$$\left(\frac{2u+1}{2u}\,\mu(u)+\frac{2u-1}{2u}\,\mu(-u)\right)=B(u)a_k(u) \tag{5.10}$$

for a polynomial $B(u)$ of degree k in u^2.

Similarly, taking the coefficient at u^{-2} in (5.3) we get

$$s_{11}^{(2)}s_{1,-1}(u)=s_{1,-1}(u)(s_{11}^{(2)}+2s_{11}^{(1)}+1)-s_{1,-1}^{(1)}(s_{11}(u)-s_{-1,-1}(u)). \tag{5.11}$$

Applying both sides to ξ, using (5.8) and the symmetry relation (2.18) we obtain

$$(s_{11}^{(2)}-\mu^{(2)}-2\mu^{(1)}-1)(a_1(u)\xi_1+\cdots+a_k(u)\xi_k)=-u^{-1}(\mu(u)-\mu(-u))\xi_1. \tag{5.12}$$

In particular, $s_{11}^{(2)}\xi_p$ is a linear combination of ξ_p and ξ_1. Finally, taking the coefficient at ξ_1 in (5.12) we find that $u^{-1}(\mu(u)-\mu(-u))=C(u)a_k(u)$ for a polynomial $C(u)$ of degree $k-1$ in u^2. Together with (5.10) this proves that the desired series is $\psi(u)=(u^{2k}a_k(u))^{-1}$. □

We shall consider (3.16) as a representation of $\mathrm{Y}^-(2)$ obtained by restriction. Equivalently, using (4.11) one may regard this representation as the tensor product of Y(2)-module (3.16) with the trivial $\mathrm{Y}^-(2)$-module.

Let $\mu(u)$ be a polynomial in u^{-1} of degree $\leqslant 2k$. Consider an expansion

$$\mu(u)=(1-\gamma_1u^{-1})\cdots(1-\gamma_{2k}u^{-1}). \tag{5.13}$$

Re-enumerating the numbers γ_i if necessary, we may assume that the following condition is satisfied [cf. (3.19)]:

for every $i=1,\ldots,k$ we have: if the multiset

$$\{\gamma_p+\gamma_q \mid 2i-1\leqslant p<q\leqslant 2k\} \text{ contains non-negative integers} \tag{5.14}$$

then $\gamma_{2i-1}+\gamma_{2i}$ is minimal among them.

The following is an analog of Proposition 3.6.

Proposition 5.2: Let $V(\mu(u))$ be an irreducible highest weight representation of $\mathrm{Y}^-(2)$ where $\mu(u)$ is a polynornial of degree $\leqslant 2k$ in u^{-1}. Suppose that decomposition (5.13) is given and condition (5.14) is satisfied. Then $V(\mu(u))$ is isomorphic to the tensor product

$$L(\gamma_1,-\gamma_2)\otimes\cdots\otimes L(\gamma_{2k-1},-\gamma_{2k}), \tag{5.15}$$

regarded as $\mathrm{Y}^-(2)$-module.

Proof: Denote the representation (5.15) by V. Let ξ_i be the highest weight vector of $L(\gamma_{2i-1},-\gamma_{2i})$. We obtain from (3.23) that the vector $\xi:=\xi_1\otimes\cdots\otimes\xi_k$ satisfies the relations

$$\begin{gathered} t_{-1,1}(u)\xi=0, \\ t_{11}(u)\xi=(1-\gamma_2u^{-1})\cdots(1-\gamma_{2k}u^{-1})\xi, \\ t_{-1,-1}(u)\xi_i=(1+\gamma_1u^{-1})\cdots(1+\gamma_{2k-1}u^{-1})\xi. \end{gathered} \tag{5.16}$$

Hence, by (2.15)

$$s_{11}(u)\xi=\mu(u)\xi, \quad s_{-1,1}(u)\xi=0. \tag{5.17}$$

Thus, the cyclic $\mathrm{Y}^-(2)$-span of the vector ξ in V is a highest weight module with the highest weight $\mu(u)$. Therefore, to prove Proposition 5.2 it suffices to show that the representation V of $\mathrm{Y}^-(2)$ is irreducible.

We use induction on k. For $k=1$ this is obvious, because the restriction of $L(\gamma_{2i-1},-\gamma_{2i})$ to sp(2) is irreducible and so its extension to $\mathrm{Y}^-(2)$ is.

Suppose now that $k>1$. If $\widetilde{V}$ is a nonzero submodule of V then $\widetilde{V}$ contains a nonzero vector η such that $s_{-1,1}(u)\,\eta=0$. Write η in the form

$$\eta=\sum_{r=0}^{p}(E_{1,-1})^r\xi_1\otimes\eta_r, \tag{5.18}$$

for some $p\geqslant 0$, where $\eta_r\in L(\gamma_3,-\gamma_4)\otimes\cdots\otimes L(\gamma_{2k-1},-\gamma_{2k})$; and if $\gamma_1+\gamma_2\in\mathbb{Z}_+$ then $p\leqslant\gamma_1+\gamma_2$. We may assume that $\eta_p\neq 0$. By (2.31) we have

$$\begin{aligned} s_{-1,1}(u)((E_{1,-1})^r\xi_1\otimes\eta_r)=&-t_{-1,-1}(u)t_{-1,1}(-u)(E_{1,-1})^r\xi_1\otimes s_{-1,-1}(u)\,\eta_r \\ &+t_{-1,-1}(u)t_{-1,-1}(-u)(E_{1,-1})^r\xi_1\otimes s_{-1,1}(u)\,\eta_r \\ &-t_{-1,1}(u)t_{-1,1}(-u)(E_{1,-1})^r\xi_1\otimes s_{1,-1}(u)\,\eta_r \\ &+t_{-1,1}(u)t_{-1,-1}(-u)(E_{1,-1})^r\xi_1\otimes s_{1,1}(u)\,\eta_r. \end{aligned} \tag{5.19}$$

Rewriting (3.25) and (3.26) we obtain

$$t_{-1,-1}(u)(E_{1,-1})^r\xi_1=(1+(\gamma_1-r)u^{-1})(E_{1,-1})^r\xi_1 \tag{5.20}$$

and

$$t_{-1,1}(u)(E_{1,-1})^r\xi_1=u^{-1}r(\gamma_1+\gamma_2-r+1)(E_{1,-1})^{r-1}\xi_1. \tag{5.21}$$

Taking the coefficient at $(E_{1,-1})^p\xi_1$ in the relation $s_{-1,1}(u)\,\eta=0$ gives

$$(1-(\gamma_1-p)u^{-2})s_{-1,1}(u)\,\eta_p=0.$$

So, $s_{-1,1}(u)\,\eta_p=0$. By the induction hypotheses, the representation $L(\gamma_3,-\gamma_4)\otimes\cdots\otimes L(\gamma_{2k-1},-\gamma_{2k})$ of $\mathrm{Y}^-(2)$ is irreducible, and hence

$$\eta_p=\mathrm{const}\cdot\xi_2\otimes\cdots\otimes\xi_k\,, \tag{5.22}$$

where ''const'' is a nonzero constant; see Remark 4.4. Suppose now that $p\geqslant 1$ and take the coefficient at $(E_{1,-1})^{p-1}\xi_1$ in the relation $s_{-1,1}(u)\,\eta=0$. Using (5.19)–(5.21) we obtain

$$\begin{aligned}&(1-(\gamma_1-p+1)^2u^{-2})s_{-1,1}(u)\,\eta_{p-1}\\&\quad+u^{-1}p(\gamma_1+\gamma_2-p+1)(1+(\gamma_1-p+1)u^{-1})s_{-1,-1}(u)\,\eta_p\\&\quad+u^{-1}p(\gamma_1+\gamma_2-p+1)(1-(\gamma_1-p)u^{-1})s_{11}(u)\,\eta_p=0.\end{aligned} \tag{5.23}$$

The symmetry relation (2.18) gives

$$s_{-1,-1}(u)=\frac{2u+1}{2u}\,s_{11}(-u)-\frac{1}{2u}\,s_{11}(u) \tag{5.24}$$

and

$$s_{-1,1}^{(2r-1)}=2s_{-1,1}^{(2r)},\quad r\geqslant 1. \tag{5.25}$$

Using (5.24) and multiplying (5.23) by $u^{2k}/(2u+1)$ we bring it to the form

$$\begin{aligned}&(u^2-(\gamma_1-p+1)^2)u^{2k-2}\,\frac{s_{-1,1}(u)}{2u+1}\,\eta_{p-1}+p(\gamma_1+\gamma_2-p+1)\\&\times\frac{1}{2u}\,((u+\gamma_1-p+1)u^{2k-2}s_{11}(-u)+(u-\gamma_1+p-1)u^{2k-2}s_{11}(u))\,\eta_p=0.\end{aligned} \tag{5.26}$$

Due to (3.18) and (2.15) the elements $s_{ij}^{(r)}$ with $r>2k-2$ act as zero operators in $L(\gamma_3,-\gamma_4)\otimes\cdots\otimes L(\gamma_{2k-1},-\gamma_{2k})$. Hence, the operators $u^{2k-2}s_{ij}(u)$ are polynomials in u, as well as $u^{2k-2}s_{-1,1}(u)/(2u+1)$ is, because of (5.25). Further, by (5.22) and (5.16),

$$u^{2k-2}s_{11}(u)\,\eta_p=(u-\gamma_3)\cdots(u-\gamma_{2k})\,\eta_p\,.$$

Putting $u=\gamma_1-p+1$ in (5.26) we get

$$p(\gamma_1+\gamma_2-p+1)(\gamma_1+\gamma_3-p+1)\cdots(\gamma_1+\gamma_{2k}-p+1)=0.$$

However, this is impossible because of the condition (5.14). Therefore, p has to be equal to 0 and so, η is a multiple of ξ.

To complete the proof we have to show that the submodule of V generated by ξ coincides with V. The representation of $\mathrm{Y}(2)$ dual to (5.15) is isomorphic to

$$L'(-\gamma_1,\gamma_2)\otimes\cdots\otimes L'(-\gamma_{2k-1},\gamma_{2k}); \tag{5.27}$$

see (3.31). On the other hand, using the antiautomorphism (2.26) we can equip the vector space V^* dual to V with an action of $\mathrm{Y}^-(2)$:

$$(y\cdot f)(v)=f(\sigma(y)v),\quad y\in\mathrm{Y}^-(2),\quad f\in V^*,\quad v\in V.$$

Since the antiautomorphism (2.26) is a restriction of (2.7), the representation V^* is isomorphic to the restriction of (5.27) to $\mathrm{Y}^-(2)$. Similarly to the case of representation V, any nonzero submodule of V^* contains a nonzero vector η' such that $s_{1,-1}(u)\,\eta'=0$. Modifying the previous argument for lowest weight representations of $\mathrm{Y}^-(2)$ we prove that η' coincides (up to a nonzero factor) with the vector $\xi'=\xi'_1\otimes\cdots\otimes\xi'_k$, where ξ'_i is the lowest weight vector of

$L'(-\gamma_{2i-1},\gamma_{2i})$. Now, if the submodule in V generated by ξ is proper, then its annihilator in V^* is a nonzero submodule which does not contain ξ'. Contradiction. □

We are now able to give necessary and sufficient conditions for $V(\mu(u))$ to be finite-dimensional (cf. Proposition 3.7).

Proposition 5.3: Let $V(\mu(u))$ be an irreducible representation of $\mathrm{Y}^-(2)$ with the highest weight $\mu(u)$. Then $V(\mu(u))$ is finite-dimensional if and only if there exists a formal series $\psi(u)\in 1+u^{-2}\mathbb{C}[[u^{-2}]]$ such that $\psi(u)\mu(u)$ is a polynomial in u^{-1} with a decomposition

$$\psi(u)\mu(u)=(1-\gamma_1 u^{-1})\cdots(1-\gamma_{2k}u^{-1}), \tag{5.28}$$

and $\gamma_{2i-1}+\gamma_{2i}\in\mathbb{Z}_+$, $i=1,...,k$ for a certain re-enumeration of the γ_i.

Proof: Let $\dim V(\mu(u))<\infty$. By Proposition 5.1, taking the composition of our representation with an automorphism of the form (2.29) we may assume that (5.28) is satisfied for a certain series $\psi(u)$. Re-enumerate the γ_i in such a way that condition (5.14) be satisfied. Now use Proposition 5.2. Since representation (5.15) is finite-dimensional this gives the relations $\gamma_{2i-1}+\gamma_{2i}\in\mathbb{Z}_+$ for all $i=1,...,k$.

Conversely, let (5.28) hold with $\gamma_{2i-1}+\gamma_{2i}\in\mathbb{Z}_+$, $i=1,...,k$. Then representation (5.15) is finite-dimensional and the composition of $V(\mu(u))$ with the automorphism (2.29) corresponding to the series $\psi(u)$ is isomorphic to the irreducible quotient of the $\mathrm{Y}^-(2)$-cyclic span in V of the vector ξ; see (5.17). Therefore, $\dim V(\mu(u))<\infty$. □

Proposition 5.3 can be reformulated with the use of monic polynomials in u as follows (cf. Theorem 3.8).

Theorem 5.4: *The irreducible highest weight representation $V(\mu(u))$ of $\mathrm{Y}^-(2)$ is finite-dimensional if and only if there exists a monic polynomial $P(u)\in\mathbb{C}[u]$ such that $P(u)=P(-u+1)$ and*

$$\frac{\mu(-u)}{\mu(u)}=\frac{P(u+1)}{P(u)}. \tag{5.29}$$

In this case $P(u)$ is unique.

Proof: If $\dim V(\mu(u))<\infty$ then by Proposition 5.3 relation (5.28) holds for a certain even series $\psi(u)$ and $\gamma_{2i-1}+\gamma_{2i}\in\mathbb{Z}_+$ for all i. Set

$$\begin{aligned}\sigma(u)&=(1+\gamma_1 u^{-1})(1+\gamma_3 u^{-1})\cdots(1+\gamma_{2k-1}u^{-1}),\\ \tau(u)&=(1-\gamma_2 u^{-1})(1-\gamma_4 u^{-1})\cdots(1-\gamma_{2k}u^{-1}).\end{aligned} \tag{5.30}$$

Then there exists a monic polynomial $Q(u)$ in u such that

$$\frac{\sigma(u)}{\tau(u)}=\frac{Q(u+1)}{Q(u)}; \tag{5.31}$$

see the proof of Theorem 3.8. Define $P(u)$ by

$$P(u)=Q(u)Q(-u+1)(-1)^{\deg Q}. \tag{5.32}$$

Then $P(u)$ is monic and $P(u)=P(-u+1)$. Moreover,

$$\frac{\tau(-u)}{\sigma(-u)}=\frac{Q(-u)}{Q(-u+1)}. \tag{5.33}$$

Therefore, since $\psi(u)\mu(u)=\sigma(-u)\tau(u)$, relation (5.29) holds due to (5.31) and (5.33).

Conversely, let (5.29) be satisfied for a monic polynomial $P(u)$ such that $P(u)=P(-u+1)$. Then it has an even degree and the multiset of its roots is invariant with respect to the transformation $u\mapsto -u+1$ (the symmetry in $\mathbb{C}$ with the center at 1/2). Therefore, we may write the roots in the form $\{-\delta_1,\ldots,-\delta_s,\delta_1+1,...,\delta_s+1\}$ for a certain s. Set

$$\mu'(u)=(1-(\delta_1+1)u^{-1})\cdots(1-(\delta_s+1)u^{-1})(1+\delta_1 u^{-1})\cdots(1+\delta_s u^{-1}).$$

By Proposition 5.3 the representation $V(\mu'(u))$ is finite-dimensional. Moreover, the polynomial $\mu'(u)$ satisfies (5.29) and so, the ratio $\mu(u)/\mu'(u)$ is an even formal series in u^{-1}. This proves that $V(\mu(u))$ is also finite-dimensional.

The uniqueness of $P(u)$ is established in the proof of Theorem 3.8. □

The following notation is motivated by Theorem 5.4 [cf. (3.35)]. For two formal series $\mu(u)$ and $\nu(u)$ in u^{-1} we shall write

$$\mu(u) \Rightarrow \nu(u), \tag{5.34}$$

if there exists a monic polynomial $P(u)$ in u such that $P(u)=P(-u+1)$ and

$$\frac{\mu(u)}{\nu(u)} = \frac{P(u+1)}{P(u)}.$$

Obviously, this is only possible if $\mu(u)$ and $\nu(u)$ satisfy the relation $\mu(u)\mu(-u) = \nu(u)\nu(-u)$.

Proposition 5.2 and Theorem 5.4 imply the following parametrization of representations of the special twisted Yangian $\mathrm{SY}^-(2)$ (cf. Corollary 3.9).

Corollary 5.5. There is a one-to-one correspondence between finite-dimensional irreducible representations of the special twisted Yangian $\mathrm{SY}^-(2)$ *and the monic polynomials* $P(u)$ *in u such that* $P(u)=P(-u+1)$. *Every such representation is isomorphic to a representation of the form (5.15).* □

Remark 5.6: Tensoring $V(\mu(u))$ by factors of the form $L(\gamma,\gamma)$ is equivalent to multiplying the highest weight $\mu(u)$ by $1-\gamma^2u^{-2}$. However, the representations $V(\mu(u))$ and $V((1-\gamma^2u^{-2})\mu(u))$ of $\mathrm{Y}^-(2)$ belong to the same similarity class. Therefore, we might add to Corollary 5.5 the condition that in (5.15) all $\gamma_{2i-1}+\gamma_{2i}$ are positive integers. □

The following corollary provides a criterion of irreducibility for the representations of $\mathrm{Y}^-(2)$ [or $\mathrm{SY}^-(2)$] of the form (5.15) (cf. Corollary 3.11). We formulate it in terms of the strings $S(\alpha,\beta)$ introduced in Sec. III. Note that two strings $S(\alpha,-\beta)$ and $S(\beta,-\alpha)$ are symmetric to each other with respect to the center $-1/2$ in $\mathbb{C}$. Therefore, $S(\alpha_1,-\beta_1)$ and $S(\alpha_2,-\beta_2)$ are in general position whenever $S(\beta_1,-\alpha_1)$ and $S(\beta_2,-\alpha_2)$ are.

Corollary 5.7: Consider an irreducible finite-dimensional representation of $\mathrm{Y}(2)$ *of the form*

$$V = L(\gamma_1,-\gamma_2)\otimes\cdots\otimes L(\gamma_{2k-1},-\gamma_{2k}). \tag{5.35}$$

Then its restriction to $\mathrm{Y}^-(2)$ *is irreducible if and only if for each pair* $i<j$ *the strings* $S(\gamma_{2i}, -\gamma_{2i-1})$ *and* $S(\gamma_{2j-1},-\gamma_{2j})$ *are in general position.*

Proof: By Corollary 3.11, the strings $S(\gamma_{2i-1},-\gamma_{2i})$, $i=1,\ldots,k$ are pairwise in general position. Permuting the tensor factors in (5.35) if necessary, we may assume that $\gamma_1+\gamma_2\leqslant\cdots\leqslant\gamma_{2k-1}+\gamma_{2k}$. Suppose that the strings $S(\gamma_{2i},-\gamma_{2i-1})$ and $S(\gamma_{2j-1},-\gamma_{2j})$ are in general position for all $i<j$. Then one easily checks that (5.14) is satisfied and so, by Proposition 5.2 representation (5.35) of $\mathrm{Y}^-(2)$ is irreducible.

Conversely, let V be irreducible as a $\mathrm{Y}^-(2)$-module. Consider the module V' obtained by replacement of some of the tensor factors $L(\gamma_{2i-1},-\gamma_{2i})$, respectively, by $L(\gamma_{2i},-\gamma_{2i-1})$. Then V' is isomorphic to V. Indeed, $\dim V=\dim V'$ and one easily checks using (2.15) that V is isomorphic to the irreducible quotient of the $\mathrm{Y}^-(2)$-submodule in V' generated by the tensor product of the highest weight vectors of the factors. So, V' is irreducible as a $\mathrm{Y}^-(2)$-module and hence, as a $\mathrm{Y}(2)$-module. By Corollary 3.11 the corresponding strings are pairwise in general position. □

The following theorem together with Theorem 4.3 provides a description of finite-dimensional irreducible representations of $\mathrm{Y}^-(2n)$ (cf. Theorem 3.12). We use notations (3.35) and (5.34).

Theorem 5.8: *The irreducible highest weight representation* $V(\mu(u))$, $\mu(u)=(\mu_1(u),\ldots,\mu_n(u))$ *of* $\mathrm{Y}^-(2n)$ *is finite-dimensional if and only if the following relation holds:*

$$\mu_1(-u)\Rightarrow\mu_1(u)\to\mu_2(u)\to\cdots\to\mu_n(u). \tag{5.36}$$

Proof: Suppose that $\dim V(\mu(u))<\infty$. By Proposition 4.5 we have

$$\mu_1(u)\to\mu_2(u)\to\cdots\to\mu_n(u). \tag{5.37}$$

The subalgebra in $\mathrm{Y}^-(2n)$ generated by the coefficients of the series $s_{ij}(u)$ with $i,j=-1,1$ is isomorphic to $\mathrm{Y}^-(2)$. The cyclic span of the highest weight vector of $V(\mu(u))$ with respect to this subalgebra is a representation with the highest weight $\mu_1(u)$. Its irreducible quotient is finite-dimensional and so, by Theorem 5.4 we have $\mu_1(-u)\Rightarrow\mu_1(u)$.

Conversely, let (5.36) hold. Then

$$\frac{\mu_1(-u)}{\mu_1(u)}=\frac{P_1(u+1)}{P_1(u)}, \tag{5.38}$$

and

$$\frac{\mu_{i-1}(u)}{\mu_i(u)}=\frac{P_i(u+1)}{P_i(u)} \tag{5.39}$$

for certain polynomials $P_i(u)$ of the form

$$P_i(u)=(u+\delta_1^{(i)})\cdots(u+\delta_{s_i}^{(i)}),\quad i=2,...,n \tag{5.40}$$

and

$$P_1(u)=(u+\delta_1^{(1)})\cdots(u+\delta_{s_1}^{(1)})(u-\delta_1^{(1)}-1)\cdots(u-\delta_{s_1}^{(1)}-1); \tag{5.41}$$

see the proof of Theorem 5.4. Consider the irreducible highest weight representation $L(\lambda(u))$ with $\lambda(u)=(\lambda_{-n}(u),\cdots,\lambda_n(u))$ of the Yangian $\mathrm{Y}(2n)$ where for $i=1,...,n$,

$$\lambda_i(u)=\prod_{a=1}^{i}(1+\delta_1^{(a)}u^{-1})\cdots(1+\delta_{s_a}^{(a)}u^{-1})\prod_{a=i+1}^{n}(1+(\delta_1^{(a)}+1)u^{-1})\cdots(1+(\delta_{s_a}^{(a)}+1)u^{-1}) \tag{5.42}$$

and

$$\lambda_{-i}(u)=\prod_{a=1}^{n}(1+(\delta_1^{(a)}+1)u^{-1})\cdots(1+(\delta_{s_a}^{(a)}+1)u^{-1}). \tag{5.43}$$

Then $L(\lambda(u))$ is finite-dimensional by Theorem 3.12. One easily derives from relations (2.1) and (2.15) that the cyclic $\mathrm{Y}^-(2n)$-span of its highest weight vector is a representation with the highest weight $\mu'(u)=(\mu_1'(u),...,\mu_n'(u))$ where $\mu_i'(u)=\lambda_i(u)\lambda_{-i}(-u)$. So, the representation $V(\mu'(u))$ of $\mathrm{Y}^-(2n)$ is finite-dimensional. However, the polynomials $\mu_i'(u)$ satisfy (5.38) and (5.39). Hence, there exists an automorphism of $\mathrm{Y}^-(2n)$ of the form (2.29) such that its composition with the representation $V(\mu'(u))$ is isomorphic to $V(\mu(u))$ which completes the proof. □

Theorem 5.8 implies the following parametrization of representations of the special twisted Yangian $\mathrm{SY}^-(2n)$ (cf. Corollary 3.13).

Corollary 5.9: There is a one-to-one correspondence between finite-dimensional irreducible representations of the special twisted Yangian $\mathrm{SY}^-(2n)$ *and the families* $\{P_1(u),...,P_n(u)\}$ *of monic polynomials in u with* $P_1(u)=P_1(-u+1)$. *Every such representation is isomorphic to a subquotient of a representation of the form L(λ(u)).* □

VI. REPRESENTATIONS OF $\mathrm{Y}^+(2n)$

The results for the *D* series are very similar to the previous case. However, some differences take place for $n=1$ since the twisted Yangian $\mathrm{Y}^+(2)$ corresponds to the Abelian Lie algebra o(2). In particular, contrary to the case of $\mathrm{Y}^-(2)$, it is not true that every finite-dimensional irreducible representations of $\mathrm{Y}^+(2)$ is obtained by restriction of a representation of Y(2). Also, the step from $\mathrm{Y}^+(2)$ to $\mathrm{Y}^+(2n)$, $n\geqslant 2$ requires an extra care. We omit most of the proofs in this section which are parallel to the case of $\mathrm{Y}^-(2)$ but provide all necessary additional arguments.

We start with the case $n=1$. Irreducible highest weight representations $V(\mu(u))$ of $\mathrm{Y}^+(2)$ are parametrized by formal series $\mu(u)\in 1+u^{-1}\mathbb{C}[[u^{-1}]]$.

Proposition 6.1: If $\dim V(\mu(u))<\infty$ *then there exists an even formal series* $\psi(u)\in 1+u-2\mathbb{C}[[u-2]]$ *such that* $(1+1/2u^{-1})\psi(u)\mu(u)$ *is a polynomial in* u^{-1}.

Proof: We repeat the argument of the proof of Proposition 5.1 almost word by word and only point out a few differences. First, here the symmetry relation (2.18) gives $s_{1,-1}(u)=s_{1,-1}(-u)$ and so, for any $r\geqslant 1$ we have $s_{1,-1}^{(2r-1)}=0$. Relation (5.3) is replaced by

$$[s_{11}(u),s_{1,-1}(v)]=\frac{2u+1}{u^2-v^2}\,s_{1,-1}(v)s_{11}(u)$$
$$-\frac{u+v+1}{u^2-v^2}\,s_{1,-1}(u)s_{11}(v)-\frac{1}{u+v}\,s_{1,-1}(u)s_{-1,-1}(v). \tag{6.1}$$

Instead of (5.8) we obtain here $s_{1,-1}(u)\xi=a_1(u)\xi_1+\cdots+a_k(u)\xi_k$. The counterpart of relation (5.10) has exactly the same form. However, for the remaining part of the proof instead of (5.11) we need to consider the following formula obtained from (6.1) by taking the coefficient at u^{-4}:

$$s_{11}^{(4)}s_{1,-1}(u)=s_{1,-1}(u)(s_{11}^{(4)}+2s_{11}^{(3)}+s_{11}^{(2)}+2s_{11}^{(1)}u^2+u^2)-s_{1,-1}^{(2)}((u+1)s_{11}(u)-us_{-1,-1}(u)).$$

Applying both sides to ξ and using the symmetry relation (2.18) we find that

$$(u+\tfrac{1}{2})\mu(u)-(u-\tfrac{1}{2})\mu(-u)=C(u)a_k(u)$$

for a polynomial $C(u)$ of degree k in u^2. Together with (5.10) this proves that for $\psi(u)=(u^{2k}a_k(u))^{-1}$ the series $(1+1/2u^{-1})\psi(u)\mu(u)$ is a polynomial in u^{-1} of degree $\leqslant 2k+1$. □

Note that the irreducible representation of $\mathrm{Y}^+(2)$ with the highest weight $\mu(u)=(1+\gamma u^{-1})(1+1/2u^{-1})^{-1}$, where $\gamma\in\mathbb{C}$ is one-dimensional. It is obtained by extending the one-dimensional representation of the Abelian Lie algebra o(2) given by $F_{11}\xi=(\gamma-1/2)\xi$, where ξ is the basis vector; see (4.10). We shall denote this representation of $\mathrm{Y}^+(2)$ by $V(\gamma)$.

Let $(1+1/2u^{-1})\mu(u)$ be polynomial in u^{-1} of degree $\leqslant 2k+1$. Consider an expansion

$$\mu(u)=(1-\gamma_1u^{-1})\cdots(1-\gamma_{2k+1}u^{-1})(1+\tfrac{1}{2}u^{-1})^{-1}. \tag{6.2}$$

Re-enumerating the numbers γ_i if necessary, we may assume that the following condition is satisfied [cf. (5.14)]:

$$\text{for every } i=1,\ldots,k \text{ we have: if the multiset}$$
$$\{\gamma_p+\gamma_q\,|\,2i-1\leqslant p<q\leqslant 2k+1\} \text{ contains non-negative integers} \tag{6.3}$$
$$\text{then } \gamma_{2i-1}+\gamma_{2i} \text{ is minimal among them.}$$

In the following proposition we use tensor products of representations constructed in accordance with (4.11). As before, we denote by $L(\alpha,\beta)$ a highest weight representation of the Lie algebra gl(2) which is also regarded as a Y(2)-module.

Proposition 6.2: Let $V(\mu(u))$ *be an irreducible highest weight representation of* $\mathrm{Y}^+(2)$ *where* $(1+1/2u^{-1})\mu(u)$ *is a polynomial of degree* $\leqslant 2k+1$ *in* u^{-1}. *Suppose that decomposition (6.2) is given and condition (6.3) is satisfied. Then* $V(\mu(u))$ *is isomorphic to the tensor product*

$$L(\gamma_1,-\gamma_2)\otimes\cdots\otimes L(\gamma_{2k-1},-\gamma_{2k})\otimes V(-\gamma_{2k+1}). \tag{6.4}$$

Proof: Denote representation (6.4) by V. Let ξ_i be the highest weight vector of $L(\gamma_{2i-1},-\gamma_{2i})$ and ξ_{k+1} be the basis vector of the one-dimensional represetation $V(-\gamma_{2k+1})$. Using (3.23) and (2.31) we find that the vector $\xi:=\xi_1\otimes\cdots\otimes\xi_{k+1}$ satisfies

$$s_{11}(u)\xi=\mu(u)\xi,\qquad s_{-1,1}(u)\xi=0.$$

Thus, the cyclic $\mathrm{Y}^+(2)$-span of the vector ξ in V is a highest weight module with the highest weight $\mu(u)$. So, it suffices to show that the representation V is irreducible.

We use induction on k. For $k=0$ this is obvious. Suppose that $k\geqslant 1$. Proceeding exactly as in the proof of Proposition 5.2 we obtain that if the vector η is given by (5.18) with

$$\eta_r \in L(\gamma_3,-\gamma_4)\otimes\cdots\otimes L(\gamma_{2k-1},-\gamma_{2k})\otimes V(-\gamma_{2k+1})$$

then

$$\eta_p=\mathrm{const}\cdot\xi_2\otimes\cdots\otimes\xi_{k+1}, \tag{6.5}$$

where ''const'' is a nonzero constant. Further, instead of (5.26) we get here

$$(u^2-(\gamma_1-p+1)^2)u^{2k-1}s_{-1,1}(u)\,\eta_{p-1}+p(\gamma_1+\gamma_2-p+1)u^{2k-1}$$
$$\times\left(\frac{2u+1}{2u}\,(u-\gamma_1+p-1)s_{11}(u)-\frac{2u-1}{2u}\,(u+\gamma_1-p+1)s_{11}(-u)\right)\eta_p=0. \tag{6.6}$$

The elements $s^{(r)}_{-1,1}$ and $s^{(r)}_{1,-1}$ act trivially in $V(-\gamma_{2k+1})$. Hence, by (2.31) and (4.11) we have

$$s_{-1,1}(u)(\zeta\otimes\xi_{k+1})=t_{-1,1}(u)t_{-1,-1}(-u)\zeta\otimes s_{11}(u)\xi_{k+1}+t_{-1,-1}(u)t_{-1,1}(-u)\zeta\otimes s_{-1,-1}(u)\xi_{k+1},$$

where $\zeta\in L(\gamma_3,-\gamma_4)\otimes\cdots\otimes L(\gamma_{2k-1},-\gamma_{2k})$. Using the defining relations (2.1) and the symmetry relation (2.18) we may rewrite this as follows:

$$s_{-1,1}(u)(\zeta\otimes\xi_{k+1})=t_{-1,-1}(-u)t_{-1,1}(u)\zeta\otimes\frac{2u+1}{2u}\,s_{11}(u)\xi_{k+1}$$
$$+t_{-1,-1}(u)t_{-1,1}(-u)\zeta\otimes\frac{2u-1}{2u}\,s_{11}(-u)\xi_{k+1}. \tag{6.7}$$

Now, the definition of $V(\gamma)$ and (3.18) imply that $u^{2k-1}s_{-1,1}(u)\,\eta_{p-1}$ is a polynomial in u. Further, by (6.5) we have

$$\frac{2u+1}{2u}\,u^{2k-1}s_{11}(u)\,\eta_p=(u-\gamma_3)\cdots(u-\gamma_{2k+1})\,\eta_p\,.$$

So, putting $u=\gamma_1-p+1$ in (6.6) we get

$$p(\gamma_1+\gamma_2-p+1)(\gamma_1+\gamma_3-p+1)\cdots(\gamma_1+\gamma_{2k+1}-p+1)=0.$$

However, this is impossible because of condition (6.3). Therefore, p has to be equal to 0 and so, η is a multiple of ξ.

To show that the submodule of V generated by ξ coincides with V we consider the dual representation V^* defined by

$$(y\cdot f)(v)=f(\sigma(y)v),\quad y\in\mathrm{Y}^+(2),\quad f\in V^*,\quad v\in V,$$

where σ is the antiautomorphism of $\mathrm{Y}^+(2)$ given by (2.26). One easily verifies that $V(\gamma)^*\simeq V(1-\gamma)$ and so, the representation V^* is isomorphic to

$$L'(-\gamma_1,\gamma_2)\otimes\cdots\otimes L'(-\gamma_{2k-1},\gamma_{2k})\otimes V(\gamma_{2k+1}+1),$$

where $L'(-\gamma_{2i-1},\gamma_{2i})$ is the lowest weight representation of gl(2); see (3.31). Repeating the previous argument we prove that any nonzero submodule in V^* contains the tensor product of the lowest weight vectors of the $L'(-\gamma_{2i-1},\gamma_{2i})$ and the basis vector of $V(\gamma_{2k+1}+1)$. The proof is completed exactly as that of Proposition 5.2. □

The following proposition is proved in the same way as Proposition 5.3.

Proposition 6.3: Let $V(\mu(u))$ be an irreducible representation of $\mathrm{Y}^+(2)$ with the highest weight $\mu(u)$. Then $V(\mu(u))$ is finite-dimensional if and only if there exists a formal series $\psi(u)\in 1+u^{-2}\mathbb{C}[[u^{-2}]]$ such that $(1+1/2u^{-1})\psi(u)\mu(u)$ is a polynomial in u^{-1} with a decomposition

$$(1+\tfrac{1}{2}u^{-1})\psi(u)\mu(u)=(1-\gamma_1u^{-1})\cdots(1-\gamma_{2k+1}u^{-1}), \tag{6.8}$$

and $\gamma_{2i-1}+\gamma_{2i}\in\mathbb{Z}_+$, $i=1,...,k$ for a certain re-enumeration of the γ_i. □

By analogy with Theorem 5.4 we can reformulate these conditions in terms of monic polynomials in u.

Theorem 6.4: *The irreducible hiqhest weight representation $V(\mu(u))$ of $\mathrm{Y}^+(2)$ is finite-dimensional if and only if there exists a pair $(P(u),\gamma)$, where $P(u)$ is a monic polynomial in u with $P(u)=P(-u+1)$ and $\gamma\in\mathbb{C}$ with $P(-\gamma)\neq 0$ such that*

$$\frac{\mu(-u)}{\mu(u)}=\frac{P(u+1)}{P(u)}\,\frac{(u+\gamma)(2u+1)}{(u-\gamma)(2u-1)}. \tag{6.9}$$

In this case the pair $(P(u),\gamma)$ is unique.

Proof: If $\dim V(\mu(u))<\infty$ then by Proposition 6.3 relation (6.8) holds for a certain even series $\psi(u)$. Re-enumerate the numbers γ_i to satisfy condition (6.3). By Proposition 6.2 we have $\gamma_{2i-1}+\gamma_{2i}\in\mathbb{Z}_+$ for $i=1,...,k$ since $V(\mu(u))$ is finite-dimensional. Define $P(u)$ as in the proof of Theorem 5.4 by (5.30)–(5.32) and set $\gamma=\gamma_{k+1}$. The relation $P(-\gamma)\neq 0$ is implied by (6.3).

Conversely, let (6.9) be satisfied for a monic polynomial $P(u)$ such that $P(u)=P(-u+1)$ and $\gamma\in\mathbb{C}$ with $P(-\gamma)\neq 0$. Let $\{-\delta_1,\ldots,-\delta_s,\delta_1+1,...,\delta_s+1\}$ be the roots of $P(u)$; see the proof of Theorem 5.4. Set

$$\mu'(u)=(1-(\delta_1+1)u^{-1})\cdots(1-(\delta_s+1)u^{-1})\\ \times(1+\delta_1u^{-1})\cdots(1+\delta_su^{-1})(1-\gamma u^{-1})(1+\tfrac{1}{2}u^{-1})^{-1}.$$

By Proposition 6.3 the representation $V(\mu'(u))$ is finite-dimensional. Since $\mu'(u)$ satisfies (6.9) the ratio $\mu(u)/\mu'(u)$ is an even formal series in u^{-1}. This proves that $V(\mu(u))$ is also finite-dimensional.

To prove the uniqueness of the pair $(P(u),\gamma)$ suppose that $(R(u),\delta)$ is another pair, where $R(u)$ is a monic polynomial in u such that $R(u)=R(-u+1)$, $R(-\delta)\neq 0$ and

$$\frac{P(u+1)}{P(u)}\,\frac{(u+\gamma)}{(u-\gamma)}=\frac{R(u+1)}{R(u)}\,\frac{(u+\delta)}{(u-\delta)}. \tag{6.10}$$

If $\gamma=\delta$ then we get $P(u)=R(u)$; see the proof of Theorem 3.8. Let $\gamma\neq\delta$. We prove by induction on the sum of the degrees of the polynomials $P(u)$ and $R(u)$ that (6.10) is impossible. If $P(u)=R(u)=1$ then this is obvious. Further, suppose $P(u)$ is of degree $\geqslant 2$. Take a root u_0 of $P(u)$ such that u_0+1 is not a root. Rewriting (6.10) in the form

$$P(u)R(u+1)(u+\delta)(u-\gamma)=P(u+1)R(u)(u-\delta)(u+\gamma) \tag{6.11}$$

we find that either $R(u_0)=0$, or $u_0=\delta$. If $R(u_0)=0$ then we may write

$$P(u)=P'(u)(u-u_0)(u+u_0-1),\quad R(u)=R'(u)(u-u_0)(u+u_0-1)$$

and use the induction hypotheses for the polynomials $P'(u)$ and $R'(u)$. If $u_0=\delta$ but $R(u_0)\neq 0$ then we write $P(u)=P'(u)(u-u_0)(u+u_0-1)$ and obtain from (6.11) that

$$P'(u)R(u+1)(u+u_0-1)(u-\gamma)=P'(u+1)R(u)(u-u_0+1)(u+\gamma).$$

Denote $\delta'=u_0-1$. Then we have $\delta'\neq\gamma$ because $P(-\delta')=0$. Moreover, $R(-\delta')=R(u_0)\neq 0$ and we may apply the induction hypotheses to the polynomials $P'(u)$ and $R(u)$. □

Corollary 6.5: There is a one-to-one correspondence between finite-dimensional irreducible representations of the special twisted Yangian $\mathrm{SY}^+(2)$ and the pairs $(P(u),\gamma)$, where $P(u)$ is a

monic polynomial in u such that $P(u)=P(-u+1)$ *and* $\gamma\in\mathbb{C}$ *with* $P(-\gamma)\neq 0$. *Every such representation is isomorphic to a representation of the form (6.4).* □

The following analog of Corollary 5.7 holds.

Corollary 6.6: Consider an irreducible finite-dimensional representation of $\mathrm{Y}(2)$ *of the form*

$$L(\gamma_1,-\gamma_2)\otimes\cdots\otimes L(\gamma_{2k-1},-\gamma_{2k}). \tag{6.12}$$

Then the representation

$$L(\gamma_1,-\gamma_2)\otimes\cdots\otimes L(\gamma_{2k-1},-\gamma_{2k})\otimes V(-\gamma) \tag{6.13}$$

of $\mathrm{Y}^+(2)$ *is irreducible if and only if for each pair* $1\leqslant i<j\leqslant k$ *the strings* $S(\gamma_{2i},-\gamma_{2i-1})$ *and* $S(\gamma_{2j-1},-\gamma_{2j})$ *are in general position, and for each* $i=1,\ldots,k$ *one has*

$$\gamma\notin S(\gamma_{2i-1},-\gamma_{2i}),\quad \gamma\notin S(\gamma_{2i},-\gamma_{2i-1}). \tag{6.14}$$

Proof: By Corollary 3.11, the strings $S(\gamma_{2i-1},-\gamma_{2i})$, $i=1,\ldots,k$ are pairwise in general position. Permuting the tensor factors in (6.12) if necessary, we may assume that $\gamma_1+\gamma_2\leqslant\cdots\leqslant\gamma_{2k-1}+\gamma_{2k}$. If the condition on the strings holds then one easily checks that (6.3) is satisfied for $\gamma_{2k+1}=\gamma$ and so, by Proposition 6.2 representation (6.13) is irreducible.

To prove the ''only if'' part consider first the case $k=1$. Let the representation $L(\gamma_1,-\gamma_2)\otimes V(-\gamma)$ be irreducible but condition (6.14) is violated. Note that $L(\gamma_2,-\gamma_1)\otimes V(-\gamma)$ is also irreducible. Indeed, these two representations have the same dimension and the tensor product of the highest weight vector of $L(\gamma_2,-\gamma_1)$ and the basis vector of $V(-\gamma)$ generates a highest weight module with the same highest weight as $L(\gamma_1,-\gamma_2)\otimes V(-\gamma)$. So we may assume that $\gamma\in S(\gamma_1,-\gamma_2)$ and if $\gamma+\gamma_1\in\mathbb{Z}_+$ then $\gamma+\gamma_2\leqslant\gamma+\gamma_1$. Then by Proposition 6.2 the representation $L(\gamma,-\gamma_2)\otimes V(-\gamma_1)$ is irreducible. It is isomorphic to $L(\gamma_1,-\gamma_2)\otimes V(-\gamma)$ because they have the same highest weight. Comparing the dimensions we come to a contradiction.

Consider now the general case. Let representation (6.13) be irreducible. If (6.14) is violated then we move the corresponding tensor factor in (6.13) to the right to get the tensor product of the form $L(\gamma_{2i-1},-\gamma_{2i})\otimes V(-\gamma)$. However, this representation is reducible. Contradiction.

Finally, replacing some of the tensor factors $L(\gamma_{2i-1},-\gamma_{2i})$ in (6.13), respectively, by $L(\gamma_{2i},-\gamma_{2i-1})$ we get an isomorphic representation of $\mathrm{Y}^+(2)$ (see the proof of Corollary 5.7). Hence, the representation of $\mathrm{Y}(2)$ obtained from (6.12) by this replacement is also irreducible. Therefore, by Corollary 3.11 the corresponding strings are pairwise in general position. □

Note that $V(\gamma)$ for $\gamma=1/2$ is the trivial representation of $\mathrm{Y}^+(2)$. Thus, in this particular case Corollary 6.6 provides a criterion of irreducibility of the restriction of (6.12) to $\mathrm{Y}^+(2)$.

Example 6.7: Consider the restriction of the representation $L(\gamma_1,-\gamma_2)$ of $\mathrm{Y}(2)$ with $\gamma_1+\gamma_2\in\mathbb{Z}_+$ to $\mathrm{Y}^+(2)$. By Corollary 6.6, it is reducible if and only if the string $S(\gamma_1,-\gamma_2)$ contains $-1/2$. In this case $\gamma_1,\ \gamma_2\in 1/2+\mathbb{Z}_+$. Denote the highest weight vector of $L(\gamma_1,-\gamma_2)$ by ξ and set $\xi_p=(E_{1,-1})^p\xi$. Suppose first that $\gamma_1\geqslant\gamma_2$. Then the following are $\mathrm{Y}^+(2)$-submodules in $L(\gamma_1,-\gamma_2)$:

$$L_1=\text{span of }\{\xi_0,\ldots,\xi_{\gamma_2-1/2}\},$$

$$L_2=\text{span of }\{\xi_{\gamma_1+1/2},\ldots,\xi_{\gamma_1+\gamma_2}\}.$$

By Proposition 6.2 one has $L_1\simeq L(\gamma_2,-1/2)\otimes V(-\gamma_1)$ and $L_2\simeq L(\gamma_2,-1/2)\otimes V(\gamma_1+1)$. The quotient $L(\gamma_1,-\gamma_2)/L$, where $L=L_1\oplus L_2$, is isomorphic to $L(\gamma_1,\gamma_2+1)$. If $\gamma_1\leqslant\gamma_2$ then $L(\gamma_1,-\gamma_2)$ contains the submodule

$$L=\text{span of }\{\xi_{\gamma_1+1/2},\ldots,\xi_{\gamma_2-1/2}\}$$

which is isomorphic to $L(\gamma_2,\gamma_1+1)$ and the quotient $L(\gamma_1,-\gamma_2)/L$ is isomorphic to the direct sum of $L(\gamma_1,-1/2)\otimes V(-\gamma_2)$ and $L(\gamma_1,-1/2)\otimes V(\gamma_2+1)$. □

Note that the mapping

$$s_{ij}(u)\mapsto s_{i'j'}(u), \tag{6.15}$$

where $i'=-i$ for $i=-1,1$ and $i'=i$ otherwise, defines an automorphism of the algebra $\mathrm{Y}^+(2n)$. Consider the case $n=1$ and denote the composition of this automorphism with a finite-dimensional irreducible representation $V(\mu(u))$ of $\mathrm{Y}^+(2)$ by $V(\mu(u))^\sharp$. By Theorem 4.3, this is a representation with the highest weight which we denote by $\mu(u)^\sharp$. We shall say that $\mu(u)^\sharp$ is *well-defined* if $\mu(u)$ satisfies the conditions of Proposition 6.3. Since the automorphisms (2.29) and (6.15) commute, the ratio $\mu(u)/\mu(u)^\sharp$ takes the same value for all representations from the similarity class containing $V(\mu(u))$.

Equivalently, $V(\mu(u))$ contains a unique (up to scalar multiples) nonzero vector ζ such that $s_{1,-1}(u)\zeta=0$ (cf. Remark 4.4). Then ζ is an eigenvector for $s_{-1,-1}(u)$ and $\mu(u)^\sharp$ is defined by

$$s_{-1,-1}(u)\zeta=\mu(u)^\sharp\zeta. \tag{6.16}$$

Proposition 6.8: Let $\mu(u)$ be a series given by (6.2) such that condition (6.3) is satisfied and $\gamma_{2i-1}+\gamma_{2i}\in\mathbb{Z}_+$ for $i=1,\dots,k$. Then

$$\mu(u)^\sharp=(1-\gamma_1u^{-1})\cdots(1-\gamma_{2k}u^{-1})(1+(\gamma_{2k+1}+1)u^{-1})(1+\tfrac{1}{2}u^{-1})^{-1}. \tag{6.17}$$

Proof: By Proposition 6.2 the representation $V(\mu(u))$ is isomorphic to the tensor product (6.4). In the notation of the proof of Proposition 6.2 set

$$\zeta=(E_{1,-1})^{\gamma_1+\gamma_2}\xi_1\otimes\cdots\otimes(E_{1,-1})^{\gamma_{2k-1}+\gamma_{2k}}\xi_k\otimes\xi_{k+1}.$$

Then using (2.31) we verify that ζ satisfies the relations

$$s_{-1,-1}(u)\zeta=(1-\gamma_1u^{-1})\cdots(1-\gamma_{2k}u^{-1})(1+(\gamma_{2k+1}+1)u^{-1})(1+\tfrac{1}{2}u^{-1})^{-1}\zeta$$

and $s_{1,-1}(u)\zeta=0$. Thus, $V(\mu(u))^\sharp$ is isomorphic to $V(\mu(u)^\sharp)$ with $\mu(u)^\sharp$ given by (6.17) □.

The following theorem together with Theorem 4.3 provides a description of finite-dimensional irreducible representations of $\mathrm{Y}^+(2n)$ (cf. Theorem 5.8). We use notations (3.35) and (5.34).

