$$G^{F1}(w,\xi|z',\theta')_3=\frac{1}{4}\,(z'-z_0-1)(D_{\theta'}f_+^F(z',\theta'|z_0,\theta_0))_{\theta'=0}$$
$$\times\begin{pmatrix}\left(\frac{1}{2}\,\xi D_\xi\theta_F+w\partial_w\theta_F\right)\left(\frac{1}{z'-z_F}-\frac{1}{z'-z_0}\right)\\ +\left(wK_F^2(w)+\frac{1}{2}\,\xi wK_F(w)\partial_w J_F(w)\right)\frac{\theta_F}{(z_F-z')^2}\\ -\frac{1}{2}\,\xi wK_F^3(w)\,\frac{1}{(z_F-z')^2}\end{pmatrix}+\frac{1}{4}\left(\frac{1}{z'-z_0}-1\right)$$
$$\times(\partial_{z'}f_+^F(z',\theta'|z_0,\theta_0))_{\theta'=0}$$
$$\times\begin{pmatrix}\left(\frac{1}{2}\,\xi D_\xi\theta_F+w\partial_w\theta_F\right)\frac{\sqrt{z_F-z_0}\theta_F}{z'-z_F}\\ +\left(wK_F^2(w)+\frac{1}{2}\,\xi wK_F(w)\partial_w J_F(w)\right)\frac{\sqrt{z_F-z_0}}{z'-z_F}\\ +\frac{1}{2}\,\xi wK_F^3(w)\left(\frac{\frac{1}{2}\theta_F}{(z_F-z')\sqrt{z_F-z_0}}-\frac{\sqrt{z_F-z_0}\theta_F}{(z_F-z')^2}\right)\end{pmatrix}.\tag{A13}$$

APPENDIX B: NON-N OPERATORS $g_h^{\mp jF}$ AND g_h^{jjF} IN EQ. (3.13)

In this Appendix, we shall give explicit expressions for non-N operators $g_h^{\mp jF}(\ )_\iota$'s and $g_h^{jjF}(\ )_\iota$'s in Eq. (3.13′). (We shall notice soon that they are dependent on ϵ_h^j.) Applying the contraction in the R sector (3.10) to ρ^{1F} (1.4), we obtain after straightforward calculations

$$g_h^{\mp jF}(w,\xi|z',\theta')_1=\frac{1}{2}\,(D_{\theta'}Y_h^{\mp j}(z',\theta';z_0)\partial_{z'}+\partial_{z'}Y_h^{\mp j}(z',\theta';z_0)D_{\theta'})$$
$$\times\log(z'-z_F-\theta'\theta_F(z_F-z_0)^{\mp\epsilon_h^j}),\tag{B1}$$

$$g_h^{\mp jF}(w,\xi|z',\theta')_2=\mp\frac{\epsilon_h^j\theta'\theta_F(z_F-z_0)^{\mp\epsilon_h^j}}{(z'-z_0)(z'-z_F)}\,\Psi_h^{\mp j}(z';z_0),\tag{B2}$$

and

$$g_h^{\mp jF}(w,\xi|z',\theta')_3=-\frac{1}{4}\,((z'-z_0)^{\pm 2\epsilon_h^j}-1)\,\frac{\theta_F(z_F-z_0)^{\mp\epsilon_h^j}}{z'-z_F}\,\partial_{z'}X^{\mp j}(z')$$
$$+\frac{1}{4}\,((z'-z_0)^{\mp 2\epsilon_h^j}-1)\,\frac{1}{z'-z_F}\,\Psi_h^{\mp j}(z';z_0).\tag{B3}$$

On the other hand, non-N operator $g_h^{jjF}(\ )_\iota$ (for $\iota=1-3$) is found out to be given as follows:

$$g_h^{jjF}(w,\xi;w',\theta'|z',\theta')_1$$

$$=\frac{1}{2}D_{\theta'}\log(z'-z'_F-\theta'\theta'_F(z'_F-z_0)^{-\epsilon_h^j})\partial_{z'}\log(z'-z_F-\theta'\theta_F(z_F-z_0)^{+\epsilon_h^j})$$

$$+\frac{1}{2}\partial_{z'}\log(z'-z'_F-\theta'\theta'_F(z'_F-z_0)^{-\epsilon_h^j})D_{\theta'}\log(z'-z_F-\theta'\theta_F(z_F-z_0)^{+\epsilon_h^j}), \quad \text{(B4)}$$

$$g_h^{jjF}(w,\xi;w',\xi'|z',\theta')_2=\frac{\epsilon_h^j\theta'\theta'_F\theta_F(z'_F-z_0)^{-\epsilon_h^j}(z_F-z_0)^{+\epsilon_h^j}}{(z'-z_0)(z'-z'_F)(z'-z_F)}, \quad \text{(B5)}$$

and

$$g_h^{jjF}(w,\xi;w',\xi'|z',\theta')_3=-\frac{1}{4}((z'-z_0)^{+2\epsilon_h^j}-1)\frac{\theta'_F(z'_F-z_0)^{-\epsilon_h^j}}{(z'-z'_F)(z'-z_F)}$$

$$-\frac{1}{4}((z'-z_0)^{-2\epsilon_h^j}-1)\frac{\theta_F(z_F-z_0)^{+\epsilon_h^j}}{(z'-z'_F)(z'-z_F)}. \quad \text{(B6)}$$

In Eqs. (B1)–(B6), we have used shorthand notations z_F and θ_F in Eq. (3.12), together with

$$z'_F\equiv z_F(w',\xi'), \quad \theta'_F\equiv\theta_F(w',\xi'). \quad \text{(B7)}$$

APPENDIX C: NON-N OPERATOR G_h^{jjF} IN EQ. (3.14)

In this Appendix, explicit formulas for non-N operators G_h^{jjF} in Eq. (3.14) are given. Using Eqs. (3.11) and (3.12), we find that

$$\vec{R}\cdot\tau_+^0(z',\theta';z_0):\overbrace{X^{+j}(z_F,\theta_F)X^{-j}}^{R}(z'_F,\theta'_F)\exp(-ip^{+0}Y_{N+}^{-0}(z_0,\theta_0)):_R$$

$$=:(G^{F1/2}(w,\xi|z',\theta')\partial_{z_F}+G^{F1}(w,\xi|z',\theta')D_{\theta_F})$$

$$\times\overbrace{X^{+j}(z_F,\theta_F)X^{-j}}^{R}(z'_F,\theta'_F)\exp(-ip^{+0}Y_{N+}^{-0}(z_0,\theta_0)):_R$$

$$+:(G^{F1/2}(w',\xi'|z',\theta')\partial_{z'_F}+G^{F1}(w',\xi'|z',\theta')D_{\theta'_F})$$

$$\times\overbrace{X^{-j}(z'_F,\theta'_F)X^{+j}}^{R}(z_F,\theta_F)\exp(-ip^{+0}Y_{N+}^{-0}(z_0,\theta_0)):_R$$

$$+:\tau_+^0(z',\theta';z_0)\overbrace{X^{+j}(z_F,\theta_F)X^{-j}}^{R}(z'_F,\theta'_F)\exp(-ip^{+0}Y_{N+}^{-0}(z_0,\theta_0)):_R, \quad \text{(C1)}$$

which leads to

$$G_h^{jjF}(w,\xi;w',\xi'|z',\theta')=\begin{pmatrix}G^{F\,1/2}(w,\xi|z',\theta')\partial_{z_F}+G^{F1}(w,\xi|z',\theta')D_{\theta_F}\\ +G^{F\,1/2}(w',\xi'|z',\theta')\partial_{z'_F}+G^{F1}(w',\xi'|z',\theta')D_{\theta'_F}\end{pmatrix}$$

$$\times\log\left(z_F-z'_F-\left(\frac{z_F-z_0}{z'_F-z_0}\right)^{\epsilon_h^j}\cdot\theta_F\theta'_F\right). \quad \text{(C2)}$$

As we shall see from Eq. (C2), $G_h^{jjF}(\ )$ is dependent on ϵ_h^j, while $G^{F\,1/2}$ and G^{F1} on the right-hand side of Eq. (C2) do *not* depend on ϵ_h^j.

APPENDIX D: EXPANSIONS IN THE NEIGHBORHOOD OF $z'=z_F$

Non-N operators $g_h^{\mp jF}(w,\xi|z',\theta')$ [, given by Eqs. (B1) and (B4)–(B6),] have singularities at $z'=z_F(w,\xi)$, and they can be analyzed by expanding non-N operators $Y_h^{\pm j}(z',\theta';z_0)$ at $z'=z_F(w,\xi)(\equiv z_F)$ as

$$D_{\theta'}Y_h^{\pm j}(z',\theta';z_0)=(1+(\theta'-\theta_F)D_{\theta_F}-\theta'\theta_F\partial_{z_F})D_{\theta_F}Y_h^{\pm j}(z_F,\theta_F;z_0)+(z'-z_F)\times(1+(\theta'-\theta_F)D_{\theta_F}-\theta'\theta_F\partial_{z_F})\partial_{z_F}D_{\theta_F}Y_h^{\pm j}(z_F,\theta_F;z_0)+O((z'-z_F)^2) \tag{D1}$$

and

$$\partial_{z'}Y_h^{\pm j}(z',\theta';z_0)=(1+(\theta'-\theta_F)D_{\theta_F}-\theta'\theta_F\partial_{z_F})\partial_{z_F}Y_h^{\pm j}(z_F,\theta_F;z_0)+O((z'-z_F)). \tag{D2}$$

With the help of

$$Y_h^{\pm j}(z_F,\theta_F;z_0)=X^{\pm j}(z_F,\theta_F)+\theta_F((z_F-z_0)^{\mp\epsilon_h^j}-1)D_{\theta_F}X^{\pm j}(z_F,\theta_F), \tag{D3}$$

together with Eqs. (D1) and (D2), we find from Eqs. (B1) to (B3) that $g_h^{F1/2(1)}(\ )_\iota$ in Eq. (3.15′) is given as follows: As for $(g_h^{F1}(\ )_\iota)_{\text{sing.}}$ (for $\iota=1-3$), we find

$$(g_h^{F1}(w,\xi|z',\theta')_1)_{\text{sing.}}=\frac{\frac{1}{2}\theta'\theta_F}{(z'-z_F)^2}+\frac{1/2}{z'-z_F}(z_F-z_0)^{\pm\epsilon_h^j}\pm\frac{\epsilon_h^j\theta'\theta_F}{(z'-z_F)(z_F-z_0)}, \tag{D4}$$

$$(g_h^{F1}(w,\xi|z',\theta')_2)_{\text{sing.}}=\mp\frac{\epsilon_h^j\theta'\theta_F}{(z'-z_F)(z_F-z_0)} \tag{D5}$$

and

$$(g_h^{F1}(w,\xi|z',\theta')_3)_{\text{sing.}}=\mp\frac{1/2\epsilon_h^j}{z'-z_F}\left(\sqrt{z_F-z_0}-\frac{1}{\sqrt{z_F-z_0}}\right). \tag{D6}$$

On the other hand, as for $(g_h^{F1/2}(\ )_\iota)_{\text{sing.}}$ (for $\iota=1-3$), we find

$$(g_h^{F1/2}(w,\xi|z',\theta')_1)_{\text{sing.}}=\frac{\theta'}{z'-z_F}-\frac{1/2\theta_F}{z'-z_F}\left(\sqrt{z_F-z_0}+\frac{1}{\sqrt{z_F-z_0}}\right) \tag{D7}$$

and

$$(g_h^{F1/2}(w,\xi|z',\theta')_2)_{\text{sing.}}=(g_h^{F1/2}(w,\xi|z',\theta')_3)_{\text{sing.}}=0. \tag{D8}$$

Therefore, we obtain from Eqs. (3.15″), (D7), and (D8) that

$$(g_h^{F1/2}(w,\xi|z',\theta'))_{\text{sing.}}=\frac{\theta'}{z'-z_F}-\frac{\frac{1}{2}\theta}{z'-z_F}\left(\sqrt{z_F-z_0}+\frac{1}{\sqrt{z_F-z_0}}\right), \tag{D9}$$

the right-hand side of which should be noticed to be *independent* of ϵ_h^j. On the other hand Eqs. (3.15″) and (D4)–(D6) give

$$(g_h^{F1}(w,\xi|z',\theta'))_{\text{sing.}}=\frac{\frac{1}{2}\theta'\theta_F}{(z'-z_F)^2}+\frac{1/4}{z'-z_F}\left(\sqrt{z_F-z_0}+\frac{1}{\sqrt{z_F-z_0}}\right), \tag{D10}$$

the right-hand side of which should be noticed to be *independent* of ϵ_h^j. Furthermore, with the help of formulas

$$\frac{1}{(z'-z_F)(z'-z'_F)}=\frac{1}{z_F-z'_F}\left(\frac{1}{z'-z_F}-\frac{1}{z'-z'_F}\right) \tag{D11}$$

and

$$\frac{1}{(z'-z_F)^2(z'-z'_F)}=\frac{-1}{(z_F-z'_F)^2}\left(\frac{1}{z'-z_F}-\frac{1}{z'-z'_F}\right)+\frac{1}{(z_F-z'_F)(z'-z_F)^2}, \tag{D11$'$}$$

we find from Eqs. (B4) to (B6) that non-N operator $(g_h^{jjF}(\ )_\iota)_{\text{sing.}}$ (for $\iota=1-3$) is given as follows:

$$\begin{aligned}(g_h^{jjF}(w,\xi;w',\theta'|z',\theta')_1)_{\text{sing.}}=&\frac{\theta'-1/2(z_F-z_0)^{\epsilon_h^j}\theta_F-1/2(z'_F-z_0)^{-\epsilon_h^j}\theta'_F}{(z'-z_F)(z_F-z'_F)}\\&+\frac{\theta'\theta_F\theta'_F}{(z'-z_F)(z_F-z'_F)^2}\left(\frac{z_F-z_0}{z'_F-z_0}\right)^{\epsilon_h^j}\\&-\frac{\frac{1}{2}\theta'\theta_F\theta'_F}{(z'-z_F)^2(z_F-z'_F)}\left(\frac{z_F-z_0}{z'_F-z_0}\right)^{\epsilon_h^j},\end{aligned} \tag{D12}$$

$$\begin{aligned}(g_h^{jjF}(w,\xi;w',\theta'|z',\theta')_2)_{\text{sing.}}=&-\frac{\theta'\theta_F\theta'_F\epsilon_h^j}{(z'-z_F)(z_F-z'_F)(z_F-z_0)}\left(\frac{z_F-z_0}{z'_F-z_0}\right)^{\epsilon_h^j}\\&+(\text{terms obtained by } z_F\leftrightarrow z'_F,\ \theta_F\leftrightarrow\theta'_F \text{ and } \epsilon_h^j\rightarrow-\epsilon_h^j)\end{aligned} \tag{D13}$$

and

$$\begin{aligned}(g_h^{jjF}(w,\xi;w',\theta'|z',\theta')_3)_{\text{sing.}}=&\frac{1/2(z_F-z_0)^{\epsilon_h^j}\theta_F+1/2(z'_F-z_0)^{-\epsilon_h^j}\theta'_F}{(z'-z_F)(z_F-z'_F)}\\&-\frac{1/4}{(z'-z_F)(z_F-z'_F)}\left(\left(\frac{z_F-z_0}{z'_F-z_0}\right)^{\epsilon_h^j}\theta'_F+\theta_F\right)\\&\times\left(\sqrt{z_F-z_0}+\frac{1}{\sqrt{z_F-z_0}}\right)\\&+(\text{terms obtained by } z_F\leftrightarrow z'_F,\ \theta_F\leftrightarrow\theta'_F \text{ and } \epsilon_h^j\rightarrow-\epsilon_h^j).\end{aligned} \tag{D14}$$

Summing up Eqs. (D12)–(D14), we find from Eq. (3.13″) that

$$\begin{aligned}&(g_h^{jjF}(w,\xi;w',\theta'|z',\theta'))_{\text{sing.}}\\&=\frac{\theta'}{z'-z_F}\left(\frac{1}{z_F-z'_F}\left(1-\frac{\epsilon_h^j\theta_F\theta'_F}{z_F-z_0}\left(\frac{z_F-z_0}{z'_F-z_0}\right)^{\epsilon_h^j}\right)+\frac{\theta_F\theta'_F}{(z_F-z'_F)^2}\left(\frac{z_F-z_0}{z'_F-z_0}\right)^{\epsilon_h^j}\right)\\&-\frac{1/4}{(z'-z_F)(z_F-z'_F)}\left(\left(\frac{z_F-z_0}{z'_F-z_0}\right)^{\epsilon_h^j}\theta'_F+\theta_F\right)\left(\sqrt{z_F-z_0}+\frac{1}{\sqrt{z_F-z_0}}\right)\\&-\frac{1/2\theta'\theta_F\theta'_F}{(z'-z_F)^2(z_F-z'_F)}\left(\frac{z_F-z_0}{z'_F-z_0}\right)^{\epsilon_h^j}\\&+(\text{terms obtained by } z_F\leftrightarrow z'_F,\ \theta_F\leftrightarrow\theta'_F \text{ and } \epsilon_h^j\rightarrow-\epsilon_h^j).\end{aligned} \tag{D15}$$

It is remarkable that Eq. (D15) can be shown to be rewritten into Eq. (3.16), on the right-hand side of which the singular terms $(g_h^{F1/2}(\ ))_{\text{sing.}}$ (D9) and $(g_h^{F1}(\ ))_{\text{sing.}}$ (D10) have been found to be *independent* of ϵ_h^j.

APPENDIX E: ABSENCE OF SINGULARITIES AT $z'=z_F(w,\xi)$

In this Appendix, we shall prove that both $(H^{F1/2}(w,\xi|z',\theta'))_{\text{sing.}}$ $(H^{F1}(w,\xi|z',\theta'))_{\text{sing.}}$ in Eq. (3.18) are zero. First, we notice that non-N operator $f_+^F(z',\theta'|z_0,\theta_0)$ (A10) can be expanded as

$$\begin{aligned} f_+^F(z',\theta'|z_0,\theta_0)=&(1+(\theta'-\theta_F)D_{\theta_F}-\theta'\theta_F\partial_{z_F})f_+^F(z_F,\theta_F|z_0,\theta_0)+(z'-z_F)(1+(\theta'-\theta_F)D_{\theta_F}\\ &-\theta'\theta_F\partial_{z_F})\partial_{z_F}f_+^F(z_F,\theta_F|z_0,\theta_0))+\frac{(z'-z_F)^2}{2}(1+(\theta'-\theta_F)D_{\theta_F}\\ &-\theta'\theta_F\partial_{z_F})\partial_{z_F}^2f_+^N(z_F,\theta_F|z_0,\theta_0))+O((z'-z_F)^3). \end{aligned} \tag{E1}$$

Furthermore, with the help of

$$f^F(z_F,\theta_F|z_0,\theta_0)\equiv\frac{X^{+0}(z_F,\theta_F)}{ip^{+0}}-\log(z_F-z_0-\sqrt{z_F-z_0}\,\theta_F\theta_0), \tag{E2}$$

we find that

$$\begin{aligned} &f^F(z_F,\theta_F|z_0,\theta_0)-\left(\theta_F-\frac{\theta_F}{\sqrt{z_F-z_0}}\right)D_{\theta_F}f^F(z_F,\theta_F|z_0,\theta_0)\\ &=\frac{Y_+^{+0}(z_F,\theta_F;z_0)}{ip^{+0}}-\log(z_F-z_0-\theta_F\theta_0)(\equiv f_+^F(z_F,\theta_F|z_0,\theta_0)), \end{aligned} \tag{E3}$$

on the left-hand side of which we have from Eqs. (E2) and (1.18) the following relation.

$$f^F(z_F,\theta_F|z_0,\theta_0)=-\log w+\frac{X^{+0}(z_0)}{ip^{+0}}. \tag{E4}$$

We can derive from Eq. (E3)

$$D_{\theta_F}f_+^F(z_F,\theta_F|z_0,\theta_0)=\frac{1}{\sqrt{z_F-z_0}}D_{\theta_F}f^F(z_F,\theta_F|z_0,\theta_0)+\left(\theta_F-\frac{\theta_F}{\sqrt{z_F-z_0}}\right)\partial_{z_F}f^F(z_F,\theta_F|z_0,\theta_0), \tag{E5}$$

$$\begin{aligned} \partial_{z_F}f_+^F(z_F,\theta_F|z_0,\theta_0)=&\partial_{z_F}f^F(z_F,\theta_F|z_0,\theta_0)\\ &-\frac{\frac{1}{2}\theta_F}{(\sqrt{z_F-z_0})^3}D_{\theta_F}f^F(z_F,\theta_F|z_0,\theta_0)\\ &-\left(\theta_F-\frac{\theta_F}{\sqrt{z_F-z_0}}\right)\partial_{z_F}D_{\theta_F}f^F(z_F,\theta_F|z_0,\theta_0), \end{aligned} \tag{E6}$$

$$\begin{aligned} &\partial_{z_F}D_{\theta_F}f_+^F(z_F,\theta_F|z_0,\theta_0)\\ &=-\frac{1/2}{(\sqrt{z_F-z_0})^3}D_{\theta_F}f^F(z_F,\theta_F|z_0,\theta_0)+\frac{1}{\sqrt{z_F-z_0}}\partial_{z_F}D_{\theta_F}f^F(z_F,\theta_F|z_0,\theta_0)\\ &+\frac{\frac{1}{2}\theta_F}{(\sqrt{z_F-z_0})^3}\partial_{z_F}f^F(z_F,\theta_F|z_0,\theta_0)+\left(\theta_F-\frac{\theta_F}{\sqrt{z_F-z_0}}\right)\partial_{z_F}^2f^F(z_F,\theta_F|z_0,\theta_0), \end{aligned} \tag{E7}$$

$$\partial_{z_F}^2 f_+^F(z_F,\theta_F|z_0,\theta_0)=\partial_{z_F}^2 f^F(z_F,\theta_F|z_0,\theta_0)+\frac{\frac{3}{4}\theta_F}{(\sqrt{z_F-z_0})^5}\,D_{\theta_F}f^F(z_F,\theta_F|z_0,\theta_0)$$
$$-\frac{\theta_F}{(\sqrt{z_F-z_0})^3}\,\partial_{z_F}D_{\theta_F}f^F(z_F,\theta_F|z_0,\theta_0)$$
$$-\left(\theta_F-\frac{\theta_F}{\sqrt{z_F-z_0}}\right)\partial_{z_F}^2 D_{\theta_F}f^F(z_F,\theta_F|z_0,\theta_0), \tag{E8}$$

and

$$\partial_{z_F}^2 D_{\theta_F}f_+^F(z_F,\theta_F|z_0,\theta_0)$$
$$=\frac{3/4}{(\sqrt{z_F-z_0})^5}\,D_{\theta_F}f^F(z_F,\theta_F|z_0,\theta_0)-\frac{1}{(\sqrt{z_F-z_0})^3}\,\partial_{z_F}D_{\theta_F}f^F(z_F,\theta_F|z_0,\theta_0)$$
$$+\frac{1}{\sqrt{z_F-z_0}}\,\partial_{z_F}^2 D_{\theta_F}f^F(z_F,\theta_F|z_0,\theta_0)-\frac{3/4\theta_F}{(\sqrt{z_F-z_0})^5}\,\partial_{z_F}f^F(z_F,\theta_F|z_0,\theta_0)$$
$$+\frac{\theta_F}{(\sqrt{z_F-z_0})^3}\,\partial_{z_F}^2 f^F(z_F,\theta_F|z_0,\theta_0)+\left(\theta_F-\frac{\theta_F}{\sqrt{z_F-z_0}}\right)\partial_{z_F}^3 f^F(z_F,\theta_F|z_0,\theta_0). \tag{E9}$$

On the right-hand sides of Eqs. (E5)–(E9), we can use the following expressions which can be derived from Eqs. (2.19) and (E4) [together with Eq. (1.6)]:

$$D_{\theta_F}f^F(z_F,\theta_F|z_0,\theta_0)=-\frac{\xi}{wD_\xi\theta_F}=-\frac{\xi}{wK_F(w)}, \tag{E10}$$

$$\partial_{z_F}f^F(z_F,\theta_F|z_0,\theta_0)=-\frac{1}{w(D_\xi\theta_F)^2}-\frac{\xi\partial_w\theta_F}{w(D_\xi\theta_F)^3}=-\frac{1}{wK_F^2(w)}+\frac{\xi\partial_w J_F(w)}{wK_F^3(w)}, \tag{E11}$$

$$\partial_{z_F}D_{\theta_F}f^F(z_F,\theta_F|z_0,\theta_0)=\frac{\partial_w\theta_F}{w(D_\xi\theta_F)^4}+\xi\left(\frac{\partial_w\theta_F}{w^2(D_\xi\theta_F)^3}+\frac{\partial_w D_\xi\theta_F}{w(D_\xi\theta_F)^4}\right)$$
$$=\frac{\partial_w J_F(w)}{wK_F^4(w)}+\xi\left(\frac{2\partial_w K_F(w)}{wK_F^4(w)}+\frac{1}{w^2K_F^3(w)}\right), \tag{E12}$$

and

$$\partial_{z_F}^2 f^F(z_F,\theta_F|z_0,\theta_0)$$
$$=\frac{1}{w^2(D_\xi\theta_F)^4}+\frac{2\partial_w D_\xi\theta_F}{w(D_\xi\theta_F)^5}+\xi\left(\frac{2\partial_w\theta_F}{w^2(D_\xi\theta_F)^5}-\frac{\partial_w^2\theta_F}{w(D_\xi\theta_F)^5}+\frac{4\partial_w\theta_F\partial_w D_\xi\theta_F}{w(D_\xi\theta_F)^6}\right)$$
$$=\frac{1}{w^2K_F^4(w)}+\frac{2\partial_w K_F(w)}{wK_F^5(w)}+\xi\left(-\frac{2\partial_w J_F(w)}{w^2K_F^5(w)}+\frac{\partial_w^2 J_F(w)}{wK_F^5(w)}-\frac{6\partial_w J_F(w)\partial_w K_F(w)}{wK_F^6(w)}\right). \tag{E13}$$

Non-N-operator $(G^{F(1/2)(1)}(w,\xi|z',\theta')_\iota)_{\text{sing.}}$ is calculated by using Eqs. (A8)–(A10) [(A11)–(A13)], with the help of Eq. (E1) together with Eqs. (E5)–(E13). After extremely tedious but straightforward calculations, we obtain the following final results:

$$(G^{F1/2}(w,\xi|z',\theta')_1)_{\text{sing.}}$$

$$=\frac{1}{z'-z_F}\begin{pmatrix} -\theta'+1/2\theta_F\left(\sqrt{z_F-z_0}+\dfrac{1}{\sqrt{z_F-z_0}}\right)-\xi J_F(w)K_F(w)\dfrac{\theta'}{z_F-z_0} \\ +1/2\xi K_F(w)\left(\sqrt{z_F-z_0}-\dfrac{1}{\sqrt{z_F-z_0}}\right)\end{pmatrix}, \tag{E14}$$

$$(G^{F1/2}(w,\xi|z',\theta')_2)_{\text{sing.}}=\frac{1}{z'-z_F}\left(\xi J_F(w)K_F(w)\frac{\theta'}{z_F-z_0}\right) \tag{E15}$$

and

$$(G^{F1/2}(w,\xi|z',\theta')_3)_{\text{sing.}}=\frac{-1}{z'-z_F}\left(1/2\xi K_F(w)\left(\sqrt{z_F-z_0}-\frac{1}{\sqrt{z_F-z_0}}\right)\right). \tag{E16}$$

Furthermore, we find that

$$(G^{F1}(w,\xi|z',\theta')_1)_{\text{sing.}}=\frac{1}{(z'-z_F)^2}\left(-\frac{1}{2}\theta'\theta_F+\frac{1}{4}\xi J_F(w)K_F(w)\left(\sqrt{z_F-z_0}-\frac{1}{\sqrt{z_F-z_0}}\right)\right)$$

$$+\frac{1}{z'-z_F}\begin{pmatrix} \dfrac{1}{8}\xi J_F(w)K_F(w)\dfrac{1}{(\sqrt{z_F-z_0})^3} \\ +\dfrac{\frac{1}{2}\theta'}{z_F-z_0}J_F(w)\left(-1+\dfrac{\xi\partial_w J_F(w)}{K_F(w)}\right) \\ +\dfrac{1}{8}\xi J_F(w)K_F(w)\dfrac{1}{\sqrt{z_F-z_0}} \\ +\dfrac{1}{4}\left(-1+\dfrac{\xi\partial_w J_F(w)}{K_F(w)}\right)\left(\sqrt{z_F-z_0}-\dfrac{1}{\sqrt{z_F-z_0}}\right) \\ -\dfrac{1}{4}\left(\sqrt{z_F-z_0}+\dfrac{1}{\sqrt{z_F-z_0}}\right)\end{pmatrix} \tag{E17}$$

$$(G^{F1}(w,\xi|z',\theta')_2)_{\text{sing.}}=-\frac{\frac{1}{2}\theta'}{(z'-z_F)(z_F-z_0)}J_F(w)\left(-1+\frac{\xi\partial_w J_F(w)}{K_F(w)}\right) \tag{E18}$$

and

$$(G^{F1}(w,\xi|z',\theta')_3)_{\text{sing.}}=-\frac{1/4}{(z'-z_F)^2}\xi J_F(w)K_F(w)\left(\sqrt{z_F-z_0}-\frac{1}{\sqrt{z_F-z_0}}\right)$$

$$+\frac{1}{z'-z_F}\begin{pmatrix} -\dfrac{1}{8}\xi J_F(w)K_F(w)\dfrac{1}{(\sqrt{z_F-z_0})^3} \\ -\dfrac{1}{8}\xi J_F(w)K_F(w)\dfrac{1}{\sqrt{z_F-z_0}} \\ -\dfrac{1}{4}\left(-1+\dfrac{\xi\partial_w J_F(w)}{K_F(w)}\right)\left(\sqrt{z_F-z_0}-\dfrac{1}{\sqrt{z_F-z_0}}\right)\end{pmatrix}. \tag{E19}$$

Therefore, we find that

$$(G^{F1/2}(w,\xi|z',\theta'))_{\text{sing.}}=-(g_h^{F1/2}(w,\xi|z',\theta'))_{\text{sing.}}, \tag{E20}$$

the right- (left-) hand side of which is given by Eq. (D10) [Eq. (3.12′) with Eqs. (E14)–(E16)]. Furthermore, we find that

$$(G^{F1}(w,\xi|z',\theta'))_{\text{sing.}}=-(g_h^{F1}(w,\xi|z',\theta'))_{\text{sing.}}, \tag{E21}$$

the right- (left-) hand side of which is given by Eq. (D11) [Eq. (3.12′) with Eqs. (E17)–(E19)].

Lie-series approach to the evolution of resonant and nonresonant anharmonic oscillators in quantum mechanics

A. W. Sáenz
Department of Physics, Catholic University, Washington, DC 20064
and Naval Research Laboratory, Washington, DC 20375

(Received 30 April 1996; accepted for publication 4 September 1997)

A version of a normal-form method of Kummer and Gompa, analogous to the Lie-series methods of classical mechanics, is used to rigorously construct uniform long-time approximations to the quantum evolution of a system of resonant or nonresonant anharmonic oscillators. The Hamiltonian H_ε governing the system is a self-adjoint operator in the Hilbert space $\mathscr{H}=L^2(\mathbf{R}^\nu)$ $(\nu\geqslant 2)$, given formally by $H_0+\varepsilon V$. Here, H_0 denotes the Hamiltonian of ν one-dimensional simple harmonic oscillators and εV their anharmonic coupling, $\varepsilon\geqslant 0$ being a small parameter and V an operator of multiplication by a smooth function of polynomial growth at infinity. We treat the case in which an arbitrary number $\rho\geqslant 1$ of the frequencies of these oscillators are rationally independent, imposing a standard diophantine condition on the independent frequencies if $\rho\geqslant 2$. Under these assumptions, stated precisely in the paper, an Nth-order approximant $\psi_N(t,\varepsilon)$ to the exact solution $\psi(t,\varepsilon)$ of the Schrödinger equation $id\psi(t,\varepsilon)/dt=H_\varepsilon\psi(t,\varepsilon)$, satisfying the initial condition $\psi(0,\varepsilon)=\psi_0$, is constructed inductively, where the initial state ψ_0 belongs to a family of smooth functions dense in $\mathscr{H}$. The main result is that $\psi_N(t,\varepsilon)$ differs in $\mathscr{H}$-norm from $\psi(t,\varepsilon)$ by $\leqslant \text{const}\,\varepsilon^{N+1}|t|$ for $t\in\mathbf{R}$ and ε in an arbitrary compact interval $[0,\varepsilon_0]$. This result is obtained by an approach simpler and quite different from that of Kummer and Gompa, and extends their work to oscillators with nonpolynomial couplings, under very general resonance conditions. © *1998 American Institute of Physics.* [S0022-2488(98)01203-1]

I. INTRODUCTION

Two normal-form methods for obtaining uniform long-time approximations to the quantum evolution of a system of harmonic oscillators, coupled by a potential which is a polynomial in coordinates and momenta, have been proposed by Kummer and Gompa.[1,2] The first method is close in spirit to the perturbation theory discussed by Born and Jordan[3] in the early days of quantum mechanics. The second, and presumably more accurate method, is based on a Lie-series approach by which the Hamiltonian of the coupled system is reduced to the pertinent normal form to any desired order by a suitable product of exponential operators.[4] This approach is analogous to those used in mathematical studies of vector fields and classical Hamiltonian systems,[5–8] and in related physical applications.[9] It is elegantly formulated in the setting of Bargmann's space of entire analytic functions.[10] Both procedures have the merit of avoiding the secular terms which plague the usual time-dependent perturbation theory in quantum mechanics (see also Refs. 11 and 12), thus limiting its validity to relatively short time intervals. However, the restrictions on the allowed initial states imposed in these procedures severely limit their usefulness for dealing with resonant cases.[13]

In a recent paper,[14] we developed a rigorous procedure for approximating uniformly over long times the quantum evolution of a wide class of systems of resonant and nonresonant harmonic oscillators coupled by potentials with polynomial growth at infinity, without necessarily being polynomials. The approach in that paper was a rigorous version of the first normal-form method in Refs. 1 and 2, but our methods of proof were quite different from the ones used in these references.[15]

In the present paper, we use a modification of the second method to approximate the long-time

 © 1998 American Institute of Physics

evolution of such systems. The time-development of interest is defined by the initial-value problem (IVP)[16]

$$i\,\frac{d\psi(t,\varepsilon)}{dt}=H_\varepsilon\psi(t,\varepsilon), \tag{1.1a}$$

$$\psi(0,\varepsilon)=\psi_0. \tag{1.1b}$$

Here, H_ε denotes a self-adjoint operator acting in the Hilbert space $\mathscr{H}=L^2(\mathbf{R}^\nu)$ $(\nu\geqslant 2)$ and is given formally by

$$H_\varepsilon=H_0+\varepsilon V, \tag{1.2}$$

and d/dt denotes the strong t-derivative in $\mathscr{H}$. In (1.2), H_0 stands for the Hamiltonian of ν uncoupled harmonic oscillators, or more exactly, for the unique self-adjoint operator on $\mathscr{H}$ which acts as

$$H_0=\frac{1}{2}\sum_{i=1}^{\nu}\left(-\frac{\partial^2}{\partial x_i^2}+\omega_i^2x_i^2\right) \tag{1.3}$$

on $C_0^\infty(\mathbf{R}^\nu)$. Moreover, $\varepsilon\geqslant 0$ is a small parameter and V an operator of multiplication by a smooth function which together with its derivatives has polynomial growth at infinity, again without necessarily being a polynomial. The frequencies ω_i are assumed to be fixed positive numbers, an arbitrary number ρ of them being rationally independent. If $\rho=1$, i.e., if there is a positive real ω_0 such that $\omega_i=k_i\omega_0$ $(i=1,...,\nu)$, the k_i being positive integers, then one has the analog of the classical $k_1:k_2:\ldots:k_\nu$ resonance. In this case the k_i are allowed to be completely arbitrary. If $\rho\geqslant 2$, we subject the rationally independent frequencies to a standard diophantine condition. No other requirements are imposed on the frequencies. Finally, the initial state ψ_0 is assumed to lie in a suitable dense subset of $\mathscr{H}$, a condition which is not unduly restrictive physically.

The Lie-series formalism discussed in this paper is an inductive procedure for reducing H_ε to the desired normal form to $O(\varepsilon^N)$ $(N\geqslant 1)$ in a sense explained heuristically in Sec. II and rigorously in Secs. III and IV. We define an Nth-order approximant $\psi_N(t,\varepsilon)$ $(N\geqslant 1)$ to the exact solution $\psi(t,\varepsilon)$ of the IVP (1.1) in terms of this normal form and prove that it satisfies the uniform error estimate

$$\|\psi(t,\varepsilon)-\psi_N(t,\varepsilon)\|\leqslant \text{const}\ \varepsilon^{N+1}|t| \tag{1.4}$$

for $t\in\mathbf{R}$, $0\leqslant\varepsilon\leqslant\varepsilon_0$, where ε_0 is an arbitrary positive constant and $\|.\|$ denotes the usual $L^2(\mathbf{R}^\nu)$-norm. This estimate is our main result. It improves the corresponding Nth-order error estimate $O(\varepsilon^{N+1}(|t|+1))$ obtained in Ref. 14 by using a modification of the first normal-form method. The proof of (1.4) is lengthy, but the basic ideas underlying it are simple, as will be clear from its heuristic proof given near the end of Sec. II.

Reference 14 and the present work are the first to have discussed long-time approximations to the evolution of systems of resonant and nonresonant harmonic oscillators with nonpolynomial couplings under such general conditions on the frequencies. The methods of proof used in this paper are quite different and conceptually simpler than those in Refs. 1 and 2. In the first place, our discussions are carried out in the framework of the L^2-space $\mathscr{H}$, rather than in the corresponding Bargmann space, which is unsuitable for dealing with a Hamiltonian of type (1.2) equipped with a local potential V of the present degree of generality. Second, a key role in the paper is played by an associative algebra $\mathscr{M}$ of infinite matrices and a set M of generally unbounded operators, which are those represented by these matrices in a suitable basis, and to which H_0, V, and most of the other operators of the theory belong. The operators in M have the important property of leaving invariant a common dense subset of $\mathscr{H}$ containing the initial state ψ_0.[17] Moreover, when restricted to this subset they constitute an algebra M_0 isomorphic to $\mathscr{M}$. This isomorphism is not a mere mathematical curiosity, but plays an essential role in allowing one to prove simply and rigorously that certain key relations satisfied by operators in M hold. We note that the simple proof given in this paper of the essential self-adjointness of the truncated normal

form $K^{[N]}(\varepsilon)$ of interest here is based on the fact that its unique self-adjoint extension is an operator associated with a suitable matrix in $\mathscr{M}$. The existence of such an extension is needed to define the approximant $\psi_N(t,\varepsilon)$ in a satisfactory manner, as well as for other reasons.

The paper is organized as follows. Leaving rigor aside, Sec. II is devoted to a discussion of the normal-form method used in the present study, as well as to a heuristic construction of $\psi_N(t,\varepsilon)$. These considerations motivate the precise mathematical approach followed in Secs. III and IV. In the former section, we state our hypotheses on V and the frequencies ω_i, specify the set $\mathscr{M}$ and define key operators of the theory in terms of the matrices therein, give a precise definition of $\psi_N(t,\varepsilon)$, and state Theorem 1, which asserts that (1.4) holds at the above mentioned t,ε -values under these hypotheses. It is proved in Sec. IV on the basis of the technical Lemmas 1–9. The elementary Lemma 1 serves to control the small denominators which would otherwise defeat our normal-form approach, while Lemma 2 entails that V lies in M. Both of these results were proved in Ref. 14 and are essential first steps in the proof of Theorem 1. The invariance of the previously mentioned dense subset under M is stated in Lemma 4 and the above isomorphism result is contained in Lemma 5, whose main relevance to the paper lies in the corollary to these two lemmas which is included in this section. The corollary asserts that if a finite number of matrices in $\mathscr{M}$ satisfy an equation of suitable type, then the operators in M which they represent obey a similar equation on this dense subset. We illustrate this corollary by a simple example and then apply it to prove Lemma 6, which states that the key operator relations alluded to in the previous paragraph hold. In a first reading of the paper, the short proof of Theorem 1, placed near the end of Sec. IV, could be immediately perused after reading the statement of Lemma 9, since it is the only lemma in the section which is directly involved in the proof.

In addition to leading to this theorem, our Lie-series approach promises to be an effective vehicle for generalizing the exact quantization results of Degli Esposti, Graffi, and Herczinski[4] to resonant oscillator systems of the type considered here.

II. FORMAL CONSTRUCTION OF THE *N*TH-ORDER APPROXIMANT

This section is devoted to a heuristic review of a version of the second normal-form method alluded to in Sec. I.

We begin by introducing some notation. $\mathbf{N}$ denotes the positive integers and $\mathbf{Z}_+^p$ $(p\in\mathbf{N})$ stands for the set of all vectors $r=(r_i,\ldots,r_p)$ whose components r_i are non-negative integers. We denote by $\Phi=\{\Phi_m\}$ $(m\in\mathbf{Z}_+^\nu)$ the complete orthonormal set of eigenfunctions of H_0 of the form

$$\Phi_m(x_1,\ldots,x_\nu)=\prod_{i=1}^{\nu}\varphi_{m_i}^{(i)}(x_i), \tag{2.1a}$$

where $\varphi_{m_i}^{(i)}(x_i)$ is the usual (real) eigenfunction of $\frac{1}{2}(-(d^2/dx_i^2)+\omega_i^2x_i^2)$ $(i=1,...,\nu)$ having unit $L^2(\mathbf{R})$-norm. Hence for all $m\in\mathbf{Z}_+^\nu$,

$$H_0\Phi_m=\lambda_m\Phi_m, \tag{2.1b}$$

where

$$\lambda_m=\sum_{i=1}^{\nu}\omega_i(m_i+1/2). \tag{2.1c}$$

Since some of the frequencies $\omega_1,\ldots,\omega_\nu$ may be rationally dependent, the eigenvalues λ_m of H_0 are generally degenerate.

Let $\mathscr{L}(\mathscr{H})$ be the set of linear operators on $\mathscr{H}$, i.e., those whose domains and ranges are in $\mathscr{H}$. For every $A\in\mathscr{L}(\mathscr{H})$, we define an operator ad A which acts on each $B\in\mathscr{L}(\mathscr{H})$ by ad $A(B)=$ad $AB=[A,B]=AB-BA$. In this section, we will use the splitting

$$A=\widetilde{A}+\hat{A}, \tag{2.2}$$

for operators $A\in\mathscr{L}(\mathscr{H})$, ignoring domain questions. Here $\widetilde{A}$ and $\hat{A}$ are operators in $\mathscr{L}(\mathscr{H})$ with matrix elements $\widetilde{A}_{mn}=\langle\Phi_m,\widetilde{A}\Phi_n\rangle$, $\hat{A}_{mn}=\langle\Phi_m,\hat{A}\Phi_n\rangle$ given by

$$\tilde{A}_{mn}=(1-\delta_{\lambda_m,\lambda_n})A_{mn}, \quad \hat{A}_{mn}=\delta_{\lambda_m,\lambda_n}A_{mn}, \tag{2.3a}$$

where $A_{mn}=\langle\Phi_m,A\Phi_n\rangle$.[18] Hence, the splitting (2.2) induces the decomposition.

$$A_{mn}=\tilde{A}_{mn}+\hat{A}_{mn} \tag{2.3b}$$

of each of these matrix elements. We define X (resp., Y) as the set composed of operators $A \in \mathscr{L}(\mathscr{H})$ for which $\tilde{A}=0$ (resp., $\hat{A}=0$). Roughly speaking, X and Y are the image and kernel of ad H_0, but to make this statement exact would require refinements of the relevant definitions which would be out of place in this section.

We will denote by M^∞ the set of formal power series

$$B(\varepsilon)=\sum_{i=0}^{\infty}\varepsilon^i B^{(i)} \tag{2.4}$$

whose coefficients $B^{(i)}$ are in $\mathscr{L}(\mathscr{H})$. On the other hand, N^∞ will denote the set of such formal series with coefficients which are linear operators (superoperators) mapping $\mathscr{L}(\mathscr{H})$ into itself. In both cases, we will write $B^{[i]}(\varepsilon)$ for the ith-order truncation of $B(\varepsilon)$

$$B^{[i]}(\varepsilon)=\sum_{j=0}^{i}\varepsilon^j B^{(j)}. \tag{2.5}$$

The normal-form method advocated in the present paper can be succinctly described as a procedure for finding operators $S^{(i)}\in X$ and $K^{(i)}\in Y$ $(i=1,...,N)$, such that H_ε is reduced to normal form to order ε^N for some $N\geqslant 1$. By this we mean that the equation

$$\begin{aligned}&\exp(\varepsilon^N S^{(N)})\cdots\exp(\varepsilon S^{(1)})H_\varepsilon\ \exp(-\varepsilon S^{(1)})\cdots\exp(-\varepsilon^N S^{(N)})\\ &\quad=K^{[N]}(\varepsilon)+O(\varepsilon^{N+1})\end{aligned} \tag{2.6}$$

holds for this N in the sense of formal power series. Here

$$K^{[N]}(\varepsilon)=\sum_{i=0}^{N}\varepsilon^i K^{(i)} \tag{2.7}$$

is the Nth order truncation of the pertinent normal form in M^∞ and $O(\varepsilon^{N+1})$ denotes a series in M^∞ in which the coefficients of ε^i for $i\leqslant N$ are the zero operator. Later in this section, we will consider briefly the relation between this normal form and Rayleigh–Schrödinger perturbation theory.

We begin by discussing the method in the simplest case: $N=1$. Setting $N=1$ in (2.6) and equating the coefficients of ε^0, ε^1 on both sides of this equation, we obtain

$$K^{(0)}=H_0, \tag{2.8a}$$

$$\text{ad } H_0 S^{(1)}=V-K^{(1)}. \tag{2.8b}$$

We require that $S^{(1)}$, besides belonging to X, should satisfy

$$\text{ad } H_0 S^{(1)}=\tilde{V}. \tag{2.8c}$$

This equation and the condition $S^{(1)}\in X$ determine $S^{(1)}$ uniquely, at least in a formal sense, since they completely determine the matrix elements of this operator in the Φ basis:

$$\langle\Phi_m,S^{(1)}\Phi_n\rangle=\begin{cases}\langle\Phi_m,V\Phi_n\rangle/(\lambda_m-\lambda_n) & (\lambda_m\neq\lambda_n),\\ 0 & (\lambda_m=\lambda_n).\end{cases} \tag{2.9}$$

By (2.2), (2.8b), and (2.8c),

$$K^{(1)}=\hat{V}. \tag{2.8d}$$

We next consider the present method in the general case $N\geqslant 1$. We first rewrite (2.6) in the form

$$H_\varepsilon=R_N(\varepsilon)K^{[N]}(\varepsilon)+\varepsilon^{N+1}Z_{N+1}(\varepsilon), \tag{2.10}$$

where

$$R_N(\varepsilon)=\exp(-\varepsilon\ \mathrm{ad}\ S^{(1)})\cdots\exp(-\varepsilon^N\ \mathrm{ad}\ S^{(N)}) \tag{2.11}$$

and $Z_{N+1}(\varepsilon)\in M^\infty$.[19] To arrive at (2.10), we have used the relation[20]

$$\exp(\alpha\ \mathrm{ad}\ B)A=\exp(\alpha B)A\ \exp(-\alpha B)\quad(\alpha\in\mathbf{R};A,B\in\mathscr{L}(\mathscr{H})). \tag{2.12}$$

The requirement (2.10) can be replaced by two conditions. The first includes all terms of $O(\varepsilon^k)$ in (2.10) with $k\leqslant 2N$ and the second all those with $k>2N$. The first condition can be expressed in the form

$$H_\varepsilon=R_N^{[N]}(\varepsilon)K^{[N]}(\varepsilon)+\varepsilon^{N+1}W_{N+1}(\varepsilon), \tag{2.13}$$

where $W_{N+1}(\varepsilon)=Z_{N+1}^{[N-1]}(\varepsilon)$ and where, of course, $R_N^{[N]}(\varepsilon)$ denotes the truncation of the formal power series in N^∞ symbolized by (2.11) after the term of order ε^N. As we will show in a moment, (2.13) completely determines a truncated normal form $K^{[N]}(\varepsilon)$ with the desired properties. The second condition merely determines the coefficients $Z_{N+1}^{(k)}$ with $k\geqslant N$ in the formal series $Z_{N+1}(\varepsilon)$ in terms of the $K^{(i)}$ with $i\leqslant N$, and will be of no further interest here. We write

$$W_{N+1}(\varepsilon)=\sum_{i=0}^{N-1}\varepsilon^i W_{N+1}^{(i)}, \tag{2.14}$$

the operators $W_{N+1}^{(i)}$ being, of course, ε-independent.

We claim that (2.13) holds if the polynomials $R_N^{[N]}(\varepsilon),K^{[N]}(\varepsilon),W_{N+1}(\varepsilon)$ in ε are constructed in terms of the operators $S^{(i)},K^{(i)},W_{i+1}^{(j)}$ which will now be specified. $S^{(i)}$ is defined as the unique solution in X of the equation

$$\mathrm{ad}\ H_0S^{(i)}=V_i-K^{(i)}\quad(i\geqslant 1), \tag{2.15a}$$

K_0 is given by (2.8b), and

$$K^{(i)}=\hat{V}_i\quad(i\geqslant 1), \tag{2.15b}$$

whence $K^{(i)}\in Y$ for $i\geqslant 0$. In (2.15a) and (2.15b),

$$V_1=V, \tag{2.16a}$$

$V^{(i)}(i\geqslant 2)$ is defined recursively in terms of $S^{(j)},K^{(k)}(1\leqslant j\leqslant i-1,0\leqslant k\leqslant i-1)$ by

$$V_i=-\sum_{j=1}^{i}R_{i-1}^{(j)}K^{(i-j)}\quad(i\geqslant 2) \tag{2.16b}$$

and we define the operators $W_{i+1}^{(j)}\in\mathscr{L}(\mathscr{H})$ by

$$W_{i+1}^{(j)}=-\sum_{k=j+1}^{i}R_i^{(k)}K^{(i+j-k+1)}\quad(0\leqslant j\leqslant i-1,i\geqslant 1). \tag{2.15c}$$

Here, $R_j^{(k)}$ denotes the coefficient of ε^k $(k\geqslant 0)$ in the formal-power-series representation of the operator $R_j(\varepsilon)\in N^\infty$, and is given by

$$R_j^{(0)}A=A \quad (j\geqslant 1,\ A\in\mathscr{L}(\mathscr{H})), \tag{2.17a}$$

$$R_j^{(k)}A=\sum_{n\in\mathbf{Z}_+^j,\,s(n)=k}\frac{(-1)^{|n|}}{n!}\,(\mathrm{ad}\,S^{(1)})^{n_1}\cdots(\mathrm{ad}\,S^{(j)})^{n_j}A \quad (j\geqslant 1,k\geqslant 1,A\in\mathscr{L}(\mathscr{H})), \tag{2.17b}$$

where $|n|=\Sigma_{r=1}^{j}n_r$, $n!=n_1!\cdots n_j!$ and $s(n)=\Sigma_{r=1}^{j}rn_r$ for each $n=(n_1,\ldots,n_j)\in\mathbf{Z}_+^j$, and where, as usual, $(\mathrm{ad}\,S)^0A=A,(\mathrm{ad}\,S)^kA=(\mathrm{ad}\,S)^{k-1}(\mathrm{ad}\,SA)(k\in\mathbf{N},A\in\mathscr{L}(\mathscr{H}))$.

To prove the above claim, we begin by operating on the truncated normal form $K^{[N]}(\varepsilon)$ with the truncated superoperator $R_N^{[N]}(\varepsilon)$ in a purely formal way, thus obtaining

$$R_N^{[N]}(\varepsilon)K^{[N]}(\varepsilon)=\sum_{i=0}^{N}\varepsilon^i\sum_{j=0}^{i}R_N^{(j)}K^{(i-j)}+\varepsilon^{N+1}\sum_{i=0}^{N-1}\varepsilon^i\sum_{j=i+1}^{N}R_N^{(j)}K^{(i-j+N+1)}, \tag{2.18}$$

and use (2.18) and (2.14) to express the rhs of (2.13) as a polynomial of order $2N$ in ε. We then equate coefficients of ε^i in both sides of (2.13) for $0\leqslant i\leqslant 2N$. If $N=1$, our previous calculations for $i=0$, 1, when supplemented by a trivial calculation for $i=2$ show that the claim is true. Henceforth, until further notice, we will assume that $N\geqslant 2$. In this case, it is only necessary to equate coefficients of ε^i in the subcases $2\leqslant i\leqslant N$ and $N+1\leqslant i\leqslant 2N$, since the results of doing this for $i=0$, 1 merely reproduce those obtained in the case $N=1$. Equating coefficients of ε^i in the first subcase yields the condition

$$\sum_{j=0}^{i}R_N^{(j)}K^{(i-j)}=0 \quad (2\leqslant i\leqslant N). \tag{2.19}$$

To show that (2.19) is satisfied by the $S^{(i)}$ and K_i specified in the preceding paragraph, we note that (2.8a), (2.15a), (2.16b), (2.17a), and the relations

$$R_i^{(j)}A=R_k^{(J)}A \quad (1\leqslant j\leqslant i\leqslant k,A\in\mathscr{L}(\mathscr{H})), \tag{2.20a}$$

$$R_i^{(i)}A=-\,\mathrm{ad}\,S^{(i)}A+R_{i-1}^{(i)}A \quad (i\geqslant 2,\ A\in\mathscr{L}(\mathscr{H})) \tag{2.20b}$$

(following directly from (2.17b)), entail that definition (2.16b) can be written in the form (2.19) for arbitrary $N\geqslant 2$.

Finally, it is trivial to verify that the expression for $W_{N+1}^{(j)}$ obtained by equating coefficients of ε^i for $N+1\leqslant i\leqslant 2N$ $(N\geqslant 2)$, agrees with definition (2.15c). Since the conditions on the coefficients of ε^i have been shown to be satisfied for all $N\geqslant 1$ by the $S^{(i)},K^{(i)},W_i^{(j)}$ specified in the penultimate paragraph, the proof of the claim is complete.

This concludes the formal construction of the relevant operators $S^{(i)}\in X$, $K^{(i)}\in Y$, $W_{N+1}^{(j)}$ satisfying (2.13) for arbitrary $N\geqslant 1$, an inequality which we suppose to hold henceforth. We note that the matrices $(K_{mn}^{(i)})$ $(i\geqslant 0)$, and therefore $(K_{mn}^{[N]}(\varepsilon))$, representing $K^{(i)}$ and $K^{[N]}(\varepsilon)$ in the Φ-basis, are Hermitian. The hermiticity property follows from the corresponding property possessed by the matrices representing H_0 and V, the relevant definitions, and a simple inductive argument, which will be stated precisely in Sec. IV. (The fact that these matrices are real in the Φ-basis is immaterial to our purposes.)

To illustrate these general considerations, we record the following formulas for the matrix elements of $K^{(1)},K^{(2)}$ in this basis, obtained from (2.15b), (2.16), and (2.17):

$$K_{mn}^{(1)}=\delta_{\lambda_m,\lambda_n}V_{mn},$$

$$K_{mn}^{(2)}=\delta_{\lambda_m,\lambda_n}\sum_{r\lambda_r\neq\lambda_m}\frac{V_{mr}V_{rn}}{\lambda_m-\lambda_r}.$$

Using these formulas, one can show that for $k=1,2$ the eigenvalues of $K^{[k]}(\varepsilon)$ coincide to within $O(\varepsilon^k)$ with those of H_ε formally given by kth order degenerate Rayleigh–Schrödinger perturbation theory. We conjecture that this is also the case for general $k\geqslant 1$, but will not pursue the matter

any further here, since it would involve us in questions which are not strictly relevant to our present goals. Nevertheless, it would be interesting to pursue them in a separate investigation.

The Nth-order approximant to the exact solution $\psi(t,\varepsilon)$ of the IVP (1.1) is defined by[1]

$$\psi_N(t,\varepsilon)=R_N^{[N]}(\varepsilon)(U_N(t,\varepsilon))\psi_0, \tag{2.21}$$

where the parenthesis around $U_N(t,\varepsilon)$ emphasizes that $R_N^{[N]}(\varepsilon)$ acts on it and where

$$U_N(t,\varepsilon)=\exp(-itK^{[N]}(\varepsilon)). \tag{2.22}$$

Since we require that $U_N(t,\varepsilon)$ be a well-defined unitary operator and want to avoid mathematical subtleties with which we cannot cope in this section, we shall assume for the moment that $K^{[N]}(\varepsilon)$ is self-adjoint. In Secs. III and IV we shall replace $K^{[N]}(\varepsilon)$ by its self-adjoint extension in (2.22), thus avoiding this assumption.

More explicitly, (2.21), (2.22), and (2.17) yield for $N=1,2,3$:[1]

$$\psi_1(t,\varepsilon)=(I-\varepsilon\tau_1)U_1(t,\varepsilon),$$

$$\psi_2(t,\varepsilon)=\{I-\varepsilon\tau_1+\varepsilon^2[\tfrac{1}{2}\tau_1^2-\tau_2]\}U_2(t,\varepsilon),$$

$$\psi_3(t,\varepsilon)=\{I-\varepsilon\tau_1+\varepsilon^2[\tfrac{1}{2}\tau_1^2-\tau_2]+\varepsilon^3[-\tfrac{1}{6}\tau_1^3+\tau_1\tau_2-\tau_3]\}U_3(t,\varepsilon),$$

where I is the unit superoperator on $\mathscr{L}(\mathscr{H})$ and $\tau_i=\mathrm{ad}\,S^{(i)}$. It is worth remarking that $\psi_N(t,\varepsilon)$ could be calculated, in a practical numerical sense, for sufficiently small ν and N and ''simple'' enough initial states ψ_0 (e.g., finite linear combinations of Φ_k's). In particular, note that for any given $m\in\mathbf{Z}_+^\nu$, the matrix elements $\langle\Phi_m,U_N(t,\varepsilon)\Phi_n\rangle$ are nonvanishing for at most a finite number of n-values, namely, those with $\lambda_m\neq\lambda_n$. Hence the calculation of $U_N(t,\varepsilon)\Phi_k$ for any $k\in\mathbf{Z}_+^\nu$ can be reduced to an elementary diagonalization procedure in a finite-dimensional space. This is also the case for the more satisfactorily defined operator $U_N(t,\varepsilon)$ considered in Secs. III and IV.

Our next goal is to show that $\psi_N(t,\varepsilon)$ satisfies a differential equation which only differs from (1.1a) by terms of order ε^{N+1}. We find by formally differentiating (2.21) and then proceeding as described below

$$\begin{aligned} i\frac{d\psi_N(t,\varepsilon)}{dt}&=R_N^{[N]}(\varepsilon)(K^{[N]}(\varepsilon)U_N(t,\varepsilon))\psi_0\\ &=\sum_{i=0}^{N}\varepsilon^i R_N^{(i)}(K^{[N]}(\varepsilon)U_N(t,\varepsilon))\psi_0\\ &=\sum_{i=0}^{N}\varepsilon^i\sum_{j=0}^{i}R_N^{(j)}K^{[N]}(\varepsilon)\cdot R_N^{(i-j)}(U_N(t,\varepsilon))\psi_0\\ &=R_N^{[N]}(\varepsilon)K^{[N]}(\varepsilon)\cdot R_N^{[N]}(\varepsilon)(U_N(t,\varepsilon))\psi_0+\varepsilon^{N+1}\rho_N(t,\varepsilon), \end{aligned} \tag{2.23}$$

where

$$\rho_N(t,\varepsilon)=-\sum_{i=0}^{N-1}\varepsilon^i\sum_{j=i+1}^{N}R_N^{(j)}K^{[N]}(\varepsilon)\cdot R_N^{(i-j+N+1)}(U_N(t,\varepsilon))\psi_0 \tag{2.24}$$

and where we have carried out obvious formal manipulations, analogous to those employed to arrive at (2.18), and have invoked the relation[21]

$$R_j^{(i)}(AB)=\sum_{k=0}^{i}R_j^{(k)}A\cdot R_j^{(i-k)}B. \tag{2.25}$$

By (2.23), (2.21), and (2.13), we see that $\psi_N(t,\varepsilon)$ satisfies the differential equation

$$i\,\frac{d\psi_N(t,\varepsilon)}{dt}=H_\varepsilon\psi_N(t,\varepsilon)+\varepsilon^{N+1}\varphi_N(t,\varepsilon), \tag{2.26a}$$

where

$$\varphi_N(t,\varepsilon)=-W_{N+1}(\varepsilon)\psi_N(t,\varepsilon)+\rho_N(t,\varepsilon). \tag{2.27}$$

Furthermore, by (2.21), (2.22), and (2.17),

$$\psi_N(0,\varepsilon)=\psi_0. \tag{2.26b}$$

Hence $\psi_N(t,\varepsilon)$ satisfies the same Schrödinger evolution equation (1.1a) as $\psi(t,\varepsilon)$ to within terms of $O(\varepsilon^N)$ and fulfills exactly the same initial condition (1.1b) as $\psi(t,\varepsilon)$. The last fact plays an essential role in the heuristic derivation of the error estimate (1.4) in the next paragraph, as well as in its rigorous counterpart in Sec. IV.

Integrating (2.26a) by the method of variation of constants and using (2.26b), we obtain

$$\psi_N(t,\varepsilon)=\exp(-itH_\varepsilon)\psi_0-i\varepsilon^{N+1}\int_0^t\exp[-i(t-s)H_\varepsilon]\varphi_N(s,\varepsilon)ds. \tag{2.28}$$

By (2.28), $\psi(t,\varepsilon)=\exp(-itH_\varepsilon)\psi_0$, the unitarity of $\exp(-itH_\varepsilon)$, and the boundedness of $\|\varphi_N(t,\varepsilon)\|$ for $t\in\mathbf{R}$, $0\leqslant\varepsilon\leqslant\varepsilon_0<\infty$ (see (4.19)), implied by our conditions on V and the frequencies ω_i which are stated in Sec. III, we infer that

$$\|\psi(t,\varepsilon)-\psi_N(t,\varepsilon)\|\leqslant\varepsilon^{N+1}\left|\int_0^t\|\varphi_N(s,\varepsilon)\|ds\right|\leqslant\text{ const }\varepsilon^{N+1}|t| \tag{2.29}$$

at each of the latter t,ε-values. We emphasize that these conditions are satisfied by a very wide class of resonant and nonresonant oscillators.

III. ASSUMPTIONS, DEFINITIONS, AND STATEMENT OF MAIN RESULT

As a first step in making precise the heuristic discussions in Sec. II, we state our assumptions on V and the ω_i. Fixing $\nu\geqslant 2$, we will assume henceforth that V possesses the following properties:

(I) V is a maximal operator of multiplication in $\mathscr{H}=L^2(\mathbf{R}^\nu)$ by a real-valued function in $C^\infty(\mathbf{R}^\nu)$ which will also be denoted by V.

(II) For each $r=(r_1,\ldots,r_\nu)\in\mathbf{Z}_+^\nu$, there exist non-negative constants Γ_r,μ_r such that

$$\left|\frac{\partial^{|r|}V(x)}{\partial x_1^{r_1}\cdots\partial x_\nu^{r_\nu}}\right|\leqslant\Gamma_r(|x|+1)^{\mu},$$

at each $x=(x_1,\ldots,x_\nu)\in\mathbf{R}^\nu$, where $|r|=r_1+\cdots+r_\nu$ and $|x|=\Sigma_{i=1}^\nu|x_i|$.

(III) The differential operator

$$\frac{1}{2}\sum_{i=1}^{\nu}\left(-\frac{\partial^2}{\partial x_i^2}+\omega_i^2x_i^2\right)+\varepsilon V(x_1,\ldots,x_\nu)$$

on $C_0^\infty(\mathbf{R}^\nu)$ is essentially self-adjoint in $\mathscr{H}$ for each $\varepsilon\geqslant 0$, its unique self-adjoint extension being denoted by H_ε at each such ε. The frequencies ω_i are fixed positive numbers.

Remark: Property (III) is entailed by (I) and (II) if $\frac{1}{2}\Sigma_{i=1}^\nu\omega_i^2x_i^2+\varepsilon V(x)$ is bounded below on $\mathbf{R}^\nu$ for each $\varepsilon\geqslant 0$.[22]

Letting ρ be the maximum number of rationally independent frequencies ω_i, we will number then as $\omega_1,\ldots,\omega_\rho$ w.l.g. Writing $|j|_\rho=\Sigma_{i=1}^\rho|j_i|$ for the norm of vectors $j\in\mathbf{R}^\rho$, we suppose that the following diophantine condition is satisfied:

(IV) If $\rho\geqslant 2$, there exist positive constants γ, η such that for all $0\neq k=(k_1,\ldots,k_\rho)\in\mathbf{Z}^\rho$,

$$\left|\sum_{i=1}^{\rho} \omega_i k_i\right| \geqslant \gamma |k|_\rho^{-\eta}, \tag{3.1}$$

where $\mathbf{Z}^\rho$ is the set of all vectors $(j_1,\ldots,j_\rho)$ with integer components.

Remarks: (1) Condition (IV) is imposed to avoid convergence difficulties in sums involving differences $\lambda_m-\lambda_n$ in denominators. These difficulties are analogous to ones occurring in classical canonical perturbation theory.[23] One only needs to assume that (IV) is satisfied for $\rho\geqslant 2$. Indeed, if $\rho=1$, the ω_i are multiples of some $\omega_0>0$, and thus $|\lambda_m-\lambda_n|$ is bounded away from zero for each fixed $m\in\mathbf{Z}_+^\nu$ as n ranges over this set. Hence (3.1) is automatically satisfied in this case.

(2) It is well known that if $\rho\geqslant 2$ and $\eta\geqslant\nu$, then the set of vectors $(\omega_1,\ldots,\omega_\rho)$ with positive components for which there exists no $\gamma>0$ such that the condition (3.1) holds for all $0\neq k\in\mathbf{Z}^\rho$ has Lebesgue measure zero.[24]

In order to state our main result rigorously, we need to define the Nth-order approximant $\psi_N(t,\varepsilon)$ more precisely than in Sec. II. The following definitions and remarks are made for this purpose, as well as to prepare the way for the developments in Sec. IV.

Definition 1: If A is an operator on $\mathscr{H}$, then we write[25]

$$C^\infty(A)=\bigcap_{j=1}^{\infty} D(A^j).$$

Remarks: (1) If $A\in\mathscr{L}(\mathscr{H})$ is self-adjoint, then $C^\infty(A)$ is dense in $\mathscr{H}$.[26] In particular, $C^\infty(H_0)$ is dense in $\mathscr{H}$ and contains the Schwartz space $S(\mathbf{R}^\nu)$ of functions of fast decrease.

(2) $C^\infty(H_0)$ is invariant under H_0, V, and the other operators of the theory.

Our last assumption is motivated by these properties of $C^\infty(H_0)$, as well as by the desire to avoid unessential complications which would ensue by admitting ε-dependent initial states.

(V) The initial state $\psi_0=\psi(0,\varepsilon)$ has the following properties:

$$\psi_0=\psi(0,\varepsilon)\in C^\infty(H_0), \tag{3.2a}$$

$$\psi_0 \text{ is } \varepsilon\text{-independent.} \tag{3.2b}$$

Remark: Conditions (III) and (V) entail that $\psi_0\in D(H_\varepsilon)$ holds for each $\varepsilon\geqslant 0$, and thus that the IVP (1.1) has the unique solution $\psi(t,\varepsilon)=\exp(-itH_\varepsilon)\psi_0$ for all $t\in\mathbf{R}$, $\varepsilon\geqslant 0$. Indeed, at all such ε, $(H_0+\varepsilon V)|C^\infty(H_0)$ is a symmetric extension of $(H_0+\varepsilon V)|C_0^\infty(\mathbf{R}^\nu)$ having H_ε as its unique self-adjoint extension (by (III) and $C_0^\infty(\mathbf{R}^\nu)\subset C^\infty(H_0)$).[25] Thus under these conditions, (1.2) holds on $C^\infty(H_0)$ and $\psi_0\in C^\infty(H_0)\subset D(H_\varepsilon)$.

The next definition makes precise the sense in which the infinite sums occurring in the sequel are to be understood. Henceforth, it is convenient to set $\Omega=\mathbf{Z}_+^\nu$.

Definition 2: Let $\{\Delta_k\}(k=(k_1,k_2,\ldots,k_\nu)\in\Omega)$ be a sequence of subsets $\Delta_k=[0,k_1]\times[0,k_2]\times\cdots\times[0,k_\nu]$. A sum of the form $\Sigma_{m\in\Omega}f_m$, where each $f_m\in\mathbf{C}$, is defined as $\lim_{k_1,\ldots,k_\nu\to\infty}\Sigma_{m\in\Delta_k}f_m$ if this limit exists in $\mathbf{C}$. Analogously, a sum of the form $\Sigma_{m\in\Omega}g_m\Phi_m$, where each $g_m\in\mathbf{C}$, is defined as the strong limit $\mathrm{s}-\lim_{k_1,\ldots,k_\nu\to\infty}\Sigma_{m\in\Delta_k}g_m\Phi_m$ in $\mathscr{H}$ if this limit exists.

Given matrices $\mathscr{A}=(A_{mn})$, $\mathscr{B}=(B_{mn})(m,n\in\Omega)$, we naturally define their product $\mathscr{A}\mathscr{B}$ as the matrix $(\Sigma_{r\in\Omega}A_{mr}B_{rn})$ provided that this sum exists in the sense of Definition 2 for each of the latter m,n.[27]

Moreover, we will denote the adjoint of an operator A by A^*, the hermitian adjoint of a matrix $\mathscr{A}$ by $\mathscr{A}^*$, and the complex conjugate of $z\in\mathbf{C}$ by $\overline{z}$.

Definition 3: Denote the inner product in $\mathscr{H}$ by $\langle .,. \rangle$, assuming that it is antilinear in the first argument and linear in the second. Let $\mathscr{A}=(A_{mn})$ $(m,n\in\Omega)$ be a matrix of complex numbers which is square-summable by rows and columns, i.e., $\Sigma_{m\in\Omega}|A_{mn}|^2<\infty$ $(n\in\Omega)$ and $\Sigma_{n\in\Omega}|A_{mn}|^2<\infty$ $(m\in\Omega)$, respectively. An operator $A\in\mathscr{L}(\mathscr{H})$ is said to be *associated* with $\mathscr{A}$, or $A\leftrightarrow\mathscr{A}$ in symbols, if

$$D(A)=\left\{ f\in\mathscr{H}\colon \sum_{m\in\Omega}\left|\sum_{n\in\Omega} A_{mn}\langle\Phi_n,f\rangle\right|^2<\infty\right\}, \tag{3.3a}$$

and

$$Af=\sum_{m\in\Omega}\left(\sum_{n\in\Omega} A_{mn}\langle\Phi_n,f\rangle\right)\Phi_m \quad (f\in D(A)). \tag{3.3b}$$

Remarks: (1) Stone[28] has considered linear operators associated with infinite matrices in a more general sense than that of Definition 3. In general, infinite matrices have various pathological properties which make them unsuitable for representing unbounded linear operators.[29] In particular, they may not be associative under matrix multiplication.[30] However, the infinite matrices considered in this paper are well enough behaved to be useful tools for establishing its conclusions.

(2) The sums over n in (3.3a) and (3.3b) converge absolutely, because of the square-summability of $\mathscr{A}$ by columns, Schwarz's inequality in $\ell^2(\Omega)$, and Parseval's identity.

(3) The relation $A\leftrightarrow\mathscr{A}$ between the set J of operators A specified by Definition 3 and the set $\mathscr{J}$ of matrices $\mathscr{A}=(A_{mn})$ with the properties stated in this definition is a bijective map from J onto $\mathscr{J}$. Indeed, by the square summability of each $\mathscr{A}\in\mathscr{J}$ by rows and the orthonormality of the Φ_k, one sees that the entries of each such matrix $\mathscr{A}$ are uniquely determined by the operator $A\leftrightarrow\mathscr{A}$, namely, $A_{mn}=\langle\Phi_m,A\Phi_n\rangle$.

We proceed to define the matrices and operators of the theory. In contrast with the heuristic ''definitions'' given in Sec. II, most of the operators of interest will now be defined as those associated with infinite matrices of the type specified next.

Definition 4: We denote by $\mathscr{M}$ the set of matrices $\mathscr{A}=(A_{mn})$ $(m,n\in\Omega)$ over $\mathbf{C}$ such that the inequalities

$$|A_{mn}|\leqslant \text{const}\ \lambda_m^{a(p)}\lambda_n^{-p}, \tag{3.4a}$$

$$|A_{mn}|\leqslant \text{const}\ \lambda_n^{a(p)}\lambda_m^{-p} \tag{3.4b}$$

hold for all $m,n\in\Omega$ and all $p\in\mathbf{N}$, where const and the $a(p)$ are real constants independent of m,n. The $a(p)$ are called *exponents* of $\mathscr{A}$. The set whose members are those operators in $\mathscr{L}(\mathscr{H})$ associated with matrices in $\mathscr{M}$ is denoted by M.[31] That composed of operators in M restricted to $C^\infty(H_0)$ is called M_0.

Remark: By Lemma 3(2) (Sec. IV),[32] all matrices in $\mathscr{M}$ are square-summable by rows and columns. Hence the definition of $\underline{M}$ makes sense (recall Definition 3).

Analogously to the notation $\tilde{A},\hat{A}$ for operators used in Sec. II, for any matrix $\mathscr{B}=(B_{mn})$ we will denote by $\tilde{\mathscr{B}}$, $\hat{\mathscr{B}}$ the matrices with entries $(1-\delta_{\lambda_m,\lambda_n})B_{mn}$, $\delta_{\lambda_m,\lambda_n}B_{mn}$, respectively. Moreover, for each matrix $\mathscr{B}\in\mathscr{M}$ we denote by ad $\mathscr{B}$ the linear operator from $\mathscr{M}$ to $\mathscr{M}$ acting by ad $\mathscr{B}\mathscr{C}=\mathscr{B}\mathscr{C}-\mathscr{C}\mathscr{B}$. This last definition is legitimate because $\mathscr{M}$ is an associative matrix algebra over $\mathbf{C}$ when equipped with the usual definition of matrix identity, with the usual operations of multiplication by scalars and matrix summation, and with matrix multiplication as defined after Definition 2 (see Lemma 3(1)).

The key matrices and operators acting on matrices specified by Definitions 5(a) and 5(b) below have the same ''structure'' as do the analogous expressions in terms of the operators in $\mathscr{L}(\mathscr{H})$ and the operators acting on them which were introduced formally in Sec. II. Indeed, these definitions anticipate the isomorphism existing between $\mathscr{M}$ and M_0 when viewed as associative algebras, which is stated in Lemma 5.

Definition 5(a): The infinite matrices $\mathscr{S}^{(i)}=(S_{mn}^{(i)})$, $\mathscr{V}_i=((V_i)_{mn})$, $\mathscr{K}^{(i)}=(K_{mn}^{(i)})$ $(i\geqslant 1)$ and $\mathscr{W}_{i+1}^{(j)}=((\mathscr{W}_{i+1}^{(j)})_{mn})$ $(0\leqslant j\leqslant i-1,\ i\geqslant 1)$ are defined inductively as follows:

(1) $\mathscr{S}^{(i)},\mathscr{K}^{(i)}$ are the unique matrices with $(\mathscr{S}^{(i)})\hat{}=0$, $(\mathscr{K}^{(i)})\tilde{}=0$ which satisfy

$$\text{ad}\,\mathscr{K}^{(0)}\mathscr{S}^{(i)}=\mathscr{V}_i-\mathscr{K}^{(i)} \quad (i\geqslant 1), \tag{3.5}$$

or, equivalently,

$$\text{ad}\,\mathscr{K}^{(0)}\mathscr{S}^{(i)}=(\mathscr{V}_i)^{\sim}\quad(i\geqslant 1),\tag{3.6a}$$

$$\mathscr{K}^{(i)}=(\mathscr{V}_i)^{\wedge}\quad(i\geqslant 1).\tag{3.6b}$$

Here, $\mathscr{K}^{(0)}$ is the diagonal matrix with which H_0 is associated:

$$\mathscr{K}^{(0)}=(\lambda_m\delta_{m,n}).\tag{3.7}$$

(2) One defines

$$\mathscr{V}_1=(\langle\Phi_m,V\Phi_n\rangle)=(V_{mn}),\tag{3.8a}$$

$$\mathscr{V}_i=-\sum_{j=1}^{i}\mathscr{R}_{i-1}^{(j)}\mathscr{K}^{(i-j)}\quad(i\geqslant 2),\tag{3.8b}$$

$$\mathscr{W}_{i+1}^{(j)}=-\sum_{k=j+1}^{i}\mathscr{R}_i^{(k)}\mathscr{K}^{(i+j-k+1)}\quad(0\geqslant j\geqslant i-1,i\geqslant 1),\tag{3.8c}$$

where $\mathscr{R}_j^{(k)}$ $(j\geqslant 1,\ k\geqslant 0)$ denotes a linear operator from $\mathscr{M}$ into $\mathscr{M}$ acting by

$$\mathscr{R}_j^{(0)}\mathscr{A}=\mathscr{A}\quad(j\geqslant 1,\mathscr{A}\in\mathscr{M}),\tag{3.9a}$$

$$\mathscr{R}_j^{(k)}\mathscr{A}=\sum_{n\in\mathbf{Z}_+^j,\,s(n)=k}\frac{(-1)^{|n|}}{n!}(\text{ad}\,\mathscr{S}^{(1)})^{n_1}\cdots(\text{ad}\,\mathscr{S}^{(j)})^{n_j}\mathscr{A},$$

$$(j\geqslant 1,k\geqslant 1,\mathscr{A}\in\mathscr{M}).\tag{3.9b}$$

Remarks: (1) Note that each term in the sums in (3.8b) and (3.8c) is a linear combination of finite products of matrices in $\mathscr{M}$ [see (3.9b) and the proof of Lemma 6(1)], and is thus well defined since $\mathscr{M}$ is an associative algebra over **C** under the stated operations.

(2) Obviously, Definition 5(a) implies that for each $i\geqslant 1$,

$$S_{mn}^{(i)}=\begin{cases}(V_i)_{mn}/(\lambda_m-\lambda_n) & (\lambda_m\neq\lambda_n),\\ 0 & (\lambda_m=\lambda_n),\end{cases}\tag{3.10}$$

Definition 5(b): (1) $S^{(i)},V_i,K^{(i)}$ $(i\geqslant 1)$ and $W_{i+1}^{(j)}$ $(0\leqslant j\leqslant i-1,\ i\geqslant 1)$ are the operators in $\mathscr{L}(\mathscr{H})$ which are associated with the respective matrices $\mathscr{S}^{(i)},\hat{\mathscr{V}}_i,\mathscr{K}^{(i)},\mathscr{W}_{i+1}^{(j)}$. Moreover, we set $K^{(0)}=H_0$.

(2) For each $i\geqslant 1$, $\varepsilon\geqslant 0$, the operator $K^{[i]}(\varepsilon)$ is defined as the operator sum

$$K^{[i]}(\varepsilon)=\sum_{j=0}^{i}\varepsilon^jK^{(j)},\tag{3.11}$$

while the operators $K_i(\varepsilon)$ and $W_{i+1}(\varepsilon)$ are those associated with the respective matrices

$$\mathscr{K}^{[i]}(\varepsilon)=\sum_{j=0}^{i}\varepsilon^j\mathscr{K}^{(j)},\tag{3.12}$$

$$\mathscr{W}_{i+1}(\varepsilon)=\sum_{j=0}^{i-1}\varepsilon^j\mathscr{W}_{i+1}^{(j)}.\tag{3.13}$$

Remarks: (1) Part (1) of this definition makes sense because the matrices mentioned therein are in $\mathscr{M}$, thus being square-summable by rows and columns.

(2) By Lemma 7, $K_i(\varepsilon)$ in Part (2) of Definition 5(b) is the unique self-adjoint extension of $K^{[i]}(\varepsilon)$ in (3.11) for $i\geqslant 1$, $\varepsilon\geqslant 0$.

Definition 5(c): For each $i,N\geqslant 1$, $R_i^{[N]}(\varepsilon)$ denotes the superoperator acting by $R_i^{[N]}A=\Sigma_{j=0}^{N}\varepsilon^j R_i^{(j)}A$ on each $A\in\mathscr{L}(\mathscr{H})$, where the $R_i^{(j)}$ are defined by (2.17), the operators $S^{(k)}$ in (2.17b) being those specified by Definition 5(b).

Definition 5(d): The Nth-order approximant to the solution of the IVP (1.1) is defined by

$$\psi_N(t,\varepsilon)=R_N^{[N]}(\varepsilon)(U_N(t,\varepsilon))\psi_0 \tag{3.14}$$

for all $N\geqslant 1$, $t\in\mathbf{R}$, $0\leqslant\varepsilon\leqslant\varepsilon_0$. Here,

$$U_N(t,\varepsilon)=\exp(-itK_N(\varepsilon)), \tag{3.15}$$

$K_N(\varepsilon)$ being the self-adjoint operator in Part (2) of Definition 5(b) and ψ_0 satisfying conditions (3.2).

Remark: Definition (3.14) makes sense by properties (a) and (b) in the proof of Lemma 8. Note that in (3.15) the self-adjoint operator $K_N(\varepsilon)$ replaces the operator $K^{[N]}(\varepsilon)$ in (2.22), which was loosely defined in Sec. II and is now precisely specified by Part (2) of Definition 5(b). This replacement has been made because $K^{[N]}(\varepsilon)$ is not generally self-adjoint, and therefore $\exp(-itK^{[N]}(\varepsilon))$ is not generally well-defined. If it were not, a breakdown of our analysis would occur.

Our principal result is as follows.

Theorem 1: Let H_0 and V obey conditions (I)–(III), let (IV) hold if $\rho\geqslant 2$, and let the initial state ψ_0 satisfy (V). Then for each $N\geqslant 1$, $0\leqslant\varepsilon_0<\infty$ we have the uniform error estimate

$$\|\psi(t,\varepsilon)-\psi_N(t,\varepsilon)\|\leqslant C_N\varepsilon^{N+1}|t| \tag{3.16}$$

if $t\in\mathbf{R}$, $0\leqslant\varepsilon\leqslant\varepsilon_0$, where $\|.\|$ is the $\mathscr{H}$-norm and $C_N=C_N(\psi_0,\varepsilon_0)$ a positive constant.

Remarks: (1) This theorem is the first rigorous error estimate for the present normal-form method of this degree of generality, applying to cases in which V is not necessarily a polynomial and/or H_0 has degenerate eigenvalues.

(2) Under certain nonresonance conditions, an error estimate of type (3.16) was obtained in Refs. 1 and 2 for the case of a system of simple harmonic oscillators coupled by a potential which was a polynomial in the coordinates and momenta.

(3) From Theorem 1, one immediately infers that for any $\delta\in(0,N+1]$ and any pair T,ε_0 of positive numbers, the uniform error estimate

$$\|\psi(t,\varepsilon)-\psi_N(t,\varepsilon)\|\leqslant C'_{N,\delta,T}\varepsilon^{N+1-\delta}$$

holds for all $|t|\leqslant T\varepsilon^{-\delta}$, $\varepsilon\in[0,\varepsilon_0]$, where $C'_{N,\delta,T}=C'_{N,\delta,T}(\psi_0,\varepsilon_0)$ is a positive constant.

IV. AUXILIARY RESULTS AND PROOF OF THEOREM 1

The proof of Theorem 1 is based on Lemmas 1–9 below. Once Lemma 9 has been proved, the theorem will follow readily.

Assertions (1) and (2) of Lemma 1 are immediate consequences of Lemma 1(1) and 1(2) of Ref. 14, respectively. The proof of the latter lemma involves the use of Condition (IV) in an essential way.

Lemma 1: (1) If $m,n\in\mathbf{Z}_+^\nu$ and $\lambda_m\neq\lambda_n$, the inequality

$$|\lambda_m-\lambda_n|\geqslant\text{const }\lambda_m^{-\eta}\lambda_n^{-\eta} \tag{4.1a}$$

holds, where η is the positive constant in Condition (IV) and const is independent of m,n.

(2) For each $m\in\mathbf{Z}_+^\nu$, the estimate

$$g_m\leqslant\text{const }\lambda_m^{\nu-\rho} \tag{4.1b}$$

holds for the degeneracy g_m of each eigenvalue λ_m, where const is independent of m.[33]

The two results asserted in the next lemma are contained in the respective Lemmas 2 and 5 of Ref. 14, and are proved in detail there. The first of these results is indispensable in this section because it constitutes the initial step of the inductive process by which we will prove that the matrices entering into the present theory belong to the set $\mathscr{M}$ (Definition 4).

Lemma 2: The matrix $\mathscr{V}_1=(V_{mn})=(\langle\Phi_m,V\Phi_n\rangle)$ is in $\mathscr{M}$ and the operator $V_1\leftrightarrow\mathscr{V}_1$ has the property[25]

$$V_1=V \quad \text{on} \quad C^\infty(H_0). \tag{4.2}$$

The next three lemmas are basic building blocks for subsequent developments in this section.

Lemma 3: The set of matrices $\mathscr{M}$ has the following properties:

(1) Under the standard definition of matrix equality and when equipped with the usual operations of multiplication by complex numbers and matrix summation, and with matrix multiplication as specified after Definition 2, $\mathscr{M}$ is an associative algebra over **C**.

(2) Each matrix in $\mathscr{M}$ is square-summable by rows and columns.

Remark: (1) Once it has been proved that $\mathscr{M}$ is closed under such matrix multiplication, the associativity of this operation follows immediately from the facts that multiplication of operators belonging to $\mathscr{L}(\mathscr{H})$ is associative and that there is a bijection $\varphi:\mathscr{M}\to M_0$ having the property $\varphi(\mathscr{A}\mathscr{B})=\varphi(\mathscr{A})\varphi(\mathscr{B})$ for all $\mathscr{A},\mathscr{B}\in\mathscr{M}$ (see the proof of Lemma 5). The associativity of this matrix multiplication is established directly in the proof of the present lemma.

(2) As we have already remarked in Sec. III, assertion (2) of this lemma entails that the definition of M as the set of operators in $\mathscr{H}$ associated with matrices in $\mathscr{M}$ makes sense.

Proof: (1) We will prove that $\mathscr{M}$ has the following three properties:

$$\text{(a)}\quad \mathscr{A},\mathscr{B}\in\mathscr{M}\Rightarrow\mathscr{A}+\mathscr{B}\in\mathscr{M};$$

$$\text{(b)}\quad \mathscr{A},\mathscr{B}\in\mathscr{M}\Rightarrow\mathscr{A}\mathscr{B}\in\mathscr{M};$$

$$\text{(c)}\quad \mathscr{A},\mathscr{B},\mathscr{C}\in\mathscr{M}\Rightarrow\mathscr{A}(\mathscr{B}\mathscr{C})=(\mathscr{A}\mathscr{B})\mathscr{C}.$$

Given these properties, it is a trivial matter to show that assertion (1) of the lemma holds.

Let $\mathscr{A}=(A_{mn})$, $\mathscr{B}=(B_{mn})$, $\mathscr{C}=(C_{mn})$ be in $\mathscr{M}$. To prove (a), note that

$$|A_{mn}+B_{mn}|\leqslant|A_{mn}|+|B_{mn}|\leqslant\text{const}\ (\lambda_m^{a(p)}\lambda_n^{-p}+\lambda_m^{b(p)}\lambda_n^{-p})\leqslant\text{const}\ \lambda_m^{\alpha(p)}\lambda_n^{-p} \tag{4.3}$$

for all $p\in\mathbf{N}$, where const is independent of m,n; $a(p),b(p)$ are exponents of $\mathscr{A}$, $\mathscr{B}$, respectively; and $\alpha(p)=\max\{a(p),b(p)\}$. Here, we have invoked the fact each A_{mn} and B_{mn} satisfies an inequality of the form (3.4a). Since they also obey inequalities of the form (3.4b), (4.3) obtains with m,n interchanged on the rhs.[34] Hence (a) follows.

As to (b), note that[35]

$$\left|\sum_r A_{mr}B_{rn}\right|\leqslant\sum_r|A_{mr}|.|B_{rn}|\leqslant\text{const}\ \lambda_m^{a(q)}\lambda_n^{-p}\sum_r\lambda_r^{b(p)}\lambda_r^{-q}\leqslant\text{const}\ \lambda_m^{a(q)}\lambda_n^{-p} \tag{4.4}$$

for all $p\in\mathbf{N}$ if one chooses a positive integer $q=q(p)>b(p)+\nu$. Here, we have used (3.4a), (3.4b), and the estimate[36]

$$\sum_{r\in\mathbf{Z}_+^\nu}\lambda_r^{-\mu}<\infty \quad (\mu>\nu). \tag{4.5}$$

Similar arguments show that (4.4) is true with m,n interchanged in the expression after the second inequality, and hence we have proved (b).

Statement (c) follows from the absolute convergence of $\Sigma_{r,s}A_{mr}B_{rs}C_{sn}$. To prove this property, one uses (3.4a) and (4.5), thus obtaining

$$\sum_{r,s}|A_{mr}|.|B_{rs}|.|C_{sn}|\leqslant\text{const}\ \lambda_m^{a(p)}\lambda_n^{-t}\left(\sum_r\lambda_r^{-p+b(q)}\right)\left(\sum_s\lambda_s^{-q+c(t)}\right)<\infty$$

for each $t\in\mathbf{N}$ if for every such t one first chooses a positive integer $q=q(t)>c(t)+\nu$ and then a positive integer $p=p(q(t))>b(q(t))+\nu$. Of course, here $c(t)$ denotes an exponent of $\mathscr{C}$.

(2) Let $\mathscr{A}$ be as in part (1) of the proof. Its square-summability by rows follows from

$$\sum_m |A_{mn}|^2 \leqslant \text{const}\ \lambda_n^{2a(p)} \sum_m \lambda_m^{-2p} < \infty \quad (p > \nu/2),$$

where $a(p)$ denotes an exponent of $\mathscr{A}$ and where we have once more used (3.4a) and (4.5). The square-summability of $\mathscr{A}$ by columns can be proved similarly by invoking (3.4b) and (4.5). □

Lemma 4: If $A \in M$, then A and A^* have domains containing the set $C^\infty(H_0)$ and leave it invariant.

Proof: (1) An operator $A \in \mathscr{L}(\mathscr{H})$ associated with a matrix (A_{mn}) of the type specified in Definition 3 has the properties $D(A) \supset C^\infty(H_0)$, $AC^\infty(H_0) \subset C^\infty(H_0)$ iff the condition

$$\sum_m \lambda_m^{2p} \left| \sum_n A_{mn} \langle \Phi_n, f \rangle \right|^2 < \infty \quad (p \in \mathbf{N}, f \in C^\infty(H_0)),$$

is satisfied, as follows from the spectral theorem for H_0^p and Definition 3. By the positivity of the λ_m and Schwarz's inequality in $\mathscr{C}^2(\Omega)$, this condition holds if

$$\sum_m \lambda_m^{p} \left| \sum_n A_{mn} \langle \Phi_n, f \rangle \right| < \infty \quad (p \in \mathbf{N}, f \in C^\infty(H_0)). \tag{4.6}$$

To prove that (4.6) holds when $(A_{mn}) \in \mathscr{M}$, we will use the inequality

$$|\langle \Phi_n, f \rangle| \leqslant \lambda_n^{-q} \|H_0^q f\| \quad (q \in \mathbf{N}, f \in C^\infty(H_0)), \tag{4.7}$$

which follows by the fact that H_0 is invertible (because its spectrum lies at a positive distance from $0 \in \mathbf{R}$), Schwarz's inequality, and the normalization $\|\Phi_k\| = 1$ $(k \in \Omega)$. By (3.4b), (4.7), and (4.5), we have

$$\sum_{m,n} \lambda_m^p |A_{mn}| . |\langle \Phi_n, f \rangle| \leqslant \text{const} \sum_m \lambda_m^{p-q} \sum_n \lambda_n^{a(q)-r} < \infty$$

for each p and f in (4.6) if we choose positive integers $q = q(p) > p + \nu$ and $r > a(q) + \nu$, where the $a(q)$ are exponents of A.

(2) Let $A \in M$. Since $D(A)$ is dense in $\mathscr{H}$, A^* exists. For reasons of the same kind as those adduced in an analogous connection in the proof of Lemma 4(2) of Ref. 14, A^* leaves $C^\infty(H_0)$ invariant if the matrix (A_{mn}) with which A is associated has the properties

$$\sum_{m,n} \lambda_m^p |A_{nm}| . |\langle \Phi_n, f \rangle| < \infty \quad (p \in \mathbf{N}, f \in C^\infty(H_0)), \tag{4.8a}$$

$$\sum_{m,n} |A_{mn}| . |\langle \Phi_n, f \rangle| . |\langle \Phi_m, g \rangle| < \infty \quad (f, g \in C^\infty(H_0)). \tag{4.8b}$$

Statement (4.8a) (resp., (4.8b)) can be proved similarly to (4.6), by using (3.4a), (4.7), and (4.5) (resp., (3.4b), (4.7), and (4.5)). □

The considerable relevance of the next lemma to this paper was already mentioned in Sec. I and will be discussed more precisely after its proof below. In the proof of this lemma and hereafter, we will denote the restriction of an operator $A \in \mathscr{L}(\mathscr{H})$ to $C^\infty(H_0)$ by $(A)_0$.

Lemma 5: When equipped with the usual operations of operator addition and multiplication, and multiplication by scalars, M_0 is an algebra over $\mathbf{C}$ which is isomorphic to the matrix algebra $\mathscr{M}$.[37]

Proof: The mapping $\varphi: \mathscr{M} \to M_0$ of each element $\mathscr{A} \in \mathscr{M}$ into the element $(A)_0 \in M_0$, where A is the operator associated with $\mathscr{A}$, is a bijection, as follows for reasons similar to those mentioned in Remark (3) to Definition 3 in a similar connection. We will show that the relations

$$\varphi(\mathscr{A} + \mathscr{B}) = \varphi(\mathscr{A}) + \varphi(\mathscr{B}), \tag{4.9a}$$

$$\varphi(\mathscr{A}\mathscr{B}) = \varphi(\mathscr{A})\varphi(\mathscr{B}), \tag{4.9b}$$

$$\varphi(\alpha.\mathscr{A})=\alpha\varphi(\mathscr{A}) \tag{4.9c}$$

hold for all $\mathscr{A},\mathscr{B}\in\mathscr{M}$ and all $\alpha\in\mathbf{C}$. Relations (4.9a) and (4.9b) entail that M_0 is closed under operator summation and multiplication, and it is obviously closed under multiplication by complex numbers. Moreover, it is well-known and easily provable that the set of all operators in $\mathscr{L}(\mathscr{H})$, restricted to a linear manifold $\mathscr{D}\subset\mathscr{H}$ which they leave invariant, is an operator algebra over $\mathbf{C}$ if it is closed under each of these operations. Hence M_0 is such an algebra. By the properties (4.9a)–(4.9c) of the bijection φ, the algebras $\mathscr{M}$ and M_0 are isomorphic.

Fix such a triple $\mathscr{A},\mathscr{B},\alpha$ and let $A\leftrightarrow\mathscr{A},B\leftrightarrow\mathscr{B}$. We first prove (4.9a). By Lemma 3 and Definition 3, it is legitimate to define the operator $C\leftrightarrow\mathscr{A}+\mathscr{B}$, and Definition 3 and Schwarz's inequality in $\mathscr{L}^2(\Omega)$ entail that $C\supset A+B$. Since the domains of A,B,C contain $C^\infty(H_0)$ (Lemma 4), it follows that $(C)_0=(A+B)_0=(A)_0+(B)_0$, and thus that (4.9a) holds. As to (4.9c), it is an immediate consequence of $\alpha A\leftrightarrow\alpha.\mathscr{A}$, which in turn follows from Definition 3 and the fact that the mapping of $\mathscr{M}$ onto M prescribed in that definition is bijective.

To prove (4.9b), we proceed as follows. Let $G\leftrightarrow\mathscr{A}\mathscr{B}$, which is a legitimate definition by Lemma 3 and Definition 3. We will show that

$$G=AB \quad \text{on} \quad C^\infty(H_0). \tag{4.10}$$

Since A,B leave $C^\infty(H_0)$ invariant, (4.9b) follows immediately by (4.10). To prove (4.10), we fix $f\in C^\infty(H_0)$ and note that the repeated use of Definition 3 yields

$$ABf=\sum_m\left(\sum_n A_{mn}\sum_r B_{nr}\langle\Phi_r,f\rangle\right)\Phi_m. \tag{4.11}$$

If it were allowable to interchange the order of the n and r summations, (4.11) would yield

$$ABf=\sum_m\left(\sum_r\left(\sum_n A_{mn}B_{nr}\right)\langle\Phi_r,f\rangle\right)\Phi_m=Gf,$$

and we would be done. To justify this interchange, we note that

$$\begin{aligned}\left|\sum_n A_{mn}\sum_r B_{nr}\langle\Phi_r,f\rangle\right| &\leqslant\sum_n|A_{mn}|\sum_r|B_{nr}|.|\langle\Phi_r,f\rangle| \\ &\leqslant\|f\|\sum_{n,r}|A_{mn}|.|B_{nr}| \\ &\leqslant\text{const}\,\lambda_m^{a(p)}\left(\sum_n\lambda_n^{-p+b(q)}\right)\left(\sum_r\lambda_r^{-q}\right)<\infty\end{aligned} \tag{4.12}$$

for each $q\in\mathbf{N}$ greater than ν, provided that we choose $p=p(q)\in\mathbf{N}$ such that $p(q)>b(q)+\nu$. Here $a(p),b(q)$ denote exponents of A,B, respectively, and we have invoked (3.4a) and (4.5). The absolute convergence of the repeated sum over n,r in the lhs of the inequality in the first line of (4.12) legitimizes the above interchange. □

The main reason why Lemma 5 is of interest in this paper is that it and Lemma 4 have the following corollary.

Corollary: Let $\mathscr{A}_1,\ldots,\mathscr{A}_r,\mathscr{B}_1,\ldots,\mathscr{B}_s$ $(r,s<\infty)$ denote matrices in $\mathscr{M}$ which satisfy an equation of the form

$$g(\mathscr{A}_1,\ldots,\mathscr{A}_r)=h(\mathscr{B}_1,\ldots,\mathscr{B}_s), \tag{4.13}$$

where g (resp., h) denote finite linear combinations of products of $\mathscr{A}_i$'s (resp., $\mathscr{B}_j$'s) with coefficients in $\mathbf{C}$. Then the linear operators $A_1,\ldots,A_r$, $B_1,\ldots,B_s$ in M associated with these respective matrices satisfy the operator equation

$$g(A_1,\ldots,A_r)=h(B_1,\ldots,B_s) \quad \text{on} \quad C^\infty(H_0). \tag{4.13′}$$

Remark: This result allows one to recover in a rigorous form certain operator equations stated loosely in Sec. II, which play key roles in the present section. Here is a simple illustration. By (3.5), the equation

$$\text{ad } \mathscr{K}^{(0)}\mathscr{S}^{(1)}=\mathscr{V}_1-\mathscr{K}^{(1)}$$

holds. Since $H_0,S^{(1)},V_1,K^{(1)}$ are the operators associated with the respective matrices $\mathscr{K}^{(0)},\mathscr{S}^{(1)},\mathscr{V}_1,\mathscr{K}^{(1)}$ in $\mathscr{M}$ (by the line preceding (3.7), Definition 5(b), and the proof of Lemma 6), it follows from the corollary that the equation

$$\text{ad } H_0S^{(1)}=V_1-K^{(1)}$$

holds on $C^\infty(H_0)$. More complete information on operator equations obtaining on this dense set which were proved in this manner is provided by Lemma 6.

Proof: By (4.13) and the isomorphism between the algebras M_0 and $\mathscr{M}$, the equation $g((A_1)_0,\ldots,(A_r)_0)=h((B_1)_0,\ldots,(B_s)_0)$ emerges, where we recall that $(A_i)_0,(B_j)_0$ denote the restrictions of the respective operators A_i,B_j to $C^\infty(H_0)$. Since these restricted operators leave $C^\infty(H_0)$ invariant by Lemma 4, the last equation is equivalent to (4.13′). □

Lemma 6: (1) The operators $S^{(i)},V_i$ $(i\geqslant 1)$ and $K^{(i)}$ $(i\geqslant 0)$, together with $W_{i+1}^{(j)}$ $(0\leqslant j\leqslant i-1,\ i\geqslant 1)$ and $K_i(\varepsilon),W_{i+1}(\varepsilon)$ $(i\geqslant 1,\ \varepsilon\geqslant 0)$ are in M. (2) Equations (2.14), (2.15a), (2.15c), (2.16a), (2.16b) hold on $C^\infty(H_0)$.

Proof: (1) In view of Definitions 4 and 5(a)–5(c), $\mathscr{K}^{(0)}\in\mathscr{M}$, and the fact that $\mathscr{M}$ is an associative algebra, it suffices to show that $\mathscr{S}^{(i)},\mathscr{V}_i,\mathscr{K}_i\in\mathscr{M}$ for $i\geqslant 1$ in order to prove assertion (1) of the lemma. Note in particular that these properties of $\mathscr{S}^{(i)},\mathscr{K}^{(i)}(i\geqslant 1)$ and $\mathscr{M}$, together with (3.8c) and (3.9b), entail that $\mathscr{W}_{i+1}^{(j)}\in\mathscr{M}$ $(0\leqslant j\leqslant i-1,i\geqslant 1)$. Actually, it suffices to show that $\mathscr{V}_i\in\mathscr{M}$ for $i\geqslant 1$ to prove assertion (1), as can be seen from the following simple argument.

Suppose that $\mathscr{V}_k\in\mathscr{M}$ for some fixed $k\geqslant 1$, and hence that the following inequalities are fulfilled for all $p\in\mathbf{N}$, for suitable exponents $\alpha(k,p)$:

$$|(V_k)_{mn}|\leqslant\text{const }\lambda_m^{\alpha(k,p)}\lambda_n^{-p},\tag{4.14a}$$

$$|(V_k)_{mn}|\leqslant\text{const }\lambda_n^{\alpha(k,p)}\lambda_m^{-p}.\tag{4.14b}$$

By (3.10), (4.14a), and (4.1a), one has

$$|S_{mn}^{(k)}|\leqslant\text{const }\lambda_m^{\alpha(k,p)+\eta}\lambda_n^{-p+\eta}\leqslant\text{const }\lambda_m^{\alpha(k,p)+\eta}\lambda_n^{-p+[\eta]+1}\quad(p\in\mathbf{N}),$$

where $[x]$ denotes the integer part of $x\in\mathbf{R}$ and where we have used the fact that $\lambda_n^{\eta}\lambda_n^{-([\eta]+1)}$ is bounded for $n_1,\ldots,n_\nu\to\infty$, where $n=(n_1,\ldots,n_\nu)\in\Omega$. Therefore, choosing $q=p-[\eta]-1$ for each positive integer $p>[\eta]+1$, one sees that

$$|S_{mn}^{(k)}|\leqslant\text{const }\lambda_m^{\beta(k,q)}\lambda_n^{-q}\quad(q\in\mathbf{N}),\tag{4.15}$$

where $\beta(k,q)=\alpha(k,q+[\eta]+1)+\eta$. A similar proof using (4.14b) shows that (4.15) holds with m and n interchanged on its rhs, and with $\beta(k,q)$ possibly replaced by a larger exponent. We have therefore proved that $\mathscr{V}_k\in\mathscr{M}$ entails $\mathscr{S}^{(k)}\in\mathscr{M}$. On the other hand, $\mathscr{V}_k\in\mathscr{M}$ entails $\mathscr{K}^{(k)}\in\mathscr{M}$ by (3.6b). Next, we recall that $\mathscr{V}_1\in\mathscr{M}$ by Lemma 2 and we assume inductively that $\mathscr{V}_i\in\mathscr{M}$ for $1\leqslant i\leqslant\ell$, where ℓ is some positive integer. By combining

$$\mathscr{V}_{l+1}=-\sum_{j=1}^{l+1}\mathscr{K}_l^{(j)}\mathscr{K}^{(l+1-j)}\tag{4.16}$$

[recall definition (3.8b)] with the consequence $\mathscr{S}^{(i)},\mathscr{K}^{(i)}\in\mathscr{M}(1\leqslant i\leqslant\ell)$ of the inductive hypothesis and with $\mathscr{K}^{(0)}\in\mathscr{M}$, (3.9b), and Lemma 3(1), it follows that $\mathscr{V}_{\ell+1}\in\mathscr{M}$, and thus that $\mathscr{V}_i\in\mathscr{M}$ $(i\geqslant 1)$. Whence $\mathscr{S}^{(i)},\mathscr{K}^{(i)}\in\mathscr{M}$ at each such i. We have thus proved assertion (1).

(2) To prove assertion (2) of the lemma, we remark that each of the matrix Eqs. (3.13), (3.5), (3.8c), (3.8a), (3.8b) can be written as a relation of the form (4.13) involving only matrices in $\mathscr{M}$.

Furthermore, these equations formally yield the respective operator equations Eqs. (2.14), (2.15a), (2.15c), (2.16a), (2.16b) if they are subjected to the following substitutions. First, one replaces the matrices appearing explicitly in each of these equations by the operators with which they are associated according to Definition 5(b). Second, one replaces each operator $\mathscr{R}_{i-1}^{(j)}$ (resp., $\mathscr{R}_i^{(k)}$) occurring in (3.8b) (resp., (3.8c)) by the operator $R_{i-1}^{(j)}$ (resp., $R_i^{(k)}$), understood in the sense of Definition 5(c). In view of this remark and the above corollary, the operator equations mentioned in the first sentence of this paragraph are true on $C^\infty(H_0)$. □

The next lemma entails that $U_N(t,\varepsilon)$ in (3.14) is a well-defined unitary operator.

Lemma 7: For each $i\geqslant 1$, $\varepsilon\geqslant 0$ the operator $K_i(\varepsilon)$ is the unique self-adjoint extension of $K^{[i]}(\varepsilon)$ (Definition 5(b)).[38]

Proof: We fix $\varepsilon\geqslant 0$ and omit the ε-dependence of the relevant matrices and operators. We divide the proof into three parts. In the first, we show that each matrix $\mathscr{V}_i$ ($i\geqslant 1$) is Hermitian, a property which together with (3.6b), (3.7), and (3.12) immediately entails that every $\mathscr{K}^{[i]}$ ($i\geqslant 1$) is Hermitian. This last result is a basic ingredient in the proof of the self-adjointness of the K_i given in the second step. In the third step, we sketch a proof of the essential self-adjointness of the $K^{[i]}$.

(i) We prove that $\mathscr{V}_i^*=\mathscr{V}_i (i\geqslant 1)$ inductively. Note first that $\mathscr{V}_1^*=\mathscr{V}_1$ by (3.8a) and $V_{mn}=\overline{V_{nm}}$. Note next that if $\mathscr{V}_i^*=\mathscr{V}_i$ at any given $i\geqslant 1$, then $\mathscr{K}^{(i)}=\mathscr{K}^{(i)*}$ by (3.6b) and $\mathscr{S}^{(i)*}=-\mathscr{S}^{(i)}$ by (3.10) at this i. We now assume inductively that $\mathscr{V}_i=\mathscr{V}_i^*$ for $1\leqslant i\leqslant \ell$, where ℓ is some positive integer. By this assumption, together with $\mathscr{K}^{(0)}=\mathscr{K}^{(0)*}$ and (3.9b), each summand on the rhs of (4.16) is a Hermitian matrix, since it is a linear combination with real coefficients of finite products of factors ad $S^{(r)}$ ($1\leqslant r\leqslant \ell$) acting on operators $\mathscr{K}^{(s)}$ ($0\leqslant s\leqslant \ell$).[39] Thus $\mathscr{V}_{\ell+1}^*=\mathscr{V}_{\ell+1}$.

(ii) We fix $i\geqslant 1$ henceforth in the proof. In part (2) of Definition 5(b), we defined $K^{[i]}$ as the operator sum (3.11) and K_i as the operator associated with the matrix $\mathscr{K}^{[i]}$ in (3.12). From these definitions, Definition 3, and Schwarz's inequality in $\ell^2(\Omega)$, it follows that $K_i(\varepsilon)\supset K^{[i]}(\varepsilon)$. Since $\mathscr{K}^{(0)}$ is diagonal and the entries $\langle\Phi_m,K^{(j)}\Phi_n\rangle$ of $\mathscr{K}^{(j)}$ for $j\geqslant 1$ vanish if $\lambda_m\neq\lambda_n$, it follows that the quantities $\langle\Phi_m,K_i\Phi_n\rangle$ have the same vanishing property. Let $\{\Lambda_\sigma\}(\sigma\in N)$ be the set of all distinct eigenvalues Λ_σ of H_0, numbered in a fixed but arbitrary manner, and for each $\sigma\in\mathbf{N}$ let $\mathscr{J}_\sigma$ be the set of all λ_k's equal to Λ_σ. Since the degeneracy of each λ_k is finite, it follows that the $\mathscr{J}_\sigma$'s have the same properties attributed to the J_σ's in the Corollary to Lemma A.4, Ref. 14, in the special case $\mathscr{X}=\mathscr{H}$, $\Gamma=\Omega$, $\Psi=\Phi$, $\mathscr{A}=\mathscr{K}^{[i]}$. By this fact and the Hermiticity of $\mathscr{K}^{[i]}$, we may apply this corollary to infer that K_i is self-adjoint.

(iii) Since $K^{[i]}$ is a densely defined restriction of K_i, it is symmetric. That K_i is the unique self-adjoint extension of $K^{[i]}$ follows by standard arguments of the type invoked in step (4) of the proof of Lemma 6 in Ref. 14, including the use of the fact that $C^\infty(H_0)$ is invariant under $U_N(t)$ (see the proof of Lemma 8). □

Henceforth in this section, we fix $N\leqslant 1$.

Lemma 8: The Nth-order approximant $\psi_N(t,\varepsilon)$ is a well-defined element of $C^\infty(H_0)$ (Definition 5(d)).

Proof: We again fix $\varepsilon\geqslant 0$ and omit it in the relevant symbols. Definitions (3.14) and (3.15) make sense because: (a) $\psi_0\in C^\infty(H_0)$ and $U_N(t)$ is a well-defined unitary operator on $\mathscr{H}$ which leaves $C^\infty(H_0)$ invariant; (b) $R_N^{[N]}$ maps each operator in $\mathscr{L}(\mathscr{H})$ which leaves this set invariant into one having the same property. As to (a), in order for $U_N(t)C^\infty(H_0)\subset C^\infty(H_0)$ to hold, it suffices that the condition (4.6) be satisfied with A_{mn} replaced by $\langle\Phi_m,U_N(t)\Phi_n\rangle$ (see the first paragraph of the proof of Lemma 4). That it is satisfied follows by using the inequality

$$|\langle\Phi_m,U_N(t)\Phi_n\rangle|\leqslant\delta_{\lambda_m,\lambda_n} \tag{4.17}$$

(to which we will return in a moment), together with (4.7), (4.1b), and (4.5), to conclude that

$$\sum_{m,n}\lambda_m^p|\langle\Phi_m,U_N(t)\Phi_n\rangle|\cdot|\langle\Phi_n,f\rangle|\leqslant\text{const}\sum_m g_m\lambda_m^{p-q}\|H_0^q f\|\leqslant\text{const}\sum_m\lambda_m^{p-q+\nu-\rho}$$

$$<\infty\quad(p\in\mathbf{N},f\in C^\infty(H_0)),$$

if for each such p we choose $q \in \mathbf{N}$ large enough. Here, g_m denotes the degeneracy of λ_m. As to property (b), $(R_N^{[N]}A)_0$ (and in fact any $(R_j^{[i]}A)_0$) can be expressed as a finite linear combination of finite products of $(A)_0$ and $(S^{(i)})_0$'s if the operator A leaves $C^\infty(H_0)$ invariant [see Definition 5(c), (2.17), and the sentence containing (4.21)]. Since each $S^{(i)} \in M$, the $(S^{(i)})_0$'s leave the latter set invariant, whence (b) follows. To prove (4.17), we first note that since $\langle \Phi_m, K_N \Phi_n \rangle$ vanishes for $\lambda_m \neq \lambda_n$, the self-adjoint operators H_0 and K_N commute in the usual technical sense.[40] This and (3.15) entail that $\langle \Phi_m, U_N(t)\Phi_n \rangle$ has the same vanishing property. The proof of (4.17) is completed by invoking the unitarity of $U_N(t)$, Schwarz's inequality, and the normalization of the Φ_k. □

We now state the main lemma of this section.

Lemma 9: The following statements hold:

(1) At all $\varepsilon \geqslant 0$, $t \in \mathbf{R}$, $\psi_N(t,\varepsilon)$ satisfies the differential equation

$$i \frac{d\psi_N(t,\varepsilon)}{dt} = H_\varepsilon \psi_N(t,\varepsilon) + \varepsilon^{N+1} \varphi_N(t,\varepsilon), \tag{4.18a}$$

and at each such ε

$$\psi_N(0,\varepsilon) = \psi_0, \tag{4.18b}$$

where d/dt denotes the strong derivative in $\mathscr{H}$ and $\varphi_N(t,\varepsilon)$ is defined by (2.27) where $W_{N+1}(\varepsilon)$ and $\psi_N(t,\varepsilon)$ are as in Definitions 5(b) and 5(d), respectively, and where $\rho_N(t,\varepsilon)$ is given by (2.24), in terms of the relevant operators and superoperators specified by Definitions 5(b)–5(d).

(2) At each fixed $\varepsilon \geqslant 0$, $\varphi_N(t,\varepsilon)$ is strongly continuous in t at all $t \in \mathbf{R}$ and

$$\sup_{(t,\varepsilon) \in \mathbf{R} \times [0,\varepsilon_0]} \|\varphi_N(t,\varepsilon)\| < \infty \tag{4.19}$$

for each compact interval $[0,\varepsilon_0]$.

Proof: (1) We will prove assertion (1) of the lemma in steps (i) and (ii) below, but step (ii) also contains results which will be used to prove assertion (2).

(i) In this step, we will show that (2.13) holds on $C^\infty(H_0)$. To do this, we will prove that the rhs and lhs of (2.13), when restricted to this dense set, can be written as polynomials in ε and that the operator coefficients of the powers of ε involved agree on $C^\infty(H_0)$. As to the lhs of (2.13), note that $H_\varepsilon = H_0 + \varepsilon V_1$ on this set by the Remark to Condition V and by Eq. (4.2). The rhs of (2.13) can be expressed rigorously on $C^\infty(H_0)$ as a polynomial in ε, because of the statement

$$R_N^{[N]}(\varepsilon) K^{[N]}(\varepsilon) = \sum_{i,j=0}^{N} \varepsilon^{i+j} R_N^{(i)} K^{(j)} \quad \text{on} \quad C^\infty(H_0) \tag{4.20}$$

and since (2.14) also holds on this dense set [Lemma 6(2)]. Note that (4.20) is equivalent to (2.18) holding on the latter set. To prove (4.20), we will need the formally obvious fact that

$$(\text{ad } S^{(1)})^{n_1} \cdots (\text{ad } S^{(k)})^{n_k} \left(\sum_{j=0}^{r} \varepsilon^j A_j \right) = \sum_{j=0}^{r} \varepsilon^j (\text{ad } S^{(1)})^{n_1} \cdots (\text{ad } S^{(k)})^{n_k} A_j \quad \text{on} \quad C^\infty(H_0)$$

$$(n_1, \ldots, n_k \geqslant 0,\ k \geqslant 1), \tag{4.21}$$

where the A_j are operators in $\mathscr{L}(\mathscr{H})$ leaving $C^\infty(H_0)$ invariant. Indeed, (4.20) follows by Definition 5(c), (2.17), (3.11), the invariance of $C^\infty(H_0)$ under the $K^{(j)}$ $(j \geqslant 1)$ [Lemmas 4 and 6(1)], and (4.21), specialized to the case $A_j = K^{(j)}$ $(0 \leqslant j \leqslant r = N)$. To prove (4.21), we first note that ad $S^{(1)}(\Sigma_{j=0}^r \varepsilon^j A_j) = \Sigma_{j=0}^r \varepsilon^j \text{ad } S^{(1)} A_j$ on $C^\infty(H_0)$, since $(S^{(1)})_0$ and the $(A_i)_0$ belong to the complex algebra of all operators in $\mathscr{L}(\mathscr{H})$ having this invariance property. Second, we note that ad $S^{(1)}B$ leaves $C^\infty(H_0)$ invariant if $B \in \mathscr{L}(\mathscr{H})$ does. These two remarks and an easy inductive argument show that (4.21) holds for $k=1$, $n_1 \geqslant 1$. The proof of (4.21) can be completed by arguments of similar type which invoke the invariance of $C^\infty(H_0)$ under the $S^{(i)}$ and A_j.

Expressing the rhs and lhs of (2.13) on $C^\infty(H_0)$ as polynomials and using (2.17a), (2.17b), (2.20a), and (2.20b), together with the facts that (2.15a), (2.15c), (2.16a), and (2.16b) hold on this dense set by Lemma 6(2), it follows that the coefficients of each ε^i $(0\leqslant i\leqslant 2N)$ on the rhs and lhs of (2.13) are equal on $C^\infty(H_0)$.

(ii) The only nontrivial claim in assertion (1) of the lemma is (4.18a), since (4.18b) follows immediately by (3.14), (3.15), and (2.17b). The heart of our proof of (4.18a) is the justification of the relation

$$i\,\frac{d\psi_N(t)}{dt}=R_N^{[N]}(K_N U_N(t))\psi_0, \tag{4.22}$$

where here and henceforth, until further notice, we once more fix $\varepsilon\geqslant 0$ and suppress the ε-dependence of the vectors and operators considered. The remainder of the proof of (4.18a) is easy. If the operators $S^{(i)}$ in $R_N^{[N]}$ were bounded (which they are not in general), (4.22) would legitimately follow by differentiating (3.14) strongly wrt t and interchanging the strong differentiation operator d/dt with $R_N^{[N]}$ on the rhs. We will prove (4.22) by the following uniform convergence argument in which no hypotheses on the boundedness of these operators are made.

Note that if $A\in\mathscr{L}(\mathscr{H})$ leaves $C^\infty(H_0)$ invariant, then

$$R_N^{[N]}A=\sum_{\alpha\in I_N} c_\alpha T_\alpha A T'_\alpha \quad \text{on} \quad C^\infty(H_0) \tag{4.23}$$

holds, where the T_α and T'_α denote finite products of operators in M, namely, finite products of $S^{(i)}$'s or the unit operator in $\mathscr{H}$; the $c_\alpha=c_\alpha(\varepsilon)$ are monomials in ε with real coefficients; and the sum over α ranges over a finite index set $I_N\subset\mathbf{N}$. The N-dependence of the T_α, T'_α, and c_α has been suppressed for simplicity. To prove (4.23), one uses Definition 5(c), (2.17), and an inductive argument analogous to that used to arrive at (4.21). By (3.14) and (4.23), and since $\psi_0\in C^\infty(H_0)$ and $U_N(t)$ leaves $C^\infty(H_0)$ invariant (see the proof of Lemma 8),

$$\psi_N(t)=\sum_{\alpha\in I_N} c_\alpha T_\alpha U_N(t) T'_\alpha\psi_0. \tag{4.24}$$

This equation and the relation $T'_\alpha\psi_0\in C^\infty(H_0)$ motivate us to consider a time-dependent vector $TU_N(t)u\in\mathscr{H}$. Here $T=A_1\cdots A_r$ for some $r\geqslant 1$, with $A_i\in M$ $(i=1,...,r)$; $u\in C^\infty(H_0)$; and the A_i and u are ε- and t-independent. We write[35]

$$TU_N(t)u=\sum_m F_m(t)\Phi_m, \tag{4.25}$$

where

$$F_m(t)=\langle\Phi_m, TU_N(t)u\rangle=\langle A_r^*\cdots A_1^*\Phi_m, U_N(t)u\rangle. \tag{4.26}$$

Here, we have used the facts that $D(A_i^*)\supset C^\infty(H_0)\supset\Phi$ for each i and that each A_i^* leaves $C^\infty(H_0)$ invariant, which follow from the assumption that the A_i are in M (Lemma 4). Because $u\in C^\infty(H_0)\subset D(K_N)$ [Lemmas 4 and 6(1)], $U_N(t)u$ has a strongly continuous t-derivative $d(U_N(t)u)/dt=-iK_N U_N(t)u$ on $\mathbf{R}$. Thus $F_m\in C^1(\mathbf{R})$ by (4.26). In addition, each A_i leaves $\mathbf{C}^\infty(H_0)$ invariant, and hence

$$\frac{dF_m(t)}{dt}=-i\langle A_r^*\cdots A_1^*\Phi_m, K_N U_N(t)u\rangle=-i\langle\Phi_m, TK_N U_N(t)u\rangle=-i\langle\Phi_m, TU_N(t)K_N u\rangle. \tag{4.27}$$

The series (4.25) and the series

$$\sum_m \frac{dF_m(t)}{dt}\,\Phi_m \tag{4.28}$$

obtained from it by termwise strong differentiation converge uniformly on $\mathbf{R}$ wrt t in the strong $L^2(\mathbf{R}^\nu)$-sense. This follows from the respective estimates

$$\sum_m \sup_{t\in\mathbf{R}}|F_m(t)|<\infty, \tag{4.29a}$$

$$\sum_m \sup_{t\in\mathbf{R}}\left|\frac{dF_m(t)}{dt}\right|<\infty, \tag{4.29b}$$

which will be proved shortly. Since each F_m is continous on $\mathbf{R}$, and since the series (4.25) has the above uniform convergence property, we conclude that its sum $TU_N(t)u$ is strongly continous on $\mathbf{R}$, and by (4.29a) it is also bounded thereon:

$$\sup_{t\in\mathbf{R}}\|TU_N(t)u\|<\infty. \tag{4.30}$$

Similarly, by the strong convergence of the series (4.25) on $\mathbf{R}$, the strong uniform convergence of the series (4.28) thereon, and the continuity of the derivatives dF_m/dt on $\mathbf{R}$, strong termwise differentiation of the series (4.25) is legitimate at all $t\in\mathbf{R}$, and thus

$$\frac{d}{dt}\,TU_N(t)u=\sum_m\ \frac{dF_m(t)}{dt}\,\Phi_m=-iTU_N(t)K_Nu, \tag{4.31}$$

where we have used (4.27).

The desired result (4.22) is proved by using (4.24), (4.31), and (4.23), keeping in mind that each T_α (resp., $T'_\alpha\psi_0$) is a special case of T (resp., u), that $C^\infty(H_0)$ is invariant under K_N [Lemmas 4 and 6(1)] and $U_N(t)$, and that the sums over α in (4.23) and (4.24) contain only a finite number of terms.

Estimates (4.29) can be established in a way which closely parallels that used to obtain estimate (4.48) in Ref. 14. However, since these estimates play such a crucial role in the proof of the present lemma, we will now prove (4.29b), the proof of (4.29a) being almost identical. Setting $w=K_Nu$ in the expression after the third equality sign in (4.27), we obtain

$$\begin{aligned}\left|\frac{dF_m(t)}{dt}\right|&=|\langle\Phi_m,TU_N(t)w\rangle|=\left|\sum_r\ T_{mr}\sum_s\ \langle\Phi_r,U_N(t)\Phi_s\rangle\langle\Phi_s,w\rangle\right|\\&\leqslant\sum_{r,s}\ |T_{mr}|\,\delta_{\lambda_r,\lambda_s}|\langle\Phi_s,w\rangle|\\&\leqslant\text{const}\sum_r\ \lambda_r^{t(p)}\lambda_m^{-p}g_r\lambda_r^{-q}\|H_0^qw\|\\&\leqslant\text{const}\,\lambda_m^{-p}\sum_r\ \lambda_r^{t(p)+\upsilon-\rho-q}\leqslant\text{const}\,\lambda_m^{-p}\quad(p\in\mathbf{N}),\end{aligned} \tag{4.32}$$

if for each such p we choose $q>2\nu+t(p)-\rho$. Here, $t(p)$ denotes an exponent of the matrix $(T_{mn})=\langle\Phi_m,T\Phi_n\rangle\in\mathscr{M}$. To arrive at (4.32), we also used the following results. To derive the second equality in (4.32), we applied Lemma A2 of Ref. 14 [corrected according to part (3) of Ref. 15 and with $r=2,\mathscr{X}=\mathscr{H}$, $\Gamma=\Omega$, $\Psi=\Phi,\mathscr{N}=C^\infty(H_0)$, $A^{(1)}=T,A^{(2)}=U_N(t)$]. This application was legitimate because T and $U_N(t)$ leave $C^\infty(H_0)$ invariant, $\Phi\subset C^\infty(H_0)\subset D(T^*)$, $D(U_N(t))=\mathscr{H}$, and $w\in C^\infty(H_0)$.[41] To prove the inequalities in (4.32), we used the fact that each T_{mn} satisfies an inequality of the form (3.4b) and that (4.17), (4.1b), (4.7), and (4.5) hold. Summing over all $m\in\Omega$ in (4.32) and choosing $p>\nu$, (4.29b) follows by (4.5).

In order to complete the proof of (4.18a), we will show briefly that the four equalities in (2.23) hold rigorously if the operators and superoperators in (2.23) are understood in the present sense. This, together with (3.14), $\psi_N(t)\in C^\infty(H_0)$ (Lemma 8), the fact that (2.13) holds on $C^\infty(H_0)$, and definition (2.27) (understood as stated in the present lemma), implies trivially that (4.18a) is true.

As to the first equality (2.23), we remark that the invariance of $C^\infty(H_0)$ under K_N and $U_N(t)$ and the fact that $(K_N)_0=(K^{[N]})_0$ entail that $K_N U_N(t)$ and $K^{[N]}U_N(t)$ are equal on $C^\infty(H_0)$ and that they both leave this set invariant. By this, together with (4.23), the fact that T'_α has this invariance property, and $\psi_0 \in C^\infty(H_0)$, it follows that (4.22) holds with K_N replaced by $K^{[N]}$, and thus that the first equality (2.23) obtains. The second equality (2.23) follows trivially from Definition 5(c). The third follows by applying relation (2.25), with $A=K^{[N]}$ and $B=U_N(t)$, which is legitimate because of $\psi_0 \in C^\infty(H_0)$ and the invariance of $C^\infty(H_0)$ under $K^{[N]}$, $U_N(t)$, and the $S^{(i)}$.[21] Finally, the fourth can be proved rigorously by a procedure similar to that used to establish (4.20).

(2) To prove assertion (2) of the lemma, it is convenient to exhibit the dependence on ε of the vectors and operators considered. A key element in the proof is the formula

$$\varphi_N(t,\varepsilon)=\sum_k \varepsilon^k \sum_\beta V_{k\beta} U_N(t,\varepsilon) V'_{k\beta}\psi_0, \tag{4.33}$$

where the number of terms in each of the two sums is finite, the $V_{k\beta}$ and $V'_{k\beta}$ are finite products of t-independent operators in M (their N-dependence has been omitted for simplicity), and the only ε-dependence is that shown explicitly. Hence, each term in the β-sum is a special case of the vector $TU_N(t,\varepsilon)u$ defined immediately after (4.24). Equation (4.33) follows from (2.27), the facts that (2.14) holds on $C^\infty(H_0)$ [Lemma 6(2)] and that the $W^{(i)}_{N+1}$ leave $C^\infty(H_0)$ invariant [Lemmas 4 and 6(1)], (4.24) and (2.24), and arguments of the type adduced to prove (4.20). We also note the boundedness property

$$\sup_{(t,\varepsilon)\in \mathbf{R}\times[0,\infty]} \|TU_N(t,\varepsilon)u\|<\infty. \tag{4.30$'$}$$

In view of the stated properties of the rhs of (4.33), together with the strong continuity of $TU_N(t,\varepsilon)u$ in t on $\mathbf{R}$ at each $\varepsilon \geqslant 0$, (4.30′), and the compactness of the interval $[0,\varepsilon_0]$, assertion (2) follows. To prove (4.30′), one observes that steps analogous to those in (4.32) show that $|F_m(t,\varepsilon)| \leqslant \text{const}\, \lambda_m^p (p \in \mathbf{N})$, where we now exhibit the ε-dependence of $F_m(t)$ and where the constant is m- and ε-independent. By this result and proceeding in a way analogous to that in which (4.29b) was derived using (4.32), (4.30′) follows. □

We proceed to use use Lemma 9 to give a short rigorous proof of Theorem 1.

Proof of Theorem 1: We will need the following simple proposition.[42]

Let $A \in \mathscr{L}(\mathscr{H})$ be self-adjoint, let $u:\mathbf{R}\to\mathscr{H}$ be strongly differentiable on $\mathbf{R}$, with $u(t) \in D(A) (t \in \mathbf{R})$, and let

$$i\,\frac{du(t)}{dt}=Au(t)+f(t) \quad (t\in\mathbf{R}),$$

$$u(0)=u_0,$$

where $f:\mathbf{R}\to\mathscr{H}$ is strongly continuous. Then

$$\|u(t)\| \leqslant \|u_0\| + \left| \int_0^t \|f(s)\| ds \right|. \tag{4.34}$$

We fix $\varepsilon \geqslant 0$ for the moment and consider the case when $u(t)=\psi(t,\varepsilon)-\psi_N(t,\varepsilon)$, $A=H_\varepsilon$, and $f(t)=\varepsilon^{N+1}\varphi_N(t,\varepsilon)$, whence $u_0=0$. The hypotheses of the proposition are fulfilled in this case, since H_ε is self-adjoint, $\psi(t,\varepsilon)$ and $\psi_N(t,\varepsilon)$ are in $D(H_\varepsilon)$ for $t\in\mathbf{R}$, and Lemma 9 holds. Specializing (4.34) to the case in question and taking into account the boundedness property (4.19), we recover (2.29) for $t\in\mathbf{R}$, $0\leqslant\varepsilon\leqslant\varepsilon_0$. This completes the proof of Theorem 1. □

[15] See the Erratum for Ref. 14 in J. Math. Phys. **38**, 4398 (1997). In addition, the following corrections should be made in Ref. 14. (1) Definition 2 on p. 2189 of Ref. 14 should be replaced by a slightly more general version of Definition 2 of the present paper. More precisely the following changes should be made on p. 2189 of Ref. 14: (a) in lines 2 and 3, replace ''and $\{\Delta_n\}$ be a sequence of finite subsets $\Delta_n \subset \Gamma$ such that Δ_n eventually contains any given finite subset of Γ.'' by ''and $\{\Delta_n\}$ $(n=(n_1,\ldots,n_p)\in\Gamma)$ be a sequence of subsets of $\mathbf{R}^p$ of the form $\Delta_n=[0,n_1]\times\cdots\times[0,n_p]$.''; (b) in line 3 (resp., lines 4 and 5), replace $\lim_{n\to\infty}$ (resp., $\mathrm{s}-\lim_{n\to\infty}$) by $\lim_{n_1,\ldots,n_p\to\infty}$ (resp., $\mathrm{s}-\lim_{n_1,\ldots,n_p\to\infty}$). (2) In the second line of the displayed relations for $\|\psi(t,\varepsilon)-\psi_N(t,\varepsilon)\|$ in p. 2187 and in Eq. (4.52) of p. 2202, replace $\int_0^{|t|}\|g_N(s,\varepsilon)\|ds$ by $|\int_0^t\|g_N(s,\varepsilon)\|ds|$. (3) In the Appendix, p. 2202, omit the final comma in line 3; replace $A_{\alpha\beta}=0(\alpha\in\Gamma)(\alpha\in\Gamma)$ at the beginning of line 4 by $(\alpha\in\Gamma)$; and in line 5 replace ''matrix element'' by ''matrix element $\langle\Psi_\alpha,A\Psi_\beta\rangle$.'' In Lemma A2, p. 2203, the condition $f\in\mathscr{M}$ should read $f\in\mathscr{N}$.
[16] Here and henceforth, all equations involving t (resp., ε) hold for $t\in\mathbf{R}$ (resp., $\varepsilon\geqslant 0$), in the absence of an explicit statement to the contrary.
[17] The relevant definitions are given in Sec. III.
[18] Here and henceforth, equations involving unsummed subscripts m,n which label matrix elements of linear operators in the Φ-basis are intended to hold for all $m,n\in\mathbf{Z}_+^\nu$.
[19] The obvious formal power series defining the exponentials in (2.11) are analogous to the Lie series occurring in classical mechanics. See, e.g., Refs. 8 and 9.
[20] We mention in passing that, strictly speaking, A in Eq. (2.12) stands for a formal power series in which the coefficient of ε^0 is A and in which the higher-order coefficients are the zero operator. In general, (2.12) is not rigorously true as a formal-operator-series identity, but does hold strictly if the equality sign is replaced by $\supset$, signifying that the operator coefficient of each ε^i $(i\geqslant 0)$ in the formal series on the lhs is an extension of the corresponding coefficient on the rhs. For a review of formal power series with coefficients in $\mathscr{L}(\mathscr{H})$, based on the properties of the pseudo-algebra of unbounded linear operators, see Ref. 2, Chap. 1, Sec. 1.1. The basic rules of calculation with unbounded operators in Hilbert space are given, e.g., by F. Riesz B. Sz. Nagy, *Functional Analysis* (F. Ungar Publishing, New York, 1955), p. 299. In the rigorous discussions in Sec. IV, we will avoid using formal power series.
[21] According to Theorem 1.13 in p. 15 of Ref. 2, generally (2.25) does not hold as an operator identity, but is true on any linear manifold in $\mathscr{H}$ which is invariant under A, B, and the $S^{(i)}$.

[23] See, for example, V. I. Arnold, Russ. Math. Surveys **18**, 85 (1963) and G. Gallavotti, *The Elements of Mechanics* (Springer-Verlag, New York, 1983), Sec. 5.12.
[24] C. L. Siegel and J. K. Moser, *Lectures in Celestial Mechanics* (Springer-Verlag, Berlin, 1971), pp. 260, 261.
[25] If A is an operator on $\mathscr{H}$, its domain is denoted by $D(A)$ and its restriction to a subset $\mathscr{D}\subset D(A)$ of $\mathscr{H}$ by $A|\mathscr{D}$. If A,B are operators on $\mathscr{H}$, then we write $A=B$ iff A and B have the same domain and range; we say that $A=B$ on $\mathscr{D}\subset\mathscr{H}$ if $\mathscr{D}\subset D(A)\cap D(B)$ and $A|\mathscr{D}=B|\mathscr{D}$; and $A\subset B$ (resp., $A\supset B$) means that A is a restriction (resp., an extension) of B.
[26] See the above volume of Reed and Simon,[22] p. 201.
[27] The range of the rows and columns of matrices denoted by $\mathscr{A}=(A_{mn})$, $\mathscr{B}=(B_{mn})$, etc., will always be Ω, even if this is not stated explicitly.

[30] See, for example, Ref. 28, p. 88 and R. G. Cooke, *Infinite Matrices and Sequence Spaces* (Macmillan and Co., Ltd., London, 1950), pp. 8–9.
[31] The meaning of $\mathscr{M}$ in this paper is different from the one it has in Ref. 14, where it denotes the set of operators in $\mathscr{L}(\mathscr{H})$ which leave $C^\infty(H_0)$ invariant.
[32] The notations Lemma 2(2), Lemma 4(1), etc., denote assertion (2) of Lemma 2, assertion (1) of Lemma 4, etc. The

lemmas cited in the text are those stated in Sec. IV of the present paper, unless a statement to the contrary is made.

[33] The symbol ''const'' appearing in a relation involving the unsummed indices m or n should be understood to be a constant which is independent of these indices.

[34] Whenever inequalities (3.4a) or (3.4b) are invoked in an argument in the text, allusion is being made to the fact that the entries of the matrix in $\mathscr{M}$ considered in the argument satisfy an inequality of one of these respective forms.

[35] Symbols of the type $\Sigma_r f_r$, $\Sigma_s g_s$,..., where the $f_r, g_s, \ldots$ are complex numbers or vectors in $\mathscr{H}$ whose indices $r,s,\ldots$ label matrix elements, are abbreviations for sums $\Sigma_{r\in\Omega} f_r$, $\Sigma_{s\in\Omega} g_s$,..., respectively, understood in the sense of Definition 2. Similarly, ''double'' sums $\Sigma_{r,s} f_{rs}$ of complex numbers f_{rs} labeled by such indices are, naturally, defined as $\lim_{k_1,\ldots k_v, l_1,\ldots,l_v\to\infty} \Sigma_{r\in\Delta_k}\Sigma_{s\in\Delta_l} f_{rs}$ if this limit exists. Here $\Delta_k, \Delta_l (k=(k_1,\ldots,k_v)\in\Omega,\ l=(l_1,\ldots,l_v)\in\Omega)$ are as specified in Definition 2.

[36] This estimate follows readily by using, in particular, Cauchy's integral test for the convergence of multiple infinite series, together with (2.1c) and the positivity of the ω_i.

[37] Recall that two algebras A, A' over the same field F are isomorphic if there exists a bijective map $h: A\to A'$ such that $h(ab)=h(a)h(b)$, $h(a+b)=h(a)+h(b)$, and $h(\alpha a)=\alpha h(a)$ for all $a,\ b\in A$ and all $\alpha\in F$.

[38] Of course, arguments analogous to ones used in the proof of this lemma show that each $K^{(i)}$ $(i\geqslant 1)$ is self-adjoint.

[39] We recall an elementary fact. Let $\mathscr{F}$ be a set of matrices of the form $\mathscr{A}=(A_{mn})$ $(m,n\in\Omega)$ with entries in $\mathbf{C}$ which is an associative algebra over $\mathbf{C}$ when equipped with the usual operations of matrix summation and multiplication by scalars, and with matrix multiplication in the sense specified in Sec. III. Then, if $\mathscr{A}_r=-\mathscr{A}_r^*$ $(r=1,...,s<\infty)$ and $\mathscr{B}=\mathscr{B}^*$ are in $\mathscr{F}$, it follows that $(\mathrm{ad}\,\mathscr{A}_1\ldots\mathrm{ad}\,\mathscr{A}_s)\mathscr{B}$ is hermitian.

[40] See, for example, M. Reed and B. Simon, *Methods of Modern Mathematical Physics*, Vol. I, (Academic, New York, 1972), pp. 270, 271.

[41] To show that $(T_{mn})\in\mathscr{M}$ and that the operators T and T^* have the properties ascribed to them in this sentence of the text, we proceed as follows. T leaves $C^\infty(H_0)$ invariant since $T=A_1\ldots A_r$ and since each $A_i\in M$. Define $T'\leftrightarrow\mathscr{A}_1\ldots\mathscr{A}_r$, where $\mathscr{A}_i$ is the matrix in $\mathscr{M}$ with which A_i is associated. Hence $T'\in M$ and $T'\supset T$ [by Definition 3 and Schwarz's inequality in $\ell^2(\Omega)$]. Therefore, $D(T'^*)\supset C^\infty(H_0)$ (Lemma 4). But $T'\supset T$ entails $T^*\supset T'^*$, and hence $D(T^*)\supset C^\infty(H_0)\supset\Phi$. Since $T'\supset T$ and $D(T)\supset\Phi$, it follows that $(T_{mn})=(\langle\Phi_m, T\Phi_n\rangle)=(\langle\Phi_m, T'\Phi_n\rangle)\in\mathscr{M}$.

[42] This result is a slight variant of Proposition 10.6, p. 186 of V. P. Maslov and M. V. Fedoriuk, *Semi-Classical Approximation in Quantum Mechanics* (Reidel, Dordrecht, 1981).

Generalized Pöschl–Teller, Toda, Morse potentials and $SL(2,R)$ group

M. Sezgin, A. Y. Verdiyev,[a] and Y. A. Verdiyev[b]
Trakya University, Department of Mathematics, 22030, Edirne, Turkey

(Received 28 July 1997; accepted for publication 19 December 1997)

Quantum integrable systems related with $SL(2,R)$ group manifold in various coordinate systems defined by the various decompositions: KHK, HAH, HKH, NHN, NHK of the group $SL(2,R)$ on one parameter subgroups K,H,A,N are considered. The explicit expressions for waves functions, spectra, and S-matrices are given.

I. INTRODUCTION

The one dimensional integrable quantum systems related to Lie algebra and symmetric spaces are considered in Refs. 1–3. The key point of the relation between the theory of homogeneous spaces and quantum systems is the existence of a simple transformation of the radial part Laplace–Beltrami operators on homogeneous spaces to some Hamiltonian quantum systems. Here we consider the quantum systems with generalized Pöschl–Teller, Toda, and Morse potentials:

$$V(x)=\begin{cases}\dfrac{m^2+n^2-2mn\cosh x-1/4}{\sinh^2 x}, & m,n=0,\pm1,\pm2,\ldots\\ \dfrac{-1/16+m_2^2}{\sinh^2(x/2)}+\dfrac{1/16-m_1^2}{\cosh^2(x/2)} & \\ -\dfrac{\mu^2+\nu^2-2\mu\nu\cosh x+1/4}{\sinh^2 x}, & \dfrac{\mu^2+\nu^2-2\mu\nu\cos x+1/4}{\sin^2 x}\\ -\lambda\mu e^{-x}, \quad \lambda^2e^{-2x}-2n\lambda e^{-x}, & -\infty<\lambda,\mu,\nu<\infty, \quad n=0,\pm1,\pm2,\ldots\end{cases} \tag{1.1}$$

related to various coordinate systems on $SL(2,R)$ group manifold.

In the special case, when **m** or **n=0** (Pöschl–Teller potential), the quantum systems have only scattering states,[1,2] but in the case when $mn>0$ the quantum systems have also bound states.

This report is a generalization of the results given in Ref. 2 and carries on the research reviewed in Ref. 4.

The special linear group $SL(2,R)$ in two dimensional space over the real field consist of matrices:

$$g=\begin{bmatrix}ab\\cd\end{bmatrix}, \quad a,b,c,d\in R, \quad \det g=ad-bc=1. \tag{1.2}$$

They satisfy the condition $glg^t=I$, where $I=\left[\begin{smallmatrix}0&1\\-1&0\end{smallmatrix}\right]$. The metric in the space of the matrices X given by $[x_1,x_2]=\mathrm{tr}(Ix_1Ix_2^t)$, $x_1,x_2\in X$ define the $SL(2,R)$ group manifold $[g,g]=2$, $g\in SL(2,R)$ in this space. The metric matrix in this manifold is given by the formula:

$$h_{ij}=2\,\mathrm{tr}(I\dot{g}_{t_i}I\dot{g}^t_{t_j}), \quad i,j=1,2,3, \tag{1.3}$$

where $\dot{g}_{t_i}=dg_{t_i}/dt_i$, t_i are the coordinates of the manifold. The coordinate systems on the manifold are defined by the decompositions of the group $SL(2,R)$ on one parameter subgroups K,H,A,N.

In this study, we consider the decompositions:[5] $g=k(\varphi)h(\theta)k(\psi)$, $g=h(\varphi)a(\theta)h(\psi)$, $g=h(\varphi)k(\theta)h(\psi)$, $g=n(t)h(\theta)n^t(q)$, $g=n(t)h(\theta)k(\varphi)$, $g\in SL(2,R)$, $h\in H$, $k\in K$, $a\in A$, $n\in N$, *where*

$$n(t)=\begin{pmatrix}1&0\\t&1\end{pmatrix},\quad h(\theta)=\mathrm{diag}(e^{\theta/2},e^{-\theta/2}),\quad a(\theta)=\begin{pmatrix}\cosh\,\theta/2&\sinh\,\theta/2\\\sinh\,\theta/2&\cosh\,\theta/2\end{pmatrix},$$

$$k(\theta)=\begin{pmatrix}\cos\,\theta/2&\sinh\,\theta/2\\-\sin\,\theta/2&\cos\,\theta/2\end{pmatrix}. \tag{1.4}$$

The one dimensional quantum systems related with the above decompositions are presented in the Sec. II. Here we give explicit expressions for wave functions, spectra, and S-matrices.

II. THE QUANTUM SYSTEMS RELATED WITH $SL(2,R)$ GROUP MANIFOLD

Let us consider the various decompositions of the elements g of the group $SL(2,R)$:

$$g=k(\varphi)h(\theta)k(\psi),\quad -\infty<\theta<\infty,-2\pi<\varphi,\psi<2\pi. \tag{2.1}$$

Using Eq. (1.3) for this factorization we have the metric

$$ds^2=d\theta^2-d\varphi^2-d\psi^2-2\cosh\,\theta d\varphi d\psi \tag{2.2}$$

and the Laplace–Beltrami operator

$$\Delta_{L,B}=\frac{1}{\sinh\,\theta}\frac{\partial}{\partial\theta}\sinh\,\theta\frac{\partial}{\partial\theta}+\frac{1}{\sinh^2\,\theta}\left(\frac{\partial^2}{\partial\varphi^2}+\frac{\partial^2}{\partial\psi^2}-2\cosh\,\theta\frac{\partial^2}{\partial\psi\partial\varphi}\right). \tag{2.3}$$

The free motion on the $SL(2,R)$ group manifold is defined by the equation

$$\Delta_{L,B}f(\varphi,\theta,\psi)=\sigma(\sigma+1)f(\varphi,\theta,\psi). \tag{2.4}$$

The solutions of Eq. (2.4) are the matrix elements of the representations of the group $SL(2,R)$ [or the group $SO(1,2)$] in the basis associated with compact subgroup $\mathbf{K}$.[4,5]

After the substitution $f(\varphi,\theta,\psi)=u(\theta)e^{-im\varphi}e^{-in\psi}$ we have

$$\Delta_\theta u(\theta)=\sigma(\sigma+1)u(\theta), \tag{2.5}$$

where the radial part of the Laplace–Beltrami operator Δ_θ has the form

$$\Delta_\theta=\frac{d^2}{d\theta^2}+\tanh\,\theta\frac{d}{d\theta}-\left(\frac{m^2+n^2-2mn\,\cosh\,\theta}{\sinh^2\,\theta}\right).$$

Using $dg=\sqrt{h}d\theta d\varphi d\psi$, $h=|\det(h_{ij})|=\sinh^2\,\theta$, and making the transformation

$$u(\theta)=\frac{1}{\sqrt[4]{h(\theta)}}\Psi_E,\quad \sqrt[4]{h}\Delta_\theta\frac{1}{\sqrt[4]{h}}=H+1/4, \tag{2.6}$$

Eq. (2.5) is reduced to the one dimensional Schrödinger equation

$$\frac{d^2\Psi_E(\theta)}{d\theta^2}+(E-V(\theta))\Psi_E(\theta)=0 \tag{2.7}$$

with the generalized Pöschl–Teller potential

$$V(\theta)=\frac{m^2+n^2-2mn\ \cosh\ \theta-1/4}{\sinh^2\ \theta} \tag{2.8}$$

and the energy spectrum $E=-(\sigma+1/2)^2$.

The regular solution of the Schrödinger equation (2.7) at $\theta=0$ is given by

$$\Psi(\theta)=c\left(\cosh\frac{\theta}{2}\right)^{|-m-n|+1/2}\left(\sinh\frac{\theta}{2}\right)^{|n-m|+1/2}F\left(\sigma-|m|+1,-\sigma-|m|;|n-m|+1;-\sinh^2\frac{\theta}{2}\right). \tag{2.9}$$

It follows that the quantum system has the bound and scattering states. The square integrable normalized wave functions $\Psi_E(\theta)$:

$$\int_0^\infty|\Psi_E(\theta)|^2d\theta=1 \tag{2.10}$$

for $E=-(l+1/2)^2$ with $|m|=l+1+k,\ l,k=0,1,2,...$ have the form:

$$\Psi_E(\theta)=\frac{\Gamma(l-|m|+1)}{\Gamma(l-|n|+1)(|n|-|m|)!}\left(\cosh\frac{\theta}{2}\right)^{|-m-n|+1/2}\left(\sinh\frac{\theta}{2}\right)^{|n-m|+1/2}$$
$$\times F\left(l-|m|+1,-l-|m|;|n-m|+1;-\sinh^2\frac{\theta}{2}\right). \tag{2.11}$$

For the continuous spectrum $\sigma=-1/2+i\rho,\ E=\rho^2>0$ using the analytical continuation formula for the hypergeometric function 2.10.(2)[6] we find the following asymptotic expression:

$$\underset{\theta\to\infty}{\Psi(\theta,\rho)}=c_1[B(m,n,\rho)e^{-i\rho\theta}+\hat{B}(m,n,\rho)e^{i\rho\theta}], \tag{2.12}$$

where

$$B(m,n,\rho)=\frac{\Gamma(|n|-|m|+1)\Gamma(-2i\rho)}{\Gamma(1/2-|m|-i\rho)\Gamma(1/2+|n|-i\rho)}.$$

The solutions of the Schrödinger equation (2.7) satisfying the condition

$$\int_0^\infty\Psi_E(\theta)\overline{\Psi_{E'}(\theta)}d\theta=\delta(\rho-\rho') \tag{2.13}$$

have the form:

$$\Psi_E(\theta)=c_1\left(\cosh\frac{\theta}{2}\right)^{|-m-n|+1/2}\left(\sinh\frac{\theta}{2}\right)^{|n-m|+1/2}$$
$$\times F\left(\frac{1}{2}-|m|+i\sqrt{E},\ \frac{1}{2}-|m|-i\sqrt{E};|n-m|+1;-\sinh^2\frac{\theta}{2}\right), \tag{2.14}$$

where $|c_1|=1/2\sqrt{\pi}|B|$.

The S-matrix is found to be given by

$$S=\frac{B}{\bar{B}}=\frac{\Gamma(-2i\sqrt{E})\Gamma(\frac{1}{2}-|m|+i\sqrt{E})\Gamma(\frac{1}{2}+|n|+i\sqrt{E})}{\Gamma(2i\sqrt{E})\Gamma(\frac{1}{2}-|m|-i\sqrt{E})\Gamma(\frac{1}{2}+|n|-i\sqrt{E})}. \tag{2.15}$$

The decomposition $g=k(\varphi)h(\theta)k(\psi)$ corresponds to the spherical coordinate system on $SL(2,R)$ group manifold. The substitution $\varphi\to\varphi_1+\varphi_2,\ \psi\to\varphi_1-\varphi_2$ define the bispherical coordinate system on this manifold.

Then we have the metric

$$ds^2 = d\theta^2 - 4\cosh^2\ \theta/2 d\varphi_1^2 + 4\sinh^2\ \theta/2 d\varphi_2^2. \tag{2.16}$$

The solutions of the related quantum systems with potential:

$$V(\theta) = \frac{-1/16 + m_2^2}{\sinh^2\ \theta/2} + \frac{1/16 - m_1^2}{\cosh^2\ \theta/2} \tag{2.17}$$

are obtained from the solutions of Eq. (2.9) by the substitutions $m \to m_1 + m_2$, $n \to m_1 - m_2$. For the factorization

$$g = h(\varphi)a(\theta)h(\psi), \quad \theta, \varphi, \psi \in (-\infty, \infty); \tag{2.18}$$

we have the metric

$$ds^2 = d\theta^2 + d\varphi^2 + d\psi^2 + 2\cosh\ \theta d\varphi d\psi \tag{2.19}$$

and Laplace–Beltrami operator

$$\Delta_{L,B} = \frac{1}{\sinh\ \theta} \frac{\partial}{\partial\theta} \sinh\ \theta \frac{\partial}{\partial\theta} - \frac{1}{\sinh^2\ \theta} \left(\frac{\partial^2}{\partial\varphi^2} + \frac{\partial^2}{\partial\psi^2} - 2\cosh\ \theta \frac{\partial^2}{\partial\psi\partial\varphi} \right). \tag{2.20}$$

The solutions

$$f(\varphi, \theta, \psi) = u(\theta) e^{-i\mu\varphi} e^{-i\nu\psi}, \quad \mu, \nu \in (-\infty, \infty) \tag{2.21}$$

of the equation:

$$\Delta_{L,B} f(\varphi, \theta, \psi) = \sigma(\sigma + 1) f(\varphi, \theta, \psi) \tag{2.22}$$

are the matrix elements of the representations of the group $SL(2,R)$ in the basis associated with noncompact subgroup H. These solutions are calculated in Ref. 5, but they have not symmetry with respect to $\sigma \to -1 - \sigma$. The symmetrization (unitarization) of these solutions by the intertwining operator of the representation of the group $SO(1,2)$ has been done in Ref. 4.

Related quantum system has the potential:

$$V(\theta) = -\frac{\mu^2 + \nu^2 - 2\mu\nu\ \cosh\ \theta + 1/4}{\sinh^2\ \theta} \tag{2.23}$$

and energy spectrum $E = -(\sigma + 1/2)^2$.

The solutions of the Schrödinger equation (2.7) with the condition

$$\int_{-\infty}^{\infty} \Psi_E(\theta) \overline{\Psi_{E'}(\theta)} d\theta = \frac{1}{(\sigma + 1/2)\tanh(\sigma + 1/2)\pi} \delta(\sigma - \sigma'), \quad \text{for} \quad \sigma = -1/2 + i\rho \tag{2.24}$$

are given in Ref. 4. They have the form

$$\Psi_E(\theta) = (\cosh\ \theta/2)^{1/2} (\sinh\theta/2)^{1/2} \times [q(\mu, \nu, \sigma) P_\sigma^{-i\mu, -i\nu}(\cosh\ \theta) + q(-\mu, -\nu, \sigma) P_\sigma^{i\mu, i\nu}(\cosh\ \theta)], \tag{2.25}$$

where

$$P_\sigma^{\pm i\mu, \pm i\nu}(\cosh\ \theta) = \frac{1}{\Gamma(1 \pm i\nu \mp i\mu)} (\cosh\ \theta/2)^{\mp i(\mu - \nu)} (\sinh\ \theta/2)^{\mp i(\mu + \nu)} \times F(\sigma + 1 \mp i\mu, -\sigma \mp i\mu, 1 \pm i\nu \mp i\mu, -\sinh^2\ \theta/2),$$

and

$$q(\mu,\nu;\sigma)=q_{\mu,\nu}=\frac{1}{\sinh[(i\mu-i\nu)/2]\pi}\sqrt{\Gamma(1+\sigma-i\mu)\Gamma(-\sigma-i\mu)\Gamma(1+\sigma+i\nu)\Gamma(-\sigma+i\nu)}$$
$$\times\sqrt{\sin\frac{\sigma+i\mu}{2}\pi\cos\frac{\sigma-i\mu}{2}\pi\cos\frac{\sigma+i\nu}{2}\pi\sin\frac{\sigma-i\nu}{2}\pi}.$$

Using the analytical continuation formula for the hypergeometric functions 2.10.(2)[6] we find the asymptotic expression of Eq. (2.25) for $\sigma=-1/2+i\rho,\ \rho=\sqrt{E}$ as

$$\Psi^{E}_{\theta\to\infty}(\theta)=[q_{-\mu,-\nu}B(\mu,\nu,\rho)+q_{\mu,\nu}B(-\mu,-\nu,\rho)]e^{-i\rho\theta}$$
$$+[q_{-\mu,-\nu}B(\mu,\nu,-\rho)q_{\mu,\nu}B(-\mu,-\nu,\rho)]e^{i\rho\theta},\tag{2.26}$$

where

$$B(\mu,\nu,\sigma)=\frac{(i\nu-i\mu)\Gamma(-2i\rho)}{\Gamma(1/2-i\rho-i\mu)\Gamma(1/2-i\rho+i\nu)}.$$

The S-matrix is found to be given by

$$S=\frac{q_{-\mu,-\nu}B(\mu,\nu,\rho)+q_{\mu,\nu}B(-\mu,-\nu,\rho)}{q_{-\mu,-\nu}B(\mu,\nu,-\rho)+q_{\mu,\nu}B(-\mu,-\nu,-\rho)}.\tag{2.27}$$

The square integrable solution of Schrödinger equation is found from (2.25) by setting $\sigma=l=0,1,2,\ldots$.

$$\Psi_E(\theta)=q(-\mu,-\nu,l)(\cosh\theta/2)^{1/2}(\sinh\theta/2)^{1/2}\Big\{P_l^{i\mu,i\nu}(\cosh\theta)$$
$$\times\frac{\Gamma(1+l+i\nu)}{\Gamma(1+l-i\nu)}\frac{\Gamma(1+l-i\mu)}{\Gamma(1+l+i\mu)}P_l^{-i\mu,-i\nu}(\cosh\theta)\Big\}.\tag{2.28}$$

Using the analytical continuation formula for hypergeometric functions 2.10.(4)[6] we have

$$\Psi_E(\theta)=\dot{q}(-\mu,-\nu,l)(\cosh\theta/2)^{1/2}(\sinh\theta/2)^{1/2}Q_l^{i\mu,i\nu}(\cosh\theta),$$

where

$$\dot{q}(-\mu,-\nu,l)=\sqrt{\Gamma(1+l+i\mu)\Gamma(-l+i\mu)\Gamma(1+l-i\nu)\Gamma(-l-i\nu)}\times\sqrt{\sinh\nu\pi\sinh\mu\pi}$$

and

$$Q_l^{i\mu,i\theta}(\cosh\theta)=\frac{\Gamma(1+l-i\mu)\Gamma(1+l+i\nu)}{2\Gamma(2l+2)}\left(\frac{\cosh\theta-1}{2}\right)^{(i\nu-i\mu)/2}\left(\frac{\cosh\theta+1}{2}\right)^{-l-1-(i\nu-i\mu)/2}$$
$$\times F\left(1+l-i\mu,1+l+i\nu;2l+2;\frac{2}{1+\cosh\theta}\right).\tag{2.29}$$

These functions are square integrable and the orthogonality condition

$$\int_{\infty}^{\infty}\Psi_E(\theta)\overline{\Psi_{E'}(\theta)}d\theta=\frac{1}{E}\delta_{E,E'}\tag{2.30}$$

follows from the condition Eq. (2.24) by analytical continuation.

The quantum system related with the decomposition:

$$g=h(\varphi)k(\theta)h(\psi),\quad \varphi,\psi\in(-\infty,\infty),\quad -\pi/2<\theta<\pi/2$$

has the potential

$$V(\theta)=\frac{\mu^2+\nu^2-2\mu\nu\ \cosh\ \theta+1/4}{\sin^2\ \theta}. \tag{2.31}$$

The solutions of this quantum system are obtained from Eq. (2.29) by the analytical continuation $\theta\rightarrow i\theta$. For the factorization

$$g=n(t)h(\theta)n^t(q), \quad -\infty<t,\theta,q<\infty;$$

we have the metric

$$ds^2=d\theta^2-4e^{\theta}dtdq \tag{2.32}$$

and Laplace–Beltrami operator

$$\Delta_{L,B}=\frac{\partial^2}{\partial\theta^2}+\frac{\partial}{\partial\theta}-e^{-\theta}\frac{\partial^2}{\partial t\partial q}. \tag{2.33}$$

The solutions

$$f(t,\theta,q)=u(\theta)e^{-i\lambda t}e^{-i\mu q}, \quad \lambda,\mu\in(-\infty,\infty) \tag{2.34}$$

of the equation:

$$\Delta_{L,B}f(t,\theta,q)=\sigma(\sigma+1)f(t,\theta,q) \tag{2.35}$$

are the matrix elements of the representations of the group $SL(2,R)$ [or the group $SO(1,2)$] in the basis associated with noncompact subgroup N.[5] The related quantum system has the potential

$$V(\theta)=-\lambda\mu e^{-\theta} \quad \text{(generalized Toda potential)} \tag{2.36}$$

and energy spectrum $E=-(\sigma+1/2)^2$. This quantum system has only scattering states when $\lambda\mu<0$ and the wave functions $\Psi_E(\theta)$ are given by the Macdonald K-functions:

$$\Psi_E(\theta)=\tilde{c}_3e^{\theta/2}K_{2i\sqrt{E}}(2\sqrt{-\lambda\mu}e^{-\theta/2}). \tag{2.37}$$

In order to calculate S-matrix and $\tilde{c}_3$-factor we use the definition of the K-function 7.2.2.(12) and (13) Ref. 6;

$$K_\nu(z)=\frac{\pi}{2\sin\ \nu\pi}\,[I_{-\nu}(z)-I_\nu(z)], \tag{2.38}$$

where

$$I_\nu(z)=\frac{(z/2)^\nu}{\Gamma(\nu+1)}\,{}_0F_1\left(\nu+1;\frac{z^2}{4}\right).$$

It follows that

$$I_\nu\underset{z\rightarrow 0}{}(z)\rightarrow\frac{z^\nu}{2^\nu\Gamma(1+\nu)}. \tag{2.39}$$

Thus we have:

$$\Psi_E\underset{\theta\rightarrow\infty}{}(\theta)=\tilde{c}_3[De^{2i\rho\theta}+\bar{D}e^{-2i\rho\theta}], \quad \rho=\sqrt{E}; \tag{2.40}$$

where

$$D=\frac{(\sqrt{\lambda\mu})^{-2i\rho}}{\Gamma(1-2i\rho)}.$$

So, the S-matrix to be found is given by

$$S=\frac{D}{\bar{D}}=\frac{(\sqrt{\lambda\mu})^{-i4\sqrt{E}}\Gamma(1+2i\sqrt{E})}{\Gamma(1-2i\sqrt{E})}. \tag{2.41}$$

From the condition

$$\int_{-\infty}^{\infty}\Psi_E(\theta)\overline{\Psi_{E'}(\theta)}d\theta=\delta(\rho-\rho') \tag{2.42}$$

it follows that $|\tilde{c}_3|=1/2\sqrt{\pi}|D|$.

When $\lambda\mu>0$ in the quantum system Eq. (2.36) has bound and scattering states. For the bound states the wave functions are $\Psi_E(\theta)$, $E=-(l+1/2)^2$ with the condition

$$\int_0^{\infty}|\Psi_E(\theta)|^2d\theta=1 \tag{2.43}$$

has the form:

$$\Psi_E(\theta)=\frac{1}{2\sqrt{l+1/2}}\,e^{\theta/2}J_{2l+1}(2\sqrt{\lambda\mu}e^{-\theta/2}). \tag{2.44}$$

The wave functions $\Psi_E(\theta)$, $E=\rho^2$ for the scattering states are obtained from Eq. (2.38) by analytical continuation: $\sqrt{-\lambda\mu}\to i\sqrt{\lambda\mu}$, $\lambda\mu>0$.

Finally we consider decomposition:

$$g=n(t)h(\theta)k(\varphi),\quad -\infty<t,\theta<\infty,0\leqslant\varphi<2\pi. \tag{2.45}$$

For this factorization we have the metric

$$ds^2=d\theta^2-d\varphi^2+2e^{\theta}\,dtd\varphi \tag{2.46}$$

and Laplace–Beltrami operator

$$\Delta_{L,B}=\frac{\partial^2}{\partial\theta^2}+\frac{\partial}{\partial\theta}+e^{-2\theta}\,\frac{\partial^2}{\partial t^2}+2e^{-\theta}\,\frac{\partial^2}{\partial t\partial\varphi}. \tag{2.47}$$

The solutions

$$f(t,\theta,\varphi)=u(\theta)e^{i\lambda t}e^{-in\varphi} \tag{2.48}$$

of the equation:

$$\Delta_{L,B}f(t,\theta,\varphi)=\sigma(\sigma+1)f(t,\theta,\varphi) \tag{2.49}$$

are the matrix elements of the representations of the group $SL(2,R)$ in the mixed basis associated with noncompact **N** and compact **K** subgroups. This matrix elements are calculated in Refs. 5 and 7. Here we give the orthogonality conditions and calculate normalization factors in continuous $\sigma=-1/2+i\rho$, $0<\rho<\infty$ and discrete $\sigma=l$, $l=0,1,2,...$ cases. The related quantum system has the potential

$$V(\theta)=\frac{\lambda^2}{e^{2\theta}}-\frac{2n\lambda}{e^{\theta}}\quad\text{(generalized Morse potential)} \tag{2.50}$$

and energy spectrum $E=-(\sigma+1/2)^2$.

The solutions of this quantum system which tend to zero $\Psi \to 0$ when $\theta \to -\infty$ are given by the Whittaker functions.

$$\Psi_E(\theta) = c_2 e^{\theta/2} W = c_2 e^{\theta/2} \left\{ \frac{\Gamma(-2i\rho)}{\Gamma(1/2 - i\rho - n\alpha)} M_{n\alpha, i\rho}(2|\lambda| e^{-\theta}) + \frac{\Gamma(2i\rho)}{\Gamma(1/2 + i\rho - n\alpha)} M_{n\alpha, -i\rho}(2|\lambda| e^{-\theta}) \right\}, \tag{2.51}$$

where $\alpha = \text{sign}\,\lambda$, $M_{n\alpha, \pm i\rho}(2|\lambda|z) = (2|\lambda|z)^{1/2 \pm i\rho} e^{-|\lambda| z}\, {}_1F_1(\pm i\rho - n\alpha + 1/2, \pm 2i\rho + 1; 2|\lambda|z)$, $z = e^{-\theta}$. For the scattering states with spectrum $E = -(\sigma + 1/2)^2 = \rho^2$ the asymptotic expression of the $\Psi_E(\theta)$-function when $\theta \to \infty$ has the form:

$$\Psi_E(\theta) \underset{\theta \to \infty}{=} c_2 [A(\rho, n\alpha) e^{-i\rho\theta} + \overline{A}(\rho, n\alpha) e^{i\rho\theta}], \tag{2.52}$$

where

$$A(\rho, n\alpha) = \frac{\Gamma(-2i\rho)(2|\lambda|)^{i\rho + 1/2}}{\Gamma(1/2 - i\rho\text{-}n\alpha)}.$$

The normalization factor c_2 is defined from the condition

$$\int_{-\infty}^{\infty} \Psi_E(\theta) \overline{\Psi_{E'}(\theta)}\, d\theta = \delta(\rho - \rho'). \tag{2.53}$$

It follows that

$$|c_2| = \frac{1}{2\sqrt{\pi}|A|}.$$

The S-matrix is found to be given by

$$S = \frac{A}{\overline{A}} = \frac{(2|\lambda|)^{2i\rho} \Gamma(-2i\sqrt{E}) \Gamma(1/2 + i\sqrt{E} - n\alpha)}{\Gamma(2i\sqrt{E}) \Gamma(1/2 - i\sqrt{E} - n\alpha)}. \tag{2.54}$$

From the expression of the potential Eq. (2.50) it follows that for $n\lambda > 0$ and $n\lambda > \lambda^2$ quantum systems have also bound states with spectrum $E = -(l + 1/2)^2$. For the bound states the solutions have the form:

$$\Psi_E(\theta) = \chi z^{l + 1/2} e^{-|\lambda| z}\, {}_1F_1(l + 1 - n\alpha, 2l + 2; 2|\lambda|z), \quad z = e^{-\theta}, \tag{2.55}$$

where $l + 1 - n\alpha = -k$, $k = 0, 1, 2, \ldots$.

Using the formula 6.4.(14)[6] for the degenerate hypergeometric functions from the condition

$$\int_{-\infty}^{\infty} |\Psi_E(\theta)|^2 d\theta = 1 \tag{2.56}$$

for the normalization factor χ, we obtain

$$\chi = \sqrt{\frac{(2l + 2)_k (2|\lambda|)^{2l + 1}}{(2l)!(n\alpha - l - 1)!}}. \tag{2.57}$$

In conclusion, we see one dimensional integrable quantum systems are the results of the broken symmetry of the free one particle motion by the geodesic paths.

Duality, partial supersymmetry, and arithmetic number theory

Donald Spector[a)]
Department of Physics, Eaton Hall, Hobart and William Smith Colleges, Geneva, New York 14456

(Received 13 October 1997; accepted for publication 8 December 1997)

We find examples of duality among quantum theories that are related to arithmetic functions by identifying distinct Hamiltonians that have identical partition functions at suitably related coupling constants or temperatures. We are led to this after first developing the notion of partial supersymmetry, in which some, but not all, of the operators of a theory have superpartners, and using it to construct fermionic and parafermionic thermal partition functions, and to derive some number theoretic identities. In the process, we also find a bosonic analog of the Witten index, and use this, too, to obtain some number theoretic results related to the Riemann zeta function. © *1998 American Institute of Physics.* [S0022-2488(98)03303-9]

I. INTRODUCTION

Arithmetic quantum theories, theories for which the partition function is related to the Riemann zeta function or other Dirichlet series, have yielded compelling results in mathematical physics.[1,2] In addition to providing physical derivations and interpretations of various number theoretic results, such as an understanding of the Möbius inversion formula based on supersymmetry, these theories possess, as does string theory, a Hagedorn temperature, and so these theories may serve as toy models for certain aspects of string theory.

In this paper, I find further evidence of the usefulness of arithmetic quantum theories in these areas. Most importantly, I find examples of duality in arithmetic theories, that is, of distinct arithmetic theories at different couplings that in fact have the same partition function. Such dualities are analogous to the coupling constant dualities of string theory. See Sec. VII for a fuller discussion of this comparison. In addition, I find physical underpinnings for additional number theoretic results. The most interesting examples here rest on ''partial supersymmetry,'' a property identified in this paper, in which some, but not all, of the creation and annihilation operators have superpartners. This leads not only to a physical basis for some number theoretic results, but also to a formulation of parafermions of noninteger order and to the identification of an analog for the Witten index based on a bosonic grading.

II. REVIEW OF NOTATION AND IDEAS

We here review the notation and way of thinking that allow a connection to be drawn between arithmetic number theory and quantum field theory.

Consider some noninteracting quantum field theories defined in terms of their creation and annihilation operators. Let $b_k^\dagger$ and b_k denote bosonic creation and annihilation operators, and let $f_k^\dagger$ and f_k denote fermionic creation and annihilation operators. In addition, we label the prime numbers p_k in order of increasing magnitude, so that $p_1=2$, $p_2=3$, $p_3=5$, etc.

For use throughout this paper, we define the bosonic Hamiltonian

$$H_B=\omega\sum_{k=1}^{\infty}\log(p_k)b_k^\dagger b_k, \tag{2.1}$$

and the fermionic Hamiltonian

a)Electronic mail: spector@hws.edu

 © 1998 American Institute of Physics

$$H_F=\omega\sum_{k=1}^{\infty}\ \log(p_k)f_k^\dagger f_k\,. \tag{2.2}$$

We label the states of such theories using a Gödel numbering. Let us denote the vacuum state $|1\rangle$. For the bosonic theory, we label the states

$$(b_{i_1}^\dagger)^{r_1}(b_{i_2}^\dagger)^{r_2}\cdots(b_{i_n}^\dagger)^{r}|1\rangle=|N\rangle, \tag{2.3}$$

where $N=(p_1)^{r_1}(p_2)^{r_2}\cdots(p_n)^{r_n}$. For simplicity, we use the atypical convention that the creation and annihilation operators produce normalized states. We may use a similar labeling for the states of the fermionic theory. Note that with this labeling, the Fock space of states for the bosonic field theory is labeled by the positive integers, while the Fock space of states for the fermionic field theory is labeled by the square-free positive integers. One sees[1] that

$$\text{tr}\ e^{-\beta H_B}=\sum_{m=1}^{\infty}\ \frac{1}{m^{\beta\omega}}=\zeta(\beta\omega) \tag{2.4}$$

and

$$\text{tr}(-1)^F e^{-\beta H_F}=\sum_{m=1}^{\infty}\ \frac{\mu(m)}{m^{\beta\omega}}, \tag{2.5}$$

where $\mu(m)$ is the Möbius inversion function.[3] Supersymmetry tells us, via the Witten index,[4] that $\text{tr}[(-1)^F e^{-\beta(H_B+H_F)}]=1$, and so

$$\sum_{m=1}^{\infty}\ \frac{\mu(m)}{m^{\beta\omega}}=\text{tr}[(-1)^F e^{-\beta H_F}]=\frac{1}{\zeta(\beta\omega)}. \tag{2.6}$$

III. THERMAL PARTITION FUNCTIONS

In the preceding work, we have identified the bosonic thermal partition function with the Riemann zeta function, but only the graded fermionic partition function with a number theoretic function. On the other hand, the physics of a theory is governed by the genuine thermal partition function, and so to understand the thermodynamics of the fermionic field theory of H_F, we need to evaluate the partition function

$$Z_F(\beta,\omega)=\text{tr}\ e^{-\beta H_F}. \tag{3.1}$$

To calculate this partition function, we will introduce a notion of partial supersymmetry. This will then give us a physical and algebraic understanding for a particular zeta function identity. This partition function, like the parafermionic one of the next section, was obtained through number theoretic arguments in Ref. 2. Thus it is our method in this section that is new, not the result.

Our approach is to start with the bosonic partition function and to cancel out just the right states so that we are left with the fermionic partition function. Suppose, then, that we define operators $q_k=(b_k)^2$ and $q_k^\dagger=(b_k^\dagger)^2$, and in addition we define operators c_k and $c_k^\dagger$ which have the same effect as b_k and $b_k^\dagger$, respectively, except that c_k and $c_k^\dagger$ both square to zero. It is easy to see, then, that we can write the bosonic Hamiltonian

$$H_B=\omega\sum_k\ \log(p_k)c_k^\dagger c_k+\omega\sum_k\ 2\log(p_k)q_k^\dagger q_k\,. \tag{3.2}$$

The two portions of this decomposition of H_B commute, and so

$$\text{tr}\ e^{-\beta H_B}=\text{tr}[e^{-\beta\omega\Sigma_k\ \log(p_k)c_k^\dagger c_k}]\text{tr}[e^{-\beta\omega\Sigma_k 2\log(p_k)q_k^\dagger q_k}]. \tag{3.3}$$

Because the c_k and $c_k^\dagger$ square to zero, the first term in this product is exactly the fermionic partition function.

Notice that the $q_k^\dagger$ and q_k operators just appear as ordinary creation and annihilation operators, albeit associated with energy $2\log(p_k)$. (Due to our nonconventional normalization convention, there is no problem with how the resulting states are normalized.) Adding to the original Hamiltonian the expression $\omega\Sigma_{k=1}^{\infty} 2\log(p_k) f_k^\dagger f_k$, we are in a position to cancel out all but the c_k and $c_k^\dagger$ terms by taking a graded sum, by means of a Witten index type of result. It is this situation in which we have fermionic superpartners for some of the bosonic creation and annihilation operators (the $q_k^\dagger$ and q_k) but not others (the $c_k^\dagger$ and c_k) that we term partial supersymmetry. We thus find that

$$Z_f(\beta,\omega) = \mathrm{tr}[e^{-\beta\omega\Sigma_k \log(p_k) c_k^\dagger c_k}] = \mathrm{tr}[(-1)^F e^{-\beta\omega\Sigma_k(\log(p_k) c_k^\dagger c_k + 2\log(p_k) q_k^\dagger q_k + 2\log(p_k) f_k^\dagger f_k)}]$$
$$= \mathrm{tr}[(-1)^F e^{-\beta(H_B + 2\beta H_F)}]. \tag{3.4}$$

The bosonic and fermionic pieces in the final expression in (3.4) factorize into pieces that are easy to evaluate (see Ref. 1), leading to the number theoretic result

$$Z_f(\beta,\omega) = \sum_{m=1}^{\infty} \frac{|\mu(m)|}{m^s} = \frac{\zeta(s)}{\zeta(2s)}, \tag{3.5}$$

where $s = \beta\omega$. Notice that we have obtained this number theoretic identity using a partial supersymmetry of a quantum mechanical theory, rather than the conventional explicit calculations of number theory using infinite products.

Our use of partial supersymmetry to reduce a bosonic to a fermionic theory appears calculationally much like a BRST[5] cancellation. However, there is no gauge symmetry that is enforcing these cancellations, and so we stick to the term ''partial supersymmetry.'' If one could identify a gauge invariance underlying this result, then one could perhaps recast these results as proper BRST cancellations. Such a result would undoubtedly provide further deep insights into the structure of these number theoretic quantum models.

IV. PARAFERMIONS OF ARBITRARY ORDER

A natural generalization of the above results is to consider

$$Z_r(\beta,\omega) = \mathrm{tr}[(-1)^F e^{-\beta(H_B + rH_F)}]. \tag{4.1}$$

As we know, $Z_1 = 1$, as the H_F terms cancel all the H_B terms, yielding the Witten index of theory,while, as we just saw, $Z_2 = Z_F$, because the fermionic terms cancel all quadratic and higher powers of the original bosonic creation operators.

For higher integers r, we can identify a partial supersymmetry as well. Let us define $\chi_k^\dagger$ and χ_k such that their rth powers, but no lower powers, vanish as operators, and let $r_k^\dagger = (b_k^\dagger)^r$ and $r_k = b_k^r$. Thus

$$H_B = \omega\sum_{k=1}^{\infty} (\log(p_k)\chi_k^\dagger\chi_k + \log(p_k^r) r_k^\dagger r_k). \tag{4.2}$$

Then the fermionic terms in the expression for Z_r (4.1) cancel the $r_k^\dagger$ and r_k terms in H_B, and so

$$Z_r(\beta,\omega) = \mathrm{tr}[(-1)^F e^{-\beta(H_B + rH_F)}] = \mathrm{tr}\ e^{-\beta H_r}, \tag{4.3}$$

where $H_r = \omega\Sigma_{k=1}^{\infty} \log(p_k)\chi_k^\dagger\chi_k$ is the Hamiltonian for order r parafermions for the logarithmic spectrum we are studying. We can evaluate this expression, as the bosonic and fermionic pieces of (4.1) are noninteracting and hence factorize. One sees that the partition function for parafermions of order r, i.e., objects that are subject to an exclusion principle that states that no more than $r-1$ parafermions can have the same quantum numbers, is given by

$$Z_r(\beta,\omega)=\frac{\zeta(\beta\omega)}{\zeta(r\beta\omega)}. \tag{4.4}$$

What is compelling about this result is that we have found it using partial supersymmetry.

One knows, of course, that the bosons are the infinite order limit of parafermions. It is interesting to see how that appears in this context. As we take r to infinity, the energies of states with fermionic excitations go to infinity, and so the fermionic creation and annihilation operators decouple,[6] leaving behind the purely bosonic partition function. Thus the recovery of the bosonic theory at infinite r is, in our language, a decoupling effect.

One of the most intriguing features of the partition function Z_r is that it is well-defined for noninteger values of r. We do not simply mean that noninteger values of r can be plugged into the zeta function expression (4.4). Rather, we can put noninteger values of r into (4.1) quite sensibly and naturally—after all, why should the parameters of a Hamiltonian be integral—and this yields, from an expression with ordinary bosons and fermions, a partition function for exotic parafermions, parafermions of nonintegral order. Thus although there is no simple exclusion principle that one could state for such exotic parafermions, nor a simple Hamiltonian directly in terms of creation and annihilation operators for such exotic parafermions, we can obtain the thermal partition function quite easily from

$$Z_r(\beta,\omega)=\mathrm{tr}[(-1)^F e^{-\beta(H_B+rH_F)}]. \tag{4.5}$$

What is the meaning of such theories? On the one hand, the partition function tells us what the theory is, so any quest for further interpretations might be viewed as superfluous. On the other hand, understanding what nonintegral parafermions mean in a practical sense is physically intriguing. It is worth observing that the ability to vary the parameter r continuously in (4.3) means that we have a way to vary continuously from conventional parafermions of one integer order to another. This should enable one to connect results in the different conventional parafermion theories, presumably through analyticity or topological arguments.

Note that for parafermions of order r real and less than 1, there is a temperature less than the Hagedorn temperature[1,7] where the thermal partition function vanishes, indicating that the physical sense of these theories is limited to $r>1$. This is no surprise. At $r=1$, the corresponding order 1 parafermions obey an exclusion principle such that states with one or more excitations are forbidden, which means that only the vacuum state is physical. (Indeed, $r=1$ is simply the case of the Witten index calculation, in which all states but the vacuum state are canceled out.) Phrased in this way, parafermions of order $r<1$ seem clearly to be physically untenable, as well as mathematically troublesome.

V. SUPERSYMMETRY AND BOSON NUMBER

Recall from Ref. 1 that the mathematical interpretation of the supersymmetry Witten index result

$$\mathrm{tr}\, e^{-\beta H_B}\ \mathrm{tr}[(-1)^F e^{-\beta H_F}]=1 \tag{5.1}$$

is

$$\sum_{m=1}^{\infty}\ \frac{\mu(m)}{m^s}=\frac{1}{\zeta(s)}, \tag{5.2}$$

while we also know from (5.1) that the graded fermionic partition function is the inverse of the thermal bosonic partition function. Now that we have just calculated the thermal fermionic partition function, we can ask what its inverse is. We will find the result physically, and give its corresponding mathematical interpretation.

Supersymmetry, we know, pairs bosonic and fermionic states. Consider the Hamiltonian $H_S=H_B+H_F$. Supersymmetry pairs each b_k with f_k and each $b_k^\dagger$ with $f_k^\dagger$. Let us define $(-1)^{N_B}$ to be the operator that has value $+1$ for Fock space states with an even number of bosonic creation operators, and -1 for Fock space states with an odd number of bosonic creation

operators. Note that $(-1)^{N_B}$ commutes with $f_k^\dagger$ and f_k. Because the supercharges of H_S involve terms like $b_k^\dagger f_k$ and $f_k^\dagger b_k$, all states with nonzero energy come in superpartnerships with an equal number of even and odd N_B states. Only the zero energy states need not be paired in this way, as they are the supersymmetry singlet states. Consequently, for the theory with Hamiltonian $H_S = H_B + H_F$, we see

$$\mathrm{tr}[(-1)^{N_B} e^{-\beta(H_B+H_F)}] = 1, \tag{5.3}$$

which is analogous to but distinct from the familiar Witten index result for $\mathrm{tr}[(-1)^F e^{-\beta H_s}]$. Since H_B and H_F commute with each other, we see that

$$\mathrm{tr} e^{-\beta H_F} = \frac{1}{\mathrm{tr}[(-1)^{N_B} e^{-\beta H_B}]}. \tag{5.4}$$

The inverse of the thermal fermionic partition function is the graded bosonic partition function.

The mathematical translation of this is as follows. Using the Gödel numbering described above, we can represent $(-1)^{N_B}$ by the arithmetic function $\psi(m)$, where $\psi(m)$ is totally multiplicative [i.e., $\psi(m)\psi(n) = \psi(mn)$ for all natural numbers m and n] and with $\psi(p^r) = (-1)^r$ for any prime number p. Thus, using the connection with Dirichlet convolution described in Ref. 1, we see that

$$\psi * |\mu|(m) = \mathbf{1}(m), \tag{5.5}$$

where $\mathbf{1}$ is the identity function for Dirichlet convolution, $\mathbf{1}(m) = \delta_{m,0}$, or, equivalently,

$$\sum_{m=1}^{\infty} \frac{\psi(m)}{m^s} = \frac{1}{\sum_{m=1}^{\infty}[|\mu|(m)/m^s]} = \frac{\zeta(2s)}{\zeta(s)}. \tag{5.6}$$

Thus we have used our thinking about number theory to recognize that, generically, we can introduce a bosonic grading quite analogous to the fermionic grading, and this has led us physically to another number theoretic identity, namely (5.6). We note that the bosonically graded index is topological in nature, unaffected by deformations of the parameters of a theory as long as the supercharges remain odd under $(-1)^{N_B}$, and thus it is reliably calculable even by approximation methods. Supersymmetry is unbroken if this bosonic index is nonzero. Note, too, that $(-1)^F$ corresponds to the arithmetic function μ, and $(-1)^{N_B}$ to the arithmetic function ψ. One learns from supersymmetry that the inverses of these functions under Dirichlet convolution obey a nice symmetry: $\mu^{-1} = |\psi|$, while $\psi^{-1} = |\mu|$. It would be interesting to find other pairs of functions with this type of partnering when taking the inverse, and to see if there is a supersymmetric reason underlying such a relationship.

VI. GRADED PARAFERMION PARTITION FUNCTIONS

Our discussion of graded partition functions leads us naturally to consider graded parafermion partition functions. Here we present some results, but leave the detailed calculation to the readers, and reserve speculation on these results for elsewhere.

Consider the parafermions of order r discussed previously. Define the operator $\hat{\eta}$ such that a one-parafermion state has $\hat{\eta}$-eigenvalue η, where $\eta^r = 1$. Then

$$\mathrm{tr}[\hat{\eta} e^{-\beta H_r}] = \mathrm{tr}[\hat{\eta} e^{-\beta H_B}]\mathrm{tr}[(-1)^F e^{-\beta r H_F}] \tag{6.1}$$

using our representation of parafermions (4.3) and partial supersymmetry. Note that the bosonic creation operators also have $\hat{\eta}$-eigenvalue η, while the fermionic creation operators are $\hat{\eta}$-neutral.

There is an alternative graded partition function that one can naturally define. Let $\hat{\xi}$ be an operator such that a one-parafermion state has $\hat{\xi}$-eigenvalue ξ where $\xi^r = -1$. Then using our method of partial supersymmetry and the notion of the bosonic index (5.3), we find that

$$\mathrm{tr}[\hat{\xi} e^{-\beta H_r}] = \mathrm{tr}[\hat{\xi} e^{-\beta H_B}]\mathrm{tr}[e^{-\beta r H_F}]. \tag{6.2}$$

The convention, again, is that the bosonic creation operators have $\hat{\xi}$-eigenvalue ξ, while the fermionic creation operators are $\hat{\xi}$-neutral.

The $\hat{\eta}$- and $\hat{\xi}$-graded partition functions can be written in these factorized forms involving products of purely bosonic and purely fermionic terms because of the existence of a partial supersymmetry in these expressions, which leads to cancellations along the lines of the Witten index in (6.1) and of the bosonically graded index (5.3) in (6.2). Other gradings would not admit such a factorization.

VII. DUALITY

The identities we have obtained above provide relationships for partition functions (thermal and graded) at different temperatures. This offers an interesting possibility, akin to duality in supersymmetric and string theories: that we can identify two distinct theories at distinct temperatures that nonetheless give rise to the same thermodynamics. We will in fact realize this possibility, with an example in which the Euler totient function plays a central role.

Before proceeding further, it is worth commenting on our use of the term ''duality.'' In string theory, this term is most conventionally used to refer to relationships that directly relate the weak and strong coupling regimes (roughly speaking, replacing a coupling constant g by $1/g$). Here we use the term in a somewhat broader sense to refer to identities among theories at different coupling constants in general. Although the relationships we identify do not simply involve inverting a coupling constant, they can be iterated to related weak and strong couplings. Furthermore, even without such iteration, the identities we find between arithmetic quantum theories can clearly play a role analogous to the role played by weak–strong coupling dualities in string theory, establishing the equivalence of superficially distinct theories, and thus allowing the use of one formulation of a theory to analyze another. Hence we employ the term ''duality'' to characterize the identities among arithmetic quantum theories that we establish below.

To begin our analysis, then, consider the thermal partition functions associated with the original Hamiltonians H_B and H_F, which we will denote as Z_B and Z_F, respectively. Then (3.5) can be interpreted as

$$Z_F(\beta)Z_B(2\beta)=Z_B(\beta). \tag{7.1}$$

Alternatively, if we denote the fermionic partition function graded with $(-1)^F$ as Δ_F, we have

$$\Delta_F(2\beta)=Z_F(\beta)\Delta_F(\beta). \tag{7.2}$$

What is interesting about these expressions is that they relate partition functions at different temperatures. There are two interpretations possible here:

(a) In (7.1), we have a noninteracting mixture of two systems, each at its own temperature, equivalent to a third system at its own temperature.

(b) In (7.2), we have a mixture of two systems thermalized with each other at one temperature equivalent to a different system at a different temperature.

Note that in (b) not all the partition functions are thermal (some are fermionically graded), while in (a) we have an unthermalized mixture of two systems. Ideally, we would like a thermalized system at one temperature equivalent to a thermalized system at a different temperature. It turns out that this is possible to achieve.

Consider the Euler totient function, defined by $\varphi(m)=\Sigma_{d:(d,m)=1}1$, i.e., it is the number of positive integers less than m that are relatively prime to m. Then it is a standard result in number theory that

$$\zeta(s-1)=\zeta(s)\sum_{m=1}^{\infty}\frac{\varphi(m)}{m^s}. \tag{7.3}$$

We can interpret this physically as follows. Let us imagine two theories, one is governed by the original Hamiltonian H_B from (2.1) above. The other has the same spectrum as H_B, but has degeneracies given by the totient function; it has $\varphi(m)$ states with energy $\omega\log(m)$. We call the Hamiltonian for this theory H_φ and its partition function Z_φ.

Then we see that, in terms of the dimensionless parameter $s=\beta\omega$,

$$Z_B(s-1)=Z_B(s)Z_\varphi(s). \tag{7.4}$$

In other words, a thermalized mixture of two ideal gases, governed by the Hamiltonians H_B and H_φ, is equivalent simply to a higher-temperature gas governed by H_B. Alternatively, we can phrase this as a coupling constant duality. The Hamiltonian H_B at coupling constant $\omega-1/\beta$ and the Hamiltonian H_B+H_φ at coupling constant ω have the same partition function at temperature $T=\beta^{-1}$. The presence of this duality indicates an important additional similarity connecting arithmetic quantum theories and string theories.

The duality described above is clearly intriguing. There are two especially interesting directions to consider.

(1) These expressions give a way to shift temperature via coupling new systems. Let us call a system governed by Hamiltonian H_B a Riemann gas, and one governed by H_φ a totient gas. Then what we have found is that if we start with a Riemann gas at one temperature, and then mix it with a totient gas at the same temperature, this is simply equivalent to taking the Riemann gas and increasing its temperature a certain amount. Note that we can iterate this process by mixing in additional totient gases, and thereby shift the temperature further. This gives us an alternative to standard methods such as the renormalization group for thinking about how to shift temperatures; relating such distinct methods is potentially powerful. The most interesting outcome would be to determine a way to generalize this notion of obtaining a temperature shift by mixing in a new quantum system, finding ways to apply it to theories not so closely tied to the Riemann zeta function.

(2) We have now identified, among the class of arithmetically based quantum models, theories that exhibit duality behavior in their partition functions, with the best example being the duality (7.4) occurring for the theory with Hamiltonian H_B. We also know that this same theory exhibits a Hagedorn temperature. Both these traits, existence of duality and existence of a Hagedorn temperature, are distinguishing characteristics of string theory. This adds further support to the notion that the H_B theory and its relatives are related in a meaningful way to string theory, and thus that exploration of these arithmetic theories will prepare us to understand better the nature of string theory.

We can expand on this idea a bit further. It is well-known that in string theory, the duality between large and small radii effectively means there is a minimum distance in string theory. On the other hand, the Hagedorn temperature means there is a maximum temperature in a theory. Perhaps, in some similar fashion, the existence of a maximum temperature is associated with a temperature duality (recall that the duality we found could be understood as a temperature or as a coupling constant duality) in and of itself. These number theoretic field theories offer us an arena other than string theory in which to explore this question.

VIII. MORE WITH PARTIAL SUPERSYMMETRY

In earlier sections, we found that we could evaluate certain physically interesting partition functions and simultaneously obtain some interesting number theoretic identities, using partial supersymmetry, in which some but not all of the bosonic creation operators had fermionic superpartners. There are other number theoretic results which appear as if they should have an interpretation via partial supersymmetry. We give here two particular examples to show the kinds of results that it appears ought to be possible to derive via partial supersymmetry, although to date no such derivation exists.

As a first example, consider the function

$$\sigma_\alpha(m)=\sum_{d|m} d^\alpha, \tag{8.1}$$

where the summation is over all positive integers d that are factors of the positive integer m. The Dirichlet series of this function is related to the Riemann zeta function by

$$\zeta(s-\alpha)=\frac{1}{\zeta(s)}\sum_{m=1}^{\infty}\frac{\sigma_\alpha(m)}{m^s}. \tag{8.2}$$

Let us define H_{σ_α} to be the Hamiltonian that has as its spectrum $\sigma_\alpha(m)$ states of energy $\omega\ \log(m)$. Then

$$\mathrm{tr}[e^{-(\beta-\alpha/\omega)H_B}]=\mathrm{tr}[(-1)^F e^{-\beta(H_{\sigma_\alpha}+H_F)}]. \tag{8.3}$$

The right side involves a partial supersymmetric cancellation (note that none of the degeneracies go to zero) at temperature β^{-1}, resulting in a theory a different temperature.

A second representative case comes from rewriting the identity (7.3) of the preceding section as

$$Z_\varphi(\beta,\omega)=\frac{\zeta(s-1)}{\zeta(s)}=\mathrm{tr}[e^{-(\beta-1/\omega)H_B}]\mathrm{tr}[(-1)^F e^{-\beta H_F}]. \tag{8.4}$$

In this context, the Euler totient function appears as the degeneracy factor resulting after a cancellation between bosons and fermions at different temperatures. This is a variation on the partial supersymmetry used above; here, if the bosons and fermions were at the same temperature, the cancellation would be complete. Mathematically, the right side of (8.4) resembles a partition function for a supersymmetric Hamiltonian with nonsupersymmetric boundary conditions.

Needless to say, these two examples could both be written as identities involving a single temperature but different coupling constants.

The importance of highlighting these identities is to demonstrate what partial supersymmetry can offer. If these and a host of similar identities involving ratios of zeta functions and other Dirichlet series can be understood in this way, partial supersymmetry promises to be a valuable new tool for enriching our understanding of arithmetic number theory.

IX. CONCLUSIONS

Arithmetic quantum theories have provided some of the most aesthetically pleasing examples of connections between mathematics and physics, and in this paper, we have found that these connections are even more compelling and worthy of study.

Most importantly, we have found dualities among the partition functions for arithmetic quantum theories, dualities that can be interpreted as coupling constant or temperature dualities, demonstrating the equivalence of apparently distinct Hamiltonians. Our work has suggested that there may actually be a reason to expect a connection between some types of dualities and the existence of a Hagedorn temperature, an area that warrants further investigation. With these dualities, it is possible to shift the temperature of a certain theory by mixing in additional quantum excitations at the original temperature; relating this interpretation to more familiar methods such as the renormalization groups should also provide useful insights into, or constraints on, the behavior of these theories. We are interested, too, in finding more useful applications of the bosonically graded topological index.

On the technical side, the most significant result of this paper is the identification of the technique of partial supersymmetry. This has given a physical basis for a variety of number theoretic results, and we have identified further types of results that should yield to such an analysis. Indeed, one would expect this method to be useful beyond the realm of arithmetic quantum theories.

This technique of partial supersymmetry has given us a physically based formalism for interpolating from one Dirichlet series to another using ordinary bosons and fermions. Indeed, it is this idea that underlies our formulation of noninteger order parafermions. This is a potentially powerful idea, as it may allow the use of topological insights to study arithmetic number theory, by using continuity arguments to connect the behavior of different Dirichlet series.

It is our hope that the ideas introduced in this paper will be of value not only in understanding arithmetic quantum theories and directly related examples (physical ones such as string theory, mathematical ones such as Dirichlet series), but may also be extended to a wider range of theories. There is no reason to think that the notion of partial supersymmetry or our particular approach to

duality and its implications should not, in some fashion, be extended to relativistic, interacting theories with a variety of spectra (and not simply those theories so closely tied to the Riemann zeta function and other Dirichlet series), nor that we have exhausted the physical insights into number theories that consideration of quantum theories will provide. We hope further work will shed light on these possibilities.

Symmetry and symmetry breaking in quantum-chromo (flavor)-dynamics

A. H. Völkel
Institut für Mathematik I, Freie Universität Berlin, 14195 Berlin, Germany

(Received 22 January 1997; accepted for publication 3 September 1997)

Symmetries of flavored quantum-chromo(flavor)-dynamics (QCD) and their breaking are reinvestigated within the Lagrange–Hamilton frame as well as on the basis of axiomatic gauge quantum field theory aiming at the resolution of some shortcomings by which QCD is still burdened despite all its undisputable successes: The Noether energy momentum tensors arising from those general representations (substitution rules) of the translation group that leave the standard SU(3) local color gauge and global flavor invariant chiral QCD-Lagrangian (and hence the Euler–Lagrange field equations) form invariant are shown to contain, besides the standard color and flavor symmetric canonical part, additional terms breaking the internal SU(3) symmetries of the Lagrangian down to chiral SU(2)×U(1) flavor symmetry, and in case of color confinement also the color group down to U(1)×SU(2) color symmetry only. With these general representations (covariance conditions) of the translation group as an input, a strictly Poincaré covariant gauge-quantum-field theory with color confinement is formulated and flavor Goldstone states are shown to occur with *finite masses* due to relative Einstein causality, the spectrum condition in color neutral sectors, translational covariance, and current conservation. Identifying the finite mass Goldstone states with pseudoscalar mesons, the axial vector part of the chiral SU(3) flavor symmetry is spontaneously broken, leaving only the chiral SU(2)×U(1) subgroup as a strict flavor symmetry of QCD. © *1998 American Institute of Physics.* [S0022-2488(98)02203-8]

I. INTRODUCTION

In spite of its indisputable success all unitary symmetry schemes from SU(3) to SU(?) of flavored quantum-chromo(flavor)-dynamics (QCD) showed right from the beginning some deficiencies leaving the state of affairs a little bit artificially flavored. Some authors of textbooks state it this way: ''Put more concisely, the theory would be more convincing if the symmetry breaking was 'intrinsic' to the scheme, in the sense that it emerges automatically, without it having to be put in 'by hand' '' [1] (Part C, Chap. 18). ''Considering the fact that m_π is much smaller than the mass differences $m_K - m_\pi$ and $m_\eta - m_\pi$, it seems quite strange that H_{asym} can be treated as a perturbation'' [2] (Chap. 12).

In the hierarchy of flavor interactions, the strongest symmetry conserving part of the Hamiltonian is invariant under all SU(3) transformations, whereas the ''medium strong'' one is assumed to break the symmetry and the ''rest symmetry group'' is SU(2)×U(1), with SU(2) being the isospin group. In view of the rather large mass splittings between the isotopic submultiplets within a SU(3) multiplet, it is not possible to assert the effect of the ''medium strong'' interaction to be a small one. But then the question arises at once as to the significance of the SU(3) [respectively, SU(?)] group. Is its role merely to specify rather roughly the multiplets or is there something more in the unitary symmetry scheme still hidden in the underground?

Indeed, right at the outset the unitary scheme met the flaw, that in contrast to the baryon multiplets the masses in the splitting relations for the pseudoscalar meson octet had—again by hand—to be replaced by their squares in order to fit the experimental data[1–7] to an acceptable accuracy. Critically seen, however, even then three pion masses squared are still missing. Concerning the higher multiplets when grouped into octets in such a way that the mass differences are all small compared to a medium mass value of the multiplet, the linear mass formulas fit the experimental values, at least with the same accuracy as the quadratic ones and apart from the

lowest lying pseudovector octet 1^{--} ($\omega-\phi$ mixing) with a variation of less than 2.5%. Moreover, the chiral flavor symmetry meets the further flaw that the conservation of its axial vector current in combination with either parity conservation in a strong interaction[2] (Chap. 24.1–3) or the finite meson-decay constants in leptonic weak decays[4] (Chap. 2.8) dictates in both cases zero masses for the pseudoscalar mesons, which on the one hand seems compatible with the role of Goldstone states for the spontaneous breaking of the chiral symmetry ascribed to them but on the other hand contradicts the finiteness of their experimental masses. Hence the pseudoscalar meson octet seems to play an exceptional role for ''some unknown weaker mechanism,'' [5] breaking the unitary flavor symmetry of the strong interaction, which still hides itself behind all plausible explanations.

In Sec. II the conserved energy–momentum tensors and hence the Hamilton densities are derived that arise via Noether's Theorem from the form invariance of the usual flavored QCD-Lagrangian with respect to space–time translations, if, besides the familiar standard representation of the translation group for the basic quark and gluon fields, more general one-dimensional ones affiliated to the flavor and color degrees of freedom are admitted. The result is a continuum of admitted energy–momentum tensors parametrized by five arbitrary four-vectors, one of which is affiliated to the color degrees of freedom and the remaining four to the flavor ones. The Hamilton density corresponding to each of them except the standard one is a sum of the standard canonical one, the conserved Noether current generating the color charge, and last but not least the ''medium strong'' and unitary symmetry breaking conserved flavor current, usually added ''by hand.'' On the basis of these Noether currents the symmetry breaking is reconsidered in Sec. III. The global SU(3) flavor symmetry is, on the algebraic level, seen to be broken in the sense that the flavored CD-Lagrangian is form invariant with respect to the whole SU(3) group of flavor transformations, but depending on the representation chosen for the translation group its infinitesimal generators, in general, do not commute with the Hamilton density, that is with the generator of the time translation. However, for a subclass of representations of the translation group selected from the continuum by taking one of the four flavor vectors to be a fixed multiple of a certain other one of them, the global flavor $SU(2)\times U(1)$ subgroup remains a strict symmetry with its infinitesimal generators commuting with those of the space–time translation.

On the other hand, it is proved in Sec. VI that in the representations of the translation group with nonzero flavor (and/or color) parameters, Goldstone states occur with *nonzero* masses. Taking the pseudoscalar mesons with their finite experimental masses as Goldstone particles affiliated to the conserved axial vector currents of the chiral SU(3) flavor group, then the flavor parameters of representations of the translation group and hence of Hamiltonians admitted by the chiral QCD-Lagrangian are restricted to certain Lorentz orbits within the subclass stated above, in which the chiral $SU(2)\times U(1)$ flavor group remains a strict symmetry group commuting with the space–time translations.

In Sec. IV a Poincaré covariant general gauge quantum field theory of flavored chromodynamics with color-charge confinement, which mirrors the basic structures (especially of the color confining and internal symmetry breaking representations of the subgroup of translation) obtained in Secs. II and III within the Lagrange–Hamilton frame, is formulated in a Hilbert space equipped with an additional indefinite metric. Poincaré invariance requires that this indefinite metric space is the direct integral of such spaces attached to every point of a Lorentz orbit in the space of the flavor parameters and the color vector describing color confinement. The direct integral is taken with respect to the invariant measure of these orbits.

In Sec. V the spectrum condition is formulated and the construction of one particle state is sketched. By means of them and the direct integral structure of the underlying indefinite metric space, it is rather obvious that the finite meson-decay constants together with the conservation of the axial vector current do not imply anymore that the masses of the pseudoscalar mesons vanish.

In Sec. VI, finally, the generalized Goldstone Theorems are proved by means of relative locality, and it is shown that the conserved vector currents of the SU(3) flavor group generate a representation of this group that is isometric with respect to the indefinite metric. Hence, it lifts to a unitary one in the physical Hilbert space obtained in the familiar way via factorization and completion of some subspaces. But only its restriction to the subgroup $SU(2)\times U(1)$ commutes with the translation operators. The corresponding chiral flavor group, however, is spontaneously broken, since some axial charges do not exist due to the presence of the pseudoscalar K mesons with finite masses.

II. NOETHER CURRENTS OF LCD

The Lagrangian of (quantum-)chromodynamics is built up from two SU(3)-color triplets, respectively, SU(n)-flavor multiplets ($n\geqslant 3$) $\varphi^{3,n}_{a,f}(x)$ and $\varphi^{3^*,n^*}_{a,f}(x)$ of Dirac spinors called quark, respectively, antiquark fields and a SU(3)-color octet (flavor singlet) $\varphi^{8,1}_{a}(x)$ of Lorentz vectors called gluon (gauge) fields.[1–4] Here we will restrict the flavor group $G(3)_{\mathscr{F}}$ to be SU(3), respectively, some subgroup of it [isomorphic to SU(2)×U(1) or U(1)×U(1)], which means consider a system with three flavors (up, down, strange). However, all considerations may easily be extended to a flavor group of higher degree in order to include charmed, bottom, top, and so on quarks. The two ''different'' SU(3) groups will be marked by a suffix $\mathscr{C}$ for color, respectively, $\mathscr{F}$ for flavor whenever it seems necessary to avoid confusion.

For the sake of notational shortness, the unitary irreducible matrix representations $D^{(p,q)}$, $(p,q)\in\mathbb{N}_0\times\mathbb{N}_0$ of SU(3) with dimension $d=1/2[(1+p)^2(1+q)+(1+p)(1+q)^2]$ will be denoted by $R^d=D^{(p,q)}$ for $p\geqslant q$, respectively, $R^{d^*}=D^{(p,q)}$ for $p\leqslant q$. Then *conventionally* for any triple (α,u,v) from the direct product $\mathrm{SL}(2,\mathbb{C})\times\mathrm{SU}(3)_{\mathscr{C}}\times G(3)_{\mathscr{F}}$ the fields are supposed to transform according to

$$\varphi^{m,n}_{\mu,a,f}(x)\to(U(\alpha,u,v)\varphi)^{m,n}_{\mu,a,f}(x):=S^{(m,n)}(\alpha)^{\nu}_{\mu}R^{m}_{\mathscr{C}}(u^{-1})^{b}_{a}R^{n}_{\mathscr{F}}(v^{-1})^{g}_{f}\varphi^{m,n}_{\nu,b,g}(\Lambda(\alpha)x), \tag{1}$$

with

$$S^{(m,n)}(\alpha)^{\mu}_{\nu}:=\begin{cases} S^{1/2}(\alpha^{-1})_{\nu\mu}, & \text{for } (m,n)=(3,3),\\ \Lambda(\alpha^{-1})^{\mu}_{\nu}, & \text{for } (m,n)=(8,1),\\ S^{1/2}(\alpha)_{\mu\nu}, & \text{for } (m,n)=(3^*,3^*),\end{cases} \tag{2}$$

and

$$S^{1/2}(\alpha)^{-1}\gamma^{\mu}S^{1/2}(\alpha)=\Lambda(\alpha)^{\mu}_{\nu}\gamma^{\nu};\quad \gamma^0S^{1/2}(\alpha)^{+}\gamma^0=S^{1/2}(\alpha)^{-1};$$

$$\Lambda(\alpha)^{\mu}_{\nu}g_{\mu\sigma}\Lambda(\alpha)^{\sigma}_{\kappa}=g_{\nu\kappa}. \tag{3}$$

The Dirac matrices are assumed to have the hermiticity properties $(\gamma^{\mu})^{+}=(\overline{\gamma^{\mu}})^{t}=g^{\mu\mu}\gamma^{\mu}$, $(\gamma^0)^t=\gamma^0$. With respect to the group SU(3) and its representations, we adopt the conventions and (apart from minor changes) the notations of de Swart.[5–7] The color/flavor indices are triples $a=(I,I^3,Y)$ running over the index set Γ_d defined by the Okubo rule:[6]

$$\Gamma_d(p,q):=\{(I,I^3,Y)\,|\,I=1/2(\lambda-\rho);\quad I^3=-I,\ldots,I;\quad Y=\lambda+\rho-1/3(2p+4q);\quad \lambda,\rho\in\mathbb{N}_0;$$

$$0\leqslant\rho\leqslant q\}. \tag{4}$$

$I\ldots$ is interpreted to be the total ''color/flavor isospin,'' $I^3\ldots$ its third component, and $Y\ldots$ the ''color/flavor hypercharge.'' An immediate consequence of the definition of Γ_d is

$$(I,I^3,Y)\in\Gamma_d(\Gamma_{d^*})\Leftrightarrow(I,-I^3,-Y)\in\Gamma_{d^*}(\Gamma_d). \tag{5}$$

In accordance with this relation the negative of an index triple $a=(I,I^3,Y)$ is by definition the triple $-a:=(I,-I^3,-Y)$. Hence the ''color/flavor charge,''

$$Q(a)\ldots=Q(I,I^3,Y)\ldots:=I^3\ldots+\frac{1}{2}\,Y\ldots, \tag{6}$$

satisfies $Q(-a)\ldots=-Q(a)\ldots$. Finally, there exists an important connection between the complex conjugate representation $\overline{R^d}(\overline{R^{d^*}})$ and the representation $R^{d^*}(R^d)$. Adopting the notational convention $d^{**}=(d^*)^*=d$ it reads for all d and d^*,

$$R^{d^*}(u)^{b}_{a}=(-1)^{Q(b)-Q(a)}\overline{R^d(u)}^{-b}_{-a};\quad a,b\in\Gamma_{d^*},\quad u\in\mathrm{SU}(3). \tag{7}$$

In case of the adjoint (octet) representation as well as all other (''diagonal'') representations with $R^d = D^{(p,p)} = R^{d*}$ the condition (7) is an equation between different elements of the same matrix, which is called *self-conjugateness*. As an immediate consequence the gluon fields form a self-conjugate color octet:

$$\overline{\varphi^{8,1}_{\mu,a}(x)} = (-1)^{Q(a)_{\mathscr{C}}} \varphi^{8,1}_{\mu,-a}(x). \tag{8}$$

Dirac indices will often be dropped by the usual conventions and $\varphi^{3,3}_{a,f}$ is considered to be a column, whereas $\varphi^{3^*,3^*}_{a,f}$ a row. Then the Dirac adjoint of $\varphi^{3,3}_{a,f}$ is connected to $\varphi^{3^*,3^*}_{a,f}$ by

$$\widetilde{\varphi}^{3,3}_{a,f}(x) := \varphi^{3,3}_{a,f}(x)^+ \gamma^0 = (-1)^{-Q(a)_{\mathscr{C}} - Q(f)_{\mathscr{F}} - 2/3} \varphi^{3^*,3^*}_{-a,-f}(x). \tag{9}$$

In terms of these fields the Lagrangian of chromodynamics reads as

$$\begin{aligned} L(\varphi(x), B(x)) = &-1/4(-1)^{Q(a)_{\mathscr{C}}} G_{\mu\nu,-a}(x) G^{\mu\nu,a}(x) + \widetilde{\varphi}^{3,3}_{a,f}(x)[(i/2)\gamma^\mu \{\delta^b_a \overleftrightarrow{\partial}_\mu + ig(\tau_c)^b_a \varphi^{8,1}_{\mu,c}(x)\} \\ &- \delta^b_a \varrho_f] \delta^e_f \varphi^{3,3}_{b,e}(x) - (-1)^{Q(a)_{\mathscr{C}}} [\varphi^{8,1}_{\mu,-a}(x) \partial^\mu B^{8,1}_a(x) - (\alpha/2) B^{8,1}_{-a}(x) B^{8,1}_a(x)], \end{aligned} \tag{10}$$

with the gluon field tensor

$$G_{\mu\nu,a}(x) := \partial_\mu \varphi^{8,1}_{\nu,a}(x) - \partial_\nu \varphi^{8,1}_{\mu,a}(x) + ig\sqrt{3} \begin{pmatrix} 8 & 8 & 8_A \\ b & c & a \end{pmatrix} \varphi^{8,1}_{\mu,b}(x) \varphi^{8,1}_{\nu,c}(x), \tag{11}$$

being obviously a self-conjugate color octet (flavor singlet).

τ_a, $a \in \Gamma_8$ denote the traceless (3,3) matrices of the self-conjugate fundamental representation of the (complex) Lie algebra su(3) satisfying the relations[5–7]

$$[\tau_a, \tau_b]_- = -2\sqrt{3} \begin{pmatrix} 8 & 8 & 8_A \\ a & b & c \end{pmatrix} \tau_c, \quad \mathrm{tr}(\tau_a \cdot \tau_b^+) = 2\delta_{ab}, \quad \tau_a^+ = (-1)^{Q(a)} \tau_{-a}. \tag{12}$$

The gauge fixing field $B^{8,1}_a$ is related to the gluon octet via the Euler–Lagrange field equation $\partial^\nu \varphi^{8,1}_{\nu,a}(x) + \alpha B^{8,1}_a(x) = 0$. Usually, there is added a further term to the Lagrangian describing FP ghosts.[8] In order to keep the explicit formulas as short as possible, we dropped it, since it would only add some further terms to the explicit expression of the Noether currents in terms of the basic fields without being in any way tangent to the general structure of these currents that we are going to use in our considerations. The members of the set $\{\varphi^{3,3}_{\mu,a,f}, \widetilde{\varphi}^{3,3}_{\mu,a,f}, \varphi^{8,1}_{k,b}, B^{8,1}_b | \mu = 0,...,3; k = 1,2,3; a,f \in \Gamma_3; b \in \Gamma_8\}$ are taken as an independent canonical variable.

By construction, the Lagrangian is form invariant under the global color group $\mathrm{SU}(3)_{\mathscr{C}}$ and the corresponding eight conserved Noether currents read ($c \in \Gamma_8$) as

$$\begin{aligned} j^{8,\mu}_c(x)_{\mathscr{C}} := &-\frac{1}{2} \left\{ \widetilde{\varphi}^{3,3}_{a,f}(x) \gamma^\mu (\tau_c)^b_a \varphi^{3,3}_{b,f}(x) + i2\sqrt{3}(-1)^{Q(a)_{\mathscr{C}}} \begin{pmatrix} 8 & 8 & 8_A \\ c & b & a \end{pmatrix} [G^{\mu\epsilon}_{-a}(x) \varphi^{8,1}_{\epsilon,b}(x) \right. \\ &\left. + \varphi^{8,1}_{\lambda,-a}(x) g^{\mu\lambda} B^{8,1}_b(x)] \right\} \\ = &\frac{1}{g} (-1)^{Q(a)_{\mathscr{C}}} \left\{ \delta^a_c \partial_\lambda G^{\mu\lambda}_{-a}(x) + g^{\mu\lambda} \left[\delta^a_c \partial_\lambda + ig\sqrt{3} \begin{pmatrix} 8 & 8 & 8_A \\ c & d & a \end{pmatrix} \varphi^{8,1}_{\lambda,d}(x) \right] B^{8,1}_{-a}(x) \right\}. \end{aligned} \tag{13}$$

In the last row the Euler–Lagrange equations have been used.

Here we are especially interested in the combination $j^{8,\mu}_{(1,0,0)}(x) + (1/\sqrt{3}) j^{8,\mu}_{(0,0,0)}(x)$ because it will reoccur in the Noether energy momentum tensor below. From the explicit connection between the real self-conjugate traceless matrices τ_c, $c \in \Gamma_8$ and the Hermitian traceless matrices λ_j, $j = 1,...,8$ of Gell-Mann,

$$\tau_{(0,0,0)}=\lambda_8, \quad \tau_{(1,0,0)}=\lambda_3, \quad \tau_{(1,1,0)}=-\frac{1}{\sqrt{2}}(\lambda_1+i\lambda_2)$$

$$\tau(1/2,1/2,1)=-\frac{1}{\sqrt{2}}(\lambda_4+i\lambda_5), \quad \tau_{(1/2,-1/2,1)}=-\frac{1}{\sqrt{2}}(\lambda_6+i\lambda_7),$$

respectively, multiplying the commutation relations (12) by $(\tau_e)^+$ and taking the trace it follows at once:

$$\left(\tau_{(1,0,0)}+\frac{1}{\sqrt{3}}\tau_{(0,0,0)}\right)^b_a=2Q(a)\delta^b_a,$$

$$2\sqrt{3}\left[\begin{pmatrix} 8 & 8 & 8_A \\ (1,0,0) & b & a \end{pmatrix}+\frac{1}{\sqrt{3}}\begin{pmatrix} 8 & 8 & 8_A \\ (0,0,0) & b & a \end{pmatrix}\right]=2Q(a)\delta_{ba},$$

and therefore

$$j^{8,\mu}_{(1,0,0)}(x)_{\mathscr{C}}+\frac{1}{\sqrt{3}}j^{8,\mu}_{(0,0,0)}(x)_{\mathscr{C}}=-\{Q(a)_{\mathscr{C}}\tilde{\varphi}^{3,3}_{a,f}(x)\gamma^\mu\varphi^{3,3}_{a,f}(x)+i(-1)^{Q(a)_{\mathscr{C}}}Q(a)_{\mathscr{C}}[G^{\mu,\epsilon}_{-a}(x)\varphi^{8,1}_{\epsilon,a}(x)$$
$$+g^{\mu\epsilon}\varphi^{8,1}_{\epsilon,-a}(x)B^{8,1}_a(x)]\}. \tag{14}$$

Concerning the flavor transformations the subgroup of SU(3) with respect to which the CD Lagrangian is form invariant, is determined alone by the ''mass'' matrix of the quarks,

$$\varrho=\begin{pmatrix} \varrho_u & 0 & 0 \\ 0 & \varrho_d & 0 \\ 0 & 0 & \varrho_s \end{pmatrix}=\begin{pmatrix} \varrho_{(1/2,1/2,1/3)} & 0 & 0 \\ 0 & \varrho_{(1/2,-1/2,1/3)} & 0 \\ 0 & 0 & \varrho_{(0,0,-2/3)} \end{pmatrix},$$

which is not observable, but can only be estimated indirectly. If all three quark ''masses'' are equal $G(3)_{\mathscr{F}}$ is of course again SU(3). If $\varrho_u=\varrho_d\neq\varrho_s$ form invariance holds only for the subgroup

$$G(3)_{\mathscr{F}}=\left\{\begin{pmatrix} & & 0 \\ & g & \\ & & 0 \\ 0 & 0 & 1 \end{pmatrix}\exp\left[i\frac{t}{2\sqrt{3}}\tau_{(0,0,0)}\right]\middle| g\in \mathrm{SU}(2)\wedge t\in\mathbb{R}\right\}$$

isomorphic to SU(2)×U(1). Finally, if all three ''masses'' are pairwise different their remains only the subgroup,

$$G(3)_{\mathscr{F}}=\left\{\exp i/2\left(\tau_{(1,0,0)}\rho+\frac{1}{\sqrt{3}}\tau_{(0,0,0)}t\right)\middle|\rho,t\in\mathbb{R}\right\},$$

isomorphic to U(1)×U(1).

Corresponding to these three cases the Noether Theorem delivers the existence of eight, four, respectively, two locally conserved flavor currents:

$$j^{8,\mu}_c(x)_{\mathscr{F}}=-1/2\{\tilde{\varphi}^{3,3}_{a,f}(x)\gamma^\mu(\tau_c)^e_f\varphi^{3,3}_{a,e}(x)\}, \tag{15}$$

with

$$c \in \cdot \begin{cases} \Gamma_8, & \text{if} \quad G(3)_{\mathscr{F}} = \mathrm{SU}(3), \\ \{(0,0,0),(1,0,0),(1,1,0),(1,-1,0)\}, & \text{if} \quad G(3)_{\mathscr{F}} \sim \mathrm{SU}(2)\times\mathrm{U}(1), \\ \{(0,0,0),(1,0,0)\}, & \text{if} \quad G(3)_{\mathscr{F}} \sim \mathrm{U}(1)\times\mathrm{U}(1). \end{cases}$$

It is generally accepted[1–4] that $\varrho_d \approx \varrho_u \approx 0$ and $\varrho_u + 100\ \mathrm{MeV} \leqslant \varrho_s \leqslant \varrho_u + 200\ \mathrm{MeV}$, which reflects the mass splitting in the hadron spectrum with the splitting within an isospin submultiplit due to electromagnetism. In the last two cases, where the Noether theorem delivers only four or two instead of eight conserved currents, one can define four, respectively, six further currents—the missing ones with respect to the full SU(3) symmetry—by the right-hand side of Eq. (18). Of course they are not conserved. Important for the following is that the two currents $j^{8,\mu}_{(1,0,0)}(x)_{\mathscr{F}}$ and $j^{8,\mu}_{(0,0,0)}(x)_{\mathscr{F}}$ that will reoccur in the Noether energy–momentum tensor are locally conserved in all three cases above.

Besides the irreducible octet operator formed by the eight generators τ_a, $a \in \Gamma_8$, there exists a second linear independent one:[7]

$$\sigma_a : 2\sqrt{5}/3 \begin{pmatrix} 8 & 8 & 8_S \\ b & c & a \end{pmatrix} \tau_b \tau_c .$$

In terms of the total isospin operator $\mathscr{T}^2$, the hypercharge $\mathscr{Y}$, and the second-order Casimir operator $\mathscr{C}^2$ [with eigenvalues $I(a)(I(a)+1)$, $Y(a)$, and $K(d)$, respectively] its (0,0,0) and (1,0,0) components read explicitly as

$$\begin{aligned} \sigma_{(0,0,0)} &= 2[\mathscr{T}^2 - 1/4\mathscr{Y}^2 - 1/3\mathscr{C}^2], \\ \sigma_{(1,0,0)} &= 10/(3\sqrt{3})\,\tau_{(1,0,0)}. \end{aligned} \tag{16}$$

Unless the quark ''masses'' are pairwise different, the Lagrangian is form invariant with respect to the substitutions

$$\begin{aligned} \varphi^{3,3}_{a,f}(x) &\to \varphi^{3,3\wedge}_{a,f}(x) = (\exp\, i/2\sigma_{(r,0,0)}t)^e_f \varphi^{3,3}_{a,e}(x), \\ \widetilde{\varphi}^{3,3}_{a,f}(x) &\to \widetilde{\varphi}^{3,3\wedge}_{a,f}(x) = (\exp - i/2\sigma_{(r,0,0)}t)^e_f \widetilde{\varphi}^{3,3}_{a,e}(x), \end{aligned} \tag{17}$$

with $r = 0,1$ and the gluon, respectively, gauge fields unchanged. But then the Noether Theorem delivers two further conserved flavor currents:

$$j^{8_S,\mu}_{(r,0,0)}(x)_{\mathscr{F}} = -\tfrac{1}{2}\widetilde{\varphi}^{3,3}_{a,f}(x)\,\gamma^\mu(\sigma_{(r,0,0)})^e_f \varphi^{3,3}_{a,e}(x), \tag{18}$$

with $r = 0,1$, which also are going to reoccur in the Noether energy momentum tensor.

Next we consider the translation group $(\mathbb{R}_4, +)$. For any fixed complex four-vector $\delta \in \mathbb{C}_4$ and any fixed real four-vectors (κ, ω, M, N), a representation $T^{\delta,M,N}_{\kappa,w}$ of the translation group may be defined by

$$\begin{aligned} (T^{\delta,M,N}_{\kappa,\omega}(y)\varphi)^{n,d}_{\mu,a,f}(x) :&= \exp[Q(a)_{\mathscr{C}}(\delta\cdot y)]R^d(\exp\, i/2[\sigma_{(1,0,0)}(N\cdot y) \\ &\quad + \sigma_{(0,0,0)}(M\cdot y)])^b_f R^d \\ &\quad \times (\exp\, i/2[\tau_{(1,0,0)}(\kappa\cdot y) + (1/\sqrt{3})\,\tau_{(0,0,0)}(\omega\cdot y)])^e_b \varphi^{n,d}_{\mu,a,e}(x+y), \end{aligned} \tag{19}$$

with $(n,d) \in \{(3,3),(3^*,3^*),(8,1)\}$, and $B^{8,1}_a$ transforming in the same way as the gluon field $\varphi^{8,1}_{\ldots,a}$ (i.e., color octet and flavor singlet). By means of the equation (7) and (9), it follows for the Dirac adjoint spinor $\widetilde{\varphi}^{3,3}$,

$$(T^{\delta,M,N}_{\kappa,\omega}(y)\widetilde{\varphi})^{3,3}_{a,f}(x)=(-1)^{-Q(a)_{\mathscr{C}}-Q(f)_{\mathscr{F}}-2/3}(T^{\delta,M,N}_{\kappa,\omega}(y)\varphi)^{3^*,3^*}_{-a,-f}(x)$$
$$=\exp[-Q(a)_{\mathscr{C}}(\delta\cdot y)](\exp(-i/2)[\sigma_{(1,0,0)}(N\cdot y)+\sigma_{(0,0,0)}(M\cdot y)])^b_f$$
$$\times(\exp(-i/2)[\tau_{(1,0,0)}(\kappa\cdot y)+(1/\sqrt{3})\tau_{(0,0,0)}(\omega\cdot y)])^e_b\widetilde{\varphi}^{3,3}_{a,e}(x+y). \quad (20)$$

The equations (19) are nothing else than the definition of a set of operations $\{T^{\cdots}_{\cdots}(y)\,|\,y\in\mathbb{R}_4\}$ satisfying the (Abelian) composition law $T^{\cdots}_{\cdots}(x)\circ T^{\cdots}_{\cdots}(y)=T^{\cdots}_{\cdots}(x+y)$ of the translation group and therefore generating a representation of it. (For $M=N=m=\kappa=\omega=0$ it is just the standard ''transformation law'' of fields under translations well known from any textbook.) The essential point comes now.

The *CD-Lagrangian as given by the equations (10)–(11) is form invariant; that means* $L(\hat{\varphi}(\hat{x}),\hat{B}(\hat{x}))=L(\varphi(x),B(x))$, *under the following group of substitutions:*

$$x\to\hat{x}=x+y,\quad y\in\mathbb{R}_4,$$
$$\varphi^{n,d}_{\mu,a,f}(x)\to\hat{\varphi}^{n,d}_{\mu,a,f}(\hat{x}):=(T^{\delta,M}_{\kappa,\omega}(-y)\varphi)^{n,d}_{\mu,a,f}(x+y),(n,d)\in\{(3,3),(3^*,3^*),(8,1)\}, \quad (21)$$
$$B^{8,1}_a(x)\to\hat{B}^{8,1}_a(\hat{x}):=(T^{\delta,M}_{\kappa,\omega}(-y)B)^{8,1}_a(x+y).$$

The proof for the flavor part is obvious since the Lagrangian is diagonal in the flavor indices. The proof of the color part is given in the appendix of Ref. 9 and consists mainly in showing that $(\tau_c)^b_a=0$ unless $Q(a)=Q(b)+Q(c)$.

Due to the form invariance of the Lagrangian under the (four-parameter) group of translations above Noether's Theorem[10] dictates the existence of four locally conserved currents $\Theta^{\delta,M,N}_{\kappa,\omega}(x)^\mu_\nu[\nu=0,1,2,3,\partial_\mu\Theta^{\delta,M,N}_{\kappa,\omega}(x)^\mu_\nu=0]$, which are considered as the components of the energy–momentum density tensor, provided they possess the necessary reality properties of an observable. In the case at hand they read explicitly as

$$\Theta^{\delta,M,N}_{\kappa,\omega}(x)^\mu_\nu=\Theta(x)^\mu_\nu+i\,\delta_\nu Q(a)_{\mathscr{C}}\widetilde{\varphi}^{3,3}_{a,f}(x)\,\gamma^\mu\varphi^{3,3}_{a,f}(x)-\frac{1}{2}\,\widetilde{\varphi}^{3,3}_{a,f}(x)\,\gamma^\mu\Big[\kappa_\nu(\tau_{(1,0,0)})^e_f$$
$$+\frac{1}{\sqrt{3}}\,\omega_\nu(\tau_{(0,0,0)})^e_f\Big]\varphi^{3,3}_{a,e}(x)-\frac{1}{2}\,\widetilde{\varphi}^{3,3}_{a,f}(x)\,\gamma^\mu(N_\nu\sigma_{(1,0,0)}+M_\nu\sigma_{(0,0,0)})^e_f\varphi^{3,3}_{a,e}(x)$$
$$-Q(a)_{\mathscr{C}}(-1)^{Q(a)_{\mathscr{C}}}[G^{\mu\epsilon}_{-a}(x)\varphi^{8,1}_{\epsilon,a}(x)+g^{\mu\epsilon}\varphi^{8,1}_{\epsilon,-a}(x)B^{8,1}_a(x)]\delta_\nu. \quad (22)$$

Here $\Theta(x)^\mu_\nu=\Theta^{0,0,0}_{0,0}(x)^\mu_\nu$ is the (standard) *canonical* energy–momentum density tensor,

$$\Theta(x)^\mu_\nu=-\delta^\mu_\nu L(\varphi(x),B(x))+\frac{i}{2}\,\widetilde{\varphi}^{3,3}_{a,f}(x)\,\gamma^\mu\overleftrightarrow{\partial}_\nu\varphi^{3,3}_{a,f}(x)-(-1)^{Q(a)}[G^{\mu\epsilon}_{-a}(x)\partial_\nu\varphi^{8,1}_{\epsilon,a}(x)$$
$$+g^{\mu\epsilon}\varphi^{8,1}_{\epsilon,-a}(x)\partial_\nu B^{8,1}_a(x)].$$

Especially $\Theta(x)^0_0$ is just the *canonical* Hamiltonian density.

Comparing the right-hand side of the equation (22) with the equations (14) and (15), we see that due to the relation (14) the terms occurring in addition to the canonical part are just special components of the locally conserved flavor, respectively, color currents. Hence the final result for the locally conserved Noether tensor obtained from translational invariance reads as

$$\Theta^{\delta,M,N}_{\kappa,\omega}(x)^\mu_\nu=\Theta(x)^\mu_\nu-i\,\delta_\nu\Big[j^{8,\mu}_{(1,0,0)}(x)_{\mathscr{C}}+\frac{1}{\sqrt{3}}\,j^{8,\mu}_{(0,0,0)}(x)_{\mathscr{C}}\Big]+\kappa_\nu j^{8,\mu}_{(1,0,0)}(x)_{\mathscr{F}}+\frac{1}{\sqrt{3}}\,\omega_\nu j^{8,\mu}_{(0,0,0)}(x)_{\mathscr{F}}$$
$$+N_\nu j^{8_S,\mu}_{(1,0,0)}(x)_{\mathscr{F}}+M_\nu j^{8_S,\mu}_{(0,0,0)}(x)_{\mathscr{F}}, \quad (23)$$

with $\delta\in\mathbb{C}_4$ and $M,N,\kappa,\omega\in\mathbb{R}_4$.

All further considerations and results will be based on this formula without any reference to the dependence of the currents on the basic quark and gluon fields with the exception of their properties under translations originating from them. They follow directly from the equations (15), (16), and (18)–(21) for $\rho=8,8_s$:

$$(T^{\delta,M,N}_{\kappa,\omega}(y)j)^{\rho,\mu}_a(x)_{\mathscr{F}}=R^8(\exp\cdot[i/2(y\cdot\wp)])^b_a j^{\rho,\mu}_b(x+y)_{\mathscr{F}},$$

$$\wp:=\tau_{(1,0,0)}\kappa+1/\sqrt{3}\,\tau_{(0,0,0)}\omega+\sigma_{(1,0,0)}N+\sigma_{(0,0,0)}M, \tag{24}$$

which in turn leads to

$$(T^{\delta,M,N}_{\kappa,\omega}(y)j)^{\rho,\mu}_a(x)_{\mathscr{F}}=\exp\cdot[i(p(8,a)\cdot y)]j^{\rho,\mu}_a(x+y)_{\mathscr{F}},$$

$$p(8,a)=\Sigma_{b\in\Gamma_3}\Sigma_{c\in\Gamma_{3^*}}\begin{pmatrix}3 & 3^* & 8\\ b & c & a\end{pmatrix}^2(p(3,b)-p(3,-c)),$$

$$p(d,a)_\mu:=-i\partial_\mu R^d(\exp[i/2(\wp\cdot y)])^a_{a_{|y=0}}. \tag{25}$$

In the remainder of this section the dependence of the fields, respectively, currents on the parameters $(\kappa,\omega,\delta,M,N)$ is not written out explicitly, but should be kept in mind (especially in connection with relativistic covariance). Its consequences for the total action, the Euler–Lagrange field equations, the Noether currents, and their total charges are considered at the end of Sec. III after the region over which these variables vary have been determined by the Goldstone theorem.

In classical field theories as well as in quantized ones using a noncovariant gauge (Coulomb gauge, for instance), which admits a (positive definite) Hilbert space $(\mathscr{H},(\cdot|\cdot))$ spanned by physical states the components $\Theta^{\delta,M,N}_{\kappa,\omega}(x)^0_\nu$, $\nu=0,...,3$ are interpreted as the energy momentum density. Hence $\Theta^{\delta,M,N}_{\kappa,\omega}(x)^0_\nu$ has to be a real, respectively, Hermitian operator. Therefore κ, ω, M, N have to be real and δ_ν purely imaginary. In other words, all representations of the translation group that do not meet these conditions would be excluded via physical interpretation. Besides losing explicit Lorentz covariance and Einstein causality (locality) in the intermediate steps within these gauges, the fact that only color singlets are realized in nature and hence admitted in the physical Hilbert space has to be put in as an additional condition ''by hand.''

The situation is different (for the color coupling δ_ν) in a covariant gauge of the Gupta–Bleuler type and especially in the case of QCD at hand with colored basic fields and only color singlets admitted to the physical Hilbert space. In such a gauge,[11–22] the physical Hilbert space $(\mathscr{H}_{\text{phys}},\langle\cdot,\cdot\rangle)$ is detached from a Hilbert space $(\mathscr{H},(\cdot|\cdot))$ in which the basic fields, symmetry transformations, currents, etc. act as operators. It is obtained via factorization H/H_0 of two subspaces $H_0\subset H\subset\mathscr{H}$ generated by an indefinite metric $\langle\cdot,\cdot\rangle=(\cdot|\eta\cdot)$ on $\mathscr{H}$ that is positive semidefinite on H and zero on $\mathscr{H}_0\supset H_0=\mathscr{H}_0\cap H$. Moreover, the scalar product on $\mathscr{H}_{\text{phys}}=\overline{H/H_0}$ is again given by the metric $\langle\cdot,\cdot\rangle$ and, of course, is positive definite on this space. The local gauge invariance of the theory is reflected in the requirement[13,21]

$$\langle\Psi,(j^{8,\mu}_a(x)_{\mathscr{C}}-\partial_\nu G^{\mu\nu}_a(x))\Phi\rangle=0, \tag{26}$$

for all Φ from a dense subspace of H and all $\Psi\in H$.

This is the situation in case $\delta=0$. For $\delta\neq 0$, Poincaré covariance is again lost for the intermediate steps in the unphysical Hilbert space $(\mathscr{H},(\cdot|\cdot))$, but invariance is restored via color confinement in the physical Hilbert space $\mathscr{H}_{\text{phys}}$, provided δ is real.[9,11]

On the other hand, the generally accepted physical picture behind the confinement mechanism, namely, that the forces between the quarks grow in strength with the distance between them[1–4] demands the translation group to be represented by nonisometric operators in the nonphysical Hilbert space $(\mathscr{H},(\cdot|\cdot))$, because otherwise there would arise a contradiction to the cluster properties of the Wightman functions.[22] However, it is well known[23] (Theorem 4.2) that in gauge quantum field theories with the vacuum being an eigenstate of the metric operator an

η-isometric representation of the translation group is nonunitary in $(\mathscr{H},(\cdot|\cdot))$ if and only if Re $\delta\neq 0$. (We note in passing that the vacuum being an eigenstate of the metric operator is only a sufficient condition, but *not* a necessary one).

As will be shown in Sec. IV in order to achieve both color confinement and besides Poincaré invariance in the physical Hilbert space also Poincaré covariance everywhere in the intermediate steps the Hilbert space $(\mathscr{H},(\cdot|\cdot))$ with metric operator η, respectively, indefinite metric $\langle\cdot,\cdot\rangle$ and corresponding subspaces H and H_0 have to be replaced by a set of such objects $(\mathscr{H}(m)$, $(\cdot|\cdot)m)$, $\eta m,\langle\cdot,\cdot\rangle m, H(m), H_0(m)$, with m running through some Lorentz orbit in the parameter space $\{(\delta,\kappa,w,M,N)\}$ of the representations of the translation group. The physical Hilbert space $\mathscr{H}_{\text{phys}}$ is then given by the direct integral of the completed factor spaces $(\overline{H(m)/H_0(m)},\langle\cdot,\cdot\rangle_m)$ with respect to the invariant measure of this Lorentz orbit.

In contrast to the imaginary color coupling $i\delta$, the flavor couplings have to be real, because otherwise the same mechanism as in the case of color confinement would ban all charged flavor states from $\mathscr{H}_{\text{phys}}$.

In accordance with the discussion above in the following $\delta_\nu\neq 0$ will be taken real (for the covariant gauges). Then the energy density $E^{\delta,M,N}_{\kappa,\omega}(x):=\Theta^{\delta,M,N}_{\kappa,\omega}(x)^0_0$ reads as

$$E^{\delta,M,N}_{\kappa,\omega}(x)=H(x)-i\delta_0\left[j^{8,0}_{(1,0,0)}(x)_{\mathscr{C}}+\frac{1}{\sqrt{3}}\,j^{8,0}_{(0,0,0)}(x)_{\mathscr{C}}\right]+\kappa_0 j^{8,0}_{(1,0,0)}(x)_{\mathscr{F}}+\frac{\omega_0}{\sqrt{3}}\,j^{8,0}_{(0,0,0)}(x)_{\mathscr{F}}$$
$$+N_0 j^{8_S,0}_{(1,0,0)}(x)_{\mathscr{F}}+M_0 j^{8_S,0}_{(0,0,0)}(x)_{\mathscr{F}}, \tag{27}$$

with $\delta_0,\kappa_0,\omega_0,M_0,N_0\in\mathbb{R}$, and $H(x)$ the *canonical* Hamiltonian density.

III. SYMMETRY BREAKING

Of particular interest are the four flavor SU(3)—octet terms that occur on the right-hand side of (27), in addition to the flavor singlet canonical Hamiltonian and the flavor singlet color terms in the first row. They are just identical with the flavor symmetry breaking ''medium strong interaction Hamiltonian'' ($j^{8,0}_{(0,0,0)}$ and $j^{8_S,0}_{(0,0,0)}$), respectively, the electromagnetic interaction $j^{8,0}_{(1,0,0)}$ and $j^{8_S,0}_{(1,0,0)}$, which have been successfully used to calculate the mass splitting within hadron multiplets,[1–7] and especially derive the famous Gell-Mann–Okubo mass formulas.[24,25] Up to now either these terms have to be added by hand to the flavor singlet canonical Hamiltonian or the first few terms have to be selected again by hand from the expansion of a mass operator into ''SU(3) multipoles'' that preserve the selection rules for isospin and hypercharge. The medium strong flavor terms $j^{\cdots}_{(0,0,0)}(x)_{\mathscr{F}}$ do not touch total isospin and hypercharge conservation, and they are responsible for the mass splitting between the different isospin multiplets within a flavor multiplet, whereas $j^{\cdots}_{(1,0,0)}$ leaves only the third component of the isospin besides the hypercharge conserved and could cause the splitting within an isospin multiplet.

However, it seems rather curious that the electromagnetic mass splitting within an isospin multiplet could be achieved without an electromagnetic interaction term showing up in the Lagrangian. Indeed, it will be shown below that the Goldstone Theorem with the pseudoscalar mesons as Goldstone particles implies, $\kappa=-16/\sqrt{27}N$. This, in turn, enforces [via Eq. (16)] the mutually compensation of the isospin breaking terms ($\sim\tau_{(1,0,0)}$) in the two flavor currents $j^{8,\mu}_{(1,0,0)}$ and $j^{8_S,\mu}_{(1,0,0)}$ on the right-hand side of the equations (23) and (26). Hence the mass splitting within an isospin submultiplet is not due to a genuine Goldstone mechanism.

The first main new result of our investigation is that the form invariance of the CD-Lagrangian with respect to (nonstandard) representations of the translation group produces exactly these mass splitting (flavor symmetry breaking) terms in the corresponding conserved Noether current (energy momentum density tensor); in short, they are derived from translational invariance. Hence the ''unknown medium strong interaction Hamiltonian'' has come to be known (to those who want to know it).

Since the representations of the (Abelian) translation group occurring in Eq. (19) are the most general one-dimensional ones that leave the CD-Lagrangian form invariant, our result explains why the octet model i.e., the assumption that all the higher flavor tensor operators $j^{27}_{(0,0,0)}$,

$j^{64}_{(0,0,0)}\ldots$, respectively, $j^{27}_{(1,0,0)}$, $j^{64}_{(1,0,0)},\ldots$, do not contribute to the hadron mass splitting, works so well. In other words, the symmetry breaking is intrinsic to the scheme, in the sense that it emerges automatically, without having to be put in by hand.

One may even turn the argument around and take the hadron mass splitting as an indication that nature prefers to select (for the strong interaction) a representation with $(\kappa_0,\ \omega_0,\ M_0,\ N_0)$ unequal to zero instead of the standard one. Because whenever one adds the flavor symmetry breaking interaction Hamiltonian—by hand or otherwise—to the strong symmetry conserving canonical one, the resulting states of the system cannot transform any more with the standard representation of the translation group.

From the equation (27) all the hadron mass formulas known in the literature[1–7,24,25] can easily be reproduced by means of the usual and generally accepted rules of the game to be found in any textbook on this topic. They consist in taking the expectation value for the various one-particle hadron states and adding the following two assumptions: (i) The flavor SU(3) breaking interaction Hamiltonian, which means in the present scheme the four flavor currents in Eq. (27), are members of an irreducible octet tensor operator of the SU(3) flavor group. (ii) The one-particle hadron states may be grouped together into and approximately treated as exact SU(3) flavor multiplets. For instance, the Gell-Mann–Okubo mass formula for the barion sector is directly obtained from Eq. (27) with $\kappa=N=0$.

Now a second result within our scheme is that the property (i) must not be put in as an additional assumption but follows via Noether's Theorem, provided all three quark ''masses'' in the CD-Lagrangian (10) are equal $(\rho_u=\rho_d=\rho_s)$. However, similarly to the case of the physical hadrons above, the observed splitting of the phenomenological quark masses is obtained via Eq. (27), starting with equal and even zero quark mass parameters in the CD-Lagrangian and taking the expectation values for the (color and flavor) quark triplet with the (positive definite) scalar product $(\cdot|\cdot)_m$ in the unphysical Hilbert space $\mathscr{H}(m)$. [In every representation with Im $\delta_0\neq 0$ there emerges also a contribution from the color charge density $j^{8,0}_{(1,0,0)}(x)_{\mathscr{C}}+(1/\sqrt{3}),j^{8,0}_{(0,0,0)}(x)_{\mathscr{C}}$.] Hence there exists no physical reason that can prevent one from starting with a CD Lagrangian, which is SU(3) form invariant with respect to both the color and the flavor group and even with vanishing quark mass parameters $(\rho_u=\rho_d=\rho_s=0)$.

The physical hadron mass splitting as well as the phenomenological quark masses then emerge via a *(algebraic) symmetry breaking of the global flavor group, in the sense that the* CD-Lagrangian *and hence the* Euler–Lagrange *field equations are form invariant with respect to these groups, but their infinitesimal generators* τ_a *with* $a\neq(1,0,0),(0,0,0)$ *may not commute with the energy operator (i.e., the total Hamiltonian consisting of the canonical plus the symmetry breaking one).* Since they do not commute with the generator of the time translations, the corresponding charges may not be conserved in time, if they exist at all. For $\delta\neq 0$ the equation (27) implies a symmetry breaking in the same sense (at least on the Lagrange–Hamilton level) for the global subgroup of the SU(3) local gauge color group.

Hence, in general, the form invariance of the CD-Lagrangian under the substitution rules of the basic fields with respect to SU(3) transformations do not evoke the corresponding SU(3) symmetry of the physical system. Depending critically on the representation $T^{\delta,M,N}_{\kappa,\omega}$ of the translation group selected out of all those that themselves leave the Lagrangian, respectively, the Euler–Lagrange field equations form invariant the SU(3) symmetry is broken in the sense above, with only a rest symmetry with respect to some subgroup being left. For instance in all representations with $\kappa=-10/\sqrt{27}N$ due to mutual compensation, all terms containing $\tau_{(1,0,0)}$ disappear from the exponentials of the flavor matrices $R\cdots$ in the substitution rules (19), (20), respectively, (24), (25), and hence from the Hamilton density (27). Therefore all generators of the SU(2) subgroup commute with the translations, respectively, the Hamiltonian. Furthermore, in view of Eq. (16), the generator $\tau_{(0,0,0)}$ (hypercharge) of the unitary subgroup U(1) obviously commutes with the translations and, of course, with all generators of SU(2). Therefore in all representations with $\kappa=-10/\sqrt{27}N$, the subgroup SU(2)×U(1) remains a symmetry group on the Lagrange–Hamilton or field algebra level. Of course in the standard representation the full flavor SU(3) symmetry holds.

The (algebraic) symmetry breaking discussed so far should not be confused with the spontaneous symmetry breaking via a Goldstone mechanism. This eventually occurs in the next step, when the representation of the field algebra in an inner product space or Hilbert space is taken into

account, giving rise to a further reduction of the symmetry of the system. As will be shown below, the existence of the pseudoscalar K mesons with their finite physical masses evokes the spontaneous symmetry breaking of the *chiral* flavor symmetry via a genuine Goldstone mechanism and at the same time ruling out all representations $T^{\delta,M,N}_{\kappa,\omega}$ of the translation group with $\kappa \neq -10/\sqrt{27}N$ from quantum flavor dynamics.

Postponing the Goldstone problem for a moment, let us shortly consider the chiral flavor symmetry. With all ρ_f, $f=u$, d, s being zero the quark triplet may be decomposed into a left-handed $\varphi^{3,3,L}_{\ldots}:=(1+\gamma_5)\varphi^{3,3}_{\ldots}$ and a right-handed $\varphi^{3,3,R}_{\ldots}:=(1-\gamma_5)\varphi^{3,3}_{\ldots}$ one ($\gamma_5:=i\gamma^0\gamma^1\gamma^2\gamma^3$). Then the Lagrangian (10) reads as

$$L(\varphi(x),B(x))=-1/4(-1)^{Q(a)}G_{\mu,\nu-a}(x)G^{\mu\nu}{}_{,a}(x)+\sum_{h=L,R}\widetilde{\varphi}^{3,3,h}_{a,f}(x)\,\frac{i}{2}\,\gamma^\mu\{\delta^b_a\overleftrightarrow{\partial}_\mu + ig(\tau_c)^b_a\varphi^{8,1}_{\mu,c}(x)\}\varphi^{3,3,h}_{b,f}(x)-(-1)^{Q(a)}\left[\varphi^{8,1}_{\mu,-a}(x)\partial^\mu B^{8,1}_a-\frac{\alpha}{2}\,B^{8,1}_{-a}(x)B^{8,1}_a(x)\right], \tag{28}$$

and is now form invariant under the chiral flavor group $\mathrm{SU}(3)_{\mathscr{F},L}\times\mathrm{SU}(3)_{\mathscr{F},R}$.

Performing everywhere the replacements

$$\varphi^{3,3}_{\ldots}(x)\to\varphi^{3,3,h}_{\ldots}(x),\quad j^{8,\mu}_{\ldots}(x)_{\mathscr{F}}\longrightarrow j^{8,h,\mu}_{\ldots}(x)_{\mathscr{F}},\quad j^{8_S,\mu}_{\ldots}(x)_{\mathscr{F}}\longrightarrow j^{8_S,h,\mu}_{\ldots}(x)_{\mathscr{F}}, \tag{29}$$

and summing on the right-hand side of the equations (13), (15), (22)–(24), and (27) all terms carrying the new chiral index over $h=L$, R, everything that has been said before remains true also in the chiral case with the groups SU(3), respectively, SU(2)×U(1) replaced by their chiral counterparts.

The implicit assumption that left- and right-handed quark fields transform under translations with the same representation ($\kappa_L=\kappa_R,\ldots$) is enforced by parity conservation, since in this way only vector currents $j^{\ldots}_{\ldots,\nu}:=j^{\ldots,L}_{\ldots}+j^{\ldots,R}_{\ldots}$ occur in the Noether energy momentum tensor (23), respectively (27), but no axial ones $j^{\ldots}_{\ldots,A}:=j^{\ldots,L}_{\ldots}-j^{\ldots,R}_{\ldots}$. A second reason is that only in this case the vector and axial vectors transform covariantly with respect to translations.

The spontaneous symmetry breaking mechanism and especially the Goldstone problem deserves a detailed and rigorous reinvestigation, since some changes concerning the mass of the Goldstone particles are to be expected due to the difference in the representations of the translation group considered here compared to the usually applied (standard) one. In the standard case $\delta=w=\kappa=M=N=0$; the generalizations of the Goldstone theorem from classical (nongauge) quantum field theories to gauge theories with an indefinite metric (see, e.g., Refs. 26–29, respectively,[13,21] and references therein) state that the spontaneous breaking of an algebraic (global) symmetry group whose generators are associated to conserved currents is necessarily accompanied by the occurrence of $\delta(p^2)$ singularities (Goldstone particles), which are created by the corresponding conserved currents from the vacuum and are pushed via the local gauge condition (26) into the unphysical sections of the Hilbert space in case the (global) symmetry group is the subgroup with constant elements of a local gauge group like the color group in QCD.[13,21] In case the spontaneous broken (global) symmetry group is not considered to be a subgroup of a local gauge group like the flavor group in QCD, the massless Goldstone states may be lying either in the unphysical sections or in the physical one $H\backslash H_0$ and then occur as real particles in $\mathscr{H}_{\mathrm{phys}}$ (genuine Goldstone mechanism).

However, as far as the zero mass of the Goldstone states is concerned, these results may not hold true anymore in the case at hand, since they are strongly tied to the standard representation of the translation group (with $\omega=\kappa=\delta=M=N=0$) and the four-momentum spectrum of the states allowed in both the physical and the unphysical sections of the total Hilbert space $\mathscr{H}$ (for details see Refs. 13, 21, 28). Obviously, the exponential factors in the representations (19) and (20), respectively (24), which make the difference to the standard one will displace and even deform the support of the spectral functions in the Jost–Lehmann–Dyson representation of the commutator matrix elements involved, thereby moving the light cone of the Goldstone particles, and even edge them away from the light cone.

Indeed our second main result is that the Goldstone particles accompanying the spontaneous symmetry breaking of the chiral flavor group must possess the squared mass $p(8,a)^2$, $a \in \Gamma_8$. The proof follows in almost the classical way[13,21,27–29] from a generalized Jost–Lehmann–Dyson representation for the commutator matrix element of the current $j^{8,0}_{a,h}(x)_{\mathscr{F}}$ involved and an element $\phi(f)$ from the polynomial + algebra generated by the basic fields that incorporates automatically besides locality (Einstein causality) and the spectrum condition also the current conservation. The proof and the precise definition of the current generated charges,

$$Q^{\cdots}_{a}(y)^{\kappa N}_{\delta,M,\omega} = '' \int d^3\mathbf{x} (T^{\delta,M,N}_{\kappa,\omega}(y) j)^{8,0}_{a,\ldots}(0,\mathbf{x})_{\mathscr{F}}'',$$

are given in Sec. VI below.

From the equations (25) we obtain

$$\begin{aligned} p(8,(1/2,\pm 1/2,1)) &= -p(8,(1/2,\pm 1/2,-1)) \\ &= I(1/2,\pm 1/2,1/3)[I(1/2,\pm 1/2,1/3)+1]M + 1/2Y(1,\pm,1) \\ &\quad + 1/2M + 2I^3(1/2,\pm 1/2,1/3)(\kappa + 10/\sqrt{27}N), \end{aligned} \tag{30}$$

$$p(8,(1,\pm 1,0)) = 2I^3(1,\pm 1,0)(\kappa + 10/\sqrt{27}N), \tag{31}$$

$$p(8,(1,0,0)) = p(8,(0,0,0)) = 0. \tag{32}$$

Hence there is no representation $T^{\delta,M,N}_{\kappa,\omega}$ of the translation group for which the (finite mass) pseudoscalar π_0 or η meson is a Goldstone particle.

In every representation with the properties

$$m(K_+)^2 = p(8,(1/2,1/2,1))^2 = p(8,1/2,-1/2,-1))^2 = m(K_-)^2,$$

$$m(K_0)^2 = p(8,(1/2,-1/2,1)) = p(8,(1/2,1/2,-1))^2 = m(\bar{K_0})^2,$$

which means satisfying the Goldstone conditions:

$$4(\kappa + 10/\sqrt{27}N)^2 + (\omega + 5/3M)^2 = 2m(K_+)^2 + 2m(K_0)^2,$$

$$2(\kappa + 10/\sqrt{27}N)(\omega + 5/3M) = m(K_+)^2 - m(K_0)^2, \tag{33}$$

the (finite mass) pseudoscalar K-meson doublets are Goldstone particles. Therefore the chiral U-spin subgroup is spontaneously broken by the charged $K_{+/-}$ mesons and the V-spin subgroup by the neutral ones $K_{0/\bar{0}}$, because current generated axial charges carrying nonzero hypercharge $Q^A_a(y)^{\kappa,N}_{\delta,M,\omega}$ with $a \in \{(1/2,1/2,\pm 1),(1/2,-1/2,\pm 1)\}$ do not exist. On the other hand, the remaining axial charges with $a \in \{(1,\pm 1,0),(1,0,0),(0,0,0)\}$ together with all vector charges $Q^V_a(y)^{\kappa,N}_{\delta,M,\omega}$, $a \in \Gamma_8$ exist as *bona fide* operators destroying the vacuum. In general, not all of them commute with the translation operators. They are translational covariant but not invariant. In other words, they depend on the space–time coordinates y that simply reflects the algebraic symmetry breaking on the Lagrangian level just discussed before. On the basis of a mathematically consistent and careful formulation of the content of the commutation relations between the Noether currents and the basic fields of the chiral Lagrangian that follow on the formal Lagrangian level by blindly applying equal time canonical commutation relations, it follows (Sec. VI) that the left- and right-handed charges,

$$\{Q^{L/R}_a(0)^{\cdots}_{\cdots} := 1/2(Q^V_a(0)^{\cdots}_{\cdots} \pm Q^A_a(0)^{\cdots}_{\cdots}) | a \in \{(1,\pm 1,0),(1,0,0),(0,0,0)\}\}, \tag{34}$$

form a self-conjugate representation of the (complexified) chiral subalgebra $(\mathrm{su}(2)\oplus\mathrm{u}(1))_L \oplus (\mathrm{su}(2)\oplus\mathrm{u}(1))_R$ and the vector charges $Q^V_a(0)^{\cdots}_{\cdots} a \in \Gamma_8$ separately a representation of su(3) both

generating via exponentiation an η_m-isometric representation of the corresponding Lie Groups $(\mathrm{SU}(2)\times\mathrm{U}(1))_L\times(\mathrm{SU}(2)\times\mathrm{U}(1))_R$, respectively, SU(3). Furthermore, the charges $Q_a^{\cdots}(y)_{\cdots}^{\cdots}$ commute with the translation operators if and only if

$$[\wp,\tau_a]_-=(2I^3(a)(\kappa+10/\sqrt{27N})+Y(a)(\omega+5/3M))\tau_a=0, \tag{35}$$

with $\wp$ given in Eq. (24). Therefore the η_m-isometric representation of the chiral SU(2)×U(1) subgroup emerging from the two octets of conserved chiral currents via the Goldstone theorem is a strict symmetry if and only if

$$\kappa=-10/\sqrt{27N}, \tag{36}$$

which means only in the representations of the translation group satisfying, besides the Goldstone conditions (33), the condition (36). But this in turn demands equal masses of charged and uncharged K mesons. Hence the mass splitting within isospin submultiplets may only be covered by the introduction of the usual electromagnetic interaction term $j_{el}^{\mu}\cdot A_{\mu}$ into the Lagrangian.

By the same reasoning, the condition (35) implies only the restriction of the η_m-isometric representation of SU(3) emerging from the octet of conserved vector currents to the subgroup SU(2)×U(1) isomorphic to the diagonal subgroup of the chiral group $(\mathrm{SU}(2)\times\mathrm{U}(1))_L\times(\mathrm{SU}(2)\times\mathrm{U}(1))_R$ to be a strict symmetry.

Summing up: *In every representation of the translation group satisfying the conditions (33) and (36) the (finite mass) K mesons are Goldstone particles, and the two octets of conserved chiral currents generate an η_m-isometric representation of the chiral group* $(\mathrm{SU}(2)\times\mathrm{U}(1))_L\times(\mathrm{SU}(2)\times\mathrm{U}(1))_R$ *commuting with the translations, provided the masses of charged and uncharged K mesons are considered equal. The octet of conserved vector currents generates an η_m-isometric representation of SU(3), but only its restriction to the subgroup* SU(2)×U(1) *commutes with the translations.*

Similarly, due to Eq. (31) in every representation, with the properties

$$m(\pi_+)^2=p(8,(1,1,0))^2=p(8,(1,-1,0))^2=m(\pi_-)^2,$$

which means satisfying the Goldstone condition,

$$4(k+10/\sqrt{27N})^2=m(\pi_{\pm})^2, \tag{37}$$

the charged pions are Goldstone particles breaking spontaneously the chiral I-spin subgroup, since the axial charges $Q^A_{(1,\pm1,0)}(y)_{\cdots}^{\cdots}$ do not exist. In the same way as above the chiral charges $Q^{L/R}_{(1,0,0)}(0)_{\cdots}^{\cdots}$, $Q^{L}_{(0,0,0)}(0)_{\cdots}^{\cdots}$ together with $Q^{L/R}_{(1/2,-1/2,1)}(0)_{\cdots}^{\cdots}$, $Q^{L/R}_{(1/2,1/2,-1)}(0)_{\cdots}^{\cdots}$ generate an η_m-isometric representation of the chiral U-spin subgroup, together with $Q^{L/R}_{(1/2,1/2,1)}(0)_{\cdots}^{\cdots}$, $Q^{L/R}_{(1/2,-1/2,-1)}(0)_{\cdots}^{\cdots}$ an η_m-isomeric representation of the chiral V-spin subgroup and the vector charges $Q^V_a(0)_{\cdots}^{\cdots}$, $a\in\Gamma_8$ separately one of SU(3). However, none of them is a strict symmetry since the condition (35) for commutativity with the translation operators requires, in contradiction to the Goldstone condition (37), $\kappa=-10/\sqrt{27N}$ and $\omega=-5/3M$, unless $I^3(a)=Y(a)=0$. Hence only the chiral U(1)×U(1) subgroup is left as a strict symmetry.

Since the Goldstone conditions (33) and (37) together admit no solution unless the masses of the charged pions are taken to be zero, only representations $T^{\delta,M,N}_{\kappa,\omega}$ of the translation group with

$$\kappa=-10/\sqrt{27N}\wedge(\omega+5/3M)^2=4m(K)^2, \tag{38}$$

seem to be selected by nature for flavored chiral QCD. Every solution of the equations (38) fixes an admissible representation of the translation group, and hence an admissible Hamiltonian for chiral flavor dynamics with chiral SU(3) symmetry of the Lagrangian being spontaneously broken by the K mesons down to chiral SU(2)×U(1) symmetry. Moreover, the success of the Gell–Mann–Okulo mass formula in the barion sector seems to indicate that the representations with $N=\kappa=0$ are the most relevant ones for flavored QCD.

To classify all Lorentz orbits and their invariant measures is beyond the scope of this paper. We state them only for the special cases (which in our opinion cover the most relevant ones):

$\omega=(2/\alpha-5/3)M$, $N=\beta M$, $\delta=\gamma M$ with $\alpha\in\mathbb{R}\backslash\{0\}$ and β, $\gamma\in\mathbb{R}$ just to demonstrate the existence of Lorentz orbits and invariant measures covering the Goldstone conditions (38). In these cases the Lorentz orbits are just the hyperboloids $\mathcal{O}_{\mathscr{L}}=\mathcal{O}_{\alpha}^{\pm}=\{M\in\mathbb{R}_4|M^2=\alpha^2 m(K)^2, M_0\gtrless 0\}$ with the invariant measures

$$d\mu_{\alpha}^{\pm}(M)=\Theta(\pm M_0)\,\delta(M^2-\alpha^2 m(K)^2)d^4M.$$

Due to the occurrence of the conserved color currents $i\delta_0(j^{8,0}_{(1,0,0)}(x)_{\mathscr{C}}+1/\sqrt{3}j^{8,0}_{(0,0,0)}(x)_{\mathscr{C}})$ in the Hamilton density (27) in case of confinement ($\delta\neq 0$) also the SU(3)-color symmetry is broken on the algebraic level and the remaining color symmetry group is the subgroup

$$G(3)_C=\left\{\exp\cdot[it/2(\tau_{(1,0,0)}+1/\sqrt{3}\,\tau_{(0,0,0)})]\begin{pmatrix}1&0&0\\0&&\\&&g\\0&&\end{pmatrix}\,\middle|\, t\in\mathbb{R}, g\in \mathrm{SU}(2)\right\}, \tag{39}$$

isomorphic to $\mathrm{U}(1)\times\mathrm{SU}(2)$. However, due to color confinement (Sec. IV), there exists no physical reason that the generators of the color group must commute with the Hamiltonian as long as δ is real. It will be shown in Sec. VI that the color symmetry is not spontaneously broken unless there exist states of discrete mass $\kappa(a)=0$ created by the conserved color current $j_a^{8,0}(x)_{\mathscr{C}}$ from the vacuum. However, due to the local gauge condition (26) they are confined in the unphysical section of the Hilbert space.

Before proceeding to the general quantum theory, some remarks should be made concerning the total action from which, via the principles of stationary or least action, the Euler–Lagrange field equations (Hamilton's principle), respectively, the conserved currents (Noether Theorem) are derived. Due to the dependence of the fields on the ''flavor'' vectors $\mathscr{M}=(M,N,\omega)$ and the ''color'' vector δ the total action contains, in addition to the integration over the space–time variables x, an integration with the invariant measure $d\mu_{\mathscr{L}}(\delta,\mathscr{M})$ over the Lorentz orbit $\mathcal{O}_{\mathscr{L}}$, respectively, parts of them;

$$A:=\int d^4x\; d\mu_{\mathscr{L}}(\delta,\mathscr{M})L(\varphi(x)_{(\delta,\mathscr{M})},B(x)_{(\delta,\mathscr{M})}).$$

Even the standard case may be viewed to belong to the (exceptional) Lorentz orbits consisting of only one point $\delta=0$, respectively, $M=N=\omega=0$ with the Dirac δ^4-functions as the invariant measures. Hence the additional integrals disappear in this case.

Since the Lagrangians (10), respectively (28), contain *no* derivative of the fields with respect to any of the variables $(\delta,\mathscr{M})$, it is easily seen that the Euler–Lagrange field equations are the same for all Lorentz orbits. Because, in addition, for the internal symmetry transformations as well as for the translations, the variables $(\delta,\mathscr{M})$ are kept fixed—the corresponding variations are zero!—the Noether currents of the internal symmetries are again the same for all Lorentz orbits, and the energy–momentum density differs only by terms due to the different substitution rule (19) for the fields. Hence, in the calculations before the additional variables $(\delta,\mathscr{M})$ could be considered as fixed parameters and the integration over them be dropped. It is needless to mention that in the step from the densities to the total charges (for instance the total Hamiltonian) the integrations over the Lorentz orbits are to be included.

The situation changes if Lorentz transformations are considered, since then the new vector variables change in the same way as the space–time vector. Thus their variations do not vanish any more and in the Noether spin-density tensor contributions due to the internal geometry of the Lorentz orbits could be expected. However, the detailed calculation shows that these contributions compensate each other in the Noether conservation law. Thus the Noether spin-angular–momentum tensor is the same for all orbits (up to the dependence of the fields on the color and flavor variables). The reason once again is the nonoccurrence of derivatives with respect to these variables in the Langrangian and the independence of the Euler–Lagrange field equations from the orbits.

Finally, on the basis of these remarks the direct integral structure of the quantum theoretical Hilbert space $\mathscr{H}$ with its components $\mathscr{H}(\delta,\mathscr{M})$ being clued together via the Lorentz group is perhaps rather obvious.

IV. POINCARÉ COVARIANCE AND CONFINEMENT

In view of the considerations and results of the foregoing sections, the transformation laws (1) of the basic fields that are clued to the standard representation ($w=M=N=\delta=0$) of the translation group [that is to a (Noether) Hamiltonian without symmetry breaking and confinement] have to be reinvestigated and modified according to what is prescribed by the symmetry breaking dynamics of QCD mirrored in the choice of the representation for the (time) translation group, or equivalently the Hamiltonian.

Furthermore, as already stated in Sec. III in the general representation (19), the basic quark and gluon fields depend in addition to the space time variable x on the ''color vector'' δ and the ''flavor vector'' triple (M,N,w) specifying the representation. For the sake of notational shortness it has been dropped before but gains decisive importance in the construction of a Poincaré covariant quantum theory. According to the equations (19), (24), (25), and (32), the dependence on the flavor triple $\mathscr{M}:=(M,N,w)$ comes via the matrix

$$\wp(\mathscr{M}):=\sigma_{(0,0,0)}M+(\sigma_{(1,0,0)}-10/\sqrt{27}\tau_{(1,0,0)})N+1/\sqrt{3}\,\tau_{(0,0,0)}w, \tag{40}$$

with eigenvalues of its representatives in the representation R^d:

$$p_{\mathscr{M}}(d,a)_\mu=-i\partial_\mu R^d(\exp[i/2(\wp(\mathscr{M})\cdot x)])^a_{a_{|x=0}}. \tag{41}$$

For every fixed quartet $m=(\delta,\mathscr{M})=(\delta,M,N,w)$ of four vectors from the Lorentz orbit $\mathscr{O}_{\mathscr{L}}$ besides the smeared fields,

$$\varphi^{n,d}_{\nu,a,b}(f)_m:=\int d^4x f(x)\varphi^{n,d}_{\nu,a,b}(x)_m, \tag{42}$$

and conserved currents (vector and axial vector indices are dropped in the following):

$$j^{8,\nu}_a(f)_{m_{\mathscr{F}/\mathscr{C}}}:=\int d^4x f(x) j^{8,\nu}_a(x)_{m,\mathscr{F}/\mathscr{C}}, \tag{43}$$

two- and three-fold composite quark fields [from which the one particle meson—respectively barion—states are constructed], are defined by

$$\varphi^{3^*3,3^*3}_{\nu_1\nu_2,a_1a_2,b_1b_2}(f)_m:=\int d^4x_1 d^4x_2 f(x_1,x_2)(-1)^{-Q(a_1)-Q(b_1)-2/3}\varphi^{3^*,3^*}_{\rho,-a_1,-b_1}\times(x_1)_m(\gamma^0)^\rho_{\nu_1}\varphi^{3,3}_{\nu_2,a_2,b_2}(x_2)_m, \tag{44}$$

respectively, for $n\in\{3,3^*\}$:

$$\varphi^{nnn,nnn}_{\nu_1\nu_2\nu_3,a_1a_2a_3,b_1b_2b_3}(f)_m:=\int d^4x_1 d^4x_2 d^4x_3 f(x_1,x_2,x_3)\varphi^{n,n}_{\nu_1,a_1,b_1}(x_1)_m\ldots\varphi^{n,n}_{\nu_3,a_3,b_3}(x_2)_m. \tag{45}$$

Here f is from the countably normed space $S(\mathbb{R}_{4k})$, $k=1,2,3$ of strongly decreasing $\mathscr{C}^\infty$ functions in all variables. With the abbreviations $|x|^2_k:=\Sigma^k_{i=1}\Sigma^3_{j=0}(x^j_i)^2$ and $\partial^{|r|}_x$ for the partial differential operator in the components x^j_i of total order $|r|=\Sigma^k_{i=1}\Sigma^r_{j=0}r^j_i$, $r^j_i\in\mathbb{N}_0$ the norms $\|f\|_n=\sqrt{[f,f]_n}$, $n\in\mathbb{N}_0$ are defined via the scalar products[30] (Chap. I, Sec. 3.6):

$$[f,h]_n=\int d^4x_1\cdots d^4x_k(1+|x|_k)^{2n}\sum_{\substack{r\in\mathbb{N}_0^{4k}\\ |r|\leqslant n}}(\overline{\partial^{|r|}_x f(x)})\partial^{|r|}_x h(x). \tag{46}$$

For every fixed $m \in \mathcal{O}_{\mathcal{L}}$ the smeared fields are closable linear operators with a common dense subdomain in a Hilbert space $(\mathcal{H}(m),(\cdot|\cdot)_m,\eta_m)$ with η_m a bounded symmetric operator generating the nondegenerate indefinite metric $\langle\cdot,\cdot\rangle_m := (\cdot|\eta_m\cdot)_m$, which is non-negative on a proper maximal subspace $H(m)$ and zero on the subset $\mathcal{H}_0(m)$. η_m maps the common dense subdomain of all fields into itself. The counterpart to the complex conjugate $\overline{\varphi_m}$ and Dirac adjoint field $\widetilde{\varphi}_m$ of the classical level now is the η_m-adjoint field operator $\varphi^{\cdots\,+}_{\cdots}(f)_m := \varphi^{\cdots}_{\cdots}(\hat{f})^{+}_m$, respectively, $\widetilde{\varphi}^{\cdots}_{\cdots}(f)_m = \varphi^{\cdots\,+}_{\cdots}(f)_m\gamma^0$ with $\hat{f}(x_1\ldots x_k) := \overline{f(x_k,\ldots,x_1)}$. Accordingly, the self-conjugateness (8) of the gluon fields and conserved currents, respectively, the relation (9) between the (anti-)quark fields read on the operator level with * denoting the Hilbert adjoint operator,

$$\varphi^{8,1*}_{\mu,c}(f)_m\eta_m = \eta_m(-1)^{Q(c)}\varphi^{8,1}_{\mu,-c}(f)_m, \quad j^{8,\mu*}_{a,\ldots}(f)_m\eta_m = \eta_m(-1)^{Q(a)}j^{8,\mu}_{-a,\ldots}(f)_m, \tag{47}$$

$$\varphi^{3^*3,3^*3*}_{\mu_1\mu_2,c_1c_2,a_1a_2}(f)_m\eta_m = \eta_m\varphi^{3^*3,3^*3}_{\mu_2\mu_1,c_2c_1,a_2a_1}(f)_m, \tag{48}$$

$$\begin{aligned}\eta_m\widetilde{\varphi}^{nnn,nnn}_{\mu_1\ldots\mu_k,c_1\ldots c_k,a_1\ldots a_k}(f)_m &= \varphi^{nnn,nnn*}_{\nu_1\ldots\nu_k,c_1\ldots c_k,a_1\ldots a_k}(f)_m\Pi_{i=1}^k(\gamma^0)^{\nu_i}_{\mu_i}\eta_m \\ &= \eta_m(\Pi_{i=1}^k(-1)^{-Q(c_i)-Q(a_i)-2/3})\varphi^{n^*n^*n^*,n^*n^*n^*}_{\mu_1\ldots\mu_k,-c_1\ldots-c_k,-a_1\ldots-a_k}(f)_m,\end{aligned} \tag{49}$$

with $n \in \{3,3^*\}, k \in \{1,3\}$.

In the subset $H(m)\backslash H_0(m)$ with $H_0(m) := H(m)\cap\mathcal{H}_0$ exists a normalized eigenvector $\Psi_0(m)$ of η_m with $\langle\Psi_0(m),\Psi_0(m)\rangle_m = 1$ that is cyclic for the polynomial + algebra $\pi(\varphi_m,j_m)$ spanned by the basic (including the conserved currents) and the composite field operators; that means the subspace $\mathcal{D}(m) := \pi(\varphi_m,j_m)\Psi_0(m)$ is dense in $(\mathcal{H}(m),(\cdot|\cdot)_m)$. Moreover, the subspace $\mathcal{D}_H(m) := \mathcal{D}(m)\cap H(m)$ is assumed to be dense in $H(m)$. Last but not least, the matrix elements of the field operators with all states from $\mathcal{D}(m)$ are continuous linear functionals on $S(\mathbb{R}_{4k})$, $k = 1,2,3$.

On $\mathcal{D}(m)$ a representation of the translation group is obtained by a linear extension of the operators $\mathcal{T}_m(y)$ defined successively via the following covariance equations on all states created by products of the field operators from $\Psi_0(m)$:

$$\mathcal{T}_m(y)\Psi_0(m) := \Psi_0(m), \tag{50}$$

$$\begin{aligned}&\mathcal{T}_m(y)\varphi^{n_1\ldots n_k,d_1\ldots d_k}_{\nu_1\ldots\nu_k,c_1\ldots c_k,a_1\ldots a_k}(f)_m\mathcal{T}_m(-y) \\ &\quad := \int d^{4k}x f(x_1,\ldots,x_k)\Pi_{i=1}^k(T^{\delta,M,N}_{-10/\sqrt{27}N,w}(y)\varphi)^{n_i,d_i}_{\nu_i,c_i,a_i}(x_i)_m \\ &\quad = (\Pi_{i=1}^k\exp[Q(c_i)(\delta\cdot y)])(\Pi_{j=1}^k R^{dj}(\exp[i/2(\wp(\mathcal{M})\cdot y)])^{b_j}_{a_j}) \\ &\qquad\times\varphi^{n_1\ldots n_k,d_1\ldots d_k}_{\nu_1\ldots\nu_k,c_1\ldots c_k,b_1\ldots b_k}(f_{(1,y)})_m,\end{aligned} \tag{51}$$

with $k \in \{1,2,3\}$ and $f_{(\Lambda(\alpha),y)}$, defined by

$$f_{(\Lambda(\alpha),y)}(x_1,\ldots,x_k) := f(\Lambda(\alpha)^{-1}(x_1-y),\ldots,\Lambda(\alpha)^{-1}(x_k-y)). \tag{52}$$

Here and in the following the covariance equations for the currents are not written down explicitly because they are obtained by obvious replacements from those of the gluon fields.

This representation is certainly not isometric with respect to the Hilbert scalar product $(\cdot|\cdot)_m$[9,11,23] and by many authors[13–22] claimed to be even unbounded also in the standard case $[\mathcal{M}=(0,0,0),\ \delta=0]$. However, it has to be isometric with respect to the indefinite metric $\langle\cdot,\cdot\rangle_m$ in order that it can be lifted to a unitary representation in the physical Hilbert space.[11] In other words, the metric operator η_m has to be constructed in such a way that this so-called η-isometry does hold.

In the same way as before, a representation of the internal symmetry group $G(3)_{\mathcal{C}}\times G(3)_{\mathcal{F}}$ that commutes with the translation operators $\mathcal{T}_m(y)$ is obtained from the covariance equations:

$$I_m(u,v)\Psi_0(m) := \Psi_0(m) \tag{53}$$

$$I_m(u,v)\varphi^{n_1\ldots n_k,d_1\ldots d_k}_{\nu_1\ldots\nu_k,c_1\ldots c_k,e_1\ldots e_k}(f)_m I_m(u^{-1},v^{-1})$$

$$:= (\Pi_{i=1}^k R^{n_i}(u^{-1})^{a_i}_{c_i} R^{d_i}(v^{-1})^{b_i}_{e_i})\varphi^{n_1\ldots n_k,d_1\ldots d_k}_{\nu_1\ldots\nu_k,a_1\ldots a_k,b_1\ldots b_k}(f)_m . \tag{54}$$

As will be shown in Sec. VI, this representation is the η_m-*isometric* integral or exponential of the representation of the Lie algebra $\mathscr{G}(3)_{\mathscr{C}}\oplus\mathscr{G}(3)_{\mathscr{F}}$, which is given by the space integral over the zeroth component of the η_m-self-conjugate conserved color currents $j^{8,\mu}_{\pm}(f)_{m,\mathscr{C}} = \pm 1/2[j^{8,\mu}_{(1,0,0)}(f)_{m,\mathscr{C}} \pm \sqrt{3}^{\mp 1} j^{8,\mu}_{(0,0,0)}(f)_{m,\mathscr{C}}], j^{8,\mu}_{(1/2,1/2,-1)}(f)_{m,\mathscr{C}}, j^{8,\mu}_{(1/2,-1/2,1)}(f)_{m,\mathscr{C}}$, respectively, the flavor (vector) currents $j^{8,\mu}_{a,V}(f)_{m,\mathscr{F}}, a\in\{(1,0,0),(1,\pm 1,0),(0,0,0)\}$. (In the cases where the algebraic color symmetry or part of it is spontaneously broken, this is still true for the remaining unbroken subgroup and in any case for the flavor subgroup $I^{\mathscr{F}}_m(v)=I_m(1,v),\ v\in G(3)_{\mathscr{F}}$).

It should be remarked in passing that the irreducible matrix representations R^d of SU(3) become completely reducible when restricted to the subgroup $G(3)\sim \mathrm{SU}(2)\times\mathrm{U}(1)$. They decompose into a direct sum of irreducible representation D^I of SU(2) labeled by the total isospin I and each term carrying a specific hyperchage Y. Explicitly we have

$$R^d(r,t)^{(I,I^3,Y)}_{(\tilde{I},\tilde{I}^3,\tilde{Y})} = \delta_{I\tilde{I}}\delta_{\tilde{Y}Y} D^I(r)^{I^3}_{\tilde{I}^3}\exp(iYt), \tag{55}$$

with $(I,Y)\in\{(1/2,1/3),(0,-2/3)\}$ for $d=3$ and $(I,Y)\in\{(1/2,1),(1,0),(0,0),(1/2,-1)\}$ for $d=8$, etc.

Concerning the Lorentz- and even more the Poincaré-group matters are more involved. It is known[23] (Secs. VII, VIII) that there does not exist a representation of the Poincaré group in $\mathscr{H}(m)$ resembling the substitution rule (1) of Sec. II for Lorentz transformations, together with the representation $\mathscr{T}_m$, $m\neq 0$ of the subgroup of translations. However, for every Lorentz transformation $\Lambda(\alpha)$, $\alpha\in\mathrm{SL}(2,\mathbb{C})$, a closable linear operator $\mathscr{L}(\alpha)_m$ from $\mathscr{D}(m)\subset\mathscr{H}(m)$ onto $\mathscr{D}(\Lambda(\alpha)m)\subset\mathscr{H}(\Lambda(\alpha)m)$ is obtained in the same way as before (the successive definition on product states and linear extension) by

$$\mathscr{L}(\alpha)_m\Psi_0(m) := \Psi_0(\Lambda(\alpha)m), \tag{56}$$

$$\mathscr{L}(\alpha)_m\varphi^{n_1\ldots n_k,d_1\ldots d_k}_{\nu_1\ldots\nu_k,\ldots,\ldots}(f)_m\mathscr{L}(\alpha)^{-1}_m := (\Pi_{i=1}^k S^{(n_i,d_i)}(\alpha)^{\rho_i}_{\nu_i})\varphi^{n_1\ldots n_k,d_1\ldots d_k}_{\rho_1\ldots\rho_k,\ldots,\ldots}(f_{(\Lambda(\alpha),0)})_{\Lambda(\alpha)m}, \tag{57}$$

with $f_{(\Lambda(\alpha),0)}$ defined in Eq. (52) and the matrices $S^{(n,d)}(\alpha)$ given by the equations (2), (3) of Sec. II. The operators $\mathscr{L}(\alpha)_m$ obviously satisfy the composition law $\mathscr{L}(\alpha_1)_{\Lambda(\alpha_2)m}\mathscr{L}(\alpha_2)_m = \mathscr{L}(\alpha_1\alpha_2)_m$. η-isometry for the Lorentz operators means for all $\Psi,\Phi\in\mathscr{D}(m)$:

$$\langle\mathscr{L}(\alpha)_m\Psi,\mathscr{L}(\alpha)_m\Phi\rangle_{\Lambda(\alpha)m} = \langle\Psi,\Phi\rangle_m \quad \text{or} \quad \mathscr{L}(\alpha)^*_m\eta_{\Lambda(\alpha)m}\mathscr{L}(\alpha)_m\Phi = \eta_m\Phi. \tag{58}$$

For all $y\in\mathbb{R}_4$, $\alpha\in\mathrm{SL}(2,\mathbb{C})$, the linear operators $\mathscr{T}_m(y)$ and $\mathscr{L}(\alpha)_m$ satisfy the commutation relations $\mathscr{T}_{\Lambda(\alpha)m}(y)\mathscr{L}(\alpha)_m\Psi(m) = \mathscr{L}(\alpha)_m\mathscr{T}_m(\Lambda(\alpha^{-1})y)\Psi(m)$, and therefore

$$W(\alpha,y)_m:\mathscr{D}(m)\to\mathscr{D}(\Lambda(\alpha)m), \Psi(m)\to W(\alpha,y)_m\Psi(m) := \mathscr{T}_{\Lambda(\alpha)m}(y)\mathscr{L}(\alpha)_m\Psi(m) \tag{59}$$

defines linear operators satisfying the composition law of the Poincaré group, and, in addition, η-isometry if the Lorentz operators $\mathscr{L}(\alpha)_m$ do so. The question of if the η-isometry of $\mathscr{L}(\alpha)_m$ can be derived from the presence of a conserved tensor current (corresponding to the Noether spin tensor) as in the case of the internal flavor, respectively, color symmetry is a problem of its own and will be treated together with the spin of Goldstone particles in a separate note.

Due to the exponential factor in the representations (51) of the translation group, the problem of cluing these representations and the Lorentz operators $\mathscr{L}$ together to form a unitary representation of the Poincaré group in a suitable Hilbert space, is closely connected with the color confinement. The key to its solution is the following theorem, which states that no colored state

exists in the ''physical section'' $H(m)\backslash H_0(m)$ for any m. They all have a nonpositive η_m norm.

Theorem (color confinement): (a) *Every state* $\Psi^{n_1\ldots n_r}_{c_1\ldots c_r}(m)\in H(m)$ *with total color charge* $Q_{\mathscr{C}}=\Sigma_{j=1}^{r}Q(c_j)\neq 0$ *belongs to* $H_0(m)=H(m)\cap\mathscr{H}_0(m)$, *that is,*

$$\langle\Psi^{n_1\ldots n_r}_{c_1\ldots c_r}(m),\Psi^{n_1\ldots n_r}_{c_1,\ldots c_r}(m)\rangle_m=0.$$

(b) $\langle\Pi_{j=1}^{r}\varphi^{n_j,d_J}_{\ldots,c_j,a_j}(f_j)_m\Psi_0(m),\Pi_{i=1}^{t}\varphi^{q_i,l_i}_{\ldots,e_i,b_i}(h_i)_m\Psi_0(m)\rangle_m=0$ *unless* $\Sigma_{j=1}^{r}Q(c_j)=-\Sigma_{i=1}^{t}Q(e_i)$. (*Hence all these colored states are from* $\mathscr{H}_0$!)

Proof: Since $\mathscr{D}_H(m)$ is dense in $H(m)$ and the metric $\langle\cdot,\cdot\rangle_m$ is semipositive on $H(m)$ it suffices to prove the validity only for all states from $\mathscr{D}_H(m)$ that are created from $\Psi_0(m)$ by pure or mixed products of the basic (again including the conserved currents) and composite field operators. A typical example reads as

$$\Psi^{n_1\ldots n_r,d_1\ldots d_r}_{\ldots,c_1\ldots c_r,a_1\ldots a_r}(m)=\Pi_{i=1}^{r}\,\varphi^{n_i,d_i}_{\ldots,c_i,a_i}(f_i)_m\Psi_0(m).$$

Denoting by $|\eta_m|$ the operator norm of the metric operator η_m, it follows by means of the η_m-isometry of $\mathscr{T}_m$ for all $y\in R_4$:

$$\begin{aligned}
&|\langle\Pi_{k=1}^{r}\,\varphi^{n_k,d_k}_{\ldots,c_k,a_k}(f_k)_m\Psi_0(m),\Pi_{j=1}^{r}\,\varphi^{n_j,d_j}_{\ldots,c_j,a_j}(f_j)_m\Psi_0(m)\rangle_m|\\
&\quad=(\Pi_{i=1}^{r}\,\exp[2Q(c_i)(\delta\cdot y)])|(\Pi_{k=1}^{r}\,\varphi^{n_k,d_k}_{\ldots,c_k,b_k}((f^{d_k}_{k(1,y)})^{b_k}_{a_k})_m\Psi_0(m)\\
&\quad\times|\,\eta_m\Pi_{j=1}^{r}\,\varphi^{n_j,d_j}_{c_j,b_j}((f^{d_j}_{j(1,y)})^{b_j}_{a_j})_m\Psi_0(m))_m|\\
&\quad\leqslant|\,\eta_m|\exp[2Q_{\mathscr{C}}(\delta\cdot y)]\\
&\qquad\times\sum_{b_1,e_1\in\Gamma_{d_1}}\cdots\sum_{b_r,e_r\in\Gamma_{d_r}}\|\Pi_{k=r}^{1}\,\varphi^{n_k,d_k*}_{\ldots,c_k,e_k}((\hat{f}^{d_k}_{k(1,y)})^{e_k}_{a_k})_m\Psi_0(m)\|_m\\
&\qquad\times\|\Pi_{j=1}^{r}\,\varphi^{n_j,d_J}_{\ldots,c_j,b_j}((f^{d_j}_{j(1,y)})^{b_j}_{a_j})_m\Psi_0(m)\|_m,
\end{aligned}$$

with $f^{d_k}_{k(1,y)}:=R^{d_k}(\exp[i/2(\wp(\mathscr{M})\cdot y)])f_{k(1,y)}$. Since every norm in the $2r$-fold sum on the right-hand side is a continuous linear functional on the $2r$-fold tensor product of the countably normed nuclear space $S(\mathbb{R}_4)$, it is of finite order $n_0(e_1\ldots e_r,b_1\ldots b_r)$ (see Ref. 31 Vol. 2). Therefore, there exists a positive, real number A and a natural number $n_0=\max\{n_0(e_1\ldots e_r,b_1\ldots b_r)|e_i,b_i\in\Gamma_{d_i},\ i=1,\ldots,r\}$, such that

$$\begin{aligned}
&|\langle\Pi_{k=1}^{r}\,\varphi^{n_k,d_k}_{\ldots,c_k,d_k}(f_k)_m\Psi_0(m),\Pi_{j=1}^{r}\,\varphi^{n_j,d_j}_{\ldots,c_j,a_j}(f_j)_m\Psi_0(m)\rangle_m|\\
&\quad\leqslant A\cdot|\,\eta_m|\exp[2Q_{\mathscr{C}}(\delta\cdot y)]\sum_{b_1,e_1\in\Gamma_{d_1}}\cdots\sum_{b_r,e_r\in\Gamma_{d_r}}\\
&\qquad\times\|[\Pi_{k=1}^{r}\,(\hat{f}^{d_k}_{k(1,y)})^{e_k}_{a_k}]\Pi_{j=1}^{r}\,(f^{d_J}_{j(1,y)})^{b_J}_{a_j}\|_{n_0}\leqslant A\cdot|\,\eta_m|\exp[2Q_{\mathscr{C}}(\delta\cdot y)]\\
&\qquad\times\sum_{b_1,e_1\in\Gamma_{d_1}}\cdots\sum_{b_r,e_r\in\Gamma_{d_r}}\Pi_{j=1}^{r}\,\|(f^{d_j}_{j(1,y)})^{e_j}_{a_j}\|_{n_0}\|(f^{d_j}_{j(1,y)})^{b_J}_{a_J}\|_{n_0}.
\end{aligned}$$

The elements of the diagonal unitary matrix $R^d(\exp[i/2(\wp\cdot y)])^a_b=\delta^a_b\exp[i(p_{\mathscr{M}}(a,d)\cdot y)]$ with $\wp$ and $p_{\mathscr{M}}(a,d)$ given in the equations (40)–(41), together with all derivatives with respect to the components of $\mathscr{M}=(M,N,w)$, are bounded by polynomials in y. Therefore the equations (52) and (46) imply the whole $2r$-fold sum on the right-hand side of the last inequality to be bounded by a polynomial $\Pi_m(y)$ in y. Thus we arrive at the bound:

$$|\langle\Pi_{k=1}^{r}\,\varphi^{n_k,d_k}_{\ldots,c_k,a_k}(f_k)_m\Psi_0(m),\Pi_{j=1}^{r}\,\varphi^{n_j,d_j}_{\ldots,c_j,a_j}(f_j)_m\Psi_0(m)\rangle_m|\leqslant A|\,\eta_m|\Pi_m\,(y)\exp[2Q_{\mathscr{C}}(\delta\cdot y)],$$

which proves the theorem, since for every $\delta \neq 0$ and $Q_{\mathscr{C}} \neq 0$ there is a direction in $\mathbb{R}_4$ in which the exponential goes to zero for y going to infinity. Part (b) follows in the same way, since in case of these states positive semidefiniteness need not be applied. □

Now it is rather obvious how to proceed in order to construct a carrier space for an isometric representation of the Poincaré group resembling the color confining representations of the translation group as well as the Lorentz transformations $\mathscr{L}$ given by the equations (50)–(52), respectively, (56)–(58). Let $d\mu_{\mathscr{L}}(m)$ denote the invariant measures of the Lorentz orbit $\mathscr{O}_{\mathscr{L}}$ and $\mathscr{V}_H$ the *vector space* of vector-valued mappings,

$$\psi: \mathscr{O}_{\mathscr{L}} \to \cup_{m \in \mathscr{O}_{\mathscr{L}}} \mathscr{D}_H(m), \quad m \to \Psi(m) \in \mathscr{D}_H(m) \subset H(m), \tag{60}$$

with the properties $\langle \Psi(m), e_\nu(m) \rangle_m$, is $\mu_{\cdots}^{\cdots}$ measurable for every member of some orthonormal basis $(e_\nu(m))_{\nu \in \mathbb{N}}$ in $H(m)$ and

$$\int_{\mathscr{O}_{\mathscr{L}}} d\mu_{\mathscr{L}}(m) \langle \Psi(m), \Psi(m) \rangle_m < +\infty.$$

In $\mathscr{V}_H$, vector addition and multiplication by complex numbers are defined in the usual way:

$$\psi + \phi: \mathscr{O}_{\mathscr{L}} \to \cup_{m \in \mathscr{O}_{\mathscr{L}}} \mathscr{D}_H(m), \quad m \to (\Psi + \Phi)(m) = \Psi(m) + \Phi(m),$$

$$\alpha\psi: \mathscr{O}_{\mathscr{L}} \to \cup_{m \in \mathscr{O}_{\mathscr{L}}} \mathscr{D}_H(m), \quad m \to (\alpha\Psi)(m) = \alpha\Psi(m).$$

The *vector space* $\mathscr{V}_H$ is just a subspace of the Cartesian product $\times_{m \in \mathscr{O}_{\mathscr{L}}} H(m)$. Since the metric $\langle \cdot, \cdot \rangle_m$ is positive semidefinite on $H(m)$ and hence also on $\mathscr{D}_H(m)$, a positive semidefinite inner product on $\mathscr{V}_H$ is given by

$$\langle \psi, \phi \rangle := \int_{\mathscr{O}_{\mathscr{L}}} d\mu_{\mathscr{L}}(m) \langle \Psi(m), \Phi(m) \rangle_m. \tag{61}$$

Moreover, the invariance of the measure $\mu_{\mathscr{L}}$ implies $\langle \psi, \psi \rangle = 0$ if and only if $\langle \Psi(m), \Psi(m) \rangle_m = 0$ almost every where on $\mathscr{O}_{\mathscr{L}}$. Hence an isometric representation $\mathscr{P}: ISL(2,\mathbb{C}) \to \mathrm{Aut}\, \mathscr{V}_H$, $(\alpha, y) \to \mathscr{P}(\alpha, y)$ of the Poincaré group on the inner product space $(\mathscr{V}_H, \langle \cdot, \cdot \rangle)$, which leaves the subspace $\mathscr{V}_H^0 := \{\psi \in \mathscr{V}_H | \langle \psi, \psi \rangle = 0\}$ invariant, is given by

$$\mathscr{P}(\alpha, y): \mathscr{V}_H \to \mathscr{V}_H, \quad \psi \to \mathscr{P}(\alpha, y)\psi,$$

$$\mathscr{P}(\alpha, y)\psi: \mathscr{O}_{\mathscr{L}} \to \cup_{m \in \mathscr{O}_{\mathscr{L}}} \mathscr{D}_H(m),$$

$$m \to (\mathscr{P}(\alpha, y)\psi)(m) := \mathscr{T}_{\Lambda(\alpha)m}(y) \mathscr{L}(\alpha)_m \Psi(m) = \mathscr{L}(\alpha)_m \mathscr{T}_m(\Lambda(\alpha^{-1})y) \Psi(m), \tag{62}$$

where $\mathscr{T}_m(y)$ and $\mathscr{L}(\alpha)_m$ are the η-isomeric operators defined via the equations (50)–(52), respectively, (56)–(57).

In the same way, an isometric representation of the internal symmetry group $G(3)_{\mathscr{C}} \times G(3)_{\mathscr{F}}$ and therefore also of its direct product with the Poincaré group, is obtained by

$$\mathscr{I}(u, v): \mathscr{V}_H \to \mathscr{V}_H, \quad \psi \to \mathscr{I}(u, v)\psi,$$

$$\mathscr{I}(u, v)\psi: \mathscr{O}_{\mathscr{L}} \to \cup_{m \in \mathscr{O}_{\mathscr{L}}} \mathscr{D}_H(m), \quad m \to (\mathscr{I}(u, v)\psi)(m) = I_m(u, v)\Psi(m), \tag{63}$$

with the η-isometric operators $I_m(u, v)$ defined via the equations (53)–(55).

It is the triple $(\mathscr{V}_H, \langle \cdot, \cdot \rangle, \mathscr{V}_H^0)$ from which the physical Hilbert space is obtained via factorization and completion $(\mathscr{H}_{\text{phys}}, \langle \cdot, \cdot \rangle) = (\overline{\mathscr{V}_H / \mathscr{V}_H^0}, \langle \cdot, \cdot \rangle)$ and the isometric representations on $\mathscr{V}_H$ [respectively, η-isometric ones in $\mathscr{H}(m)$] are lifted to unitary representations in $\mathscr{H}_{\text{phys}}$.

A direct way to the physical Hilbert space and the unitary representations of the (rest) symmetry groups in it which shortcuts the introduction of the vector space $\mathscr{V}_H$ is to take the direct integral of the completed factor spaces $(\overline{H(m)/H_0(m)}, \langle \cdot, \cdot \rangle_m)$ over the orbits $\mathscr{O}_{\mathscr{L}}$:

$$\mathscr{H}'_{\text{phys}} = \int_{\otimes} d\mu_{\mathscr{L}}(m)\overline{H(m)/H_0(m)},$$

with its scalar product again given by the equation (61) [where $\Psi(m)$ and $\Phi(m)$ now denote classes from $\overline{H(m)/H_0(m)}$]. $\mathscr{H}'_{\text{phys}}$ is unitary equivalent to $\mathscr{H}_{\text{phys}}$ as it follows from Theorem 3.3 in Ref. 23.

In the case of the Lorentz orbits $\mathscr{O}_{\mathscr{L}} = \mathscr{O}_{\alpha}^{\pm}$, given explicitly in Sec. III due to the direct integral structure required by Poincaré invariance, there are only three real parameters α, β, γ left free in the theory: β may be fixed to be zero by the barion mass spectrum, α interpreted as the coupling constant or strength of the flavor interaction, and γ be considered as the strength of the color confinement.

V. ONE-PARTICLE HADRON STATES

For the remainder of our investigations and especially the construction of one-particle hadron states, a spectrum condition on the fields and translation operators has to be specified that ensures that the physical Hilbert space $\mathscr{H}_{\text{phys}}$, respectively, the ''physical section'' $\mathscr{V}_H \backslash \mathscr{V}_H^0$ of the inner product space $\mathscr{V}_H$, contains only states carrying non-negative energy and non-negative momentum (mass) squares.

Let $\mathscr{D}_0(m) := L.H.\{\Pi_{j=1}^{L} \varphi^{n_j \cdots}_{\ldots, c_j, \ldots}(f_j)_m \Psi_0(m) \in \mathscr{D}(m) | Q_{\mathscr{C}}(L) = \Sigma_{j=1}^{L}\, Q(c_j) = 0, L \in \mathbb{N}_0\}$ be the linear hull of all states from $\mathscr{D}(m)$ with total color charge zero. Then the restriction $\mathscr{T}_m(y)\lceil \mathscr{D}_0(m)$ satisfies the preconditions of Theorem 4.2 in Ref. 9, which states that $\mathscr{T}_m(y)\lceil \mathscr{D}_0(m)$ is isometric with respect to the Hilbert scalar product $(\cdot|\cdot)_m$ for every $y \in \mathbb{R}_4$ and therefore has a unique unitary extension $\mathscr{T}_m^0(y)$ onto the closure $\overline{\mathscr{D}_0(m)}$. Being a unitary operator on the Hilbert subspace $(\overline{\mathscr{D}_0(m)}, (\cdot|\cdot)_m)$, it allows a spectral resolution $\mathscr{T}_m^0(y) = \int_{\mathbb{R}_4} \exp[i(q \cdot y)] dE_m(q)$ with a bounded measure E_m. Now, the *spectrum condition* reads as follows: *For μ-almost all m the support of E_m is contained in the closed forward cone,*

$$\text{supp } E_m \subseteq \overline{V_+^0} = \{q \in \mathbb{R}_4 | q^2 \geqslant 0 \wedge q^0 \geqslant 0\}.$$

The spectrum condition implies

$$\int_{\mathbb{R}_4} dy h(y) (\Psi(m) \Big| \mathscr{T}_m^0(y)\Phi(m))_m = (2\pi)^{3/2} \int_{\mathbb{R}_4} \tilde{h}(-q) d(\Psi(m) | E_m(q)\Phi(m)_m = 0, \quad (64)$$

for $\Phi(m) \in \overline{\mathscr{D}_0(m)}$, μ-almost all m, and all $h \in S(\mathbb{R}_4)$, whose Fourier transforms,

$$\tilde{h}(q) = (2\pi)^{-3/2} \int d^4y \, \exp[-i(q \cdot y)] h(y), \quad (65)$$

vanish in a neighborhood of the closed backward cone $\overline{V_-^0} = \{q \in \mathbb{R}_4 | q^2 \geqslant 0 \wedge q^0 \leqslant 0\}$.

In quantum field theories with unitary translation operators, the states of discrete mass κ arise from a δ function of the form $\delta(q^2 - \kappa^2)$ in the spectral support of the translation operators. For the translation operators at hand, the occurrence of a state ψ_κ with discrete mass κ may be characterized via the existence of a sufficiently small neighborhood $\mathscr{N}_\kappa$ of the branch of the hyperboloid $q^2 = \kappa^2$ in the backward cone V_-^0, such that for all $\Phi(m) \in \mathscr{H}(m)$ and almost all $m \in \mathscr{O}_{\mathscr{L}}$,

$$\int d^4y \langle \Phi(m), \mathscr{T}_m(y)\Psi_\kappa(m)\rangle_m (\Box_y + \kappa^2) h_\kappa(y) = 0, \quad (66)$$

for all $h_\kappa \in S(\mathbb{R}_4)$ with supp $\tilde{h}_\kappa \subseteq \mathscr{N}_\kappa$, but

$$\int d^4y h_\kappa(y) \langle \Psi_\kappa(m), \mathscr{T}_m(y)\Psi_\kappa(m)\rangle_m \neq 0, \quad (67)$$

for at least one $h_\kappa \in S(\mathbb{R}_4)$ with supp $\widetilde{h}_\kappa \subseteq \mathscr{N}_\kappa$.

Once the existence of discrete mass states is established by the spectrum condition, the explicit construction of the corresponding one-particle states in $\mathscr{V}_H \backslash \mathscr{V}_H^0$, which means the relativistic color singlet states with definite spin, (flavor-)isospin I and (flavor-)hypercharge Y satisfying the Klein–Gordon, respectively, Dirac equation, etc., with mass parameter $\kappa(I,Y)$ is easily performed, applying suitable linear combinations of the composite fields (44), respectively, (45) or the currents (43) with suitably restricted test functions to the cyclic state $\Psi_0(m)$ in $H(m)$. Since this construction is well known from the formation of so-called ''one-particle excitation operators'' in the Haag–Ruelle scattering theory of classical Wightman quantum field theories (see, e.g., Refs. 29, 32 and references therein) we may drop all details. Furthermore, we restrict ourselves to the meson states especially (axial-)vector and (pseudo)scalar states. The barion states are obtained from the three-fold products of quark fields (45) in the same way as the meson states from the two-fold ones (44).

(Pseudo)scalar mesons: In order to obtain (pseudo)scalar meson multiples we take for $\mu_i \in \{0,...,3\}$, $c_i \in \Gamma_3$, $a_i \in \Gamma_3$, $\alpha \in \Gamma_d$ and $d \in \{1,8\}$ the special functions

$$h^{[\mu_1\mu_2,c_1,c_2,a_1,a_2]\lambda}_{p_{\mathscr{M}}(d,\lambda),0\pm,d}(x_1,x_2) = (-1)^{Q(c_1)+Q(a_1)-Q(\lambda)} \begin{pmatrix} 3^* & 3 & 1 \\ -c_1 & c_2 & 0 \end{pmatrix} \times \begin{pmatrix} 3^* & 3 & d \\ -a_1 & a_2 & -\lambda \end{pmatrix} E^{\mu_1\mu_2}_{0\pm} h^{0\pm,d}_{\kappa(I(\lambda),Y(\lambda))}(x_1,x_2,p_{\mathscr{M}}(d,\lambda)), \quad (68)$$

with E_{0+} the unit matrix $E_{0-} = \gamma_5$ and $h^{0\pm,d}_{\kappa(\ldots)}(x_1,x_2,q)$ a Lorentz-invariant function from $S(\mathbb{R}_{12})$ and consider the states created in $\mathscr{D}_H(m)$ from the cyclic state $\Psi_0(m)$ by the translated twofold composite field (44) smeared with these special functions:

$$\begin{aligned} &\Psi^\lambda(x,m,h^{0\pm,d}_{\kappa(\ldots)}) \\ &:= \mathscr{T}_m(x)\varphi^{3^*3,3^*3}_{\mu_1\mu_2,c_1c_2,a_1a_2}(h^{[\mu_1\mu_2,c_1c_2,a_1a_2]\lambda}_{p_{\mathscr{M}}(d,\lambda),0\pm,d})_m \Psi_0(m) \\ &= (-1)^{Q(c_1)+Q(a_1)-Q(\lambda)} \begin{pmatrix} 3^* & 3 & 1 \\ -c_1 & c_2 & 0 \end{pmatrix} \begin{pmatrix} 3^* & 3 & d \\ -a_1 & a_2 & -\lambda \end{pmatrix} \\ &\quad \times \int d^4x_1 d^4x_2 h^{0\pm,d}_{\kappa(\ldots)}(x_1-x,x_2-x,p_{\mathscr{M}(d,\lambda)}) \exp[-i(x\cdot p_{\mathscr{M}}(d,\lambda))] \widetilde{\varphi}^{3,3}_{\mu_1,c_1,a_1}(x_1)_m \\ &\quad \times E^{\mu_1\mu_2}_{0\pm} \varphi^{3,3}_{\mu_2,c_2,a_2}(x_2)_m \Psi_0(m). \end{aligned} \quad (69)$$

For the second equality the transformation properties (50)–(52) and the relation

$$R^{3^*}(v)^{b_1}_{a_1} R^3(v)^{b_2}_{a_2} \begin{pmatrix} 3^*3d \\ a_1a_2\lambda \end{pmatrix} = R^d(v)^\rho_\lambda \begin{pmatrix} 3^*3d \\ b_1b_2\rho \end{pmatrix} \quad (70)$$

have been used together with the fact that $R^d(\exp -i/2(\wp(\mathscr{M})\cdot x))$ is a diagonal matrix. The color exponential of Eq. (51) has disappeared due to the first Clebsch–Gordan coefficient in Eq. (68), which at the same time ensures that these states are color singlets and thus escape the fate of confinement.

By straightforward, however, tedious Clebsch–Gordan calculations, it follows from the transformation properties of the quark fields, the Lorentz invariance of $h^{\cdots}_{\cdots}$ together with the equation (70) and the special structure (55) of the representation R^d restricted to the subgroup SU(2)×U(1) that the states $\Psi^\lambda(x,m,h^{\cdots}_{\cdots})$ transform under the QCD (rest) symmetry group $ISL(2,\mathbb{C}) \times G(3)_{\mathscr{C}} \times G(3)_{\mathscr{F}}$, according to

$$\begin{aligned}&\mathscr{U}((\alpha,y),u,v)_m\Psi^{\lambda}(x,m,h^{0\pm,d}_{\kappa(I(\lambda),Y(\lambda))})\\&\quad:=\mathscr{T}_{\Lambda(\alpha)m}(y)\mathscr{L}(\alpha)_{m'}\mathscr{T}_m(u,v)\Psi^{\lambda}(x,m,h^{0\pm,d}_{\kappa(I(\lambda),Y(\lambda))})\\&\quad=R^d(v)^{\lambda}_{\rho}\Psi^{\rho}(\Lambda(\alpha)x+y,\Lambda(\alpha)m,h^{0\pm,d}_{\kappa(I(\rho),Y(\rho))}).\end{aligned}\tag{71}$$

Finally, taking into account only Lorentz-invariant functions $h^{0\pm,d}_{\kappa(\ldots)}(x_1,x_2,q)$ such that the support of their Fourier transform,

$$\tilde{h}^{\cdots}_{\cdots}(k_1,k_2,q)=(2\pi)^{-3}\int d^4x_1d^4x_2\ \exp[-i(x_1k_1+x_2k_2)]h^{\cdots}_{\cdots}(x_1,x_2,q)$$

in the variable k_1+k_2+q is contained in the neighborhood $\mathscr{N}_{\kappa(I(\lambda),Y(\lambda))}$ of the backward branch of the mass shell $(k_1+k_2+q)^2=\kappa(I(\lambda),Y(\lambda))^2$ specified in the spectrum condition before, then the resulting states $\Psi^{\lambda}(x,m,h^{0\pm,d}_{\kappa(\ldots)})$ are positive frequency solutions of the Klein–Gordon equation,

$$(\Box_x+\kappa(I(\lambda),Y(\lambda))^2)\Psi^{\lambda}(x,m,h^{0\pm,d}_{\kappa(I(\lambda),Y(\lambda))})=0.$$

This is most easily seen by rewriting the equation (69) in terms of Fourier transforms with respect to the space–time variables and using the spectrum condition (66). But then, also, the states generated in the inner product space $(\mathscr{V}_H,\langle\cdot,\cdot\rangle)$ by the above ones (in $\mathscr{D}_H(m)$):

$$\Psi^{0\pm,d;\lambda}_{k(I(\lambda),Y(\lambda))}(x):\mathscr{O}_{\mathscr{L}}\rightarrow\cup_{m\in\mathscr{O}_{\mathscr{L}}}\mathscr{D}_H(m),m\rightarrow\Psi^{\lambda}(x,m,h^{0\pm,d}_{\kappa(I(\lambda),Y(\lambda))})\tag{72}$$

are positive frequency solutions of the Klein–Gordon equation with mass parameter $\kappa(I(\lambda),Y(\lambda))$, transforming under the QCD (rest) symmetry group according to

$$\mathscr{U}((\alpha,y),u,v)\psi^{0\pm,d;\lambda}_{\kappa(I(\lambda),Y(\lambda))}(x)=R^d(v)^{\lambda}_{\rho}\psi^{0\pm,d;\rho}_{\kappa(I(\lambda),Y(\lambda))}(\Lambda(\alpha)x+y),\tag{73}$$

with R^d the d-dimensional reducible representation of the flavor subgroup SU(2)×U(1) of SU(3) explicitly given in Eq. (55). Hence, they describe (pseudo)scalar, color singlet and SU(2)×U(1) flavor one-particle multiplets with isospin $I(\lambda)$, hypercharge $Y(\lambda)$, and mass $\kappa(I(\lambda),Y(\lambda))$.

(Axial-) vector mesons: The (axial-)vector mesons could be obtained in the same way as before from the two-fold composite quark field by special choices of (pseudo-)vectorial test functions. However, since it is rather complicated to build in the tranversality condition, it is much simpler to use the conserved flavor (axial-)vector currents $j^{8,\mu,V(A)}_{a,\mathscr{F}}(f)_m$ of Eq. (43) for the flavor octets, which *a priori* satisfy this condition due to current conservation.

Let $h_{\kappa(I(\lambda),Y(\lambda))}(x,q)$ be a Lorentz-invariant function from $S(\mathbb{R}_8)$ and the support of its Fourier transform $\tilde{h}(k,p_{\mathscr{M}}(8,\lambda))$ in the variable $k+p_{\mathscr{M}}(8,\lambda)$ be contained in the neighborhood $\mathscr{N}_{\kappa(I(\lambda),Y(\lambda))}$ of the backward branch of the mass shell $(k+p_{\mathscr{M}}(8,\lambda))^2=\kappa(I(\lambda),Y(\lambda))^2$. Then in exactly the same way as before, it follows that the states,

$$\begin{aligned}\Psi^{\nu,\lambda}_{8,V(A)}(x,m,h_{\kappa(I(\lambda),Y(\lambda))}):&=\mathscr{T}_m(x)j^{8,\nu,V(A)+}_{\lambda,\mathscr{F}}(h_{\kappa(I(\lambda),Y(\lambda))})_m\Psi_0(m)\\&=(-1)^{Q(\lambda)}\int d^4x h_{\kappa(I(\lambda),Y(\lambda))}(x,p_{\mathscr{M}}(8,\lambda))\\&\quad\times\exp[-i(x\cdot p_{\mathscr{M}}(8,\lambda)]j^{8,\nu,V(A)}_{-\lambda}(x)_{m,\mathscr{F}}\Psi_0(m),\end{aligned}\tag{74}$$

are positive frequency solutions of the Klein–Gordon equation with mass parameter $\kappa(I(\lambda),Y(\lambda))$ satisfying the transversality condition

$$\partial_\nu\Psi^{\nu,\lambda}_{8,V(A)}(x,m,h_{\kappa(I(\lambda),Y(\lambda))})=0,$$

and transforming under the QCD (rest) symmetry group according to

$$\mathscr{U}((\alpha,y),u,v)_m \Psi^{\nu,\lambda}_{8,V(A)}(x,m,h_{\kappa(I(\lambda),Y(\lambda))}) = R^8(v)^\lambda_\rho \Lambda(\alpha^{-1})^\nu_\mu \Psi^{\mu,\rho}_{8,V(A)}(\Lambda(\alpha)x + y, \Lambda(\alpha)m, h_{\kappa(I(\lambda),Y(\lambda))}). \tag{75}$$

But then the states $\psi^{8,V(A);\mu,\lambda}_{\kappa(I(\lambda),Y(\lambda))}(x)$ arising from them in $\mathscr{V}_H \backslash \mathscr{V}^0_H$ share the analogous properties. Hence they describe colorless (pseudo)vector SU(2)×U(1) flavor one-particle octets with spin 1, isospin $I(\lambda)$, hypercharge $Y(\lambda)$, and mass $\kappa(I(\lambda),Y(\lambda))$.

VI. GENERALIZED GOLDSTONE THEOREMS

In this section we prove the generalization of the Goldstone Theorem for the spontaneously broken symmetries to the general representations of the translation group. The proof rests on a Jost–Lehmann–Dyson representation for the commutator of the conserved currents $j^{8,\mu}_{a,\dots}(f)_{m,\dots}$ with the elements of the polynomial field algebra $\pi(\varphi_m, j_m)$ that incorporates locality, spectrum condition, and current conservation. Besides the ingredient that the flavor currents create from $\Psi_0(m)$ only states in $H(m)$ and thus due to the spectrum condition (64) only states with non-negative energy and non-negative four momentum squares, a locality or causality condition is needed. Each current is assumed to commute with all basic fields and currents (inclusively itself) at space-like separated points (*relative Einstein causality*):

$$[j^{8,\mu}_{a,\dots}(x)_{m,\dots}\varphi^{\dots}_{\dots}(y)_m]_- = [j^{8,\mu}_{a,\dots}(x)_{m,\dots}, j^{\dots}_{\dots}(y)_{m,\dots}]_- = 0, \quad \text{for} \quad (x-y)^2 < 0. \tag{76}$$

Finally, let $f_R(|\mathbf{x}|)$ be from $S(\mathbb{R}_3)$, where $f_R(|\mathbf{x}|)$, besides being equal to 1 for $0 \leqslant |\mathbf{x}| \leqslant R$ and zero for $|\mathbf{x}| > R + \Delta R$, satisfies the bound $|Rd/dr f_R(r)| \leqslant c < +\infty$ for all $R > 0$. Then the Goldstone Theorem[13,21,26–29] reads as follows.

(Generalized Flavor-) Goldstone Theorem: The flavor symmetry generated by the conserved current $j^{8,\mu}_{a,\dots}(h)_{m,\mathscr{F}}$ is not spontaneously broken, that is

$$\left\langle \Psi_0(m), \int d^3\mathbf{x} f_R(|\mathbf{x}|)[j^{8,0}_{a,\dots}(x)_{m,\mathscr{F}}\phi(f)]_- \Psi_0(m) \right\rangle_m = 0, \tag{77}$$

for all $|x^0| < \epsilon, \phi(f) \in \pi(\varphi_m, j_m)$ with test functions f of compact support and all $R > R(\epsilon, f)$, unless there exists a particle of mass $\kappa(a)^2 = p_{\mathscr{M}}(8,a)^2$ created from $\Psi_0(m)$ by $j^{8,0}_{a,\dots}(f)_{m,\mathscr{F}}$, that is, a state $\Psi_{\kappa(a)}(m) \in H(m)$ of discrete mass $\kappa(a)$ with $\langle \Psi_{\kappa(a)}(m), j^{8,0}_{a,\dots}(0,f_R)_{m,\mathscr{F}} \Psi_0(m) \rangle_m \neq 0$ for almost all $m \in \mathscr{O}_{\mathscr{L}}$.

Proof: Following the pattern of Wightman,[33] Vladimirov,[34] and especially the version of Araki, Hepp, and Ruelle,[32] it can be shown that in consequence of Einstein causality, spectrum condition, and translational covariance, the vacuum expectation value of the commutator may be represented by the following Jost–Lehmann–Dyson representation:

$$\langle \Psi_0(m), [j^{8,\mu}_{a,\dots}(x)_{m,\mathscr{F}}, \phi(f)]_- \Psi_0(m) \rangle_m = \exp\{-i(p(a)x)\} \int d^3\mathbf{u} \int_0^\infty ds [\rho^\mu_a(\mathbf{u},s,m)_1 \times \Delta_s(x^0, \mathbf{x}-\mathbf{u}) + \rho^\mu_a(\mathbf{u},s,m)_2 (\partial/\partial x^0) \Delta_s(x^0, \mathbf{x}-\mathbf{u})], \tag{78}$$

with $p(a) := p_{\mathscr{M}}(8,a)$ and

$$\Delta_s(x) = \frac{1}{i(2\pi)^3} \int d^4k \, \exp\{-i(kx)\} \epsilon(k^0) \delta(k^2 - s) \tag{79}$$

being the solution of the initial value problem

$$(\Box_x + s)\Delta_s(x) = 0, \quad \Delta_s(x)_{|x^0=0} = 0, \quad \frac{\partial}{\partial x^0} \Delta_s(x)_{|x^0=0} = -\delta(\mathbf{x}), \quad s \geqslant 0. \tag{80}$$

The structure of this representation is determined by the spectrum condition (77) via a solution of a five-dimensional wave equation in configuration space. The spectral functions $\rho^{\dots}_{\dots}(\mathbf{u},s,m)\dots$ are

strongly decreasing distributions in the variable s and $\mathscr{C}^\infty$-functions in $\mathbf{u}$ with compact support as a consequence of Einstein causality. The exponential factor in Eq. (78) arises from translational covariance.

Remark: The unitarity of the translation operator in $\mathscr{H}(m)$ used in Ref. 32 is not a necessary precondition to establish the structure of the representation (78). It can be dropped for the price of some gymnastics in (tempered) distribution theory along the lines of Ref. 35 and the exploitation of the unitarity of $\mathscr{T}_m^0$ on $(\overline{\mathscr{D}_0(m)},(\cdot|\cdot)_m)$.

The most important point for the following is now the application of current conservation $\partial_\mu j^{8,\mu}_{a,\ldots}(x)_{m,\mathscr{T}}=0$. By straightforward calculations it leads to the following two relations between the spectral functions:

$$\rho_a^0(\mathbf{u},s,m)_1=ip_0(a)\rho_a^0(\mathbf{u},s,m)_2+\left(\frac{\partial}{\partial u^j}+ip_j(a)\right)\rho_a^j(\mathbf{u},s,m)_2,$$

$$\left(\frac{\partial}{\partial u^j}+ip_j(a)\right)[\rho_a^j(\mathbf{u},s,m)_1+ip_0(a)\rho_a^j(\mathbf{u},s,m)_2]=(\Delta\mathbf{u}-s+p_0(a)^2)\rho_a^0(\mathbf{u},s,m)_2. \tag{81}$$

Here and in the following, summation over the Latin double index j from 1 to 3 is understood. Introducing instead of $\rho_a^j(\mathbf{u},s,m)_1$ the new spectral function $\sigma_a^j(\mathbf{u},s,m)$ via

$$\rho_a^j(\mathbf{u},s,m)_1+ip_0(a)\rho_a^j(\mathbf{u},s,m)_2=-\left(\frac{\partial}{\partial u^j}-ip^j(a)\right)\rho_a^0(\mathbf{u},s,m)_2+\sigma_a^j(\mathbf{u},s,m), \tag{82}$$

the second of the equations (81) reduces to the much simpler one,

$$(s-p(a)^2)\rho_a^0(\mathbf{u},s,m)_2=\left(\frac{\partial}{\partial u^j}+ip_j(a)\right)\sigma_a^j(\mathbf{u},s,m), \tag{83}$$

with the most general solution,[36]

$$\rho_a^0(\mathbf{u},s,m)_2=\left(\frac{\partial}{\partial u^j}+ip_j(a)\right)(s-p(a)^2)^{-1}\sigma_a^j(\mathbf{u},s,m)+\delta(s-p(a)^2)E_a(\mathbf{u},m). \tag{84}$$

$E_a(\mathbf{u})$ is a $\mathscr{C}^\infty$-function with compact support since all other spectral functions share these properties. Feeding the equations (82) and (84) together with the first one of the system (81) back into the representation (78) and integrating by parts over the variables u_j, we end up with the following representation for the zeroth component of the commutator matrix element:

$$\begin{aligned}&\langle\Psi_0(m),[j^{8,0}_{a,\ldots}(x)_{m,\mathscr{T}},\phi(f\ )]_-\Psi_0(m)\rangle_m\\&\quad=\exp\{-i(p(a)x)\}\int d^3\mathbf{u}\Bigg\{E_a(\mathbf{u},m)\left(ip_0(a)+\frac{\partial}{\partial x^0}\right)\Delta_{p(a)^2}(x^0,\mathbf{x}-\mathbf{u})\\&\qquad-\int_0^\infty ds\left[\sigma_a^j(\mathbf{u},s,m)_1+\sigma_a^j(\mathbf{u},s,m)_2\,\frac{\partial}{\partial x^0}\right]\left(\frac{\partial}{\partial x^j}-ip_j(a)\right)\Delta_s(x^0,\mathbf{x}-\mathbf{u})\Bigg\}.\end{aligned} \tag{85}$$

Here the abbreviations,

$$\sigma_a^j(\mathbf{u},s,m)_1:=\rho_a^j(\mathbf{u},s,m)^2+ip_0(a)(s-p(a)^2)^{-1}\sigma_a^j(\mathbf{u},s,m),$$

$$\sigma_a^j(\mathbf{u},s,m)_2:=(s-p(a)^2)^{-1}\sigma_a^j(\mathbf{u},s,m), \tag{86}$$

have been used and for the partial integration the compact support of the spectral functions. By means of a further partial integration we get, from Eq. (85),

$$\left\langle \Psi_0(m), \int d^3\mathbf{x} f_R(|\mathbf{x}|)[j^{8,0}_{a,\ldots}(x)_{m,\mathscr{F}}, \phi(f\ )]_- \Psi_0(m) \right\rangle_m - \int d^3\mathbf{u} E_a(\mathbf{u},m) \int d^3\mathbf{x} f_R(|\mathbf{x}|)$$

$$\times \exp\{-i(p(a)\cdot x)\}\left(ip_0(a) + \frac{\partial}{\partial x^0}\right)\Delta_{p(a)^2}(x^0, \mathbf{x}-\mathbf{u})$$

$$= \int d^3\mathbf{x}\left(\frac{\partial}{\partial x^j} f_R(|\mathbf{x}|)\right)\exp\{-i(p(a)\cdot x)\}$$

$$\times \int d^3\mathbf{u} \int_0^\infty ds \left[\sigma^j_a(\mathbf{u},s,m)_1 + \sigma^j_a(\mathbf{u},s,m)_2 \frac{\partial}{\partial x^0}\right]\Delta_s(x^0, \mathbf{x}-\mathbf{u}). \tag{87}$$

Now, the further arguments are the same as in the standard case. For all $|x^0|$ smaller than some $\epsilon > 0$ the right-hand side vanishes for all R larger than some fixed $R_0(\epsilon)$ as a consequence of the support properties of the spectral functions and the commutator function $\Delta_s(x)$, since the derivative of f_R is unequal to zero only in the ring region between R and $R+\Delta R$. By the same reasons, the second term on the left-hand side becomes independent from f_R for $R > R_0(\epsilon)$, that is, only the ball $|\mathbf{x}| \leqslant R_0(\epsilon)$ contributes to the x integrations. Hence, the only contribution to the left-hand side of (77) comes from the one-particle intermediate state in the commutator with the internal quantum numbers $a=(I,I^3,Y)$ of the current and the mass $p(a)^2$. □

From the initial values (80) we obtain for $x^0=0$ and all $R > R_0(\epsilon)$,

$$\left\langle \Psi_0(m), \int d^3\mathbf{x} f_R(|\mathbf{x}|)[j^{8,0}_{a,\ldots}(x)_{m,\mathscr{F}}, \phi(f\ )]_- \Psi_0(m) \right\rangle_{m|x^0=0}$$

$$= -\int d^3\mathbf{u} E_a(\mathbf{u},m)\exp[i(\mathbf{p}(a)\cdot\mathbf{u})] = -\widetilde{E}_a(\mathbf{p}_{\mathscr{M}}(a,8),m). \tag{88}$$

The remaining considerations rest essentially on the identity

$$\langle \Psi_0(m), [\mathscr{T}_m(y) j^{8,0}_{a,\ldots}(x^0, f_R)_{m,\mathscr{F}} \mathscr{T}_m(-y), \phi(f\ )]_- \Psi_0(m)\rangle_m$$

$$= \langle \Psi_0(m), [j^{8,0}_{a,\ldots}(x^0, f_R)_{m,\mathscr{F}}, \mathscr{T}_m(y)\phi(f\ )\mathscr{T}_m(-y)]_- \Psi_0(m)\rangle_m, \tag{89}$$

which is easily obtained from the η_m isometry of the translation operators and the invariance of $\Psi_0(m)$ under the translations [Eq. (59)].

Let $\pi(\varphi_m, j_m)_{SL}$ denote the subalgebra of $\pi(\varphi_m, j_m)$ defined by taking only test functions of compact support in the smeared fields and $\mathscr{D}(m)_{SL} \subset \mathscr{D}(m)$ the corresponding dense subspace of $\mathscr{H}(m)$. Then, in the same way as in the case of a Wightman theory[27,37,38] for every $y \in \mathbb{R}_4$, an octet of current generated charges may be defined on $\mathscr{D}(m)_{SL}$ by

$$\mathbf{Q}^{\cdots}_a(y)_{m,\mathscr{F}}\phi(f\ )\Psi_0(m) := [\mathscr{T}_m(y) j^{8,0}_{a,\ldots}(f_\epsilon, f_R)_{m,\mathscr{F}} \mathscr{T}_m(-y), \phi(f\ )]_{-|R\rangle R(\epsilon,f\ )}\Psi_0(m). \tag{90}$$

Here f_ϵ is an arbitrary $\mathscr{C}^\infty$-function with support contained in $[-\epsilon,\epsilon]$ and normalized according to $\int dx^0 f_\epsilon(x^0) = 1$.

Due to the Goldstone Theorem, the invariance of $\Psi_0(m)$ under η_m, the η_m-isometry of the translation operators and the relations (47)–(49), it follows by literally the same arguments as in Ref. 27.

(I) $\mathbf{Q}^{\cdots}_a(y)_{m,\mathscr{F}}$ is a well-defined linear operator on $\mathscr{D}(m)_{SL}$ independent of the details of f_ϵ and f_R if and only if the equation (77) of the Goldstone Theorem holds. Therefore, due to the equations (30)–(32) and (36) the vector charges $\mathbf{Q}^V_a(y)_{m,\mathscr{F}}$, $a \in \Gamma_8$ and (unless the π and η mesons have zero mass) the axial charges $\mathbf{Q}^A_a(y)_{m,\mathscr{F}}$ with $a \in \{(0,0,0),(1,0,0),(1,+/-1,0)\}$ exist as *bona fide* linear operators, since no discrete scalar particles, respectively, no massless pseudoscalar particles, are known in nature, whereas the axial vector charges $\mathbf{Q}^A_a(y)_{m,\mathscr{F}}$ with $a \in \{(1/2,1/2,+/-1),(1/2,-1/2,+/-1)\}$ do not exist as linear operators due to the presence of the finite mass pseudoscalar K mesons. Hence the chiral SU(3) symmetry is spontaneously broken.

(II) The charge operators $\mathbf{Q}^{\cdots}_a(y)_{m,\mathscr{F}}$ are closable, η_m-self-conjugate and translational covariant operators mapping $\mathscr{D}(m)_{SL}$ into itself,

$$\mathbf{Q}_a^{\cdots}(y)^*_{m,\mathscr{F}}\eta_m\Psi=\eta_m(-1)^{Q(a)}\mathbf{Q}^{\cdots}_{-a}(y)_{m,\mathscr{F}}\Psi,$$

$$\mathscr{T}_m(y)\mathbf{Q}_a^{\cdots}(x)_{m,\mathscr{F}}\mathscr{T}_m(-y)=\mathbf{Q}_a^{\cdots}(x+y)_{m,\mathscr{F}},$$

$$\mathbf{Q}_a^{\cdots}(y)_{m,\mathscr{F}}\mathscr{D}(m)_{SL}\subseteq\mathscr{D}(m)_{SL}. \tag{91}$$

Up to this point, besides the spectrum condition, relative Einstein causality, and translational covariance, only current conservation and the nonexistence of discrete scalar particles, respectively, *massless* pseudoscalar particles have been exploited. In order to proceed we have to tighten the bonds between the chiral currents $j_a^{8,\mu,h}$, $h\in\{L,R\}$ and the Noether currents arising from the flavor transformations in Lagrangian field theory (Sec. II) by imposing the commutation relations,[27,28] which in Lagrangian field theory define the infinitesimal flavor transformations.

For $a\in\hat{\Gamma}_8:=\{a\in\Gamma_8|Q(a)\geqslant 0\}$, $h\in\{L,R\}$ let $j^{\cdots h}_{a+/-}:=1/2i^{1/2+/-1/2}(j_a^{\cdots h}+/-j^{\cdots h}_{-a})$ if $Q(a)=1$ and $j^{\cdots h}_{a+/-}:=1/2i^{1/2-/+1/2}(j_a^{\cdots h}+/-j^{\cdots h}_{-a})$ if $Q(a)=0$ denote the η_m-symmetric chiral flavor currents and $\tau^a_{+/-}$ the same Hermitian combinations of the traceless self-conjugate τ matrices. Then the following commutation relations are assumed to hold for $a\in\hat{\Gamma}_8$, h, $h'\in\{L,R\}$, $\Psi\in\mathscr{D}(m)_{SL}$ and supp f compact:

$$[j^{8,0,h}_{c+/-}(f_\epsilon,f_R)_{m,\mathscr{F}},\varphi^{n,d,h'}_{\cdots,b}(f)_m]_{-|R\rangle R(\epsilon,f)}\Psi=-i\,\delta_{hh'}\,\frac{d}{dt}\,R^d(\exp[i/2t\tau^c_{+/-}])^b_a\varphi^{n,d,h}_{\cdots,b}(f)_{m|t=0}\Psi, \tag{92}$$

and the same ones with $\varphi^{\cdots,h}_{\cdots}$ replaced by the chiral flavor currents $[(n,d)=(1,8)]$, respectively, the color currents $[(n,d)=(8,1)]$ or gluon fields $\varphi^{8,1}_{\cdots}$.

The equations (92) are a mathematically consistent and careful formulation of the content of the commutation relations that follow on the formal Lagrangian level by blindly applying equal-time canonical commutation relations. The corresponding commutation relations with the composite fields (44), (45) are easily derived from the above ones.

Now it follows by a straightforward calculation from the equations (50)–(52) and (92) that the charges $\mathbf{Q}^h_a(x)_{m,\mathscr{F}}$ commute with the translations if and only if $[\wp(\mathscr{M}),\tau_a]_-=0$, with $\wp(\mathscr{M})$ explicitly given in Eq. (40), that is, for $a\in\{(1,\pm 1,0),(1,0,0),(0,0,0)\}$. In other words, the charges representing the Lie generators of the $\mathrm{SU}(2)_{\mathscr{F}}\times\mathrm{U}(1)_{\mathscr{F}}$ chiral subgroup and only these are constant in space and time:

$$\mathbf{Q}^h_a(0)_{m,\mathscr{F}}=\mathbf{Q}^h_a(x)_{m,\mathscr{F}},\quad \text{for } a\in\{(1,\pm 1,0),(1,0,0),(0,0,0)\},h\in\{L,R\}. \tag{93}$$

Due to the commutation relations (92) and the analogous ones for the currents and composite fields, the charges operate on $\mathscr{D}(m)_{SL}$ via finite-dimensional matrices acting on the space of indices. Therefore $\mathscr{D}(m)_{SL}[\eta_m\mathscr{D}(m)_{SL}]$ is a dense set of analytic vectors for the charge operators $\mathbf{Q}^{\cdots}_{a+/-}(0)_{m,\mathscr{F}}[\mathbf{Q}^{\cdots}_{a+/-}(0)^*_{m,\mathscr{F}}]$, since the exponential power series of them (respectively, of the finite-dimensional matrices corresponding to them) converge on $\mathscr{D}(m)_{SL}$ in the Hilbert norm of $\mathscr{H}(m)$,[27,39] giving rise to one-parameter groups of η_m-isometric linear operators that map $\mathscr{D}(m)_{SL}[\eta_m\mathscr{D}(m)_{SL}]$ into itself and can be lifted to unitary ones on $\overline{H(m)/H_0(m)}$:

$$I_{a+/-}(t)_{m,\mathscr{F}}\phi(f)\Psi_0(m):=\sum_{n=0}^{\infty}\frac{1}{n!}\,(it\mathbf{Q}^{\cdots}_{a+/-}(0)_{m,\mathscr{F}})^n\phi(f)\Psi_0(m),$$

$$I^*_{a+/-}(t)_{m,\mathscr{F}}\eta_m\phi(f)\Psi_0(m)=I_{a+/-}(-t)^*_{m,\mathscr{F}}\eta_m\phi(f)\Psi_0(m)=\eta_m I_{a+/-}(t)_{m,\mathscr{F}}\phi(f)\Psi_0(m),$$

$$t\in\mathbb{R},\phi(f)\in\pi(\varphi_m,j_m)_{SL}. \tag{94}$$

In view of the commutation relations (92), the flavor charge operators $\mathbf{Q}^{\cdots}_{a+/-}(0)_{m,\mathscr{F}}$ form a representation $\mathscr{Q}_m$ of the Lie algebra $\mathscr{G}(3)_{\mathscr{F}}=(\mathrm{su}(2)\oplus\mathrm{u}(1))_L\oplus(\mathrm{su}(2)\oplus\mathrm{u}(1))_R$ or $\mathscr{G}(3)_{\mathscr{F}}=\mathrm{su}(3)$ of the chiral flavor group $G(3)_{\mathscr{F}}=(\mathrm{SU}(2)\times\mathrm{U}(1))_L\times(\mathrm{SU}(2)\times\mathrm{U}(1))_R$, respectively, $G(3)_{\mathscr{F}}=\mathrm{SU}(3)$ on $\mathscr{D}(m)_{SL}$. The final step in our program is the integration or exponentiation of this

representation, which means to establish the existence of a η_m-isometric representation $I_m^{\mathscr{F}}$ of the flavor group $G(3)_{\mathscr{F}}$ on $\mathscr{D}(m)\supset\mathscr{D}(m)_{SL}$, such that the restriction of its differential $\partial I_m^{\mathscr{F}}$ to $\mathscr{D}(m)_{SL}$ is equal to $\mathscr{Q}_m$,

$$\partial I_m^{\mathscr{F}}(\tau_{+/-}^a)\lceil\mathscr{D}(m)_{SL}=\mathbf{Q}_{a+/-}^{\cdots}(0)_{m,\mathscr{F}}. \tag{95}$$

The details are given only for the vector charges $\mathbf{Q}_{a+/-}^V(0)_{m,\mathscr{F}}$ and $G(3)_{\mathscr{F}}=\mathrm{SU}(3)$. The construction for the chiral case runs literally the same way. If η_m commutes with $\mathbf{Q}_a^V(0)_{m,\mathscr{F}}$, then the one-parameter groups (94) consist of strongly continuous operators on $\mathscr{D}(m)_{SL}$ and hence admit a unique unitary extension onto $\mathscr{H}(m)$. According to criterions of Simon[40] and Jorgensen,[41] this establishes the integrability of $\mathscr{Q}_m$. The difficulties arising in the general case rest in the fact that the charge operators $\mathbf{Q}_{a+/-}^V(0)_{m,\mathscr{F}}$ are not symmetric with respect to the Hilbert scalar product $(\cdot|\cdot)$ and therefore do not establish the strong continuity of the operators $I_{a+/-}^{(*)}(t)_{m,\mathscr{F}}$. Hence, none of the classical integrability criterions (known to the author) is directly applicable.

However, due to the commutation relations (92), the representation $\mathscr{Q}_m$ on $\mathscr{D}(m)_{SL}$ is directly connected with a representation of $su(3)$ in the underlying countably normed test function space. For the domain, $\mathscr{D}(m)$ is the linear hull of states created from $\Psi_0(m)$ by polynomials of the Wightman–Gårding fields[11] with respect to the flavor group:

$$\phi_{\mu,c}^{n,d}(\mathbf{f})_m:=\sum_{b\in\Gamma_d}\phi_{\mu,c,b}^{n,d}(f^b)_m, \tag{96}$$

with $\phi_{\cdots}^{\cdots}$ denoting any one of the basic fields or currents and $f^b\in S(\mathbb{R}_4)$. The corresponding expressions for the composite fields are obvious. For the sake of shortness we do not write them down explicitly, neither here nor in the following. Now the equations (90)–(92) imply for all f_i^b with compact support and $a\in\hat{\Gamma}_8$,

$$\begin{aligned}&\mathbf{Q}_{a+/-}^V(0)_{m,\mathscr{F}}\prod_{i=1}^k\phi_{\mu_i,c_i}^{n_i,d_i}(f_i)_m\Psi_0(m)\\&\quad=\sum_{j=1}^k\left(\prod_{i=1}^{j-1}\phi_{\mu_i,c_i}^{n_i,d_i}(\mathbf{f}_i)_m\right)\phi_{\mu_j,c_j}^{n_j,d_j}(\delta^{d_j}(\tau_{+-/}^a)\mathbf{f}_j\Bigg)_m\prod_{\ell=j+1}^k\phi_{\mu_\ell,c_\ell}^{n_\ell,d_\ell}(\mathbf{f}_\ell)_m\Psi_0(m),\end{aligned} \tag{97}$$

where δ^d is defined for all $\mathbf{f}=(f^1,\ldots,f^d)\in S(\mathbb{R}_4,\mathbb{C}_d)$ by

$$(\delta^d(\tau_{+/-}^a)\mathbf{f})^e:=\sum_{b\in\Gamma_d}i\frac{d}{dt}R^d(\exp-i/2\tau_{+/-}^at)_b^ef_{|t=0}^b. \tag{98}$$

Obviously the $\delta^d(\tau_{+/-}^a)$ as defined in Eq. (98) make up a basis for a d-dimensional representation Δ^d of su(3) on the test function space $S(\mathbb{R}_4,\mathbb{C}_d)$ equipped with the countable set of norms $\|\mathbf{f}\|_n^d$, $n\in\mathbb{N}_0$ derived from the scalar products $[\mathbf{f},\mathbf{f}]_n^d=\Sigma_{a\in\Gamma_d}[f^a,f^a]_n$. The representatives once again act via d-dimensional matrices only on the space of indices. Therefore every element of $S(\mathbb{R}_4,\mathbb{C}_d)$ is an analytic vector (with respect to every norm) for the representation Δ^d. In addition, $\delta^d(\tau_{+/-}^a)$ is skew symmetric with respect to every scalar product $[\mathbf{f},\mathbf{f}]_n^d$, $n\in\mathbb{N}_0$. But then due to the general theory of unbounded representations of symmetry groups in gauge quantum field theories,[23,24] there exists a unique strongly continuous representation $R^d:\mathrm{SU}(3)\to\mathrm{Aut}\,S(\mathbb{R}_4,\mathbb{C}_d)$, $v\to R^d(v)$ on the countably normed space $S(\mathbb{R}_4,\mathbb{C}_d)$, the differential ∂R^d of which is equal to Δ^d (Ref. 42, Sec. IV, Theorem 4.1) and moreover an η_m-isometric representation $I_m^{\mathscr{F}}:\mathrm{SU}(3)\to\mathrm{Aut}\,\mathscr{D}(m)$, $v\to I_m^{\mathscr{F}}(v)$ on $\mathscr{D}(m)$ with $I_m^{\mathscr{F}}(v)=I_m(1,v)$ explicitly given in the equations (53), (54) and satisfying the condition (95) (Ref. 42, Theorem 3.1 and 5.1).

Summing up we have arrived at the following result.

Theorem (Flavor Symmetry): *The 16 conserved chiral flavor currents* $j_a^{S,\mu,h}(f)_{m,\mathscr{F}}$, $a\in\Gamma_8$, $h\in\{L,R\}$ *generate on* $\mathscr{D}(m)$ *a* η_m*-isometric representation [unitary one on* $(H(m)/H_0(m),\langle\cdot,\cdot\rangle_m)$, *respectively,* $\mathscr{H}_{\mathrm{phys}}$*] of the chiral (sub)group* $(\mathrm{SU}(2)\times\mathrm{U}(1))_L\times(\mathrm{SU}(2)\times\mathrm{U}(1))_R$ *that commutes with the translation operators and a further* η_m*-isometric one of*

the flavor group SU(3) for which only its restriction to the subgroup $\mathrm{SU}(2)\times\mathrm{U}(1)$ *(isomorphic to the diagonal subgroup of the chiral one) commutes with the translations.*

In order to extend the investigation above to the color group, it has to be minded that the spectrum condition (64) holds only in the closure $\overline{\mathscr{D}_0(m)}$ of the subspace of uncolored states. Therefore the Jost–Lehmann–Dyson representation (78) cannot be established anymore for the colored currents $j_c^{8,\mu}(f)_{m,\mathscr{C}}$ with $Q(c)\neq 0$. But the four color currents affiliated to the (algebraically unbroken) color group $G(3)_{\mathscr{C}}\sim\mathrm{U}(1)\times\mathrm{SU}(2)$ carry the color charge $Q(c)=0$. Then the generalized Goldstone Theorem and its consequences for color transformations are obtained in literally the same way as above just by replacing everywhere the flavor current by the color current and $p(a)=p_{\mathscr{M}}(8,a)$ by zero.

(Generalized Color-) Goldstone Theorem: The color symmetry generated by the conserved current $j_a^{8,\mu}(h)_{m,\mathscr{C}}$ *with* $Q(a)=0$ *is not spontaneously broken, that is,*

$$\left\langle \Psi_0(m), \int d^3\mathbf{x} f_R(|\mathbf{x}|)[j_a^{8,0}(x)_{m,\mathscr{C}}, \phi(f)]_- \Psi_0(m)\right\rangle_m = 0, \tag{99}$$

for all $|x^0|<\epsilon$, $\phi(f)\in\pi(\varphi_m, j_m)_{SL}$ *and all* $R>R(\epsilon, f)$, *unless there exists a state* $\Psi_{\kappa(a)}(m)\in\mathscr{H}(m)$ *with mass* $\kappa(a)=0$ *and* $\langle\Psi_{\kappa(a)}(m), j_a^{8,0}(f)_{m,\mathscr{C}}\Psi_0(m)\rangle_m\neq 0$ *for almost all* $m\in\mathscr{O}_{\mathscr{D}}$.

In other words, in all representations, uncolored Goldstone states with zero mass can exist. If uncolored ones occur at all, they may appear in any part of $\mathscr{H}(m)$. If, however, a local gauge condition of the type (26) holds in $\mathscr{H}(m)$, then also the uncolored Goldstone states are confined in the unphysical section $(\mathscr{H}(m)\backslash H(m))\cup H_0(m)$.

Similarly to Wightman theories there may be further restrictions concerning the spin- or helicity-quantum numbers of the Goldstone states.[28,43,44] However, in view of the indefinite metric and the direct integral structure of the representation of the Lorentz group this is a problem of its own beyond the present note.

(Received 13 January 1997; accepted for publication 19 November 1997)

Wave scattering is analyzed in a one-dimensional nonconservative medium governed by the generalized Schrödinger equation $d^2\psi/dx^2+k^2\psi=[ikP(x)+Q(x)]\psi$, where $P(x)$ and $Q(x)$ are real, integrable potentials with finite first moments. Various properties of the scattering solutions are obtained. The corresponding scattering matrix is analyzed, and its small-k and large-k asymptotics are established. The bound states, which correspond to the poles of the transmission coefficient in the upper-half complex plane, are studied in detail. When the medium is not purely absorptive, i.e., unless $P(x)\leqslant 0$, it is shown that there may be bound states at complex energies, degenerate bound states, and singularities of the transmission coefficient imbedded in the continuous spectrum. Some explicit examples are provided illustrating the theory. © *1998 American Institute of Physics.* [S0022-2488(98)01503-5]

I. INTRODUCTION

Wave propagation in a one-dimensional nonconservative medium is described, in the frequency domain, by the generalized Schrödinger equation

$$\psi^{+\prime\prime}(k,x)+k^2\psi^+(k,x)=[ikP(x)+Q(x)]\psi^+(k,x), \quad x\in\mathbf{R}, \tag{1.1}$$

where $\mathbf{R}$ is the real line, the prime denotes the derivative with respect to the spatial coordinate x, k is the wave number (also known as the momentum), k^2 is the energy, $P(x)$ describes the combined effect of energy absorption and energy generation, and $Q(x)$ denotes the restoring force density. In the time domain, (1.1) corresponds to a wave equation of the form

$$\frac{\partial^2 u}{\partial x^2}-\frac{\partial^2 u}{\partial t^2}-P(x)\,\frac{\partial u}{\partial t}=Q(x)u, \quad t,x\in\mathbf{R},$$

where the wave speed is equal to 1. When $P(x)\leqslant 0$, there is net absorption; however, unless otherwise stated we will not put any restriction on the sign of $P(x)$. In the sequel a significant role will be played by the associated equation

$$\psi^{-\prime\prime}(k,x)+k^2\psi^-(k,x)=[-ikP(x)+Q(x)]\psi^-(k,x), \quad x\in\mathbf{R}, \tag{1.2}$$

where the sign of $P(x)$ in (1.1) has been changed.

Let $L^p_q(I)$ denote the measurable functions $f(x)$ such that $\int_I dx\ (1+|x|)^q|f(x)|^p<+\infty$, and let $L^p(I)=L^p_0(I)$. Throughout the paper we will use $\|f\|_1$ and $\|f\|_{1,1}$ to denote the $L^1(\mathbf{R})$ and $L^1_1(\mathbf{R})$ norms, $\int_{-\infty}^{\infty}dx\ |f(x)|$ and $\int_{-\infty}^{\infty}dx\ [1+|x|]|f(x)|$, respectively. All the results given in this paper are valid if we assume that P and Q are real valued and belong to $L^1_1(\mathbf{R})$. The existence of the first moment is needed for certain results that involve the limit $k\to 0$. Some results, however, will be proved under the weaker conditions $P,Q\in L^1(\mathbf{R})$.

 © 1998 American Institute of Physics

The scattering solutions of (1.1) and (1.2) are those behaving like e^{ikx} or e^{-ikx} as $x\to\pm\infty$, and such solutions occur when $k^2>0$. Among the scattering solutions are the Jost solution from the left $f_l^{\pm}(k,x)$ and the Jost solution from the right $f_r^{\pm}(k,x)$ satisfying the boundary conditions

$$f_l^{\pm}(k,x)=\begin{cases} e^{ikx}+\mathrm{o}(1), & x\to+\infty,\\ \dfrac{1}{T^{\pm}(k)}\,e^{ikx}+\dfrac{L^{\pm}(k)}{T^{\pm}(k)}\,e^{-ikx}+\mathrm{o}(1), & x\to-\infty,\end{cases} \tag{1.3}$$

$$f_r^{\pm}(k,x)=\begin{cases} \dfrac{1}{T^{\pm}(k)}\,e^{-ikx}+\dfrac{R^{\pm}(k)}{T^{\pm}(k)}\,e^{ikx}+\mathrm{o}(1), & x\to+\infty,\\ e^{-ikx}+\mathrm{o}(1), & x\to-\infty,\end{cases} \tag{1.4}$$

where $T^{\pm}(k)$ are the transmission coefficients, and $R^{\pm}(k)$ and $L^{\pm}(k)$ are the reflection coefficients from the right and from the left, respectively. The scattering matrices $\mathbf{S}^{+}(k)$ associated with (1.1) and $\mathbf{S}^{-}(k)$ with (1.2) are given by

$$\mathbf{S}^{\pm}(k)=\begin{bmatrix} T^{\pm}(k) & R^{\pm}(k)\\ L^{\pm}(k) & T^{\pm}(k)\end{bmatrix}.$$

When $P(x)\leqslant 0$, it will be seen that $\mathbf{S}^{+}(k)$ exists for all $k\in\mathbf{R}$; however, when $P(x)\geqslant 0$ or when $P(x)$ has mixed sign, we will see that $\mathbf{S}^{+}(k)$ may not exist at $k=0$ or at some other real values of k.

In this paper we analyze the direct scattering problem in preparation of a more detailed study of various inverse scattering problems for (1.1). One of these inverse problems consists of the recovery of $P(x)$ and $Q(x)$ from an appropriate set of scattering data. In the radial case, when there are no bound states, Jaulent and Jean[1] presented an inversion method with real $Q(x)$ and imaginary $P(x)$. They[2,3] also extended their method to solve the full-line one-dimensional inverse problem for real $Q(x)$ and imaginary $P(x)$. In this method, using the scattering data $\{R^{+}(k),R^{-}(k)\}$, a pair of two coupled Marchenko integral equations is solved and these solutions are used in a first-order ordinary differential equation whose solution leads to $P(x)$. Jaulent[4] also extended this method to the case when $P(x)$ is real although complete details and proofs were not given. When $P(x)$ is purely imaginary and $\int_{-\infty}^{\infty}dz\ P(z)=0$, Sattinger and Szmigielski[5] showed that one can simplify the method of Jaulent and Jean and recover $P(x)$ by solving an algebraic equation rather than a differential equation.

We should also mention the study by Kaup[6] on the direct and inverse scattering problem for

$$\phi''+\left[k^2+\frac{1}{4\beta^2}\right]\phi=[ikP(x)+Q(x)]\phi, \tag{1.5}$$

where β is a nonzero constant and $P,Q\in L_1^1(\mathbf{R})$. Under certain additional assumptions on $P(x)$, Tsutsumi[7] studied the scattering problem for (1.5) with $\beta=\frac{1}{2}$ using a 2×2 matrix analog of (1.1) with k replaced by $\sqrt{k^2+1}$. When P and Q are in the Schwartz space, $\int_{-\infty}^{\infty}dz\ P(z)=0$, and $\beta=\frac{1}{2}$, Sattinger and Szmigielski[8] also studied the inverse scattering problem for (1.5). In Refs. 6 and 8 the inverse scattering problem is analyzed by studying a Riemann–Hilbert problem on a particular Riemann surface.

When $P(x)$ is purely imaginary, the methods available for self-adjoint differential operators can be employed to analyze the inverse scattering problem for (1.1); furthermore, in this case[2] the scattering matrices $\mathbf{S}^{\pm}(k)$ are unitary, and hence the reflection coefficients cannot exceed 1 in absolute value. However, when $P(x)$ is real valued, the differential operator pertaining to (1.1) is no longer self-adjoint and the scattering matrices $\mathbf{S}^{\pm}(k)$ are no longer unitary. Consequently, the analysis of the direct and inverse scattering problems with real $P(x)$ is different and more difficult than with imaginary $P(x)$. The standard proof[9,10] of the absence of singularities of the transmission coefficient for $k\in\mathbf{R}$, which relies heavily on the self-adjointness of the differential operator, breaks down. Since the reflection coefficients may be larger than one in absolute value, the standard proof of the unique solvability of the Marchenko integral equations is no longer valid. Fortunately, when $P(x)\leqslant 0$, some of the usual properties of the one-dimensional Schrödinger

equation given in (2.6), such as the simplicity of the poles of the transmission coefficient, the confinement of these poles to the imaginary axis in the upper-half complex plane $\mathbf{C}^+$, and the absence of singularities of the transmission coefficient when $k \in \mathbf{R}$ are still valid for (1.1), and the proofs of such properties are obtained by a variation of the arguments used for (2.6).

This paper is organized as follows. In Secs. II and III, relying on techniques established in a variety of papers,[10–12] we study the analyticity properties of the Jost solutions of (1.1) and analyze their small-k and large-k asymptotics. In Secs. IV–VI we analyze various properties of the scattering matrices $\mathbf{S}^{\pm}(k)$. In Sec. VII we study the change in the scattering coefficients when $P(x)$ and $Q(x)$ are perturbed. In Sec. VIII we analyze the relation between the poles of $T^+(k)$ in $\mathbf{C}^+$ and the bound states; we also study multiple poles of $T^+(k)$ in terms of Jordan chains of the differential operator given in (8.3). Recall that the bound state solutions of (1.1) and (1.2) are those nontrivial solutions belonging to $L^2(\mathbf{R})$. In the radial case when $P(x) \leqslant 0$, under certain additional conditions on $P'(x)$, using the theory of abstract operator polynomials, Pivovarchik has shown that[13] the number of bound states is independent of $P(x)$ and that[14–16] the bound states are simple and can only occur when k is located on the positive imaginary axis. In Sec. IX we study the bound states for (1.1) further and show that the poles of $T^+(k)$ in $\mathbf{C}^+$ can only occur in a certain region in $\mathbf{C}^+$ determined by $P(x)$ and $Q(x)$. When $P(x) \leqslant 0$, we derive Pivovarchik's results in an elementary way without using the theory of abstract operator polynomials and without assuming the differentiability of $P(x)$; we also show that the bound states can only occur at certain negative energies and obtain some lower and upper bounds for these energies. In Sec. IX we also obtain a Levinson theorem relating the number of bound states to the change in the argument of $T^+(k)$, and we show that the number of bound states is unchanged under certain small perturbations of P and Q. In Sec. X we analyze the zeros of the Jost solutions and obtain various results concerning the number and location of these zeros and their relationship to the bound states; we also show that the number of bound states of (1.1) with real energies is greater than or equal to the number of bound states with $P(x) = 0$. In Sec. XI, we show by examples that there may be bound states with complex energies and that the multiplicity of a bound state (in the sense of the order to which $1/T^+(k)$ vanishes) may be larger than one. Finally, in the Appendix we obtain various small-k estimates that are needed in the proof of Theorem 5.2.

II. ANALYTICITY AND SMALL-k ASYMPTOTICS OF JOST SOLUTIONS

Let us define the Faddeev functions from the left, $m_l^{\pm}(k,x)$, and from the right, $m_r^{\pm}(k,x)$, by

$$m_l^{\pm}(k,x) = e^{-ikx} f_l^{\pm}(k,x), \quad m_r^{\pm}(k,x) = e^{ikx} f_r^{\pm}(k,x).$$

Then $m_l^{\pm}(k,x)$ satisfies

$$m_l^{\pm}(k,x) = 1 + \frac{1}{2ik} \int_x^{\infty} dy \; [e^{2ik(y-x)} - 1][\pm ikP(y) + Q(y)] m_l^{\pm}(k,y), \tag{2.1}$$

$$m_l^{\pm\prime}(k,x) = -\int_x^{\infty} dy \; e^{2ik(y-x)} [\pm ikP(y) + Q(y)] m_l^{\pm}(k,y). \tag{2.2}$$

By $\overline{\mathbf{C}^+}$ we denote $\mathbf{C}^+ \cup \mathbf{R}$. In the following theorem and throughout the paper we will use C to denote a generic constant (independent of x and k) that does not necessarily assume the same value at each appearance.

Theorem 2.1: (i) Assume $P, Q \in L^1(\mathbf{R})$. Then, for each $x \in \mathbf{R}$, the functions $m_l^{\pm}(k,x)$, $m_r^{\pm}(k,x)$, $m_l^{\pm\prime}(k,x)$, and $m_r^{\pm\prime}(k,x)$ are analytic in $\mathbf{C}^+$ and continuous in $\overline{\mathbf{C}^+} \backslash \{0\}$. Consequently, for each $x \in \mathbf{R}$ the Jost solutions $f_l^{\pm}(k,x), f_r^{\pm}(k,x)$ and their derivatives $f_l^{\pm\prime}(k,x), f_r^{\pm\prime}(k,x)$ are analytic in $\mathbf{C}^+$ and continuous in $\overline{\mathbf{C}^+} \backslash \{0\}$. Moreover, for each $k \in \overline{\mathbf{C}^+} \backslash \{0\}$ we have

$$|m_l^{\pm}(k,x)| \leqslant Ce^{C/|k|}, \quad |m_r^{\pm}(k,x)| \leqslant Ce^{C/|k|}, \tag{2.3}$$

$$m_l^{\pm}(k,x) = 1 + o(1), \quad m_l^{\pm\prime}(k,x) = o(1), \quad x \to +\infty,$$

$$m_r^{\pm}(k,x) = 1 + o(1), \quad m_r^{\pm\prime}(k,x) = o(1), \quad x \to -\infty.$$

(ii) Assume $P \in L^1(\mathbf{R})$ and $Q \in L_1^1(\mathbf{R})$. Then the continuity of the functions in (i) extends to $\overline{\mathbf{C}^+}$. Moreover, for $k \in \overline{\mathbf{C}^+}$ we have

$$|m_l^{\pm}(k,x)| \leqslant C[1 + \max\{0,-x\}], \quad |m_r^{\pm}(k,x)| \leqslant C[1 + \max\{0,x\}], \tag{2.4}$$

$$m_l^{\pm\prime}(k,x) = o(1/x), \quad x \to +\infty; \quad m_r^{\pm\prime}(k,x) = o(1/x), \quad x \to -\infty.$$

Proof: The proof is obtained from (2.1), (2.2), and similar equations for $m_r^{\pm}(k,x)$ in a manner analogous[10] to the case with $P(x) = 0$. In the proof of (ii), one also uses the estimates

$$|1 - e^{2ik(y-x)}| \leqslant 2, \quad |1 - e^{2ik(y-x)}| \leqslant 2|k|(y-x),$$

for $k \in \overline{\mathbf{C}^+}$ and $y \geqslant x$. ∎

When $P \in L^1(\mathbf{R})$ and $Q \in L_1^1(\mathbf{R})$, using (2.1), (2.2), and Theorem 2.1 (ii), we obtain

$$m_l^{\pm}(k,x) = m_l^{\pm}(0,x) + o(1), \quad m_l^{\pm\prime}(k,x) = m_l^{\pm\prime}(0,x) + o(1), \quad k \to 0 \text{ in } \overline{\mathbf{C}^+}, \tag{2.5}$$

uniformly on compact x-intervals. Let us consider the Schrödinger equation obtained from (1.1) and (1.2) by setting $P(x) = 0$, namely

$$\psi^{[0]\prime\prime}(k,x) + k^2\psi^{[0]}(k,x) = Q(x)\psi^{[0]}(k,x), \quad x \in \mathbf{R}. \tag{2.6}$$

Let $f_l^{[0]}(k,x)$ and $f_r^{[0]}(k,x)$ denote the Jost solutions of (2.6) from the left and from the right, respectively. From (1.1) and the corresponding boundary conditions we see that $f_l^{\pm}(0,x), f_r^{\pm}(0,x)$, and their derivatives are determined by $Q(x)$ alone and

$$m_l^{\pm}(0,x) = f_l^{\pm}(0,x) = f_l^{[0]}(0,x), \quad m_l^{\pm\prime}(0,x) = f_l^{\pm\prime}(0,x) = f_l^{[0]\prime}(0,x), \tag{2.7}$$

As seen from (2.6) and (2.7) we have

$$Q(x) = \frac{f_l^{\pm\prime\prime}(0,x)}{f_l^{\pm}(0,x)} = \frac{f_l^{[0]\prime\prime}(0,x)}{f_l^{[0]}(0,x)}.$$

Let $\mathbf{S}^{[0]}(k)$ denote the scattering matrix associated with (2.6):

$$\mathbf{S}^{[0]}(k) = \begin{bmatrix} T^{[0]}(k) & R^{[0]}(k) \\ L^{[0]}(k) & T^{[0]}(k) \end{bmatrix},$$

where $T^{[0]}(k)$ is the transmission coefficient and $R^{[0]}(k)$ and $L^{[0]}(k)$ are the reflection coefficients from the right and from the left, respectively. Generically $f_l^{\pm}(0,x)$ and $f_r^{\pm}(0,x)$ are linearly independent, but in the so-called exceptional case these two functions are linearly dependent. We have[9,10]

$$[f_l^{[0]}(0,x); f_r^{[0]}(0,x)] = \int_{-\infty}^{\infty} dy\, Q(y) f_l^{[0]}(0,y) = \int_{-\infty}^{\infty} dy\, Q(y) f_r^{[0]}(0,y) = \lim_{k \to 0} \frac{-2ik}{T^{[0]}(k)}, \tag{2.8}$$

where $[f;g] = fg' - f'g$ denotes the Wronskian. Thus $T^{[0]}(0) = 0$ generically and $T^{[0]}(0) \neq 0$ in the exceptional case. In the exceptional case, let us define

$$\gamma = \frac{f_l^{[0]}(0,x)}{f_r^{[0]}(0,x)}. \tag{2.9}$$

Then γ is a nonzero real constant determined by $Q(x)$ alone, and we have $\gamma=f_l^{[0]}(0,-\infty)$.

III. LARGE-k ASYMPTOTICS OF JOST SOLUTIONS

In this section we analyze the large-k asymptotics of the Jost solutions. We assume that $P\in L^1(\mathbf{R})$ and $Q\in L^1_1(\mathbf{R})$. The results given here will be used in Sec. VI to obtain the large-k asymptotics of the scattering matrix $\mathbf{S}^+(k)$.

Let us define

$$\eta_l^{\pm}(k,x)=e^{\pm\zeta}m_l^{\pm}(k,x)=e^{-ikx\pm\zeta}f_l^{\pm}(k,x),$$
$$\eta_r^{\pm}(k,x)=e^{\pm p\mp\zeta}m_r^{\pm}(k,x)=e^{ikx\pm p\mp\zeta}f_r^{\pm}(k,x), \tag{3.1}$$

where

$$\zeta=\zeta(x)=\frac{1}{2}\int_x^{\infty}dz\ P(z),\quad p=\frac{1}{2}\int_{-\infty}^{\infty}dz\ P(z), \tag{3.2}$$

so that $\int_{-\infty}^{x}dz\ P(z)/2=p-\zeta$. Thus

$$f_l^{\pm}(k,x)=e^{ikx\mp\zeta}\eta_l^{\pm}(k,x),$$
$$f_l^{\pm\prime}(k,x)=e^{ikx\mp\zeta}[(ik\pm P/2)\,\eta_l^{\pm}(k,x)+\eta_l^{\pm\prime}(k,x)], \tag{3.3}$$

$$f_r^{\pm}(k,x)=e^{-ikx\mp p\pm\zeta}\eta_r^{\pm}(k,x),$$
$$f_r^{\pm\prime}(k,x)=e^{-ikx\mp p\pm\zeta}[(-ik\mp P/2)\,\eta_r^{\pm}(k,x)+\eta_r^{\pm\prime}(k,x)]. \tag{3.4}$$

Theorem 3.1: Assume $P,Q\in L^1(\mathbf{R})$. Then, for each $x\in\mathbf{R}$, the functions $\eta_l^{\pm}(k,x)$ and $\eta_r^{\pm}(k,x)$ are analytic in $\mathbf{C}^+$, continuous in $\overline{\mathbf{C}^+}\backslash\{0\}$, and we have

$$|\eta_l^{\pm}(k,x)|\leq Ce^{C/|k|},\quad |\eta_r^{\pm}(k,x)|\leq Ce^{C/|k|},\quad k\in\overline{\mathbf{C}^+}\backslash\{0\}. \tag{3.5}$$

If $P\in L^1(\mathbf{R})$ and $Q\in L^1_1(\mathbf{R})$, then, for each $x\in\mathbf{R}$, the functions $\eta_l^{\pm}(k,x)$ and $\eta_r^{\pm}(k,x)$ are continuous in $\overline{\mathbf{C}^+}$, and we have

$$|\eta_l^{\pm}(k,x)|\leq C[1+\max\{0,-x\}],\quad |\eta_r^{\pm}(k,x)|\leq C[1+\max\{0,x\}],\quad k\in\overline{\mathbf{C}^+}. \tag{3.6}$$

Moreover, if $P,Q\in L^1(\mathbf{R})$, then

$$\eta_l^{\pm}(k,x)=1+o(1),\quad \eta_r^{\pm}(k,x)=1+o(1),\quad k\to\infty\ \text{ in }\ \overline{\mathbf{C}^+}, \tag{3.7}$$

$$\eta_l^{\pm\prime}(k,x)=o(k),\quad \eta_r^{\pm\prime}(k,x)=o(k),\quad k\to\infty\ \text{ in }\ \overline{\mathbf{C}^+}. \tag{3.8}$$

Proof: The analyticity in $\mathbf{C}^+$, the continuity in $\overline{\mathbf{C}^+}\backslash\{0\}$, and (3.5) and (3.6) follow from (3.1) and Theorem 2.1 (i). To prove (3.7) we use (3.1) in (2.1). Letting $z(k,x)=\eta_l^+(k,x)-1$, after some simplifications, we obtain

$$z(k,x)=z_0(k,x)+\frac{1}{2ik}\int_x^{\infty}dy\ [e^{2ik(y-x)}-1]e^{\zeta(x)-\zeta(y)}[ikP(y)+Q(y)]z(k,y), \tag{3.9}$$

with

$$z_0(k,x)=\frac{1}{2}\int_x^{\infty}dy\ e^{2ik(y-x)}e^{\zeta(x)-\zeta(y)}P(y)+\frac{1}{2ik}\int_x^{\infty}dy\ [e^{2ik(y-x)}-1]e^{\zeta(x)-\zeta(y)}Q(y). \tag{3.10}$$

Using (2.4) in (3.10) we get

$$|z_0(k,x)|\leqslant C_1\int_x^\infty dy\ [|P(y)|+|Q(y)|/|k|],\quad k\in\overline{\mathbf{C}^+}\backslash\{0\},$$

where C_1 is a suitable constant. For each $x\in\mathbf{R}$, let $s_x(k)=\sup_{t\geqslant x}|z_0(k,t)|$. Solving (3.9) by iteration we obtain

$$|z(k,x)|\leqslant s_x(k)e^{C_1\int_x^\infty dy\ [|P(y)|+|Q(y)|/|k|]}. \tag{3.11}$$

Applying the Riemann–Lebesgue lemma to (3.10), we get

$$s_x(k)=\mathrm{o}(1),\quad k\to\pm\infty. \tag{3.12}$$

Using (3.11) and (3.12) we see that $z(k,x)$ is uniformly bounded in $\overline{\mathbf{C}^+}$ for $|k|\geqslant a>0$ for each $x\in\mathbf{R}$ and $a>0$. Hence, in view of (3.12) and a Phragmén–Lindelöf theorem[17] we conclude that $z(k,x)\to 0$ as $k\to\infty$ in $\overline{\mathbf{C}^+}$. The proof of (3.7) for $\eta_l^-(k,x)$ and $\eta_r^\pm(k,x)$ is similar. To prove (3.8) for $\eta_l^{+\prime}(k,x)$ we introduce the functions

$$\begin{aligned}\xi_l^\pm(k,x)&=\frac{1}{2ik}\,[\pm P(x)\,\eta_l^\pm(k,x)+2\,\eta_l^{\pm\prime}(k,x)],\\ \xi_r^\pm(k,x)&=\frac{1}{2ik}\,[\mp P(x)\,\eta_r^\pm(k,x)+2\,\eta_r^{\pm\prime}(k,x)].\end{aligned} \tag{3.13}$$

Since $\xi_l^\pm(k,x)=(1/ik)\ m_l^{\pm\prime}(k,x)e^{\pm\zeta}$, it follows from (3.1) and (3.13) that

$$\xi_l^+(k,x)=-\int_x^\infty dy\ [P(y)-iQ(y)/k]e^{2ik(y-x)}e^{\zeta(x)-\zeta(y)}\eta_l^+(k,y). \tag{3.14}$$

Thus, using (3.5), we see that the integrand on the right-hand side of (3.14) is bounded by the integrable function $C_a[|P(y)|+|Q(y)|/a]$, uniformly in x and $k\in\overline{\mathbf{C}^+}$ for $|k|\geqslant a>0$ and each $a>0$, where the constant C_a only depends on a but not on x and k. By a variant of the Riemann–Lebesgue lemma, we conclude that the right-hand side of (3.14) is o(1) as $k\to\pm\infty$, so that by a Phragmén–Lindelöf theorem,[17] we see that the left-hand side of (3.14) is o(1) as $k\to\infty$ in $\overline{\mathbf{C}^+}$. Consequently, $\xi_l^+(k,x)=\mathrm{o}(1)$ as $k\to\infty$ in $\overline{\mathbf{C}^+}$, and so (3.8) for $\eta_l^{+\prime}(k,x)$ follows by using (3.13). The proof of (3.8) for $\eta_l^{-\prime}(k,x)$ and $\eta_r^{\pm\prime}(k,x)$ is similar. ■

Let us also mention that it is possible to study the large k-behavior of the solutions of (1.1) by converting it into a system of two coupled, first-order differential equations. We will not give the details here but refer the interested reader to Ref. 18.

IV. SCATTERING COEFFICIENTS

In this section we summarize some basic facts about the scattering coefficients. In particular, we are concerned with symmetries, Wronskian relations, analyticity, and continuity properties. Applications and refinements of these results will be given in the subsequent sections. Note that, since $P(x)$ is assumed to be real, $\mathbf{S}^\pm(k)$ is not unitary. However, there are certain relations (Proposition 4.3) involving the scattering coefficients which reduce to the usual unitarity relations when $P(x)=0$.

We begin with the observation that when $k\in\mathbf{R}$, the quantities $f_l^-(-k,x)$ and $f_r^-(-k,x)$ are also solutions of (1.1) and hence can be expressed as linear combinations of $f_l^+(k,x)$ and $f_r^+(k,x)$, unless the latter functions are linearly dependent. Using (1.3) and (1.4) we obtain the two vector equations

$$\begin{bmatrix}f_l^\mp(-k,x)\\ f_r^\mp(-k,x)\end{bmatrix}=\begin{bmatrix}T^\pm(k) & -R^\pm(k)\\ -L^\pm(k) & T^\pm(k)\end{bmatrix}\begin{bmatrix}f_r^\pm(k,x)\\ f_l^\pm(k,x)\end{bmatrix},\quad k\in\mathbf{R}. \tag{4.1}$$

In general, $f_l^\mp(-k,x)$ and $f_r^\mp(-k,x)$ cannot be continued to $\mathbf{C}^+$ as functions of k because $f_l^\pm(k,x)$ and $f_r^\pm(k,x)$ usually cannot be extended to the lower-half complex plane $\mathbf{C}^-$.

Using (1.3) and (1.4), the scattering coefficients can be expressed[2] in terms of Wronskians:

$$[f_l^{\pm}(k,x);f_r^{\pm}(k,x)]=-\frac{2ik}{T^{\pm}(k)},\quad k\in\overline{\mathbf{C}^+},\tag{4.2}$$

$$[f_l^{\pm}(k,x);f_r^{\mp}(-k,x)]=\frac{2ikL^{\pm}(k)}{T^{\pm}(k)}=-\frac{2ikR^{\mp}(-k)}{T^{\mp}(-k)},\tag{4.3}$$

$$[f_r^{\pm}(k,x);f_l^{\mp}(-k,x)]=-\frac{2ikR^{\pm}(k)}{T^{\pm}(k)}=\frac{2ikL^{\mp}(-k)}{T^{\mp}(-k)},\tag{4.4}$$

$$[f_l^{\pm}(k,x);f_l^{\mp}(-k,x)]=-2ik=-2ik\,\frac{1-L^{\pm}(k)L^{\mp}(-k)}{T^{\pm}(k)T^{\mp}(-k)},\tag{4.5}$$

$$[f_r^{\pm}(k,x);f_r^{\mp}(-k,x)]=2ik=2ik\,\frac{1-R^{\pm}(k)R^{\mp}(-k)}{T^{\pm}(k)T^{\mp}(-k)}.\tag{4.6}$$

Let an overline denote complex conjugation. It is already known[2] that

$$f_l^{\pm}(-\overline{k},x)=\overline{f_l^{\pm}(k,x)},\quad f_r^{\pm}(-\overline{k},x)=\overline{f_r^{\pm}(k,x)},\quad k\in\overline{\mathbf{C}^+},\tag{4.7}$$

$$f_l^{\pm}(-k,x)=\overline{f_l^{\pm}(k,x)},\quad f_r^{\pm}(-k,x)=\overline{f_r^{\pm}(k,x)},\quad k\in\mathbf{R},\tag{4.8}$$

$$\frac{1}{T^{\pm}(-\overline{k})}=\frac{1}{\overline{T^{\pm}(k)}},\quad k\in\overline{\mathbf{C}^+}\backslash\{0\},\tag{4.9}$$

$$\mathbf{S}^{\pm}(-k)=\overline{\mathbf{S}^{\pm}(k)},\quad \mathbf{S}^{\pm}(k)\mathbf{S}^{\mp}(-k)^t=\mathbf{I},\quad k\in\mathbf{R},\tag{4.10}$$

where $\mathbf{I}$ is the 2×2 unit matrix and the superscript t denotes the matrix transpose. It is understood that (4.10) holds only at the points where the scattering coefficients are defined; we will see later that $\mathbf{S}^{\pm}(k)$ may not be defined for certain real values of k.

From (4.10) we see that

$$T^{\mp}(k)=\frac{T^{\pm}(-k)}{T^{\pm}(-k)^2-L^{\pm}(-k)R^{\pm}(-k)},$$

and therefore

$$\det\mathbf{S}^{\pm}(k)=T^{\pm}(k)^2-L^{\pm}(k)R^{\pm}(k)=\frac{T^{\pm}(k)}{T^{\mp}(-k)},\quad k\in\mathbf{R}.\tag{4.11}$$

It follows from (4.9) that the zeros of $1/T^{\pm}(k)$ either lie on or are symmetrically located with respect to the imaginary axis in $\overline{\mathbf{C}^+}$; in particular, $1/T^{+}(k_0)=0$ for some $k_0\in\mathbf{R}\backslash\{0\}$ implies that $1/T^{+}(-k_0)=0$.

Proposition 4.1: Assume $P,Q\in L^1(\mathbf{R})$. Then: (i) $1/T^{\pm}(k)$ are analytic in $\mathbf{C}^+$, continuous in $\overline{\mathbf{C}^+}\backslash\{0\}$, and bounded in the sector $\{k\in\overline{\mathbf{C}^+}:|k|\geqslant a>0\}$ for every $a>0$. If, in addition, $Q\in L^1_1(\mathbf{R})$, then $k/[(k+i)T^{\pm}(k)]$ are continuous and bounded in $\overline{\mathbf{C}^+}$, and $kL^{\pm}(k)/T^{\pm}(k)$ and $kR^{\pm}(k)/T^{\pm}(k)$ are continuous and bounded in $\mathbf{R}$. Consequently, $T^{\pm}(k)$ cannot have any zeros in $\overline{\mathbf{C}^+}\backslash\{0\}$. (ii) The zeros of $k/[(k+i)T^{\pm}(k)]$ in $\mathbf{C}^+$ are all isolated, and their accumulation points, if any, must lie on the real axis or at infinity.

Proof: All the assertions follow from (4.3), (4.4), (4.9), and Theorem 2.1. ■

Note that contrary to the case where $P(x)$ is either zero or purely imaginary, we cannot *a priori* rule out possible singularities of the scattering coefficients $T^{\pm}(k)$, $R^{\pm}(k)$, and $L^{\pm}(k)$ on the real axis. In Examples 11.2 and 11.4, we show that $1/T^{+}(k)$ may have zeros on $\mathbf{R}$ or off the imaginary axis in $\mathbf{C}^+$.

Proposition 4.2: Assume $P,Q\in L^1(\mathbf{R})$. Then, for any $k_0\in\mathbf{R}\backslash\{0\}$, the quantities $1/T^+(k_0)$ and $R^\pm(k_0)/T^\pm(k_0)$ cannot be zero simultaneously; similarly, $1/T^+(k_0)$ and $L^\pm(k_0)/T^\pm(k_0)$ cannot be zero simultaneously. If $1/T^+(k_0)=0$ for some $k_0\in\mathbf{R}\backslash\{0\}$, then none of the eight quantities $R^\pm(k_0)/T^\pm(k_0)$, $L^\pm(k_0)/T^\pm(k_0)$, $R^\pm(-k_0)/T^\pm(-k_0)$, $L^\pm(-k_0)/T^\pm(-k_0)$ are zero. Moreover, $R^+(k)$ is continuous for $k\in\mathbf{R}\backslash\{0\}$ if and only if $1/T^+(k)$ does not vanish for $k\in\mathbf{R}\backslash\{0\}$. Similarly, $L^+(k)$ is continuous for $k\in\mathbf{R}\backslash\{0\}$ if and only if $1/T^+(k)$ does not vanish for $k\in\mathbf{R}\backslash\{0\}$.

Proof: By Proposition 4.1 we know that $1/T^\pm(k)$, $R^\pm(k)/T^\pm(k)$, $L^\pm(k)/T^\pm(k)$ are continuous when $k\in\mathbf{R}\backslash\{0\}$. Moreover, the right-hand sides in (4.5) and (4.6) cannot be zero when $k\neq 0$. ∎

Note that, if $1/T^+(k_0)=0$ for some $k_0\in\mathbf{R}\backslash\{0\}$, from (4.2) we see that $f_l^+(k_0,x)$ and $f_r^+(k_0,x)$ are linearly dependent, and from (1.3) and (1.4) we obtain

$$\frac{f_l^+(k_0,x)}{f_r^+(k_0,x)}=\frac{L^+(k_0)}{T^+(k_0)}=\frac{T^+(k_0)}{R^+(k_0)}.$$

Moreover, if $1/T^+(k)=c(k-k_0)^m+\mathrm{o}(k-k_0)^m$ as $k\to k_0$, for some nonzero constant c and positive integer m, then $R(k)=d(k-k_0)^{-m}+\mathrm{o}(k-k_0)^{-m}$ as $k\to k_0$ with $d\neq 0$. Thus, we see that $T^+(k)$ is continuous for $k\in\mathbf{R}\backslash\{0\}$ if and only if $R^+(k)$ [or $L^+(k)$] is continuous.

Proposition 4.3: Assume $P,Q\in L^1(\mathbf{R})$. The scattering coefficients satisfy

$$\frac{1}{|T^\pm(k)|^2}=1+\left|\frac{L^\pm(k)}{T^\pm(k)}\right|^2\mp\int_{-\infty}^{\infty}dx\ |f_l^\pm(k,x)|^2P(x),\quad k\in\mathbf{R}\backslash\{0\},\tag{4.12}$$

$$\frac{1}{|T^\pm(k)|^2}=1+\left|\frac{R^\pm(k)}{T^\pm(k)}\right|^2\mp\int_{-\infty}^{\infty}dx\ |f_r^\pm(k,x)|^2P(x),\quad k\in\mathbf{R}\backslash\{0\}.\tag{4.13}$$

Hence, if $P(x)\leqslant 0$, then $1/T^+(k)$ cannot have any zeros for $k\in\mathbf{R}$, and we have

$$|T^+(k)|^2+|L^+(k)|^2\leqslant 1,\quad |T^+(k)|^2+|R^+(k)|^2\leqslant 1,\quad k\in\mathbf{R}\backslash\{0\}.\tag{4.14}$$

If $1/T^+(k)$ does not have any zeros for $k\in\mathbf{R}\backslash\{0\}$ and $P(x)\geqslant 0$, then we have

$$|T^+(k)|^2+|L^+(k)|^2\geqslant 1,\quad |T^+(k)|^2+|R^+(k)|^2\geqslant 1,\quad k\in\mathbf{R}\backslash\{0\}.\tag{4.15}$$

Moreover, if $P(x)\leqslant 0$, then $1/|T^+(k)|\geqslant 1/|T^-(k)|$ for $k\in\mathbf{R}\backslash\{0\}$.

Proof: From (1.1) and (1.2) we obtain

$$\frac{d}{dx}[f_l^\pm(-k,x);f_l^\pm(k,x)]=\pm 2ikf_l^\pm(-k,x)f_l^\pm(k,x)P(x),\tag{4.16}$$

$$\frac{d}{dx}[f_r^\pm(-k,x);f_r^\pm(k,x)]=\pm 2ikf_r^\pm(-k,x)f_r^\pm(k,x)P(x).\tag{4.17}$$

Hence, using (1.3), (1.4), (4.8), (4.10) in (4.16) and (4.17), for $k\in\mathbf{R}\backslash\{0\}$, we obtain (4.12) and (4.13), which imply (4.14) and (4.15). The last inequality follows from (4.10) by subtracting (4.12) from (4.13). ∎

V. SMALL-*k* ANALYSIS OF SCATTERING COEFFICIENTS

In this section we analyze the small-k asymptotics of $\mathbf{S}^\pm(k)$. Our results will depend on whether we are in the generic or the exceptional case.

Proposition 5.1: Assume $P\in L^1(\mathbf{R})$ and $Q\in L^1_1(\mathbf{R})$ and suppose that we are in the generic case. Then $R^\pm(0)=L^\pm(0)=-1$, $T^\pm(k)$ vanish linearly as $k\to 0$ in $\overline{\mathbf{C}^+}$, and

$$\lim_{k\to 0}\frac{2ik}{T^+(k)}=\lim_{k\to 0}\frac{2ik}{T^-(k)}=\lim_{k\to 0}\frac{2ik}{T^{[0]}(k)}.\tag{5.1}$$

Furthermore, $\det \mathbf{S}^{\pm}(0)=-1$, and

$$T^{\pm}(k)=\frac{-2ik}{\int_{-\infty}^{\infty}dy\ Q(y)f_l^{[0]}(0,y)}+o(k),\quad k\to 0\ \text{ in }\ \overline{\mathbf{C}^+}. \tag{5.2}$$

Proof: (5.1) follows from (4.2) and Theorem 2.1 (ii). Since generically $R^{[0]}(0)=L^{[0]}(0)=-1$, from (4.3) and (4.4) in the limit $k\to 0$ we get $R^{\pm}(0)=L^{\pm}(0)=-1$. Then, using (4.11) we obtain $\det S^{\pm}(0)=-1$. From (2.8) and (5.1) we obtain (5.2). ■

Under stronger conditions on P and Q, the small-k asymptotics of the scattering coefficients in the generic case were known [see, e.g., Ref. 2 in the case with imaginary $P(x)$]. Next we study the small-k asymptotics of the scattering coefficients in the exceptional case, and we show that $S^{\pm}(0)$ is affected by $P(x)$.

Theorem 5.2: In the exceptional case, under the assumptions $P,Q\in L_1^1(\mathbf{R})$, we have

$$T^{\pm}(0)=\frac{2\gamma}{\gamma^2+1\mp\int_{-\infty}^{\infty}dx\ P(x)f_l^{[0]}(0,x)^2}, \tag{5.3}$$

$$L^{\pm}(0)=\frac{\gamma^2-1\pm\int_{-\infty}^{\infty}dx\ P(x)f_l^{[0]}(0,\ x)^2}{\gamma^2+1\mp\int_{-\infty}^{\infty}dx\ P(x)f_l^{[0]}(0,x)^2}, \tag{5.4}$$

$$R^{\pm}(0)=\frac{1-\gamma^2\pm\int_{-\infty}^{\infty}dx\ P(x)f_l^{[0]}(0,x)^2}{\gamma^2+1\mp\int_{-\infty}^{\infty}dx\ P(x)f_l^{[0]}(0,x)^2}, \tag{5.5}$$

where γ is the constant defined in (2.9).

Proof: The technical details of the proof are given in the Appendix. As in the case $P(x)=0$ the difficulty is to prove that the transmission coefficients are continuous at $k=0$. This is only straightforward if $P,Q\in L_2^1(\mathbf{R})$ as[10] in the case $P(x)=0$, but not if $P,Q\in L_1^1(\mathbf{R})$. We obtain $T^{+}(0)$ in (5.3) by using (A18) and (A19) in (A17) and also using (4.2). The value of $T^{-}(0)$ in (5.3) is obtained by changing the sign of $P(x)$. In order to obtain $L^{+}(0)$ in (5.4), as in the displayed equation following (A32) of Ref. 12, we first derive

$$\begin{aligned}
&f_l(0,0)[f_l^{+}(k,x);f_r^{-}(-k,x)]\\
&\quad=f_r^{-}(-k,0)\left[-ikf_l(0,0)+f_l'(0,0)+\int_0^{\infty}dz\ e^{ikz}[ikP(z)+Q(z)]\widetilde{\psi}(k,z)\right]\\
&\qquad-f_l^{+}(k,0)\left[-ikf_l(0,0)+f_l'(0,0)-\int_{-\infty}^{0}dz\ e^{ikz}[ikP(z)+Q(z)]\widetilde{\psi}(k,z)\right],
\end{aligned} \tag{5.6}$$

where $\widetilde{\psi}(k,x)$ is the function in (A2). Estimating various terms in (5.6) as in the proof of Proposition A.4 in connection with (A17), and also by using (4.3), we obtain $L^{+}(0)$ in (5.4). Similarly we obtain $R^{+}(0)$ in (5.5). The values of $L^{-}(0)$ and $R^{-}(0)$ are obtained from $L^{+}(0)$ and $R^{+}(0)$ by changing the sign of $P(x)$. ■

In the exceptional case, it is possible that $\mathbf{S}^{\pm}(k)$ is discontinuous at $k=0$, and as seen from (5.3)–(5.5) this happens if and only if $\int_{-\infty}^{\infty}dx\ P(x)f_l^{[0]}(0,x)^2=\pm(\gamma^2+1)$. For example, if $Q(x)=0$, we have $f_l^{[0]}(0,x)=f_r^{[0]}(0,x)=1$, and hence $\gamma=1$. Thus

$$\frac{1}{T^{\pm}(0)}=1\mp\frac{1}{2}\int_{-\infty}^{\infty}dx\ P(x). \tag{5.7}$$

Hence, if $\int_{-\infty}^{\infty}dx\ P(x)=\pm 2$, then $\mathbf{S}^{\pm}(0)$ is undefined.

We remark that in the exceptional case, when $\mathbf{S}^{\pm}(k)$ is continuous at $k=0$, we can obtain (5.3)–(5.5) also as follows. In (4.1) let $k\to 0$ and use (2.7) and (2.9) to get

$$\gamma=\frac{f_l^{\pm}(0,x)}{f_r^{\pm}(0,x)}=\frac{T^{\pm}(0)}{1+R^{\pm}(0)}=\frac{T^{[0]}(0)}{1+R^{[0]}0}=\frac{1+L^{[0]}(0)}{T^{[0]}(0)}=\frac{1+L^{\pm}(0)}{T^{\pm}(0)}. \tag{5.8}$$

Combining (5.8) with (4.12) for $k=0$ and eliminating $L^{\pm}(0)/T^{\pm}(0)$, we get

$$1+\gamma^2-\frac{2\gamma}{T^{\pm}(0)}=\pm\int_{-\infty}^{\infty}dx\ P(x)f_l^{[0]}(0,x)^2,$$

which gives us (5.3). Then, using (5.3) in (5.8) we obtain (5.4) and (5.5).

In the exceptional case, since $\mathbf{S}^{\pm}(0)$ is real valued, from (5.8) it is seen that $\mathbf{S}^{\pm}(0)$ is a unitary matrix if and only if $R^{\pm}(0)=-L^{\pm}(0)$. By (5.4) and (5.5), this occurs when the integral $\int_{-\infty}^{\infty}dx\ P(x)f_l^{[0]}(0,x)^2$ vanishes in which case we have $\mathbf{S}^{\pm}(0)=\mathbf{S}^{[0]}(0)$ and $\det\mathbf{S}^{\pm}(0)=1$.

From the discussion above and Theorem 5.2 we obtain:

Proposition 5.3: Assume that $P\in L^1(\mathbf{R})$ and $Q\in L_1^1(\mathbf{R})$ in the generic case and that $P,Q\in L_1^1(\mathbf{R})$ in the exceptional case. If any one of the quantities $1/T^{\pm}(k)$, $R^{\pm}(k)/T^{\pm}(k)$, $L^{\pm}(k)/T^{\pm}(k)$ is discontinuous at $k=0$, then all six are discontinuous at $k=0$ and we are in the generic case. If any one of the quantities $1/T^{\pm}(k)$, $R^{\pm}(k)/T^{\pm}(k)$, $L^{\pm}(k)/T^{\pm}(k)$ is continuous at $k=0$, then all six are continuous at $k=0$ and we are in the exceptional case. Moreover, the three quantities $T^{+}(k)$, $R^{+}(k)$, $L^{+}(k)$ [or $T^{-}(k)$, $R^{-}(k)$, $L^{-}(k)$] are all continuous on $\mathbf{R}$, or they are all discontinuous on $\mathbf{R}$.

VI. LARGE-*k* ANALYSIS OF SCATTERING COEFFICIENTS

In this section we analyze the large-k asymptotics of $\mathbf{S}^{\pm}(k)$. Similar results were obtained under stronger conditions on $P(x)$ and $Q(x)$ [see, e.g., Ref. 2 in the case with imaginary $P(x)$].

Theorem 6.1: Assume $P,Q\in L^1(\mathbf{R})$. Then

$$\frac{1}{T^{\pm}(k)}\,e^{\pm p}=1+\mathrm{o}(1),\quad k\to\infty\ \text{ in }\ \overline{\mathbf{C}^{+}}, \tag{6.1}$$

$$\frac{R^{\pm}(k)}{T^{\pm}(k)}=\mathrm{o}(1),\quad \frac{L^{\pm}(k)}{T^{\pm}(k)}=\mathrm{o}(1),\quad k\to\pm\infty, \tag{6.2}$$

where p is the constant defined in (3.2).

Proof: From (4.2) using (3.3) and (3.4), we obtain

$$\frac{2ik}{T^{\pm}(k)}\,e^{\pm p}=[2ik\pm P(x)]\,\eta_l^{\pm}(k,x)\,\eta_r^{\pm}(k,x)+\eta_l^{\pm\prime}(k,x)\,\eta_r^{\pm}(k,x)-\eta_l^{\pm}(k,x)\,\eta_r^{\pm\prime}(k,x). \tag{6.3}$$

Now (6.1) follows from (3.7), (3.8), and (6.3). Similarly, using (3.3), (3.4), and (4.4), we have

$$-\frac{2ikR^{\pm}(k)}{T^{\pm}(k)}=e^{-2ikx\mp p\pm 2\zeta}[\,\eta_r^{\pm}(k,x);\eta_l^{\mp}(-k,x)\,],\quad k\in\mathbf{R}, \tag{6.4}$$

and the first relation in (6.2) follows by using (3.7) and (3.8) in (6.4). The proof of the second relation in (6.2) is analogous, using (4.3). ■

Note that from (6.1) it follows that e^{p} is known when either of $T^{\pm}(k)$ is known. From Proposition 4.1 and Theorem 6.1, we have:

Corollary 6.2: Assume $P,Q\in L^1(\mathbf{R})$. If $1/T^{\pm}(k)$ does not vanish for $k\in\mathbf{R}$, then its number of zeros in $\mathbf{C}^{+}$ is finite.

VII. PERTURBATION OF SCATTERING COEFFICIENTS

In this section we establish the stability of $1/T^+(k)$, $R^+(k)/T^+(k)$, and $L^+(k)/T^+(k)$ under small perturbations of P and Q in the norm of either $L^1(\mathbf{R})$ or $L^1_1(\mathbf{R})$. We will not state the results for $R^+(k)/T^+(k)$, since they are identical to those for $L^+(k)/T^+(k)$. An application of these results will be given in Sec. IX.

Given two sets of potentials $P_j(x)$ and $Q_j(x)$ with $j=1,2$, we consider the generalized Schrödinger equations

$$\psi_j^{+\prime\prime}(k,x)+k^2\psi_j^+(k,x)=[ikP_j(x)+Q_j(x)]\psi_j^+(k,x), \quad x\in\mathbf{R}, \tag{7.1}$$

and denote their corresponding Faddeev solutions by $m^+_{l;j}(k,x)$ and $m^+_{r;j}(k,x)$, their transmission coefficients by $T_j^+(k)$, and their reflection coefficients from the right and from the left by $R_j^+(k)$ and $L_j^+(k)$, respectively.

Proposition 7.1: Assume $P_j, Q_j\in L^1(\mathbf{R})$ for $j=1,2$. Then for $k\in\overline{\mathbf{C}^+}$ with $|k|\geq 1$, we have

$$\left|\frac{1}{T_1^+(k)}-\frac{1}{T_2^+(k)}\right|\leq C(\|P_1-P_2\|_1+\|Q_1-Q_2\|_1), \tag{7.2}$$

and for $k\in\mathbf{R}$ with $|k|\geq 1$, we have

$$\left|\frac{L_1^+(k)}{T_1^+(k)}-\frac{L_2^+(k)}{T_2^+(k)}\right|\leq C(\|P_1-P_2\|_1+\|Q_1-Q_2\|_1). \tag{7.3}$$

Proof: First, by iterating (2.1) and using (2.3), we obtain

$$|m^+_{l;1}(k,x)-m^+_{l;2}(k,x)|\leq C_1(\|P_1-P_2\|_1+\|Q_1-Q_2\|_1), \tag{7.4}$$

for some constant C_1. Furthermore, from (1.3) and (2.1) we obtain

$$\frac{1}{T^\pm(k)}=1-\frac{1}{2ik}\int_{-\infty}^{\infty}dy\ [\pm ikP(y)+Q(y)]m_l^\pm(k,y), \tag{7.5}$$

$$\frac{L^\pm(k)}{T^\pm(k)}=\frac{1}{2ik}\int_{-\infty}^{\infty}dy\ e^{-2iky}[\pm ikP(y)+Q(y)]m_l^\pm(k,y). \tag{7.6}$$

Now using (7.4) in (7.5) we get (7.2). The proof of (7.3) is similarly obtained by using (7.4) and (7.6). ■

Proposition 7.2: Assume $P_j\in L^1(\mathbf{R})$ and $Q_j\in L^1_1(\mathbf{R})$ for $j=1,2$. Then, for $k\in\overline{\mathbf{C}^+}$ with $|k|\leq 1$, we have

$$\left|\left(\frac{k}{T_1^+(k)}-\frac{k}{T_2^+(k)}\right)\right|\leq C(\|P_1-P_2\|_1+\|Q_1-Q_2\|_{1,1}), \tag{7.7}$$

and for $k\in\mathbf{R}$ with $|k|\leq 1$, we have

$$\left|\left(\frac{kL_1^+(k)}{T_1^+(k)}-\frac{kL_2^+(k)}{T_2^+(k)}\right)\right|\leq C(\|P_1-P_2\|_1+\|Q_1-Q_2\|_{1,1}). \tag{7.8}$$

Proof: Iterating (2.1) with the help of (2.4) and the inequality

$$\frac{1+\max\{0,-y\}}{1+\max\{0,-x\}}(y-x)\leq 1+|y|, \quad y\geq x, \tag{7.9}$$

we obtain

$$|km^+_{l;j}(k,x)|\leq C_1, \quad |k|\leq 1 \tag{7.10}$$

$$|m^+_{l;1}(k,x)-m^+_{l;2}(k,x)|\leq C_2[1+\max\{0,-x\}](\|P_1-P_2\|_1+\|Q_1-Q_2\|_{1,1}), \tag{7.11}$$

$$|km^+_{l;1}(k,x)-km^+_{l;2}(k,x)|\leq C_3(\|P_1-P_2\|_1+\|Q_1-Q_2\|_{1,1}), \quad |k|\leq 1, \tag{7.12}$$

for some constants C_1, C_2, and C_3. Then (7.7) and (7.8) follow from using (2.4), (7.10)–(7.12) in (7.5) and (7.6). ■

Proposition 7.3: Assume $P_j, Q_j \in L^1_1(\mathbf{R})$ for $j=1,2$ and $Q_1(x)=Q_2(x)$. Then, we have

$$\left|\frac{1}{T^+_1(k)}-\frac{1}{T^+_2(k)}\right|\leq C\|P_1-P_2\|_{1,1}, \quad k\in\overline{\mathbf{C}^+}, \tag{7.13}$$

$$\left|\frac{L^+_1(k)}{T^+_1(k)}-\frac{L^+_2(k)}{T^+_2(k)}\right|\leq C\|P_1-P_2\|_{1,1}, \quad k\in\mathbf{R}. \tag{7.14}$$

Proof: First from (2.4), (7.9), and (2.1) we get

$$|m^+_{l;1}(k,x)-m^+_{l;2}(k,x)|\leq C_1|k|[1+\max\{0,-x\}]\|P_1-P_2\|_{1,1}, \tag{7.15}$$

for some constant C_1. Using (2.4), (7.11), and (7.15) in (7.5) and (7.6) we obtain (7.13) and (7.14). ■

VIII. BOUND STATES AND JORDAN CHAINS

Recall that the bound states of (1.1) are its nontrivial solutions belonging to $L^2(\mathbf{R})$. In this section we show that the zeros of $1/T^+(k)$ in $\mathbf{C}^+$ correspond to the bound states of (1.1). We also analyze the order of each zero of $1/T^+(k)$ in $\mathbf{C}^+$ in terms of Jordan chains of the differential operator $\mathbf{W}(k)$ defined in (8.3).

Proposition 8.1: Assume $P, Q \in L^1(\mathbf{R})$. A point $k_0 \in \mathbf{C}^+$ corresponds to a bound state of (1.1) if and only if $1/T^+(k_0)=0$. If $k_0 \in \mathbf{R}\backslash\{0\}$ and $1/T^+(k_0)=0$, then k_0 does not correspond to a bound state of (1.1); if we further assume $Q \in L^1_1(\mathbf{R})$, then $k=0$ cannot correspond to a bound state even when $1/T^+(0)=0$.

Proof: The first assertion follows from (4.2) and Theorem 2.1 (i). For $k_0 \in \mathbf{R}\backslash\{0\}$ every nontrivial solution of (1.1) has the asymptotic form $c_+e^{ik_0x}+c_-e^{-ik_0x}+\mathrm{o}(1)$ as $x\to+\infty$, with the constants c_+ and c_- not both equal to zero, and hence cannot be in $L^2(\mathbf{R})$. If $Q \in L^1_1(\mathbf{R})$, then $k_0=0$ cannot be a bound state because any nontrivial solution of (1.1) for $k=0$ has the asymptotic form $c_1x[1+o(1)]+c_2+\mathrm{o}(1)$ as $x\to+\infty$, with c_1 and c_2 not both equal to zero. Hence, the proof is complete. ■

Next we analyze multiple poles of $T^+(k)$. Let us differentiate (1.1) with $\psi=f^+_l(k,x)$ or $\psi=f^+_r(k,x)$ with respect to k repeatedly. Defining

$$g^+_{l,n}(k,x)=\frac{1}{n!}\left(\frac{\partial}{\partial k}\right)^n f^+_l(k,x), \quad g^+_{r,n}(k,x)=\frac{1}{n!}\left(\frac{\partial}{\partial k}\right)^n f^+_r(k,x), \quad n=0,1,2,..., \tag{8.1}$$

and $g^+_{l,n}(k,x)=g^+_{r,n}(k,x)=0$ for $n=-1,-2,...$, we obtain the coupled system of differential equations

$$\begin{aligned} &g^{+\prime\prime}_{l,n}(k,x)+k^2g^+_{l,n}(k,x)+2kg^+_{l,n-1}(k,x)+g^+_{l,n-2}(k,x)\\ &\quad=[ikP(x)+Q(x)]g^+_{l,n}(k,x)+iP(x)g^+_{l,n-1}(k,x),\\ &g^{+\prime\prime}_{r,n}(k,x)+k^2g^+_{r,n}(k,x)+2kg^+_{r,n-1}(k,x)+g^+_{r,n-2}(k,x)\\ &\quad=[ikP(x)+Q(x)]g^+_{r,n}(k,x)+iP(x)g^+_{r,n-1}(k,x). \end{aligned} \tag{8.2}$$

Defining the differential operator

$$\mathbf{W}(k)=-k^2-\frac{d^2}{dx^2}+ikP+Q, \tag{8.3}$$

so that $\dot{\mathbf{W}}(k)=-2k+iP$ and $\ddot{\mathbf{W}}(k)=-2\mathbf{I}$, we obtain the system of linear equations

$$\mathbf{T}(k)\mathbf{g}_l^+(k,x)=\mathbf{0}, \tag{8.4}$$

where $\mathbf{0}$ is the zero column vector of m components, $\mathbf{g}_l^+(k,x)$ is the column vector

$$[g_{l,m-1}^+(k,x),\ldots,g_{l,0}^+(k,x)]^t,$$

and $\mathbf{T}(k)$ is the $m\times m$ Toeplitz matrix given by

$$\mathbf{T}(k)=\begin{bmatrix} \mathbf{W}(k) & \dot{\mathbf{W}}(k) & \frac{1}{2}\ddot{\mathbf{W}}(k) & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\ 0 & \mathbf{W}(k) & \dot{\mathbf{W}}(k) & \frac{1}{2}\ddot{\mathbf{W}}(k) & 0 & 0 & \cdots & 0 & 0 & 0 \\ 0 & 0 & \mathbf{W}(k) & \dot{\mathbf{W}}(k) & \frac{1}{2}\ddot{\mathbf{W}}(k) & 0 & \cdots & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & 0 & 0 & \cdots & 0 & \mathbf{W}(k) & \dot{\mathbf{W}}(k) \\ 0 & 0 & 0 & 0 & 0 & 0 & \cdots & 0 & 0 & \mathbf{W}(k) \end{bmatrix}.$$

Using the Leibnitz formula for repeated derivatives of products, we find from (4.2)

$$\frac{1}{n!}\left(\frac{d}{dk}\right)^n\frac{-2ik}{T^+(k)}=\sum_{j=0}^{n}[g_{l,j}^+(k,x);g_{r;n-j}^+(k,x)]. \tag{8.5}$$

We call $k_0\in\mathbf{C}^+$ an eigenvalue of $\mathbf{W}(k)$ if there exists a nontrivial $\phi\in L^2(\mathbf{R})$ such that $\mathbf{W}(k_0)\phi=0$. Because of Proposition 8.1, this is equivalent to $1/T^+(k_0)=0$. Further, ϕ is called an eigenfunction of $\mathbf{W}(k)$ corresponding to the eigenvalue k_0. More generally,[19] if k_0 is an eigenvalue of $\mathbf{W}(k)$, then the string of functions $\phi_0,\ldots,\phi_{m-1}$ in $L^2(\mathbf{R})$ is called a Jordan chain of length m corresponding to the eigenvalue k_0 if $\phi_0\neq 0$ and (8.4) holds with $[g_{l,m-1}^+(k_0,x),\ldots,g_{l,0}^+(k_0,x)]^t$ replaced by the column vector $[\phi_{m-1}(k_0,x),\ldots,\phi_0(k_0,x)]^t$.

Proposition 8.2: Assume $P,Q\in L^1(\mathbf{R})$ and let $k_0\in\mathbf{C}^+$ be an eigenvalue of $\mathbf{W}(k)$. If $\{g_{l,j}^+(k_0,\cdot)\}_{j=0}^{m-1}$ is a Jordan chain of $\mathbf{W}(k)$ of length m at the eigenvalue k_0, then for $n=0,1,\ldots,m-1$, we have as $x\to\pm\infty$

$$g_{l,n}^+(k_0,x)=\mathrm{O}[(1+|x|)^n e^{-|x|\mathrm{Im}\,k_0}],\quad g_{r,n}^+(k_0,x)=\mathrm{O}[(1+|x|)^n e^{-|x|\mathrm{Im}\,k_0}], \tag{8.6}$$

$$g_{l,n}^{+\prime}(k_0,x)=\mathrm{O}[(1+|x|)^n e^{-|x|\mathrm{Im}\,k_0}],\quad g_{r,n}^{+\prime}(k_0,x)=\mathrm{O}[(1+|x|)^n e^{-|x|\mathrm{Im}\,k_0}]. \tag{8.7}$$

Proof: If $k_0\in\mathbf{C}^+$ is an eigenvalue of $\mathbf{W}(k)$, by Proposition 8.1 we have $1/T^+(k_0)=0$. Hence $f_l^+(k_0,x)$ and $f_r^+(k_0,x)$ are linearly dependent, and thus we need to prove (8.6) and (8.7) only for $g_{l,n}^+(k_0,x)$ and $g_{l,n}^{+\prime}(k_0,x)$. For $n=0$ these follow from Theorem 2.1 (i). The following argument used to prove (8.6) and (8.7) for $n=m-1$ can be used recursively for $n=1,\ldots,m-2$. Note that, for each $k\in\mathbf{C}^+$, (1.1) has[20] an unbounded solution $X(k,x)$ such that

$$X(k,x)=\mathrm{O}(e^{|x|\mathrm{Im}\,k}),\quad X'(k,x)=\mathrm{O}(e^{|x|\mathrm{Im}\,k}),\quad x\to\pm\infty. \tag{8.8}$$

Let us choose $X(k_0,x)$ such that $[f_l^+(k_0,x);X(k_0,x)]=1$. Let us consider (8.2) as a second-order linear, nonhomogeneous differential equation for $g_{l,m-1}^+(k_0,x)$ and solve it by variation of parameters using the linearly independent solutions $f_l^+(k_0,x)$ and $X(k_0,x)$ of (1.1). We obtain

$$g_{l,m-1}^+(k_0,x)=a_{m-1}f_l^+(k_0,x)+b_{m-1}X(k_0,x)-\int_0^x dy([iP(y)-2k_0]g_{l,m-2}^+(k_0,y)$$
$$-g_{l,m-3}^+(k_0,y))[f_l^+(k_0,x)X(k_0,y)-f_l^+(k_0,y)X(k_0,x)], \tag{8.9}$$

with arbitrary constants a_{m-1} and b_{m-1}. Since $g_{l,n}(k_0,\cdot)\in L^2(\mathbf{R})$ for $n=0,1,\ldots, m-2$ and $X(k_0,x)$ is unbounded as $x\to\pm\infty$, the term proportional to $X(k_0,x)$ in (8.9) must vanish. Thus we must have

$$b_{m-1}+\int_0^\infty dy([iP(y)-2k_0]g^+_{l,m-2}(k_0,y)-g^+_{l,m-3}(k_0,y))f^+_l(k_0,y)=0,$$

$$b_{m-1}-\int_{-\infty}^\infty dy([iP(y)-2k_0]g^+_{l,m-2}(k_0,y)-g^+_{l,m-3}(k_0,y))f^+_l(k_0,y)=0,$$

and hence

$$\int_{-\infty}^\infty dy([iP(y)-2k_0]g^+_{l,m-2}(k_0,y)-g^+_{l,m-3}(k_0,y))f^+_l(k_0,y)=0. \tag{8.10}$$

Using (8.10), we can write (8.9) as

$$g^+_{l,m-1}(k_0,x)=A(k_0,x)X(k_0,x)+f^+_l(k_0,x)\times\left[a_{m-1}-\int_0^x dy([iP(y)-2k_0]g^+_{l,m-2}(k_0,y)-g^+_{l,m-3}(k_0,y))X(k_0,y)\right], \tag{8.11}$$

where we have

$$A(k_0,x)=\begin{cases}\displaystyle\int_{-\infty}^x dy([iP(y)-2k_0]g^+_{l,m-2}(k_0,y)-g^+_{l,m-3}(k_0,y))f^+_l(k_0,y), & x\leqslant 0,\\ \displaystyle\int_x^\infty dy([iP(y)-2k_0]g^+_{l,m-2}(k_0,y)-g^+_{l,m-3}(k_0,y))f^+_l(k_0,y), & x\geqslant 0.\end{cases} \tag{8.12}$$

Using (8.6) for $n=0,1,\ldots, m-2$, (8.8), and (8.12), we obtain (8.6) for $g^+_{l,m-1}(k_0,x)$. Differentiating (8.11) and using (8.10), we obtain

$$g^{+\prime}_{l,m-1}(k_0,x)=[a_{m-1}-I_1(x)]f^{+\prime}_l(k_0,x)+X'(k_0,x)I_2(x),$$

where

$$I_1(x)=\int_0^x dy([iP(y)-2k_0]g^+_{l,m-2}(k_0,y)-g^+_{l,m-3}(k_0,y))X(k_0,y),$$

$$I_2(x)=\int_{-\infty}^x dy([iP(y)-2k_0]g^+_{l,m-2}(k_0,y)-g^+_{l,m-3}(k_0,y))f^+_l(k_0,y).$$

Finally, we obtain (8.7) for $g^{+\prime}_{l,m-1}(k_0,x)$ by using (8.6) for $n=0,1,\ldots, m-2$, (8.8), and (8.12).■

Proposition 8.3: Assume $P,Q\in L^1(\mathbf{R})$ and let $k_0\in\mathbf{C}^+$ be an eigenvalue of $\mathbf{W}(k)$. Then for $n=0,1,\ldots, m-1$, we have

$$\int_{-\infty}^\infty dy([iP(y)-2k_0]g^+_{l,n-1}(k_0,y)-g^+_{l,n-2}(k_0,y))f^+_l(k_0,y)=0 \tag{8.13}$$

if and only if $\{g^+_{l,j}(k_0,\cdot)\}_{j=0}^{m-1}$ is a Jordan chain of $\mathbf{W}(k)$ of length m corresponding to the eigenvalue k_0.

Proof: If (8.13) holds for $n=1$, then we must have $f^+_l(k_0,\cdot)\in L^2(\mathbf{R})$; from Proposition 8.2 and its proof it is seen that $f^+_l(k_0,\cdot)\in L^2(\mathbf{R})$ only if $g^+_{l,0}(k_0,x)=f^+_l(k_0,x)$ is an eigenvector of $\mathbf{W}(k)$. Recursively, we can show that $g^+_{l,n}$ given in (8.1) satisfies (8.4), (8.6), and (8.7), and hence

$g^+_{l,n}(k_0,\cdot)\in L^2(\mathbf{R})$ for $n=1,...,m-1$. Thus $\{g^+_{l,j}(k_0,\cdot)\}^{m-1}_{j=0}$ is a Jordan chain of $\mathbf{W}(k)$ of length m corresponding to the eigenvalue k_0. The converse is proved by proceeding recursively as in the proof of Proposition 8.2 leading to (8.10). ■

Theorem 8.4: Assume $P,Q\in L^1(\mathbf{R})$ and let $k_0\in\mathbf{C}^+$. Then the following four statements are equivalent:

(a) $\mathbf{W}(k)$ has a Jordan chain of length m corresponding to the eigenvalue k_0.
(b) $\{g^+_{l,j}(k_0,\cdot)\}^{m-1}_{j=0}$ is a Jordan chain of $\mathbf{W}(k)$ of length m corresponding to the eigenvalue k_0.
(c) $\{g^+_{r,j}(k_0,\cdot)\}^{m-1}_{j=0}$ is a Jordan chain of $\mathbf{W}(k)$ of length m corresponding to the eigenvalue k_0.
(d) $1/T^+(k)$ has a zero at k_0 of order at least m.

Proof: Clearly (b) implies (a). Now assume (a) holds and let $\{\phi_j\}^{m-1}_{j=0}$ be a Jordan chain of $\mathbf{W}(k)$ of length m at the eigenvalue k_0. Then ϕ_0 must be proportional to $f^+_l(k_0,x)$ and $f^+_r(k_0,x)$ because the latter two are linearly dependent and $\phi_0(k_0,x)$ is a solution of (1.1) for $k=k_0$. Thus we have $\mathbf{W}(k_0)g^+_{l,0}(k_0,x)=0$ and consequently (8.2) is satisfied for $n=0,1,...,m-1$. Hence (b) holds.

Note that (b) and (c) are equivalent because, if $\mathbf{W}(k_0)g^+_{l,0}(k_0,x)=0$ for some $k_0\in\mathbf{C}^+$ and $g^+_{l,0}(k_0,\cdot)\in L^2(\mathbf{R})$, by Proposition 8.1 we must have $1/T^+(k_0)=0$ and hence $g^+_{r,0}(k_0,x)$ must be a constant multiple of $g^+_{l,0}(k_0,x)$.

If (b) holds, then (8.6) and (8.7) must hold for $n=0,1,...,m-1$ because of Proposition 8.2. Then, for $n=0,1,...,m-1$, by evaluating the right-hand side of (8.5) at $x=-\infty$ or at $x=+\infty$, we find that its left-hand side must be zero and thus (d) holds. Now assume that (d) holds and let us show that (b) is true. By Proposition 8.3 it is sufficient to show that (8.13) is satisfied for $n=0,1,...,m-1$. We will do this recursively. First notice that (8.13) trivially holds for $n=0$ because $g^+_{l,-1}(k_0,x)=g^+_{l,-2}(k_0,x)=0$ and that (8.6) and (8.7) hold for $g^+_{l,0}$ and $g^{+\prime}_{l,0}$, respectively, because $1/T^+(k_0)=0$ and thus $f^+_l(k_0,x)$ is exponentially decaying as $|x|\to\infty$. For $n=1,...,m-2$, the proofs of (8.13) and of (8.6) and (8.7) for $g^+_{l,n}$ and $g^{+\prime}_{l,n}$, respectively, are similar to the case when $n=m-1$. Thus, it suffices to give the proofs for $n=m-1$ by assuming that these equations hold for $n=1,...,m-2$. Using (1.1) for $g^+_{r,0}(k_0,x)$ and (8.2) for $g^+_{l,m-1}(k_0,x)$, we obtain the Wronskian relation

$$-\frac{d}{dx}[g^+_{l,m-1}(k_0,x);g^+_{r,0}(k_0,x)]=([iP(x)-2k_0]g^+_{l,m-2}(k_0,x)-g^+_{l,m-3}(k_0,x))g^+_{r,0}(k_0,x). \tag{8.14}$$

In a similar way, we obtain

$$\frac{d}{dx}[g^+_{l,0}(k_0,x);g^+_{r,m-1}(k_0,x)]=([iP(x)-2k_0]g^+_{r,m-2}(k_0,x)-g^+_{r,m-3}(k_0,x))g^+_{l,0}(k_0,x). \tag{8.15}$$

Integrating (8.14) and (8.15) we get

$$\int_{-\infty}^{\infty}dy\ ([iP(y)-2k_0]g^+_{l,m-2}(k_0,y)-g^+_{l,m-3}(k_0,y))g^+_{r,0}(k_0,y)$$
$$=\lim_{x\to-\infty}[g^+_{l,m-1}(k_0,x);g^+_{r,0}(k_0,x)]-\lim_{x\to+\infty}[g^+_{l,m-1}(k_0,x);g^+_{r,0}(k_0,x)], \tag{8.16}$$

$$\int_{-\infty}^{\infty}dy\ ([iP(y)-2k_0]g^+_{r,m-2}(k_0,y)-g^+_{r,m-3}(k_0,y))g^+_{l,0}(k_0,y)$$
$$=\lim_{x\to+\infty}[g^+_{l,0}(k_0,x);g^+_{r,m-1}(k_0,x)]-\lim_{x\to-\infty}[g^+_{l,0}(k_0,x);g^+_{r,m-1}(k_0,x)]. \tag{8.17}$$

Because (8.6) and (8.7) hold for $n=0,1,...,m-2$, we have

$$\lim_{x\to\pm\infty}\sum_{j=1}^{m-2}[g^+_{l,j}(k_0,x);g^+_{r;m-j}(k_0,x)]=0. \tag{8.18}$$

Since $1/T^+(k_0)$ is assumed to have a zero of order at least m, using (8.5) for $n=m-1$ and (8.18), we obtain

$$\lim_{x\to\pm\infty}([g^+_{l,0}(k_0,x);g^+_{r,m-1}(k_0,x)]+[g^+_{l,m-1}(k_0,x);g^+_{r,0}(k_0,x)])=0. \tag{8.19}$$

Using the linear dependence of $g^+_{l,0}(k_0,x)$ and $g^+_{r,0}(k_0,x)$ and the exponential decay of $g^+_{l,m-1}(k_0,x)$ as $x\to+\infty$ and of $g^+_{r,m-1}(k_0,x)$ as $x\to-\infty$, we first conclude that

$$\lim_{x\to+\infty}[g^+_{l,m-1}(k_0,x);g^+_{r,0}(k_0,x)]=0,\quad \lim_{x\to-\infty}[g^+_{l,0}(k_0,x);g^+_{r,m-1}(k_0,x)]=0. \tag{8.20}$$

Now, from (8.19) and (8.20) we see that

$$\lim_{x\to-\infty}[g^+_{l,m-1}(k_0,x);g^+_{r,0}(k_0,x)]=0,\quad \lim_{x\to+\infty}[g^+_{l,0}(k_0,x);g^+_{r,m-1}(k_0,x)]=0, \tag{8.21}$$

and thus using (8.20) and (8.21) in (8.16) and (8.17), we get

$$\int_{-\infty}^{\infty}dy\ ([iP(y)-2k_0]g^+_{l,m-1}(k_0,y)-g^+_{l,m-2}(k_0,y))g^+_{r,0}(k_0,y)=0.$$

Thus (8.13) is proved for $n=m-1$, and hence (b) holds. ■

IX. BOUND STATES AND POLES OF $T^+(k)$

In this section we further analyze the poles of $T^+(k)$ in $\mathbf{C}^+$. We show that such poles cannot occur in certain regions in $\mathbf{C}^+$ determined in terms of the constants defined in (9.1). When $P(x)\leqslant 0$, we show that such poles are confined to a certain interval on the positive imaginary axis. We analyze the change in the number of bound states when P and Q are perturbed. In the generic case we find that the number of bound states is unchanged under small perturbations of P and Q; in the exceptional case we find that the number of bound states is unchanged under small perturbations of $P(x)$. When $P(x)\leqslant 0$ we show that the number of bound states is independent of $P(x)$. We also present a Levinson theorem relating the number of bound states to the change in the argument of $T^+(k)$.

Next we obtain some simple conditions on $P(x)$ and $Q(x)$ guaranteeing that there are no bound states outside certain k-regions in $\mathbf{C}^+$ determined by the following parameters:

$$P_{\min}=\operatorname{ess}\inf_{x\in\mathbf{R}}P(x),\quad P_{\max}=\operatorname{ess}\sup_{x\in\mathbf{R}}P(x),\quad Q_{\min}=\operatorname{ess}\inf_{x\in\mathbf{R}}Q(x). \tag{9.1}$$

Let us also define $\beta^*=P_{\max}/2+\sqrt{P^2_{\max}/4-Q_{\min}}$. Note that if $P,Q\in L^1(\mathbf{R})$, then it follows that $P_{\max}\geqslant 0$ with the equality holding if and only if $P(x)\leqslant 0$, that $Q_{\min}\leqslant 0$ with the equality holding if and only if $Q(x)\geqslant 0$, and that $P_{\min}\leqslant 0$ with the equality holding if and only if $P(x)\geqslant 0$. Furthermore, $\beta^*\geqslant P_{\max}$ with the equality holding if and only if $Q(x)\geqslant 0$. Note also that $\beta^*\geqslant 0$ with the equality holding if and only if $P(x)=Q(x)=0$; hence, the case $\beta^*=0$ is trivial.

Theorem 9.1: Assume $P,Q\in L^1(\mathbf{R})$, $P(x)\not\equiv 0$, and $P_{\max}$ is finite. Then for $P_{\max}/2\leqslant \operatorname{Im}k<\beta^*$ the zeros of $1/T^+(k)$ can only occur on the imaginary axis, and all such zeros are simple. If, in addition, $Q_{\min}$ is finite, then there are no zeros of $1/T^+(k)$ in the region $\{k\in\mathbf{C}^+:(\operatorname{Im}k)^2-(\operatorname{Re}k)^2-(\operatorname{Im}k)P_{\max}\geqslant -Q_{\min}\}$. Consequently, $1/T^+(k)$ has no zeros in $\mathbf{C}^+$ satisfying $\operatorname{Im}k\geqslant\beta^*$.

Proof: From (1.1), after using (4.7), we obtain

$$\frac{d}{dx}\{f^+_l(-\overline{k_0},x)f^{+\prime}_l(k_0,x)\}=|f^{+\prime}_l(k_0,x)|^2+[-k_0^2+ik_0P(x)+Q(x)]|f^+_l(k_0,x)|^2. \tag{9.2}$$

If $k_0 \in \mathbf{C}^+$ is a zero of $1/T^+(k)$, then by integrating (9.2) and using (4.7) and Theorem 2.1 (i), we obtain

$$\int_{-\infty}^{\infty} dx\ |f_l^+{}'(k_0,x)|^2 = \int_{-\infty}^{\infty} dx\ [k_0^2 - ik_0 P(x) - Q(x)]|f_l^+(k_0,x)|^2. \tag{9.3}$$

Letting $k_0 = \alpha + i\beta$ and separating the real and imaginary parts in (9.3), we obtain

$$i\alpha \int_{-\infty}^{\infty} dx\ [2\beta - P(x)]|f_l^+(k_0,x)|^2 = 0, \tag{9.4}$$

$$\int_{-\infty}^{\infty} dx\ |f_l^+{}'(k_0,x)|^2 = \int_{-\infty}^{\infty} dx\ [\alpha^2 - \beta^2 + \beta P(x) - Q(x)]|f_l^+(k_0,x)|^2. \tag{9.5}$$

From (9.4) we see that we must have $\alpha = 0$ when $P_{\max} \leqslant 2\beta$, and hence any zero of $1/T^+(k)$ with $\operatorname{Im} k \geqslant P_{\max}/2$ can only occur on the positive imaginary axis. All such zeros are simple; otherwise, a zero of order two or higher would imply (8.13) with $n=1$, i.e., $\int_{-\infty}^{\infty} dx\ [P(x) - 2\operatorname{Im} k_0]|f_l^+(k_0,x)|^2 = 0$, which cannot happen if $\operatorname{Im} k_0 \geqslant P_{\max}/2$. From (9.5) we see that we cannot have $\alpha^2 - \beta^2 + \beta P(x) - Q(x) \leqslant 0$. Hence there are no zeros of $1/T^+(k)$ in $\{\alpha + i\beta \in \mathbf{C}^+ : \beta^2 - \alpha^2 - \beta P_{\max} \geqslant -Q_{\min}\}$. The analysis of the corresponding region in the $\alpha\beta$-plane indicates that there cannot be any zeros of $1/T^+(k)$ on the imaginary axis when $\operatorname{Im} k \geqslant \beta^*$, and hence there cannot be any zeros of $1/T^+(k)$ either on or off the imaginary axis when $\operatorname{Im} k \geqslant \beta^*$. ■

When $P(x) \leqslant 0$, from Theorem 9.1 we obtain the following corollary.

Corollary 9.2: Assume $P(x) \leqslant 0$ and $P, Q \in L^1(\mathbf{R})$. Then, the poles of $T^+(k)$ in $\mathbf{C}^+$ are all purely imaginary and simple. In addition, assume that $Q_{\min}$ defined in (9.1) is finite; then there are no zeros of $1/T^+(k)$ in $\mathbf{C}^+$ for $\operatorname{Im} k \geqslant \sqrt{-Q_{\min}}$.

Theorem 9.3: Assume $Q(x) \equiv 0$ and $P \in L_1^1(\mathbf{R})$. If $\int_{-\infty}^{\infty} dx\ P(x) > 2$, then (1.1) has at least one bound state at $k = i\beta$ for some positive β. If $\int_{-\infty}^{\infty} dx\ |P(x)| \leqslant 2$, then $1/T^+(k)$ has no zeros in $\mathbf{C}^+$.

Proof: When $\int_{-\infty}^{\infty} dx\ P(x) > 2$, from (5.7) we see that $1/T^+(i\beta)$ is negative at $\beta = 0$ and from (6.1) we see that it is positive as $\beta \to +\infty$. Being a real-valued, continuous function of β, $1/T^+(i\beta)$ must have a zero for some positive β. Now let us prove the second statement. Assume $k \in \mathbf{C}^+$ corresponds to a bound state; we can transform (1.1) into

$$\varphi(k,x) = \int_{-\infty}^{\infty} dy\ \mathscr{B}(k;x,y)\varphi(k,y), \tag{9.6}$$

where we have defined

$$\varphi(k,x) = |P(x)|^{1/2}\psi^+(k,x), \quad \mathscr{B}(k;x,y) = \tfrac{1}{2}e^{ik|x-y|}|P(x)|^{1/2}P(y)/|P(y)|^{1/2}.$$

When $P \in L^1(\mathbf{R})$ and $k \in \mathbf{C}^+$, the integral operator in (9.6) is Hilbert–Schmidt with the Hilbert–Schmidt norm

$$\|\mathscr{B}\|_{\mathrm{HS}}^2 = \tfrac{1}{4}\int_{-\infty}^{\infty} dx \int_{-\infty}^{\infty} dy |P(x)| e^{-2|x-y|\operatorname{Im} k} |P(y)|,$$

and hence, if $k \in \mathbf{C}^+$ and $\int_{-\infty}^{\infty} dx\ |P(x)| \leqslant 2$, we have $\|\mathscr{B}\|_{\mathrm{HS}} < 1$. Thus the operator norm of that integral operator is also strictly less than 1 and hence $\varphi = 0$, implying that there cannot be any bound states of (1.1) for $k \in \mathbf{C}^+$. ■

It is already known[9] that if $Q \in L_1^1(\mathbf{R})$, then the number of bound states for (2.6) is finite; let us denote that number by $\mathscr{N}$, and let $i\kappa_1, \ldots, i\kappa_{\mathscr{N}}$ with $0 < \kappa_1 < \ldots < \kappa_{\mathscr{N}}$ denote the zeros of $1/T^{[0]}(k)$ in $\mathbf{C}^+$. In the following, we generalize the second result of Theorem 9.3 to the case $Q(x) \not\equiv 0$.

Theorem 9.4: Assume $P,Q\in L^1_1(\mathbf{R})$. The k-values in $\mathbf{C}^+$ satisfying $\int_{-\infty}^{\infty}dx\ |ikP(x)+Q(x)|\leqslant 2|k|$ cannot be zeros of $1/T^+(k)$. Moreover, there are no zeros of $1/T^+(k)$ in $\mathbf{C}^+\backslash\{i\kappa_1,\ldots,i\kappa_{\mathcal{N}}\}$ satisfying $|T^{[0]}(k)|\|P\|_{1,1}<2e^{-\|Q\|_{1,1}}$.

Proof: Let $k\in\mathbf{C}^+$ correspond to a bound state of (1.1). We can transform (1.1) into (9.6) with

$$\varphi(k,x)=|ikP(x)+Q(x)|^{1/2}\psi^+(k,x),$$

$$\mathscr{B}(k;x,y)=\frac{1}{2ik}\,e^{ik|x-y|}|ikP(x)+Q(x)|^{1/2}\,\frac{[ikP(y)+Q(y)]}{|ikP(y)+Q(y)|^{1/2}}.$$

A sufficient condition for the absence of bound states is $\|\mathscr{B}\|_{\mathrm{HS}}<1$. Proceeding as in the proof of Theorem 9.3, for $k\in\mathbf{C}^+$ we obtain $\|\mathscr{B}\|_{\mathrm{HS}}<\int_{-\infty}^{\infty}dx\ |ikP(x)+Q(x)|/(2|k|)$, and hence there are no zeros of $1/T^+(k)$ at the k-values in $\mathbf{C}^+$ satisfying $\int_{-\infty}^{\infty}dx\ |ikP(x)+Q(x)|\leqslant 2|k|$. In the special case $P(x)\equiv 0$, this implies that there are no bound states when $|k|>\int_{-\infty}^{\infty}dx\ |Q(x)|/2$. To prove the second part of the theorem, we note that the kernel of the resolvent of the operator $[-d^2/dx^2+Q(x)-k^2]^{-1}$ is given by[20]

$$\mathscr{R}(k;x,y)=\frac{\theta(y-x)f_r^{[0]}(k,x)f_l^{[0]}(k,y)+\theta(x-y)f_l^{[0]}(k,x)f_r^{[0]}(k,y)}{[f_l^{[0]}(k,\cdot);f_r^{[0]}(k,\cdot)]},\tag{9.7}$$

where $f_l^{[0]}(k,x)$ and $f_r^{[0]}(k,x)$ are the Jost solutions of (2.6) and $\theta(x)$ is the Heaviside function. As seen from (2.8), the Wronskian in (9.7) is equal to $-2ik/T^{[0]}(k)$, and hence we get

$$\|ik|P(x)|^{1/2}\mathscr{R}(k;x,y)P(y)/|P(y)|^{1/2}\|^2_{\mathrm{HS}}=\tfrac{1}{4}|T^{[0]}(k)|^2C(k),\tag{9.8}$$

where we have defined

$$C(k)=\int_{-\infty}^{\infty}dx\ |P(x)||f_l^{[0]}(k,x)|^2\int_{-\infty}^{x}dy\ |f_r^{[0]}(k,y)|^2|P(y)|$$
$$+\int_{-\infty}^{\infty}dx\ |P(x)||f_r^{[0]}(k,x)|^2\int_{x}^{\infty}dy\ |f_l^{[0]}(k,y)|^2|P(y)|.\tag{9.9}$$

Using (2.1) with $P(x)=0$, we deduce that

$$|f_l^{[0]}(k,x)|\leqslant(1+\max\{0,-x\})e^{-x\ \mathrm{Im}\,k}e^{\int_x^{\infty}dy\ (1+|y|)|Q(y)|},\quad k\in\overline{\mathbf{C}^+},\tag{9.10}$$

$$|f_r^{[0]}(k,x)|\leqslant(1+\max\{0,x\})e^{x\ \mathrm{Im}\,k}e^{\int_{-\infty}^{x}dy\ (1+|y|)|Q(y)|},\quad k\in\overline{\mathbf{C}^+}.\tag{9.11}$$

In (9.9), using (9.10), (9.11), and the estimates $1+\max\{0,\pm x\}\leqslant 1+|x|$ and $e^{\mp 2(x-y)\mathrm{Im}\,k}\leqslant 1$ for $\pm(x-y)\geqslant 0$, we obtain $|C(k)|\leqslant\|P\|^2_{1,1}e^{2\|Q\|_{1,1}}$. Hence the Hilbert–Schmidt norm on the left-hand side of (9.8) is strictly less than 1, provided $|T^{[0]}(k)|<2e^{-\|Q\|_{1,1}}/\|P\|_{1,1}$. Under this condition on k, there is no bound state corresponding to that $k\in\mathbf{C}^+$. ■

Let us denote the number of bound states of (1.1), i.e., the number of zeros of $1/T^+(k)$ in $\mathbf{C}^+$ (including multiplicities) by $N(P,Q)$. In the next two propositions we obtain some stability results for $N(P,Q)$ under certain perturbations of P and Q. As in Sec. VII, we let $T_j^+(k)$ denote the transmission coefficient corresponding to (7.1) for $j=1,2$.

Proposition 9.5: Assume $P_1,P_2\in L^1(\mathbf{R})$, $Q_1,Q_2\in L^1_1(\mathbf{R})$, $1/T_1^+(k)$ does not have any real zeros, and $Q_1(x)$ is a generic potential. If $\|P_1-P_2\|_1+\|Q_1-Q_2\|_{1,1}$ is small, i.e., if (9.13) is satisfied, then

(a) $1/T_2^+(k)$ does not have any real zeros.

(b) $N(P_2,Q_2)=N(P_1,Q_1)$.

(c) If all zeros of $1/T_1^+(k)$ are simple and purely imaginary, so are those of $1/T_2^+(k)$.

Proof: For $a>0$ let Γ_a be the positively oriented contour consisting of the interval $[-a,a]$ and the semicircle $\{k\in\overline{\mathbf{C}^+}:|k|=a\}$, and let us choose a large enough so that all zeros of $1/T_1^+(k)$ in $\mathbf{C}^+$ have an absolute value less than a. Putting $F_j(k)=k/[(k+i)T_j^+(k)]$ for $j=1,2$, from Propositions 7.1 and 7.2 we get

$$\left|\frac{F_1(k)-F_2(k)}{F_1(k)}\right| \leqslant \frac{C}{|F_1(k)|}\,(\|P_1-P_2\|_1+\|Q_1-Q_2\|_{1,1}). \tag{9.12}$$

If $1/T_1^+(k)$ does not have any real zeros, then in the generic case $F_1(k)$ cannot have any real zeros; thus, $F_1(k)$ does not vanish on Γ_a. Moreover, by Proposition 4.1, $F_1(k)$ is continuous and bounded in $\overline{\mathbf{C}^+}$. Hence $\min_{k\in\Gamma_a}|F_1(k)|>0$. Now choosing

$$\|P_1-P_2\|_1+\|Q_1-Q_2\|_{1,1}<\frac{1}{C}\min_{k\in\Gamma_a}\left|\frac{k}{(k+i)T_1^+(k)}\right|, \tag{9.13}$$

from (9.12) we obtain

$$\left|\frac{F_1(k)-F_2(k)}{F_1(k)}\right|<1, \quad k\in\Gamma_a. \tag{9.14}$$

Hence from (9.14) we see $F_2(k)$ cannot vanish on Γ_a, which implies (a). Part (b) follows from (9.14) with the use of Rouché's theorem. Part (c) follows by replacing Γ_a with the union of $N(P_1,Q_1)$ small, positively oriented circles centered at the zeros of $1/T_1^+(k)$ and by applying Rouché's theorem. ■

Proposition 9.6: Assume $Q_1=Q_2=Q$ in (7.1), $1/T_1^+(k)$ does not have any real zeros, $Q(x)$ is an exceptional potential, and $P_1,P_2,Q\in L_1^1(\mathbf{R})$. If $\|P_1-P_2\|_{1,1}$ is small, i.e., if (9.15) is satisfied, then we have

(a) $1/T_2^+(k)$ does not have any real zeros.

(b) $N(P_2,Q)=N(P_1,Q)$.

(c) If all zeros of $1/T_1^+(k)$ are simple and purely imaginary, so are those of $1/T_2^+(k)$.

Proof: We will proceed as in the proof of Proposition 9.5. Let us choose Γ_a as in that proof but define $F_j(k)=1/T_j^+(k)$ for $j=1,2$, instead. Note that $F_1(k)$ is bounded, continuous, and nonzero on Γ_a. From (7.13) we have

$$\left|\frac{F_1(k)-F_2(k)}{F_1(k)}\right|\leqslant C\|P_1-P_2\|_{1,1}.$$

From (9.8) we get

$$\left|\frac{F_1(k)-F_2(k)}{F_1(k)}\right|\leqslant \frac{C}{|F_1(k)|}\,\|P_1-P_2\|_{1,1},$$

and hence by choosing

$$\|P_1-P_2\|_{1,1}<\frac{1}{C}\min_{k\in\Gamma_a}\left|\frac{1}{T_1^+(k)}\right|, \tag{9.15}$$

and proceeding as in the proof of Proposition 9.5, we complete the proof. ■

Theorem 9.7: Assume $P,Q\in L^1(\mathbf{R})$ and $P(x)\leqslant 0$. Then, either $N(P,Q)$ and $N(0,Q)$ are both infinite, or they are both finite and $N(P,Q)=N(0,Q)$. Thus the number of bound states of (1.1) coincides with the number of bound states of (2.6).

Proof: Since $P(x)\leqslant 0$, by Corollary 9.2 we know that the bound states of (1.1) can only occur when k is on the positive imaginary axis. Let us write (1.1) with $k=i\beta$ as two simultaneous equations:

$$-\psi''+V(\beta,x)\psi=E(\beta)\psi, \tag{9.16}$$

$$E(\beta)=-\beta^2, \tag{9.17}$$

where β is considered to be a parameter in the potential $V(\beta,x)=Q(x)-\beta P(x)$ of the Schrödinger equation (9.16), and $E(\beta)$ denotes the corresponding energy for each β. Each bound-state energy $-\kappa_j^2$ of (2.6) gives rise to an eigenvalue branch $E_j(\beta)$. From (9.16) we have

$$E'(\beta)=\frac{\langle \psi,-P\psi\rangle}{\langle \psi,\psi\rangle}, \tag{9.18}$$

where $\langle\cdot,\cdot\rangle$ denotes the usual scalar product on $L^2(\mathbf{R})$. If $P(x)\leqslant 0$, from (9.18) we see that $E'(\beta)\geqslant 0$ and hence each $E_j(\beta)$ is a nondecreasing function of β. Therefore for $\beta\geqslant 0$, the graph of $E_j(\beta)$ must intersect the parabola $E=-\beta^2$ at exactly one point, say $(\beta_j,-\beta_j^2)$, and each $E_j(\beta)$ gives rise to exactly one solution of (9.17). The number $N(P,Q)$ is equal to the number of intersections of the eigenvalue branches $E_j(\beta)$ with the parabola given in (9.17) for $j\geqslant 1$. Since each of the $N(0,Q)$ branches is responsible for exactly one intersection, we conclude that $N(P,Q)=N(0,Q)$. Note that if $Q\in L^1(\mathbf{R})$ but $Q\notin L_1^1(\mathbf{R})$, it is possible that $N(0,Q)=+\infty$, but then we also have $N(P,Q)=+\infty$. ■

If $P,Q\in L^1(\mathbf{R})$ and $P(x)\leqslant 0$, then either $N(P,Q)=+\infty$, in which case the set of bound-state energies of (1.1) consists of a strictly decreasing sequence of negative numbers converging to 0, or $N(P,Q)$ is finite and equal to $\mathcal{N}$, in which case we let $k=i\beta_j$ for $j=1,\ldots,\mathcal{N}$, with $0<\beta_1<\ldots<\beta_{\mathcal{N}}$ denote the zeros of $1/T^+(k)$ in $\mathbf{C}^+$. Since the condition $Q\in L_1^1(\mathbf{R})$ guarantees the finiteness of $N(0,Q)$, from Theorem 9.1 we obtain the following:

Corollary 9.8: Assume $P(x)\leqslant 0$, $Q(x)\geqslant 0$, $P\in L^1(\mathbf{R})$, and $Q\in L_1^1(\mathbf{R})$. Then, there are no zeros of $1/T^+(k)$ in $\overline{\mathbf{C}^+}$.

In the next theorem, when $P(x)\leqslant 0$, using the constant $P_{\min}$ defined in (9.1), we obtain some upper and lower bounds on each bound-state energy of (1.1).

Theorem 9.9: Assume $N(0,Q)$ is finite and nonzero, $P_{\min}$ is finite, $P(x)\leqslant 0$, and $P,Q\in L^1(\mathbf{R})$; let $k=i\kappa_j$ correspond to the bound states of (2.6) for $j=1,\ldots,\mathcal{N}$. Then, the zeros of $1/T^+(k)$ in $\mathbf{C}^+$ occur at $k=i\beta_j$ satisfying $\beta_*\leqslant\beta_j\leqslant\kappa_j$ for $j=1,\ldots,\mathcal{N}$, where $\beta_*=P_{\min}/2+\sqrt{P_{\min}^2/4+\kappa_1^2}$. In particular, $\beta_1\geqslant\beta_*$ and $\beta_{\mathcal{N}}\leqslant\kappa_{\mathcal{N}}$, with the equalities holding if and only if $P(x)=0$.

Proof: At a bound state with $k=i\beta_j$ of (1.1), replacing k_0 in (9.5) by $0+i\beta_j$, we get

$$\int_{-\infty}^{\infty}dx\ f_l^{+\prime}(i\beta_j,x)^2=\int_{-\infty}^{\infty}dx\ [-\beta_j^2+\beta_j P(x)-Q(x)]f_l^+(i\beta_j,x)^2. \tag{9.19}$$

On the other hand, since $-\kappa_{\mathcal{N}}^2$ is the lowest bound-state energy for (2.6), we have

$$-\kappa_{\mathcal{N}}^2\leqslant\frac{\int_{-\infty}^{\infty}dx\ [f_l^{+\prime}(i\beta_j,x)^2+Q(x)f_l^+(i\beta_j,x)^2]}{\int_{-\infty}^{\infty}dx\ f_l^+(i\beta_j,x)^2}, \tag{9.20}$$

with the equality holding if and only if $f_l^{[0]}(i\kappa_{\mathcal{N}},x)$ and $f_l^+(i\beta_j,x)$ are linearly dependent. From (9.19) and (9.20) we obtain

$$-\kappa_{\mathcal{N}}^2\leqslant-\beta_j^2+\beta_j\frac{\int_{-\infty}^{\infty}dx\ P(x)f_l^+(i\beta_j,x)^2}{\int_{-\infty}^{\infty}dx\ f_l^+(i\beta_j,x)^2}. \tag{9.21}$$

Since $P(x)\leqslant 0$, from (9.21) we see that $\beta_j\leqslant\kappa_{\mathcal{N}}$ with the equality holding if and only if $P(x)=0$ and $j=\mathcal{N}$. Thus $\beta_j\in(0,\kappa_{\mathcal{N}}]$ for $j=1,\ldots,\mathcal{N}$. Now let us improve the bounds on β_j. From the proof of Theorem 9.7, recall that each eigenvalue branch $E_j(\beta)$ gives rise to exactly one solution of (9.17) starting with $-\kappa_j^2$ at $\beta=0$ and ending with $-\beta_j^2$ at $\beta=\beta_j$. Since $E_j(\beta)$ is an increasing function of β, we get $-\kappa_j^2=E_j(0)\leqslant E_j(\beta_j)=-\beta_j^2$, and hence $\beta_j\leqslant\kappa_j$. Now consider $E_1(\beta)$, the eigenvalue branch corresponding to β_1. From (9.18) using $P_{\min}\leqslant P(x)$, we obtain $0\leqslant E_1'(\beta)\leqslant -P_{\min}$; more specifically, $0<E_1'(\beta)<-P_{\min}$ unless $P(x)=0$. Since $E_1(0)=-\kappa_1^2$ and $E_1(\beta)$ is nondecreasing, we get $E_1(\beta)\leqslant-\beta P_{\min}-\kappa_1^2$. Thus from the inequality $-\beta_1^2\leqslant-\beta_1P_{\min}-\kappa_1^2$, we get $\beta_1\geqslant\beta_*$. Note that the equality in $\beta_1\geqslant\beta_*$ holds if and only if $P(x)=0$ because $\beta_*\geqslant\kappa_1$ with the equality holding if and only if $P(x)\geqslant 0$. ■

From the proof of Theorem 9.9 we get the following corollary that holds even when (2.6) has infinitely many bound states.

Corollary 9.10: Assume $P,Q\in L^1(\mathbf{R})$ and $P(x)\leqslant 0$, and let $\{\mathscr{E}_j\}$ and $\{\mathscr{E}_j^{[0]}\}$ for $j\geqslant 1$ denote the bound-state energies of (1.1) and (2.6), respectively, ordered such that $\mathscr{E}_j<\mathscr{E}_{j+1}$ and $\mathscr{E}_j^{[0]}<\mathscr{E}_{j+1}^{[0]}$. Then we have $\mathscr{E}_j^{[0]}\leqslant\mathscr{E}_j<0$ for $j\geqslant 1$, and hence the bound-state energies of (1.1) cannot occur below the lowest bound-state energy of (2.6).

Recall that the Levinson theorem[21] relates the number of bound states for the usual Schrödinger equation to the change in the phase of the transmission coefficient. Next we generalize the Levinson theorem to (1.1).

Theorem 9.11: Assume that $P\in L^1(\mathbf{R})$ in the generic case and $P\in L_1^1(\mathbf{R})$ in the exceptional case and that $Q\in L_1^1(\mathbf{R})$, and suppose $1/T^+(k)$ does not have any real zeros. Then the number of bound states of (1.1) is given by

$$\arg\, T^+(0+)=\pi\left[N(P,Q)-\frac{d}{2}\right], \tag{9.22}$$

where $d=0$ in the exceptional case and $d=1$ in the generic case, and $\arg\, T^+(k)$ denotes the continuous branch of the argument of $T^+(k)$ normalized such that $\arg\, T^+(+\infty)=0$.

Proof: For $b>a>0$, let $\Gamma_{a,b}$ be the positively oriented contour consisting of the circular arcs $\{k\in\overline{\mathbf{C}^+}:|k|=a\}$ and $\{k\in\overline{\mathbf{C}^+}:|k|=b\}$ and the segments $[-b,-a]$ and $[a,b]$. Let us choose a and b so that all zeros of $1/T^+(k)$ in $\mathbf{C}^+$ are enclosed by $\Gamma_{a,b}$. By the argument principle we have

$$N(P,Q)=-\frac{1}{2\pi i}\int_{\Gamma_{a,b}}dk\,\frac{\dot{T}^+(k)}{T^+(k)}=-\frac{1}{2\pi}\,\Delta_{\Gamma_{a,b}}[\arg\, T^+(k)], \tag{9.23}$$

where $\Delta_{\Gamma_{a,b}}[\arg\, T^+(k)]$ indicates the change in the argument of $T^+(k)$ when $\Gamma_{a,b}$ is traversed once. This change is independent of a and b, and hence we evaluate it by letting $a\to 0$ and $b\to+\infty$. By Theorem 6.1 the contribution to that change from the large semicircle $\{k\in\overline{\mathbf{C}^+}:|k|=b\}$ vanishes as $b\to+\infty$. In view of (5.2) and (5.3), we see that the contribution from the small semicircle $\{k\in\overline{\mathbf{C}^+}:|k|=a\}$ in the limit $a\to 0$ is equal to 0 in the exceptional case and $-\pi$ in the generic case. Thus the contribution from the interval $(0,+\infty)$ is given by $\arg\, T^+(+\infty)-\arg\, T^+(0+)=-\arg\, T^+(0+)$. By the first equality in (4.10), the contribution from the interval $(-\infty,0)$ is the same. Hence, the right-hand side in (9.23) is equal to $(1/\pi)\arg\, T^+(0+)$ in the exceptional case and $(1/2)+(1/\pi)\arg\, T^+(0+)$ in the generic case, which gives us (9.22). ■

Finally, let us show that in the special case when P and Q have support in a half-line, we can relate the poles of the transmission coefficient to the poles of a reflection coefficient. Since there is no loss of generality in choosing our half-lines as $\mathbf{R}^+=(0,+\infty)$ or $\mathbf{R}^-=(-\infty,0)$ instead of $(a,+\infty)$ or $(-\infty,b)$, respectively, for some constants a and b, we will state the following proposition using $\mathbf{R}^\pm$.

Proposition 9.12: Assume $P(x)=Q(x)=0$ for $x\in\mathbf{R}^-$ and $P,Q\in L^1(\mathbf{R}^+)$. Then $L^+(k)$ is meromorphic in $\mathbf{C}^+$ having poles coinciding with the poles of $T^+(k)$. Furthermore, none of the zeros of $L^+(k)$ coincide with the poles of $T^+(k)$ in $\mathbf{C}^+$. These assertions remain valid if $\mathbf{R}^-$ and $L^+(k)$ are replaced by $\mathbf{R}^+$ and $R^+(k)$, respectively.

Proof: If $P(x)=Q(x)=0$ for $x\in\mathbf{R}^-$, from Theorem 2.1 (i), we see that $f_l^+(k,0)$ and $f_l^{+\prime}(k,0)$ are analytic in $\mathbf{C}^+$. Hence using (1.3) we can conclude that $L^+(k)/T^+(k)$ is analytic in $\mathbf{C}^+$, allowing us to conclude that the poles of $L^+(k)$ and $T^+(k)$ must coincide in $\mathbf{C}^+$. Since $f_l^+(k,0)$ and $f_l^{+\prime}(k,0)$ cannot vanish simultaneously, it follows that $1/T^+(k)$ and $L^+(k)/T^+(k)$ cannot vanish simultaneously in $\mathbf{C}^+$, and hence the zeros of $L^+(k)$ and the poles of $T^+(k)$ cannot coincide in $\mathbf{C}^+$. The proof when P and Q have support in $\mathbf{R}^-$ is obtained in a similar manner. ■

X. EIGENVALUE CURVES AND ZEROS OF JOST SOLUTIONS

In this section we study the zeros of the Jost solutions of (1.1) for a fixed $k\in\overline{\mathbf{C}^+}$ and analyze the number of such zeros in relation to the bound states of (1.1) and (2.6). As in Sec. IX, we let $N(P,Q)$ denote the number of bound states of (1.1). When $P(x)\leqslant 0$ we show that the number of

zeros of the Jost solutions of (1.1) is related to $N(P,Q)$ in a simple manner, and we present some examples showing that this relation does not hold in general. We establish the connection between the results of Sec. VIII on Jordan chains and certain zeros of the Jost solutions of (1.1). This connection uses the eigenvalue branches introduced in the proof of Theorem 9.7. We also show that the number of bound states of (1.1) with real energies is greater than or equal to $N(0,Q)$.

In the first proposition, we collect some results about the oscillation properties of solutions of generalized Schrödinger equations related by inequalities involving the coefficients. Although the methods for proving such results are familiar,[20,22] we include a proof for the convenience of the reader.

Consider the pair of generalized Schrödinger equations

$$\chi_j''(\mu,x)-\mu^2\chi_j(\mu,x)=V_j(\mu,x)\chi_j(\mu,x),\quad \mu\geqslant 0,\quad j=1,2. \tag{10.1}$$

Note that if we let $V_j(\mu,x)=-\mu P(x)+Q(x)$ in (10.1), we get (1.1) for $k=i\mu$.

Proposition 10.1: Assume $V_j(\mu,\cdot)\in L^1(\mathbf{R})$ if $\mu>0$, $V_j(0,\cdot)\in L^1_1(\mathbf{R})$, and $V_1(\mu_2,x)\leqslant V_2(\mu_1,x)$ if $0\leqslant\mu_1\leqslant\mu_2$. Let $\chi_1(\mu_1,x)$ and $\chi_2(\mu_2,x)$ denote two nontrivial solutions of (10.1) with the corresponding coefficients $V_1(\mu_1,x)$ and $V_2(\mu_2,x)$, respectively. Then:

(i) Suppose $\chi_2(\mu_2,x)$ has two successive zeros a and b with $a<b$. If $0\leqslant\mu_1<\mu_2$, then $\chi_1(\mu_1,x)$ has at least one zero in (a,b). If $0\leqslant\mu_1=\mu_2$ and $V_1(\mu_1,x)\not\equiv V_2(\mu_1,x)$ on (a,b), then $\chi_1(\mu_1,x)$ has at least one zero in (a,b). If $0\leqslant\mu_1=\mu_2$, $V_1(\mu_1,x)\equiv V_2(\mu_1,x)$ on (a,b), and $\chi_1(\mu_1,x)$ and $\chi_2(\mu_1,x)$ are linearly independent in (a,b), then $\chi_1(\mu_1,x)$ has exactly one zero in (a,b).

(ii) Suppose $\chi_2(\mu_2,x)$ remains bounded as $x\to+\infty$. Let a denote the largest zero of $\chi_2(\mu_2,x)$, and set $b=+\infty$. Then the assertions of (i) remain true if we replace the interval (a,b) by $(a,+\infty)$.

(iii) If $0\leqslant\mu_1\leqslant\mu_2$, $\chi_2(\mu_2,x)$ is bounded as $x\to+\infty$, and $\chi_1(\mu_1,x)$ has no zeros in $\mathbf{R}$, then $\chi_2(\mu_2,x)$ has no zeros in $\mathbf{R}$ either.

(iv) If $\chi_2(\mu_2,x)$ is bounded as $x\to-\infty$ and a is the smallest zero of $\chi_2(\mu_2,x)$, then the assertion of (iii) holds, and the assertions in (i) remain true if we replace the interval (a,b) by $(-\infty,a)$.

Proof: We will omit the proof of (i) because on a finite interval such results are known (e.g., Theorem 1.1 on p. 208 of Ref. 20). Moreover, our proof of (ii) is easily modified to prove (i). The proof of (iv) is analogous to the proofs of (ii) and (iii), and hence we will only prove (ii) and (iii).

(ii) The proof can be given using contradiction. Without loss of generality we may assume that $\chi_1(\mu_1,x)$ and $\chi_2(\mu_2,x)$ are strictly positive in $(a,+\infty)$. When $b>a$, where a is the largest zero of $\chi_2(\mu_2,x)$, from (10.1) we get

$$\begin{aligned}&\chi_2(\mu_2,b)\chi_1'(\mu_1,b)-\chi_2'(\mu_2,b)\chi_1(\mu_1,b)+\chi_2'(\mu_2,a)\chi_1(\mu_1,a)\\&\quad=\int_a^b dx\,[V_1(\mu_1,x)-V_2(\mu_2,x)+\mu_1^2-\mu_2^2]\chi_1(\mu_1,x)\chi_2(\mu_2,x).\end{aligned} \tag{10.2}$$

Note that, by the asymptotic properties of the solutions and their assumed positivity in the interval $(a,+\infty)$, we have for $\mu_2>0$ and some $c_2>0$

$$\chi_2(\mu_2,x)=c_2e^{-\mu_2x}+o(e^{-\mu_2x})\quad \chi_2'(\mu_2,x)=-c_2\mu_2e^{-\mu_2x}+o(e^{-\mu_2x}),\quad x\to+\infty. \tag{10.3}$$

Furthermore, if $\chi_1(\mu_1,x)$ is unbounded as $x\to+\infty$, then for some $c_1>0$ we have

$$\chi_1(\mu_1,x)=c_1e^{\mu_1x}+o(e^{\mu_1x}),\quad \chi_1'(\mu_1,x)=c_1\mu_1e^{\mu_1x}+o(e^{\mu_1x}),\quad x\to+\infty. \tag{10.4}$$

If $\mu_1=0$ and $\chi_1(0,x)$ is unbounded as $x\to+\infty$, then for some $\tilde{c}_1>0$

$$\chi_1(0,x)=\tilde{c}_1x+o(x),\quad \chi_1'(0,x)=\tilde{c}_1+o(1),\quad x\to+\infty. \tag{10.5}$$

If $\chi_2(0,x)$ is bounded as $x\to+\infty$, then for some $\tilde{c}_2>0$ we have

$$\chi_2(0,x)=\tilde{c}_2+o(1), \quad \chi_2'(0,x)=o(1/x), \quad x\to+\infty. \tag{10.6}$$

Using (10.3)–(10.6) we will let $b\to+\infty$ in (10.2). When $0\leqslant\mu_1\leqslant\mu_2$, the limit as $b\to+\infty$ of the right-hand side of (10.2) exists and is nonpositive; it is equal to zero precisely when $\mu_1=\mu_2$ and $V_1(\mu_1,x)\equiv V(\mu_2,x)$ on $(a,+\infty)$. If $0\leqslant\mu_1<\mu_2$, the limit of the left-hand side of (10.2) is equal to $\chi_2'(\mu_2,a)\chi_1(\mu_1,a)$, which is nonnegative. Hence we have a contradiction, and thus $\chi_1(\mu_1,x)$ must have a zero in $(a,+\infty)$. If $0<\mu_1=\mu_2$ and $\chi_1(\mu_1,x)$ is unbounded, then the limit on the left-hand side of (10.2) is equal to $2c_1c_2\mu_1+\chi_2'(\mu_1,a)\chi_1(\mu_1,a)$, which is strictly positive; the right-hand side is nonpositive and so again we have a contradiction. If $0<\mu_1=\mu_2$ and $\chi_1(\mu_1,x)$ is bounded, then the limit of the left-hand side is equal to $\chi_2'(\mu_2,a)\chi_1(\mu_1,a)$, which is nonnegative. If also $V_1(\mu_1,x)\not\equiv V_2(\mu_2,x)$ on $(a,+\infty)$, then the right-hand side is strictly negative and we have a contradiction. If $V_1(\mu_1,x)\equiv V_2(\mu_2,x)$ on $(a,+\infty)$, then $\chi_1(\mu_1,a)>0$ due to the linear independence of $\chi_1(\mu_1,x)$ and $\chi_2(\mu_2,x)$, and so the left-hand side of (10.2) is strictly positive while its right-hand side is zero. In this case, by (i), there can only be one zero of $\chi_1(\mu_1,x)$ in $(a,+\infty)$. If $0=\mu_1=\mu_2$ and $\chi_1(0,x)$ is unbounded, then because of (10.6) the left-hand side of (10.2) approaches $\tilde{c}_1\tilde{c}_2+\chi_2'(0,a)\chi_1(0,a)$, which is again strictly positive. If $\mu_2=\mu_1=0$ and $\chi_1(0,x)$ is bounded, then the limit of the left-hand side of (10.2) is $\chi_2'(0,a)\chi_1(0,a)$, which is nonnegative. If $V_1(0,x)\not\equiv V_2(0,x)$ on $(a,+\infty)$, then the right-hand side of (10.2) is strictly negative, while if $V_1(0,x)\equiv V_2(0,x)$ on $(a,+\infty)$, then its right-hand side is zero and its left-hand side is strictly positive due to the linear independence of $\chi_1(0,x)$ and $\chi_2(0,x)$. In both cases we arrive at a contradiction. As in (i), if $V_1(0,x)\equiv V_2(0,x)$ on $(a,+\infty)$, we conclude that there is exactly one zero of $\chi_1(0,x)$ in $(a,+\infty)$.

(iii) Suppose $\chi_2(\mu_2,x)$ does have some zeros, the largest of which is a. Then, under the assumptions made in (i) and (ii), it follows that $\chi_1(\mu_1,x)$ has a zero to the right of a, contradicting the assumptions of (iii). The only situation not covered by (i) and (ii) is when $\mu_2=\mu_1$, $V_1(\mu_1,x)\equiv V_2(\mu_2,x)$ on $(a,+\infty)$, and $\chi_1(\mu_1,x)$ and $\chi_2(\mu_1,x)$ are linearly dependent in $(a,+\infty)$, but then $\chi_2(\mu_1,a)=0$ implies $\chi_1(\mu_1,a)=0$, which is again a contradiction. ■

From Proposition 10.1 we obtain the following:

Corollary 10.2: Assume $P,Q\in L^1(\mathbf{R})$ and let $\beta>0$. Suppose that $f_l^+(i\beta,x)$ and $f_r^+(i\beta,x)$ are linearly independent. Then $f_l^+(i\beta,x)$ and $f_r^+(i\beta,x)$ have the same number of zeros and their zeros are separated, i.e., between two successive zeros of $f_l^+(i\beta,x)$ there is a zero of $f_r^+(i\beta,x)$ and vice versa. Moreover, to the right of the largest zero of $f_l^+(i\beta,x)$ there is a zero of $f_r^+(i\beta,x)$, and to the left of the smallest zero of $f_r^+(i\beta,x)$ there is a zero of $f_l^+(i\beta,x)$.

Our next result concerns the zeros of the Jost solutions of (2.6). Since some theorems of this type have already been proved elsewhere (see, e.g., Theorem 14.10 of Ref. 22 or Theorem XIII.8 on p. 90 of Ref. 23), we only comment on certain details that may not be obvious from those references. Recall that $N(0,Q)$ denotes the number of bound states of (2.6).

Proposition 10.3: (i) Suppose $Q\in L^1(\mathbf{R})$ and assume $\beta>0$. Then the number of zeros of $f_l^{[0]}(i\beta,x)$ is equal to the number of bound states of (2.6) with energies contained in the interval $(-\infty,-\beta^2)$.

(ii) Suppose further that $Q\in L_1^1(\mathbf{R})$. Then the number of zeros of $f_l^{[0]}(0,x)$ is equal to $N(0,Q)$.

Proof: (i) Since we only assume $Q\in L^1(\mathbf{R})$, there may be infinitely many bound states of (2.6) with energies accumulating at zero. All such energies are negative, and let us denote them by $-\gamma_j^2$ with $\gamma_j>\gamma_{j+1}>0$ for $j\geqslant 1$. It is known (Theorem 14.10 of Ref. 22) that $f_l^{[0]}(i\gamma_j,x)$ has exactly $(j-1)$ zeros. Hence we only need to consider the zeros of $f_l^{[0]}(i\beta,x)$ when β is not equal to any γ_j. If $\beta>\gamma_1$, then from Proposition 10.1 (iii) with $V_1=V_2=Q$, $\mu_1=\gamma_1$, $\mu_2=\beta$, $\chi_1(\mu_1,x)=f_l^{[0]}(i\gamma_1,x)$, and $\chi_2(\mu_2,x)=f_l^{[0]}(i\beta,x)$, it follows that $f_l^{[0]}(i\beta,x)$ has no zeros. If $\beta\in(\gamma_{j+1},\gamma_j)$, then, by Proposition 10.1 (i) and (ii) with $\mu_1=\beta$ and $\mu_2=\gamma_j$, we observe that $f_l^{[0]}(i\beta,x)$ has at least j zeros. On the other hand, using Proposition 10.1, we can conclude that $f_l^{[0]}(i\beta,x)$ cannot have more than j zeros because the number of its zeros is nondecreasing as β decreases and $f_l^{[0]}(i\gamma_{j+1},x)$ has exactly j zeros. Thus $f_l^{[0]}(i\beta,x)$ has exactly j zeros when $\beta\in(\gamma_{j+1},\gamma_j)$. This proves (i) when $N(0,Q)=+\infty$ because the bound states of (2.6) can only occur when k is on the positive imaginary axis. If $N(0,Q)$ is finite and is denoted by $\mathcal{N}$, then we must still consider the case when $\beta\in(0,\gamma_{\mathcal{N}})$. Then using Lemma 1 on p. 91 of Ref. 23 we conclude

that $f_l^{[0]}(i\beta,x)$ has exactly $\mathcal{N}$ zeros because if it had more than $\mathcal{N}$ zeros one could find a subspace of dimension at least $\mathcal{N}+1$ on which the expectation value of $(-d^2/dx^2+Q-\beta P)$ is less than or equal to $-\beta^2$, and this would imply the existence of at least $(\mathcal{N}+1)$ eigenvalues less than or equal to $-\beta^2$.

(ii) In this case the condition $Q\in L_1^1(\mathbf{R})$ guarantees that $N(0,Q)$ is finite. It only remains to consider the case $\beta=0$. Note that $f_l^{[0]}(0,x)$ cannot have more than $\mathcal{N}$ zeros; this is because $f_l^{[0]}(i\beta,x)$ has exactly $\mathcal{N}$ zeros when β is sufficiently small and by (2.5) we see that as $\beta\to 0$ we have $f_l^{[0]}(i\beta,x)\to f_l^{[0]}(0,x)$ uniformly on compact x-intervals. On the other hand, in (10.1) by setting $\mu_1=0$, $\mu_2=\beta$, $V_1(\mu_1,x)=Q(x)$, $V_2(\mu_2,x)=Q(x)-\beta P(x)$, $V_1(\mu_1,x)=Q(x)$, and $\chi_2(\mu_2,x)=f_l^{[0]}(\beta,x)$, and using Proposition 10.1, we see that $f_l^{[0]}(0,x)$ has at least $\mathcal{N}$ zeros. Hence $f_l^{[0]}(0,x)$ must have exactly $\mathcal{N}$ zeros. ■

If $Q\in L_1^1(\mathbf{R})$, then $N(0,Q)$ is finite and as in Sec. IX we let $k=i\kappa_j$ for $j=1,...,\mathcal{N}$ denote the bound states of (2.6). From Theorems 9.7 and 9.9, when $P\in L^1(\mathbf{R})$, $Q\in L_1^1(\mathbf{R})$, and $P(x)\leqslant 0$, we already know that the bound states of (1.1) occur at $k=i\beta_j$ satisfying $\beta_j\leqslant\kappa_j$ for $j=1,...,\mathcal{N}$. In the next theorem, we extend Proposition 10.3 to (1.1) and analyze the number of zeros of the Jost solutions of (1.1) when k is on the positive imaginary axis.

Theorem 10.4: Assume that $P\in L^1(\mathbf{R})$, $Q\in L_1^1(\mathbf{R})$, and $P(x)\leqslant 0$. Then, for each $\beta\geqslant 0$, the functions $f_l^+(i\beta,x)$ and $f_r^+(i\beta,x)$ have the same number of zeros, and this number is equal to the number of bound states of (1.1) with energies contained in the interval $(-\infty,-\beta^2)$.

Proof: From Proposition 10.1 (i) and (ii), we see that $f_l^+(i\beta,x)$ and $f_r^+(i\beta,x)$ have the same number of zeros. Since $P(x)\leqslant 0$, from the proof of Theorem 9.7 it follows that, for any fixed $\beta>0$, the number of eigenvalues of the operator $(-d^2/dx^2+Q-\beta P)$ below $-\beta^2$ is equal to the number of $E_j(\beta)$-values that lie below $-\beta^2$. Note that if $\beta\in[\beta_j,\beta_{j+1})$ for $j=1,...,\mathcal{N}-1$, then the $(\mathcal{N}-j)$ values $E_{\mathcal{N}}(\beta),E_{\mathcal{N}-1}(\beta),\ldots,E_{j+1}(\beta)$ lie strictly below $-\beta^2$; if $\beta\in[\beta_{\mathcal{N}},+\infty)$ then there are no eigenvalues below $-\beta^2$, and if $\beta\in[0,\beta_1)$ then exactly $\mathcal{N}$ eigenvalues lie below $-\beta^2$. Using Proposition 10.3 when the potential $Q(x)$ in (2.6) is replaced by $Q(x)-\beta P(x)$, we conclude that $f_l^+(i\beta,x)$ has no zeros for $\beta\in[\beta_{\mathcal{N}},+\infty)$, $\mathcal{N}$ zeros for $\beta\in[0,\beta_1)$, and $(\mathcal{N}-j)$ zeros for $\beta\in[\beta_j,\beta_{j+1})$ for $j=1,...,\mathcal{N}-1$. ■

If we weaken the condition $P(x)\leqslant 0$ in Theorem 10.4, the number of bound states may not be easily related to the number of zeros of the Jost solutions, as we will see in Example 11.2. From Proposition 10.1 and Theorem 10.4 we have the following:

Corollary 10.5: Assume that $P,Q\in L^1(\mathbf{R})$ and that $P(x)\leqslant 0$. The zeros of $f_l^+(i\beta_j,x)$ separate the zeros of $f_l^+(i\beta_{j+1},x)$, i.e., between two consecutive zeros of $f_l^+(i\beta_j,x)$ there is exactly one zero of $f_l^+(i\beta_{j+1},x)$, where $k=i\beta_j$ for $j=1,...,\mathcal{N}$ correspond to the bound states of (1.1). Similarly, the zeros of $f_r^+(i\beta_j,x)$ separate the zeros of $f_r^+(i\beta_{j+1},x)$.

When we no longer have $P(x)\leqslant 0$, then there may be bound states of (1.1) with complex energies and $N(P,Q)$ may be larger than $N(0,Q)$. We refer the reader to Examples 11.2 and 11.4. In the next theorem, when $P\in L^1(\mathbf{R})$ and $Q\in L_1^1(\mathbf{R})$, we analyze the bound states of (1.1) when k is on the positive imaginary axis, establish the connection between Theorem 8.4 and the zeros of $f_r^+(i\beta,x)$, and also consider multiple zeros of $1/T^+(k)$ on the positive imaginary axis.

Theorem 10.6: Suppose $P\in L^1(\mathbf{R})$ and $Q\in L_1^1(\mathbf{R})$. Then:

(i) If (2.6) has $\mathcal{N}$ bound states with $\mathcal{N}\geqslant 1$, then (1.1) has at least $\mathcal{N}$ bound states with real (negative) energies.

(ii) $1/T^+(i\beta)$ has a zero of order m at some positive β_0 if and only if the function $E_0(\beta)+\beta^2$ has a zero of order m at β_0, where $E_0(\beta)$ denotes the unique eigenvalue branch of the operator $(-d^2/dx^2+Q-\beta P)$ satisfying $E_0(\beta)\to-\beta_0^2$ as $\beta\to\beta_0$. If $m=1$, then the graph of $E_0(\beta)$ and the graph of the parabola $E=-\beta^2$ intersect with different slopes at β_0. If $m\geqslant 2$ and m is even, then the graphs touch at β_0 but do not cross each other. If $m\geqslant 3$ and m is odd, then the graphs cross smoothly such that at the point of intersection they have the same slope.

(iii) The lowest eigenvalue branch $E_{\mathcal{N}}(\beta)$ satisfies $E''_{\mathcal{N}}(\beta)<0$ for $\beta>0$ unless $P(x)\equiv 0$, in which case $E_{\mathcal{N}}(\beta)$ is a constant. Hence the graph of the lowest eigenvalue branch is concave down if $P(x)\not\equiv 0$.

(iv) The number of zeros of $f_l^+(i\beta,x)$ behaves in the following manner as β is increased from $\beta_0-\epsilon$ to $\beta_0+\epsilon$ when ϵ is sufficiently small: If m is even, then the number of zeros is either constant throughout the interval $(\beta_0-\epsilon,\beta_0+\epsilon)$ or it is constant in $(\beta_0-\epsilon,\beta_0)\cup(\beta_0,\beta_0+\epsilon)$ but

one less at β_0. If m is odd, then the number of zeros either increases or decreases by one as β crosses β_0. The number of zeros of $f_l^+(i\beta,x)$ can only change at β-values corresponding to bound states of (1.1).

Proof: (i) Since we are only interested in the bound states corresponding to $k=i\beta$ for $\beta>0$, we first derive a lower bound for $E_{\mathscr{N}}(\beta)$, which will show that $E_{\mathscr{N}}(\beta)=o(\beta^2)$ as $\beta\to+\infty$. Let us indicate the Fourier transform by a caret:

$$\hat{\psi}(q)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}dx\ e^{iqx}\psi(x),\quad \psi(x)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}dq\ e^{-iqx}\hat{\psi}(q).$$

Then, letting $\|\cdot\|_2$ denote the norm on $L^2(\mathbf{R})$, for $a>0$ we get (cf. Theorem IX.28 of Ref. 24)

$$|\psi(x)|\leqslant\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}dq\ |\hat{\psi}(q)|\leqslant\frac{1}{\sqrt{2a}}\left[\int_{-\infty}^{\infty}dq\ (q^2+a^2)|\hat{\psi}(q)|^2\right]^{1/2}=\frac{1}{\sqrt{2a}}\,(\|\psi'\|_2^2+a^2\|\psi\|_2^2)^{1/2},\tag{10.7}$$

where we have used the Schwarz inequality, $\|\psi\|_2=\|\hat{\psi}\|_2$, $\int_{-\infty}^{\infty}dq/(a^2+q^2)=\pi/a$, and $\hat{\psi}'=-iq\hat{\psi}$. Next we use (10.7) to estimate the quadratic forms $\langle Q\psi,\psi\rangle$ and $\langle P\psi,\psi\rangle$. From (10.7) we obtain

$$\int_{-\infty}^{\infty}dx\ |Q(x)||\psi(x)|^2\leqslant\frac{1}{2a}\,(\|\psi'\|_2^2+a^2\|\psi\|_2^2)\left(\int_{-\infty}^{\infty}dx|Q(x)|\right).\tag{10.8}$$

If $P(x)\equiv0$, then (1.1) and (2.6) become identical, and in this trivial case both equations have exactly $\mathscr{N}$ bound states. Thus there is no loss of generality in assuming $P(x)\not\equiv0$. In order to estimate the integral $\int_{-\infty}^{\infty}dx\ |P(x)||\psi(x)|^2$, we split it into two parts: one over the region $\{x:|P(x)|>M\}$ and the other over the region $\{x:|P(x)|\leqslant M\}$, where the constant $M\geqslant0$ is arbitrary for the moment but will be fixed later. Then, for any $b>0$, (10.7) implies

$$\int_{-\infty}^{\infty}dx\ |P(x)||\psi(x)|^2\leqslant\frac{1}{2b}\,(\|\psi'\|_2^2+b^2\|\psi\|_2^2)\left(\int_{\{|P(x)|>M\}}dx\ |P(x)|\right)+M\|\psi\|_2^2.\tag{10.9}$$

Combining (10.8) and (10.9) we get

$$\langle-\psi''+Q\psi-\beta P\psi,\psi\rangle\geqslant J_1\|\psi'\|_2^2-J_2\|\psi\|_2^2,$$

where

$$J_1=1-\frac{1}{2a}\int_{-\infty}^{\infty}dx\ |Q(x)|-\frac{\beta}{2b}\int_{\{|P(x)|>M\}}dx\ |P(x)|,$$

$$J_2=\frac{a}{2}\int_{-\infty}^{\infty}dx\ |Q(x)|+\frac{\beta b}{2}\int_{\{|P(x)|>M\}}dx\ |P(x)|+\beta M.$$

We now set

$$a=\int_{-\infty}^{\infty}dx\ |Q(x)|,\quad b=\beta\int_{\{|P(x)|>M\}}dx\ |P(x)|,$$

and assume that ψ is a normalized eigenfunction corresponding to the eigenvalue $E_{\mathscr{N}}(\beta)$. Then the left-hand side of (10.9) is equal to $E_{\mathscr{N}}(\beta)$ and hence

$$E_{\mathscr{N}}(\beta)\geqslant-\frac{1}{2}\left(\int_{-\infty}^{\infty}dx\ |Q(x)|\right)^2-\frac{\beta^2}{2}\left(\int_{\{|P(x)|>M\}}dx\ |P(x)|\right)^2-\beta M.\tag{10.10}$$

Since by choosing M large enough we can make the second term on the right-hand side of (10.10) as small as we please, it follows that $E_{\mathscr{N}}(\beta)=o(\beta^2)$ as $\beta\to+\infty$. Thus $E_{\mathscr{N}}(\beta)>-\beta^2$ for β sufficiently large, while $E_{\mathscr{N}}(0)=-\kappa_{\mathscr{N}}^2<0$. Hence by the intermediate value theorem, the equation $E_{\mathscr{N}}(\beta)=-\beta^2$ has at least one solution. A similar argument shows that each of the remaining eigenvalue branches $E_j(\beta)$ for $j=1,...,\mathscr{N}-1$ must intersect the parabola $E=-\beta^2$ at least once. Since each intersection increases the number of negative-energy bound states of (1.1), the proof of (i) is complete. Note that if an eigenvalue branch $E_j(\beta)$ touches or intersects the parabola $E=-\beta^2$ at other points, such additional points are also responsible for additional negative-energy bound states of (1.1). Moreover, there may be other eigenvalue branches $E(\beta)$ starting at $(\widetilde{\beta},0)$ for some $\widetilde{\beta}>0$ and intersecting or touching the parabola $E=-\beta^2$ at one or more points; again, each of such points also increases the number of negative-energy bound states of (1.1).

(ii) If $P(x)\equiv 0$, each eigenvalue branch $E_0(\beta)$ becomes the horizontal line $E_0(\beta)=-\beta_0^2$ for $\beta\geqslant 0$, and hence $E_0''(\beta)=0$ for $\beta>0$. Thus in the rest of the analysis we can assume that $P(x)\not\equiv 0$. Associated with the eigenvalue $E_0(\beta)$ there exists[25] a real-valued, analytic eigenvector $\psi(\beta,x)$. Near $\beta=\beta_0$ we have the convergent expansions

$$E_0(\beta)=\sum_{n=0}^{\infty} a_n(\beta-\beta_0)^n, \quad \psi(\beta,x)=\sum_{n=0}^{\infty}\psi_n(x)(\beta-\beta_0)^n, \tag{10.11}$$

with $\psi_n\in L^2(\mathbf{R})$ for $n\geqslant 0$. Substituting (10.11) in (1.1) we get the following set of equations (see pp. 333 and 334 of Ref. 26) for $n\geqslant 0$:

$$\psi_n''(x)-\beta_0^2\psi_n(x)+a_1\psi_{n-1}(x)+a_2\psi_{n-2}(x)=[-\beta_0 P(x)+Q(x)]\psi_n(x)-P(x)\psi_n(x) - \sum_{j=3}^{n} a_j\psi_{n-j}(x), \tag{10.12}$$

where it is assumed that $a_{-n}=\psi_{-n}(x)=0$ if $n\geqslant 1$. From (9.17) and (9.18) we see that

$$a_0=E_0(\beta_0), \quad a_1=-\frac{1}{\|\psi_0\|_2^2}\int_{-\infty}^{\infty} dx\ P(x)\psi_0(x)^2. \tag{10.13}$$

We may choose $\psi_0(x)=f_l^+(i\beta_0,x)$. It suffices to prove that $1/T^+(i\beta)$ has a zero of order at least m at β_0 if and only if $E_0(\beta)+\beta^2$ has a zero of order at least m at β_0. From Proposition 8.1 we know that this is true when $m=1$. If β_0 is a zero of $E_0(\beta)+\beta^2$ of order m for some $m\geqslant 2$, then the coefficients a_n in (10.3) are determined for $n=0,1,...,m-1$ by expanding $E_0(\beta)+\beta^2$ about β_0. Thus for $m=2$ we get $a_0=-\beta_0^2$, $a_1=-2\beta_0$; for $m=3$ we get $a_0=-\beta_0^2$, $a_1=-2\beta_0$, $a_2=-1$; for $m\geqslant 4$ we get $a_0=-\beta_0^2$, $a_1=-2\beta_0$, $a_2=-1$, and $a_3=\cdots=a_{m-1}=0$. Then, comparing (10.12) and (8.2) and using the fact that the functions $g_{l,n}^+(i\beta_0,x)$ are uniquely determined as solutions of (8.2) by the requirement that $g_{l,n}^+(i\beta_0,\cdot)\in L^2(\mathbf{R})$, we obtain

$$\psi_n(x)=i^n g_{l,n}^+(i\beta_0,x), \quad n=0,...,m-1. \tag{10.14}$$

Thus, by Theorem 8.4, we see that $1/T^+(i\beta)$ has a zero of order at least m at β_0. Conversely, suppose $1/T^+(i\beta)$ has a zero of order at least m at β_0. From (10.12) one can derive (see p. 334 of Ref. 26) the following recursion formula for the coefficients a_n:

$$a_n=-\frac{1}{\|\psi_0\|_2^2}\int_{-\infty}^{\infty} dx\ \psi_0(x)\left(P(x)\psi_{n-1}(x)+\sum_{j=1}^{n-1} a_j\psi_{n-j}(x)\right), \quad n\geqslant 2. \tag{10.15}$$

Now assume $m\geqslant 2$. Since the functions $\{g_{l,n}^+(i\beta_0,\cdot)\}_{n=0}^{m-1}$ form a Jordan chain of length m, using (8.13) with $n=1$ and (10.13) we get $a_1=-2\beta_0$. Hence $E_0(\beta)+\beta^2$ has a zero of order at least 2 at β_0. If $m\geqslant 3$, then using (8.13) with $n=2$, (10.14), and (10.15) we obtain $a_2=-1$ and this, in turn, implies that $E_0(\beta)+\beta^2$ has a zero of order at least 3 at β_0. If $m\geqslant 4$, then (8.13) and (10.15) give $a_3=0$ and then $a_j=0$ for all $j=3,...,m-1$. As a result, $E_0(\beta)+\beta^2$ has a zero of order at

least m at β_0. If m is even, then $E_0(\beta)$ touches the parabola $E=-\beta^2$ at β_0 but stays either above or below the parabola; if m is odd, then $E_0(\beta)$ intersects the parabola by crossing from one side to the other.

(iii) For the lowest eigenvalue, we need to show that a_2 in (10.11) is negative for any $\beta_0>0$. We have (see p. 334 of Ref. 26)

$$\psi_1(x)=-\psi_0(x)\int_{x_0}^{x}\frac{dt}{\psi_0(t)^2}\int_{-\infty}^{t}ds\ \psi_0(s)[P(s)\psi_0(s)+a_1\psi_0(s)], \tag{10.16}$$

where the constant x_0 is arbitrary; however, since changing x_0 amounts to adding a constant multiple of $\psi_0(x)$ to $\psi_1(x)$, with the help of (10.6) one can show that the value of a_n given in (10.15) is independent of x_0. Using (10.16) in (10.15) with $n=2$ and the positivity of $\psi_0(x)$, after performing an integration by parts, we get

$$a_2=-\frac{1}{\|\psi_0\|_2^2}\int_{-\infty}^{\infty}\frac{dx}{\psi_0(x)^2}\left(\int_{-\infty}^{x}dt\ \psi_0(t)^2[P(t)+a_1]\right)^2<0.$$

Thus $a_2<0$ in (10.11) for any $\beta_0>0$, and hence we have $E_{\mathcal{N}}''(\beta)<0$ for any $\beta>0$.

(iv) Let us consider the number of zeros of $f_l^+(i\beta,x)$ in relation to the behavior of the eigenvalue branch $E_0(\beta)$ near β_0. From Proposition 10.3 (i), when $Q(x)$ in (2.6) is replaced by $Q(x)-\beta P(x)$, we know that the number of zeros of $f_l^+(i\beta,x)$ is equal to the number of eigenvalue branches lying below $-\beta^2$. Let I_{β_0} denote the interval $(\beta_0-\epsilon,\beta_0+\epsilon)$ and let J_{β_0} denote $(\beta_0-\epsilon,\beta_0)\cup(\beta_0,\beta_0+\epsilon)$ for sufficiently small $\epsilon>0$, and let us consider the number of eigenvalue branches below $-\beta^2$ when $\beta\in I_{\beta_0}$. If m is even, then $E_0(\beta)$ touches the parabola $E=-\beta^2$ at β_0 but stays either above or below that parabola; in the former case $E_0(\beta)>-\beta^2$ for $\beta\in J_{\beta_0}$ and hence the number of zeros of $f_l^+(i\beta,x)$ remains unchanged for $\beta\in I_{\beta_0}$; in the latter case $E_0(\beta)<-\beta^2$ for $\beta\in J_{\beta_0}$ and hence the number of zeros of $f_l^+(i\beta,x)$ for $\beta\in J_{\beta_0}$ is exactly one more than the number of zeros of $f_l^+(i\beta_0,x)$. If m is odd, then $E_0(\beta)$ intersects the parabola $E=-\beta^2$ by crossing from one side to the other of that parabola; if $E_0(\beta)<-\beta^2$ on $(\beta_0-\epsilon,\beta_0)$, then the number of zeros of $f_l^+(i\beta,x)$ decreases by one as β increases through β_0; if $E_0(\beta)>-\beta^2$ on $(\beta_0-\epsilon,\beta_0)$, then the number of zeros increases by one as β increases through β_0. In order to prove that the number of zeros of $f_l^+(i\beta,x)$ can only change if β corresponds to a bound state of (1.1) with real (negative) energy, we can proceed as follows. If β_1 and β_2 with $\beta_1<\beta_2$ correspond to two consecutive real bound-state energies of (1.1), then no eigenvalue branch can intersect the parabola $E=-\beta^2$ for $\beta\in(\beta_1,\beta_2)$. Hence the number of eigenvalue branches that lie below $-\beta^2$ is constant for $\beta\in(\beta_1,\beta_2)$, or equivalently, the number of zeros of $f_l^+(i\beta,x)$ is constant for $\beta\in(\beta_1,\beta_2)$. ■

We remark that statement (iii) is a familiar result that also follows from the min-max principle. An example illustrating Theorem 10.6 is given in the next section (Example 11.3).

Proposition 10.7: Assume $P,Q\in L^1(\mathbf{R})$ and let $k_0=\alpha+i\beta$ for some $\alpha\neq 0$ and $\beta>0$. If $P(x)\leqslant 2\beta$, then $f_l^+(k_0,x)$ and $f_r^+(k_0,x)$ cannot vanish for any $x\in\mathbf{R}$.

Proof: Using (4.7) in (4.16) we obtain

$$\frac{d}{dx}[f_l^+(-\overline{k_0},x);f_l^+(k_0,x)]=2i\alpha[P(x)-2\beta]|f_l^+(k_0,x)|^2. \tag{10.17}$$

Suppose $f_l^+(k_0,x)$ has at least one zero and let d be the right-most zero of $f_l^+(k_0,x)$. Note that, as seen from (4.7), the zeros of $f_l^+(-\overline{k_0},x)$ and $f_l^+(k_0,x)$ coincide. Integrating (10.17) over $(d,+\infty)$ and using (8.1) and (8.2), we obtain

$$2i\alpha\int_{d}^{\infty}dx\ [P(x)-2\beta]|f_l^+(k_0,x)|^2=0.$$

This is impossible if $\alpha\neq 0$ and $P(x)\leqslant 2\beta$; note that $P(x)=2\beta$ on a semi-infinite interval would contradict $P\in L^1(\mathbf{R})$. Hence $f_l^+(k_0,x)$ cannot vanish for any $x\in\mathbf{R}$. The proof for $f_r^+(k_0,x)$ is analogous. ■

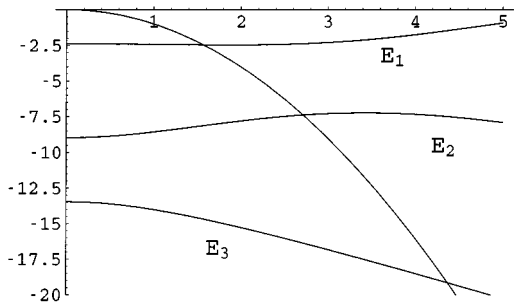

FIG. 1. Eigenvalue curves $E_1(\beta)$, $E_2(\beta)$, $E_3(\beta)$ intersecting the parabola $E=-\beta^2$.

XI. EXAMPLES

In this section we illustrate our results on the number and location of the zeros of $1/T^+(k)$ and on the zeros of the Jost solutions with some explicit examples. Example 11.1 shows the typical behavior of some eigenvalues branches as it was discussed in Secs. IX and X. Example 11.2 exhibits the possibility of real zeros of $1/T^+(k)$ and of complex zeros off the imaginary axis in $\mathbf{C}^+$. In Example 11.3 we consider the zeros on the imaginary axis and the corresponding eigenvalue branches. We also demonstrate the possibility of a double zero on the positive imaginary axis. While Examples 11.1–11.3 involve simple step potentials, Example 11.4 concerns potentials that decay exponentially.

Example 11.1: For real parameters $a_\pm$ and $b_\pm$, let

$$P(x)=\begin{cases} b_+, & x\in(0,1),\\ b_-, & x\in(-1,0),\\ 0, & \text{elsewhere,}\end{cases} \qquad Q(x)=\begin{cases} a_+, & x\in(0,1),\\ a_-, & x\in(-1,0),\\ 0, & \text{elsewhere.}\end{cases} \tag{11.1}$$

Then by straightforward calculations one obtains

$$\frac{e^{-2ik}}{T^+(k)}=\cos s_+ \cos s_- + F_+ \sin s_+ \cos s_- + F_- \cos s_+ \sin s_- - G \sin s_+ \sin s_-, \tag{11.2}$$

where

$$s_\pm=\sqrt{k^2-ikb_\pm-a_\pm}, \quad F_\pm=\frac{k^2+s_\pm^2}{2iks_\pm}, \quad G=\frac{s_+^2+s_-^2}{2s_+s_-}.$$

For $a_\pm=-15$, $b_+=2$, and $b_-=-2$ we get three purely imaginary bound states at $k=1.568\overline{i}$, $k=2.717i$, and $k=4.376\overline{i}$. Here and below we use an overline on the last digit to indicate round-off. These are all the bound states because a plot of $\arg T^+(k)$ for $k\in\mathbf{R}^+$ reveals that $\arg T^+(0+)=5\pi/2$, so that by (9.22) we have $N(P,Q)=3$; note that we are in the generic case. Figure 1 shows the eigenvalue curves associated with the potential $V(\beta,x)=Q(x)-\beta P(x)$ [cf. (9.16)]. The analysis shows that the branches $E_2(\beta)$ and $E_1(\beta)$ are not concave, only $E_3(\beta)$ is concave down. This, in particular, illustrates part (iii) of Theorem 10.6.

Example 11.2: In this example we demonstrate the existence of nonreal zeros of $1/T^+(k)$. Putting $a_-=0$, $a_+=a$, $b_-=0$, and $b_+=b$ in (11.1) and (11.2), we get

$$\frac{1}{T^+(k)}=e^{ik}\left[\cos s+\frac{k^2+s^2}{2iks}\sin s\right], \tag{11.3}$$

where $s=\sqrt{k^2-ibk-a}$. By Theorem 9.3, if $a=0$ and $b>2$, then we must have a bound state at $k=i\beta$ for some positive β. Indeed, if $a=0$ and $b=21/10$, we obtain a bound state at $k=0.15\overline{i}$ and this is the only bound state. When $a=-9$ and $b=5$, we find bound states at $k_1=5.619i$, $k_2^\pm$

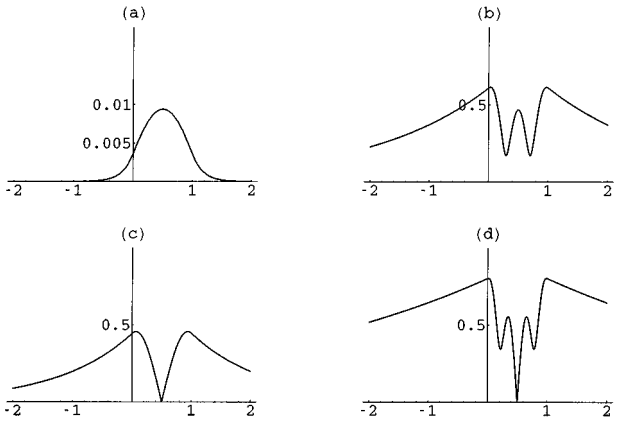

FIG. 2. (a) $f_l^+(k_1,x)$, (b) $|f_l^+(k_2^+,x)|$, (c) $|f_l^+(k_3^+,x)|$, and (d) $|f_l^+(k_4^+,x)|$.

$=\pm 6.28\overline{8}+0.49\overline{5}i$, $k_3^{\pm}=\pm 0.83\overline{8}+0.8\overline{1}i$, and $k_4^{\pm}=\pm 9.89\overline{8}+0.219\overline{2}i$. As in Example 11.1 it follows that these are all the bound states. In Fig. 2 we plot $f_l^+(k_1,x)$, $|f_l^+(k_2^+,x)|$, $|f_l^+(k_3^+,x)|$, and $|f_l^+(k_4^+,x)|$ on the interval $x\in(-2,2)$. Let us remark that the functions $f_l^+(k_1,x)$ and $f_l^+(k_2^{\pm},x)$ are even with respect to $x=1/2$, and the functions $f_l^+(k_3^{\pm},x)$ and $f_l^+(k_4^{\pm},x)$ are odd with respect to $x=1/2$. When $a=-9.2738$ and $b=3.9708$, we obtain a zero of $1/T^+(k)$ at $k=1$. In the special case when $a=0$ we have

$$\frac{1}{T^+(0)}=1-\frac{b}{2},\quad \frac{L^+(0)}{T^+(0)}=\frac{R^+(0)}{T^+(0)}=\frac{b}{2}.$$

Hence $1/T^+(0)=0$ if and only if $b=2$. Note that the bound states may occur even when $Q(x)\geqslant 0$. For example, when $a=1$ and $b=10$, we obtain over 200 bound states, four of which correspond to k values on the positive imaginary axis with $k=i\beta_j$, where

$$\beta_1=0.1\overline{3},\quad \beta_2=2.5\overline{0},\quad \beta_3=5.6\overline{3},\quad \beta_4=9.1\overline{6}.$$

When $a=0$ and $b=100$, we obtain 31 bound states on the positive imaginary axis with $k=i\beta_j$, where

$$\beta_1=0.1\overline{0},\quad \beta_2=0.4\overline{1},\quad \beta_3=0.9\overline{3},\quad \beta_4=1.6\overline{7},\quad \beta_5=2.6\overline{4},\quad \beta_6=3.8\overline{5},\quad \beta_7=5.3\overline{3},$$

$$\beta_8=7.0\overline{9},\quad \beta_9=9.1\overline{9},\quad \beta_{10}=11.6\overline{9},\quad \beta_{11}=14.6\overline{3},\quad \beta_{12}=18.2\overline{0},\quad \beta_{13}=22.6\overline{1},$$

$$\beta_{14}=28.4\overline{3},\quad \beta_{15}=37.6\overline{3},\quad \beta_{16}=60.4\overline{1},\quad \beta_{17}=69.6\overline{9},\quad \beta_{18}=75.6\overline{0},\quad \beta_{19}=80.1\overline{1},$$

$$\beta_{20}=83.7\overline{7},\quad \beta_{21}=86.8\overline{3},\quad \beta_{22}=89.4\overline{2},\quad \beta_{23}=91.6\overline{3},\quad \beta_{24}=93.5\overline{2},\quad \beta_{25}=95.1\overline{2},$$

$$\beta_{26}=96.4\overline{6},\quad \beta_{27}=97.5\overline{7},\quad \beta_{28}=98.4\overline{6},\quad \beta_{29}=99.1\overline{4},\quad \beta_{30}=99.6\overline{2},\quad \text{and}\quad \beta_{31}=99.9\overline{1},$$

and there are also many more bound states corresponding to k-values off the imaginary axis in $\mathbf{C}^+$. In this case, one finds that $f_l^+(i\beta,x)$ has no zeros for $\beta=0$, no zeros for $\beta\in(\beta_{31},+\infty)$, one zero for $\beta\in(0,\beta_1)$, and one zero for $\beta\in(\beta_{30},\beta_{31})$, j zeros for $\beta\in(\beta_{j-1},\beta_j)$ and j zeros for $\beta\in(\beta_{31-j},\beta_{32-j})$ with $j=2,3,...,15$, and 16 zeros for $\beta\in(\beta_{16},\beta_{17})$.

Example 11.3: (a) Let $a=0$ and $b=10$ in Example 11.2, and hence $Q(x)=0$ and $P(x)\geqslant 0$. Note that $N(0,Q)=0$. From (9.16) we obtain [cf. (11.3)]

$$2\Delta\sqrt{-E}\cos\Delta=(\Delta^2+E)\sin\Delta, \tag{11.4}$$

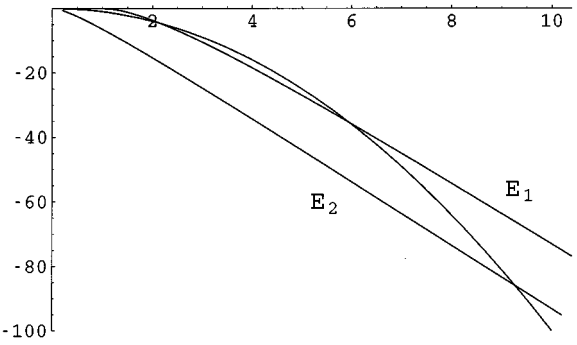

FIG. 3. The parabola $E=-\beta^2$ intersecting the eigenvalue curves $E_1(\beta)$ and $E_2(\beta)$.

where $E=E(\beta)$ is the energy in (9.16) and $\Delta=\sqrt{\beta b-a+E}$. Using the half-angle formula for the tangent function, we can write (11.4) as a pair of equations determining the eigenvalue curves:

$$\tan\left(\frac{\Delta}{2}\right)=\frac{\sqrt{-E}}{\Delta},\quad \tan\left(\frac{\Delta}{2}\right)=-\frac{\Delta}{\sqrt{-E}}. \tag{11.5}$$

Recall from the proof of Theorem 9.7 that the bound states of (1.1) with real energies correspond to the β-values where the eigenvalue curves intersect the parabola $E=-\beta^2$. When $a=0$ and $b=10$, from (11.5) we obtain two eigenvalue branches intersecting the parabola $E=-\beta^2$. Let $E_2(\beta)$ denote the eigenvalue branch responsible for the lowest real bound-state energy. We see that $E_2(\beta)$ emerges from (0,0) and intersects the parabola $E=-\beta^2$ at $\beta_3=9.273\overline{3}$. The second eigenvalue branch, $E_1(\beta)$, emerges from zero at $\beta=\pi^2/10$ and then intersects the parabola $E=-\beta^2$ at $\beta_1=2.114$ and at $\beta_2=5.963$. These eigenvalue branches and the parabola $E=-\beta^2$ are plotted in Fig. 3. The values β_1, β_2, and β_3 correspond to simple zeros of $1/T^+(i\beta)$. If $\beta\geqslant\beta_3$, then $f_l^+(i\beta,x)$ has no zeros. If $\beta\in[\beta_2,\beta_3)$, then $f_l^+(i\beta,x)$ has one zero because $E_2(\beta)$ is the only eigenvalue below $-\beta^2$. If $\beta\in(\beta_1,\beta_2)$, then $f_l^+(i\beta,x)$ has two zeros because both $E_2(\beta)$ and $E_1(\beta)$ lie below $-\beta^2$. If $\beta\in(0,\beta_1]$ then $f_l^+(i\beta,x)$ has one zero, and if $\beta=0$ then $f_l^+(0,x)$ has no zeros because (2.6) with $Q(x)=0$ has no bound states.

(b) When $a=0$, one can choose the parameter b such that the branch $E_1(\beta)$ just touches the parabola $E=-\beta^2$ at β_1. Then the slope of the eigenvalue curve at β_1 must be equal to $-2\beta_1$, and this happens when

$$\tan\left(\frac{\sqrt{b^2-4}}{4}\right)=-\frac{\sqrt{b+2}}{\sqrt{b-2}},$$

from which we get $b=9.206\overline{6}$, leading to $\beta_1=3.60\overline{3}$, and β_1 corresponds to a double zero of $1/T^+(i\beta)$. The eigenvalue branch $E_2(\beta)$ intersects the parabola $E=-\beta^2$ at β_2; we have $\beta_2=8.433$, which is responsible for the lowest real bound-state energy. In this case, $f_l^+(i\beta,x)$ has no zeros for $\beta=0$, one zero for $\beta\in(0,\beta_2)$, and no zeros for $\beta\in[\beta_2,+\infty)$. We show the two eigenvalue branches and the parabola $E=-\beta^2$ in Fig. 4.

(c) When $b=10$ we can find a such that the lowest real bound-state energy corresponds to a double zero of $1/T^+(i\beta)$. Proceeding as in (b), we get

$$a=\frac{10\beta_1(\beta_1-4)}{\beta_1-3},$$

where β_1 is obtained by solving

$$\tan\left(\frac{\sqrt{10\beta+3\beta^2-\beta^3}}{2\sqrt{\beta-3}}\right)=\frac{\beta\sqrt{\beta-3}}{\sqrt{10\beta+3\beta^2-\beta^3}}. \tag{11.6}$$

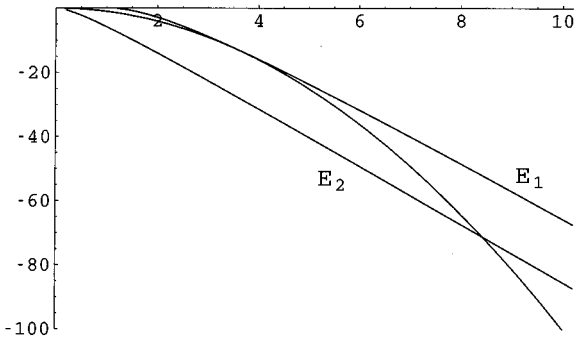

FIG. 4. The parabola $E=-\beta^2$ touching $E_1(\beta)$ and intersecting $E_2(\beta)$.

From (11.6) we get $\beta_1=4.724\overline{}$ and hence $a=19.852\overline{}$. In this case $f_l^+(i\beta,x)$ has no zeros for any $\beta\geqslant 0$. The eigenvalue curve $E_1(\beta)$ and the parabola $E=-\beta^2$ are plotted in Fig. 5, and it is seen that there are no other real bound-state energies besides $-\beta_1^2$.

Example 11.4: Let

$$\eta_l^+(k,x)=1-\frac{2i(1+b)\epsilon}{k+i\epsilon}\,\frac{ce^{-2\epsilon x}}{1+ce^{-2\epsilon x}},\quad x\geqslant 0, \tag{11.7}$$

$$\eta_r^+(k,x)=1-\frac{2i(1+b)\epsilon}{k+i\epsilon}\,\frac{ce^{2\epsilon x}}{1+ce^{2\epsilon x}},\quad x\geqslant 0, \tag{11.8}$$

where c, ϵ are positive parameters and b is a real parameter. Using (1.1), (1.2), (3.3), (3.4), (11.7), and (11.8), we obtain

$$P(x)=\frac{4b\epsilon ce^{-2\epsilon|x|}}{1+ce^{-2\epsilon|x|}},$$

$$Q(x)=\frac{4\epsilon^2 ce^{-2\epsilon|x|}[-3b-2+b^2ce^{-2\epsilon|x|}]}{(1+ce^{-2\epsilon|x|})^2}.$$

Hence $e^p=(1+c)^{2b}$ and using (6.3) we get

$$T^+(k)=\frac{k(k+i\epsilon)^2e^p}{(k-k_0)(k-k_+)(k-k_-)},$$

where we have defined

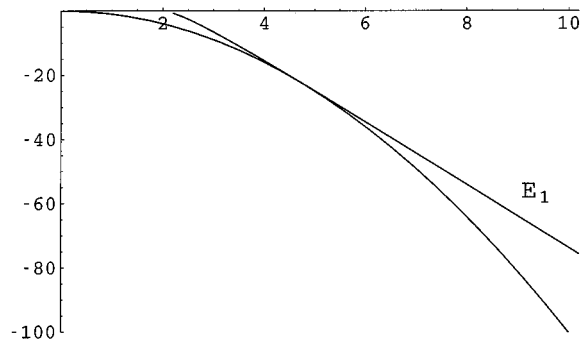

FIG. 5. The parabola $E=-\beta^2$ touching the eigenvalue curve $E_1(\beta)$.

$$k_0 = i\,\frac{\epsilon}{1+c}\,[-1+c+2bc],$$

$$k_\pm = \frac{i\epsilon}{2(1+c)}\,[(-1+c+4bc) \pm \sqrt{1+c^2+14c+16bc}]. \tag{11.9}$$

Let us now analyze the poles of $T^+(k)$. First note that ϵ simply acts as a scaling parameter for the location of the poles; thus the relevant parameters are b and c. We can divide the half-plane $\{(c,b): c>0\}$ into four separate regions by using the three nonintersecting curves $b=\Gamma_+(c)$, $b=\Gamma_0(c)$, and $b=\Gamma_-(c)$, where

$$\Gamma_0(c) = \frac{1-c}{2c}, \quad \Gamma_\pm(c) = -\frac{c-3}{4c} \pm \sqrt{\frac{(c-3)^2}{16c^2} + \frac{1}{c}}.$$

On these three curves the exceptional case occurs; note that $k_-=0$ on Γ_+, $k_+=0$ on Γ_-, and $k_0=0$ on Γ_0. The number of bound states changes by one as we cross each of these three curves; otherwise, we are in the generic case. Note that:

(i) If $b>\Gamma_+(c)$, then k_0, k_+, and k_- all lie on the positive imaginary axis, and hence we have three bound states.

(ii) If $\Gamma_0(c)<b\leqslant\Gamma_+(c)$, then k_0 and k_+ lie on the positive imaginary axis, but $k_-\notin \mathbf{C}^+$; hence we have two bound states.

(iii) If $\Gamma_-(c)<b\leqslant\Gamma_0(c)$, then there is exactly one bound state because k_+ lies on the positive imaginary axis but k_0 and k_- are not in $\mathbf{C}^+$.

(iv) There are no bound states when $b\leqslant\Gamma_-(c)$ because none of k_0, k_+, and k_- lie in $\mathbf{C}^+$. In this case, k_0 is always located on the imaginary axis; k_+ and k_- lie on the imaginary axis when $b\geqslant -(c+14+1/c)/16$ and they lie in $\mathbf{C}^-$ symmetrically located with respect to the imaginary axis.

This example can also be specialized to show the occurrence of a double zero of $1/T^+(k)$. Indeed, choose $b=-(c+14+1/c)/16$ and $c\in(-1,-5+2\sqrt{5})$. Then, from (11.9) we see that $k_+=k_-=-i\epsilon(c^2+10c+5)/[8(1+c)]$, and hence $T^+(k)$ has a double pole on the positive imaginary axis in $\mathbf{C}^+$ for any $c\in(-1,-5+2\sqrt{5})$. Note also that when $b=(1-c)/(4c)$ and $c\in(-1,-5+2\sqrt{5})$, although k_0 is located on the negative imaginary axis, k_+ and k_- are symmetrically located on the real axis; thus, in this case $T^+(k)$ has poles on the real axis. When $b=-(5+\sqrt{5})/10$ and $c=-5+2\sqrt{5}$, both k_+ and k_- vanish, and hence we get a simple pole for $T^+(k)$ at $k=0$; this illustrates the exceptional case when the denominator in (5.3) vanishes.

APPENDIX: SMALL-k ESTIMATES

In this Appendix, proceeding as in Refs. 11 and 12, we obtain various small-k estimates that are needed in the proof of Theorem 5.2.

In the exceptional case, let $\tilde{\psi}(k,x)$ be the solution of (1.1) satisfying the initial conditions

$$\tilde{\psi}(k,0) = f_l(0,0), \quad \tilde{\psi}'(k,0) = f_l'(0,0), \quad k\in\mathbf{R}. \tag{A1}$$

Note that $\tilde{\psi}(0,x)=f_l(0,x)$, and hence $\tilde{\psi}(0,x)$ is bounded in such a way that $\tilde{\psi}(0,+\infty)=1$ and $\tilde{\psi}(0,-\infty)=\gamma$, where γ is the constant defined in (2.9). We have

$$\tilde{\psi}(k,x) = f_l(0,0)\cos kx + f_l'(0,0)\,\frac{\sin kx}{k} + \frac{1}{k}\int_0^x dy\,\sin k(x-y)[ikP(y)+Q(y)]\tilde{\psi}(k,y). \tag{A2}$$

Let $\psi_1(k,x)$ denote the solution of (1.1) with $P(x)=0$ and satisfying (A1). We have

$$\psi_1(k,x) = f_l(0,0)\cos kx + f_l'(0,0)\,\frac{\sin kx}{k} + \frac{1}{k}\int_0^x dy\,\sin k(x-y)Q(y)\psi_1(k,y). \tag{A3}$$

Note that $\tilde{\psi}(0,x)=\psi_1(0,x)$.

Proposition A.1: Assume $Q\in L^1_1(\mathbf{R})$. For $x,k\in\mathbf{R}$, we have

$$|\psi_1(k,x)-\psi_1(0,x)|\leq C\left(\frac{|kx|}{1+|kx|}\right)^2, \quad |\psi_1(k,x)|\leq C(1+|k|). \tag{A4}$$

Proof: Note that $\psi_1(0,x)=f_l(0,x)$ and hence it is uniformly bounded for $x\in\mathbf{R}$. Furthermore,

$$\psi_1(0,x)=f_l(0,0)+xf_l'(0,0)+\int_0^x dy\ (x-y)Q(y)\psi_1(0,y). \tag{A5}$$

Subtracting (A5) from (A3) and iterating the resulting integral equation as in the proof of Proposition A.1 of Ref. 12 (using $H(x)\equiv H_+=1$ there) we obtain the first inequality in (A4). Using that inequality and the boundedness of $\psi_1(0,x)$, we obtain the second inequality in (A4). ■

Let us choose a second linearly independent solution of (1.1) with $P(x)=0$ such that the Wronskian $[\psi_1(k,x);\psi_2(k,x)]$ is equal to 1. For example, we can choose $\psi_2(k,x)$ so that it satisfies the initial conditions $\psi_2(k,0)=0$ and $\psi_2'(k,0)=1/f_l(0,0)$; note that there is no loss of generality in assuming $f_l(0,0)\neq 0$, since the case $f_l(0,0)=0$ can be handled by a shift of the origin. We have

$$\psi_2(k,x)=\frac{\sin kx}{kf_l(0,0)}+\frac{1}{k}\int_0^x dy\ \sin k(x-y)Q(y)\psi_2(k,y). \tag{A6}$$

Proposition A.2: Assume $Q\in L^1_1(\mathbf{R})$. Then, for $x,k\in\mathbf{R}$ we have

$$|\psi_2(k,x)|\leq\frac{C|x|}{1+|kx|}, \quad |\psi_2(k,x)-\psi_2(0,x)|\leq C|x|\left(\frac{|kx|}{1+|kx|}\right)^2. \tag{A7}$$

Proof: Iterating (A6) as in the proof of Proposition A.1 of Ref. 12, we obtain the first inequality in (A7). Note that from (A6) we have

$$\psi_2(0,x)=\frac{x}{f_l(0,0)}+\int_0^x dy\ (x-y)Q(y)\psi_2(0,y). \tag{A8}$$

Subtracting (A8) from (A6) and iterating the resulting integral equation, we obtain the second inequality in (A7). ■

Proposition A.3: Assume $P,Q\in L^1_1(\mathbf{R})$. Then, for $x\in\mathbf{R}$ and as $k\to 0$ in $\mathbf{R}$, we have

$$\begin{aligned}\tilde{\psi}(k,x)-\psi_1(k,x)=&-ik\psi_1(0,x)\int_0^x dz\ \psi_2(0,z)P(z)\psi_1(0,z)\\&+ik\psi_2(0,x)\int_0^x dz\ P(z)\psi_1(0,z)^2+\mathrm{O}\left(|kx|\left[\frac{|kx|}{1+|kx|}\right]^2\right).\end{aligned} \tag{A9}$$

Proof: Recall that $\psi_1(k,x)$ and $\psi_2(k,x)$ are two linearly independent solutions of (1.1) when $P(x)=0$. Using variation of parameters on (1.1), we obtain (assuming $x\geq 0$)

$$\begin{aligned}\tilde{\psi}(k,x)-\psi_1(k,x)=&-ik\psi_1(k,x)\int_0^x dz\ \psi_2(k,z)P(z)\tilde{\psi}(k,z)\\&+ik\psi_2(k,x)\int_0^x dz\ \psi_1(k,z)P(z)\tilde{\psi}(k,z).\end{aligned} \tag{A10}$$

Let us write (A10) as

$$\tilde{\psi}(k,x)-\psi_1(k,x)=A_1+A_2+A_3+A_4+A_5+A_6+A_7+B_1+B_2, \tag{A11}$$

where we have defined

$$B_1=-ik\psi_1(k,x)\int_0^x dz\ \psi_2(k,z)P(z)[\widetilde{\psi}(k,z)-\psi_1(k,z)],$$

$$B_2=ik\psi_2(k,x)\int_0^x dz\ \psi_1(k,z)P(z)[\widetilde{\psi}(k,z)-\psi_1(k,z)],$$

$$A_1=-ik\psi_1(0,x)\int_0^x dz\ \psi_2(0,z)P(z)\psi_1(0,z),$$

$$A_2=-ik[\psi_1(k,x)-\psi_1(0,x)]\int_0^x dz\ \psi_2(k,z)P(z)\psi_1(k,z),$$

$$A_3=-ik\psi_1(0,x)\int_0^x dz\ [\psi_2(k,z)-\psi_2(0,z)]P(z)\psi_1(k,z),$$

$$A_4=-ik\psi_1(0,x)\int_0^x dz\ \psi_2(0,z)P(z)[\psi_1(k,z)-\psi_1(0,z)],$$

$$A_5=ik\psi_2(0,x)\int_0^x dz\ P(z)\psi_1(0,z)^2,$$

$$A_6=ik[\psi_2(k,x)-\psi_2(0,x)]\int_0^x dz\ P(z)\psi_1(k,z)^2,$$

$$A_7=ik\psi_2(0,x)\int_0^x dz\ [\psi_1(k,z)-\psi_1(0,z)][\psi_1(k,z)+\psi_1(0,z)]P(z).$$

Using the estimates in (A4) and (A7), we obtain

$$|A_2|\leq C|k|(1+|k|)\left(\frac{|kx|}{1+|kx|}\right)^2\int_0^x dz\ z|P(z)|, \tag{A12}$$

$$|A_3|\leq C|k|(1+|k|)\left(\frac{|kx|}{1+|kx|}\right)^2\int_0^x dz\ z|P(z)|, \tag{A13}$$

$$|A_4|\leq C|k|\left(\frac{|kx|}{1+|kx|}\right)^2\int_0^x dz\ z|P(z)|, \tag{A14}$$

$$|A_6|\leq C|kx|(1+|k|)^2\left(\frac{|kx|}{1+|kx|}\right)^2\int_0^x dz\ |P(z)|, \tag{A15}$$

$$|A_7|\leq C|kx|(1+|k|)\left(\frac{|kx|}{1+|kx|}\right)^2\int_0^x dz\ |P(z)|. \tag{A16}$$

For $x<0$ analogous estimates hold. Iterating the integral equation for $\widetilde{\psi}(k,x)-\psi_1(k,x)$ given in (A11) and using (A12)–(A16), we obtain (A9). ■

In order to estimate the small-k asymptotics of $T^+(k)$, we will use (4.2). Note that as in (A24) of Ref. 12 we have

$$f_l(0,0)[f_l^+(k,x);f_r^+(k,x)]=f_r^+(k,0)\left[-ikf_l(0,0)+f_l'(0,0)+\int_0^\infty dz\ e^{ikz}[ikP(z)+Q(z)]\widetilde{\psi}(k,z)\right]$$
$$-f_l^+(k,0)\left[ikf_l(0,0)+f_l'(0,0)-\int_{-\infty}^0 dz\ e^{-ikz}[ikP(z)\right.$$
$$\left.+Q(z)]\widetilde{\psi}(k,z)\right]. \tag{A17}$$

Proposition A.4: Assume $P,Q\in L_1^1(\mathbf{R})$. Then, as $k\to 0$ we have

$$\int_0^\infty dz\ e^{ikz}[ikP(z)+Q(z)]\widetilde{\psi}(k,z)=-f_l'(0,0)+ikf_l(0,0)-ik+ik\int_0^\infty dz\ P(z)f_l(0,z)^2+o(|k|), \tag{A18}$$

$$\int_{-\infty}^0 dz\ e^{ikz}[ikP(z)+Q(z)]\widetilde{\psi}(k,z)=f_l'(0,0)-ik\gamma+ikf_l(0,0)$$
$$+(ik/\gamma)\int_{-\infty}^0 dz\ P(z)f_l(0,z)^2+o(|k|), \tag{A19}$$

where γ is the constant defined in (2.9).

Proof: Let us write

$$\int_0^\infty dz\ e^{ikz}[ikP(z)+Q(z)]\widetilde{\psi}(k,z)=J_1+J_2+J_3+J_4+J_5+J_6, \tag{A20}$$

where

$$J_1=\int_0^\infty dz\ Q(z)\widetilde{\psi}(0,z),\quad J_2=\int_0^\infty dz\ Q(z)[e^{ikz}-1]\widetilde{\psi}(0,z),$$
$$J_3=ik\int_0^\infty dz\ e^{ikz}P(z)\widetilde{\psi}(0,z),$$
$$J_4=\int_0^\infty dz\ e^{ikz}Q(z)[\psi_1(k,z)-\widetilde{\psi}(0,z)],$$
$$J_5=ik\int_0^\infty dz\ e^{ikz}P(z)[\widetilde{\psi}(k,z)-\widetilde{\psi}(0,z)],$$
$$J_6=\int_0^\infty dz\ e^{ikz}Q(z)[\widetilde{\psi}(k,z)-\psi_1(k,z)].$$

As in (A25) and (A26) of Ref. 12 we have $J_1=-f_l'(0,0)$ and

$$J_2=ik[f_l(0,0)-1]+o(|k|),\quad k\to 0.$$

As $k\to 0$, using (A4) we obtain $J_4=o(|k|)$ and

$$J_3=ik\int_0^\infty dz\ P(z)\widetilde{\psi}(0,z)+o(|k|),$$

and using (A9) we have $J_5=o(|k|)$ and

$$J_6=ik\int_0^\infty dz\ Q(z)\left[-\psi_1(0,z)\int_0^z dt\ \psi_2(0,t)P(t)\psi_1(0,t)+\psi_2(0,z)\int_0^z dt\ P(t)\psi_1(0,t)^2\right]$$
$$+o(|k|). \tag{A21}$$

Notice that $[\psi_1(k,x);\psi_2(k,x)]=1$ and $Q(z)\psi_s(0,z)=\psi_s''(0,z)$ for $s=1,2$. Therefore, using $\psi_2'(0,+\infty)=1$, $\psi_1'(0,z)=o(z^{-1})$ as $z\to+\infty$, $\psi_1(0,z)=\widetilde{\psi}(0,z)$, and integration by parts twice in (A21), we obtain

$$J_6 = -ik \int_0^\infty dz\ P(z)\overline{\psi}(0,z) + ik \int_0^\infty dz\ P(z)\overline{\psi}(0,z)^2 + o(|k|), \quad k \to 0.$$

Thus, from (A20) we obtain (A18). Similarly, using $\psi_1'(0,-\infty)=0$ and $\psi_1(0,-\infty)=\gamma$, we get (A19).

Geodesic flow on an hyperboloid model and the two-body motion under repulsive Coulomb forces

Alejandro M. Mesón[a] and Fernando Vericat[b]
Instituto de Física de Líquidos y Sistemas Biológicos (IFLYSIB)-UNLP-CONICET, cc. 565-(1900) La Plata, Argentina and Grupo de Aplicaciones Matemáticas y Estadísticas de la Facultad de Ingeniería, (GAMEFI), Departamento de Fisicomatemática, Facultad de Ingeniería, Universidad Nacional de La Plata, Argentina

(Received 19 November 1997; accepted for publication 12 January 1998)

We show that (in n dimension) the flow defined by the Hamiltonian system for two charged particles of the same sign, is mapped into the geodesic flow over the non-Euclidean space: $\mathscr{H}^{n+} \sqcup_{\partial} \mathscr{H}^{n-} - \{P\}$, say the hyperboloid with the axis along $\hat{e}_0$ which besides having its ''boundaries at infinite'' identified, it is also punctured at the point $P \equiv (\xi_0, \xi_1, \ldots, \xi_n) = (-1,0,...,0)$ (corresponding to the collision states) and whose metric is of negative curvature. © *1998 American Institute of Physics.* [S0022-2488(98)02104-5]

I. INTRODUCTION

The problem of the movement of two interacting particles (the two-body problem) has drawn for centuries the attention of physicists and mathematicians and its general solution is well known.[1] This is particularly true for the so-called Kepler's problem that considers the classical dynamics of two massive particles which interact via the attractive force of Newton or two particles with charges of the opposite sign so that between them an attractive electrostatic Coulomb force acts. The problem is best described in the reduced form in which the center of mass is at rest, and we have to study the motion of a single mass point only. In n dimensions the position and the momentum of the mass point are given by points of $\mathscr{R}^n$: $q=(q_1,q_2,\ldots,q_n)$ and $p=(p_1,p_2,\ldots,p_n)$, respectively. Defining the modulus $|k|^2=(k/k)=\Sigma_{i=1}^n k_i^2$ and after an appropriate choice of the mass (and charge) unit, we can write Kepler's Hamiltonian system as $\dot{q}=\partial H_K/\partial p$, $\dot{p}=-\partial H_K/\partial q$, where $H_K=\frac{1}{2}|p|^2-1/|q|$ is the corresponding Hamilton function.

An interesting property of Kepler's problem was demonstrated some time ago by Moser. He showed the ''equivalence'' between the motion of a particle in an attractive Newtonian (or Coulombian) field of forces and that of a particle constrained to freely move on a sphere surface. Specifically he proved that the surfaces of constant negative energy for Kepler's problem can be mapped one to one into the unit tangent bundle of the n-dimensional sphere $\mathscr{S}^n$. Then the flow associated to H_K is mapped into the geodesic flow on $\mathscr{S}^n - \{P\}$, the sphere punctured at one point (the ''north pole'' corresponding to the collision states).[2] With relation to the equivalence between Kepler's problem and the geodesic flow in spaces of constant curvature see also Refs. 3 and 4. In particular, the case of constant positive energies is treated by Belbruno in Ref. 3.

Here we report the corresponding property for a Hamiltonian system that describes the motion of two particles with equal sign charges or, in reduced form, a point charge interacting with a repulsive central field of Coulomb forces.

II. GEODESIC FLOW ON AN HYPERBOLOID AND THE MOTION OF TWO CHARGES OF THE SAME SIGN

In the units we are considering, the Hamitonian system for the movement of a charged particle in a repulsive Coulomb field reads $\dot{q}=\partial H_C/\partial p$, $\dot{p}=-\partial H_C/\partial q$, where the dot denotes the derivative with respect to the time and

$$H_C=\frac{1}{2}|p|^2+\frac{1}{|q|} \tag{1}$$

is the Hamilton function.

The property in which we are interested here is the ''equivalence'' between the flow described by the Hamilton function (1) and the motion of a particle constrained to freely move on the surface of the hyperboloid whose axis is along the unit vector $\hat{e}_0$, whose ''boundaries at infinite'' are identified and that is punctured at the point $P\equiv(\xi_0,\xi_1,\ldots,\xi_n)=(-1,0,\ldots,0)$, the metric being of negative curvature. Denoting this hyperboloid $\mathscr{H}^{n\pm}_{-P}\equiv\mathscr{H}^{n+}\sqcup_{\partial}\mathscr{H}^{n-}-\{P\}$, the previous statement can be put into more precise terms:

Theorem: For a positive constant h, the energy surface $H_C=h$ can be mapped one to one into the unit tangent bundle of $\mathscr{H}^{n\pm}_{-P}$ so that, after a change of variables, the flow defined by H_C is mapped into the geodesic flow on $\mathscr{H}^{n\pm}_{-P}$.

The demonstration closely follows that of Moser for the Kepler's problem. We begin describing the geodesic flow on $\mathscr{H}^{n\pm}_{-P}$ and then, by introducing suitable mappings, we transform it into the two-body problem for charges of the same sign.

If $\xi=(\xi_0,\xi_1,\ldots,\xi_n)\in\mathscr{R}^{n+1}$ and define the inner product $\langle\xi^{(a)},\xi^{(b)}\rangle=\sum_{i=1}^n\xi_i^{(a)}\xi_i^{(b)}-\xi_0^{(a)}\xi_0^{(b)}$ then the hyperbolic spaces $\mathscr{H}^{n+}$ and $\mathscr{H}^{n-}$ are given by $\mathscr{H}^{n+}=\{\xi:\langle\xi,\xi\rangle=-1;\xi_0>0\}$ and $\mathscr{H}^{n-}=\{\xi:\langle\xi,\xi\rangle=-1;\xi_0<0\}$, respectively, with the metric given by $d(\xi^{(a)},\xi^{(b)})=\inf_\gamma\{L(\gamma)\}$. Here $L(\gamma)=\int\langle\gamma',\gamma'\rangle ds$, the inf is taken over all the curves $\gamma(s)$ joining the points $\xi^{(a)}$ and $\xi_{(b)}$ and $\gamma'\equiv d\gamma/ds$. The union of both spaces will be simply denoted by $\mathscr{H}^n$. Considering $\xi=\xi(s)$, then $\eta=\xi'=d\xi/ds$ so that $(\xi,\eta)\in T(\mathscr{H}^n)$, the tangent bundle of $\mathscr{H}^n$. With this notation, the geodesic flow can be described by the variational problem

$$\delta\int\langle\xi',\xi'\rangle ds=0 \tag{2}$$

with the condition

$$\langle\xi,\xi\rangle=-1. \tag{3}$$

This is equivalent to consider the Hamiltonian system

$$\frac{\partial\Phi(\xi,\eta)}{\partial\eta}=\xi'\Omega;\quad\frac{\partial\Phi(\xi,\eta)}{\partial\xi}=-\eta'\Omega, \tag{4}$$

where the form is defined by the $(n+1)\times(n+1)$ matrix Ω whose entries are zero except the diagonal elements: $\Omega_{00}=-1$; $\Omega_{ii}=1$ $(i=1,2,\ldots,n)$ and

$$\Phi(\xi,\eta)=-\tfrac{1}{2}\langle\xi,\xi\rangle\langle\eta,\eta\rangle \tag{5}$$

is its Hamilton function.

To describe this flow in $\mathscr{R}^n$, we use the symplectic transformations $(i=1,2,\ldots,n)$:

$$x_i=\frac{\xi_i}{1+\xi_0} \tag{6}$$

and

$$y_i=\eta_i(1+\xi_0)-\xi_i\eta_0. \tag{7}$$

In the Euclidean space we define the scalar product $(x^{(a)}/x^{(b)})=\sum_{i=1}^n x_i^{(a)}x_i^{(b)}$ so that $|x|^2=(x/x)=(\xi_0-1)/(\xi_0+1)$ and the inverse relations of Eqs. (6) and (7) read $\xi_i=2x_i/(1-|x|^2)$; $\eta_i=x_i(x/y)+y_i(1-|x|^2)/2$ for $i=1,2,\ldots,n$ and $\xi_0=(1+|x|^2)/(1-|x|^2)$; $\eta_0=(x/y)$. We observe that Eq. (6) transforms $\mathscr{H}^{n+}$ into the disc $\mathscr{D}^n=\{x:|x|\leqslant 1\}$ and $\mathscr{H}^{n-}$ into the set $\{x:|x|\geqslant 1\}$. In particular the point $(1,0,0,\ldots,0)$ of $\mathscr{H}^{n+}$ gives the center of $\mathscr{D}^n$ and its ideal border, say $\partial^+=\partial(\mathscr{H}^{n+})=\{\xi:\xi\in\mathscr{H}^{n+};\xi_0=\infty\}$, gives the border of $\mathscr{D}^n$: $\partial(\mathscr{D}^n)=\{x:|x|=1\}$. On the other

hand, the ideal border of $\mathscr{H}^{n-}$, $\partial^- = \partial(\mathscr{H}^{n-}) = \{\xi : \xi \in \mathscr{H}^{n-}; \xi_0 = -\infty\}$, yields $\partial(\mathscr{D}^n)$ too, whereas the ''image'' of the point $P \equiv (-1,0,0,...,0)$ is interpreted as the compactification point of $\mathscr{R}^n$ and we will, in principle, omit it. Thus, to have a one to one correspondence we identify ∂^+ and ∂^- and call both of them simply ∂. In this way, we are considering a one to one mapping between the punctured hyperboloid $\mathscr{H}^{n+} \sqcup_\partial \mathscr{H}^{n-} - \{P\} \subset \mathscr{R}^{n+1}$ and $\mathscr{R}^n$.

With the previous transformations we have $\langle \eta, \eta \rangle = [(1-|x|^2)/2]^2 |y|^2$ and Eq. (5) yields, using Eq. (3),

$$\Phi(\xi, \eta) = F(x,y) = \tfrac{1}{8}(1-|x|^2)^2 |y|^2. \tag{8}$$

From this Hamilton function we have the transformed motion equations

$$x' = \frac{\partial F}{\partial y}; \quad y' = -\frac{\partial F}{\partial x}. \tag{9}$$

Here and in any case in which Euclidean space is involved, the canonical symplectic form is considered.

To prove the mapping of the Hamiltonian system Eqs. (8) and (9) into repulsive two-body Coulomb problem on positive energy surfaces $H_C = h$, it is enough to consider the particular case $h = \frac{1}{2}$ since the general case of an arbitrary positive energy surface reduces to that case by a simple scaling of the variables.

Defining the function $G(x,y) = \sqrt{2F(x,y)} - 1$, we see that the system given by Eq. (9) on the surface $F(x,y) = \frac{1}{2}$ goes over into the Hamiltonian system

$$x' = \frac{\partial G}{\partial y}; \quad y' = -\frac{\partial G}{\partial x} \tag{10}$$

on the surface $G = 0$. Changing the independent variable s to $t = \int |y(s)| ds$, the system (10) yields, always on $G = 0$:

$$\dot{x} = |y|^{-1} \frac{\partial G}{\partial y}; \quad \dot{y} = -|y|^{-1} \frac{\partial G}{\partial x}, \tag{11}$$

where $\dot{z} \equiv dz/dt$.

Therefore, on $H = \frac{1}{2}$ we have the Hamiltonian system

$$\dot{x} = \frac{\partial H}{\partial y}; \quad \dot{y} = -\frac{\partial H}{\partial x} \tag{12}$$

with Hamilton function given by

$$H = \frac{1}{2} - |y|^{-1} G = \frac{1}{2} - |y|^{-1} (\sqrt{2F(x,y)} - 1) = \frac{1}{2}|x|^2 + \frac{1}{|y|}. \tag{13}$$

So that, doing $p = -x$ and $q = y$, the Hamiltonian system

$$\dot{q} = \frac{\partial H_C}{\partial p}; \quad \dot{p} = -\frac{\partial H_C}{\partial q} \tag{14}$$

for the function of Hamilton (1) on the energy surface $H_C = \frac{1}{2}$ is obtained. The generalization to arbitrary positive energy surfaces $H_C = \frac{1}{2}\alpha^2$ reduces to the previous particular case by simply scaling the variables: $q \to \alpha^2 q$; $.p \to p/\alpha$ and $t \to \alpha^3 t$.

Till now, we have omitted the point $P \equiv (-1,0,0,...,0)$ of the hyperboloid and the energy surface can be compactified by restoring it. In this way the regularization of the flow is obtained, the geodesics through the point P corresponding to the collision states $|p| = \infty$; $q = 0$.

Using the transformation given by Eq. (7), we can easily obtain the center of mass orbits for two charged particles of the same sign corresponding to the surface energy $H_C=\frac{1}{2}$. Since the orbits are planar, we consider $n=2$. Then geodesics in the hyperboloid $\mathscr{H}^{2+}\sqcup_{\partial}\mathscr{H}^{2-}\subset\mathscr{R}^3$ are given by the intersection of

$$-\xi_0^2+\xi_1^2+\xi_2^2=-1 \tag{15}$$

with the plane in which the geodesic lies, say β.

Choosing the coordinate system $(\hat{e}_0,\hat{e}_1,\hat{e}_2)$ in such a way that $\hat{e}_0$ is along the hyperboloid axis and the geodesic plane β contains $\hat{e}_2$, then

$$\xi_1=\xi_0\tan(\theta), \tag{16}$$

where θ is the dihedral angle between β and the plane defined by $\hat{e}_1$ and $\hat{e}_2$. Moreover, ξ_0, ξ_1 and ξ_2 can be parameterized in the form:

$$\xi_0=\frac{1}{\sqrt{1-\tan^2(\theta)}}\cosh(z);\quad \xi_1=\sinh(z);\quad \xi_2=\frac{\tan(\theta)}{\sqrt{1-\tan^2(\theta)}}\cosh(z) \tag{17}$$

and since, from Eq. (7),

$$y_i=\xi_i'(1+\xi_0)-\xi_i\xi_0';\quad i=1,2, \tag{18}$$

then the orbit for a particle in a repulsive Coulomb central field is obtained in the well known form:[1]

$$q_1=y_1=\sqrt{e^2-1}\,\sinh(z), \tag{19}$$

$$q_2=y_2=\cosh(z)+e, \tag{20}$$

where $e=1/\sqrt{1-\tan^2(\theta)}$ is the eccentricity of the hyperbola on the plane.

It has therefore been shown that the Eqs. (6), (7) and $t=\int|y(s)|ds$, map the unit tangent bundle $T(\mathscr{H}^n)=\{(\xi,\eta):\xi\in\mathscr{H}^n;\eta=d\xi(s)/ds\}$ into the $2n$-dimensional phase space $\mathscr{R}^{2n}=\{(q,p):q\in\mathscr{R}^n;p=dq(t)/dt\}$ and that the geodesic orbits on the hyperboloid map into the hyperbolas for a charged particle in a repulsive Coulomb field, as the theorem states.

Diagrams in classical and semiclassical perturbation theory

Panayotis Panayotaros
Department of Physics, The University of Texas at Austin, Austin, Texas 78712-1081

(Received 21 May 1996; accepted for publication 24 November 1997)

We describe a diagrammatic method for the Poincare–Birkhoff normal forms algorithm of classical mechanics, and indicate the use of the diagrams with an example from hydrodynamics. We also present a generalization of the diagrammatic method to quantum mechanics. The quantum diagrams can be used in the semiclassical version of normal forms developed by Graffi, Paul, and others. © *1998 American Institute of Physics.* [S0022-2488(98)02503-1]

I. INTRODUCTION

The dynamics of a Hamiltonian system near an elliptic fixed point is one of the basic problems of classical physics, arising in the stability of motion in mechanics, in weakly nonlinear waves in fluids, plasmas, and other media, and in many other situations. A powerful tool to analyze such dynamical systems is the Poincare–Birkhoff normal forms method of eliminating nonresonant terms in the Hamiltonian via canonical transformations (see, e.g., Ref. 1). Normal forms also appear in generalizations of the Bohr–Sommerfeld quantization condition to near-integrable systems. A recent approach to this question, developed by in Refs. 2–4 and others, led to a theory of semi-classical Poincare–Birkhoff normal forms that can be applied to many problems of quantum perturbation theory.

In most recent applications of classical normal forms, canonical transformations are constructed by the so-called Lie series method (see, e.g., Refs. 5–7). An analog of the Lie series is also used in semiclassical normal forms to construct unitary transformations (see, e.g., Refs. 3 and 8). A computational issue in using Lie series and its semiclassical analog is the efficient evaluation of repeated Poisson brackets (see, e.g., Ref. 9). In this note we point out that these operations have an elementary diagrammatic interpretation and that using the diagrams speeds up the calculations significantly. We indicate the use of the diagrams with an example of a normal form for an infinite-dimensional Hamiltonian system arising in hydrodynamics. We also show that diagrams and the operations between them have a natural ''quantization,'' and that in the $\hbar \to 0$ limit we obtain the classical diagrams. Quantum diagrams can be applied to semi-classical normal forms calculations, very much along the lines of the classical case.

II. CLASSICAL DIAGRAMS

The classical diagrammatic method consists of a correspondence between diagrams and functions on the phase space M, and a rule for assigning a new graph to the Poisson bracket of two graphs.

The classical phase space M will be $\mathbf{R}^{2d}$ with the canonical symplectic structure and corresponding Poisson bracket. Given a harmonic oscillator Hamiltonian with frequencies $\omega = [\omega_1,\ldots,\omega_d]$ we define the complex variables a_i, a_i^* by

$$a_i = \frac{1}{\sqrt{2}}\left(\sqrt{\omega_i}q_i + i\,\frac{p_i}{\sqrt{\omega_i}}\right), \quad a_i^* = \frac{1}{\sqrt{2}}\left(n\sqrt{\omega_i}q_i - i\,\frac{p_i}{\sqrt{\omega_i}}\right). \tag{2.1}$$

The map $a(q,p)$ embeds M canonically to $\mathbf{C}^{2d}$ with the Poisson bracket J given by

$$J(f,g) = \{f,g\} = i\sum_{i=1}^{d}\left(\frac{\partial f}{\partial a_i}\frac{\partial g}{\partial a_i^*} - \frac{\partial g}{\partial a_i}\frac{\partial f}{\partial a_i^*}\right). \tag{2.2}$$

 © 1998 American Institute of Physics

We may also consider infinite-dimensional analogs of the above phase space, e.g., with the index i running over $\mathbf{Z}^n$. What follows applies to the infinite-dimensional case as well. Observables will be assumed to be real analytic (i.e., polynomials in a_i, a_j^* for the purposes of formal calculations), vanishing at the origin. We now describe the diagrammatic rules.

(1) The set of graphs will be the set D of simply connected directed trees with indices at each leg (branch). (Legs will meet at vertices.) Legs connecting two vertices will be referred to as internal legs, while legs with a free end will be referred to as external legs. The one-vertex trees obtained by cutting the internal legs of a multi-vertex tree t will be called the one-vertex subtrees of t. External legs will carry one index. Internal legs will carry two indices, one for each vertex being connected, so that the one-vertex subtrees will be in D.

(2) To describe the correspondence between trees and polynomials, we start with one-vertex trees. We assign to each homogeneous polynomial term

$$\sum_{\kappa_1,\ldots,\kappa_n,\lambda_1,\ldots,\lambda_m} I_{\kappa_1\ldots\kappa_n\lambda_1\ldots\lambda_m} a_{\kappa_1}\cdots a_{\kappa_r} a^*_{\lambda_1}\cdots a^*_{\lambda_m}$$

a vertex with $n+m$ legs (branches), one leg corresponding to each of the a_{κ_i} and $a^*_{\lambda_j}$. On each leg there will be an arrow, pointing into the vertex for legs representing the $a^*_{\lambda_j}$ and outwards from the vertex for legs representing the a_{κ_i}. Also, each leg will carry the index of the a_{κ_i} or $a^*_{\lambda_j}$ it represents. The dots in the vertices represent the coefficients $\omega_{\kappa\lambda}$, $A_{\kappa\lambda\mu}$, etc., and the summation over the indices. The dots in the vertices should be represented by different symbols, e.g., boxes, triangles letters, so that we can distinguish between graphs with the same number of in-going and out-going legs but different coefficients.

(3) A multi-vertex tree represents a homogeneous polynomial in the variables indexed by the external legs of the tree. The out-going and in-going arrows represent the a_{κ_i} and $a^*_{\lambda_j}$, respectively. The coefficient of this polynomial will be the product of the coefficients of all the one-vertex subtrees of the multi-vertex tree, summed over all the indices appearing in external legs and contracted over the pairs of indices representing legs that connect vertices. Also, the polynomial represented by multi-vertex tree may be alternatively represented by a one-vertex tree with an appropriate coefficient.

Proposition 2.1: With the above conventions, the Poisson bracket $\{f,g\}$ of two trees $f,g \in D$ is the sum of the graphs obtained by joining an out-going arrow of f to an in-going arrow of g and the trees obtained by joining an in-going arrow of f to an out-going arrow of g. The trees obtained this way will also have signs: $(-i)$ for trees obtained by joining an out-going arrow of f to an in-going arrow of g, and $(+i)$ for trees formed by joining an in-going arrow of f to an out-going arrow of g.

Proof: Let

$$F=\sum_{c_1,\ldots,c_n,c_{n+1},\ldots,c_{n+m}} I_{c_1\ldots c_n c_{n+1}\ldots c_{n+m}} a_{c_1}\cdots a_{c_n} a^*_{c_{n+1}}\cdots a^*_{c_{n+m}}$$

and F' same as F with the I, n, and m primed. Using the bilinearity and the derivation property of the bracket we have

$$\{F,F'\}=\sum_{i,j}\sum_{\substack{c_1,\ldots,c_n,c_{n+1},\cdots,c_{n+m}\\ c_{1'},\ldots,c_{n'},c_{n'+1},\ldots,c_{n'+m'}}} I_{c_1\ldots c_n c_{n+1}\ldots c_{n+m}} I'_{c_{1'}\ldots c'_n c_{n'+1}\ldots c_{n'+m'}} \times\{f_{c_i},f_{c_j}\}\prod_{\alpha=1,\alpha\neq i}^{n+m} f_{c_\alpha}\prod_{\beta=1,\beta\neq j}^{n'+m'} f_{c_\beta}$$

with $f_{c_\alpha}=a_{c_\alpha}$ if $\alpha<n$, $f_{c_\alpha}=a^*_{c_\alpha}$ otherwise, and similarly for f_{c_β}. From $\{a_\kappa,a^*_\lambda\}=-i\delta_{\kappa\lambda}$, $\{a_\kappa,a_\lambda\}=\{a^*_\kappa,a^*_\lambda\}=0$, and the correspondence between trees and polynomials we obtain the rule. ■

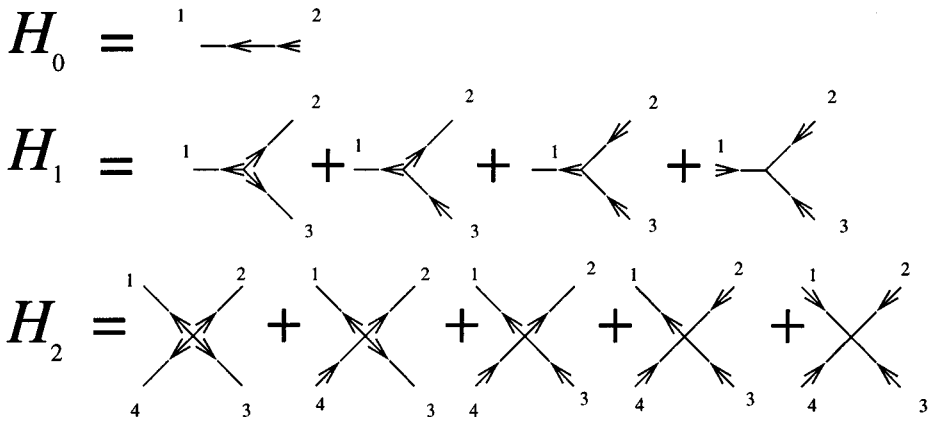

FIG. 1. The quartic water wave Hamiltonian.

The rules are essentially the same if we use the variables (q_γ, p_γ) or the well-known action-angle variables. Also, the diagrammatic notation can be compressed by considering diagrams without arrows or indices. One can calculate Poisson brackets with such trees and add arrows and indices afterwards.

III. AN APPLICATION TO FLUID MECHANICS

We indicate the use of diagrams with a normal form calculation for a Hamiltonian model of waves on the surface of a fluid layer surrounding a gravitating sphere. A detailed description of the model can be found in Ref. 10.

The canonical variables are the wave amplitude q and the surface hydrodynamic potential p, both functions on the two-sphere. The Hamiltonian is the total energy of the system. We denote the ith spherical harmonic coefficient of q,p by q_i, p_i, respectively. The index i runs over the pairs (l,m) with l a positive integer, $m=-l,-l+1,...,l$. Using the frequencies of the linearized problem we also define the complex variables a_i and a_i^* as in (2.1). The Poisson bracket is (after a change of coordinates) as in (2.2). The Hamiltonian H can be written as $H=H_0+\epsilon H_1+\epsilon^2 H_2+\cdots$, with H_m homogeneous polynomials of degree $m+2$ in a_i, a_i^* and ϵ a small dimensionless parameter. Physically, ϵ is the ratio of the typical wave amplitude over the thickness of the fluid layer. The other dimensionless parameter of the problem, the ratio β of depth over radius, is set here to $O(1)$. Graphically H is as in Fig. 1.

The normal form calculation consists of eliminating the cubic and part of the quartic terms of H by canonical transformations. It is convenient to use the multi-index notation $z^k \bar{z}^{\bar{k}} a_1^{k_1}\cdots a_d^{k_d}\cdots (a_1^*)^{\bar{k}_1}\cdots (a_d^*)^{\bar{k}_d}\cdots$, with $|k|=k_1+k_2+\cdots$, $|\bar{k}|=\bar{k}_1+\bar{k}_2+\cdots$, and write $H_m=\Sigma_{|\kappa|+|\bar{\kappa}|=m+2} A^m_{|\kappa|,|\bar{\kappa}|} z^k \bar{z}^{\bar{k}}$. Following the Lie series method (in the version of Ref. 6), we seek a function S_1 for which $\exp \epsilon \mathrm{Ad}_{S_1} H$ has no cubic terms. We are led to the ''homological equation'' $\{S_1,H_0\}+H_1=0$, which is solved by

$$S_1=\sum_{\kappa+\bar{\kappa}=3} \frac{A^1_{\kappa,\bar{\kappa}}}{\Sigma_i \omega_i (k_i-\bar{k}_i)} z^k \bar{z}^{\bar{k}},$$

i.e., the resonance condition is $\Sigma_i \omega_i (k_i-\bar{k}_i)=0$. In Ref. 10 we have shown that when the resonance condition is satisfied for some $k,\bar{k}$, the corresponding $A^1_{\kappa,\bar{\kappa}}$ must vanish, and thus ϵH_1 is formally eliminated. Next we eliminate the nonresonant terms of $\tilde{H}_2$, the quartic terms of $\exp \epsilon \mathrm{Ad}_{S_1} H$. We have that $\tilde{H}_2=H_2+\frac{1}{2}\{S_1,H_1\}$. Writing S_1 as in Fig. 2, we obtain $\tilde{H}_2$ graphically. We have shown that the resonant part of $\tilde{H}_2$ (denoted by $\bar{H}_2$) can only consist of terms corresponding to diagrams with two out-going and two in-going legs. $\bar{H}_2$ is represented in Fig. 3.

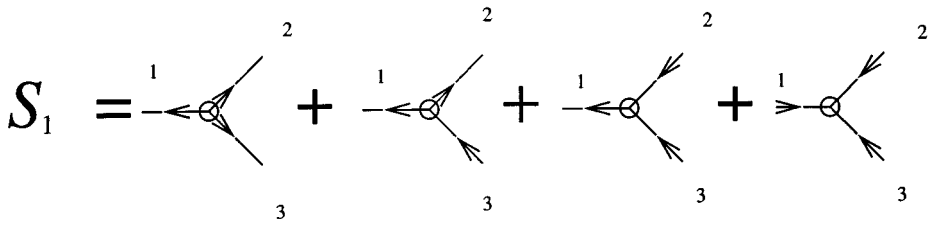

FIG. 2. The function S_1.

The normal form Hamiltonian $H_0+\overline{H}_2$ has several interesting properties. We can easily identify families of periodic and quasiperiodic orbits (the former representing traveling and standing waves) and finite-dimensional invariant manifolds. Also finite-dimensional truncations of $H_0+\overline{H}_2$, restricted to axisymmetric solutions, are completely integrable.

IV. SEMI-CLASSICAL DIAGRAMS

The rules for classical graphs have an interesting quantization that we now describe. As with the classical graphs, the natural application of the quantum diagrams is in semiclassical normal forms algorithm, for which we refer to Ref. 3.

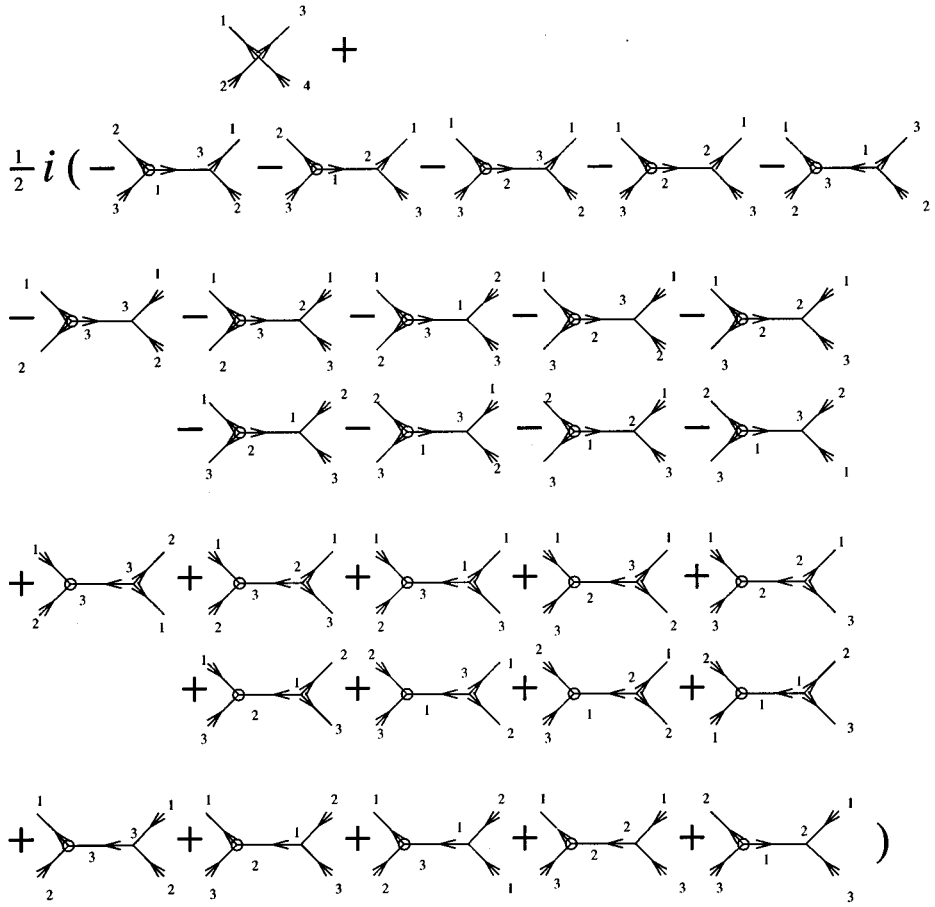

FIG. 3. The quartic part of the normal form Hamiltonian.

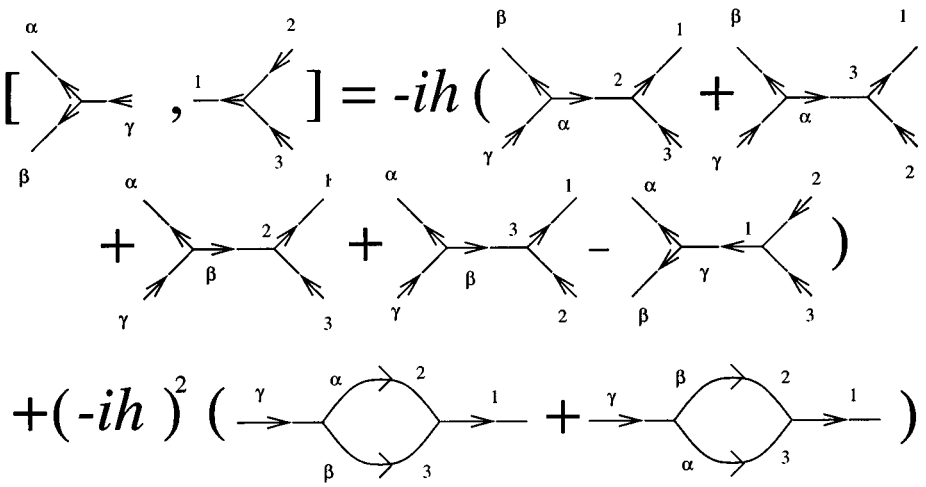

FIG. 4. Commutator of two quantum diagrams.

To describe the quantum diagrams, it is sufficient to consider the associative algebra W generated by the vectors $(a_j^*)\hat{}, \hat{a}_i$, $i,j=1,2,...,d$, that also satisfy the commutation relations

$$[\hat{a}_i,\ (a_j^*)\hat{}\,]=-i\hbar\,\delta_{ij},\quad [\hat{a}_i,\ \hat{a}_j]=[(a_i^*)\hat{},\ (a_j^*)\hat{}\,]=0,\quad \forall i,j=1,2...,d, \tag{4.1}$$

with $[f,g]=fg-gf$, $f,g\in W$. Informally, the $(a_j^*)\hat{}, \hat{a}_i$ are the ''creation–annihilation'' operators.

The graphical rules assign graphs to elements (polynomials) of W and also to the commutator of two graphs. Without loss of generality, we will assign graphs only to elements $\hat{w}$ of W that are Wick-ordered, i.e., with the $(a_j^*)\hat{}$ preceding the $\hat{a}_i$ in each monomial of $\hat{w}$. The rules are as follows:

(1) The set of graphs we consider will now be denoted by D_q. An element of D_q will be a directed tree with indices, constructed recursively in the following way: we take κ one-vertex elements t_i of D (as in Sec. II) and start by joining s_1 out-going (in-going) legs of t_1 to s in-going(out-going) legs of t_2. Denote this by $t_1\cup t_2$. At the ith step we join s_i out-going (in-going) legs of the $t_1\cup\cdots\cup t_i$ to s_i in-going(out-going) legs of t_{i+1}, until $i=\kappa-1$. The s_i are arbitrary. The external legs will carry one index, while internal legs will carry two indices, one for each vertex being joined. Note that $D\subset D_q$.

(2) We first discuss one-vertex trees. To a Wick-ordered homogeneous polynomial

$$\sum_{\kappa_1,...,\kappa_n,\lambda_1,...,\lambda_m} I_{\kappa_1...\kappa_n,\lambda_1...\lambda_m}(a_{\lambda_1}^*)\hat{}\cdots(a_{\lambda_m}^*)\hat{}\,\hat{a}_{\kappa_1}\cdots\hat{a}_{\kappa_n}$$

we assign a vertex with $n+m$ indexed legs with arrows, one out-going (in-going) leg for each $a_{k_i}(a_{k_j}^*)$. [This rule follows the classical one verbatim, with the $\hat{a}_i,(a_j^*)\hat{}$ playing the role of the a_i,a_j^*, respectively.]

The rule for assigning polynomials to multi-vertex graphs is similar to the one for the classical graphs. A multi-vertex tree represents a homogeneous polynomial in the variables indexed by the external legs of the tree. The out-going and in-going arrows represent the a_{κ_i} and $a_{\lambda_j}^*$, respectively. The coefficient of this polynomial will be the product of the coefficients of all the one-vertex subtrees of the multi-vertex tree, summed over all the indices appearing in external legs and contracted over the pairs of indices representing legs that connect vertices. Note that now multi-vertex graphs can be multiply connected. An example is in Fig. 4.

Proposition 4.1: The commutator $[F,G]$ of two graphs F,G is the sum of all graphs obtained by joining n in-going arrows of F to n out-going arrows of G and n out-going arrows of F to n in-going arrows of G, where $n=1,2,3,...$. The graphs will be multiplied by signs and powers of $\hbar$:

$(-i\hbar)^n$ for graphs obtained by joining n out-going legs from F to n in-going of G, and $-(-i\hbar)^n$ for graphs obtained by joining n in-going legs from F to n out-going from G.

Proof: We consider the commutator of two operators

$$\hat{F}=\sum A_{\overline{\kappa}_1,\ldots,\overline{\kappa}_{\overline{\mu}},\kappa_1,\ldots,\kappa_\mu}(a^*_{\overline{\kappa}_1})\hat{}\cdots(a^*_{\overline{\kappa}_{\overline{\mu}}})\hat{}\,\hat{a}_{\kappa_1}\cdots\hat{a}_{\kappa_\mu}$$

and

$$\hat{G}=\sum B_{\overline{\lambda}_1,\ldots,\overline{\lambda}_{\overline{\nu}},\lambda_1,\ldots,\lambda_\nu}(a^*_{\overline{\lambda}_1})\hat{}\cdots(a^*_{\overline{\lambda}_{\overline{\nu}}})\hat{}\,\hat{a}_{\lambda_1}\cdots\hat{a}_{\lambda_\nu}.$$

We first Wick-order $\hat{F}\hat{G}$ by passing the $\hat{a}_{\kappa_i}$ to the right of the $(a^*_{\overline{\lambda}_j})$ in a systematic way. We order the pairs of the subindices (i,j) of the $\hat{a}_{\kappa_i},(a^*_{\overline{\lambda}_j})\hat{}$ lexicographically, i.e., $(1,1)<(1,2)<\cdots<(\mu,\overline{\nu})$. Also we use the multi-index $\gamma=(i,j)$ and for $\gamma=(a,b)$ let $I(\gamma)=a$, $J(\gamma)=b$. Also $\Gamma_0=\{(i,j)|i=1,\ldots,\mu,j=1,\ldots,\overline{\nu}\}$. Define $L_{ij}\hat{F}\hat{G}$ to be $\hat{F}\hat{G}$ with $\hat{a}_{\kappa_i}$ and $(a^*_{\overline{\lambda}_j})\hat{}$ interchanged, and $R_{ij}\hat{F}\hat{G}$ to be $\hat{F}\hat{G}$ with $\hat{a}_{\kappa_i}$ and $(a^*_{\overline{\lambda}_j})\hat{}$ replaced by $[\hat{a}_{\kappa_i},(a_{\lambda_j})\hat{}]$. We write

$$\hat{F}\hat{G}=L_{1,1}\hat{F}\hat{G}+R_{1,1}\hat{F}\hat{G}=L_{1,2}L_{1,1}\hat{F}\hat{G}+R_{1,2}L_{1,1}\hat{F}\hat{G}+R_{1,1}\hat{F}=\cdots,$$

i.e., apply $L_{i,j}$ repeatedly, in the order induced by the (i,j), each time producing a commutator, and so that at most one commutator appears in each term. The procedure terminates after μ steps and we have $\hat{F}\hat{G}=S_1\hat{F}\hat{G}$ with

$$S_1\hat{F}\hat{G}=\sum_{\gamma_1\in\Gamma_1}\widetilde{R}_{\gamma_1}\prod_{\tau_1\in T_1}L_\tau\hat{F}\hat{G},$$

where $\Gamma_1=\Gamma_0$ and $\widetilde{R}_{\gamma_1}=L_{\gamma_1}$ if $\gamma_1=\max\{\gamma\in\Gamma_1\}$, R_{γ_1} otherwise, and $T_1\equiv T(\gamma_1)=\{\tau\in\Gamma_1|\tau<\gamma_1\}$. We repeat the procedure to terms of $S_1\hat{F}\hat{G}$ that are not Wick-ordered, so as to have at most two commutators. We get $S_2\hat{F}\hat{G}$, and similarly $\hat{F}\hat{G}=S_1\hat{F}\hat{G}=\cdots=S_n\hat{F}\hat{G}=\cdots$ with

$$S_n\hat{F}\hat{G}=\sum_{\gamma_1\in\Gamma_1}\left(\cdots\left(\sum_{\gamma_{n-1}\in\Gamma_{n-1}}\left(\sum_{\gamma_n\in\Gamma_n}\widetilde{R}_{\gamma_n}\prod_{\tau_n\in T_n}L_{\tau_n}\right)\widetilde{R}_{\gamma_{n-1}}\prod_{\tau_{n-1}\in T_{n-1}}L_{\tau_{n-1}}\right)\cdots\cdots\right)$$
$$\times\widetilde{R}_{\gamma_1}\prod_{\tau_1\in T_1}L_{\tau_1}\hat{F}\hat{G},$$

where $\Gamma_p=\{\gamma\in\Gamma_0|I(\gamma)>I(\gamma_{p-1}),J(\gamma)\neq J(\gamma_{p-1}),\ldots,J(\gamma_1)\}$, $T_p\equiv T(\gamma_p)=\{\tau\in\Gamma_p|\tau<\gamma_p\}$ and $\widetilde{R}_{\gamma_p}=L_{\gamma_p}$ if $\gamma_p=\max\{\gamma\in\Gamma_p\}$, R_{γ_p} otherwise.

Then note that, first in $S_n\hat{F}\hat{G}$ we encounter all the possible products of commutators $[\hat{a}_{\kappa_{\sigma_1}},(a^*_{\overline{\lambda}_{\rho_1}})\hat{}]\cdots[\hat{a}_{\kappa_{\sigma_n}},(a^*_{\overline{\lambda}_{\rho_n}})\hat{}]$ with $\sigma_1<\sigma_2<\cdots<\sigma_n$ and $\rho_j\neq\{\rho_1,\ldots,\rho_{j-1}\}$, $j=1,\ldots,n$, each such product appearing once as a summand of $S_n\hat{F}\hat{G}$. Moreover, in $S_{n+1}\hat{F}\hat{G}$ all these terms are Wick-ordered and therefore, from the diagrammatic interpretation at $S_{n+1}\hat{F}\hat{G}$, we have all the diagrams with m out-going legs of $\hat{F}$ joined to m in-going legs of $\hat{G}$, with $m=1,2,\ldots,n$, plus $\hat{F}\hat{G}$ Wick-ordered.

Applying the algorithm to $\hat{G}\hat{F}$ we similarly obtain the diagrams with m in-going legs of $\hat{F}$ joined to m out-going legs of $\hat{G}$, with $m=1,2,\ldots,n$, plus $\hat{F}\hat{G}$ Wick-ordered. Considering $\hat{F}\hat{G}-\hat{G}\hat{F}$, we have the proposition.

■

Remark 3.1: Comparing the last rule with its classical analog we have, graphically, the classical limit (see, e.g., Ref. 11)

$$\lim_{\hbar \to 0} \frac{i}{\hbar} [\hat{f}, \hat{g}] = \{f, g\}.$$

In discussing the quantum graphs, quantization, i.e., the map from functions on the phase space to operators in a Hilbert space (see Ref. 11), enters only indirectly, through the commutation relations. In applying the graphs to the semi-classical normal form algorithm of Ref. 2, it is assumed that the quantization step is already taken and that the Hamiltonian operator has been Wick-ordered. Thus we only deal with Wick-ordered operators.

In conclusion, we have presented simple diagrammatic rules for classical and semi-classical normal forms. The rules highlight the combinatorial nature of the computations and can also be implemented in the computer.

Exact solutions for nonconservative two-velocity discrete Boltzmann models

H. Cornille
Service de Physique théorique, CE Saclay, F-91191 Gif-sur-Yvette, France

(Received 31 January 1997; accepted for publication 29 December 1997)

Extended discrete kinetic theory (which we call nonconservative), including sources, sinks, creation and annihilation of test particles, inelastic scattering,... added to the elastic collisions, was recently introduced. For instance, the mass conservation law, by adding polynomials of the mass, becomes nonconservative. To the classical two-velocity elastic collision models, we associate two nonconservative models with polynomials of the first and second degree. We obtain exact stationary, similarity, $(1+1)$-dimensional and periodic solutions. For their stability we study the corresponding nodes and saddles. © *1998 American Institute of Physics.* [S0022-2488(98)01304-8]

I. INTRODUCTION

Recently,[1–3] extended discrete kinetic theory (nonconservative) became a popular field of research. The reason being, as it is written in the literature, that the *study of a gas with only elastic scattering between the molecules seems to be too idealized for application to the real world*. So they add a background medium, external sources and sinks, effects of absorption and generation due to inelastic scattering... . A great difference, with conservative discrete kinetic theory,[4] is that the conservation laws are modified by including polynomials in the mass variable. While for conservative models the determination of exact solutions is well understood,[5] for *nonconservative models exact solutions are missing*. One advantage of these nonconservative models is that important difficulties of the conservative ones disappear. For instance, the models with two-velocity violating momentum conservation relation, those with only one speed for which mass and energy conservation laws cannot be distinguished, the problem of appearance of spurious conservation laws for which ternary, quaternary collisions (not present in the Boltzmann equation) must be introduced... . However, I recall that in the instance of shock waves, the existence of conservation laws[4] is useful for the study of supersonic and subsonic inequalities and applications of the Whitham and Lax criteria. There remains, in both cases, the problem of the link between discrete and continuous theory (see Cercignani[4]).

On the other hand, for the exact solutions of conservative models, the existence of linear conservation laws is crucial for the understanding of these solutions. Let us summarize: for the similarity solutions let us first consider the models where in addition to the linear conservation laws, only one nonlinear quadratic equation remains. When we introduce the properties coming from the linear differential conservation law, the nonlinear one is reduced to a scalar Riccati[6] equation that we can integrate. Second consider the models with two, three,... remaining nonlinear quadratic equations. Integrating the linear conservation laws leaves only two, three... independent densities satisfying a 2×2, 3×3,... Riccati coupled system. Then, with the compatibility condition, we can still obtain scalar Riccati-type of solutions. However, other solutions exist[5] which are not of the scalar Riccati-type. Let us now consider $(1+1)$, $(2+1)$ dimensional solutions which are sums $f=\Sigma f_i$ of two, three similarity solutions. From the superposition principle they are automatically satisfied for the linear differential conservation laws. For the remaining nonlinear equations we obtain compatibility conditions between the loss and gain collision terms. For quadratic, cubic... collision terms we have constraints coming from the products $f_i f_j$, $f_i f_j f_k$,... .

Now clearly when the linear conservation laws do not exist, they cannot be obtained in this context; our goal is to try to obtain a new characterization of the exact solutions. For simplicity we limit our study to elastic collisions with two velocities—the Illner[7] models which include the

 © 1998 American Institute of Physics

McKean, Carleman, and dual McKean models. The addition of only constants in the linear conservation laws, previously studied,[1–5] will not be considered.

For a two-velocity model with densities N_i, $i=1,2$ associated to the velocities ± 1 let us consider the mass conservation law for the mass $\rho=N_1+N_2$ and the momentum $j=N_1-N_2$. For the nonconservative models the rhs becomes a polynomial of degree k in ρ,

$$\rho_t+j_x=0\rightarrow P_k(\rho). \tag{1.1}$$

It remains a nonlinear equation which, for the conservative models, depends only on the elastic collision term. Here we consider the Illner model with collision terms for N_i,

$$\mathrm{Col}_{N_1}=-\mathrm{Col}_{N_2}=aN_1^2-(a+c)N_1N_2+cN_2^2,\ \ a\leqslant 0,\ \ c\geqslant 0,$$

called McKean when $a=0$, $c=1$, Carleman for $-a=c=1$, and dual McKean for $a=-1$, $c=0$. For the nonconservative model, Col_{N_i} correspond to the collisions between the test particles and we add another polynomial in ρ, j,

$$\rho_x+j_t-(a+c)j^2-j\rho(a-c)=0\rightarrow Q_k(\rho,j). \tag{1.2}$$

In Sec. II we consider the Platkowski–Spiga[2] linear nonconservative model,

$$P_1=(\eta-\epsilon)\rho+S,\ \ S=S_1-S_2,\ \ Q_1=-j\epsilon+\eta\rho(2\kappa-1)+S_1+S_2, \tag{1.3}$$

with $\epsilon\geqslant 0$ ($\eta\geqslant 0$), for the absorption collision (generation) by the background and $\kappa\in(0,1)$ (or $1-\kappa$) for the secondary particles generated with velocity $+1$ (or -1) with the background. $S_1>0$, ($S_2>0$) are associated to the external source (sink). We determine exact solutions and study their stability properties. The equilibrium states for the mass ρ is given by $P_1=0$ with only one state for this model. Up to now we have not found that traveling satisfies the positivity constraints. Let us consider stationary solutions for the associated conservative model. We get $j=c_1$, $\rho_x=c_2+c_3\rho$ ($c_i=$const.) and exponential type solutions which are not bounded when $|x|=\infty$. The nonconservative models could be interesting if we obtain solutions bounded when $|x|=\infty$. For stationary solutions the (1.1)–(2)–(3) equations give, for the momentum $j=j_0+j_1J(x)$, a second-order nonlinear differential equation satisfying the necessary Painlevé condition for the nonexistence of movable critical singularities except poles.[8] We want to give examples of Riccati solutions either bounded or not. For a first class (Figs. 1) with only j_0 as asymptotic state, Sec. II A, we apply the Bureau[8] transform giving Riccati equations with or without x-dependent coefficients. We obtain either solutions written in terms of the modified Bessel function $I_0(e^{Cx/2})$ not bounded when $|x|=\infty$ and we require a specular reflection boundary condition, or solutions[9] $j(x)=j_0+j_1/(x+d)$, infinite for $x+d=0$, $d>0$ or <0 but there exist positive $N_i(x)$ solutions. For a second class with j_0, j_0+j_1 asymptotic states, Sec. II B, we apply another transform, still reducing to Riccati equations with either solutions of the modified Bessel-type or solutions $j(x)=j_0+j_1/(1+de^{\gamma x})$ bounded when $|x|=\infty$ (Figs. 2). For the two classes we must satisfy the same parameters $S(a,c,\epsilon,\eta,\kappa)$ condition. For the elementary solutions with d an arbitrary integration constant, contrary to solutions with inverse powers, those with inverse exponentials and $d>0$ are not infinite for a particular x value. For these solutions, we find two cases for the positivity of the densities: either only solutions with $d>0$, (finite for any x value) or for both $d>0$ and $d<0$ (infinite for one x value). We study their stability properties and determine the saddles and nodes. We consider two classes of models; either with only absorption $\epsilon\neq 0$, $\eta=0$ and source, sink S_i or adding generation $\eta\neq 0$, $\kappa\neq 0$. With $S_1\neq 0$ we find either sinks $S_2>0$ or $S_2=0$. For the Illner model, we obtain positive solutions for $a/c\in(0,-0.1)$ and for the dual McKean model new solutions with $S_1<0$ (sink) and $S_2<0$ (source).

In Sec. III we consider the Piechòr–Platkowski[3] quadratic nonconservative model where the nonlinear (including Illner term) equations are written for the densities N_i, $i=1,2$,

$$\begin{gathered}P_2=(\alpha-\beta)\rho^2+(\eta-\epsilon)\rho+\sigma,\ \ \sigma=S_1+S_2+\zeta,\ \ L_i\equiv N_{i,t}+(-1)^{i+1}N_{i,x}\equiv R_i,\\ R_i\equiv\mathrm{Col}_{N_i}+(2-i+(-1)^i\kappa)[\alpha\rho^2+\eta\rho+\zeta]-N_i(\beta\rho+\epsilon)+S_i,\end{gathered} \tag{1.4}$$

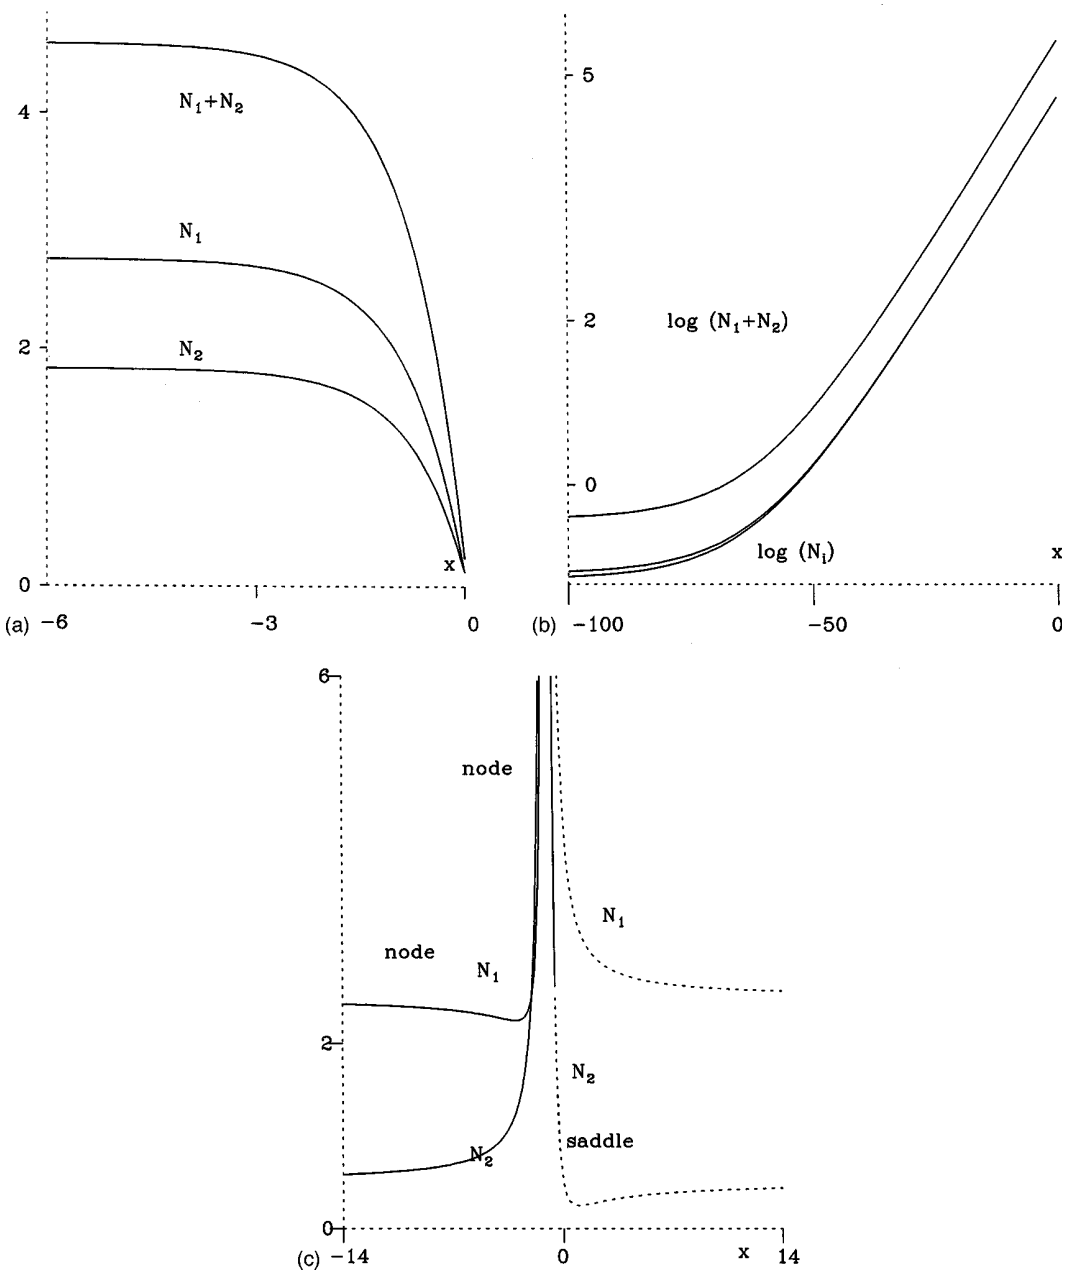

FIG. 1. Linear nonconservative model. (a), (b) Modified Bessel stationary solutions with specular reflection at $x=0$. (a) $a=-0.4$, $c=0.2$ S_1 source, S_2 source and (b) $a=-0.95$, $c=1$ S_1 sink, S_2 sink. (c) Inverse power-like stationary solution for McKean $a=0$, $c=1$, $\epsilon=1$ model with S_1 source, S_2 sink.

with $\beta\geqslant 0$, $\epsilon\geqslant 0$ ($\alpha\geqslant 0,\eta\geqslant 0,\zeta\geqslant 0$) for the annihilation (creation) of test particles as a result of inelastic collisions, $\kappa=0$ or 1 represents the fraction of secondary particles generated with velocity $+1$ or -1 and $\sigma>0$ is essentially the external bulk source.

Here, contrary to the previous model, the equilibrium states for the mass ρ are the two different roots of $P_2=0$. We are more interested in similarity, $(1+1)$-dimensional and periodic solutions. Firstly we show that the similarity (stationary) solutions with the variable $z=x-\xi t(z=x)$ can be obtained from a compatibility condition between two Riccati equations with constant coefficients or equivalently between two linear first-order differential equations. These solutions are rational functions of an exponential variable $de^{\gamma z}$. We study the stability at the two asymptotic states. Second, for the $(1+1)$-dimensional solutions (which are not sum of two similarity solutions) we find the same structure, the exponential variable being replaced by a sum of an arbitrary

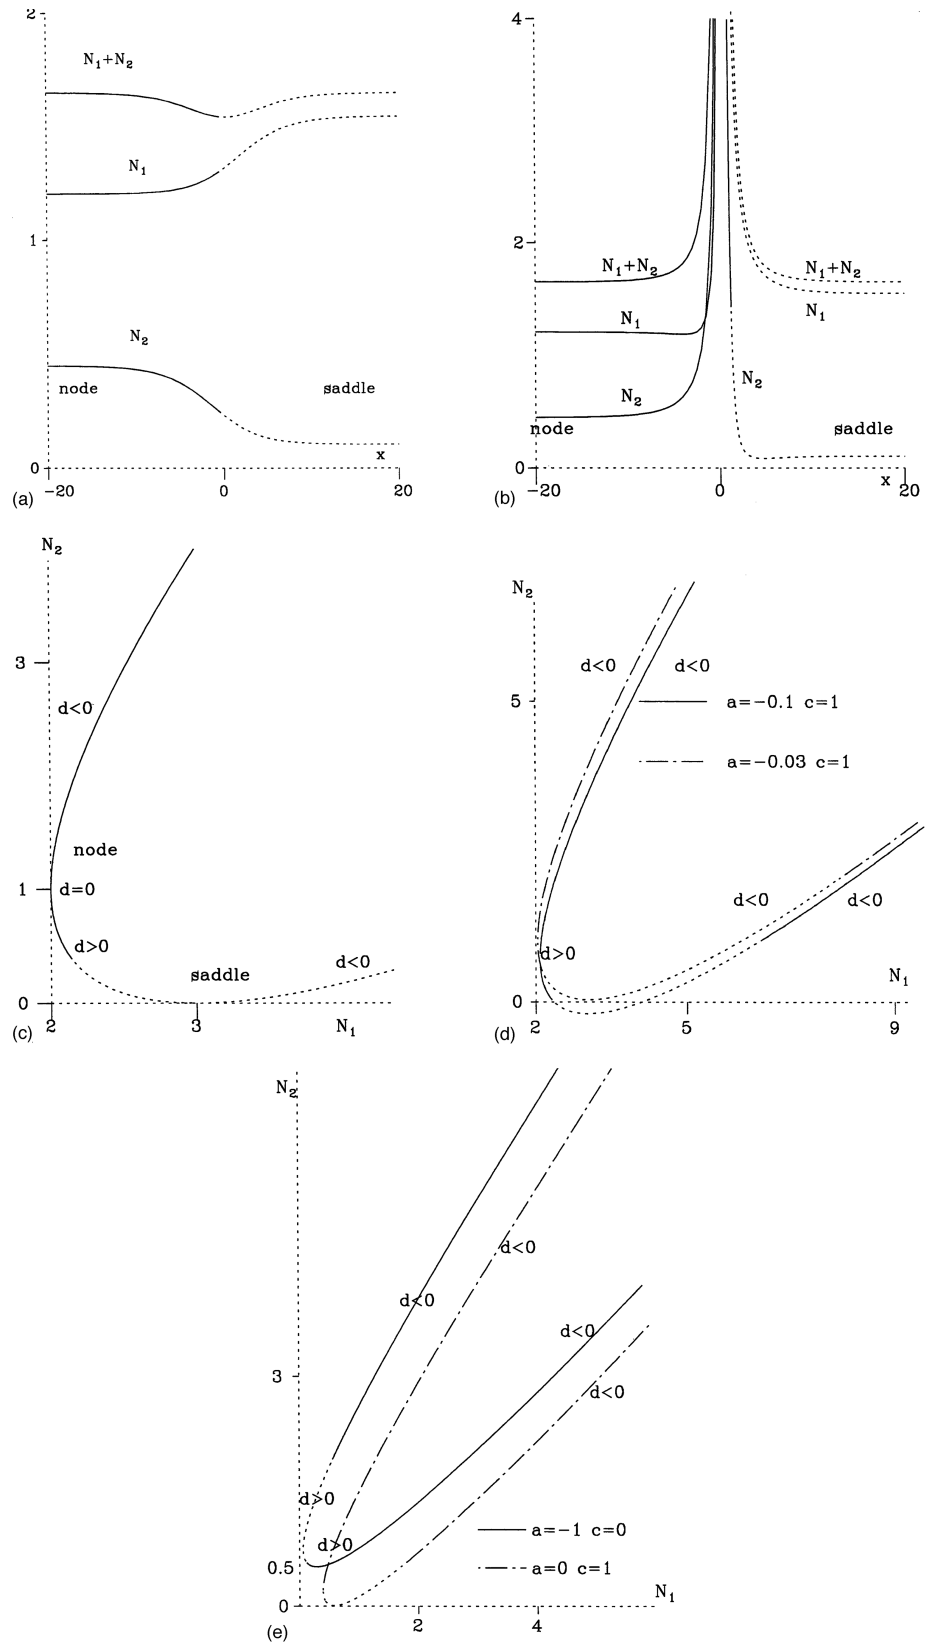

FIG. 2. Linear nonconservative model. Stationary solutions. Only absorption and McKean model $a=0$, $c=1$. $d>0$ in (a) $d<0$ in (b) and N_1, N_2 curve for $d>0$, <0 in (c). (d) Stationary solutions. Only absorption and Illner model, $c=1$ and N_1, N_2 curves for $d>0$, <0. For $a=-0.03$ both $N_i>0$ while for $a=-1$ part of $N_2<0$ for $d<0$. (e) Stationary solution. Absorption, generation, and positive N_1, N_2 curve for $d>0$, <0. Both McKean model with $a=0$, $c=1$, S_i source, sink and dual McKean model with $a=-1$, $c=0$, S_i sink, source.

number of $d_i e^{\gamma i(x-\xi_i t)}$ terms, one density being constant and only for the McKean and dual McKean models. In Sec. III A for the model with $\kappa=0$ we study the similarity solutions for both the Illner, McKean, Carleman, and dual McKean models. In Sec. III B for the McKean and its dual models we get both $(1+1)$-dimensional and periodic solutions.

II. EXACT SOLUTIONS FOR THE MODELS WITH A LINEAR NONCONSERVATIVE RELATION

For the Platkowski–Spiga models with mass ρ and momentum j we rewrite both (1.1)–(2)–(3),

$$\rho_t+j_x=(\eta-\epsilon)\rho+S,\ \ S_1>0,\ \ S=S_1-S_2>0,\ \ \epsilon>0,\ \ \eta>0, \tag{2.1}$$

$$\rho_x+j_t=j^2(a+c)+j(\rho(a-c)-\epsilon)+\rho\eta(2\kappa-1)+S_1+S_2,\quad \kappa\in(0,1). \tag{2.2}$$

We have found both similarity (functions of $x-\xi t$), $(1+1)$ and stationary solutions but only the last ones are positive. For these stationary N_i solutions we mainly study those with second-order movable poles in the variable $w=de^{\gamma x}$ (d being arbitrary). What is new, compared with previous similar exact solutions, is that there exist solutions $N_i(x,d)$ which remain positive for both $d>0$ and <0 values.

For the stationary solutions we rewrite (2.1)–(2), define ($'=d/dx$), the constant asymptotic values $\rho_{\rm as}=\rho_0$, $G(j_{\rm as})=0$ when $j'=0$,

$$j(x)=j_0+j_1J(x),\ \ \rho(x)=\rho_0+j'/(\eta-\epsilon),\ \ \rho_0=S/(\epsilon-\eta)=\rho_{\rm as}, \tag{2.1$'$}$$

$$[J'-J^2(a-c)j_1/2-J(j_0(a-c)+\eta(2\kappa-1)]'\equiv\overline{G}(J,j_0,j_1)+G(j_0)/j_1, \tag{2.2$'$}$$

$$\overline{G}=(\eta-\epsilon)[J^2j_1(a+c)+J[2j_0(c+a)+\rho_0(a-c)-\epsilon)]],$$

$$G(j_{\rm as})/(\eta-\epsilon)=j_{\rm as}^2(c+a)+j_{\rm as}[\rho_0(a-c)-\epsilon]+S_1+S_2+\rho_0\eta(2\kappa-1). \tag{2.3}$$

No J'^2 term is present in (2.2$'$) which belongs, in the Painlevé classification,[8] to a well-known class. We seek Riccati-type of solutions. Different cases occur with $G(j_0)=0,\neq 0$, $G(j_0+j_1)=0,\neq 0$... . As we shall see $j(x)$, for $N_i(x)>0$ solutions, can be not bounded, in particular when $|x|=\infty$, or bounded for all x.

A. Bureau transform with only $G(j_0)=0$

In Appendix A1 we give a transform[8] $W(x)=J'(x)+J^2(x)$, $W'=CW$ leading to Riccati-type of equations for $W\neq 0,=0$. First, in (A11) we get $J(x)=\partial_x \log I_0(e^{Cx/2})$ (I_0 modified Bessel function) with momentum $j(x)$ not bounded when $e^{Cx/2}\to\infty$. We introduce a specular reflection boundary condition $N_1(0)=N_2(0)$ and $N_i(x)$ along a half-axis $Cx\leqslant 0$. In Fig. 1(a), (b) we get S_i sources (sinks). For $(a,c,\eta,\epsilon,\kappa,S_1,S_2,S,C)$ we have in Fig. 1(a) $(-0.4,0.2,0.85<2.7,0.91,0.2,-8.31,>0,1.26)$ and in Fig. 1(b), $(-0.95,1,2.65>0.67,0.51,-0.7,0.62,<0,0.1)$.

Second,[9] in (A13) we consider a class $J(x)(x+d)=1$ of power-like N_i solutions, infinite when $x=-d$ ($d>0$ or <0), but positive [see (A3)–(A3$'$)]. In Fig. 1(c) we present a McKean solution with $c=\epsilon=d=1$, $a=\eta=\kappa=0$, $S_i=3.5,0.5$ (source and sink).

B. Transform associated with $G(j_0)=G(j_0+j_1)=0$

In Appendix A2 we give a transform $\gamma:=j_1(a-c)/2$, $W(x)=J'(x)-\gamma J(J-1)$, $W'=CW$ leading to Riccati-type of equations with $W\neq 0,=0$. From $G(j_{\rm as})=0$ we get a j_0,j_1 relation and rewrite $\overline{G}$,

$$j_1+2j_0=[S(a-c)+\epsilon(\eta-\epsilon)]/(a+c)(\eta-\epsilon),\ \ \overline{G}=j_1(a+c)(\eta-\epsilon)J(J-1). \tag{2.4}$$

In the sequel we are restrict to $W(x)=0$ and (2.2$'$)–(4) leads to two Riccati equations,

$$J'=\gamma J(J-1)=-[j_1(a+c)(\eta-\epsilon)]J(J-1)/[(j_1/2+j_0)(a-c)+\eta(2\kappa-1)]. \tag{2.5}$$

TABLE I. Stationary solutions for the linear nonconservative models.

$\delta \doteq [\rho_0(c-a+\epsilon)/2(a+c)]^2-[S_1+S_2+\rho_0\eta(2\kappa-1)]/(a+c)$
$j_0=[\rho_0(c-a)+\epsilon]/2(a+c)\pm\sqrt{\delta},\ j_1=\mp 2\sqrt{\delta}=2\gamma/(a-c),$
$j(x)=j_0\mp 2\sqrt{\delta}/\Delta(x),\ \Delta(x)-1=w(x)=de^{\gamma x},\ \gamma=\pm(c-a)\sqrt{\delta}$
$(\epsilon-\eta)\rho(x)=S+2\delta(a-c)w(x)/\Delta^2(x),\ de^{\gamma x}=-1+j_1/(N_1-N_2-j_0)$
$j_1^2(N_1+N_2-\rho_0)=\rho_1(N_1-N_2-j_0)(j_1-N_1+N_2+j_0)$

McKean model $a=\eta=0,\ c=1,\ S_1=3\epsilon^2+S_2$:
$S_2\neq 0$: $j(x)=2\epsilon\pm\sqrt{\delta}[1-2/\Delta(x)],\ \rho(x)=3\epsilon-2\delta w(x)/\epsilon\Delta^2,$
$\Delta-1=w(x)=de^{\pm\sqrt{\delta}x},$
$\delta=\epsilon^2-2S_2,\ 2n_{1,\mathrm{as}}=5\epsilon\pm\sqrt{\delta}>0,\ 2n_{2,\mathrm{as}}=\epsilon\mp\sqrt{\delta}>0$
$S_2=0$: $S_1=S=3\epsilon^2,\ j/\epsilon=2\pm 1\mp 2/\Delta,\ \rho/\epsilon=3-2w/\Delta^2,$
$\Delta(x)-1=w(x)=de^{\pm\epsilon x}$
$N_1/\epsilon=(5\pm 1)/2-[\pm 1+w(\pm 1+1)]/\Delta^2,$
$N_2/\epsilon=(1\mp 1)/2+[\pm 1+w(\pm 1-1)]/\Delta^2$

The compatibility gives, with (2.4), a relation between the model parameters $S(\epsilon,\eta,\kappa,a,c)$,

$$S(c-a)=[2(\epsilon-\eta)(c+a)/(a-c)]^2-(\epsilon-\eta)[\epsilon+2\eta(1-2\kappa)(c+a)/(c-a)]. \tag{2.6}$$

Writing $J=1/\Delta(x)$ we get $\Delta=1+w,\ w=de^{\gamma x}$ with d arbitrary (see Table I).

In Appendix A21 we study the linear stability around the asymptotic values $|x|=\infty$ and for any finite x. One characteristic value is $\eta-\epsilon$ negative for $\eta=0$, while the other has opposite values for $|x|=\infty$ and vanishes for one finite $w=de^{\gamma x}>0$ and another <0 values. Consequently, for both $d>0$ and $d<0$ solutions, the second characteristic vanishes only one time and we always have both a node (attractive for $\eta=0$) and a saddle.

Illner models with only absorption, $-0.1\leqslant a/c\leqslant 0$ *and* $\epsilon\neq 0$. In Appendix A22 we give the positivity proof and in Table I summarize the McKean results for $S_2\neq 0,=0$.

Numerical calculations for N_i, $\rho=N_1+N_2$ and both the McKean (dual) models [Figs. 2(a)–2(c) and 2(e)] and the Illner model $|a/c|\leqslant 0.1$, Fig. 2(d). The solid and dotted lines correspond, respectively, to attractive nodes and saddle-points,

Figs. 2	a	c	ϵ	S_1	S_2	S	d
a,b,c	0	1	0.55,0.55,1	1	0.092,0.092,0	0.9,0.9,1	$0.9,-0.9$
							$>0<0$
d,e	$-0.1,-0.03$	1	1.6,1.15	4.5,3.6	0.596,0.33	3.9,3.27	$>0<0$

In Fig. 2(a) with $d>0$, $(1+w)^2\neq 0$ and we find N_i monotonic and ρ nonmonotonic. On the contrary $d<0$ in Fig. 2(b), the denominator of ρ has a double root and $\rho>0$ while with a simple root $j>0$ and <0. The positivity conditions, only for N_i,ρ, (infinite for a particular value) are satisfied. In Fig. 2(b) both N_i and ρ are nonmonotonic. Other $d>0$, <0 values lead to similar patterns. The transition value being $d=0$, we choose in Fig. 2(c),

$$N_1(x)=3-(1+2w(x))/\Delta^2,\ \ N_2(x)=1/\Delta^2,\ \ N_1=3+N_2+\zeta 2\sqrt{N_2},\ \ \zeta^2=1, \tag{2.7}$$

and present the N_1,N_2 curve which is d-independent but different for $d>0$ or <0. The two $d>0$, <0 curves are separated; both $N_2<1$, $N_1<3$ for $d>0$, $\zeta=-1$ and either $N_2>1$, $\zeta=-1$ or $N_1>3$ for $d<0$, $\zeta=1$. $d=0$ is at the transition $N_2=1$, $N_1=0$. The change between solid and dotted lines, depending only on a w fixed value, is independent of d and is always the same here. We find for $d>0$, $w=(\sqrt{5}-1)/2$, $N_2=0.38$, $N_1=2.14$ and for $d<0$, $w=-(\sqrt{5}+1)/2$, $N_2=2.6$, $N_1=8.85$ [not present in Fig. 2(c)].

For the Illner models ($a<0$) we can write the N_2,N_1 curve independent of $w(x,d)$ and deduce the sign of $de^{\gamma x}$ (Table I). One N_2 curve with $d<0$ can violate positivity. In Fig. 2(d), $a=-0.1$, $d>0$, $N_i>0$ corresponds to $N_1\in(2.38,2.49)$, $N_2\in(0.04,0.056)$ while for $d<0$ and $N_1\in(2.44,4.12)$ one branch of the N_2 curve is negative. For $a=-0.03$, $N_i>0$ for $d>0$ and <0. Starting with $a=0$ or $-a$ small, $N_i>0$ for $d>0$, <0 exist while when $-a$ increases, after a critical a value, positivity subsists only for $d>0$.

Models with absorption and generation $\eta\neq 0$, $\epsilon\neq 0$. For $\eta<\epsilon$, η sufficiently small all the previous solutions with $\eta=0$, $S_1>0$ (source) and $S_2\geqslant 0$ (sink) can be extended but new $\eta\neq 0$ solutions exist. For the dual McKean model we find for $\kappa\in(0,1)$ positive solutions with $S_1<0$ (sink) and $S_2<0$ (source). In Fig. 2(e) for $\eta=0.01$, $d>0$, <0, for the McKean $a=0$, $c=1$ and the dual McKean $a=-1$, $c=0$ models we, respectively, choose for $(\epsilon,\kappa,S_1,S_2,S)$: (0.2,1,0.11,0,0.11) and (0.237,0,−0.025,−0.182,0.157).

III. EXACT SOLUTIONS FOR MODELS WITH A QUADRATIC NONCONSERVATIVE RELATION

For the Piechor–Platkowski models (1.4), for the mass ρ and one of the two densities $w=2N_2$ we rewrite both the nonconservative equation and the w nonlinear equation, including the Illner models, with non-negative constants α, β, ζ, η, ϵ, σ and $\kappa=0$ or 1,

$$\rho_t+j_x=\rho_t+\rho_x-w_x=(\alpha-\beta)\rho^2+(\eta-\epsilon)\rho+\sigma,\quad \alpha\neq\beta, \tag{3.1}$$

$$w_x-w_t=2a\rho^2+(c+a)w^2-\rho w(3a+c)+w(\beta\rho+\epsilon)-2\kappa(\alpha\rho^2+\rho\eta+\zeta)+2S_2. \tag{3.2}$$

A. Similarity solution $\rho(z=x-\xi t)$, $w(z)$, $N_i(z)$

We define $'=d/dz$, begin with the (1.4) coupled Riccati equations and look at the standard[10] solutions. For the Riccati-projectif, from the N_i' equation without N_j^2 term, we get $a=c=\alpha=0$ not possible. For the conformal Riccati solution and a generalization[5] we get as necessary conditions either $\alpha=\beta$ or $c-a+\beta=0$, both not possible.

We write the asymptotic (3.1)–(3.2) states $\rho_{as}=\rho_0$, $\rho_0+\rho_1$ and $w_{as}=w_0$, w_0+w_1,

$$(\alpha-\beta)\rho_{as}^2+(\eta-\epsilon)\rho_{as}+\sigma=0,\quad \rho_1=-2\rho_0-(\eta-\epsilon)/(\alpha-\beta), \tag{3.3}$$

$$w_{as}^2(a+c)=w_{as}(\rho_{as}(3a+c-\beta)-\epsilon)-2a\rho_{as}^2+2\kappa(\alpha\rho_{as}^2+\eta\rho_{as}+\zeta)-2S_2. \tag{3.4}$$

In Appendix B1 we start with $\rho=\rho_0+R(z)/D(z)$, $w=w_0+W(z)/D(z)$, substitute into (3.1)–(3.2), get a D^{-1} polynomial, assume that the coefficient of the most singular term D^{-2} is zero and deduce $R\propto W$. We go on writing $\rho=\rho_0+\rho_1 Y(z)$, $w=w_0+w_1 Y(z)$. We get two scalar Riccati equations $C_i Y'=Y(Y-1)$ with C_i constants and a compatibility condition $C_1=C_2$ or equivalently two linear first-order differential equations for $\Delta(z)=1/Y$. We integrate, get a variable $de^{\gamma z}$ and deduce γ and the speed wave ξ (see Table II).

For stationary solutions, it is sufficient to require $\xi=0$, leading to a constraint between the model parameters: $\alpha,\beta,\eta,\epsilon,a,c$.

B. Similarity solutions for the models $c\geqslant 0$, $a\leqslant 0$, $\kappa=S_2=0$, and w_{as}, $(c+a)w_{as}^2-w_{as}(\rho_{as}(3a+c-\beta)-\epsilon)+2a\rho_{as}^2=0$

We begin with the Illner models, $a<0$, $c>0$, $a+c>0$ and discuss the positivity conditions for the asymptotic states (3.3)–(3.4). For ρ_{as} we assume $\alpha>\beta$, $\eta<\epsilon$, the conditions in order that the two roots ρ_0, $\rho_0+\rho_1$ are real and they are positive. The product of the two w_{as} roots is negative. Respective to ρ_0, $\rho_0+\rho_1$ we associate the positive w_{as} roots for N_2. For $N_1=\rho-w/2>0$ or $n_{1as}=\rho_{as}-w_{as}/2>0$ we give a rough estimate—more accurate results require heavy analytical studies,

$$-2<3a/c<-1+\beta\rightarrow \text{sign } n_{1as}=\rho_{as}^2(3a+3c)+w_{as}(\epsilon+\rho_{as}(\beta-3a-c)/2)>0.$$

Numerically for $-1\leqslant a\leqslant 0$, $c=1$ we have found restrictions on the other parameters.

TABLE II. Similarity solutions for quadratic nonconservative models.

$\rho=\rho_0+\rho_1/\Delta(z)$, $w=w_0+w_1/\Delta(z)$, $\Delta=1+de^{\gamma(x-\xi t)}$, $\overline{w_1}=w_1/\rho_1$
$N_1=-N_2(1-2\rho_1/w_1)+\rho_0-\rho_1 w_0/w_1=n_{01}+n_1/\Delta$
$X=\overline{w_1}(c+a)+2(a-\alpha\kappa)/\overline{w_1}-3a-c+\beta$, $\gamma=\rho_1 X/(1+\xi)$,
$\xi=(\beta-\alpha+(1-\overline{w_1})X)/(\alpha-\beta+X)$, [$\rho_{as}$, w_{as} in (3.3)–(3.4)]

For the Carleman model with $a+c=0$ we define $Z=\epsilon+\rho_{as}(2c+\beta)>0$ and all n_{ias} are positive; $w_{as}=2\rho_{as}^2 c/Z>0$, $n_{1as}=\rho_{as}(\epsilon+\rho_{as}(c+\beta))/Z>0$.

For the McKean model with $a=0$ we write w_{as} with two different cases,

$$w_{as}=0\rightarrow n_{1as}=\rho_{as}>0,$$

$$cw_{as}=-\epsilon+\rho_{as}(c-\beta)\rightarrow n_{1as}=\rho_{as}/2+(\epsilon+\beta\rho_{as})/2c>0.$$

For $w_{as}>0$, a sufficient condition is given by $(c-\beta)(\epsilon-\eta)/(\alpha-\beta)>2\epsilon$ (satisfied for c sufficiently large), if for ρ_{as} we choose in (3.3) the root with positive discriminant.

For the dual McKean model with $c=0$, $a<0$ the w_{as} are given by a quadratic polynomial with positive product and sum so that if they are real,

$$w_{as}^2+w_{as}(\rho_{as}(-3+\beta/a)+\epsilon/a)+2\rho_{as}^2=0\rightarrow w_{as}>0. \tag{3.5}$$

In Appendix B2 we study the linear stability around the two asymptotic states ρ_{as}, w_{as} and determine the two characteristic values. For the Illner model we find a node and a saddle, for the Carleman model the node is attractive, for the McKean model and the dual McKean model we can have either nodes or saddles or node, saddle.

Numerical calculations for the densities $N_i(z)$, mass $\rho(z)$, and curves N_1, N_2 for the Illner $(a,c)=(-0.1,1)$, Figs. 3(a)–3(b), Carleman $(-1,1)$, Fig. 3(b), and dual McKean models$(-1,0)$, Fig. 3(d). We choose the same model parameters values $\alpha=0.05$, $\beta=0.01$, $\eta=1.81$, $\epsilon=2.1$, $\sigma=0.5$ and deduce $(\xi,\gamma)=(0.75,0.1)$, $(0.65,1.05)$, $(0.5,1.7)$.

The $N_i(z)$ curves are very similar with N_i increasing from a saddle $(z=-\infty)$ to an attractive node $(z=\infty)$ so that for the two last models, for brevity, we only present in Fig. 3(b) the N_1, N_2 curves which are straight lines. However, for the dual McKean model [curve (c) in Fig. 3(b)], the above theoretical prediction was that the pair (attractive node saddle) could change. So we keep all the above parameters values except $\epsilon\in[2.1,3.1]$. We obtain a transition for $\epsilon\sharp 3$, find a repulsive node at $z=-\infty$, and a saddle at $z=\infty$. While the γ sign is the same we have $\xi>1$ and the transition occurs when $\xi=1$.

In Fig. 3(c) for the McKean model with the theoretical predictions that the pair (saddle-node) could change, we choose the same model parameters values $\alpha=0.05$, $\beta=0.01$, $\eta=0.25$, $\sigma=0.012$ except for $\epsilon=0.3$, 0.32 leading to $(\xi,\gamma)=(-0.55,0.045)$, $(0.91,-0.07)$. We find, respectively, saddle, attractive node and saddle, saddle. At the transition $|\xi|\rightarrow\infty$, $\xi\rightarrow 0$ and ξ, γ change of signs, so that the $N_i(z)$ which were decreasing become increasing. For the characteristics at the $z=\infty$ state, the attractive node with $\xi<0$ becomes repulsive (but $\xi>1$) and finally a saddle ($\xi<1$). At the $z=-\infty$ state the saddle ($\xi<1$) becomes a repulsive node (but $\xi>1$) and finally a node ($\xi<1$).

C. (1+1)-dimensional solutions

We introduce similarity variables $\nu_i=d_i e^{\gamma_i(x-\xi_i t)}$. In Appendix B3.1 we first show that the sum of two similarity solutions is not possible. For conservative models such solutions lead to conditions between loss and gain terms while here in (3.1) only ρ^2 is present. Second, starting from solutions which are ratios of first-order ν_i polynomials by second-order ones, we obtain from (3.1), the following possible solutions:

$$\rho=\rho_0+\rho_1/\Delta,\quad w=w_0+w_1/\Delta,\quad \Delta=1+\sum\ \nu_i,\quad \nu_i=d_i e^{\gamma i(z-\xi_i t)}. \tag{3.6}$$

In Appendix B32, starting with (3.6), we obtain, from both (3.1)–(3.2), two possibilities,

$$\text{dual McKean:}\quad c=0,\ \kappa=1,\ \beta+a=0,\ w_1=2\rho_1,\ N_1=w_0-2\rho_0=\text{const.} \tag{3.7a}$$

$$\text{McKean}\quad a=0,\ \kappa=0,\ \beta-c=0,\ w_1=0,\ N_2=w_0/2=\text{const.} \tag{3.7b}$$

(1+1)-dimensional solutions for the McKean (dual) models. We present a more general formalism starting from (1.4) and assuming

$$N_i(x,t)=n_{0i}+n_i N(x,t),\quad R_i(n_{1as},n_{2as})\equiv 0,\quad n_{ias}=n_{0i},n_{0i}+n_i. \tag{3.8}$$

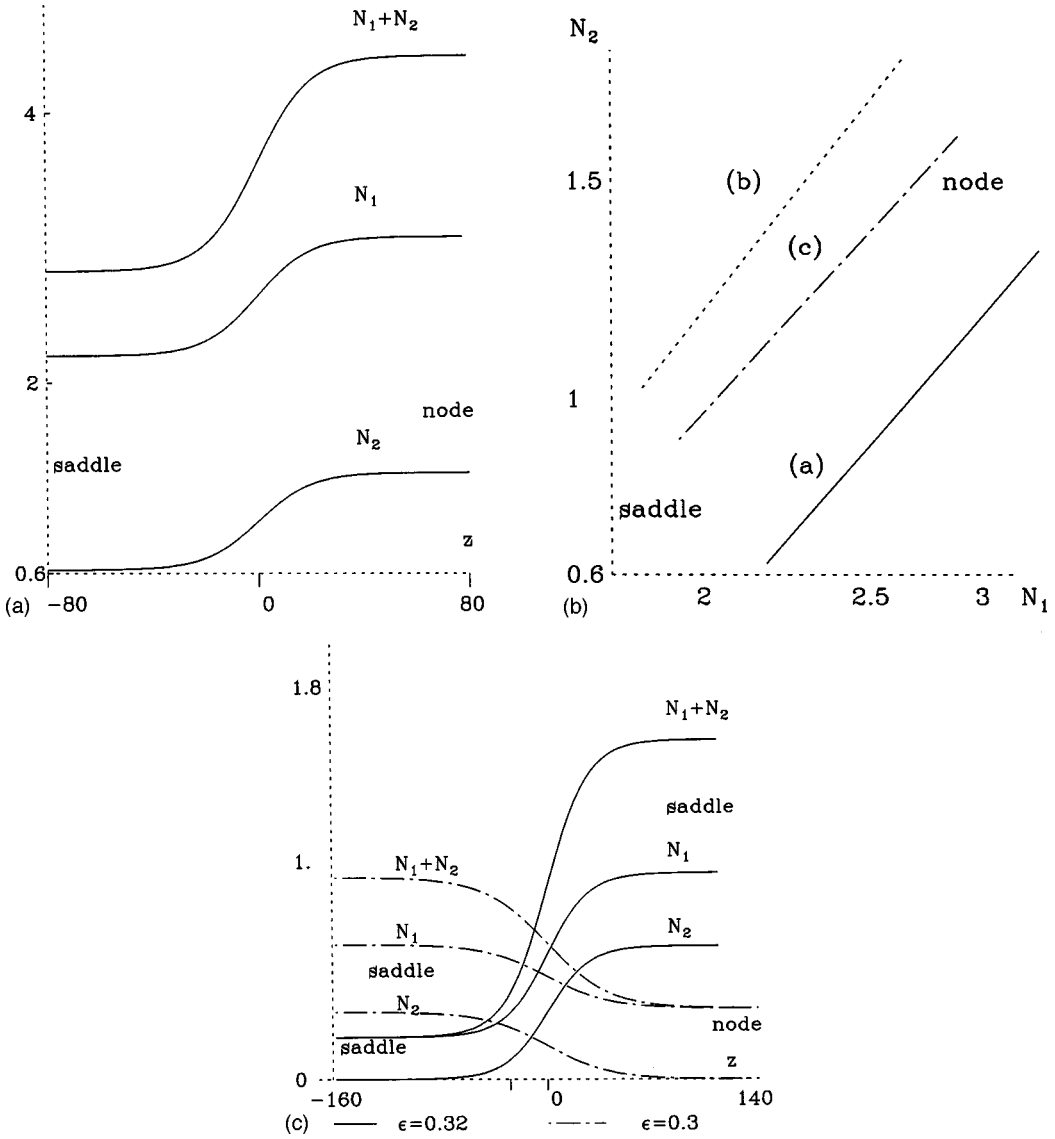

FIG. 3. Quadratic nonconservative model. Similarity solutions. Illner model $a=-0.1$, $c=1$ in (a), McKean model $a=0$, $c=1$ in (c); Illner, dual McKean $a=-1$, $c=0$ plus Carleman $c=1=-a$ models in (b). In (c) when $\epsilon \in (0.3,0.32)$ we observe a transition node, saddle becoming saddle, saddle.

TABLE III. $(1+1)$ solutions: a) dual McKean, b) McKean, $\kappa=1$

(a) $c=\alpha+\beta=0$, $\kappa=1$

$N_1=n_{01}$, $N_2=n_{02}+n_2/\Delta$, $\Delta=1+\Sigma\nu_i$, $\nu_i=d_i e^{\gamma_i(x-\xi_i t)}$,
$2an_{01}^2-n_{01}\epsilon+S_1=0\rightarrow n_{01}$,
$(\alpha+a)\rho_0^2+(\eta-\epsilon)\rho_0+\sigma \quad =0\rightarrow\rho_0=n_{02}+n_{01}\rightarrow n_{02}$
$(\alpha+a)(n_2+2\rho_0)+\eta-\epsilon=0\rightarrow n_2$,
$\gamma_i(1+\xi_i)+(\alpha+a)n_2 \quad =0\rightarrow\gamma_i$
with arbitrary number of ν_i terms and arbitrary ξ_i

(b) $a=0=-c+\beta=0$, $\kappa=0$

$(N_1,N_2,n_{01},n_{02},n_2,a,\xi_i,\gamma_i,S_1)$
$\rightarrow(N_2,N_1,n_{02},n_{01},n_1, \quad -c,-\xi_i,-\gamma_i,S_2)$
$\rho=\rho_0+\rho_1/\Delta$ with $\rho_1=n_1(n_2)$ for the McKean (dual) models.