Theorem 6.9: *The irreducible highest weight representation $V(\mu(u))$, $\mu(u)=(\mu_1(u),\dots,\mu_n(u))$ of $\mathrm{Y}^+(2n)$, $n\geqslant 2$ is finite-dimensional if and only if $\mu_1(u)^\sharp$ is well-defined and either one of the following four relations holds:*

$$\mu_1(-u)\Rightarrow\mu_1(u)\to\mu_2(u)\to\cdots\to\mu_n(u), \tag{6.18}$$

$$\frac{2u-1}{2u+1}\,\mu_1(-u)\Rightarrow\mu_1(u)\to\mu_2(u)\to\cdots\to\mu_n(u), \tag{6.19}$$

$$\mu_1(-u)^\sharp\Rightarrow\mu_1(u)^\sharp\to\mu_2(u)\to\cdots\to\mu_n(u), \tag{6.20}$$

$$\frac{2u-1}{2u+1}\,\mu_1(-u)^\sharp\Rightarrow\mu_1(u)^\sharp\to\mu_2(u)\to\cdots\to\mu_n(u). \tag{6.21}$$

Proof: Suppose that $\dim V(\mu(u))<\infty$. Then by Proposition 4.5 we have

$$\mu_1(u)\to\mu_2(u)\to\cdots\to\mu_n(u). \tag{6.22}$$

Denote the composition of $V(\mu(u))$ with the automorphism (6.15) by $V(\mu(u))^\sharp$. By Theorem 4.3 the representation $V(\mu(u))^\sharp$ is highest weight. To find its highest weight vector consider the cyclic span $V=\mathrm{Y}^+(2)\xi$, where ξ is the highest weight vector of $V(\mu(u))$, and $\mathrm{Y}^+(2)$ is identified with the subalgebra in $\mathrm{Y}^+(2n)$ generated by the coefficients of the series $s_{ij}(u)$ with $i,j=-1,1$. We claim that V is an irreducible $\mathrm{Y}^+(2)$-module. Indeed, let J be the left ideal in $\mathrm{Y}^+(2n)$ generated by the $s_{kl}^{(r)}$ with $k<l$ and $(k,l)\neq(-1,1)$. Then V is annihilated by J. This follows from the fact that $J\xi=0$ and the relations

$$[s_{ij}(u),s_{kl}(v)]\equiv 0 \bmod J, \tag{6.23}$$

where $i,j=\pm 1$, and $k<l$ with $(k,l)\neq(-1,1)$. To verify (6.23) we may assume, applying (2.18) if necessary, that $l\geqslant 2$. However, in this case (6.23) is immediate from (2.17). Now, if $\widetilde{V}$ is a nonzero submodule in V then there exists a nonzero vector $\eta\in\widetilde{V}$ such that $s_{-1,1}(u)\,\eta=0$. Then $s_{kl}(u)\,\eta=0$ for all $k<l$ since V is annihilated by J. So, η is a multiple of ξ; see Remark 4.4. This proves that $\widetilde{V}=V$.

Thus, V is isomorphic to the representation $V(\mu_1(u))$ of $\mathrm{Y}^+(2)$. Since $\dim V<\infty$ there exists a nonzero vector $\zeta\in V$ such that

$$s_{-1,-1}(u)\zeta=\mu_1(u)^{\sharp}\zeta,\quad s_{1,-1}(u)\zeta=0;$$

see (6.16). Moreover, we have $s_{kk}(u)\zeta=\mu_k(u)\zeta$ for $k=2,\ldots,n$. This is implied by the following relations which are immediate from (2.17):

$$[s_{ij}(u),s_{kk}(v)]\equiv 0 \bmod J,$$

where $i,j=\pm 1$ and $k\geqslant 2$. Since ζ is annihilated by J we may conclude that ζ is the highest weight vector of $V(\mu(u))^{\sharp}$ and so, the latter is a representation with the highest weight $(\mu_1(u)^{\sharp},\mu_2(u),\ldots,\mu_n(u))$. Applying Proposition 4.5 again, we find that

$$\mu_1(u)^{\sharp}\to\mu_2(u)\to\cdots\to\mu_n(u). \tag{6.24}$$

Further, since the representation $V(\mu_1(u))$ of $\mathrm{Y}^+(2)$ is finite-dimensional, then by Proposition 6.3 we may assume, applying an automorphism of the form (2.29) if necessary, that $(1+1/2u^{-1})\mu_1(u)$ is a polynomial in u^{-1}. By (6.22) we have

$$\frac{\mu_1(u)}{\mu_2(u)}=\frac{P(u+1)}{P(u)} \tag{6.25}$$

for a monic polynomial $P(u)$ in u. Hence, applying an automorphism (2.29) again, we may assume that both $(1+1/2u^{-1})\mu_1(u)$ and $(1+1/2u^{-1})\mu_2(u)$ are polynomials in u^{-1}:

$$\mu_1(u)=(1-\gamma_1u^{-1})\cdots(1-\gamma_{2k+1}u^{-1})(1+\tfrac{1}{2}u^{-1})^{-1},$$

$$\mu_2(u)=(1-\delta_1u^{-1})\cdots(1-\delta_{2k+1}u^{-1})(1+\tfrac{1}{2}u^{-1})^{-1}.$$

Re-enumerating the γ_i if necessary, we may assume that condition (6.3) holds. Moreover, $\gamma_{2i-1}+\gamma_{2i}\in\mathbb{Z}_+$ for $i=1,\ldots,k$ since $\dim V(\mu_1(u))<\infty$; see Proposition 6.2. Further, (6.25) implies that there exists a re-enumeration of the δ_i such that

$$\delta_i-\gamma_i\in\mathbb{Z}_+\quad\text{for } i=1,\ldots,2k+1. \tag{6.26}$$

To see this, choose a string-type subset $\{a+1,a+2,\ldots,b\}$ of roots of $P(u)$ such that a and $b+1$ are not roots. Then we find from (6.25) that $\gamma_i=a$ for a certain i, and b equals one of the δ's which we re-denote by δ_i. Therefore, $\delta_i-\gamma_i\in\mathbb{Z}_+$ and we can write

$$\mu_1(u)=(1-au^{-1})\mu_1'(u),\quad \mu_2(u)=(1-bu^{-1})\mu_2'(u)$$

and

$$\frac{P(u+1)}{P(u)}=\frac{P'(u+1)}{P'(u)}\cdot\frac{u-a}{u-b},$$

where $P(u)=(u-a-1)\cdots(u-b)P'(u)$. Then we proceed by induction applying the same argument to the series $\mu_1'(u)$, $\mu_2'(u)$ and the polynomial $P'(u)$.

Now we use Proposition 6.8. Exactly as above, we obtain from (6.24) that there exists a permutation $\pi\in\mathfrak{S}_{2k+1}$ such that

$$\delta_{\pi(i)}-\gamma_i\in\mathbb{Z}_+,\ \ i=1,\ldots,2k,\qquad \delta_{\pi(2k+1)}+\gamma_{2k+1}+1\in\mathbb{Z}_+. \tag{6.27}$$

Now, (6.26) and (6.27) imply that $\delta_{\pi(i)}-\delta_i\in\mathbb{Z}$ for $i=1,...,2k$. But then this has to be true for $i=2k+1$ as well. Thus, $2\gamma_{2k+1}+1\in\mathbb{Z}$, that is, the number $\gamma:=\gamma_{2k+1}$ belongs to $\frac{1}{2}\mathbb{Z}$.

Suppose first that $\gamma\in\frac{1}{2}+\mathbb{Z}$ and $\gamma\geqslant-\frac{1}{2}$. Then exactly as in the proof of Theorem 5.4 we obtain that $\mu_1(-u)\Rightarrow\mu_1(u)$. Similarly, if $\gamma\in\frac{1}{2}+\mathbb{Z}$ and $\gamma\leqslant-\frac{1}{2}$ then $\mu_1(-u)^\sharp\Rightarrow\mu_1(u)^\sharp$. Further, let $\gamma\in\mathbb{Z}$ and $\gamma\geqslant 0$. Then writing

$$(1+\tfrac{1}{2}u^{-1})\mu_1(u)=(1-\gamma_1u^{-1})\cdots(1-\gamma_{2k}u^{-1})(1-\gamma u^{-1})(1-0u^{-1})$$

we see that $(1-1/2u^{-1})\mu_1(-u)\Rightarrow(1+1/2u^{-1})\mu_1(u)$, or, equivalently,

$$\frac{2u-1}{2u+1}\,\mu_1(-u)\Rightarrow\mu_1(u).$$

Similarly, if $\gamma\in\mathbb{Z}$ and $\gamma\leqslant-1$ then using Proposition 6.8 we obtain

$$\frac{2u-1}{2u+1}\,\mu_1(-u)^\sharp\Rightarrow\mu_1(u)^\sharp.$$

Combining these relations with (6.22) or (6.24) we complete the proof of the ''only if'' part.

Suppose now that relation (6.18) is satisfied. Then we repeat the corresponding argument of the proof of Theorem 5.8 to show that $V(\mu(u))$ is finite-dimensional. Similarly, if (6.20) holds then the irreducible representation with the highest weight $(\mu_1(u)^\sharp,\mu_2(u),\ldots,\mu_n(u))$ is finite-dimensional, and so is $V(\mu(u))$, since the automorphism (6.15) is involutive. If (6.19) holds then

$$\frac{\mu_1(-u)}{\mu_1(u)}=\frac{P_1(u+1)}{P_1(u)}\cdot\frac{2u+1}{2u-1} \tag{6.28}$$

for a monic polynomial $P_1(u)$ of the form (5.41), and relations (5.39) hold for polynomials $P_i(u)$ of the form (5.40). Define the $\lambda_j(u)$ by (5.42) and (5.43). Then the representation $L(\lambda(u))$ of $\mathrm{Y}(2n)$ is finite-dimensional by Theorem 3.12.

Let $V(\mu_0)$ denote the irreducible representation of the Lie algebra $\mathrm{o}(2n)$ with the highest weight $\mu_0=(-1/2,...,-1/2)$. It is finite-dimensional; see (4.6) and (4.7). Extend $V(\mu_0)$ to a representation of $\mathrm{Y}^+(2n)$ by using (2.23) and consider the tensor product $L(\lambda(u))\otimes V(\mu_0)$. The tensor product of the highest weight vectors of $L(\lambda(u))$ and $V(\mu_0)$ generates a $\mathrm{Y}^+(2n)$-submodule with the highest weight $\mu'(u)=(\mu_1'(u),\ldots,\mu_n'(u))$ where $\mu_i'(u)=\lambda_i(u)\lambda_{-i}(-u)(1+1/2u^{-1})^{-1}$; see (4.10) and (4.11). So the representation $V(\mu'(u))$ of $\mathrm{Y}^+(2n)$ is finite-dimensional. However, the polynomials $\mu_i'(u)$ satisfy (6.28) and (5.39). Hence, there exists an automorphism of $\mathrm{Y}^+(2n)$ of the form (2.29) such that its composition with the representation $V(\mu'(u))$ is isomorphic to $V(\mu(u))$ which completes the proof in this case. Finally, if relation (6.21) holds then the same argument shows that the representation $V(\mu_1(u)^\sharp,\mu_2(u),\ldots,\mu_n(u))$ is finite-dimensional, and so $V(\mu(u))$ is. □

We conclude this section with the following description of representations of the special twisted Yangian $\mathrm{SY}^+(2n)$ implied by Theorem 6.9 (cf. Corollary 5.9).

Corollary 6.10: There is a one-to-one correspondence between finite-dimensional irreducible representations of the special twisted Yangian $\mathrm{SY}^+(2n)$, $n\geqslant 2$ *and the families* $\{P_1(u),\ldots,P_n(u),\epsilon\}$, *where the* $P_i(u)$ *are monic polynomials in* u *with* $P_1(u)=P_1(-u+1)$, *and the parameter* ϵ *takes values in* $\{1,2,3,4\}$; *the values* $\epsilon=1$ *and* $\epsilon=3$ *are identified if* $P_1(1/2)\neq 0$. *Every such representation is isomorphic to a subquotient of a representation of the form* $L(\lambda(u))$ *or* $L(\lambda(u))\otimes V(\mu_0)$.

Proof: Each of the four conditions (6.18)–(6.21) allows one to naturally associate a family $\{P_1(u),\ldots,P_n(u)\}$ of monic polynomials to the corresponding similarity class of finite-dimensional irreducible representations of $\mathrm{Y}^+(2n)$; see the proof of Theorem 6.9. We associate the values of ϵ, respectively, to conditions (6.18)–(6.21). It follows from the proof of Theorem 6.9 that two families of monic polynomials with values of $\epsilon=1$ and $\epsilon=3$ correspond to the same similarity class if and only if $P_1(1/2)\neq 0$. One easily checks that identifying these values we obtain the desired one-to-one correspondence. The second claim also follows from the proof of Theorem 6.9. □

VII. REPRESENTATIONS OF $\mathrm{Y}^+(2n+1)$

The description of finite-dimensional irreducible representations of $\mathrm{Y}^+(2n+1)$ is based on the simplest nontrivial case $n=1$. Our main instrument in this case is an investigation of the restriction of an irreducible highest weight representation of $\mathrm{Y}^+(3)$ to the subalgebra $\mathrm{Y}^+(2)$ and the use of the results of Sec. VI.

Irreducible highest weight representations $V(\mu(u))$ of $\mathrm{Y}^+(3)$ are parametrized by pairs of formal series $\mu(u)=(\mu_0(u),\mu_1(u))$, where $\mu_0(u)\in 1+u^{-2}\mathbb{C}[[u^{-2}]]$ and $\mu_1(u)\in 1+u^{-1}\mathbb{C}[[u^{-1}]]$.

Proposition 7.1: If $\dim V(\mu(u))<\infty$ *then there exists a formal series* $\varphi(u)\in 1+u^{-1}\mathbb{C}[[u^{-1}]]$ *such that* $\varphi(u)\mu_0(u)$ *and* $\varphi(u)\mu_1(u)$ *are polynomials in* u^{-1}.

Proof: Denote by ξ the highest weight vector of $V(\mu(u))$. Let k denote the minimum nonnegative integer such that $s_{10}^{(k+1)}\xi$ is a linear combination of the vectors $\xi_1:=s_{10}^{(1)}\xi,\dots,\xi_k:=s_{10}^{(k)}\xi$. Relations (2.17) give

$$[s_{11}(u),s_{10}(v)]=\frac{1}{u-v}\,(s_{10}(v)s_{11}(u)-s_{10}(u)s_{11}(v))+\frac{u-v+1}{u^2-v^2}\,s_{1,-1}(v)s_{01}(u)$$
$$-\frac{1}{u+v}\,s_{1,-1}(u)s_{-1,0}(v)-\frac{1}{u^2-v^2}\,s_{1,-1}(u)s_{01}(v). \tag{7.1}$$

Since the vector ξ is annihilated by $s_{01}(u)$ [and hence by $s_{-1,0}(u)$] this makes the consideration here very similar to the case of Y(2); see Proposition 3.5. In particular, repeating the corresponding argument of the proof of Proposition 3.5 we can show that

$$s_{10}(u)\xi=a_1(u)\xi_1+\cdots+a_k(u)\xi_k$$

for certain series $a_i(u)$; cf. (3.13). By (2.17) we have

$$[s_{00}(u),s_{10}(v)]=\frac{u+v+1}{u^2-v^2}\,s_{10}(u)s_{00}(v)-\frac{1}{u+v}\,s_{0,-1}(u)s_{00}(v)-\frac{2v+1}{u^2-v^2}\,s_{10}(v)s_{00}(u). \tag{7.2}$$

Taking the coefficients at u^{-2} in (7.1) and (7.2) and using again the argument of the proof of Proposition 3.5 we find that the components of $\mu(u)$ can be written in the form

$$\mu_0(u)=B(u)a_k(u),\quad \mu_1(u)=C(u)a_k(u),$$

where $B(u)$ and $C(u)$ are monic polynomials in u of degree k. Thus, the series $\varphi(u)$ can be defined by $\varphi(u)=(a_k(u)u^k)^{-1}$. □

Write the polynomials $\varphi(u)\mu_0(u)$ and $\varphi(u)\mu_1(u)$ in the form

$$\begin{aligned}\varphi(u)\mu_0(u)&=(1+\alpha_1u^{-1})\cdots(1+\alpha_ku^{-1}),\\ \varphi(u)\mu_1(u)&=(1+\beta_1u^{-1})\cdots(1+\beta_ku^{-1}),\end{aligned} \tag{7.3}$$

with $\alpha_i,\ \beta_i\in\mathbb{C}$. Since $\mu_0(u)$ is an even series in u^{-1} we can find an appropriate automorphism of the form (2.29) such that its composition with $V(\mu(u))$ is an irreducible representation with the following highest weight which we shall again denote by $\mu(u)$:

$$\begin{aligned}\mu_0(u)&=(1-\alpha_1^2u^{-2})\cdots(1-\alpha_k^2u^{-2}),\\ \mu_1(u)&=(1-\alpha_1u^{-1})\cdots(1-\alpha_ku^{-1})(1+\beta_1u^{-1})\cdots(1+\beta_ku^{-1}).\end{aligned} \tag{7.4}$$

Our next task is to find necessary conditions for the α_i and β_i so that the representation $V(\mu(u))$ with the highest weight given by (7.4) be finite-dimensional.

Consider the following representation of Y(3):

$$L(\alpha_1,\alpha_1,\beta_1)\otimes\cdots\otimes L(\alpha_k,\alpha_k,\beta_k). \tag{7.5}$$

It follows from (2.15) that the $\mathrm{Y}^+(3)$-cyclic span of the tensor product of the highest weight vectors of the $L(\alpha_i,\alpha_i,\beta_i)$ is a representation of $\mathrm{Y}^+(3)$ with the highest weight $\mu(u)=(\mu_0(u),\mu_1(u))$ given by (7.4). The generators $t_{ij}^{(r)}$ of $\mathrm{Y}(3)$ with $r\geqslant k+1$ act trivially in representation (7.5) [cf. (3.18)]. Therefore, by (2.15) the generators $s_{ij}^{(r)}$ of $\mathrm{Y}^+(3)$ with $r\geqslant 2k+1$ act trivially in $V(\mu(u))$. The series

$$S_{ij}(u):=u^{2k}s_{ij}(u) \tag{7.6}$$

is then a polynomial operator in u and we may evaluate u to get well-defined operators in $V(\mu(u))$. Set

$$\begin{aligned} a_0(u)&=u^{2k}\mu_0(u)=(u^2-\alpha_1^2)\cdots(u^2-\alpha_k^2),\\ a_1(u)&=u^{2k}\mu_1(u)=(u-\alpha_1)\cdots(u-\alpha_k)(u+\beta_1)\cdots(u+\beta_k). \end{aligned} \tag{7.7}$$

Using Proposition 2.1 we shall now equip the vector space $V:=V(\mu(u))$ with another structure of $\mathrm{Y}^+(3)$-module. The matrix elements of the Sklyanin comatrix $\hat{S}(u)$ can be found from Ref. 31, Sect. VI. In particular,

$$\begin{aligned} \hat{s}_{00}(u)&=s_{11}(-u)s_{11}(u-1)-s_{1,-1}(-u)s_{-1,1}(u-1),\\ \hat{s}_{-1,0}(u)&=s_{0,-1}(-u)s_{-1,1}(u-1)-s_{01}(-u)s_{11}(u-1),\\ \hat{s}_{11}(u)&=s_{11}(-u)s_{00}(u-1)-s_{10}(-u)s_{-1,0}(u-1). \end{aligned} \tag{7.8}$$

Let us take the composition of the representation $V(\mu(u))$ with the automorphism $S(u)\mapsto \hat{S}(-u+1/2)$ of $\mathrm{Y}^+(3)$; see (2.27). One can easily see from (7.8) that the resulting representation is highest weight and generated by the vector ξ. The highest weight of this representation is

$$(\mu_1(u-1/2)\mu_1(-u-1/2),\ \ \mu_1(u-1/2)\mu_0(-u-1/2)). \tag{7.9}$$

We shall use the notation

$$\alpha_i^*=\tfrac{1}{2}-\beta_i,\quad \beta_i^*=\tfrac{1}{2}-\alpha_i,\quad \text{for } i=1,\ldots,k. \tag{7.10}$$

Set

$$\begin{aligned} \mu_0^*(u)&=(1-(\alpha_1^*)^2u^{-2})\cdots(1-(\alpha_k^*)^2u^{-2}),\\ \mu_1^*(u)&=(1-\alpha_1^*u^{-1})\cdots(1-\alpha_k^*u^{-1})(1+\beta_1^*u^{-1})\cdots(1+\beta_k^*u^{-1}). \end{aligned} \tag{7.11}$$

Take the composition of the irreducible representation of $\mathrm{Y}^+(3)$ with the highest weight (7.9) and the automorphism (2.29) corresponding to the series

$$\psi_0(u)=\frac{\mu_0^*(u)}{\mu_1(u-1/2)\mu_1(-u-1/2)}.$$

The resulting representation is isomorphic to $V(\mu^*(u))$, $\mu^*(u)=(\mu_0^*(u),\mu_1^*(u))$.

Thus, the vector space V carries two representations of $\mathrm{Y}^+(3)$ isomorphic to $V(\mu(u))$ and $V(\mu^*(u))$, respectively. To distinguish them we shall denote by $s_{ij}^*(u)$ the action of the generators $s_{ij}(u)$ in $V(\mu^*(u))$. By the above definition we have

$$s_{ij}^*(u)=\psi_0(u)\hat{s}_{ij}(-u+\tfrac{1}{2}). \tag{7.12}$$

Denote by $S_{ij}^*(u)$ the corresponding polynomial operator (7.6) in $V(\mu^*(u))$. By analogy with (7.7) set

$$a_0^*(u)=u^{2k}\mu_0^*(u), \quad a_1^*(u)=u^{2k}\mu_1^*(u).$$

For the proof of the next proposition fix an index $i\in\{1,...,k\}$ and set $\alpha:=\alpha_i$, $\beta^*:=\frac{1}{2}-\alpha_i$. Given non-negative integer p introduce the following vector in V:

$$\eta_p=S_{10}(-\alpha+p-1)\cdots S_{10}(-\alpha)\xi.$$

Proposition 7.2: We have the relations

$$S_{00}(u)\,\eta_p=a_0(u)\,\frac{u^2-(\alpha-p)^2}{u^2-\alpha^2}\,\eta_p, \tag{7.13}$$

$$S_{-1,0}(u)\,\eta_p=pa_0(u)a_1(-\alpha+p-1)\,\frac{u+\alpha-p}{u^2-\alpha^2}\,\eta_{p-1}, \tag{7.14}$$

$$S^*_{-1,1}(u)\,\eta_p=0, \tag{7.15}$$

$$S^*_{11}(u)\,\eta_p=a_1^*(u)\,\frac{u+\beta^*+p}{u+\beta^*}\,\eta_p. \tag{7.16}$$

Proof: We use induction on p to prove (7.13)–(7.16) simultaneously. For $p=0$ all the relations are obvious. Suppose now that $p\geqslant 1$. Using the induction hypotheses and (7.2) we obtain

$$S_{00}(u)\,\eta_p=S_{00}(u)S_{10}(-\alpha+p-1)\,\eta_{p-1}=\frac{u^2-(\alpha-p)^2}{u^2-(\alpha-p+1)^2}\,S_{10}(-\alpha+p-1)S_{00}(u)\,\eta_{p-1},$$

which proves (7.13). Further, (2.28) gives

$$[\hat{s}_{11}(u),s_{10}(v)]=-\frac{1}{u-v-2}\,(\hat{s}_{1,-1}(u)s_{-1,0}(v)+\hat{s}_{10}(u)s_{00}(v)+\hat{s}_{11}(u)s_{10}(v)). \tag{7.17}$$

Hence, using the induction hypotheses and (7.12) we can write

$$S^*_{11}(u)\,\eta_p=S^*_{11}(u)S_{10}(-\alpha+p-1)\,\eta_{p-1}=\frac{u+\beta^*+p}{u+\beta^*+p-1}\,S_{10}(-\alpha+p-1)S^*_{11}(u)\,\eta_{p-1},$$

which proves (7.16). The proof of (7.15) is the same; it suffices to use the expansion for $[\hat{s}_{-1,1}(u),s_{10}(v)]$ implied by (2.28). Finally, to prove (7.14) consider the following relation implied by (2.17):

$$\begin{aligned}[s_{-1,0}(u),s_{10}(v)]=&\frac{1}{u-v}\,(s_{10}(u)s_{-1,0}(v)-s_{10}(v)s_{-1,0}(u))\\&+\frac{u-v-1}{u^2-v^2}\,s_{11}(v)s_{00}(u)-\frac{1}{u+v}\,s_{-1,-1}(u)s_{00}(v)\\&+\frac{1}{u^2-v^2}\,s_{11}(u)s_{00}(v).\end{aligned} \tag{7.18}$$

Using the induction hypotheses we obtain

$$S_{-1,0}(u)\,\eta_p = S_{-1,0}(u)S_{10}(-\alpha+p-1)\,\eta_{p-1}$$
$$= \frac{u+\alpha-p}{u+\alpha-p+1}\,S_{10}(-\alpha+p-1)S_{-1,0}(u)\,\eta_{p-1}$$
$$+\frac{u+\alpha-p}{u^2-(\alpha-p+1)^2}\,S_{11}(-\alpha+p-1)S_{00}(u)\,\eta_{p-1}. \tag{7.19}$$

Using (7.13) and applying further (7.19) to $S_{-1,0}(u)\,\eta_{p-1}$, etc., we find that

$$S_{-1,0}(u)\,\eta_p = a_0(u)\,\frac{u+\alpha-p}{u^2-\alpha^2}\,\eta_p^{(1)}, \tag{7.20}$$

where

$$\eta_p^{(1)} = \sum_{q=1}^{p} S_{10}(-\alpha+p-1)\cdots S_{11}(-\alpha+q-1)\cdots S_{10}(-\alpha)\,\xi$$

and $S_{11}(-\alpha+q-1)$ takes the qth position from the right.

On the other hand, by (7.8)

$$\hat{s}_{11}(u+1) = s_{11}(-u-1)s_{00}(u) - s_{10}(-u-1)s_{-1,0}(u).$$

Let us multiply both sides of this relation by $(u(u+1))^{2k}$ and apply them to the vector η_{p-1}. By (7.12) we have

$$\hat{s}_{11}(u+1) = s_{11}^{*}(-u-\tfrac{1}{2})\,\psi_0(u+\tfrac{1}{2})^{-1}.$$

So, we can use (7.16) to calculate $(u(u+1))^{2k}\hat{s}_{11}(u+1)\,\eta_{p-1}$. Performing this calculation and using (7.13) and (7.20) we come to the relation

$$a_1(-u-1)\,\eta_{p-1} = \frac{u-\alpha+p-1}{u-\alpha}\,S_{11}(-u-1)\,\eta_{p-1} - \frac{1}{u-\alpha}\,S_{10}(-u-1)\,\eta_{p-1}^{(1)}. \tag{7.21}$$

Note that

$$\eta_p^{(1)} = S_{11}(-\alpha+p-1)\,\eta_{p-1} + S_{10}(-\alpha+p-1)\,\eta_{p-1}^{(1)}.$$

Therefore, putting $u=\alpha-p$ into (7.21) we get

$$\eta_p^{(1)} = p\,a_1(-\alpha+p-1)\,\eta_{p-1}. \tag{7.22}$$

Together with (7.20) this completes the proof of (7.14). □

Given non-negative integers $p_1,\ldots,p_k$ introduce vectors in V of a more general form:

$$\eta_{p_1,\ldots,p_k} = \left(\prod_{i=1,\ldots,k}^{\rightarrow} S_{10}(-\alpha_i+p_i-1)\cdots S_{10}(-\alpha_i)\right)\xi. \tag{7.23}$$

Set

$$S_{-1,0}^{\natural}(u) = \frac{S_{-1,0}(u)}{(u+\alpha_1-p_1)\cdots(u+\alpha_k-p_k)}.$$

Proposition 7.3: (i) *The series* $S_{-1,0}^{\natural}(u)\,\eta_{p_1,\ldots,p_k}$ *is a polynomial in u with values in V and for every* $i=1,\ldots,k$,

$$S^{\natural}_{-1,0}(\alpha_i-p_i)\,\eta_{p_1,\dots,p_k}=-a_1(-\alpha_i+p_i-1)\prod_{j=1}^{k}(\alpha_i-\alpha_j-p_i)\,\eta_{p_1,\dots,p_i-1,\dots,p_k}. \tag{7.24}$$

(ii) *One has the relation*

$$S_{00}(u)\,\eta_{p_1,\dots,p_k}=(u^2-(\alpha_1-p_1)^2)\cdots(u^2-(\alpha_k-p_k)^2)\,\eta_{p_1,\dots,p_k}. \tag{7.25}$$

Proof: First we verify (ii) by using (7.2) and repeating the corresponding argument of the proof of Proposition 7.2. Next, by an obvious induction with the use of (7.18) and (7.25) [cf. the proof of (7.20)] we show that

$$S_{-1,0}(u)\,\eta_{p_1,\dots,p_k}=(u+\alpha_1-p_1)\cdots(u+\alpha_k-p_k)\sum_{j=1}^{k}(u-\alpha_1)\cdots(u-\alpha_{j-1})$$
$$\times(u-\alpha_{j+1}+p_{j+1})\cdots(u-\alpha_k+p_k)\,\eta^{(j)}_{p_1,\dots,p_k}, \tag{7.26}$$

where $\eta^{(j)}_{p_1,\dots,p_k}$ is the vector in V obtained from $\eta_{p_1,\dots,p_k}$ by replacing the product

$$S_{10}(-\alpha_j+p_j-1)\cdots S_{10}(-\alpha_j) \tag{7.27}$$

in (7.23) with the sum

$$\sum_{q=1}^{p_j}S_{10}(-\alpha_j+p_j-1)\cdots S_{11}(-\alpha_j+q-1)\cdots S_{10}(-\alpha_j);$$

here $S_{11}(-\alpha_j+q-1)$ takes the qth position from the right. This proves that the series $S^{\natural}_{-1,0}(u)\,\eta_{p_1,\dots,p_k}$ is a polynomial in u. Moreover, (7.26) and (7.22) imply (7.24) for $i=k$. To complete the proof we show that $\eta_{p_1,\dots,p_k}$ is not changed if we arbitrarily permute the products (7.27) in the definition (7.23). We only need to show this for permutations of adjacent products. By (7.25) it suffices to verify the following auxiliary claim: if a vector $\eta\in V$ satisfies

$$S_{00}(u)\,\eta=(u^2-\gamma_1^2)\cdots(u^2-\gamma_k^2)\,\eta$$

then

$$S_{10}(\gamma_1)S_{10}(\gamma_2)\,\eta=S_{10}(\gamma_2)S_{10}(\gamma_1)\,\eta. \tag{7.28}$$

Indeed, relations (2.17) give

$$[s_{10}(u),s_{10}(v)]=-\frac{1}{u+v}\,(s_{1,-1}(u)s_{00}(v)-s_{1,-1}(v)s_{00}(u)). \tag{7.29}$$

Therefore, if $\gamma_1+\gamma_2\neq 0$ then (7.28) holds because $S_{00}(\gamma_i)\,\eta=0$. Further, we obtain from (7.29) that

$$[S_{10}(-u),S_{10}(u)]=\frac{dS_{1,-1}(u)}{du}\,S_{00}(u)-S_{1,-1}(u)\,\frac{dS_{00}(u)}{du}.$$

So, if $\gamma_1+\gamma_2=0$ then (7.28) holds since in this case η is annihilated by both the values of $S_{00}(u)$ and its derivative at $u=\gamma_2$. □

We suppose, as before, that the p_i are non-negative integers.

Proposition 7.4: The vector $\eta_{p_1,\dots,p_k}\in V$ satisfies the relations

$$S^{*}_{-1,1}(u)\,\eta_{p_1,\dots,p_k}=0, \tag{7.30}$$

$$S^{*}_{11}(u)\,\eta_{p_1,\dots,p_k}=(u-\alpha_1^{*})\cdots(u-\alpha_k^{*})(u+\beta_1^{*}+p_1)\cdots(u+\beta_k^{*}+p_k)\,\eta_{p_1,\dots,p_k}. \tag{7.31}$$

Proof: Relation (7.31) follows from (7.17) and Proposition 7.3 by an easy induction; cf. the proof of (7.16). The proof of (7.30) is the same with the use of (7.12) and the expansion for $[\hat{s}_{-1,1}(u),s_{10}(v)]$ given by (2.28). □

Recall that the representation $L(\gamma,\gamma,\delta)$ of Y(3) is finite-dimensional if and only if $\gamma-\delta \in \mathbb{Z}_+$; see Sec. III.

Proposition 7.5: Let the irreducible representation $V(\mu(u))$ of $\mathrm{Y}^+(3)$ with the components of $\mu(u)$ given by (7.4) be finite-dimensional and let $\widetilde{\mu}(u)$ be defined by (7.4) with the corresponding parameters $\widetilde{\alpha}_i$ and $\widetilde{\beta}_i$, where

$$\widetilde{\alpha}_i=\alpha_i+l_i, \quad \widetilde{\beta}_i=\beta_i-m_i, \quad i=1,...,k \tag{7.32}$$

and l_i, $m_i\in\mathbb{Z}_+$. Then the representation $V(\widetilde{\mu}(u))$ is also finite-dimensional.

Proof: For each i the representation $L(\alpha_i+l_i,\alpha_i+l_i,\alpha_i)\otimes V(\mu(u))$ of $\mathrm{Y}^+(3)$ is finite-dimensional. The tensor product of the highest weight vectors of $L(\alpha_i+l_i,\alpha_i+l_i,\alpha_i)$ and $V(\mu(u))$ generates a $\mathrm{Y}^+(3)$-module with the highest weight $\mu'(u)$, where

$$\mu_0'(u)=\mu_0(u)(1-(\alpha_i+l_i)^2u^{-2},$$

$$\mu_1'(u)=\mu_1(u)(1-(\alpha_i+l_i)u^{-1})(1+\alpha_i\mu^{-1});$$

see (2.31) and (4.11). The composition of this module and the automorphism (2.29) with the series $\psi(u)=(1-\alpha_i^2u^{-2})^{-1}$ yields a finite-dimensional representation with the highest weight obtained from $\mu(u)$ by replacing α_i with α_i+l_i.

Similarly, considering tensor products of the form $L(\beta_i,\beta_i,\beta_i-m_i)\otimes V(\mu(u))$ we show that the representation with the highest weight obtained from $\mu(u)$ by replacing β_i with β_i-m_i is also finite-dimensional. □

We are now in a position to establish necessary and sufficient conditions for $V(\mu(u))$ to be finite-dimensional.

Proposition 7.6: The irreducible highest weight representation $V(\mu(u))$ of $\mathrm{Y}^+(3)$ with the components of $\mu(u)$ given by (7.4) is finite-dimensional if and only if there exist a re-enumeration of the α_i and a re-enumeration of the β_i such that either one of the following two conditions is satisfied:

$$\alpha_i-\beta_i\in\mathbb{Z}_+ \quad \text{for } i=1,...,k; \tag{7.33}$$

$$\alpha_i-\beta_i\in\mathbb{Z}_+ \quad \text{for } i=1,...,k-1 \quad \text{and } \alpha_k\in\tfrac{1}{2}+\mathbb{Z}_+, \quad \beta_k\in-\mathbb{Z}_+. \tag{7.34}$$

Proof: Suppose that $\dim V(\mu(u))<\infty$. As before, we equip the vector space $V=V(\mu(u))$ with one more structure of $\mathrm{Y}^+(3)$-module. This module is isomorphic to $V(\mu^*(u))$ with $\mu^*(u)$ given by (7.11). Our basic idea is to construct nonzero vectors which generate highest weight $\mathrm{Y}^+(2)$-submodules in $V(\mu^*(u))$ and then use the conditions on the highest weight imposed by Proposition 6.3.

Consider the multiset $M=\{\alpha_1^*,\dots,\alpha_k^*,\beta_1^*,\dots,\beta_k^*\}$. Let us represent it as a disjoint union

$$M=\bigsqcup_{z\in\mathbb{C}/\mathbb{Z}} M_z, \quad M_z=(z+\mathbb{Z})\cap M.$$

Let

$$M_z=\{\alpha_{i_1}^*,\dots,\alpha_{i_r}^*,\beta_{j_1}^*,\dots,\beta_{j_s}^*\} \tag{7.35}$$

with both sequences written in the increasing order of the real parts, where $I_z=\{i_1,\dots,i_r\}$ and $J_z=\{j_1,\dots,j_s\}$ are subsets of $\{1,...,k\}$ depending on z.

Assume first that for each M_z the following conditions are satisfied:

$$\alpha_{i_1}^*=\cdots=\alpha_{i_r}^*, \quad \beta_{j_1}^*=\cdots=\beta_{j_s}^*, \quad \text{Re } \beta_{j_1}^*<0,$$
$$\text{and if } \beta_{j'}^*\in M_{-z} \text{ then } \alpha_{i_1}^*+\beta_{j'}^*>0. \tag{7.36}$$

Consider the vector $\eta_{p_1,\dots,p_k}$ [see (7.23)] with the numbers p_i defined as follows. For M_z given by (7.35) set $p_{j_b}=\alpha_{j_b}+\alpha_{j'}$, $b=1,\dots,s$ if there exists $\beta_{j'}^*\in M_{-z}$; otherwise set $p_{j_b}=0$. Starting with $\eta_{p_1,\dots,p_k}$ we shall apply repeatedly appropriate operators $S_{-1,0}^{\natural}(\alpha_i-q_i)$ to the vectors of the form $\eta_{q_1,\dots,q_k}$ to get the highest weight vector $\xi=\eta_{0,\dots,0}$ with a certain coefficient. By conditions (7.36) and the choice of the numbers p_i this can be done in such a way that the coefficient would be nonzero, as follows from (7.24). This proves that $\eta_{p_1,\dots,p_k}\neq 0$.

On the other hand, by Proposition 7.4 the vector $\eta_{p_1,\dots,p_k}$ generates a $\mathrm{Y}^+(2)$-submodule in $V(\mu^*(u))$ with the highest weight

$$(1-\alpha_1^*u^{-1})\cdots(1-\alpha_k^*u^{-1})(1+(\beta_1^*+p_1)u^{-1})\cdots(1+(\beta_k^*+p_k)u^{-1}). \tag{7.37}$$

This submodule is finite-dimensional. However, for all i we have $-\beta_i^*-p_i-\frac{1}{2}\notin\mathbb{Z}_+$ and for all $i<j$ we have $-\beta_i^*-p_i-\beta_j^*-p_j\notin\mathbb{Z}_+$. So, Proposition 6.3 implies that there exist re-enumerations of the α_i^* and of the β_i^* such that either

$$\alpha_i^*-\beta_i^*\in\mathbb{Z}_+ \quad \text{for } i=1,\dots,k; \tag{7.38}$$

or

$$\alpha_i^*-\beta_i^*\in\mathbb{Z}_+ \quad \text{for } i=1,\dots,k-1; \quad \text{and } \alpha_k^*\in\tfrac{1}{2}+\mathbb{Z}_+. \tag{7.39}$$

Let now the parameters α_i^* and β_i^* be arbitrary. We can choose non-negative integers l_i and m_i in such a way that conditions (7.36) are satisfied for any z by the shifted parameters $\alpha_i^*+l_i$ and $\beta_i^*-m_i$. Therefore, by Proposition 7.5 either (7.38) or (7.39) with $\mathbb{Z}_+$ replaced by $\mathbb{Z}$ will still hold.

Let us consider the multisets M_{z_0} for different z_0. Suppose first that $z_0\not\equiv 0,\frac{1}{2} \bmod \mathbb{Z}$. Then in (7.35) the index s may only be equal to r or $r+1$. Let us prove that

$$\alpha_{i_t}^*-\beta_{j_t}^*\in\mathbb{Z}_+ \quad \text{for } t=1,\dots,r. \tag{7.40}$$

Indeed, if this condition is violated then there exists an index $m\in\{1,..,r\}$ such that the number of the elements $\beta_{j_t}^*$ satisfying $\alpha_{i_m}^*-\beta_{j_t}^*\in\mathbb{Z}_+$ is less than m. Now we use Proposition 7.5 again. Applying shifts of the form (7.32), if necessary, we may assume that conditions (7.36) are satisfied for all $z\not\equiv z_0 \bmod \mathbb{Z}$ while for the elements of M_{z_0} we have:

$$\alpha_{i_1}^*=\cdots=\alpha_{i_m}^*, \quad \alpha_{i_{m+1}}^*=\cdots=\alpha_{i_r}^*,$$
$$\beta_{j_1}^*=\cdots=\beta_{j_l}^*, \quad \beta_{j_{l+1}}^*=\cdots=\beta_{j_s}^*, \tag{7.41}$$

where $\text{Re } \beta_{j_1}^*<0$, and if $\beta_{j'}^*\in M_{-z_0}$ then $\alpha_{i_r}^*+\beta_{j'}^*>0$. Here $l<m$ and the differences $\alpha_{i_1}^*-\beta_{j_1}^*$, $\beta_{j_s}^*-\alpha_{i_1}^*$ and $\alpha_{i_r}^*-\beta_{j_s}^*$ are positive integers.

Consider the vector $\eta_{p_1,\dots,p_k}$ with the p_i defined as in the previous argument except for $i\in J_{z_0}\cup J_{-z_0}$. In the latter case set $p_{j_b}=\alpha_{j_b}+\alpha_{j'}$ for $b=l+1,\dots,s$ if there exists $\beta_{j'}^*\in M_{-z_0}$; otherwise set $p_{j_b}=0$ (shifting further $\beta_{j'}^*\to\beta_{j'}^*-m_{j'}$ we may suppose that the p_{j_b} are non-negative integers). Let each of the remaining p_i with $i\in J_{z_0}\cup J_{-z_0}$ be equal to zero. Using (7.24) again we find that $\eta_{p_1,\dots,p_k}\neq 0$ and so by Proposition 7.4 it generates a finite-dimensional $\mathrm{Y}^+(2)$-submodule in $V(\mu^*(u))$ with the highest weight given by (7.37). However, one easily checks that the condition of Proposition 6.3 is not satisfied. Contradiction.

Further, if $z_0 \equiv 0 \mod \mathbb{Z}$ the same argument shows that (7.40) holds. The only difference is that here $M_{z_0} = M_{-z_0}$ and one should take j' to be equal to j_1 or j_s depending on whether $\beta^*_{j_s} \in 1 + \mathbb{Z}_+$ or $\beta^*_{j_s} \in -\mathbb{Z}_+$.

Finally, let $z_0 \equiv \frac{1}{2} \mod \mathbb{Z}$. In (7.35) the index s must be equal to r or $r-1$. We shall prove that either condition (7.40) holds (then $s = r$), or

$$\alpha^*_{i'_t} - \beta^*_{j_t} \in \mathbb{Z}_+ \quad \text{for } t = 1,...,r-1 \quad \text{and } \alpha^*_{i'_r} \in \tfrac{1}{2} + \mathbb{Z}_+ \tag{7.42}$$

for a permutation $(i'_1,\dots,i'_r)$ of the elements of I_{z_0}. Suppose that (7.40) is violated. Then we can again represent M_{z_0} in the form (7.41). If either $\beta^*_{j_s} \in \frac{3}{2} + \mathbb{Z}_+$ with $\alpha^*_{i_1} \in -\frac{1}{2} - \mathbb{Z}_+$, or $\beta^*_{j_s} \in \frac{1}{2} - \mathbb{Z}_+$ then we come to a contradiction exactly as above. So, we must have $\beta^*_{j_s} \in \frac{3}{2} + \mathbb{Z}_+$, $\alpha^*_{i_1} \in \frac{1}{2} + \mathbb{Z}_+$. Taking $j' = j_1$ and repeating the previous argument we obtain the inequality $s - l \leqslant r - m$. It can only be satisfied if $s = r-1$ and $l = m-1$. Note that this conclusion is valid for all possible values of the parameter m. Let us now assume that m takes the minimum value. Then (7.42) will be satisfied for the indices $i'_1,\dots,i'_r$ defined as follows:

$$i'_t = i_t \quad \text{for } t = 1,...,m-1,$$

$$i'_t = i_{t+1} \quad \text{for } t = m,\dots,r-1,$$

$$i'_r = i_m .$$

Thus, we have proved that if $V(\mu(u))$ is finite-dimensional then there exist re-enumerations of the α_i and of the β_i such that either (7.38), or (7.39) holds. Conditions (7.38) are equivalent to (7.33), while (7.39) means that

$$\alpha_i - \beta_i \in \mathbb{Z}_+ \quad \text{for } i = 1,...,k-1; \quad \text{and } \beta_k \in -\mathbb{Z}_+ ; \tag{7.43}$$

see (7.10). Applying this result to the representation $V(\mu^*(u))$ instead of $V(\mu(u))$ we obtain that either relation (7.33) holds, or there exist permutations $\sigma, \tau \in \mathfrak{S}_k$ such that

$$\alpha_{\sigma(i)} - \beta_{\tau(i)} \in \mathbb{Z}_+ \quad \text{for } i = 1,...,k-1; \quad \text{and } \alpha_{\sigma(k)} \in \tfrac{1}{2} + \mathbb{Z}_+ . \tag{7.44}$$

If $\sigma(k) = k$ then (7.34) is satisfied. Otherwise, set $l = \sigma(k)$ and rewrite (7.44) as follows:

$$\alpha_i - \beta_{\rho(i)} \in \mathbb{Z}_+ \quad \text{for } i \neq l; \quad \text{and } \alpha_l \in \tfrac{1}{2} + \mathbb{Z}_+ ,$$

where $\rho \in \mathfrak{S}_k$. Consider the cycle of ρ of the form $k \to i_1 \to \cdots \to i_s \to k$. Suppose that it does not contain l. Then setting $\beta'_i = \beta_{\rho(i)}$ if i belongs to the cycle, and $\beta'_i = \beta_i$ otherwise, we obtain by (7.43) that $\alpha_i - \beta'_i \in \mathbb{Z}_+$ for all $i = 1,...,k$, that is, (7.33) holds.

Suppose now that the cycle contains l: $k \to i_1 \to \cdots \to i_t \to l$. Set $\alpha'_k = \alpha_l$, $\alpha'_{\rho(i)} = \alpha_i$ for $i = k, i_1, \dots, i_t$ and $\alpha'_i = \alpha_i$ for the remaining indices i. Then by (7.43) relation (7.34) is satisfied for the α'_i and β_i which completes the proof of the ''only if'' part of the proposition.

Now let (7.33) hold. Then representation (7.5) of $\mathrm{Y}^+(3)$ is finite-dimensional. However, $V(\mu(u))$ is isomorphic to its subquotient and therefore $\dim V(\mu(u)) < \infty$.

Finally, let (7.34) hold. Consider the highest weight representation $V(\mu)$ of the Lie algebra $\mathrm{o}(3)$ and extend it to $\mathrm{Y}^+(3)$ by using the homomorphism (2.23). We obtain a representation with the highest weight given by (4.10). By (4.9) the representation $V(\mu)$ is finite-dimensional for $\mu = \beta_k - \frac{1}{2}$. Therefore the representation of $\mathrm{Y}^+(3)$ of the form

$$L(\alpha_1,\alpha_1,\beta_1) \otimes \cdots \otimes L(\alpha_{k-1},\alpha_{k-1},\beta_{k-1}) \otimes L(\alpha_k,\alpha_k,\tfrac{1}{2}) \otimes V(\beta_k - \tfrac{1}{2}) \tag{7.45}$$

is also finite-dimensional. However, we find from (2.31) and (4.11) that $V(\mu(u))$ is isomorphic to a subquotient of (7.45) and so, $\dim V(\mu(u)) < \infty$. □

The following theorem together with Theorem 4.3 provides a description of finite-dimensional irreducible representations of $\mathrm{Y}^+(2n+1)$ (cf. Theorems 5.8 and 6.9). We use notation (3.35).

Theorem 7.7: *The irreducible highest weight representation* $V(\mu(u)),\mu(u)=(\mu_0(u),\ldots,\mu_n(u))$ *of* $\mathrm{Y}^+(2n+1)$ *is finite-dimensional if and only if either one of the following two relations holds:*

$$\mu_0(u)\to\mu_1(u)\to\cdots\to\mu_n(u), \tag{7.46}$$

$$\frac{2u}{2\mu+1}\,\mu_0(u)\to\mu_1(u)\to\cdots\to\mu_n(u). \tag{7.47}$$

Proof: Suppose that $\dim V(\mu(u))<\infty$. Then by Proposition 4.5 we have

$$\mu_1(u)\to\mu_2(u)\to\cdots\to\mu_n(u).$$

The subalgebra in $\mathrm{Y}^+(2n+1)$ generated by the coefficients of the series $s_{ij}(u)$ with $i,j=-1,0,1$ is isomorphic to $\mathrm{Y}^+(3)$. The cyclic span of the highest weight vector of $V(\mu(u))$ with respect to this subalgebra is a representation with the highest weight $(\mu_0(u),\mu_1(u))$. Its irreducible quotient is finite-dimensional and so, by Proposition 7.6 we have $\mu_0(u)\to\mu_1(u)$ or $(2u/2u+1)\mu_0(u)\to\mu_1(u)$ depending on whether condition (7.33) or (7.34) is satisfied; see the proof of Theorem 3.8.

Conversely, let relation (7.46) hold. Then for $i=1,\ldots,n$ we have

$$\frac{\mu_{i-1}(u)}{\mu_i(u)}=\frac{P_i(u+1)}{P_i(u)} \tag{7.48}$$

for monic polynomials $P_i(u)$. Let

$$P_i(u)=(u+\delta_1^{(i)})\cdots(u+\delta_{s_i}^{(i)}),\quad i=1,\ldots,n. \tag{7.49}$$

Consider the irreducible highest weight representation $L(\lambda(u))$ with $\lambda(u)=(\lambda_{-n}(u),\ldots,\lambda_n(u))$ of the Yangian $\mathrm{Y}(2n+1)$ where the $\lambda_i(u)$ are defined by (5.42) for $i=1,\ldots,n$ and by (5.43) for $i=0,\ldots,n$. Then $L(\lambda(u))$ is finite-dimensional by Theorem 3.12 and we conclude by repeating the corresponding argument of the proof of Theorem 5.8.