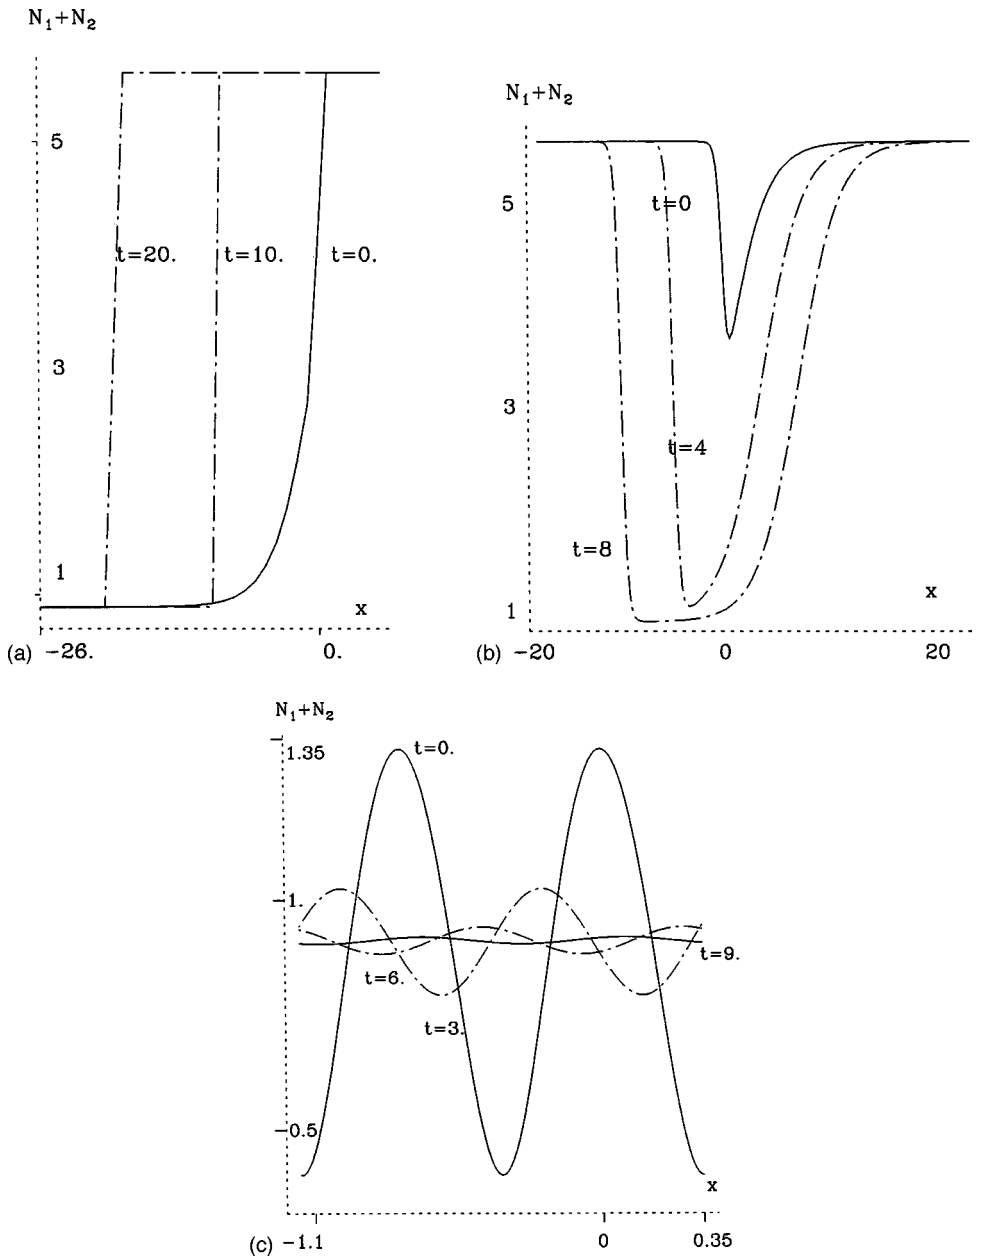

FIG. 4. Quadratic nonconservative model. $(1+1)$-dimensional solutions for the dual McKean model $a=-1$, $c=0$. In (a) we observe two asymptotic states and only one in (b). In (c) we observe a damped periodic solution.

We substitute into (1.4), take into account the asymptotic $n_{i\mathrm{as}}$ states and get

$$(\partial_t+(-1)^{i+1}\partial_x)n_iN=C_iN(N-1)\rightarrow[(\partial_t+\partial_x)n_1C_2-(\partial_t-\partial_x)n_2C_1]N=0, \tag{3.9}$$

with C_i coefficients of N^2, $-N$ written down in Appendix B3.3 and two possibilities for $(1+1)$ solutions; either $n_1=C_1=0$ leading to (3.7a) or $n_2=C_2=0$ leading to (3.7b). We are reduced to only one NLPDE for $N(x,t)$ or one linear PDE for $\Delta(x,t)=1/N$,

$$\text{dual McKean: } (\partial_t-\partial_x)N=(\alpha+a)n_2N(N-1),\ (\partial_t-\partial_x)\Delta(x,t)=(\alpha+a)n_2(\Delta-1), \tag{3.10}$$

$$\text{McKean: } (\partial_t+\partial_x)N=(\alpha-c)n_1N(N-1),\ (\partial_t+\partial_x)\Delta(x,t)=(\alpha-c)n_1(\Delta-1), \tag{3.10$'$}$$

that we integrate easily for $\Delta=1+\Sigma\,\nu_i$ (see Table III).

For the periodic solutions (3.8) and Table III with only two ν_i complex conjugate,

$$1/N(x,t)=\Delta=1+\nu+\nu^*,\ \ \nu=de^{rt+i\gamma_I x},\ \ \tau=\tau_R+i\tau_I,\ \ n_{0i},n,d\ \ \text{real}, \tag{3.11}$$

only γ_i, ξ_i are changed. Extensions with $\nu_{i+1}=\nu_i^*$, $i=1,3,...$ exist,

$$\text{dual McKean:}\ \ \gamma_I=\tau_I,\ \ \tau_R=(\alpha+a)n_2,\ \ \Delta=1+2de^{\tau_R t}\cos\ \gamma_I(x+t), \tag{3.12}$$

$$\text{McKean:}\ \ \gamma_I=-\tau_I,\ \ \tau_R=(\alpha-c)n_1,\ \ \Delta=1+2de^{\tau_R t}\cos\ \gamma_I(x-t), \tag{3.12'}$$

γ_I and d are arbitrary in both cases. The oscillations are propagating with time and if τ_R is negative we have a damping factor when $t\to\infty$ leading to the asymptotic states ρ_0+n_2, $n_{02}+n_2$ for ρ, N_2 (dual McKean) and ρ_0+n_1, $n_{01}+n_1$ for ρ, N_1 (McKean).

Numerical $(1+1)$*-dimensional solutions* with, for brevity, only $\rho(x,t)$, two ν_i, and the dual McKean model. In Figs. 4(a)–4(c) we arbitrarily choose the same values for the model parameters from which we deduce the asymptotic states,

$$\begin{gathered}c=0,\ \ a=-1=-\beta,\ \ \alpha=1.1,\ \ \eta=0.006,\ \ \epsilon=0.7,\ \ \sigma=S_1=0.5,\ \ \zeta=S_2=0,\\ \rho_0=5.61,\ \ \rho_0+\rho_1=0.892,\ \ n_{02}=5.25,\ \ n_2=-4.71,\ \ N_1=n_{01}=0.355.\end{gathered} \tag{3.13}$$

In Fig. 4(a) we present a solution vs x, give the arbitrary parameters ξ_i and deduce γ_i, $d_i=1$, $\xi_1=0.9$, $\xi_2=-0.95$, $\gamma_1=0.5$, $\gamma_2=18.8$. Due to $\gamma_1\gamma_2>0$ we observe for, $|x|$ large, the two asymptotic states ρ_0, $\rho_0+\rho_1$ and roughly speaking a translation of ρ when t is increasing. Other features can occur for $\gamma_1\gamma_2<0$, in Fig. 4(b), with the only change $\xi_2=-1.25$ leading to $\gamma_2=-3.7$, we see only one asymptotic state for t fixed and $|x|$ large. In Fig. 4(c) for $\rho>0$ vs x we present a periodic solution with $n_2/(1+2d)\leqslant\rho(x,0)-\rho_0\leqslant n_2/(1-2d)$ and, from (3.12), $\tau_R=-0.47<0$. For the arbitrary parameters we choose $d=0.05$, $\tau_I=\gamma_I=9$. The oscillations are propagating when t increases and, due to the damping factor, the asymptotic ($t\to\infty$) limit is a constant $\rho_0+\rho_1$.

IV. CONCLUSION

Comparing both conservative and nonconservative Illner, Carleman, and McKean discrete models, we see that the classes of exact solutions are different. Instead of solutions coming from only one Riccati scalar equation, here we also construct solutions compatible with two scalar Riccati equations. For the linear nonconservative models (and only for stationary solutions) we find solutions built-up with elementary functions [Figs. 1(c) and 2(a)–2(e)] or with modified Bessel functions [Figs. 1(a)–1(b)] for which we add boundary conditions. For the quadratic models, the similarity solutions found [Figs. 3(a)–3(c)] still result from a compatibility between two scalar Riccati equations and they are built-up with elementary exponential terms. The $(1+1)$-dimensional solutions are very different in conservative and nonconservative models. The sums of similarity solutions are not possible for the nonconservative present models. The $(1+1)$ solutions [Figs. 4(a)–4(c)] correspond to one of the densities being constant and, due to the fact that the problem is reduced to a linear partial differential equation, they can be sums of an arbitrary number of exponential similarity variables. Such solutions are not possible for the present associated conservative models.

The present study has been extended to the nonconservative Broadwel models, which means compatibility between three Riccati equations. For nonconservative models it will be useful to study exact solutions satisfying boundary conditions[1] other than the simplest one considered here for only one class of solutions, with modified Bessel functions. Very often in the literature it is written that nonelementary analytical solutions including elliptic... functions exist, but without proving that they do or do not satisfy (which is not always trivial[11]) physical properties like positivity and boundedness.

ACKNOWLEDGMENT

I thank T. Platkowski who suggested that I study the exact solutions for the nonconservative models.

APPENDIX A: LINEAR NONCONSERVATIVE MODELS

A1: Bureau[8] transform for stationary solutions. We recall $\rho_0=S/(\epsilon-\eta)$, $(\prime=\partial_x)$ and with four conditions reduce (2.2′) to a linear $J'+J^2$ equation,

$$W=J'+J^2,\ \ W'=CW+G(j_0)/j_1,\ \ C=2(\eta-\epsilon)(c+a)/(c-a),\ \ j_1=2/(c-a),$$

$$j_0=[C+\eta(1-2\kappa)]/(a-c)=[\rho_0(c-a)S+\epsilon]/2(a+c),\rightarrow(2.6)\ \text{relation}, \tag{A1}$$

$$j=j_0+j_1J(x),\ \ \rho(x)=\rho_0+j_1J'(x)/(\eta-\epsilon),\ \ 2N_i(x)=\rho+(-1)^{i+1}j. \tag{A2}$$

A1.1: $G(j_0)=0$, $C\neq0$, $W\neq0$. We get $W=de^{Cx}$, assume $4d=C^2$ and the Riccati equation $J'+J^2=C^2/4e^{Cx}$ gives the modified Bessel $I_0(z)$ for $z=e^{Cx/2}\in(0,\infty)$,

$$J=\partial_x\widetilde{J}/\widetilde{J},\rightarrow\partial_{z^2}\widetilde{J}+z^{-1}\partial_z\widetilde{J}=\widetilde{J}\rightarrow\widetilde{J}=I_0(z),\ \ J(x)=\partial_x\log I_0(e^{Cx/2}),$$

$$f:=[1-(y/z)^2]^{-1/2},\ \ J(x)\propto\int_{-z}^{z}ye^{-y}fdy\Big/\int_{-z}^{z}e^{-y}fdy\rightarrow\infty\ \text{ when }\ z\ \text{ or }\ Cx\rightarrow\infty.$$

We add a specular reflection boundary condition $N_1(0)=N_2(0)$, $j(0)=0$. Notice that $J(0)/C=\Sigma ma_m/\Sigma a_m$ with $a_m=(!m)^{-2}4^{-m}$ is a known number. From a, c, η, κ, $J(0)$ given we deduce $\epsilon=\eta+\eta(2\kappa-1)(c-a)/[2(c-a)(1-2J(0)/C)]$ and C, j_0 from (A1). We assume S_1 arbitrary and from the (2.6) condition deduce S and S_2. Finally from j_0 in both (A1), (2.3) we get a compatibility condition from which a is fixed while $c,\eta\kappa,S_1$ are still arbitrary but j_1,ρ_0 are known. [Notice that if $G(j_0)\neq0$, $C\neq0$, in (2.3), we define $G(j_0)/j_1C=:(C\nu/2)^2$ and get $J(x)=\partial_x\log I_\nu(x)$ still not bounded when $z\rightarrow\infty$.] In the sequel we assume $G(j_0)=0$ but either $C=0$, $W=0,\neq0$ or $W=0$, $C\neq0$.

A1.2:[9] $G(j_0)=C=a+c=0$, $W=\beta$. (A1) gives $j_1c=1$ but $\rho_0=-\epsilon/2c<0$. First $\beta=W=0$, $J'=-1/(x+d)^2$ substituted in (A2) gives $\rho(x)\rightarrow\rho_0<0$ when $|x|\rightarrow\infty$. Second, for $\beta\neq0$ we get two cases: either $J'/\beta=1-[1-\alpha e^{-2x\sqrt{\beta}}/(1+\alpha e^{-2x\sqrt{\beta}})]^2$ with $\beta>0$ and $\rho(x)\rightarrow\rho_0<0$ when $|x|\rightarrow\infty$ or $\beta<0$ and $J'/\beta=1+[(\alpha-tgx\sqrt{-\beta})/(1+\alpha tgx\sqrt{-\beta})]^2$, $\rho(x)\rightarrow\infty$ for an infinite number of $|x|\in(0,\infty)$ values.

A1.3:[9] $G(j_0)=W=0$, $J=1/(x+d)$ with (A1)–(A2) and simple models $\eta=\kappa=0$, $\epsilon\neq0$: McKean $c=1$, $a=0$: $j_1=2$, $j_0=2\epsilon$, $\rho_0=3\epsilon$, $S_i=(13-6i)\epsilon^2/2$

$$4\epsilon(x+d)^2N_i(x)=(17-8i)[\epsilon(x+d)]^2+[\epsilon(x+d)+(-2)^{i+1}]^2\geqslant0,\ \ i=1,2; \tag{A3}$$

dual McKean $a=-1$, $c=0$: $j_1=2$, $j_0=-2\epsilon$, $\rho_0=3\epsilon$, $S_i=(5-6i)\epsilon^2/2$,

$$4\epsilon(x+d)^2N_i(x)=(8-7i)[\epsilon(x+d)]^2+[\epsilon(x+d)+(-2)^{i+1}]^2>0,\ \ i=1,2. \tag{A3′}$$

A2: Transform associated with $G(j_0)=G(j_0+j_1)=0$ and (2.2′)–(2.4). With $\gamma:=j_1(a-c)/2$ we add $J'\gamma$ in both sides and with $W=J'-\gamma J(J-1)$ get $W'=\overline{C}W$ or $W=\overline{d}e^{\overline{C}x}$

$$[J'-J(J-1)\gamma]'=J'[(j_0+j_1/2)(a-c)+\eta(2\kappa-1)]+j_1(a+c)(\eta-\epsilon)J(J-1). \tag{A4}$$

We get $\overline{C}=\eta(2\kappa-1)+(a-c)\epsilon/2(a+c)+S(a-c)^2/2(a+c)(\eta-\epsilon)$ from the rhs $\overline{C}W$ and a compatibility condition which is (2.6). For $W=0$ we get $J(1+e^{\gamma x})=1$. For $W\neq0$ we define $z=e^{\overline{C}x/2}$, $\nu=\gamma\overline{C}/4$, assume $\overline{d}\gamma4/\overline{C}^2=1$. The Riccati equation $J'-\gamma J(J-1)=\overline{d}e^{\overline{C}x}$ still leads to modified Bessel functions, $\gamma J=\partial_z\log[z^{-(\gamma\overline{C})/2}I_\nu(z)]$. In the sequel we consider the II.2, $W=0$ solution (see Table I).

A2.1: Linear stability of the x-dependent stationary solutions $\rho(x,t)=\rho(x)+e^{lt}X_\rho$, $j(x,t)=j(x)+e^{lt}X_j$. We give the characteristic l_i, $i=1,2$,

$$l_1=\eta-\epsilon,\ \ l_2=2j(x)(a+c)+\rho(x)(a-c)-\epsilon=N_1(3a+c)-N_2(3c+a)-\epsilon. \tag{A5}$$

We study the sign of l_2. At the two asymptotic states (see Table I) we get opposite values,

$$l_{2\text{as}}=2j_{\text{as}}(a+c)+\rho_{\text{as}}(a-c)-\epsilon=\pm 2(a+c)\sqrt{\delta},$$

$$w=de^{\gamma x}\to l_2=0 \ \text{ if } \ w^2-1\pm w(c-a)^2\sqrt{\delta}/(\epsilon-\eta)(c+a)=0. \tag{A6}$$

The two w roots have opposite sign ($\pm$ is fixed for a solution), one is associated to $d>0$ and the other to $d<0$ but independent of the d and x values except in the product $de^{\gamma x}$.

A2.2: Positivity for the $-0.1\leqslant a/c\leqslant 0$ models at the asymptotic stationary values $|x|=\infty$. For $\epsilon\neq 0,\ \eta=\kappa=0$, we rewrite (see Table I) $S,\ \rho_0,\ j_{\text{as}},\ j_0,\ \delta$,

$$S=(3c+a)(3a+c)\epsilon^2/(c-a)^3>0 \ \text{ if } \ -1/3<a/c\leqslant 0,\ \ \rho_0=S/\epsilon>0,$$

$$j_{\text{as}}^2-j_{\text{as}}4\epsilon(c+a)/(c-a)^2+(S_1+S_2)/(c+a)=0,\ \ j_0=2\epsilon(a+c)/(c-a)^2\pm\sqrt{\delta}, \tag{A7}$$

$$\text{sign } \delta+2S_2/(c+a)=[7a^3+19a^2c+5ac^2+c^3]>0,$$

with a constraint on $S_2>0$ small such that $\delta>0$. $j_0>0$ is one of the two $j_{\text{as}}>0$ roots. For N_i or $2n_{i,\text{as}}=\rho_0-(-1)^i j_{\text{as}}>0$ for $i=1$ we get positivity conditions for $i=2$,

$$n_{2,\text{as}}^2-n_{2,\text{as}}\epsilon(5a^2+10ac+c^2)/(c-a)^3+(S_2+a(S/\epsilon)^2)/2(c+a)=0,$$
$$n_{2,\text{as}}>0 \ \text{ if } \ S_2+a(S/\epsilon)^2>0 \ \text{ and } \ -1+2/\sqrt{5}\simeq -0.1<a/c\leqslant 0. \tag{A8}$$

APPENDIX B: QUADRATIC NONCONSERVATIVE MODELS

B1: Similarity solutions functions of $z=x-\xi t$. First we substitute $\rho=\rho_0+R(z)/D(z)$, $w=w_0+W(z)/D(z)$ into (3.1)–(3.2), find $\Sigma A_k(z)/D(z)^k$, assume $A_2(z)=0$, define $c_R=R/D'$, $c_W=W/D'$ and get a cubic polynomial with $c_R=$ const.,

$$c_W=c_R[1-\xi+(\alpha-\beta)c_R],$$

$$(1+\xi)c_W+2(a-\alpha\kappa)c_R^2=(3a+c-\beta)c_Wc_R-(c+a)c_W^2. \tag{B1}$$

Second we start with $\rho=\rho_0+\rho_1 Y,\ w=w_0+w_1 Y,\ Y(z)$ unknown while $\rho_0,\rho_0+\rho_1$ and w_0, w_0+w_1 are the asymptotic states (3.3)–(3.4). From (3.1) to (3.2) we get two Riccati equations for $Y(z)$ or two first-order linear differential equations for $\Delta(z)=1/Y$ and X in Table II,

$$Y(1-Y)=Y'(\overline{w}_1-1+\xi)/(\alpha-\beta)\rho_1=Y'(1+\xi)/\rho_1 X,\to\Delta=1+de^{\gamma z}. \tag{B2}$$

B2: Linear stability of the $\kappa=0$ similarity solutions $\rho(z)=\rho_{\text{as}}(1+e^{lz}X_\rho),\ w(z)=w_{\text{as}}(1+e^{lz}X_w)$. We give the two characteristic values $l=l_1,l_2$,

$$l^2A_2+lA_1+A_0=0,\ \ \xi^2<1\to A_2=1-\xi^2>0. \tag{B3}$$

For the Illner model $a<0,\ c>0,\ a+c>0$ we first rewrite the asymptotic states,

$$\rho_{\text{as}}2(\alpha-\beta)+\eta-\epsilon=-\zeta\sqrt{\Delta_\rho},\ \ \zeta=\pm 1,$$

$$2(c+a)w_{\text{as}}=\rho_{\text{as}}(3a+c-\beta)-\epsilon+\zeta_2\sqrt{\Delta_w}>0,\ \ \zeta_2=1,\to\zeta A_0=\sqrt{\Delta_\rho\Delta_w}>0,$$

$$A_1=(1-\xi)\sqrt{\Delta_w}+(1+\xi)\zeta\sqrt{\Delta_\rho}-4a\rho_{\text{as}}+w_{\text{as}}(3a+c-\beta), \tag{B4}$$

sign $l_1l_2=\zeta$ and we have at one asymptotic state a node and a saddle at the other.

For the Carleman model $a+c=0$ we get $\zeta A_0=\sqrt{\Delta_\rho}2c\rho_{\text{as}}^2/w_{\text{as}}>0$ and

$$A_1=(1+\xi)\zeta\sqrt{\Delta_\rho}+2\rho_{\text{as}}c(1-\xi)\rho_{\text{as}}/w_{\text{as}}+2c\rho_{\text{as}}^2/w_{\text{as}}+\epsilon>0 \ \text{ for } \ \zeta=1.$$

At the $\zeta=1$ asymptotic state we have an attractive node and a saddle at $\zeta=-1$.

For the McKean model $a=0$ we get $w_{as}\neq 0$, $\zeta A_0=\sqrt{\Delta_\rho}w_{as}>0$ and $w_{as}=0$, $\zeta A_0=\sqrt{\Delta_\rho}(\rho_{as}(\beta-c)+\epsilon)$. For $w_{as}\neq 0$ we have a node or a saddle depending whether $\zeta=1$ or -1 whereas for $w_{as}=0$, independently of ζ we can have saddle or node.

For the dual Mc Kean model $c=0$ we get $A_0=\zeta\zeta_2\sqrt{\Delta_\rho\Delta_w}$. At each state we can have either a node or a saddle depending whether $\zeta\zeta_2=\pm$.

B3: Possible $(1+1)$-dimensional exact solutions.

B3.1: Constraints coming from (3.1). First, we start with the sum,

$$\rho(x,t)=\rho_0+\Sigma\rho_i/\Delta_i,\ \ w(x,t)=w_0+\Sigma w_i/\Delta_i,\ \ \Delta_i=1+\nu_i,\ \ \nu_i=d_ie^{\gamma_i(x-\xi_it)} \tag{B5}$$

of two similarity solutions which, substituted into (3.1), gives for $1/\Delta_1\Delta_2$ the condition $\rho_1\rho_2=0$ which is not possible. Second we substitute into (3.1) another ansatz,

$$\rho=\rho_0+(\rho_{00}+\Sigma\rho_i\nu_i)/\Delta,\ \ w=\ldots,\ \ \Delta=1+\Sigma\nu_i+\mu\nu_1\nu_2,\ \ \nu_i=d_ie^{\gamma_i(x-\xi_it)}, \tag{B6}$$

with $\mu\neq 1$ because $\mu=1$ corresponds to (B5) and ρ_0 one ρ_{as} (3.3). We get,

$$\Delta^{-2}[a_0+\Sigma\nu_ia_i+b_i\nu_i^2+c_j\nu_i^2\nu_j+a_{12}\nu_1\nu_2]\equiv 0,\ \ a_0=a_i=b_i=\cdots=0. \tag{B7}$$

From a_0, b_i, a_i, a_{12} we get $\rho_{00}=\rho_1=\rho_2$, $w_{00}=w_1=w_2$, $\mu\rho_{00}^2=0$, and $\mu=0$. Third we restrict to $\mu=\rho_{00}=0$ in (B6) and substitute into (3.1),

$$\rho=\rho_0+(\Sigma\rho_i\nu_i)/\Delta,\ \ w=w_0+(\Sigma w_i\nu_i)/\Delta,\ \ \Delta=1+\Sigma\nu_i. \tag{B8}$$

We have terms of the (B7) type and $a_0=c_j=0$, give that $\rho_0+\rho_i=\rho_{as}$, $i=1,2$. Two possibilities follow. (i) $\rho_1=\rho_2$, we deduce $(w_1-w_2)(\gamma_1-\gamma_2)=0$ and either $w_1=w_2$ with (B8) rewritten: $\rho=\rho_0+\rho_1-\rho_1/\Delta$ (similarly for w) or $\gamma_1=\gamma_2$ but (3.2) still leads to $w_1=w_2$. (ii) $\rho_1\neq 0$, $\rho_2=0$, deduce $w_1\neq 0$, $w_2=0$, with (B8) rewritten $\rho=\rho_0+\rho_1/\bar{\Delta}$, $\bar{\Delta}=1+\nu_1^{-1}(1+\nu_2)$. In conclusion, starting with (B7)–(B8), (3.1) leads to $(1+1)$ of the type,

$$\begin{gathered}\rho=\rho_0+\rho_1/\Delta,\ \ w=w_0+w_1/\Delta,\ \ \Delta=1+\Sigma\nu_i,\ \ \rho_{as}=\rho_0,\rho_0+\rho_1,\\ \text{def: }\ \bar{w}_1=w_1/\rho_1,\ \ \gamma_i(1-\xi_i-\bar{w}_1)=\rho_1(\alpha-\beta),\ \ i=1,2.\end{gathered} \tag{B9}$$

B3.2: Constraints coming from Eq. (3.2) with the Illner term. We substitute (B9) into (3.2) with the w_{as} relation (3.4) satisfied by w_0 and get the identity, $\Delta^{-2}[a_0+\Sigma\nu_ia_i]\equiv 0$. $a_0=0$ gives the other $w_{as}=w_0+w_1$, while $a_i=0$ lead to

$$\gamma_i(1+\xi_i)=(c+a)w_1+2\rho_1(a-\alpha\kappa)/\bar{w}_1-\rho_1(3a+c-\beta),\ \ i=1,2. \tag{B10}$$

From (B9) to (B10) we first get $\bar{w}_1=2$, $N_1=w_0-2\rho_0\neq 0$ is a constant and $c+\alpha(1-\kappa)=0$ or $c=0$, $\kappa=1$. From the relations $\rho_{as}=\rho_0+\rho_1$, $w_{as}=w_0+2\rho_1$ we get (B11). Another compatibility for (B9)–(B10) is $w_1=0$, $N_2=w_0/2=$const. in (3.4) with $w_{as}=w_0$, $\rho_{as}=\rho_0,\rho_0+\rho_1$, the coefficients of ρ_1 are zero and we get (B11′),

$$\text{dual McKean: }\ \gamma_i(1+\xi_i)=-(\alpha+a)\rho_1,\ \ w_1=2\rho_1,\ \ c=0,\ \ \kappa=1,\ \ \beta+a=0, \tag{B11}$$

$$\text{McKean: }\ \gamma_i(1-\xi_i)=(\alpha-c)\rho_1,\ \ a=0,\ \ \kappa=0,\ \ \beta=c. \tag{B11′}$$

B3.3: In (1.4) we write $R_i(N)=C_iN(N-1)$ with $N_i=n_{0i}+n_iN$, $R_i(n_{1as},n_{2as})\equiv 0$,

$$\begin{aligned}C_i=&n_1^2((-1)^{i+1}-\beta)+(-1)^i(a+c)+\beta)n_1n_2+(-1)^{i+1}cn_2^2\\ &+(2-i+(-1)^i\kappa)(n_1+n_2)^2\alpha\\ -C_i=&2n_{01}n_1((-1)^{i+1}-\beta)+(-1)^i(a+c)(n_1n_{02}+n_2n_{01})+(-1)^{i+1}c2n_2n_{02}\\ &-n_i(\beta(n_{01}+n_{02})+\epsilon)+(2-i+(-1)^i\kappa)(n_1+n_2)(2(n_{01}+n_{02})\alpha+\eta).\end{aligned} \tag{B12}$$

First, with $n_1=C_1=0$ we get $c=\beta+\alpha=0$, $\kappa=1$ (B11) and with $n_2=C_2=0$ we get $a=\kappa=\beta-c=0$ (B11′).

Infinite moments of the partition function for random walks in a random potential

Lester N. Coyle[a)]
Department of Mathemetical Sciences, Loyola College, Baltimore, Maryland 21210

(Received 9 May 1997; accepted for publication 17 November 1997)

We consider a system of random walks (directed polymers) in a potential which is random in space and time. Investigations into untypical behavior and the inverse of the partition function leads to the result that, regardless of the strength of the potential and in all dimensions, all higher moments of the partition function are unbounded as time goes to infinity. One can interpret this result in a many-body quantum mechanical setting as saying that no matter how small the strength of an attractive potential, in any dimension one can find N (the number of particles) large enough so that there is a bound state. © *1998 American Institute of Physics.* [S0022-2488(98)01904-5]

I. INTRODUCTION

Random walks in a random potential (otherwise referred to as directed polymers in a random potential) have been used to model many physical processes. For example, the interface in two-dimensional Ising models with random exchange interactions can be modeled by a one-dimensional random walk in a random potential (see Ref. 1). While superdiffusive behavior is conjectured for this dimension $d=1$ case, no rigorous results have been obtained. For a background on this subject see Refs. 2 and 3.

Imbrie and Spencer[3] considered the following model of a random walk in a random potential. Let $v(t,x)$ be independent for each t and x, with $v(t,x)=\pm 1$ with probability 1/2 where $x \in \mathbb{Z}^d$, $t \in \mathbb{Z}^+$, and $d=$dimension. Without loss of generality we start all walks at the origin unless otherwise stated. Let $dW_T(X)$ be the probability measure for the symmetric nearest neighbor discrete time random walk (i.e., simple random walk) on $\mathbb{Z}^d$, where $X(t)$ represents the position of the walk at integer time t. For $0<\epsilon<1$, the probability measure for the random walk in a random potential is given by

$$d\mu_T = \prod_{0<t\leqslant T} [1+\epsilon v(t,X(t)]dW_T/Z(T),$$

so that

$$P(X(T)=x) = \int \delta(X(T)-x) \prod_{0<t\leqslant T} [1+\epsilon v(t,X(t)]dW_T/Z(T),$$

where δ is the Kronecker delta, and $Z(T)$ is the partition function, given by

$$Z(T) = \int \prod_{0<t\leqslant T} [1+\epsilon v(t,X(t)]dW_T.$$

The partition function is needed in order to normalize the probability density.

Note that this is a distinctly different model than the random walk in random environment studied by Kesten in Ref. 4. Also note that in Ref. 5 the authors considered random walks in a random potential where the random potential had no time dependence [i.e., the model described above with $v=v(x)$], and proved subdiffusive behavior in all dimensions. In this paper we only consider time-dependent potentials.

Let $P_x(\cdot)$ and $E_x[\cdot]$ denote probability and expectation (respectively) with respect to the simple random walk measure dW_T for walks starting at x, $P_v(\cdot)$ and $\langle\cdot\rangle_v$ denote probability and expectation (respectively) with respect to the random potential v, and $E_x^v[\cdot]$ denote expectation with respect to the random walk in a random potential measure $d\mu_T$ for walks starting at x. Note that $\langle Z(T)\rangle_v = 1$.

A. Known rigorous results

Imbrie and Spencer[3] proved the following result:

Theorem I.1: *For small enough* $\epsilon > 0$ *and dimension* $d > 2$,

$$\lim_{T\to\infty}\left(E_0^v\left[\frac{X(T)^2}{T}\right]\right) = 1 \quad \text{almost surely.}$$

Bolthausen[6] used martingales to extend this theorem to arbitrary powers of $X(T)/\sqrt{T}$. Song and Zhou[7] showed that Bolthausen's result holds in dimensions $d \geqslant 3$ for any $\epsilon \in (0,1)$. Sinai[8] considered random potentials having a general distribution and showed, under conditions on the distribution of $v(x,t)$, that theorem I.1 holds. Conlon and Olsen[9] considered a continuous time and space version of the random walk in a random potential and showed that, under the conditions of theorem I.1, $\lim_{T\to\infty} E_0^v[f(X(T)/\sqrt{T})] = E[f(Y)]$ almost surely, where Y is a Gaussian variable and for a wide class of functions f which include polynomials and exponentials, provided the limit is taken exponentially fast. Coyle[10] considered a continuous time version of the random walk in a random potential, and proved a result similar to that of Conlon's and Olsen's without the restriction of an exponentially fast limit.

B. Why study the partition function?

No rigorous results are known for the random walk in a random potential in one or two dimensions though scaling of the form

$$\frac{\langle E_0^v[X(T)^2]\rangle_v}{T^{4/3}} \to 1$$

has been conjectured both numerically and heuristically in both dimensions $d=1$ and $d=2$ (see Refs. 1 and 11–14). In an attempt to understand the $d=1$ case, Fisher and Hwa[2] have studied rare events in the random walk in a random potential system (with $d=1$) by mapping onto Burgers's equation with random forcing. Also, numerical studies (e.g., Ref. 15) indicate the system in dimension $d=1$ is particularly sensitive to the details of the realization of the random potential. In the time-independent random potential case (see Ref. 5), the system is dominated by untypical behavior, namely paths that pass through regions with a large concentration of positive v's. We believe that something similar is occurring in dimensions 1 and 2 when the potential is time dependent, though it is not yet clear just what the crucial untypical behavior is. We believe that, as in Ref. 5, analysis of the partition function will be key in understanding the importance of untypical behavior.

We conjecture that in dimensions $d=1$ and $d=2$ the partition function goes to zero as $T \to \infty$ with probability one. Thus we desire to study

$$\lim_{T\to\infty}\left\langle \frac{1}{Z(T)}\right\rangle_v$$

in all dimensions to see whether there is a drastic change in this quantity as we go from dimension $d=3$ to dimensions $d=1$ and $d=2$. Let $N(T) = \int X(T)^2 \Pi_{0<t\leqslant T}[1+\epsilon v(t,X(t)]dW_T$. Imbrie and Spencer[3] showed that for ϵ sufficiently small in dimension $d>2$

$$\lim_{T\to\infty}\left\langle E_0^v\left[\frac{X(T)^2}{T}\right]\right\rangle_v = \lim_{T\to\infty}\left\langle \frac{N(T)}{TZ(T)}\right\rangle_v = 1.$$

We know that $N(T)/(TZ(T))\to 1$ with probability 1 (in v) and it is easy to see that $\langle N(T)/T\rangle_v = 1$ and $\langle Z(T)\rangle_v = 1$. It would appear that it should be no more difficult to find $\lim_{T\to\infty}\langle 1/Z(T)\rangle_v$. Suppose $\lim_{T\to\infty}\langle 1/Z(T)\rangle_v = C<\infty$. Then for $0<\delta\ll 1$, Chebyshev gives

$$\lim_{T\to\infty} P_v(Z(T)<\delta) = \lim_{T\to\infty} P_v\left(\frac{1}{Z(T)}>\frac{1}{\delta}\right) \leqslant \lim_{T\to\infty} \delta\left\langle \frac{1}{Z(T)}\right\rangle_v = \delta C.$$

However, the best that Imbrie's and Spencer's calculations appear to yield (see the Appendix) is

$$P_v(Z(T)<\delta)<\frac{c}{|\log\ \delta|}.$$

The best upper bounds achieved in Refs. 9 and 10 were of the form $P_v(Z(T)<\delta)\leqslant C|\log(\delta)|^{-\alpha}$ for some $\alpha>0$. It certainly appears that some information is lacking regarding the partition function in all dimensions. If one were to do a Taylor expansion of $\langle 1/Z(T)\rangle_v$ one would need to consider the higher moments of the partition function, and we have proven the following result.

C. Main result

Theorem I.2: *For any ϵ satisfying $0<\epsilon<1$, and in any dimension d, there exists $n_0\in\mathbb{Z}^+$ such that for all $n\geqslant n_0$*

$$\lim_{T\to\infty}\langle Z(T)^n\rangle_v = \infty.$$

In particular, $n_0=2$ in dimensions 1 and 2, and $n_0=C/\epsilon^d$ for $d>2$.

This result verifies that the analysis of Imbrie and Spencer cannot be extended to dimensions 1 and 2, since finiteness of $\langle Z(T)^2\rangle_v$ was essential in their calculations. In the dimension $d>2$ regime, where diffusive behavior has been proven, we have the result that the partition function is very large with a sizable (nonzero) probability. This shows that the random potential really does effect the system in the case of $d>2$ in a manner which is not detected in results such as theorem I.1.

D. Connection to many-body quantum mechanics

Letting $\epsilon' = \tanh(\epsilon)$, we have

$$\prod_{0<t\leqslant T}[1+\epsilon' v(t,X(t)] = (\cosh(\epsilon))^{-T} e^{c\Sigma_{t=1}^{T} v(t,X(t))}.$$

So up to normalization factors, the analysis writing $e^{\epsilon v}$ rather than $1+\epsilon v$ will be the same. With this in mind, we can make the following connection to quantum mechanics.

We have $\langle v(t_1,x_1)v(t_2,x_2)\rangle_v = \delta(t_1-t_2)\delta(x_1-x_2)$. Let $V(x_1,x_2)=\delta(x_1-x_2)$. Going to the continuum system, there exists the following relationship (given by the Hubbard–Stratanovich transformation, see Ref. 16):

$$\langle Z(T)^n\rangle_v = \int dx_1\cdots dx_n e^{-TH_n}(0,...,0|x_1,\ldots,x_n),$$

where $x_k\in\mathbb{R}^d \forall k$ and H_n is the n-body quantum mechanical Hamiltonian with attractive potential $V(x)$. For $n=2$, it is known (see Ref. 17) that if $V(x)$ is a short-range *attractive* potential, then in

dimensions 1 and 2 H_2 has a bound state, and this would indicate that in dimensions 1 and 2, $\lim_{T\to\infty}\langle Z(T)^2\rangle_v=\infty$, which is true. On the other hand theorem I.2 indicates that if $n>C/(\epsilon^d)$, where ϵ is the strength of the potential, then H_n has a bound state in dimension d. Thus we can think of theorem I.2 as being a consequence of the lack of stability of the corresponding quantum mechanical system.

II. PROOF OF INFINITE MOMENTS

To prove theorem I.2 we will use the local central limit theorem (see e.g., Ref. 18); throughout this paper we shall refer to it as the local CLT.

For the simple random walk, one version of the local CLT is

$$P_0(X(n)=x)=2\left(\frac{d}{2\pi n}\right)^{d/2}e^{-d|x|^{2/(2n)}}+O(n^{-(d+2)/2}).$$

We also need:

Proposition II.1: Let $C_M=(-M,M)^d\cap\mathbb{Z}^d$, *for* $M\in\mathbb{R}$, *and let* $N\in\mathbb{Z}^+$. *There exists positive constants C and c such that* $\forall T\in\mathbb{Z}^+$,

$$P_0(X(t)\in C_N,0\leqslant t\leqslant T)\geqslant Ce^{-cT/N^2}. \tag{1}$$

Also, for N sufficiently large, $N^2\leqslant t\leqslant T$, *and* $x\in C_{N/2}$, *there exists constants* K_1 *and* K_2 *such that*

$$\frac{K_1}{N^d}\leqslant P_0(X(t)=x|\text{stay in } C_N \text{ up to time } T)\leqslant\frac{K_2}{N^d}. \tag{2}$$

Note that $P(\cdot|A)$ denotes probability conditioned on the set of events A. We prove proposition II.1 in Sec. III. Intuitively, Eq. (1) makes sense since we know that simple random walks on average travel a distance $\sqrt{T}$ in time T, so if $T<N^2$, there is a good chance of staying in the cube, and if $T>N^2$, it is unlikely that the walk will stay in the cube. Turning our attention to Eq. (2), it is reasonable that given the walk stays in C_N, after N^2 steps there should be no particularly favored sites in the sub-cube $C_{N/2}$.

Note that we can rewrite the partition function as

$$Z(T)=\int\prod_{0<t\leqslant T}\prod_{x\in\mathbb{Z}^d}[1+\epsilon v(t,X(t))\delta(X(t)-x)]dW_T.$$

We first consider the simpler case of dimension $d\leqslant 2$,

$$\begin{aligned}Z(T)^2=&\int\int\prod_{0<s\leqslant T}\prod_{x\in\mathbb{Z}^d}\{[1+\epsilon v(s,X_1(s))\delta(X_1(s)-x)]\\&\times[1+\epsilon v(s,X_2(s))\delta(X_2(s)-x)]\}d\mu_T(X_1)d\mu_T(X_2)\\\Rightarrow\langle Z(T)^2\rangle_v=&\int\int\prod_{0<s\leqslant T}\prod_x[1+\epsilon^2\delta(X_1(s)-x)\delta(X_2(s)-x)]d\mu_T(X_1)d\mu_T(X_2).\end{aligned} \tag{3}$$

Expanding the products over s and x and fixing $x_0=0$, we have

$$\begin{aligned}\langle Z(T)^2\rangle_v=&\sum_{n=1}^{T}\sum_{0=s_0\leqslant s_1\leqslant\cdots\leqslant s_n\leqslant T}\epsilon^{2n}\prod_{i=1}^{n}\left[\sum_{x_i\in\mathbb{Z}^d}P_0(X(s_i-s_{i-1})=x_i-x_{i-1})^2\right]\\\geqslant&\sum_{n=1}^{T}\sum_{s_0\leqslant\leqslant\cdots\leqslant s_n}\epsilon^{2n}\prod_{i=1}^{n}\left[\sum_{\{x_i:|x_i-x_{i-1}|\leqslant\sqrt{s_i-s_i-1}\}}P_0(X(s_i-s_{i-1})=x_i-x_{i-1})^2\right].\end{aligned}$$

By the local CLT $\exists M>0$ and $C_1>0$ such that if $|s_i-s_{i-1}|>M$ and $|x_i-x_{i-1}| \leqslant \sqrt{s_i-s_{i-1}}$, then

$$P_0(X(s_i-s_{i-1})=x_i-x_{i-1}) \geqslant \frac{C_1}{(s_i-s_{i-1})^{d/2}}.$$

Also $\exists C_M>0$ such that if $|s_i-s_{i-1}| \leqslant M$ and $|x_i-x_{i-1}| \leqslant \sqrt{s_i-s_{i-1}}$, then $P_0(X(s_i-s_{i-1})=x_i-x_{i-1}) \geqslant C_M$. Thus

$$\sum_{\{x_i:|x_i-x_{i-1}| \leqslant \sqrt{s_i-s_{i-1}}\}} [P_0(X(S_i-S_{i-1})=x_i-x_{i-1})]^2 \geqslant \begin{cases} \dfrac{C_1^2}{(s_i-s_{i-1})^{d/2}} & \text{if } |s_i-s_{i-1}|>M \\ C_M^2 c M^{d/2}=C_2 & \text{if } |s_i-s_{i-1}| \leqslant M. \end{cases}$$

Thus $\langle Z(T)^2 \rangle_v$ diverges as $T \to \infty$ for $d \leqslant 2$. For $n>2$, it is easy to see that $\langle Z(T)^n \rangle_v$ is greater than the right-hand side of Eq. (3), and the result follows.

Now we turn our attention to dimension $d>2$. The idea of the proof goes as follows. Whenever two of the n walks intersect, this increases $\langle Z(T)^n \rangle_v$ by a factor e^{ϵ} (approximately); however, the probability of intersections is exponentially small. We constrain all walks to remain in the cube C_N, so that there is a strong likelihood of intersections. We choose n and N so that the cost of staying in the cube is outweighed by the benefit of more intersections. Letting X_k denote the walk indexed by k, we have

$$\begin{aligned} \langle Z(T)^n \rangle_v &= E_0\left[\prod_{0 \leqslant s \leqslant T} \prod_{x \in \mathbb{Z}^d} \left\{ 1+\epsilon^2 \sum_{1 \leqslant i<j \leqslant n} \delta(X_i(s)-x)\,\delta(X_j(s)-x)+\cdots \right\} \right] \\ &\geqslant E_0\left[\prod_{0 \leqslant s \leqslant T} \prod_{x \in \mathbb{Z}^d} \left\{ 1+\epsilon^2 \sum_{1 \leqslant i<j \leqslant n} \delta(X_i(s)-x)\,\delta(X_j(s)-x) \right\} \right] \\ &= E_0\left[\exp\left\{ \sum_{0 \leqslant s \leqslant T, x \in \mathbb{Z}^d} \log\left(1+\epsilon^2 \sum_{1 \leqslant i<j \leqslant n} \delta(X_i(s)-x)\,\delta(X_j(s)-x) \right) \right\} \right] \\ &\geqslant E_0\left[\exp\left\{ \sum_{0 \leqslant s \leqslant T, x \in C_N} \log\left(1+\epsilon^2 \sum_{1 \leqslant i<j \leqslant n} \delta(X_i(s)-x)\,\delta(X_j(s)-x) \right) \right\} \right. \\ &\qquad \left. \Big| \text{all paths stay in } C_N \right] P(\text{all paths stay in } C_N \text{ up to time } T). \end{aligned}$$

Writing $E_0^{C_N}[\,\cdot\,]=E_0[\,\cdot\,|$ all paths stay in C_N up to time $T]$, we use Jensen's theorem, the fact that

$$\log\left(1+\epsilon^2 \sum_{i<j} y_i y_j \right) \geqslant c\,\epsilon^2 \sum_{i<j} y_i y_j e^{-\Sigma_k y_k},$$

where $0 \leqslant y_i \leqslant 1$, and proposition II.1 to get that for sufficiently large N

$$\langle Z(T)^n\rangle_v \geqslant \exp\left\{ E_0^{C_N}\left[\sum_{0\leqslant s\leqslant T, x\in C_{N/2}} \log\left\{ 1+\epsilon^2 \sum_{1\leqslant i<j\leqslant n} \delta(X_i(s)-x)\,\delta(X_j(s)-x)\right\}\right]\right\}(Ce^{-cT/N^2})^n$$

$$\geqslant \exp\left\{ E_0^{C_N}\left[\sum_{s,x} c_1\epsilon^2 \sum_{i<j} \delta(X_i(s)-x)\,\delta(X_j(s)-x) e^{-\Sigma_{1\leqslant k\leqslant n}\delta(X_k(s)-x)}\right]\right\} C' e^{-cTn/(N^2)}$$

$$\geqslant \exp\left[\sum_{0\leqslant s\leqslant T, x\in C_{N/2}} C_1\epsilon^2 \sum_{1\leqslant i<j\leqslant n} P_0(X_i(s)=x|\text{stay in } C_N) P_0(X_j(s)=x|\text{stay in } C_N)\right.$$

$$\left. \times \prod_{k\neq i,j} \{1-P_0(X_k(s)=x|\text{stay in } C_N)\}\right] C' e^{-cTn/(N^2)}$$

$$\geqslant \exp\left[(T-N^2)c_2 N^d c_1\epsilon^2 n^2 \frac{K_1}{N^d}\frac{K_1}{N^d}\left(1-\frac{K_2}{N^d}\right)^n\right] C' e^{-cTn/(N^2)}$$

$$\geqslant C'' \exp\left[\frac{T_n}{N^2}\left\{ \frac{C_3\epsilon^2 n}{N^{d-2}}\left(1-\frac{C}{N^d}\right)^n - c\right\}\right],$$

where the constants are independent of T. We need $\epsilon^2 n/N^{d-2} > c'$ which implies $n \geqslant N^{d-2}$ and we need $n \leqslant N^d$ to bound $(1-C/(N^d))^n$, so we choose $n=N^d$. Then we need $c_3\epsilon^2 N^2 - c > 0$, so $N > c/\epsilon$, which implies $n > C/\epsilon^d$. With this choice of n and N, we have

$$\langle Z(T)^n\rangle_v \to \infty \text{ as } T\to\infty. \qquad \blacksquare$$

III. WALKS THAT REMAIN IN A CUBE

The goal of this section is to prove proposition II.1. We first need to prove a number of lemmas concerning simple random walks that are constrained to a cube. In general let $P(x,y,t) = P_x(X(t)=y)$ and $P_D(x,y,t) = P_x(X(t)=y; X(s)\in D, 0\leqslant s\leqslant t)$, where D is some domain in $\mathbb{Z}^d$.

Lemma III.1: Let Δ_L be the d-dimensional lattice Laplacian. Then if φ_0 is an eigenfunction of Δ_L on a domain D, satisfying $\varphi_0(x)=0$, for x on the boundary of $D=\delta D$ (where $D\cap\delta D=\theta$), with eigenvalue λ_0, we have that for $x\in D$,

$$\sum_{y\in D} P_D(x,y,n)\varphi_0(y) = (1+\lambda_0)^n \varphi_0(x).$$

Proof: Let 1_A be the indicator function of a set A (referred to as the characteristic function in analysis), let i_k be the unit vector in the kth direction, and let

$$u(x,n) = E_x[f(X(n))1_{(X(s)\in D, 0\leqslant s\leqslant n)}],$$

for some function f. Then, by the Markov property and defining

$$\overline{u}(x,n) = \begin{cases} u(x,n) & \text{if } x\in D \\ 0 & \text{if } x\in \delta D, \end{cases}$$

we have, for $x\in D$,

$$u(x,n+1)-u(x,n) = \frac{1}{2d}\left\{ \sum_{k=1}^{d} [\overline{u}(x+i_k,n)+\overline{u}(x-i_k,n)-2u(x,n)]\right\}$$

$$= \overline{\Delta}_L u(x,n) \quad (\text{this defines } \overline{\Delta}_L) \Rightarrow u(x,n) = (1+\overline{\Delta}_L)^n u(x,0).$$

For any $y\in D$, let $f_y(X(n)) = 1_{(X(n)=y)}$. Then

$$E_x[f_y(X(n))1_{(X(s)\in D, 0\leqslant s\leqslant n)}] = P_D(x,y,n).$$

If φ_0 is an eigenfunction of Δ_L on D, satisfying $\varphi_0(x)=0$ for $x\in\partial D$, with eigenvalue λ_0, then φ_0 is also an eigenfunction of Δ_L with eigenvalue λ_0 and we have that for $x\in D$,

$$\sum_{y\in D} P_D(x,y,n)\varphi_0(y)=\sum_{y\in D}(1+\bar{\Delta}_L)^n P_D(x,y,0)\varphi(y)=(1+\lambda_0)^n\varphi_0(x). \quad \blacksquare$$

In general, let $y\leftrightarrow t$ denote the assertion that y and t have the same parity [i.e., if $y=(y_1,\ldots,y_d)$, then $y_1+\cdots y_d+t$ is even] and $\lfloor\cdot\rfloor$ is the greatest integer function. We now want to investigate walks on $\mathbb{Z}$ that remain in an interval.

A. One-dimensional walks

Lemma III.2: Suppose $0<\rho<1$, $0<\mu$, $0<\beta$, $x, y\in\mathbb{Z}$, $y\leftrightarrow x$, *and*

$$|x|<\rho\mu R, \quad |y-x|<\left(\frac{1-\rho}{2}\right)\mu R.$$

Let $N=\max\{k\in\mathbb{Z}:k\leqslant\mu R\}$, $D_{\mu R}=(-N,N)\cap\mathbb{Z}$, $m=\min\{r\in\mathbb{Z}:r\geqslant\beta R^2$ and $r\leftrightarrow(y-x)\}$. *Then for* $R>10/(1-\rho)\mu$, *we have*

$$P_{D_{\mu R}}(x,y,m)\geqslant\frac{C(\rho,\mu,\beta)}{R},$$

where $C(\rho,\mu,\beta)$ *is a constant depending on* ρ, μ, *and* β.

Proof: Fix $x\in\mathbb{Z}^d$ and γ so that $0<\gamma\leqslant\beta$. Fix $z\in\mathbb{Z}$ with $|z-x|<\frac{3}{4}(1-\rho)\mu R$. Let $n=\min\{r\in\mathbb{Z}:r>\gamma R^2$ and $r\leftrightarrow(z-x)\}$. Also let

$$\sigma_1(t)=P_x(\text{exit } (-N,N) \text{ at } N \text{ at time } t),$$

and

$$\sigma_2(t)=P_x(\text{exit } (-N,N) \text{ at } -N \text{ at time } t).$$

Then we have

$$P_{D_{\mu R}}(x,z,n)=P(x,z,n)-\sum_{t=1}^{n}\sigma_1(t)P(N,z,n-t)-\sum_{t=1}^{n}\sigma_2(t)P(-N,z,n-t). \tag{4}$$

By the local CLT, we have that for $1\leqslant t\leqslant n-1$,

$$P(N,z,n-t)\leqslant\max_{1\leqslant t\leqslant n-1}\frac{c}{\sqrt{n-t}}\,e^{-c(N-(3+\rho)\mu R/4)^2/(n-t)}\leqslant\frac{C}{\mu R(1-\rho)}.$$

Then using the reflection principle and the local CLT, we have

$$\begin{aligned}\sum_{t=1}^{n}\sigma_1(t)&\leqslant P_x(\text{time to exit } (-N,N)\leqslant n)\\&\leqslant P_0(\max_{0\leqslant t\leqslant n}|X(t)|\geqslant N-x)\\&\leqslant 2P_0(|X(n)|\geqslant(1-\rho)\mu R)\\&\leqslant\sum_{x=\lfloor(1-\rho)\mu R\rfloor}^{\infty}\frac{C}{\sqrt{n}}\exp\left[-\frac{x^2}{2n}\right]\leqslant\frac{C\sqrt{\gamma}}{(1-\rho)\mu}\exp[-(1-\rho)^2\mu^2/(2\gamma)].\end{aligned}$$

Similarly,

$$P(-N,z,n-t)\leqslant\frac{C}{\mu R(1-\rho)},$$

$$\sum_{t=1}^{n} \sigma_2(t) \leqslant \frac{C\sqrt{\gamma}}{(1-\rho)\mu \exp[-(1-\rho)^2\mu^2/(2\gamma)]}.$$

Also, the local CLT gives

$$P(x,z,n) \geqslant \frac{c}{\sqrt{\gamma}R} \exp\left[-\frac{9(1-\rho)^2\mu^2}{32\gamma}\right].$$

Returning to Eq. 4, we have

$$P_{D_{\mu R}}(x,z,n) \geqslant \frac{c}{\sqrt{\gamma}R} \exp\left[-\frac{9(1-\rho)^2\mu^2}{32\gamma}\right] - \frac{C}{\mu R(1-\rho)} \frac{\sqrt{r}}{(1-\rho)\mu} \exp\left[-\frac{(1-\rho)^2\mu^2}{2\gamma}\right].$$

By choosing γ sufficiently small, we get

$$P_{D_{\mu R}}(x,z,n) \geqslant \frac{C(\rho,\mu)}{R}. \tag{5}$$

Let $M = \max\{m \in \mathbb{Z} : m \leqslant \frac{3}{4}(1-\rho)\mu R\}$, and $D_x = [x-M, x+M]$. For fixed $x \in \mathbb{R}$, we have $\varphi_0(z) = \cos(\pi(z-x)/(2M))$ is an eigenfunction of Δ_L on D_x, with eigenvalue $\lambda_0 = -\sin^2(\pi/(4M))$ and $\varphi_0(y) = 0$ if $y \in \partial D_x$. Using Eq. (5), lemma III.1, and $\max_{z \in D_x}\{\varphi_0(z)\} = 1$, we have

$$P_{D_{\mu R}}(x,y,m) \geqslant \sum_{z \in D_x} P_{D_{\mu R}}(z,y,m-n) P_{D_{\mu R}}(x,z,n) \geqslant \frac{C(\rho,\mu)}{R} \sum_{z \in D_x} P_{D_x}(z,y,m-n)\varphi_0(z)$$

$$= \frac{C(\rho,\mu)}{R} (1-\sin^2(\pi/(4M)))^{m-n} \varphi_0(y).$$

Noticing that $\varphi_0(y) \geqslant \cos(\pi/3)$ and

$$(1-\sin^2(\pi/(4M)))^{m-n} \geqslant \exp\left[-\frac{C\beta}{(1-\rho)^2\mu^2}\right],$$

we are done. ■

Lemma III.3: Suppose $0 < \rho < c < 1$, $0 < \mu$, $0 < \beta < c < 1$, $0 < \gamma$, *and* $R > 10/(1-c)\mu$. *Let* $n = \min\{r \in \mathbb{Z} : r \geqslant \gamma R^2$ *and* $r \leftrightarrow (y-x)\}$, *where* $x, y \in \mathbb{Z}$, $x \leftrightarrow y$, $|x| < \rho\mu R$, *and* $|y| < \beta\mu R$. *Letting* $D_{\mu R}$ *be the domain defined in lemma III.2, we have*

$$P_{D_{\mu R}}(x,y,n) \geqslant \frac{C(\rho,\mu,\gamma,\beta)}{R}.$$

Proof: If $|y-x| \leqslant (1-\rho)\mu R/2$, then the lemma holds by lemma III.2. Otherwise, let

$$\operatorname{sgn}(y-x) = \begin{cases} +1 & \text{if } y-x > 0 \\ -1 & \text{if } y-x < 0 \end{cases}$$

and

$$m=\left\lfloor \frac{|y-x|}{\left(\frac{1-\rho}{4}\right)\mu R}\right\rfloor = C(\rho,\beta).$$

Also let $E_1=\{y_1\in\mathbb{Z}:|y_1-x|<(1-\rho)\mu R/2,|y_1-y|<|x-y|-(1-\rho)R\mu/4,\lfloor n/m\rfloor\leftrightarrow(x-y_1)\}$ and for $2\leqslant k\leqslant m-1$, let $E_k=\{y_k\in\mathbb{Z}:|y_k-(x+\mathrm{sgn}(y-x)k(1-\rho)R\mu/4)|\leqslant(1-\rho)R\mu/4,\ |y_k-y|\leqslant|x-y|-k(1-\rho)R\mu/4,\lfloor n/m\rfloor\leftrightarrow(y_k-y_{k-1})\}$. Then by lemma III.2

$$\begin{aligned}P_{D_{\mu R}}(x,y,n)&\geqslant \sum_{y_k\in E_k,1\leqslant k\leqslant m-1} P_{D_{\mu R}}(x,y_1,\lfloor n/m\rfloor)P_{D_{\mu R}}(y_1,y_2,\lfloor n/m\rfloor)\cdots\\ &\quad\times P_{D_{\mu R}}(y_{m-1},y,n-(m-1)\lfloor n/m\rfloor)\\ &\geqslant\left(\frac{(1-\rho)R\mu}{8}\right)^{m-1}\left(\frac{C(\rho,\mu,\gamma)}{R}\right)^m\geqslant\frac{C(\rho,\mu,\gamma,\beta)}{R}.\end{aligned}$$ ■

B. *d*-dimensional walks

*Lemma III.4: For the simple random walk on $\mathbb{Z}^d$, let $S_n^{(k)}$ be the number of steps taken in the (positive or neqative) k*th *direction out of a total of n steps taken on $\mathbb{Z}^d$. Then*

$$P\left(\frac{3n}{4d}\leqslant S_n^{(k)}\leqslant\frac{5n}{4d},k=1,\ldots,d\right)\geqslant 1-\frac{16d(d-1)}{n}.$$

Proof: By Chebyshev,

$$\begin{aligned}P\left(\left|S_n^{(k)}-\frac{n}{d}\right|\geqslant\frac{n}{4d}\right)&\leqslant\frac{16d^2}{n^2}E\left[\left(S_n^{(k)}-\frac{n}{d}\right)^2\right]=\frac{16(d-1)}{n}\\ &\Rightarrow P\left(\left|S_n^{(k)}-\frac{n}{d}\right|<\frac{n}{4d},k=1,\ldots,d\right)\\ &\geqslant 1-\left\{\sum_{k=1}^d P\left(\left|S_n^{(k)}-\frac{n}{d}\right|\geqslant\frac{n}{4d}\right)\right\}\geqslant 1-\frac{16d(d-1)}{n}.\end{aligned}$$ ■

Note that henceforth, N will represent a large positive integer.

Lemma III.5: Let $C_N=[-(N-1),N-1]^d\cap\mathbb{Z}^d$, $\partial C_N=\{[-N,N]^d\cap\mathbb{Z}^d\}\backslash C_N$, $C_{N/2}=(-N/2,N/2)^d\cap\mathbb{Z}^d$, and

$$P_{C_N}(x,y,T)=P_x(X(T)=y;X(t)\in C_N,0\leqslant t\leqslant T).$$

Then there exists a constants C_1 and C_2 such that for all $y\in C_{N/2}$,

$$\frac{C_1}{N^d}\leqslant P_{C_N}(0,y,N^2)\leqslant\frac{C_2}{N^d}.$$

Proof: Letting $n_i(\gamma_i,y_i)=\min\{k\in\mathbb{Z}:k\geqslant\gamma_iN^2$ and $k\leftrightarrow y_i\}$, and $y=(y_1,\ldots,y_d)$, we have by lemmas III.3 and III.4,

$$P_{C_N}(0,y,N^2)\geqslant\inf_{3/(4d)\leqslant\gamma_i\leqslant5/(4d),|y_i|<N/2}\left\{\prod_{i=1}^d P_{D_N}(0,y_i,n_i(\gamma_i,y_i))\right\}\frac{1}{2^d}\left(1-\frac{16d(d-1)}{n}\right)\geqslant\frac{C_1}{N^d}.$$

Also, by the local CLT

$$P_{C_N}(0,y,N^2) \leqslant P_0(X(N^2)=y) \leqslant \frac{C_2}{N^d}. \qquad \blacksquare$$

We shall only use the dimension 1 version of the following lemma. For completeness we have included the d-dimensional version.

Lemma III.6: Suppose R is a sufficiently large positive real number. Let

$$\partial B_R = \{x \in \mathbb{Z}^d : |x| \leqslant R \ \text{ and } \ \exists x' \in \mathbb{Z}^d \text{ s.t.} |x-x'|=1 \ \text{ and } \ |x'|>R\},$$

$$B_R = \{x \in \mathbb{Z}^d : |x| < R \ \text{ and } \ x \notin \partial B_R\}.$$

Then there exists a universal constant C such that, $\forall x \in B_R$ *and* $t \in \{s \in \mathbb{Z} : s \geqslant R^2\}$,

$$\sum_{y \in B_R} P_{B_R}(x,y,t) \leqslant C \sum_{|y|<R/(2\sqrt{d})} P_{B_R}(x,y,t). \tag{6}$$

Proof: Let $n = \min\{s \in \mathbb{Z} : s \geqslant R^2\}$, and suppose the lemma is true for $t=n$. Then by the Markov property, we have, for $t>n$,

$$\begin{aligned}\sum_{y \in B_R} P_{B_R}(x,y,t) &= \sum_{z \in B_R} P_{B_R}(x,z,t-n) \sum_{y \in B_R} P_{B_R}(z,y,n) \\ &\leqslant \sum_{z \in B_R} P_{B_R}(x,z,t-n) C \sum_{|y|<R/(2\sqrt{d})} P_{B_R}(z,y,n) \\ &= C \sum_{|y|<R/(2\sqrt{d})} P_{B_R}(x,y,t).\end{aligned}$$

So we need only consider $t=n$. Suppose $0<\alpha<c_1<1$, for some constant c_1. For any x so that $R/(2\sqrt{d}) < |x| < \alpha(R-1)$, and for $\nu = 1/4d\alpha$, let

$$\begin{aligned}C_{R,x} = [-|x_1| - \lfloor (1-\alpha)(R-1)\nu \rfloor, |x_1| + \lfloor (1-\alpha)(R-1)\nu \rfloor] \times \cdots \times [-|x_d| \\ - \lfloor (1-\alpha)(R-1)\nu \rfloor, |x_d| + \lfloor (1-\alpha)(R-1)\nu \rfloor],\end{aligned}$$

where $x=(x_1,\ldots,x_d)$. Clearly $x \in C_{R,x}$, and if $z \in C_{R,x}$, then

$$|z|^2 \leqslant (|x_1| + (1-\alpha)(R-1)\nu)^2 + \cdots + (|x_d| + (1-\alpha)(R-1)\nu)^2 \leqslant (R-1)^2.$$

If $|x| \leqslant R/(2\sqrt{d})$, let

$$C_{R,x} = [-\lfloor R/\sqrt{d} \rfloor, \lfloor R/\sqrt{d} \rfloor] \times \cdots \times [-\lfloor R/\sqrt{d} \rfloor, \lfloor R/\sqrt{d} \rfloor] \subset B_R.$$

Therefore for all x such that $|x| \leqslant \alpha(R-1)$, $\exists C_{R,x}$ s.t. $x \in C_{R,x}$ and $C_{R,x} \subset B_R$. How close can x be to the side of the box $C_{R,x}$? If $|x| \leqslant R/(2\sqrt{d})$, then $|x_i|/R/\sqrt{d} \leqslant \frac{1}{2}$. If $R/(2\sqrt{d}) < |x| \leqslant \alpha(R-1)$, then

$$\frac{|x_i|}{|x_i| + \lfloor (1-\alpha)(R-1)\nu \rfloor} \leqslant \frac{\alpha}{\alpha + (1-\alpha)/(4d\alpha)} = \rho_1(\alpha) < 1.$$

So if $|x| \leqslant R/(2\sqrt{d})$, let $\rho = 1/2$ and $\mu_i = 1/\sqrt{d}$, for $1 \leqslant i \leqslant d$. Otherwise let $\rho = \rho_1$ and $\mu_i = [|x_i| + (1-\alpha)(R-1)\nu]/(R-1)$. Note that $(1-\alpha)\nu(\alpha) \leqslant \mu_i \leqslant \alpha + (1-\alpha)\nu(\alpha)$. Letting $n_i(\gamma_i, x_i, y_i) = \min\{k \in \mathbb{Z} : k \geqslant \gamma_i R^2 \text{ and } k \leftrightarrow (y_i - x_i)\}$, and $x=(x_1,\ldots,x_d)$, we have by lemmas III.4 and III.3

$$\sum_{|y|<R/(2\sqrt{d})} P_{B_R}(x,y,n) \geqslant \sum_{|y|<R/(2\sqrt{d}),\, y\in C_{R/2,x}} P_{C_{R,x}}(x,y,n)$$

$$\geqslant C \sum_{|y|<R/(2\sqrt{d}),\, y\in C_{R/2,x}} \inf_{3/4d\leqslant\gamma_i\leqslant 5/4d,\, |y_i|<\mu_i R/2} \prod_{i=1}^{d} P_{D_{\mu_i(R-1)}}(x_i,y_i,n_i(\gamma_i,x_i,y_i))$$

$$\geqslant C \sum_{|y|<R/(2\sqrt{d}),\, y\in C_{R/2,x}} \inf_{3/4d\leqslant\gamma_i\leqslant 5/4d} \prod_{i=1}^{d} \frac{C(\rho_i(\alpha),\mu_i(\alpha),\gamma_i)}{R}$$

$$\geqslant \sum_{|y|<R/(2\sqrt{d}),\, y\in C_{R/2,x}} \frac{C(\alpha)}{R^d} = C(\alpha), \tag{7}$$

for $R \geqslant 1/(1-\rho_1(c_1))$, where $C(\alpha)$ is a positive constant depending only on α. Since the left-hand side (lhs) of Eq. (6) is bounded above by 1, Eq. (6) holds for $t=n$ and $\forall x$ satisfying $|x| < \alpha(R-1)$. Note that as $|x|\to R$, both the right-hand side (rhs) and the lhs of Eq. (6) go to zero, so we need to find some estimates of these quantities close to the boundary of B_R.

Let τ be the first time for the random walk $X(t)$ to exit B_R and $E_x[\tau]=u(x)$. Then by Chebyshev

$$\sum_{y\in B_R} P_{B_R}(x,y,n) = P_x(\tau>n) \leqslant \frac{u(x)}{n}. \tag{8}$$

We also have $\Delta_L u(x) = -1$ where $u(x)=0$ if $x\in\partial B_R$. Let $u_1(x)=R^2-r^2$, where $r=|x|$. Then $\Delta_L u_1(x) = -1$ and $u_1(x)=0$ if $|x|=R$. Therefore, $\forall x\in B_R$, $\Delta_L(u(x)-u_1(x))=0$, and $\forall x \in \partial B_R$, $u(x)-u_1(x)\leqslant 0$, and by the maximum principle,

$$u(x) \leqslant R^2 - r^2 \forall x \in B_R. \tag{9}$$

Let $\partial B_{\alpha R} = \{x\in\mathbb{Z}^d : |x| \geqslant \alpha(R-1)$ and $\exists x'$ s.t. $|x-x'|=1$ and $|x'|<\alpha(R-1)\}$, and let $U_{\alpha R}=\{x \in \mathbb{Z}^d : \alpha(R-1)\leqslant|x|\leqslant R$ and $x\notin\partial B_{\alpha R}, x\notin\partial B_R\}$. Then for $x\in U_{\alpha R}$,

$$\begin{aligned}
&\sum_{|y|<R/(2\sqrt{d})} P_{B_R}(x,y,n) \\
&\quad = P_x(X(t) \text{ exits } U_{\alpha R} \text{ through } \partial B_{\alpha R}; X(t)\in B_R, 0\leqslant t\leqslant n; X(n)<R/(2\sqrt{d})) \\
&\quad \geqslant P_x(X(t) \text{ exits } U_{\alpha R} \text{ through } \partial B_{\alpha R} \text{ in time } \tau<n/2) \\
&\qquad \times \inf_{y\in\partial B_{\alpha R}, 0<\tau<n/2} P_y\left(X(t)\in B_R, 0<t<n-\tau; |X(n-\tau)|<\frac{R}{2\sqrt{d}} \right) \\
&\quad \geqslant P_x(X(t) \text{ exits } U_{\alpha R} \text{ through } \partial B_{\alpha R} \text{ in time } \tau<n/2) \\
&\qquad \times \inf_{y\in\partial B_{\alpha R}, n/2\leqslant m\leqslant n} \sum_{|z|<R/(2\sqrt{d})} P_{B_R}(y,z,m) \\
&\quad \geqslant C_\alpha P_x(X(t) \text{ exits } U_{\alpha R} \text{ through } \partial B_{\alpha R} \text{ in time } \tau<n/2),
\end{aligned} \tag{10}$$

using Eq. (7). Letting τ_U=time to exit $U_{\alpha R}$, Chebyshev gives

$$P_x(X(t) \text{ exits } U_{\alpha R} \text{ through } \partial B_{\alpha R} \text{ in time } \tau\geqslant n/2) \leqslant \frac{2E_x[\tau_U]}{n}.$$

Therefore

$$P_x(X(t) \text{ exits } U_{\alpha R} \text{ through } \partial B_{\alpha R} \text{ in time } \tau<n/2)$$

$$\geqslant P_x(X(t) \text{ exits } U_{\alpha R} \text{ through } \partial B_{\alpha R}) - \frac{2E_x[\tau_U]}{n}. \tag{11}$$

Let $v(x) = P_x(X(t)$ exits $U_{\alpha R}$ through $\partial B_{\alpha R})$. We have $\Delta_L v(x) = 0$ with $v(x) = 1$ if $x \in \partial B_{\alpha R}$ and $v(x) = 0$ if $x \in \partial B_R$. Let $v_1(x) = \alpha^d/(1-\alpha^d)((R-1)^d/r^d - 1)$. Taylor's theorem gives

$$\Delta_L v_1(x) = \frac{\alpha^d (R-1)^d}{2d(1-\alpha^d)} \left\{ \frac{2d}{r^{2+d}} + O\left(\frac{1}{r^{4+d}} \right) \right\},$$

and we can see that for $x \in U_{\alpha R}$, with α close to one, and R large, $\Delta_L v_1(x) > 0$. The maximum principle gives

$$v_1(x) \leqslant v(x) \forall x \in U_{\alpha R}. \tag{12}$$

Let $w(x) = E_x[\tau_U]$ and $w_1(x) = R^2 - r^2$. The maximum principle gives

$$w < w_1 \text{ on } U_{\alpha R}. \tag{13}$$

Returning to Eq. (10) we have by Eqs. (11)–(13), that for $x \in U_{\alpha R}$,

$$\sum_{|y| < R/(2\sqrt{d})} P_{B_R}(x,y,n) \geqslant C_\alpha \left\{ \frac{\alpha^d}{1-\alpha^d} \left(\frac{(R-1)^d}{r^d} - 1 \right) - \frac{2(R^2 - r^2)}{n} \right\}.$$

Choosing α sufficiently close to one, there exists a constant C_1 so that for all $x \in U_{\alpha R}$ with $|x| \leqslant R-2$,

$$\sum_{|y| < R/(2\sqrt{d})} P_{B_R}(x,y,n) \geqslant C_1 \frac{2(R^2 - r^2)}{n} \geqslant C_1 \sum_{y \in B_R} P_{B_R}(x,y,n), \tag{14}$$

using Eqs. (8) and (9). If $x \in B_R$ and $|x| > R-2$, then there exists $x' \in \mathbb{Z}^d$ so that $|x'| < R-2$ and it is possible for a walk to get from x to x', staying in B_R in less than $2d$ steps. Then we have, using Eqs. (8) and (9) again,

$$\begin{aligned}
\sum_{|y| < R/(2\sqrt{d})} P_{B_R}(x,y,n) &= \sum_{|y| < R/(2\sqrt{d})} \sum_{z \in B_R} P_{B_R}(z,y,n-2d) P_{B_R}(x,z,2d) \\
&\geqslant \sum_{|y| < R/(2\sqrt{d})} \frac{1}{(2d)^{2d}} P_{B_R}(x',y,n-2d) \\
&\geqslant \frac{C_1}{(2d)^{2d}} \frac{2(R^2 - |x'|^2)}{n-2d} \\
&\geqslant \frac{C_1}{(2d)^{2d}} \frac{2(R^2 - |x'|^2)}{n} \\
&\geqslant \frac{C_1}{(2d)^{2d}} \sum_{y \in B_R} P_{B_R}(x,y,n).
\end{aligned} \tag{15}$$

Letting $1/C = \min\{C_1/(2d)^{2d}, C(\alpha)\}$, the lemma is proved. ■

Corollary III.7: For N a sufficiently large positive integer, there exists a universal constant C such that $\forall x \in CN$, *and* $\forall t \geqslant N^2$,

$$\sum_{y \in C_N} P_{C_N}(x,y,t) \leqslant C \sum_{y \in C_{N/2}} P_{C_N}(x,y,t).$$

Proof: As in lemma III.6, by the Markov property, we need only consider $t=n=N^2$. We can write $S_n^{(k)}=Y_1+\cdots+Y_n$, where the Y_i are independent and identically distributed, $Y_i=1$ with probability $1/d$, and $Y_i=0$ with probability $1-1/d$. Fix θ so that $0<\theta\leqslant 1/2$. Then by the central limit theorem, for n sufficiently large,

$$P\left(\left|\frac{S_n^{(k)}-n/d}{(\sqrt{d-1}/d)\ \sqrt{n}}\right|>n^{\theta}\right)<\frac{4}{\sqrt{2\pi}}\int_{n^{\theta}}^{\infty}e^{-x^2/2}dx$$

$$\Rightarrow P\left(\left|S_n^{(k)}-\frac{n}{d}\right|>n^{\theta+1/2}\right)<\frac{2}{n^{\theta}}\,e^{-n^{2\theta}/2}.$$

We thus have, writing $(P_{C_N}(x,y,n);A)=P_x(X(n)=y;X(t)\in C_N,0\leqslant t\leqslant n;A)$,

$$\sum_{y\in C_N}P_{C_N}(x,y,n)\leqslant\sum_{y\in C_N}(P_{C_N}(x,y,n);|S_n^{(k)}-n/d|\leqslant n^{\theta+1/2}\forall k=1,\ldots,d)+\frac{2}{n^{\theta}}\,e^{-n^{2\theta}/2}. \quad (16)$$

Let $n_i(\gamma_i,y_i)=\min\{p\in\mathbb{Z}:p\geqslant\gamma_iN^2 \text{ and } p\leftrightarrow y_i\}$. Noting $n=N^2$, there exists positive constants c_1, c_2, and N_0 such that $\forall N>N_0$,

$$c_1n\leqslant n/d-n^{\theta+1/2}<n/d+n^{\theta+1/2}\leqslant c_2n.$$

Then, using the dimension 1 version of lemma III.6, where $B_N=[-(N-1),N-1]$,

$$\begin{aligned}\sum_{y\in C_{N/2}}P_{C_N}(x,y,n)&\geqslant\sum_{|y_i|<N/2,c_1\leqslant\gamma_i\leqslant c_2,\Sigma_{i=1}^d n_i=n}\prod_{i=1}^{d}P_{B_N}(x_i,y_i,n_i(\gamma_i,y_i))\\&\geqslant C\sum_{|y_i|<N,c_1\leqslant\gamma_i\leqslant c_2,\Sigma_{i=1}^d n_i=n}\prod_{i=1}^{d}P_{B_N}(x_i,y_i,n_i(\gamma_i,y_i))\\&\geqslant C\sum_{|y_i|<N}(P_{C_N}(x,y,n);c_1n<S_n^{(k)}<c_2n,\forall k=1,\ldots,d)\\&\geqslant\frac{1}{C_1}\sum_{y\in C_N}(P_{C_N}(x,y,n);|S_n^{(k)}-n/d|\leqslant n^{\theta+1/2},\forall k=1,\ldots,d), \quad (17)\end{aligned}$$

where C_1 is a constant. Equation (17) also gives, using Eqs. (7), (14), and (15), and $|x_i|\leqslant N-1$,

$$\sum_{y\in C_{N/2}}P_{C_N}(x,y,n)\geqslant\frac{C}{N^d}.$$

Therefore there exists constants $N_1\in\mathbb{Z}^+$ and C_2 such that (for $N>N_1$)

$$C_2\sum_{y\in C_{N/2}}P_{C_N}(x,y,n)\geqslant\frac{2}{n^{\theta}}\,e^{-n^{2\theta}/2}.$$

Returning to Eq. (16), we have for $N>\max\{N_0,N_1\}$,

$$\sum_{y\in C_N}P_{C_N}(x,y,n)\leqslant(C_1+C_2)\sum_{y\in C_{N/2}}P_{C_N}(x,y,n)=C\sum_{y\in C_{N/2}}P_{C_N}(x,y,n). \quad \blacksquare$$

*Lemma III.8: Let $x\in C_{N/2}$. Then there exists positive constants C_1 and C_2*s.t.*$\forall n\in\mathbb{Z}^+$, and N sufficiently large*

$$C_1(1+\lambda_0)^n\leqslant\sum_{y\in C_N}P_{C_N}(x,y,n)\leqslant C_2(1+\lambda_0)^n,$$

where

$$-\frac{2\pi^2}{16N^2}\leqslant\lambda_0\leqslant-\frac{\pi^2}{16N^2}.$$

Proof: $\varphi_0(x)=\Pi_{k=1}^{d}\cos(\pi x_k/(2N))$ is an eigenfunction of Δ_L on C_N, with eigenvalue $\lambda_0=-2\sin^2(\pi/(4N))$ and $\varphi_0(x)=0$ if $x\in\partial C_N$, and we have

$$-\frac{2\pi^2}{16N^2}\leqslant\lambda_0\leqslant-\frac{\pi^2}{16N^2}.$$

Using lemma III.1, $\sup_{y\in C_N}\varphi_0(y)\leqslant 1$, and $\inf_{x\in C_{N/2}}\varphi_0(x)\geqslant C>0$, we have

$$\sum_{y\in C_N}P_{C_N}(x,y,n)\geqslant C_1(1+\lambda_0)^n.$$

Also, by corollary III.7, and using lemma III.1 again, we have, for $n\geqslant N^2$,

$$\sum_{y\in C_N}P_{C_N}(x,y,n)\leqslant C\sum_{y\in C_{N/2}}P_{C_N}(x,y,n)\varphi_0(y)\leqslant C'\sum_{y\in C_N}P_{C_N}(x,y,n)\varphi_0(y)\leqslant C'(1+\lambda_0)^n.$$

Letting $C''=\inf_{1\leqslant n\leqslant N^2}(1+\lambda_0)^n$, we have, for $n\leqslant N^2$,

$$\sum_{y\in C_N}P_{C_N}(x,y,n)\leqslant 1\leqslant\frac{(1+\lambda_0)^n}{C''}.$$

Choosing $C_2=\max\{C',1/C''\}$, we are done. ■

We are now ready to prove proposition II.1. From lemma III.8, we have

$$\sum_{y\in C_N}P_{C_N}(x,y,T)\geqslant C_1\left(1-2\frac{\pi^2}{16N^2}\right)^T\geqslant Ce^{-cT/N^2}.$$

This proves Eq. (1). Also, using lemma III.5 and corollary III.7, we have

$$\begin{aligned}P_{C_N}(0,x,t)&\geqslant\sum_{y\in C_{N/2}}P_{C_N}(0,y,N^2)P_{C_N}(y,x,t-N^2)\\&\geqslant\frac{C_1}{N^d}\sum_{y\in C_{N/2}}P_{C_N}(y,x,t-N^2)\geqslant\frac{C'}{N^d}\sum_{y\in C_N}P_{C_N}(y,x,t-N^2),\end{aligned}$$

and

$$P_{C_N}(0,x,t)=\sum_{y\in C_N}P_{C_N}(0,y,N^2)P_{C_N}(y,x,t-N^2)\leqslant\frac{C_2}{N^d}\sum_{y\in C_N}P_{C_N}(y,x,t-N^2).$$

We have, using lemma III.8,

$$\begin{aligned}&P_0(X(t)=x\,|\,\text{stay in } C_N \text{ up to time } T)\\&\quad=\frac{P_{C_N}(0,x,t)\Sigma_{y\in C_N}P_{C_N}(x,y,T-t)}{\Sigma_{y\in C_N}P_{C_N}(0,y,T)}\\&\quad\geqslant\frac{C''}{N^d}\frac{(1+\lambda_0)^{t-N^2}(1+\lambda_0)^{T-t}}{(1+\lambda_0)^T}\geqslant\frac{C''}{N^d}\frac{1}{\left(1-\frac{\pi^2}{16N^2}\right)^{N^2}}\geqslant\frac{C_1}{N^d}.\end{aligned}$$

A similar calculation yields the upper bound, and hence Eq. (2) holds. ■

ACKNOWLEDGMENTS

Much of this work constituted part of the author's dissertation at The University of Michigan. The author wishes to thank his dissertation advisor, Joseph Conlon, for his help and inspiration, and Greg Lawler for useful discussions.

APPENDIX: PROBABILITY THAT THE PARTITION FUNCTION IS SMALL

Proposition: Given $\epsilon>0$ and $\delta>0$ both sufficiently small, we have that for all T sufficiently large in dimensions $d>2$,

$$P_v(Z(T)<\delta)\leqslant \frac{c}{|\log(\delta)|},$$

where c is a constant that depends on ϵ.

Proof: Using the notation of Imbrie and Spencer,[3] propositions 2.2 and 3.1 of Ref. 3 (choosing $\eta=0.5$ and $\kappa=1$) imply that for any $k\in\mathbb{Z}^+$, ϵ sufficiently small, letting $s=2^k-1$ and $T>s$,

$$P_v\left(\frac{Z(T)}{Z(s)}\geqslant cs^{-d}(1-c\epsilon^{1/2})\right)\geqslant P_v\Big(\bigcap_{j\geqslant k} E_j^{(k)}\Big)$$

$$\geqslant 1-\sum_{j\geqslant k} P_v(E_j^{(k)c})\geqslant 1-\sum_{j=k+1}^{\infty}\epsilon 2^{-j}=1-\epsilon 2^{-k}.$$

Note that $Z(s)\geqslant(1-\epsilon)^s$. Therefore

$$P_v(Z(T)<c(2^k-1)^{-d}(1-c\epsilon^{1/2})(1-\epsilon)^{2k-1})<\epsilon 2^{-k}$$

$$\Rightarrow P_v(Z(T)<c'2^{-kd}(1-\epsilon)^{2^k})<\epsilon 2^{-k}.$$

Choose k sufficiently large so that $c'(1-\epsilon)^{2^k}2^{-kd}>(1-\epsilon^{1/2})^{2^k}$ and $\delta=(1-\epsilon^{1/2})^{2^k}$. Then for all $T>s$,

$$P_v(Z(T)<\delta)<\frac{c}{|\log\ \delta|}.$$

Note that if $T\leqslant s$,

$$P_v(Z(T)<\delta)=P_v(Z(T)<(1-\epsilon^{1/2})^{2^k})\leqslant P_v(Z(T)<(1-\epsilon)^s)=0.$$ ■

Algebraic approach to scattering theory of the Fokker–Planck equation

Toru Miyazawa
Department of Physics, Gakushuin University, Mejiro, Toshima-ku, Tokyo 171, Japan

(Received 14 July 1997; accepted for publication 7 January 1998)

The one-variable Fokker–Planck equation is studied in a scattering formalism. Scattering processes are represented by paths in one-dimensional space, and the paths are treated as algebraic objects that constitute infinite-dimensional representations of SL(2, **C**). Various expressions for the scattering coefficients are derived in a systematic way by means of algebraic methods with considerations on symmetries. © *1998 American Institute of Physics.* [S0022-2488(98)02304-4]

I. INTRODUCTION

The Fokker–Planck equation, which is a fundamental equation describing fluctuations in nonlinear systems, has also come to play an important role in quantum mechanics in connection with stochastic approaches to quantization.[1] Fundamental studies of the Fokker–Planck equation are important not only for the application to nonequilibrium phenomena but also for a better understanding of quantum mechanics.

The one-variable Fokker–Planck equation describing the diffusion process in a potential $V(x)$ has the form[2]

$$\frac{\partial}{\partial t}P(x;t)=\frac{\partial^2}{\partial x^2}P(x;t)-2\frac{\partial}{\partial x}[f(x)P(x;t)] \tag{1.1}$$

with

$$f(x)=-\frac{1}{2}\frac{d}{dx}V(x). \tag{1.2}$$

We set $P(x;t)=e^{-k^2t}\phi(x)$, where the parameter k is a complex number. Then we obtain

$$-\frac{d^2}{dx^2}\phi(x)+2\frac{d}{dx}[f(x)\phi(x)]=k^2\phi(x). \tag{1.3}$$

Equation (1.3) is equivalent to the Schrödinger equation

$$-\frac{d^2\psi}{dx^2}+\left(f^2+\frac{df}{dx}\right)\psi=k^2\psi, \tag{1.4}$$

where

$$\psi(x)=e^{V(x)/2}\phi(x). \tag{1.5}$$

Inversely, a Schrödinger equation

$$-\frac{d^2}{dx^2}\psi(x)+V_S(x)\psi(x)=\epsilon\psi(x) \tag{1.6}$$

can be converted into the Fokker–Planck equation (1.3) with

 © 1998 American Institute of Physics

$$\phi(x)=\psi_0(x)\psi(x), \quad f(x)=\frac{(d/dx)\psi_0(x)}{\psi_0(x)}, \quad k^2=\epsilon-\epsilon_0, \tag{1.7}$$

where $\psi_0(x)$ and ϵ_0 are the wave function and the energy eigenvalue of the ground state satisfying

$$-\frac{d^2}{dx^2}\psi_0(x)+V_S(x)\psi_0(x)=\epsilon_0\psi_0(x). \tag{1.8}$$

From the second equation of (1.7) it follows that

$$V(x)=-2\log\psi_0(x)+\text{constant}, \quad V_S(x)=[f(x)]^2+\frac{d}{dx}f(x)+\epsilon_0. \tag{1.9}$$

Thus, with knowledge of the ground state, a problem of quantum mechanics can be described by a Fokker–Planck equation. The merit of the Fokker–Planck equation as opposed to the Schrödinger equation lies in its symmetrical structure. Because of the symmetries the Fokker–Planck equation is more suitable for theoretical studies than the Schrödinger equation, and we can gain a better insight into the the problem by studying the Fokker–Planck equation.

One of the remarkable features of the Fokker–Planck equation is that the high-energy expansion (which corresponds to the Born series) and the low-energy expansion are related by a symmetry transformation. The difference between these two expressions are merely a difference of viewpoint. The Fokker–Planck equation has a structure that does not depend on the viewpoint, and, as it turns out, such a structure is well described in terms of paths in one-dimensional space. (The meaning of the ''path'' will be explained in due course.) In order to deal with the paths it is convenient to use the language of scattering theory, as we will shortly see.

As mentioned above, it is natural to study the Fokker–Planck equation in a formalism of scattering theory.[3–7] The aim of the present paper is to provide a unified view on the scattering formalism from an algebraic standpoint. In particular, our main interest is in the structure of the scattering coefficients (the transmission and reflection coefficients). It should be stressed that the usefulness of the scattering formalism is not limited within so-called scattering problems. Almost everything can be described in the scattering formalism. For example, the Green's function can be expressed in terms of the scattering coefficients, and the asymptotic behavior of solutions can be studied through the analysis of these scattering coefficients. The eigenvalue problem can be formulated in terms of the reflection coefficients, too, as we shall see later in this section.

Incidentally, the study of the scattering coefficients is also significant in relation to theories of integrable systems.[8] The Fokker–Plank equation is equivalent to the linear problem that is used in the inverse scattering method for the modified Korteweg–de-Vries equation.[9] Linear scattering problems associated with other nonlinear integrable equations, such as the nonlinear Schrödinger equation, are also similar in structure. So a systematic theory of the scattering coefficients will also shed light on the study of integrable systems.

In this paper we study the Fokker–Planck equation in the time-independent form (1.3), or equivalently (1.4). We do not assume a specific form of the potential $V(x)$. We can deal with not only potentials that have a finite limit at $x\to\pm\infty$ but also potentials that diverge at either $x\to+\infty$ or $x\to-\infty$ or both, or even the cases where $V(x)$ diverges at some finite x. In particular, three-dimensional problems with a spherically symmetric potential, which reduce to one-dimensional problems for the radial part, are also manageable in our formalism.

We define the transmission and reflection coefficients for an interval (x_a,x_b). (The usual transmission and reflection coefficients, which are defined with regard to the behavior of solutions at infinity, are obtained by taking the limit $x_a\to-\infty, x_b\to+\infty$.) Here we give two equivalent definitions. The first definition is the one commonly used in conventional scattering theories.[10] As shown in Fig. 1, we cut out the potential within the interval (x_a,x_b), and assume that the potential is constant outside this interval. That is to say, we consider the potential

$$\overline{V}(x)\equiv\begin{cases} V(x_a), & (x<x_a),\\ V(x), & (x_a\leqslant x\leqslant x_b),\\ V(x_b), & (x_b<x),\end{cases} \tag{1.10}$$

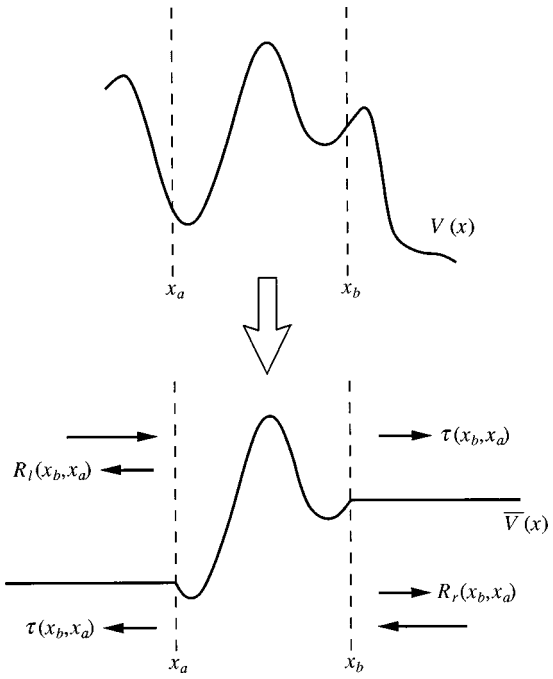

FIG. 1. Definition of the transmission and reflection coefficients for a finite interval.

instead of $V(x)$, and corresponding to (1.4) the Schrödinger equation

$$-\frac{d^2\psi}{dx^2}+\left(\overline{f}^2+\frac{d\overline{f}}{dx}\right)\psi=k^2\psi, \quad \overline{f}(x)=-\frac{1}{2}\frac{d}{dx}\overline{V}(x). \tag{1.11}$$

Since $\overline{f}=0$ outside the interval (x_a,x_b), any solution of Eq. (1.11) can be expressed as a linear combination of e^{ikx} and e^{-ikx} outside (x_a,x_b). In particular, we can construct two solutions ψ_1 and ψ_2 that have the form

$$\psi_1(x)=\begin{cases} e^{ik(x-x_a)}+R_l(x_b,x_a;k)e^{-ik(x-x_a)} & (x<x_a), \\ T(x_b,x_a;k)e^{ik(x-x_a)} & (x_b<x), \end{cases} \tag{1.12a}$$

$$\psi_2(x)=\begin{cases} T(x_b,x_a;k)e^{-ik(x-x_b)} & (x<x_a), \\ e^{-ik(x-x_b)}+R_r(x_b,x_a;k)e^{ik(x-x_b)} & (x_b<x). \end{cases} \tag{1.12b}$$

This defines the transmission coefficient T and the reflection coefficients R_r, R_l for the interval (x_a,x_b). When dealing with a finite interval, it is convenient to define

$$\tau(x_b,x_a)\equiv e^{ik(x_b-x_a)}T(x_b,x_a). \tag{1.13}$$

In this paper we use τ rather than T, and we shall call τ the transmission coefficient.

There is another way of defining the scattering coefficients, which is maybe more essential than the previous one. The transmission of a particle through the interval (x_a,x_b) is a process in which the particle travels from the point x_a to the point x_b undergoing multiple scattering by the potential. It is natural to define the transmission coefficient as the sum over all possible multiple scattering processes. This can be done as follows.[7] We define the transmission coefficient as the sum over all the diagrams such as the one shown in Fig. 2(a) with the following rules: A line element connecting the points x_1 and x_2 $(x_2 \geqslant x_1)$ represents the free propagator of the particle, $e^{ik(x_2-x_1)}$ [Fig. 3(a)]. A single scattering at position x gives a factor $+f(x)$ or $-f(x)$. The sign is plus if the particle comes to x from the right, and minus if it comes from the left [Figs. 3(b), (c)]. (Note that the particle always changes its direction with each single scattering.) The transmission coefficient $\tau(x_b,x_a)$ is defined as the sum over all the diagrams that connect the points x_a and x_b

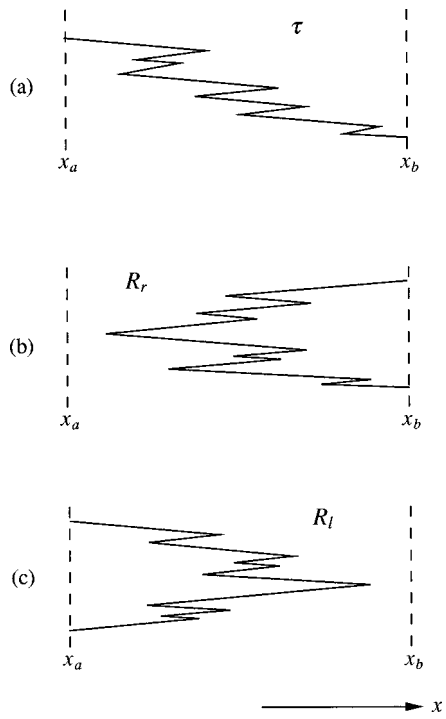

FIG. 2. The transmission and reflection coefficients are obtained as the sum over these diagrams. The rules for interpreting the diagrams are given in Fig. 3. The horizontal direction of this figure corresponds to the space coordinate. The vertical direction has no meaning.

without leaving the interval (x_a, x_b). A diagram can also be regarded as a path in one-dimensional space. We can say that the transmission coefficient $\tau(x_b, x_a)$ is the sum over all configurations of a path that penetrates the interval (x_a, x_b). Similarly, the reflection coefficients can be defined as the sum over all configurations of a path that starts from one of the endpoints and returns to that point. [Figs. 2(b), (c)] These definitions can be written as

$$\tau(x_b, x_a) = \sum_{N=0}^{\infty} (-1)^N \int dx_1 \cdots \int dx_{2N} \left[\prod_{n=1}^{2N} f(x_n) \right] \exp\left(\sum_{n=0}^{2N} ik|x_{n+1} - x_n| \right),$$

$$(x_0 \equiv x_a, x_{2N+1} \equiv x_b), \tag{1.14a}$$

$$R_r(x_b, x_a) = \sum_{N=0}^{\infty} (-1)^N \int dx_1 \cdots \int dx_{2N+1} \left[\prod_{n=1}^{2N+1} f(x_n) \right] \exp\left(\sum_{n=0}^{2N+1} ik|x_{n+1} - x_n| \right),$$

$$(x_0 \equiv x_b, x_{2N+2} \equiv x_b), \tag{1.14b}$$

$$R_l(x_b, x_a) = \sum_{N=0}^{\infty} (-1)^{N+1} \int dx_1 \cdots \int dx_{2N+1} \left[\prod_{n=1}^{2N+1} f(x_n) \right] \exp\left(\sum_{n=0}^{2N+1} ik|x_{n+1} - x_n| \right),$$

$$(x_0 \equiv x_a, x_{2N+2} \equiv x_a). \tag{1.14c}$$

The integral variables x_n $(n = 1,2,...)$ in Eqs. (1.14) correspond to the points where the scattering occurs, or in other words, the turning points of the path. Since the path changes its direction at x_n, the domain of integration for the variable x_n is

$$x_{n-1} \leqslant x_n \leqslant x_b \quad (n \text{ odd}), \quad x_a \leqslant x_n \leqslant x_{n-1} \quad (n \text{ even}) \tag{1.15a}$$

in Eqs. (1.14a) and (1.14c), and

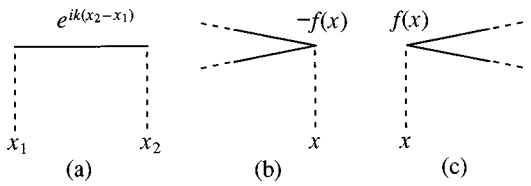

FIG. 3. Rules for the representation of scattering processes in terms of diagrams.

$$x_a \leqslant x_n \leqslant x_{n-1} \quad (n \text{ odd}), \quad x_{n-1} \leqslant x_n \leqslant x_b \quad (n \text{ even}) \tag{1.15b}$$

in Eq. (1.14b). It can be shown[3,4] that the scattering coefficients defined by (1.14) are the same as the ones defined by (1.12). We graphically express these scattering coefficients as shown in Fig. 4. These graphs represent the sum over all possible configurations of the paths in Fig. 2.

As an example of application, let us consider the eigenvalue problem. When $V(x)$ diverges (to either $+\infty$ or $-\infty$) at both $x \to +\infty$ and $x \to -\infty$ sufficiently fast (faster than linear functions of x, as a matter of fact), equation (1.3) can be interpreted as an eigenvalue problem, where k^2 is the eigenvalue of the Fokker–Planck operator $-d^2/dx^2+2(d/dx)f$. Now the quantity k is real. The eigenvalues are determined from the condition[4]

$$R_l(\infty,x_0;k)R_r(x_0,-\infty;k)=1, \tag{1.16}$$

where x_0 is arbitrary. [The value $k=0$ is an exception. Even if $k=0$ satisfies (1.16), it does not correspond to an eigenvalue unless $V(x)$ diverges to plus infinity at both $x \to +\infty$ and $x \to -\infty$.] For example, the reflection coefficients for the parabolic potential $V(x)=x^2$ [which corresponds to the Schrödinger potential $V_S(x)=x^2-1$] can be obtained as[11]

$$R_l(\infty,0;k)=R_r(0,-\infty;k)=\frac{2\Gamma\left(1-\frac{k^2}{4}\right)+ik\Gamma\left(\frac{1}{2}-\frac{k^2}{4}\right)}{2\Gamma\left(1-\frac{k^2}{4}\right)-ik\Gamma\left(\frac{1}{2}-\frac{k^2}{4}\right)}, \tag{1.17}$$

where we have chosen $x_0=0$. From (1.17) and (1.16) we can reproduce the well-known result for the eigenvalues, $k^2=2n$ $(n=0,1,2,...)$. Of course, in general it is not possible to calculate the reflection coefficients exactly. A convenient approximation method for evaluating low-lying eigenvalues is to use power series expressions of the reflection coefficients in terms of k. If we express

$$\begin{aligned} \log R_l(\infty,0;k)&=a_1k+a_3k^3+a_5k^5+\ldots, \\ \log R_r(0,-\infty;k)&=b_1k+b_3k^3+b_5k^5+\ldots \end{aligned} \tag{1.18}$$

[only odd powers of k appear in (1.18); see Sec. XIII], from (1.16) we can obtain the nth eigenvalue as the solution of

$$(a_1+b_1)k+(a_3+b_3)k^3+(a_5+b_5)k^5+\cdots=2n\pi i. \tag{1.19}$$

An example of such evaluation of eigenvalues can be found in Ref. 6. The power series expressions are also useful for analyzing the long time behavior of solutions.[4,5]

Power series expressions for the scattering coefficients such as (1.18) as functionals of the potential $V(x)$ have already been obtained in previous works.[5,6] However, the derivations were rather specific and lacked a general prospect on the problem. In particular, it was not clear why the

FIG. 4. Graphical representation of the scattering coefficients.

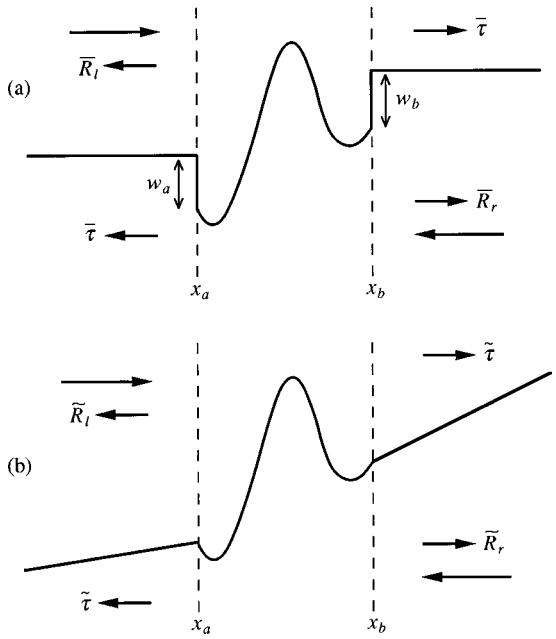

FIG. 5. Generalized scattering coefficients.

resulting expression should have the form it has. It is one of the purposes of the present work to give a general and systematic method for deriving expressions like (1.18) with a clear view on the underlying algebraic structure. This method not only reproduces previously obtained results in a transparent way but also brings forth new useful expressions.

We generalize the definition of the scattering coefficients in Sec. II. These generalized scattering coefficients play an essential role in our analysis. In Sec. III we briefly review some basic matters indispensable for the discussion in the present paper. The evolution operator is introduced here. In Sec. IV we give an intuitive interpretation of the evolution operator in terms of paths. In Sec. V we study a special representation that is related to the reflection coefficients. In Sec. VI we investigate symmetrical structures of the Fokker–Planck equation and set up our theory in a form that makes use of these symmetries. We introduce some mathematical tools in Sec. VII in order to treat the paths algebraically. Using these tools we study the structure of the scattering coefficients in Secs. VIII–XIII.

II. GENERALIZED SCATTERING COEFFICIENTS

There is some arbitrariness in the definition of scattering coefficients for a finite interval. Indeed, we can generalize the definition (1.10)–(1.13) by using, instead of (1.10),

$$\overline{V}(x)\equiv\begin{cases} V(x_a)+w_a & (x<x_a) \\ V(x) & (x_a\leqslant x\leqslant x_b), \\ V(x_b)+w_b & (x_b<x) \end{cases} \tag{2.1}$$

with arbitrary parameters w_a and w_b [Fig. 5(a)]. Since this $\overline{V}(x)$ still gives $\overline{f}=0$ outside the interval (x_a,x_b), by replacing (1.10) with (2.1) we can define a set of scattering coefficients in the same way as we did in (1.11) and (1.12). We write the transmission and reflection coefficients obtained by this generalization as $\overline{\tau}(x_b,x_a;w_b,w_a)$, $\overline{R}_r(x_b,x_a;w_b,w_a)$, and $\overline{R}_l(x_b,x_a;w_b,w_a)$. (We shall omit to write the dependence on k.) Needless to say, we have

$$\tau=\overline{\tau}(w_b=w_a=0), \quad R_r=\overline{R}_r(w_b=w_a=0), \quad R_l=\overline{R}_l(w_b=w_a=0). \tag{2.2}$$

The potential $\overline{V}$ defined by (2.1) has discontinuities at both x_a and x_b (unless $w_a=0$ or $w_b=0$). We can say that $\overline{\tau}$, $\overline{R}_r$, and $\overline{R}_l$ are the scattering coefficients including the effect of these discontinuities. This set of generalized scattering coefficients plays a crucial role in our subsequent studies.

There is still another natural way to generalize the definition of the scattering coefficients. We know that if $f(x)$ is a constant ($\equiv c$), then any solution of Eq. (1.4) can be expressed as a linear combination of $\exp[i(k^2-c^2)^{1/2}]$ and $\exp[-i(k^2-c^2)^{1/2}]$. Therefore, to define the scattering coefficients for the potential $V(x)$ within the interval (x_a,x_b) we can use

$$\overline{V}(x)\equiv\begin{cases} V(x_a)-2c_a(x-x_a) & (x<x_a)\\ V(x) & (x_a\leqslant x\leqslant x_b),\\ V(x_b)-2c_b(x-x_b) & (x_b<x)\end{cases} \tag{2.3}$$

where c_a and c_b are constants [Fig. 5(b)]. This $\overline{V}(x)$ gives $\overline{f}(x)=c_a$ for $x<x_a$ and $\overline{f}(x)=c_b$ for $x_b<x$. So Eq. (1.11) with $V(x)$ given by (2.3) has two independent solutions of the form

$$\psi_1(x)=\begin{cases} e^{ip_a(x-x_a)}+\widetilde{R}_l(x_b,x_a;c_b,c_a)e^{-ip_a(x-x_a)} & (x<x_a)\\ \sqrt{p_a/p_b}\,\widetilde{\tau}(x_b,x_a;c_b,c_a)e^{ip_b(x-x_b)} & (x_b<x),\end{cases} \tag{2.4a}$$

$$\psi_2(x)=\begin{cases} \sqrt{p_b/p_a}\,\widetilde{\tau}(x_b,x_a;c_b,c_a)e^{-ip_a(x-x_a)} & (x<x_a)\\ e^{-ip_b(x-x_b)}+\widetilde{R}_r(x_b,x_a;c_b,c_a)e^{ip_b(x-x_b)} & (x_b<x),\end{cases} \tag{2.4b}$$

with

$$p_a\equiv(k^2-c_a^2)^{1/2},\quad p_b\equiv(k^2-c_b^2)^{1/2}. \tag{2.5}$$

(Here p_a and p_b may not necessarily be real.) The factors $\sqrt{p_a/p_b}$ and $\sqrt{p_b/p_a}$ in (2.4) are now necessary in order to make the transmission coefficients $\widetilde{\tau}$ identical in both expressions (2.4a) and (2.4b). By (2.4) we can define another set of scattering coefficients, $\widetilde{\tau}$, $\widetilde{R}_r$, and $\widetilde{R}_l$, and also

$$\widetilde{T}(x_b,x_a;c_b,c_a)\equiv e^{i(p_ax_a-p_bx_b)}\widetilde{\tau}(x_b,x_a;c_b,c_a). \tag{2.6}$$

These $\widetilde{T}$, $\widetilde{R}_r$, and $\widetilde{R}_l$ are significant in connection with scattering problems (in a narrow sense) for the Schrödinger equation.[10] Let us consider the Schrödinger equation (1.6) with potential $V_S(x)$ that tends to a finite limit at both $x\to+\infty$ and $x\to-\infty$

$$\lim_{x\to-\infty}V_S(x)=V_a,\quad \lim_{x\to+\infty}V_S(x)=V_b. \tag{2.7}$$

If $V(x)$ converges to these limits sufficiently fast, the transmission and reflection coefficients T^S, R_r^S and R_l^S for this Schrödinger equation can be defined from two independent solutions of (1.6) with the asymptotic form

$$\psi_1(x)\sim\begin{cases} e^{ip_ax}+R_l^Se^{-ip_ax} & (x\to-\infty)\\ \sqrt{p_a/p_b}\,T^Se^{ip_bx} & (x\to+\infty),\end{cases}\quad \psi_2(x)\sim\begin{cases} \sqrt{p_b/p_a}\,T^Se^{-ip_ax} & (x\to-\infty)\\ e^{-ip_bx}+R_r^Se^{ip_bx} & (x\to+\infty),\end{cases} \tag{2.8}$$

where $p_a=\sqrt{\epsilon-V_a}$, $p_b=\sqrt{\epsilon-V_b}$. The wave function of the ground state behaves like e^{c_ax} and e^{c_bx} at $x\to-\infty$ and $x\to+\infty$, respectively, where $c_a=\sqrt{V_a-\epsilon_0}$, $c_b=-\sqrt{V_b-\epsilon_0}$. From the second equation of (1.7) we find that $f(x)$ behaves as $f(x)\sim c_a$ at $x\to-\infty$ and $f(x)\sim c_b$ at $x\to+\infty$. Therefore the corresponding Fokker–Planck potential $V(x)$ has the same asymptotic form as $\overline{V}(x)$ given by (2.3). Comparing (2.4) with (2.8) we find

$$T^S=\lim_{\substack{x_a\to-\infty\\ x_b\to+\infty}}\widetilde{T}(x_b,x_a;c_b,c_a), \tag{2.9a}$$

$$R_r^S=\lim_{\substack{x_a\to-\infty\\ x_b\to+\infty}} e^{-2ip_bx_b}\tilde{R}_r(x_b,x_a;c_b,c_a),\quad R_l^S=\lim_{\substack{x_a\to-\infty\\ x_b\to+\infty}} e^{2ip_ax_a}\tilde{R}_l(x_b,x_a;c_b,c_a). \tag{2.9b}$$

It is also possible to replace c_b and c_a in (2.9) by $f(x_b)$ and $f(x_a)$, respectively.

Thus we have defined two sets of generalized scattering coefficients, $(\bar{\tau},\bar{R}_r,\bar{R}_l)$ and $(\tilde{\tau},\tilde{R}_r,\tilde{R}_l)$. We shall see later how they can be described in our formalism. For the time being we work with the ''ordinary'' scattering coefficients τ, R_r, and R_l.

III. PRELIMINARIES

Here we review minimal basic materials that are necessary for our discussion. Details can be found in Refs. 7 and 4. Throughout this paper $V(x)$ denotes the potential for the Fokker–Planck equation, and $f(x)$ is its derivative multiplied by $-1/2$ [Eq. (1.2)].

We define the evolution operator $U(x,x')$, which is an element of the SL(2,**C**) Lie group, as the solution of the first-order differential equation

$$\frac{\partial}{\partial x}U(x,x')=[2ikJ_3-2f(x)J_1]U(x,x') \tag{3.1}$$

with the initial condition $U(x',x')=1$ (identity element). Here J_1 and J_3 are operators satisfying the SU(2) commutation relations

$$[J_1,J_2]=iJ_3,\quad [J_2,J_3]=iJ_1,\quad [J_3,J_1]=iJ_2 \tag{3.2a}$$

or, with the raising and lowering operators $J_\pm\equiv J_1\pm iJ_2$,

$$[J_+,J_-]=2J_3,\quad [J_3,J_\pm]=\pm J_\pm. \tag{3.2b}$$

This $U(x,x')$ is an analog of the time evolution operator in ordinary quantum mechanics, and it satisfies the product rule

$$U(x_c,x_b)U(x_b,x_a)=U(x_c,x_a). \tag{3.3}$$

The Fokker–Planck equation (1.3) is equivalent to Eq. (3.1). To see this, let us consider the fundamental representation given by

$$J_1=\frac{1}{2}\begin{pmatrix}0&-1\\-1&0\end{pmatrix},\quad J_2=\frac{1}{2}\begin{pmatrix}0&-i\\i&0\end{pmatrix},\quad J_3=\frac{1}{2}\begin{pmatrix}-1&0\\0&1\end{pmatrix}. \tag{3.4}$$

In this representation Eq. (3.1) reads

$$\frac{\partial}{\partial x}U(x,x')=\begin{pmatrix}-ik&f(x)\\f(x)&ik\end{pmatrix}U(x,x'), \tag{3.5}$$

and $U(x,x')$ is a 2×2 matrix with unit determinant. We write its elements as

$$U(x,x')=\begin{pmatrix}\alpha^+(x,x')&\beta^-(x,x')\\\beta^+(x,x')&\alpha^-(x,x')\end{pmatrix}. \tag{3.6}$$

If we define

$$\phi^+(x,x')\equiv\alpha^+(x,x')+\beta^+(x,x'),\quad \phi^-(x,x')\equiv\alpha^-(x,x')+\beta^-(x,x'), \tag{3.7}$$

then it is easy to see from (3.5) that ϕ^+ and ϕ^-, as functions of x, are two independent solutions of (1.4). We can easily show that the scattering coefficients are expressed in terms of these matrix elements as

$$\tau(x_b,x_a)=\frac{1}{\alpha^+(x_b,x_a)}, \tag{3.8a}$$

$$R_r(x_b,x_a)=\frac{\beta^+(x_b,x_a)}{\alpha^+(x_b,x_a)}, \quad R_l(x_b,x_a)=-\frac{\beta^-(x_b,x_a)}{\alpha^+(x_b,x_a)}. \tag{3.8b}$$

We can obtain a different picture by writing Eq. (3.1) in a different representation. Let us consider the boson representation[12]

$$J_+=-\tfrac{1}{2}a^\dagger a^\dagger, \quad J_-=\tfrac{1}{2}aa, \quad J_3=\tfrac{1}{4}(aa^\dagger+a^\dagger a)=\tfrac{1}{2}a^\dagger a+\tfrac{1}{4}, \tag{3.9}$$

where a and $a^\dagger$ are boson creation-annihilation operators satisfying $[a,a^\dagger]=1$. Now Eq. (3.1) takes the form

$$\frac{\partial}{\partial x}U(x,x')=\left[ik\left(aa^\dagger+\frac{1}{2}\right)-\frac{1}{2}f(x)(aa-a^\dagger a^\dagger)\right]U(x,x'). \tag{3.10}$$

It is easy to interpret the meaning of Eq. (3.10) by comparing it with Fig. 2 or Fig. 3. In this description the paths in Fig. 2 are interpreted as consisting of propagation lines of the boson, and the scattering is described as pair creation or pair annihilation of bosons. Obviously the scattering coefficients can be written as

$$\tau(x,x')=\frac{\langle 0|aU(x,x')a^\dagger|0\rangle}{\langle 0|U(x,x')|0\rangle}, \tag{3.11a}$$

$$R_r(x,x')=\frac{\langle 0|aaU(x,x')|0\rangle}{\langle 0|U(x,x')|0\rangle}, \quad R_l(x,x')=\frac{\langle 0|U(x,x')a^\dagger a^\dagger|0\rangle}{\langle 0|U(x,x')|0\rangle}, \tag{3.11b}$$

where $|0\rangle$ denotes the vacuum state. The quantity $\langle 0|U|0\rangle$ in the denominator is necessary in order to cancel out disconnected bubble diagrams.

We can use Eq. (3.1) in any other representation. In any representation the evolution operator can be expressed in terms of the scattering coefficients as

$$U(x,x')=e^{-R_r(x,x')J_+}[\tau(x,x')]^{2J_3}e^{R_l(x,x')J_-} \tag{3.12}$$

[where $\tau^{2J_3}\equiv e^{(2\log\tau)J_3}$]. We can also rewrite the expressions (3.8) or (3.11) in a form that holds in any representation. We define an inner product, which we shall write as $(\cdots,\cdots)$, that have the following properties:

$$(u,v)=(v,u)^*, \quad (u,J_3v)=(J_3u,v), \quad (u,J_\pm v)=-(J_\mp u,v). \tag{3.13}$$

Here u and v are arbitrary vectors in the representation space. This inner product need not satisfy the positivity condition $(u,u)\geqslant 0$. We assume that there exists a lowest state vector u_0 in the representation space. It is the state annihilated by the lowering operator:

$$J_-u_0=0. \tag{3.14}$$

Then the reflection coefficients can be expressed in the representation-independent form as

$$R_r=\frac{1}{2}\frac{(u_0,J_-Uu_0)}{(u_0,J_3Uu_0)}, \quad R_l=-\frac{1}{2}\frac{(u_0,UJ_+u_0)}{(u_0,UJ_3u_0)}, \tag{3.15}$$

which is the generalized form of (3.8b) or (3.11b).

For the most part we shall deal with irreducible representations with a definite ''spin,'' where the lowest state is an eigenstate of J_3. Namely, $J_3u_0=-ju_0$, where j is the spin index. If j is not a positive integer or half-odd-integer, the representation space is infinite dimensional. We define $\nu\equiv -2j$, and we shall label the representation by this ν. For example, we write

$$J_3^{(\nu)}u_0^{(\nu)}=\frac{\nu}{2}\,u_0^{(\nu)}, \tag{3.16}$$

and we express the inner product in this representation as $(u,v)^{(\nu)}$. We use ν as the label[13] rather than j, since we will mainly deal with infinite-dimensional representations with $\nu\geqslant 0$.

Now let us explicitly write out expressions for the representation labeled by ν. We choose the basis such that the representation matrices of $J_\pm$ and J_3 have the form

$$J_+^{(\nu)}=\begin{pmatrix} 0 & & & & & \\ -1 & 0 & & & & \\ & -2 & 0 & & & \\ & & -3 & 0 & & \\ & & & \ddots & \ddots & \end{pmatrix}, \qquad J_-^{(\nu)}=\begin{pmatrix} 0 & \nu & & & & \\ & 0 & \nu+1 & & & \\ & & 0 & \nu+2 & & \\ & & & 0 & \ddots & \\ & & & & \ddots & \end{pmatrix}, \tag{3.17a}$$

$$J_3^{(\nu)}=\begin{pmatrix} \frac{\nu}{2} & & & & \\ & \frac{\nu}{2}+1 & & & \\ & & \frac{\nu}{2}+2 & & \\ & & & \ddots & \end{pmatrix}. \tag{3.17b}$$

In this basis the symmetry relation between $J_+^{(\nu)}$ and $J_-^{(\nu)}$ is expressed as

$$M^{(\nu)}J_+^{(\nu)}(M^{(\nu)})^{-1}=-(J_-^{(\nu)})^T, \tag{3.18}$$

where $M^{(\nu)}$ is the diagonal matrix whose (n,n) element is

$$(M^{(\nu)})_{nn}=\frac{\nu(\nu+1)\cdots(\nu+n-1)}{n!}=\binom{\nu+n-1}{n}, \quad (n=0,1,2,\ldots). \tag{3.19}$$

[For $n=0$ we have $\binom{\nu-1}{0}=1$.] The inner product satisfying (3.13) can be defined using this $M^{(\nu)}$ as

$$(v,u)^{(\nu)}\equiv(v^*)^TM^{(\nu)}u, \tag{3.20}$$

where u and v are column vectors, and T denotes transposition. The lowest state vector satisfying (3.14) is the column vector $u_0^{(\nu)}=(1,0,0,\ldots)^T$. The representation space is spanned by the basis $u_n^{(\nu)}$ $(n=0,1,2,\ldots)$, where

$$u_n^{(\nu)}=(-1)^n\,\frac{1}{n!}\,[J_+^{(\nu)}]^nu_0^{(\nu)}=(\overbrace{0,\ldots,0}^{n},1,0,\ldots)^T. \tag{3.21}$$

In this representation, the matrix elements of $U^{(\nu)}=e^{-R_rJ_+^{(\nu)}}\tau^{2J_3^{(\nu)}}e^{R_lJ_-^{(\nu)}}$ [Eq. (3.12)] are obtained as

$$(U^{(\nu)})_{mn}=\frac{1}{\binom{\nu+m-1}{m}}\,(u_m^{(\nu)},U^{(\nu)}u_n^{(\nu)})^{(\nu)}=\sum_{i=0}^{\min(m,n)}\binom{m}{i}\binom{\nu+n-1}{n-i}R_r^{m-i}R_l^{n-i}\tau^{\nu+2i} \tag{3.22}$$

$(m,n=0,1,2,\ldots)$. Note that the binomial coefficients are defined as in Eq. (3.19). In particular, since $(U^{(\nu)})_{00}=\tau^\nu$ we have, for any ν,

$$\tau=[(u_0^{(\nu)},U^{(\nu)}u_0^{(\nu)})^{(\nu)}]^{1/\nu}. \tag{3.23}$$

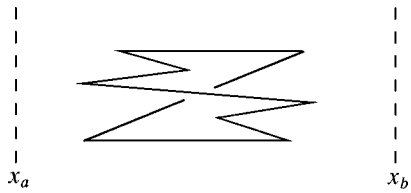

FIG. 6. The quantity $\log Z$ is obtained as the sum over connected loop diagrams like this one.

The representation given by the matrices in (3.4) is the spin-1/2 representation, and hence $\nu=-1$. The matrix U in Eqs. (3.5) and (3.6) is $U^{(-1)}$ in our present notation. From (3.6), (3.19), and (3.20) it is obvious that $(u_0^{(-1)}, U^{(-1)}u_0^{(-1)})^{(-1)}=\alpha^+$, and thus we can see that (3.8a) is obtained from (3.23) by setting $\nu=-1$.

The boson representation given by (3.9) is reducible. The spaces with even number and odd number of bosons form two invariant subspaces, each corresponding to $\nu=1/2$ and $\nu=3/2$, respectively. In fact, if we choose as the basis

$$u_n^{(1/2)}=\frac{1}{n!}\left(\frac{1}{2}\,a^\dagger a^\dagger\right)^n|0\rangle, \quad u_n^{(3/2)}=\frac{1}{n!}\left(\frac{1}{2}\,a^\dagger a^\dagger\right)^n a^\dagger|0\rangle, \tag{3.24}$$

the matrix expression of the operators (3.9) is given by (3.17) with $\nu=1/2$ and $\nu=3/2$, respectively. The inner product (3.20) is equivalent to the ordinary inner product in the boson Fock space. Obviously Eqs. (3.11b) are a special case of (3.15). The relation (3.23) with $\nu=1/2$ and $\nu=3/2$, respectively, can be written in the boson representation as

$$\tau^{1/2}=\langle 0|U|0\rangle, \quad \tau^{3/2}=\langle 0|aUa^\dagger|0\rangle. \tag{3.25}$$

We can reproduce (3.11a) from (3.25).

In the boson representation we define the vacuum amplitude Z as

$$Z(x,x')\equiv e^{-(1/2)ik(x-x')}\langle 0|U(x,x')|0\rangle. \tag{3.26}$$

It is the sum over all bubble diagrams. [The factor $e^{-(1/2)ik(x-x')}$ cancels the evolution caused by the term $\frac{1}{2}ikU$ on the right-hand side of (3.10).] From (3.25) and (3.26) we obtain a relation between the transmission coefficient and the vacuum amplitude,

$$\tau(x,x')=e^{ik(x-x')}[Z(x,x')]^2, \tag{3.27}$$

and therefore

$$\log\,\tau(x,x')=2\,\log\,Z(x,x')+ik(x-x'). \tag{3.28}$$

We remark that $\log Z$ is obtained as the sum over all connected loop diagrams, while Z includes disconnected diagrams. (See Fig. 6. Note that Z and $\log Z$, respectively, correspond to the partition function and the free energy in statistical mechanics.) Thus the quantity $\log \tau(x,x')$, apart from $ik(x-x')$, is obtained as the sum over all configurations of a connected closed path. Because of the factor 2 in front of $\log Z$ on the right-hand side, we regard mirror images as different diagrams. We shall see later that the evolution of $\log \tau$ is described by the $\nu=0$ representation.

IV. DIAGRAMMATIC INTERPRETATION

The expressions given in the last section are valid for any real values of ν, no matter whether it is positive or negative, integer or noninteger. However, in order to describe the scattering coefficients, representations with a positive integer ν are of particular importance. For example, the transmission coefficient τ is the (0,0) element of the evolution matrix for $\nu=1$. So in order to study the transmission coefficient it is natural to deal with the $\nu=1$ representation.

When ν is a positive integer, the evolution operator can be given an intuitive interpretation in terms of diagrams. Let us sketch out the basic idea. The transmission coefficient $\tau(x_2,x_1)$ is the

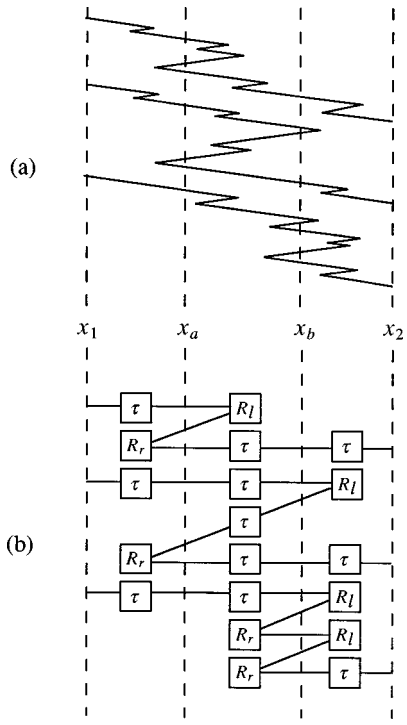

FIG. 7. (a) A diagram contributing to τ^3. (b) The diagram in (a) is included in this graph.

sum over all possible configurations of a path that connects x_1 and x_2. Therefore the quantity $(U^{(\nu)})_{00}=\tau^\nu$ can be understood as the sum over configurations of ν such paths. In other words, it is the sum over all such diagrams as the one shown in Fig. 7(a). Suppose that we dissect such a diagram at two points x_a and x_b $(x_1<x_a<x_b<x_2)$. The matrix elements of $U^{(\nu)}(x_b,x_a)$ correspond to the fragments that appear by the dissection. [See Fig. 7(b).] The precise meaning of this statement will soon become clear.

Before discussing the evolution operator, let us give a graphical interpretation to the basis given by Eq. (3.21) and the inner product defined by (3.20). We express the basis vector $u_n^{(\nu)}$ graphically as shown in Fig. 8. It consists of ν objects with one external leg (open circles) and n objects with two legs (solid circles). Its transpose $(u_n^{(\nu)})^T$ is expressed in a similar way with the legs pointing to the opposite direction. The inner product of two basis vectors $(u_m^{(\nu)},u_n^{(\nu)})^{(\nu)}$ is interpreted as the number of ways in which the legs of $u_n^{(\nu)}$ and $(u_m^{(\nu)})^T$ can be connected without creating a loop. If $m\neq n$, such a connection is impossible since the legs do not match. If $m=n$, there are $\binom{\nu+n-1}{n}$ possible ways of doing so, which is the number of ways to divide the n solid circles among the ν open circles (Fig. 9). Thus we can reproduce

$$(u_m^{(\nu)},u_n^{(\nu)})^{(\nu)}=(u_m^{(\nu)})^T M^{(\nu)} u_n^{(\nu)}=\binom{\nu+n-1}{n}\delta_{mn}, \tag{4.1}$$

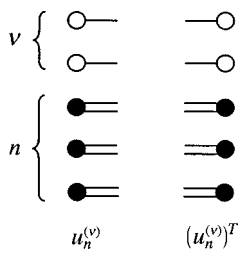

FIG. 8. Graphical representation of $u_n^{(\nu)}$ and its transpose.

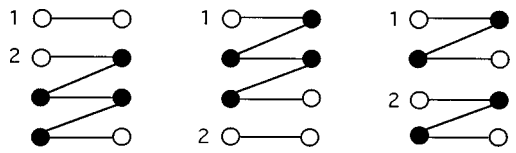

FIG. 9. Graphical interpretation of the inner product $(u_n^{(\nu)},u_n^{(\nu)})^{(\nu)}=\binom{\nu+n-1}{n}$. In this example, $\nu=2$, $n=2$, and $\binom{\nu+n-1}{n}=3$. As shown here, there are three possible ways of connecting the legs of $u_2^{(2)}$ and $(u_2^{(2)})^T$. The open circles on the left side (1 and 2 in this figure) are treated as distinct. The open circles on the right side are not distinguished. (It would be double counting if we distinguished them as well.)

which is the inner product defined by (3.20) with (3.19). As shown in Fig. 10, the matrix $M^{(\nu)}$ stands for the reshuffling of the legs. We define the conjugate of a vector v as

$$v^\dagger \equiv (v^*)^T M^{(\nu)}. \tag{4.2}$$

Namely, $v^\dagger$ includes the rearrangements of the legs. In particular, the conjugate of a basis vector $u_n^{(\nu)}$ is $(u_n^{(\nu)})^\dagger=(M^{(\nu)})_{nn}(u_n^{(\nu)})^T=\binom{\nu+n-1}{n}(u_n^{(\nu)})^T$. As can be seen from Fig. 10, this $(u_n^{(\nu)})^\dagger$ corresponds to $\binom{\nu+n-1}{n}$ graphs with different arrangement of the legs. Generally, graphs representing a column vector have only right legs, and graphs corresponding to a row vector have only left legs. Taking the inner product amounts to connecting the legs so as to create ν paths without a closed loop.

Now we can give a graphical interpretation to the evolution operator $U^{(\nu)}$. Let us first consider the simplest case, $\nu=1$. For $\nu=1$ the matrix $M^{(\nu)}$ is the identity matrix and we have $(u_m^{(1)},u_n^{(1)})^{(1)}=\delta_{mn}$. Namely, there is only one possible way of connecting the legs of $u_n^{(1)}$ and $(u_n^{(1)})^T$, and hence $(u_n^{(1)})^\dagger$ has only one possible arrangement of the legs. The (m,n) component of the matrix $U^{(1)}$ is obtained as

$$(U^{(1)})_{mn}=(u_m^{(1)})^\dagger U^{(1)} u_n^{(1)}. \tag{4.3}$$

Corresponding to the graphical interpretation of the inner product explained above, we can interpret the matrix element $(U^{(1)})_{mn}$ as follows: The matrix element $(U^{(1)})_{mn}$ is the sum of all the diagrams with $2n+1$ left legs and $2m+1$ right legs, such that one connected path is obtained when its left and right legs are connected with the graph of $u_n^{(1)}$ and $(u_m^{(1)})^\dagger$, respectively, as in Fig. 11. Here a diagram means the one like Fig. 2 or Fig. 7(a) with the rules given by Fig. 3. [A ''left leg'' of a diagram means an endpoint on the left side. For example, the diagram shown in

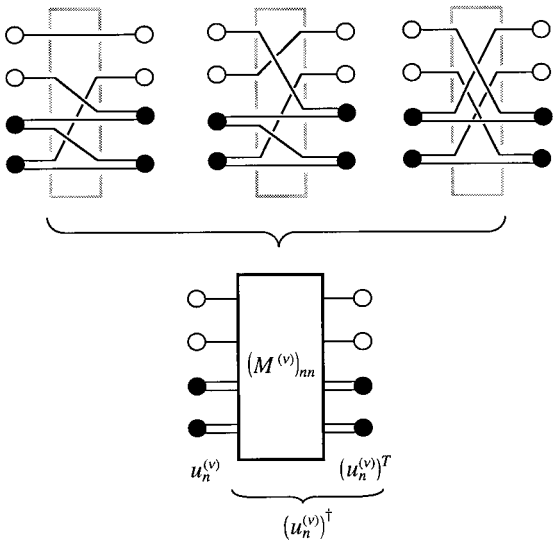

FIG. 10. We reexpress Fig. 9 like this, placing the open circles at the top. Now the matrix element $(M^{(\nu)})_{nn}=\binom{\nu+n-1}{n}$ can be graphically interpreted as representing the $\binom{\nu+n-1}{n}$ different ways of rearranging the legs.

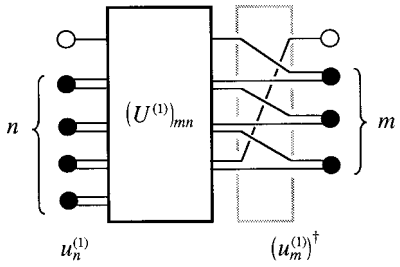

FIG. 11. The matrix element $(U^{(1)})_{mn}$ is the sum of all the diagrams that make a path connecting the two open circles when inserted in the box shown here.

Fig. 7(a) has three left legs and three right legs for the whole interval (x_1,x_2), and the part within the interval (x_a,x_b) has seven left legs and nine right legs.] The endpoints of the resulting path are the two open circles, and there should be no closed loop. An example is shown in Fig. 12.

Let us now consider general positive integer ν. We have

$$(U^{(\nu)})_{mn}=\frac{1}{\binom{\nu+m-1}{m}}\,(u_m^{(\nu)},U^{(\nu)}u_n^{(\nu)})^{(\nu)}=\frac{1}{\binom{\nu+m-1}{m}}\,(u_m^{(\nu)})^\dagger U^{(\nu)}u_n^{(\nu)}. \tag{4.4}$$

The graphical interpretation of $(U^{(\nu)})_{mn}$ given above for $\nu=1$ can be naturally extended to general ν as follows: The matrix element $(U^{(\nu)})_{mn}$ is the sum of all the diagrams with $2n+\nu$ left legs and $2m+\nu$ right legs, such that ν paths are obtained when its left and right legs are connected with $u_n^{(\nu)}$ and $(u_m^{(\nu)})^\dagger$, respectively, just like Fig. 11. Each of the ν paths should connect an open circle on the left side and one on the right side.

The above statement might be somewhat ambiguous for $\nu\geqslant 2$, since $(u_m^{(\nu)})^\dagger$ includes $\binom{\nu+m-1}{m}$ possible ways of arranging the legs. Let us explain this with the example shown in Fig. 13 ($\nu=2$, $n=1$, $m=2$). The graphical expression of $(u_2^{(2)})^\dagger$ has three possible arrangements of the legs (A,B,C in Fig. 13; see also Fig. 10). We arbitrarily choose one of these arrangements, say A. Then there are four distinct ways of making two connected paths, as shown in Fig. 13. Different paths are obtained by replacing A in Fig. 13 by B or C, but we do not count them. [This is what the factor $1/\binom{\nu+m-1}{m}$ in Eq. (4.4) means.] For example, the paths in Fig. 14(a) should not be counted as a different contribution since they are identical to the ones in Fig. 14(b), which are

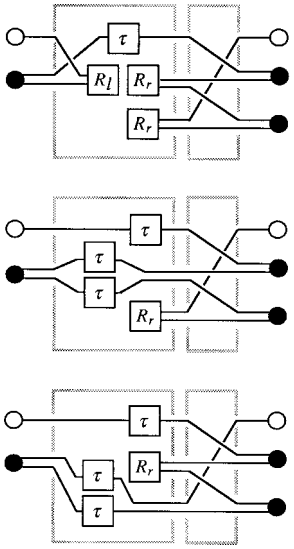

FIG. 12. An example: $\nu=1$, $n=1$, $m=2$. As shown here, there are three different ways of making a connected path. These three paths add up to $\tau R_r^2 R_l$, $\tau^3 R_r$, and $\tau^3 R_r$, respectively. Hence we find $(U^{(1)})_{21}=\tau R_r^2 R_l+2\tau^3 R_r$.

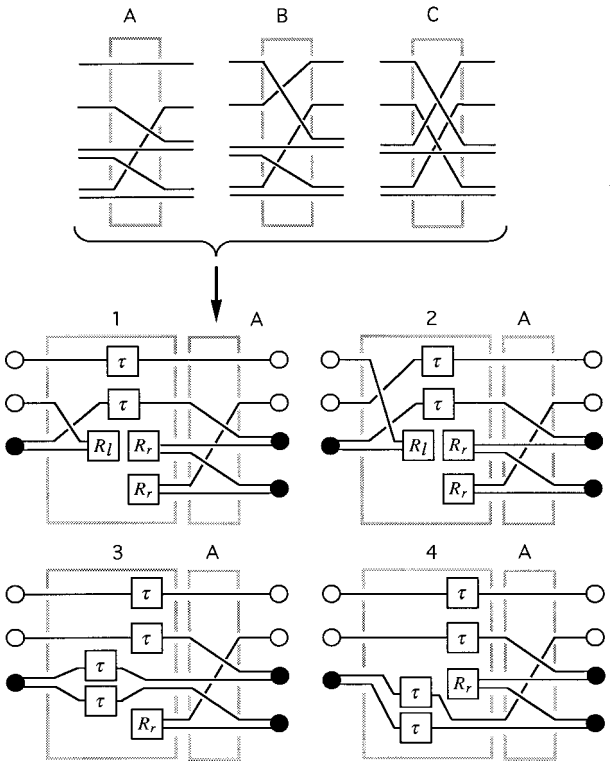

FIG. 13. An example: $\nu=2$, $m=2$, $n=1$. There are four distinct ways of making two connected paths, each adding up to $\tau^2R_r^2R_l$, $\tau^2R_r^2R_l$, τ^4R_r, and τ^4R_r. Hence we find $(U^{(2)})_{21}=2\tau^2R_r^2R_l+2\tau^4R_r$. (Remember that the open circles on the left side are distinguished, so the graphs 1 and 2 in this figure are considered different. See also Figs. 14 and 15.)

obtained from graph 4 of Fig. 13 with arrangement B. Thus, in this example we obtain $(U^{(2)})_{21}=2\tau^2R_r^2R_l+2\tau^4R_r$. It is also possible to derive the general result (3.22) from diagrammatic considerations. Details are given in Appendix A.

We can now graphically interpret the product rule (3.3). As shown in Fig. 15, the multiplication of $U^{(\nu)}(x_c,x_b)$ and $U^{(\nu)}(x_b,x_a)$ is achieved in the graphical representation simply by connecting their legs at x_b. The product rule describes how a path in the interval (x_c,x_a) can be decomposed into fragments in the intervals (x_c,x_b) and (x_b,x_a).

Thus we have found that the representation labeled by ν (positive integer) describes the evolution of ν paths. Paths penetrating a larger interval can be obtained by connecting segments in smaller intervals, and that is what manifests itself algebraically as the property of a group.

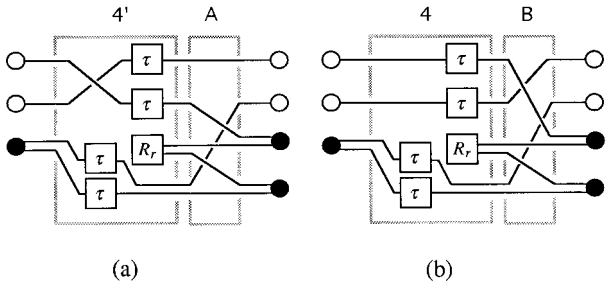

FIG. 14. The paths in (a) and (b) are identical, and so 4 and 4′ should not be regarded as distinct contributions.

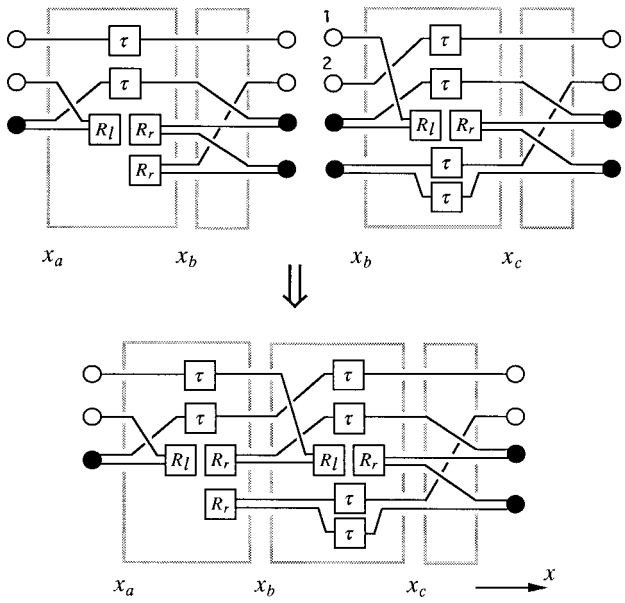

FIG. 15. Graphical explanation of $U^{(\nu)}(x_c,x_a)=U^{(\nu)}(x_c,x_b)U^{(\nu)}(x_b,x_a)$ for $\nu=2$. This figure also explains why it is necessary to distinguish the open circles on the left side. It is obvious that different paths are obtained by interchanging the open circles 1 and 2 in this figure.

V. THE $\nu=0$ REPRESENTATION

Next let us consider the case $\nu=0$. What we mean by ''the $\nu=0$ representation'' is not the trivial scalar representation but the infinite-dimensional representation in which the operators $J_{\pm}$ and J_3 are represented by the infinite-dimensional matrices obtained by setting $\nu=0$ in (3.17). [In fact, this is nothing but the standard representation of the global conformal group, which is given by the operators (7.1) in Sec. VII.] In this representation the evolution operator becomes the matrix

$$U^{(0)}=e^{-R_r J_+^{(0)}}\tau^{2J_3^{(0)}}e^{R_l J_-^{(0)}}=\begin{pmatrix} 1 & 0 & 0 & \cdots \\ R_r & \tau^2 & \tau^2 R_l & \cdots \\ R_r^2 & 2\tau^2 R_r & 2\tau^2 R_r R_l+\tau^4 & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}. \tag{5.1}$$

Obviously this representation is not irreducible. The vector $u_0^{(0)}=(1,0,0,...)^T$ spans a one-dimensional invariant subspace, which gives the trivial representation. It is a matter of course since the spin-0 irreducible representation is the scalar representation. It is important to consider the infinite-dimensional representation given by (5.1) because the reflection coefficients belong to this representation. The matrix elements of $U^{(0)}$ are

$$(U^{(0)})_{mn}=\sum_{i=0}^{\min(m,n)}\binom{m}{i}\binom{n-1}{n-i}R_r^{m-i}R_l^{n-i}\tau^{2i}, \tag{5.2}$$

and we have $R_r=(U^{(0)})_{10}$. The left reflection coefficient R_l is not obtained as a matrix element of $U^{(0)}$. To deal with R_l we use the matrix $U^{(0)L}$ defined by

$$U^{(0)L}\equiv(M^{(0)})^{-1}U^{(0)}M^{(0)}=\lim_{\epsilon\to 0}(M^{(\epsilon)})^{-1}U^{(\epsilon)}M^{(\epsilon)}. \tag{5.3}$$

Its matrix elements are $(U^{(0)L})_{mn}=(n/m)(U^{(0)})_{mn}$ for $m\neq 0$ and $(U^{(0)L})_{0n}=R_l^n$, so we have $R_l=(U^{(0)L})_{01}$.

For $\nu=0$ the inner product defined by (3.20) seems meaningless, since $(u_n^{(0)},u_n^{(0)})^{(0)}=0$ unless $n=0$. We can define a meaningful inner product for $\nu=0$ by an appropriate change of

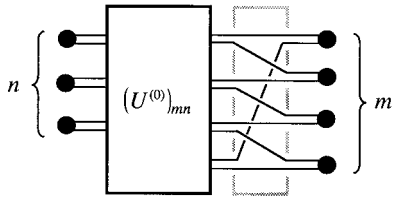

FIG. 16. The matrix element $(U^{(0)})_{mn}$ is the sum of all the diagrams that make one connected loop when inserted in the box shown here.

scale. Let us set $\nu=\epsilon$ and take the limit $\epsilon\to 0$. To the lowest order in ϵ we have $(u_m^{(\epsilon)},u_n^{(\epsilon)})^{(\epsilon)}=(\epsilon/m)\delta_{mn}$. Dividing this by ϵ before taking the limit $\epsilon\to 0$, we can define the rescaled inner product as

$$(u_{m,}^{(0)},u_n^{(0)})^0\equiv\lim_{\epsilon\to 0}\frac{1}{\epsilon}(u_m^{(\epsilon)},u_n^{(\epsilon)})^{(\epsilon)}=\frac{1}{m}\delta_{mn}. \tag{5.4}$$

Then $(u_n^{(0)},u_n^{(0)})^0$ has a finite value unless $n=0$. (It is divergent for $n=0$.) From (4.4) and (5.4) we obtain the expression for the matrix elements as

$$(U^{(0)})_{mn}=m(u_m^{(0)},U^{(0)}u_n^{(0)})^0. \tag{5.5}$$

In particular, we have $R_r=(u_1^{(0)},U^{(0)}u_0^{(0)})^0=(u_0^{(0)},J_-^{(0)}U^{(0)}u_0^{(0)})^0$. In a similar way, the left reflection coefficient can be written as $R_l=-(u_0^{(0)},U^{(0)}J_+^{(0)}u_0^{(0)})^0$.

In the graphical representation the vector $u_n^{(0)}$ and its transpose $(u_n^{(0)})^T$ have the form shown in Fig. 8 without open circles. Obviously it is impossible to connect their legs without making a loop. If we try to make a connected path out of these things, it inevitably becomes a loop. Hence we can guess that this $\nu=0$ representation is related to a closed path, not paths with a beginning and an end. Indeed, the rescaled inner product (5.4) can be interpreted as the operation of making a loop by connecting the legs of $(u_m^{(0)})^T$ and $u_n^{(0)}$.

The graphical interpretation of the matrix elements for $\nu=0$ is as follows. The matrix element $(U^{(0)})_{mn}$ $(m\neq 0)$ is the sum of all the diagrams with $2n$ left legs and $2m$ right legs, such that one closed path (i.e., a loop) is obtained when the left and the right legs are connected with $u_n^{(0)}$ and $(u_m^{(0)})^T$, respectively, as in Fig. 16. Note that the legs of $(u_m^{(0)})^T$ are rearranged so as to make a loop when connected with $u_m^{(0)}$. We choose one of the solid circles on the right side (say the uppermost one) as the reference point, and distinguish the paths keeping track of this point. [This is what the factor m in (5.5) means.] Examples are shown in Fig. 17. Note that A, B, and C in Fig. 17(a) are identical except for the reference point. [So are E and F in Fig. 17(b), too.] If we had chosen one of the solid circles on the left side as the reference point, we would have obtained an element of $U^{(0)L}$ instead of $U^{(0)}$.

It is possible to give a diagrammatic interpretation to the group property for $\nu=0$, too. As shown in Fig. 18, a loop in a larger interval can be made up of loops in smaller intervals. This is what the product rule (3.3) means for $\nu=0$. From Fig. 18 we can also see why it is necessary to specify the reference point; graphs with different positions of the reference point make different loops in a larger interval. The reference point is needed only in the process of making a larger loop. It is no longer necessary once the loop is completed. In order to disregard the reference point, we have to divide the final result by m. This is the meaning of the factor $1/m$ in (5.4).

Thus the $\nu=0$ representation describes the evolution of a closed path. This is consistent with the fact that, as we saw in Sec. III, the quantity $\log\tau$ corresponds to a closed path.

VI. SYMMETRIES OF THE FOKKER–PLANCK EQUATION AND A COVARIANT FORMULATION

The Fokker–Planck equation is characterized by its symmetrical structure. Let us rewrite the evolution equation (3.1) to make its symmetries more transparent. We rescale the space coordinate and the potential as

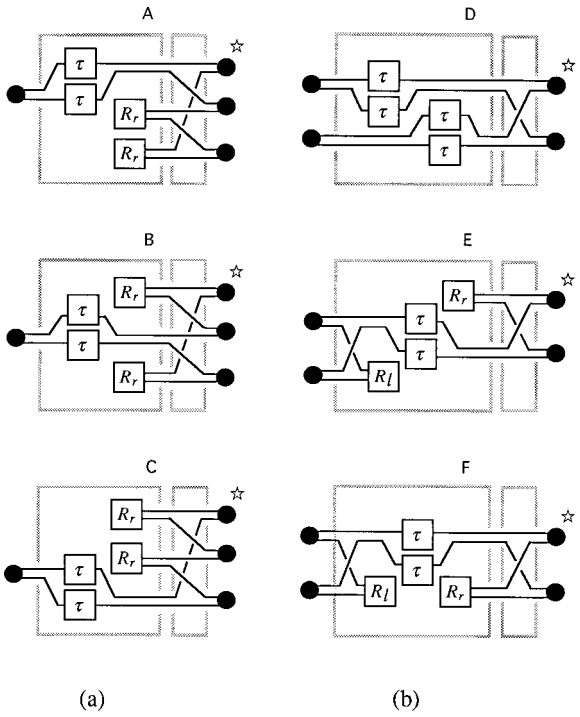

FIG. 17. Examples: (a) $m=3$, $n=1$, (b) $m=2$, $n=2$. The reference point is marked with a star. Hence we have $(U^{(0)})_{31}=3\tau^2R_r^2$ and $(U^{(0)})_{22}=\tau^4+2\tau^2R_rR_l$.

$$X\equiv ikx, \quad Y\equiv \tfrac{1}{2}V(x). \tag{6.1}$$

Then Eq. (3.1) can be written as

$$dU=2[(dX)J_3+(dY)J_1]U. \tag{6.2}$$

It is easy to see that Eq. (6.2) and the commutation relations (3.2) are invariant under the transformation

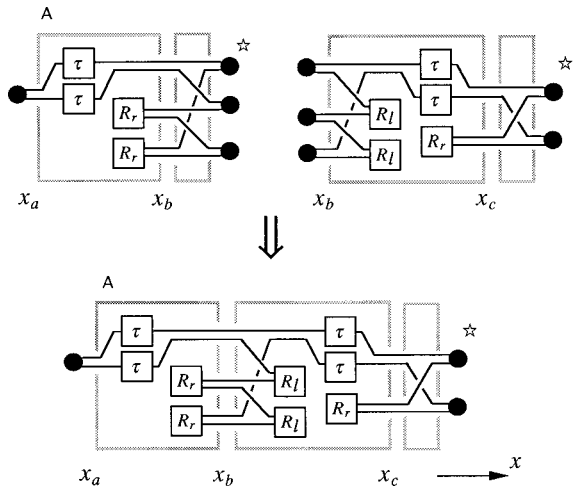

FIG. 18. Graphical interpretation of $U^{(0)}(x_c,x_a)=U^{(0)}(x_c,x_b)U^{(0)}(x_b,x_a)$. A closed loop for a larger interval (x_a,x_c) is obtained by simply connecting the legs of $U^{(0)}$ for smaller intervals (x_a,x_b) and (x_b,x_c). Note that a different loop is obtained if we replace A in this figure by B or C of Fig. 17(a). This is the reason why it is necessary to specify the reference point.

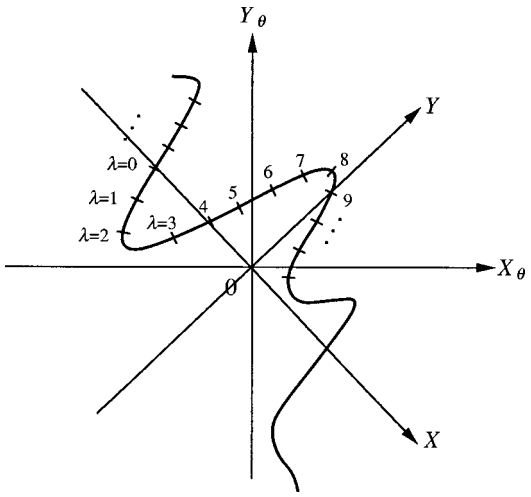

FIG. 19. Rotation of the coordinate axes and parameterization of the potential curve.

$$\begin{pmatrix} X \\ Y \end{pmatrix} \to \begin{pmatrix} X_\theta \\ Y_\theta \end{pmatrix} \equiv \begin{pmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{pmatrix} \begin{pmatrix} X \\ Y \end{pmatrix}, \tag{6.3a}$$

$$\begin{pmatrix} J_3 \\ J_1 \\ J_2 \end{pmatrix} \to \begin{pmatrix} J_{3,\theta} \\ J_{1,\theta} \\ J_{2,\theta} \end{pmatrix} \equiv \begin{pmatrix} \cos\theta & \sin\theta & 0 \\ -\sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} J_3 \\ J_1 \\ J_2 \end{pmatrix}, \tag{6.3b}$$

where θ is an arbitrary complex number. If θ is real and k is pure imaginary, the transformation (6.3a) amounts to pictorially rotating the graph of the potential (Fig. 19). (Since θ is not necessarily real, this transformation is not necessarily a rotation. However, for simplicity we will sometimes call it a rotation.) Any linear transformation that leaves both (6.2) and (3.2) invariant is either of the form (6.3) or obtained as a combination of (6.3) and the discrete transformation $(X,Y)\to(-X,Y)$ with $(J_3,J_1,J_2)\to(-J_3,J_1,-J_2)$, which corresponds to the reversal of the sign of k.

We define the operator $P(\theta)\equiv e^{-i\theta J_2}$, which induces the transformation (6.3b) as

$$J_{a,\theta}=P(\theta)J_aP(-\theta) \quad (a=1,2,3). \tag{6.4}$$

Obviously we have $[P(\theta)]^{-1}=P(-\theta)$. We can also express this operator as[14]

$$P(\theta)=e^{-\tan(\theta/2)J_+}[\cos(\theta/2)]^{-2J_3}e^{\tan(\theta/2)J_-}=e^{\tan(\theta/2)J_-}[\cos(\theta/2)]^{2J_3}e^{-\tan(\theta/2)J_+}. \tag{6.5}$$

Since we have $(dX)J_3+(dY)J_1=(dX_\theta)J_{3,\theta}+(dY_\theta)J_{1,\theta}$ with arbitrary θ, multiplying Eq. (6.2) by $P(-\theta)$ from the left and $P(\theta)$ from the right we obtain

$$dU_\theta=2[(dX_\theta)J_3+(dY_\theta)J_1]U_\theta, \tag{6.6}$$

where we have defined

$$U_\theta\equiv P(-\theta)UP(\theta). \tag{6.7}$$

Thus we find that the evolution equation in the rotated coordinates (X_θ,Y_θ) with arbitrary θ has locally the same form as in the original coordinates (X,Y), with U replaced by U_θ.

The relation (6.1) with a given potential $V(x)$ defines a curve in the (X_θ,Y_θ) space. (Restricting the original coordinate x to be real, it is a one-dimensional manifold in $\mathbf{C}^2$.) This curve determines the relation between X_θ and Y_θ. Since Y_θ cannot, in general, be expressed as a

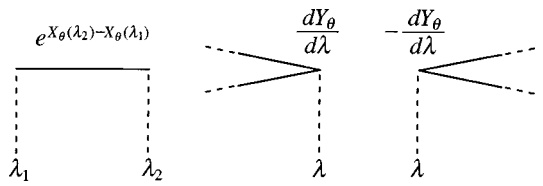

FIG. 20. Diagrammatic rules for general θ.

single-valued function of X_θ, we need to parameterize the curve as $X_\theta(\lambda)$, $Y_\theta(\lambda)$ with some real parameter λ (Fig. 19). This λ is arbitrary as long as it is monotonously increasing (or decreasing) along the curve. Using λ we can write Eq. (6.6) in the form

$$\frac{\partial}{\partial\lambda}U_\theta=2\left(\frac{dX_\theta}{d\lambda}J_3+\frac{dY_\theta}{d\lambda}J_1\right)U_\theta. \tag{6.8}$$

If $V(x)$ is a single-valued function as usually assumed [we can also deal with $V(x)$ that is not single-valued, though], we may use the original space coordinate x in place of λ.

By generalizing the diagrammatic rules explained in Sec. I, we can define the scattering coefficients in the rotated frame (X_θ,Y_θ) with arbitrary θ. Comparing (6.8) with (3.1) we can see that the diagrammatic rules in the rotated frame are obtained by the replacement

$$\frac{d}{dx}\to\frac{d}{d\lambda},\quad ikx=X\to X_\theta,\quad \frac{1}{2}V(x)=Y\to Y_\theta. \tag{6.9}$$

In diagrams for the original coordinate system (Fig. 2), the unperturbed path between x' and x was $\exp[ik(x-x')]$, and each single scattering gave a factor $\pm f$ (see Fig. 3). Now, in the rotated coordinate system, the horizontal axis x in Fig. 2 is replaced by a general parameter λ (though it is possible to use x in place of λ). According to (6.9) we have

$$e^{ik(x-x')}=e^{X(\lambda)-X(\lambda')}\to e^{X_\theta(\lambda)-X_\theta(\lambda')},\quad -f(x)=\frac{dY}{dx}\to\frac{dY_\theta}{d\lambda}. \tag{6.10}$$

Namely, the unperturbed path between points λ' and $\lambda(\lambda\geqslant\lambda')$ is $\exp[X_\theta(\lambda)-X_\theta(\lambda')]$, as shown in Fig. 20, and the factor given by each scattering is

$$\mp\frac{dY_\theta}{d\lambda}=\mp\frac{d}{d\lambda}\left[\frac{1}{2}V(x)\cos\theta-ikx\sin\theta\right]. \tag{6.11}$$

We define the scattering coefficients in the rotated frame, τ_θ, $R_{r,\theta}$, and $R_{l,\theta}$, as the sum over the diagrams similar to the ones in Fig. 2, now with the rules given in Fig. 20. Namely, τ_θ is written explicitly as

$$\tau_\theta(\lambda_b,\lambda_a)=\sum_{N=0}^{\infty}(-1)^N\int\cdots\int_{\substack{\lambda_{n-1}\leqslant\lambda_n\leqslant\lambda_b\ (n\ \text{odd})\\ \lambda_a\leqslant\lambda_n\leqslant\lambda_{n-1}\ (n\ \text{even})}}d\lambda_1\ldots d\lambda_{2N}\left[\prod_{n=1}^{2N}\frac{d}{d\lambda}Y_\theta(\lambda_n)\right]$$
$$\times\exp\left(\sum_{n=0}^{2N}(-1)^n[X_\theta(\lambda_{n+1})-X_\theta(\lambda_n)]\right). \tag{6.12}$$

($\lambda_0\equiv\lambda_a,\lambda_{2N+1}\equiv\lambda_b$.) Of course, this expression reduces to (1.14a) when we set $\theta=0$. In a similar way, the expressions for $R_{r,\theta}$ and $R_{l,\theta}$ can be obtained from (1.14b,c) by the replacement (6.10), with the integral variables x_n replaced by λ_n.

Since Eq. (6.2) is invariant under (6.3), the evolution operator given by the expression (3.12) does not change under the replacement $(\tau,R_r,R_l)\to(\tau_\theta,R_{r,\theta},R_{l,\theta})$ with $(J_3,J_+,J_-)\to(J_{3,\theta},J_{+,\theta},J_{-,\theta})$. (We have defined $J_{\pm,\theta}\equiv J_{1,\theta}\pm iJ_{2,\theta}$.) Therefore, we have

$$U=e^{-R_{r,\theta}J_{+,\theta}}(\tau_\theta)^{2J_{3,\theta}}e^{R_{l,\theta}J_{-,\theta}} \tag{6.13}$$

for arbitrary θ. Applying $P(-\theta)$ to (6.13) from the left and $P(\theta)$ from the right we obtain

$$U_\theta = e^{-R_{r,\theta} J_+} (\tau_\theta)^{2J_3} e^{R_{l,\theta} J_-}. \tag{6.14}$$

We may say that equation (6.8), together with the expression (6.14), is covariant with respect to the rotation, under which the coordinates and the scattering coefficients change as $(X,Y) \to (X_\theta, Y_\theta)$, $(\tau, R_r, R_l) \to (\tau_\theta, R_{r,\theta}, R_{l,\theta})$. The matrix elements of U_θ in the ν representation (see Sec. III) with the basis (3.21) can be obtained from (3.22) by the replacement $U^{(\nu)} \to U_\theta^{(\nu)}$ with $(\tau, R_r, R_l) \to (\tau_\theta, R_{r,\theta}, R_{l,\theta})$.

We can use these expressions for any complex number θ, but particularly important values are $\theta = \pm \pi/2$. We have $X_{\pm\pi/2} = \pm Y = \pm \frac{1}{2} V(x)$, $Y_{\pm\pi/2} = \mp X = \mp ikx$, and thus the roles of the space coordinate and the potential are completely exchanged at $\theta = \pm \pi/2$. If we choose the parameterization as $\lambda = x$, the factor assigned to each scattering vertex becomes $(d/dx) Y_{\pm\pi/2} = \mp ik$. Consequently, the diagrammatic expression with $\theta = \pm \pi/2$ gives a power series expansion in terms of k. We can use this property for studying the behavior of the scattering coefficients at small k.

Finally, let us remark that if the potential $V(x)$ is a linear function of x, say $V(x) = -2cx$, there is no scattering in the coordinates (X_θ, Y_θ) with $\theta = \arctan(-Y/X) = \arctan(-ic/k)$. This is almost obvious from Fig. 19, and indeed from (6.11) we can see $dY_\theta/d\lambda = 0$ for $\theta = \arctan(-ic/k)$. We will see the significance of this fact in Sec. X.

VII. REALIZATION IN TERMS OF DIFFERENTIAL OPERATORS

As shown in Sec. IV, the evolution equation (3.1) describes how to make paths penetrating a larger interval by connecting fragmentary paths in smaller intervals. We wish to describe the operation of connecting the paths as an algebraic manipulation. To this end we use a realization of the SU(2) [or SL(2, **C**)] generators as differential operators. What we are going to do in this section is in its spirit analogous to the path-integral description of boson systems using coherent states,[15] although we do not deal with path integrals explicitly.

It is well-known that the set of the differential operators

$$\mathscr{J}_+ = -\xi^2 \frac{\partial}{\partial \xi}, \quad \mathscr{J}_- = \frac{\partial}{\partial \xi}, \quad \mathscr{J}_3 = \xi \frac{\partial}{\partial \xi} \tag{7.1}$$

satisfies the commutation relations (3.2). (We use the symbol $\mathscr{J}$ for differential operators, instead of J.) The operators $\mathscr{J}_3$, $\mathscr{J}_-$, and $\mathscr{J}_+$ are, respectively, the generator of dilatation, translation, and special conformal transformation.[16] That is, for an arbitrary function $g(\xi)$ and a constant c we have

$$\exp(c\mathscr{J}_3) g(\xi) = g(e^c \xi), \quad \exp(c\mathscr{J}_-) g(\xi) = g(\xi + c), \quad \exp(c\mathscr{J}_+) g(\xi) = g\left(\frac{\xi}{1 + c\xi}\right). \tag{7.2}$$

The representation space is the space of all analytic functions of ξ. The lowest state u_0 satisfying $\mathscr{J}_- u_0 = 0$ is $u_0 = 1$ (constant), and since $\mathscr{J}_3 u_0 = 0$ we find from (3.16) that this representation corresponds to $\nu = 0$.

Let us try to generalize (7.1) for other values of ν. We need to find a set of differential operators $\mathscr{J}_+^{(\nu)}$, $\mathscr{J}_-^{(\nu)}$, and $\mathscr{J}_3^{(\nu)}$ satisfying the commutation relations (3.2), such that the function $u_0^{(\nu)}(\xi)$ satisfying $\mathscr{J}_-^{(\nu)} u_0^{(\nu)} = 0$ also satisfies $\mathscr{J}_3^{(\nu)} u_0^{(\nu)} = (\nu/2) u_0^{(\nu)}$. It is easy to see that the following set of operators fulfills the requirements:

$$\mathscr{J}_+^{(\nu)} = -\gamma^\nu \xi^{-\nu+2} \frac{\partial}{\partial \xi} \xi^\nu \gamma^{-\nu}, \quad \mathscr{J}_-^{(\nu)} = \gamma^\nu \frac{\partial}{\partial \xi} \gamma^{-\nu}, \quad \mathscr{J}_3^{(\nu)} = \gamma^\nu \xi^{-(\nu/2)+1} \frac{\partial}{\partial \xi} \xi^{\nu/2} \gamma^{-\nu}, \tag{7.3}$$

where $\gamma(\xi)$ is an arbitrary function of ξ. (We will specify the explicit form of $\gamma(\xi)$ in the next section.) As a generalization of Eqs. (7.2) we can easily derive

$$\exp(c\mathscr{J}_3^{(\nu)}) \gamma^\nu g(\xi) = \gamma^\nu (e^c)^{\nu/2} g(e^c \xi), \quad \exp(c\mathscr{J}_-^{(\nu)}) \gamma^\nu g(\xi) = \gamma^\nu g(\xi + c),$$

$$\exp(c\mathscr{J}_+^{(\nu)})\gamma^\nu g(\xi)=\gamma^\nu\left(\frac{1}{1+c\xi}\right)^\nu g\left(\frac{\xi}{1+c\xi}\right). \tag{7.4}$$

Now the representation space is the space of functions of the form $[\gamma(\xi)]^\nu g(\xi)$, where g is an analytic function of ξ. The lowest state is $u_0^{(\nu)}(\xi)=[\gamma(\xi)]^\nu$. We choose other base states as

$$u_n^{(\nu)}(\xi)\equiv(-1)^n\frac{1}{n!}[\mathscr{J}_+^{(\nu)}]^n u_0^{(\nu)}(\xi)=\binom{\nu+n-1}{n}\gamma^\nu\xi^n \tag{7.5}$$

[cf. Eq. (3.21)], and then the representation matrices for the operators (7.3) coincide with (3.17). Let us compare the expression (7.5) with Fig. 8. We can see that a γ and a ξ corresponds to an open circle and solid circle, respectively. The factor $\binom{\nu+n-1}{n}$, which corresponds to the rearrangement of the legs, is also included in this expression.

We define the inner product between the base states as

$$(u_m^{(\nu)},u_n^{(\nu)})^{(\nu)}=\binom{\nu+n-1}{n}\delta_{mn}, \tag{7.6}$$

which is equivalent to (3.20). For $\nu\geqslant 1$, such an inner product can be explicitly written as

$$(u,v)^{(\nu)}=\frac{\nu-1}{2\pi i}\int_{|\xi|<1}\frac{(1-\xi^*\xi)^{\nu-2}}{|\gamma(\xi)|^{2\nu}}[u(\xi)]^* v(\xi)d\xi\, d\xi^*, \tag{7.7}$$

where $d\xi\, d\xi^*/(2i)=d(\mathrm{Re}\,\xi)\,d(\mathrm{Im}\,\xi)$, and the domain of integration is the inside of the unit circle on the complex ξ-plane. [For $\nu=1$, the right-hand side of (7.7) should be understood as a limit.] Indeed, using the formula

$$(\nu-1)\int_0^1 t^n(1-t)^{\nu-2}dt=(\nu-1)\frac{\Gamma(n+1)\Gamma(\nu-1)}{\Gamma(\nu+n)}=\frac{1}{\binom{\nu+n-1}{n}}, \tag{7.8}$$

we can readily verify that the inner product given by (7.7) satisfies (7.6). However, in this paper we do not need the expression (7.7). All we need is Eq. (7.6). For arbitrary $v(\xi)$, the inner product with $u_n^{(\nu)}$ singles out the coefficient of ξ^n in $v(\xi)/[\gamma(\xi)]^\nu$:

$$(u_n^{(\nu)},v)^{(\nu)}=\frac{1}{n!}\frac{\partial^n}{\partial\xi^n}\frac{v(\xi)}{[\gamma(\xi)]^\nu}\bigg|_{\xi=0}. \tag{7.9}$$

The completeness of the basis is expressed as

$$v(\xi)=\sum_{n=0}^{\infty}u_n^{(\nu)}\frac{1}{\binom{\nu+n-1}{n}}(u_n^{(\nu)},v)^{(\nu)}. \tag{7.10}$$

The right-hand side of (7.10) is nothing but the Taylor expansion in terms of ξ.

By using the inner product defined above, we can express a differential operator in terms of an integral kernel. Let $\mathscr{A}$ be a differential operator acting on functions of ξ. We define the integral kernel $A(\xi,\eta^*)$ associated with $\mathscr{A}$ as

$$\begin{aligned}A(\xi,\eta^*)&\equiv\sum_{n=0}^{\infty}\mathscr{A}u_n^{(\nu)}(\xi)\frac{1}{\binom{\nu+n-1}{n}}[u_n^{(\nu)}(\eta)]^*\\&=\sum_{m=0}^{\infty}\sum_{n=0}^{\infty}\binom{\nu+m-1}{m}[\gamma(\xi)\gamma^*(\eta)]^\nu\xi^m\eta^{*n}A_{mn},\end{aligned} \tag{7.11}$$

where

$$A_{mn}=\frac{1}{\binom{\nu+m-1}{m}}\,(u_m^{(\nu)},\mathscr{A}u_n^{(\nu)})^{(\nu)}$$

are the matrix elements of the operator $\mathscr{A}$. This $A(\xi,\eta^*)$ is an integral kernel in the sense that the operation of $\mathscr{A}$ can be expressed as

$$\mathscr{A}v(\xi)=\frac{\nu-1}{2\pi i}\int_{|\eta|<1}\frac{(1-\eta^*\eta)^{\nu-2}}{|\gamma(\eta)|^{2\nu}}A(\xi,\eta^*)v(\eta)d\eta\,d\eta^*, \tag{7.12}$$

although we do not use (7.12) in this paper. The integral kernel can be also interpreted as a generating function for the matrix elements A_{mn}. The matrix elements are obtained from $A(\xi,\eta^*)$ as

$$A_{mn}=\frac{1}{\binom{\nu+m-1}{m}m!n!}\frac{\partial^n}{\partial\xi^n}\frac{\partial^n}{\partial\eta^{*n}}\frac{A(\xi,\eta^*)}{[\gamma(\xi)\gamma^*(\eta)]^\nu}\bigg|_{\xi=0,\eta^*=0}. \tag{7.13}$$

The kernel of the identity operation is

$$I^{(\nu)}(\xi,\eta^*)=\sum_{n=0}^{\infty}u_n^{(\nu)}(\xi)\frac{1}{\binom{\nu+n-1}{n}}[u_n^{(\nu)}(\eta)]^*=\left[\frac{\gamma(\xi)\gamma^*(\eta)}{1-\xi\eta^*}\right]^\nu. \tag{7.14}$$

From (7.11) and (7.14) we can see that the kernel of an arbitrary differential operator $\mathscr{A}$ is obtained as $A(\xi,\eta^*)=\mathscr{A}I^{(\nu)}(\xi,\eta^*)$.

Now let us consider the evolution operator $U^{(\nu)}$. Its form as a differential operator is obtained from Eq. (3.12) by replacing J with $\mathscr{J}$:

$$\mathscr{U}^{(\nu)}(x,x')=e^{-R_r(x,x')\mathscr{J}_+^{(\nu)}}[\tau(x,x')]^{2\mathscr{J}_3^{(\nu)}}e^{R_l(x,x')\mathscr{J}_-^{(\nu)}}. \tag{7.15}$$

We let $U_K^{(\nu)}(x,x';\xi,\eta^*)$ denote the kernel of this operator. (The subscript K is added here to stress that it is a kernel.) Using (7.4) we can calculate it as

$$\begin{aligned}U_K^{(\nu)}(x,x';\xi,\eta^*)&=\mathscr{U}^{(\nu)}(x,x')I^{(\nu)}(\xi,\eta^*)=e^{-R_r\mathscr{J}_+^{(\nu)}}\tau^{2\mathscr{J}_3^{(\nu)}}e^{R_l\mathscr{J}_-^{(\nu)}}\left[\frac{\gamma(\xi)\gamma^*(\eta)}{1-\xi\eta^*}\right]^\nu\\&=e^{-R_r\mathscr{J}_+^{(\nu)}}\tau^{2\mathscr{J}_3^{(\nu)}}\left[\frac{\gamma(\xi)\gamma^*(\eta)}{1-(\xi+R_l)\eta^*}\right]^\nu\\&=e^{-R_r\mathscr{J}_+^{(\nu)}}\left[\frac{\tau\gamma(\xi)\gamma^*(\eta)}{1-(\tau^2\xi+R_l)\eta^*}\right]^\nu=\left[\frac{\tau\gamma(\xi)\gamma^*(\eta)}{1-R_r\xi-R_l\eta^*-(\tau^2-R_rR_l)\xi\eta^*}\right]^\nu.\end{aligned} \tag{7.16}$$

We can write all these expressions in a covariant form with respect to the rotation discussed in Sec. VI. The differential operator corresponding to $P(\theta)$ [Eq. (6.5)] is

$$\mathscr{P}^{(\nu)}(\theta)=e^{-\tan(\theta/2)\mathscr{J}_+^{(\nu)}}[\cos(\theta/2)]^{-2\mathscr{J}_3^{(\nu)}}e^{\tan(\theta/2)\mathscr{J}_-^{(\nu)}}=e^{\tan(\theta/2)\mathscr{J}_-^{(\nu)}}[\cos(\theta/2)]^{2\mathscr{J}_3^{(\nu)}}e^{-\tan(\theta/2)\mathscr{J}_+^{(\nu)}}. \tag{7.17}$$

Applying this operator to $u_n^{(\nu)}$ [Eq (7.5)] we obtain the basis in the rotated frame as

$$u_{n,\theta}^{(\nu)}\equiv\mathscr{P}^{(\nu)}(\theta)u_n^{(\nu)}=\binom{\nu+n-1}{n}\gamma_\theta^\nu\xi_\theta^n, \tag{7.18}$$

where

$$\xi_\theta \equiv \frac{\tan(\theta/2)+\xi}{1-\xi\,\tan(\theta/2)}, \quad \gamma_\theta(\xi) \equiv \frac{\gamma(\xi)}{\cos(\theta/2)-\xi\,\sin(\theta/2)}. \tag{7.19}$$

In deriving the last expression of (7.18), we successively used the three equations of (7.4) as we did in (7.16). In terms of ξ_θ and γ_θ we can write $\mathscr{J}^{(\nu)}_{a,\theta}=\mathscr{R}^{(\nu)}(\theta)\mathscr{J}^{(\nu)}_{a}\mathscr{R}^{(\nu)}(-\theta)$ as

$$\mathscr{J}^{(\nu)}_{+,\theta}=-\gamma_\theta^\nu\xi_\theta^{-\nu+2}\frac{\partial}{\partial\xi_\theta}\xi_\theta^\nu\gamma_\theta^{-\nu}, \quad \mathscr{J}^{(\nu)}_{-,\theta}=\gamma_\theta^\nu\frac{\partial}{\partial\xi_\theta}\gamma_\theta^{-\nu}, \quad \mathscr{J}^{(\nu)}_{3,\theta}=\gamma_\theta^\nu\xi_\theta^{-(\nu/2)+1}\frac{\partial}{\partial\xi_\theta}\xi_\theta^{\nu/2}\gamma_\theta^{-\nu}. \tag{7.20}$$

From (3.13) and (7.17) it follows that $(u,v)=(\mathscr{R}(-\theta^*)u,\mathscr{R}(\theta)v)$ for arbitrary u and v. Therefore the kernel of identity can be rewritten as

$$I^{(\nu)}(\xi,\eta^*)=\sum_{n=0}^{\infty}[\mathscr{R}(\theta)u_n(\xi)]\frac{1}{\binom{\nu+n-1}{n}}[\mathscr{R}(-\theta^*)u_n(\eta)]^*=\left[\frac{\gamma_\theta(\xi)\gamma^*_{-\theta}(\eta)}{1-\xi_\theta\eta^*_{-\theta}}\right]^\nu, \tag{7.21}$$

where, as in (7.19), $\eta^*_{-\theta}=(-\tan(\theta/2)+\eta^*)/(1+\eta^*\tan(\theta/2))$, $\gamma^*_{-\theta}(\eta)=\gamma^*(\eta)/(\cos(\theta/2)+\eta^*\sin(\theta/2))$. (Note that $\eta^*_{-\theta}=(\eta_{-\theta^*})^*$ and $\gamma^*_{-\theta}(\eta)=[\gamma_{-\theta^*}(\eta)]^*$.) Using (6.13) and (7.21) we can generalize the expression (7.16) to arbitrary θ as

$$\begin{aligned}U^{(\nu)}_K(x,x';\xi,\eta^*)&=e^{-R_{r,\theta}\mathscr{J}^{(\nu)}_{+,\theta}}(\tau_\theta)^{2\mathscr{J}^{(\nu)}_{3,\theta}}e^{R_{l,\theta}\mathscr{J}^{(\nu)}_{-,\theta}}\left[\frac{\gamma_\theta(\xi)\gamma^*_{-\theta}(\eta)}{1-\xi_\theta\eta^*_{-\theta}}\right]^\nu\\&=\left[\frac{\tau_\theta\gamma_\theta(\xi)\gamma^*_{-\theta}(\eta)}{1-R_{r,\theta}\xi_\theta-R_{l,\theta}\eta^*_{-\theta}-(\tau_\theta^2-R_{r,\theta}R_{l,\theta})\xi_\theta\eta^*_{-\theta}}\right]^\nu.\end{aligned} \tag{7.22}$$

The kernel of the evolution operator introduced in this section is not merely an abstract tool. We shall see in the next section that $U^{(1)}_K$ can be identified with the generalized transmission coefficient $\bar{\tau}$ defined in Sec. II.

VIII. IDENTIFICATION OF $\bar{\tau}$ AS A GENERATING FUNCTION

In this section we show that $U^{(1)}_K$ is equivalent to $\bar{\tau}$. To simplify the notation, we shall hereafter use ξ' in place of η^* and write the kernel of the evolution operator as $U^{(\nu)}_K(x,x';\xi,\xi')$. The kernel of identity [Eqs. (7.14) and (7.21)] is written as

$$I^{(\nu)}(\xi,\xi')=\left(\frac{\gamma\gamma'}{1-\xi\xi'}\right)^\nu=\left(\frac{\gamma_\theta\gamma'_{-\theta}}{1-\xi_\theta\xi'_{-\theta}}\right)^\nu, \tag{8.1}$$

where $\gamma\equiv\gamma(\xi)$, $\gamma'\equiv\gamma^*(\xi'^*)$, $\gamma_\theta\equiv\gamma_\theta(\xi)$, and $\gamma'_{-\theta}\equiv\gamma^*_{-\theta}(\xi'^*)$. Just like (7.19) we have $\xi'_{-\theta}=(-\tan(\theta/2)+\xi')/(1+\xi'\tan(\theta/2))$ and $\gamma'_{-\theta}=\gamma'/(\cos(\theta/2)+\xi'\sin(\theta/2))$.

First, we remark that $I^{(\nu)}(\xi,\xi')$ can be written as

$$I^{(\nu)}(\xi,\xi')=\left(\frac{\gamma\gamma'}{1-\xi\xi'}\right)^\nu=(\gamma\gamma')^\nu(u_0^{(\nu)},e^{\xi J^{(\nu)}_-}e^{-\xi' J^{(\nu)}_+}u_0^{(\nu)})^{(\nu)}. \tag{8.2}$$

This equation can be verified by using Eqs. (3.16), (3.14), (3.13), and the formula[17]

$$e^{AJ_-}e^{BJ_+}=(1+AB)^{-J_3}e^{BJ_+}e^{AJ_-}(1+AB)^{-J_3}. \tag{8.3}$$

In the last expression of (8.2), the representation space is not the space of functions of ξ discussed in Sec. VII, but some other arbitrary space. The vector $u_0^{(\nu)}$ is not the function of ξ defined by

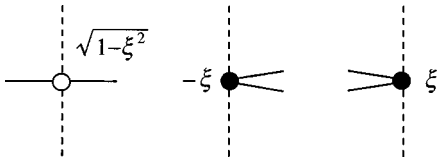

FIG. 21. Graphical representation of transmission and reflection at a potential discontinuity. The vertical dashed line stands for the discontinuity.

(7.5), and the operators J are different from the operators $\mathscr{J}$ defined by (7.3). Here ξ and ξ' are merely parameters. Now let us apply the differential operators (7.3) to (8.2). We can prove the relation

$$\mathscr{J}_a^{(\nu)}\gamma^\nu(u_0^{(\nu)},e^{\xi J_-^{(\nu)}}\cdots)^{(\nu)}=\gamma^\nu(u_0^{(\nu)},e^{\xi J_-^{(\nu)}}J_a^{(\nu)}\cdots)^{(\nu)} \quad (a=1,2,3, \text{ or } \pm), \tag{8.4}$$

where ''...'' is arbitrary. (See Appendix B.) From (7.15), (8.2), and (8.4) we obtain

$$\begin{aligned} U_K^{(\nu)}(x,x';\xi,\xi') &= e^{-R_r\mathscr{J}_+^{(\nu)}}\tau^{2\mathscr{J}_3^{(\nu)}}e^{R_l\mathscr{J}_-^{(\nu)}}(\gamma\gamma')^\nu(u_0^{(\nu)},e^{\xi J_-^{(\nu)}}e^{-\xi' J_+^{(\nu)}}u_0^{(\nu)})^{(\nu)} \\ &= (\gamma\gamma')^\nu(u_0^{(\nu)},e^{\xi J_-^{(\nu)}}e^{-R_r J_+^{(\nu)}}\tau^{2J_3^{(\nu)}}e^{R_l J_-^{(\nu)}}e^{-\xi' J_+^{(\nu)}}u_0^{(\nu)})^{(\nu)} \\ &= (\gamma\gamma')^\nu(u_0^{(\nu)},e^{\xi J_-^{(\nu)}}U^{(\nu)}(x,x')e^{-\xi' J_+^{(\nu)}}u_0^{(\nu)})^{(\nu)}. \end{aligned} \tag{8.5}$$

Next let us think about $\overline{\tau}$. As explained in Sec. II, the quantities $\overline{\tau}$, $\overline{R_r}$, and $\overline{R_l}$ can be interpreted as the scattering coefficients that include the effect of potential discontinuities at the endpoints. Let us fist see the effect of a discontinuity. Suppose that the potential $V(x)$ has a finite discontinuity of magnitude w at position x_0

$$\lim_{\epsilon\to 0+}[V(x_0+\epsilon)-V(x_0-\epsilon)]=w. \tag{8.6}$$

Then the reflection coefficients across the discontinuity, $R_r(x_0+\epsilon,x_0-\epsilon)$ and $R_l(x_0+\epsilon,x_0-\epsilon)$, have nonzero values in the limit $\epsilon\to 0$. It can be shown that[4]

$$\lim_{\epsilon\to 0+} R_r(x_0+\epsilon,x_0-\epsilon)=-\xi, \quad \lim_{\epsilon\to 0+} R_l(x_0+\epsilon,x_0-\epsilon)=\xi$$

$$\lim_{\epsilon\to 0+} \tau(x_0+\epsilon,x_0-\epsilon)=\sqrt{1-\xi^2}, \tag{8.7}$$

where

$$\xi\equiv -\frac{1-e^w}{1+e^w}. \tag{8.8}$$

The coefficients (8.7) represent the scattering caused by the discontinuity, as shown in Fig. 21. (Of course, these coefficients do not depend on the position x_0.) Substituting (8.7) into (3.12) we obtain the evolution operator across the discontinuity as

$$\lim_{\epsilon\to 0} U(x_0+\epsilon,x_0-\epsilon)=D(\xi), \tag{8.9}$$

where

$$D(\xi)\equiv e^{\xi J_+}(1-\xi^2)^{J_3}e^{\xi J_-}. \tag{8.10}$$

From the multiplication rule (3.3) we find

$$U(x_0+\epsilon,z)=D(\xi)U(x_0-\epsilon,z), \quad U(z,x_0-\epsilon)=U(z,x_0+\epsilon)D(\xi) \tag{8.11}$$

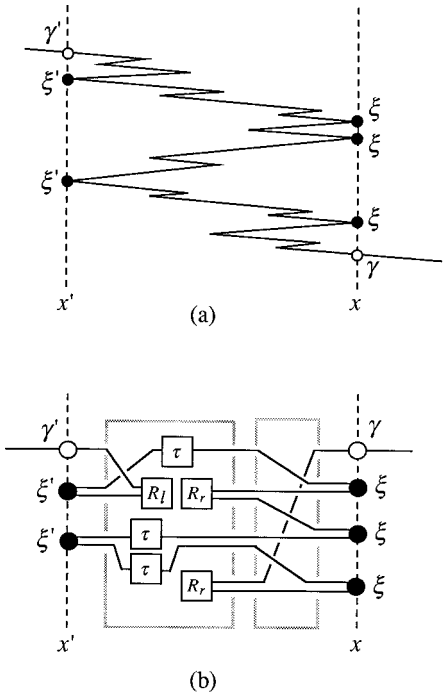

FIG. 22. (a) A diagram contributing to $\bar{\tau}$. This diagram is included in (b).

for arbitrary z and positive infinitesimal ϵ. In other words, the evolution operator is multiplied by $D(\xi)$ when the discontinuity is crossed.

Now let us return to general $V(x)$ and consider $\bar{\tau}$, $\bar{R}_r$, and $\bar{R}_l$ for the interval (x_a, x_b). The $\bar{V}$ given by (2.1) has discontinuities at x_a and x_b. Just like (8.9), the scattering at these discontinuities is described by $D(-\xi_a)$ and $D(\xi_b)$, respectively, where $\xi_a \equiv -(1-e^{w_a})/(1+e^{w_a})$, $\xi_b \equiv -(1-e^{w_b})/(1+e^{w_b})$. [Owing to the definition of the sign of w_a in (2.1), the scattering at x_a corresponds to $D(-\xi_a)$ rather than $D(\xi_a)$.] From (8.11) we can see that the evolution operator including the discontinuities is given by

$$\bar{U}(x_b, x_a; w_b, w_a) \equiv D(\xi_b) U(x_b, x_a) D(-\xi_a). \tag{8.12}$$

It is obvious that $\bar{\tau}$, $\bar{R}_r$, and $\bar{R}_l$ are related to $\bar{U}$ as $\bar{U} = e^{-\bar{R}_r J_+} \bar{\tau}^{2J_3} e^{\bar{R}_l J_-}$, in the same way as (3.12). Relations such as (3.15), (3.22), or (3.23) also hold with the replacement $(U, \tau, R_r, R_l) \to (\bar{U}, \bar{\tau}, \bar{R}_r, \bar{R}_l)$.

From now on we write $(x, x'; w, w')$ in place of $(x_b, x_a; w_b, w_a)$. The transmission coefficient including the discontinuities is obtained from (3.23) as

$$\bar{\tau}(x, x'; w, w') = (u_0^{(1)}, \bar{U}^{(1)} u_0^{(1)})^{(1)} = (u_0^{(1)}, D^{(1)}(\xi) U^{(1)}(x, x') D^{(1)}(-\xi') u_0^{(1)})^{(1)}, \tag{8.13}$$

where ξ is defined by (8.8), and ξ' is given by (8.8) with w replaced by w'. Substituting (8.10) into (8.13) and using $J_- u_0 = 0$ and $J_3^{(\nu)} u_0^{(\nu)} = (\nu/2) u_0^{(\nu)}$, we obtain

$$\bar{\tau}(x, x'; w, w') = [(1-\xi^2)(1-\xi'^2)]^{1/2} (u_0^{(1)}, e^{\xi J_-^{(1)}} U^{(1)}(x, x') e^{-\xi' J_+^{(1)}} u_0^{(1)})^{(1)}. \tag{8.14}$$

Comparing (8.14) with (8.5) we find that $U_K^{(1)}$ is identical with $\bar{\tau}$ if we identify γ and γ' as

$$\gamma = (1-\xi^2)^{1/2}, \quad \gamma' = (1-\xi'^2)^{1/2}. \tag{8.15}$$

Graphically, $\bar{\tau}$ is obtained as the sum over all such diagrams as shown in Fig. 22. A diagram contributing to $\bar{\tau}$ is similar to the one in Fig. 2(a), but now includes the effect of scattering at the endpoints. Each reflection at x and x' gives a factor ξ and ξ', respectively, and we have a factor

γ and γ' corresponding to the transmission through each of the endpoints. Comparing Fig. 22(b) with the definition of the integral kernel [Eq. (7.11) or (7.13)] we can indeed see the exact likeness between $\tau(x,x';w,w')$ and $U_K^{(1)}(x,x';\xi,\xi')$.

Hereafter we assume that γ and γ' are given by (8.15). Now we have $\overline{\tau}=U_K^{(1)}$, and from (7.16) we also find $\overline{\tau^\nu}=U_K^{(\nu)}$. Substituting (8.15) into (7.3) we obtain

$$\mathscr{J}_+^{(\nu)}=-\frac{\nu\xi}{1-\xi^2}-\xi^2\frac{\partial}{\partial\xi},\quad \mathscr{J}_-^{(\nu)}=\frac{\nu\xi}{1-\xi^2}+\frac{\partial}{\partial\xi},\quad \mathscr{J}_3^{(\nu)}=\frac{\nu}{2}\frac{1+\xi^2}{1-\xi^2}+\xi\frac{\partial}{\partial\xi}. \tag{8.16}$$

Equations (8.15), together with the definition (8.8), can be expressed as

$$\xi=\tanh(w/2),\quad \xi'=\tanh(w'/2),\quad \gamma=\frac{1}{\cosh(w/2)},\quad \gamma'=\frac{1}{\cosh(w'/2)}. \tag{8.17}$$

From (7.19) and (8.15) we have

$$\gamma_\theta=[(1-\xi_\theta^2)\cos\,\theta+2\xi_\theta\,\sin\,\theta]^{1/2},\quad \gamma'_{-\theta}=[(1-\xi'^2_{-\theta})\cos\,\theta-2\xi'_{-\theta}\,\sin\,\theta]^{1/2}. \tag{8.18}$$

Let us also remark that $\mathscr{J}_1^{(\nu)}=\frac{1}{2}(\mathscr{J}_+^{(\nu)}+\mathscr{J}_-^{(\nu)})$ is θ-invariant and independent of ν:

$$\mathscr{J}_1^{(\nu)}=\frac{1}{2}\,\gamma^2\frac{\partial}{\partial\xi}=\frac{1}{2}\,\gamma_\theta^2\frac{\partial}{\partial\xi_\theta}. \tag{8.19}$$

To summarize, we have

$$\overline{\tau}=U_K^{(1)}=\frac{\tau\gamma\gamma'}{1-R_r\xi-R_l\xi'-(\tau^2-R_rR_l)\xi\xi'}=\frac{\tau_\theta\gamma_\theta\gamma'_{-\theta}}{1-R_{r,\theta}\xi_\theta-R_{l,\theta}\xi'_{-\theta}-(\tau_\theta^2-R_{r,\theta}R_{l,\theta})\xi_\theta\xi'_{-\theta}}. \tag{8.20}$$

Note that $\overline{\tau}$ is invariant with respect to rotation; it does not depend on θ. Therefore, the diagrammatic interpretation shown in Fig. 22(a) holds in any rotated frame (with the rules given by Fig. 20) if we replace $(\xi,\xi',\gamma,\gamma')$ by $(\xi_\theta,\xi'_{-\theta},\gamma_\theta,\gamma'_{-\theta})$. The quantity $\overline{\tau}$ serves as a generating function for the evolution matrix elements. Since $U_K^{(\nu)}=\overline{\tau^\nu}$, from (7.13) we have

$$(U^{(\nu)})_{mn}=\frac{1}{\binom{\nu+m-1}{m}m!n!}\frac{\partial^m}{\partial\xi^m}\frac{\partial^n}{\partial\xi'^n}\left(\frac{\overline{\tau}}{\gamma\gamma'}\right)^\nu\Bigg|_{\xi=\xi'=0}. \tag{8.21}$$

The matrix elements of $U^{(0)}$ are obtained by taking the limit $\nu\to0$ in (8.21). Since $x^\nu=1+\nu\log x+O(\nu)$ and $\binom{\nu+m-1}{m}=(\nu/m)+O(\nu)$, we find

$$(U^{(0)})_{mn}=\frac{m}{m!n!}\frac{\partial^m}{\partial\xi^m}\frac{\partial^n}{\partial\xi'^n}\log\left(\frac{\overline{\tau}}{\gamma\gamma'}\right)\Bigg|_{\xi=\xi'=0}. \tag{8.22}$$

In particular, the transmission and reflection coefficients are obtained as

$$\tau=\frac{\overline{\tau}}{\gamma\gamma'}\Bigg|_{\xi=\xi'=0},\quad R_r=\frac{\partial}{\partial\xi}\log\left(\frac{\overline{\tau}}{\gamma\gamma'}\right)\Bigg|_{\xi=\xi'=0},\quad R_l=\frac{\partial}{\partial\xi'}\log\left(\frac{\overline{\tau}}{\gamma\gamma'}\right)\Bigg|_{\xi=\xi'=0}. \tag{8.23}$$

The matrix elements of U_θ with arbitrary θ are given by (8.21) or (8.22) with the replacement $(\xi,\xi',\gamma,\gamma')\to(\xi_\theta,\xi'_{-\theta},\gamma_\theta,\gamma'_{-\theta})$. The scattering coefficients in the rotated frame are

$$\tau_\theta=\frac{\overline{\tau}}{\gamma_\theta\gamma'_{-\theta}}\Bigg|_{\xi_\theta=\xi'_{-\theta}=0}, \tag{8.24a}$$

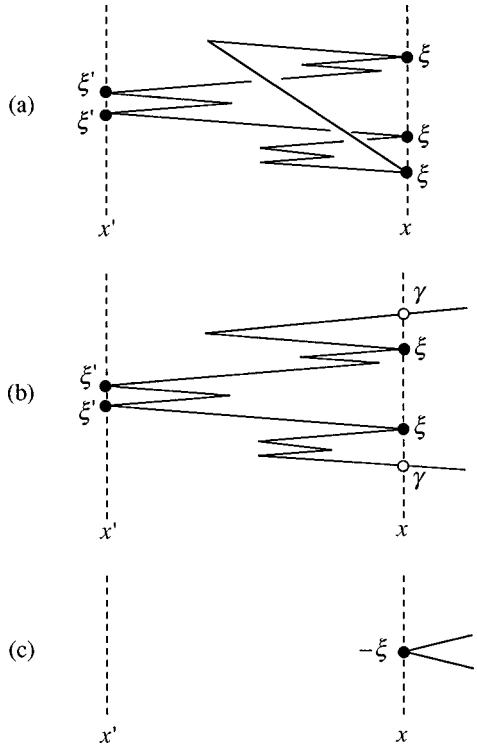

FIG. 23. (a) A diagram contributing to $\log \overline{Z}$. (b) A typical diagram contributing to $\overline{R_r}$. (c) The only contribution to $\overline{R_r}$ that is not included in $2\gamma^2(\partial/\partial\xi)\log \overline{Z}$.

$$R_{r,\theta}=\frac{\partial}{\partial \xi_\theta}\log\left(\frac{\overline{\tau}}{\gamma_\theta \gamma'_{-\theta}}\right)\Bigg|_{\xi_\theta=\xi'_{-\theta}=0}, \quad R_{l,\theta}=\frac{\partial}{\partial \xi'_{-\theta}}\log\left(\frac{\overline{\tau}}{\gamma_\theta \gamma'_{-\theta}}\right)\Bigg|_{\xi_\theta=\xi'_{-\theta}=0}. \tag{8.24b}$$

Using (8.18) and (7.19) we can rewrite (8.24a) as

$$\tau_\theta=\frac{\overline{\tau}}{\cos\,\theta}\Bigg|_{\xi=-\tan(\theta/2),\,\xi'=\tan(\theta/2)}. \tag{8.25}$$

We will see in the next section that (8.24b) can be rewritten in terms of $\overline{R_r}$ and $\overline{R_l}$ just like (8.25).

IX. STRUCTURE OF $\overline{R_r}$ AND $\overline{R_l}$

In this section we study the generalized reflection coefficients $\overline{R_r}$ and $\overline{R_l}$. Before doing that, let us generalize Eq. (3.26) and define

$$\overline{Z}(x,x';\xi,\xi')\equiv e^{-(1/2)ik(x-x')}\langle 0|e^{(1/2)\xi a a}U(x,x')e^{(1/2)\xi' a^\dagger a^\dagger}|0\rangle, \tag{9.1}$$

where U is the operator in the boson representation satisfying (3.10). The operators $e^{(1/2)\xi aa}$ and $e^{(1/2)\xi' a^\dagger a^\dagger}$ in (9.1) stand for the reflection at the endpoints. Just like $\log Z$ discussed in Sec. III, the quantity $\log \overline{Z}$ is obtained by taking the sum over all configurations of a single closed loop, now with reflection at the endpoints. Each reflection at x and x' gives a factor ξ and ξ', respectively [Fig. 23(a)]. Equation (8.5) with $\nu=1/2$ can be written in the boson representation as $\overline{\tau}^{1/2}=(\gamma\gamma')^{1/2}\langle 0|e^{(1/2)\xi aa}Ue^{(1/2)\xi' a^\dagger a^\dagger}|0\rangle$. (Recall that $U_K^{(1/2)}=\overline{\tau}^{1/2}$.) Therefore, we have, as a generalization of (3.27),

$$\overline{\tau}=e^{ik(x-x')}\gamma\gamma'\overline{Z}^2. \tag{9.2}$$

We can obtain $\overline{R_r}$ by taking the sum over diagrams in the same way as we did for R_r. The only difference is that we also take account of the scattering at the endpoints. A typical diagram contributing to $\overline{R_r}$ is shown in Fig. 23(b). We remark that this diagram can be obtained from the diagram of $\log Z$ shown in Fig. 23(a) by replacing a ξ by two γ's. Therefore, the sum over all these diagrams can be expressed as $2\gamma^2(\partial/\partial\xi)\log Z$. (The factor 2 means that we make distinction between mirror images.) The diagram shown in Fig. 23(c) is the only exception. This diagram, which also contributes to $\overline{R_r}$, is not included in $2\gamma^2(\partial/\partial\xi)\log Z$, and so it must be added separately. Thus we have

$$\overline{R_r}=2\gamma^2\frac{\partial}{\partial\xi}\log\overline{Z}-\xi. \tag{9.3}$$

Using (9.2), (8.15) and (8.19) we may write

$$\overline{R_r}=\gamma^2\frac{\partial}{\partial\xi}\log\overline{\tau}=2\mathscr{J}_1\log\overline{\tau}. \tag{9.4}$$

[A different derivation of (9.4) is given in Appendix C.]

Substituting (8.20) into (9.4) we can calculate $\overline{R_r}$ as

$$\begin{aligned}\overline{R_r}&=\gamma^2\frac{\partial}{\partial\xi}\log\gamma-\gamma^2\frac{\partial}{\partial\xi}\log[1-R_r\xi-R_l\xi'-(\tau^2-R_lR_r)\xi\xi']\\&=-\xi+\gamma^2\frac{R_r+(\tau^2-R_lR_r)\xi'}{1-R_r\xi-R_l\xi'-(\tau^2-R_lR_r)\xi\xi'}.\end{aligned} \tag{9.5}$$

We may rewrite (9.5) in the form

$$\overline{R_r}=-\xi+\gamma^2\frac{\rho_r}{1-\rho_r\xi},\quad \rho_r\equiv R_r+\frac{\tau^2\xi'}{1-R_l\xi'}. \tag{9.6}$$

We can clearly see the structure of Eqs. (9.6) by writing them as

$$\overline{R_r}=-\xi+\gamma^2\rho_r\sum_{n=0}^{\infty}(\rho_r\xi)^n,\quad \rho_r=R_r+\tau^2\xi'\sum_{n=0}^{\infty}(R_l\xi')^n. \tag{9.7}$$

These equations are graphically represented as in Fig. 24. As explained before, $\overline{R_r}(x,x';\xi,\xi')$ includes the effect of scattering at both endpoints x and x', while $R_r(x,x')$ is the reflection coefficient without scattering at the endpoints. The quantity $\rho_r(x,x';\xi')$ defined in Eq. (9.6) is the reflection coefficient with scattering at x' but not at x.

It is straightforward to generalize these expressions for the rotated coordinate system with arbitrary θ. The quantity corresponding to $\overline{R_r}$ in the rotated frame can be obtained from (9.6) by the replacement $(\xi,\xi',\gamma)\to(\xi_\theta,\xi'_{-\theta},\gamma_\theta)$ and $(\tau,R_r,R_l)\to(\tau_\theta,R_{r,\theta},R_{l\theta})$:

$$\overline{R_{r,\theta}}=-\xi_\theta+\gamma_\theta^2\frac{\rho_{r,\theta}}{1-\rho_{r,\theta}\xi_\theta},\quad \rho_{r,\theta}\equiv R_{r,\theta}+\frac{\tau_\theta^2\xi'_{-\theta}}{1-R_{l,\theta}\xi'_{-\theta}}. \tag{9.8}$$

On the other hand, since $\mathscr{J}_1$ is invariant with respect to θ [see (8.19)], we can write (9.4) as

$$\overline{R_r}=\gamma_\theta^2\frac{\partial}{\partial\xi_\theta}\log\overline{\tau}, \tag{9.9}$$

and using the last expression of (8.20) we obtain

$$\overline{R_r}=\sin\theta-\xi_\theta\cos\theta+\gamma_\theta^2\frac{\rho_{r,\theta}}{1-\rho_{r,\theta}\xi_\theta}. \tag{9.10}$$

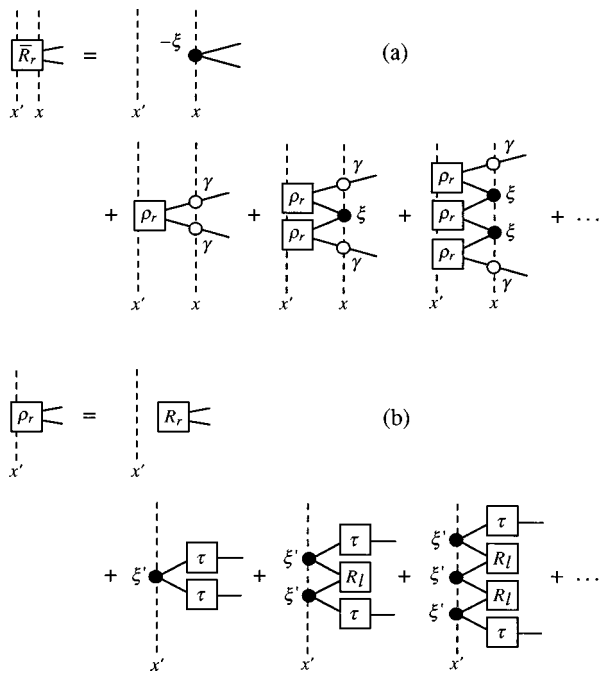

FIG. 24. Graphical representation of Eqs. (9.7).

Comparing (9.10) and (9.8) we find that $\overline{R_r}$ and $\overline{R_{r,\theta}}$ are almost identical; the difference is a term proportional to ξ_θ and a constant term, both independent of the potential $V(x)$:

$$\overline{R_r}=\overline{R_{r,\theta}}+(1-\cos\ \theta)\xi_\theta+\sin\ \theta. \tag{9.11}$$

We can do without $\overline{R_{r,\theta}}$ since it is essentially the same as $\overline{R_r}$. It is enough if we deal with only $\overline{R_r}$. The quantities $\rho_{r,\theta}$ and $R_{r,\theta}$ can be obtained from R_r as

$$\rho_{r,\theta}=\left.\frac{\overline{R_r}-\sin\ \theta}{\cos\ \theta}\right|_{\xi_\theta=0},\quad R_{r,\theta}=\rho_{r,\theta}|_{\xi'_{-\theta}=0}, \tag{9.12}$$

where we have used $\gamma_\theta^2|_{\xi_\theta=0}=\cos\ \theta$ [Eq. (8.18)]. From (9.12) and (7.19) we have

$$R_{r,\theta}=\left.\frac{\overline{R_r}-\sin\ \theta}{\cos\ \theta}\right|_{\xi=-\tan(\theta/2),\xi'=\tan(\theta/2)}. \tag{9.13}$$

This result can also be obtained from (8.24b) with (9.9).

In the same way we can derive expressions for the left reflection coefficient. We have

$$\overline{R_l}=\gamma'^2\frac{\partial}{\partial\xi'}\log\ \overline{\tau}=2\mathscr{J}_1'\log\ \overline{\tau},\quad R_{l,\theta}=\left.\frac{\overline{R_l}+\sin\ \theta}{\cos\ \theta}\right|_{\xi=-\tan(\theta/2),\xi'=\tan(\theta/2)}. \tag{9.14}$$

X. IDENTIFICATION OF $\tilde{\tau}$, $\tilde{R}_r$, AND $\tilde{R}_l$

Here we consider $\widetilde{\tau}$, $\widetilde{R}_r$, and $\widetilde{R}_l$ defined by (2.4). We found in Sec. VI that a linear potential $V(x)=2cx$ can be nullified by the transformation $P(\theta)$ [Eq. (6.5)] with $\theta=\arctan(-ic/k)$. So, in order to deal with the potential $\overline{V}$ given by (2.3) it seems appropriate to assign different rotation angles to both endpoints of the interval. Generalizing (6.7) we define the ''twisted'' evolution operator as

$$U^{(\nu)}_{\theta\theta'}\equiv P^{(\nu)}(-\theta)U^{(\nu)}P^{(\nu)}(\theta')=e^{-R_{r,\theta\theta'}J_+}[\tau_{\theta\theta'}]^{2J_3}e^{R_{l,\theta\theta'}J_-}. \tag{10.1}$$

By the last expression of (10.1) we defined the twisted scattering coefficients $\tau_{\theta\theta'}$, $R_{r,\theta\theta'}$, and $R_{l,\theta\theta'}$. [Cf. Eq. (6.14).] It is not difficult to show that

$$\tau_{\theta\theta'}=\left.\frac{\overline{\tau}}{(\cos\,\theta\,\cos\,\theta')^{1/2}}\right|_{\xi=-\tan(\theta/2),\xi'=\tan(\theta'/2)}, \tag{10.2a}$$

$$R_{r,\theta\theta'}=\left.\frac{\overline{R}_r-\sin\,\theta}{\cos\,\theta}\right|_{\xi=-\tan(\theta/2),\xi'=\tan(\theta'/2)}, \quad R_{l,\theta\theta'}=\left.\frac{\overline{R}_l+\sin\,\theta'}{\cos\,\theta'}\right|_{\xi=-\tan(\theta/2),\xi'=\tan(\theta'/2)}. \tag{10.2b}$$

[Cf. (8.25), (9.13), and (9.14).] Inversely, we can obtain $\overline{\tau}$, $\overline{R}_r$, and $\overline{R}_l$ from $\tau_{\theta\theta'}$, $R_{r,\theta\theta'}$, and $R_{l,\theta\theta'}$ by setting $\theta=-2\arctan\xi$, $\theta'=2\arctan\xi'$. Thus $\overline{\tau}$, $\overline{R}_r$, and $\overline{R}_l$ are essentially equivalent to $\tau_{\theta\theta'}$, $R_{r,\theta\theta'}$, and $R_{l,\theta\theta'}$, respectively. This can be understood in view of the similarity between $P(\theta)$ and $D(\xi)$ [Eqs. (6.5) and (8.10)].

As a matter of fact, $\widetilde{\tau}$, $\widetilde{R}_r$, and $\widetilde{R}_l$ are proportional to these twisted scattering coefficients. Namely, we have

$$\widetilde{\tau}(x_b,x_a;c_b,c_a)=\left(\frac{1-\tan(\theta_b/2)}{1+\tan(\theta_b/2)}\right)^{1/2}\left(\frac{1+\tan(\theta_a/2)}{1-\tan(\theta_a/2)}\right)^{1/2}\tau_{\theta_b\theta_\alpha}(x_b,x_a), \tag{10.3a}$$

$$\widetilde{R}_r=\frac{1-\tan(\theta_b/2)}{1+\tan(\theta_b/2)}\,R_{r,\theta_b\theta_\alpha}, \quad \widetilde{R}_l=\frac{1+\tan(\theta_a/2)}{1-\tan(\theta_a/2)}\,R_{l,\theta_b\theta_a}, \tag{10.3b}$$

where $\theta_a=\arctan(-ic_a/ik)$, $\theta_b=\arctan(-ic_b/ik)$. A derivation of (10.3) is given in Appendix D. Therefore, we find that the set of coefficients $(\widetilde{\tau},\widetilde{R}_r,\widetilde{R}_l)$ is essentially equivalent to $(\overline{\tau},\overline{R}_r,\overline{R}_l)$.

XI. POWER SERIES EXPRESSIONS OF SCATTERING COEFFICIENTS

Equation (3.1) is a general expression that holds for any representation. Any operator U that has the form (3.12) satisfies (3.1). Therefore, the operator $\mathscr{U}$ given by (7.15) also satisfies

$$\frac{\partial}{\partial x}\,\mathscr{U}^{(\nu)}(x,x')=[2ik\mathscr{J}_3^{(\nu)}-2\,f(x)\,\mathscr{J}_1^{(\nu)}]\mathscr{U}^{(\nu)}(x,x'). \tag{11.1}$$

From $\overline{\tau}^{\nu}=\mathscr{U}^{(\nu)}(x,x')I^{(\nu)}(\xi,\xi')$ it is obvious that $\overline{\tau}^{\nu}$ satisfies the same equation:

$$\frac{\partial}{\partial x}\,[\overline{\tau}(x,x';\xi,\xi')]^{\nu}=[2ik\mathscr{J}_3^{(\nu)}-2\,f(x)\,\mathscr{J}_1^{(\nu)}][\overline{\tau}(x,x';\xi,\xi')]^{\nu}. \tag{11.2}$$

Since $\mathscr{U}(x=x')=1$, from (8.1) and (8.17) we obtain the initial condition for (11.2) as

$$[\overline{\tau}(x=x')]^{\nu}=I^{(\nu)}(\xi,\xi')=\left(\frac{\gamma\gamma'}{1-\xi\xi'}\right)^{\nu}=\left[\cosh\left(\frac{w-w'}{2}\right)\right]^{-\nu}. \tag{11.3}$$

The equation for $\log\overline{\tau}$ can be derived by taking the limit $\nu\to0$ in Eq. (11.2). Since

$$\overline{\tau}^{\nu}=1+\nu\,\log\,\overline{\tau}+O(\nu^2), \quad \mathscr{J}_3^{(\nu)}=\mathscr{J}_3^{(0)}+\frac{\nu}{2}\,\frac{1+\xi^2}{1-\xi^2}, \quad \mathscr{J}_1^{(\nu)}=\mathscr{J}_1^{(0)}, \tag{11.4}$$

retaining terms of order ν in Eq. (11.2) we obtain

$$\frac{\partial}{\partial x}\log\,\overline{\tau}(x,x';\xi,\xi')=[2ik\mathscr{J}_3^{(0)}-2\,f(x)\mathscr{J}_1^{(0)}]\log\,\overline{\tau}(x,x';\xi,\xi')+ik\,\frac{1+\xi^2}{1-\xi^2}. \tag{11.5}$$

Note that this equation, unlike Eq. (11.2), contains an inhomogeneous term.

Substituting (8.17) into (8.16) and (8.19) we can write the operators $\mathscr{J}_1^{(\nu)}$ and $\mathscr{J}_3^{(\nu)}$ as

$$\mathscr{J}_1^{(\nu)}=\frac{\partial}{\partial w},\quad \mathscr{J}_3^{(\nu)}=\frac{1}{2}\left[e^{w}\left(\frac{\nu}{2}+\frac{\partial}{\partial w}\right)+e^{-w}\left(\frac{\nu}{2}-\frac{\partial}{\partial w}\right)\right]. \tag{11.6}$$

Therefore, equation (11.2) reads

$$\frac{\partial}{\partial x}\,\overline{\tau}^{\nu}=ik\left[e^{w}\left(\frac{\nu}{2}+\frac{\partial}{\partial w}\right)+e^{-w}\left(\frac{\nu}{2}-\frac{\partial}{\partial w}\right)\right]\overline{\tau}^{\nu}-2\,f\,\frac{\partial}{\partial w}\,\overline{\tau}^{\nu}. \tag{11.7}$$

We can eliminate the last term on the right-hand side of (11.7) by changing the independent variables from (x,x',w,w') [or (x,x',ξ,ξ')] to (x,x',W,W'), where

$$W\equiv V(x)+w,\quad W'\equiv V(x')+w'. \tag{11.8}$$

By this change of variables the partial derivatives change as

$$\frac{\partial}{\partial x}\to\frac{\partial}{\partial x}+\frac{dV}{dx}\,\frac{\partial}{\partial W}=\frac{\partial}{\partial x}-2\,f(x)\,\frac{\partial}{\partial W},\quad \frac{\partial}{\partial w}\to\frac{\partial}{\partial W}, \tag{11.9}$$

and Eq. (11.7) becomes

$$\frac{\partial}{\partial x}\,\overline{\tau}^{\nu}=ik[e^{-V(x)}\hat{\mathscr{J}}_+^{(\nu)}+e^{V(x)}\hat{\mathscr{J}}_-^{(\nu)}]\overline{\tau}^{\nu}, \tag{11.10}$$

where

$$\hat{\mathscr{J}}_{\pm}^{(\nu)}\equiv e^{\pm W}\left(\frac{\nu}{2}\pm\frac{\partial}{\partial W}\right),\quad \hat{\mathscr{J}}_3^{(\nu)}\equiv\frac{\partial}{\partial W}. \tag{11.11}$$

In (11.10), and in the rest of this section, the independent variables are (x,x',W,W'). It is obvious that the operators $\hat{\mathscr{J}}_+$, $\hat{\mathscr{J}}_-$, and $\hat{\mathscr{J}}_3$ satisfy the commutation relations (3.2). Note that we are now working in the rotated frame with $\theta=\pm\pi/2$. Indeed, the operators (11.11) can be expressed in terms of $\mathscr{J}_{a,\theta}$ [Eqs. (7.20)] as

$$\hat{\mathscr{J}}_{\pm}^{(\nu)}=-e^{\pm V(x)}\mathscr{J}_{\pm,(\pi/2)}^{(\nu)}=e^{\pm V(x)}\mathscr{J}_{\mp,-(\pi/2)}^{(\nu)},\quad \hat{\mathscr{J}}_3^{(\nu)}=\mathscr{J}_{3,(\pi/2)}^{(\nu)}=-\mathscr{J}_{3,-(\pi/2)}^{(\nu)}. \tag{11.12}$$

It is also convenient to define, in correspondence with (11.11),

$$\hat{\xi}_+\equiv e^{W},\quad \hat{\xi}_-\equiv-e^{-W},\quad \hat{\xi}'_+\equiv e^{W'},\quad \hat{\xi}'_-\equiv-e^{-W'}. \tag{11.13}$$

From (7.19) and (8.8) we find $\xi_{\pm(\pi/2)}=\pm e^{\pm w}$. So (11.13) means $\hat{\xi}_{\pm}=e^{\pm V(x)}\xi_{\pm(\pi/2)}$. In terms of $\hat{\xi}_+$ or $\hat{\xi}_-$ the operators $\hat{\mathscr{J}}_{\pm}$ and $\hat{\mathscr{J}}_3$ have the form

$$\hat{\mathscr{J}}_{\pm}^{(\nu)}=(\hat{\xi}_+)^{\pm1}\left(\frac{\nu}{2}\pm\hat{\xi}_+\,\frac{\partial}{\partial\hat{\xi}_+}\right)=-(\hat{\xi}_-)^{\mp1}\left(\frac{\nu}{2}\mp\hat{\xi}_-\,\frac{\partial}{\partial\hat{\xi}_-}\right),\quad \hat{\mathscr{J}}_3^{(\nu)}=\hat{\xi}_+\,\frac{\partial}{\partial\xi_+}=-\hat{\xi}_-\,\frac{\partial}{\partial\xi_-}. \tag{11.14}$$

Similarly, after the change of independent variables to (W,W'), equation (11.5) becomes

$$\frac{\partial}{\partial x}\log\,\overline{\tau}=ik[e^{-V(x)}\hat{\mathscr{J}}_+^{(0)}+e^{V(x)}\hat{\mathscr{J}}_-^{(0)}]\log\,\overline{\tau}+ik\,\cosh[W-V(x)], \tag{11.15}$$

where we have used $(1+\xi^2)/(1-\xi^2)=\cosh w$. In much the same way we can also derive

$$\frac{\partial}{\partial x'}\,\overline{\tau^{\nu}}=-ik[e^{-V(x')}\hat{\mathscr{J}}'^{(\nu)}_{+}+e^{V(x')}\hat{\mathscr{J}}'^{(\nu)}_{-}]\hat{\tau}^{\nu}, \tag{11.16}$$

$$\frac{\partial}{\partial x'}\log\,\overline{\tau}=-ik[e^{-V(x')}\hat{\mathscr{J}}'^{(0)}_{+}+e^{V(x')}\hat{\mathscr{J}}'^{(0)}_{-}]\log\,\overline{\tau}-ik\,\cosh[W'-V(x')], \tag{11.17}$$

where $\hat{\mathscr{J}}'_{+}$ and $\hat{\mathscr{J}}'_{-}$ are defined by (11.11) with W replaced by W'. (Note the prime on $\hat{\mathscr{J}}$.)

Equations for $\overline{R_r}$ and $\overline{R_l}$ can be obtained from (11.15) and (11.17). In terms of the variables W and W', equations (9.4) and (9.14) can be expressed simply as

$$\overline{R_r}=2\frac{\partial}{\partial W}\log\,\overline{\tau},\quad \overline{R_l}=2\frac{\partial}{\partial W'}\log\,\overline{\tau}. \tag{11.18}$$

Differentiating Eq. (11.15) [or Eq. (11.17)] with respect to W (or W'), and using the relation $(\partial/\partial W)\hat{\mathscr{J}}^{(0)}_{\pm}=\hat{\mathscr{J}}^{(2)}_{\pm}(\partial/\partial W)$, which can be easily derived from (11.11), we obtain

$$\frac{\partial}{\partial x}\,\overline{R_r}=ik[e^{-V(x)}\hat{\mathscr{J}}^{(2)}_{+}+e^{V(x)}\hat{\mathscr{J}}^{(2)}_{-}]\overline{R_r}+2ik\,\sinh[W-V(x)], \tag{11.19a}$$

$$\frac{\partial}{\partial x'}\,\overline{R_r}=-ik[e^{-V(x')}\hat{\mathscr{J}}'^{(0)}_{+}+e^{V(x')}\hat{\mathscr{J}}'^{(0)}_{-}]\overline{R_r}, \tag{11.19b}$$

$$\frac{\partial}{\partial x}\,\overline{R_l}=ik[e^{-V(x)}\hat{\mathscr{J}}^{(0)}_{+}+e^{V(x)}\hat{\mathscr{J}}^{(0)}_{-}]\overline{R_l}, \tag{11.19c}$$

$$\frac{\partial}{\partial x'}\,\overline{R_l}=-ik[e^{-V(x')}\hat{\mathscr{J}}'^{(2)}_{+}+e^{V(x')}\hat{\mathscr{J}}'^{(2)}_{-}]\overline{R_l}-2ik\,\sinh[W'-V(x')]. \tag{11.19d}$$

It should be noted that $\hat{\mathscr{J}}^{(2)}_{+}$ and $\hat{\mathscr{J}}^{(2)}_{-}$ appear in (11.19a) instead of $\hat{\mathscr{J}}^{(0)}_{+}$ and $\hat{\mathscr{J}}^{(0)}_{-}$. This is quite understandable with the diagrammatic interpretation of $\overline{R_r}$. Each diagram contributing to $\overline{R_r}$ has two right legs and no left legs. That is the reason why the representation is $\nu=2$ in (11.19a) and $\nu=0$ in (11.19b).

The equations for $\overline{\tau}$ are obtained by setting $\nu=1$ in (11.10) and (11.16):

$$\frac{\partial}{\partial x}\,\overline{\tau}=ik[e^{-V(x)}\hat{\mathscr{J}}^{(1)}_{+}+e^{V(x)}\hat{\mathscr{J}}^{(1)}_{-}]\overline{\tau},\quad \frac{\partial}{\partial x'}\,\overline{\tau}=-ik[e^{-V(x')}\hat{\mathscr{J}}'^{(1)}_{+}+e^{V(x')}\hat{\mathscr{J}}'^{(1)}_{-}]\overline{\tau}. \tag{11.20}$$

Equations (11.19) and (11.20) are the basic equations for the generalized scattering coefficients. To solve these equations, we need to know the initial condition. From (11.3) and (11.8) we have

$$\overline{\tau}(x=x')=\left[\cosh\left(\frac{w-w'}{2}\right)\right]^{-1}\Bigg|_{x=x'}=\left[\cosh\left(\frac{W-W'}{2}\right)\right]^{-1}\equiv\tau_0, \tag{11.21a}$$

$$\overline{R_r}(x=x')=2\frac{\partial}{\partial W}\log\,\overline{\tau}(x=x')=-\tanh\left(\frac{W-W'}{2}\right)\equiv r_0, \tag{11.21b}$$

$$\overline{R_l}(x=x')=2\frac{\partial}{\partial W'}\log\,\overline{\tau}(x=x')=\tanh\left(\frac{W-W'}{2}\right)\equiv l_0. \tag{11.21c}$$

We define the operators $\mathscr{L}$ and $\mathscr{L}'$ as

$$\mathscr{L}^{(\nu)}g(x,x';W,W')\equiv\int_{x'}^{x}dz[e^{-V(z)}\hat{\mathscr{J}}^{(\nu)}_{+}+e^{V(z)}\hat{\mathscr{J}}^{(\nu)}_{-}]g(z,x';W,W'), \tag{11.22a}$$

$$\mathscr{L}'^{(\nu)}g(x,x';W,W')\equiv\int_{x'}^{x}dz[e^{-V(z)}\hat{\mathscr{T}}_{+}'^{(\nu)}+e^{V(z)}\hat{\mathscr{T}}_{-}'^{(\nu)}]g(x,z;W,W'),\tag{11.22b}$$

for an arbitrary function g. They are integral operators with respect to x or x', and differential operators with respect to W or W'. The differential equations (11.20) and (11.19) with the initial condition (11.21) are equivalent to

$$\overline{\tau}=\tau_0+ik\mathscr{L}^{(1)}\overline{\tau},\quad \overline{\tau}=\tau_0+ik\mathscr{L}'^{(1)}\overline{\tau},\tag{11.23a}$$

$$\overline{R_r}=r_0+ik\mathscr{L}^{(2)}\overline{R_r}+2ik\int_{x'}^{x}\sinh[W-V(z)]dz,\quad \overline{R_r}=r_0+ik\mathscr{L}'^{(0)}\overline{R_r},\tag{11.23b}$$

$$\overline{R_l}=l_0+ik\mathscr{L}^{(0)}\overline{R_l},\quad \overline{R_l}=l_0+ik\mathscr{L}'^{(2)}\overline{R_l}+2ik\int_{x'}^{x}\sinh[W'-V(z)]dz.\tag{11.23c}$$

Let us derive expressions of scattering coefficients as power series in terms of k. We write

$$\overline{\tau}=\sum_{n=0}^{\infty}\tau_n k^n,\quad \overline{R_r}=\sum_{n=0}^{\infty}r_n k^n,\quad \overline{R_l}=\sum_{n=0}^{\infty}l_n k^n.\tag{11.24}$$

The coefficients of expansion τ_n, r_n, and l_n can be obtained by substituting (11.24) into (11.23). The coefficients for $n=0$ are given by (11.21). Using (11.13) we can also express them in terms of $\hat{\xi}_{\pm}$ and $\hat{\xi}'_{\mp}$. It is convenient to use either $(\hat{\xi}_{+},\hat{\xi}'_{-})$ or $(\hat{\xi}_{-},\hat{\xi}'_{+})$ as a set. We can write

$$\tau_0=\frac{2(-\hat{\xi}_{\pm}\hat{\xi}'_{\mp})^{1/2}}{1-\hat{\xi}_{\pm}\hat{\xi}'_{\mp}}=2i\sum_{m=0}^{\infty}(\hat{\xi}_{\pm}\hat{\xi}'_{\mp})^{m+(1/2)},\tag{11.25a}$$

$$r_0=-l_0=\pm\frac{1+\hat{\xi}_{\pm}\hat{\xi}'_{\mp}}{1-\hat{\xi}_{\pm}\hat{\xi}'_{\mp}}=\pm1\pm2\sum_{m=1}^{\infty}(\hat{\xi}_{\pm}\hat{\xi}'_{\mp})^{m}.\tag{11.25b}$$

To express τ_n, r_n, and $l_n(n\geqslant1)$ in an explicit form, we introduce the notation

$$[s_1,s_2,\ldots,s_n]_{x'}^{x}\equiv\int_{x'}^{x}dz_1\int_{z_1}^{x}dz_2\cdots\int_{z_{n-1}}^{x}dz_n\,\exp\left[\sum_{i=1}^{n}s_iV(z_i)\right],\tag{11.26}$$

where $s_i=\pm1$. The domain of integration in (11.26) is $x'\leqslant z_1\leqslant z_2\leqslant\cdots\leqslant z_n\leqslant x$. From the two equations of (11.23a) we obtain, respectively,

$$\tau_n=i^n(\mathscr{L}^{(1)})^n\tau_0=i^n\sum_{s_1=\pm1}\cdots\sum_{s_n=\pm1}[s_1,\ldots,s_n]_{x'}^{x}\hat{\mathscr{T}}_{-s_n}^{(1)}\cdots\hat{\mathscr{T}}_{-s_1}^{(1)}\tau_0,\tag{11.27a}$$

$$\tau_n=i^n(\mathscr{L}'^{(1)})^n\tau_0=i^n\sum_{s_1=\pm1}\cdots\sum_{s_n=\pm1}[s_1,\ldots,s_n]_{x'}^{x}\hat{\mathscr{T}}'^{(1)}_{-s_1}\cdots\hat{\mathscr{T}}'^{(1)}_{-s_n}\tau_0.\tag{11.27b}$$

Here $\mathscr{T}_{-s}^{(\nu)}$ stands for $\mathscr{T}_{-}^{(\nu)}$ and $\mathscr{T}_{+}^{(\nu)}$ for $s=+1$ and $s=-1$, respectively. (Note that $\mathscr{T}_{-s}^{(\nu)}$ with $s=-1$ is not $\mathscr{T}_{1}^{(\nu)}$ but $\mathscr{T}_{+}^{(\nu)}$.) For R_r we obtain two expressions of different form. The second equation of (11.23b) yields

$$r_n=i^n(\mathscr{L}'^{(0)})^nr_0=i^n\sum_{s_1=\pm1}\cdots\sum_{s_n=\pm1}[s_1,\ldots,s_n]_{x'}^{x}\hat{\mathscr{T}}'^{(0)}_{-s_1}\cdots\hat{\mathscr{T}}'^{(0)}_{-s_n}r_0.\tag{11.28}$$

On the other hand, from the first equation of (11.23b) we obtain

$$r_1=i\mathscr{L}^{(2)}r_0+ie^{W}[-1]_{x'}^{x}-ie^{-W}[+1]_{x'}^{x}=i\sum_{s_1\pm1}[s_1]_{x'}^{x}(\hat{\mathscr{T}}_{-s_1}^{(2)}r_0+\hat{\xi}_{-s_1}),\tag{11.29a}$$

$$r_n = i^{n-1}(\mathscr{L}^{(2)})^{n-1} r_1 = i^n \sum_{s_1=\pm 1} \cdots \sum_{s_n=\pm 1} [s_1,\ldots,s_n]^x_{x'} \hat{\mathscr{T}}^{(2)}_{-s_n} \cdots \hat{\mathscr{T}}^{(2)}_{-s_2} (\hat{\mathscr{T}}^{(2)}_{-s_1} r_0 + \hat{\xi}_{-s_1}), \tag{11.29b}$$

where $\hat{\xi}_{-s_1}$ means $\hat{\xi}_{\mp}$ for $s_1 = \pm 1$. Similar results for $\overline{R_l}$ can be obtained from (11.23c). To summarize, τ, $\overline{R_r}$, and $\overline{R_l}$ can be expressed as

$$\overline{\tau} = \tau_0 + \sum_{n=1}^{\infty} i^n k^n \sum_{\{s_1,\ldots,s_n\}} [s_1,\ldots,s_n]^x_{x'} \hat{\mathscr{T}}^{(1)}_{-s_n} \cdots \hat{\mathscr{T}}^{(1)}_{-s_1} \tau_0 \tag{11.30a}$$

$$= \tau_0 + \sum_{n=1}^{\infty} i^n k^n \sum_{\{s_1,\ldots,s_n\}} [s_1,\ldots,s_n]^x_{x'} \hat{\mathscr{T}}'^{(1)}_{-s_1} \cdots \hat{\mathscr{T}}'^{(1)}_{-s_n} \tau_0, \tag{11.30b}$$

$$\overline{R_r} = r_0 + \sum_{n=1}^{\infty} i^n k^n \sum_{\{s_1,\ldots,s_n\}} [s_1,\ldots,s_n]^x_{x'} \hat{\mathscr{T}}^{(2)}_{-s_n} \cdots \hat{\mathscr{T}}^{(2)}_{-s_2} (\hat{\mathscr{T}}^{(2)}_{-s_1} r_0 + \hat{\xi}_{-s_1}) \tag{11.30c}$$

$$= r_0 + \sum_{n=1}^{\infty} i^n k^n \sum_{\{s_1,\ldots,s_n\}} [s_1,\ldots,s_n]^x_{x'} \hat{\mathscr{T}}'^{(0)}_{-s_1} \cdots \hat{\mathscr{T}}'^{(0)}_{-s_n} r_0, \tag{11.30d}$$

$$\overline{R_l} = l_0 + \sum_{n=1}^{\infty} i^n k^n \sum_{\{s_1,\ldots,s_n\}} [s_1,\ldots,s_n]^x_{x'} \hat{\mathscr{T}}^{(0)}_{-s_n} \cdots \hat{\mathscr{T}}^{(0)}_{-s_1} l_0 \tag{11.30e}$$

$$= l_0 + \sum_{n=1}^{\infty} i^n k^n \sum_{\{s_1,\ldots,s_n\}} [s_1,\ldots,s_n]^x_{x'} \hat{\mathscr{T}}'^{(2)}_{-s_1} \cdots \hat{\mathscr{T}}'^{(2)}_{-s_{n-1}} (\hat{\mathscr{T}}'^{(2)}_{-s_n} l_0 + \hat{\xi}'_{-s_n}). \tag{11.30f}$$

Here $\Sigma_{\{s_1,\ldots,s_n\}}$ stands for $\Sigma_{s_1=\pm 1} \cdots \Sigma_{s_n=\pm 1}$. Equations (11.30a) and (11.30b) can be generalized to arbitrary ν as

$$\overline{\tau^{\nu}} = \tau_0^{\nu} + \sum_{n=1}^{\infty} i^n k^n \sum_{\{s_1,\ldots,s_n\}} [s_1,\ldots,s_n]^x_{x'} \hat{\mathscr{T}}^{(\nu)}_{-s_n} \cdots \hat{\mathscr{T}}^{(\nu)}_{-s_1} \tau_0^{\nu} \tag{11.31a}$$

$$= \tau_0^{\nu} + \sum_{n=1}^{\infty} i^n k^n \sum_{\{s_1,\ldots,s_n\}} [s_1,\ldots,s_n]^x_{x'} \hat{\mathscr{T}}'^{(\nu)}_{-s_1} \cdots \hat{\mathscr{T}}'^{(\nu)}_{-s_n} \tau_0^{\nu}. \tag{11.31b}$$

Using (11.25) and (11.14) we can write the expressions (11.30) in terms of either $(\hat{\xi}_+, \hat{\xi}'_-)$ or $(\hat{\xi}_-, \hat{\xi}'_+)$. The original scattering coefficients $\tau(x,x')$, $R_r(x,x')$, and $R_l(x,x')$ are obtained from these expressions by setting $\hat{\xi}_+ = e^{V(x)}$ and $\hat{\xi}'_- = -e^{-V(x')}$, or $\hat{\xi}_- = -e^{-V(x)}$ and $\hat{\xi}'_+ = e^{V(x')}$.

XII. SCATTERING COEFFICIENTS FOR $\theta = \pm \pi/2$

In Sec. XI we studied power series expansion of $\overline{\tau}$, $\overline{R_r}$, and $\overline{R_l}$. The coefficients of expansion are written in terms of the integrals of the form (11.26). When the potential $V(x)$ is given, all we need to do is to evaluate such integrals by some means. As a matter of fact, it is not necessary to calculate all these integrals. As we shall see below, it is sufficient if we evaluate only the integrals of the form $[s_1,\ldots,s_n]$ with $\Sigma_{i=1}^n s_i = 0$, 1, and -1. All the terms that appear in the expressions (11.30) can be obtained from them.

As mentioned in Sec. VI, when dealing with power series expressions in terms of k it is natural to work in the rotated frame with $\theta = \pm \pi/2$. In this section we study the scattering coefficients for $\theta = \pm \pi/2$ in order to clarify the structure of the power series expressions. What was said in the above paragraph can also be verified through this analysis.

It is convenient to define

$$\hat{\tau}^{\pm}(x,x') = e^{\mp [V(x) - V(x')]/2} \tau_{\pm(\pi/2)}(x,x'), \tag{12.1a}$$

$$\hat{R}_r^{\pm}(x,x')=e^{\mp V(x)}R_{r,\pm(\pi/2)}(x,x'),\quad \hat{R}_l^{\pm}(x,x')=e^{\pm V(x')}R_{l,\pm(\pi/2)}(x,x'),\tag{12.1b}$$

$$\hat{\rho}_r^{\pm}\equiv e^{\mp V(x)}\rho_{r,\pm(\pi/2)},\quad \hat{\rho}_l^{\pm}\equiv e^{\pm V(x')}\rho_{l,\pm(\pi/2)}.\tag{12.1c}$$

In the following analysis we deal with $\theta=+\pi/2$. The expressions for $\theta=-\pi/2$ can be easily obtained from these results by considering the symmetry. Setting $\theta=\pi/2$ in (8.20) and (9.10), and using (8.18) we obtain

$$\overline{\tau}=\frac{2(-\hat{\xi}_+\hat{\xi}'_-)^{1/2}\hat{\tau}^+}{1-\hat{R}_r^+\hat{\xi}_+-\hat{R}_l^+\hat{\xi}'_--[(\hat{\tau}^+)^2-\hat{R}_r^+\hat{R}_l^+]\hat{\xi}_+\hat{\xi}'_-},\tag{12.2}$$

$$\overline{R}_r=\frac{1+\hat{\rho}_r^+\hat{\xi}_+}{1-\hat{\rho}_r^+\hat{\xi}_+}=1+2\sum_{n=1}^{\infty}(\hat{\rho}_r^+\hat{\xi}_+)^n,\quad \hat{\rho}_r^+=\hat{R}_r^+ +\frac{(\hat{\tau}^+)^2\hat{\xi}'_-}{1-\hat{R}_l^+\hat{\xi}'_-},\tag{12.3}$$

and similarly for $\overline{R_l}$. From (12.3) it follows that

$$(\hat{\rho}_r^+)^n=\frac{1}{2n!}\frac{\partial^n\overline{R}_r}{\partial\hat{\xi}_+^n}\bigg|_{\hat{\xi}_+=0},\quad (\hat{R}_r^+)^n=\frac{1}{2n!}\frac{\partial^n\overline{R}_r}{\partial\hat{\xi}_+^n}\bigg|_{\hat{\xi}_+=\hat{\xi}'_-=0}\tag{12.4}$$

for any positive integer n. Since

$$\frac{1}{2n!}\frac{\partial^n}{\partial\hat{\xi}_+^n}r_0\bigg|_{\hat{\xi}_+=0}=(\hat{\xi}'_-)^n$$

[Eq. (11.25b)], from (12.4) we find that $(\hat{\rho}_r^+)^n$ is obtained by replacing r_0 in Eq. (11.30d) with $(\hat{\xi}'_-)^n$:

$$(\hat{\rho}_r^+)^n=(\hat{\xi}'_-)^n+\sum_{m=1}^{\infty}(ik)^m\sum_{\{s_1,\ldots,s_m\}}[s_1,\ldots,s_m]_{x'}^{x}\hat{\mathscr{T}}'^{(0)}_{-s_1}\cdots\hat{\mathscr{T}}'^{(0)}_{-s_m}(\hat{\xi}'_-)^n.\tag{12.5}$$

We obtain $(\hat{R}_r^+)^n$ by setting $\hat{\xi}'_-=0$ in (12.5). Since the operators $\hat{\mathscr{T}}'^{(0)}_-$ and $\hat{\mathscr{T}}'^{(0)}_+$ raises and lowers, respectively, the power of $\hat{\xi}'_-$ by one, setting $\hat{\xi}'_-=0$ in (12.5) is equivalent to imposing the restriction $\Sigma_{i=1}^m s_i=-n$ on the summation. Thus we have

$$(\hat{R}_r^+)^n=\sum_{m=1}^{\infty}(ik)^m\sum_{\substack{\{s_1,\ldots,s_m\}\\ \Sigma_{i=1}^m s_i=-n}}[s_1,\ldots,s_m]_{x'}^{x}\hat{\mathscr{T}}'^{(0)}_{-s_1}\cdots\hat{\mathscr{T}}'^{(0)}_{-s_m}(\hat{\xi}'_-)^n,\tag{12.6}$$

for arbitrary positive integer n. In (12.6), only even (odd) m's survive in the summation for even (odd) n.

It is also possible to express $\hat{R}_r^+$ in terms of operators in the $\nu=2$ representation. From (12.3) it follows that

$$\overline{R}_r|_{\hat{\xi}'_-=0}=1+2\sum_{n=1}^{\infty}(\hat{R}_r^+\hat{\xi}_+)^n.\tag{12.7}$$

On the other hand, setting $\hat{\xi}'_-=0$ in Eq. (11.30c) we obtain

$$\overline{R}_r|_{\hat{\xi}'_-=0}=1+2\sum_{m=1}^{\infty}(ik)^m\sum_{\{s_2,\ldots,s_m\}}[-1,s_2,\ldots,s_m]_{x'}^{x}\hat{\mathscr{T}}^{(2)}_{-s_m}\cdots\hat{\mathscr{T}}^{(2)}_{-s_2}\hat{\xi}_+.\tag{12.8}$$

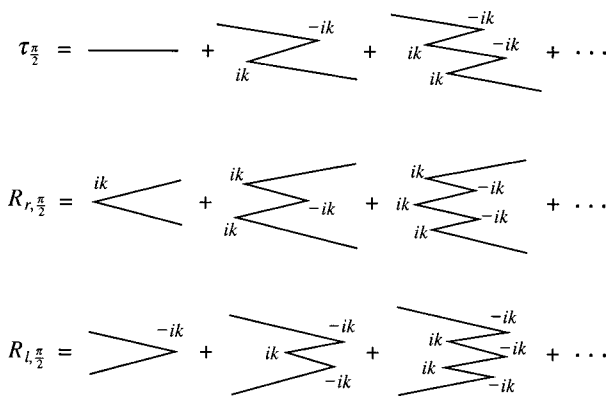

FIG. 25. Diagrammatic representation of the power series expression of the scattering coefficients for $\theta=\pi/2$.

(The term of order $m=1$ in the summation is $2ik[-1]^x_{x'}\hat{\xi}_+$.) The operators $\hat{\mathscr{T}}^{(2)}_+$ and $\hat{\mathscr{T}}^{(2)}_-$ raises and lowers, respectively, the power of $\hat{\xi}_+$ by one. Therefore by comparing (12.7) with (12.8) we find

$$(\hat{R}^+_r\hat{\xi}_+)^n=\sum_{m=1}^{\infty}(ik)^m\sum_{\substack{\{s_2,\ldots,s_m\}\\ \Sigma_{i=2}^m s_i=1-n}}[-1,s_2,\ldots,s_m]^x_{x'}\hat{\mathscr{T}}^{(2)}_{-s_m}\cdots\hat{\mathscr{T}}^{(2)}_{-s_2}\hat{\xi}_+. \tag{12.9}$$

[As can be seen from (12.9), only the terms with $s_1=-1$ survive in the expression (12.6), too. The quantity $\hat{\mathscr{T}}'^{(0)}_{-s_1}\cdots\hat{\mathscr{T}}'^{(0)}_{-s_m}(\hat{\xi}'_-)^n$ vanishes for $s_1=+1$ if $\Sigma_{i=1}^m s_i=-n$.]

It is easy to derive the expressions for $\hat{\tau}^+$. As can be seen from (12.2), we have

$$\hat{\tau}^+=\tfrac{1}{2}(-\hat{\xi}_+\hat{\xi}'_-)^{-1/2}\overline{\tau}\big|_{\hat{\xi}_+=\hat{\xi}'_-=0}. \tag{12.10}$$

From (11.30a), (11.30b), and (11.25a) we obtain

$$\hat{\tau}^+=(\hat{\xi}_+)^{-1/2}\sum_{j=0}^{\infty}(ik)^{2j}\sum_{\substack{\{s_i,\ldots,s_{2j}\}\\ \Sigma_{i=0}^{2j}s_i=0}}[s_1,\ldots,s_{2j}]^x_{x'}\hat{\mathscr{T}}^{(1)}_{-s_{2j}}\cdots\hat{\mathscr{T}}^{(1)}_{-s_1}(\hat{\xi}_+)^{1/2} \tag{12.11a}$$

$$=(\hat{\xi}'_-)^{-1/2}\sum_{j=0}^{\infty}(ik)^{2j}\sum_{\substack{\{s_i,\ldots,s_{2j}\}\\ \Sigma_{i=0}^{2j}s_i=0}}[s_1,\ldots,s_{2j}]^x_{x'}\hat{\mathscr{T}}'^{(1)}_{-s_1}\cdots\hat{\mathscr{T}}'^{(1)}_{-s_{2j}}(\hat{\xi}'_-)^{1/2}. \tag{12.11b}$$

Only even powers of k are present in (12.11) because of the restriction $\Sigma s_i=0$.

To be concrete, let us write down lower order terms of $\hat{\tau}^+$, $\hat{R}^+_r$, and $\hat{R}^+_l$ explicitly. From the above results we have

$$\hat{\tau}^+=1+[--+]k^2+(4[----++]+[--+--+])k^4+\cdots, \tag{12.12a}$$

$$\hat{R}^+_r=[-]ik+2[---+]ik^3+(12[-----++]+4[---+--+])ik^5+\cdots, \tag{12.12b}$$

$$\hat{R}^+_l=-[+]ik-2[-++]ik^3-(12[-----+++]+4[--+--+++])ik^5+\cdots, \tag{12.12c}$$

where $[--+]$, etc., is the shorthand notation for $[-1,-1,+1]^x_{x'}$, etc. The expressions for $\hat{\tau}^-$, $\hat{R}^-_r$, and $\hat{R}^-_l$ are obtained from (12.12) by interchanging the plus and minus signs in $[\cdots]$, and replacing k by $-k$. The quantities $\hat{\tau}^+$, $\hat{R}^+_r$, and $\hat{R}^+_l$ are the scattering coefficients for $\theta=\pi/2$ apart from the factors $e^{-[V(x)-V(x')]/2}$, $e^{-V(x)}$, and $e^{V(x')}$, respectively. So Eqs. (12.12) can be diagrammatically expressed as in Fig. 25. The diagrams in Fig. 25 are to be interpreted according

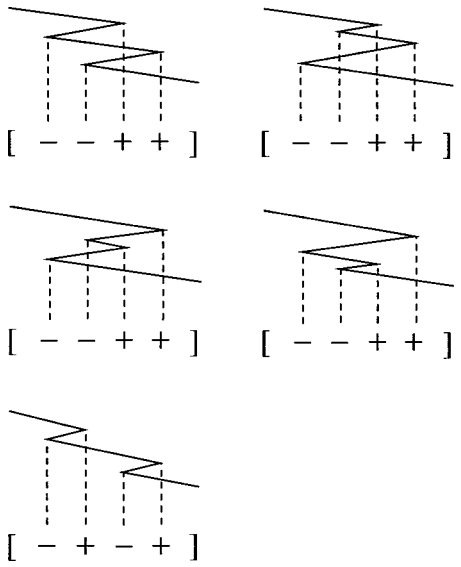

FIG. 26. The correspondence between the diagrams of order k^4 in $\hat{\tau}^+$ and the expression $4[--++]+[-+-+]$.

to the rules in Fig. 20 with $\theta=\pi/2$. Each line element connecting the points x_a and x_b stands for $\exp[X_{\pi/2}(x_b)-X_{\pi/2}(x_a)]=\exp[\frac{1}{2}V(x_b)-\frac{1}{2}V(x_a)]$, and the scattering factor is $\mp ik$, as explained in Sec. VI. As an example, Fig. 26 explains how the diagrams for the term of order k^4 in $\hat{\tau}^+$ correspond to the expression $4[--++]+[-+-+]$ as in Eq. (12.12a).

Thus τ, R_r, and R_l can be expressed in terms of $\hat{\tau}^+$, $\hat{R}_r^+$, and $\hat{R}_l^+$, (or $\hat{\tau}^-$, $\hat{R}_r^-$, and $\hat{R}_l^-$,) which include fewer types of integrals. Since the power series expressions of $\bar{\tau}$, R_r, and R_l can be obtained by substituting (12.12) into (12.2) and (12.3), we can see that the coefficients τ_n, r_n, and l_n in (11.24) can also be expressed in terms of integrals $[s_1,\ldots,s_n]$ where $\Sigma s_i=0$, $+1$, or -1. Therefore in practical problems we have only to evaluate $[s_1,\ldots,s_n]$ with $\Sigma s_i=0$, $+1$, and -1.

XIII. REFLECTION COEFFICIENT FOR SEMI-INFINITE INTERVALS

Until now we have studied the scattering coefficients for the interval (x',x) assuming that both x and x' are finite. However, $R_r(x,x')$ is well-defined even for $x'=-\infty$. [Similarly, $R_l(x,x')$ is well-defined for $x=+\infty$.] Indeed, for a semi-infinite interval that has only the right endpoint, the right-reflection coefficient R_r is the only quantity that is ''experimentally'' measurable from outside. Here let us think about R_r for the semi-infinite interval $(-\infty,x)$.

We first consider the case where the potential converges to a finite limit at minus infinity; $\lim_{z\to-\infty}V(z)=V(-\infty)$, where $V(-\infty)$ is a finite value. In this case, the quantities $\hat{\tau}^+$, $\hat{R}_r^+$, and $\hat{R}_l^+$ do not have a definite value. It is easy to see that all the integrals appearing in (12.12), $[-]_{-\infty}^x$, $[+]_{-\infty}^x$, $[-+]_{-\infty}^x$, etc., are divergent. Nevertheless, the reflection coefficient $R_r(-\infty,x)$ itself has a definite value, and it can be expressed as a power series in terms of k with finite expansion coefficients. Although all the integrals $[s_1,\ldots,s_n]_{-\infty}^x$ in (11.30c) or (11.30d) are divergent, the divergence is canceled. This can be understood diagrammatically. Figure 27 shows diagrams contributing to $R_r(x,x')$ in the rotated frame with $\theta=\pi/2$, where a reflection at the endpoint x' gives a factor $\xi'_{-\pi/2}=e^{V(x')}\hat{\xi}'_-$. From this figure it can be seen that the integrals $[-1,s_2,\ldots,s_n]$ and $[+1,s_2,\ldots,s_n](\hat{\xi}'_-)^2$, which correspond to the two diagrams shown here, always appear as a pair with the same weight and the opposite sign. Therefore, the divergence of these two integrals cancel out if we set $\hat{\xi}'_-=-e^{-V(-\infty)}$ [provided that $V(x)$ converges to the finite limit $V(-\infty)$ sufficiently fast at $x\to-\infty$].

Next we consider the case $V(-\infty)=+\infty$, or more precisely, $\lim_{z\to-\infty}V(z)=+\infty$. The expression for the reflection coefficient becomes much simpler in this case. As $x'=-\infty$ now, we have $\hat{\xi}'_-=e^{-V(-\infty)}\xi'_{-(\pi/2)}=0$. (We are assuming that $\xi'_{-(\pi/2)}=-e^{-w'}$ is finite. Recall that R_r is obtained by setting $w=w'=0$.) Thus R_r becomes independent of w'. From (12.3) we have $\hat{\rho}_r^+$

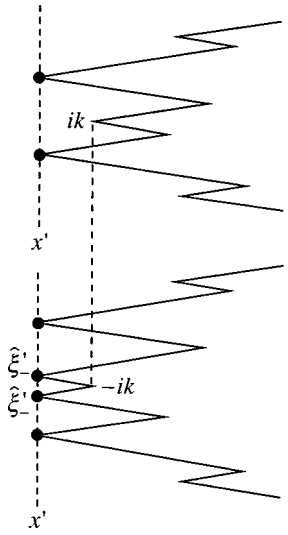

FIG. 27. As shown here, the integrals $[-1,s_2,\ldots,s_n]_{x'}^{x}$ and $[+1,s_2,\ldots,s_n]_{x'}^{x}(\hat{\xi}'_-)^2$ appear as a pair with the same weight and opposite sign in the expression for $R_r(x,x')$ or $\hat{\rho}_r^+(x,x')$.

$=\hat{R}_r^+$, and the expression for $\overline{R_r}$ is given by (12.8). [This holds true not only for semi-infinite intervals but also for the cases where $\lim_{z\downarrow x'}V(z)=+\infty$ at some finite x'. Similarly, if $V(-\infty)=-\infty$ we have $\hat{\xi}'_+=0$ and $\hat{\rho}_r^-=\hat{R}_r^-$.] We find from the first equation of (12.3) and $\hat{\rho}_r^+=\hat{R}_r^+$ that the expression for $\log R_r(x,x')$ has the form

$$\log \overline{R_r}=\log(1+\hat{R}_r^+\hat{\xi}_+)-\log(1-\hat{R}_r^+\hat{\xi}_+)=2\sum_{n=1,3,5,\cdots}\frac{1}{n}(\hat{R}_r^+\hat{\xi}_+)^n. \tag{13.1}$$

The power series expression of $\log \overline{R_r}$ can be obtained by substituting (12.9) into (13.1). After some manipulation we obtain

$$\log \overline{R_r}=2ik[-1]\hat{\xi}_+ +2\sum_{m=3,5,7,\cdots}(ik)^m\sum_{\{s_2,\ldots,s_m\}}[-1,s_2,\ldots,s_{m-1},s_m]\hat{\xi}_{-s_m}\hat{\mathscr{T}}^{(2)}_{-s_{m-1}}\cdots\hat{\mathscr{T}}^{(2)}_{-s_2}\hat{\xi}_+, \tag{13.2}$$

where we have used $\hat{\xi}_-=-(\hat{\xi}_+)^{-1}$. This is the power series expression in (1.18).

XIV. CONCLUDING REMARKS

In the present work we confined ourselves to general features of the scattering formalism, without specifying the form of the potential $V(x)$. The expressions obtained here will serve as a basis on which various approximation methods can be constructed for specific problems. Although we have focused our attention on power series expansion in terms of k, the resulting expressions are not merely approximations for small k. In fact, it is possible to convert the expressions such as (11.30) into large-k expressions through an algebraic manipulation. It is also possible to study various analytic properties in the intermediate-k region on the basis of these expressions.

In this paper we left aside the Green's function. As discussed in a previous paper,[7] the Green's function can be described in terms of a superalgebra, which allows the spin to change at the beginning and the end of a path. The transmission coefficient is also naturally described in terms of this superalgebra. In order to fully understand the scattering processes, it will be necessary to study the supersymmetric structure.

APPENDIX A: DIAGRAMMATIC DERIVATION OF (3.22)

A diagram contributing to $[U^{(\nu)}(x_b,x_a)]_{mn}$ consists of:

(i) ν paths that start from x_a and end at x_b. Each of them amounts to $\tau(x_b,x_a)$ when summed over all possible configurations.
(ii) Additional i pairs of $\tau(x_b,x_a)$'s. [The difference between (i) and (ii) is explained below.] The number i cannot exceed $\min(m,n)$.
(iii) $n-i$ paths that start from x_a and return to x_a, each amounting to $R_l(x_a,x_b)$.
(iv) $m-i$ paths that start from x_b and return to x_b, each amounting to $R_r(x_a,x_b)$.

Let us study the combinatorial factors that arise when we try to connect their left and right legs with $u_n^{(\nu)}$ and $(u_m^{(\nu)})^\dagger$, respectively, so as to make ν connected paths without a loop.

First, we connect the left legs of these elements with $u_n^{(\nu)}$, leaving the right legs disconnected. As in Fig. 10, the ν open circles are distinguished. In addition, we distinguish the i pairs of τ's in (ii). Then there are $\binom{\nu+n-1}{n-i}$ different ways of making such a connection. It is the number of ways to distribute the R_l's among the $\nu+i$ elements in either (i) or (ii). [Each τ belonging to (i) is connected with an open circle of $u_n^{(\nu)}$ either directly or indirectly. The τ's in (ii) are not connected with an open circle of $u_n^{(\nu)}$. Instead, the two τ's of a pair are connected with each other through one or more solid circles of $u_n^{(\nu)}$.] Hence we have the second factor on the right-hand side of (3.22).

Next we connect the right legs with $(u_m^{(\nu)})^\dagger$. Different paths are obtained by reordering of the $m-i$ right-reflection coefficients and the i pairs of τ's [which belong to (ii) above]. The R_r's and the pairs of τ's can be arranged in $\binom{m}{i}$ different ways, and this gives the first factor on the right-hand side of (3.22). (Now the τ-pairs are not distinguished.) Thus we have diagrammatically reproduced the expression (3.22).

APPENDIX B: DERIVATION OF (8.4)

Here we use the formulas

$$C^{J_3}J_\pm = J_\pm C^{J_3\pm 1}, \quad [J_3, e^{CJ_\pm}] = \pm CJ_\pm e^{CJ_\pm}, \tag{B1}$$

$$[J_\pm, e^{CJ_\mp}] = \pm(2CJ_3 \pm C^2 J_\mp)e^{CJ_\mp} = \pm e^{CJ_\mp}(2CJ_3 \mp C^2 J_\mp), \tag{B2}$$

which immediately follow form the commutation relations (3.2). We may calculate

$$\begin{aligned}
\mathscr{J}_3^{(\nu)}\gamma^\nu(u_0^{(\nu)}, e^{\xi J_-^{(\nu)}}\cdots)^{(\nu)} &= \gamma^\nu\left(u_0^{(\nu)}, \left(\frac{\nu}{2} + \xi\frac{\partial}{\partial\xi}\right)e^{\xi J_-^{(\nu)}}\cdots\right)^{(\nu)} \\
&= \gamma^\nu\left(u_0^{(\nu)}, \left(\frac{\nu}{2} + \xi J_-^{(\nu)}\right)e^{\xi J_-^{(\nu)}}\cdots\right)^{(\nu)} \\
&= \gamma^\nu(u_0^{(\nu)}, (J_3^{(\nu)} + \xi J_-^{(\nu)})e^{\xi J_-^{(\nu)}}\cdots)^{(\nu)} \\
&= \gamma^\nu(u_0^{(\nu)}, e^{\xi J_-^{(\nu)}} J_3^{(\nu)}\cdots)^{(\nu)}.
\end{aligned} \tag{B3}$$

The relations for $\mathscr{J}_+$ and $\mathscr{J}_-$ can be derived in a similar way. Let us also note that in terms of the operator $D(\xi)$ defined by (8.10) we can rewrite (8.4) as

$$\mathscr{J}_a^{(\nu)}(u_0^{(\nu)}, D(\xi)\cdots)^{(\nu)} = (u_0^{(\nu)}, D(\xi)J_a^{(\nu)}\cdots)^{(\nu)}. \tag{B4}$$

APPENDIX C: DIFFERENT DERIVATION OF (9.4)

Here we derive (9.4) by direct calculation without using diagrams. We have

$$\log\overline{\tau} = \lim_{\epsilon\to 0}\frac{1}{\epsilon}[(u_0^{(\epsilon)}, DUD'u_0^{(\epsilon)})^{(\epsilon)} - 1], \quad \overline{R_r} = \lim_{\epsilon\to 0}\frac{1}{\epsilon}(u_0^{(\epsilon)}, J_- DUD' u_0^{(\epsilon)})^{(\epsilon)}, \tag{C1}$$

where $D \equiv D(\xi)$ and $D' \equiv D(-\xi')$ with the definition (8.10). By using (B1), (B2), (8.3), and (8.15) we can show that

$$DJ_1 = J_1 D. \tag{C2}$$

From (B4), (C1), and (C2) we can derive $\overline{R_r} = 2\mathscr{J}_1 \log \overline{\tau}$.

APPENDIX D: DERIVATION OF (10.3)

Setting $\nu = -1$ in (10.1) we obtain

$$U^{(-1)}_{\theta\theta'} = \begin{pmatrix} \cos(\theta/2) & \sin(\theta/2) \\ -\sin(\theta/2) & \cos(\theta/2) \end{pmatrix} \begin{pmatrix} \alpha^+ & \beta^- \\ \beta^+ & \alpha^- \end{pmatrix} \begin{pmatrix} \cos(\theta'/2) & -\sin(\theta'/2) \\ \sin(\theta'/2) & \cos(\theta'/2) \end{pmatrix} \equiv \begin{pmatrix} \alpha^+_{\theta\theta'} & \beta^-_{\theta\theta'} \\ \beta^+_{\theta\theta'} & \alpha^-_{\theta\theta'} \end{pmatrix}, \tag{D1}$$

where $\alpha^\pm$ and $\beta^\pm$ are the matrix elements of $U^{(-1)}$ defined by (3.6). By comparing (D1) with the last expression of (10.1) we have

$$\tau_{\theta\theta'} = \frac{1}{\alpha^+_{\theta\theta'}}, \quad R_{r,\theta\theta'} = \frac{\beta^+_{\theta\theta'}}{\alpha^+_{\theta\theta'}}, \quad R_{l,\theta\theta'} = -\frac{\beta^-_{\theta\theta'}}{\alpha^+_{\theta\theta'}}. \tag{D2}$$

Now let us consider the Fokker–Planck equation with the potential $\overline{V}$ given by Eq. (2.3). We define $\theta_a \equiv \arctan(-ic_a/k)$ and $\theta_b \equiv \arctan(-ic_b/k)$. As (3.7), two independent solutions of (1.11) are given by

$$\phi^+_{0,\theta_0}(x,x_0) \equiv \alpha^+_{0,\theta_0}(x,x_0) + \beta^+_{0,\theta_0}(x,x_0), \quad \phi^-_{0,\theta_0}(x,x_0) \equiv \alpha^-_{0,\theta_0}(x,x_0) + \beta^-_{0,\theta_0}(x,x_0), \tag{D3}$$

where x_0 and θ_0 are arbitrary. It is easy to see that

$$U^{(-1)}_{\theta_b\theta_b}(x,x_b) = \begin{pmatrix} e^{-ip_b(x-x_b)} & 0 \\ 0 & e^{ip_b(x-x_b)} \end{pmatrix} \quad (x > x_b),$$

$$U^{(-1)}_{\theta_a\theta_a}(x,x_a) = \begin{pmatrix} e^{-ip_a(x-x_a)} & 0 \\ 0 & e^{ip_a(x-x_a)} \end{pmatrix} \quad (x < x_a), \tag{D4}$$

where p_a and p_b are defined by (2.5). From (D1) and the multiplication property of the evolution operator it follows that

$$\begin{aligned} U^{(-1)}_{0,\theta_a}(x,x_a) &= \begin{pmatrix} \cos(\theta_a/2) & -\sin(\theta_a/2) \\ \sin(\theta_a/2) & \cos(\theta_a/2) \end{pmatrix} U^{(-1)}_{\theta_a\theta_a}(x,x_a) \\ &= \begin{pmatrix} \cos(\theta_b/2) & -\sin(\theta_b/2) \\ \sin(\theta_b/2) & \cos(\theta_b/2) \end{pmatrix} U^{(-1)}_{\theta_b\theta_b}(x,x_b) \begin{pmatrix} \alpha^+_{\theta_b\theta_a}(x_b,x_a) & \beta^-_{\theta_b\theta_a}(x_b,x_a) \\ \beta^+_{\theta_b\theta_a}(x_b,x_a) & \alpha^-_{\theta_b\theta_a}(x_b,x_a) \end{pmatrix}. \end{aligned} \tag{D5}$$

Using (D4) and (D5) we find that $\phi^+_{0,\theta_a}(x,x_a)$ behaves as

$$\begin{aligned} \phi^+_{0,\theta_a}(x,x_a) &= \left(\cos\frac{\theta_a}{2} + \sin\frac{\theta_a}{2}\right) e^{-ip_a(x-x_a)} \qquad (x < x_a) \\ &= \left(\cos\frac{\theta_b}{2} + \sin\frac{\theta_b}{2}\right) \alpha^+_{\theta_b\theta_a}(x_b,x_a) e^{-ip_b(x-x_b)} \\ &\quad + \left(\cos\frac{\theta_b}{2} - \sin\frac{\theta_b}{2}\right) \beta^+_{\theta_b\theta_a}(x_b,x_a) e^{ip_b(x-x_b)} \qquad (x > x_b). \end{aligned} \tag{D6}$$

Since $p_a/p_b=(\cos^2(\theta_b/2)-\sin^2(\theta_b/2))/(\cos^2(\theta_a/2)-\sin^2(\theta_a/2))$, from (D6), (D2) and (2.4) we obtain (10.3). (The relation for $\widetilde{R}_l$ can be derived in the same way.)

A reformulation of simple liquids theory—Renormalization by one-, two-, and three-particle densities

Ko Okumura
Theoretical Studies, Institute for Molecular Science, Myodaiji, Okazaki, Aichi 444-8585, Japan

(Received 27 May 1997; accepted for publication 6 January 1998)

We reformulate the theory of simple liquids in a field theoretical way by taking into account the triplet potential w_{ijk}, in addition to the external potential u_i and the pair potential v_{ij}. The innovation here is *the inversion method* and *the on-shell expansion* which are the building blocks of a novel use of Legendre transformation developed in field theory. By the inversion method, we renormalize the theory in terms of one-, two-, and three-particle densities, and present a diagrammatic representation for a thermodynamical functional, which is the entropy except for a trivial constant, in terms of renormalized variables. In other words, we present an expression for the entropy in terms of only one-, two-, and three-particle densities: the n-particle density where $n \geqslant 4$ does not appear in the expression. The on-shell condition, which is a starting point of the on-shell expansion, of the thermodynamical functional thus obtained (the entropy) leads to a set of three self-consistent equations for one-, two-, and three-particle densities. Through one of the self-consistent equations, we can systematically improve the Kirkwood's superposition approximation for the three-particle density. The on-shell conditions for other thermodynamical functionals, also obtained in this article, are found to be extentions of various well-known equations in the theory of simple liquids. The formulation presented here is complementary to the conventional re-summation techniques for renormalization of diagrams. In the present formulation, we do not have to care about the topological structure of diagrams, often characterized by the irreducibility of diagrams. Instead, by a perturbative calculation, we can automatically single out the diagrams with the topological structure predicted by the re-summation techniques. © *1998 American Institute of Physics.* [S0022-2488(98)01604-1]

I. INTRODUCTION

In the theory of simple liquids, renormalization of the theory in terms of one-, and two-particle densities is essential. (The n-particle density here is sometimes called the correlation function of the n-th order.) To perform such renormalization, re-summation techniques of diagrams had been extensively developed.[1–4] Such techniques, though elegant and attractive, are sometimes complex and difficult to understand. In such techniques, the topological structure of the diagrams for the renormalized theory is determined by using graphical terms such as irreducibility of diagrams. If one wants to obtain higher order diagrams, we have to single out, by hand, diagrams which have the topological structure thus determined, after considering all possible diagrams of that order. At a higher order, this task can be laborious.

In the present reformulation, however, we can obtain the renormalized diagrams automatically order by order through simple (but sometimes tedious) calculations. We do not have to care about the topological structure at all; the diagrams with the demanded topology are automatically singled out. In this sense, this reformulation is complementary to the conventional re-summation techniques.

The innovation here is a novel use of the Legendre transformation which has been developed in field theory and has been applied to quantum systems.[5] In this article we present the first application to a classical system. This methodology consists of the inversion method and the one-shell expansion, which shall be reviewed briefly below. However, in short, the former is a method by which we can obtain a non-perturbative result through a sort of perturbative calculation, and the latter is a formalism in which we can systematically extract all physical information

 © 1998 American Institute of Physics

concerning a physical variable of interest, starting from an effective action. (The effective action is a kind of thermodynamical functional in a classical system as we see below.)

The systematic expansion of the entropy of simple liquids theory in terms of the correlation function has received considerable attention. Such an expansion for the canonical ensemble was studied in Ref. 6, which followed by the works for the grand canonical ensemble.[7,8] Recently, these expansion schemes have been revisited[9–12] and numerically examined[13,14] by several researchers. In all these works, the entropy is expanded in terms of one-particle density and the n-th order term contains the correlation function up to the n-th order: the entropy is expressed by the n-particle densities where $n=0,1,...,\infty$.

However, as shown below, the entropy functional, which is the effective action except for a trivial term, can be described by the correlation functions of the order *up to the n-th* if we neglect higher-body potential than n-body. Indeed, the entropy given in Ref. 1 is described only by one- and two-particle densities since, as in conventional simple liquids theory, the triplet and higher-body potential are neglected there.

In this article we present an expression for the entropy as functional of one-, two-, and three-particle densities of the grand canonical ensemble. The expansion does not include correlation functions of the order higher than three and thus the theory is renormalized in terms of one, two-, and three-particle densities.

To renormalize the theory in terms of the three-particle density, in the present paper, we first explicitly include a triplet potential into a theory, and then, make a Legendre transformation from the triplet potential to the three particle density. The triplet potential can be set to zero after the renormalization if we like to go back to the (conventional) liquids theory without the triplet potential. Note here that, by first introducing the triplet potential and then by setting the potential at the end, we can extract new information, which can not be obtained if we neglect the potential from the start.

Extention of the liquid theory to include triplet potentials is not new and had been studied, though the above viewpoint for the triplet potential as a tool for the Legendre transformation might have not. For example, for a weak triplet potential, they included the effects of the triplet potential by modifying the pair potential with the aid of diagrams.[15–17] Other important references can be found in Refs. 12, 18.

Furthermore, inclusion of the general m-body potential ($m=1,2,3,4,...$) into the liquid theory is performed in Ref. 19 in a simple and clear way. There, various diagrammatic rules are neatly given and are renormalized up to the two-particle densities. In the present work, we further renormalize the theory by the three-particle densities though our case is limited to the special case where there are no more-than-three-body potentials. (See Sec. VII.)

In the present formalism, the stationary conditions for the entropy or the effective action come out as identities of the Legendre transformation. The set of conditions can be seen as a set of self-consistent equations to be solved for the variables of interest.

In this article, we obtain three kinds of the effective actions, which are closely related to the entropy. As stationary conditions for these actions, we get three sets of self-consistent equations, some of which can be seen as a generalization of well-known equations in simple liquids theory.

Especially, one of the self-consistent equations leads to successive improvement of the Kirkwood's superposition approximation[4] for the three-particle densities. The zero-th order approximation of this theory coincides with the previously known approximation (for example, see Refs. 20, 12), which reduces to the Kirkwood's approximation for the system without the triplet potential. The first order approximation of ours can be seen as an improvement over the well-known approximations.[21–24]

Let us review the inversion method and the on-shell expansion briefly. Consider a physical variable of interest ϕ in a system described by a Hamiltonian H. In a classical system at an equilibrium, a physical variable is a thermal expectation value of some quantity $\hat{\phi}$. (In a quantum system a physical variable is a quantum expectation value of an operator $\hat{\phi}$.) In the inversion method, we modify the Hamiltonian H to $H+J\hat{\phi}$ where J is an artificial external source which should be set to zero at the end of calculation. However, if the original Hamiltonian H already has a term proportional to $\hat{\phi}$, say $j\hat{\phi}$, we merely replace j with an artificial source J and set it back

to j at the end of calculation. After this modification of the Hamiltonian, we calculate ϕ by a perturbative expansion in terms of the expansion parameter, say g, in the presence of the artificial source J. We have an expansion called *the original series* of the form,

$$\phi=\phi(J)=\phi^{(0)}(J)+\phi^{(1)}(J)+\phi^{(2)}(J)+\cdots, \tag{1.1}$$

where $\phi^{(i)}$ is the i-th order in g when we regard J as independent of g. Now we invert Eq. (1.1) in favor of J to get *the inversion series*,

$$J=J(\phi)=J^{(0)}(\phi)+J^{(1)}(\phi)+J^{(2)}(\phi)+\cdots, \tag{1.2}$$

where $J^{(i)}(\phi)$ is the i-th order in g when we regard ϕ as independent of g. In order to obtain an explicit form of $J^{(i)}(\phi)$, we insert Eq. (1.2) into Eq. (1.1):

$$\phi=\phi^{(0)}(J^{(0)}+J^{(1)}+J^{(2)}+\cdots)+\phi^{(1)}(J^{(0)}+J^{(1)}+\cdots)+\phi^{(2)}(J^{(0)}+\cdots)+\cdots, \tag{1.3}$$

or

$$\begin{aligned}\phi=&\phi^{(0)}(J^{(0)})+\phi^{(0)\prime}(J^{(0)})J^{(1)}+\phi^{(1)}(J^{(0)})+\phi^{(0)\prime}(J^{(0)})J^{(2)}+\tfrac{1}{2}\phi^{(0)\prime\prime}(J^{(0)})\cdot(J^{(1)})^2\\&+\phi^{(1)\prime}(J^{(0)})J^{(1)}+\phi^{(2)}(J^{(0)})+\cdots.\end{aligned} \tag{1.4}$$

The trick of the inversion method is to regard ϕ in the left-hand side of this equation as independent of g. Then we get a set of equations called *inversion formulae*:

$$\phi=\phi^{(0)}(J^{(0)}), \tag{1.5}$$

$$\phi^{(0)\prime}(J^{(0)})J^{(1)}+\phi^{(1)}(J^{(0)})=0, \tag{1.6}$$

$$\phi^{(0)\prime}(J^{(0)})J^{(2)}+\frac{1}{2}\,\phi^{(0)\prime\prime}(J^{(0)})\cdot(J^{(1)})^2+\phi^{(1)\prime}(J^{(0)})J^{(1)}+\phi^{(2)}(J^{(0)})=0, \tag{1.7}$$

$$\begin{aligned}&\phi^{(0)\prime}(J^{(0)})J^{(3)}+\phi^{(0)\prime\prime}(J^{(0)})J^{(1)}J^{(2)}+\frac{1}{3!}\,\phi^{(0)\prime\prime\prime}(J^{(0)})\cdot(J^{(1)})^3+\phi^{(1)\prime}(J^{(0)})J^{(2)}\\&+\frac{1}{2}\,\phi^{(1)\prime\prime}(J^{(0)})\cdot(J^{(1)})^2+\phi^{(2)\prime}(J^{(0)})J^{(1)}+\phi^{(3)}(J^{(0)})=0,\end{aligned} \tag{1.8}$$

and so on. In this way we can obtain $J^{(i)}(\phi)$ up to the desired order. Note here that all the derivatives of $\phi^{(i)}$ and $\phi^{(i)}$ itself in the above formulae are evaluated at $J=J^{(0)}$, which is determined by the lowest inversion formula (1.5). Finally, we set the artificially introduced source J back to the original value, say j, to go back to the original theory:

$$J^{(0)}(\phi)+J^{(1)}(\phi)+\cdots=j. \tag{1.9}$$

If we truncate the original series (1.1) at the i-th order, we obtain Eq. (1.9) truncated at the i-th order. However, these two truncated equations are not equivalent and the latter, which can be regarded as an equation determining ϕ, is a more improved equation for ϕ than the former.

The trick of regarding ϕ as independent of g corresponds to making the Legendre transformation; ϕ and g are dealt with as mutually independent in the Legendre transformation. To further clarify this point, we introduce a generating function W which satisfies the relation

$$\phi(J)=\frac{dW(J)}{dJ}. \tag{1.10}$$

In the case of an equilibrium system W is nothing but the thermodynamical potential [$W=\Omega=-(1/\beta)\ln\Xi$: see Eq. (2.8)]. Now we introduce *the effective action* Γ by the Legendre transfor-

mation: $\Gamma = W(J,g) - J\phi(J,g)$ where $\phi(J,g) = \partial W(J,g)/\partial J$. Here, we have emphasized the g dependence. The variation of Γ, *if we assume that J and g are independent variables*, is expressed as

$$d\Gamma = \frac{\partial W(J,g)}{\partial J}\, dJ + \frac{\partial W(J,g)}{\partial g}\, dg - dJ\phi(J,g) - Jd\phi(J,g) = \frac{\partial W(J,g)}{\partial g}\, dg - Jd\phi(J,g). \tag{1.11}$$

Hence, as is well known, we see that the quantity Γ can be regarded as a function of two independent variables ϕ and g—$\Gamma = \Gamma(\phi,g)$. Equation (1.11) seems trivial but is essential in the present discussion. What is implied in Eq. (1.11) is as follows: if we solve (or invert) the relation $\phi(J,g) = \partial W(J,g)/\partial J$ in favor of J, *assuming that two quantities ϕ and g are mutually independent*, to obtain $J = J(\phi,g)$ and then insert this expression of J into all J appearing in $W(J,g) - J\phi$, this quantity $W(J,g) - J\phi$ is automatically written by only two independent variables ϕ and g. In other words, this inversion process of the Legendre transformation is carried out regarding ϕ as independent of g. This is the justification of the trick of the inversion method. Note that once the inversion or the Legendre transformation is performed and after the sources are set to an appropriate value, j for example, the resultant ϕ depends on g. In many quantum cases such as Quantum Electrodynamics (QED),[25] Superconductivity,[26] Hubbard model,[27] and Superfluidity,[5] it is known that this trick of the inversion method reproduces the mean field approximation at the first order (in which we truncate the series at $i = 1$). In this sense, the inversion method offers a way to systematically advance the mean field approximation.

Reciprocal to Eq. (1.10), there is an identity,

$$J = -\frac{d\Gamma(\phi)}{d\phi}. \tag{1.12}$$

This equation is equivalent to the inversion series (1.2) and, at an appropriate value of J, say j, corresponds to Eq. (1.9). In other words, Eq. (1.12) at $J = j$ is an equation which determines ϕ. This equation corresponds to the on-shell condition in field theory. The on-shell expansion is an expansion of the right-hand side of the on-shell condition $j = -d\Gamma(\phi)/d\phi$ at the point $\phi = \phi_0 + \Delta\phi$ around the solution of the on-shell condition $\phi = \phi_0$ [i.e., $j = -d\Gamma(\phi_0)/d\phi_0$]. Through the on-shell expansion, we obtain a set of equations containing all the physical information related to ϕ such as excitations and scatterings. However, since we concentrate on equilibrium properties of liquids in this article, the higher order on-shell equations shall not be examined. Such an important issue is reserved for a future work. In this sense, a real application of the on-shell expansion to a classical system is relegated to a separate work, which shall deal with dynamical properties of simple liquids.

In the above we consider a simple case where ϕ is scalar and position independent. However, the generalization to a case where ϕ is a tensor and position dependent is straightforward [see, for example, Eq. (4.10) below].

Organization of this article is as follows. In Section II, we reformulate the simple liquids theory in a field theoretical way and successively introduce three kinds of effective actions $(\Gamma_1, \Gamma_2, \Gamma_3)$ through the first, the second, and the third Legendre transformation. We then give the on-shell condition for each effective action. It is stressed here that the effective action Γ_3 is the entropy except for a trivial term and it can be written as a functional of the correlation functions of *up to the third order*. In Section III, we present a diagrammatic expression for the thermodynamic potential with explicitly including the triplet potential w_{ijk}. The introduction of *pseudo 2-bonds* is essential for the presentation of the diagrams with the triplet potential. Sections IV to VI deal with renormalization of the theory in terms of one-, two-, and three-particle densities, respectively. After renormalization, we obtain a diagrammatic expression for Γ_1, Γ_2, or Γ_3 (the entropy) and show that the on-shell condition for each Γ_i $(i = 1,2,3)$ can be considered as some extension of various well-known equations in simple liquids theory. In Section VI, we obtain a systematic way of improving the Kirkwood's superposition approximation for the three-particle densities.

II. A REFORMULATION OF THE SIMPLE LIQUIDS THEORY

Consider an N-particle classical system subject to the potential $u(\mathbf{r})$, the pair potential $v(\mathbf{r},\mathbf{r}')$, and the triplet potential $w(\mathbf{r},\mathbf{r}',\mathbf{r}'')$,[28]

$$\mathscr{H}_N \equiv \mathscr{H}_N(\mathbf{p}_1,\ldots,\mathbf{p}_N,\mathbf{q}_1,\ldots,\mathbf{q}_N) = \frac{1}{2m}\sum_{i=1}^{N}|\mathbf{p}_i|^2 + V_N, \tag{2.1}$$

$$V_N \equiv V_N(\mathbf{q}_1,\ldots,\mathbf{q}_N) = \sum_{i=1}^{N} u(\mathbf{q}_i) + \sum_{i<j}^{N} v(\mathbf{q}_i,\mathbf{q}_j) + \sum_{i<j<k}^{N} w(\mathbf{q}_i,\mathbf{q}_j,\mathbf{q}_k). \tag{2.2}$$

Here the pair potential $v(\mathbf{r}_i,\mathbf{r}_j)$ and $w(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3)$ are symmetric under the interchange of position variables [$v(\mathbf{r}_1,\mathbf{r}_2)=v(\mathbf{r}_2,\mathbf{r}_1)$ etc.]. By introducing the n-particle density for an N-particle system $(n=1,2,3)$ by

$$\rho_N^{(1)}(\mathbf{r}) = \sum_{i=1}^{N}\delta(\mathbf{r}-\mathbf{q}_i), \tag{2.3}$$

$$\rho_N^{(2)}(\mathbf{r},\mathbf{r}') = \sum_{i\neq j}^{N}\delta(\mathbf{r}-\mathbf{q}_i)\,\delta(\mathbf{r}'-\mathbf{q}_j) = \rho_N^{(1)}(\mathbf{r})\rho_N^{(1)}(\mathbf{r}') - \delta(\mathbf{r}-\mathbf{r}')\rho_N^{(1)}(\mathbf{r}), \tag{2.4}$$

$$\rho_N^{(3)}(\mathbf{r},\mathbf{r}',\mathbf{r}'') = \sum_{i\neq j\neq k}^{N}\delta(\mathbf{r}-\mathbf{q}_i)\,\delta(\mathbf{r}'-\mathbf{q}_j)\,\delta(\mathbf{r}''-\mathbf{q}_k), \tag{2.5}$$

the grand potential $V_N-\mu N$ is cast into the form

$$V_N-\mu N = \int d\mathbf{r}_1\,\tilde{u}(\mathbf{r}_1)\rho_N^{(1)}(\mathbf{r}_1) + \frac{1}{2}\int d\mathbf{r}_1\int d\mathbf{r}_2\, v(\mathbf{r}_1,\mathbf{r}_2)\rho_N^{(2)}(\mathbf{r}_1,\mathbf{r}_2) + \frac{1}{3!}\int d\mathbf{r}_1\int d\mathbf{r}_2\int d\mathbf{r}_3\, w(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3)\rho_N^{(3)}(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3), \tag{2.6}$$

where

$$\tilde{u}(\mathbf{r}) = -\mu + u(\mathbf{r}). \tag{2.7}$$

This expression for the potential plays a key role in our reformulation of the simple liquids theory in a field theoretical way. From this expression, we can identify $(J,\hat{\phi})$ of the inversion method with $(\tilde{u},\rho_N^{(1)})$, $(v,\rho_N^{(2)})$, or $(w,\rho_N^{(3)})$.

The grand partition function Ξ and the thermodynamic potential,

$$\Omega = -\frac{1}{\beta}\ln\Xi, \tag{2.8}$$

is defined by

$$e^{-\beta\Omega} = \Xi = \sum_{N=0}^{\infty}\frac{1}{N!}\frac{1}{h^{3N}}\int d\mathbf{p}^N\int d\mathbf{q}^N e^{-\beta(\mathscr{H}_N-\mu N)}, \tag{2.9}$$

where $\int d\mathbf{p}^N$ and $\int d\mathbf{q}^N$ implies the integrations over $\mathbf{p}_1,\mathbf{p}_2,\ldots,\mathbf{p}_N$ and $\mathbf{q}_1,\mathbf{q}_2,\ldots,\mathbf{q}_N$, respectively.

Regarding quantities Ω and Ξ as functionals of the potentials $\tilde{u}(\mathbf{r})$, $v(\mathbf{r},\mathbf{r}')$, and $w(\mathbf{r},\mathbf{r}',\mathbf{r}'')$, we have the n-particle density $(n=1,2,3)$ by differentiating Ω with respect to $\tilde{u}$, v, or w:[29]

$$\rho^{(1)}(\mathbf{r}) \equiv \frac{d\Omega}{\delta\tilde{u}(\mathbf{r})} = \langle\rho_N^{(1)}(\mathbf{r})\rangle, \tag{2.10}$$

$$\rho^{(2)}(\mathbf{r},\mathbf{r}')\equiv\frac{\delta\Omega}{\delta\,\dfrac{1}{2}\,v(\mathbf{r},\mathbf{r}')}=\langle\rho_N^{(2)}(\mathbf{r},\mathbf{r}')\rangle, \tag{2.11}$$

$$\rho^{(3)}(\mathbf{r},\mathbf{r}',\mathbf{r}'')\equiv\frac{\delta\Omega}{\delta\,\dfrac{1}{3!}\,w(\mathbf{r},\mathbf{r}',\mathbf{r}'')}=\langle\rho_N^{(3)}(\mathbf{r},\mathbf{r}',\mathbf{r}'')\rangle. \tag{2.12}$$

Here, the expectation implies[30]

$$\langle\mathscr{O}_N\rangle=\frac{1}{\Xi}\sum_{N=0}^{\infty}\frac{1}{N!}\frac{1}{h^{3N}}\int d\mathbf{p}^N\int d\mathbf{q}^N\mathscr{O}_N\,e^{-\beta(\mathscr{H}_N-\mu N)}, \tag{2.13}$$

and we have used the relations

$$\frac{\delta\tilde{u}(\mathbf{r})}{\delta\tilde{u}(\mathbf{r}')}=\delta(\mathbf{r}-\mathbf{r}'), \tag{2.14}$$

$$\frac{\delta v(\mathbf{r}_1,\mathbf{r}_2)}{\delta v(\mathbf{r}_{1'},\mathbf{r}_{2'})}=\frac{1}{2!}\left[\delta(\mathbf{r}_1-\mathbf{r}_{1'})\delta(\mathbf{r}_2-\mathbf{r}_{2'})+\delta(\mathbf{r}_1-\mathbf{r}_{2'})\delta(\mathbf{r}_2-\mathbf{r}_{1'})\right], \tag{2.15}$$

$$\frac{\delta w(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3)}{\delta w(\mathbf{r}_{1'},\mathbf{r}_{2'},\mathbf{r}_{3'})}=\frac{1}{3!}\left[\delta(\mathbf{r}_1-\mathbf{r}_{1'})\delta(\mathbf{r}_2-\mathbf{r}_{2'})\delta(\mathbf{r}_3-\mathbf{r}_{3'})+(3!-1)\text{terms}\right]. \tag{2.16}$$

In order to rewrite the theory in terms of $\rho^{(1)}(\mathbf{r})$, $\rho^{(2)}(\mathbf{r},\mathbf{r}')$, and $\rho^{(3)}(\mathbf{r},\mathbf{r}',\mathbf{r}'')$ instead of $\tilde{u}(\mathbf{r})$, $v(\mathbf{r},\mathbf{r}')$, and $w(\mathbf{r},\mathbf{r}',\mathbf{r}'')$, the Legendre transformations are successively performed. The first, the second, and the third Legendre transformations are, respectively, defined by

$$\Gamma_1[\rho^{(1)},v]\equiv\Omega[\tilde{u},v,w]-\int d\mathbf{r}_1\tilde{u}(\mathbf{r}_1)\rho^{(1)}(\mathbf{r}_1), \tag{2.17}$$

$$\Gamma_2[\rho^{(1)},\rho^{(2)}]\equiv\Gamma_1[\rho^{(1)},v]-\frac{1}{2}\int d\mathbf{r}_1\int d\mathbf{r}_2 v(\mathbf{r}_1,\mathbf{r}_2)\rho^{(2)}(\mathbf{r}_1,\mathbf{r}_2), \tag{2.18}$$

$$\Gamma_3[\rho^{(1)},\rho^{(2)},\rho^{(3)}]\equiv\Gamma_2[\rho^{(1)},\rho^{(2)},w]-\frac{1}{3!}\int d\mathbf{r}_1\int d\mathbf{r}_2\int d\mathbf{r}_3 w(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3)\rho^{(3)}(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3). \tag{2.19}$$

In these equations, $(\tilde{u},\rho^{(1)})$, $(v,\rho^{(2)})$, or $(w,\rho^{(3)})$ can be regarded as (J,ϕ) of the inversion method. In the present case, the original Hamiltonian already has a term proportional to ϕ: we should set $J=-\mu+u$, v, or w (instead of $J=0$) at the end. (In the conventional simple liquids theory where the triplet potential is neglected, we have to set $J=w=0$ at the end.) By using the relation

$$\begin{aligned}\delta\Omega[\tilde{u},v,w]=&\int d\mathbf{r}_1\,\frac{\delta\Omega}{\delta\tilde{u}(\mathbf{r}_1)}\,\delta\tilde{u}(\mathbf{r}_1)+\int d\mathbf{r}_1\int d\mathbf{r}_2\,\frac{\delta\Omega}{\delta v(\mathbf{r}_1,\mathbf{r}_2)}\,\delta v(\mathbf{r}_1,\mathbf{r}_2)\\&+\int d\mathbf{r}_1\int d\mathbf{r}_2\int d\mathbf{r}_3\,\frac{\delta\Omega}{\delta w(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3)}\,\delta w(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3),\end{aligned} \tag{2.20}$$

we can explicitly confirm that Γ_1, Γ_2, and Γ_3 are functionals of $(\rho^{(1)},v,w)$, $(\rho^{(1)},\rho^{(2)},w)$, and $(\rho^{(1)},\rho^{(2)},\rho^{(3)})$, respectively, with the identities

$$\frac{\delta\Gamma_1[\rho^{(1)},v,w]}{\delta\rho_1^{(1)}}=-\widetilde{u}_1,\quad \frac{\delta\Gamma_1[\rho^{(1)},v,w]}{\delta\,\frac{1}{2}\,v_{12}}=\rho_{12}^{(2)},\quad \frac{\delta\Gamma_1[\rho^{(1)},v,w]}{\delta\,\frac{1}{3!}\,w_{123}}=\rho_{123}^{(3)}, \tag{2.21}$$

$$\frac{\delta\Gamma_2[\rho^{(1)},\rho^{(2)},w]}{\delta\rho_1^{(1)}}=-\widetilde{u}_1,\quad \frac{\delta\Gamma_2[\rho^{(1)},\rho^{(2)},w]}{\delta\,\frac{1}{2}\,\rho_{12}^{(2)}}=-v_{12},\quad \frac{\delta\Gamma_2[\rho^{(1)},\rho^{(2)},w]}{\delta\,\frac{1}{3!}\,w_{123}}=\rho_{123}^{(3)}, \tag{2.22}$$

$$\frac{\delta\Gamma_3[\rho^{(1)},\rho^{(2)},\rho^{(3)}]}{\delta\rho_1^{(1)}}=-\widetilde{u}_1,\quad \frac{\delta\Gamma_3[\rho^{(1)},\rho^{(2)},\rho^{(3)}]}{\delta\,\frac{1}{2}\,\rho_{12}^{(2)}}=-v_{12},\quad \frac{\delta\Gamma_3[\rho^{(1)},\rho^{(2)},\rho^{(3)}]}{\delta\,\frac{1}{3!}\,\rho_{123}^{(3)}}=-w_{123}. \tag{2.23}$$

Here, we have used simple and self-evident notations. These can be seen as the on-shell conditions for the first, second, and third Legendre transformations, respectively, and shall be shown to correspond to familiar equations of simple liquids theory.

The effective actions introduced above are some thermodynamic functionals and closely related to the entropy. We notice that the entropy functional is given by

$$S/k=-\beta\Gamma_3+3\langle N\rangle/2, \tag{2.24}$$

where k is the Boltzmann constant, because the definition of the entropy S is given by

$$\Omega=\langle E\rangle-TS-\mu\langle N\rangle, \tag{2.25}$$

where T is the temperature, and because there is the identity

$$\langle E-\mu N\rangle=\frac{3}{2}\,\langle N\rangle kT+\int d1\widetilde{u}_1\rho_1^{(1)}+\int d1\int d2v_{12}\rho_{12}^{(2)}+\int d1\int d2\int d3w_{123}\rho_{123}^{(3)}. \tag{2.26}$$

It also follows that, if we neglect the three-body potential, the entropy is expressed as

$$S/k=-\beta\Gamma_2+3\langle N\rangle/2\quad (w=0), \tag{2.27}$$

and, if we further neglect the two-body potential, it is given by

$$S/k=-\beta\Gamma_1+3\langle N\rangle/2\quad (v=w=0). \tag{2.28}$$

We stress here that the stationary condition for the entropy, which leads to the self-consistent equations, automatically comes out as identities of the Legendre transformation. For example, the identities in (2.23) are equivalent to

$$\frac{\partial S/k}{\partial\rho_1^{(1)}}=\beta\widetilde{u}_1+\frac{3}{2},\quad \frac{\partial S/k}{\partial\rho_{12}^{(2)}}=\beta v_{12},\quad \frac{\partial S/k}{\partial\rho_{123}^{(3)}}=\beta w_{123}. \tag{2.29}$$

From the above argument it may be clear that, in general, the entropy of simple liquids theory, where potentials of higher than m-body are neglected, can be written as a functional of the correlation functions of the order up to the m-th. In such a case, higher order correlation functions can be expressed by the correlation functions of up to the m-th order.

By using the results given in this section, we can establish the general statement that n-particle density can be given as an explicit functional of s-particle densities where $s\leqslant n-1$. From the second equality in Eq. (2.21) we readily notice that $\rho^{(2)}$ is given as a functional of $\rho^{(1)}$, v, and w. From the last equality in Eq. (2.22), we notice that $\rho^{(3)}$ is given by $\rho^{(2)}$, $\rho^{(1)}$, and w. In the same way, if we introduce Γ_n by taking into general m-body potentials, we can confirm that Γ_n is a functional of $\rho^{(s)}$ $(s=1,2,...,n)$ as a consequence of the basic property of the Legendre transfor-

mation. Since $\rho^{(n)}$ is given by the derivative of Γ_{n-1} as in Eqs. (2.21) and (2.22), we arrive at the general statement. This statement is not limited to the classical case; the parallel argument in relativistic quantum field theory is developed in Ref. 31.

III. DIAGRAMMATIC EXPRESSION FOR THE THERMODYNAMIC POTENTIAL

The thermodynamic potential can be expressed as

$$e^{-\beta\Omega}=\Xi=\sum_{N=0}^{\infty}\frac{1}{N!}\int d[N]\left[\prod_i z_i^*\right]\cdot\left[\prod_{i<j}(1+f_{ij})\right]\cdot\left[\prod_{i<j<k}(1+t_{ijk})\right], \tag{3.1}$$

where

$$\int d[N]\equiv\int d\mathbf{q}_1\int d\mathbf{q}_2\cdots\int d\mathbf{q}_N, \tag{3.2}$$

$$z_i^*\equiv z^*(\mathbf{q}_i)=ze^{-\beta u(\mathbf{q}_i)}, \tag{3.3}$$

$$f_{ij}\equiv f(\mathbf{q}_i,\mathbf{q}_j)=e^{-\beta v(\mathbf{q}_i,\mathbf{q}_j)}-1, \tag{3.4}$$

and

$$t_{ijk}\equiv t(\mathbf{q}_i,\mathbf{q}_j,\mathbf{q}_k)=e^{-\beta w(\mathbf{q}_i,\mathbf{q}_j,\mathbf{q}_k)}-1. \tag{3.5}$$

Here, we have introduced the activity

$$z=\frac{e^{\beta\mu}}{\Lambda^3}, \tag{3.6}$$

where the de Broglie thermal wavelength $\Lambda=\sqrt{2\pi\beta\hbar^2/m}$ originates from the momentum integration $\int dp e^{-\beta|p|^2/2m}/h=\Lambda^{-1}$.

Diagrammatically $-\beta\Omega$ can be expressed as a sum of connected diagrams built up with black circles, 2-bonds, 3-bonds, and pseudo 2-bonds, where every pair of circles connected by the same 3-bond should be connected by a pseudo 2-bond.[32] Here, the graphical terms are defined as follows. A 2-bond connects a pair of circles but a pair can not be connected directly more than once by 2-bonds. A 3-bond connects a triplet of circles but a triplet can not be connected directly more than once by 3-bonds. A pseudo 2-bond is basically the same as the 2-bond: it connects a pair of circles but a pair can not be connected directly more than once by pseudo 2-bonds. The difference between 2-bonds and pseudo 2-bonds is the following: if a pair is connected by the same 3-bond, the pair should be connected by a pseudo 2-bond; otherwise, simply by a 2-bond. The pseudo 2-bond is found to be very useful for a collective representation of diagrams which contain 3-bonds. Without use of pseudo 2-bonds, the number of diagrams is dramatically increased. We give all diagrams of $-\beta\Omega$ explicitly up to the fourth order in the activity z:

$$-\beta\Omega=-\beta\Omega^{(1)}+-\beta\Omega^{(2)}+\cdots, \tag{3.7}$$

where

$-\beta\Omega^{(1)}=$ (3.8)

$-\beta\Omega^{(2)}=$  (3.9)

$-\beta\Omega^{(3)}=$ (3.10)

TABLE I. Analytical expressions corresponding to the symbols in the specified parts of the text. The white circles are the same as the black circles but no integrations are associated with them.

Symbol	Eqs. (3.8)–(4.7)	Eqs. (4.12)–(5.8) Appendix A	Eqs. (5.12)–(6.6) Appendix B	Eqs. (6.11)–(6.14)
1	z_1^*	n_1	n_1	n_1
1 2	f_{12}	f_{12}	h_{12}	h_{12}
1 2	$1+f_{12}$	$1+f_{12}$	$1+h_{12}$	$1+h_{12}$
3 1 2	t_{123}	t_{123}	t_{123}	γ_{123}

$-\beta\Omega^{(4)} =$  (3.11)

We note here that, as suggested above, every triplet connected by a 3-bond forms a triangle whose sides are pseudo 2-bonds. We can convince ourselves that all the diagrams at the fourth order are written out in Eq. (3.11) if we note the following three points, which, respectively, concern the fourth order diagrams including two, three, and four 3-bonds. (1) If we chose two distinct triplets from four distinct points, two (and only two) points are necessarily shared by the two triplets. (2) If we chose three distinct triplets from four distinct points, one (and only one) point is necessarily shared by the three triplets, while each of the other three points is shared by two (and only two) of the three triplets. (3) If we chose four distinct triplets from four distinct points, every point is necessarily shared by three (and only three) of the four triplets, and every pair of points should be shared by two (and only two) of the four triplets.

The algebraic expression corresponding to a diagram is obtained by the following steps (see Table I).

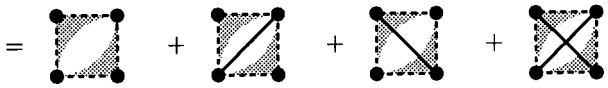
1. Assign the numbers 1,2,...,n to all the black circles in an arbitrary way. We associate the factors $z_1^*, z_2^*, \ldots, z_n^*$ to the black circles labeled 1,2,...,n, respectively. Here n is the total number of black circles in the diagram.
2. Associate the factor f_{ij} and $1+f_{ij}$ to the 2-bond and the pseudo 2-bond, respectively, whose ends are labeled i and j in the first step.
3. Associate the factor t_{ijk} to the 3-bond whose ends are labeled i, j, and k in the the first step.
4. Integrate the product of all the factors z^*, f, $1+f$ and t over the variables $\mathbf{q}_1, \ldots, \mathbf{q}_n$.
5. Multiply the integral by the inverse of the symmetry number S of the diagram.

The symmetry number is the number of all possible ways of labeling (one of which is done in the first step) topologically equivalent to each other. For example, if a diagram contains j black circles

which play equivalent roles (in the sense any interchange of the labels among those circles does not change the topology of the graph), the set of j circles contributes the symmetry factor $j!$. The symmetry numbers for the diagrams in Eqs. (3.8)–(3.11) are successively given by 1,2, (2,3!,3!), (2,3!,$2\cdot 4$,2!,2!2!,4!,…,4!).

Since the pseudo 2-bonds are not conventional, we present two examples of diagrams which contain the pseudo 2-bonds:

$$= \frac{1}{2}\int d1\int d2\int d3\int d4\; n_1 n_2 n_3 n_4 t_{123} f_{34}(1+f_{12})(1+f_{23})(1+f_{31}) \tag{3.12}$$



(3.13)

Though Eq. (3.13) is mathematically correct under the above rules 1–5 for analytical expressions, only the second expression (which consists of two diagrams) accords with our convention of distinguishing 2-bonds from pseudo ones. (For example, in the first expression, a pair which is not connected by the same 3-bond is connected by a pseudo 2-bond and thus this expression violates our convention.) Because of this, we employ the second expression in what follows.

IV. INVERSION FROM ONE-BODY POTENTIAL TO ONE-PARTICLE DENSITY

In this section we renormalize the theory in terms of the one-particle density by using the inversion method. To this end we identify ϕ in the inversion formulae with the one-particle density $n_1 \equiv \rho^{(1)}(\mathbf{r}_1)$. The diagram expression for n_1 can be easily obtained from that for $-\beta\Omega$ if we notice that the differentiation by the one-particle potential u_1 changes one of the black circles to a white circle. This is understood from

$$-\beta n_1 = -\beta \frac{\delta\Omega}{\delta u_1}, \tag{4.1}$$

and

$$\frac{\delta z_1^*}{\delta u_{1'}} = -\beta z_1^* \delta_{11'}. \tag{4.2}$$

Here, a white circle should be associated with z_i^* but no integration is performed over the variable i. Except for this rule for a white circle, the rules for obtaining an analytical expression from a diagram are not changed (see Table I).

We give all the diagrams up to the fourth order in the activity z:

$$n_1 = n_1^{(0)}[\tilde{u}\,] + n_1^{(1)}[\tilde{u}\,] + \cdots, \tag{4.3}$$

where

$$n_1^{(0)}[\tilde{u}] = \tag{4.4}$$

$$n_1^{(1)}[\tilde{u}] = \tag{4.5}$$

$$n_1^{(2)}[\tilde{u}] =$$  (4.6)

$$n_1^{(3)}[u] =$$  (4.7)

where $\cdots$ represents derivatives of the last six diagrams written in Eq. (3.11).

In the above $n^{(0)}$ is NOT the zero-th order in z and, strictly speaking, we should identify ϕ in the inversion formulae not with n_1 but n_1/z. However, here, we have identified ϕ with n_1 since the result is the same. We have also identified J with $\tilde{u}$ and regarded $\tilde{u}$ as an *artificial* source, though it should be set to the original value at the end. In other words, in the following we shall use the same symbol $\tilde{u}$ for both J and j.

From Eq. (1.5), or $n_1 = n_1^{(0)}[\tilde{u}^{(0)}]$, and from Eq. (4.4), we have

$$n_1 = e^{-\beta \tilde{u}_1^{(0)}}/\Lambda^3 \quad (-\beta \tilde{u}_1^{(0)} = \ln n_1 + 3 \ln \Lambda). \tag{4.8}$$

This relation implies

$$z_1^*|_{\tilde{u}\to\tilde{u}^{(0)}} = n_1. \tag{4.9}$$

This means that the replacement $\tilde{u}\to\tilde{u}^{(0)}$, as implied in the inversion formulae Eqs. (1.5)–(1.8), is equivalent to a change of interpretation of circles: in the new diagram all the white and black circles should be associated not with z_i^* but with n_i.

In the present case where $\phi = n_1$, Eq. (1.6) can be re-written as

$$\int d1' \, \frac{\delta n_1^{(0)}[\tilde{u}^{(0)}]}{\delta \tilde{u}_{1'}^{(0)}} \, \tilde{u}_{1'}^{(1)} + n_1^{(1)}[\tilde{u}^{(0)}] = 0, \tag{4.10}$$

where, from Eq. (4.4),

$$\frac{\delta n_1^{(0)}[\tilde{u}^{(0)}]}{\delta \tilde{u}_{1'}^{(0)}} = -\beta n_1 \delta_{11'}. \tag{4.11}$$

Thus, from Eq. (4.5), Eq. (4.10) is diagrammatically expressed as

$$-\beta n_1 \tilde{u}_1^{(1)} +$$  $$= 0,$$ (4.12)

from which we obtain

$$\beta\tilde{u}_1^{(1)} = \quad \text{—●} \quad . \tag{4.13}$$

We stress here in the above two graphs the white and black circles now correspond not to z_i^* but to n_i. This is because these diagrams originate from the inversion formula in which we replace $\tilde{u}_1$ by $\tilde{u}_1^{(0)}$ and, as explained above, this replacement changes the circles in the diagrams from z_1^* to n_i. By the same token, all the circles should be associated with n_i in what follows (see Table I).

The first term in Eq. (1.7) can be written as $-\beta n_1 \tilde{u}_1^{(2)}$ as above. The second term in Eq. (1.7) in this case is written as

$$\frac{1}{2}\phi^{(0)''}(J^{(1)})^2 = \frac{1}{2}\int d1' \int d2' \frac{\delta^2 n_1^{(0)}[\tilde{u}^{(0)}]}{\delta\tilde{u}_{1'}^{(0)}\delta\tilde{u}_{2'}^{(0)}}\tilde{u}_{1'}^{(1)}\tilde{u}_{2'}^{(1)}, \tag{4.14}$$

where, from Eq. (4.4),

$$\frac{\delta^2 n_1^{(0)}[\tilde{u}^{(0)}]}{\delta\tilde{u}_{1'}^{(0)}\tilde{u}_{2'}^{(0)}} = (-\beta)^2\delta_{11'}\delta_{12'} \quad \text{○} \quad . \tag{4.15}$$

From Eq. (4.13), Eq. (4.14) can be expressed as .

Since $\phi^{(1)\prime}$ in Eq. (1.7), in this case, implies [from Eq. (4.5)]

$$\frac{\delta n_1^{(1)}[\tilde{u}^{(0)}]}{\delta\tilde{u}_{1'}^{(0)}} = -\beta \quad \text{○—○}_{1\quad 1'} \quad -\beta\delta_{11'} \quad \text{○—●} \quad , \tag{4.16}$$

the third term in Eq. (1.7) can be expressed as  .

Here the factor 2 in front of the second graph appears because the symmetry factor of the graph is 2. (Up to now we have omitted the index 1 for a white circle, if there is only one white circle in the diagram.) Thus, Eq. (1.7) reduces to

$$-\beta n_1\tilde{u}_1^{(2)} + \quad \text{△} \quad -\left(\quad \text{△} \quad +2 \quad \text{△}\quad\right) + n_1^{(2)}[\tilde{u}^{(0)}] = 0. \tag{4.17}$$

In this equation, we see that the three diagrams explicitly written exactly cancel the 1-reducible diagrams appearing in $n_1^{(2)}[\tilde{u}^{(0)}]$. Here, the 1-reducible diagram is a diagram in which there is at least one circle the removal of which leads to a separation of the diagram. Thus we have

$$\beta\tilde{u}_1^{(2)} = \quad \overset{1}{\text{△}} \quad + \quad \overset{1}{\text{▲}} \quad . \tag{4.18}$$

Concerning Eq. (1.8), in a similar manner, we have (see Appendix A)

$$\phi^{(0)\prime}J^{(3)} = -\beta n_1\tilde{u}_1^{(3)}, \tag{4.19}$$

$$\phi^{(0)''}J^{(1)}J^{(2)} \rightarrow \quad \text{△} \quad + \quad \text{▲} \quad , \tag{4.20}$$

$$\frac{1}{3!}\phi^{(0)\prime\prime\prime}(J^{(1)})^3 \to -$$, (4.21)

$$\phi^{(1)\prime}J^{(2)} \to -$$  , (4.22)

$$\frac{1}{2}\phi^{(1)\prime\prime}(J^{(1)})^2 \to$$  , (4.23)

$$\phi^{(2)\prime}J^{(1)} \to -$$  . (4.24)

By substituting these results in Eq. (1.8), we see again that all the 1-reducible diagrams exactly cancel out. As a result we have

$$\beta\tilde{u}_1^{(3)} =$$  , (4.25)

where $\cdots$ represents derivatives of the last six diagrams written in Eq. (3.11).

We have derived $\tilde{u}_1$ explicitly up to the third order in n_1 (black circle) and in principle we can continue such a calculation up to the desired order. Then the inversion series is given by

$$\beta\tilde{u}_1 = \beta\tilde{u}_1^{(0)} + \beta\tilde{u}_1^{(1)} + \beta\tilde{u}_1^{(2)} + \cdots , \tag{4.26}$$

where $\tilde{u}_1^{(i)}$ $(i=0,1,2,3)$ are given in Eqs. (4.8), (4.13), (4.18), and (4.25). As we see below in Eq. (4.30), this inversion series, obtained by the inversion method, can be regarded as the on-shell condition and as a generalization of a well-known formula in simple liquids theory.

Now we can integrate the expression (4.26) to get a generating functional $\Gamma_1[n,v,w]$ due to the relation $\beta\tilde{u}_1 = -\beta\delta\Gamma_1[n,v,w]/\delta n_1$. The result is given by

$$-\beta\Gamma_1 = \int d1 n_1(1 - \ln n_1 - 3\ln\Lambda) +$$  . (4.27)

We stress here that in the above diagram circles are associated with n_i and thus all the diagrams are functional not of z_i^* but of n_i. All the diagrams up to the fourth order of n_i are explicitly shown in Eq. (4.27).

Equation (4.27) can be related to the previously known results for the entropy and the thermodynamic potential. The entropy in the case where $v=w=0$ can be given by $-\beta\Gamma_1+(3/2)\times\langle N\rangle$, as stated before. Indeed, if we further set $u=0$ (the ideal gas), we recover the entropy of the ideal gas, $S/k=Vn(5/2-\ln n-3\ln\Lambda)$, where n and V is the density and the volume of the system, respectively. If we neglect the triplet potential, Eq. (4.27) reduces to the standard expression for the thermodynamic potential renormalized by one-particle density:[1,2]

$$-\beta\Omega=\int d1\, n_1(1-\ln n_1+\ln z-\beta u_1)+\mathscr{K}^{(1)}[n,f], \tag{4.28}$$

where $\mathscr{K}^{(1)}[n,f]$ is the whole class of the 1-irreducible (1IR) diagrams built up with n-circles and f-bonds (f-bonds are functionals of v). Here the 1IR diagram is the one in which deletion of any one of the black circles does not cause a separation of the diagram.

The on-shell condition for the first Legendre transformation [the first equation in (2.21)], or

$$\beta\,\frac{\delta\Gamma_1[n,v,w]}{\delta n_1}=-\beta\tilde{u}_1, \tag{4.29}$$

for Γ_1 in Eq. (4.27), reduces to

$$\beta u_1=-\ln n_1+\ln z+$$  $$+\cdots, \tag{4.30}$$

which is equivalent to the inversion series (4.26), as stated above. This inversion series is a generalization of a familiar equation in the simple liquid theory:[1,4]

$$\ln(n_1/z_1^*)=K_1^{(1)}[n,f], \tag{4.31}$$

where $K_1^{(1)}[n,f]=\delta\mathscr{K}^{(1)}[n,f]/\delta n_1$ is a sum of all 1-irreducible diagrams consisting of one white circle labeled 1, one or more black circles, and f-bonds. If we again neglect the triplet potential and set u to zero (a homogeneous liquid), Eq. (4.30) reduces to this standard result (4.31).

V. INVERSION FROM PAIR POTENTIAL TO TWO-PARTICLE DENSITY

In this section we renormalize the theory in terms of the two-particle density by using the inversion method. To this end we try to identify ϕ in the inversion formulae with the two-particle density $n_{12}\equiv\rho^{(2)}(\mathbf{r}_1,\mathbf{r}_2)$. The diagram expression for n_{12} can be easily obtained from that for Γ_1 if we notice that the differentiation by the two-particle potential v_{12} removes one of the (pseudo) 2-bonds with making black circles of both ends white circles if we multiply the resultant diagram by a factor $1+f_{12}$. This is understood from the relations

$$-\beta n_{12}=-\beta\,\frac{\delta\Omega[u,v,w]}{\delta\,\frac{1}{2}\,v_{12}}=-\beta\,\frac{\delta\Gamma_1[n,v,w]}{\delta\,\frac{1}{2}\,v_{12}}, \tag{5.1}$$

and

$$\frac{\delta f_{12}}{\delta\,\frac{1}{2}\,v_{1'2'}}=-\beta(1+f_{12})(\delta_{11'}\delta_{22'}+\delta_{12'}\delta_{21'}). \tag{5.2}$$

Thus, we have

$$n_{12} = (1 + f_{12})(\circ\ \circ + \text{ } + \cdots) \tag{5.3}$$

We notice here that all the diagrams have two white circles, which stand for n_i. This implies that, if we consider n_i as the expansion parameter of the inversion method, $n_{12}^{(0)}$ vanishes while the inversion method assumes a non-zero $\phi^{(0)}$. To avoid this difficulty we identify ϕ with a new quantity defined by

$$h_{12} \equiv \frac{n_{12}}{n_1 n_2} - 1. \tag{5.4}$$

It is diagrammatically given as

$$h_{12} = h_{12}^{(0)}[v] + h_{12}^{(1)}[v] + \cdots, \tag{5.5}$$

where

$$h_{12}^{(0)}[v] = \text{ } \tag{5.6}$$

$$h_{12}^{(1)}[v] = (1 + f_{12})(\text{  }) \tag{5.7}$$

$$h_{12}^{(2)}[v] = (1 + f_{12})(\text{  }) \tag{5.8}$$

Here, the terms represented by $\cdots$ are the derivatives of the last three diagrams in Eq. (4.27).

From Eq. (1.5), or $h_{12} = h_{12}^{(0)}[v^{(0)}]$, and from Eq. (5.6), we have

$$h_{12} = e^{-\beta v_{12}^{(0)}} - 1 \quad [-\beta v_{12}^{(0)} = \ln(h_{12} + 1)]. \tag{5.9}$$

This implies

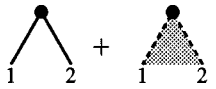
$$f_{12}|_{v \to v(0)} = h_{12}. \tag{5.10}$$

Equation (1.6) in this case can be written as

$$\int d1' \int d2' \, \frac{\delta h_{12}^{(0)}[v^{(0)}]}{\delta v_{1'2'}^{(0)}} \, v_{1'2'}^{(1)} + h_{12}^{(1)}[v^{(0)}] = 0, \tag{5.11}$$

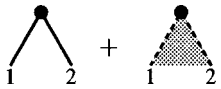
which reduces to (see Appendix B)

$$-\beta(1+h_{12})v_{12}^{(1)} + (1+h_{12})\Big(\quad + \quad \Big) = 0. \tag{5.12}$$



Thus, we have

$$\beta v_{12}^{(1)} = \quad + \quad . \tag{5.13}$$



In the above diagrams the (pseudo) 2-bonds are not f-bonds but (pseudo) h-bonds due to the replacement $v \to v^{(0)}$ in the inversion formula (1.6) [see Eq. (5.10)]. Similarly the 2-bonds and the pseudo 2-bonds appearing in the following diagrams should all be associated with h_{ij} and $1+h_{ij}$, respectively (see Table I).

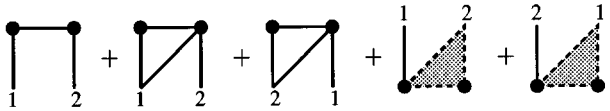
The terms in Eq. (1.7) are calculated as follows (see Appendix B):

$$\phi^{(0)\prime} J^{(2)} = -\beta(1+h_{12})v_{12}^{(2)}, \tag{5.14}$$

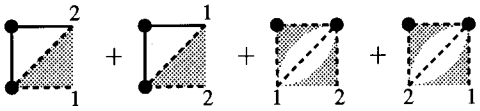
$$\frac{1}{2}\phi^{(0)\prime\prime}(J^{(1)})^2 \to (1+h_{12})\Big(\quad + \quad + \quad \Big), \tag{5.15}$$

$$\phi^{(1)\prime} J^{(1)} \to -(1+h_{12})\Big(2\Big(\quad + \quad + \quad \Big)$$

$$+2 \quad + \quad + \quad + \quad + \quad$$



$$+ \quad + \quad + \quad + \quad \Big). \tag{5.16}$$

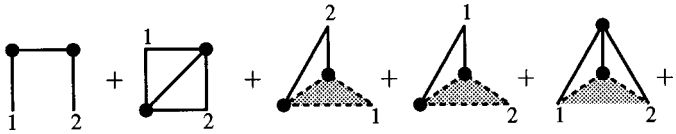


By substituting these results in Eq. (1.7), we see that all the 2-reducible diagrams except

exactly cancel out. Here, the 2-reducible diagrams are defined as follows. First, we make a 0-diagram from the diagram by connecting external points 1,2 by a (pseudo) 2-bond along with n_1, n_2 and then by integrating the diagram over the variables 1, 2. (The 0-diagram, here, is a diagram which has no external points and white circles.) Then the original diagram is 2-reducible if the resultant 0-diagram is the one in which there is at least one pair of circles the deletion of which leads to a separation of the diagram.

From Eqs. (5.14) to (5.16), we have

$$\beta v_{12}^{(2)} = - \quad + \quad + \quad + \quad + \quad + \cdots, \tag{5.17}$$



where $\cdots$ represents derivatives of the last three diagrams in Eq. (4.27).

We have derived v_{12} explicitly up to the second order in n_1 (black circle) and in principle we can continue such a calculation up to the desired order. Then the inversion series is given by

$$\beta v_{12} = \beta v_{12}^{(0)} + \beta v_{12}^{(1)} + \beta v_{12}^{(2)} + \cdots, \tag{5.18}$$

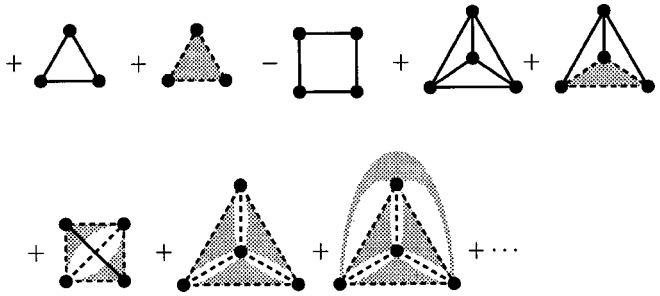
where $\beta v_{12}^{(i)}$ $(i=0,1,2)$ are given in Eqs. (5.9), (5.13), and (5.17). As we see below in Eq. (5.35), Eq. (5.18) can be regarded as the on-shell condition and as a generalization of some equations familiar in the theory of simple liquids.

Now we can integrate the inversion series (5.18) to get a generating functional $\Gamma_2[n,h,w]$ due to the relation $\beta v=-2\beta\delta\Gamma_2[n,h,w]/\delta\rho^{(2)}$, or

$$\beta v_{12}=-\beta\frac{2}{n_1n_2}\frac{\delta\Gamma_2[n,h,w]}{\delta h_{12}}, \tag{5.19}$$

and the result is given by

$$-\beta\Gamma_2=\int d1n_1(1-\ln n_1-3\ln\Lambda)+\frac{1}{2}\int d1\int d2n_1n_2[h_{12}-(1+h_{12})\ln(1+h_{12})]$$



(5.20)

We stress here that in the above diagram circles, 2-bonds, and pseudo 2-bonds are associated with n_i, h_{ij} and $1+h_{ij}$, respectively, and thus all the diagrams are functional of n_i, h_{ij}, and w_{ijk}. All the diagrams up to the fourth order of n_i are explicitly shown in Eq. (5.20). As stated before, from this expression we can readily obtain the entropy for the system without the triplet potential, which coincides with the expression given in Ref. 1.

If we neglect the triplet potential, Eq. (5.20) reduces to the standard expression for the thermodynamic potential renormalized by one-particle density:[1,2]

$$-\beta\Omega=\int d1n_1(1-\ln n_1+\ln z-\beta u_1)-\frac{\beta}{2}\int d1\int d2\rho_{12}^{(2)}v_{12}$$
$$+\frac{1}{2}\int d1\int d2n_1n_2\{h_{12}-[1+h_{12}]\ln[1+h_{12}]\}+\mathcal{N}[n,h]+\mathcal{K}^{(2)}[n,h]. \tag{5.21}$$

$\mathcal{N}[n,h]$ are made up of polygonal diagrams and, if we regard $[nh]_{12}\equiv n_1h_{12}$ is the (1,2) element of the functional matrix $[nh]$, it is given by

$$\mathcal{N}[n,h]=-\sum_{p=3}^{\infty}\frac{(-1)^p}{2p}\mathrm{Tr}[nh]^p=\frac{1}{2}\mathrm{Tr}\left[\ln(1+nh)-nh+\frac{1}{2}(nh)^2\right]. \tag{5.22}$$

$\mathcal{K}^{(2)}[n,h]$ is the whole class of the 2-irreducible (2IR) diagrams built up with n-circles and h-bonds. Here, a 2IR diagram is the one in which the deletion of any pair of the black circles does not cause a separation of the diagram.

In the conventional definition, a 2-irreducible diagram consists of circles and 2-bonds but not of 3-bonds and pseudo 2-bonds. However, in the following, we include such diagrams consisting of 3-bonds and pseudo 2-bonds into the definition of 2IR diagrams, and call the whole class of such 2IR diagrams $\mathcal{K}^{(2)}[n,h,w]$ instead of $\mathcal{K}^{(2)}[n,h]$. Then, Eq. (5.20) is equivalent to Eq. (5.21) where $\mathcal{K}^{(2)}[n,h]$ is replaced by $\mathcal{K}^{(2)}[n,h,w]$.

The on-shell condition for the second Legendre transformation [the first two equations in (2.22)] are equivalent to

$$\frac{\delta\Gamma_2[n,h,w]}{\delta n_1} = -\tilde{u}_1 - \int d2\, n_2(1+h_{12})v_{12}, \tag{5.23}$$

$$\frac{\delta\Gamma_2[n,h,w]}{\delta \frac{1}{2} h_{12}} = -n_1 n_2 v_{12}, \tag{5.24}$$

from which we have

$$\ln z - \ln n_1 + \int d2\, n_2\{h_{12} - (1+h_{12})\ln(1+h_{12})\} + \frac{\delta\mathscr{N}[n,h]}{\delta n_1} + \frac{\delta\mathscr{Z}^{(2)}[n,h,w]}{\delta n_1}$$
$$= \beta u_1 + \beta \int d2\, n_2(1+h_{12})v_{12}, \tag{5.25}$$

$$-\ln(1+h_{12}) + \frac{2}{n_1 n_2}\left(\frac{\delta\mathscr{N}[n,h]}{\delta h_{12}} + \frac{\delta\mathscr{Z}^{(2)}[n,h,w]}{\delta h_{12}}\right) = \beta v_{12}, \tag{5.26}$$

where

$$\frac{\delta\mathscr{N}[n,h]}{\delta n_1} = \frac{1}{2}\left(h\cdot\frac{1}{1+[nh]} - h + h\cdot[nh]\right)_{11}, \tag{5.27}$$

$$\frac{2}{n_1 n_2}\frac{\delta\mathscr{N}[n,h]}{\delta h_{12}} = \left(h - h\,\frac{1}{1+[nh]}\right)_{12}. \tag{5.28}$$

This set of equations, corresponding to Eq. (4.30) in the previous section, is to be solved self-consistently for the two variables n and h. In the above, h and $[nh]$ stand for the functional matrix as before. The diagrammatic expression for the sum of derivatives of $\mathscr{N}[n,h]$ or $\mathscr{Z}[n,h,w]$ in Eq. (5.25) and in Eq. (5.26) can be easily obtained from the diagrams in Eq. (5.20) by removing, in all possible ways, one of the black circles and one of the (pseudo) 2-bonds (along with two black circles at the both ends), respectively.

If we introduce the direct correlation function $c(\mathbf{r}_1,\mathbf{r}_2)=c_{12}$ by the so-called Ornstein–Zernike relation,

$$h_{12} = c_{12} + \int d3\, c_{13} n_3 h_{32}, \tag{5.29}$$

or, in our simplified notation,

$$h = c + c\cdot[nh] = c + c\cdot[nc] + c\cdot[nc]^2 + \cdots, \tag{5.30}$$

we have

$$c = h - c\cdot[nh] = h - h\cdot[nh] + h\cdot[nh]^2 - \cdots = h\,\frac{1}{1+[nh]}. \tag{5.31}$$

Thus we obtain

$$\frac{\delta\mathscr{N}[n,h]}{\delta n_1} = \frac{1}{2}\,(c - h + h\cdot[nh])_{11}, \tag{5.32}$$

$$\frac{2}{n_1 n_2}\frac{\delta\mathscr{N}[n,h]}{\delta h_{12}} = h_{12} - c_{12}, \tag{5.33}$$

from which we have

$$\ln z-\ln n_1+\int d2n_2\{h_{12}-(1+h_{12})[\ln(1+h_{12})+\beta v_{12}]\}+\frac{1}{2}\left(c_{11}-h_{11}+\int d2h_{12}n_2h_{21}\right)$$
$$+\frac{\delta\mathscr{K}^{(2)}[n,h,w]}{\delta n_1}=\delta u_1, \tag{5.34}$$

$$-\ln(1+h_{12})+h_{12}-c_{12}+\frac{2}{n_1n_2}\frac{\delta\mathscr{K}^{(2)}[n,h,w]}{\delta h_{12}}=\beta v_{12}. \tag{5.35}$$

Note here that c_{12} and the derivatives of $\mathscr{K}^{(2)}[n,h,w]$ are explicitly given as functionals of n and h. This set of equations are self-consistent equations for n_i,h_{ij}, which is equivalent to the set of (5.25) and (5.26), and Eq. (5.35) can be regarded as another expression of the inversion series (5.18), as stated above.

The inversion series (5.35), obtained as the on-shell condition, is a generalization of a familiar exact relation,

$$h_{12}-c_{12}-\ln(1+h_{12})=\beta v_{12}-d_{12}, \tag{5.36}$$

which was derived by van Leenwen *et al.*,[4] if d_{12}, originally given by the f-bond expansion, is rewritten as an h-bond expansion.

The hypernetted-chain (HNC) approximation,

$$h_{12}-c_{12}-\ln(1+h_{12})=\beta v_{12}, \tag{5.37}$$

is reproduced if we neglect all the 2IR diagrams in Eq. (5.35).

The Percus–Yevick (PY) approximation can be expressed as

$$\beta v_{12}+\ln(1+h_{12})=\ln(1+h_{12}-c_{12}), \tag{5.38}$$

implying the approximation

$$h_{12}-c_{12}+\frac{2}{n_1n_2}\frac{\delta\mathscr{K}^{(2)}[n,h,w]}{\delta h_{12}}\simeq\ln(1+h_{12}-c_{12}). \tag{5.39}$$

VI. INVERSION FROM TRIPLET POTENTIAL TO THREE-PARTICLE DENSITY

In this section we renormalize the theory in terms of three-particle density by using the inversion method. To this end we try to identify ϕ in the inversion formulae with the two-particle density $n_{12}\equiv\rho^{(2)}(\mathbf{r}_1,\mathbf{r}_2)$. The diagram expression for n_{123} can be easily obtained from that for Γ_2 if we notice that the differentiation by the three-particle potential w_{123} removes one of the 3-bonds with making black circles of the three ends white circles if we multiply the resultant diagram by a factor $1+t_{123}$. This is understood from the relations

$$-\beta n_{123}=-\beta\frac{\delta\Omega[u,v,w]}{\delta\frac{1}{3!}w_{123}}=-\beta\frac{\delta\Gamma_2[n,h,w]}{\delta\frac{1}{3!}w_{123}} \tag{6.1}$$

and

$$\frac{\delta t_{123}}{\delta\frac{1}{3!}w_{1'2'3'}}=-\beta(1+t_{123})[\delta_{11'}\delta_{22'}\delta_{33'}+(3!-1)\text{terms}]. \tag{6.2}$$

Then, we notice that all the diagrams of n_{123} have three white circles. This implies that, if we regard n_i as the expansion parameter of the inversion method, $n_{123}^{(0)}$ vanishes while the inversion

method assumes non-zero $\phi^{(0)}$. In addition, since, in all the diagrams of $\Gamma_2[n,h,w]$, every t_{ijk} is accompanied by a factor $n_i n_j n_k(1+h_{ij})(1+h_{jk})(1+h_{ki})$, it is convenient to identify ϕ not with n_{123} but with γ_{123} defined by

$$\gamma_{123}=\frac{n_{123}}{n_1 n_2 n_3(1+h_{12})(1+h_{23})(1+h_{31})}-1. \tag{6.3}$$

Then this quantity is diagrammatically given as

$$\gamma_{123}=\gamma_{123}^{(0)}+\gamma_{123}^{(1)}+\cdots, \tag{6.4}$$

where

$\gamma_{123}^{(0)} =$ 
, (6.5)

$\gamma_{123}^{(1)} = (1+t_{123})($ 
$).$ (6.6)

From Eq. (1.5), or $\gamma_{123}=\gamma_{123}^{(0)}[w^{(0)}]$, and from Eq. (6.5), we have

$$\gamma_{123}=e^{-\beta w_{123}^{(0)}}-1 \quad [-\beta w_{123}^{(0)}=\ln(\gamma_{123}+1)]. \tag{6.7}$$

This implies

$$t_{123}|_{w\to w^{(0)}}=\gamma_{123}. \tag{6.8}$$

Equation (1.6) in this case can be written as

$$\int d1'\int d2'\int d3'\,\frac{\delta\gamma_{123}^{(0)}[w^{(0)}]}{\delta w_{1'2'3'}^{(0)}}\,w_{1'2'3'}^{(1)}+\gamma_{123}^{(1)}[w^{(0)}]=0, \tag{6.9}$$

where

$$\frac{\delta\gamma_{123}^{(0)}[w^{(0)}]}{\delta w_{1'2'3'}^{(0)}}=-\frac{\beta}{3!}\,(1+\gamma_{123})[\,\delta_{11'}\delta_{22'}\delta_{33'}+(3!-1)\text{terms}]. \tag{6.10}$$

Thus, we have

$\beta w_{123}^{(1)} =$ 
(6.11)

Here, the 3-bonds should be associated not with t_{ijk} but with γ_{ijk} [see Eq. (6.8) and Table I].

We have derived w_{123} explicitly up to the first order in n_1 (black circle) and in principle we can continue such a calculation up to the desired order. Then the inversion series is given as

$$\beta w_{123}=\beta w_{123}^{(0)}+\beta w_{123}^{(1)}+\beta w_{123}^{(2)}+\cdots , \tag{6.12}$$

where $\beta w_{123}^{(i)}$ $(i=0,1)$ are given in Eqs. (6.7) and (6.11). As we see below in Eq. (6.20), this inversion series can be obtained from the on-shell condition and can be seen as a series which systematically improve the Kirkwood's approximation for the three-particle density.

Now we can integrate the inversion series (6.12) to get a generating functional $\Gamma_3[n,h,\gamma]$ due to the relation $\beta w=-3!\beta\delta\Gamma_3[n,h,\gamma]/\delta\rho^{(3)}$, or

$$\beta w_{123}=-\beta\,\frac{3!}{n_1n_2n_3(1+h_{12})(1+h_{23})(1+h_{31})}\,\frac{\delta\Gamma_3[n,h,\gamma]}{\delta\gamma_{123}}, \tag{6.13}$$

and the result is given by

$$-\beta\Gamma_3=\int d1n_1(1-\ln n_1-3\ln\Lambda)+\frac{1}{2}\int d1\int d2n_1n_2[h_{12}-(1+h_{12})\ln(1+h_{12})]$$

$$+\frac{1}{3!}\int d1\int d2\int d3n_1n_2n_3(1+h_{12})(1+h_{23})(1+h_{31})[\gamma_{123}-(1+\gamma_{123})\ln(1+\gamma_{123})]$$

 (6.14)

In the above diagrams, the 3-bonds are not t-bonds but γ-bonds due to the replacement $w\to w^{(0)}$ in the inversion formula (1.6) [see Eq. (6.8) and Table 1]. We stress here that, in the above diagram, circles, 2-bonds, pseudo 2-bonds, and 3-bonds are associated with n_i, h_{ij}, $1+h_{ij}$, and γ_{ijk}, respectively, and thus all the diagrams are functional of n_i, h_{ij}, and γ_{ijk}. All the diagrams up to the fourth order of n_i are explicitly shown in Eq. (6.14).

From Eq. (6.14), the renormalized entropy S/k of the system can be easily obtained as a functional of one- to three-particle densities due to the relation $S/k=-\beta\Gamma_3+(3/2)\int d1n_1$, as stated earlier. This result for the entropy should be compared with the previously known result, for example, given in Ref. 8. Up to the third order (in n_i), these two coincide with each other. However, above this order, they look different. For example, while the fourth order of $\Delta S/k$ given in Ref. 8 includes the four-particle density, our expression does not contain the four-particle density and is written in terms of only one- to three-particle densities. This implies that, for the system without higher-body potential than 3-body, the four-particle density can be written in terms of one- to three-particle densities.

The result (6.14) was suggested in Ref. 2, where the diagrammatic part is collectively called $\mathscr{T}[n,h,\gamma]$. In there, $\mathscr{T}[n,h,\gamma]$ is not defined explicitly and any diagrams contained in it are not presented, unfortunately.

The on-shell conditions for the third Legendre transformation [the three equations in (2.23)] are equivalent to

$$\frac{\delta\Gamma_3}{\delta n_1}=-u_1-\int d2n_2(1+h_{12})v_{12}-\frac{1}{2}\int d2d3n_2n_3(1+h_{12})(1+h_{23})(1+h_{31})(1+\gamma_{123})w_{123}, \tag{6.15}$$

$$\frac{\delta\Gamma_3}{\delta h_{12}}=-\frac{1}{2}n_1n_2v_{12}-\frac{1}{2}n_1n_2\int d3n_3(1+h_{23})(1+h_{31})(1+\gamma_{123})w_{123}, \tag{6.16}$$

$$\frac{\delta\Gamma_3}{\delta\gamma_{123}}=-\frac{1}{3!}n_1n_2n_3(1+h_{12})(1+h_{23})(1+h_{31})w_{123}, \tag{6.17}$$

from which we have

$$\ln z-\ln n_1+\int d2n_2[h_{12}-(1+h_{12})\{\ln(1+h_{12})+\beta v_{12}\}]+\frac{1}{2}\int d2d3n_2n_3(1+h_{12})(1+h_{23})$$

$$\times(1+h_{31})[\gamma_{123}-(1+\gamma_{123})\{\ln(1+\gamma_{123})+\beta w_{123}\}]+\frac{\delta\mathscr{T}}{\delta n_1}=\beta u_1, \tag{6.18}$$

$$-\ln(1+h_{12})+\int d3n_3(1+h_{23})(1+h_{31})[\gamma_{123}-(1+\gamma_{123})\{\ln(1+\gamma_{123})+\beta w_{123}\}]$$

$$+\frac{2}{n_1n_2}\frac{\delta\mathscr{T}}{\delta h_{12}}=\beta v_{12}, \tag{6.19}$$

$$-\ln(1+\gamma_{123})+\frac{3!}{n_1n_2n_3(1+h_{12})(1+h_{23})(1+h_{31})}\frac{\delta\mathscr{T}}{\delta\gamma_{123}}=\beta w_{123}. \tag{6.20}$$

This set of equations, corresponding to the set of (5.25) and (5.26) in the previous section, is to be solved for the three variables n, h, and γ.

This set can also be seen as a generalization of Eqs. (6)–(8) in Ref. 12. If we approximate $\mathscr{T}$ by the fifth term in Eq. (5) in Ref. 12, which is originally obtained in Ref. 11, this set of equations here reduce to Eqs. (6)–(8) in Ref. 12. However, we notice that our diagrammatic expression for $\mathscr{T}$ does not have diagrams directly corresponding to the fifth term in Eq. (5) in Ref. 12. This is because this fifth term originates from the last term in Eq. (4) of Ref. 12, and this term, which should be equal to $\mathscr{T}$ for the system without higher order potential than the third, contains correlation functions of up to the infinite order while $\mathscr{T}$ here contains correlation functions up to the third order.

As mentioned above, Eq. (6.20) can be expressed as

$$\beta w_{123}=\beta w^{(0)}+\beta w^{(1)}+\beta w^{(2)}+\cdots, \tag{6.21}$$

where

$$\beta w^{(0)}=-\ln(1+\gamma_{123}), \tag{6.22}$$

$$\beta w^{(1)}=\int d4n_4h_{41}h_{42}h_{23}+\cdots, \tag{6.23}$$

where $\cdots$ represents γ-dependent terms which correspond to the last seven diagrams in Eq. (6.11).

Equation (6.21) or (6.20) can be related to some of the previously known approximations. If we truncate the inversion series (6.21) at $i=0$, we obtain the well-known approximation $\gamma_{123}=e^{-\beta w_{123}}-1$ (for example, see Ref. 12). At $w_{123}=0$, this approximation reduces to the Kirkwood's superposition approximation,

$$n_{123}=n_1n_2n_3(1+h_{12})(1+h_{23})(1+h_{31}). \tag{6.24}$$

If we truncate the series at $i=1$ and further neglect the γ-dependent terms in $\beta w^{(1)}$ (with $w_{123}=0$), we get the first order approximation given in Ref. 24,

$$n_{123}=n_1n_2n_3(1+h_{12})(1+h_{23})(1+h_{31})\exp\left[\int d4n_4h_{41}h_{42}h_{43}\right]. \tag{6.25}$$

Equation (6.25) with h-bonds in the exponential replaced by f-bonds had also been studied (see, for example, Refs. 21–23).

Thus, in our formulation, the zero-th order approximation reproduces the superposition approximation and the first order approximation, which is the solution of the equation [obtained from Eq. (6.11)],

$$\begin{aligned}\beta w_{123}=&-\ln(1+\gamma_{123})+\int d4n_4h_{41}h_{42}h_{43}+\int d4n_4h_{41}(1+h_{42})(1+h_{43})\gamma_{423}\\&+\int d4n_4h_{42}(1+h_{41})(1+h_{43})\gamma_{413}+\int d4n_4h_{43}(1+h_{41})(1+h_{42})\gamma_{412}\\&+\int d4n_4(1+h_{41})(1+h_{42})(1+h_{43})(\gamma_{412}\gamma_{423}+\gamma_{421}\gamma_{413}+\gamma_{413}\gamma_{423})\\&+\int d4n_4(1+h_{41})(1+h_{42})(1+h_{43})\gamma_{412}\gamma_{423}\gamma_{431},\end{aligned} \tag{6.26}$$

contains more information than the first approximation in Ref. 24. Solving our first order approximation is practically an interesting problem, which is reserved for a future work. Further systematic improvement of the approximation is obtained if we calculate $\beta w^{(2)},\beta w^{(3)},\ldots$, by the inversion method.

VII. DISCUSSION

In this paper, we applied the inversion method to a classical system and renormalized liquid theory in terms of one-, two-, and three-particle densities in the presence of the three-body potential. Our approach here complements the previously known re-summation techniques. We showed that the entropy functional can be expressed by up to three-particle densities and gave lower order diagrams of the entropy explicitly. We also pointed out that the stationary conditions for the entropy leads to a set of self-consistent equations. In a certain case, the self-consistent equation can be a base for a systematic advancement of the Kirkwood's superposition approximation.

Some of the results presented here are mere repetition or only a slight extension of the well-known results as suggested frequently in the text. We could not avoid mixing up known and unknown results to explain our approach explicitly. Here, we appreciate and clarify to what extent these results can be considered original. In Section II, the introduction of Γ_3 and its relation to the entropy seems a rather novel viewpoint. In Sections III–V, all the results are at least implied in the previous literature (see, for example, Ref. 19). However, we pointed out that, if one introduces the pseudo 2-bonds, the diagrams of Ω and Γ_n in the presence of the 3-body potential can be written economically and we gave the diagrams of (up to) the fourth order ($\Omega^{(4)}$, etc.) explicitly; otherwise the number of diagrams is too many to be included in a paper—this may be one reason the fourth order diagrams (in the presence of the 3-body potential) have not been given explicitly in the literature. In addition, the derivation of Γ_n based on the inversion method has originality and complements the previously known ways. The results in Sec. VI are the renormalization in terms

of one-, two-, and three-particle densities. In that the entropy does not include more-than-three-particle densities, this explicit diagrammatic result may be original. The result reduces to some previously known approximations in special cases.

The present work can be related to the work by Stell[19] in the following way. In the second article in Ref. 19, he gave diagrammatic rules for some correlation functions in terms of ρ_1, h_2, and f_s (where $s \geqslant 3$) in his notation. In the special case where there are no more-than-three-body potentials, his result can be regarded as the diagrammatic rule in terms of one- and two-particle densities and the three-body potential. (Notice here that his f_3 is our t_{ijk}.) This corresponds to the description by Γ_2, which is still a functional of the three-body potential w_{123} (or f_3), in our language: the theory is renormalized up to the two-particle densities. In the present work, though it is limited to the special case (without m-body potential where $m \geqslant 4$), we further changed the variable w_{ijk} (or f_3) of the theory to the three-particle density $\rho^{(3)}$ or γ_{ijk}. This is accomplished by use of Γ_3, which is a functional of $\rho^{(3)}$, and then the theory is renormalized up to the three-particle density. For example, $w_3(123)$ in Eq. (3.12) of the second article in Ref. 19 (which is expressed in terms of $\rho^{(1)}$, h_{ij}, and t_{ijk}), coincides with the second term on the left-hand side of Eq. (6.20) of this article (which is expressed in terms of $\rho^{(1)}$, h_{ij}, and γ_{ijk}), when renormalized up to the three-particle densities by changing the variable from t_{ijk} to γ_{ijk}.

ACKNOWLEDGMENT

The author would like to thank Professor Fumio Hirata for an informative discussion.

APPENDIX A: USEFUL FORMULAE FOR THE INVERSION FROM ONE-PARTICLE POTENTIAL TO ONE-PARTICLE DENSITY

In this appendix, we present useful formulae for the inversion process. Below $\phi^{(i)\prime\cdots\prime}$ stands for $\delta^k n_1^{(i)}[u^{(0)}]/\delta\tilde{u}_{1'}^{(0)}\delta\tilde{u}_{2'}^{(0)}\cdots\delta\tilde{u}_{k'}^{(0)}$:

$$\phi^{(0)\prime} \to -\beta\delta_{11'} \quad 1 \tag{A1}$$

$$\phi^{(0)\prime\prime} \to (-\beta)^2\delta_{11'}\delta_{12'} \quad 1 \tag{A2}$$

[28] If we consider the system without the three-body force, $w(\mathbf{r},\mathbf{r}',\mathbf{r}'')$ here is artificial. We can still extract new information, which otherwise could not be obtained, by setting $w(\mathbf{r},\mathbf{r}',\mathbf{r}'')=0$ at the end (as mentioned before).
[29] The two-particle density can also be obtained by noting the following relation:
$$-(1/\beta)[\,\delta^2\Omega/\delta u(\mathbf{r})\,\delta u(\mathbf{r}')\,]=\langle\rho_N^{(1)}(\mathbf{r})\rho_N^{(1)}(\mathbf{r}')\rangle-\langle\rho_N^{(1)}(\mathbf{r})\rangle\langle\rho_N^{(1)}(\mathbf{r}')\rangle=\rho^{(2)}(\mathbf{r},\mathbf{r}')+\delta(\mathbf{r}-\mathbf{r}')\rho^{(1)}(\mathbf{r})-\rho^{(1)}(\mathbf{r})\rho^{(1)}(\mathbf{r}'). \tag{B7}$$
The second equality can be understood from
$$\rho^{(2)}(\mathbf{r},\mathbf{r}')=\langle\rho_N^{(1)}(\mathbf{r})\rho_N^{(1)}(\mathbf{r}')\rangle=\delta(\mathbf{r}-\mathbf{r}')\rho^{(1)}(\mathbf{r}), \tag{B8}$$
which is obtained by taking the expectation of Eq. (2.4).
[30] We tacitly assume $\rho_N^{(1)}(\mathbf{r})=0$ for $N=0$, $\rho_N^{(2)}(\mathbf{r},\mathbf{r}')=0$ for $N=0$, 1, and $\rho_N^{(3)}(\mathbf{r},\mathbf{r}',\mathbf{r}'')=0$ for $N=0,1,2$.
[31] K. Okumura, Prog. Theor. Phys. **87**, 703 (1992).
[32] The right-hand side of Eq. (3.1) can be expressed by a sum of all possible diagrams built up with the four elements (black circles, 2-bonds, 3-bonds, and pseudo 2 ponds), which includes disconnected diagrams. Here, as suggested in the text, if there is a 3-bond, every pair from the triplet (connected by the 3-bond) should be connected by a pseudo 2-bond. On the other hand, due to the operation of logarithm, $-\beta\Omega$ does not include disconnected diagrams.

Integrable coupled KdV systems

We give the conditions for a system of N-coupled Korteweg de Vries (KdV) type of equations to be integrable. We find the recursion operators of each subclass and give all examples for $N=2$. © *1998 American Institute of Physics.* [S0022-2488(98)03003-5]

I. INTRODUCTION

In Ref. 1 we gave an extension of the recently proposed Svinolupov Jordan KdV[2,3] systems to a class of integrable multicomponent KdV systems and gave their recursion operators. This class is known as the degenerate subclass of the KdV system. In this work we will extend it to a more general KdV type of system equations containing both the degenerate and nondegenerate cases. This is a major step towards the complete classification of KdV systems. In addition we give a new extension of such a system of equations.

Let us consider a system of N nonlinear equations of the form

$$q_t^i = b_j^i q_{xxx}^j + s_{jk}^i q^j q_x^k, \tag{1}$$

where $i,j,k=1,2,...,N$, q^i are functions depending on the variables x, and t, and b_j^i, and S_{jk}^i are constants. The purpose of this work is to find the conditions on these constants so that the equations in (1) are integrable. In general the existence of infinitely many conserved quantities is admitted as the definition of integrability. This implies the existence of infinitely many generalized symmetries. In this work we assume the following definition for integrability:

Definition: A system of equations is said to be integrable if it admits a recursion operator.

The recursion operator (if it exists) of the system of equations given in (1), in general, may take a very complicated form. Let the highest powers of the operators D and D^{-1} be respectively defined by $m=$degree of R and $n=$order nonlocality of R. In this work we are interested in a subclass of equations admitting a recursion operator with $m=2$ and $n=1$. Namely, it is of the form

$$R_j^i = b_j^i D^2 + a_{jk}^i q^k + c_{jk}^i q_x^k D^{-1}, \tag{2}$$

where D is the total x derivative, D^{-1} is the inverse operator, and a_{jk}^i and c_{jk}^i are constants with

$$s_{jk}^i = a_{kj}^i + c_{jk}^i. \tag{3}$$

Before starting to the classification of (1) we recall a few fundamental properties of the recursion operator. An operator R_j^i is a recursion operator if it satisfies the following equation

$$R_{j,t}^i = F_k'^i R_j^k - R_k^i F_j'^k, \tag{4}$$

where $F_k'^i$ is the Fréchet derivative of the system (1), which is given by

$$\sigma_t^i = F_j'^i \sigma^j, \tag{5}$$

 © 1998 American Institute of Physics

where σ^i's are called the symmetries of the system (1). The condition (3) implies that Eq. (1) itself is assumed to be in the family of the hierarchy of equations (or flows)

$$q^i_{\tau_n}=\sigma^i_n,$$

where for all $n=0,1,...$, σ^i_n denotes the symmetries of the integrable KdV system (1). For instance, for $n=0,1$ we have respectively the classical symmetries $\sigma^i_0=q^i_x$ and $\sigma^i_1=q^i_t$.

Equation (5) is called the symmetry equation of (1) with

$$F'^{\,i}_j=b^i_jD^3+s^i_{jk}q^k_x+s^i_{kj}q^kD. \tag{6}$$

Recursion operators are defined as operators mapping symmetries to symmetries, i.e.,

$$R^i_j\sigma^j=\lambda\sigma^i, \tag{7}$$

where λ is an arbitrary constant. Equations (5) and (7) imply (4). It is the equation (4) which determines the constants a^i_{jk} and c^i_{jk} in terms of b^i_j and s^i_{jk}'s. The same equation (4) brings severe constraints on b^i_j and s^i_{jk}.

We shall obtain a classification of (1) based on the matrix b^i_j,

(i) $\det(b^i_j)=0$,
(ii) $\det(b^i_j)\neq 0$,

and also we divide the classification procedure, for each class, into two parts where $s^i_{jk}=s^i_{kj}$ and $s^i_{jk}\neq s^i_{kj}$. For the system of equations admitting a recursion operator we have the following proposition.

Proposition 1: Let $q^i(t,x)$ be functions of t and x satisfying the N KdV equations (1) and admitting a recursion operator R^i_j in (2). Then the constants b^i_j, s^i_{jk}, a^i_{jk}, and c^i_{jk} satisfy [in addition to the (3)] the following relations:

$$b^k_lc^i_{jk}-b^i_kc^k_{jl}=0, \tag{8}$$

$$b^k_la^i_{jk}-b^i_k(a^i_{jl}+3c^k_{jl}-s^k_{jl})=0, \tag{9}$$

$$b^i_k(3a^k_{jl}+3c^k_{jl}-2s^k_{jl}-s^k_{lj})=0, \tag{10}$$

$$c^i_{jk}s^k_{lm}-s^i_{lk}c^k_{jm}=0, \tag{11}$$

$$c^i_{jk}s^k_{lm}+c^i_{jk}s^k_{ml}-c^k_{jm}s^i_{kl}-c^k_{jl}s^i_{km}=0, \tag{12}$$

$$a^i_{jk}s^k_{lm}-s^i_{km}a^k_{jl}-s^i_{lk}a^k_{jm}-s^i_{lk}c^k_{jm}+s^k_{jl}c^i_{km}+a^i_{kl}s^k_{jm}=0, \tag{13}$$

$$c^i_{km}(s^k_{pj}-s^k_{jp})=0. \tag{14}$$

Now we will discuss the problem of classifying the integrable system of equations (1) for the two exclusive cases depending upon the matrix b^i_j.

II. CLASSIFICATION FOR THE CLASS $\det(b^i_j)=0$

In this subclass we assume the rank of the matrix b^i_j as $N-1$. Investigation of the subclasses for other ranks of matrix b can be done similarly. For this case we may take $b^i_j=\delta^i_j-k^ik_j$ where k_i is a unit vector, $k^ik_i=1$. In this work we use the Einstein convention, i.e., repeated indices are summed up from 1 to N. We find the following solution of (8)–(14) for the parameters a^i_{jk} and c^i_{jk} for all N

Proposition 2: Let k^i be a constant unit vector and $b^i_j=\delta^i_j-k^ik_j$. Then the complete solutions of the equations (8)–(14) are given by

$$a^i_{lj}=\tfrac{2}{3}s^i_{jl}+\tfrac{1}{3}[k^i(k_ja_l-2k_ln_j)+(-ak^i+b^i)k_lk_j],$$
$$c^i_{jl}=\tfrac{1}{3}s^i_{lj}-\tfrac{1}{3}[k^i(k_la_j+k_jn_l)+(-ak^i+b^i)k_lk_j]+k^ik_ln_j, \tag{15}$$

where

$$n_j=k^kk_is^i_{jk}-ak_j, \quad a_j=k^kk_is^i_{kj}-nk_j, \quad b^i=k^lk^ks^i_{lk}-nk^i, \tag{16}$$

$a=k^na_n$, $n=k^in_i$ and s^i_{jk}'s are subject to satisfy the following:

$$c^i_{jk}s^k_{lm}=c^k_{jm}s^i_{lk}, \tag{17}$$

$$s^i_{jk}-s^i_{kj}=k^i[k_j(a_k-n_k)-k_k(a_j-n_j)], \tag{18}$$

$$k_ns^n_{lj}=n_lk_j+k_la_j, \tag{19}$$

$$k^ns^i_{jn}=k^in_j+b^ik_j, \tag{20}$$

$$k^ns^i_{nj}=(n-a)k^ik_j+k^ia_j+b^ik_j, \tag{21}$$

$$n[(a_i-n_i)k_j-(a_j-n_j)k_i]=0, \tag{22}$$

$$a_i=\rho n_i+ak_i, \tag{23}$$

where ρ is a constant. At this point we will discuss the classification procedure with respect to the symbol s^i_{jk} whether it is symmetric or nonsymmetric with respect to its lower indices.

A. The symmetric case, $s^i_{jk}=s^i_{kj}$

Among the constraints listed in Proposition 2 the one given in (22) implies that s^i_{jk}'s are symmetric if and only if $a_i-n_i=\alpha k_i$ where $\alpha=a-n$. There are two distinct cases depending on whether $n=0$ or $n\neq 0$. We shall give these two subcases as corollaries of the previous proposition.

Corollary 1: Let $s^i_{jk}=s^i_{kj}$ and $n=0$. Then we have the following solution for all N:

$$a^i_{kj}=\tfrac{2}{3}s^i_{jk}+\tfrac{1}{3}[k^i(k_ja_k-2k_kn_j)+k_kk_jb^i],$$
$$c^i_{jk}=\tfrac{1}{3}s^i_{jk}-\tfrac{1}{3}[k^i(k_ja_k-2k_kn_j)+k_kk_jb^i], \tag{24}$$

where $a=0$, $\rho=1$, and

$$a_l=n_l, n_l=k_ik^js^i_{lj}, b^i=k^jk^ls^i_{lj}. \tag{25}$$

The vector k^i and s^i_{jk} are not arbitrary; they satisfy the following constraints:

$$s^i_{jk}s^k_{lm}-s^i_{lk}s^k_{jm}=-2(k_jn_l-k_ln_j)(-k^in_m+b^ik_m),$$
$$k_ns^n_{lj}=n_lk_j+k_ln_j, \quad k^ns^i_{jn}=k^in_j+b^ik_j. \tag{26}$$

As an illustration we give an example for this case.[1] A particular solution of the equations (26) for $N=2$ is

$$b^i_j=\delta^i_j-y^iy_j=x^ix_j,$$
$$s^i_{jk}=\frac{3}{2}\alpha_1x^ix_jx_k+\alpha_2x^iy_jy_k+\frac{\alpha_1}{2}y^i(y_jx_k+y_kx_j), \tag{27}$$

where $i,j=1,2$ and

$$x^i=\delta^i_1, y^i=\delta^i_2, \tag{28}$$

and

$$k_i=y_i, \quad n_i=\tfrac{1}{2}\alpha_1 x_i, \quad b^i=\alpha_2 x^i. \tag{29}$$

Constants a^i_{jk} and c^i_{jk} appearing in the recursion operator are given by

$$\begin{aligned} a^i_{jk}&=\alpha_1 x^i x_j x_k+\alpha_2 x^i y_j y_k+\frac{\alpha_1}{2} y^i x_j y_k, \\ c^i_{jk}&=\frac{\alpha_1}{2} x^i x_j x_k+\frac{\alpha_1}{2} y^i x_j y_k. \end{aligned} \tag{30}$$

Taking $\alpha_1=2$ and $\alpha_2=1$ (without loss of generality) we obtain the following coupled system

$$u_t=u_{xxx}+3uu_x+vv_x, \quad v_t=(uv)_x. \tag{31}$$

The above system was first introduced by Ito[4] and the multi-Hamiltonian structure studied by Antonowicz and Fordy[5] and by Olver and Rosenau.[6] The recursion operator of this system is given by

$$R=\begin{pmatrix} D^2+2u+u_xD^{-1} & v \\ v+v_xD^{-1} & 0 \end{pmatrix}. \tag{32}$$

In Ref. 1 we have another example for $N=3$.

For the case $n\neq 0$ for all N we have the following.

Corollary 2: Let $s^i_{jk}=s^i_{kj}$, $n\neq 0$, and $\rho=0$. Then the solution given in Proposition 2 reduces to

$$\begin{aligned} a^i_{lj}&=\tfrac{2}{3}s^i_{jl}+\tfrac{1}{3}(a-2n)k^ik_jk_l, \\ c^i_{jl}&=\tfrac{1}{3}s^i_{lj}-\tfrac{1}{3}(a-2n)k^ik_jk_l, \end{aligned} \tag{33}$$

where

$$n_j=nk_j, \quad a_j=ak_j, \quad b^i=ak^i, \tag{34}$$

and the constraint equations

$$s^i_{kj}s^k_{ml}-s^k_{mj}s^i_{kl}=0, \quad k_ns^n_{lj}=(a+n)k_lk_j, \quad k^ns^i_{jn}=(a+n)k^ik_j. \tag{35}$$

For this case we point out that solution of (33) and (35) gives decoupled systems.

B. The nonsymmetric case, $s^i_{jk}\neq s^i_{kj}$

In this case the constraints in Proposition 1, in particular (22), implies that we must have $n=0$. In this case we have the following expressions for a^i_{lj} and c^i_{lj} for all N:

$$\begin{aligned} a^i_{lj}&=\tfrac{2}{3}s^i_{jl}+\tfrac{1}{3}[k^i(k_ja_l-2k_ln_j)+(-ak^i+b^i)k_lk_j], \\ c^i_{jl}&=\tfrac{1}{3}s^i_{lj}-\tfrac{1}{3}[k^i(k_la_j+k_jn_l)+(-ak^i+b^i)k_lk_j]+k^ik_ln_j, \end{aligned} \tag{36}$$

where

$$\begin{aligned} n_j&=k^kk_is^i_{jk}-ak_j, \\ a_j&=k^kk_is^i_{kj}, \quad b^i=k^lk^ks^i_{lk}, \end{aligned} \tag{37}$$

and the constraint equations among the parameters are

$$c^i_{jk}c^k_{lm}-c^i_{lk}c^k_{jm}=0, \tag{38}$$

$$(a^i_{jk}-c^i_{jk})s^k_{lm}+(c^i_{km}-a^i_{km})s^k_{lj}+(s^i_{mk}-s^i_{km})a^k_{jl}+(s^k_{jm}-s^k_{mj})a^i_{kl}=0. \tag{39}$$

For $N=2$ we will give an example. Constants a^i_{jk} and c^i_{jk} appearing in the recursion operator are given by

$$\begin{aligned} a^i_{jk}&=\alpha_1 x^i x_j x_k+\alpha_2 x^i y_j y_k+\alpha_3 y^i x_j y_k,\\ c^i_{jk}&=\frac{\alpha_1}{2}x^i x_j x_k+\alpha_1 y^i x_j y_k, \end{aligned} \tag{40}$$

where α_1, α_2, and α_3 are arbitrary constants and

$$k_i=y_i, \quad n_i=\alpha_3 x_i, \quad b^i=\alpha_2 x^i, \quad a_i=\alpha_1 x_i. \tag{41}$$

We obtain the following coupled system:

$$\begin{aligned} u_t&=u_{xxx}+3\alpha_1 u u_x,\\ v_t&=\alpha_3 u_x v+\alpha_1 u v_x, \end{aligned} \tag{42}$$

which is equivalent to the symmetrically coupled KdV system[7]

$$\begin{aligned} u_t&=u_{xxx}+v_{xxx}+6uu_x+4uv_x+2u_x v,\\ u_t&=u_{xxx}+v_{xxx}+6vv_x+4vu_x+2v_x u, \end{aligned} \tag{43}$$

and the recursion operator for this integrable system of equations (42) is

$$R=\begin{pmatrix} D^2+\alpha_1(2u+u_xD^{-1}) & 0\\ \alpha_3 v+\alpha_1 v_x D^{-1} & 0 \end{pmatrix}. \tag{44}$$

III. CLASSIFICATION FOR THE CASE det $(b^i_j)\neq 0$

As in the degenerate case det $(b^i_j)=0$, we have two subcases, symmetric and nonsymmetric. Before these we have the following proposition.

Proposition 3: Let det $(b^i_j)\neq 0$. Then the solution of equations given Proposition 1 is given as follows:

$$\begin{aligned} a^i_{jl}&=\tfrac{2}{9}(s^i_{lj}+2s^i_{jl})-\tfrac{1}{9}C^k_l b^i_m K^m_{jk},\\ c^i_{lj}&=\tfrac{1}{9}(7s^i_{lj}-4s^i_{jl})+\tfrac{1}{9}C^k_l b^i_m K^m_{jk}, \end{aligned} \tag{45}$$

where

$$K^i_{lj}=s^i_{lj}-s^i_{jl} \tag{46}$$

and the constraint equations

$$b^k_l c^i_{jk}-b^i_k c^k_{jl}=0, \tag{47}$$

$$5C^m_i K^i_{rj}-C^l_r K^m_{lj}-C^l_j K^m_{rl}=0, \tag{48}$$

$$c^k_{jm}K^i_{lk}+c^k_{jl}K^i_{mk}=0, \tag{49}$$

$$c^i_{jk}s^k_{lm}-c^k_{jm}s^i_{lk}=0, \tag{50}$$

$$K^k_{lj}c^i_{km}=0, \tag{51}$$

$$(a^i_{jk}-c^i_{jk})s^k_{lm}+(c^i_{km}-a^i_{km})s^k_{lj}+K^i_{mk}a^k_{jl}+K^k_{jm}a^i_{kl}=0. \tag{52}$$

where C^i_r is the inverse of b^r_i.

A. The nonsymmetric case, $s^i_{jk}\neq s^i_{kj}$

Equations (47)–(52) define an over-determined system for the components of s^i_{jk}. Any solution of this system leads to the determination of the parameters a^i_{jl} and c^i_{jl} by (45).

As an example we give the following, for $N=2$, coupled system

$$v_t=av_{xxx}+2bvv_x,$$

$$u_t=4au_{xxx}+2bu_xv+buv_x, \tag{53}$$

where a and b are arbitrary constants. This system, under a change of variables, is equivalent to the KdV equation with the time evolution part of its Lax equation.[8] The recursion operator of the system (53) is

$$R=\begin{pmatrix} \frac{4}{3}(3aD^2+bv) & \frac{b}{3}(3u+2u_xD^{-1}) \\ 0 & \frac{1}{3}(3aD^2+4bv+2bv_xD^{-1}) \end{pmatrix}. \tag{54}$$

Hence the KdV equation coupled to time evolution part of its Lax-pair is integrable and its recursion operator is given above. This is the only new example for $N=2$ system.

B. The symmetric case, $s^i_{jk}=s^i_{kj}$

When the symbol s^i_{jk} is symmetric with respect to subindices, the parameters K^i_{jk} vanish. Then the equations (45)–(52) reduce to

$$a^i_{jk}=\tfrac{2}{3}s^i_{jk}, \quad c^i_{jk}=\tfrac{1}{3}s^i_{jk}, \tag{55}$$

where the parameters b^i_k and s^i_{jk} satisfy

$$b^k_l s^i_{jk}-b^i_k s^k_{jl}=0, \tag{56}$$

$$s^i_{jk}s^k_{lm}-s^i_{lk}s^k_{jm}=0. \tag{57}$$

We shall not study this class in detail, because in Ref. 1 some examples of this class are given for $N=2$. Here we give another example which correspond to the perturbation expansion of the KdV equation. Let $q^i=\delta^i u$, where $i=0,1,2,...,N$, and u satisfies the KdV equation $u_t=u_{xxx}+6uu_x$. The q^i's satisfy a system of KdV equations which belong to this subclass:

$$q^0_t=q^0_{xxx}+6q^0q^0_x, \tag{58}$$

$$q^1_t=q^1_{xxx}+6(q^0q^1)_x, \tag{59}$$

$$q^2_t=q^2_{xxx}+6[(q^1)^2+q^0q^2]_x, \tag{60}$$

$$\cdots. \tag{61}$$

$$q^N_t=q^N_{xxx}+3\sum_{i=1}^{N}[\delta^i(q^0)^2]_x. \tag{62}$$

IV. FOKAS–LIU EXTENSION

The classification of the KdV system given in this work with respect to the symmetries can be easily extended to the following simple modification of (1):

$$q_t^i = b_j^i q_{xxx}^j + s_{jk}^i q^j q_x^k + \chi_j^i q_x^j, \tag{63}$$

where χ_j^i's are arbitrary constants. Equation (63) without the last term will be called the principle part of that equation. Hence the equation (1) we have studied so far is the principle part of its modification (63). We assume the existence of a recursion operator corresponding to the above system in the form

$$R_j^i = b_j^i D^2 + a_{jk}^i q^k + c_{jk}^i q_x^k D^{-1} + w_j^i, \tag{64}$$

where w_j^i's are constants. We have the following proposition corresponding to the integrability of the above system.

Proposition 4: The operator given in (64) is the recursion operator of the KdV system (63) if in addition to the equations listed in Proposition 1 [(8)–(14)] the following constraints on the constants χ_j^i and w_j^i are satisfied:

$$\chi_l^k a_{jk}^i - \chi_k^i a_{jl}^k - \chi_k^i c_{jl}^k + \chi_j^k c_{kl}^i - w_j^k s_{kl}^i + w_k^i s_{jl}^k = 0, \tag{65}$$

$$\chi_l^k c_{jk}^i - \chi_k^i c_{jl}^k = 0, \tag{66}$$

$$\chi_k^i w_j^k - \chi_j^k w_k^i = 0, \tag{67}$$

$$(\chi_j^k - w_j^k) b_k^i - (\chi_k^i - w_k^i) b_j^k = 0, \tag{68}$$

$$\chi_j^k a_{kl}^i - \chi_k^i a_{jl}^k + w_k^i s_{lj}^k - w_j^k s_{lk}^i = 0. \tag{69}$$

Since the constraints (8)–(14) are enough to determine the coefficients a_{jk}^i and c_{jk}^i with some constraints on the given constants b_j^i and s_{jk}^i, we have the following corollary of the above proposition.

Corollary 3: The KdV system in (63) is integrable if and only if its principle part is integrable.

The principle part of (63) is obtained by ignoring the last term (the term with χ_j^i). Hence the proof of this corollary follows directly by observing that the constraints on the constants χ_j^i and w_j^i listed in (65)–(69) are independent of the constraints on the constants of the principle part listed in (8)–(14). Before the application of this corollary let us go back to the Proposition 4 and ask the question whether the KdV system (63) admits a recursion operator with $w_j^i = 0$.

Corollary 4: The KdV system (63) admits a recursion operator of the principle part. Then the last term $\chi_j^i q_x^j$ is a symmetry of the principle part. If $w_j^i = 0$, the above equations (65)–(69) reduce to

$$\chi_l^k a_{jk}^i - \chi_k^i a_{jl}^k - \chi_k^i c_{jl}^k + \chi_j^k c_{kl}^i = 0, \tag{70}$$

$$\chi_l^k s_{jk}^i - \chi_k^i s_{jl}^k = 0, \tag{71}$$

$$\chi_j^k b_k^i - \chi_k^i b_j^k = 0, \tag{72}$$

$$\chi_l^k c_{jk}^i - \chi_k^i c_{jl}^k = 0. \tag{73}$$

In order that the term $\chi_j^i q_x^j$ be a symmetry of the principle part, the constants χ_j^i are subject to satisfy the following equations:

$$\chi_l^k s_{jk}^i - \chi_k^i s_{jl}^k = 0, \tag{74}$$

$$\chi_j^k b_k^i - \chi_k^i b_j^k = 0, \tag{75}$$

$$\chi_l^k K_{jk}^i+\chi_j^k K_{lk}^i=0. \tag{76}$$

These equations simply follow from the set of equations (70)–(73), and hence the quantities $\sigma^i=\chi_j^i q_x^j$ are symmetries of the principle part.

By the application of Corollary 3, the full classification of the system (63) with the recursion operator (64) such that q_t^i (i.e., the system of equations themselves) belong to the symmetries of this system is possible. To each subclass given in the previous sections there exists a Fokas–Liu extension such that $w_j^i=\chi_j^i$ with the following constraints:

$$\chi_k^i c_{jl}^k-\chi_l^k c_{jk}^i=0, \tag{77}$$

$$\chi_l^k a_{jk}^i-\chi_j^k a_{lk}^i-\chi_k^i(a_{jl}^k-a_{lj}^k)=0. \tag{78}$$

The above constraints are identically satisfied for the class [$\det(b_j^i)\neq 0$, symmetrical case] when $\chi_j^i=\alpha\delta_j^i+\beta b_j^i$. Hence the Fokas–Liu extension of the nondegenerate symmetrical case is straightforward with this choice of χ_j^i. Here α and β are arbitrary constants.

For the degenerate case the set of equations (77) and (78) must solved for a given principle part, b_j^i and a_{jk}^i. Recently a system of integrable KdV system with $N=2$ has been introduced by Fokas and Liu.[9] This system is a nice example for the application of Corollary 3. We shall give this system in its original form first and then simplify:

$$\begin{aligned} &u_t+v_x+(3\beta_1+2\beta_4)\beta_3 uu_x+(2+\beta_1\beta_4)\beta_3(uv)_x+\beta_1\beta_3 vv_x\\ &\quad+(\beta_1+\beta_4)\beta_2 u_{xxx}+(1+\beta_1\beta_4)\beta_2 v_{xxx}=0, \end{aligned} \tag{79}$$

$$\begin{aligned} &v_t+u_x+(2+3\beta_1\beta_4)\beta_3 vv_x+(\beta_1+2\beta_4)\beta_3(uv)_x+\beta_1\beta_3\beta_4 uu_x\\ &\quad+(\beta_1+\beta_4)\beta_2\beta_4 u_{xxx}+(1+\beta_1\beta_4)\beta_2\beta_4 v_{xxx}=0, \end{aligned} \tag{80}$$

where β_1, β_2, β_3, and β_4 are arbitrary constants. The recursion operator of this system is given in Ref. 8. Consider now a linear transformation

$$u=m_1 r+n_1 s, \quad v=m_2 r+n_2 s, \tag{81}$$

where m_1, m_2, n_1, and n_2 are constants, and s and r are new dynamical variables, $q^i=(s,r)$. Choosing these constants properly, the Fokas–Liu system reduces to a simpler form

$$\begin{aligned} r_t&=(rs)_x+\alpha_1 r_x+\alpha_2 s_x,\\ s_t&=\gamma_1 s_{xxx}+\gamma_2 r r_x+3ss_x+\alpha_3 r_x+\alpha_4 s_x, \end{aligned} \tag{82}$$

where we are not giving the coefficients $\alpha_1, \alpha_2, \alpha_3$, and α_4 in terms of the parameters of the original equation given above, because these expressions are quite lengthy. The only condition on the parameters α_i is given by $\alpha_3=\gamma_2\alpha_2$. This guarantees the integrability of the above system (82). On the other hand, the transformation parameters are given by

$$m_2=-\frac{\beta_1+\beta_4}{1+\beta_1\beta_4}m_1, \quad n_2=\beta_4 n_1, \tag{83}$$

$$n_1=-\frac{1}{\delta\beta_3}, \quad \delta=\beta_1(1+\beta_4^2)+2\beta_4. \tag{84}$$

The principle part of the Fokas–Liu system (82) is exactly the Ito system given in (31) and hence the recursion operator is the sum of the one given in (32) and χ_j^i which are given by $\chi_1^1=\alpha_4$, $\chi_2^1=\alpha_3$, $\chi_1^2=\alpha_2$, $\chi_2^2=\alpha_1$. That is,

$$R=\begin{pmatrix} \gamma_1 D^2+2s+s_x D^{-1}+\alpha_4 & \gamma_2 r+\alpha_3\\ r+r_x D^{-1}+\alpha_2 & \alpha_1 \end{pmatrix}. \tag{85}$$

Another example was given very recently[10] in a very different context for $N=2$:

$$u_t=\tfrac{1}{2}v_{xxx}+2uv_x+u_xv, \quad v_t=3vv_x+2au_x. \tag{86}$$

The principle part of these equations is transformable to the Fuchssteiner system given in (42). Taking $\alpha_1=2$, $\alpha_3=4$, and scaling x and t properly we obtain (without losing any generality)

$$r_t=2r_{xxx}+6rr_x, \quad s_t=2s_xr+4sr_x. \tag{87}$$

The transformation between the principle part ($a=0$) of (86) and (87) is simply given by $u=m_1s+\frac{1}{2}r$, $v=2r$. Then the recursion operator of the system (86) is given by

$$R=\begin{pmatrix} 0 & \frac{1}{2}D^2+2u+u_xD^{-1} \\ 2a & 2v+v_xD^{-1} \end{pmatrix}. \tag{88}$$

V. CONCLUSION

We have given a classification of a system of KdV equations with respect to the existence of a recursion operator. This is indeed a partial classification. Although we have found all conditions for each subclass, we have not presented them explicitly. We obtained three distinct subclasses for all values of N and gave the corresponding recursion operators. We also gave an extension of such systems by adding a linear term containing the first derivative of dynamical variables. We called such systems the Fokas–Liu extensions. We proved that these extended systems of KdV equations are also integrable if and only if their principle parts are integrable. For $N=2$, we have given all subclassess explicitly. Among these the recursion operator of the KdV coupled to the time evolution part of its Lax pair seems to be new. Here we would like to add that when $N=2$ recursion operators, including the Fokas–Liu extensions, are hereditary.[11]

Our classification crucially depends on the form of the recursion operator. The recursion operators used in this work were assumed to have degree two (highest degree of the operator D in R) and nonlocality order one (highest degree of the operator D^{-1} in R). The next work in this program should be the study on the classification problems with respect to the recursion operators with higher degree and higher nonlocalities. For instance, when $N=2$, Hirota–Satsuma, Boussinesq, and Bogoyavlenskii coupled KdV equations admit recursion operators with $m=4$ and $n=1$.[12] Hence these equations do not belong to our classification given in this work.

(Received 24 September 1996; accepted for publication 22 August 1997)

By means of the conformal invariance (Möbious transformation invariance), the well known KdV equation is extended to (i) a (1+1)-dimensional space-time symmetric form; (ii) two (2+1)-dimensional space isotropic forms; and (iii) general (3+1)-dimensional and N-dimensional forms. The extensions are proven to be integrable under the meaning that they possess the Painlevé property. © *1998 American Institute of Physics.* [S0022-2488(98)02303-2]

I. INTRODUCTION

The soliton theory has attracted much attention from a rather diverse group of scientists (e.g., both physicists and mathematicians) because it is widely applied in many physically significant fields (such as plasma physics, fluids, optics, relative field theory, astrophysics and geophysics, etc.) and demonstrates a deep and fundamental relationship with both modern and core Mathematics (e.g., algebraic and differential geometry, analysis, group theory and chaos). However, there is still a long list of important open problems in soliton theory.[1] Here are three of them:

(i) Because of the real physical space is (3+1)-dimensional, one hopes to find some (3+1)-dimensional integrable models. Unfortunately, except for the ''2+2''-dimensional self-dual Yang–Mills (SDYM) equations, there is no one known integrable model in more than (2+1)-dimensions.

(ii) Usually, the physical space is isotropic. That is to say the physical laws should be invariant under the exchange of space variables. However, except for the Davey–Stewartson (DS) and the Nizhnik–Novikov–Veselov (NNV) equations, almost all the known (2+1)-dimensional integrable models are non-invariant under the exchange of the space variables.

(iii) If we consider relativistic physics, the models should be also invariant under the exchange of the space-time. Nevertheless, most of the famous integrable models are non-symmetric with respect to space-time.

In this paper, we would like to treat these problems by means of the Painlevé analysis. The Painlevé tests, as formulated by Ablowitz, Ramani and Segur (ARS)[2] and Weiss, Tabor and Carnevale (WTC),[3] have been proven to be useful criteria for the identification of completely integrable models.

In the next section, according to the fact that the conformal invariance in solution space (Möbious transformations of fields) plays important roles, we propose a (1+1)-dimensional integrable model with space-time exchange symmetry under the meaning that the model can be changed to a variant form with the Painlevé property.

Using the same idea, two space isotropic (2+1)-dimensional models are studied in section III. In section IV, a general (3+1)-dimensional Schwartz KdV extension is proved to be integrable under the meaning that a variant of the model possesses the Painlevé property. Section V is devoted to discussion of the integrability of an N-dimensional extension. The last section is a summary and discussion.

II. A SPACE-TIME SYMMETRIC (1+1)-DIMENSIONAL KdV EXTENSION

It is known that the symmetry study is one of the important works both in physics and in mathematics, especially in the study of the soliton systems because every integrable model possesses infinitely many symmetries.[4–6] Recently we found that the conformal invariance (Möbious transformation invariance) of the Schwartz form is quite important.[7] For instance, for the KdV equation

$$U_t+U_{xxx}-6UU_x=0, \tag{1}$$

three sets of infinitely many nonlocal symmetries and one set of local symmetries and the Darbourx transformation can be derived from the conformal invariance of the Schwartz KdV equation

$$\frac{\phi_t}{\phi_x}+\{\phi;x\}=0, \tag{2}$$

where $\{\phi;x\}\equiv(\phi_{xx}/\phi_x)_x-\frac{1}{2}(\phi_{xx}/\phi_x)^2$ is the Schwartz derivative, while the KdV equation (1) and its Schwartz form (2) are related by[8]

$$U=-\frac{1}{2}\left(\frac{\phi_{xx}}{\phi_x}\right)_x+\frac{1}{4}\left(\frac{\phi_{xx}}{\phi_x}\right)^2.$$

This fact hints to us that if we want to construct an integrable model, the conformal invariant equations may be good candidates. In this paper we would like to construct some KdV type of extensions by using this idea.

First, because of the relativity requirement, we extend (2) to a space time symmetric form

$$\frac{\phi_t}{\phi_x}+\{\phi;x\}+c_1\left(\frac{\phi_x}{\phi_t}+\{\phi;t\}\right)=0, \tag{3}$$

where we have inserted a constant c_1 in such that (3) can be reduced to the usual Schwartz KdV (2) when $c_1=0$. Equation (3) is symmetric for the exchange of the space-time $x\leftrightarrow t$ for $c_1=1$. The model is obviously conformal invariant in the solution space ϕ. In other words, (3) is invariant under the Möbious transformation

$$\phi\rightarrow\frac{a+b\phi}{c+d\phi},\quad ad\neq bc. \tag{4}$$

To check whether the model (3) is integrable or not, we make some transformations first. Using the transformation

$$\phi=\exp F, \tag{5}$$

eq. (3) is changed to

$$\frac{F_t}{F_x}+\{F;x\}-\frac{1}{2}F_x^2+c_1\left(\frac{F_x}{F_t}+\{F;t\}-\frac{1}{2}F_t^2\right)=0. \tag{6}$$

The further transformations

$$F_x=u,\quad F_t=v \tag{7}$$

make (6) become an equation system possessing the Painlevé property,

$$2uv(vu_{xx}+c_1uv_{tt})-3(c_1u^2v_t^2+v^2u_x^2)-u^2v^2(u^2+c_1v^2)+2uv(v^2+c_1u^2)=0, \tag{8}$$

$$u_t=v_x, \tag{9}$$

where eq. (9) comes from the compatibility condition of the transformations (7).

To prove the Painlevé property of the system (8) and (9), we can use the standard WTC approach.[3] According to the WTC paper, we say a model has the Painlevé property if its solutions are single valued about an arbitrary movable singular manifold which is given by $\Phi(x_1,x_2,\ldots,x_n,t)=0$. For the system (8) and (9), we can expand u and v as

$$u=\sum_{j=0}^{\infty} u_j\Phi^{j+\alpha}, \quad v=\sum_{j=0}^{\infty} v_j\Phi^{j+\beta}, \tag{10}$$

with $\{u_j,v_j\}$ being arbitrary functions of (x,t) and $\{u_0\neq 0,v_0\neq 0\}$. By using leading order analysis (i.e., substituting $u\sim u_0\Phi^{\alpha}$, $v\sim v_0\Phi^{\beta}$, into (8), (9)), we have

$$\alpha=-1, \quad \beta=-1, \quad u_0^2=\Phi_x^2, \quad v_0=u_0\Phi_t/\Phi_x. \tag{11}$$

Now substituting (10) with (11) into (8) and (9), we can get the recursion relations on the functions u_j and v_j:

$$(j+1)(j-1)(u_0u_j+c_1v_0v_j)=f \quad (u_i,v_i,i\leqslant j-1), \tag{12}$$

$$(j-1)(v_ju_0-u_jv_0)=u_{j-1,t}-v_{j-1,x}, \tag{13}$$

where f is a complicated function of $\{u_i,v_i,i\leqslant j-1\}$ and the derivatives of the singularity manifold Φ. From (12) and (13), the resonance values of j are given by

$$\begin{vmatrix} (j-1)u_0 & -(j-1)v_0 \\ c_1(j^2-1)v_0 & (j^2-1)u_0 \end{vmatrix}=(j+1)(j-1)^2(u_0^2+c_1v_0^2)=0, \tag{14}$$

i.e.,

$$j=-1,1,1. \tag{15}$$

The resonance at $j=-1$ corresponds to the arbitrary singularity manifold Φ. At two other resonances, j=1, there are two compatibility conditions

$$u_0v_0\left(\Phi_{xx}+c_1\Phi_{tt}-\frac{u_{0x}}{u_0}\Phi_x-c_1\frac{v_{0t}}{v_0}\Phi_t\right)=0, \tag{16}$$

$$u_{0t}-v_{0x}=0, \tag{17}$$

that need to be satisfied. It is clear that (16) and (17) are satisfied identically due to (11). The Painlevé property of the system (8) and (9) is proven. So the equation system (8) and (9) is integrable under the meaning that it possesses the Painlevé property. Now we turn to study (2+1)-dimensional examples.

III. TWO SPACE ISOTROPIC (2+1)-DIMENSIONAL EXTENSIONS

The well known KdV equation has some different extensions in (2+1)-dimensions, say, the Kadomtsev–Petviashvili (KP) equation,[9]

$$(u_t+u_{xxx}-6uu_x)_x+3u_{yy}=0, \tag{18}$$

the Boiti–Leon–Manna–Pempinelli (BLMP) equation[10]

$$u_t+u_{xxx}-3(u\partial_y^{-1}u_x)_x=0, \tag{19}$$

and the Nizhnik–Novikov–Veselov (NNV) equation,[11]

$$u_t+u_{xxx}+u_{yyy}-3(u\partial_y^{-1}u_x)_x-3(u\partial_x^{-1}u_y)_y=0, \tag{20}$$

etc. Actually, the NNV equation is only a combination of two BLMP equations because of $u_{xxx}-3(u\partial_y^{-1}u_x)_x$ and $u_{yyy}-3(u\partial_x^{-1}u_y)_y$ being commutative. Correspondingly, the extensions of the Schwartz KdV to Schwartz KP and Schwartz BLMP equations have the forms[12]

$$\left(\frac{\phi_t}{\phi_x}+\{\phi;x\}+\frac{3\phi_y^2}{2\phi_x^2}\right)_x+3\left(\frac{\phi_y}{\phi_x}\right)_y=0, \tag{21}$$

and

$$\left(\partial_y+\frac{\phi_y}{\phi_x}\partial_x-\left(\frac{\phi_y}{\phi_x}\right)_{xy}-\frac{\phi_y}{\phi_x}\left(\frac{\phi_y}{\phi_x}\right)_{xx}+2\left(\frac{\phi_y}{\phi_x}\right)_x^2\right)$$
$$\times\left(\frac{\phi_t}{\phi_x}+\{\phi;x\}\right)_y-3\{\phi;x\}_y\left(\frac{\phi_y}{\phi_x}\right)_x^2=0, \tag{22}$$

respectively. In this section, we would like to propose two new types of (2+1)-dimensional Schwartz KdV extensions with the space exchange, $x\leftrightarrow y$, invariance.

The first one is

$$\frac{\phi_t}{\phi_x}+\{\phi;x\}+\frac{\phi_t}{\phi_y}+\{\phi;y\}=0, \tag{23}$$

which will be reduced back to the Schwartz KdV (2) for $x=y$. The second extension is

$$\left(\frac{\phi_t}{\phi_x}+\{\phi;x\}+\frac{3\phi_y^2}{2\phi_x^2}\right)_x+3\left(\frac{\phi_y}{\phi_x}\right)_y+a\left(\left(\frac{\phi_t}{\phi_y}+\{\phi;y\}+\frac{3\phi_x^2}{2\phi_y^2}\right)_y+3\left(\frac{\phi_x}{\phi_y}\right)_x\right)=0, \tag{24}$$

which will be reduced back to the Schwartz KP (21) for $a=0$ and to the Schwartz KdV (2) for $x=y$.

Similar to the (1+1)-dimensional case, making the transformation

$$\phi=\exp F \tag{25}$$

for both (23) and (24), we obtain

$$\frac{F_t}{F_x}+\{F;x\}+\frac{F_t}{F_y}+\{F;y\}-(F_x^2+F_y^2)=0 \tag{26}$$

for (23) and

$$\left(\frac{F_t}{F_x}+\{F;x\}+\frac{3F_y^2}{2F_x^2}\right)_x+3\left(\frac{F_y}{F_x}\right)_y$$
$$+a\left(\left(\frac{F_t}{F_y}+\{F;y\}+\frac{3F_x^2}{2F_y^2}\right)_y+3\left(\frac{F_x}{F_y}\right)_x\right)-F_xF_{xx}-aF_yF_{yy}=0 \tag{27}$$

for (24).

Furthermore, making the transformations

$$F_x=u,\quad F_y=v,\quad F_t=w, \tag{28}$$

eq. (26) becomes

$$2uvw(u+v)-3(v^2u_x^2+u^2v_y^2)+2uv(vu_{xx}+uv_{yy})-u^2v^2(u^2+v^2)=0, \tag{29}$$

$$u_t = w_x, \tag{30}$$

$$v_t = w_y \tag{31}$$

after multiplying it by u^2v^2 while eq. (27) is changed to

$$u^2v^2(w_xv + aw_yu + vu_{xxx} + auv_{yyy} + 3vv_y + 3auu_x) - 3v^5u_x - 3au^5v_y$$
$$- uv(wv^2u_x + awu^2v_y + 4v^2u_xu_{xx} + 4au^2v_yv_{yy}) + 3u_x^3v^3$$
$$+ 3av_y^3u^3 - u^3v^3(uu_x + avv_y) = 0, \tag{32}$$

$$u_t = w_x, \tag{33}$$

$$v_t = w_y \tag{34}$$

after multiplying it by u^3v^3.

To prove the Painlevé property of (29)–(31), we expand $\{u,v,w\}$ as

$$u = \sum_{j=0}^{\infty} u_j\Phi^{j+\alpha}, \quad v = \sum_{j=0}^{\infty} v_j\Phi^{j+\beta}, \quad w = \sum_{j=0}^{\infty} w_j\Phi^{j+\gamma} \tag{35}$$

with

$$\alpha = \beta = \gamma = -1, \quad w_0^2 = \Phi_t^2, \quad u_0 = w_0\Phi_x/\Phi_t, \quad v_0 = w_0\Phi_y/\Phi_t, \tag{36}$$

where eq. (36) is given by leading order analysis. Substituting (35) with (36) into the system (29)–(31), we have

$$(j+1)(j-1)(u_0u_j + v_0v_j) = f(u_i, v_i, w_i, i \leqslant j-1), \tag{37}$$

$$(j-1)(w_ju_0 - u_jw_0) = u_{j-1,t} - w_{j-1,x}, \tag{38}$$

$$(j-1)(w_jv_0 - v_jw_0) = v_{j-1,t} - w_{j-1,y}, \tag{39}$$

where f is a function of $\{u_i, v_i, w_i, i \leqslant j-1\}$ and the derivatives of the singularity manifold Φ. It is clear that the resonances occur at $j = -1,1,1,1$. From (37)–(39), we can get three resonance conditions which should be satisfied identically and have the forms

$$u_0v_0(\Phi_{xx} + \Phi_{yy}) - u_0\Phi_yv_{0y} - v_0\Phi_xu_{0x} = 0, \tag{40}$$

$$u_{0t} - w_{0x} = 0, \tag{41}$$

$$v_{0t} - w_{0y} = 0. \tag{42}$$

Obviously, (40)–(42) are true because of (36).

Using the leading order analysis to the system (32)–(34) leads to the same Laurent series (35) with (36). Substituting (35) with (36) into (32)–(34) yields

$$(j+1)(j-1)(j-2)u_0^3v_0^3(u_0^2u_j + av_0^2v_j) = f(u_i, v_i, i \leqslant j-1), \tag{43}$$

$$(j-1)(w_ju_0 - u_jw_0) = u_{j-1,t} - w_{j-1,x}, \tag{44}$$

$$(j-1)(w_jv_0 - v_jw_0) = v_{j-1,t} - w_{j-1,y}, \tag{45}$$

where f is again a function of $\{u_i, v_i, w_i, i \leqslant j-1\}$ and the derivatives of Φ. Now the resonances are located at

$$j=-1,1,1,1,\ 2, \tag{46}$$

and the corresponding compatibility conditions are

$$u_0^2v_0^2(2u_0v_0\Phi_x\Phi_{xx}-v_0\Phi_x^2u_{0x}-u_0^2v_0u_{0x})$$
$$-au_0^2v_0^2(2u_0v_0\Phi_y\Phi_{yy}-u_0\Phi_y^2v_{0y}-v_0^2u_0v_{0y})=0, \tag{47}$$

$$u_0v_0^3(u_{0x}^2\Phi_x+u_0^2\Phi_{xxx}+3u_0v_0\Phi_y-u_0u_{0x}\Phi_{xx}-u_0u_{0xx}\Phi_x-3v_0^2\Phi_x)$$
$$-av_0u_0^3(v_{0y}^2\Phi_y+v_0^2\Phi_{yyy}+3u_0v_0\Phi_x-v_0v_{0y}\Phi_{yy}-v_0v_{0yy}\Phi_y-3u_0^2\Phi_y)=0, \tag{48}$$

$$u_{0t}-w_{0x}=0, \tag{49}$$

$$v_{0t}-w_{0y}=0. \tag{50}$$

The compatibility conditions (47) and (48) come from (43) for $j=1$ and $j=2$, respectively. It is also straightforward to see that the conditions (47)–(50) are satisfied identically because of eq. (36).

From the above calculations, we know that both systems (29)–(31) and (32)–(34) possess the Painlevé property. Then two space symmetric (2+1)-dimensional Schwartz KdV extensions (23) and (24) are integrable under the meaning that they can be changed to the variant forms with the Painlevé property.

The excellent property of the (1+1)-dimensional and (2+1)-dimensional Schwartz equations leads us to construct integrable models in higher dimensions.

IV. A GENERALIZED (3+1)-DIMENSIONAL KdV EXTENSION

As mentioned in the Introduction, because the real physical space-time is (3+1)-dimensional, we discuss a (3+1)-dimensional extension of the Schwartz KdV equation before discussing more general higher dimensional extension.

According to discussions of the last two sections, one may guess that the following (3+1)-dimensional system,

$$u^2v^2w^2g^2\left(a_1\frac{u_{xx}}{u}+a_2\frac{v_{yy}}{v}+a_3\frac{w_{zz}}{w}+a_4\frac{g_{tt}}{g}-\frac{3}{2}\left(a_1\frac{u_x^2}{u^2}+a_2\frac{v_y^2}{v^2}+a_3\frac{w_z^2}{w^2}+a_4\frac{g_t^2}{g^2}\right)\right.$$
$$-\frac{1}{2}(a_1u^2+a_2v^2+a_3w^2+a_4g^2)+a_5\frac{g}{u}+a_6\frac{u}{g}+a_7\frac{u}{v}+a_8\frac{v}{u}+a_9$$
$$\left.\times\left(\frac{u}{w}+a_{10}\frac{w}{u}+a_{11}\frac{v}{w}+a_{12}\frac{w}{v}+a_{13}\frac{g}{w}+a_{14}\frac{w}{g}+a_{15}\frac{g}{v}+a_{16}\frac{v}{g}\right)=0, \tag{51}$$

$$u_t=g_x, \tag{52}$$

$$v_t=g_y, \tag{53}$$

$$w_t=g_z, \tag{54}$$

with arbitrary constants a_i, $i=1,2,\ldots,16$, may possess the Painlevé property. The system (51)–(54) can be simplified to a single Schwartz form

$$a_1\{\phi;x\}+a_2\{\phi;y\}+a_3\{\phi;z\}+a_4\{\phi;t\}+a_5\frac{\phi_t}{\phi_x}+a_6\frac{\phi_x}{\phi_t}+a_7\frac{\phi_x}{\phi_y}+a_8\frac{\phi_y}{\phi_x}+a_9\frac{\phi_x}{\phi_z}+a_{10}\frac{\phi_z}{\phi_x}$$
$$+a_{11}\frac{\phi_y}{\phi_z}+a_{12}\frac{\phi_z}{\phi_y}+a_{13}\frac{\phi_t}{\phi_z}+a_{14}\frac{\phi_z}{\phi_t}+a_{15}\frac{\phi_t}{\phi_y}+a_{16}\frac{\phi_y}{\phi_t}=0, \tag{55}$$

with $\phi=\exp F$, $u=F_x$, $v=F_y$, $w=F_z$, and $g=F_t$.

To check the Painlevé property of the system (51)–(54), we use the leading order analysis first again. Substituting

$$\{u,v,w,g\}\sim\{u_0\Phi^{\alpha},v_0\Phi^{\beta},w_0\Phi^{\gamma},g_0\Phi^{\delta}\} \tag{56}$$

to (51)–(54) leads to

$$\alpha=\beta=\gamma=\delta=-1,\quad g_0^2=\Phi_t^2,\quad u_0=g_0\frac{\Phi_x}{\Phi_t},\quad v_0=g_0\frac{\Phi_y}{\Phi_t},\quad w_0=g_0\frac{\Phi_z}{\Phi_t}. \tag{57}$$

Then the Laurent expansions of $\{u,v,w,g\}$ have the forms

$$\begin{aligned} u&=\sum_{j=0}^{\infty}u_j\Phi^{j-1},\quad v=\sum_{j=0}^{\infty}v_j\Phi^{j-1},\\ w&=\sum_{j=0}^{\infty}w_j\Phi^{j-1},\quad g=\sum_{j=0}^{\infty}g_j\Phi^{j-1}. \end{aligned} \tag{58}$$

Using (58) with (57) in (51)–(54), we get

$$(j+1)(j-1)(a_1u_0u_j+a_2v_0v_j+a_3w_0w_j+a_4g_0g_j)=f(u_i,v_i,w_i,g_i,i\leqslant j-1), \tag{59}$$

$$(j-1)(g_ju_0-u_jg_0)=u_{j-1,t}-g_{j-1,x}, \tag{60}$$

$$(j-1)(g_jv_0-v_jg_0)=v_{j-1,t}-g_{j-1,y}, \tag{61}$$

$$(j-1)(g_jw_0-w_jg_0)=w_{j-1,t}-g_{j-1,z} \tag{62}$$

with the resonances

$$j=-1,1,1,1. \tag{63}$$

The remaining discussions are similar to that of the last two sections. Four compatibility conditions

$$\begin{aligned} &u_0v_0w_0g_0(a_1\Phi_{xx}+a_2\Phi_{yy}+a_3\Phi_{zz}+a_4\Phi_{tt})-a_1w_0v_0g_0\Phi_xu_{0x}\\ &-a_2u_0w_0g_0\Phi_yv_{0y}-a_3u_0v_0g_0\Phi_zw_{0z}-a_4u_0v_0w_0\Phi_tg_{0t}=0, \end{aligned} \tag{64}$$

$$u_{0t}-g_{0x}=0, \tag{65}$$

$$v_{0t}-g_{0y}=0, \tag{66}$$

and

$$w_{0t}-g_{0z}=0 \tag{67}$$

are satisfied naturally thanks to (57). So the system (51)–(54) possesses Painlevé property and the generalized (3+1)-dimensional Schwartz system (55) is integrable because it can be transformed to some variants with Painlevé property.

Some special cases of (55) are worth mentioning. (i) When we take the constants $a_i=0$ except $a_1=a_4=a_5=a_6=1$, the model (55) reduces back to the (1+1)-dimensional space-time symmetric model given in section II. (ii) If we take $a_1=a_2=a_5=a_{15}=1$ and all other a_i being zero, we get the (2+1)-dimensional space isotropic model (23). (iii) If we take all the constants as one, then the model (55) becomes a (3+1)-dimensional relativistic integrable model, i.e., the model is space-time exchange invariant.

Actually, one can easily obtain various other types of $(3+1)$-dimensional models by means of the conformal invariant quantities (which are invariant under the Möbious transformation). However, we prefer to give a possible integrable generalization in arbitrary dimensions rather than to discuss this problem further.

V. AN *N*-DIMENSIONAL KdV EXTENSION

Generally, an N-dimensional conformal invariant model may have the form

$$G\left(\{\phi;x_i\},\frac{\phi_{x_i}}{\phi_{x_j}},i,j,=1,2,\ldots,N\right)=0, \tag{68}$$

where G is an arbitrary functions of the conformal invariants $\{\phi;x_i\},\phi_{x_i}/\phi_{x_j},(i,j,=1,2,\ldots,N)=0$ and their derivatives. We believe that there are many types of special function G which may be changed to a variant form with the Painlevé property. In this section, we write down only one special G and change it to a form with the Painlevé property.

Using the same idea as in lower dimensions discussed in sections II–IV, we may prove the following special case of (68),

$$\sum_{k=0}^{N} a_k\{\phi;x_k\}+g\left(\frac{\phi_{x_i}}{\phi_{x_j}},i,j,=1,2,\ldots,N\right)=0, \tag{69}$$

where g is an arbitrary polynomial functions of $\phi_{x_i}/\phi_{x_j}(i,j,=1,2,\ldots,N)$, may be transformed to a form possessing Painlevé property. Taking the transformations

$$\phi=\exp F,\quad u_i=F_{x_i},\quad i=1,2,\ldots N, \tag{70}$$

eq. (69) is changed to

$$\left(\prod_{k=1}^{N} u_k^{m_k}\right)\left[\sum_{k=1}^{N} a_k\left(n;\frac{u_{kx_kx_k}}{u_k}-\frac{3u_{kx_k}^2}{2u_k^2}-\frac{1}{2}u_k^2\right)+g\left(\frac{u_i}{u_j},i,j=1,2,\ldots,N\right)\right]=0, \tag{71}$$

$$u_{1x_i}=u_{ix_i},\quad i=1,2,\ldots,N, \tag{72}$$

where $m_j\geqslant 2$ are positive integers and are fixed such that $(\Pi_{k=1}^{N} u_k^{m_k})g(u_i/u_j,\ i,j=1,2,\ldots,N)$ is only a polynomial function of $u_i,\ i=1,2,\ldots,N$.

To prove the Painlevé property of (71) and (72), we expand u_i as

$$u_i=\sum_{j=0}^{\infty} u_{ij}\Phi^{j+\alpha_i},\quad i=1,2,\ldots,N, \tag{73}$$

where α_i and u_{i0} are fixed by leading order analysis. The result is

$$\alpha_i=-1,\quad u_{i0}=\Phi_{x_i},\quad i=1,2,\ldots,N. \tag{74}$$

Substituting eq. (73) with (74) into (71) and (72), we obtain

$$(j+1)(j-1)\sum_{k=1}^{N} a_k u_{k0}u_{kj}=f(u_{ki},k=1,2,\ldots,N,i\leqslant j-1), \tag{75}$$

$$(j-1)(u_{1j}u_{k0}-u_{kj}u_{10})=u_{k(j-1),t}-u_{1(j-1),x_k},\ \ k=2,3,\ldots,N \tag{76}$$

with $N+1$ resonances,

$$j=-1,\underbrace{1,1,\ldots,1}_{N}, \tag{77}$$

where f is a very complicated function of u_{ki}, $k=1,2,\ldots,N, i\leqslant j-1$. The resonances $j=-1$ corresponds to the arbitrary singular manifold Φ. For other resonances, $j=1$, after finishing some tedious calculations, we get N compatibility conditions

$$\sum_{k=0}^{N} a_k\left(\Phi_{x_kx_k}-\frac{u_{k0,x_k}}{u_{k0}}\Phi_{x_k}\right)=0, \tag{78}$$

$$u_{k0,t}-u_{10,x_k}=0, \quad (k=2,3,\ldots,N). \tag{79}$$

Obviously the resonance conditions (78) and (79) are satisfied identically because of eq. (74). Then equation (69) are integrable under the meaning that its variant (71) and (72) possesses the Painlevé property.

VI. SUMMARY AND DISCUSSION

According to the fact that many integrable models can be transformed to the conformal invariant forms (Schwartz forms) and various integrable properties such as the Darbourx transformation, infinitely many symmetries, etc., can be derived from the conformal invariance, we believe that one may get various integrable models by extending the known integrable Schwartz equations. Starting from this idea, we have constructed some significant KdV extensions. Some of them are isotropic in space and some of them are relativistic (i.e., space-time symmetric). Especially the (Schwartz) KdV equation has been extended to real (3+1)-dimensional physical space. The Painlevé properties of these extensions are all proved by using the standard WTC approach.

Though the extensions are all proven to be integrable under the meanings that they possess the Painlevé property and the Schwartz forms with conformal invariance, there are still many important problems worth further study:

(i) Usually, one would say a model is integrable under some different meanings. For instance, a model is integrable under the meanings that it can be solved by the inverse scattering transformation, it possesses the Painlevé property, it possesses Lax Pairs, it possesses bi-Hamiltonian structure and infinitely many symmetries and conservation laws and so on. Are the models obtained here integrable under other meanings, say, under the meaning that they can be solved by inverse scattering transformation?

(ii) Though the models are obtained only from the consideration of the integrability, we believe that they may be found also from the real physical systems because the real physical space-time is isotropic, relativistic and (3+1)-dimensional. The most possible physical systems which can be used to derive these models are the SDYM equations because of the considerably increasing the validity of Ward's conjecture[13,1]:
''many (and perhaps all?) of the ordinary and partial differential equations that are regarded as being integrable or solvable may be obtained from the self-dual gauge field equations (or its generalizations) by reduction.''
Almost all the known integrable models, say, the KdV, KP, DS, N-wave interaction equations, nonlinear Schrödinger, chiral field equation, Toda equations and sine-Gordon equation, have been obtained from the reduction of the SDYM equations.[1] How do we get the model obtained in this paper from concrete physical systems, say, SDYM equation?

(iii) Generally, one can construct an N-dimensional integrable model (which possesses the Painlevé property) quite freely by means of the conformal invariants. For instance, an arbitrary polynomial function of some conformal invariants has been included in our special example (69). Though not all the equations in the Schwartz form are integrable (can be changed to a form with the Painlevé property), it is still significant to ask: What kind of

conformal invariant form (function G in (68)) may be changed to a form with Painlevé property?

(Received 29 September 1997; accepted for publication 12 November 1997)

Using a moving space curve formalism, geometrical as well as gauge equivalence between a (2+1) dimensional spin equation (M-I equation) and the (2+1) dimensional nonlinear Schrödinger equation (NLSE) originally discovered by Calogero, discussed then by Zakharov and recently rederived by Strachan, have been established. A compatible set of three linear equations are obtained and integrals of motion are discussed. Through stereographic projection, the M-I equation has been bilinearized and different types of solutions such as line and curved solitons, breaking solitons, induced dromions, and domain wall type solutions are presented. Breaking soliton solutions of (2+1) dimensional NLSE have also been reported. Generalizations of the above spin equation are discussed. © *1998 American Institute of Physics.* [S0022-2488(98)00504-0]

I. INTRODUCTION

The two dimensional sigma-models with nontrivial topological structures are known to play a useful role in modern field theory. This set of models constitute a laboratory for studying two dimensional analogues of elementary particles within the framework of classical field theory.[1] In this context, important case studies concern with the existence of localized coherent structures (dromions, lumps, etc.) and other types of soliton-like solutions of some classical nonlinear field models such as, for example, the Ishimori and the other (2+1) dimensional spin systems.[1–3]

Generally speaking, in (2+1) dimensions we have a number of remarkable properties, which may not exist in (1+1) dimensionsal counterparts. For example,

1. These equations possess the so called localized coherent structures (such as dromions, lumps and so on), which may undergo both elastic and inelastic scattering depending upon the initial conditions.
2. The corresponding spectral parameter (eigenvalue) of the associated linear problem (the Lax representation) can be dependent on the t (time) and y (space) variables and satisfy even nonlinear equations (see, for instance, Refs. 3 and 4). As a consequence, the original soliton equation can have breaking solutions.[4–6] Besides, in this case, for finding solutions one even needs to use nonisospectral Inverse Scattering Transform (IST).[5]
3. Each integrable (1+1) dimensional equation may admit several integrable (and nonintegrable) extensions[2,3] in (2+1) dimensions. For example, the KdV equation has integrable extensions such

[a)]Electronic mail: cnlpmyra@satsun.sci.kz

 © 1998 American Institute of Physics

as KP, NNV and breaking soliton equations.[6]

4. Regarding the subject of the present paper, many of the (2+1) dimensional spin equations possess the topological invariant-with the so called topological charge

$$Q=\frac{1}{4\pi}\int dxdy\vec{S}\cdot\vec{S}_x\wedge\vec{S}_y, \tag{1}$$

and their solutions are classified by the integer values of Q_N, $N=0,\pm1,\pm2,\ldots$ Here, $\vec{S}=(S_1,S_2,S_3)$ and $|\vec{S}|^2=S_1^2+S_2^2+S_3^2=1$ and $\vec{S}_x=(\partial\vec{S}/\partial x)$, $\vec{S}_y=(\partial\vec{S}/\partial y)$. This property can be realised, for example, in the (2+1) dimensional analogues of the well known (1+1) dimensional Heisenberg ferromagnet model (or the (1+1) dimensional isotropic Landau–Lifshitz equation (LLE))[7–9]

$$\vec{S}_t=\vec{S}\wedge\vec{S}_{xx}. \tag{2}$$

The Heisenberg ferromagnetic spin equation (2) possesses many useful (2+1) dimensional extensions: Some of them are as follows:

(a) The Ishimori equation[10]

$$\vec{S}_t=\vec{S}\wedge(\vec{S}_{xx}+\epsilon^2\vec{S}_{yy})+u_x\vec{S}_y+u_y\vec{S}_x, \tag{3a}$$

$$u_{xx}-\epsilon^2u_{yy}=-2\epsilon^2\vec{S}\cdot(\vec{S}_x\wedge\vec{S}_y). \tag{3b}$$

(b) The M-I equation[5]

$$\vec{S}_t=(\vec{S}\wedge\vec{S}_y+u\vec{S})_x, \tag{4a}$$

$$u_x=-\vec{S}\cdot(\vec{S}_x\wedge\vec{S}_y). \tag{4b}$$

(c) The (2+1) dimensional isotropic LLE[11]

$$\vec{S}_t=\vec{S}\wedge(\vec{S}_{xx}+\vec{S}_{yy}). \tag{5}$$

Here u is a scalar function and $\epsilon^2=\pm1$. It turns out that Eqs. (3) and (4) are integrable, while Eq. (5) is apparently nonintegrable. All the three Eqs. (3)–(5) describe the nonlinear dynamics of the classical spin systems in the plane and in the (1+1) dimensional case reduce to one and the same Eq. (2). Properties of Eqs. (3) are relatively well studied (see, for example, Refs. 3 and 10). In this paper we wish to concentrate on studying the M-I equation (4). In particular, we wish to identify the geometrically equivalent (2+1) dimensional NLSE for (4) and study the nature of the nonlinear excitations admitted by the spin system.

The paper is organized as follows. In Sec. II we briefly review some necessary informations about (4) relevant to this paper. The geometrical and gauge equivalent counterpart of Eq. (4) is constructed in Sec. III and Sec. IV, respectively. Integrals of motion are discussed in Sec. V. In Sec. VI the Hirota bilinear form of Eq. (4) is derived. The solitons (line and curved), domain walls and dromion-like solutions as well as their breaking analogues are obtained in Sec. VII and breaking solitons and dromions for its equivalent counterpart are obtained in Sec. VIII. In Sec. IX we comment on the possible further extensions and we conclude in Sec. X.

II. THE M-I EQUATION

The Lax representation of Eq. (4) can be shown to take the form[5]

$$\phi_{1x}=U_1\phi_1, \tag{6a}$$

$$\phi_{1t}=V_1\phi_1+\lambda\phi_{1y}, \tag{6b}$$

with

$$U_1=\frac{i\lambda}{2}S, \tag{7a}$$

$$V_1=\frac{\lambda}{4}([S,S_y]+2iuS). \tag{7b}$$

Here

$$S=\begin{pmatrix} S_3 & rS^- \\ rS^+ & -S_3 \end{pmatrix}, \tag{8}$$

$S^{\pm}=S_1\pm iS_2$ and λ is the eigenvalue parameter, which satisfies the following nonlinear equation

$$\lambda_t=\lambda\lambda_y. \tag{9}$$

Hence, using the compatibility of Eqs. (6a) and (6b), we get

$$iS_t=([S,S_y]+2iuS)_x, \tag{10a}$$

$$u_x=-\frac{1}{2i}\mathrm{tr}(SS_xS_y), \tag{10b}$$

where tr denotes the trace of the matrix. This system is obviously the matrix form of Eq. (4).

Thus, for solving Eq. (4), we must use the nonisospectral extension of IST.[5] As a consequence, Eq. (4) admits besides the usual solutions, corresponding to constant solution of Eq. (9), breaking analogues related to the t and y dependence of λ. Note that Eq. (9) itself is the compatibility condition of the following system of the linear equations,

$$f_x=\frac{i\lambda}{2}f, \tag{11a}$$

$$f_t=\lambda f_y. \tag{11b}$$

Another useful form of Eq. (4) can be obtained by using the complex (stereographic) variable $\omega(x,y,t)$ defined through the relations

$$S^+=S_1+iS_2=\frac{2\omega}{1+|\omega|^2}, \quad S_3=\frac{1-|\omega|^2}{1+|\omega|^2}. \tag{12}$$

In this case, Eq. (4) takes the form

$$i(\omega_t-u\omega_x)+\omega_{xy}-\frac{2\omega^*\omega_x\omega_y}{1+|\omega|^2}=0, \tag{13a}$$

$$u_x+\frac{2i(\omega_x\omega_y^*-\omega_x^*\omega_y)}{(1+|\omega|^2)^2}=0. \tag{13b}$$

We will use this form also frequently in our following analysis.

III. L-EQUIVALENT COUNTERPART

It is well known that in (1+1) dimensions there exists geometrical equivalence between spin systems and nonlinear Schrödinger type equations,[7,12] which in Ref. 5 was called the Lakshmanan equivalence or shortly the L-equivalence (see also Refs. 12–14). In Refs. 5,13–15 a (2+1) dimensional generalization of the L-equivalence was presented. In this section we find the L-equivalent counterpart of Eq. (4). For this purpose, we will extend the geometrical method appli-

cable to (1+1) dimensional systems suitably to the (2+1) dimensional case. We now associate a moving space curve parametrised by the arclength x, and endowed with an additional coordinate y, with the spin system.[12,16] Then the Serret–Frenet equation associated with the curve has the form

$$\vec{e}_{ix}=\vec{D}\wedge\vec{e}_i, \tag{14}$$

where

$$\vec{D}=\tau\vec{e}_1+\kappa\vec{e}_3 \tag{15}$$

and $\vec{e}_i$'s, $i=1,2,3$, form the orthogonal trihedral.

Mapping the spin variable on the unit tangent vector

$$\vec{S}(x,y,t)=\vec{e}_1, \tag{16}$$

the curvature and the torsion are given by

$$\kappa(x,y,t)=(\vec{S}_x^2)^{1/2}, \tag{17a}$$

$$\tau(x,y,t)=\kappa^{-2}\vec{S}\cdot(\vec{S}_x\wedge\vec{S}_{xx}). \tag{17b}$$

Due to the orthonormality nature of the trihedral, $\vec{e}_{it}.\vec{e}_i=0$, $\vec{e}_{iy}.\vec{e}_i=0$, $i,j=1,2,3$ and using the compatibility condition $\vec{e}_{ixy}=\vec{e}_{iyx}$, we find the equation for the y-part

$$\vec{e}_{iy}=\vec{\gamma}\wedge\vec{e}_i, \tag{18}$$

where $\vec{\gamma}=(\gamma_1,\gamma_2,\gamma_3)$ and

$$\gamma_1=u+\partial_x^{-1}\tau_y, \tag{19a}$$

$$\gamma_2=\frac{u_x}{\kappa}, \tag{19b}$$

$$\gamma_3=\partial_x^{-1}\left(\kappa_y-\frac{\tau u_x}{\kappa}\right). \tag{19c}$$

Alternatively the trihedral $\vec{e}_i(x,y,t)$, $i=1,2,3$ could be thought of as defining a suitable surface in E^3 (so that Eqs. (14) and (18) represent the Gauss–Weingarten equations in orthogonal coordinates and that the compatibility condition $\vec{e}_{ixy}=\vec{e}_{iyx}$ gives rise to the Codazzi–Mainardi equations), which is then set in motion. Now, from Eq. (4) and using Eqs. (14) and (18), we can easily find the time evolution of the trihedral as

$$\vec{e}_{it}=\vec{\Omega}\wedge\vec{e}_i, \tag{20}$$

with

$$\vec{\Omega}=(\omega_1,\omega_2,\omega_3)=\left(\frac{\kappa_{xy}}{\kappa}-\tau\partial_x^{-1}\tau_y,-\kappa_y,-\kappa\partial_x^{-1}\tau_y\right). \tag{21}$$

Ultimately, the compatibility condition $\vec{e}_{ixt}=\vec{e}_{itx}$, which is also consistent with the relation $\vec{e}_{iyt}=\vec{e}_{ity}$, $i=1,2,3$ yields the following evolution equations for the curvature and torsion,

$$\kappa_t=-(\kappa\tau)_y-\kappa_x\partial_x^{-1}\tau_y, \tag{22a}$$

$$\tau_t=\left[\frac{\kappa_{xy}}{\kappa}-\tau\partial_x^{-1}\tau_y\right]_x+\kappa\kappa_y\,. \tag{22b}$$

On making the complex transformation[7]

$$\psi(x,y,t)=\frac{\kappa(x,y,t)}{2}\exp\left[-i\int_{-\infty}^{x}\tau(x',y,t)dx'\right], \tag{23}$$

the set of Eq. (22) reduces to the following (2+1) dimensional NLSE

$$i\psi_t=\psi_{xy}+r^2V\psi, \tag{24a}$$

$$V_x=2\partial_y|\psi|^2. \tag{24b}$$

Here, $r^2=+1$, that is, we have the attractive type NLSE (the case $r^2=-1$ corresponds to the repulsive case). Equation (24) belongs to the class of equations discovered by Calogero[17] and then discussed by Zakharov[18] and recently rederived by Strachan (for $r^2=+1$).[19] Its Painlevé property and some exact solutions were also obtained.[20] N-soliton solutions of Eq. (24) for both the cases ($r^2=\pm1$) can be found in Ref. 21. Thus, we have proved that Eq. (24) is equivalent to Eq. (4) in the geometrical sense.

Linearization

Introducing now the complex variable corresponding to an orthogonal rotation

$$z_l=\frac{e_{2l}+ie_{3l}}{1-e_{1l}},\quad e_{1l}^2+e_{2l}^2+e_{3l}^2=1,\quad l=1,2,3$$

the spatial and temporal evolution of the trihedral [Eqs. (14), (18) and (20)] can be rewritten as a set of the following three Riccati equations:

$$z_{lx}=-i\tau z_l+\frac{\kappa}{2}[1+z_l^2], \tag{25a}$$

$$z_{ly}=-i\gamma_1 z_l+\frac{1}{2}[\gamma_3+i\gamma_2]z_l^2+\frac{1}{2}[\gamma_3-i\gamma_2], \tag{25b}$$

$$z_{lt}=-i\omega_1 z_l+\frac{1}{2}[\omega_3+i\omega_2]z_l^2+\frac{1}{2}[\omega_3-i\omega_2]. \tag{25c}$$

It is easy to check that Eq. (25a) is equivalent to the Serret–Frenet Eqs. (14), (25b) is equivalent to the y-variation of the trihedral Eq. (18), while the temporal evolution (25c) is equivalent to (20).

Further introducing the transformation

$$z_l=\frac{v_2}{v_1}, \tag{26}$$

Eq. (25) can be written as a system of three coupled two component first order equations,

$$\begin{pmatrix}v_{1x}\\ v_{2x}\end{pmatrix}=\begin{pmatrix}\frac{i\tau}{2} & \frac{-\kappa}{2}\\ \frac{\kappa}{2} & \frac{-i\tau}{2}\end{pmatrix}\begin{pmatrix}v_1\\ v_2\end{pmatrix}, \tag{27a}$$

$$\begin{pmatrix} v_{1y} \\ v_{2y} \end{pmatrix} = \begin{pmatrix} \frac{i\gamma_1}{2} & \frac{-1}{2}(\gamma_3 + i\gamma_2) \\ \frac{1}{2}(\gamma_3 - i\gamma_2) & \frac{-i\gamma_1}{2} \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}, \tag{27b}$$

$$\begin{pmatrix} v_{1t} \\ v_{2t} \end{pmatrix} = \begin{pmatrix} \frac{i\omega_1}{2} & \frac{-1}{2}(\omega_3 + i\omega_2) \\ \frac{1}{2}(\omega_3 - i\omega_2) & \frac{-i\omega_1}{2} \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}. \tag{27c}$$

Once again one can check that the compatibility of the three sets of Eqs. (27) gives rise to the evolution equation (22).

IV. GAUGE EQUIVALENT COUNTERPART

Next, it is also of interest to note that Eqs. (4) and (12) are gauge equivalent to each other in the sense of Zakharov and Takhtajan.[22] To obtain the gauge equivalent counterpart of Eq. (4), in the usual way we consider the following gauge transformation

$$\phi_1 = g^{-1}\phi_2, \tag{28}$$

where $g(x,y,t)$ and $\phi_2(x,y,t,\lambda)$ are arbitrary (2×2) matrix functions of the type defined on a compact manifold $S^2 = SU(2)/U(1)$. Substituting Eq. (28) into Eq. (6), after some algebra we get the following system of linear equations for ϕ_2,

$$\phi_{2x} = U_2\phi_2, \tag{29a}$$

$$\phi_{2t} = V_2\phi_2 + \lambda\phi_{2y} \tag{29b}$$

with

$$U_2 = \frac{i\lambda}{2}\sigma_3 + G, \quad G = \begin{pmatrix} 0 & \phi \\ -r^2\phi^* & 0 \end{pmatrix}, \quad r^2 = +1, \tag{30a}$$

$$V_2 = -i\sigma_3\left(\frac{VI}{2} + G_y\right), \quad I = \mathrm{diag}(1,1), \tag{30b}$$

$$V = 2\partial_x^{-1}\partial_y(|\psi|^2). \tag{30c}$$

The compatibility condition of Eq. (29) along with (9) becomes (24), that is, Eq. (4) and Eq. (24) are gauge equivalent to each other. The above transformation is in fact reversible and we can similarly prove that Eq. (24) is gauge equivalent to Eq. (4). It is also of interest to note that the set of linear Eqs. (27) can be recast in the form (29) after suitable transformations.

Next, we present some important formulae which are just consequences of the geometrical/gauge equivalence of Eqs. (4) and (24). We have

$$\mathrm{tr}(S_x^2) = 8|\psi|^2 = 2\vec{S}_x^2. \tag{31a}$$

In a similar manner we find that

$$-2i\vec{S}\cdot(\vec{S}_x \wedge \vec{S}_{xx}) = \mathrm{tr}(SS_xS_{xx}) = 4(\psi^*\psi_x - \psi\psi_x^*). \tag{31b}$$

These relations are obviously equivalent to Eq. (23). One notes that these are of the same form as in the case of $(1+1)$ dimensional Heisenberg spin chain.[7,8]

V. INTEGRALS OF MOTION

The spin Eq. (4) allows an infinite number of integrals of motion as a consequence of integrability. These integrals can be consructed using for example the Lax representation (6). However some of the integrals can be constructed using that L-equivalence property. Now from (22a), it follows that

$$(\kappa^2)_t=[-\kappa^2\partial_x^{-1}\tau_y]_x+[-k^2\tau]_y. \tag{32a}$$

Hence we get the first integral

$$K_1=\int \kappa^2 dxdy. \tag{32b}$$

Similarly (22b) leads to

$$K_2=\int \kappa^2\tau dxdy. \tag{33}$$

In terms of the spin vector the corresponding two conservation laws are

$$(\vec{S}_x^2)_t+\partial_x\left[\vec{S}_x^2\partial_x^{-1}\left(\frac{\vec{S}\cdot\vec{S}_x\wedge\vec{S}_{xx}}{\vec{S}_x^2}\right)_y\right]+\partial_y[\vec{S}\cdot\vec{S}_x\wedge\vec{S}_{xx}]=0, \tag{34}$$

$$[\vec{S}\cdot\vec{S}_x\wedge\vec{S}_{xx}]_t+\partial_x\left[\frac{(\vec{S}_x^2)_x(\vec{S}_x^2)_y}{4\vec{S}_x^2}+\vec{S}\cdot\vec{S}_x\wedge\vec{S}_{xx}\partial_x^{-1}\left(\frac{\vec{S}\cdot\vec{S}_x\wedge\vec{S}_{xx}}{\vec{S}_x^2}\right)_y\right]$$
$$+\partial_y\left\{\frac{(\vec{S}_x^2)_x^2}{4\vec{S}_x^2}+\frac{(\vec{S}\cdot\vec{S}_x\wedge\vec{S}_{xx})^2}{\vec{S}_x^2}-\frac{(\vec{S}_x^2)_{xx}}{2}-\frac{\vec{S}_x^4}{4}\right\}=0. \tag{35}$$

Note that these integrals have the same forms as in the (1+1) dimensional case. More interesting integrals of purely (2+1) dimensional nature can be obtained from the condition

$$\vec{e}_{jxy}=\vec{e}_{jyx}. \tag{36}$$

Making use of the various relations in Sec. III and after some algebra we have

$$(-\kappa\gamma_2)_t=(-\gamma_{1t})_x+(\tau_t)_y, \tag{37}$$

$$(-\tau\gamma_2)_t=(\gamma_{3t})_x+(-\kappa_t)_y. \tag{38}$$

These equations give two integrals

$$K_3=\int (-\kappa\gamma_2)dxdy, \tag{39}$$

and

$$K_4=\int (-\tau\gamma_2)dxdy. \tag{40}$$

In terms of the spin vector $\vec{S}$ these integrals of motion take the forms

$$K_1=\int (\vec{S}_x^2)dxdy, \tag{41}$$

$$K_2=\int \vec{S}\cdot\vec{S}_x\wedge\vec{S}_{xx}dxdy, \tag{42}$$

$$K_3=\int \vec{S}\cdot(\vec{S}_x\wedge\vec{S}_y)dxdy \tag{43}$$

and

$$K_4=\int \frac{[\vec{S}\cdot(\vec{S}_x\wedge\vec{S}_y)][\vec{S}\cdot(\vec{S}_x\wedge\vec{S}_{xx})]}{(\vec{S}_x^2)^{3/2}}dxdy. \tag{44}$$

Note that K_3 is the topological charge given by Eq. (1) to within a constant. One can proceed to find the other integrals of motion using the eigenvalue problem (29).

VI. HIROTA BILINEAR FORM

In order to solve the Cauchy initial value problem of Eq. (4), it will be of interest to investigate the system in the framework of the inverse spectral transform method, for example, by the d-bar dressing method.[2,3] However, for our present purpose we concentrate on exact analytic solutions of Eq. (4). In doing so, it is convenient to rewrite Eq. (4) or its equivalent stereographic form (13) in the Hirota bilinear form. On writing

$$\omega=\frac{g}{f}, \tag{45}$$

Eq. (4) or Eq. (13) becomes

$$(iD_t-D_xD_y)(f^*\circ g)=0, \tag{46a}$$

$$(iD_t-D_xD_y)(f^*\circ f-g^*\circ g)=0, \tag{46b}$$

$$D_x(f^*\circ f+g^*\circ g)=0, \tag{46c}$$

while the potential u takes the form

$$u(x,y,t)=-\frac{iD_y(f^*\circ f+g^*\circ g)}{f^*\circ f+g^*\circ g}, \tag{46d}$$

where g and f are complex valued functions. Here D_x is the Hirota bilinear operator, defined by

$$D_x^kD_y^mD_t^n(f\circ g)=(\partial_x-\partial_{x'})^k(\partial_y-\partial_{y'})^m(\partial_t-\partial_{t'})^nf(x,y,t)g(x,y,t)\|_{x=x',y=y',t=t'}. \tag{47}$$

Using the above definition of the D-operator, we get from (31d) that

$$u_x=-2i[D_y(f\circ g)D_x(f^*\circ g^*)-c.c]. \tag{48a}$$

In terms of g and f, the spin field takes the form

$$S^+=\frac{2f^*g}{|f|^2+|g|^2},\quad S_3=\frac{|f|^2-|g|^2}{|f|^2+|g|^2}. \tag{48b}$$

Equation (46) represents the starting point to obtain interesting classes of solutions for the spin system (4).The construction of the solutions is standard. One expands the functions g and f as a series

$$g=\epsilon g_1+\epsilon^3g_3+\epsilon^5g_5+\cdots, \tag{49a}$$

$$f=1+\epsilon^2 f_2+\epsilon^4 f_4+\epsilon^6 f_6+\ \ldots\ . \tag{49b}$$

Substituting these expansions into (46 a,b,c) and equating the coefficients of ϵ, one obtains the following system of equations from (46a):

$$\epsilon^1: ig_{1t}+g_{1xy}=0, \tag{50a}$$

$$\epsilon^3: [i\partial_t+\partial_x\partial_y]g_3=[iD_t-D_xD_y](f_2^*.g_1), \tag{50b}$$

$$\ldots$$

$$\ldots$$

$$\ldots$$

$$\epsilon^{2n+1}: [i\partial_t+\partial_x\partial_y]g_{2n+1}=\sum_{k+m=n}[iD_t-D_xD_y](f_{2k}^*.g_{2m+1}), \tag{50c}$$

and from (46b):

$$\epsilon^2: i\partial_t(f_2^*-f_2)-\partial_x\partial_y(f_2^*+f_2)=[iD_t-D_xD_y](g_1^*.g_1), \tag{51a}$$

$$\epsilon^4: i\partial_t(f_4^*-f_4)-\partial_x\partial_y(f_4^*+f_4)=[iD_t-D_xD_y](g_1^*.g_3+g_3^*.g_1-f_2^*.f_2), \tag{51b}$$

$$\ldots$$

$$\ldots$$

$$\ldots$$

$$\epsilon^{2n}: i\partial_t(f_{2n}^*-f_{2n})-\partial_x\partial_y(f_{2n}^*+f_{2n})=(iD_t-D_xD_y)\left(\sum_{n_1+n_2=n-1} g_{2n_1+1}^*.g_{2n_2+1}\right)$$
$$-(iD_t-D_xD_y)\left(\sum_{m_1+m_2=n} f_{2m_1}^*.f_{2m_2}\right). \tag{51c}$$

Further from (46c), we have the following:

$$\epsilon^2: \partial_x(f_2^*-f_2)=-D_x(g_1^*.g_1), \tag{52a}$$

$$\epsilon^4: \partial_x(f_4^*-f_4)=-D_x(g_1^*.g_3+g_3^*.g_1+f_2^*.f_2), \tag{52b}$$

$$\ldots$$

$$\ldots$$

$$\ldots$$

$$\epsilon^{2n}: \partial_x(f_{2n}^*-f_{2n})=-D_x\left[\sum_{n_1+n_2=n-1}\left(g_{2n_1+1}^*.g_{2n_2+1}+\sum_{n_1+n_2=n} f_{2n_1}^*.f_{2n_2}\right)\right]. \tag{52c}$$

Solving recursively the above equations, we obtain many interesting classes of solutions to Eq. (4).

VII. SOLUTIONS OF THE SPIN SYSTEM

Using the results of the previous section, we are in a position to construct many exact solutions such as solitons, domain walls, breaking solitons and induced dromions of Eq. (4). To obtain such solutions, we can use Eqs. (46) as the starting point.

A. The 1-line soliton and curved soliton solutions

On solving Eq. (50a), we obtain

$$g_1=\sum_{j=1}^{N}\exp\chi_j, \quad \chi_j=a_jx+b_j(y,t)+c_j, \tag{53a}$$

where $b_j(y,t)$ is an arbitrary function of (y,t) satisfying the relation

$$b_j(y,t)=b_j(\rho)=b_j(y+ia_jt), \tag{53b}$$

and a_j and c_j are complex constants. In order to construct the one soliton solution, we take the case of $N=1$ in (53a) and substitute it in Eq. (51a). We obtain

$$f_2=\exp(\chi_1+\chi_1^*+\psi). \tag{54a}$$

Using Eqs. (51a) and (52a), it is found that

$$\exp\psi=-\frac{a_1^2}{(a_1+a_1^*)^2}. \tag{54b}$$

If we use the above forms of g_1 and f_2 in Eqs. (50b), (51b) and (52b), we can see that $g_j=0$ for $j\geqslant 3$ and $f_j=0$ for $j\geqslant 4$. By substituting the values of g_1 and f_2 in Eqs. (48a) and (48b), we obtain the expressions for the 1-soliton solution for the spin components and for the potential for example with the choice $\exp c_1=2a_{1R}/a_1^*$ as

$$S^+(x,y,t)=\frac{2a_{1R}}{a_{1R}^2+a_{1I}^2}\exp\, i\chi_{1I}[ia_{1I}-a_{1R}\tanh\chi_{1R}]\operatorname{sech}\chi_{1R}, \tag{55a}$$

$$S_3(x,y,t)=1-\frac{2a_{1R}^2}{a_{1R}^2+a_{1I}^2}\operatorname{sech}^2\chi_{1R}, \tag{55b}$$

and the potential as

$$u(x,y,t)=\frac{2a_{1R}}{a_{1R}^2+a_{1I}^2}(a_{1I}b_{1R}'-a_{1R}b_{1I}')\operatorname{sech}^2\chi_{1R}. \tag{55c}$$

It follows from Eqs. (55) that one can identify two types of solitons.

1. Line solitons

If we choose the function $b_1(y,t)$ in Eq. (53b) as

$$b_1(y,t)=b_1y+ib_1a_1t, \tag{56a}$$

then

$$\chi_1=a_1x+b_1y+ia_1b_1t+c_1, \tag{56b}$$

where b_1 is now a complex constant, and Eqs. (55) correspond to the line solitons. In this case the spin vector $\vec{S}\to(0,0,1)$ for fixed t as x, $y\to\pm\infty$, except along the line

$$\chi_{1R}=a_{1R}x+b_{1R}y-(a_{1R}b_{1I}+a_{1I}b_{1R})t+c_{1R}=0, \tag{57}$$

where it is still bounded.

2. Curved solitons

However for arbitrary form of $b_1(\rho)=b_1(y+ia_1t)$ in Eq. (53b) and for fixed (y,t), it follows from (55) that $\vec{S}\to(0,0,1)$ as $x,y\to\pm\infty$ and the wavefront itself is defined by the equation

$$\chi_{1R}=a_{1R}x+b_{1R}(\rho)+c_{1R}=0. \tag{58}$$

We may call such solitons (which do not decay along the curve (58)) as curved solitons.[23]

B. The 2-soliton and N-soliton solutions

To generate a 2 line or curved soliton solution (2-SS), we take $N=2$ in (53a) and hence g_1 takes the form

$$g_1=\exp\,\chi_1+\exp\,\chi_2. \tag{59}$$

Substituting (59) in (50)–(52), after some calculation we obtain

$$f_2=N_{11}\exp(\chi_1+\chi_1^*)+N_{12}\exp(\chi_1+\chi_2^*)+N_{21}\exp(\chi_1^*+\chi_2)+N_{22}\exp(\chi_2+\chi_2^*), \tag{60a}$$

$$g_3=L_{12}N_{11}N_{12}\exp(\chi_1+\chi_1^*+\chi_2)+L_{12}N_{22}N_{21}\exp(\chi_1+\chi_2+\chi_2^*), \tag{60b}$$

$$f_4=L_{12}L_{12}^*N_{11}N_{12}N_{21}N_{22}\exp(\chi_1+\chi_1^*+\chi_2+\chi_2^*), \tag{60c}$$

where

$$N_{rs}=-\frac{a_r^2}{(a_r+a_s^*)^2},\quad L_{rs}=-\frac{(a_r-a_s)^2}{a_s^2}, \tag{60d}$$

and $g_j=0$ for $j\geqslant 5$ and $f_j=0$ for $j\geqslant 6$. Inserting (60) into (48b) we get

$$S^+(x,y,t)=2\frac{(1+f_2^*+f_4^*)(g_1+g_3)}{|1+f_2+f_4|^2+|g_1+g_3|^2}, \tag{61a}$$

$$S_3(x,y,t)=\frac{|1+f_2+f_4|^2-|g_1+g_3|^2}{|1+f_2+f_4|^2+|g_1+g_3|^2}, \tag{61b}$$

and similarly the expression for the potential can also be obtained from (48a) or (46d).

Finally by taking g_1 as

$$g_1=\sum_{j=1}^{N}\exp\,\chi_j$$

and extending the above procedure, one can obtain the N-SS also.

C. The domain wall type solution

The soliton solutions of (55) and (61) correspond to the boundary condition

$$\vec{S}(x,y,t)=(0,0,1),\quad \text{as}\quad x,y\to\pm\infty. \tag{62}$$

Another class of physically interesting solutions are the domain wall type solutions, which have the asymptotic form

$$\vec{S}(x,y,t)=(0,0,\pm 1),\quad \text{as}\quad x,y\to\pm\infty. \tag{63}$$

In order to obtain domain wall solutions in the present model, we make the choice

$$\omega(x,y,t)=g(x,y,t),\quad f(x,y,t)=1. \tag{64}$$

Then, Eq. (46) reduces to

$$ig_t+g_{xy}=0, \tag{65a}$$

$$g_x^*g_y+g_y^*g_x=0, \tag{65b}$$

$$g_x^*g-g^*g_x=0, \tag{65c}$$

which is consistent with Eq. (13). Alternately, we can use another substitution

$$\omega(x,y,t)=\frac{1}{f(x,y,t)},\quad g(x,y,t)=1. \tag{66}$$

Here also it follows from (46) that

$$if_t^*-f_{xy}^*=0, \tag{67a}$$

$$f_x^*f_y+f_xf_y^*=0, \tag{67b}$$

$$f_x^*f-f^*f_x=0. \tag{67c}$$

Comparing Eqs. (65) and (67), we see that if $\omega(x,y,t)$ is a solution of Eq. (13), so also

$$\omega'(x,y,t)=\pm\frac{1}{\omega(x,y,t)} \tag{68}$$

are solutions of Eq. (13). This is an obvious consequence of the fact that Eq. (13) is invariant under inversion.

Now, we find the simplest nontrivial solutions for example of Eq. (65). Let us take the ansatz

$$g=\exp(ax+iby-abt), \tag{69}$$

where a, b are real constants. The components of the spin vector $\vec{S}$ are given by

$$S^+(x,y,t)=\frac{\exp\ iby}{\cosh[a(x-bt-x_0)]}, \tag{70a}$$

$$S_3(x,y,t)=-\tanh[a(x-bt-x_0)]. \tag{70b}$$

We can also have a more general solution of the form

$$g=\exp[ax+im(y,t)], \tag{71}$$

where a is a real constant and $m(y,t)$ is an arbitrary function of y and t. From Eq. (65a), it follows that

$$m=m(\rho)=m(y+iat),\quad \rho=y+iat. \tag{72}$$

Expressions for the spin components are then given by

$$S^+(x,y,t)=\frac{\exp[i\ \mathrm{Re}(m(\rho))]}{\cosh[ax-\mathrm{Im}(m(\rho))]}, \tag{73a}$$

$$S_3(x,y,t)=-\tanh[ax+\mathrm{Re}(m(\rho))], \tag{73b}$$

and the potential is

$$u(x,y,t)=-2m_R'\{1+\exp[-2(ax-m_I)]\}^{-1}, \tag{74}$$

where the $'$ denotes the differentiation with respect to the real part of the argument. Naturally even more general solutions can be obtained by taking more general forms for $g(x,y,t)$ than (69) or (71).

D. The breaking soliton solution

We have already noted in Sec. II that for the present system (4), we have a nonisospectral problem, as the spectral parameter λ satisfies Eq. (9). The above presented solutions all correspond to the constant solution of Eq. (9), namely, $\lambda=\lambda_1=$ constant. One may consider other interesting solutions of Eq. (9). For example, one can have a special solution

$$\lambda=\lambda_1=\delta(y,t)+i\xi(y,t)=\frac{y+k+i\eta}{q-t}, \tag{75}$$

where q, k and η are real constants. Corresponding to this case, we may call the resulting solutions of Eqs. (4) and (24) as breaking solitons.[4] Using the Hirota method, one can also construct the breaking 1-SS of Eq. (4) associated with (75). For this purpose, we take g_1 in the form

$$g=g_1=\exp\chi, \quad \chi=ax+m+c=\chi_R+i\chi_I, \tag{76}$$

where $a=a(y,t)$, $m=m(y,t)$ and $c=c(t)$ are functions to be determined. Substituting (76) into the first of Eq. (53), we get

$$ia_t+aa_y=0, \quad im_t+am_y=0, \quad iA_t+Aa_y=0, \tag{77}$$

where $A=\exp(c)$. Particular solutions of Eqs. (77) have the forms

$$a=-i\lambda=\frac{\eta-i(y+k)}{q-t}, \quad m=m\left(\frac{y+k+i\eta}{q-t}\right), \quad A=\frac{A_0}{q-t}, \tag{78}$$

where η, k, q and A_0 are some constants. From Eqs. (50)-(52), we obtain

$$f_2=B\exp 2\chi_R, \quad B=\frac{(y+k+i\eta)^2}{4\eta^2}. \tag{79}$$

Now, we can write the breaking 1-SS of Eq. (4) (using equations (48b), (76)–(79)),

$$S^+(x,y,t)=\frac{\exp\left[i\chi_{1I}+\ln\dfrac{2\eta}{y+k+i\eta}\right]\operatorname{sech}\left[\chi_{1R}+\ln\dfrac{y+k+i\eta}{2\eta}\right]}{1+\dfrac{\eta^2}{(y+k)^2+\eta^2}\operatorname{sech}\left[\chi_{1R}+\ln\dfrac{y+k+i\eta}{2\eta}\right]\operatorname{sech}\left[\chi_{1R}+\ln\dfrac{y+k-i\eta}{2\eta}\right]}, \tag{80a}$$

$$S_3(x,y,t)=\frac{1-\dfrac{\eta^2}{(y+k)^2+\eta^2}\operatorname{sech}\left[\chi_{1R}+\ln\dfrac{y+k+i\eta}{2\eta}\right]\operatorname{sech}\left[\chi_{1R}+\ln\dfrac{y+k-i\eta}{2\eta}\right]}{1+\dfrac{\eta^2}{(y+k)^2+\eta^2}\operatorname{sech}\left[\chi_{1R}+\ln\dfrac{y+k+i\eta}{2\eta}\right]\operatorname{sech}\left[\chi_{1R}+\ln\dfrac{y+k-i\eta}{2\eta}\right]}, \tag{80b}$$

where $\chi_1=\chi$ as defined in Eq. (76). We see that the solution (80) corresponds to an algebraically decaying solution for large x, y.

E. Localized coherent structures (dromions)

Next, we present the dromion type localized solutions of Eq. (4), the so-called induced localized structures/or induced dromions[23] for the potential $u(x,y,t)$. This is possible by utilizing the freedom in the choice of the arbitrary functions b_{1R} and b_{1I} of b_1 in Eq. (55c) and (53b). For example, if we make the ansatz

$$b_{1I}(\rho_R)=kb_{1R}(\rho_R)=\tanh(\rho_R), \tag{81}$$

$$u=2\eta(\xi-\eta k)\operatorname{sech}^2\ \rho_R\ \operatorname{sech}[\ \eta x+\tanh\ \rho_R-\eta x_0], \tag{82}$$

where $\rho_R=y-a_{1I}t$ and k is a constant. Similarly, the expressions for the spin can be obtained from Eqs. (55 a,b). The solution (82) for $u(x,y,t)$ decays exponentially in all the directions, even though the spin $\vec{S}$ itself is not fully localized. Analogously we can construct another type of ''induced dromion'' solution with the choice

$$b_{1I}=kb_{1R}=\int \frac{d\rho_R}{(\rho_R+\rho_0)^2+1}+b_0, \tag{83}$$

where ρ_0 and b_0 are constants, so that

$$u(x,y,t)=\frac{2\eta(\xi-ky)}{(\rho_R+\rho_0)^2+1}\operatorname{sech}^2\left[\ \eta x+\int \frac{d\rho_R}{(\rho_R+\rho_0)^2+1}-\eta x_0\right]. \tag{84}$$

Proceeding in this way we can construct even more general solutions and multidromions for the potential.

VIII. SOLUTIONS OF (2+1) DIMENSIONAL NLSE

In this section, we wish to consider briefly the corresponding solutions of the equivalent generalized NLSE Eq. (24). Already this equation has received some attention in the literature. The following types of solutions are available:[23,24]

(a) Line solitons,

(b) Induced dromions.

Now, we can construct the N-breaking soliton solutions of Eq. (24) as well. As an example, let us obtain the 1-breaking soliton solution of Eq. (24). The Hirota bilinear form of Eq. (24) can be obtained by using the transformation.

$$\psi=\frac{h}{\phi} \tag{85}$$

as[20,24]

$$[iD_t+D_xD_y](h\circ\phi)=0, \tag{86a}$$

$$D_x^2(\phi\circ\phi)=2hh^*. \tag{86b}$$

We look for the 1-breaking soliton solution in the following form:

$$h=\exp\ \chi, \tag{87a}$$

$$\phi=1+\phi_2, \tag{87b}$$

where $\chi=b(y,t)x+n(y,t)+c(t)$. Substituting (87) into (86), we get

$$ib_t+bb_y=0, \tag{88a}$$

$$in_t+bn_y=0, \tag{88b}$$

$$iB_t+Bb_y=0, \tag{88c}$$

and

$$\phi_2=\frac{1}{(b+b^*)^2}\exp\ \chi+\chi^*=\exp\ 2(b_Rx+n_R+\chi_0), \tag{89}$$

where $\exp\ 2\chi_0=1/4b_R^2$, $B=\exp\ c(t)$ and $b_R=b_R(t)=\mathrm{Re}(b)$. Now, formula (85) provides us the 1-breaking soliton solution of Eq. (24),

$$\psi(x,y,t)=\frac{b_R(t)\exp\ i[b_I(y,t)x+n_I(y,t)+c_0]}{\cosh[b_Rx+n_R(y,t)+\chi_0]}, \tag{90}$$

where $b(y,t)=b_R+ib_I$, $n(y,t)=n_R+in_I$ and $B(t)$ are the solutions of Eqs. (88). Just as in the case of Eq. (77), if we take the following particular solutions of the system of Eqs. (88);

$$b=-i\lambda=\frac{\eta-i(y+k)}{q-t},\quad n=\frac{y+k+i\eta}{q-t},\quad B=\frac{B_0}{(q-t)}, \tag{91}$$

then the 1-breaking soliton solution of Eq. (24) takes the form

$$\psi(x,y,t)=-\frac{\eta}{q-t}\exp\ i\left[-\frac{y+k}{q-t}x+n_I(y,t)+c_0\right]\mathrm{sech}\ Z, \tag{92}$$

where $Z=(\eta/q-t)\,x+n_R(y,t)+\chi_0$ and c_0, χ_0 are constants.

Similarly, we obtain the breaking N-SS of (24). In this case we can take the ansatz

$$g_1=\sum_{j=1}^{N}\exp\ \chi_j \tag{93}$$

with $\chi_j=b_j(y,t)x+n_j(y,t)+c_j(t)$. Inserting (93) into (92), one is lead to

$$ib_{jt}+b_jb_{jy}=0, \tag{94a}$$

$$in_{jt}+b_jn_{jy}=0, \tag{94b}$$

$$iB_{jt}+B_jb_{jy}=0. \tag{94c}$$

Proceeding as before, one can obtain breaking N-soliton solution.

IX. SIMPLEST INTEGRABLE EXTENSIONS

As mentioned above in Ref. 5 (see also Refs. 25,26) a new class of (2+1) dimensional integrable spin equations was proposed. In particular, Eq. (4) is a particular reduction of the following so called M-III equation (according to the notations of Ref. 5)

$$\vec{S}_t=(\vec{S}\wedge\vec{S}_y+u\vec{S})_x+2l(cl+d)\vec{S}_y-4cV\vec{S}_x+\vec{S}\wedge A\vec{S}, \tag{95a}$$

$$u_x=-\vec{S}\cdot(\vec{S}_x\wedge\vec{S}_y), \tag{95b}$$

$$V_x=\frac{1}{4(2lc+d)^2}(\vec{S}_x^2)_y, \tag{95c}$$

where l, c and d are constants and A is the anisotropy tensor. This equation possesses some integrable reductions. For example, one obtains

(a) the isotropic M-I equation (4), when $c=0$, $A=0$;

(b) the isotropic M-II equation, when $d=0$, $A=0$;

(c) the isotropic M-III equation, when $c\neq0\neq d$, $A=0$;

(d) the anisotropic M-I equation, when $c=0$,

and so on. All these equations are integrable in the sense that each one of such reduction has a Lax representation.[5] As an example, let us present the associated linear problem for the isotropic M-III equation,[5]

$$\psi_{1x}=U_1\psi_1, \tag{96a}$$

$$\psi_{1t}=V_1\psi_1+(2c\lambda^2+2d\lambda)\psi_{1y}, \tag{96b}$$

with

$$U_1=[ic(\lambda^2-l^2)+id(\lambda-l)]S+\frac{c(\lambda-l)}{2cl+d}SS_x, \tag{97a}$$

$$V_1=[2c(\lambda^2-l^2)+2d(\lambda-l)]B+\lambda^2F_2+\lambda F_1+F_0, \tag{97b}$$

where

$$F_2=-4ic^2VS,$$

$$F_1=-4icdVS-\frac{4c^2V}{2cl+d}VSS_x-\frac{ic}{2cl+d}S\{(SS_x)_y-[SS_x,B]\}, \tag{98}$$

$$F_0=-lF_1-l^2F_2.$$

Here

$$B=\frac{1}{4}([S,S_y]+2iuS),\quad S=\vec{S}\cdot\vec{\sigma}.$$

From these equations one can deduce the corresponding Lax representations of the isotropic M-I and M-II equations by choosing $c=0$ and $d=0$, respectively. We note that Eq. (95) for the isotropic M-III equation reduction case is gauge[27] and L-equivalent[14] to the following equation

$$i\phi_t=\phi_{xy}-4ic(V\phi)_x+2d^2V\phi, \tag{99a}$$

$$V_x=(|\phi|^2)_y. \tag{99b}$$

This equation has two integrable cases: (a) if $c=0$, Eq. (99) reduces to Eq. (24); (b) if $d=0$, we get the Strachan equation.[19] The Lax representations corresponding to (99) is obtained as follows.

$$\psi_{2x}=U_2\psi_2, \tag{100a}$$

$$\psi_{2t}=V_2\psi_2+(2c\lambda^2+2d\lambda)\psi_{2y}, \tag{100b}$$

with

$$U_2=i[(c\lambda^2+d\lambda)\sigma_3+(2c\lambda+d)Q], \tag{101a}$$

$$V_2=\lambda^2B_2+\lambda B_1+B_0. \tag{101b}$$

Here

$$B_2=-4ic^2V\sigma_3,$$

$$B_1=-4idcV\sigma_3+2c\sigma_3Q_y-8ic^2VQ, \tag{102}$$

$$B_0=\frac{d}{2c}B_1-\frac{d^2}{4c^2}B_2,$$

$$Q=\begin{pmatrix} 0 & \phi \\ -\phi^* & 0 \end{pmatrix}.$$

X. CONCLUSIONS

In this paper we have obtained many interesting classes of exact solutions of Eq. (4) and its equivalent counterpart Eq. (24), after establishing their L-equivalence and gauge equivalence. The equivalence concept was also extended to more general cases in Sec. IX. Another interesting class of solutions are the periodic solutions which for Eq. (4) are given by

$$S_1(x,y,t)=\frac{CD-AB}{AD-BC},\quad S_2(x,y,t)=-i\frac{CD+AB}{AD-BC},$$

$$S_3(x,y,t)=\frac{AD+BC}{AD-BC}, \tag{103}$$

where

$$A=\theta\left(z-\frac{r}{2}-\frac{\delta}{2},\tau\right),\quad B=\theta\left(z+\frac{r}{2}-\frac{\delta}{2},\tau\right),$$

$$C=\theta\left(z-\frac{r}{2}+\frac{\delta}{2},\tau\right),\quad D=\theta\left(z+\frac{r}{2}+\frac{\delta}{2},\tau\right). \tag{104}$$

Here, $\theta(z,\tau)$ is the Riemann θ functions and r, δ are some constants. More detailed investigation of the periodic solution (103) will be considered elsewhere.

Also we would like to note that the extended version of the L-equivalence method which we used in Sec. III works out for many other (2+1) dimensional spin equations as well, for instance, to the Ishimori equation.[14] In the later case, the unit vectors $\vec{e}_k$, $k=1,2,3$, satisfy the Eqs. (14) and (18), while the vector $\vec{e}_1\equiv\vec{S}$ satisfies the Ishimori equation

$$\vec{e}_{1t}=\vec{e}_1\wedge(\vec{e}_{1xx}+\epsilon^2\vec{e}_{1yy})+u_x\vec{e}_{1y}+u_y\vec{e}_{1x}, \tag{105a}$$

$$u_{xx}-\epsilon^2u_{yy}=-2\epsilon^2\vec{e}_1\cdot(\vec{e}_{1x}\wedge\vec{e}_{1y}). \tag{105b}$$

Proceeding as in Sec. III, we can obtain an evolution equation for the curvature κ and torsion τ in the form

$$\kappa_t=\omega_{3x}+\tau\omega_2, \tag{106a}$$

$$\tau_t=\omega_{1x}-\kappa\omega_2, \tag{106b}$$

where

$$\omega_1=\frac{\tau\omega_3-\omega_{2x}}{\kappa},\quad \omega_2=u_x\gamma_2-\kappa_x-\epsilon^2\gamma_{3y}+\gamma_1\gamma_2,$$

$$\omega_3=-\kappa\tau+\kappa u_y+u_x\gamma_3+\epsilon^2\gamma_{2y}-\gamma_1\gamma_3,\quad \gamma_2=\frac{(u_{xx}-\epsilon^2u_{yy})}{2\epsilon^2\kappa}$$

and the values of γ_1 and γ_3 can be obtained from the relations (19a) and (19c) respectively. Then the complex transformation

$$\phi = a \exp ib, \tag{107}$$

where

$$a = \frac{1}{2}[\kappa^2 + \gamma_2^2 + \gamma_3^2 - 2\kappa\gamma_2]^{1/2}, \tag{108a}$$

$$b = \partial_x^{-1}\left(\tau - \frac{u_y}{2} + \frac{\gamma_2\gamma_{3x} - \gamma_3\gamma_{2x} - \kappa\gamma_{3x}}{\kappa^2 + \gamma_2^2 + \gamma_3^2 - 2\kappa\gamma_2}\right) \tag{108b}$$

satisfies the Davey–Stewartson equation for $\epsilon^2 = -1$,

$$i\phi_t = \phi_{yy} - \phi_{xx} + 2\phi u, \tag{109a}$$

$$u_{yy} + u_{xx} + (|\phi|)^2_{xx} - (|\phi|)^2_{yy} = 0, \tag{109b}$$

where u is a function of x, y and t. Here κ and τ have the forms (17). Thus the geometrical equivalence between (105) and (109) can be established using the generalized transformation (107).

To summarize, in this paper, we have shown the equivalence of the (2+1) dimensional spin equation (4) and the generalized (2+1) dimensional NLSE (24). Besides we have found interesting classes of exact solutions for Eq. (4) and NLSE (24). However, many questions remain open and deserve further investigation. These include the existence of, for example, localized coherent structures (other than the induced dromion-like solution presented here), the determination of the Hamiltonian structure and the finding of possible physical applications of the solutions obtained above. Another interesting problem is the classification of solitons by the values of the topological charge. These questions are being pursued further.

Positivity properties of the Bel–Robinson tensor

Göran Bergqvist[a)]
Department of Mathematics, Mälardalen University, S-721 23 Västerås, Sweden

(Received 28 April 1997; accepted for publication 15 December 1997)

The Bel–Robinson tensor is a rank 4 tensor constructed from the Weyl curvature tensor. It is well known that when it is contracted with four future-pointing vectors a non-negative value is always obtained. In this paper we investigate various cases in which the value zero is attained and show that it occurs in some situations where space–time is of an algebraically special type. This is of importance for expressions of gravitational energy related to the Bel–Robinson tensor. Some new invariant ways of classifying the Petrov type of space–times using the Bel–Robinson tensor are also presented. © *1998 American Institute of Physics.* [S0022-2488(98)01204-3]

I. INTRODUCTION

In this paper we present some properties and applications of the Bel–Robinson tensor. This rank 4 tensor was introduced independently in 1958–1959 by Bel[1] and Robinson (unpublished). Let C_{abcd} denote the Weyl curvature tensor for a manifold of any dimension and any signature of the metric and let $*C_{abcd}$ denote the dual of C_{abcd} with respect to the first two indices. Then we define the Bel–Robinson tensor T_{abcd} as

$$T_{abcd}=\tfrac{1}{4}(C_a{}^e{}_b{}^f C_{cedf}+*C_a{}^e{}_b{}^f *C_{cedf}). \tag{1.1}$$

Sometimes the factor $\frac{1}{4}$ is omitted, but we shall follow the notation and conventions of Penrose and Rindler.[2] The main interest for this tensor has been in general relativity. As we shall see, it has certain positivity properties and this has led to speculations about relations to energy. However, a clear physical interpretation is still lacking and the applications have been of a more mathematical nature.

Here we shall use spinors to study the Bel–Robinson tensor and therefore we restrict our attention to space–time manifolds. We assume that the dimension is four and that we have a metric g_{ab} of signature $(+---)$ as is natural when spinors are used. The notation will be the abstract index notation[2] where tensors have indices $a,b,c,\ldots$ and spinors $A,A',B,B',\ldots$ with the usual identification $a=AA'$. The antisymmetric spinor ϵ_{AB} is related to the metric by $g_{ab}=\epsilon_{AB}\overline{\epsilon}_{A'B'}$. Let Ψ_{ABCD} denote the Weyl spinor. The Weyl spinor is totally symmetric so $\Psi_{ABCD}=\Psi_{(ABCD)}$ and trace-free $\Psi_{ABC}{}^C=0$.[2] Furthermore, in vacuum we have $\nabla^{AA'}\Psi_{ABCD}=0$. The Weyl tensor can be expressed as

$$C_{abcd}=\Psi_{ABCD}\overline{\epsilon}_{A'B'}\overline{\epsilon}_{C'D'}+\overline{\Psi}_{A'B'C'D'}\epsilon_{AB}\epsilon_{CD}. \tag{1.2}$$

Using the Weyl spinor, the expression (1.1) can be written as[2]

$$T_{abcd}=T_{AA'BB'CC'DD'}=\Psi_{ABCD}\overline{\Psi}_{A'B'C'D'}, \tag{1.3}$$

which is a much simpler form than (1.1) to work with. The properties of the Weyl spinor translate to

$$T_{abcd}=T_{(abcd)} \tag{1.4}$$

and

a)Electronic mail: gbt@mdh.se

 © 1998 American Institute of Physics

$$T_{abc}{}^{c}=0, \tag{1.5}$$

so T_{abcd} is totally symmetric and trace-free. In vacuum it becomes divergence-free, i.e.,

$$\nabla^{a}T_{abcd}=0. \tag{1.6}$$

If C_{abcd} in (1.1) is substituted by the Riemann curvature tensor R_{abcd} one obtains a tensor called the Bel tensor. Originally, the Bel–Robinson tensor was just considered as the special case of the Bel tensor in vacuum. However, (1.1) has become the standard definition of the Bel–Robinson tensor in any space–time. For more details on the early work on these tensors, see Ref. 3.

The Bel–Robinson tensor has certain positivity properties which we shall study in the following sections. Recall that a vector v^{a} is said to be future-pointing if it lies within the future half of the null cone in the tangent space. It is timelike if $v_{a}v^{a}>0$ and null if $v_{a}v^{a}=0$. The simplest positivity property of T_{abcd} is that

$$T_{abcd}a^{a}b^{b}c^{c}d^{d}\geqslant 0 \tag{1.7}$$

for all future-pointing vectors a^{a}, b^{a}, c^{a}, and d^{a} (we return to this inequality in Sec. II). This property, which is similar to the dominant energy condition

$$T_{ab}a^{a}b^{b}\geqslant 0 \tag{1.8}$$

for all future-pointing vectors a^{a} and b^{a}, where T_{ab} is the energy momentum tensor, has led to attempts to give physical interpretation to the Bel–Robinson tensor. Relations to gravitational energy or superenergy have been discussed in, for instance, Refs. 4–8. It has also been related to definitions of quasilocal energy in situations with small surfaces in vacuum (see Refs. 9 and 10 and the references therein). Note that T_{abcd} has the dimension of energy squared, but the positivity property (1.7) has also led to a definition of a kind of tensorial square root of T_{abcd} with the dimension of energy density (see Ref. 3).

Non-negative quantities are also useful in mathematical proofs and the Bel–Robinson tensor was used by Christodoulou and Klainerman[11] in their work on the stability of Minkowski space–time. Recently Bonilla and Senovilla[12] also used it to study causal propagation of gravity in vacuum. They also used the Bel–Robinson tensor to provide a new way of characterizing Petrov type N space–times. We recall that the Weyl spinor can always be written[2]

$$\Psi_{ABCD}=\alpha_{(A}\beta_{B}\gamma_{C}\delta_{D)}, \tag{1.9}$$

i.e., as the symmetric product of four spinors α_{A}, β_{A}, γ_{A}, and δ_{A} (which are uniquely determined up to scaling and ordering). These are called the principal null directions of the Weyl spinor (or Weyl tensor) or the gravitational principal null directions (GPNDs).[13] Space–times are said to be Petrov type I if they are all distinct (by which we really mean nonparallel), of type II if two are equal, of type D if there are two pairs of equal ones, of type III if three are equal and of type N if all four are equal. All types except type I are called algebraically special. Sometimes one also calls the null vector $k_{a}=\alpha_{A}\overline{\alpha}_{A'}$ a GPND if α_{A} is a GPND. In Sec. III we present some new invariant ways of finding Petrov types using the Bel–Robinson tensor. These results generalize the results of Ref. 12.

Before that, we study in Sec. II some cases when we have equality in Eq. (1.7) and this will also be seen to occur mainly in algebraically special space–times. With relations between the Bel–Robinson tensor and gravitational energy it is important to know when the value zero can be attained.

II. POSITIVITY PROPERTIES

We begin by formulating an elementary result on future-pointing vectors.

Lemma 1: Let k^{a} be a given future-pointing null vector and s^{a} a given future-pointing timelike vector. Then there is a future-pointing null vector n^{a} such that $s^{a}=ck^{a}+n^{a}$, where $c=s_{a}s^{a}/(2s_{a}k^{a})>0$.

Proof: Define $n^a=s^a-ck^a$ with c as above. $c>0$ as both s^a and k^a are future-pointing. Furthermore, $n_an^a=s_as^a-2cs_ak^a+c^2k_ak^a=s_as^a-s_as^a=0$ so n^a is null, and $n_as^a=s_as^a-s_as^a/2=s_as^a/2>0$ so n^a is also future-pointing.

Next we recall a well-known positivity result for the Bel–Robinson tensor (see, e.g., Ref. 2).

Theorem 1: $T_{abcd}a^ab^bc^cd^d\geqslant 0$ for all future-pointing vectors a^a, b^a, c^a, and d^a.

The proof is done most simply using spinors, and we illustrate it here since the ideas will be useful in other proofs in this paper. By Lemma 1, any future-pointing timelike vector can be written as the sum of two future-pointing null vectors. The vectors a^a, b^a, c^a, and d^a can be either timelike or null. Writing those that are timelike as a sum of two null vectors, $T_{abcd}a^ab^bc^cd^d$ can be expressed as the sum of between 1 and 16 terms of the type $T_{abcd}e^af^bg^ch^d$ where e^a, f^a, g^a, and h^a are null. Using spinors to write each null vector as $e^a=E^A\overline{E^{A'}}$ and so on and using (1.3) we have

$$T_{abcd}e^af^bg^ch^d=|\Psi_{ABCD}E^AF^BG^CH^D|^2\geqslant 0, \tag{2.1}$$

and of course the sum of such terms is non-negative.

We also remark that Theorem 1 is more general than proposition 1 of Ref. 12. Given a future-pointing timelike vector u^a, define

$$\tau_a=\tau_a(u,u,u)=T_{abcd}u^bu^cu^d. \tag{2.2}$$

Then proposition 1 of Ref. 12 states that $\tau_a\tau^a\geqslant 0$. This follows immediately from Theorem 1 above, since obviously $\tau_aa^a\geqslant 0$ for any future-pointing vector a^a, and this also implies that τ^a is future-pointing (so $\tau_a\tau^a\geqslant 0$).

We now continue by studying some cases in which $T_{abcd}a^ab^bc^cd^d$ takes the value 0. The results are summarized in the following theorem:

Theorem 2: Assume that $T_{abcd}\neq 0$, k^a is a future-pointing null vector, and s^a, u^a, v^a, and w^a are future-pointing timelike vectors. Then

(i) $T_{abcd}s^au^bv^cw^d>0$.
(ii) $T_{abcd}k^au^bv^cw^d=0\Leftrightarrow T_{abcd}k^a=0\Leftrightarrow$space–time is of type N and k^a is a GPND of multiplicity 4.
(iii) $T_{abcd}k^ak^bv^cw^d=0\Leftrightarrow T_{abcd}k^ak^b=0\Leftrightarrow$space–time is of type III or N and k^a is a GPND of multiplicity at least 3.
(iv) $T_{abcd}k^ak^bk^cw^d=0\Leftrightarrow T_{abcd}k^ak^bk^c=0\Leftrightarrow$space–time is of type II, D, III, or N and k^a is a GPND of multiplicity at least 2.
(v) $T_{abcd}k^ak^bk^ck^d=0\Leftrightarrow k^a$ is a GPND.

Before the proof we make some comments. The proof of statement (v) is indicated in Ref. 2. Statement (ii) generalizes a result of Ref. 12, which says that for τ^a defined by (2.2) we have $\tau_a\tau^a=0$ (as $T_{abcd}\neq 0$) if and only if space–time is of type N. To see this, $\tau_a\tau^a=0$ means that τ^a is a null vector and therefore there is another null vector k^a (proportional to τ^a) such that $\tau_ak^a=0$. This implies that $T_{abcd}k^au^bu^cu^d=0$, which by (ii) is equivalent to that space–time is of type N.

Proof of Theorem 2: For completeness we also give the proof of (v) as it is a natural starting point for the other results. Writing $k^a=K^A\overline{K^{A'}}$ and using (1.3) we have that $T_{abcd}k^ak^bk^ck^d=0$ is equivalent to

$$\Psi_{ABCD}K^AK^BK^CK^D=0. \tag{2.3}$$

Using (1.9) to express Ψ_{ABCD} in terms of the GPNDs we obtain

$$\alpha_{(A}\beta_B\gamma_C\delta_{D)}K^AK^BK^CK^D=0, \tag{2.4}$$

but as

$$\alpha_{(A}\beta_B\gamma_C\delta_{D)}K^AK^BK^CK^D=\alpha_A\beta_B\gamma_C\delta_DK^AK^BK^CK^D=(\alpha_AK^A)(\beta_BK^B)(\gamma_CK^C)(\delta_DK^D) \tag{2.5}$$

we find

$$(\alpha_A K^A)(\beta_B K^B)(\gamma_C K^C)(\delta_D K^D)=0. \tag{2.6}$$

This means that at least one factor is zero, e.g., $\alpha_A K^A=0$. Then K^A is proportional to α^A and thus K^A is a GPND of the Weyl spinor or, on vector form, we say that k^a is a GPND which proves (v).

To prove (iv) we first assume that k^a is a GPND of multiplicity at least 2. Then

$$\Psi_{ABCD}=K_{(A}K_B\gamma_C\delta_{D)}, \tag{2.7}$$

which obviously implies that

$$\Psi_{ABCD}K^AK^BK^C=0 \tag{2.8}$$

as every term will contain some contraction of the form $K_AK^A=0$. The tensor form of (2.8) is $T_{abcd}k^ak^bk^c=0$. This trivially implies that

$$T_{abcd}k^ak^bk^cw^d=0. \tag{2.9}$$

It remains to be proven that (2.9) implies that k^a is a GPND of multiplicity at least 2. To do this we use Lemma 1 to write $w^d=ck^d+n^d$. Then

$$T_{abcd}k^ak^bk^cw^d=cT_{abcd}k^ak^bk^ck^d+T_{abcd}k^ak^bk^cn^d \tag{2.10}$$

with $c>0$. By Theorem 1, both terms on the right-hand side are non-negative so (2.9) implies that both are zero. By (v) we obtain that the first term is zero if k^a is a GPND and therefore $\Psi_{ABCD}=K_{(A}\beta_B\gamma_C\delta_{D)}$. Writing $n^d=N^D\overline{N}^{D'}$ the second term is zero if

$$0=\Psi_{ABCD}K^AK^BK^CN^D=K_{(A}\beta_B\gamma_C\delta_{D)}K^AK^BK^CN^D=(K_AN^A)(\beta_BK^B)(\gamma_CK^C)(\delta_DK^D), \tag{2.11}$$

since all the terms containing $K_AK^A=0$ vanish. Now, as w^d is timelike, n^d is not proportional to k^d. Therefore N^A is not proportional to K^A and $K_AN^A\neq0$. Thus we obtain that, for instance, $\beta_BK^B=0$, so β^A is proportional to K^A and hence K^A is a GPND of multiplicity at least 2 which proves (iv).

We prove (ii) and (iii) in a similar way. In (iii) we first assume that k^a is a GPND of multiplicity at least 3. Then $\Psi_{ABCD}=K_{(A}K_BK_C\delta_{D)}$ and $\Psi_{ABCD}K^AK^B=0$ since all terms contain contractions K_AK^A. Then we have $T_{abcd}k^ak^b=0$, which again trivially implies that

$$T_{abcd}k^ak^bv^cw^d=0. \tag{2.12}$$

To show that (2.12) implies that k^a is a GPND of multiplicity at least 3 we use Lemma 1 to write $v^c=c_1k^c+n_1^c$ and $w^d=c_2k^d+n_2^d$ with $c_1>0$ and $c_2>0$. Substituting this into (2.12) we obtain

$$c_1c_2T_{abcd}k^ak^bk^ck^d+c_1T_{abcd}k^ak^bk^cn_2^d+c_2T_{abcd}k^ak^bk^cn_1^d+T_{abcd}k^ak^bn_1^cn_2^d=0, \tag{2.13}$$

where each term is non-negative and therefore each term has to be zero. By (v) the first term is zero if k^a is a GPND. Thus $\Psi_{ABCD}=K_{(A}\beta_B\gamma_C\delta_{D)}$. As in (2.11) the second and third terms are then zero if k^a is a GPND of multiplicity of at least 2 so $\Psi_{ABCD}=K_{(A}K_B\gamma_C\delta_{D)}$. Writing $n_1^d=N_1^D\overline{N}_1^{D'}$ and $n_2^d=N_2^D\overline{N}_2^{D'}$, where neither N_1^A nor N_2^A is proportional to K^A, the fourth term is zero if

$$0=\Psi_{ABCD}K^AK^BN_1^CN_2^D=K_{(A}K_B\gamma_C\delta_{D)}K^AK^BN_1^CN_2^D=(K_AN_1^A)(K_BN_2^B)(\gamma_CK^C)(\delta_DK^D). \tag{2.14}$$

The two first factors are nonzero so we must have that, e.g., $\gamma_CK^C=0$, which means that γ^A and K^A are proportional and therefore K^A is now a GPND of multiplicity at least 3 which proves (iii).

In (ii) first assume that k^a is a GPND of multiplicity 4 so $\Psi_{ABCD}=K_AK_BK_CK_D$ and $T_{abcd}=k_ak_bk_ck_d$. Then obviously $T_{abcd}k^a=0$ and

$$T_{abcd}k^a u^b v^c w^d = 0. \tag{2.15}$$

Conversely, if (2.15) holds, use Lemma 1 to write $u^b = c_1 k^b + n_1^b$, $v^c = c_2 k^c + n_2^c$, and $w^d = c_3 k^d + n_3^d$. Substituting these into (2.15) we obtain that each of the following expressions must be zero: $T_{abcd}k^a k^b k^c k^d$, $T_{abcd}k^a k^b k^c n_3^d$, $T_{abcd}k^a k^b n_2^c n_3^d$, and $T_{abcd}k^a n_1^b n_2^c n_3^d$. With the same argument as above, the first three are zero if k^a is a GPND of multiplicity at least 3 so $\Psi_{ABCD} = K_{(A}K_B K_C \delta_{D)}$. The fourth expression is zero if

$$0 = \Psi_{ABCD}K^A N_1^B N_2^C N_3^D = (K_A N_1^A)(K_B N_2^B)(K_C N_3^C)(\delta_D K^D). \tag{2.16}$$

As before, the first three factors are nonzero and therefore $\delta_D K^D = 0$ which implies that δ^A and K^A are proportional and hence K^A is a GPND of multiplicity 4 and this proves (ii).

In (i) we know that $T_{abcd}s^a u^b v^c w^d \geqslant 0$ by Theorem 1. Assume that $T_{abcd} \neq 0$ and $T_{abcd}s^a u^b v^c w^d = 0$. Let k^a be an *arbitrary* future-pointing null vector and write $s^a = c_1 k^a + n_1^a$, $u^b = c_2 k^b + n_2^b$, $v^c = c_3 k^c + n_3^c$, and $w^d = c_4 k^d + n_4^d$ with $c_i > 0$ for $i = 1,2,3,4$. Then

$$0 = T_{abcd}s^a u^b v^c w^d = c_1 c_2 c_3 c_4 T_{abcd}k^a k^b k^c k^d + 15 \text{ more terms.} \tag{2.17}$$

All 16 terms in (2.17) are non-negative so all must be zero. Therefore $T_{abcd}k^a k^b k^c k^d = 0$ which by (v) means that k^a is a GPND. However, k^a is an arbitrary future-pointing null vector and as there can be at most four different GPNDs as $T_{abcd} \neq 0$, we get a contradiction. Thus $T_{abcd}s^a u^b v^c w^d > 0$ when $T_{abcd} \neq 0$ and (i) is proved.

This ends the proof of Theorem 2.

Remark: In case there is more than one different null vector contracted with the Bel–Robinson tensor it is more difficult to draw conclusions. As an example, consider a case similar to (iv) of Theorem 2. Suppose that

$$T_{abcd}k^a k^b k^c n^d = 0, \tag{2.18}$$

where both k^a and n^a are future-pointing null vectors but assumed not to be parallel. The corresponding spinor equation is

$$\Psi_{ABCD}K^A K^B K^C N^D = 0. \tag{2.19}$$

Suppose that we have a space–time with four different GPNDs $\alpha_A, \beta_A, \gamma_A = \alpha_A + 2\beta_A$, and $\delta_A = 2\alpha_A + \beta_A$. Then if $K_A = \alpha_A + \beta_A$ and $N_A = \alpha_A - \beta_A$ (thus neither of them is a GPND), we have

$$\begin{aligned}
4\Psi_{ABCD}K^A K^B K^C N^D &= 4\alpha_{(A}\beta_B\gamma_C\delta_{D)}K^A K^B K^C N^D \\
&= 4\alpha_A\beta_B\gamma_C\delta_D K^{(A}K^B K^C N^{D)} \\
&= \alpha_A\beta_B(\alpha_C + 2\beta_C)(2\alpha_D + \beta_D)[(\alpha^A + \beta^A) \\
&\quad \times (\alpha^B + \beta^B)(\alpha^C + \beta^C)(\alpha^D - \beta^D) + (\alpha^A + \beta^A) \\
&\quad \times (\alpha^B + \beta^B)(\alpha^C - \beta^C)(\alpha^D + \beta^D) \\
&\quad + (\alpha^A + \beta^A)(\alpha^B - \beta^B)(\alpha^C + \beta^C)(\alpha^D + \beta^D) \\
&\quad + (\alpha^A - \beta^A)(\alpha^B + \beta^B)(\alpha^C + \beta^C)(\alpha^D + \beta^D)] \\
&= (\alpha_A\beta^A)(-3 + 3 + 1 - 1) = 0.
\end{aligned} \tag{2.20}$$

Hence $T_{abcd}k^a k^b k^c n^d = 0$ in a space–time with four distinct GPNDs (i.e., an algebraically general space–time) and neither k^a nor n^a is a GPND.

III. INVARIANT PETROV CLASSIFICATIONS

We now give some alternative ways of classifying the Petrov type of the Weyl tensor using the Bel–Robinson tensor. As opposed to the results of the previous section, some of the results here could equivalently be written directly in terms of the Weyl spinor.

Theorem 3: Suppose that $T_{abcd}\neq 0$. Then

(i) $T_{abcd}T^{abcd}=0\Leftrightarrow T_{abcd}T^{abce}=0\Leftrightarrow$space–time is of type III or N, and
(ii) $T_{abcd}T^{abef}=0\Leftrightarrow T_{abcd}T^{aefg}=0\Leftrightarrow$space–time is of type N.

Proof: The case with $T_{abcd}T^{abcd}=0$ is proven in Ref. 13. We first note that using spinors we have

$$T_{abcd}T^{abcd}=0\Leftrightarrow\Psi_{ABCD}\Psi^{ABCD}=0, \tag{3.1a}$$

$$T_{abcd}T^{abce}=0\Leftrightarrow\Psi_{ABCD}\Psi^{ABCE}=0, \tag{3.1b}$$

$$T_{abcd}T^{abef}=0\Leftrightarrow\Psi_{ABCD}\Psi^{ABEF}=0, \tag{3.1c}$$

$$T_{abcd}T^{aefg}=0\Leftrightarrow\Psi_{ABCD}\Psi^{AEFG}=0. \tag{3.1d}$$

If space–time is of type N, then $\Psi_{ABCD}=\alpha_A\alpha_B\alpha_C\alpha_D$ and clearly all terms in all expressions in (3.1) contain at least one contraction $\alpha_A\alpha^A=0$. If space–time is of type III, then $\Psi_{ABCD}=\alpha_{(A}\alpha_B\alpha_C\beta_{D)}$ and all terms of the expressions (3.1a) and (3.1b) with three or four contractions must contain at least one contraction of type $\alpha_A\alpha^A=0$. This proves the implications from right to left of the theorem. Note that in (3.1c) and (3.1d) with only one or two contractions there are terms without $\alpha_A\alpha^A$ factors, e.g., in (3.1c) we have $(\alpha_A\beta^A)(\beta_B\alpha^B)\alpha_C\alpha_D\alpha^E\alpha^F\neq 0$.

Conversely, to prove the implications from left to right we begin by noting that a proof of the fact that $\Psi_{ABCD}\Psi^{ABCD}=0$ implies type III or N is given in Ref. 13. Next we use the equality[2]

$$\Psi_{ABCD}\Psi^{ABCE}=\tfrac{1}{2}\Psi_{ABCF}\Psi^{ABCF}\epsilon_D{}^E \tag{3.2}$$

or, on tensor form,

$$T_{abcd}T^{abce}=\tfrac{1}{4}T_{abcf}T^{abcf}g_d{}^e \tag{3.3}$$

to see that $T_{abcd}T^{abce}=0$ is equivalent to $T_{abcd}T^{abcd}=0$. This proves case (i) of the theorem.

Consider now Eq. (3.1d). Express Ψ_{ABCD} in a standard spinor basis (o^A,ι^A) as[2]

$$\begin{aligned}\Psi_{ABCD}=&\Psi_0\iota_A\iota_B\iota_C\iota_D-\Psi_1(\iota_A\iota_B\iota_C o_D+\iota_A\iota_B o_C\iota_D+\iota_A o_B\iota_C\iota_D+o_A\iota_B\iota_C\iota_D)+\Psi_2(\iota_A\iota_B o_C o_D\\&+\iota_A o_B\iota_C o_D+\iota_A o_B o_C\iota_D+o_A\iota_B\iota_C o_D+o_A\iota_B o_C\iota_D+o_A o_B\iota_C\iota_D)-\Psi_3(\iota_A o_B o_C o_D\\&+o_A\iota_B o_C o_D+o_A o_B\iota_C o_D+o_A o_B o_C\iota_D)+\Psi_4 o_A o_B o_C o_D\,.\end{aligned} \tag{3.4}$$

A straightforward calculation of all the independent components of $\Psi_{ABCD}\Psi^{AEFG}=0$ with respect to the basis leads to the following equations:

$$\Psi_0\Psi_2=\Psi_1^2, \tag{3.5a}$$

$$\Psi_0\Psi_3=\Psi_1\Psi_2, \tag{3.5b}$$

$$\Psi_0\Psi_4=\Psi_1\Psi_3, \tag{3.5c}$$

$$\Psi_1\Psi_3=\Psi_2^2, \tag{3.5d}$$

$$\Psi_1\Psi_4=\Psi_2\Psi_3, \tag{3.5e}$$

$$\Psi_2\Psi_4=\Psi_3^2. \tag{3.5f}$$

We may now assume that o^A is one of the GPNDs. Then $\Psi_{ABCD}o^Ao^Bo^Co^D=\Psi_0=0$ which by (3.5a) implies that $\Psi_1=0$. By (3.5d) we then get $\Psi_2=0$, which substituted into (3.5f) gives $\Psi_3=0$ and hence only $\Psi_4\neq 0$. By (3.4)

$$\Psi_{ABCD}=\Psi_4 o_A o_B o_C o_D\,, \tag{3.6}$$

so o^A is a GPND of multiplicity 4 which means that space–time is of type N.

Finally we check (3.1c). A similar calculation of the components of $\Psi_{ABCD}\Psi^{ABEF}$ leads to a set of six equations which are (3.5a), (3.5b), (3.5d)–(3.5f), and $\Psi_0\Psi_4+\Psi_2^2=2\Psi_1\Psi_3$. Subtracting (3.5d) from the last equation gives (3.5c) and therefore this new set of equations is equivalent to (3.5), so again space–time must be of type N. This finishes the proof of the theorem.

There are other possibilities for invariant Petrov classification of the Weyl tensor/spinor using quantities constructed from the Weyl spinor (see Chap. 8, of Ref. 13 for some results).

One can also construct other quantities from the Bel–Robinson tensor which can be used for Petrov classification. As mentioned in Sec. II, for the quantity τ_a defined by (2.2) we have if $T_{abcd}\neq 0$ that $\tau_a\tau^a=0$ if and only if space–time is of type N. Similarly, if we define

$$\tau_{abc}=\tau_{abc}(u)=T_{abcd}u^d, \tag{3.7}$$

then, using (3.3),

$$\tau_{abc}\tau^{abc}=T_{abcd}T^{abc}{}_e u^d u^e=\tfrac{1}{4}T_{abcf}T^{abcf}g_{de}u^d u^e. \tag{3.8}$$

Hence, if u^a is a null vector, then (3.8) always implies $\tau_{abc}\tau^{abc}=0$, while if u^a is timelike, then by Theorem 3 and (3.8) $\tau_{abc}\tau^{abc}=0$ as $T_{abcd}\neq 0$ if and only if space–time is of type III or N. Thus, if u^a is timelike, a space–time is of type III if and only if $\tau_{abc}\tau^{abc}=0\neq\tau_a\tau^a$.

IV. SUMMARY

We have studied various non-negative expressions involving the Bel–Robinson tensor and especially under what circumstances these expressions can be zero. There are two immediate applications of these results. The first is that it provides some new invariant ways of determining the Petrov type of space–time. The other is that one can determine when expressions of gravitational energy built on the Bel–Robinson tensor are zero. Although it is not known which kind of expressions for gravitational energy one can expect to be always well defined or unique, there are (as mentioned in the Introduction) relations between the Bel–Robinson tensor and various proposed energy expressions. More specific implications of the results of this paper to these expressions will be studied in coming work.

We would also like to emphasize the advantages of using spinors when studying the Bel–Robinson tensor. Most results presented here, as well as other well-known properties of the Bel–Robinson tensor, are definitely simpler to prove using spinor techniques. Moreover, even when proofs are done using spinors, most results are easy to express in terms of tensor like, for instance, the classification of Petrov types.

Rotating dust solutions of Einstein's equations with three-dimensional symmetry groups. III. All Killing fields linearly independent of u^α and w^α

Andrzej Krasiński[a)]
N. Copernicus Astronomical Center and College of Science, Polish Academy of Sciences, Bartycka 18, 00 716 Warszawa, Poland

(Received 18 July 1997; accepted for publication 21 August 1997)

This is the third and last part of a series of three papers. Using the same method and the same coordinates as in papers I and II, rotating dust solutions of Einstein's equations are investigated that possess three-dimensional symmetry groups, under the assumption that each of the Killing vectors is linearly independent of velocity u^α and rotation w^α at every point of the spacetime region under consideration. The Killing fields are found and the Killing equations are solved for the components of the metric tensor in every case that arises. No progress was made with the Einstein equations in any of the cases, and no previously known solutions were identified. A brief overview of literature on solutions with rotating sources is given. © *1998 American Institute of Physics.* [S0022-2488(98)01004-4]

I. SUMMARY OF THE METHOD

This paper is the third and last part of a series of three papers; for papers I and II see Refs. 1 and 2. For convenience to the readers, this section is repeated after Paper II.

This is a concise summary of results that will be used in this paper. For proofs, motivations and references see Paper I.[1]

Every timelike vector field u^α of unit length that has zero acceleration and nonzero rotation defines the functions $\tau(x), \eta(x)$ and $\xi(x)$ such that:

$$u_\alpha = \tau_{,\alpha} + \eta\xi_{,\alpha}. \tag{1.1}$$

These functions are defined up to the transformations:

$$\tau = \tau' - S(\xi', \eta'), \quad \xi = F(\xi', \eta'), \quad \eta = G(\xi', \eta'), \tag{1.2}$$

where the functions F and G obey:

$$F_{,\xi'}G_{,\eta'} - F_{,\eta'}G_{,\xi'} = 1 \tag{1.3}$$

(this guarantees that the Jacobian of the transformation is 1), and S is determined by:

$$S_{,\xi'} = GF_{,\xi'} - \eta', \quad S_{,\eta'} = GF_{,\eta'}. \tag{1.4}$$

If u^α is the velocity field of a fluid whose number of particles is conserved:

$$(\sqrt{-g}nu^\alpha)_{,\alpha} = 0 \tag{1.5}$$

(where g is the determinant of the metric tensor and n is the particle number density), then one more function $\zeta(x)$ exists such that:

$$\sqrt{-g}nu^\alpha = \varepsilon^{\alpha\beta\gamma\delta}\xi_{,\beta}\eta_{,\gamma}\zeta_{,\delta}, \tag{1.6}$$

[a)]Electronic mail: akr@alfa.camk.edu.pl

 © 1998 American Institute of Physics

and it is determined up to the transformations:

$$\zeta=\zeta'+T(\xi',\eta'). \tag{1.7}$$

Note that n is not defined uniquely by (1.5). For example, if $u^\alpha=\delta^\alpha{}_0$ and n obeys (1.5), then $n'=nf(x,y,z)$ (where f is an arbitrary function) will also obey (1.5). This nonuniqueness allows for a greater freedom in the choice of ζ than (1.7), and the freedom will be used in some cases.

The following relations hold:

$$u^\alpha\tau_{,\alpha}=1,\quad u^\beta\xi_{,\beta}=u^\beta\eta_{,\beta}=u^\beta\zeta_{,\beta}=0,$$

$$\frac{\partial(\tau,\eta,\xi,\zeta)}{\partial(x^0,x^1,x^2,x^3)}=\sqrt{-g}n\neq 0. \tag{1.8}$$

The last of (1.8) guarantees that $\{\tau,\xi,\eta,\zeta\}$ can be chosen as coordinates, they will be called Plebański coordinates. Then, with $\{\tau,\xi,\eta,\zeta\}=\{x^0,x^1,x^2,x^3\}=\{t,x,y,z\}$:

$$u^\alpha=\delta^\alpha{}_0,\quad u_\alpha=\delta^0{}_\alpha+y\delta^1{}_\alpha,$$

$$g_{00}=1,\quad g_{01}=y,\quad g_{02}=g_{03}=0,\quad g=\det(g_{\alpha\beta})=-n^{-2},$$

$$w^\alpha=n\delta^\alpha_3,\quad \omega_{\alpha\beta}=-\omega_{\beta\alpha}=(\tfrac{1}{2})\delta^1{}_\alpha\delta^2{}_\beta, \tag{1.9}$$

where w^α is the rotation vector field, and $\omega_{\alpha\beta}$ is the rotation tensor corresponding to the velocity field u_α:

$$\omega_{\alpha\beta}=\tfrac{1}{2}(u_{\alpha,\beta}-u_{\beta,\alpha}-\dot{u}_\alpha u_\beta+\dot{u}_\beta u_\alpha),\quad w^\alpha=-(1/\sqrt{-g})\varepsilon^{\alpha\beta\gamma\delta}u_\beta\omega_{\gamma\delta}. \tag{1.10}$$

If $\omega_{\alpha\beta}\neq 0$ and $\dot{u}^\alpha=0$ (what is assumed throughout), then necessarily the pressure $p=$const and κp may be interpreted as the cosmological constant ($\kappa:=8\pi G/c^4$).

If any Killing vector field exists on a manifold (on which all the assumptions specified so far are fulfilled), then, in the coordinates of (1.9), it must be of the form:

$$k^\alpha=(C+\phi-y\phi_{,y})\delta^\alpha{}_0+\phi_{,y}\delta^\alpha{}_1-\phi_{,x}\delta^\alpha{}_2+\lambda\delta^\alpha{}_3, \tag{1.11}$$

where C is an arbitrary constant and $\phi(x,y)$ and $\lambda(x,y)$ are arbitrary functions of two coordinates. Whenever $\phi_{,\alpha}\neq 0$, a transformation of the class (1.2)–(1.4) can be found that leads to:

$$k^\alpha=\delta^\alpha{}_1. \tag{1.12}$$

The metric then becomes independent of x, and the coordinates preserving (1.12) are determined up to the transformations:

$$t'=t-\int yH_{,y}dy+A,\quad x'=x+H(y),\quad y'=y,\quad z'=z+T(y), \tag{1.13}$$

where A is an arbitrary constant and H,T are arbitrary functions.

The condition $\phi_{,\alpha}\neq 0$ that allows one to fulfill (1.12) means that the Killing vector k^α is linearly independent of the vectors u^α and w^α at every point of the spacetime region under consideration. In Paper I, solutions of the Killing equations and of the Einstein equations were considered under the assumption that there exist three Killing vector fields on the manifold, two of which have $\phi=$ const in (1.11), while the third one has $\phi_{,\alpha}\neq 0$ and can be transformed to the form (1.12). In Paper II, it was assumed that only one Killing field has $\phi=$ const, while two have $\phi_{,\alpha}\neq 0$. In the present paper, all three Killing fields will be assumed to have $\phi_{,\alpha}\neq 0$. One of them ($k_{(1)}$) can be transformed to the simple form (1.12), while the remaining two will have the general form (1.11).

In this Paper III, no progress was made with the Einstein equations in any of the cases. Also, no related results were found in the literature except in case 1.1.2.2 (see the end of Sec. V).

II. THE LIE ALGEBRA OF THE SYMMETRY GROUP

According to the assumptions made in the preceding section, there exist the following three Killing vector fields:

$$k^{\alpha}_{(1)}=\delta^{\alpha}_{1},$$

$$k^{\alpha}_{(2)}=(C_2+\phi-y\phi_{,y})\delta^{\alpha}_{0}+\phi_{,y}\delta^{\alpha}_{1}-\phi_{,x}\delta^{\alpha}_{2}+\lambda_2(x,y)\delta^{\alpha}_{3},$$

$$k^{\alpha}_{(3)}=(C_3+\psi-y\psi_{,y})\delta^{\alpha}_{0}+\psi_{,y}\delta^{\alpha}_{1}-\psi_{,x}\delta^{\alpha}_{2}+\lambda_3(x,y)\delta^{\alpha}_{3}, \tag{2.1}$$

where C_2 and C_3 are arbitrary constants, and ϕ, ψ, λ_2 and λ_3 are unknown functions of (x,y), to be determined from the commutation relations. The coordinates of (2.1) are determined up to (1.13).

The fields $k_{(1)},k_{(2)}$ and $k_{(3)}$ will form a Lie algebra if constants $a,\ldots,j$ exist such that:

$$[k_{(1)},k_{(2)}]=ak_{(1)}+bk_{(2)}+ck_{(3)},$$

$$[k_{(1)},k_{(3)}]=dk_{(1)}+ek_{(2)}+fk_{(3)},$$

$$[k_{(2)},k_{(3)}]=gk_{(1)}+hk_{(2)}+jk_{(3)}. \tag{2.2}$$

Equations (2.2) are equivalent to the following set:

$$\phi_{,x}-y\phi_{,xy}=b(C_2+\phi-y\phi_{,y})+c(C_3+\psi-y\psi_{,y}), \tag{2.3a}$$

$$\phi_{,xy}=a+b\phi_{,y}+c\psi_{,y}, \tag{2.3b}$$

$$\phi_{,xx}=b\phi_{,x}+c\psi_{,x}, \tag{2.3c}$$

$$\lambda_{2,x}=b\lambda_2+c\lambda_3, \tag{2.3d}$$

$$\psi_{,x}-y\psi_{,xy}=e(C_2+\phi-y\phi_{,y})+f(C_3+\psi-y\psi_{,y}), \tag{2.3e}$$

$$\psi_{,xy}=d+e\phi_{,y}+f\psi_{,y}, \tag{2.3f}$$

$$\psi_{,xx}=e\phi_{,x}+f\psi_{,x}, \tag{2.3g}$$

$$\lambda_{3,x}=e\lambda_2+f\lambda_3, \tag{2.3h}$$

$$\begin{aligned}&\phi_{,y}(\psi_{,x}-y\psi_{,xy})+y\phi_{,x}\psi_{,yy}-\psi_{,y}(\phi_{,x}-y\phi_{,xy})-y\psi_{,x}\phi_{,yy}\\&\quad=h(C_2+\phi-y\phi_{,y})+j(C_3+\psi-y\psi_{,y}),\end{aligned} \tag{2.3i}$$

$$\phi_{,y}\psi_{,xy}-\phi_{,x}\psi_{,yy}-\psi_{,y}\phi_{,xy}+\psi_{,x}\phi_{,yy}=g+h\phi_{,y}+j\psi_{,y}, \tag{2.3j}$$

$$-\phi_{,y}\psi_{,xx}+\phi_{,x}\psi_{,xy}+\psi_{,y}\phi_{,xx}-\psi_{,x}\phi_{,xy}=-h\phi_{,x}-j\psi_{,x}, \tag{2.3k}$$

$$\phi_{,y}\lambda_{3,x}-\phi_{,x}\lambda_{3,y}-\psi_{,y}\lambda_{2,x}+\psi_{,x}\lambda_{2,y}=h\lambda_2+j\lambda_3. \tag{2.3l}$$

The Eqs. (2.3a)–(2.3c) are integrated with the result:

$$\phi_{,x}=ay+b\phi+c\psi+bC_2+cC_3; \tag{2.4a}$$

the Eqs. (2.3e)–(2.3g) are integrated with the result:

$$\psi_{,x}=dy+e\phi+f\psi+eC_2+fC_3; \tag{2.4b}$$

and the Eqs. (2.3i)–(2.3k) are integrated with the result:

$$\phi_{,y}\psi_{,x}-\phi_{,x}\psi_{,y}=gy+h\phi+j\psi+hC_2+jC_3. \tag{2.4c}$$

The equations are now sorted as follows. Equations (2.3d) and (2.3h) form a set that determines λ_2 and λ_3, Eqs. (2.4a)–(2.4b) form a set that determines ϕ and ψ, the remaining two equations [(2.4c) and (2.3l)] are consistency conditions to be imposed on the solutions of the two former sets.

Note that the set (2.4a)–(2.4b) and the set {(2.3d), (2.3h)} are of the same general form: each of them is an (ordinary differential) linear vector equation of first order:

$$U_{,x}=AU+W, \tag{2.5}$$

where, for (2.4a)–(2.4b), the constant matrix A and the vectors U and W are:

$$A=\begin{pmatrix} b & c \\ e & f \end{pmatrix}, \quad U=\begin{pmatrix} \phi \\ \psi \end{pmatrix}, \quad W=y\begin{pmatrix} a \\ d \end{pmatrix}+A\begin{pmatrix} C_2 \\ C_3 \end{pmatrix}, \tag{2.6}$$

while the set {(2.3d), (2.3h)} is homogeneous, so $W=0$ in (2.5), the matrix A is the same as in (2.6) and

$$U=\begin{pmatrix} \lambda_2 \\ \lambda_3 \end{pmatrix}.$$

With the constants b, c, e and f being all arbitrary, several cases will have to be considered separately. Just as in Paper II, the cases that arise will be organized into a binary tree and numbered in a positional system that will enable one to quickly identify the complementary part of each alternative (see Fig. 1).

The first alternative appears in solving the characteristic equation for the matrix A. Its eigenvalues are:

$$\alpha_{1,2}=\tfrac{1}{2}(b+f+\varepsilon_{1,2}\sqrt{\Delta}), \tag{2.7}$$

where:

$$\Delta:=(b-f)^2+4ce, \quad \varepsilon_1=1, \quad \varepsilon_2=-1. \tag{2.8}$$

We first consider:

Case 1: $\Delta\neq 0$ *(i.e., A has two distinct eigenvalues).* The second alternative appears immediately in finding the eigenvectors of A: the cases $c\neq 0$ and $c=0$ have to be considered separately.

Case 1.1: $c\neq 0$. The solution of the set {(2.3d), (2.3h)} is then:

$$\lambda_2=2cL_2(y)e^{\alpha_1 x}+2cL_3(y)e^{\alpha_2 x},$$

$$\lambda_3=(f-b+\sqrt{\Delta})L_2(y)e^{\alpha_1 x}+(f-b-\sqrt{\Delta})L_3(y)e^{\alpha_2 x}, \tag{2.9}$$

where $L_2(y)$ and $L_3(y)$ are arbitrary functions. The cases $\Delta>0$ and $\Delta<0$ could be considered together for a large part of the reasoning. When $\Delta<0$, α_1 and α_2 are complex and $\alpha_2=\overline{\alpha_1}$. Then, L_2 and L_3 have to be complex, too, with $L_3=\overline{L_2}$. However, the two cases lead to different sets of Bianchi types, and so it will be convenient to split them here.

Case 1.1.1: $\Delta>0$ *(i.e., both eigenvalues are real).* Then, in solving the set (2.4a)–(2.4b), the cases $\det A\neq 0$ and $\det A=0$ have to be considered separately. In the end, however, the case $\det A=0$ turns out to be empty, i.e., in all subcases that arise in it there exists a linear combination of the Killing vectors $k_{(2)}$ and $k_{(3)}$ with constant coefficients that is spanned on u and w. This means that all these subcases are in the domain of Paper II and need not be considered here. Therefore we will do away with the case $\det A=0$ by only indicating the method of verification of the statement above.

When $\det A=0$, the following is true (from (2.7)–(2.8)):

$$e=bf/c, \quad \Delta=(b+f)^2, \quad \alpha_1=b+f:=\alpha, \quad \alpha_2=0. \tag{2.10}$$

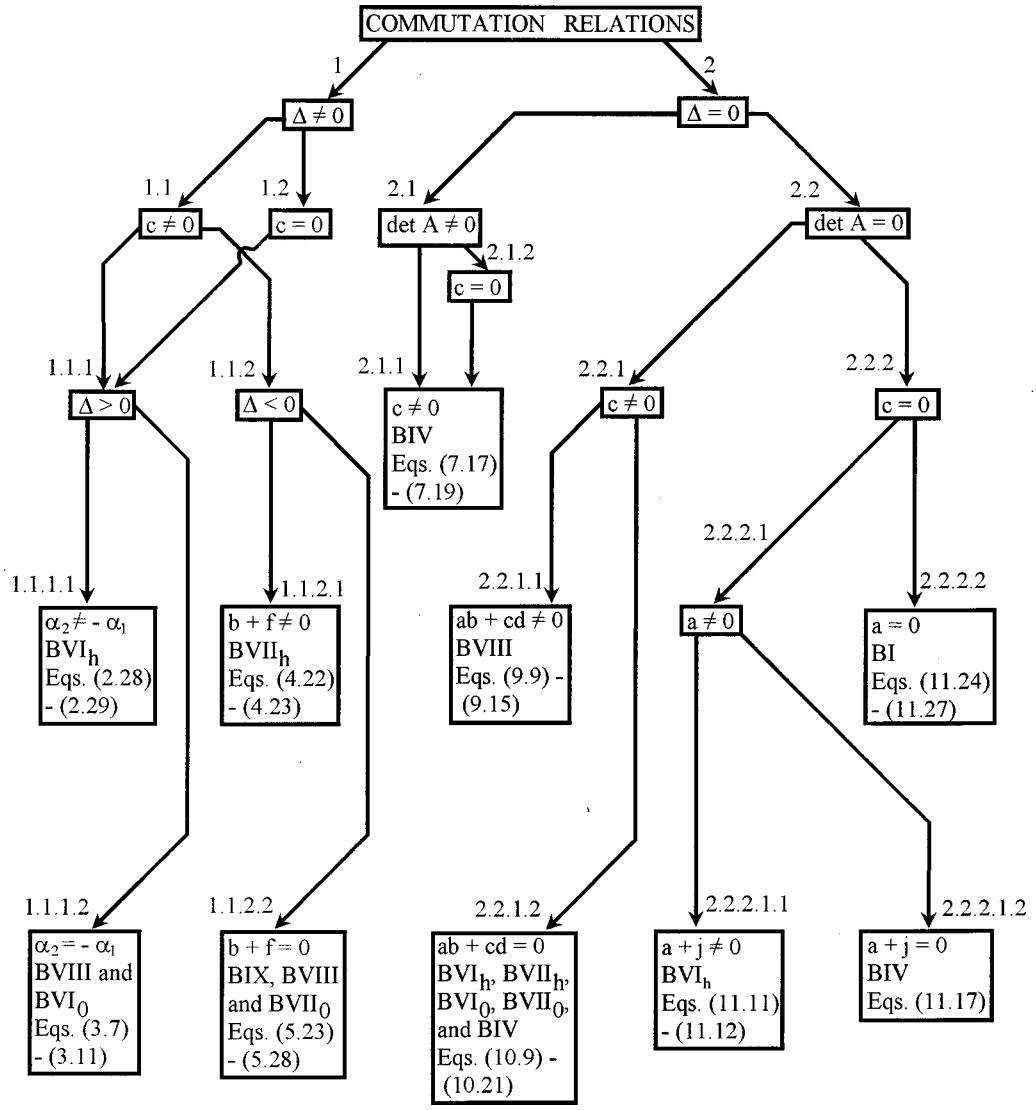

FIG. 1. The classes of metrics considered in the paper. Arrows point from more general classes to subclasses. The numbers at arrows are the case-numbers used in the text. The first entry in each rectangle is the property defining the case; all the symbols are introduced in Eqs. (2.1)–(2.8). The subsequent entries give the following information: 1. The Bianchi type of the corresponding algebra (2.2); 2. The equation-numbers corresponding to the final result in the given case. No progress was made with the Einstein equations in any of the cases. Apart from case 1.1.2.2 for which a subcase was discussed in Ref. 3, none of the cases seem to have appeared in earlier literature (see Sec. XIII). The diagram does not show the links to the entries in the corresponding diagram in Paper II; they are numerous and would obscure the drawing.

Since we are still in case 1 in which $\alpha_2 \neq \alpha_1$ by assumption, we can take it for granted that $\alpha \neq 0$ here. The solutions of (2.3d), (2.3h) and (2.4a)–(2.4b) are:

$$\lambda_2 = 2c[L_2(y) + L_3(y)e^{\alpha x}], \quad \lambda_3 = 2fL_2(y) - 2bL_3(y)e^{\alpha x},$$

$$\phi = F(y)e^{\alpha x} + (af - cd)xy/\alpha + P(y) - (ab + cd)y/\alpha^2 - C_2,$$

$$\psi = (f/c)F(y)e^{\alpha x} - (b/c)(af - cd)xy/\alpha - (b/c)P(y) - (f/c)(ab + cd)y/\alpha^2 - C_3, \quad (2.11)$$

where $F(y)$ and $P(y)$ are other arbitrary functions. The further procedure goes exactly as for the case det $A \neq 0$ presented below, and leads to the results specified above.

From now on, in case 1.1.1 we assume that:

$$\det A = bf - ce \neq 0. \quad (2.12)$$

Then the solution of (2.4)–(2.4b) is:

$$\phi = 2cF(y)e^{\alpha_1 x} + 2cP(y)e^{\alpha_2 x} - \frac{af-cd}{bf-ce}y - C_2,$$

$$\psi = (f-b+\sqrt{\Delta})F(y)e^{\alpha_1 x} + (f-b-\sqrt{\Delta})P(y)e^{\alpha_2 x} - \frac{-ae+bd}{bf-ce}y - C_3. \tag{2.13}$$

The solutions (2.9) and (2.13) must now obey the consistency conditions (2.4c) and (2.3l). Equation (2.4c) is a polynomial in $e^{\alpha_1 x}$ and $e^{\alpha_2 x}$ whose coefficients are functions of y, the polynomial contains $e^{(\alpha_1+\alpha_2)x}, e^{\alpha_1 x}, e^{\alpha_2 x}$ and terms independent of x. The cases $\alpha_2 \neq -\alpha_1$ and $\alpha_2 = -\alpha_1$ require separate consideration. We first consider:

Case 1.1.1.1: $\alpha_2 \neq -\alpha_1$. Comparison of coefficients of $e^{(\alpha_1+\alpha_2)x}$ on both sides of (2.4c) leads to:

$$-\alpha_2 F_{,y} P + \alpha_1 F P_{,y} = 0. \tag{2.14}$$

If $F=0$, then (2.14) is fulfilled identically, and this case has to be considered separately. The result is similar to the case $\det A = 0$. The consideration, parallel to the one that follows below, reveals that with $F=0$ either one of the Killing fields becomes collinear with rotation (and this situation is in the domain of Paper II) or the symmetry group becomes two dimensional (which case is not considered here at all). Consequently, we proceed assuming $F \neq 0$. The solution of (2.14) is then:

$$P = \beta F^{\alpha_2/\alpha_1}, \tag{2.15}$$

where β is an arbitrary constant; $\alpha_1 \neq 0$ because $\det A \neq 0$.

The coefficients of $Fe^{\alpha_1 x}$ on both sides of (2.4c) imply:

$$h = [\alpha_1/(bf-ce)]\left[-\frac{1}{2c}(af-cd)(f-b+\sqrt{\Delta}) - ae + bd\right] - \frac{j}{2c}(f-b+\sqrt{\Delta}). \tag{2.16}$$

In considering the coefficients of $e^{\alpha_2 x}$ in (2.4c) we have to set aside the case $P=0$ for separate consideration because the terms with $e^{\alpha_2 x}$ all vanish identically when $P=0$. However, the case $P=0$ is in fact empty in the same sense as the case $F=0$: either the Killing field $k_{(3)}$ becomes collinear with rotation, and this situation is in the domain of Paper II, or the symmetry group becomes two-dimensional. Hence, we shall follow the case $P \neq 0$ only. Then the coefficients of $Pe^{\alpha_2 x}$ on both sides of (2.4c) imply:

$$j = (bf-ce)^{-1}[-(af-cd)f + (-ae+bd)c], \tag{2.17}$$

and the terms independent of x imply:

$$g = (bf-ce)^{-1}[-(af-cd)d + (-ae+bd)a]. \tag{2.18}$$

Equation (2.3l) is a polynomial in exponential functions of x that involves $e^{2\alpha_1 x}$, $e^{2\alpha_2 x}$, $e^{(\alpha_1+\alpha_2)x}$, $e^{\alpha_1 x}$, and $e^{\alpha_2 x}$. In consequence of (2.9)–(2.18) most of the resulting equations are fulfilled identically, the only one that brings in new information is:

$$-2\alpha_2 F_{,y} L_3 + 2\alpha_1 F L_{3,y} + 2(\beta\alpha_2 F^{\alpha_2/\alpha_1})(L_2 F_{,y}/F - L_{2,y}) = 0. \tag{2.19}$$

This is integrated with the result:

$$L_3 = (1/\alpha_1)F^{\alpha_2/\alpha_1}(\gamma + \beta\alpha_2 L_2/F), \tag{2.20}$$

where γ is a new arbitrary constant.

Finally, the following Killing fields resulted:

$$k^\alpha_{(1)}=\delta^\alpha_1,$$

$$\begin{aligned}
k^\alpha_{(2)}=&\left[2c(F-yF_{,y})e^{\alpha_1 x}+2c\beta F^{\alpha_2/\alpha_1}\left(1-\frac{\alpha_2}{\alpha_1}yF_{,y}/F\right)e^{\alpha_2 x}\right]\delta^\alpha_0\\
&+\left(2cF_{,y}e^{\alpha_1 x}+2c\beta\frac{\alpha_2}{\alpha_1}F^{\alpha_2/\alpha_1-1}F_{,y}e^{\alpha_2 x}-\frac{af-cd}{bf-ce}\right)\delta^\alpha_1\\
&-(2c\alpha_1 Fe^{\alpha_1 x}+2c\alpha_2\beta F^{\alpha_2/\alpha_1}e^{\alpha_2 x})\,\delta^\alpha_2\\
&+\left[2cL_2e^{\alpha_1 x}+2\frac{c}{\alpha_1}F^{\alpha_2/\alpha_1}(\gamma+\beta\alpha_2 L_2/F)e^{\alpha_2 x}\right]\delta^\alpha_3,\\
k^\alpha_{(3)}=&\left[(f-b+\sqrt{\Delta})(F-yF_{,y})e^{\alpha_1 x}+(f-b-\sqrt{\Delta})\beta F^{\alpha_2/\alpha_1}\left(1-\frac{\alpha_2}{\alpha_1}yF_{,y}/F\right)e^{\alpha_2 x}\right]\delta^\alpha_0\\
&+\left[(f-b+\sqrt{\Delta})F_{,y}e^{\alpha_1 x}+(f-b-\sqrt{\Delta})\beta\frac{\alpha_2}{\alpha_1}F^{\alpha_2/\alpha_1-1}F_{,y}e^{\alpha_2 x}-\frac{-ae+bd}{bf-ce}\right]\delta^\alpha_1\\
&-[(f-b+\sqrt{\Delta})\alpha_1 Fe^{\alpha_1 x}+(f-b-\sqrt{\Delta})\beta\alpha_2 F^{\alpha_2/\alpha_1}e^{\alpha_2 x}]\,\delta^\alpha_2\\
&+\left[(f-b+\sqrt{\Delta})L_2e^{\alpha_1 x}+(f-b-\sqrt{\Delta})\frac{1}{\alpha_1}F^{\alpha_2/\alpha_1}(\gamma+\beta\alpha_2 L_2/F)e^{\alpha_2 x}\right]\delta^\alpha_3.
\end{aligned}\tag{2.21}$$

These formulae are simplified by changing the basis in the algebra of the Killing vectors. Taking $k'^\alpha_{(2)}=k^\alpha_{(2)}+[(af-cd)/(bf-ce)]k^\alpha_{(1)}$ and $k'^\alpha_{(3)}=k^\alpha_{(3)}+[(-ae+bd)/(bf-ce)]k^\alpha_{(1)}$ instead of $k^\alpha_{(2)}$ and $k^\alpha_{(3)}$ we obtain the same result as if:

$$a=d=0.\tag{2.22}$$

With (2.22), we take $k'^\alpha_{(3)}=(2\sqrt{\Delta})^{-1}[k^\alpha_{(3)}-(1/2c)(f-b-\sqrt{\Delta})k^\alpha_{(2)}]$ instead of $k^\alpha_{(3)}$ and $k'^\alpha_{(2)}=(2c\beta)^{-1}(k^\alpha_{(2)}-2ck'^\alpha_{(3)})$ instead of $k^\alpha_{(2)}$. Further simplification results from the transformation (1.13) with:

$$H=\alpha_1^{-1}\ln F,\quad T_{,y}=L_2/(\alpha_1 F).\tag{2.23}$$

The Killing field $k^\alpha_{(1)}$ does not change, while the other two become (all primes dropped):

$$k^\alpha_{(2)}=e^{\alpha_2 x}\{\delta^\alpha_0-\alpha_2\delta^\alpha_2+[\gamma/(\beta\alpha_1)]\delta^\alpha_3\},\quad k^\alpha_{(3)}=e^{\alpha_1 x}(\delta^\alpha_0-\alpha_1\delta^\alpha_2).\tag{2.24}$$

Using (2.22) in (2.16)–(2.18) we obtain:

$$g=h=j=0.\tag{2.25}$$

Looking at the commutation relations one can see that in effect we have also achieved $c=e=0$, $\alpha_1=b$, $\alpha_2=f$, even though the initial basis (2.21) was calculated under the assumption $c\neq 0$. This allows us to predict that in the case $c=0$, set aside for separate consideration, we will obtain (2.24) again; see case 1.2 in Sec. VI. In view of the assumptions made earlier, we have:

$$b+f\neq 0\neq b-f,\quad b\neq 0\neq f,\tag{2.26}$$

and consequently the Bianchi type is VI_h, with the free parameter being $a_B=(b+f)/(b-f)$.

The Killing fields are simplified even further after the following transformation that leads out of the Plebański class:

$$t'=(b-f)^{-1}e^{-fx}(bt+y),\quad x'=x,\quad y'=(b-f)^{-1}be^{-bx}(ft+y),$$

$$z'=-\gamma[\beta(b-f)]^{-1}(t+y/b)+z, \tag{2.27}$$

that results in (primes dropped):

$$k^\alpha_{(1)}=-ft\delta^\alpha_0+\delta^\alpha_1-by\delta^\alpha_2,\quad k^\alpha_{(2)}=\delta^\alpha_0,\quad k^\alpha_{(3)}=\delta^\alpha_2,$$

$$u^\alpha=(b-f)^{-1}[be^{-fx}\delta^\alpha_0+bfe^{-bx}\delta^\alpha_2-(\gamma/\beta)\delta^\alpha_3],\quad w^\alpha=n\delta^\alpha_3. \tag{2.28}$$

In the new coordinates, the Killing equations imply for the metric:

$$g_{00}=e^{2fx}[1-(f/b)^2+\gamma^2g_{33}/(b\beta)^2-2f\gamma h_{23}/(b\beta)+f^2h_{22}],$$

$$g_{01}=e^{fx}[\gamma g_{13}/(b\beta)-fh_{12}],\quad g_{02}=e^{(b+f)x}[\gamma h_{23}/(b\beta)-(b-f)/b^2-fh_{22}],$$

$$g_{03}=e^{fx}[\gamma g_{33}/(b\beta)-fh_{23}],\quad g_{12}=e^{bx}h_{12},\quad g_{22}=e^{2bx}h_{22},\quad g_{23}=e^{bx}h_{23}, \tag{2.29}$$

where g_{11}, h_{12}, g_{13}, h_{22}, h_{23} and g_{33} are arbitrary functions of z.

III. CASE 1.1.1.2: $\alpha_2=-\alpha_1$

All equations up to (2.13) still apply, but (2.4c) has to be reconsidered. With $\alpha_2=-\alpha_1$ the following equations hold:

$$f=-b,\quad \Delta=4(b^2+ce),\quad \alpha_1=\sqrt{\Delta}/2=-\alpha_2. \tag{3.1}$$

In considering Eqs. (2.4c) and (2.3l) it may be assumed that $F\neq0\neq P$ because the opposite cases lead, just as before, out of the domain of this paper. With $F\neq0\neq P$, the coefficients of e^{α_1x}, of $e^{-\alpha_1x}$ and the terms independent of x (which now include the coefficients of $e^{(\alpha_1+\alpha_2)x}$) in (2.4c) imply, respectively:

$$h=\Delta^{-1/2}[-(ab/c+d)(-2b+\sqrt{\Delta})-2(-ae+bd)]-j(-2b+\sqrt{\Delta})/(2c),$$

$$j=a,\quad c\Delta FP=(1/2)\{g+\Delta^{-1}[-h(ab+cd)+a(-ae+bd)]\}y^2+B, \tag{3.2}$$

where B is an arbitrary constant.

In Eq. (2.3l) only the terms independent of x provide a piece of new information, the other parts of the equation are fulfilled identically in consequence of (3.1)–(3.2). The new information is:

$$L_3=\gamma/(\alpha_1F)-PL_2/F \tag{3.3}$$

(the integration constant γ was chosen so as to correspond to (2.20)). Like in Sec. II, we first construct the Killing fields by substituting (3.1)–(3.3), (2.9) and (2.13) into (2.1), then simplify the result by changing the basis in the Lie algebra and carrying out the coordinate transformations (1.13) (the difference is that here the coefficient in the formula for $k'^\alpha_{(2)}$ is Δ instead of $(2c\beta)^{-1}$). The result is:

$$a=d=0,\quad k^\alpha_{(1)}=\delta^\alpha_1,\quad k^\alpha_{(3)}=e^{\alpha_1x}(\delta^\alpha_0-\alpha_1\delta^\alpha_2),$$

$$k^\alpha_{(2)}=e^{-\alpha_1x}[(-gy^2+2B)\delta^\alpha_0+2gy\delta^\alpha_1+\alpha_1(gy^2+2B)\delta^\alpha_2+2(c\gamma\Delta/\alpha_1)\delta^\alpha_3]. \tag{3.4}$$

The commutation relations are:

$$[k_{(1)},k_{(2)}]=-\alpha_1k_{(2)},\quad [k_{(2)},k_{(3)}]=2g\alpha_1k_{(1)},\quad [k_{(3)},k_{(1)}]=-\alpha_1k_{(3)}, \tag{3.5}$$

and they correspond to the Bianchi type VIII when $g\neq0$ and type VI_0 when $g=0$ (note that $\alpha_1\neq0$ by the assumption defining case 1.1.1).

The Killing fields are further simplified by the coordinate transformation:

$$t'=t+y/\alpha_1-[2B\alpha_1/(c\gamma\Delta)]z,\quad x'=x,\quad y'=y,\quad z'=[\alpha_1/(2c\gamma\Delta)]z \tag{3.6}$$

that results (with primes dropped) in:

$$k^\alpha_{(1)}=\delta^\alpha_1,\quad k^\alpha_{(2)}=e^{-\alpha_1 x}[2gy\delta^\alpha_1+\alpha_1(gy^2+2B)\delta^\alpha_2+\delta^\alpha_3],\quad k^\alpha_{(3)}=-\alpha_1 e^{\alpha_1 x}\delta^\alpha_2,$$

$$u^\alpha=\delta^\alpha_0,\quad w^\alpha=[n\alpha_1/(2c\gamma\Delta)](-4B\delta^\alpha_0+\delta^\alpha_0),$$

$$g_{00}=1,\quad g_{01}=y,\quad g_{02}=-1/\alpha_1,\quad g_{03}=4B, \tag{3.7}$$

the other components of g_{ij} being just unknown functions. The Killing equations for $k^\alpha_{(1)}$ now imply that the metric is independent of x, while those for $k^\alpha_{(3)}$ are solved by:

$$g_{11}=(\alpha_1 y)^2 g_{22}-2\alpha_1 y H_{12}+H_{11},$$

$$g_{12}=-\alpha_1 y g_{22}+H_{12},\quad g_{13}=-\alpha_1 y g_{23}+H_{13}, \tag{3.8}$$

where H_{11}, H_{12}, H_{13}, g_{22}, g_{23} and g_{33} are arbitrary functions of t and z.

In solving the Killing equations for $k^\alpha_{(2)}$, three cases have to be considered separately:

Case I: $gB\neq 0$. In fact, the cases $gB>0$ and $gB<0$ lead to different results, but the formulae for $gB<0$ can be easily reconstructed from those for $gB>0$ by taking real combinations of the complex solutions. Hence, we shall only present the formulae for $gB>0$. The solution of the Killing equations is:

$$\mu:=(2gB)^{1/2}\alpha_1,\quad U:=h_{12}\cos(4\mu z)-k_{12}\sin(4\mu z),$$

$$V:=h_{13}\cos(2\mu z)-k_{13}\sin(2\mu z),$$

$$H_{11}=-(2B\alpha_1^2/\mu)U+h_{11},\quad H_{12}=h_{12}\sin(4\mu z)+k_{12}\cos(4\mu z)-H_{13}/(4B\alpha_1),$$

$$H_{13}=h_{13}\sin(2\mu z)+k_{13}\cos(2\mu z),\quad g_{22}=(g/\mu)U-[g/(2B\alpha_1\mu)]V+h_{22},$$

$$g_{23}=[\mu/(2B\alpha_1^2)]V-h_{33}/(4B\alpha_1),\quad g_{33}=h_{33}, \tag{3.9}$$

where the $h_{ij}(t)$ and $k_{ij}(t)$ are arbitrary functions.

When $gB<0$, μ is imaginary. Then the trigonometric functions go over into the appropriate hyperbolic functions, and h_{12} and h_{13} have to be taken imaginary, too.

Case II: $B=0$. The solution of the Killing equations for $k^\alpha_{(2)}$ is then:

$$H_{11}=h_{33}(\alpha_1 z)^2+2\alpha_1 h_{13}z+h_{11},$$

$$H_{12}=-\alpha_1^2 g h_{33}z^3-3\alpha_1 g h_{13}z^2+(\alpha_1 h_{23}-2g h_{11})z+h_{12},\quad H_{13}=\alpha_1 h_{33}z+h_{13},$$

$$g_{22}=(\alpha_1 g)^2 h_{33}z^4+4\alpha_1 g^2 h_{13}z^3-2g(\alpha_1 h_{23}-2g h_{11})z^2-4g h_{12}z+h_{22},$$

$$g_{23}=-\alpha_1 g h_{33}z^2-2g h_{13}z+h_{13},\quad g_{33}=h_{33}, \tag{3.10}$$

where the $h_{ij}(t)$ are arbitrary functions.

Case III: $g=0$. The Killing equations for $k^\alpha_{(2)}$ imply here:

$$H_{11}=[(4B\alpha_1)^2 h_{22}+8B\alpha_1 h_{23}+h_{33}](\alpha_1 z)^2+(8B\alpha_1 h_{12}+2h_{13})\alpha_1 z+h_{11},$$

$$H_{12}=(4B\alpha_1 h_{22}+h_{23})\alpha_1 z+h_{12},\quad H_{13}=(4B\alpha_1 h_{23}+h_{33})\alpha_1 z+h_{13},$$

$$g_{22}=h_{22},\quad g_{23}=h_{23},\quad g_{33}=h_{33}, \tag{3.11}$$

where the $h_{ij}(t)$ are arbitrary functions.

With this, case 1.1.1 is exhausted and we go back to (2.9) to consider the other branch of the alternative.

IV. CASE 1.1.2: $\Delta<0$ (i.e., THE EIGENVALUES α_1 AND α_2 ARE COMPLEX AND CONJUGATE TO EACH OTHER)

As stated before, it is more convenient to reparametrize (2.9) so that it contains only real quantities, and then repeat the procedure of case 1.1.1 in this new parametrization. We denote:

$$\sqrt{-\Delta}=D,\quad F=G+iJ,\quad P=G-iJ,\quad L_2=M+iN,\quad L_3=M-iN, \tag{4.1}$$

where G, J, M and N are new unknown functions of y, and then:

$$\alpha_{1,2}=\tfrac{1}{2}(b+f)+\tfrac{1}{2}i\varepsilon_{1,2}D,\quad \varepsilon_1=1,\quad \varepsilon_2=-1. \tag{4.2}$$

In this notation, Eqs. (2.9) and (2.13) adapted to the case $\Delta<0$ are:

$$\begin{aligned}
\lambda_2&=4ce^{(b+f)x/2}[M\ \cos(Dx/2)-N\ \sin(Dx/2)],\\
\lambda_3&=\frac{1}{2c}(f-b)\lambda_2-2De^{(b+f)x/2}[M\ \sin(Dx/2)+N\ \cos(Dx/2)],\\
\phi&=4ce^{(b+f)x/2}[G\ \cos(Dx/2)-J\ \sin(Dx/2)]-\frac{af-cd}{bf-ce}y-C_2,\\
\psi&=2(f-b)e^{(b+f)x/2}[G\ \cos(Dx/2)-J\ \sin(Dx/2)]\\
&\quad-2De^{(b+f)x/2}[G\ \sin(Dx/2)+J\ \cos(Dx/2)]-\frac{-ae+bd}{bf-ce}y-C_3.
\end{aligned} \tag{4.3}$$

Just as in case 1.1.1, these expressions must now satisfy the consistency conditions (2.4c) and (2.3l). However, in considering them, the cases $b+f\neq 0$ and $b+f=0$ have to be taken separately.

Case 1.1.2.1: $b+f\neq 0$. Both sides of (2.4c) are then polynomials in $e^{(b+f)x/2}$, and some of their coefficients involve $\cos(Dx/2)$ and $\sin(Dx/2)$. The coefficient of $e^{(b+f)x}$ leads to the equation:

$$4cD[-D(GG_{,y}+JJ_{,y})+(b+f)(GJ_{,y}-G_{,y}J)]=0. \tag{4.4}$$

We are working in the case $c\neq 0\neq D$, so only the expression in square brackets can vanish. Its form suggests the substitution:

$$G=K\ \cos L,\quad J=K\ \sin L, \tag{4.5}$$

where K and L are new functions of y. Equation (4.4) becomes then $-DKK_{,y}+(b+f)K^2L_{,y}=0$, and its solution is:

$$K=Be^{(b+f)L/D}, \tag{4.6}$$

where B is an arbitrary constant; $B\neq 0$ or else we are back in the domain of Paper II. Equations (4.5) and (4.6) provide a parametric representation of G and J in terms of the function L, which is arbitrary at this stage.

The coefficients of $e^{(b+f)x/2}$ in (2.4c) involve sin and cos that always go in fixed pairs. The coefficients of $\{e^{(b+f)x/2}[G\ \cos(Dx/2)-J\ \sin(Dx/2)]\}$ imply:

$$h=[4c(bf-ce)]^{-1}[(af-cd)(b^2-f^2+D^2)+2c(b+f)(-ae+bd)]-j(f-b)/(2c), \tag{4.7}$$

and the coefficients of $\{e^{(b+f)x/2}[G\ \sin(Dx/2)+J\ \cos(Dx/2)]\}$ imply:

$$j=-(bf-ce)^{-1}[f(af-cd)-c(-ae+bd)]. \tag{4.8}$$

Finally, the terms independent of x imply:

$$g=-(bf-ce)^{-1}[h(af-cd)+j(-ae+bd)]. \tag{4.9}$$

With (4.7)–(4.8), Eq. (2.3l) is reduced to:

$$4cDe^{(b+f)x}[-D(GM_{,y}+G_{,y}M+JN_{,y}+J_{,y}N)+(b+f)(GN_{,y}-G_{,y}N-JM_{,y}+J_{,y}M)]=0. \tag{4.10}$$

Only the expression in square brackets can vanish in the case now considered. After (4.5) and (4.6) are substituted into (4.10), the resulting equation integrates to:

$$e^{-(b+f)L/D}\{-M[D\ \cos L+(b+f)\sin L]+N[(b+f)\cos L-D\ \sin L]\}=\gamma B(b+f)=\text{const}. \tag{4.11}$$

Since $b+f\neq 0\neq D$ by assumption, this can be solved for N:

$$N=[(b+f)\cos L-D\ L]^{-1}\{\gamma B(b+f)e^{-(b+f)L/D}+M[D\ \cos L+(b+f)\sin L]\}. \tag{4.12}$$

The resulting Killing fields are:

$$k^{\alpha}_{(1)}=\delta^{\alpha}_{1},$$

$$\begin{aligned}
k^{\alpha}_{(2)}=&\,4ce^{(b+f)x/2}[(G-yG_{,y})\cos(Dx/2)-(J-yJ_{,y})\sin(Dx/2)]\delta^{\alpha}_{0}\\
&+\left\{4ce^{(b+f)x/2}[G_{,y}\cos(Dx/2)-J_{,y}\sin(Dx/2)]-\frac{af-cd}{bf-ce}\right\}\delta^{\alpha}_{1}\\
&-2ce^{(b+f)x/2}\{(b+f)[G\ \cos(Dx/2)-J\ \sin(Dx/2)]-D[G\ \sin(Dx/2)+J\ \cos(Dx/2)]\}\delta^{\alpha}_{2}\\
&+4ce^{(b+f)x/2}[M\ \cos(Dx/2)-N\ \sin(Dx/2)]\delta^{\alpha}_{3},\\
k^{\alpha}_{(3)}=&\,2e^{(b+f)x/2}\{(f-b)[(G-yG_{,y})\cos(Dx/2)-(J-yJ_{,y})\sin(Dx/2)]\\
&-D[(G-yG_{,y})\sin(Dx/2)+(J-yJ_{,y})\cos(Dx/2)]\}\delta^{\alpha}_{0}\\
&+2e^{(b+f)x/2}\left\{(f-b)[G_{,y}\ \cos(Dx/2)-J_{,y}\sin(Dx/2)]-D[G_{,y}\ \sin(Dx/2)+J_{,y}\ \cos(Dx/2)]\right.\\
&\left.-\frac{-ae+bd}{bf-ce}\right\}\delta^{\alpha}_{1}-e^{(b+f)x/2}\{(f^2-b^2-D^2)[G\ \cos(Dx/2)-J(Dx/2)]-2fD[G\ \sin(Dx/2)\\
&+J\ \cos(Dx/2)]\}\delta^{\alpha}_{2}+e^{(b+f)x/2}\{2(f-b)[M\ \cos(Dx/2)-N\ \sin(Dx/2)]-2D[M\ \sin(Dx/2)\\
&+N\ \cos(Dx/2)]\}\delta^{\alpha}_{3}.
\end{aligned} \tag{4.13}$$

Again, the formulae simplify when the basis in the Lie algebra is changed. First, we take $k'^{\alpha}_{(2)}=k^{\alpha}_{(2)}+[(af-cd)/(bf-ce)]k^{\alpha}_{(1)}$ and $k'^{\alpha}_{(3)}=k^{\alpha}_{(3)}+[(-ae+bd)/(bf-ce)]k^{\alpha}_{(1)}$ instead of $k^{\alpha}_{(2)}$ and $k^{\alpha}_{(3)}$, respectively. The result is equivalent to:

$$a=d=0, \tag{4.14}$$

and then (4.7)–(4.9) simplify to:

$$g=h=j=0. \tag{4.15}$$

With (4.14) taken into account, we change the basis again by taking $k'^{\alpha}_{(3)}=(-2BD)^{-1}\{k^{\alpha}_{(3)}-[(f-b)/2c]k^{\alpha}_{(2)}\}$ and $k'^{\alpha}_{(2)}=(4cB)^{-1}k^{\alpha}_{(2)}$ instead of $k^{\alpha}_{(3)}$ and $k^{\alpha}_{(2)}$, and carry out the transformation (1.13) with:

$$H=2L/D,\quad T_{,y}=2[B(b+f)]^{-1}e^{-(b+f)L/D}(M\ \cos L+N\ \sin L). \tag{4.16}$$

The result is equivalent to $L=0=M$, i.e.:

$$G=B,\quad J=0,\quad N=\gamma B. \tag{4.17}$$

The resulting Killing fields are:

$$k^\alpha_{(1)}=\delta^\alpha_1,$$

$$k^\alpha_{(2)}=e^{(b+f)x/2}[\cos(Dx/2)\,\delta^\alpha_0-\tfrac{1}{2}W\delta^\alpha_2-\gamma\,\sin(Dx/2)\,\delta^\alpha_3],$$

$$k^\alpha_{(3)}=e^{(b+f)x/2}[\sin(Dx/2)\,\delta^\alpha_0-\tfrac{1}{2}V\delta^\alpha_2+\gamma\,\cos(Dx/2)\,\delta^\alpha_3], \tag{4.18}$$

where:

$$W:=(b+f)\cos(Dx/2)-D\,\sin(Dx/2),$$

$$V:=D\,\cos(Dx/2)+(b+f)\sin(Dx/2). \tag{4.19}$$

The commutation relations are:

$$[k_1,k_2]=\tfrac{1}{2}(b+f)k_2-\tfrac{1}{2}Dk_3,\quad [k_2,k_3]=0,\quad [k_3,k_1]=-\tfrac{1}{2}Dk_2-\tfrac{1}{2}(b+f)k_3, \tag{4.20}$$

and they correspond to Bianchi type VII_h with the free parameter $a_B=-(b+f)/D$. Since $[k_2,k_3]=0$, coordinates can be adapted to k_2 and k_3 simultaneously. The following transformation does it:

$$t'=-D^{-1}e^{-(b+f)x/2}[Wt+2\cos(Dx/2)y],\quad x'=x,$$

$$y'=e^{-(b+f)x/2}\{D^{-1}Vt-2W^{-1}[1-D^{-1}\,\cos(Dx/2)V]y\},$$

$$z'=(\gamma/D)(b+f)t+2(\gamma/D)y+z, \tag{4.21}$$

but the new coordinates are no longer in the Plebański class. After the transformation, with primes dropped:

$$k^\alpha_{(1)}=\tfrac{1}{2}[-(b+f)t+Dy]\delta^\alpha_0+\delta^\alpha_1-\tfrac{1}{2}[Dt+(b+f)y]\delta^\alpha_2,\quad k^\alpha_{(2)}=\delta^\alpha_2,\quad k^\alpha_{(3)}=\delta^\alpha_0,$$

$$u^\alpha=D^{-1}e^{-(b+f)x/2}(-W\delta^\alpha_0+V\delta^\alpha_2)+(\gamma/D)(b+f)\,\delta^\alpha_3,\quad w^\alpha=n\delta^\alpha_3. \tag{4.22}$$

The formulae for $g_{0\alpha}$ $(\alpha=0,1,2,3)$ in terms of g_{ij} $(i,j=1,2,3)$ in the new coordinates are given in Appendix A.

In the new coordinates, the metric is independent of t and y, while the Killing equations for $k^\alpha_{(1)}$ have the following solution:

$$g_{11}=h_{11},\quad g_{12}=e^{(b+f)x/2}[Wh_{12}-2(\gamma/D^2)(b+f)\cos(Dx/2)h_{13}],\quad g_{13}=h_{13},$$

$$g_{22}=e^{(b+f)x}\{\left[\gamma^2(b+f)^2/D^2+\tfrac{1}{2}D\right]\cos^2(Dx/2)-2(\gamma/D)(b+f)\cos(Dx/2)Wh_{23}+W^2h_{22}\},$$

$$g_{23}=e^{(b+f)x/2}[Wh_{23}-(\gamma/D)(b+f)\cos(Dx/2)h_{33}],\quad g_{33}=h_{33}, \tag{4.23}$$

where the $h_{ij}(z)$ are arbitrary functions. The components $g_{0\alpha}$ in terms of those given above are given in Appendix A.

V. CASE 1.1.2.2: $f=-b$

We go back to Eqs. (4.3) which simplify as follows:

$$\lambda_2=4c[M\,\cos(Dx/2)-N\,\sin(Dx/2)],$$

$$\lambda_3=-(b/c)\lambda_2-2D[M\,\sin(Dx/2)+N\,\cos(Dx/2)], \tag{5.1}$$

$$\phi = 4c[G\ \cos(Dx/2) - J\ \sin(Dx/2)] - \frac{ab+cd}{b^2+ce}y - C_2,$$

$$\psi = -4b[G\ \cos(Dx/2) - J\ \sin(Dx/2)]$$

$$-2D[G\ \sin(Dx/2) + J\ \cos(Dx/2)] + \frac{-ae+bd}{b^2+ce}y - C_3, \tag{5.2}$$

With these new forms of ϕ, ψ, λ_2 and λ_3 we reconsider (2.4c) and (2.3l). Equation (2.4c) is now linear inhomogeneous in $\sin(Dx/2)$ and $\cos(Dx/2)$. The coefficients of $\cos(Dx/2)$, of $\sin(Dx/2)$ and the terms independent of x imply, respectively:

$$\frac{ab+cd}{b^2+ce}D^2G - 2aDJ = 4chG - 4bjG - 2jDJ, \tag{5.3}$$

$$-\frac{ab+cd}{b^2+ce}D^2J - 2aDG = -4chJ + 4bjJ - 2jDG, \tag{5.4}$$

$$-4cD^2(GG_{,y} + JJ_{,y}) = gy + (b^2+ce)^{-1}[-h(ab+cd) + j(-ae+bd)]y. \tag{5.5}$$

From (5.3) and (5.4) it follows that $2(j-a)D(G^2+J^2) = 0$. Since $D \neq 0$ by assumption, and $G = J = 0$ leads to the domain of Paper II, this implies:

$$j = a. \tag{5.6}$$

With (5.6), Eqs. (5.3) and (5.4) reduce to:

$$h = [4c(b^2+ce)]^{-1}(ab+cd)D^2 + ab/c. \tag{5.7}$$

The integral of (5.5) is:

$$-2cD^2(G^2+J^2) = \{g + (b^2+ce)^{-1}[-h(ab+cd) + a(-ae+bd)\}y^2/2 + B, \tag{5.8}$$

where $B = \text{const}$.

Equation (2.3l) leads now to two additional equations, one of which has the solution:

$$GM + JN = \gamma/D = \text{const}, \tag{5.9}$$

and what remains of (2.3l) is then:

$$4aD[M\ \sin(Dx/2) + N\ \cos(Dx/2)] = 0. \tag{5.10}$$

This has two solutions, $a = 0$ and $M = N = 0$, that must be considered separately. However, the case $M = N = 0$ turns out to be included as the subcase $\gamma = 0$ of the formulae below. Hence:

$$a = j = 0, \quad h = \tfrac{1}{4}(b^2+ce)^{-1}dD^2. \tag{5.11}$$

The resulting Killing fields are:

$$k^\alpha_{(1)} = \delta^\alpha_1,$$

$$k^\alpha_{(2)} = 4c[(G - yG_{,y})\cos(Dx/2) - (J - yJ_{,y})\sin(Dx/2)]\delta^\alpha_0$$
$$+ \left\{4c[G_{,y}\ \cos(Dx/2) - J_{,y}\ \sin(Dx/2)] - \frac{cd}{b^2+ce}\right\}\delta^\alpha_1$$
$$+ 2cD[G\ \sin(Dx/2) + J\ \cos(Dx/2)]\delta^\alpha_2 + 4c[M\ \cos(Dx/2) - N\ \sin(Dx/2)]\delta^\alpha_3,$$

$$k^{\alpha}_{(3)}=\{-4b[(G-yG_{,y})\cos(Dx/2)-(J-yJ_{,y})\sin(Dx/2)]$$
$$-2D[(G-yG_{,y})\sin(Dx/2)+(J-yJ_{,y})\cos(Dx/2)]\}\delta^{\alpha}_{0}$$
$$+\left\{-4b[G_{,y}\cos(Dx/2)-J_{,y}\sin(Dx/2)]-2D[G_{,y}\sin(Dx/2)+J_{,y}\cos(Dx/2)]+\frac{bd}{b^2+ce}\right\}\delta^{\alpha}_{1}$$
$$+\{2bD[-G\sin(Dx/2)-J\cos(Dx/2)]+D^2[G\cos(Dx/2)-J\sin(Dx/2)]\}\delta^{\alpha}_{2}$$
$$+\{-4b[M\cos(Dx/2)-N\sin(Dx/2)]-2D[M\sin(Dx/2)+N\cos(Dx/2)]\}\delta^{\alpha}_{3}. \tag{5.12}$$

By changing the basis to $k'^{\alpha}_{(2)}=k^{\alpha}_{(2)}+(b^2+ce)^{-1}cdk^{\alpha}_{(1)}$ and $k'^{\alpha}_{(3)}=k^{\alpha}_{(3)}-(b^2+ce)^{-1}bdk^{\alpha}_{(1)}$ the result equivalent to:

$$d=h=0 \tag{5.13}$$

is achieved, and then, from (5.8):

$$G^2+J^2=-(gy^2+2B)/(4cD^2). \tag{5.14}$$

Equation (5.14) suggests the parametrization:

$$G=K\cos L,\quad J=K\sin L, \tag{5.15}$$

then, from (5.14):

$$K^2=G^2+J^2=-(gy^2+2B)/(4cD^2), \tag{5.16}$$

and L remains arbitrary. With $a=d=0$ we change the basis again to $k''^{\alpha}_{(2)}=(4c)^{-1}k'^{\alpha}_{(2)}$ and $k''^{\alpha}_{(3)}=(-2D)^{-1}[k'^{\alpha}_{(3)}+(b/c)k'^{\alpha}_{(2)}]$ and we carry out the transformation (1.13) with:

$$H=2L/D,\quad T_{,y}=-2(M\sin L-N\cos L)/(DK). \tag{5.17}$$

The result is equivalent to $L=0=N$ which implies:

$$J=0,\ G=K,\quad M=\gamma/(DK), \tag{5.18}$$

and the Killing fields become:

$$k^{\alpha}_{(1)}=\delta^{\alpha}_{1},$$
$$k^{\alpha}_{(2)}=(K-yK_{,y})\cos(Dx/2)\,\delta^{\alpha}_{0}+K_{,y}\cos(Dx/2)\,\delta^{\alpha}_{1}$$
$$+\tfrac{1}{2}DK\sin(Dx/2)\,\delta^{\alpha}_{2}+[\gamma/(DK)]\cos(Dx/2)\,\delta^{\alpha}_{3},$$
$$k^{\alpha}_{(3)}=(K-yK_{,y})\sin(Dx/2)\,\delta^{\alpha}_{0}+K_{,y}\sin(Dx/2)\,\delta^{\alpha}_{1}$$
$$-\tfrac{1}{2}DK\cos(Dx/2)\,\delta^{\alpha}_{2}+[\gamma/(DK)]\sin(Dx/2)\,\delta^{\alpha}_{3}. \tag{5.19}$$

The commutation relations are:

$$[k_1,k_2]=\tfrac{1}{2}Dk_3,\quad [k_2,k_3]=-[g/(8cD)]k_1,\quad [k_3,k_1]=-\tfrac{1}{2}Dk_2. \tag{5.20}$$

The Bianchi type depends on the constant g: for $g/c>0$ it is type IX, for $g/c<0$ it is type VIII and for $g=0$ it is type VII_0. The last case is contained in (4.20)–(4.23) as the subcase $b+f=0$.

The Killing equations for $k^{\alpha}_{(1)}$ imply that the metric tensor is independent of x. Knowing this, one can simplify the Killing equations for $k^{\alpha}_{(2)}$ and $k^{\alpha}_{(3)}$. Since $k^{\alpha}_{(2)}$ and $k^{\alpha}_{(3)}$ are linear in $\sin(Dx/2)$

and $\cos(Dx/2)$, while $g_{\alpha\beta}$ are independent of x, each Killing equation implies two equations: the coefficients of $\cos(Dx/2)$ and of $\sin(Dx/2)$ have to vanish separately. The pair of equations implied by $k^{\alpha}_{(2)}$ is identical to the pair implied by $k^{\alpha}_{(3)}$, and it is:

$$\begin{aligned}(K-yK,_y)g_{\alpha\beta,t}+[\gamma/(DK)]g_{\alpha\beta,z}+\tfrac{1}{4}D^2K\delta^1_\alpha g_{2\beta}\\ +\delta^2_\alpha\{-yK,_{yy}g_{0\beta}+K,_{yy}g_{1\beta}-[\gamma K,_y/(DK^2)]g_{3\beta}\}+\tfrac{1}{4}D^2K\delta^1_\beta g_{\alpha 2}\\ +\delta^2_\beta\{-yK,_{yy}g_{\alpha 0}+K,_{yy}g_{\alpha 1}-[\gamma K,_y/(DK^2)]g_{\alpha 3}\}=0,\end{aligned}\tag{5.21}$$

$$\begin{aligned}Kg_{\alpha\beta,y}+\delta^1_\alpha\{-(K-yK,_y)g_{0\beta}-K,_yg_{1\beta}-[\gamma/(DK)]g_{3\beta}\}+K,_y\delta^2_\alpha g_{2\beta}\\ +\delta^1_\beta\{-(K-yK,_y)g_{\alpha 0}-K,_yg_{\alpha 1}-[\gamma/(DK)]g_{\alpha 3}\}+K,_y\delta^2_\beta g_{\alpha 2}=0.\end{aligned}\tag{5.22}$$

The solution of (5.22) is:

$$g_{11}=y^2+2H_{33}(\gamma K/D)^2\int K^{-3}R(y)dy+2(\gamma/D)K^2H_{13}R(y)+K^2H_{11},$$

$$g_{12}=(\gamma/D)H_{23}R(y)+H_{12},\quad g_{13}=(\gamma/D)H_{33}KR(y)+KH_{13},$$

$$g_{22}=H_{22}/K^2,\quad g_{23}=H_{23}/K,\quad g_{33}=H_{33},\tag{5.23}$$

where the $H_{ij}(t,z)$ are arbitrary functions, and $R(y)$ is:

$$R(y):=\int K^{-3}\mathrm{d}y.\tag{5.24}$$

With K given by (5.16), $R(y)$ and $\int K^{-3}R(y)dy$ can be easily calculated, but the result has to be given separately for $gB\neq 0$, for $g=0$ and for $B=0$, so Eq. (5.24) is the most compact notation (but see below).

Note that γ and B cannot vanish simultaneously; if $\gamma=0=B$, then $K-yK,_y=0=K,_{yy}$, and then Eq. (5.21) implies $g_{12}=g_{22}=g_{23}=0$. Together with $g_{02}=0$ (we are still in the Plebański class) this means that $\det(g_{\alpha\beta})=0$. Also, g and B cannot vanish simultaneously because with $g=0=B$ we are back in the domain of Paper II. With $\gamma^2+B^2\neq 0$, the following new variables can be introduced for solving (5.21):

$$u=2cD\gamma t+Bz,\quad v=-Bt+2cD\gamma z.\tag{5.25}$$

With γ and B running through all possible values, the hypersurfaces $u=\text{const}$ are timelike, null or spacelike. However, the solution of the Killing equations has the same dependence on u and v in every case.

For solving (5.21), the cases $gB\neq 0$ and $gB=0$ have to be separated.

Case I: $gB\neq 0$. (This means we are considering the Bianchi types IX and VIII here, but not VII_0.) In this case:

$$R=-2cD^2y/(BK),\tag{5.26}$$

and the solution of (5.21) (with (5.23)–(5.24) already taken into account) is:

$$\lambda^2:=gB/(8\delta^4D^2),\quad \delta^2:=(B/D)^2+(2c\gamma)^2,\quad U:=h_{12}\sinh(2\lambda v)+k_{12}\cosh(2\lambda v),$$

$$H_{11}=-cD^2U/(2\delta^2\lambda)+h_{11},\quad H_{12}=h_{12}\cosh(2\lambda v)+k_{12}\sinh(2\lambda v),$$

$$H_{13}=-[cD^2/(2\delta^2\lambda)][h_{23}\sinh(\lambda v)+k_{23}\cosh(\lambda v)],$$

$$H_{22}=-2\delta^2\lambda U/(cD^2)-[gB/(2c^2D^6)]h_{11}-[8c\gamma^2/(BD^2)]h_{33},$$

$$H_{23}=h_{23}\cosh(\lambda v)+k_{23}\sinh(\lambda v),H_{33}=h_{33},\tag{5.27}$$

where the $h_{ij}(u)$ and $k_{ij}(u)$ are arbitrary functions.

Equations (5.27) are adapted to the case $gB>0$. When $gB<0$, $\lambda^2<0$, i.e., λ is imaginary. Then k_{12} and k_{23} have to be taken imaginary (and U becomes imaginary in consequence of this), the hyperbolic functions go over into the corresponding trigonometric functions in the well-known way, and the functions H_{ij} remain real.

Case II: $gB=0$. Then $K_{,yy}=0$. The form of $R(y)$ still depends on whether $g\neq 0$ or $g=0$ and $B\neq 0$ or $B=0$. The formulae below apply in each case. The solution of (5.21) (again with (5.23)–(5.24) already taken into account) is here:

$$H_{11}=\frac{(c\gamma gy)^2}{64\delta^8D^2K^2}h_{33}v^4-\frac{c^2\gamma Dgy}{8\delta^6}h_{23}v^3+\left(\frac{c^2D^4}{4\delta^4}h_{22}+\frac{c\gamma gy}{4\delta^4DK}h_{13}\right)v^2-\frac{cD^2}{\delta^2}h_{12}v+h_{11},$$

$$H_{12}=-\frac{c(\gamma gy)^2}{16\delta^6D^4K^2}h_{33}v^3+\frac{3c\gamma gy}{8\delta^4D}h_{23}v^2-\left(\frac{cD^2}{2\delta^2}h_{22}+\frac{\gamma gy}{2\delta^2D^3K}h_{13}\right)v+h_{12},$$

$$H_{13}=\frac{c\gamma gy}{8\delta^4DK}h_{33}v^2-\frac{cD^2}{2\delta^2}Kh_{23}v+h_{13},\quad H_{22}=\frac{(\gamma gy)^2}{4\delta^4D^6K^2}h_{33}v^2-\frac{\gamma gy}{\delta^2D^3}h_{23}v+h_{22},$$

$$H_{23}=-\frac{\gamma gy}{2\delta^2D^3K}h_{33}v+Kh_{23},H_{33}=h_{33}. \tag{5.28}$$

The subcase of (5.28) in which $g=0$ and the hypersurfaces $u=$const are spacelike should have a common subset with the class considered by Demiański and Grishchuk.[3] These authors considered Bianchi type VII_0 models with nonzero rotation, with spacelike orbits of the symmetry group which are flat and with the source being a perfect fluid (the pressure is not constant in their class). A member of the present collection should result when $p=$const. However, Ref. 3 does not contain sufficient information to identify it.

With this, case 1.1 is exhausted. We go back to (2.8) with $\Delta\neq 0$ and consider:

VI. CASE 1.2: $c=0$

Just as it was announced in the paragraph after (2.25), this case brings no new information. Three situations occur here:

(1) The group becomes two-dimensional (because two Killing vectors become collinear); these cases are not considered here.
(2) A linear combination of the Killing fields with constant coefficients is spanned on u^α and w^α; these cases are in the domain of Paper II.
(3) In the case when the group is three-dimensional and none of the Killing fields is spanned on u^α and w^α, the formulae are equivalent to (2.25)–(2.29) and (3.2)–(3.11) (both sets reappear).

The proof consists simply in retracing the whole reasoning from (2.8) on with $c=0$. As seen from (2.8), with $c=0$ necessarily $\Delta\geqslant 0$, and so no analog of case 1.1.2 arises here. The essential steps of the reasoning are described in Appendix B.

Case 1 is exhausted at this point.

VII. CASE 2: $\Delta=0$ (i.e., A HAS ONE DOUBLE EIGENVALUE)

The reasoning from (2.8) on has to be repeated with this new assumption. Then the double eigenvalue is α and:

$$b=f\pm 2\sqrt{-ce},\quad \alpha=f\pm\sqrt{-ce}=(b+f)/2. \tag{7.1}$$

The double sign denotes two different cases, but they will be considered at one go. In finding the solutions of (2.5), the cases $\det A\neq 0$ and $\det A=0$ have to be considered separately. We first consider:

Case 2.1: det $A \neq 0$. This means:

$$b+f \neq 0 \neq \alpha. \tag{7.2}$$

In the next step, the case $c=0$ has to be set aside for separate consideration, so we first assume:

Case 2.1.1: $c \neq 0$. The solutions for $\lambda_{2,3}, \phi$ and ψ are here:

$$\lambda_2 = \{[1+(b-f)x/2]L_2(y) + cxL_3(y)\}e^{(b+f)x/2},$$

$$\lambda_3 = \{-(b-f)^2 xL_2(y)/(4c) + [1+(f-b)x/2]L_3(y)\}e^{(b+f)x/2}, \tag{7.3}$$

$$\phi = \{[1+(b-f)x/2]F(y) + cxP(y)\}e^{(b+f)x/2} + 4(cd-af)y/(b+f)^2 - C_2,$$

$$\psi = \{-(b-f)^2 xF(y)/(4c) + [1+(f-b)x/2]P(y)\}e^{(b+f)x/2}$$

$$-[a(b-f)^2/c + 4bd]y/(b+f)^2 - C_3. \tag{7.4}$$

With such $\lambda_{2,3}$, ϕ and ψ, Eq. (2.4c) involves polynomials of second degree in $e^{(b+f)x/2}$ and also of second degree in x. The equations implied by the coefficients of $x^2 e^{(b+f)x}$ and of $xe^{(b+f)x}$ are fulfilled identically, while the remaining ones are:

$$-(4c)^{-1}(b-f)^2 FF_{,y} + fF_{,y}P - bFP_{,y} - cPP_{,y} = 0, \tag{7.5}$$

$$[(b-f)F/2 + cP][d-h+(a+j)(b-f)/(2c)] = 0, \tag{7.6}$$

$$[(b-f)F/2 + cP]\{[a(b-3f)+4cd]/(b+f) - j\} = 0, \tag{7.7}$$

$$g = \{-4h(cd-af) + j[a(b-f)^2/c + 4bd]\}/(b+f)^2. \tag{7.8}$$

The vanishing of the first factor in (7.6) and (7.7) leads to the relation:

$$k^\alpha_{(3)} + \frac{b-f}{2c}k^\alpha_{(2)} - \frac{a(f-b)-2cd}{c(b+f)}k^\alpha_{(1)} = \left(\frac{b-f}{2c}L_2 + L_3\right)e^{(b+f)x/2}\delta^\alpha_3,$$

which means that the combination on the left is collinear with w^α, and so this case belongs to the domain of Paper II. Hence, (7.6) and (7.7) imply:

$$h = d + (a+j)(b-f)/(2c), \quad j = [a(b-3f)+4cd]/(b+f). \tag{7.9}$$

The solution of (7.5) may be represented parametrically by:

$$F = 2(\mathscr{A}R + cR\ \ln R)/(b+f), \quad P = -(b-f)F/(2c) + R, \tag{7.10}$$

where $\mathscr{A}$ is an arbitrary constant and $R(y)$ is an arbitrary function. It can be assumed that $R \neq 0$ because otherwise we are back in the domain of Paper II.

Equation (2.3l), with the functions given by (7.3)–(7.4) is a polynomial of the same form as (2.4c) and only the coefficients of $e^{(b+f)x}$ provide a new equation:

$$-(4c)^{-1}(b-f)^2(F_{,y}L_2 + FL_{2,y}) + fF_{,y}L_3 - bFL_{3,y} - c(L_{3,y}P + L_3P_{,y})$$

$$-bL_2P_{,y} + FL_{2,y}P = 0. \tag{7.11}$$

Using (7.10), the solution is found again in a parametric form:

$$L_2 = 2S(\mathscr{A} + c\ln R + c)/(b+f) + \gamma R, \quad L_3 = -(b-f)L_2/(2c) + S, \tag{7.12}$$

where γ is another arbitrary constant and S is another arbitrary function. The resulting Killing fields are now calculated from (2.1) using (7.10) and (7.12). Since this procedure has already been performed a few times in this paper, we shall not quote the intermediate results. It turns out that

$k^\alpha_{(2)}$ and $k^\alpha_{(3)}$ contain terms which are constant multiples of $k^\alpha_{(1)}$, these are removed when a new basis, $k'^\alpha_{(2)}$ and $k'^\alpha_{(3)}$ is appropriately defined. Then we change $k^\alpha_{(3)}$ again, to $k''^\alpha_{(3)} = k'^\alpha_{(3)} + [(b-f)/(2c)]k'^\alpha_{(2)}$ and carry out the transformation (1.13) with:

$$H = 2\ln R/(b+f), \quad T = 2(b+f)^{-1}\int (S/R)\mathrm{d}y. \tag{7.13}$$

The Killing fields that result are (with primes dropped):

$$k^\alpha_{(1)} = \delta^\alpha_1,$$

$$k^\alpha_{(2)} = e^{(b+f)x/2}\{[cx + 2\mathscr{A}/(b+f)]\delta^\alpha_0 - [c + \mathscr{A} + (b+f)cx/2]\delta^\alpha_2 + \gamma\delta^\alpha_3\},$$

$$k^\alpha_{(3)} = e^{(b+f)x/2}[\delta^\alpha_0 - \tfrac{1}{2}(b+f)\delta^\alpha_2]. \tag{7.14}$$

It can be assumed now that $\mathscr{A} = 0$ because this is equivalent to changing the basis to $k'^\alpha_{(2)} = k^\alpha_{(2)} - 2\mathscr{A}k^\alpha_{(3)}/(b+f)$. The commutation relations are:

$$[k_{(1)}, k_{(2)}] = \tfrac{1}{2}(b+f)k_{(2)} + ck_{(3)}, \quad [k_{(2)}, k_{(3)}] = 0, \quad [k_{(3)}, k_{(1)}] = -\tfrac{1}{2}(b+f)k_{(3)}, \tag{7.15}$$

and they correspond to Bianchi type IV.

Because of $[k_{(2)}, k_{(3)}] = 0$, coordinates can be adapted to $k_{(2)}$ and $k_{(3)}$ simultaneously. The following transformation does it:

$$t' = e^{-(b+f)x/2}[t + \tfrac{1}{2}(b+f)tx + xy], \quad x' = x,$$

$$y' = -c^{-1}e^{-(b+f)x/2}[\tfrac{1}{2}(b+f)t + y], \quad z' = \gamma(b+f)t/(2c) + \gamma y/c + z, \tag{7.16}$$

and it results in (primes dropped):

$$k^\alpha_{(1)} = -[\tfrac{1}{2}(b+f)t + cy]\delta^\alpha_0 + \delta^\alpha_1 - \tfrac{1}{2}(b+f)y\delta^\alpha_2, \quad k^\alpha_{(2)} = \delta^\alpha_2, \quad k^\alpha_{(3)} = \delta^\alpha_0,$$

$$u^\alpha = e^{-(b+f)x/2}[\delta^\alpha_0 - (2c)^{-1}(b+f)\delta^\alpha_2 + \gamma(2c)^{-1}(b+f)\delta^\alpha_3], \quad w^\alpha = n\delta^\alpha_3. \tag{7.17}$$

In the new coordinates the metric is independent of t and y. After the coordinate transformation (7.16) and after solving the Killing equations for $k^\alpha_{(1)}$ it assumes the form:

$$g_{00} = \tfrac{1}{4}(b+f)^2 e^{(b+f)x}h_{22}, \quad g_{01} = \tfrac{1}{2}(b+f)e^{(b+f)x/2}h_{12},$$

$$g_{02} = e^{(b+f)x}[-2c/(b+f) + \tfrac{1}{2}(b+f)Wh_{22} + \tfrac{1}{2}(b+f)\gamma h_{23}],$$

$$g_{03} = \tfrac{1}{2}(b+f)e^{(b+f)x/2}h_{23}, \quad g_{11} = h_{11},$$

$$g_{12} = e^{(b+f)x/2}(Wh_{12} + \gamma h_{13}), \quad g_{13} = h_{13},$$

$$g_{22} = e^{(b+f)x}\{-8c(b+f)^{-2}W + [2c/(b+f)]^2 + 2bWh_{23} + \gamma^2 h_{33} + W^2 h_{22}\},$$

$$g_{23} = e^{(b+f)x/2}(Wh_{23} + \gamma h_{33}), \quad g_{33} = h_{33}, \tag{7.18}$$

where the $h_{ij}(z)$ are arbitrary functions, and W, not to be confused with the same symbol from Sec. IV, is:

$$W := \tfrac{1}{2}(b+f)cx + c. \tag{7.19}$$

VIII. CASE 2.1.2: $c = 0$

It follows from (7.1) that in this case:

$$b = f = \alpha \neq 0. \tag{8.1}$$

Similar to what happened in Sec. VI, it turns out that this case is included in the case $c\neq 0$. When the procedure of Sec. VII is retraced with (8.1), the Killing fields that result at the stage corresponding to (7.14) are equivalent to (7.14), with $b+f=2b$, e playing the role of c and the roles of $k_{(2)}$ and $k_{(3)}$ interchanged.

IX. CASE 2.2: det $A=0$

With $\Delta=\det A=0$, the following follows from (2.8) and (2.6):

$$bf=ce,\quad f=-b,\quad \alpha_1=\alpha_2=0, \tag{9.1}$$

and the matrix A is nilpotent, $A^2=0$. Again the case $c=0$ has to be set aside for separate consideration, so we first follow:

Case 2.2.1: $c\neq 0$. The solutions of (2.5)–(2.6) are here:

$$\lambda_2=L_2(y)+cxL_3(y),\quad \lambda_3=-(b/c)\lambda_2+L_3(y), \tag{9.2}$$

$$\phi=F(y)+cxP(y)+\tfrac{1}{2}(ab+cd)x^2y,$$

$$\psi=-(b/c)\phi+P(y)+c^{-1}(ab+cd)xy+c^{-1}(-ay-bC_2-cC_3). \tag{9.3}$$

In considering Eqs. (2.4c) and (2.3l), the case $ab+cd=0$ has to be considered separately, so now we follow:

Case 2.2.1.1: $ab+cd\neq 0$. Equation (2.4c) is now a polynomial of second degree in x, and it implies the following equations:

$$j=a,\quad h=-d,\quad (ab+cd)(yF_{,y}+F+C_2)-c^2PP_{,y}=(cg-a^2)y. \tag{9.4}$$

The integral of the last equation is:

$$F=\tfrac{1}{2}(ab+cd)^{-1}[(cP)^2/y+(cg-a^2)y]+\mathscr{A}(ab+cd)/y-C_2. \tag{9.5}$$

Equation (2.3l) reduces to the single equation:

$$-c^2(L_{3,y}P+L_3P_{,y})+(ab+cd)(yL_{2,y}+L_2)=0. \tag{9.6}$$

In solving (9.6) the case $P=0$ has to be considered separately. However, although some of the intermediate steps of the calculation depend on the assumption $P\neq 0$, in the final formulae for the Killing fields $P=0$ is achieved by a transformation of the (1.13) set. The result is identical to the one obtained with $P=0$ from (9.6) on.

With $P\neq 0$, the solution of (9.6) is:

$$L_3=(ab+cd)[yL_2-\gamma(ab+cd)]/(c^2P). \tag{9.7}$$

We change the basis of the resulting Killing fields by taking $k'^{\alpha}_{(3)}=k^{\alpha}_{(3)}+(a/c)k^{\alpha}_{(1)}+(b/c)k^{\alpha}_{(2)}$, then carry out the transformation (1.13) with:

$$H=cP/[y(ab+cd)],\quad T_{,y}=cL_3/[y(ab+cd)], \tag{9.8}$$

and again change the basis to $k'^{\alpha}_{(2)}=(ab+cd)^{-1}[k^{\alpha}_{(2)}-\tfrac{1}{2}(ab+cd)^{-1}(cg-a^2)k^{\alpha}_{(1)}]$, $k''^{\alpha}_{(3)}=c(ab+cd)^{-1}k'^{\alpha}_{(3)}$. The final Killing fields are:

$$k^{\alpha}_{(1)}=\delta^{\alpha}_1,\quad k^{\alpha}_{(2)}=(2\mathscr{A}/y)\,\delta^{\alpha}_0+(-\mathscr{A}/y^2+x^2/2)\,\delta^{\alpha}_1-xy\,\delta^{\alpha}_2+(\gamma/y)\,\delta^{\alpha}_3,$$

$$k^{\alpha}_{(3)}=x\,\delta^{\alpha}_1-y\,\delta^{\alpha}_2. \tag{9.9}$$

The commutation relations are:

$$[k_{(1)},k_{(2)}]=k_{(3)},\quad [k_{(2)},k_{(3)}]=-k_{(2)},\quad [k_{(3)},k_{(1)}]=-k_{(1)}, \tag{9.10}$$

and they correspond to Bianchi type VIII.

The Killing equations for $k_{(1)}$ imply that the metric is independent of x. Those for $k_{(3)}$ are solved by:

$$g_{11}=H_{11}y^2,\quad g_{12}=H_{12},\quad g_{13}=H_{13}y,$$

$$g_{22}=H_{22}/y^2,\quad g_{23}=H_{23}/y,\quad g_{33}=H_{33}, \tag{9.11}$$

where the $H_{ij}(t,z)$ are arbitrary functions (the components $g_{0\alpha}$ are as in (1.9), we are still in the Plebański class in this case). In solving the Killing equations for $k_{(2)}$ it is useful to observe that $\mathscr{A}$ and γ cannot vanish simultaneously: with $\mathscr{A}=\gamma=0$, the Killing equations for $k_{(2)}$ imply that $g_{12}=g_{22}=g_{23}=0$, i.e., $\det(g_{\alpha\beta})=0$. With $\mathscr{A}^2+\gamma^2\neq 0$, the following variables can be introduced:

$$u=\gamma t-2.\mathscr{A}z,\quad v=2.\mathscr{A}t+\gamma z. \tag{9.12}$$

The Killing equations for $k^{\alpha}_{(2)}$ have to be solved separately for $\mathscr{A}\neq 0$ and for $\mathscr{A}=0$. When $\mathscr{A}\neq 0$, we define δ and λ by:

$$\delta^2=4.\mathscr{A}^2+\gamma^2,\quad \lambda^2=-2.\mathscr{A}/\delta^4, \tag{9.13}$$

and then the solution is:

$$U:=h_{12}\sinh(2\lambda v)+k_{12}\cosh(2\lambda v),\quad V:=h_{23}\sinh(\lambda v)+k_{23}\cosh(\lambda v),$$

$$H_{11}=(-2.\mathscr{A})^{-1/2}U+(\gamma/.\mathscr{A})(-2.\mathscr{A})^{-1/2}V+h_{11},$$

$$H_{12}=h_{12}\cosh(2\lambda v)+k_{12}\sinh(2\lambda v)+\gamma H_{23}/(2.\mathscr{A}),$$

$$H_{13}=(-2.\mathscr{A})^{-1/2}V+\gamma h_{33}/(2.\mathscr{A}),\quad H_{22}=(-2.\mathscr{A})^{1/2}U+2.\mathscr{A}h_{11}-\gamma^2 h_{33}/(2.\mathscr{A}),$$

$$H_{23}=h_{23}\cosh(\lambda v)+k_{23}\sinh(\lambda v),\quad H_{33}=h_{33}, \tag{9.14}$$

where the $h_{ij}(u)$ are arbitrary functions. Equations (9.14) are adapted to the case $\lambda^2>0$ ($\mathscr{A}<0$), but the solution for $\lambda^2<0$ can be easily constructed from this one.

When $\mathscr{A}=0$, necessarily $\gamma\neq 0$ and the Killing equations for $k^{\alpha}_{(2)}$ are solved in the original variables (t,z) as follows:

$$H_{11}=h_{33}z^4/(2\gamma)^2+h_{23}z^3/\gamma^2+(h_{22}/\gamma^2+h_{13}/\gamma)z^2+2h_{12}z/\gamma+h_{11},$$

$$H_{12}=h_{33}z^3/(2\gamma)+3h_{23}z^2/(2\gamma)+(h_{22}/\gamma+h_{13})z+h_{12},$$

$$H_{13}=h_{33}z^2/(2\gamma)+h_{23}z/\gamma+h_{13},\quad H_{22}=h_{33}z^2+2h_{23}z+h_{22},$$

$$H_{23}=h_{33}z+h_{23},\quad H_{33}=h_{33}, \tag{9.15}$$

where the $h_{ij}(t)$ are arbitrary functions.

Equations (9.14) and (9.15) are very similar in form to (5.27) and (5.28), respectively. This suggests that case 2.2.1.1 considered here may be included in case 1.1.2.2 of Sec. V as a limit (combined with a coordinate transformation). However, this author was not able to prove or disprove this hypothesis.

We go back now to (9.3) and consider:

X. CASE 2.2.1.2: $ab+cd=0$

Equations (9.2) still apply and Eqs. (9.3) simplify in the obvious way. The difference with Sec. IX is that Eqs. (2.4c) and (2.3l) impose weaker conditions here. The case $P=0$ leads to the domain of Paper 2, so it may be assumed that $P\neq 0$. Then, the consequences of (2.4c) are:

$$h=bj/c, \tag{10.1}$$

$$cPP_{,y}+(j-a)P+(g-aj/c)y=0. \tag{10.2}$$

Equation (10.2) defines P as a function of y. The consequence of Eq. (2.3) is:

$$c(L_3P)_{,y}+(j-a)L_3=0, \tag{10.3}$$

which defines L_3 once P is given. The functions F and L_2 are still arbitrary at this point.

In the resulting Killing fields we take $k'^{\alpha}_{(3)}=k^{\alpha}_{(3)}+(a/c)k^{\alpha}_{(1)}+(b/c)k^{\alpha}_{(2)}$ instead of $k^{\alpha}_{(3)}$, and carry out the transformation (1.13) with:

$$H=(F+C_2)/(cP), \quad T_{,y}=(L_2/c-HL_3)/P. \tag{10.4}$$

The result of the change of basis and of (10.4) is equivalent to:

$$F=-C_2, \quad L_2=a=b=d=0, \quad c=1, \tag{10.5}$$

and the Killing fields become:

$$k^{\alpha}_{(1)}=\delta^{\alpha}_1, \quad k^{\alpha}_{(2)}=x(P-yP_{,y})\delta^{\alpha}_0+xP_{,y}\delta^{\alpha}_1-P\delta^{\alpha}_2+xL_3\delta^{\alpha}_3,$$

$$k^{\alpha}_{(3)}=(P-yP_{,y})\delta^{\alpha}_0+P_{,y}\delta^{\alpha}_1+L_3\delta^{\alpha}_3. \tag{10.6}$$

Note that with (10.5) fulfilled, the subcase $g=0$ implies $P_{,y}=$const, and then $k^{\alpha}_{(3)}-P_{,y}k^{\alpha}_{(1)}$ is spanned on u^{α} and w^{α}, i.e., this case is in the domain of Paper II. Hence, in what follows it will be assumed that $g\neq 0$. For the same reason it will also be assumed that $(P-yP_{,y})\neq 0$.

The commutation relations (with (10.5) already taken into account) are:

$$[k_{(1)},k_{(2)}]=k_{(3)}, \quad [k_{(2)},k_{(3)}]=jk_{(3)}+gk_{(1)}, \quad [k_{(3)},k_{(1)}]=0. \tag{10.7}$$

The collection of Bianchi types contained in (10.7) is as follows. When:

(a) $g<j^2/4$, the Bianchi type is VI_h with the free parameter $a_B=j/(j^2-4g)^{1/2}$; and VI_0 when $j=0$.
(b) $g>j^2/4$, the Bianchi type is VII_h with the free parameter $a_B=j/(4g-j^2)^{1/2}$; and VII_0 when $j=0$.
(c) $g=j^2/4$, the Bianchi type is IV if $j\neq 0$ and II if $j=0$. This last case belongs to the domain of Paper II, as explained above, and will not be presented here.

The Killing equations have to be solved separately for these three cases.

The coordinates are adapted to $k_{(1)}$ and $k_{(3)}$ by the following transformation:

$$t'=t/(P-yP_{,y}), \quad x'=x-tP_{,y}/(P-yP_{,y}), \quad y'=y,$$

$$z'=-L_3t/(P-yP_{,y})+z. \tag{10.8}$$

In the new coordinates, with primes dropped:

$$k^{\alpha}_{(1)}=\delta^{\alpha}_1, \quad k^{\alpha}_{(2)}=(x-jt)\delta^{\alpha}_0-gt\delta^{\alpha}_1-P\delta^{\alpha}_2, \quad k^{\alpha}_{(3)}=\delta^{\alpha}_0,$$

$$u^{\alpha}=(P-yP_{,y})^{-1}(\delta^{\alpha}_0-P_{,y}\delta^{\alpha}_1-L_3\delta^{\alpha}_3), \quad w^{\alpha}=\delta^{\alpha}_3,$$

$$g_{00}=P^2-y^2P_{,y}{}^2+P_{,y}{}^2g_{11}+2L_3P_{,y}g_{13}+L_3{}^2g_{33},$$

$$g_{01}=y(P-yP_{,y})+P_{,y}g_{11}+L_3g_{13},$$

$$g_{02}=P_{,y}g_{12}+L_3g_{23}, \quad g_{03}=P_{,y}g_{13}+L_3g_{33}. \tag{10.9}$$

The Killing equations for $k_{(1)}$ and $k_{(3)}$ imply now that the metric is independent of t and x, while those for $k_{(2)}$ are:

$$-Pg_{11,y}+2y(P-yP_{,y})+2P_{,y}g_{11}+2L_3g_{13}=0,$$

$$-Pg_{12,y}+L_3g_{23}=0,\quad -Pg_{13,y}+P_{,y}g_{13}+L_3g_{33}=0,$$

$$-Pg_{22,y}-2P_{,y}g_{22}=0,\quad -Pg_{23,y}-P_{,y}g_{23}=0,\quad -Pg_{33,y}=0. \tag{10.10}$$

The last three have the same solutions in all three cases:

$$g_{22}=h_{22}/P^2,\quad g_{23}=h_{23}/P,\quad g_{33}=h_{33}, \tag{10.11}$$

where the $h_{ij}(z)$ in the formulae (10.11)–(10.21) are arbitrary functions. The remaining equations in (10.10) have to be solved separately for each case. In each case it is useful to introduce the new variable $Y(y)$ by:

$$Y_{,y}=1/P. \tag{10.12}$$

Then Eq. (10.3) (with (10.5) taken into account) has the solution:

$$L_3=(\gamma/P)e^{-jY}. \tag{10.13}$$

In order to find P one has to differentiate (10.2) (again with (10.5) taken into account) by Y and use $y_{,Y}=P$. The equation becomes:

$$P_{,YY}+jP_{,Y}+gP=0, \tag{10.14}$$

and y is then found from $y=\int PdY$. The solutions of (10.10) and of (10.14) are now as follows:

Case I: $g<j^2/4$.

$$P=Me^{\mu_1 Y}+Ne^{\mu_2 Y},\quad y=(M/\mu_1)e^{\mu_1 Y}+(N/\mu_2)e^{\mu_2 Y}+y_0, \tag{10.15}$$

where M, N and y_0 are arbitrary constants and

$$\mu_{1,2}=-j/2+\varepsilon_{1,2}(j^2/4-g)^{1/2},\quad \varepsilon_1=1,\quad \varepsilon_2=-1. \tag{10.16}$$

It can be assumed that $MN\neq 0$ because in both the cases $M=0$ and $N=0$ we are back in the domain of Paper II (then $P_{,y}=$ const). The solutions of the remaining Killing equations are here:

$$g_{11}=y^2+h_{11}P^2-2\gamma h_{13}e^{\mu_2 Y}P/[M(\mu_1-\mu_2)]+\gamma^2 h_{33}e^{2\mu_2 Y}/[M(\mu_1-\mu_2)]^2,$$

$$g_{12}=h_{12}-\gamma h_{23}e^{\mu_2 Y}/[M(\mu_1-\mu_2)P],\quad g_{13}=h_{13}P-\gamma h_{33}e^{\mu_2 Y}/[M(\mu_1-\mu_2)]. \tag{10.17}$$

Case II: $g>j^2/4$. Here we define:

$$D=(g-j^2/4)^{1/2},\quad U:=M\ \cos(DY)+N\ \sin(DY),$$

$$V:=M\ \sin(DY)-N\ \cos(DY), \tag{10.18}$$

where M and N are arbitrary constants, and then the solutions are:

$$P=e^{-jY/2}U,\quad y=(4D^2+j^2)^{-1}e^{-jY/2}(4DV-2jU)+y_0,$$

$$g_{11}=y^2+h_{11}P^2+2\gamma h_{13}e^{-jY}UV/[D(M^2+N^2)]+\gamma^2 h_{33}e^{-jY}/[D^2(M^2+N^2)],$$

$$g_{12}=h_{12}+\gamma h_{23}V/[D(M^2+N^2)U],\quad g_{13}=h_{13}P+\gamma h_{33}PV/[D(M^2+N^2)U]. \tag{10.19}$$

Case III: $g=j^2/4\neq 0$. With M,N and y_0 being arbitrary constants, the solutions for P and y are here:

$$P=(MY+N)e^{-jY/2},\quad y=-2P/j-4Me^{-jY/2}j^2+y_0. \tag{10.20}$$

We can assume $M\neq 0$ because with $M=0$ again $P_{,y}=$const. Then, the solutions of the Killing equations are as follows:

$$g_{11}=y^2+h_{11}P^2-2\gamma h_{13}e^{-jY/2}P/M+\gamma^2 h_{33}e^{-jY}/M^2,$$

$$g_{12}=h_{12}-\gamma h_{23}/[M(My+N)],\quad g_{13}=h_{13}P-\gamma h_{33}e^{-jY/2}/M. \tag{10.21}$$

With this, case 2.2.1 is exhausted. We go back to (9.1) and consider:

XI. CASE 2.2.2: $c=0$

With $\Delta=\det A=c=0$ the only element of the matrix A that may be nonzero is e. The solutions of (2.5)–(2.6) are here:

$$\lambda_2=L_2(y),\quad \lambda_3=exL_2+L_3(y), \tag{11.1}$$

$$\phi=axy+F(y),\quad \psi=\tfrac{1}{2}aex^2y+(dy+eC_2+eF)x+P(y). \tag{11.2}$$

Equation (2.4c) now implies that either $j=a$ or $a=0$ or $e=0$. However, $j=a$ leads to a result equivalent to (9.9) and $a=0$ leads to a result equivalent to (10.6). Hence:

$$e=0, \tag{11.3}$$

which makes the whole matrix $A=0$. The remaining implications of (2.4c) and (2.3l) are:

$$ah+dj=0,\quad y(dF_{,y}-aP_{,y}-g)=h(F+C_2)+j(P+C_3),$$

$$y(dL_{2,y}-aL_{3,y})=hL_2+jL_3. \tag{11.4}$$

In solving these conditions, again several cases have to be considered separately.

Case 2.2.2.1: $a\neq 0$. Then:

$$h=-dj/a, \tag{11.5}$$

but in solving the second of (11.4) the case $j=-a$ has to be set aside for separate consideration. We first follow:

Case 2.2.2.1.1: $j\neq -a$. Then:

$$P=-gy/(j+a)+By^{-j/a}-C_3+(d/a)(F+C_2),$$

$$L_3=-\mathscr{A}y^{-j/a}+(d/a)L_2, \tag{11.6}$$

where $\mathscr{A}$ and B are arbitrary constants. In the resulting Killing fields we change the basis to $k'^{\alpha}_{(2)}=a^{-1}k^{\alpha}_{(2)}$, $k'^{\alpha}_{(3)}=k^{\alpha}_{(3)}-(d/a)k^{\alpha}_{(2)}+[g/(j+a)]k^{\alpha}_{(1)}$, and then carry out the transformation (1.13) with:

$$H=(C_2+F)/(ay),\quad T_{,y}=L_2/(ay). \tag{11.7}$$

The final Killing fields are:

$$k^{\alpha}_{(1)}=\delta^{\alpha}_1,\quad k^{\alpha}_{(2)}=x\delta^{\alpha}_1-y\delta^{\alpha}_2,$$

$$k^{\alpha}_{(3)}=y^{-j/a}[B(j/a+1)\delta^{\alpha}_0-Bj(ay)^{-1}\delta^{\alpha}_1-\mathscr{A}\delta^{\alpha}_3]. \tag{11.8}$$

The commutation relations are:

$$[k_{(1)},k_{(2)}]=k_{(1)},\quad [k_{(2)},k_{(3)}]=(j/a)k_{(3)},\quad [k_{(3)},k_{(1)}]=0, \tag{11.9}$$

and they correspond to Bianchi type VI_h with the free parameter $a_B=(j-a)/(j+a)$.

The coordinates will be adapted to $k_{(1)}$ and $k_{(3)}$ after the transformation:

$$t'=aty^{j/a}/[B(j+a)],\quad x'=jt/[(j+a)y]+x,\quad y'=y,\quad z'=\mathscr{A}at+B(j+a)z. \tag{11.10}$$

After the transformation:

$$k^\alpha_{(1)}=\delta^\alpha_1,\quad k^\alpha_{(2)}=-jt\delta^\alpha_0+ax\delta^\alpha_1-ay\delta^\alpha_2,\quad k^\alpha_{(3)}=\delta^\alpha_0,$$

$$u^\alpha=(j+a)^{-1}[aB^{-1}y^{j/a}\delta^\alpha_0+(j/y)\delta^\alpha_1]+\mathscr{A}a\delta^\alpha_3,\quad w^\alpha=B(j+a)n\delta^\alpha_3,$$

$$g_{00}=(By^{-j/a})^2[1-(j/a)^2+(j/a)^2g_{11}/y^2+2\mathscr{A}j(j/a+1)g_{13}/y+\mathscr{A}^2(j+a)^2g_{33}],$$

$$g_{01}=By^{-j/a}[(j/a+1)y-(j/a)g_{11}/y-\mathscr{A}(j+a)g_{13}],$$

$$g_{02}=-By^{-j/a}[(j/a)g_{12}/y+\mathscr{A}(j+a)g_{23}],\quad g_{03}=-By^{-j/a}[(j/a)g_{13}/y+\mathscr{A}(j+a)g_{33}], \tag{11.11}$$

and the Killing equations imply:

$$g_{11}=h_{11}y^2,\quad g_{12}=h_{12},\quad g_{13}=h_{13}y,$$

$$g_{22}=h_{22}/y^2,\quad g_{23}=h_{23}/y,\quad g_{33}=h_{33}, \tag{11.12}$$

where the $h_{ij}(z)$ are arbitrary functions.

Case 2.2.2.1.2: $j=-a$. The formulae for h and L_3 simply follow from (11.5) and (11.6) while the second of (11.4) now has a different integral:

$$P=(-g/a)y\ \ln y+By-C_3+(d/a)(F+C_2). \tag{11.13}$$

In the resulting Killing fields we change the basis to $k'^\alpha_{(2)}=a^{-1}k^\alpha_{(2)}$, $k'^\alpha_{(3)}=k^\alpha_{(3)}-(d/a)k^\alpha_{(2)}+(g/a-B)k^\alpha_{(1)}$, and then carry out the transformation (1.13) with the same H and T as in (11.7). The final Killing fields $k^\alpha_{(1)}$ and $k^\alpha_{(2)}$ are the same as in (11.8), and:

$$k^\alpha_{(3)}=y\delta^\alpha_0-\ln y\,\delta^\alpha_1-\mathscr{A}y\delta^\alpha_3. \tag{11.14}$$

The commutation relations are:

$$[k_{(1)},k_{(2)}]=k_{(1)},\quad [k_{(2)},k_{(3)}]=k_{(1)}-k_{(3)},\quad [k_{(3)},k_{(1)}]=0, \tag{11.15}$$

and they correspond to Bianchi type IV.

In order to adapt the coordinates to $k^\alpha_{(1)}$ and $k^\alpha_{(2)}$ we now carry out the transformation:

$$t'=t/y,\quad x'=(t/y)\ln y+x,\quad y'=y,\quad z'=\mathscr{A}t+z, \tag{11.16}$$

and it leads to:

$$k^\alpha_{(1)}=\delta^\alpha_1,\quad k^\alpha_{(2)}=t\delta^\alpha_0+(x-t)\delta^\alpha_1-y\delta^\alpha_2,\quad k^\alpha_{(3)}=\delta^\alpha_0,$$

$$u^\alpha=y^{-1}(\delta^\alpha_0+\ln y\,\delta^\alpha_1)+\mathscr{A}\delta^\alpha_3,\quad w^\alpha=n\delta^\alpha_3,$$

$$g_{00}=y^2-2y^2\ \ln y+(\ln y)^2g_{11}+2\mathscr{A}y\ \ln yg_{13}+(\mathscr{A}y)^2g_{33},$$

$$g_{01}=y^2-\ln yg_{11}-\mathscr{A}yg_{13},\quad g_{02}=-\ln yg_{12}-\mathscr{A}yg_{23},$$

$$g_{03}=-\ln yg_{13}-\mathscr{A}yg_{33}, \tag{11.17}$$

and the Killing equations lead to formulae for the other metric components that are identical to (11.12).

Case 2.2.2.2: $a=0$. Then the first of (11.4) implies that either $d=0$ or $j=0$. However, if $d=0$, then either the algebra of the Killing vectors necessarily becomes two-dimensional (this case is not considered here) or

$$j=0 \tag{11.18}$$

follows anyway. Hence only (11.18) will be considered further. Then, with $0\neq d\neq h$, a result equivalent to (11.8) follows, and when $0\neq d=h$, a result equivalent to case 2.2.2.1.2 follows. Therefore, new results are contained only in the case:

$$d=0. \tag{11.19}$$

Then, from (11.4):

$$h(F+C_2)+gy=0. \tag{11.20}$$

If $h\neq 0$, then (11.20) implies that the combination of the Killing fields $k^\alpha_{(2)}+(g/h)k^\alpha_{(1)}$ is collinear with w^α, and this case is in the domain of Paper II. Hence, from (11.20):

$$h=g=0, \tag{11.21}$$

which leaves us with an Abelian algebra (Bianchi type I) and the functions F, P, L_2 and L_3 being all arbitrary. To avoid landing in the domain of Paper II, we have to assume:

$$F_{,y}\neq 0\neq P_y, \quad C_2+F-yF_{,y}\neq 0\neq C_3+P-yP_{,y}. \tag{11.22}$$

We will denote:

$$W_F:=C_2+F-yF_{,y}, \quad W_P:=C_3+P-yP_{,y}, \tag{11.23}$$

and then the Killing fields are:

$$k^\alpha_{(1)}=\delta^\alpha_1, \quad k^\alpha_{(2)}=W_F\delta^\alpha_0+F_{,y}\delta^\alpha_1+L_2\delta^\alpha_3, \quad k^\alpha_{(3)}=W_P\delta^\alpha_0+P_{,y}\delta^\alpha_1+L_3\delta^\alpha_3. \tag{11.24}$$

It may also be assumed that:

$$\mathscr{L}:=L_3-L_2W_P/W_F\neq 0 \tag{11.25}$$

because if $\mathscr{L}=0$, then the Killing equations imply that either the symmetry group becomes two-dimensional or the metric is singular. With $\mathscr{L}\neq 0$, the following transformation is permissible:

$$t'=(L_3t-W_Pz)/(\mathscr{L}W_F), \quad x'=(L_2P_{,y}-L_3F_{,y})t/(\mathscr{L}W_F)+x-(P_{,y}-F_{,y}W_P/W_F)z/\mathscr{L},$$

$$y'=y, \quad z'=-L_2t/(\mathscr{L}W_F)+z/\mathscr{L}, \tag{11.26}$$

after which the Killing fields become:

$$k^\alpha_{(1)}=\delta^\alpha_1, \quad k^\alpha_{(2)}=\delta^\alpha_0, \quad k^\alpha_{(3)}=\delta^\alpha_3. \tag{11.27}$$

The resulting metric depends only on y, but the Einstein equations are hopelessly complicated.

This is the end of the collection of solutions of the Killing equations.

XII. PERSPECTIVES

The research for this series of papers was motivated by the desire to find a rotating (exact) perturbation of the Friedmann–Lemaître cosmological models. Several papers have been published whose authors found exact solutions of Einstein's equations with a rotating source (see a brief overview in Sec. XIII), but all except one of them are either stationary from the beginning or become static in the limit of zero rotation. The one exception is the solution 2 by Stephani[4] that has still nonzero expansion in the limit $\omega\to 0$, but it is a rotating perturbation of a degenerate limit of the hyperbolically symmetric Kantowski–Sachs solution[5] (see Ref. 6 for more on this point) and cannot reproduce any Robertson–Walker geometry.

There is no proof available that a rotating perturbation of the F–L models can be spatially homogeneous. However, if it has any spatially homogeneous subcases and has a dust source, then the subcases must be contained among the metrics listed in this series of papers—just because this is a complete list of all hypersurface-homogeneous rotating dust metrics (and, over all three papers, all Bianchi types appeared on the list, some of them more than once). Hence, from now on, instead of testing various metric ansatzes for rotating dust by trial and error, one can choose an ansatz from a limited collection. It is well-known[7] that the Robertson–Walker geometries have the following relation to the spatially homogeneous Bianchi-type geometries:

The spatially flat ($k=0$) R–W geometry is a common subset of Bianchi types I and VII_0.

The R–W geometry with negative spatial curvature ($k=-1$) is a common subset of Bianchi types V and VII_h.

The R–W geometry with positive spatial curvature ($k=+1$) is a subset of Bianchi type IX geometries.

With this information, the following can be concluded:

(1) The metrics from Paper I do not contain any generalization of the F–L models; the Bianchi type I class contained there has timelike symmetry orbits and the velocity field is tangent to the orbits.
(2) The same is true for the Bianchi type I metrics from Paper II (cases 2.1.2.2 and 2.2) and from the present paper (Eqs. (11.22)–(11.27)). This is in agreement with Theorem 3.1 of King and Ellis[8] which says that no tilted Bianchi type I models exist (tilted means that the velocity field is not orthogonal to the symmetry orbits. Bianchi models with rotation obviously must be tilted).
(3) The Bianchi type V metrics from Paper II (cases 1.2.1 and 1.2.2.2) with suitably chosen parameters do have spacelike symmetry orbits and so may harbour some generalization of the $k=-1$ F–L model.
(4) The Bianchi type VII_h metrics of the present paper [Eqs. (4.23) and (10.19)] may have spacelike symmetry orbits at least on some open subsets of the manifold, i.e., they may contain generalizations of the $k=-1$ F–L model.
(5) The same is true for the Bianchi type IX and type VII_0 metrics of the present paper (Eqs. (5.23) with (5.27) or (5.28)); generalizations of the $k=+1$ and $k=0$ F-L models may be contained there.

Hence, the cases listed in points 3, 4 and 5 are most promising from the point of view of cosmology.

XIII. A BRIEF OVERVIEW OF LITERATURE

Partly in order to justify the claim made in the first paragraph of Sec. XII, a brief overview of literature on solutions of Einstein's equations with rotating sources will be presented here. For the period up to 1973, the overview is based on a thorough survey of subject indexes to *Physics Abstracts* starting with the year 1915 (made in connection with Refs. 57–59). For the period 1973–1996 the survey was less thorough—I was looking for only four keywords: ''Bianchi,'' ''homogeneous,'' ''rotation'' and ''spatially homogeneous.'' In both searches the following sections of *Physics Abstracts* were surveyed: Cosmology, General Relativity, Gravitation, and Space-Time Configurations (of course, references in the papers included in the survey were also checked). Ref. 9 is a more extended survey that covers the period up to 1973, and papers in which perturbative methods were used were also listed in it, these are omitted here. Vacuum solutions are omitted, too.

As a rule, each paper is mentioned in one sentence, so this overview does not pretend to represent the contents of the papers; it is only meant to sort the papers by subjects and serve as an introductory guide through the literature.

Lanczos[10] found the historically earliest exact solution with rotating matter (although he may have been unaware of its rotation); it is a dust solution in which the velocity field and the rotation field are collinear with Killing fields. Van Stockum[11] rediscovered the $\Lambda=0$ subcase of the Lanczos solution; Ref. 11 contains in addition important contributions to the techniques of solving

the Einstein equations for stationary axisymmetric metrics (i.e., with a two-dimensional symmetry group) with a rigidly rotating source. Ref. 12 is another rediscovery of the Lanczos solution, and Refs. 13 and 14 contain discussions of its properties.

Gödel's solution[15] has a five-dimensional symmetry group whose orbit is the whole space–time, and consequently the physical scalars in it are all constant. Its source is dust of zero expansion and shear, and constant matter density and rotation scalars. Rediscoveries of the Gödel solution were published in Refs. 16 and 17 (see Ref. 18). Reference 17 contains in addition a stationary axisymmetric perfect fluid solution.

References 19–32 deal with properties of a metric form that is a modest generalization of the Gödel solution and is known in the literature as the ''Gödel-type metric.'' This notion was introduced in Ref. 19, and in Ref. 20 (which in fact preceded Ref. 19) it was shown that the only Gödel-type metric with a perfect fluid source is the Gödel solution itself. However, various Gödel-type solutions with nonperfect fluid sources have been derived and investigated in Refs. 19 and 21–32.

In Refs. 33–40 solutions of Einstein–Maxwell equations with a charged fluid source were discussed, some of them under the additional assumption that the Lorentz force is zero. The latter are fully within the scope of the formalism used in the present series of papers because the charged dust in them moves with zero acceleration. The relation of the results of these papers to those obtained here was described in Paper I. Some of them are generalizations of the Lanczos[10] and Gödel[15] solutions. Those from Refs. 33–39 are stationary cylindrically symmetric, i.e., are closely related to those from Paper I, the one from Ref. 40 has a two-dimensional symmetry group. The solutions in Ref. 39 are coordinate transforms of those from Ref. 38.

A generalization of the $\Lambda=0$ subcase of the Lanczos solution to a mixture of scalar field and dust was found by Santos and Mondaini.[41]

Other generalizations of the Gödel solution were found in Refs. 42–50. Raval and Vaidya[42] found two solutions with anisotropic pressure, one of them nonstationary. Bray[43] found a collection of solutions with the rotating fluid immersed in a magnetic field. Novello and Rebouças,[44] Kitamura[45–47] and Ray[48] found generalizations with heat flow (the second of Kitamura's solutions presented in Ref. 45 is a coordinate transform of the Gödel solution). Rebouças[49] found a generalization with free electromagnetic field; see Ref. 51 and Paper I for an explanation of the relation between the solutions in Refs. 49 and 37. Finally, Panov[50] found a generalization with two scalar fields, anisotropic fluid, null radiation and heat conduction.

Other solutions with rotating charged matter source were obtained in Refs. 52–55. The Einstein–Maxwell equations for stationary axisymmetric charged dust were analyzed by Bonnor.[56]

In addition, several solutions with a perfect fluid source (i.e., with nonconstant pressure) and with the same Bianchi type I symmetry as was considered in Paper I have been published. These include a family of solutions by this author[57–60] in which the velocity and the rotation fields are collinear with the Killing fields. For the solutions considered in Refs. 57 and 59 the proportionality factor between w^α and the Killing field is explicitly given. For the family of metrics from Ref. 60, the factor is an arbitrary function and the family is defined by a differential equation. The solutions by Davidson[61,62] are explicit examples from the family of Ref. 60, possibly they are also coordinate transforms of members of the family from Ref. 57 defined by certain fixed values of parameters, but Refs. 61 and 62 do not contain sufficient information for precise identification.

Nilsson and Uggla[63] did a qualitative analysis (using the theory of dynamical systems) of perfect fluid solutions with the same symmetry that obey the linear barotropic equation of state.

The list above includes papers that are related to Paper I of this series. Results related to those of Paper II are contained in Refs. 64–77.

Among the solutions found by Ellis[64] there are some that directly belong to the collection of Paper II, they are identified and described in Paper II. Also within the scope of Paper II are the results of King[65] who investigated properties of the subcase $\beta=h_{13}=0$ of case 2.1.2.2 (of Paper II) and provided a few examples of explicit solutions. Other explicit solutions in King's class were found by Maitra,[66] Zimmerman[67] (this reference was not given in Paper II) and Vishveshwara and Winicour.[68]

In Refs. 69–73 rotating dust solutions with four-dimensional symmetry groups were found; at least some of them have three-dimensional subgroups and are within the domain of Paper II.

However, as mentioned in Paper II, these papers do not contain sufficient information for a complete identification of all such subcases. The first three of the six solutions given in Ref. 70 are among the case 2.1.2.2 metrics of Paper II.

Davidson[74] found an example of a solution with King's subclass of symmetry (stationary, cylindrically symmetric, differentially rotating) and with a perfect fluid source obeying the linear barotropic equation of state. Two other stationary cylindrically symmetric perfect fluid solutions were found by Garcia and Kramer,[75] the first is differentially rotating and has the symmetry of King's subclass, the other is rigidly rotating and so has the Bianchi type I symmetry of the class considered in Paper I. Nilsson and Uggla[76] analyzed by the method of dynamical systems the Einstein equations for a metric with a Bianchi type II symmetry and a perfect fluid source that obeys the linear barotropic equation of state. Its set of Killing fields is in the subcase $\lambda_3=0$ of case 1.1.2.2 of Paper II. Stewart and Ellis[77] considered perfect fluid generalizations of the Ellis (dust) solutions from Ref. 64, they also considered sources with anisotropic pressure, viscosity and electric charge.

The only paper directly relevant to the present Paper III is Ref. 3, see Sec. V. The remaining part of the present section is a list of papers in which various problems connected with rotating matter were discussed, but which are more remotely related to the present series of papers.

Stephani[4] found a solution that is unique in one more respect in addition to that mentioned in Sec. XII: it is so far the only rotating matter (dust) solution with no symmetry. (Note: solution 3 in Ref. 4 is not a perfect fluid solution, contrary to the paper's statement.)

Stationary axisymmetric (i.e., with two-dimensional symmetry groups) perfect fluid solutions were found in Refs. 78–83. Wahlquist[78] found a rigidly rotating solution with the equation of state $\epsilon=-3p+\text{const}$ that, with specific values of two parameters, can describe the interior of a body with compact outer surface. Herlt[79] found a source of the NUT vacuum solution and Kramer[80] found another solution, both are rigidly rotating (Kramer's solution was rediscovered by Patra and Roy,[81] see Ref. 82). Another class of rigidly rotating stationary axisymmetric solutions was found by Herlt.[83]

Several stationary axisymmetric metrics were devised as nonperfect fluid sources of the Kerr solution. Results in this class that were published up to 1976 are reviewed in Ref. 84. Later, a few more papers on this subject were published, but in those that are known to the present author the source is either a surface distribution of matter or an energy-momentum tensor that does not correspond to any identifiable kind of matter, hence they are not mentioned here.

A spatially homogeneous solution of Bianchi type VI_0 with a rotating perfect fluid source was found by Rosquist;[85] it has the equation of state $\epsilon=3p$ and nonzero expansion. Spatially homogeneous solutions with heat-conducting sources were found in Refs. 86–89. Two other hypersurface-homogeneous perfect fluid solutions were found by Wainwright,[90] one has a three-dimensional symmetry group of unidentified Bianchi type, the other has a four-dimensional multiply transitive symmetry group.

The remaining papers (Refs. 91–116) contain results obtained without finding explicit solutions of Einstein's equations. This part of the survey is likely to be incomplete.

Narlikar[91] proposed a metric form for a rotating dust model in which dust particles move on 3-cylinders (axial symmetry is not assumed) whose orthogonal sections are two-dimensional surfaces of constant curvature. Winicour[98] reduced the Einstein equations with a stationary axisymmetric dust source to a sequence of integrations. This author[101] presented results of partial integration of the Einstein equations for a cylindrically symmetric nonstationary perfect fluid.

Bampi and Cianci[102] investigated spacetimes with an Abelian two-dimensional group of symmetries that has null orbits; the example of exact solution provided is a vacuum. Wils and van den Bergh[104] showed that a stationary axisymmetric differentially rotating charged dust has either a nonvanishing Lorentz force of a nonconstant ratio of charge density to mass density.

In Refs. 105–110 general properties of rotating spatially homogeneous Bianchi type IX models were investigated without attempting to solve the Einstein equations. Of these, Ref. 109 gives a kinetic theory description of sources in such models and Ref. 110 gives a qualitative analysis of rotating mixmaster models.

References 111–113 contain general considerations about rotating matter models, and Refs. 8 and 114 contain more general results, applicable also to nonrotating models, but having consequences for rotating models as well. Collins[111] considered properties of shearfree rotating perfect

fluids. Again Collins[112] reviewed arguments for the hypothesis that shear being zero implies that either rotation or expansion is zero (apart from several specific examples, this is still unproven). Mason and Pooe[113] investigated properties of the Lie derivative of the rotation vector along the velocity vector in rigidly rotating matter. King and Ellis[8] investigated properties of tilted spatially homogeneous models and Nilsson and Uggla[114] investigated hypersurface homogeneous and hypersurface self-similar perfect fluid models by the method of dynamical systems.

Hawking[115] and Collins and Hawking[116] investigated limits set on the rotation parameter in Bianchi-type models by the observations of the CMB radiation.

Finally, there is a paper in the domain of the history of science. Ellis[117] described the influence of Gödel's ideas presented in Refs. 15 and 105 on the development of several concepts and research programs in relativity, such as, among other things, the Bianchi-type models, singularity theorems and causal structure of space–time.

ACKNOWLEDGMENT

Calculations for this paper were done with use of the algebraic computer program ORTOCARTAN.[118,119]

Note added in proof: The Gödel-type metric of Refs. 19–32 was discussed also in Ref. 120. Other rotating solutions of Einstein–Maxwell equations were discussed in Refs. 121 and 122. I am grateful to M. J. Rebouças and A. Georgiou for this information.

APPENDIX A: THE RESULT OF TRANSFORMATION (4.21) ON THE METRIC

The coordinate transformation (4.21) changes the metric tensor from the Plebański form (1.9) to one in which the following relations hold (primes dropped, all the components displayed are expressed in the new coordinates):

$$\begin{aligned}
g_{00} &= e^{(b+f)x}[\sin^2(Dx/2)-(V/W)^2\cos^2(Dx/2)]+(V/W)^2 g_{22}\\
&\quad +2(V/W)\gamma e^{(b+f)x/2}[\cos(Dx/2)+(V/W)\sin(Dx/2)]g_{23}\\
&\quad +\gamma^2 e^{(b+f)x}[\cos(Dx/2)+(V/W)\sin(Dx/2)]^2 g_{33},\\
g_{01} &= (V/W)g_{12}+\gamma e^{(b+f)x/2}[\cos(Dx/2)+(V/W)\sin(Dx/2)]g_{13},\\
g_{02} &= e^{(b+f)x}\cos(Dx/2)[\sin(Dx/2)-(V/W)\cos(Dx/2)]+(V/W)g_{22}\\
&\quad +\gamma e^{(b+f)x/2}[\cos(Dx/2)+(V/W)\sin(Dx/2)]g_{23},\\
g_{03} &= (V/W)g_{23}+\gamma e^{(b+f)x/2}[\cos(Dx/2)+(V/W)\sin(Dx/2)]g_{33}.
\end{aligned}$$

APPENDIX B: THE EQUIVALENCE OF CASE 1.2 AND CASE 1.1.1

These are the main points of the reasoning from (2.8) on in the case $c=0$. When $c=0$, Eqs. (2.7)–(2.8) imply:

$$\alpha_1=b, \quad \alpha_2=f, \tag{B1}$$

and $b\neq f$ since $\Delta\neq 0$. The calculation requires checking several cases separately.

Case 1.2.1: det $A\neq 0$. The formulae corresponding to (2.9) and (2.13) are then:

$$\begin{aligned}
&\lambda_2=L_2(y)e^{bx}, \quad \lambda_3=[e/(b-f)]L_2(y)e^{bx}+L_3(y)e^{fx}, \quad \phi=F(y)e^{bx}-ay/b-C_2,\\
&\psi=[e/(b-f)]F(y)e^{bx}+P(y)e^{fx}-[-ae/(bf)+d/f]y-C_3.
\end{aligned} \tag{B2}$$

In verifying (2.4c) and (2.3l) the cases $F=0$ and $P=0$ have to be considered separately. The results are as follows:

When $F=0\neq P$ and $L_2=0$ the group becomes two-dimensional.

When $F=0\neq P$ and $L_2\neq 0$, the Killing field $[k^\alpha_{(2)}+(a/b)k^\alpha_{(1)}]$ is collinear with w^α, and this case is in the domain of Paper II.

When $P=0$, another linear combination of the Killing vectors with constant coefficients is collinear with w^α.

When $F\neq 0\neq P$, formulae equivalent to (2.24)–(2.29) result.

Case 1.2.2: det $A=0$. Two different (but equivalent) subcases have to be considered here: $b=0$ and $f=0$ ($b\neq f$ because of the assumption $\Delta\neq 0$).

When $f=0$, the functions λ_2,λ_3 and ϕ are given by the limit $f=0$ of (B.2), while ψ is:

$$\psi=(e/b)F(y)e^{bx}+P(y)-aey/b^2+(d-ae/b)xy-C_3. \tag{B3}$$

Equations (2.4c) and (2.3l) show then that there always exists a linear combination of the Killing fields with constant coefficients which is spanned on u^α and w^α.

When $b=0$, the conclusion is the same, only the functions in (B.2) are different at the starting point. λ_2 and λ_3 are the limits $b=0$ of those from (B.2), and:

$$\phi=F(y)+axy-C_2,$$

$$\psi=-(e/f)(\phi+C_2)+P(y)e^{fx}-(d/f+ae/f^2)y-C_3. \tag{B4}$$

Riemannian space-times of Gödel type in five dimensions

M. J. Rebouças[a] and A. F. F. Teixeira[b]
Centro Brasileiro de Pesquisas Físicas, Departamento de Relatividade e Partículas, Rua Dr. Xavier Sigaud 150, 22290-180 Rio de Janeiro-RJ, Brazil

(Received 20 May 1997; accepted for publication 11 December 1997)

The five-dimensional (5D) Riemannian Gödel-type manifolds are examined in light of the equivalence problem techniques, as formulated by Cartan. The necessary and sufficient conditions for local homogeneity of these 5D manifolds are derived. The local equivalence of these homogeneous Riemannian manifolds is studied. It is found that they are characterized by two essential parameters m^2 and ω: identical pairs (m^2,ω) correspond to locally equivalent 5D manifolds. An irreducible set of isometrically nonequivalent 5D locally homogeneous Riemannian Gödel-type metrics are exhibited. A classification of these manifolds based on the essential parameters is presented, and the Killing vector fields as well as the corresponding Lie algebra of each class are determined. It is shown that apart from the $(m^2=4\omega^2,\omega\neq 0)$ and $(m^2\neq 0,\omega=0)$ classes the homogeneous Riemannian Gödel-type manifolds admit a seven-parameter maximal group of isometry (G_7). The special class $(m^2=4\omega^2,\omega\neq 0)$ and the degenerated Gödel-type class $(m^2\neq 0,\omega=0)$ are shown to have a G_9 as maximal group of motion. The breakdown of causality in these classes of homogeneous Gödel-type manifolds are also examined.

I. INTRODUCTION

Kaluza–Klein-type theories in five and more dimensions have been of notable interest in several contexts. In the framework of gauge theories they have been used in the quest for unification of the fundamental interactions in physics. The idea that the various interactions in nature might be unified by enlarging the dimensionality of the space-time has a long and honorable history that goes back to the works of Nordström, Kaluza, and Klein.[1–3] Its earlier adherents were mainly interested in extending general relativity, but a late increased interest has been apparent in the particle physics community, especially among those investigating supersymmetry.

The possibility that space-time has more than four dimensions has also received much attention regarding its cosmological aspects. Investigation has been focused on attempts to understand, for example, why the universe presently appears to have only four space-time dimensions, and whether it is a higher-dimensional dynamically evolving manifold, the space-time expands while the extra dimensions contract or remain constant. The first cosmological model in which the extra dimension contracts as a result of the cosmological evolution was proposed by Chodos and Detweiler.[4] Since then, a great deal of work has emerged along this line of research, particularly regarding exact solutions of Einstein's equations, entropy production during the contracting process,[5] resolution of the horizon and flatness problems,[6] and the like (see Ref. 7 and references therein).

From a purely technical viewpoint higher-dimensional Kaluza–Klein-type theories have also been used as a way of finding new exact solutions of Einstein's equations in four dimensions.[8–10]

More recently Wesson[11–13] has given a new impetus to the study of (4+1)-gravity by investigating a five-dimensional extension of general relativity with a variable rest mass (see also Refs. 14 and 15). In this theory we have space-time-mass (STM) Riemannian manifolds, and the fifth dimension is a convenient mathematical way of geometrizing the rest mass and of allowing one to study the possibility that it may be variable. The four-dimensional (4D) general relativity theory is recovered when the rate of change of the rest mass is zero. Ever since the foundations of this

 © 1998 American Institute of Physics

Kaluza–Klein-type STM theory were laid, there have been investigations of its potentialities and physical consequences, particularly as concerns its consistency with Mach's principle,[16] causality conditions and inflation,[14,17] confrontation between theory and observation,[18,19] and the solutions of its field equations.[15]

In 1949 Gödel found a solution of Einstein's field equations with cosmological constant for incoherent matter with rotation.[20] Owing to its striking properties, the cosmological solution presented by Gödel has a well-recognized importance and has to a large extent motivated the investigations on rotating cosmological space-times within the framework of general relativity. Particularly, the search for rotating Gödel-type space-times has received a good deal of attention in recent years, and the literature on these geometries is fairly large today (see Refs. 21–34 and references therein).

However, the general problem of space-time local homogeneity (ST homogeneity, hereafter[35]) of four-dimensional Riemannian manifolds endowed with a Gödel-type metric was considered for the first time only in 1980 by Raychaudhuri and Thakurta.[36] They found the necessary conditions for ST homogeneity of these manifolds. Three years later, Rebouças and Tiomno[37] proved that Raychaudhuri–Thakurta necessary conditions are also sufficient for ST homogeneity of Gödel-type manifolds. However, in both articles[36,37] the study of ST homogeneity is limited in that only time-independent Killing vector fields were considered.[38] The Raychaudhuri–Thakurta–Rebouças–Tiomno conditions were finally proved to be the necessary and sufficient conditions for a Gödel-type manifold to be ST homogeneous without assuming any such simplifying hypothesis in Ref. 39, where the powerful equivalence problem techniques for Riemannian space-times, as formulated in terms of spinors by Karlhede[40] and embodied in a suite of computer algebra programs called CLASSI[41] written in SHEEP,[42] were used.