Finally, let (7.47) hold. Then there exist monic polynomials (7.49) such that (7.48) holds for $i=2,\ldots,n$ and

$$\frac{\mu_0(u)}{\mu_1(u)}=\frac{P_1(u+1)}{P_1(u)}\,\frac{2u+1}{2u}. \tag{7.50}$$

Let $V(\mu_0)$ denote the irreducible representation of the Lie algebra $\mathrm{o}(2n+1)$ with the highest weight $\mu_0=(-1/2,\ldots,-1/2)$. It is finite-dimensional; see (4.6) and (4.9). Extend $V(\mu_0)$ to a representation of $\mathrm{Y}^+(2n+1)$ by using (2.23) and consider the tensor product $L(\lambda(u))\otimes V(\mu_0)$, where $L(\lambda(u))$ is the defined above representation of $\mathrm{Y}(2n+1)$. The tensor product of the highest weight vectors of $L(\lambda(u))$ and $V(\mu_0)$ generates a $\mathrm{Y}^+(2n+1)$-submodule with the highest weight $\mu'(u)=(\mu_0'(u),\ldots,\mu_n'(u))$ where $\mu_i'(u)=\lambda_i(u)\lambda_{-i}(-u)(1+1/2\mu^{-1})^{-1}$ for $i=1,\ldots,n$ and $\mu_0'(u)=\lambda_0(u)\lambda_0(-u)$; see (2.31) and (4.11). Therefore the representation $V(\mu'(u))$ of $\mathrm{Y}^+(2n+1)$ is finite-dimensional. Moreover, the $\mu_i'(u)$ satisfy both (7.48) for $i=2,\ldots,n$, and (7.50). It remains to repeat the corresponding argument of the proof of Theorem 6.9. □

Theorem 7.7 implies the following parametrization of representations of the special twisted Yangian $\mathrm{SY}^+(2n+1)$ (cf. Corollaries 5.9 and 6.10).

Corollary 7.8: There is a one-to-one correspondence between finite-dimensional irreducible representations of the special twisted Yangian $\mathrm{SY}^+(2n+1)$ *and the families* $\{P_1(u),\ldots,P_n(u),\epsilon\}$, *where the* $P_i(u)$ *are monic polynomials in u and the parameter* ϵ *takes values in* $\{1,2\}$. *Every such representation is isomorphic to a subquotient of a representation of the form* $L(\lambda(u))$ *or* $L(\lambda(u))\otimes V(\mu_0)$. □

Remark 7.9: One can use Propositions 7.3 and 7.4 to get a branching rule for the restriction of a ''generic'' finite-dimensional irreducible representation V of $\mathrm{Y}^+(3)$ to the subalgebra $\mathrm{Y}^+(2)$ and thus to construct an analog of Gelfand-Tsetlin basis in V; cf. Refs. 17 and 18. □

Invariant tensors and Casimir operators for simple compact Lie groups

Arthur J. Mountain[a)]
Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Silver Street, Cambridge CB3 9EW, United Kingdom

(Received 17 April 1998; accepted for publication 8 June 1998)

The Casimir operators of a Lie algebra are in one-to-one correspondence with the symmetric invariant tensors of the algebra. There is an infinite family of Casimir operators whose members are expressible in terms of a number of primitive Casimirs equal to the rank of the underlying group. A systematic derivation is presented of a complete set of identities expressing nonprimitive symmetric tensors in terms of primitive tensors. Several examples are given including an application to an exceptional Lie algebra. © *1998 American Institute of Physics.*

I. INTRODUCTION

The Casimir operators for a simple Lie algebra are constructed from symmetric tensors invariant under the adjoint action of the group. Given a simple compact Lie group of rank l, it is known that there are l such primitive symmetric invariant tensors of order m_i, $i=1\cdots l$. The orders m_i are in fact also known because of the correspondence of the primitive symmetric invariant tensors with cocycles of order $(2m_i-1)$ which are representatives of the de Rham cohomology classes of G. However, most methods of constructing symmetric invariant tensors give rise naturally to an infinite family of them, of which only the finite number l can be primitive.

In this paper, we consider the set of invariant tensors arising from symmetrized traces of products of Lie algebra basis elements. These correspond to Casimir operators and arise naturally in many physical theories. It is often useful to be able to express this (infinite) family of tensors in terms of the l primitive tensors (see above). We present a method which systematically generates a complete set of identities expressing nonprimitive symmetric invariant tensors of this form in terms of primitive tensors. We illustrate our methods for the classical series of Lie algebras and perform explicit calculations for the examples A_2, B_2, and G_2.

A. Notation and conventions

In this paper, we will follow the ''physical'' convention for Lie groups and use Hermitian generators $\{X_i\}$ and the normalization $\mathrm{Tr}(X_iX_j)=2\delta_{ij}$. When the generators are assumed to be in *matrix* form, we take them to be in the defining representation of the algebra. We will assume there is no distinction between upper and lower indices, their position being dictated by notational convenience. We will take $\epsilon_{i_1i_2\cdots i_n}$ to be the standard totally antisymmetric tensor, with $\epsilon_{123\cdots n}=1$. We will define from this the unit-weight symbol

$$\epsilon^{j_1j_2\cdots j_n}_{i_1i_2\cdots i_n}=\frac{1}{n!}\epsilon_{i_1i_2\cdots i_n}\epsilon^{j_1j_2\cdots j_n}=\frac{1}{n!}\sum_{\sigma\in S_n}(-1)^{\pi(\sigma)}\delta^{j_{\sigma(1)}}_{i_1}\cdots\delta^{j_{\sigma(n)}}_{i_n}, \tag{1.1}$$

where $\pi(\sigma)$ is the parity of the permutation σ.

II. INVARIANT SYMMETRIC TENSORS AND CASIMIRS

Let $\mathcal{G}$ be a simple algebra of rank l with basis $\{X_i\}$, $[X_i,X_j]=f^k_{ij}X_k$, $i=1\cdots\dim\mathcal{G}$, and let G be its (compact) associated Lie group. Let $\{\omega^j\}$ be the dual basis in $\mathcal{G}^*$, $\omega^j(X_i)=\delta^j_i$, and consider a G-invariant symmetric tensor h of order m

a)Electronic mail: A.J.Mountain@damtp.cam.ac.uk

 © 1998 American Institute of Physics

$$h = h_{i_1 \cdots i_m} \omega^{i_1} \otimes \cdots \otimes \omega^{i_m}. \tag{2.1}$$

The G-invariance (ad-invariance) of h means that

$$\sum_{s=1}^{m} f^{\rho}_{\nu i_s} h_{i_1 \cdots \hat{i}_s \rho i_{s+1} \cdots i_m} = 0. \tag{2.2}$$

This is the case for the symmetric tensors $k^{(m)}$ given by the coordinates

$$k^{(m)}_{i_1 \cdots i_m} = \mathrm{sTr}(X_{i_1} \cdots X_{i_m}) \equiv \mathrm{Tr}(X_{(i_1} \cdots X_{im)}). \tag{2.3}$$

where sTr is the unit-weight symmetric trace,

$$\mathrm{sTr}(X_{i_1} \cdots X_{i_m}) = \frac{1}{m!} \Sigma_{\sigma \in S_m} \mathrm{Tr}(X_{i_{\sigma(1)}} \cdots X_{i_{\sigma(m)}}).$$

Indices inside round brackets $(i_1, \ldots, i_m)$ will also be understood as symmetrized with unit weight. In fact,[1] a complete set of l primitive (see below) invariant tensors may be constructed in this way by selecting suitable representations.

Let G be compact so that the Killing tensor may be taken as the unit matrix and let $h_{i_1 \cdots i_m}$ be an arbitrary symmetric invariant tensor. Then the order m element in the enveloping algebra $\mathcal{U}(\mathcal{G})$ defined by

$$\mathcal{C}^{(m)} = h^{i_1 \cdots i_m} X_{i_1} \cdots X_{i_m}, \tag{2.4}$$

commutes with all elements of $\mathcal{G}$. This is so because the commutator $[X_\rho, \mathcal{C}^{(m)}]$ may be written as

$$[X_\rho, \mathcal{C}^{(m)}] = \sum_{s=1}^{m} f^{i_s}_{\rho \nu} h^{i_1 \cdots \hat{i}_s \nu \cdots i_m} X_{i_1} \cdots X_{i_m} = 0, \tag{2.5}$$

which is indeed zero as a result of the invariance condition (2.2). In fact, the only conditions for the m-tensor h to generate a Casimir operator $\mathcal{C}^{(m)}$ of $\mathcal{G}$ of order m are its symmetry (nonsymmetric indices would allow us to reduce the order m of $\mathcal{C}^{(m)}$ by replacing certain products of generators by commutators) and its invariance [Eq. (2.5)]; h does not need to be obtained from a symmetric trace (2.3). Thus for any invariant symmetric tensor h of order m, $\mathcal{C}^{(m)} = h^{i_1 \cdots i_m} X_{i_1} \cdots X_{i_m}$ is a Casimir of $\mathcal{G}$ of the same order m.

It is well known[1–8] that a simple algebra of rank l has l independent (primitive) Casimir–Racah operators of order $m_1, \cdots, m_l$, the first of them given by the familiar quadratic Casimir[9] operator $k_{ij} X^i X^j$ obtained from the Killing tensor $(m_1 = 2)$. Thus there must be (Cayley–Hamilton) relations among the invariant tensors obtained from (2.3) for $m \neq m_l$ or otherwise one would obtain an arbitrary number of primitive Casimirs. We shall demonstrate this explicitly for several examples.

III. RELATIONS AMONG SYMMETRIC TENSORS

The results in this section involve an important result that, for a matrix A, we have the relationship

$$\det A = \exp(\mathrm{Tr} \log A). \tag{3.1}$$

This is clearly true for diagonal A and can be seen to be true generally by conjugation of A. We apply this to the case $A = \mathbf{1} + \alpha F$, with $\mathbf{1}$ the identity matrix and α an arbitrary parameter. We can treat the right hand side of (3.1) as a power series in α, giving

$$\det(\mathbf{1}+\alpha F)=1-\frac{\alpha^2}{2}\mathrm{Tr}\,F^2+\frac{\alpha^3}{3}\mathrm{Tr}\,F^3+\alpha^4\left[-\frac{1}{4}\mathrm{Tr}\,F^4+\frac{1}{8}(\mathrm{Tr}\,F^2)^2\right]$$
$$+\alpha^5\left[\frac{1}{5}\mathrm{Tr}\,F^5-\frac{1}{6}\mathrm{Tr}\,F^2\mathrm{Tr}\,F^3\right]$$
$$+\alpha^6\left[-\frac{1}{6}\mathrm{Tr}\,F^6+\frac{1}{18}(\mathrm{Tr}\,F^3)^2+\frac{1}{8}\mathrm{Tr}\,F^2\mathrm{Tr}\,F^4-\frac{1}{48}(\mathrm{Tr}\,F^2)^3\right]$$
$$+\alpha^7\left[\frac{1}{7}\mathrm{Tr}\,F^7-\frac{1}{10}\mathrm{Tr}\,F^2\mathrm{Tr}\,F^5-\frac{1}{12}\mathrm{Tr}\,F^3\mathrm{Tr}\,F^4+\frac{1}{24}(\mathrm{Tr}\,F^2)^2\mathrm{Tr}\,F^3\right]$$
$$+\alpha^8\left[-\frac{1}{8}\mathrm{Tr}\,F^8+\frac{1}{12}\mathrm{Tr}\,F^2\mathrm{Tr}\,F^6+\frac{1}{15}\mathrm{Tr}\,F^3\mathrm{Tr}\,F^5+\frac{1}{32}(\mathrm{Tr}\,F^4)^2\right.$$
$$\left.-\frac{1}{32}\mathrm{Tr}\,F^4(\mathrm{Tr}\,F^2)^2-\frac{1}{36}(\mathrm{Tr}\,F^3)^2\mathrm{Tr}\,F^2+\frac{1}{16.4!}(\mathrm{Tr}\,F^2)^4\right]+\cdots. \tag{3.2}$$

In the above, $\mathrm{Tr}\,F^n$ is defined as $F_{i_1i_2}F_{i_2i_3}\cdots F_{i_ni_1}$. All the terms to $\mathcal{O}(\alpha^8)$ are given as these are the terms we shall use below. It is easy to calculate the terms in higher powers of α. We will now show how to express nonprimitive symmetric invariant tensors in terms of primitive tensors.

A. The algebras A_l

We consider a matrix representation of SU(n) with matrix generators $\{X_i\}$. For our purposes we will always work with the fundamental representation so that X_i are $n\times n$ matrices. The rank of the group is $l=n-1$ and its Lie algebra is $A_l=\mathrm{su}(l+1)$. A basis of the symmetric invariant tensors of A_l is given by the order m symmetric traces $k^{(m)}, m=2,3,\ldots$ from Eq. (2.3). The algebra A_l has l primitive symmetric invariant tensors. A basis of these is given by $k^{(m)}$, $m=2\cdots n$.

We now define the matrix F [see Eq. (3.2)] to be a linear combination of the X_i, introducing a vector $\mathbf{y}$, as $(F)_{ab}=y^i(X_i)_{ab}$. As $\{X_i\}$ are $n\times n$ matrices, no terms of $\mathcal{O}(\alpha^m)$ can appear on the right hand side of (3.2) for $m>n$. Thus these terms must vanish identically, giving us one equation at each order in α. This gives us one equation for each of the nonprimitive tensors of the form (2.3) in terms of primitive tensors.

B. The algebras B_l and C_l

The fundamental matrix representations of the algebras $B_l=\mathrm{so}(2l+1)$ and $C_l=\mathrm{sp}(2l)$ are in terms of $(2l+1)\times(2l+1)$ and $2l\times 2l$ matrices, respectively. In their defining representations these groups preserve the euclidean or symplectic metric η, respectively, and thus the generators X_i of these algebras satisfy

$$X_i\eta=-\eta X_i^t, \tag{3.3}$$

where $i=1,\ldots,l(2l+1)$. The symmetrized products of an *odd* number of generators of the orthogonal and symplectic groups also satisfies (3.3); hence, they are a member of their respective algebras. In particular, as the generators of both B_l and C_l are traceless, we find that the odd-order tensors $k^{(2m+1)}$ [see Eq. (2.3)], arising from symmetrized traces, vanish identically. For both B_l and C_l, we have the property that a basis for the symmetric invariant tensors is given by $k^{(m)}$ for $m=2,4,6,\ldots$. Thus for these examples, all odd powers of α in the expansion (3.2) vanish identically. A basis for the primitive symmetric invariant tensors is given by $k^{(m)}$, $m=2,4,6,\ldots 2l$. As above, we can write $F_{ab}=y^i(X_i)_{ab}$, where $\{X_i\}$ is a basis for the required Lie algebra in the fundamental representation. Substituting this into (3.2), we see that all terms of $\mathcal{O}(\alpha^m)$ must vanish for $m>2l$. This gives precisely one equation for each of the nonprimitive tensors of the form (2.3) in terms of primitive tensors.

C. The algebras D_l

The algebra $D_l = \mathrm{so}(2l)$ is the algebra of antisymmetric $(2l)\times(2l)$ matrices. The odd-order tensors $k^{(2m+1)}$ vanish identically using an identical argument to that used above for B_l. There are l primitive symmetric invariant tensors of which only $(l-1)$ can be expressed in the form (2.3). These are $k^{(m)}$, $m=2,4,6,\ldots,2(l-1)$. The final primitive tensor is the Pfaffian, given by

$$Pf_{i_1 i_2 \cdots i_l} = \frac{1}{2^l l!}\epsilon^{a_1 a_2 \cdots a_{2l}}(X_{i_1})_{a_1 a_2}(X_{i_2})_{a_3 a_4}\cdots(X_{i_l})_{a_{(2l-1)}a_{2l}}. \tag{3.4}$$

As before, we introduce a vector $\mathbf{y}$ and write $F_{ab} = y_i (X^i)_{ab}$. We rewrite the expression (3.2) in the form

$$\begin{aligned}\det(\mathbf{1}+\alpha F) = 1 &+ \alpha^2 \epsilon^{b_1 b_2}_{a_1 a_2} F^{a_1}{}_{b_1} F^{a_2}{}_{b_2} + \alpha^4 \epsilon^{b_1 b_2 b_3 b_4}_{a_1 a_2 a_3 a_4} F^{a_1}{}_{b_1} F^{a_2}{}_{b_2} F^{a_3}{}_{b_3} F^{a_4}{}_{b_4} + \cdots \\ &+ \alpha^{2n} \epsilon^{b_1 b_2 \cdots b_{2n}}_{a_1 a_2 \cdots a_{2n}} F^{a_1}{}_{b_1} F^{a_2}{}_{b_2} \ldots F^{a_{2n}}{}_{b_{2n}} + \cdots .\end{aligned} \tag{3.5}$$

The terms of $\mathcal{O}(\alpha^{2m})$ for $m>l$ express the nonprimitive symmetric tensors $k^{(2m)}$ [see Eq. (2.3)] in terms of primitive tensors. For the $\mathcal{O}(\alpha^{2l})$ terms, we must use the identity

$$\begin{aligned}\epsilon^{b_1 b_2 \cdots b_{2l}}_{a_1 a_2 \cdots a_{2l}} F^{a_1}{}_{b_1} F^{a_2}{}_{b_2} \cdots F^{a_{2l}}{}_{b_{2l}} &= \left(\frac{1}{2^l l!} \epsilon_{a_1 a_2 \cdots a_{2l}} F_{a_1 a_2} F_{a_3 a_4} \cdots F_{a_{(2l-1)} a_{2l}} \right)^2 \\ &= Pf_{(i_1 \cdots i_l} Pf_{i_{l+1} \cdots i_{2l})} y^{i_1} \cdots y^{i_{2l}}.\end{aligned} \tag{3.6}$$

This expresses the nonprimitive tensor $k^{(2l)}$ in terms of the Pfaffian Pf and the $(l-1)$ tensors $k^{(2m)}$, $m<l$, which together are the l primitive symmetric tensors of D_l.

IV. EXAMPLES

Below are given three explicit examples of construction of nonprimitive tensors for simple Lie algebras in terms of primitive tensors. Connections are also made to the geometry of the associated Lie groups. In particular, simple compact Lie groups can be expressed as products of spheres of odd dimension, as far as the cohomology is concerned. Decomposing a Lie group into such a product gives the de Rham cohomology as the Betti numbers[10] for a sphere S^n are known to be

$$b^{(0)}=1,\ b^{(n)}=1,\ b^{(k)}=0 \quad \text{otherwise.} \tag{4.1}$$

We can also associate with each symmetric invariant tensor k of order m an antisymmetric invariant tensor of order $(2m-1)$ according to

$$\Omega_{i_1 \cdots i_{2m-2}\sigma} = f^{j_1}_{[i_1 i_2} \cdots f^{j_{m-1}}_{i_{2m-3} i_{2m-2}} k_{\sigma] j_1 \cdots j_{m-1}}. \tag{4.2}$$

If k is primitive, this gives a $(2m-1)$-form on G representing a Lie algebra cocycle of order $(2m-1)$. If k is nonprimitive, the expression is identically zero.[11]

A. The algebras A_l

The group $\mathrm{SU}(l+1)$ has algebra $\mathrm{su}(l+1)=A_l$. The cohomology of the group manifold is the cohomology of l spheres as $\mathrm{SU}(l+1)\to S^{2l+1}\times S^{2l-1}\times\cdots\times S^3$. Thus there are l nontrivial cocycles and l corresponding primitive symmetric invariant tensors as in (4.2). There is a basis for the symmetric invariant tensors of A_l given by Sudbery,[12] consisting of one symmetric tensor $d^{(k)}$ at each order $k=2,3,\ldots$. Given a normalized basis $\{\lambda_i\}$ for $\mathrm{su}(l+1)$, we have the multiplication law

$$\lambda_i \lambda_j = \frac{2}{l+1}\delta_{ij} + (d_{ijk} + i f_{ijk})\lambda_k. \tag{4.3}$$

The tensors f and d are, respectively, the totally antisymmetric and symmetric structure constants. The two lowest-order symmetric invariant tensors are δ_{ij} and d_{ijk}. In terms of these, the Sudbery basis for symmetric tensors is

$$\begin{aligned} d^{(4)}_{i_1i_2i_3i_4} &= d_{(i_1i_2}{}^x d_{i_3i_4)x}, \\ d^{(5)}_{i_1i_2i_3i_4i_5} &= d_{(i_1i_2}{}^x d^x{}_{i_3}{}^y d_{i_4i_5)y}, \\ d^{(6)}_{i_1i_2i_3i_4i_5i_6} &= d_{(i_1i_2}{}^x d^x{}_{i_3}{}^y d^y{}_{i_4}{}^z d_{i_5i_6)z}. \\ &\vdots \end{aligned} \tag{4.4}$$

We can choose a basis $d^{(k)}$, $k=2,3,\ldots,l+1$ of the primitive symmetric invariant tensors of A_l. These will give rise to representatives of the l primitive cocycles of A_l via (4.2).

B. The algebra A_2

The fundamental representation of the algebra $A_2=\mathrm{su}(3)$ is in terms of eight (3×3) Hermitian matrix generators $\{\lambda_i\}$. The rank of A_2 is two so we have two primitive invariant symmetric tensors; these are given by

$$\tfrac{1}{2}\,\mathrm{Tr}(\lambda_i\lambda_j)=\delta_{ij}, \quad \tfrac{1}{2}\,\mathrm{sTr}(\lambda_i\lambda_j\lambda_k)=d_{ijk}. \tag{4.5}$$

As far as the cohomology is concerned, the group manifold SU(3) can be decomposed into $S^5\times S^3$ and there are three- and five-cocycles associated with δ_{ij} and d_{ijk}, respectively, [see (4.2)]. Defining an arbitrary eight-vector $\mathbf{y}$, writing $(F)_{ab}=y^i(X_i)_{ab}$ and substituting this into (3.2) gives expressions for $d^{(m)}$, $m>3$ in terms of the tensors (4.5). Defining $k_{i_1\cdots i_m}=\mathrm{sTr}(X_{i_1}\cdots X_{i_m})$ as in (2.3), the first few of these are

$$k_{i_1i_2i_3i_4}=2\,\delta_{(i_1i_2}\delta_{i_3i_4)}, \tag{4.6}$$

$$k_{i_1i_2i_3i_4i_5}=\tfrac{10}{3}\,\delta_{(i_1i_2}d_{i_3i_4i_5)}, \tag{4.7}$$

$$k_{i_1i_2i_3i_4i_5i_6}=\tfrac{4}{3}\,d_{(i_1i_2i_3}d_{i_4i_5i_6)}+2\,\delta_{(i_1i_2}\delta_{i_3i_4}\delta_{i_5i_6)}. \tag{4.8}$$

The first three nonprimitive terms in the Sudbery basis for the symmetric invariant tensors of A_2 can then be computed as

$$\begin{aligned} d^{(4)}_{i_1i_2i_3i_4} &= d_{(i_1i_2}{}^x d_{i_3i_4)x}=\tfrac{1}{3}\,\delta_{(i_1i_2}\delta_{i_3)i_4}, \\ d^{(5)}_{i_1i_2i_3i_4i_5} &= d_{(i_1i_2}{}^x d^x{}_{i_3}{}^y d_{i_4i_5)y}=\tfrac{1}{3}\,\delta_{(i_1i_2}d_{i_3i_4i_5)}, \end{aligned} \tag{4.9}$$

$$d^{(6)}_{i_1i_2i_3i_4i_5i_6}=d_{(i_1i_2}{}^x d^x{}_{i_3}{}^y d^y{}_{i_4}{}^z d_{i_5i_6)z}=\tfrac{2}{15}\,d_{(i_1i_2i_3}d_{i_4i_5i_6)}+\tfrac{1}{15}\,\delta_{(i_1i_2}\delta_{i_3i_4}\delta_{i_5i_6)}. \tag{4.10}$$

C. The algebras B_n

The fundamental representation of the algebra $B_n=\mathrm{so}(2n+1)$ is in terms of $(2n+1)\times(2n+1)$ antisymmetric matrices. We define a basis $\{X_i\}$, normalized as $\mathrm{Tr}(X_iX_j)=2\,\delta_{ij}$. There will be n primitive symmetric invariant tensors (equal to the rank of the group). The first two of these are $\delta_{ij}=\frac{1}{2}\mathrm{Tr}(X_iX_j)$ and the order four totally symmetric tensor[13] given by

$$\mathrm{Tr}(X_{(i}X_jX_{k)})=d^{(4)}_{ijkl}X_l. \tag{4.11}$$

We notice that the tensors $k^{(m)}$ [given by (2.3)] vanish for m odd and we have a basis for the symmetric tensors of B_n in analogy with Sudbery's basis for A_n, i.e.,

$$d^{(6)}_{i_1i_2i_3i_4i_5i_6} = d_{(i_1i_2i_3}{}^x d_{i_4i_5i_6)x},$$

$$d^{(8)}_{i_1i_2i_3i_4i_5i_6i_7i_8} = d_{(i_1i_2i_3}{}^x d^x{}_{i_4i_5}{}^y d^y{}_{i_6i_7i_8)}.$$

$$\vdots \tag{4.12}$$

The algebra B_n will have n primitive symmetric tensors of orders $2,4,\ldots,2n$, giving rise to cocycles of orders $3,7,\ldots,(4n-1)$ via (4.2).

D. The algebra B_2

The fundamental representation of the algebra $B_2=\mathrm{so}(5)$ is in terms of (5×5) antisymmetric matrices with a basis $\{X_i\}$, normalized as above. As far as the cohomology is concerned, the group manifold decomposes as $\mathrm{SO}(5)\sim S^3\times S^7$, giving nontrivial three- and seven-cocycles. The three-cocycle is associated with the symmetric tensor $\delta_{ij}=\frac{1}{2}\mathrm{Tr}(X_iX_j)$ and the seven-cocycle with the order four symmetric tensor $d^{(4)}_{ijkl}=\frac{1}{2}\mathrm{Tr}(X_{(i}X_jX_{k)}X_l)$ according to (4.2). As above, we define an arbitrary vector $\mathbf{y}$, write $(F)_{ab}=y^i(X_i)_{ab}$ and substitute this into (3.2). The antisymmetry of the algebra elements means that all traces of odd powers of F vanish identically, giving the result at $\mathcal{O}(\alpha^6)$

$$\mathrm{Tr}\ F^6=\tfrac{3}{4}\mathrm{Tr}\ F^2\mathrm{Tr}\ F^4-\tfrac{1}{8}(\mathrm{Tr}\ F^2)^3, \tag{4.13}$$

or equivalently

$$k^{(6)}_{i_1i_2i_3i_4i_5i_6}=\tfrac{3}{2}\,\delta_{(i_1i_2}k^{(4)}_{i_3i_4i_5i_6)}-\delta_{(i_1i_2}\delta_{i_3i_4}\delta_{i_5i_6)}. \tag{4.14}$$

Expressions for the higher-order symmetric tensors can be obtained easily.

E. The algebra G_2

The algebra G_2 can be embedded into so(7); the generators of $SO(7)$ decompose into representations $\mathbf{21}\rightarrow\mathbf{7}\oplus\mathbf{14}$ under the action of G_2. We will work with the seven-dimensional representation of G_2 embedded into the fundamental representation of so(7). This has generators $\{X_i\}$, normalized as $\mathrm{Tr}(X_iX_j)=2\,\delta_{ij}$. As for the orthogonal groups, the terms odd in F in the expansion (3.2) will vanish identically. It is known[13] that there are two primitive symmetric invariant tensors of G_2, of order two and six, given by the tensors $k^{(2)}$ and $k^{(6)}$ defined in (2.3). We note the result from[14]

$$\mathrm{sTr}(X_iX_jX_kX_l)=\tfrac{1}{4}\,\mathrm{Tr}(X_{(i}X_j)\mathrm{Tr}(X_kX_{l)}). \tag{4.15}$$

Using this and the methods described above, we can now write any symmetric invariant tensor of G_2 in terms of the two primitive symmetric tensors

$$k_{i_1i_2}=\mathrm{Tr}(X_{i_1}X_{i_2}),\quad k_{i_1i_2i_3i_4i_5i_6}=\mathrm{sTr}(X_{i_1}X_{i_2}X_{i_3}X_{i_4}X_{i_5}X_{i_6}). \tag{4.16}$$

V. CONCLUSION

A simple Lie group has a number of primitive symmetric invariant tensors equal to the rank of the group. Other symmetric invariant tensors must be expressible in terms of these. This is equivalent to expressing nonprimitive Casimirs in terms of primitive Casimirs. We have presented a systematic method for doing this which has been illustrated with three examples including one example of an exceptional Lie algebra.

Twisting cocycles in fundamental representation and triangular bi-crossproduct Hopf algebras

A. I. Mudrov[a)]
Department of Theoretical Physics, Institute of Physics, St. Petersburg State University, Ulyanovskaya 1, Stary Petergof, St. Petersburg 198904, Russia

(Received 6 April 1998; accepted for publication 18 May 1998)

We find the general solution to the twisting equation in the tensor bialgebra $T(\mathbf{R})$ of an associative unital ring $\mathbf{R}$ viewed as that of fundamental representation for a universal enveloping Lie algebra and its quantum deformations. We suggest a procedure of constructing twisting cocycles belonging to a given quasitriangular sub-bialgebra $\mathscr{H}\subset T(\mathbf{R})$. This algorithm generalizes Reshetikhin's approach, which involves cocycles fulfilling the Yang–Baxter equation. Within this framework we study a class of quantized inhomogeneous Lie algebras related to associative rings in a certain way, for which we build twisting cocycles and universal R-matrices. Our approach is a generalization of the methods developed for the case of commutative rings in our recent work including such well-known examples as Jordanian quantization of the Borel subalgebra of sl(2) and the null-plane quantized Poincaré algebra by Ballesteros *et al.* We reveal the role of special group 1-cocycles in this process and establish the bi-crossproduct structure of the examples studied. © *1998 American Institute of Physics.* [S0022-2488(98)01410-8]

I. INTRODUCTION

Quantum deformations of Lie groups and algebras are at present a subject of intensive studies from the viewpoints of collecting facts and crystallizing mathematical concepts as well as of searching for new physical applications. Among the established notions of the quantum group theory one should mention Drinfeld's twisting[1,2] and Majid's bi-crossproduct and double crossproduct constructions.[3] Twisting, realizing a specific equivalence between two Hopf algebras, plays an important role for the geometrical and physical reasons because it controls deformation not only of the symmetry algebra of a manifold but of its whole geometry coherently. Therefore a classification of quantum deformations of, say, a universal enveloping Lie algebra ought to provide the answer about twist-equivalence between its different types. Majid's double crossproduct construction has a close connection with twisting and the quantum double in particular.[4–6] As for the bi-crossproduct, its relation to quasitriangularity and twisting is not so well understood, despite numerous examples including quasitriangular Hopf algebras. The most significant step in that direction was made in Ref. 7, where the double of the algebra $\mathbb{C}(\mathbf{M})\bowtie\mathbb{C}\mathbf{G}$, built on a matched pair of groups $\mathbf{M}$ and $\mathbf{G}$, was shown to be a bi-crossproduct itself. As examples of bi-crossproducts we would like to mention the κ deformation of the Poincaré algebra,[8,9] the canonical example of the Jordanian quantization of the Borel subalgebra of sl(2),[3] and the null-plane quantized Poincaré algebra.[10,11] The last two are the results of twisting of classical universal enveloping algebras and are therefore triangular. As we have shown in Ref. 12, they are associated with commutative rings (throughout the paper by ring we mean a finite-dimensional algebra over a field $\mathbf{K}$ so as to reserve the word ''algebra'' for Hopf algebras), one dimensional in the first case and that spanned by matrices

$$\alpha_1=\begin{pmatrix}0&0&1\\0&0&0\\0&0&0\end{pmatrix},\quad \alpha_2=\begin{pmatrix}0&0&0\\0&0&1\\0&0&0\end{pmatrix},\quad \alpha_3=\begin{pmatrix}1&0&0\\0&1&0\\0&0&1\end{pmatrix}$$

in the second. Along this line we have found a generalization of the examples mentioned for an arbitrary commutative ring. The algebras studied in Ref. 12 were twisted classical universal

enveloping algebras and also bi-crossproduct Hopf algebras, although not considered in that context. In the present paper we formulate a generalization of our approach to an arbitrary associative ring providing a new class of quasitriangular bi-crossproduct Hopf algebras. The Hopf operations are explicitly written out in terms of generators and the twisting 2-cocycles and universal R-matrices are presented. The class under investigation arises as an example of twisting which may be regarded as a generalized Reshetikhin's procedure[13–15] involving a solution to the Yang–Baxter equation as a twisting cocycle. We come to this generalization analyzing solutions to the twisting equation in the tensor bialgebra $T(\mathbf{R})$ of an associative unital ring $\mathbf{R}$, considered as that of the fundamental representation of a given Hopf algebra $\mathscr{H}$ (we call a homomorphism $\mathscr{H} \to \mathbf{R}$ fundamental if its lifting to whole $T(\mathbf{R})$, which always exists, is nondegenerate).

The paper is organized as follows. Section II is auxiliary and contains a general description of the tensor bialgebra $T(\mathbf{R})$ structure, its sub-bialgebras and homomorphisms. This part may be considered as the ''noncoordinate'' formulation of the Faddeev–Reshetikhin–Takhtajan (FRT) method[16] suitable for an arbitrary associative unital ring. Since rings with identities have exact matrix realizations, e.g., by the regular representations on themselves, such a reformulation does not supply us with particularly new information compared with the traditional matrix approach. Nevertheless, it provides certain technical convenience, so we find it possible to present this formulation here. Section III is devoted to solving the twisting equation in $T(\mathbf{R})$. Therein we develop a procedure of constructing ''universal'' cocycles starting from elements of $\mathbf{R}^{\otimes 2}$ obeying certain conditions. This algorithm is illustrated in Sec. IV on inhomogeneous Lie algebras related in a sense to associative rings. We build the deformed coproduct, quantum commutation relations, find twisting cocycles and universal R-matrices. In Sec. V the connection between the investigated algebras and the bi-crossproduct construction is established.

II. BIALGEBRA $T(\mathbf{R})$

To perform algebraic manipulations it is convenient to formulate the algorithm by Faddeev, Reshetikhin, and Takhtajan[16] in the part of constructing quantum algebra $\mathrm{Fun}_q(\mathbf{R})$ of functions on matrix rings for an arbitrary associative ring $\mathbf{R}$. We need some information concerning its structure and the structure of homomorphisms from a Hopf algebra or, more generally, bialgebra $\mathscr{H}$ into $\mathrm{Fun}_q(\mathbf{R})$. Let μ be the multiplication in $\mathbf{R}$. We choose a basis $(x^\alpha) \subset \mathbf{R}$ such that x^0 is the identity of $\mathbf{R}$. The dual basis in $\mathbf{R}^*$ will be marked with subscripts. Denote $F(\mathbf{R})$ the algebra over a field $\mathbf{K}$ freely generated by 1 and $(x_\alpha) \in \mathbf{R}^*$. Introduce the coproduct and the counit defining them on the generators as

$$\Delta(x_\alpha) = \mu_\alpha^{\rho\sigma} x_\rho \otimes x_\sigma, \quad \Delta(1) = 1 \otimes 1,$$

$$\epsilon(1) = 1, \quad \epsilon(x_0) = 1, \quad \epsilon(x_i) = 0, \quad i \neq 0$$

and extending over whole $F(\mathbf{R})$ homomorphically. The dual bialgebra $T(\mathbf{R}) = F^*(\mathbf{R})$ appears to be a direct sum of its ideals $\Sigma_{n=0}^{\infty} \mathbf{R}^{\otimes n}$, where $\mathbf{R}^0$ coincides the field $\mathbf{K}$ of scalars. The multiplication in $T(\mathbf{R})$ is characterized by the property $\mathbf{R}^{\otimes n} \mathbf{R}^{\otimes m} = 0$ for $m \neq n$. The identity of $T(\mathbf{R})$ is expanded as the sum $\Sigma_{n=0}^{\infty} e^n$ of idempotents, where e^0 is the unity of $\mathbf{K}$, and e^n with $n > 0$ are those of $\mathbf{R}^{\otimes n}$. Multiplying by e^n carries out the projection homomorphism

$$\pi^m : T(\mathbf{R}) \to \mathbf{R}^{\otimes m},$$

and for $n = 0$ this is just the bialgebra counit. The coproduct in $T(\mathbf{R})$ is determined by the product of its dual algebra $F(\mathbf{R})$ and on the basis elements is defined by the formula

$$\Delta(x^{i_1 \cdots i_n}) = e^0 \otimes x^{i_1 \cdots i_n} + \cdots + x^{i_1 \cdots i_k} \otimes x^{i_{k+1} \cdots i_n} + \cdots + x^{i_1 \cdots i_n} \otimes e^0, \quad x^{i_1 \cdots i_n} \in \mathbf{R}^{\otimes n}.$$

It follows from here that the composite mapping

$$\mathbf{R}^{\otimes (i+j)} \to T(\mathbf{R}) \xrightarrow{\Delta} T(\mathbf{R}) \otimes T(\mathbf{R}) \to \mathbf{R}^{\otimes i} \otimes \mathbf{R}^{\otimes j},$$

where the left arrow means the injection and the right one is the projection homomorphism, turns out to be a ring isomorphism. Quotient of $F(\mathbf{R})$ by the ideal J generated by quadratic relations of

the form $x_\alpha x_\beta = B^{\rho\sigma}_{\beta\alpha} x_\rho x_\sigma$ inherits the coproduct if and only if the subspace $\mathbf{S} \in \mathbf{R}^{\otimes 2}$ of functionals annihilating these relations is a subalgebra in $\mathbf{R}^{\otimes 2}$. In particular, such a subalgebra can be determined as the set of solutions to the equation

$$RzR^{-1} = \tau z, \quad z \in \mathbf{R}^{\otimes 2},$$

(τ permutes the factors in $\mathbf{R}^{\otimes 2}$), and then the relations in the dual algebra will look as

$$R_{\gamma\nu} \mu^{\gamma\rho}_\alpha \mu^{\nu\sigma}_\beta x_\rho x_\sigma = x_\sigma x_\rho \mu^{\rho\gamma}_\alpha \mu^{\sigma\nu}_\beta R_{\gamma\nu}.$$

The bialgebra $\mathscr{U}$ dual to the factor-bialgebra $\mathscr{A} \equiv F(\mathbf{R})/J$ is decomposed into the direct sum of its ideals $\Sigma_{n=0}^{\infty} \pi^n(\mathscr{U})$, where $\pi^1(\mathscr{U})$ is isomorphic to the ring $\mathbf{R}$ itself and each addend $\pi^n(\mathscr{U})$ at $n>1$ is a subring in $\mathbf{R}^{\otimes n}$ characterized by the condition $z_{\dots\alpha\beta\dots} = B^{\rho\sigma}_{\beta\alpha} z_{\dots\rho\sigma\dots}$ for $z \in \pi^n(\mathscr{U})$. Evidently, $\pi^n(\mathscr{U})$ is the intersection of all possible subalgebras $\mathbf{R}^{\otimes i} \otimes \pi^2(\mathscr{U}) \otimes \mathbf{R}^{\otimes j}$, such that $i + j + 2 = n$.

Let us describe the structure of a homomorphism ϕ of an arbitrary bialgebra $\mathscr{H}$ to $\mathscr{U}$. The composition of ϕ with the projector π^n is an algebraic mapping. We set $\rho \equiv \pi^1 \circ \phi$ and $\rho^n \equiv \pi^n \circ \phi$ and also introduce the notations

$$\Delta^1 \equiv id : \mathscr{H} \to \mathscr{H}, \quad \Delta^2 \equiv \Delta : \mathscr{H} \to \mathscr{H} \otimes \mathscr{H}, \quad \Delta^3 \equiv (\Delta \otimes id)\Delta : \mathscr{H} \to \mathscr{H} \otimes \mathscr{H} \otimes \mathscr{H}, \dots .$$

Let $h \in \mathscr{H}$ and $x_{\vec{\alpha}} \in \mathscr{A}$, where $\vec{\alpha}$ is a multi-index of length n. From the chain of equalities

$$\begin{aligned}
\langle \rho^n(h), x_{\vec{\alpha}} \rangle &= \langle \pi^n \circ \phi(h), x_{\vec{\alpha}} \rangle \\
&= \langle \phi(h), x_{\vec{\alpha}} \rangle \\
&= \langle \Delta^n \circ \phi(h), x_{\alpha_1} \otimes \cdots \otimes x_{\alpha_n} \rangle \\
&= \langle \phi^{\otimes n} \circ \Delta^n(h), x_{\alpha_1} \otimes \cdots \otimes x_{\alpha_n} \rangle \\
&= \langle (\pi^1 \circ \phi)^{\otimes n} \circ \Delta^n(h), x_{\alpha_1} \otimes \cdots \otimes x_{\alpha_n} \rangle = \langle \rho^{\otimes n} \circ \Delta^n(h), x_{\alpha_1} \otimes \cdots \otimes x_{\alpha_n} \rangle
\end{aligned}$$

we find that conditions

(1) $\rho^n = \rho^{\otimes n} \circ \Delta^n$

and

(2) $\rho^2(\mathscr{H}) \subset \mathbf{S} = \pi^2(\mathscr{U})$

are satisfied, and these completely specify ϕ. Namely, if an algebraic mapping $\rho : \mathscr{H} \to \mathbf{R}$ fulfills condition 2, there exists the unique bialgebra homomorphism of $\phi : \mathscr{H} \to \mathscr{U}$ such that $\pi^n \circ \phi = \rho^n$. Indeed, mapping $\rho^{\otimes n} \circ \Delta^n$ respects the algebraic structure for every n. Obviously, $\rho^{\otimes(n+2)} \circ \Delta^{n+2}(\mathscr{H}) \subset \mathbf{R}^{\otimes i} \otimes \mathbf{S} \otimes \mathbf{R}^{\otimes(n-i)}$ for every $i \leqslant n$, because of the coassociativity of the coproduct. We define ϕ via the formula $\phi(h) = e^0 \varepsilon(h) + \Sigma_{n>0} \rho^{\otimes n} \circ \Delta^n(h)$ and verify that it is also a coalgebra homomorphism (its algebraic property is evident). For two multi-indices $\vec{\alpha}$ and $\vec{\beta}$ of lengths m and n we have

$$\begin{aligned}
\langle (\phi \otimes \phi)\Delta(h), x_{\vec{\alpha}} \otimes x_{\vec{\beta}} \rangle &= \langle (\rho \otimes \cdots \otimes \rho)\Delta^{m+n}(h), x_{\alpha_1} \otimes \cdots \otimes x_{\alpha_m} \otimes x_{\beta_1} \otimes \cdots \otimes x_{\beta_n} \rangle \\
&= \langle \phi(h), x_{\vec{\alpha}} x_{\vec{\beta}} \rangle = \langle \Delta \circ \phi(h), x_{\vec{\alpha}} \otimes x_{\vec{\beta}} \rangle
\end{aligned}$$

that proves what is required. Conditions 1 and 2 are convenient practical criteria for checking out the homomorphic properties of mappings from $\mathscr{H}$ to $\mathscr{U}$.

III. TWISTING EQUATION IN $T(\mathbf{R})$

Algebras we are interested in, namely, universal enveloping Lie algebras and their quantum deformations appear to be embedded into $T(\mathbf{R})$ associated with their fundamental representation ring $\mathbf{R}$. Since twisting of a subalgebra induces that of the whole algebra,[15] the problem can be put

forward of describing all solutions to the twisting equations in $T(\mathbf{R})$ with the hope of further selecting among them those belonging to required subalgebras. We can point out the following advantages of such an approach. As far as the composition of two twistings is concerned, we avoid the inconvenience of dealing with a bialgebra different from the original after performing the first deformation. Another remarkable feature of such a description is a possibility to reduce the elaborate task of constructing the universal twistor to the much easier problem of solving a system of equations, rather nonlinear, in a finite-dimensional ring. Our study resulted in finding the general solution to the twisting equation in $T(\mathbf{R})$. We have managed to formulate conditions more general than those employed in Reshetikhin's approach[13,14] which ensure that the twisting cocycle built on its image in $\mathbf{R}^{\otimes 2}$ would lie in the required subalgebra.

Consider the twisting equation

$$(\Delta\otimes id)(\Phi)\Phi_{12}=(id\otimes\Delta)(\Phi)\Phi_{23}, \tag{1}$$

in the tensor cube of a bialgebra $\mathscr{H}$ where the subscripts determine the embeddings $\mathscr{H}^{\otimes 2}\to\mathscr{H}^{\otimes 3}$. An invertible solution to this equation can be normalized in such a way that

$$(\epsilon\otimes id)(\Phi)=(id\otimes\epsilon)(\Phi)=1. \tag{2}$$

Such a solution takes part in transforming bialgebra $\mathscr{H}$ into a new one with the same multiplication and the coproduct $\widetilde{\Delta}(h)=\Phi^{-1}\Delta(h)\Phi$, $h\in\mathscr{H}$. Other objects, e.g., the counit, antipode, universal $\mathscr{R}$-matrix, if any, are connected with the old ones via the well-known formulas which can be found in Ref. 2. We are going to prove the following assertion.

Theorem 1: For every set of invertible elements $\Phi^{1,k}\in\mathbf{R}\otimes\mathbf{R}^k$, there exists the unique solution $\Phi\in T(\mathbf{R})\otimes T(\mathbf{R})$ to the twisting equation, such that $(\pi^1\otimes\pi^k)(\Phi)=\Phi^{1,k}$.

Having applied the projector $\pi^m\otimes\pi^n\otimes\pi^k$ to the both sides of equality (1), we come to the equation in $\mathbf{R}^{\otimes(m+n+k)}$:

$$\Phi^{m+n,k}\Phi_b^{m,n}=\Phi^{m,n+k}\Phi_e^{n,k}, \tag{3}$$

where $\Phi^{m,n}$ is the image of the twisting cocycle $(\pi^m\otimes\pi^n)(\Phi)$. Letters b and e indicate that the elements $\Phi_b^{m,n}$ and $\Phi_e^{n,k}$ are embedded into $\mathbf{R}^{\otimes(m+n+k)}$ from the ''beginning'' and from the ''end,'' respectively: $\Phi_b^{m,n}\in\mathbf{R}^{\otimes(m+n)}\otimes e^k\subset\mathbf{R}^{\otimes(m+n+k)}$, $\Phi_e^{n,k}\in e^m\otimes\mathbf{R}^{\otimes(n+k)}\subset\mathbf{R}^{\otimes(m+n+k)}$. Because of (2), for every $k\geqslant 0$ we have $\Phi^{0,k}=e^0\otimes e^k$ and $\Phi^{k,0}=e^k\otimes e^0$. Suppose now that the elements $\Phi^{1,k}$ are known. Then, using Eq. (3), $\Phi^{m,k}$ can be defined recursively for all m and k greater than 1:

$$\Phi^{m+1,k}\equiv\Phi^{m,1+k}\Phi_e^{1,k}\overline{\Phi}_b^{m,1} \tag{4}$$

(the bar stands for the inverse). This implies the uniqueness of the solution. Obviously, Eq. (3) is true when one of the numbers m, n, and k are equal to zero. By construction, it is fulfilled for $n=1$ and all m as well. So we must show that Eq. (3) is satisfied for arbitrary m, n, and k. Assume the required property proved for all m and n which sum is less than $N>2$. Then for $m+n=N$ and $k>1$ we have

$$\Phi^{m+n,k}=\Phi^{m+n-1,1+k}\Phi_e^{1,k}\overline{\Phi}_b^{m+n-1,1}.$$

Within the assumption made, we decompose the first factor on the right-hand side of this equality, according to (4), and rewrite (3) in the equivalent form

$$\Phi^{m,n+k}\Phi_c^{n-1,1+k}\overline{\Phi}_b^{m,n-1}\Phi_e^{1,k}\overline{\Phi}_b^{m+n-1,1}=\Phi^{m,n+k}\Phi_e^{n,k}\overline{\Phi}_b^{m,n}.$$

Dividing both sides by the first factor we come to condition

$$\Phi_e^{n-1,1+k}\overline{\Phi}_b^{m,n-1}\Phi_e^{1,k}\overline{\Phi}_b^{m+n-1,1}=\Phi_e^{n,k}\overline{\Phi}_b^{m,n}.$$

Again, decomposing the first factor on the right-hand side according to the recursion assumption we find

$$\Phi_e^{n-1,1+k}\overline{\Phi}_b^{m,n-1}\Phi_e^{1,k}\overline{\Phi}_b^{m+n-1,1}=\Phi_e^{n-1,1+k}\Phi_e^{1,k}\overline{\Phi}_{\{m+1\}}^{n-1,1}\overline{\Phi}_b^{m,n},$$

where the subscript in $\overline{\Phi}^{n-1,1}_{\{m+1\}}$ means that it is embedded into $\mathbf{R}^{\otimes(m+n+k)}$ beginning from $\{m+1\}$th place. It is important that the factor $\overline{\Phi}^{m,n-1}_b$ on the left-hand side can be permuted with $\Phi^{1,k}_e$. Division by $\Phi^{n-1,1+k}_e\Phi^{1,k}_e$ yields

$$\overline{\Phi}^{m,n-1}_b\overline{\Phi}^{m+n-1,1}_b=\overline{\Phi}^{n-1,1}_{\{m+1\}}\overline{\Phi}^{m,n}_b$$

or

$$\Phi^{m+n-1,1}_b\Phi^{m,n-1}_b=\Phi^{m,n}_b\Phi^{n-1,1}_{\{m+1\}}.$$

This is exactly twisting equation (3) for $k\to 1$ and $n\to n-1$. According to the induction principle we consider the theorem proved.

Thus the family of solutions to Eq. (1) in the bialgebra $T(\mathbf{R})$ turns out to be very large: it is parametrized by an arbitrary set of invertible elements $\Phi^{1,k}$, $k>0$. On the other hand, we are interested only in those Φ which belong to the subalgebra $\mathscr{U}\otimes\mathscr{U}$. We cannot propose the general method to build such solutions. However, we can point out an algorithm which can help to solve the problem at least for quasitriangular $\mathscr{U}$ and which can be interpreted as a generalization of Reshetikhin's approach. Starting form $\Phi^{1,1}$ as known, set $\Phi^{1,k}\equiv\Phi_{12}\Phi_{13}\cdots\Phi_{1(k+1)}$. Here Φ_{1i} are the images of $\Phi^{1,1}$ via the corresponding embeddings $\mathbf{R}^{\otimes 2}\to\mathbf{R}\otimes\mathbf{R}^{\otimes k}$. For $\Phi^{1,k}$ to belong to $\mathscr{U}\otimes\mathscr{U}$, it is necessary and sufficient to require

$$R_{23}\Phi_{12}\Phi_{13}=\Phi_{13}\Phi_{12}R_{23}. \tag{5}$$

Further, element $\Phi^{2,1}$ lies in $\mathscr{U}\otimes\mathscr{U}$ if and only if $R_{12}\Phi^{2,1}=(\tau\otimes id)(\Phi^{2,1})R_{12}$. Having expressed $\Phi^{2,1}$ through $\Phi^{1,1}$ we come to equation $R_{12}\Phi_{12}\Phi_{13}\Phi_{23}\overline{\Phi}_{12}=\Phi_{21}\Phi_{23}\Phi_{13}\Phi_{21}R_{12}$ or, the matrix $\widetilde{R}=\overline{\Phi}_{21}R\Phi$ introduced, to equation

$$\widetilde{R}_{12}\Phi_{13}\Phi_{23}=\Phi_{23}\Phi_{13}\widetilde{R}_{12}. \tag{6}$$

Verification of the condition $R_{12}\Phi^{2,k}=(\tau\otimes id)(\Phi^{2,k})R_{12}$ for $k>1$ boils down to equality $\widetilde{R}_{12}\Phi_{13}\cdots\Phi_{1k+2}\Phi_{23}\cdots\Phi_{2k+2}=\Phi_{23}\cdots\Phi_{2k+2}\Phi_{13}\cdots\Phi_{1k+2}\widetilde{R}_{12}$, which, as can be easily seen, follows from (6). Now, with further use of identity (3) one can see that $\Phi^{m,n}$ belongs to $\mathscr{U}\otimes\mathscr{U}$ for every m and n, indeed.

IV. TWISTING OF INHOMOGENEOUS LIE ALGEBRAS

One can notice that the example of solution to the twisting equation built at the end of the previous section satisfies the identities

$$(id\otimes\Delta)(\Phi)=\Phi_{12}\Phi_{13}, \tag{7}$$

$$(\widetilde{\Delta}\otimes id)(\Phi)=\Phi_{13}\Phi_{23}, \tag{8}$$

where $\widetilde{\Delta}$ is the twisted coproduct: $\widetilde{\Delta}(h)=\overline{\Phi}\Delta(h)\Phi$. Reshetikhin's conditions are obtained from here if Φ solves the Yang–Baxter equation and, besides, $(\Delta\otimes id)(\Phi)=\Phi_{23}\Phi_{13}$. This generalization of Reshetikhin's twisting is nontrivial, the nonstandard quantization of the Borel subalgebra of sl(2) taken into account. The twisting cocycle for $U(b(2))$ has the form $\exp(X\otimes H)$, where H is the primitive element in $U(b(2))$ and X is the primitive element in $U_h(b(2))$.[17] This example was generalized in Ref. 12 for an arbitrary commutative ring which in the case of $U(b(2))$ coincides with the field of scalars. In the present section we shall formulate the analogous generalization for an arbitrary associative ring $\mathbf{L}$, not necessarily commutative. Let the multiplication in $\mathbf{L}$ be defined by the structure constants $B^{\sigma}_{\mu\nu}$. Consider a Lie algebra built on $H_\mu\in\mathbf{L}$ and $X^\nu\in\mathbf{L}^*$ subjected to the commutation relations

$$[H_\mu,H_\nu]=(B^{\sigma}_{\mu\nu}-B^{\sigma}_{\nu\mu})H_\sigma,\quad [H_\mu,X^\nu]=-B^{\nu}_{\mu\sigma}X^\sigma.$$

The subalgebra $\mathbf{L}^*$ generated by X^ν is assumed to be commutative. It is easy to see that the element $H_\nu\otimes X^\nu-X^\nu\otimes H_\nu$ satisfies the classical Yang–Baxter equation. The subspace $\mathbf{L}^*$ is a

right module over ring **L**. Let us affiliate the identity to $\mathbf{L}\triangleright\mathbf{L}^*$ and denote the resulting ring **R**. The product in **R** is evaluated according to the rules

$$\hat{H}_\mu\hat{H}_\nu=B^\sigma_{\mu\nu}\hat{H}_\sigma,\quad \hat{X}^\nu\hat{H}_\mu=B^\nu_{\mu\sigma}\,\hat{X}^\sigma,\quad \hat{X}^\mu\hat{X}^\nu=0,\quad \hat{H}_\mu\hat{X}^\nu=0,$$

plus evident expressions involving identity $\hat{E}$. Starting from this multiplication, one can see that the element

$$\tilde{R}=\hat{E}\otimes\hat{E}+\hat{H}_\nu\otimes\hat{X}^\nu-\hat{X}^\nu\otimes\hat{H}_\nu \tag{9}$$

is a solution to the quantum Yang–Baxter equation, and the element

$$\Phi^{1,1}=\hat{E}\otimes\hat{E}-\hat{X}^\nu\otimes\hat{H}_\nu \tag{10}$$

obeys (5) and (6) where R should be set to $\hat{E}\otimes\hat{E}$. Correspondence $1\to\hat{E}$, $X\to\hat{X}$, $H\to\hat{H}$ is extended to a homomorphism (nondegenerate) of the universal enveloping algebra $U(\mathbf{R})$ into $T(\mathbf{R})$.

Theorem 2: Twisting cocycle Φ expanding $\Phi^{1,1}$ [Eq. (10)] by modified Reshetikhin's procedure belongs to $U(\mathbf{L}^*)\otimes U(\mathbf{L})$ and has the form $\exp(-\tilde{X}^\nu\otimes H_\nu)$, where $\tilde{X}^\nu$ are expressed by series in X^ν.

Indeed, $\Phi^{1,k}\in U(\mathbf{L}^*)\otimes U(\mathbf{L})$ by construction. From defining formula (4), recursively using the facts that $\mathrm{Span}(\hat{E},\hat{H}_\mu)$ and $\mathrm{Span}(\hat{X}^\mu)$ form a subring and an ideal in **R**, respectively, we get the first assertion of the theorem. Now the announced form of the twisting cocycle follows from (7).

Unemployed so far identity (8) enables us to determine the twisted coproduct on the generators $\tilde{X}^\nu$. It turns out that $\tilde{\Delta}(\tilde{X}^\nu)=D^\nu(1\otimes\tilde{X},\tilde{X}\otimes 1)$, where $D(a,b)$ is the Campbell–Hausdorff series: $e^{D(a,b)}=e^ae^b$ for arbitrary a and b from the Lie algebra of the ring **L**. Thus the commutative algebra $U_q(\mathbf{L}^*)$ is isomorphic to the function algebra on the group $\exp(\mathbf{L})$ taken with the opposite coproduct. We have yet to evaluate the twisted coproduct on H_ν and to determine commutation relations $[H_\nu,\tilde{X}^\mu]=f(\tilde{X})^\mu_\nu$. What can be said about functions $f(x)^\mu_\nu$ is that they are subject to the ''boundary'' conditions

$$f(0)^\mu_\nu=0,\quad \partial_\sigma f(0)^\mu_\nu=-B^\mu_{\nu\sigma}. \tag{11}$$

It is accounted for the following. First of all, knowing the image $\Phi^{1,1}$ of the cocycle Φ in $\mathbf{R}^{\otimes 2}$ we conclude that $\partial\tilde{X}^\mu/\partial X^\nu|_{x=0}=\delta^\mu_\nu$. Now the required properties of $f(x)^\mu_\nu$ are conditioned by the homomorphism from $U(\mathbf{R})$ to **R** and the strong nilpotence of $\hat{X}^\mu$.

Having introduced matrices of the left and right regular representations $L(X)^\mu_\nu\equiv B^\mu_{\sigma\nu}\,X^\sigma$, $R(X)^\mu_\nu\equiv B^\mu_{\nu\sigma}\,X^\sigma$, from the definition of $\tilde{\Delta}$ we find

$$\begin{aligned}\tilde{\Delta}(H_\mu)&=\exp(\tilde{X}\otimes H)(H_\mu\otimes 1+1\otimes H_\mu)\exp(-\tilde{X}\otimes H)\\&=H_\mu\otimes 1-\left(\frac{e^{L(\tilde{X})-R(\tilde{X})}-1}{L(\tilde{X})-R(\tilde{X})}\,f(\tilde{X})\right)^\nu_\mu\otimes H_\nu+(e^{L(\tilde{X})-R(\tilde{X})})^\nu_\mu\otimes H_\nu=H_\mu\otimes 1+g(\tilde{X})^\nu_\mu\otimes H_\nu.\end{aligned} \tag{12}$$

The coassociativity requirement imposed, formula (12) implies $g(D(1\otimes\tilde{X},\tilde{X}\otimes 1))=g(1\otimes\tilde{X})g(\tilde{X}\otimes 1)$, and this with necessity entails $g(\tilde{X})=e^{A(\tilde{X})}$, where A represents a left action of **L** on itself. Resolving $g(\tilde{X})$ with respect to $f(\tilde{X})$ and using conditions (11) we come finally to $A(\tilde{X})^\mu_\nu=L(\tilde{X})^\mu_\nu=B^\mu_{\sigma\nu}\,X^\sigma$. The resulting formulas describing the Hopf structure of the twisted algebra $U_q(\mathbf{R})$ read

$$\begin{gathered}\tilde{\Delta}(\tilde{X}^\mu)=D(1\otimes\tilde{X},\tilde{X}\otimes 1),\qquad \tilde{\Delta}(H_\mu)=H_\mu\otimes 1+(e^{L(\tilde{X})})^\nu_\mu\otimes H_\nu,\\ [H_\mu,H_\nu]=(B^\sigma_{\mu\nu}-B^\sigma_{\nu\mu})H_\sigma,\qquad [H_\nu,\tilde{X}^\mu]=\left(\frac{L(\tilde{X})-R(\tilde{X})}{e^{L(\tilde{X})-R(\tilde{X})}-1}\,(e^{L(\tilde{X})-R(\tilde{X})}-e^{L(\tilde{X})})\right)^\mu_\nu.\end{gathered} \tag{13}$$

The antipode is easily found from the coproduct:

$$S(\tilde{X}^\mu)=-\tilde{X}^\mu, \quad S(H_\mu)=-(e^{-L(\tilde{X})})^\nu_\mu H_\nu.$$

The expressions obtained generalize formulas deduced for commutative rings in Ref. 12. In the latter case the value of the commutator $[H_\nu,\tilde{X}^\mu]$ is simplified because of $L(\tilde{X})=R(\tilde{X})$ and turns into $(1-e^{L(\tilde{X})})$, as for the well-known example of the Borel subalgebra of sl(2). The universal R-matrix is expressed through the twisting cocycle by the standard formula $\mathscr{R}=\Phi_{21}^{-1}\Phi:^1$

$$\mathscr{R}=\exp(H_\nu\otimes\tilde{X}^\nu)\exp(-\tilde{X}^\nu\otimes H_\nu) \tag{14}$$

and has the form familiar from the theories of the Jordanian quantization of sl(2)[17] and the null-plane quantized Poincaré algebra.[12,18] Thus we obtain a closed and complete description of the deformed algebra $U_q(\mathbf{R})$, although it would be desirable to find the relation between $\tilde{X}^\mu$ and the classical generators X^μ. To this end, let us calculate the twisted coproduct on elements X^μ:

$$\tilde{\Delta}(X^\mu)=\exp(\tilde{X}\otimes H)(1\otimes X^\mu+X^\mu\otimes 1)\exp(-\tilde{X}\otimes H)=X^\mu\otimes 1+(e^{-L(\tilde{X})})^\mu_\nu\otimes X^\nu,$$

that results in the functional equation

$$\varphi(\Delta(\tilde{X}))=\varphi(\tilde{X}')+e^{-L(\tilde{X}')}\varphi(\tilde{X}''), \tag{15}$$

where the primes distinguish the tensor components, and φ is the transformation connecting the quantum and classical generators: $X^\mu=\varphi^\mu(\tilde{X})$. This equation is well known from the theory of the group cohomologies[19] and its solution is

$$\varphi(\tilde{X})=\frac{e^{-L(\tilde{X})}-1}{-L(\tilde{X})}\,\tilde{X}.$$

This formula solves the problem of proceeding to the classical basis of $U_q(\mathbf{R})$.

The analysis of the solution found allows us to perform a further generalization of the examples considered above in the following direction. Let $\mathbf{G}$ be a Lie group and $\mathbf{L}$ its Lie algebra with the basis elements H_μ. Assume a left action $H_\mu\triangleright H_\nu=B^\sigma_{\mu\nu}H_\sigma$ of $\mathbf{L}$ on itself, which, as a rule, does not coincide with the adjoint representation. Let function φ: $\mathbf{G}\to\mathbf{L}$ be a group 1-cocycle, that is $\varphi(ba)=\varphi(a)+a^{-1}\triangleright\varphi(b)$, $a,b\in\mathbf{G}$. It can be viewed as a mapping defined in some neighborhood of the origin in $\mathbf{L}$. We suppose φ to be invertible and denote its inverse ψ. By the left conjugate action $H_\mu\triangleright X^\nu=-B^\nu_{\mu\sigma}X^\sigma$ on the dual space we build the semidirect sum $\mathbf{L}\triangleright\mathbf{L}^*$, where $\mathbf{L}^*$ is considered as an Abelian subalgebra.

Theorem 3: Element $\Phi=\exp(-\psi^\nu(X)\otimes H_\nu)$ is a twisting cocycle for the universal enveloping Hopf algebra $U(\mathbf{L}\triangleright\mathbf{L}^*)$.

Notice that $\exp(-\psi^\nu(X)\otimes H_\nu)$ satisfies identity (7). Hence in order to prove the theorem the second identity (8) should be stated. Making use of the fact that $\tilde{\Delta}$ is an algebraic mapping for arbitrary Φ, we evaluate $\tilde{\Delta}(\tilde{X})$ on the elements $\tilde{X}^\mu=\psi^\mu(X)$ and come to the equation (15), where operator $L(\tilde{X})$ is defined via tensor B as above. Because of the invertibility of φ, this implies $\Delta(\tilde{X}^\mu)=D^\mu(1\otimes\tilde{X},\tilde{X}\otimes 1)$. Then identity (8) is obeyed as well.

V. BI-CROSSPRODUCT STRUCTURE

To exhibit the bi-crossproduct structure of the examples considered let us use the FRT method and recover the quantum groups with the solution to the quantum Yang–Baxter equation (9). Modulo the order of the factors, they are isomorphic to the quantum algebras, and the isomorphism is realized via the universal R-matrix (14).

In terms of the basis (e,x_μ,h^ν) dual to the basis $(\hat{E},\hat{H}_\mu,\hat{X}^\nu)$ of the ring $\mathbf{R}$ the coproduct, according to the scheme rendered in Sec. II, has the form

$$\Delta(h^\sigma)=h^\sigma\otimes e+e\otimes h^\sigma+B^\sigma_{\mu\nu}h^\mu\otimes h^\nu,\quad \Delta(x_\sigma)=x_\sigma\otimes e+e\otimes x_\sigma+B^\nu_{\mu\sigma}x_\nu\otimes h^\mu,$$

$$\Delta(e)=e\otimes e.$$

The counit is determined by the rule $\varepsilon(e)=1$, $\varepsilon(x_\mu)=0$, $\varepsilon(h^\mu)=0$. Imposing RTT-type relations with the matrix R given by (9), we come to the following permutation rules

$$[x_\mu,x_\nu]=(B^\sigma_{\nu\mu}-B^\sigma_{\mu\nu})x_\sigma e, \tag{16}$$

$$[x_\mu,h^\nu]=B^\nu_{\mu\sigma}h^\sigma e+B^\nu_{\sigma\alpha}B^\sigma_{\beta\mu}h^\alpha h^\beta. \tag{17}$$

Other commutation relations are trivial and, in particular, the element e belongs to the center of the algebra. Note that the ideal $(e-1)$ is a Hopf one and set $e=1$. Introduce quantities η^μ starting from equality $h^\mu\otimes\hat{H}_\mu=e^{\eta^\mu\otimes\hat{H}_\mu}-1\otimes\hat{E}$. In terms of new generators (η^μ,x_μ) the coproduct turns out to be opposite to that of the algebra $\tilde{U}(\mathbf{L})$, and that is seen through the substitution $\eta^\mu\to\tilde{X}^\mu$, $x_\mu\to-H_\mu$. Commutation relation (16) is thus recovered exactly. It has yet to be shown that relation (17) goes over into the last expression in (13). This is guaranteed by the uniqueness of the value of the commutator (17) as a function in h^μ compatible with the given coproduct and fulfilling $\partial[x_\mu,h^\nu]/\partial h^\sigma|_{h=0}=B^\nu_{\mu\sigma}$. This boundary condition is determined by the homomorphism from the quantum group into the ring $\mathbf{L}$ via the ''square'' matrix R (9).

According to Ref. 3, bi-crossproduct $\mathscr{A}\bowtie\mathscr{B}$ of Hopf algebras $\mathscr{A}$ and $\mathscr{B}$ is defined via a left action $\triangleright$ of $\mathscr{A}$ on $\mathscr{B}$ and a right coaction β of $\mathscr{B}$ on $\mathscr{A}$. The latter is a mapping from $\mathscr{A}$ into the tensor product $\mathscr{A}\otimes\mathscr{B}$. The conjugate mapping to β realizes a right action $\mathscr{A}^*\triangleleft\mathscr{B}^*$. These operations are subjected to the set of consistency conditions.[3] Multiplication and comultiplication on $\mathscr{A}\bowtie\mathscr{B}$ are evaluated via

$$(a\otimes h)(b\otimes g)=a(h_{(1)}\triangleright b)\otimes h_{(2)}g,\qquad \Delta(a\otimes h)=(a_{(1)}\otimes\bar{h}^{(1)}_{(1)})\otimes(a_{(2)}\bar{h}^{(2)}_{(1)}\otimes h_{(2)}),$$

where $a,b\in\mathscr{A}$, $h,g\in\mathscr{B}$, $\Delta(h)=h_{(1)}\otimes h_{(2)}$, and $\beta(h)=\bar{h}^{(1)}\otimes\bar{h}^{(2)}$. Turning to $U_q(\mathbf{R})$ constructed in the previous section we see that algebraically it has the same structure as $U^*(\mathbf{L})\triangleleft U(\mathbf{L})$, whereas its dual quantum group has the form $U(\mathbf{L})\triangleright U^*(\mathbf{L})$. In terms of generators h^μ and x_ν the left action is $x_\mu\triangleright h^\nu=B^\nu_{\mu\sigma}h^\sigma+B^\nu_{\sigma\alpha}B^\sigma_{\beta\mu}h^\alpha h^\beta$, and the right coaction β can be computed from the coproduct formula

$$1\otimes\beta(h)\otimes1=(id\otimes id\otimes id\otimes\varepsilon)\circ\Delta(1\otimes h).$$

This yields

$$\beta(x_\sigma)=x_\sigma\otimes1+B^\nu_{\mu\sigma}x_\nu\otimes h^\mu$$

for the generators x^μ thus stating the bi-crossproduct structure of $U^*_q(\mathbf{R})$ and $U_q(\mathbf{R})$.

VI. DISCUSSIONS

The problem of explicitly calculating twisting 2-cocycles for Hopf algebras is a nontrivial one even if their existence is *a priori* known. Difficulties arise already in the simplest case of classical universal enveloping Lie algebras, despite advanced Drinfeld's theory on quantizing triangular Lie bialgebras.[1] This explains why examples of explicitly given twisting 2-cocycles are in short supply. So, it seems quite natural to reduce the problem to studying ''quadratic'' 2-cocycles which are images of ''universal'' ones in fundamental representations, provided there exists some ''fusion'' procedure to expand those matrix solutions over representations of higher spins. There are two algorithms of this kind,[14,20–22] both based on factorization properties of twisting elements[5,6,13,23] $(\Delta\otimes id)(\Phi)=\Phi_{13}\Phi_{23}$ or $(\Delta\otimes id)(\Phi)=\Phi_{23}\Phi_{13}$ (and appropriate identities involving $id\otimes\Delta$). Depending on the order of the factors on the right-hand side, additional requirements like $\Phi_{12}\Phi_{23}=\Phi_{23}\Phi_{12}$ or the Yang–Baxter equation are imposed on Φ. Although most of explicitly known universal twisting 2-cocycles are due to these two options, it is clear that they cannot cover all possibilities. The idea of proceeding to fundamental representation in a finite-

dimensional ring **R** in studying twist-equivalences among various quantizations seems yet more fruitful because the associated bialgebra $T(\mathbf{R})$ plays the role of a container, in a general situation, for all the deformations of a Hopf algebra. Thus every twisting cocycle of a sub-bialgebra undergoing deformation remains so for whole $T(\mathbf{R})$. This makes it reasonable to consider twisting equation in $T(\mathbf{R})$ and then try to select solutions belonging to the given sub-bialgebra. The first part of this program has been completely solved in the present paper, while for the second we have suggested a new kind of fusion procedure which appears to be close to Reshetikhin's twisting. The novelty is that the conditions imposed on Φ employ both twisted and untwisted coproducts. To demonstrate effectiveness of the proposed scheme we have considered a class of inhomogeneous universal enveloping Lie algebras related to associative rings in a special way and quantized them along that line. The technique can be viewed as a generalization of the theory developed in our previous work[12] dealing exclusively with commutative rings, which was motivated by the Jordanian quantization of sl(2) and the null-plane quantized Poincaré algebra. We have also exposed the bi-crossproduct structure of the objects investigated thus providing new examples of quasitriangular bi-crossproduct Hopf algebras. A remarkable fact is that the class considered may be treated directly with the use of special Lie group 1-cocycles which take part in building twisting elements. Relevance of Hopf algebra cohomologies to the twisting procedure and bi-crossproduct construction was already pointed out in Ref. 3, so the present study gives a new insight to their role in the theory. It is interesting to generalize cohomological methods applied here for classical universal enveloping algebras to Hopf algebras of a more general nature.

(Received 27 January 1998; accepted for publication 17 June 1998)

Among the 50 nonlinear second-order differential equations of Painlevé and Gambier, those which are linearizable provide a natural scheme for deriving the Lax pair and the Darboux transformation of a nonlinear partial differential equation when the order of the scattering problem is three. This new method allows one to obtain, from singularity analysis only, the Bäcklund transformation of the Kaup–Kupershmidt equation, a result which was missing until now. © *1998 American Institute of Physics.* [S0022-2488(98)03610-X]

I. INTRODUCTION

Among the numerous definitions of the *integrability* of a partial differential equation (PDE), one of the most widely accepted is the existence of a Bäcklund transformation (BT).[1,2] A BT between two given PDEs, taken for simplicity in two independent variables x,t,

$$E_1(u,x,t)=0, \quad E_2(U,X,T)=0 \tag{1}$$

is by definition (Ref. 3, Vol. III, Chap. XII, Ref. 4) a pair of relations

$$F_j(u,u_x,u_t,\ldots,U,U_x,U_t,\ldots,x,t,X,T)=0, \quad j=1,2, \tag{2}$$

with a transformation law between (x,t) and (X,T), such that the elimination of u (respectively, U) between (F_1,F_2) implies $E_2(U,X,T)=0$ [respectively, $E_1(u,x,t)=0$]. In case the two PDEs are the same, the BT is called auto-BT.

There exist several direct methods to obtain the BT of a PDE, among them the singularity approach initiated by Weiss, Tabor, and Carnevale (WTC).[5,6] Their ''truncation procedure'' and its homographically invariant version[7] have later been extended to process some equations which escaped the original method: first by the ''two-singular manifold method'' [8,9] to handle the modified Korteweg–de Vries, sine-Gordon and Broer-Kaup equations, second by taking account of involutions[10] to handle the nonlinear Schrödinger equation. The notion of ''singular manifold equation'' of Weiss has also been clarified[11] by implementing an additional degree of freedom of the invariant Painlevé analysis.

Very few well known $1+1$-dimensional PDEs still fail to provide, with the truncation procedure and its extensions, the auto-Bäcklund transformation. One of them is the Kaup–Kupershmidt equation.[12,13] This gap is filled in the present article. Preliminary results have been announced in Cargèse lecture notes.[14]

The paper is organized as follows. In Sec. II, we rephrase the method for PDEs with one family of movable singularities, mainly dissociating the role of two entire functions τ and ψ; the application to the Boussinesq equation allows one to extend an old result of Hirota and Satsuma.

Section III is the core of the paper: We introduce a link between the unknown BT and the nonlinear ordinary differential equations (ODEs) which possess two properties, namely the Painlevé property and the linearizability; this restricts the ODE part of the BT to a very small number

 © 1998 American Institute of Physics

of possibilities, namely the Riccati equation for scattering problems of second order, the Gambier equations numbered 5 and 25 for scattering problems of third order, and it also provides the explicit link between τ and ψ.

In Sec. IV, we recall the singularity structure of Sawada–Kotera (SK) and Kaup–Kupershmidt (KK) equations, two equations deeply interconnected as well as their hierarchies[13,15,16] and argue that, for each of them, only one of their two families is relevant, thus fitting the one-family scheme.

In Sec. V, for both the SK and KK equations, we try the three possibilities allowed at second and third scattering orders, and obtain the BT of both PDEs.

II. METHOD FOR A ONE-FAMILY EQUATION

Let us rephrase, more simply than in our previous work,[7] the procedure for PDEs with only one family of movable singularities, for which the *singular part operator* is denoted $\mathscr{D}$. This will be followed by an example.

First step. Assume a Darboux transformation (DT)[17] defined as

$$u = U + \mathscr{D} \log \tau, \quad E(u) = E(U) = 0, \tag{3}$$

with u, U two different solutions of the PDE under consideration and τ some ''entire'' function. A consequence of this assumption is the existence of the involution

$$(u, U, \tau) \to (U, u, \tau^{-1}), \tag{4}$$

since the operator $\mathscr{D}$ is linear.

Second step. Choose the order two, then three, then ..., for the unknown scalar Lax pair and represent this Lax pair by an equivalent, multicomponent, Riccati pseudopotential $\mathbf{Y} = (Y_1, \dots)$. A second-order scalar Lax pair in canonical form, written here in the case of two independent variables,

$$L_1\psi \equiv \psi_{xx} + \frac{S}{2}\psi = 0, \tag{5}$$

$$L_2\psi \equiv \psi_t + C\psi_x - \frac{C_x}{2}\psi = 0, \tag{6}$$

$$2[L_1, L_2] \equiv S_t + C_{xxx} + CS_x + 2C_xS = 0, \tag{7}$$

is thus represented by the one-component Riccati pseudopotential $\mathbf{Y} = \psi_x/\psi = \chi^{-1}$,

$$(\chi^{-1})_x = -\chi^{-2} - \frac{S}{2}, \tag{8}$$

$$(\chi^{-1})_t = C\chi^{-2} - C_x\chi^{-1} + \frac{CS + C_{xx}}{2}. \tag{9}$$

A third-order scalar Lax pair in canonical form

$$L_1\psi \equiv \psi_{xxx} - a\psi_x - b\psi = 0, \tag{10}$$

$$L_2\psi \equiv \psi_t - c\psi_{xx} - d\psi_x - e\psi = 0, \tag{11}$$

$$[L_1, L_2] \equiv X_0 + X_1\partial_x + X_2\partial_x^2, \tag{12}$$

$$X_0 \equiv -b_t - ae_x + e_{xxx} + b_{xx}c + 3bc_{xx} + 3b_xc_x + 3bd_x + b_xd = 0, \tag{13}$$

$$X_1 \equiv -a_t + 3e_{xx} + 2b_xc + a_{xx}c + d_{xxx} + 3ac_{xx} + 2ad_x + 3a_xc_x + 3bc_x + a_xd = 0, \tag{14}$$

$$X_2 \equiv (2ac + c_{xx} + 3d_x + 3e)_x = 0, \tag{15}$$

is similarly represented by the two-component Riccati pseudopotential $\mathbf{Y} = (Y_1, Y_2)$ of projective type[18,7,19]

$$Y_1 = \frac{\psi_x}{\psi}, \quad Y_2 = \frac{\psi_{xx}}{\psi}, \tag{16}$$

$$Y_{1,x} = -Y_1^2 + Y_2, \tag{17}$$

$$Y_{2,x} = -Y_1 Y_2 + aY_1 + b, \tag{18}$$

$$Y_{1,t} = -(dY_1 + cY_2)Y_1 + (ac + d_x)Y_1 + (c_x + d)Y_2 + e_x + bc \tag{19}$$

$$= (cY_2 + dY_1 + e)_x, \tag{20}$$

$$Y_{2,t} = -(dY_1 + cY_2)Y_2 + (2ac_x + a_x c + bc + d_{xx} + ad + 2e_x)Y_1 + (c_{xx} + 2d_x + ac)Y_2 + 2bc_x + b_x c + bd + e_{xx}, \tag{21}$$

$$(Y_{1,t})_x - (Y_{1,x})_t = X_1 + X_2 Y_1, \tag{22}$$

$$(Y_{2,t})_x - (Y_{2,x})_t = -X_0 + X_2 Y_2. \tag{23}$$

Remark: In case the PDE has more than one family of movable singularities, it is necessary to introduce an additional degree of freedom in the scattering problem, such as a term $A\psi_x$ in (5).[11]

Third step. Choose an explicit link

$$\mathscr{D} \log \tau = f(\psi), \tag{24}$$

between the function τ and the solution ψ of a scalar Lax pair. For most PDEs, this is simply

$$\tau = \psi, \tag{25}$$

but it is more complicated for some tricky PDEs like Kaup–Kupershmidt (KK), see (63) below. It will be shown in Sec. III that, at each scattering order, there exists only a finite number of choices (24).

Fourth step. Define the ''truncation'' and solve it, that is to say: With the assumptions (3) for a DT, (24) for a link between τ and ψ, (8)–(9) or (17)–(21) for the gradient of $\mathbf{Y}$, express $E(u) - E(U)$ as a polynomial in $\mathbf{Y}$,

$$E(u) - E(U) = \sum_{j=0}^{-q} E_j(S, C, U)\chi^{j+q} \quad \text{(for second order)}, \tag{26}$$

$$E(u) - E(U) = \sum_{k \geqslant 0} \sum_{l \geqslant 0} E_{k,l}(a, b, c, d, e, U) Y_1^k Y_2^l \quad \text{(for third order)}, \tag{27}$$

and solve the set of *determining equations*

$$\forall j E_j(S, C, U) = 0 \quad \text{(for second order)}, \tag{28}$$

$$\forall k \forall l E_{k,l}(a, b, c, d, e, U) = 0 \quad \text{(for third order)}, \tag{29}$$

for the unknown coefficients (S, C) or (a, b, c, d, e) as functions of U. Our previous formulas (39) and (40) in Ref. 7 contained a useless restriction to the above written formulas (27) and (29).

The second, third and fourth steps must be repeated until a success occurs. The process is successful if and only if the following three conditions are met:

(1) U comes out unconstrained, apart from being a solution of the PDE,

(2) the vanishing of the commutator $[L_1,L_2]$ is equivalent to the vanishing of $E(U)$,
(3) in the $1+1$-dimensional case only, the coefficients depend on an arbitrary constant λ, the spectral or Bäcklund parameter.

At this stage, one has obtained the DT and the Lax pair.

Fifth step. Obtain the two equations for the BT by eliminating ψ^{20} between the DT and the scalar Lax pair. This sometimes uneasy operation may become elementary by eliminating the appropriate component of the multicomponent pseudopotential $\mathbf{Y}$ rather than ψ, and this is the only reason for introducing $\mathbf{Y}$ in the second step. Assume for instance that $\tau=\psi$ and $\mathscr{D}=\partial_x$. Then Eq. (3) reads

$$Y_1=u-U \tag{30}$$

and the BT is computed as follows: Eliminate all the components of $\mathbf{Y}$ but Y_1 between the equations for the gradient of $\mathbf{Y}$, then in the resulting equations substitute Y_1 as defined in (30).

Remark: In this fifth step, the elimination of ψ is made between three equations and results in two equations, as expected for a BT. For an nth order Lax pair with $n-1$ components in $\mathbf{Y}$, the elimination of all components of $\mathbf{Y}$ but Y_1 results in n equations instead of two, but, at least in the case of evolution equations to which we restrict ourselves in this article, $n-2$ of them must be discarded, namely those defining $Y_{k,t}, k=2,\ldots,n-1$. The two resulting equations in Y_1 are then one nonlinear ODE and one PDE. For $n=2$ these are

$$Y_{1,xx}+3Y_1Y_{1,x}+Y_1^3-aY_1-b=0, \tag{31}$$

$$Y_{1,t}-(cY_{1,x}+cY_1^2+dY_1+e)_x=0, \tag{32}$$

$$(Y_{1,xx})_t-(Y_{1,t})_{xx}=X_0+X_1Y_1+X_2Y_1^2=0. \tag{33}$$

To fix the ideas, let us take the Boussinesq equation (Bq) in its two-component evolution form[21]

$$\mathrm{sBq}(u,r)\equiv\begin{cases} u_t-r_x=0,(\alpha,\beta,\varepsilon)\text{constant},\\ r_t+\varepsilon^2((u+\alpha)^2+(\beta^2/3)u_{xx})_x=0, \end{cases} \tag{34}$$

and consider its one-component ''potential'' form

$$\mathrm{pBq}(v)\equiv v_{tt}+\varepsilon^2((v_x+\alpha)^2+(\beta^2/3)v_{xxx})_x=0,\quad u=v_x,\quad r=v_t. \tag{35}$$

Equation (35) has only one family of movable singularities

$$p=-1,\quad q=-5,\quad \text{indices}\ -1,1,4,6,\quad \mathscr{D}=2\beta^2\partial_x \tag{36}$$

and it passes the Painlevé test.[22] Since (35) is a conservation law, the computations to come can be reduced by considering the ''second potential Bq'' equation

$$\mathrm{ppBq}(w)\equiv w_{tt}+\varepsilon^2((w_{xx}+\alpha)^2+(\beta^2/3)w_{xxxx})=0,\quad u=v_x=w_{xx}, \tag{37}$$

whose single family is of the logarithmic type $w\sim 2\beta^2\log\chi$,

$$p=0^-,\quad q=-4,\quad \text{indices}\ -1,0,1,6,\quad \mathscr{D}=2\beta^2. \tag{38}$$

The assumptions (3) and (25)

$$w=2\beta^2\log\tau+W,\quad \log\tau=\log\psi,\quad \mathrm{ppBq}(w)=0,\quad \mathrm{ppBq}(W)=0, \tag{39}$$

with ψ solution of the unknown second-order scalar Lax pair (5)–(6), generate the usual WTC truncation in the invariant formalism[23]

$$\mathrm{ppBq}(w)-\mathrm{ppBq}(W)\equiv\sum_{j=0}^{4}E_j\chi^{j-4}=0, \tag{40}$$

$$E_2\equiv(4/3)\beta^2\varepsilon^2S-2C^2-4\varepsilon^2(W_{xx}+\alpha)=0, \tag{41}$$

$$E_3\equiv-2(C_t+CC_x-(\beta^2\varepsilon^2/3)S_x)=0, \tag{42}$$

$$E_4\equiv(SE_2-E_{3,x})/2+C_x^2=0. \tag{43}$$

Their general solution depends on three arbitrary constants

$$S=3(c_2-c_0c_1t-c_1^2t^2/2+c_1x)/(\beta\varepsilon)^2, \tag{44}$$

$$C=c_1t+c_0, \tag{45}$$

$$W_{xx}=U=-\alpha+(c_1x-c_1^2t^2-2c_0c_1t+c_2-c_0^2/2)/\varepsilon^2, \tag{46}$$

and, because of the constraint on U, it cannot define a Lax pair and just defines the particular solution

$$u=-\alpha+(c_1x-c_1^2t^2-2c_0c_1t+c_2-c_0^2/2)/\varepsilon^2+2\beta^2\partial_x^2\ \log\ \mathrm{Ai}(S), \tag{47}$$

where Ai is the Airy function, solution of the ODE (5). In case $c_1=0$, this is the one-soliton solution.

Going to third order, the assumption (39), with ψ solution of the unknown scalar Lax pair (10)–(11), generates

$$\mathrm{ppBq}(w)-\mathrm{ppBq}(W)\equiv\sum_{k=0}^{2}\sum_{l=0}^{2}E_{k,l}Y_1^kY_2^l,\quad k+l\leqslant 2. \tag{48}$$

These six determining equations $E_{k,l}=0$, plus the three compatibility conditions $X_j=0$, $j=0,1,2$, are solved as follows:[19]

$$\begin{aligned}
&E_{02}\equiv(\beta\varepsilon)^2-c^2=0 && \Rightarrow c=\beta\varepsilon,\\
&E_{11}\equiv d=0 && \Rightarrow d=0,\\
&E_{20}\equiv 3(V_x+\alpha)+2\beta^2a=0 && \Rightarrow a=-3(V_x+\alpha)/(2\beta^2),\\
&E_{10}\equiv\varepsilon V_{xx}-\beta e_x=0 && \Rightarrow e_x=\beta^{-1}\varepsilon V_{xx},\\
&X_1\equiv 3V_{xt}+3\beta\varepsilon V_{xxx}+4\beta^3\varepsilon b_x=0 && \Rightarrow b=g(t)-3(\beta^{-2}V_{xx}+\beta^{-3}\varepsilon^{-1}V_t)/4,\\
&E_{00}\equiv 2\beta^2g'(t)=0 && \Rightarrow g(t)=\lambda,
\end{aligned} \tag{49}$$

in which λ is an arbitrary constant. The coefficients a,b,c,d,e are

$$a=-(3/2)\beta^{-2}(V_x+\alpha),\quad b=\lambda-(3/4)\beta^{-2}V_{xx}-(3/4)\beta^{-3}\varepsilon^{-1}V_t,$$

$$c=\beta\varepsilon,\quad d=0,\quad e=\beta^{-1}\varepsilon(V_x+\alpha), \tag{50}$$

$$X_0=(3/(4\varepsilon\beta^2))\mathrm{pBq}(V),\quad X_1=0,\quad X_2=0, \tag{51}$$

and they define a third-order Lax pair of the potential Boussinesq equation (35).[24,21,25]

The BT is just (31)–(32) or equivalently, after substitution of $Y_1=(v-V)/(2\beta^2)$,

$$(v-V)_{xx}+3\beta^{-1}\varepsilon^{-1}(v+V)_t+3\beta^{-2}(v-V)((v+V)_x+2\alpha)+\beta^{-4}(v-V)^3-8\beta^2\lambda=0, \tag{52}$$

$$(v+V)_{xx}-\beta^{-1}\varepsilon^{-1}(v-V)_t+\beta^{-2}(v-V)(v-V)_x=0. \tag{53}$$

Written in bilinear notation,

$$(\beta\varepsilon D_x^3+3D_xD_t+(6\alpha\beta^{-1}\varepsilon-3K)D_x-4\beta\varepsilon\lambda)f.g=0, \tag{54}$$

$$(\beta\varepsilon D_x^2-D_t+K)f.g=0, \tag{55}$$

$$v=2\beta^2\partial_x \log f, \quad V=2\beta^2\partial_x \log g, \tag{56}$$

this result, in which K is an irrelevant arbitrary integration constant, is an extension to $\lambda\neq 0$ of the bilinear BT given by Hirota and Satsuma.[26,27]

III. THE HELP FROM GAMBIER

In the case of $1+1$-dimensional evolution equations to which we restrict ourselves in this article, one of the two equations defining the BT to be found is an ordinary differential equation, e.g., (8) or (31). This nonlinear ODE for Y, with coefficients depending on U and an arbitrary constant λ, has two properties. First, it is linearizable since it results from the Lax pair, a linear system, and the Darboux transformation by an elimination process.[20] Second, it has the Painlevé property since it is linearizable. Therefore, if its order is small (at most three), it belongs to the appropriate finite list established by the Painlevé school between 1900 and 1910.

These very special nonlinear ODEs provide a link to both the Lax pair, via their linearizing transformation, and the Darboux transformation, via an involution which leaves them invariant.

The only ODE of first order and degree one with the Painlevé property is the Riccati equation, it is linearizable into a second-order linear equation and this defines a unique choice (24) for describing scattering problems which have order two.

Next, the ODEs of order two and degree one with the Painlevé property which are also linearizable have been listed by Gambier himself, page 21 of his thesis,[28] these are the equations numbered 5, 6, 14, 24, 25, 27, in his classification of 50 equations inequivalent under the homographic group of transformations, with the respective orders for the associated linear equations, i.e., in our context for the unknown scattering problem: 3, 2, 2, 2, 3, 2 (and 4 or 3 for the case $n=2$ in equation 27).

Therefore, the only two generic choices for describing scattering problems of third order are the two classes of equivalence numbered 5 and 25 by Gambier. The representative equation of interest to us in each class of equivalence is what Painlevé calls the ''complete equation'' (in the present section, the $(')$ symbol means ∂_x)

$$Y''+3YY'+Y^3+rY+q=0, \tag{G5}$$

$$Y''-3Y'^2/(4Y)+3YY'/2+Y^3/4-q'(Y'+Y^2)/(2q)-rY-q=0, \tag{G25}$$

in which q and r are two arbitrary functions. These two classes are equivalent under the birational group, as shown by the explicit transformation between (G5) $(y;q,r)$ and (G25) $(Y;Q,R)$

$$Y=\frac{Q}{2z'+z^2-(Q'/Q)z-R}, \quad z=y+\frac{Q'}{2Q}, \quad 2y=\frac{Y'}{Y}+Y+\frac{Q'}{Q}, \tag{57}$$

$$r=-R+\frac{Q''}{Q}-\frac{5Q'^2}{4Q^2}, \quad q=-\frac{Q}{2}-\frac{R'}{2}+\frac{Q'''}{2Q}-\frac{7Q'Q''}{4Q^2}+\frac{5Q'^3}{4Q^3}. \tag{58}$$

Equation (G5) for $Y(x)$ is identical to (31) and it is linked to the fifth equation chosen by Gambier for $\tilde{Y}(\tilde{x})$ by (Ref. 29 Eq. (1) Tableau IV)

$$\tilde{Y}''+3\tilde{Y}\tilde{Y}'+\tilde{Y}^3-a=0, \tag{59}$$

$$Y=\lambda(x)\tilde{Y}+\mu(x), \quad \tilde{x}=\xi(x), \tag{60}$$

$$\xi' = \lambda, \quad \lambda'/\lambda = -\mu, \quad 2\mu' + \mu^2 + r = 0, \quad a = (r'/2 - q)\lambda^{-3}. \tag{61}$$

The linearizing transformations are

$$\text{(G5)} \quad Y = \frac{\tau'}{\tau} = \frac{\psi'}{\psi}, \quad \psi''' + r\psi' + q\psi = 0, \tag{62}$$

$$\text{(G25)} \quad \begin{cases} Y = \dfrac{\tau'}{\tau} = \dfrac{q}{2z' + z^2 - (q'/q)z - r}, \quad z = \dfrac{\psi'}{\psi}, \\ \psi''' - \dfrac{3q'}{2q}\psi'' - \left(r + \dfrac{q''}{q} - \dfrac{q'^2}{q^2} \right)\psi' - \left(\dfrac{r'}{2} + \dfrac{q}{2} - \dfrac{q'r}{2q} \right)\psi = 0. \end{cases} \tag{63}$$

The corresponding involutions

$$\text{(G5)} \quad (Y, q, r) \to (-Y, -q, r + 6Y'), \tag{64}$$

$$\text{(G25)} \quad (Y, q, r) \to (-Y, -q, r - 3Y' - (q'/q)Y) \tag{65}$$

will be seen to define the Darboux transformation.

The method exposed in Sec. II remains unchanged, apart from its third step: The assumption for a link $\mathscr{D} \log \tau = f(\psi)$ becomes, at the third scattering order, a choice between the two *and only two* above linearization formulas (62) and (63), which thus replace the assumption (10). Consequently, in the determining equations of the fourth step, the unknowns (a, b) are replaced by the unknowns (q, r) of the Gambier equations numbered 5 and 25.

These two and only two possibilities were rediscovered in 1980 in the context of scattering theory by Caudrey[30] and Kaup.[12]

Let us apply this to the Kaup–Kupershmidt equation.

IV. SINGULARITY STRUCTURE OF SK AND KK EQUATIONS

Because of their duality,[12,15] it is convenient to handle at the same time SK and KK. They are defined as

$$\mathrm{SK}(u) \equiv \beta u_t + \left(u_{xxxx} + \frac{30}{\alpha} u u_{xx} + \frac{60}{\alpha^2} u^3 \right)_x = 0, \tag{66}$$

$$\mathrm{pSK}(v) \equiv \beta v_t + v_{xxxxx} + \frac{30}{\alpha} v_x v_{xxx} + \frac{60}{\alpha^2} v_x^3 = 0, \tag{67}$$

$$\mathrm{KK}(u) \equiv \beta u_t + \left(u_{xxxx} + \frac{30}{\alpha} u u_{xx} + \frac{45}{2\alpha} u_x^2 + \frac{60}{\alpha^2} u^3 \right)_x = 0, \tag{68}$$

$$\mathrm{pKK}(v) \equiv \beta v_t + v_{xxxxx} + \frac{30}{\alpha} v_x v_{xxx} + \frac{45}{2\alpha} v_{xx}^2 + \frac{60}{\alpha^2} v_x^3 = 0, \tag{69}$$

in which u denotes the conservative field and v the potential one, with $u = v_x$.

KK has escaped all previous singularity-based attempts: Weiss,[15] Musette and Conte,[7] Conte, Musette, and Pickering (see page 71 in Ref. 10), Pickering.[11]

The t part of the BT of KK has never been published. The x part of the BT of KK obtained by Rogers and Carillo[16] is restricted to a zero Bäcklund parameter λ, and the introduction of such a parameter is probably uneasy since it has never been published.

The DT of KK found by Levi and Ragnisco[31] allows one in principle to deduce the BT by an elimination process between the Lax pair and the DT, but in practice (contrary to the case of SK) this is so difficult that it has not yet been done, to our knowledge.

Both equations have the Painlevé property.[15] Each of them has two families of movable singularities, whose leading order (in potential form) $v \sim v_0 \chi^p$ and Fuchs indices are the following:[15]

$$\text{pSK, F1: } p=-1, \quad v_0=\alpha, \quad \text{indices } -1,1,2,3,10, \tag{70}$$

$$\text{pSK, F2: } p=-1, \quad v_0=2\alpha, \quad \text{indices } -2,-1,1,5,12, \tag{71}$$

$$\text{pKK, F1: } p=-1, \quad v_0=\alpha/2, \quad \text{indices } -1,1,3,5,7, \tag{72}$$

$$\text{pKK, F2: } p=-1, \quad v_0=4\alpha, \quad \text{indices } -7,-1,1,10,12. \tag{73}$$

The singular part operator $\mathscr{D}$ attached to a given family is $\mathscr{D}=v_0\partial_x$.

The two families have residues which are not opposite, which makes the two-singular manifold method inapplicable.[8]

Hopefully, each potential equation possesses in its hierarchy a ''minus-one'' equation[32]

$$\text{pSK}_{-1}: v_{xxt}+\frac{6}{\alpha}v_x v_t=0, \tag{74}$$

$$\text{pKK}_{-1}: v_t v_{xxt}-\frac{3}{4}v_{xt}^2+\frac{6}{\alpha}v_x v_t^2=0. \tag{75}$$

These equations have only one family, and the first one, initially written by Hirota and Satsuma,[33] has already been processed successfully[7,19] by the one-family method recalled in Sec. II. This is a strong indication that the same method should also succeed for the KK_{-1} and the KK equations, by restricting to their unique common family F1 Eq. (72).

V. ONE-FAMILY TRUNCATION OF THE KK EQUATION

We follow the method of Sec. II and process the potential equations.

First step. The assumption (3) is

$$v=v_0\partial_x \log \tau+V, \tag{76}$$

with (v,V) two solutions pSK or pKK, and v_0 the residue for family F1.

Second step. One successively chooses the second-order Lax pair (5)–(6) and the third order one (10)–(11).

Third step. If the Lax order is two, the only choice is Riccati, i.e., $\tau=\psi$, since this is a one-family truncation. If the order is three, the two choices are (G5) and (G25), i.e., (62) and (63).

Fourth step. For each PDE, there are only three possibilities to examine: order two and Riccati, order three and (G5), order three and (G25).