In light of the equivalence problem techniques, as formulated by Cartan[43] and using CLASSI, we extend these investigations by examining a class of five-dimensional (5D) Riemannian Gödel-type manifolds. The necessary and sufficient conditions for local homogeneity of these 5D manifolds are derived. The local equivalence of these homogeneous space-time-mass Riemannian manifolds is discussed; they are found to be characterized by two essential parameters m^2 and ω: identical pairs (m^2,ω) correspond to locally equivalent STM manifolds. An irreducible set of isometrically nonequivalent 5D homogeneous Riemannian Gödel-type metrics are exhibited. A classification of these manifolds based on the essential parameters is presented, and the Killing vector fields as well as the corresponding Lie algebra of each class are determined. We show that apart from the $(m^2=4\omega^2,\omega\neq 0)$ and $(m^2\neq 0,\omega=0)$ classes the 5D locally homogeneous Riemannian Gödel-type manifolds have a seven-parameter maximal group of isometry (G_7). The special class $(m^2=4\omega^2,\omega\neq 0)$ and the degenerated Gödel-type class $(m^2\neq 0,\omega=0)$ are shown to admit a G_9 as maximal group of motion. The breakdown of causality in these classes of homogeneous Gödel-type manifolds is also examined and shown to have the same basic features of the corresponding 4D counterparts.

To close this Introduction, we should like to emphasize that although the STM Wesson's theory of gravitation is often referred to, the results of the following sections hold for any five-dimensional Riemannian Gödel-type manifold regardless of the underlying 5D Kaluza–Klein-type theory[44–47] one may be concerned with.

II. HOMOGENEITY, IRREDUCIBLE SET, AND CAUSALITY

The arbitrariness in the choice of coordinates in the geometric theories of gravitation gives rise to the problem of deciding whether or not two Riemannian manifolds whose metrics g and $\tilde{g}$ are given explicitly in terms of coordinates, viz.,

$$ds^2=g_{\mu\nu}dx^\mu dx^\nu \quad \text{and} \quad d\tilde{s}^2=\tilde{g}_{\mu\nu}d\tilde{x}^\mu d\tilde{x}^\nu, \tag{2.1}$$

are locally the same. This is the so-called equivalence problem (see Cartan[43] for the local equivalence of n-dimensional Riemannian manifolds, Karlhede[40] and MacCallum[42,48,49] for the special case $n=4$ of general relativity).

The Cartan solution[43] to the equivalence problem for Riemannian manifolds can be reworded as follows. Two n-dimensional Lorentzian Riemannian manifolds M and $\tilde{M}$ are locally equivalent

if there exist coordinate and generalized n-dimensional Lorentz transformations such that the following *algebraic* equations relating the frame components of the curvature tensor and their covariant derivatives:

$$
\begin{aligned}
R^{A}{}_{BCD} &= \widetilde{R}^{A}{}_{BCD}, \\
R^{A}{}_{BCD;M_1} &= \widetilde{R}^{A}{}_{BCD;M_1}, \\
R^{A}{}_{BCD;M_1M_2} &= \widetilde{R}^{A}{}_{BCD;M_1M_2}, \\
&\vdots \\
R^{A}{}_{BCD;M_1\ldots M_{p+1}} &= \widetilde{R}^{A}{}_{BCD;M_1\ldots M_{p+1}}
\end{aligned}
\tag{2.2}
$$

are compatible as equations in (x^{μ},ξ^{A}). Here and in what follows we use a semicolon to denote covariant derivatives. Note that x^{μ} are coordinates on the manifold M while ξ^{A} parametrize the group of allowed frame transformations [n-dimensional generalized Lorentz group usually denoted[50] by $O(n-1,1)$]. Reciprocally, Eqs. (2.2) imply local equivalence between the n-dimensional manifolds M and $\widetilde{M}$.

In practice, a fixed frame is chosen to perform the calculations so that only coordinates appear in the components of the curvature tensor, i.e., there is no explicit dependence on the parameters ξ^{A} of the generalized Lorentz group.

Another important practical point to be considered, once one wishes to test the local equivalence of two Riemannian manifolds, is that before attempting to solve Eqs. (2.2) one can extract and compare partial pieces of information at each step of differentiation as, for example, the number $\{t_0,t_1,\ldots,t_p\}$ of functionally independent functions of the coordinates x^{μ} contained in the corresponding set

$$
I_p=\{R^{A}{}_{BCD},R^{A}{}_{BCD;M_1},R^{A}{}_{BCD;M_1M_2},\ldots,R^{A}{}_{BCD;M_1M_2\ldots M_p}\},
\tag{2.3}
$$

and the isotropy subgroup $\{H_0,H_1,\ldots,H_p\}$ of the symmetry group G_r under which the corresponding set I_p is invariant. They must be the same for each step $q=0,1,\ldots,p$ if the manifolds are locally equivalent.

In practice it is also important to note that in calculating the curvature and its covariant derivatives, in a chosen frame, one can stop as soon as one reaches a step at which the pth derivatives (say) are algebraically expressible in terms of the previous ones, and the residual isotropy group (residual frame freedom) at that step is the same isotropy group of the previous step, i.e., $H_p=H_{(p-1)}$. In this case further differentiation will not yield any new piece of information. Actually, if $H_p=H_{(p-1)}$ and, in a given frame, the pth derivative is expressible in terms of its predecessors, for any $q>p$ the qth derivatives can all be expressed in terms of the 0th, 1st, $\ldots$,$(p-1)$th derivatives.[43,51,42] As in the worst case we have only one functionally independent function of the coordinates x^{μ} at each step of the differentiation process, and the generalized Lorentz group has $n(n-1)/2$ independent parameters, it follows that for five-dimensional Riemannian manifolds $p+1\leqslant 15$.

Since there are t_p essential coordinates, in 5D clearly $5-t_p$ are ignorable, so the isotropy group will have dimension $s=\dim(H_p)$, and the group of isometries of the metric will have dimension r given by (see Cartan[43])

$$
r=s+5-t_p,
\tag{2.4}
$$

acting on an orbit with dimension

$$
d=r-s=5-t_p.
\tag{2.5}
$$

The line element of the five-dimensional Riemannian Gödel-type manifolds M_5 we are concerned with in this work is given by

$$ds^2 = dt^2 + 2H(x)dtdy - dx^2 - G(x)dy^2 - dz^2 - du^2, \tag{2.6}$$

where $H(x)$ and $G(x)$ are arbitrary real functions of x, and the five STM coordinates clearly are t,x,y,z,u. As a matter of fact, to ensure the local Lorentzian character of (2.6) one has to require that $H^2(x)+G(x)>0$. At an arbitrary point of M_5 one can choose the following set of linearly independent one-forms θ^A:

$$\theta^0 = dt + H(x)dy, \quad \theta^1 = dx, \quad \theta^2 = D(x)dy, \qquad \theta^3 = dz, \quad \theta^4 = du, \tag{2.7}$$

such that the Gödel-type line element (2.6) can be written as

$$ds^2 = \eta_{AB}\theta^A\theta^B = (\theta^0)^2 - (\theta^1)^2 - (\theta^2)^2 - (\theta^3)^2 - (\theta^4)^2, \tag{2.8}$$

where $D^2(x) = G + H^2$. Here and in what follows capital letters are pentad indices (or Lorentz frame indices) and run from 0 to 4; they are raised and lowered with Lorentz matrices $\eta^{AB} = \eta_{AB} = \text{diag}(+1,-1,-1,-1,-1)$, respectively.

Using as input the one-forms (2.7) and the Lorentz frame (2.8), the computer algebra package CLASSI gives the following nonvanishing Lorentz frame components R_{ABCD} of the curvature:

$$R_{0101} = R_{0202} = -\frac{1}{4}\left(\frac{H'}{D}\right)^2, \tag{2.9}$$

$$R_{0112} = \frac{1}{2}\left(\frac{H'}{D}\right)', \tag{2.10}$$

$$R_{1212} = \frac{D''}{D} - \frac{3}{4}\left(\frac{H'}{D}\right)^2, \tag{2.11}$$

where the prime denotes derivative with respect to x.

For STM homogeneity from Eq. (2.5) one must have $t_q = 0$ for $q = 0,1,\ldots,p$, that is, the number of functionally independent functions of x^μ in the set I_p must be zero. Therefore from Eqs. (2.9)–(2.11) we conclude that for STM homogeneity it is necessary that

$$\frac{H'}{D} = \text{const} \equiv -2\omega, \tag{2.12}$$

$$\frac{D''}{D} = \text{const} \equiv m^2. \tag{2.13}$$

We shall now show that the above necessary conditions are also sufficient for STM local homogeneity. Indeed, under these conditions the nonvanishing frame components of the curvature reduce to

$$R_{0101} = R_{0202} = -\omega^2, \tag{2.14}$$

$$R_{1212} = m^2 - 3\omega^2. \tag{2.15}$$

Following Cartan's method for the local equivalence, we next calculate the first covariant derivative of the Riemann tensor. Now one obtains the following non-null covariant derivatives of the curvature:

$$R_{0112;1} = R_{0212;2} = \omega(m^2 - 4\omega^2). \tag{2.16}$$

As the first covariant derivative of the curvature is algebraically expressible in terms of the Riemann tensor and for a given pair (m^2,ω) the isotropy group H_1 is the same as H_0 (see next paragraph), no new covariant derivative of the curvature should be calculated. Clearly one also has $t_0=t_1=0$.

As far as the dimension of the residual isotropy group is concerned we distinguish two different classes of locally homogeneous 5D Gödel-type Riemannian manifolds, according to the relevant parameters m^2 and ω, namely[52]

(i) $m^2\neq 4\omega^2$ and $\omega\neq 0$ for which $\dim(H_0)=\dim(H_1)=2$;

(ii) $m^2=4\omega^2$ with $\omega\neq 0$, and the degenerated Gödel-type manifolds $m^2\neq 0$ and $\omega=0$. Here one has $\dim(H_0)=\dim(H_1)=4$.

Thus from Eqs. (2.4) and (2.5) one finds that the locally homogeneous 5D Riemannian Gödel-type manifolds admit a (local) G_r, with either $r=7$ or $r=9$, acting on an orbit of dimension 5, that is on the whole STM manifold.

The above results can be collected together in the following theorems:

Theorem 1: *The necessary and sufficient conditions for a five-dimensional Riemannian Gödel-type manifold to be locally homogeneous are those given by Eqs. (2.12) and (2.13).*

Theorem 2: *The five-dimensional locally homogeneous Riemannian Gödel-type manifolds admit group of isometry G_r with*

(i) $r=7$ if $m^2\neq 4\omega^2$ and $\omega\neq 0$;

(ii) $r=9$ if $m^2=4\omega^2$ with $\omega\neq 0$, or when $m^2\neq 0$ and $\omega=0$.

Theorem 3: *The five-dimensional homogeneous Riemannian Gödel-type manifolds are locally characterized by two independent parameters m^2 and ω: identical pairs (m^2,ω) specify locally equivalent manifolds.*

We remark that the particular case $m^2=\omega=0$ has not been included in our study inasmuch as, from (2.14) and (2.15), it is clearly the 5D flat manifold.

We shall now be concerned with the irreducible set of isometrically nonequivalent homogeneous Gödel-type metrics. To this end, we distinguish four classes of metrics according to:

Class I: $m^2>0,\omega\neq 0$. For this case, the general solution of (2.12) and (2.13) can be written as

$$D(x)=a_0e^{mx}+a_1e^{-mx} \quad \text{and} \quad H(x)=-\frac{2\omega}{m}(a_0e^{mx}-a_1e^{-mx})+a_2, \tag{2.17}$$

where a_0, a_1, and a_2 are arbitrary constants. According to the above theorem (Theorem 3), the constants a_0, a_1, and a_2 are not essential. In other words they can be eliminated by coordinate transformations. Indeed, if one performs the coordinate transformation $u'=u$ and successively the transformations (3.10), (3.15), and (3.16) of Ref. 37 one finds that the line element for this class of homogeneous Gödel-type manifolds is brought into the form

$$ds^2=[dt+H(r)d\phi]^2-D^2(r)d\phi^2-dr^2-dz^2-du^2 \tag{2.18}$$

in cylindrical coordinates (r,ϕ,z), where

$$H(r)=\frac{2\omega}{m^2}[1-\cosh(mr)] \quad \text{and} \quad D(r)=\frac{1}{m}\sinh(mr). \tag{2.19}$$

Class II: $m^2=0,\omega\neq 0$. For this case, the general solution of (2.12) and (2.13) is

$$D(x)=b_0x-b_1 \quad \text{and} \quad H(x)=-\omega x(b_0x-2b_1)+b_2, \tag{2.20}$$

where b_0,b_1, and b_2 are arbitrary constants. By trivial coordinate transformations the line element for this class can be brought to the form (2.18) but now with

$$H(r)=-\omega r^2 \quad \text{and} \quad D(r)=r, \tag{2.21}$$

where only the essential parameter ω appears ($m^2=0$, for this class).

Class III: $m^2 \equiv -\mu^2 < 0, \omega \neq 0$. Similarly for this class, the integration of the conditions for homogeneity (2.12) and (2.13) leads to

$$D(x) = c_0 \sin(\mu x) + c_1 \cos(\mu x) \quad \text{and} \quad H(x) = \frac{2\omega}{\mu}[c_0 \cos \mu x) - c_1 \sin(\mu x)] + c_2. \tag{2.22}$$

Here again the nonessential constants c_0, c_1, and c_2 can be eliminated by coordinate transformations so that the line element for this class reduces to (2.18) with

$$H(r) = \frac{2\omega}{\mu^2}[\cos(\mu r) - 1] \quad \text{and} \quad D(r) = \frac{1}{\mu} \sin(\mu r). \tag{2.23}$$

Class IV: $m^2 \neq 0, \omega = 0$. We refer to the manifolds of this class as degenerated Gödel-type manifolds, since the cross term in the line element, related to the rotation ω in the Gödel model, vanishes. By a trivial coordinate transformation one can make $H = 0$ with $D(r)$ given, respectively, by (2.19) or (2.23) depending on whether $m^2 > 0$ or $m^2 \equiv -\mu^2 < 0$.

In three out of the above four classes of homogeneous Gödel-type manifolds there are closed timelike curves. Indeed, the Gödel's analysis for 4D manifolds can be extended to the 5D manifolds in a straightforward way to prove this. To this end, we write the line element (2.18) as

$$ds^2 = dt^2 + 2H(r)dtd\phi - dr^2 - G(r)d\phi^2 - dz^2 - du^2, \tag{2.24}$$

where $G(r) = D^2 - H^2$ and (r, θ, ϕ) are cylindrical coordinates.

The existence of closed timelike curves of the Gödel-type depends on the behavior of $G(r)$. Indeed, if $G(r) < 0$ for a certain range of r ($r_1 < r < r_2$, say), Gödel's circles[53] $u, t, z, r = const$ are closed timelike curves.

It is, therefore, easy to show that for the above Class II there is a critical radius r_c, defined by $|\omega| r_c = 1$, such that for $r_c < r < \infty$ the circles $u, t, z = const$ and $r = const > r_c$ are closed timelike curves. So there is breakdown of causality for this class.

For the Class III noncausal Gödel circles occur depending on the root r_n of the equation

$$\sin^2\left[\frac{\mu r_n}{2}\right] = \left[1 + \frac{4\omega^2}{\mu^2}\right]^{-1} \leqslant 1. \tag{2.25}$$

Thus for this class there are alternatively causal and noncausal regions (circular rings) in the surfaces $u, t, z = const$.

For the Class I if $m^2 < 4\omega^2$ the noncausal Gödel circles occur for $r > r_1$, where

$$\sinh^2\left[\frac{m r_1}{2}\right] = \left[1 + \frac{4\omega^2}{m^2}\right]^{-1} \geqslant 1. \tag{2.26}$$

However, for $m^2 \geqslant 4\omega^2$ then $G(r) > 0$ and there is no breakdown of causally of Gödel-type. As a matter of fact, following Calvão's reasoning[53] one can show that: (a) although causal, the $m^2 = 4\omega^2$ manifolds are not stably causal,[50] that is, an arbitrary small perturbation of this metric gives rise to causality violation; (b) the family $m^2 > 4\omega^2$ is stably causal, which means that the causal properties of this family are invariant under arbitrary small perturbation of its metrics. We remark that Calvão's approach holds only if the 5D homogeneous Riemannian Gödel-type manifolds are endowed with the topology of $\mathscr{R}^5$.

Finally, for the degenerated Gödel-type geometries (Class IV), as $G(r) = D^2 > 0$ there is no closed timelike curve of Gödel type.

III. ISOMETRIES

In this section we shall be concerned with the isometries of the homogeneous 5D Riemannian Gödel-type manifolds, whose line element (2.18) can be brought into the Lorentzian form (2.8) but now with the one-forms θ^A given by

$$\theta^0 = dt + H(r)d\phi, \quad \theta^1 = dr, \quad \theta^2 = D(r)d\phi,$$
$$\theta^3 = dz, \quad \theta^4 = du, \tag{3.1}$$

where the functions $H(r)$ and $D(r)$ are given by (2.19), (2.21), or (2.23) depending on the sign of m^2.

Denoting the coordinate components of a generic Killing vector field K by $K^\mu \equiv (Q,R,S,Z,U)$, where Q,R,S,Z, and U are functions of all coordinates t,r,ϕ,z,u, then the 15 Killing equations

$$K_{(A;B)} \equiv K_{A;B} + K_{B;A} = 0 \tag{3.2}$$

can be written in the Lorentz frame (2.8)–(3.1) as

$$T_t = 0, \quad T_z - Z_t = 0, \tag{3.3}$$

$$R_r = 0, \quad Z_r + R_z = 0, \tag{3.4}$$

$$Z_z = 0, \tag{3.5}$$

$$D(T_r - R_t) - H_r P = 0, \tag{3.6}$$

$$DP_z + Z_\phi - HZ_t = 0, \tag{3.7}$$

$$T_\phi + H_r R - DP_t = 0, \tag{3.8}$$

$$R_\phi - HR_t - D_r P + DP_r = 0, \tag{3.9}$$

$$P_\phi - HP_t + D_r R = 0, \tag{3.10}$$

$$T_u - U_t = 0, \tag{3.11}$$

$$R_u + U_r = 0, \tag{3.12}$$

$$DP_u - HU_t + U_\phi = 0, \tag{3.13}$$

$$U_z + Z_u = 0, \tag{3.14}$$

$$U_u = 0, \tag{3.15}$$

where the subscripts denote partial derivatives, and where we have made

$$T \equiv HS + Q \quad \text{and} \quad P \equiv DS \tag{3.16}$$

to make easier the comparison and the use of the results obtained in Ref. 38. To this end we note that in the present form Eqs. (3.3)–(3.10) are formally identical to the Killing Eqs. (4)–(11) of Ref. 38. However, in the above Eqs. (3.3)–(3.10) the functions T,R,P,Z depend additionally on the fifth coordinate u. Taking into account this similitude, the integration of the Killing Eqs. (3.3)–(3.15) can be obtained in two steps as follows. First, by analogy with (4)–(11) of Ref. 38 one integrates (3.3)–(3.10), but at this step instead of the integration constants one has integration functions of the fifth coordinate u. Second, one uses the remaining Eqs. (3.11)–(3.15) to achieve explicit forms for these integration functions and to obtain the last component U of K.

In what follows we shall use the above two-steps procedure to integrate the Killing Eqs. (3.3)–(3.15) for the Class I of Sec. II in detail. However, for the sake of brevity, for the remaining classes we shall only present the Killing vector fields and the corresponding Lie algebras without going into the details of calculation, which can be similarly obtained, or simply verified by using

the computer algebra program KILLNF, written in CLASSI by Åman,[41] with further extensions by MacCallum.[42] As a matter of fact, even the Killing Eqs. (3.3)–(3.15) have been achieved by using KILLNF.

Class I: $m^2>0,\omega\neq 0$. In the integration of the Killing equation for this general class one is led to distinguish two different classes of solutions depending on whether $m^2\neq 4\omega^2$ or $m^2=4\omega^2$. We shall refer to these subclasses as Classes Ia and Ib, respectively.

Class Ia: $m^2>0,m^2\neq 4\omega^2$. According to the above two-steps procedure, from (3.16) and according to Eqs. (36)–(39) of Ref. 38 one finds

$$Q=\alpha+2\omega(\gamma D_r+\delta D\ \sin\ \phi+\epsilon D\ \cos\ \phi)+\frac{H}{D}\,(\gamma\ m^2 D+\delta\ D_r\ \sin\ \phi+\epsilon D_r\ \cos\ \phi), \tag{3.17}$$

$$R=\delta\ \cos\ \phi-\epsilon\ \sin\ \phi, \tag{3.18}$$

$$S=-\gamma\ m^2-\frac{D_r}{D}(\delta\ \sin\ \phi+\epsilon\ \cos\ \phi), \tag{3.19}$$

$$Z=\beta, \tag{3.20}$$

$$U=U(t,r,\phi,z,u), \tag{3.21}$$

where $\alpha,\beta,\gamma,\delta,$ and ϵ are integration functions of the fifth coordinate u.

From (3.14) and (3.15) one finds

$$\beta=\kappa_7 u+\kappa_2, \tag{3.22}$$

$$U=-\kappa_7 z+\zeta(t,r,\phi), \tag{3.23}$$

where κ_2 and κ_7 are arbitrary constants and $\zeta(t,r,\phi)$ is an arbitrary function.

Equation (3.12) can now be used to obtain the integration functions δ and ϵ and to simplify the expression of U. In doing so one finds

$$\delta=\delta_0 u+\kappa_4,\quad \epsilon=\epsilon_0 u+\kappa_5, \tag{3.24}$$

$$U=-\kappa_7 z-\delta_0 r\ \cos\ \phi+\epsilon_0 r\ \sin\ \phi+\nu(t,\phi), \tag{3.25}$$

where $\delta_0,\epsilon_0,\kappa_4,\kappa_5$ are constants and $\nu(t,\phi)$ is an arbitrary function.

Finally, Eqs. (3.11) and (3.12) give the remaining integration functions α, γ and reduce the functions δ, ϵ, and U to

$$\gamma=const\equiv m^{-1}\kappa_3,\quad \alpha=const\equiv\kappa_1, \tag{3.26}$$

$$\delta=\kappa_4,\quad \epsilon=\kappa_5,\quad U=-\kappa_7 z+\kappa_6, \tag{3.27}$$

where κ_6 is a new arbitrary constant.

Inserting (3.22), (3.26), and (3.27) into (3.17)–(3.21) and using (2.19) one obtains

$$Q=\kappa_1+\frac{2\omega}{m}\kappa_3-\frac{H}{D}(\kappa_4\ \sin\ \phi+\kappa_5\ \cos\ \phi), \tag{3.28}$$

$$R=\kappa_4\ \cos\ \phi-\kappa_5\ \sin\ \phi, \tag{3.29}$$

$$S=-\kappa_3 m-\frac{D_r}{D}(\kappa_4\ \sin\ \phi+\kappa_5\ \cos\ \phi), \tag{3.30}$$

$$Z=\kappa_7 u+\kappa_2, \tag{3.31}$$

$$U=-\kappa_7 z+\kappa_6. \tag{3.32}$$

Thus in the coordinate basis in which (2.18) is given, a set of linearly independent Killing vector fields K_N (N is an enumerating index) can be written as

$$K_1=\partial_t, \quad K_2=\partial_z, \quad K_3=\frac{2\omega}{m}\partial_t-m\partial_\phi, \tag{3.33}$$

$$K_4=-\frac{H}{D}\sin\phi\partial_t+\cos\phi\partial_r-\frac{D_r}{D}\sin\phi\partial_\phi, \tag{3.34}$$

$$K_5=-\frac{H}{D}\cos\phi\partial_t-\sin\phi\partial_r-\frac{D_r}{D}\cos\phi\partial_\phi, \tag{3.35}$$

$$K_6=\partial_u, \quad K_7=u\partial_z-z\partial_u. \tag{3.36}$$

The Lie algebra has the following nonvanishing commutators:

$$[K_2,K_7]=-K_6, \quad [K_3,K_4]=-m\,K_5, \tag{3.37}$$

$$[K_3,K_5]=m\,K_4, \quad [K_4,K_5]=m\,K_3, \tag{3.38}$$

$$[K_6,K_7]=K_2. \tag{3.39}$$

So, the corresponding algebra is $\mathscr{L}_{Ia}=t^2\subset\!\!\!+\,\mathrm{so}(2)\oplus\tau\oplus\mathrm{so}(2,1)$. The semidirect sum of subalgebras $t^2\subset\!\!\!+\,\mathrm{so}(2)$ corresponds to the translations K_2 and K_6, and the rotation K_7. The symbol τ is associated to the time translation K_1. Finally, the infinitesimal generators of subalgebra so(2,1) are K_3, K_4, and K_5.

Class Ib: $m^2=4\omega^2, \omega\neq 0$. For this class, using the results of Ref. 38 and (3.16) one finds

$$Q=\alpha+\gamma-\frac{H}{D}(\delta\sin\phi+\epsilon\cos\phi)-\frac{H}{D}[\eta\sin(mt+\phi)+\xi\cos(mt+\phi)], \tag{3.40}$$

$$R=\delta\cos\phi-\epsilon\sin\phi+\xi\sin(mt+\phi)-\eta\cos(mt+\phi), \tag{3.41}$$

$$S=-\gamma m-\frac{D_r}{D}(\delta\sin\phi+\epsilon\cos\phi)+\frac{1}{D}[\eta\sin(mt+\phi)+\xi\cos(mt+\phi)], \tag{3.42}$$

$$Z=Z(u), \tag{3.43}$$

$$U=U(t,r,\phi,z,u), \tag{3.44}$$

where $\alpha,\gamma,\delta,\epsilon,\xi$, and η are (new) integration functions of the fifth coordinate u.

Again, from (3.14) and (3.15) one finds

$$Z=k_8u+k_2, \tag{3.45}$$

$$U=-k_8z+\chi(t,r,\phi), \tag{3.46}$$

where k_2 and k_8 are arbitrary constants and $\chi(t,r,\phi)$ is an arbitrary function.

Similarly to the Class Ia, Eq. (3.12) can be used to obtain a first expression for the integration functions ξ, η, δ, ϵ, and to reduce U according to

$$\xi=\xi_0u+k_6, \quad \eta=\eta_0u+k_7, \tag{3.47}$$

$$\delta=\delta_0u+k_4, \quad \epsilon=\epsilon_0u+k_5, \tag{3.48}$$

$$U=-k_8z+r[-\delta_0\cos\phi+\epsilon_0\sin\phi-\xi_0\sin(mt+\phi)+\eta_0\cos(mt+\phi)]+\sigma(t,\phi), \tag{3.49}$$

where $\xi_0,\eta_0,\delta_0,\epsilon_0, k_4,\ldots,k_7$ are constants, and $\sigma(t,\phi)$ is an arbitrary function.

Equations (3.11) and (3.12) give the remaining integration functions α, γ and reduce the functions ξ,η,δ,ϵ, and U to

$$\xi=k_6,\quad \eta=k_7,\quad \gamma=const\equiv k_3,\quad \alpha=const\equiv k_1, \tag{3.50}$$

$$\delta=k_4,\quad \epsilon=k_5,\quad U=-k_8z+k_9, \tag{3.51}$$

where k_9 is a new arbitrary constant.

Inserting (3.45), (3.50), and (3.51) into (3.40)–(3.44) one obtains

$$Q=k_1+k_3-\frac{H}{D}(k_4\sin\phi+k_5\cos\phi)-\frac{H}{D}[k_7\sin(mt+\phi)+k_6\cos(mt+\phi)], \tag{3.52}$$

$$R=k_4\cos\phi-k_5\sin\phi+k_6\sin(mt+\phi)-k_7\cos(mt+\phi), \tag{3.53}$$

$$S=-k_3m-\frac{D_r}{D}(k_4\sin\phi+k_5\cos\phi)+\frac{1}{D}[k_7\sin(mt+\phi)+k_6\cos(mt+\phi)], \tag{3.54}$$

$$Z=k_8u+k_2, \tag{3.55}$$

$$U=-k_8z+k_9, \tag{3.56}$$

which give rise to the Killing vector fields

$$K_1=\partial_t,\quad K_2=\partial_z,\quad K_3=\partial_t-m\partial_\phi, \tag{3.57}$$

$$K_4=-\frac{H}{D}\sin\phi\partial_t+\cos\phi\partial_r-\frac{D_r}{D}\sin\phi\partial_\phi, \tag{3.58}$$

$$K_5=-\frac{H}{D}\cos\phi\partial_t-\sin\phi\partial_r-\frac{D_r}{D}\cos\phi\partial_\phi, \tag{3.59}$$

$$K_6=-\frac{H}{D}\cos(mt+\phi)\partial_t+\sin(mt+\phi)\partial_r+\frac{1}{D}\cos(mt+\phi)\partial_\phi, \tag{3.60}$$

$$K_7=-\frac{H}{D}\sin(mt+\phi)\partial_t-\cos(mt+\phi)\partial_r+\frac{1}{D}\sin(mt+\phi)\partial_\phi, \tag{3.61}$$

$$K_8=u\partial_z-z\partial_u,\quad K_9=\partial_u, \tag{3.62}$$

whose Lie algebra is given by

$$[K_1,K_6]=-mK_7,\quad [K_1,K_7]=mK_6,\quad [K_2,K_8]=-K_9, \tag{3.63}$$

$$[K_3,K_4]=-mK_5,\quad [K_3,K_5]=mK_4,\quad [K_4,K_5]=mK_3, \tag{3.64}$$

$$[K_6,K_7]=mK_1,\quad [K_8,K_9]=-K_2. \tag{3.65}$$

So, the corresponding algebra for this case is $\mathscr{L}_{Ib}=t^2\subset\!\!\!+\,\mathrm{so}(2)\oplus\mathrm{so}(2,1)\oplus\mathrm{so}(2,1)$. The semidirect sum $t^2\subset\!\!\!+\,\mathrm{so}(2)$ comprises the translations K_2 and K_9 and the rotation K_8, while the two subalgebras so(2,1) are generated by the Killing vector fields K_1,K_6,K_7 and K_3,K_4,K_5.

Class II: $m^2=0,\omega\neq0$. Similarly for this class, using (2.21) and the results of Ref. 37 the above two-steps procedure gives rise to the following Killing vector fields:

$$K_1=\partial_t, \quad K_2=\partial_z, \quad K_3=\partial_\phi, \tag{3.66}$$

$$K_4=-\omega r \sin\phi\partial_t-\cos\phi\partial_r+\frac{1}{r}\sin\phi\partial_\phi, \tag{3.67}$$

$$K_5=-\omega r \cos\phi\partial_t+\sin\phi\partial_r+\frac{1}{r}\cos\phi\partial_\phi, \tag{3.68}$$

$$K_6=u\partial_z-z\partial_u, \quad K_7=\partial_u. \tag{3.69}$$

The Lie algebra has the following nonvanishing commutators:

$$[K_2,K_6]=-K_7, \quad [K_3,K_4]=K_5, \tag{3.70}$$

$$[K_3,K_5]=-K_4, \quad [K_4,K_5]=2\omega K_1, \tag{3.71}$$

$$[K_6,K_7]=-K_2. \tag{3.72}$$

Therefore the corresponding algebra for this case is $\mathscr{L}_{II}=t^2\subset\!\!\!+\,\mathrm{so}(2)\oplus\mathscr{L}_4$. The semidirect sum of subalgebras corresponds here to the translations K_2 and K_7, and the rotation K_6. The subalgebra $\mathscr{L}_4$ is generated by K_1,K_3,K_4, and K_5. This algebra $\mathscr{L}_4$ is soluble and does not contain Abelian 3D subalgebras; it is classified as type *III* with $q=0$ by Petrov.[54]

Class III: $m^2\equiv-\mu^2<0,\omega\neq0$. Again for this class using (2.23) and Ref. 38, the above outlined two-step procedure furnishes

$$K_1=\partial_t, \quad K_2=\partial_z, \quad K_3=\frac{2\omega}{\mu}\partial_t+\mu\partial_\phi, \tag{3.73}$$

$$K_4=-\frac{H}{D}\sin\phi\partial_t+\cos\phi\partial_r-\frac{D_r}{D}\sin\phi\partial_\phi, \tag{3.74}$$

$$K_5=-\frac{H}{D}\cos\phi\partial_t-\sin\phi\partial_r-\frac{D_r}{D}\cos\phi\partial_\phi, \tag{3.75}$$

$$K_6=u\partial_z-z\partial_u, \quad K_7=\partial_u. \tag{3.76}$$

The Lie algebra has the following nonvanishing commutators:

$$[K_2,K_6]=-K_7, \quad [K_3,K_4]=\mu K_5, \tag{3.77}$$

$$[K_3,K_5]=-\mu K_4, \quad [K_4,K_5]=\mu K_3, \tag{3.78}$$

$$[K_6,K_7]=-K_2. \tag{3.79}$$

Thus the corresponding algebra for this case is $\mathscr{L}_{III}=t^2\subset\!\!\!+\,\mathrm{so}(2)\oplus\tau\oplus\mathrm{so}(3)$. The semidirect sum of subalgebras corresponds again to the translations K_2 and K_7, and the rotation K_6. Here τ is associated to the Killing vector field K_1, whereas to the subalgebra so(3) correspond K_3, K_4, and K_5.

Class IV: $m^2\neq0,\omega=0$. This class corresponds to the so-called degenerated Gödel-type manifolds. By a similar procedure one obtains for this class the following Killing vector fields:

$$K_1=\partial_t, \quad K_2=\partial_z, \quad K_3=z\,\partial_t+t\partial_z, \tag{3.80}$$

$$K_4=\cos\phi\partial_r-\frac{D_r}{D}\sin\phi\partial_\phi, \tag{3.81}$$

$$K_5 = -\sin\,\phi\partial_r - \frac{D_r}{D}\cos\,\phi\partial_\phi, \quad K_6 = \partial_\phi, \tag{3.82}$$

$$K_7 = u\,\partial_z - z\,\partial_u, \quad K_8 = u\,\partial_t + t\partial_u, \quad K_9 = \partial_u, \tag{3.83}$$

where $D(r)=(1/m)\sinh mr$ for $m^2>0$, or $D(r)=(1/\mu)\sin \mu r$ for $m^2\equiv -\mu^2<0$. The Lie algebra has the following nonvanishing commutators:

$$[K_1,K_3]=K_2, \quad [K_1,K_8]=K_9, \quad [K_2,K_3]=K_1, \tag{3.84}$$

$$[K_2,K_7]=-K_9, \quad [K_3,K_7]=-K_8, \quad [K_3,K_8]=-K_7, \tag{3.85}$$

$$[K_4,K_5]=-m^2K_6, \quad [K_4,K_6]=-K_5, \quad [K_5,K_6]=K_4, \tag{3.86}$$

$$[K_7,K_8]=-K_3, \quad [K_7,K_9]=-K_2, \quad [K_8,K_9]=-K_1, \tag{3.87}$$

where one should substitute $-m^2$ by μ^2 if $m^2<0$. So, when $m^2>0$ the corresponding algebra is $\mathscr{L}_{IV}=t^3 \subsetplus \mathrm{so}(2,1)\oplus\mathrm{so}(2,1)$, where to t^3 correspond K_1, K_2, and K_9. The infinitesimal generators of so(2,1) in the semidirect sum are K_3, K_7, and K_8, while to the other so(2,1) correspond K_4, K_5, and K_6. When $m^2<0$ the algebra associated to K_4, K_5, and K_6 is so(3), instead.

It is worth noting that none of the above Lie algebras is semisimple, but some of their subalgebras are. Besides, most of the simple subalgebras are noncompact. The 3D subalgebras so(3) present in the cases $\mathscr{L}_{III}$ and $\mathscr{L}_{IV}$ with $m^2<0$ are compact, though.

We have therefore succeeded in finding the maximal group of motions of all classes of 5D homogeneous Riemannian Gödel-type manifolds we have studied in the previous section.

Equations (3.33)–(3.36), (3.57)–(3.62), (3.66)–(3.69), (3.73)–(3.76), and (3.80)–(3.83) make explicit that the 5D locally homogeneous Riemannian Gödel-type manifolds admit maximal group of isometry G_r with: (a) $r=7$ if $m^2\neq 4\omega^2$ and $\omega\neq 0$; or (b) $r=9$ if $m^2=4\omega^2$ with $\omega\neq 0$, or when $m^2\neq 0$ and $\omega=0$, in agreement with Theorem 2 of the previous section. Actually the integration of the Killing equations constitutes a different way of deriving that theorem. Furthermore, these equations also show that the isotropy subgroup H of G_r is such that $\dim(H)=2$ for $m^2\neq 4\omega^2$ and $\omega\neq 0$, while for $m^2=4\omega^2$ with $\omega\neq 0$ as well as for the degenerated Gödel-type ($m^2\neq 0$ and $\omega=0$) we have $\dim(H)=4$, also in agreement with the previous section.

To conclude, we should like to emphasize again that the results of this work hold for any five-dimensional locally homogeneous Riemannian Gödel-type manifold, regardless of the underlying 5D Kaluza–Klein-type theory of gravitation one may be concerned with. This gives a measure of the generality of our results in the context of these theories, in which the 5D Riemannian manifolds are the underlying arena for the formulation of the physical laws.

(Received 4 August 1997; accepted for publication 29 December 1997)

In the modern version of 5-D general relativity where the fifth dimension induces matter in 4-D space–time, a choice of coordinates and its restrictions on the geometry (a gauge) dictates the physics of the gravitational, electromagnetic, and scalar fields (spin 2, 1, 0). We extend previous work by concentrating on two related problems. First, we use the lapse and shift formalism to carry out a $(4+1)$ split of Kaluza–Klein theory valid in any gauge. Second, we use a conformal gauge to simplify the 5-D field equations, find a plane-wave solution, and identify the energy and momentum of the particle associated with it. © *1998 American Institute of Physics.* [S0022-2488(98)01504-7]

I. INTRODUCTION

It has been known since 1921 that in vacuum the Kaluza–Klein equations contain the Einstein equations of general relativity and the Maxwell equations of classical electromagnetism without sources.[1,2] It has been known since 1992 that the 15 Kaluza–Klein equations for apparently empty space can be rewritten as 10 Einstein equations *with* sources, 4 conservation equations, and 1 scalar-wave equation (Ref. 3; for a review of Kaluza–Klein, see Ref. 4). The latter result was proved algebraically using a special choice of 4 of the 5 available coordinate degrees of freedom to set 4 of the 15 metric coefficients to zero with consequent simplification of the associated tensors (in short, a gauge condition). That particular gauge has proven useful in showing, among other things, that exact cosmological solutions of the 5-D field equations have induced properties of matter which agree with observation.[5] It also applies to exact one-body solutions which are in agreement with the classical tests of relativity in the solar system.[6] However, while a practical gauge for elucidating the gravitational and scalar (matter) fields, it curtails investigation of the electromagnetic field. Exact solutions for the latter are known,[7] but hitherto there has not been any decomposition done of the general Kaluza–Klein field equations into parts relevant to the three classical fields of physics. In what follows we aim to rectify this situation. We will extend previous work[3,8] and give a $(4+1)$ split of the 5-D field equations that defers gauge conditions as far as possible, leaving the choice of gauge to be applied later and as required by physics. We will also, in what follows, treat a related problem, namely how to apply the induced-matter prescription to particles. We will extend previous work[9,10] and use a conformal gauge to put the field equations into a form where they admit a wave solution whose parameters relate to the energy and momentum of the associated particle.

Before proceeding, we wish to make some comments on the usefulness (or otherwise) of certain gauges in 5-D Kaluza–Klein theory. This theory, which exists in several versions, has as its basic geometrical object a 5×5 symmetric tensor g_{ab} with 15 independent components. There are, in general, five conditions that can be applied to the metric tensor and/or geometrical objects derived from it, corresponding to the freedom to choose five coordinates x^a. The theory is commonly regarded as a unified description of the gravitational, electromagnetic, and scalar fields. That is, it is a classical theory of a spin-2 graviton, a spin-1 photon and a spin-0 boson. However, whether or not these three fields can be disentangled from each other and identified with their 4-D

counterparts (Einstein, Maxwell, and Higgs fields) depends crucially on a choice of 5-D gauge. Some of the latter are useful and some (the vast majority) are not. For example, one could use up the five available gauge choices by setting $g_{4\alpha}=0$, $g_{44}=1$ ($a=0-4$, $\alpha=0-3$). This is mathematically appealing, but physically confusing because the gravitational, electromagnetic, and scalar interactions are combined in the 4×4 sector of the theory. A considerably more useful gauge is the ''electromagnetic'' one of the original Kaluza–Klein theory.[1,2] This consists of $g_{\alpha\beta}=g_{\alpha\beta}(x^{\gamma})$, $g_{4\alpha}=A_{\alpha}(x^{\beta})$, and $g_{44}=1$, and enables us to identify the potentials of classical electromagnetism. However, the restriction $\partial g_{ab}/\partial x^4=0$ (the ''cylinder condition'') makes it problematic to describe anything other than radiationlike matter. Hence the ''matter'' gauge of modern Kaluza–Klein theory.[3] This consists of $g_{\alpha\beta}=g_{\alpha\beta}(x^a)$, $g_{4\alpha}=0$, and $g_{44}=g_{44}(x^a)$, and enables us to describe the pressure, density, and equation of state of macroscopic matter. But even this latter gauge is lacking in that it does not enable us to see how electromagnetism interacts with gravity (including its source matter) and the scalar field. It also does not help much in enabling us to identify the four-momenta and mass of microscopic matter.

A natural question, and one we wish to answer before proceeding, concerns the status of the 5-D analog of the 4-D harmonic gauge. The latter is extensively used in general relativity, notably to describe gravitational waves in the weak-field limit of Einstein's theory.[11] The corresponding 5-D harmonic gauge, in terms of the Christoffel symbol and the determinant of the metric, is given by

$$g^{ab}\Gamma^{c}_{ab}=-\frac{1}{g^{1/2}}\frac{\partial}{\partial x^{d}}\,(g^{1/2}g^{cd})=0. \tag{1.1}$$

These are five conditions, but since Γ^{c}_{ab} is not a tensor the conditions (1.1) are not 5-D covariant. This is the classical analog of the situation in quantum field theory involving noncovariant gauges.[12] In physical terms, fields which are split on one hypersurface of the metric will in general be mixed on another hypersurface, implying a problem when comparing 5-D and 4-D physics. By analog with the latter, we assume that the metric is close to flat:

$$g_{ab}=\eta_{ab}+h_{ab}, \quad \eta_{44}=\pm1, \quad |h_{ab}|\ll1. \tag{1.2}$$

Here we should not presume the sign of η_{44}, since exact solutions of the 5-D field equations with good 4-D physical properties exist for both signs.[4] The gauge conditions (1.1) with (1.2) now read

$$\frac{\partial}{\partial x^{a}}\,h^{a}_{b}=\frac{1}{2}\frac{\partial}{\partial x^{b}}\,h^{a}_{a}. \tag{1.3}$$

We note in passing that these conditions are very restrictive, being first-order relations that must be applied to second-order field equations. The latter in the approximation (1.2) become

$$\Box h_{ab}=0, \quad \Box\equiv\eta^{ab}\frac{\partial^2}{\partial x^{a}\partial x^{b}}. \tag{1.4}$$

This 5-D box operator can be written in terms of its 4-D counterpart ${}^{(4)}\Box\equiv\eta^{\alpha\beta}\partial^2/\partial x^{\alpha}\partial x^{\beta}$, so (1.4) then read

$${}^{(4)}\Box h_{ab}=-2\,\eta^{\alpha4}\frac{\partial^2}{\partial x^{\alpha}\partial x^{4}}\,h_{ab}-\eta^{44}\frac{\partial^2}{\partial x^{4}\partial x^{4}}\,h_{ab}. \tag{1.5}$$

That is, free waves in five dimensions become waves with sources in four dimensions. Denoting the right-hand side of (1.5) by S_{ab}, solutions can be written at least in principle in terms of retarded Green's functions:[13]

$$h_{ab}(r,t;x^4)=-\frac{1}{4\pi}\int d^3\bar{r}\,\frac{S_{ab}(\bar{r},t-|r-\bar{r}|;x^4)}{|r-\bar{r}|}, \tag{1.6}$$

where

$$\frac{1}{|r-\bar{r}|}=\frac{1}{r}+\frac{x^{\alpha}\bar{x^{\alpha}}}{r^3}+\frac{1}{2}\frac{x^{\alpha}x^{\beta}}{r^5}(3\bar{x^{\alpha}}\bar{x^{\beta}}-\bar{r^2}\delta^{\alpha\beta})+\cdots .$$

In practice, the signature may present problems that would require an imaginary coordinate transformation (Wick rotation) depending on the sign of the last part of the metric. Our conclusion is that the 5-D harmonic gauge confirms the general property of modern Kaluza–Klein theory, namely that source-free equations in five dimensions become ones with sources in four dimensions, but that there are several problems with it.

We therefore proceed in the next two sections to elucidate what appear to us to be two major issues in Kaluza–Klein theory. In Sec. II we will extend previous work,[3] and give a gauge-deferred decomposition of 5-D to 4-D relations, using the lapse and shift formalisms.[14–16] In Sec. III we will look again at the issue of how field and particle properties relate,[9] and give an identification of energy and momentum using a conformal form of the metric.[10] Section IV is a conclusion.

II. A (4+1) SPLIT USING LAPSE AND SHIFT

The purely geometric field equations of Kaluza–Klein theory in terms of the Ricci tensor are

$$R_{ab}=0 \quad (a,b=0-3,4). \tag{2.1}$$

The field equations of general relativity with sources are the Einstein equations

$$R_{\alpha\beta}-\frac{R}{2}g_{\alpha\beta}-\Lambda g_{\alpha\beta}=T_{\alpha\beta} \quad (\alpha,\beta=0-3). \tag{2.2}$$

Here $R_{\alpha\beta}$ is the 4-D Ricci tensor, R is the 4-D Ricci scalar, Λ is the cosmological constant, and $g_{\alpha\beta}$ is the 4-D part of the 5-D metric tensor whose interval is defined by $dS^2=g_{ab}\,dx^a\,dx^b$. The coordinates x^a we leave unspecified for now, and we absorb physical constants by an appropriate choice of units. As mentioned above, it is known that (2.2) are a ten-component subset of the 15 equations (2.1). However, the algebraic method employed to prove this used the gauge condition $g_{\alpha 4}=0$,[3] and if we wish to investigate (2.1) without the initial imposition of such a gauge it becomes apparent that a simple decomposition of (2.1) is algebraically forbidding. Therefore we will apply the lapse and shift formalism, which is well known in the (3+1) split of Einstein's theory. For Kaluza–Klein theory, we proceed to write out the 10, 4, 1 components of (2.1) in a general way.

The 5-D space–time is chosen to be foliated by 4-D hypersurfaces Σ_{ℓ} which are defined to be surfaces $x^4\equiv\ell=$constants. The normal vectors to these surfaces Σ_{ℓ} satisfy

$$n^a n_a=\varepsilon=\pm 1, \tag{2.3}$$

so that n^a may be either spacelike ($\varepsilon=-1$) or timelike ($\varepsilon=+1$). In addition to a normal vector on Σ_{ℓ} we define a 4-D intrinsic metric tensor

$$ds^2=g_{\alpha\beta}(x^{\Sigma},\ell)\,dx^{\alpha}\,dx^{\beta}, \tag{2.4}$$

which is related to the 5-D metric tensor by using a (4+1) lapse and shift decomposition imported from the (3+1) split of 4-D space–time. Thus the 5-D metric tensor may be written as

$$dS^2=g_{\alpha\beta}(dx^{\alpha}+N^{\alpha}\,d\ell)(dx^{\beta}+N^{\beta}\,d\ell)+\varepsilon\Phi^2\,d\ell^2, \tag{2.5}$$

where $\Phi=\Phi(x^{\Sigma},\ell)$ is the lapse function, and $N^{\alpha}=N^{\alpha}(x^{\Sigma},\ell)$ is the 4-D shift vector (N^{α} transforms as a four-vector on Σ_{ℓ}). In matrix form the 5-D metric and its inverse are given by

$$g_{ab}=\begin{pmatrix} g_{\alpha\beta} & N_{\alpha} \\ N_{\beta} & \varepsilon\Phi^2+N_{\gamma}N^{\gamma}\end{pmatrix}, \quad g^{ab}=\begin{pmatrix} g^{\alpha\beta}+\dfrac{\varepsilon N^{\alpha}N^{\beta}}{\Phi^2} & \dfrac{-\varepsilon N^{\alpha}}{\Phi^2} \\ \dfrac{-\varepsilon N^{\beta}}{\Phi^2} & \dfrac{\varepsilon}{\Phi^2}\end{pmatrix}, \tag{2.6}$$

where 4-D vectors can be raised and lowered by the intrinsic metric on Σ_ℓ ($N_\gamma = g_{\gamma\delta}N^\delta$). The normal vector n_a is given in component form by

$$n_a = (0,0,0,0,\varepsilon\Phi), \tag{2.7}$$

from which we obtain n^a by raising with g^{ab}:

$$n^a = g^{ab}n_a = \left(\frac{-N^\alpha}{\Phi}, \frac{1}{\Phi}\right). \tag{2.8}$$

We will also need a projection tensor, since our goal is to obtain field equations in the 4-D space–time of Σ_ℓ from the 5-D space. This is

$$h_{ab} = g_{ab} - \varepsilon n_a n_b, \tag{2.9}$$

which will project out 4-D tensor components of 5-D tensors. The projection tensor and its inverse are given in matrix form as

$$h_{ab} = \begin{pmatrix} g_{\alpha\beta} & N_\alpha \\ N_\beta & N_\gamma N^\gamma \end{pmatrix}, \quad h^{ab} = \begin{pmatrix} g^{\alpha\beta} & 0 \\ 0 & 0 \end{pmatrix}, \tag{2.10}$$

and in mixed form (useful for calculations) as

$$h_a{}^b = \begin{pmatrix} \delta_\alpha{}^\beta & 0 \\ N^\beta & 0 \end{pmatrix}, \quad h^b{}_a = \begin{pmatrix} \delta^\beta{}_\alpha & N^\beta \\ 0 & 0 \end{pmatrix}. \tag{2.11}$$

From (2.9) and (2.10) the projection tensor has the properties

$$h_{ab}n^a = 0, \quad h_{ab}h^b{}_c = h_{ac}, \quad h^a{}_a = 4, \tag{2.12}$$

and may be thought of as the metric on Σ_ℓ.

Since Σ_ℓ is embedded in a 5-D space, we need to describe the rate of change of Σ_ℓ as it moves in the normal direction. The geometrical object which provides this is the second fundamental form of the surface Σ_ℓ, usually called the extrinsic curvature tensor:

$$K_{ab} = -h_b{}^c\nabla_c n_a. \tag{2.13}$$

This is symmetric and orthogonal to n^a:

$$K_{ab}n^a = 0. \tag{2.14}$$

Using the matrix form of h_b^c and the usual definition of the 5-D covariant derivative operator ∇_c, it is easily shown that the matrix form of K_{ab} is

$$K_{ab} = \begin{pmatrix} K_{\alpha\beta} & N^\gamma K_{\alpha\gamma} \\ N^\gamma K_{\beta\gamma} & 0 \end{pmatrix}, \tag{2.15}$$

$$K_{\alpha\beta} = \frac{1}{2\Phi}(D_\alpha N_\beta + D_\beta N_\alpha - \partial_\ell g_{\alpha\beta}), \tag{2.16}$$

where D_α is the derivative operator defined on Σ_ℓ and $\partial_\ell \equiv \partial/\partial\ell$. The action of D_α on scalar and vector fields is defined by

$$D_\alpha\Phi = \partial_\alpha\Phi, \quad D_\alpha N_\beta = \partial_\alpha N_\beta - \Gamma^\gamma_{\alpha\beta}N_\gamma,$$

where $\Gamma^\gamma_{\alpha\beta}$ is the 4-D Christoffel symbol associated with the metric $h_{\alpha\beta} = g_{\alpha\beta}$.

We can now decompose the 15 5-D field equations $R_{ab}=0$ into $10+4+1$ 4-D equations. These are ten field equations for the 4-D Ricci tensor $R_{\alpha\beta}$, four Gauss–Codazzi equations for the curvature which have the form of conservation laws, and one relation for the scalar field which resembles a wave equation. Explicitly, they are

$$R_{\alpha\beta}=\frac{1}{\Phi}D_\alpha D_\beta\Phi+\frac{\varepsilon}{\Phi}(\mathcal{L}_N K_{\alpha\beta}-\partial_\perp K_{\alpha\beta})+\varepsilon(KK_{\alpha\beta}-2K_{\alpha\gamma}K^\gamma{}_\beta), \tag{2.17}$$

$$0=D_\alpha(K^\alpha{}_\beta-\delta^\alpha{}_\beta K), \tag{2.18}$$

$$\varepsilon\Box\Phi=\partial_\perp K-N^\alpha D_\alpha K-\Phi K^{\alpha\beta}K_{\alpha\beta}. \tag{2.19}$$

Here $\mathcal{L}_N K_{\alpha\beta}$ is the Lie derivative of $K_{\alpha\beta}$ wrt N^α, $K\equiv g^{\alpha\beta}K_{\alpha\beta}$, and $\Box\equiv g^{\alpha\beta}D_\alpha D_\beta$. From (2.17), we can obtain the 4-D Ricci scalar and the 4-D Einstein tensor. The latter defines the 4-D (induced) energy-momentum tensor, whose trace defines the equation of state of the matter. Explicitly, we have

$$R=\varepsilon(K^2-K^{\alpha\beta}K_{\alpha\beta}), \tag{2.20}$$

$$T_{\alpha\beta}\equiv G_{\alpha\beta}=\frac{1}{\Phi}D_\alpha D_\beta\Phi+\frac{\varepsilon}{\Phi}(\mathcal{L}_N K_{\alpha\beta}-\partial_\perp K_{\alpha\beta})$$
$$+\varepsilon(KK_{\alpha\beta}-2K_{\alpha\gamma}K^\gamma{}_\beta)-\frac{\varepsilon}{2}g_{\alpha\beta}(K^2-K^{\alpha\beta}K_{\alpha\beta}), \tag{2.21}$$

$$T=-R=-\varepsilon(K^2-K^{\alpha\beta}K_{\alpha\beta}). \tag{2.22}$$

These are 4-D physical objects derived from 5-D geometrical ones. To amplify the role of the Gauss–Codazzi equations (2.18), we can write them as explicit conservation relations:

$$D_\alpha\left(\frac{1}{\sqrt{-g}}\,\pi^{\alpha\beta}\right)=0,\quad \pi^{\alpha\beta}\equiv\sqrt{-g}(K^{\alpha\beta}-g^{\alpha\beta}K). \tag{2.23}$$

Here $\pi_{\alpha\beta}$ is the momentum canonically conjugate to the metric $g_{\alpha\beta}$. Apart from the dimension and the determinant of the hypersurface, (2.23) is the same as in the $3+1$ split of space–time.[16] We hope to report on a Hamiltonian treatment of $4+1$ space–time in the near future.

The expression for the energy-momentum tensor, the conservation equations, and the scalar equation are in general quite complicated, unless $K_{\alpha\beta}$ possesses some symmetries which condense the algebra.[17] Significant simplification occurs when the N^α are Killing vectors on $\Sigma_\perp$ or

$$D_\alpha N_\beta+D_\beta N_\alpha=0. \tag{2.24}$$

Then the extrinsic curvature (2.16) reduces to

$$K_{\alpha\beta}=-\frac{1}{2\Phi}\partial_\perp g_{\alpha\beta}. \tag{2.25}$$

The gauge choice $N^\alpha=0$ studied by Wesson and Ponce de Leon[3] is a trivial solution of Killing's equation on $\Sigma_\perp$, and hence Eqs. (2.17)–(2.19) with the extrinsic curvature (2.25) exactly reproduce their results. In particular $T_{\alpha\beta}$, the conservation equations, and the scalar equation are

$$T_{\alpha\beta}=\frac{1}{\Phi}D_\alpha D_\beta\Phi-\frac{\varepsilon}{2\phi^2}\left\{\frac{\dot\Phi}{\Phi}\dot g_{\alpha\beta}-\ddot g_{\alpha\beta}+g^{\lambda\mu}\dot g_{\alpha\lambda}\dot g_{\beta\mu}-\frac{1}{2}g^{\mu\nu}\dot g_{\mu\nu}\dot g_{\alpha\beta}\right.$$
$$\left.+\frac{1}{4}g_{\alpha\beta}[\dot g^{\mu\nu}\dot g_{\mu\nu}+(g^{\mu\nu}\dot g_{\mu\nu})^2]\right\}, \tag{2.26}$$

$$0 = D_\alpha \left[\frac{1}{\Phi} \left(g^{\alpha\gamma} \dot{g}_{\gamma\beta} - \delta^\alpha{}_\beta g^{\mu\nu} \dot{g}_{\mu\nu} \right) \right], \tag{2.27}$$

$$\varepsilon \Phi \Box \Phi = \frac{1}{2\Phi} \dot{\Phi} g^{\alpha\beta} \dot{g}_{\alpha\beta} - \frac{1}{2} \left(g^{\alpha\beta} \ddot{g}_{\alpha\beta} + \frac{1}{2} \dot{g}^{\alpha\beta} \dot{g}_{\alpha\beta} \right). \tag{2.28}$$

For the case $\dot{g}_{\alpha\beta} \equiv \partial g_{\alpha\beta} / \partial \ell = 0$, we see that the conservation relations (2.27) drop out, the last relation becomes a wave equation for a massless scalar field, and $T \equiv g^{\alpha\beta} T_{\alpha\beta}$ becomes zero (which implies a radiationlike equation of state if the induced matter is modeled as a perfect fluid). As mentioned previously, these results would hold equally well if the N_α satisfy Killing's equations and $\partial_\ell g_{\alpha\beta} = 0$. If $N_\alpha \neq 0$ and do not satisfy Killing's equation, and $\partial_\ell g_{\alpha\beta} \neq 0$, then the $T_{\alpha\beta}$ will in general be complicated and the solutions to $R_{ab} = 0$ will not describe 4-D matter with a radiationlike equation of state.

III. THE CONFORMAL GAUGE

The ansatz for the metric presented here is a generalization of conformally scaled metrics that have sometimes been used in Kaluza–Klein theory.[4] The 5-D metric is assumed to be independent of the fifth coordinate $x^4 = \ell$ ($\partial_\ell g_{ab} = 0$) and the off-diagonal metric elements are set to zero ($g_{a4} = 0$). The 5-D metric then has the form

$$ds^2 = g_{ab}\, dx^a\, dx^b = g_{\alpha\beta}(x^\gamma)\, dx^\alpha\, dx^\beta + \varepsilon \Phi^2(x^\gamma)\, d\ell^2. \tag{3.1}$$

The field equations induced from the 5-D vacuum equation $R_{ab} = 0$ are

$$R_{\alpha\beta} = \frac{1}{\Phi} D_\beta \Phi_\alpha, \tag{3.2}$$

$$\Box \Phi = 0. \tag{3.3}$$

The above field equations are independent of the sign of the extra dimension ε, which implies that so should be their solutions. This may explain the existence of the ''vacuum wave'' solutions of 5-D cosmology.[18]

In 4-D general relativity a conformal rescaling of the metric transforms each metric component equally. We wish to retain this character in 5-D theory as a hypersurface (ℓ = constant) limit. This suggests that the 5-D metric should be conformally scaled by two factors such that

$$\begin{aligned} g_{\alpha\beta}(x^\gamma) &\to e^{2a\Phi} g_{\alpha\beta}(x^\gamma), \\ g_{44} = \varepsilon \Phi^2(x^\gamma) &\to g_{44} = \varepsilon e^{2b\Phi}, \end{aligned} \tag{3.4}$$

where a and b are constants and $\Phi = \Phi(x^\gamma)$. The 5-D metric in the conformal gauge then has the form

$$dS^2 = e^{2a\Phi} g_{\alpha\beta}(x^\gamma)\, dx^\alpha\, dx^\beta + \varepsilon e^{2b\Phi}\, d\ell^2, \tag{3.5}$$

which on a hypersurface ℓ = constant is the 4-D conformal metric. The ten field equations and one scalar wave equation arising from $R_{ab} = 0$ are now

$$R_{\alpha\beta} = (b^2 - 2a^2 - 2ab) \Phi_\alpha \Phi_\beta + (2a + b) D_\beta \Phi_\alpha, \tag{3.6}$$

$$\Box \Phi = -(b + 2a) \Phi^\gamma \Phi_\gamma, \tag{3.7}$$

where as before $R_{\alpha\beta}$ is the Ricci tensor associated with $g_{\alpha\beta}$, $\Box \Phi \equiv g^{\alpha\beta} D_\alpha D_\beta \Phi$, and $\Phi_\alpha \equiv D_\alpha \Phi = \partial_\alpha \Phi$. The induced 4-D energy-momentum tensor defined by $T_{\alpha\beta} \equiv G_{\alpha\beta}$ is then

$$T_{\alpha\beta} = (b^2 - 2a^2 - 2ab) \Phi_\alpha \Phi_\beta + (2a + b) D_\beta \Phi_\alpha + 3a(b + a) \Phi^\gamma \Phi_\gamma g_{\alpha\beta}. \tag{3.8}$$

To simplify the above equations, it is convenient to make the parameter choice $2a+b=0$, which eliminates the covariant-derivative term $D_\beta \Phi_\alpha$ and reduces the metric, field equations, and energy-momentum tensor to

$$dS^2 = e^{2a\Phi} g_{\alpha\beta}(x^\gamma)\ dx^\alpha\ dx^\beta + \varepsilon e^{-4a\Phi}\ d\ell^2, \tag{3.9}$$

$$R_{\alpha\beta} = 6a^2 \Phi_\alpha \Phi_\beta, \tag{3.10}$$

$$\Box \Phi = 0, \tag{3.11}$$

$$T_{\alpha\beta} = 6a^2 (\Phi_\alpha \Phi_\beta - \tfrac{1}{2} g_{\alpha\beta} \Phi^\gamma \Phi_\gamma). \tag{3.12}$$

The equations (3.10) and (3.11) can be recognized as the field equations for a scalar field coupled to gravity with coupling $6a^2$. We note that the field equations do not constrain the constant a to be real. If we let $a=-i\alpha/\sqrt{6}$, the coupling changes sign ($6a^2=-\alpha^2$) and the metric becomes complex. Such solutions have been considered before, notably in Kaluza–Klein theory where quantities calculated from the metric turn out to be real,[18] and in Euclidean quantum gravity where they allow one to calculate the action.[19] We now proceed to show such a solution, which describes a plane wave of the type used in quantum theory to describe a moving particle.

If we consider a plane wave propagating in the z direction, the 4-D metric in terms of $u=t+z$ and $v=t-z$ can be expressed as

$$ds^2 = g_{\alpha\beta}\ dx^\alpha\ dx^\beta = du\,dv - e^{2\lambda}\ dx^2 - e^{2\mu}\ dy^2, \tag{3.13}$$

where λ and μ are functions of u only. The 5-D metric (with $a=-i\alpha/\sqrt{6}$) then has the form

$$dS^2 = e^{-2i\alpha\Phi/\sqrt{6}}(du\ dv - e^{2\lambda}\ dx^2 - e^{2\mu}\ dy^2) + \varepsilon e^{4i\alpha\Phi/\sqrt{6}}\ d\ell^2. \tag{3.14}$$

Here the scalar function is $\Phi=\Phi(u)$. A simple solution exists when $\mu=-\lambda=\alpha\Phi$, the constant α and the function Φ still being arbitrary. It is

$$dS^2 = e^{-2i\alpha/\sqrt{6}}(du\,dv - e^{2\alpha\Phi} dx^2 - e^{-2\alpha\Phi} dy^2) + \varepsilon e^{4i\alpha\Phi/\sqrt{6}}\ d\ell^2. \tag{3.15}$$

For this, $\Phi^\gamma \Phi_\gamma = 0$ and the energy-momentum tensor is found from (3.12) to be

$$T_{\alpha\beta} = -\alpha^2 \Phi_\alpha \Phi_\beta. \tag{3.16}$$

This is algebraically simple, but implies that the choice $a=-i\alpha/\sqrt{6}$ leads to a negative effective energy density:

$$T_{uu} = -\alpha^2 \left(\frac{\partial \Phi}{\partial u} \right)^2. \tag{3.17}$$

This may physically be interpreted as the energy density of a classical or de Sitter vacuum associated with a negative cosmological constant.[20]

The metric (3.15) can always be put into the form

$$dS^2 = e^{-2i\alpha\Phi/\sqrt{6}}(dt^2 - dz^2 - e^{2\alpha\Phi}\ dx^2 - e^{-2\alpha\Phi}\ dy^2) + \varepsilon e^{4i\alpha\Phi/\sqrt{6}}\ d\ell^2, \tag{3.18}$$

where $\Phi=\Phi(t,z)$. A simple solution to the wave equation (3.11) is now

$$\Phi = Et - pz. \tag{3.19}$$

Here the condition $\Phi^\gamma \Phi_\gamma = 0$ implies $E=\pm|p|$. The trace of the energy-momentum tensor for this specific case of Φ is

$$T = \alpha^2 (E^2 - p^2) = 0. \tag{3.20}$$

This implies by the quantum energy equation $E^2-p^2=m^2$ that we are dealing with a particle of zero rest mass. In fact (3.18) and (3.19) describe a wave propagating in the z direction which has associated with it a particle of energy E, momentum p, and zero rest mass. The energy-momentum tensor (3.8) effectively extends the induced-matter approach from fluids[3] to particles; and while the trace (3.20) is zero for the solution examined here, we expect to report in the future on corresponding solutions for massive particles.

IV. CONCLUSION

In Kaluza–Klein theory, the electromagnetic gauge[1,2] is mathematically restrictive, the matter gauge[3] is inconvenient for the physics of particles, and the harmonic gauge (1.1) and (1.3) is noncovariant. Therefore, it is advisable to use the lapse-and-shift technique[14–16] to provide a gauge-invariant decomposition of the 15 field equations of 5-D Kaluza–Klein theory into the sets of 10, 4, 1 useful in 4-D physics. These are given by (2.17)–(2.19), and their associated induced energy-momentum tensor is given by (2.21). However, if one wishes to apply a gauge, a useful one particularly in regard to wave equations and their associated particles is the conformal gauge (3.5). For this, the 4-D induced energy-momentum tensor in general form is (3.8), and for a special choice of parameters is (3.12). This gauge admits wavelike solutions. A simple plane-wave solution is (3.15) or (3.18). In the latter form, it depends on two constants which physically correspond to the energy and momentum of the particle associated with the wave. However, the trace of the associated energy-momentum tensor is zero (3.20), so the particle has zero rest mass.

While the decomposition from five to four dimensions in Sec. II here is general, what we have done in the conformal gauge in Sec. III can clearly be extended.

Geodesics and geodesic deviation for impulsive gravitational waves

R. Steinbauer[a)]
Institute for Theoretical Physics, University of Vienna, Boltzmanng. 5
A-1090 Wien, Austria

(Received 4 November 1997; accepted for publication 19 November 1997)

The geometry of impulsive pp-waves is explored via the analysis of the geodesic and geodesic deviation equation using the distributional form of the metric. The geodesic equation involves formally ill-defined products of distributions due to the nonlinearity of the equations and the presence of the Dirac δ-distribution in the space–time metric. Thus, strictly speaking, it cannot be treated within Schwartz's linear theory of distributions. To cope with this difficulty we proceed by first regularizing the δ-singularity, then solving the regularized equation within classical smooth functions and, finally, obtaining a distributional limit as solution to the original problem. Furthermore, it is shown that this limit is independent of the regularization without requiring any additional condition, thereby confirming earlier results in a mathematically rigorous fashion. We also treat the Jacobi equation which, despite being linear in the deviation vector field, involves even more delicate singular expressions, like the ''square'' of the Dirac δ-distribution. Again the same regularization procedure provides us with a perfectly well behaved smooth regularization and a regularization-independent distributional limit. Hence it is concluded that the geometry of impulsive pp-waves can be described consistently using distributions as long as careful regularization procedures are used to handle the ill-defined products. © *1998 American Institute of Physics.*

I. INTRODUCTION

Plane fronted gravitational waves with parallel rays (pp-waves) are space–times characterized by the existence of a covariantly constant null vector field, which can be used to write the metric tensor in the form[1]

$$ds^2 = H(u,x,y)du^2 - du\ dv + dx^2 + dy^2, \tag{1}$$

where u, v is a pair of null coordinates ($u=t-z$, $v=t+z$) and x, y are transverse (Cartesian) coordinates. In this paper we shall deal especially with impulsive (in the diction of Penrose[2]) pp-waves where the profile function H is proportional to a δ-distribution, i.e., takes the form $H(u,x,y)=f(x,y)\,\delta(u)$, where we leave the (smooth) function f of the transverse coordinates arbitrary for the moment. This metric is flat everywhere except on the null hypersurface $u=0$, where it has a δ-shaped ''shock.''

Such space–times arise most prominently as ultrarelativistic limits of black hole geometries as first derived by Aichelburg and Sexl for the Schwarzschild case.[3–5] On the other hand, Penrose has given a more intrinsic description of such space–times by his ''scissor and paste'' approach,[6] which essentially consists of glueing together two pieces of Minkowski space–time along the null hypersurface $u=0$ with a shift in the v-direction. A similar idea was used by Dray and t'Hooft,[7] who introduced a coordinate shift along geodesics in Minkowski space–time to rederive the Aichelburg–Sexl geometry as well as Penrose's junction conditions from the field equations.

The philosophy of the present work is somehow complementary. We take the δ-shaped metric literally and try to explore the properties of this geometry via investigation of geodesics and the

a)Electronic mail: stein@doppler.thp.univie.ac.at

 © 1998 American Institute of Physics

geodesic deviation, thereby following the approaches of Ferrari, Pendenza, and Veneziano[8] and Balasin.[9]

The main purpose of this work is to deal with the singular, i.e., distributional quantities in a mathematically rigorous fashion. A thorough analysis of the geodesic equation shows that it involves ill-defined products of the δ-distribution with the step function. This difficulty can be circumvented by a proper regularization procedure providing us with a perfectly well behaved smooth approximation, which has a distributional limit coinciding with the earlier results.[8,9] However, we neither have to impose ''multiplication rules'' like $\delta\theta=(1/2)\delta$, nor to use any additional requirements as the constancy of the norm of the geodesic's tangent vector across the shock. In fact, this property comes out as a result in our approach. The details of this calculation are given in Sec. II.

Further investigations show that the Jacobi equation involves ill-defined terms of an even worse type, such as the ''square'' of the Dirac δ-distribution and the square of the step function times the δ-distribution. However, our regularization strategy again provides us with a smooth approximation and a well behaved distributional limit, even in this case, where it seems to be hopeless to use ''*ad-hoc* extensions'' of Schwartz's linear distribution theory such as special ''multiplication rules.'' We give the details of the rather lengthy calculation in Sec. III. Our distributional ''solution'' of the Jacobi equation fits perfectly well in the (heuristically) expected picture, showing the consistency of our approach. Finally, we make some comments and give an outlook to future work in Sec. IV.

II. GEODESIC EQUATION

We start with an impulsive pp-wave metric of the form

$$ds^2=f(x^i)\,\delta(u)du^2-du\;dv+(dx^i)^2, \tag{2}$$

where $x^i(i=1,2)$ denote the transverse coordinates. It is straightforward to derive the geodesic equation. The nonvanishing Christoffel symbols are

$$\Gamma^v_{uu}=-f\dot{\delta},\quad \Gamma^i_{uu}=-\tfrac{1}{2}\partial_i f\,\delta,\quad \Gamma^v_{ui}=\Gamma^v_{iu}=-\partial_i f\,\delta, \tag{3}$$

where we have denoted the partial derivatives of f by $\partial_i f$ and the derivative of the δ-distribution by $\dot{\delta}$. Hence we get the equations

$$u''=0,\quad v''=f\dot{\delta}+2(\partial_i f x^{i\prime})u'\delta,\quad x^{i\prime\prime}=\tfrac{1}{2}\partial_i f u'^2\delta, \tag{4}$$

where $'$ denotes the derivative with respect to an affine parameter and summation over i is understood. We use the first equation to introduce u as a new affine parameter (there excluding trivial geodesics parallel to the shock hypersurface) to get

$$\begin{aligned}\ddot{v}(u)&=f(x^i(u))\,\dot{\delta}(u)+2(\partial_i f(x^i(u))\dot{x}^i(u))\,\delta(u),\\ \ddot{x}^i(u)&=\tfrac{1}{2}\partial_i f(x^i(u))\,\delta(u),\end{aligned} \tag{5}$$

where $\cdot$ again denotes the derivative with respect to u and we have inserted all the dependences explicitly. Equations (5) form a system of three coupled, nonlinear ODEs of second order in the vectorspace $\mathscr{D}'$ of distributions. For $u\neq 0$ all the right hand sides vanish, which is clear from the form of the metric tensor, and we expect the geodesics to be broken, possibly refracted straight lines. However, if we take a closer look at system (5) we see immediately that the first equation cannot be taken literally in the sense of distributions as the terms $\dot{x}^i\delta$ involve ill-defined products of the δ-distribution with the step function.

To analyze the situation in some more detail we integrate the last two equations using the (distributional) identity $f(x^i(u))\,\delta(u)=f(x^i(0))\,\delta(u)$ to get

$$x^i(u)=\text{initial values}+\tfrac{1}{2}\partial_i f(x^i(0))u_+, \tag{6}$$

where we have denoted the ''kink''-function $u\theta(u)$ by u_+. Note, however, that distributions can only be multiplied by C^∞-functions, whereas it's not clear *a priori* that the solution $x^i(u)$ will be smooth; in fact as suggested by Eq. (6) and as shown later in our calculations the solution will not even be differentiable at $u=0$. If we still try to go on by brute force it comes even worse: inserting (6) into the first equation (5) we see that the term $\dot{x}^i(u)\delta(u)$ gives rise to the ill-defined product $\theta\delta$. (For some further comments on this product see Ref. 10, p. 21.)

To overcome the undefinedness described in detail above, we apply a careful regularization procedure. More precisely we regularize the δ-distribution by a (standard) mollifier or model δ-net, i.e., a net ρ_ϵ, defined as follows. Let ρ be a smooth function with support contained in the interval $[-1,1]$ and $\int\rho=1$; now put $\rho_\epsilon(x)=(1/\epsilon)\rho(x/\epsilon)$, $(\epsilon>0)$. Hence system (5) takes the regularized form

$$\begin{aligned}\ddot{v}_\epsilon(u)&=f(x^i_\epsilon(u))\dot{\rho}_\epsilon(u)+2\partial_i f(x^i_\epsilon(u))\dot{x}^i_\epsilon(u)\rho_\epsilon(u),\\ \ddot{x}^i_\epsilon(u)&=\tfrac{1}{2}\partial_i f(x^i_\epsilon(u))\rho_\epsilon(u).\end{aligned}\tag{7}$$

Next we choose initial conditions in $u=-1$ (i.e., ''long before the shock''), more precisely

$$\begin{aligned}v_\epsilon(-1)&=v_0,\quad x^i_\epsilon(-1)=x^i_0,\\ \dot{v}_\epsilon(-1)&=\dot{v}_0,\quad \dot{x}^i_\epsilon(-1)=\dot{x}^i_0,\end{aligned}\tag{8}$$

for all ϵ. Note that choosing initial conditions in $u=0$ would mean to ''start at the shock'' and one cannot expect to (and indeed does) end up with a regularization independent result in this case.

Due to the regularization procedure we now have to deal with the fully nonlinear character of the last equation of (7). However, as shown in appendix A the special form of the right hand side of the equation guarantees global existence of the solutions for small ϵ. These are given implicitly by

$$\begin{aligned}v_\epsilon(u)&=v_0+\dot{v}_0(1+u)+(\theta*\theta*\ddot{v}_\epsilon)(u),\\ x^i_\epsilon(u)&=x^i_0+\dot{x}^i_0(1+u)+(\theta*\theta*\ddot{x}^i_\epsilon)(u),\end{aligned}\tag{9}$$

where ''$*$'' denotes convolution.

We are going to calculate the (distributional) limits of the solutions (9) as ϵ tends to zero. Since distributions supported in an acute cone form a convolution algebra (where, in particular, convolution is a separately continuous operation) it suffices to calculate the limits of the right hand sides of (7); the distributional limits of the solutions (9) are then computed simply by integration.

We begin with the latter two equations of system (7) and choose a test function φ. We have to calculate the limit of

$$\frac{1}{2}\int_{\mathbb{R}}\partial_i f(x^i_\epsilon(u))\rho_\epsilon(u)\varphi(u)du=\frac{1}{2}\int_{-1}^{1}\partial_i f(x^i_\epsilon(\epsilon u))\rho(u)\varphi(\epsilon u)du.\tag{10}$$

Since (for small ϵ) $x_\epsilon(u)$ is bounded uniformly on compact sets (see the Appendix) we can use Lebesgue's dominated convergence. Hence the only term we have to compute is

$$\begin{aligned}\lim_{\epsilon\to 0}x^i_\epsilon(\epsilon u)&=\lim\left(x^i_0+\dot{x}^i_o(1+\epsilon u)+\frac{1}{2}\int_{-\epsilon}^{\epsilon u}\int_{-\epsilon}^{v}\partial_i f(x^i_\epsilon(s))\rho_\epsilon(s)ds\ dv\right)\\ &=x^i_o+\dot{x}^i_o+\frac{1}{2}\lim\underbrace{\int_{-\epsilon}^{\epsilon u}\int_{-1}^{v/\epsilon}\partial_i f(x^i_\epsilon(\epsilon s))\rho(s)ds\ dv}_{|\int\int\leqslant\|\partial_i f\|\,\|\rho\|\int\int ds\ dv}.\end{aligned}\tag{11}$$

For $\epsilon\to 0$ the last integral gives zero, since in the limit the range of integration only covers a set of zero measure. Hence we get (as expected)

$$\ddot{x}^i_\epsilon(u)=\tfrac{1}{2}\partial_i f(x^i_\epsilon(u))\rho_\epsilon(u)\to\tfrac{1}{2}\partial_i f(x^i_0+\dot{x}^i_0)\,\delta(u), \tag{12}$$

within distributions.

Next we turn to the ''critical'' first equation in (7) and again calculate the limit of the right hand side, i.e., of the expression

$$\begin{aligned}\ddot{v}_\epsilon(u)&=f(x^i_\epsilon(u))\dot{\rho}_\epsilon(u)+2\partial_i f(x^i_\epsilon(u))\dot{x}^i_\epsilon(u)\rho_\epsilon(u)\\&=(f(x^i_\epsilon(u))\rho_\epsilon(u))^{\cdot}+\partial_i f(x^i_\epsilon(u))\dot{x}^i_\epsilon(u)\rho_\epsilon(u).\end{aligned} \tag{13}$$

The limit of the first term is easily seen to be $f(x^i_0+\dot{x}^i_0)\,\dot{\delta}(u)$, and we are only left with the second term which contains the ''critical products.'' Inserting (9) and (7) respectively, we have

$$\begin{aligned}\partial_i f(x^i_\epsilon)\dot{x}^i_\epsilon\rho_\epsilon&=\partial_i f(x^i_\epsilon)(\dot{x}^i_0+\theta*\ddot{x}^i_\epsilon)\rho_\epsilon\\&=\partial_i f(x^i_\epsilon)\dot{x}^i_0\rho_\epsilon+\partial_i f(x^i_\epsilon)(\theta*[\tfrac{1}{2}\partial_i f(x^i_\epsilon)\rho_\epsilon])\rho_\epsilon.\end{aligned} \tag{14}$$

The limit of the first term again is easily seen to give $\dot{x}^i_0\partial_i f(x^i_0+\dot{x}^i_0)\,\delta(u)$, and we are finally left with the task of computing the limit of the convolution term, i.e., the expression ''$\theta\delta$.'' Using

$$\begin{aligned}(\theta*[\partial_i f(x^i_\epsilon)\rho_\epsilon])(u)&=\int_{-\infty}^{u}\partial_i f(x^i_\epsilon(s))\rho_\epsilon(s)ds\\&=\int_{-1}^{u/\epsilon}\partial_i f(x^i_\epsilon(\epsilon s))\rho(s)ds\end{aligned} \tag{15}$$

and again denoting by φ a test function we get

$$\begin{aligned}&\lim_{\epsilon\to 0}\left(\frac{1}{2}\int_{-1}^{1}\partial_i f(x^i_\epsilon(\epsilon u))\left[\int_{-1}^{u}\partial_i f(x^i_\epsilon(\epsilon s))\rho(s)ds\right]\rho(u)\varphi(\epsilon u)du\right)\\&=\frac{1}{2}(\partial_i f(x^i_0+\dot{x}^i_0))^2\varphi(0)\underbrace{\int_{1}^{1}\left[\int_{-1}^{u}\rho(s)ds\right]\rho(u)du}_{1/2}\\&=\frac{1}{4}(\partial_i F(x^i_0+\dot{x}^i_o))^2\varphi(0).\end{aligned} \tag{16}$$

Collecting things together we have

$$\lim_{\epsilon\to 0}\ddot{v}_\epsilon=f(x^i_0+\dot{x}^i_0)\,\dot{\delta}+\dot{x}^i_0\partial_i f(x^i_0+\dot{x}^i_0)\,\delta+\tfrac{1}{4}(\partial_i f(x^i_0+\dot{x}^i_0))^2\delta \tag{17}$$

within distributions.

At the end of this section let us give a summary on what we have done so far. We have regularized the distributionally ill-defined geodesic equations (5) by replacing the δ-distribution by a (generic) class of mollifiers to obtain (7). These equations, although nonlinear, provide us with global solutions v_ϵ and x^i_ϵ for small ϵ (as shown in the Appendix), implicitly given by (9). Using the latter formula we have shown that the smooth solutions have a regularization independent distributional limit given by

$$\begin{aligned}v_\epsilon(u)&\to v_0+\dot{v}_0(1+u)+f(0)\,\theta(u)+\partial_i f(0)(\dot{x}^i_0+\tfrac{1}{4}\partial_i f(0))u_+,\\x^i_\epsilon(u)&\to x^i_0+\dot{x}^i_0(1+u)+\tfrac{1}{2}\partial_i f(0)u_+,\end{aligned} \tag{18}$$

where we have used the abbreviation $f(0)=f(x^i_0+\dot{x}^i_0)$.

Hence, viewed distributionally the geodesics are given by refracted, broken straight lines as expected. Of course, equations (18) coincide with the earlier results.[8,9] However, from the point of view of our approach the (deeper) reason why here the ''rule'' $\theta\delta=(1/2)\,\delta$ used by Ref. 8 [which

in fact coincides with the ''determination of the point value'' $\theta(0)=1/2$ used by Ref. 9] leads to a physically reasonable result is the following: The geodesic equations involve *only one* singular object and hence the δ's as well as the θ's appearing above share the same root: namely the δ-shaped wave profile. Hence, when regularizing the equations (which in fact corresponds to the physical idea of viewing the impulsive wave as an idealized sandwich wave) both factors of the ill-defined product naturally involve the same regularization which immediately leads to the (regularization-independent) result $\rho_\epsilon \int \rho_\epsilon \to (1/2)\,\delta$.

We thus conclude that the geodesic equation can be treated consistently by regularization, leading to a regularization-independent distributional result. This, of course, is only possible at all due to the relatively mild character of the singular terms which allows for a distributional limit of the solutions to the regularized problem. However, we shall see in a moment that even in the considerably more complicated case of the Jacobi equation our strategy can be applied successfully.

III. JACOBI EQUATION

In this section we solve the Jacobi equation for an impulsive pp-wave. To keep formulas more transparent we restrict ourselves to the axisymmetric case. More precisely we restrict the function f of the transverse coordinates $x^i=(x,y)$ in the metric tensor (2) to depend on the two-radius $r=\sqrt{x^2+y^2}$ only and work entirely within the $y=0$-hypersurface (initial conditions $x_0^2\equiv y_0=0=\dot{x}_0^2\equiv\dot{y}_0$). Furthermore, we take initial values $v_0=0=\dot{x}_0$. With these assumptions equations (18) simplify to

$$\begin{aligned} v_\epsilon(u) &\to \dot{v}_0(1+u)+f(x_0)\,\theta(u)+\tfrac{1}{4}f'(x_0)^2 u_+ ,\\ x_\epsilon^1(u)\equiv x_\epsilon(u) &\to x_0+\tfrac{1}{2}f'(x_0)u_+ ,\\ x_\epsilon^2(u)\equiv y_\epsilon(u) &= 0, \end{aligned} \tag{19}$$

where f' denotes the derivative with respect to the single variable $r=x$. Hence we shall deal with a geodesic tangent vector of the form

$$T^a(u)=\begin{pmatrix} 1 \\ \dot{v}_0+f(x_0)\,\delta(u)+\tfrac{1}{4}f'(x_0)^2\,\theta(u) \\ \tfrac{1}{2}f'(x_0)\,\theta(u) \\ 0 \end{pmatrix}, \tag{20}$$

where we are going to use the abbreviations $A:=f(x_0)\,\delta(u)+(1/4)f'(x_0)^2\theta(u)$ and $B:=(1/2)f'(x_0)\,\theta(u)$ for its components.

Our next task is to compute the explicit form of the Jacobi equation $D^2N^a/du=-R^a_{bcd}T^bT^dN^c$ for a vector field $N^a(u)=(N^u(u),N^v(u),N^x(u),N^y(u))$ over the geodesic. After some (tedious) calculations we end up with the following form of the system:

$$\begin{aligned} &\ddot{N}^u=0, \quad \ddot{N}^v=2[N^xf'\delta]^{\cdot}-N^xf'\dot{\delta}+[N^uf\delta]^{\cdot\cdot}-N^uf''B^2\delta-N^uf'\dot{B}\delta,\\ &\ddot{N}^x=[\dot{N}^uf'+\tfrac{1}{2}N^xf'']\delta+\tfrac{1}{2}f'N^u\dot{\delta}, \quad \ddot{N}^y=0, \end{aligned} \tag{21}$$

where we have suppressed the dependence on the parameter u and the variable x. Equations (21) form a system of four coupled ODE's linear in the components of the vector field N^a but nonlinear in the derivatives of the metric. From the fact that B involves the step function we see immediately that (in the second equation) we again have to deal with distributionally ill-defined expressions, but now of even worse type than before. Indeed, the term $\dot{B}\delta$ is proportional to the ''square'' of the Dirac δ-distribution, and the term $B^2\delta$ involves an expression ''$\theta^2\delta$.'' Note, however, that the critical terms arise from the second covariant derivative, where some of the Christoffel symbols get multiplied, and not from the Riemann tensor in which components are just proportional to the δ-distribution. To overcome these problems we apply the same regularization procedure as in the case of the geodesic equation. In particular, we use the regularized geodesic tangent vector

$$T^a_\epsilon = \begin{pmatrix} 1 \\ \dot v_0 + \theta * \ddot v_\epsilon \\ \theta * \ddot x_\epsilon \\ 0 \end{pmatrix}, \tag{22}$$

where $\ddot v_\epsilon(u) = f(x_\epsilon(u))\dot\rho_\epsilon(u) + 2f'(x_\epsilon(u))\dot x_\epsilon(u)\rho_\epsilon(u)$, $\ddot x_\epsilon(u) = (1/2)f'(x_\epsilon(u))\rho_\epsilon(u)$ and from now on we use the new abbreviations $A_\epsilon := \theta * \ddot v_\epsilon$ and $B_\epsilon := \theta * \ddot x_\epsilon$. Denoting the regularized Jacobi field by $N^a_\epsilon(u) = (N^u_\epsilon(u), N^v_\epsilon(u), N^x_\epsilon(u), N^y_\epsilon(u))$, system (21) takes the regularized form

$$\ddot N^u_\epsilon = 0,$$

$$\ddot N^v_\epsilon = 2[N^x_\epsilon f'(x_\epsilon)\rho_\epsilon]^{\cdot} - N^x_\epsilon f'(x_\epsilon)\dot\rho_\epsilon + [N^u_\epsilon f(x_\epsilon)\rho_\epsilon]^{\cdot\cdot} - N^u_\epsilon f''(x_\epsilon)[\theta * \ddot x_\epsilon]^2\rho_\epsilon - N^u_\epsilon f'(x_\epsilon)\ddot x_\epsilon\rho_\epsilon,$$

$$\ddot N^x_\epsilon = [\dot N^u_\epsilon f'(x_\epsilon) + \tfrac{1}{2}N^x_\epsilon f''(x_\epsilon)]\rho_\epsilon + \tfrac{1}{2}f'(x_\epsilon)N^u_\epsilon\dot\rho_\epsilon, \quad \ddot N^y_\epsilon = 0. \tag{23}$$

To maintain transparency of formulas we choose appropriate and simple initial conditions on the Jacobi field N^a_ϵ at $u = -1$, i.e.,

$$N^a_\epsilon(-1) = (0,0,0,0), \quad \dot N^a_\epsilon(-1) = (a,b,0,0), \tag{24}$$

for all ϵ. Note that this corresponds to a focal point at $u = -1$, and that ''nearby'' geodesics have relative initial velocities only in the u- and v-direction.

The first and the last equation of system (23) are easily solved to give

$$N^u_\epsilon(u) = a(1+u), \quad N^y_\epsilon(u) = 0. \tag{25}$$

For the remaining, more complicated equations of system (23) we apply the same strategy as in the preceeding section. Since the equations are linear in the components of the deviation vector field we obtain globally defined (smooth) solutions which, due to the initial conditions (24), are implicitly given by

$$N^v_\epsilon(u) = b(1+u) + [\theta * \theta * \ddot N^v_\epsilon](u), \quad N^x_\epsilon(u) = [\theta * \theta * \ddot N^x_\epsilon](u). \tag{26}$$

Again it suffices to compute the distributional limits of the right hand sides of equation (23), since by continuity of the convolution we immediately get the limits of N^v_ϵ and N^x_ϵ.

We start with the third equation of the system (23). The main problem we have to face here is due to the fact that the unknown function N^x_ϵ (which, in the limit, we cannot even expect to be continuous at $u = 0$) appears on the right hand side. Inserting the initial conditions (24) and the solutions (25) we get

$$\ddot N^x_\epsilon(u) = \underbrace{af'(x_\epsilon(u))\rho_\epsilon(u)}_{I_\epsilon} + \underbrace{\tfrac{1}{2}f'(x_\epsilon(u))a(1+u)\dot\rho_\epsilon(u)}_{II_\epsilon} + \underbrace{\tfrac{1}{2}N^x_\epsilon(u)f''(x_\epsilon(u))\rho_\epsilon(u)}_{III_\epsilon}. \tag{27}$$

The distributional limits of the first two terms in equation (27) are easily seen (using similar methods as in the previous section) to be

$$\lim_{\epsilon\to 0} \mathrm{I}_\epsilon = af'(x_0)\delta,$$

$$\lim_{\epsilon\to 0} \mathrm{II}_\epsilon = \tfrac{1}{2}af'(x_0)(\dot\delta - \delta) - \tfrac{1}{8}af'(x_0)f''(x_0)\delta. \tag{28}$$

However, the last term in equation (27) requires a more detailed analysis. Inserting again $\theta * \theta * \ddot N^x_\epsilon$ for the unknown function N^x_ϵ and denoting by φ a test function we obtain

$$\mathrm{III}_\epsilon(u)=\frac{1}{2}\,\epsilon\int_{-1}^{1}\varphi(\epsilon u)f''(x_\epsilon(\epsilon u))\rho(u)\int_{-1}^{u}\int_{-1}^{s}\Big[af'(x_\epsilon(\epsilon r))$$
$$+\frac{1}{2}\,N^x_\epsilon(\epsilon r)f''(x_\epsilon(\epsilon r))\Big]\rho(r)dr\;ds\;du$$
$$+\frac{1}{4}\,a\int_{-1}^{1}\varphi(\epsilon u)f''(x_\epsilon(\epsilon u))\rho(u)\int_{-1}^{u}\int_{-1}^{s}f'(x_\epsilon(\epsilon r))\dot\rho(r)dr\;ds\;du$$
$$+\frac{1}{4}\,a\epsilon\int_{-1}^{1}\varphi(\epsilon u)f''(x_\epsilon(\epsilon u))\rho(u)\int_{-1}^{u}\int_{-1}^{s}f'(x_\epsilon(\epsilon r))r\dot\rho(r)dr\;ds\;du. \tag{29}$$

The last term in equation (29) goes to zero, since φ, f', f'' are smooth functions and x_ϵ is bounded uniformly on compact sets (see the Appendix). For the same reasons the second summand in equation (29) approaches the limit

$$\tfrac{1}{8}a\varphi(0)f'(x_0)f''(x_0), \tag{30}$$

whereas the first line also vanishes in the limit, since $N^x_\epsilon(\epsilon r)$ is bounded on the compact range of integration. (Note, however, that $\lim N^x_\epsilon$ is not continuous at 0!) In some more detail the latter argument can be seen from

$$N^x_\epsilon(\epsilon u)=\int_{-1}^{u}\int_{-1}^{s}\Big\{af'(x_\epsilon(\epsilon r))\epsilon\rho(r)+\frac{1}{2}\,af'(x_\epsilon(\epsilon r))[\dot\rho(r)+r\epsilon\dot\rho(r)]\Big\}dr\;ds$$
$$+\frac{1}{2}\int_{-\epsilon}^{\epsilon u}\int_{-1}^{s/\epsilon}N^x_\epsilon(\epsilon r)f''(x_\epsilon(\epsilon r))\rho(r)dr\;ds, \tag{31}$$

where we have now used equation (26) for the third time. Hence we have for $u\leqslant T$, where T is some constant, and for fixed ϵ

$$|N^x_\epsilon(\epsilon u)|\leqslant C+C'\int_{-\epsilon}^{\epsilon u}\int_{-1}^{s/\epsilon}|N^x_\epsilon(\epsilon r)||\rho(r)|dr\;ds\leqslant C+2C'\int_{-1}^{u}|N^x_\epsilon(\epsilon r)||\rho(r)|dr, \tag{32}$$

where $C=C(T)$ and C' denote constants. From Gronwall's inequality we gain

$$|N^x_\epsilon(\epsilon u)|\leqslant Ce^{2C'\int_{-1}^{u}|\rho(r)|dr}, \tag{33}$$

which is bounded by a constant for $u\leqslant T$.

Collecting things together [equations (28) and (30)] we find that within distributions

$$\ddot N^x_\epsilon\to\tfrac{1}{2}af'(x_0)(\delta+\dot\delta), \tag{34}$$

which gives us immediately the distributional limit of the regularized solution of the third equation of system (23), i.e.,

$$N^x_\epsilon(u)\to\tfrac{1}{2}af'(x_0)(u_++\theta(u)). \tag{35}$$

Now we face the most complicated equation of system (23) which contains the distributionally ill-defined expressions, namely

$$\ddot N^v_\epsilon(u)=2[N^x_\epsilon(u)f'(x_\epsilon(u))\rho_\epsilon(u)]^{\cdot}+[N^u_\epsilon(u)f(x_\epsilon(u))\rho_\epsilon(u)]^{\cdot\cdot}-N^u_\epsilon(u)f''(x_\epsilon(u))[\theta*\ddot x_\epsilon]^2(u)\rho_\epsilon(u)$$
$$-N^x_\epsilon(u)f'(x_\epsilon(u))\dot\rho_\epsilon(u)-N^u_\epsilon(u)f'(x_\epsilon(u))\ddot x_\epsilon(u)\rho_\epsilon(u), \tag{36}$$

where we have inserted all the dependences explicitly. Note that in addition to the obvious troublesome fifth term which involves the ''square'' of the δ-distribution ($\ddot x_\epsilon\propto\rho_\epsilon$!), also the fourth term contains divergent and regularization-dependent contributions, since the derivatives of

$f(x)$ and N_ϵ^x produce δ- and step functions, respectively. We are going to calculate the distributional limits of the right hand side of equation (36) term by term, which can easily be done for the first three using yet well known techniques.

First, second and third term:

$$\lim_{\epsilon\to 0} 2[N_\epsilon^x(u) f'(x_\epsilon(u))\rho_\epsilon(u)]^{\cdot} = \tfrac{1}{2} a f'(x_0)^2 \dot{\delta},$$

$$\lim_{\epsilon\to 0} [N_\epsilon^u(u) f(x_\epsilon(u))\rho_\epsilon(u)]^{\cdot\cdot} = a f(x_0)\ddot{\delta}, \tag{37}$$

$$\lim_{\epsilon\to 0} N_\epsilon^u(u) f''(x_\epsilon(u))[\theta * \ddot{x}_\epsilon]^2(u)\rho_\epsilon(u) = \tfrac{1}{12} a f'(x_0)^2 f''(x_0)\delta.$$

We now come to the expressions involving the divergent and regularization-dependent factors. We outline the calculations in some detail.

Fourth term: $(\mathrm{iv}) := -N_\epsilon^x(u) f'(x_\epsilon(u))\dot{\rho}_\epsilon(u)$.
By integration by parts we obtain (φ again a test function)

$$-\int_{-\epsilon}^{\epsilon} \varphi(u) N_\epsilon^x(u) f'(x_\epsilon(u))\dot{\rho}_\epsilon(u)\,du = \underbrace{\int_{-1}^{1} \dot{\varphi}(\epsilon u) N_\epsilon^x f'(x_\epsilon(\epsilon u))\rho(u)\,du}_{A}$$

$$+ \underbrace{\int_{-1}^{1} \varphi(\epsilon u) N_\epsilon^x(\epsilon u) f''(x_\epsilon(\epsilon u))\dot{x}_\epsilon(\epsilon u))\rho(u)\,du}_{B} + \underbrace{\int_{-1}^{1} \varphi(\epsilon u)\dot{N}_\epsilon^x(\epsilon u) f'(x_\epsilon(\epsilon u))\rho(u)\,du}_{C}. \tag{38}$$

Inserting $\theta * \theta * \ddot{N}_\epsilon^x$ according to equations (26) and (27) for N_ϵ^x we find for the expressions labeled A and B

$$A \to -\tfrac{1}{4} a f'(x_0)^2 \dot{\delta}, \tag{39}$$

$$B \to \tfrac{1}{12} a f'(x_0)^2 f''(x_0)\delta. \tag{40}$$

Finally, we have for the most complicated expression

$$C = \frac{1}{2} a \underbrace{\int_{-1}^{1} \varphi(\epsilon u) f'(x_\epsilon(\epsilon u))\rho(u) \int_{-1}^{u} f'(x_\epsilon(\epsilon s))\dot{\rho}(s)\,ds\,du}_{C1}$$

$$+ \frac{1}{2} a \underbrace{\int_{-1}^{1} \varphi(\epsilon u) f'(x_\epsilon(\epsilon u))\rho(u) \int_{-1}^{u} f'(x_\epsilon(\epsilon s)) s\dot{\rho}(s)\,ds\,du}_{C2}$$

$$+ \underbrace{\int_{-1}^{1} \varphi(\epsilon u) f'(x_\epsilon(\epsilon u))\rho(u) \int_{-1}^{u} [a f'(x_\epsilon(\epsilon s)) + \frac{1}{2} N_\epsilon^x(\epsilon s) f''(x_\epsilon(\epsilon s))]\rho(s)\,ds\,du}_{C3}. \tag{41}$$

The term labeled $C1$ diverges due to the factor ϵ^{-1}. However, as we shall see later, this expression combined with another one arising from the fifth term of equation (36) will provide us with a finite result.

The term labeled $C2$ involves a regularization-dependent factor, i.e.,

$$C2 \to \frac{1}{2}\, af'(x_0)^2 \delta \int_{-1}^{1} \rho(u) \int_{-1}^{u} s\dot{\rho}(s) ds\ dt. \tag{42}$$

As in the case of the previous term $C1$, this problem will be resolved later on, so that we are now left with the task of computing the limit of $C3$. Again using similar techniques we obtain

$$C3 \to \tfrac{1}{2} af'(x_0)^2 \delta + \tfrac{1}{24} af'(x_0)^2 f''(x_0)\delta. \tag{43}$$

Collecting together the results of equations (39), (40) and (43), we finally have

$$(\mathrm{iv}) - C1 - C2 \to -\tfrac{1}{4} af'(x_0)^2 \dot{\delta} + \tfrac{1}{8} af'(x_0)^2 f''(x_0)\delta + \tfrac{1}{2} af'(x_0)^2 \delta, \tag{44}$$

where now, by an abuse of notation $C1$ and $C2$ denote the respective quantities in equation (41) without integration over the test function.

Now we finally come to the last term in equation (36) which will resolve the problems with the expressions $C1$ and $C2$.

Fifth term: $(\mathrm{v}) := -N_\epsilon^u(u) f'(x_\epsilon(u))\ddot{x}_\epsilon(u)\rho_\epsilon(u)$
Inserting solution (25) we find

$$-\int_{-\epsilon}^{\epsilon} \varphi(u) N_\epsilon^u(u) f'(x_\epsilon(u))\ddot{x}_\epsilon(u)\rho_\epsilon(u) du = \underbrace{-\frac{1}{2\epsilon} a \int_{-1}^{1} \varphi(\epsilon u) f'(x_\epsilon(\epsilon u))^2 \rho(u)^2 du}_{(*)}$$
$$\underbrace{-\frac{1}{2} a \int_{-1}^{1} \varphi(\epsilon u) f'(x_\epsilon(\epsilon u))^2 u \rho(u)^2 du}_{(**)}. \tag{45}$$

We see now that the expression (*) diverges, but that the sum $C1+(*)$ converges. More precisely, by integration by parts we get

$$C_1 + (*) = -\frac{1}{4}\, a \int_{-1}^{1} \varphi(\epsilon u) f'(x_\epsilon(\epsilon u))\rho(u) \int_{-1}^{u} f''(x_\epsilon(\epsilon s))\rho(s) \int_{-1}^{s} f'(x_\epsilon(\epsilon r))\rho(r) dr\ ds\ du$$
$$\to -\frac{1}{4}\, a\varphi(0) f'(x_0)^2 f''(x_0) \underbrace{\int_{-1}^{1} \rho(u) \int_{-1}^{u} \rho(s) \int_{-1}^{s} \rho(r) dr\ ds\ du}_{1/6}$$
$$= -\frac{1}{24}\, a\varphi(0) f'(x_0)^2 f''(x_0). \tag{46}$$

Hence we have the distributional limit

$$C1 + (*) \to -\tfrac{1}{24}\, af'(x_0)^2 f''(x_0)\delta. \tag{47}$$

On the other hand expression (**) contains a regularization-dependent factor which is proportional to the one contained in the term $C2$. More precisely, from equation (42) and the fact that

$$(**) \to -\tfrac{1}{2}\, af'(x_0)^2 \delta \int_{-1}^{1} u\rho(u)^2\ du \tag{48}$$

we have

$$C2+(**)\to\frac{1}{2}af'(x_0)^2\delta\underbrace{\left[\int_{-1}^{1}\rho(u)\left[\int_{-1}^{u}s\dot{\rho}(s)ds-u\rho(u)\right]du\right]}_{1/2}$$

$$=-\frac{1}{4}af'(x_0)^2\delta. \tag{49}$$

We are now ready to collect together all five terms of equation (36), i.e., of the second equation of the regularized system (23). From equations (37), (44), (47) and (49) we get the following result:

$$\ddot{N}^v_\epsilon\to af(x_0)\ddot{\delta}+\tfrac{1}{4}af'(x_0)^2(\dot{\delta}+\delta), \tag{50}$$

which, using initial condition (24), we readily integrate to

$$N^v_\epsilon(u)\to b(1+u)+a[f(x_0)\delta+\tfrac{1}{4}f'(x_0)^2(\theta(u)+u_+)]. \tag{51}$$

Finally we have for the whole system (23) the following (distributional limits of the) solutions

$$\begin{aligned}
N^u_\epsilon(u)&=a(1+u),\\
N^v_\epsilon(u)&\to b(1+u)+a[f(x_0)\delta+\tfrac{1}{4}f'(x_0)^2(\theta(u)+u_+)],\\
N^x_\epsilon(u)&\to\tfrac{1}{2}af'(x_0)(\theta(u)+u_+),\\
N^y_\epsilon(u)&=0.
\end{aligned} \tag{52}$$

Hence, viewed distributionally, the Jacobi field suffers a kink, a jump and a δ-like pulse in the v-direction as well as a kink and jump in the x-direction overlapping the linear flat space behavior. These effects can be understood heuristically from the corresponding behavior of the geodesics, given by equation (18). The constant factor a, which gives the ''scale'' of all the nonlinear effects, arises from the ''time advance'' of the ''nearby'' geodesics, represented by the initial velocity of the Jacobi field in the u-direction [cf. initial conditions (24)].

Note, however, that this ''time advance'' is not the only effect generically generating deviations from the flat space behavior, but rather arises as an artifact of our initial conditions. One can easily show that different initial conditions on the deviation vector field, even without ''time advance,'' produce kinks and jumps as well. For example, let

$$N^a_\epsilon(-1)=(0,0,0,0)\quad\text{and}\quad N^a_\epsilon(-1)=(0,a,b,0); \tag{53}$$

then a similar (but now even simpler) calculation leads to the following (distributional limits of the) regularized Jacobi field

$$\begin{aligned}
N^u_\epsilon&=0,\\
N^v_\epsilon&\to a(1+u)+\tfrac{1}{4}bf'(x_0)f''(x_0)u_+ +bf'(x_0)\theta(u),\\
N^x_\epsilon&\to b(1+u)+\tfrac{1}{2}bf''(x_0)u_+,\\
N^y_\epsilon&=0.
\end{aligned} \tag{54}$$

The kink of the x-component of the deviation field now arises from the fact that a ''nearby'' geodesic passes the shock at an x-value of x_0+b, hence according to equation (18) suffers a kink of ''strength'' $(1/2)f'(x_0+b)$. Taylor expansion yields $f'(x_0+b)\approx f'(x_0)+f''(x_0)b$, such that

the kink difference of ''nearby'' geodesics is given by $(1/2)f''(x_0)b$, which is exactly the factor given in the third equation of (54). The kink and jump in v-direction can be explained by similar heuristic arguments.

IV. CONCLUSION

We have shown that the geodesic and Jacobi equation of impulsive pp-waves can be treated consistently using the distributional form of the space–time metric (2).

The main problem was to deal with products ill-defined within Schwartz's linear distribution theory. The geodesic equation involves terms proportional to ''$\theta\delta$'' while the Jacobi equation, although linear in the components of the deviation vector field, contains even more singular terms like ''δ^2'' and ''$\theta^2\delta$.'' Our strategy consisted essentially in a careful and general regularization procedure, replacing the δ-distribution by a mollifying sequence ρ_ϵ. While mathematically sound, this procedure corresponds to the physical idea of viewing the impulsive wave as the limiting case of a sandwich wave of ever decreasing support but constant strength. Our approach leads to smooth solutions of the regularized equations which possess a regularization-independent limit within the vector space of distributions. However, this is not obvious (cf., for example, Ref. 11), but rather should strengthen our trust in impulsive waves as reasonable solutions of Einstein's equations. Furthermore our distributional ''solutions'' of the geodesic and Jacobi equation perfectly coincide with physical expectations, showing that the geometry of impulsive pp-waves can be described in a consistent way using the distributional form of the metric, as long as one applies proper regularization methods as opposed to ''ad-hoc strategies'' involving certain ''multiplication rules.'' In fact when dealing with nonlinear operations (of a certain complexity) on singular, i.e., distributional data, reliable results can only be achieved by careful regularization procedures (cf. the comments on ''common errors'' even in the mathematical literature given by Hájek[12]).

However, from an even more formal point of view, the approach taken in this paper suffers from the fact that we do not really have an elaborated solution concept for the regularized equations. Such a notion is provided by the theory of Nonlinear Generalized Functions[10,13,14] due to Colombeau and others, where—loosely speaking—the regularized sequence is viewed as one mathematical object, i.e., a generalized function. Recently, singular, nonlinear ODEs (exactly the type of equations we were dealing with) have been studied in the context of this new mathematical framework,[15,16] providing a powerful tool to handle both, *singular* data and especially this type of *nonlinear* differential equations. Future work will be concerned with the analysis of the geodesic and Jacobi equation for pp-waves from the point of view of this new solution concept.

ACKNOWLEDGMENT

APPENDIX

In this appendix we prove (for small ϵ) the global existence and uniform boundedness (in ϵ) of the solutions to the last equation of system (7). For simplicity we only treat the one-dimensional case and write g instead of Df. The main idea is to use $\|\ \|_1$-bounds on the regularizing sequence ρ_ϵ. We start with the following statement.

Proposition: Let $g:\mathbb{R}\to\mathbb{R}$ *smooth and* $\rho\in\mathscr{D}([-1,1])$, $\int\rho=1$, $\rho_\epsilon(x):=(1/\epsilon)\rho(x/\epsilon)$. *For fixed* ϵ *consider the differential equation*

$$\ddot{x}_\epsilon(t)=g(x_\epsilon(t))\rho_\epsilon(t), \tag{A1}$$

with initial conditions $x_\epsilon(-1)=x_0$ *and* $\dot{x}_\epsilon(-1)=\dot{x}_0>0$. *Then there exists a unique solution* $x_\epsilon(t)$ *on the interval* $J_\epsilon:=[-1,-\epsilon+\alpha]$, *where*

$$\alpha:=\min\left\{\frac{b}{\|g\|_{\infty,I}\|\rho\|_1+\dot{x}_0},\frac{1}{2L}\right\}\quad(b>0), \tag{A2}$$

$I := \{x \in \mathbb{R} : |x - x_0| \leq b + \dot{x}_0\}$ *and* L *is a Lipschitz constant for* g *on* I.

The *Proof* is just a modification of the proof of the classical (first order) ODE existence and uniqueness theorem. We work on the (nonempty, closed) subset $X_\epsilon := \{x_\epsilon \in C(J_\epsilon) : |x_\epsilon(t) - x_0| \leq b + \dot{x}_0\}$ of the Banach space of continuous functions on the interval J_ϵ. Since no first order derivative of x_ϵ enters the right hand side of equation (A1) we may define the integration operator A by

$$(Ax_\epsilon)(t) := x_0 + \dot{x}_0(t+1) + \int_{-\epsilon}^{t}\int_{-\epsilon}^{s} g(x_\epsilon(r))\rho_\epsilon(r)\,dr\,ds. \tag{A3}$$

By construction $Ax_\epsilon \in C(J_\epsilon)$, but we even have $Ax_\epsilon \in X_\epsilon$ since

$$\begin{aligned} |[Ax_\epsilon](t) - x_0| &\leq \dot{x}_0(t+1) + \int_{-\epsilon}^{t}\int_{-\epsilon}^{s} |g(x_\epsilon(r))|\,|\rho_\epsilon(r)|\,dr\,ds \\ &\leq \alpha(\dot{x}_0 + \|g\|_{\infty,I}\|\rho\|_1) + \dot{x}_0 \leq b + \dot{x}_0. \end{aligned} \tag{A4}$$

By a similar estimate one shows that A, in fact, is a contraction on X_ϵ. Hence by the fixed point theorem we have a unique solution $x_\epsilon \in X_\epsilon$. □

Since α is independent of ϵ we have for small ϵ: $-\epsilon + \alpha \geq \epsilon$. But at $t = \epsilon$ the right hand side of the differential equation (A1) has already been ''turned off.'' Hence for small ϵ the solutions are defined on the whole real line.

Furthermore, since for all ϵ the solution lies in X_ϵ, x_ϵ is bounded uniformly in ϵ for say $t \leq \alpha/2$ (for ϵ small enough). For larger values of t x_ϵ grows only linearly with $\dot{x}_\epsilon$ which is bounded by $\dot{x}_0 + \|g\|_{\infty,I}\|\rho\|_1$. Hence (for small ϵ) $x_\epsilon(t)$ is bounded uniformly in ϵ on every compact set.

The Einstein–Hilbert–Yang–Mills–Higgs action and the Dirac–Yukawa operator

Jürgen Tolksdorf[a)]

(Received 9 September 1997; accepted for publication 23 September 1997)

In this article we show in some detail how the full action functional of the standard model of elementary particle physics can be described within the geometrical setting of generalized Dirac operators. We thereby introduce a new model building kit for (a certain class of) gauge invariant theories which provides a unified geometrical description of Einstein's theory of gravity and Yang–Mills gauge theories on the ''classical'' level. Moreover, when the gauge symmetry is spontaneously broken, the Higgs sector as well has a natural geometrical interpretation. It turns out that the Higgs field is related to the gravitational potential. Since the full action functional of the standard model is derived in one stroke, the appropriate parameters of the model have to satisfy certain relations similar to those in the Connes–Lott approach. Likewise, this may yield some phenomenological consequences, which is illustrated by using the gauge group of the standard model in the case of N generations of leptons and quarks. © *1998 American Institute of Physics.* [S0022-2488(98)02103-3]

I. INTRODUCTION

In this article we propose a certain model building kit which permits derivation of the action functional of the standard model of elementary particle physics with gravity included in terms of generalized Dirac operators. For this we introduce the following geometrical data:

$$(\mathrm{G},\rho,\mathrm{D}), \tag{1}$$

where G denotes a real compact semi-simple Lie group, ρ is its unitary representation on an N-dimensional Hermitian vector space V, and D denotes a Dirac operator acting on sections into a Clifford module bundle $\mathscr{E}:=\mathrm{S}\otimes\mathrm{E}$, such that $\mathrm{E}:=\mathscr{P}\times_\rho V$. Here, S denotes the spinor bundle over a closed compact orientable Riemannian spin manifold $(\mathscr{M},g)$ without boundary and of even dimension $(2n>2)$; $\mathscr{P}$ is a G-principal bundle over $\mathscr{M}$.

Having given the geometrical setting we propose the following functional:

$$\mathscr{T}_\mathrm{D}:=(\psi,i\mathrm{D}\psi)_{\Gamma(\mathscr{E})}+\mathrm{res}_\zeta(\mathrm{D}^{-2n+2}). \tag{2}$$

Here, res denotes the Wodzicki residue, ζ is an element of the commutant defined by (G,ρ), satisfying $[\mathrm{D},\zeta]=[\chi,\zeta]=0$, $\zeta>0$, with χ the involution operator on $\mathscr{E}$, and $(,)_{\Gamma(\mathscr{E})}$ denotes the induced Hermitian product on the $C^\infty(\mathscr{M})$ module $\Gamma(\mathscr{E})$ of sections ψ into $\mathscr{E}$. In our frame this functional serves as a ''general action'' functional.

Using this frame the main result of this paper may be summarized in the following.

Theorem: *There exists a natural generalization (1) of the Dirac–Yukawa operator of the standard model such that the functional (2) is proportional to the full action of the standard model with gravity included.*

As a consequence we obtain certain relations between the parameters involved. Especially, the mass of the Higgs field m_h is a function of the fermion masses. In the most general case the range for the electroweak angle θ_w reads

$$0.25\leqslant\sin^2\theta_w\leqslant 0.45.$$

[a)]Electronic mail: Tolkdorf@euler.math.uni-mannheim.de

 © 1998 American Institute of Physics

In the case where all irreducible subspaces of the fermion representation are equally weighted we obtain the GUT preferred relations

$$\sin^2\theta_w=\tfrac{3}{8},\quad g_{(3)}=g_{(2)},$$

where, respectively, $g_{(3)}$ and $g_{(2)}$ are the strong and weak coupling constants. Of course, all derived relations are expected to be scale dependent and thus the corresponding renormalization flux must be carefully taken into account. We stress that the corresponding hyperchanges of the particles involved in the model are fixed when the electrical charges are assumed to be known.

The model building kit as defined by the generalized Dirac operator (1) and the universal action (2) is motivated by the assumption that the basic objects in nature are fermions and that their dynamics are described by Dirac's equation. Then, the appropriate dynamics of the various fields involved in the definition of the fermionic interactions should be a consequence of the latter and not independent thereof. Mathematically, this may be rephrased as follows: when fermions are geometrically described by sections into a twisted spinor bundle, the most natural operator acting on those objects is a Dirac operator. A Dirac operator, however, is but a Clifford superconnection (i.e., a certain generalization of a connection) defined by (homomorphism-valued) differential forms of *various* degrees. Then, fixing the admissible fermionic interactions geometrically means fixing the admissible differential forms defining a certain superconnection and thus a certain Dirac operator. The idea of the kit, proposed here, is that the functionals leading to the field equations of the differential forms defining the Dirac operator are not arbitrary but determined by this operator. As it turns out, this idea not only permits a geometrical understanding of the Higgs action but also a new geometrical interpretation of the Einstein–Hilbert and Yang–Mills functional $(\mathscr{T}_{\mathrm{EH}},\mathscr{T}_{\mathrm{YM}})$. Indeed, from this point of view the former occurs—in a sense—as a natural ''companion'' of the latter and both are ''consequences'' of the fermionic interaction. In this (classical) description of particle physics the *a priori* assumption of a flat space–time seems artificial. To make this more clear, let us assume we consider a ''free'' fermion. From a geometrical viewpoint, such an object may be considered as a section into a twisted spinor bundle, where now the twisting part is assumed to possess a trivial connection. Nevertheless, the Clifford module bundle may be nonflat. Indeed, the fermion carries energy and thereby produces a nontrivial gravitational field. Hence, the corresponding spin connection is nontrivial in general. Of course, under ''normal'' conditions the energy of an elementary particle is so weak that the appropriate gravitational field cannot be measured. From our point of view this simply means that in the particular case at hand the energy-momentum tensor—defined by the Dirac action—is ignorable with respect to any inertial frame and, therefore, space–time becomes *approximately* flat. Though this is usually accepted by physicists, the point here is that the functional $\mathscr{T}_{\mathrm{D}}$ fixes the energy-momentum tensor. Consequently, in our approach a vanishing Einstein tensor *a priori* makes no sense. This can strictly hold iff there are no fermions in the world (whatever such a world looks like!). Next, let us consider the case when the fermion becomes massive. Then, the interaction with the Higgs field must be taken into account. As it turns out, geometrically, the Higgs field defines a certain connection on the Clifford module bundle where the fermions live. The corresponding curvature is nonzero, even in the case when the Higgs field represents a (classical) nontrivial vaccum. Of course, since the energy-momentum of the Higgs field is nonzero, space–time must be curved as well. Note that this holds true even in the case when the world ''sits in the (classical) vaccum.'' We stress that in our scheme the Higgs field seems intimately related to gravity. Of course, we are only considering classical field theory and one may object that on the level of elementary particles quantum theory has to be taken into account and then gravity may look completely different from that described by Einstein's equation. However, as a ''first step'' towards a real understanding of the interplay between gravity and particle physics it might be useful to have a unified geometrical description of all interactions on the level of the classical field equations known so far.

Mathematically, it is evident that the action (2) is gauge invariant. Hence, our kit provides a general scheme for building (a certain class of) gauge invariant theories. It therefore might be worth remembering the input of a general Yang–Mills model and to compare both building kits, correspondingly. Here, we adopt the notation as given in Ref. 1.

The input of a *general Yang–Mills model* consists of the following data:

(1) a finite-dimensional real, compact Lie group G,

(2) a unitary representation $\rho_f=\rho_{\mathrm{L}}\oplus\rho_{\mathrm{R}}$ on the $\mathbb{Z}_2$-graded Hermitian vector space $V_f=V_{\mathrm{L}}\oplus V_{\mathrm{R}}$ of the left- and right-handed fermions,

(3) a finite set of positive constants $\{g_{(k)}\}$ (the gauge coupling constants), parametrizing the general Killing form of the Lie algebra $\mathscr{G}$ of G [the number of these constants is defined as the number of simple components of $\mathscr{G}$, including u(1) factors],

(4) a unitary representation ρ_h on a Hermitian vector space V_h of the Higgs field,

(5) a G-invariant polynomial (Higgs potential) $V_h\overset{V}{\to}\mathbb{R}$ of order four, which is bounded from below,

(6) one complex constant (the Yukawa coupling constant) g_y for every one-dimensional invariant subspace in the decomposition of the representation

$$(V_L^*\otimes V_R\otimes V_h)\oplus(V_L^*\otimes V_R\otimes V_h^*),$$

(7) and an action functional

$$\mathscr{I}:=\mathscr{I}_{\mathrm{EH}}+\mathscr{I}_{\mathrm{Dirac}}+\mathscr{I}_{\mathrm{Yukawa}}+\mathscr{I}_{\mathrm{YM}}+\mathscr{I}_{\mathrm{Higgs}}.$$

Usually, it is assumed that space–time is flat, so that $\mathscr{I}_{\mathrm{EH}}$ is ignored. In particular, the *standard model* is defined by

$$G:=\mathrm{SU}(3)\times\mathrm{SU}(2)\times\mathrm{U}(1) \tag{3}$$

with three coupling constants $(g_{(3)},g_{(2)},g_{(1)})$;

$$\mathrm{V_L}:=\bigoplus_1^3[(1,2,-1/2)\oplus(3,2,1/6)], \tag{4}$$

$$\mathrm{V_R}:=\bigoplus_1^3[(1,1,-1)\oplus(3,1,-1/3)\oplus(3,1,2/3)], \tag{5}$$

where (n_3,n_2,n_1) denote the tensor product, respectively, of an n_3-dimensional representation of SU(3), an n_2-dimensional representation of SU(2), and a one-dimensional representation of U(1) with ''hypercharge'' $y:\rho(e^{i\theta}):=e^{iy\theta}$, $y\in\mathbb{Q}$, $\theta\in[0,2\pi[$;

$$V:=\lambda(\varphi\varphi^*)^2-\mu^2\varphi\varphi^*, \tag{6}$$

with $\lambda,\mu>0$. There are 27 Yukawa coupling constants which, however, are not all independent. In fact, the standard model can be parametrized by 18 constants (cf. Ref. 2).

The full action functional (i.e., with gravity included) in the usual description of the standard model ($N=3$) reads

$$\mathscr{I}:=\frac{1}{16\pi G}\int_{\mathscr{M}}{}^*r_{\mathscr{M}} \tag{7}$$

$$+\int_{\mathscr{M}}{}^*(\psi^{(l)*}i\mathrm{D}_{(l)}\psi^{(l)}+\psi^{(q)*}i\mathrm{D}_{(q)}\psi^{(q)}) \tag{8}$$

$$-\int_{\mathscr{M}}{}^*\Bigg(\sum_{i,j=1}^{N}(\mathbf{g}_y^{(l)})_{ij}\overline{\psi}_{\mathrm{L}_i}^{(l)}(\gamma_5\varphi)\psi_{\mathrm{R}_j}^{(l)}+(\mathbf{g}_y^{(q)})_{ij}\overline{\psi}_{\mathrm{L}_i}^{(u)}$$

$$\times(\gamma_5\varphi)\psi_{\mathrm{R}_j}^{(u)}+(\mathbf{g}_y'^{(q)})_{ij}\overline{\psi}_{\mathrm{L}_i}^{(d')}(\gamma_5\overline{\boldsymbol{\epsilon}\varphi})\psi_{\mathrm{R}_j}^{(d')}\Bigg)+\text{comp. conj.} \tag{9}$$

$$+\frac{1}{g_{(3)}^2}\int_{\mathscr{M}}\mathrm{tr}(\mathbf{C}\wedge{}^*\mathbf{C})+\frac{1}{g_{(2)}^2}\int_{\mathscr{M}}\mathrm{tr}(\mathbf{W}\wedge{}^*\mathbf{W})+\frac{1}{2g_{(1)}^2}\int_{\mathscr{M}}B\wedge{}^*B \tag{10}$$

$$+\int_{\mathscr{M}}(\nabla\varphi)^{*}\wedge *(\nabla\varphi)+\int_{\mathscr{M}} *V \tag{11}$$

$$\equiv \mathscr{T}_{\mathrm{EH}}+\mathscr{T}_{\mathrm{Dirac}}+\mathscr{T}_{\mathrm{Yukawa}}+\mathscr{T}_{\mathrm{YM}}+\mathscr{T}_{\mathrm{Higgs}}. \tag{12}$$

The traces in the definition of the Yang–Mills action (10) are taken with respect to the corresponding fundamental representations of SU(3) and SU(2). Note that $\mathscr{M}$ denotes a Riemannian manifold, which explains the occurence of the apparently wrong relative sign in front of the Higgs potential and the occurence of γ_5 in the Yukawa coupling term (9).

In contrast to a general Yang–Mills model our proposed kit (1) and (2) has the following input:

(1) a finite-dimensional real, compact Lie group G,
(2) a unitary representation $\rho=\rho_{\mathrm{L}}\oplus\rho_{\mathrm{R}}$ on the $\mathbb{Z}_2$-graded Hermitian vector space $\mathrm{V}=\mathrm{V}_{\mathrm{L}}\oplus\mathrm{V}_{\mathrm{R}}$ of the left- and right-handed fermions,
(3) a Dirac operator D,
(4) the general functional: $\mathscr{T}_{\mathrm{D}}$.

As in the ''noncommutative approach'' introduced by Connes and Lott (cf. Refs. 3 and 4), the Higgs representation is not arbitrary but has to lie within the fermionic representation, symbolically: $\rho_h\subset\rho_f$. In fact, this has significant consequences with respect to the relations between the various parameters involved in the model. Hence it might not come as a surprise that there are certain similarities between the Connes–Lott model and the model introduced here in this respect (see below). Of course, the mathematical background is quite different. We mention that with respect to our physical interpretation it is quite natural that all fields involved in the model carry the same representation.

Concerning the *standard model*, the Dirac operator $\mathrm{D}\equiv\widetilde{D}_{\phi}$ is defined by a generalization of the *Dirac–Yukawa operator* D_{ϕ}. It is well known that the Yukawa coupling (9) together with the (standard) Dirac operator D defining (8) can be considered as a new Dirac operator D_{ϕ}—the Dirac–Yukawa operator. The main feature, then, is that this Dirac operator is a ''nonstandard'' Dirac operator (i.e., not associated with a Clifford connection, see below). In fact, such Dirac operators will play a key role in our geometrical description of the standard model. Correspondingly, we shall discuss those operators in some detail in the first part of our paper, which is totally concerned with the mathematical frame of our model. Though the larger portion of Part 1 is actually not new and may be found in much more detail, e.g., in Ref. 5, we nevertheless summarize the basic mathematical notions in order for our paper to be self-contained and to permit full understanding of the issue also for those who are not familiar with the notion of nonstandard Dirac operators. Also, we have emphasized the relations between nonstandard Dirac operators and connections on a (general) Clifford module bundle. This is of technical significance and, moreover, explains how the Higgs field yields a certain connection on a Clifford module bundle. In Part 2 we introduce a certain generalization of the Dirac–Yukawa operator and prove our main theorem. Moreover, we also investigate the ''phenomenological'' consequences of our scheme with respect to the standard model. Finally, we mention some similarities to the Connes–Lott model (cf. Refs. 3, 4, and, concerning the new approach, 6–8). We conclude this paper with an outlook.

Before we start to describe the mathematical frame of our model building kit, however, some remarks concerning its similarity to the Connes–Lott approach to the standard model seem appropriate. Obviously, our notion of a generalized Dirac operator, as defined by (1), is similar to Connes' notion of a ''spectral triple.'' Needless to say that the latter notion is more profound, mathematically, since it offers the possibility of ''new mathematics,'' like Connes' noncommutative geometry (cf. Ref. 4). Also, the idea to of *derive* specific functionals, such as in the case of the standard model of particle physics, from a ''universal functional'' must go back to Connes. For example, in the Connes–Lott approach to the standard model the Dixmier trace serves as the general action functional (cf. Refs. 3 and 4). In a sense this trace can be considered as a special case of the more general Wodzicki residue. Unfortunately, using the Dixmier trace as the universal action functional it seems hard to derive both the Einstein–Hilbert and the Yang–Mills (–Higgs)

action in one stroke (for the pure EH functional see Ref. 9). In fact, in the Connes–Lott description of the standard model the geometric information contained in the Dirac operator is lost. But as Connes has remarked, the Wodzicki residue of D^{-2n+2} with D a Standard Dirac operator (see below) becomes proportional to the Einstein–Hilbert action of gravity (cf. Ref. 10). However, this time the geometrical information contained in the Yang–Mills potential is lost. This follows immediately from D being a Standard Dirac operator (see below). As a natural question one may ask whether it is possible to derive the full action functional (EHYMH action) by considering ''nonstandard'' Dirac operators. In Ref. 11 this has been investigated and affirmatively answered in the case of the Einstein–Hilbert–Yang-Mills functional. In the case of the full action of the standard model and with gravity included the above question was investigated in Ref. 12. However, in this work there is a mistake. In fact, the definition of the Dirac–Yukawa operator is wrong and, as a consequence, the derived functional does not coincide with the action functional of the standard model. As we shall show in the paper at hand, however, by using the right definition of the Dirac–Yukawa operator the properly corrected generalized Dirac–Yukawa operator proposed in Ref. 12 is but a special case of the generalized Dirac–Yukawa operator introduced in part two of our paper and which in fact gives rise to the full action of the standard model. Though the basic idea of our kit is already introduced in Ref. 12, and which indeed affirmatively answers the above-mentioned question, the scheme in Ref. 12, however, is still not general enough to discuss physical implications of the proposed model building kit. This is because in Ref. 12 neither the considered Dirac operator—even if properly corrected—nor the proposed universal action functional is general enough. Both have been remedied in this article.

II. PART 1: THE MATHEMATICAL FRAME

The geometrical setting which we propose in order to describe gauge theories is that of a Clifford module bundle $(\mathscr{E},c)$ over a Riemannian manifold $(\mathscr{M},g)$ of even dimension. Within this setting there exists a distinguished class of operators called generalized Dirac operators. [In the following, the term ''generalized'' simply means ''nonstandard,'' though by a generalized Dirac operator we actually mean the triple (G, ρ, D), with D a (nonstandard) Dirac operator.] We therefore start with a brief review on the notion of Clifford modules and generalized Dirac operators. More details of this issue can be found, e.g., in Ref. 5. Afterwards we shall discuss at some length how a given generalized Dirac operator (1) determines a particular functional $\mathscr{T}_D(\nabla^{\mathscr{E}},\psi)$, using (2).

To get started, let us denote by $(\mathscr{M},g)$ a smooth, closed compact *Riemannian* (spin) manifold without boundary and of even dimension: $\dim(\mathscr{M})\equiv m:=2n(>2)$. Moreover, let $\mathscr{E}:=\mathscr{E}^+\oplus\mathscr{E}^-$ be (the total space of) a $\mathbb{Z}_2$-graded Hermitian vector bundle $\mathscr{E}\xrightarrow{\pi}\mathscr{M}$ over $\mathscr{M}$. The corresponding Hermitian product on $\mathscr{E}$ is indicated by $(,)_{\mathscr{E}}$. If $\Gamma(\mathscr{E})$ denotes the $C^\infty(\mathscr{M})$ module of smooth sections into $\mathscr{E}$, then the induced Hermitian product $(,)_{\Gamma(\mathscr{E})}$ on $\Gamma(\mathscr{E})$ is given by $(,)_{\Gamma(\mathscr{E})}:=\int_{\mathscr{M}}*(,)_{\mathscr{E}}$. Here, ''$*$'' means the Hodge map regarding the Riemannian metric g on $\mathscr{M}$.

Definition 1: A *generalized Dirac operator* D is any odd first-order differential operator acting on sections $\psi\in\Gamma(\mathscr{E})$:

$$D:\Gamma(\mathscr{E}^\pm)\to\Gamma(\mathscr{E}^\mp), \tag{13}$$

so that D^2 is a *generalized Laplacian*, i.e., there exists a connection: $\Gamma(\mathscr{E})\xrightarrow{\hat\nabla^{\mathscr{E}}}\Gamma(T^*\mathscr{M}\otimes\mathscr{E})$ on the vector bundle $\mathscr{E}$ and an endomorphism $\mathscr{F}\in\Gamma(\mathrm{End}(\mathscr{E}))$, both uniquely defined by D, such that

$$D^2=\Delta^{\hat\nabla^{\mathscr{E}}}+\mathscr{F}. \tag{14}$$

Here, $\Delta^{\hat\nabla^{\mathscr{E}}}:=-ev_g(\hat\nabla^{T^*\mathscr{M}\otimes\mathscr{E}}\hat\nabla^{\mathscr{E}})$ denotes the horizontal (Bochner) Laplacian associated with the connection $\hat\nabla^{\mathscr{E}}$, and ''ev_g'' means the evaluation map regarding the metric g.

Remark 1: D exists on $\mathscr{E}$ iff $\mathscr{E}$ denotes a *Clifford module* bundle over $(\mathscr{M},g)$, i.e., there exists a graded (left) action on $\mathscr{E}$.

$$c:\mathscr{C}(\mathscr{M})\times\mathscr{E}\to\mathscr{E}. \tag{15}$$

of the Clifford bundle $\mathscr{C}(\mathscr{M})\overset{\tau}{\to}\mathscr{M}$ associated with the metric g. [Here, the fiber $\tau^{-1}(x)$ is isomorphic to the Clifford algebra generated by the elements $u,v\in T_x^*\mathscr{M}$, using the relation: $uv+vu:=-2g_x(u,v)$, $\forall x\in\mathscr{M}$.] This holds because in the case that D denotes a generalized Dirac operator, this operator induces via

$$\mathscr{C}(\mathscr{M})\times\mathscr{E}\to\mathscr{E}(df,\psi)\mapsto c(df)\psi:=[\mathrm{D},f]\psi,\quad f\in C^\infty(\mathscr{M}) \tag{16}$$

a graded left action of the Clifford bundle on $\mathscr{E}$ (cf. Ref. 5). Conversely, if $(\mathscr{E},c)$ denotes a Clifford module bundle over $(\mathscr{M},g)$, then the well-known construction

$$\Gamma(\mathscr{E})\overset{\nabla^{\mathscr{E}}}{\to}\Gamma(T^*\mathscr{M}\otimes\mathscr{E})\hookrightarrow\Gamma(\mathscr{C}(\mathscr{M})\otimes\mathscr{E})\overset{c}{\to}\Gamma(\mathscr{E}) \tag{17}$$

defines an operator $D_{\nabla^{\mathscr{E}}}:=c(\nabla^{\mathscr{E}})$ satisfying (13) and (14) for any connection $\nabla^{\mathscr{E}}$ on $\mathscr{E}$. Moreover, it is easily checked that such a defined operator also fulfills (16).

Hence, from now on $\mathscr{E}\equiv(\mathscr{E},c)$ will always denote a Clifford module bundle over $\mathscr{M}\equiv(\mathscr{M},g)$. As a consequence, the endomorphism bundle End $(\mathscr{E})$ is also a Clifford module and it follows that (cf. Ref. 5)

$$\mathrm{End}(\mathscr{E})\simeq\mathscr{C}(\mathscr{M})\otimes\mathrm{End}_{\mathrm{Cl}}(\mathscr{E}), \tag{18}$$

where $\mathrm{End}_{\mathrm{Cl}}(\mathscr{E})$ denotes the algebra bundle of bundle endomorphisms of $\mathscr{E}$ supercommuting with the action of $\mathscr{C}(\mathscr{M})$, i.e.,

$$\mathrm{End}_{\mathrm{Cl}}(\mathscr{E}):=\{\sigma\in\mathrm{End}(\mathscr{E})\,|\,[\![c(a),\sigma]\!]=0,\forall a\in\mathscr{C}(\mathscr{M})\}. \tag{19}$$

If in addition $\mathscr{M}$ is assumed to be a spin manifold, we have $\mathscr{C}(\mathscr{M})_{\mathrm{C}}\simeq\mathrm{End}(\mathrm{S})$ and correspondingly $\mathrm{End}_{\mathrm{Cl}}(\mathscr{E})\simeq\mathrm{End}(\mathrm{E})$, where S denotes the *spinor* bundle and E a vector bundle over $\mathscr{M}$. In this case $\mathscr{E}$ is called a *twisted spinor bundle* over $\mathscr{M}$ and we have (cf. Ref. 5)

$$\mathscr{E}\simeq\mathrm{S}\otimes\mathrm{E}. \tag{20}$$

We say that the Clifford module bundle $(\mathscr{E},c)$ has a *twisting graduation* if $\mathrm{End}_{\mathrm{Cl}}(\mathscr{E})$ possesses a (nontrivial) $\mathbb{Z}_2$ graduation (cf. Ref. 11). Clearly, in the case of (20) this is equivalent to saying that the vector bundle $\mathrm{E}=\underset{\sim}{\mathrm{E}}_{\mathrm{L}}\oplus\mathrm{E}_{\mathrm{R}}$ is $\mathbb{Z}_2$ graded, as well.

Definition 2: Let $\widetilde{\mathrm{D}}$ be a generalized Dirac operator on $\mathscr{E}$. It is said to be compatible with the Clifford action c if it satisfies the relation (16). Then, let

$$\mathscr{D}(\mathscr{E}):=\{\widetilde{\mathrm{D}}\,|\,[\widetilde{\mathrm{D}},f]=c(df\ ),\forall f\in C^\infty(\mathscr{M})\} \tag{21}$$

be the set of all generalized Dirac operators on $\mathscr{E}$ which are compatible with the Clifford action c. We have

$$\mathscr{D}(\mathscr{E})\simeq\Omega^0(\mathscr{M},\mathrm{End}^-(\mathscr{E})). \tag{22}$$

[Since the bundle $\mathscr{E}=\mathscr{E}^+\oplus\mathscr{E}^-$ is $\mathbb{Z}_2$ graded, so is the associated endomorphism bundle $\mathrm{End}(\mathscr{E})$, i.e., $\mathrm{End}(\mathscr{E})=\mathrm{End}^+(\mathscr{E})\oplus\mathrm{End}^-(\mathscr{E})$, with $\mathrm{End}^+(\mathscr{E}):=\mathrm{End}(\mathscr{E}^+)\oplus\mathrm{End}(\mathscr{E}^-)$ and $\mathrm{End}^-(\mathscr{E}):=Hom(\mathscr{E}^+,\mathscr{E}^-)\oplus Hom(\mathscr{E}^-,\mathscr{E}^+)$.] Also, let us denote by

$$\mathscr{A}(\mathscr{E}):=\{\nabla^{\mathscr{E}}\,|\,\Gamma(\mathscr{E})\overset{\nabla^{\mathscr{E}}}{\to}\Gamma(T^*\mathscr{M}\otimes\mathscr{E})\} \tag{23}$$

the set of all (even) connections on $\mathscr{E}$.

As a consequence of (18), there exists a natural class of connections—called *Clifford connections*—on any Clifford module bundle $\mathscr{E}$:

$$\mathscr{A}_{\mathrm{Cl}}(\mathscr{E}):=\{\nabla^{\mathscr{E}}\in\mathscr{A}(\mathscr{E})\,|\,[\nabla^{\mathscr{E}},c(a)]=c(\nabla^{\mathrm{Cl}}a),\forall a\in\Gamma(\mathscr{C}(\mathscr{M}))\}\subset\mathscr{A}(\mathscr{E}), \tag{24}$$

where ∇^{Cl} is the induced Levi–Cevita connection on $\mathscr{C}(\mathscr{M})$. Note, in the case of a twisted spinor bundle (20) any Clifford connection $\nabla^{\mathscr{E}} \in \mathscr{A}_{\mathrm{Cl}}(\mathscr{E})$ takes the form of a tensor product connection (cf. Ref. 5)

$$\nabla^{\mathscr{E}} \equiv \nabla^{\mathrm{S}\otimes\mathrm{E}} := \nabla^{\mathrm{S}} \otimes \mathbf{1}_E + \mathbf{1}_S \otimes \nabla^{\mathrm{E}}, \tag{25}$$

where, respectively, ∇^{S} denotes the spin connection on S and ∇^{E} any connection on the vector bundle E. In general we have

$$\begin{aligned} \mathscr{A}(\mathscr{E}) &\simeq \Omega^1(\mathscr{M}, \mathrm{End}^+(\mathscr{E})), \\ \mathscr{A}_{\mathrm{Cl}}(\mathscr{E}) &\simeq \Omega^1(\mathscr{M}, \mathrm{End}^+_{\mathrm{Cl}}(\mathscr{E})), \end{aligned} \tag{26}$$

where the latter isomorphism follows from (18).

Remark 2: Using the linear isomorphism

$$\begin{aligned} \Lambda T^*\mathscr{M} &\xrightarrow{\mathbf{c}} \mathscr{C}(\mathscr{M}), \\ e^{i_1} \wedge e^{i_2} \cdots \wedge e^{i_k} &\mapsto e^{i_1} e^{i_2} \cdots e^{i_k}, \quad \forall\, 0 \leqslant k \leqslant m, \end{aligned} \tag{27}$$

between the Grassmann and the Clifford bundle, where $\{e^i\}_{1\leqslant i\leqslant m}$ denotes a local orthonormal basis in $T^*\mathscr{M}$ and Clifford multiplication is indicated by juxtaposition, the Clifford action c induces a linear mapping, also denoted by c,

$$\begin{aligned} \Omega^p(\mathscr{M}, \mathrm{End}^{\pm}(\mathscr{E})) &\xrightarrow{c} \Omega^0(\mathscr{M}, \mathrm{End}^{\mp}(\mathscr{E})), \\ \alpha &\mapsto c(\alpha). \end{aligned} \tag{28}$$

Lemma 1: In the case of $p=1$ *the linear mapping (28) has a canonical right inverse defined by*

$$\begin{aligned} \delta_\xi : \Omega^p(\mathscr{M}, \mathrm{End}^{\mp}(\mathscr{E})) &\to \Omega^{p+1}(\mathscr{M}, \mathrm{End}^{\pm}(\mathscr{E})), \\ \alpha &\mapsto \xi \wedge \alpha, \end{aligned} \tag{29}$$

where $\xi \in \Omega^1(\mathscr{M}, \mathrm{End}^-(\mathscr{E}))$ *is locally given by*

$$\xi := -\frac{1}{m}\, g(e_a, e_b) e^a \otimes c(e^b) \otimes \mathbf{1}_{\mathrm{End}_{\mathrm{Cl}}(\mathscr{E})}. \tag{30}$$

(Throughout this paper we adopt Einstein's convention for summation.) The product in (29) simply means $(\sigma\otimes a)\wedge(\sigma'\otimes a') := \sigma\wedge\sigma'\otimes aa'$ for all homogeneous elements $\sigma\otimes a, \sigma'\otimes a' \in \Omega^*(\mathscr{M}, \mathrm{End}(\mathscr{E})) \simeq \Gamma(\Lambda T^*\mathscr{M} \otimes \mathrm{End}(\mathscr{E}))$. Again, $\{e^a\}_{1\leqslant a\leqslant m}$ is a basis in $T^*\mathscr{M}$ and $\{e_a\}_{1\leqslant a\leqslant m}$ is its dual. Note that this ''wedge product'' is not graded commutative and that $\Omega^*(\mathscr{M}, \mathrm{End}(\mathscr{E}))$ is a bigraded algebra. The map (29) is even with respect to the total grading.

Proof: Obviously, this follows by construction.

Remark 3: The form ξ, locally defined by (30), can be characterized via

$$\begin{aligned} \nabla^{T^*\mathscr{M}\otimes\mathrm{End}(\mathscr{E})}\xi &\equiv 0, \quad \forall\, \nabla^{\mathscr{E}} \in \mathscr{A}_{\mathrm{Cl}}(\mathscr{E}), \\ c(\xi) &= \mathbf{1}_{\mathscr{E}}. \end{aligned} \tag{31}$$

Lemma 2: Let c *be the linear mapping (28) restricted to* $\Omega^1(\mathscr{M}, \mathrm{End}^+(\mathscr{E}))$. *Then we have*

$$\mathscr{D}(\mathscr{E}) \simeq \mathscr{A}(\mathscr{E})/\ker(c). \tag{32}$$

Proof: For $p := \delta_\xi c : \Omega^1(\mathscr{M}, \mathrm{End}^+(\mathscr{E})) \to \Omega^1(\mathscr{M}, \mathrm{End}^+(\mathscr{E}))$ we get $p^2 = p$ and thus

$$\Omega^1(\mathscr{M},\mathrm{End}^+(\mathscr{E}))=\mathrm{im}(p)\oplus\mathrm{im}(q), \tag{33}$$

with $q:=\mathbf{1}-p$. Restricting the linear mapping (28) to $\Omega^1(\mathscr{M},\mathrm{End}^+(\mathscr{E}))$ yields the identities

$$pc\equiv p,\quad cp\equiv c. \tag{34}$$

Since δ_ξ is a right inverse of c we have $\ker(c)\subset\mathrm{im}(q)$. Moreover, for all $\alpha\in\mathrm{im}(p)$ with $c(\alpha)=0$ (34) implies $\alpha\equiv 0$. Hence

$$\ker(c)=\mathrm{im}(q). \tag{35}$$

The statement follows from

$$\mathscr{A}(\mathscr{E})\simeq\Omega^1(\mathscr{M},\mathrm{End}^+(\mathscr{E}))\overset{c}{\to}\Omega^0(\mathscr{M},\mathrm{End}^-(\mathscr{E}))\simeq\mathscr{D}(\mathscr{E}) \tag{36}$$

and we are done. Note that actually we have shown that the sequence

$$0\to\ker(c)\to\Omega^1(\mathscr{M},\mathrm{End}^+\ \mathscr{E})\overset{c}{\to}\Omega^0(\mathscr{M},\mathrm{End}^-\ \mathscr{E})\to 0$$

is exact and splits. Also, in this case the kernel of the mapping (28) becomes explicit.

Definition 3: Two connections $\nabla^{\mathscr{E}},\widetilde{\nabla}^{\mathscr{E}}\in\mathscr{A}(\mathscr{E})$ are defined to be equivalent iff

$$\nabla^{\mathscr{E}}-\widetilde{\nabla}^{\mathscr{E}}\in\ker(c). \tag{37}$$

By the preceding Lemma this is equivalent to

$$\nabla^{\mathscr{E}}\sim\widetilde{\nabla}^{\mathscr{E}}\Leftrightarrow\widetilde{\nabla}^{\mathscr{E}}=\nabla^{\mathscr{E}}+\omega,$$

$$\omega\in\mathrm{im}(q)\subset\Omega^1(\mathscr{M},\mathrm{End}^+(\mathscr{E})). \tag{38}$$

Therefore, any Dirac operator $\mathrm{D}\in\mathscr{D}(\mathscr{E})$ is uniquely associated with an equivalence class of connections $[\nabla^{\mathscr{E}}]$ on $\mathscr{E}$ so that $\mathrm{D}_{\nabla^{\mathscr{E}}}=\mathrm{D}$.

Remark 4: Let $\widetilde{\mathrm{D}}\in\mathscr{D}(\mathscr{E})$ be a given Dirac operator on $\mathscr{E}$. Then,

$$\widetilde{\nabla}^{\mathscr{E}}:=\nabla^{\mathscr{E}}+\delta_\xi(\widetilde{\mathrm{D}}-\mathrm{D}_{\nabla^{\mathscr{E}}}) \tag{39}$$

defines a connection on $\mathscr{E}$, so that

$$\mathrm{D}_{\widetilde{\nabla}^{\mathscr{E}}}=\widetilde{\mathrm{D}}, \tag{40}$$

where $\nabla^{\mathscr{E}}\in\mathscr{A}(\mathscr{E})$ denotes any connection on $\mathscr{E}$. Clearly, this ambiguity simply reflects that $\mathscr{D}(\mathscr{E})$ is an affine space and thus a given Dirac operator $\widetilde{\mathrm{D}}\in\mathscr{D}(\mathscr{E})$ may be decomposed in infinitely many ways like

$$\widetilde{\mathrm{D}}=\mathrm{D}+\Phi_{\mathrm{D}} \tag{41}$$

with $\Phi_{\mathrm{D}}:=\widetilde{\mathrm{D}}-\mathrm{D}\in\Omega^0(\mathscr{M},\mathrm{End}^-(\mathscr{E}))$.

Definition 4: We call a Dirac operator $\mathrm{D}\in\mathscr{D}(\mathscr{E})$ a *standard Dirac operator* (SDO) if there is a Clifford connection $\nabla^{\mathscr{E}}\in\mathscr{A}_{\mathrm{Cl}}(\mathscr{E})$ so that

$$\mathrm{D}=\mathrm{D}_{\nabla^{\mathscr{E}}}. \tag{42}$$

Lemma 3: Let $\nabla^{\mathscr{E}},\widetilde{\nabla}^{\mathscr{E}}\in\mathscr{A}_{\mathrm{Cl}}(\mathscr{E})$ be Clifford connections on the Clifford module bundle $\mathscr{E}$ with $\nabla^{\mathscr{E}}\sim\widetilde{\nabla}^{\mathscr{E}}$. Then we have $\nabla^{\mathscr{E}}\equiv\widetilde{\nabla}^{\mathscr{E}}$.

Proof: Using (38), $\nabla^{\mathscr{E}},\widetilde{\nabla}^{\mathscr{E}}\in\mathscr{A}_{\mathrm{Cl}}(\mathscr{E})$ implies that there exists a $\omega:=\nabla^{\mathscr{E}}-\widetilde{\nabla}^{\mathscr{E}}=\mathbf{1}_{\mathrm{Cl}}\otimes A$ with $A\in\Omega^1(\mathscr{M},\mathrm{End}^+_{\mathrm{Cl}}(\mathscr{E}))$. By assumption, we have

$$c(\omega)=c(e^\mu)\otimes A_\mu=0, \tag{43}$$

where $\{e^\mu\}_{1\leqslant\mu\leqslant m}$ is a local orthonormal frame. Hence, $A_\mu=0$, $\forall\,\mu=1,...,m$, which proves the lemma.

We therefore have shown that the class of connections defining a SDO on $\mathscr{E}$ admits a canonical representative. In what follows we shall always denote by $\mathrm{D}\in\mathscr{D}(\mathscr{E})$ a SDO and by $\nabla^{\mathscr{E}}\in\mathscr{A}_{\mathrm{Cl}}(\mathscr{E})$ the appropriate Clifford connection, so that $\mathrm{D}=\mathrm{D}_\nabla$. In contrast, by $\widetilde{\mathrm{D}}\in\mathscr{D}(\mathscr{E})$ and $\widetilde{\nabla}^{\mathscr{E}}\in\mathscr{A}(\mathscr{E})$, respectively, we denote an arbitrary Dirac operator and connection on $\mathscr{E}$.

Let $\widetilde{\mathrm{D}}\in\mathscr{D}(\mathscr{E})$ be an arbitrary Dirac operator on the Clifford module bundle $\mathscr{E}$ and let

$$\widetilde{\nabla}^{\mathscr{E}}:=\nabla^{\mathscr{E}}+\delta_\xi(\widetilde{\mathrm{D}}-\mathrm{D}). \tag{44}$$

Then, in Ref. 11 it is shown that (see also Ref. 13)

$$\widetilde{\mathrm{D}}^2=\Delta^{\hat{\nabla}^{\mathscr{E}}}+\mathscr{F}^{\widetilde{\nabla}^{\mathscr{E}}}. \tag{45}$$

Here, respectively, the connection $\hat{\nabla}\in\mathscr{A}(\mathscr{E})$ and the endomorphism $\mathscr{F}^{\widetilde{\nabla}^{\mathscr{E}}}\in\Gamma(\mathrm{End}(\mathscr{E}))$ are defined by

$$\hat{\nabla}^{\mathscr{E}}:=\widetilde{\nabla}^{\mathscr{E}}+\omega_{\widetilde{\nabla}^{\mathscr{E}}} \tag{46}$$

and

$$\mathscr{F}^{\widetilde{\nabla}^{\mathscr{E}}}:=c(\widetilde{\nabla}^{\mathscr{E}\,2})+\mathrm{ev}_g(\widetilde{\nabla}^{T^*\mathscr{M}\otimes\mathrm{End}(\mathscr{E})}\omega_{\widetilde{\nabla}^{\mathscr{E}}}+\omega^2_{\widetilde{\nabla}^{\mathscr{E}}}), \tag{47}$$

where the one-form $\omega_{\widetilde{\nabla}^{\mathscr{E}}}\in\Omega^1(\mathscr{M},\mathrm{End}^+(\mathscr{E}))$ is locally given by

$$\omega_{\widetilde{\nabla}^{\mathscr{E}}}:=-\tfrac{1}{2}g(e_\mu,e_\nu)e^\mu\otimes c(e^\lambda)([\widetilde{\nabla}^{\lambda}_{\mathscr{E}},c(e^\nu)]+\Gamma^{\nu}_{\sigma\lambda}c(e^\sigma)). \tag{48}$$

The Γ's denote the Christoffel symbols defined by the metric g.

Lemma 4: The endomorphism $\mathscr{F}^{\widetilde{\nabla}^{\mathscr{E}}}$ defined in (47) is independent of the representative $\widetilde{\nabla}^{\mathscr{E}}\in\mathscr{A}(\mathscr{E})$ of the class of connections defining the Dirac operator $\widetilde{\mathrm{D}}$.

Proof: To prove this lemma we introduce the affine mapping

$$\overline{\omega}:\mathscr{A}(\mathscr{E})\to\mathscr{A}(\mathscr{E}),\quad \widetilde{\nabla}^{\mathscr{E}}\mapsto\widetilde{\nabla}^{\mathscr{E}}+\omega_{\widetilde{\nabla}^{\mathscr{E}}} \tag{49}$$

on $\mathscr{A}(\mathscr{E})$ and show that this mapping is well defined on $\mathscr{A}(\mathscr{E})/\ker(c)$. Let $[\widetilde{\nabla}^{\mathscr{E}}]$ be the equivalence class of connections defining the given Dirac operator $\widetilde{\mathrm{D}}\in\mathscr{D}(\mathscr{E})$ and denote by $\widetilde{\nabla}^{\mathscr{E}},\widetilde{\nabla}'^{\mathscr{E}}\in[\widetilde{\nabla}^{\mathscr{E}}]$ two representatives of this class. Hence, $\alpha:=\widetilde{\nabla}^{\mathscr{E}}-\widetilde{\nabla}'^{\mathscr{E}}\in\ker(c)$ and with respect to a local orthonormal frame we obtain

$$\hat{\nabla}^{\mathscr{E}}-\hat{\nabla}'^{\mathscr{E}}=\alpha-\tfrac{1}{2}\delta_{\mu\nu}e^\mu\otimes c(e^\lambda)[i_\lambda\alpha,c(e^\nu)] \tag{50}$$

$$=\tfrac{1}{2}\delta_{\mu\nu}e^\mu\otimes[c(\alpha),c(e^\nu)]_+ \tag{51}$$

$$=0, \tag{52}$$

where i_μ is the inner derivative with respect to the local vector field e_μ and $[,]_+$ means the anticommutator. Consequently, the map: $\widetilde{\mathrm{D}}\mapsto\Delta^{\hat{\nabla}^{\mathscr{E}}}$ with $\hat{\nabla}^{\mathscr{E}}$ given by (46), is well defined. Hence the endomorphism $\mathscr{F}^{\widetilde{\nabla}^{\mathscr{E}}}=\widetilde{\mathrm{D}}^2-\Delta^{\hat{\nabla}^{\mathscr{E}}}$ only depends on the Dirac operator $\widetilde{\mathrm{D}}\in\mathscr{D}(\mathscr{E})$ which proves the lemma.

Corollary 1: The endomorphism $\mathscr{F}^{\widetilde{\nabla}^{\mathscr{E}}}\in\Gamma(\mathrm{End}(\mathscr{E}))$ does not depend on the decomposition (44). In particular, it does not depend on the chosen Clifford connection $\nabla^{\mathscr{E}}$.

Proof: By Lemma 4 the proof is obvious.

Remark 5: The corresponding linear part of the affine map (49) has a nontrivial kernel; especially

$$\overline{\omega}|_{\mathscr{A}_{\mathrm{Cl}}(\mathscr{E})}=\mathbf{1}_{\mathscr{A}_{\mathrm{Cl}}(\mathscr{E})}. \tag{53}$$

In this case the decomposition of the square of the appropriate SDO is but the usual *Lichnerowicz formula* and the endomorphism $\mathscr{F}$ takes its well-known form

$$\mathscr{F}^{\nabla^{\mathscr{E}}} = c[(\nabla^{\mathscr{E}})^2] \tag{54}$$

$$= \tfrac{1}{4} r_{\mathscr{M}}\, \mathbf{1}_{\mathscr{E}} + c(F^{\mathscr{E}/S}), \tag{55}$$

where $r_{\mathscr{M}}$ is the Ricci scalar curvature on the base manifold $\mathscr{M}$ and $F^{\mathscr{E}/S} := (\nabla^{\mathscr{E}})^2 - (\nabla^{\mathrm{Cl}})^2 \otimes 1_{\mathrm{End}_{\mathrm{Cl}}(\mathscr{E})}$ denotes the relative curvature on the Clifford module bundle $\mathscr{E}$. Since in this particular case the relative curvature only depends on the connection on the twisting part of the Clifford module bundle $\mathscr{E}$, $F^{\mathscr{E}/S}$ is also called the *twisting curvature*.

We now turn to the notion of superconnections which can be considered as a generalization of connections on a $\mathbb{Z}_2$-graded vector bundle. As is well known, superconnections permit the generalization of the one-to-one correspondence between SDO and Clifford connections to arbitrary Dirac operators and Clifford superconnections on a Clifford module bundle. Hence, there is no essential difference between talking about Dirac operators and Clifford superconnections. We therefore call into mind the following.

Definition 5: A *superconnection* on a $\mathbb{Z}_2$-graded vector bundle $\mathscr{E}$ is any odd first-order differential operator ($\pm$ is understood with respect to the *total* grading)

$$\boldsymbol{\nabla}^{\mathscr{E}} : [\Omega^*(\mathscr{M}, \mathscr{E})]^{\pm} \to [\Omega^*(\mathscr{M}, \mathscr{E})]^{\mp}, \tag{56}$$

satisfying the generalized Leibniz rule

$$\boldsymbol{\nabla}^{\mathscr{E}}(\lambda \wedge \alpha) = \mathrm{d}\lambda \wedge \alpha + (-1)^{|\alpha|} \alpha \wedge \boldsymbol{\nabla}^{\mathscr{E}} \alpha, \tag{57}$$

for all $\lambda \in \Omega^*(\mathscr{M})$ and $\alpha \in \Omega^*(\mathscr{M}, \mathscr{E})$. If in addition $\mathscr{E}$ denotes a Clifford module bundle and the superconnection fulfills

$$[\boldsymbol{\nabla}^{\mathscr{E}}, c(a)] = c(\nabla^{\mathrm{Cl}} a), \quad \forall a \in \Gamma(\mathscr{C}(\mathscr{M})), \tag{58}$$

it is called a *Clifford superconnection* (CSC) (cf. Ref. 5). In this case we have (cf. loc. cit.)

$$\boldsymbol{\nabla}^{\mathscr{E}} \mapsto \mathrm{D}_{\boldsymbol{\nabla}} \varepsilon := c(\boldsymbol{\nabla}^{\mathscr{E}}) \tag{59}$$

is one-to-one. [Note, by abuse of notation we suppress the linear isomorphism (27).] Note that because of the generalized Leibniz rule any superconnection locally takes the form

$$\begin{gathered} \boldsymbol{\nabla}^{\mathscr{E}} = d + \sum_{k=0}^{m} \mathscr{A}_{[k]}, \\ \mathscr{A}_{[k]} \in [\Omega^k(\mathscr{M}, \mathrm{End}(\mathscr{E}))]^{-}. \end{gathered} \tag{60}$$

In particular, in the case of a CSC

$$\begin{gathered} \mathscr{A}_{[1]} = \boldsymbol{\omega}^{\mathrm{Cl}} \otimes \mathbf{1}_{\mathrm{End}_{\mathrm{Cl}}(\mathscr{E})} + \mathbf{1}_{\mathrm{Cl}} \otimes A, \\ \mathscr{A}_{[k]} = \sum_{1 \le i_1 < \cdots < i_k \le m} e^{i_1} \wedge \cdots \wedge e^{i_k} \otimes \mathbf{1}_{\mathrm{Cl}} \otimes B_{i_1 \ldots i_k}, \quad \forall k = 0,2,\ldots,m, \end{gathered} \tag{61}$$

where $\boldsymbol{\omega}^{\mathrm{Cl}}$ denotes the induced Levi-Civita form on the Clifford bundle $\mathscr{C}(\mathscr{M})$ and $A, B \in [\Omega^*(\mathscr{M}, \mathrm{End}_{\mathrm{Cl}}(\mathscr{E}))]^{-}$. Again, $\{e^i\}_{1 \le i \le m}$ is a local orthonormal frame in $T^*\mathscr{M}$. Moreover, if $\mathscr{M}$ denotes a spin-manifold, then any CSC is of the form (cf. Ref. 5)

$$\boldsymbol{\nabla}^{\mathscr{E}} = \nabla^S \otimes \mathbf{1}_{\mathrm{E}} + \mathbf{1}_{\mathrm{S}} \otimes \boldsymbol{\nabla}^{\mathrm{E}}. \tag{62}$$

Clearly, the notion of a CSC completely parallels that of a Clifford connection and coincides with the latter iff $B\equiv 0$. However, in general a CSC is not just defined by an element of $\Omega^1(\mathscr{M},\mathrm{End}^+_{\mathrm{Cl}}(\mathscr{E}))$. This will be of crucial importance in what follows. Indeed, in Ref. 11 it was shown how the combined Einstein–Hilbert–Yang–Mills (EHYM) action functional can be derived using non-SDOs. Before we define a particular functional on $\mathscr{D}(\mathscr{E})$ we still give another remark.

Remark 6: Let $\widetilde{\mathrm{D}}\in\mathscr{D}(\mathscr{E})$ be a Dirac operator on $\mathscr{E}$ and $\boldsymbol{\nabla}^{\mathscr{E}}$ be the corresponding CSC. Then we have

$$\widetilde{\nabla}'^{\mathscr{E}}:=\nabla^{\mathscr{E}}+\omega \tag{63}$$

with

$$\omega:=\omega_\phi+e^i\otimes\left(\sum_{k=1}^{m-1}\frac{1}{k!}\sum_{i_1,\ldots,i_k=1}^{m}c(e^{i_1})\cdots c(e^{i_k})\otimes B_{ii_1\ldots i_k}\right), \tag{64}$$

where $\omega_\phi:=\delta_\xi\phi$, $\phi\equiv\mathscr{A}_{[0]}\in\Omega^0(\mathscr{M},\mathrm{End}^-(\mathscr{E}))$, so that

$$\mathrm{D}_{\widetilde{\nabla}'^{\mathscr{E}}}=\widetilde{\mathrm{D}}. \tag{65}$$

In particular, $\widetilde{\nabla}'^{\mathscr{E}}\sim\widetilde{\nabla}^{\mathscr{E}}$, where the latter is defined by (44). Note, the local decomposition of the form $\omega\in\Omega^1(\mathscr{M},\mathrm{End}^+(\mathscr{E}))$ may also contain a degree $[k]=1$ form.

After summarizing the notion of Clifford modules and generalized Dirac operators we have also proved some lemmas, which permit an understanding of the relations between Dirac operators and connections on a Clifford module bundle. The reason to clarify these relations mainly is motivated by the following.

Definition 6: Let $(\mathscr{M},g)$ be a closed, compact, orientable Riemannian manifold of even dimension $(m=2n>2)$ and without boundary. Also, let $(\mathscr{E},c)$ be a Clifford module bundle over $\mathscr{M}$ and let $\mathscr{D}(\mathscr{E})$ be the affine space of all (generalized) Dirac operators compatible with the Clifford action c on $\mathscr{E}$. Then, we introduce the functional

$$\begin{aligned}\mathrm{res}:\mathscr{D}(\mathscr{E})&\to\mathbb{C}\\ \widetilde{\mathrm{D}}&\mapsto\mathrm{res}(\widetilde{\mathrm{D}}^{-2n+2}).\end{aligned} \tag{66}$$

Here, res means the Wodzicki residue, which in this case takes the explicit form (cf. Refs. 14–17)

$$\mathrm{res}(\widetilde{\mathrm{D}}^{-2n+2})=\frac{2}{\Gamma(n-1)}\int_{\mathscr{M}}*\mathrm{tr}_{\mathscr{E}}\left[\frac{1}{6}\,r_{\mathscr{M}}-\mathscr{F}^{\widetilde{\nabla}^{\mathscr{E}}}\right]. \tag{67}$$

and where the endomorphism $\mathscr{F}^{\widetilde{\nabla}^{\mathscr{E}}}\in\Gamma(\mathrm{End}(\mathscr{E}))$ is given by (47).

Since there exists a connection $\widetilde{\nabla}^{\mathscr{E}}\in\mathscr{A}(\mathscr{E})$ for every $\widetilde{\mathrm{D}}\in\mathscr{D}(\mathscr{E})$, so that $\widetilde{\mathrm{D}}=\widetilde{\mathrm{D}}_{\widetilde{\nabla}^{\mathscr{E}}}$, this functional may be interpreted, alternatively, as a functional defined on $\mathscr{A}(\mathscr{E})$. However, we are interested less in the functional (66) itself than in the fact that for a *given* Dirac operator $\widetilde{\mathrm{D}}\in\mathscr{D}(\mathscr{E})$ the Wodzicki residue of $\widetilde{\mathrm{D}}^{-2n+2}$ can be considered as a functional

$$\mathscr{T}'_{\mathrm{D}}(\widetilde{\nabla}^{\mathscr{E}}):=\mathrm{res}(\widetilde{\mathrm{D}}^{-2n+2}), \tag{68}$$

of all connections $\widetilde{\nabla}\in\mathscr{A}(\mathscr{E})$ so that $c(\widetilde{\nabla}^{\mathscr{E}})=\widetilde{\mathrm{D}}$. In other words, with respect to a given Dirac operator (68) can be considered as a certain functional on the subspace of all (endomorphism valued) differential forms defining this Dirac operator. In the case that $\widetilde{D}$ denotes a SDO the functional (68) is proportional to the Einstein–Hilbert action. We again stress that this was recognized by Connes (cf. Ref. 10) and was proved in Ref. 18. From a more general point of view (see below) this was also discovered in Ref. 17, which in turn was the starting point to deal with non-SDOs in Refs. 19 and 11.

There is still another motivation for (68): the connection of (68) to the heat trace associated with (the square of) a Dirac operator. For this let us remind the reader that there is a natural functional on $\mathscr{D}(\mathscr{E})$:

$$\begin{aligned} \mathscr{D}(\mathscr{E}) &\to \mathbb{C}, \\ \widetilde{\mathrm{D}} &\mapsto \mathrm{Tr}\, e^{-\tau\widetilde{\mathrm{D}}^2}. \end{aligned} \tag{69}$$

Though in general one is not able to calculate this functional, it is well known that it has an asymptotic expansion:

$$\mathrm{Tr}\, e^{-\tau\widetilde{\mathrm{D}}^2} \sim (4\pi\tau)^{-n} \sum_{k\geqslant 0} \tau^{(k-2n)/2} \sigma_k(\widetilde{\mathrm{D}}^2) \quad (\tau \to 0), \tag{70}$$

where the coefficients (Seeley–DeWitt coefficients)

$$\sigma_k(\widetilde{\mathrm{D}}^2) := \int_{\mathscr{M}} * \mathrm{tr}_{\mathscr{E}}\, \sigma_k(x;\widetilde{\mathrm{D}}^2) \tag{71}$$

are known to contain geometric information. In particular, the subleading term $\sigma_2(\widetilde{\mathrm{D}}^2)$ is of the general form (cf. Ref. 20)

$$\sigma_2(\widetilde{\mathrm{D}}^2) = \int_{\mathscr{M}} * \mathrm{tr}_{\mathscr{E}} \left[\frac{1}{6}\, r_{\mathscr{M}} - \mathscr{F} \right], \tag{72}$$

and thus is proportional to (66). Of course, this is by no means accidental. In general, for all $(2n-k)/2 \notin \mathbb{Z}_-$ ($\mathscr{M}$ smooth) one has (cf. Ref. 15)

$$\sigma_k(\widetilde{\mathrm{D}}^2) = \frac{\Gamma((2n-k)/2)}{2}\, \mathrm{res}(\widetilde{\mathrm{D}}^{-2n+k}). \tag{73}$$

From this point of view the statement of our main theorem (as given in the Introduction) may be rephrased as follows:

There exists a Hamiltonian (generalized Laplacian) $\mathscr{H}$ such that the subleading term in the asymptotic expansion of the corresponding heat trace associated with this Hamiltonian is proportional to the classical bosonic action of the standard model with gravity included. Moreover, this Hamiltonian has a square root, $\mathscr{H} = \widetilde{\mathrm{D}}^2$, which gives rise also to the fermionic action of the standard model.

In what follows we assume that $\mathscr{M}$ denotes a *spin* manifold. (Indeed, it is widely believed by physicists that fermions are geometrically described by spinors.) Although this is not necessary, since we are only interested in local objects (densities), it simplifies notation. Consequently, the (total space of the) Clifford module bundle globally takes the form $\mathscr{E} = \mathrm{S} \otimes \mathrm{E}$. To get in touch with gauge theory we assume that E denotes an associated (Hermitian) vector bundle: $\mathrm{E} = \mathscr{P} \times_\rho V$, where $\mathscr{P}$ is a G-principal bundle over $\mathscr{M}$ and $\rho : \mathrm{G} \to V$ is a unitary representation of the (real, compact and semi-simple) Lie group G on a Hermitian vector space V. By $\mathscr{G}$ we denote the corresponding Lie algebra of G and by ρ' we denote the induced representation of $\mathscr{G}$ on $\mathrm{End}(V)$. Consequently, any connection form A on E takes its values in $\rho'(\mathscr{G}) \subset \mathrm{End}(V)$. This offers the possibility of defining the slightly more general functional

$$\mathscr{T}_{\mathrm{D}}(\widetilde{\nabla}^{\mathscr{E}}) := \mathrm{res}_\zeta(\widetilde{\mathrm{D}}^{-2n+2}) \equiv \mathrm{res}((\zeta\widetilde{\mathrm{D}}^2)^{-n+1}). \tag{74}$$

[That this functional actually is more adequate than (68) becomes clear when discussing the physical implications of the proposed model (cf. Sec. III).] Here, $\zeta \in \Gamma(\mathrm{End}(\mathscr{E}))$ denotes an element of the commutant defined by (G,ρ). More precisely, let us recall the simple fact that any section $s \in \Gamma(\mathrm{E})$ in an associated vector bundle $\mathrm{E} = \mathscr{P} \times_\rho V$ uniquely corresponds to an equivariant section $\overline{s} \in \Gamma_{eq}(\mathscr{P}, V)$. Here, equivariant means $\overline{s}(pg) = \rho^{-1}(g)\overline{s}(p)$, $\forall g \in G$, $p \in \mathscr{P}$. We then have the following.

Definition 7: For a given generalized Dirac operator, consisting of the triple

$$(G,\rho,\widetilde{\mathrm{D}}) \tag{75}$$

with $\widetilde{\mathrm{D}}\in\mathscr{D}(\mathscr{E})$, let us denote by $\overline{z}\in\Gamma_{aq}(\mathscr{P},\mathrm{End(V)})$ an element of the *commutant*

$$\mathscr{C}_\rho(\mathrm{G}):=\{a\in\mathrm{End(V)}|[\rho(g),a]=0,\forall g\in G\}, \tag{76}$$

and by $z\in\Gamma(\mathrm{End(E)})$ its corresponding section in the endomorphism bundle associated with E. (In the following we shall not distinguish between s and $\overline{s}$.) Since End(S) is simple, this generalizes to End($\mathscr{E}$) via $\zeta:=\mathbf{1}_\mathrm{S}\otimes z$. We impose the following three conditions on ζ: it is a positive operator ($\zeta>0$) and satisfies $[\widetilde{\mathrm{D}},\zeta]=[\chi,\zeta]=0$, where $\chi\in\Gamma(\mathrm{End}(\mathscr{E}))$ denotes the grading operator on $\mathscr{E}=\mathscr{E}^+\oplus\mathscr{E}^-$.

Lemma 5: As a consequence, ζ^α has a constant spectrum (i.e., it is independent of $x\in\mathscr{M}$) and the operator: $\zeta^\alpha\widetilde{\mathrm{D}}^2$ is elliptic for any power $\alpha\in\mathbb{R}$. Using this, we obtain

$$\mathrm{res}_\zeta(\widetilde{\mathrm{D}}^{-2n+2})=\frac{2}{\Gamma(n-1)}\int_\mathscr{M}*\mathrm{tr}_\mathscr{E}(\zeta\sigma_2(x;\widetilde{\mathrm{D}}^2)). \tag{77}$$

Proof: Let us denote by spec $\zeta(x)=\{\lambda_1\ldots\lambda_k\}|_x$, $x\in\mathscr{M}$, the spectrum of the positive operator $\zeta\in\Gamma(\mathrm{End}(\mathscr{E}))$. Here, k indicates the number of distinct eigenvalues of ζ. We first prove that the spectrum is independent of $x\in\mathscr{M}$.

Since $z\in\mathscr{C}_\rho(G)$ this section is gauge invariant, i.e., for all gauge transformations $f\in\Gamma_{eq}(\mathrm{Aut}(\mathscr{P}))\simeq\Gamma(\mathscr{P}\times_{ad}\mathrm{G})$ of $\mathscr{P}$ we have $f^*z=z$. Hence, it is sufficient to consider a local situation. Using the fact that locally, any Dirac operator $\widetilde{\mathrm{D}}\in\mathscr{D}(\mathscr{E})$ may be written as

$$\widetilde{\mathrm{D}}=c(\mathrm{d})+\sum_{j=0}^{m}c(\mathscr{A}_{[j]}), \tag{78}$$

it follows that $[\widetilde{\mathrm{D}},\zeta]=0$ is equivalent to

$$\begin{aligned}&[c(\mathscr{A}_{[j]},\zeta)]=0,\quad\forall j=0,2,...,m,\\&c(\mathrm{d}\zeta)=-[c(\mathscr{A}_{[1]}),\zeta].\end{aligned} \tag{79}$$

However, the latter implies $\mathrm{d}z=0$. Indeed, $\mathscr{A}_{[1]}=\omega^S\otimes\mathbf{1}_\mathrm{E}+\mathbf{1}_\mathrm{S}\otimes\mathrm{A}$, $\mathrm{A}\in\Omega^1(\mathscr{M},\rho'(\mathscr{G}))$ and thus $[\mathrm{A},z]=0$. Consequently, ζ must be constant, which yields the first assertion.

Since the spectrum of z is constant we obtain

$$\mathrm{E}=\oplus_{j=1}^k\ker(z-\lambda_j)=:\oplus_{j=1}^k\mathrm{E}_j\,. \tag{80}$$

Hence,

$$\begin{aligned}\zeta&=\oplus_{j=1}^k\lambda_j\mathbf{1}_{\mathscr{E}_j},\\\mathrm{D}&=\oplus_{j=1}^k\mathrm{D}_j,\end{aligned} \tag{81}$$

where $\widetilde{\mathrm{D}}_j$ is the restriction of $\widetilde{D}$ to $\mathscr{E}_j:=\mathrm{S}\otimes\mathrm{E}_j$. Consequently, we end up with

$$\zeta\widetilde{\mathrm{D}}^2=\oplus_{j=1}^k\lambda_j\widetilde{\mathrm{D}}_j^2, \tag{82}$$

which implies

$$\mathrm{Tr}\;e^{-\tau\zeta\widetilde{\mathrm{D}}^2}=\sum_{j=1}^k\mathrm{Tr}\;e^{-\tau\lambda_j\widetilde{\mathrm{D}}_j^2}\sim\sum_{l\geqslant0}\sum_{j=1}^k\tau^{(l-m)/2}\lambda_j^{(l-m)/2}\int_\mathscr{M}*\mathrm{tr}_{\mathscr{E}_j}\sigma_l(x,\widetilde{\mathrm{D}}_j^2), \tag{83}$$

and thus proves the lemma, when ζ is replaced by ζ^{-n+1}.

Since we now have fixed the mathematical frame we conclude this part by summarizing the proposed model building kit as follows: Let

$$(\mathrm{G},\rho,\widetilde{\mathrm{D}}) \tag{84}$$

be a given generalized Dirac operator defined on a Clifford module bundle $\mathscr{E}$. Then, the general action functional on $\mathscr{A}(\mathscr{E})\times\Gamma(\mathscr{E})$ is defined as

$$\mathscr{I}_{\widetilde{\mathrm{D}}}\equiv\mathscr{I}_{\mathrm{fermionic}}(\widetilde{\nabla}^{\mathscr{E}},\psi)+\mathscr{I}_{\mathrm{bosonic}}(\widetilde{\nabla}^{\mathscr{E}}):=(\psi,\widetilde{\mathrm{D}}\psi)_{\Gamma(\mathscr{E})}+\mathrm{res}_{\zeta}(\widetilde{\mathrm{D}}^{-2n+2}), \tag{85}$$

where $c(\widetilde{\nabla}^{\mathscr{E}})=\widetilde{\mathrm{D}}$.

III. PART 2: THE STANDARD MODEL

In this part of the paper we are concerned with the application of the kit introduced in Part 1 concerning the standard model of particle physics. We therefore shall introduce in the following section an appropriate generalization of the Dirac–Yukawa operator and prove our main theorem. Moreover, we shall discuss some consequences regarding the various parameters involved in the model.

A. The Dirac–Yukawa operator and the EHYMH action

To get started let us give the following.

Definition 8: Let $\mathscr{E}:=\mathrm{S}\otimes\mathrm{E}$ be a Clifford module bundle with a twisting graduation $(\mathrm{E}=\mathrm{E_L}\oplus\mathrm{E_R})$ and denote by $\chi:=\gamma_5\otimes\chi^E$ the appropriate grading operator: $\chi^2=\mathbf{1}_{\mathscr{E}}$, $\chi^*=\chi$. (Later we shall be mostly interested in the case $n=2$.) A Dirac operator D_ϕ is called a (Euclidean) *Dirac–Yukawa* operator if it takes the form

$$\begin{aligned}\mathrm{D}_\phi&:=\mathrm{D}+i\gamma_5\otimes\begin{pmatrix}0&\widetilde{\phi}\\ \widetilde{\phi}^*&0\end{pmatrix},\\ &\equiv\mathrm{D}+\gamma_5\otimes\phi,\end{aligned} \tag{86}$$

where D is a SDO and $\widetilde{\phi}\in\Gamma(\mathrm{Hom}(\mathrm{E_R},\mathrm{E_L}))$.

Since the Yukawa coupling (9) geometrically can be considered as defining a particular section ϕ (see below), one may try to naturally generalize the operator (86) in such a way that it not only defines the fermionic action (8) and (9), but also yields the bosonic action (10) and (11). Here, ''naturally'' means that the generalization of (86) is determined by only those elements which already determine the Dirac–Yukawa operator, i.e., by (g,ϕ,A).

Theorem 1: *Let $\mathscr{E}=\mathrm{S}\otimes\mathrm{E}$ be a twisted Clifford module over $\mathscr{M}$, with $\mathrm{E}:=\mathrm{E_L}\oplus\mathrm{E_R}$. The functional (74) evaluated with respect to the Dirac operator*

$$\widetilde{\mathrm{D}}_\phi:=\mathrm{D}+a_4\Phi+\mathscr{J}(a_2c(F^{\mathscr{E}/S})+a_3c(\nabla^{\mathrm{End}(\mathscr{E})}\Phi)+a_0\Phi^2) \tag{87}$$

defined on $\widetilde{\mathscr{E}}:=\mathrm{S}\otimes\widetilde{\mathrm{E}}$ yields

$$\begin{aligned}\mathrm{res}_{\zeta}(\widetilde{\mathrm{D}}_\phi^{-2n+2})=-\frac{\mathrm{tr}_{\mathscr{E}}\,\zeta}{3\Gamma(n-1)}\int_{\mathscr{M}}*\{&r_{\mathscr{M}}+a_4'\,\mathrm{tr}_E(z\phi^2)-a_2'\,\mathrm{tr}_E(zF_{\mu\nu}F^{\mu\nu})\\ &+a_3'\,\mathrm{tr}_E(z\nabla_\mu\phi\nabla^\mu\phi)+a_0'\,\mathrm{tr}_E(z\phi^4)\},\end{aligned} \tag{88}$$

with

$$\begin{aligned}a_0'&:=\frac{24n(1-1/2n)}{\mathrm{tr_E}z}\,a_0^2,\quad a_2':=\frac{24(2n-3)}{\mathrm{tr_E}z}\,a_2^2,\\ a_3'&:=\frac{24(n-1)}{\mathrm{tr_E}z}\,a_3^2,\quad a_4':=\frac{12}{\mathrm{tr_E}z}\,a_4^2.\end{aligned} \tag{89}$$

Here, $\Phi := \gamma_5 \otimes \phi$ and $F \in \Omega^2(\mathscr{M}, \rho'(\mathscr{G}))$ is the Yang–Mills curvature, induced by the gauge potential A in the definition of the SDO $D \in \mathscr{D}(\mathscr{E})$. The covariant derivative $\nabla\phi$ is defined with respect to the adjoint representation of G, where the ϕ sits [i.e., the corresponding equivariant section $\phi \in \Gamma_{eq}(\mathscr{P}, \mathrm{End}(V))$ fulfills $\phi(pg) = \rho^*(g)\phi(p)\rho(g)$, $\forall p \in \mathscr{P}$, $g \in G$.] The a's denote arbitrary (complex) constants. The structure group G is assumed to act on $\widetilde{E} := E \oplus E$ via the representation $\widetilde{\rho} := \rho \oplus \rho$, and the automorphism $\widetilde{E} \xrightarrow{\mathscr{J}} \widetilde{E}$ denotes the corresponding ''complex structure'' on $\widetilde{E}$. Moreover, we have used the canonical identification

$$A + \mathscr{J}(B) = \begin{pmatrix} A & -B \\ B & A \end{pmatrix} \tag{90}$$

for all $A, B \in \mathrm{End}(E)$. Note, in what follows we do not distinguish between the Clifford action c on the Clifford module $\mathscr{E}$ and the corresponding action $\widetilde{c} := c \oplus c$ on the (canonically) induced Clifford module $\widetilde{\mathscr{E}}$. Likewise, we do not distinguish between the representation ρ and $\widetilde{\rho}$.

Consequently, if the constant a_3 is purely imaginary and the other constants are real, the functional (74) with respect to the generalized Dirac–Yukawa operator (87) becomes proportional to the Einstein–Hilbert–Yang–Mills–Higgs action (EHYMH) of the standard model. Moreover, if one considers ''diagonal sections,'' $\widetilde{\psi} := (\psi, \psi)$, $\psi \in \Gamma(\mathscr{E})$ only, the fermionic functional in (85) becomes proportional to the Dirac–Yukawa action. Note, in (85) there is still a length scale missing because the fields do not yet have the right dimensions. This will be discussed in the next section where we shall consider some constraints of our approach to the standard model.

Remark 7: The (Euclidean) Dirac–Yukawa operator (86) is uniquely defined by the Clifford superconnection

$$\boldsymbol{\nabla}^{E} := \nabla^{E} + \boldsymbol{\epsilon}, \quad \boldsymbol{\epsilon} := i^n * \phi \tag{91}$$

on E, where we have used the fact that the grading operator γ_5 of the spinor bundle S is proportional to the volume form on $\mathscr{M}$. More precisely, we have $c(i^n * 1) = \gamma_5 \otimes \mathbf{1}_E \in \Gamma(\mathrm{End}^+(\mathscr{E}))$.

Hence, the (Euclidean) Dirac–Yukawa operator is determined by a one-form (gauge potential) and the $2n$-form in (91). In four dimensions, however, the most general Dirac operator in addition depends on a zero-form, a two-form, and a three-form. By considering only those forms which already determine the Dirac–Yukawa operator, (91) naturally yields the following ansatz,

$$\boldsymbol{\nabla}^{\widetilde{E}} := \nabla^{E} + a_4\boldsymbol{\epsilon} + \mathscr{J}(a_2 F - a_3 * \nabla^{\mathrm{End}(E)}(*\boldsymbol{\epsilon}) + a_0(*\boldsymbol{\epsilon})^2), \tag{92}$$

on $\widetilde{E}$. Note that the forms within the brackets are even with respect to the total degree and hence $\mathscr{J}(\cdots)$ becomes odd (cf. also the final section). It is easily checked that

$$\widetilde{D}_{\boldsymbol{\nabla}^{\widetilde{\mathscr{E}}}} = \widetilde{D}_{\phi} \tag{93}$$

with $\nabla^{\widetilde{\mathscr{E}}} := \nabla^{S} \otimes \mathbf{1}_E + \mathbf{1}_S \otimes \boldsymbol{\nabla}^{\widetilde{E}}$.

There are two interesting choices for the constants a_k so that (87) takes a particularly nice geometric form: First, the most natural choice is $a_k \equiv 1$, $\forall k = 0,2,...,4$. In this case the Dirac operator (87) reads

$$\widetilde{D}_{\phi} = c(\nabla^{\mathscr{E}} + \Phi) + \mathscr{J}(c(\mathscr{R}_{\widetilde{\boldsymbol{\nabla}}}\tilde{e})) =: c(\boldsymbol{\nabla}^{\mathscr{E}}) + \mathscr{J}(c(\mathscr{R}_{\widetilde{\boldsymbol{\nabla}}}\tilde{e})) = D_{\phi} + \mathscr{J}(c(\mathscr{R}_{\widetilde{\boldsymbol{\nabla}}}\tilde{e})) \equiv D_{\widetilde{\boldsymbol{\nabla}}}\tilde{e} \tag{94}$$

with the ''super relative curvature'' $\mathscr{R}_{\widetilde{\boldsymbol{\nabla}}}\tilde{e} := (\widetilde{\boldsymbol{\nabla}}^{\mathscr{E}})^2 - (\nabla^{S})^2 \otimes \mathbf{1}_E$.

However, there is still another nice choice: $a_0 = a_3 := (1 - 1/2n)$, $a_2 = a_4 := 1$; in this case the generalization (87) of the Dirac–Yukawa operator (86) reads

$$\begin{aligned} \widetilde{D}_{\phi} &= c(\nabla^{\mathscr{E}} + \omega_{\phi}) + \mathscr{J}(c(F^{\mathscr{E}/S} + d^{\nabla^{\mathscr{E}}}\omega_{\phi} + \omega_{\phi} \wedge \omega_f)) \\ &=: c(\widetilde{\boldsymbol{\nabla}}^{\mathscr{E}}) + \mathscr{J}(c(\mathscr{R}_{\widetilde{\nabla}}\tilde{e})) = D_{\phi} + \mathscr{J}(c(\mathscr{R}_{\widetilde{\nabla}}\tilde{e})) \equiv D_{\widetilde{\nabla}}\tilde{e}, \end{aligned} \tag{95}$$

with the ''*Higgs form*'' $\omega_\phi := \delta_\xi \Phi \in \Omega^1(\mathscr{M}, \mathrm{End}^+(\mathscr{E}))$ and the relative curvature $\mathscr{R}_{\tilde{\nabla}^{\mathscr{E}}} := (\tilde{\nabla}^{\mathscr{E}})^2 - (\nabla^S)^2 \otimes \mathbf{1}_E$. Because of

$$D_{\tilde{\mathbf{\nabla}}}\tilde{\mathscr{E}} - D_{\tilde{\nabla}}\tilde{\mathscr{E}} = \frac{1}{2n}\,\mathscr{J}(c(\mathscr{R}_{\tilde{\mathbf{\nabla}}}\mathscr{E} - \mathrm{F}^{\mathscr{E}/S})), \tag{96}$$

the Dirac operators $D_{\tilde{\mathbf{\nabla}}}\tilde{\mathscr{E}}$ and $D_{\tilde{\nabla}}\tilde{\mathscr{E}}$ however, are different. Therefore, strictly speaking, the definition (87) gives a whole class of Dirac operators, parametrized by the constants $a_0, \ldots, a_4$, and which all yield (88).

After this remark let us turn to the proof of the theorem.

Proof: Clearly, to prove this theorem we just have to calculate the endomorphism (47) with respect to the Dirac operator (87). This tedious but straightforward calculation can most easily be achieved using the local form of (47):

$$\begin{aligned}\mathscr{F}^{\tilde{\nabla}^{\tilde{\mathscr{E}}}} = {} & \tfrac{1}{4} r_{\mathscr{M}} \mathbf{1}_{\tilde{\mathscr{E}}} + \tfrac{1}{2}\gamma^{\mu\nu} \otimes \mathrm{F}_{\mu\nu} + \tfrac{1}{2}[\gamma^\mu[\omega_\mu, \gamma^\nu], \omega_\nu] + \gamma^{\mu\nu}({}'\nabla_\mu \omega_\nu) - \tfrac{1}{2}\gamma^\mu[({}'\nabla_\nu \omega_\mu), \gamma^\nu] \\ & + \tfrac{1}{2}\gamma^{\mu\nu}[\omega_\mu, \omega_\nu] + \tfrac{1}{4} g_{\mu\nu}\gamma^\alpha[\omega_\alpha, \gamma^\mu]\gamma^\beta[\omega_\beta, \gamma^\nu],\end{aligned} \tag{97}$$

where $\mathscr{C}(\mathscr{M})_{\mathbb{C}} \xrightarrow{\gamma} \mathrm{End}(S)$ denotes the (chiral) representation of the complexified Clifford algebra and $\gamma^\mu \equiv c\,\gamma(e^\mu)$ with $\{e^\mu\}_{1 \leqslant \mu \leqslant 2n}$ a local frame in $T^*\mathscr{M}$. Also we use the shorthand notation $\gamma^{\mu\nu} := [\gamma^\mu, \gamma^\nu]/2$. Moreover, F is the curvature on E, associated to the connection form A. The connection $\tilde{\nabla}^{\tilde{\mathscr{E}}} \in \mathscr{A}(\mathscr{E})$ denotes any representative of the corresponding class defining the Dirac operator (87) and $\omega := \tilde{\nabla}^{\mathscr{E}} - \nabla^{\tilde{\mathscr{E}}}$, with $\nabla^{\tilde{\mathscr{E}}} \in \mathscr{A}_{\mathrm{Cl}}(\mathscr{E})$ arbitrarily chosen, and ${}'\nabla_\mu$ denotes the covariant derivative induced by this Clifford connection on $\mathrm{End}(\mathscr{E})$.

In particular, we may choose $\tilde{\nabla}^{\tilde{\mathscr{E}}}$ such that

$$\omega := \omega^0 + \omega^2 + \omega^3 + \omega^4$$

with

$$\begin{aligned}\omega^0 := a_0 \delta_\xi \mathscr{J}(\Phi^2), \quad \omega^2 := a_2 e^\mu \otimes \gamma^\nu \otimes \mathscr{J}(F_{\mu\nu}), \\ \omega^3 := a_3 \mathscr{J}(\nabla\Phi), \quad \omega^4 := a_4 \delta_\xi(\Phi).\end{aligned} \tag{98}$$

Note, we have already omitted $\omega^1 := \omega^S \otimes \mathbf{1}_E + \mathbf{1}_S \otimes A$, which would change the Clifford connection $\nabla^{\tilde{\mathscr{E}}}$ only and not the functional (88) by Corollary 1. The main advantage of the local form (97) is that the whole calculation becomes purely algorithmic. Moreover, because of the trace $\mathrm{tr}_{\tilde{\mathscr{E}}}$ in (77), one only has to calculate the last four terms in (97). For the same reason most of the terms to be calculated will drop out. Indeed, using (98), it is easily checked that the two derivative terms in (97), actually, do not contribute to the functional (74). Hence, all that is left to be done is to calculate the last two quadratic terms in (97) up to ''traceless'' contributions. This calculation becomes even more simplified by the following.

Remark 8: Let $\mathscr{E}_j$, $j = 1,2$, be two Clifford modules over $\mathscr{M}$ with the appropriate actions c_j. Then, $(\mathscr{E}, c)$ with $\mathscr{E} := \mathscr{E}_1 \oplus \mathscr{E}_1$ and $c := c_1 \oplus c_2$ is also a Clifford module. The most general Dirac operator on this Clifford module takes the form

$$\tilde{\mathrm{D}} = \begin{pmatrix} \mathrm{D}_1 & A_{12} \\ A_{21} & \tilde{\mathrm{D}}_2 \end{pmatrix}, \tag{99}$$

where, respectively, $\tilde{\mathrm{D}}_j \in \mathscr{D}(\mathscr{E}_j)$, $j = 1,2$, $A_{12} \in \Gamma(\mathrm{Hom}(\mathscr{E}_2, \mathscr{E}_1))$ and $A_{21} \in \Gamma(\mathrm{Hom}(\mathscr{E}_1, \mathscr{E}_2))$. The Wodzicki residue of $\tilde{\mathrm{D}}^{-2n+2}$ is such that there are no terms ''mixing the diagonal with the off-diagonal'' (cf. Ref. 11).

As a consequence, in calculating the corresponding quadratic terms of (97), products of the generic form $\omega^4 \omega^k$, $k = 0,\ldots,3$, may be omitted as well. As a result we end up with

$$\frac{1}{2}\,\gamma^{\mu\nu}[\omega_\mu,\ \omega_\nu]=a_0^2\left(1-\frac{1}{2n}\right)\Phi^4+a_2^2\mathrm{ev}_g(\mathrm{F}^{\mathscr{E}/\mathrm{S}^2})+a_4^2\left(1-\frac{1}{2n}\right)\Phi^2 \tag{100}$$

and

$$\frac{1}{4}\,g_{\mu\nu}\gamma^\alpha[\omega_\alpha,\ \gamma^\mu]\gamma^\beta[\omega_\beta,\ \gamma^\nu]=2na_0^2\left(1-\frac{1}{2n}\right)^2\Phi^4+(5-4n)a_2^2\mathrm{ev}_g(\mathrm{F}^{\mathscr{E}/\mathrm{S}^2})$$

$$+2(n-1)a_3^2\mathrm{ev}_g((\nabla^{\mathrm{End}(\mathscr{E})}\Phi)^2)+\frac{1}{2n}\,a_4^2\Phi^2. \tag{101}$$

Note that both equalities hold up only to traceless terms! Finally, if we put everything together, the theorem is proven.

To summarize: we have introduced a certain Dirac operator (87), generalizing the Dirac–Yukawa operator (86), such that the functional (74) looks like that of the bosonic action of the standard model with gravity including. This result is independent of the specific structure group G and its appropriate (fermionic) representation. To get in touch with physics, however, we also have to specify the pair (G,ρ). In other words, we have to define the generalized Dirac operator of the standard model.

B. The generalized Dirac–Yukawa operator of the standard model

To begin with, we give the following.

Definition 9: Let $\mathscr{E}$ be a twisted spinor bundle, so that $\mathrm{E}=\mathrm{E}_\mathrm{L}\oplus\mathrm{E}_\mathrm{R}$. We call

$$(\mathrm{G},\rho,\mathrm{D}) \tag{102}$$

the *generalized Dirac–Yukawa operator of the standard model* provided the structure group G takes the form

$$\mathrm{G}:=\mathrm{SU}(3)\times\mathrm{SU}(2)\times\mathrm{U}(1) \tag{103}$$

and has the (fermionic) representation $\rho:=\rho_\mathrm{L}\oplus\rho_\mathrm{R}\colon \mathrm{G}\to\mathrm{Aut}(V)$,

$$\rho_\mathrm{L}(\mathbf{c},\mathbf{w},b):=\begin{pmatrix}\mathbf{c}\otimes\mathbf{1}_\mathrm{N}\otimes\mathbf{w}b_\mathrm{L}^q & 0\\ 0 & \mathbf{1}_\mathrm{N}\otimes\mathbf{w}b_\mathrm{L}^l\end{pmatrix}, \tag{104}$$

$$\rho_R(\mathbf{c},\mathbf{w},b):=\begin{pmatrix}\mathbf{c}\otimes\mathbf{1}_\mathrm{N}\otimes\mathbf{B}_\mathrm{R}^q & 0\\ 0 & \mathbf{B}_\mathrm{R}^l\end{pmatrix}, \tag{105}$$

on the typical fiber

$$V:=V_\mathrm{L}\oplus V_\mathrm{R} \tag{106}$$

$$\simeq[(\mathbb{C}_q^{6\mathrm{N}}\oplus\mathbb{C}_l^{2\mathrm{N}})]_\mathrm{L}\oplus[(\mathbb{C}^{3\mathrm{N}})_q\oplus\mathbb{C}_l^\mathrm{N}]_\mathrm{R} \tag{107}$$

$$\simeq\mathbb{C}_\mathrm{L}^{8\mathrm{N}}\oplus\mathbb{C}_\mathrm{R}^{7\mathrm{N}}. \tag{108}$$

Moreover, the Dirac operator

$$\mathrm{D}:=\widetilde{\mathrm{D}}_\phi \tag{109}$$

is the generalized Dirac–Yukawa operator (87), where the homomorphism $\widetilde{\phi}\in\Gamma(\mathrm{Hom}(\mathrm{E}_\mathrm{R},\mathrm{E}_\mathrm{L}))$ is defined by

$$\widetilde{\phi}:=\begin{pmatrix}\mathbf{1}_3\oplus(\mathbf{g}_y'^q\otimes\varphi,\mathbf{g}_y^q\otimes\boldsymbol{\epsilon}\overline{\varphi}) & 0\\ 0 & \mathbf{g}_y^l\otimes\varphi\end{pmatrix} \tag{110}$$

$$\equiv \begin{pmatrix} \mathbf{1}_3 \otimes \widetilde{\varphi}_q & 0 \\ 0 & \widetilde{\varphi}_l \end{pmatrix}. \tag{111}$$

Here, respectively, $\mathbf{g}_y'^q$, $\mathbf{g}_y^q \in \mathbf{M}_N(\mathbb{C})$ denote the matrices of the Yukawa coupling constants for quarks of electrical charge $-\frac{1}{3}$ and $\frac{2}{3}$ (i.e., of quarks of ''d'' type, and of ''u'' type) and $\mathbf{g}_y^l \in \mathbf{M}_N(\mathbb{C})$ is the matrix of the Yukawa coupling constants for the leptons of charge -1 (i.e., of leptons of ''electron'' type). While $\mathbf{g}_y^q$ and $\mathbf{g}_y^l$ can be assumed to be diagonal and real, the matrix $\mathbf{g}_y'^q$ is related to the Kobayashi–Maskawa matrix and therefore is neither diagonal nor real. The ''weak hypercharges'' for the left- and right-handed quarks (indicated by the subscript ''q'') and leptons (subscript ''l'') are defined by $\rho(b) := e^{iy\theta}$, $b \in \mathrm{U}(1)$, $y \in \mathbb{Q}$, $\theta \in [0, 2\pi[$ (cf. the Introduction). Then the two by two diagonal matrices $\mathbf{B}_R^q$ and $\mathbf{B}_R^l$ in the definition (105) are $\mathbf{B}_R^q := \mathrm{diag}\,(b_R^{d'}, b_R^u)$ and $\mathbf{B}_R^l := b_R^l \mathbf{1}_N$. In (110), φ denotes a section into a rank two subbundle E_h of the vector bundle E and carries the defining representation ρ_h of the electroweak subgroup $G_h := \mathrm{SU}(2) \times \mathrm{U}(1)$ of the structure group G_h i.e., when φ is considered as an element of $\Gamma_{eq}(\mathscr{P}, V)$ it transforms like $\varphi(pg) = \rho_h(g)^* \varphi(p)$ with $g := (\mathbf{w}, b) \in G_h = \mathrm{SU}(2) \times \mathrm{U}(1)$ and $\rho_h(\mathbf{w}, b) := \mathbf{w} e^{iy_h\theta}$. Finally, $\boldsymbol{\epsilon}$ is the antidiagonal matrix $\boldsymbol{\epsilon} := \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$ and $\overline{\varphi}$ here means the complex conjugate of φ.

Hence, the Higgs field φ defines an element Φ in $\Omega^0(\mathscr{M}, \mathrm{End}^-(\mathscr{E}))$ and thus a Dirac–Yukawa operator (86). Of course, the particular form of $\widetilde{\phi}$ in (110) is such that Φ gives the correct Yukawa coupling term (9) in the definition of the fermionic action of the standard model. However, since the section $\phi \in \Gamma(\mathrm{End}^-(E))$ transforms with respect to the (ρ-induced) adjoint representation of G it follows that the hypercharge y_h of the Higgs field and, respectively, the hypercharges y_L^l, y_R^l of the left-and right-handed leptons and the hypercharges $y_L^q, y_R^{d'}, y_R^u$ of the left- and right-handed quarks must satisfy the following well-known relations:

$$y_h = y_L^l - y_R^l = y_L^q - y_R^{d'} = y_R^u - y_L^q. \tag{112}$$

In other words, when the Yukawa coupling is of the form as defined by (9) the corresponding hypercharges are not all independent but have to satisfy the relations (112). Moreover, since we know the electrical charge of the particles, the numerical values of the ''y's'' are fixed:

$$(y_L^q, y_L^l) = (\tfrac{1}{6}, -\tfrac{1}{2}), \tag{113}$$

$$((y_R^{d'}, y_R^u), y_R^l) = ((-\tfrac{1}{3}, \tfrac{2}{3}), -1). \tag{114}$$

This is a consequence of the generalized Gell–Mann–Nishijima relation

$$\mathbf{Q} = \mathbf{T}_3 + \mathbf{Y}, \tag{115}$$

where $\{i\mathbf{T}_3 := \rho'((i\boldsymbol{\tau}_3)/2),\ i\mathbf{Y} := \rho'(i)\}$ is a basis of the maximal Cartan subalgebra of $\rho'(\mathrm{su}(2) \oplus \mathrm{u}(1))$, so that $i\mathbf{Q}$ generates the residual structure group, in more physical terms the ''electromagnetic gauge group,''

$$\mathrm{U}_{elm}(1) \subset \mathrm{SU}(2) \times \mathrm{U}(1) \tag{116}$$

in the fermionic representation ρ after the mechanism of *spontaneous symmetry breaking* is established. [As usual we use $\{\mathbf{E}_k\}_{1 \leqslant k \leqslant 12} := \{(i\boldsymbol{\lambda}_a)/2, (i\boldsymbol{\tau}_b)/2, i\}_{\substack{1 \leqslant a \leqslant 8 \\ 1 \leqslant b \leqslant 3}}$ as a basis of $\mathrm{su}(3) \oplus \mathrm{su}(2) \oplus \mathrm{u}(1)$, where $\boldsymbol{\lambda}_a$, $a = 1, \ldots, 8$, denote the Gell–Mann matrices and $\boldsymbol{\tau}_b$, $b = 1, \ldots, 3$, denote the Pauli matrices.] To make the latter more precise mathematically, let us remember how the notion of spontaneous symmetry breaking can be geometrically rephrased in terms of the reduction of a G-principal bundle (cf. Refs. 21 and 22).

Let therefore $H \subset G$ be a Lie subgroup of G and, respectively, $\mathscr{P}_G$ and $\mathscr{P}_H$ be the (total spaces of the) corresponding principal bundles over the same base manifold $\mathscr{M}$. Then, $\mathscr{P}_H$ is called an H reduction of $\mathscr{P}_G$ iff $\mathscr{P}_H \subset \mathscr{P}_G$ is a submanifold, so that the injection $\mathscr{P}_H \hookrightarrow \mathscr{P}_G$ is a bundle homomorphism. A necessary and sufficient condition for a G-principal bundle $\mathscr{P}$ to be H reducible is that the $\mathscr{P}$-associated fiber bundle $\mathscr{P}_G/H \to \mathscr{M}$, with typical fiber G/H, admits a global section.

Definition 10: A solution (g,A,φ,Ψ) of the Euler–Lagrange equations corresponding to the functional (12) is called a *classical vacuum* iff $A=\Psi=0$, the Higgs field $\varphi=\varphi_0$ minimizes the Higgs potential

$$V:\Gamma(E_h)\to\mathbb{R},\quad V'|_{\varphi=\varphi_0}=0, \tag{117}$$

and the metric g satisfies the corresponding Einstein equation. Here, E_h denotes the (total space of the) bundle where the Higgs field lives (see below) and, in principle, V may be any gauge invariant polynomial of order less than or equal to 4 of the Higgs field φ. Again, it is assumed that V is bounded from below. Of course, concerning the standard model, V has its well-known fashion (6). Note that in the vacuum (g,φ_0) the metric has to fulfill

$$\mathrm{Ric}(g)=\Lambda(\varphi_0)g,$$

where Ric denotes the Ricci curvature associated with the metric g and Λ denotes a constant proportional to $V(\varphi_0)$. Hence, if $\varphi=\varphi_0$, then $(\mathscr{M},g)$ must be a *Einstein manifold* (see also our corresponding remark in the Introduction).

Let us denote by $\Sigma\subset V_h$ the (disjoint union of) orbits of classical vacuums with respect to the representation ρ_h that carries the Higgs field φ of the structure group G_h. In the special case of the standard model this group is identified with the ''electroweak gauge group'' $\mathrm{SU}(2)\times\mathrm{U}(1)\subset\mathrm{G}$ and, correspondingly, $\mathrm{E}_h:=\mathscr{P}\times_{\rho_h}\mathrm{V}_h\subset\mathrm{E}$ denotes the rank two subbundle describing, geometrically, the Higgs sector of the standard model. In the so-called ''minimal version'' of the standard model the typical fiber is $\mathrm{V}_h\simeq\mathbb{C}^2$. Note that in the usual (nongeometrical) description of the standard model the fermion representation ρ, defined by (104)–(108), and the Higgs representation ρ_h are completely independent. Let us denote by $\mathrm{I}(\varphi_0)\subset\rho_h(\mathrm{G}_h)\subset\mathrm{End}(\mathrm{V}_h)$ the isotropy group associated with a chosen classical vacuum $\varphi_0\in\Sigma'\subset\Sigma$, connected. Up to onjugation this isotropy group can be identified with some Lie subgroup H of G_h and we have $\Sigma'\simeq(\rho_h(\mathrm{G}_h)/\rho_h(\mathrm{H}))$. Therefore, φ_0 considered as an element in $\Gamma_{\mathrm{eq}}(\mathscr{P}_h,\mathrm{V}_h)$ uniquely induces a section (also denoted by φ_0) $\mathscr{M}\overset{\varphi_0}{\to}\mathscr{P}_h/\mathrm{H}$. In other words, from a geometrical point of view a necessary condition for a (classical) vacuum to exist is that the G_h bundle must be H reducible, where the Lie subgroup $\mathrm{H}\subset\mathrm{G}_h$ is identified with the isotropy group of some choosen Higgs field φ_0, minimizing the Higgs potential V.

Definition 11: The gauge symmetry is called *spontaneously* broken by the (classical) vacuum, represented by φ_0, iff $\mathrm{H}\subset\mathrm{G}_h$ is a proper subgroup.

Note that the H reduction of $\mathscr{P}_h$ is only necessary but not sufficient for φ_0 to represent a classical vacuum. It is also required that $\mathscr{P}_h$ possesses a flat connection. In the particular case of the (minimal) standard model we obtain $\Sigma=\{\rho_h(\mathbf{w},b)\varphi_0\}\amalg\{0\}$, with $\varphi_0:=(0,v/\sqrt{2})^T$, $v:=\sqrt{\mu^2/\lambda}\in\mathbb{R}$, and $(\mathbf{w},b)\in\mathrm{G}_h=\mathrm{SU}(2)\times\mathrm{U}(1)$. Then, the isotropy group associated with the nontrivial φ_0 is generated by the anti-Hermitian operator $i\mathbf{Q}$, and the corresponding residual structure group H can be identified with $\mathrm{U}_{\mathrm{elm}}(1)$ [cf. (115) and (116)]. Actually, the full residual structure group (''little group'') of the standard model reads

$$\mathrm{H}=\mathrm{SU}(3)\times\mathrm{U}_{\mathrm{elm}}(1), \tag{118}$$

since the structure group G is given by (103).

Consequently, assuming that $\mathscr{P}\equiv\mathscr{P}_{\mathrm{G}}$ is H reducible and φ_0 represents an appropriate (nontrivial) classical vacuum of the standard model the section $\mathscr{D}\in\Omega^0(\mathscr{M},\mathrm{End}^-(\mathrm{E}))$, defined by

$$\mathscr{D}\equiv\phi_0:=\phi|_{\varphi=\varphi_0}=:i\begin{pmatrix}0 & \mathbf{M}\\ \mathbf{M}^* & 0\end{pmatrix}, \tag{119}$$

is H invariant and thus well defined on the reduced bundle. Fixing the gauge so that $\varphi_0=(0,v/\sqrt{2})^T$ (''unitary gauge'') we may further write

$$\mathbf{M}\equiv\begin{pmatrix}\mathbf{1}_3\otimes\mathbf{M}_q & 0\\ 0 & \mathbf{M}_l\end{pmatrix},$$

with

$$\mathbf{M}_q = \begin{pmatrix} 0 & \mathbf{m}^{d\prime} \\ \mathbf{m}^u & 0 \end{pmatrix}, \tag{120}$$

$$\mathbf{M}_l = \begin{pmatrix} 0 \\ \mathbf{m}^l \end{pmatrix}, \tag{121}$$

where, respectively, the matrices $\mathbf{m}^l := (v/\sqrt{2})\mathbf{g}_y^l \in \mathrm{M_N}(\mathbb{C})$ and $\mathbf{m}^u := (v/\sqrt{2})\mathbf{g}_y^q \in \mathrm{M_N}(\mathbb{C})$ denote the ''mass matrices'' of the charged leptons (l) and quarks (q) of ''u type.'' They can be assumed to be diagonal and real. The corresponding N×N matrix $\mathbf{m}^{d'} := (v/\sqrt{2})\mathbf{g}_y'^q$ of ''d-type'' quarks is neither diagonal nor real. It is related to the mass matrix of ''d-type'' quarks $\mathbf{m}^d = \mathrm{diag}(m^{d_1},...,m^{d_N})$, $m^{d_k} \in \mathbb{R}$, $k = 1,...,N$, via the Kobayashi–Maskawa matrix $\mathbf{V} \in \mathrm{U(N)}$: $\mathbf{m}^{d'} = \mathbf{V}\mathbf{m}^d\mathbf{V}^*$.

Obviously, $\mathbf{M}$ denotes the *fermionic mass matrix* and we have recovered the ''internal Dirac operator'' $\mathscr{D}$ of the Connes–Lott approach to the standard model (cf. Ref. 3 and the corresponding references therein). Again, we stress that $\mathscr{D}$ minimizes the Higgs potential V but represents a classical vacuum only if $\mathscr{P}_\mathrm{H}$ (and thus $\mathscr{P}$) possesses a flat connection (cf. Ref. 22).

As we have already mentioned, in the usual approach to the standard model the representation ρ_h of the Higgs field φ is independent of the fermionic representation ρ_f as defined by (104)–(108). However, to be consistent one has to impose the relations (112) to the hypercharges. That these relations are not accidental and, actually, must not be chosen by hand follows from the Dirac–Yukawa operator of the standard model:

$$(\mathrm{G}, \rho, \mathrm{D}_\phi), \tag{122}$$

with $(\mathrm{G}, \rho \equiv \rho_f)$ as in (103)–(108) and D_ϕ defined by (110). In other words, whenever one starts with (122) the representation of the Higgs field must be contained in the fermionic representation and then the relations between the hypercharge of the Higgs field and those of the corresponding fermions are fixed. If this does not hold, the Yukawa coupling (9) would not define a generalized Dirac operator.

We now turn to the consequences as implied by the generalization $(\mathrm{G}, \rho, \widetilde{\mathrm{D}}_\phi)$ of (122). We therefore compare the functional (88), derived from the generalized Dirac–Yukawa operator (87), with the corresponding bosonic action of the standard model. Before we can do this, however, we still have to give the various fields involved in the model their right dimensions, i.e., we first have to introduce an arbitrary length scale ''l.'' Also, we may choose to introduce a second endomorphism ϕ' on E in order to define the ''off-diagonal'' of (87). This additional endomorphism is defined by (110), but with the Yukawa-coupling matrices $\mathbf{g}_y'^q, \mathbf{g}_y^q, \mathbf{g}_y^l$ replaced by arbitrary matrices $\mathbf{\Lambda}'^q, \mathbf{\Lambda}^q, \mathbf{\Lambda}^l$ of the corresponding size. This freedom arises from the fact that the form of the functional (88) does not change by this replacement and that the off-diagonal of $\widetilde{\mathrm{D}}_\phi$ does not act on the fermions Ψ, giving the matrices $\mathbf{g}_y$ their physical interpretation. [At least, when one restricts oneself to diagonal sections, $\widetilde{\Psi} = (\Psi, \Psi) \in \Gamma(\mathscr{E})$. The more general case of nondiagonal sections will be discussed in a future paper, when also further phenomenological consequences of our model and a physical interpretation of the doubling of the ''internal freedoms,'' $E \to \widetilde{E} = E \oplus E$, are considered (cf. our remarks at the end of this paper.)] Note that this freedom is crucial for the definition of the mass matrix of the gauge bosons. Moreover, without loss of generality we may assume that ϕ' is Hermitian, so that all the constants ''a'' are real [cf. (89)]. With these replacements the ''bosonic part'' of the universal functional (85) reads

$$\mathscr{I}_\mathrm{bosonic} = \mathscr{I}_\mathrm{EH} + \alpha_2 \int_\mathscr{M} \mathrm{tr_E}(zF^* \wedge {*F}) \tag{123}$$

$$+ \alpha_3 \int_\mathscr{M} \mathrm{tr_E}(z(\nabla\phi')^* \wedge {*}(\nabla\phi')) \tag{124}$$

$$-\alpha_4 \int_{\mathscr{M}} *\mathrm{tr}_{\mathrm{E}}(\mathrm{z}\phi^*\phi) \tag{125}$$

$$+\alpha_0 \int_{\mathscr{M}} *\mathrm{tr}_{\mathrm{E}}(\mathrm{z}(\phi'^*\phi')^2) \tag{126}$$

with the constants

$$\alpha_0 := \frac{3n(1-1/2n)}{2\pi\ \mathrm{tr}_{\mathrm{E}}\,\mathrm{z}} \left(\frac{l}{l_p}\right)^2 a_0^2, \tag{127}$$

$$\alpha_2 := \frac{3(2n-3)}{\pi\ \mathrm{tr}_{\mathrm{E}}\,\mathrm{z}} \left(\frac{l}{l_p}\right)^2 a_2^2, \tag{128}$$

$$\alpha_3 := \frac{3(n-1)}{2\pi\ \mathrm{tr}_{\mathrm{E}}\,\mathrm{z}} \left(\frac{l}{l_p}\right)^2 a_3^2, \tag{129}$$

$$\alpha_4 := \frac{3}{4\pi\ \mathrm{tr}_{\mathrm{E}}\,\mathrm{z}}\, m_p^2 a_4^2. \tag{130}$$

Here, z is considered as an element of $\Gamma_{\mathrm{eq}}(\mathscr{P},\mathrm{End}(V))$ that lies in the commutant (76) and satisfies

$$[\mathrm{z}, \chi^{\mathrm{E}}]=[\mathrm{z}, \phi]=[\mathrm{z}, \phi']=0, \tag{131}$$

as well as $\mathrm{z}>0$.

Since we use our units so that $c=\hbar=1$ we have identified Newtons gravitational constant G with the (square of the) ''Planck length'' $l_p \equiv m_p^{-1}$. Moreover, we already have normalized the Einstein–Hilbert functional $\mathscr{T}_{\mathrm{EH}}$ so that

$$\mathscr{T}_{\mathrm{EH}} = \frac{1}{16\pi l_p^2} \int_{\mathscr{M}} *r_{\mathscr{M}}. \tag{132}$$

The corresponding normalized fermionic action reads (again, when restricted to diagonal sections)

$$\mathscr{T}_{\mathrm{fermionic}} = \int_{\mathscr{M}} *(\Psi, iD\Psi)_\varepsilon \tag{133}$$

$$+a_4 \int_{\mathscr{M}} *(\Psi, i\Phi\Psi)_\varepsilon, \tag{134}$$

with Φ defined by (110) and D a SDO. Note that only the constant α_4 carries a dimension.

We now can compare the derived functionals (123)–(126) and (133)–(134) with the corresponding bosonic and fermionic action functionals of the standard model

$$\mathscr{T}_{\mathrm{EHYMH}} := \frac{1}{16\pi l_p^2} \int_{\mathscr{M}} *r_{\mathscr{M}} + \int_{\mathscr{M}} *\left\{\frac{1}{2}\,\mathrm{tr}\,(\mathbf{C}_{\mu\nu}\mathbf{C}^{\mu\nu}) + \frac{1}{2}\,\mathrm{tr}\,(\mathbf{W}_{\mu\nu}\mathbf{W}^{\mu\nu}) + \frac{1}{4}\,B_{\mu\nu}\,B^{\mu\nu}\right\} \tag{135}$$

$$+\int_{\mathscr{M}} *(\nabla_\mu\,\varphi)^*(\nabla^\mu\varphi) \tag{136}$$

$$+\int_{\mathscr{M}} *[\lambda(\varphi^*\varphi)^2 - \mu^2\varphi^*\varphi] \tag{137}$$

and

$$\mathcal{I}_{\mathrm{DY}}=\int_{\mathcal{M}}*(\Psi,i\gamma^{\mu}\nabla_{\mu}\,\Psi)_{\mathcal{E}} \tag{138}$$

$$+\int_{\mathcal{M}}*(\Psi,i\Phi\Psi)_{\mathcal{E}}. \tag{139}$$

Here, respectively,

$$\begin{aligned}\mathbf{C}_{\mu\nu}&:=\partial_{\mu}\mathbf{C}_{\nu}-\partial_{\nu}\mathbf{C}_{\mu}+ig_{(3)}[\mathbf{C}_{\mu},\,\mathbf{C}_{\nu}],\\ \mathbf{W}_{\mu\nu}&:=\partial_{\mu}\mathbf{W}_{\nu}-\partial_{\nu}\mathbf{W}_{\mu}+ig_{(2)}[\mathbf{W}_{\mu},\,\mathbf{W}_{\nu}],\\ B_{\mu\nu}&:=\partial_{\mu}B_{\nu}-\partial_{\nu}B_{\mu}\end{aligned} \tag{140}$$

denote the su(3), su(2), and u(1) valued curvatures with respect to a local coordinate system and in the fundamental representation. Moreover, the covariant derivatives, acting on the Higgs field φ and on the fermions Ψ, are locally defined as

$$\nabla_{\mu}\varphi:=\left(\partial_{\mu}+ig_{(2)}W_{\mu}^{b}\,\frac{\boldsymbol{\tau}_{b}}{2}+ig_{(1)}y_{h}B_{\mu}\right)\varphi, \tag{141}$$

$$\nabla_{\mu}\Psi:=(\partial_{\mu}+ig_{(3)}C_{\mu}^{a}\mathbf{1}_{\mathrm{S}}\otimes\mathbf{F}_{a}+ig_{(2)}W_{\mu}^{b}\mathbf{1}_{\mathrm{S}}\otimes\mathbf{T}_{b}+ig_{(1)}B_{\mu}\mathbf{1}_{\mathrm{S}}\otimes\mathbf{Y})\Psi, \tag{142}$$

where again $(g_{(3)},g_{(2)},g_{(1)})$ are the coupling constants and $\{i\mathbf{F}_{a},i\mathbf{T}_{b},i\mathbf{Y}\}_{1\leqslant b\leqslant 3}^{1\leqslant a\leqslant 8}$ denote the generators of $\rho(\mathrm{SU}(3)\times\mathrm{SU}(2)\times\mathrm{U}(1))$; $\lambda,\mu^{2}>0$ are the positive real constants, parametrizing the classical vacuum. Note that the curvatures (140) are Hermitian.

Lemma 6: The derived functionals (123)–(126) and (133)–(134) are identical with the bosonic and fermionic action functionals of the standard model (135)–(140), iff the following relations hold:

$$\mathrm{N}\alpha_{2}g_{(1)}^{2}=\frac{1}{2(3y_{q}\lambda_{q}+y_{l}\lambda_{l})}, \tag{143}$$

$$\mathrm{N}\alpha_{2}g_{(2)}^{2}=\frac{1}{(3\lambda_{g}+\lambda_{l})}, \tag{144}$$

$$\mathrm{N}\alpha_{2}g_{(3)}^{2}=\frac{1}{4\lambda_{q}}, \tag{145}$$

and

$$2\alpha_{0}[3\lambda_{q}\,\mathrm{tr}\,(\boldsymbol{\Lambda}_{q}^{*}\boldsymbol{\Lambda}_{q})^{2}+\lambda_{l}\,\mathrm{tr}\,(\boldsymbol{\Lambda}_{l}^{*}\boldsymbol{\Lambda}_{l})^{2}]=\lambda, \tag{146}$$

$$2\alpha_{3}[3\lambda_{q}\,\mathrm{tr}\,\boldsymbol{\Lambda}_{q}^{*}\boldsymbol{\Lambda}_{q}+\lambda_{l}\,\mathrm{tr}\,\boldsymbol{\Lambda}_{l}^{*}\boldsymbol{\Lambda}_{l}]=1, \tag{147}$$

$$2\alpha_{4}[3\lambda_{q}\,\mathrm{tr}\,\mathbf{g}_{q}^{*}\mathbf{g}_{q}+\lambda_{l}\,\mathrm{tr}\,\mathbf{g}_{l}^{*}\mathbf{g}_{l}]=\mu^{2}, \tag{148}$$

$$a_{4}=1, \tag{149}$$

with the abbreviations

$$
\begin{aligned}
y_q &:= 2(y_{\mathrm{L}}^q)^2 + (y_{\mathrm{R}}^u)^2 + (y_{\mathrm{R}}^{d'})^2 \in \mathbb{R}_+ ,\\
y_l &:= 2(y_{\mathrm{L}}^l)^2 + (y_{\mathrm{R}}^l)^2 \in \mathbb{R}_+ ,\\
\mathbf{\Lambda}_q &:= (\mathbf{\Lambda}'^q, \mathbf{\Lambda}^q) \in \mathbf{M}_{2\mathrm{N}\times\mathrm{N}}(\mathbb{C}),\\
\mathbf{g}_q &:= (\mathbf{g}'^q, \mathbf{g}^q) \in \mathbf{M}_{2\mathrm{N}\times\mathrm{N}}(\mathbb{C}),\\
\mathbf{\Lambda}_l &:= \mathbf{\Lambda}^l \in \mathbf{M}_{\mathrm{N}}(\mathbb{C}),\\
\mathbf{g}_l &:= \mathbf{g}^l \in \mathbf{M}_{\mathrm{N}}(\mathbb{R}).
\end{aligned}
\tag{150}
$$

Proof: The proof of this lemma mainly consists in determining z of the commutant, yielding

$$
\mathrm{z} = \begin{pmatrix} \mathrm{z}_{\mathrm{L}} & 0 \\ 0 & \mathrm{z}_{\mathrm{R}} \end{pmatrix}, \tag{151}
$$

$$
\mathrm{z}_{\mathrm{L}} = \begin{pmatrix} \lambda_q \mathbf{1}_{6\mathrm{N}} & 0 \\ 0 & \lambda_l \mathbf{1}_{2\mathrm{N}} \end{pmatrix}, \tag{152}
$$

$$
\mathrm{z}_{\mathrm{R}} := \begin{pmatrix} \lambda_q \mathbf{1}_{6\mathrm{N}} & 0 \\ 0 & \lambda_l \mathbf{1}_{\mathrm{N}} \end{pmatrix}, \tag{153}
$$

with λ_q, $\lambda_l \in \mathbb{R}_+$. Then, rewriting the functionals (123)–(126) into the form (135)–(137) gives the desired relations. Clearly, the relation for a_4 simply follows by direct comparison of the corresponding fermionic functionals.

Remark 9: Note that we still have one more free parameter, α say, to introduce in our model kit and to write instead of (85):

$$
\mathscr{T}_{\widetilde{\mathrm{D}}} = (\psi, \widetilde{\mathrm{D}}\psi)_{\Gamma(\mathscr{E})} + \alpha \ \mathrm{res}_\zeta(\widetilde{\mathrm{D}}^{-2n+2}).
$$

Of course, this additional parameter indicates that in the definition of the universal action (2) the fermionic and the bosonic action functionals are considered as independent of each other. Alternatively, one may put $\alpha \equiv 1$ and then rescale both functionals independently (although we only have one overall constant!). This is what we did, actually, to obtain (132)–(134). Note that the right normalization of (124) crucially depends on the relations (112), which the hypercharges have to satisfy. Also note that the reason that each generation of quarks and each generation of leptons is equally weighted by the corresponding two constants λ_q and λ_l, respectively, is a consequence of the arbitrariness of the matrices $\mathbf{\Lambda}$ used in the definition of the endomorphism ϕ'.

The derived relations (143)–(149) can be related to physically measurable parameters. First, we have the following.

Lemma 7: The ''electroweak angle'' θ_{W} has the range

$$
0.25 \leqslant \sin^2\theta_{\mathrm{W}} \leqslant 0.45. \tag{154}
$$

Proof: By definition, the electroweak angle θ_{W} measures the portion of electromagnetism to weak force:

$$
\sin\theta_{\mathrm{W}} := \frac{\|\mathbf{T}_3\|}{\|\mathbf{Q}\|}. \tag{155}
$$

The norm $\|.\|$ used here is defined with respect to the ''su(N) normalization:'' $\kappa(\mathbf{E}_a, \mathbf{E}_b) := (1/2g_{\mathrm{N}}^2)\delta_{ab}$, where $\{\mathbf{E}_a\}_{1\leqslant a\leqslant \dim \mathrm{su}(\mathrm{N})}$ denotes an appropriate basis in the fundamental representation of su(N), $\mathrm{N} \geqslant 2$. To explain this more mathematically, we remind the reader of the fact that the general Killing form $\widetilde{\kappa}$ on a simple Lie algebra $\mathscr{G}$ may be written as $\widetilde{\kappa}(a,b) = (\lambda/g^2)(\rho'(a), \rho'(b)) \forall a, b \in \mathscr{G}$, where (.,.) denotes any ad-invariant scalar product on

$\rho'(\mathcal{G})\subset \mathrm{End}(V)$ with representation $\mathcal{G}\overset{\rho'}{\to}\mathrm{End}(V)$. Here, the constant λ depends on the scalar product and g is an arbitrarily positive constant, parametrizing the scalar product. This holds true also when $\mathcal{G}$ is semi-simple. However, the constant g—the ''coupling constant'' in physical terms—may be chosen differently for each simple component. Without loss of generality we can assume that $\lambda(\rho'(\mathbf{E}_a),\rho'(\mathbf{E}_b))=\delta_{ab}$ to obtain the well-known formula

$$\sin^2\theta_{\mathrm{W}}=\frac{g_{(1)}^2}{g_{(1)}^2+g_{(2)}^2} \tag{156}$$

for the electroweak angle. Hence,

$$\sin^2\theta_{\mathrm{W}}=\frac{\lambda_l+3\lambda_q}{(1+2y_l)\lambda_l+3(1+2y_q)\lambda_q}. \tag{157}$$

The range (154) then follows by the appropriate numerical values (113) and (114) of the hypercharges.

Remark 10: Since all norms proportional to each other give the same $\sin\theta_{\mathrm{W}}$ we may choose, alternatively, $(\rho'(a),\rho'(b)):=\mathrm{tr}(\mathrm{z}\rho'(a)^*,\rho'(b))$ to define the norm in (155). Hence,

$$\sin^2\theta_{\mathrm{W}}=\frac{(\mathbf{T}_3,\mathbf{T}_3)}{(\mathbf{Q},\mathbf{Q})}, \tag{158}$$

which, again, leads to (156). In this form, however, it becomes evident how the range (154) does depend on the generalized Dirac–Yukawa operator of the standard model, namely just by fixing the commutant.

The analog holds true for the ratio $g_{(2)}^2/g_{(3)}^2$ of the weak and strong coupling constants, yielding

$$g_{(2)}^2/g_{(3)}^2=\frac{4\lambda_q}{3\lambda_q+\lambda_l}. \tag{159}$$

Note that when we disregarded the possibility of introducing the element ζ in the definition of the bosonic action functional (74), the relations (157) and (159) were just a consequence of the fermionic representation ρ used in the derived Yang–Mills action. Obviously, the same holds true in the case of $\lambda_q=\lambda_l$, giving the ''GUT-preferred'' numerical values:

$$\begin{aligned}\sin^2\theta_{\mathrm{W}}&=\tfrac{3}{8},\\ g_{(3)}&=g_{(2)}.\end{aligned} \tag{160}$$

On the today energy scale, however, $\lambda_q\ll\lambda_l$ seems to be preferred (cf. Ref. 2). Hence, $g_{(2)}\ll g_{(3)}$, which might be expected, intuitively.

A more model-specific relation may be obtained concerning the ratio m_h/m_w of the ''Higgs mass'' and the ''W-boson mass'' of the electroweak interaction. By definition, having fixed a (classical) vacuum $\varphi_0\in\Sigma$, the masses of the gauge bosons are given by the quadratic form

$$\begin{aligned}\Omega^1(\mathcal{M},\rho_h'(\mathcal{G}))&\overset{\mathbf{M}^2}{\to}C^\infty(\mathcal{M})\\ \alpha&\mapsto \tfrac{1}{2}\,\mathbf{M}_{ab}^2*(\alpha^a\wedge *\alpha^b).\end{aligned} \tag{161}$$

with $\mathbf{M}_{ab}^2:=\varphi_0^*[\rho_h'(\mathbf{E}_a),\,\rho_h'(\mathbf{E}_b)]_+\varphi_0$ and $[.,.]_+$ the anti-commutator; $\{\mathbf{E}_a\}_{1\leqslant a\leqslant\dim\mathcal{G}}$ is a basis in the (semi-simple) Lie algebra $\mathcal{G}$ of the structure group G, so that $\alpha=\alpha^a\otimes\rho_h'(\mathbf{E}_a)$. In the unitary gauge: $\varphi_0=(0,v/\sqrt{2})^T$ we get $m_w^2=g_{(2)}^2v^2/4$.

The mass (matrix) of the Higgs field is defined with respect to the quadratic form:

$$\begin{aligned}\Gamma(E_h) &\xrightarrow{\mathbf{M}_h^2} C^\infty(\mathscr{M})\\ h &\mapsto \tfrac{1}{2}\,(h, V''|_{\varphi=\varphi_0} h)_{\mathrm{E}_h},\end{aligned} \tag{162}$$

with $h:=\varphi-\varphi_0$ and $(.,.)_{\mathrm{E}_h}$ the induced scalar product on the subbundle $\mathrm{E}_h\subset\mathrm{E}$. In the unitary gauge this yields $m_h^2=2\lambda v^2$.

Consequently, using (146) and (148) we end up with

$$\frac{m_h^2}{m_w^2}=\frac{4(2n-1)(2n-3)}{N\pi^2}\left(\frac{l}{l_p}\right)^4\frac{3\lambda_q+\lambda_l}{(4\lambda_q+\lambda_l)^2}\,(3\lambda_q\Lambda_q^4+\lambda_l\Lambda_l^4)(a_0a_2)^2, \tag{163}$$

with the abbreviation $\Lambda^4:=\mathrm{tr}\,(\mathbf{\Lambda}^*\mathbf{\Lambda})^2$. Some further investigations similar to those in Ref. 23 are needed in order to find out whether there are sufficiently relations between the unknowns on the right-hand side of (163) determining a range where the Higgs mass has to lie.

We finish this section by considering the special case of $\mathbf{\Lambda}\equiv\mathbf{g}$, yielding the following.

Lemma 8: Let $\phi'=-i\phi$ as defined by (110). Then the mass squared of the Higgs field and of the W-boson reads

$$m_h^2=\frac{2(2n-1)}{(n-1)}\left(\frac{a_0}{a_3}\right)^2\frac{3M_q^4+M_l^4}{3M_q^2+M_l^2}, \tag{164}$$

$$m_w^2=\frac{(n-1)}{2(2n-3)N}\left(\frac{a_3}{a_2}\right)^2\frac{3M_q^2+M_l^2}{3\lambda_q+\lambda_l}, \tag{165}$$

with $M_q^2:=\mathrm{tr}(\mathbf{\lambda}_q\mathbf{m}_q^*\mathbf{m}_q)$ *and* $M_l^2:=\mathrm{tr}(\mathbf{\lambda}_l\mathbf{m}_l^*\mathbf{m}_l)$. [Note, by abuse of notation $M^4\equiv\mathrm{tr}(\mathbf{\lambda}(\mathbf{m}^*\mathbf{m})^2)$.] Here, we used the abbreviation $\mathbf{m}_q^*\mathbf{m}_q\equiv\mathbf{m}_d^*\mathbf{m}_d+\mathbf{m}_u^*\mathbf{m}_u$ and $\mathbf{\lambda}_q:=\lambda_q\mathbf{1}_N$, $\mathbf{\lambda}_l=\mathrm{diag}(\lambda_{l_1},\ldots,\lambda_{l_N})\in\mathbf{M}_\mathrm{N}(\mathbb{R})$. Correspondingly, $\lambda_q:=\mathrm{tr}\,\mathbf{\lambda}_q/\mathrm{N}$, as before. However, $\lambda_l:=\mathrm{tr}\,\mathbf{\lambda}_l/\mathrm{N}$. Note that by the commutant all irreducible subspaces of the fermionic representation space V are now independently weighted. Because of the Kobayashi–Maskawa matrix the quark sector is considered as irreducible.

Proof: Since $m_h^2=2\lambda v^2$ we have with (146)

$$m_h^2=16\alpha_0\,\frac{3M_q^4+M_l^4}{v^2}; \tag{166}$$

The relation (147) then implies (164). With

$$l^2=\frac{1}{2(2n-1)}\left(\frac{1}{a_0}\right)^2\frac{3M_q^2+M_l^2}{3M_q^4+M_l^4}, \tag{167}$$

and

$$v^2=\frac{(n-1)}{\pi(2n-1)N}\left(\frac{a_3}{a_0}\right)^2\frac{(3M_q^2+M_l^2)^2}{3M_q^4+M_l^4}\,\frac{m_p^2}{4\lambda_q+\lambda_l}, \tag{168}$$

an analogous calculation yields (165).

Note that in the two geometrically distinguished cases where either the Higgs field defines a certain supercurvature or a certain differential form, the Higgs form ω_ϕ, as discussed in (94) and (95), the Higgs mass is determined by the mass of the fermions, and its range depends on the weights of all the irreducible subspaces of the fermionic representation. In this sense the parameter ''Higgs-mass'' in the standard model may be considered as *derived* from the generalized Dirac–Yukawa operator of the standard model. Clearly, the same holds for all other (possible) derivable relations between physical parameters. We stress that the commutant in the definition of the bosonic functional (85) is motivated mainly by the fact that absolute values of the physical

parameters, like the masses or charges of the particles involved, are of no physical significance. In this sense the generalization (74) becomes very plausible. Again, one has to take into account that the parameters defining the commutant are scale dependent in general.

IV. OUTLOOK

To summarize, in this paper we have introduced a particular geometrical model building kit based on the notion of generalized Dirac operators, considered as a triple $(\mathrm{G},\rho,\mathrm{D})$. Correspondingly, the geometrical setting is given by a Clifford module bundle $(\mathscr{E},c)$ over a (closed, compact) Riemannian (spin-) manifold $(\mathscr{M},g)$ of even dimension $2n>2$. Within this geometrical frame we proposed the universal functional

$$\mathscr{T}_{\mathrm{D}} := (\Psi, i\mathrm{D}\Psi)_{\Gamma(\mathscr{E})} + \mathrm{res}_{\zeta}(\mathrm{D}^{-2n+2}) \tag{169}$$

on $\Gamma(\mathscr{E})\times\mathscr{A}(\mathscr{E})$, $\mathrm{D}_{\nabla}=\mathrm{D}$, generalizing the classical action functional of the standard model. Indeed, we have shown how the action functional of the standard model—with the gravity action included—can be derived from a generalization of the Dirac–Yukawa operator. For this we have introduced a certain class of Dirac operators, parametrized by some constants. Two particular choices of these constants are distinguished geometrically. In particular, we have shown that the structure of the Yukawa coupling is such that it naturally defines a certain one-form $\omega_{\phi} := \delta_{\xi}\Phi$ on a twisted Clifford module bundle $\mathscr{E}$ (the Higgs form) and hence a particular connection thereof. Using this connection to define a certain Dirac operator and then evaluate the proposed functional (85) (with respect to diagonal sections) one obtains the full action of the standard model. Having derived the action we have shown how the free parameters of the model are linked to physical quantities like masses and charges of the various fields involved. Depending on the number of independent parameters of the model this may then lead to nontrivial relations between the physical quantities. For a special case we derived a relation between the mass of the Higgs field and the masses of the fermions.

The basic idea is that the fermionic interactions determine the dynamics of *all* the fields involved in the theory. In the case of the standard model the fermionic interaction is defined with respect to the Yukawa coupling (besides the gauge covariant coupling), giving rise to a nonstandard Dirac operator—the Dirac–Yukawa operator. Here, ''nonstandard'' means that the appropriate class of connections, defining the Dirac operator in question, does not contain a Clifford connection as a representative and thus indicates that the basic geometrical setting is that of a Clifford module bundle instead of the particular case of a twisted spinor bundle. Indeed, according to the Higgs form, the tensor product structure of the Clifford module is ignored. In contrast to mathematical applications, where mainly SDOs are of interest, in physics non-SDOs seem to play a dominant role. Let us assume that all particles are massless. In this case the fermionic interaction is described by a gauge potential. Accordingly, the corresponding Dirac operator D is a SDO. However, in our scheme one has to consider not this operator but, instead, $\widetilde{\mathrm{D}} := D + \mathscr{J}(c(F))$, where F is the relative curvature (in this case the twisting curvature) on the Clifford module bundle $\mathscr{E}$. Clearly, this new Dirac operator $\widetilde{\mathrm{D}}$ on $\widetilde{\mathscr{E}}$ is nonstandard. Evaluation of the functional (85) with respect to this operator leads to the Einstein–Hilbert–Yang–Mills action and hence the description of the full dynamics of the physical system under consideration (cf. Ref. 11) therefore, although in the case where the dynamics of the fermions are described by a SDO it seems to be more natural, actually, to consider the non-SDO $\widetilde{\mathrm{D}}$, describing the full dynamics. As a consequence of this scheme, however, one necessarily has to double the ''internal degrees of freedom'' of the fermions: $\mathrm{E}\to\widetilde{\mathrm{E}} := \mathrm{E}\oplus\mathrm{E}$. Moreover, both parts have to carry the same fermionic representation. Note that this doubling may be described, geometrically, as the pullback bundle $\Delta^*(\mathrm{E}\times\mathrm{E})$ of $\mathrm{E}\times\mathrm{E}\to\mathscr{M}\times\mathscr{M}$ with respect to the diagonal map $\mathscr{M}\ni x\overset{\Delta}{\to}(x,x)\in\mathscr{M}\times\mathscr{M}$. The latter may be identified with $\mathscr{M}\times\{\pm 1\}$ and thus, implicitly, also a doubling of space time is involved in our scheme. Since this construction is fundamental we are left to interpret this doubling physically (cf. discussion to follow).

With respect to the standard model, our model building kit somehow parallels the Connes–Lott approach. In fact, both approaches yield analogous results concerning the relations between the various parameters of the models. It therefore might be worth comparing both approaches,

though the general mathematical frame work is quite different and there is no doubt that, from a mathematical point of view, Connes' noncommutative geometry is much more indepth (cf. Refs. 4, 24, and 25 for a good review). Obviously, both kits have in common that the basic building block are Dirac operators. In the Connes–Lott scheme it is the internal Dirac operator $\mathscr{D}$ and in the kit proposed here it is the Dirac–Yukawa operator D_ϕ. As already mentioned in the Introduction, the basic ideas of our model and, especially, the approach of considering the Yukawa coupling as the fundamental input to derive the bosonic action of the standard model with gravity included was already proposed in Ref. 12. [By use of the correct Yukawa coupling (9), the generalized Dirac–Yukawa operator in Ref. 12 is of the form (95) of the paper at hand, and thus gives rise to the EHYMH action.] Indeed, also in the Chamseddine–Connes scheme the Dirac–Yukawa operator is considered as the main ingredient (cf. Refs. 6 and 8). In this scheme the universal action is defined by the heat trace in contrast to the original Connes–Lott description of the standard model, where the action was defined via the Dixmier trace (cf. the corresponding remarks in the Introduction). Concerning the standard model, in the Chamseddine–Connes approach one has to consider all Seeley–deWitt coefficients at least up to order four in the asymptotic expansion of the heat trace since the heat kernel is defined with respect to the Dirac–Yukawa operator D_ϕ. In our scheme, however, the generalized Dirac–Yukawa operator $\widetilde{\mathrm{D}}_\phi$ is considered as the basic Dirac operator. Hence, the full action of the standard model is given by the subleading term of the asymptotic expansion of the corresponding heat trace. Note that the latter yields exactly the action of the standard model, which is not the case in the Chamseddine–Connes scheme. Since in this scheme the derived action obtained by the Dirac–Yukawa operator is more general than the action of the standard model (it also contains the well-known *quadratic* terms in the curvature of the base manifold), one obtains more constraints for the parameters involved in the model (cf. Ref. 8). However, the relations (112) for the weak hypercharges and the relations (157) and (159) for the electroweak angle and the coupling constants, respectively, are merely a consequence of the Yukawa coupling (9) and that all fields involved in the model carry the fermionic representation. Hence, in this respect, the Chamseddine–Connes scheme and our kit yield similar results.

The power ''$-2n+2$'' in the definition of the action $\mathscr{S}_\mathrm{D}$ proposed here is motivated by the fact that there exists a generalized Dirac operator (in our sense) that gives back the *exact* action of the standard model. In fact, σ_2 is the only coefficient in the asymptotic expansion of the heat trace which is linear in the curvature of the base manifold. Also by formal analogy between the asymptotic expansion of the heat trace and the asymptotic expansion of the effective action in quantum field theory one may expect, intuitively, that the ''classical action'' is covered by the subleading term, only. As already mentioned, while the bosonic functional (68) was already considered in Ref. 10, and in Ref. 18 in the case of the pure gravity action, and in Ref. 17 from a somewhat more general perspective, the possibility to also derive the Yang–Mills and Higgs action from (68) was not taken into account.

If the former is considered as ''facts,'' we now turn to some ''fictions.'' As we have already mentioned, the price we have to pay for ''adding even terms'' to Dirac operators and thereby changing the emphasis from SDOs to non-SDOs is the additional structure $(\mathscr{E},\mathscr{J})$, which we have to introduce in our model. Of course, this needs some physical interpretation. A physically satisfying way to understand this additional structure may consist of interpreting the doubling of the internal degrees of fermionic freedoms by introducing the notion of ''antiparticles'' in our scheme. Hence, we have to incorporate the notion of ''charge conjungation'' within our model, which will be done in a forthcoming paper where we shall also investigate in more detail the relation (163).

Another point that we have in mind concerns spectral geometry. Since the whole dynamics of the fields involved in a physical theory should be determined by a single (generalized) Dirac operator, and, moreover, the corresponding fermionic action is proposed—naturally enough—to take its well-known form, one may ask whether the bosonic action actually can be considered as ''generalizing'' the fermionic action. Indeed, it is well known by physicists that, in a sense, the bosonic action can be recovered from the fermionic action by considering the former as a ''one-loop'' correction of the latter. For this, one has to introduce a zeta-regularized determinant of a certain operator. This may be the point where spectral geometry comes in. In other words, if the bosonic action is considered as a modification of the fermionic action, like above, we are left with the mathematical question of how the proposed bosonic action in our model can be expressed as a zeta-regularized determinant of a Dirac operator. Moreover, as we have seen, from a geometrical

point of view the action functional of the standard model is but the subleading term of the asymptotic expansion of the heat trace of a certain Hamiltonian. Therefore, it might be natural to ask whether the higher terms in the expansion permit a physical interpretation as well. Again, so far this is but fiction. However, it might be worth investigating these points more carefully in a future paper.

Still quite another point, of course, is concerned with the fact that we are dealing with Riemannian manifolds instead of Lorentzian manifolds. Hence, the notion of gravity is just formal. However, our model may be flexible enough to work also in the case when Lorentzian manifolds are considered. The point here is that also the kernels of differential operators of ''Huygens-type'' have an asymptotic expansion like the heat trace of an elliptic operator (cf. Ref. 26). Of course, spectral geometry in this case is not so well established, but see, e.g., Ref. 27 and the corresponding references therein. Finally, since the basic geometrical setting of our model kit is a Clifford module bundle and there is a one-to-one correspondence between Dirac operators and Clifford superconnections, it might be possible to incorporate the notion of ''supersymmetry'' in our scheme. Thus, one may put more emphasis on the ''superformalism,'' as developed by Quillen *et al.* (cf. Refs. 5, 28, and 29), in the case of physics. Concerning our model, this point of view was taken, e.g., in Ref. 30.

We finish this paper with a citation, which expresses the feeling of many physicists. We do, however, hope to have convinced the reader that in fact the contrary holds true:

> ''... this prescription [via the Yukawa-coupling] of the fermion masses is one of the least satisfactory aspects of the theory [standard model]. It is an entirely *ad hoc* procedure... .'' [31]

ACKNOWLEDGMENTS

I would like to thank Th. Schücker for explaining to me the beauty of noncommutative geometry and its application to physics. However, I would like to thank him much more for his ''stubbornness.'' Also, I would like to thank Th. Ackermann for many discussions on this subject, yielding three joined works, and E. Binz for his encouragements. Finally, I would like to thank M. Lesch for very helpful discussions and for explaining the calculation of Eq. (80) to me.

We consider a paraboliclike system of differential equations involving geometrical quantities to examine uniformization theorems for two- and three-dimensional closed orientable manifolds. We find that in the two-dimensional case there is a simple gauge theoretic flow for a connection built from a Riemannian structure, and that the convergence of the flow to the fixed points is consistent with the Poincare Uniformization Theorem. We construct a similar system for the three-dimensional case. Here the connection is built from a Riemannian geometry, an SO(3) connection and two other 1-form fields which take their values in the SO(3) algebra. The flat connections include the eight homogeneous geometries relevant to the three-dimensional uniformization theorem conjectured by Thurston. The fixed points of the flow include, besides the flat connections (and their local deformations), nonflat solutions of the Yang–Mills equations. These latter ''instanton'' configurations may be relevant to the fact that generic 3-manifolds do not admit one of the homogeneous geometries, but may be decomposed into ''simple 3-manifolds'' which do. © *1998 American Institute of Physics.* [S0022-2488(98)01903-3]

I. INTRODUCTION

The uniformization theorem in two dimensions is a powerful tool in geometry and topology, with applications in physics. In essence, the theorem states that the topology of a closed orientable two-dimensional manifold (a Riemann surface) determines which geometries it admits. In particular, if the manifold has handle number zero, it admits the spherical geometry and its local deformations; handle number one admits the flat geometry and its local deformations; and for handle number two or greater, the admissible geometry is that of the hyperbolic plane and its local deformations. It is important that one cannot deform any of these three geometries to obtain one of the other two.

This theorem was proved finally around the beginning of the twentieth century by Poincare.[1] It is a heroic proof, using the most sophisticated mathematics of the day. Unfortunately, the classical proof depended heavily on results in complex analysis, and the generalization to three or higher dimensions was not obvious. In fact, the three-dimensional analog of this theorem was first consistently formulated only in the late 1970's by Thurston and is called Thurston's Geometrization Conjecture.[2] To date, although no counterexamples have emerged and it has been shown to hold for very large classes of manifolds, the conjecture remains unproved.

Recently, Hamilton and Chow have constructed a new proof of the two-dimensional uniformization theorem using techniques not obviously restricted to that number of dimensions.[3,4] They consider a one parameter family of Riemannian metrics $g_{\mu\nu}$ on an n-dimensional smooth manifold M_n, with the ''flow'' governed by the Ricci curvature tensor $R_{\mu\nu}$:

$$\frac{\partial g_{\mu\nu}}{\partial t} = -2R_{\mu\nu} + \frac{2}{n} r g_{\mu\nu}. \tag{1}$$

In the above, r is given by

TABLE I. The eight homogeneous geometries.

Manifold	Isometry group	Metric
S^3	SO(4)	$\cos^2 y\,dx^2+dy^2+(dz-\sin y\,dx)^2$
E^3	$R^3\times$SO(3)	$dx^2+dy^2+dz^2$
H^3	PSL(2,C)	$dx^2+e^{2x}(dy^2+dz^2)$
$S^2\times E^1$	$(\mathrm{Isom}(S^2)\times\mathrm{Isom}(E^1))^+$	$dx^2+dy^2+\sin^2 y\,dz^2$
$H^2\times E^1$	$(\mathrm{Isom}(H^2)\times\mathrm{Isom}(E^2))^+$	$dx^2+dy^2+e^{2x}dz^2$
$\widetilde{\mathrm{SL}(2,R)}$	$\mathrm{Isom}(H^2)\times R$	$\cosh^2 y\,dx^2+dy^2+(dz+\sinh y\,dx)^2$
Nil	$\mathrm{Isom}(E^2)\times R$	$dx^2+dy^2+(dz-x\,dy)^2$
Sol	$\mathrm{Sol}\times(Z_2)^2$	$dx^2+e^{-2x}\,dy^2+e^{2x}\,dz^2$

$$r:=\left(\int_{M_n} d^n x\sqrt{g}\right)^{-1}\int_{M_n} d^n x\sqrt{g}R, \tag{2}$$

where $d^n x\sqrt{g}$, with $g=\det(g_{\mu\nu})$, is the volume element on M_n. It is easy to show that (i) $\partial r/\partial t=0$ along the flow; and (ii) the fixed points of the flow are the ''Einstein metrics'', satisfying $R_{\mu\nu}=(r/n)g_{\mu\nu}$. In two dimensions, the Einstein metrics have constant curvature, and include all homogeneous geometries; in three dimensions, the Einstein metrics include the constant curvature, but not all the homogeneous geometries; and finally, in four and higher dimensions, the Einstein metrics do not have nearly so clear a geometric significance as they do in lower dimensions.

The Hamilton/Chow proof of the uniformization theorem in two dimensions analyzes the ''Ricci scalar flow''

$$\frac{\partial R}{\partial t}=\Delta R+R(R-r), \tag{3}$$

derived from the flow of the metric above. For the cases where R is nonpositive, it is fairly straightforward to show that the flow converges to the fixed points with nonpositive constant curvature.[3] It took a few more years to analyze the case of $R>0$, since this involves a repulsive fixed point.[4]

Isenberg and Jackson[5] examined the Ricci flow in three dimensions in order to shed light on Thurston's Geometrization Conjecture.[2] Unlike the two-dimensional case, it is not true in three dimensions that all closed orientable manifolds admit one of the constant curvature geometries. Rather, one must first canonically decompose the given manifold M into its prime pieces,[6] obtained by cutting along 2-spheres and gluing 3-balls onto the cuts until one or both pieces is homeomorphic to the 3-ball; then cutting along incompressible T^2 until the pieces are either Seifert fiber spaces or contain no embedded incompressible T^2. Denoting the resulting manifolds by M_i, so that $M=M_1\#M_2\#\ldots$, Thurston then conjectures that the universal covers $\widetilde{M}_i$ of each M_i admits one and only one of the *eight* homogeneous geometries possible in three dimensions. See Table I for a list of these eight geometries.

The problem with the approach of Isenberg and Jackson is that on the one hand, there does not seem to be sufficient structure in the Ricci flow to cope with the necessity of decomposing the given manifold as above; and on the other, the fixed points are the constant curvature geometries, a proper subset of the homogeneous geometries. Hence, one must first cut and paste the manifold, then flow the geometry on each piece; and one must look in general for asymptotics, rather than convergence to fixed points.

What we propose here is a one-parameter family of *connections* whose flow converges to flat connections. In two dimensions, these flat connections are equivalent to the constant curvature geometries. This suggests the possibility of another proof of the two-dimensional uniformization theorem. What is important here is that this flow generalizes to three dimensions such that the fixed points of the flow are the eight homogeneous geometries plus certain ''instanton'' configurations, which describe ''necks'' between three-manifolds. We believe that this is a promising approach to proving Thurston's Geometrization Conjecture.

In Sec. II, motivated by the gauge-theoretic formulation of certain two-dimensional gravity theories, we will recast the structure equations for a constant curvature Riemannian *metric* into the form of a flatness condition on an appropriate *connection*. This sets the stage for constructing a one-parameter family of connections—the Yang–Mills flow. In Sec. III, the properties of the Yang–Mills flow will be explicated. We will show that the fixed points of the flow are Yang–Mills connections, a subclass of which is the set of flat connections, and that the latter describe Riemannian metrics of constant curvature. In Sec. IV, we analyze the behavior of the flow. For the cases of spherical and flat Euclidean topologies, we may conclude that the flow converges to the fixed points. We present arguments to show that with initial conditions consistent with regular torsion-free Riemannian geometries, the flow actually converges to the fixed points associated with flat connections, and hence to constant curvature Riemannian geometries. This leads us to believe that one may prove the two-dimensional uniformization theorem using the Yang–Mills flow. In Sec. V, we outline a numerical integration of the Yang–Mills flow. Finally, in Sec. VI, we will propose a generalization of the Yang–Mills flow to three dimensions. We will conclude by sketching the outline of the form that a proof of the Thurston Geometrization Conjecture, using this three-dimensional flow, might take.

II. GAUGE THEORY FORM OF 2D GRAVITY

One of the most fruitful areas of research in fundamental physics at the moment begins with the reformulation of Einstein's theory of gravity—the general theory of relativity—as a *gauge theory* of the (complexified) rotation group SO(3). This approach, pioneered by Ashtekar and his collaborators,[7] has resulted in some progress in constructing a quantum theory of gravity. This is in part due to the fact that the constraints in the theory become polynomial when expressed in terms of the above connection and its conjugate momentum; and this in turn has allowed for the construction of solutions of the constraints. Even more striking results have been attained by reformulating lower dimensional gravity theories as gauge theories. In particular, three-dimensional general relativity can be formulated as a Chern–Simons gauge theory,[8] and some simple two-dimensional gravity theories can be expressed as topological field theories of the so-called BF type.[9,10]

This suggests that it might be useful to examine the flow of connections constructed from the Riemannian geometry, rather than the flow of the metrics themselves. For one thing, as in the above theories of gravity, when expressed in connection form, we expect that the partial differential equations that describe the flow will be polynomial, unlike the Ricci flow, where the terms involving the curvature tensor are nonpolynomial in the metric. More importantly, we note that the connection formulation of lower dimensional gravity theories are topological field theories, and provide a more direct route to the global issues that must be addressed.

The fixed points of the Ricci flow are the Einstein spaces. In two dimensions these are just the spaces which have constant curvature Riemannian metrics: $R=2k$. About ten years ago, Jackiw and Teitelboim (separately) considered the above as a toy model of gravity in two dimensions.[11] A few years later, at least three groups constructed a gauge theory formulation.[9] In this formulation, the field equations of the theory required that a certain connection over spacetime is flat; this in turn was equivalent to the existence of a constant curvature (pseudo-) Riemannian geometry on the spacetime. In the following, we will construct the connection which has this property.

We now consider Riemannian geometry in the first-order Cartan formalism. Instead of the metric tensor $g_{\mu\nu}$ we consider a frame-field e^a, a set of two 1-form fields on M^2. The indices $a,b,\ldots=1,2$. The metric and frame-fields are related by $g_{\mu\nu}=\delta_{ab}e^a_\mu e^b_\nu$. Instead of the Christoffel symbols, we have the spin-connection $\omega_b{}^a$, also a set of 1-form fields on M^2. The spin-connection is skew-symmetric in the indices a,b, so in two dimensions, there is only one algebraically independent component, which we denote simply by ω, defined by $\omega_b{}^a=-\omega\epsilon_b{}^a$.

We can now define a connection 1-form field A:

$$A:=e^aP_a+\omega J, \tag{4}$$

where $\{P_a,J\}$ generate the Lie algebra:

$$[P_a,P_b]=k\epsilon_{ab}J;[J,P_a]=\epsilon_{ab}\delta^{bc}P_c, \tag{5}$$

with δ^{ab} the Euclidean metric. The algebra generated by $\{P_a, J\}$ is so(3) if $k=+1$, iso(2) (the ''Poincare algebra'') if $k=0$, or so(2,1) if $k=-1$. If the torsion

$$T^a := de^a - \epsilon^a{}_b \omega \wedge e^b = 0, \tag{6}$$

then the connection A determines a Riemannian geometry.

The curvature 2-form corresponding to the connection A is given by

$$F(A) := dA + \tfrac{1}{2}[A,A], \tag{7}$$

$$= T^a P_a + \left(d\omega + \frac{k}{2} \epsilon_{ab} e^a \wedge e^b \right) J, \tag{8}$$

$$= T^a P_a - \tfrac{1}{2}(R-2k) v J. \tag{9}$$

In the above, $v = \frac{1}{2}\epsilon_{ab} e^a \wedge e^b$ is the volume element on the manifold M induced by the Riemannian metric.

If the connection A is flat, then the curvature $F=0$, and hence

$$T^a = 0; \tag{10}$$

$$R = 2k. \tag{11}$$

Hence, a flat connection A, with algebra given by k, determines a Riemannian geometry with constant curvature $2k$, and vice-versa.

III. YANG–MILLS FLOW

In this section, we will describe a one-parameter family of connections, of the form given in the previous section.

We start with a two-dimensional manifold M and an admissible Riemannian metric $\bar{g}_{\mu\nu}$ and a (not necessarily compatible) spin-connection $\bar{\omega}$. We use this structure to define the *duals* of form fields, e.g.,

$$*(b_\mu dx^\mu) := \bar{g}^{1/2} \epsilon_{\mu\nu} \bar{g}^{\nu\sigma} b_\sigma \, dx^\mu, \tag{12}$$

where $\bar{g}$ is the determinant of $\bar{g}_{\mu\nu}$. The algebra Eq. (5) is characterized by the constant k. This is determined from the topological structure of M by the Euler number $\chi(M)$

$$k := \frac{\chi(M)}{|\chi(M)|}, \tag{13}$$

if $\chi(M) \neq 0$, and by

$$k = 0, \tag{14}$$

if $\chi(M) = 0$. In fact, $\chi(M)$ can be computed from $\bar{g}_{\mu\nu}$ by

$$\chi(M) = \frac{1}{4\pi} \int_M d^2x \sqrt{\bar{g}} \bar{g}^{\mu\nu} \bar{R}_{\mu\nu}, \tag{15}$$

where $\bar{R}_{\mu\nu}$ is the Ricci tensor of $\bar{g}_{\mu\nu}$. The Euler number $\chi(M)$ is related to the handle number, or genus $h(M)$ of M by $\chi(M) = 2-2h(M)$.

We now flow the connection $A(t)$ given by

$$A(t) = e^a(t) P_a + \omega(t) J. \tag{16}$$

The initial values are given by

$$A(0)=\overline{e^a}P_a+\overline{\omega}J. \tag{17}$$

The differential equations that determine the flow are

$$\frac{\partial A}{\partial t}=-*D_A*F(A). \tag{18}$$

The dual $*$ and the Lie algebra are determined by the initial fields, as discussed above. Hence $*$ and $\partial/\partial t$ commute.

The paraboliclike structure of the flow is displayed most transparently in the equations for the flow of the *curvature*. Using Eq. (18) and the duality in two dimensions of 2-forms with 0-forms, we arrive at

$$\frac{\partial f}{\partial t}=\Delta_A f, \tag{19}$$

where $f:=*F(A)$ is a Lie algebra valued 0-form equivalent to the curvature; and $\Delta_A:=-(*D_A*D_A+D_A*D_A*)$ is the Laplacian with respect to the connection $A(t)$.

The fixed points of the flow are the Yang–Mills connections A_{ym}, i.e., connections which satisfy the Yang–Mills equations:

$$-*D_{A_{ym}}*F(A_{ym})=0. \tag{20}$$

There are two types of Yang–Mills connections. The first are flat connections, i.e., $F(A)=0$. If the e^a are nondegenerate, these connections are equivalent to the constant curvature Riemannian geometries, as we discussed in the last section. The second type of Yang–Mills connections are ''instantons,'' with $F(A)\neq 0$. In this case, the structure group of the connection is reduced to a subgroup which commutes with $f:=*F$.[12]

In order to prove a two-dimensional uniformization theorem, we must establish the following.

Conjecture: From an initial connection corresponding to a sufficiently smooth nondegenerate Riemannian geometry on a 2-manifold M with Euler number $\chi(M)$, the Yang–Mills flow converges to the flat connection corresponding to a Riemannian geometry with constant curvature having the same sign as $\chi(M)$.

In the following two sections we will provide analytical and numerical evidence for this conjecture.

IV. CONVERGENCE OF THE YANG–MILLS FLOW: ANALYTICAL EVIDENCE

There has been some discussion of the properties of Yang–Mills (and related) flows by mathematicians and mathematical physicists.[13] It is clear from this literature, in particular from the thesis of Rade, that the flow exists and is unique for short times, at least for the case of nonnegative Euler number. Unfortunately, the situation with regard to the question of the convergence of flow as $t\to\infty$ is not clear at the moment. In the following, we will discuss the question of convergence from an analytic (but fairly heuristic) perspective. In the next section, encouraging results from numerical treatment will be presented.

The Yang–Mills flow resembles the heat equation

$$\frac{\partial \phi}{\partial t}=\Delta \phi, \tag{21}$$

where Δ is the Laplacian operator with respect to some Riemannian structure defined on the manifold M upon which the field ϕ takes its values. The existence/uniqueness for short times and the convergence as $t\to\infty$ to the ''average'' initial data is well-known.[14] Indeed, it is easy to see that for initial data infinitesimally close to a fixed point, the Yang–Mills flow is parabolic. In general, the Yang–Mills flow is polynomially nonlinear.

We will now discuss the question of convergence for each of the cases $k=0$ and $k=+1$. The $k=-1$ case is the least well-understood at the moment, and is under investigation by the authors.

For the case $k=0$ the Lie group is ISO(2), which is a semidirect product of the Abelian group SO(2) with the two-parameter group of translations. The Yang–Mills flow itself splits into an SO(2) piece which depends only on the A^2-component of the ISO(2) connection:

$$\frac{\partial A^2}{\partial t} = -*d*dA^2. \tag{22}$$

Although this is not strictly parabolic, the flow of the corresponding dual of the curvature component, $f^2 := *F^2 = *dA^2$ is a parabolic system:

$$\frac{\partial f^2}{\partial t} = \overline{\Delta} f^2, \tag{23}$$

where $\overline{\Delta}$ is the Laplacian with respect to the initial Riemannian geometry. Now the average of the initial curvature component,

$$\overline{F^2} := \int_{M^2} dA^2 = 0, \tag{24}$$

where the last equality follows from the fact the in this case M^2 has Euler number zero. Since f^2 converges to a constant 0-form, it must converge to zero everywhere on M_2.

What we have shown is that the manifold which is topologically T^2, i.e., which has Euler number 0, admits a closed 1-form. This is a sufficient condition that the manifold admits a Riemanian geometry with a compatible spin-connection with zero curvature. To see this, consider the following: Let ω be a closed 1-form. But since for T^2 the space of harmonic 1-forms is two-dimensional, there is a harmonic 1-form β such that $\omega \wedge \beta \neq 0$. We can find a chart in which there is a function $p(x)$, such that $\partial_\mu p(x) = \beta_\mu(x)$. Now define the 1-forms e^0, e^1 in this chart by $\epsilon^0(x) = p(x)\omega(x)$, $e^1(x) = -dp(x)$. In the chart, the volume element $e^0(x) \wedge e^1(x) \neq 0$ by construction, and the compatibility condition $de^a - \epsilon^a_b \omega \wedge e^b = 0$ since $d\omega = 0$.

It remains to address the question of which initial conditions, if any, determine flows which converge to the instantons, with $F(A_\infty) \neq 0$.

In the $k=+1$ case, for which the gauge group is SO(3), we have the results of Rade[13] wherein it is proved that for compact simple gauge groups, e.g., SO(3), the Yang–Mills flow converges with respect to the Sobolev norm H^1 to a Yang–Mills connection. What remains here is the question of the instantons, as well as whether the flow converges under stronger smoothness requirements. (It is easy to show that, analytically, a round sphere with arbitrary radius will exponentially converge to the sphere with ''correct'' radius $\sqrt{2}$, i.e., so that $R=2$.)

V. CONVERGENCE OF THE YANG–MILLS FLOW: EXPERIMENTAL DIFFERENTIAL GEOMETRY

The system of coupled partial differential equations Eq. (18) is comprised of polynomially *nonlinear* PDEs, and is therefore potentially quite complicated. However, the right-hand side of Eq. (18) contains second derivatives in the spatial variables and is therefore much like a diffusive system with strange convective terms. If we effectively restrict consideration to the very high frequency components of Eq. (18) by only retaining terms that contain the highest number of spatial derivatives, we find that

$$\frac{\partial A}{\partial t} \approx \delta\, dA, \tag{25}$$

where $\delta = -*d*$. The right-hand side of Eq. (25) is not the Laplacian on M defined by the initial connection, which would be given by $\Delta = \delta d + d\delta$. Thus the system does not, even in this approximation, represent an exact diffusive evolution. However, under the same conditions for which Eq. (25) is valid, we have

$$\frac{\partial f}{\partial t} \approx \Delta f, \tag{26}$$

which *is* a diffusive equation. It is therefore highly probable that high frequency spatial perturbations in the curvature and torsion induced on M by $A(t)$ are rapidly damped as $t \to \infty$. We would therefore expect a breakdown of our conjectured convergence behavior of the flow only if the low frequency modes do not have the appropriate evolution. These modes are dominated by the nonlinear coupling in Eq. (18).

It seems highly probable that such a system will not lend itself to easy analytic study. Rather, before attempting such an analysis, it seems appropriate that we should verify the conjectured behavior as best we can. To do this, we resort to techniques of *experimental mathematics*, wherein we view the conjectured convergence behavior as a *hypothesis*. We will seek experimental evidence for or against the hypothesis.

We can then study the following two questions:

(1) Does A evolve smoothly under Eq. (18) from smooth initial data?
(2) Does A converge to a fixed point in an appropriate space of connections over M? (In general, we expect convergence within an appropriately normed space, which we would have to describe. However, since the computer experiments use only a fixed number of mesh points to represent the manifold, all norms are effectively equivalent for purposes of this section.) If both questions have affirmative answers, we would also like to answer the concomitant question:
(3) Does $F(A) \to 0$ as $t \to \infty$?

Should the answers to these questions turn out to be yes, for a reasonably wide set of initial conditions and topologies, we would have hope that further study of the flow method ought to be useful in understanding uniformization theorems. We might further hope that our numerical ''experiments'' would enable us to observe useful properties of Eq. (18) that help suggest ways to prove our conjecture. To the contrary, should we find a numerical counterexample to our conjecture, we could rapidly verify that the conjecture would be false. This is the heart of the experimental mathematics concept. Given that we conjecture Eq. (18) to be diffusive and parabolic, we must first choose a numerical method appropriate to such equations. It is then an important part of the experimental process to verify the consistency of the chosen method. The explicit forward Euler method is the most naive numerical integration method appropriate for diffusive parabolic PDEs. It is important to choose carefully. Assume for the moment that the ''convection'' terms were to dominate over the ''diffusion'' terms, producing dynamics for A that are far more like hyperbolic systems. Hyperbolic PDEs are generally unstable when evolved via naive numerical methods, such as the forward Euler method. Furthermore, it would seem improbable that A would converge if Eq. (18) was primarily hyperbolic in nature and if M was compact.

In the Euler method, the iterated value of the connection at time $t_{n+1} > t_n$ is taken to be

$$A_{n+1} = A_n - \kappa(*D_A f(A_n)), \tag{27}$$

where A_n is the value of A at a time $t_n := t_0 + n\kappa$, $\kappa > 0$, and where A_i is given on a mesh of discrete points approximating the manifold M. Such an approximation is shown in Fig. 1, where an initial connection is represented on a torus. The curvature is represented by variations of the torus geometry, and the actual torus generated is only a representation of the state of $A(t)$ and $f(t)$.

We wish to compare Eq. (18) to the evolution of a linear system of the form

$$\frac{\partial u}{\partial t} = Ku(t), \tag{28}$$

where u is a quantity given on M, and K is a linear operator acting on u. The corresponding forward Euler method is

$$u_{n+1} = u_n + \kappa K u_n, \tag{29}$$

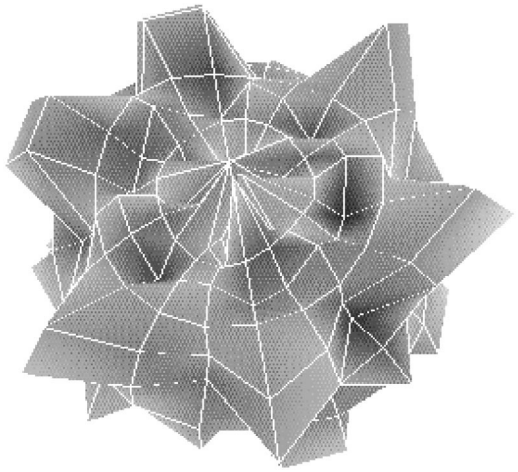

FIG. 1. An initial toroidal mesh.

where everything is expressed on a mesh over M. It is well-known that Eq. (29) fails to produce a valid approximation to the solution of the hyperbolic equation Eq. (28): The numerically produced solution undergoes rapid growth in modes that are high in spatial frequency. The approximation is bad, independently of how small we take κ to be. Diffusive parabolic systems are different in behavior: For κ small enough, the numerical solution obeys Eq. (28).

In view of this comparison, part of our experiment consists of identifying whether Eq. (27) produces a stable approximation (suggesting parabolic behavior) or an unstable one (suggesting hyperbolic behavior).

The experimental procedure is as follows: the symbolic system MAPLE is used to write part of the computer program, converting Eq. (27) into computer code representing evolution on an appropriate mesh with cell size h and time-step κ. We then verify the stability behavior for κ vs h. If we observe the expected stability behavior, we can then analyze the resulting evolution to see if it is consistent with our conjecture.

Happily, Eq. (27) does indeed display, for $k=0$, the precise behavior of a diffusive parabolic PDE. To be precise, for a toroidal rectangular mesh, the numerical stability is observed when κ is smaller than a value that is of order h^2, for a wide range of initial conditions. One particular example of this can be seen in Fig. 2. This is the anticipated signature of a diffusive system, whence we have verified one part of our conjecture, as discussed above. Furthermore, we obtain evidence that, for the $k=0$ case, all three of our earlier questions may be answered in the affirmative. We find that the numerical evolution of Eq. (18) under Eq. (27) produces a convergent A_n, and that $F(A_n)\to 0$, as $n\to\infty$. This is shown in the final state of the mesh; cf. Fig. 3, also drawn on top of the representative torus. We have therefore found support for our conjectured convergence behavior of solutions of Eq. (18), at the experimental level, for $k=0$.

The conjecture can also be experimentally verified for the $k=1$ (spherical topology) case. In the spherical case, we construct an initial connection on a mesh with spherical topology, as shown in Fig. 4. The radius from the center in this image denotes the curvature radius at that point. The flow equations can then be evolved. The connection then flows to one corresponding to a unit 2-sphere, as shown in Fig. 5. We thus have experimental confirmation of the conjecture for $k=0$ and $k=1$.

It remains to verify the conjecture for $k<0$. Unfortunately, Eq. (27) is not very useful in this case. The fact that κ must be smaller than something of order h^2 means that the equations cannot be evolved quickly when we wish to have h small. For complicated topologies that arise for $k<0$ (particularly handlebodies, which do not arise in the other cases), we need many cells, and h *must* be small. Furthermore, it becomes difficult to control the build up of numerical noise with such a naive, conditionally stable, method. For $k<0$ (*and* the 3-D flow described in the next section), more sophisticated techniques will be needed. These techniques will have to deal with the fact that M will generally need to be covered by more than one coordinate patch, more than one gauge patch, will have complicated topology, and even more nonlinear behavior. The best prac-

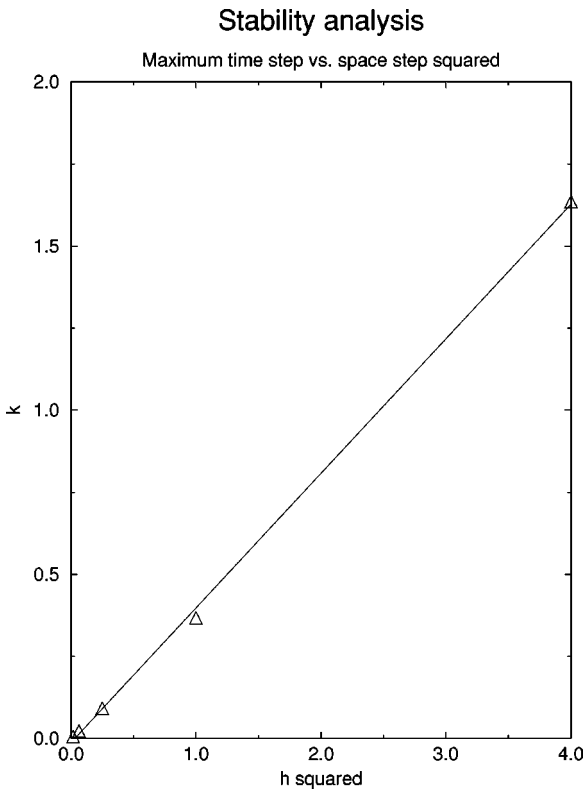

FIG. 2. Stability behavior of the forward Euler method for the flow equations. Line marks linear fit.

tical algorithms seem to be those using multigrid finite element methods. One of us (S.P.B.) is currently developing such techniques.

VI. THE 3-D FLOW

The gauge-theoretic version of a two-dimensional theory of gravity was the starting point for a new approach to proving the two-dimensional uniformization theorem. We emphasize here that we have not completely succeeded in constructing the proof; we have only demonstrated its plausibility. Nevertheless, this suggests that it might be useful to examine gauge-theoretic versions of 3-D gravity theories as possible starting points for a proof of the 3-D uniformization theorem conjectured by Thurston.

Such theories are well-known. Einstein gravity (with or without a cosmological constant) can be formulated as a Chern–Simons gauge theory with gauge group ISO(3) (if the cosmological constant is zero) or SO(4) or SO(3,1) if the cosmological constant is positive or negative.[8] This suggests that we consider a flow of the form

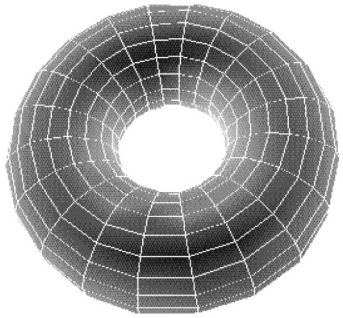

FIG. 3. The final configuration, after numerical evolution.

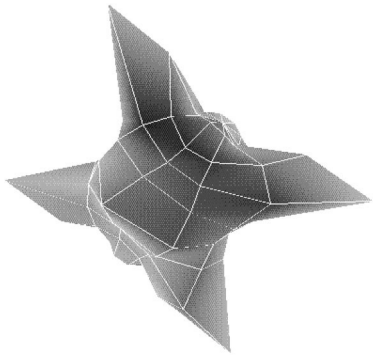

FIG. 4. An initial connection for a spherical topology.

$$\frac{\partial A}{\partial t} = *D_A * F(A), \tag{30}$$

where A is the connection 1-form on some 3-manifold for some gauge group G. One recovers the Riemannian geometry from the connection 1-form via a relation of the form:

$$A = \omega^a G_a + e^a F_a + \cdots , \tag{31}$$

where the G_a, F_n are generators of G, and the ϵ^a, ω^a can be interpreted as a frame field and spin-connection, respectively. The $\cdots$ indicates other terms in any additional generators of the gauge group G. The idea is to choose the gauge group G so that the flat connections (which are a subset of the fixed points of the flow) include at least the *eight* homogeneous geometries that occur in Thurston's conjecture. This is not the case if one chooses one of the groups [ISO(3), etc.] relevant to Einstein gravity. The flat connections for these groups determine frame-fields e^a and compatible spin-connections ω^a which have *constant curvature.*

There is a gauge group whose flat connections include the eight homogeneous three-dimensional geometries. The group is the ''doubly inhomogenized'' group IISO(3). This group is the semidirect product of the ''Poincare group'' ISO(3) with its Lie algebra. It is a 12 parameter noncompact group, whose Lie algebra is

$$[F^a, G^b] = \tfrac{1}{2}\epsilon^{abc} F_c ; \quad [G^a, G^b] = \tfrac{1}{2}\epsilon^{abc} G_c ; \tag{32}$$

$$[G^a, J^b] = \tfrac{1}{2}\epsilon^{abc} J_c ; \quad [G^a, K^b] = \tfrac{1}{2}\epsilon^{abc} K_c ; \tag{33}$$

$$[J^a, K^b] = \tfrac{1}{2}\epsilon^{abc} F_c . \tag{34}$$

The remaining brackets vanish. The G^a generate the SO(3) subgroup, while the remaining generators F^a, J^a, K^a behave like generators of translations, except that the latter two do not commute.

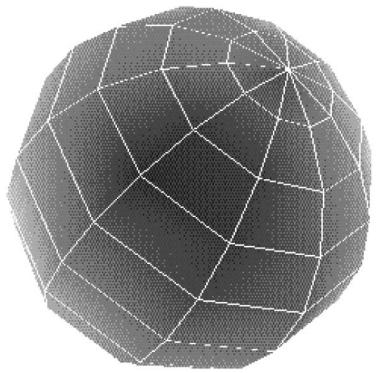

FIG. 5. Final, unit sphere, result of evolution.

TABLE II. Frame fields for homogeneous geometries.

3-manifold	(e^1,e^2,e^3)
S^3	$(\cos y\,dx,dy,dz-\sin y\,dx)$
E^3	(dx,dy,dz)
H^3	$(dx,e^x dy,e^x dz)$
$S^2\times E^1$	$(dx,dy,\sin y\,dz)$
$H^2\times E^1$	$(dx,dy,e^x dz)$
$\mathrm{SL}(\widetilde{2},R)$	$(\cosh y\,dx,dy,dz+\sinh y\,dx)$
Nil	$(dx-z dy,dy,dz)$
Sol	$(dx,e^{-x}dy,e^x dz)$

It was shown in Ref. 15 that the Chern–Simons functional with this gauge group is equivalent to a three-dimensional theory of gravity interacting with topological matter. This is accomplished by constructing the IISO(3) connection as follows:

$$A=\omega^a G_a+e^a F_a+B^a J_a+C^a K_a\,. \tag{35}$$

If A is flat, i.e., $F(A)=0$, then by use of the algebra Eq. (34) it follows that ω^a is a flat SO(3) connection, B^a,C^a are covariantly constant with respect to ω^a and e^a satisfies:

$$D_\omega e^a+\tfrac{1}{2}\epsilon^{abc}B_b\wedge C_c=0, \tag{36}$$

where D_ω is the gauge covariant derivative with respect to the connection ω^a.

One may now construct a spin-connection which is compatible with the frame-field e^a, and hence determines a Riemannian geometry. In particular, one can show that if the e^a are the frame-fields for a homogeneous geometry, then there exist flat connections ω^a and fields B^a,C^a satisfying $D_\omega B^a=0$, $D_\omega C^a=0$ such that ϵ^a satisfies Eq. (36). The explicit expressions are shown in Tables II and III, where we have taken $\omega^a=0$ for simplicity.

It must be remarked here that one may perform an IISO(3) gauge transformation on the flat connection equivalent to the homogeneous geometries. The connections are still flat, of course, but in general the e^a are no longer frame-fields for a homogeneous geometry. It is not clear at this point how general the gauge-transformed e^a are; though it was shown in Ref. 15 that for the case of the 3-manifold topology $S^2\times S^1$, all admissible e^a could be obtained from the ''trivial'' configuration $\omega^a=e^a=B^a=C^a=0$ by a gauge transformation.

If it could be shown that an arbitrary IISO(3) connection on the 3-manifold flowed to one of the flat connections, then it would follow that the 3-manifold would admit the *homogeneous* representative of the gauge orbit. This is what we expect of a proof of the uniformization conjecture for 3-manifolds.

In the two-dimensional Yang–Mills flow, the fixed points of the system are the Yang–Mills connections. However, it seems to be the case that regular initial conditions will flow to the appropriate subclass of flat connections. The reason for this is that in two dimensions, the nonflat

TABLE III. B and C 1-form fields for homogeneous geometries.

3-manifold	(B^1,B^2,B^3)	(C_1,C_2,C_3)
S^3	$(0,dx,0)$	$(d(2\sin y),0,d(2\cos y))$
E^3	$(0,0,0)$	$(0,0,0)$
H^3	$(d(2e^x),0,0)$	$(0,d(-z).dy)$
$S^2\times E^1$	$(d(-2\sin y),0,0)$	$(0,dz,0)$
$H^2\times E^1$	$(d(-2e^x),0,0)$	$(0,dz,0)$
$\mathrm{SL}(\widetilde{2},R)$	$(0,dx,0)$	$(d(-2\sinh y),0,d(2\cosh y))$
Nil	$(0,dy,0)$	$(0,0,d(-2z))$
Sol	$\left(d\left(\frac{z-y}{2}\right),d(e^x),d(-e^{-x})\right)$	$\left(d\left(\frac{z+y}{2}\right),d(2e^x),d(2e^{-x})\right)$

Yang–Mills connections are reducible. This is not the case in three dimensions, since the duals of the curvature 2-forms are 1-forms, and hence *not* gauge parameters. Hence we conjecture that in three dimensions some regular connections, built from nondegenerate Riemannian metrics, will flow to instanton fixed points, not flat fixed points. This might be related to a fundamental difference between the two- and three-dimensional cases. Indeed, as we discussed in Sec. I, in contrast to the two-dimensional case, a given closed orientable 3-manifold does not in general admit a homogeneous Riemannian geometry. Thurston's conjecture is that any 3-manifold admits a canonical decomposition into the connected sum of *simple manifolds*, i.e., prime manifolds which either have no incompressible embedded T^2 or are Seifert fiber spaces; and each simple manifold in turn admits one and only one of the eight homogeneous geometries. If the flow converged to fixed points which were flat connections, then in general it would have to be singular when the manifold was not simple.

However, consider the flow of the curvature as above. The fixed points are the flat connections $F(A)=0$ *and* the Yang–Mills instantons which satisfy $*D_A*F(A)=0$, $F(A)\neq 0$. It would be interesting to examine IISO(3) connections on 3-manifolds to see if the Yang–Mills equations have nonflat solutions when the manifold is simple. If it turns out that simple 3-manifolds admit flat solutions of the Yang–Mills equations, then the next question to examine would be the structure of 3-manifolds which consist of two simple manifolds joined by a ''neck.'' If Thurston's conjecture is correct, then the following scenario should hold: the manifold-with-neck would presumably admit an instanton which was asymptotically flat at the ends of the neck. In general, nonsimple 3-manifolds would *not* admit nontrivial flat IISO(3) connections. Work in this direction is underway by the authors.

Integral equation formulation of the spinless Salpeter equation

F. Brau[a),b)]
Université de Mons-Hainaut, Place du Parc 20, B-7000 Mons, Belgique

(Received 27 June 1997; accepted for publication 12 November 1997)

The spinless Salpeter equation presents a rather particular differential operator. In this paper we rewrite this equation into integral and integro-differential equations. These kinds of equations are well known and can be more easily handled. We also present some analytical results concerning the spinless Salpeter equation and the action of the square-root operator. © *1998 American Institute of Physics.* [S0022-2488(98)00403-4]

I. INTRODUCTION

The Schrödinger equation is a very well defined partial derivative equation since its differential operator is a Laplacian. Moreover it reduces to a simple differential equation when the interaction is central. This equation has been intensively studied and it is well understood. A simple relativistic version of the Schrödinger equation, the spinless Salpeter equation (SSE), presents more difficulties. This equation is

$$(\sqrt{\mathbf{p}^2+m_1^2}+\sqrt{\mathbf{p}^2+m_2^2})\Psi(\mathbf{r})=(E-V(\mathbf{r}))\Psi(\mathbf{r}), \tag{1}$$

where m_1, m_2 are the masses of the particles, $\mathbf{p}$ is their relative momentum, $V(\mathbf{r})$ is the potential interaction and E the eigenenergy of the stationary state $\Psi(\mathbf{r})$ ($\hbar=c=1$). $\mathbf{p}$ and $\mathbf{r}$ are conjugate variables. Actually, this last equation is not so well defined since the kinetic energy operator is a nonlocal one. Its action on a function $f(\mathbf{r})$ is known only if $f(\mathbf{r})$ is an eigenfunction of the operator $\mathbf{p}^2$. In this case we obtain

$$\sqrt{\mathbf{p}^2+m^2}f(\mathbf{r})=\sqrt{\alpha+m^2}f(\mathbf{r}), \tag{2}$$

where α is the corresponding eigenvalue of $\mathbf{p}^2$. Consequently this operator is difficult to handle. However the SSE is not a marginal equation. The correct description of the bound states of two particles is achieved with the Bethe–Salpeter equation.[1] This last reduces to the SSE (Ref. 2, p. 297) when the following occurs.

- The elimination of any dependences on timelike variables is performed (which leads to the Salpeter equation[3]).
- Any references to the spin degrees of freedom of particles are neglected as well as negative energy solutions.

Despite the presence of a so particular operator, the SSE is often used (see for instance Refs. 4–10) since its numerical resolution is very easy for bound states (see for example Refs. 9,11–13). However, it would be interesting to reformulate this equation in a way to better understand it or even to better use it. The main problem is the nonlocality hidden inside the kinetic energy operator. The idea is thus to extract this nonlocality to put it into evidence. That is why in this work we rewrite the SSE as integral or integro-differential equations where the nonlocality is then explicit. Moreover these kinds of equations are well known and defined. Another integral equation, different from those presented here, was found in Ref. 11. This formalism allows us to define the action of the square-root operator on wave functions and calculate the resulting functions.

This paper is organized as follows. In Sec. II, we present the integral and integro-differential equations and we calculate their kernels. In Sec. III, we find some analytical results concerning the action of the square-root operator and solutions of the SSE. At last, we present, in Sec. IV, a summary of this work.

II. INTEGRAL EQUATION FORMULATION

It is possible to rewrite the SSE into different forms. The first one that we present is an integral equation. It is obtained using the Green functions of the kinetic energy operator. The corresponding kernels are different depending on whether the particles are identical or not. The second one is an integro-differential equation. It is obtained taking the square of the square-root operator and is only valid for two identical particles. For these formulations of the SSE only local interactions can be used contrary to the formulation proposed in Ref. 11.

A. First form

In the Introduction we gave the operator expression of the SSE. We are going now to formulate the integral expression of this equation. To obtain it, we use the Green functions of the kinetic energy operator. We first present the equal masses case. Let us consider the following function:

$$G(\Delta)=\frac{1}{(2\pi)^3}\int \frac{\exp(-i\mathbf{p}.\boldsymbol{\Delta})}{2\sqrt{p^2+m^2}}d\mathbf{p}, \tag{3}$$

with $\boldsymbol{\Delta}=\mathbf{r}-\mathbf{r}'$ and $\Delta=|\boldsymbol{\Delta}|$. Then, $G(\Delta)$ is the Green function of the equal masses square-root operator since

$$2\sqrt{\mathbf{p}^2+m^2}G(\Delta)=\frac{1}{(2\pi)^3}\int \exp(-i\mathbf{p}\cdot\boldsymbol{\Delta})d\mathbf{p}=\delta^3(\mathbf{r}-\mathbf{r}'). \tag{4}$$

The solution of the SSE can be written as

$$\Psi(\mathbf{r})=\Psi_0(\mathbf{r})+\int G(\Delta)(E-V(\mathbf{r}'))\Psi(\mathbf{r}')d\mathbf{r}', \tag{5}$$

with $\sqrt{\mathbf{p}^2+m^2}\Psi_0(\mathbf{r})=0$. The solutions of this last equation are $\Psi_0(\mathbf{r})=0$ and $\Psi_0(\mathbf{r})=i_l(mr)Y_{lm}(\hat{r})$, where $i_l(x)=\sqrt{(\pi/2x)}\,I_{l+1/2}(x)$, $I_\nu(x)$ is a modified Bessel function (Ref. 14, p. 952), $Y_{lm}(\hat{r})$ is a spherical harmonic, $r=|\mathbf{r}|$ and $\hat{r}=\mathbf{r}/r$. In Appendix B we show that $\Psi_0(\mathbf{r})=k_l(mr)Y_{lm}(\hat{r})$ is not a solution, the function $k_l(x)$ being defined as equal to $\sqrt{(2/\pi x)}K_{l+1/2}(x)$, with $K_\nu(x)$ a modified Bessel function (Ref. 14, p. 952). Thus only the vanishing solution is relevant for physical problems. One sees immediately that the utilization of nonlocal potentials is impossible if we want to obtain a 1-dimensional integral equation. Calculating the 3-dimensional integral (3) we obtain

$$G(\Delta)=\frac{m}{4\pi^2\Delta}K_1(m\Delta). \tag{6}$$

If we consider only the case of central potentials, the wave function can be written in the form $\Psi(\mathbf{r})=R_l(r)Y_{lm}(\hat{r})$ where $R_l(r)$ is the radial part of the wave function. If, moreover, we place the z axis along $\mathbf{r}$, the angular dependence of Δ is just given by the angle between the vector $\mathbf{r}'$ and the z axis. Then knowing that (Ref. 15, p. 158)

$$Y_{lm}(0,\varphi)=\sqrt{\frac{2l+1}{4\pi}}\delta_{m0}, \tag{7}$$

Eq. (5) is written as

$$R_l(r)\sqrt{\frac{2l+1}{4\pi}}\delta_{m0}=\frac{m}{4\pi^2}\int_0^\infty r'^2(E-V(r'))R_l(r')dr'\int_0^\pi \sin\,\theta'\frac{K_1(m\Delta)}{\Delta}d\theta'\int_0^{2\pi}Y_{lm}(\hat{r}')d\varphi'. \tag{8}$$

We can now perform the integration over the angular variables. We have the well known relations

$$\int_0^{2\pi}Y_{lm}(\hat{r}')d\varphi'=2\pi Y_{lm}(\hat{r}')\delta_{m0}, \tag{9}$$

and (Ref. 15, p. 133)

$$Y_{lm}(\theta,\varphi)=\exp(im\varphi)\sqrt{\frac{2l+1(l-m)!}{4\pi(l+m)!}}P_l^m(\cos\,\theta), \tag{10}$$

where the functions $P_l^m(x)$ are the Legendre functions (Ref. 14, p. 998). Finally, using Eqs. (8)–(10) and the regularized function $u_l(r)=rR_l(r)$, we can write the spinless Salpeter equation on the form of the following integral equation:

$$u_l(r)=\frac{1}{2\pi}\int_0^\infty \mathscr{G}_l(mr,mr')(E-V(r'))u_l(r')dr', \tag{11}$$

with

$$\mathscr{G}_l(mr,mr')=mrr'\int_0^\pi \sin\,\theta'\frac{K_1(m\Delta)}{\Delta}P_l(\cos\,\theta')d\theta', \tag{12}$$

where the functions $P_l(x)$ are the Legendre polynomials (Ref. 14, p. 1025). The functions $\mathscr{G}_l(mr,mr')$ are analytic for each value of l. Performing the transformation $y=\sqrt{r^2+r'^2-2rr'\,\cos\,\theta'}$, we obtain

$$\mathscr{G}_l(mr,mr')=m\int_{|r-r'|}^{r+r'}K_1(my)P_l\left(\frac{r^2+r'^2-y^2}{2rr'}\right)dy. \tag{13}$$

For each value of l, we can find the primitive and thus calculate the kernel. Indeed, we have the following relations (Ref. 16, p. 87):

$$\int x^{\nu+1}K_\nu(x)dx=-x^{\nu+1}K_{\nu+1}(x), \tag{14a}$$

$$\int x^{-\nu+1}K_\nu(x)dx=-x^{-\nu+1}K_{\nu-1}(x). \tag{14b}$$

With these it is easy to show that

$$\int x^\nu K_\mu(x)dx=-x^\nu K_{\mu-1}(x)-(\nu+\mu-1)x^{\nu-1}K_\mu(x)+(\nu+\mu-1)(\nu-\mu-1)\int x^{\nu-2}K_\mu(x)dx. \tag{15}$$

This last relation is useful when one calculates the kernel for $l\geqslant 2$. The modified Bessel functions recursion relation is (Ref. 14, p. 970)

$$K_{\nu+1}(x)=\frac{2\nu}{x}K_\nu(x)+K_{\nu-1}(x). \tag{16}$$

With Eq. (13) we see that the polynomial under the integral is composed only of even powers of the integration variable. Then with relation (15), we can calculate analytically the kernel for each value of l. Another way (more simple) to calculate the kernel is to use the relation derived in Ref. 11,

$$\mathcal{G}_l(x,x')=2^l z^{l+1}\left(\frac{1}{z}\frac{\partial}{\partial z}\right)^l \frac{1}{z}[(y-z)^{l/2}K_l(\sqrt{y-z})-(y+z)^{l/2}K_l(\sqrt{y+z})], \tag{17}$$

with $y=x^2+x'^2, z=2xx'$. The kernel has as an expression for $l=0$ and $l=1$,

$$\mathcal{G}_0(x,x')=K_0(|x-x'|)-K_0(x+x'), \tag{18}$$

$$\mathcal{G}_1(x,x')=K_0(|x-x'|)+K_0(x+x')+\frac{1}{xx'}[(x+x')K_1(x+x')-|x-x'|K_1(|x-x'|)]. \tag{19}$$

The expressions (18) and (19) show that kernels decrease exponentially when arguments are important enough ($(x+x')$ and $|x-x'|\gg 1$) since $K_\nu(x)\sim\sqrt{\pi/(2x)}\exp(-x)$ when $|x|\gg 1$ (Ref. 14, p. 961). This behavior indicates that when the masses of particles are large, the nonlocality becomes negligible, the SSE becomes almost local and its spectrum coincides with the Schrödinger spectrum. However the explicit limit cannot be done in this formalism. One can remark that these kernels present a logarithmic singularity for $r=r'$.

We treat now the unequal masses case. After the previous calculations, it is obvious that the Green function for the unequal masses kinetic energy operator is given by

$$\widetilde{G}(\Delta)=\frac{1}{(2\pi)^3}\int \frac{\exp(-i\mathbf{p}.\mathbf{\Delta})}{\sqrt{p^2+m_1^2}+\sqrt{p^2+m_2^2}}d\mathbf{p}. \tag{20}$$

This equation becomes, if $m_1\neq m_2$,

$$\widetilde{G}(\Delta)=\frac{1}{(2\pi)^3}\frac{1}{m_1^2-m_2^2}\int (\sqrt{p^2+m_1^2}-\sqrt{p^2+m_2^2})\exp(-i\mathbf{p}.\mathbf{\Delta})d\mathbf{p}. \tag{21}$$

The solution of the SSE can be written as a form similar to Eq. (5) and the function $\Psi_0(\mathbf{r})$ is here always null. One can find it easily by acting the operator $(\sqrt{\mathbf{p}^2+m_1^2}-\sqrt{\mathbf{p}^2+m_2^2})$ on the equation $(\sqrt{\mathbf{p}^2+m_1^2}+\sqrt{\mathbf{p}^2+m_2^2})\Psi_0(\mathbf{r})=0$. Extracting the operator $(-\Delta+m^2)$ from Eq. (21), performing the integration over the momenta and using the Green's theorem (see Ref. 11), one can show that

$$\Psi(\mathbf{r})=\frac{m_1}{2\pi^2(m_1^2-m_2^2)}\int\frac{K_1(m_1\Delta)}{\Delta}(-\Delta_{r'}+m_1^2)(E-V(r'))\Psi(\mathbf{r}')d\mathbf{r}'+(m_1\to m_2). \tag{22}$$

Again, placing the z axis along $\mathbf{r}$ and repeating the previous calculation we obtain

$$u_l(r)=\frac{1}{\pi(m_1^2-m_2^2)}\int_0^\infty \widetilde{\mathcal{G}}_l(m_1 r,m_1 r')(E-V(r'))u_l(r')dr'+(m_1\to m_2), \tag{23}$$

with

$$\widetilde{\mathcal{G}}_l(mr,mr')=\mathcal{G}_l(mr,mr')\left[-\frac{d^2}{dr'^2}+\frac{l(l+1)}{r'^2}+m^2\right]. \tag{24}$$

B. Second form

This second rewriting of the SSE leads to an integro-differential equation. By acting the kinetic energy operator on the left of the equal masses SSE we obtain

$$4(\mathbf{p}^2+m^2)\Psi(\mathbf{r})=E(E-V(\mathbf{r}))\Psi(\mathbf{r})-2\sqrt{\mathbf{p}^2+m^2}V(\mathbf{r})\Psi(\mathbf{r}). \tag{25}$$

Thus, we must calculate the action of the square-root operator on the product of functions $V(\mathbf{r})\Psi(\mathbf{r})$. If we consider only central potentials this product gives a function for which the angular dependence is a spherical harmonic. One can show, with the formalism developed in Ref. 11, that the radial part $g(r)$ of the function $g(r)Y_{lm}(\hat{r})$, resulting from the action of the kinetic energy operator on the function $h(r)Y_{lm}(\hat{r})$, is given by

$$g(r)=\frac{1}{\pi r}\int_0^\infty \mathcal{G}_l(mr,mr')\tilde{h}(r')dr', \tag{26}$$

with $\tilde{h}(x)=xh(x)$. When the right-hand side integral is relevant, this rewriting gives meaning to the action of the kinetic energy operator on a central problem wave function. With this result, one obtains from Eq. (25),

$$\left[\frac{d^2}{dr^2}-\frac{l(l+1)}{r^2}-m^2+\frac{E(E-V(r))}{4}\right]u_l(r)=\frac{1}{2\pi}\int_0^\infty \mathcal{G}_l(mr,mr')V(r')u_l(r')dr'. \tag{27}$$

This last equation is interesting because this is a kind of nonlocal Klein–Gordon Equation (KGE). This shows how the SSE differs from KGE when a nonvanishing interaction is introduced (the free SSE leads to a the free KGE with a different wave number k). Thus the difference is partially given by the nonlocal right-hand side of Eq. (27).

To show how the square-root operator can be particular, we give a simple example in which we show how the hidden nonlocality of the kinetic energy operator could lead to some problems. Let us consider a square well with a range r_c and a depth $-V_0$. In this case, according to r is less than r_c or not, the right-hand side of equal masses SSE is a constant (E or $E+V_0$) times the wave function. Then one can think that in each area this equation leads to

$$[\Delta+\mathrm{Sgn}(r_c-r)k^2]\Psi(\mathbf{r})=0, \tag{28}$$

with

$$k^2=\frac{(E+V_0)^2}{4}-m^2, \quad \text{if } r<r_c,$$

$$k^2=m^2-\frac{E^2}{4}, \quad \text{if } r>r_c.$$

The continuity conditions, for the interior and exterior solutions, at distance $r=r_c$, fix the wave function and the energy. But this method to resolve the SSE does not take into account the nonlocality of the kinetic operator and we obtain the same kind of solution as the KGE. Actually, the problem is the discontinuity. The potential is not a constant for all values of r and the kinetic operator does not commute with it. Thus the equal masses SSE does not lead to Eq. (28). However, in Eq. (27) the nonlocality is contained in the potential part and we can now write an equation for each area ($r<r_c$ and $r>r_c$). We remark that this equation does not reduce to the free KGE when $r>r_c$ because the right-hand side does not vanish. Thus Eq. (27) leads to different solutions that these obtained with KGE for the same square well.

We conclude this section with some remarks concerning these integral equations. The equation derived in Ref. 11 is, for the equal masses case,

$$[E-V(r)]u_l(r)=\frac{2}{\pi}\int_0^\infty \mathcal{G}_l(mr,mr')u_l(r')dr'. \tag{29}$$

Thus if the potential is just a constant, $V(r)=V$, using this equation and Eq. (27) we obtain

$$\left[\frac{d^2}{dr^2}-\frac{l(l+1)}{r^2}-m^2+\frac{(E-V)^2}{4}\right]u_l(r)=0. \tag{30}$$

The nonlocality disappears and we find the corresponding Klein–Gordon equation.

It is easy to show, with the operator expression of the SSE, that the free radial solutions are $R_l(r)\propto j_l(kr)$ where the function $j_l(kr)$ is the regular spherical Bessel function defined as

$$j_l(x)=\sqrt{\frac{\pi}{2x}}J_{l+1/2}(x), \tag{31}$$

where the function $J_\nu(x)$ is the Bessel function of the first kind (Ref. 14, p. 951). The wave number k is given by

$$k^2=\left(\frac{1}{4E^2}(m_1^2-m_2^2+E^2)^2-m_1^2\right). \tag{32}$$

In Appendix A we show that

$$\int_0^\infty \mathcal{G}_l(mr,mr')\gamma r' j_l(\gamma r')dr'=\frac{\pi}{\sqrt{\gamma^2+m^2}}\gamma r j_l(\gamma r). \tag{33}$$

Then one can verify that Eqs. (11), (23) and (27) are true for a vanishing potential when γ is replaced by k. In Appendix B, we show that the situation is rather different if one considers the irregular spherical Bessel functions.