A. First possibility: Order two and Riccati, for both PDEs

The one-family truncation (26) with $\tau=\psi$ generates the three equations for SK:[34]

$$E_4 \equiv \beta C-4S^2+9S_{xx}+60SV_x/\alpha-180(V_x/\alpha)^2-30V_{xxx}/\alpha=0, \tag{77}$$

$$E_5 \equiv -\beta C_x-2SS_x+S_{xxx}+30S_xV_x/\alpha=0, \tag{78}$$

$$E_6 \equiv (SE_4-E_{5,x})/2+5S_x(3V_{xx}/\alpha-S_x/2)=0, \tag{79}$$

and the three ones for KK:

$$E_2 \equiv 15(S/4-3V_x/\alpha)=0, \tag{80}$$

$$E_4 \equiv \beta C/2+7S^2/4+3S_{xx}/4-15SV_x/\alpha-90(V_x/\alpha)^2-15V_{xxx}/\alpha=0, \tag{81}$$

$$E_6 \equiv (S/2)E_4/\alpha + (4\beta(CS + C_{xx}) - S^3 + (21/2)S_x^2 + 14SS_{xx} - 4S_{xxxx})/16 + (15/4)(3S^2 - 2S_{xx})V_x/\alpha - 45S(V_x/\alpha)^2 = 0. \quad (82)$$

The constraints $S_x(6V_x - \alpha S)_x = 0$ for SK and $12V_x - \alpha S = 0$ for KK imply that only particular solutions are available, meaning a failure to obtain the Lax pair at this second order. For SK, one obtains the two particular solutions,

$$V = 2\alpha(\zeta - 12g_3 t/\beta), \quad (83)$$

$$S = -12\wp - 6K, \quad (84)$$

$$C = 144(\wp^2 - K\wp + K^2)/\beta - 2c, (K, c, g_3, x_0) \text{arbitrary constants}, \quad (85)$$

in which the Weierstrass functions $\wp(z, g_2, g_3)$ and $\zeta(z, g_2, g_3)$ are taken at point $(x - ct - x_0, \beta c/12, g_3)$, and

$$V = \alpha\left(\zeta(x - (c - c_0)t - x_0, \frac{k^4}{12} + \beta\frac{c_0}{9}, g_3) - \frac{k^2}{12}x + (5(k^4 + \beta c_0)\frac{k^2}{36} - 12g_3)\frac{t}{\beta}\right), \quad (86)$$

$$S = -k^2/2, \quad (87)$$

$$C = k^4/\beta + 5c_0/3, \quad (88)$$

$$c = k^4/\beta + 2c_0/3, (k^2, c_0, g_3, x_0) \text{arbitrary constants}. \quad (89)$$

For KK, one obtains the particular solution

$$V = \alpha\left(-\frac{k^2}{24}(x - x_0) + \frac{5}{1152}k^6 t/\beta\right), \quad (90)$$

$$S = -k^2/2, \quad (91)$$

$$C = \frac{k^4}{16\beta}, (k^2, x_0) \text{arbitrary constants}. \quad (92)$$

Given these values of the homographic invariants (S, C), the integration of the system (5)–(6) provides another solution v defined by Eq. (76). For the second above listed solution of SK, one thus obtains a degeneracy of the more general solution

$$v/\alpha = \zeta(x - ct - x_0, g_2, g_3) + \zeta(x - c't - x_0', g_2', g_3') - 12(g_3 + g_3')t/\beta, \quad (93)$$

$$\beta c = 15g_2' - 3g_2, \quad (94)$$

$$\beta c' = 15g_2 - 3g_2', \quad (95)$$

depending on six arbitrary constants $(x_0, g_2, g_3, x_0', g_2', g_3')$; this is an extrapolation to two different velocities c, c' of the solitary wave found by Chazy in 1910.[35]

In the case of KK, one does not even obtain the one-soliton solution.

Remarks:

(1) Had we left V unconstrained instead of requiring it to satisfy the PDE, we would have recovered the result of Weiss,[15] namely: from SK, Miura transformations to KK and to the Fordy–Gibbons equation[13] and a second-order Lax pair of KK without spectral parameter; from KK, Miura transformations to SK and to the Fordy–Gibbons equation and a second-order Lax pair of SK without spectral parameter.

(2) If the PDE were KdV5, the method would succeed at this point.

B. Second possibility: Order three and G5, for both PDEs

This generates 6 determining equations (29) for SK and 13 for KK, which are solved exactly as was done for Boussinesq in Sec. II.

The process is successful for SK:[15,36]

$$q=-\lambda, \tag{96}$$

$$r=6U/\alpha, \tag{97}$$

$$L_1=\partial_x^3+6\frac{U}{\alpha}\partial_x-\lambda, \tag{98}$$

$$L_2=\beta\partial_t+\left(18\frac{U_x}{\alpha}-9\lambda\right)\partial_x^2+\left(36\frac{U^2}{\alpha^2}-6\frac{U_{xx}}{\alpha}\right)\partial_x-36\lambda\frac{U}{\alpha}, \tag{99}$$

$$\beta[L_1,L_2]=(6/\alpha)\mathrm{SK}(U). \tag{100}$$

This is the Lax pair given by Satsuma and Kaup.[37]

For KK, this truncation fails and provides no solution at all, not even the one-soliton solution. Indeed, the one-soliton solution of Kaup corresponds to constant coefficients for the scalar Lax pair (10)–(11), and, with the above procedure, the only way to obtain it[38,11] is to enforce the two first integrals K_1 and K_2 which result from the zero value of b,

$$K_1=\psi_{xx}-a\psi, \quad K_2=\psi_x^2-a\psi^2-2K_1\psi. \tag{101}$$

C. Third possibility: Order three and G25

This has to be done for KK only. We do not assume $\mathrm{pKK}(V)=0$, so we suppress the second term $-\mathrm{pKK}(V)$ in the lhs of Eq. (27). This generates 38 determining equations (29) in the basis $(\psi_x/\psi,\psi_{xx}/\psi-((\psi_x/\psi)^2+q_x\psi_x/(q\psi)+r)/2)$, out of which only 15 are linearly independent; they are solved as follows (g_k denotes an arbitrary integration function, λ an arbitrary constant):

$$\begin{gathered}
E_{4,5}: q=2g_1(t),\\
E_{4,4}: c=9g_1/\beta,\\
E_{3,5}: r=-6V_x/\alpha,\\
E_{1,5}: d=(3V_{xxx}/\alpha-(6V_x/\alpha)^2)/\beta,\\
E_{0,5}: g_1=\lambda,\\
E_{0,6}: \mathrm{pKK}(V)=0,\\
E_{1,4}: e=g_2(t)+(36\lambda V_x/\alpha+72V_xV_{xx}/\alpha^2+3V_{xxxx}/\alpha)/\beta,\\
X_2: a=g_3(t)-6V_x/\alpha,\\
X_1: b=g_4(t)-3V_{xx}/\alpha+g_3\lambda^{-1}((2V_x/\alpha)^2+V_{xxx}/(3\alpha))+\beta x g_3'/(18\lambda),\\
X_0: g_3=0 \ \text{ and } \ g_4=\lambda,
\end{gathered} \tag{102}$$

and the result is, with $U=V_x$,

$$q=2\lambda, \tag{103}$$

$$r=-6U/\alpha, \tag{104}$$

$$\partial_x \log \tau=\frac{\lambda}{\psi_{xx}/\psi-(1/2)(\psi_x/\psi)^2+3(U/\alpha)}, \tag{105}$$

$$L_1=\partial_x^3+6\frac{U}{\alpha}\partial_x+3\frac{U_x}{\alpha}-\lambda, \tag{106}$$

$$L_2=\beta\partial_t-9\lambda\partial_x^2+\left(3\frac{U_{xx}}{\alpha}+36\frac{U^2}{\alpha^2}\right)\partial_x-3\frac{U_{xxx}}{\alpha}-72\frac{UU_x}{\alpha^2}-36\lambda\frac{U}{\alpha}, \tag{107}$$

$$\beta[L_1,L_2]=(6/\alpha)\mathrm{KK}(U)\partial_x+(3/\alpha)\mathrm{KK}(U)_x. \tag{108}$$

This is the Lax pair given by Kaup.[12] The integration of the first-order ODE (105) *modulo* the Lax pair yields the DT given by Levi and Ragnisco:[31]

$$\tau=\psi\psi_{xx}-(1/2)\psi_x^2+3(U/\alpha)\psi^2,\quad \tau_x=\lambda\psi^2, \tag{109}$$

which shows that τ is an entire function, as expected.

Although the relation $\tau_x/\psi^2=$constant is the same as in the case of KdV (see Eq. (4.14) in Ref. 5), it cannot be taken as an *a priori* assumption, it is the result of the method.

Starting from the *vacuum* solution $U=0$, the general solution ψ of $L_1\psi=0, L_2\psi=0$,

$$\psi=c_1e^{Kx+9K^5t/\beta}+c_2e^{jKx+9j^2K^5t/\beta}+c_3e^{j^2Kx+9jK^5t/\beta},\quad j^3=1,\quad K^3=\lambda, \tag{110}$$

in which c_1,c_2,c_3,K are arbitrary complex constants, leads by (3) to the one-soliton solution of Kaup[12]

$$u=(\alpha/2)\partial_x^2\ \log(2+\cosh(k/2)(x-(k/2)^4t/\beta)),\quad k\in\mathscr{R} \tag{111}$$

for the choice $(c_1,c_2,c_3)=(0,j^2,-j)$, $K^2=-k^2/12$, which corresponds to the entire function

$$\tau=-(k^2/12)(2+\cosh(k/2)(x-(k/2)^4t/\beta))e^{(k/2)(x+(k/2)^4t/\beta)}. \tag{112}$$

The fifth step is performed in Sec. VI.

VI. BÄCKLUND TRANSFORMATION

This is the fifth and last step.

The two equations which define the BT result from the elimination of ψ between the DT and the two equations of the scalar Lax pair.

In order to perform this elimination easily, it is convenient to choose one of the two components of the pseudopotential $\mathbf{Y}$ so as to characterize the DT,

$$\mathrm{SK}:\frac{v-V}{\alpha}=\frac{\psi_x}{\psi}=Y_1, \tag{113}$$

$$\mathrm{KK}:\frac{2(v-V)}{\alpha}=\frac{\tau_x}{\tau}=Z. \tag{114}$$

The chosen equivalent systems are the canonical projective Riccati system (17)–(21) in (Y_1,Y_2) for SK, and the following system in (Y_1,Z) for KK:

$$Y_1=\frac{\psi_x}{\psi},\quad Z=\frac{\tau_x}{\tau}, \tag{115}$$

$$Y_{1,x}=-Y_1^2/2+\lambda Z^{-1}-3U/\alpha, \tag{116}$$

$$Z_x=2Y_1Z-Z^2, \tag{117}$$

$$\beta Y_{1,t}=[9\lambda Y_1^2/2-(3U_{xx}/\alpha+36(U/\alpha)^2)Y_1+9\lambda^2Z^{-1}+3U_{xxx}/\alpha+72UU_x/\alpha^2+9\lambda U/\alpha]_x, \tag{118}$$

$$\beta Z_t=[18\lambda U/\alpha+9\lambda^2 Z^{-1}+9\lambda Y_1^2 + (45(U/\alpha)^2+6(U_{xx}/\alpha)-18(U_x/\alpha)Y_1+27(U/\alpha)Y_1^2+(9/4)Y_1^4)Z]_x. \quad (119)$$

The BT of SK results from the elimination of Y_2, which provides Eqs. (31)–(32) for $Y_1=Y$,

$$Y_{xx}+3YY_x+Y^3+6(U/\alpha)Y-\lambda=0, \quad (120)$$

$$\beta Y_t-9[(\lambda-2U_x/\alpha)(Y_x+Y^2)+4(\lambda U/\alpha-(U/\alpha)^2Y)+(2/3)(U_{xx}/\alpha)Y]_x=0, \quad (121)$$

$$\beta((Y_{xx})_t-(Y_t)_{xx})/Y=-(6/\alpha)\mathrm{SK}(U), \quad (122)$$

followed by the substitution $Y=(v-V)/\alpha$,

$$(v-V)_{xx}/\alpha+3(v-V)(v+V)_x/\alpha^2+(v-V)^3/\alpha^3-\lambda=0, \quad (123)$$

$$\beta(v-V)_t/\alpha-(3/2)[(v-V)_{xxxx}/\alpha+(5(v-V)(v+V)_{xxx} + 15(v+V)_x(v-V)_{xx})/\alpha^2+(15(v-V)^2(v-V)_{xx}+30(v-V)(v+V)_x^2)/\alpha^3 + 30(v-V)^3(v+V)_x/\alpha^4+6(v+V)^5/\alpha^5]_x=0, \quad (124)$$

a result due to Satsuma and Kaup.[37]

The BT of KK arises from the elimination of Y_1 between (116), (117) and (119) [Eq. (118) must be discarded], which results in the two equations for $Z=Y$,

$$Y_{xx}-(3/4)Y_x^2/Y+3YY_x/2+Y^3/4+6(U/\alpha)Y-2\lambda=0, \quad (125)$$

$$\beta Y_t-(3/16)[3Y^5+15YY_x^2+30Y^2Y_{xx}+8Y_{xxxx}+30(Y^3+2Y_{xx})(Y_x+4V_x/\alpha) + 60Y(Y_x+4V_x/\alpha)^2+30Y_x(Y_{xx}+4V_{xx}/\alpha)+20Y(Y_{xxx}+4V_{xxx}/\alpha)]_x=0, \quad (126)$$

$$\beta((Y_{xx})_t-(Y_t)_{xx})/Y=-(6/\alpha)\mathrm{KK}(U), \quad (127)$$

followed by the substitution $Y=2(v-V)/\alpha$,

$$(v-V)_{xx}/\alpha-(3/4)(v-V)_x^2/(\alpha(v-V))+3(v-V)(v+V)_x/\alpha^2+(v-V)^3/\alpha^3-\lambda=0, \quad (128)$$

$$\beta(v-V)_t/\alpha-(3/2)[2(v-V)_{xxxx}/\alpha+60(v-V)^3(v+V)_x/\alpha^4+12(v-V)^5/\alpha^5 + (10(v-V)(v+V)_{xxx}+30(v+V)_x(v-V)_{xx}+15(v-V)_x(v+V)_{xx})/\alpha^2 + (30(v-V)^2(v-V)_{xx}+60(v-V)(v+V)_x^2+15(v-V)(v-V)_x^2)/\alpha^3]_x=0. \quad (129)$$

The simple form of the conservative equations (124) and (129) results from the addition of suitable differential consequences of (123) and (128).

If we write (116)–(117) in the variables $(Y_1, Z_2=Z^{-1})$,

$$Y_{1,x}=-Y_1^2/2+\lambda Z_2-3U/\alpha, \quad (130)$$

$$Z_{2,x}=-2Y_1Z_2+1, \quad (131)$$

both systems (17)–(18) and (130)–(131) are coupled Riccati systems, with the difference that the transformation from Y_1 to ψ_x/ψ is a point transformation while the one from Z_2 to ψ_x/ψ is a contact one. Thus, the Riccati system (17)–(18) is in the classification of linearizable coupled Riccati systems given by Lie (this is the projective one), while the Riccati system (130)–(131) is outside it.

The bilinear representation of the BT of SK

$$(D_x^3-\lambda)f.g=0, \tag{132}$$

$$(D_x^5+5\lambda D_x^2-(2/3)\beta D_t)f.g=0, \tag{133}$$

$$v=\alpha\partial_x \log f, \quad V=\alpha\partial_x \log g, \tag{134}$$

was already known;[37] the one for KK requires four fields

$$(D_x^4-8\lambda D_x)f.g-(1/2)(gh_1+fh_2)=0, \tag{135}$$

$$(D_x^5-(16\beta/9)D_t)f.g-(5/6)(D_xg.h_1-D_xf.h_2)=0, \tag{136}$$

$$D_x^4f.f-fh_1=0, \tag{137}$$

$$D_x^4g.g-gh_2=0, \tag{138}$$

$$v=(\alpha/2)\partial_x \log f, \quad V=(\alpha/2)\partial_x \log g, \tag{139}$$

and this is a new result, for which the help of Johan Springael is warmly acknowledged. Let us recall, for reference, the bilinear representation of the PDEs[37,39]

$$\text{SK:}(D_x^6+\beta D_tD_x)f.f=0, \quad v=\alpha\partial_x \log f, \tag{140}$$

$$\text{KK:}(D_x^6+16\beta D_xD_t)f.f+15D_x^2f.h=0, \quad D_x^4f.f=fh, \quad v=(\alpha/2)\partial_x \log f. \tag{141}$$

VII. CONCLUSION

Finding the BT of a PDE is equivalent to finding its Lax pair and its DT. At every order of the assumed Lax pair with unknown coefficients, there exists only a finite list of admissible Darboux transformations, which makes the process of finding the BT a finite one given some upper bound for the Lax order. In the case of $1+1$-dimensional evolution equations, these DTs are the involutions, like (64) and (65), of nonlinear ODEs classified by the Painlevé school. The Kaup–Kupershmidt equation has offered the simplest, nontrivial application of this new method.

Complementary group resolution of the SU(n) outer multiplicity problem. I. The Littlewood rules and a complementary $\mathcal{U}(2n-2)$ group structure

Feng Pan[a] and J. P. Draayer
Department of Physics and Astronomy, Louisiana State University, Baton Rouge, Louisiana 70803-4001

(Received 28 April 1997; accepted for publication 8 June 1998)

A complementary group to SU(n) is found that realizes all features of the Littlewood rules for Kronecker products of SU(n) representations. This is accomplished by considering a state of SU(n) to be a special Gel'fand state of the complementary group $\mathcal{U}(2n-2)$ with labels of the latter used to distinguish multiple occurrences of irreducible representations of SU(n) (irreps) in the SU(n)$\times$SU(n)$\downarrow$SU(n) decomposition that is obtained from the Littlewood rules. Furthermore, this realization also helps us to determine SU(n)$\supset$SU($n-1$)$\times$U(1) Reduced Wigner Coefficients (RWCs, frequently called Isoscalar Factors) and Clebsch–Gordan Coefficients [CGCs, or full (nonreduced) Wigner Coefficients] of SU(n), using algebraic or numeric methods, in either the canonical or a noncanonical basis. New explicit formulas for the SU(3) and SU(4) multiplicities are obtained by using this technique. © *1998 American Institute of Physics.* [S0022-2488(98)04410-7]

I. INTRODUCTION

Reduced Wigner Coefficients (RWCs) of SU(n)$\supset$SU($n-1$)$\times$U(1) are of importance in many physical applications. Except for those of SU(2), which have been discussed extensively and expressed in various forms, RWCs of SU(n)$\supset$SU($n-1$)$\times$U(1), which can be used to evaluate Clebsch–Gordan Coefficients (CGCs) of SU(n) in the canonical basis according to the Racah Factorization Lemma, have only been given analytically for some special cases. [Reduced Wigner Coefficients are often called Isoscalar Factors and Clebsch–Gordan Coefficients as used in this article are also known as full (nonreduced) Wigner Coefficients or simply Wigner Coefficients.] The biggest challenge involves the outer multiplicity in the decomposition of Kronecker products of SU(n)$\times$SU(n)$\downarrow$SU(n). The first nontrivial but simplest $n=3$ case was studied as part of the first applications of nonmultiplicity-free CGCs of SU(3) in nuclear and particle physics. There are several distinct approaches to the problem: (i) a tensor operator method; (ii) an infinitesimal generator approach, in which matrix elements of SU(n) generators are used to determine recursion relations for the RWCs and CGCs; (iii) a polynomial basis and generating invariants, in which a convenient model space is used to realize a basis of irreps; and (iv) use of the Schur–Weyl duality relation between SU(n) and the symmetric group S_f. Among these are various means of addressing the problem; indeed, sometimes a combination of two or more methods is used. There are also different schemes for handling the outer multiplicity, especially for SU(3), and these are usually referred to as either the canonical or a noncanonical labeling scheme.

A thoroughly discussed approach to this problem is the canonical unit tensor operator method developed by Biedenharn and collaborators in a series of publications.[1–8] The unit tensor operator approach is particularly useful for deriving multiplicity-free CGCs of U(n). The techniques that are part of this method have also proven to be useful in other approaches, but this methodology has not been used to produce a closed algebraic solution to the general outer multiplicity problem. This method was revisited in the late 1980s in a Bargmann–Hilbert space representation using Vector Coherent State (VCS) theory.[9–11] Although the results seem no simpler than those found earlier, they do show that there is a relationship between U(3)$\supset$U(2) RWCs and $3nj$ coefficients

of SU(2), with some of these being a consequence of the Schur–Weyl duality relation between the unitary and symmetric groups given by Ališuaskas *et al.*[12–14]

Noncanonical definitions of SU(n) outer multiplicity labels, especially of SU(3), have also been discussed rather extensively, for example, by Moshinsky *et al.*,[15,16] Derome and Sharp,[17,18] Resnikoff,[19] and Pluhař *et al.*[20,21] A wider class of RWCs has been considered by Hecht,[22] Klimyk and Gavrilik,[23] and Le Blanc and Rowe,[24] who used definitions related to the canonical scheme. Generally, however, these results are for noncanonical labeling schemes. A further example is the extensive work of Ališauskas,[25–28] who investigated paracanonical coupling relations and symmetries and various pseudocanonical coupling schemes, which lead to biorthogonalities among the corresponding coefficients. It should be stated that noncanonical definitions for SU(n) coupling coefficients normally lead to nonorthogonality with respect to the outer multiplicity. In such cases, a Gram–Schmidt process can be adopted to recover orthonormality, but this procedure includes an arbitrary choice in ordering the orthogonalized elements. In addition, except for a few simple cases where analytical expressions are available, only numerical implementations of the corresponding algorithm is possible.[24–28]

The Schur–Weyl duality relation between SU(n) and S_f is another method that has been used by several authors. This method was studied first by Moshinsky,[16] Kramer,[29] and Alisauskas and Jucy,[12–14] who were able to show that the scheme works for nonmultiplicity-free as well as multiplicity-free cases. For nonmultiplicity-free couplings, however, numerical orthogonalizition is again required. This approach is illustrated for some simple cases in the work of Chen *et al.*,[30] and by Pan and Chen for the $U_q(n)$ generalization of U(n).[31]

Based on these methods, several packages have been developed for numerically evaluating CGCs of U(n), especially of SU(3). The earliest one is the well-known Akiyama–Draayer code for SU(3) based on a combination of the tensor operator and infinitesimal generator methods.[32,33] Another is Chen's code for various couplings of U(n) based on symmetric group techniques.[30] Still another is the RWC and CGC code for SU(3) developed by Kaeding and Williams.[34–36]

Very recently, Parkash and Sharatchandra worked out an algebraic formula for the general CGCs of SU(3).[37] The method used in their paper is based on a polynomial realization in Bargmann space using generating functions, which was first studied by Shelepin and Karasev for the multiplicity-free case.[38,39] Up to a normalization factor, the final results are expressed in terms of a restricted sum over 33 variables. To determine the value of a single CGC within this formulation is not easy; neither the algebraic nor numeric results are simple. Nevertheless, it is the first algebraic expression for CGCs of SU(3) with multiplicity. It should be noted, however, that to extend this method to $n \geqslant 4$ cases will be much more complicated. Therefore, another simpler and more direct approach to a resolution of the outer multiplicity problem for SU(n) is desirable.

The present paper is the first (I) in a series which has this as its objective. First of all, a complementary group $\mathcal{U}(2n-2)$ realization of the Kronecker product SU(n)$\times$SU(n)$\downarrow$SU(n) is found according to the well-known Littlewood rules. The scheme gives a simple exact resolution of the outer multiplicity. An analysis of the Littlewood rules is also used to derive a new multiplicity formula for SU(n). Examples are given for the SU(3) and SU(4) cases, which can, in principle, be extended to SU(n). A procedure for evaluating CGCs or RWCs of SU(n)$\supset$SU($n-1$)$\times$U(1) will be given for the SU(3) and SU(4) cases in Parts (II) and (III) of the series, respectively. It should be noted that the RWCs or CGCs obtained in this way are orthogonal with respect to the outer multiplicity labels, and in this sense the scheme is canonical.

II. LITTLEWOOD RULES AND THE COMPLEMENTARY GROUP

The Littlewood rules[40] for determining Kronecker products of SU(n) in SU(n)$\times$SU(n)$\supset$SU(n) is a reflection of the Schur–Weyl duality relation between SU(n) and the symmetric group S_f. According to the Schur–Weyl duality relation, an irrep $[\lambda]$ of SU(n) can also be regarded as the same irrep of S_f with $\Sigma_{i=1}^{n}\lambda_i = f$. Therefore, the Kronecker product of two SU(n) irreps $[\lambda]\times[\mu]$ in the decomposition SU(n)$\times$SU(n)$\downarrow$SU(n) can be obtained from the product of two S functions of the corresponding symmetric groups:[41]

$$[\lambda]\times[\mu] = \sum_{\nu} \{\lambda\mu\nu\}[\nu], \tag{2.1}$$

where $\{\lambda\mu\nu\}$ is the number of occurrences of $[\nu]$ in the product. To determine all the irreps that appear on the rhs of (2.1), one can use the well-known Littlewood rules:[40] First fill in the Young diagram $[\mu]=[\mu_1,\mu_2,\ldots,\mu_n]$ with μ_1 symbols a_1 in the first row, μ_2 symbols a_2 in the second row, μ_3 symbols a_3 in the third row,..., and μ_n symbols a_n in the nth row. Then, the final irrep denoted by a Young diagram $[\nu]$ can be obtained by augmenting the Young diagram $[\lambda]$ with the μ_1 a_1 symbols, μ_2 a_2 symbols,..., and μ_n a_n symbols, respectively, in ways specified by the following three conditions.

(a) No identical symbols should appear in the same column of the diagram.

(b) If the $a_1,a_2,\ldots,a_n$ symbols are counted from right to left starting at the top, then at each stage the number of a_1 symbols must not be less than the number of a_2 symbols, which must not be less than the number of a_3 symbols, and so on.

(c) The Young diagram $[\nu]$ obtained after the addition of each symbol must be standard, that is, $\nu_1\geqslant\nu_2\geqslant\cdots\geqslant\nu_n$.

The Young diagram $[\nu]$ filled with symbols $a_1,a_2,\ldots,a_n$ under restrictions (a)–(c) can be regarded as a special Weyl tableau of a unitary group. Recall some basic definitions for the Weyl tableau: A Weyl tableau is a Young diagram with the boxes filled by a set of ordered indices $a_1,a_2,\ldots,a_n$, with the filling done such that (i) no identical symbols should appear in the same column; (ii) the symbols must be in nondecreasing order from left to right in any row and in increasing order from top to bottom in any column.

Every irrep $[\nu]$ of U(n) can be characterized by a partition $[\nu]\equiv[m_{in}]\equiv[m_{1n},m_{2n},\ldots,m_{nn}]$ of n non-negative integers obeying the relation $m_{in}\geqslant m_{i+1n}$; conversely, every such partition denotes a unique irrep. It is well known that any basis vector of U(n) in its canonical basis, i.e., the basis adapted to $\mathrm{U}(n)\supset\mathrm{U}(n-1)\supset\cdots\supset\mathrm{U}(2)\supset\mathrm{U}(1)$ can be labeled by the Gel'fand symbol,

$$\begin{pmatrix}[\nu]\\(m)\end{pmatrix}=\begin{pmatrix} m_{1n} & m_{2n} & \cdots & m_{n-1n} & m_{nn}\\ m_{1n-1} & m_{2n-1} & \cdots & m_{n-1n-1} & \\ & \cdots & & & \\ & m_{12} & m_{22} & & \\ & & m_{11} & & \end{pmatrix}.$$

Equivalently, sometimes the Weyl tableau is also convenient in labelling the canonical basis of U(n). The one-to-one correspondence between the Gel'fand symbol and the Weyl tableau is realized in the following way:

$$\begin{pmatrix}[\nu]\\(m)\end{pmatrix}\Longleftrightarrow W^{[\nu]}=\begin{array}{|l|l|l|l|l|}\hline f_{11}a_1\text{'s} & f_{12}a_2\text{'s} & \cdots & \cdots & f_{1n}a_n\text{'s}\\\hline f_{22}a_2\text{'s} & f_{23}a_3\text{'s} & \cdots & f_{2n}a_n\text{'s} & \\\cline{1-4} \cdots\cdots\cdots & & & & \\\cline{1-1} f_{nn}a_n\text{'s} & & & & \\\cline{1-1}\end{array} \tag{2.2}$$

where

$$\begin{aligned} &f_{1k}=m_{1k}-m_{1k-1},\quad f_{2k}=m_{2k}-m_{2k-1},\ldots,\\ &f_{k-1k}=m_{k-1k}-m_{k-1k-1},\quad f_{kk}=m_{kk}. \end{aligned} \tag{2.3}$$

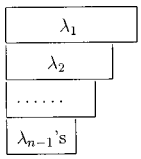
In other words, a Weyl tableau $W^{[\nu]}$ filled with $a_1,a_2,\ldots,a_n$, corresponds to the n partitions, $[\nu](=[m_{in}]),[m_{in-1}],\ldots,[m_{i2}]$ and $[m_{11}]$ of a Gel'fand symbol, where $[m_{ik}]$ is the Young diagram resulting from deleting all the boxes in the Weyl tableau occupied by the symbols $a_n,a_{n-1},\ldots,a_{k+1}$.

It is clear that the definition of a Weyl tableau and the rules for placing symbols in a Young diagram given by Littlewood rules are the same except for some of the restrictions given by (b), that is, a_k's can appear in the ith rows with $i<k$, and the number of a_k's can be greater than the number of a_i's with $i<k$ counted from right to left and from top to bottom, while these cases are forbidden by the restriction (b) of the Littlewood rules. Therefore, it is obvious that the Littlewood

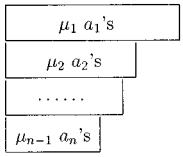
rules for placing symbols in a Young diagram can be regarded as a special Weyl tableau for a unitary group. Hence, under the restrictions of Littlewood rules given by (b), one obtains a special Gel'fand basis of a corresponding unitary group, which is called the complementary group for Kronecker products of SU(n).

Assume the irrep $[\lambda]$ has p_1 rows, while $[\mu]$ has p_2 rows. Then, the final irrep $[\nu]$ has, at most, p_1+p_2 rows, with $p_1+p_2 \leqslant n$. Therefore, the complementary group corresponding to the Kronecker product of SU(n) is $\mathcal{U}(p_1+p_2)$. A general SU(n) irrep has, at most, $n-1$ rows because one can always use the equivalence condition $[m_{1n}m_{2n}\cdots m_{nn}]=[m_{1n}-m_{nn},m_{2n}-m_{nn},\ldots,m_{1n-1}-m_{nn}]$ to remove the nth row if it exists. From this, it follows that the minimum complementary group is $\mathcal{U}(2n-2)$ for general Kronecker products of SU(n).

Using the correspondence between the Weyl tableau and a Gel'fand symbol, one can easily find the following relations among coupled and uncoupled state labels of $\mathcal{U}(2n-2)$.



$$\Rightarrow \begin{pmatrix} [\lambda_1\lambda_2\cdots\lambda_{n-1}\dot{0}] \\ \Gamma_1 \end{pmatrix} = \begin{pmatrix} [\lambda_1\lambda_2\cdots\lambda_{n-1}\dot{0}] & \mathcal{U}(2n-2) \\ \cdots\cdots & \\ [\lambda_1\lambda_2\cdots\lambda_{n-1}\dot{0}] & \mathcal{U}(n-1) \\ \rho & \end{pmatrix} \tag{2.4a}$$



$$\Rightarrow \begin{pmatrix} [\mu_1\mu_2\cdots\mu_{n-1}\dot{0}] \\ \Gamma_2 \end{pmatrix} = \begin{pmatrix} [\mu_1\mu_2\cdots\mu_{n-1}\dot{0}] & \mathcal{U}(2n-2) \\ [\mu_1\mu_2\cdots\mu_{n-2}\dot{0}] & \mathcal{U}(2n-3) \\ \cdots\cdots & \\ [\mu_1\mu_2\dot{0}] & \mathcal{U}(n+1) \\ [\mu_1\dot{0}] & \mathcal{U}(n) \\ [\dot{0}] & \mathcal{U}(n-1) \end{pmatrix} \tag{2.4b}$$

while the final coupled $\mathcal{U}(2n-2)$ basis is

$$\begin{pmatrix} [\nu_1\nu_2\cdots\nu_n\dot{0}] \\ \Gamma(\tau) \end{pmatrix} = \begin{pmatrix} [\nu_1\nu_2\cdots\nu_n\dot{0}] & \mathcal{U}(2n-2) \\ (\tau) & \\ [\lambda_1\lambda_2\cdots\lambda_{n-1}\dot{0}] & \mathcal{U}(n-1) \\ \rho & \end{pmatrix}, \tag{2.4c}$$

where (τ) stands for intermediate sublabels between $\mathcal{U}(2n-2)$ and $\mathcal{U}(n-1)$ given by the Littlewood rules, which can be regarded simultaneously as the outer multiplicity label of both $\mathcal{U}(2n-2)$ and SU(n), and ρ represents sublabels of $\mathcal{U}(n-1)$, which is unimportant for labeling the multiplicity of SU(n)$\times$SU(n).

In order to make this point clear, let us give an example for SU(3)$\times$SU(3)$\downarrow$SU(3) for the coupling [21]$\times$[21]$\downarrow$[321]. According to our procedure, uncoupled basis vectors of SU(3)$\times$SU(3) for the irreps [21]$\times$[21] can be labeled as

$$\left|\begin{matrix} \Gamma_1 \\ [210] \\ (\nu_1) \end{matrix}\right\rangle \left|\begin{matrix} \Gamma_2 \\ [210] \\ (\nu_2) \end{matrix}\right\rangle = \left|\begin{matrix} \rho \\ [21] \\ [210] \\ [210] \\ (\nu_1) \end{matrix}\right\rangle \left|\begin{matrix} 0 \\ [00] \\ [200] \\ [210] \\ (\nu_2) \end{matrix}\right\rangle, \tag{2.5a}$$

where (ν_1), (ν_2) are sublabels for two SU(3) irreps [210], respectively,

$$\Gamma_1 = \begin{pmatrix} [210] \\ [21] \\ \rho \end{pmatrix}, \quad \Gamma_2 = \begin{pmatrix} [200] \\ [00] \\ 0 \end{pmatrix}, \tag{2.5b}$$

are $\mathcal{U}(4)$ sublabels for the same irreps [2100] required from the Littlewood rule, and ρ stands for unimportant sublabels of $\mathcal{U}(2)$. While the final coupled basis vectors for [321] is denoted by

$$\left|\begin{matrix}\Gamma(\eta)\\ [321]\\ (\nu)\end{matrix}\right\rangle = \left|\begin{matrix}\rho\\ [21]\\ [32-\eta\eta]\\ [321]\\ (\nu)\end{matrix}\right\rangle, \tag{2.5c}$$

where $\eta=0$, or 1, which is determined by the Littlewood rule directly, can be understood as the multiplicity label.

From this procedure, it can be seen that the $\mathcal{U}(2n-2)$ labels are twofold. On the one hand, the final coupled $\mathcal{U}(2n-2)$ sublabels $\Gamma(\eta)$ can be used to label the outer multiplicity of $\mathrm{SU}(n)\times\mathrm{SU}(n)\downarrow\mathrm{SU}(n)$, while the uncoupled $\mathcal{U}(2n-2)$ sublabels Γ_1 and Γ_2 just indicate how the final coupled sublabels of $\mathcal{U}(2n-2)$, which gives the multiplicity labels, can be obtained. General cases for SU(3) and SU(4) will be shown in the next section. Therefore, this situation is similar to the upper Gel'fand pattern introduced by Biedenharn *et al.*,[1–8] in which the upper Gel'fand patterns Γ_2 of $\mathcal{U}(n)$ are used to label the outer multiplicity of $\mathrm{U}(n)\times\mathrm{U}(n)$, while other two upper Gel'fand patterns Γ_1 and Γ of $\mathcal{U}(n)$ are set to the highest weight. While, in our scheme, the sublabels of uncoupled $\mathcal{U}(2n-2)$ labels are fixed according to the Littlewood rule, the final coupled $\mathcal{U}(2n-2)$ sublabels $\Gamma(\eta)$, which can be taken as different values according to the Littlewood rule, are used as outer multiplicity labels for $\mathrm{SU}(n)\times\mathrm{SU}(n)$. However, in the SU(3) case, for example, in their upper pattern scheme, there are some restrictions on the ranges of Γ_{22} in the upper pattern $[\Gamma_{12},\Gamma_{22}]=[m_1+m_2-\lambda_1-2\mu_1-\Gamma_{22},\Gamma_{22}]$ for the coupling $(\lambda_1\mu_1)\times(\lambda_2\mu_2)\downarrow[m_1m_2m_3]$ that come from the Littlewood rules for SU(3). Actually, the ranges of Γ_{22} should be the same as those of η, to be determined in the next section, which cannot be derived directly from restrictions on upper pattern labels. For example, [422] occurs only once in the decomposition $[310]\times[310]$, but there are two sets of upper pattern labels:

$$\begin{pmatrix}\Gamma_{11}\\ \Gamma_{12}\quad\Gamma_{22}\end{pmatrix}=\begin{pmatrix}1\\ 2\quad 0\end{pmatrix};\quad\begin{pmatrix}1\\ 1\quad 1\end{pmatrix}$$

are both allowed by the upper pattern labeling scheme, but according to the Littlewood rules the

$$\begin{pmatrix}1\\ 1\quad 1\end{pmatrix}$$

result should be eliminated. Therefore, in addition to the usual rules for determining allowed upper Gel'fand patterns, restrictions that follow from an application of Littlewood rules must be applied, a result not noted in the papers of Refs. 1–8 and, indeed, one that cannot be deduced directly from their upper Gel'fand pattern methodology. While, in our scheme, the possible values of η gives exactly the outer multiplicity of SU(3). In this sense, the complementary group is meaningless, but it provides us with the labeling scheme for the outer multiplicity of $\mathrm{SU}(n)\times\mathrm{SU}(n)$, and tells us how these labels can be obtained. On the other hand, in order to evaluate the CGCs of $\mathrm{SU}(n)$, one can consider the following $\mathrm{SU}(n)\star\mathcal{U}(2n-2)$ coupling coefficients, for example, in the canonical chain $(\mathrm{SU}(n)\supset\mathrm{SU}(n-1)\supset\cdots\supset\mathrm{U}(1))\star(\mathcal{U}(2n-2)\supset\mathcal{U}(2n-3)\supset\cdots\supset\mathcal{U}(1))$:

$$\left(\begin{matrix}(\Gamma_1) & (\Gamma_2)\\ [\lambda] & [\mu]\\ (\kappa_1) & (\kappa_2)\end{matrix}\middle|\begin{matrix}(\Gamma(\eta))\\ [\nu]\\ (\kappa)\end{matrix}\right), \tag{2.6}$$

where $[\lambda]$, $[\mu]$, and $[\nu]$ are irreps of $\mathrm{SU}(n)$ and $\mathcal{U}(2n-2)$, simultaneously, (Γ_1), (Γ_2), and $(\Gamma(\eta))$ are sublabels of $\mathcal{U}(2n-2)$, and κ_1, κ_2, and κ are sublabels of $\mathrm{SU}(n)$. Using the recoupling method, which will be discussed in detail in paper II, we have

$$\left(\begin{array}{cc|c} (\Gamma_1) & (\Gamma_2) & (\Gamma(\eta)) \\ [\lambda] & [\mu] & [\nu] \\ (\kappa_1) & (\kappa_2) & (\kappa) \end{array}\right) = \sum_{\eta'} \left(\begin{array}{cc|c} \Gamma_1 & \Gamma_2 & \Gamma(\eta') \\ [\lambda] & [\mu] & [\nu] \\ (\kappa_1) & (\kappa_2) & (\kappa) \end{array}\right) \left(\begin{array}{cc|c} \Gamma_1 & \Gamma_2 & \Gamma(\eta') \\ [\lambda] & [\mu] & [\nu] \\ (\Gamma_1) & (\Gamma_2) & (\Gamma(\eta)) \end{array}\right), \tag{2.7}$$

where the coupling coefficient of $SU(n) \star \mathcal{U}(2n-2)$ on the lhs of (2.7) can be evaluated by using many methods, which will be discussed in (II), while, on the rhs of (2.7), there is a sum over the outer multiplicity labels η' of a products of $SU(n)$ and $\mathcal{U}(2n-2)$ CG coefficients, the symbols (Γ_i) with $i=1,2$, and $(\Gamma(\eta))$ are used to denote sublabels of $\mathcal{U}(2n-2)$, which are the same as those derived from the Littlewood rule discussed above, and the same symbols without parentheses are used to label the outer multiplicities in the coupling. Equation (2.7) can be used to derive CGCs of $SU(n)$ algebraically or numerically. A general procedure for SU(3) and SU(4) will be outlined in papers (II) and (III), respectively. From this point of view, the complementary group $\mathcal{U}(2n-2)$ is indeed active in obtaining the CGCs of $SU(n)$.

III. OUTER MULTIPLICITY PROBLEM OF SU(3) AND SU(4)

As noted above, the outer multiplicity in the decomposition of the Kronecker products of $SU(n) \times SU(n) \downarrow SU(n)$ is the main obstacle in applications of algebraic methods to physical problems. There are a lot of articles devoted to this subject. In order to resolve the problem for SU(3), Hecht[22] proposed an external labeling operator of third order, an operator that may be related to the one proposed by Moshinsky[16] in terms of the complementary $U(4) \supset U(2) \times U(2)$ chain. Alisauskas and Kulish[42] have also proposed an external labeling operator, a fourth-order form suggested by Sharp[43] in a study of Yang–Baxter equations. There are also other articles on this subject. For example, new Casimir operators, the so-called chiral Casimirs, were introduced in Refs. 16, and 44–45. Also, various formulas[19,46–49] for the multiplicity of SU(3) exist in the literature, however, such expressions are normally not linked to the SU(3) coupling and recoupling coefficients problem. There is still no general formula for the outer multiplicity of $SU(n)$ with $n \geqslant 4$. In this article and forthcoming papers, the complementary group $\mathcal{U}(2n-2)$ to the $SU(n) \times SU(n) \downarrow SU(n)$ will be shown to be a powerful tool for deriving both multiplicity formulas and coupling and recoupling coefficients of $SU(n)$. Multiplicity formulas for SU(3) and SU(4) are considered below.

(1) *SU(3) case*. Consider the general Keronecker product $(\lambda_1 \mu_1) \times (\lambda_2 \mu_2)$, where the well-known notation for SU(3) in physics is adopted. The irrep $(\lambda \mu)$ can be expressed in terms of a two-rowed Young diagram $[\nu_1 \nu_2]$ with $\nu_1 = \lambda + \mu$ and $\nu_2 = \mu$. Using the Littlewood rules, the decomposition of $(\lambda_1 \mu_1) \times (\lambda_2 \mu_2)$ can be expressed in terms of a quintuple sum,

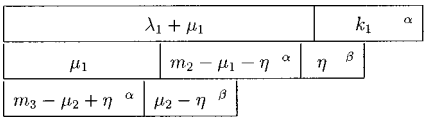
$$\begin{aligned} (\lambda_1 \mu_1) \times (\lambda_2 \mu_2) = & \sum_{k_1=0}^{\lambda_2+\mu_2} \sum_{k_2=0}^{\min(\lambda_1, \lambda_2+\mu_2-k_1)} \sum_{k_3=0}^{\min(\mu_1, \lambda_2+\mu_2-k_1-k_2)} \sum_{n_1=0}^{\min(\lambda_1+k_1-k_2, \mu_2, k_1)} \\ & \times \sum_{n_2=0}^{\min(\mu_2-n_1, \mu_1+k_2-k_3, k_1+k_2-n_1)} [\lambda_1+\mu_1+k_1, \mu_1+k_2+n_1, k_3+n_2], \end{aligned} \tag{3.1}$$

where the constraints

$$\sum_{i=1}^{3} k_i = \lambda_2 + \mu_2, \quad \sum_{i=1}^{2} n_i = \mu_2 \tag{3.2}$$

apply in the summation. Expression (3.1) can be further simplified, for example, to O'Reilly's formula[48] in which only a triple sum appears. However, (3.1) can be used to help determine a multiplicity formula and determine the multiplicity labels of the complementary group.

Consider a Young diagram of the resultant irrep $[m_1m_2m_3]$ according to (3.1) with conditions given by (3.2):



(3.3)

where α and β are the a_i symbols of the Littlewood rules for SU(3). The labels in (3.3) have been arranged to accommodate the constraints of (3.2) and to yield a multiplicity formula in a straightforward manner. In this form it is obvious that a diagram with the same number of boxes in each row can only appear repeatedly when η is not a fixed integer. Therefore, η can be regarded as the multiplicity label of SU(3).

According to Littlewood rules (a)–(c), it is easy to derive the following limits on η:

$$\eta_{\min}\leqslant\eta\leqslant\eta_{\max}, \tag{3.4}$$

where

$$\begin{aligned}\eta_{\max}&=\min(m_1-\lambda_1-\mu_1,\mu_2,m_2-\mu_1,\lambda_2+\mu_2-m_3,\mu_1+\mu_2-m_3,m_2-m_3),\\ \eta_{\min}&=\max(0,\mu_2-m_3,m_2-\lambda_1-\mu_1).\end{aligned} \tag{3.5}$$

Hence, the multiplicity of $[m_1m_2m_3]\equiv(m_1-m_3,m_2-m_3)$ occurring in the Kronecker product $(\lambda_1\mu_1)\times(\lambda_2\mu_2)$ is given by

$$\mathrm{Multi}(\mathrm{SU}_3)=\eta_{\max}-\eta_{\min}+1. \tag{3.6}$$

This expression is very simple and more transparent than others found in the literature.

In this case, the complementary group is $\mathcal{U}(4)$. The Gel'fand symbol of $\mathcal{U}(4)$ corresponding to the resultant irrep of SU(3) given in (3.3) is

$$\begin{pmatrix} & [m_1m_2m_30] & \\ [m_1 & m_2-\eta \quad m_3-\mu_2+\eta] & \\ & [\lambda_1+\mu_1\mu_1] & \\ & \rho & \end{pmatrix}, \quad \eta=\eta_{\min}, \quad \eta_{\min}+1,\ldots,\eta_{\max}, \tag{3.7}$$

where ρ is the intrinsic label for $\mathcal{U}(1)$, which is not important for our purpose. Some conditions in (3.5) can also be easily obtained from the betweenness conditions of the entries in the Gel'fand symbol (3.7). However, the remaining conditions in (3.5) can only be deduced from the Littlewood rules (b), and cannot be obtained from the betweenness conditions. Hence, only one outer multiplicity label is needed in the decomposition of $\mathrm{SU}(3)\times\mathrm{SU}(3)\downarrow\mathrm{SU}(3)$. This is why the CGCs of SU(3) can be determined numerically by using only one type of tensor operator.[32–36]

In contrast with the so-called canonical labeling scheme proposed by Biedenharn *et al.*, in which three independent shifts determined by an upper pattern are introduced, the complementary $\mathcal{U}(4)$ group provides only one outer multiplicity label in the SU(3) case. The complementary group labeling scheme is therefore a very economical way to label the outer multiplicity of SU(3), and by extension of SU(n).