III. ANALYTICAL RESULTS

In this section we present some analytical results concerning both the action of the square-root operator and solutions of the SSE. We first calculate the action of the kinetic energy operator on the functions $r^n \exp(-mr)$ ($n\geqslant -1$ and n integer). The Fourier transform, $\tilde{f}(p)$, of these functions are

$$\tilde{f}(p)=(-)^{n+1}\sqrt{\frac{2}{\pi}}\frac{\partial^{n+1}}{\partial m^{n+1}}\frac{1}{p^2+m^2}. \tag{34}$$

Then for each value of n we can calculate the action of the square-root operator. We have, for $n=-1$ and $n=0$,

$$\sqrt{\mathbf{p}^2+m^2}\ \frac{\exp(-mr)}{r}=\frac{2m}{\pi r}K_1(mr), \tag{35}$$

$$\sqrt{\mathbf{p}^2+m^2}\ \exp(-mr)=\frac{4m}{\pi}K_0(mr). \tag{36}$$

We can get two more relations knowing the following integrals (Ref. 14, p. 429):

$$\int_0^\infty \frac{x^{2b+1}\sin(ax)}{(m^2+x^2)^{n+1/2}}dx=(-)^{b+1}\frac{\sqrt{\pi}}{2^n\, m^n\,\Gamma\left(n+\frac{1}{2}\right)}\frac{\partial^{\,2b+1}}{\partial\, a^{2b+1}}[a^n\, K_n(ma)], \tag{37}$$

with $a>0$, Re $m>0$, $-1\leqslant b\leqslant n$ and

$$\int_0^\infty \frac{x^{2b+1}\sin(ax)}{(m^2+x^2)^{n+1}}dx=(-)^{b+n}\frac{\pi}{2\,n!}\left[\frac{\partial^n}{\partial\,\gamma^n}(\gamma^b\,\exp(-a\sqrt{\gamma}))\right]_{\gamma=m^2}, \tag{38}$$

with $a>0$, $0\leqslant b\leqslant n$, $|\arg(m^2)|<\pi$. Rewriting these integrals as 3-dimensional integrals, extracting the square-root operator and integrating the resulting integrals one obtains the following formulas:

$$\sqrt{\mathbf{p}^2+m^2}\left\{\frac{1}{r}\left[\frac{\partial^n}{\partial\,\gamma^n}(\gamma^b\,\exp(-r\sqrt{\gamma}))\right]_{\gamma=m^2}\right\}=(-)^{n+1}\frac{2\,n!}{\pi\,m^n\,(2n-1)!!\,r}\frac{\partial^{\,2b+1}}{\partial\,r^{2b+1}}[r^n\,K_n(mr)], \tag{39}$$

and

$$\sqrt{\mathbf{p}^2+m^2}\left\{\frac{1}{r}\frac{\partial^{\,2b+1}}{\partial\,r^{2b+1}}(r^{n+1}\,K_{n+1}(mr))\right\}=(-)^{n+1}\frac{\pi\,m^{n+1}(2n+1)!!}{2\,n!\,r}\times\left[\frac{\partial^n}{\partial\,\gamma^n}(\gamma^b\,\exp(-r\sqrt{\gamma}))\right]_{\gamma=m^2}. \tag{40}$$

These two equations are valid for $0\leqslant b\leqslant n$.

With these results we can find easily some analytical solutions of the SSE with a nonlocal interaction. Let us consider the following equation:

$$2\sqrt{\mathbf{p}^{\,2}+m^2}\,R_0(r)=E\,R_0(r)-\int_0^\infty W(r,r')\,R_0(r')\,dr'. \tag{41}$$

If we choose

$$W(r,r')=\left[\alpha\,\exp(-mr)-\frac{8m}{\pi}\,(\beta+m)\,K_0(mr)\right]\exp(-\beta r'), \tag{42}$$

then using Eq. (36) we obtain the solution

$$R_0(r)\propto\exp(-mr), \tag{43}$$

$$E=\frac{\alpha}{\beta+m}. \tag{44}$$

Thus it is easy to construct a set of solutions with the operator expression of the SSE, we must just consider a well chosen interaction. We can also find analytical solutions using Eq. (29) with a nonlocal interaction:

$$\frac{2}{\pi}\int_0^\infty\tilde{\mathscr{G}}_l(mr,mr')\,u_l(r')\,dr'=E\,u_l(r)-\int_0^\infty W(r,r')\,u_l(r')\,dr'. \tag{45}$$

Choosing, for example, $l=0$ and

$$W(r,r')=-\frac{2}{\pi}\,\mathscr{G}_0(mr,mr')\left[\frac{2\beta}{r'}+(m^2-\beta^2)\right]+\gamma r\,\exp(-\beta r-\alpha r'), \tag{46}$$

then we get the solution

$$u_0(r)\propto r\,\exp(-\beta r), \tag{47}$$

$$E=\frac{\gamma}{(\alpha+\beta)^2}. \tag{48}$$

Again we can construct with this representation of the SSE a set of analytical solutions corresponding to a set of well chosen interactions.

IV. SUMMARY

In this work our purpose was to rewrite the spinless Salpeter equation into forms more easy to handle, since its differential operator is so particular. To perform it we have extracted the hidden nonlocality of the kinetic energy operator to get it really explicit. Thus we have obtained in Sec. II the following equations:

• For $m_1=m_2$,

$$u_l(r)=\frac{1}{2\pi}\int_0^\infty \mathscr{G}_l(mr,mr')\ (E-V(r'))\ u_l(r')\ dr',$$

and

$$\left[\frac{d^2}{dr^2}-\frac{l(l+1)}{r^2}-m^2+\frac{E(E-V(r))}{4}\right]\ u_l(r)=\frac{1}{2\pi}\int_0^\infty \tilde{\mathscr{G}}_l(mr,mr')\ V(r')\ u_l(r')\ dr',$$

with

$$\tilde{\mathscr{G}}_l(mr,mr')=\mathscr{G}_l(mr,mr')\left[-\frac{d^2}{dr'^2}+\frac{l(l+1)}{r'^2}+m^2\right].$$

• And for $m_1\neq m_2$,

$$u_l(r)=\frac{1}{\pi(m_1^2-m_2^2)}\int_0^\infty \tilde{\mathscr{G}}_l(m_1r,m_1r')\ (E-V(r'))\ u_l(r')\ dr'+(m_1\rightarrow m_2).$$

The kernel $\mathscr{G}_l(mr,mr')$ was first derived in Ref. 11. It is analytic for each value of angular momentum and is given in Sec II. There are two integral equations and one integro-differential equation. These kind of equations are well known. The problem of a definition, connected to the particular kinetic energy operator, are removed when the spinless Salpeter equation is rewritten into these forms or into the form (29) (derived in Ref. 11). Moreover with this last one we can calculate the action of the square-root operator on any functions of the form $h(r)\ Y_{lm}(\hat{r})$ and find the radial part of the resulting functions. If $g(r)$ is this radial part, we have

$$g(r)=\frac{1}{\pi r}\int_0^\infty \tilde{\mathscr{G}}_l(mr,mr')\ \tilde{h}(r')\ dr',$$

with $\tilde{h}(x)=x\ h(x)$. When the integral in the right-hand side is relevant, this expression gives meaning to the action of the square-root operator on central problem wave functions. Indeed, this last relation allows us to explicitly calculate the resulting functions.

In Sec. III we have found some analytical results concerning the action of the square-root operator on some particular functions. With these results and the integral formalism we have shown how to construct a set of analytical solutions of the SSE with well chosen interactions.

ACKNOWLEDGMENTS

We thank Dr. C. Semay and Professor R. Ceuleneer for their availability and useful discussions.

APPENDIX A: FREE SOLUTIONS OF THE INTEGRAL FORM OF THE SPINLESS SALPETER EQUATION

In this section we show, with the integral equation formalism, that the free radial solutions are the regular spherical Bessel functions. It is easy to prove it with the operator expression of the SSE because one can rewrite it as

$$(\Delta+k^2)\ \Psi(\mathbf{r})=0, \tag{A1}$$

where k is given by Eq. (32).

To prove it with the integral formulation, we use the integral expression of the kernel $\mathcal{G}_l(mr,mr')$ [see Eq. (25), Ref. 11],

$$\mathcal{G}_l(mr,mr')=\frac{m^2}{2}\,r\,r'\int_0^\infty \exp\left[-\frac{1}{u}-\frac{m^2}{4}(r^2+r'^2)u\right] i_l\left(\frac{1}{2}m^2rr'u\right)\,du. \tag{A2}$$

Then knowing that

$$j_l(x)=\sqrt{\frac{\pi}{2x}}\,J_{l+1/2}(x),\quad i_l(x)=\sqrt{\frac{\pi}{2x}}\,I_{l+1/2}(x), \tag{A3}$$

and (Ref. 14, p. 718)

$$\int_0^\infty x\,\exp(-\alpha x^2)\,I_\nu(\beta x)\,J_\nu(\gamma x)\,dx=\frac{1}{2\alpha}\exp\left(\frac{\beta^2-\gamma^2}{4\alpha}\right)J_\nu\left(\frac{\beta\gamma}{2\alpha}\right) \tag{A4}$$

(with Re $\alpha>0$, Re $\nu>-1$), we have

$$\int_0^\infty \mathcal{G}_l(mr,mr')\,\gamma r'\,j_l(\gamma r')\,dr'=\frac{\sqrt{\pi}}{m}\,\gamma r\,j_l(\gamma r)\int_0^\infty\frac{\exp[(-1/u)(1+\gamma^2/m^2))]}{u^{3/2}}\,du$$

$$=\frac{\pi}{\sqrt{\gamma^2+m^2}}\,\gamma r\,j_l(\gamma r). \tag{A5}$$

APPENDIX B: SINGULARITY AND THE RELATIVISTIC COULOMB PROBLEM

We know that the relation

$$\sqrt{-\Delta+m^2}\,G(r)=\sqrt{\pm\beta^2+m^2}\,G(r), \tag{B1}$$

leads to $G(r)\propto j_l(\beta r)$ (plus sign) or $G(r)\propto i_l(\beta r)$ (minus sign). The situation is rather different for the irregular spherical Bessel functions $n_l(x)$ and $k_l(x)$ ($n_l(x)=\sqrt{(\pi/2x)}N_{l+1/2}(x)$, where $N_\nu(x)$ is the Bessel function of the second kind). To illustrate, we just consider the function $k_0(x)=\exp(-x)/x$. We see that the right-hand side of Eq. (35) is different from zero as we could expect from Eq. (B1). Then we can write

$$\sqrt{\mathbf{p}^2+m^2}\,\frac{\exp(-\gamma r)}{r}=\sqrt{m^2-\gamma^2}\,\frac{\exp(-\gamma r)}{r}+f(r), \tag{B2}$$

where

$$(\sqrt{\mathbf{p}^2+m^2}+\sqrt{m^2-\gamma^2})f(r)=4\pi\delta(\mathbf{r}), \tag{B3}$$

since

$$(\Delta-\gamma^2)\frac{\exp(-\gamma r)}{r}=-4\pi\delta(\mathbf{r}). \tag{B4}$$

From Eq. (B3) we deduce

$$f(r)=\frac{2}{\pi r}\int_0^\infty\frac{p\,\sin(pr)}{\sqrt{p^2+m^2}+\sqrt{m^2-\gamma^2}}\,dp. \tag{B5}$$

Thus we see that the singularity at the origin of the functions $n_l(x)$ and $k_l(x)$ is very important and very annoying. Indeed, if $f(r)$ was null it would be easy to solve the equal masses relativistic Coulomb problem for $l=0$. In this case one can show that

$$\sqrt{\mathbf{p}^2+m^2}\exp(-\gamma r)=\sqrt{m^2-\gamma^2}\exp(-\gamma r)+\frac{\gamma}{\sqrt{m^2-\gamma^2}}\frac{\exp(-\gamma r)}{r} \tag{B6}$$

and

$$\sqrt{\mathbf{p}^2+m^2}r\ \exp(-\gamma r)=\sqrt{m^2-\gamma^2}r\ \exp(-\gamma r)+\frac{2\gamma}{\sqrt{m^2-\gamma^2}}\exp(-\gamma r)-\frac{m^2}{(m^2-\gamma^2)^{3/2}}\frac{\exp(-\gamma r)}{r}. \tag{B7}$$

Acting as the square-root operator on the left of these relations one can verify them. The equation to solve is

$$2\sqrt{\mathbf{p}^2+m^2}R_l(r)=\left(E+\frac{\kappa}{r}\right)R_l(r). \tag{B8}$$

Using Eq. (B6), we find that the ground state is

$$R_0(r)\propto\exp\left(-\frac{\kappa m}{\sqrt{4+\kappa^2}}r\right), \tag{B9}$$

with

$$E=\frac{2m}{\sqrt{1+(\kappa/2)^2}}. \tag{B10}$$

Using Eqs. (B6) and (B7), the first excited state is given by

$$R_0(r)\propto\left(1-\frac{16\kappa m}{(16+\kappa^2)^{3/2}}r\right)\exp\left(-\frac{\kappa m}{\sqrt{16+\kappa^2}}r\right), \tag{B11}$$

with

$$E=\frac{2m}{\sqrt{1+(\kappa/4)^2}}. \tag{B12}$$

This spectrum is a rather good approximation. For example, the error is $\approx 0.25\%$, for the ground state, if $\kappa=0.456$ and $m=1$ GeV (see Ref. 13). These energies were first obtained in Ref. 17. Let us remark that the wave functions are Schrödinger-like wave functions.

P. Moylan
Physics Department, The Pennsylvania State University, Abington, Pennsylvania 19001

(Received 13 June 1997; accepted for publication 3 November 1997)

An algebraic isomorphism of an extension of the Lie field of so(1,4) and an extension of the Poincaré Lie field was given in Havlicek and Moylan [J. Math Phys. **34**, 5320 (1993)]. Here we use the isomorphism described in that paper in order to obtain matrix elements of the Poincaré Lie algebra generators in a normalizable basis for an arbitrary unitary spherical principal series representation of $SO_0(1,4)$.

I. INTRODUCTION AND NOTATION

In Ref. 1 we have constructed an isomorphism between certain algebraic extensions of the Lie fields of the de Sitter algebra so(1,4) and of the Poincaré Lie algebra. The construction of this isomorphism is based on solving equations of the form $f_\nu(P_\mu)=B_\nu$ $(\mu,\nu=0,1,2,3)$ for unknown, but mutually commuting P_μ where f_ν are algebraic functions of the P_μ and of $(P_\mu P^\mu)^{1/2}$ with coefficients in the enveloping algebra of so(1,4). The B_ν are certain $SO_0(1,4)$ generators. The consequences of our algebraic results for the representation theory of these groups and algebras was studied in Ref. 2. We introduced, on the Hilbert space of a unitary spherical principal series representation of $SO_0(1,4)$,[3] a domain on which the P_μ are skew symmetric operators.

Here we apply these investigations to obtain some precise results about actions of the Poincaré Lie algebra generators in a normalizable basis for an arbitrary spherical principal series representation of $SO_0(1,4)$. Our mathematically rigorous approach is to be contrasted with the very formal results obtained in Ref. 4 for the action of the Poincaré Lie algebra in the ''Lorentz basis.''[4,5] In particular, the matrix elements of the (skew symmetric) Poincaré translation generators in our basis satisfy the properties, which one would expect of the matrix elements of a skew symmetric operator in Hilbert space.

Our notation and conventions are the same as in Ref. 1. In particular we denote by bold faced characters objects such as abstract Lie algebra elements and enveloping algebra elements.

II. MAIN THEOREM

Let $G=SO_0(1,4)$ and let H be a Lorentz subgroup of G. Denote by $\mathscr{G}$ the Lie algebra of G. Let $\mathbf{L}_{ab}$ $(a,b=0,1,2,3,4)$, be the basis for $\mathscr{G}$ as defined in Ref. 1. (They are just the usual generators of pseudo-rotations in the various planes of the five dimensional pseudo-Euclidean space in which the de Sitter space is embedded.) Denote by $\mathscr{E}(\mathscr{G})$ the universal enveloping algebra of $\mathscr{G}$. Let P be the Poincaré group, and denote its Lie algebra by $\mathscr{P}$. A basis for the Poincaré Lie algebra is given by the $\mathbf{L}_{0i}$ and $\mathbf{L}_{ij}$ $(i,j=1,2,3)$ of H together with a commuting Lorentz vector operator $\mathbf{P}_\mu$, which generates the translations.

Now we define the following operators:

$$\mathbf{L}_{12},\mathbf{L}^2,\mathbf{Q}_2=\mathbf{L}_{01}^2+\mathbf{L}_{02}^2+\mathbf{L}_{03}^2-\mathbf{L}^2$$

$$\mathbf{Q}_4=(\mathbf{L}_{12}\mathbf{L}_{30}+\mathbf{L}_{23}\mathbf{L}_{10}+\mathbf{L}_{31}\mathbf{L}_{20})^2,$$

$$\mathbf{D}_2=\mathbf{L}_{04}^2+\mathbf{L}_{01}^2+\mathbf{L}_{02}^2+\mathbf{L}_{03}^2-\mathbf{\Delta}$$

 © 1998 American Institute of Physics

$$\mathbf{D}_4=[\tfrac{1}{4}(\lambda-\rho)]^2-(\mathbf{L}_{12}\mathbf{L}_{30}+\mathbf{L}_{23}\mathbf{L}_{10}+\mathbf{L}_{31}\mathbf{L}_{20})^2 - \left(\sum_{\substack{ijk\\lm=1}}^{3}(\epsilon_{ijk}\{\tfrac{1}{2}\mathbf{L}_{04}\mathbf{L}_{jk}-\mathbf{L}_{0j}\mathbf{L}_{4k}\})(\epsilon_{ilm}\{\tfrac{1}{2}\mathbf{L}_{04}\mathbf{L}_{lm}-\mathbf{L}_{0l}\mathbf{L}_{4m}\})\right), \tag{2.1}$$

where

$$\mathbf{\Delta}=\mathbf{L}_{12}^2+\mathbf{L}_{23}^2+\mathbf{L}_{31}^2+\mathbf{L}_{14}^2+\mathbf{L}_{24}^2+\mathbf{L}_{34}^2, \tag{2.2}$$

and

$$\tfrac{1}{4}(\lambda-\rho)=\mathbf{L}_{12}\mathbf{L}_{34}+\mathbf{L}_{23}\mathbf{L}_{14}+\mathbf{L}_{31}\mathbf{L}_{24}. \tag{2.3}$$

$-\mathbf{L}^2$ and $-i\mathbf{L}_{12}$ are operators for the total angular momentum squared and the third component of the total angular momentum, respectively. $\mathbf{Q}_2$ and $\mathbf{Q}_4$ are the second order and fourth order Casimir operators of H, respectively. The center $Z(G)$ of the universal enveloping algebra $\mathscr{E}(\mathscr{G})$ of $SO_0(1,4)$ is generated by $\mathbf{D}_2$ and $\mathbf{D}_4$, which are second and fourth order Casimir operators of G, respectively.

The Poincaré Lie algebra is generated by the $\mathbf{L}_{0i}$ and $\mathbf{L}_{ij}$ $(i,j=1,2,3)$ of H together with a commuting Lorentz vector operator $\mathbf{P}_\mu$, which generates the translations. Thus, we have the following commutation relations between the $\mathbf{P}_\mu$ and the $\mathbf{L}_{\mu\nu}$:

$$\begin{aligned}[\mathbf{L}_{ij},\mathbf{P}_k]&=-\delta_{ik}\mathbf{P}_j+\delta_{jk}\mathbf{P}_i,\\ [\mathbf{L}_{0i},\mathbf{P}_j]&=-\delta_{ij}\mathbf{P}_0,\\ [\mathbf{P}_\mu,\mathbf{P}_\nu]&=0.\end{aligned} \tag{2.4}$$

Next consider the following objects constructed out of the $\mathbf{L}_{\mu\nu}$ and $\mathbf{P}_\mu$ of P:

$$\tilde{\mathbf{L}}_{\mu 4}=\frac{\lambda}{\sqrt{\mathbf{P}_\rho\mathbf{P}^\rho}}[\mathbf{Q}_2,\mathbf{P}_\mu]-\mathbf{P}_\mu \quad (\lambda\in\mathbb{R})(\mu=0,1,2,3). \tag{2.5}$$

[,] means commutator, and $\mathbf{Q}_2$ is the second order Casimir operator of H as defined in Ref. 1. The $\lambda^{-1}\tilde{\mathbf{L}}_{\nu 4}$ and the $\tilde{\mathbf{L}}_{\mu\nu}:=\mathbf{L}_{\mu\nu}$ satisfy the commutation relations of the generators of G. The $\tilde{\mathbf{L}}_{\mu 4}$ and the $\tilde{\mathbf{L}}_{\mu\nu}$ are a basis for an isomorphic copy of $\mathscr{G}$, which differs from $\mathscr{G}$ by a scaling factor λ in the $\mathbf{L}_{\mu 4}$ directions. We shall refer to this Lie algebra and the corresponding Lie group by $\mathscr{G}_\lambda$ and G_λ, respectively.

Now let $\tilde{\mathbf{C}}_2^\lambda=-\tilde{\mathbf{D}}_2^\lambda+\frac{5}{2}\lambda^2\mathbf{I}$ and $\tilde{\mathbf{C}}_4^\lambda=\tilde{\mathbf{D}}_4^\lambda+\frac{1}{4}\tilde{\mathbf{D}}_2^\lambda-\frac{9}{16}\mathbf{I}\lambda^2$. [$\mathbf{I}$ is the identity in $\mathscr{E}(\mathscr{G})$.] A proof of the following result is given in Refs. 1 and 2. It involves solving Eqs. (2.5) for the $\mathbf{P}_\mu$.

Theorem I:

Let π_ρ $(\rho\in\mathbb{R})$ be a unitary spherical principal series representation of G_λ on an Hilbert space $\mathscr{H}$, and let $d\pi_\rho$ denote the representation of $\mathscr{G}_\lambda$ on $\mathscr{H}$ corresponding to π_ρ. The representation $d\pi_\rho$ of $\mathscr{G}_\lambda$ lifts to a representation $d\pi_\rho^*$ of $\mathscr{E}(\mathscr{G}_\lambda)$ on $\mathscr{H}$. Let $\mathbf{Y}$ be given by

$$\mathbf{Y}=-\rho\mathbf{I}, \tag{2.6}$$

and let

$$\begin{aligned}\tilde{\mathbf{A}}_\mu^\nu=&-\lambda^{-2}\tilde{\mathbf{C}}_4^\lambda\delta_\mu^\nu+\frac{1}{2}\left[\left(\mathbf{Q}_2+\frac{1}{4}\right)\delta_\mu^\nu-\frac{3}{2}\tilde{\mathbf{L}}_\mu^\nu-\tilde{\mathbf{L}}_{\mu\rho}\tilde{\mathbf{L}}^{\rho\nu}-\mathbf{Q}_4\epsilon_{\mu\rho\tau}^\nu\tilde{\mathbf{L}}^{\rho\tau}\right]\frac{\mathbf{Y}}{\lambda}\\ &+\left[\left(\mathbf{Q}_2+\frac{1}{4}-\frac{1}{\lambda^2}\tilde{\mathbf{C}}_2^\lambda\right)\delta_\mu^\nu-\tilde{\mathbf{L}}_\mu^\nu-\tilde{\mathbf{L}}_{\mu\rho}\tilde{\mathbf{L}}^{\rho\nu}\right]\frac{\mathbf{Y}^2}{\lambda^2}-\left(\frac{1}{2}\delta_\mu^\nu-\tilde{\mathbf{L}}_\mu^\nu\right)\frac{\mathbf{Y}^3}{\lambda^3}\end{aligned} \tag{2.7}$$

and

$$\tilde{\mathbf{D}}=\left(\mathbf{Q}_4^2+\frac{1}{4}\,\mathbf{Q}_2-\frac{1}{\lambda^2}\,\tilde{\mathbf{C}}_4^{\lambda}+\frac{3}{16}\right)+\left(\mathbf{Q}_2+\frac{1}{2}\right)\frac{\mathbf{Y}}{\lambda}+\left(\mathbf{Q}_2-\frac{1}{\lambda^2}\,\tilde{\mathbf{C}}_4^{\lambda}-\frac{1}{2}\right)\frac{\mathbf{Y}^2}{\lambda^2}-\frac{2\mathbf{Y}^3}{\lambda^3}. \tag{2.8}$$

Then there is a skew symmetric representation $d\tilde{\pi}_\rho(\mathscr{P})$ of the Lie algebra $\mathscr{P}$ of the Poincaré group on $\mathscr{H}$ with the action of the generators $\mathbf{P}_\mu$ and $\mathbf{L}_{\mu\nu}$ given by

$$d\tilde{\pi}_\rho(\mathbf{P}_\mu)=d\pi_\rho^*(\tilde{\mathbf{D}})^{-1}d\pi_\rho^*(\tilde{\mathbf{A}}_\mu^\nu\tilde{\mathbf{L}}_{\nu 4}),\quad d\tilde{\pi}_\rho(\mathbf{L}_{\mu\nu})=d\pi_\rho(\tilde{\mathbf{L}}_{\mu\nu}). \tag{2.9}$$

Furthermore, the representation $d\tilde{\pi}_\rho(\mathscr{P})$ has a common invariant dense domain in the Hilbert space of the $SO_0(1,4)$ representation.

III. MATRIX ELEMENTS OF L_{ab} IN AN SO(1,4) BASIS

We now introduce a basis for the representation space of a given π_ρ, which is called the *K*-finite basis and which diagonalizes the following chain of subgroups:

$$SO(2)\subseteq SO(3)\subseteq SO(4)\subseteq SO_0(1,4). \tag{3.1}$$

This orthonormal basis is the set of all vectors

$$|klm\rangle \tag{3.2}$$

with k and l being positive integers and m is any integer such that $l\leqslant m\leqslant l$. We let $b(k+l)$ = linear span of $\{|klm>|k+l$ fixed$\}$. Then $\mathscr{H}$ is the completion of

$$\sum_{k+l=0}^{\infty}\oplus b(k+l) \tag{3.3}$$

with respect to the $SO_0(1,4)$ invariant norm on $\mathscr{H}$.[3]

The following result is well known:[6]

Theorem II:

The action of the $\mathbf{L}_{ij}$ $(i,j=1,2,3,4)$ and $\mathbf{L}_{04}$ on the basis fields of Eq. (2.4) in the representation π_ρ is given by

(i) The action of the $\mathbf{L}_{ij}$ $(i,j=0,1,2,3,4)$ is

$$d\pi_\rho(-i\mathbf{L}_{12})|klm\rangle=m|klm\rangle, \tag{3.4}$$

$$d\pi_\rho(\mathbf{L}_{31}-i\mathbf{L}_{23})|klm\rangle=(l-m)^{1/2}(l+m+1)^{1/2}|klm+1\rangle, \tag{3.5}$$

$$d\pi_\rho(-\mathbf{L}_{31}-i\mathbf{L}_{23})|klm\rangle=(l+m)^{1/2}(l-m+1)^{1/2}|klm-1\rangle, \tag{3.6}$$

$$\begin{aligned}d\pi_\rho(-i\mathbf{L}_{34})|klm\rangle=&\left(\frac{(l+m+1)(l-m+1)(k+2l+2)(k)}{(2l+1)(2l+3)}\right)^{1/2}|k-1l+1m\rangle\\&+\left(\frac{(l+m)(l-m)(k+2l+1)(k+1)}{(2l-1)(2l+1)}\right)^{1/2}|k+1l-1m\rangle,\end{aligned} \tag{3.7}$$

$$\begin{aligned}d\pi_\rho(\mathbf{L}_{24}-i\mathbf{L}_{14})|klm\rangle=&-\left(\frac{(l+m+1)(l+m+2)(k+2l+2)(k)}{(2l+1)(2l+3)}\right)^{1/2}|k-1l+1m+1\rangle\\&+\left(\frac{(l-m)(l-m-1)(k+2l+1)(k+1)}{(2l+1)(2l-1)}\right)^{1/2}|k+1l-1m+1\rangle,\end{aligned} \tag{3.8}$$

and

$$d\pi_\rho(\mathbf{L}_{24}+i\mathbf{L}_{14})|klm\rangle=-\left(\frac{(l-m+1)(l-m+2)(k+2l+2)(k)}{(2l+1)(2l+3)}\right)^{1/2}|k-1\,l+1\,m-1\rangle$$
$$+\left(\frac{(l+m)(l+m-1)(k+2l+1)(k+1)}{(2l-1)(2l+1)}\right)^{1/2}|k+1\,l-1\,m-1\rangle. \tag{3.9}$$

(ii) The action of $\mathbf{L}_{04}$ is:

$$d\pi_\rho(\mathbf{L}_{04})|klm\rangle=\frac{1}{2}\{k+l+3/2+i\rho\}\left[\frac{(k+1)(k+2l+2)}{(k+l+2)(k+l+1)}\right]^{1/2}|k+1\,lm\rangle$$
$$-\frac{1}{2}\{k+l+1/2-i\rho\}\left[\frac{(k)(k+2l+1)}{(k+l+1)(k+l)}\right]^{1/2}|k-1\,lm\rangle. \tag{3.10}$$

IV. MATRIX ELEMENTS OF THE POINCARÉ TRANSLATION GENERATORS IN AN SO(1,4) BASIS

We now consider the application of these results to the problem of determining the matrix elements of a basis for the Poincaré Lie algebra in the above K-finite basis. In order to determine the action of $\mathbf{P}_0$ in this basis we use Theorem I. From Eqs. (1.6) and (1.7) of Theorem I together with Theorem II we find

$$\begin{aligned}
d\pi_\rho^*(\tilde{\mathbf{A}}_0^\nu\tilde{\mathbf{L}}_{\nu 4})|klm\rangle=&-i\rho\Bigg\{\Bigg[\frac{1}{8}\left(\left(k+l+\frac{3}{2}+i\rho\right)\sqrt{\frac{(k+1)(k+2l+2)}{(k+l+2)(k+l+1)}}\right)\\
&+\frac{1}{16}\left(k+l+\frac{3}{2}+i\rho\right)\left(-\rho^2-\frac{9}{4}-(k+l+1)(k+l+3)\right)\\
&\times\sqrt{\frac{(k+1)(k+2l+2)}{(k+l+2)(k+l+1)}}\Bigg)-\frac{1}{16}\left(\left(-\rho^2-\frac{9}{4}-(k+l)(k+l+2)\right)\right.\\
&\left.\times\left(k+l+\frac{3}{2}+i\rho\right)\sqrt{\frac{(k+1)(k+2l+2)}{(k+l+2)(k+l+1)}}\right)\Bigg]|k+1\,lm\rangle\\
&+\Bigg[-\frac{1}{8}\left(k+l+\frac{1}{2}-i\rho\right)\sqrt{\frac{k(k+2l+1)}{(k+l+1)(k+l)}}\\
&-\frac{1}{16}\left(\left(k+l+\frac{1}{2}-i\rho\right)\left(-\rho^2-\frac{9}{4}-(k+l-1)(k+l+1)\right)\right.\\
&\left.\times\sqrt{\frac{k(k+2l+1)}{(k+l+1)(k+l)}}\right)\\
&+\frac{1}{16}\left(\left(-\rho^2-\frac{9}{4}-(k+l)(k+l+2)\right)\left(k+l+\frac{1}{2}-i\rho\right)\right.\\
&\left.\times\sqrt{\frac{k(k+2l+1)}{(k+l+1)(k+l)}}\right)\Bigg]|k-1\,lm\rangle\Bigg\}\\
&-\rho^2\Bigg\{\Bigg[\frac{5}{8}\left(\left(k+l+\frac{3}{2}+i\rho\right)\sqrt{\frac{(k+1)(k+2l+2)}{(k+l+2)(k+l+1)}}\right)\\
&+\frac{1}{4}\left(\left(k+l+\frac{3}{2}+i\rho\right)\left(-\rho^2-\frac{9}{4}-(k+l+1)(k+l+3)\right)\right.
\end{aligned}$$

$$\times\sqrt{\frac{(k+1)(k+2l+2)}{(k+l+2)(k+l+1)}}-\frac{1}{4}\left(\left(-\rho^2-\frac{9}{4}-(k+l)(k+l+2)\right)\right.$$
$$\left.\times\left(k+l+\frac{3}{2}+i\rho\right)\sqrt{\frac{(k+1)(k+2l+2)}{(k+l+2)(k+l+1)}}\right)|k+1lm\rangle$$
$$+\left[-\frac{5}{8}\left(k+l+\frac{1}{2}-i\rho\right)\sqrt{\frac{k(k+2l+1)}{(k+l+1)(k+l)}}-\frac{1}{4}\left(\left(k+l+\frac{1}{2}-i\rho\right)\right.\right.$$
$$\left.\times\left(-\rho^2-\frac{9}{4}-(k+l-1)(k+l+1)\right)\sqrt{\frac{k(k+2l+1)}{(k+l+1)(k+l)}}\right)$$
$$+\frac{1}{4}\left(\left(-\rho^2-\frac{9}{4}-(k+l)(k+l+2)\right)\left(k+l+\frac{1}{2}-i\rho\right)\right.$$
$$\left.\left.\times\sqrt{\frac{k(k+2l+1)}{(k+l+1)(k+l)}}\right)\right]|k-1lm\rangle\Bigg\}+i\rho^3\Bigg\{\Bigg[\left(\left(k+l+\frac{3}{2}+i\rho\right)\right.$$
$$\left.\times\sqrt{\frac{(k+1)(k+2l+2)}{(k+l+2)(k+l+1)}}\right)$$
$$+\frac{1}{4}\left(\left(k+l+\frac{3}{2}+i\rho\right)\left(-\rho^2-\frac{9}{4}-(k+l+1)(k+l+3)\right)\right.$$
$$\left.\times\sqrt{\frac{(k+1)(k+2l+2)}{(k+l+2)(k+l+1)}}\right)-\frac{1}{4}\left(k+l+\frac{3}{2}+i\rho\right)$$
$$\times\left(-\rho^2-\frac{9}{4}-(k+l)(k+l+2)\right)$$
$$\left.\times\sqrt{\frac{(k+1)(k+2l+2)}{(k+l+2)(k+l+1)}}\right)\Bigg]|k+1lm\rangle+\Bigg[-\left(k+l+\frac{1}{2}-i\rho\right)$$
$$\times\sqrt{\frac{k(k+2l+1)}{(k+l+1)(k+l)}}-\frac{1}{4}\left(\left(k+l+\frac{1}{2}-i\rho\right)\right.$$
$$\times\left(-\rho^2-\frac{9}{4}-(k+l-1)(k+l+1)\right)$$
$$\times\sqrt{\frac{k(k+2l+1)}{(k+l+1)(k+l)}}+\frac{1}{4}\left(\left(k+l+\frac{1}{2}-i\rho\right)\right.$$
$$\left.\left.\times\left(-\rho^2-\frac{9}{4}-(k+l)(k+l+2)\right)\sqrt{\frac{k(k+2l+1)}{(k+l+1)(k+l)}}\right)\right]|k-1lm\rangle\Bigg\}$$
$$+\rho^4\left\{\frac{1}{2}\left(k+l+\frac{3}{2}+i\rho\right)\sqrt{\frac{(k+1)(k+2l+2)}{(k+l+2)(k+l+1)}}\,|k+1lm\rangle\right.$$
$$\left.-\frac{1}{2}\left(k+l+\frac{1}{2}-i\rho\right)\sqrt{\frac{k(k+2l+1)}{(k+l+1)(k+l)}}\,|k-1lm\rangle\right\}. \tag{4.1}$$

Now from Eq. (2.8) we easily obtain

$$\tilde{\mathbf{D}}=\left(-i\rho+\frac{1}{2}\right)^2\left[\mathbf{Q}_2+\frac{3}{2}+\rho^2-i\rho\right] \tag{4.2}$$

and a straightforward application of Theorem II yields

$$
\begin{aligned}
d\widetilde{\pi}_\rho(\widetilde{\mathbf{D}})|klm\rangle = \Bigg(& +i\rho - \frac{3}{2} + \frac{1}{4}\frac{\left(k+l+\frac{3}{2}+i\rho\right)(k+1)(k+2l+2)\left(k+\frac{3}{2}+l-i\rho\right)}{(k+l+2)(k+l+1)} \\
& + \frac{1}{4}\frac{\left(k+\frac{1}{2}+l-s\right)k(k+1+2l)\left(k+l+\frac{1}{2}-i\rho\right)}{(k+l+1)(k+l)} \\
& - (k+l)(k+l+2)+l(l+1)\Bigg)|klm\rangle \\
& - \frac{1}{4}\left\{\left(k+l+\frac{3}{2}+i\rho\right)\sqrt{\frac{(k+1)(k+2l+2)}{(k+l+2)(k+l+1)}}\left(k+\frac{5}{2}+l+i\rho\right)\right. \\
& \left.\times\sqrt{\frac{(k+2)(k+3+2l)}{(k+3+l)(k+l+2)}}\right\}|k+2lm\rangle - \frac{1}{4}\left\{\left(k+l+\frac{1}{2}-i\rho\right)\right. \\
& \left.\times\sqrt{\frac{k(k+1+2l)}{(k+l+1)(k+l)}}\left(k-\frac{1}{2}+l-i\rho\right)\sqrt{\frac{(k-1)(k+2l)}{(k+l)(k-1+l)}}\right\}|k-2lm\rangle.
\end{aligned}
\tag{4.3}
$$

We now determine $d\widetilde{\pi}_\rho(\mathbf{P}_0)|klm\rangle$ by assuming an expansion in a series of the form

$$
d\widetilde{\pi}_\rho(\mathbf{P}_0)|klm\rangle = \sum_{k'=k+1,k+3,\ldots}^{\infty} c^+_{lm}(k,k')|k'lm\rangle \tag{4.4}
$$

for even k, and an expansion of the form

$$
d\widetilde{\pi}_\rho(\mathbf{P}_0)|klm\rangle = \sum_{k'=0,2,\ldots}^{k-1} c^-_{lm}(k,k')|k'lm\rangle \tag{4.5}
$$

for odd k. [It is clear from Eq. (2.4) that $d\widetilde{\pi}_\rho(\mathbf{P}_0)$ cannot change l and m, and it is clear from (2.5) together with (3.10) and (4.3) that that states $|k'lm\rangle$ with $k'=k+n$ where n is an even integer cannot occur in these expansions.] The following equation is an immediate consequence of Eq. (2.9):

$$
d\widetilde{\pi}_\rho(\widetilde{\mathbf{D}})d\widetilde{\pi}_\rho(\mathbf{P}_0)|klm\rangle = d\pi^*_\rho(\widetilde{\mathbf{A}}^\nu_\mu\widetilde{\mathbf{L}}_{\nu 4})|klm\rangle. \tag{4.6}
$$

By substituting the expansions (4.4) and (4.5) into this equation we obtain a three term recurrence relation for the expansion coefficients $c^\pm_{lm}(k,k')$. We now treat in detail the case of even k. For $k'>k+3$ we obtain:

$$
\begin{aligned}
& \frac{1}{4}\left(k'+\frac{5}{2}+l-i\pi\right)\left(k'+\frac{3}{2}+l-i\pi\right) \\
& \quad\times\sqrt{\frac{(k'+2)(k'+2l+3)(k'+1)(k'+2l+2)}{(k'+l+3)(k'+l+2)(k'+l+2)(k'+l+1)}}\,c^+_{lm}(k,k'+2) \\
& = \Bigg\{\left[-\frac{9}{4}+\rho^2\right]-(k'+l)(k'+l+2)+l(l+1) \\
& \quad + \frac{1}{4}\frac{\left(k'+\frac{3}{2}+l+i\pi\right)\left(k'+\frac{3}{2}+l-i\pi\right)(k'+1)(k'+2l+2)}{(k'+l+2)(k'+l+1)}
\end{aligned}
$$

$$+\frac{1}{4}\frac{\left(k'+\frac{1}{2}+l+i\pi\right)\left(k'+\frac{1}{2}+l-i\pi\right)(k')(k'+2l+1)}{(k'+l+1)(k'+l)}\Bigg\}\, c^{+}_{lm}(k,k')$$
$$-\frac{1}{4}\left(k'-\frac{1}{2}+l+i\pi\right)\left(k'+\frac{1}{2}+l+i\pi\right)$$
$$\times\sqrt{\frac{(k'-1)(k'+2l)(k')(k'+2l+1)}{(k'+l)(k'+l-1)(k'+l+1)(k'+l)}}\, c^{+}_{lm}(k,k'-2). \tag{4.7}$$

Now $c^{+}_{lm}(k,k'=1)$ and $c^{+}_{lm}(k,k'=3)$ are easily determined from Eq. (4.6) as special cases: evaluating the right hand side of (4.6) with the help of (4.1) gives

$$(|k-1lm\rangle, d\tilde{\pi}_{\rho}(\tilde{\mathbf{D}})d\tilde{\pi}_{\rho}(\mathbf{P}_0)|klm\rangle) = \frac{i\rho}{2}\left(\frac{1}{2}-i\rho\right)^2\left(k+l+\frac{1}{2}-i\rho\right)\left(k+l+\frac{3}{2}-i\rho\right)$$
$$\times\sqrt{\frac{(k)(k+2l+1)}{(k+l+1)(k+l)}}, \tag{4.8}$$

and, using Eqs. (4.2) and (4.3), we obtain

$$(|k-1lm\rangle, d\tilde{\pi}_{\rho}(\tilde{\mathbf{D}})d\tilde{\pi}_{\rho}(\mathbf{P}_0)|klm\rangle) = -\frac{1}{4}\left(\frac{1}{2}-i\rho\right)^2\left(k+l+\frac{1}{2}-i\rho\right)\left(k+l+\frac{3}{2}-i\rho\right)$$
$$\times\sqrt{\frac{(k)(k+1)(k+2l+1)(k+2l+2)}{(k+l+1)^2(k+l)(k+l+2)}}\, c^{+}_{lm}(k,k+1). \tag{4.9}$$

Thus by equating the right hand sides of Eqs. (4.8) and (4.9) and then solving the resulting equation for $c^{+}_{lm}(k,k+1)$, we obtain:

$$c^{+}_{lm}(k,k+1) = -2i\rho\sqrt{\frac{(k+l+1)(k+l+2)}{(k+2l+2)(k+1)}}. \tag{4.10}$$

Similarly, we have

$$(|k+1lm\rangle, d\tilde{\pi}_{\rho}(\tilde{\mathbf{D}})d\tilde{\pi}_{\rho}(\mathbf{P}_0)|klm\rangle) = \frac{i\rho}{2}\left(\frac{1}{2}-i\rho\right)^2\left(k+l+\frac{1}{2}+i\rho\right)\left(k+l+\frac{3}{2}+i\rho\right)$$
$$\times\sqrt{\frac{(k+1)(k+2l+2)}{(k+l+2)(k+l+1)}}, \tag{4.11}$$

and

$$(|k+1lm\rangle, d\tilde{\pi}_{\rho}(\tilde{\mathbf{D}})d\tilde{\pi}_{\rho}(\mathbf{P}_0)|klm\rangle) = -\frac{1}{4}\left(\frac{1}{2}-i\rho\right)^2\left(k+l+\frac{9}{2}-i\rho\right)\left(k+l+\frac{7}{2}-i\rho\right)$$
$$\times\sqrt{\frac{(k+3)(k+4)(k+2l+4)(k+2l+5)}{(k+l+4)^2(k+l+3)(k+l+5)}}$$
$$\times c^{+}_{lm}(k,k+3)+\left(\frac{1}{2}-i\rho\right)^2\Bigg\{-\left[\frac{9}{4}+\rho^2\right]$$
$$-(k+l+1)(k+l+3)+l(l+1)$$
$$+\frac{1}{4}\Bigg[\left\{\left(k+l+\frac{5}{2}\right)^2+i\rho^2\right\}\frac{(k+2)(k+2l+3)}{(k+l+3)(k+l+2)}$$

$$+\left\{\left(k+l+\frac{3}{2}\right)^2+i\rho^2\right\}\frac{(k+1)(k+2l+2)}{(k+l+1)(k+l+2)}\Bigg]\Bigg\}$$
$$\times c^+_{lm}(k,k+1). \tag{4.12}$$

By substituting $c^+_{lm}(k,k+1)$ from Eq. (4.10) into this equation and substituting the right hand side of Eq. (4.11) into the left hand side of this equation we obtain a formula for $c^+_{lm}(k,k+3)$, which simplifies to

$$c^+_{lm}(k,k+3)=+2i\rho\sqrt{\frac{(k+2)(k+2l+3)(k+l+1)(k+l+4)}{(k+2l+4)(k+2l+2)(k+3)(k+1)}}. \tag{4.13}$$

With the initial values of $c^+_{lm}(k,k+1)$ and $c^+_{lm}(k,k+3)$ given in Eqs. (4.10) and (4.13) we solve by successive iteration for higher $c^+_{lm}(k,k+n)$ and then readily establish the following result by mathematical induction:

$$\begin{aligned}c^+_{lm}(k,k+n)&=(-1)^{(n+1)/2}2i\rho\\&\quad\times\left[\frac{k+2)(k+4)\ldots(k+n-1)(k+2l+3)(k+2l+5)\ldots(k+2l+n)}{(k+1)(k+3)\ldots(k+n)(k+2l+2)(k+2l+4)\ldots(k+2l+n+1)}\right]^{1/2}\\&\quad\times\{(k+l+1)(k+l+n+1)\}^{1/2}\\&=2(-1)^{(1/2n+1/2)}i\rho\Bigg(\Gamma\left(\frac{1}{2}n+\frac{1}{2}+\frac{1}{2}k\right)\Gamma\left(\frac{1}{2}n+1+\frac{1}{2}k+l\right)\Gamma\left(\frac{1}{2}k+\frac{1}{2}\right)\\&\quad\times\Gamma\left(\frac{1}{2}k+l+1\right)(k+l+1)(k+l+n+1)\Bigg)\Bigg/\Bigg(\Gamma\left(\frac{1}{2}k\right)\Gamma\left(\frac{1}{2}k+l+\frac{1}{2}\right)\\&\quad\times\Gamma\left(\frac{1}{2}n+1+\frac{1}{2}k\right)\Gamma\left(\frac{1}{2}n+\frac{3}{2}+\frac{1}{2}k+l\right)k(k+2l+1)\Bigg)\Bigg)^{1/2}.\end{aligned} \tag{4.14}$$

Determination of the coefficients $c^-_{lm}(k,k')$ proceeds in a completely similar manner. The details of this are left to the reader. The final result is:

$$\begin{aligned}c^-_{lm}(k,k-n)&=-(-1)^{(n+1)/2}2i\rho\\&\quad\times\left[\frac{k-n+2)(k-n+4)\ldots(k-1)(k-n+2l+3)(k-n+2l+5)\ldots(k+2l)}{(k-n+1)(k-n+3)\ldots(k)(k-n+2l+2)(k-n+2l+4)\ldots(k+2l+1)}\right]^{1/2}\\&\quad\times\{(k-n+l+1)(k+l+1)\}^{1/2}.\end{aligned} \tag{4.15}$$

Evaluation of the action of $d\tilde{\pi}_\rho(\mathbf{P}_i)$ $(i=1,2,3)$ on the $|klm\rangle$ follows from the commutation relations $\mathbf{P}_i=[\mathbf{L}_{0i},\mathbf{P}_0]$. Such expressions are now determined straightforwardly, but since the answers are rather lengthy we do not bother to write them down here.

V. CONCLUSIONS

In the above we have determined the matrix elements of a set of generators for the Poincaré Lie algebra. ($\mathbf{L}_{ij},\mathbf{L}_{0i}$, and $\mathbf{P}_0$ generate $\mathscr{P}$.) It is easily seen from Eqs. (4.14) and (4.15) that

$$(|klm\rangle,d\tilde{\pi}_\rho(\mathbf{P}_0)|k'l'm'\rangle)=-(d\tilde{\pi}_\rho(\mathbf{P}_0)|klm\rangle,|k'l'm'\rangle). \tag{5.1}$$

This equation is to be expected of a skew-symmetric operator on a Hilbert space, but, according to the authors of Ref. 4, such an equation does not hold for matrix elements of $d\tilde{\pi}_\rho(\mathbf{P}_0)$ on ''Lorentz basis'' vectors. Although our analysis does not shed any light on a possible explanation of the strange behavior of operators on ''distributional bases'' which is described in that paper, our results do show that one obtains a much cleaner analysis, when working with ''bona fida'' elements of the Hilbert space. For example we easily convince ourselves that $d\tilde{\pi}_\rho(\mathbf{P}_0)|klm\rangle$ for k odd is in the Hilbert space, and $d\tilde{\pi}_\rho(\mathbf{P}_0)|klm\rangle$ for k even lies outside of the Hilbert space.

(Received 9 September 1997; accepted for publication 15 December 1997)

We construct a realization of the Yangian double $DY_\hbar(gl_N)_k$ and $DY_\hbar(sl_N)_k$ for an arbitrary level k in terms of free boson fields with a continuous parameter. In the $\hbar \to 0$ limit this realization becomes the Wakimoto realization of affine Lie algebras gl_N and sl_N, respectively. The vertex operators and the screening currents are also constructed with the same spirits; the screening currents commute with $DY_\hbar(sl_N)$ modulo total difference. © *1998 American Institute of Physics.* [S0022-2488(98)00104-2]

I. INTRODUCTION

Quantum algebra and Yangian were proposed by Drinfeld as generalizations of universal enveloping algebras of classical Lie algebra and loop algebra with nontrivial Hopf algebra structures.[1–3] Following the Faddeev–Reshetikhin–Takhtajan (FRT) formalism,[4] both kinds of algebras can be considered as associative algebras defined through the Yang–Baxter relation (i.e., RLL relations) with the structure constants determined by the solutions of the quantum Yang–Baxter equation (QYBE). Quantum affine algebra[3] and Yangian double with center (the central extension of the quantum double of Yangian)[5–8] are affine extensions of universal enveloping algebras of classical Lie algebra and Yangian. The latter algebras can also be viewed from the RLL viewpoint, with the R matrix being the trigonometric solution of QYBE and rational one, respectively, if one regards the Reshetikhin–Semenov–Tian–Shansky realization (RS)[9] as the affine analog of Faddeev–Reshetikhin–Takhtajan formalism. They both were proved to have important applications in certain physical problems, especially in describing the dynamical symmetries of the integrable massive quantum field theories, calculating the correlation functions and form factors of some two-dimensional exactly solvable lattice statistical model and $(1+1)$-dimensional completely integrable quantum field theories.[10–12] In these cases, they play crucial role, which is similar to the role of the Virasoro algebras and affine Lie algebras in the conformal field theories. In such physical applications, the infinite-dimensional representations of quantum affine algebra and Yangian double are required. In another words, Yangian double with central is needed, especially the representations with higher $(k>1)$ level.

In practice, free field realization is proved to be quite effective and useful approach to study complicated algebras structure. In this aspect, the Heisenberg algebra (or free boson) representation has become a common method for obtaining representations of quantum affine algebras. For examples, the free boson representations of $U_q(\widehat{sl}_2)$ with an arbitrary level have been obtained in

Refs. 13–17. Free boson representation of $U_q(\widehat{sl}_N)$ with level 1 was constructed in Ref. 18. Free boson representations of $U_q(\widehat{sl}_3)$ and $U_q(\widehat{sl}_N)$ with arbitrary level were constructed in Refs. 19 and 20, respectively. For the Yangian double with center, the free field representation of $DY_\hbar(sl_2)$ with level k was constructed in Ref. 21. The level 1 free boson representation of $DY_\hbar(gl_N)$ and $DY_\hbar(sl_N)$ was given in Ref. 22. In Ref. 23 the free field representation of the Yangian double $DY_\hbar(sl_N)$ with arbitrary level k are obtained by a simple correspondence between the quantum affine algebra $U_q(\widehat{sl_N})$ and the Yangian double $DY_\hbar(sl_N)$. This correspondence makes our derivation of free field representation for $DY_\hbar(sl_N)$ greatly simplified. However, we have been unable to obtain the vertex operators and screening currents for $DY_\hbar(sl_N)$ following the same spirit, so the relations of quantum affine algebras and the Yangian double with center is nontrivial. Construct a free field realization of the screening current operator is one of the motivations of this paper.

Another motivation is that, in Ref. 24, Frenkel and Reshetikhin used the free field realization of the quantum affine algebra $U_q(\widehat{gl_2})_k$ at critical level $k=-2$, to investigate the structure of the infinite-dimensional center of formal completion of the quantum affine algebra $U_q(\widehat{gl_2})_k$. Using the Wakimoto realization of the quantum affine algebra they define a new Poisson bracket algebra, which is nothing but the q-deformation of the classical Virasoro algebra ${}_qVir$ (in the general case are the q-deformations of the classical $\mathscr{W}_q(sl_N)$ algebras). Similarly to the quantum affine cases, infinite-dimensional centers exist for the Yangian double with center at critical level, which are just the classical $\mathscr{W}_\hbar(sl_N)$ algebras.[25] In the simplest case, ${}_\hbar$Virasoro is considered in Ref. 26 by using the free field realization of the Yangian double with center $DY_\hbar(gl_2)_k$ at level $k=-2$. Similarly, one way to study the structure of the $\mathscr{W}_\hbar(g)$ algebras is through the free field realization of the Yangian double with center $DY_\hbar(g)_k$ at critical level, where the Lie algebra g has a higher rank. However, it is difficult to obtain the free field realization of the currents for Yangian double $DY_\hbar(gl_N)$ in the higher rank cases (rank greater than one) with the boson fields using in Ref. 23, either no consistent realization of quantum determinant, which decomposes the $DY_\hbar(gl_N)_c$ to its subalgebra $DY_\hbar(sl_N)_c$ could be given.

In this paper, we introduce free fields involved with a continuous parameter, and we obtain the $DY_\hbar(gl_N)$ and $DY_\hbar(sl_N)$ currents, and the screening currents and vertex operators.

The manuscript is arranged as follows. In Sec. II we first briefly review the Drinfeld new realization of the Yangian $Y(g)$; then we give the defining relations of Drinfeld generators of the Yangian double with center $DY_\hbar(gl_N)_k$. The RS realization is also given, and the isomorphism between these two realization can be established through Ding–Frenkel correspondence. In Sec. III the three set of free boson fields with a continuous parameter are introduced; some relations, which will be used in the forthcoming sections, are listed. With the help of the results obtained in Sec. III, we give a free fields realization of $DY_\hbar(gl_N)_k$ and $DY_\hbar(sl_N)_k$ in Sec. IV. In Sec. V we give the free field realization of the screening currents and the vertex operators, and brief discussions are given at the final section of the paper.

II. DRINFELD GENERATORS OF YANGIAN DOUBLE $DY_\hbar(gl_N)$

First, we introduce some notations, which will be used in the sequel. Let $\boldsymbol{\epsilon}_\mu$ $(1\leqslant\mu\leqslant N)$ be the orthonormal basis in R^N. We have the inner product $\langle\boldsymbol{\epsilon}_\mu,\boldsymbol{\epsilon}_\nu\rangle=\delta_{\mu,\nu}$. Define

$$\bar{\boldsymbol{\epsilon}}_\mu=\boldsymbol{\epsilon}_\mu-\boldsymbol{\epsilon},\quad \boldsymbol{\epsilon}=\frac{1}{N}\sum_{\mu=1}^{N}\boldsymbol{\epsilon}_\mu. \tag{2.1}$$

Obviously, $\Sigma_{\mu=1}^{N}\bar{\boldsymbol{\epsilon}}_\mu=0$. The simple roots, fundamental weights are,

$$\alpha_\mu=\boldsymbol{\epsilon}_\mu-\boldsymbol{\epsilon}_{\mu+1},\quad \Lambda_\mu=\sum_{\nu=1}^{\mu}\bar{\boldsymbol{\epsilon}}_\nu, \tag{2.2}$$

respectively. For simple, denote half of the Cartan matrix $a_{\mu,\nu}$ as $B_{\mu,\nu}$.

There are three realizations of Yangian $Y(g)$: Drinfeld realization,[1,2] Drinfeld new realization,[3] and R-matrix realization or FRT realization.[27,4] The isomorphism between the Drinfeld new realization and the R-matrix (or FRT) realization can be established by using the Ding

and Frenkel correspondence.[28] Here, we only give the definition of the Drinfeld new realization of Yangian, for the Yangian double is defined in terms of quantum double of the Drinfeld new realization, while the Yangian double with center is the central extension of the Yangian double. There is the following theorem:

Theorem 1:[3] *The Yangian $Y(g)$ is isomorphic to the associative algebra with generators, $x^{\pm}_{\mu,r}$, $h_{\mu,r}$, $\mu=1,...,$ rank g, $r\in Z_{\geqslant 0}$, and the following defining relations:*

$$[h_{\mu,r}h_{\nu,s}]=0,$$

$$[h_{\mu,0},x^{\pm}_{\nu,s}]=\pm 2d_{\mu}B_{\mu,\nu}x^{\pm}_{\mu,s},$$

$$[h_{\mu,r+1},x^{\pm}_{\nu,s}]-[h_{\mu,r},x^{\pm}_{\nu,s+1}]=\pm\hbar d_{\mu}B_{\mu,\nu}(h_{\mu,r}x^{\pm}_{\nu,s}+x^{\pm}_{\nu,s}h_{\mu,r}),$$

$$[x^{+}_{\mu,r},x^{-}_{\nu,s}]=\delta_{\mu,\nu}h_{\mu,r+s},$$

$$[x^{\pm}_{\mu,r+1},x^{\pm}_{\nu,s}]-[x^{\pm}_{\mu,r},x^{\pm}_{\nu,s+1}]=\pm\hbar d_{\mu}B_{\mu,\nu}(x^{\pm}_{\mu,r}x^{\pm}_{\nu,s}+x^{\pm}_{\nu,s}x^{\pm}_{\mu,r}),$$

$$\sum_{\pi}[x^{\pm}_{\mu,r_{\pi(1)}},[x^{\pm}_{\mu,r_{\pi(2)}},\ldots,[x^{\pm}_{\mu,r_{\pi(m)}},x^{\pm}_{\nu,s}]\ldots]]=0,$$

for all sequences of non-negative integers $r_1,\ldots,r_{\nu}$, where $m=1-2B_{\mu,\nu}$, $2d_{\mu}B_{\mu,\nu}$ is the symmetric Cartan matrix. And the sum is over all permutations π of $1,\ldots,m$.

As an associative algebra, the Yangian double with center $DY_{\hbar}(gl_N)_c$ is generated by the Drinfeld generators $\{k^{+}_{\mu,r},k^{-}_{\mu,s}x^{+}_{\nu,m},\ x^{-}_{\nu,m}|\mu=1,2,...,N;\ \nu=1,2,...,N-1;\ r\in Z_{\geqslant 0},\ s\in Z_{<0},\ m\in Z\}$, derivation operator d and the center c.

The generating function of the Drinfeld generators of Yangian double with center $DY_{\hbar}(gl_N)_c$ are $k^{\pm}_{\mu}(u)$ and $X^{\pm}_{\nu}(u)$,

$$k^{+}_{\mu}(u)=\sum_{r\geqslant 0}k_{\mu,r}u^{-r-1},\quad k^{-}_{\mu}(u)=\sum_{s<0}h_{\nu,s}u^{-s-1},$$

$$X^{+}_{\mu}(u)=\sum_{m\in Z}x^{+}_{\mu,m}u^{-m-1},\quad X^{-}_{\mu}(u)=\sum_{m\in Z}x^{-}_{\mu,m}u^{-m-1},$$

and they satisfy the following commutation relations:

$$[d,\chi(u)]=\frac{dX}{du},\quad [c,\chi(u)]=0,\quad \chi(u)=k^{\pm}_{\mu}(u),\quad X^{+}_{\mu}(u),\quad X^{-}_{\mu}(u),$$

$$k^{\pm}_{\mu}(u)k^{\pm}_{\nu}(v)=k^{\pm}_{\nu}(v)k^{\pm}_{\mu}(u),$$

$$\rho(u-v-c\hbar)k^{+}_{\mu}(u)k^{-}_{\mu}(v)=k^{-}_{\mu}(v)k^{+}_{\mu}(u)\rho(u-v),$$

$$\rho(u-v-c\hbar)\frac{u-v-c\hbar}{u-v+\hbar-c\hbar}k^{+}_{\mu}(u)k^{-}_{\nu}(v)=k^{-}_{\nu}(v)k^{+}_{\mu}(u)\frac{u-v}{u-v+\hbar}\rho(u-v),\quad \mu<\nu,$$

$$\rho(u-v-c\hbar)\frac{u-v-\hbar-c\hbar}{u-v-c\hbar}k^{+}_{\mu}(u)k^{-}_{\nu}(v)=k^{-}_{\nu}(v)k^{+}_{\mu}(u)\frac{u-v-\hbar}{u-v}\rho(u-v),\quad \mu>\nu,$$

$$k^{\pm}_{\mu}(u)X^{+}_{\mu}(v)k^{\pm}_{\mu}(u)^{-1}=\frac{u-v}{u-v+\hbar}X^{+}_{\mu}(v),$$

$$k^{\pm}_{\mu+1}(u)X^{+}_{\mu}(v)k^{\pm}_{\mu+1}(u)^{-1}=\frac{u-v}{u-v-\hbar}X^{+}_{\mu}(v),$$

$$k_\mu^-(u)X_\mu^-(v)k_\mu^-(u)^{-1}=\frac{u-v+\hbar}{u-v}\,X_\mu^-(v),$$

$$k_{\mu+1}^-(u)X_\mu^-(v)_{\mu+1}^-(u)^{-1}=\frac{u-v-\hbar}{u-v}\,X_\mu^-(v),$$

$$k_\mu^+(u)X_\mu^-(v)k_\mu^+(u)^{-1}=\frac{u-v+\hbar-c\hbar}{u-v-c\hbar}\,X_\mu^-(v),$$

$$k_{\mu+1}^+(u)X_\mu^-(v)k_{\mu+1}^+(u)^{-1}=\frac{u-v-\hbar-c\hbar}{u-v-c\hbar}\,X_\mu^-(v), \tag{2.3}$$

$$k_\mu^\pm(u)X_\nu^+(v)k_\mu^\pm(u)^{-1}=X_\nu^+(v),\quad \mu-\nu\geqslant 2,\ \text{or}\ \ \mu-\nu\leqslant -1,$$

$$k_\mu^\pm(u)X_\nu^-(v)k_\mu^\pm(u)^{-1}=X_\nu^-(v),\quad \mu-\nu\geqslant 2,\ \text{or}\ \ \mu-\nu\leqslant -1,$$

$$(u-v\mp\hbar)X_\mu^\pm(u)X_\mu^\pm(v)=(u-v\pm\hbar)X_\mu^\pm(v)X_\mu^\pm(u),$$

$$(u-v+\hbar)X_\mu^+(u)X_{\mu+1}^+(v)=(u-v)X_{\mu+1}^+(v)X_\mu^+(u),$$

$$(u-v)X_\mu^-(u)X_{\mu+1}^-(v)=(u-v+\hbar)X_{\mu+1}^-(v)X_\mu^-(u),$$

$$X_\mu^\pm(u_1)X_\mu^\pm(u_2)X_\nu^\pm(v)-2X_\mu^\pm(u_1)X_\nu^\pm(v)X_\mu^\pm(u_2)+X_\nu^\pm(v)X_\mu^\pm(u_1)X_\mu^\pm(u_2)+\{u_1\leftrightarrow u_2\}=0,$$

$$|\mu-\nu|=1,$$

$$X_\mu^\pm(u)X_\nu^\pm(v)=X_\nu^\pm(v)X_\mu^\pm(u),\quad |\mu-\nu|\geqslant 2,$$

$$[X_\mu^+(u),X_\nu^-(v)]=\delta_{\mu,\nu}(\delta(u-(v+c\hbar))k_{\mu+1}^+(u)k_\mu^+(u)^{-1}-\delta(u-v)k_{\mu+1}^-(v)k_\mu^-(v)^{-1}),$$

in which the scalar factor

$$\rho^+(u)=\frac{\Gamma\left(\frac{1}{N}-\frac{u}{N\hbar}\right)\Gamma\left(1-\frac{1}{N}-\frac{u}{N\hbar}\right)}{\Gamma\left(-\frac{u}{N\hbar}\right)\Gamma\left(1-\frac{u}{N\hbar}\right)}, \tag{2.4}$$

and $\delta(u-v)=\Sigma_{m+n=-1}u^m v^n$. These relations are understood as relations between formal series. The above relations can be derived through the RS realization; in the following we will turn to the RS realization.

The RS realization[9] originated from the quantum inverse scattering method. One of the advantages of the RS realization is that the central elements can be written explicitly by the quantum trace.[9] For this purpose, in the following we will drop the d operator in the Yangian double with center, and denote as $DY_\hbar'(gl_N)$. Introduce the following operators:

$$L^\pm(u)=(l_{\mu\nu}^\pm(u))_{1\leqslant\mu,\nu\leqslant N}; \tag{2.5}$$

where the generating function,

$$l_{\mu\nu}^+(u)=\delta_{\mu,\nu}+\hbar\sum_{m=0}^{\infty}l_{\mu,\nu}^+[m]u^{-m-1};\quad l_{\mu\nu}^-(u)=\delta_{\mu,\nu}-\hbar\sum_{m=-1}^{-\infty}l_{\mu,\nu}^-[m]u^{-m-1}; \tag{2.6}$$

and the R-matrix $R^\pm(u)$,

$$R^\pm(u)=\rho^\pm(u)\overline{R}(u), \tag{2.7}$$

$$\rho^{-}(u)=\left(\frac{\Gamma(1/N+u/N\hbar)\Gamma(1-1/N+u/N\hbar)}{\Gamma(u/N\hbar)\Gamma(1+u/N\hbar)}\right)^{-1}=\frac{1}{\rho^{+}(-u)}, \tag{2.8}$$

and $\overline{R}(u)=(uI+\hbar P)/(u+\hbar)$ is the Yang's solution of QYBE. The P is the flip operator of $u\otimes v$, $Pu\otimes v=v\otimes u$, and the choice of the scalar function $\rho^{\pm}(u)$ can be determined by the unitarity condition and crossing symmetry.[29] But here we adopt another approach, which will be explained later in this paper.

From the universal R-matrix for the central extended Yangian double obtained in Refs. 5–7, $L^{\pm}(u)$ have the following unique decompositions:

$$L^{+}(u)=\begin{pmatrix} 1 & 0 & \cdots & 0 \\ \hbar f^{+}_{2,1}(u-c\hbar) & 1 & & \\ & \vdots & \ddots & \ddots \\ \hbar f^{+}_{N,1}(u-c\hbar) & \cdots & \hbar f^{+}_{N,N-1}(u-c\hbar) & 1 \end{pmatrix}\begin{pmatrix} k^{+}_{1}(u) & 0 & \cdots & 0 \\ & \ddots & & \\ & & \ddots & \\ 0 & \cdots & \cdots & k^{+}_{N}(u) \end{pmatrix}$$
$$\times\begin{pmatrix} 1 & \hbar e^{+}_{1,2}(u) & \cdots & \hbar e^{+}_{1,N}(u) \\ & \ddots & \ddots & \\ 0 & & \ddots & \hbar e^{+}_{N-1,N}(u) \\ 0 & \cdots & \cdots & 1 \end{pmatrix},$$

$$L^{-}(u)=\begin{pmatrix} 1 & 0 & \cdots & 0 \\ \hbar f^{-}_{2,1}(u) & 1 & & \\ & \vdots & \ddots & \ddots \\ \hbar f^{-}_{N,1}(u) & \cdots & \hbar f^{-}_{N,N-1}(u) & 1 \end{pmatrix}\begin{pmatrix} k^{-}_{1}(u) & 0 & \cdots & 0 \\ & \ddots & & \\ & & \ddots & \\ 0 & \cdots & \cdots & k^{-}_{N}(u) \end{pmatrix}$$
$$\times\begin{pmatrix} 1 & \hbar e^{-}_{1,2}(u) & \cdots & \hbar e^{-}_{1,N}(u) \\ & \ddots & \ddots & \\ & & \ddots & \hbar e_{N-1,N}(u) \\ 0 & \cdots & \cdots & 1 \end{pmatrix},$$

the defining relations in $DY'_{\hbar}(gl_N)$ are given as follows:

$$\begin{aligned} R^{\pm}(u-v)L^{\pm}_{1}(u)L^{\pm}_{2}(v)&=L^{\pm}_{2}(v)L^{\pm}_{1}(u)R^{\pm}(u-v), \\ R^{+}(u-v-c\hbar)L^{+}_{1}(u)L^{-}_{2}(v)&=L^{-}_{2}(v)L^{+}_{1}(u)R^{+}(u-v), \end{aligned} \tag{2.9}$$

and the notation

$$L_1(u)=L(u)\otimes 1, \quad L_2(u)=1\otimes L(u),$$

is used. From the above expression, if we set

$$X^{-}_{\mu}(u)=f^{+}_{\mu+1,\mu}(u)-f^{-}_{\mu+1,\mu}(u),$$

$$X^{+}_{\mu}(u)=e^{+}_{\mu,\mu+1}(u)-e^{-}_{\mu,\mu+1}(u),$$

which defines an isomorphism between the Drinfeld realization and the RS realization. The statement can be proved following the Ding–Frenkel equivalence.[28]

Similar to $DY_{\hbar}(gl_N)'_c$, an associative algebra, the Yangian double with center $DY_{\hbar}(sl_N)'_c$ is a subalgebra of $DY_{\hbar}(gl_N)'_c$, which is obtained with decomposing the $DY_{\hbar}(gl_N)'_c$ by the quantum determinant. If we define the following currents:

$$H_\mu^\pm(u)=k_{\mu+1}^\pm\left(u+\frac{\mu}{2}\hbar\right)k_\mu^\pm\left(u+\frac{\mu}{2}\hbar\right)^{-1},$$

$$K^\pm(u)=\prod_{\mu=1}^{N}k_\mu^\pm(u+(\mu-1)\hbar),$$

$$E_\mu(u)=\frac{1}{\hbar}X_\mu^+\left(u+\frac{\mu}{2}\hbar\right),\quad F_\mu(u)=\frac{1}{\hbar}X_\mu^-\left(u+\frac{\mu}{2}\hbar\right),\tag{2.10}$$

with the mode expansions,

$$H_\mu^+(u)=1+\hbar\sum_{m\geqslant 0}h_{\mu,m}u^{-m-1},\quad H_\mu^-(u)=1-\hbar\sum_{m<0}h_{\mu,m}u^{-m-1},$$

$$E_\mu(u)=\sum_{m\in Z}e_{\mu,m}u^{-m-1},\quad F_\mu(u)=\sum_{m\in Z}f_{\mu,m}u^{-m-1}.$$

With these notation, the Drinfeld generators of $DY'_\hbar(sl_N)_c$ are $\{h_{\nu,m},\ e_{\nu,m},\ f_{\nu,m},\ c\,|\,\nu=1,2,...,N-1;\ m\in Z.\}$

Now we can write the generating relations for $DY'_\hbar(sl_N)$ as follows:[22]

$$[H_\mu^\pm(u),\quad H_\nu^\pm(v)]=0,\quad [c,\text{everything}]=0,$$

$$(u-v+B_{\mu,\nu}\hbar\mp c\hbar)(u-v-B_{\mu,\nu}\hbar)H_\mu^\pm(u)H_\nu^\mp(v)$$
$$=(u-v-B_{\mu,\nu}\hbar\mp c\hbar)(u-v+B_{\mu,\nu}\hbar)H_\nu^\mp(v)H_\mu^\pm(u),$$

$$(u-v-B_{\mu,\nu}\hbar)H_\mu^\pm(u)E_\nu(v)=(u-v+B_{\mu,\nu}\hbar)E_\nu(v)H_\mu^\pm(u),$$

$$(u-v+B_{\mu,\nu}\hbar-c\hbar)H_\mu^+(u)F_\nu(v)=(u-v-B_{\mu,\nu}\hbar-c\hbar)F_\nu(v)H_\mu^+(u),$$

$$(u-v+B_{\mu,\nu}\hbar)H_\mu^-(u)F_\nu(v)=(u-v-B_{\mu,\nu}\hbar)F_\nu(v)H_\mu^-(u),$$

$$(u-v-B_{\mu,\nu}\hbar)E_\mu(u)E_\nu(v)=(u-v+B_{\mu,\nu}\hbar)E_\nu(v)E_\mu(u),$$

$$(u-v+B_{\mu,\nu}\hbar)F_\mu(u)F_\nu(v)=(u-v-B_{\mu,\nu}\hbar)F_\nu(v)F_\mu(u),$$

$$[E_\mu(u),F_\nu(v)]=\frac{\delta_{\mu,\nu}}{\hbar}(\delta(u-(v+c\hbar))H_\mu^+(u)-\delta(u-v)H_\mu^-(v)),$$

$$E_\mu(u_1)E_\mu(u_2)E_\nu(v)-2E_\mu(u_1)E_\nu(v)E_\mu(u_2)+E_\nu(v)E_\mu(u_1)E_\mu(u_2)+(\text{replacement:}\quad u_1\leftrightarrow u_2)$$
$$=0\ \text{ for }\ |\mu-\nu|=1,$$

$$F_\mu(u_1)F_\mu(u_2)F_\nu(v)-2F_\mu(u_1)F_\nu(v)F_\mu(u_2)+F_\nu(v)F_\mu(u_1)F_\mu(u_2)+(\text{replacement:}\quad u_1\leftrightarrow u_2)$$
$$=0\ \text{ for }\ |\mu-\nu|=1,$$

$$E_\mu(u)E_\nu(v)=E_\nu(v)E_\mu(u)\ \text{ for }\ |\mu-\nu|=1,$$

$$F_\mu(u)F_\nu(v)=F_\nu(v)F_\mu(u)\ \text{ for }\ |\mu-\nu|>1,$$

$$[K^\pm(u),K^\pm(v)]=0,$$

$$K^+(u)K^-(v)=K^-(v)K^+(u),$$

$$[K^\epsilon(u),H_\mu^\pm(v)]=[K^\epsilon(u),E_\mu(v)]=[K^\epsilon(u),F_\mu(v)]=0,\quad \forall\epsilon=\pm,\forall 1\leqslant\mu\leqslant N,$$

which are obtained by direct calculation. From the above commutation relations, $K^{\pm}(u)$ commute with all of the elements of $DY_{\hbar}(gl_N)'_c$, so the Fourier coefficients of the power series $K(u)-1$ are the central elements of the $DY_{\hbar}(gl_N)'_c$. It is obvious that the Heisenberg subalgebra of $DY_{\hbar}(gl_N)'_c$ is generated by the quotient of $DY_{\hbar}(gl_N)'_c$ by the ideal generated by this central elements. In fact we have formula $K^{\pm}(u)=\det_q L^{\pm}(u)$, and the scalar function is chosen so that the quantum determinant commutes with all of the currents and with itself.

III. FREE BOSON WITH CONTINUOUS PARAMETER

In the next section we would construct a free boson representation of $DY_{\hbar}(sl_N)_k$ with arbitrary level k ($c=k$ henceforth). For $N=2$ this problem has already been solved in Ref. 21. For generic N, the Yangian double currents can be obtained using the quantum affine-Yangian double correspondence.[23] However, screening currents and vertex operators cannot be obtained in the same way; at least, they cannot be expressed in a nice form. So this correspondence are somewhat nontrivial. In this section, we introduce another kinds Heisenberg algebras to overcome these problems.

N^2 free boson fields are needed to construct the $DY_{\hbar}(gl_N)$ generators with arbitrary level. So we introduce three set boson fields $\hat{\lambda}_{\mu}(1\leqslant\mu\leqslant N)$, $\hat{b}_{\mu,\nu}$, and $\hat{c}_{\mu,\nu}(1\leqslant\mu<\nu\leqslant N)$, and while $\hat{b}_{\mu,\nu}=\hat{c}_{\mu,\nu}\equiv 0$, for $\mu\geqslant\nu$. The quantum Heisenberg algebra $\mathscr{A}_{\hbar,k}(gl_N)$ generated by $\hat{\lambda}_{\mu}(t)$, $\hat{b}_{\mu,\nu}(t)$, $\hat{c}_{\mu,\nu}(t)$ is involved with continuous parameters $t(t\in R-\{0\})$, which enjoy the the following commutation relations

$$[\hat{\lambda}_{\mu}(t),\hat{\lambda}_{\mu}(t')]=\frac{\sinh\frac{k+g}{2}\hbar t\,\sinh\frac{(N-1)}{2}\hbar t\,\sinh\frac{\hbar}{2}t}{t\hbar^2\,\sinh\frac{N}{2}\hbar t}\,\delta(t+t'), \tag{3.1}$$

$$[\hat{\lambda}_{\mu}(t),\hat{\lambda}_{\nu}(t')]=-\frac{\sinh\frac{k+g}{2}\hbar t\,\sinh^2\frac{\hbar}{2}t}{t\hbar^2\,\sinh\frac{N}{2}\hbar t}\,e^{\mathrm{sign}(\mu-\nu)(N/2)\hbar t}\delta(t+t'), \tag{3.2}$$

$$[\hat{b}_{\mu,\nu}(t),\hat{b}_{\mu',\nu'}(t')]=-\frac{1}{\hbar^2 t}\sinh^2\frac{\hbar t}{2}\,\delta_{\mu,\mu'}\delta_{\nu,\nu'}\delta(t+t'), \tag{3.3}$$

$$[\hat{c}_{\mu,\nu}(t),\hat{c}_{\mu',\nu'}(t')]=\frac{1}{\hbar^2 t}\sinh^2\frac{\hbar t}{2}\,\delta_{\mu,\mu'}\delta_{\nu,\nu'}\delta(t+t'), \tag{3.4}$$

and the other commutators vanish identically, where $g=N$ is the dual Coxeter number for the sl_N algebra. Here $\hat{\lambda}_{\mu}(t)$ are the ''fundamental weight type'' fields, while $\hat{b}_{\mu,\nu}(t)$, $\hat{c}_{\mu,\nu}(t)$ are ''ghost type'' fields in conformal field theory alike. For the subalgebra $\mathscr{A}_{\hbar,k}(sl_N)$ of the quantum Heisenberg algebra $\mathscr{A}_{\hbar,k}(gl_N)$, one more constraint

$$\sum_{\mu=1}^{N} e^{(1-\mu)\hbar t}\hat{\lambda}_{\mu}(t)=0,$$

is needed. In fact, the free boson fields defined above are chosen in an analogous way as these yielding representation for the algebra $\mathscr{A}_{\hbar,\eta}(\widehat{sl_N})$.[30]

The Fock space corresponding to the above Heisenberg algebras can be specified as follows. Let $|0\rangle$ be the vacuum state defined by

$$\lambda_{\mu}(t)|0\rangle=b_{\mu,\nu}(t)|0\rangle=c_{\mu,\nu}(t)|0\rangle=0,\quad (t>0). \tag{3.5}$$

The Fock space $\mathscr{F}(l_{\lambda},l_b,l_c)$ is then generated by the actions of the negative modes of λ_{μ}, $b_{\mu,\nu}$, $c_{\mu,\nu}$. The normal ordering $::$ is defined as: $\hat{\chi}_{\mu,\nu}(t)\hat{\chi}_{\mu,\nu}(t'):=:\hat{\chi}_{\mu,\nu}(t')\hat{\chi}_{\mu,\nu}(t):=\hat{\chi}_{\mu,\nu}(t')\hat{\chi}_{\mu,\nu}(t)$,

for $t>0$, where $\hat{\chi}_{\mu,\nu}(t)$ stands for $\hat{\lambda}_{\mu}(t)$, $\hat{b}_{\mu,\nu}(t)$, $\hat{c}_{\mu,\nu}(t)$. We shall see later that this Fock space actually forms a (Wakimoto-like[31,32]) module for the Yangian double $DY_{\hbar}(sl_N)$ with level k.

We define the free boson fields $\chi_{\mu,\nu}(\beta|u;\alpha)$ and $\chi^{\pm}_{lm}(u)$ through

$$\chi_{\mu,\nu}(\beta|u;\alpha)=\exp\left\{-\hbar\int_{-\infty}^{0}\frac{dt}{2\pi i}\,\frac{1}{\sinh\dfrac{\beta}{2}\hbar t}\,\hat{\chi}_{\mu,\nu}(t)e^{\alpha\hbar t}e^{-iut}\right\}$$

$$\times\exp\left\{-\hbar\int_{0}^{+\infty}\frac{dt}{2\pi i}\,\frac{1}{\sinh\dfrac{\beta}{2}\hbar t}\,\hat{\chi}_{\mu,\nu}(t)e^{-\alpha\hbar t}e^{-iut}\right\}, \tag{3.6}$$

$$\chi^{+}_{\mu,\nu}(u)=\exp\left\{2\hbar\int_{0}^{+\infty}\frac{dt}{2\pi i}\,\hat{\chi}_{\mu,\nu}(t)e^{-iut}\right\}, \tag{3.7}$$

$$\chi^{-}_{\mu,\nu}(u)=\exp\left\{-2\hbar\int_{-\infty}^{0}\frac{dt}{2\pi i}\,\hat{\chi}_{\mu,\nu}(t)e^{-iut}\right\}, \tag{3.8}$$

where $\chi_{\mu,\nu}(u)$ [$\chi^{\pm}_{\mu,\nu}(u)$) stands for $\lambda_{\nu}(u)$, $b_{\mu,\nu}(u)$ or $c_{\mu,\nu}(u)(\lambda^{\pm}_{\nu}(u)$, $b^{\pm}_{\mu,\nu}(u)$ or $c^{\pm}_{\mu,\nu}(u)]$. Then following the standard procedure (normal ordering), we have (here and below, all OPE relations should be understood to hold in the analytic continuation sense):

$$b_{\mu,\nu}(u)b^{-}_{\mu',\nu'}(v)=\exp\left\{-2\int_{\widetilde{c}}\frac{dt\,\ln(-t)}{2\pi i}\,\frac{\sinh\dfrac{\hbar}{2}t}{t}\,\delta_{\mu,\mu'}\delta_{\nu,\nu'}e^{-i(u-v)t}\right\}:b_{\mu,\nu}(u)b^{-}_{\mu',\nu'}(v):$$

$$=\left(\frac{\Gamma^2\left(\dfrac{i(u-v)}{\hbar}+\dfrac{1}{2}\right)}{\Gamma\left(\dfrac{i(u-v)}{\hbar}-\dfrac{1}{2}\right)\Gamma\left(\dfrac{i(u-v)}{\hbar}+\dfrac{3}{2}\right)}\right)^{\delta_{\mu,\mu'}\delta_{\nu,\nu'}}b^{-}_{\mu',\nu'}(v)b_{\mu,\nu}(u)$$

$$=\left(\frac{u-v+i\dfrac{\hbar}{2}}{u-v-i\dfrac{\hbar}{2}}\right)^{\delta_{\mu,\mu'}\delta_{\nu,\nu'}}b^{-}_{\mu',\nu'}(v)b_{\mu,\nu}(u), \tag{3.9}$$

where the $\widetilde{c}$ indicate the circle from $+\infty$ to 0 in the upper half plain and 0 to ∞ in the lower half plain.[33,30] To derive Eq. (3.9), the identity

$$\int_{\widetilde{c}}\frac{dt\,\ln(-t)}{2i\pi t}\,\frac{e^{-ut}}{1-e^{-t/\eta}}=\ln\Gamma(\eta u)+(\eta u-1/2)(\gamma-\ln\eta)-\frac{1}{2}\ln 2\pi \tag{3.10}$$

is used, in which the γ is the Euler number. In the same way, we can get the following identities;

$$b^{+}_{\mu,\nu}(u)b_{\mu',\nu'}(v)=\left(\frac{u-v+i\dfrac{\hbar}{2}}{u-v-i\dfrac{\hbar}{2}}\right)^{\delta_{\mu,\mu'}\delta_{\nu,\nu'}}b_{\mu',\nu'}(v)b^{+}_{\mu,\nu}(u), \tag{3.11}$$

$$c_{\mu,\nu}(u)c^{-}_{\mu',\nu'}(v)=\left(\frac{u-v-i\dfrac{\hbar}{2}}{u-v+i\dfrac{\hbar}{2}}\right)^{\delta_{\mu,\mu'}\delta_{\nu,\nu'}}c^{-}_{\mu',\nu'}(v)c_{\mu,\nu}(u), \tag{3.12}$$

$$c^{+}_{\mu,\nu}(u)c_{\mu',\nu'}(v)=\left(\frac{u-v-i\,\frac{\hbar}{2}}{u-v+i\,\frac{\hbar}{2}}\right)^{\delta_{\mu,\mu'}\delta_{\nu,\nu'}} c_{\mu',\nu'}(v)c^{+}_{\mu,\nu}(u), \tag{3.13}$$

$$\lambda^{+}_{\mu}(u)\lambda_{\mu}(k+N|v;\alpha)$$

$$=\frac{\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha}{N}\right)\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha}{N}+1\right)}{\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha+1}{N}\right)\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha-1}{N}'+1\right)}\lambda_{\mu}(k+N|v;\alpha)\lambda^{+}_{\mu}(u),$$

$$\lambda_{\mu}(k+N|u;\alpha)\lambda^{-}_{\mu}(v)$$

$$=\frac{\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha}{N}\right)\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha}{N}+1\right)}{\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha+1}{N}\right)\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha-1}{N}+1\right)}\lambda^{-}_{\mu}(v)\lambda_{\mu}(k+N|u;\alpha), \tag{3.14}$$

$$\lambda^{+}_{\mu}(u)\lambda_{\nu}(k+N|v;\alpha)$$

$$=\frac{\Gamma^2\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha}{N}\right)}{\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha+1}{N}\right)\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha-1}{N}\right)}\lambda_{\nu}(k+N|v;\alpha)\lambda^{+}_{\nu}(u),$$

$$\lambda_{\mu}(k+N|u;\alpha)\lambda^{-}_{\nu}(v)$$

$$=\frac{\Gamma^2\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha}{N}\right)}{\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha+1}{N}\right)\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha-1}{N}\right)}\lambda^{-}_{\nu}(v)\lambda_{\mu}(k+N|u;\alpha), \quad \mu>\nu, \tag{3.15}$$

$$\lambda^{+}_{\mu}(u)\lambda_{\nu}(k+N|v;\alpha)$$

$$=\frac{\Gamma^2\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha}{N}+1\right)}{\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha+1}{N}+1\right)\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha-1}{N}+1\right)}\lambda_{\nu}(k+N|v;\alpha)\lambda^{+}_{\mu}(u),$$

$$\lambda_{\mu}(k+N|u;\alpha)\lambda^{-}_{\nu}(v)$$

$$=\frac{\Gamma^2\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha}{N}+1\right)}{\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha+1}{N}+1\right)\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{\alpha-1}{N}+1\right)}\lambda^{-}_{\nu}(v)\lambda_{\mu}(k+N|u;\alpha), \quad \mu<\nu, \tag{3.16}$$

and

$$\lambda_{\mu}^{+}(u)\lambda_{\mu}^{-}(v)=\frac{\Gamma\left(\frac{i(u-v)}{N\hbar}+1-\frac{1}{N}-\frac{k+N}{2N}\right)\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{k+N}{2N}\right)}{\Gamma\left(\frac{i(u-v)}{N\hbar}+1-\frac{1}{N}+\frac{k+N}{2N}\right)\Gamma\left(\frac{i(u-v)}{N\hbar}-\frac{k+N}{2N}\right)}$$

$$\times\frac{\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{1}{N}-\frac{k+N}{2N}\right)\Gamma\left(\frac{i(u-v)}{N\hbar}+1+\frac{k+N}{2N}\right)}{\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{1}{N}+\frac{k+N}{2N}\right)\Gamma\left(\frac{i(u-v)}{N\hbar}+1-\frac{k+N}{2N}\right)}\lambda_{\mu}^{-}(v)\lambda_{\mu}^{+}(u),$$

$$=\frac{\rho^{+}\left(i(u-v)-\frac{k+N}{2}\hbar\right)}{\rho^{+}\left(i(u-v)+\frac{k+N}{2}\hbar\right)}\lambda_{\mu}^{-}(v)\lambda_{\mu}^{+}(u),$$

$$\lambda_{\mu}^{+}(u)\lambda_{\nu}^{-}(v)=\frac{\Gamma\left(\frac{i(u-v)}{N\hbar}-\frac{1}{N}-\frac{k+N}{2N}\right)\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{1}{N}-\frac{k+N}{2N}\right)}{\Gamma\left(\frac{i(u-v)}{N\hbar}-\frac{1}{N}+\frac{k+N}{2N}\right)\Gamma\left(\frac{i(u-v)}{N\hbar}+\frac{1}{N}+\frac{k+N}{2N}\right)}$$

$$\times\frac{\Gamma^{2}\left(\frac{i(u-v)}{N\hbar}+\frac{k+N}{2N}\right)}{\Gamma^{2}\left(\frac{i(u-v)}{N\hbar}-\frac{k+N}{2N}\right)}\lambda_{\nu}^{-}(v)\lambda_{\mu}^{+}(u),\quad \mu>\nu, \tag{3.17}$$

$$\lambda_{\mu}^{+}(u)\lambda_{\nu}^{-}(v)=\frac{\Gamma\left(\frac{i(u-v)}{N\hbar}+1-\frac{1}{N}-\frac{k+N}{2N}\right)\Gamma\left(\frac{i(u-v)}{N\hbar}+1+\frac{1}{N}-\frac{k+N}{2N}\right)}{\Gamma\left(\frac{i(u-v)}{N\hbar}+1-\frac{1}{N}+\frac{k+N}{2N}\right)\Gamma\left(\frac{i(u-v)}{N\hbar}+1+\frac{1}{N}+\frac{k+N}{2N}\right)}$$

$$\times\frac{\Gamma^{2}\left(\frac{i(u-v)}{N\hbar}+1+\frac{k+N}{2N}\right)}{\Gamma^{2}\left(\frac{i(u-v)}{N\hbar}+1-\frac{k+N}{2N}\right)}\lambda_{\nu}^{-}(v)\lambda_{\mu}^{+}(u),\quad \mu<\nu, \tag{3.18}$$

$$b_{\mu,\nu}^{+}(u)b_{\mu',\nu'}^{-}(v)=\left(\frac{\Gamma^{3}\left(\frac{i(u-v)}{\hbar}\right)\Gamma\left(\frac{i(u-v)}{\hbar}+2\right)}{\Gamma^{3}\left(\frac{i(u-v)}{\hbar}+1\right)\Gamma\left(\frac{i(u-v)}{\hbar}-1\right)}\right)^{\delta_{\mu,\mu'}\delta_{\nu,\nu'}}b_{\mu',\nu'}^{-}(v)b_{\mu,\nu}^{+}(u)$$

$$=\left(\frac{(u-v)^{2}}{(u-v-i\hbar)(u-v+i\hbar)}\right)^{\delta_{\mu,\mu'}\delta_{\nu,\nu'}}b_{\mu',\nu'}^{-}(v)b_{\mu,\nu}^{+}(u), \tag{3.19}$$

$$c_{\mu,\nu}^{+}(u)c_{\mu',\nu'}^{-}(v)=\left(\frac{\Gamma^{3}\left(\frac{i(u-v)}{\hbar}+1\right)\Gamma\left(\frac{i(u-v)}{\hbar}-1\right)}{\Gamma^{3}\left(\frac{i(u-v)}{\hbar}\right)\Gamma\left(\frac{i(u-v)}{\hbar}+2\right)}\right)^{\delta_{\mu,\mu'}\delta_{\nu,\nu'}}c_{\mu',\nu'}^{-}(v)c_{\mu,\nu}^{+}(u)$$

$$=\left(\frac{(u-v-i\hbar)(u-v+i\hbar)}{(u-v)^{2}}\right)^{\delta_{\mu,\mu'}\delta_{\nu,\nu'}}c_{\mu',\nu'}^{-}(v)c_{\mu,\nu}^{+}(u). \tag{3.20}$$

In the process of constructing the boson realization of $DY_{\hbar}(sl_N)_k$, the following four identities are useful. In fact, the relations of the arguments in different terms are decided by these identities, there are

$$\frac{b^+_{\mu,\nu}(u):b^-_{\mu',\nu'}(v)b_{\mu',\nu'}\left(v-i\frac{\hbar}{2}\right):}{b^+_{\mu,\nu}(u)b_{\mu',\nu'}\left(v+i\frac{\hbar}{2}\right)}=\frac{:b^-_{\mu',\nu'}(v)b_{\mu',\nu'}\left(v-i\frac{\hbar}{2}\right):b^+_{\mu,\nu}(u)}{b_{\mu',\nu'}\left(v+i\frac{\hbar}{2}\right)b^+_{\mu,\nu}(u)}, \tag{3.21}$$

$$\frac{:b^+_{\mu,\nu}(u)b^-_{\mu,\nu}\left(u+i\frac{\hbar}{2}\right):b^-_{\mu',\nu'}(v)}{b^+_{\mu,\nu}\left(u-i\frac{\hbar}{2}\right)b^-_{\mu',\nu'}(v)}=\frac{b^-_{\mu',\nu'}(v):b^+_{\mu,\nu}(u)b^-_{\mu,\nu}\left(u+i\frac{\hbar}{2}\right):}{b^-_{\mu',\nu'}(v)b^+_{\mu,\nu}\left(u-i\frac{\hbar}{2}\right)}, \tag{3.22}$$

$$\frac{:b^+_{\mu,\nu}\left(u+i\frac{\hbar}{2}\right)b^-_{\mu,\nu}(u)^{-1}:b^-_{\mu',\nu'}(v)}{b^+_{\mu,\nu}(u+i\hbar)^{-1}b^-_{\mu',\nu'}(v)}=\frac{b^-_{\mu',\nu'}(v):b^+_{\mu,\nu}\left(u+i\frac{\hbar}{2}\right)b^-_{\mu,\nu}(u)^{-1}:}{b^-_{\mu',\nu'}(v)b^+_{\mu,\nu}(u+i\hbar)^{-1}}, \tag{3.23}$$

$$\frac{b^+_{\mu,\nu}(u):b^-_{\mu',\nu'}\left(v+i\frac{\hbar}{2}\right)b_{\mu',\nu'}(v+i\hbar)^{-1}:}{b_{\mu',\nu'}(v)^{-1}b^+_{\mu,\nu}(u)}=\frac{:b^-_{\mu',\nu'}\left(v+i\frac{\hbar}{2}\right)b_{\mu',\nu'}(v+i\hbar)^{-1}:b^+_{\mu,\nu}(u)}{b^+_{\mu,\nu}(u)b_{\mu',\nu'}(v)^{-1}}. \tag{3.24}$$

The above four identities are only indicated that each of the normal ordering factor of one numerator and its denominator is the same.

IV. FREE BOSON REPRESENTATION OF $DY_\hbar(gl_N)_k$ AND $DY_\hbar(sl_N)_k$

In this section, by using the results obtained in the above sections, we can define a $DY_\hbar(gl_N)_k$ module on the $\mathscr{F}_{\lambda,b,c}$. Then with the help of Eq. (2.11), we get a module of $DY_\hbar(sl_N)_k$ on the $\mathscr{F}_{\lambda,b,c}$. The results can be expressed in terms as:

Proposition 1: There is a homomorphism $\psi_{\hbar,k}$ from $DY_\hbar(gl_N)_k$ to $\mathscr{A}_{\hbar,k}(gl_N)$, which is defined on the generators as follows:

$$k^+_\mu(u)\mapsto:\lambda^+_\mu\left(u+\frac{k-N}{4}i\hbar\right)^{-1}\prod_{\alpha=1}^{\mu-1}\prod_{\beta=\mu+1}^{N}\frac{b^+_{\alpha,\mu}\left(u+\frac{\mu-\alpha}{2}i\hbar\right)}{b^+_{\mu,\beta}\left(u+\frac{\mu-\beta}{2}i\hbar\right)}:, \tag{4.1}$$

$$k^-_\mu(u)\mapsto:\lambda^-_\mu\left(u-\frac{k-N}{4}i\hbar\right)^{-1}\prod_{\rho=1}^{\mu-1}\prod_{\alpha=1}^{\mu}\prod_{\gamma=\mu}^{N}\prod_{\beta=\mu+1}^{N}\frac{b^-_{\rho,\gamma}\left(u+\frac{\rho+\gamma}{2}i\hbar\right)}{b^-_{\alpha,\beta}\left(u+\frac{\alpha+\beta-2}{2}i\hbar\right)}:,$$

$$1\leqslant\mu\leqslant N; \tag{4.2}$$

$$X^+_\nu(u)\mapsto\sum_{m=1}^{\nu}:\left\{\frac{b^+_{m,\nu+1}\left(u-\frac{m-\nu-1}{2}i\hbar\right)}{(b+c)_{m,\nu+1}\left(u-\frac{m-\nu}{2}i\hbar\right)}-\frac{b^-_{m,\nu+1}\left(u-\frac{m-\nu-1}{2}i\hbar\right)}{(b+c)_{m,\nu+1}\left(u-\frac{m-\nu-2}{2}i\hbar\right)}\right\}(b+c)_{m,\nu}$$

$$\times\left(u-\frac{m-\nu-1}{2}i\hbar\right)\prod_{n=1}^{m-1}\frac{b^+_{n,\nu+1}\left(u-\frac{n-\nu-1}{2}i\hbar\right)}{b^+_{n,\nu}\left(u-\frac{n-\nu}{2}i\hbar\right)}:, \tag{4.3}$$

$$
\begin{aligned}
X_\nu^-(u)\mapsto:\Bigg\{ & \sum_{m=1}^{\nu} \lambda_\nu^-\left(u-\frac{k-N}{4}\,i\hbar\right)\lambda_{\nu+1}^-\left(u-\frac{k-N}{4}\,i\hbar\right)^{-1}(b+c)_{m,\nu+1}\left(u+\frac{\nu+m}{2}\,i\hbar\right)\\
&\times\Bigg[(1+\delta_{m,\nu})b_{m,\nu}^-\left(u+\frac{\nu+m}{2}\,i\hbar\right)^{-1}(b+c)_{m,\nu}\left(u+\frac{\nu+m-1}{2}\,i\hbar\right)^{-1}\\
&-b_{m,\nu}^+\left(u+\frac{\nu+m}{2}\,i\hbar\right)^{-1}(b+c)_{m,\nu}\left(u+\frac{\nu+m+1}{2}\,i\hbar\right)^{-1}\Bigg]\\
&\times\prod_{n=m+1}^{\nu}\prod_{s=\nu+1}^{N}\frac{b_{n,\nu+1}^-\left(u+\frac{\nu+n-1}{2}\,i\hbar\right)}{b_{n,\nu}^-\left(u+\frac{\nu+n}{2}\,i\hbar\right)}\frac{b_{\nu,s+1}^-\left(u+\frac{\nu+s}{2}\,i\hbar\right)}{b_{\nu+1,s}^-\left(u+\frac{\nu+s-1}{2}\,i\hbar\right)}\\

$$\times\prod_{n=m+1}^{\mu}\prod_{s=\mu+1}^{N}\frac{b^-_{n,\mu+1}\left(u+\frac{n-1}{2}\,i\hbar\right)}{b^-_{n,\mu}\left(u+\frac{n}{2}\,i\hbar\right)}\frac{b^-_{\mu,s+1}\left(u+\frac{s}{2}\,i\hbar\right)}{b^-_{\mu+1,s}\left(u+\frac{s-1}{2}\,i\hbar\right)}-\sum_{m=\mu+1}^{N}\lambda^+_\mu$$

$$\times\left(u-\frac{3k+N}{4}\,i\hbar-i\mu\,\frac{\hbar}{2}\right)\lambda^+_{\mu+1}\left(u-\frac{3k+N}{4}\,i\hbar-i\mu\,\frac{\hbar}{2}\right)^{-1}(b+c)_{\mu,m}$$

$$\times\left(u-\frac{2k+m-1}{2}\,i\hbar\right)\left[(1+\delta_{m,\mu+1})\frac{b^+_{\mu+1,m}\left(u-\frac{2k+m-1}{2}\,i\hbar\right)}{(b+c)_{\mu+1,m}\left(u-\frac{2k+m}{2}\,i\hbar\right)}\right.$$

$$\left.\left.-\frac{b^-_{\mu+1,m}\left(u-\frac{2K+m-1}{2}\,i\hbar\right)}{(b+c)_{\mu+1,m}\left(u-\frac{2k+m-2}{2}\,i\hbar\right)}\right]\prod_{n=m}^{N}\frac{b^+_{\mu,n}\left(u-\frac{2k+n}{2}\,i\hbar\right)}{b^+_{\mu+1,n}\left(u-\frac{2k+n-1}{2}\,i\hbar\right)}:,\right. \tag{4.9}$$

$(1\leqslant\mu\leqslant N-1)$ without confusion. The following corollary are the direct result of Proposition 1.

Corollary 1: The fields $H^\pm_\mu(u)$, $E^\pm_\mu(u)$ defined in equations (4.6)–Eq. (4.9) are well-defined on the Fock space $\mathscr{F}(\lambda,l_b,l_c)$ and satisfy all of the equations of Eqs. (2.11) with $\hbar$ replaced by $-i\hbar$.

The corollary is also followed by a straightforward calculation. For the sake of illustration, here we give only an example. First, consider the case

$$H^+_\mu(u)H^-_\mu(v)=\frac{u-v+ik\hbar+i\hbar}{u-v+ik\hbar-i\hbar}\,\frac{u-v-iN\hbar-i\hbar}{u-v-iN\hbar+i\hbar}$$

$$\times\prod_{n=1}^{\mu}\prod_{m=\mu+1}^{N}\left(\frac{u-v-i(n-1)\hbar}{u-v-i(n-2)}\,\frac{u-v-in\hbar}{u-v-i(n+1)\hbar}\right)$$

$$\times\left(\frac{u-v-i(m-1)\hbar}{u-v-i(m-2)\hbar}\,\frac{u-v-im\hbar}{u-v-i(m+1)\hbar}\right)H^-_\mu(v)H^+_\mu(\mu)$$

$$=\frac{u-v+ik\hbar+i\hbar}{u-v+ik\hbar-i\hbar}\frac{u-v-iN\hbar-i\hbar}{u-v+iN\hbar+i\hbar}$$
$$\times\prod_{n=1}^{N}\left(\frac{u-v-i(n-1)\hbar}{u-v-i(n-2)\hbar}\frac{u-v-in\hbar}{u-v-i(n+1)\hbar}\right)H_{\mu}^{-}(v)H_{\mu}^{+}(u)$$
$$=\frac{u-v+ik\hbar+i\hbar}{u-v+ik\hbar-i\hbar}\frac{u-v-i\hbar}{u-v+i\hbar}H_{\mu}^{-}(v)H_{\mu}^{+}(u), \tag{4.10}$$

and

$$H_{\mu}^{+}(u)H_{\mu\pm1}^{-}(v)=\frac{u-v+ik\hbar-i\frac{\hbar}{2}}{u-v+ik\hbar+i\frac{\hbar}{2}}\frac{u-v-iN\hbar+i\frac{\hbar}{2}}{u-v-iN\hbar-i\frac{\hbar}{2}}$$
$$\times\prod_{n=1}^{N}\left(\frac{(u-v-i(n-3/2)\hbar)(u-v-i(n+1/2)\hbar)}{(u-v-i(n-1/2)\hbar)^2}\right)H_{\mu\pm1}^{-}(v)H_{\mu}^{+}(u)$$
$$=\frac{u-v+ik\hbar-i\frac{\hbar}{2}}{u-v+ik\hbar+i\frac{\hbar}{2}}\frac{u-v+i\frac{\hbar}{2}}{u-v-i\frac{\hbar}{2}}H_{\mu\pm1}^{-}(v)H_{\mu}^{+}(u), \tag{4.11}$$

$$H_{\mu}^{+}(u)H_{\nu}^{-}(v)=H_{\nu}^{-}(v)H_{\mu}^{+}(u),\quad \text{for}|\mu-\nu|\geqslant 2. \tag{4.12}$$

The above three equation can be expressed as the second equation of Eqs. (2.11) with $\hbar$ replaced by $-i\hbar$. In the above calculation the identities in the above sections are used without mention. The remaining calculation are the similar.

Remark 1: Obviously, the defining relations of the Yangian double $DY_{\hbar}(gl_N)_k$ is identical to the OPEs of the currents $k_{\mu}^{\pm}$, $X_{\mu}^{\pm}$ up to the regular terms with replacing the $\hbar$ in Eqs. (2.3) by $-i\hbar$ (Wick rotation) [the relations for the Yangian double $DY_{\hbar}(sl_N)_k$ and OPEs of the currents Eq. (4.6)–Eq. (4.9) are similar]. But, the realization of Eq. (4.1) – Eq. (4.4) should not be considered to be isomorphic with the Yangian double $DY_{\hbar}(gl_N)_k$, because the free field realization carries a continuous parameter, while the Yangian double $DY_{\hbar}(sl_N)_k$ has discrete mode. For $g=sl_2$, see Ref. 30 for more information on this point.

So, we give the following proposition:

Proposition 2: Under a homomorphic map, the free field realization Eq. (4.1)–Eq. (4.4) and Eq. (4.6)–Eq. (4.9) give a representation of the Yangian double $DY_{\hbar}(gl_N)_k$ and $DY_{\hbar}(sl_N)_k$, respectively.

V. SCREENING CURRENTS

In Ref. 23 the author give a boson field realization for the currents $DY_{\hbar}(sl_N)$ by the so-called q-affine-Yangian double correspondence. There we use ordinary oscillators with discrete mode, and the screening currents and the vertex operators are difficult to obtain by such boson fields. Because of the importance of the vertex operators and screening currents in the field theories, so construction of screening currents in terms of free fields are one of the main objects in the theories. Especially if we know these quantities we could have been able to calculate the cohomology of the action of our bosonization formulas on the Fock spaces $\mathscr{F}(\lambda,l_b,l_c)$. This problem can be overcome by using the boson fields defined in Eq. (3.1), Eq. (3.3), and Eq. (3.4). The screening currents $S^{l}(u)$, $l=1,...,N-1$ can be expressed as the below nice form (under the homomorphism of course),

$$S_{\mu}(u)\mapsto:\lambda_{\mu+1}(k+N|u;(k+N)/4)\lambda_{\mu}(k+N|u;(k+N)/4)^{-1}\widetilde{S}_{\mu}(u): \tag{5.1}$$

where

$$\widetilde{S}_\mu(u)\mapsto -\frac{1}{\hbar}\sum_{m=\mu+1}^{N}(b+c)_{\mu+1,m}\left(u-\frac{N-m}{2}\,i\hbar\right)\left\{b^-_{\mu,m}\left(u-\frac{N-m}{2}-i\hbar\right)\right\}^{-1}$$

$$\times(c+b)_{\mu,m}\left(u-\frac{N-m+1}{2}\,i\hbar\right)^{-1}-b^+_{\mu,m}\left(u-\frac{N-m}{2}\,i\hbar\right)^{-1}$$

$$\times(c+b)_{\mu,m}\left(u-\frac{N-m-1}{2}\,i\hbar\right)^{-1}\prod_{n=m+1}^{N}\frac{b^-_{\mu+1,m}\left(u-\frac{N-n+1}{2}\,i\hbar\right)}{b^-_{\mu,n}\left(u-\frac{N-n}{2}\,i\hbar\right)}. \quad (5.2)$$

Then by a direct calculation, one can prove that the currents have the following properties:

$$H^\pm_\mu(u)S_\nu(v)\simeq S_\nu(v)H^\pm_\mu(u)\sim reg.,$$

$$E_\mu(u)S_\nu(v)\simeq S_\nu(v)E_\mu(u)\sim reg.,$$

$$(u-v-iB_{\mu,\nu})\widetilde{S}_\mu(u)\widetilde{S}_\nu(v)\simeq(u-v-iB_{\mu,\nu})\widetilde{S}_\nu(v)\widetilde{S}_\mu(u)\sim reg., \quad (5.3)$$

$$F_\mu(u)S_\nu(v)\simeq S_\nu(v)F(u)\sim reg.+\frac{\delta_{\mu,\nu}}{i\hbar}\left(\frac{1}{u-v+\frac{N}{2}\,i\hbar}-\frac{1}{u-v-ik\hbar-\frac{N}{2}\,i\hbar}\right)\lambda_{\mu+1}(k+N|\mu;$$

$$-(k+N)/4)\lambda_\mu(k+N|u;-(k+N)/4)^{-1}$$

$$=reg.+\delta_{\mu,\nu(k+N)}\partial_v\left(\frac{1}{u-v}\,\lambda_{\mu+1}(k+N|u;-(k+N)/4)\right.$$

$$\left.\times\lambda_\mu(k+N|u;-(k+N)/4)^{-1}\right), \quad (5.4)$$

where

$${}_{k+\alpha}\partial_u f(u)=\frac{1}{i\hbar}\left(f\left(u-i\alpha\,\frac{\hbar}{2}\right)-f\left(u+ik\hbar+i\alpha\,\frac{\hbar}{2}\right)\right). \quad (5.5)$$

For the purpose to define the vertex operators, one first introduce the state, $|p_\lambda,0,0\rangle$. It can be easy to show that this state is just the highest weight state with weight $\Lambda=l^1\Lambda_1+\ldots+l^{N-1}\Lambda_{N-1}=(l^1,\ldots,l^{N-1})$. If the vertex operators with weight is given as

$$\Phi_\Lambda(u;\alpha)\mapsto:\sum_{\mu=1}^{N-1}\exp\left\{-\hbar\int_{-\infty}^{0}\frac{dt}{2\pi i}\,\frac{\sinh\frac{l^\mu}{2}\hbar t}{\sinh\frac{k+N}{2}\hbar t\,\sinh\frac{\hbar}{2}t}\,\hat{\lambda}_\mu(t)e^{\alpha\hbar t}e^{-iut}\right\}$$

$$\times\exp\left\{-\hbar\int_{0}^{+\infty}\frac{dt}{2\pi i}\,\frac{\sinh\frac{l^\mu}{2}\hbar t}{\sinh\frac{k+N}{2}\hbar t\,\sinh\frac{\hbar}{2}t}\,\hat{\lambda}_\mu(t)e^{-\alpha\hbar t}e^{-iut}\right\}:, \quad (5.6)$$

and the highest weight state of $DY_\hbar(sl_N)$, can be obtained from the vacuum $|0\rangle$ state by this operators, so the vertex operator is similar to the primary fields in the conformal field theory. The vertex related to the intertwining operators of type one and type two will be discussed elsewhere.

VI. DISCUSSIONS

In this paper we establish the free boson representation of the Yangian double $DY_\hbar(sl_N)$ with arbitrary level k. Such representations of the Yangian double $DY_\hbar(sl_N)$ are expected to be useful in calculating the correlation functions of various quantum integrable systems in $(1+1)$-spacetime dimensions, e.g., the spin Calogero–Sutherland model,[34] the quantum nonlinear Schrödinger equation,[35] and some field theoretic models such as the Thirring model, the Gross–Neveu model with $U(N)$ gauge symmetries, etc. Our representation of $DY_\hbar(sl_N)$ may also be used to analyze the behavior of Yangian double at the critical level $k=-g$, a very fascinating area of great interest of study[24] which corresponds to the $W_\hbar$ algebra. For the length of the manuscript, we will discuss this problem in a separate paper.

(Received 29 August 1997; accepted for publication 28 October 1997)

Γ-conformal algebra is an axiomatic description of the operator product expansion of chiral fields with simple poles at finitely many points. We classify these algebras and their representations in terms of Lie algebras and their representations with an action of the group Γ. To every Γ-conformal algebra and a character of Γ we associate a Lie algebra generated by fields with the OPE with simple poles. Examples include twisted affine Kac–Moody algebras, the sin algebra (which is a ''Γ-conformal'' analogue of the general linear algebra) and its analogues, the algebra of pseudodifferential operators on the circle, etc. © *1998 American Institute of Physics.* [S0022-2488(98)00904-9]

I. INTRODUCTION

In the past there have been a number of papers in which the effect of splitting of a pole of order N in the operator product expansion (OPE) occurs. Examples include representations of twisted affine Kac–Moody algebras,[1] of the Lie algebras of quantum torus,[2] of quantum affine algebras,[3] and of the central extension of the double of Yangian.[4] These constructions found many applications in the theory of integrable systems and exactly solvable models in quantum field theory.

The simplest motivation to consider the OPE with simple poles, but in the shifted points is the following. Consider the OPE of two local fields $a(z)$ and $b(z)$:

$$a(z)b(w)\sim\sum_{j=0}^{N-1}\frac{c^j(w)}{(z-w)^{j+1}} \tag{1.1}$$

and replace $(z-w)^n$ by its q-analogue $(z-w)_q^n=(z-w)(z-qw)\cdots(z-q^{n-1}w)$. The result of this q-deformation is an OPE with only simple poles. A natural generalization is to consider Γ-deformation, where Γ is a subgroup of the multiplicative group of non-zero complex numbers $\mathbb{C}^\times$. Namely, for an n-element subset S of Γ we let

$$(z-w)_S^n=\prod_{\alpha\in S}(z-\alpha w)$$

and consider a collection of fields satisfying the condition of Γ-locality, i.e.,

$$(z-w)_S^n[a(z),b(w)]=0. \tag{1.2}$$

The study of algebraic properties of Γ-locality lead us to a formal definition of a Γ-conformal algebra given below. Property (1.2) is equivalent to the following form of the OPE (Proposition II.1):

$$a(z)b(w)\sim\sum_{\alpha\in S}\frac{c^\alpha(w)}{z-\alpha w}. \tag{1.3}$$

[a)]Electronic mail: kutuzova@geometrie.univ-lyon1.fr
[b)]Electronic mail: kac@math.mit.edu

 © 1998 American Institute of Physics

We view the field $c^{\alpha}(w)$ as an ''α-product'' of the fields $a(z)$ and $b(z)$:

$$c^{\alpha}(w)=(a_{(\alpha)}b)(w). \tag{1.4}$$

Introduce operators $T_{\alpha}(\alpha\in\mathbb{C}^{\times})$ on the space of fields by

$$T_{\alpha}a(z)=\alpha a(\alpha z). \tag{1.5}$$

Let R be a space over $\mathbb{C}$ of Γ-local fields which is closed under products (1.4) and invariant under operators (1.5) for all $\alpha\in\Gamma$. Then one can show (Proposition III.1) that the following properties hold, where $a,b,c\in R$, $\alpha,\beta\in\Gamma$:

(C0) $a_{(\alpha)}b=0$ for all but finitely many $\alpha\in\Gamma$,
(C1) $(T_{\alpha}a)_{(\beta)}b=a_{(\beta\alpha)}b$,
(C2) $a_{(\alpha)}b=-T_{\alpha}(b_{(\alpha^{-1})}a)$,
(C3) $[a_{(\alpha)},b_{(\beta)}]c=(a_{(\beta^{-1}\alpha)}b)_{(\beta)}c$.

Now we observe that one can forget that Γ is a subgroup of $\mathbb{C}^{\times}$ and that R is a space of fields. What remains is a (not necessarily abelian) group Γ, its representation space R and $\mathbb{C}$-bilinear products $a_{(\alpha)}b$ on R for each $\alpha\in\Gamma$, such that the axioms (C0)–(C3) hold. This is the basic object of our study, called a Γ-*conformal algebra*.

Recall that the OPE (1.1) of local fields similarly leads to the notion of a conformal algebra.[5,6] However, conformal algebras and Γ-conformal algebras have dramatically different properties.

Our first result on Γ-conformal algebras is Theorem IV.1 which gives their classification in terms of admissible pairs $(\mathfrak{g},\varphi)$, where $\mathfrak{g}$ is a Lie algebra and φ is a homomorphism of Γ to the group Aut$\mathfrak{g}$ of automorphisms of $\mathfrak{g}$ such that for any $a,b\in\mathfrak{g}$ one has

$$[T_{\alpha}a,b]=0 \text{ for all but finitely many } \alpha\in\Gamma. \tag{1.6}$$

Of course, if Γ is a finite subgroup of Aut$\mathfrak{g}$, then (1.6) holds. The associated Γ-conformal algebra is called a twisted current conformal algebra. A more interesting example corresponds to the admissible pair $(g\mathscr{l}_{\infty},\mathbb{Z})$, where $g\mathscr{l}_{\infty}$ is the Lie algebra of all $\mathbb{Z}\times\mathbb{Z}$-matrices (a_{ij}) over $\mathbb{C}$ with a finite number of non-zero entries and the action of $\mathbb{Z}$ is by translations along the diagonal: $n\cdot(a_{i,j})=(a_{i+n,j+n})$, $n\in\mathbb{Z}$. This $\mathbb{Z}$-conformal algebra is denoted by $gc_1(\mathbb{Z})$ for reasons explained below.

To a Γ-conformal algebra and a homomorphism χ of Γ to $\mathbb{C}^{\times}$ (or, more generally, to the group of meromorphic transformations of $\mathbb{C}$, see Sec. VI) one canonically associates an infinite-dimensional Lie algebra. This construction produces many known (and a lot of new) examples of infinite-dimensional Lie algebras which appear in deformation of conformal field theories. For example, the Lie algebra of q-differential operators on the circle (the sin-algebra) is obtained from the $\mathbb{Z}$-conformal algebra $gc_1(\mathbb{Z})$ by using $\chi:\mathbb{Z}\to\mathbb{C}^{\times}$ defined by $\chi(n)=q^n$. Taking the same $\mathbb{Z}$-conformal algebra, but the homomorphism $\chi:\mathbb{Z}\to GL_2(\mathbb{C})$ defined by $\chi(n)z=z+n$, $z\in\mathbb{C}$, instead, produces the Lie algebra of pseudodifferential operators on the circle (see Sec. VI).

Representations of Γ-conformal algebras are classified by equivariant $(\mathfrak{g},\Gamma)$-modules satisfying a finiteness condition (Theorem V.1). On the other hand, to any representation π of the group Γ we canonically associate the general Γ-conformal algebra $gc(\pi,\Gamma)$, which plays the role of the general linear group in the sense that representations of a Γ-conformal algebra R correspond to homomorphisms $R\to gc(\pi,\Gamma)$ (Theorem V.2). The most important case is when π is a free $\mathbb{C}[\Gamma]$-module of rank N. The corresponding general Γ-conformal algebra, denoted by $gc_N(\Gamma)$, is a generalization of $gc_1(\mathbb{Z})$ mentioned above. It is an analogue of gc_N in the theory of conformal algebras.[6,7]

In the present paper we consider the simplest case of simple poles and of one indeterminate z. It is straightforward to generalize this to the case of multiple poles and the case of several indeterminates. This will be discussed elsewhere.

II. *S*-LOCAL FORMAL DISTRIBUTIONS

Recall that a formal distribution with coefficients in a vector space U is an expression of the form

$$a(z)=\sum_{n\in\mathbb{Z}} a_n z^{-n-1}, \quad \text{where} \quad a_n\in\mathbb{Z}.$$

They form a vector space denoted by $U[[z,z^{-1}]]$. We shall use the standard notation:

$$\operatorname*{Res}_{z=0} a(z)=a_0.$$

Similarly, a formal distribution in z and w is an expression of the form

$$a(z,w)=\sum_{m,n\in\mathbb{Z}} a_{m,n} z^{-m-1} w^{-n-1}, \text{ where } a_{m,n}\in U.$$

It may be viewed as a formal distribution in z with coefficients in $U[[w,w^{-1}]]$.

Recall that the formal δ-function is the following formal distribution in z and w with coefficients in $\mathbb{C}$:

$$\delta(z-w)=\sum_{n\in\mathbb{Z}} z^{n-1} w^{-n}.$$

It has the following two basic properties:

$$(z-w)\,\delta(z-w)=0 \tag{2.1}$$

$$\operatorname*{Res}_{z=0} a(z)\,\delta(z-w)=a(w) \quad \text{for } a(z)\in U[[z,z^{-1}]]. \tag{2.2}$$

We shall use the formal distribution

$$\delta(\alpha z-\beta w)=\sum_{n\in\mathbb{Z}} (\alpha z)^{n-1}(\beta w)^{-n}, \quad \alpha,\beta\in\mathbb{C}^\times,$$

and the following obvious property

$$\delta(\alpha z-\beta w)=\alpha^{-1}\delta(z-\alpha^{-1}\beta w)=\beta^{-1}\delta(\alpha\beta^{-1}z-w). \tag{2.3}$$

We shall use also the following equality of distributions in z_1, z_2 and z_3:

$$\delta(z_1-z_2)\,\delta(z_2-z_3)=\delta(z_1-z_2)\,\delta(z_1-z_3) \tag{2.4}$$

Let S be an N-element set of (distinct) non-zero complex numbers. We shall use the following notation:

$$(z-w)_S^N=\prod_{\alpha\in S}(z-\alpha w). \tag{2.5}$$

Definition II.1: Two formal distributions $a(z)$ and $b(z)$ with coefficients is Lie algebra $\mathfrak{g}$ are called S-local if in $\mathfrak{g}[[z,z^{-1},w,w^{-1}]]$ *one has:*

$$(z-w)_S^N[a(z),b(w)]=0. \tag{2.6}$$

Note that S-local formal distributions are S'-local for any finite subset S' of $\mathbb{C}^\times$ containing S.

Proposition II.1: If $a(z)$ and $b(z)$ are S-local formal distributions, then there exists a unique decomposition of the form

$$[a(z),b(w)]=\sum_{\alpha\in S} c_\alpha(w)\,\delta(z-\alpha w). \tag{2.7}$$

The formal distributions $c_\alpha(w)$ are given by the formula

$$c_\alpha(w)=\operatorname*{Res}_{z=0} P_{S,\alpha}\left(\frac{z}{w}\right)[a(z),b(w)], \tag{2.8}$$

where

$$P_{S,\alpha}(u)=\prod_{\substack{\beta\in S\\ \beta\neq\alpha}}\frac{u-\beta}{\alpha-\beta}. \tag{2.9}$$

Proof of this proposition is immediate by the following lemma.

Lemma II.1: (a) Each formal distribution $a(z,w)$ *can be uniquely written in the form:*

$$a(z,w)=\sum_{\alpha\in S} c_\alpha(w)\,\delta(z-\alpha w)+b(z,w), \tag{2.10}$$

where

$$c_\alpha(w)=\operatorname*{Res}_{z=0} P_{S,\alpha}\left(\frac{z}{w}\right)a(z,w) \tag{2.11}$$

and

$$\operatorname*{Res}_{z=0} P_{S,\alpha}\left(\frac{z}{w}\right)b(z,w)=0 \quad \text{for all } \alpha\in S. \tag{2.12}$$

(b) If $b(z,w)$ *satisfies (2.12) and* $(z-w)_S^N b(z,w)=0$ then b $(z,w)=0$.

Proof: Consider the following operator on the space of formal distributions in z and w:

$$\pi_S a(z,w)=\sum_{\alpha\in S} c_\alpha(w)\,\delta(z-\alpha w),$$

where $c_\alpha(w)$ are given by (2.11). It is clear using (2.2) that $\pi_S^2=\pi_S$, which implies (a). Furthermore, suppose that $(z-w)_S^N b(z,w)=0$. It follows from Ref. 5 [Corollary 2.2] that for each $\alpha\in S$:

$$P_{S,\alpha}b(z,w)=d_\alpha(w)\,\delta(z-\alpha w)$$

for some formal distribution $d_\alpha(w)$. If also (2.12) holds, then $\operatorname{Res}_{z=0} d_\alpha(w)\ \delta(z-\alpha w)=0$, hence $d_\alpha(w)=0$ by (2.2), and

$$P_{S,\alpha}\left(\frac{z}{w}\right)b(z,w)=0 \quad \text{for all } \alpha\in S. \tag{2.13}$$

This implies that $b(z,w)=0$ since the polynomials, $P_{S,\alpha}$ are relatively prime. (Indeed $\Sigma_{\alpha\in S}P_{S,\alpha}u_\alpha=1$ for some polynomials u_α. Multiplying both sides of (2.13) by $u_\alpha(z/w)$ and summing over α, we get $b(z,w)=0$.) This proves (b). □

Corollary II.1: The formal distributions $a(z)$ *and* $b(z)$ *are S-local if there exists a decomposition of the form* (2.7)

Proof: Follows from Proposition II.1 and (2.1). □

Remark II.1: The coefficients $c_\alpha(w)$ are independent of the choice of S for which (2.6) holds. This follows from the uniqueness of the decomposition (2.10).

Remark II.2: Formula (2.7), written out in modes, looks as follows:

$$[a_m,b_n]=\sum_{\alpha\in S}\alpha^m c_{\alpha,m+n}.$$

III. α-PRODUCTS OF Γ-LOCAL FORMAL DISTRIBUTIONS

Let Γ be a subgroup of $\mathbb{C}^\times$. Two formal distributions $a(z)$ and $b(z)$ are called Γ-local if they are S-local for some finite subset S of Γ. For $\alpha\in\Gamma$ define the α-product $(a_{(\alpha)}b)(w)$ as the coefficient $c_\alpha(z)$ in the expansion (2.7). In other words,

$$(a_{(\alpha)}b)(w)=\operatorname*{Res}_{z=0}P_{S,\alpha}\left(\frac{z}{w}\right)[a(z),b(w)]. \tag{3.1}$$

Due to Remark II.1, the α-product is independent of the choice of S.

For $\beta\in\Gamma$ introduce the following operator:

$$T_\beta(a(z))=\beta a(\beta z).$$

It is clear that T_β preserves Γ-locality.

We collect below the main properties of α-products.

Proposition III.1: For Γ-local formal distributions one has the following properties $(\alpha,\beta\in\Gamma)$:

(a) (Translation invariance) $(T_\alpha a)_{(\beta)}b=a_{(\alpha\beta)}b$, and $a_{(\beta)}T_\alpha b=T_\alpha(a_{(\beta\alpha^{-1})}b)$.

(b) (Skewsymmetry) $a_{(\alpha)}b=-T_\alpha(b_{(\alpha^{-1})}a)$.

(c) (Jacobi identity) $a_{(\alpha)}(b_{(\beta)}c)=(a_{(\alpha\beta^{-1})}b)_{(\beta)}c+b_{(\beta)}(a_{(\alpha)}c)$ *provided that all the suitable localities hold.*

Proof:

(a) We have:

$$[T_\alpha a(z),b(w)]=\sum_{\beta\in\Gamma}((T_\alpha a)_{(\beta)}b)(w)\,\delta(z-\beta w),$$

$$[T_\alpha a(z),b(w)]=[\alpha a(\alpha z),b(w)]=\sum_{\gamma\in\Gamma}\alpha(a_{(\gamma)}b)(w)\,\delta(\alpha z-\gamma w)$$

$$=\sum_{\gamma\in\Gamma}(a_{(\gamma)}b)(w)\,\delta(z-\alpha^{-1}\gamma w).$$

Comparing coefficients, we get the first equation of (a).

(b) We have using (2.7) and (2.3):

$$[a(z),b(w)]=-[b(w),a(z)]=-\sum_{\beta\in\Gamma}(b_{(\beta)}a)(z)\,\delta(w-\beta z)$$

$$=-\sum_{\beta\in\Gamma}\beta(b_{(\beta^{-1})}a)(\beta w)\,\delta(z-\beta w).$$

Comparing with (2.7), we obtain (b). The second equation of (a) follows from the first and (b).

(c) We have:

$$[a(z),[b(w),c(t)]]=\sum_{\alpha,\beta\in\Gamma}(a_{(\alpha)}(b_{(\beta)}c))(t)\,\delta(z-\alpha t)\,\delta(w-\beta t),$$

$$[a(z),b(w)],c(t)]=\sum_{\alpha,\beta\in\Gamma}((a_{(\alpha\beta^{-1})}b)_{(\beta)}c)(t)\,\delta(z-\alpha\beta^{-1}w)\,\delta(w-\beta t)$$

$$=\sum_{\alpha\in\Gamma}((a_{(\alpha\beta^{-1})}b)_{(\beta)}c)(t)\,\delta(z-\alpha t)\,\delta(w-\beta t).$$

We have used here (2.3) and (2.4). We also have:

$$[b(w),[a(z),c(t)]]=\sum_{\alpha,\beta\in\Gamma} b_{(\beta)}(a_{(\alpha)}c)(t)\,\delta(w-\beta t)\,\delta(z-\alpha t).$$

Equating the first equality with the sum of the remaining two and using Jacobi identity in $\mathfrak{g}$, we obtain equality (c) due to linear independence of $\delta(w-\beta t)\,\delta(z-\alpha t)$ for $\alpha,\beta\in\Gamma$. □

IV. Γ-CONFORMAL ALGEBRAS AND LIE ALGEBRAS OF Γ-LOCAL FORMAL DISTRIBUTIONS

The above considerations motivate the following definitions. Let Γ be a group and let $\mathbb{C}[\Gamma]$ be the group algebra of Γ with basis T_α ($\alpha\in\Gamma$), so that $T_\alpha T_\beta=T_{\alpha\beta}$, $T_1=1$. Since Γ is not necessarily abelian we must distinguish the case of left and right $\mathbb{C}[\Gamma]$-modules.

Definition IV.1:A left $\mathbb{C}[\Gamma]$*-module R is called a left* Γ-conformal algebra *if it is equipped with a* $\mathbb{C}$*-bilinear product* $a_{(\alpha)}b$ *for each* $\alpha\in\Gamma$ *such that the following axioms hold* ($a,b,c\in R$, $\alpha,\beta\in\Gamma$):

(C0) $a_{(\alpha)}b=0$ for all but finitely many $a\in\Gamma$,
(C1) $(T_\alpha a)_{(\beta)}b=a_{(\beta\alpha)}b$,
(C2) $a_{(\alpha)}b=-T_\alpha(b_{(\alpha^{-1})}a)$,
(C3) $a_{(\alpha)}(b_{(\beta)}c)=(a_{(\beta^{-1}\alpha)}b)c+b_{(\beta)}(a_{(\alpha)}c)$.

A right $\mathbb{C}[\Gamma]$-module R is called a *right* Γ*-conformal algebra* if axioms (C1), (C2) and (C3) are replaced by:

$(\mathrm{C1})_\mathrm{R}$ $(aT_\alpha)_{(\beta)}b=a_{(\alpha\beta)}b$,
$(\mathrm{C2})_\mathrm{R}$ $a_{(\alpha)}b=-(b_{(\alpha^{-1})}a)T_\alpha$,
$(\mathrm{C3})_\mathrm{R}$ $a_{(\alpha)}(b_{(\beta)}c)=(a_{(\alpha\beta^{-1})}b)_{(\beta)}c+b_{(\beta)}(a_{(\alpha)}c)$.

Unless otherwise specified, we will consider left Γ-conformal algebras and will drop the adjective left.

Remark IV.1: (a) Properties (C1) and (C2) (resp. $(\mathrm{C1})_\mathrm{R}$ and $(\mathrm{C2})_\mathrm{R}$) imply
(C1′) $a_{(\beta)}T_\alpha b=T_\alpha(a_{(\alpha^{-1}\beta)}b)$ (resp. $(\mathrm{C1}')_\mathrm{R}$ $a_{(\beta)}(bT_\alpha)=(a_{(\beta\alpha^{-1})}b)T_\alpha$)
(b) (C1) and (C1′) (resp. $(\mathrm{C1})_\mathrm{R}$ and $(\mathrm{C1}')_\mathrm{R}$) imply

$$(T_\alpha a)_{(\beta)}(T_\alpha b)=T_\alpha(a_{(\alpha^{-1}\beta\alpha)}b)\quad(\text{resp.}(aT_\alpha)_{(\beta)}(bT_\alpha)=(a_{(\alpha\beta\alpha^{-1})}b)T_\alpha).$$

In particular, each T_α is an automorphism of the product $a_{(1)}b$ for each $\alpha\in\Gamma$.

(c) With respect to the product $a_{(1)}b$, R is a Lie algebra over $\mathbb{C}$. Due to (C1) all other products are expressed via the 1-product:

$$a_{(\alpha)}b=(T_\alpha a)_{(1)}b.$$

Due to Remark IV.1, we can associate to a Γ-conformal algebra R a pair $(\mathfrak{g},\varphi)$, where $\mathfrak{g}$ is a Lie algebra over $\mathbb{C}$ whose underlying space is R and bracket is $[a,b]=a_{(1)}b$, and φ is a homomorphism of Γ to the group $\mathrm{Aut}(\mathfrak{g})$ such that

$$[T_\alpha a,b]=0\ \text{ for all but finitely many }\ \widetilde{\Phi}\alpha\in\Gamma. \tag{4.1}$$

We call such $(\mathfrak{g},\varphi)$ an *admissible pair*. Conversely, given an admissible pair $(\mathfrak{g},\varphi)$ we denote by $R(\mathfrak{g},\varphi)$ the $\mathbb{C}[\Gamma]$-module $\mathfrak{g}$ with $\mathbb{C}$-bilinear products

$$a_{(\alpha)}b=[T_\alpha a,b]. \tag{4.2}$$

It is straightforward to check that $R(\mathfrak{g},\varphi)$ is a Γ-conformal algebra.

We have proved the following result:

Theorem IV.1: Γ-conformal algebras *are classified by admissible pairs* $(\mathfrak{g},\varphi)$.

Fix now a homomorphism $\chi:\Gamma\to\mathbb{C}^\times$. Let $\mathfrak{s}$ be a Lie algebra and let R be a family of pairwise $\chi(\Gamma)$-local formal distributions with coefficients in $\mathfrak{s}$, which span $\mathfrak{s}$ over $\mathbb{C}$. Assume that R is stable under all T_α and all α-products for $\alpha\in\chi(\Gamma)$. Then $\mathfrak{s}$ is called a *Lie algebra* of $\chi(\Gamma)$-*local formal distributions*.

It follows from Proposition III.1 that R is a $\chi(\Gamma)$-conformal algebra. Conversely, given a Γ-conformal algebra R, we associate to it a Lie algebra $\mathfrak{s}(R)$ of $\chi(\Gamma)$-local formal distributions as follows. Consider a vector space over $\mathbb{C}$ with the basis a_n, where $a\in R$ and $n\in\mathbb{Z}$, and denote by $\mathfrak{s}(R,\chi)$ the quotient of this space by the $\mathbb{C}$-span of elements of the form ($n\in\mathbb{Z}$):

$$(\lambda a+\mu b)_n-\lambda a_n-\mu b_n, \quad \text{where } \lambda,\mu\in\mathbb{C},\ a,b\in R, \tag{4.3a}$$

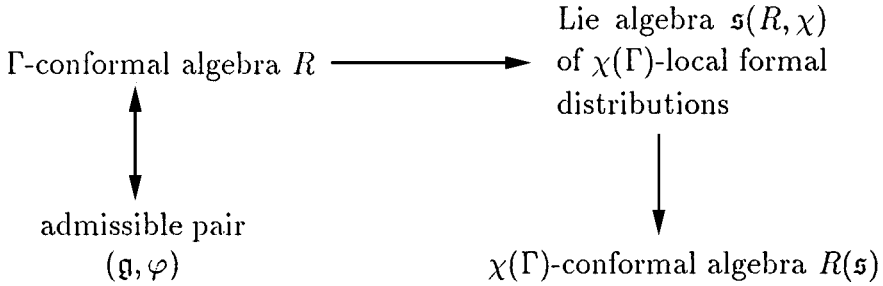
$$(T_\alpha a)_n-\chi(\alpha)^{-n}a_n, \quad \text{where } \alpha\in\Gamma,\ a\in R. \tag{4.3b}$$

Then it is straightforward to check that the formula (cf. Remark II.2)

$$[a_m,b_n]=\sum_{\gamma\in\Gamma}\chi(\gamma)^m(a_{(\gamma)}b)_{m+n} \tag{4.4}$$

gives a well-defined structure of a Lie algebra on $\mathfrak{s}(R,\chi)$ of $\chi(\Gamma)$-local formal distributions $a(z)=\Sigma_{n\in\mathbb{Z}}a_nz^{-n-1}$, $a\in R$ The associated $\chi(\Gamma)$-conformal algebra is denoted by $R(\mathfrak{s})$.

The relations between the constructed objects can be summarized by the following diagram:



Now we turn to the most important examples of Γ-conformal algebras and related constructions.

Example IV.1: Let $(\mathfrak{g},\mathbb{Z}/N\mathbb{Z})$ be a finite-dimensional (simple) Lie algebra $\mathfrak{g}$ with the action of the group $\Gamma=\mathbb{Z}/N\mathbb{Z}$ by automorphisms of $\mathfrak{g}$. Due to this action T_α, $\alpha\in\Gamma$, we have the eigenspace decomposition ($\hat{\Gamma}$ is the group of characters of Γ):

$$\mathfrak{g}=\bigoplus_{j\in\hat{\Gamma}}\mathfrak{g}_j.$$

The Γ-conformal algebra $R(\mathfrak{g},\varphi)$ is defined as $\mathbb{C}[\Gamma]$-module with underlying space $\mathfrak{g}$ and $\mathbb{C}$-bilinear products $a_{(\alpha)}b=[T_\alpha a,b]$, $a,b\in\mathfrak{g}$, $\alpha\in\mathbb{Z}/N\mathbb{Z}$. Fix a homomorphism $\chi:\Gamma\to\mathbb{C}^\times$ such that $\chi(n)=\epsilon^n$, where $\epsilon\in\mathbb{C}$ is an N-th root of 1. The corresponding Lie algebra of $\chi(\Gamma)$-local formal distributions $\mathfrak{s}(R,\chi)$ is nothing but the twisted affine algebra:[8]

$$[a_m,b_n]=\sum_{k\in\mathbb{Z}/N\mathbb{Z}}\epsilon^{km}[T_ka,b]_{m+n}.$$

Equivalently:

$$[a(z),b(w)]=\sum_{\alpha\in\mathbb{Z}/N\mathbb{Z}}[T_\alpha a,b](w)\,\delta(z-\alpha w).$$

Suppose that $a\in\mathfrak{g}_j$, then $T_ka=\epsilon^{kj}a$ and

$$[a_m,b_n]=\begin{cases}0 & \text{if } m\neq -j \mod N\\ N[a,b]_{m+n} & \text{if } m=-j \mod N.\end{cases}$$

Thus we put $a_m=0$ for $m\neq -j \bmod N$, which is the same as to take a quotient by relations (4.3b).

Example IV.2: Consider $\Gamma=\mathbb{Z}$ and the admissible pair $(\mathfrak{g},\varphi)$, where $\mathfrak{g}=g\mathcal{A}_\infty$ is the Lie algebra of all $\mathbb{Z}\times\mathbb{Z}$ matrices over $\mathbb{C}$ with finitely many non-zero entries. Let E_{ij} $(i,j\in\mathbb{Z})$ be its standard basis, with the usual relations:

$$[E_{ij},E_{k\ell}]=\delta_{j,k}E_{i\ell}-\delta_{\ell,i}E_{kj}.$$

Let T be the image of $1\in\mathbb{Z}$ under φ. Consider two different actions of T on $g\mathcal{A}_\infty$.

(a) $T:E_{ij}\to E_{i+1,j+1}$. In this case $g\mathcal{A}_\infty$ is a free $\mathbb{C}[T,T^{-1}]$-module with the generators $A^m=E_{0,m}$, $m\in\mathbb{Z}$. As follows from Definition IV.1 of a Γ-conformal algebra, it is sufficient to define the Γ-products only on generators of the $\mathbb{C}[\Gamma]$-module. So, for the case under consideration we have:

$$A^m_{(r)}A^n=[T^rA^m,A^n]=[E_{r,m+r},E_{0,n}]=\delta_{r,-m}T^{-m}A^{m+n}-\delta_{r,n}A^{m+n},\quad r\in\mathbb{Z}. \tag{4.5}$$

Take a homomorphism $\chi=\chi_q:\mathbb{Z}\to\mathbb{C}^\times$ defined by $\chi_q(1)=q\in\mathbb{C}^\times$. The corresponding Lie algebra $\mathfrak{s}(R,\chi)$ is the Lie algebra with the basis A^m_k, $m,k\in\mathbb{Z}$, and the commutation relations:

$$[A^m_k,A^n_\ell]=\sum_{r\in\mathbb{Z}}q^{rk}(A^m_{(r)}A^n)_{k+\ell}=(q^{m\ell}-q^{kn})A^{m+n}_{k+\ell}. \tag{4.6}$$

This is the Lie algebra of q-pseudodifferential operators on the circle (sin-algebra).

(b) Now define the action of $\varphi(1)=\widetilde{T}$ by $\widetilde{T}(E_{i,j})=-E_{j+1,i+1}$. We have $\widetilde{T}=\epsilon T$, where ϵ is an order 2 automorphism of $g\mathcal{A}_\infty$ defined by $\epsilon(E_{ij})=-E_{ji}$. In this case $g\mathcal{A}_\infty$ is a free $\mathbb{C}[\widetilde{T},\widetilde{T}^{-1}]$-module with generators $A^m=E_{0,m}$ and $B^m=\epsilon(A^m)=-E_{m,0}$, $m\in\mathbb{Z}_+$. Let us compute the r-product, $r\in\mathbb{Z}$, for the elements of the basis of $\mathbb{C}[\Gamma]-module$. Suppose $n-m\geqslant 0$ (for $n-m<0$ we can use axiom (C2)):

$$A^m_{(r)}A^n=[\widetilde{T}^rA^m,A^n]=\begin{cases}\delta_{r,-m}T^{-m}A^{m+n}-\delta_{r,m}A^{m+n}, & m,n \text{ even};\\ \delta_{r,-m}T^{-m}A^{m+n}+\delta_{r,n-m}A^{n-m}, & m \text{ even}, n \text{ odd};\\ -\delta_{r,n}A^{m+n}+\delta_{r,n-m}A^{n-m}, & m \text{ odd}, n \text{ even}\\ 0, & m,n \text{ odd}.\end{cases}$$

$$B^m_{(r)}B^n=\epsilon[\widetilde{T}^rA^m,A^n]$$

$$B^m_{(r)}A^n=\begin{cases}-\delta_{r,0}\widetilde{T}^mA^{n-m}+\delta_{r,n-m}A^{n-m}, & m,n \text{ even};\\ -\delta_{r,0}\widetilde{T}^mA^{n-m}-\delta_{r,n}A^{m+n}, & m \text{ even}, n \text{ odd};\\ -\delta_{r,0}\widetilde{T}^mB^{n-m}+\delta_{r,-m}\widetilde{T}^{-m}B^{n+m}, & m \text{ odd}, n \text{ even};\\ -\delta_{r,0}\widetilde{T}^nB^{n-m}+\delta_{r,n-m}A^{n+m}\\ \quad+\delta_{r,-m}\widetilde{T}^{-m}B^{n+m}-\delta_{r,n}A^{m+n}, & m,n \text{ odd}.\end{cases}$$

The corresponding Lie algebra $\mathfrak{s}(R,\chi_q)$ is a Lie algebra with basis $\{A^m_k\}$ and $\{B^n_\ell\}$, $m,n\in\mathbb{Z}_+$, $k,\ell\in\mathbb{Z}$. From (4.4) and (4.5) we have for $n-m\geqslant 0$:

$$[A^m_k,A^n_\ell]=\begin{cases}(q^{m\ell}-q^{nk})A^{m+n}_{k+\ell}, & m,n \text{ even},\\ q^{m\ell}A^{m+n}_{k+\ell}+q^{k(n-m)}A^{n-m}_{k+\ell}, & m \text{ even}, n \text{ odd};\\ -q^{nk}A^{m+n}_{k+\ell}+q^{k(n-m)}A^{n-m}_{k+\ell}, & m \text{ odd}, n \text{ even};\\ 0, & m,n \text{ odd},\end{cases}$$

$$[B_k^m, B_{\ell}^n] = \text{ the same as for } [A_n^m, A_{\ell}^n] \text{ with change } A \to B.$$

$$[B_k^m, A_{\ell}^n] = \begin{cases} q^{-mk}(q^{kn} - q^{-m\ell})A_{k+\ell}^{n-m}, & m,n \text{ even}, \\ -q^{-m(k+\ell)}A_{k+\ell}^{n-m} - q^{kn}A_{k+\ell}^{m+n}, & m \text{ even}, n \text{ odd}; \\ -q^{-m(k+\ell)}B_{k+\ell}^{n-m} + q^{m\ell}B_{k+\ell}^{n+m}, & m \text{ odd}, n \text{ even}; \\ -q^{-m(k+\ell)}B_{k+\ell}^{n-m} + q^{k(n-m)}A_{k+\ell}^{n-m} \\ \quad + q^{m\ell}B_{k+\ell}^{n+m} - q^{nk}A_{k+\ell}^{n+m}, & m,n \text{ odd}. \end{cases}$$

This Lie algebra is apparently new. It contains as a subalgebra the sin-algebra $\{\widetilde{A}_n^k\}$, where $\widetilde{A}_k^n = A_k^n$, $n>0$, n even; $A_k^n = q^{nk}B_k^{-n}$, $n<0$, n even; and the subalgebra isomorphic to B-series of Lie algebras of quantum torus (see Ref. 2) for n odd.

Example IV.3: Consider the group $\Gamma = \mathbb{Z}_2 \times \mathbb{Z}$ and admissible pair $(g\ell_\infty, \varphi)$, where homomorphism $\varphi: \Gamma \to \operatorname{Aut} g\ell_\infty$ is determined by two elements ϵ and T as in Example IV.2 (b). With respect to the Γ-action $g\ell_\infty$ is a free module with the generators $B^m = E_{0,m}$, $m \geqslant 0$. The corresponding conformal algebra $R(g\ell_\infty, \varphi)$ is defined by the Γ-products:

$$\begin{aligned} B_{(r)}^m B^n &= [T^r B^m, B^n] = \delta_{r,-m} T^{-m} B^{n+m} - \delta_{n,r} B^{m+r}, \\ B_{(\epsilon r)}^m B^n &= [\epsilon T^r B^m, B^n] = \begin{cases} -\delta_{r,0} T^m B^{n-m} + \delta_{r,n-m} B^{n-m}, & n-m \geqslant 0 \\ \delta_{r,0} \epsilon T^n B^{n-m} - \delta_{r,n-m} B^{m-n}, & n-m < 0. \end{cases} \end{aligned} \tag{4.7}$$

Fix the homomorphism $\chi: \Gamma \to \mathbb{C}^\times$ such that $\chi(\epsilon) = -1$, $\chi(1) = q \in \mathbb{C}^\times$. The Lie algebra $\mathfrak{s}(R(g\ell_\infty, \varphi), \chi)$ is a Lie algebra with the basis B_k^m, $m \in \mathbb{Z}_+$, $k \in \mathbb{Z}$, and commutation relations:

$$[B_k^m, B_{\ell}^n] = (q^{m\ell} - q^{nk}) B_{k+\ell}^{m+n} - \begin{cases} (-1)^k (q^{k(n-m)} - q^{-m(k+\ell)}) B^{n-m}, & n-m>0, \\ (-1)^k ((-q)^{-n(k+\ell)} \\ -(-1)^{-n(k+\ell)} (-q)^{m(k+\ell)} B_{k+\ell}^{m-n}), & n-m<0. \end{cases}$$

After the renormalization of the basis $\widetilde{B}_k^m = q^{mk/2} B_k^M$ we get exactly the commutation relations for B-series of sin Lie algebras, introduced in Ref. 2:

$$[\widetilde{B}_k^m, \widetilde{B}_{\ell}^n] = (q^{(m\ell - nk)/2} - q^{[-(m\ell - nk]/2)} \widetilde{B}_{k+\ell}^{n+m} - (-1)^k (q^{(kn+m\ell)/2} - q^{-(m\ell + kn)/2}) \widetilde{B}_{k+\ell}^{n-m}.$$

V. REPRESENTATIONS OF Γ-CONFORMAL ALGEBRAS AND THE GENERAL Γ-CONFORMAL ALGEBRA $gc(\pi, \Gamma)$

Definition V.1: *A (left) module over a Γ-conformal algebra R is a $\mathbb{C}[\Gamma]$-module M with a $\mathbb{C}$-linear map $a \mapsto a_\alpha^M$ of R to $End_{\mathbb{C}} M$ for each $\alpha \in \Gamma$ such that the following properties hold (here $a, b \in R$, $\alpha, \beta \in \Gamma$ and the action of Γ on M is denoted by $\alpha \mapsto T_\alpha^M$):*

(M0) $a_{(\alpha)}^M v = 0$ *for* $v \in M$ *and all but finitely many* α.
(M1) $(T_\alpha a)_{(\beta)}^M = a_{\beta\alpha}^M$, $a_{(\beta)}^M T_\alpha^M = T_\alpha^M a_{(\alpha^{-1}\beta)}^M$,
(M2) $[a_{(\alpha)}^M, b_{(\beta)}^M] = (a_{(\beta^{-1}\alpha)} b)_{(\beta)}^M$.

For example, $a \mapsto a_{(\alpha)}^R$ is the *adjoint representation* of R on itself.
It follows from (M1) that

$$(T_\alpha a)_{(\beta)}^M (T_\alpha^M v) = T_\alpha^M (a_{(\alpha^{-1}\beta\alpha)}^M v), \quad v \in M. \tag{5.1}$$

This leads us to:

Theorem V.1: *Let R be a Γ-conformal algebra and let $(\mathfrak{g}, \varphi)$ be the associated admissible pair. Then R-modules M are classified by equivariant $(\mathfrak{g}, \Gamma)$-modules such that for any $a \in \mathfrak{g}$ and $v \in M$ one has:*

$$(T^{\mathfrak{g}}_{\alpha}a)v=0 \qquad \text{for all but finitely many } \alpha\in\Gamma. \tag{5.2}$$

Proof: It follows from (M2) that $a\mapsto a_{(1)}$ is a representation of $\mathfrak{g}$. It satisfies (5.1) due to (M2), and it is equivariant, i.e. $(T^{\mathfrak{g}}_{\alpha}a)(T^{M}_{\alpha}v)=T^{M}_{\alpha}(av)$ due to (5.1). Conversely, given an equivariant $(\mathfrak{g},\Gamma)$-module M, it becomes an R-module by letting

$$a^{M}_{\alpha}=(T^{\mathfrak{g}}_{\alpha}a)^{M}_{(1)} \text{ on } M.$$

□

Consider a representation $\alpha\mapsto T_{\alpha}$ of the group Γ in a vector space V over $\mathbb{C}$. We define a Γ-*conformal endomorphism* of V as a collection $a=\{a_{(\beta)}\}_{\beta\in\Gamma}$ of $\mathbb{C}$-endomorphisms of V such that

$$a_{(\beta)}T_{\alpha}=T_{\alpha}a_{(\alpha^{-1}\beta)}, \quad \alpha,\beta\in\Gamma, \tag{5.3}$$

and for each $v\in V$

$$a_{(\alpha)}v=0 \quad \text{for all but finitely many } \alpha\in\Gamma. \tag{5.4}$$

We denote the set of all Γ-conformal endomorphisms of V by $gc(V,\Gamma)$.

Define a $\mathbb{C}[\Gamma]$-module structure on the space $gc(V,\Gamma)$ by

$$(T_{\alpha}a)_{(\beta)}=a_{(\beta\alpha)}, \alpha,\beta\in\Gamma, \tag{5.5}$$

and α-product for each $\alpha\in\Gamma$ by

$$(a_{(\alpha)}b)_{(\beta)}=[a_{(\beta\alpha)},b_{(\beta)}]. \tag{5.6}$$

It is immediate to check that axioms (C1), (C2) and (C3) of a Γ-conformal algebra hold (though axiom (C0) probably does not hold in general).

It is clear that we have by definitions:

Proposition V.1:To give a Γ-module V a structure of a module over a Γ-conformal algebra R is the same as to give a homomorphism $R\to gc(V,\Gamma)$ (i.e. a $\mathbb{C}[\Gamma]$-module homomorphism preserving all α-products).

We will show now that axiom (C0) holds, hence $gc(V,\Gamma)$ is a Γ-conformal algebra, provided that the $\mathbb{C}[\Gamma]$-module V is finitely generated. Toward this end we shall give a different construction of $gc(V,\Gamma)$ in the case when V is a free $\mathbb{C}[\Gamma]$-module of rank 1.

Let $gc_1(\Gamma)=\oplus_{r\in\Gamma}\mathbb{C}[\Gamma]a^r$ be a free $\mathbb{C}[\Gamma]$-module with free generators a^r labeled by elements of Γ. For each $\alpha\in\Gamma$ define the α-product by

$$a^{r}{}_{(\alpha)}a^{s}=\delta_{\alpha,r^{-1}}T_{r^{-1}}a^{rs}-\delta_{\alpha,s}a^{sr}, \tag{5.7}$$

extending to the whole R by axioms (C1) and (C1').

Theorem V.2: *(a) The $\mathbb{C}[\Gamma]$-module $gc_1(\Gamma)$ with products* (5.7) *is a Γ-conformal algebra.*

(b) Let $V=\mathbb{C}[\Gamma]v$ be a free $\mathbb{C}[\Gamma]$-module of rank 1. Define the action of $gc_1(\Gamma)$ on V by letting

$$(a^{s})^{V}_{(\alpha)}v=\delta_{\alpha,s^{-1}}T_{\alpha}v \tag{5.8}$$

and extending to V by (M1). This gives V a structure of a $gc_1(\Gamma)$-module.

(c) The $gc_1(\Gamma)$-module $V=\mathbb{C}[\Gamma]v$ contains all Γ-conformal endomorphisms of V. In particular, the Γ-conformal algebras $gc(V,\Gamma)$ and $gc_1(\Gamma)$ are isomorphic.

Proof: To prove (a) we need to check that the axioms (C0)–(C3) are satisfied. (C0) is obvious. (C1) and (C2) come from the definition (5.7) of $gc_1(\Gamma)$. Check the skew symmetry (C2):

$$(a^{r}_{(\alpha)}a^{s})_{(\beta)}=\delta_{\alpha,r^{-1}}(T_{r^{-1}}a^{rs})_{(\beta)}-\delta_{\alpha,s}a^{sr}_{(\beta)},$$

$$T_{\alpha}(a^{s}_{(\alpha^{-1})}a^{r})_{\beta}=\delta_{\alpha,s}T_{\alpha s^{-1}}a^{sr}-\delta_{\alpha,r^{-1}}T_{r^{-1}}a^{rs}=-(\delta_{\alpha,r^{-1}}T_{r^{-1}}a^{rs}-\delta_{\alpha,s}a^{sr}).$$

For (C3) we need to check that both sides of

$$a^m_{(\beta\alpha)}(a^r_{(\beta)}a^s)=(a^m_{(\alpha)}a^r)_{(\beta)}a^s+a^r_{(\beta)}(a^m_{(\beta\alpha)}a^s)$$

are equal.

$$\begin{aligned}\text{LHS:}\quad a^m_{(\beta\alpha)}(a^r_{(\beta)}a^s)&=a^m_{(\beta\alpha)}(\delta_{\beta,r^{-1}}T_{r^{-1}}a^{rs}-\delta_{\beta,s}a^{sr})\\&=\delta_{\beta,r^{-1}}T_{r^{-1}}a^m_{(\alpha)}a^{rs}-\delta_{\beta,s}a^m_{(\beta\alpha)}a^{sr}\\&=\delta_{\beta,r^{-1}}\delta_{\alpha,m^{-1}}T_{(mr)^{-1}}a^{mrs}-\delta_{\beta,r^{-1}}\delta_{\alpha,rs}T_{r^{-1}}a^{rsm}\\&\quad-\delta_{\beta,s}\delta_{\beta\alpha,m^{-1}}T_{m^{-1}}a^{msr}+\delta_{\beta,s}\delta_{\beta\alpha,sr}a^{srm},\end{aligned}$$

$$\begin{aligned}\text{RHS:}\quad (a^m_{(\alpha)}a^r)_{(\beta)}a^s+a^r_{(\beta)}(a^m_{(\beta\alpha)}a^s)&=\delta_{\alpha,m^{-1}}\delta_{\beta\alpha,(mr)^{-1}}T_{(mr)^{-1}}a^{mrs}-\delta_{\alpha_1m^{-1}}\delta_{\beta\alpha,s}a^{smr}\\&\quad-\delta_{\alpha,r}\delta_{\beta,(rm)^{-1}}a^{rms}+\delta_{\alpha,r}\delta_{\beta,s}a^{srm}\\&\quad+\delta_{\beta\alpha,m^{-1}}\delta_{\beta,r}T_{(rm)^{-1}}a^{rms}-\delta_{\beta\alpha,m^{-1}}\delta_{\alpha^{-1},ms}T_{m^{-1}}a^{msr}\\&\quad-\delta_{\beta\alpha,s}\delta_{\beta,r^{-1}}a^{rsm}+\delta_{\beta\alpha,s}\delta_{\beta,sm}a^{smr},\end{aligned}$$

and we have LHS=RHS.

To prove (b) we need to check only axiom (M2) on V:

$$(a^r_{(\alpha)}a^s)_{(\beta)}v=[a^r_{(\beta\alpha)},a^s_{(\beta)}]v.$$

$$\begin{aligned}\text{LHS:}\quad (a^r_{(\alpha)}a^s)_{(\beta)}v&=(\delta_{\alpha,r^{-1}}a^{rs}_{\beta\alpha}-\delta_{\alpha,s}a^{sr}_{(\beta)})v\\&=(\delta_{\alpha,r^{-1}}\delta_{\beta,s^{-1}}T_{(rs)^{-1}}-\delta_{\alpha,s}\delta_{\beta(s2)^{-1}}T_\beta)v,\end{aligned}$$

$$\begin{aligned}\text{RHS:}\quad [a^r_{(\beta\alpha)},a^s_{(\beta)}]v&=(\delta_{\beta,s^{-1}}T_{s^{-1}}a^r_{(\alpha)}-\delta_{\beta\alpha,r^{-1}}T_{r^{-1}}a^s_{(\alpha^{-1})})v\\&=(\delta_{\beta,s^{-1}}\delta_{\alpha,r^{-1}}T_{(rs)^{-1}}-\delta_{\beta\alpha,r^{-1}}\delta_{\alpha,s}T_{(sr)^{-1}})v\end{aligned}$$

so LHS=RHS. Finally, (c) is clear. □

Corollary V.1: If V is a finitely generated $\mathbb{C}[\Gamma]$-module, then $gc(V,\Gamma)$ is a conformal algebra.

Proof: We may assume that $V=\mathbb{C}[\Gamma]^{\oplus N}$ is a free $\mathbb{C}[\Gamma]$-module of rank N. Then $gc(V,\Gamma)$ may be viewed as a $\mathbb{C}[\Gamma]$-submodule of $gc_1(\Gamma^N)$ using the diagonal homomorphism $\mathbb{C}[\Gamma]\to\mathbb{C}[\Gamma]^{\oplus N}$. Corollary now follows from Theorem V.2a. □

If V is a free $\mathbb{C}[\Gamma]$-module of rank N, we use notation $gc_N(\Gamma)=gc(V,\Gamma)$.

Example V.1: Consider $\Gamma=\mathbb{Z}^N$. For the $gc_1(\mathbb{Z}^N)$ defined by (5.7) the corresponding Lie algebra $(\mathfrak{g},\varphi)$ is a Lie algebra with generators $a^\beta_\alpha=T_\alpha a^\beta$, $\alpha,\beta\in\mathbb{Z}^N$ and commutation relations:

$$[a^\delta_\alpha,a^\gamma_\beta]=\delta_{\alpha,\beta\delta^{-1}}a^{\delta\gamma}_{\beta\delta^{-1}}-\delta_{\alpha,\beta\gamma}a^{\gamma\delta}_\beta.$$

Fix $\bar{q}=(q_1,\dots,q_N)\in(\mathbb{C}^\times)^N$ and define the homomorphism $\chi_{\bar{q}}:\mathbb{Z}^N\to\mathbb{C}^\times$, such that $\chi_{\bar{q}}(\alpha)=\bar{q}^\alpha$, where $\alpha\in\mathbb{Z}^N$ and $\bar{q}^\alpha=q_1^{\alpha_1}\cdots q_N^{\alpha_N}$. The Lie algebra $\mathfrak{s}(R,\chi_{\bar{q}})$ of formal distributions is a Lie algebra with generators a^α_m, $\alpha\in\mathbb{Z}^N$, $m\in\mathbb{Z}$. Define the generating functions $a^\alpha(z)=\sum_{m\in\mathbb{Z}}a^\alpha_m z^{-m-1}$. From (4.4) we have:

$$[a^\alpha(z),a^\beta(w)]=\sum_{\gamma\in\mathbb{Z}^N}(a^\alpha_{(\gamma)}a^\beta)(w)\,\delta(z-\chi(\gamma)w),$$

and for modes:

$$[a_m^\alpha, a_n^\beta] = \sum_{\gamma \in \mathbb{Z}^N} \chi(\gamma)^m (a_{(\gamma)}^\alpha a^\beta)_{m+n}.$$

$$= \overline{q}^{-\alpha m} (T_{-\alpha} a^{\alpha+\beta})_{m+n} - \overline{q}^{\beta m} (a^{\alpha+\beta})_{m+n}$$

$$= (\overline{q}^{\alpha n} - \overline{q}^{\beta m}) a_{m+n}^{\alpha+\beta}.$$

This is a vector generalization of sin-algebra, considered in Ref. 2.

VI. NON-COMMUTATIVE GENERALIZATION OF Γ-LOCAL FORMAL DISTRIBUTIONS

In Sec. IV we associated to a Γ-conformal algebra R a Lie algebra $\mathfrak{s}(R,\chi)$ of $\chi(\Gamma)$-local formal distributions, by fixing a homomorphism $\chi:\Gamma \to \mathbb{C}^\times$. Conversely, each Lie algebra of $\chi(\Gamma)$-conformal formal distribution defines a right $\chi(\Gamma)$-conformal algebra. In this paragraph we will consider more general case, where $\chi(\Gamma)$ is a subgroup of the group of meromorphic transformations of $\mathbb{C}$. In all examples we will consider $\chi:\Gamma \to GL_2(\mathbb{C})$. For $\alpha \in \Gamma$ we will denote by $\alpha(z)$ the corresponding under the homomorphism χ transformation from $GL_2(\mathbb{C})$. Consider the generalization of the property (2.2) of the δ-function:

Proposition VI.1: Let $\alpha(z)$ and $\beta(z)$ be from $GL_2(\mathbb{C})$, then:

$$\begin{aligned} \alpha'(z)\,\delta(\alpha(z)-w) &= \delta(z-\alpha^{-1}(w)), \\ \beta'(w)\,\delta(z-\beta(w)) &= \delta(\beta^{-1}(z)-w). \end{aligned} \tag{6.1}$$

Proof: The group $GL_2(\mathbb{C})$ is generated by the transformations a) $z \mapsto dz$, $\alpha \in \mathbb{C}$; b) $z \to z-\alpha$, $\alpha \in \mathbb{C}$; c) $z \mapsto 1/z$. It is sufficient to prove (6.1) for (a), (b) and (c) transformations. For (a) this is (2.3). To prove (b), let

$$\delta(z-(w-\alpha)) = \sum_{k \in \mathbb{Z}} z^{-k-1}(w-\alpha)^k \tag{6.2a}$$

$$\delta((z+\alpha)-w) = \sum_{k \in \mathbb{Z}} (z+\alpha)^{-k-1} w^k. \tag{6.2b}$$

We define

$$(z+\alpha)^{-\ell-1} = \sum_{k=0}^{\infty} \frac{(k+\ell)!}{k!\ell!} z^{-\ell-k-1}(-\alpha)^k \tag{6.3}$$

for $\ell \geqslant 0$. Using (6.3) and comparing coefficients of $z^{-k-1}w^\ell$ in right-hand sides of (6.2a) and (6.2b) we get (b). So, the function

$$\delta(z-w+\alpha) = \sum_k z^{-k-1}(w-\alpha)^k = \sum_\ell (z+\alpha)^{-\ell-1} w^\ell \tag{6.4}$$

is well defined. The proof of (c) is similar. □

Further we will suppose for simplicity that $\Gamma \subset GL_2(\mathbb{C})$. For an N-element subset $S \subset \Gamma$ we shall use the notation

$$(z-w)_S^N = \prod_{\alpha \in S} (z-\alpha(w)).$$

Definition VI.1: Two formal distributions $a(z)$ and $b(z)$ *with coefficients in a Lie algebra $\mathfrak{g}$ are called S-local if in $\mathfrak{g}[[z,z^{-1},w,w^{-1}]]$ one has:*

$$(z-w)_S^N [a(z), b(w)] = 0.$$

Proposition VI.2: If $a(z)$ and $b(z)$ are S-local formal distributions, then there exists a unique decomposition

$$[a(z),b(w)]=\sum_{\alpha\in S}(a_{(\alpha^{-1})}b)(w)\,\delta(z-\alpha(w)). \tag{6.5}$$

The formal distributions $(a_{(\alpha^{-1})}b)(w)$ are given by the formula:

$$(a_{(\alpha^{-1})}b)(w)=\operatorname*{Res}_x\prod_{\substack{\beta\in S\\ \beta\neq\alpha}}\frac{z-\beta(w)}{\alpha(w)-\beta(w)}[a(z),b(w)]. \tag{6.5a}$$

Proof is the same as the proof of Proposition II.1.

For $\alpha\in\Gamma$ introduce the following operator:

$$T_{\alpha^{-1}}a(z)=\alpha'(z)a(\alpha(z)). \tag{6.6}$$

It is clear, that T_α, $\alpha\in\Gamma$, preserve Γ-locality.

For α-products $a(\alpha b)(w)$ defined as (6.5a) we have all the properties of left Γ-conformal algebras (see Definition IV.1). Conversely, if we have a Γ-conformal algebra R and a homomorphism $\chi:\Gamma\to GL_2(\mathbb{C})$, we can construct a Lie algebra $\mathfrak{s}(R,\chi)$ of $\chi(\Gamma)$ local formal distributions as follows. Consider a vector space over $\mathbb{C}$ with the basis a_n, $a\in R$, $n\in\mathbb{Z}$, and denote by $\mathfrak{s}(R,\chi)$ the quotient of this space by the $\mathbb{C}$-space of elements of the form:

$$\begin{aligned}&(\lambda a+\beta b)_n-\lambda a_n-\beta b_n,\quad \lambda,\beta\in\mathbb{C},\quad a,b\in R\\ &(T_\alpha^{-1}a)_n-(\alpha'(z)a(\alpha(z)))_n,\quad \text{where}\ \ \alpha\in\Gamma,\end{aligned} \tag{6.7}$$

and $(\alpha'(z)a(\alpha(z)))_n$ is the coefficient of z^{-n-1} in the Fourier series decomposition. Then the formula

$$[a(z),b(w)]=\sum_{\alpha\in\Gamma}(a_{(\alpha^{-1})}b)(w)\,\delta(z-\alpha(w)) \tag{6.8}$$

gives a Lie algebra structure on $\mathfrak{s}(R,\chi)$ of Γ-local formal distributions $a(z)=\Sigma_{n\in\mathbb{Z}}a_nz^{-n-1}$.

Remark VI.1: If we let $a(z)T_\alpha=\alpha'(z)a(\alpha(z))$, then we have all properties of right Γ-conformal algebras. We prefer (the more customary) left Γ-modules.

Consider some important examples.

Example VI.1: Lie algebra of pseudodifferential operators on the circle.

Let R be the general $\mathbb{Z}$-conformal algebra $gc_1(\mathbb{Z})$ defined by (5.7). Fix a homomorphism $\chi:\mathbb{Z}\to GL_2(\mathbb{C})$ defined as $\chi(n)=\left(\begin{smallmatrix}1 & n\\ 0 & 1\end{smallmatrix}\right)$, $n\in\mathbb{Z}$. The corresponding Lie algebra $\mathfrak{s}(\mathbb{Z},\chi)$ is a Lie algebra with basis a_k^m, $m,k\in\mathbb{Z}$. Let $a^m(z)=\Sigma_k a_k^mz^{-k-1}$ be the generating function. Then from (6.8) we have:

$$\begin{aligned}[a^m(z),a^n(w)]&=\sum_{s\in\mathbb{Z}}(a^m_{(s)}a^n)(w)\,\delta(z-w+s)\\ &=(T_{-m}a^{m+n})(w)\,\delta(z-w-m)-a^{m+n}(w)\,\delta(z-w+n).\end{aligned} \tag{6.9}$$

To write down explicitly the commutation relations for coefficients of formal distributions $a^m(z)$, consider the Lie algebra $\mathrm{pdiff}(S^1)$ of pseudodifferential operators on the circle (see Refs. 9–11 for more details). This is a Lie algebra of the associative algebra with the basis $x^m\partial^n$, $m,n\in\mathbb{Z}$. The commutation relations are defined from the commutation relations on x and ∂:

$$\partial\circ f(x)=f(x)\circ\partial+f'(x),$$

$$\partial^{-1}\circ f(x)=\sum_{n=0}^{\infty}(-1)^nf^{(n)}(x)\partial^{-n-1},$$

where $f(x)\in C^\infty(S^1)$. Introduce a new basis of pdiff(S^1) with generators x^mD^k, $m,k\in\mathbb{Z}$, where $D=x\partial$. These generators have simpler commutation relations:

$$[x^mD^k,x^nD^\prime]=x^{m+k}((D+n)^kD^\prime-(D+m)^\prime D^k). \tag{6.10}$$

For $k<0$ we will understand $(D+n)^k$ as an expansion by the negative powers of D (see (6.3)). Introduce the generating function:

$$a^m(z)=-\sum_{k\in\mathbb{Z}}x^{-m}D^kz^{-k-1}. \tag{6.11}$$

Using the property (6.4) of δ-function, we have

$$\begin{aligned}[a^m(z),a^n(w)]&=\sum_{k,l\in\mathbb{Z}}x^{-(m+n)}((D-n)^kD^\prime z^{-k-1}w^{-\prime-1}\\&\quad-(D-m)^\prime D^kz^{-k-1}w^{-\prime-1})\\&=x^{-(m+n)}\Bigg(\sum_{k,\prime\in\mathbb{Z}}D^kD^\prime(z+n)^{-k-1}w^{-\prime-k-1}w^k\\&\quad-D^\prime D^k(w+m)^{-\prime-k-1}(w+m)^kz^{-k-1}\Bigg)\\&=a^{m+n}(w+m)\,\delta(z-w-m)-a^{m+n}(w)\,\delta(z-w-n).\end{aligned} \tag{6.12}$$

Comparing (6.9) and (6.12), we see that the Lie algebra $\mathfrak{s}(\Gamma,\chi)$ is isomorphic to the Lie algebra pdiff(S^1).

Thus, we have shown, that the Lie algebra of $q-$pdiff(S^1) [see Example IV.2 (a)] and the Lie algebra of pdiff(S^1) correspond to the same general $\mathbb{Z}$-conformal algebra $gc_1(\mathbb{Z})$, but to the different homomorphisms $\mathbb{Z}\to GL_2(\mathbb{C})$.

More generally, we can consider the general conformal algebra $gc_1(GL_2(\mathbb{C}))$ with the usual action of $GL_2(\mathbb{C})$ on $\mathbb{C}$. Let $A,B,C\in GL_2(\mathbb{C})$. By (5.7) we have:

$$a^A_{(C)}a^B=\delta_{C,A^{-1}}T_{A^{-1}}a^{AB}-\delta_{C,B}a^{BA}.$$

It is clear, that the general conformal algebra admit reduction to the subalgebra. This reduction is well defined at the level of the Lie algebra $\mathfrak{s}(g_1(GL(\mathbb{C})))$:

$$[a^A(z),a^B(w)]=A(w)^\prime_wa^{AB}(A(w))\,\delta(z-A(w))-a^{BA}(w)\,\delta(z-B^{-1}(w)). \tag{6.13}$$

As was shown, for the subgroup $H_1=\{\left(\begin{smallmatrix}q^{-m/2}&0\\0&q^{m/2}\end{smallmatrix}\right),m\in\mathbb{Z}\}$ we get the Lie algebra of $q-$pdiff(S^1); for the subgroup $H_2=\{\left(\begin{smallmatrix}1&m\\0&1\end{smallmatrix}\right),\ m\in\mathbb{Z}\}$ we get the Lie algebra pdiff(S^1). For the subgroup $H_3\subset GL_2(\mathbb{C})$, generated by two elements $a=\left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)$ and $b=\left(\begin{smallmatrix}q^{-1/2}&\\&q^{-1/2}\end{smallmatrix}\right)$ we get the Lie algebra, that contains as subalgebra the Lie algebra of pdiff(S^1) and $q-$pdiff(S^1). Taking different subgroups H in $GL(2,\mathbb{C})$ (not necessarily discrete) we get a family of infinite-dimensional Lie algebras $\mathfrak{s}(gc_1(H))$.

Example VI.2: Consider the group Γ generated by two elements ϵ and T with relations: $\epsilon^2=1$ and $\epsilon T=T^{-1}\epsilon$. Fix two homomorphisms $\varphi_i:\Gamma\to\mathrm{Aut}(g_\infty)$, $i=1,2$.

$$\varphi_1:\begin{cases}\epsilon(E_{ij})=-E_{-j,-i}\\T(E_{ij})=E_{i+1,j+1}\end{cases}\quad\text{and}\quad\varphi_2:\begin{cases}\epsilon(E_{ij})=E_{-i,-j}\\T(E_{ij})=E_{i+1,j+1}\end{cases}.$$

In both cases g_∞ is a free $\mathbb{C}[\Gamma]$ module with the basis $A^m=E_{0,m}$, $m\in\mathbb{Z}_+$. The Γ-products on generators A^m are as follows:

(a) For φ_1 we have:

$$A^m_{(\gamma)}A^n=[T^rA^m,A^n]=\delta_{r,-m}T^{-m}A^{m+n}-\delta_{r,n}A^{m+n} \quad \text{for } \gamma=T^r,$$

$$A^m_{(\gamma)}A^n=[\epsilon T^rA^m,A^n]=-\delta_{r,0}T^{-m}A^{n+m}+\delta_{m+n,-r}A^{m+n} \quad \text{for } \gamma=\epsilon T^r.$$

(b) For φ_2 we have:

$$A^m_{(\gamma)}A^n=\delta_{r,-m}T^{-m}A^{m+n}-\delta_{r,n}A^{m+n} \quad \text{for } \gamma=T^r$$

$$A^m_{(\gamma)}A^n=-\delta_{r,-m}T^mB^{n-m}-\delta_{r,-n}B^{n-m} \quad \text{for } \gamma=\epsilon T^r \text{ and } n\geqslant m.$$

These give us two structures of a Γ-conformal algebra, which we will denote R_1 and R_2 respectively. Consider two homomorphisms $\chi_i:\Gamma\to GL_2(\mathbb{C})$, $i=1,2$:

$$\text{(a)}\chi_1(\epsilon)=\begin{pmatrix}0&1\\-1&0\end{pmatrix}, \quad \epsilon_1(z)=-\frac{1}{z};$$

$$\chi_1(T)=\begin{pmatrix}q^{1/2}&0\\0&q^{-1/2}\end{pmatrix}, \quad T_1(z)=qz,$$

$$\text{(b)}\chi_2(\epsilon)=\begin{pmatrix}1&0\\0&-1\end{pmatrix}, \quad \epsilon_2(z)=-z;$$

$$\chi_2(T)=\begin{pmatrix}1&1\\0&1\end{pmatrix}, \quad T(z)=z+1.$$

We can define four Lie algebras $\mathfrak{s}(R_i,\chi_j)$, $i,j=1,2$, of Γ-local formal distributions with generators A^m_n, $m\in\mathbb{Z}_+$, $n\in\mathbb{Z}$, and the generating function $A^m(z)=\Sigma_nA^m_nz^{-n-1}$.

(a) $S(R,\chi_1)$:

$$=q^mA^{m+n}(q^mw)\,\delta(z-q^mw)-A^{m+n}(w)\,\delta(z-q^{-n}w)$$

$$-q^mA^{m+n}(q^mw)\,\delta\left(z+\frac{1}{w}\right)+A^{m+n(w)}\,\delta\left(z+\frac{q^{m+n}}{w}\right).$$

For the coefficients A^m_k we have the commutation relations

$$[A^m_k,A^n_\ell]=(q^{-m\ell}-q^{-nk})A^{m+n}_{k+\ell}-(-1)^kq^{mk}(q^{-n\ell}-q^{nk})A^{m+n}_{\ell-k}.$$

This is the C-series of Lie algebras of quantum torus (Ref. 2).

(b) $\mathfrak{s}(R_2,\chi_1)$:

$$[A^m(z),A^n(z)]=A^{m+n}(q^mw)\,\delta(z-q^nw)-A^{m+n}(z-q^{-n}w)$$

$$-q^{-m}A^{n-m}(q^{-m}w)\,\delta\left(z+\frac{q^m}{w}\right)+A^{n-m}(w)\,\delta\left(z+\frac{q^n}{w}\right),$$

$$\text{for } m,n\in\mathbb{Z},n\geqslant m$$

and

$$[A^m_k,A^n_\ell]=(q^{-m\ell}-q^{-k\ell})A^{m+n}_{k+\ell}-(-1)^k(q^{m\ell}-q^{nk})A^{n-m}_{\ell-k}.$$

(c) $S(R_1,\chi_2)$:

$$[A^m(z),A^n(w)]=A^{m+n}(w+m)\,\delta(z-w-m)-A^{m+n}(w)\,\delta(z-w+n)$$

$$-A^{m+n}(w+m)\,\delta(z+w)+A^{m+n}(w)\,\delta(z+w-m-n). \tag{6.14}$$

Consider in pdiff(S^1) with the basis (6.11) a subalgebra, stable under the automorphism ω defined by: $\omega(x^m D^k)=x^m(m-D)^k$. This is a Lie algebra with the basis $x^m D^k-\omega(x^m D^k)$. Introduce the generating function of the form:

$$C^m(z)=-\sum_{k\in\mathbb{Z}}(x^{-m}D^k-x^{-m}(-m-D)^k)z^{-k-1}$$
$$=a^m(z)+a^m(m-z),$$

where $a^m(z)$ are given by (6.12). It is easy to check, that the fields $C^m(z)$ satisfy equation (6.15). We call this subalgebra a C-series of pdiff(S^1).

(d) $S(R_2,\chi_2)$: For generating functions we have:

$$[A^m(z),A^n(w)]=A^{m+n}(w+m)\,\delta(z-w-m)-A^{m+n}\delta(z-w+n)$$
$$+A^{n-m}(w-m)\,\delta(z+w-m)-A^{n-m}\delta(z+w+n), \tag{6.15}$$

for $m,n\in\mathbb{Z}_+$, and $n\geqslant m$. This subalgebra is called the B-series of pdiff(S^1). It can be defined as a subalgebra stable under the second-order automorphism σ defined by $\sigma(x^n D^n)=x^{-n}(-D)^n$. Relations (6.15) are exactly the relations on generating series $B^m(z)=\Sigma_{k\in\mathbb{Z}}(x^{-m}D^k+\sigma(x^{-m}D^k))z^{-k-1}=a^m(z)-a^{-m}(-z)$.

(Received 9 September 1997; accepted for publication 2 December 1997)

The product of two Heisenberg–Weil algebras contains the Jordan–Schwinger representation of $su(2)$. This algebra is quotiented by the square-root of the Casimir to produce a nonassociative algebra denoted by Ψ. This algebra may be viewed as the right-module over one of its associative subalgebras which corresponds to the algebra of scalar fields on the noncommutative sphere. It is now possible to interpret other subspaces as the space of spinor or vector fields on the noncommutative sphere. A natural basis of Ψ is given which may be interpreted as the deformed entries in the rotation matrices of $SU(2)$. © *1998 American Institute of Physics.* [S0022-2488(98)02803-5]

I. INTRODUCTION

The noncommutative or ''fuzzy'' sphere has been considered by several authors in different contexts, including the general quantization procedure, coherent states, noncommutative geometry, the theory of membranes, and the quantum Hall effect (see references in 1–4).

Normally the approximation for the algebra of functions on a sphere (scalar fields) is in terms of matrices,[2,5,6] where the functions on a sphere appear only in the limit as the size of the matrix tends to infinity. An alternative approach was presented in Ref. 1 as a two parameter algebra of polynomials $\mathscr{P}(\varepsilon,R)$ with $\varepsilon,R\in\mathbb{R}$.

The standard way of defining a vector field is to consider it as a derivation on the algebra of functions. If the latter is replaced by a matrix algebra then all such derivations are the adjoint action of elements in that algebra.[2,7] As such they do not form a module over the algebra of functions like standard vector fields do. If $\{x^1,x^2,x^3\}$ are the coordinate functions for the noncommutative sphere then the corresponding derivations $X_i=\mathrm{ad}_{x^i}=[x_i,\cdot]$ obey the equation $\Sigma_{i=1}^3 x^i X_i=0$ only in the commutative limit. Here we give an alternative definition for the analogue of vector fields which both forms a module over the algebra of functions and solves this equation. However, these vector fields are derivations only in the limit $\varepsilon=0$.

The idea of using the Jordan–Schwinger representation of $su(2)$ to describe spinor fields have been pursued by many authors.[3,4,8–10] They discovered that one could view spinor fields as rectangular matrices.

This article may be consider as an extension of Ref. 1 to spinor and vector fields by the use of the Jordan–Schwinger representation of $su(2)$.

A. Structure of the article

We present $\mathscr{W}$, an algebra which is the product of two Heisenberg–Weil algebra, generated by $[a_-,a_+]=\varepsilon$ and $[b_-,b_+]=\varepsilon$. This naturally contains the Jordan-Schwinger representation of both $su(2)$ given by $\{J_0,J_+,J_-\}$ and $su(1,1)$ given by $\{K_0,K_+,K_-\}$ defined in (3).

The idea is to consider the algebra generated by $\{J_0,J_+,J_-\}$ to be equivalent to the analogue of the algebra of functions (or scalar fields) on the sphere as presented in Ref. 1. In this paper the algebra generated by $\{J_0,J_+,J_-\}$, which is the universal covering algebra of $su(2)$, is quotiented by the ideal generated by the Casimir $J_0^2+\frac{1}{2}J_+J_-+\frac{1}{2}J_-J_+\sim R^2$ where $R^2\in\mathbb{R}$. Since the Casimir

 © 1998 American Institute of Physics

operator commutes with the set $\{J_0, J_+, J_-\}$ this ideal is two sided and the corresponding quotient is an algebra.

In this paper, by contrast, the Casimir operator is given by $J_0^2+\frac{1}{2}J_+J_-+\frac{1}{2}J_-J_+=K_0^2-\frac{1}{4}\varepsilon^2$. We would like to take the square root of this equation and consider quotienting $\mathscr{W}$ by the ideal generated by $K_0\sim\hat{R}=(R^2+\frac{1}{4}\varepsilon^2)^{1/2}$. However, although K_0 commutes with any polynomial in $\{J_0, J_+, J_-\}$, it does not commute with all the elements in $\mathscr{W}$. Therefore the left ideal generated by $K_0\sim\hat{R}$ is not two sided and the corresponding quotient product is not associative. However our persistence is rewarded.

We define the subspace $\Psi\subset\mathscr{W}$ as all the totally symmetric polynomials in (a_+, a_-, b_+, b_-) which contain no factor of K_0. This is achieved by defining the *formal trace*. We can define two products on Ψ, ρ, and $\rho^\star$ by quotienting by either the left or right ideal generated by $K_0\sim\hat{R}$.

There is a natural basis of Ψ given by the set $\{\psi_n^{(r,m)}|2n, n+r, n+m \in\mathbb{Z}, n\geqslant 0, |r|\leqslant n|m|\leqslant n\}$. The basis element $\psi_n^{(r,m)}$ is the unique (up to scale factor) homogeneous polynomial of degree $2n$, which is an eigenstate of both ad_{K_0} and ad_{J_0} with corresponding eigenvalues εr and εm. These basis elements are also orthogonal with respect to a sesquilinear form defined in a similar way to the sesquilinear form in Ref. 1.

These basis elements may be thought of as entries in a deformed rotation matrix, since, in the limit $\varepsilon=0$, $\psi_n^{(r,m)}$ is proportional to $D^n_{mr}(\alpha,\beta,\gamma)$ where α,β,γ are the Euler angles. As a result we may interpret the algebra (Ψ,ρ) as the noncommutative and nonassociative analogue of functions on the group $SU(2)$.

We label the eigenspace $\Psi_\bullet^{(r,\bullet)}=\mathrm{span}\{\psi_n^{(r,m)}\forall n,m\}$. Since the eigenspace $\Psi_\bullet^{(0,\bullet)}$ corresponds to all elements of Ψ which commute with K_0, these elements can be written as polynomials in $\{J_0, J_+, J_-\}$ and thus correspond to the scalar fields on the noncommutative sphere. Now, as stated, the product ρ on Ψ is not associative, but we show that $\Psi_\bullet^{(r,\bullet)}$, for each r, can be viewed as a right module over $\Psi_\bullet^{(0,\bullet)}$. This is analogous to the fact that standard spinor and vector fields are modules over the space of scalar fields.

It is natural to call the set $\Psi_\bullet^{(1,\bullet)}$ the analogue of vectors fields, and to call $\Psi_\bullet^{(-1,\bullet)}$ the analogue of covector fields or 1-forms. Using this interpretation we may define an exterior ''derivative'' $d:\Psi_\bullet^{(0,\bullet)}\mapsto\Psi_\bullet^{(-1,\bullet)}$. This map obeys the Leibniz rule only in the limit $\varepsilon=0$. Likewise the interpretation of vectors as derivations on the algebra of function is also true only in this limit. By contrast the equation $x^iX_i=0$ is true for all ε not just in the limit. Thus its swings and roundabouts: one must use one's personal conviction, or a physical interpretation, to decide which properties of vector fields are fundamental.

The spaces $\Psi_\bullet^{(1/2,\bullet)}$ and $\Psi_\bullet^{(-1/2,\bullet)}$ are the analogues of spinor fields on the noncommutative sphere. They may be viewed as contra-variant and co-variant spinor fields, or positive and negative chiral spinor fields depending on one's interpretation. We justify the definition of a spinor field on two grounds. First the product of two spinor fields is a vector, and secondly, the rotation of a spinor though 2π inverses the sign of the spinor. Alternatively, writing the spinors as 2-dimensional vectors with entries in $\Psi_\bullet^{(-1/2,\bullet)}\oplus\Psi_\bullet^{(1/2,\bullet)}$, we obtain the standard definition of spinors in the limit $\varepsilon=0$.

B. Contents of the article

In most of this article we are concerned with the mathematical structure necessary to define Ψ and its products. In section II, we examine the Heisenberg–Weil algebra $\mathscr{W}$. We define the formal trace and give some of its properties. In section III, we present the vector space Ψ and some of its subspaces. We define the nonassociative products ρ and $\rho^\star$ and show that when they are restricted to the space of scalar fields they are associative. We also define the sesquilinear Hermitian product that fails to be positive definite, (although it is positive definite in the case $\varepsilon=0$).

In section IV, we define the orthogonal basis for Ψ in a similar vain to that in Ref. 1. In section V, we give useful formulae for calculating the product ρ on Ψ. We show how to write the basis elements either as rectangular matrices or in terms of Hahn polynomials.

In section VI, we demonstrate how $\psi_n^{(r,m)}$ may be regarded as the deformed rotation matrix entry, and also how $\Psi_\bullet^{(1,\bullet)}$ can be viewed as the space of vector fields and $\Psi_\bullet^{(-1,\bullet)}$ the space of covector fields, and $\Psi_\bullet^{(1/2,\bullet)}$ as the space of spinor fields on the noncommutative sphere.

Finally, in section VII we discuss some of the problems with this interpretation. We also suggest how this methodology can be extended to scalar, spinor, and vector fields on more exotic symmetric spaces such as the Einstein–deSitter universe.

C. Notations

The summation convention is not used in this article.

The notational difference with Ref. 1 is that (1) the basis elements are not normalized; (2) we use ε instead of κ; and (3) since the product is not associative, it is written explicitly whenever used.

$\hat{R}$ is always given in relation to R by (23). In most cases we do not write the dependence on R and ε explicitly unless there is room for confusion. The implicit dependencies on $\hat{R}$ and ε are given by

	$\hat{R}$	ε
$\mathscr{W}$ as a vector space	No	No
$\mathscr{W}$ as an algebra	No	Yes
$S(s,t,u,v)$	No	No
Ψ, $\Psi_n^{(\bullet,\bullet)}$, $\Psi_\bullet^{(r,\bullet)}$, $\Psi_\bullet^{(\bullet,m)}$ as vector spaces	No	No
$\rho:\mathscr{W}\mapsto\Psi$ as a projection	Yes	No
$\rho:\Psi\times\Psi$ as a product	Yes	Yes
$\psi_n^{(r,m)}$	No	No

We shall use the following notation for elements of each set:

Space	Description	General elements	Basis
$\mathscr{W}$	Polynomials in (a_+,a_-,b_+,b_-)	$w,w_1,w_2,\ldots$	$S(s,t,u,v)$
Ψ	Formally traceless symmetric polynomials	$\xi,\zeta,\ldots$	$\psi_n^{(r,m)}$
$\Psi_\bullet^{(0,\bullet)}$	Analogue of functions	$f,g,\ldots$	$\psi_n^{(0,m)}$
$\Psi_\bullet^{(1,\bullet)}$	Analogue of vectors fields	$X,Y,\ldots$	$\psi_n^{(1,m)}$
$\Psi_\bullet^{(-1,\bullet)}$	Analogue of 1-forms	$\xi,\zeta,\ldots$	$\psi_n^{(-1,m)}$
$\Psi_\bullet^{(1/2,\bullet)}$	Analogue of spinors	$\xi,\zeta,\ldots$	$\psi_n^{(1/2,m)}$

II. $\mathscr{W}$-EXPRESSIONS: THE FREE ALGEBRA OF THE PRODUCT OF TWO HEISENBERG–WEIL ALGEBRAS

As stated in the Introduction in this section we define the algebra $\mathscr{W}=\mathscr{W}(\varepsilon)$ which is the product of two Heisenberg–Weil algebras. This naturally contains the Jordan Schwinger representation of $su(2)$ and $su(1,1)$. We define a basis for this algebra in terms totally symmetric polynomials. Since we wish to quotient out by $K_0=\hat{R}$ we need to find representative of the $\mathscr{W}$ which contain no factor of K_0. This is achieved by defining the *formal trace*. We give some basic properties of the formal trace including that it commutes with the adjoint representation of $su(2)$. Finally we show a convenient way of writing the elements of $\mathscr{W}$ as nonsymmetric polynomials.

For $\varepsilon\in\mathbb{R}$ let

$$\mathscr{W}(\varepsilon)=\Big\{\text{free algebra of finite polynomials in}(a_+,a_-,b_+,b_-)\Big\}/\sim, \tag{1}$$

where

$$[a_-,a_+]\sim\varepsilon,\quad [b_-,b_+]\sim\varepsilon,\quad [a_\pm,b_\pm]\sim 0. \tag{2}$$

This may be viewed as the tensor product of two copies of the Heisenberg–Weil algebra $\mathscr{W}(\varepsilon)=\mathscr{W}_A(\varepsilon)\otimes\mathscr{W}_B(\varepsilon)$ where $\mathscr{W}_A(\varepsilon)$ is the algebra of polynomials of (a_+,a_-), and likewise for $\mathscr{W}_B(\varepsilon)$.

From now on we write $\mathscr{W}=\mathscr{W}(\varepsilon)$ when there is no doubt about ε. A natural basis for $\mathscr{W}$ is given by $S(s,t,u,v)$ which is the totally symmetric homogeneous polynomial with each term a permutation of $a_-^s a_+^t b_-^u b_+^v$ and having coefficient 1.

Let $\mathscr{W}^n$ for $2n\in\mathbb{Z}$, $n\geqslant 0$ be the space of all symmetric homogeneous polynomials of degree $2n$. The basis for $\mathscr{W}^n$ is now given by $\{S(s,t,u,v)|s+t+u+v=2n\}$. It is easy to show the dimension of $\mathscr{W}^n$ is given by $\dim(\mathscr{W}^n)=\frac{1}{6}(2n+1)(2n+2)(2n+3)$.

The subspace $\mathscr{W}^1$ has dimension 10. Out of these 6 elements turn out to be very important and are given special names (written in a nonsymmetric but more convenient form):

$$\begin{gathered} J_0=\tfrac{1}{2}(a_+a_--b_+b_-),\quad J_+=a_+b_-,\quad J_-=a_-b_+,\\ K_0=\tfrac{1}{2}(a_+a_-+b_+b_-+\varepsilon),\quad K_+=a_+b_+,\quad K_-=a_-b_-. \end{gathered} \tag{3}$$

It is easy to show that $\{J_0,J_+,J_-\}$ forms a representation of $su(2)$ with $[J_0,J_+]=\varepsilon J_+$, etc., and that $\{K_0,K_+,K_-\}$ form a representation of $su(1,1)$ with $[K_0,K_+]=\varepsilon K_+$. The Casimirs of these are given by

$$J_0^2+\tfrac{1}{2}J_+J_-+\tfrac{1}{2}J_-J_+=K_0^2-\tfrac{1}{4}\varepsilon^2, \tag{4}$$

$$K_0^2-\tfrac{1}{2}K_+K_--\tfrac{1}{2}K_-K_+=J_0^2-\tfrac{1}{4}\varepsilon^2. \tag{5}$$

Furthermore K_0 commutes with $\{J_0,J_+,J_-\}$ and J_0 commutes with $\{K_0,K_+,K_-\}$. The entire set $\mathscr{W}^1$ forms a representation of $so(3,2)$.[11]

There is a *conjugation* of elements in $\mathscr{W}$ given by

$$\dagger:\mathscr{W}\mapsto\mathscr{W},$$

$$(w_1w_2)^\dagger=w_2^\dagger w_1^\dagger,(a_\pm)^\dagger=a_\mp,(b_\pm)^\dagger=b_\mp,\lambda^\dagger=\overline{\lambda},\forall w_1,w_2\in\mathscr{W},\lambda\in\mathbb{C}. \tag{6}$$

On the basis elements it is easy to show that

$$S(s,t,u,v)^\dagger=S(t,s,v,u). \tag{7}$$

We define the *formal trace* of an element $w\in\mathscr{W}$ as follows:

$$\mathrm{tr}:\mathscr{W}\mapsto\mathscr{W},:\mathscr{W}^n\mapsto\mathscr{W}^{n-1} \tag{8}$$

with w as a totally symmetric polynomial. There are sixteen possible combinations for the last two elements of each term. Collecting these terms together, we can now write

$$w=w_1a_+a_-+w_2a_-a_++w_3b_+b_-+w_4b_-b_++w_5a_+^2+\cdots+w_{16}b_-^2.$$

Then

$$\mathrm{tr}(w)=w_1+w_2+w_3+w_4. \tag{9}$$

The *adjoint* is given by $\mathrm{ad}_T(w)=[T,w]$ for $T,w\in\mathscr{W}$. This vanishes if $\varepsilon=0$. However the limit $\lim_{\varepsilon\to0}(1/\varepsilon)\mathrm{ad}_T(w)$ is defined. If T is in the set $\{J_0,J_+,J_-,K_0\}$ then we can write $T=\Sigma_{\mu,\nu=0}^2\chi_+^\mu T^{\mu\nu}\chi_-^\nu$. Where $\chi_\pm^1=a_\pm$ and $\chi_\pm^2=b_\pm$. In this case, which covers most situations, we have

$$\lim_{\varepsilon\to0}(1/\varepsilon)\mathrm{ad}_T(w)=\sum_{\mu,\nu=0}^2\left(\chi_+^\mu T^{\mu\nu}\frac{\partial w}{\chi_-^\nu}-\frac{\partial w}{\chi_+^\mu}T^{\mu\nu}\chi_-^\nu\right). \tag{10}$$

Lemma 1: The formal trace of a basis element is given by

$$\mathrm{tr}(S(s,t,u,v))=2S(s-1,t-1,u,v)+2S(s,t,u-1,v-1). \tag{11}$$

This commutes with the adjoint action of J_0,J_+,J_- and K_0,

$$\mathrm{tr}\circ\mathrm{ad}_{J_0}=\mathrm{ad}_{J_0}\circ\mathrm{tr},\quad \mathrm{tr}\circ\mathrm{ad}_{J_+}=\mathrm{ad}_{J_+}\circ\mathrm{tr},\quad \mathrm{tr}\circ\mathrm{ad}_{J_-}=\mathrm{ad}_{J_-}\circ\mathrm{tr},\quad \mathrm{tr}\circ\mathrm{ad}_{K_0}=\mathrm{ad}_{K_0}\circ\mathrm{tr}, \tag{12}$$

but not with K_+, K_-. *It also commutes with taking the conjugate* $\mathrm{tr}(w^\dagger)=(\mathrm{tr}(w))^\dagger$.

Proof: By reasoning similar to the appendix in Ref. 1, we can split the basis element for any $d\in\mathbb{Z}^+$,

$$S(u_1,u_2,u_3,u_4)=\sum_{v_1+v_2+v_3+v_4=d} S(u_1-v_1,u_2-v_2,u_3-v_3,u_4-v_4)S(v_1,v_2,v_3,v_4).$$

Setting $d=2$ then

$$\mathrm{tr}(S(s,t,u,v))=\widetilde{\mathrm{tr}}(S(s-1,t-1,u,v)S(1,1,0,0))+\widetilde{\mathrm{tr}}(S(s,t,u-1,v-1)S(0,0,1,1)),$$

since all other terms vanish, hence (11).

For (12) we need to set up a basis for each $\mathscr{W}_A$ and $\mathscr{W}_B$ given by $S_A(s,t)$ the totally symmetric homogeneous polynomial with each term a permutation of $a_-^s a_+^t$ and having coefficient 1. Likewise for $S_B(u,v)$. These are related to $S(s,t,u,v)$ by

$$(s+t)!(u+v)!S(s,t,u,v)=(s+t+u+v)!S_A(s,t)S_B(u,v).$$

The commutator and anti-commutator of $S_A(s,t)$ with $a_\pm$ is given by

$$[a_+,S_A(s,t)]=-\varepsilon(s+t)S_A(s,t-1),\ \ [a_-,S_A(s,t)]=\varepsilon(s+t)S_A(s-1,t),$$

$$[a_+,S_A(s,t)]_+=2s(s+t+1)^{-1}S_A(s,t-1),\ \ [a_-,S_A(s,t)]_+=2t(s+t+1)^{-1}S_A(s-1,t),$$

where $[w_1,w_2]_+=w_1w_2+w_2w_1$ is the anti-commutator. The expressions for the commutators may be proved by induction on the degree $(s+t)$. The expressions for the anti-commutators by use of the formula

$$[a_+a_-,S_A(s,t)]=\varepsilon(s+t)S_A(s,t).$$

Now Eqs. (12) follow from direct calculation.

Lemma 2: If $w\in\mathscr{W}$ *then it may be written as a sum of elements,*

$$w=\sum_{r,m} w_{rm},\quad \text{where,}\quad \mathrm{ad}_{K_0}w=\varepsilon rw,\quad \mathrm{ad}_{J_0}w=\varepsilon mw. \tag{13}$$

We can write w_{rm} *as a nonsymmetric polynomial,*

$$w_{rm}=a_\pm^{r+m}b_\pm^{r-m}p_{rm}(J_0,K_0), \tag{14}$$

where

$$a_\pm^r=\begin{cases} a_+^r, & \text{if } r>0,\\ 1, & \text{if } r=0,\\ a_-^{-r}, & \text{if } r<0,\end{cases} \tag{15}$$

and likewise for $b_\pm^r$ *and where* $p_{rm}(J_0,K_0)$ *is a polynomial in* J_0 *and* K_0.

Proof: Since ad_{K_0} and ad_{J_0} commute we can diagonalize w with respect to these operators.

Since the $a_\pm$ commute with the $b_\pm$ collect all the $a_\pm$'s together. Use $a_-a_+=J_0+K_0+\varepsilon/2$ to remove a_-a_+ and $a_+a_-=J_0+K_0-\varepsilon/2$ to remove a_+a_-. By using $[J_0,a_+]=(\varepsilon/2)a_+$, etc., we can move all J_0 and K_0 to the right. From (13) we know that for each term in w the number of a_+ minus the number of a_- is $m+r$. Thus what remains on the left is $a_\pm^{m+r}$. Similarly with $b_\pm$, hence result. □

III. (Ψ,ρ): A NONASSOCIATIVE AND NONCOMMUTATIVE ALGEBRA OF FORMALLY TRACELESS SYMMETRIC POLYNOMIALS IN $\mathscr{W}$

In this section we introduce the subspace Ψ of $\mathscr{W}$ of all formally traceless symmetric polynomials. We introduce two products ρ and $\rho^\star$ on Ψ neither of which are associative, and show they are well defined. In lemma 4 we show that Ψ contains a subspace $\Psi_\bullet^{(0,\bullet)}$ which is an associative algebra, analogous to the algebra of functions on a sphere, and that the spaces $\Psi_\bullet^{(r,\bullet)}$ may be viewed as modules over $\Psi_\bullet^{(0,\bullet)}$. We also show the order to which Ψ is associative.

Let $\Psi\subset\mathscr{W}$ be the subspace of all traceless symmetric polynomials in (a_+,a_-,b_+,b_-):

$$\Psi=\ker(\mathrm{tr})\subset\mathscr{W}. \tag{16}$$

We define the subspace

$$\Psi_n^{(\bullet,\bullet)}=\ker(\mathrm{tr})\cap\mathscr{W}^n,\ \text{for } 2n\in\mathbb{Z} \text{ and } n\geqslant 0, \tag{17}$$

i.e., the space of all formally traceless symmetric homogeneous polynomials of order n. Since $\Psi_n^{(\bullet,\bullet)}$ is the kernel of the restriction $\mathrm{tr}:\mathscr{W}^n\mapsto\mathscr{W}^{n-1}$, which is surjective, the dimension of $\Psi_n^{(\bullet,\bullet)}$ is $\dim(\Psi_n^{(\bullet,\bullet)})=(2n+1)^2$. We define the projection π_n,

$$\pi_n:\Psi\mapsto\bigoplus_{m=0}^{2n}\Psi_{m/2}^{(\bullet,\bullet)}. \tag{18}$$

We may divide the space Ψ in three different ways, since for each $\xi\in\Psi$ both $\mathrm{ad}_{J_0}(\xi),\mathrm{ad}_{K_0}(\xi)\in\Psi$:

$$\Psi_\bullet^{(\bullet,m)}=\{\xi\in\Psi\,|\,\mathrm{ad}_{J_0}\xi=\varepsilon m\xi\}, \tag{19}$$

$$\Psi_\bullet^{(r,\bullet)}=\{\xi\in\Psi\,|\,\mathrm{ad}_{K_0}\xi=\varepsilon r\xi\}. \tag{20}$$

We will show in the next section that if $2n,n+m,n+r\in\mathbb{Z}$ and $n\geqslant 0,|m|\leqslant n,|r|\leqslant n$ then $\dim(\Psi_n^{(\bullet,\bullet)}\cap\Psi_\bullet^{(r,\bullet)}\cap\Psi_\bullet^{(\bullet,m)})=1$, otherwise it has dimension 0.

So far we have considered Ψ simply as a vector space. On this vector space we define two products. These products are given by the projections ρ_R and $\rho_R^\star$.

The intention is that $R\geqslant 0$ represents the radius of the sphere or the Casimir. From (4) we want $R^2=K_0^2-\frac{1}{4}\varepsilon^2$. We take the positive square root of this equation by $K_0=\hat{R}=(R^2+\frac{1}{4}\varepsilon^2)^{1/2}$. Since K_0 is not in the center of the algebra we must be careful about quotienting by this equation. We therefore consider two projections:

$$\begin{aligned}&\rho_R:\mathscr{W}\mapsto\Psi,(\rho_R)^2=\rho_R,\\ &\rho_R^\star:\mathscr{W}\mapsto\Psi,(\rho_R^\star)^2=\rho_R^\star,\end{aligned} \tag{21}$$

defined by their kernels,

$$\begin{aligned}&\ker(\rho_R)=\{w(K_0-\hat{R})\,|\,w\in\mathscr{W}\},\\ &\ker(\rho_R^\star)=\{(K_0-\hat{R})w\,|\,w\in\mathscr{W}\},\end{aligned} \tag{22}$$

where

$$\hat{R}=\left(R^2+\tfrac{1}{4}\varepsilon^2\right)^{1/2},\quad R,\hat{R}\in\mathbb{R},\quad R\geqslant 0,\quad \hat{R}>0. \tag{23}$$

From now on we shall write ρ and $\rho^\star$ when there is only one possible R. $\hat{R}$ will always be given by (23). Note that $\hat{R}\to R$ as $\varepsilon\to 0$. These projections are surjective (onto Ψ) due to Lemma 3.

Lemma 3:

$$\mathscr{W}^{\cdot}=\Psi\oplus\ker(\rho)=\Psi\oplus\ker(\rho^{\star}). \tag{24}$$

Proof: Let $w\in\mathscr{W}^n$, $n\neq 0$; then wK_0 has a component in $\mathscr{W}^{n+1}$. Furthermore this component has nonzero trace, so $\mathrm{tr}(wK_0)$ has a component in $\mathscr{W}^n$. Now $\mathrm{tr}(w\hat{R})$ cannot have a component in $\mathscr{W}^n$ so $\mathrm{tr}(w(K_0-\hat{R}))\neq 0$ and

$$\Psi\cap\ker(\rho)=\{0\}. \tag{25}$$

We show $\mathscr{W}^{\cdot}=\Psi\oplus\ker(\rho_R)$ by dimensional argument. For this proof only let

$$\hat{\mathscr{W}}^n=\bigoplus_{m=0}^{2n}\mathscr{W}^{m/2},\quad \hat{\Psi}^n=\bigoplus_{m=0}^{2n}\Psi^{(\bullet,\bullet)}_{m/2},$$

while we also let

$$\hat{V}^n=\ker(\rho_R)\cap\hat{\mathscr{W}}^n=\{w(K_0-\hat{R})\,|\,w\in\hat{\mathscr{W}}^{n-1}\}.$$

So

$$\dim(\hat{V}^n)=\dim(\hat{\mathscr{W}}^{n-1})=\sum_{m=0}^{2n-2}\dim(\mathscr{W}^m).$$

Also,

$$\dim(\hat{\Psi}^n)=\sum_{m=0}^{2n}\dim\Psi^{(\bullet,\bullet)}_{m/2}=\sum_{m=0}^{2n}(\dim\mathscr{W}^{m/2}-\dim\mathscr{W}^{m/2-1}).$$

Thus

$$\dim(\hat{\Psi}^n)+\dim(\hat{V}^n)=\dim(\hat{\mathscr{W}}^n).$$

By intersecting (25) by $\hat{\mathscr{W}}^n$ we have $\hat{\Psi}^n\cap\hat{V}^n=\{0\}$. Combining these last two equations gives $\hat{\Psi}^n\oplus\hat{V}^n=\hat{\mathscr{W}}^n$. □

For a given ε,R we define the products, also called ρ and $\rho^{\star}$, by

$$\Psi\times\Psi\mapsto\Psi,\quad \xi,\zeta\mapsto\rho(\xi\zeta),\quad \xi,\zeta\mapsto\rho^{\star}(\xi\zeta). \tag{26}$$

Since $\ker(\rho)$ is not a two sided ideal, the product in Ψ is not associative and thus (Ψ,ρ) is not an algebra. For example $\rho(\rho(a_+a_-)a_-)=\rho(J_0a_-+(\hat{R}-\varepsilon/2)a_-)$ while $\rho(a_+\rho(a_-a_-))=\rho(a_+a_-a_-)=\rho(J_0a_-+(\hat{R}-\varepsilon)a_-)$.

However the restriction $(\Psi^{(0,\bullet)}_{\cdot},\rho)$ is an associative algebra. This algebra is identified with the analogue of the algebra of functions given in Ref. 1. Both Ψ and $\Psi^{(r,\bullet)}_{\cdot}$, for all r, are modules overs $\Psi^{(0,\bullet)}_{\cdot}$ in the same way the space of spinors and vector fields are modules over the space of functions. For reasons that will become apparent we will call the elements of $\Psi^{(1,\bullet)}_{\cdot}$ vectors, the elements of $\Psi^{(-1,\bullet)}_{\cdot}$ forms, and the elements of $\Psi^{(1/2,\bullet)}_{\cdot}$ and $\Psi^{(-1/2,\bullet)}_{\cdot}$ spinors. We also define a sesquilinear product and quadratic map:

$$\langle\bullet,\bullet\rangle:\Psi\times\Psi\mapsto\mathbb{C},\quad \langle\xi,\zeta\rangle=\pi_0(\rho_R(\xi^{\dagger}\zeta)), \tag{27}$$

$$\|\bullet\|^2:\Psi\mapsto\mathbb{R},\quad \|\zeta\|^2=\langle\zeta,\zeta\rangle. \tag{28}$$

As we will see this sesquilinear product is Hermitian but not positive definite, and that $\|\zeta\|^2$ may be positive negative or zero.

Lemma 4: For a given ε and R, the product ρ when restricted to the space $\Psi^{(0,\bullet)}_{\cdot}$ is closed and associative making $(\Psi^{(0,\bullet)}_{\cdot},\rho)$ an algebra. It is also equal to the product $\rho^{\star}$ on $\Psi^{(0,\bullet)}_{\cdot}$.

Both these algebras are equivalent to algebra $\mathscr{P}(\varepsilon,R)$ given by

$$\mathscr{P}(\varepsilon,R)=\{\text{ Free noncommuting algebra of polynomials in } (J_+,J_-,J_0)\}/\sim, \tag{29}$$

where $\sim$ *are the relations*

$$[J_0,J_+]\sim\varepsilon J_+,\ \ [J_0,J_-]\sim-\varepsilon J_-,\ \ [J_+,J_-]\sim 2\varepsilon J_0,\ \ J_0^2+\tfrac{1}{2}J_+J_-+\tfrac{1}{2}J_-J_+=R^2. \tag{30}$$

This algebra is described in detail in Ref. 1.

For general $w_1,w_2\in\Psi$ *we have* $\rho(w_1\rho(w_2))=\rho(w_1w_2)$ *whilst* $\rho(\rho(w_1)w_2)-\rho(w_1w_2)=O(\varepsilon)$. *In terms of the algebra* (Ψ,ρ) *this means that for* $\xi_1,\xi_2,\xi_3\in\Psi$,

$$\rho(\xi_1\rho(\xi_2\xi_3))=\rho(\xi_1\xi_2\xi_3),$$

$$\rho(\rho(\xi_1\xi_2)\xi_3)-\rho(\xi_1\xi_2\xi_3)=O(\varepsilon). \tag{31}$$

If $\xi\in\Psi_\bullet^{(r_1,\bullet)}$ *and* $\zeta\in\Psi_\bullet^{(r_2,\bullet)}$ *then* $\xi^\dagger\in\Psi_\bullet^{(-r_1,\bullet)}$ *and* $\rho(\xi\zeta)\in\Psi_\bullet^{(r_2+r_1,\bullet)}$.

Both Ψ *and* $\Psi_\bullet^{(r,\bullet)}$, *for all* r, *are right modules overs* $\Psi_\bullet^{(0,\bullet)}$, *since given* $\xi\in\Psi$ *and* $f,g\in\Psi_\bullet^{(0,\bullet)}$; *then*

$$\rho(\rho(\xi f)g)=\rho(\xi\rho(fg))=\rho(\xi fg). \tag{32}$$

The sesquilinear product $\langle\bullet,\bullet\rangle$ *is Hermitian:*

$$\langle\xi,\zeta\rangle=\overline{\langle\zeta,\xi\rangle},\ \ \forall\xi,\zeta\in\Psi. \tag{33}$$

Proof: If $f,g\in\Psi_\bullet^{(0,\bullet)}$ then it is clear that $\mathrm{ad}_{K_0}(fg)=0$, so $\rho(fg)=\rho^\star(fg)$. From lemma 2 we can write $fg=a_\pm^m b_\pm^{-m}p(J_0,K_0)$, thus $\rho(fg)=\Sigma_m a_\pm^m b_\pm^{-m}p(J_0,\hat{R})$. But $a_\pm^m b_\pm^{-m}=J_+^m$ for $m>0$ and $a_\pm^m b_\pm^{-m}=J_-^{-m}$ for $m<0$ so $\rho(fg)$ is a polynomial in $\{J_0,J_+,J_-\}$ and all such polynomials are elements in $\mathscr{P}(\varepsilon,R)$. From (4) these two algebras are equivalent.

Given $w_1,w_2\in\mathscr{W}$ then from (24) we may write uniquely $w_1=\rho(w_1)+w_1'(K_0-\hat{R})$. Thus $\rho(w_2w_1)=\rho(w_2\rho(w_1)+w_2w_1'(K_0-\hat{R}))=\rho(w_2\rho(w_1))$. While $\rho(\rho(w_1)w_2)-\rho(w_1w_2)=\rho(w_1'(K_0-\hat{R})w_2)=\rho(w_1'\mathrm{ad}_{K_0}(w-2))=O(\varepsilon)$.

If $f,g\in\Psi_\bullet^{(0,\bullet)}$ and $\xi\in\Psi$ then we write $\xi f=\rho(\xi f)+\xi_1(K_0-\hat{R})$ so, $\rho(\xi fg)-\rho(\rho(\xi f)g)=\rho(\xi_1(K_0-\hat{R})g)=0$ since $[K_0,g]=0$.

Given $\xi\in\Psi_\bullet^{(r_1,\bullet)}$ and $\zeta\in\Psi_\bullet^{(r_2,\bullet)}$ then $\langle\xi,\zeta\rangle\neq0$ only if $r_1=r_2$. In this case, $\rho^\star(\xi^\dagger\zeta)=\rho(\xi^\dagger\zeta)$, thus $\overline{\pi_0(\rho(\zeta^\dagger\xi))}=(\pi_0(\rho(\zeta^\dagger\xi)))^\dagger=\pi_0(\rho^\star(\xi^\dagger\zeta))=\pi_0(\rho(\xi^\dagger\zeta))$. □

IV. $\psi_n^{(r,m)}$: ORTHOGONAL BASIS FOR Ψ

Theorem 5: *There is a natural basis of* Ψ *given by*

$$\{\psi_n^{(r,m)}|2n,r+n,m+n\in\mathbb{Z},|r|\leqslant n,|m|\leqslant n\}, \tag{34}$$

where

$$\psi_n^{(r,m)}=\varepsilon^{m-n}\left(\frac{(n+m)!}{(2n)!(n-m)!}\right)^{1/2}(\mathrm{ad}_{J_-})^{n-m}(a_+^{n+r}b_-^{n-r}). \tag{35}$$

This definition is extended to the case $\varepsilon=0$ *by the use of (10). When written as formally traceless symmetric homogeneous polynomials,* $\psi_n^{(r,m)}$ *is independent of* R *and* ε. *The basis elements are orthogonal with respect to the sesquilinear form* $\langle\bullet,\bullet\rangle$:

$$\langle\psi_{n_1}^{(r_1,m_1)},\psi_{n_2}^{(r_2,m_2)}\rangle=\delta_{n_1,n_2}\delta_{r_1,r_2}\delta_{m_1,m_2}\|\psi_{n_1}^{(r_1,m_1)}\|^2, \tag{36}$$

where $\|\psi_n^{(r,m)}\|^2$ *may be positive negative or zero and is independent of* m.

For each n, *the set* $\{\psi_n^{(r,m)}|\forall r,m\}$ *forms an orthogonal basis for the set* Ψ^n. *These elements are eigenstates of the operators* ad_{J_0}, ad_{K_0}, *and* Δ:

$$\mathrm{ad}_{J_0}\psi_n^{(r,m)} = \varepsilon m \psi_n^{(r,m)}, \tag{37}$$

$$\Delta \psi_n^{(r,m)} = \varepsilon^2 n(n+1)\psi_n^{(r,m)}, \tag{38}$$

$$\mathrm{ad}_{K_0}\psi_n^{(r,m)} = \varepsilon r \psi_n^{(r,m)}, \tag{39}$$

where $\Delta = \mathrm{ad}_{J_0}\mathrm{ad}_{J_0} + \frac{1}{2}\mathrm{ad}_{J_+}\mathrm{ad}_{J_-} + \frac{1}{2}\mathrm{ad}_{J_-}\mathrm{ad}_{J_+}$, *so*

$$\Psi_n^{(\bullet,\bullet)} \cap \Psi_\bullet^{(r,\bullet)} \cap \Psi_\bullet^{(\bullet,m)} = \mathrm{span}\{\psi_n^{(r,m)}\}. \tag{40}$$

The operators ad_{J_+} *and* ad_{J_-} *act as Ladder operators within* $\Psi_n^{(\bullet,\bullet)} \cap \Psi_\bullet^{(r,\bullet)}$:

$$\mathrm{ad}_{J_+}\psi_n^{(r,m)} = \varepsilon (n-m)^{1/2}(n+m+1)^{1/2}\psi_n^{(r,m+1)}, \tag{41}$$

$$\mathrm{ad}_{J_-}\psi_n^{(r,m)} = \varepsilon (n+m)^{1/2}(n-m+1)^{1/2}\psi_n^{(r,m-1)}. \tag{42}$$

Proof: It is clear that $\psi_n^{(r,n)}$ is a formally traceless symmetric homogeneous polynomial of degree $2n$, from lemma 1 so are $\psi_n^{(r,m)}$ for all m. Equations (37)–(42) may be proved in the same way as the equivalent theorem in Ref. 1 theorem 2. Likewise for (36), where it is necessary to first show that $\pi_0(\rho(\mathrm{ad}_{J_+}x)) = \pi_0(\mathrm{ad}_{J_+}(\rho(w))) = 0$ for all $w \in \mathscr{W}$. This also comes from lemma 1. □

A formula for the conjugate of the basis element $(\psi_n^{(r,m)})^\dagger$ is given in corollary 10. As stated in lemma 4, the subspace $\Psi_\bullet^{(0,\bullet)}$ is equivalent to the algebra $\mathscr{P}(\varepsilon, R)$ given in Ref. 1. By comparing the two definitions for the basis vectors, one sees that $\psi_n^{(0,m)} = P_n^m/\alpha_n$. As a point of notation, the basis vectors here are left unnormalized, by contrast to the notation used in the above article. This avoids having to continually divide by a normalization constant, which here would depend on both r and n.

V. USEFUL FORMULAE FOR THE PRODUCT ρ ON Ψ

In this section we give a number of formulae which are useful for various calculations and the physical interpretations. All these formulae are extensions of the corresponding formulae for the basis of scalars on the noncommutative sphere,[1] but with added care taken due to the nonassociative nature of Ψ.

We start with a Hilbert space representation of $\mathscr{W}$ (subsection V A). As well as being used to calculate the value of the norm of the basis elements (subsection V B), it is also useful since it can be programmed into a symbolic mathematics program such as Maple, and hence used to calculate explicit formulae. This is followed by expressions to write $\psi_n^{(r,m)}$ as rectangular matrices (subsection V C) and in terms of Hahn polynomials (subsection V D). Finally in subsection V E we extend Ref. 1, Lemma 9 to give a formula which is useful for the definition of the exterior derivative.

A. A Hilbert space representation of $\mathscr{W}$

Let $\mathscr{H}$ be a Hilbert space with a basis given by $|k,j\rangle$ where $2k, j+k \in \mathbb{Z}$ and $k \geqslant 0$, $|j| \leqslant k$. The dual basis is represented by $\langle k,j|$ where $\langle k_1,j_1||k_2,j_2\rangle = \delta_{k_1k_2}\delta_{j_1j_2}$.

The action of $\mathscr{W}$ on $\mathscr{H}$ is given by

$$a_+|k,j\rangle = \varepsilon^{1/2}(k+j+1)^{1/2}|k+\tfrac{1}{2},j+\tfrac{1}{2}\rangle, \quad b_+|k,j\rangle = \varepsilon^{1/2}(k-j+1)^{1/2}|k+\tfrac{1}{2},j-\tfrac{1}{2}\rangle,$$

$$a_-|k,j\rangle = \varepsilon^{1/2}(k+j)^{1/2}|k-\tfrac{1}{2},j-\tfrac{1}{2}\rangle, \quad b_-|k,j\rangle = \varepsilon^{1/2}(k-j)^{1/2}|k-\tfrac{1}{2},j+\tfrac{1}{2}\rangle. \tag{43}$$

The dual action is given by $(\langle k_1,j_1|w)|k_2,j_2\rangle = \langle k_1,j_1|(w|k_2,j_2\rangle)$. The effect of the six elements J's and K's are given by

$$J_0|k,j\rangle=\varepsilon j|k,j\rangle,\quad K_0|k,j\rangle=\varepsilon(k+\tfrac{1}{2})|k,j\rangle,$$

$$J_+|k,j\rangle=\varepsilon(k-j)^{1/2}(k+j+1)^{1/2}|k,j+1\rangle,\quad K_+|k,j\rangle=\varepsilon(k-j+1)^{1/2}(k+j+1)^{1/2}|k+1,j\rangle,$$

$$J_-|k,j\rangle=\varepsilon(k+j)^{1/2}(k-j+1)^{1/2}|k,j-1\rangle,\quad K_-|k,j\rangle=\varepsilon(k-j)^{1/2}(k+j)^{1/2}|k-1,j\rangle. \tag{44}$$

One sees that the the effect of J_+,J_-,J_0 are exactly the same as the elements in the algebra in Ref. 1.

Lemma 6: Given $w\in\mathscr{W}$ which is independent of R and ε,

$$w|k,j\rangle=0\ \ \forall|k,j\rangle\in\mathscr{H}\ \ \Leftrightarrow\ \ \rho_R(w)=0\ \ \forall R\ \ \Leftrightarrow\ \ w=0. \tag{45}$$

If $\mathrm{ad}_{K_0}w=\varepsilon rw$ *and* $\mathrm{ad}_{J_0}w=\varepsilon mw$ *then*

$$w|k,j\rangle\in\mathrm{span}\{|k+r,j+m\rangle\}. \tag{46}$$

If $R^2=\varepsilon^2k(k+1)$ *then*

$$\rho_R(w)|k,j\rangle=w|k,j\rangle, \tag{47}$$

$$\pi_0(\rho_R(w))=\frac{1}{2k+1}\sum_{j=-k}^{k}\langle k,j|w|k,j\rangle. \tag{48}$$

Proof: Given $w\in\mathscr{W}$ such that $\mathrm{ad}_{K_0}w=\varepsilon rx$ and $\mathrm{ad}_{J_0}w=\varepsilon mx$ we use lemma 2 to write w in form (13). From (43), (46) is obvious.

If $\rho_R(w)=0,\forall R$ then it is clear that $w|k,j\rangle=0,\forall j,k$. To prove the reverse, $w\in\mathscr{W}$ can be written as a sum of elements $w=\Sigma_{rm}w_{rm}$ with w_{rm} in the eigenspace of ad_{K_0} and ad_{J_0}. From (46) each w_{rm} satisfies $w_{rm}|k,j\rangle=0$.

Using lemma 2 write

$$w_{rm}=a_\pm^{r+m}b_\pm^{r-m}p(K_0,J_0).$$

Then

$$0=w_{rm}|k,j\rangle=p\left(\varepsilon\left(k+\frac{1}{2}\right),\varepsilon j\right)a_\pm^{r+m}b_\pm^{r-m}|j,k\rangle,\quad\forall j,k.$$

Writing $\hat{p}(k,j)=p(\varepsilon(k+\frac{1}{2}),\varepsilon j)$ then $\hat{p}(k,j)=0$ for all j,k such that $2j,2k\in\mathbb{Z}$, $k\geqslant\max(0,-r)$ and $\max(-k,-k-m)\leqslant j\leqslant\min(k,k-m)$. Now writing $\hat{p}(k,j)=\Sigma_s p_s(j)k^s$ then $p_s(j)=0$ for above range of j. Chosing k greater than the degree of $\hat{p}$ implies $p_s\equiv0$. Thus $\hat{p}\equiv0$; thus $w=0$.

Finally, if $w\in\Psi$ write $w=\Sigma_{rm}w_{rm}$ as before. From (46) it is clear that the right hand side of (48) vanishes for all but the w_{00} term. Now w_{00} may be written as a polynomial in J_0. We can use the result of Ref. 1, Theorem 3. □

We note that the Hilbert space representation of $\psi_n^{(r,m)}$ is related to the Wigner operator,

$$\left\langle\begin{array}{ccc} & n+r & \\ 2n & & 0 \\ & n+m & \end{array}\right\rangle.$$

One can use this to find an expression for the product of two basis elements in terms of the Wigner $6j$ symbols (Ref. 12, Eqs. (3.341), (3.350), and Refs. 13,14.)

B. The value of $\|\psi_n^{(r,m)}\|^2$

Theorem 7: *The value of* $\|\psi_n^{(r,m)}\|^2$ *is given by*

$$\|\psi_n^{(r,m)}\|^2=\pi_0(a_-^{n+r}a_+^{n+r}b_+^{n-r}b_-^{n-r})=\frac{(n+r)!(n-r)!}{(2n+1)!}\prod_{s=1}^{n-r}(2\hat{R}-\varepsilon s)\prod_{s=1}^{n+r}(2\hat{R}+\varepsilon s). \quad (49)$$

The sign of this now depends on ε *and* R *and is given by*

$$\operatorname{sign}(\|\psi_n^{(r,m)}\|^2)=\begin{cases}1, & \text{if } 2\hat{R}/\varepsilon>n-r,\\ 0, & \text{if } 2\hat{R}/\varepsilon\in\mathbb{Z},1\leqslant 2\hat{R}/\varepsilon\leqslant n-r,\\ (-1)^{(n-r-\lfloor 2\hat{R}/\varepsilon\rfloor)}, & \text{if } 2\hat{R}/\varepsilon\notin\mathbb{Z},0<2\hat{R}/\varepsilon<n-r,\end{cases} \quad (50)$$

where $\lfloor 2R/\varepsilon\rfloor$ *is the largest integer less than or equal to* $2R/\varepsilon$.

Proof: This proof is similar to the proof of Ref. 1, Theorem 6. Consider $\hat{R}=\varepsilon(k+\frac{1}{2})$, we have

$$\pi_0(a_-^{n+r}a_+^{n+r}b_+^{n-r}b_-^{n-r})=\frac{1}{2k+1}\sum_{j=-k}^{k}\langle k,j|a_-^{n+r}a_+^{n+r}b_+^{n-r}b_-^{n-r}|k,j\rangle$$

$$=\frac{\varepsilon^{2k}}{2k+1}\sum_{j=-k}^{k}\frac{(k+j+r+n)!(k-j)!}{(k+j)!(k-j-n+r)!}.$$

Substituting $j=s-k$ and removing vanishing terms,

$$=\frac{\varepsilon^{2k}}{2k+1}\sum_{j=-k}^{2k-n+r}\frac{(s+r+n)!(2k-s)!}{s!(2k-n+r-s)!}$$

$$=\varepsilon^{2k}\frac{(r+n)!(2k)!}{(2k+1)(2k-n+r)!}\sum_{j=-k}^{2k-n+r}\frac{(r+n+1)_s(-2k+n-r)_s}{s!(-2k)_s}$$

$$=\varepsilon^{2k}\frac{(r+n)!(2k)!}{(2k+1)(2k-n+r)!}F(r+n+1,n-r-2k;-2k;1)$$

$$=\varepsilon^{2k}\frac{(r+n)!(2k)!}{(2k+1)(2k-n+r)!}\lim_{\kappa\to 0}F(r+n+1,n-r-2k;\kappa-2k;1)$$

$$=\varepsilon^{2k}\frac{(r+n)!(2k)!}{(2k+1)(2k-n+r)!}\lim_{\kappa\to 0}\frac{\Gamma(\kappa-2k)\Gamma(\kappa-2n-1)}{\Gamma(\kappa-2k-r-n-1)\Gamma(\kappa-n+r)}$$

$$=\varepsilon^{2k}\frac{(r+n)!(n-r)!(2k+1+r+n)!}{(2k+1)(2n+1)!(2k-n+r)!}.$$

Substituting $\hat{R}=\varepsilon(k+\frac{1}{2})$ and using lemma 6 gives us this result. □

C. Matrix representations for $\psi_n^{(r,m)}$

If $\hat{R}=\varepsilon(k+\frac{1}{2})$ then (as already noted) we can quotient the space of functions $\Psi_{\bullet}^{(0,\bullet)}$ to give the algebra of matrices $M_{2k+1}(\mathbb{C})$. This interpretation may be extended for each $\Psi_{\bullet}^{(r,\bullet)}$ but with caution to reflect its nonassociative nature. The elements of $\Psi_{\bullet}^{(r,\bullet)}$ now become rectangular matrices with $2k+2r+1$ rows and $2k+1$ columns; i.e., elements of $M_{(2k+2r+1)\times(2k+1)}(\mathbb{C})$.

Lemma 8: *Given* $\hat{R}=\varepsilon(k+\frac{1}{2})$ *then the mapping*

$$\varphi_k^r : \Psi_\bullet^{(r,\bullet)} \mapsto M_{(2k+2r+1)\times(2k+1)}(\mathbb{C}),$$

$$(\varphi_k^r(\xi))_{\mu\nu} = \langle k+r, \mu-k-r-1 | \xi | k, \nu-k-1 \rangle, \tag{51}$$

where $1 \leqslant \mu \leqslant 2k+2r+1$ *and* $1 \leqslant \nu \leqslant 2k+1$, *satisfies the following properties:*

$$\varphi_k^r(\rho(\xi f)) = \varphi_k^r(\xi)\varphi_k^0(f), \quad \forall \xi \in \Psi_\bullet^{(r,\bullet)}, \quad f \in \Psi_\bullet^{(0,\bullet)}, \tag{52}$$

$$(\varphi_k^r(\xi))^\dagger \varphi_k^r(\zeta) = \varphi_k^0(\rho(\xi^\dagger \zeta)), \tag{53}$$

$$\varphi_k^r(\psi_n^{(r,m)}) = 0, \quad \text{if } n \geqslant 2k+r+1. \tag{54}$$

Proof: Equation (52) follows from the use of (47) to remove the ρ, simple matrix multiplication, and observing that $\Sigma_{\mu=1}^{2k+1} |k, \mu-k-1\rangle\langle k, \mu-k-1|$ is the unit matrix in $M_{2k+1}(\mathbb{C})$. Likewise (53) follows from the same plus the recognition that, $\langle k, \mu-k-1 | \xi^\dagger | k+r, \nu-k-r-1 \rangle = ((\varphi_k^r(\xi))^\dagger)_{\mu\nu}$.

For $n \geqslant 2k+r+1$ then from theorem 7,

$$0 = \langle \psi^{(r,m)}{}_n, \psi_n^{(r,m)} \rangle = \pi_0(\rho(\psi_n^{(r,m)\dagger} \psi_n^{(r,m)}))$$

$$= \frac{1}{2k+1} \mathrm{TR}(\varphi_k^0(\rho(\xi^\dagger \xi))) = \frac{1}{2k+1} \sum_{\mu=0}^{2k+2r+1} \sum_{\nu=0}^{2k+1} |\varphi_k^r(\psi_n^{(r,m)})_{\mu\nu}|^2,$$

where TR represents the matrix trace. Hence (54). □

By counting dimensions we see that the $\ker(\varphi_k^r) = \mathrm{span}\{\psi_n^{(r,m)} | \forall m,n \text{ s.t. } n \geqslant 2k+r+1\}$. This is not an ideal in general but it does have the property: if $\xi \in \ker(\varphi_k^r)$ and $f \in \Psi_\bullet^{(0,\bullet)}$ then $\rho(\xi f) \in \ker(\varphi_k^r)$.

D. Writing $\psi_n^{(r,m)}$ in terms of Hahn polynomials

Lemma 9: *The highest degree term in the expansions of* $\psi_n^{(r,m)}$ *is given by*

$$\psi_n^{(r,m)} = (-1)^{n-\max(r,m)} \binom{2n}{n+m}^{1/2} a_\pm^{r+m} b_\pm^{r-m} J_0^{n-\max(|r|,|m|)} + \text{ Lower Degree Terms in } J_0, \tag{55}$$

where $a_\pm$ *and* $b_\pm$ *are given by (15).*

Proof: By repeated application of the formula

$$\mathrm{ad}_{J_-}(a_+^x b_+^{n+r-x} a_-^{n-r-v} b_-^v) = \varepsilon x a_+^{x-1} b_+^{n-r-x+1} a_-^{n-r-v} b_-^v - \varepsilon v a_+^x b_+^{n+r-x} a_-^{n-r-v+1} b_-^{v-1}, \tag{56}$$

we see that

$$(\mathrm{ad}_{J_-})^{n-m}(a_+^{n+r} b_+^{n-r})$$

$$= \varepsilon^{n-m} \sum_{s=\max(0,r-m)}^{\min(n-m,n+r)} \frac{(n-m)!(n+r)!(n-r)!(-1)^{n-m-s}}{s!(n-m-s)!(n+r-s)!(m-r+s)!} a_+^{n+r-s} b_+^s a_-^{n-m-s} b_-^{m-r+s}. \tag{57}$$

Using $a_+ a_- = J_0 + \text{ LDT}$ and $b_+ b_- = -J_0 + \text{ LDT}$, where LDT means ''Lower Degree Terms in J_0,'' we have

$$a_+^{n+r-s} b_+^s a_-^{n-m-s} b_-^{m-r+s} = a_\pm^{r+m} b_\pm^{r-m} J_0^{n+\min(r,-m)+\min(0,m-r)} (-1)^{s+\min(0,m-r)} + \text{ LDT}$$

$$= a_\pm^{r+m} b_\pm^{r-m} J_0^{n-\max(|r|,|m|)} (-1)^{s+\min(0,m-r)} + \text{ LDT},$$

where the last expression comes from considering each of the four cases below separately.

We have to consider separately the cases $m\geqslant r$ and $r\geqslant m$. We use the equations $(N+s)!=N!(N+1)_s$ and $N!=(N-s)!(-1)^s(-N)_s$ to convert our sum into a hypergeometric function. Since the coefficient is 1 we can use the summation formula to get an explicit form in terms of factorials.

For $m\geqslant r$ we have

$$
\begin{aligned}
&(\mathrm{ad}_{J_-})^{n-m}(a_+^{n+r}b_+^{n-r})\\
&\quad=\varepsilon^{n-m}a_\pm^{r+m}b_\pm^{r-m}J_0^{n-\max(|r|,|m|)}\frac{(-1)^{n-m}(n-r)!}{(m-r)!}\sum_{s=0}^{n+\min(-m,r)}\frac{(m-n)_s(-n-r)_s}{s!(m-r+1)_s}+\text{LDT}\\
&\quad=\varepsilon^{n-m}a_\pm^{r+m}b_\pm^{r-m}J_0^{n-\max(|r|,|m|)}\frac{(-1)^{n-m}(n-r)!}{(m-r)!}F(m-n,-n-r;m-r+1;1)+\text{LDT}\\
&\quad=\varepsilon^{n-m}a_\pm^{r+m}b_\pm^{r-m}J_0^{n-\max(|r|,|m|)}\frac{(-1)^{n-m}(2n)!}{(n+m)!}+\text{LDT},
\end{aligned}
$$

whilst for $m\leqslant r$,

$$
(\mathrm{ad}_{J_-})^{n-m}(a_+^{n+r}b_+^{n-r})=\varepsilon^{n-m}a_\pm^{r+m}b_\pm^{r-m}J_0^{n-\max(|r|,|m|)}\frac{(-1)^{n-r}(2n)!}{(n+m)!}+\text{LDT}.
$$

Using (35) gives this result. □

Corollary 10: The Hermitian conjugate is given by

$$
(\psi_n^{(r,m)})^\dagger=(-1)^{(r+m)}\psi_n^{(-r,-m)}. \tag{58}
$$

Proof: By putting $m=-n$ in above we have the exact formula

$$
\psi_n^{(r,-n)}=(-1)^{r+n}a_-^{n-r}b_+^{n+r}.
$$

Taking the conjugate of (35), using $(\mathrm{ad}_{J_-}(f))^\dagger=-\mathrm{ad}_{J_+}(f^\dagger)$, and substituting (59) gives (58). □

Theorem 11: *We can write the polynomials $\psi_n^{(r,m)}$ as*

$$
\psi_n^{(r,m)}=\begin{cases}
(-1)^{n-r}\varepsilon^{n-r}\dbinom{2n}{n+m}^{1/2}\dbinom{2n}{n+r}^{-1}a_+^{r+m}b_+^{r-m}h_{n-r}^{(r-m,r+m)}\left(\dfrac{(J_0+\hat R)}{\varepsilon}-\dfrac12,\dfrac{2\hat R}{\varepsilon}\right),\\
\qquad for\ -r\leqslant m\leqslant r,\\
(-1)^{n-m}\varepsilon^{n-m}\dbinom{2n}{n+m}^{1/2}a_+^{r+m}b_-^{m-r}h_{n-m}^{(m-r,r+m)}\left(\dfrac{(J_0+\hat R)}{\varepsilon}-\dfrac12,\dfrac{2\hat R}{\varepsilon}+r-m\right),\\
\qquad for\ -m\leqslant r\leqslant m,\\
(-1)^{n-r}\varepsilon^{n+m}\dbinom{2n}{n+m}^{1/2}a_-^{-r-m}b_+^{r-m}\\
\qquad\times h_{n+m}^{(r-m,-r-m)}\left(\dfrac{(J_0+\hat R)}{\varepsilon}-\dfrac12+r+m,\dfrac{2\hat R}{\varepsilon}+r+m\right),\quad for\ m\leqslant r\leqslant -m,\\
(-1)^{n-m}\varepsilon^{n+r}\dbinom{2n}{n+m}^{1/2}\dbinom{2n}{n+r}^{-1}a_-^{-r-m}b_-^{m-r}\\
\qquad\times h_{n+r}^{(m-r,-r-m)}\left(\dfrac{(J_0+\hat R)}{\varepsilon}-\dfrac12+r+m,\dfrac{2\hat R}{\varepsilon}+2r\right),\quad for\ r\leqslant m\leqslant -r
\end{cases}. \tag{59}
$$

Proof: It is clear we shall have to consider the four cases separately. For each case the proof is not too different from Ref. 1, Theorem 7. Let us here prove the theorem for the first case where $-r\leqslant m\leqslant r$, the other cases are similarly proved.

Given two basis elements $\psi_{n_1}^{(r_1,m_1)}$ and $\psi_{n_2}^{(r_2,m_2)}$ it is clear that $\langle \psi^{(r_1,m_1\rangle}{}_{n_1}, \psi_{n_2}^{(r_2,m_2)}\rangle = 0$ unless $m_1=m_2$ and $r_1=r_2$. Use lemma 2 so the $\psi_{n_1}^{(r,m)} = a_+^{r+m} b_+^{r-m} p(J_0,K_0)$. Thus $\psi_{n_1}^{(r,m)} = \rho(\psi_{n_1}^{(r,m)}) = a_+^{r+m} b_+^{r-m} p_{n_1}(J_0)$ for the polynomial $p_{n_1}(J_0)$ which we want to determine.

Let $R^2=\varepsilon^2 k(k^1)$ so $R'=\varepsilon(k+\frac{1}{2})$. Using (48) we have for $n_1\neq n_2$,

$$\begin{aligned} 0 &= \langle \psi^{(r,m\rangle}{}_{n_1}, \psi_{n_2}^{(r,m)}\rangle \\ &= \sum_{j=-k}^{k} \langle k,j| p_{n_1}(J_0) a_+^{r+m} b_+^{r-m} a_+^{r+m} b_+^{r-m} p_{n_2}(J_0) |k,j\rangle \\ &= \sum_{j=-k}^{k} p_{n_1}(\varepsilon j) p_{n_2}(\varepsilon j) \frac{(k+j+r+m)!(k-j+r-m)!}{(k+j)!(k-j)!}. \end{aligned}$$

Thus $p_n(\varepsilon j)$ are polynomials orthogonal with respect to a weight function. This weight function is precisely the same as that for the Hahn polynomials $h_{n'}^{(\alpha,\beta)}(x,N)$ where $\alpha=r-m$, $\beta=r+m$, $x=j+k$ and $N=2k+1$. We see that $n'=n-r$ since $h_{n'}^{(\alpha,\beta)}(x,N)$ is a polynomial of order n' in x, and from (55), $p_n(J_0)$ is a polynomial of order $n-r$. Comparing the coefficient for the J_0^{n-r} term we have from Ref. 14,

$$h_{n-r}^{(r-m,r+m)}\left(\frac{(J_0+\hat{R})}{\varepsilon}-\frac{1}{2},\frac{2\hat{R}}{\varepsilon}\right) = \frac{(2n)!}{(n-r)!(r+n)!}\frac{J_0^{n-r}}{\varepsilon^{n-r}} + \text{LDT}.$$

Hence the result for the range $-r\leqslant m\leqslant r$. Since this is true for all k then using lemma 6 gives result for all ε,R. The other ranges are proved similarly. □

In the limit $\varepsilon=0$ the Hahn polynomials become Jacobi Polynomials ($P_n^{(\alpha,\beta)}(z)$). Thus we have

$$\begin{aligned} \psi_n^{(r,m)}|_{\varepsilon=0} &= (-1)^{n-\max(r,m)}(2R)^{n-\max(|r|,|m|)} \\ &\quad\times\binom{2n}{n+m}^{1/2}\binom{2n}{n-\max(|r|,|m|)}^{-1} a_\pm^{r+m} b_\pm^{r-m} P_{n-\max(|r|,|m|)}^{(|r-m|,|r+m|)}\left(\frac{J_0}{R}\right). \end{aligned} \tag{60}$$

E. Another useful theorem

Here we extend Ref. 1, Lemma 9 to give a formula which is useful for the definition of the exterior derivative.

Theorem 12: *For r_1,r_2,n let*

$$\omega_n^{r_1r_2}:\Psi\mapsto\Psi,$$

$$\omega_n^{r_1r_2}(\xi) = \sum_{m=-n}^{n} \rho(\psi_n^{(r_2,m)\dagger}\xi\psi_n^{(r_1,m)}). \tag{61}$$

Then $\omega_n^{r_1r_2}$ commutes with ad_{J_0}, ad_{J_+}, ad_{J_-}, Δ *and satisfies*

$$\mathrm{ad}_{K_0}\omega_n^{r_1r_2}(\xi) = \varepsilon(r_1-r_2)\omega_n^{r_1r_2}(\xi) + \omega_n^{r_1r_2}(\mathrm{ad}_{K_0}\xi). \tag{62}$$

Its effect on the basis elements is given by

$$\omega_{n_1}^{r_1r_2}(\psi_n^{(r,m)}) = \omega_{n_1n}^{r_1r_2r}\psi_n^{(r+r_1-r_2,m)}, \tag{63}$$

where $\omega_{n_1 n}^{r_1 r_2 r} \in \mathbb{C}$. *For* $\xi = 1$,

$$\omega_n^{r_1 r_2}(1) = \delta_{r_1 r_2}(2n+1)\|\psi_n^{(r_1,m)}\|^2. \tag{64}$$

Proof: The effect of ad_{J_0}, ad_{J_+}, ad_{J_-}, and ad_{K_0} comes from direct calculation using (37), (41), (42), and (39), respectively. The effect of Δ comes from ad_{J_+} and ad_{J_-}. From this, it is clear that $\omega_{n_1}^{r_1 r_2}(\psi_n^{(r,m)})$ must be proportional to $\psi_n^{(r+r_1-r_2,m)}$ and that the proportionality constant must be independent of m since $\omega_{n_1}^{r_1 r_2}$ commutes with ad_{J_+}.

Since $\omega_n^{r_1 r_2}(1)$ is proportional to $\psi_0^{(r_1-r_2,0)}$ it is clear that it vanishes unless $r_1 = r_2$. In this case taking π_0 in the expression gives this result. □

VI. PHYSICAL INTERPRETATION

There are two ways of interpreting the algebra (Ψ,ρ) and the basis elements $\psi_n^{(r,m)}$. In subsection VI A we show that $\psi_n^{(r,m)}$ may be thought of as the deformed rotation matrices for $SU(2)$, whilst in subsections VI B–VI D we use them to construct the analogue of scalar, vector, and spinor fields.

A. Deformed rotation matrices

In the limit $\varepsilon = 0$ the elements of Ψ may be regarded as complex functions over S^3 or $SU(2)$. The product ρ becomes pointwise multiplication. The basis elements $\psi_n^{(r,m)}$ are proportional to the rotation matrix D_{mr}^n. Thus we may interpret $\psi_n^{(r,m)}$ as the deformed (or noncommutative) rotation matrices.

Just as in standard quantum mechanics the noncommutativity in the quantum domain becomes the Poisson Bracket in the commutative case, we can define a bracket (68) as the limit of the commutator. However, since for $\varepsilon \neq 0$ ρ is not associative, this bracket is neither a derivation nor satisfies the Jacobi identity. Therefore, it is not a Poisson Bracket. This is reflected in the existence of the number operator δ_N in (69). It would be nice if one could find a physical interpretation for this bracket.

Lemma 13: In the limit $\varepsilon = 0$ *the noncommutative, nonassociative algebra* (Ψ,ρ) *becomes the commutative associative algebra* $C_0(SU(2))$. *This is the algebra of complex valued polynomial functions on SU(2) with pointwise multiplication.*

If we use the Euler angles (α,β,γ) *to parameterise SU(2) then the generators of* Ψ *may be written as*

$$\begin{aligned} a_+ &= \sqrt{2R}\,\cos(\beta/2)e^{-i/2(\alpha+\gamma)}, \quad b_+ = -i\sqrt{2R}\,\sin(\beta/2)e^{i/2(\alpha-\gamma)}, \\ a_- &= \sqrt{2R}\,\cos(\beta/2)e^{i/2(\alpha+\gamma)}, \quad b_- = i\sqrt{2R}\,\sin(\beta/2)e^{-i/2(\alpha-\gamma)}. \end{aligned} \tag{65}$$

The basis elements of Ψ *are given by the rotation matrices*

$$\psi_n^{(r,m)}\big|_{\varepsilon=0} = (i)^{m-r}(-1)^{n-r}(2R)^n \binom{2n}{r}^{-1/2} D_{mr}^n(\alpha,\beta,\gamma), \tag{66}$$

where $D_{mr}^n(\alpha,\beta,\gamma)$ *uses the notation in Ref. 13. The bilinear form on* Ψ *becomes a true inner product and is given by*

$$\langle \xi,\zeta\rangle = \frac{1}{8\pi^2}\int_0^{2\pi} d\alpha \int_0^{2\pi} d\gamma \int_0^{\pi} d\beta \sin(\beta)\,\overline{\xi}\zeta. \tag{67}$$

There is a bracket defined by

$$\{\bullet,\bullet\}: C_0(SU(2))\times C_0(SU(2)) \mapsto C_0(SU(2)), \quad \{\xi,\zeta\} = \lim_{\varepsilon\to 0} \frac{1}{i\varepsilon}\rho([\xi,\zeta]), \tag{68}$$

which is given by

$$\{\xi,\zeta\}=\frac{1}{R\sin\beta}\left(\frac{\partial\xi}{\partial\alpha}\frac{\partial\zeta}{\partial\beta}-\frac{\partial\xi}{\partial\beta}\frac{\partial\zeta}{\partial\alpha}\right)+\left(\delta_N(\xi)\frac{\partial\zeta}{\partial\gamma}-\frac{\partial\xi}{\partial\gamma}\delta_N(\zeta)\right)+\frac{\cot\beta}{R}\left(\frac{\partial\xi}{\partial\beta}\frac{\partial\zeta}{\partial\gamma}-\frac{\partial\xi}{\partial\gamma}\frac{\partial\zeta}{\partial\beta}\right), \tag{69}$$

where δ_N is the number operator,

$$\delta_N:C_0(SU(2))\mapsto C_0(SU(2)),\quad \delta_N(\psi_n^{(r,m)})=n\psi_n^{(r,m)}. \tag{70}$$

Proof: By setting $\varepsilon=0$ it is clear that the algebra is commutative and associative. The condition that $K_0=R$ implies that the elements of Ψ are functions on S^3, or alternatively $SU(2)$. Assuming (65) then (66) follows from (60). The inner product (67) follows from the orthogonality of the rotation matrix elements.

In the limit $\varepsilon=0$ the algebra $\mathscr{W}(0)$ is the algebra $C_0(\mathbb{R}^4)$ of complex valued polynomial functions over $\mathbb{R}^4$. The Poisson Bracket corresponding to the limit of the commutator is given by

$$\{f,g\}_{\mathscr{W}}=\frac{\partial f}{\partial a_+}\frac{\partial g}{\partial a_-}-\frac{\partial f}{\partial a_-}\frac{\partial g}{\partial a_+}+\frac{\partial f}{\partial b_+}\frac{\partial g}{\partial b_-}-\frac{\partial f}{\partial b_-}\frac{\partial g}{\partial b_+}.$$

Writing this with respect to the coordinates (R,α,β,γ) gives (69) but with δ_N replaced by $\partial/\partial R$. However, for every polynomial $w(a_+,a_-,b_+,b_-)$ not explicitly dependent on R, $\partial w/\partial R=\delta_N(w)$. Thus restriction of $\{\bullet,\bullet\}_{\mathscr{W}}$ to $C_0(SU(2))$ is valid. □

B. The exterior derivative and 1-forms

In standard geometry there are many equivalent definitions of a vector field. However, not all of them can be extended to the noncommutative case at the same time. If one takes the definition of a vector field, that it must satisfy the Leibniz formula, and extends this definition to noncommutative geometry, then, at least for the matrix case, the vector fields are given by $X=\mathrm{ad}_f$ for some $f\in\Psi_\bullet^{(0,\bullet)}$. This can then be used to give a definition of the exterior derivative and the exterior algebra.[2]

Here we give another definition of covectors by use of the analogue of the following definition of the exterior derivative of scalar fields:

$$df=\sum_i\frac{\partial f}{\partial x^i}dx^i. \tag{71}$$

If we consider the noncommutative sphere as a three dimensional manifold with normalized basis coordinates $x^m=(2\hat{R}+\varepsilon)^{-1/2}\psi_1^{(0,m)}$ for $m\in\{-1,0,1\}$ we can define the basis 1-forms as

$$dx^m=(2\hat{R}+\varepsilon)^{-1/2}\psi_1^{(-1,m)},\ \text{for } m\in\{-1,0,1\}. \tag{72}$$

This enables us to define the *exterior derivative* on the space of functions as

$$d:\Psi_\bullet^{(0,\bullet)}\mapsto\Psi_\bullet^{(-1,\bullet)},\quad df=\varepsilon^{-1}(2\hat{R}+\varepsilon)^{-1}\omega_1^{01}(f),\quad \forall f\in\Psi_\bullet^{(0,\bullet)}. \tag{73}$$

Since $\omega_1^{01}(1)=0$, we see that

$$df=\frac{1}{\varepsilon}\sum_{m=-1}^{1}(-1)^{m+1}dx^{-m}\mathrm{ad}_{x^m}f, \tag{74}$$

which is analogous to (71). This obeys the following.

Lemma 14: The two definition of the 1-forms dx^m given by (72) and (73) agree. For the basis elements which are functions,

$$d\psi_n^{(0,m)}=2n(\hat{R}+\varepsilon n/2)(\hat{R}+\varepsilon)^{-1}\psi_n^{(-1,m)}, \tag{75}$$

and in the limit as $\varepsilon\to 0$,

$$d(fg)=d(f)g+f(dg)+O(\varepsilon). \tag{76}$$

Proof: From the definition we see that

$$J_+=\psi_1^{(0,1)}, \qquad -\sqrt{2}J_0=\psi_1^{(0,0)}, \qquad -J_-=\psi_1^{(0,-1)},$$
$$b_-^2=\psi_1^{(-1,1)}, \quad \sqrt{2}a_-b_-=\psi_1^{(-1,0)}, \quad a_-^2=\psi_1^{(-1,-1)}.$$

By manipulations of J_+, J_- we can show that

$$[J_-, J_+^n]=-2\varepsilon J_+^{n-1}(nz+\varepsilon n(n-1)/2).$$

From theorem 12 we know that $\omega_1^{01}(\psi_n^{(-1,m)})$ is proportional to $\psi_n^{(0,m)}$ and its coefficient is independent of m. Therefore taking $m=n\geqslant 1$ we have

$$\omega_1^{01}(\psi_n^{(0,n)})=a_-^2\,\mathrm{ad}_{J_+}(J_+^n)+2a_-b_-\,\mathrm{ad}_{J_0}(J_+^n)+b_-^2\,\mathrm{ad}_{J_-}(J_+^n)$$
$$=2n\varepsilon a_-b_-J_+^n-2\varepsilon b_-^2J_+^{n-1}(nz+\varepsilon n(n-1)/2).$$

Now $b_-^2J_+^{n-1}=a_+^{n-1}b_-^{n+1}=\psi_n^{(-1,n)}$ while

$$a_-b_-a_+^nb_-^n=(J_0+K_0+\varepsilon/2)a_+^{n-1}b_-^{n+1}$$
$$=a_+^{n-1}b_-^{n+1}(J_0+K_0+n\varepsilon-\varepsilon/2)).$$

Hence (75). We show that the two definitions of dx^m are equivalent by substituting $n=1$ into this formula. Finally we note that

$$\sum_{m=-1}^{1}(\psi_1^{(1,m)\dagger}fg\psi_1^{(0,m)}-\psi_1^{(1,m)\dagger}f\psi_1^{(0,m)}g-f\psi_1^{(1,m)\dagger}g\psi_1^{(0,m)})=[\psi_1^{(1,m)\dagger},f][g,\psi_1^{(0,m)}]=O(\varepsilon^2).$$

□

C. Vector fields

We can now define the vectors fields as the set $\Psi_\bullet^{(1,\bullet)}$. The action of a vector on a scalar is given by

$$X(f)=\rho((df)X). \tag{77}$$

By the same reasoning as (76), this is also only a derivation in the limit

$$X(fg)=X(f)g+fX(g)+O(\varepsilon). \tag{78}$$

However if we define X_m to be the conjugate of dx^m, $X_m=(dx^m)^\dagger=(-1)^{m+1}(2\hat{R}+\varepsilon)^{-1/2}\psi_1^{(1,-m)}$ then from $\omega_1^{1,0}(1)=\omega_1^{0,-1}(1)=0$ we have

$$\sum_{m=-1}^{1}x^mX_m=\sum_{m=-1}^{1}X_mx^m=0, \tag{79}$$

identically, for all ε, and not just in the limit $\varepsilon=0$.

We can now define a *metric*,

$$g:\Psi_\bullet^{(1,\bullet)}\times\Psi_\bullet^{(1,\bullet)}\mapsto\Psi_\bullet^{(0,\bullet)}, \quad g(X,Y)=\rho(X^\dagger Y). \tag{80}$$

This can be extended for all spaces $\Psi_\bullet^{(r,\bullet)}$.

D. Spinor fields

It is natural now to define the set $\Psi_{\bullet}^{(1/2,\bullet)}$ as the space of spinor fields and its dual $\Psi_{\bullet}^{(-1/2,\bullet)}$. This means that a vector is the product of two spinors. We may also consider the space $\Psi_n^{(r,\bullet)}=\Psi_n^{(\bullet,\bullet)}\cap\Psi_{\bullet}^{(r,\bullet)}$ as a $2n+1$ dimensional representation of $su(2)$ given by the adjoint representation, $\mathrm{ad}_u:\Psi_n^{(r,\bullet)}\mapsto\Psi_n^{(r,\bullet)}$ for any nonzero element $u\in su(2)$. The $2n+1$ eigenvalues of this mapping are given by the set $\{m\|u|/2|m+n\in\mathbb{Z},|m|\leqslant n\}$, where $\|u\|$ corresponds to the Killing form. Thus

$$e^{\pi iu/\|u\|}\psi_n^{(r,m)}e^{-\pi iu/\|u\|}=(-1)^{2n}\psi_n^{(r,m)}.$$

Hence rotation by 2π does not change the sign of $\psi_n^{(r,m)}$ if n is an integer, i.e., for scalars, vectors, and other ''Bosons.'' While $\psi_n^{(r,m)}$ changes sign under rotation of 2π for spinors tensor fields and other ''Fermions.''

An alternative way to define spinor fields is as the set

$$\mathscr{S}=\left\{\begin{pmatrix}a_+\\b_+\end{pmatrix}f_1+\begin{pmatrix}a_-\\b_-\end{pmatrix}f_2\,\middle|\,f_1,f_2\in\Psi_{\bullet}^{(0,\bullet)}\right\}. \tag{81}$$

This is usually regarded as the space of spinors. It is decomposed into $\mathscr{S}=\mathscr{S}_+\oplus\mathscr{S}_-$ corresponding to the eigenspaces of ad_{K_0} which is now regarded as the Chirality operator. This interpretation is now equivalent to the one proposed by Grosse *et al.*,[4,9,10] who go on to define and solve the Dirac equation. We note that $\mathscr{S}$ is not equivalent to simply two copies of $\Psi_{\bullet}^{(-1/2,\bullet)}\oplus\Psi_{\bullet}^{(1/2,\bullet)}$, but a proper subset. This is because the element $\binom{a_+}{0}\notin\mathscr{S}$. In the commutative limit $\varepsilon=0$ we can replace $a_+=a_-=R^{1/2}\cos(\theta/2)$ and $b_+=\overline{b_-}=R^{1/2}\sin(\theta/2)e^{-i\phi}$ to obtain the standard spinors on a sphere of radius R and coordinates $(0\leqslant\theta\leqslant\pi,0\leqslant\phi\leqslant2\pi)$.

VII. PROBLEMS AND OUTLOOK

There are many problems with this interpretation of our system. Here is a list of cases where this noncommutative geometry is different from the commutative geometry even in the limit $\varepsilon=0$.

(1) The space $\Psi_{\bullet}^{(-1,\bullet)}$ is the image of $\Psi_{\bullet}^{(0,\bullet)}$ under d. This means that all 1-forms are closed.

(2) The definition (73) can be extended as a map $d:\Psi_{\bullet}^{(r,\bullet)}\mapsto\Psi_{\bullet}^{(r-1,\bullet)}$ for all r. However this map does not satisfy $d^2=0$ even in the limit. As a result no exterior calculus is defined here.

(3) The set of vectors X_i are not dual, in the usual sense, to the set of 1-forms dx^j, or alternatively the vectors X_i are not orthogonal with respect to the metric g. This is because for $i\neq j$,

$$g(X_i,X_j)=\rho(dx^iX_j)=X_j(x^i)\neq0,$$

for all ε even when $\varepsilon=0$. However we do have $\pi_0(g(X_i,X_j))=\delta_{ij}$.

Some of these problems, together with the nonderivative nature of d may be solved by redefining the space of covectors. For example it may be similar to (81).

As stated at the end of subsection VI A the bracket (68) is in need of an interpretation.

Since ρ is not associative it would be nice to know what rules (if any) it obeys. Note, for example, even $(\rho(\xi\xi)\xi)\neq\rho(\xi\xi\xi)$ so ξ^n is not well defined.

In the limit $\varepsilon=0$ there is a formula for the combination of two matrix rotation entries D^n_{rm}. In the general case we can use the Wigner–Eckart theorem to give

$$\psi_{n_1}^{(r_1,m_1)}\psi_{n_2}^{(r_2,m_2)}=\sum_{n=|n_1-n_2|}^{n_1+n_2}C^{n_1,n_2,n}_{m_1,m_2,m_1+m_2}R^{n_1,n_2,n}_{r_1,r_2,r_1+r_2}\psi_n^{(r_1+r_2,m_1+m_2)},$$

where $C^{n_1,n_2,n}_{m_1,m_2,m_1+m_2}$ is the Wigner or Clebsch–Gordan coefficient and $R^{n_1,n_2,n}_{r_1,r_2,r_1+r_2}$ the corresponding reduced matrix element. It has since been shown[12] that $R^{n_1,n_2,n}_{r_1,r_2,r_1+r_2}$ may be written in terms of Wigner $6j$ symbols.

Since the space of spinor and vector fields naturally form modules over the space of scalar fields one can use this as a starting point for algebraic connections.[15]

As stated $\mathscr{W}$ contains a representation of $su(1,1)$. If one quotiented $\mathscr{W}$ by the ideals created by $J_0 \sim \hat{R}$, one would gain a very similar structure which could be interpreted as the basis of scalar, spinor, and vector fields on the noncommutative analogue of either the two dimensional deSitter space or the Hyperbolic plane.

The Jordan–Schwinger representation can be used for any Lie algebra. Hence one should be able to construct spinor fields on any symmetric manifold. The combination of these two steps would give one a description of scalar, spinor, and vector fields on more exotic symmetric spaces, such as the Einstein–deSitter Universe.

Extremal eigenvalue gaps for the Schrödinger operator with Dirichlet boundary conditions

Samir Karaa

(Received 12 May 1997; accepted for publication 9 July 1997)

We consider the problems of minimizing and maximizing the gap between the two lowest Dirichlet eigenvalues of the Schrödinger operator $-\Delta+V(x)$ on a bounded domain in R^n, when the potential V is subjected to a p-norm constraint. We give characterization theorems for extremizing potentials. We prove in particular that a second eigenvalue corresponding to a minimizing potential is always single. © *1998 American Institute of Physics.* [S0022-2488(98)03903-6]

I. INTRODUCTION

Let Ω be an open bounded domain in R^n with smooth boundary. We consider the Schrödinger operator $L=-\Delta+V(x)$ acting on $L^2(\Omega)$, with zero Dirichlet boundary conditions. The real-valued function $V(x)$, called potential, is measurable and non-negative. As is well known, the eigenvalues of the operator L can be interpreted as the energy levels, in atomic units, of a particle traveling under the external force field of a potential $V(x)$ in R^n equal to $V(x)$ in the domain Ω and imagined as $+\infty$ outside Ω, and the corresponding eigenfunctions are wave functions of the Schrödinger equation

$$-\Delta y+V(x)y=\lambda y. \tag{1.1}$$

Moreover, for reasonable potentials V, the spectrum of L is discrete and consists of non-negative eigenvalues $\{\lambda_k\}$ which can be arranged in a nondecreasing order as follows:

$$0<\lambda_1<\lambda_2\leqslant\lambda_3\leqslant\cdots\leqslant\lambda_m\leqslant\cdots .$$

There are both physical and mathematical interests in studying the problem of minimizing and maximizing the functional $\Gamma(V)$ defined as

$$\Gamma(V)=\lambda_2(V)-\lambda_1(V),$$

when the non-negative potential $V(x)$ is subjected to some kind of constraints. The motivation of our work comes especially from quantum mechanical considerations. See Refs. 1 and 2 for concrete examples. The functional Γ will be called the *fundamental gap* of the operator L.

Bounds for the fundamental gap in terms of the geometry of Ω (V is assumed identically zero) have been the subject of many recent works (see, for example, Refs. 3–6 and the references quoted there). The most important result established recently is due to Benguria and Ashbaugh who proved that the fundamental gap achieves its maximum value at a ball having the same measure that Ω (see Refs. 3 and 4). In Ref. 6, lower and upper bounds for $\Gamma(V)$ have been obtained in terms of the geometrical invariants of Ω and the given potential V, with some assumptions imposed on both V and Ω. If d is the diameter of the domain Ω and D is the diameter of the largest inscribed ball in Ω, then with the assumption that V and Ω are convex, we have

$$C_{1.}d^{-2}\leqslant\Gamma(V)\leqslant C_{2.}D^{-2}+C_3,$$

where C_1, C_2, and C_3 are positive constants independent of Ω, whereas Kirsch and Simon[5–7] found that the fundamental gap can be estimated from below by a polynomial in d times exp

 © 1998 American Institute of Physics

$(-\text{const. } d)$. Another problem has been studied in Ref. 2. The authors considered the problem of minimizing and maximizing the fundamental gap $\Gamma(V)$ when the potential $V(x)$ is constrained to the set

$$S_{\alpha,M}=\{V:\text{supp } V\subset\Omega,\|V\|_{\alpha}\leqslant M\},$$

M is a fixed positive number, and α is assumed greater than $n/2$ when $n\geqslant 2$. In our work below we extend the analysis of Ref. 2 to the case of all $\alpha\geqslant 1$ at the price of imposing a second constraint, viz., a pointwise bound. The potential V is then allowed to vary over the set

$$K_{\alpha}=\left\{V\in L^{\infty}(\Omega),0\leqslant V(x)\leqslant H,\int_{\Omega}V^{\alpha}(x)=M\right\},$$

where H and M are positive numbers satisfying $M<H^{\alpha}|\Omega|$ and $\alpha\geqslant 1$.

It is known that for every potential in K_{α}, the operator L is strictly elliptic and self-adjoint with the quadratic-form domain $W_0^{1,2}(\Omega)$, its spectrum is discrete, and the first eigenvalue λ_1 is nondegenerate with a positive eigenfunction.[8,9] We begin by a discussion of the existence of optimal potentials and we give some regularity results. The next section deals with some characterizations of the optimal potentials.

Remark: Many authors have studied the problem of maximizing the first eigenvalue of some classes of second-order elliptic operators. See, for example, Refs. 10–13. In view of the simplicity of the first eigenvalue of the elliptic operators considered, the preoccupations of these papers are different from those presented in our work.

II. EXISTENCE

We first observe that Γ is uniformly bounded in K_{α} for any $\alpha\geqslant 1$. This follows from the fact that λ_1 and λ_2 are both bounded uniformly there because of the min–max principle and the operator inequalities

$$-\Delta\leqslant L\leqslant -\Delta+H.$$

Theorem 2.1: *Let Ω be a fixed smooth open domain in R^n and let the operator L be as above. Then the functional $\Gamma(V)$ attains its minimum and its maximum on K_{α} for any $\alpha\geqslant 1$.*

The proof is close to that given in Ref. 2. It is based on straightforward compactness arguments. We only note that the proof needs the following result:

$$\Delta y\in L^2(\Omega)\quad\text{and}\quad y\in W_0^{1,2}(\Omega)\Rightarrow y\in W^{2,2}(\Omega),$$

which is true if $\partial\Omega$ is C^2 (see Ref. 8, Chap. 8).

Proposition 2.1: Let V be in K_{α}, $\alpha\geqslant 1$. If a function $y\in W_0^{1,2}(\Omega)$ satisfies $Lu=\lambda u$ for some $\lambda\in\mathbb{R}$, then $y\in W_{\text{loc}}^{2,2}(\Omega)\cap C^1(\Omega)$. If, moreover, $\partial\Omega$ is of class C^2, then

$$y\in W^{2,2}(\Omega)\cap C_B^1(\Omega)\cap C^0(\overline{\Omega}),$$

where

$$C_B^1(\Omega)=\{u\in C^1(\Omega),D_iu\in L^{\infty}(\Omega),\ \ i=1,...,n\}.$$

Proof: Since $y\in L^2(\Omega)$, Eq. (1.1) shows that Δy is also in $L^2(\Omega)$ and hence $y\in W_{\text{loc}}^{2,2}(\Omega)$. Consequently, $y\in C^1(\Omega)$ if $n\leqslant 4$ and $y\in L_{\text{loc}}^{s}(\Omega)$ with $s=2n/(n-4)$ if $n>4$. For $n>4$, we can continue this reasoning so that $y\in W_{\text{loc}}^{2,r}(\Omega)$ for a high enough index r satisfying $2r>n$, which shows that $y\in C^1(\Omega)$. If $\partial\Omega$ is C^2, then $\Delta y\in L^2(\Omega)$ and therefore $y\in W^{2,2}(\Omega)$ (see Ref. 8). Repeating this argument we find that $y\in W^{2,r}(\Omega)$ for any $r\geqslant 1$ and hence $y\in C_B^1(\Omega)$. Furthermore, $y\in C^0(\overline{\Omega})$ because $y\in W_0^{1,r}(\Omega)$ for any $r\geqslant 1$. □

Remark: Let $\Gamma_0=\inf_{V\in K_{\alpha}}\Gamma(V)$, $\alpha\geqslant 1$ is fixed. Since Γ_0 is achieved by Γ at some $V_0\in K_{\alpha}$, then Γ_0 must be positive. Define the set

$$S(\Gamma_0)=\{V\in L^\infty(\Omega),\quad 0\leqslant V\leqslant H,\ \ \Gamma(V)=\Gamma_0\},$$

and the functional $\psi: S(\Gamma_0)\to]0,+\infty[$ by $\psi(V)=\|V\|_\alpha^\alpha$. Then it can be shown that the functional ψ attains its minimum on $S(\Gamma_0)$ at some V^* which is also a minimizer for $\Gamma(V)$ on K_α, i.e., $\|V^*\|_\alpha^\alpha=M$.

III. CHARACTERIZATION OF THE OPTIMAL POTENTIALS

We shall deal with the question of characterizing the external potentials. It is well known that in such a problem, at the optimum, the second eigenvalue λ_2 can be degenerate (i.e., multiple) and so it does not vary smoothly with V. Thus, some complications appear when we want to establish necessary (and sufficient) optimality conditions for our problem. Similar difficulties arise in the problem of Lagrange which consists in determining a non-negative function $A(x)$ defined on the interval $[0,l]$, $l>0$, which maximizes the first eigenvalue of the following problem,

$$(A^2w'')''+\lambda w''=0,$$

$$w(0)=w'(0)=0,\quad w(l)=w'(l)=0,$$

under the condition that

$$\int_0^l A(x)\ dx=\xi_0,\quad A(x)\geqslant 0,$$

ξ_0 being a given positive constant. The eigenvalue problem above does not exclude multiple first eigenvalue. For a long history upon the problem see Refs. 14–16.

Definitions: (1) A potential V in K_α is said to be bang-bang if

$$\text{meas}\ \{x\in\Omega,\ \ 0<V(x)<H\}=0.$$

(2) A real-valued bounded measurable function $P(x)$ defined on Ω is an admissible perturbation of a potential $V\in K_\alpha$ if $V+tP\in K_\alpha$ for all sufficiently small $|t|$. The function $P(x)$ is a right-admissible (resp. left-admissible) perturbation if $V+tP$ remains in K_α for positive (resp. negative) t. Any perturbation satisfies

$$\int_\Omega P(x)V(x)^{\alpha-1}\ dx=0\quad \text{if}\ \ \alpha>1,$$

and

$$\int_\Omega P(x)\ dx=0\quad \text{if}\ \ \alpha=1.$$

Let V be in K_α, α is fixed. We recall that if $\lambda_2(v)$ is nondegenerate, then it is Fréchet differentiable in a neighboorhood of V and

$$\frac{d\lambda_2(V+tP)}{dt}=\int_\Omega P(x)y_2^2(x)\ dx\quad \text{at}\ \ t=0$$

for any $P\in L^\infty(\Omega)$ (see Refs. 17, 18, and 9). Hence in the nondegenerate case we have

$$\frac{d\Gamma(V+tP)}{dt}=\int_\Omega P(x)(y_2^2-y_1^2)\ dx\quad \text{at}\ \ t=0,$$

where we assume the eigenfunctions y_1 and y_2 associated to $\lambda_2(V)$ to be normalized. If λ_2 is degenerate, then it is directionally differentiable at V in any direction P and it can split into a cluster of m eigenvalues $\lambda_{2,j}$, which can be considered as a set of analytic functions near $t=0$. If, for example, λ_2 is m-fold degenerate, then we have

$$\lambda_{2,j}(V+tP)=\lambda_2(V)+t\mu_j+o(t), \quad j=1,...,m, \tag{3.1}$$

where μ_j $(j=1,...,m)$ are the eigenvalues of the $m\times m$ self-adjoint matrix A with entries

$$a_{ij}=\int_\Omega P(x)y_{2,i}(x)y_{2,j}(x)\ dx,$$

and $\{y_{2,i}\}_{i=1}^m$ is an orthonormal eigenbasis for $\lambda_2(V)$. The eigenvalues $\lambda_{2,j}$ $(j=1,...,m)$ cannot be ordered in general in the increasing order because the lowest one for $t<0$ will typically be the highest for $t>0$. Moreover, the directional derivative of λ_2 at V in the direction P is the smallest eigenvalue of the group of eigenvalues μ_j, see Ref. 17. Finally, if Γ_j denotes the gap $\lambda_{2,j}-\lambda_1$ $(j=1,...,m)$, then the m derivatives

$$\frac{d\Gamma_j(V+tP)}{dt} \quad (t=0)$$

coincide with the eigenvalues of the $m\times m$ self-adjoint matrix B with entries

$$b_{ij}=\int_\Omega P(x)[y_{2,i}(x)y_{2,j}(x)-y_1^2(x)\,\delta_{ij}]\ dx=\langle Py_{2,i},y_{2,j}\rangle-\langle Py_1,y_1\rangle\delta_{ij}, \tag{3.2}$$

where $\langle,\rangle$ is the scalar product in $L^2(\Omega)$.

The main result of this work is the following.

Theorem 3.1: *Let Ω be a fixed smooth bounded domain in R^n and let the operator L be as above. If a function V_0 minimizes Γ over K_1, then*
(a) *$\lambda_2(V_0)$ is nondegenerate.*
(b) *In any open domain $\mathcal{O}$ in which V_0 does not achieve 0 and H, V_0 is infinitely differentiable, and is related to its first and second normalized eigenfunction y_1 and y_2 by*

$$V_0(x)=C[(\lambda_2 y_2^2(x)-\lambda_1 y_1^2(x))-(|\nabla y_2(x)|^2-|\nabla y_1(x)|^2)]$$

in $\mathcal{O}$, for some nonzero constant C.

Proof: (a) Suppose that $\lambda_2(V_0)$ is an m-fold eigenvalue. To prove that this assumption cannot hold, we shall distinguish two cases

First case. Assume that V_0 is not bang-bang and let $\mathcal{O}$ be an open domain where V_0 is between 0 and H. Since V_0 minimizes Γ over K_1, we must have in view of (3.1)

$$b_{ij}=\int_\Omega P(x)[y_{2,i}(x)y_{2,j}(x)-y_1^2(x)\,\delta_{ij}]\ dx=0, \quad 1\leqslant i,\ j\leqslant m,$$

for any admissible perturbation P satisfying supp $P\subset\mathcal{O}$. Since $\int_{\mathcal{O}}P(x)\ dx=0$, one deduces that

$$y_{2,i}^2(x)-y_1^2(x)=C_{ii} \quad \text{in } \mathcal{O}, \tag{3.3}$$

$$y_{2,i}(x)y_{2,j}(x)=C_{ij} \quad \text{in } \mathcal{O}, \tag{3.4}$$

for $1\leqslant i,\ j\leqslant m$. From (3.3) and (3.4) we obtain in particular

$$y_{2,2}^2-y_{2,1}^2=C_{22}-C_{11} \quad \text{in } \mathcal{O}, \tag{3.5}$$

$$y_{2,1}=C_{21}/y_{2,2} \quad \text{in } \mathcal{O}. \tag{3.6}$$

Thus, combining (3.5) and (3.6) we obtain the fourth-order equation

$$y_{2,2}^4(x)+(C_{22}-C_{11})y_{2,2}^2(x)-C_{21}=0,$$

holding for every x in $\mathcal{O}$. This implies that

$$y_{2,2}=\text{const.} \quad \text{in } \mathcal{O}.$$

From (3.3) we deduce that y_1 is also equal to a constant in $\mathcal{O}$ and therefore $\lambda_1=\lambda_2$, which is impossible since λ_1 is nondegenerate.

Second case. Suppose now that V_0 is bang-bang (i.e., we cannot find an admissible perturbation for V_0). Then for any right-admissible perturbation P, the eigenvalues of the matrix B must be non-negative, i.e., B must be positive semidefinite. Hence, we have in particular

$$\int_\Omega P(x)[y_{2,i}^2(x)-y_1^2(x)]\,dx\geqslant 0, \quad i=1,...,m,$$

for any right-admissible perturbation P. Put

$$B_+=\{x\in\Omega,|y_{2,1}(x)|<y_1(x)\}, \quad B_-=\{x\in\Omega,|y_{2,1}(x)|>y_1(x)\},$$

$$S_+=\{x\in\Omega,V_0(x)=H\}, \tag{3.7}$$

$$S_-=\{x\in\Omega,V_0(x)=0\}. \tag{3.8}$$

If $B_+\neq S_+$ and $B_-\neq S_-$, it is possible to find a right-admissible perturbation P (P takes negative values in S_+ and positive values in S_-) such that

$$\int_\Omega P(x)[y_{2,1}^2-y_1^2]\,dx<0.$$

This implies that either $B_+=S_+$ or $B_-=S_-$ is true. But since V_0 is bang-bang we have $B_+=S_+$ and $B_-=S_-$. The reasoning above is valid for $i=1,...,m$.

Let y be any normalized eigenfunction in the eigenspace of $\lambda_2(V_0)$ so that

$$y=\sum_{i=1}^m \alpha_i y_{2,i}, \quad \sum_{i=1}^m |\alpha_i|^2=1,$$

$$\alpha=(\alpha_1,\alpha_2,\ldots,\alpha_m)\in R^n.$$

A straightforward calculation yields

$$\int_\Omega P(x)[y(x)^2-y_1(x)^2]\,dx=\sum_{1\leqslant i,j\leqslant m}\alpha_i\alpha_j\int_\Omega P(x)[y_{2,i}(x)y_{2,j}(x)-y_1^2(x)\,\delta_{ij}]\,dx=(B\alpha,\alpha)\geqslant 0$$

for any right-admissible perturbation P. Reasoning as above we find that $\{x\in\Omega,|y(x)|<y_1(x)\}=S_+$ and $\{x\in\Omega,|y(x)|>y_1(x)\}=S_-$. Since the interior of S_- (S_-^0) is not empty, we can find a point x_0 in S_-^0 such that $y_{2,1}(x_0)\neq 0$ and $y_{2,2}(x_0)\neq 0$. Let α_1 and α_2 be two nonzero reals such that $\alpha_1^2+\alpha_2^2=1$ and $\alpha_1 y_{2,1}(x_0)+\alpha_2 y_{2,2}(x_0)=0$, and consider the normalized eigenfunction $y=\alpha_1 y_{2,1}+\alpha_2 y_{2,2}$. Then we have $y(x_0)=0$ and $x_0\in S_-^0$, what is not compatible with the set equality: $S_-=\{x\in\Omega,|y(x)|>y_1(x)\}$. Consequently, $\lambda_2(V_0)$ is nondegenerate.

Let now y_2 be a normalized second eigenfunction for $\lambda_2(V_0)$ and suppose that V_0 is not bang-bang. Reasoning as above we arrive at

$$y_2^2(x)-y_1^2(x)=C \quad \text{in } \mathcal{O},$$

for some constant $C\neq 0$. This implies that $\Delta(y_2^2-y_1^2)=0$ in $\mathcal{O}$. However,

$$\Delta y_2^2=2|\nabla y_2|^2+2y_2\Delta y_2=2|\nabla y_2|^2+2(V_0-\lambda_2)y_2^2,$$

and similarly

$$\Delta y_1^2=2|\nabla y_1|^2+2(V_0-\lambda_1)y_1^2$$

in $\mathcal{O}$. Therefore,

$$V_0(x)=C^{-1}[(\lambda_2 y_2^2(x)-\lambda_1 y_1^2(x))-(|\nabla y_2(x)|^2-|\nabla y_1(x)|^2)]$$

in $\mathcal{O}$. Since y_1 and y_2 are $C^1(\Omega)$, we deduce that V_0 is continuous on $\mathcal{O}$. Repeating this argument leads to the conclusion that $V_0 \in C^k(\Omega)$ for any $k \geqslant 1$, which proves (b).

Remark: In the foregoing theorem we have proven that the degenerate case is excluded. Moreover, the argument used in the second part of the proof shows that one of the following cases,

$$\{|y_{2,1}|<y_1\}=S_+ \quad \text{or} \quad \{|y_{2,1}|>y_1\}=S_- \quad \text{a.e.},$$

must hold. S_+ and S_- are defined by (3.7) and (3.8), respectively. The remaining question is to know whether the potential V_0 is bang-bang. The answer is not clear even in the one-dimensional case.

Theorem 3.2: *Under the assumptions of the last theorem, if a function V_0 minimizes Γ over K_α, $\alpha>1$, then (a) $\lambda_2(V_0)$ is nondegenerate (b) In any open domain $\mathcal{O}$ in which V_0 does not equal 0 and H, V_0 is infinitely differentiable. Furthermore, y_1, y_2, and V_0 are related in $\mathcal{O}$ by*

$$y_2^2(x)-y_1^2(x)=CV_0(x)^{\alpha-1}$$

for some nonzero constant C, where y_1 (resp. y_2) is a normalized first (resp. second) eigenfunction for $\lambda_1(V_0)$ (resp. $\lambda_2(V_0)$).

The proof is entirely analogous to the one given above. To conclude that V_0 is infinitely differentiable we must take into account the fact that $y_2^2(x)$ cannot be equal to $y_1^2(x)$ for some x in $\mathcal{O}$ since $C \neq 0$.

Theorem 3.3: *Under the assumptions of Theorem 3.1, if a function V^0 maximizes Γ over K_1, then in any open domain $\mathcal{O}$ in which V_0 does not achieve 0 and H, it is infinitely differentiable. If $\lambda_2(V^0)$ is m-fold degenerate, then there exist m reals $s_1, s_2, \ldots, s_m$, such that*

$$\sum_{1 \leqslant i \leqslant m} s_i[y_{2,i}^2(x)-y_1^2(x)]=C \quad \text{in } \mathcal{O}$$

for some constant $C \neq 0$. $\{y_{2,j}\}_{i=1}^m$ is an eigenbasis for $\lambda_2(V^0)$.

Proof: Suppose that V^0 is m-fold degenerate. We have already seen that $\lambda_2(V^0)$ can split into a cluster of m eigenvalues $\lambda_{2,j}$ near $t=0$ and that if Γ_j denotes the gap $\lambda_{2,j}-\lambda_1$,

$$\Gamma_j(V^0+tP)=\Gamma(V^0)+t\nu_j+o(t),$$

where ν_j $(j=1,\ldots,m)$ are the eigenvalues of the self-adjoint matrix B with entires given by (3.2). Since V^0 maximizes Γ over K_1, for every admissible perturbation P there exist at least two eigenvalues ν_i and ν_j such that

$$\nu_i \nu_j \leqslant 0.$$

Let $\mathcal{O}$ be an open domain in which V_0 is between 0 and H. Let us consider the system of functions g_{ij} $(1 \leqslant i \leqslant j \leqslant m)$ defined by

$$g_{ij}=[y_{2,i}(x)y_{2,j}(x)-y_1^2(x)\delta_{ij}]\chi_{\mathcal{O}}, \quad 1 \leqslant i \leqslant j \leqslant m,$$

and $g_0=\chi_{\mathcal{O}}$. We prove that if g_0 and g_{ij} $(1 \leqslant i \leqslant j \leqslant m)$ are linearly independent, then there exists a bounded measurable function P defined on Ω such that supp $P \subset \overline{\mathcal{O}}$ and

$$\int_{\mathcal{O}} P(x)dx=0, \quad \int_{\mathcal{O}} P(x)g_{ij}(x)dx=\beta\delta_{ij}, \quad 1 \leqslant i \leqslant j \leqslant m,$$

where β is a given positive constant. The idea, based on Hahn–Banach theorem, is close to that used in Ref. 14 for solving a one-dimensional optimization problem.

The functions g_0 and g_{ij} are obviously in $L^1(\mathcal{O})$. Let $\mathcal{M}$ be the linear space formed by those functions and define the linear functional $F:\mathcal{M}\to R$ by $F(g_{ij})=\beta\delta_{ij}$ for $1\leqslant i\leqslant j\leqslant m$ and $F(g_0)=0$. For $g\in\mathcal{M}$, $g=\Sigma_{1\leqslant i\leqslant j\leqslant m}c_{ij}g_{ij}+c_0g_0$, we have

$$F(g)=\sum_{1\leqslant i\leqslant j\leqslant m} c_{ij}F(g_{ij})+c_0F(g_0)=\beta\sum_{i=1}^{m} c_{ii},$$

so the functional is well defined on $\mathcal{M}$. To prove the continuity of F, it is sufficient to find a number d for which

$$|F(g)|=\beta\left|\sum_{i=1}^{m} c_{ii}\right|\leqslant d\int_{\mathcal{O}}\sum_{1\leqslant i\leqslant j\leqslant m}|c_{ij}g_{ij}+c_0g_0|\,dx$$

for all $g\in\mathcal{M}$. This number can be chosen as

$$d=\sup_{\Sigma_{1\leqslant i\leqslant j\leqslant m}|c_{ij}|+|c_0|=1}\beta\left|\sum_{i=1}^{m} c_{ii}\right|\left(\int_{\mathcal{O}}\left|\sum_{1\leqslant i\leqslant j\leqslant m} c_{ij}g_{ij}+c_0g_0\right|\,dx\right)^{-1}.$$

The supremum of the last expression is finite by the assumption of the linear independence of the system of functions g_0 and g_{ij} $(1\leqslant i\leqslant j\leqslant m)$, which proves the continuity of F. The functional F constructed on the set $\mathcal{M}$ can, by the Hahn–Banach theorem, be extended by a continuous linear functional over the whole space $L^1(\mathcal{O})$. Therefore, there exists a function $P^*\in L^\infty(\mathcal{O})$ such that

$$\int_{\mathcal{O}}P^*(x)\,dx=0,\quad F(g)=\int_{\mathcal{O}}P^*(x)g(x)\,dx$$

for all $g\in\mathcal{M}$. If we extend the function P^* to the whole domain Ω by zero, we obtain a new function $P\in L^\infty(\Omega)$ satisfying

$$\text{Supp } P\subset\overline{\mathcal{O}},\quad \int_{\Omega}P(x)\,dx=0, \tag{3.9}$$

$$\int_{\Omega}P(x)[y_{2,i}y_{2,j}-y_1^2\delta_{ij}]\,dx=\beta\delta_{ij}. \tag{3.10}$$

Conditions (3.9) imply that P is an admissible perturbation and (3.10) show that the eigenvalues ν_j of the matrix B are all equal to β, i.e., the matrix B is positive definite, which is impossible. Consequently, g_0 and g_{ij} $(1\leqslant i\leqslant j\leqslant m)$ must be linearly dependent, i.e., there exist r_0 and r_{ij} $(1\leqslant i\leqslant j\leqslant m)$ nonzero reals such that

$$\sum_{1\leqslant i\leqslant j\leqslant m} r_{ij}g_{ij}(x)=r_0\quad\text{in }\mathcal{O}.$$

This expression can be written in a convenable orthonormal eigenbasis $\{z_{2,i}\}_{i=1}^m$ of $\lambda_2(V^0)$ as

$$\sum_{i=1}^{m} s_i(z_{2,i}^2-z_1^2)=s_0\quad\text{in }\mathcal{O}, \tag{3.11}$$

for some nonzero constants s_0 and s_i $(i=1,...,m)$. In (3.11), $z_1(x)=y_1(x)$. Reasoning as in the proof of Theorem 3.1, we find that

$$V^0(x)=s_0^{-1}\left(\lambda_2\sum_{i=1}^{m} z_{2,i}^2(x)-\lambda_1z_1^2(x)\right)-s_0^{-1}\left(\sum_{i=1}^{m}|\nabla z_{2,i}(x)|^2-|\nabla z_1(x)|^2\right)$$

in $\mathcal{O}$, which proves that V^0 is infinitely differentiable in $\mathcal{O}$.

I. INTRODUCTION

In this work we develop the perturbation theory for the two-component hyperbolic Dirac equation:

$$\begin{pmatrix} \partial_\xi & 0 \\ 0 & \partial_\eta \end{pmatrix} \psi = -\frac{1}{2} \begin{pmatrix} 0 & q_1 \\ q_2 & 0 \end{pmatrix} \psi. \tag{1}$$

We have constructed the basis functions using formulas of the potential variations and of the scattering data variations. If we take into account $q_1 = Q$ and $q_2 = \sigma\overline{Q}$ (here the overbar denotes the complex conjugation), where the time evolution of Q is given by the Davey–Stewartson I equation (DS-I),[1,2]

$$\begin{gathered} i\partial_t Q + (\partial_\xi^2 + \partial_\eta^2)Q + (g_1 + g_2)Q = 0, \\ \partial_\xi g_1 = -\frac{\sigma}{2}\,\partial_\eta |Q|^2, \quad \partial_\eta g_2 = -\frac{\sigma}{2}\,\partial_\xi |Q|^2, \quad \sigma = \pm 1, \end{gathered} \tag{2}$$

then these basis functions make it possible to solve the DS-I equation linearized at Q and g_{12} as a background (LDS-I),

$$\begin{gathered} i\partial_t U + (\partial_\xi^2 + \partial_\eta^2)U + (g_1 + g_2)U + (V_1 + V_2)Q = F(\xi, \eta, t), \\ \partial_\xi V_1 = -\frac{\sigma}{2}\,\partial_\eta(Q\overline{U} + \overline{Q}U), \quad \partial_\eta V_2 = -\frac{\sigma}{2}\,\partial_\xi(Q\overline{U} + \overline{Q}U), \end{gathered} \tag{3}$$

by the Fourier method. These are two main results of the work, which are accurately formulated in Theorems 1 and 2.

The Davey–Stewartson equation (2) and the auxiliary linear system (1) were studied in Refs. 3–7. A system more general than (1) was studied in Ref. 8 as an auxiliary linear system for the three-wave interaction equation. A Hamiltonian structure and some properties of solutions for the Davey–Stewartson equation were studied in Refs. 9–12. A useful auxiliary linear system for a Davey–Stewartson hierarchy was studied in Ref. 13. Exact solutions of the equation were constructed in Refs. 14–17.

The results of the completeness for the squared solutions for the one-dimensional Dirac and Schrödinger equations were obtained in Refs. 18–23. They make it possible to solve the $1+1$-dimensional linearizations of the integrable equations and to investigate perturbations of the

$1+1$-dimensional integrable equations.[22,24–29] The same perturbation theory for the $2+1$-dimensional equation was obtained for the Kadomtsev–Petviashili equation and an auxiliary linear problem—a nonstationary Schrödinger equation in the periodic case.[30] We note also that the perturbation of the lump solution of the Davey–Stewartson II equation (which is found in Ref. 31) and the elliptic version of the two-component Dirac equation were investigated in Ref. 32.

In this work the results on the basis functions associated with the one-dimensional Dirac equation[18–20,22,23] are generalized to the two-dimensional Dirac equation. This makes it possible to solve the LDS-I equation by the Fourier method for arbitrary initial data and enables one to study a nonintegrable perturbation of some exact solutions for the DS-I in the same fashion as the perturbations of the $1+1$-dimensional integrable equations.[22–27]

There are two notes to be made now. First, the expansion on the basis functions is founded on the variation formulas for the potential and for the scattering data, hence the above expansion is the effect of a reversibility for the inverse scattering transform for (1), which was proved in Refs. 3 and 6. From this point of view we have constructed a reversible transform for the potential variations. Second, the result may be used for definition transform between the potentials and the Hamilton–Jacobi ''action-angle'' variables for the DS-I equation.[9,12]

In this work we use formulas of the inverse scattering transform for (2) from Refs. 3–7. The formulas are necessary for the accurate statement of the results for the paper. The main results of the work are formulated in Theorems 1 and 2 in the end of Sec. II. In Sec. III we deduce the formulas for the variations of the potential and of the scattering data. Section IV contains the theorem on the basic functions for finite potentials. In Sec. V we prove Theorem 1 through the approximation of an arbitrary integrable potential by a sequence of the finite potentials. Section VI contains the proof of Theorem 2.

II. THE MAIN RESULTS

After introducing some notations and results from the inverse scattering transform for the two-dimensional Dirac equation,[3–7] we state the main results of this paper in Theorems 1 and 2.

Let ψ^+ and ψ^- be the matrix solutions to the Goursat problems for the Dirac equation with the boundary conditions

$$\psi^+_{11}|_{\xi\to-\infty}=\exp\,(ik\eta),\quad \psi^+_{12}|_{\xi\to-\infty}=0,$$

$$\psi^+_{21}|_{\eta\to\infty}=0,\quad \psi^+_{22}|_{\eta\to-\infty}=\exp(-ik\xi);$$

$$\psi^-_{11}|_{\xi\to-\infty}=\exp(ik\eta),\quad \psi^-_{12}|_{\xi\to\infty}=0,$$

$$\psi^-_{21}|_{\eta\to-\infty}=0,\quad \psi^-_{22}|_{\eta\to-\infty}=\exp(-ik\xi).$$

These notations correspond to the notations in Ref. 5.

Denote by $\psi^+_{(j)}$, $j=1,2$, the column of the matrix ψ^+. Define the bilinear form:

$$(\chi,\mu)_q=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} d\xi\, d\eta(\chi_1\mu_1q_2+\chi_2\mu_2q_1). \tag{4}$$

Here χ_i and μ_i are elements of the columns χ and μ.

We denote by $\phi_{(1)}$ and $\phi_{(2)}$ the solutions conjugated to $\psi^+_{(1)}$ and $\psi^-_{(2)}$ with respect to bilinear form (4).

Using the formulas for the scattering data,[5] we can write the scattering data in the form

$$s_1(k,l)=\frac{1}{4\pi}\,(\psi^+_{(1)}(\xi,\eta,k),E_{(1)}(il\xi))_q, \tag{5}$$

$$s_2(k,l)=\frac{1}{4\pi}\,(\psi^-_{(2)}(\xi,\eta,k),E_{(2)}(il\eta))_q. \tag{6}$$

Here $E(z)=\mathrm{diag}\,(\exp(z),\exp(-z))$.

In Ref. 5 it was shown that the elements of matrix $\psi^{\pm}$ are analytic functions with respect to k at $\pm \mathrm{Im}(k)>0$. Using the scattering data, we can write the Riemann–Hilbert problem for ψ_{11}^{-} and ψ_{12}^{+} (see Ref. 5):

$$\psi_{11}^{-}(\xi,\eta,k)=\exp(ik\eta)+\exp(ik\eta)\left(\exp(-ik\eta)\int_{-\infty}^{\infty} dl\ s_1(k,l)\psi_{12}^{+}(\xi,\eta,l)\right)^{-},$$

$$\psi_{12}^{+}(\xi,\eta,k)=\exp(-ik\xi)\left(\exp(ik\xi)\int_{-\infty}^{\infty} dl\ s_2(k,l)\psi_{11}^{-}(\xi,\eta,l)\right)^{+}.$$

Here

$$(f(k))^{\pm}=\frac{1}{2i\pi}\int_{-\infty}^{\infty}\frac{dk'\ f(k')}{k'-(k\pm i0)}.$$

The Riemann–Hilbert problem for ψ_{21}^{-} and ψ_{22}^{+} is the following:

$$\psi_{21}^{-}(\xi,\eta,k)=\exp(ik\eta)\left(\exp(-ik\eta)\int_{-\infty}^{\infty} dl\ s_1(k,l)\psi_{22}^{+}(\xi,\eta,l)\right)^{-},$$

$$\psi_{22}^{+}(\xi,\eta,k)=\exp(-ik\xi)+\exp(-ik\xi)\left(\exp(ik\xi)\int_{-\infty}^{\infty} dl\, s_2(k,l)\psi_{21}^{-}(\xi,\eta,l)\right)^{+}.$$

Also, below we introduce the second bilinear form:

$$\langle\chi,\mu\rangle_s=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} dk\ dl\,(\chi^1(l)\mu^1(k)s_2(k,l)+\chi^2(l)\mu^2(k)s_1(k,l)), \tag{7}$$

where χ^j is the element of the row χ.

Denote by $\varphi^{(j)}$, $j=1,2$, the row conjugated to $\psi^{(j)}=[\psi_{j1}^{-},\psi_{j2}^{+}]$ with respect to the bilinear form (7). Now we formulate the main result.

Theorem 1: *Let q_1 and q_2 be such that $\partial^{\alpha}q_{1,2}\in L_1\cap C^1$ for $|\alpha|\leqslant 3$ if $h_1(\xi,\eta)$ and $h_2(\xi,\eta)$ satisfy the following conditions: $\partial^{\alpha}h_{1,2}\in L_1\cap C^1$ for $|\alpha|\leqslant 4$ then h_1 and h_2 may be represented in the form*

$$h_1=\frac{-1}{\pi}\langle\psi^{(1)}(\xi,\eta,l),\varphi^{(1)}(\xi,\eta,k)\rangle_{\hat{h}},\quad h_2=\frac{1}{\pi}\langle\psi^{(2)}(\xi,\eta,l),\varphi^{(2)}(\xi,\eta,k)\rangle_{\hat{h}},$$

where

$$\hat{h}_1=\frac{1}{4\pi}(\psi_{(1)}^{+}(\xi,\eta,k),\phi_{(1)}(\xi,\eta,l))_h,\quad \hat{h}_2=\frac{1}{4\pi}(\psi_{(2)}^{-}(\xi,\eta,k),\phi_{(2)}(\xi,\eta,l))_h.$$

The next statement makes it possible to solve the LDS-I equation by the Fourier method.

Theorem 2: *Let $q_1=Q$ and $q_2=\sigma\bar{Q}$ where Q is the solution of the DS-I equation with the boundary conditions $g_1|_{\xi\to-\infty}=0$ and $g_2|_{\eta\to-\infty}=0$, and Q satisfies the conditions of Theorem 1 at $t\in[0,T_0]$, $T_0>0$. If the solution of the LDS-I equation is the smooth and integrable function U with respect to ξ and η, where $\partial^{\alpha}U\in L_1\cap C^1$ and $\partial^{\alpha}F\in L_1\cap C^1$, for $|\alpha|\leqslant 4$ and $t\in[0,T_0]$, then*

$$\partial_t\hat{U}_1=i(k^2+l^2)\hat{U}_1+\hat{F}_1,$$

$$\partial_t\hat{U}_2=-i(k^2+l^2)\hat{U}_2+\hat{F}_2.$$

III. THE CONJUGATED FUNCTIONS AND VARIATIONS OF THE SCATTERING DATA

In this section we get the Volterra equations for the functions conjugated to $\psi^+_{(1)}$ and $\psi^-_{(2)}$ with respect to the first bilinear form (4). The next step is deduction of formulas for variations of the potentials and variations of the scattering data.

The Volterra equation for $\psi^+_{(1)}$ has the form

$$\psi^+_{(1)}(\xi,\eta,k)=E_{(1)}(ik\eta)+G_1[q]\psi^+_{(1)}.$$

Here $E_{(j)}(z)$ is the jth column of the matrix $E(z)$ and the operator $G_1[q]$ is

$$G_1[q]\psi^+_{(1)}=-\frac{1}{2}\begin{bmatrix}\int_{-\infty}^{\xi} d\xi'\ q_1(\xi',\eta)\psi^+_{21}(\xi',\eta,k)\\ \int_{-\infty}^{\eta} d\eta'\ q_2(\xi,\eta')\psi^+_{11}(\xi,\eta',k)\end{bmatrix}.$$

The operator conjugated to G_1 with respect to (4) is defined by the formula

$$(G_1[q]\mu,\chi)_q=(\mu,H_1[q]\chi)_q.$$

The column $\phi_{(1)}$ conjugated to $\psi^+_{(1)}$ is the solution of the equation

$$\phi_{(1)}(\xi,\eta,k)=E_{(1)}(ik\xi)+H_1[q]\phi_{(1)}.$$

Now we consider the variation formulas. Let δq_i be the variation of the potential. The equation for the variation of $\psi^+_{(1)}$ has the form

$$\delta\psi^+_{(1)}=G_1[q]\delta\psi^+_{(1)}+G_1[\delta q]\psi^+_{(1)}. \tag{8}$$

Compute the bilinear form:

$$(\delta\psi^+_{(1)}(\xi,\eta,k),\phi_{(1)}(\xi,\eta,l))_q=(G_1[q]\delta\psi^+_{(1)},\phi_{(1)})_q+(G_1[\delta q]\psi^+_{(1)},\phi_{(1)})_q.$$

After evaluations we obtain

$$(\psi^+_{(1)}(\xi,\eta,k),\phi_{(1)}(\xi,\eta,l))_{\delta q}=(\delta\psi^+_{(1)}(\xi,\eta,k),E_{(1)}(il\xi))_q+(\psi^+_{(1)}(\xi,\eta,k),E_{(1)}(il\xi))_{\delta q}.$$

On the other hand, we can derive the variation of $s_1(k,l)$:

$$\delta s_1(k,l)=\frac{1}{4\pi}(\delta\psi^+_{(1)}(\xi,\eta,k),E_{(1)}(il\xi))_q+\frac{1}{4\pi}(\psi^+_{(1)}(\xi,\eta,k),E_{(1)}(il\xi))_{\delta q}.$$

It yields

$$\delta s_1(k,l)=\frac{1}{4\pi}(\psi^+_{(1)}(\xi,\eta,k),\phi_{(1)}(\xi,\eta,l))_{\delta q}. \tag{9}$$

So, we have the formula connecting the variations of the potentials with the variation of $s_1(k,l)$.

The second formula for the variation of the scattering data is obtained in a similar manner from the Volterra equation for $\psi^-_{(2)}$:

$$\psi^-_{(2)}(\xi,\eta,k)=E_{(2)}(ik\eta)+G_2[q]\psi^-_{(2)}.$$

Here

$$G_2[q]\psi^-_{(2)}=-\frac{1}{2}\begin{bmatrix} -\int_\xi^\infty d\xi' q_1(\xi',\eta)\psi^-_{22}(\xi',\eta,k) \\ \int_{-\infty}^\eta d\eta' q_2(\xi,\eta')\psi^-_{12}(\xi,\eta',k) \end{bmatrix}.$$

The column $\phi_{(2)}$ is conjugated to $\psi^-_{(2)}$. The variation formula for $s_2(k,l)$ has the form

$$\delta s_2(k,l)=\frac{1}{4\pi}(\psi^-_{(2)}(\xi,\eta,k),\phi_{(2)}(\xi,\eta,l))_{\delta q}. \tag{10}$$

Now we construct the functions conjugated with respect to the second bilinear form (7). In this way we get the formulas connecting the scattering data variations and the potential variations. These formulas are the mapping of the scattering data variations into the potential variations.