(2) *SU(4) case*. A general SU(4) irrep has three rows. Using the Littlewood rules, the following formula for the decomposition of $\mathrm{SU}(4)\times\mathrm{SU}(4)\downarrow\mathrm{SU}(4)$ can be determined:

$$\begin{aligned}[\lambda_1\lambda_2\lambda_3]\times[\mu_1\mu_2\mu_3]=&\sum_{k_1=0}^{\mu_1}\sum_{k_2=0}^{\min(\mu_1-k_1,\lambda_1-\lambda_2)}\sum_{k_3=0}^{\min(\lambda_2-\lambda_3,\mu_1-k_1-k_2)}\sum_{k_4=0}^{\min(\lambda_3,\mu_1-k_1-k_2-k_3)}\\ &\times\sum_{l_1=0}^{\min(\lambda_1+k_1-\lambda_2-k_2,\mu_2,k_1)}\sum_{l_2=0}^{\min(\lambda_2+k_2-\lambda_3-k_3,\mu_2-l_1,k_1+k_2-l_1)}\end{aligned}$$

$$\times \sum_{l_3=0}^{\min(\lambda_3+k_3-k_4,\mu_2-l_1-l_2,k_1+k_2+k_3-l_1-l_2)} \sum_{n_1=0}^{\min(\lambda_2+k_2+l_1-\lambda_3-k_3-l_2,\mu_3,l_1)}$$

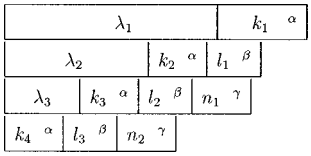
$$\times \sum_{n_2=0}^{\min(\lambda_3+k_3+l_2-k_4-l_3,\mu_3-n_1,l_1+l_2-n_1)}$$

$$\times[\lambda_1+k_1,\lambda_2+k_2+l_1,\lambda_3+k_3+l_2+n_1,k_4+l_3+n_2], \tag{3.8}$$

where the following constraints:

$$\sum_{i=1}^{4} k_i=\mu_1, \quad \sum_{i=1}^{3} l_1=\mu_2, \quad \sum_{i=1}^{2} n_i=\mu_3, \tag{3.9}$$

apply in the summation. In the resultant irrep $[\nu_1\nu_2\nu_3\nu_4]\equiv[\lambda_1+k_1,\lambda_2+k_2+l_1,\lambda_3+k_3+l_2+n_1,k_4+l_3+n_2]$, with the restrictions given by (3.9), there may be six ways to relabel the configuration that leave the irrep unchanged:



(3.10a)

where

$$k_1=\nu_1-\lambda_1, \qquad k_2=\nu_2-\lambda_2-\xi_1-\xi_2,$$

$$k_3=\nu_3-\lambda_3-\mu_2+\xi_1-\xi_3-\xi_5-\xi_6,$$

$$k_4=\nu_4-\mu_3+\xi_2+\xi_3+\xi_5+\xi_6, \tag{3.10b}$$

$$l_1=\xi_1+\xi_2, \qquad l_2=\mu_2-\xi_1-\xi_4+\xi_5, \qquad l_3=\xi_4-\xi_2-\xi_5,$$

$$n_1=\xi_3+\xi_4+\xi_6, \qquad n_2=\mu_3-\xi_3-\xi_4-\xi_6,$$

and α, β, and γ are the symbols filling in each box according to the Littlewood rules. However, by using the following transformation:

$$\eta_1=\xi_1+\xi_2, \quad \eta_2=\xi_3+\xi_4+\xi_6, \quad \eta_3=\xi_4-\xi_2-\xi_5, \tag{3.11}$$

it can be shown that only three variables η_i with $i=1$, 2, and 3 are independent. Therefore, (3.10) can be relabeled in terms of these three variables:

$$k_1=\nu_1-\lambda_1, \qquad k_2=\nu_2-\lambda_2-\eta_1,$$

$$k_3=\nu_3-\lambda_3-\mu_2+\eta_1-\eta_2+\eta_3,$$

$$k_4=\nu_4-\mu_3+\eta_2-\eta_3, \tag{3.12}$$

$$l_1=\eta_1, \qquad l_2=\mu_2-\eta_1-\eta_3,$$

$$l_3=\eta_3, \qquad n_1=\eta_2, \qquad n_2=\mu_3-\eta_2.$$

Applying the Littlewood rules to this result yields the following boundary conditions for the outer multiplicity labels η_1, η_2, and η_3:

$$\eta_{1\,\min}\leqslant\eta_1\leqslant\eta_{1\,\max}, \quad \eta_{2\,\min}\leqslant\eta_2\leqslant\eta_{2\,\max}, \quad \eta_{3\,\min}\leqslant\eta_3\leqslant\eta_{3\,\max}, \tag{3.13}$$

where

$$\begin{aligned}
&\eta_{1\,\min}=\max(0,\nu_2-\lambda_1),\quad \eta_{1\,\max}=\min(\nu_2-\lambda_2,\nu_1-\lambda_1),\\
&\eta_{2\,\min}=\max(\nu_3-\nu_2+\eta_1,0),\quad \eta_{2\,\max}=\min(\eta_1,\mu_3,\nu_3-\nu_4),\\
&\eta_{3\,\min}=\max(2\eta_2-\eta_1+\mu_2+\nu_4-\nu_3-\mu_3,\eta_2-\eta_1+\lambda_3+\mu_2-\nu_3,\eta_2+\nu_4-\lambda_3\\
&\quad-\mu_3,\eta_2+\lambda_1+\lambda_2+\lambda_3+2\mu_2-\nu_1-\nu_2-\nu_3,\eta_1+\lambda_1+\lambda_2+\mu_2-\nu_1\\
&\quad-\nu_2,0,\mathrm{Int}[(\eta_2+\lambda_1+\lambda_2+\lambda_3+2\mu_2-\nu_1-\nu_2-\nu_3)/2]),\\
&\eta_{3\,\max}=\min(\mu_2-\eta_1,\nu_4-\mu_3+\eta_2,\mu_2-\mu_3,\lambda_2-\nu_3+\mu_2-\eta_1+\eta_2,\mu_2-\eta_2),
\end{aligned}\tag{3.14}$$

where $\mathrm{Int}[x]$ is the integer part of x. Thus, the multiplicity of $[\nu_1,\nu_2,\nu_3,\nu_4]\equiv[\nu_1-\nu_4,\nu_2-\nu_4,\nu_3-\nu_4]$ appearing in the Kronecker product $[\lambda_1\lambda_2\lambda_3]\times[\mu_1\mu_2\mu_3]$ can be calculated by

$$\mathrm{Multi}(\mathrm{SU}_4)=\sum_{\eta_1=\eta_{1\,\min}}^{\eta_{1\,\max}}\ \sum_{\eta_2=\eta_{2\,\min}(\eta_1)}^{\eta_{2\,\max}(\eta_1)}\ \sum_{\eta_3=\eta_{3\,\min}(\eta_1,\eta_2)}^{\eta_{3\,\max}(\eta_1,\eta_2)}1. \tag{3.15}$$

The complementary group of the Kronecker product $[\lambda_1\lambda_2\lambda_3]\times[\mu_1\mu_2\mu_3]$ of SU(4) is $\mathcal{U}(6)$, with the following special Gel'fand labels:

$$\left\langle\begin{array}{cc}
[\nu_1\nu_2\nu_3\nu_4] & \mathcal{U}(6)\\
[\nu_1,\nu_2,\nu_3-\eta_2,\nu_4-\mu_3+\eta_2,0] & \mathcal{U}(5)\\
[\nu_1,\nu_2-\eta_1,\nu_3-\mu_2+\eta_1+\eta_3-\eta_2,\nu_4-\mu_3+\eta_2-\eta_3] & \mathcal{U}(4)\\
[\lambda_1\lambda_2\lambda_3] & \mathcal{U}(3)\\
\rho &
\end{array}\right\rangle. \tag{3.16}$$

The Gel'fand labels of $[\lambda_1\lambda_2\lambda_3 0]$ and $[\mu_1\mu_2\mu_3\dot{0}]$ for $\mathcal{U}(6)$ are

$$\left\langle\begin{array}{cc}
[\lambda_1\lambda_2\lambda_3\dot{0}] & \mathcal{U}(6)\\
[\lambda_1\lambda_2\lambda_3\dot{0}] & \mathcal{U}(5)\\
[\lambda_1\lambda_2\lambda_3\dot{0}] & \mathcal{U}(4)\\
[\lambda_1\lambda_2\lambda_3] & \mathcal{U}(3)\\
\rho &
\end{array}\right\rangle \quad\text{and}\quad \left\langle\begin{array}{cc}
[\mu_1\mu_2\mu_3\dot{0}] & \mathcal{U}(6)\\
[\mu_1\mu_2\dot{0}] & \mathcal{U}(5)\\
[\mu_1 0] & \mathcal{U}(4)\\
[\dot{0}] & \mathcal{U}(3)
\end{array}\right\rangle. \tag{3.17}$$

Again, most of the boundary conditions for the multiplicity labels η_1, η_2, and η_3 can be obtained from the betweenness conditions for the Gel'fand symbol shown in (3.16). However, the remaining conditions can only be deduced from the Littlewood rules because (3.16) is a special Gel'fand basis for the canonical chain $\mathcal{U}(6)\supset\mathcal{U}(5)\supset\cdots\supset(2)\supset\mathcal{U}(1)$. From this development it is clear that there are at most, three quantum numbers needed to label the outer multiplicity for the decomposition $\mathrm{SU}(4)\times\mathrm{SU}(4)\downarrow\mathrm{SU}(4)$. In the canonical unit tensor approach proposed by Biedenharn *et al.* for the SU(4) case, there are four shifts out of six upper labels, of which only three labels are independent.[1–8] As for the SU(3) case, restrictions that follow from the Littlewood rules must be applied to eliminate spurious upper Gel'fand patterns.

It should be noted that any SU(n) function, for example, CGCs, RWCs, or Racah coefficients, etc., is rank n independent, and only depends on boxes contained in the Young diagrams of the corresponding irreps because of the Schur-Weyl duality relation between SU(n) and S_f. For example, the multiplicity of the Kronecker product for two two-rowed irreps of SU(n) is the same as that of SU(3), and that for two three-rowed irreps is the same as that of SU(4), and so on. Hence, the results for SU(3) and SU(4) apply for the general SU(n) case as well. As a trivial example, note that the SU(3) multiplicity expression follows from the one for SU(4) in the two-rowed limit ($\eta_1\rightarrow\eta$, $\eta_2=0$, and $\eta_3=0$) of the theory, though this fact cannot be clearly seen from (3.14).

IV. CONCLUSIONS

In this paper, a complementary group $U(2n-2)$ to $SU(n)$ is found that gives a complete realization of all the features of the Littlewood rules in the Kronecker product decomposition of $SU(n)\times SU(n)\downarrow SU(n)$. By using this scheme, the outer multiplicity labels for $SU(n)$ can be easily assigned, being nothing other than a set of sublabels of the special Gel'fand basis of the complementary $\mathcal{U}(2n-2)$ group. Furthermore, within this framework, most of the boundary conditions on the multiplicity labels can be easily obtain from the betweenness conditions of the Gel'fand symbols of $\mathcal{U}(2n-2)$, while the remaining conditions must be deduced from the Littlewood rules. The method was used to obtain simple multiplicity formulas for SU(3) and SU(4). In addition, in the coupling of two $SU(n)$ irreps, the basis for $SU(n)$ can further be labeled by the final $\mathcal{U}(2n-2)$ sublabels η_i obtained from the coupling of two uncoupled basis vectors of the corresponding special Gel'fand basis of $\mathcal{U}(2n-2)$, which are missing within the $SU(n)$ group. This situation is similar to the canonical unit tensor approach proposed by Biedenharn *et al.* However, in the canonical unit tensor approach, there are n independent shifts indicated by the upper pattern of $U(n)$ from the $n(n-1)/2$ upper labels. While these upper indices can be used to label the outer multiplicity of $U(n)$, there may very well be spurious degrees of freedom among the labels, and these have to be eliminated according to restrictions of the Littlewood rules of $SU(n)$.

It should be noted that the same complementary group for a resolution of $SU(n)$ was considered in Ref. 15. However, the method used and the final outcome are all different from those of this article. First, in Ref. 15, the complementary group structure was derived through boson realizations,[16] whereas in the present case it comes directly from the Littlewood rules. Second, according to Ref. 15, the complementary group should be labeled in terms of a noncanonical chain $\mathcal{U}(2n-2)\supset\mathcal{U}(n-1)\times\mathcal{U}(n-1)$. In this way, the RWCs of $SU(n)$ cannot be derived easily because new inner multiplicity occurs in the decomposition $\mathcal{U}(2n-2)\downarrow\mathcal{U}(n-1)\times\mathcal{U}(n-1)$. In order to overcome this problem, another type of Wigner coefficients, so-called auxiliary Wigner coefficients, was introduced, which is different from the standard definition and which satisfies other orthogonality conditions. These special Wigner coefficients will be considered in the next paper, where it will also be shown that one can derive analytical expressions for some simple cases and algorithms for $SU(n)$ RWCs or CGCs with general multiplicity in canonical as well as noncanonical bases if the multiplicity-free coefficients in these bases are known.

The complementary $\mathcal{U}(2n-2)$ group scheme for labeling outer multiplicities in Kronecker products of $SU(n)$ is canonical because the basis of $SU(n)$ labeled in this way is orthogonal with respect to the outer multiplicity labels. A general procedure for evaluating RWCs or CGCs for SU(3) and SU(4) will be given in forthcoming papers.

Complementary group resolution of the SU(n) outer multiplicity problem. II. Recoupling approach for SU(3)⊃U(2) reduced Wigner coefficients

Feng Pan[a] and J. P. Draayer
Department of Physics and Astronomy, Louisiana State University, Baton Rouge, Louisiana 70803-4001

(Received 6 August 1997; accepted for publication 8 June 1998)

A general procedure for the derivation of SU(3)⊃U(2) reduced Wigner coefficients (RWCs) for the coupling $(\lambda_1\mu_1)\times(\lambda_2\mu_2)\downarrow(\lambda\mu)^{\eta}$, where η is the outer multiplicity label required in the decomposition, is proposed based on a recoupling approach that follows the complementary group technique for a resolution of the outer multiplicity of SU(n) introduced in Part (I) of this series. RWCs of SU(n) are not unique under a canonical resolution of the outer multiplicity; the transformation from one set to another are elements of SO(m), where m is the number of occurrences of the $(\lambda\mu)$ irrep in the decomposition $(\lambda_1\mu_1)\times(\lambda_2\mu_2)\downarrow(\lambda\mu)$. A special resolution of the multiplicity is identified that leads to a recursive procedure for the determination of RWCs. New features of these special RWCs and differences from those obtained with other choices are discussed. The method can be applied to the derivation of general SU(n) Wigner or RWCs. Algebraic expressions for another kind of RWCs, the so-called reduced auxiliary Wigner coefficients for SU(3)⊃U(2), are also obtained. © *1998 American Institute of Physics.* [S0022-2488(98)03210-1]

I. INTRODUCTION

Wigner coefficients (WCs) or reduced Wigner coefficients (RWCs) of SU(3) in the SU(3)⊃U(2) reduction have been discussed by many authors, including, for example, Biedenharn *et al.*[1–10] using a canonical unit tensor operator method, Moshinsky *et al.*[11–14] using an infinitesimal generator approach along with a complementary group prescription, and most recently Ališauskas *et al.* using a symmetric group approach[15–17] and paracanonical and pseudocanonical coupling schemes.[18–21] Certain classes of RWCs have been considered by Hecht,[22] Resnikoff,[23] Shelepin and Karasev,[24,25] Klimyk and Gavrilik,[26] Le Blanc and Rowe,[27] and others. Among these approaches, only the unit tensor operator method is canonical in the sense that it leads directly to the usual RWC orthogonality relations. Other methods for labeling the outer multiplicity are noncanonical, i.e., the RWCs produced are in general nonorthogonal with respect to the outer multiplicity label. In this case a Gram–Schmidt process must be adopted, which then depends upon an arbitrary choice of order for carrying out the orthogonalization. In this case a numerical algorithm is required such as the one used by Draayer and Akiyama[28,29] or Kaeding and Williams.[30–32] In Ref. 33, RWCs associated with the 27-plet operator, which has a maximum multiplicity of three, are studied in full detail. Recently, Parkash and Sharatchandra[34] worked out an algebraic formula for general WCs for SU(3) in the canonical basis. However, the final result, which involves a summation over 33 variables with some restrictions, requires a separate normalization procedure. This means the scheme is neither algebraically or numerically easy to implement.

In this paper, the complementary group representation proposed in (I) is used to determine RWCs of SU(3)⊃U(2) from known multiplicity-free RWCs through simple recoupling procedures. This new approach, in principle, is labeling scheme independent. For example, the RWCs of SU(3)⊃U(2) in the scheme proposed by Biedenhran *et al.* can be derived using the present method. However, values of the RWCs with different canonical outer multiplicity labeling

schemes will be related to one another through an SO(m) group transformation within the multiplicity space.

In Sec. II, the nonuniqueness of the concept of a canonical resolution of the multiplicity is addressed with the transformation from one set of RWCs to another shown to be elements of SO(m), where m is the number of occurrences of the resultant irrep in the decomposition $(\lambda_1\mu_1)\times(\lambda_2\mu_2)$. A special choice for a resolution of the outer multiplicity is then identified, one that yields a recursive procedure for the determination of RWCs with multiplicity. In Sec. III, a new recoupling procedure is proposed for the evaluation of the RWCs from known multiplicity-free RWCs of SU(n)$\supset$U($n-1$) given previously by Ališauskas *et al.*[15] New features of these RWCs, different from ones with other choices for the outer multiplicity, are discussed in Sec. IV. In Sec. V, an analytical expression for another kind of RWCs, the so-called reduced auxiliary WCs proposed by Brody, Moshinsky, and Renero[11] is derived using the recoupling approach. Further observations are given in Sec. VI.

II. RELATIONS AMONG DIFFERENT CHOICES FOR THE MULTIPLICITY LABELS

Let $|[\lambda]\xi,\rho\rangle\equiv|[\lambda_1][\lambda_2][\lambda]\xi,\rho\rangle$ be coupled basis vectors of U(n)$\times$U(n)$\downarrow$U(n), where ξ denotes multiplicity labels that are needed in the decomposition $[\lambda_1]\times[\lambda_2]\downarrow[\lambda]$, and ρ denotes sublabels of the resultant irrep $[\lambda]$. The completeness condition for $|[\lambda]\xi,\rho\rangle$ is

$$\sum_{\xi[\lambda]\rho}|[\lambda]\xi,\rho\rangle\langle[\lambda]\xi,\rho|=1. \tag{2.1}$$

The choice for the multiplicity labels is not unique. If there are m distinct ξ values, denoted $\xi=\xi_1,\xi_2,\ldots,\xi_m$, the transformation from one scheme to another is given by

$$|[\lambda]\eta,\rho\rangle=\sum_{\xi}y(\xi,\eta)|[\lambda]\xi,\rho\rangle, \tag{2.2}$$

where η denotes another set of multiplicity labels for U(n) and $y(\xi,\eta)$ is an element of an SU(m) transformation between the two. This can be seen by noting that

$$\begin{aligned}\sum_{\xi}y(\xi,\eta)y^*(\xi,\eta')&=\delta_{\eta\eta'},\\ \sum_{\eta}y(\xi,\eta)y^*(\xi',\eta)&=\delta_{\xi\xi'}.\end{aligned} \tag{2.3}$$

The $\{y(\xi,\eta)\}$ define a unitary transformation of the basic representation of SU(m). A unitary transformation $\mathbf{Y}\in$SU(m), where m is the number of occurrences of $[\lambda]$ in the decomposition $[\lambda_1]\times[\lambda_2]$, that transforms from one set of outer multiplicity labels to another always exists. Usually, the WCs of U(n) are taken to be real in which case the internal symmetry group for the transformation of the outer multiplicity labels can then be chosen to be SO(m). It is clear that the dimension of the transformation group is the number of occurrences of the resultant irrep $[\lambda]$ in the decomposition $[\lambda_1]\times[\lambda_2]\downarrow[\lambda]$, and the basis vectors of $[\lambda]$ remain orthonormal with respect to one another under the transformation. This freedom accounts for the fact that there exists different forms for RWCs or WCs with respect to the outer multiplicity labels. In what follows, RWCs are considered to be real.

Although the discussion will now be restricted to SU(3)$\supset$U(2), it can be extended easily to the general SU(n) case. The common notation for SU(3) irreps $(\lambda\mu)\equiv[\lambda+\mu,\mu]$ will also be used, where $[\lambda+\mu,\mu]$ is a usual two-rowed label corresponding to the irrep described by the two-rowed Young diagram with $\lambda+\mu$ boxes in the first row, and μ boxes in the second row. In (I) it was shown that there is only one multiplicity label needed in the decomposition $(\lambda_1\mu_1)\times(\lambda_2\mu_2)\downarrow[m_1m_2m_3]$. The multiplicity is labeled ξ with $\xi=\xi_1,\xi_2,\ldots,\xi_m$, where m is the number of occurrences of $[m_1m_2m_3]$ in the decomposition.

The key relation in our evaluation of SU(3) WCs or RWCs is the transformation

$$\sum_{\xi}\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2)\\ \rho_1 & \rho_2\end{matrix}\middle|\begin{matrix}\xi[m_1m_2m_3]\\ \rho\end{matrix}\right\rangle y(\xi,\eta)=\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2)\\ \rho_1 & \rho_2\end{matrix}\middle|\begin{matrix}\eta[m_1m_2m_3]\\ \rho\end{matrix}\right\rangle, \quad (2.4)$$

where ρ_1, ρ_2, and ρ are sublabels of SU(3) if

$$\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2)\\ \rho_1 & \rho_2\end{matrix}\middle|\begin{matrix}\xi[m_1m_2m_3]\\ \rho\end{matrix}\right\rangle$$

is a WC or if a RWC then the corresponding U(2) labels, and the $y(\xi,\eta)$ are a special set of matrix elements of SO(m) chosen in a manner that will now be specified.

Assume

$$\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2)\\ \rho_1 & \rho_2\end{matrix}\middle|\begin{matrix}\xi[m_1m_2m_3]\\ \rho\end{matrix}\right\rangle, \quad \xi=\xi_1,\xi_2,\ldots,\xi_m, \quad (2.5)$$

is a set of WCs satisfying the orthogonality relation

$$\sum_{\rho_1\rho_2}\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2)\\ \rho_1 & \rho_2\end{matrix}\middle|\begin{matrix}\xi[m_1m_2m_3]\\ \rho\end{matrix}\right\rangle\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2)\\ \rho_1 & \rho_2\end{matrix}\middle|\begin{matrix}\xi'[m_1'm_2'm_3']\\ \rho'\end{matrix}\right\rangle=\delta_{m_im_i'}\delta_{\xi\xi'}\delta_{\rho\rho'}, \quad (2.6a)$$

$$\sum_{\xi\rho m_i}\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2)\\ \rho_1 & \rho_2\end{matrix}\middle|\begin{matrix}\xi[m_1m_2m_3]\\ \rho\end{matrix}\right\rangle\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2)\\ \rho_1' & \rho_2'\end{matrix}\middle|\begin{matrix}\xi[m_1m_2m_3]\\ \rho\end{matrix}\right\rangle=\delta_{\rho_1\rho_1'}\delta_{\rho_2\rho_2'}, \quad (2.6b)$$

or RWCs satisfying

$$\sum_{\xi m_i}\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2)\\ \rho_1 & \rho_2\end{matrix}\middle|\begin{matrix}\xi[m_1m_2m_3]\\ \rho\end{matrix}\right\rangle\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2)\\ \rho_1' & \rho_2'\end{matrix}\middle|\begin{matrix}\xi[m_1m_2m_3]\\ \rho\end{matrix}\right\rangle=\delta_{\rho_1\rho_1'}\delta_{\rho_2\rho_2'}, \quad (2.6c)$$

$$\sum_{\rho_1\rho_2}\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2)\\ \rho_1 & \rho_2\end{matrix}\middle|\begin{matrix}\xi[m_1m_2m_3]\\ \rho\end{matrix}\right\rangle\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2)\\ \rho_1 & \rho_2\end{matrix}\middle|\begin{matrix}\xi'[m_1'm_2'm_3']\\ \rho\end{matrix}\right\rangle=\delta_{m_im_i'}\delta_{\xi\xi'}. \quad (2.6d)$$

According to the Schur–Weyl duality relation, the RWCs for SU(3)⊃U(2) given by (2.5) are also RWCs for SU(4)⊃U(3) for the same coupling with the same set of outer multiplicity labels $\{\xi_i\}$. Also, according to the complementary group technique outlined in (I), the complementary group for the SU(3) coupling is $\mathcal{U}(4)$. Therefore, consider the same coupling of $\mathcal{U}(4)$ in the special Gel'fand basis assigned according to the Littlewood rule, namely,

$$\left\langle \begin{matrix}[\lambda_1+\mu_1,\mu_1] & [\lambda_2+\mu_2,\mu_2]\\ [\lambda_1+\mu_1,\mu_1] & [\lambda_2+\mu_2,0]\end{matrix}\middle|\begin{matrix}\xi[m_1m_2m_3]\\ [m_1,m_2-\eta,m_3-\mu_2+\eta]\end{matrix}\right\rangle. \quad (2.7)$$

Next recall that there is an $m\times m$ orthonormal matrix Y that transforms the RWCs or WCs between two sets of multiplicity labels (ξ) and ($\tilde{\eta}$), where the range of ξ and $\tilde{\eta}$ is the same as the sublabels η in the SU(3) subirrep $[m_1,m_2-\eta,m_3-\mu_2+\eta]$. Specifically, in (I) it is shown that the number of occurrences of $[m_1,m_2,m_3]$ in the Kronecker product $[\lambda_1+\mu_1,\mu_1]\times[\lambda_2+\mu_2,\mu_2]$ can be described exactly by η within the range

$$\eta_{\min}\leqslant\eta\leqslant\eta_{\max} \quad (2.8a)$$

where

$$\eta_{\max}=\min(m_1-\lambda_1-\mu_1,\mu_2,m_2-\mu_1,\lambda_2+\mu_2-m_3,\mu_1+\mu_2-m_3,m_2-m_3), \quad (2.8b)$$

$$\eta_{\min}=\max(0,\mu_2-m_3,m_2-\lambda_1-\mu_1).$$

Thus, we require

$$\sum_{\xi} y(\xi,\eta)\left\langle \begin{matrix}[\lambda_1+\mu_1,\mu_1] & [\lambda_2+\mu_2,\mu_2]\\ [\lambda_1+\mu_1,\mu_1] & [\lambda_2+\mu_2,0]\end{matrix}\middle| \begin{matrix}\xi[m_1m_2m_3]\\ [m_1,m_2-\eta,m_3-\mu_2+\eta]\end{matrix}\right\rangle$$
$$=\left\langle \begin{matrix}[\lambda_1+\mu_1,\mu_1] & [\lambda_2+\mu_2,\mu_2]\\ [\lambda_1+\mu_1,\mu_1] & [\lambda_2+\mu_2,0]\end{matrix}\middle| \begin{matrix}\tilde{\eta}[m_1m_2m_3]\\ [m_1,m_2-\eta,m_3-\mu_2+\eta]\end{matrix}\right\rangle', \tag{2.9}$$

where $\tilde{\eta},\ \eta=\eta_1,\ \eta_2,\ldots,\eta_m$, and the prime indicates a new RWC.

The RWCs,

$$\left\langle \frac{\xi}{\eta}\right\rangle \equiv \left\langle \begin{matrix}[\lambda_1+\mu_1,\mu_1] & [\lambda_2+\mu_2,\mu_2]\\ [\lambda_1+\mu_1,\mu_1] & [\lambda_2+\mu_2,0]\end{matrix}\middle| \begin{matrix}\xi[m_1m_2m_3]\\ [m_1,m_2-\eta,m_3-\mu_2+\eta]\end{matrix}\right\rangle \tag{2.10}$$

with fixed η can be regarded as a vector in $\mathbf{R}^m$ space.

$$\left\langle \frac{\xi}{\eta}\right\rangle, \quad \xi=\xi_1,\xi_2,\ldots,\xi_m. \tag{2.11}$$

Now consider a special transformation,

$$\mathbf{Y}\begin{pmatrix} \left\langle \frac{\eta_1}{\eta_1}\right\rangle \\ \left\langle \frac{\eta_2}{\eta_1}\right\rangle \\ \vdots \\ \left\langle \frac{\eta_m}{\eta_1}\right\rangle \end{pmatrix} = \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_1}\right\rangle' \\ 0 \\ \vdots \\ 0 \end{pmatrix}, \tag{2.12}$$

so all of the components of the old vectors $\langle \xi/\eta_1\rangle$ can be expressed by the following relation:

$$\left\langle \frac{\xi}{\eta_1}\right\rangle = y(\eta_1,\xi)\left\langle \frac{\eta_1}{\eta_1}\right\rangle. \tag{2.13}$$

The other $m-1$ vectors $\langle \xi/\eta_i\rangle$, $i=2,3,...,m$, undergo the same transformation. The complete transformation is specified by requiring

$$\mathbf{Y}\begin{pmatrix} \left\langle \frac{\eta_1}{\eta_2}\right\rangle \\ \left\langle \frac{\eta_2}{\eta_2}\right\rangle \\ \vdots \\ \left\langle \frac{\eta_m}{\eta_2}\right\rangle \end{pmatrix} = \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_2}\right\rangle' \\ \left\langle \frac{\eta_2}{\eta_2}\right\rangle' \\ 0 \\ \vdots \\ 0 \end{pmatrix}, \quad \mathbf{Y}\begin{pmatrix} \left\langle \frac{\eta_1}{\eta_3}\right\rangle \\ \left\langle \frac{\eta_2}{\eta_3}\right\rangle \\ \left\langle \frac{\eta_3}{\eta_3}\right\rangle \\ \vdots \\ \left\langle \frac{\eta_m}{\eta_3}\right\rangle \end{pmatrix} = \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_3}\right\rangle' \\ \left\langle \frac{\eta_2}{\eta_3}\right\rangle' \\ \left\langle \frac{\eta_3}{\eta_3}\right\rangle' \\ 0 \\ \vdots \\ 0 \end{pmatrix},\ldots, \tag{2.14}$$

$$\mathbf{Y}\begin{pmatrix} \left\langle \frac{\eta_1}{\eta_{m-1}} \right\rangle \\ \left\langle \frac{\eta_2}{\eta_{m-1}} \right\rangle \\ \vdots \\ \left\langle \frac{\eta_m}{\eta_{m-1}} \right\rangle \end{pmatrix} = \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_{m-1}} \right\rangle' \\ \left\langle \frac{\eta_2}{\eta_{m-1}} \right\rangle' \\ \vdots \\ \left\langle \frac{\eta_{m-1}}{\eta_{m-1}} \right\rangle' \\ 0 \end{pmatrix}, \quad \mathbf{Y}\begin{pmatrix} \left\langle \frac{\eta_1}{\eta_m} \right\rangle \\ \left\langle \frac{\eta_2}{\eta_m} \right\rangle \\ \vdots \\ \left\langle \frac{\eta_m}{\eta_m} \right\rangle \end{pmatrix} = \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_m} \right\rangle' \\ \left\langle \frac{\eta_2}{\eta_m} \right\rangle' \\ \vdots \\ \left\langle \frac{\eta_m}{\eta_m} \right\rangle' \end{pmatrix},$$

where the zero components (the special RWCs) have clearly been written out after the transformation. Other components are in general nonzero.

In the following, an example for the $m=3$ case is given to show that such a transformation is always possible. In the $m=3$ case, one can make the following special rotation A_1 around the third axis such that

$$\begin{pmatrix} \cos\theta_1 & -\sin\theta_1 & \\ \sin\theta_1 & \cos\theta_1 & \\ & & 1 \end{pmatrix} \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_1} \right\rangle \\ \left\langle \frac{\eta_2}{\eta_1} \right\rangle \\ \left\langle \frac{\eta_3}{\eta_1} \right\rangle \end{pmatrix} = \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_1} \right\rangle' \\ 0 \\ \left\langle \frac{\eta_3}{\eta_1} \right\rangle \end{pmatrix},$$

$$\begin{pmatrix} \cos\theta_1 & -\sin\theta_1 & \\ \sin\theta_1 & \cos\theta_1 & \\ & & 1 \end{pmatrix} \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_2} \right\rangle \\ \left\langle \frac{\eta_2}{\eta_2} \right\rangle \\ \left\langle \frac{\eta_3}{\eta_2} \right\rangle \end{pmatrix} = \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_2} \right\rangle' \\ \left\langle \frac{\eta_2}{\eta_2} \right\rangle' \\ \left\langle \frac{\eta_3}{\eta_2} \right\rangle' \end{pmatrix}, \tag{2.15}$$

$$\begin{pmatrix} \cos\theta_1 & -\sin\theta_1 & \\ \sin\theta_1 & \cos\theta_1 & \\ & & 1 \end{pmatrix} \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_3} \right\rangle \\ \left\langle \frac{\eta_2}{\eta_3} \right\rangle \\ \left\langle \frac{\eta_3}{\eta_3} \right\rangle \end{pmatrix} = \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_3} \right\rangle' \\ \left\langle \frac{\eta_2}{\eta_3} \right\rangle' \\ \left\langle \frac{\eta_3}{\eta_3} \right\rangle' \end{pmatrix}.$$

Then, make another rotation A_2 around the second axis with

$$\begin{pmatrix} \cos\theta_2 & & -\sin\theta_2 \\ 0 & 1 & 0 \\ \sin\theta_2 & & \cos\theta_2 \end{pmatrix} \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_1} \right\rangle' \\ 0 \\ \left\langle \frac{\eta_3}{\eta_1} \right\rangle \end{pmatrix} = \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_1} \right\rangle'' \\ 0 \\ 0 \end{pmatrix},$$

$$\begin{pmatrix} \cos\theta_2 & & -\sin\theta_2 \\ 0 & 1 & 0 \\ \sin\theta_2 & & \cos\theta_2 \end{pmatrix} \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_2} \right\rangle' \\ \left\langle \frac{\eta_2}{\eta_2} \right\rangle' \\ \left\langle \frac{\eta_3}{\eta_2} \right\rangle' \end{pmatrix} = \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_2} \right\rangle'' \\ \left\langle \frac{\eta_2}{\eta_2} \right\rangle'' \\ \left\langle \frac{\eta_2}{\eta_2} \right\rangle'' \end{pmatrix}, \tag{2.16}$$

$$\begin{pmatrix} \cos\theta_2 & & -\sin\theta_2 \\ 0 & 1 & 0 \\ \sin\theta_2 & & \cos\theta_2 \end{pmatrix} \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_3} \right\rangle' \\ \left\langle \frac{\eta_2}{\eta_3} \right\rangle' \\ \left\langle \frac{\eta_3}{\eta_3} \right\rangle' \end{pmatrix} = \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_3} \right\rangle'' \\ \left\langle \frac{\eta_2}{\eta_3} \right\rangle'' \\ \left\langle \frac{\eta_2}{\eta_3} \right\rangle'' \end{pmatrix}.$$

Finally, make a special rotation A_3 around the first axis with

$$\begin{pmatrix} 1 & & \\ & \cos\theta_3 & -\sin\theta_3 \\ & \sin\theta_3 & \cos\theta_3 \end{pmatrix} \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_1} \right\rangle'' \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_1} \right\rangle'' \\ 0 \\ 0 \end{pmatrix},$$

$$\begin{pmatrix} 1 & & \\ & \cos\theta_3 & -\sin\theta_3 \\ & \sin\theta_3 & \cos\theta_3 \end{pmatrix} \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_2} \right\rangle'' \\ \left\langle \frac{\eta_2}{\eta_2} \right\rangle'' \\ \left\langle \frac{\eta_3}{\eta_2} \right\rangle'' \end{pmatrix} = \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_2} \right\rangle'' \\ \left\langle \frac{\eta_2}{\eta_2} \right\rangle''' \\ 0 \end{pmatrix}, \tag{2.17}$$

$$\begin{pmatrix} 1 & & \\ & \cos\theta_3 & -\sin\theta_3 \\ & \sin\theta_3 & \cos\theta_3 \end{pmatrix} \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_3} \right\rangle'' \\ \left\langle \frac{\eta_2}{\eta_3} \right\rangle'' \\ \left\langle \frac{\eta_3}{\eta_3} \right\rangle'' \end{pmatrix} = \begin{pmatrix} \left\langle \frac{\eta_1}{\eta_3} \right\rangle''' \\ \left\langle \frac{\eta_2}{\eta_3} \right\rangle''' \\ \left\langle \frac{\eta_2}{\eta_3} \right\rangle''' \end{pmatrix}.$$

Hence, the special orthogonal matrix $\mathbf{Y}$ is

$$Y = A_3 A_2 A_1. \tag{2.18}$$

It should be clear that the angle θ_1 is fixed by $\langle \eta_1/\eta_1 \rangle$ and $\langle \eta_2/\eta_1 \rangle$, θ_2 by $\langle \eta_1/\eta_1 \rangle'$ and $\langle \eta_3/\eta_1 \rangle$, and θ_3 by $\langle \eta_2/\eta_2 \rangle''$ and $\langle \eta_3/\eta_2 \rangle''$. One can extend this procedure to the m-dimensional space and prove that there are indeed unique solutions for m rotational angles if the final form (2.14) is selected.

It is important to note that the choice of the rotation is not unique because there is an infinite number of solutions for RWCs or WCs with outer multiplicity, all related through SO(m) transformations. However, once the special rotation given in (2.14) is chosen, the resolution of the outer multiplicity is fixed; there remains no other arbitrariness in specifying the RWCs with multiplicity except for an over all phase factor. We will now show that the overall phase factor can be chosen as

$$\left\langle \frac{\eta_i}{\eta_i} \right\rangle \geqslant 0 \tag{2.19}$$

for $i=1,2,...,m$. The RWCs are then uniquely determined.

It is easy to prove that the orthogonality conditions for the WCs or RWCs given by (2.6) remain valid after the transformation for both the $\mathcal{U}(4)\supset\mathcal{U}(3)$ and SU(3)$\supset$U(2) cases. First of all note that the $\mathcal{U}(4)\supset\mathcal{U}(3)$ or SU(3)$\supset$U(2) RWCs all undergo the same transformation $\mathbf{Y}$. One can easily verify that the orthogonality conditions are valid for the $\mathcal{U}(4)\supset\mathcal{U}(3)$ case. Since, according to the Schur–Weyl duality relation, SU(3) WCs or SU(3)$\supset$U(2) RWCs are a subset of those of $\mathcal{U}(4)$ or $\mathcal{U}(4)\supset\mathcal{U}(3)$, the same conclusion applies to WCs of SU(3) or RWCs of SU(3)$\supset\mathcal{U}(2)$ as well.

Although the orthogonality conditions survive, other properties such as Biedneharn's $1\leftrightarrow 2$ exchange symmetry, is lost in this new scheme. Questions of this type will be considered further in Sec. IV.

Finally, we want to show what is actually achieved by the special rotation $\mathbf{Y}$. If the RWCs of $\mathcal{U}(4)\supset\mathcal{U}(3)$ in terms of an $m\times m$ matrix are arranged such that the columns are set by the outer multiplicity label $\tilde{\eta}=\eta_1,\ \eta_2,\ldots,\eta_m$ and the rows by the label η in the (irrep) $[m_1,m_2-\eta,m_3-\mu_2+\eta]$ for $\mathcal{U}(3)$, the RWCs have the following structure:

$$\left(\left\langle \frac{\tilde{\eta}}{\eta} \right\rangle\right)=\begin{pmatrix} \times & 0 & \cdots & \cdots & 0 \\ \times & \times & 0 & \cdots & 0 \\ \times & \times & \times & 0\cdots & 0 \\ \cdots & \cdots & & & \\ \times & \times & \cdots & \times & 0 \\ \times & \times & \cdots & \cdots & \times \end{pmatrix}, \tag{2.20}$$

i.e., one achieves a lower triangular structure for the RWCs with the multiplicity postulated by Braunschweig.[35] This development shows that it is always possible to choose such a structure. Hecht, in Ref. 22, argued that one can resolve the SU(3) multiplicity problem simply by requiring a similar lower triangular structure. Le Blanc and Rowe also pointed out that such a resolution becomes *ipso facto* equivalent to a canonical labeling scheme.[27] Actually, one can also choose an upper triangular structure for the RWCs. (Under row-column interchange there are clearly a total of $m(m-1)/2$ ''equivalent'' choices.) The structure of the RWCs is not unique, it depends on what kind of special transformation is chosen.

Now recall Biedenharn's definition for a canonical resolution to the outer multiplicity problem. In Ref. 6, ''canonical'' implies there no free choices involved in the resolution of the multiplicity. This definition must be understood within the context of the procedure introduced for resolving the multiplicity problem. As shown here, there is not a single ''canonical'' resolution of the multiplicity; ''canonical'' has to be understood within the context of the methodology offered for a resolution of the multiplicity. The same applies to the definition of a canonical basis for U(n). A ''canonical'' construction has to be understood in terms of an equivalent class associated with a particular U(1), out of the set of all equivalent U(1) subgroups, at each stage of the decomposition.

The special transformation given by (2.14) makes it possible to evaluate RWCs of SU(3) in any basis using only recoupling procedures. In the following RWCs for SU(3) in the canonical SU(3)$\supset$U(2) basis will be considered; RWCs for SU(3) in the noncanonical SU(3)$\supset$O(3) basis will be discussed elsewhere.

III. RECOUPLING APPROACH FOR SU(3)$\supset$U(2) RWCs

In this section, a new procedure for evaluating RWCs with multiplicity for SU(3)$\supset$U(2), or SU(n)$\supset$U($n-1$) in general, is introduced. It uses known results, including the analytic expression for RWCs of U(n)$\supset$U($n-1$) with one symmetric irrep[15] given by Ališauskas *et al.*, and a special choice for the multiplicity transformation. U(3)$\supset$U(2) RWCs of the type given by Ališauskas *et al.* can also be found in the work of Chacon *et al.*,[5] who derived their results using the

canonical unit tensor operator method proposed by Biedenharn *et al.* The result of Chacon and that of Ališauskas *et al.* are the same, including the choice of phase. To make every step clear, this section is divided into several subsections.

A. A recoupling approach

Using analytic expressions for multiplicity free RWCs given, for example, in Ref. 15, one can construct an expression for the product of general $\mathcal{U}(4)$ or SU(3) RWCs and their respective special recoupling coefficients,[36,37]

$$\begin{aligned}\sum_{\xi} U_{\xi}\begin{pmatrix}(\lambda_{\iota}\mu_1) & [\lambda_2+\mu_2\ 0] & [\overline{m}]\\ [\mu_2 0] & [m_1m_2m_3] & (\lambda_2\mu_2)\end{pmatrix}\left\langle\begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2)\\ \rho_1 & \rho_2\end{matrix}\middle|\begin{matrix}\xi[m_1m_2m_3]\\ \rho\end{matrix}\right\rangle\\ =\sum\left\langle\begin{matrix}(\lambda_1\mu_1) & [\lambda_2+\mu_2 0]\\ \rho_1 & \rho_2'\end{matrix}\middle|\begin{matrix}[\overline{m}]\\ \overline{\rho}\end{matrix}\right\rangle\left\langle\begin{matrix}[\overline{m}] & [\mu_2 0]\\ \overline{\rho} & \rho_2''\end{matrix}\middle|\begin{matrix}[m_1m_2m_3]\\ \rho\end{matrix}\right\rangle\\ \times\left\langle\begin{matrix}[\lambda_2+\mu_2 0] & [\mu_2 0]\\ \rho_2' & \rho_2''\end{matrix}\middle|\begin{matrix}(\lambda_2\mu_2)\\ \rho_2\end{matrix}\right\rangle.\end{aligned} \tag{3.1}$$

In this equation, U is the unitary form of a Racah coefficient for $\mathcal{U}(4)$ or SU(3), respectively, and the sum on the rhs is over ρ_2', ρ_2'', and $\overline{\rho}$.

It is convenient to introduce the following abbreviated notation:

$$U_{\xi}([\overline{m}])\equiv U_{\xi}\begin{pmatrix}(\lambda_1\mu_1) & [\lambda_2+\mu_2\ 0] & [\overline{m}]\\ [\mu_2 0] & [m_1m_2m_3] & (\lambda_2\mu_2)\end{pmatrix}$$

for the Racah coefficients,

$$\left\langle\frac{\tilde{\eta}}{\eta}\right\rangle\equiv\left\langle\begin{matrix}[\lambda_1+\mu_1,\mu_1] & [\lambda_2+\mu_2,\mu_2]\\ [\lambda_1+\mu_1,\mu_1] & [\lambda_2+\mu_2,0]\end{matrix}\middle|\begin{matrix}\tilde{\eta}[m_1m_2m_3]\\ [m_1,m_2-\eta,m_3-\mu_2+\eta]\end{matrix}\right\rangle$$

for a special set of $\mathcal{U}(4)\supset$U(3) RWCs,

$$\left\langle\frac{\tilde{\eta}}{\rho_1\rho_2\rho}\right\rangle\equiv\left\langle\begin{matrix}[\lambda_1+\mu_1,\mu_1] & [\lambda_2+\mu_2,\mu_2]\\ \rho_1 & \rho_2\end{matrix}\middle|\begin{matrix}\tilde{\eta}[m_1m_2m_3]\\ \rho\end{matrix}\right\rangle$$

for SU(3) WCs, or SU(3)$\supset$U(2) RWCs if ρ_1, ρ_2, and ρ are the corresponding U(2) labels,

$$\begin{pmatrix}\eta'\\ \eta\end{pmatrix}\equiv\begin{pmatrix}[\lambda_1+\mu_1\mu_1] & [\lambda_2+\mu_2 0] & [m_1m_2-\eta' m_3-\mu_2+\eta']\\ [\lambda_1+\mu_1\mu_1] & [\lambda_2+\mu_2\mu_2] & [m_1m_2m_3]\\ [\lambda_1+\mu_1] & [\lambda_2+\mu_2 0] & [m_1m_2-\eta m_3-\mu_2+\eta]\end{pmatrix}$$

for $(\mathcal{U}4\supset\mathcal{U}(3))\star(\mathcal{U}(4)\supset\mathcal{U}(3))$ reduced coupling coefficients, and

$$\begin{pmatrix}\eta'\\ \rho_1\rho_2\rho\end{pmatrix}\equiv\begin{pmatrix}[\lambda_1+\mu_1\mu_1] & [\lambda_2+\mu_2 0] & [m_1m_2-\eta' m_3-\mu_2+\eta']\\ [\lambda_1+\mu_1\mu_1] & [\lambda_2+\mu_2\mu_2] & [m_1m_2m_3]\\ \rho_1 & \rho_2 & \rho\end{pmatrix}$$

for $(\mathcal{U}(4)\supset\mathcal{U}(3))\star$SU(3) coupling coefficients.

For the $\mathcal{U}(4)\supset\mathcal{U}(3)$ case, only the simpler case

$$\sum_{\xi} U_{\xi}([\overline{m}])\left\langle\frac{\xi}{\eta}\right\rangle=G([\overline{m}],\eta), \tag{3.2}$$

needs to be considered, where

$$G([\bar{m}],\eta)=\sum_{p_1p_2[\bar{m}']}\left\langle\begin{matrix}[\lambda_1+\mu_1\mu_1] & [\lambda_2+\mu_2 0] & \\ [\lambda_1+\mu_1\mu_1] & p_1 & [\bar{m}'] \\ [\lambda_1+\mu_1\mu_1] & 0 & [\lambda_1+\mu_1\mu_1]\end{matrix}\right\rangle \times\left\langle\begin{matrix}[\bar{m}] & [\mu_2 0] & \\ [\bar{m}'] & p_2 & [m_1m_2m_3] \\ [\lambda_1+\mu_1\mu_1] & 0 & [m_1m_2-\eta m_3-\mu_2+\eta] \\ & & [\lambda_1+\mu_1\mu_1]\end{matrix}\right\rangle \times\left\langle\begin{matrix}[\lambda_2+\mu_2 0] & [\mu_2 0] & [\lambda_2+\mu_2\mu_2] \\ p_1 & p_2 & [\lambda_2+\mu_2 0]\end{matrix}\right\rangle \times\left\langle\left\langle\begin{matrix}[\lambda_1+\mu_1\mu_1] & [\lambda_2+\mu_2 0] & \\ [\lambda_1+\mu_1\mu_1] & 0 & [m_1m_2-\eta m_3-\mu_2+\eta] \\ & & [\lambda_1+\mu_1\mu_1]\end{matrix}\right\rangle\right\rangle^{-1}. \tag{3.3}$$

While for SU(3), the following expression is important:

$$\sum_{\xi} U_{\xi}([\bar{m}])\left\langle\begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2) & \\ \rho_1 & \rho_2 & \xi[m_1m_2m_3] \\ & & \rho\end{matrix}\right\rangle=G([\bar{m}],\rho_1\rho_2\rho), \tag{3.4}$$

where

$$\left\langle\begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2) & \\ \rho_1 & \rho_2 & \xi[m_1m_2m_3] \\ & & \rho\end{matrix}\right\rangle$$

is the WCs of SU(3), and $G([\bar{m}],\rho_1\rho_2\rho)$ is the expression given by the rhs of (3.1).

Using these G polynomials, one can easily construct the following coupling coefficients:

$$\left(\begin{matrix}\eta' \\ \eta\end{matrix}\right)=\sum_{[\bar{m}]} G([\bar{m}],\eta)G([\bar{m}],\eta'), \tag{3.5}$$

which is a symmetric function with respect to the labels η, η'. What (3.5) gives is nothing but reduced coupling coefficient of $\mathcal{U}(4)\star\mathcal{U}(4)$,

$$\left\langle\left(\begin{matrix}[\lambda_1+\mu_1\mu_1] \\ [\lambda_1+\mu_1\mu_1] \\ [\lambda_1+\mu_1\mu_1]\end{matrix}\right);\left(\begin{matrix}[\lambda_2+\mu_2 0] \\ [\lambda_2+\mu_2\mu_2] \\ [\lambda_2+\mu_2 0]\end{matrix}\right)\middle|\left(\begin{matrix}[m_1m_2-\eta' m_3-\mu_2+\eta'] \\ [m_1m_2m_3] \\ [m_1m_2-\eta m_3-\mu_2+\eta]\end{matrix}\right)\right\rangle. \tag{3.6}$$

Similarly,

$$\left(\begin{matrix}\eta \\ \rho_1\rho_2\rho\end{matrix}\right)=\sum_{[\bar{m}]} G([\bar{m}],\eta)G([\bar{m}],\rho_1\rho_2\rho), \tag{3.7}$$

which is the following $\mathcal{U}(4)\star$SU(3) coupling coefficient

$$\left\langle\left(\begin{matrix}[\lambda_1+\mu_1\mu_1] \\ [\lambda_1+\mu_1\mu_1] \\ \rho_1\end{matrix}\right);\left(\begin{matrix}[\lambda_2+\mu_2 0] \\ [\lambda_2+\mu_2\mu_2] \\ \rho_2\end{matrix}\right)\middle|\left(\begin{matrix}[m_1m_2-\eta m_3-\mu_2+\eta] \\ [m_1m_2m_3] \\ \rho\end{matrix}\right)\right\rangle. \tag{3.8}$$

As pointed out by Biedenharn *et al.*,[2] there are close relations between RWCs of U(n) and the coupling coefficients of U(n)$\star$U(n). They have proved that such coupling coefficients can be expressed in terms of the product of two U(n) WCs with summation over the outer multiplicity labels. One can directly verify by using the recoupling technique that

$$\left(\begin{matrix}\eta' \\ \eta\end{matrix}\right)=\sum_{[\bar{m}]} G([\bar{m}],\eta)G([\bar{m}],\eta')=\sum_{\xi}\left\langle\frac{\xi}{\eta}\right\rangle\left\langle\frac{\xi}{\eta'}\right\rangle \tag{3.9}$$

and

$$\left(\begin{matrix}\eta\\ \rho_1\rho_2\rho\end{matrix}\right)=\sum_{[\bar{m}]} G([\bar{m}],\eta)G([\bar{m}],\rho_1\rho_2\rho)=\sum_{\xi}\left\langle\frac{\xi}{\eta}\right\rangle\left\langle\frac{\xi}{\rho_1\rho_2\rho_3}\right\rangle. \tag{3.10}$$

B. Explicit expressions of *G* polynomials

Using the recoupling technique, it is possible to evaluate explicit expressions for the G polynomials defined in the above subsection from the known multiplicity-free RWCs of $\mathrm{U}(n)\supset\mathrm{U}(n-1)$ given by Ališauskas *et al.*,

$$\begin{aligned}G(k_1k_2,\eta)=&\left[\frac{(m_3-\mu_2+\eta)!^2(m_2-\eta+1)!^2(m_1+2)!\lambda_1!(\lambda-\mu_1-2k_1-k_2+2)(\mu_1+k_1-k_2+1)}{(\lambda_2+\mu_2)!^2(\mu_1+\mu_2-m_3-\eta)!(\lambda_2+\mu_2+1)}\right.\\
&\times\frac{(\lambda-k_1-k_2-\lambda_1-\mu_1)!(\lambda-k_1-k_2-\mu_1+1)!(m_1-m_2+1)!(m_1-m_3+2)!(m_2-m_3+1)}{(\lambda_1-k_1)!(\lambda_1+\mu_1-k_2+1)!(\mu_1-k_2)!(\mu_2-\eta)!(\lambda_1+\mu_1-m_2+\eta)!(\lambda_1+\mu_1+\mu_2-m_3-\eta+1)!}\\
&\times\frac{(\lambda-k_1-k_2-m_2)!(\lambda-k_1-k_2-m_3+1)!(\lambda-k_1-k_2+2)!(\mu_1+k_1-m_3)!(\mu_1+k_1+1)!k_1!k_2!}{(m_1-\lambda_1+k_1+k_2)!(m_1-\mu_1-k_1+1)!(m_1-k_2+2)!(m_2-\mu_1-k_1)!(m_2+1)!m_3!(m_3-k_2)!}\\
&\left.\times\frac{(\lambda_2+1)!\mu_2!(m_2-m_3-\eta)!(m_1-\lambda_1-\mu_1)!(m_1-\mu_1+1)!(m_2-\mu_1-\eta)!}{(m_1-m_2+\eta+1)!(m_1-m_3+\mu_2+2)!\,\eta!(m_2-m_3+\mu_2-\eta+1)!}\right]^{1/2}\\
&\times\sum_{p=0}^{\mu_2}\sum_{m_{23}=\min(m_{23})}^{\max(m_{23})}\sum_{m_{33}=\min(m_{33})}^{\max(m_{33})}(-)^p\frac{p!(\lambda_1-m_{23})!(\lambda_1+\mu_1-m_{33}+1)!(\mu_1-m_{33})!(\lambda_2+\mu_2-p)!}{(\lambda-p-m_{23}-m_{33}-\lambda_1-\mu_1)!(\lambda-p-m_{23}-m_{33}-\mu_1+1)!m_{23}!}\\
&\times\frac{(\lambda-p-2m_{23}-m_{33}-\mu_1+1)(\lambda-p-m_{23}-2m_{33}+2)(m_{23}-m_{33}+\mu_1+1)}{(\lambda-p-m_{23}-m_{33}+2)!(\mu_1+m_{23}+1)!m_{33}!}\\
&\times F_3\left(\begin{matrix}[\lambda-k_1-k_2,\mu_1+k_1,k_2]\\ [\lambda-p-m_{23}-m_{33},m_{23}+\mu_1,m_{33}]\end{matrix}\;;\;\begin{matrix}[m_1m_2m_3]\\ [m_1m_2-\eta\ m_3-\mu_2+\eta]\end{matrix}\right),\end{aligned} \tag{3.11}$$

where

$$\lambda=\lambda_1+\mu_1+\lambda_2+\mu_2, \tag{3.12a}$$

$$[\bar{m}]=[\lambda-k_1-k_2,\mu_1+k_1,k_2]. \tag{3.12b}$$

Boundary conditions for m_{23} and m_{33} in these expressions can be obtained by using the Littlewood rule for the Kronecker products involved and the betweenness conditions for the decomposition $\mathrm{U}(n)\downarrow\mathrm{U}(n-1)$,

$$\begin{aligned}\max(m_{23})&=\min(\lambda_1,k_1,\lambda_2+\mu_2-p,m_2-\eta-\mu_1),\\ \min(m_{23})&=\max(0,m_2-\eta-\mu_1-p,m_3-\mu_1-\mu_2+\eta),\end{aligned} \tag{13.12c}$$

for fixed p, while

$$\begin{aligned}\max(m_{33})=&\min(\lambda-p-m_{23}-m_2+\eta,m_3-\mu_2+\eta,\mu_1,\\ &\lambda_2+\mu_2-p-m_{23},\ \lambda-p-m_{23}-\mu_1-k_1,\ \lambda-p-m_{23}-\lambda_1-\mu_1),\\ \min(m_{33})=&\max(0,m_2+m_3+\mu_1-\mu_2-p+m_{23},k_1+k_2-p-m_{23},k_2)\end{aligned} \tag{3.12d}$$

for fixed p and m_{23}. Furthermore,

$$
F_3\left(\begin{matrix}[h_1h_2h_3] \\ [q_1q_2q_3]\end{matrix} \quad ; \quad \begin{matrix}[m_1m_2m_3] \\ [n_1n_2n_3]\end{matrix}\right)
$$

$$
\begin{aligned}
&=\sum_{xyz}(-)^{x+y+z-q_1-q_2-q_3} \\
&\times\frac{(x-y+1)(x-z+2)(y-z+1)(x-h_3+1)!}{(h_2-y)!(n_2-z+1)!(h_3-z)!(h_1-z+2)!(h_1-y+1)!} \\
&\times\frac{(q_1-y)!(q_1-z+1)!(q_2-z)!(x-n_2)!(x-n_3+1)!(y-n_3)!(y-h_3)!}{(x-q_1)!(x-q_2+1)!(x-q_3+2)!(y-q_2)!(y-q_3+1)!(z-q_3)!(n_1-x)!(n_1-y+1)!(n_1-z+2)!} \\
&\times\frac{(m_1-x)!(m_1-y+1)!(m_1-z+2)!(m_2-y)!(m_2-z+1)!(m_3-z)!(x-h_2)!}{(n_2-y)!(n_2-z+1)!(n_3-z)!(x-m_2)!(x-m_3+1)!(y-m_3)!(h_1-x)!}.
\end{aligned}
\tag{3.13}
$$

Similarly,

$$
\begin{aligned}
&G(k_1k_2;[m_{12}m_{22}][m'_{12}m'_{22}][m''_{12}m''_{22}]) \\
&=\sum_{\xi}U_{\xi}(k_1k_2)\left\langle\begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2) \\ [m_{12}m_{22}] & [m'_{12}m'_{22}]\end{matrix}\middle|\begin{matrix}\xi[m_1m_2m_3] \\ [m''_{12}m''_{22}]\end{matrix}\right\rangle \\
&=\Bigg[\frac{(\lambda_2+1)!(\mu_2-m'_{22})!(m_1-m_2+1)(m_1-m_3+2)(m_2-m_3+1)(m''_{12}-m_2)!}{(\lambda_2+\mu_2-m'_{12})!(\lambda_2+\mu_2-m'_{22}+1)!(m'_{12}-\mu_2)!(m_2-k_2+1)!(m_1-m''_{12})!(m_2-m''_{22})!} \\
&\times\frac{(\lambda-k_1-k_2-m_2)!(\mu_1+k_1-m_3)!(\lambda-k_1-k_2-m_3+1)!(m''_{22}-m_3)!(m''_{12}-m_3+1)!}{(m_1-\lambda+k_1+k_2)!(m_2-\mu_1-k_1)!(m_3-k_2)!(m_1-\mu_1-k_1+1)!(m_1-k_2+2)!} \\
&\times\frac{(\mu_1-k_2)!(\lambda_1+\mu_1-k_2+1)!(\lambda_1+\mu_1-m_{12})!(\mu_1-m_{22})!(\lambda_1+\mu_1-m_{22}+1)!}{(\mu_1+k_1+1)!(m_{12}-\mu_1)!m_{22}!(m_{12}+1)!(m_1-m''_{22}+1)!}\Bigg]^{1/2} \\
&\times\sum_{p=0}^{\mu_2}\sum_{q=\min(q)}^{\max(q)}(-1)^{p-m'_{22}}(\lambda_2+\mu_2+p-m'_{12}-m'_{22})! \\
&\times((m'_{12}-p)!(m''_{12}+m''_{22}-p-q-m_{12})!(q-m_{22})!)^{1/2} \\
&\times\left(\frac{(m''_{12}+m''_{22}-p-q-m_{22}+1)!(m''_{12}+m''_{22}-p-2q+1)(p+q-m''_{22})!(m''_{22}-q+1)!}{(p-m'_{22})!(m''_{12}-p-q)!(m''_{12}+m''_{22}-p-q-\mu_1-k_1)!(m_{12}-q)!}\right)^{1/2} \\
&\times U\left(\begin{matrix}[m_{12}m_{22}] & [m'_{12}+m'_{22}-p0] & [m''_{12}+m''_{22}-p-q,q] \\ [p0] & [m''_{12}m''_{22}] & [m'_{12}m'_{22}]\end{matrix}\right) \\
&\times F_2\left(\begin{matrix}[\lambda-k_1-k_2,\mu_1+k_1,k_2] & [m_1m_2m_3] \\ [m''_{12}+m''_{22}-p-q,q] & [m''_{12}m''_{22}]\end{matrix}\right) \\
&\times F_2\left(\begin{matrix}[\lambda_1+\mu_1\mu_1] & [\lambda-k_1-k_2,\mu_1+k_1,k_2] \\ [m_{12}+m_{22}0] & [m''_{12}+m''_{22}-p-q,q]\end{matrix}\right),
\end{aligned}
\tag{3.14}
$$

where

$$
\begin{aligned}
\max(q)&=\min(\mu_1+k_1,m''_{12}+m''_{22}-p-\mu_1-k_1), \\
\min(q)&=\max(k_2,m''_{12}+m''_{22}-p-\lambda+k_1+k_2),
\end{aligned}
\tag{3.15a}
$$

U is an SU(2) Racah coefficient in unitary form, and

$$F_2\begin{pmatrix}[h_1h_2h_3] & [m_1m_2m_3]\\ [q_1q_2] & [n_1n_2]\end{pmatrix}=\sum_{xy}(-)^{x+y-q_1-q_2}(x-y+1)$$
$$\times\frac{(x-n_2)!(m_1-x)!(x-h_2)!(x-h_3+1)!}{(x-q_1)!(x-q_2+1)!(n_1-x)!(x-m_2)!(x-m_3+1)!(h_1-x)!}$$
$$\times\frac{(q_1-y)!(m_1-y+1)!(m_2-y)!(y-h_3)!}{(y-q_2)!(n_2-y)!(n_1-y+1)!(y-m_3)!(h_1-y+1)!(h_2-y)!}. \tag{3.15b}$$

Using these expressions, (3.9) and (3.10) can be expressed explicitly as

$$\begin{pmatrix}\eta'\\ \eta\end{pmatrix}=\sum_{k_1=\min(k_1)}^{\max(k_1)}\sum_{k_2=\min(k_2)}^{\max(k_2)}G(k_1,k_2,\eta)G(k_1,k_2,\eta'), \tag{3.16a}$$

$$\begin{pmatrix}\eta\\ \rho_1\rho_2\rho\end{pmatrix}=\sum_{k_1=\min(k_1)}^{\max(k_1)}\sum_{k_2=\min(k_2)}^{\max(k_2)}G(k_1,k_2,\eta)G(k_1,k_2,\rho_1\rho_2\rho), \tag{3.16b}$$

where

$$\begin{aligned}\max(k_1)&=\min(m_2-\mu_1,\lambda_1,\lambda_2+\mu_2),\\ \min(k_1)&=\max(m_3-\mu_1,m_2-\mu_1-\mu_2,0),\\ \max(k_2)&=\min(\mu_1,\lambda_2+\mu_2-k_1,\lambda_2+\mu_2-k_1+\lambda_1+\mu_1-m_2),\\ \min(k_2)&=\max(m_2+m_3-\mu_1-\mu_2-k_1).\end{aligned} \tag{3.16c}$$

C. Recursive procedure for the evaluation of all SU(3)⊃U(2) RWCs

The G polynomials can be used to construct $\mathcal{U}(4)\star\mathcal{U}(4)$ as well as $\mathcal{U}(4)\star\mathrm{SU}(3)$ reduced coupling coefficients as given by (3.16a) and (3.16b), and these, in turn, can be used to evaluate all RWCs of SU(3)⊃U(2) after the special transformation given in Sec. II. It can be proved that

$$\sum_{\xi}\left\langle\frac{\xi}{\eta}\right\rangle\left\langle\frac{\xi}{\eta}\right\rangle\neq 0 \tag{3.17}$$

for any η. First, if there exists an η such that

$$\sum_{\xi}\left\langle\frac{\xi}{\eta}\right\rangle\left\langle\frac{\xi}{\eta}\right\rangle=0, \tag{3.18}$$

then

$$\left\langle\frac{\xi}{\eta}\right\rangle=0 \tag{3.19}$$

for $\xi=\eta_1,\eta_2,\ldots,\eta_m$ because the condition (3.18) can be written as $\boldsymbol{\eta}\cdot\boldsymbol{\eta}=0$ in $\mathbf{R}^m$ space, which then implies its components are all zero, i.e.,

$$\left\langle\begin{matrix}[\lambda_1+\mu_1,\mu_1] & [\lambda_2+\mu_2,\mu_2]\\ [\lambda_1+\mu_1,\mu_1] & [\lambda_2+\mu_2,0]\end{matrix}\middle|\begin{matrix}\xi[m_1m_2m_3]\\ [m_1,m_2-\eta,m_3-\mu_2+\eta]\end{matrix}\right\rangle=0 \tag{3.20}$$

for any multiplicity label ξ and fixed η. However, using the build-up principle, one can deduce that (3.20) is valid if and only if

$$G([\bar{m}],\eta)=0, \tag{3.21}$$

where the expression of $G([\overline{m}],\eta)$ is given by (3.3). In this case, the unitarity condition for $U(n)\supset U(n-1)$ RWCs to prove that (3.21) is satisfied only when one type of the WCs or RWCs involved are zero. However, one can verify from the explicit expressions for these WCs or RWCs given by Ališauskas *et al.*[15] that (3.21) is satisfied only when the irreps involved in the coupling do not satisfy the Littlewood rule for the Kronecker products involved or betweenness conditions for the decomposition. But these are all trivial cases and need not be considered. Hence, (3.17) is valid in general for all nontrivial cases.

Hence, after applying the special transformation given in Sec. II, the rhs of (3.9) has, in general, k nonzero terms in the summation when a smaller η which is a label in $[m_1 m_2-\eta\ m_3 -\mu_2+\eta]$ equals to η_k, namely

$$\left\langle \begin{matrix}\eta_k\\ \eta_l\end{matrix}\right\rangle=\sum_{\xi=\eta_1}^{\eta_k}\left\langle \frac{\xi}{\eta_k}\right\rangle\left\langle \frac{\xi}{\eta_l}\right\rangle,\quad \text{for } k\leqslant l,\ \ k\leqslant m. \tag{3.22}$$

Using (3.22), it can be shown that

$$\left\langle \frac{\eta_k}{\eta_k}\right\rangle=+\left[\left\langle \begin{matrix}\eta_k\\ \eta_k\end{matrix}\right\rangle-\sum_{\xi=\eta_1}^{\eta_{k-1}}\left\langle \frac{\xi}{\eta_k}\right\rangle^2\right]^{1/2}, \tag{3.23}$$

where the sign is chosen positive for any k, fixing the overall phase. Then,

$$\left\langle \frac{\eta_k}{\eta_k}\right\rangle\left\langle \frac{\eta_k}{\eta_l}\right\rangle=\left\langle \begin{matrix}\eta_k\\ \eta_l\end{matrix}\right\rangle-\sum_{\xi=\eta_1}^{\eta_{k-1}}\left\langle \frac{\xi}{\eta_k}\right\rangle\left\langle \frac{\xi}{\eta_l}\right\rangle \tag{3.24}$$

for $l>k$. It can also be proven that (3.23) cannot be zero. First, $\langle \eta_k/\eta_k\rangle^2$ is a square of the component of the vector $\boldsymbol{\eta}_k$ in $\mathbf{R}^{\mathrm{m}}$. Therefore,

$$\left\langle \frac{\eta_k}{\eta_k}\right\rangle^2\geqslant 0,\quad \text{for } k\leqslant m. \tag{3.25a}$$

Second, if (3.23) is zero, (3.24) should also be zero for any l values. This only occurs when the multiplicity equals to $k-1$. However, an initial assumption was that $m\geqslant k$. Hence, (3.24) cannot be zero for $k\leqslant m$. Hence,

$$\left\langle \frac{\eta_k}{\eta_k}\right\rangle^2>0,\quad \text{for } k\leqslant m. \tag{3.25b}$$

Thus, (3.23) and (3.24) allow us to calculate all of the special RWCs of $\mathcal{U}(4)\supset\mathcal{U}(3)$ recursively,

$$\left\langle \frac{\eta_1}{\eta_1}\right\rangle=\left\langle \begin{matrix}\eta_1\\ \eta_1\end{matrix}\right\rangle^{1/2},$$

$$\left\langle \frac{\eta_1}{\eta}\right\rangle=\left\langle \begin{matrix}\eta_1\\ \eta_1\end{matrix}\right\rangle^{-1/2}\left\langle \begin{matrix}\eta_1\\ \eta\end{matrix}\right\rangle, \tag{3.26a}$$

$$\left\langle \frac{\eta_2}{\eta}\right\rangle=\left[\left\langle \begin{matrix}\eta_2\\ \eta\end{matrix}\right\rangle-\left\langle \begin{matrix}\eta_1\\ \eta_1\end{matrix}\right\rangle^{-1}\left\langle \begin{matrix}\eta_1\\ \eta_2\end{matrix}\right\rangle\left\langle \begin{matrix}\eta_1\\ \eta\end{matrix}\right\rangle\right]\Big/\left\langle \frac{\eta_2}{\eta_2}\right\rangle, \tag{3.26b}$$

where

$$\left\langle \frac{\eta_2}{\eta_2}\right\rangle=\left[\left\langle \begin{matrix}\eta_2\\ \eta_2\end{matrix}\right\rangle-\left\langle \begin{matrix}\eta_1\\ \eta_1\end{matrix}\right\rangle^{-1}\left\langle \begin{matrix}\eta_1\\ \eta_2\end{matrix}\right\rangle^2\right]^{1/2}. \tag{3.26c}$$

$$\cdots\ \cdots$$

Once the $\langle(\eta_{k-1})/\eta\rangle$ for any η are known from the $(k-1)$th step, $\langle\eta_k/\eta\rangle$ can be obtained by using (3.23) and (3.24). Thus, one obtains all the special RWCs of $\mathcal{U}(4)\supset\mathcal{U}(3)$, which are important in determining the RWCs of SU(3)⊃U(2).

Using (3.10) and known special RWCs of $\mathcal{U}(4)\supset\mathcal{U}(3)$, SU(3) WCs or SU(3)⊃U(2) RWCs can be determined from

$$\left\langle\frac{\eta_1}{\rho_1\rho_2\rho}\right\rangle=\left\langle\frac{\eta_1}{\eta_1}\right\rangle^{-1}\begin{pmatrix}\eta_1\\ \rho_1\rho_2\rho\end{pmatrix},$$

$$\left\langle\frac{\eta_2}{\rho_1\rho_2\rho}\right\rangle=\left[\begin{pmatrix}\eta_2\\ \rho_1\rho_2\rho\end{pmatrix}-\left\langle\frac{\eta_1}{\eta_1}\right\rangle^{-1}\left\langle\frac{\eta_1}{\eta_2}\right\rangle\begin{pmatrix}\eta_1\\ \rho_1\rho_2\rho\end{pmatrix}\right]\Big/\left\langle\frac{\eta_2}{\eta_2}\right\rangle, \tag{3.27}$$

$$\cdots\ \cdots$$

$$\left\langle\frac{\eta_k}{\rho_1\rho_2\rho}\right\rangle=\left[\begin{pmatrix}\eta_k\\ \rho_1\rho_2\rho\end{pmatrix}-\sum_{\eta'=\eta_1}^{\eta_{k-1}}\left\langle\frac{\eta'}{\rho_1\rho_2\rho}\right\rangle\left\langle\frac{\eta'}{\eta_k}\right\rangle\right]\Big/\left\langle\frac{\eta_k}{\eta_k}\right\rangle,\quad\text{for } k\leqslant m. \tag{3.28}$$

It should be noted that (3.28) determines not only SU(3) WCs in the canonical basis, and SU(3)⊃U(2) RWCs, but also SU(4)⊃U(3) RWCs for the same coupling.

D. Some algebraic expressions

In this subsection, some algebraic expressions for SU(3)⊃U(2) RWCs and related Racah coefficients of SU(3) are worked out. Starting from $\eta=\eta_1$, and using (3.23) and (3.24), one obtains

$$\left\langle\frac{\eta_1}{\eta_1}\right\rangle=\sum_{k_1k_2}G^2(k_1,k_2,\eta_1),$$

$$\left\langle\frac{\eta_1}{\eta_{1+i}}\right\rangle=\left\langle\frac{\eta_1}{\eta_1}\right\rangle^{-1}\sum_{k_1k_2}G(k_1k_2,\eta_{i+1})G(k_1k_2,\eta_1),$$

$$\left\langle\frac{\eta_2}{\eta_2}\right\rangle^2=\left\langle\frac{\eta_1}{\eta_1}\right\rangle^{-2}\sum_{i=0}^{1}\sum_{k_1k_2k_1'k_2'}(-)^{[i/2]}G(k_1k_2,\eta_2)G(k_1k_2,\eta_{2-i})G(k_1'k_2',\eta_{1+i})G(k_1'k_2',\eta_1), \tag{3.29}$$

$$\cdots\ \cdots$$

$$\begin{aligned}\left\langle\frac{\eta_3}{\eta_3}\right\rangle^2=&\left\langle\frac{\eta_1}{\eta_1}\right\rangle^{-5}\left\langle\frac{\eta_2}{\eta_2}\right\rangle^{-1}\sum_{i=0}^{2}{}'\sum_{j=0}^{1}{}'\sum_{k=0}^{1}{}'\sum_{k_l,p_l,q_l,n_l}(-)^{[i/2]+[j/2]+[k/2]}G(k_1k_2,\eta_3)\\ &\times G(k_1k_2,\eta_{3-i-j})\\ &\times G(p_1p_2,\eta_{1+i})G(p_1p_2,\eta_1)G(q_1q_2,\eta_{2+j})\\ &\times G(q_1q_2,\eta_{2-k})G(n_1n_2,\eta_{1+k})G(n_1n_2,\eta_1),\end{aligned}$$

where the primes on the summation signs indicate that the sums should be restricted by

$$i+j+k\leqslant 2, \tag{3.30}$$

and

$$[x]=\begin{cases}x & \text{if } x \text{ is an integer,}\\ 2x & \text{if } x \text{ is a half-integer.}\end{cases} \tag{3.31}$$

The expression becomes more complicated with increasing k in η_k. Once $\langle \eta_k / \eta_k \rangle$ for $k=1,2,...,m$ are known, one can similarly get the WCs or RWCs of SU(3)⊃U(2) with multiplicity,

$$\left\langle \frac{\eta_k}{\rho_1\rho_2\rho} \right\rangle = \left(\prod_{t=0}^{k-1} \left\langle \frac{\eta_t}{\eta_t} \right\rangle^{-1} \sum_{i_t=0}^{k-t}{}' \right) \sum_{k_1 k_2} G(k_1,k_2,\rho_1\rho_2\rho) G(k_1,k_2,\eta_{k-\Sigma_{j=1}^{k-1} i_j}) \times (-)^{\Sigma_{p=1}^{k-1}[i_p/2]} \prod_{q=1}^{k-1} \left\langle \frac{\eta_q}{\eta_{q+i_p}} \right\rangle, \tag{3.32}$$

where the prime on the summation sum indicates that the condition

$$\sum_{t=0}^{k-1} i_t \leqslant k-1 \tag{3.33}$$

should be satisfied. Similarly, define

$$V\left(\frac{\eta_i}{\eta_j} \right) = \left\langle \frac{\eta_i}{\eta_i} \right\rangle^{-1} \left\langle \frac{\eta_i}{\eta_j} \right\rangle. \tag{3.34a}$$

Then the Racah coefficient of SU(3) can be expressed as

$$\begin{aligned} R_{\eta_1}([\bar{m}]) \left\langle \frac{\eta_1}{\eta_1} \right\rangle &= G([\bar{m}],\eta_1), \\ R_{\eta_2}([\bar{m}]) \left\langle \frac{\eta_2}{\eta_2} \right\rangle &= G([\bar{m}],\eta_2) - V\left(\frac{\eta_1}{\eta_2} \right) G([\bar{m}],\eta_1), \\ &\cdots \cdots \\ R_{\eta_j}([\bar{m}]) \left\langle \frac{\eta_j}{\eta_j} \right\rangle &= G([\bar{m}],\eta_j) + \sum_{i_1=1}^{j-1} \sum_{k=1}^{j-1} (-)^k \sum_{i_1 \leqslant i_2 \leqslant \cdots \leqslant i_k < j} G([\bar{m}],\eta_{i_1}) V\left(\frac{\eta_{i_k}}{\eta_j} \right) \prod_{l=1}^{k-1} V\left(\frac{\eta_{i_l}}{\eta_{i_{l+1}}} \right). \end{aligned} \tag{3.34b}$$

IV. Some features of the new SU(3)⊃U(2) RWCs

In this section, symmetry properties of WCs of SU(3) in the canonical basis will be considered. In Sec. III, the phase

$$\left\langle \begin{matrix} [\lambda_1+\mu_1,\mu_1] & [\lambda_2+\mu_2,\mu_2] \\ [\lambda_1+\mu_1,\mu_1] & [\lambda_2+\mu_2,0] \end{matrix} \middle| \begin{matrix} \eta[m_1m_2m_3] \\ [m_1,m_2-\eta,m_3-\mu_2+\eta] \end{matrix} \right\rangle \geqslant 0 \tag{4.1}$$

was chosen. Then, the relative phase is completely determined by the recursion relations (3.23) and (3.24). When $\mu_2=0$ one can check that this phase choice is consistent with that of (Ref. 15), which is the same as that of (Ref. 5) with the same phase structure defined by Biedenharn *et al.*[10] as it should be because the multiplicity-free RWCs of (Refs. 5 and 15) are used. Hence, in order to discuss symmetry properties of the SU(3) WCs, one can expand the WCs obtained in this paper in terms of those defined in (Ref. 10),

$$\left\langle \begin{matrix} (\lambda_1\mu_1) & (\lambda_2\mu_2) \\ \rho_1 & \rho_2 \end{matrix} \middle| \begin{matrix} \eta[m_1m_2m_3] \\ \rho \end{matrix} \right\rangle = \sum_{\xi} y(\xi,\eta) \left[\begin{matrix} (\lambda_1\mu_1) & (\lambda_2\mu_2) \\ \rho_1 & \rho_2 \end{matrix} \middle| \begin{matrix} \xi[m_1m_2m_3] \\ \rho \end{matrix} \right], \tag{4.2a}$$

where the coupling coefficients on the rhs in square brackets are the WCs defined in (Ref. 10), and $y(\xi,\eta)$ is the corresponding special transformation matrix element. Using the orthogonality relations for $y(\xi,\eta)$ and symmetry properties of the WCs discussed in (Ref. 10), one can prove that

$$\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2) \\ \rho_1 & \rho_2\end{matrix} \middle| \begin{matrix}\eta'[m_1m_2m_3] \\ \rho\end{matrix} \right\rangle$$

$$=\sum_{\eta}\sum_{\xi} y(\xi,\eta)y(\xi,\eta')(-)^{\phi(\xi)}\left\langle \begin{matrix}(\lambda_2\mu_2) & (\lambda_1\mu_1) \\ \rho_2 & \rho_1\end{matrix} \middle| \begin{matrix}\eta[m_1m_2m_3] \\ \rho\end{matrix} \right\rangle, \tag{4.2b}$$

where the phase factor $(-)^{\phi(\xi)}$ comes from

$$\left[\begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2) \\ \rho_1 & \rho_2\end{matrix} \middle| \begin{matrix}\xi[m_1m_2m_3] \\ \rho\end{matrix} \right]=(-)^{\phi(\xi)}\left[\begin{matrix}(\lambda_2\mu_2) & (\lambda_1\mu_1) \\ \rho_2 & \rho_1\end{matrix} \middle| \begin{matrix}\xi[m_1m_2m_3] \\ \rho\end{matrix} \right] \tag{4.3}$$

given in Ref. 10,

$$\phi(\xi)=\Gamma_{12}-\Gamma_{11}+\mu_1+\mu_2-m_2+m_1. \tag{4.4}$$

The multiplicity label ξ in this case can be regarded as

$$\xi=\Gamma_{12}-\Gamma_{11}, \tag{4.5}$$

where Γ_{ij} are multiplicity labels from the upper SU(3) pattern defined by Biedenharn *et al.*

It is obvious that

$$Z_{\eta\eta'}=Z\left(\begin{matrix}(\lambda_1\mu_1) & (0) & (\lambda_1\mu_1)\eta' \\ (\lambda_2\mu_2) & [m_1m_2m_3] & (\lambda_2\mu_2)\eta\end{matrix} \right)=\sum_{\xi} y(\xi,\eta)y(\xi,\eta')(-)^{\phi(\xi)}, \tag{4.6}$$

where $Z_{\eta\eta'}$ is a special Z coefficient[38] defined by Millener, which transforms the coupling coefficients from the coupling $(\lambda_1\mu_1)\times(\lambda_2\mu_2)$ to $(\lambda_2\mu_2)\times(\lambda_1\mu_1)$. Equation (4.2) can only be simplified when the coupling is multiplicity-free. In this case, the transformation matrix Y is 1×1 with $y(\xi,\eta)=1$ for fixed ξ and η, and

$$Z_{\eta\eta'}=\delta_{\eta\eta'}(-)^{\phi(\xi)}, \tag{4.7}$$

where ξ can be expressed in terms of λ_1, μ_1, λ_2, μ_2, and m_i with $i=1, 2, 3$.

Similarly, one can deduce the following symmetry properties for the WCs of SU(3):

$$\left\langle \begin{matrix}(\mu_1\lambda_1) & (\mu_2\lambda_2) \\ \tilde{\rho}_1 & \tilde{\rho}_2\end{matrix} \middle| \begin{matrix}\eta'[-m_3-m_2-m_1] \\ \tilde{\rho}\end{matrix} \right\rangle$$

$$=\sum_{\eta} Z_{\eta\eta'}(-)^{m_1-m_3}\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2) \\ \rho_1 & \rho_2\end{matrix} \middle| \begin{matrix}\eta[m_1m_2m_3] \\ \rho\end{matrix} \right\rangle, \tag{4.8a}$$

where $\tilde{\rho}$ is the conjugation of ρ defined by

$$|\tilde{\rho}\rangle\equiv|\tilde{m}\rangle=\left| \begin{matrix}-m_{22}-m_{12} \\ -m_{11}\end{matrix} \right\rangle, \tag{4.8b}$$

and

$$\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2) \\ \rho_1 & \rho_2\end{matrix} \middle| \begin{matrix}\eta'[m_1m_2m_3] \\ \rho\end{matrix} \right\rangle=\left[\frac{\dim([m_1m_2m_3])}{\dim((\lambda_1\mu_1))}\right]^{1/2}(-)^{\phi_3-\phi_1}$$

$$\times\sum_{\eta} Z_{\eta\eta'}\left\langle \begin{matrix}[m_1m_2m_3] & (\mu_2\lambda_2) \\ \rho & \tilde{\rho}_2\end{matrix} \middle| \begin{matrix}\eta(\lambda_1\mu_1) \\ \rho_1\end{matrix} \right\rangle, \tag{4.9}$$

where

$$\phi_3=m''_{11}-m''_{12}-m''_{22}+m_1, \tag{4.10}$$

TABLE I. RWCs of SU(3)⊃U(2), $\langle {}^{[21]}_{[q_1q_2]}\ {}^{[21]}_{[q_1'q_2']}|\ {}^{\eta[m_1m_2m_3]}_{[32]}\rangle$.

[20] [21]	$\sqrt{\frac{1}{20}}$	$\sqrt{\frac{9}{20}}$	$\sqrt{\frac{1}{4}}$	$\sqrt{\frac{1}{4}}$
[21] [11]	$\sqrt{\frac{9}{20}}$	$-\sqrt{\frac{1}{20}}$	$-\sqrt{\frac{1}{4}}$	$\sqrt{\frac{1}{4}}$
[11] [21]	$\sqrt{\frac{9}{20}}$	$-\sqrt{\frac{1}{20}}$	$\sqrt{\frac{1}{4}}$	$-\sqrt{\frac{1}{4}}$
[21] [20]	$-\sqrt{\frac{1}{20}}$	$\sqrt{\frac{7}{10}}$	0	$\sqrt{\frac{1}{4}}$
[20] [21]	$\sqrt{\frac{1}{20}}$	$-\sqrt{\frac{2}{35}}$	$\sqrt{\frac{9}{14}}$	$\sqrt{\frac{1}{4}}$
[21] [11]	$\sqrt{\frac{9}{20}}$	$-\sqrt{\frac{1}{70}}$	$-\sqrt{\frac{2}{7}}$	$\sqrt{\frac{1}{4}}$
[11] [21]	$\sqrt{\frac{9}{20}}$	$\sqrt{\frac{8}{35}}$	$\sqrt{\frac{1}{14}}$	$-\sqrt{\frac{1}{4}}$
$\uparrow[q_1q_2][q_1'q_2']\backslash[m_1m_2m_3]$	[420]	$[321]_{\eta=0}$	$[321]_{\eta=1}$	[300]

$$\phi_1 = m_{11} - m_{12} - m_{22} + \lambda_1 + \mu_1,$$

and

$$\rho = \begin{pmatrix} [m''_{12} m''_{22}] \\ m''_{11} \end{pmatrix}, \quad \rho_1 = \begin{pmatrix} [m_{12} m_{22}] \\ m_{11} \end{pmatrix}. \tag{4.11}$$

Explicit examples for the coupling $[21]\times[21]\downarrow[321]$, which illustrate main features of the new RWCs, will now be given. The following notation will be used:

$$\begin{aligned} \left\langle \frac{0}{0} \right\rangle &= \left\langle \begin{matrix} [21] & [21] \\ [21] & [20] \end{matrix} \middle| \begin{matrix} \eta=0 \\ \end{matrix} \begin{matrix} [321] \\ [32] \end{matrix} \right\rangle, \quad \left\langle \frac{1}{0} \right\rangle = \left\langle \begin{matrix} [21] & [21] \\ [21] & [20] \end{matrix} \middle| \begin{matrix} \eta=1 \\ \end{matrix} \begin{matrix} [321] \\ [32] \end{matrix} \right\rangle \\ \left\langle \frac{0}{1} \right\rangle &= \left\langle \begin{matrix} [21] & [21] \\ [21] & [20] \end{matrix} \middle| \begin{matrix} \eta=0 \\ \end{matrix} \begin{matrix} [321] \\ [311] \end{matrix} \right\rangle, \quad \left\langle \frac{1}{1} \right\rangle = \left\langle \begin{matrix} [21] & [21] \\ [21] & [20] \end{matrix} \middle| \begin{matrix} \eta=1 \\ \end{matrix} \begin{matrix} [321] \\ [311] \end{matrix} \right\rangle. \end{aligned} \tag{4.12}$$

Using the recursion relations given by (3.23) and (3.24), it is simple to show that

$$\begin{pmatrix} \left\langle \frac{0}{0} \right\rangle & \left\langle \frac{1}{0} \right\rangle \\ \left\langle \frac{0}{1} \right\rangle & \left\langle \frac{1}{1} \right\rangle \end{pmatrix} = \begin{pmatrix} \sqrt{\frac{7}{10}} & 0 \\ -\sqrt{\frac{1}{42}} & \sqrt{\frac{10}{21}} \end{pmatrix}. \tag{4.13}$$

With this result in hand, Tables I and II can be worked out by using (3.28). In the tables, the upper parts are taken from de Swart,[39] while the lower parts are derived by the new method. These two types of RWCs with multiplicity two can be transformed with each other by a two dimensional rotation. Furthermore, one can check that the new RWCs satisfy the orthogonality conditions for SU(3) RWCs given by (2.6).

V. REDUCED AUXILIARY WIGNER COEFFICIENTS FOR SU(3)⊃U(2)

The complementary U(4) group is also used in Ref. 11 to label the multiplicity of SU(3). However, in that case the U(4) group is labeled in a noncanonical U(2)×U(2) chain. The authors also point out that the so-called auxiliary Wigner coefficient (AWC) of SU(3) can be calculated from a U(4)⋆SU(3) scalar product. The reduced AWCs satisfy

$$\sum_{\lambda_2\mu_2 q_1' q_i''} \left\langle \begin{matrix} (\lambda_1\mu_1) & (\lambda_2\mu_2) \\ [q_1'q_2'] & [q_1''q_2''] \end{matrix} \middle| \begin{matrix} [m_1m_2m_3] \\ [q_1q_2] \end{matrix} ; [u_1u_2u_3] \right\rangle \left\langle \begin{matrix} (\lambda_1\mu_1) & (\lambda_2\mu_2) \\ [q_1'q_2'] & [q_1''q_2''] \end{matrix} \middle| \begin{matrix} [\bar{m}_1\bar{m}_2\bar{m}_3] \\ [q_1q_2] \end{matrix} ; [\bar{u}_1\bar{u}_2\bar{u}_3] \right\rangle$$

$$= \prod_i \delta_{\bar{u}_i u_i} \delta_{m_i m_i}, \tag{5.1}$$

TABLE II. RWCs of SU(3)⊃U(2), $\langle {}^{[21]}_{[q_1q_2]}\ {}^{[21]}_{[q_1'q_2']}|{}^{\eta[m_1m_2m_3]}_{[22]}\rangle$.

$\downarrow[q_1q_2][q_1'q_2']\backslash[m_1m_2m_3]$	[420]	$[321]_1$	$[321]_2$	[330]
[10] [21]	$\sqrt{\frac{3}{20}}$	$\sqrt{\frac{1}{10}}$	$\sqrt{\frac{1}{2}}$	$\sqrt{\frac{1}{4}}$
[21] [10]	$-\sqrt{\frac{3}{20}}$	$-\sqrt{\frac{1}{10}}$	$\sqrt{\frac{1}{2}}$	$-\sqrt{\frac{1}{4}}$
[20] [20]	$-\sqrt{\frac{1}{40}}$	$-\sqrt{\frac{3}{5}}$	0	$\sqrt{\frac{3}{8}}$
[11] [11]	$\sqrt{\frac{27}{40}}$	$-\sqrt{\frac{1}{5}}$	0	$-\sqrt{\frac{1}{8}}$
[10] [21]	$\sqrt{\frac{3}{20}}$	$\sqrt{\frac{16}{35}}$	$-\sqrt{\frac{1}{7}}$	$\sqrt{\frac{1}{4}}$
[21] [10]	$-\sqrt{\frac{3}{20}}$	$\sqrt{\frac{1}{35}}$	$-\sqrt{\frac{4}{7}}$	$-\sqrt{\frac{1}{4}}$
[20] [20]	$-\sqrt{\frac{1}{40}}$	$-\sqrt{\frac{27}{70}}$	$-\sqrt{\frac{3}{14}}$	$\sqrt{\frac{3}{8}}$
[11] [11]	$\sqrt{\frac{27}{40}}$	$-\sqrt{\frac{9}{70}}$	$-\sqrt{\frac{1}{14}}$	$-\sqrt{\frac{1}{8}}$
$\uparrow[q_1q_2][q_1'q_2']\backslash[m_1m_2m_3]$	[420]	$[321]_{\eta=0}$	$[321]_{\eta=1}$	[330]

$$\sum_{u_i m_i} \left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2)\\ [q_1'q_2'] & [q_1''q_2'']\end{matrix}\middle| \begin{matrix}[m_1m_2m_3]\\ [q_1q_2]\end{matrix};[u_1u_2u_3]\right\rangle \left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2)\\ [\overline{q_1'}\overline{q_2'}] & [\overline{q_1''}\overline{q_2''}]\end{matrix}\middle| \begin{matrix}[m_1m_2m_3]\\ [q_1q_2]\end{matrix};[u_1u_2u_3]\right\rangle$$
$$= \prod_i \delta_{\overline{q_i'}q_i''}\delta_{\overline{q_i}q_i'}, \tag{5.2}$$

where $[u_1u_2u_3]$ are labels of $\mathcal{U}(3)$ which is the subgroup of U(4). The AWCs can be shown to be equivalent to those constructed using the recoupling approach. First of all, assume the irrep $(\lambda_2\mu_2)$ is a coupled irrep, namely,

$$\left|\begin{matrix}(\lambda_2\mu_2)\\ \rho_2\end{matrix}\right\rangle = \sum_{\rho_2'\rho_2''} \left\langle \begin{matrix}(\lambda_2'+\mu_2'0) & (\mu_2'0)\\ \rho_2' & \rho_2''\end{matrix}\middle| \begin{matrix}(\lambda_2\mu_2)\\ \rho_2\end{matrix}\right\rangle \left|\begin{matrix}\lambda_2'+\mu_2' & ; & \mu_2'\\ \rho_2' & & \rho_2''\end{matrix}\right\rangle, \tag{5.3}$$

where ρ_2, ρ_2', ρ_2'' are sublabels of SU(3) in the canonical basis. Special final coupled basis vectors can then be written as

$$\left|((\lambda_1\mu_1),(\lambda_2'+\mu_2'0))[u_1u_2u_3],(\mu_2'0),{}^{[m_1m_2m_3]}_{\rho}\right\rangle$$
$$\equiv \left|{}^{[m_1m_2m_3]}_{\rho};[u_1u_2u_3]\right\rangle$$
$$= \sum \left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2'+\mu_2'0)\\ \rho_1 & \rho_2'\end{matrix}\middle| \begin{matrix}[u_1u_2u_3]\\ \overline{\rho}\end{matrix}\right\rangle \left\langle \begin{matrix}[u_1u_2u_3] & (\mu_2'0)\\ \overline{\rho} & \rho_2''\end{matrix}\middle| \begin{matrix}[m_1m_2m_3]\\ \rho\end{matrix}\right\rangle$$
$$\times \left\langle \begin{matrix}(\lambda_2'+\mu_2'0) & (\mu_2'0)\\ \rho_2' & \rho_2''\end{matrix}\middle| \begin{matrix}(\lambda_2\mu_2)\\ \rho_2\end{matrix}\right\rangle \left|\begin{matrix}(\lambda_1\mu_1) & ; & (\lambda_2'+\mu_2'0) & ; & (\mu_2'0)\\ \rho_1 & & \rho_2' & & \rho_2''\end{matrix}\right\rangle, \tag{5.4}$$

where the sum is over ρ_1, ρ_2', ρ_2'', $\overline{\rho}$, and the WCs involved in the summation are all given by Ališauskas *et al.*[15] and Chacon *et al.*[5]

The AWCs can be evaluated by the overlap

$$\left\langle \begin{matrix}(\lambda_1\mu_1) \\ \rho_1\end{matrix} ; \begin{matrix}(\lambda_2\mu_2) \\ \rho_2\end{matrix} \middle| \begin{matrix}[m_1m_2m_3] \\ \rho\end{matrix} ; [u_1u_2u_3] \right\rangle = \sum_{\rho_2'\rho_2''\overline{\rho}} \left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2'+\mu_2'0) \\ \rho_1 & \rho_2'\end{matrix} \middle| \begin{matrix}[u_1u_2u_3] \\ \overline{\rho}\end{matrix} \right\rangle \times \left\langle \begin{matrix}[u_1u_2u_3] & (\mu_2'0) \\ \overline{\rho} & \rho_2''\end{matrix} \middle| \begin{matrix}[m_1m_2m_3] \\ \rho\end{matrix} \right\rangle \times \left\langle \begin{matrix}(\lambda_2'+\mu_2'0) & (\mu_2'0) \\ \rho_2' & \rho_2''\end{matrix} \middle| \begin{matrix}(\lambda_2\mu_2) \\ \rho_2\end{matrix} \right\rangle. \tag{5.5}$$

One can check that the labels u_1, u_2, u_3 take the same values as those given by Brody *et al.*[11] One can also get reduced AWCs as follows:

$$\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2\mu_2) \\ [q_1q_2] & [q_1'q_2']\end{matrix} \middle| \begin{matrix}[m_1m_2m_3] \\ [q_1''q_2'']\end{matrix} ; [u_1u_2u_3] \right\rangle = \sum_{pq_1q_2} \left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2'+\mu_2'0) \\ [q_1q_2] & [\lambda_2'+\mu_2'-p0]\end{matrix} \middle| \begin{matrix}[u_1u_2u_3] \\ [\overline{q_1}\overline{q_2}]\end{matrix} \right\rangle \left\langle \begin{matrix}[u_1u_2u_3] & (\mu_2'0) \\ [\overline{q_1}\overline{q_2}] & [p0]\end{matrix} \middle| \begin{matrix}[m_1m_2m_3] \\ [q_1''q_2'']\end{matrix} \right\rangle \times \left\langle \begin{matrix}(\lambda_2'+\mu_2'0) & (\mu_2'0) \\ [\lambda_2'+\mu_2'-p0] & [p0]\end{matrix} \middle| \begin{matrix}(\lambda_2\mu_2) \\ [q_1'q_2']\end{matrix} \right\rangle U\left(\begin{matrix}[q_1q_2] & [\lambda_2'+\mu_2'-p0] & [\overline{q_1}\overline{q_2}] \\ [p0] & [q_1''q_2''] & [q_1'q_2']\end{matrix} \right). \tag{5.6}$$

One can verify that the reduced AWCs given by (5.5) indeed satisfy the orthogonality relations (5.1) and (5.2). Using the explicit expression of the multiplicity-free RWCs involved in the sum, one can get a closed algebraic expression for the reduced AWCs. Such AWCs may also be useful, especially in two-particle coupling problems. It should be pointed out that though the result (5.6) is the same as required by Brody *et al.*, the labeling scheme is not the same. The multiplicity labels of their AWCs are specified by a U(4) subgroup U(3), while they are now specified by the irrep of SU(3) coupled from the first two irreps.