The formulas for the potentials are obtained in Ref. 5. Using the second bilinear form (7), we write them in the form

$$q_1(\xi,\eta)=\frac{-1}{\pi}\langle\Psi^{(1)}(\xi,\eta,l),E^{(1)}(ik\xi)\rangle_s, \tag{11}$$

$$q_2(\xi,\eta)=\frac{1}{\pi}\langle\Psi^{(2)}(\xi,\eta,l),E^{(2)}(ik\eta)\rangle_s. \tag{12}$$

Where $\psi^{(j)}$ is the row $[\psi^-_{j1},\psi^+_{j2}]$, analogously $E^{(j)}(z)$ is the row of the matrix $E(z)$.

From (11) the variation of the potential is

$$\delta q_1=\frac{-1}{\pi}\langle\delta\psi^{(1)}(\xi,\eta,l),E^{(1)}(ik\xi)\rangle_s-\frac{1}{\pi}\langle\psi^{(1)}(\xi,\eta,l),E^{(1)}(ik\xi)\rangle_{\delta s}.$$

Consider the Riemann–Hilbert problem for the row $\psi^{(1)}=[\psi^-_{11},\psi^+_{12}]$:

$$\psi^{(1)}=E^{(1)}(ik\eta)+S[s]\psi^{(1)}.$$

Here $E^{(1)}(z)$ is the first row of the matrix $E(z)$ and operator $S[s]$ is defined by the formula

$$S[s]\psi^{(1)}=\Bigg[\exp(ik\eta)\Bigg(\exp(-ik\eta)\int_{-\infty}^\infty dls_1(k,l)\psi^+_{12}(\xi,\eta,l)\Bigg)^-,$$

$$\exp(-ik\xi)\Bigg(\exp(ik\xi)\int_{-\infty}^\infty dls_2(k,l)\psi^-_{11}(\xi,\eta,l)\Bigg)^+\Bigg].$$

The row conjugated to $\psi^{(1)}$ with respect to the second bilinear form (7) satisfies the Riemann–Hilbert problem:

$$\varphi^{(1)}(\xi,\eta,l)=E^{(1)}(il\xi)+T[s]\varphi^{(1)}.$$

Here

$$T[s]\varphi^{(1)}=\Bigg[-\exp(il\xi)\Bigg(\exp(-il\xi)\int_{-\infty}^\infty dks_1(k,l)\varphi^{(1)}_2(\xi,\sigma,k)\Bigg)^-,$$

$$-\exp(-il\eta)\Bigg(\exp(il\eta)\int_{-\infty}^\infty dks_2(k,l)\varphi^{(1)}_1(\xi,\eta,k)\Bigg)^+\Bigg],$$

where $\varphi^{(1)}_j$, $j=1,2$, is a component of the row $\varphi^{(1)}$.

Let δs_1 and δs_2 be the variations of the scattering data. The equation for the variation of the row $\psi^{(1)}$ has the form

$$\delta\psi^{(1)}(\xi,\eta,l)=S[s]\delta\psi^{(1)}+S[\delta s]\psi^{(1)}.$$

Compute the bilinear form:

$$\langle\delta\psi^{(1)}(\xi,\eta,l),\varphi^{(1)}(\xi,\eta,k)\rangle_s=\langle S[s]\delta\psi^{(1)},E^{(1)}(ik\xi)\rangle_s+\langle\psi^{(1)}(\xi,\eta,l),E^{(1)}(ik\xi)\rangle_{\delta s}.$$

From (11) after evaluations we obtain

$$\delta q_1=\frac{-1}{\pi}\langle\psi^{(1)}(\xi,\eta,l),\varphi^{(1)}(\xi,\eta,k)\rangle_{\delta s}. \tag{13}$$

In a similar manner we define the row $\phi^{(2)}$ conjugated to $\psi^{(2)}=[\psi^-_{21},\psi^-_{22}]$. The formula for the variation of q_2 has the form

$$\delta q_2=\frac{1}{\pi}\langle\psi^{(2)}(\xi,\eta,l),\varphi^{(2)}(\xi,\eta,k)\rangle_{\delta s}. \tag{14}$$

The formulas (9) and (10) define the mapping of the variations of the potentials into the variations of the scattering data, and the inverse map is defined by the formulas (13) and (14).

IV. THE FINITE POTENTIALS

In this section we prove that the formulas (9), (10), (13), and (14) define an expansion through the basis functions.

Denote $\delta q_i=f_i$, $i=1,2$. The composition of the formulas (13), (14), (9), and (10) are

$$\begin{aligned}
\hat f_1&=\frac{1}{4\pi}(\psi^+_{(1)}(\xi,\eta,k),\phi_{(1)}(\xi,\eta,l))_f,\\
\hat f_2&=\frac{1}{4\pi}(\psi^-_{(2)}(\xi,\eta,k),\phi_{(2)}(\xi,\eta,l))_f;\\
h_1&=\frac{-1}{\pi}\langle\psi^{(1)}(\xi,\eta,l),\varphi^{(1)}(\xi,\eta,k)\rangle_{\hat f},\\
h_2&=\frac{1}{\pi}\langle\psi^{(2)}(\xi,\eta,l),\varphi^{(2)}(\xi,\eta,k)\rangle_{\hat f}.
\end{aligned} \tag{15}$$

Our purpose is to show the equivalence $h_i\equiv f_i$. The proof is based on two properties of the elements of the matrix ϕ and ψ. The first property is the analyticity of the functions with respect to $k,l\in\mathbb{C}$, if q_1 and q_2 have a finite support. The analyticity is evident from the Volterra equations for these functions. The second property is the asymptotic behavior of ϕ and ψ at $|k|$ or $|l|\to\infty$.

The asymptotics of $\psi^{\pm}_{(1)}$ and $\psi^{\pm}_{(2)}$ are obtained in Ref. 5:

$$\psi^{\pm}_{(1)}(\xi,\eta,k)=\left(\begin{bmatrix}1\\0\end{bmatrix}+\frac{1}{k}\begin{bmatrix}\dfrac{-i}{4}\displaystyle\int_{-\infty}^{\xi}d\xi'\ q_1(\xi',\eta)q_2(\xi',\eta)\\ \dfrac{i}{2}q_2\end{bmatrix}+O\left(\frac{1}{k^2}\right)\right)\exp(ik\eta),$$

$$\psi^{\mp}_{(2)}(\xi,\eta,k)=\left(\begin{bmatrix}0\\1\end{bmatrix}+\frac{1}{k}\begin{bmatrix}\dfrac{-i}{2}q_1\\ \dfrac{i}{4}\displaystyle\int_{-\infty}^{\eta}d\eta'\ q_1(\xi,\eta')q_2(\xi,\eta')\end{bmatrix}+O\left(\frac{1}{k^2}\right)\right)\exp(-ik\xi).$$

The columns $\phi_{(1)}$ and $\phi_{(2)}$ have the same asymptotic behavior:

$$\phi_{(1)}(\xi,\eta,k)=\left(\begin{bmatrix}1\\0\end{bmatrix}+\frac{1}{k}\begin{bmatrix}\dfrac{-i}{4}\displaystyle\int_{-\infty}^{\eta}d\eta'\ q_1(\xi,\eta')q_2(\xi,\eta')\\ \dfrac{-i}{2}\,q_2\end{bmatrix}+O\left(\frac{1}{k^2}\right)\right)\exp(ik\xi),$$

$$\phi_{(2)}(\xi,\eta,k)=\left(\begin{bmatrix}0\\1\end{bmatrix}+\frac{1}{k}\begin{bmatrix}\dfrac{i}{2}\,q_1\\ \dfrac{i}{4}\displaystyle\int_{-\infty}^{\xi}d\xi\ q_1(\xi',\eta)q_2(\xi',\eta)\end{bmatrix}+O\left(\frac{1}{k^2}\right)\right)\exp(-ik\eta).$$

Construct the asymptotics of $\varphi^{(1)}$ at $|k|\to\infty$. The leading term and the correction of the asymptotic behavior are the following:

$$\varphi^{(1)}(\xi,\eta,k)=\Bigg([\exp(ik\xi),0]+\frac{1}{k}\Bigg[\frac{1}{2i\pi}\exp(ik\xi)\int_{-\infty}^{\infty}dk'\int_{-\infty}^{\infty}dl\ s_1(l,k')\varphi_2^{(1)}\times(\xi,\eta,l)\exp(ik'\xi),\ \frac{1}{2i\pi}\exp(-ik\eta)\int_{-\infty}^{\infty}dk'\int_{-\infty}^{\infty}dl\ s_2(l,k')\varphi_1^{(1)}(\xi,\eta,l)\exp(ik'\eta)\Bigg]+O\left(\frac{1}{k^2}\right).$$

On the other hand,

$$q_1=\frac{-1}{\pi}\langle E^{(1)}(il\eta),\varphi^{(1)}(\xi,\eta,k)\rangle_s,$$

$$\int_{-\infty}^{\eta}d\eta'\ q_1(\xi,\eta')q_2(\xi,\eta')=\frac{2}{\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}dl\ dk\ s_2(k,l)\exp(ik\xi)\psi_{21}^{-}(\xi,\eta,l).$$

The second of these formulas was obtained in Ref. 5. It yields

$$\int_{-\infty}^{\eta}d\eta'\ q_1(\xi,\eta')q_2(\xi,\eta')=\frac{2}{\pi}\langle\psi^{(2)}(\xi,\eta,l),E^{(1)}(ik\xi)\rangle_s=\frac{2}{\pi}\langle E^{(2)}(il\eta),\varphi^{(1)}(\xi,\eta,k)\rangle_s.$$

The asymptotic of the $\varphi^{(1)}$ at $|k|\to\infty$ has the form

$$\varphi^{(1)}(\xi,\eta,k)=[\exp(ik\xi),0]+\frac{1}{k}\left[\frac{\exp(ik\xi)}{4i}\int_{-\infty}^{\eta}d\eta'\ q_1(\xi,\eta')q_2(\xi,\eta),\ \frac{\exp(-ik\eta)}{-2i}\,q_1\right]+O\left(\frac{1}{k^2}\right).$$

In a similar manner we obtain the asymptotic behavior of $\varphi^{(1)}$ at $|k|\to\infty$:

$$\varphi^{(2)}(\xi,\eta,k)=[0,\exp(-ik\eta)]+\frac{1}{k}\left[\frac{\exp(ik\xi)}{2i}\,q_2,\quad\frac{\exp(-ik\eta)}{-4i}\int_{-\infty}^{\xi}d\xi'\ q_1(\xi',\eta)q_2(\xi',\eta)\right]+O\left(\frac{1}{k^2}\right).$$

Prove the equivalence $h_i=f_i$. The composition of the formulas (13), (9), and (10) gives

$$h_1=\frac{1}{4\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}dk\ dl\Big(\psi_1^{(1)}(\xi,\eta,l)\varphi_1^{(1)}(\xi,\eta,k)$$

$$\times\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}d\xi'\ d\eta'[\psi^1_{(2)}(\xi',\eta',k)\phi^1_{(2)}(\xi',\eta',l)f_2(\xi',\eta')$$

$$+\psi^2_{(2)}(\xi',\eta',k)\phi^2_{(2)}(\xi',\eta',l)f_1(\xi',\eta')]+\psi^{(1)}_2(\xi,\eta,l)\varphi^{(1)}_2$$

$$\times(\xi,\eta,k)\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}d\xi'\ d\eta'[\psi^1_{(1)}(\xi',\eta',k)\phi^1_{(1)}(\xi',\eta',l)f_2(\xi',\eta')$$

$$+\psi^2_{(1)}(\xi',\eta',k)\phi^2_{(1)}(\xi',\eta',l)f_1(\xi',\eta')]\Bigg).$$

Represent the integrals with respect to k and l as a divergent improper integrals:

$$\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}dk\ dl(\cdots)=\lim_{R\to\infty}\int_{-R}^{R}\int_{-R}^{R}dk\ dl(\cdots).$$

Replace the integrals with respect to ξ' and η' with the integrals with respect to k and l. The integrand is an analytic function with respect to k and l as k and $l\in\mathbb{C}$. Hence we can transform the paths of the integration with respect to k and l to large semicircles in the upper or lower half-planes of the complex parameters k and l. We denote the paths of the integration by C_R^+ or C_R^-. We represent the integrals with respect to ξ' and η' as the sum of the integrals over $\xi'\in(-\infty,\xi]$, $\eta'\in(-\infty,\eta]$ and $\xi'\in(\xi,\infty)$, $\eta'\in(\eta,\infty)$. Transform the path of the integration with respect to k and l to C_R^+ or C_R^-, respectively. Substitute the asymptotics of the integrand at $|k|\to\infty$ and $|l|\to\infty$. As a result we obtain

$$h=\frac{1}{4\pi}\lim_{R\to\infty}\Bigg[\Bigg(\int_{-\infty}^{\xi}\int_{-\infty}^{\eta}d\xi'\ d\eta'\ f_2(f',\eta')\int_{C_R^+}dk\int_{C_R^+}dl$$

$$+\int_{\xi}^{\infty}\int_{\eta}^{\infty}d\xi'\ d\eta'\ f_2(\xi',\eta')\int_{C_R^-}dk\int_{C_R^-}dl\Bigg)$$

$$\times\left[\frac{\exp(il(\eta-\eta'))}{l}\,\frac{i}{2}\,q_1(\xi',\eta')\,\frac{\exp(ik(\xi-\xi'))}{k}\,\frac{-i}{2}\,q_1(\xi',\eta')\right]$$

$$+\Bigg(\int_{-\infty}^{\xi}\int_{-\infty}^{\eta}d\xi'\ d\eta'\ f_2(\xi',\eta')\int_{C_R^+}dk\int_{C_R^+}dl+\int_{\xi}^{\infty}\int_{\eta}^{\infty}d\xi'\ d\eta'\ f_2(\xi',\eta')\int_{C_R^-}dk\int_{C_R^-}dl\Bigg)$$

$$\times\left[\frac{\exp(il(\xi'-\xi))}{l}\,\frac{-i}{2}\,q_1(\xi,\eta)\,\frac{\exp(ik(\eta'-\eta))}{k}\,\frac{i}{2}\,q_1(\xi,\eta)\right]$$

$$+\Bigg(\int_{-\infty}^{\xi}\int_{-\infty}^{\eta}d\xi'\ d\eta'\ f_1(\xi',\eta')\int_{C_R^+}dk\int_{C_R^+}dl+\int_{\xi}^{\infty}\int_{\eta}^{\infty}d\xi'\ d\eta'\ f_1(\xi',\eta')\int_{C_R^-}dk\int_{C_R^-}dl\Bigg)$$

$$\times f_1(\xi',\eta')\int_{C_R}dk\int_{C_R}dl\Bigg[\left(1+\frac{1}{l}\,\frac{-i}{4}\int_{-\infty}^{\xi}d\xi''\ q_1(\xi'',\eta)q_2(\xi'',\eta)\right)$$

$$\times\exp(il\eta)\left(1+\frac{1}{k}\,\frac{1}{4i}\int_{-\infty}^{\eta}d\eta''\ q_1(\xi,\eta'')q_2(\xi,\eta'')\right)$$

$$\times\exp(ik\xi)\left(1+\frac{1}{k}\,\frac{i}{4}\int_{-\infty}^{\eta'}d\eta''\ q_1(\xi',\eta'')q_2(\xi',\eta'')\right)$$

$$\times\exp(-ik\xi')\left(1+\frac{1}{l}\,\frac{i}{4}\int_{-\infty}^{\xi'}d\xi''\ q_1(\xi'',\eta')q_2(\xi'',\eta')\right)\exp(-il\eta')\Bigg]\Bigg].$$

Then transform the paths of integration to the axis $\mathrm{Im}(l)=0$ and $\mathrm{Im}(k)=0$. It yields

$$h=\frac{1}{4\pi}\lim_{R\to\infty}\int_{-\infty}^{\infty}d\xi'\int_{-\infty}^{\infty}d\eta'\int_{-R}^{R}dk\int_{-R}^{R}dl\ f_1(\xi',\eta')\exp(il(\eta-\eta'))\exp(ik(\xi-\xi'))=f_1.$$

Thus we have proved the statement.

Theorem 3: *Let q_1 and q_2 be smooth functions with finite support. If f_1 and f_2 are smooth integrable functions with respect to $\xi,\eta\in\mathbb{R}$, then we may represent f_1 and f_2 in the form*

$$f_1=\frac{-1}{\pi}\langle\psi^{(1)}(\xi,\eta,l),\varphi^{(1)}(\xi,\eta,k)\rangle_{\hat{f}},\quad f_2=\frac{1}{\pi}\langle\psi^{(2)}(\xi,\eta,l),\varphi^{(2)}(\xi,\sigma,k)\rangle_{\hat{f}},$$

where

$$\hat{f}_1=\frac{1}{4\pi}(\psi^{+}_{(1)}(\xi,\eta,k),\phi_{(1)}(\xi,\eta,l))_f,\quad \hat{f}_2=\frac{1}{4\pi}(\psi^{-}_{(2)}(\xi,\eta,k),\phi_{(2)}(\xi,\eta,l))_f.$$

V. THE COMPLETENESS THEOREM

In the above section we proved the theorem of the representation of functions from $L_1\cap C^1$ through basis functions connecting with the Dirac system, when $q_{1,2}$ has a finite support. Here it is shown that this expansion is appropriate for the more general-type potentials. In this case there are additional restrictions on the functions to be expanded.

To prove Theorem 1 we approximate the potentials q_1 and q_2 by the potentials $\overset{N}{q}_1$ and $\overset{N}{q}_2$ with finite support. For $\varepsilon>0$ we take $N(\varepsilon)>0$ such that $\|\partial^\alpha\overset{N}{q}_{1,2}-\partial^\alpha q_{1,2}\|_{L_1}=O(\varepsilon)$, where $|\alpha|\leqslant 3$ and $\overset{N}{q}_{1,2}=q_{1,2}$ for $\xi^2+\eta^2\leqslant N(\varepsilon)$; and $\overset{N}{q}_{1,2}=0$ for $\xi^2+\eta^2>2N(\varepsilon)$. We denote an error of the approximation by $\overset{\varepsilon}{q}_{1,2}=q_{1,2}-\overset{N}{q}_{1,2}$. Throughout in this section we use a notation with an upper symbol N for solutions of the Goursat problems with potentials $\overset{N}{q}_{1,2}$. The upper symbol ε denotes functions associated with the approximation error $\overset{\varepsilon}{q}_{1,2}$.

Lemma 1: $\|\overset{N}{\psi}{}^{\pm}_{ij}-\psi^{\pm}_{ij}\|_{C^3}=O(\varepsilon)$, *for* $i,j=1,2$. *Here* $\overset{N}{\psi}{}^{\pm}_{ij}$ *are elements of the matrices being the solutions of the Goursat problems with the potentials* $\overset{N}{q}_1$ *and* $\overset{N}{q}_2$.

The proof: Denote by $\chi^{\pm}$ an expression

$$\chi^{\pm}(\xi,\eta,k)=\begin{pmatrix}\exp(-ik\eta) & 0\\ 0 & \exp(ik\xi)\end{pmatrix}\psi^{\pm}(\xi,,\eta,k). \tag{16}$$

Represent the matrix $\chi^{\pm}$ in a form $\chi^{\pm}=\overset{N}{\chi}{}^{\pm}+\overset{\varepsilon}{\chi}{}^{\pm}$. Here $\overset{N}{\chi}{}^{\pm}$ has the same representation through $\overset{N}{\psi}$ as (16). The Volterra equations for the column $\overset{\varepsilon}{\chi}{}^{+}_{(1)}$ have the form

$$\overset{\varepsilon}{\chi}{}^{+}_{(1)}=\overset{\varepsilon}{\mathscr{G}}_1[q]\overset{N}{\chi}{}^{+}_{(1)}+\overset{\varepsilon}{\mathscr{G}}_1[q]\overset{\varepsilon}{\chi}{}^{+}_{(1)}, \tag{17}$$

where

$$\overset{\varepsilon}{\mathscr{G}}_1[q]\overset{\varepsilon}{\chi}{}^{+}_{(1)}=\frac{1}{2}\begin{pmatrix}-\int_{-\infty}^{\xi}d\xi'\ q_1(\xi',\eta)\overset{\varepsilon}{\chi}{}^{+}_{21}(\xi',\eta,k)\\ \int_{\eta}^{\infty}d\eta'\ q_2(\xi,\eta')\overset{\varepsilon}{\chi}{}^{+}_{11}(\xi,\eta',k)\exp(ik(\eta'-\eta))\end{pmatrix}.$$

The Neyman series for this system converge and $|\overset{\varepsilon}{\chi}{}^{+}_{11}|+|\overset{\varepsilon}{\chi}{}^{+}_{21}|=O(\varepsilon)$ for $\forall \xi,\eta\in\mathbb{R}$. The same estimates are also true for derivatives: $|\partial^{\alpha}\overset{\varepsilon}{\chi}{}^{+}_{11}|+|\partial^{\alpha}\overset{\varepsilon}{\chi}{}^{+}_{21}|=O(\varepsilon)$ for $\forall \xi,\eta\in\mathbb{R}$ as $|\alpha|\leqslant 3$.

Similar results are obtained for $\overset{\varepsilon}{\chi}{}^{\pm}_{(2)}$ and $\overset{\varepsilon}{\chi}{}^{-}_{(1)}$. Hence the lemma is proved.

Below we shall use the asymptotic behavior of the $\overset{\varepsilon}{\chi}{}^{\pm}$ when $|k|\to\infty$.

Lemma 2: When $|k|\to\infty$ the asymptotic behavior of $\overset{\varepsilon}{\chi}{}^{\pm}$ has the form

$$\overset{\varepsilon}{\chi}{}^{\pm}_{(1)}=\frac{1}{k}\begin{pmatrix} -\frac{i}{4}\int_{-\infty}^{\xi} d\xi'(\overset{\varepsilon}{q}_1\overset{N}{q}_2+\overset{\varepsilon}{q}_2q_1) \\ \frac{i}{2}\overset{\varepsilon}{q}_2 \end{pmatrix}+O(k^{-2}). \tag{18}$$

The formula is true uniformly with respect to $\xi,\eta\in\mathbb{R}$. The remainder is differentiable with respect to ξ:

$$\overset{\varepsilon}{\chi}{}^{\pm}_{(2)}=\frac{1}{k}\begin{pmatrix} \frac{-i}{2}\overset{\varepsilon}{q}_1 \\ \frac{i}{4}\int_{-\infty}^{\xi} d\eta'(\overset{\varepsilon}{q}_2\overset{N}{q}_1+\overset{\varepsilon}{q}_1q_2) \end{pmatrix}+O(k^{-2}). \tag{19}$$

The formula is true uniformly with respect to $\xi,\eta\in\mathbb{R}$. The remainder is differentiable with respect to η.

The asymptotics can be constructed in the same way as the asymptotics of the $\psi^{\pm}$.

Prove Theorem 1. Denote

$$\overset{N}{f}_i=\frac{1}{4\pi}(\overset{N}{\psi}_{(i)}(\xi,\eta,k),\overset{N}{\phi}_{(i)}(\xi,\eta,l))_f.$$

Represent f_1 as

$$f_1=\frac{-1}{\pi}\langle\overset{N}{\psi}{}^{(1)}(\xi,\eta,l),\overset{N}{\varphi}{}^{(1)}(\xi,\eta,k)\rangle^{N}_{f}.$$

Estimate the difference f_1-h_1, where

$$h_1=\frac{-1}{\pi}\langle\psi^{(1)}(\xi,\eta,l),\varphi^{(1)}(\xi,\eta,k)\rangle_{\hat{f}}, \tag{20}$$

$$\begin{aligned} f_1-h_1&=\frac{-1}{\pi}\langle\overset{N}{\psi}{}^{(1)}(\xi,\eta,l),\overset{N}{\varphi}{}^{(1)}(\xi,\eta,k)\rangle^{N}_{f}+\frac{1}{\pi}\langle\psi^{(1)}(\xi,\eta,l),\varphi^{(1)}(\xi,\eta,k)\rangle_{\hat{f}} \\ &=\frac{-1}{\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}dk\,dl[\overset{N}{f}_2(k,l)(\overset{N}{\psi}{}^{-}_{11}(\xi,\eta,l)\overset{N}{\varphi}_{11}(\xi,\eta,k)-\psi^{-}_{11}(\xi,\eta,l)\varphi_{11}(\xi,\eta,k)) \\ &\quad+(\overset{N}{f}_2(k,l)-\hat{f}_2(k,l))\psi^{-}_{11}(\xi,\eta,l)\varphi_{11}(\xi,\eta,k)+\overset{N}{f}_1(k,l)(\overset{N}{\psi}{}^{+}_{12}(\xi,\eta,l)\overset{N}{\varphi}_{12}(\xi,\eta,k) \\ &\quad-\psi^{+}_{12}(\xi,\eta,l)\varphi_{12}(\xi,\eta,k))+(\overset{N}{f}_1(k,l)-\hat{f}_1(k,l))\psi^{+}_{12}(\xi,\eta,l)\varphi_{12}(\xi,\eta,k)]. \end{aligned}$$

Consider the diverse terms and estimate them individually. Denote

$$I_1=\frac{-1}{\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}dk\ dl\ \overset{N}{f}_2(k,l)(\overset{N}{\psi}{}^{-}_{11}(\xi,\eta,l)\overset{N}{\varphi}_{11}(\xi,\eta,k)-\psi^{-}_{11}(\xi,\eta,l)\varphi_{11}(\xi,\eta,k)).$$

From Lemma 1 it follows that

$$|\overset{N}{\psi}{}^{-}_{11}(\xi,\eta,l)\overset{N}{\varphi}_{11}(\xi,\eta,k)-\psi^{-}_{11}(\xi,\eta,l)\varphi_{11}(\xi,\eta,k)|=O(\varepsilon).$$

To show that $I_1=O(\varepsilon)$ it is sufficient that $\overset{N}{f}_2(k,l)\in L_1$.

Lemma 3: $\overset{N}{f}_2(k,l)\in L_1$.

The proof: Construct the asymptotics of $\overset{N}{f}_2(k,l)$ as $|k|\to\infty$ uniformly when $l\in\mathbb{R}$ and asymptotics of $\overset{N}{f}_2(k,l)$ as $|l|\to\infty$ uniformly when $k\in\mathbb{R}$:

$$\overset{N}{f}_2=\frac{1}{4\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}d\xi\ d\eta\left[\left(\frac{-1}{2k}\overset{N}{q}_1(\xi,\eta)+O(k^{-2})\right)\exp(-ik\xi)\overset{N}{\phi}_{12}(\xi,\eta,l)\right.$$
$$\left.+\left(1+\frac{i}{4k}\int_{-\infty}^{\eta}d\eta'\overset{N}{q}_1(\xi,\eta')\overset{N}{q}_2(\xi,\eta')+O(k^{-2})\right)\exp(-ik\xi)\overset{N}{\phi}_{22}(\xi,\eta,l)\right].$$

Represent the integral as a sum of integrals. Integrate the terms with asymptotics $O(k^{-1})$ as $|k|\to\infty$ by parts with respect to ξ. Twice integrate by parts with respect to ξ the term

$$I_1'=\frac{1}{4\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}d\xi\ d\eta\ f_2(\xi,\eta)\exp(-ik\xi)\overset{N}{\phi}_{22}(\xi,\eta,l).$$

As a result we obtain

$$\overset{N}{f}_2=O(k^{-2}),\quad \text{as}\quad |k|\to\infty\quad \text{uniformly when}\quad l\in\mathbb{R}.$$

In the same way we can show

$$\overset{N}{f}_2=O(l^{-2}),\quad \text{as}\quad |l|\to\infty\quad \text{uniformly when}\quad k\in\mathbb{R}.$$

Hence $\overset{N}{f}_2\in L_1$. The lemma is proved.

We get $I_1=O(\varepsilon)$.

Consider one more term of the formulas (20):

$$I_2=\frac{1}{\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}dk\ dl\ \psi^{-}_{11}(\xi,\eta,l)\varphi_{11}(\xi,\eta,k)(\overset{N}{f}_2(k,l)-\hat{f}_2(k,l)).$$

Lemma 4: $\|\overset{N}{f}_2-\hat{f}_2(k,l)\|_{L_1}=O(\varepsilon)$.

The proof:

$$\overset{N}{f}_2(k,l)-\hat{f}_2(k,l)=\frac{1}{4\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}d\xi\ d\eta[f_2(\xi,\eta)[(\overset{N}{\psi}_{12}(\xi,\eta,k)-\psi_{12}(\xi,\eta,k))\overset{N}{\phi}_{12}(\xi,\eta,l)$$
$$+(\overset{N}{\phi}_{12}(\xi,\eta,l)-\phi_{12}(\xi,\eta,l))\overset{N}{\psi}_{12}(\xi,\eta,k)]+f_1(\xi,\eta)[(\overset{N}{\psi}_{22}(\xi,\eta,k)$$

$$-\psi_{22}(\xi,\eta,k))\overset{N}{\phi}_{22}(\xi,\eta,l)+(\overset{N}{\phi}_{22}(\xi,\eta,l)-\phi_{22}(\xi,\eta,l))\overset{N}{\psi}_{22}(\xi,\eta,k)]]. \tag{21}$$

Represent the integral as a sum of the integrals with respect to ξ and η. Consider the asymptotic behavior of one of the terms when $|k|\to\infty$:

$$J_1=\frac{1}{4\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}d\xi\,d\eta\,f_1(\xi,\eta)(\overset{N}{\psi}_{22}(\xi,\eta,k)-\psi_{22}(\xi,\eta,k))\overset{N}{\phi}_{22}(\xi,\eta,l)$$

$$=\frac{1}{4\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}d\xi\,d\eta\,f_1(\xi,\eta)\left[\frac{i}{4k}\int_{-\infty}^{\eta}d\eta'(\overset{\varepsilon}{q}_2(\xi,\eta')\overset{N}{q}_1(\xi,\eta')+\overset{\varepsilon}{q}_1(\xi,\eta')\overset{N}{q}_2(\xi,\eta'))+O(k^{-2})\right]\exp(ik\xi)\overset{N}{\phi}_{22}(\xi,\eta,l).$$

After integration by parts with respect to ξ we obtain

$$J_1=O(\varepsilon)O(k^{-2}) \quad \text{as} \quad |k|\to\infty, l\in\mathbb{R}.$$

By the same way we obtain

$$J_1=O(\varepsilon)O(l^{-2}) \quad \text{as} \quad |l|\to\infty, k\in\mathbb{R}.$$

Moreover, $J_1=O(\varepsilon)$ as $k,l\in\mathbb{R}$. It follows from Lemma 1. As a result we obtain

$$\|J_1\|_{L_1}=O(\varepsilon).$$

By the same way we can estimate the remaining terms in (21). As a result we obtain the statement of Lemma 4.

From Lemma 4 it follows $I_2=O(\varepsilon)$. The other terms of the formula (20) are estimated in the same way. As a result we obtain

$$|f_1-h_1|=O(\varepsilon) \quad \text{as} \quad \xi,\eta\in\mathbb{R}.$$

The similar formula is true for f_2 and h_2:

$$|f_2-h_2|=O(\varepsilon) \quad \text{as} \quad \xi,\eta\in\mathbb{R}.$$

Let $\varepsilon\to 0$. Then we obtain the statement of Theorem 1.

VI. THE TIME EVOLUTION OF THE SCATTERING DATA VARIATIONS

In this section we study the time evolution of the scattering data variations in the special case, where $q_1=Q$, $q_2=\sigma\overline{Q}$, and Q is the solution of the DS-I equation with the boundary conditions $g_1|_{\xi\to-\infty}=0$ and $g_2|_{\eta\to-\infty}=0$.

The variations of the scattering data are

$$\hat{U}_2=\frac{1}{4\pi}(\psi^-_{(2)}(\xi,\eta,k),\phi_{(2)}(\xi,\eta,l))_U, \quad \hat{U}_1=\frac{1}{4\pi}(\psi^+_{(1)}(\xi,\eta,k),\phi_{(1)}(\xi,\eta,l))_U.$$

Here $U(\xi,\eta,t)$ is the solution of the LDS-I (3) and $U_2=\sigma\overline{U_1}$. In this case $\psi^+_{(1)}=\psi^+_{(1)}(\xi,\eta,k,t)$ and it is the solution of the system of the equations[4]

$$\partial_t\psi^+_{(1)}=ik^2\psi^+_{(1)}+i\begin{pmatrix}1&0\\0&-1\end{pmatrix}(\partial_\xi-\partial_\eta)^2\psi^+_{(1)}+i\begin{pmatrix}0&q_1\\q_2&0\end{pmatrix}(\partial_\xi-\partial_\eta)\psi^+_{(1)}+\begin{pmatrix}ig_1&-i\partial_\eta q_1\\i\partial_\xi q_2&-ig_2\end{pmatrix}\psi^+_{(1)}. \tag{22}$$

We can show that $\phi_{(1)}$ satisfies the system:

$$\partial_t\phi_{(1)}=ik^2\phi_{(1)}+i\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}(\partial_\eta-\partial_\xi)^2\phi_{(1)}-i\begin{pmatrix}0 & q_1\\ q_2 & 0\end{pmatrix}(\partial_\eta-\partial_\xi)\phi_{(1)}+\begin{pmatrix}ig_2 & i\partial_\xi q_1\\ -i\partial_\eta q_2 & -ig_1\end{pmatrix}\phi_{(1)}. \tag{23}$$

Take the derivative of the function $\hat{U}_1$ with respect to t:

$$\partial_t\hat{U}_1=\frac{1}{4\pi}(\partial_t\psi^+_{(1)}(\xi,\eta,k),\phi_{(1)}(\xi,\eta,l))_U+\frac{1}{4\pi}(\psi^+_{(1)}(\xi,\eta,k),\partial_t\phi_{(1)}(\xi,\eta,l))_U$$

$$+\frac{1}{4\pi}(\psi^+_{(1)}(\xi,\eta,k),\phi_{(1)}(\xi,\eta,l))_{\partial_t U}.$$

The derivative of $\psi^+_{(1)}$ is replaced by (22), the derivative of $\phi_{(1)}$ is replaced by (23), and the derivatives of U_1 and U_2 are replaced by (3). After some speculations we obtain

$$\partial_t\hat{U}_1=i(k^2+l^2)\hat{U}_1+\hat{F}_1.$$

In a similar way we obtain

$$\partial_t\hat{U}_2=-i(k^2+l^2)\hat{U}_2+\hat{F}_2.$$

The theorem 2 is proved.

Wavelets, known to be useful in nonlinear multiscale processes and in multiresolution analysis, are shown to have a q-deformed algebraic structure. The translation and dilation operators associate to any scaling equation a nonlinear, two parameter algebra. This structure can be mapped onto the quantum group $\mathrm{sl}_q(2)$ in one limit, and approaches a Fourier series generating algebra, in another limit. A duality between any scaling function and its corresponding nonlinear algebra is obtained. Examples for the Haar and B-wavelets are worked out in detail. © *1998 American Institute of Physics.* [S0022-2488(98)00703-8]

I. INTRODUCTION

Interest in wavelet theory and its applications in the multiresolution analysis[1] has grown over the last decade, involving new and linking disparate fields of research from pure mathematics and physics to down-to-earth signal engineering. It is being widely applied in signal processing and data compression,[2–4] pattern recognition,[5] statistical physics and turbulence,[6] jet dynamics,[7] field theory,[8,9] solid state physics,[10–12] quantum mechanical applications,[13–16] nonlinear dynamics,[6,7,17] soliton theory,[18,19] etc.

The rise in interest in wavelet theory is motivated by the fact that Fourier analysis is quite ineffective when dealing with nonlinear models and localize sharp features.[6–18] A central property of wavelet theory is the ability to expand and analyze functions with respect to a self-similar set of localized basis functions (scaling functions and wavelets) and to processes them locally, without affecting the scale. The wavelet method is recursive and therefore ideal for computational applications. Moreover, the scaling functions and the corresponding wavelets are very well localized both in the time and frequency domains. Wavelets are the natural tool in the analysis of phenomena where different space/time scales occur. They provide mathematical representations that can handle both analytical and numerical difficulties due to singular phenomena.[6,7] Like Fourier analysis, wavelet theory uses expansion functions with different characteristic scales. However, Fourier analysis has the advantage of being based on a simple and solid algebraic foundation.[20] A challenge is to see if an algebraic framework for the foundation of the wavelet analysis can be constructed.

This paper is a first step in this direction. It is mainly concerned in obtaining a closed algebraic method for the construction of the scaling and wavelet functions. We present results for the Haar and B-wavelets. The purpose of this paper is to show that wavelets are not only multiresolution bases of self-similar functions but they have a definite nonlinear symmetry associated with a q-deformation of the Fourier series generating algebra. In a following second paper we will show that wavelets also have variational properties: all multiscale equations follow from Hamilton's equation of an infinite-dimensional Hamiltonian system.

We also show that the central object of wavelet theory, the two-scale equation, has an algebraic counterpart, arising from a quantum algebra.[21] Applications of this result can be realized using supercomputers and efficient numerical schemes which have led to discrete modeling of complex continuous systems or of genuine discrete physical systems defined on lattices. The

discrete symmetries related to complete solvability[22] or to discrete-continuous transitions,[23] and their basic tool, the finite difference equations, are new and central items in any analysis of discrete systems. On uniform lattices the symmetry algebras of partial differential equations is left unchanged by the discretization.[24] In the case of nonuniform lattices one needs to introduce generalized symmetries, like quantum algebras.[25] This is an example when the q-deformation of some initial symmetries can play an important role. An outcome of the present paper is an extension of the traditional Fourier analysis towards wavelet expansions that can be accomplished by q-deforming the Fourier algebra.

The finite-difference and scaling operators involved in the dilation equation are algebraically closed with respect to certain nonlinear commutation relations. This symmetry is better emphasized when the operators are realized in terms of q-deformed derivatives.[26] By expressing the translation and dilation operators as q-deformed derivatives, the scaling and difference operators can be mapped onto the generators of nonlinear algebra and the action of the q-deformed derivatives is extended to nondifferentiable functions. Moreover, such nonlinear algebras can be undeformed to the Fourier series generating algebra or can be mapped onto the $\mathrm{sl}_q(2)$ algebra.

After devoting Sec. II to definitions and notations, we present in Sec. III the deformation of a Fourier algebra into a scaling function generating algebra, and identify a spectral problem with the Haar dilation equation. In Sec. IV we introduce the definition of the most general scaling function and wavelet algebra. The uniqueness of the algebraic formulation of the dilation equation is proved. A duality relation is obtained between any scaling function and certain nonlinear algebra, which associates to any given scaling function (wavelet) an algebra and, for a given algebra of a certain type, one finds the appropriate wavelet structure. In Sec. V we give examples of scaling function algebras for the Haar and the B-wavetes. We use some new limiting procedures in order to solve the q-difference and finite-difference equations. In Sec. VI we have used a variant and extension of the deforming functional technique,[28,29,31] wherein we can obtain a mapping of the generators of nonlinear algebras to those of $\mathrm{sl}_q(2)$. Finally, Sec. VII comprises concluding comments, further extensions, and remarks.

II. BASIC ELEMENTS

An algebraic structure can be provided for any scaling function system and wavelet basis. In order to realize this construction we need three building blocks: the algebraic structure of the Fourier system (starting point), the wavelet theory (final aim), and q-deformation (intermediate tool).

A. Fourier algebras

In order to demonstrate our approach, we give an example for Fourier series, i.e., algebras having Fourier series as basis for their representation spaces.[20] In the following we shall denote $\partial^k f/\partial x^k=\partial_k f=f^k$. The trigonometric (Fourier) system $\{|k>=e^{ikx}\}_{k\in Z}$ diagonalizes all translation invariant operators acting on $L^2([0,2\pi])$. We introduce three generators within a differential realization $J_0=-i\partial$, $J_\pm=e^{\pm ix}(-i\partial)^p$, satisfying the commutation relations for $p=0$, 1 only

$$[J_0,\ J_\pm]=\pm J_\pm,\quad [J_+,\ J_-]=1-(1-2i\partial)^p. \tag{1}$$

For $p=0$ Eqs. (1) describe an algebra, denoted $\mathscr{T}_0$, that is isomorphic to an analytical prolongation, $e(2,C)$, of the Euclidean algebra $e(2,R)$ of rigid motions in the plane. The algebra $e(2,R)$, generated by $P_x=P_x^\dagger$, $P_y=P_y^\dagger$, and $R=-R^\dagger$, with the commutators $[R,\ P_{x,y}]=\pm P_{y,x}$, $[P_x,\ P_y]=0$, is mapped through the generator mapping

$$J_0=iR,\quad J_\pm=P_x\pm iP_y,$$

onto the $\mathscr{T}_0$ algebra. The unitary irreducible representations (unirreps) of $\mathscr{T}_0$ are based on the eigenvectors of the self-adjoint operator J_0, $J_0|n\rangle=n|n\rangle$. For any two distinct eigenstates, $|n\rangle$ and $|n'\rangle$, by using the first commutator in Eq. (1), we obtain $n'=n+1$ and hence the spectrum of J_0 is unbounded, discrete and consists in equidistant eigenvalues. Hence the space of representations is generated by the Fourier system and the other generators $J_\pm|n\rangle=|n\pm1\rangle$ act like ladder operators on the $|n\rangle$ states, increasing/decreasing the scale by unity. For $p=1$ Eqs. (1) describe another Lie algebra, $\mathscr{T}_1$, isomorphic with the symplectic algebra $\mathrm{sp}(2,R)\simeq\mathrm{su}(1,1)\simeq\mathrm{so}(2,1)$. This differ-

ential realization has the same representation space as $\mathscr{T}_0$ but it is not irreducible. The action of the generators of $\mathscr{T}_1$ is similar to that of the generators of $\mathscr{T}_0$ for $n\neq 0$. Unlike the $\mathscr{T}_0$ case, however, we have $J_{\pm}|\mp 1\rangle=|0\rangle$ and the subspaces $\{e^{inx}\}_{n\in N}$ and $\{e^{-inx}\}_{n\in N}$ are invariant subspaces of $\mathscr{T}_1$. The algebras $\mathscr{T}_{0,1}$ suggest the possibility of other constructions in terms of the operator ∂ and the complex exponential functions of different scales.

B. Scaling functions and wavelets

Wavelets are able to reconstruct a signal through regular sampling, i.e., by analyzing the signal at different scales (which increase/decrease exponentially) with the step size between each scale being the same. Different from the ordinary Fourier transform, which reproduces a function as a superposition of complex exponentials, or from the windowed Fourier transform, which introduces a scale into the analysis of signals, multiresolution analysis processes the signal locally, using the appropriate local scale. Basically, wavelets are constructed with a pair of operators: the dilation (scaling) and finite difference (combinations of translations) operators, acting on $L^2(R)$ and defined by $T^{\alpha}f(x)=f(x+\alpha)$, $\mathscr{D}^{\beta}f(x)=2^{\beta}f(2^{\beta}x)$, with α,β arbitrary real numbers. In the following we will use the operator $D^{\beta}=2^{-\beta}\mathscr{D}^{\beta}$ for simplicity in equations ($\mathscr{D}^{\beta}$ is the dilation operator consistent with wavelet theory). They are invertible, unitary, and fulfill $T^{\alpha}D^{\beta}=D^{\beta}T^{2^{\beta}\alpha}$, $T^{\alpha}T^{\beta}=T^{\alpha+\beta}$, $D^{\alpha}D^{\beta}=D^{\alpha+\beta}$. The formal Taylor series of these operators are $T^{\alpha}=e^{\alpha\partial}$ and $D^{\beta}=2^{\beta}e^{\beta\ln 2x\partial}$. On the space of compact supported or rapidly decreasing functions, any holomorphic function $f(T)$ is locally polynomial. Indeed, if f is holomorphic, and its action is taken on the compact supported function subspace of $\Phi\in L^2(R)$, then the action of $f(T)=\Sigma_{k\in Z}\,C_kT^k$ reduces to that of a Laurent polynomial by keeping only a finite number of terms in the sum.

The wavelet system is given by a set of scaled and translated copies of a pair of functions: the scaling function Φ and the mother wavelet Ψ. The basic fact about wavelets is that both these fundamental functions are finite linear combinations of Φ, reflecting the self-similar character of the wavelet system. The defining equation for the scaling function (the dilation equation) is a linear finite-difference equation, including a scale change (q-difference[27])

$$\Phi(x)=D\sum_{k=0}^{n}C_kT^{-k}\Phi(x)=Dg(T)\Phi(x), \tag{2}$$

where the RHS sum is a polynomial in $T,g(T)$. Equation (2) is a fixed-point equation and consequently it has only one unique solution.[1–7,11,13] The scaling function $\Phi(x)$, as a solution of Eq. (2), is required to have two properties[1–5]

(1) $\int_R\Phi(x)dx=1$, the average value property;
(2) $\langle\Phi_n,\Phi\rangle\equiv\int_R\Phi(x+n)\Phi(x)dx=\delta_{n,0}$, for any $n\in Z$, the orthogonality condition.

These conditions introduce restrictions on the coefficients C_k in Eq. (2),[1–4]

$$\sum_{k=0}^{n}C_k=2,\quad \sum_{k=0}^{n}C_kC_{k+2l}=\delta_{0l},\quad l\in Z. \tag{3}$$

The condition Eq. (3) yield a pattern of $L^2(R)$ as a chain of subspaces $V_j\subset V_{j+1}$, each one being generated by all the translations of $D^j\Phi$, $j\in Z$. By repeated application of D and T on Φ, $D^jT^n\Phi(x)=\Phi(2^jx+n)\equiv\Phi_{j,n}$, one obtains a nonorthogonal basis in $L^2(R)$. The action of the operator $-T^{-\lambda}Dg(-T^{-1})$ on Φ, λ being a unique odd integer, provides the mother wavelet function,

$$\Psi(x)=-T^{-\lambda}Dg(-T^{-1})\Phi(x)=-T^{-\lambda}\sum_k\,(-1)^kC_{-k+1}\Phi(2x-k). \tag{4}$$

The wavelet $\Psi(x)$ has the property that $\{\Psi_{j,n}\}_{j,n\in Z}$ is an orthonormal basis of $L^2(R)$ Refs. 1–3 and $L^2(R)$ is a direct sum of the orthogonal subspaces W_j (the orthogonal complements of V_j), each of them generated by all possible translations of $D^j\Psi=\Psi_{j,0}$ with integral m:$L^2(R)$

$=\oplus_{j\in Z}W_j$.[1–5] Hence translated and dilated copies of the mother wavelet, $\Psi(2^jx+k)$, generate a true orthonormal basis. Recursively applications of the Eqs. (2) and (4) relate all the scaling functions and wavelets.

The simplest example is provided by the Haar wavelet, defined by the scaling function $\Phi_{\text{Haar}}(x)=1$ if $|x-1/2|\leqslant 1/2$ and 0 otherwise. In this case we have $D(1+T^{-1})\Phi_{\text{Haar}}=\Phi_{\text{Haar}}$ and $g_{\text{Haar}}(T)=1+T^{-1}$ ($C_0=C_{-1}=1$ and the rest 0 in Eq. (2)). The corresponding Haar wavelet is $\Psi_{\text{Haar}}=D(1-T^{-1})\Phi_{\text{Haar}}$, i.e., $\lambda=1$ in Eq. (4).

There are similarities and differences between the Fourier and the wavelet approaches. From an algebraic point of view, in both approaches, there are eigenfunction equations, which keep the scale constant, and the ladder operators, which change the scale. The dilation equation, Eq. (2), has its analog in the Fourier formalism, though it is a fixed-point equation and has only one solution. The mother wavelet, Eq. (4), has no analog in Fourier analysis. Each Fourier eigenfunction carries one scale; a wavelet function $\Psi(x)$ involves two scales, e.g., $\Phi_{0,k}$ and $\Phi_{2,k}$. Because of their localization, wavelets possess a degree of freedom beyond that of a Fourier system; namely, the width of the support of Φ. In the present approach this degree of freedom is associated with the deformation parameter, q.

C. Quantum deformations

A possibility for constructing scaling functions/wavelets within an algebraic approach is to deform the Fourier algebraic structure into a nonlinear system. In general, the scaling functions and wavelets are not differentiable. This suggests the use of finite-difference operators instead of derivatives. Finite-difference operators are closed with respect to commutation but only within nonlinear algebraic constructions. Consequently, it is natural to use q-deformed derivatives to find a foundation for wavelet theory in q deformed algebras.

Quantum algebras refer to some specific deformations of Lie algebras, to which they reduce when the deformation parameter q is set equal to unity (for a recent monograph see Ref. 21, and references therein). The simplest example of a q-algebra is $\text{sl}_q(2)$ whose Jordan–Schwinger realization is given in terms of q-bosonic operators.[26] The q-deformed algebras have been applied in various branches of physics like spin-chain models, noncommutative spaces, rotational spectra of deformed nuclei, Hamiltonian quantization, and dynamical symmetry breaking. The basic element is the q-deformation of a certain object x, which can be a number, an operator, or a function,

$$[x]_s=\frac{q^x-q^{-x}}{q-q^{-1}}\xrightarrow{s\to 0}x, \tag{5}$$

where $q=e^s$. The Taylor expansion of T and D are related to the q-deformation of the derivative operator, according to the definition of the coordinate description of the q-deformed oscillator introduced in Ref. 26,

$$[\partial]_s f=\frac{T^s-T^{-s}}{2\sinh(s)}f(x). \tag{6}$$

Analogously, we introduce the operator

$$[x\partial]_{s\ln 2}f(x)=\frac{f(2^sx)-f(2^{-s}x)}{2\sinh(s\ln 2)}=\frac{D^s-D^{-s}}{2\sinh(s\ln 2)}f(x). \tag{7}$$

When $s\to 0$, $[\partial]_s\to\partial$ and $[x\partial]_{s\ln 2}\to x\partial$, Eqs. (6) and (7) can be inverted and the occurrence of the q-deformed derivative and the translation/dilation operators becomes immediate

$$T^{\pm s}=\frac{1}{2}\left(\pm\frac{[\partial]_s}{\eta(s)}+\frac{[\partial]^2_{s/2}}{\eta^2(s/2)}+2\right), \tag{8}$$

$$D^{\pm s}=\frac{1}{2}\left(\pm\frac{[x\partial]_s}{\eta(s\ln 2)}+\frac{[x\partial]^2_{s/2}}{\eta^2(s\ln 2/2)}+2\right), \tag{9}$$

where $s \in N$ (or more general $\in R$) and $\eta(s)=1/(e^s-e^{-s})$. The q-deformed algebra $\mathrm{sl}_q(2)$, generated by $\{J_0, J_\pm\}$, is defined by the q-deformed version of the commutation relation

$$[J_+, J_-]=[2J_0]_s,$$

while the other two commutator relations remain undeformed, as for with $\mathrm{sl}(2)$. In addition to this traditional version of $\mathrm{sl}_q(2)$, several generalized forms have been introduced, in two different ways. First, by deforming only the commutator $[J_+, J_-]$ by using some arbitrary function $F(J_0,q)$, $[J_+, J_-]=F(J_0,q)$ independently proposed in Refs. 28, 29, and 30. The second way is by deformations involving all three commutation relations, using two functions $G(J_0,q)$ and $F(J_0,q)=[J_+, J_-]$, introduced in Ref. 31. Unlike the former, for which the spectrum of J_0 is linear, the latter is characterized by an exponential spectrum for J_0. Since in wavelet theory the domains of analysis are divided exponentially, rather than linearly with bands of equal widths, such algebras are used in the following analyses.

III. HAAR SCALING FUNCTION ALGEBRA, $\mathscr{A}_{s,\alpha}$

The aim in this section is to obtain operators depending on D and T, closed under some nonlinear algebra. This structure must provide an algebraic form for Eqs. (2), (4) and must be mapped into one Fourier algebra, $\mathscr{T}_{0,1}$. Consider an operator depending on T and two real parameters s, α,

$$W_0(s,\alpha)=\frac{T^{s\alpha}-T^{-s\alpha}\cos s\pi}{2\xi(\alpha)\sinh s}, \tag{10}$$

where $\xi(\alpha)=[1/\sinh(1)]\sin(\alpha\pi/2)-2i\cos(\alpha\pi/2)$. The (s,α) parameters allow W_0 to approach ∂ or combinations of T,

$$W_0(0,\alpha)=\frac{\alpha}{\xi(\alpha)}\,\partial, \tag{11}$$

$$W_0\left(\frac{1}{2},\alpha\right)=\frac{1}{2\sinh(1/2)\xi(\alpha)}\,T^{\alpha/2}, \tag{12}$$

$$W_0(1,\alpha)=\frac{T^{\alpha}+T^{-\alpha}}{2\sinh(1)\xi(\alpha)}, \tag{13}$$

$$W_0(2,\alpha)=\frac{T^{2\alpha}-T^{-2\alpha}}{2\sinh(2)\xi(\alpha)}. \tag{14}$$

In the limit $s\to 0$, W_0 reduces to the normal derivative with respect to x, Eq. (11). In the limit $s=\frac{1}{2}$, we obtain a power of the translation operator T, Eq. (12). Equation (13) defines a q-deformation of unity, i.e., $W_0(1,0)=[i/4\sinh(1)]$. $W_0(s,\alpha)$ can be a Hermitian or anti-Hermitian operator, $W_0(1,\alpha)=\pm W_0(1,\alpha)^\dagger$, depending on α. The last limit, Eq. (14), represents a finite difference operator and is proportional to the q-derivative with respect to the α-deformation $[2\partial]_\alpha$, similar to Eqs. (6)–(9). For $\alpha=2k$ in Eq. (12), $\alpha=k$ in Eq. (13) and $\alpha=k/2$ in Eq. (14), the corresponding $W_0(s,\alpha)$ are Laurent polynomials in T, providing a direct connection to the wavelet operators. For some values of α, Eqs. (12)–(14) give invertible operators with respect to $T, T=T(W_0)$.

In order to introduce the dilation operator D, we define

$$W_\pm(s)=\tfrac{1}{2}e^{\mp ix(s-1)/2}D^{\mp s}e^{\mp ix(s-1)/2}(1+T^{\pm s}). \tag{15}$$

In order to fulfil the Hermiticity condition $(W_+)^\dagger=W_-$ on $L^2(R)$ these generators can be redefined in the form

$$W_\pm\to\widetilde{W}_\pm=2^{-1\mp,s/2}e^{\mp ix(s-1)/2}D^{\mp s}e^{\mp ix(s-1)/2}(1+e^{-i[s(s-1)(1+2^s)]/4}T^{\pm s(2^{(s/2)(1\mp 1)}}.$$

By using the commutators relations between D and T and by performing an integration by parts, one has a direct check of the relation $(\widetilde{W}_+)^\dagger=\widetilde{W}_-$,

$$\langle f_1,\widetilde{W}_+ f_2\rangle=\int_R f_1^*(x)\widetilde{W}_+ f_2(x)dx=\langle \widetilde{W}_- f_1,f_2\rangle.$$

From Eqs. (10) and (15) one obtains the commutators,

$$[W_0(s,\alpha),\ W_+(s)]=G(s,T)W_+(s), \tag{16}$$

$$[W_0(s,\alpha),\ W_-(s)]=-W_-(s)G(s,T), \tag{17}$$

$$[W_+(s),\ W_-(s)]=F(s,T), \tag{18}$$

with

$$G(s,T)=W_0(s,\alpha)-\frac{T^{2^s s\alpha}e^{is\alpha(1+2^s)(s-1)/2}-T^{-2^s s\alpha}e^{-is\alpha(1+2^s)(s-1)/2}\cos s\pi}{2\sinh(s)\xi(\alpha)} \tag{19}$$

and

$$F(s,T)=\frac{1}{4}\left((1+e^{is(1+2^s)(s-1)/2}T^{2^s s})(1+T^{-s})-(1+e^{is(1+2^{-s})(s-1)/2}(T^{-2^{-s}s})(1+T^s)\right). \tag{20}$$

Equations (10), (15)–(20) describe a nonlinear associative algebra, generated by $T^\pm, D^\pm$, denoted $\mathscr{A}_{s,\alpha}$. The eigenvalue problem for $W_\pm$ provides the algebraic form for the scaling equation. When $W_0(s,\alpha)$ is invertible with respect to T, the algebra has $W_0, W_\pm$ as generators which depend on two parameters (s,α) and is homeomorphic with a special q-deformed algebra, namely, the two-color quasitriangular Hopf algebra $\mathscr{A}^\pm$.[31] The spectrum of W_0 is not equidistant because $F(s,T)\neq \text{const}\times W_0$. The Casimir operator of the algebra $\mathscr{A}_{s,\alpha}$ is given by[28–31]

$$C=W_-W_++H(W_0)=W_+W_-+H(W_0)-F(W_0), \tag{21}$$

where H is a real function, holomorphic in a neighborhood of 0 and which must satisfy the functional equation

$$H(\xi)-H(\xi-G(\xi))=F(\xi) \tag{22}$$

with ξ generic. The irreps of $\mathscr{A}_{s,\alpha}$ are labeled by the eigenvalues a of W_0 and those of the Casimir operator. The commutator in Eq. (16) can be written in the form

$$W_+W_0=(W_0-G)W_+. \tag{23}$$

If $|a\langle\neq|a'\rangle$ are eigenvectors of W_0, with the corresponding eigenvalues a,a', we have from Eq. (23) a nonlinear recursion relation for all the eigenvalues

$$a'=a-G(a). \tag{24}$$

The algebra $\mathscr{A}_{s,\alpha}$ can be mapped into $e(2,C)$, the Lie algebra of a Fourier series, in the limit $s\to 0$, $\alpha\to 2$: $W_\pm\to e^{\pm ix}=J_\pm$, $W_0\to -i\partial=J_0$, where we take these limits in the order $\mathscr{A}_{s_0,\alpha_0}=\lim_{\alpha\to\alpha_0}\lim_{s\to s_0}\mathscr{A}_{s,\alpha}$. The continuous mapping $\mathscr{A}_{s,\alpha}\to\mathscr{A}_{0,2}\simeq e(2,C)$ is an algebraic morphism and one can consider wavelets as q-deformed generalizations of the Fourier series, in the above sense.

As a first example, the Haar scaling function can be associated with a particular case of $\mathscr{A}_{s,\alpha}$, i.e., the algebra $\mathscr{A}_{1,1}$. In the algebra $\mathscr{A}_{1,1}$ the eigenproblem for W_- provides the dilation equation for the Haar scaling function $\Phi(x)$ defined by Eq. (2) with $g(T)=1+T^{-1}$. We have in this case $G=W_0-2W_0^2+1$, and $W_\pm=\frac{1}{2}D^{\mp 1}(1+T^{\pm 1})$ and the commutators,

$$[W_0,\ W_+]=(W_0-2W_0^2+1)W_+,$$

$$[W_0,\ W_-]=-W_-(W_0-2W_0^2+1), \tag{25}$$

$$[W_+,\ W_-]=\tfrac{1}{4}(T^2(W_0)-T^{1/2}(W_0)-T^{-1/2}(W_0)+T^{-1}(W_0)),$$

where $T(W_0)$ is the solution of the equation $2W_0=T+T^{-1}$, a pseudodifferential operator. The Casimir operator of $\mathscr{A}_{1,1}$ is a constant. Indeed, Eq. (22) for the general Casimir operator becomes

$$H(W_0)-H(2W_0^2-1)=F(W_0), \tag{26}$$

and has, in terms of the $T=T(W_0)$ operator, the form

$$\chi(T)-\chi(T^2)=\frac{1}{4}\,(T^2-T^{1/2}-T^{-1/2}+T^{-1}), \tag{27}$$

where $\chi(T)=H[(T+T^{-1})/2]$. The unique analytical solution for Eq. (27) reads

$$\chi(T)=\tfrac{1}{4}(\text{const}-T-T^{1/2}-T^{-1/2}), \tag{28}$$

which gives for the Casimir operator a constant.

The spectrum of W_0 consists of periodic functions satisfying the equation $\Phi(x+1)+\Phi(x-1)=2\Phi(x)$. This takes one back to Fourier analysis. The way to the Haar scaling function is to use the spectrum of $W_\pm$ since in $\mathscr{A}_{1,1}$ the eigenproblem for W_- gives the dilation equation for the Haar scaling function $\Phi(x)$. Once Φ is obtained from $2W_-\Phi=\Phi$ the generator W_0 carries Φ into an infinite sequence of functions $W_0^n\Phi$. These functions are mutual orthogonal and generate the space V_0. The action of $W_\pm$ on Φ yields the subsequence $W_0^{2n}\Phi$. Consequently, V_0 is an invariant space for all the generators of the algebra $\mathscr{A}_{1,1}$.

The spectrum of W_0 depends on the values of the parameters s,α. In the case of $\mathscr{A}_{1,1}$ this relation is $a'=2a^2-1$. The corresponding representations are infinite-dimensional and the eigenvalues of $W_0|_{1,1}$ are $a_n=\cosh(2^n\tilde{a})$, $n\in Z$ for any $\tilde{a}$. The corresponding eigenfunctions have the form $|a_n\rangle_\pm=e^{\pm 2^n\tilde{a}x}$ which results in an exponential spectrum for a_n similar to the sequence of scales in wavelet theory. This is a self-similar spectrum with respect to $\tilde{a}$, like the sequence of scales in wavelet theory. A part of this spectrum is shown in Fig. 1. The action of $W_\pm$ is

$$W_\pm|a_n\rangle_\pm=\frac{1+e^{\pm 2^n\tilde{a}}}{2}\,|a_{n\pm 1}\rangle_\pm. \tag{29}$$

Another basis for a representation of $\mathscr{A}_{1,1}$ is given by $\underline{|k\rangle}=e(i\pi x/k)$, $k\in Z$. We have the action

$$W_0\underline{|k\rangle}=\cos\frac{\pi}{k}\,\underline{|k\rangle},\quad W_\pm\underline{|k\rangle}=\frac{1}{2}\,(1+e^{\pm i\pi/k})\underline{|2^{\pm 1}k\rangle},$$

and on this basis $(W_+)^\dagger=W_-$. There are two invariant spaces, $\underline{|2^k\rangle}$ and $\underline{|2^{-k}\rangle}$, $k\in N$, with $W_\pm\underline{|0\rangle}=1$.

The same procedure can be followed for any set of the parameters s,α. For example, if we choose the algebra $\mathscr{A}_{2,1/2}$ with W_0 defined in Eq. (12), we obtain the spectrum of W_0 described by the recursion relation

$$a'=a\left(a+\sqrt{a^2+1}+\frac{1}{a+\sqrt{a^2+1}}\right), \tag{30}$$

which also gives a nonlinear, unbounded, discrete representation of $\mathscr{A}_{2,1/2}$.

The last thing to prove is the uniqueness of the two-scale equation in the $\mathscr{A}_{1,1}$ scaling function generating algebra. The two-scale equation, Eq. (2), in its algebraic form $2W_-\Phi=\Phi$ is not unique

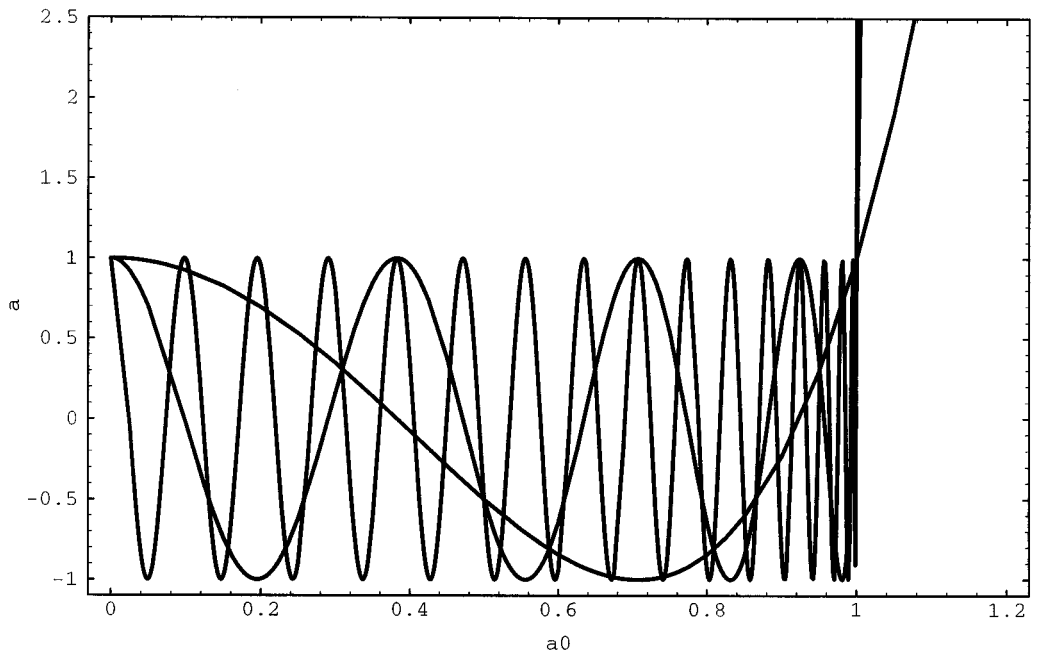

FIG. 1. The dependence on a_0 of three eigenvalues a_n of W_0 in $\mathscr{A}_{1,1}$, for $n=2$ (the largest period), 4 and 6 (the smallest period). The three spectra have self-similar structure for $a_0 \in [0, 1]$.

in $\mathscr{A}_{1,1}$ if there exists an operator, similar with that occurring in the dilation equation, which commutes with W_-. This operator should contain higher powers in T and consequently is an element of $U(\mathscr{A}_{1,1})$.

Proposition 1: In $U(\mathscr{A}_{1,1})$ *there exists a unique operator* $X=Dx(T^{-1})$ *such that* $[W_-, X]=0$. *The function* $x(\xi)$ *is an integer, it is not a polynomial and it is unbounded, for generic* ξ.

Proof: We take for X a Laurent series $x(T^{-1})=\Sigma_{k\in Z} C_k T^{-k}$ then the condition $[W_-, X]=0$ results in a recursion relation for the coefficients C_k,

$$C_{2k+1}=C_k-C_{2k-1}, \quad C_{2k}=C_k-C_{2k-2}, \tag{31}$$

for any $k\in Z$. Equations (31) have one trivial solution which reproduces W_-, $x(T^{-1})=C_{-1}(1+T^{-1})$ and only one different solution, with $C_k=\pm C_{-1}$ or 0, uniquely defined ($C_2=C_{\pm 3}=C_{-4}=C_5=C_{-6}=C_7=C_{-8}=C_{-11}\cdots=0$, $C_{-2}=C_{-5}=C_6=C_{-9}=C_{-10}=C_{10}=C_{11}=\cdots=C_{-1}$ and $C_1=C_4=C_{-7}=C_8=C_9=C_{-12}=C_{12}=\cdots-C_{-1}$, etc.). The sequence of nonzero coefficients is infinite, and $\{C_k\}$ is not a Cauchy sequence. (q.e.d.) We note that the $\mathscr{A}_{1,1}$ algebra is also a Hopf algebra,[21,30,31] defined by Eqs. (25) and by the coproduct, counit and antipode in the form,

$$\Delta T^{\pm}=T^{\pm}\otimes T^{\pm}, \quad \Delta D^{\pm}=D^{\pm}\otimes D^{\pm}, \quad \epsilon(T^{\pm})=\epsilon(D^{\pm})=1,$$

$$S(T^{\pm})=T^{\mp}, \quad S(D^{\pm})=D^{\mp}.$$

All its generators are primitive elements.

IV. GENERAL SCALING AND WAVELET ALGEBRA

This algebraic approach for the Haar scaling function can be generalized to yield a nonlinear algebra for any scaling function, and conversely, to find the dilation equation and scaling function for a certain type of algebra. The procedure starts with an algebra generated by dilation and translation and constructs, within this algebra, the two-scale equation. The generators of the $\mathscr{A}_{s,\alpha}$ algebra can be generalized as

$$W_0 \to j_0(T), \quad W_{\pm} \to j_{\pm}(D,T)=e^{\mp ix(s-1)/2} D^{\mp s} e^{\mp ix(s-1)/2} j(T^{\pm 1}), \tag{32}$$

with $j_0(T)$ and $j(T)$ being arbitrary functions of T and s, holomorphic in a neighborhood of $T=1$, with their dependence on s being such that in the limit $s\to 0$, $j_0(T)\to -i\partial$, $j(T)\to 1$. In this case the commutation relations, Eqs. (16)–(20), become

$$[j_0, j_+]=\widetilde{G}j_+, \quad [j_0, j_-]=-j_-\widetilde{G}, \quad [j_+, j_-]=\widetilde{F}, \tag{33}$$

with $\widetilde{G},\widetilde{F}$ depending on T through j_0, j, respectively,

$$\widetilde{G}=\widetilde{G}(s,T)=j_0(s,T)-j_0(s,T^{2^s}e^{i(1+2^s)(s-1)/2}), \tag{34}$$

$$\widetilde{F}=\widetilde{F}(s,T)=j(s,e^{i(s-1)/2(1+2^s)}T^{2^s})j(s,T^{-1})-j(s,T^{-2^{-s}}e^{i(s-1)/2(1+2^{-s})})j(s,T). \tag{35}$$

Equations (33)–(35) define a nonlinear algebra denoted $\mathscr{A}_{j_0,j}$ as a generalization of $\mathscr{A}_{s,\alpha}$. If the function $j(T)$ is invertible with respect to T, $\mathscr{A}_{j_0,j}$ can be expressed in terms of the generators $j_0, j_\pm$ only and then $\widetilde{G}(T)=\mathscr{G}(j_0)$, $\widetilde{F}(T)=\mathscr{F}(j_0)$. The algebraic morphism $j_0(T)\to W_0$ and $j(T)\to 1+T^s$ provides the mapping $\mathscr{A}_{j_0,j}\to\mathscr{A}_{s,\alpha}$. Since the first two commutators of $\mathscr{A}_{j_0,j}$, Eq. (33), do not depend on the function $j(T)$, and the third commutator in Eq. (33) does not depend on the function $j_0(T)$, the closure condition for $\mathscr{A}_{j_0,j}$ is independent of the functions $j_0(T)$ and $j(T)$ and hence they can be chosen in a convenient way to provide any dilation equation in the form of the eigenproblem for j_-. The algebraic closure conditions for $\mathscr{A}_{j_0,j}$, together with the definitions of j, j_0 require

$$j_0(T^2)-j_0(T)=\mathscr{G}(j_0(T^2)), \tag{36}$$

$$j(T^2)j(T^{-1})-j(T^{-1/2})j(T)=\mathscr{F}(j_0(T)). \tag{37}$$

Both Eqs. (36) and (37) are nonlinear, and in general, difficult to solve analytically. The unique solution for the dilation equation are $j_\pm$ since the Casimir operator of this algebra depends on T only. Choosing $g(T)=j(T)$ yields the dilation equation in the form $2j_-\Phi=\Phi$. In the limit of $\mathscr{A}_{s,\alpha}$ this provides again the Haar two-scale equation. The corresponding scaling function belongs to the basis of the representation of j_- with eigenvalue 1/2. The remaining arbitrary function j_0 can now be selected to obtain the wavelet generating operator $j_-j_0\Phi=\Psi$, in agreement with Eq. (4). One can formally construct a basis of the representation for j_- with the functions $|n\rangle=(\ln T)^n\Phi$. The procedure is the following: for a given algebra $\mathscr{A}_{j_0 j}$ (therefore given functions $\mathscr{G}$, $\mathscr{F}$) solve Eqs. (36) and (37) with respect to the functions $j_0, j_\pm$ and obtain the corresponding dilation equation in the form $2j_-\Phi=\Phi$. A certain combination of generators produces the corresponding wavelet equation for Ψ. Conversely, given a scaling/wavelet function, and consequently its dilation equation and $g(T)$, one can choose $j_-=Dg(T)$ and then solves the equation $Dg(-T^{-1})=j_-j_0$ with respect to j_0. With $j_0, j_\pm$ known one can solve Eqs. (36) and (37) with respect to $\mathscr{G}$, $\mathscr{F}$ to construct the algebra.

This algebraic approach is in some sense universal, what is modified is the specific realization of the nonlinear algebra in terms of D and T. Constraints are imposed by the two limiting approaches (two-scale equation and Fourier limit). Loosely speaking, the closure of the algebra provides the fixed-point dilation equation and the nonlinearity of the algebra provides the exponential scaling.

We also note that $V_0=\{\Sigma_k C_k T^k\Phi\}$, i.e., the space generated by all the integer translations of Φ, and any other $V_j=D^jV_0$, is not invariant to the action of j_-. For example, the condition $j_-D\Phi=\Sigma_k C_k T^k D\Phi$ implies the existence of an operator containing D, whose commutator with j_- is a function of T only. From the definition of the algebra this is impossible, and consequently this proves the above conjecture. The V_j spaces form, by recursion, a basis in $L^2(R)$.

In order to prove the uniqueness of the two-scale equation in the general case, we again use Proposition 1, for $W_-\to j_-=Dj(T^{-1})=D\Sigma_{k\in Z}\, j_k T^k$. We have to solve the commutation equation $[Dj(T^{-1}), X)]=0$ for $x(T)=\Sigma_{k\in Z}X_kT^k$, $X=Dx(T)$. This implies that the arbitrary functions $x(\xi)$ and $j(\xi)$ must fulfill the functional condition (ξ a generic variable)

$$x(\xi^2)j(\xi)=x(\xi)j(\xi^2). \tag{38}$$

Equation (38) does not carry any restriction with respect to the values of the functions in 0 and 1. Since $Dj(T)$ represents a scaling operator we have, according to the dilation equation, $j(1)=1$, $j(-1)=0$ which implies $x(-1)=0$. If Φ is the corresponding scaling function for j_- then $X\Phi$ is also an eigenfunction of j_-, $j_-(X\Phi)=X\Phi$. In order for $Dx(T)$ to satisfy the average value property (1) in Sec. II B, we impose the additional condition $x(1)=1$. The last condition requires $DX(T)$, the orthogonality condition (2) of Sec. II B, be equivalent to the condition[1–4]

$$|x(T)|^2+|x(-T)|^2=1. \tag{39}$$

By introducing Eq. (38) into Eq. (39) we obtain $X=j_-$ which provides the trivial indentity solution, and hence the uniqueness.

V. CONSTRUCTION OF THE SCALING AND WAVELET ALGEBRA

The link between the scaling function and wavelet, and the corresponding scaling algebra is supported by the solutions of Eqs. (36) and (37). In the following we present a method for solving these equations, from the wavelets towards the algebra. The dilation equation Eq. (2) has the form of a fixed-point equation. Therefore we must try to find its eigenvectors as limits of some functional sequences. The limits of these sequences should be compact supported or rapidly decreasing functions for two reasons; to obtain scaling functions with good localization, and to provide correct behavior of the action of the operators $f(T)$. Since the scaling function will be expressed as a limit of a sequence, one has to look for operators which commute with the limit (are absorbed in the limit). We choose a test function $\Delta_0(x)$ and a sequence of operators f_n from the universal covering $U(\mathcal{A}_{j_0,j})$ of the scaling function algebra introduced in the preceding section, such that the limit $\Phi(x)=\lim_{n\to\infty} f_n\Delta_0(x)$ exists in the weak topology and it provides the scaling function.

In the following we show how to construct the scaling algebra $\mathcal{A}_{j_0,j}$ from the dilation equation, written in the form $j_-(T,D,s)\Phi=\Phi$. We have the following proposition in the framework of the algebra $\mathcal{A}_{j_0,j}$, for $s=1$.

Proposition 2: Let $f_n(j_0)$ be a functional sequence in $U(\mathcal{A}_{j_0,j})$, $s=1$, $\Delta_0(x)$ a (test) function and $\Phi(x)$ the scaling function. If the limit $\Phi(x)=\lim_{n\to\infty} f_n(j_0)j_-^n\Delta_0(x)$ exists, and $\lim_{n\to\infty}[f_n(j_0-\mathcal{G}(s,j_0))/f_{n-1}(j_0)]=1$, then $j_-\Phi(x)=\Phi(x)$.

Proof: From the RHS of the first condition in the hypothesis and from Eq. (33) we have

$$f_n(j_0)j_-^n=j_-f_n(j_0-\mathcal{G}(s,j_0))j_-^{n-1}=j_-\frac{f_n(j_0-\mathcal{G}(s,j_0))}{f_{n-1}(j_s)}f_{n-1}(j_0)j_-^{n-1}.$$

It follows

$$j_-\Phi=\lim_{n\to\infty} j_-f_n(j_0)\Delta_0(x)=\Phi,$$

q.e.d. It follows from Proposition 2 that for a given dilation equation $j_-\Phi=\Phi$, (both j_- and Φ given) we can find out a sequence $f_n(j_0)$, the operator $\mathcal{G}(s,j_0)$ and a test function $\Delta_0(x)$, such that these objects satisfy the hypothesis of Proposition 2. Then it follows that one can construct the scaling algebra, since with j_0 and $\mathcal{G}(s,j_0)$ found, $\mathcal{F}(s,j_0)$ results from the last commutator in Eq. (33). In general, one starts with j_0 as an arbitrary function of T which can be deformed into $-i\partial$ when mapping $\mathcal{A}_{j_0,j}$ to $\mathcal{T}_{0,1}$. As j_- is provided by the two-scale equation, $j_-\Phi=\Phi$, other solutions are forbidden. If $\lim_{n\to\infty} f_n(j_0)=f_\infty(j_0)\neq$ const., this limit should commute with j_- which is forbidden by Proposition 1. This procedure closes the construction of the algebra $\mathcal{A}_{j_0,j}$.

In the following we give an algorithm for finding $f_n(j_0)$ and $j_0(T)$ and illustrate it with two examples. Since any mother scaling function is defined by the dilation equation ($Dh(T)\Phi=\Phi$ or $j_-\Phi=\Phi$) it is natural to search for solutions by using a recursion algorithm. For instance, we can find a test function $\Delta_0(x)$ and a triple of operators A,B,C such that the limit $\Phi(x)=B\lim_{n\to\infty} A^n\Delta_0(x)$ exists and in addition $CB=BA^k$, for a finite positive integer k. Then, we have the property $C\Phi(x)=\Phi(x)$. Indeed, $C\Phi=CB\lim_{n\to\infty} A^n\Delta_0=B\lim_{n\to\infty} A^{n+k}\Delta_0=B\lim_{n\to\infty} A^n\Delta_0=\Phi$. From the dilation equation we know that C should have the form C

$=Dc(T)$ with $c(T)$ a function of T. One of the simplest choices is to use $A=D$ and $B=b(T)$. Then we have $CB=Dc(T)b(T)=c(T^{1/2})b(T^{1/2})D=b(T)A$; that is, $k=1$ and a restriction for the arbitrary functions $c(T)$ and $b(T)$ arises,

$$c(T^{1/2})b(T^{1/2})=b(T). \tag{40}$$

This equation is useful in both directions (algebraic↔dilation equation), since one can start with a given scaling function (given $c(T)$) and find the operator $b(T)$ involved in the algebra and conversely.

Now consider the algorithm for the Haar scaling function, $c(T)=1+T^{-1}$. We look for solutions of Eq. (40) as Laurent series for $b(T)=\Sigma_{k\in Z}b_kT^k$. In this case Eq. (40) has an unique solution, $b(T)=\text{const.}\cdot(1-T^{-1})$. This gives again a unique solution for $\Phi=(1-T^{-1})\lim_{n\to\infty}D^n\Delta_0$. We stress that $Db(T)$ is exactly the operator which gives the Haar wavelet. Further, we can express Φ_{Haar} in the form $\Phi(x)=H(x)-H(x-1)$, where $H(x)$ is the Heaviside distribution. For any sequence of C^∞ functions $\delta_n(x)\to\delta(x)$, we have $\Delta_n(x)=\int\delta_n(x)dx\to H(x)$ and we can write

$$\Phi(x)=\lim_{n\to\infty}(\Delta_n(x)-\Delta_n(x-1)). \tag{41}$$

For example, we can use the sequences $\delta_n=(1/\pi)[2^{-n}/(x^2+2^{-2n})]$ or $\delta_n=[2^{n-1}/\cosh^2(2^nx)]$ and $\Delta_n=[\arctan(2^nx)/\pi]$ or $\Delta_n=\frac{1}{2}\tanh(2^nx)$, respectively. The latter example is a soliton-like shape, having good localization. These sequences converge to $\delta(x)$, respectively. In this way we have selected subsequences that step in powers of 2. Equation (41) can be written as

$$\Phi(x)=\lim_{n\to\infty}(1-T^{-1})D^n\Delta_0(x). \tag{42}$$

We can express this definition in terms of the algebra $\mathscr{A}_{1,1}$. By using Eq. (25) and the properties of the operators D and T, we can write Eq. (42) in the form

$$\Phi(x)=\lim_{n\to\infty}(1-T^{-2^{-n}})(2W_-)^n\Delta_0(x). \tag{43}$$

Indeed, from the commutation relation between D and T and the definition of W_- we have

$$\begin{aligned}(2W_-)^n&=(D(1+T^{-1}))^n=D^n(1+T^{-1}+\cdots+T^{-2^n+1})\\&=(1+T^{-2^{-n}}+(T^{-2^{-n}})^2+\cdots+(T^{-2^{-n}})^{2^n-1})D^n.\end{aligned} \tag{44}$$

Hence, we can write $(1-T^{-1})D^n=(1-T^{-2^{-n}})(2W_-)^n$ Moreover, we can write, by using the inverted form for $W_-(T)$, the dilation equation in a pure algebraic form,

$$\Phi(x)=\lim_{n\to\infty}(1-T^{-2^{-n}}(W_0))(2W_-)^n\Delta_0(x). \tag{45}$$

From this last equation it follows that $2W_-\Phi=\Phi$, i.e., the Haar dilation equation. If the function $\Delta_0(x)$ is chosen from a class of suitable functions for a wavelet analyzis then its scaling function, $\Phi(x)$, Eq. (45), gives a rapidly convergent wavelet expansion. In order to exemplify we show in Fig. 2 scaling functions obtained by this procedure for different values of the parameter s within $\mathscr{A}_{s,\alpha}$. For $s=0$ and 1 this functions yields the Haar scaling function.

We give another example for the Φ_2 B-scaling function and the Ψ_2 B-wavelet. We define

$$\Phi_2(x)=\begin{cases}0 & x\leqslant 0,\ x\geqslant 1\\ 4x & 0\leqslant x\leqslant 1/2\\ -4x+4 & 1/2\leqslant x\leqslant 1\end{cases}, \tag{46}$$

or

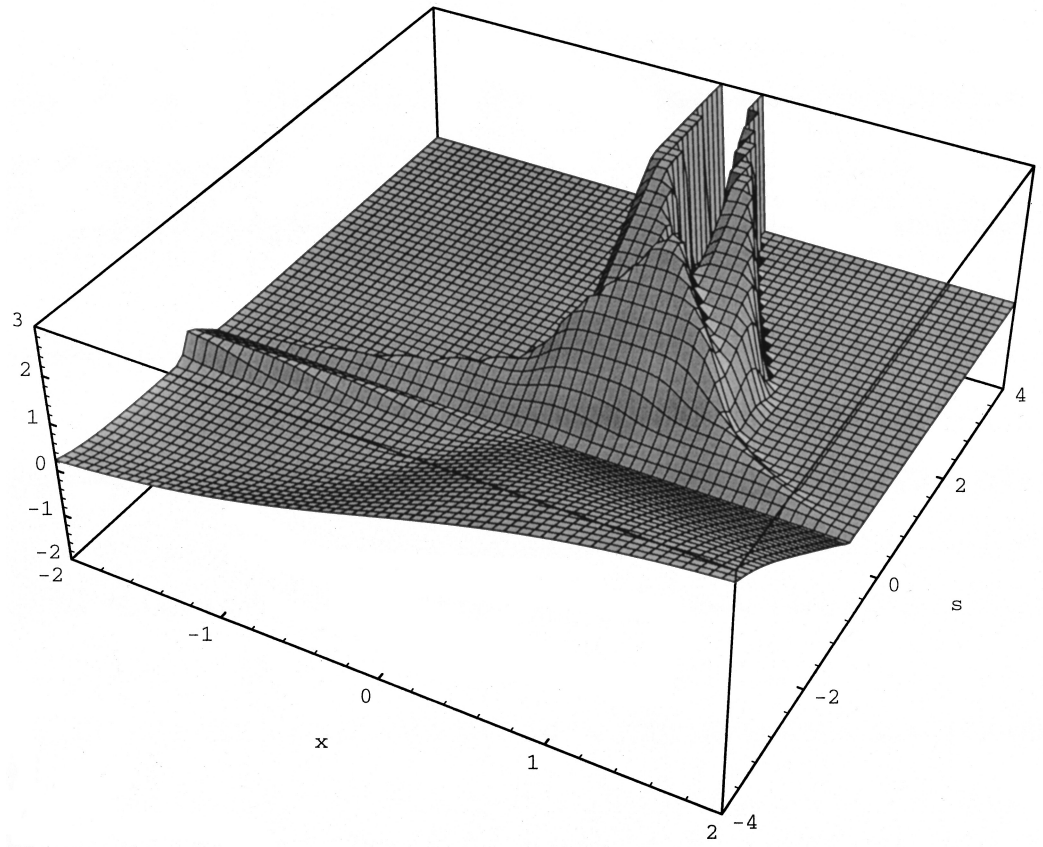

FIG. 2. The continuous deformation of the scaling function Φ in $\mathscr{A}_{s,\alpha}$ as function of the parameter s. For $s=0,1$ this is the Haar scaling function.

$$\Phi_2(x)=\lim_{n\to\infty}\frac{1}{2^{-n+1}}\,(1-2T^{-1/2}+T^{-1})D^n\Delta_{0,\mathrm{tri}}(x), \tag{47}$$

with

$$\Delta_{0,\mathrm{tri}}(x)=\frac{2x}{\pi}\arctan(2x)-\frac{\ln(1+4x^2)}{2\pi}=\int_0^{2\pi}\Delta_0(x)dx. \tag{48}$$

Following the above algorithm we obtain the corresponding dilation equation,

$$j_-|_{\mathrm{tri}}\Phi_2(x)=\frac{D}{2}\,(1+T^{-1/2})^2\Phi_2(x). \tag{49}$$

By using the commutation relation $\partial D=2D\partial$ and the dilation equation Eq. (49) we can obtain a self-contained equation for the wavelet,

$$\Psi_{\mathrm{tri}}(x)=D(1+2T^{-1/2}+T^2)^2\Psi_{\mathrm{tri}}. \tag{50}$$

The corresponding algebras for Haar and Φ_2 B-scaling functions are different. For the B-wavelet we have, in $\mathscr{A}_{1,1}$,

$$G(W_0)=W_0-W_0^2-\tfrac{1}{2}. \tag{51}$$

This new algebra, fulfills different commutation relations and consequently has a different spectrum for W_0, not the Haar scaling algebra. The algorithm introduced above can also be used to generate other scaling functions and their corresponding algebras. An interesting line is to obtain

polygon-like wavelets or, by following the same procedure which guided us to obtain the B-scaling function from the Haar scaling function, to obtain smoother scaling functions.

VI. THE $sl_q(2)$ LIMIT OF $\mathscr{A}_{j_0,j}$

The quantum group $sl_q(2)$ or its extensions[21–26,28–31] are associative algebras over C generated by three operators, $J_0=(J_0)^\dagger$, J_+, and $J_-=(J_+)^\dagger$, satisfying the commutation relations,

$$[J_0,\ J_+]=J_+,\quad [J_0,\ J_-]=-J_-,\quad [J_+,\ J_-]=[J_0]_s, \tag{52}$$

where $[J_0]$ is a deformation of J_0, that is, a real, parameter-dependent function of J_0, holomorphic in the neighborhood of zero, approaching $2J_0$ in the limit $s\to 0$. We have to find a deforming functional that transforms the $\mathscr{A}_{j_0,j}$ generators into operators satisfying the commutation relations Eq. (52). For this purpose the first equation in Eqs. (33) can be written as

$$(j_0-\mathscr{G}(s,J_0))j_+=j_+j_0, \tag{53}$$

and hence, for every entire function $p(\xi)$, we can write

$$p(j_0-\mathscr{G}(s,j_0))j_+=j_+p(j_0). \tag{54}$$

Let us consider the functional equation:

$$\Gamma(\xi-\mathscr{G}(s,\xi))=\Gamma(\xi)-1 \tag{55}$$

for a given function $\Gamma(\xi)$, with ξ generic. If this equation has a solution $\Gamma(\xi)$ that is an entire function, then Eq. (55) can be written, for $p(\xi)=\Gamma(\xi)$, in the form $[\Gamma(j_0)\ j_+]=j_+$, and correspondingly $[\Gamma(j_0),\ j_-]=-j_-$. These equations give the correspondence between the wavelet algebras and the q-deformed algebras like $sl_q(2)$ or other extensions of them. They map the structure of $\mathscr{A}_{j_0,j_\pm}$, Eq. (33), onto the structure described by the first two equations in Eq. (52). For the third commutator of each of these algebras we use the function $\Gamma(\xi)$, which allows Eqs. (33) to be reduced to the third equation in Eqs. (52) through the mapping,

$$J_0=\Gamma(j_0),\quad J_\pm=j_\pm. \tag{56}$$

If Γ is invertible, the third equation in Eqs. (33) in $\mathscr{A}_{j_0,j}$ can be reduced to the third equation of Eqs. (52) of an algebra defined by the function $[J_0]$ with the identification $\mathscr{F}\circ\Gamma^{-1}=[\,]$ where $[\,]\circ\Gamma$ means the composition of the two functions, i.e., $([\,]\circ\Gamma)(\xi)=[\Gamma(\xi)=[\Gamma(\xi)]$. In the case of $sl_q(2)$, i.e., $[J_0[=[2J_0]_q$, the function $\mathscr{F}(s,j_0,s)$ becomes

$$\mathscr{F}(s,j_0)=-\frac{(\phi(j_0))^2-(\phi(j_0))^{-2}}{q-q^{-1}}, \tag{57}$$

where $q=e^s, \phi(\xi)\equiv q^{-\Gamma(\xi)}$ has to satisfy the equation $\phi(\xi-\mathscr{G}(s,\xi))=q\,\phi(\xi)$. Consequently, Eqs. (53)–(55) provide the reduction of $sl_q(2)$ into $\mathscr{A}_{j_0,j}$, through Γ. For details of the above technique of mapping and reduction of nonlinear algebras one can see examples in Ref. 31. In the case of the algebra $\mathscr{A}_{1,1}$ Eqs. (53)–(55) give the condition

$$p(W_0-1)=W_0-G(1,W_0), \tag{58}$$

which has the solution

$$J_0=p(W_0)\big|_{\mathscr{A}_{1,1}}=\cosh(2^{-W_0}b), \tag{59}$$

for any arbitrary constant b. By inverting Eq. (59) we obtain

$$W_0=\mp\frac{1}{\ln(2)}\ln\left(\frac{\partial}{b}\right). \tag{60}$$

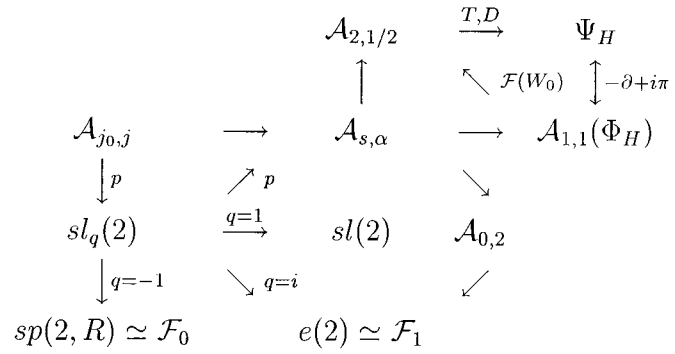

FIG. 3. A diagrammatic representation of the algebraic maps (arrows) and morphisms ($\simeq$) of $\mathscr{A}_{j_0 j}$, $\mathscr{A}_{s,\alpha}$, $\mathrm{sl}_q(2)$, sl(2), and $\mathscr{F}_{0,1}$.

Conversely, starting from $\mathrm{sl}_q(2)$ and its deformation $[\,]_q$ and mapping it into $\mathscr{A}_{1,1}$ we obtain for the operator $F(s,T)=F(s,T(W_0))$,

$$F=f(\Gamma(W_0))=f(p^{-1}(W_0))=[2p^{-1}(W_0)]. \tag{61}$$

A diagram containing these algebra morphisms is presented in Fig. 3.

VII. FURTHER EXTENSIONS, COMMENTS, AND CONCLUSIONS

In this paper we present a method for connecting classes of nonlinear (q-deformed) algebras, with scaling functions and wavelets. This connection is reciprocal. The algebra $\mathscr{A}_{j_0,j}|_{s=1}$ allows the choice of different dilation equations, i.e., for different functions $j(1,T)$ one can obtain different scaling functions. The function $j_0(1,T)$ should be chosen in order to give the correct wavelet function through the action of $j_0 j_-$. The connection with quantum groups is more transparent if we choose for $j_0=[\partial]_{s=1/2}=W_0(2,1/2)$, Eq. (14), and for Φ, the Haar scaling function, $j_-=D(1+T^{-1})$. The action of the q-derivative $[\partial]_{1/2}$ on Φ gives exactly the Haar wavelet. In this example the operator j_0 is anti-Hermitian and we can identify its spectrum (imaginary eigenvalues) from the commutation relations. We also have the relation $\Psi=(j_0-\widetilde{G}(1,j_0)\Phi$, so that one can express the eigenvectors $|a\rangle$ of J_0 in the wavelet basis of the algebra. If $|a\rangle=\Sigma_{j,n}\, C_{j,n}\Phi_{j,n}$, we obtain a recursion relation for the coefficients of $|a\rangle$ and for the eigenfunctions of $j_0\,\Sigma_k\, C_{j,p-2j_k}C_k=aC_{j,p}$ for any j and p integer, where C_k are the Taylor coefficients of the function $-\xi^{-\lambda}g(-\xi)$. We note that by using the q-derivative instead of a function of T we obtain exactly the same mother wavelet (Haar wavelet).

We want to note a natural extension of the above developments, coming from a different realization of sp(2,R) in terms of the full algebra of symmetry of the real line: $X_0=x\partial$ (dilations), $X_-=\partial$ (translations), and $X_+=x^2\partial$ (expansions). This is the maximal finitely generated real Lie algebra with generators in the form $x^n\partial$. By exponentiation, the generators X_0, X_- provide D and T and the last generator has the action $E^a=e^{aX_+}f(x)=f(x/1-ax)$. For $a>0$ the action corresponds to a contraction of the function and for $-1<a<0$ it is a dilation. But, for $a<-1$ and $|a|\geqslant 1$ we obtain a splitting of the function in two Heaviside distributions, $E^a f(x)=H(x)+H(-x+1/a)$. A possible closed nonlinear algebra containing D, T, and E could be an opportunity for wavelets with multiscale properties.[18,19]

In conclusion, we found that the operators of dilation and translation (D,T) can be combined in such a way as to generate nonlinear algebras, depending on certain parameters (s,α). We have investigated these algebras from the point of view of quantum groups, discussing their unirreps, Casimir operators, and reductions of these algebras to other q-deformed algebras, like $\mathrm{sl}_q(2)$ or to the Fourier series generating algebra. It has been shown that such algebras provide an appropriate framework for the foundation of the wavelets analysis and for the obtaining the corresponding scaling functions. We have worked out two examples, the Haar and the B-scaling functions. The

algorithm provides a general algebraic method for finding specific scaling function. Direct applications of such an approach can found in the theory of finite-difference equations and q-difference equations.[21–25,27]

This study represents only a first step towards understanding the relation between the theory of nonlinear algebras (having exponential spectra) and wavelets with their finite-difference equations. We conjecture that such an algebraic approach (nonlinear algebras) to scale invariant structures can lead to interesting mathematical constructions like tools for identifying isolated coherent structures associated with certain mother wavelets and limiting nonlinear algebraic structures. The tranzition between such self-organized structures can be carried out through the modification of the deformation parameter q, with the intermediate domain reprezenting ''noise'' (nonclosed algebraic structures).

Existence of parallel spinors on nonsimply connected Riemannian manifolds

Brett McInnes[a)]
International Centre for Theoretical Physics, Trieste, Italy

(Received 27 May 1997; accepted for publication 30 October 1997)

It is well known, and important for applications, that Ricci-flat Riemannian manifolds of nongeneric holonomy always admit a parallel (covariant constant) spinor if they are simply connected. The nonsimply connected case is much more subtle, however. We show that a parallel spinor can still be found in this case *provided* that the (real) dimension is not a multiple of four, and *provided* that the spin structure is carefully chosen. © *1998 American Institute of Physics.*

I. INTRODUCTION

In string and brane theories, the internal part of the vacuum space–time model is taken to be a Ricci-flat Riemannian manifold. This is *necessary* if the manifold is to admit a parallel spinor, which in turn is necessary if $N=1$ supersymmetry is to be preserved.[1] One must ask, however, whether Ricci flatness is *sufficient* to ensure the existence of a parallel spinor, and this is the subject of the present work. This question is particularly topical now that internal manifolds K of dimension other than six are being considered,[2] since the spin geometry of compact Ricci-flat manifolds K varies quite strongly as the dimension n changes. (Throughout this work, ''dimension'' always means ''real dimension.'')

As the only known[3] examples of compact Ricci-flat Riemannian manifolds have nongeneric holonomy [that is, their linear holonomy groups are proper subgroups of $O(n)$, or of $\mathrm{SO}(n)$ in the orientable case] we shall assume henceforth that K is a compact, orientable, Ricci-flat manifold of nongeneric holonomy. Our question is simply this: must K admit a parallel spinor? The answer may be surprising: it is ''no.'' For example, let K be an Enriques surface,[4] so that K is a compact Kähler 4-manifold that admits a Ricci-flat metric. As we shall see, there is no parallel spinor on this manifold. Clearly, it is important to arrive at a better understanding of this situation.

Ricci flatness arises as the *local* integrability condition of the differential equations, expressing the condition that some spinor field be parallel. The question is whether the parallel spinor locally so defined can be extended globally. One finds that complications arise *only if K is not simply connected*. The complications are of two kinds. First, the existence of noncontractible loops can make it impossible to define global parallel spinors altogether; this is what happens in the case of the Enriques surfaces. The second, more subtle complication is as follows. If a spin manifold is not simply connected, then it may have *more than one* spin structure.[5] In such cases, it turns out that the success of any attempt to extend a local parallel spinor *depends on the choice of spin structure*. In fact, in a specific sense to be explained below, ''most'' spin structures on ''most'' nonsimply connected K *do not* permit the extension to be made. However, on six-dimensional Calabi–Yau manifolds, there is always (precisely) one spin structure that does admit a parallel spinor.

Recently, Joyce[6] has given examples of compact seven-manifolds with linear holonomy group isomorphic to G_2. Some of these manifolds are not simply connected, and so we must ask whether global parallel spinors exist on them, and, if so, we should identify those spin structures that permit parallel spinors and those that do not. In fact, these problems can be analyzed in a very direct and explicit way, as we shall now explain.

II. THE CASE $n=4m$

When n, the dimension of K, is a multiple of 4, the situation is quite clear cut. We have the following theorem.

Theorem 1: Let K be any compact, locally irreducible, Ricci-flat manifold of nongeneric holonomy and real dimension $n=4m$, where m is any integer $\geqslant 1$. Then K admits a parallel spinor if and only if it is simply connected.

Proof: If K is simply connected, its linear holonomy group must be connected, and so the holonomy group must be SU($2m$) or Sp(m) or Spin(7) if $n=8$. Recall[3] that local irreducibility means that K is not a product. All of these groups are themselves simply connected, and so K is a spin manifold.[5] Since every loop in K is contractible, parallel transport of locally constant spinors is unambiguous, and so a global parallel spinor can be constructed. Conversely, suppose that K admits a global parallel spinor with respect to some spin structure. In this case, the given information merely forces the *restricted*[3] holonomy group to be SU($2m$), Sp(m), or Spin(7). This means that a certain canonical form (the holomorphic $2m$-form in the first two cases, the Cayley form in the third) exists locally, but perhaps not globally.[7] However, via the ''squaring'' construction, these canonical forms can be expressed in terms of the parallel spinor.[5] The existence of the global parallel spinor thus forces the canonical forms to exist globally, and so the *full* linear holonomy group of K is a connected group. But this is possible, if $n=4m$, only if K is simply connected.[7,8] This completes the proof.

In connection with the second part of the proof, one should note that the Enriques surfaces mentioned earlier do not have a *connected* linear holonomy group and do not admit a global holomorphic two-form. They are not simply connected and do not admit a parallel spinor. (In fact, they are not spin manifolds.)

From the point of view of applications, Theorem 1 is rather disappointing, since one expects interesting physical consequences if K is not simply connected. For example, nontrivial *flat* gauge configurations (''Wilson loop'' or Hosotani[1] effects) are possible only if K is not simply connected. In physical language, Theorem 1 means that *if n is a multiple of 4, then $N=1$ supersymmetry is inconsistent with Wilson loop effects*.

III. THE CASE $n\neq 4m$

The situation when n is not a multiple of 4 is more satisfactory, but also more subtle. Let K be an n-dimensional spin manifold; that is, there exists a Spin(n) principal bundle Spin(K) over K such that Spin(K) is a nontrivial double cover of SO(K), a bundle of oriented orthonormal frames with respect to some fixed Riemannian structure on K. Let V be some vector space that affords a faithful representation ρ of Spin(n). A spinor on K can be interpreted as a V-valued function ψ on Spin(K) that satisfies $\psi(sg)=\rho(g^{-1})\psi(s)$ for each s in Spin(K) and each g in Spin(n). [This is precisely analogous to the interpretation[9] of vector fields as $\mathbb{R}^n$-valued function on SO(K).]

In general, there is no unique spin structure on K if it is not simply connected. In the case of compact, orientable, Ricci-flat, locally irreducible Riemannian manifolds of nongeneric holonomy, we can construct these explicitly, as follows. First, note that, by the Cheeger–Gromoll theorem,[3] K can be expressed as $K=\widetilde{K}/\Gamma$, where $\widetilde{K}$ is the universal Riemannian cover and Γ is a *finite* group of isometries acting freely on $\widetilde{K}$. If $n\neq 4m$, then both K and $\widetilde{K}$ are spin manifolds. To see this, note that in this case the *full* (not just the restricted) holonomy group of K must be connected:[7] in fact, it must be isomorphic to SU($2r+1$), $r\geqslant 1$, $n=4r+2$, or perhaps to the exceptional group G_2 if $n=7$. [Here we are using the assumption that K is orientable. Nonorientable compact, Ricci-flat manifolds of nongeneric holonomy do exist in these dimensions, and their full holonomy groups are disconnected, as is usually the case for non-simply-connected Riemannian manifolds.] Since SU($2r+1$) and G_2 are simply connected, K is spin, and similarly for $\widetilde{K}$. As $\widetilde{K}$ is simply connected, its first homology group $H_1(\widetilde{K},\mathbb{Z})$ is trivial, and hence so is its first cohomology group with $\mathbb{Z}_2$ coefficients, $H^1(\widetilde{K},\mathbb{Z}_2)$. As the latter counts[5] the spin structures on a spin manifold, we see that $\widetilde{K}$ has a unique spin structure, Spin($\widetilde{K}$).

Let f be any element of Γ, and let $\widetilde{f}$ be its natural lift,[9] so that, because f is isometric, $\widetilde{f}:\mathrm{SO}(\widetilde{K})\to\mathrm{SO}(\widetilde{K})$ is a bundle automorphism of SO($\widetilde{K}$). If we think of Spin($\widetilde{K}$) as a $\mathbb{Z}_2$ principal

bundle over $\mathrm{SO}(\widetilde{K})$, then we can construct an induced bundle[9] $\widetilde{f}^{-1}(\mathrm{Spin}(\widetilde{K}))$, which is again a $\mathbb{Z}_2$ bundle over $\mathrm{SO}(\widetilde{K})$ equipped with a bundle homomorphism $\hat{f}$ that covers $\widetilde{f}$. As usual,[9] $\hat{f}$ is unique modulo automorphisms of $\widetilde{f}^{-1}(\mathrm{Spin}(\widetilde{K}))$ that preserve $\widetilde{f}$. Now in this case $\mathrm{Spin}(\widetilde{K})$ is the only spin structure over $\widetilde{K}$, and so $\hat{f}$ is an automorphism of $\mathrm{Spin}(\widetilde{K})$ covering $\widetilde{f}$. If we denote by $-\hat{f}$ the composite of $\hat{f}$ with -1, where -1 is the action by $-1 \in \mathrm{Spin}(n)$ on $\mathrm{Spin}(\widetilde{K})$, then because -1 is central, $-\hat{f}$ is also an automorphism of $\mathrm{Spin}(\widetilde{K})$ covering $\widetilde{f}$. As f has no fixed point, nor have $\widetilde{f}$ or $\hat{f}$ or $-\hat{f}$.

Let p be the order of f. Then, by the chain rule, p is also the order of $\widetilde{f}$, and so $\hat{f}^p = \pm 1$. In the present case the minus sign can be ignored, as follows. First, if p is odd and $\hat{f}^p = -1$, then $(-\hat{f})^p = 1$ since -1, as an automorphism, commutes with every other automorphism of $\mathrm{Spin}(\widetilde{K})$. Thus if p is odd, there is exactly one automorphism of $\mathrm{Spin}(\widetilde{K})$ of order p covering $\widetilde{f}$; in this case, we pick $\hat{f}$ to be this automorphism and so there is no ambiguity here. Suppose now that p is even, and assume that $\hat{f}^p = -1$. Now K has a canonical parallel form: the holomorphic $(2r+1)$-form if the holonomy group is $\mathrm{SU}(2r+1)$, or the associative calibration[5] in the case of G_2. In each case these forms pull back to a parallel form ω on $\widetilde{K}$, and we have $f^*\omega = \omega$. [We draw the reader's attention to the fact that it is essentially this relation that distinguishes this case from the $(4m)$-dimensional case: for, in the latter, f^* cannot preserve ω. One can still take a quotient in some cases, but then the holonomy group of the quotient manifold will be disconnected.] This relation has the following interpretation in terms of holonomy theory. Let $\widetilde{P}$ be a linear holonomy bundle[9] over $\widetilde{K}$: it is a subbundle of $\mathrm{SO}(\widetilde{K})$ with a structural group isomorphic to the linear holonomy group. The relation $f^*\omega = \omega$ simply means that the natural lift, $\widetilde{f}$, maps $\widetilde{P}$ into itself, $\widetilde{f}\widetilde{P} = \widetilde{P}$. Now the Levi-Civitá connection on $\mathrm{SO}(\widetilde{K})$ induces a canonical Dirac connection on $\mathrm{Spin}(\widetilde{K})$. The holonomy bundles in $\mathrm{Spin}(\widetilde{K})$ cover the holonomy bundles in $\mathrm{SO}(\widetilde{K})$. Let $\hat{P}$ be a Dirac holonomy bundle covering $\widetilde{P}$; then we have $\hat{f}\hat{P} = \pm\hat{P}$, where again -1 acts on $\hat{P}$ through the overall action of $\mathrm{Spin}(n)$ on $\mathrm{Spin}(\widetilde{K})$. Thus $(\hat{f})^2\hat{P} = \hat{P}$, and, since p is even, $(\hat{f})^p\hat{P} = \hat{P}$. If $(\hat{f})^p = -1$, then $-\hat{P} = \hat{P}$, which is only possible if -1 is an element of the structural group of $\hat{P}$. Now $\widetilde{K}$ is simply connected, so the holonomy group of any connection on any principal bundle over $\widetilde{K}$ must be connected; therefore the structural group of $\hat{P}$ is $\mathrm{SU}(2r+1)$ or G_2. But all of these groups have centers isomorphic to an odd cyclic group, and so none contains -1. Thus $\hat{f}^p = +1$. In short, we may take it that $\hat{f}$ has the same order as f itself.

Proceeding in this way, one shows that, just as Γ acts freely on $\widetilde{K}$, so also it acts (in the form of the induced automorphisms $\hat{f}$) freely on $\mathrm{Spin}(\widetilde{K})$. Precisely because the $\hat{f}$ are automorphisms, they commute with the action of $\mathrm{Spin}(n)$ on $\mathrm{Spin}(\widetilde{K})$, and so there is a natural action of $\mathrm{Spin}(n)$ on $\mathrm{Spin}(\widetilde{K})/\Gamma$. It is not difficult to show that $\mathrm{Spin}(\widetilde{K})/\Gamma$ is in fact a principal $\mathrm{Spin}(n)$ bundle over $\widetilde{K}/\Gamma = K$. Of course, Γ also acts freely, through the natural lifts on $\mathrm{SO}(\widetilde{K})$, and we have $\mathrm{SO}(\widetilde{K})/\Gamma = \mathrm{SO}(K)$. Thus $(\mathrm{Spin}(\widetilde{K})/\Gamma)/\mathbb{Z}_2 = \mathrm{SO}(K)$, and, in fact, $\mathrm{Spin}(\widetilde{K})/\Gamma$ is a spin structure over K. However, it is clear from this explicit construction *that there is a crucial ambiguity in the way* Γ *acts on* $\mathrm{Spin}(\widetilde{K})$: namely, each f of even order can be represented *either* by $\hat{f}$ or by $-\hat{f}$. That is, there is an ambiguity not in the structure of Γ, but rather in the way it acts on $\mathrm{Spin}(\widetilde{K})$. (When Γ is not Abelian, there are additional complications because conjugation by some element of the group can mix a given element with others, so that $\hat{f}$ cannot be replaced with $-\hat{f}$ without affecting the conjugate. In this case we simply replace Γ by its Abelianization, and the above remarks apply to the Abelianization.) These various actions by Γ produce different spin structures when we take the quotient $\mathrm{Spin}(\widetilde{K})/\Gamma$, and this is how K can have more than one spin structure. One can show that the resulting spin structures are in one-to-one correspondence with the group of homomorphisms from the Abelianization of Γ to $\mathbb{Z}_2$; this group is isomorphic to $H^1(K,\mathbb{Z}_2)$, and so we recover the well-known fact that $H^1(K,\mathbb{Z}_2)$ counts the spin structures on a spin manifold K.

Some examples will clarify the basic idea. Let K be one of Joyce's[6] compact seven-manifolds with holonomy G_2 and the fundamental group isomorphic to $\mathbb{Z}_2$, so that $K = \widetilde{K}/\mathbb{Z}_2$, with $\mathbb{Z}_2$ generated by an involution f. Then $\widetilde{K}$ has a unique spin structure $\mathrm{Spin}(\widetilde{K})$, but K has two distinct spin structures, $\mathrm{Spin}(\widetilde{K})/\{1,\hat{f}\}$ and $\mathrm{Spin}(\widetilde{K})/\{1,-\hat{f}\}$. Again, suppose that K is a six-dimensional Calabi–Yau manifold of the form $\widetilde{K}/(\mathbb{Z}_2\times\mathbb{Z}_2)$, with $\mathbb{Z}_2\times\mathbb{Z}_2$ generated by a pair of involutions

(a,b). Then K has *four* distinct spin structures, given, respectively, by factoring $\mathrm{Spin}(\tilde{K})$ by $\{1,\hat{a},\hat{b},\hat{a}\hat{b}\}$, $\{1,-\hat{a},\hat{b},-\hat{a}\hat{b}\}$, $\{1,\hat{a},-\hat{b},-\hat{a}\hat{b}\}$, and $\{1,-\hat{a},-\hat{b},\hat{a}\hat{b}\}$. Finally, suppose that Γ is the non-Abelian group of order 12 generated by a,b,c satisfying $a^2=b^2=c^3=1$, $ab=ba$, $cac^{-1}=b$, $cbc^{-1}=ab$. The relation $\hat{c}\hat{a}\hat{c}^{-1}=\hat{b}$ shows that $\hat{a}$ can be replaced by $-\hat{a}$ only if $\hat{b}$ is replaced by $-\hat{b}$, but this is inconsistent with $\hat{c}\hat{b}\hat{c}^{-1}=\hat{a}\hat{b}$. Hence $K=\tilde{K}/\Gamma$ has only *one* spin structure in this case.

With the aid of this explicit construction of the spin structures over K, we can now easily prove the following result.

Theorem 2: Let K be any compact, orientable, locally irreducible, Ricci-flat manifold of nongeneric holonomy and real dimension not a multiple of four. Then there exists *exactly one* spin structure over K admitting a parallel spinor; all other spin structures admit *no* parallel spinor.

Proof: As in the proof of Theorem 1, $\tilde{K}$, the universal cover, admits a parallel spinor. If the holonomy group is G_2, this spinor is essentially unique (the space of parallel spinors is one dimensional); if the holonomy group is $\mathrm{SU}(2r+1)$, it is unique modulo complex conjugation.[10] Let ψ be the corresponding V-valued function on $\mathrm{Spin}(\tilde{K})$, and let ω be the canonical form on $\tilde{K}$. Set $K=\tilde{K}/\Gamma$, and let f be any element of Γ; then $f^*\omega=\omega$ implies, since ω may be obtained from the parallel spinor by ''squaring,'' that $\hat{f}^*\psi=\pm\psi$. But we have seen that the spin structures on K are obtained precisely by taking the quotient of $\mathrm{Spin}(\tilde{K})$ by the various possible actions of Γ on $\mathrm{Spin}(\tilde{K})$. A given spin structure over K will inherit the parallel spinor from $\mathrm{Spin}(\tilde{K})$ if and only if $\hat{f}^*\psi=+\psi$, never $-\psi$, for every f in Γ. Now since $\psi(sg)=\rho(g^{-1})\psi(s)$ for all s in $\mathrm{Spin}(\tilde{K})$ and all g in $\mathrm{Spin}(n)$, we have $\psi(-s)=-\psi(s)$, and so

$$(-\hat{f})^*\psi=-\hat{f}^*\psi.$$

Therefore, if $\hat{f}^*\psi=-\psi$, we have $(-\hat{f})^*\psi=+\psi$. By suitably distributing minus signs, we can therefore always find an action by Γ on $\mathrm{Spin}(\tilde{K})$ that preserves ψ; but only one such arrangement will work. Thus ψ projects to a parallel spinor on *one* spin structure over K, but it fails to do so for every other spin structure. This completes the proof.

For example, we saw that Joyce's manifold with a fundamental group isomorphic to $\mathbb{Z}_2$ has two spin structures, $\mathrm{Spin}(\tilde{K})/\{1,\hat{f}\}$ and $\mathrm{Spin}(\tilde{K})/\{1,-\hat{f}\}$. Since either $\hat{f}^*\psi=\psi$ or $(-\hat{f})^*\psi=\psi$, one of these has a parallel spinor, and the other does not. In the case where the fundamental group is $\mathbb{Z}_2\times\mathbb{Z}_2$, one spin structure has a parallel spinor, while the other three do not.

Readers familiar with Ref. 5 may wonder how Theorem 2 can be consistent with Proposition 10.1 in Chap. IV of that work, which claims that a global spinor always exists if the holonomy group is contained in the isotropy subgroup of the spin group at any point. The subtle point here is that the parallel transport of spinors is governed by different connections [the connections on $\mathrm{Spin}(K)^i$, where i labels the various spin structures] to the one that defines parallel transport of vectors [the connection on $\mathrm{SO}(K)$]. Thus we cannot speak of ''the'' holonomy group until we specify which of these connections is meant. In fact, one can show that while the *linear* connections of these manifolds always have a connected holonomy group, this is not necessarily true of the spinor or Dirac holonomy groups. Thus, requiring the *linear* holonomy group to be contained in the isotropy group may not suffice to ensure that the relevant *Dirac* holonomy group is so contained: this will depend on the choice of spin structure. In fact, Theorem 2 asserts that this kind of argument will usually fail.

In conclusion, then, compact Ricci-flat orientable six-manifolds of nongeneric holonomy behave very differently to their four- and eight-dimensional counterparts: even when they are not simply connected, they always admit a parallel spinor with respect to *some* spin structure. The Joyce manifolds in dimension seven behave, in this respect, exactly like six-dimensional Calabi–Yau manifolds.

IV. CONCLUSION

The results of this work are easily summarized. Let K be a compact, orientable, locally irreducible, Ricci-flat Riemannian manifold of nongeneric holonomy and dimension n. Suppose that K is not simply connected. Then if $n=4m$, K has no parallel spinor; while if $n\neq 4m$, K does

have a parallel spinor, but *only* if one makes precisely the right choice of spin structure. A bad choice of spin structure, then, will break supersymmetry. One might regard this as evidence that Calabi–Yau six-manifolds or Joyce seven-manifolds with several spin structures should be avoided. More speculatively, one might imagine that some kind of ''averaging over spin structures'' on such a manifold could shed some light on the problem of supersymmetry breaking in these theories.

(Received 17 December 1996; accepted for publication 21 October 1997)

The coregular real representations of the compact simple Lie groups are classified and the equalities and inequalities defining their orbit spaces are determined in the case of 2, 3 and 4 basic polynomial invariants. The results are obtained making use of the classification of the complex coregular simple Lie groups given by G. W. Schwarz and of the determination of all the allowable metric matrices for q-dimensional ($q \leqslant 4$) orbit spaces of compact coregular linear groups, recently obtained by the present authors. The results are used to determine in a rigorous way the minima of two SO(10) and E_6 invariant Higgs potentials. © *1998 American Institute of Physics.* [S0022-2488(98)03503-8]

I. INTRODUCTION

This paper is part of a program aimed at the determination and classification of the orbit spaces of compact groups, thought of as natural domains of definition of invariant functions. In particular, in this article we shall determine all coregular real representations of simple compact Lie groups, and the corresponding orbit spaces in all the cases in which the number of basic invariants does not exceed four. The results may be used as effective tools in the analysis of invariant potentials, as we shall show working out in detail two substantial examples.

Invariant functions play an important role in all the sectors of physics where symmetries are relevant and an analysis of their properties is often required. As an example, which concerns both elementary particle and solid state physics, let us consider the determination of patterns of spontaneous symmetry breaking in theories in which the ground state of the system is determined by the minimum of an invariant potential $V(x)$ (Refs. 1–4) (V might be a Higgs potential in a gauge field theory or a thermodynamic potential in a Landau theory of structural phase transitions). The problem can be formalized in the following way. The ground state is represented by a vector x_0 belonging to the Euclidean space $\mathbb{R}^n$, on which the symmetry group G (of the formalism describing the system) acts as a group of linear transformations; x_0 is determined as the point at which $V(x)$ assumes its absolute minimum and the isotropy subgroup of G at x_0 (the little group of x_0), G_{x_0}, is the true symmetry group of the system. Generally, the potential depends also on parameters γ (for instance, scalar self-couplings in Higgs potentials, or pressure and temperature in thermodynamic potentials), that cannot be determined from invariance requirements under transformations of G. In this case x_0 and G_{x_0} can depend on the γ's, and various patterns of spontaneous symmetry breaking are allowed, corresponding to distinct structural *phases* of the system.

In supersymmetric field theories the absolute minimum of the potential controls both the spontaneous symmetry and supersymmetry breaking (see, for instance, Ref. 5 and references therein), and often the features of the two breaking schemes are related.[6]

Since the isotropy subgroups of G at nearby points may be different, in all the cases just mentioned, the determination of the point x_0 has to be analytical. This is generally a difficult

computational task, also in the cases in which polynomial approximations are used for the potential, owing to the large number n of variables x_i that are generally involved. An additional difficulty is related to the degeneracy of the stationary points of the potential, which is an unavoidable consequence of the invariance properties of the potential; it prevents, in fact, a direct application[7,8] of Morse's theory.[9]

A more economical approach to the problem was proposed by Gufan,[10,11] who noted that, according to a theorem by Hilbert,[12] a G-invariant polynomial function $V(x)$ can be expressed as a function $\hat{V}(p_1(x),\ldots,p_q(x))$ of a finite set $p(x)=(p_1(x),\ldots,p_q(x))$ of basic polynomial invariant functions, i.e., of a *Minimal Integrity Basis* (abbreviated to MIB) of the ring of G-invariant polynomial functions. When the point $p\in\mathbb{R}^q$ ranges in the domain spanned by $p(x)$, $x\in\mathbb{R}^n$, the function $\hat{V}(p)$ has the same range as $V(x)$, but is not plagued by the same degeneracies. Gufan's proposal found immediate applications in crystal field theory (see, for instance, Refs. 13–17). A full and correct exploitation of his idea required, however, an exact determination of the ranges of the functions $p_i(x)$, a non-trivial problem that was solved only when it was independently remarked that any G-invariant function can be thought of as a function in the orbit space $\mathbb{R}^n/G$ of the action of G in $\mathbb{R}^n$,[18,19] where the p_i's can be used advantageously to parametrize the orbits. In $\mathbb{R}^n/G$, the images of all the points of $\mathbb{R}^n$ with the same invariance properties under G transformations form smooth sub-manifolds, which are usually called *strata*. By varying the parameters γ, the location of the minimum of $V(x;\gamma)$ may shift from a stratum to a different one, thus causing a structural phase transition of the system.

A sensible progress in the characterization of the geometry of the orbit spaces of the compact linear groups (CLG's) was achieved with the discovery that the orbit spaces of the CLG's are connected semi-algebraic varieties, whose defining equations and inequalities can be expressed in the form of positivity conditions of matrices $\hat{P}(p)$, hereafter called $\hat{P}$-matrices, determined only from the gradients of the basic polynomial invariants $p_1(x),\ldots,p_q(x)$:[18–21]

$$\hat{P}_{ab}(p(x))=\sum_1^n{}_i \frac{\partial p_a(x)}{\partial x_i}\frac{\partial p_b(x)}{\partial x_i}, \quad a,b=1,\ldots,q. \tag{1}$$

Using this result, one can obtain a concrete realization of the orbit space of all CLG's whose sets of basic invariant polynomial functions are known.

The definition of a MIB does not exclude the possibility of algebraic relations among its elements, the important point is that none of them can be expressed as a *polynomial* function of the others. If there are no algebraic relations among the elements of a MIB of a linear group G, then G is said to be *coregular*.

The *finite coregular* linear groups coincide with the finite groups generated by reflections[22] and sets of basic polynomial invariants have been given by many authors (see, e.g., Ref. 23 and references therein). However, the classification of all the coregular CLG's and the determination of their MIB's is a non-trivial problem, which is still open; but for the finite groups, partial information is available only about simple[24] and semisimple[25] Lie groups.

In the case of *non-coregular* CLG's, the non-independence of the elements of the MIB's, makes their determination much more difficult.

An alternative indirect method of computation of the $\hat{P}$-matrices, which somehow bypasses the problem of determining a complete set of basic polynomial invariants, was proposed in Refs. 26 and 27, where the $\hat{P}$-matrices were shown to be solutions of a universal *master* equation, satisfying convenient initial conditions (*allowable solutions*). The statement of the master equation does not require the explicit knowledge of a MIB and its solution involves as free parameters only the number and the degrees of the elements of a MIB.

For coregular CLG's, with less than 5 elements in the MIB's, this approach enabled us to determine the orbit spaces, thus proving that, for each fixed choice of their degrees, they can be classified in a finite (and small, for small dimensions and degrees) number of isomorphism classes.[26–28]

This result makes particularly appealing the orbit space approach to the study of invariant functions and spontaneous symmetry breaking. In fact, invariance properties are often the only bounds which are imposed on the potential (beyond regularity and stability properties and/or

bounds on the degree, when the potential is a polynomial function) and, if the symmetry groups of the potentials of different theories share isomorphic orbit spaces, the potentials have the same formal expression and the same domain when written as functions in orbit space, despite the completely different physical meaning of the variables and parameters involved in the definition of the potentials. Thus, the problems of determining the geometric features of the phase space, the location and stability properties of the minima of the potential, the number of phases and the allowed phase transitions are identical in all these theories.[19,29,26,27]

For coregular CLG's, the determination of all the allowable solutions of the master equation has been accomplished for $q \leqslant 4$ (see Refs. 27 and 28); for $q > 4$, it appears to be still possible, but extremely lengthy. This difficulty can be at least partially overcome through inductive procedures.[30]

For non-coregular CLG's, the determination of convenient additional (''initial'') conditions, allowing us to find all the significant solutions of the master equation, is still an open problem, which has been solved only in the case of only one independent relation among the elements of the MIB.

In any case, the master equation and the associated initial conditions are only a set of necessary conditions; even if quite stringent, they need not be sufficient. Therefore, once the allowable solutions of the master equation have been determined, the problem remains of selecting those which are really generated by a group.

This problem was solved in Refs. 31 and 32 with regard to the finite coregular linear groups, for which, as already remarked, complete information is available concerning classification and basic sets of invariants. The $\hat{P}$-matrices of all the finite compact linear groups with up to 4 basic invariants were explicitly calculated and checked to be present in the list of allowable solutions of the master equation determined in Refs. 26–28.

In this article we shall solve the analogous problem in the case of compact simple Lie groups, that is, we shall identify among the allowable $\hat{P}$-matrices (abbreviated to A$\hat{P}$M's) listed in Refs. 26–28, those corresponding to coregular real representations of compact simple Lie groups. As far as we know, an explicit classification of these groups cannot be found in the mathematical literature, and only partial information is available about their sets of basic polynomial invariants. We shall derive the missing pieces of information from results obtained by G. W. Schwarz,[24] who classified the *coregular complex* representations of complex simple Lie groups and determined the degrees of the corresponding basic invariant polynomials. In Schwarz's paper, hints can also be found allowing us to construct explicitly MIB's for most of the coregular complex representations of complex simple Lie groups.

Once the list of the real coregular representations of the compact simple Lie groups has been obtained, the identification of the associated $\hat{P}$-matrices turns out to be trivial or easy in the following two cases:

(1) There is only one allowable solution of the master equation in correspondence with a given set of degrees of the basic polynomial invariants.
(2) The representation is the adjoint representation. As we shall show, the $\hat{P}$-matrix of the adjoint representation is the same as the $\hat{P}$-matrix of the corresponding Weyl group, which is a finite group, so that the results of Ref. 32 can be used.

In all the other cases a sounder analysis of each particular situation has been necessary. In some cases the explicit knowledge of the full MIB could be inferred from Ref. 24, thus the determination of the $\hat{P}$-matrix has been easy. In some other cases, even if only partial information about the MIB is provided in Ref. 24, this turned out to be sufficient to single out the correct $\hat{P}$-matrix.

In order to make clear how our results can be exploited in physically interesting situations, we have worked out a rigorous and complete discussion of the minima of two Higgs potentials that have been the object of some attention in model building of grand unified gauge field theories.[33,34] This will prove that, in all the cases in which the relevant $\hat{P}$-matrix is known, like in the cases listed in Table V, the problem of determining the localization of the absolute minimum of the potential and the possible patterns of spontaneous symmetry breaking is reduced to an almost trivial exercise, at least in the case of fourth degree polynomial potentials.

The paper will be organized in the following way. We shall collect in Section II all the definitions and results concerning group actions and the $\hat{P}$-matrix approach to the determination of the orbit spaces of coregular CLG's, in order to make our work as self-contained as possible. Section III deals with adjoint representations, and Sections IV, V and VI report the theorems and the results needed to determine and classify the real coregular representations of compact simple Lie groups from the complex coregular representatations of complex simple Lie groups classified in Ref. [24]. In Section VII are identified the $\hat{P}$-matrices of all the coregular real representations of compact simple Lie groups with less than 5 basic polynomial invariants. Section VIII is devoted to a complete determination of the minima of two general fourth degree polynomial (Higgs) potentials invariant under the compact groups SO(10) and, respectively, E_6 and of the corresponding phase diagrams. The conclusions are reported in Section IX.

In the body of the paper we shall continue to use the following abbreviations:

CLG = Compact Linear Group;

MIB = Minimal Integrity Basis;

A$\hat{P}$M = Allowable $\hat{P}$ Matrix.

II. AN OVERVIEW OF THE GEOMETRY OF LINEAR GROUP ACTIONS

In this section, we shall first define most of our notations and recall, without proofs, some results concerning invariant theory and the geometry of orbit spaces of CLG's. For the unreferenced results see, for instance, Refs. 35 and 36.

A. Orbits, strata and orbit spaces

A couple (G,X) is called a *G-space* if G is topological group and X is a topological space in which G acts as a group of transformations.

We shall denote by $g\cdot x$ the image of $x\in X$ under the action of $g\in G$ and by Ω_x the *G-orbit* through x: $\Omega_x=\{g\cdot x|g\in G\}$. Distinct orbits are disjoint.

The isotropy subgroup of G at x (little group of x) will be denoted by G_x: $G_x=\{g\in G|g\cdot x=x\}$. Isotropy subgroups of G, at points lying on the same orbit Ω_x, are conjugated subgroups in G: $G_{g\cdot x}=gG_xg^{-1},\forall g\in G$.

The class $[G_x]$ of all the subgroups of G conjugated to G_x in G is called the *orbit type of* Ω_x (and of its points). In the set of all orbit types a partial ordering relation can be introduced. We shall write $[G_x]<[G_{x'}]$ if G_x is conjugated to a proper subgroup of $G_{x'}$. In this case we shall say that Ω_x (or anyone of its points) has a *lower symmetry* than $\Omega_{x'}$ (or anyone of its points).

The points $x\in\mathbb{R}^n$ (or, equivalently, the orbits of G) sharing the same orbit type are said to form an *isotropy type stratum* of the action of G in $\mathbb{R}^n$. The connected components of a stratum can be shown to be smooth iso-dimensional sub-manifolds of $\mathbb{R}^n$.

In this paper we shall be interested only in compact Lie group actions. Owing to a famous theorem of Mostow,[37] if these actions are sufficiently regular, they can be reduced to *real linear orthogonal* actions, to which we shall devote most of our attention in the following. Complex linear actions will be considered only as auxiliary tools. Therefore, in the rest of this paper, X will denote $\mathbb{R}^n$ or $\mathbb{C}^n$ and these spaces will be considered both as affine spaces and as vector spaces in which G will be assumed to act as a linear group of unitary operators. By introducing in X the standard basis and the standard Hermitian scalar product the elements of G will be represented by unitary matrices.

The *orbit space* of the action of G in $\mathbb{R}^n$ is defined as the quotient space $\mathbb{R}^n/G$ (obtained through the equivalence relation relating point belonging to the same orbit) endowed with the quotient topology and differentiable structure.

We shall denote by π the canonical projection $\mathbb{R}^n\to\mathbb{R}^n/G$. Whole orbits of G are mapped by π into single points of $\mathbb{R}^n/G$. The image through π of a stratum of $\mathbb{R}^n$ will be called an (*isotropy type*) *stratum of* $\mathbb{R}^n/G$; all its connected components turn out to be smooth iso-dimensional manifolds.

Almost all the points of $\mathbb{R}^n/G$ belong to a unique stratum Σ_p, the *principal stratum*, which is a connected open dense subset of $\mathbb{R}^n/G$. The boundary $\overline{\Sigma}_p\backslash\Sigma_p$ of Σ_p is the union of disjoint *singular* strata. All the strata lying on the boundary $\overline{\Sigma}\backslash\Sigma$ of a stratum Σ of $\mathbb{R}^n/G$ are open in $\overline{\Sigma}\backslash\Sigma$.

The orbit type $[H]$ of a stratum Σ of $\mathbb{R}^n/G$ is contained in the orbit types $[H_b]$ of all the strata Σ_b lying in its boundary; therefore, more peripheral strata are formed by points representing orbits with higher symmetry under G transformations.

The number of distinct orbit types of G is finite and there is a unique minimum orbit type, the *principal orbit type*, corresponding to the principal stratum, and also a unique maximum orbit type $[G]$, corresponding to the image through π of the set of points of $\mathbb{R}^n$, which are invariant under G; this set contains at least the origin of $\mathbb{R}^n$.

A faithful image of $\mathbb{R}^n/G$ can be obtained in the framework of the geometric invariant theory.

A function $f(x)$ is said to be G-invariant if

$$f(g\cdot x)=f(x), \quad \forall x\in\mathbb{R}^n, \quad g\in G. \tag{2}$$

The set of all real, G-invariant, polynomial functions of x forms a ring $\mathbb{R}[x]^G$. By a celebrated theorem of Hilbert, which he first proved for SL(N) and which was extended by Nagata to much more general situations,[12,38,39] including all compact linear groups, the ring of polynomial invariants of reductive algebraic groups is finitely generated, that is, there exists a finite collection of invariant polynomial functions, which we shall denote by $p(x)=(p_1(x),p_2(x),\ldots,p_q(x))$, such that any element $F\in\mathbb{R}[x]^G$ can be expressed as a polynomial function $\hat{F}$ of $p(x)$:

$$F(x)=\hat{F}(p(x)), \quad \forall x\in\mathbb{R}^n, \quad \forall F\in\mathbb{R}[x]^G. \tag{3}$$

As proved by G.W. Schwarz,[40] Eq. (3) holds true also if F is any G-invariant C^∞ function. In this case $\hat{F}$ is a C^∞ function.

The polynomial function $\hat{F}(p)$, $p\in\mathbb{R}^q$, will be said to have weight w if w is the degree of the polynomial $F(x)=\hat{F}(p(x))$, and it will be said to be w-homogeneous of *weight* w if $F(x)$ is homogeneous of degree w. We shall denote by $w(\hat{F})$ the weight of $\hat{F}$.

The elements of a basis of $\mathbb{R}[x]^G$ can be chosen to be homogeneous polynomials. The number q of elements of a MIB and their homogeneity degrees d_i's are only determined by the group G.

Without loss of generality and to avoid trivial situations, in this paper we shall only consider linear groups with no fixed points, but for the origin of $\mathbb{R}^n$. In this case, the minimum degree of the elements of a MIB is necessarily 2, and, because of the orthogonality of the G-action, the following conventions can be adopted:

$$d_1\geqslant d_2\geqslant \ldots d_q=2; \quad p_q(x)=\|x\|^2=\sum_1^n{}_i\, x_i^2. \tag{4}$$

Hereafter, by a MIB we shall mean a *minimal homogeneous* integrity basis satisfying the conventions (4).

The orbits of a compact group G are separated by the elements of its MIB's, i.e., at least one element of a MIB takes on different values on two distinct orbits. But more can be said. Each MIB $\{p_1(x),\ldots,p_q(x)\}$, defines an orbit map $p:\mathbb{R}^n\to\mathbb{R}^q$ which maps all the points of $\mathbb{R}^n$ lying on an orbit of G into a single point of $\mathbb{R}^q$:

$$p:\mathbb{R}^n\to\mathbb{R}^q$$

$$x\mapsto(p_1(x),\ldots,p_q(x)).$$

The range $p(\mathbb{R}^n)$ of the orbit map p yields a faithful image of the orbit space of G, and the elements $\{p_1,\ldots,p_q\}$ of the MIB, thought of as coordinates in the space $\mathbb{R}^q$, provide a smooth parametrization of the points of $\mathbb{R}^n/G$. In fact, every orbit map induces a diffeomorphism of $\mathbb{R}^n/G$ onto a semi-algebraic closed connected subset $\overline{\mathscr{S}}$ of $\mathbb{R}^q$

$$\overline{\mathscr{S}}=p(\mathbb{R}^n)\simeq\mathbb{R}^n/G. \tag{5}$$

The orbit space $\mathbb{R}^n/G$ will be identified to its image $\overline{\mathscr{S}}$, which is a connected semi-algebraic sub-variety of $\mathbb{R}^q$, that is a subset of $\mathbb{R}^q$ defined by polynomial equalities and inequalities. Like all

semi-algebraic varieties,[41] $\overline{\mathscr{S}}$ presents a natural stratification in connected disjoint semi-algebraic sub-varieties $\sigma_i^{(\alpha)}$, called *primary strata*, such that $\overline{\mathscr{S}}=\cup_{i,\alpha}\sigma_i^{(\alpha)}$ and the boundary of each $\sigma_i^{(\alpha)}$ is empty, or the union of lower-dimensional $\sigma_j^{(\beta)}$'s $(j>i)$. Each $\sigma_i^{(\alpha)}$ is open in its closure and it is defined recursively on i (which distinguishes semi-algebraic sets of different dimensions) as the α-th connected component of the set of regular points of the semi-algebraic varieties $\mathscr{W}_i=\overline{\mathscr{S}}\setminus\cup_{0<j<i}\sigma_j^{(\beta)}$, $i=1,2\ldots$. A simple example of a compact connected semi-algebraic variety of $\mathbb{R}^3$ is yielded by a polyhedron. Its interior points form its unique 3-dimensional primary stratum, while 2-, 1- and 0-dimensional primary strata are formed, respectively, by the interior points of each face, by the interior points of each edge and by each vertex.

A ring of polynomial functions $f(p_1,\ldots,p_q)$ is said to be *regular* if it isomorphic to a polynomial ring in q indeterminates, that is, if the elements of its integrity bases are algebraically independent.

The linear group G is said to be *coregular* if its ring of invariant polynomial functions is regular.

In this paper we shall only deal with coregular CLG's.

B. The $\hat{P}(p)$ matrix

Let $\{p(x)\}=\{p_1(x),\ldots,p_q(x)\}$ be a MIB for the group G and let $d_1,\ldots,d_q$ be the corresponding degrees. We shall associate to $\{p(x)\}$ the following square matrix whose elements, defined in terms of G-invariant Euclidean scalar products, are G-invariant polynomials in x; therefore they can be expressed in terms of polynomial functions $\hat{P}_{ab}(p)$, according to Hilbert's theorem

$$P_{ab}(x)=\sum_{1}^{n}{}_i\frac{\partial p_a(x)}{\partial x_i}\cdot\frac{\partial p_b(x)}{\partial x_i}=\hat{P}_{ab}(p(x)),\quad a,b=1,\ldots,q. \tag{6}$$

In our conventions, $\hat{P}(p)$ is a real $q\times q$ symmetric matrix, whose elements $\hat{P}_{ab}(p)$ are w-homogeneous polynomials of weight $w(\hat{P}_{ab})=d_a+d_b-2$ and $\hat{P}_{qa}(p)=\hat{P}_{aq}(p)=2d_ap_a$, $a=1,2,\ldots,q$.

A characterization of the image $\overline{\mathscr{S}}=p(\mathbb{R}^n)$ of the orbit space of G as a semi-algebraic variety can be easily obtained through the matrix $\hat{P}(p)$ associated to one of its MIB's and the following fundamental theorem:[18,19,21]

Theorem II.1: *Let G be a compact coregular matrix subgroup of $\mathrm{O}_n(\mathbb{R})$, p be the orbit map $\mathbb{R}^n\to\mathbb{R}^q$ defined by the homogeneous MIB $\{p_1(x),p_2(x),\ldots,p_q(x)\}$ and $\hat{P}(p)$ be the matrix defined in (6). Then $\overline{\mathscr{S}}=p(\mathbb{R}^n)$ is the semi-algebraic subset $\mathbb{R}^q$ where $\hat{P}(p)$ is positive semi-definite. The set $\mathscr{S}$ is connected. The k-dimensional primary strata of $\mathscr{S}$ are the connected components of the set $\hat{W}^{(k)}=\{p\in\mathbb{R}^q;|\hat{P}(p)\geqslant 0,\ \mathrm{rank}\,(\hat{P}(p))=k\}$; they are the images of the connected components of the k-dimensional isotropy type strata of $\mathbb{R}^n/G$. In particular the interior $\mathscr{S}$ of $\overline{\mathscr{S}}$, where $\hat{P}(p)$ has the rank q, is the image of the principal stratum and is connected.*

Distinct MIB's of G, $\{p(x)\}$ and $\{p'(x)\}$, are related by morphisms that we shall call MIB transformations:

$$\begin{aligned} p'_\alpha&=p'_\alpha(p),\quad \alpha=1,\ldots,q-1,\\ p'_q&=p_q\,. \end{aligned} \tag{7}$$

In (7), each polynomial function $p'_\alpha(p)$ depends only on the p_β's of weights d_β not greater than d'_α. The associated $\hat{P}$-matrices satisfy the following relation:

$$\hat{P}'(p'(p))=J(p)\cdot\hat{P}(p)\cdot J^T(p), \tag{8}$$

where $J(p)$ is the Jacobian matrix of the transformation:

$$J_{ab}(p)=\partial p'_a(p)/\partial p_b\,,\quad a,b=1,\ldots,q; \tag{9}$$

since $w(J_{ab})=d_a-d_b$, $J(p)$ is a block upper triangular matrix with constant determinant. Then $\hat{P}'(p'(p))$ and $\hat{P}(p)$ have the same rank, $\forall p \in \overline{\mathscr{S}}$.

Definition II.1: Two matrices $\hat{P}(p)$ and $\hat{P}'(p')$ will be said to be equivalent if they are connected by a relation like (8)*, where $J(p)$ is the Jacobian matrix of a MIB transformation $p'=p'(p)$.*

Thus to every real linear group an equivalence class of $\hat{P}$-matrices is uniquely associated.

If $\varphi(G)$ and $\varphi'(G)$ are unitarily equivalent real orthogonal matrix representations of G:

$$\varphi'(g)=O\varphi(g)O^{-1}, \quad g\in G, \quad OO^T=\mathbb{1}, \tag{10}$$

and if $\{p(x)\}$ is a MIB for $\varphi(G)$, then $\{p'(x)\}$, defined as

$$\{p'(x)\}=\{p(O^{-1}x)\}, \tag{11}$$

is a MIB for $\varphi'(G)$ and $\hat{P}'(p')=\hat{P}(p')$. Thus, the equivalence classes of $\hat{P}$-matrices associated to equivalent linear orthogonal groups coincide and an equivalence class of $\hat{P}$-matrices can be uniquely associated to each orthogonal representation of G.

The semi-positivity domains of equivalent $\hat{P}$-matrices are isomorphic semi-algebraic sets. Therefore, images of the orbit space of G obtained from different MIB's are isomorphic semi-algebraic sets.

The notions of MIB transformations and of equivalence of $\hat{P}$-matrices can be defined in abstract terms and extended to the case of different coregular groups G and G', provided that their MIB's have the same number of elements, with the same degrees. Thus the classification of the isomorphism classes of the orbit spaces of the coregular CLG's rests on the determination of a representative for each class of equivalent $\hat{P}(p)$ matrices.

This can be done, in principle, for all coregular CLG's, even if these groups have been only partially classified, and in many cases their MIB's are not known. The matrices $\hat{P}(p)$ have been shown,[26] in fact, to be solutions of a *master equation*, satisfying convenient initial conditions (*allowable* solutions).The master equation does involve only the number q of the elements of the MIB's as a free parameter and, in convenient bases (*A-bases*),[27] can be put in the following *canonical* form:

$$\sum_1^q {}_b\hat{P}_{ab}(p)\partial_b A(p)=2\delta_{aq}w(A)A(p), \quad a=1,\ldots,q, \tag{12}$$

where $A(p)$ is the unique generator of the ideal $\mathscr{I}(\mathscr{B})$, associated to the union $\mathscr{B}$ of all the $(q-1)$-dimensional strata of $\mathscr{S}$ (the closure of $\mathscr{B}$ forms the boundary of $\mathscr{S}$).

The following results have been proved in Ref. 27 to hold true in every A-basis:

Proposition II.1: i) The point $p^{(0)}=(0,\ldots,0,1)$ lies in the interior $\mathscr{S}$ of $\mathscr{S}$; it is the image of a particular G-orbit lying on the unit sphere of $\mathbb{R}^n$.

ii) A(p) is a factor of $\det \hat{P}(p)$*; it can be normalized to an arbitrary positive value at $p^{(0)}$:*

$$A(p^{(0)})>0, \tag{13}$$

and its weight is bounded:

$$2d_1 \leqslant w(A) \leqslant w(\det\hat{P})=2\sum_1^q {}_a\, d_a-2q. \tag{14}$$

iii) The restriction $A(p)|_{p\in\Pi}$, of $A(p)$ to the hyperplane $\Pi=\{p\in\mathbb{R}^q | p=(p_1,\ldots,p_{q-1},1)\}$ of $\mathbb{R}^q$, has a unique local non-degenerate maximum, lying at $p^{(0)}$; thus

$$\partial_\alpha A(p)|_{p=p^{(0)}}=0, \quad \alpha=1,\ldots,q-1. \tag{15}$$

iv) $\hat{P}(p^{(0)})$ *is block diagonal, each block being associated to a subset of* p_a*'s sharing the same weight, and, in a subclass of A-bases (standard A-bases), it is diagonal:*

$$\hat{P}_{ab}(p^{(0)})=\kappa_a\delta_{ab}, \quad \kappa_a>0, \quad a,b=1,\ldots,q. \tag{16}$$

Definition II.2: The solutions $(\hat{P}(p),A(p))$ *of the canonical equation satisfying the initial conditions specified in* (13) *and* (16) *will be called allowable solutions and the corresponding* $\hat{P}$ *matrices, allowable* $\hat{P}$ *matrices.*

All the $\hat{P}$-matrices associated to the different MIB's of any coregular CLG with no fixed points are necessarily equivalent to an allowable $\hat{P}$-matrix. At present we do not know if the converse holds also true, i.e., if every *allowable* $\hat{P}$-matrix is generated by a coregular CLG with no fixed points.

The allowable solutions of the canonical equations for $q\leqslant 4$ have been determined in Refs. 27 and 28. For each choice of the degrees $\{d_1,d_2,\ldots,d_q\}$, only a finite or null number of nonequivalent solutions has been found, showing the existence of *selection rules* for the degrees of the MIB's of the coregular CLG's. The solutions can be organized in *towers*; the degrees of the elements of the same tower can be written in the form $d_\alpha=sd_\alpha^{(0)}, \alpha=1,\ldots,q-1$, $d_q=2$, where s is an integer scale parameter. All $\hat{P}$-matrices of the same tower coincide on the hyperplane $p_q=1$, corresponding to the image of the unit sphere of $\mathbb{R}^n$ in $\mathbb{R}^q$; this means that the sections for $p_q=1$ of the semi-positivity regions $\overline{\mathscr{S}}$ are equal for all the $\hat{P}$-matrices in the same tower.

In this paper we shall recognize, among the allowable $\hat{P}$-matrices classified in Refs. 27 and 28, those corresponding to coregular real representations of compact simple Lie groups.

III. $\hat{P}$-MATRICES ASSOCIATED TO ADJOINT REPRESENTATIONS OF SIMPLE LIE GROUPS

The isomorphism between the ring of invariant polynomial functions of the adjoint representation of a simple compact Lie group G and the ring of invariant polynomial functions of its Weyl group has been known for a long time.[22] In this section we shall show that there is identity between the equivalence class of the $\hat{P}$-matrices associated to the adjoint representation of any compact simple Lie group and the equivalence class of the $\hat{P}$-matrices associated to the corresponding Weyl group.

Let $\mathscr{G}$ be the real Lie algebra of the compact simple Lie group G and let $\{\tau_i\}_{1\leqslant i\leqslant n}$, be an orthonormal basis of $\mathscr{G}$ with respect to the Killing form:

$$(\tau_i,\tau_j)=-\delta_{ij}. \tag{17}$$

In this basis the structure constants c_{ijk} are completely antysymmetric and the operators Adj g, $g\in G$ are represented by real orthogonal matrices $O(g)$:

$$\text{Adj } g\cdot\tau_i=g\tau_i g^{-1}=\sum_1^n {}_jO_{ji}(g)\tau_j; \quad O(g)^TO(g)=\mathbb{1}. \tag{18}$$

We shall consider the real linear group $\Gamma=\{O(g)|g\in G\}$ of the real orthogonal matrices realizing the adjoint representation in $\mathbb{R}^n$.

As is well known,[42] with reference to a fixed Cartan sub-algebra $\mathscr{H}$ of $\mathscr{G}$ and a set of primitive roots $\{\alpha_i\}_{1\leqslant i\leqslant l}$, a basis in the complexification $\mathscr{G}_c=\mathscr{G}+i\mathscr{G}$ of $\mathscr{G}$ can be chosen in the following way:

$$\{h_1,\ldots,h_l,e_\alpha,e_{-\alpha},\ldots\} \tag{19}$$

where $\{ih_j\}_{1\leqslant j\leqslant l}$ is an orthonormal basis in $\mathscr{H}$ and α ranges over all the positive roots of $\mathscr{H}$ in $\mathscr{G}$.

Correspondingly, the basis $\{\tau\}$ in $\mathscr{G}$ can be chosen so that

$$\{\tau\}=\left\{ih_1,\ldots,ih_l,\frac{e_\alpha+e_{-\alpha}}{\sqrt{2}},\frac{e_{-\alpha}-e_\alpha}{i\sqrt{2}},\ldots\right\}. \tag{20}$$

To each root α a reflection S_α can be associated in the dual space $\mathscr{H}^*$:

$$S_\alpha\cdot\beta=\beta-\frac{2(\beta,\alpha)}{(\alpha,\alpha)}\alpha. \tag{21}$$

The Weyl group is defined as the group of linear transformations generated by the reflections S_α, α ranging over all the positive roots.

The action of the Weyl group on $\mathscr{H}^*$ defines a dual action of the group on $\mathscr{H}$:

$$S_\alpha^*\cdot h=h-\frac{2(h,h_\alpha)}{(h_\alpha,h_\alpha)}h_\alpha. \tag{22}$$

With respect to the basis introduced in $\mathscr{G}$, the Weyl group is therefore represented by a linear group W of real orthogonal $l\times l$ matrices.

By defining

$$S_\alpha^*\cdot e_\beta=e_{S_\alpha\cdot\beta}, \tag{23}$$

the action of the Weyl group can be extended by linearity to the whole of $\mathscr{G}_c$. In this way, the action of S_α^* defines an automorphism of $\mathscr{G}_c$, which leaves $\mathscr{H}$ invariant and is, therefore, an inner automorphism.

Let now $p(x)$, $x\in\mathbb{R}^n$, be a Γ-invariant polynomial function. On the basis of what we have just said, $p(x)$ will also be invariant with respect to transformations induced by the dual action of the Weyl group. As a consequence, the restriction of $p(x)$ to the subspace of $\mathbb{R}^n$ determined by the vectors $(x_1,\ldots,x_l,0,\ldots,0)$ defines a W-invariant polynomial $p^{(\mathscr{H})}(\xi)$, $\xi\in\mathbb{R}^l$:

$$p^{(\mathscr{H})}(\xi)=p(\xi_1,\ldots,\xi_l,0,\ldots,0). \tag{24}$$

It has been shown by Chevalley[22] that all the W-invariant polynomials can be generated in this way. Therefore the ring $\mathbb{R}[\mathbb{R}^n]^\Gamma$ formed by the real Γ-invariant polynomials is isomorphic to the ring $\mathbb{R}[\mathbb{R}^l]^W$ formed by the real W-invariant polynomials and, if $\{p_1(x),\ldots,p_q(x)\}$ is a MIB for Γ, then $\{p_1^{(\mathscr{H})}(\xi),\ldots,p_q^{(\mathscr{H})}(\xi)\}$ is a MIB for W. Since W is an irreducible finite linear group generated by reflections, acting in an l-dimensional space, its MIB's are formed by l elements. Therefore, in the rest of this section we shall set $q=l$.

Since the group W is generated by reflections, it is a coregular group, whichever the simple Lie group G may be. As a consequence the adjoint representations of all the compact simple Lie groups define coregular real linear groups.

The MIB's for the adjoint representations of the simple Lie groups have been determined, for instance, in Refs. 43 and 44, where it has been shown that they can be built in the following way.

Let φ denote a real or complex representation of $\mathscr{G}$ and let us set

$$\mathscr{G}\ni X=\sum_1^n{}_i\, x_i\tau_i,\quad x\in\mathbb{R}^n, \tag{25}$$

$$I_\varphi^{(k)}(x)=\mathrm{Tr}[\varphi(X)]^k. \tag{26}$$

Then, for every $O(g)$, $g\in G$, making use of (18) one finds

$$\begin{aligned} I_\varphi^{(k)}(O(g)x)=\mathrm{Tr}\left[\varphi\left(\sum_1^n{}_{ij}O_{ij}(g)x_j\tau_i\right)\right]^k&=\mathrm{Tr}\left[\varphi\left(\sum_1^n{}_j\, x_j g\tau_j g^{-1}\right)\right]^k\\ &=\mathrm{Tr}[\varphi(g)\varphi(X)\varphi(g)^{-1}]^k\\ &=\mathrm{Tr}[\varphi(X)]^k=I_\varphi^{(k)}(x). \end{aligned} \tag{27}$$

Thus $I_\varphi^{(k)} \in K[\mathbb{R}^n]^\Gamma$, with $K=\mathbb{R}$ or $\mathbb{C}$, according to φ being real or complex.

The $q=l$ elements of a MIB can be obtained from the set of invariants $\{I_\varphi^{(k)}\}$ by choosing a convenient subset of φ's and k's.

Below we shall need the following Lemma:

Lemma III.1: $(\partial_j I_\varphi^{(k)})(x_1,\ldots,x_l,0,\ldots,0)=0$ *for* $j=l+1,\ldots,n$ *and* $k\geqslant 2$.

Proof: Let us set $H=\Sigma_{j=1}^{l} x_j\tau_j=\Sigma_{j=1}^{l} x_j h_j$. Then, from the definition of $I_\varphi^{(k)}(x)$ one immediately obtains

$$(\partial_j I_\varphi^{(k)})(x_1,\ldots,x_l,0,...,0)=k\ \mathrm{Tr}(\varphi(H)^{k-1}\varphi(\tau_j))=k\sum_\lambda \langle\lambda|\varphi(H)^{k-1}\varphi(\tau_j)|\lambda\rangle, \tag{28}$$

where $\{|\lambda\rangle\}$ is an orthonormal basis in W_φ, formed by weight vectors of $\varphi(\mathscr{H})$.

Owing to the form of the τ_j for $j=l+1,\ldots,n$, specified in (20), each term in (28) vanishes, since the weights of the vectors $|\lambda\rangle$ and $\varphi(H)^{k-1}\varphi(e_{\pm\alpha})|\lambda\rangle$ are different for every $j=l+1,\ldots,n$.

Theorem III.1: *Let* $\{p(x)\}=\{p_1(x),\ldots,p_q(x)\}$ *be a MIB for the linear group* Γ, *which is a real orthogonal realization of the adjoint representation. Then the* $\hat{P}$*-matrix* $\hat{P}^\Gamma(p)$ *associated to the MIB* $\{p(x)\}$ *coincides with the* $\hat{P}$*-matrix* $\hat{P}^W(p)$, *associated to the MIB* $\{p^{(\mathscr{H})}(\xi)\}=\{p_1^{(\mathscr{H})}(\xi),\ldots,p_q^{(\mathscr{H})}(\xi)\}$, *for the Weyl group W.*

Proof: By definition

$$\hat{P}^\Gamma_{ab}(p)|_{p=p(x)}=\sum_1^n{}_i\ \partial_i p_a(x)\partial_i p_b(x) \tag{29}$$

and

$$\hat{P}^W_{ab}(p)|_{p=p^{(\mathscr{H})}(\xi)}=\sum_1^l{}_i\ \partial_i p_a^{(\mathscr{H})}(\xi)\partial_i p_b^{(\mathscr{H})}(\xi). \tag{30}$$

Now, if the p_a's are chosen out of the set of invariants $I_\varphi^{(k)}$, because of Lemma III.1, we have

$$\begin{aligned}\hat{P}^\Gamma_{ab}(p)|_{p=p(\xi_1,\ldots,\xi_l,0,\ldots,0)}&=\sum_1^n{}_i\ (\partial_i p_a)(\xi_1,\ldots,\xi_l,0,...,0)(\partial_i p_b)(\xi_1,\ldots,\xi_l,0,...,0)\\&=\sum_1^l{}_i\ \partial_i p_a^{(\mathscr{H})}(\xi)\partial_i p_b^{(\mathscr{H})}(\xi)=\hat{P}^W_{ab}(p)|_{p=p(\xi_1,\ldots,\xi_l,0,\ldots,0)}.\end{aligned} \tag{31}$$

The equality just derived shows that $\hat{P}^\Gamma(p)=\hat{P}^W(p)$, for all $p\in\{p^{(\mathscr{H})}(\xi|\xi\in\mathbb{R}^l)\}$, which is a q-dimensional semialgebraic set of the space $\mathbb{R}^q$ spanned by $(p_1,\ldots,p_q)$. The equality $\hat{P}^\Gamma(p)=\hat{P}^W(p)$ holds true, therefore, for all $p\in\mathbb{R}^q$.

IV. REAL REPRESENTATIONS OF COMPACT LIE GROUPS

As claimed, one of our purposes, which is, in fact, a preliminary problem to solve, is to obtain the *real coregular* representations of *compact* simple Lie groups from Schwarz's classification of the *complex coregular* representations of *complex* simple Lie groups.

In this section, we shall characterize the complex representations of complex simple Lie groups subducing real representations for their maximal compact subgroups. We shall begin by recalling some more or less known results concerning the subject.

Let G be a compact Lie group. The connected component of the identity of G, G^0, is a real analytic group. Then G and G^0 share the same (real) Lie algebra $\mathscr{G}$.

The quotient group G/G^0 is a finite group and its order $|G/G^0|$ coincides with the number of connected components of G.

A *universal complexification* (Ref. 45, p. 204) of a real analytic Lie group G^0 is a continuous homomorphism γ of G^0 into a complex analytic group ${G^0}_c$ having the following property: for every continuous homomorphism η of G^0 into a complex analytic group H, there is one and only one complex analytic homomorphism η_c of ${G^0}_c$ into H such that $\eta_c\circ\gamma=\eta$.

The complexification $G^0{}_c$ of G^0, is so defined that its Lie algebra is the *complexification* $\mathcal{G}_c=\mathcal{G}+i\mathcal{G}$ of $\mathcal{G}$.

The *complexification* G_c of G is the Lie group defined as follows:

$$G_c=(G/G^0)\cdot G^0{}_c=G\cdot G^0{}_c.$$

The group $G^0{}_c$ is the connected component of the identity of G_c and G_c has the same number $|G/G^0|$ of connected components as G.

The following theorem states the connection between G and its complexification G_c.

Theorem IV.1:[45] *The group G_c is the smallest complex Lie group that contains G, which is a maximal compact subgroup of G_c. All the maximal compact subgroups of G_c are conjugated in G_c. Vice versa, every complex semi-simple Lie group is the complexification of a compact semi-simple Lie group.*

There is a one-to-one correspondence between the complex analytic representations of G_c and the representations of G. In fact, a complex analytic representation φ of G_c in the complex vector space V_φ defines obviously a, generally complex, representation of G. Vice versa, let φ be a representation of the compact Lie group G in a real or complex vector space W_φ. The representation φ of the group G defines uniquely a representation of the real Lie algebra $\mathcal{G}$ of G in W_φ (which we shall also denote by φ). The representation φ of $\mathcal{G}$ in W_φ defines uniquely a complex representation of $\mathcal{G}_c$ (also denoted by φ) in the complex vector space $V_\varphi=\mathbb{C}\otimes W_\varphi$:

$$\varphi(\mathcal{G}_c)=\varphi(\mathcal{G}+i\mathcal{G})=\varphi(\mathcal{G})+i\varphi(\mathcal{G}).$$

Analytic representations of $G^0{}_c$ and of G_c, which will still be denoted by φ, are then obtained from $\varphi(\mathcal{G}_c)$ by exponentiation,

$$\varphi(G^0{}_c)=\exp\ \varphi(\mathcal{G}_c),$$

and by defining

$$\varphi(G_c)=\varphi(G)\cdot\varphi(G^0{}_c).$$

With regard to their reality properties the irreducible complex matrix representations of a compact group G can be collected into three disjoint classes:[46,47]

Type 1: representations which admit a *real form*, that is representations which are equivalent to real matrix representations;

Type 2: representations φ which are equivalent to their complex conjugate representations $\overline{\varphi}$, but do not admit a real form;

Type 3: representations which are not equivalent to their complex conjugate representations.

Let us recall that the complex conjugate $\overline{\varphi}$ of a unitary matrix representation φ coincides with the contragradient representation (or star representation) φ^*:

$$\overline{\varphi}(g)=\varphi^T(g)^{-1}=\varphi^*(g),\quad \forall g\in G. \tag{32}$$

A complex representation of a group can be transformed into a real representation through the standard process of *realification*. There is, in fact, a one-to-one correspondence between points and matrices acting in $\mathbb{C}^n$ and points and matrices acting in the real space $\mathbb{R}^{2n}$, defined by

$$\begin{aligned}&\mathbb{C}^n\ni z=(z_1,\ldots,z_n)\leftrightarrow\xi=(\Re z_1,\ldots,\Re z_n,\Im z_1,\ldots,\Im z_n)\in\mathbb{R}^{2n}\\&\mathrm{GL}(n,\mathbb{C})\ni M\leftrightarrow M_R=\begin{pmatrix}M_1 & -M_2\\ M_2 & M_1\end{pmatrix}\in\mathrm{GL}(2n,\mathbb{R}),\end{aligned} \tag{33}$$

where M_1 and M_2 are the real and imaginary parts of M. In this way, starting from a complex matrix representation of $G{:}g\to\varphi(g)$, one gets a real matrix representation of $G{:}g\to\varphi_R(g)$, which is called the realification of φ.

The representation φ_R is orthogonal if and only if φ is unitary. Moreover, thinking of φ_R as acting on the complexification $\mathbb{C}^{2n}$ of $\mathbb{R}^{2n}$, φ_R is equivalent to the direct sum $\varphi \oplus \overline{\varphi}$, the equivalence being induced by the matrix

$$T = \frac{1}{\sqrt{2}} \begin{pmatrix} I_n & \imath I_n \\ I_n & -\imath I_n \end{pmatrix}.$$

Therefore, φ_R is irreducible on the reals if φ is a complex irreducible representation of type 2 or 3; it is reducible if φ is of type 1.

Since every real matrix representation of G can be decomposed into a direct sum of irreducible (on the reals) real matrix representations, the following proposition will be sufficient to characterize all the real representations of G in terms of irreducible complex representations.

Proposition IV.1: Let φ a real irreducible (on the reals) representation of a compact group G. Then either φ is irreducible on the complexes and type 1, or it is the realification of a type 2 or type 3 complex irreducible representation.

The types of the irreducible unitary representations of compact simple Lie groups were determined by Mehta and Srivastava.[48,49] Our notations will be different from the notations used in Refs. 48 and 49; we prefer in fact to order the roots in the Dynkin diagrams as in Ref. 24. To aid the reader, in our tables we shall also report the dimensions of the representations.

V. POLYNOMIAL INVARIANTS OF COMPACT LIE GROUPS AND OF THEIR COMPLEXIFICATIONS

In this section, following the line sketched in Ref. 36 and developed in Ref. 50, we shall determine the relationship between the G-invariant polynomial functions, defined in a real vector space W_φ, hosting a real representation φ of a compact Lie group G, and the G_c-invariant polynomial functions, defined in the complex vector space $V_\varphi = \mathbb{C} \otimes W_\varphi$, hosting the representation $\varphi(G_c)$ of the complexification G_c of G.

We shall need some results and standard techniques from algebraic group theory and classical invariant theory that we shall report below, trying to be as self-contained as possible, without entering too many details.These can be found, for instance, in Refs. 51–54.

Let K be the field of complex or real numbers. The set $K^n = K \times K \times \cdots \times K$ is called the *affine n-space* and denoted by A^n and the sets of common zeros in A^n of finite collections of polynomials are called *affine varieties*. The affine varieties are the closed sets in the natural topology of A^n, the *Zariski topology*.

A closed set X in the Zariski topology is a closed set in the usual Haussdorf T_2 topology in A^n. The converse does not hold true, in general.

If X is Zariski closed in A^n and T denotes a n-ple of indeterminates, a polynomial $f(T) \in K[T]$ defines a K-valued function on X: $x \mapsto f(x)$. Different polynomials need not define different functions; in fact, denoting by $\mathcal{I}(X)$ the ideal of the polynomials vanishing on X, the polynomial functions on X are in a one-to-one correspondence with the elements of the residue class ring $K[T]/\mathcal{I}(X) \equiv K[X]$, which is called the *affine algebra* on X.

Let $X \subset A^n$ and $Y \subset A^m$ be arbitrary affine varieties. A mapping $\psi: X \mapsto Y$, $\psi(x_1,\ldots,x_n) = (\psi_1(x),\ldots,\psi_m(x))$, is called a *morphism* if $\psi_i \in K[X]$, $i = 1,\ldots,m$.

Let G be an algebraic variety, endowed with a group structure such that the maps $(x,y) \mapsto x \cdot y$ and $x \mapsto x^{-1}$ are morphisms. Then G is called an (*affine*) *algebraic group*.

The group $\mathrm{GL}(n,K)$ of the $n \times n$ regular matrices over K is endowed with a structure of algebraic group if its elements M are thought of as points of coordinates $(M_{11}, M_{12}, \ldots, M_{nn}, \Delta)$ in K^{n^2+1}, lying on the affine variety defined by the equation $\Delta \cdot \det(M) - 1 = 0$.

By definition, a *linear algebraic group* is a Zarisky closed subgroup of the algebraic group $\mathrm{GL}(n,K)$.

The Zarisky closure $\mathrm{cl}(G)$ in K^{n^2+1} of any subgroup G of $\mathrm{GL}(n,K)$ is a linear algebraic group (Ref. 54, Proposition A, p. 54).

Every affine algebraic group defined over K is isomorphic to an algebraic linear group defined over K (Ref. 51, Proposition 1.10, p. 101). Therefore, in the following it will not be restrictive to identify algebraic groups with linear algebraic groups.

Well known examples of linear algebraic groups are $\mathrm{SL}(n,K)$, $\mathrm{SO}(n,K)$, and $\mathrm{Sp}(2n,K)$.

Theorem V.1 *(Ref.* 55, *Theorem 2.1.2, p. 45): Every complex (real) linear algebraic group is a complex (real) Lie group.*

The converse of Theorem V.1 does not hold true; the real Lie group of complex matrices $\mathrm{SU}(n)$, for instance, is not a linear algebraic group.

By definition, a representation φ of a group G is an *analytic* (C^∞) homomorphism, if G is a Lie group, and a *rational* (polynomial) homomorphism, if G is algebraic. As a consequence, we have the following:

Theorem V.2: *A representation φ of a (complex or real) Lie group G defines a (complex or real) Lie group of matrices $\varphi(G)$. A representation φ of a complex algebraic group G defines a linear complex algebraic group $\varphi(G)$ (Ref.* 53, *p. 122).*

The second part of the theorem is not valid for real linear algebraic groups.

Since a complex linear algebraic group is also a Lie group (Theorem V.1), it admits both rational and analytic representations.

A complex Lie group (admitting at least one complex analytic representation) is said to be *reductive* if all its complex analytic representations are completely reducible. As is well known, every finite dimensional complex analytic representation of a compact Lie group G is completely reducible. The complexification G_c of G shares with G this property, so G_c is reductive. Vice versa, every reductive complex Lie group is the complexification of a compact Lie group (Ref. 56, th. 3.1). Therefore, we have the following:

Theorem V.3: *A complex Lie group is reductive if and only if it is the complexification of a compact Lie group.*

Theorem V.4: *Every complex reductive Lie group can be identified with a complex linear algebraic group so that its complex analytic representations coincide with its rational representations.*

Proof: A compact group has at the most a finite number of connected components. By Theorem V.3, this property is shared by all complex reductive Lie groups. The thesis is then obtained from Ref. 57, th. 9.2 and th. 9.5. □

We need now Theorems V.1, V.2, V.3 and V.4 to obtain the following theorem:

Theorem V.5: *Let G be a compact Lie group and G_c be its complexification. Then*

1. G is Zariski dense in G_c.

2. For every analytic representation φ of G, or of G_c, $\varphi(G)$ is Zariski dense in $\varphi(G_c)$.

Proof:

(1) By Theorems V.3 and V.4 we can identify the complex Lie group G_c with a complex algebraic group containing G and, consequently, also $\mathrm{cl}(G)$, which is the smallest algebraic group containing G. But, by Theorem V.1, $\mathrm{cl}(G)$ is a Lie group, so $\mathrm{cl}(G) \supseteq G_c$, since G_c is the smallest complex Lie group containing G. This is sufficient to conclude that $\mathrm{cl}(G) = G_c$.

(2) As remarked in Section IV, every analytic representation φ of G can be extended to a complex analytic representation φ of G_c and, by Theorem V.4, every complex analytic representation of G_c is a rational representation. Then, by Theorem V.2, $\varphi(G_c)$ is both a complex Lie group of matrices and a complex linear algebraic group, and $\varphi(G)$ is a compact Lie group of complex matrices. Its Zariski closure $\mathrm{cl}(\varphi(G))$ is a complex linear algebraic group contained in $\varphi(G_c)$. Being φ Zarisky continuous, $\varphi^{-1}(\mathrm{cl}(\varphi(G)))$ is a Zarisky closed subgroup of G_c containing G. It must therefore coincide with G_c, because of the first part of the Theorem G is Zariski dense in G_c. This implies that $\mathrm{cl}(\varphi(G)) \equiv \varphi(G_c)$. □

Theorem V.6: *Let V be a complex vector space on which an arbitrary group $G \subseteq GL(V)$ acts and let* $\mathrm{cl}(G)$ *be the Zariski closure of G. Then, the ring of polynomial G-invariant functions defined on V and the ring of polynomial* $\mathrm{cl}(G)$*-invariant functions defined on V coincide, that is,*

$$\mathbb{C}[V]^G \equiv \mathbb{C}[V]^{\mathrm{cl}(G)}.$$

Proof (Ref. 58, p. 347): Since $\mathrm{cl}(G) \supseteq G$, the relation $\mathbb{C}[V]^{\mathrm{cl}(G)} \subseteq \mathbb{C}[V]^G$ is obviously true. Let us prove the converse relation $\mathbb{C}[V]^G \subseteq \mathbb{C}[V]^{\mathrm{cl}(G)}$. To this end, for every $p_1 \in \mathbb{C}[V]^G$ let $R_1 = \{g \cdot p_1,\ g \in \mathrm{cl}(G)\}$, with $(g \cdot p_1)(x) = p_1(g^{-1} \cdot x), \forall x \in V$. The degree of each of the polynomials $g \cdot p_1$, $\forall g \in \mathrm{cl}(G)$ does not exceed the degree of p_1, thus R_1 is a finite dimensional subspace of $\mathbb{C}[V]$. Let $p_1, \ldots, p_t$, be a basis of R_1. The action of $\mathrm{cl}(G)$ in R_1 is linear and in the

basis $\{p_i\}$ every $g \in \mathrm{cl}(G)$ is represented by a matrix $\varphi(g) \in \mathrm{GL}(t,\mathbb{C})$. By Theorem V.2, $\varphi(\mathrm{cl}(G))$ is a complex linear algebraic group. The largest subgroup H of $\varphi(\mathrm{cl}(G))$ leaving p_1 invariant is a complex linear algebraic group, since it is defined by algebraic equations ($H=\{\varphi(g), g \in \mathrm{cl}(G) | \varphi(g)p_i = \delta_{i1}p_1\}$). Obviously $H \supseteq \varphi(G)$. Since φ is Zarisky continuous, $\varphi^{-1}(H)$ is Zarisky closed, therefore $G \subseteq \varphi^{-1}(H) \subseteq \mathrm{cl}(G)$, which immediately implies $\varphi^{-1}(H) = \mathrm{cl}(G)$, that is, $\varphi(\mathrm{cl}(G)) = H$. □

Theorems V.5 and V.6 enable us to reduce the determination of the G-invariant polynomial functions, defined on complex representation spaces of G, to the determination of the G_c-invariant polynomial functions defined in the same space. This result can be summarized in the following way:

Theorem V.7: *Let G be a compact Lie group and G_c be its complexification. Then for every complex analytic representation φ of G_c in a complex vector space V_φ, there is identity between the G-invariant and the G_c-invariant polynomial functions defined on V_φ:*

$$\mathbb{C}[V_\varphi]^{\varphi(G)} \equiv \mathbb{C}[V_\varphi]^{\varphi(G_c)}.$$

An obvious consequence is the following:

Corollary V.8: The polynomials $p_1,\ldots,p_q$ form an integrity basis for $\mathbb{C}[V_\varphi]^{\varphi(G)}$ if and only if they form an integrity basis for $\mathbb{C}[V_\varphi]^{\varphi(G_c)}$.

Let us now concentrate our attention on the real representations of compact Lie groups.

Let W be a real vector space and V its complexification. Since a polynomial function is essentially determined by its coefficients, the following identity holds true:

$$\mathbb{C}[W] = \mathbb{C} \otimes \mathbb{R}[W],$$

and there is a natural isomorphism

$$K[W] \simeq K[V], \quad K = \mathbb{R}, \mathbb{C}.$$

Theorem V.9: *Let G be a compact Lie group and G_c be its complexification. Then, for every analytic representation φ of G in the real space W_φ and of G_c in the complex space $V_\varphi = \mathbb{C} \otimes W_\varphi$, the following relation holds true:*

$$\mathbb{C}[V_\varphi]^{\varphi(G_c)} \simeq \mathbb{C} \otimes \mathbb{R}[W_\varphi]^{\varphi(G)}.$$

Proof: If W_φ is the real representation space of a compact Lie group G and V_φ is its complexification. Then from Theorem V.7,

$$\mathbb{C}[V_\varphi]^{\varphi(G)} = \mathbb{C}[V_\varphi]^{\varphi(G_c)}.$$

Moreover,

$$\mathbb{C}[V_\varphi]^{\varphi(G)} \simeq \mathbb{C}[W_\varphi]^{\varphi(G)} = (\mathbb{C} \otimes \mathbb{R}[W_\varphi])^{\varphi(G)} = \mathbb{C} \otimes \mathbb{R}[W_\varphi]^{\varphi(G)},$$

where the last equality is a consequence of the reality of $\varphi(G)$, implying that both the real and imaginary parts of a complex $\varphi(G)$-invariant function are $\varphi(G)$-invariant. □

All polynomial invariant functions in $\mathbb{C}[V_\varphi]^{\varphi(G_c)}$ can then be expressed as polynomials with complex coefficients of a polynomial basis for $\mathbb{R}[W_\varphi]^{\varphi(G)}$, with the following obvious consequences:

Corollary V.10: If the polynomial functions $p_1,\ldots,p_q$ form an integrity basis for $\mathbb{R}[W_\varphi]^{\varphi(G)}$, they form also an integrity basis for $\mathbb{C}[V_\varphi]^{\varphi(G_c)}$.

Corollary V.11: Let φ be an analytic representation of G_c in the complex space $V_\varphi = \mathbb{C} \otimes W_\varphi$, admitting a real form as a representation of the maximal compact subgroup G of G_c. Then the ring $\mathbb{C}[V_\varphi]^{\varphi(G_c)}$ admits integrity bases formed by polynomials with real coefficients (real integrity bases).

To conclude, we have the following.

Theorem V.12: *Let G be a compact Lie group, G_c be its complexification and φ be a real analytic representation of G in W_φ. Then, $\mathbb{R}[W_\varphi]^{\varphi(G)}$ is a regular ring if and only if $\mathbb{C}[V_\varphi]^{\varphi(G_c)}$ is a regular ring.*

TABLE I. Irreducible real representations of simple compact Lie groups.

$\mathscr{G}$ and or G	Rank		Conditions on the highest weight $\mathbf{\Lambda}=(\Lambda_1,\Lambda_2,\ldots)$
A_n, SU$(n+1)$	$n\geqslant 1$	$n=0,2,3 \pmod 4$	$\Lambda_i=\Lambda_{n-i+1}$, $\forall i=1,\ldots,n$
		$n=1 \pmod 4$	$\Lambda_i=\Lambda_{n-i+1}$, $\forall i=1,\ldots,n$, and $\Lambda_{(n+1)/2}$ even
B_n, SO$(2n+1)$	$n\geqslant 2$	$n=0,3 \pmod 4$	none
		$n=1,2 \pmod 4$	Λ_n even
C_n, Sp$(2n)$	$n\geqslant 3$		$(\Lambda_1+\Lambda_3+\Lambda_5+\ldots)$ even
D_n, SO$(2n)$	$n\geqslant 4$	$n=0 \pmod 4$	none
		$n=1,3 \pmod 4$	$\Lambda_{n-1}=\Lambda_n$
		$n=2 \pmod 4$	$(\Lambda_{n-1}+\Lambda_n)$ even
E_6	6		$\Lambda_1=\Lambda_5$ and $\Lambda_2=\Lambda_4$
E_7	7		$(\Lambda_1+\Lambda_3+\Lambda_7)$ even
E_8	8		none
F_4	4		none
G_2	2		none

Proof: According to Corollary V.10, let $p_1,\ldots,p_q$ be a real integrity basis for both $\mathbb{C}[V_\varphi]^{\varphi(G_c)}$ and $\mathbb{R}[W_\varphi]^{\varphi(G)}$. If $\mathbb{C}[V_\varphi]^{\varphi(G_c)}$ is not regular, there exists a complex polynomial, $f(T)$, in the indeterminates $T_1,\ldots,T_q$, such that $f(p(z))=f(p_1(z),\ldots,p_q(z))=0,\forall z\in V_\varphi$. Then $f(p(x))=0,\forall x\in W_\varphi$ and, if f_1 and f_2 are the real and imaginary parts of f, also $f_1(p(x))=0=f_2(p(x)),\forall x\in W_\varphi$. This proves that $\mathbb{R}[W_\varphi]^{\varphi(G)}$ is not regular.

If the ring $\mathbb{R}[W_\varphi]^{\varphi(G)}$ is not regular, then there exist real polynomials, $f(T)$, in the indeterminates $T_1,\ldots,T_q$, such that $f(p(x))=0,\forall x\in W_\varphi$. As a consequence, $f(p(z))=0,\forall z\in V_\varphi$, so that the ring $\mathbb{C}[V_\varphi]^{\varphi(G_c)}$ is not regular. □

VI. REAL COREGULAR REPRESENTATIONS OF COMPACT SIMPLE LIE GROUPS

Theorem V.12 states the link enabling us to determine all the real coregular representations of compact simple Lie groups from Schwarz's classification of the complex coregular representations of complex simple Lie groups.[24] What one has to do is simply to select, for each simple complex Lie group G_c, those complex representations which are complexifications of real representations of its maximal compact subgroup G.

The conditions, which have to be satisfied by the weights of a complex irreducible matrix representation φ of a complex simple Lie group G_c, with maximal compact subgroup G, so that $\varphi(G)$ admits a real form, can be found, for example, in Refs. 59, 48, and 49. The relevant results are summarized in Tables I and II.

The irreducible representations of highest weight $\Lambda=(\Lambda_1,\Lambda_2,\ldots)$ will be denoted by the symbol ${\varphi_1}^{\Lambda_1}{\varphi_2}^{\Lambda_2}\ldots$ and ${\varphi_i}^{\Lambda_i}$ will be omitted when $\Lambda_i=0$ and shortened to φ_i when $\Lambda_i=1$.

The following theorem will make our task easier, as it assures the existence of *maximally coregular representations*.

TABLE II. Contragradient fundamental representations of simple complex Lie groups.

$\mathscr{G}$	Rank	$\varphi\leftrightarrow\varphi^*$	
A_n	$n\geqslant 1$	$\varphi_i\leftrightarrow\varphi_{n-i+1}$	$i=1,\ldots,n$

Theorem VI.1: *Every proper subrepresentation φ' of a coregular representation, φ, of a reductive group G is coregular. The basic invariants for $\varphi'(G)$ can be chosen to be a proper subset of the basic invariants for $\varphi(G)$.*

Proof: Let $p_1,\ldots,p_q$ be a MIB for $\varphi(G)$ and $p'_1,\ldots,p'_{q'}$ be a MIB for $\varphi'(G)$. The proof of the Theorem stems from the observation that if $\varphi=\varphi'\oplus\varphi'_\perp$, all the elements of a MIB for $\varphi'(G)$ and for $\varphi'_\perp(G)$ can be included as elements of a MIB for $\varphi(G)$. With this choice, any algebraic relation among the elements of the MIB for $\varphi'(G)$ would be an algebraic relation among the elements of the MIB for $\varphi(G)$. □

Let us illustrate the standard procedure we followed to obtain our results, working out, step by step, a particular case.

Let us start, for instance, from Entry 3 in Table 1a of Ref. 24, where the following items are found:

(1) The symbol $\mathrm{SL}(n,\mathbb{C})$, $n\geqslant 4$ of the class of simple complex Lie groups one is dealing with;
(2) the decomposition $\varphi=3\varphi_1+\varphi_2+(n-2)\varphi_{n-1}$ of the maximally coregular complex representation φ of each group $\mathrm{SL}(n,\mathbb{C})$ in complex irreducible sub-representations;
(3) the number $\frac{1}{2}n(n+1)+1$ of elements in a MIB for the linear group $\varphi(\mathrm{SL}(n,\mathbb{C}))$;
(4) a specification of the structure of a MIB: $(3n-6)\langle 2\rangle,4\langle 3\rangle,\frac{1}{2}(n-2)(n-3)\langle 4\rangle$, meaning that there are $(3n-6)$ invariants of type $\langle 2\rangle$, 4 invariants of type $\langle 3\rangle$ and so on; the invariant of type $\langle k\rangle$ is roughly specified in Entry k of Table 1b of Ref. 24, from which one can also recover its degree.

The maximal compact subgroup of $\mathrm{SL}(n,\mathbb{C})$ is $\mathrm{SU}(n)$. Let us examine the reality properties of the sub-representations φ_1, φ_2, φ_{n-1}, contained in $\varphi(\mathrm{SU}(n))$.

(i) φ_1 and φ_{n-1}, for $n\geqslant 4$ (see Table I and Table II for A_{n-1}) are not of type 1, but are mutually contragradient, so $\varphi_{n-1}=\varphi_1^*=\overline{\varphi_1}$. The representations $k(\varphi_1+\varphi_{n-1})$ admit therefore a real form: the realification of $k\varphi_1$.
(ii) φ_2 (see Table I for A_{n-1}) is of type 1 only for $n=4$.

From Theorem VI.1, therefore, the representation $\varphi(\mathrm{SU}(n))$ contains the following coregular real representations, with the MIB's specified aside:

$\mathrm{SU}(n)$,	$n\geqslant 4$	$\varphi_1+\varphi_{n-}$	$1\langle 2\rangle$	(degree 2)	
$\mathrm{SU}(n)$,	$n\geqslant 4$	$2(\varphi_1+\varphi_{n-1})$	$4\langle 2\rangle$	(degree 2)	
$\mathrm{SU}(n)$,	$n\geqslant 5$	$3(\varphi_1+\varphi_{n-1})$	$9\langle 2\rangle$	(degree 2)	
$\mathrm{SU}(4)$		φ_2	$1\langle 3\rangle$	(degree 2)	
$\mathrm{SU}(4)$		$\varphi_1+\varphi_2+\varphi_3$	$1\langle 2\rangle$,	$1\langle 3\rangle$	(degree 2)
$\mathrm{SU}(4)$		$2\varphi_1+\varphi_2+2\varphi_3$	$4\langle 2\rangle$,	$1\langle 3\rangle$	(degree 2)
			$2\langle 3\rangle$	(degree 3)	

Among these, only the representations $\varphi_1+\varphi_{n-1}$, for $\mathrm{SU}(n)$, and φ_2, for $\mathrm{SU}(4)$, are irreducible on the reals.

The invariants listed in the last column have been obtained through a selection of the invariants reported in Schwarz's tables, made in such a way that the invariants can be constructed out of the representation spaces which are available. For instance, for $n=4$, the invariant of type $\langle 3\rangle$ in Schwarz's tables is constructed out of i vectors of the same space, V_{φ_2}, and $4-2i$ vectors of $4-2i$ different copies of spaces V_{φ_1}, with $2\leqslant 2i\leqslant 4$. Thus, in the space of the representation $2\varphi_1+\varphi_2+2\varphi_3$ of $\mathrm{SU}(4)$ it is possible to construct two invariants of type $\langle 3\rangle$ with $i=1$ (degree 3) (one using φ_1 and one using φ_3; in fact in this particular case φ_1 and φ_3 are related by an isomorphism of the Dynkin diagram of A_3), and one invariant of type $\langle 3\rangle$ with $i=2$ (degree 2). (One of the two invariants of type $\langle 3\rangle$ (degree 3) coincides also with an invariant of type $\langle 4\rangle$.)

The results we have obtained following the standard procedure described in the example are summarized in Tables III and IV, where all the real coregular representations of simple compact Lie groups are listed.

TABLE III. Real coregular representations of compact simple Lie groups (I). In each row, the following items are listed: A simple compact Lie group, G, specified by the Lie algebra of its complexification; a real coregular representations, φ, of G; the real dimensions, dim, and the reducibility properties, i/r, of φ; the indication, Source, of the Table and the Entry of Ref. 24, where φ is quoted; the number, q, and the degrees, d_i, of the basic invariants of (G,φ).

	$\varphi_2=\mathrm{Ad}$	14	i	5a.2	2	6,2

The representations listed are real, so one can always think of them as realized by real orthogonal matrices. In the column ''Source,'' we have reported the tables and the entries of Ref. 24 where the representations are obtained from. As a rule, only one source entry is indicated, also if it is not the unique one.

In all the tables, to avoid isomorphisms, the ranks are limited in the following way: $B_n, n\geqslant 2$, $C_n, n\geqslant 3$, $D_n, n\geqslant 4$. For A_n permutations of φ_i and φ_{n-i}, $i=1,\ldots,[n/2]$, for D_n permutations of φ_{n-1} and φ_n, and for D_4 permutations of φ_1, φ_3, φ_4, are avoided.

VII. THE $\hat{P}$-MATRICES OF THE REAL COREGULAR SIMPLE COMPACT LIE GROUPS WITH 2, 3, AND 4 BASIC INVARIANTS

In this section we shall identify, among the allowable $\hat{P}$-matrices (abbreviated to A$\hat{P}$M's) reported in Refs. 27 and 28, those generated by the real coregular linear compact simple Lie groups (reported in Tables III and IV) that have less than 5 basic invariants.

TABLE IV. Real coregular representations of compact simple Lie groups (II). In each row, the following items are listed: A simple compact Lie group, G, specified by the Lie algebra of its complexification; a real coregular representation, φ, of G; the real dimensions, dim, and the reducibility properties, i/r, of φ; the indication, Source, of the Table and the Entry of Ref. 24, where φ is quoted; the number, q, and the degrees, d_i, of the basic invariants of (G,φ).

49		$\varphi_2=\mathrm{Ad}$	14	i	6,2	1	I_2

The results we have obtained are listed in the last column of Table V, where the notations are those of Refs. 27 and 28 and I_1 and I_2 denote, respectively, the unique isomorphism class of orbit spaces of dimension 1 and 2.

In the column labelled by n, we have reported the number of different A$\hat{P}$M's associated to sets of invariants with given weights d_i. When $n=1$ there is only one possible A$\hat{P}$M. When $n>1$ one has to select the right A$\hat{P}$M.

When not explicitly specified, the scale parameter s, identifying different isomorphism classes of A$\hat{P}$M's belonging to the same tower, will be assumed equal to 1.

Below, except for the cases in which the identification of the correct A$\hat{P}$M is obvious since there is only one possible choice, we shall explain the way our results were obtained, for each entry in the tables. The *standard procedure* used to calculate $\hat{P}_{ij}(p)$, which works in most of the cases, is first to evaluate $P_{ij}(x)$ from its definition (Eq. (6)), and then to guess the form of $\hat{P}(p)$, on the basis of the last equality in Eq. (6).

Then one has to perform a MIB transformation to reach the form of one of the A$\hat{P}$M's listed in Refs. 27 and 28 (*standard* A$\hat{P}$M's). In some cases the standard procedure cannot be adopted since the explicit form of some of the invariants is not known. In these cases the alternative procedure will be explained in full detail.

Let us spell out our notations. We shall denote by $x,y,\ldots$ the vectors belonging to the spaces hosting the representation we are concerned with; as a rule, different letters will be used to label vectors lying in spaces hosting unequivalent representations, while vectors $x_1,x_2,\ldots$, distinguished only by subscripts, label vectors lying in different copies of the same representation space. The first letters of the alphabet will be reserved to real constants. Scalar products will be denoted by x_1x_2 or x^2. The symbol Γ will denote a vector operator, and $z(x\Gamma y)$ will be used for the scalar product between the vectors z and $(x\Gamma y)$. To specify that x is a vector of the real space W_φ of the representation φ, we shall simply write $x\in\varphi$.

• Entries 22, 27, 33, 39, 41, 46: (B_3,φ_2), (B_4,φ_2), (D_4,φ_2), (C_3,φ_1^2), (C_4,φ_1^2), (F_4,φ_4). All of them correspond to adjoint representations. As shown in Section III, the related $\hat{P}$-matrices are equivalent to the $\hat{P}$-matrices of the associated Weyl groups, and these have been identified in Ref. 32.

• Entry 3: $(A_1,2\varphi_1^2)$. One has to choose between the following two classes of A$\hat{P}$M's: $I(1,1)$ and $II(1)$. Let $x_1,x_2\in\varphi_1^2$. The basic invariants suggested by Schwarz are the following: $q_1=x_1^2$, $q_2=x_2^2$, and $q_3=x_1x_2$. A better choice, to meet the standard form assumed for p_3, is the following: $p_1=q_1-q_2={x_1}^2-{x_2}^2$, $p_2=2q_3=2x_1x_2$, and $p_3=q_1+q_2={x_1}^2+{x_2}^2$. Through the standard procedure one finds the following non-trivial elements of the $\hat{P}$-matrix: $\hat{P}_{11}=4p_3$, $\hat{P}_{12}=0$, and $\hat{P}_{22}=4p_3$, which coincide with those of the $\hat{P}$-matrix of class $I(1,1)$.

• Entry 6: $(A_{n\geqslant 2},2\cdot(\varphi_1+\varphi_n))$. One has to choose among the following five classes of A$\hat{P}$M's: $A1(1,1,1,1)$, $A3(1,1,1)$, $A4(1,1)$, $A5(1,1,1)$, and $A7(1,1)$.

Let $x_1,x_2\in\varphi_1,y_1,y_2\in\varphi_n$. A possible choice for the elements of a MIB, leading through the standard procedure to the $\hat{P}$-matrix of class $A1(1,1,1,1)$, is the following: $p_1=2(x_1y_2+x_2y_1)$, $p_2=2(x_1x_2-y_1y_2)$, $p_3=x_1^2-x_2^2+y_1^2-y_2^2$, and $p_4=x_1^2+x_2^2+y_1^2+y_2^2$. (Note that, for $z_1=x_1+iy_1$ and $z_2=x_2+iy_2$, one obtains $p_1=2\mathrm{Im}(z_1z_2)$, $p_2=2\mathrm{Re}(z_1z_2)$, $p_3=z_1^*z_1-z_2^*z_2$, and $p_1=z_1^*z_1+z_2^*z_2$.)

• Entry 12: $(A_3,2\varphi_2)$. Let $x_1,x_2\in\varphi_2$. The elements of the MIB can be chosen as in Entry 3 and the corresponding A$\hat{P}$M turns out to be the same.

• Entry 16: $(A_6,\varphi_2+\varphi_5)$. One has to choose among the following three classes of A$\hat{P}$M's: $I(2,1)$ $(d_2=4)$, $II(2)$ $(s=2)$, and $III.2$.

Let $x\in\varphi_2$ and $y\in\varphi_5=\overline{\varphi_2}$. The complex vectors x and y can be realized as antisymmetric 7×7 complex matrices, which can be decomposed into their real and imaginary parts u and v: $x=u+iv$, $y=u-iv$. The elements of a MIB can be chosen to be the following (repeated indexes are summed):

$$q_3=\varepsilon^{i_1i_2i_3i_4i_5i_6i_7}x_{i_6i_7}\varepsilon_{i_1i_2i_3i_4i_5j_6j_7}y^{j_6j_7},$$
$$=2\times 5!\,x_{i_6i_7}y^{i_6i_7},$$

$$q_2=\varepsilon^{i_1i_2i_3i_4i_5i_6i_7}x_{i_4i_5}x_{i_6i_7}\varepsilon_{i_1i_2i_3j_4j_5j_6j_7}y^{j_4j_5}y^{j_6j_7}$$
$$=4\,3!\,x_{i_4i_5}x_{i_6i_7}(y^{i_4i_5}y^{i_6i_7}-2y^{i_4i_6}y^{i_5i_7}),$$

$$q_1=\varepsilon^{i_1i_2i_3i_4i_5i_6i_7}x_{i_2i_3}x_{i_4i_5}x_{i_6i_7}\varepsilon_{i_1j_2j_3j_4j_5j_6j_7}y^{j_2j_3}y^{j_4j_5}y^{j_6j_7}$$
$$=8\,x_{i_2i_3}x_{i_4i_5}x_{i_6i_7}(y^{i_2i_3}y^{i_4i_5}y^{i_6i_7}-4y^{i_2i_3}y^{i_4i_6}y^{i_5i_7}+2y^{i_2i_4}y^{i_3i_6}y^{i_5i_7}).$$

A better choice of independent invariants is the following one:

$$p_3=-x_{i_6i_7}y^{i_6i_7}=\mathrm{Tr}(xy)=\mathrm{Tr}(uu+vv),$$

$$p_2=x_{i_4i_5}x_{i_6i_7}y^{i_4i_6}y^{i_5i_7}=\mathrm{Tr}(xyxy)=\mathrm{Tr}(u^4+v^4-2uvuv+4u^2v^2),$$

$$p_1=-x_{i_2i_3}x_{i_4i_5}x_{i_6i_7}y^{i_2i_4}y^{i_3i_6}y^{i_5i_7}=\mathrm{Tr}(xyxyxy)$$
$$=\mathrm{Tr}(u^6+6u^4v^2-6u^3vuv+3u^2vu^2v$$
$$+3uv^2uv^2-6v^3uvu+6u^2v^4+v^6).$$

The elements of the matrix $P(u,v)$ are obtained from the scalar products of the gradients of the invariants with respect to the independent variables u_{ij} and v_{ij}, $i<j$. The expressions of the non-trivial elements of $P(u,v)$ one obtains are awfully long and do not allow a determination of $\hat{P}(p)$ by simple inspection. This difficulty can be bypassed in the following way. One writes for each $\hat{P}_{ij}(p)$, $i,j=1,2$, the most general w-homogeneous polynomial in p_1,p_2 and p_3 with the correct weight d_i+d_j-2:

$$\hat{P}_{22}=a_1p_1+a_2p_2p_3+a_3p_3^3,$$

$$\hat{P}_{12}=b_1p_1p_3+b_2p_2^2+b_3p_2p_3^2+b_4p_3^4,$$

$$\hat{P}_{11}=c_1p_1p_2+c_2p_1p_3^2+c_3p_2^2p_3+c_4p_2p_3^3+c_5p_3^5,$$

where a_i, b_i, c_i are unknown constants. These unknown parameters can be determined by solving systems of linear equations obtained from the identities $\hat{P}_{ij}(p(u,v))=P_{ij}(u,v)$, evaluated for conveniently chosen numerical values of the u_{ij} and v_{ij}. By using an overdetermined system of equations, one gets, as a bonus, a check of the correctness of the results. In this way, one obtains the following expressions for the non-trivial elements of the $\hat{P}$-matrix:

$$\hat{P}_{22}=16p_1,$$

$$\hat{P}_{12}=16p_1p_3+6p_2^2-6p_2p_3^2+\frac{1}{2}p_3^4,$$

$$\hat{P}_{11}=\frac{3}{8}(40p_1p_2+20p_1p_3^2-10p_2p_3^3+p_3^5),$$

which can be reduced to the standard A$\hat{P}$M of class $III.2$ after the following MIB transformation:

$$p_1'=1296p_1-864p_2p_3+124p_3^3,$$

$$p_2'=36p_2-10p_3^2.$$

• Entry 17: $(A_8,\varphi_2+\varphi_7)$. One has to choose between the following classes of A$\hat{P}$M's: $A4(1,2)(s=2)$, $A8(3,2)(s=2)$, $B4(1)(s=2)$, and $E3$. Let $x\in\varphi_2$ and $y\in\varphi_7=\overline{\varphi_2}$. The complex vectors x and y can be realized as antisymmetric 9×9 complex matrices, which can be decomposed into their real and imaginary parts u and v: $x=u+iv$, $y=u-iv$. The elements of a MIB, as in Entry 16, can be chosen to be the following (repeated indexes are summed):

$$q_4=\varepsilon^{i_1i_2i_3i_4i_5i_6i_7i_8i_9}x_{i_8i_9}\varepsilon_{i_1i_2i_3i_4i_5i_6i_7j_8j_9}y^{j_8j_9},$$

$$q_3=\varepsilon^{i_1i_2i_3i_4i_5i_6i_7i_8i_9}x_{i_6i_7}x_{i_8i_9}\varepsilon_{i_1i_2i_3i_4i_5j_6j_7j_8j_9}y^{j_6j_7}y^{j_8j_9},$$

$$q_2=\varepsilon^{i_1i_2i_3i_4i_5i_6i_7i_8i_9}x_{i_4i_5}x_{i_6i_7}x_{i_8i_9}\varepsilon_{i_1i_2i_3j_4j_5j_6j_7j_8j_9}y^{j_4j_5}y^{j_6j_7}y^{j_8j_9},$$

$$q_1=\varepsilon^{i_1i_2i_3i_4i_5i_6i_7i_8i_9}x_{i_2i_3}x_{i_4i_5}x_{i_6i_7}x_{i_8i_9}\varepsilon_{i_1j_2j_3j_4j_5j_6j_7j_8j_9}y^{j_2j_3}y^{j_4j_5}y^{j_6j_7}y^{j_8j_9}.$$

A better choice of independent invariants is the following one:

$$p_4=\mathrm{Tr}(xy)=\mathrm{Tr}(uu+vv),$$

$$p_3=\mathrm{Tr}(xyxy)=\mathrm{Tr}(u^4+v^4-2uvuv+4u^2v^2),$$

$$p_2=\mathrm{Tr}(xyxyxy)=\mathrm{Tr}(u^6+6u^4v^2-6u^3vuv+3u^2vu^2v+3uv^2uv^2-6v^3uvu+6u^2v^4+v^6),$$

$$\begin{aligned}p_1=&\mathrm{Tr}(xyxyxyxy)\\&=\mathrm{Tr}(2u^8+16u^6v^2-16u^5vuv+16u^4vu^2v+16u^4v^4-8u^3vu^3v-16u^3vuv^3+16u^3v^2uv^2\\&\quad+8u^2v^2u^2v^2-16u^2v^2uvuv+16u^2vuv^2uv+4uvuvuvuv-16u^2vuvuv^2+16u^2vu^2v^3\\&\quad-16u^3v^3uv-8uv^3uv^3+16uv^2uv^4-16uvuv^5+16u^2v^6+2v^8).\end{aligned}$$

With the same technique used to obtain the results of Entry 16, one sets

$$\hat{P}_{33}=a_1p_2+a_2p_3p_4+a_3p_4^3,$$

$$\hat{P}_{23}=b_1p_1+b_2p_2p_4+b_3p_3^2+b_4p_3p_4^2+b_5p_4^4,$$

$$\hat{P}_{22}=c_1p_1p_4+c_2p_2p_3+c_3p_2p_4^2+c_4p_3^2p_4+c_5p_3p_4^3+c_6p_4^5,$$

$$\hat{P}_{13}=d_1p_1p_4+d_2p_2p_3+d_3p_2p_4^2+d_4p_3^2p_4+d_5p_3p_4^3+d_6p_4^5,$$

$$\hat{P}_{12}=e_1p_1p_3+e_2p_1p_4^2+e_3p_2^2+e_4p_2p_3p_4+e_5p_2p_4^3+e_6p_3^3+e_7p_3^2p_4^2+e_8p_3p_4^4+e_9p_4^6,$$

$$\begin{aligned}\hat{P}_{11}=&f_1p_1p_2+f_2p_1p_3p_4+f_3p_1p_4^3+f_4p_2^2p_4+f_5p_2p_3^2+f_6p_2p_3p_4^2+f_7p_2p_4^4+f_8p_3^3p_4+f_9p_3^2p_4^3\\&+f_{10}p_3p_4^5+f_{11}p_4^7,\end{aligned}$$

where a_i, b_i, c_i, d_i, e_i, and f_i are unknown constants, and from the identities $P(u,v)=\hat{P}(p(u,v))$ one obtains the following expressions for the non-trivial elements of the $\hat{P}$-matrix:

$$\hat{P}_{33}=16p_2,$$

$$\hat{P}_{23}=12p_1,$$

$$\hat{P}_{22}=\frac{3}{32}[20(6p_1p_4+8p_2p_3-4p_2p_4^2-3p_3^2p_4+p_3p_4^3)-p_4^5],$$

$$\hat{P}_{13}=\frac{1}{6}[20(6p_1p_4+8p_2p_3-4p_2p_4^2-3p_3^2p_4+p_3p_4^3)-p_4^5],$$

$$\hat{P}_{12}=\frac{1}{8}[2(72p_1p_3+36p_1p_4^2+64p_2^2-32p_2p_4^3-12p_3^3-18p_3^2p_4^2+9p_3p_4^4)-p_4^6],$$

$$\hat{P}_{11}=\frac{1}{12}[14(32p_1p_2+24p_1p_3p_4+4p_1p_4^3+16p_2p_3^2-16p_2p_3p_4^2-4p_2p_4^4-12p_3^3p_4+2p_3^2p_4^3 + p_3p_4^5)-p_4^7],$$

which can be reduced to the standard A$\hat{P}$M of class $E3$, after the following MIB transformation:

$$p_1'=-54(8192p_1-10240p_2p_4-4096p_3^2+3648p_3p_4^2-279p_4^4),$$

$$p_2'=36(256p_2-144p_3p_4+17p_4^3),$$

$$p_3'=-3(32p_3-7p_4^2).$$

• Entry 19, 32: $(B_{n\geqslant 2},2\varphi_1)$, $(D_{n\geqslant 4},2\varphi_1)$. Let $x_1,x_2\in\varphi_1$. The elements of the MIB can be chosen as in Entry 3 and the $\hat{P}$-matrix turns out to be the same.

• Entry 25: $(B_3,2\varphi_1+\varphi_3)$. One has to choose among the following classes of A$\hat{P}$M's: $A1(1,1,1,1)$, $A3(1,1,1)$, $A4(1,1)$, $A5(1,1,1)$, and $A7(1,1)$. Let x_1, $x_2\in\varphi_1$, $y\in\varphi_3$. The basic invariants suggested by Schwarz are the following: $q_1=x_1^2$, $q_2=x_2^2$, $q_3=x_1x_2$, and $q_4=y^2$. A better choice for our purposes is the following one: $p_1=3q_1-3q_2=3{x_1}^2-3{x_2}^2$, $p_2=6q_3=6x_1x_2$, $p_3=q_1+q_2-2q^4={x_1}^2+{x_2}^2-2y^2$, and $p_4=q_1+q_2+q_4={x_1}^2+{x_2}^2+y^2$. The standard procedure leads to a $\hat{P}$-matrix with the following non-trivial elements: $\hat{P}_{11}=12(p_3+2p_4)$, $\hat{P}_{12}=0$, $\hat{P}_{13}=4p_1$, $\hat{P}_{22}=12(p_3+2p_4)$, $\hat{P}_{23}=4p_2$, and $\hat{P}_{33}=4(2p_4-p_3)$, which is equal to the $\hat{P}$-matrix of the class $A3(1,1,1)$.

• Entry 26: $(B_3,2\varphi_3)$. Let $x_1,x_2\in\varphi_3$. The elements of the MIB can be chosen as in Entry 3 and the $\hat{P}$-matrix turns out to be the same.

• Entry 29: $(B_4,\varphi_1+\varphi_4)$. One has to choose between the following two classes of A$\hat{P}$M's: $I(2,1)$ and $II(2)$. Let $x\in\varphi_1$, $y\in\varphi_4$. A possible choice for the elements of a MIB is the following: $p_1=x(y\Gamma y)$, $p_2=y^2$, and $p_3=x^2+y^2$. The following elements of the $\hat{P}$-matrix are easily obtained with the standard procedure: $\hat{P}_{12}(p)=4p_1$ and $\hat{P}_{22}(p)=4p_2$. As far as $\hat{P}_{11}(p)$ is concerned, an explicit calculation starting from $P_{11}(x,y)$ would require an explicit determination of the vector operators Γ. One can bypass this difficulty arguing as follows. In $P_{11}(x,y)$ there must be terms of the form $(y\Gamma y)(y\Gamma y)$ and x^2y^2; this suggests the following choice: $\hat{P}_{11}(p)=ap_2^2+bp_2p_3$. The determinant of $\hat{P}(p)$ has the following expression:

$$\det(\hat{P}(p))=16[p_1^2(3p_2-4p_3)-p_2^2(p_2-p_3)(ap_2+bp_3)].$$

A direct check proves that it does not satisfy the canonical equation and thus the complete active factor $A(p)$ has to factorize in $\det(\hat{P}(p))$. Owing to item *iii)* of Prop. II.1, $A(p)$ must be at least quadratic in p_1. This implies that the coefficient of p_1^2 in $\det(\hat{P}(p))$, which is irreducible, must be a factor of the whole determinant, and this requires $a=-\frac{3}{4}b$. After the following MIB transformation, $p_2'=-3p_2+2p_3$, and choosing the free parameter $b=108$, one ends up with the $\hat{P}$-matrix of the class $I(2,1)$.

• Entry 30: $(B_4,2\varphi_4)$. One has to choose among the following 10 classes of A$\hat{P}$M's: $A1(1,1,2,2)$, $A2(1,1,2,1)$, $A2(1,1,1,2)$, $A3(1,3,1)$, $A3(1,2,2)$, $A5(1,1,3)$, $A5(2,1,2)$, $A7(1,3)$, $A8(3,1)$, and $A9(3)$. Let $x_1,x_2\in\varphi_4$. A possible MIB, as suggested by Schwarz, is the following: $q_1=(x_1\Gamma x_1)(x_2\Gamma x_2)$, $q_2=x_1^2$, $q_3=x_2^2$, and $q_4=x_1x_2$. Like in Entry 3, it is convenient to chose the following form for the invariants: $p_1=q_1$, $p_2={x_1}^2-{x_2}^2$, $p_3=2x_1x_2$, and $p_4={x_1}^2+{x_2}^2$. The following elements of $\hat{P}(p)$ are easily determined through the standard procedure: $\hat{P}_{22}(p)=4p_4$, $\hat{P}_{23}(p)=0$, and $\hat{P}_{33}(p)=4p_4$. Moreover, $\hat{P}_{12}(p)=0$ because it is the difference of two equal terms, which are linear in p_1. The polynomial $P_{11}(x_1,x_2)$ is symmetric under the exchange $x_1\leftrightarrow x_2$ and contains terms of sixth degree: fourth in x_1 and second in x_2 and vice versa, thus, taking into account the symmetry $x_1\leftrightarrow x_2$, the polynomial $\hat{P}_{11}(p)$ can be written in the following general form:

$$\hat{P}_{11}(p)=ap_1p_4+bp_3^2p_4+2c^2[(p_4-p_2)^2(p_4+p_2)+(p_4+p_2)^2(p_4-p_2)].$$

The polynomial $P_{13}(x_1,x_2)$ contains terms of the form $(x_1\Gamma x_1)(x_1\Gamma x_2)+(x_1\leftrightarrow x_2)$, so its general expression in terms of the basic invariants must be $\hat{P}_{13}(p)=4dp_3p_4$. The determinant of $\hat{P}(p)$ factorizes p_4^2 and so, because of the condition in item *iii)* of Prop. II.1, the unique possibility we are left with is a complete active factor $A(p)$ of weight 8. Now the active factor $A(p)$ contains a monomial in $p_1p_4^2$ that must vanish in an A-basis, and this requires $a=0$. The canonical equation is then satisfied by $A(p)$ only if $b=4(d^2-c^2)$. After the following MIB transformation:

$$p_1'=\frac{4}{c}(2p_1-dp_3^2) \quad (c,d\neq 0),$$

$$p_2'=2p_2,$$

one ends up with the standard A$\hat{P}$M of class $A1(1,1,2,2)$. The free parameters c and d are no longer present in the $\hat{P}$-matrix, since they have been absorbed in the redefinition of the MIB.

• Entry 35: $(D_4,\varphi_1+\varphi_3+\varphi_4)$. One has to choose among the following 6 classes of A$\hat{P}$M's: $A2(1,1,1,1)$, $A3(1,2,1)$, $A5(1,1,2)$, $A5(2,1,1)$, $A7(1,2)$, and $A8(2,1)$. Let $x\in\varphi_1$, $y\in\varphi_3$, $z\in\varphi_4$. A possible MIB, as suggested by Schwarz, is the following: $p_1=x(y\Gamma z)$, $p_2=x^2$, $p_3=y^2$, and $p_4=x^2+y^2+z^2$. The following elements of $\hat{P}(p)$ are then easily determined through the standard procedure: $\hat{P}_{12}(p)=2p_1$, $\hat{P}_{13}(p)=2p_1$, $\hat{P}_{22}(p)=4p_2$, $\hat{P}_{23}(p)=0$, and $\hat{P}_{33}(p)=4p_3$. As for $\hat{P}_{11}(p)$, the polynomial $P_{11}(x,y,z)$ contains terms of fourth degree which are at most quadratic separately in x y and z; so its general expression in terms of the basic invariants is the following: $\hat{P}_{11}(p)=(p_4-p_2-p_3)(ap_2+bp_3)+cp_2p_3$.

The determinant of $\hat{P}(p)$ has the following expression:

$$\det\hat{P}(p)=64[F(p_2,p_3,p_4){p_1}^2+G(p_2,p_3,p_4)],$$

where $F(p)={p_2}^2+p_2p_3+{p_3}^2-p_2p_4-p_3p_4$ and $G(p)$ are polynomials not depending on p_1. A direct check proves that $\det\hat{P}(p)$ does not satisfy the canonical equation and, thus, the complete active factor $A(p)$ has to factorize in $\det(\hat{P}(p))$. Owing to item *iii)* of Prop. II.1, $A(p)$ must be at least quadratic in p_1, and this implies that the coefficient of p_1^2 in $\det(\hat{P}(p))$, which is irreducible, must be a factor of the whole determinant, and this requires $a=b=c$. The weight of the complete active factor is then equal to 6. After the following MIB transformation and choosing the free parameter $c=5184$,

$$p_2'=12p_2+6p_3-6p_4,$$

$$p_3'=-6p_3+2p_4,$$

one ends up with the standard A$\hat{P}$M of class $A2(1,1,1,1)$.

• Entry 36: $(D_4,\varphi_1+2\varphi_3)$. Let $x_1,x_2\in\varphi_3,z\in\varphi_1$. The elements of the MIB can be chosen as in Entry 25 and the $\hat{P}$-matrix turns out to be the same.

• Entry 48: $(G_2,2\varphi_1)$. Let $x_1,x_2\in\varphi_1$. The elements of the MIB can be chosen as in Entry 3 and the $\hat{P}$-matrix turns out to be the same.

VIII. MINIMIZATION OF HIGGS POTENTIALS: TWO EXAMPLES

In this section we shall make use of the theory and some of the results reported in this paper in order to yield a complete and rigorous discussion of the minima of two particular Higgs potentials. Our aim is just to show, in two substantial samples, that, even in relatively complex situations, the problem of minimizing a general polynomial invariant potential of degree 4 can be reduced to an almost trivial exercise in the $\hat{P}$-matrix approach, without needing to introduce any *ad hoc* assumptions or additional symmetries to eliminate intriguing terms in the potential.

In gauge theory model building the choice of the ground state is controlled by the minimum of a fourth degree invariant polinomial function $V(\phi)$ of the scalar real (Higgs) fields ϕ of the model. The fields ϕ are chosen to transform according to a real representation of the gauge group, which defines a real linear group G. The potential is generally built as the most general G-invariant fourth degree polynomial function of ϕ. The isotropy group of the point ϕ_0 at which the potential takes on its absolute minimum is the true symmetry group of the theory after spontaneous symmetry breaking. In the following, to be consistent with the notations used throughout the paper, we shall denote by $x \in \mathbb{R}^n$ the set of Higgs fields.

The two examples we shall work out are based on the grand unification gauge groups SO(10) and E_6. Models based on these groups have been extensively studied by many authors.[33,34] In the following we shall only be concerned with some technical group theoretical problems that are met in these analyses.

A. An effective approach to the determination of minima of *G*-invariant functions

In order to solve the minimization problem in the $\hat{P}$-matrix approach to the study of regular G-invariant functions mentioned in the Introduction, all one has to do is the following:

(1) Identify a MIB $p_1(x),\ldots,p_q(x)$ of G and the associated $\hat{P}$-matrix.
(2) Determine the equalities and inequalities defining the orbit space $\overline{\mathscr{S}}$ of G and its stratification, according to Theorem II.1.
(3) Write down the potential $\hat{V}(p)$ as a function of the basic invariants $(p_1,\ldots,p_q)$ and determine the conditions under which it turns out to be bounded below. It will not be restrictive to assume $\hat{V}(0)=0$.
(4) Determine the constrained minima of $\hat{V}(p)$ on the different primary strata of the orbit space $\overline{\mathscr{S}}$ of G and compare them in order to single out the absolute minimum.
(5) Identify the symmetry (isotropy type) of the stratum/a containing the orbits at which the potential can take on its absolute minimum.

The following remarks allow for considerable simplifications in the determination of the minimum of $\hat{V}(p)$, $p \in \overline{\mathscr{S}}$:

a) Owing to the w-homogeneity properties of the equalities and inequalities determining the stratification of the orbit spaces, it turns out to be convenient to adopt the following strategy:

i) introduce homogeneous variables

$$\eta_k = p_k / p_q^{d_k/2}, \quad k=1,\ldots,q-1, \tag{34}$$

so that, when p spans $\overline{\mathscr{S}}$, η spans the intersection $\overline{\mathscr{S}}_1$ of $\overline{\mathscr{S}}$ with the hyperplane of equation $p_q=1$;

ii) Define the auxiliary function $\hat{V}_{p_q}(\eta)$:

$$\hat{V}_{p_q}(\eta) = \hat{V}(\eta_1 p_q^{d_1/2},\ldots,\eta_{q-1} p_q^{d_{q-1}/2}, p_q), \quad \eta \in \overline{\mathscr{S}}_1, \ p_q>0, \tag{35}$$

which, for fixed η, is generally equal to p_q times a polynomial in $p_q^{1/2}$.

iii) After calling $\sigma^{(\alpha)}$, $\alpha=0,1,\ldots$, $(\sigma^{(0)}=\{0\})$ and $\sigma_1^{(\alpha)}$, $\alpha=1,\ldots$, the primary strata of $\overline{\mathscr{S}}$ and, respectively, of $\overline{\mathscr{S}}_1$, for each fixed p_q determine the constrained minima, $\hat{V}^{(\alpha)}(p_q)$, of the restrictions of $\hat{V}_{p_q}(\eta)$ to the strata $\sigma_1^{(\alpha)}$. We shall set $\hat{V}^{(0)}=\hat{V}(0)=0$.

iv) determine the minima of the functions $\hat{V}^{(\alpha)}(p_q)$, $p_q>0$, and compare them, in order to single out the absolute minimum of $\hat{V}(p)$, recalling that $\hat{V}(0)=0$.

b) Let us assume that $\hat{V}(p)$ depends on the invariants p_j, $j \in \mathscr{J}$, where $\mathscr{J}$ is a subset of $\{1,\ldots,q\}$ and let us denote by $\mathscr{S}'^{*}$ the orthogonal projection of $\mathscr{S}'$ in the linear subspace of $\mathbb{R}^{q-1}$ spanned by the variables η_j, $j \in \mathscr{J}\setminus\{q\}$. Then we have the following.

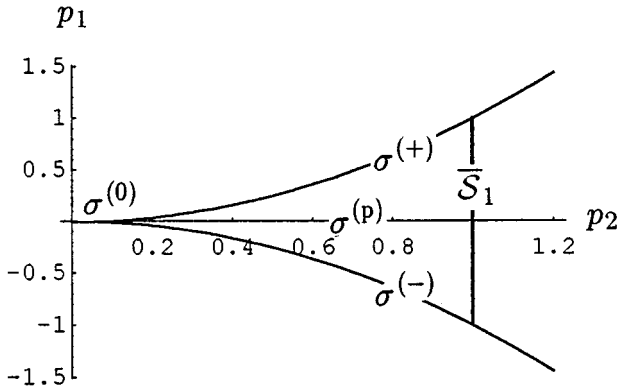

FIG. 1. Orbit space $\overline{\mathcal{S}}$ of the linear group (SO(10),**32**). $\overline{\mathcal{S}}_1$ is the intersection of $\overline{\mathcal{S}}$ with the straight line $p_2=1$.

1) If $\partial_j \hat{V}(p)$, for some $j \in \mathcal{I}\backslash\{q\}$ has no zero in $\mathcal{S}$, then the absolute minimum of $\hat{V}_{p_q}(\eta)$, $\eta \in \overline{\mathcal{S}}_1$, lies on the boundary of $\mathcal{S}_1$. This is the case[60] if there are elements of degree three and/or four in the MIB and the potential is assumed to be a fourth degree polynomial (for instance, because of renormalizability, in the case of Higgs potentials, or as a low order approximation, in the case of Landau potentials).

2) If $\hat{V}(p)$ depends only linearly on the p_j, $j \in \mathcal{I}\backslash\{q\}$ and if $\overline{\mathcal{S}}_1^*$ is contained in a convex polyhedron with vertices at points A_i which are points of $\mathcal{S}_1^*$, then $\hat{V}_{p_q}(\eta)$, $\eta \in \overline{\mathcal{S}}_1^*$ takes on its absolute minimum at one of the points A_i. The reason is that, in this case, for each fixed value of $p_q>0$, the functions $\hat{V}_{p_q}(\eta)$ are constant along linear varieties π_κ of equation $\hat{V}_{p_q}(\eta)=\kappa$. Thus, the absolute minimum of $\hat{V}_{p_q}(\eta)$, $\eta \in \overline{\mathcal{S}}_1^*$ is the lowest value of κ for which π_κ touches $\overline{\mathcal{S}}_1^*$. The set of contact points necessarily contains at least one vertex of the polyhedron.

The two examples worked out in the following subsections will clarify the procedure just described in the particular case of fourth degree polynomial potentials.

B. Minima of a general fourth degree polynomial invariant under the group (SO(10), 32)

The matrix group G is obtained by ''realizing'' a complex 16-dimensional matrix representation of the compact group SO(10).

According to Entry 37 in Table V, G is coregular and its MIB's are formed by two polynomials of degrees (4,2). If the MIB is chosen to be an A-basis, the $\hat{P}$-matrix takes on the following form:[26,27]

$$\hat{P}(p)=\begin{pmatrix} 16p_2^3 & 8p_1 \\ 8p_1 & 4p_2 \end{pmatrix}. \tag{36}$$

The active factor, $A(p)=p_2^4-p_1^2$, is proportional to the determinant of $\hat{P}(p)$ and an analysis of the semi-positivity properties of $\hat{P}(p)$ shows that the orbit space $\overline{\mathcal{S}}$ is the disjoint union of the primary strata $\sigma^{(\alpha)}$, $\alpha=0,\pm,\mathrm{p}$ (see Figure 1), whose defining equalities and inequalities are listed in Table VI.

A general G-invariant fourth degree polynomial in $x \in \mathbb{R}^{32}$ has the following form:

$$V(x)=\hat{V}(p(x)), \quad \hat{V}(p)=a_0p_2^2+a_1p_1+a_2p_2. \tag{37}$$

We shall assume $a_1 \neq 0$ in order to avoid trivial situations.

TABLE VI. Primary strata of the compact real linear group (SO(10), **32**). $\overline{x}$ denotes a conveniently chosen point in the stratum and $p(\overline{x})=(p_1(\overline{x}),p_2(\overline{x}))$. The coordinates, $(u_1,\ldots,u_{16},v_1,\ldots,v_{16})$, of $\overline{x}$ are referred to the basis specified in the Appendix.

Primary strata	Defining relations	Non-zero components of $\overline{x}$	$p(\overline{x})$	Isotropy subalgebras
$\sigma^{(0)}$	$p_1=p_2=0$	none	(0,0)	D_5
$\sigma^{(-)}$	$p_1=-p_2^2,\ p_2>0$	$u_1=1$	$(-1,1)$	A_4
$\sigma^{(+)}$	$p_1=p_2^2,\ p_2>0$	$u_1=u_{11}=\frac{1}{\sqrt{2}}$	(1,1)	B_3
$\sigma^{(p)}$	$p_1^2<p_2^4,\ p_2>0$	$2u_1=u_{11}=\frac{2}{\sqrt{5}}$	(0,1)	A_3

The function $\hat{V}(p),\ p\in\overline{\mathscr{S}}$ is bounded below only for $a_0>|a_1|$ or $a_0=|a_1|,\ a_2\geqslant 0$. Under these conditions, let us discuss the location of its absolute minimum as a function of the parameters a_i.

Using Remark b), it is easy to realize that the absolute minimum of $V(p)$ lies at $\sigma^{(0)}$ or on one of the subprincipal strata $\sigma^{(\pm)}$. The restrictions, $\hat{V}^{(\alpha)}(p_2)$, of $\hat{V}(p)$ to the strata $\sigma^{(\alpha)}$, $\alpha=0,+,-$, have the following form:

$$\hat{V}^{(0)}=0,\quad \hat{V}^{(\pm)}(p_2)=[(a_0\pm a_1)p_2+a_2]p_2, \tag{38}$$

so it is straightforward to derive the results summarized in Table VII, without exploiting the homogeneous variable η_1.

Let us stress that, up to this point, the discussion has been done with no reference to the specific linear group generating the $\hat{P}$-matrix.

In order to determine the isotropy types of the various primary strata one needs some more pieces of information about the particular MIB giving rise to the $\hat{P}$-matrix of equation (36). After setting $z=u+iv,\ u,v\in\mathbb{R}^{16}$, a general vector x of the real vector space $\mathbb{R}^{32}$ in which the compact linear group $G=(\mathrm{SO}(10),32)$ acts, may be written in the form $x=(u,v)$ and, from 3a.22 of Ref. 24 and the theorems reported in Section V, a possible choice of a MIB is the following:

$$p_1'(x)=\sum_1^{10}{}_k\ (\overline{z},\Gamma^k\overline{z})(z,\Gamma^k z)=\|(z,\Gamma^k z)\|^2,\quad p_2(x)=(\overline{z},z), \tag{39}$$

where $z\in\mathbb{C}^{16}$, (z,z') is the bilinear form $\Sigma_{j=1}^{16}z_jz_j'$ and the Γ^k are real symmetric 16×16 matrices, whose elements are proportional to Clebsch–Gordan coefficients coupling the representations 10 and 16×16 of the complex Lie algebra D_5.

The invariance properties of $p_1'(x)$ determine the relative values of the components Γ_{ij}^k, leaving indetermined only an overall numerical factor.

Let us show that it is possible to choose the normalization of the Γ's so that

TABLE VII. Primary strata, σ, hosting the absolute minimum of a general fourth degree polynomial invariant under (SO(10),**32**). The stratum is specified as a function of the parameters $a_i, i=0,1,2$, entering the definition of the potential, $\epsilon=-\mathrm{sign}(a_1)$ and a_1 is assumed $\neq 0$.

Boundedness conditions	Further conditions	σ
$a_0>\|a_1\|$	$a_2\geqslant 0$	$\sigma^{(0)}$
	$a_2<0$	$\sigma^{(\epsilon)}$
$a_0=\|a_1\|,\ a_2\geqslant 0$	none	$\sigma^{(0)}$
	$a_2=0$	$\sigma^{(\epsilon)}$

$$p_1(x)=p_1'(x)-p_2^2(x), \tag{40}$$

where $(p_1(x),p_2(x))$ form an A-basis, giving rise to the $\hat{P}$-matrix of equation (36).

With $(p_1'(x),p_2(x))$ being a MIB, only for homogeneity reasons, there will be real constants β_1,β_2,b_1,b_2 such that

$$\|\partial p_1'(x)\|^2=b_1p_1'(x)p_2(x)+b_2p_2^3(x) \tag{41}$$

and

$$p_1(x)=\beta_1p_1'(x)+\beta_2p_2^2(x), \tag{42}$$

where it is not restrictive to assume $\beta_1>0$, since a change of sign of p_1 does not change the $\hat{P}$-matrix.

By a detailed inspection of the weights of the representations 10 and 16 of D_5 (reported in the Appendix) one easily realizes that $\Gamma_{jj}^k=0$, for all $k=1,\ldots,10$, $j=1,\ldots,16$. Then, by choosing $x=x^{(j)}=(u^{(j)},0)$, where $u^{(j)}$ has components $u_i^{(j)}=\delta_{ij}$, one obtains the following relations:

$$p_1'(x^{(j)})=0,\quad \partial p_1'(x^{(j)})=0,\quad p_2(x^{(j)})=1, \tag{43}$$

which, when inserted into (41), immediately imply $b_2=0$. Moreover, since $\|\partial p_1'(x)\|^2$ and $p_1'(x)$ are positive semi-definite, by conveniently choosing the overall normalization of the Γ's it is possible to require, for instance, $b_1=32$.

By comparing the expression of $\|\partial p_1(x)\|^2=\hat{P}_{11}(p(x))=16p_2^3(x)$, obtained from (36), and the expression of $\|\partial p_1(x)\|^2$, calculated from (42) and (41), one obtains $\beta_1=-\beta_2=1$, so that (40) is satisfied.

For later use let us also note that (41) reduces to

$$\|\partial p_1'(x)\|^2=32p_1'(x)p_2(x). \tag{44}$$

The determination of the isotropy types of the different strata proceeds through the choice, for each stratum $\sigma^{(\alpha)}$, of a particular point lying in $\sigma^{(\alpha)}$ and through the identification of the corresponding isotropy group. The problem can be solved bypassing a complete determination of the Γ's. Let us prove our claim for the two subprincipal strata, using the results reported in Table VI and equation (40).

$\sigma^{(-)}$: On this stratum $p_1'(x)=0$, therefore, from (43), $p(x^{(j)})$, $j=1,\ldots16$ lies in $\sigma^{(-)}$.

$\sigma^{(+)}$: On this stratum $p_1'(x)=2p_2^2(x)$. Now, the weights of the representation 10 of D_5 are not degenerate. As a consequence, for each choice of $i,j=1,\ldots,16$, there is at most a $k=1,\ldots,10$, such that $\Gamma_{ij}^k\neq0$. Let us choose i,j,k so that $\Gamma_{ij}^k\neq0$ and define the vectors $x^{(ij)}$ so that $x_l^{(ij)}=\delta_{li}+\delta_{lj}$, $l=1,\ldots,32$. Then, from (39),

$$p_1'(x^{(ij)})=4\Gamma_{ij}^{k\,2}, \tag{45}$$

while (44) requires

$$\Gamma_{ij}^k=\pm\sqrt{2}, \tag{46}$$

so that

$$p_2(x^{(ij)})=2,\quad p_1'(x^{(ij)})=8=2p_2^2(x^{(ij)}), \tag{47}$$

assuring that $p(x^{(ij)})\in\sigma^{(+)}$.

The isotropy subalgebras of the Lie algebra of the compact group SO(10) at the points $x^{(j)}$ and $x^{(ij)}$ can be determined by standard methods and turn out to be isomorphic, respectively, to the compact forms of the Lie algebras A_4 and B_3.

Just for completeness in the Appendix we have listed the weight vectors of the two representations 10 and 16 of D_5 and the values of the non trivial components of the Γ's. These data can be used to check our arguments.

TABLE VIII. Primary strata σ, of the compact real linear group (E_6, **54**). In the columns, $\bar{x}$ denotes a conveniently chosen point in the stratum σ, $p(\bar{x})=(p_1(\bar{x}),\ldots,p_4(\bar{x}))$ and IS is the isotropy subalgebra of σ. The coordinates, $(u_1,\ldots,u_{27},v_1,\ldots,v_{27})$, of $\bar{x}$ are referred to the basis specified in the Appendix. The isotropy subalgebras of the strata $\sigma^{(3)}$ and $\sigma^{(4)}$ are distinct (so(9),**54**) subalgebras of (E_6, **54**) and $\gamma_\pm=\frac{1}{2}\sqrt{1\pm\sqrt{2/3}}$.

σ	Defining relations	Non-zero components of $\bar{x}$	p($\bar{x}$)	IS

C. Minima of a general fourth degree polynomial invariant under the linear group (E_6,54)

The matrix group G is obtained by ''realizing'' a complex 27-dimensional matrix representation of the compact group E_6.

According to Entry 44 in Table V, G is coregular and its MIB's are formed by four polynomials of degrees (4,3,3,2). In a standard A-basis the $\hat{P}$-matrix takes on the following form (see Ref. 28, class B2):

$$\hat{P}(p)=\begin{pmatrix} 16(-p_1p_4+p_2^2+p_3^2+2p_4^3), & 24p_2p_4, & 24p_3p_4, & 8p_1 \\ 24p_2p_4, & 9(p_1+2p_4^2), & 0, & 6p_2 \\ 24p_3p_4, & 0, & 9(p_1+2p_4^2), & 6p_3 \\ 8p_1, & 6p_2, & 6p_3, & 4p_4 \end{pmatrix}. \tag{48}$$

After defining

$$A_\pm(p)=(2p_4^2-p_1)^{3/2}\pm(p_2^2+p_3^2-3p_1p_4+2p_4^3), \tag{49}$$

the active factor, $A(p)$, of the determinant can be written in the form

$$A(p)=A_+(p)A_-(p); \tag{50}$$

therefore, the singular strata are contained in the variety of equation $A(p)=0$.

Adding convenient rank and positivity conditions on the matrix $\hat{P}(p)$, one obtains the relations, reported in Table VIII, defining the primary strata $\sigma^{(\alpha)}$, $\alpha=0,\ldots,5$, of the orbit space $\bar{\mathscr{S}}$.

The intersection, $\bar{\mathscr{S}}_1$, of the orbit space $\bar{\mathscr{S}}$ with the hyperplane of equation $p_4=1$ has rotational symmetry around the p_1 axis. A section of $\bar{\mathscr{S}}_1$ with a plane through the symmetry axis is shown in Figure 2(a). Owing to this symmetry, it will not be restrictive to assume that the elements

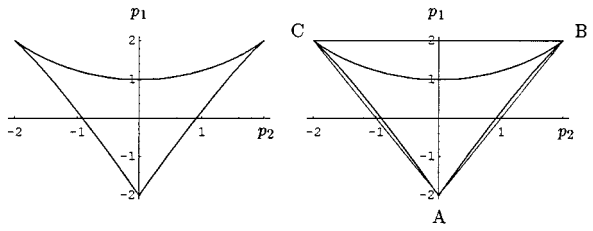

FIG. 2. Orbit space $\bar{\mathscr{S}}_1$ of the action of the linear group (E_6, **54**) in the unit sphere $p_4(x)=1$ of $\mathbb{R}^{54}$: (a) Intersection with the plane $p_3=0$; (b) orthogonal projection on the plane $p_3=0$.

TABLE IX. Primary strata, σ, hosting the absolute minimum of a general fourth degree polynomial invariant under E_6,**54**). The stratum is specified as a function of the parameters $\alpha_i=a_i/a_0$, $i=1,\ldots,4$, $a_0\neq 0$, $|\alpha_1|\leqslant 1/2$, entering the definition of the potential. $f_1(\alpha_1,\alpha_2)$ and $f_2(\alpha_1,\alpha_2)$ are functions of α_1 and α_2, defined by the relations: $f_1=\alpha_2^2/(1+2\alpha_1)$, $|\alpha_1|<1/2$; $f_2=-\alpha_2^2\sqrt{1-2\alpha_1}\,[(2+5\alpha_1)\sqrt{1-2\alpha_1}+2\sqrt{(1+\alpha_1)^3}]/[8\alpha_1^2(1+2\alpha_1)]$, for $0<\alpha_1<1/2$, and $f_2=-\infty$, for $-1/2<\alpha_1\leqslant 0$.

Boundedness conditions	Further conditions	σ
$\alpha_0>0$, $\lvert\alpha_1\rvert<\frac{1}{2}$	$(\alpha_2\neq 0,\ \alpha_4\geqslant f_1)$ or $(\alpha_2=0,\ \alpha_4\geqslant 0)$	$\sigma^{(0)}$
	$(\alpha_2\neq 0,\ f_2\leqslant\alpha_4\leqslant f_1)$ or $(\alpha_1\leqslant 0,\ \alpha_2=0,\ \alpha_4<0)$	$\sigma^{(2)}$
	$(\alpha_2\neq 0,\ \alpha_4\leqslant f_2)$ or $(\alpha_1\geqslant 0,\ \alpha_2=0,\ \alpha_4<0)$	$\sigma^{(1)}$
$a_0>0$, $\alpha_1=\frac{1}{2}$, $\alpha_4\geqslant 0$	$(\alpha_2\neq 0,\ \alpha_2^2\geqslant 2\alpha_4)$ or $\alpha_2=0$	$\sigma^{(0)}$
	$\alpha_2\neq 0,\ \alpha_2^2\geqslant 2\alpha_4$	$\sigma^{(2)}$
	$\alpha_2=0,\ \alpha_4=0$	$\sigma^{(1)}$
$\alpha_0>0$, $\alpha_1=-\frac{1}{2}$, $\alpha_2=0$, $\alpha_4\geqslant 0$	none	$\sigma^{(0)}$
	$\alpha_4=0$	$\sigma^{(2)}$

of the MIB have been chosen so that the general form of a fourth degree G-invariant real polynomial in $x\in\mathbb{R}^{54}$ is $V(x)=\hat{V}(p(x))$, where $\hat{V}(p)$ does not depend on p_3:

$$\hat{V}(p)=a_0p_4^2+a_1p_1+a_2p_2+a_4p_4,\quad a_i\in\mathbb{R}, \tag{51}$$

so that

$$\hat{V}_{p_q}(\eta)=[(a_0+a_1\eta_1)p_4+a_2\eta_2p_4^{1/2}+a_4]p_4. \tag{52}$$

Thus, the problem of determining the minima of $\hat{V}(p)$ in $\overline{\mathscr{S}}$ reduces to the analogous problem in the orthogonal projection of $\overline{\mathscr{S}}$ on an hyperplane of equation $p_3=\text{const}$.

We shall assume $a_0\neq 0$ in order to avoid trivial situations.

The conditions under which the function $\hat{V}(p)$, $p\in\overline{\mathscr{S}}$, is bounded below are not difficult to establish, if one makes use of the specification of the strata reported in Table VIII. We have reported the conclusions in the first column of Table IX.

Since the orthogonal projection, $\overline{\mathscr{S}}_1^*$, of $\overline{\mathscr{S}}_1$ on a plane of equation $p_3=\text{const}$ is contained in a triangle with vertices A, B, C (see Figure 2(b)), according to the Remark b), for fixed p_4, the function $\hat{V}_{p_4}(\eta)$, $\eta\in\overline{\mathscr{S}}_1^*$, attains its absolute minimum at A and/or B and/or C, depending on the slope of the straight lines of equations $V_{p_4}(\eta)=\kappa$ in the plane (η_1,η_2). Therefore, the absolute minimum of $\hat{V}(p)$, $p\in\overline{\mathscr{S}}$ lies on one of the primary strata $\sigma^{(\alpha)}$, $\alpha=0,1,2$.

Using the equalities and inequalities defining the primary strata reported in Table VIII, one obtains the following expressions for the restrictions of $\hat{V}(p)$ to $\sigma^{(1)}$ and $\sigma^{(2)}$:

$$\hat{V}(p)\big|_{\sigma^{(1)}}=\hat{V}_{p_4}(-2,0)=[(a_0-2a_1)p_4+a_4]p_4, \tag{53}$$

$$\hat{V}(p)\big|_{\sigma^{(2)}}=\hat{V}_{p_4}(2,\eta_2)=[(a_0+2a_1)p_4+a_2\eta_2p_4^{1/2}+a_4]p_4,\quad -2\leqslant\eta_2\leqslant 2, \tag{54}$$

whose absolute minima, for fixed p_4, are

$$\begin{aligned}\hat{V}^{(1)}(p_4)&=[(a_0-2a_1)p_4+a_4],\\ \hat{V}^{(2)}(p_4)&=[(a_0+2a_1)p_4-2|a_2|p_4^{1/2}+a_4]p_4.\end{aligned} \tag{55}$$

By comparing $\hat{V}^{(0)}$ and the minima of the funtions $\hat{V}^{(\alpha)}(p_4)$, $\alpha=1,2$, as functions of the parameters a_i, with standard manipulations, one finds the results summarized in Table IX, which give rise to the phase diagram of Figure 3, for $a_2\neq 0$.

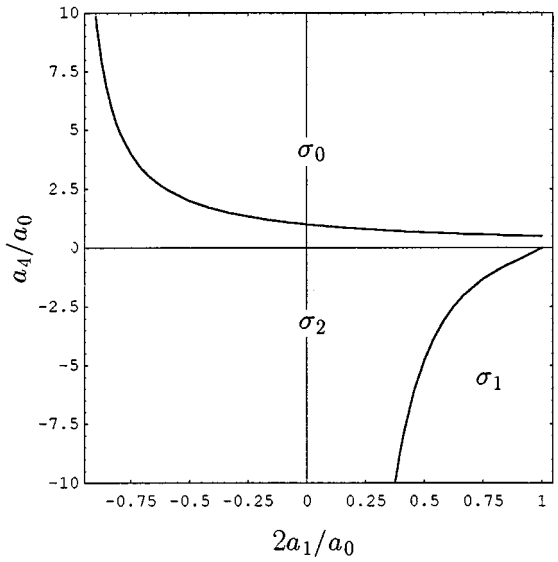

FIG. 3. Phase diagram for a general fourth degree polynomial potential invariant under the linear group (E_6, **54**). The ratio a_2/a_0 plays the role of a scale parameter and has been set equal to 1.

In order to determine the isotropy types of the various primary strata one needs some more pieces of information about the MIB giving rise to the $\hat{P}$-matrix of equation (48).

After setting $z=u+iv$, $u,v\in\mathbb{R}^{27}$, a general vector, x, of the real vector space $\mathbb{R}^{54}$ in which the compact real linear group $G=(E_6,54)$ acts, may be written in the form $x=(u,v)$ and, from 5a.6 of Ref. 24 and the theorems reported in Section V, a possible choice of a MIB can be done in the following way. Let us denote by $Q(z)$ the unique independent polynomial invariant of degree 3 of the complex linear group $(E_6,27)$:

$$Q(z)=\sum_{ijk}^{27}\Gamma_{ijk}z_iz_jz_k, \quad z\in\mathbb{C}^{27}, \tag{56}$$

where the Γ_{ijk} are real and completely symmetric in ijk. The invariance properties of $Q(z)$ only determine the relative values of the components Γ_{ijk}, leaving indetermined an overall numerical factor.

The 2 independent real trilinear invariants of G can be chosen to be the real and imaginary parts of $Q(z)$. The unique independent invariant of degree two is $p_4(x)=(\overline{z},z)$, while the unique independent fourth degree invariant can be obtained from the invariant $\|\partial p_2(x)\|^2=\|\partial p_3(x)\|^2$.

A simple inspection of the weights of the representation 27 of E_6 shows that for each choice of ij, there is at most a k such that $\Gamma_{ijk}\neq 0$ and this can occur only if i,j,k are all different. Arguing as in the preceding example, this piece of information turn out to be sufficient to conclude that, if the overall normalization factor in the definition of $Q(z)$ is conveniently chosen, an A-basis, giving rise to the $\hat{P}$-matrix of equation (48), is the following:

$$\begin{aligned} p_1(x)&=\frac{1}{3}\|\partial p_2(x)\|^2-2x^2, \quad p_2(x)=\Re\left(\sum_{ijk}^{27}\Gamma_{ijk}z_iz_jz_k\right),\\ p_3(x)&=-\Im\left(\sum_{ijk}^{27}\Gamma_{ijk}z_iz_jz_k\right), \quad p_4(x)=x^2. \end{aligned} \tag{57}$$

Like in the preceding example, the determination of the isotropy types of the various strata can be achieved bypassing the complete determination of the Γ's. We shall skip the details of the calculation and report only the final results in Table VIII.

TABLE X. Real compact coregular linear Lie groups with less than 5 basic invariants and isomorphic orbit spaces. In each row, the following items are listed: A label, Class, specifying the equivalence class of a $\hat{P}$-matrix, $\hat{P}(p)$; the degrees, d_i, of the set of basic invariants $\{p\}$; and all the linear simple compact Lie groups that generate $\hat{P}$-matrices of the given Class (they are specified by the Lie algebras, $(\mathscr{G},\varphi)$, of their complexifications).

Class	d_i	$(\mathscr{G},\varphi)$
I_1	2	All groups with 1 basic invariant
I_2	d,2	(A_1,φ_1^4), (A_2,Ad), $(A_3,\varphi_1+\varphi_2+\varphi_3)$, $(A_4,\varphi_2+\varphi_3)$, (B_2,Ad), $(B_3,\varphi_1+\varphi_3)$, $(D_4,\varphi_1+\varphi_3)(D_5,\varphi_4+\varphi_5)$, (C_3,φ_2), (F_4,φ_1),(G_2,Ad)
$I(1,1)$	2,2,2	$(A_1,2\varphi_1^2)$, $(A_3,2\varphi_2)$, $(B_{n\geqslant 2},2\varphi_1)$, $(D_{n\geqslant 4},2\varphi_1)$, $(B_3,2\varphi_3)$, $(D_4,2\varphi_3)$, $(G_2,2\varphi_1)$
$I(2,1)$	3,2,2	$(B_4,\varphi_1+\varphi_4)$
$III.1$	4,3,2	(A_3,Ad), (C_4,φ_2)
$III.2$	6,4,2	$(A_6,\varphi_2+\varphi_5)$, (B_3,Ad), (C_3,Ad)
$A1(1,1,1,1)$	2,2,2,2	$(A_{n\geqslant 2},2\varphi_1+2\varphi_n)$
$A1(1,1,2,2)$	4,2,2,2	$(B_4,2\varphi_4)$
$A2(1,1,1,1)$	3,2,2,2	$(D_4,\varphi_1+\varphi_3+\varphi_4)$
$A3(1,1,1)$	2,2,2,2	$(B_3,2\varphi_1+\varphi_3)$, $(D_4,\varphi_1+2\varphi_3)$
$B2$	4,3,3,2	$(A_2,\varphi_1^2+\varphi_2^2)$, $(A_5,\varphi_2+\varphi_4)$, $(E_6,\varphi_1+\varphi_5)$
$E1$	5,4,3,2	(A_4,Ad), (B_2,φ_1^2), (C_5,φ_2)
$E2$	6,4,4,2	(D_4,Ad)
$E3$	8,6,4,2	$(A_8,\varphi_2+\varphi_7)$, (B_4,Ad), (C_4,Ad)
$E4$	12,8,6,2	(F_4,Ad)

TABLE XI. Weight vectors for the representations 10 and 16 of SO(10) and 27 of E_6.

i	(SO(10),**10**) weight vectors	i	(SO(10),**16**) weight vectors	i	(E_6,**27**) weight vectors
1	(1,0,0,0,0)	1	(0,0,0,0,1)	1	(1,0,0,0,0,0)
2	(−1,1,0,0,0)	2	(0,0,1,0,−1)	2	(−1,1,0,0,0,0)
3	(0,−1,1,0,0)	3	(0,1,−1,1,0)	3	(0,−1,1,0,0,0)

6	(0,0,0,1,−1)	6	(−1,0,0,1,0)	6	(0,0,0,1,0,−1)
7	(0,0,1,−1,−1)	7	(1,−1,1,−1,0)	7	(0,0,0,0,−1,1)
8	(0,1,−1,0,0)	8	(−1,0,1,−1,0)	8	(0,0,1,−1,1,−1)
9	(1,−1,0,0,0)	9	(1,0,−1,0,1)	9	(0,0,1,0,−1,−1)
10	(−1,0,0,0,0)	10	(−1,1,−1,0,1)	10	(0,1,−1,0,1,0)
		11	(1,0,0,0,−1)	11	(0,1,−1,1,−1,0)
		12	(0,−1,0,0,1)	12	(1,−1,0,0,1,0)
		13	(−1,1,0,0,−1)	13	(1,−1,0,1,−1,0)
		14	(0,−1,1,0,−1)	14	(0,1,0,−1,0,0)
		15	(0,0,−1,1,0)	15	(−1,0,0,0,1,0)
		16	(0,0,0,−1,0)	16	(−1,0,0,1,−1,0)
				17	(1,−1,1,−1,0,0)
				18	(−1,0,1,−1,0,0)
				19	(1,0,−1,0,0,1)
				20	(−1,1,−1,0,0,1)
				21	(1,0,0,0,0,−1)
				22	(0,−1,0,0,0,1)
				23	(−1,1,0,0,0,−1)
				24	(0,−1,1,0,0,−1)
				25	(0,0,−1,1,0,0)
				26	(0,0,0,−1,1,0)
				27	(0,0,0,0,−1,0)

Just for completeness in the Appendix we have listed the weight vectors of the representation 27 of E_6 and the values of the non-trivial components of the Γ's. These data can be used to check our arguments.

IX. CONCLUSIONS

After classifying the coregular real representations of the compact simple Lie groups, we have determined the isomorphism classes of their orbit spaces in all cases in which the number q of basic polynomial invariants does not exceed 4. The identification of the isomorphism classes has been obtained by determining, for each real coregular representation, a matrix $\hat{P}(p)$, which yields a faithful image of the orbit space as the semi-algebraic set of points $\overline{\mathscr{S}}=\{p\in\mathbb{R}^q|\hat{P}(p)\geqslant 0\}$. The results we have found are a partial check of the correctness of the classification of allowable $\hat{P}$-matrices of coregular compact linear groups with up to 4 basic polynomial invariants, reported in Refs. 27 and 28 and turn out to be quite effective tools in the analysis of invariant potentials. They also confirm the following facts:

i) Not all the allowable $\hat{P}$-matrices of dimensions $\leqslant 4$ correspond to coregular compact simple Lie groups, or to coregular finite groups.[32] Part of them are surely related to coregular non-simple compact groups, some are, or might be, generated by non-coregular compact groups; and for others there might be no generating group. It has to be stressed, however, that the $\hat{P}$-matrix of whichever compact coregular linear group with less than five basic polynomial invariants should be found in the classification given in Refs. 27 and 28.

ii) Several unequivalent linear groups may share isomorphic orbit spaces; these groups may realize unequivalent representations of the same group or even representations of non homomorphic groups. To stress this phenomenon, in Table X, we have listed all the linear coregular simple Lie groups generating each allowable $\hat{P}$-matrix occurring in Table V.

iii) In all the orbit spaces realized by the compact coregular Lie groups listed in Table X, the scale parameter s,[27,28] labelling the different solutions of a tower of allowable $\hat{P}$-matrices, is always equal to 1. This supports the conjecture that only the allowable $\hat{P}$-matrices, corresponding to the lowest value of s, are significant; the other ones are spurious solutions of the canonical equation, originating from a scale symmetry that seems not to be the consequence of some property of the orbit spaces of the compact linear groups.

The method used in Refs. 27 and 28 to determine the allowable $\hat{P}$-matrices of dimensions $\leqslant 4$ may be applied also in higher dimensions, but the first attempts in this direction showed that the calculations needed to solve the canonical equation in these cases are awfully cumbersome. Some inductive methods to speed up the calculations have been discovered, but for the moment they enable us only to obtain part of the allowable solutions in dimensions $q+1$, from the solutions in lower dimensions. Thus the problems of determining all the allowable solutions of the canonical equation and of characterizing those effectively generated by some compact linear group are still open.

APPENDIX: WEIGHT VECTORS AND CLEBSCH-GORDAN COEFFICIENTS FOR THE REPRESENTATIONS 10 AND 16 OF SO(10) AND 27 OF E_6

The bases in the spaces of the representations 10 and 16 of D_5 and of 27 of E_6 can be chosen to be the weight vectors e_k relative to the weights λ_k, ordered as indicated in Table XI.

With reference to these bases the nontrivial components of Γ^k_{ij} for $(D_5,16)$ and Γ_{ijk} for $(E_6,\mathbf{27})$ take on the values $\pm\sqrt{2}$, and $\pm\sqrt{3}$, respectively, in correspondence for the following sets $\tau^{\pm}_{D_5}$ and $\tau^{\pm}_{E_6}$ of values of the indices (k,i,j):

$$\tau^{+}_{D_5}=\{(1,1,11),(1,3,7),(2,1,13),(2,3,8),(3,1,14),(3,4,8),(4,1,15),(4,4,10),(5,1,16),$$
$$(5,7,10),(6,2,15),(6,4,13),(7,2,16),(7,7,13),(8,3,16),(8,9,13),(9,4,16),(9,9,14),$$
$$(10,6,16),(10,10,14),\quad \text{and permutations of } (i,j)\},$$

$$\tau^{-}_{D_5}=\{(1,2,9),(1,4,5),(2,2,10),(2,5,6),(3,2,12),(3,6,7),(4,3,12),(4,6,9),$$
$$(5,5,12),(5,8,9),(6,3,14),(6,6,11),(7,5,14),(7,8,11),(8,5,15),$$
$$(8,10,11),(9,7,15),(9,11,12),(10,8,15),(10,12,13),\quad \text{and permutations of } (i,j)\}.$$

$$\tau^{+}_{E_6}=\{(1,15,27),(1,18,25),(1,22,23),(2,13,26),(2,19,24),(3,10,27),(3,14,25),$$
$$(3,20,21),(4,9,26),(4,17,23),(5,6,27),(5,11,24),(5,16,21),(6,14,22),$$
$$(6,18,19),(7,8,25),(7,12,23),(8,13,20),(9,10,22),(9,15,19),$$
$$(10,16,17),(11,12,18),(13,14,15),\text{and permutations of } (i,j,k)\},$$

$$\tau^{-}_{E_6}=\{(1,16,26),(1,20,24),(2,12,27),(2,17,25),(2,21,22),$$
$$(3,11,26),(3,19,23),(4,8,27),(4,14,24),(4,18,21),(5,9,25),(5,13,23),$$
$$(6,7,26),(6,17,20),(7,10,24),(7,15,21),(8,11,22),(8,16,19),(9,12,20),$$
$$(10,13,18),(11,15,17),(12,14,16),\quad \text{and permutations of } (i,j,k)\}.$$

Entropy and the Segal-Bargmann transform

Stephen Bruce Sontz[a)]
Universidad Autonoma Metropolitana, Iztapalapa, Mexico DF 09340, Mexico

(Received 21 August 1997; accepted for publication 31 October 1997)

The Segal-Bargmann transform A is a unitary isomorphism of the quantum mechanical configuration space $L^2(\mathbf{R}^n,\nu)$ onto the Segal-Bargmann, or phase, space $HL^2(\mathbf{C}^n,\mu)$ of entire functions square integrable with respect to μ. Here μ and ν are Gaussian measures, and for $z\in\mathbf{C}^n$ and measurable $f:\mathbf{R}^n\to\mathbf{C}$ $Af(z) := \int_{\mathbf{R}^n} d\nu(t) f(t)\exp(-z^2/2+\sqrt{2}z\cdot t)$ if the integral converges. Af is defined for all $f\in L^p(\mathbf{R}^n,\nu)$ if $1<p\leqslant\infty$, but A does not preserve L^p structure if $p\neq 2$. Specifically, it is proven here that A is a compact map from $L^p(\mathbf{R}^n,\nu)$ to $L^q(\mathbf{C}^n,\mu)$ if $1\leqslant q<2$ and $p>1+q/2$ (which implies $p>q$) and in this case $\|A\|_{p\to q}\leqslant((1+q/2-p'q/2)(1-q/2))^{-n/2q}$ where p' is the dual of p. Moreover, a calculation with test functions shows that $\|A\|_{p\to q}=\infty$ if $q>2$ or $p<1+q/2$ (which is implied by $p<q$). Using an improved operator norm estimate (analogous to the Hausdorff-Young inequality) we prove Hirschman type entropy inequalities for $f\in L^2(\mathbf{R}^n,\nu)$, $(p^{-1}-2^{-1})S(f)\leqslant(q^{-1}-2^{-1})S(Af)+nC_{p,q}\|f\|_2^2$, where $1\leqslant q<2$, $p>1+q/2$, $C_{p,q}$ is given explicitly as a function of p and q and $S(g)$ is the entropy of g. Examples given here show A is *not* entropy preserving. So these inequalities provide constraints on the change in entropy. Similarly, we get energy-entropy, or log-Sobolev, inequalities $a_1S(Af)+a_2S(f)\leqslant a_3\|f\|_2^2+a_4\langle f,Nf\rangle$, for f in a dense subspace of $L^2(\mathbf{R}^n,\nu)$. Here $\langle f,Nf\rangle$ is the Dirichlet form of the energy operator N in the configuration space and the a_i can have various signs and are also given explicitly. The principal results of this article are generalized Heisenberg uncertainty relations, namely they are constraints on Af, the phase space representation, given information about f, the configuration space representation. © *1998 American Institute of Physics.* [S0022-2488(98)03403-3]

I. INTRODUCTION

The Segal-Bargmann transform (see Refs. 1–3) is used in mathematical physics to ''diagonalize'' creation and annihilation operators. The Segal-Bargmann space itself dates back to the work of Fischer[4] in mathematics and Fock[5] in physics. The Segal-Bargmann space as well as the standard quantum mechanical configuration space $L^2(\mathbf{R}^n,d^nx)$ carry irreducible representations of the exponentiated (Weyl) canonical commutation relations, and these representations are unitarily equivalent by a theorem of Stone[6] and von Neumann.[7] This unitary equivalence is realized explicitly by the Bargmann transform. In this article, the point of view is taken that the usual configuration space $L^2(\mathbf{R}^n,d^nx)$ should be replaced by a unitarily equivalent configuration space $L^2(\mathbf{R}^n,\nu)$, known as the ground state representation, where a Gaussian probability measure ν has replaced the Lebesgue measure d^nx. Consequently, the Segal-Bargmann transform is defined as a unitary map from the ground state representation space to the Segal-Bargmann space. This unitarity, as well as the preservation of the creation and annihilation operators, and consequently the energy operator and its associated Dirichlet form, says that the quantum mechanical formulations are equivalent. However, these two representations are different in some sense as well. Intuitively, the difference is that the ground state representation is in a configuration space, while the Segal-Bargmann space representation is in a phase space (see Ref. 8).

Much of the analysis of this article is motivated, both physically and mathematically, by analogy to the Fourier transform. By the Plancherel theorem, the Fourier transform is also a unitary map of Hilbert spaces (actually, L^2 spaces), but the nontrivial relation between the source

a)Electronic mail: sontz@xanum.uam.mx

and target Hilbert spaces of the Fourier transform can be seen by considering the action of the Fourier transform on individual functions. For example, the Heisenberg uncertainty principle, with all of its physical intuition, can be understood mathematically as an inequality involving a function and its Fourier transform. Another way of analyzing the Fourier transform is by investigating its action on spaces other than L^2. In this regard, the Hausdorff-Young inequality gives information about the L^p mapping properties of the Fourier transform, namely that $L^p(\mathbf{R}^n, d^n x)$ is mapped boundedly to $L^{p'}(\mathbf{R}^n, d^n x)$ where p' is the dual index of p, provided that $1 \leqslant p < 2$.

I analyze the Segal-Bargmann transform A, already described in the abstract, in a similar way in this article, whose contents I now outline. First, I ask what are the pairs of indices p and q for which the operator norm $\|A\|_{p\to q}$ is finite. I show in Theorem 3.1 that a sufficient condition is $1 \leqslant q < 2$ and $p > 1 + q/2$ and that the operator is actually compact in this case. Notice that these conditions on p and q imply $p > q$. Moreover by using a Hille-Tamarkin norm $|||A^T|||_{q',p'}$ (whose definition is given later), I get the estimate $\|A\|_{p\to q} \leqslant |||A^T|||_{q',p'} = (1 + q/2 - p'q/2)^{-n/2p'} (1 - q/2)^{-n/2q} (1 + q/2)^{-n(1/q - 1/p')/2}$ of the operator norm. Using test functions, I show at the end of the article that $\|A\|_{p\to q} = \infty$ if $q > 2$ or $p < 1 + q/2$. Zhou has already shown this in the case $q > 2$ in Ref. 9.

Also, the result $\|A\|_{2\to 2} = 1$ is a cornerstone to this theory; it is due to Segal in Refs. 1 and 2 and to Bargmann in Ref. 3. Specifically, they show that A is unitary onto the Segal-Bargmann space if $p = q = 2$. This last statement implies via two applications of Hölder's inequality that $\|A\|_{p\to q} = 1$ whenever $2 \leqslant p \leqslant \infty$ and $1 \leqslant q \leqslant 2$. This means that the only case for which the finiteness or infiniteness of $\|A\|_{p\to q}$ has not yet been established is when $q < 2$ and $p = 1 + q/2$. Even though the kernel of the Segal-Bargmann transform is a Gaussian, the results of Lieb[10] do not apply here to prove $\|A\|_{p\to q} < \infty$, because this occurs only when $p > q$ (except if $p = q = 2$) and the kernel of A is the exponential of a complex quadratic form. See Ref. 10 for the specific hypotheses that must be fulfilled.

The estimate for $\|A\|_{p\to q}$ goes to infinity as the pair (p,q) approaches the pair (2,2). To get an estimate on the operator norm that behaves better, I use the Riesz-Thorin interpolation theorem. Specifically, in Theorem 3.2 I get an estimate of the operator norm which is a log-convex function of the interpolating parameter. This estimate is an analogue for the Segal-Bargmann transform of the Hausdorff-Young inequality for the Fourier transform. With this information about the boundedness of A from L^p to L^q, plus the specific estimate of the operator norm, I can apply a technique of Hirschman. This technique consists in differentiating a parameterized family of inequalities with respect to the parameter to get a new inequality. (Another condition must be satisfied as discussed in the article.) In Theorem 4.1 this yields the inequality

$$(p^{-1} - 2^{-1}) S(f) \leqslant (q^{-1} - 2^{-1}) S(Af) + (\log |||A^T|||_{q',p'}) \|f\|_2^2$$

for $1 \leqslant q < 2$ and $p > 1 + q/2$ and all $f \in L^2(\mathbf{R}^n, \nu)$. This inequality is an analogue to an inequality for the Fourier transform conjectured by Hirschman in Ref. 11. Although Hirschman did not prove this inequality, which is known nonetheless as Hirschman's inequality, he did prove a version of it with a nonoptimal constant. Beckner in Ref. 12 later gave a proof of Hirschman's inequality with the best constant. My analogue to Hirschman's inequality expresses the nontriviality of the Segal-Bargmann transform as it acts on individual functions, and it brings to the forefront the entropy of the elements of the relevant Hilbert spaces as an appropriate quantity for analysis. Specifically, the Segal-Bargmann transform does not preserve entropy as calculations presented in Section VII. As we shall see the entropy may increase, decrease or remain unchanged. So my analogue to Hirschman's inequality provides a constraint on the change in entropy. As Carlen points out in Ref. 13, any result delimiting the range of the Segal-Bargmann transform can be considered as a generalized Heisenberg principle, since such a delimitation is a way of describing how a physical state can be situated in phase space. (However, beware that Carlen does not use the ground state representation in his paper.[13])

I also present a similar analysis where a weight factor is introduced into the measure of the target space. I then establish in Theorem 5.1 that there exists some Gaussian weight factor making the Segal-Bargmann transform a compact operator from L^p to ''weighted'' L^q if $1 < p \leqslant \infty$ and $1 \leqslant q < \infty$. I also prove an estimate on the operator norm. Again, I do this by computing the Hille-Tamarkin norm for this situation. To improve the estimates, I again use an interpolation

argument in Theorem 5.3, although this time based on a theorem of Stein in Ref. 14. These interpolation estimates can be thought of as ''weighted'' analogues to the Hausdorff-Young theorem. Then I apply the differentiation technique of Hirschman, and I thereby prove in Theorem 6.1 ''weighted'' analogues to Hirschman's inequality of the form

$$a_1 S(Af) + a_2 S(f) \leqslant a_3 \|f\|_2^2 + a_4 \langle f, Nf \rangle \tag{1.1}$$

for f in a dense subspace of $L^2(\mathbf{R}^n, \nu)$ where N is the energy, or number, operator and $\langle f, Nf \rangle$ is its associated Dirichlet form. The constants a_i are given explicitly in Theorem 6.1, and they can have various algebraic signs. This energy-entropy inequality can be interpreted as a log-Sobolev inequality (see Refs. 15 and 16) for the Segal-Bargmann transform itself. This leads to a generalization of the concept of a log-Sobolev inequality, which is defined in Definition 6.2 Again, following the remark of Carlen in Ref. 13, these results are generalizations of the Heisenberg principle. The article ends by quoting a few specific calculations for some Gaussian functions.

It should be noted that the techniques of this article are mainly those of real analysis. Specifically, as is usually the case in L^p analysis, Hölder's inequality is heavily relied on. Nonetheless, interpolation theory (via the three lines lemma of Hadamard) does depend on complex analysis. However, the fact that the functions in the Segal-Bargmann space are analytic enters only in an interesting identity (6.2) of Bargmann, while the existence of a reproducing kernel function for this space is not used at all. (See Ref. 17 for a similar analysis of the reproducing kernel function.) This is a little strange, since the fact that the range of the Segal-Bargmann transform is contained in the set of entire functions is already a generalized Heisenberg principle, according to the observation of Carlen.

II. PRELIMINARIES

We begin by introducing some notation and stating some basic results. For each integer $n \geqslant 1$ we define the Segal-Bargmann space $HL^2(\mathbf{C}^n, \mu)$ (Refs. 1–3) to be the Hilbert space of all entire analytic functions $f: \mathbf{C}^n \to \mathbf{C}$ which are square integrable with respect to the Gaussian measure μ given for $z \in \mathbf{C}^n$ by

$$d\mu(z) := \pi^{-n} \exp(-z^* \cdot z) d^n x d^n y. \tag{2.1}$$

Here for each $z = (z_1, \ldots, z_n) \in \mathbf{C}^n$ and $w = (w_1, \ldots, w_n) \in \mathbf{C}^n$ we define $z^* := (z_1^*, \ldots, z_n^*)$ and $z \cdot w := z_1 w_1 + \cdots + z_n w_n$. Also λ^* denotes the complex conjugate of the complex number λ and $d^n x d^n y$ is Lebesgue measure in $\mathbf{C}^n$. We write $z^2 := z \cdot z$ for $z \in \mathbf{C}^n$. In particular, $t^2 := t \cdot t$ for $t \in \mathbf{R}^n$. The configuration space, sometimes called the ground state representation, is $L^2(\mathbf{R}^n, \nu)$ where ν is the Gaussian measure defined by

$$d\nu(t) := \pi^{-n/2} \exp(-t^2) d^n t, \tag{2.2}$$

where $t \in \mathbf{R}^n$ and $d^n t$ is Lebesgue measure in $\mathbf{R}^n$. For $z \in \mathbf{C}^n$ and measurable $f: \mathbf{R}^n \to \mathbf{C}$ the Segal-Bargmann transform A is defined by

$$Af(z) := \int_{\mathbf{R}^n} d\nu(t) A(z,t) f(t) \tag{2.3}$$

provided that the integral converges. Here the kernel function is defined by

$$A(z,t) := \exp(-z^2/2 + \sqrt{2} z \cdot t) \tag{2.4}$$

for $z \in \mathbf{C}^n$ and $t \in \mathbf{R}^n$. It follows from Hölder's inequality that Af is well defined for all $f \in L^p(\mathbf{R}^n, \nu)$ with $1 < p \leqslant \infty$, and Af is also entire in this case. A basic theorem (Refs. 1–3) says that $A: L^2(\mathbf{R}^n, \nu) \to HL^2(\mathbf{C}^n, \mu)$ is a unitary, onto map. In this formulation, the Segal-Bargmann transform A is a map between two L^2 spaces, each being with respect to a probability measure. While this is not the formulation of Bargmann in Ref. 3, where Lebesgue measure in $\mathbf{R}^n$ is used,

it is more natural in that it relates spaces for which hypercontractivity results are known (see Refs. 9, 13, 18, 19). It is however the formulation of Segal in an infinite dimensional context where Lebesgue measure does not exist (see Refs. 1 and 2).

If (X,μ) is a measure space and $1\leqslant p\leqslant\infty$, then the L^p norm is denoted by $\|f\|_p$ or by $\|f\|_{L^p(\mu)}$ depending on how explicit we need to be. The corresponding complex Banach space is denoted by $L^p(X,\mu)$, or simply by L^p. If (X,μ) and (Y,ν) are measure spaces and B is a linear transformation defined on a dense subspace D of $L^p(X,\mu)$ for $1\leqslant p\leqslant\infty$ and if $Bf: Y\to\mathbf{C}$ is measurable for all $f\in D$, then we define the operator norm by

$$\|B\|_{p\to q} := \sup\{\|Bf\|_{L^q(\nu)} : f\in D \text{ and } \|f\|_{L^p(\mu)}=1\} \tag{2.5}$$

for any $1\leqslant q\leqslant\infty$. Notice that this norm is a number in $[0,\infty]$. If this operator norm is finite, then as is well known B can be extended uniquely to a continuous linear map from $L^p(X,\mu)$ to $L^q(Y,\nu)$. Though this notation $\|\cdot\|_{p\to q}$ is standard, it is ambiguous, since the measure spaces and the measures are suppressed from it. However, context should make the meaning clear.

The spaces $HL^2(\mathbf{C}^n,\mu)$ and $L^2(\mathbf{R}^n,\nu)$ have standard unbounded self-adjoint energy, or number, operators acting in them. The operator $N := -\frac{1}{2}\Delta + t\cdot\nabla$ acts in $L^2(\mathbf{R}^n,\nu)$, where ∇ is the gradient and Δ is the Laplacian while the operator $\widetilde{N} := z_1(\partial/\partial z_1)+\cdots+z_n(\partial/\partial z_n)$ acts in $HL^2(\mathbf{C}^n,\mu)$ where we use the usual definition

$$\frac{\partial}{\partial z_k} := \frac{1}{2}\left(\frac{\partial}{\partial x_k} - i\,\frac{\partial}{\partial y_k}\right).$$

Here $z_k\in\mathbf{C}$ is written as $z_k = x_k + iy_k$ with x_k, $y_k\in\mathbf{R}$. The Segal-Bargmann transform A intertwines N and $\widetilde{N}$, namely, $AN=\widetilde{N}A$ (modulo domain considerations). We refer to this fact by saying that A preserves the energy. Another way to express this is in terms of the associated Dirichlet forms defined by

$$\langle f, Nf\rangle := \sum_{k=1}^{n}\left\|\frac{\partial f}{\partial x_k}\right\|^2_{L^2(\nu)} \tag{2.6}$$

for all $f\in L^2(\mathbf{R}^n,\nu)$ and by

$$\langle g, \widetilde{N}g\rangle := \sum_{k=1}^{n}\left\|\frac{\partial g}{\partial z_k}\right\|^2_{L^2(\mu)} \tag{2.7}$$

for all $g\in HL^2(\mathbf{C}^n,\mu)$. These Dirichlet forms are then preserved by the Segal-Bargmann transform A, namely $\langle f,Nf\rangle = \langle Af,\widetilde{N}Af\rangle$ for all $f\in L^2(\mathbf{R}^n,\nu)$.

Given a measure space (Ω,μ) and $f\in L^2(\Omega,\mu)$, define the entropy $S(f)$ by

$$S(f) := \int_\Omega d\mu |f|^2 \log|f|^2 - \|f\|_2^2 \log\|f\|_2^2. \tag{2.8}$$

Here $\log x$ is the natural logarithm (base e) of the real number $x>0$. We always use the standard convention $0\log 0 = 0$. If $\mu(\Omega)=\infty$, the integral in (2.8) may not make sense, in which case $S(f)$ is undefined. And if it does make sense, it may be $+\infty$ or $-\infty$. However, if (Ω,μ) is a probability measure space, $S(f)$ is always defined and by Jensen's inequality one gets that $S(f)\geqslant 0$ though $S(f)=\infty$ is possible. Shannon[20] originally introduced this concept of entropy in information theory.

Since the Segal-Bargmann transform A is an integral kernel operator, we will use some standard results from the theory of such operators. In the following (X,μ) and (Y,ν) are σ-finite measure spaces and $p,q\in[1,\infty]$. We say that any measurable function $K: X\times Y\to\mathbf{C}$ is a kernel function. The transpose kernel $K^T: Y\times X\to\mathbf{C}$ is defined by $K^T(y,x) := K(x,y)$ for all $(y,x)\in Y\times X$. Next, we define the Hille-Tamarkin norm (see Refs. 21, 22) of the kernel K by

$$|||K|||_{p,q} := \|K_p\|_{L^q(\mu)}, \tag{2.9}$$

where $K_p(x) := \|K(x,\cdot)\|_{L^{p'}(\nu)}$ for all $x \in X$. Here p' denotes the usual dual index of p. In particular, if $1 < p \leqslant \infty$ and $1 \leqslant q < \infty$ then

$$|||K|||_{p,q} = \left\{ \int_X d\mu(x) \left(\int_Y d\nu(y) |K(x,y)|^{p'} \right)^{q/p'} \right\}^{1/q} \tag{2.10}$$

and in the special case $p = q = 2$, this becomes the Hilbert-Schmidt norm. Notice that the notation $|||\cdot|||_{p,q}$ has the same ambiguity as the operator norm notation, namely, the measure spaces and their measures are suppressed from the notation. Again, the meaning should be clear from context. Given a kernel function K, we define its associated integral operator by

$$Kf(x) := \int_Y d\nu(y) K(x,y) f(y) \tag{2.11}$$

for $x \in X$ and measurable $f: Y \to \mathbf{C}$ whenever this integral converges. This conforms with the usual practice, already used above, of using the same symbol for the kernel function and for its associated operator. If the integral operator K given in (2.11) has a kernel function with a finite Hille-Tamarkin norm for some $p, q \in [1, \infty]$, we say the operator K is a Hille-Tamarkin operator from $L^p(Y, \nu)$ to $L^q(X, \mu)$. This terminology is justified by the first part of the following result from Ref. 22. (We continue to use the notation and hypotheses as above.)

Proposition 2.1: $\|K\|_{p \to q} \leqslant |||K|||_{p,q}$ *and* $\|K\|_{p \to q} \leqslant |||K^T|||_{q',p'}$.

The proof is by Hölder's inequality. Here is another result from Ref. 22.

Proposition 2.2: If $|||K|||_{p,q} < \infty$ *and* $1 \leqslant q < \infty$ *and* $1 < p \leqslant \infty$ *then* K *is a compact operator from* $L^p(Y, \nu)$ *to* $L^q(X, \mu)$.

Of course, in the case $p = q = 2$, this is the well known result that a Hilbert-Schmidt operator is compact. Here is one more result from Ref. 22. It tells us which of the two upper bounds in Proposition 2.1 is better.

Proposition 2.3: If $p' \geqslant q$, *then* $|||K^T|||_{q',p'} \leqslant |||K|||_{p,q}$. *If* $p' \leqslant q$, *then* $|||K|||_{p,q} \leqslant |||K^T|||_{q',p'}$.

This follows from Minkowski's inequality for integrals in the case $1 < p \leqslant \infty$ and $1 \leqslant q < \infty$. The remaining cases are equally straightforward.

III. L^p MAPPING PROPERTIES

Theorem 3.1: *For the Segal-Bargmann transform* A *to be a Hille-Tamarkin operator from* $L^p(\mathbf{R}^n, \nu)$ *to* $L^q(\mathbf{C}^n, \mu)$ *a necessary and sufficient condition is that* p *and* q *satisfy the inequalities* $1 \leqslant q < 2$ *and* $p > 1 + q/2$. *In this case,* A *is a compact operator with*

$$\|A\|_{p \to q} \leqslant |||A|||_{p,q} = (1 + q/2 - p'q/2)^{-n/2q} (1 - q/2)^{-n/2q} < \infty \tag{3.1}$$

and

$$\|A\|_{p \to q} \leqslant |||A^T|||_{q',p'} = (1 + q/2 - p'q/2)^{-n/2p'} (1 - q/2)^{-n/2q} (1 + q/2)^{-n/2(1/q - 1/p')} < \infty. \tag{3.2}$$

Notice that these conditions on p *and* q *imply that* $p > q$.

Proof: We compute the Hille-Tamarkin norms of A, the Segal-Bargmann transform, by evaluating the Gaussian integrals explicitly. First, notice that for $z \in \mathbf{C}^n$ and $t \in \mathbf{R}^n$, and using (2.4), we have

$$|A(z,t)| = |\exp(-z^2/2 + \sqrt{2}z \cdot t)| = \exp(-x^2/2 + y^2/2 + \sqrt{2}x \cdot t), \tag{3.3}$$

where $z = x + iy$ with $x, y \in \mathbf{R}^n$. (In the following, this will always be the meaning of the symbols x, y and z.) If $1 < p \leqslant \infty$, we have

$$A_p(z) = \|A(z,\cdot)\|_{p'} = \exp((-x^2 + y^2 + p'x^2)/2) \tag{3.4}$$

by computing the Gaussian integral. Also, $A_1(z)=\|A(z,\cdot)\|_\infty=\infty$ if $x\neq 0$ so that $|||A|||_{1,q}=\infty$ for all $1\leqslant q\leqslant\infty$. Next for $1\leqslant q<\infty$ and $1<p\leqslant\infty$, again by computing the Gaussian integral, we have that

$$|||A|||_{p,q}=\|A_p\|_q=(1+q/2-p'q/2)^{-n/2q}(1-q/2)^{-n/2q}<\infty$$

if and only if $p>1+q/2$ and $1\leqslant q<2$. If either of these inequalities fails, then $|||A|||_{p,q}=\infty$, but if they both hold we have $\|A\|_{p\to q}\leqslant|||A|||_{p,q}<\infty$. Also, $|||A|||_{p,\infty}=\|A_p\|_\infty=\infty$, if $p>1$ by (3.4). The estimate (3.2) is shown by a similar calculation. The theorem now follows from Propositions 2.1 and 2.2 □

In the rest of this article we shall use the estimate (3.2) though everything works *mutatis mutandis* with the estimate (3.1). However, as we shall see later, (3.2) is the better estimate in the case which will interest us.

It is important to notice that $|||A|||_{2,2}=\infty$ even though $\|A\|_{2\to 2}=1$. This is so since the range of A is infinite dimensional (as is its domain $L^2(\mathbf{R}^n,\nu)$) and so the unitary operator A sends the closed unit ball in $L^2(\mathbf{R}^n,\nu)$ onto a closed, noncompact subset in $L^2(\mathbf{C}^n,\mu)$. In short, A is not a compact operator from L^2 to L^2, and so by Proposition 2.2, $|||A|||_{2,2}=\infty$. Worse yet, according to (3.1), $|||A|||_{p,q}\to\infty$ as $(p,q)\to(2,2)$. Also similar remarks apply to $|||A^T|||_{q',p'}$. Because we will be using interpolation theory to mollify this behavior, it is more convenient to use the points (p^{-1},q^{-1}) in the unit square $S:=[0,1]\times[0,1]$ which correspond to the indices (p,q) in $[1,\infty]\times[1,\infty]$. We will use the standard conventions that $\infty^{-1}=0$ and $0^{-1}=\infty$. We say that a point (p^{-1},q^{-1}) in S is *admissible* if $\|A\|_{p\to q}<\infty$.

Theorem 3.2: *If* $1\leqslant q<2$ *and* $p>1+q/2$ *and* $p(s)$ *and* $q(s)$ *are defined implicitly by*

$$p(s)^{-1}=sp^{-1}+(1-s)2^{-1}\qquad\text{and}\qquad q(s)^{-1}=sq^{-1}+(1-s)2^{-1}\tag{3.5}$$

for $0\leqslant s\leqslant 1$, *then*

$$1\leqslant\|A\|_{p(s)\to q(s)}\leqslant(\|A\|_{p\to q})^s\leqslant(|||A^T|||_{q',p'})^s<\infty.\tag{3.6}$$

Proof: By Theorem 3.1 (p^{-1},q^{-1}) is admissible. But for any admissible point (p^{-1},q^{-1}) in S we apply the Riesz-Thorin theorem (see Refs. 23 and 24) to interpolate along the line segment in S between (p^{-1},q^{-1}) and $(2^{-1},2^{-1})$, the latter point also being admissible. The result is

$$\|A\|_{p(s)\to q(s)}\leqslant(\|A\|_{2\to 2})^{1-s}(\|A\|_{p\to q})^s=(\|A\|_{p\to q})^s.$$

The lower bound in (3.6) follows from $\|A\|_{p_1\to q_1}\geqslant 1$ for all $p_1,q_1\in[1,\infty]$ which is true because $A1=1$ where 1 denotes the function that is constantly equal to 1. Now Theorem 3.1 and Propositions 2.1 and 2.2 establish the theorem. □

The inequality (3.6) is analogous to the Hausdorff-Young inequality, which is also obtained by using the Riesz-Thorin theorem. However, (3.6) is really a family of inequalities, one for each pair (p,q) satisfying the hypotheses, whereas there is only one Hausdorff-Young inequality in Fourier analysis. Notice that the estimate (3.6) on the operator norm goes to 1 as $s\to 0$. Also $(p(s)^{-1},q(s)^{-1})$ goes to $(2^{-1},2^{-1})$ along a line segment in S as $s\to 0$.

IV. HIRSCHMAN TYPE INEQUALITIES

We can now apply a technique of Hirschman from Ref. 11. We take (p^{-1},q^{-1}) satisfying $1\leqslant q<2$ and $p>1+q/2$ and $p(s)$, $q(s)$ with $0\leqslant s\leqslant 1$ as in equations (3.5) above. Then by (3.6)

$$\|Af\|_{q(s)}\leqslant(|||A^T|||_{q',p'})^s\|f\|_{p(s)},\tag{4.1}$$

where f is a fixed function in $L^2(\mathbf{R}^n,\nu)$. The point here is that this inequality reduces to an *equality* at $s=0$ since A is an L^2 isometry. Then formally the derivative of (4.1) at $s=0$ generates a new inequality. This is the idea behind the next result, which is analogous to an entropy inequality in Fourier analysis first proved by Hirschman in Ref. 11. But first we quote two well known results that will allow us to differentiate under the integral sign. The proofs use standard measure theory and convexity arguments. Here (Ω,μ) is a probability measure space and

$\psi:[1,\infty)\to[0,\infty]$ is defined by $\psi(r) := \int_\Omega d\mu |f|^r$ where $r\in[1,\infty)$ and $f:\Omega\to\mathbf{C}$ is measurable. The first result says that if $f\in L^2(\Omega,\mu)$, then the left side derivative of $\psi(r)$ at $r=2$ is given by

$$\psi'(2^-) := \lim_{h<0,h\to 0} \frac{\psi(2+h)-\psi(2)}{h} = \int_\Omega d\mu |f|^2 \log|f| \tag{4.2}$$

which is either a finite real number or $+\infty$. The second result says that if $f\in L^{2+\epsilon}(\Omega,\mu)$ for some $\epsilon>0$, then the right side derivative of $\psi(r)$ at $r=2$ is given by

$$\psi'(2^+) := \lim_{h>0,h\to 0} \frac{\psi(2+h)-\psi(2)}{h} = \int_\Omega d\mu |f|^2 \log|f| \tag{4.3}$$

which is a finite real number.

Theorem 4.1: *The Hirschman type entropy inequality*

$$(p^{-1}-2^{-1})S(f) \leqslant (q^{-1}-2^{-1})S(Af) + (\log|||A^T|||_{q',p'})\|f\|_2^2 \tag{4.4}$$

holds for all $f\in L^2(\mathbf{R}^n,\nu)$ *where* $1\leqslant q<2$ *and* $p>1+q/2$ *and* $|||A^T|||_{q',p'}$ *is given in (3.2).*

Proof: The result is trivial if $f=0$, so we only consider nonzero $f\in L^2(\mathbf{R}^n,\nu)$. As noted above, (4.1) holds under our hypotheses here. Next by taking the right side derivative of (4.1) at $s=0$, one obtains a new inequality

$$\left.\frac{d}{ds}\right|_{s=0+} \|Af\|_{q(s)} \leqslant \left.\frac{d}{ds}\right|_{s=0+} (|||A^T|||_{q',p'})^s \|f\|_{p(s)}$$

or, equivalently,

$$\left.\frac{d}{ds}\right|_{s=0+} \|Af\|_{q(s)} \leqslant (\log|||A^T|||_{q',p'})\|f\|_2 + \left.\frac{d}{ds}\right|_{s=0+} \|f\|_{p(s)}, \tag{4.5}$$

where the right side derivative is used since (4.1) holds for $0\leqslant s\leqslant 1$. In general, derivation is not order preserving, but in this case it is since at $s=0$ the inequality (4.1) becomes an *equality*. Of course, we must show the existence of the derivatives in (4.5). The inequality (4.1) is trivial for a fixed $f\in L^2(\mathbf{R}^n,\nu)$ if $\|f\|_{p(s)}$ is infinite for all $0<s\leqslant 1$. To make the following argument work we need $\|f\|_{p(s)}$ to be finite for all $s\in(0,\epsilon]$ for some $\epsilon>0$. If $1\leqslant p<2$, then $p(s)<2$ and so $\|f\|_{p(s)}\leqslant\|f\|_2<\infty$ for all $0<s\leqslant 1$. This means that we can take $\epsilon=1$ in this case. (As we shall see later, the case $p\geqslant 2$ is trivial.) Also notice that by differentiating (3.5) implicitly with respect to s we have

$$p'(0)=4(2^{-1}-p^{-1}) \quad\text{and}\quad q'(0)=4(2^{-1}-q^{-1}). \tag{4.6}$$

The reader should beware that $p'(0)$ here is a derivative and is totally distinct from p', the dual index.

Suppose that $p<2$. Then $p(s)$ increases to 2 as s decreases to zero. So by (4.2) and elementary calculus we have

$$\left.\frac{d}{ds}\right|_{s=0^+} \|f\|_{p(s)} = \frac{p'(0)S(f)}{4\|f\|_2}$$

with $0\leqslant S(f)\leqslant\infty$ where the entropy $S(f)$ is defined in (2.8). Similarly,

$$\left.\frac{d}{ds}\right|_{s=0^+} \|Af\|_{q(s)} = \frac{q'(0)S(Af)}{4\|Af\|_2}$$

with $0\leqslant S(f)\leqslant\infty$ follows from the hypothesis $1\leqslant q<2$. So inequality (4.5) says

$$\frac{q'(0)S(Af)}{4\|Af\|_2} \leqslant (\log|||A^T|||_{q',p'})\|f\|_2 + \frac{p'(0)S(f)}{4\|f\|_2}. \tag{4.7}$$

Notice that $p'(0)<0$ and $q'(0)<0$. So $S(f)=\infty$ implies $S(Af)=\infty$. Since the coefficients of the entropy terms in (4.4) are positive in this case we see that (4.4) is trivially true if $S(f)=\infty$. If $S(f)<\infty$, we can rearrange the terms in the inequality (4.7), multiply by $\|f\|_2=\|Af\|_2$ and use (4.6) to get (4.4).

It remains to show (4.4) in the case $p\geqslant 2$. But then $p^{-1}-2^{-1}\leqslant 0$, and so (4.4) is trivially true since the left hand side is nonpositive and the right hand side is nonnegative. (Recall that $\log|||A^T|||_{q',p'}\geqslant \log\|A\|_{p\to q}\geqslant \log 1=0$.) This terminates the proof of the theorem. □

As the proof shows, the significance of inequality (4.4) arises in the case $p<2$, which is not trivial because then the coefficients of the entropy terms in (4.4) are positive. But $p<2$ together with $p>1+q/2$ imply that $p'>q$, so that by Proposition 2.3 the estimate (3.2) is better than (3.1) in the nontrivial case. By (3.2), the coefficient of $\|f\|_2^2$ is $nC_{p,q}$ where

$$C_{p,q}=\frac{1}{n}\log|||A^T|||_{q',p'}=-\frac{1}{2}\left\{\frac{1}{p'}\log\left(1+\frac{q}{2}-\frac{p'q}{2}\right)+\frac{1}{q}\log\left(1-\frac{q}{2}\right)+\left(\frac{1}{q}-\frac{1}{p'}\right)\log\left(1+\frac{q}{2}\right)\right\}.$$

This makes it the only coefficient in (4.4) with a dependence on the dimension n. Also for any admissible (p^{-1},q^{-1}) we have by the same proof that

$$(p^{-1}-2^{-1})S(f)\leqslant (q^{-1}-2^{-1})S(Af)+(\log\|A\|_{p\to q})\|f\|_2^2.$$

It remains an open question whether an inequality of the form $S(f)\leqslant cS(Af)$ holds for all $f\in L^2(\mathbf{R}^n,\nu)$ where $c>0$ is some constant independent of f. This would hold, for example, if one could show that $\|A\|_{p\to q}=1$ for some p and q satisfying $1<p<2$ and $1\leqslant q<2$. If such an inequality holds, then it would be interesting to know the best constant c for which it holds. If such an inequality does not hold, we can rewrite (4.4) (in the nontrivial case $p<2$) in the form $S(f)\leqslant cS(Af)+\epsilon\|f\|_2^2$ with c and ϵ positive. So the best constant for the coefficient of $S(Af)$ is a function of ϵ, say $c(\epsilon)$. Then it would be interesting to know the behavior of $c(\epsilon)$ as a function of ϵ. Since $|||A^T|||_{q',p'}>1$, the coefficient of the $\|f\|_2$ term in the log-Sobolev inequality (4.4) proved here is strictly positive. Similarly, $|||A|||_{p,q}>1$.

By considering characteristic functions in $L^2(\mathbf{R}^n,\nu)$, we can easily see that states (that is, functions f satisfying $\|f\|_2=1$) which are highly concentrated have arbitrarily large entropy while states which are not concentrated have small, though nonnegative, entropy. Also, the measure space $(\mathbf{C}^n,\mu)$ is isomorphic to the measure space $(\mathbf{R}^{2n},\nu)$ since putting $2n$ in place of n in (2.2) yields (2.1) using the usual identification of $\mathbf{R}^{2n}$ and $\mathbf{C}^n$. So the same remarks hold for the entropy of states in $L^2(\mathbf{C}^n,\mu)$, and hence for its closed subspace $HL^2(\mathbf{C}^n,\mu)$. Because of this behavior, some authors refer to $S(f)$ as an information, and reserve the word entropy for the quantity $-S(f)$. Regardless of the terminology, the fact is that a sequence of states $\{f_k\}_{k\geqslant 0}$ in $L^2(\mathbf{R}^n,\nu)$, which become more and more concentrated, transforms under the Segal-Bargmann transform to a sequence of states $\{Af_k\}_{k\geqslant 0}$ in $HL^2(\mathbf{C}^n,\mu)$, which also become more and more concentrated. It should be emphasized that the concentration of the states is being measured with respect to a Gaussian measure; the nonconstant elements of the Segal-Bargmann space are unbounded near infinity, since they are entire functions. It should be noted again that the calculations in Section VII show that the Segal-Bargmann transform does not preserve entropy, so that (4.4) gives a constraint on the change in entropy.

See Hirschman's article[11] for the first appearance of the entropy inequality which bears his name. Beckner in Ref. 12 proves this inequality with the best constant. There is also a nice discussion of this in the paper of Białynicki-Birula and Mycielski.[25] Hirschman's inequality expresses the idea of the Heisenberg uncertainty principle in Fourier analysis, and the analogue proved in (4.4) does much the same in Segal-Bargmann analysis.

V. WEIGHTED ANALOGUES OF HAUSDORFF-YOUNG INEQUALITY

As we will see in Section VII, the operator norm $\|A\|_{p\to q}$ can be infinite for some $p,q\in[1,\infty]$. The next theorem shows how a change in measure can give a different result.

Theorem 5.1: *Let* $d\mu_{ab}(z) := c_{ab}\exp(-ax^2-by^2)d\mu(z)$ *define a probability measure where* $z\in\mathbf{C}^n$, *a and b are real numbers and* $c_{ab}=(1+a)^{n/2}(1+b)^{n/2}$ *is a normalization constant. For there to exist real numbers a and b such that A is a Hille-Tamarkin operator from* $L^p(\mathbf{R}^n,\nu)$ *to* $L^q(\mathbf{C}^n,\mu_{ab})$ *a necessary and sufficient condition is that p and q satisfy* $1<p\leqslant\infty$ *and* $1\leqslant q<\infty$. *If this holds, A is a compact operator, and a and b can be taken to be any real numbers satisfying*

$$a>-1-q/2+p'q/2 \quad \text{and} \quad b>-1+q/2, \tag{5.1}$$

and consequently

$$\|Af\|_{L^q(\mu_{ab})}\leqslant |||A|||_{p,q}\|f\|_{L^p(\nu)} \tag{5.2}$$

for all $f\in L^p(\mathbf{R}^n,\nu)$ *where*

$$|||A|||_{p,q}=c_{ab}^{1/q}((a+1+q/2-p'q/2)(b+1-q/2))^{-n/2q}<\infty. \tag{5.3}$$

Under the same restrictions on p, q, a and b one has

$$\|Af\|_{L^q(\mu_{ab})}\leqslant |||A^T|||_{q',p'}\|f\|_{L^p(\nu)} \tag{5.4}$$

for all $f\in L^p(\mathbf{R}^n,\nu)$ *where*

$$|||A^T|||_{q',p'}=c_{ab}^{1/q}\left(a+1+\frac{q}{2}\right)^{-(n/2)((1/q)-(1/p'))}\left(b+1-\frac{q}{2}\right)^{-(n/2q)}\left(a+1+\frac{q(1-p')}{2}\right)^{-(n/2p')}.$$

Remark: Notice that (5.1) implies $a>-1$ and $b>-1$ so that c_{ab}, and hence μ_{ab}, is well defined. Proposition 2.3 tells us which of the two inequalities (5.2) and (5.4) is better.

Proof: The question is if it is possible to find $a,b\in\mathbf{R}$ so that $|||A|||_{p,q}<\infty$, where the Hille-Tamarkin norm is with respect to the measures ν and μ_{ab}. So we compute this Hille-Tamarkin norm. Since the definition of $A_p(z)$ is the same as in Section III, we again have equation (3.4) for $1<p\leqslant\infty$. By doing the Gaussian integral for $1\leqslant q<\infty$, we have

$$|||A|||_{p,q}=\|A_p\|_{L^q(\mu_{ab})}=c_{ab}^{1/q}((a+1+q/2-p'q/2)(b+1-q/2))^{-n/2q}<\infty$$

provided that (5.1) holds. Clearly, for any $1<p\leqslant\infty$ and $1\leqslant q<\infty$ there are solutions a and b in $\mathbf{R}$ of the inequalities (5.1). So, the operator is Hille-Tamarkin in this case, and hence compact by Proposition 2.2. The inequality (5.2) follows from Proposition 2.1 This shows the sufficiency of the condition on p and q.

Let's next analyze the cases $p=1$ and $q=\infty$. First, if $p=1$, then by (3.3)

$$A_1(z)=\sup_{t\in\mathbf{R}^n}|A(z,t)|=\sup_{t\in\mathbf{R}^n}\exp(-x^2/2+y^2/2+\sqrt{2}x\cdot t)=\infty \tag{5.5}$$

for all $z=x+iy\in\mathbf{C}^n$ with $x\neq 0$. So it follows that $|||A|||_{1,q}=\|A_1\|_q=\infty$ for any $1\leqslant q\leqslant\infty$. Next, if $q=\infty$ and $p>1$, then we have by (3.4)

$$|||A|||_{p,\infty}=\sup_{z\in\mathbf{C}^n}|A_p(z)|=\sup_{z\in\mathbf{C}^n}\exp((-x^2+y^2+p'x^2)/2)=\infty. \tag{5.6}$$

Summarizing, $|||A|||_{p,q}=\infty$ if $p=1$ or $q=\infty$. This shows the necessity of the conditions on p and q and so concludes the proof up to (5.3). The remainder of the theorem follows from similar calculations. □

If we select a and b satisfying (5.1) and so that $a=b$ (which is always possible), we can think of the codomain space in terms of a Segal-Bargmann space, but with a value of Planck's constant different from that of the domain space. See Woodhouse[26] for a presentation of the Segal-Bargmann space with an explicit Planck's constant. We can consider the codomain space to be a generalized Segal-Bargmann space even in the case $a\neq b$, though now with *two* distinct values of

Planck's constant. From now on we will use estimate (5.2) rather than estimate (5.4) even though by Proposition 2.3 the latter is sometimes sharper. Everything works *mutatis mutandis* with the latter estimate.

Again, the behavior of the estimate $|||A|||_{p,q}$ of the operator norm as (p,q) approaches (2,2) needs to be improved. As the formula (5.3) shows, the bound $|||A|||_{p,q}$ depends on a and b (as well as on p and q), but a and b depend on p and q only through the inequalities (5.1), and not in a functional way. Also, when $p=q=2$, we find from (5.1) that $a>0$ and $b>0$, so that the estimate (5.2) in this case is not the statement that A is an isometry into the unweighted L^2 space. So we will apply interpolation theory to this situation in order to get better estimates of the operator norms. First, pick p and q with $1<p\leqslant\infty$ and $1\leqslant q<\infty$. Next, pick a and b in $\mathbf{R}$ satisfying inequalities (5.1). Then with respect to the measures ν and μ_{ab} one has that $\|A\|_{p\to q}\leqslant|||A|||_{p,q}<\infty$. Since A is an L^2 isometry, $\|A\|_{2\to 2}=1$ with respect to the unweighted L^2 norms. We interpolate between these two norm estimates using an interpolation theorem of E. M. Stein, which is proved as Theorem 2 in Ref. 14 and as Theorem 3.6 in Ref. 27. Since it is not as well known as the Riesz-Thorin theorem, we give a statement of this theorem taken from Ref. 14. Recall that a simple function is defined to be a measurable function f with finite range I such that $f^{-1}(i)$ has finite measure for all nonzero $i\in I$.

Theorem 5.2 (Stein): *Let (M,ν) and (N,μ) be σ-finite measure spaces. Let T be a linear transformation defined on simple functions of M to measurable functions on N. Suppose p_0, p_1, q_0 and q_1 are in $[1,\infty]$ and define p_s and q_s for $0\leqslant s\leqslant 1$ by $p_s^{-1}=(1-s)p_0^{-1}+sp_1^{-1}$ and $q_s^{-1}=(1-s)q_0^{-1}+sq_1^{-1}$. Suppose that for some weight functions $k_0,k_1:N\to[0,\infty)$ and $u_0,u_1:M\to[0,\infty)$ and for all simple functions $f:M\to\mathbf{C}$ one has*

$$\|(Tf)k_0\|_{q_0}\leqslant M_0\|fu_0\|_{p_0} \tag{5.7}$$

and

$$\|(Tf)k_1\|_{q_1}\leqslant M_1\|fu_1\|_{p_1} \tag{5.8}$$

for some M_0 and M_1 in $\mathbf{R}$. (The right hand side of either of these inequalities may be infinite for some f.) Define new weight functions $k_s:=k_0^{1-s}k_1^s$ on N and $u_s:=u_0^{1-s}u_1^s$ on M for $0\leqslant s\leqslant 1$. Then T can be uniquely extended to a linear transformation on all functions f satisfying $\|fu_s\|_{p_s}<\infty$ so that

$$\|(Tf)k_s\|_{q_s}\leqslant M_0^{1-s}M_1^s\|fu_s\|_{p_s}. \tag{5.9}$$

Let us note that this theorem can be interpreted as saying that the measures as well as the Lebesgue indices vary in the interpolation. It is a consequence of Theorem 1 of Ref. 14, which is usually called the Stein interpolation theorem. See also Refs. 23, 24, and 27. We now have the following result:

Theorem 5.3: *Suppose that $1<p\leqslant\infty$ and $1\leqslant q<\infty$. Then A is a bounded operator from $L^{p(s)}(\mathbf{R}^n,\nu)$ into $L^{q(s)}(\mathbf{C}^n,\mu_{ab}^s)$ for all $0\leqslant s\leqslant 1$ and for all real numbers a and b satisfing (5.1) where the interpolating indices are*

$$p(s)^{-1}=(1-s)2^{-1}+sp^{-1} \qquad \text{and} \qquad q(s)^{-1}=(1-s)2^{-1}+sq^{-1}$$

and the interpolating measure is

$$d\mu_{ab}^s(z)=\exp\left(-\frac{sq(s)}{q}(ax^2+by^2)\right)d\mu(z).$$

Moreover, $\|A\|_{p(s)\to q(s)}\leqslant(|||A|||_{p,q})^s$ where $|||A|||_{p,q}$ is given by (5.3). This means that

$$\|Af\|_{L^{q(s)}(\mu_{ab}^s)}\leqslant(|||A|||_{p,q})^s\|f\|_{L^{p(s)}(\nu)} \tag{5.10}$$

for all $0\leqslant s\leqslant 1$ and for all $f\in L^{p(s)}(\mathbf{R}^n,\nu)$, or equivalently,

$$\|(Af\,)k_1^s\|_{L^{q(s)}(\mu)} \leq (|||A|||_{p,q})^s \|f\|_{L^{p(s)}(\nu)}, \tag{5.11}$$

where we define

$$k_1(z) := \exp\left(-\frac{1}{q}(ax^2+by^2)\right) \tag{5.12}$$

for all $z \in \mathbf{C}^n$.

Proof: Let a and b satisfy (5.1). Then, in Stein's Theorem 5.2, we take the Lebesgue indices to be $p_0=q_0=2$ and $p_1=p$ and $q_1=q$. We also take the weight functions to be $k_0(z)=1$ and $k_1(z)$ as in (5.12) and $u_0(t)=u_1(t)=1$ where $z \in \mathbf{C}^n$ and $t \in \mathbf{R}^n$. We then have that

$$\|(Af\,)k_1\|_{L^{q(\mu)}} = \|Af\|_{L^{q(\mu_{ab})}} \leq |||A|||_{p,q} \|f\|_{L^{p(\nu)}} < \infty$$

for all $f \in L^p(\mathbf{R}^n, \nu)$ by the relations (5.2) and (5.3) in Theorem 5.1, which is applicable here. This verifies the hypothesis (5.8) of Stein's Theorem 5.2 with $M_1 = |||A|||_{p,q}$. The hypothesis (5.7) holds since A is an L^2 isometry, namely $\|Af\|_2 = M_0\|f\|_2$ where $M_0=1$. Then Stein's Theorem 5.2 gives $k_s(z)=k_1^s(z)$ and $u_s(t)=1$ for $0 \leq s \leq 1$, $z \in \mathbf{C}^n$ and $t \in \mathbf{R}^n$. So (5.9) becomes (5.11). Using the identity $\|(Af\,)k_1^s\|_{L^{q(s)}(\mu)} = \|Af\|_{L^{q(s)}(\mu_{ab}^s)}$ we get (5.10) from (5.11). □

These inequalities (5.11) are the weighted analogues of the Hausdorff-Young inequality for the current situation. This is because, as in the unweighted case, they are derived by interpolating between a (p,q) mapping estimate and a (2,2) estimate, thereby giving us an operator norm estimate that is well behaved in the interpolating parameter. Also the estimate depends only on one choice of constants a and b, namely that at the endpoint corresponding to $s=1$.

VI. LOGARITHMIC SOBOLEV INEQUALITIES

The differentiation technique of Hirschman again can be applied to the weighted analogues of the Hausdorff-Young inequality of the previous section. This now leads to entropy-energy inequalities which, as we shall see, are generalized logarithmic Sobolev inequalities.

Theorem 6.1: *Suppose that* $f \in L^2(\mathbf{R}^n, \nu)$ *satisfies* $Af \in L^{2+\epsilon}(\mathbf{C}^n, \mu)$ *for some* $\epsilon > 0$. *Suppose also that* $1 < p \leq \infty$ *and* $1 \leq q < \infty$. *If* $p > 2$, *suppose also that* $f \in L^{2+\xi}(\mathbf{R}^n, \nu)$ *for some* $\xi > 0$. *Then for any real number* a *satisfying* $a > \max(-1-q/2+p'q/2, -1+q/2)$ *we have the entropy-energy inequality*

$$(2^{-1}-q^{-1})S(Af\,) - (2^{-1}-p^{-1})S(f\,) \leq \frac{a}{q}\langle f, Nf\rangle + \Lambda\|f\|_2^2, \tag{6.1}$$

where $\Lambda = (n/q)[a - \frac{1}{2}\log((a+1+q/2-p'q/2)(a+1-q/2))]$ *and where* $\langle f, Nf\rangle$ *is the Dirichlet form defined in (2.6). Here* $S(f\,)$, $S(Af\,)$ *and* $\langle f, Nf\rangle$ *are all finite nonnegative real numbers.*

Proof: Since the results are trivial for $f=0$, we assume $f \in L^2(\mathbf{R}^n, \nu)$ is nonzero hereafter. First note that by (4.3) and the hypothesis on Af we have that $S(Af\,) < \infty$. The proof that $\langle f, Nf\rangle$ is finite is based on the following identity which comes from Bargmann's article,[3] formula (3.17). It says that for every $g \in HL^2(\mathbf{C}^n, \mu)$ one has

$$\int_{\mathbf{C}^n} d\mu(z)|g(z)|^2|z|^2 = n\|g\|_2^2 + \langle g, \widetilde{N}g\rangle, \tag{6.2}$$

where the Dirichlet form $\langle g, \widetilde{N}g\rangle$ is defined in (2.7). This is proved by expanding g in its Taylor series. But, by Hölder's inequality, we obtain

$$\int_{\mathbf{C}^n} d\mu(z)|g(z)|^2|z|^2 \leq \|g\|_{2r}^2 \|z\|_{2r'}^2, \tag{6.3}$$

for any $1 \leq r \leq \infty$. Here $\|z\|_{2r'}$ really means $\|\,|z|\,\|_{2r'}$. Taking $g=Af$ and $r=1+\epsilon/2$ where $\epsilon>0$ is chosen so that $Af \in L^{2+\epsilon}(\mathbf{C}^n, \mu)$ we have $\|g\|_{2r} = \|Af\|_{2+\epsilon} < \infty$. But $r>1$ and so we have $r' < \infty$. Consequently, $\|z\|_{2r'} < \infty$. Thus, by (6.2) and (6.3)

$$n\|Af\|_2^2+\langle Af,\widetilde{N}Af\rangle=\int_{\mathbf{C}^n}d\mu(z)|Af(z)|^2|z|^2\leqslant\|Af\|_{2+\epsilon}^2\|z\|_{2r'}^2<\infty, \tag{6.4}$$

which implies $\langle f,Nf\rangle=\langle Af,\widetilde{N}Af\rangle<\infty$ since A preserves energy. It should be noted that the identity (6.2) of Bargmann depends on the analyticity of the elements of the Segal-Bargmann space. Moreover, the inequality (6.4) is the *reverse* of a Sobolev inequality, since it says that if a function in the Segal-Bargmann space possesses just a bit more integrability than square integrability, then the function has finite expected energy.

To show the inequality (6.1) we start with the inequality (5.11) of Theorem 5.3 which does apply here because of our current hypotheses, provided that a and b also satisfy (5.1). So for $0\leqslant s\leqslant 1$ we have

$$\|(Af)k_1^s\|_{L^{q(s)}(\mu)}\leqslant(|||A|||_{p,q})^s\|f\|_{L^{p(s)}(\nu)}.$$

Since this becomes an equality at $s=0$ for $f\in L^2(\mathbf{R}^n,\nu)$, we have by the same argument which gave us (4.5) that

$$\left.\frac{d}{ds}\right|_{s=0^+}\|(Af)k_1^s\|_{q(s)}\leqslant(\log|||A|||_{p,q})\|f\|_2+\left.\frac{d}{ds}\right|_{s=0^+}\|f\|_{p(s)}, \tag{6.5}$$

provided that the derivatives on both sides of (6.5) exist. By the rules of calculus and a differentiation under the integral sign (which will be justified shortly), the derivative on the left hand side is

$$\left.\frac{d}{ds}\right|_{s=0^+}\|(Af)k_1^s\|_{q(s)}=\frac{q'(0)S(Af)}{4\|Af\|_2}+\frac{1}{\|Af\|_2}\int d\mu(z)\left.\frac{d}{ds}\right|_{s=0^+}k_1(z)^s|Af(z)|^2.$$

In Ref. 17 it is shown that

$$\left.\frac{d}{ds}\right|_{s=0^+}\int_{\mathbf{C}^n}d\mu(z)(k_1(z)^s|g(z)|)^{q(s)}$$
$$=\int_{\mathbf{C}^n}d\mu(z)\left(2|g(z)|^2\left.\frac{d}{ds}\right|_{s=0^+}(k_1(z)^s)+q'(0)|g(z)|^2\log|g(z)|\right),$$

where $g\in HL^2(\mathbf{C}^n,\mu)$, provided that $g\in L^{2+\epsilon}(\mathbf{C}^n,\mu)$ for some $\epsilon>0$. This justifies the above derivation under the integral sign. Using both

$$\left.\frac{d}{ds}\right|_{s=0^+}k_1(z)^s=\log k_1(z)=\frac{1}{q}\log c_{ab}-\frac{1}{q}(ax^2+by^2)$$

and $\|Af\|_2=\|f\|_2$ we then obtain

$$\left.\frac{d}{ds}\right|_{s=0^+}\|(Af)k_1^s\|_{q(s)}=\frac{q'(0)S(Af)}{4\|f\|_2}+\frac{1}{q}\|f\|_2\log c_{ab}-\frac{1}{q\|f\|_2}\int_{\mathbf{C}^n}d\mu(z)|Af(z)|^2(ax^2+by^2).$$

Notice that this derivative is a finite real number, since the integral term is bounded above and below by finite real numbers by Bargmann's identity (6.2) and since the entropy $S(Af)$ is also finite.

By taking $a=b>\max(-1-q/2+p'q/2,-1+q/2)$, one gets

$$\left.\frac{d}{ds}\right|_{s=0^+}\|(Af)k_1^s\|_{q(s)}=\frac{q'(0)S(Af)}{4\|f\|_2}+\frac{n}{q}\|f\|_2\log(1+a)-\frac{a}{q\|f\|_2}\int_{\mathbf{C}^n}d\mu(z)|Af(z)|^2|z|^2$$

because $c_{aa}=(1+a)^n$. Next we use Bargmann's identity (6.2), the unitarity of A, and the fact that A preserves energy to get

$$\left.\frac{d}{ds}\right|_{s=0^+} \|(Af)k_1^s\|_{q(s)} = \frac{q'(0)S(Af)}{4\|f\|_2} + \frac{n}{q}\|f\|_2 \log(1+a) - \frac{an}{q}\|f\|_2 - \frac{a}{q\|f\|_2}\langle f, Nf\rangle. \quad (6.6)$$

Now we establish

$$\left.\frac{d}{ds}\right|_{s=0^+} \|f\|_{p(s)} = \frac{p'(0)S(f)}{4\|f\|_2} \quad (6.7)$$

by examining three cases. If $p<2$, (6.7) follows from (4.2). If $p>2$, (6.7) follows from (4.3) and the extra hypothesis on f in the case $p>2$. If $p=2$, then $p(s)=2$ for all $0\leqslant s\leqslant 1$ and so $p'(0)=0$. Then both sides of (6.7) are zero, where we use the usual convention that $0\cdot\infty=0$. So $S(f)=\infty$ is still a possibility if $p\leqslant 2$. By substituting (6.6) and (6.7) into (6.5) and using (5.3) in the case $a=b$ we have (6.1). The finiteness of $S(f)$ now follows from (6.1) in the case $1<p<2$. This concludes the proof. □

It is easy to verify that the set of functions satisfying the hypotheses of Theorem 6.1 is a dense subspace of $L^2(\mathbf{R}^n,\nu)$. Also, it is straightforward to show by elementary calculus that $\Lambda\geqslant(.28)n/q>0$. The coefficient of $S(f)$ in the inequality (6.1) can be positive, negative or zero. The same holds for the coefficient of $S(Af)$. So we can have nine qualitatively different types of inequalities in (6.1). The question of best constants is a bit complicated for an inequality

$$a_1S(Af)+a_2S(f)\leqslant a_3\|f\|_2^2+a_4\langle f,Nf\rangle$$

of the form (6.1). While it is also possible to show such an inequality with $a_3=0$, it may be possible to prove it with $a_3<0$. In general, by dividing by $|a_1|$ or $|a_2|$ to normalize one of the coefficients on the left hand side, the question is to find the best constant for the other coefficient on the left hand side, given coefficients for the two terms on the right hand side. Notice that the case $a_1=a_2=0$ trivially has best constants $a_3=a_4=0$. This case arises in (6.1) for $p=q=2$, which is a valid case of Stein's theorem, namely the case when the Lebesgue indices do not vary but only the weight functions vary. In the case $a_1=0$, $a_2>0$ (respectively, $a_1>0$, $a_2=0$) one obtains a log-Sobolev inequality in the space $L^2(\mathbf{R}^n,\nu)$ (respectively, $HL^2(\mathbf{C}^n,\mu)$). It should be noted that this manner of demonstrating log-Sobolev inequalities for the individual spaces arises from the L^p mapping properties of the Segal-Bargmann transform, and not from hypercontractivity estimates. Next, let us consider the case $a_4<0$ which arises in (6.1) if $1\leqslant q<2$ and $p>1+q/2$. Notice that $q<2$ implies $a_1<0$ and that $a_2<0$ if $p>2$. By rearranging terms if $p>2$ and $q<2$ one has the energy bounded by a positive linear combination of the entropies, modulo the $\|f\|_2$ term. Similarly if $q<2$ and $p<2$ one has an upper bound on $S(f)$ in terms of $S(Af)$, again modulo the norm and energy terms. This seems weaker than (4.4), but it is not always since it includes the possibility that $a_4<0$. Finally, when $a_1>0$ and $a_2<0$ (that is, $p>2$ and $q<2$) we can bound $S(Af)$ above by $S(f)$, modulo norm and energy terms as usual. In this case, as an examination of the results in Proposition 7.1 shows, one must have $a_4>0$. Moreover, a recent result in Ref. 17 shows that one has an upper bound on $S(Af)$ by nothing more than the energy and norm terms, which means that we can take $a_2=0$ in this case.

Actually, the inequality (6.1) itself can be considered as a generalization of a log-Sobolev inequality, if it is thought of as a log-Sobolev inequality of the operator A, which preserves the norms and the Dirichlet forms. The next definition captures this generalization.

Definition 6.2: Let (X,μ) and $(\widetilde{X},\widetilde{\mu})$ be probability measure spaces with nonnegative self-adjoint operators N and $\widetilde{N}$ acting in $L^2(X,\mu)$ and in a closed subspace T of $L^2(\widetilde{X},\widetilde{\mu})$ respectively. Suppose that A is a unitary map from $L^2(X,\mu)$ onto T, and that A intertwines N and $\widetilde{N}$ in the sense that A preserves the Dirichlet forms. Then we say that A satisfies a logarithmic Sobolev inequality if there exist constants c_1, c_2, c_3 and c_4 (excluding the case when both c_1 and c_2 are nonpositive and both c_3 and c_4 are nonnegative) such that

$$c_1S(Af)+c_2S(f)\leqslant c_3\|f\|_2^2+c_4\langle f,Nf\rangle \quad (6.8)$$

for all f in some dense subspace of $L^2(X,\mu)$ for which the right hand side of (6.8) is finite.

Here the Dirichlet form $\langle f,Nf\rangle$ is defined to be $\|N^{1/2}f\|_2^2$ for all f in the domain of the operator $N^{1/2}$ (which is the unique nonnegative square root of the nonnegative self-adjoint operator N). Otherwise, $\langle f,Nf\rangle$ is defined to be $+\infty$.

An inequality of this sort has already appeared in an article of Carlen. (See Theorem 6 of Ref. 28.) In the case when (X,μ) and $(\widetilde{X},\widetilde{\mu})$ are equal, $N=\widetilde{N}$ and A is the identity operator, this definition reduces to the usual definition of a log-Sobolev inequality (see Ref. 16).

VII. CALCULATIONS

In this section we present the results of some specific calculations.

Proposition 7.1: Define $g_\lambda(t) := \exp(\lambda\cdot t-(\mathrm{Re}\,\lambda)^2/2)$ *in* $L^2(\mathbf{R}^n,\nu)$ *where* $t\in\mathbf{R}^n$ *and* $\lambda\in\mathbf{C}^n$. *Then we have* $\|g_\lambda\|_2=1$ *and*

$$S(g_\lambda)=(\mathrm{Re}\,\lambda)^2,$$

$$Ag_\lambda(z)=\exp\left(\frac{\sqrt{2}\lambda\cdot z}{2}+\frac{\lambda^2}{4}-\frac{(\mathrm{Re}\,\lambda)^2}{2}\right),$$

$$S(Ag_\lambda)=|\lambda|^2/2,$$

$$\|g_\lambda\|_{L^p(\nu)}=\exp\left(\left(\frac{p-2}{4}\right)(\mathrm{Re}\,\lambda)^2\right),$$

$$\|Ag_\lambda\|_{L^q(\mu)}=\exp\left(\left(\frac{q-2}{8}\right)|\lambda|^2\right),$$

$$\langle g_\lambda,Ng_\lambda\rangle=\langle Ag_\lambda\widetilde{N}Ag_\lambda\rangle=|\lambda|^2/2,$$

where $z\in\mathbf{C}^n$, $1\leqslant p<\infty$ *and* $1\leqslant q<\infty$.

The proof of this proposition is a computation of the Gaussian integrals (see Ref. 29). As the functions g_λ show, the Segal-Bargmann transform A can increase entropy, decrease entropy or leave the entropy unchanged.

Here is a corollary of Proposition 7.1 which complements Theorem 3.1

Corollary 7.2: $\|A\|_{p\to q}=\infty$ *if* $q>2$ *or if* $p<1+q/2$ *where* A *is the Segal-Bargmann transform. Notice these conditions on* p *and* q *are implied by* $p<q$.

Proof: If $1\leqslant p<\infty$ and $1\leqslant q<\infty$ we use the functions g_λ from Proposition 7.1 to get the lower bound

$$\|A\|_{p\to q}\geqslant\sup_{\lambda\in\mathbf{C}^n}\frac{\|Ag_\lambda\|_q}{\|g_\lambda\|_p}=\sup_{\lambda\in\mathbf{C}^n}\exp\left(\left(\frac{q-2p+2}{8}\right)(\mathrm{Re}\,\lambda)^2+\left(\frac{q-2}{8}\right)(\mathrm{Im}\,\lambda)^2\right).$$

So, $\|A\|_{p\to q}=\infty$ if $q>2$ or if $q-2p+2>0$. For $p=\infty$, we use g_λ with $\lambda\in i\mathbf{R}^n$. Then $\|g_\lambda\|_\infty=1$ and for $1\leqslant q<\infty$ we have

$$\|A\|_{\infty\to q}\geqslant\sup_{\lambda\in\mathbf{C}^n}\frac{\|Ag_\lambda\|_q}{\|g_\lambda\|_\infty}=\sup_{\lambda\in\mathbf{C}^n}\exp\left(\left(\frac{q-2}{8}\right)|\lambda|^2\right),$$

and so it follows that $\|A\|_{\infty\to q}=\infty$ if $2<q<\infty$. Finally, for $q=\infty$, we use the inequality $\|A\|_{p\to\infty}\geqslant\|A\|_{\infty\to q_1}$ for any $2<q_1<\infty$ and $1\leqslant p\leqslant\infty$ (which follows from Hölder's inequality) and the previous case. □

Zhou in Ref. 9 has shown the case $q>2$ of Corollary 7.2 by considering the functions g_λ for $\lambda\in i\mathbf{R}^n$. Also, by Hölder's inequality, for $q=2$ and $2\leqslant p\leqslant\infty$, we have $\|A\|_{p\to q}=1$. So, together with Theorem 3.1, we see that the only indices p and q for which the finiteness or infiniteness of $\|A\|_{p\to q}$ has yet to be established are those satisfying $q<2$ and $p=1+q/2$.

VIII. CONCLUDING REMARKS

The Hille-Tamarkin norm is a useful tool for analyzing the Segal-Bargmann transform because these norms become Gaussian integrals, which are then explicitly evaluated. This happens since the measures (2.1) and (2.2) and the kernel (2.4) are Gaussians. So this sort of analysis works in a more general Gaussian situation, for example in Ref. 17 where the reproducing kernel function of the Segal-Bargmann space is analyzed. However, the Hille-Tamarkin norm provides a weak estimate on the operator norm. Explicitly, this means that the inequalities in Proposition 2.1 need not be sharp. Nonetheless, this method does correctly describe the general behavior of the Segal-Bargmann transform with respect to the L^p scale of spaces. Specifically, for all pairs (p,q) except those with $q=2$ and $p\geqslant 2$ and those with $1\leqslant q<2$ and $p=1+q/2$, we have that either A is compact from $L^p(\mathbf{R}^n,\nu)$ to $L^q(\mathbf{C}^n,\mu)$ or $\|A\|_{p\to q}=\infty$. Similar behavior is seen with the integral transform whose kernel is the reproducing kernel function of the Segal-Bargmann space. This transform is also generically either compact or unbounded (see Ref. 17). So the unitarity of the Segal-Bargmann transform from $L^2(\mathbf{R}^n,\nu)$ to $HL^2(\mathbf{C}^n,\mu)$ is atypical of the behavior of this transform with respect to the L^p scale of spaces. Another way to see this is in terms of the integral transform L whose kernel function is $L(z,t) := |A(z,t)|$ for all $z\in\mathbf{C}^n$ and $t\in\mathbf{R}^n$ where $A(z,t)$ is defined in (2.4). Then $|||L|||_{p,q}=|||A|||_{p,q}$ for all $p,q\in[1,\infty]$, so that L is Hille-Tamarkin for a pair of indices if and only if A is. Moreover, by using the functions g_λ of Proposition 7.1, one sees that $\|L\|_{p\to q}=\infty$ if either $q\geqslant 2$ or if $p<1+q/2$. Note that these are not quite the same conditions on p and q as in Corollary 7.2. So the transform L is also generically compact or unbounded. Also the only indices p and q for which the finiteness or infiniteness of $\|L\|_{p\to q}$ has yet to be determined are those with $q<2$ and $p=1+q/2$, and these are precisely the same indices for which the same question remains open for $\|A\|_{p\to q}$. But the operator L is *not* a unitary operator on $L^2(\mathbf{R}^n,\nu)$. This follows from $\|L\|_{2\to 2}=\infty$ which is a particular case of the above analysis or simply by noting that $L1$ is not square integrable. So the phase information in the kernel function $A(z,t)$ is playing a critical role in the L^2 theory, but is generically unimportant on the L^p scale of spaces.

All of the results presented so far in this article are consistent with what might be called the ''one-infinity'' law for the operator norm $\|A\|_{p\to q}$. This would mean that for every pair of indices $p,q\in[1,\infty]$, one would have either $\|A\|_{p\to q}=1$ or $\|A\|_{p\to q}=\infty$. However, calculations with Gaussian functions show that $\|A\|_{p_0\to q_0}>(1.007)^n$ for $p_0=1.6$ and $q_0=1.1$. But these indices also satisfy $1\leqslant q_0<2$ and $p_0>1+q_0/2$ so that $\|A\|_{p_0\to q_0}<\infty$ by Theorem 3.1. Therefore the ''one-infinity'' law fails for the Segal-Bargmann transform, and the operator norm can have nontrivial dependence on the dimension n. This may be different from the case of the integral transform associated with the reproducing kernel function of the Segal-Bargmann space, where the question of whether the ''one-infinity'' law holds remains open (see Ref. 17).

There are various avenues for continued research here. Since there are many generalizations and deformations of the Segal-Bargmann transform, I hope that these techniques can be applied to some of them in order to understand better the nature of the range of these various transforms. Some references for these transforms are the book of Perelomov[30] and the articles of Thomas and Wassell[31] and of Hall.[32] Among the open problems in this field of research is to establish exactly the range of the L^p space under the Segal-Bargmann transform and to find the best constants for the various inequalities proved in this paper. Finally, it would be interesting to know as well the relationships between entropy and the Segal-Bargmann transform when n, the number of degrees of freedom, is not finite.

ACKNOWLEDGMENTS

I wish to thank my dissertation advisor, Lawrence Thomas, for his continual assistance and encouragement with my mathematical education and particularly with this research, most of which was done during my graduate career at the University of Virginia. I also thank T. Goebeler, B. Hall and R. Strichartz for reading a preliminary version of this paper and offering many useful comments. I also wish to thank Brian Hall for providing me with a preprint of Ref. 8. Part of this research was started during the U.S.-Sweden Workshop on Spectral Methods held at the Mittag-Leffler Institute, Djursholm, Sweden, 1992-1993 (NSF Grant No. 9217529) during the year on Schrödinger operators. I thank the organizers (B. Helffer, P. Hislop, A. Jensen, and J. Sjöstrand) and the participants for the stimulating mathematical environment at the Mittag-Leffler Institute.

Ordered products, W_∞-algebra, and two-variable, definite-parity, orthogonal polynomials

A. Verçin[a)]

(Received 10 September 1997; accepted for publication 10 November 1997)

It has been shown that the Cartan subalgebra of W_∞-algebra is the space of the two-variable, definite-parity polynomials. Explicit expressions of these polynomials, and their basic properties are presented. It also has been shown that they carry the infinite dimensional irreducible representation of the su(1,1) algebra having the spectrum bounded from below. A realization of this algebra in terms of difference operators is also obtained. For particular values of the ordering parameter s they are identified with the classical orthogonal polynomials of a discrete variable, such as the Meixner, Meixner–Pollaczek, and Askey–Wilson polynomials. With respect to variable s they satisfy a second order eigenvalue equation of hypergeometric type. Exact scattering states with zero energy for a family of potentials are expressed in terms of these polynomials. It has been put forward that it is the İnönü–Wigner contraction and its inverse that form a bridge between the difference and differential calculus. © *1998 American Institute of Physics.* [S0022-2488(98)00304-1]

I. INTRODUCTION

The classical orthogonal polynomials of a discrete variable (the Hahn, Meixner, Krawtchouk, Charlier, Pollaczek, and Meixner–Pollaczek polynomials) which are the difference analogues of the classical orthogonal polynomials of the mathematical physics have surfaced in various problems of the theoretical and mathematical physics, in group representation theory and in computational physics and techniques (Refs. 1–3 and references therein). Close relationships have been established between the generalized spherical harmonics for su(2) and the Krawtchouk polynomials, and between the Wigner $6j$-symbols and the Racah polynomials which are the discrete analogues of the Jacobi polynomials on a quadratic lattice.[1,4] The Clebsch–Gordan coefficients and $6j$-symbols for the su(1,1) can also be expressed in terms of the Hahn and Racah polynomials.[4] An important development in connection with these polynomials in the last decade was that the Hahn and Meixner polynomials can be analytically continued in the complex plane, both in variable and parameter, such that they become real polynomials which satisfy orthogonality relations with respect to continuous measure.[5,2] These polynomials are referred to as the continuous Hahn and Meixner, or, as the Hahn and Meixner polynomials of an imaginary argument (in fact, the second ones should be called the Meixner–Pollaczek polynomials[2]). The continuous Hahn polynomials are also closely related to the unitary irreducible representations of the Lorentz group SO(3,1).

Recent interest in these polynomials are mainly due to modifications and generalizations of them in connection with their q-analogues on non-uniform lattices (Ref. 6 and references therein). Another line of development, which has not attracted the sufficient interest it deserves, was determination of their connections with the ordered products of the Heisenberg–Weyl (HW) algebra.[7,8] Connection between the ordered products of the HW-algebra and particular classes of the continuous Hahn polynomials was, for the first time, investigated in Ref. 7 to find a solution for the unitarity problem in the finite element approximation to quantum field equations. This connection was established when ordering rules that gives Hermitian products are used.[7,8] In terms of ordering parameter $s \in \mathbf{C}$, henceforth used in this paper, this corresponds to pure imaginary values of s of which the well-known Weyl ordering is a special $s=0$ case. One of the purposes of

this study is to revive interest in this direction by carrying out a systematic investigation in the most general framework.

In two recent studies,[9,10] we managed to develop explicit expressions for the implicitly defined conventional s-ordered products widely used in the Weyl–Wigner–Groenevold–Moyal quantization and quantum optics.[9–11] In Section II, we briefly review the ordered products, W_∞-algebra and its Cartan subalgebra in their most general forms. Making use of these expressions, we firstly associate with each element of the Cartan subalgebra of the W_∞-algebra in a general s-basis a two-variable, definite-parity, and (continuous and discrete) orthogonal polynomials which are two-variable generalization of those appeared in literature. Our variables are s, and the c-number correspondence of the operator $\hat{x}=(\hat{q}\hat{p}+\hat{p}\hat{q})/2$ denoted by x (or, in some cases the variable $u=(x/i\hbar)-(1/2)$. These polynomials solve a hypergeometric type differential equation with respect to s, and a hypergeometric type difference equation with respect to x. For generic values of s this difference equation is identical with that satisfied by a particular class of Meixner polynomials. Other basic properties, and difference-differential relations are also presented. We also show that they carry the irreducible representation of the su(1,1)-algebra and obtain its realization in terms of difference operators (Section III). Secondly, for particular values of s, we identify these polynomials with particular classes of the Meixner, Meixner–Pollaczek, Askey–Wilson, and Hahn polynomials, and give the discrete and continuous orthogonality relations for them (Section IV). Thirdly, we show that exact zero-energy scattering states for a family of the Pösch–Teller type potentials are expressed in terms of these polynomials (Section V). Finally, we conclude by pointing out the role played by the İnönü–Wigner contraction and its inverse transformation in connection with differential-difference calculus.

II. ORDERED PRODUCTS, W_∞ – ALGEBRA AND ITS CARTAN SUBALGEBRA

Let us consider the HW-algebra: $[\hat{q},\hat{p}]=i\hbar\hat{I}$, where $\hbar,\hat{I},\hat{q}$ and $\hat{p}$ are the Planck's constant, the identity operator and the Hermitian position and momentum operators, respectively. Here and henceforth operators and functions of operators acting in a Hilbert space $\mathscr{H}$ are denoted by a $\hat{}$ over letters. We define the s-ordered products $\hat{t}^{(s)}_{nm}\equiv\{(\hat{q})^n(\hat{p})^m\}_s$, containing n factors of $\hat{q}$ and m factors of $\hat{p}$, by the following explicit equivalent formulas

$$\begin{aligned}\hat{t}^{(s)}_{nm}&=2^{-n}\sum_{j=0}^{n}\binom{n}{j}(1+s)^j(1-s)^{n-j}\hat{q}^j\hat{p}^m\hat{q}^{n-j}\\&=2^{-m}\sum_{k=0}^{m}\binom{m}{k}(1-s)^k(1+s)^{m-k}\hat{p}^k\hat{q}^n\hat{p}^{m-k}.\end{aligned}\tag{1}$$

These give for $s=\pm1,\hat{t}^{(1)}_{nm}=\hat{q}^n\hat{p}^m$; $\hat{t}^{(-1)}_{nm}=\hat{p}^m\hat{q}^n$ and for $s=0$, $\hat{t}^{(0)}_{nm}=2^{-n}\Sigma^n_{j=0}\binom{n}{j}\hat{q}^j\hat{p}^m\hat{q}^{n-j}=2^{-m}\Sigma^m_{k=0}\binom{m}{k}\hat{p}^k\hat{q}^n\hat{p}^{m-k}$. While the first two of these expressions exhibit the standard and antistandard rules of ordering, respectively, that corresponding to $s=0$ are two well-known expressions of the Weyl, or symmetrically ordered products. It is possible to write many equivalent forms of the above relations, but, for later use only two of them have been written. Although there are not any known physical applications apart from the three principle ones corresponding to $s=1,0,-1$, embedding orderings in a continuum provides a natural context for viewing their differences and interrelationships in a continuous manner and enable us to carry out the related analyses in their most general forms.

An arbitrary s-ordered product can be expressed in terms of a polynomial in s'-ordered product as follows

$$\hat{t}^{(s)}_{nm}=\sum_{k=0}^{(n,m)}2^{-k}\binom{n}{k}\binom{m}{k}k![i\hbar(s-s')]^k\hat{t}^{(s')}_{n-k,m-k},\tag{2}$$

where (n,m) denotes the smaller of the integers n and m, $\binom{n}{k}=n![(n-k)!k!]^{-1}$ is a binomial coefficient, and s' is also arbitrary complex number. Note that $i\hbar$ in Eq. (2) is the sign of the

commutator of the corresponding operators there. Thus, relations (1) and (2) can be used for any pair of the operators $\hat{A},\hat{B}$ of any algebra satisfying the commutation relation $[\hat{A},\hat{B}]=i\lambda,\lambda\in\mathbf{C}$. From (1) it easily follows that

$$[\hat{t}^{(s)}_{nm}]^{\dagger}=\hat{t}^{(\bar{-s})}_{nm}, \tag{3}$$

where † stands for the Hermitian conjugation and $\bar{a}$ is the complex conjugation of a. That is, for general n,m integers, $\hat{t}^{(s)}_{nm}$ are Hermitian if and only if $\bar{s}=-s$. In particular, the Weyl ordered products $\hat{t}^{(0)}_{nm}$ are Hermitian. For general $s,\alpha\in\mathbf{C}$ one can form combinations such as $\hat{\kappa}_{nm}(s)=\alpha\hat{t}^{(s)}_{nm}+\bar{\alpha}\hat{t}^{(\bar{-s})}_{nm}$ that are Hermitian.

The W_∞-algebra is the infinite algebra generated by the ordered products $\hat{t}^{(s)}_{nm}$.[10,12,13] Up to a trivial central element it is the universal enveloping algebra of the HW-algebra. In the most general basis the structure constants of the W_∞-algebra can be read off from

$$[\hat{t}^{(s)}_{kl},\hat{t}^{(s)}_{nm}]=-\sum_{j=0}^{j_{max}}\frac{i^j}{j!}\left[\sum_{r=0}^{j'}\binom{j}{r}f_{srj}a_{nmkl,rj}\right]\hat{t}^{(s)}_{n+k-j,m+l-j}, \tag{4}$$

where the prime over the second summation indicates that the maximum value that r may take is $r_{max}=(m,k)$ and

$$j_{max}=(n+r_{max},l+r_{max}),\quad a_{nmkl,rj}=\frac{n!m!k!l!}{(n+r-j)!(m-r)!(k-r)!(l+r-j)!}. \tag{5}$$

The restrictions imposed on summations also follows from the expression of $a_{nmkl,rj}$. In relation (4) $f_{srj}=(s^-)^r(-s^+)^{j-r}-(s^-)^{j-r}(-s^+)^r$, $s^{\pm}=\hbar(1\pm s)/2$, is the only factor depending on the chosen rule of ordering. Here we observe that anti-commutator of the ordered products is given by the same relation as (4) only provided that the ordering factor is replaced by $f^{+}_{srj}=(s^-)^r(-s^+)^{j-r}+(s^-)^{j-r}(-s^+)^r$. Relation (4), which was first reported in Ref. 10, for $s=0,\pm1$ coincides with those appeared in literature,[14] and generalize them for arbitrary values of s.

W_∞ has some finite and infinite dimensional subalgebras. But, for the purpose of this work we will be concerned only with the infinite abelian subalgebra consisting of the generators $\hat{H}^{(s)}_n\equiv\hat{t}^{(s)}_{nn}$. The commutativity of the generators $[\hat{H}^{(s)}_n,\hat{H}^{(s)}_k]=0$ follows from (4). But, for our purpose we prove this, and $[\hat{H}^{(s)}_n,\hat{H}^{(s')}_k]=0$ by showing that for any values of $n\geqslant0$ and $s\in\mathbf{C}$ all the ordered products of the form $\hat{H}^{(s)}_n\equiv\hat{t}^{(s)}_{nn}$ can be expressed in terms of single operator $\hat{x}\equiv(\hat{q}\hat{p}+\hat{p}\hat{q})/2$. To see this, let us first consider $\hat{H}^{(1)}_n=\hat{q}^n\hat{p}^n$ which can be written as

$$\begin{aligned}\hat{H}^{(1)}_n&=\hat{q}^{n-1}\hat{q}\hat{p}\hat{p}^{n-1}=\hat{q}^{n-1}\hat{p}^{n-1}[\hat{x}+\hat{c}(2n-1)]\\&=\hat{q}^{n-2}\hat{p}^{n-2}[\hat{x}+\hat{c}(2n-3)][\hat{x}+\hat{c}(2n-1)].\end{aligned}$$

Hence, by induction, we have

$$\hat{H}^{(1)}_n=\prod_{j=1}^{n}[\hat{x}+\hat{c}(2j-1)],\quad \hat{H}^{(-1)}_n=\prod_{j=1}^{n}[\hat{x}-\hat{c}(2j-1)], \tag{6}$$

where $\hat{c}\equiv i\hbar\hat{I}/2$ and the relations $\hat{q}\hat{p}=\hat{x}+\hat{c}$, $[\hat{x},\hat{p}^k]=2\hat{c}k\hat{p}^k$ are used. The second relation is written by making use of (3).

III. TWO-VARIABLE, DEFINITE-PARITY POLYNOMIALS

Now, evaluating (2) for $s'=\pm1$ by making use of (6), and then replacing $\hat{x}$ in results by the c-number variable x, we obtain two-variable polynomials $P_n(s,x)$ for each element of the Cartan subalgebra. Here the variables are the (dimensionless) ordering parameter $s\in\mathbf{C}$ and $x\in\mathbf{R}$ which

has dimension of angular momentum (since $\hat{x}$ is an hermitian operator we consider x as a real variable). Two equivalent, explicit expressions for these polynomials are as follows

$$\begin{aligned} P_n(s,x) &= \sum_{k=0}^{n} \binom{n}{k}^2 k![-c(1-s)]^k \prod_{j=1}^{n-k} [x+c(2j-1)] \\ &= \sum_{k=0}^{n} \binom{n}{k}^2 k![c(1+s)]^k \prod_{j=1}^{n-k} [x-c(2j-1)], \end{aligned} \tag{7}$$

where $c=i\hbar/2$. From these relations it is obvious that under the action of two dimensional parity transformation in $\mathbf{C}\times\mathbf{R}$, they transform as

$$P_n(-s,-x)=(-1)^n P_n(s,x), \tag{8}$$

that is, they have the same parity with n. The following recursion relation can also be verified

$$P_{n+1}(s,x)=[x+c(2n+1)s]P_n(s,x)+c^2(1-s^2)n^2 P_{n-1}(s,x). \tag{9}$$

The easiest way of obtaining this relation may be first noting the relation

$$[\hat{x},\hat{t}^{(s)}_{nm}]_+ = 2[\hat{t}^{(s)}_{n+1,m+1} - cs(m+n+1)\hat{t}^{(s)}_{nm} - c^2 nm(1-s^2)\hat{t}^{(s)}_{n-1,m-1}],$$

where $[,]_+$ stands for the anticommutator. They also obey the following derivatives and difference relations:

$$\partial_s^k P_n(s,x) = c^k \left[\frac{n!}{(n-k)!}\right]^2 P_{n-k}(s,x), \tag{10}$$

$$(x\pm c)P_n(s,x\pm 2c)=[x\pm c(2n+1)]P_n(s,x)+2c^2n^2(1\mp s)P_{n-1}(s,x), \tag{11}$$

with respect to s and x, respectively. This last property immediately results by first noting the relations

$$(x\pm c)P_n(\pm 1,x\pm 2c)=[x\pm c(2n+1)]P_n(\pm 1,x), \tag{12}$$

which easily result from (6).

From (9) and (10) we see that, with respect to s the lowest order differential equation obeyed by these polynomials is the following hypergeometric type differential equation

$$\{(1-s^2)\partial_s^2+[x/c+(2n-1)s]\partial_s - n^2\}P_n(s,x)=0. \tag{13}$$

The difference relations (12) can also be recast in a form in which the discrete differences are in a more conventional form by using the central first and second differences;

$$D_h f(x)=\frac{f(x+h)-f(x-h)}{2h}, \quad D_h^2 f(x)=\frac{f(x+h)-2f(x)+f(x-h)}{h^2}, \tag{14}$$

which approximate the usual first and the second derivatives on a lattice with the constant mesh $\Delta x=h$ up to second order in h.[1,8] For this purpose we take the sum and difference of two relations given by (12)

$$(x+c)P_n(s,x+2c)-(x-c)P_n(s,x-2c)=c(4n+2)P_n(s,x)-4sc^2n^2P_{n-1}(s,x), \tag{15}$$

$$(x+c)P_n(s,x+2c)+(x-c)P_n(s,x-2c)=2xP_n(s,x)+4c^2n^2P_{n-1}(s,x), \tag{16}$$

which, in terms of D_h and D_h^2 can be rewritten as follows

$$(c^2D_h^2+xD_h-n)P_n(s,x)=-scn^2P_{n-1}(s,x), \tag{17}$$

$$(xD_h^2+D_h)P_n(s,x)=n^2P_{n-1}(s,x), \tag{18}$$

where $h=2c$ and D_h denote the partial difference operation with respect to x. Note that all the difference operations are with respect to variable x and all the derivatives are with respect to the ordering variable s.

Now, by making use of the recursion relation (9), and (17), (18) we have

$$\begin{aligned} J_-P_n(s,x)&=n^2P_{n-1}(s,x),\\ J_+P_n(s,x)&=P_{n+1}(s,x),\\ J_0P_n(s,x)&=(n+\tfrac{1}{2})P_n(s,x), \end{aligned} \tag{19}$$

where

$$J_-=[xD_h^2+D_h]=\left[\frac{4x}{\hbar^2}\sin^2\left(\frac{\hbar}{2}\partial_x\right)+\frac{1}{\hbar}\sin(\hbar\partial_x)\right], \tag{20}$$

$$\begin{aligned} J_+&=c^2(1+s^2)J_-+2cs(c^2D_h^2+xD_h)+(x+cs)\\ &=c^2(1+s^2)J_-+2cs\left[-\sin^2\left(\frac{\hbar}{2}\partial_x\right)+\frac{x}{\hbar}\sin(\hbar\partial_x)\right]+(x+cs), \end{aligned} \tag{21}$$

$$\begin{aligned} J_0&=c(c+sx)D_h^2+(x+cs)D_h+\frac{1}{2}\\ &=c(c+sx)\frac{4}{\hbar^2}\sin^2\left(\frac{\hbar}{2}\partial_x\right)+(x+cs)\frac{1}{\hbar}\sin(\hbar\partial_x)+\frac{1}{2}. \end{aligned} \tag{22}$$

It is not hard to verify that by their actions on an arbitrary function, the generators $(J_0,J_\pm)$ obey the standard defining relations of the su(1,1) algebra

$$[J_+,J_-]=-2J_0,\quad [J_0,J_\pm]=\pm J_\pm. \tag{23}$$

The value of the Casimir operator $J^2=-J_-J_++J_0^2+J_0$ is found to be $J^2P_n(s,x)=-\frac{1}{4}P_n(s,x)$. Thus, we have obtained a realization of the su(1,1) algebra in terms of the difference operators, and the polynomials we have found carry the infinite dimensional irreducible representation of this algebra having the spectrum bounded from below which is designated by $D^+_{-\frac{1}{2}}$.[15]

Finally, in this section we write down explicit expressions of the first five polynomials;

$$\begin{aligned} P_0(s,x)&=1,\\ P_1(s,x)&=x+cs,\\ P_2(s,x)&=x^2+4csx+c^2(2s^2+1),\\ P_3(s,x)&=x^3+9csx^2+c^2(18s^2+5)x+3c^3s(2s^2+3),\\ P_4(s,x)&=x^4+16csx^3+2c^2(36s^2+7)x^2+16c^3s(6s^2+5)x+3c^4(8s^4+24s^2+3). \end{aligned} \tag{24}$$

The values of these polynomials at $(s,x=0)$ and at $(s=0,x=0)$ can be easily obtained from (7).[16,17] Because of (3), these are real valued for pure imaginary s. Note that the relation (2), which enables us to write $P_n(s,x)$ in terms of $P_n(s',x)$, in view of (10), is nothing more than a Taylor expansion.

IV. CONNECTIONS WITH THE MEIXNER, MEIXNER–POLLACZEK AND CONTINUOUS HAHN POLYNOMIALS

To compare the polynomials we have found with the classical orthogonal polynomials of a discrete variable we use

$$u=\frac{x}{2c}-\frac{1}{2}. \tag{25}$$

In that case we have the following difference relations

$$(u+1)P_n(s,u+1)=(u+n+1)P_n(s,u)+c(1-s)n^2P_{n-1}(s,u), \tag{26}$$

$$uP_n(s,u-1)=(u-n)P_n(s,u)+c(1+s)n^2P_{n-1}(s,u). \tag{27}$$

Eliminating the last terms between these two relations and writing out the result in terms of the difference operators

$$\Delta f(u)=f(u+1)-f(u),\quad \nabla f(u)=f(u)-f(u-1), \tag{28}$$

we arrive at

$$\left\{u\Delta\nabla-\left[\frac{2}{1-s}u+\frac{1+s}{1-s}\right]\Delta+\frac{2n}{1-s}\right\}P_n(s,u)=0. \tag{29}$$

This is the same type of difference equation satisfied by the Meixner polynomials $m_n^{(\gamma,\mu)}(u)$:

$$\{u\Delta\nabla+[(\mu-1)u+\mu\gamma]\Delta+\lambda_n\}m_n^{(\gamma,\mu)}(u)=0. \tag{30}$$

Comparing with Eq. (29) we have

$$\mu=\frac{s+1}{s-1},\quad \gamma=1,\quad \lambda_n=\frac{2n}{1-s}. \tag{31}$$

The Meixner polynomials are normalized as follows: $\Delta^n m_n^{(\gamma,\mu)}(u)=n![(\mu-1)/\mu]^n$. On the other hand, the polynomials $P_n(s,u)$ obey the relation $\Delta^nP_n(s,u)=(2c)^nn!$. (For a polynomial $q_m(u)$ of degree m the mth differences and mth derivatives are equal: $\Delta^m q_m(u)=\nabla^m q_m(u)=\partial_u^m q_m(u)$. Thus, we obtain

$$P_n(s,u)=[c(s+1)]^n m_n^{(1,(s+1)/(s-1))}(u). \tag{32}$$

If the conditions $\gamma>0$, and $0<\mu<1$ are satisfied the Meixner's polynomials obey the discrete-orthogonality relation

$$\sum_{u=0}^{\infty} m_n^{(\gamma,\mu)}(u)m_m^{(\gamma,\mu)}(u)\rho(u)=\delta_{nm}d_n^2. \tag{33}$$

Thus, provided that $s<-1$ this relation in terms of $P_n(s,u)$ is as follows:

$$\sum_{u=0}^{\infty} P_n(s,u)P_m(s,u)\rho'(u)=\delta_{nm}d_n'^2, \tag{34}$$

where, (for $s<-1$) the weight $\rho'(u)$, and the squared norm $d_n'^2$ are found to be

$$\rho'(u)=\left(\frac{s+1}{s-1}\right)^u\frac{\Gamma(u+1)}{u!},\quad d_n'^2=\frac{1}{2}(n!)^2c^{2n}(1-s)(s^2-1)^n. \tag{35}$$

Here $\Gamma(z)$ is the gamma function. It is also easy to verify that, the three-term recursion relation (9) for the polynomials $P_n(s,u)$ is the same as that obeyed by Meixner's polynomials

$$\mu m_{n+1}^{(\gamma,\mu)}(u)=[\gamma\mu+(1+\mu)n-(1-\mu)u]m_n^{(\gamma,\mu)}(u)-n(n+\gamma-1)m_{n-1}^{(\gamma,\mu)}(u), \tag{36}$$

provided that relations given by (31) are satisfied.

In Ref. 5 by considering the analytic continuation of the orthogonality relation (33) in the parameter $\mu=\exp(-2i\phi)$ the polynomials

$$P_n^{\lambda}(\phi,t)=\frac{e^{-in\phi}}{n!}m_n^{(2\lambda,\mu)}(-\lambda+it), \tag{37}$$

which, under the conditions $\lambda>0$, and $0<\phi<\pi$, obey the orthogonality relation

$$\int_{-\infty}^{\infty}P_n^{\lambda}(\phi,t)P_m^{\lambda}(\phi,t)\rho_P(t)dt=\delta_{nm}\frac{\Gamma(2\lambda+n)}{n!} \tag{38}$$

with respect to continuous measure are obtained. Here the weight ρ_P is as follows

$$\rho_P(t)=\frac{1}{2\pi}(2\sin\phi)^{2\lambda}|\Gamma(\lambda+it)|^2\exp[(2\phi-\pi)t]. \tag{39}$$

These polynomials should be called the Meixner–Pollaczek polynomials.[2] In view of the relation (32), if we identify $\hat{x}/\hbar$ with the real variable t we find that $\lambda=1/2$ and $s=i\cot\phi$. Thus, with the help of (37), we obtain

$$P_n\left(s,i\frac{x}{\hbar}-\frac{1}{2}\right)=n!\left(\frac{-\hbar}{2\sin\phi}\right)^n P_n^{1/2}\left(\phi,\frac{x}{\hbar}\right). \tag{40}$$

In terms of $P_n(s,u)$ the orthogonality relation (38) is as follows:

$$\int_{-\infty}^{\infty}P_n\left(s,i\frac{x}{\hbar}-\frac{1}{2}\right)P_m\left(s,i\frac{x}{\hbar}-\frac{1}{2}\right)\rho_0(x)dx=\delta_{nm}(n!)^2\left(\frac{\hbar}{2\sin\phi}\right)^{2n+1}, \tag{41}$$

with the weight

$$\rho_0(x)=\frac{\exp[(2\phi-\pi)(x/\hbar)]}{\cosh(\pi x/\hbar)}. \tag{42}$$

For $\lambda=1/2$, and $\phi=\pi/2$ the Meixner–Pollaczek polynomials are related to the Askey–Wilson polynomials $q_n^{(\alpha)}(x,\delta)$ as follows $q_n^{(0)}(x,1/2)=(1/2)_n P_n^{1/2}(\pi/2,x)$, where, $(a)_n=\Gamma(a+n)/\Gamma(a)$. Note that this particular case corresponds to $s=0$ (Weyl ordering) and the weight is $\rho_0(x)=\cosh(\pi x/\hbar)$. On the other hand, the Askey–Wilson polynomials are particular cases of the continuous Hahn polynomials $h_n^{(\alpha,\beta)}(z,N)$:

$$q_n^{(\alpha)}(x,\delta)=(-i)^n h_n^{(\alpha,\alpha)}(\tfrac{1}{2}ix-\tfrac{1}{2}(\alpha-\delta+1),-\alpha+\delta). \tag{43}$$

Making use of these relations we have

$$\begin{aligned}P_n\left(s=0,i\frac{x}{\hbar}-\frac{1}{2}\right)&=n!\left(\frac{-\hbar}{2}\right)^n\left[\left(\frac{1}{2}\right)_n\right]^{-1}q_n^{(0)}\left(\frac{x}{\hbar},\frac{1}{2}\right)\\&=n!\left(\frac{-\hbar}{2}\right)^n\left[\left(\frac{1}{2}\right)_n\right]^{-1}(-i)^n h_n^{(0,0)}\left(i\frac{x}{2\hbar}-\frac{1}{4},\frac{1}{2}\right).\end{aligned} \tag{44}$$

As a last remark in this section we note that for particular values, or ranges of the variables, these polynomials can also be identified with particular cases of the Jacobi polynomials and the generalized spherical harmonics (the Bargmann functions).[3]

V. RODRIGUES FORMULA, GENERATING FUNCTION, AND EXACT ZERO-ENERGY SCATTERING STATES FOR A FAMILY OF POTENTIALS

For a given x, the polynomials solve the eigenvalue equation (13), which is a differential equation of the hypergeometric type. In order to uncover more properties of these polynomials we restrict the investigation to

$$s=iy, \quad \frac{x}{c}=-iv; \quad y,v\in\mathbf{R}. \tag{45}$$

Note that in that case the corresponding ordered products are Hermitian. In terms of the new variables, Eq. (13) is as follows

$$\{(1+y^2)\partial_y^2+[v-(2n-1)y]\partial_y+n^2\}P_n(y,v)=0. \tag{46}$$

With the help of the function

$$\rho(y,v)=\frac{e^{v\tan^{-1}y}}{(1+y^2)^{(2n+1)/2}}, \tag{47}$$

which is determined from

$$\partial_y[(1+y^2)\rho]=[v-(2n-1)y]\rho, \tag{48}$$

Eq. (46) can be written in the self-adjoint form

$$\{\partial_y[(1+y^2)\rho(y,v)\partial_y]+\rho(y,v)n^2\}P_n(y,v)=0. \tag{49}$$

Thus, we have found the following Rodrigues formula, integral representation, and the generating function for these polynomials:

$$P_n(y,v)=\frac{(-ic)^n}{\rho(y,v)}\partial_y^n\left[\frac{e^{v\tan^{-1}y}}{(1+y^2)^{(1/2)}}\right], \tag{50}$$

$$P_n(y,v)=\frac{(-ic)^n n!}{2\pi i\rho(y,v)}\oint_C\frac{(1+z^2)^n}{(z-y)^{n+1}}\rho(z,v)dz, \tag{51}$$

$$\Phi(y,v,u)=(1-4uy-4u^2)^{-1/2}\frac{\rho(\xi,v)}{\rho(y,v)}, \tag{52}$$

$$(\xi=(2u)^{-1}[1-(1-4uy-4u^2)^{1/2}]).$$

In Eq. (51) C is a closed contour surrounding the point $z=y$, and the expansion of the generating function $\Phi(y,x,u)$ in power of u has, for sufficiently small $|u|$, the form

$$\Phi(y,v,u)=\sum_{n=0}^{\infty}\frac{P_n(y,v)}{n!}(-u/ic)^n. \tag{53}$$

Finally in this section, we would like to interpret these polynomials as the solutions of the Schrödinger type equations. By transforming the dependent variable as

$$\Psi_n(y,v)=[(1+y^2)\rho(y,v)]^{1/2}P_n(y,v), \tag{54}$$

the first derivative term in Eq. (46) vanishes and the equation

$$\partial_y^2\Psi_n(y,v)+\frac{y^2+2v(2n+1)y+(2n+1)^2-(v^2+3)}{4(1+y^2)^2}\Psi_n(y,v)=0 \tag{55}$$

results. η being a constant of dimension $(length)^{-1}$, Eq. (55) is the time independent Schrödinger equation for the potential

$$\frac{2m}{\eta^2\hbar^2}V_n(y,v)=-\frac{y^2+2v(2n+1)y+(2n+1)^2-(v^2+3)}{4(1+y^2)^2}. \tag{56}$$

In fact, here we have a family of potentials which are labelled by n and v, and are similar to the Pösch–Teller type ($\propto-\cosh^{-2}y$) potential holes. Thus, the wave functions given by (54) are the exact zero-energy scattering states for this family of potentials. Note that for $v=0$, $V(y,0)$ is an even function, so admit the solutions $\Psi_n(y,0)$ with the same parity as n.

VI. CONCLUSION

The main points of this study can be summarized as follows. (i) By using the explicit expression for the ordered products, which form a basis for the universal enveloping algebra of the HW-algebra, we have shown that the infinite Cartan subalgebra is, in fact, the Abelian algebra of two-variable polynomials. The variables are the ordering parameter s and the c-number correspondence of the squeeze operator $\hat{x}$ which is an element of the symplectic algebra in two dimensions. We expect that these definite-parity polynomials will play an important role in two dimensional physics in which tremendous developments are taking place in the recent years (see, for instance Ref. 13, and references therein). (ii) The realization of the su(1,1) obtained in this report, is, since it contains a single variable, a difference analogue of generalized Gelfand–Dyson realization.[18] Furthermore, the analyses of section V show that this algebra play the role of ''potential algebra'' (i.e., an algebra whose generators connect the states of the same energy in different potential strengths[18]) for a class of potentials. Regarding the role of the su(1,1) algebra in the exactly solvable problems of quantum mechanics, we expect that with its realization in terms of the difference operators found in this study, or, with appropriate generalizations, it is also the underlying algebra of the exactly solvable difference equations. This point, of course, requires further studies to be done. In particular, an algebraic approach to the polynomials of a discrete variable is now under investigation. (iii) Another particularly intriguing point requiring further studies is that the basic algebraic building block underlying the difference equations seems to be an expansion of the HW-algebra, which is the basic algebraic structure of both classical and quantum mechanics. More concretely, the algebra:

$$[x,D_h]=-\Delta_h,\quad [x,\Delta_h]=\hbar^2 D_h,\quad [D_h,\Delta_h]=0,$$

satisfied by the fundamental difference operations $\{x,D_h,2\Delta_h f(x)=f(x+h)+f(x-h)\}$ is the two-dimensional Euclidean algebra $e(2)=\{L,N_1,N_2:[L,N_1]=N_2,[L,N_2]=-N_1,[N_1,N_2]=0\}$ subjected to singular transformation (with respect to N_2): $\{x=\hbar L,\Delta_h=\hbar N_1,D_h=N_2\}$. The $\hbar\to 0$ (İnönü–Wigner) contraction of this algebra is the HW-algebra generated by

$$x,\quad \partial_x=\lim_{\hbar\to 0}D_h,\quad I=\lim_{\hbar\to 0}\Delta_h.$$

Thus, we expect that it is the İnönü–Wigner and its inverse transformation which form a bridge between the exactly solvable differential and difference equations of mathematical physics. Other results in this direction and more detailed properties of these polynomial will be given elsewhere.

[16] For $s=0$ and $\hbar=1$ these polynomials coincide, up to factors of the form $n!/2^n$, with that $S_n(x)$ investigated in Refs. 7 and 8.
[17] For $\hbar=1$, i.e., $c^2=-1/4$ and $s=0$ the last line of Eqs. (19) is the lattice analog of the differential equation satisfied by the Hermite polynomials $He_n''(\xi)-2\xi He_n'(\xi)+2nHe_n(\xi)=0$ provided that $\xi=\sqrt{2}x$. This point was first observed in Ref. 8. Here we note that, for $s=0$ or $s\neq 0$ we have two additional difference recursion relations which, as we show in the main text, reveal important properties of these polynomials.

Evaluation of nonrelativistic one-loop Feynman integrals by distributional methods

Peter Wagner
Institut für Mathematik und Geometrie, Universität Innsbruck, Technikerstr. 13, A-6020 Innsbruck, Austria

(Received 20 November 1996; accepted for publication 8 December 1997)

In this paper, we use Feynman's parameter formula and distribution theory in order to represent the integrals $\int_{\mathbb{R}^{n+1}}\Pi_{k=1}^{l}(it-(1)/(2m)|x-y_k|^2+\mu)^{-1}dt\,dx$ for $m>0$, $\mu>0$, $y_k\in\mathbb{R}^n$, by definite integrals over simplices. We obtain explicit expressions in the cases of $n=2$ and $n=l=3$, respectively. © *1998 American Institute of Physics.* [S0022-2488(98)03604-4]

I. INTRODUCTION AND NOTATIONS

As has been said above, we consider the integral

$$J:=\int_{\mathbb{R}^{n+1}}\prod_{k=1}^{l}\left(it-\frac{1}{2m}|x-y_k|^2+\mu\right)^{-1}dt\,dx \tag{1}$$

for $m>0$, $\mu>0$, $y_k\in\mathbb{R}^n$. In order to guarantee the absolute convergence of J, we suppose that $l>1+(n/2)$ and that the balls

$$B_k:=\{x\in\mathbb{R}^n:|x-y_k|^2<2m\mu\},\quad k=1,...,l,$$

are in ''general position.''

In Ref. 1, Feldman, Knörrer, Sinclair, and Trubowitz have evaluated (1) for $n=2$ by methods of algebraic geometry. In particular, for $l=3$, it was found that J vanishes whenever the disks B_1,B_2,B_3 have a point in common. This observation was made earlier by Sinclair on numerical grounds.[2]

The purpose of this paper is to apply Feynman's parameter integration method to (1) and to derive thereby a representation of (1) by integrals over simplices. (A similar treatment has been given earlier in the relativistic case.[3,4]) To avoid the divergencies introduced by the parameter formula, we use distribution theory and analytic continuation with respect to the powers of the factors in (1). The resulting representation shows that J vanishes if n is an even integer and $l=n+1$, whenever the balls $B_1,\ldots,B_l$ have nonempty intersection. Finally, we state explicit formulae for J in the cases of $n=2$ and of $n=l=3$, respectively.

Let us introduce some notations. We consider $\mathbb{R}^n$ as Euclidean space with the inner product $x\cdot y:=x_1y_1+\cdots+x_ny_n$ and write $|x|:=\sqrt{x\cdot x}$. In order to display the variable(s) referred to, we sometimes use notation as $\mathbb{R}^n_x$ or $\mathbb{R}^{n+1}_{t,x}$. We denote by Σ_{n-1} the $(n-1)$-dimensional standard simplex in $\mathbb{R}^n$, i.e.,

$$\Sigma_{n-1}:=\left\{(x_1,\ldots,x_n)\in\mathbb{R}^n:x_1\geqslant 0,...,x_n\geqslant 0,\sum_{k=1}^{n}x_k=1\right\}$$

and by $d\sigma(x)$ the measure $dx_1\cdots dx_{n-1}$ on Σ_{n-1}. When we make use of the theory of distributions, we adopt the notations from Refs. 5, 6. In particular, the Heaviside function is abbreviated by Y, $\mathscr{D}'_{L^1}$ denotes the space of integrable distributions, and $\langle\phi,T\rangle$ stands for the value of the distribution T on the test function ϕ. What concerns distributions depending analytically on parameters, we refer to Refs. 7, 8. The symbol arccot stands for the principal value of this function, i.e., that which has its range in the open interval $(0,\pi)$.

II. ALGEBRAIC REDUCTION

One-loop integrals of the type (1) with more than $n+1$ factors (i.e., $l>n+1$) can algebraically be reduced to such with exactly $n+1$ factors. This goes back to Melrose[9] and Petersson.[10] We give a short deduction accomodated to our needs.

Theorem 1: Let $m,\mu>0$, $l,n\in\mathbb{N}$, $l>n+1$, *and* $y_1,\ldots,y_l\in\mathbb{R}^n$ *be such that, for each* $j=(j_1,\ldots,j_{n+1})\in\mathbb{N}^{n+1}$ *with* $1\leqslant j_1<\cdots<j_{n+1}\leqslant l$, *the vectors* M_j *and the numbers* ρ_j *determined by the equations*

$$|y_{j_r}-M_j|=\rho_j,\quad r=1,\ldots,n+1,$$

are well-defined and unique. (Hence M_j *is the center and* ρ_j *is the radius of the circumscribing sphere through* $y_{j_1},\ldots,y_{j_{n+1}}$.*) Furthermore, suppose that the numbers*

$$c_j:=(2m)^{l-n-1}\prod_{\substack{k=1\\ k\notin\{j_1,\ldots,j_{n+1}\}}}^{l}(\rho_j^2-|y_k-M_j|^2)^{-1}$$

are well-defined for j *as above. Then, for* $0\neq t\in\mathbb{R}$ *and all* $x\in\mathbb{R}^n$, *it holds*

$$\prod_{k=1}^{l}\left(it-\frac{1}{2m}|x-y_k|^2+\mu\right)^{-1}=\sum_{\substack{j=(j_1,\ldots,j_{n+1})\\ 1\leqslant j_1<\cdots<j_{n+1}\leqslant l}}c_j\prod_{r=1}^{n+1}\left(it-\frac{1}{2m}|x-y_{j_r}|^2+\mu\right)^{-1}.$$

Proof: Let us repeat first the following many-dimensional version of Lagrange's interpolation formula (for a proof see Lemma 1, p. 86, in Ref. 3):
Suppose that $1\leqslant\nu<l$ *and* $a_1,\ldots,a_l\in\mathbb{C}^\nu$ *are such that* $a_{j_1},\ldots,a_{j_\nu}$, *as well as* $a_{j_1}-a_k,\ldots,a_{j_\nu}-a_k$ *are linearly independent for pairwise different indices* $j_1,\ldots,j_\nu,k\in\{1,\ldots,l\}$. For $j=(j_1,\ldots,j_\nu)$, $1\leqslant j_1<\cdots<j_\nu\leqslant l$, *determine* $z(j)\in\mathbb{C}^\nu$ *by the system of linear equations* $a_{j_r}\cdot z(j)=1$, $r=1,\ldots,\nu$. *Then, for each complex homogeneous polynomial* $P(z_0,z)$ *of degree* $l-\nu$ *in the* $\nu+1$ *variables* z_0, $z=(z_1,\ldots,z_\nu)$, *we have*

$$P(z_0,z)=\sum_{\substack{j=(j_1,\ldots,j_\nu)\\ 1\leqslant j_1<\cdots<j_\nu\leqslant l}}P(1,z(j))\prod_{\substack{k=1\\ k\notin\{j_1,\ldots,j_\nu\}}}^{l}\frac{(z_0-a_k\cdot z)\det(a_{j_1},\ldots,a_{j_\nu})}{\det\begin{pmatrix}1&1&\cdots&1\\ a_k&a_{j_1}&\cdots&a_{j_\nu}\end{pmatrix}}.\tag{2}$$

We apply formula (2) to the case of $\nu=n+1$, $P=z_1^{l-n-1}$, and

$$a_k=\begin{pmatrix}|y_k|^2/2m-it-\mu\\ (x-2y_k)/\sqrt{2m}\end{pmatrix},\quad k=1,\ldots,l.$$

Then, from $z(j)\cdot a_{j_r}=1$, $r=1,\ldots,n+1$, we deduce, by Cramer's rule, that

$$c_j := P(1,z(j)) \prod_{\substack{k=1 \\ k\notin\{j_1,\ldots,j_{n+1}\}}}^{l} \frac{\det(a_{j_1},\ldots,a_{j_{n+1}})}{\det\begin{pmatrix} 1 & 1 & \cdots & 1 \\ a_k & a_{j_1} & \cdots & a_{j_{n+1}} \end{pmatrix}}$$

$$= \prod_{\substack{k=1 \\ k\notin\{j_1,\ldots,j_{n+1}\}}}^{l} \frac{z(j)_1 \det(a_{j_1},\ldots,a_{j_{n+1}})}{\det\begin{pmatrix} 1 & 1 & \cdots & 1 \\ a_k & a_{j_1} & \cdots & a_{j_{n+1}} \end{pmatrix}}$$

$$= \prod_{\substack{k=1 \\ k\notin\{j_1,\ldots,j_{n+1}\}}}^{l} \frac{\det\begin{pmatrix} 1 & \cdots & 1 \\ (x-2y_{j_1})/\sqrt{2m} & \cdots & (x-2y_{j_{n+1}})/\sqrt{2m} \end{pmatrix}}{\det\begin{pmatrix} 1 & 1 & \cdots & 1 \\ |y_k|^2/2m-it-\mu & |y_{j_1}|^2/2m-it-\mu & \cdots & |y_{j_{n+1}}|^2/2m-it-\mu \\ (x-2y_k)/\sqrt{2m} & (x-2y_{j_1})/\sqrt{2m} & \cdots & (x-2y_{j_{n+1}})/\sqrt{2m} \end{pmatrix}}$$

$$= \prod_{\substack{k=1 \\ k\notin\{j_1,\ldots,j_{n+1}\}}}^{l} \frac{2m \det(y_{j_2}-y_{j_1},\ldots,y_{j_{n+1}}-y_{j_1})}{\det\begin{pmatrix} |y_{j_1}|^2-|y_k|^2 & \cdots & |y_{j_{n+1}}|^2-|y_k|^2 \\ y_{j_1}-y_k & \cdots & y_{j_{n+1}}-y_k \end{pmatrix}}.$$

Because of

$$|y_{j_r}|^2-|y_k|^2-2M_j\cdot(y_{j_r}-y_k)=|y_{j_r}-M_j|^2-|y_k-M_j|^2=\rho_j^2-|y_k-M_j|^2,$$

we have

$$\det\begin{pmatrix} |y_{j_1}|^2-|y_k|^2 & \cdots & |y_{j_{n+1}}|^2-|y_k|^2 \\ y_{j_1}-y_k & \cdots & y_{j_{n+1}}-y_k \end{pmatrix}=(\rho_j^2-|y_k-M_j|^2)\det(y_{j_2}-y_{j_1},\ldots,y_{j_{n+1}}-y_{j_1}),$$

and hence

$$c_j=(2m)^{l-n-1}\prod_{\substack{k=1 \\ k\notin\{j_1,\ldots,j_{n+1}\}}}^{l}(\rho_j^2-|y_k-M_j|^2)^{-1}.$$

Therefore, Theorem 1 follows from formula (2) upon setting $z_0=0$, $z=\binom{1}{x/\sqrt{2m}}$ which implies

$$z_0-a_k\cdot z=it-\frac{1}{2m}|x-y_k|^2+\mu.$$

□

III. REPRESENTATION OF *J* BY SIMPLEX INTEGRALS

Let $\ln w$ be defined in the usual way on the slit plane $\{w\in\mathbb{C}:\operatorname{Im} w\neq 0 \text{ or } \operatorname{Re} w>0\}$. We fix $a>0$. For $z\in\mathbb{C}$ with $\operatorname{Re} z>-2$, the almost everywhere defined function

$$T_z := (it+|x|^2-a)^z = e^{z\,\ln(it+|x|^2-a)}$$

is locally integrable on $\mathbb{R}^{n+1}_{t,x}$ and of no more than polynomial growth. Furthermore,

$$T:\{z\in\mathbb{C}:\operatorname{Re} z>-2\}\to\mathscr{S}'(\mathbb{R}^{n+1}_{t,x}):z\mapsto T_z$$

is a holomorphic distribution-valued application, as one readily sees by differentiation with respect to z.

Theorem 2: *T can be extended as a holomorphic function to the whole complex plane. T_z is an integrable distribution iff* $\operatorname{Re} z<-1-(n/2)$. *In this case,*

$$\langle 1,T_z\rangle = \frac{2\pi^{n/2}\Gamma(z+1)\sin(z\pi)}{\Gamma(z+2+n/2)}\, a^{z+1+n/2}.$$

(*When the argument of either of the gamma functions vanishes or is a negative integer, then the right-hand side expression must be interpreted as a limit with respect to* z.)

Proof: (a) First notice that T_z is discontinuous at the ball $\{(0,x):|x|\leqslant a\}$ only. This implies, for Re $z>1$,

$$\frac{\partial T_z}{\partial t} = izT_{z-1} + 2i\ \sin(z\pi)\,\delta_t \otimes Y(a-|x|^2)(a-|x|^2)^z.$$

By analytic continuation, the last equation also holds for Re $z>-1$, and it allows to recursively extend T to the whole complex plane, since the same is possible for $\sin(z\pi)Y(a-|x|^2)(a-|x|^2)^z$ (comp. Ref. 7, Ch. I, 4.2, and Ch. III).

(b) On the open set $\{(t,x)\in\mathbb{R}^{n+1}: t^2+|x|^2>2a\}$, the distribution T_z is an absolutely integrable function iff Re $z<-1-n/2$. Hence $T_z\in\mathscr{D}'_{L^1}(\mathbb{R}^{n+1}_{t,x})$ iff Re $z<-1-n/2$. If, furthermore, Re $z<-2-n/2$, then $\langle 1,\partial T_{z+1}/\partial t\rangle = 0$, and hence

$$\langle 1,T_z\rangle = \frac{2}{z+1}\,\langle 1,\sin(z\pi)Y(a-|x|^2)(a-|x|^2)^{z+1}\rangle.$$

For Re $z>-2$, $U_z := \sin(z\pi)Y(a-|x|^2)(a-|x|^2)^{z+1}$ belongs to $L^1(\mathbb{R}^n_x)$, and its holomorphic extension lies in $\mathscr{D}'_{L^1}(\mathbb{R}^n)$ for all $z\in\mathbb{C}$, since it has compact support. For Re $z>-2$, we have

$$\begin{aligned}\langle 1,U_z\rangle = \sin(z\pi)\int_{|x|\leqslant\sqrt{a}}(a-|x|^2)^{z+1}\,dx &= \frac{2\pi^{n/2}\,\sin(z\pi)}{\Gamma(n/2)}\int_0^{\sqrt{a}}(a-r^2)^{z+1}r^{n-1}\,dr\\ &= \frac{\pi^{n/2}\Gamma(z+2)\sin(z\pi)}{\Gamma(z+2+n/2)}\,a^{z+1+n/2}\end{aligned}$$

(cf. Ref. 11, formula 431.2). Since the last expression for $\langle 1,U_z\rangle$ can analytically be continued to the complex plane, this completes the proof. □

Remark: Let us notice that for *negative* a and all complex z, the function $(it+|x|^2-a)^z$ is $\mathscr{C}^\infty$ on $\mathbb{R}^{n+1}$. For Re $z<-1-n/2$, this function is integrable and its integral vanishes, as readily follows from the equation

$$\frac{\partial}{\partial t}\,(it+|x|^2-a)^z = iz(it+|x|^2-a)^{z-1}$$

by partial integration with respect to t.

If we try to apply Feynman's formula

$$\prod_{k=1}^{l} w_k^{-1} = (l-1)!\int_{\Sigma_{l-1}}\frac{d\sigma(\lambda)}{(\lambda_1 w_1+\cdots+\lambda_l w_l)^l}, \tag{3}$$

valid for Re $w_1>0,\ldots,$Re $w_l>0$, (comp. Ref. 12, Th. 7-1, p. 56; Ref. 13, p. 72) in the integral (1) defining J, we obtain divergent integrals. We therefore use analytic continuation and consider, instead of the exponent -1, a complex number z. In this case, (3) takes the form

$$\prod_{k=1}^{l} w_k^{z} = \frac{\Gamma(-lz)}{\Gamma(-z)^l}\int_{\Sigma_{l-1}}\frac{(\lambda_1\cdots\lambda_l)^{-z-1}d\sigma(\lambda)}{(\lambda_1 w_1+\cdots+\lambda_l w_l)^{-lz}}. \tag{4}$$

Furthermore, we concentrate on the case of $l=n+1$, to which case the general case of $l\geqslant n+1$ can be reduced by Theorem 1.

Theorem 3: *Let* $m,\mu>0$, *and* $y_1,\ldots,y_{n+1}\in\mathbb{R}^n$ *be in general position (i.e.,* $y_2-y_1,\ldots,y_{n+1}-y_1$ *are linearly independent) and such that the balls*

$$B_k=\{x\in\mathbb{R}^n:|x-y_k|^2<2m\mu\},\quad k=1,...,n+1,$$

are in general position (i.e., no two of its boundaries touch, etc.). If Δ denotes the simplex spanned by $y_1,\ldots,y_{n+1}$, V denotes its volume, M and ρ are the center and the radius of the circumscribing sphere through $y_1,\ldots,y_{n+1}$, respectively, then

$$J:=\int_{\mathbb{R}^{n+1}}\prod_{k=1}^{n+1}\left(it-\frac{1}{2m}|x-y_k|^2+\mu\right)^{-1}dt\,dx$$

$$=\frac{(-1)^n 2\pi^{1+n/2}}{n!\Gamma(1+n/2)V}\left(\frac{\partial}{\partial\mu}\right)^n\int_\Delta(|x-M|^2-\rho^2+2m\mu)_+^{n/2}\,dx,$$

where, for

$$s\in\mathbb{R},\quad s_+:=\begin{cases}s: & s\geqslant 0,\\ 0: & s\leqslant 0.\end{cases}$$

Proof: Let $\tilde{y}_k:=y_k/\sqrt{2m\mu}$. Detailed inspection shows that the integral

$$I(z):=\int_{\mathbb{R}^{n+1}}\prod_{k=1}^{n+1}(it+|x-\tilde{y}_k|^2-1)^z\,dt\,dx$$

is absolutely convergent iff $-1-1/n<\mathrm{Re}\,z<-1+(n)/(2(n+1))$. For complex z in a neighbourhood of -1, we then obtain from the Feynman formula (4)

$$I(z)=\left\langle 1_{\mathbb{R}^{n+1}}(t,x),\prod_{k=1}^{n+1}(it+|x-\tilde{y}_k|^2-1)^z\right\rangle$$

$$=\frac{\Gamma(-(n+1)z)}{\Gamma(-z)^{n+1}}\left\langle 1_{\mathbb{R}^{n+1}}(t,x),\ \int_{\Sigma_n}\frac{(\lambda_1\cdots\lambda_{n+1})^{-z-1}d\sigma(\lambda)}{(it-1+\Sigma_{k=1}^{n+1}\lambda_k|x-\tilde{y}_k|^2)^{-(n+1)z}}\right\rangle.$$

We interchange the simplex integral with the evaluation of the integrable distribution in t and x in the integrand. (This process can be justified by considering the integrand as a distribution in t, x, and λ.) Since, for $\lambda\in\Sigma_n$,

$$it-1+\sum_{k=1}^{n+1}\lambda_k|x-\tilde{y}_k|^2=it+\left|x-\sum_{k=1}^{n+1}\lambda_k\tilde{y}_k\right|^2-a$$

with

$$a=1+\left|\sum_{k=1}^{n+1}\lambda_k\tilde{y}_k\right|^2-\sum_{k=1}^{n+1}\lambda_k|\tilde{y}_k|^2,$$

Theorem 2 yields

$$I(z)=\frac{2\pi^{n/2}\Gamma(-(n+1)z)\Gamma((n+1)z+1)\sin((n+1)z\pi)}{\Gamma(-z)^{n+1}\Gamma((n+1)z+2+n/2)}$$

$$\times\left\langle 1_{\Sigma_n}(\lambda),(\lambda_1\cdots\lambda_{n+1})^{-z-1}\left(1+\left|\sum_{k=1}^{n+1}\lambda_k\tilde{y}_k\right|^2-\sum_{k=1}^{n+1}\lambda_k|\tilde{y}_k|^2\right)_+^{(n+1)z+1+n/2}\right\rangle.\qquad(5)$$

The distribution

$$V_z:=\frac{s_+^z}{\Gamma(z+1)}\in\mathscr{S}'(\mathbb{R}^1_s),\quad \mathrm{Re}\,z>-1,$$

is holomorphically extendable to the whole complex plane (cf. Ref. 7, Ch. I, 3.5). In Eq. (5), this distribution is composed with the $\mathscr{C}^\infty$ function

$$f(\lambda)=1+\left|\sum_{k=1}^{n+1}\lambda_k\tilde{y}_k\right|^2-\sum_{k=1}^{n+1}\lambda_k|\tilde{y}_k|^2$$

(cf. Ref. 14, 7.2, p. 81) and then evaluated on Σ_n. Hence we can fix now $z=-1$ and, using

$$\lim_{z\to-1}\Gamma((n+1)z+1)\sin((n+1)z\pi)=-\frac{\pi}{n!},$$

we obtain

$$I(-1)=-2\pi^{1+n/2}\left\langle 1_{\Sigma_n}(\lambda),V_{-n/2}\left(1+\left|\sum_{k=1}^{n+1}\lambda_k\tilde{y}_k\right|^2-\sum_{k=1}^{n+1}\lambda_k|\tilde{y}_k|^2\right)\right\rangle.$$

Since $V_{-n/2}$ is the n-th derivative of the ordinary function $s_+^{n/2}/\Gamma(1+n/2)$, we infer, with the substitutions $x=\sqrt{2m\mu}\tilde{x}$, $t=-\mu\tilde{t}$, the following:

$$\begin{aligned}J&=\int_{\mathbb{R}^{n+1}}\prod_{k=1}^{n+1}\left(it-\frac{1}{2m}|x-y_k|^2+\mu\right)^{-1}dt\,dx\\&=(-1)^{n+1}\left(\frac{2m}{\mu}\right)^{n/2}I(-1)\\&=\frac{(-1)^n2\pi^{1+n/2}}{\Gamma(1+(n/2))}\left(\frac{2m}{\mu}\right)^{n/2}\left\langle 1_{\Sigma_n}(\lambda),(s_+^{n/2})^{(n)}\left(1+\left|\sum_{k=1}^{n+1}\lambda_k\tilde{y}_k\right|^2-\sum_{k=1}^{n+1}\lambda_k|\tilde{y}_k|^2\right)\right\rangle\\&=\frac{(-1)^n2\pi^{1+n/2}}{\Gamma(1+(n/2))}\left(\frac{\partial}{\partial\mu}\right)^n\int_{\Sigma_n}\left(2m\mu+\left|\sum_{k=1}^{n+1}\lambda_k y_k\right|^2-\sum_{k=1}^{n+1}\lambda_k|y_k|^2\right)_+^{n/2}d\sigma(\lambda).\end{aligned}$$

Finally, we apply the affine transformation

$$\Sigma_n\to\Delta:\lambda\mapsto\sum_{k=1}^{n+1}\lambda_k y_k,$$

which has the Jacobian $n!V$. The quadratic form

$$\left|\sum_{k=1}^{n+1}\lambda_k y_k\right|^2-\sum_{k=1}^{n+1}\lambda_k|y_k|^2$$

vanishes on the corners of Σ_n and hence transforms to $|x-M|^2-\rho^2$. This gives

$$J=\frac{(-1)^n2\pi^{1+n/2}}{n!\Gamma(1+(n/2))V}\left(\frac{\partial}{\partial\mu}\right)^n\int_\Delta(|x-M|^2-\rho^2+2m\mu)_+^{n/2}dx.$$

and completes the proof. □

Remark: For even n, the distribution

$$\left(\frac{\partial}{\partial\mu}\right)^n(|x-M|^2-\rho^2+2m\mu)_+^{n/2}$$

has its support on the set

$$S:=\{x\in\mathbb{R}^n:|x-M|^2=\rho^2-2m\mu\},$$

which is either the empty set $\emptyset$, or a sphere. If the balls

$$B_k:=\{x\in\mathbb{R}^n:|x-y_k|^2<2m\mu\},\quad k=1,\ldots,n+1,$$

have a point, say x_0, in common, then, for $\lambda \in \Sigma_n$ and $x=\Sigma_{k=1}^{n+1}\lambda_k y_k \in \Delta$,

$$|x-M|^2-\rho^2=\left|\sum_{k=1}^{n+1}\lambda_k y_k\right|^2-\sum_{k=1}^{n+1}\lambda_k|y_k|^2=\left|\sum_{k=1}^{n+1}\lambda_k(y_k-x_0)\right|^2-\sum_{k=1}^{n+1}\lambda_k|y_k-x_0|^2>-2m\mu,$$

and hence $S\cap\Delta=\emptyset$ and consequently $J=0$.

IV. SPECIAL CASES

Let us consider first the case of two space dimensions. By Theorem 1, it is sufficient to consider three factors, i.e.,

$$J=\int_{\mathbb{R}^3}\prod_{k=1}^{3}\left(it-\frac{1}{2m}|x-y_k|^2+\mu\right)^{-1}dt\,dx.$$

As above, let Δ be the triangle spanned by y_1,y_2,y_3 in $\mathbb{R}^2$, let V denote its area, M and ρ be the center and the radius of the circumscribing circle through y_1,y_2,y_3, respectively.

Since

$$\left(\frac{\partial}{\partial\mu}\right)^2(|x-M|^2-\rho^2+2m\mu)_+=4m^2\delta(|x-M|^2-\rho^2+2m\mu),$$

three cases arise: If $\rho<\sqrt{2m\mu}$, then $J=0$. Similarly, if $\rho>\sqrt{2m\mu}$ and the circle S with center M and radius $\sqrt{\rho^2-2m\mu}$, does not meet Δ, then $J=0$. (These two cases just correspond to the intersection of B_1,B_2,B_3 being non-empty; compare the Remark above.) Finally, if $\rho>\sqrt{2m\mu}$ and the curve $\emptyset\neq S\cap\Delta$ has length L, then, by Theorem 3,

$$J=\frac{2\pi^2m^2L}{V\sqrt{\rho^2-2m\mu}}.$$

(Note that the total measure of $\delta(|x-M|^2-\rho^2+2m\mu)$ is π.)

By expressing L through the lengths and angles in the triangle Δ, we arrive at a more explicit if less visual representation of J.

Theorem 4: *Let $m,\mu>0$, $l\in\mathbb{N}$, $l\geqslant 3$, and $y_1,\ldots,y_l\in\mathbb{R}^2$ be such that no three of them lie on a line and no four of them lie on a circle. For the disks*

$$B_k=\{x\in\mathbb{R}^2:|x-y_k|^2<2m\mu\},\quad k=1,\ldots,l,$$

suppose further that no two of the boundaries ∂B_k, $k=1,\ldots,l$, touch and no three of these boundaries have a point in common.

For $j=(j_1,j_2,j_3)\in\mathbb{N}^3$ with $1\leqslant j_1<j_2<j_3\leqslant l$, let Δ_j denote the triangle with corners y_{j_1},y_{j_2},y_{j_3}, let V_j denote its area, and let M_j and ρ_j be the center and the radius of the circumscribing circle through y_{j_1},y_{j_2},y_{j_3}, respectively. As in Theorem 1 define

$$c_j:=(2m)^{l-3}\prod_{\substack{k=1\\ k\notin\{j_1,j_2,j_3\}}}^{l}(\rho_j^2-|y_k-M_j|^2)^{-1}.$$

Let ϵ_j be 0 *if the disks B_{j_1},B_{j_2},B_{j_3} meet, and 1 else. Finally, denote by*

$$a_{j,r}:=|y_{j_s}-y_{j_t}|,\quad \alpha_{j,r}:=\angle(y_{j_s}-y_{j_r},y_{j_t}-y_{j_r}),\quad \{r,s,t\}=\{1,2,3\},$$

the lengths and angles in the triangle Δ_j. Then

$$J:=\int_{\mathbb{R}^3}\prod_{k=1}^{l}\left(it-\frac{1}{2m}\,|x-y_k|^2+\mu\right)^{-1}dt\;dx$$

$$=4m^2\pi^2\sum_{\substack{j=(j_1,j_2,j_3)\\1\leqslant j_1<j_2<j_3\leqslant l}}c_j\,\frac{\epsilon_j}{V_j}\left[\pi-\sum_{r=1}^{3}Y(a_{j,r}-2\sqrt{2m\mu})\operatorname{arccot}\left(\frac{2\rho_j\cos(\alpha_{j,r})}{\sqrt{a_{j,r}^2-8m\mu}}\right)\right].$$

Proof: As above, define

$$S_j:=\{x\in\mathbb{R}^2:|x-M_j|^2=\rho_j^2-2m\mu\}$$

and denote by L_j the length of $S_j\cap\Delta_j$. According to what has been said before Theorem 4 and using Theorem 1, it remains only to be shown that, in the case of $\epsilon_j=1$,

$$\frac{L_j}{\sqrt{\rho_j^2-2m\mu}}=2\pi-2\sum_{r=1}^{3}Y(a_{j,r}-2\sqrt{2m\mu})\operatorname{arccot}\left(\frac{2\rho_j\cos(\alpha_{j,r})}{\sqrt{a_{j,r}^2-8m\mu}}\right).$$

Note that S_j intersects the edge of Δ_j spanned by y_{j_s} and y_{j_t} iff $a_{j,r}>2\sqrt{2m\mu}$. In this case, the distance of the intersection points from M_j is $\sqrt{\rho_j^2-2m\mu}$ and these points lie $\sqrt{a_{j,r}^2-8m\mu}$ apart. The corresponding angle $\beta_{j,r}$ along which the circle S_j runs outside of Δ_j then either is $\gamma_{j,r}$ or $2\pi-\gamma_{j,r}$, according to whether the angle $\alpha_{j,r}$ is acute or obtuse, and where we have set

$$\gamma_{j,r}:=2\arcsin\left(\sqrt{\frac{a_{j,r}^2/4-2m\mu}{\rho_j^2-2m\mu}}\right).$$

An easy conversion yields

$$\beta_{j,r}=2\operatorname{arccot}\left(\frac{2\rho_j\cos(\alpha_{j,r})}{\sqrt{a_{j,r}^2-8m\mu}}\right).$$ □

Finally, let us consider the case of $n=l=3$. Though it is not contained in Theorem 3, a completely analogous calculation gives

$$J=\frac{4m^2\pi^2}{V}\int_{\Delta}(|x-M|^2-\rho^2+2m\mu)_+^{-1/2}d\sigma(x),\quad s_+:=\begin{cases}s: & s\geqslant 0,\\ 0: & s\leqslant 0,\end{cases}$$

where Δ denotes the triangle in $\mathbb{R}^3$ spanned by y_1,y_2,y_3, V its area, $d\sigma(x)$ its surface measure, and M and ρ the center and the radius of the circumscribing circle through y_1,y_2,y_3, respectively.

After shifting M to the origin, we can integrate radially. These radial integrals have the form

$$\int_{(\rho^2-2m\mu)_+^{1/2}}^{c/\cos\varphi}(r^2-\rho^2+2m\mu)^{-1/2}r\;dr$$

and consequently yield angular integrals of the form

$$\int\sqrt{\frac{c^2}{\cos^2\varphi}-\rho^2+2m\mu}\;d\varphi.$$

These latter integrals also give elementary transcendental functions. Several cases must be distinguished according to whether the triangle Δ is acute or obtuse, and whether $\rho<\sqrt{2m\mu}$. We merely state the final result.

Theorem 5: *Let $m,\mu>0$, and suppose $y_1,y_2,y_3\in\mathbb{R}^3$ are not collinear and are such that the boundaries of the balls*

$$B_k=\{x\in\mathbb{R}^3:|x-y_k|^2<2m\mu\},\quad k=1,2,3,$$

do not touch.

Let Δ be the triangle in $\mathbb{R}^3$ spanned by y_1,y_2,y_3, and denote by V its area, by $\alpha_1,\alpha_2,\alpha_3$ its angles, and by ρ the radius of its circumscribing circle, respectively. Then the integral defining J is absolutely convergent and it holds

$$\begin{aligned}J&:=\int_{\mathbb{R}^4}\prod_{k=1}^{3}\left(it-\frac{1}{2m}|x-y_k|^2+\mu\right)^{-1}dt\,dx\\&=-\frac{8m^2\pi^3}{V}(2m\mu-\rho^2)_+^{1/2}+\frac{4m^2\pi^2\rho}{V}\sum_{k=1}^{3}\cos\alpha_k\ln\left(\left|\frac{\sqrt{2m\mu}+\rho\sin\alpha_k}{\sqrt{2m\mu}-\rho\sin\alpha_k}\right|\right)\\&\quad+\frac{4m^2\pi^2\sqrt{|\rho^2-2m\mu|}}{V}\begin{cases}2\displaystyle\sum_{k=1}^{3}\operatorname{arccot}\left(\frac{\sqrt{2m\mu}\cot\alpha_k}{\sqrt{2m\mu-\rho^2}}\right): & \rho^2<2m\mu,\\ \displaystyle\sum_{k=1}^{3}\ln\left(\left|\frac{\sqrt{2m\mu}\cot\alpha_k-\sqrt{\rho^2-2m\mu}}{\sqrt{2m\mu}\cot\alpha_k+\sqrt{\rho^2-2m\mu}}\right|\right): & \rho^2\geqslant 2m\mu.\end{cases}\end{aligned}$$

ACKNOWLEDGMENTS

I should like to express my gratitude to Professor Horst Knörrer, who called my attention to the integrals treated in this paper, who invited me to Zürich to discuss matters, and who pointed out two errors in a preliminary version of this paper.

(Received 13 August 1997; accepted for publication 3 November 1997)

We discuss Bloch and Wannier functions composed of Gaussian orbitals. The fact that the Bloch functions may be expressed in terms of θ-functions is used to discuss them in detail. We study not only their analyticity properties, but also features of expectation values of some specifically chosen Hamiltonians. We also investigate the localization properties of various choices of Wannier functions and compare them with the original Gauss functions. Likewise, we discuss in a more general context the relationship between the analyticity properties of Bloch functions and the localization properties of corresponding Wannier functions. © *1998 American Institute of Physics.* [S0022-2488(98)00404-6]

I. INTRODUCTION

Localized but nonorthogonal functions, like Gaussian orbitals, are widely used in physical applications (see for instance Ref. 1). In the case of periodic crystals the most prominent and important functions for describing their electronic properties are Bloch[2,3] and Wannier[4] functions. Here we study in detail Bloch and Wannier functions which are composed of Gaussian orbitals.

It was G. H. Wannier[5] who first realized that these Bloch functions may be expressed in terms of θ-functions. By choosing the phase factors appropriately he was also able to give an explicit expression for the corresponding Wannier functions. These Wannier functions, however, are not symmetric due to his specific choice of the phase factors. We extend his work by considering also a symmetric choice of Wannier functions, which are shown to be the best localized Wannier functions composed of Gaussian orbitals and we also discuss in detail the totally different analyticity properties of the corresponding Bloch functions. In addition, we study expectation values of some specifically chosen Hamiltonians. We cannot only give explicit formulas for them but also prove several monotonicity properties of them. Last we discuss in general the relationship between the analyticity properties of the Bloch functions and a generalized exponential decrease of the Wannier functions.

The paper has the following structure: First we discuss the analyticity properties of the Bloch functions composed of Gaussian orbitals. Of course, the analyticity properties of Bloch functions are, in principle, well known for one dimensional crystals since this subject was extensively discussed in the famous paper of Kohn.[6] Also much is known about the analyticity properties in higher dimensions due to the classical papers of Cloizeaux[7] and the more recent paper of Nenciu.[8] Nevertheless it seems to be interesting to discuss the analytical properties for an explicit example, since it shows that the Riemann surface may be completely different for different choices of Bloch functions. Moreover recently the analyticity of Bloch functions played an important role in the theory of band representations.[9] We explicitly give the Riemann surfaces for two different choices of Bloch functions: For Wannier's choice[5] it is just the real plane with the exception of some points, in case of a symmetric choice of Bloch functions however, the Riemann surface consists of two sheets which are stuck together at an infinity of finite intervals. The second part deals with the localization properties of the corresponding Wannier functions. Apart from the exponential decrease of the Wannier functions implied by analyticity, we discuss the uncertainty Δx of the Wannier functions. We show that a certain symmetric choice of Wannier functions have the same

 © 1998 American Institute of Physics

Δx as the original Gauss functions and these Wannier functions are the best localized ones. In the third part we discuss expectation values for some Hamiltonians. Various monotonicity properties are shown, for instance we prove that the expectation value of the kinetic energy is a monotone function of the wave vector $k \in [0,\pi]$ and a monotone function of the localization parameter describing the original Gaussians. In the last section we consider the following generalization of exponential fall off: instead of requiring that the Wannier functions fall off exponentially $|W(x)| \leqslant e^{-\gamma|x|}B$, where γ and B are positive constants and $W(x)$ is the Wannier function, we require only that the integral

$$\int_{y-\epsilon}^{y+\epsilon} |W_0(x)|^2 dx \leqslant e^{-2\gamma|y|}B(\epsilon)$$

falls off exponentially. We then prove that the Wannier functions fall off exponentially in this generalized sense if and only if the corresponding Bloch functions are vector valued analytic functions.

II. BLOCH FUNCTIONS

For the sake of simplicity we confine the discussion to the one-dimensional case exclusively, its generalization to higher dimensions should be discussed elsewhere. Let $G^\beta: \mathbb{R} \to \mathbb{R}$

$$G^\beta(x) = \left(\frac{2\beta}{\pi}\right)^{1/4} e^{-\beta x^2} \tag{1}$$

be a one-dimensional Gaussian wave function normalized to unity with respect to the usual $L^2(\mathbb{R})$-norm. Here $\beta = 1/4\sigma^2$, where σ is the standard deviation of the Gaussian distribution $|G^\beta(x)|^2$, i.e., $\sigma^2 = \int_{-\infty}^{\infty} dx x^2 |G^\beta(x)|^2 = (G^\beta, x^2 G^\beta)_\infty$, where $(\cdot,\cdot)_\infty$ denotes the usual inner product of $L^2(\mathbb{R})$. The corresponding Bloch functions $\phi_k^\beta: \mathbb{R} \to \mathbb{C}$ read (lattice constant $a=1$)

$$\phi_k^\beta(x) = N^\beta(k) \sum_{n=-\infty}^{\infty} e^{ikn} G_n^\beta(x), \tag{2}$$

where $G_n^\beta(x) = G^\beta(x-n)$ are the shifted Gaussian orbitals. The normalization constants $N^\beta(k)$ are chosen real and positive, where the Bloch functions are normalized such that $(\phi_k^\beta, \phi_k^\beta)_1 = \int_0^1 dx |\phi_k^\beta(x)|^2 = 1/2\pi$, where the entry $(\cdot,\cdot)_1$ denotes the inner product on $L^2([0,1])$. By introducing the θ-function[10–12]

$$\theta_3(z|\tau) = \sum_{n=-\infty}^{\infty} e^{in^2\pi\tau} e^{i2nz}, \quad \text{Im } \tau > 0, \tag{3}$$

the Bloch function may be written in the following way:[5]

$$\phi_k^\beta(x) = N^\beta(k) \left(\frac{2\beta}{\pi}\right)^{1/4} e^{-\beta x^2} \theta_3\left(\frac{k}{2} - i\beta x \middle| \frac{i\beta}{\pi}\right), \tag{4}$$

where the normalization constant $N^\beta(k)$ is given by

$$N^\beta(k) = \frac{1}{\sqrt{2\pi}} \frac{1}{\sqrt{\theta_3\left(\frac{k}{2}\middle|\frac{i\beta}{2\pi}\right)}}. \tag{5}$$

It is easy to verify the following symmetry properties of the Bloch functions. The reality of the Gauss functions implies the time reversal symmetry

$$(\phi_k^\beta(x))^* = \phi_{-k}^\beta(x), \tag{6}$$

and the inversion symmetry of the Gauss function gives rise to the following transformation law with respect to inversion:

$$\phi_k^\beta(-x)=\phi_{-k}^\beta(x). \tag{7}$$

Note that these Bloch functions correspond to a band representation[13] of the only nontrivial one-dimensional space group characterized by the Wyckoff position $w=0$ and the trivial one-dimensional irreducible unitary representation of the corresponding site symmetry group, which is isomorphic to C_2.

The normalization constants $N^\beta(k)$ may be expressed as an infinite product[5,10–12]

$$N^\beta(k)=\frac{1}{\sqrt{2\pi}}\prod_{n=1}^{\infty}[(1-q^{2n})^{-1/2}(1+q^{2n-1}e^{ik})^{-1/2}(1+q^{2n-1}e^{-ik})^{-1/2}], \tag{8}$$

where $q:=e^{-\beta/2}$. This formula motivated Wannier to use alternative normalization constants[5]

$$\tilde{N}^\beta(k)=\frac{1}{\sqrt{2\pi}}\prod_{n=1}^{\infty}(1-q^{2n})^{-1/2}(1+q^{2n-1}e^{-ik})^{-1}. \tag{9}$$

Obviously the expression for the normalization constants $\tilde{N}^\beta(k)$ is much simpler than the formula for $N^\beta(k)$. In addition one gets an explicit expression for the Wannier functions if one chooses $\tilde{N}^\beta(k)$ instead of $N^\beta(k)$. The great advantage of $N^\beta(k)$, however, is that the corresponding Bloch functions have the symmetry properties Eqs. (6) and (7). The corresponding Bloch functions for $\tilde{N}^\beta(k)$ only fulfill Eq. (6), whereas Eq. (7) has to be replaced by

$$\phi_k^\beta(-x)=\frac{\tilde{N}^\beta(k)}{\tilde{N}^\beta(-k)}\,\phi_{-k}^\beta(x), \tag{10}$$

which implies that the corresponding Wannier functions are not symmetric. Note in passing that both normalization constants are periodic functions in k-space, namely they satisfy the condition $N^\beta(k)=N^\beta(k+2\pi N)$, and hence in both cases the Bloch functions have the same property: $\phi_k^\beta=\phi_{k+2\pi N}^\beta$, $N\in\mathbb{Z}$.

Since needed later on we summarize some further properties of the θ-functions. There exist four different types of θ-functions. We have already mentioned θ_3, hence we state only the three other ones here:

$$\theta_1(z|\tau)=-i\sum_{n=-\infty}^{\infty}(-1)^n e^{i(n+1/2)^2\pi\tau}e^{i(2n+1)z}, \tag{11}$$

$$\theta_2(z|\tau)=\sum_{n=-\infty}^{\infty}e^{i(n+1/2)^2\pi\tau}e^{i(2n+1)z}, \tag{12}$$

$$\theta_4(z|\tau)=\sum_{n=-\infty}^{\infty}(-1)^n e^{in^2\pi\tau}e^{i2nz}. \tag{13}$$

They are linearly independent but by an appropriate change of variable each one may be transformed into each other one. For these relations as well as periodicity and quasi-periodicity properties, product expansions and Jacobi's transformation, which will be used frequently in the following, we refer to the literature.[10–12]

III. ANALYTICITY PROPERTIES OF THE BLOCH FUNCTIONS

So far x and k have been real. But obviously both G^β and ϕ_k^β may be defined for complex x and complex $k=\kappa+i\rho$, too. Here $N(k)$ is defined by Eq. (8) for complex k, too. Note that with this definition the equation $\int_0^1 dx|\phi_k^\beta(x)|^2=1/2\pi$ holds true only for real k. To discuss the

dependence of the Bloch functions ϕ_k^β on k we introduce the function $\Phi^\beta: \mathsf{R}\times\mathbb{C}\to\mathbb{C}$, $\Phi^\beta(k,x) = \phi_k^\beta(x)$, where R is an appropriate subset of the complex plane or, more generally, an appropriate Riemann surface. We will use the term Bloch function for Φ^β, too, but to our mind this should not lead to any confusion. Similarly we define the function $\mathbf{N}^\beta: \mathsf{R}\to\mathbb{C}$, $\mathbf{N}^\beta(k) = N^\beta(k)$.

We want to discuss the analyticity properties of the Bloch functions now. In this context we have to refer to the famous articles of Kohn,[6] who considered the analyticity properties for the one-dimensional case, and to the work of Cloizeaux[7] and Nenciu,[8] who discussed the analyticity problem in higher dimensions.

We investigate the analyticity properties of the Bloch function Φ^β now. To this end note that θ_3 is an entire function of z, i.e., analytic for all $z\in\mathbb{C}$. Hence the Bloch function Φ^β is an analytic function of x in the whole complex plane. The analyticity of θ_3 implies also that the Bloch function Φ^β is an analytic function of k for all k for which the normalization constant $\mathbf{N}^\beta(k)$ is analytic. Obviously $\mathbf{N}^\beta(k)$ is analytic at a point k if and only if $\theta_3(k/2|i\beta/2\pi)$ is not zero. Since the zeros of this θ-function[10–12] are given by $k=(m+\frac{1}{2})2\pi+(n+\frac{1}{2})i\beta$, the normalization constant $\mathbf{N}^\beta$ and hence the Bloch function Φ^β are analytic functions of k in the strip

$$S^\beta = \left\{ k=\kappa+i\rho : |\rho| < \frac{\beta}{2} \right\}. \tag{14}$$

Note that the width of the strip is proportional to β, which is a measure of the localization of the Gauss functions. Thus if the Bloch functions are composed of strongly localized Gaussian orbitals the strip of analyticity is broad, whereas in case of weakly localized Gaussian orbitals the strip of analyticity is small. In the limit $\beta\to 0$ the domain of analyticity vanishes, and in fact, as we show in the next section, the Bloch function is not analytic in this limiting case, it is even discontinuous.

Note in passing that the domain of analyticity can be extended consistently, namely it can be enlarged to the whole plane without cuts ranging from $k=(m+\frac{1}{2})2\pi\pm i\beta/2$ to $(m+\frac{1}{2})2\pi\pm i\infty$, respectively, thus

$$D^\beta = \mathbb{C}\setminus\left\{ k:\mathrm{Re}\ k=(2m+1)\pi,\ \ |\mathrm{Im}\ k| \geqslant \frac{\beta}{2},\ \ m\in\mathbb{Z} \right\}. \tag{15}$$

In fact, we can show also more. If we go around a singularity on a closed path, then the sign of the normalization constant $\mathbf{N}^\beta$ has changed if we return to the starting point. On the other hand if the path encloses an even number of singularities, then we return to the starting point with the same phase. From this one infers easily that the domain of analyticity can be extended to

$$D_1^\beta = \mathbb{C}\setminus\{k:\mathrm{Re}\ k=(2m+1)\pi,\ \ (2n+\tfrac{1}{2})\beta \leqslant |\mathrm{Im}\ k| \leqslant (2n+\tfrac{3}{2})\beta,\ \ m\in\mathbb{Z},\ \ n\in\mathbb{N}_0\}. \tag{16}$$

The Riemann surface consists of the two sheets D_1^β, which are stuck together at the intervals $k:\mathrm{Re}\ k=(2m+1)\pi$, $(2n+\frac{1}{2})\beta<|\mathrm{Im}\ k|<(2n+\frac{3}{2})\beta$, $m\in\mathbb{Z}$, $n\in\mathbb{N}_0$. On one sheet the normalization constant $\mathbf{N}^\beta$ has the same values as before, and on the other sheet $\mathbf{N}^\beta$ is defined with the opposite sign.

Similarly one can derive the analyticity properties of $\widetilde{\mathbf{N}}^\beta(k)$. Here half of the zeros of the denominator are removed,[5] and hence $\widetilde{\mathbf{N}}^\beta(k)$ and the corresponding Bloch function are analytic in the half-plane

$$\widetilde{S}^\beta = \left\{ k=\kappa+i\rho : \rho < \frac{\beta}{2} \right\}. \tag{17}$$

Also in this case the domain of analyticity may be extended, namely,

$$\widetilde{D}^\beta = \mathbb{C}\setminus\left\{ k:\mathrm{Re}\ k=(2m+1)\pi,\ \ \mathrm{Im}\ k \geqslant \frac{\beta}{2},\ \ m\in\mathbb{Z} \right\}. \tag{18}$$

Since the singularities $k=(m+\frac{1}{2})2\pi+i\beta(n+\frac{1}{2})$, $m\in\mathbb{Z}$, $n\in\mathbb{N}_0$ are simple poles, we infer immediately that $\widetilde{\mathbf{N}}^\beta$ is analytic in

$$\widetilde{D}_1^\beta = \mathbb{C}\backslash\{k: \mathrm{Re}\ k = (2m+1)\pi,\ \ \mathrm{Im}\ k = \beta(n+1/2),\ \ m\in\mathbb{Z},\ \ n\in\mathbb{N}_0\}. \tag{19}$$

Note that this is also the Riemann surface.

From these equations we infer that $\widetilde{\mathbf{N}}^\beta$ is analytic in a larger part of the complex plane than $\mathbf{N}^\beta$, if we restrict our considerations to the complex plane. If we compare the Riemann surfaces, then $\widetilde{\mathbf{N}}^\beta$ has obviously the simpler Riemann surface. Hence from the viewpoint of analyticity, $\widetilde{\mathbf{N}}^\beta$ is the better choice of the normalization constant.

IV. WANNIER FUNCTIONS

We adopt the following conventions for the Wannier functions $W_n^\beta: \mathbb{R}\to\mathbb{R}$:

$$W_n^\beta(x) = \frac{1}{(2\pi)^{1/2}} \int_0^{2\pi} dk\ \phi_k^\beta(x) e^{-ikn}. \tag{20}$$

Note that the Wannier functions are real $W_n^\beta(x) = W_n^\beta(x)^*$ because of the symmetry $(\phi_k^\beta)^* = \phi_{-k}^\beta$ and the periodicity $\phi_k^\beta = \phi_{k+2\pi N}^\beta$ of the Bloch functions. Note that this is valid for both choices of the normalization constant. In general, however, the Wannier functions defined by $\widetilde{W}_n^\beta(x) = (1/(2\pi)^{1/2}) \int_{-\pi}^{\pi} dk e^{i\varphi(k)} \phi_k^\beta(x) e^{-ikn}$ with arbitrary real $\varphi(k)$ are complex functions. In fact, if and only if $\varphi(-k) = -\varphi(k)$, the Wannier functions $\widetilde{W}_n$ are real, too. More generally, we may define the Wannier functions by $\widetilde{W}_n^{\beta,a}(x) = [1/(2\pi)^{1/2}] \int_{-\pi+a}^{\pi+a} dk e^{i\varphi(k)} \phi_k^\beta(x) e^{-ikn}$. Unless $e^{i\varphi(k)} = e^{i\varphi(k+2\pi)}$ for all k, the Wannier functions $\widetilde{W}_n^{\beta,a}$ will be different for different values of $a\in\mathbb{R}$, respectively.

The analyticity of the Bloch function implies the exponential decay of the corresponding Wannier functions. From theorem 1 below, we infer

$$|W_0^\beta(x)| \leqslant e^{-\gamma|x|} B^\beta(\gamma) \tag{21}$$

which holds for all $\gamma < \beta/2$, where $B^\beta(\gamma)$ is an appropriate constant. In fact, for our special Wannier functions this result can be slightly improved, namely

$$|W_0^\beta(x)| \leqslant e^{-(\beta/2)|x|} B^\beta. \tag{22}$$

This is due to the fact that the poles of $(\mathbf{N}^\beta)^2$ are simple. An explicit formula for the Wannier functions cannot be given but there is an explicit formula for its Fourier transform:

$$W_0^\beta(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{ikx} \frac{1}{\theta_3\left(\dfrac{i\pi k}{\beta}\middle|\ \dfrac{2\pi i}{\beta}\right)^{1/2}} dk = \frac{1}{2\pi} \left(\frac{2\pi}{\beta}\right)^{1/4} \int_{-\infty}^{\infty} e^{ikx} \frac{e^{-(1/4\beta)k^2}}{\theta_3\left(\dfrac{k}{2}\middle|\ \dfrac{i\beta}{2\pi}\right)^{1/2}} dk. \tag{23}$$

Now we turn to the Wannier functions $\widetilde{W}_0^\beta(x)$ corresponding to the normalization constant $\widetilde{\mathbf{N}}^\beta$. It is given explicitly[5] by

$$\widetilde{W}_0^\beta(x) = \left(\frac{2\beta}{\pi}\right)^{1/4} \prod_{n=1}^{\infty} (1-e^{-\beta n})^{-1/2} \left[e^{-\beta x^2} + \sum_{m=1}^{\infty} (-1)^m \frac{e^{-(\beta/2)m}}{\Pi_{p=1}^m (1-e^{-\beta p})} e^{-\beta(x-m)^2} \right]. \tag{24}$$

These functions are discussed exhaustively in Ref. 5, so we summarize just the main properties. For $x\to-\infty$ they fall off like Gaussians, which is due to the fact that the Bloch functions are analytic in the lower half of the complex plane. For positive x again Eq. (22) is valid.

At the first glance one would suppose that these Wannier functions $\widetilde{W}_0^\beta(x)$ are the better localized ones. But a more detailed analysis reveals that this is not true. This is due to the exponentially damped oscillating tail on the right side, whose oscillations are a few times greater then the two oscillating tails of $W_0^\beta(x)$. For large β, for instance, the oscillations of $\widetilde{W}_0^\beta(x)$ are twice as large as the oscillations of $W_0^\beta(x)$, since we have

$$W_0^\beta(x)=\left(\frac{2\beta}{\pi}\right)^{1/4}\left(e^{-\beta x^2}-\frac{e^{-\beta/2}}{2}\,(e^{-\beta(x+1)^2}+e^{-\beta(x-1)^2})\right)+O(e^{-\beta}), \tag{25}$$

$$\widetilde{W}_0^\beta(x)=\left(\frac{2\beta}{\pi}\right)^{1/4}(e^{-\beta x^2}-e^{-\beta/2}e^{-\beta(x-1)^2}). \tag{26}$$

A criterium for localization is the uncertainty Δx. Since the mean value vanishes because of symmetry, i.e., $\langle x\rangle=0$, it is sufficient to compute $\langle x^2\rangle_{W_0^\beta}$, where the index W_0^β denotes that the mean value $\langle x^2\rangle$ with respect to the Wannier function W_0^β is considered. A straightforward calculation yields

$$\langle x^2\rangle_{W_0^\beta}=1/4\beta. \tag{27}$$

Note that the same result is also valid for the original Gauss functions: $\langle x^2\rangle_{G^\beta}=1/4\beta$. The expectation value $\langle x\rangle_{\widetilde{W}_0^\beta}$ vanishes, too, although $\widetilde{W}_0^\beta$ is not symmetric. This fact can be easily checked by direct calculation, or alternatively one uses the concept of the Berry phase:[14,15] Using kq-representation[16] we get

$$\langle \widetilde{W}_0^\beta, x\widetilde{W}_0^\beta\rangle = i\int_0^1 dx\int_{-\pi}^{\pi} dk\ \tilde{\omega}_k^\beta(x)^*\ \frac{\partial}{\partial k}\ \tilde{\omega}_k^\beta(x)=\frac{1}{2\pi}\,a^\beta(2\pi), \tag{28}$$

where $\tilde{\omega}_k^\beta(x)$ is the periodic part of the Bloch functions $\tilde{\phi}_k^\beta(x)$, and $a^\beta(2\pi)$ is the Berry phase. Since the Berry phase does not depend on the particular choice of the Wannier functions, but only on the ''energy band,'' i.e., on the subspace which is spanned by the Wannier functions, we infer $\langle x\rangle_{\widetilde{W}_0^\beta}=\langle x\rangle_{W_0^\beta}=0$.

One quickly verifies that the expectation value $\langle x^2\rangle_{\widetilde{W}_0^\beta}$ is given by the following expression

$$\langle x^2\rangle_{\widetilde{W}_0^\beta}=\frac{1}{4\beta}+\frac{1}{2\pi}\int_{-\pi}^{\pi} dk\left|\frac{\partial\varphi^\beta(k)}{\partial k}\right|^2, \tag{29}$$

where $\varphi^\beta(k)$ is definded by

$$e^{i\varphi^\beta(k)}=\frac{\widetilde{N}^\beta(k)}{N^\beta(k)}=\prod_{n=1}^{\infty}\,(1+e^{-(\beta/2)(2n-1)}e^{ik})^{1/2}(1+e^{-(\beta/2)(2n-1)}e^{-ik})^{-1/2}. \tag{30}$$

An explicit expression for $\varphi^\beta(k)$ is given by

$$\varphi^\beta(k)=\sum_{n=1}^{\infty}\left[\frac{k}{2}-\arctan\left(\tanh\left(\frac{\beta}{4}\,(2n-1)\right)\tan\frac{k}{2}\right)\right]. \tag{31}$$

From Eq. (29) we infer immediately $\Delta x_{\widetilde{W}_0^\beta}>\Delta x_{W_0^\beta}$, i.e., the symmetric Wannier functions W_0^β are better localized than Wannier's Wannier functions $\widetilde{W}_0^\beta$. The integral in Eq. (29) can be evaluated and we obtain

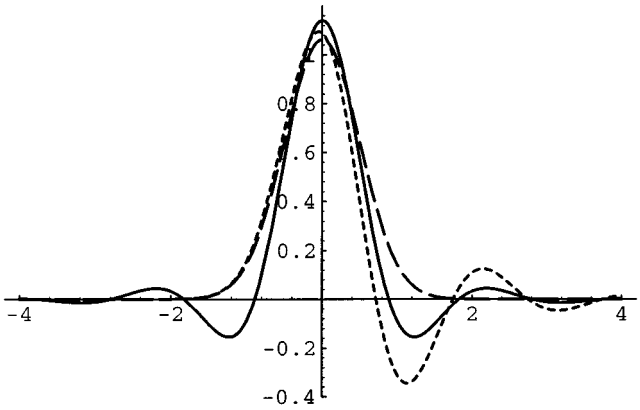

FIG. 1. Gauss function (dashed line), symmetric Wannier function and Wannier's Wannier function (dotted line) for $\beta=2$.

$$\langle x^2\rangle_{\tilde{W}_0^\beta}=\frac{1}{4\beta}+\frac{1}{2}\sum_{n=1}^{\infty}\frac{e^{-\beta n}}{(1-e^{-\beta n})^2}=\frac{1}{4\beta}+\frac{1}{48}\left(\frac{\theta_1'''\left(0\middle|\frac{i\beta}{2\pi}\right)}{\theta_1'\left(0\middle|\frac{i\beta}{2\pi}\right)}+1\right)$$

$$=\frac{1}{48}\left[1-\left(\frac{2\pi}{\beta}\right)^2\frac{\theta_1'''\left(0\middle|\frac{2\pi i}{\beta}\right)}{\theta_1'\left(0\middle|\frac{2\pi i}{\beta}\right)}\right]. \tag{32}$$

For small and large values of β one easily proves

$$(\Delta x_{\tilde{W}_0^\beta})^2=\frac{1}{4\beta}+\frac{1}{2}e^{-\beta}+O(e^{-2\beta}) \quad \text{for large } \beta \tag{33}$$

$$(\Delta x_{\tilde{W}_0^\beta})^2=\frac{\pi^2}{12\beta^2}+\frac{1}{48}+O\left(\frac{e^{-4\pi^2/\beta}}{\beta^2}\right) \quad \text{for small } \beta. \tag{34}$$

Thus for large values of β our symmetric and Wannier's Wannier functions are almost equally well localized, but for small β the symmetric Wannier functions are much better localized. See also Fig. 1 and Fig. 2.

Hence the advantage of $\tilde{W}_0^\beta(x)$ is not its localization property but the fact that there is an explicit expression for it. On the other hand, the advantage of $W_0^\beta(x)$ is its symmetry. Moreover the uncertainty Δx is smaller for the symmetric Wannier functions $W_0^\beta(x)$. In fact, this choice of Wannier functions has the smallest possible Δx. This is due to the fact that Eq. (29) is valid for any Wannier function, if $\varphi^\beta(k)$ denotes the phase by which the corresponding Bloch functions differ from our symmetric Bloch functions $\phi_k^\beta(x)$.

V. THE LIMIT $\beta\to 0$

Let us study the limit $\beta\to 0$. Note that the Gauss functions G^β converge to zero uniformly, but they do not converge to zero with respect to the $L^2(\mathbb{R})$-norm, since $\|G^\beta\|=1$ for all β. Note however that the Gauss functions converge in the weak topology to the zero function, i.e., for each square integrable function ψ the equation $\lim_{\beta\to 0}(\psi,G^\beta)_\infty=0$ holds. Since the Bloch functions and Wannier functions are normalized with respect to $L^2([0,1])$ and $L^2(\mathbb{R})$, respectively, their limits are not necessarily trivial.

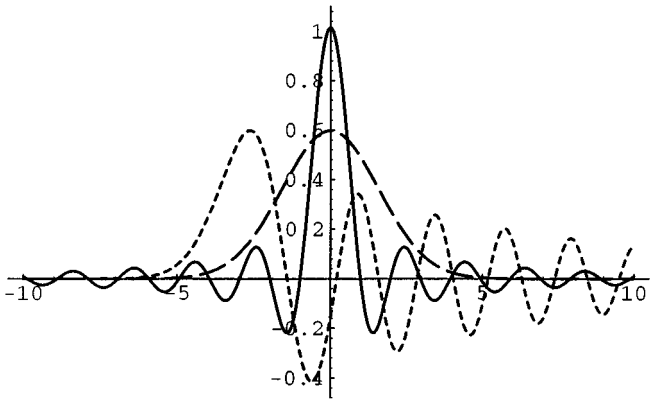

FIG. 2. Gauss function (dashed line), symmetric Wannier function and Wannier's Wannier function (dotted line) for $\beta=0.2$.

When calculating the limit of the Bloch functions $\phi_k^\beta(x)$ we use a formula which may be obtained by using the Jacobi transformation of the theta function:[5,10–12]

$$\phi_k^\beta(x)=e^{ikx}\omega_k^\beta(x), \tag{35a}$$

$$\omega_k^\beta(x)=\frac{1}{\sqrt{2\pi}}\frac{\theta_3\left(\frac{i\pi}{\beta}\frac{k}{2}+\pi x\middle|\frac{i\pi}{\beta}\right)}{\sqrt{\theta_3\left(\frac{i\pi}{\beta}k\middle|\frac{2i\pi}{\beta}\right)}}. \tag{35b}$$

Here $\omega_k^\beta(x)$ is the periodic Bloch factor. Now the limit of the Bloch functions $\phi_k^\beta(x)$ for $\beta\to 0$ is immediately obtained:

$$\phi_k^0(x)=\lim_{\beta\to 0}\phi_k^\beta(x)=\frac{1}{\sqrt{2\pi}}e^{i(k-2\pi l)x} \tag{36}$$

for $k\neq(2n+1)\pi$, where l is the unique integer for which $|k-2\pi l|<\pi$ holds, and

$$\lim_{\beta\to 0}\phi_k^\beta(x)=\frac{1}{\sqrt{\pi}}\cos(\pi x)\quad\text{for}\quad k=(2n+1)\pi. \tag{37}$$

The convergence is uniform with respect to x for any subset of $\mathbb{R}$ and uniform with respect to k for any interval $[(2n-1)\pi+\epsilon,(2n+1)\pi-\epsilon],\epsilon>0$. The convergence cannot be uniform with respect to k in a neighborhood of $(2n+1)\pi$ since the limit function $\Phi^0=\lim_{\beta\to 0}\Phi^\beta$ is not continuous at $k=(2n+1)\pi$. Note that the Bloch functions ϕ_k^β converge with respect to the $L^2([0,1])$-norm because of the uniform convergence with respect to x. Note that this limit describes the case of free electrons.

The limit of the Wannier functions is given by

$$W_0^0(x)=\lim_{\beta\to 0}W_0^\beta(x)=\frac{1}{\sqrt{2\pi}}\int_{-\pi}^{\pi}\phi_k^0(x)dk=\frac{\sin(\pi x)}{\pi x}. \tag{38}$$

Of course the Wannier functions converge uniformly with respect to x. Moreover, they converge also with respect to the $L^2(\mathbb{R})$-norm.

Note that the Bloch functions corresponding to $\tilde{\mathbf{N}}^\beta$ do not converge, since the quotient

$$\frac{\tilde{\mathbf{N}}^{\beta}}{\mathbf{N}^{\beta}}=\prod_{n=1}^{\infty}\frac{(1+q^{2n-1}e^{ik})^{1/2}}{(1+q^{2n-1}e^{-ik})^{1/2}} \tag{39}$$

does not converge for $\beta\to 0$. Hence there does not exist a limit [with respect to the $L^2(\mathbb{R})$-norm] for the corresponding Wannier functions either. However, numerical calculations suggest that the Wannier functions converge to zero uniformly on $\mathbb{R}$; see Figs. 1 and 2.

VI. EXPECTATION VALUES

One of the most interesting properties of a physical system is its energy. Here we consider the expectation values of some Hamiltonians $H=(1/2m)P^2+V$ with respect to the thetalike Bloch functions, where the potentials V are chosen specifically. Note that the expectation values are independent of the specific choice of the normalization constants and hence all the following results are equally valid for both cases.

A. The kinetic energy

First we compute the expectation value of the kinetic energy $T=(1/2m)P^2$. Due to the specific normalization of the Bloch functions, the expectation value $\langle P^2\rangle_k^{\beta}$ is given by

$$\langle P^2\rangle_k^{\beta}=2\pi(\phi_k^{\beta},P^2\phi_k^{\beta})_1. \tag{40}$$

A straightforward calculation gives the following result for the expectation value $\langle P^2\rangle_k^{\beta}$:

$$\langle P^2\rangle_k^{\beta}=\beta-\sum_{n=-\infty}^{\infty}e^{-\beta(n^2/2)}e^{-ikn}\beta^2n^2\Big/\sum_{n=-\infty}^{\infty}e^{-\beta(n^2/2)}e^{-ikn}. \tag{41}$$

This result may be written in terms of θ-functions, and by using Jacobi's transformation[10–12] we get an alternative formula:

$$\begin{aligned}\langle P^2\rangle_k^{\beta}&=\beta+2\beta^2\frac{\partial}{\partial\beta}\ln\,\theta_3\left(\frac{k}{2}\middle|\,\frac{i\beta}{2\pi}\right)\\&=2\beta^2\frac{\partial}{\partial\beta}\ln\left(e^{-k^2/2\beta}\theta_3\left(\frac{i\pi}{\beta}\,k\middle|\,\frac{2\pi i}{\beta}\right)\right)\\&=\sum_{n=-\infty}^{\infty}e^{-(k-2\pi n)^2/2\beta}(k-2\pi n)^2\Big/\sum_{n=-\infty}^{\infty}e^{-(k-2\pi n)^2/2\beta}.\end{aligned} \tag{42}$$

These formulas do not only hold true for real k but also for complex k, if we define

$$\langle P^2\rangle_k^{\beta}=2\pi(\phi_{k*}^{\beta},P^2\phi_k^{\beta})_1, \tag{43}$$

where k^* is the complex conjugate of k. Now we see easily that $\langle P^2\rangle_k^{\beta}$ is an analytic function of k in the strip $\{k=\kappa+i\rho:|\rho|<\beta/2\}$ for all $\beta>0$.

For the limit of large and small β one can derive simple formulas:

$$\langle P^2\rangle_k^{\beta}=\beta-2e^{-\beta/2}\beta^2\cos k+O(e^{-\beta}\beta^2)\quad\text{for}\quad\beta\to\infty, \tag{44a}$$

$$\langle P^2\rangle_k^{0}=k^2\quad\text{for}\quad k\in[-\pi,\pi]. \tag{44b}$$

There are some interesting monotonicity properties of $\langle P^2\rangle_k^{\beta}$: First, $\langle P^2\rangle_k^{\beta}$ is a strictly monotone increasing function of β. This is easily seen by considering the derivative of Eq. (42) and using Cauchy–Schwarz's inequality

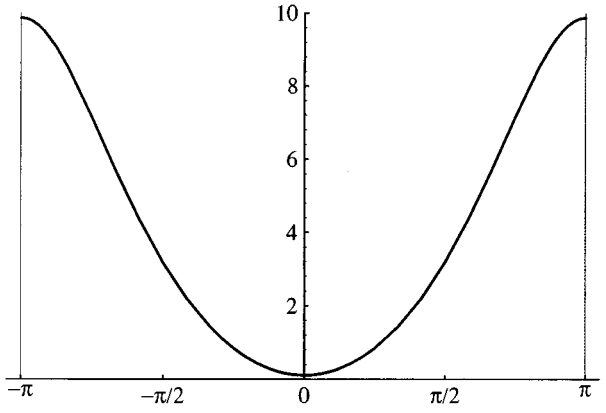

FIG. 3. $\langle P^2\rangle_k^\beta$ for $\beta=3$.

$$\frac{\partial}{\partial\beta}\langle P^2\rangle_k^\beta=\frac{1}{2\beta^2}\left(\sum_{n=-\infty}^{\infty}e^{-(k-2\pi n)^2/2\beta}(k-2\pi n)^4\Big/\sum_{n=-\infty}^{\infty}e^{-(k-2\pi n)^2/2\beta}\right)$$
$$-\frac{1}{2\beta^2}\left[\left(\sum_{n=-\infty}^{\infty}e^{-(k-2\pi n)^2/2\beta}(k-2\pi n)^2\right)^2\Big/\left(\sum_{n=-\infty}^{\infty}e^{-(k-2\pi n)^2/2\beta}\right)^2\right]>0. \tag{45}$$

$\langle P^2\rangle_k^\beta$ is also a strictly monotone increasing function of k in the interval $[0,\pi]$, because $\beta^2(\partial/\partial\beta)\ln\theta_3(k/2|i\beta/2\pi)$ is a strictly monotone increasing function of k in the interval $[0,\pi]$. A proof of this fact is given in the Appendix.

Let us have a look on the symmetry properties of $\langle P^2\rangle_k^\beta$. Obviously $\langle P^2\rangle_k^\beta$ is an even function of k. We could infer this also from the time reversal symmetry $(\phi_k^\beta)^*=\phi_{-k}^\beta$ together with the reality of P^2 or alternatively from the inversion symmetry $\phi_k^\beta(x)=\phi_{-k}^\beta(-x)$ together with the inversion symmetry of P^2. Moreover $\langle P^2\rangle_k^\beta$ is periodic in k-space.

These properties are illustrated by the following figures: Fig. 3 shows the expectation value $\langle P^2\rangle_k^\beta$ for $\beta=3$; Fig. 4 displays $\langle P^2\rangle_k^\beta$ as a function of k and β. One clearly sees the symmetry and monotonicity properties with respect to k and β, respectively.

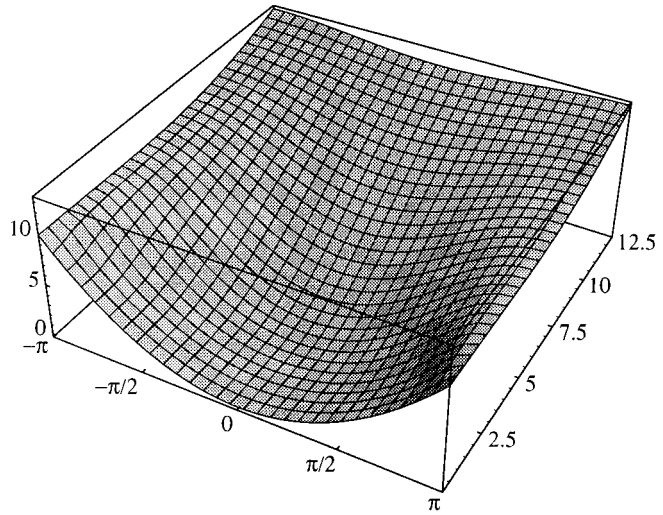

FIG. 4. $\langle P^2\rangle_k^\beta$ for $-\pi\leqslant k\leqslant\pi$ and $0.1\leqslant\beta\leqslant 12.5$.

B. The potential energy

Next we consider the expectation value of a periodic potential, whose period is equal to 1. Thus we assume $V(x)=V(x+n)$, $n\in\mathbb{Z}$. First we derive a formula for general potentials and later we discuss some special examples. To this end we need the following two θ-functions:

$$\theta_2(z|\tau)=\sum_{n=-\infty}^{\infty} e^{i(n+1/2)^2\pi\tau}e^{i(2n+1)z}, \tag{46}$$

$$\theta_4(z|\tau)=\sum_{n=-\infty}^{\infty} (-1)^n e^{in^2\pi\tau}e^{i2nz}. \tag{47}$$

We obtain the following formula:

$$\langle V\rangle_k^\beta = 2\pi(\phi_k^\beta, V\phi_k^\beta)_1 = V_+^\beta + \frac{\theta_4\left(\frac{k}{2}\middle|\frac{i\beta}{2\pi}\right)}{\theta_3\left(\frac{k}{2}\middle|\frac{i\beta}{2\pi}\right)} V_-^\beta = V_+^\beta + \frac{\theta_2\left(\frac{i\pi k}{\beta}\middle|\frac{2\pi i}{\beta}\right)}{\theta_3\left(\frac{i\pi k}{\beta}\middle|\frac{2\pi i}{\beta}\right)} V_-^\beta, \tag{48}$$

where we have used the definitions

$$V_\pm^\beta := \left(\frac{2\beta}{\pi}\right)^{1/2}\int_{-\infty}^{\infty} dx\ e^{-2\beta x^2}\frac{1}{2}\left(V(x)\pm V\left(x+\frac{1}{2}\right)\right). \tag{49}$$

Note that the expectation value of the potential depends in a simple manner on the actual shape of the potential, namely only the two parameters V_+^β and V_-^β enter in Eq. (48). Let us discuss the k-dependence of $\langle V\rangle_k^\beta$ now. First we observe that $\langle V\rangle_k^\beta$ is constant if V_-^β vanishes, i.e., if $V(x)$ has a period equal to $\frac{1}{2}$. Next assume $V_-^\beta\neq 0$. Since $\theta_4(k/2|i\beta/2\pi)$ is a strictly monotone increasing function (see the Appendix) for $k\in[0,\pi]$ and $\theta_3(k/2|i\beta/2\pi)$ is strictly monotone decreasing in the same interval, $\langle V\rangle_k^\beta$ is also strictly monotone for $k\in[0,\pi]$: it is strictly monotone increasing if V_-^β is positive and strictly monotone decreasing if V_-^β is negative.

Another interesting property of $\langle V\rangle_k^\beta$ is its inversion symmetry in k-space. This is due to the symmetry relation $|\phi_k^\beta(x)|^2=|\phi_{-k}^\beta(x)|^2$ which follows from the time reversal symmetry $(\phi_k^\beta(x))^*=\phi_{-k}^\beta(x)$. Note also that $\langle V\rangle_k^\beta$ is periodic in k-space.

Note that Eq. (48) is not only valid for real k but also for complex values of k provided that we define

$$\langle V\rangle_k^\beta = 2\pi(\phi_{k^*}^\beta, V\phi_k^\beta)_1. \tag{50}$$

With this definition $\langle V\rangle_k^\beta$ is analytic in the strip $\{k=\kappa+i\rho:|\rho|<\beta/2\}$ for all $\beta>0$. This follows immediately from Eq. (48) and the properties of the theta functions. But we can argue more generally, too. Let us assume that the potential $V(x)$ is bounded, i.e., the operator V is bounded and therefore continuous. Then the analyticity of Φ^β implies the analyticity of $V\Phi^\beta$ and together with the analyticity of Φ_*^β the analyticity of $\langle V\rangle_k^\beta$ follows. Here Φ_*^β is defined by $\Phi_*^\beta(k):=(\phi_{k^*}^\beta)^*$, where k^* is the complex conjugate of k.

Let us discuss the two coefficients $V_\pm^\beta$ in more detail. First we observe that only the symmetric part enters in the coefficients $V_\pm^\beta$, i.e., if $V(x)=V_e(x)+V_0(x)$, where $V_e(x)$ and $V_0(x)$ are the even and odd parts of the potential $V(x)$, then we have

$$V_\pm^\beta = \left(\frac{2\beta}{\pi}\right)^{1/2}\int_{-\infty}^{\infty} dx e^{-2\beta x^2}\frac{1}{2}\left(V_e(x)\pm V_e\left(x+\frac{1}{2}\right)\right). \tag{51}$$

This property is due to the inversion symmetry $|\phi_k^\beta(x)|^2=|\phi_k^\beta(-x)|^2$, which follows from Eqs. (6) and (7), and hence only the even part $V_e(x)$ contributes to the expectation value $\langle V\rangle_k^\beta$. Now let

$$V(x)=\sum_{n=-\infty}^{\infty} c_n e^{i2\pi nx} \tag{52}$$

be the Fourier expansion of the potential V. Then we have

$$V_+^\beta = c_0 + \sum_{n=1}^{\infty} e^{-2\pi^2 n^2/\beta}(c_{2n}+c_{-2n}), \tag{53a}$$

$$V_-^\beta = \sum_{n=0}^{\infty} e^{-\pi^2(2n+1)^2/2\beta}(c_{2n+1}+c_{-2n-1}), \tag{53b}$$

from which we could also infer immediately that only the even part $V_e(x)$ contributes to $\langle V\rangle_k^\beta$.

In the limit of large and small β one gets simple formulas. For small β we have the following formula:

$$\langle V\rangle_k^\beta = c_0 + \frac{2e^{-\pi^2/\beta}\cosh(k\pi/\beta)}{1+4e^{-2\pi^2/\beta}\cosh^2(k\pi/\beta)}(c_1+c_{-1}) + O(e^{-2\pi^2})$$

$$= c_0 + \frac{1}{2\cosh((\pi-k)\pi/\beta)}(c_1+c_{-1}) + O(e^{-\pi^2}), \tag{54}$$

where $k\in[-\pi,\pi]$ in the first equation and $k\in[0,\pi]$ in the second one. From this it follows immediately that the limit $\beta\to 0$ is given by

$$\langle V\rangle_k^0 = \lim_{\beta\to 0}\langle V\rangle_k^\beta = c_0 \quad \text{for} \quad k\neq(2n+1)\pi,\ \ n\in\mathbb{Z}, \tag{55a}$$

$$\langle V\rangle_k^0 = \lim_{\beta\to 0}\langle V\rangle_k^\beta = c_0+\tfrac{1}{2}(c_1+c_{-1}) \quad \text{for} \quad k=(2n+1)\pi,\ \ n\in\mathbb{Z}. \tag{55b}$$

This discontinuity is not surprising since the limit of the Bloch function for $\beta\to 0$ is not continuous either. The physical reason is evident, too: If $-\pi<k<\pi$, then $\langle V\rangle_k^0$ is simply the energy correction of the first energy band in first order perturbation theory. For $k=\pi$ perturbation theory for degenerate eigenvalues has to be used and the energy correction in first order perturbation theory is given by $c_0\pm\frac{1}{2}(c_1+c_{-1})$. Hence $\langle V\rangle_\pi^\beta$ is the energy correction for the first band if c_1+c_{-1} is negative. If $c_1+c_{-1}>0$, however, $\langle V\rangle_\pi^\beta$ is the first order energy correction for the second band. This is not surprising since $V(x)$ is attractive at $x=n$ and repulsive at $x=n+\frac{1}{2}$ for $c_1+c_{-1}<0$ (if we retain only the first terms of the Fourier expansion) and hence Bloch functions composed of Gaussian orbitals centered at $x=n$ provide us with a good approximation. For $c_1+c_{-1}>0$, however, the situation is opposite, namely, $V(x)$ is repulsive at $x=n$ and attractive at $x=n+\frac{1}{2}$, and hence it is not reasonable to use Gaussian orbitals centered at $x=n$ to construct Bloch functions for this case.

We also mention briefly the case for large β. Here we have

$$\langle V\rangle_k^\beta = V_+^\beta + (1-4e^{-\beta/2}\cos k)V_-^\beta + O(e^{-\beta}) \tag{56}$$

and in the limit $\beta\to\infty$ we obtain $\langle V\rangle_k^\infty = V(0)$.

The two cases of small and large β are illustrated in Figs. 5 and 6, respectively. In both cases we have chosen $V_-^\beta = 2\exp(-\pi^2/2\beta)$ and $V_+^\beta = 0$.

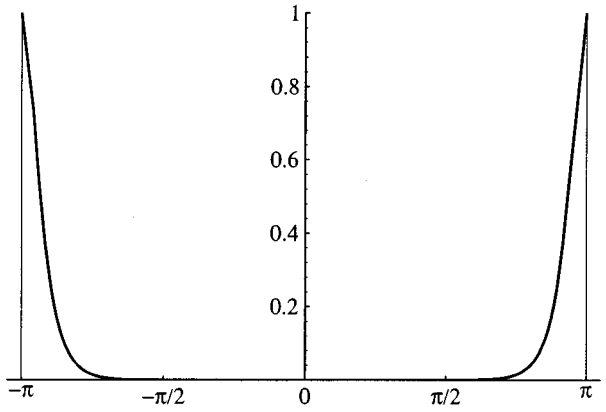

FIG. 5. $\langle V\rangle_k^\beta$ for $\beta=0.5$ with $V_-^\beta=2\exp(-\pi^2/2\beta)$ and $V_+^\beta=0$.

Example

We consider the following potential:

$$V^\alpha(x)=-\sqrt{\frac{\alpha}{\pi}}\sum_{n=-\infty}^{\infty}e^{-\alpha(x-n)^2}=-\sqrt{\frac{\alpha}{\pi}}\,e^{-\alpha x^2}\theta_3\left(i\alpha x\middle|\frac{i\alpha}{\pi}\right)$$
$$=-\theta_3\left(\pi x\middle|\frac{i\pi}{\alpha}\right)$$
$$=-1-2\sum_{n=1}^{\infty}e^{-(\pi^2/\alpha)n^2}\cos(2\pi nx). \tag{57}$$

Note that the limit of V^α for $\alpha\to\infty$ is the periodic delta function

$$\lim_{\alpha\to\infty}V^\alpha(x)=-\sum_{n=-\infty}^{\infty}\delta(x-n), \tag{58}$$

whereas for $\alpha\to 0$ we have

$$\overline{V}(x):=\lim_{\alpha\to 0}e^{\pi^2/\alpha}(V^\alpha(x)+1)=-2\cos(2\pi x). \tag{59}$$

The coefficients $V_\pm^\beta$ now depend on alpha and are denoted by $V_\pm^\beta(\alpha)$. They read as follows:

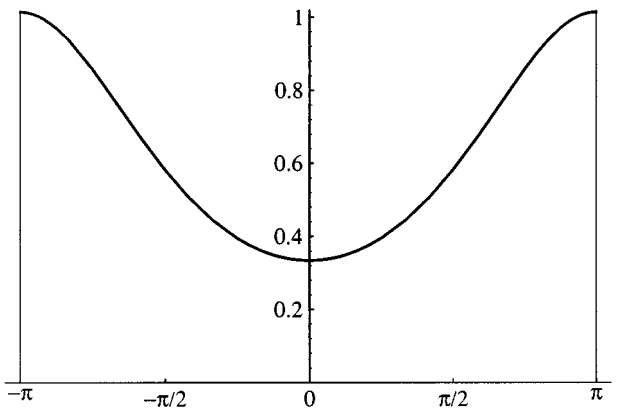

FIG. 6. $\langle V\rangle_k^\beta$ for $\beta=4$ with $V_-^\beta=2\exp(-\pi^2/2\beta)$ and $V_+^\beta=0$.

$$V_+^\beta(\alpha) = -\left(\frac{\alpha\beta}{2\pi(2\beta+\alpha)}\right)^{1/2}\theta_3\left(0\left|\frac{i\alpha\beta}{2\pi(2\beta+\alpha)}\right.\right) = -\theta_3\left(0\left|\frac{2\pi i(2\beta+\alpha)}{\alpha\beta}\right.\right), \tag{60a}$$

$$V_-^\beta(\alpha) = -\left(\frac{\alpha\beta}{2\pi(2\beta+\alpha)}\right)^{1/2}\theta_4\left(0\left|\frac{i\alpha\beta}{2\pi(2\beta+\alpha)}\right.\right) = -\theta_2\left(0\left|\frac{2\pi i(2\beta+\alpha)}{\alpha\beta}\right.\right). \tag{60b}$$

In the limit $\alpha\to\infty$ we obtain

$$V_+^\beta(\infty) = -\left(\frac{\beta}{2\pi}\right)^{1/2}\theta_3\left(0\left|\frac{i\beta}{2\pi}\right.\right) = -\theta_3\left(0\left|\frac{2\pi i}{\beta}\right.\right) = -\sum_{n=-\infty}^{\infty}\exp\left(-\frac{2\pi^2}{\beta}n^2\right), \tag{61a}$$

$$V_-^\beta(\infty) = -\left(\frac{\beta}{2\pi}\right)^{1/2}\theta_4\left(0\left|\frac{i\beta}{2\pi}\right.\right) = -\theta_2\left(0\left|\frac{2\pi i}{\beta}\right.\right) = -\sum_{n=-\infty}^{\infty}\exp\left(-\frac{\pi^2}{2\beta}(2n+1)^2\right). \tag{61b}$$

For the other limit $\alpha\to 0$ we have

$$\overline{V}_+^\beta = \lim_{\alpha\to 0} e^{\pi^2/\alpha}(V_+^\beta + 1) = 0, \tag{62a}$$

$$\overline{V}_-^\beta = -\lim_{\alpha\to 0} e^{\pi^2/\alpha}V_-^\beta = \exp\left(-\frac{\pi^2}{2\beta}\right). \tag{62b}$$

Comparing Eqs. (61) with (62) we see that they look quite similar for small β. In fact, if we introduce the rescaled potential

$$\overline{V}^\alpha(x) = e^{\pi^2/\alpha}(V^\alpha(x)+1), \tag{63}$$

we can easily prove that the corresponding coefficients $\overline{V}_\pm^\beta(\alpha)$ are nearly independent of α for small β and are approximately given by

$$\overline{V}_+^\beta(\alpha) = O\left[\exp\left(-\frac{3\pi^2}{\alpha}\right)\exp\left(-\frac{2\pi^2}{\beta}\right)\right], \tag{64a}$$

$$\overline{V}_-^\beta(\alpha) = 2\exp\left(-\frac{\pi^2}{2\beta}\right) + O\left[\exp\left(-\frac{8\pi^2}{\alpha}\right)\exp\left(-\frac{9\pi^2}{2\beta}\right)\right]. \tag{64b}$$

The reason for this is that for small β only the first terms of the Fourier expansion of the potential $V(x)$ are relevant. In Fig. 7 we present the expectation value $\langle V^\alpha\rangle_k^\beta$ of the rescaled potential $\overline{V}^\alpha(x)$ as a function of k and β. Note the symmetry and monotonicity of $V^\alpha(x)$. The expectation value of the corresponding Hamiltonian $H = P^2 + d\overline{V}^\alpha(x)$ is shown in Fig. 8, where we have chosen $\alpha = 20$ and $d = 5$.

VII. THE CONNECTION BETWEEN THE ANALYTICITY OF THE BLOCH FUNCTIONS AND THE EXPONENTIAL FALL OFF OF THE WANNIER FUNCTIONS

So far we have discussed only the special Bloch functions which are composed of Gaussian orbitals. Now we want to consider the general case of analytic Bloch functions. Here we call a Bloch function Φ analytic if the functions $\phi_x : \phi_x(k) = \Phi(k,x)$ are analytic functions of k for all $x \in \mathbb{R}$.

It is well known that the analyticity of the Bloch functions implies the exponential decrease of the Wannier functions[6,8,7] provided that the Bloch functions are continuous functions of x. But in general the Bloch functions need not to be continuous since they are only square integrable in the unit cell. Hence the Wannier functions may have infinitely many singularities and thus they do not fall off exponentially in the usual sense. Nevertheless they fall off ''almost'' exponentially in a sense explained later.

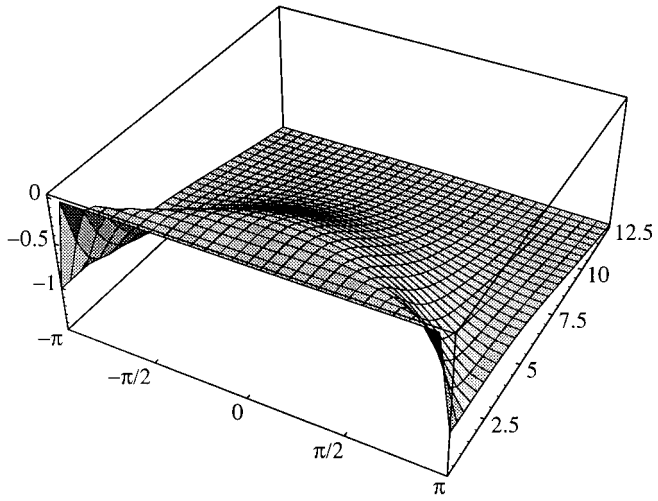

FIG. 7. $\langle V^{\alpha}\rangle_k^{\beta}$ for $\alpha=20$, $-\pi\leqslant k\leqslant\pi$, $0.1\leqslant\beta\leqslant 12.5$.

First we review the traditional arguments. Throughout this section we assume that $\Phi:\Phi(k,x)=\phi_k(x)$ be a Bloch function which is analytic in the open strip $\{k:|\mathrm{Im}\,k|<\Gamma\}$ and which is periodic in k-space: $\Phi(k+2\pi,x)=\Phi(k,x)$. Moreover we assume that Φ is normalized in the following way: $(\phi_k,\phi_k)_1=\int_0^1 dx|\phi_k(x)|^2=1/2\pi$ for real k. Again we adopt the following convention for the corresponding Wannier functions:

$$W_n(x)=\frac{1}{(2\pi)^{1/2}}\int_0^{2\pi} dk\,\phi_k(x)e^{-ikn}. \tag{65}$$

First note that we have

$$|W_0(x+n)|\leqslant e^{\mp\gamma n}\frac{1}{(2\pi)^{1/2}}\int_0^{2\pi} dk|\phi_{k\pm i\gamma}(x)| \tag{66}$$

for $\gamma<\Gamma$, which is easily proved by shifting the path of integration:

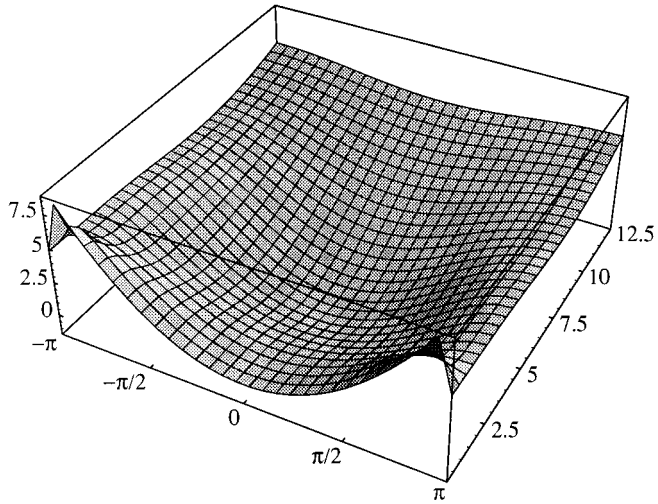

FIG. 8. $\langle H\rangle_k^{\beta}$ for $d=5$, $-\pi\leqslant k\leqslant\pi$, $0.1\leqslant\beta\leqslant 12.5$.

$$W_0(x+n)=\frac{1}{(2\pi)^{1/2}}\int_0^{2\pi}dk\,\phi_k(x)e^{ikn}=e^{\mp\gamma n}\frac{1}{(2\pi)^{1/2}}\int_0^{2\pi}dk\,\phi_{k\pm i\gamma}(x)e^{ikn}. \tag{67}$$

If we assume that the Bloch functions are bounded, e.g., if the Bloch functions are continuous with respect to x, then we derive immediately

$$|W_0(x+n)|\leqslant e^{\mp\gamma(x+n)}B(\gamma), \tag{68}$$

or equivalently

$$|W_0(x)|\leqslant e^{-\gamma|x|}B(\gamma), \tag{69}$$

where $B(\gamma)$ is defined as

$$B(\gamma)=\sup_{-1/2\leqslant x\leqslant 1/2}e^{\pm\gamma x}\frac{1}{(2\pi)^{1/2}}\int_0^{2\pi}dk|\phi_{k\pm i\gamma}(x)|. \tag{70}$$

Hence the Wannier functions fall off exponentially. The converse statement is true as well, i.e., if Eq. (69) is valid for all $\gamma<\Gamma$, then the corresponding Bloch functions are analytic in the open strip $\{k:|\mathrm{Im}\,k|<\Gamma\}$ and are periodic in k and bounded. This is easily verified by considering the expansion

$$\Phi(k,x)=\frac{1}{\sqrt{2\pi}}\sum_{n=-\infty}^{\infty}e^{ikn}W_n(x). \tag{71}$$

We summarize this in the following theorem:

Theorem 1: *Let Φ be periodic and analytic in the open strip $\{k:|\mathrm{Im}\,k|<\Gamma\}$ for fixed x, where Γ does not depend on x. If Φ is bounded in $\{k:|\mathrm{Im}\,k|\leqslant\gamma\}\times[-\frac{1}{2},\frac{1}{2}]$ with $\gamma<\Gamma$, then the Wannier functions fall off exponentially*

$$|W_0(x)|\leqslant e^{-\gamma|x|}B(\gamma), \tag{72}$$

where $B(\gamma)$ is an appropriate constant. Conversely, if Eq. (72) holds for all $\gamma<\Gamma$, then Φ is periodic and analytic in the open strip $\{k:|\mathrm{Im}\,k|<\Gamma\}$ for fixed x, and it is bounded in $\{k:|\mathrm{Im}k|\leqslant\gamma\}\times[-\frac{1}{2},\frac{1}{2}]$ for all $\gamma<\Gamma$.

In general, a square integrable[17] Bloch function ϕ_k need not be bounded, hence Φ is not bounded. So Theorem 1 is not applicable in general. Nevertheless the Wannier functions fall off ''almost'' exponentially. This means that we do not consider the probability density $|W_0(x)|^2$, instead of it we discuss the probability for finding the electron in the interval $[y-\epsilon,y+\epsilon]$, which is given by $\int_{y-\epsilon}^{y+\epsilon}|W_0(x)|^2dx$. In fact, it is this quantity that falls off exponentially.

To discuss this behavior we need the concept of a vector-valued analytic function. Let $\mathscr{H}$ be a Hilbert space and $\psi:D\to\mathscr{H}$, $D\subseteq\mathbb{C}$ a vector-valued function of the complex variable z, i.e., $\psi(z)\in\mathscr{H}$, then ψ is called a vector-valued analytic function[18,19] if for all $z\in D$ the limit $\lim_{h\to 0}[\psi(z+h)-\psi(z)]/h=:\psi'(z)$ exists as a strong limit[20] in $\mathscr{H}$. We want to apply this definition to the Bloch function Φ. Of course, for fixed k, the Bloch function ϕ_k is not square integrable on $\mathbb{R}$ and hence the Bloch function Φ cannot be interpreted as an analytic function from $\mathbb{C}$ to $L^2(\mathbb{R})$. But if we restrict the domain of definition of the Bloch functions ϕ_k to the unit cell $[-\frac{1}{2},\frac{1}{2}]$, these restricted functions are members of $L^2([-\frac{1}{2},\frac{1}{2}])$. If the domain of definition of Φ is restricted correspondingly we may view Φ as a vector valued function from $D\subseteq\mathbb{C}$ into $L^2([-\frac{1}{2},\frac{1}{2}])$. If this restriction of Φ is an analytic vector-valued function of k, we will call Φ an analytic vector-valued function.

Theorem 2: *If the Bloch function Φ is an analytic vector-valued function of k in the open strip $\{k:|\mathrm{Im}\,k|<\Gamma\}$ and if Φ is a periodic function of k with period 2π, then the following inequality holds for all $\gamma<\Gamma$:*

$$\int_{y-\epsilon}^{y+\epsilon}|W_0(x)|^2dx\leqslant e^{-2\gamma|y|}B(\gamma,\epsilon). \tag{73}$$

Proof: Squaring the inequality (66) and integrating we arrive at

$$\int_{y-\epsilon}^{y+\epsilon} |W_0(x+n)|^2 dx \leqslant e^{\mp 2\gamma n} A_\pm(\gamma,\epsilon,y), \tag{74a}$$

$$A_\pm(\gamma,\epsilon,y) = \frac{1}{(2\pi)} \int_{y-\epsilon}^{y+\epsilon} dx \left[\int_0^{2\pi} dk |\phi_{k\pm i\gamma}(x)| \right]^2. \tag{74b}$$

Since Φ is a vector-valued analytic function of k, the constant $A_\pm(\gamma,\epsilon,y)$ is finite. We rewrite the inequality in the following way:

$$\int_{y+n-\epsilon}^{y+n+\epsilon} |W_0(x)|^2 dx \leqslant e^{\mp 2\gamma(y+n)} \underbrace{e^{\pm 2\gamma y} A_\pm(\gamma,\epsilon,y)}_{=:B_\pm(\gamma,\epsilon,y)}. \tag{75}$$

Again the analyticity of Φ assures that the maximum

$$B_\pm(\gamma,\epsilon) := \max_{-\frac{1}{2} \leqslant y \leqslant \frac{1}{2}} B_\pm(\gamma,\epsilon,y)$$

is finite. Hence we have for all $y \in \mathbb{R}$ [we define $B(\gamma,\epsilon) := \max(B_\pm(\gamma,\epsilon))$]

$$\int_{y-\epsilon}^{y+\epsilon} |W_0(x)|^2 dx \leqslant e^{-2\gamma|y|} B(\gamma,\epsilon). \tag{76}$$

The converse of this theorem is true as well.

Theorem 3: *Let W_0 decrease such that the inequality*

$$\int_{y-1/2}^{y+1/2} |W_0(x)|^2 dx \leqslant e^{-2\gamma|y|} B(\gamma) \tag{77}$$

holds for all $\gamma < \Gamma$. Then the Bloch function Φ is an analytic vector-valued function of k, which has the periodicity property $\Phi(k+2\pi n,x) = \Phi(k,x)$.

Proof: Let $\|\cdot\|_1$ denote the $L^2([-\frac{1}{2}, \frac{1}{2}])$ norm. Then we have the inequality $\|W_n\|_1 \leqslant e^{-\gamma|n|} B(\gamma)$ and hence the sum

$$\Phi(k,x) = \frac{1}{\sqrt{2\pi}} \sum_{n=-\infty}^{\infty} e^{ikn} W_n(x) \tag{78}$$

converges in the $L^2([-\frac{1}{2}, \frac{1}{2}])$ norm for all $k = \kappa + iq$, $|q| < \Gamma$. The convergence is uniform with respect to k. In the same way we can prove the existence of the derivative $(\partial/\partial k)\Phi(k,x)$. Thus Φ is an analytic vector-valued function of k. Periodicity is obvious.

VIII. CONCLUSIONS

We have discussed Bloch and Wannier functions composed of Gaussian orbitals. In particular, we have compared the Bloch and Wannier functions for two different choices of the normalization constants. We have stated explicitly the domain of analyticity of these Bloch functions [see Eq. (14)] as well as the exponential decrease of the corresponding Wannier functions. Also the expectation values of kinetic and potential energy have been studied in detail. We have proved several monotonicity properties of these expectation values and we have derived simple formulas for the limits of strongly and weakly localized Gaussian orbitals. Likewise, we have discussed in general the relationship of the analyticity properties of the Bloch functions and the localization properties of the corresponding Wannier functions.

ACKNOWLEDGMENTS

Two of us (P.Z. and R.D.) are very grateful to Professor Bozejko for his extremely useful information about the theta functions. The present work was financially supported by Österreichische Nationalbank under Grant No. 5917.

APPENDIX: MONOTONICITY PROPERTIES OF ϑ-FUNCTIONS

Here we prove some monotonicity properties. In the following we always assume that τ is purely imaginary with Im $\tau>0$ and $z=\xi$ is real. In addition $q=e^{i\pi\tau}$.

First we prove that $\theta_3(\xi|\tau)$ is monotone decreasing (with respect to ξ) for $\xi\in[0,\pi/2]$. This holds true if and only if $\ln\theta_3(\xi|\tau)$ is monotone decreasing for $\xi\in[0,\pi/2]$. Using the product expansion for $\theta_3(\xi|\tau)$ one has[10–12]

$$\frac{\theta_3'(\xi|\tau)}{\theta_3(\xi|\tau)}=-4\sin(2\xi)\sum_{n=1}^{\infty}\frac{q^{2n-1}}{1+2q^{2n-1}\cos(2\xi)+q^{4n-2}}, \tag{A1}$$

which is obviously negative for $\xi\in[0,\pi/2]$. Here $\theta_3'(\xi|\tau)$ means $(\partial/\partial\xi)\theta_3(\xi|\tau)$. The proof that $\theta_4(\xi|\tau)$ is monotone increasing in the same interval is completely analogous.

Also the following monotonicity property is derived by using the product expansion of $\theta_3(\xi|\tau)$. We prove that $i(\partial/\partial\tau)\ln\theta_3(\xi|\tau)$ is a monotone increasing function of ξ for $\xi\in[0,\pi/2]$. A short calculation gives

$$i\,\frac{\partial}{\partial\xi}\frac{\partial}{\partial\tau}\ln\theta_3(\xi|\tau)=2\pi\,\sin(2\xi)\sum_{n=1}^{\infty}\frac{(2n-1)\sinh(-i\pi\tau(2n-1))}{[\cosh(-i\pi\tau(2n-1))+\cos(2\xi)]^2} \tag{A2}$$

from which the assertion follows immediately.

In this paper we construct Gamow vectors for resonances given by poles of the analytic continuation of the S matrix of any finite order. We study their modes of decay (or growth). We obtain Jordan block structures for the extended Hamiltonians and evolution operators on the subspaces spanned by these Gamow vectors. We perform this study within the context of the rigged Hilbert space extension of quantum theory. We construct an explicit Friedrichs model with a double pole resonance to illustrate the general formulation. © *1998 American Institute of Physics.* [S0022-2488(98)03204-6]

I. INTRODUCTION

Resonances appear in quantum scattering when the S-matrix in the energy representation has singularities in the complex plane. These singularities are the scattering resonances.[1–3] In the case of simple poles,[3–5] the real part of the resonance corresponds to the resonance energy while the imaginary part corresponds to the half-width of the cross section, which is twice the mean life of the corresponding unstable state.

In order to describe the unstable quantum states, Gamow conjectured[6] the existence of eigenvectors, henceforth called *Gamow vectors*, of the Hamiltonian with complex eigenvalues. These eigenvalues were precisely the points at which the singularities of the S-matrix appear. However, this is impossible within the conventional formulation of quantum theory in Hilbert space[7,8] because the Hamiltonian (being a self-adjoint operator) can only have real eigenvalues. Despite this difficulty inherent to the Hilbert space formulation, formal constructions of Gamow vectors appeared early in the literature.[9–12]

In the case of simple scattering resonances, Bohm and Gadella constructed systematically the corresponding Gamow vectors and they provided a clear mathematical meaning to these vectors in terms of a suitable extension of quantum theory on the basis of Gel'fand triplets,[13] also called rigged Hilbert spaces.[3] These three spaces are a dual pair of locally convex topological spaces[14] plus a Hilbert space which contains one of the spaces of the dual pair and is contained in the other. The Bohm–Gadella construction is based on Hardy functions[15–17] and is systematically presented in Ref. 4 where one can find the previous references as well. The extended Schrödinger evolution is intrinsically irreversible because it splits into two distinct semigroups.[4] This result was, moreover, a first step towards a rigorous treatment of the problem of irreversibility.[18–25] In fact, Bohm conjectured[5] that extensions to Gel'fand triplets may give meaning to the Brussels–Austin formalism of irreversibility developed under the direction of Prigogine.[18–21] This conjecture was verified[22] for the Friedrichs model. The Bohm–Gadella Gamow vectors follow, in fact, from the intrinsic properties of the extended evolution operators because they actually correspond to the generalized eigenprojection constructed from subdynamics.[23]

This remark is, however, much more general. For both classical and quantum unstable sys-

 © 1998 American Institute of Physics

tems independent of scattering, there exist intrinsically irreversible extensions of dynamics to suitable Gel'fand triplets which include the resonances as generalized eigenvalues.[23]

For classical chaotic systems like the baker transformation, we find poles of all multiplicities.[23–25] These degenerate poles give rise to Jordan blocks with a size equal to the order of the pole. Therefore, one may ask whether such poles arise in unstable quantum systems as well. In the case of a spherically symmetric potential, the presence of a multiple pole resonance for a given value of the angular momentum can, in principle, be tested experimentally, since its corresponding lth partial cross section no longer has the Breit–Wigner shape. For instance, if for a certain value of l the resonance is described by a pair of double poles, the corresponding partial cross section should include, in addition to the usual Breit–Wigner component, a term of the form,[3]

$$\frac{4\pi(2l+1)}{p^2}\,\frac{\Gamma^2(E-E_0)^2}{[(E-E_0)^2-\Gamma^2/4]+\Gamma^2(E-E_0)^2}. \tag{1.1}$$

Here, the poles are located at $E_0 \pm i\Gamma/2$.

Such possibilities for decay are already explicitly mentioned in the classical paper by Goldberger and Watson.[26] Double pole resonances have already been considered in the literature. Lukierski[27,28] has studied a case of double pole resonances in field theory that appears in the interaction of two scalar fields. Furthermore, he has constructed a state operator for this resonance and shown that the rate of decay is not purely exponential, but instead a polynomial factor appears,

$$(\alpha t^2+\beta t+\gamma)e^{-\Gamma t}, \tag{1.2}$$

where α, β, γ and $\Gamma \geqslant 0$ are constants.

Katznelson[29,30] studied systematically the Jordan blocks associated to resonances of the partial resolvent using complex scaling methods.[31,32] Brändas, Chatzidimitriou-Dreismann and co-workers[33–37] combined complex scaling techniques with perturbation theory to discuss resonances and Jordan block structures in the Hamiltonian,[33,34] in density matrices,[35–37] and associated with multiple poles in the resolvent in Ref. 37. Also, Mondragon and Hernandez[38] discovered these structures in their investigation of the geometric phases for degenerate resonances. Sudarshan and Bhamati[39] also discuss Jordan blocks corresponding to the Friedrichs, the Cascade, and related models assuming the existence of multiple poles in their analytic continuation of dynamics.

The purpose of this paper is to construct Gamow vectors for scattering resonances of any finite order. After a brief discussion of simple resonance scattering in Sec. II, where we introduce the terminology and review the Bohm–Gadella work, we define, in Sec. III, the Gamow vectors when the scattering matrix has a pole of finite order m. The Jordan block structure of the extended irreversible evolution of the Gamow vectors is presented in Sec. IV. A simple Friedrichs model with doubly degenerate scattering resonance is presented in Sec. V. We finish the paper with an Appendix in which three mathematical results are proven.

II. SIMPLE RESONANCE SCATTERING

In this section we intend to present a brief summary of what is called resonance scattering for simple pole resonances. We shall also establish the basic notation.

In the conventional scattering theory,[2,8,32,40,41] the ''free'' Hamiltonian H_0 and the perturbed Hamiltonian $H=H_0+V$ satisfy the asymptotic condition. Therefore, the Møller wave operators $\mathbf{\Omega}_{\mathrm{IN}}, \mathbf{\Omega}_{\mathrm{OUT}}$ exist and provide the unitary equivalence of the absolutely continuous subspaces $\mathscr{H}_{\mathrm{ac}}(H_0)$ and $\mathscr{H}_{\mathrm{ac}}(H)$ associated with the operators H_0 and H, respectively. To simplify the notation without loss of the essence of our argument, we assume that the absolutely continuous spectrum of H_0 as well as that of H is simple and covers the positive real semiaxis $\mathbb{R}^+ \equiv [0,\infty)$.

Let U be the unitary transformation which provides the spectral representation of the absolutely continuous part of H_0 (restriction of H_0 to $\mathscr{H}_{\mathrm{ac}}(H_0)$) as the multiplication operator on $L^2(\mathbb{R}^+)$. Then, we have

$$[UH_0U^{-1}](E)=E\varphi(E), \tag{2.1}$$

$$\mathscr{H}_{\rm ac}(H) \xrightarrow{(\Omega_{\rm IN})^{-1}} \mathscr{H}_{\rm ac}(H_0) \overset{U}{\to} L^2(\mathbb{R}^+), \tag{2.2}$$

$$\mathscr{H}_{\rm ac}(H) \xrightarrow{(\Omega_{\rm OUT})^{-1}} \mathscr{H}_{\rm ac}(H_0) \overset{U}{\to} L^2(\mathbb{R}^+). \tag{2.3}$$

Now, we shall briefly present here the rigged Hilbert spaces (RHS) of Hardy functions. To construct them, consider the set of spaces $\mathscr{H}_{\pm}^2 \cap S$, where $\mathscr{H}_{\pm}^2$ are the spaces of Hardy functions on the upper and the lower half-plane[15–17] and S the Schwartz space of all functions admitting derivatives at all orders such that they and their derivatives go to zero faster than the inverse of any polynomial at the infinity.[42] The restriction of any function in $\mathscr{H}_{\pm}^2 \cap S$ to $\mathbb{R}^+$ uniquely determines its values on the whole real line[43] and, as a consequence of the Tichmarsh theorem, on the corresponding half-plane. These restrictions are dense subspaces of $L^2(\mathbb{R}^+)$ (Ref. 44) and determine two one-to-one onto maps,

$$\theta_{\pm} : \mathscr{H}_{\pm}^2 \cap S \mapsto \mathscr{H}_{\pm}^2 \cap S\big|_{\mathbb{R}^+} \equiv \Delta_{\pm}. \tag{2.4}$$

As $\mathscr{H}_{\pm}^2 \cap S$ are Fréchet nuclear spaces,[13,14] this structure is transmitted to $\Delta_{\pm}$ via $\theta_{\pm}$. Also, the identity map $I: \Delta_{\pm} \mapsto L^2(\mathbb{R}^+)$ is continuous. Therefore, if ${}^{\times}(\Delta_{\pm})$ represent the respective antidual spaces of $\Delta_{\pm}$ (the spaces of all continuous *antilinear* functionals on $\Delta_{\pm}$), the triplets,

$$\Delta_{\pm} \subset L^2(\mathbb{R}^+) \subset {}^{\times}\Delta_{\pm} \tag{2.5}$$

are Gel'fand triplets or rigged Hilbert spaces (RHS).[4]

The unitary transformations U, $\mathbf{\Omega}_{\rm IN}$, and $\mathbf{\Omega}_{\rm OUT}$ allow us to transfer the Gel'fand triplet (2.5) from the spectral representation to the original representation. Therefore, the spaces denoted by

$$\mathbf{\Phi}_+ = \mathbf{\Omega}_{\rm OUT} U^{-1} \Delta_+; \quad \mathbf{\Phi}_- = \mathbf{\Omega}_{\rm IN} U^{-1} \Delta_- \tag{2.6}$$

produce the triplets

$$\mathbf{\Phi}_{\pm} \subset \mathscr{H}_{\rm ac}(H) \subset {}^{\times}\mathbf{\Phi}_{\pm}. \tag{2.7}$$

The extensions of the transformations U, $\mathbf{\Omega}_{\rm IN}$ and $\mathbf{\Omega}_{\rm OUT}$ by duality give rise to the following formulas for the duals ${}^{\times}\mathbf{\Phi}_{\pm}$:[4]

$${}^{\times}\mathbf{\Phi}_+ = \mathbf{\Omega}_{\rm OUT} U^{-1\,\times}\Delta_+; \quad {}^{\times}\mathbf{\Phi}_- = \mathbf{\Omega}_{\rm IN} U^{-1\,\times}\Delta_-. \tag{2.8}$$

From (2.4) and (2.6), we have[4]

$$\mathbf{\Phi}_+ = \mathbf{\Omega}_{\rm OUT} U^{-1} \theta_+ [\mathscr{H}_+^2 \cap S]; \quad \mathbf{\Phi}_- = \mathbf{\Omega}_{\rm IN} U^{-1} \theta_- [\mathscr{H}_-^2 \cap S]. \tag{2.9}$$

We denote by $\phi_{\pm}$ the vectors in $\mathbf{\Phi}_{\pm}$ which correspond to the functions $\varphi_{\pm}(E)$ in $\mathscr{H}_{\pm}^2 \cap S$,

$$\phi_+ = \mathbf{\Omega}_{\rm OUT} U^{-1} \theta_+ \varphi_+; \quad \phi_- = \mathbf{\Omega}_{\rm IN} U^{-1} \theta_- \varphi_-. \tag{2.10}$$

The nuclear spectral theorem now establishes that for almost all E in the spectrum of H which is equal to $\mathbb{R}^+$ in our case, there exist functionals $|E_{\pm}\rangle \in {}^{\times}\mathbf{\Phi}_{\pm}$ such that

(i) They are (generalized) eigenvectors of H with eigenvalue E, i.e.,

$$H|E_{\pm}\rangle = E|E_{\pm}\rangle. \tag{2.11}$$

(i) For $E>0$, the functions $\varphi_{\pm}(E)$ are given by $\langle E_{\pm}|\phi_{\pm}\rangle = \langle \phi_{\pm}|E_{\pm}\rangle^*$.

Due to the regularity properties of the functions in $\mathscr{H}_{\pm}^2 \cap S$ ''almost all'' can be replaced by ''all,'' so that (2.11) is indeed true for any $E>0$. We would like to mention here in passing that this is in general one of the advantages of going beyond the Hilbert space formalism.[3]

Summarizing, the correspondence given in (2.6) can be written in the following form:

$$\phi_- \mapsto \varphi_-(E) = \langle E_- | \phi_- \rangle \in \Delta_- \Leftrightarrow \varphi_-^*(E) = \langle \phi_- | E_- \rangle \in \Delta_+ ; \quad E > 0, \tag{2.12}$$

$$\phi_+ \mapsto \varphi_+(E) = \langle E_+ | \phi_+ \rangle \in \Delta_+ \Leftrightarrow \varphi_+^*(E) = \langle \phi_+ | E_+ \rangle \in \Delta_- ; \quad E > 0. \tag{2.13}$$

Here, the symbol $*$ denotes complex conjugation.

Now, define

$$\mathbb{C}^+ = \{z \in \mathbb{C}; \quad \text{Im } z > 0\}; \quad \mathbb{C}^- = \{z \in \mathbb{C}; \quad \text{Im } z < 0\}, \tag{2.14}$$

i.e., the upper and lower open half-plane. Let $\varphi_\pm(z)$, $z \in \mathbb{C}^\pm$, be the (unique) analytic functions for which $\varphi_\pm(E) \in \Delta_\pm$, $E \in \mathbb{R}^+$, is the corresponding boundary function on the positive real semi-axis. Then, for any given $z_0 \in \mathbb{C}^-$, $z_0^* \in \mathbb{C}^+$, the following maps:

$$\phi_+ \mapsto \varphi_+(z_0^*); \quad \phi_- \mapsto \varphi_-(z_0) \tag{2.15}$$

define respective continuous linear functionals on $\mathbf{\Phi}_+$ and $\mathbf{\Phi}_-$ that we denote by $\langle z_{0+}^* |$ and $\langle z_{0-} |$. With this notation, we have

$$\langle z_{0+}^* | \phi_+ \rangle = \varphi_+(z_0^*); \quad \langle z_{0-} | \phi_- \rangle = \varphi_-(z_0). \tag{2.16}$$

Analogously, the maps

$$\phi_+ \mapsto \varphi_+^*(z_0); \quad \phi_- \mapsto \varphi_-^*(z_0^*) \tag{2.17}$$

define respective continuous *antilinear* functionals on $\mathbf{\Phi}_+$ and $\mathbf{\Phi}_-$ which we denote by $|z_{0+}\rangle$ and $|z_{0-}^*\rangle$. With this notation, which is essentially Dirac[45] notation, we have

$$\langle \phi_+ | z_{0+} \rangle = \varphi_+^*(z_0); \quad \langle \phi_- | z_{0-}^* \rangle = \varphi_-^*(z_0^*). \tag{2.18}$$

Among the functionals (2.15) [or (2.16)] and (2.17) [or (2.18)], there exist the following relations:

$$\langle z_{0-} | \phi_- \rangle^* = \langle \phi_- | z_0^* \rangle; \quad \langle z_{0+}^* | \phi_+ \rangle^* = \langle \phi_+ | z_{0+} \rangle. \tag{2.19}$$

To prove these relations, we use the Tichmarsh theorem.[15–17] For the first one, we have

$$\langle z_{0-} | \phi_- \rangle^* = [\varphi_-(z_0)]^* = \left[\frac{-1}{2\pi i} \int_{-\infty}^{\infty} \frac{\varphi_-(E) dE}{E - z_0} \right]^* = \frac{1}{2\pi i} \int_{-\infty}^{\infty} \frac{\varphi_-^*(E) dE}{E - z_0^*} = \varphi_-^*(z_0^*)$$
$$= \langle \phi_- | z_{0-}^* \rangle. \tag{2.20}$$

The second one is proven analogously.

Next, we present a very important result.

Proposition: The antilinear functionals $|z_{0+}\rangle$ and $|z_{0-}^*\rangle$ are generalized right eigenvectors of H and the linear functionals $\langle z_{0-}^* |$ and $\langle z_{0-} |$ are generalized left eigenvectors of H, with eigenvalues z_0 and z_0^* respectively, i.e.,

$$H|z_{0+}\rangle = z_0 |z_{0+}\rangle; \quad H|z_{0-}^*\rangle = z_0^* |z_{0-}^*\rangle, \tag{2.21}$$

$$\langle z_{0+}^* | H = z_0 \langle z_{0+}^* |; \quad \langle z_{0-} | H = z_0^* \langle z_{0-} |. \tag{2.22}$$

A proof for (2.21) is given in Ref. 4 following the Tichmarsh theorem. The first identity in (2.22), follows from the first identity in (2.21),

$$z_0^* \langle z_{0+}^* | \phi_+ \rangle = (z_0 \langle \phi_+ | z_{0+} \rangle)^* = \langle \phi_+ | H | z_{0+} \rangle^* = \langle H \phi_+ | z_{0+} \rangle^* = \langle z_{0+}^* | H | \phi_+ \rangle. \tag{2.23}$$

By omitting the arbitrary ϕ_+ in (2.23), we obtain the desired result. Analogously, the second identity in (2.23) is a consequence of the first equation in (2.21). The second formula in (2.22) is obtained in a similar way.

The relevant eigenvectors for resonance scattering are those coinciding with the isolated singularities of the continuation of the analytic S-matrix, $S(E)$, $E\in\mathbb{R}^+$ in the energy representation. Simple scattering resonances are understood[1–3] as simple poles of the continued S-matrix from the semiaxis to the complex plane. In the language of Riemann surfaces, these poles are located in the second sheet.

For any simple pole

$$z_R=E_R-i\,\frac{\Gamma}{2},\ \ \Gamma>0$$

of the continued S-matrix from the upper to the lower half plane, the vectors $|z_{R+}\rangle$ and $|z_{R-}^*\rangle$ are *the decaying and the growing Gamow vectors*, respectively.[3,4]

Following the right/left eigenvector notation,[22,23] we can write the Gamow vectors as follows:

$$|f_0\rangle=|z_{R+}\rangle;\quad |\widetilde{f}_0\rangle=|z_{R-}^*\rangle, \tag{2.24}$$

$$\langle f_0|=\langle z_{R+}^*|;\quad \langle\widetilde{f}_0|=\langle z_{R-}|. \tag{2.25}$$

These forms provide the relation between the Bohm–Gadella approach and the Brussels–Austin approach.

III. DEGENERATE RESONANCE SCATTERING

A scattering resonance is degenerate when the continuation of the S-matrix, $S(E)$, $E>0$, from above to below has a pole of order m at the point $z_R=E_R-i\Gamma/2$. Correspondingly, the continuation from below to above has a pole of order m at $z_R^*=E_R+i\Gamma/2$. In this case, the construction of the Gamow vectors is a generalization of the construction for the simple pole presented in Sec. II.

Let

$$\varphi_\pm^{(n}=\frac{d^n}{dz^n}\,\varphi_\pm(z);\ \ n=0,1,2,..., \tag{3.1}$$

denote the nth derivative of the analytic function $\varphi_\pm(z)$ for which $\varphi_\pm(E)\in\Delta_\pm$ is the boundary function on the positive real semiaxis. Then, the maps

$$\phi_+\mapsto[\varphi_+^{(n}(z)]_{z=z_R^*};\ \ n=0,1,...,m-1 \tag{3.2}$$

define m linear functionals on Φ_+, which we denote by $\langle f_n|$; $n=0,1,...,m-1$. With this notation, we have,

$$\langle f_n|\phi_+\rangle=[\varphi_+^{(n}(z)]_{z=z_R^*};\ \ n=0,1,...,m-1. \tag{3.3}$$

For z_R, the maps

$$\phi_-\mapsto[\varphi_-^{(n}(z)]_{z=z_R};\ \ n=0,1,...,m-1 \tag{3.4}$$

define m linear functionals on $\mathbf{\Phi}_-$ which we denote by $\langle\widetilde{f}_n|$, $n=0,1,...,m-1$. With this notation, we have

$$\langle\widetilde{f}_n|\phi_-\rangle=[\varphi_-^{(n}(z)]_{z=z_R};\ \ n=0,1,...,m-1. \tag{3.5}$$

The corresponding antilinear functionals are defined as in the case of a simple pole,

$$\langle\phi_+|f_n\rangle=\langle f_n|\phi_+\rangle^*=[\varphi_+^{*(n}(z)]_{z=z_R}, \tag{3.6}$$

$$\langle\phi_-|\widetilde{f}_n\rangle=\langle\widetilde{f}_n|\phi_-\rangle^*=[\varphi_-^{*(n}(z)]_{z=z_R^*}. \tag{3.7}$$

We can easily see that the linear functionals $\langle f_n|$ and $\langle \widetilde{f}_n|$, $n=0,1,...,m-1$ are continuous. The proof goes as follows: Since the topology on $\mathbf{\Phi}_+$ has been constructed by transporting by $\mathbf{\Omega}_{\rm OUT}U^{-1}\theta_+$ the topology on $\mathscr{H}^2_+\cap S$ and the latter has been inhereted from the topology of the Schwartz space, the general theory of locally convex topological vector spaces,[14,42] shows that, in order to prove the continuity of $\langle f_n|$, it is sufficient to find a positive constant $C>0$ such that

$$|\langle f_n|\phi_+\rangle|\leqslant C\|\varphi_+(E)\|;\ \ \forall\phi_+\in\mathbf{\Phi}_+\,, \tag{3.8}$$

where $\varphi_+(E)$ is the function in $\mathscr{H}^2_+\cap S$ associated to ϕ_+ by the first formula in (2.10). In (3.8), $\|\varphi_+(E)\|$ denotes the $L^2(\mathbb{R})$ norm of $\varphi_+(E)$, i.e.,

$$\|\varphi_+(E)\|=\left[\int_{-\infty}^{\infty}|\varphi_+(E)|^2dE\right]^{1/2}, \tag{3.9}$$

which is one of the countable set of norms giving the topology on $\mathscr{H}^2_+\cap S$.

Analogously, the continuity of the linear functional $\langle \widetilde{f}_n|$ is assured if we can find a $C'>0$ such that

$$|\langle \widetilde{f}_n|\phi_-\rangle|\leqslant C'\|\varphi_-(E)\|;\ \ \forall\phi_-\in\mathbf{\Phi}_-\,, \tag{3.10}$$

where $\varphi_-(E)$ is the function in $\mathscr{H}^2_-\cap S$ associated to $\mathbf{\Phi}_-$ by the second formula in (2.10) Again, the norm in (3.10) is the usual $L^2(\mathbb{R})$ norm.

We shall prove here only (3.8). The proof for (3.10) is the same. A generalization of the Tichmarsh theorem (see Appendix) asserts that

$$\langle f_n|\phi_+\rangle=[\varphi_+^{(n)}(z)]_{z=z_R^*}=\frac{n!}{2\pi i}\int_{-\infty}^{\infty}\frac{\varphi_+(E)dE}{(E-z_R^*)^{n+1}}. \tag{3.11}$$

We want to recall that $\varphi_+(E)$ represents the function in $\mathscr{H}^2_+\cap S$ given by the boundary vales of $\varphi_+(z)$ on the real axis. The Cauchy–Schwarz inequality on $L^2(\mathbb{R})$ can be applied to the integral in (3.11) to give

$$|\langle f_n|\phi_+\rangle|\leqslant\frac{n!}{2\pi}\left\|\frac{1}{(E-z_R^*)^{n+1}}\right\|\|\varphi_+(E)\|, \tag{3.12}$$

where the norms in (3.12) are the standard $L^2(\mathbb{R})$ norms. Formula (3.12) shows that

$$\langle f_n|\phi_+\rangle\leqslant C\|\varphi_+(E)\|\ \ \text{with}\ \ C=\frac{n!}{2\pi}\left\|\frac{1}{(E-z_R^*)^{n+1}}\right\| \tag{3.13}$$

which proves the continuity of $\langle f_n|$.

In the previous section, following Refs. 3 and 4, we have called Gamow vectors the functionals $|f_0\rangle$, $|\widetilde{f}_0\rangle$, $\langle f_0|$, $\langle\widetilde{f}_0|$. We shall also call Gamow vectors the functionals $|f_n\rangle$, $|\widetilde{f}_n\rangle$, $\langle f_n|$, $\langle\widetilde{f}_n|$; $n=0,1,...,m-1$ corresponding to a resonance pole of order m. As in the simple pole case, the vectors $|f_0\rangle$ and $\langle\widetilde{f}_0|$ are generalized right and left eigenvectors of H with eigenvalue z_R and $|\widetilde{f}_0\rangle$ and $\langle f_0|$ are right and left eigenvectors of H with eigenvalue z_R^*, so that

$$H|f_0\rangle=z_R|f_0\rangle;\ \ \langle f_0|H=z_R^*\langle f_0|, \tag{3.14}$$

$$H|\widetilde{f}_0\rangle=z_R^*|\widetilde{f}_0\rangle;\ \ \langle\widetilde{f}_0|H=z_R\langle\widetilde{f}_0|. \tag{3.15}$$

For the vectors $|f_n\rangle$, $|\widetilde{f}_n\rangle$, $\langle f_n|$, $\langle\widetilde{f}_n|$; $n=0,1,...,m-1$, we can prove the following formulas:

$$H|f_n\rangle=z_R|f_n\rangle+n|f_{n-1}\rangle;\ \ \langle f_n|H=z_R^*\langle f_n|+n\langle f_{n-1}|, \tag{3.16}$$

$$H|\widetilde{f}_n\rangle=z_R^*|\widetilde{f}_n\rangle+n|\widetilde{f}_{n-1}\rangle;\ \ \langle\widetilde{f}_n|H=z_R\langle\widetilde{f}_n|+n\langle\widetilde{f}_{n-1}|. \tag{3.17}$$

The proof of (3.16) goes as follows: Since we have that, on their respective absolutely continuous subspaces,[8,42] $\mathbf{\Omega}_{\mathrm{OUT}}^{\dagger} H \mathbf{\Omega}_{\mathrm{OUT}} = K$ and we also have (2.1), the function in $\mathscr{H}_+^2 \cap S$ that corresponds to $H\phi_+$ by the first formula in (2.10) is $E\varphi_+(E)$. This function represents the set of boundary values of the complex analytic function $z\varphi_+(z)$ on the upper half-plane. As $\varphi_+(E)$ is in $\mathscr{H}_+^2 \cap S$, one has

$$E\varphi_+(E) \in \mathscr{H}_+^2 \cap S; \quad \frac{d^n}{dE^n}[E\varphi_+(E)] \in \mathscr{H}_+^2 \cap S. \tag{3.18}$$

Furthermore, we can show (see the Appendix) that $(d^n/dE^n)[E\varphi_+(E)]$, $E \in \mathbb{R}$, represent the set of boundary values of the analytic function $(d^n/dz^n)[z\varphi_+(z)]$ on the upper half-plane. With these ideas in mind, we use definition (3.3) and the Titchmarsh theorem to write

$$\begin{aligned}
\langle f_n | H\phi_+ \rangle &= [(z\varphi_+(z))^{(n)}]_{z=z_R^*} \\
&= \frac{1}{2\pi i} \int_{-\infty}^{\infty} \frac{(E\varphi_+(E))^{(n)}}{E - z_R^*}\, dE \\
&= \frac{1}{2\pi i} \int_{-\infty}^{\infty} \frac{E\varphi_+^{(n)}(E)}{E - z_R^*}\, dE + \frac{n}{2\pi i} \int_{-\infty}^{\infty} \frac{\varphi_+^{(n-1)}(E) dE}{E - z_R^*} \\
&= z_R^* [\varphi_+^{(n)}(z)]_{z=z_R^*} + n[\varphi_+^{(n-1)}(z)]_{z=z_R^*} \\
&= z_R^* \langle f_n | \phi^+ \rangle + n \langle f_{n-1} | \phi_+ \rangle.
\end{aligned} \tag{3.19}$$

Since ϕ_+ is an arbitrary element of $\mathbf{\Phi}_+$, (3.19) gives the second formula in (3.16). To obtain the first formula in (3.16), we use the complex conjugate of (3.19),

$$\langle H\phi_- | f_n \rangle = \langle \phi_+ | H | f_n \rangle = z_R \langle \phi_+ | f_n \rangle + n \langle \phi_+ | f_{n-1} \rangle. \tag{3.20}$$

To prove (3.17), we proceed analogously. Formulas (3.16) show that, in the subspace of ${}^{\times}\mathbf{\Phi}_+$ spanned by the vectors $|f_0\rangle$, $|f_1\rangle, \ldots, 1/(m-2)|f_{m-2}\rangle$, $1/(m-1)|f_{m-1}\rangle$, the extended Hamiltonian H is represented as an upper Jordan block of order m,

$$\begin{bmatrix} z_R & 1 & 0 & \cdots & 0 \\ 0 & z_R & 1 & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & \cdots & z_R \end{bmatrix} \tag{3.21}$$

and that in the subspace of $\mathbf{\Phi}_-^{\times}$ (the space of continuous *linear* functionals on $\mathbf{\Phi}_-$) spanned by $\langle f_0|, \langle f_1|, \ldots, 1/(m-2)\langle f_{m-2}|, 1/(m-1)\langle f_{m-1}|$, H is also represented as an upper Jordan block of order m,

$$\begin{bmatrix} z_R^* & 1 & 0 & \cdots & 0 \\ 0 & z_R^* & 1 & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & \cdots & z_R^* \end{bmatrix}. \tag{3.22}$$

Similar results follow from (3.17).

IV. THE IRREVERSIBLE EVOLUTION OF GAMOW VECTORS

Along the present section, we shall discuss the time evolution of Gamow vectors for degenerate resonances of any order. As the Gamow vectors live in the larger spaces ${}^{\times}\mathbf{\Phi}_+$ and ${}^{\times}\mathbf{\Phi}_-$, we have to extend the unitary evolution $U_t = e^{-itH}$ from the Hilbert space $\mathscr{H}$ to the spaces ${}^{\times}\mathbf{\Phi}_+$ and ${}^{\times}\mathbf{\Phi}_-$.

In the case of a simple scattering resonance, the extensions U_t^+ and U_t^- of U_t are given by the duality formulas,[3,4]

$$\langle \phi_+ | U_t^+ F\rangle = \langle U_t^\dagger \phi_+ | F\rangle \quad \text{for} \quad t>0, \tag{4.1}$$

$$\langle \phi_- | U_t^- \widetilde{F}\rangle = \langle U_t^\dagger \phi_- | \widetilde{F}\rangle \quad \text{for} \quad t<0, \tag{4.2}$$

where $U_t^\dagger = e^{itH}$ is the Hilbert space adjoint of U_t. Here, F and $\widetilde{F}$ are arbitrary elements of ${}^\times\mathbf{\Phi}_+$ and ${}^\times\mathbf{\Phi}_-$ and the test vectors ϕ_+ and ϕ_- are arbitrarily chosen in $\mathbf{\Phi}_+$ and $\mathbf{\Phi}_-$, respectively. The families U_t^+ for $t>0$ and U_t^- for $t<0$ define two semigroups on the topological vector spaces ${}^\times\mathbf{\Phi}_+$ and ${}^\times\mathbf{\Phi}_-$, respectively.

The action of the semigroups U_t^+ and U_t^- on the Gamow vectors is

$$U_t^+ |f_0\rangle = e^{-iz_R t}|f_0\rangle; \quad t>0, \tag{4.3}$$

$$U_t^- |\widetilde{f}_0\rangle = e^{-iz_R^* t}|\widetilde{f}_0\rangle; \quad t<0. \tag{4.4}$$

In the case of a degenerate scattering resonance associated to a pole of order m, the extensions U_t^+ and U_t^- are also defined by formulas (4.1) and (4.2). The action of the semigroups U_t^+ and U_t^- on the Gamow vectors $|f_n\rangle$, $|\widetilde{f}_n\rangle$, $n=0,1,...,m-1$, is

$$U_t^+ |f_n\rangle = e^{-iz_R t}\sum_{l=0}^{n}\binom{n}{l}(-it)^l |f_{n-l}\rangle; \quad t>0, \tag{4.5}$$

$$U_t^- |\widetilde{f}_n\rangle = e^{-iz_R^* t}\sum_{l=0}^{n}\binom{n}{l}(-it)^l |\widetilde{f}_{n-l}\rangle; \quad t<0, \tag{4.6}$$

where

$$\binom{n}{l} = \frac{n!}{l!(n-l)!}$$

are the Binomial coefficients. Note that for $n=0$, the formulas for degenerate resonances (4.5) and (4.6) coincide with (4.3) and (4.4), respectively. Let us give the proof for (4.5) and proceed by analogy to show (4.6). First of all, one can easily show that for $t>0$ the function in $\mathscr{H}_+^2 \cap S$ that corresponds to

$$U_t^\dagger \phi_+ = e^{itH}\phi_+ \tag{4.7}$$

by the first identity in (2.10) is given by

$$e^{itE}\varphi_+(E), \tag{4.8}$$

where $\varphi_+(E)$ is the function in $\mathscr{H}_+^2 \cap S$ that corresponds to ϕ_+ by the same formula. Then, we write for $t>0$,

$$\langle f_n | U_t^\dagger \phi_+\rangle = \frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{\frac{d^n}{dE^n}\{e^{itE}\varphi_+(E)\}}{E-z_R^*}\,dE = \frac{1}{2\pi i}\sum_{l=0}^{n}\binom{n}{l}(it)^l\int_{-\infty}^{\infty}\frac{e^{itE}\,\frac{d^{n-1}}{dE^{n-1}}\,\varphi(E)}{E-z_R^*}\,dE$$

$$= \sum_{l=0}^{n}\binom{n}{l}(it)^l e^{itz_R^*}\langle f_n|\phi_+\rangle. \tag{4.9}$$

In the first and third identities in (4.9), we have applied the Titchmarsh theorem,[15–17] along with the fact that, for $t>0$, the product of e^{itE} with any Hardy function on the upper half-plane, gives again a Hardy function on the upper half-plane. The complex conjugate of (4.9) gives

$$\langle U_t^\dagger \phi_+ | f_n\rangle = \langle \phi_+ | U_t^+ | f_n\rangle = e^{-itz_R}\sum_{l=0}^{n}\binom{n}{l}(-it)^l\langle \phi_+ | f_n\rangle \tag{4.10}$$

which is valid for $t>0$. Taking account of the arbitrariness of the test vector ϕ_+ in $\mathbf{\Phi}_+$, we directly obtain (4.5) from (4.10).

In the subspace of ${}^\times\mathbf{\Phi}_+$ spanned by the vectors $|f_0\rangle,|f_1\rangle,\ldots,1/(m-2)|f_{m-2}\rangle$, $1/(m-1)|f_{m-1}\rangle$, the semigroup U_t^+, $t>0$, is represented by the following upper triangular matrix,

$$e^{-itz_R}\begin{bmatrix} 1 & -it & \frac{(-it)^2}{2} & \cdots & \frac{(-it)^{m-1}}{(m-1)!} \\ 0 & 1 & -it & \cdots & \frac{(-it)^{m-2}}{(m-2)!} \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & \cdots & 1 \end{bmatrix}, \quad t>0. \tag{4.11}$$

This matrix can also be obtained by the exponentiation of the Jordan block (3.21) multiplied by $-it$, following the standard exponentiation formula for a Jordan block.

Analogously, in the subspace of ${}^\times\mathbf{\Phi}_-$ spanned by the vectors $|\tilde{f}_0\rangle,|\tilde{f}_1\rangle,\ldots,1/(m-2)|\tilde{f}_{m-2}\rangle$, $1/(m-1)|\tilde{f}_{m-1}\rangle$, the semigroup U_t^-, $t<0$ is also represented by an upper triangular matrix, i.e.,

$$e^{-itz_R^*}\begin{bmatrix} 1 & -it & \frac{(-it)^2}{2} & \cdots & \frac{(-it)^{m-1}}{(m-1)!} \\ 0 & 1 & -it & \cdots & \frac{(-it)^{m-2}}{(m-2)!} \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & \cdots & 1 \end{bmatrix}, \quad t<0. \tag{4.12}$$

Again, this matrix is obtained by exponentiation of (3.22). Time evolution for continuous functionals on $\mathbf{\Phi}_+$ and $\mathbf{\Phi}_-$ is obtained by using the complex conjugate of (4.1) and (4.2). Therefore, for the right Gamow vectors $\langle f_n|$, $\langle\tilde{f}_n|$, $n=0,1,2,\ldots,m-1$, we obtain the following time evolution:

$$\langle f_n|U_t^+ = e^{iz_R^* t}\sum_{l=0}^{n}\binom{n}{l}(it)^l\langle f_{n-l}|; \quad t>0, \tag{4.13}$$

$$\langle\tilde{f}_n|U_t^- = e^{iz_R t}\sum_{l=0}^{n}\binom{n}{l}(it)^l\langle\tilde{f}_{n-l}|; \quad t<0. \tag{4.14}$$

V. A FRIEDRICHS MODEL WITH DOUBLE RESONANCE SCATTERING

Along this last section, we shall construct an explicit potential which produces a degenerate scattering resonance in the Friedrichs model. The Friedrichs model is a typical example of resonance scattering and has been extensively discussed as a model of unstable particles as well as a toy model for quantum irreversible processes.[46,12,41,47,48,19,22,23]

In the simplest version of the Friedrichs model, we have a Hamiltonian of the following form:

$$H=H_0+\lambda V \tag{5.1}$$

in which H_0 is the free or unperturbed Hamiltonian, V is the potential and λ is a coupling parameter. The spectrum of H_0 consists of a simple eigenvalue $E_1>0$ embedded in its absolutely continuous spectrum $\mathbb{R}^+=[0,\infty)$. The interaction λV ''dissolves'' the embedded eigenvalue to the absolutely continuous spectrum and the point spectrum disappears. The operators H_0 and H satisfy the asymptotic condition for scattering mentioned in Sec. II.[12,41] The singularities of the scattering matrix $S(E)$ coincide with the singularities of the partial resolvent of H with respect to the eigenspace of E_1,

$$|1\rangle\langle 1|\,\frac{1}{E-H}\,|1\rangle\langle 1|, \tag{5.2}$$

where

$$H_0|1\rangle = E_1|1\rangle. \tag{5.3}$$

The singularities of the partial resolvent (5.2) are the zeros of the function $\eta(z)$ defined as

$$\frac{1}{\eta(z)} = \langle 1| \frac{1}{z-H} |1\rangle. \tag{5.4}$$

The function $\eta(z)$ can be calculated directly[45,12,40]

$$\eta(z) = E_1 - z + \lambda^2 \int_0^\infty dE \, \frac{|V(E)|^2}{z-E}. \tag{5.5}$$

Here, $V(E) = \langle 1|V|E\rangle$ is the form factor.

As a function on z, $\eta(z)$ is analytic on the complex plane except on the real semiaxis $\mathbb{R}^+$ on which it has a branch cut. Furthermore, it does not have zeros. This property is guaranteed if

$$\eta(0) > 0. \tag{5.6}$$

Therefore, in order to find resonances, as zeros of $\eta(z)$ we have to extend the function $\eta(z)$ through the cut. The location of the zeros of this extension depends on the value of the coupling parameter. A simple resonance corresponds to a simple zero z_R, $\mathrm{Im}\, z_R < 0$, of the analytic continuation $\eta_+(z)$ of $\eta(z)$ from the upper to the lower half-plane through the cut $\mathbb{R}^+$. The complex conjugate of z_R, z_R^*, is the zero of the analytic extension $\eta_-(z)$ of $\eta(z)$ from the lower to the upper half-plane through the cut $\mathbb{R}^+$.

The existence and the properties of the zeros of $\eta_+(z)$ and $\eta_-(z)$ depend on the form factor $V(E)$. We are interested here in the possibility of having Friedrichs models with degenerate resonances. The simplest case is a pole of second order. We shall discuss here this particular example. To this end, let us choose the following form factor:

$$|V(E)|^2 = \frac{\sqrt{E}}{P(E)}; \quad 0 \leqslant E < \infty \tag{5.7}$$

with $P(E) = (E-\alpha)(E-\alpha^*)$ for some complex number α. For the square root we choose the principal branch.[49]

Using (5.7), the function $\eta(z)$ has the form,

$$\eta(z) = E_1 - z - \pi\lambda^2 \left\{ \frac{\sqrt{-z}}{P(z)} - \frac{1}{\alpha-\alpha^*} \left(\frac{\sqrt{-\alpha}}{z-\alpha} - \frac{\sqrt{-\alpha^*}}{z-\alpha^*} \right) \right\}. \tag{5.8}$$

In order to prove it, we have to calculate the integral in (5.5) using (5.6). For any $z \notin \mathbb{R}^+$, this integral can be obtain by contour integration in the complex plane. A standard formula[49] says that

$$\int_0^\infty \frac{\sqrt{E}}{P(E)(E-z)} \, dE = \frac{-\pi \, \exp\{-\pi i(1+1/2)\}}{\sin(\pi(1+1/2)} \times \sum \left\{ \mathrm{Res} \, \frac{w^{1/2}}{P(w)(w-z)} \text{ at the poles of } \frac{1}{P(w)(w-z)} \right\}. \tag{5.9}$$

The residues in (5.9) are easily obtained and (5.8) follows straightforwardly. Since we are using the principal branch of the square root, the term $\sqrt{-z}$ shows that $\eta(z)$ has a branch cut corresponding to the positive semiaxis.

A very important remark is the following: Given an analytic function on the two sheeted Riemann surface corresponding to the square root, we obtain an analytic function on the complex plane by using the transformation $z = p^2$. These two functions have the same structure, which in particular means that if the function on the complex plane has a zero at the point p_0, the function

on the Riemann surface has a zero of the same multiplicity at the point $z_0=p_0^2$ and vice versa. We prove this fact in the Appendix. Note that the correspondence between the surface and the plane is one to one.

The above remarks will enable us to obtain the resonances by using the momentum representation, i.e., by performing the following change of variables:

$$z=p^2; \quad \alpha=b^2. \tag{5.10}$$

After this change of variables, we have the following expression for $\varphi(p)=\eta(p^2)=\eta(z)$:

$$\varphi(p)=E_1-p^2+\frac{i\pi\lambda^2}{(b-b^*)(p+b)(p-b^*)}. \tag{5.11}$$

If $\varphi(p)$ has a double zero at p_R, we must have

$$\varphi(p_R)=0; \quad \varphi'(p_R)=0; \quad \varphi''(p_R)\neq 0. \tag{5.12}$$

If this were the case, then the analytic continuation of $\eta(z)$ has a double zero at $z_R=p_R^2$ and that all the zeros of this continuation are found in the same way (see the Appendix).

As we have mentioned earlier, the analytic properties of the scattering matrix in the energy representation, $S(E)$, and $\eta^{-1}(E)$ must be identical. Correspondingly, the analytic properties of the scattering matrix in the momentum representation, $S(p)$, and $\varphi^{-1}(p)$ must be identical. We know that the singularities of $S(p)$ must lie on the lower half-plane.[1] From general considerations derived from causality conditions, we can obtain further information.[1] In fact, the possible singularities of $S(p)$ representing resonances appear as pairs of poles on the lower half-plane having symmetric positions with respect to the imaginary axis. This means that if p_R is one of these poles, the other is $-p_R^*$. These poles are zeros of $\varphi(p)$ with the same order. The condition that p_R and $-p_R^*$ must lie on the lower half-plane means that

$$\text{Im } p_R<0. \tag{5.13}$$

After all these comments, we should remark that the two first formulas in (5.12) give us four real relations for the six real parameters E_1, λ, Re p_R, Im p_R, Re b, and Im b. Therefore, we only have two free real parameters. We choose the eigenvalue E_1 of H_0 and the coupling parameter λ as free parameters. Then, we obtain for b and p_R the following expressions:

$$b=E_1^{1/2}+2i\left(\frac{\pi\lambda^2}{16E_1}\right)^{1/3}; \quad p_R=\left[E_1-\left(\frac{\pi\lambda^2}{16E_1}\right)^{2/3}\right]-\left(\frac{\pi\lambda^2}{16E_1}\right)^{1/3}. \tag{5.14}$$

The conditions required on p_R, in particular (5.13), are obviously satisfied if we impose on the independent variables E_1 and λ, the following extra condition:

$$E_1-\left(\frac{\pi\lambda^2}{16E_1}\right)^{2/3}\geqslant 0. \tag{5.15}$$

The value for p_R given in (5.14) can be carried to (5.11) to obtain

$$\varphi(p)=-\frac{(p-p_R)^2(p+p_R^*)^2}{(p+t)(p-t^*)}. \tag{5.16}$$

We observe that p_R as well as $-p_R^*$ are double zeros of $\varphi(p)$. From (5.14) and (5.15), we see that they lie on the lower half-plane. The squares $z_R=p_R^2$ and $z_R^*=(-p_R^*)^2$ are the double zeros of the analytic continuation of the extended analytic function $\eta(z)$ and, therefore, the resonances of this Friedrichs model.

A. The Gamow vectors

Now, we shall obtain the explicit form of the Gamow vectors $|f_0\rangle$ and $|f_1\rangle$ corresponding to the Friedrichs model studied above. We shall obtain the Gamow vectors directly, using the analytic properties of $\eta(z)$. To begin with, let us write the Hamiltonian (5.1) as follows:

$$H=E_1|1\rangle\langle 1|+\int_0^\infty dE E|E\rangle\langle E|+\lambda\int_0^\infty dE\{V(E)|E\rangle\langle 1|+V^*(E)|1\rangle\langle E|\}, \tag{5.17}$$

where $V(E)$ is the form factor and $|E\rangle$ is the generalized eigenvector of H_0 with positive eigenvalue E, i.e.,

$$H_0|E\rangle=E|E\rangle. \tag{5.18}$$

The next goal is to find the generalized eigenvector of H with eigenvalue $w>0$. Equivalently, we have to solve the eigenvalue equation given by

$$(H-w)\mathbf{\Psi}(w)=0. \tag{5.19}$$

Since the vectors $|1\rangle$ and $|E\rangle$, with $E>0$ form a complete set, the solution $\mathbf{\Psi}(w)$ of Eq. (5.19) must have the form

$$\mathbf{\Psi}(w)=\psi(w)|1\rangle+\int_0^\infty dE\Psi(w,E)|E\rangle, \tag{5.20}$$

where $\psi(w)$ and $\Psi(w,E)$ are functions depending on these variables, w and E. In order to obtain them, we use (5.17) and (5.20) in (5.19). We obtain the following system of equations:

$$\begin{aligned}(E_1-w)\psi(E)+\lambda\int_0^\infty dE\Psi(w,E)V^*(E)=0,\\ (E-w)\Psi(w,E)+\lambda V(E)\psi(E)=0.\end{aligned} \tag{5.21}$$

The procedure to solve the system (5.21) is standard. The second equation in (5.21) allows us to write $\psi(E)$ in terms of $\Psi(w,E)$. This relation can be carried to the first equation in (5.21) to obtain an integro-differential equation which is easily solvable. The final result is

$$\mathbf{\Psi}_+(w)=|w\rangle+\lambda V^*(w)\,\frac{1}{\eta_+(w)}\left\{|1\rangle+\lambda\int_0^\infty dE\,\frac{V(E)}{[w-E]_+}\,|E\rangle\right\}, \tag{5.22}$$

where the plus sign in the denominator of (5.22) means that the function under the integral sign in (5.22) is given by the values on $\mathbb{R}^+$ of its extension from above to below. The expression (5.26) admits an analytic extension from above to below given by $\mathbf{\Psi}_+(z)$ having poles at the zeros of $\eta_+(z)$ with the same multiplicity. Therefore, this extension has a double pole located at the point z_R. In a neighborhood of z_R, $\mathbf{\Psi}_+(z)$ has the following form, according to the Laurent[48] theorem:

$$\mathbf{\Psi}_+(z)=\frac{\mathbf{C}_1}{(z-z_R)^2}+\frac{\mathbf{C}_2}{z-z_R}+O(z), \tag{5.23}$$

where $O(z)$ in (5.27) represents an analytic function of z. Now, the vectors $\mathbf{C}_1$ and $\mathbf{C}_2$ are easily evaluated with the help of (5.22). The singular part of $\mathbf{\Psi}_+(z)$, i.e., $\mathbf{\Psi}_+(z)-O(z)$, is now given by

$$\frac{\lambda V^*(z_R)}{(z-z_R)^2}\left\{|1\rangle+\lambda\int_0^\infty dE\,\frac{V(E)}{[z-E]_+}\,|E\rangle\right\}$$
$$=\frac{\lambda V^*(z_R)}{(z-z_R)^2}\left\{|1\rangle+\lambda\int_0^\infty dE\,\frac{V(E)}{[z_R-E]_+}\,|E\rangle-\lambda(z-z_R)\int_0^\infty dE\,\frac{V(E)}{[z_R-E]_+^2}\,|E\rangle\right\}+O(z), \tag{5.24}$$

where, again, $O(z)$ represents the analytic part. From, (5.23) and (5.24), we obviously have (save for an irrelevant multiplicative constant),

$$\mathbf{C}_1=|1\rangle+\lambda\int_0^\infty dE\,\frac{V(E)}{[z_R-E]_+}\,|E\rangle, \tag{5.25}$$

$$\mathbf{C}_2=-\lambda\int_0^\infty dE\,\frac{V(E)}{[z_R-E]_+^2}\,|E\rangle. \tag{5.26}$$

We now have to show that $\mathbf{C}_1$ and $\mathbf{C}_2$ are indeed the Gamow vectors we are looking for. More precisely, we want to show that

$$|f_0\rangle=\mathbf{C}_1;\ \ |f_1\rangle=\mathbf{C}_2. \tag{5.27}$$

Due to the properties of $|f_0\rangle$ and $|f_1\rangle$ presented in Sec. III, in order to show (5.27) we have to show that

$$H|f_0\rangle=z_R|f_0\rangle;\ \ H|f_1\rangle=z_R|f_1\rangle+|f_0\rangle. \tag{5.28}$$

The first equation in (5.28) can be easily obtained by applying (5.17) directly into (5.25). We want to note that this expression for $|f_0\rangle$ has already been obtained for the case of a nondegenerate resonance.[22] In order to show that $|f_1\rangle$ fulfills the second equation in (5.28), we apply (5.17) to (5.26). One gets

$$H|f_1\rangle=-\lambda\int_0^\infty dE'E'|E'\rangle\langle E'|\int_0^\infty dE\,\frac{V(E)}{[z_R-E]_+^2}\,|E\rangle$$
$$-\lambda^2\int_0^\infty dE'V^*(E)|1\rangle\langle E'|\int_0^\infty dE\,\frac{V(E)}{[z_R-E]_+^2}\,|E\rangle$$
$$=-\lambda\int_0^\infty dE\,\frac{EV(E)}{[z_R-E]_+^2}\,|E\rangle-\left[\lambda^2\int_0^\infty dE\,\frac{|V(E)|^2}{[z_R-E]_+^2}\right]|1\rangle. \tag{5.29}$$

The coefficient of $|1\rangle$ in (5.29) is equal to one. To show it, let us go back to (5.5) and extend it analytically from above to below. Thus, we obtain the following expression:

$$\eta_+(z)=E_1-z+\lambda^2\int_0^\infty dE\,\frac{|V(E)|^2}{[z-E]_+}. \tag{5.30}$$

Its derivative with respect to z is given by

$$\eta_+'(z)=-1-\lambda^2\int_0^\infty dE\,\frac{|V(E)|^2}{[z-E]_+^2}. \tag{5.31}$$

To obtain (5.31) from (5.30) we use similar arguments than those given in the proof of the Theorem in the Appendix. Since (5.16) implies that $\eta_+'(z_R)=0$, we have that

$$\eta_+'(z_R)=0=-1-\lambda^2\int_0^\infty dE\,\frac{|V(E)|^2}{[z_R-E]_+^2}, \tag{5.32}$$

which shows our claim.

Now, (5.29) can be written as

$$H|f_1\rangle = |1\rangle + \lambda \int_0^\infty dE\, \frac{(-E+z_R)V(E)}{[z_R-E]_+^2}|E\rangle + z_R\left[-\lambda \int_0^\infty dE\, \frac{V(E)}{[z_R-E]_+^2}|E\rangle\right]$$
$$= |1\rangle + \lambda \int_0^\infty dE\, \frac{V(E)}{[z_R-E]_+}|E\rangle + z_R\left[-\lambda \int_0^\infty dE\, \frac{V(E)}{[z_R-E]_+^2}|E\rangle\right]$$
$$= |f_0\rangle + z_R|f_1\rangle. \quad \blacksquare \tag{5.33}$$

Analogously, one obtains for $|\tilde{f}_0\rangle$ and $|\tilde{f}_1\rangle$ the following expressions:

$$|\tilde{f}_0\rangle = |1\rangle + \lambda \int_0^\infty dE\, \frac{V(E)}{[z_R^*-E]_-}|E\rangle, \tag{5.34}$$

$$|\tilde{f}_1\rangle = -\lambda \int_0^\infty dE\, \frac{V(E)}{[z_R^*-E]_-^2}|E\rangle. \tag{5.35}$$

B. Remarks

The Gamow–Jordan eigenvectors $|f_0\rangle$ and $|\tilde{f}_0\rangle$ coincide with the Gamow vectors for the Friedrichs model with simple resonances.[22]

The Gamow–Jordan vectors $|f_1\rangle$ and $|\tilde{f}_1\rangle$ are not unique and can be defined up to a term proportional to $|f_0\rangle$ and $|\tilde{f}_0\rangle$, respectively.

VI. CONCLUDING REMARKS

(1) The phenomenon of resonance overlapping[50,51] might be related to the double pole resonance formalism. Resonance overlapping is a trapping effect that appears when the width of two resonances is of the same order of magnitude as their average distance. The result of this trapping effect is to replace these resonances by another pair: one with a very short mean life and a second one with a very long mean life. However, this possibility has not been explored so far.

(2) This paper actually extends the Bohm–Gadella work[3,4,5,44] from simple to degenerate scattering resonances which are also poles of the extended resolvent for the evolution operator. This is the common point between the Bohm–Gadella work and the Brussels–Austin approach[18–25] where the extension of the resolvent was obtained through subdynamics. The understanding of resonances as singularities of the extended resolvent[12,24,31,41] is the natural generalization of both Bohm–Gadella and Brussels–Austin approaches.

(3) We restricted ourselves to the extended Schrödinger evolution which is intrinsically irreversible but not intrinsically probabilistic. Intrinsically probabilistic evolutions can be obtained in the Liouville space where we study the singularities of the extended Liouville operator. The extended Liouville evolution is the natural framework for quantum statistical physics and the theory of quantum measurements. We shall discuss the rigged Liouville space and the extended dual pairs of states and observables elsewhere.[52]

ACKNOWLEDGMENTS

We want to express our gratitude to Professors I. Prigogine and A. Bohm for their constant support and encouragement. We also thank Professors E. Brändas and A. Chatzidimitriou-Dreismann who stimulated our interest in the Jordan block structures and sent us their papers. We also thank Professor L. Horwitz who demonstrated to us the natural relation of multiple resonances with Jordan blocks and introduced us to the work of Katznelson. We received financial support from the International Solvay Institutes, the Belgian Interuniversity Attraction Poles, the European Commission ESPRIT Project No. CTIAC-21042, the NATO CRG CRG940077, the Spanish DGICYT PB 95-0719, and the Junta de Castilla y León PC01/197.

APPENDIX

The aim of this appendix is to present three interesting results relative to Hardy class functions on a half-plane. These results are used in this paper and, to the knowledge of the authors, are not explicitly given in the standard literature.

Theorem: Let $\varphi_+(E)\in\mathscr{H}^2_+\cap S$ and $z\in\mathbb{C}$. Then,

$$\varphi_+^n(z)=\frac{n!}{2\pi i}\int_{-\infty}^{\infty}\frac{\varphi(E)}{(E-z)^{n+1}}\,dE. \tag{A1}$$

Proof: Let us prove it for the first derivative, then, one obtains the general result by induction. Consider

$$\frac{\varphi_+(z+w)-\varphi_+(z)}{w}=\frac{1}{2\pi i w}\int_{-\infty}^{\infty}\left\{\frac{\varphi_+(E)}{(E-z-w)}-\frac{\varphi_+(E)}{E-z}\right\}dE$$

$$=\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{\varphi_+(E)dE}{(E-z-w)(E-z)}\,. \tag{A2}$$

If we take w small enough, we always have

$$|E-(z+w)|\geqslant|E-z|-|w|\geqslant|\mathrm{Im}\ z|-|w|. \tag{A3}$$

We may always assume that $|w|\leqslant\frac{1}{2}|\mathrm{Im}\ z|=h$. Then,

$$|E-(z+w)|\geqslant h\Rightarrow\frac{1}{|E-z-w|}\leqslant\frac{1}{h}\,. \tag{A4}$$

The modulus of the last integral in (A2) is less or equal to

$$\int_{-\infty}^{\infty}\frac{|\varphi_+(E)|dE}{h|E-z|}\leqslant\frac{1}{h}\left\{\int_{-\infty}^{\infty}|\varphi_+(E)|^2dE\right\}^{1/2}\left\{\int_{-\infty}^{\infty}\frac{1}{|E-z|^2}\right\}^{1/2} \tag{A5}$$

which obviously converges. Since

$$\frac{|\varphi_+(E)|}{|E-z||E-z-w|}\leqslant\frac{1}{h}\frac{|\varphi_+(E)|}{|E-z|}\,, \tag{A6}$$

the Lebesgue theorem says that one can exchange the symbols integral and limit (as $w\to0$) in (A2) so as to have

$$\lim_{w\to0}\frac{\varphi_+(z+w)-\varphi(z)}{w}=\frac{1}{2\pi i}\int_{-\infty}^{\infty}\lim_{w\to0}\frac{\varphi_+(E)dE}{(E-z-w)(E-z)}\,dE, \tag{A7}$$

which proves our result for $n=1$. ■

Proposition: If $\varphi_+\in\mathscr{H}^2_+\cap S$, $\varphi_+^{(n}(E)$ represents the boundary values of $\varphi_+^{(n}(z)$ with $\mathrm{Im}\,z>0$.

Proof: The Payley Wiener theorem[14–16] states that if $\mathrm{Im}\,z\geqslant0$, one has

$$\varphi_+(z)=\int_{-\infty}^{0}e^{-itz}F(t)dt,\quad\text{with}\quad F(t)\in S(\mathbb{R}^+). \tag{A8}$$

Deriving n times

$$\varphi_+^{(n}(z)=\int_{-\infty}^{0}(-it)^ne^{-itz}F(t)dt. \tag{A9}$$

This procedure can be done because the function under the integral sign is absolutely integrable. Since $(z=E+iy\ y>0)$,

$$|e^{-it(E+iy)}|=e^{ty}\Rightarrow|(-it)^n e^{-itz}F(t)|\leqslant t^n e^{ty}|F(t)| \quad t<0 \tag{A10}$$

which is integrable in $(-\infty,0)$. Thus, applying the Lebesgue theorem, we obtain

$$\lim_{y\to 0}\varphi_+^{(n}(E+iy)=\int_0^\infty \lim_{y\to 0}(-it)^n e^{-it(E+iy)}F(t)dt$$

$$=\int_{-0}^{\infty}(-it)^n e^{-itE}F(t)dt=\varphi_+^{(n}(E), \tag{A11}$$

which proves the proposition. ■

The next result intends to show the following: Given an analytic function on the two sheeted Riemann surface corresponding to the square root, we obtain an analytic function on the complex plane by using the transformation $z=p^2$. These two functions have the same structure, which means in particular that if the function on the complex plane has a zero at the point p_0, the function on the Riemann surface has a zero of the same multiplicity at the point $z_0=p_0^2$ and *vice versa* as we can see from our next result. Note that the correspondence between the surface and the plane is one to one. This result remains the same if we exchange the word zero for the word pole, since a complex meromorphic function, $\varphi(z)$ has a zero of order n at a point if and only $\varphi^{-1}(z)$ has a pole of order n at the same point.

Proposition: Let $g(p)=p^2$ and $z=p^2$. The analytic function $f(z)$ has a zero of order n at p_0 where $p_0^2=z_0$.

Proof: Let us prove this result for the case of a simple zero. The proof for higher order zeros is similar. This chain rule gives

$$\frac{d}{dz}(f\circ g)(p_0)=\frac{df}{dz}(z=z_0=g(p_0))\,\frac{dg}{dp}(p_0)=2p_0\,\frac{df}{dz}(z_0). \tag{A12}$$

From (A12) it is obvious that

$$\frac{d}{dz}(f\circ g)(p_0)=0 \quad \text{if} \quad \text{and} \quad \text{only} \quad \text{if}\ \frac{df}{dz}(z_0)=0. \tag{A13}$$

This is a zero of first order if and only if the respective second derivatives are different from zero at the points p_0 and z_0. To show this, let us use the chain rule for the second derivative,

$$\frac{d^2}{dz^2}(f\circ g)(p_0)=\frac{d^2f}{dz^2}(z_0)\left(\frac{dg}{dp}(p_0)\right)^2+\frac{df}{dz}(z_0)\,\frac{d^2g}{dp^2}(z_0). \tag{A14}$$

Since $f(z)$ has a zero at z_0, (A14) yields

$$\frac{d^2}{dz^2}(f\circ g)(p_0)=4p_0^2\,\frac{d^2g}{dz^2}(z_0), \tag{A15}$$

which shows that

$$\frac{d^2}{dz^2}(f\circ g)(p_0)\neq 0 \quad \text{if} \quad \text{and only} \quad \text{if}\ \frac{d^2g}{dz^2}(z_0)\neq 0. \tag{A16}$$

This proof for simple zeros shows us how to proceed in extending it to higher order zeros. ■

Representation-theoretic aspects of two-dimensional quantum systems in singular vector potentials: Canonical commutation relations, quantum algebras, and reduction to lattice quantum systems

Asao Arai[a)]
Department of Mathematics, Hokkaido University, Sapporo 060, Japan

(Received 23 June 1997; accepted for publication 13 January 1998)

Some representation-theoretic aspects of a two-dimensional quantum system of a charged particle in a vector potential $\mathbf{A}$, which may be singular on an infinite discrete subset $\mathbf{D}$ of $\mathbf{R}^2$ are investigated. For each vector $\mathbf{v}$ in a set $\mathbf{V}(\mathbf{D})\subset\mathbf{R}^2\backslash\{\mathbf{0}\}$, the projection $P_{\mathbf{v}}$ of the physical momentum operator $\mathbf{P}:=\mathbf{p}-\alpha\mathbf{A}$ to the direction of $\mathbf{v}$ is defined by $P_{\mathbf{v}}:=\mathbf{v}\cdot\mathbf{P}$ as an operator acting in $L^2(\mathbf{R}^2)$, where $\mathbf{p}=(-iD_x, -iD_y)[(x,y)\in\mathbf{R}^2]$ with D_x (resp., D_y) being the generalized partial differential operator in the variable x (resp., y) and $\alpha\in\mathbf{R}$ is a parameter denoting the charge of the particle. It is proven that $P_{\mathbf{v}}$ is essentially self-adjoint and an explicit formula is derived for the strongly continuous one-parameter unitary group $\{e^{itP_{\mathbf{v}}}\}_{t\in\mathbf{R}}$ generated by the self-adjoint operator $\overline{P_{\mathbf{v}}}$ (the closure of $P_{\mathbf{v}}$), i.e., the magnetic translation to the direction of the vector $\mathbf{v}$. The magnetic translations along curves in $\mathbf{R}^2\backslash\mathbf{D}$ are also considered. Conjugately to $P_{\mathbf{v}}$ and $P_{\mathbf{w}}$ $[\mathbf{w}\in\mathbf{V}(\mathbf{D})]$, a self-adjoint multiplication operator $Q_{\mathbf{v},\mathbf{w}}$ is introduced, which is a linear combination of the position operators x and y, such that, if $\mathbf{A}$ is flat on $\mathbf{R}^2\backslash\mathbf{D}$, then $\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}:=\{Q_{\mathbf{v},\mathbf{w}}, Q_{\mathbf{w},\mathbf{v}}, P_{\mathbf{v}}, P_{\mathbf{w}}\}$ gives a representation of the canonical commutation relations (CCR) with two degrees of freedom. Properties of the representation $\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ are analyzed. In particular, a necessary and sufficient condition for $\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ to be unitarily equivalent (or inequivalent) to the Schrödinger representation of CCR is established. The case where $\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ is inequivalent to the Schrödinger representation corresponds to the Aharonov–Bohm effect. Quantum algebraic structures [quantum plane and the quantum group $U_q(sl_2)$] associated with the pair $\{P_{\mathbf{v}}, P_{\mathbf{w}}\}$ are also discussed. Moreover, for every $\mathbf{A}$ in a class of vector potentials having singularities on the infinite lattice $\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2):=\{m\boldsymbol{\omega}_1+n\boldsymbol{\omega}_2|m,n\in\mathbf{Z}\}$ [the case $\mathbf{D}=\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$], where $\boldsymbol{\omega}_1\in\mathbf{R}^2$ and $\boldsymbol{\omega}_2\in\mathbf{R}^2$ are linearly independent, it is shown that the magnetic translations $e^{iP\boldsymbol{\omega}_j}$, $j=1,2$, with $\mathbf{A}$ replaced by a *modified* vector potential are reduced by the Hilbert space $l^2(\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2))$ identified with a closed subspace of $L^2(\mathbf{R}^2)$. This result, which may be regarded as one of the most important novel results of the present paper, establishes a connection of continuous quantum systems in vector potentials to lattice ones. © *1998 American Institute of Physics.*

I. INTRODUCTION

This article is a continuation of the previous articles[1–5] concerning gauge theory (quantum mechanics of a particle interacting with an external gauge potential) on a nonsimply connected space in two dimensions. In such a gauge theory, a representation of the canonical commutation relations (CCR) with two degrees of freedom is realized by the position and the physical momentum operators if the gauge potential is flat. The nonsimply connectedness of the base space is essential for this representation to be nontrivial, i.e., not necessarily be equivalent to the Schrödinger representation of CCR with two degrees of freedom. The unitary equivalence or inequivalence of the representation to the Schrödinger representation is completely characterized in terms

a)Electronic mail: arai@math.sci.hokudai.ac.jp

 © 1998 American Institute of Physics

of the local Wilson loops. An interesting feature to be noted here is that the celebrated Aharonov–Bohm effect[6] may be mathematically well understood as the representation inequivalent to the Schrödinger one. Some physical implications of the inequivalent representation in the Abelian case (the case of quantum mechanics of a charged particle in an external vector potential) are discussed in terms of the Dirac–Weyl operator (Ref. 2). Moreover, it is shown that, in the case where the vector potential is given in terms of the Weierstrass Zeta function with singularities at $z=m\omega_1+in\omega_2$, $m,n\in\mathbf{Z}$ ($\omega_j>0$, $j=1,2$), the inequivalent representation induces representations of quantum planes (rotation algebras) and the quantum group $U_q(sl_2)$ with $|q|=1$, $q\in\mathbf{C}$ (Ref. 5).

In this paper we further pursue representation-theoretic aspects of a two-dimensional Abelian gauge theory in which the vector potential may have singularities on an infinite set of points in $\mathbf{R}^2$ and show by bringing some new aspects to light that such a gauge theory may have richer and deeper structures. We first demonstrate by an explicit construction that, associated with the position and the physical momentum operators, there exists a wide class of inequivalent representations of CCR that includes those given in Refs. 1 and 5. The basic idea of the construction is to consider projections of the position and the physical momentum operators to directions of vectors in $\mathbf{R}^2$. As in the previous simpler cases discussed in Refs. 1 and 5, these new discovered representations of CCR give new representations of quantum planes and $U_q(sl_2)$ if the singularities of the vector potential form an infinite lattice.

Another new aspect of the present article is concerned with magnetic translations. These objects can be defined in both continuous and lattice quantum systems in external magnetic fields. Magnetic translations in the former systems in *uniform magnetic fields* have been discussed in some detail (e.g., Refs. 7–10), but, it seems that investigations of magnetic translations in the case of *nonuniform magnetic fields* are missing in the literature. In this paper we define, in the continuous quantum system under consideration, magnetic (parallel) translations as the strongly continuous one-parameter unitary groups generated by the projected physical momentum operators and study their properties.

On the other hand, magnetic translations on lattice quantum systems have been extensively discussed in connection with models of the Hofstadter type (e.g., Refs. 11–13 and references therein). Lattice models are usually defined by *ad hoc* procedures from continuous quantum systems (e.g., ''tight-binding approximation'' or other analogies). From a unified point of view, this situation is obviously unsatisfactory. It would be natural and interesting to investigate if there exists any *internal* (non-*ad hoc*) reduction mechanism by which a lattice quantum system ''dynamically'' emerges from a continuous quantum system. In this paper we show that such a mechanism exists. We regard this result as one of the most important new results of the present paper.

We now describe the outline of the present article in more detail. As already mentioned above, we consider a continuous quantum system of a charged particle with charge $\alpha\in\mathbf{R}\backslash\{0\}$ moving in the Euclidean plane $\mathbf{R}^2$ under the influence of a perpendicular magnetic field B. We denote by

$$\mathbf{A}(\mathbf{r}):=(A_1(\mathbf{r}),A_2(\mathbf{r})),\quad \mathbf{r}=(x,y)\in\mathbf{R}^2, \tag{1.1}$$

the vector potential of the magnetic field (up to gauge transformations), so that

$$B=D_xA_2-D_yA_1, \tag{1.2}$$

where D_x and D_y are the generalized (distributional) partial differential operators in the variables x and y, respectively.

Let

$$\mathbf{D}:=\{\mathbf{a}_n=(a_{n1},a_{n2})\}_{n\in\mathbf{N}} \tag{1.3}$$

be a set of points in $\mathbf{R}^2$ such that $\mathbf{a}_n\neq\mathbf{a}_m$ if $n\neq m$ and the set $\{a_{nj}\}_{n=1}^{\infty}$ ($j=1,2$) has no accumulation point in $\mathbf{R}$. Then

$$\mathbf{M}:=\mathbf{R}^2\backslash\mathbf{D} \tag{1.4}$$

is an open set of $\mathbf{R}^2$. We assume that $\mathbf{A}$ is continuous on $\mathbf{M}$. But $\mathbf{A}$ may be singular on $\mathbf{D}$ and B may be a distribution on $\mathbf{R}^2$ with support in $\mathbf{D}$. Except for some general aspects, it is essential for

the theory presented below to be nontrivial that **A** has singularities in **D**. The Hilbert space of state vectors of the quantum system under consideration can be taken to be $L^2(\mathbf{R}^2)$.

The operators,

$$p_1 := -iD_x, \quad p_2 := -iD_y, \tag{1.5}$$

acting in $L^2(\mathbf{R}^2)$ with domain $D(p_1) := \{\Psi \in L^2(\mathbf{R}^2) | D_x\Psi \in L^2(\mathbf{R}^2)\}$ and $D(p_2) := \{\Psi \in L^2(\mathbf{R}^2) | D_y\Psi \in L^2(\mathbf{R}^2)\}$ are self-adjoint, where, for an operator T, we denote by $D(T)$ its domain. The physical momentum operator (the velocity operator up to a constant multiple) $\mathbf{P} := (P_1, P_2)$ is given by

$$P_j := p_j - \alpha A_j, \quad j = 1,2, \tag{1.6}$$

acting in $L^2(\mathbf{R}^2)$ with $D(P_j) = D(p_j) \cap D(A_j)$.

For each vector $\mathbf{v} = (v_1, v_2) \in \mathbf{R}^2 \backslash \{0\}$, we define

$$P_{\mathbf{v}} := \mathbf{v} \cdot \mathbf{P} := \sum_{j=1}^{2} v_j P_j. \tag{1.7}$$

We call it the *projection of the physical momentum operator* (or simply *the projected physical momentum operator*) to the direction of **v**. The operator P_j is a special case of $P_{\mathbf{v}}$:

$$P_j = P_{\mathbf{e}_j}, \quad j = 1,2, \tag{1.8}$$

with

$$\mathbf{e}_1 := (1,0), \quad \mathbf{e}_2 := (0,1). \tag{1.9}$$

We introduce a subset of vectors $\mathbf{R}^2$. Let

$$\mathbf{v} \wedge \mathbf{w} := v_1 w_2 - v_2 w_1, \quad \mathbf{v}, \mathbf{w} \in \mathbf{R}^2. \tag{1.10}$$

Definition 1.1: We say that $\mathbf{v} \in \mathbf{R}^2 \backslash \{0\}$ is in the set $\mathbf{V}(\mathbf{D})$ if the sequence $\{\mathbf{v} \wedge \mathbf{a}_n\}_{n=1}^{\infty}$ has no accumulation point.

By the assumption for **D** stated above, $\mathbf{e}_j \in \mathbf{V}(\mathbf{D})$, $j = 1,2$.

In Sec. II we prove the essential self-adjointness of $P_{\mathbf{v}}$ with $\mathbf{v} \in \mathbf{V}(\mathbf{D})$ and clarify the spectral properties of the self-adjoint operator $\overline{P_{\mathbf{v}}}$ (the closure of $P_{\mathbf{v}}$) (Theorems 2.4 and 2.5).

The essential self-adjointness of $P_{\mathbf{v}}$ allows one to define the *continuous magnetic translations* to the direction of **v** as the elements of the strongly continuous one-parameter unitary group,

$$T_{\mathbf{v}}^{\mathbf{A}}(t) := e^{it\overline{P_{\mathbf{v}}}}, \quad t \in \mathbf{R}, \tag{1.11}$$

generated by $\overline{P_{\mathbf{v}}}$. We prove that there exist no nontrivial finite-dimensional subspaces of $L^2(\mathbf{R}^2)$ left invariant by $T_{\mathbf{v}}^{\mathbf{A}}(t)$ (Proposition 2.6).

Section III is devoted to a basic analysis of of the continuous magnetic translations. We derive an explicit formula for $T_{\mathbf{v}}^{\mathbf{A}}(t)$ (Theorem 3.2) and, using it, we compute commutation relations of $T_{\mathbf{v}}^{\mathbf{A}}(s)$ and $T_{\mathbf{w}}^{\mathbf{A}}(t)$ $[s,t \in \mathbf{R}, \mathbf{w} \in \mathbf{V}(\mathbf{D})]$ (Theorem 3.3).

In Sec. IV we define magnetic translations along curves in **M** and investigate their properties.

Section V is devoted to analysis of representations of CCR appearing in the quantum system under consideration. We first introduce multiplication operators given as linear combinations of the position operators,

$$q_1 := x, \quad q_2 := y. \tag{1.12}$$

Namely, for vectors $\mathbf{v}, \mathbf{w} \in \mathbf{V}(\mathbf{D})$ *linearly independent*, we define

$$Q_{\mathbf{v},\mathbf{w}} := \frac{\mathbf{q} \wedge \mathbf{w}}{\mathbf{v} \wedge \mathbf{w}}, \tag{1.13}$$

where $\mathbf{q}:=(q_1,q_2)$.

We denote by $C^k(\mathbf{M})$ the set of k times continuously differentiable functions on $\mathbf{M}$ and by $C_0^k(\mathbf{M})$ the set of functions in $C^k(\mathbf{M})$ with bounded support in $\mathbf{M}$.

We say that $\mathbf{A}$ with $A_j \in C^1(\mathbf{M})$ $(j=1,2)$ is *flat* on $\mathbf{M}$ if $B(\mathbf{r})=0$ for all $\mathbf{r}\in\mathbf{M}$. The flatness of $\mathbf{A}$ on $\mathbf{M}$ physically means the magnetic field B is concentrated on the discrete set $\mathbf{D}$ in the distribution sense.

We show that, if $A_j \in C^1(\mathbf{M})$, then

$$\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}:=\{L^2(\mathbf{R}^2), C_0^2(\mathbf{M}), Q_{\mathbf{v},\mathbf{w}}, Q_{\mathbf{w},\mathbf{v}}, \overline{P}_{\mathbf{v}}, \overline{P}_{\mathbf{w}}\} \tag{1.14}$$

is a representation of the CCR with two degrees of freedom if and only if $\mathbf{A}$ is flat on $\mathbf{M}$ (for the terminology on the representation theory of CCR, we refer to Ref. 5, Sec. 1). We analyze properties of this representation. We see that results similar to those of simpler cases in Refs. 1 and 5 hold in the present case too, generalizing them.

In Sect. VI we give some remarks on quantum algebraic structures [representations of quantum planes and $U_q(sl_2)$] associated with the representation $\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$.

In the last section we consider the problem of reduction of the continuous quantum system under consideration to a lattice one. For this purpose, we fix arbitrarily two linearly independent vectors,

$$\boldsymbol{\omega}_1:=(\omega_{11},\omega_{12}), \quad \boldsymbol{\omega}_2:=(\omega_{21},\omega_{22})\in\mathbf{R}^2, \tag{1.15}$$

such that $\boldsymbol{\omega}_1\wedge\boldsymbol{\omega}_2>0$ and take as $\mathbf{D}$ an infinite lattice,

$$\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2):=\{\boldsymbol{\Omega}_{m,n}|m,n\in\mathbf{Z}\}, \tag{1.16}$$

where

$$\boldsymbol{\Omega}_{m,n}:=m\boldsymbol{\omega}_1+n\boldsymbol{\omega}_2. \tag{1.17}$$

The Hilbert space of state vectors of a quantum system on the lattice $\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$ is taken to be

$$l^2(\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)):=\left\{\psi=\{\psi(\boldsymbol{\Omega}_{m,n})\}_{m,n\in\mathbf{Z}}\,\middle|\, \psi(\boldsymbol{\Omega}_{m,n})\in\mathbf{C}, \quad m,n\in\mathbf{Z}, \right.$$
$$\left.\sum_{m,n\in\mathbf{Z}}|\psi(\boldsymbol{\Omega}_{m,n})|^2<\infty\right\}. \tag{1.18}$$

This Hilbert space can be regarded as a closed subspace of $L^2(\mathbf{R}^2)$ in a natural way. Indeed, let $\mathbf{S}_{m,n}$ be the interior domain of the parallelogram determined by the four vectors $\boldsymbol{\Omega}_{m+1,n}-\boldsymbol{\Omega}_{m,n}$, $\boldsymbol{\Omega}_{m+1,n+1}-\boldsymbol{\Omega}_{m+1,n}$, $\boldsymbol{\Omega}_{m,n+1}-\boldsymbol{\Omega}_{m,n}$, $\boldsymbol{\Omega}_{m+1,n+1}-\boldsymbol{\Omega}_{m,n+1}$ and $\chi_{m,n}$ be the characteristic function of $\mathbf{S}_{m,n}$. Then each element $\psi\in l^2(\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2))$ can be regarded as an element of $L^2(\mathbf{R}^2)$ by the correspondence

$$\psi\to\tilde{\psi}:=\sum_{m,n\in\mathbf{Z}}\psi(\boldsymbol{\Omega}_{m,n})\chi_{m,n}\in L^2(\mathbf{R}^2),$$

so that, under this correspondence, $l^2(\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2))$ can be identified with the closed subspace,

$$L^2_{\omega_1,\omega_2}(\mathbf{R}^2):=\left\{\Psi\in L^2(\mathbf{R}^2)\,\middle|\,\Psi=\sum_{m,n\in\mathbf{Z}}\Psi_{m,n}\chi_{m,n},\Psi_{m,n}\in\mathbf{C},\sum_{m,n\in\mathbf{Z}}|\Psi_{m,n}|^2<\infty\right\}, \tag{1.19}$$

consisting of elements in $L^2(\mathbf{R}^2)$ being constant on each $\mathbf{S}_{m,n}$. It is easy to see that $\boldsymbol{\omega}_j \in\mathbf{V}(\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2))$, $j=1,2$. If the unitary operators,

$$T^{\mathbf{A}}_{\pm\boldsymbol{\omega}_j}:=T^{\mathbf{A}}_{\pm\boldsymbol{\omega}_j}(1), \quad j=1,2, \tag{1.20}$$

leave $L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2)$ invariant, then they are reduced by $L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2)$ and their restriction to $L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2)$ gives a set of magnetic translations on a quantum system on the lattice $\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$. In that case, models of the Hofstadter type on $\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$ are obtained as internal or ''dynamical'' reductions of models on the continuous space $\mathbf{R}^2\backslash\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$. Thus, the problem is to determine the class of vector potentials $\mathbf{A}$ such that $T^{\mathbf{A}}_{\pm\boldsymbol{\omega}_j}$ leave $L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2)$ invariant. At first sight, such vector potentials may seem not to exist, except for some physically trivial cases. This is certainly true as long as one considers *regular* vector potentials on $\mathbf{R}^2$. But, if the vector potential is allowed to be *singular* on the lattice $\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$, then the situation changes drastically. Indeed, in that case, we can show that there exists a method of constructing vector potentials $\mathbf{A}$ for which $T^{\mathbf{A}}_{\pm\boldsymbol{\omega}_j}$ leave $L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2)$ invariant. Roughly speaking, the method is as follows. Let

$$\omega_j=\omega_{j1}+i\omega_{j2},\quad j=1,2, \tag{1.21}$$

be the complex numbers corresponding to $\boldsymbol{\omega}_j\in\mathbf{R}^2$, $j=1,2(i:=\sqrt{-1})$. We take a meromorphic function $f(z)$ on $\mathbf{C}$ with poles at

$$\Omega_{m,n}:=m\omega_1+n\omega_2,\quad m,n\in\mathbf{Z}, \tag{1.22}$$

such that $df(z)/dz$ is an elliptic function with periods ω_j, $j=1,2$ and define a vector potential $\mathbf{A}$ by

$$A_1(\mathbf{r}):=\Im f(z),\quad A_2(\mathbf{r}):=\Re f(z),\quad \mathbf{r}=(x,y)\in\mathbf{R}^2,\quad z=x+iy. \tag{1.23}$$

We show that $T^{\mathbf{A}}_{\pm\boldsymbol{\omega}_j}$ themselves may not leave $L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2)$ invariant, but there exists a correspondence $\mathbf{A}\to\tilde{\mathbf{A}}$ of the vector potential such that $T^{\tilde{\mathbf{A}}}_{\pm\boldsymbol{\omega}_j}$ do leave $L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2)$ invariant.

Unfortunately we have been unable to solve the problem of determining *all* the vector potentials $\mathbf{A}$ such that $T^{\mathbf{A}}_{\pm\boldsymbol{\omega}_j}$ $(j=1,2)$ leave $L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2)$ invariant. We leave this problem for future study.

We remark that, in the same way as in Refs. 3 and 4, the results presented in Secs. II–V can be extended in a natural way to the case of non-Abelian gauge theories. If any significant aspects are discovered in the non-Abelian case, then we shall report them in a separate paper.

II. BASIC PROPERTIES OF THE PROJECTED PHYSICAL MOMENTUM OPERATORS

A. The physical momentum operator

The mathematical analysis of the physical momentum operator $\mathbf{P}$ in the present case can be made quite similarly to that in the case where $\mathbf{D}$ is a finite discrete set (Ref. 1). But, for the reader's convenience as well as for later reference, we briefly describe some basic properties of P_j, $j=1,2$. We introduce two sets:

$$\mathbf{M}_1:=\{(x,y)\in\mathbf{R}^2|x\in\mathbf{R},y\neq a_{n2},n\in\mathbf{N}\}, \tag{2.1}$$

$$\mathbf{M}_2:=\{(x,y)\in\mathbf{R}^2|x\neq a_{n1},n\in\mathbf{N},y\in\mathbf{R}\}, \tag{2.2}$$

which, by the assumed property of $\mathbf{D}$, are open sets of $\mathbf{R}^2$. Let

$$U_1(x,y):=e^{-i\alpha\int_0^x A_1(x',y)dx'},\quad U_2(x,y):=e^{-i\alpha\int_0^y A^2(x,y')dy'}. \tag{2.3}$$

Then $U_j\in C(\mathbf{M}_j)$, $j=1,2$. Since the Lebesgue measure of the set $\{(x,y)|x\in\mathbf{R},\ y=a_{n2},\ n\in\mathbf{N}\}$ (resp., $\{(x,y)|y\in\mathbf{R},\ x=a_{n1},\ n\in\mathbf{N}\}$) is zero, U_1 (resp., U_2) defines a unique multiplication unitary operator on $L^2(\mathbf{R}^2)$, which we denote by the same symbol U_1 (resp., U_2).

In what follows, we assume the following.

Hypothesis $(A)_k$: *For a non-negative integer* k, $A_j\in C^k(\mathbf{M})$, $j=1,2$.

Proposition 2.1: The operator $P_j(j=1,2)$ *is essentially self-adjoint on* $C_0^k(\mathbf{M}_j)$ *and the operator equations,*

$$\overline{P}_j = U_j^{-1} p_j U_j, \quad j=1,2, \tag{2.4}$$

hold.

Proof: The unitary operator U_j maps $C_0^k(\mathbf{M}_j)$ to itself bijectively and, for all $\Psi \in C_0^k(\mathbf{M}_j)$, $P_j\Psi = U_j^{-1} p_j U_j \Psi$, $j=1,2$. Since p_j is essentially self-adjoint on $C_0^k(\mathbf{M}_j)$, it follows that P_j is essentially self-adjoint on $C_0^k(\mathbf{M}_j)$ and (2.4) is obtained. ∎

We denote by $\sigma(P_j)$ [resp., $\sigma_{\mathrm{ac}}(P_j)$, $\sigma_p(P_j)$, $\sigma_{\mathrm{sc}}(P_j)$] the spectrum (resp., absolutely continuous, point, singular continuous spectrum) of P_j.

Proposition 2.1 (the unitary equivalence of P_j to p_j) and the well-known spectral property of p_j imply the following.

Proposition 2.2: For $j=1,2$,

$$\sigma(\overline{P}_j) = \sigma_{\mathrm{ac}}(\overline{P}_j) = \mathbf{R}, \quad \sigma_{\mathrm{p}}(\overline{P}_j) = \sigma_{\mathrm{sc}}(\overline{P}_j) = \varnothing. \tag{2.5}$$

B. The projected physical momentum operators

Let $\mathbf{V}(\mathbf{D})$ be as in Definition 1.1. For $\mathbf{v} \in \mathbf{V}(\mathbf{D})$, we define

$$L(\mathbf{a}_n;\mathbf{v}) = \{\mathbf{a}_n + s\mathbf{v} \mid s \in \mathbf{R}\}, \tag{2.6}$$

which is the straight line passing through the point $\mathbf{a}_n$ with the direction of $\mathbf{v}$. Then

$$\mathbf{M}_{\mathbf{v}}(\mathbf{D}) := \mathbf{R}^2 \backslash \cup_{n=1}^{\infty} L(\mathbf{a}_n;\mathbf{v}), \tag{2.7}$$

is an open set of $\mathbf{R}^2$.

It is well known that the angular momentum operator,

$$L := q_1 p_2 - q_2 p_1, \tag{2.8}$$

is essentially self-adjoint on $C_0^{\infty}(\mathbf{R}^2)$ (e.g., Ref. 14, Sec. 3). We denote its closure by the same symbol L. Then, for all $\theta \in \mathbf{R}$ and $\Psi \in L^2(\mathbf{R}^2)$, we have

$$(e^{i\theta L}\Psi)(\mathbf{r}) = \Psi(R(\theta)\mathbf{r}), \quad \text{a.e } \mathbf{r} \in \mathbf{R}^2, \tag{2.9}$$

where

$$R(\theta) := \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix} \tag{2.10}$$

is the rotation matrix in $\mathbf{R}^2$.

We write $\mathbf{v} = (v_1, v_2) \in \mathbf{V}(\mathbf{D})$ in the polar coordinate as

$$v_1 = v\cos\theta_{\mathbf{v}}, \quad v_2 = v\sin\theta_{\mathbf{v}}, \quad v = |\mathbf{v}|, \quad 0 \leqslant \theta_{\mathbf{v}} < 2\pi. \tag{2.11}$$

The function

$$A_{\mathbf{v}}(\mathbf{r}) := \frac{\mathbf{v}\cdot\mathbf{A}(R(\theta_{\mathbf{v}})\mathbf{r})}{v} \tag{2.12}$$

is in $C^k(R(-\theta_{\mathbf{v}})\mathbf{M}_{\mathbf{v}}(\mathbf{D}))$. We define

$$P_1(\mathbf{v}) := p_1 - \alpha A_{\mathbf{v}}. \tag{2.13}$$

Proposition 2.3: The operator $P_1(\mathbf{v})$ is essentially self-adjoint on $C_0^k(R(-\theta_{\mathbf{v}})\mathbf{M}_{\mathbf{v}}(\mathbf{D}))$.

Proof: We need only to apply Proposition 2.1 with A_1 and $\mathbf{a}_n$ replaced by $A_{\mathbf{v}}$ and $R(-\theta_{\mathbf{v}})\mathbf{a}_n$, respectively. ∎

The following theorem is a generalization of Proposition 2.1.

Theorem 2.4: *Let $\mathbf{v} \in \mathbf{V}(\mathbf{D})$. Then $P_{\mathbf{v}}$ is essentially self-adjoint on $C_0^k(\mathbf{M}_{\mathbf{v}}(\mathbf{D}))$ and the operator equation,*

$$e^{i\theta_{\mathbf{v}}L}\overline{P}_{\mathbf{v}}e^{-i\theta_{\mathbf{v}}L}=v\overline{P_1(\mathbf{v})}, \tag{2.14}$$

holds.

Proof: Let

$$\mathbf{p}:=(p_1,p_2). \tag{2.15}$$

Then it is easy to see that, for all $\theta\in\mathbf{R}$,

$$e^{i\theta L}\mathbf{p}e^{-i\theta L}=R(\theta)\mathbf{p}, \quad \text{on} \quad C_0^\infty(\mathbf{R}^2). \tag{2.16}$$

Hence

$$e^{i\theta_{\mathbf{v}}L}\mathbf{v}\cdot\mathbf{p}e^{-i\theta_{\mathbf{v}}L}=vp_1, \quad \text{on} \quad C_0^\infty(\mathbf{R}^2). \tag{2.17}$$

It is easy to see that

$$e^{-i\theta_{\mathbf{v}}L}C_0^k(R(-\theta_{\mathbf{v}})\mathbf{M}_{\mathbf{v}}(\mathbf{D}))=C_0^k(\mathbf{M}_{\mathbf{v}}(\mathbf{D})) \tag{2.18}$$

and

$$e^{i\theta_{\mathbf{v}}L}\mathbf{v}\cdot\mathbf{A}e^{-i\theta_{\mathbf{v}}L}=vA_{\mathbf{v}}, \quad \text{on} \quad C_0^k(R(-\theta_{\mathbf{v}})\mathbf{M}_{\mathbf{v}}(\mathbf{D})).$$

Hence

$$e^{i\theta_{\mathbf{v}}L}P_{\mathbf{v}}e^{-i\theta_{\mathbf{v}}L}=vP_1(\mathbf{v}), \quad \text{on} \quad C_0^k(R(-\theta_{\mathbf{v}})\mathbf{M}_{\mathbf{v}}(\mathbf{D})). \tag{2.19}$$

It follows from Proposition 2.3, (2.18) and (2.19), that $P_{\mathbf{v}}$ is essentially self-adjoint on $C_0^k(\mathbf{M}_{\mathbf{v}}(\mathbf{D}))$. This result implies that (2.19) can be extended to the operator equation (2.14). ■

Remark 2.1: If $\mathbf{D}$ is a finite discrete set, then $P_{\mathbf{v}}$ is essentially self-adjoint for all $\mathbf{v}\in\mathbf{R}^2\backslash\{0\}$.

By (2.14) and Proposition 2.2, we obtain the following result on the spectral property of $\overline{P}_{\mathbf{v}}$.

Theorem 2.5: *For all* $\mathbf{v}\in\mathbf{V}(\mathbf{D})$,

$$\sigma(\overline{P}_{\mathbf{v}})=\sigma_{\mathrm{ac}}(\overline{P}_{\mathbf{v}})=\mathbf{R}, \quad \sigma_{\mathrm{p}}(\overline{P}_{\mathbf{v}})=\sigma_{\mathrm{sc}}(\overline{P}_{\mathbf{v}})=\varnothing. \tag{2.20}$$

C. Nonexistence of nontrivial finite-dimensional subspaces left invariant by continuous magnetic translations

Let $T_{\mathbf{v}}^{\mathbf{A}}(t)$ be defined as in (1.11). The following fact is important in considering the algebra generated by the magnetic translations $T_{\mathbf{v}_j}^{\mathbf{A}}(t)$, $j=1,...,n$ $(n\in\mathbf{N},\ \mathbf{v}_j\in\mathbf{V}(\mathbf{D}))$.

Proposition 2.6: Let $t\in\mathbf{R}\backslash\{0\}$ *and* $\mathbf{v}\in\mathbf{V}(\mathbf{D})$. *Then there exist no nontrivial finite dimensional subspaces of* $L^2(\mathbf{R}^2)$ *that are left invariant by* $T_{\mathbf{v}}^{\mathbf{A}}(t)$.

Proof: Suppose that there exists a finite-dimensional subspace $\mathscr{K}\neq\{0\}$ of $L^2(\mathbf{R}^2)$ that is left invariant by $T_{\mathbf{v}}^{\mathbf{A}}(t)$. Then $T_{\mathbf{v}}^{\mathbf{A}}(t)$ is reduced by $\mathscr{K}$. Since $T_{\mathbf{v}}^{\mathbf{A}}(t)$ is unitary and $\mathscr{K}$ is finite dimensional, the reduced part $T_{\mathbf{v}}^{\mathbf{A}}(t)[\mathscr{K}$ has an eigenvalue λ_0 with $|\lambda_0|=1$. This is also an eigenvalue of $T_{\mathbf{v}}^{\mathbf{A}}(t)$ on $L^2(\mathbf{R}^2)$. It follows from the spectral theorem of self-adjoint operators that $P_{\mathbf{v}}$ has an eigenvalue of the form $(\arg\lambda_0+2\pi n_0)/t$ $(n_0\in\mathbf{Z})$. But this contradicts the fact that $\sigma_{\mathrm{p}}(P_{\mathbf{v}})=\varnothing$ (Theorem 2.5). Thus, we obtain the desired result. ■

III. CONTINUOUS MAGNETIC TRANSLATIONS GENERATED BY THE PROJECTED PHYSICAL MOMENTUM OPERATORS

A. Explicit representations

Let

$$p_{\mathbf{v}}=\mathbf{v}\cdot\mathbf{p}, \quad \mathbf{v}\in\mathbf{R}^2. \tag{3.1}$$

Then we have for all $t\in\mathbf{R}$ and $\Psi\in L^2(\mathbf{R}^2)$,

$$(e^{itp_{\mathbf{v}}}\Psi)(\mathbf{r})=\Psi(\mathbf{v}+t\mathbf{v}),\quad \text{a.e. } \mathbf{r}\in\mathbf{R}^2. \tag{3.2}$$

Let $T^{\mathbf{A}}_{\mathbf{v}}(t)$ be defined by (1.11). Proposition 2.1 implies that, for all $t\in\mathbf{R}$,

$$T^{\mathbf{A}}_{\mathbf{e}_j}(t)=e^{itP_j}=U_j^{-1}e^{itp_j}U_j=U_j^{-1}e^{itp_{\mathbf{e}_j}}U_j,\quad j=1,2. \tag{3.3}$$

For two vectors $\mathbf{a},\mathbf{b}\in\mathbf{R}^2$, we denote by $\int_{\mathbf{a}}^{\mathbf{b}}\mathbf{A}(\mathbf{r})\cdot d\mathbf{r}$ the line integral of $\mathbf{A}$ over the straight line from $\mathbf{a}$ to $\mathbf{b}$.

Using (3.3) and (3.2), we can obtain an explicit formula for $T^{\mathbf{A}}_{\mathbf{e}_j}(t)$.

Theorem 3.1: *For all $t\in\mathbf{R}$, and $\Psi\in L^2(\mathbf{R}^2)$,*

$$(T^{\mathbf{A}}_{\mathbf{e}_j}(t)\Psi)(\mathbf{r})=e^{-i\alpha\int_{\mathbf{r}}^{\mathbf{r}+t\mathbf{e}_j}\mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}'}\Psi(\mathbf{r}+t\mathbf{e}_j)=e^{-i\alpha\int_{\mathbf{r}}^{\mathbf{r}+t\mathbf{e}_j}\mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}'}(e^{itp_{\mathbf{e}_j}}\Psi)(\mathbf{r}),\quad \text{a.e. } \mathbf{r}. \tag{3.4}$$

Theorem 3.1 can be extended to the case of the magnetic translation $T^{\mathbf{A}}_{\mathbf{v}}(t)$ with any vector $\mathbf{v}\in\mathbf{V}(\mathbf{D})$.

Theorem 3.2: *Let $\mathbf{v}\in\mathbf{V}(\mathbf{D})$. Then, for all $t\in\mathbf{R}$ and $\Psi\in L^2(\mathbf{R}^2)$,*

$$(T^{\mathbf{A}}_{\mathbf{v}}(t)\Psi)(\mathbf{r})=e^{-i\alpha\int_{\mathbf{r}}^{\mathbf{r}+t\mathbf{v}}\mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}'}\Psi(\mathbf{r}+t\mathbf{v})=e^{-i\alpha\int_{\mathbf{r}}^{\mathbf{r}+t\mathbf{v}}\mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}'}(e^{itp_{\mathbf{v}}}\Psi)(\mathbf{r}),\quad \text{a.e. } \mathbf{r}. \tag{3.5}$$

Proof: By Theorem 2.4, we have, for all $t\in\mathbf{R}$,

$$T^{\mathbf{A}}_{\mathbf{v}}(t)=e^{-i\theta_{\mathbf{v}}L}e^{itv\overline{P_1(\mathbf{v})}}e^{i\theta_{\mathbf{v}}L}. \tag{3.6}$$

Let $\Psi\in L^2(\mathbf{R}^2)$ and set $R(-\theta_{\mathbf{v}})\mathbf{r}=(x(\mathbf{v}),y(\mathbf{v}))$. Then we have, by (3.4),

$$(T^{\mathbf{A}}_{\mathbf{v}}(t)\Psi)(\mathbf{r})=e^{-i\alpha\int_{x(\mathbf{v})}^{x(\mathbf{v})+tv}A_{\mathbf{v}}(x',y(\mathbf{v}))dx'}\Psi(\mathbf{r}+tvR(\theta_{\mathbf{v}})\mathbf{e}_1),\quad \text{a.e. } \mathbf{r}.$$

Noting that $vR(\theta_{\mathbf{v}})\mathbf{e}_1=\mathbf{v}$ and

$$\int_{x(\mathbf{v})}^{x(\mathbf{v})+tv}A_{\mathbf{v}}(x',y(\mathbf{v}))dx'=t\int_0^1\mathbf{v}\cdot\mathbf{A}(\mathbf{r}+\lambda t\mathbf{v})d\lambda=\int_{\mathbf{r}}^{\mathbf{r}+t\mathbf{v}}\mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}',$$

we obtain (3.5). ■

Remark 3.1: We have, for all $t\in\mathbf{R}\backslash\{0\}$ and $\mathbf{v}\in\mathbf{V}(\mathbf{D})$,

$$t\overline{P_{\mathbf{v}}}=\overline{P_{t\mathbf{v}}}, \tag{3.7}$$

which implies that

$$T^{\mathbf{A}}_{\mathbf{v}}(t)=T^{\mathbf{A}}_{t\mathbf{v}}(1). \tag{3.8}$$

Thus, as for the magnetic translations generated by $\overline{P_{\mathbf{v}}}$, it is sufficient to consider the unitary operator,

$$T^{\mathbf{A}}_{\mathbf{v}}:=T^{\mathbf{A}}_{\mathbf{v}}(1). \tag{3.9}$$

B. Commutation relations

Let $\mathbf{v},\mathbf{w}\in\mathbf{V}(\mathbf{D})$ such that $\mathbf{v}$ and $\mathbf{w}$ are linearly independent, and set

$$\begin{aligned}C_{\mathbf{r}}(\mathbf{v},\mathbf{w}):=&\{\mathbf{r}+\lambda\mathbf{v}|0\leqslant\lambda\leqslant1\}\circ\{\mathbf{r}+\mathbf{v}+\lambda\mathbf{w}|0\leqslant\lambda\leqslant1\}\circ\{\mathbf{r}+(1-\lambda)\mathbf{v}+\mathbf{w}|0\leqslant\lambda\leqslant1\}\\&\circ\{\mathbf{r}+(1-\lambda)\mathbf{w}|0\leqslant\lambda\leqslant1\},\end{aligned} \tag{3.10}$$

which is the closed curve starting and ending at the point $\mathbf{r}$, forming the circumference of the parallelogram with vertices $\mathbf{r}$, $\mathbf{r}+\mathbf{v}$, $\mathbf{r}+\mathbf{v}+\mathbf{w}$, $\mathbf{r}+\mathbf{w}$. We introduce

$$\mathbf{M}_{\mathbf{v},\mathbf{w}}(\mathbf{D}):=\mathbf{R}^2\backslash\cup_{n=1}^{\infty}[L(\mathbf{a}_n;\mathbf{v})\cup(L(\mathbf{a}_n;\mathbf{v})-\mathbf{w})\cup L(\mathbf{a}_n;\mathbf{w})\cup(L(\mathbf{a}_n;\mathbf{w})-\mathbf{v})]. \tag{3.11}$$

Note that, if $\mathbf{r}\in\mathbf{M}_{\mathbf{v},\mathbf{w}}(\mathbf{D})$, then $C_{\mathbf{r}}(\mathbf{v},\mathbf{w})$ does not intersect $\mathbf{D}$. We define

$$\Phi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}(\mathbf{r})=\int_{C_{\mathbf{r}}(\mathbf{v},\mathbf{w})}\mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}', \quad \mathbf{r}\in\mathbf{M}_{\mathbf{v},\mathbf{w}}(\mathbf{D}), \tag{3.12}$$

which physically means the magnetic flux passing through the interior domain of $C_{\mathbf{r}}(\mathbf{v},\mathbf{w})$. Since the Lebesgue measure of $\mathbf{R}^2\backslash\mathbf{M}_{\mathbf{v},\mathbf{w}}(\mathbf{D})$ is zero, the function $\Phi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ defines a unique multiplication self-adjoint operator on $L^2(\mathbf{R}^2)$. We denote it by the same symbol.

Theorem 3.3: *Let* $\mathbf{v}$ *and* $\mathbf{w}$ *be as above. Then*

$$T^{\mathbf{A}}_{\mathbf{v}}T^{\mathbf{A}}_{\mathbf{w}}=\exp(-i\alpha\Phi^{A}_{\mathbf{v},\mathbf{w}})T^{\mathbf{A}}_{\mathbf{w}}T^{\mathbf{A}}_{\mathbf{v}}. \tag{3.13}$$

Proof: Using Theorem 3.2, we have, for all $\Psi\in L^2(\mathbf{R}^2)$ and a.e. $\mathbf{r}$,

$$(T^{\mathbf{A}}_{\mathbf{v}}T^{\mathbf{A}}_{\mathbf{w}}\Psi)(\mathbf{r})=e^{-i\alpha\int_{\mathbf{r}}^{\mathbf{r}+\mathbf{v}}\mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}'}e^{-i\alpha\int_{\mathbf{r}+\mathbf{v}}^{\mathbf{r}+\mathbf{v}+\mathbf{w}}\mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}'}\Psi(\mathbf{r}+\mathbf{v}+\mathbf{w}), \tag{3.14}$$

from which (3.13) easily follows. ■

Remark 3.2: Formula (3.13) is a generalization of a formula established in Ref. 1 [see (2.1) in Ref. 1, which corresponds to the case where $\mathbf{v}=\mathbf{e}_1$, $\mathbf{w}=\mathbf{e}_2$, and $\mathbf{A}$ may be singular on a finite discrete set of points].

IV. MAGNETIC TRANSLATIONS ALONG CURVES

In this section we consider magnetic translations along curves in $\mathbf{M}$. *Throughout this section we assume that*

$$\mathbf{V}(\mathbf{D})=\mathbf{R}^2\backslash\{0\}, \tag{4.1}$$

so that, for every vector $\mathbf{v}\in\mathbf{R}^2\backslash\{0\}$, the projected physical momentum operator $\overline{P_{\mathbf{v}}}$ can be defined as a self-adjoint operator.

An example of such $\mathbf{D}$ is given by $\mathbf{D}=\{\mathbf{\Omega}_{m,n}|m\in\mathbf{Z},n\in[-M,M']\cap\mathbf{Z}\}$, where $\mathbf{\Omega}_{m,n}$ is given by (1.17) and $M,M'\in\mathbf{N}$.

Let C be a continuous curve in $\mathbf{M}$ with parametrization $C=\{\mathbf{u}(s)|s\in[a,b]\}(-\infty<a<b<\infty)$. Let $\{s_0,s_1,\ldots,s_n\}$ be a partition of $[a,b]$ $(a=s_0<s_1<\cdots<s_{n-1}<s_n=b)$ such that $\max_{k=1,\ldots,n}(s_k-s_{k-1})\to 0(n\to\infty)$ and $\Delta\mathbf{u}_k:=\mathbf{u}(s_k)-\mathbf{u}(s_{k-1})$, $k=1,\ldots,n$. Then we define

$$U(C):=\mathrm{s}-\lim_{n\to\infty}e^{-i\overline{P}_{\Delta\mathbf{u}_n}}e^{-i\overline{P}_{\Delta\mathbf{u}_{n-1}}}\cdots e^{-i\overline{P}_{\Delta\mathbf{u}_1}}, \tag{4.2}$$

if the right-hand side (rhs) exists, where s-lim means strong limit. It follows that $U(C)$ is unitary. We call $U(C)$ the *magnetic translation along the curve* C.

We introduce

$$\Phi(C):=\int_C\mathbf{A}(\mathbf{r})\cdot d\mathbf{r}, \tag{4.3}$$

the line integral of $\mathbf{A}$ along the curve C. For $\mathbf{r}\in\mathbf{R}^2$ we define a curve $C_{\mathbf{r}}$ by

$$C_{\mathbf{r}}:=C+\mathbf{r}-\mathbf{u}(b). \tag{4.4}$$

We denote by $F(C)$ the multiplication operator by the function: $\mathbf{r}\to e^{i\alpha\Phi(C_{\mathbf{r}})}$:

$$(F(C)\Psi)(\mathbf{r})=e^{i\alpha\Phi(C_{\mathbf{r}})}\Psi(\mathbf{r}), \quad \Psi\in L^2(\mathbf{R}^2), \quad \text{a.e. } \mathbf{r}\in\mathbf{R}^2. \tag{4.5}$$

Remark 4.1: In the case where $\mathbf{A}$ has singularities on $\mathbf{D}$, the function: $\mathbf{r}\to\Phi(C_{\mathbf{r}})$ is originally defined only on $\mathbf{R}^2\backslash\cup_{n\in\mathbf{N}}\{\mathbf{a}_n+\mathbf{u}(b)-\mathbf{u}(s)|s\in[a,b]\}$. But the Lebesgue measure of the set $\cup_{n\in\mathbf{N}}\{\mathbf{a}_n+\mathbf{u}(b)-\mathbf{u}(s)|s\in[a,b]\}$ is zero, so that $e^{i\alpha\Phi(C_{\mathbf{r}})}$ defines a unique multiplication unitary operator on $L^2(\mathbf{R}^2)$.

Theorem 4.1: *The rhs of (4.2) exists and*

$$U(C)=F(C)e^{i\overline{P}_{\mathbf{u}(a)-\mathbf{u}(b)}}. \tag{4.6}$$

Proof: Let

$$U_n(C)=e^{-i\overline{P}_{\Delta\mathbf{u}_n}}e^{-i\overline{P}_{\Delta\mathbf{u}_{n-1}}}\cdots e^{-i\overline{P}_{\Delta\mathbf{u}_1}}.$$

By applying (3.5) repeatedly, we have, for all $\Psi\in L^2(\mathbf{R}^2)$,

$$(U_n(C)\Psi)(\mathbf{r})=e^{i\alpha\Phi_n(\mathbf{r})}(e^{i\overline{P}_{\mathbf{u}(a)-\mathbf{u}(b)}}\Psi)(\mathbf{r}),\quad \text{a.e.}\quad \mathbf{r},$$

with

$$\Phi_n(\mathbf{r})=\sum_{k=1}^{n-1}\int_{\mathbf{r}-\Delta\mathbf{u}_k-\Delta\mathbf{u}_{k+1}-\cdots-\Delta\mathbf{u}_n}^{\mathbf{r}-\Delta\mathbf{u}_{k+1}-\Delta\mathbf{u}_{k+2}-\cdots-\Delta\mathbf{u}_n}\mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}'+\int_{\mathbf{r}-\Delta\mathbf{u}_n}^{\mathbf{r}}\mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}'.$$

Hence

$$\int_{\mathbf{R}^2}|(U_n(C)\Psi)(\mathbf{r})-(F(C)e^{i\overline{P}_{\mathbf{u}(a)-\mathbf{u}(b)}}\Psi)(\mathbf{r})|^2d\mathbf{r}=\int_{\mathbf{R}^2}|e^{i\alpha\Phi_n(\mathbf{r})}-e^{i\alpha\Phi(C_{\mathbf{r}})}|^2|\Psi(\mathbf{r}-\mathbf{u}(b)+\mathbf{u}(a))|^2d\mathbf{r}.$$

It is easy to see that, for all $\mathbf{r}\in\mathbf{R}^2\backslash\cup_{n\in\mathbf{N}}\{\mathbf{a}_n+\mathbf{u}(b)-\mathbf{u}(s)|s\in[a,b]\}$, $\lim_{n\to\infty}\Phi_n(\mathbf{r})=\Phi(C_{\mathbf{r}})$, and

$$|e^{i\alpha\Phi_n(\mathbf{r})}-e^{i\alpha\Phi(C_{\mathbf{r}})}|^2|\Psi(\mathbf{r}-\mathbf{u}(b)+\mathbf{u}(a))|^2\leqslant 4|\Psi(\mathbf{r}-\mathbf{u}(b)+\mathbf{u}(a))|^2.$$

Hence, by the Lebesgue dominated convergence theorem, we have

$$\lim_{n\to\infty}\int_{\mathbf{R}^2}|e^{i\alpha\Phi_n(\mathbf{r})}-e^{i\alpha\Phi(C_{\mathbf{r}})}|^2|\Psi(\mathbf{r}-\mathbf{u}(b)+\mathbf{u}(a))|^2d\mathbf{r}=0.$$

Hence (4.6) follows. ■

Remark 4.2: (1) Suppose that C is continuously differentiable. Then we can show that $U(C)$ is the product integral of the operator-valued function: $s\to -i\overline{P}_{d\mathbf{u}(s)/ds}$ on the interval $[a,b]$ (for the product integral, see Ref. 15).

(2) By (4.6), we have, for all $\Psi\in L^2(\mathbf{R}^2)$,

$$(U(C)\Psi)(\mathbf{r})=e^{i\alpha\Phi(C_{\mathbf{r}})}\Psi(\mathbf{r}+\mathbf{u}(a)-\mathbf{u}(b)),\quad \text{a.e.}\quad \mathbf{r}. \tag{4.7}$$

Let $E=\mathbf{M}\times\mathbf{C}$ be the trivial vector bundle with base space $\mathbf{M}$, fibre $\mathbf{C}$, and structure group $U(1)$ (the one-dimensional unitary group), and $\mathbf{V}_{\mathbf{r}}=\mathbf{C}$ be the fibre at the point $\mathbf{r}\in\mathbf{M}$. Then the rhs of (4.7) geometrically means the parallel transport of the vector $\Psi(\mathbf{r}+\mathbf{u}(a)-\mathbf{u}(b))\in\mathbf{V}_{\mathbf{r}+\mathbf{u}(a)-\mathbf{u}(b)}$ to the point $\mathbf{r}$ along the curve $C_{\mathbf{r}}$ with the connection one-form $-iA:=(-i)(A_1dx+A_2dy)$ (see, e.g., Ref. 16).

As a corollary of Theorem 4.1, we obtain the following.

Theorem 4.2: (i) *We have*

$$U(C)^*=e^{-i\overline{P}_{\mathbf{u}(a)-\mathbf{u}(b)}}F(C)^* \tag{4.8}$$

$$=\operatorname*{s-lim}_{n\to\infty}e^{i\overline{P}_{\Delta\mathbf{u}_1}}e^{i\overline{P}_{\Delta\mathbf{u}_2}}\cdots e^{i\overline{P}_{\Delta\mathbf{u}_n}}. \tag{4.9}$$

(ii) *Let C_1 and C_2 be any continuous curves in $\mathbf{M}$ such that the terminal point of C_1 coincides with the initial point of C_2, so that the composition $C_1\circ C_2$ is also a continuous curve whose initial (resp., terminal) point is that of C_1 (resp., that of C_2). Then*

$$U(C_1)U(C_2)=U(C_1\circ C_2). \tag{4.10}$$

Proof: (i) Equation (4.8) follows from taking the adjoint of (4.6). In general, if unitary operators V_n, V on a Hilbert space satisfy s-$\lim_{n\to\infty} V_n = V$, then s-$\lim_{n\to\infty} V_n^* = V^*$. Applying this fact, we obtain (4.9).

(ii) This easily follows from applying formula (4.6). ■

Let $a \leqslant t \leqslant b$ and

$$C(t) = \{\mathbf{u}(s) | s \in [a,t]\}. \tag{4.11}$$

Then the correspondence $t \to U(C(t))$ gives an operator-valued function from $[a,b]$ into the set of unitary operators on $L^2(\mathbf{R}^2)$. We want to derive a differential equation for $U(C(t))$.

For a Hilbert space $\mathscr{H}$, we denote by $\mathsf{B}(\mathscr{H})$ the set of bounded linear operators on $\mathscr{H}$.

Lemma 4.3: Let $\mathscr{H}$ be a Hilbert space, and V and W be $\mathsf{B}(\mathscr{H})$-valued functions on $[a,b]$. Assume the following (i) and (ii): (i) V is strongly continuous on $\mathscr{H}$; (ii) there exist subspaces $\mathscr{D}_1$ and $\mathscr{D}_2$ of $\mathscr{H}$ such that V and W are strongly differentiable on $\mathscr{D}_1$ and $\mathscr{D}_2$, respectively, and $W(t)\mathscr{D}_2 \subset \mathscr{D}_1$ for all $t \in [a,b]$. Then the $\mathsf{B}(\mathscr{H})$-valued function: $t \to V(t)W(t)$ is strongly differentiable on $\mathscr{D}_2$ and, for all $\psi \in \mathscr{D}_2$,

$$\frac{d}{dt} V(t)W(t)\psi = \frac{dV(t)}{dt} W(t)\psi + V(t) \frac{dW(t)}{dt} \psi, \quad t \in [a,b], \tag{4.12}$$

where $dV(t)/dt$ [resp., $dW(t)/dt$] denotes the strong derivative of $V(t)$ [resp., $W(t)$] on $\mathscr{D}_1$ (resp., $\mathscr{D}_2$).

Proof: Let $X(t) = V(t)W(t)$ and $\psi \in \mathscr{D}_2$. Then we have for all $t \in (a,b)$ and $\epsilon \in \mathbf{R}$ with $|\epsilon|$ sufficiently small,

$$\begin{aligned}
&\frac{X(t+\epsilon)-X(t)}{\epsilon} \psi - \frac{dV(t)}{dt} W(t)\psi - V(t) \frac{dW(t)}{dt} \psi \\
&= V(t+\epsilon)\left\{ \frac{W(t+\epsilon)-W(t)}{\epsilon} \psi - \frac{dW(t)}{dt} \psi \right\} + [V(t+\epsilon)-V(t)] \frac{dW(t)}{dt} \psi \\
&\quad + \left\{ \frac{V(t+\epsilon)-V(t)}{\epsilon} - \frac{dV(t)}{dt} \right\} W(t)\psi.
\end{aligned}$$

By the strong continuity of V and the principle of uniform boundedness, we have $\sup_{t\in[a,b]} \|V(t)\| < \infty$. Using this fact and the assumed properties of V and W, we obtain the desired result. ■

Let

$$\mathbf{M}_C = \mathbf{R}^2 \backslash \cup_{n\in\mathbf{N}} \{\mathbf{a}_n + \mathbf{u}(t) - \mathbf{u}(s) | s,t \in [a,b]\}. \tag{4.13}$$

Theorem 4.4: *Let C be continuously differentiable. Suppose that $\mathbf{M}_C$ is an open set and Hypothesis $(A)_1$ holds. Then the operator-valued function $U(C(\cdot))^*$ on $[a,b]$ is strongly differentiable on $C_0^1(\mathbf{M}_C)$ with*

$$\frac{d}{dt} U(C(t))^* \Psi = iU(C(t))^* P_{d\mathbf{u}(t)/dt} \Psi, \quad t \in [a,b], \quad \Psi \in C_0^1(\mathbf{M}_C). \tag{4.14}$$

Proof (Outline)*:* Let $V(t) = e^{-i\overline{p}_{\mathbf{u}(a)-\mathbf{u}(t)}}$ and $W(t) = F(C(t))^*$. Then we have $U(C(t))^* = V(t)W(t)$. It is not so difficult to show that V is strongly continuous on $L^2(\mathbf{R}^2)$ and strongly differentiable on $C_0^1(\mathbf{R}^2)$ with

$$\frac{dV(t)}{dt} \Psi = iV(t) p_{d\mathbf{u}(t)/dt} \Psi, \quad \Psi \in C_0^1(\mathbf{R}^2)$$

(cf. the proof of Theorem 4.1). Let $\Psi \in C_0^1(M_C)$. Then

$$(W(t)\Psi)(\mathbf{r})=\exp\left(-i\alpha\int_a^t \mathbf{A}(\mathbf{u}(s)-\mathbf{u}(t)+\mathbf{r})\cdot\frac{d\mathbf{u}(s)}{ds}\,ds\right)\Psi(\mathbf{r}).$$

It follows from this formula and the present assumption for $\mathbf{A}$ that $W(t)C_0^1(\mathbf{M}_C)\subset C_0^1(\mathbf{M}_C)$ and $W(t)$ is strongly differentiable on $C_0^1(\mathbf{M}_C)$ with

$$\left(\frac{dW(t)}{dt}\,\Psi\right)(\mathbf{r})=\exp\left(-i\alpha\int_a^t \mathbf{A}(\mathbf{u}(s)-\mathbf{u}(t)+\mathbf{r})\cdot\frac{d\mathbf{u}(s)}{ds}\,ds\right)\left(-i\alpha\,\frac{d\mathbf{u}(t)}{dt}\cdot\mathbf{A}(\mathbf{r})\right.$$
$$\left.+i\alpha\sum_{j,k=1}^{2}\int_a^t\frac{du_j(t)}{dt}\,(\partial_j A_k)(\mathbf{u}(s)-\mathbf{u}(t)+\mathbf{r})\,\frac{du_k(s)}{ds}\,ds\right)\Psi(\mathbf{r}),$$

where $\partial_1:=\partial/\partial x$, $\partial_2:=\partial/\partial y$. On the other hand, we have

$$(ip_{d\mathbf{u}(t)/dt}W(t)\Psi)(\mathbf{r})=\exp\left(-i\alpha\int_a^t \mathbf{A}(\mathbf{u}(s)-\mathbf{u}(t)+\mathbf{r})\cdot\frac{d\mathbf{u}(s)}{ds}\,ds\right)$$
$$\times\left(-i\alpha\sum_{j,k=1}^{2}\int_a^t\frac{du_j(t)}{dt}\,(\partial_j A_k)(\mathbf{u}(s)-\mathbf{u}(t)+\mathbf{r})\,\frac{du_k(s)}{ds}\,ds\right)\Psi(\mathbf{r})$$
$$+(iW(t)p_{d\mathbf{u}(t)/dt}\Psi)(\mathbf{r}).$$

By applying Lemma 4.3, we obtain (4.14). ■

Remark 4.3: (1) It follows from Theorem 4.4 that

$$\frac{d}{dt}\,(\Psi,U(C(t))\Phi)_2=(iP_{d\mathbf{u}(t)/dt}\Psi,U(C(t))\Phi)_2,\quad \Psi\in C_0^1(\mathbf{M}_C),\quad \Phi\in L^2(\mathbf{R}^2),\quad (4.15)$$

where $(\cdot,\cdot)_2$ denotes the inner product of $L^2(\mathbf{R}^2)$. But, in the case where $\mathbf{A}$ has singularities on $\mathbf{D}$, it seems difficult to find a dense subspace $\mathscr{D}$ on which $U(C(t))$ is strongly differentiable and such that $U(C(t))\mathscr{D}\subset D(\overline{P_{d\mathbf{u}(t)/dt}})$.

(2) If $\mathbf{A}$ is differentiable on the whole space $\mathbf{R}^2$, then $U(C(t))$ is strongly differentiable on $C_0^1(\mathbf{R}^2)$, with

$$dU(C(t))\Psi/dt=iP_{d\mathbf{u}(t)/dt}U(C(t))\Psi,\quad \Psi\in C_0^1(\mathbf{R}^2).$$

V. REPRESENTATIONS OF CCR

In this section we show that, associated with the projected physical momentum operators, there exist representations of the CCR with two degrees of freedom and give a complete characterization on the unitary equivalence or inequivalence of the representations to the Schrödinger representation of the CCR with two degrees of freedom. The inequivalent representations correspond to the Aharonov–Bohm effect (Ref. 6). The results of this section include generalizations of those of the previous works (Refs. 1 and 5).

Let $Q_{\mathbf{v},\mathbf{w}}[\mathbf{v},\mathbf{w}\in\mathbf{V}(\mathbf{D})]$ be the self-adjoint multiplication operator given by (1.13). It is easy to see that, if $A_j\in C^1(\mathbf{M})$, $j=1,2$, then the set $\{Q_{\mathbf{v},\mathbf{w}},Q_{\mathbf{w},\mathbf{v}},\overline{P_{\mathbf{v}}},\overline{P_{\mathbf{w}}}\}$ of self-adjoint operators has the following commutation properties: for all $\Psi\in C_0^2(\mathbf{M})$,

$$[Q_{\mathbf{v},\mathbf{w}},\overline{P_{\mathbf{v}}}]\Psi=i\Psi,\quad [Q_{\mathbf{w},\mathbf{v}},\overline{P_{\mathbf{w}}}]\Psi=i\Psi,\quad (5.1)$$

$$[Q_{\mathbf{v},\mathbf{w}},\overline{P_{\mathbf{w}}}]\Psi=0,\quad [Q_{\mathbf{w},\mathbf{v}},\overline{P_{\mathbf{v}}}]\Psi=0,\quad (5.2)$$

$$[Q_{\mathbf{v},\mathbf{w}},Q_{\mathbf{w},\mathbf{v}}]\Psi=0,\quad (5.3)$$

$$[\overline{P_{\mathbf{v}}},\overline{P_{\mathbf{w}}}]\Psi=i\alpha(\mathbf{v}\wedge\mathbf{w})B\Psi.\quad (5.4)$$

Remark 5.1: Let G_d be the algebra generated by elements Q_j, Π_j, F_{jk}, $j=1,...,d$, with identity I, obeying the commutation relations

$$[Q_j,Q_k]=0, \quad [Q_j,\Pi_k]=i\delta_{jk}I, \quad [\Pi_j,\Pi_k]=iF_{jk}, \quad [F_{jk},Q_l]=0, \quad j,k,l=1,...,d.$$

These relations have an origin in a quantum theory of a charged particle in an external electromagnetic field on $\mathbf{R}^d$, where Q_j and Π_j are realized as the position and the physical momentum operators, and may be regarded as an extension or a deformation of the CCR with d degrees of freedom. A special class of representations of G_d is discussed in Ref. 14 in connection with exactly solvable models. Relations (5.1)–(5.4) show that, if $\mathbf{A}$ is in $C^\infty(\mathbf{M})$, then the operators $Q_{\mathbf{v},\mathbf{w}}$, $Q_{\mathbf{w},\mathbf{v}}$, $\overline{P_\mathbf{v}}$, and $\overline{P_\mathbf{w}}$ restricted to the subspace $C_0^\infty(\mathbf{M})$ give a representation of G_2 with the correspondence

$$Q_1\to Q_{\mathbf{v},\mathbf{w}}, \quad Q_2\to Q_{\mathbf{w},\mathbf{v}}, \quad \Pi_1\to\overline{P_\mathbf{v}}, \quad \Pi_2\to\overline{P_\mathbf{w}}, \quad F_{12}\to\alpha(\mathbf{v}\wedge\mathbf{w})B.$$

It would be interesting to classify Hilbert space representations of the algebra $\mathbf{G}_d$.

The following fact easily follows from (5.1)–(5.4).

Proposition 5.1: Assume Hypothesis $(A)_1$. *Then the set* $\pi^\mathbf{A}_{\mathbf{v},\mathbf{w}}$ *given by (1.14) is a representation of the CCR with two degrees of freedom if and only if* $\mathbf{A}$ *is flat on* $\mathbf{M}$.

We denote by $\mathscr{F}(\mathbf{D})$ the set of vector potentials $\mathbf{A}$ that satisfy Hypothesis $(\mathrm{A})_1$ and flat on $\mathbf{M}$.

The following example shows that the set $\mathscr{F}(\mathbf{D})$ is large to some extent.

Example 5.1: Let $a_n=a_{n1}+ia_{n2}\in\mathbf{C}$ $(n\in\mathbf{N})$ be the complex number corresponding to the vector $\mathbf{a}_n$ and $D:=\{a_n\}_{n=1}^\infty$. Without loss of generality, we can assume that $|a_1|\leqslant|a_2|\leqslant|a_3|\leqslant\cdots$. By the assumption for $\mathbf{D}$, we have $a_n\to\infty$ as $n\to\infty$. Let

$$P_n(z)=\frac{c_{n,1}}{z-a_n}+\frac{c_{n,2}}{(z-a_n)^2}+\cdots+\frac{c_{n,k_n}}{(z-a_n)^{k_n}},$$

where $k_n\in\mathbf{N}$ and $c_{n,j}\in\mathbf{C}$ $(j=1,...,k_n)$ are arbitrarily given constants. Then, by the Mittag–Leffler theorem, there exists a meromorphic function $f(z)$ on $\mathbf{C}$ having the following properties: (i) f is holomorphic on $\mathbf{C}\backslash D$; (ii) the principal part of f at $z=a_n$ is given by $P_n(z)$. Let $\mathbf{A}=(A_1,A_2)$ with A_j, $j=1,2$, given by (1.23). Then $A_j\in C^\infty(\mathbf{M})$. Moreover, the Cauchy–Riemann equation for f implies that $\mathbf{A}$ is flat on $\mathbf{M}$ and divergence-free:

$$\partial_xA_1+\partial_yA_2=0, \quad \text{on } \mathbf{M}. \tag{5.5}$$

Hence $\mathbf{A}\in\mathscr{F}(\mathbf{D})$. ■

The special case,

$$\pi^\mathbf{A}_{\mathbf{e}_1,\mathbf{e}_2}=\{L^2(\mathbf{R}^2),C_0^2(\mathbf{M}),\{q_j,\overline{P_j}\}_{j=1}^2\} \quad [\mathbf{A}\in\mathscr{F}(\mathbf{D})],$$

of the above representation of CCR with $\mathbf{D}$ being a finite discrete set has been analyzed in detail (Refs. 1, 2, and 17). Similar analyses can be made in the present general case.

We first consider irreducibility of the representation $\pi^\mathbf{A}_{\mathbf{v},\mathbf{w}}$ with $\mathbf{A}\in\mathscr{F}(\mathbf{D})$. For this purpose, we introduce two kinds of commutants.

A weak commutant of the representation $\pi^\mathbf{A}_{\mathbf{v},\mathbf{w}}$ may be defined by

$$(\pi^\mathbf{A}_{\mathbf{v},\mathbf{w}})':=\{T\in\mathsf{B}(L^2(\mathbf{R}^2))\,|\,(TS\Psi,\Phi)_2=(T\Psi,S\Phi)_2, \quad \text{for all } \Psi,\Phi\in C_0^2(\mathbf{M}) \quad \text{and}$$

$$S=Q_{\mathbf{v},\mathbf{w}},Q_{\mathbf{w},\mathbf{v}},P_\mathbf{v},P_\mathbf{w}\}. \tag{5.6}$$

We set

$$U_{\mathbf{v},\mathbf{w}}(t)=e^{itQ_{\mathbf{v},\mathbf{w}}}, \quad t\in\mathbf{R}. \tag{5.7}$$

Another commutant is associated with the operator algebra generated by

$$\mathscr{W}^{\mathbf{A}}_{\mathbf{v},\mathbf{w}} := \{U_{\mathbf{v},\mathbf{w}}(t), U_{\mathbf{w},\mathbf{v}}(t), T^{\mathbf{A}}_{\mathbf{v}}(t), T^{\mathbf{A}}_{\mathbf{w}}(t) | t \in \mathbf{R}\}, \tag{5.8}$$

i.e.,

$$(\mathscr{W}^{\mathbf{A}}_{\mathbf{v},\mathbf{w}})' := \{T \in \mathsf{B}(L^2(\mathbf{R}^2)) | TW = WT, \quad \text{for all} \quad W \in \mathscr{W}^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}\}. \tag{5.9}$$

It is easy to see that

$$(\mathscr{W}^{\mathbf{A}}_{\mathbf{v},\mathbf{w}})' \subset (\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}})'. \tag{5.10}$$

Theorem 5.2: *Let* $\mathbf{A} \in \mathscr{T}(\mathbf{D})$. *Then* $(\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}})' = (\mathscr{W}^{\mathbf{A}}_{\mathbf{v},\mathbf{w}})' = \mathbf{C}I$, *where* I *denotes the identity operator on* $L^2(\mathbf{R}^2)$.

Proof: Since $\mathbf{v}$ and $\mathbf{w}$ are linearly independent, q_j (resp., P_j) can be written as a linear combination of $Q_{\mathbf{v},\mathbf{w}}$ and $Q_{\mathbf{w},\mathbf{v}}$ (resp., $P_{\mathbf{v}}$ and $P_{\mathbf{w}}$). Hence, we have $(\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}})' = (\pi^{\mathbf{A}}_{\mathbf{e}_1,\mathbf{e}_2})'$. On the other hand, in quite the same way as in the proof of Theorem 3.8 of Ref. 17, we can show that $(\pi^{\mathbf{A}}_{\mathbf{e}_1,\mathbf{e}_2})' = \mathbf{C}I$. This result and (5.10) imply $(\mathscr{W}^{\mathbf{A}}_{\mathbf{v},\mathbf{w}})' = \mathbf{C}I$. ■

We next consider commutation properties of the operators in $\mathscr{W}^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$. Using Theorem 3.2, we can show that, for all $\mathbf{A}$ satisfying Hypothesis $(\mathrm{A})_0$,

$$U_{\mathbf{v},\mathbf{w}}(t) U_{\mathbf{w},\mathbf{v}}(s) = U_{\mathbf{w},\mathbf{v}}(s) U_{\mathbf{v},\mathbf{w}}(t), \tag{5.11}$$

$$U_{\mathbf{v},\mathbf{w}}(t) T^{\mathbf{A}}_{\mathbf{w}}(s) = T^{\mathbf{A}}_{\mathbf{w}}(s) U_{\mathbf{v},\mathbf{w}}(t), \quad U_{\mathbf{w},\mathbf{v}}(t) T^{\mathbf{A}}_{\mathbf{v}}(s) = T^{\mathbf{A}}_{\mathbf{v}}(s) U_{\mathbf{w},\mathbf{v}}(t), \tag{5.12}$$

$$U_{\mathbf{v},\mathbf{w}}(t) T^{\mathbf{A}}_{\mathbf{v}}(s) = e^{-its} T^{\mathbf{A}}_{\mathbf{v}}(s) U_{\mathbf{v},\mathbf{w}}(t), \quad U_{\mathbf{w},\mathbf{v}}(t) T^{\mathbf{A}}_{\mathbf{w}}(s) = e^{-its} T^{\mathbf{A}}_{\mathbf{w}}(s) U_{\mathbf{w},\mathbf{v}}(t). \tag{5.13}$$

A commutation relation between $T^{\mathbf{A}}_{\mathbf{v}}(s)$ and $T^{\mathbf{A}}_{\mathbf{w}}(t)$ is given by (3.13), with $\mathbf{v}$ and $\mathbf{w}$ replaced by $s\mathbf{v}$ and $t\mathbf{w}$, respectively.

Definition 5.3: We say that the magnetic flux is locally quantized (with respect to the pair $\{\mathbf{v},\mathbf{w}\}$) if the function $\Phi^{\mathbf{A}}_{s\mathbf{v},t\mathbf{w}}$ on $\mathbf{M}_{s\mathbf{v},t\mathbf{w}}(\mathbf{D})$ is $2\pi\mathbf{Z}/\alpha$ valued for all $s,t \in \mathbf{R}$.

Remark 5.2: It is easy to see that, if $A_j \in C^1(\mathbf{M})$, $j = 1,2$, and the magnetic flux is locally quantized, then $\mathbf{A}$ is flat on $\mathbf{M}$.

Theorem 5.4: *For all* $s,t \in \mathbf{R}$, *the set* $\mathscr{W}^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ *of unitary operators satisfies the Weyl relations with two degrees of freedom if and only if the magnetic flux is locally quantized.*

Proof: It follows from Theorem 3.3 and (3.8) that $T^{\mathbf{A}}_{\mathbf{v}}(s)$ and $T^{\mathbf{A}}_{\mathbf{w}}(t)$ commute for all $s,t \in \mathbf{R}$ if and only if the magnetic flux is locally quantized. This fact and (5.11)–(5.13) imply the desired assertion. ■

In the rest of this section, we consider only the case $\mathbf{A} \in \mathscr{T}(\mathbf{D})$; hence $\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ *is a* representation of the CCR with two degrees of freedom.

Theorems 5.2 and 5.4 together with the von Neumann uniqueness theorem on the Weyl form of CCR[18,19] give the following result.

Theorem 5.5: *The representation* $\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ *is unitarily equivalent to the Schrödinger representation* $\{q_j, p_j\}_{j=1}^2$ *if and only if the magnetic flux is locally quantized.*

Remark 5.3: As in the case of the special representation $\pi^{\mathbf{A}}_{\mathbf{e}_1,\mathbf{e}_2}$ discussed in the previous papers (Refs. 1, 2, and 5), the case where the representation $\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ is inequivalent to the Schrödinger representation, which, by Theorem 5.4, occurs if and only if the magnetic flux is not locally quantized, physically corresponds to the Aharonov–Bohm effect [see (3.13) and Remark 4.2(2)].

The function $\Phi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ can be explicitly represented, as is shown below. By the assumption for $\mathbf{D}$, we have

$$\delta := \inf_{m \neq n} |\mathbf{a}_n - \mathbf{a}_m| > 0. \tag{5.14}$$

It follows from the flatness of $\mathbf{A}$ and the Green's theorem that, for all $\epsilon \in (0,\delta)$, the line integral,

$$\gamma_{\mathbf{A}}(\mathbf{a}_n) := \int_{|\mathbf{r}-\mathbf{a}_n|=\epsilon} \mathbf{A}(\mathbf{r}) \cdot d\mathbf{r}, \tag{5.15}$$

along the circle $\{\epsilon(\cos\theta,\sin\theta)+\mathbf{a}_n|0\leqslant\theta\leqslant 2\pi\}$ is independent of ϵ. It is easy to see that

$$\Phi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}(\mathbf{r})=\sum_{\mathbf{a}_n\in D_{\mathbf{r}}(\mathbf{v},\mathbf{w})}\operatorname{sgn}(\mathbf{v}\wedge\mathbf{w})\,\gamma_{\mathbf{A}}(\mathbf{a}_n),\quad \mathbf{r}\in\mathbf{M}_{\mathbf{v},\mathbf{w}}(\mathbf{D}),\tag{5.16}$$

where $D_{\mathbf{r}}(\mathbf{v},\mathbf{w})$ is the interior domain of the curve $C_{\mathbf{r}}(\mathbf{v},\mathbf{w})$ and $\operatorname{sgn}(\lambda):=1$ (resp., -1) for $\lambda>0$ (resp., $\lambda<0$). Thus we obtain the following result.

Proposition 5.6: The magnetic flux is locally quantized if and only if $\gamma_{\mathbf{A}}(\mathbf{a}_n)\in 2\pi\mathbf{Z}/\alpha$ for all $n\in\mathbf{N}$.

This proposition and Theorem 5.4 imply the following theorem.

Theorem 5.7: *The representation $\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ is unitarily equivalent to the Schrödinger representation $\{q_j,p_j\}_{j=1}^2$ if and only if $\gamma_{\mathbf{A}}(\mathbf{a}_n)\in 2\pi\mathbf{Z}/\alpha$ for all $n\in\mathbf{N}$.*

Example 5.2: Let $\mathbf{A}$ be the vector potential given in Example 5.1. Then

$$\gamma_{\mathbf{A}}(\mathbf{a}_n)=2\pi\Re c_{n,1}.$$

Hence, if $\Re c_{n_0,1}\notin\mathbf{Z}/\alpha$ for some $n_0\in\mathbf{N}$, then $\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ is unitarily *inequivalent* to the Schrödinger representation $\{q_j,p_j\}_{j=1}^2$. Thus, there exist lots of inequivalent representations of CCR. ■

In concluding this section, we make a remark on the unitary inequivalence between the two representations $\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ and $\pi^{\mathbf{A}'}_{\mathbf{v}',\mathbf{w}'}$ [$\mathbf{A}'\in\mathscr{F}(\mathbf{D})$ and $\mathbf{v}',\mathbf{w}'\in\mathbf{V}(\mathbf{D})$ are linearly independent]. We introduce a 2×2 matrix:

$$K(\mathbf{v},\mathbf{w},\mathbf{v}',\mathbf{w}')=\frac{1}{\mathbf{v}'\wedge\mathbf{w}'}\begin{pmatrix} v_1w_2'-w_1v_2' & w_1v_1'-v_1w_1' \\ v_2w_2'-w_2v_2' & w_2v_1'-v_2w_1'\end{pmatrix}.\tag{5.17}$$

It is easy to see that $K(\mathbf{v},\mathbf{w},\mathbf{v}',\mathbf{w}')$ is bijective, with

$$\det K(\mathbf{v},\mathbf{w},\mathbf{v}',\mathbf{w}')=\frac{\mathbf{v}\wedge\mathbf{w}}{\mathbf{v}'\wedge\mathbf{w}'},\tag{5.18}$$

$$K(\mathbf{v},\mathbf{w},\mathbf{v}',\mathbf{w}')K(\mathbf{v}',\mathbf{w}',\mathbf{v},\mathbf{w})=I.\tag{5.19}$$

Proposition 5.8: Suppose that $\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ is unitarily equivalent to $\pi^{\mathbf{A}'}_{\mathbf{v}',\mathbf{w}'}$. Then, for all $s,t\in\mathbf{R}$,

$$\exp(-i\alpha\Phi^{\mathbf{A}}_{s\mathbf{v},t\mathbf{w}}(K(\mathbf{v},\mathbf{w},\mathbf{v}',\mathbf{w}')\mathbf{r}))=\exp(-i\alpha\Phi^{\mathbf{A}'}_{s\mathbf{v}',t\mathbf{w}'}(\mathbf{r})),\quad\text{a.e. }\mathbf{r}\in\mathbf{R}^2.\tag{5.20}$$

Proof: To make explicit the dependence of $P_{\mathbf{v}}$ on $\mathbf{A}$, we write $\overline{P}_{\mathbf{v}}=\overline{P}_{\mathbf{v}}(\mathbf{A})$. By the present assumption, there exists a unitary operator U on $L^2(\mathbf{R}^2)$, such that

$$UQ_{\mathbf{v},\mathbf{w}}U^{-1}=Q_{\mathbf{v}',\mathbf{w}'},\quad UQ_{\mathbf{w},\mathbf{v}}U^{-1}=Q_{\mathbf{w}',\mathbf{v}'},\tag{5.21}$$

$$U\overline{P}_{\mathbf{v}}(\mathbf{A})U^{-1}=\overline{P}_{\mathbf{v}'}(\mathbf{A}'),\quad U\overline{P}_{\mathbf{w}}(\mathbf{A})U^{-1}=\overline{P}_{\mathbf{w}'}(\mathbf{A}').\tag{5.22}$$

By Theorem 3.3 and (5.22), together with functional calculus of self-adjoint operators, we have for all $s,t\in\mathbf{R}$,

$$\exp(-i\alpha U\Phi^{\mathbf{A}}_{t\mathbf{v},s\mathbf{w}}U^{-1})=\exp(-i\alpha\Phi^{\mathbf{A}'}_{t\mathbf{v}',s\mathbf{w}'}).\tag{5.23}$$

It is easy to show that

$$q_1=v_1Q_{\mathbf{v},\mathbf{w}}+w_1Q_{\mathbf{w},\mathbf{v}},\tag{5.24}$$

$$q_2=v_2Q_{\mathbf{v},\mathbf{w}}+w_2Q_{\mathbf{w},\mathbf{v}}.\tag{5.25}$$

These relations and (5.21) imply that

$$U\mathbf{q}U^{-1}=K(\mathbf{v},\mathbf{w},\mathbf{v}',\mathbf{w}')\mathbf{q}. \tag{5.26}$$

Hence, by functional calculus, the self-adjoint operator $U\Phi^{\mathbf{A}}_{\mathbf{v},s\mathbf{w}}U^{-1}$ is equal to the multiplication operator by the function $\Phi^{\mathbf{A}}_{t\mathbf{v},s\mathbf{w}}(\mathbf{K}(\mathbf{v},\mathbf{w},\mathbf{v}',\mathbf{w}')\mathbf{r})$. This fact and (5.23) imply (5.20). ■

Remark 5.4: (1) There exist many triples $\{\mathbf{v},\mathbf{w},\mathbf{A}\}$ and $\{\mathbf{v}',\mathbf{w}',\mathbf{A}'\}$, where $\mathbf{A},\mathbf{A}'\in\mathscr{T}(\mathbf{D})$, such that (5.20) does not hold. Hence, there exist many pairs $\{\pi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}},\pi^{\mathbf{A}'}_{\mathbf{v}',\mathbf{w}'}\}$ of representations that are unitarily inequivalent to each other.

(2) In the case $\mathbf{v}=\mathbf{v}'$, $\mathbf{w}=\mathbf{w}'$, we have

$$K(\mathbf{v},\mathbf{w},\mathbf{v},\mathbf{w})=I, \tag{5.27}$$

so that (5.20) becomes

$$\exp(-i\alpha\Phi^{\mathbf{A}}_{s\mathbf{v},t\mathbf{w}}(\mathbf{r}))=\exp(-i\alpha\Phi^{\mathbf{A}'}_{s\mathbf{v},t\mathbf{w}}(\mathbf{r})),\quad \text{a.e.}\quad \mathbf{r}\in\mathbf{R}^2. \tag{5.28}$$

VI. QUANTUM ALGEBRAIC STRUCTURES

In this section we discuss quantum algebraic structures associated with continuous magnetic translations $\{T^{\mathbf{A}}_{\mathbf{v}}\}_{\mathbf{v}\in\mathbf{V(D)}}$. We first introduce a special class of vector potentials.

Definition 6.1: We say that a vector potential $\mathbf{A}$ is in $\mathscr{A}_{\mathbf{v},\mathbf{w}}(\mathbf{D})$ if the function $\Phi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ is equal to a constant on $\mathbf{M}_{\mathbf{v},\mathbf{w}}(\mathbf{D})$.

Example 6.1: Constant magnetic fields. Let $B_0\in\mathbf{R}$ be a constant and

$$A_1(\mathbf{r})=-\frac{B_0y}{2},\quad A_2(\mathbf{r})=\frac{B_0x}{2}.$$

Then $B(\mathbf{r})=B_0$, i.e., the magnetic field is uniformly constant. Hence, by the Green's theorem, we have

$$\Phi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}(\mathbf{r})=(\mathbf{v}\wedge\mathbf{w})B_0,\quad \mathbf{r}\in\mathbf{M}_{\mathbf{v},\mathbf{w}}(\mathbf{D}).$$

Thus $\mathbf{A}\in\mathscr{A}_{\mathbf{v},\mathbf{w}}(\mathbf{D})$. ■

Example 6.2: *Vector potentials singular on an infinite lattice.* Let $\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$ be the infinite lattice given by (1.16) and consider the case $\mathbf{D}=\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$ and $\mathbf{v}=\boldsymbol{\omega}_1$, $\mathbf{w}=\boldsymbol{\omega}_2$. Let $\Omega_{m,n}$ be as in (1.22) and $f(z)$ be a meromorphic function on $\mathbf{C}$ with the following properties: (i) f is holomorphic on $\mathbf{C}\backslash\{\Omega_{m,n}\}_{m,n\in\mathbf{Z}}$; (ii) the principal part of f at $z=\Omega_{m,n}$ is of the form

$$P_{m,n}(z)=\frac{c}{z-\Omega_{m,n}}+\frac{c^{(2)}_{m,n}}{(z-\Omega_{m,n})}+\cdots+\frac{c^{(k_{m,n})}_{m,n}}{(z-\Omega_{m,n})^{k_{m,n}}},$$

where $k_{m,n}\in\mathbf{N},c,c^{(j)}_{m,n}$ are constants (c is independent of m, n). The existence of such a function f is ensured by the Mittag–Leffler theorem (see Example 5.1). As in Example 5.1, we define a vector potential $\mathbf{A}=(A_1,A_2)$ by (1.23). Then $\mathbf{A}\in\mathscr{T}(\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2))$ with A_j being infinitely many times differentiable on the open set,

$$\mathbf{M}_{\mathbf{L}}:=\mathbf{R}^2\backslash\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2). \tag{6.1}$$

As in Example 5.2, we have

$$\gamma_{\mathbf{A}}(\boldsymbol{\Omega}_{m,n})=2\pi\Re c,\quad m,n\in\mathbf{Z}. \tag{6.2}$$

For all $\mathbf{r}\in\mathbf{M}_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2))$, $D_{\mathbf{r}}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$ contains only one point in $\{\boldsymbol{\Omega}_{m,n}\}_{m,n\in\mathbf{Z}}$. Hence, noting that $\mathrm{sgn}(\boldsymbol{\omega}_1\wedge\boldsymbol{\omega}_2)=1$, we have, from (5.16) and (6.2),

$$\Phi^{\mathbf{A}}_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{r})=2\pi\Re c. \tag{6.3}$$

Thus, $\mathbf{A}\in\mathscr{A}_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2))$. ■

We denote by $\mathscr{R}_{\mathbf{v},\mathbf{w},\mathbf{A}}$ the algebra generated by $T^{\mathbf{A}}_{\mathbf{v}}$ and $T^{\mathbf{A}}_{\mathbf{w}}$.

Let $\mathbf{A}\in\mathscr{A}_{\mathbf{v},\mathbf{w}}(\mathbf{D})$. Then, by definition, $\Phi^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ is a constant on $\mathbf{M}_{\mathbf{v},\mathbf{w}}(\mathbf{D})$. We denote the constant by $C^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$. By Theorem 3.3, we have

$$T^{\mathbf{A}}_{\mathbf{v}}T^{\mathbf{A}}_{\mathbf{w}}=e^{-i\alpha C^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}}T^{\mathbf{A}}_{\mathbf{w}}T^{\mathbf{A}}_{\mathbf{v}}. \tag{6.4}$$

Hence $\mathscr{R}_{\mathbf{v},\mathbf{w},\mathbf{A}}$ is a representation on $L^2(\mathbf{R}^2)$ of a rotation algebra (e.g., Ref. 20, Chap. VI) or the quantum plane with the deformation parameter $q=e^{-i\alpha C^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}}$ (Ref. 21).