Using analytic expressions for the multiplicity-free RWCs given in Ref. 15, the following algebraic expression for the reduced AWCs of SU(3)⊃U(2) can be obtained:

$$\left\langle \begin{matrix}(\lambda_1\mu_1) & (\lambda_2'+\mu_2';\mu_2')(\lambda_2\mu_2) \\ [m_1m_2] & [m_1'm_2']\end{matrix} \middle| \begin{matrix}[m_1m_2m_3] \\ [m_1''m_2'']\end{matrix} ; [u_1u_2u_3] \right\rangle$$

$$= \delta_{\lambda_2'+2\mu_2',\lambda_2+2\mu_2}\delta_{\lambda_1+2\mu_1+\lambda_2+2\mu_2,m_1+m_2+m_3}$$

$$\times\left[\frac{(\lambda_2+1)(\lambda_2'+\mu_2'-\mu_2)!\mu_2!(m_1-m_2+1)(m_1-m_3+2)(m_2-m_3+1)(m_{12}''-m_2)!}{(\lambda_2+\mu_2-\lambda_2'-\mu_2')!(\mu_2-\mu_2')!(\lambda_2+\mu_2-m_{12}')!(m_2-k_2+1)!(m_1-m_{12}'')!(m_2-m_{22}'')!}\right.$$

$$\times\frac{(\lambda-k_1-k_2-m_2)!(\mu_1'+k_1-m_3)!(\lambda-k_1-k_2-m_3+1)!(m_{22}''-m_3)!(m_{12}''-m_3+1)!}{(m_1-\lambda+k_1+k_2)!(m_2-\mu_1-k_1)!(m_3-k_2)!(m_1-\mu_1-k_1+1)!(m_1-k_2+2)!}$$

$$\left.\times\frac{(m_{12}'-\mu_2)!(\mu_1-k_2)!(\lambda_1+\mu_1-k_2+1)!(\lambda_1+\mu_1-m_{12})!(\mu_1-m_{22})!(\lambda_1+\mu_1-m_{22}+1)!}{(\mu_2-m_{22}')!(\lambda_2+\mu_2-m_{22}'+1)!(\mu_1+k_1+1)!(m_{12}-\mu_1)!m_{22}!(m_{12}+1)!(m_1-m_{22}''+1)!}\right]^{1/2}$$

$$\times\sum_{p=0}^{\mu_2'}\sum_{q=\min(q)}^{\max(q)}(\mu_2'-p)!(\lambda_2'+\mu_2'+p-m_{12}'-m_{22}')!$$

$$\times\left(\frac{(m_{12}''+m_{22}''-p-q-m_{12})!(p-m_{22}')!(q-m_{22})!}{(m_{12}'-p)!}\right)^{1/2}$$

$$\times\left(\frac{(m_{12}''+m_{22}''-p-q-m_{22}+1)!(m_{12}''+m_{22}''-p-2q+1)(p+q-m_{22}'')!(m_{22}''-q+1)!}{(m_{12}''-p-q)!(m_{12}''+m_{22}''-p-q-\mu_1-k_1)!(m_{12}-q)!}\right)^{1/2}$$

$$\times U\left(\begin{matrix}[m_{12}m_{22}] & [m_{12}'+m_{22}'-p0] & [m_{12}''+m_{22}''-p-q,q] \\ [p0] & [m_{12}''m_{22}''] & [m_{12}'m_{22}']\end{matrix} \right)\times F_2\left(\begin{matrix}[\lambda-k_1-k_2,\mu_1+k_1,k_2] & [m_1m_2m_3] \\ [m_{12}''+m_{22}''-p-q,q] & [m_{12}''m_{22}'']\end{matrix} \right)$$

$$\times F_2\begin{pmatrix}[\lambda_1+\mu_1\mu_1] & [\lambda-k_1-k_2,\mu_1+k_1,k_2]\\ [m_{12}+m_{22}0] & [m''_{12}+m''_{22}-p-q,q]\end{pmatrix}$$
$$\times F\begin{pmatrix}\lambda'_2+\mu'_2 & ; & \mu'_2 & ; & [\lambda_2+\mu_2\mu_2]\\ m'_{12}+m'_{22}-p & & p & & [m'_{12}m'_{22}]\end{pmatrix},$$

(5.7)

where the $(\lambda_2\mu_2)$ irrep is written in coupled form $(\lambda'_2 0)\times(\mu'_2 0)$ with $\lambda'_2+2\mu'_2=\lambda_2+2\mu_2$,

$$\lambda=\lambda_1+\mu_1+\lambda'_2+\mu'_2,$$

$$[u_1,u_2,u_3]=[\lambda-k_1-k_2,\mu_1+k_1,k_2],$$
$$\min(q)=\max(k_2,m''_{12}+m''_{22}-p-\lambda+k_1+k_2),$$
$$\max(q)=\min(\mu_1+k_1,m''_{12}+m''_{22}-p-\mu_1-k_1),$$

(5.8)

and

$$F\begin{pmatrix}\lambda'_2+\mu'_2 & ; & \mu'_2 & ; & [\lambda_2+\mu_2\mu_2]\\ m'_{12}+m'_{22}-p & & p & & [m'_{12}m'_{22}]\end{pmatrix}$$
$$=\sum_t (-)^t \frac{(m'_{12}-p+t)!(\lambda_2+\mu_2-m'_{12}-m'_{22}+p-t)!}{t!(\lambda'_2+\mu'_2-m'_{12}-m'_{22}+p-t)!(p-m'_{22}-t)!(m'_{12}+m'_{22}-p-\mu_2+t)!}.$$

(5.9)

VI. DISCUSSION

In this paper, the complementary group technique proposed in (I) for a resolution of outer multiplicity problem of SU(n) is used to obtain a general procedure for the derivation of SU(3)⊃U(2) RWCs with multiplicity. The procedure uses a recoupling formula together with a special transformation within the multiplicity space. The outer multiplicity labeling scheme is shown to be nonunique; one can transform from one scheme to another under SO(m), where m is the multiplicity of $[m_1m_2m_3]$ in the decomposition $(\lambda_1\mu_1)\times(\lambda_2\mu_2)$. From this perspective, Biedenharn's resolution for the outer multiplicity of SU(n) can also be regarded as a complementary group resolution. In their work, the complementary group is U(n). Unlike the resolution proposed in (I) where only special Gel'fand basis are considered, here the subirreps of the complementary group U(n) are all considered in order to resolve the multiplicity of SU(n)×SU(n). This is why the multiplicity formulae cannot be worked out easily. The canonical schemes all belong to an equivalent class.

Using the method proposed, RWCs of SU(3)⊃U(2) with multiplicity can be derived recursively. A computer algorithm based on this procedure can be easily developed, which will make numerical calculation possible in practical applications. Furthermore, one can also obtain closed algebraic expressions for these RWCs for small m values. However, the expression remains cumbersome with summation over many variables. The complexity increases with increasing the multiplicity.

Only RWCs of SU(3) in the canonical chain SU(3)⊃U(2) are discussed. Nonetheless, this method can also be applied to noncanonical basis of SU(3), for example SU(3)⊃SO(3), by using RWCs of SU(3)⊃SO(3) with one symmetric irrep, and therefore multiplicity-free.[40,41] In addition, the procedure outlined in this paper can be extended to the general SU(n) case. The SU(4)⊃U(3) RWCs will be the topic of the next paper.

A closed algebraic expression of reduced AWCs proposed in Ref. 11 is obtained using the new approach. These coefficients satisfy different orthogonality relations and therefore may be useful in many-particle coupling problems.

Comment on "An exactly solvable two-body problem with retarded interactions and radiation reaction in classical electrodynamics" [J. Math. Phys. 38, 5690 (1997)]

V. Hnizdo
Department of Physics and Schonland Research Centre for Nuclear Sciences, University of the Witwatersrand, Johannesburg, 2050 South Africa

(Received 28 January 1998; accepted for publication 7 April 1998)

[S0022-2488(98)02710-8]

A recent paper under the above title by Rivera and Villarroel[1] considers the problem of energy conservation in a system of two identical charges moving uniformly and diametrically opposite each other along a circle. Apart from the external forces needed to maintain their circular motion, the charges are subject to their retarded electromagnetic interaction and the Lorentz–Dirac radiation reaction force. We would like to point out that this interesting problem had already been investigated, in numerical calculations[2] as well as analytically,[3] with findings and conclusions similar to those of Ref. 1—namely that the rate of radiation from such a system

$$4\beta^4 \sum_{n=2,4,6,\ldots} n^2 \int_0^{\pi} \left[\left(\frac{dJ_n(n\beta \sin\theta)}{d(n\beta \sin\theta)} \right)^2 + n^2 \cos^2\theta \left(\frac{J_n(n\beta \sin\theta)}{n\beta \sin\theta} \right)^2 \right] \sin\theta \, d\theta, \tag{1}$$

equals the rate of work of the external forces against those of the Lorentz–Dirac radiation reaction and the retarded Lienard–Wiechert interaction[4]

$$\frac{4\beta^4}{3(1-\beta^2)^2} - \frac{\beta[(\beta \cos 2\psi - \sin\psi)(1-\beta^2) + 2\psi^2(\sin\psi + \beta)]}{2(1+\beta \sin\psi)^3 \cos^2\psi}. \tag{2}$$

Here, $J_n(x)$ are the Bessel functions and $\beta = \psi/\cos\psi$ is the speed of the circling motion, with ψ being the angle subtended at the position of each charge by the retarded and current positions of the other charge; units such that the speed of light, radius of the circle and magnitude of the charges are all unity are used. The above expressions also hold for a system of unlike charges of equal magnitude when the summation in Eq. (1) is changed to run over n odd and the second term in Eq. (2) is added to, instead of subtracted from, the first term. The analytical proof[5] of the equality of the expressions (1) and (2) dispenses with the task that Rivera and Villarroel set themselves to undertake in another paper.

It should be noted also that the mistake in a paper by Briggs[6] which Rivera and Villarroel have found had been corrected in an erratum,[7] and that, in a remarkable coincidence, a paper by Gordeyev[8] addressing the same problem and obtaining similar findings appeared in the literature concurrently with Ref. 1. Gordeyev has derived an analytical expression for the angle ψ in terms of the speed β

$$\psi = 2 \sum_{m=0}^{\infty} \frac{(-1)^m}{2m+1} J_{2m+1}[(2m+1)\beta]. \tag{3}$$

In his comment[1] Hnizdo brings to our knowledge a previous work[2] in which the rate of radiation of two identical charges moving with constant angular speed at opposite ends of a diameter is numerically evaluated. Although this calculation is related to part of our paper, our work is based on a more general framework, since it deals with the construction of an exact solution of the Lorentz–Dirac equation, where the external fields that make the motion possible, and their sources are studied in detail.

Regarding the calculation of the rate of radiation, Hnizdo refers to a paper by Jordan.[3] This work starts from a formula given in Jackson's book,[4] where the rate of radiation is expressed in terms of Bessel functions as a sum of the power radiated in the different harmonics. On the other hand, we work directly with the Liénard–Wiechert retarded fields and obtain an alternative representation for the power radiated [see our Eq. (3.27)]. Our method seems to be simpler, since it avoids tedious manipulations of Bessel functions in order to evaluate the rate of radiation.

Two-form gauge fields in the Becchi–Rouet–Stora–Tyutin superspace

J. Barcelos-Neto[a] and R. Thibes[b]
Instituto de Física, Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ 21945-970, Brazil

(Received 6 November 1997; accepted for publication 26 June 1998)

We consider a geometrical description for tensor gauge fields. Based on this geometrical treatment, we develop the theory involving one- and two-form gauge fields by means of the Becchi–Rouet–Stora–Tyutin (BRST) superfield formalism. This permits us to directly obtain invariant Lagrangians for both BRST and anti-BRST transformations and we shall see that all the ingredients of the formalism (ghosts, ghost-for-ghosts and all the auxiliary fields) naturally occur. We introduce collective fields to construct the field–antifield quantum action in a generic gauge. We deal with both Abelian and non-Abelian cases. In this last case, the BRST superspace formulation sheds more light on this still open problem. © *1998 American Institute of Physics.* [S0022-2488(98)00211-4]

I. INTRODUCTION

The geometrical interpretation of the Becchi–Rouet–Stora–Tyutin (BRST)[1] and anti-BRST[2] symmetries leads to a particular superspace formulation of gauge theories,[3] where the corresponding superfields are objects that naturally contain gauge, ghost, and auxiliary fields. The importance of formulating a gauge theory in terms of these superfields is that it is naturally invariant under BRST and anti-BRST transformations. As examples of the use of this formalism, we mention the usual Yang–Mills theory[3,4] and the path integral quantization of relativistic strings.[5] It can also be used in the field–antifield quantization prescription due to Batalin–Vilkovisly (BV),[6] where a set of fields called *collective fields* is introduced.[7–9] We also mention that in the case of Yang–Mills and non-Abelian two-form gauge fields, one may use the duality property to identify the antifields.[10]

Our purpose here is to apply the superfield formalism for gauge theories containing one- and two-form gauge fields, coupled in a topological way. We show that this directly leads to the quantum BV actions. We shall consider both Abelian and non-Abelian cases. We mention that the particular Abelian case without topological term has already been treated by Marchetti and Tonin, but without any relation with the BV formalism.[11]

It might be opportune to mention that the interest for tensor gauge fields dates back to more than 20 years. They were considered by Kalb and Ramond[12] with the motivation that they could carry the force in the string interaction. At the same time, Cremmer and Scherk[13] considered one- and two-form gauge fields coupled in a topological way with the purpose of obtaining a kind of dynamical symmetry breaking for the gauge symmetry and a consequent mass generation for the vector field. This same problem has been considered nowadays in a version where the mass generation is carried out as an effective theory when the tensor field is conveniently eliminated.[14–16] We also mention that tensor gauge fields appear in recent developments of string theories and supergravity models.[17]

The formulation of two-form gauge fields in the context of the BRST superspace leads to interesting systems whose characteristics are not generally found in the one-form case. We mention, for example, the reducibility condition of the Abelian formulation. This means that the first-class constraints[18] related to the gauge symmetry are not all independent. In consequence, the covariant quantization of these theories leads to the presence of ghost-for-ghosts and many aux-

iliary fields.[15,19] The BRST superfield formulation naturally contains all these ingredients. More than that, it also naturally incorporates both BRST and anti-BRST symmetries and what does not happen when the superfield formulation is not used. We shall also see that the coefficient parameter of the gauge-fixing term also affects the ghost-for-ghost terms and the ones containing the corresponding auxiliary fields (a fact that is not present when the two symmetries are considered separately).

Concerning the non-Abelian formulation for tensor gauge fields, it is opportune to say that a complete theory, that can be accepted without restrictions, still does not exist. In fact, the obtainment of such a theory is not a simple task. Let us briefly explain why this occurs.

In the Abelian formulation, we have that the theory is invariant by the following gauge transformation of the (antisymmetric) tensor gauge field

$$\delta B_{\mu\nu}=\partial_\mu\xi_\nu-\partial_\nu\xi_\mu, \tag{I.1}$$

where ξ_μ is the characteristic parameter of the gauge transformation. As usual, it shows that not all components of the gauge potential $B_{\mu\nu}$ are independent. Two of them disappear by virtue of the massless condition. So, if all components of the vector gauge parameter ξ_μ were independent, the theory would exhibit zero degrees of freedom. However, this is nonetheless the case because the Abelian theory is reducible, in a sense that if one writes ξ_μ as $\xi_\mu=\partial_\mu\xi$, where ξ is some scalar quantity, Eq. (I.1) does not lead to any gauge transformation. In other words, the four components of ξ_μ are not independent and we can conclude that the tensor gauge field $B_{\mu\nu}$ has one physical degree of freedom. Incidentally, we also mention that it is precisely this degree of freedom which is used to give mass to the vector gauge in a coupled vector–tensor gauge theory[14] and the same number of physical degrees of freedom is kept after and before the mass generation, as it should be.

In the non-Abelian case, the corresponding gauge transformation reads

$$\delta B^a_{\mu\nu}=(D_\mu\xi_\nu)^a-(D_\nu\xi_\mu)^a. \tag{I.2}$$

Now, we observe that if one replaces the gauge parameter ξ^a_μ by $\xi^a_\mu=(D_\mu\xi)^a$, we get

$$\begin{aligned}\delta B^a_{\mu\nu}&=([D_\mu,D_\nu]\xi)^a\\&=gf^{abc}F^b_{\mu\nu}\xi^c\\&\equiv g(F_{\mu\nu}\times\xi)^a,\end{aligned} \tag{I.3}$$

where f^{abc} is the structure constant of the gauge symmetry group and g is a coupling parameter. The quantity $F^a_{\mu\nu}$ is the usual non-Abelian strength tensor for the vector field. We notice that the non-Abelian tensor theory would be reducible just in the case where $F^a_{\mu\nu}=0$ (on-shell), what can be obtained from the interesting model given by Freedman and Townsend.[20] We mention that the quantization of this model has been studied in a wide variety of ways.[21] Unfortunately, besides the fact of the model to be reducible just on-shell, the Abelian limit of this formulation does not correspond to the one given by Cremmer and Scherk and consequently it would not be compatible with a complete non-Abelian treatment.

An alternative way of circumventing these problems is by introducing a kind of a Stuckelberg field.[22] This permits us to have a non-Abelian theory with vector and tensor gauge fields coupled in a topological way which has an Abelian limit compatible with the Cremmer and Scherk paper.[23] Even though this non-Abelian theory is in general not reducible, the interesting point is that the Stuckelberg field disappears in the Abelian limit, what gives the same number of physical degrees of freedom in both sectors of the theory. We also mention that it is possible to obtain a reducible theory if the transformations involve vector and tensor fields in the same relation.[24] The superfield formalism of such an irreducible model has already been worked out by Baulieu and Thierry-Mieg,[25] but without identifying the antifields of the BV quantization scheme. We also address our attention to this problem. We take this opportunity to mention the Chapline–Manton model,[26] which is a kind of mixed case since it couples non-Abelian one-form gauge fields with Abelian two-form ones, where its superfield treatment was done by Baulieu.[27]

Our paper is organized as follows: In Sec. II, we briefly review the BRST and anti-BRST superspace formalism applied to the Yang–Mills fields. We develop this section in the way we

intend to use the formalism for the two-form case. In Sec. III, we consider two-form gauge fields, both Abelian and non-Abelian, from a geometrical point of view. We shall see that even though the concept of curvature is meaningless for the two-form case, it is possible to construct another object that makes the geometrical formulation consistent. The development of the theory in this way will permit us to introduce some ingredients that will be useful in the development of the next sections and we shall also see how the problems of the non-Abelian formulation can be circumvented, based on the ideas introduced in the paper of Ref. 23. In Sec. IV, we formulate the Abelian theory involving one- and two-form gauge fields, coupled in a topological way, by using the formalism developed in the two previous sections. In Sec. V we generalize the results of Sec. IV to the non-Abelian case through the introduction of the Stuckelberg field. Section VI is devoted to the Batalin–Vilkovisky quantization prescription, where we apply the technique of collective fields to obtain the BV action directly from the known superfields of the theory. We left Sec. VII for some concluding remarks and also included two appendices to contain details of the calculations.

II. BRIEF REVIEW OF THE BRST SUPERSPACE FORMALISM FOR THE YANG–MILLS THEORY

The development of the BRST and anti-BRST symmetries in the language of superfields is done in a space of four space–time coordinates x_μ and two Grassmannian ones, θ and $\bar{\theta}$, that we suppose to be real. We then introduce the following quantities (also real)

$$\mathscr{A}^a_\mu(x,\theta,\bar{\theta})=A^a_\mu(x)+i\theta A^{\theta a}_\mu(x)+i\bar{\theta}\bar{A}^{\bar{\theta}a}_\mu(x)+i\bar{\theta}\theta A^{\bar{\theta}\theta a}_\mu(x), \tag{II.1}$$

$$\mathscr{C}^a(x,\theta,\bar{\theta})=c^a(x)+\theta C^{\theta a}(x)+\bar{\theta}\bar{C}^{\bar{\theta}a}(x)+i\bar{\theta}\theta C^{\bar{\theta}\theta a}(x), \tag{II.2}$$

$$\bar{\mathscr{C}}^a(x,\theta,\bar{\theta})=\bar{c}^a(x)+\theta b^a(x)+\bar{\theta}\bar{b}^a(x)+i\bar{\theta}\theta\bar{C}^{\bar{\theta}\theta a}(x). \tag{II.3}$$

We associate the ghost numbers 0, 1, and -1, for the superfields $\mathscr{A}^a_\mu$, $\mathscr{C}^a$, and $\bar{\mathscr{C}}^a$, respectively. With these superfields, one constructs the following connection one-form.

$$\Gamma=-ig(dx^\mu\mathscr{A}_\mu+id\theta\mathscr{C}+id\bar{\theta}\bar{\mathscr{C}}), \tag{II.4}$$

where $\mathscr{A}_\mu=\mathscr{A}^a_\mu T^a$, $\mathscr{C}=\mathscr{C}^a T^a$, and $\bar{\mathscr{C}}=\bar{\mathscr{C}}^a T^a$. The quantities T^a are the matrix generators of the gauge symmetry group and the relative positions between $d\theta$ and $\mathscr{C}$, as well as between $d\bar{\theta}$ and $\mathscr{C}$, because we are using the left derivative convention with respect to the Grassmannian coordinates.

The curvature tensor is introduced by using its well-known definition,

$$\begin{aligned}F&=\mathscr{D}\Gamma\\&=d\Gamma+\Gamma\wedge\Gamma,\end{aligned} \tag{II.5}$$

where the exterior derivative d is here defined by

$$d=dx^\mu\partial_\mu+d\theta\partial_\theta+d\bar{\theta}\partial_{\bar{\theta}}. \tag{II.6}$$

The combination of (II.4)–(II.6) leads to

$$\begin{aligned}F=&-\frac{i}{2}g\ dx^\mu\wedge dx^\nu(\partial_\mu\mathscr{A}_\nu-\partial_\nu\mathscr{A}_\mu-ig[\mathscr{A}_\mu,\mathscr{A}_\nu])-ig\ dx^\mu\wedge d\theta(i\partial_\mu\mathscr{C}-\partial_\theta\mathscr{A}_\mu+g[\mathscr{A}_\mu,\mathscr{C}])\\&-ig\ dx^\mu\wedge d\bar{\theta}(i\partial_\mu\bar{\mathscr{C}}-\partial_{\bar{\theta}}\mathscr{A}_\mu+g[\mathscr{A}_\mu,\bar{\mathscr{C}}])-g\ d\theta\wedge d\theta(\partial_\theta\mathscr{C}+g\mathscr{C}\mathscr{C})-g\ d\bar{\theta}\wedge d\bar{\theta}\\&\times(\partial_{\bar{\theta}}\bar{\mathscr{C}}+g\bar{\mathscr{C}}\bar{\mathscr{C}})-g\ d\theta\wedge d\bar{\theta}(\partial_\theta\bar{\mathscr{C}}+\partial_{\bar{\theta}}\mathscr{C}+g\mathscr{C}\bar{\mathscr{C}}+g\bar{\mathscr{C}}\mathscr{C}).\end{aligned} \tag{II.7}$$

The crucial point of the superfield formulation of the BRST and anti-BRST symmetries is to assume the so-called horizontally condition, that is, the geometry is flat along the θ and $\bar{\theta}$ directions.[3,4] Imposing this condition in the curvature tensor above, we obtain

$$\begin{aligned}
A_\mu^{\theta a} &= (D_\mu c)^a, \\
A_\mu^{\bar{\theta} a} &= (D_\mu \bar{c})^a, \\
C^{\theta a} &= -\frac{i}{2} g(c \times c)^a, \\
\bar{b}^a &= -\frac{i}{2} g(\bar{c} \times \bar{c})^a, \\
C^{\bar{\theta} a} &= -b^a - ig(c \times \bar{c})^a, \\
C^{\bar{\theta}\theta a} &= g[c \times (b + igc \times \bar{c})]^a, \\
\bar{C}^{\bar{\theta}\theta} &= -g(b \times \bar{c})^a, \\
A_\mu^{\bar{\theta}\theta a} &= (D_\mu b)^a + ig(D_\mu c \times \bar{c})^a,
\end{aligned} \tag{II.8}$$

plus many other equations that one can show to be just consistency relations for the equations above (we shall present some details of a similar calculation for the tensor case).

Using the expressions (II.8) into (II.1)–(II.3), we obtain the superfield expressions

$$\mathscr{A}_\mu = A_\mu + i\theta D_\mu c + i\bar{\theta} D_\mu \bar{c} + i\bar{\theta}\theta [D_\mu b + ig(D_\mu c) \times \bar{c}], \tag{II.9}$$

$$\mathscr{C} = c - \frac{i}{2} g\theta c \times c - \bar{\theta}(b + igc \times \bar{c}) + ig\bar{\theta}\theta c \times (b + igc \times \bar{c}), \tag{II.10}$$

$$\bar{\mathscr{C}} = \bar{c} + \theta b - \frac{i}{2} g\bar{\theta}\bar{c} \times \bar{c} - ig\bar{\theta}\theta b \times \bar{c}. \tag{II.11}$$

Let us now see how the BRST and anti-BRST symmetries are embodied in the superfields above. We generically denote by Φ any superfield and suppose it has the following general form

$$\Phi(x, \theta, \bar{\theta}) = A(x) + \theta B(x) + \bar{\theta}\bar{B}(x) + i\bar{\theta}\theta D(x). \tag{II.12}$$

Under translations λ and $\bar{\lambda}$ of the coordinates θ and $\bar{\theta}$, respectively, we obtain that the superfield Φ transforms as

$$\delta_\lambda \Phi = \lambda B + i\bar{\theta}\lambda D, \tag{II.13}$$

$$\delta_{\bar{\lambda}} \Phi = \bar{\lambda}\bar{B} - i\theta\bar{\lambda} D. \tag{II.14}$$

This leads to the following transformations for the component fields

$$\begin{aligned}
\delta_\lambda A &= \lambda B, \\
\delta_\lambda B &= 0, \\
\delta_\lambda \bar{B} &= i\lambda D, \\
\delta_\lambda D &= 0,
\end{aligned} \tag{II.15}$$

and

$$\delta_{\bar{\lambda}} A = \overline{\lambda B},$$

$$\delta_{\bar{\lambda}} B = -i\overline{\lambda D},$$

$$\delta_{\bar{\lambda}} \bar{B} = 0, \tag{II.16}$$

$$\delta_{\bar{\lambda}} D = 0.$$

In this superspace formalism, (II.15) and (II.16) are identified as the BRST and anti-BRST transformations for the component fields. In fact, considering the superfields given by (II.9)–(II.11), we obtain

$$\delta_\lambda A_\mu = i\lambda D_\mu c,$$

$$\delta_\lambda c = -\frac{i}{2} g\lambda c \times c,$$

$$\delta_\lambda \bar{c} = \lambda b, \tag{II.17}$$

$$\delta_\lambda b = 0,$$

and

$$\delta_{\bar{\lambda}} A_\mu = i\overline{\lambda} D_\mu \bar{c},$$

$$\delta_{\bar{\lambda}} c = -\overline{\lambda}(b + igc \times c),$$

$$\delta_{\bar{\lambda}} \bar{c} = \frac{i}{2} g\overline{\lambda c} \times \bar{c}, \tag{II.18}$$

$$\delta_{\bar{\lambda}} b = ig\overline{\lambda} b \times \bar{c}.$$

that are precisely the well-known BRST and anti-BRST transformations for the Yang–Mills fields.

In order to construct invariant Lagrangians under BRST and anti-BRST transformations, we look at the set of transformations (II.15) and (II.16). We then notice, for example, that this is the case when the Lagrangian is the $\theta\theta$ component of a superfield. Another example is any Lagrangian that is a singlet (a superfield independent of θ and $\bar{\theta}$). There are two more possibilities: when the Lagrangian is the θ or the $\bar{\theta}$ component of a superfield without the $\theta\theta$ term. Besides these requirements, there are others that have to be taken into account in order to obtain invariant Lagrangians. For example, the mass dimension ought to be less or equal to four for the question of renormalizeability and the ghost and parity numbers ought to be zero.

In the case of the Yang–Mills theory, one directly sees that

$$\mathscr{L}_I = \text{const tr } \mathscr{F}_{\mu\nu}\mathscr{F}^{\mu\nu} \tag{II.19}$$

is a singlet, where $\mathscr{F}_{\mu\nu}$ is a superfield defined by $\mathscr{F}_{\mu\nu} = \partial_\mu \mathscr{A}_\nu - \partial_\nu \mathscr{A}_\mu + g\mathscr{A}_\mu \times \mathscr{A}_\nu$ (we point out that the product of two superfields is a superfield also). This singlet corresponds to the usual term of the Yang–Mills theory, $-\frac{1}{4}$ tr $F_{\mu\nu}F^{\mu\nu}$.

Considering the superfields $\mathscr{C}$ and $\bar{\mathscr{C}}$, the following combinations have parities and ghost numbers zero: tr $\partial_\theta \bar{c} \partial_\theta \bar{c}$, tr $\partial_{\bar{\theta}} c \partial_{\bar{\theta}} c$, tr $\partial_\theta \bar{c} \partial_{\bar{\theta}} c$, and tr $\partial_{\bar{\theta}} \bar{c} \partial_\theta c$. One can see that the first one is a singlet related to tr bb. The second one is a superfield without the $\theta\theta$ component, so its term in $\bar{\theta}$ is invariant. However, this component cannot be used as a Lagrangian because its ghost and parity numbers are not zero. The last two terms are complete superfields. Consequently, their $\theta\theta$ components are also invariant. Thus the following Lagrangians are possible

$$\mathscr{L}_{II}^{(1)} = \text{const tr } \partial_\theta \bar{c} \partial_\theta \bar{c},$$

$$\mathscr{L}_{II}^{(2)} = \text{const tr } \partial_\theta \partial_{\bar{\theta}} (\partial_\theta \bar{c} \partial_{\bar{\theta}} c), \tag{II.20}$$

$$\mathscr{L}_{II}^{(3)} = \text{const tr } \partial_\theta \partial_{\bar{\theta}} (\partial_{\bar{\theta}} \bar{c} \partial_\theta c).$$

All of them are related to gauge-fixing Lagrangians. The first one corresponds to the usual Lorentz term. The other ones are more complicated gauge-fixing conditions.

Finally, the $\bar{\theta}\theta$ component of the superfield $\mathscr{A}_\mu \mathscr{A}^\mu$ is the term that is lacking in this formulation. In fact,

$$\mathscr{L}_{III} = \frac{i}{2} \partial_\theta \partial_{\bar{\theta}} \text{tr}(\mathscr{A}_\mu \mathscr{A}^\mu)$$

$$= 2 \text{ tr}(\partial_\mu \bar{c} D^\mu c + i A_\mu \partial^\mu b). \tag{II.21}$$

III. GEOMETRIC TREATMENT FOR ABELIAN AND NON-ABELIAN VECTOR–TENSOR GAUGE THEORIES

Let us first consider the Abelian case. Remembering, for one-form gauge field the connection one-form reads (for question of simplicity, we make the coupling parameters equal to one from now on)

$$\Gamma = -iA_\mu dx^\mu, \tag{III.1}$$

and the curvature in the Abelian case is just obtained by taking

$$F = d\Gamma$$

$$= -\frac{i}{2} F_{\mu\nu} dx^\mu \wedge dx^\nu. \tag{III.2}$$

For the two-form gauge fields we similarly write

$$\Lambda = -\frac{i}{2} B_{\mu\nu} dx^\mu \wedge dx^\nu. \tag{III.3}$$

Of course, this quantity cannot be considered as a connection. But, in spite of this, we define a geometric quantity H in the same way that F was done, i.e.,

$$H = d\Lambda. \tag{III.4}$$

We emphasize that even though H has been defined similarly to F, it cannot be identified as a curvature tensor because Λ is not a connection. We also see that this procedure may be extended for gauge tensors of any rank. The motivation of introducing H by the above definition is that a similar Lagrangian to the vector gauge field, namely

$$\mathscr{L} = -\tfrac{1}{2} * (H * H), \tag{III.5}$$

leads to the well-known Lagrangian introduced by Kalb and Ramond[12]

$$\mathscr{L} = \tfrac{1}{12} H_{\mu\nu\rho} H^{\mu\nu\rho}, \tag{III.6}$$

where $H_{\mu\nu\rho}$ is defined by $H_{\mu\nu\rho} = \partial_\mu B_{\nu\rho} + \partial_\rho B_{\mu\nu} + \partial_\nu B_{\rho\mu}$.

The gauge transformations for these objects are

$$\delta_V \Gamma = -d\epsilon,$$

$$\delta_V F = 0, \tag{III.7}$$

$$\delta_V\Lambda=0,$$

$$\delta_V H=0,$$

and

$$\begin{aligned}\delta_T\Gamma&=0,\\ \delta_T F&=0,\\ \delta_T\Lambda&=-d\xi,\\ \delta_T H&=0.\end{aligned}\tag{III.8}$$

The subscripts V and T stand for the vector and tensor gauge transformations. The quantity ξ is a one-form parameter related to the quantity introduced in Eq. (I.1).

Finally, we mention that the gauge invariant Lagrangian corresponding to the Cremmer and Scherk theory is given by[13]

$$\mathscr{L}=\tfrac{1}{2}*(F*F)-\tfrac{1}{2}*(H*H)-4m*(F\wedge\Lambda).\tag{III.9}$$

We now consider the non-Abelian case. For the one- and two-form gauge fields we have

$$\Gamma=-iT^aA^a_\mu dx^\mu,\tag{III.10}$$

$$\Lambda=-\frac{i}{2}\,T^aB^a_{\mu\nu}dx^\mu\wedge dx^\nu.\tag{III.11}$$

Now, the vector and tensor gauge transformations read

$$\begin{aligned}\delta_V\Gamma&=-D\epsilon\\ &=-d\epsilon-\Gamma\epsilon+\epsilon\Gamma,\\ \delta_V\Lambda&=\epsilon\Lambda-\Lambda\epsilon,\\ \delta_T\Gamma&=0,\\ \delta_T\Lambda&=-D\xi\\ &=-d\xi-\Gamma\wedge\xi-\xi\wedge\Gamma.\end{aligned}\tag{III.12}$$

We have considered that Λ transforms as a vector under the vector gauge transformations. This is so because tensor gauge fields are also charged in the color space. The curvature related to the vector gauge field is given by the covariant derivative of the connection and we consider, suggested by the Abelian case, that the corresponding quantity for the two-form gauge field is given in the same way, that is to say, by taking the covariant derivative over Λ. Using the transformations above, we get

$$\begin{aligned}\delta_V F&=\epsilon F-F\epsilon,\\ \delta_V H&=\epsilon H-H\epsilon,\\ \delta_T F&=0,\\ \delta_T H&=\xi\wedge F-F\wedge\xi.\end{aligned}\tag{III.13}$$

We observe from the last relation (III.13) that H is not a geometrical object under the tensor gauge transformation (it is just in the Abelian limit). Thus a Lagrangian like $-\frac{1}{2}*(H*H)$ is just invariant

for the vector gauge transformation but is not for the tensor one. Further, it is not difficult to conclude that there is no other Lagrangian we can construct by using H that can be invariant under the tensor gauge transformation.

The way we envisage having a gauge invariant Lagrangian is by redefining Λ conveniently as[28]

$$\hat{\Lambda}=\Lambda+D\Omega, \tag{III.14}$$

where Ω is a kind of Stuckelberg field one-form. Since it is also charged, we consider that it is also a vector under the vector gauge transformation, namely,

$$\delta_V\Omega=\epsilon\Omega-\Omega\epsilon. \tag{III.15}$$

If one considers

$$\delta_T\Omega=\xi, \tag{III.16}$$

we obtain

$$\delta_T\hat{\Lambda}=0. \tag{III.17}$$

Consequently,

$$\begin{aligned}\delta_T\hat{H}&=D(\delta_T\hat{\Lambda})\\&=0.\end{aligned} \tag{III.18}$$

In this case, a Lagrangian like

$$\mathscr{L}=-\tfrac{1}{2}\ \mathrm{tr}^*(\hat{H}^*\hat{H}) \tag{III.19}$$

is invariant for both vector and tensor gauge transformations. It is opportune to say that the present non-Abelian formulation is still not reducible, but we emphasize that there is no problem with respect of the number of degrees of freedom in the Abelian and non-Abelian sectors. This is so by virtue of the Stuckelberg field that does not appear in the Abelian limit because

$$\begin{aligned}\hat{H}&=d\hat{\Lambda}\\&=d\Lambda+dd\Omega\\&=H.\end{aligned} \tag{III.20}$$

For the Chern–Simons (CS) Lagrangian, we have that the introduction of the Stuckelberg field is not necessary to obtain a gauge invariant Lagrangian. One can directly see that

$$\mathscr{L}=-4m\ \mathrm{tr}^*(F\wedge\Lambda). \tag{III.21}$$

is invariant for both vector and tensor gauge transformations. Incidentally we mention that this geometric formulation has permitted us to obtain a simpler CS Lagrangian comparing with the one of Ref. 23.

Putting all these terms together, we write down the complete form of the gauge invariant Lagrangian for a vector–tensor non-Abelian theory

$$\mathscr{L}=\tfrac{1}{2}\ \mathrm{tr}^*(F^*F)-\tfrac{1}{2}\ \mathrm{tr}^*(\hat{H}^*\hat{H})-4m\ \mathrm{tr}^*(F\wedge\Lambda). \tag{III.22}$$

IV. BRST SUPERSPACE FOR THE ABELIAN TWO-FORM GAUGE FIELDS

Our goal is to use the formalism discussed in Sec. II for two-form gauge fields. It might be instructive to consider the Abelian case first. This is not only because it is simpler than the non-Abelian one, but because it has the reducibility property that is not found in the non-Abelian counterpart. Let us then introduce the two-form quantity

$$\Lambda = -i(dx^\mu \wedge dx^\nu \mathscr{B}_{\mu\nu} + d\theta \wedge dx^\mu \mathscr{G}_\mu + d\bar{\theta} \wedge dx^\mu \bar{\mathscr{G}}_\mu + d\theta \wedge d\theta \mathscr{G} + d\bar{\theta} \wedge d\bar{\theta} \bar{\mathscr{G}} + d\theta \wedge d\bar{\theta} \mathscr{K}). \tag{IV.1}$$

We identify the following ghost numbers for the quantities that appear in the equation above

$$\begin{gathered} \mathrm{gh}[\mathscr{B}_{\mu\nu}] = 0, \quad \mathrm{gh}[\mathscr{G}_\mu] = 1, \quad \mathrm{gh}[\bar{\mathscr{G}}_\mu] = -1, \\ \mathrm{gh}[\mathscr{G}] = 2, \quad \mathrm{gh}[\bar{\mathscr{G}}] = -2, \quad \mathrm{gh}[\mathscr{K}] = 0. \end{gathered} \tag{IV.2}$$

In terms of component fields, we may conveniently write

$$\begin{aligned} \mathscr{B}_{\mu\nu} &= B_{\mu\nu} + i\theta B^\theta_{\mu\nu} + i\bar{\theta} B^{\bar{\theta}}_{\mu\nu} + i\bar{\theta}\theta B^{\bar{\theta}\theta}_{\mu\nu}, \\ \mathscr{G}_\mu &= g_\mu + \theta \bar{e}_\mu + \bar{\theta} e_\mu + i\bar{\theta}\theta G^{\bar{\theta}\theta}_\mu, \\ \bar{\mathscr{G}}_\mu &= \bar{g}_\mu + \theta \bar{G}^\theta_\mu + \bar{\theta} G^{\bar{\theta}}_\mu + i\bar{\theta}\theta \bar{G}^{\bar{\theta}\theta}_\mu, \\ \mathscr{G} &= G + i\theta G^\theta + i\bar{\theta} G^{\bar{\theta}} + i\bar{\theta}\theta G^{\bar{\theta}\theta}, \\ \bar{\mathscr{G}} &= \bar{G} + i\theta \bar{G}^\theta + i\bar{\theta} \bar{G}^{\bar{\theta}} + i\bar{\theta}\theta \bar{G}^{\bar{\theta}\theta}, \\ \mathscr{K} &= K + i\theta f + i\bar{\theta} \bar{f} + i\bar{\theta}\theta K^{\bar{\theta}\theta}. \end{aligned} \tag{IV.3}$$

We now define a three-form H as it was done in the previous section, i.e.,

$$H = d\Lambda. \tag{IV.4}$$

Introducing (IV.1) into the expression above and also imposing that the components along θ and $\bar{\theta}$ are zero, we obtain the equations:

$$\begin{gathered} \partial_\theta \mathscr{B}_{\mu\nu} - \tfrac{1}{2}(\partial_\mu \mathscr{G}_\nu - \partial_\nu \mathscr{G}_\mu) = 0, \\ \partial_{\bar{\theta}} \mathscr{B}_{\mu\nu} - \tfrac{1}{2}(\partial_\mu \bar{\mathscr{G}}_\nu - \partial_\nu \bar{\mathscr{G}}_\mu) = 0, \\ \partial_\theta \mathscr{G}_\mu - \partial_\mu \mathscr{G} = 0, \\ \partial_{\bar{\theta}} \bar{\mathscr{G}}_\mu - \partial_\mu \bar{\mathscr{G}} = 0, \\ \partial_\mu \mathscr{K} - \partial_\theta \bar{\mathscr{G}}_\mu - \partial_{\bar{\theta}} \mathscr{G}_\mu = 0, \\ \partial_\theta \mathscr{G} = 0, \\ \partial_{\bar{\theta}} \bar{\mathscr{G}} = 0, \\ \partial_\theta \bar{\mathscr{G}} + \partial_{\bar{\theta}} \mathscr{K} = 0, \\ \partial_{\bar{\theta}} \mathscr{G} + \partial_\theta \mathscr{K} = 0. \end{gathered} \tag{IV.5}$$

Considering the expansion expressions given by (IV.3), we obtain

$$
\begin{aligned}
B^{\theta}_{\mu\nu} &= -\frac{i}{2}(\partial_\mu g_\nu - \partial_\nu g_\mu),\\
B^{\bar{\theta}}_{\mu\nu} &= -\frac{i}{2}(\partial_\mu \bar{g}_\nu - \partial_\nu \bar{g}_\mu),\\
B^{\bar{\theta}\theta}_{\mu\nu} &= -\frac{i}{2}(\partial_\mu e_\nu - \partial_\nu e_\mu),\\
\bar{e}_\mu &= \partial_\mu G,\\
\bar{G}^{\theta}_{\mu} &= -e_\mu + \partial_\mu K,\\
\bar{G}^{\bar{\theta}}_{\mu} &= \partial_\mu \bar{G},\\
G^{\bar{\theta}\theta}_{\mu} &= \partial_\mu f,\\
\bar{G}^{\bar{\theta}\theta}_{\mu} &= -\partial_\mu \bar{f},\\
G^{\theta} &= 0,\\
G^{\bar{\theta}} &= -f,\\
\bar{G}^{\theta} &= -\bar{f},\\
\bar{G}^{\bar{\theta}} &= 0,\\
G^{\bar{\theta}\theta} &= 0,\\
\bar{G}^{\bar{\theta}\theta} &= 0,\\
K^{\bar{\theta}\theta} &= 0,
\end{aligned}
\tag{IV.6}
$$

plus many other equations that are just consistency relations for the results above (see Appendix A). The combination of (IV.3) and (IV.6) gives the superfield expressions

$$
\begin{aligned}
\mathscr{B}_{\mu\nu} &= B_{\mu\nu} + \tfrac{1}{2}\theta(\partial_\mu g_\nu - \partial_\nu g_\mu) + \tfrac{1}{2}\bar{\theta}(\partial_\mu \bar{g}_\nu - \partial_\nu \bar{g}_\mu) - \tfrac{1}{2}\bar{\theta}\theta(\partial_\mu e_\nu - \partial_\nu e_\mu),\\
\mathscr{G}_\mu &= g_\mu + \theta\partial_\mu G + \bar{\theta} e_\mu + i\bar{\theta}\theta\partial_\mu f,\\
\bar{\mathscr{G}}_\mu &= \bar{g}_\mu + \theta(\partial_\mu K - e_\mu) + \bar{\theta}\partial_\mu \bar{G} - i\bar{\theta}\theta\partial_\mu \bar{f},\\
\mathscr{G} &= G - \bar{\theta} f,\\
\bar{\mathscr{G}} &= \bar{G} - \theta \bar{f},\\
\mathscr{K} &= K + i\theta f + i\bar{\theta}\bar{f}.
\end{aligned}
\tag{IV.7}
$$

The fields that appear in the expressions above are the net fields of the theory. We notice that they appear naturally in BRST superspace formalism. It would be instructive to compare them with conventional treatments,[19] where a lot of careful arguments have to be taken into account in order to introduce all of them.

We list below the ghost and parity numbers for these fields.

$$\begin{gathered}
\mathrm{gh}[B_{\mu\nu},e_\mu,K]=0,\\
\mathrm{gh}[g_\mu,f]=1,\\
\mathrm{gh}[\bar{g}_\mu,\bar{f}]=-1,\\
\mathrm{gh}[G]=2,\\
\mathrm{gh}[\bar{G}]=-2,\\
\epsilon[B_{\mu\nu},e_\mu,K,G,\bar{G}]=0,\\
\epsilon[g_\mu,\bar{g}_\mu,f,\bar{f}]=1.
\end{gathered} \tag{IV.8}$$

Considering expressions (II.15), (II.16), and (IV.7), we also naturally obtain the BRST and anti-BRST transformations for these fields

$$\begin{gathered}
\delta_\lambda B_{\mu\nu}=\tfrac{1}{2}\lambda(\partial_\mu g_\nu-\partial_\nu g_\mu),\\
\delta_\lambda g_\mu=\lambda\partial_\mu G,\\
\delta_\lambda \bar{g}_\mu=\lambda(\partial_\mu K-e_\mu),\\
\delta_\lambda G=0,\\
\delta_\lambda \bar{G}=-\lambda\bar{f},\\
\delta_\lambda K=i\lambda f,\\
\delta_\lambda e_\mu=-\lambda\partial_\mu f,\\
\delta_\lambda f=0,\\
\delta_\lambda \bar{f}=0,
\end{gathered} \tag{IV.9}$$

and

$$\begin{gathered}
\delta_{\bar{\lambda}} B_{\mu\nu}=\tfrac{1}{2}\bar{\lambda}(\partial_\mu \bar{g}_\nu-\partial_\nu \bar{g}_\mu),\\
\delta_{\bar{\lambda}} g_\mu=\bar{\lambda}e_\mu,\\
\delta_{\bar{\lambda}} \bar{g}_\mu=\bar{\lambda}\partial_\mu \bar{G},\\
\delta_{\bar{\lambda}} G=-\bar{\lambda}f,\\
\delta_{\bar{\lambda}} \bar{G}=0,\\
\delta_{\bar{\lambda}} K=i\bar{\lambda}\bar{f},\\
\delta_{\bar{\lambda}} e_\mu=0,\\
\delta_{\bar{\lambda}} f=0,\\
\delta_{\bar{\lambda}} \bar{f}=0.
\end{gathered} \tag{IV.10}$$

We observe that contrary to the Abelian vector formulation, the BRST and anti-BRST transformations for the tensor case are not symmetric.

To obtain invariant Lagrangians under these transformations, we follow the same steps of the vector treatment. First, one can directly show that $\mathscr{H}_{\mu\nu\rho}\mathscr{H}^{\mu\nu\rho}$ is a singlet, where $\mathscr{H}_{\mu\nu\rho}$ is defined by

$$\mathscr{H}_{\mu\nu\rho}=\partial_\mu\mathscr{B}_{\nu\rho}+\partial_\rho\mathscr{B}_{\mu\nu}+\partial_\nu\mathscr{B}_{\rho\mu}. \tag{IV.11}$$

So, a term involving the product above is both BRST and anti-BRST invariant. We then write[12]

$$\mathscr{L}_I=\tfrac{1}{12}\mathscr{H}_{\mu\nu\rho}\mathscr{H}^{\mu\nu\rho}. \tag{IV.12}$$

Considering that the $\bar{\theta}\theta$ component of a superfield is BRST and anti-BRST invariant, we conveniently write another invariant Lagrangian

$$\mathscr{L}_{II}=\tfrac{1}{2}\partial_\theta\partial_{\bar{\theta}}\mathscr{B}_{\mu\nu}\mathscr{B}^{\mu\nu}, \tag{IV.13}$$

that in components fields corresponds to

$$\mathscr{L}_{II}=-B_{\mu\nu}\partial^\mu e^\nu-\tfrac{1}{2}(\partial_\mu\bar{g}_\nu-\partial_\nu\bar{g}_\mu)\partial^\mu g^\nu. \tag{IV.14}$$

The gauge-fixing term is given by

$$\mathscr{L}_{III}=\beta\partial_\theta\partial_{\bar{\theta}}\bar{\mathscr{G}}_\mu\mathscr{G}^\mu. \tag{IV.15}$$

In components, we have

$$\mathscr{L}_{III}=\beta[i\bar{g}_\mu\partial^\mu f+(e_\mu-\partial_\mu K)e^\mu+\partial_\mu\bar{G}\partial^\mu G-i\partial_\mu\bar{f}g^\mu]. \tag{IV.16}$$

We observe that the gauge-fixing term related to the auxiliary field, namely $e_\mu e^\mu$, does not appear isolated. This would occur just for the anti-BRST symmetry. It is also important to emphasize that the ghost-for-ghost term also depends on the gauge-fixing parameter β. We mention that in the cases treated in Refs. 19 and 15 this does not occur because just one of these two symmetries was considered.

It is just a matter of algebraic calculation to show that other invariant terms we can construct with the superfields (IV.7), that have parity and ghost numbers equal to zero, do not lead to any new independent result.

Finally we deal with the topological term. One can directly show that the combination $\epsilon^{\mu\nu\rho\kappa}\partial_\mu\mathscr{A}_\nu\mathscr{B}_{\rho\kappa}$ is a singlet in a sense that the terms along θ and $\bar{\theta}$ are total derivatives. So the topological Lagrangian reads

$$\mathscr{L}_{IV}=-m\epsilon^{\mu\nu\rho\kappa}\mathscr{T}_{\mu\nu}\mathscr{B}_{\rho\kappa}. \tag{IV.17}$$

V. THE NON-ABELIAN CASE

For the non-Abelian case, we start from the two-form quantity (IV.3), but now considering that

$$\mathscr{B}_{\mu\nu}=\mathscr{B}^a_{\mu\nu}T^a,$$

$$\mathscr{G}_\mu=\mathscr{G}^a_\mu T^a, \quad \text{etc.}, \tag{V.1}$$

and defining the three-form H by taking the covariant derivative over Λ, i.e.,

$$\begin{aligned} H&=\mathscr{D}\Lambda \\ &=d\Lambda+\Gamma\wedge\Lambda-\Lambda\wedge\Gamma, \end{aligned} \tag{V.2}$$

where Γ is the connection one-form given by (II.4). The requirement that the components of H along θ and $\bar{\theta}$ directions are zero leads us to the equations

$$
\begin{gathered}
\partial_\theta \mathscr{B}_{\mu\nu} - \tfrac{1}{2}(\mathscr{D}_\mu \mathscr{G}_\nu - \mathscr{D}_\nu \mathscr{G}_\mu) + i\mathscr{C} \times \mathscr{B}_{\mu\nu} = 0, \\
\partial_{\bar\theta} \mathscr{B}_{\mu\nu} - \tfrac{1}{2}(\mathscr{D}_\mu \bar{\mathscr{G}}_\nu - \mathscr{D}_\nu \bar{\mathscr{G}}_\mu) + i\bar{\mathscr{C}} \times \mathscr{B}_{\mu\nu} = 0, \\
\partial_\theta \mathscr{G}_\mu - \mathscr{D}_\mu \mathscr{G} + i\mathscr{C} \times \mathscr{G}_\mu = 0, \\
\partial_{\bar\theta} \bar{\mathscr{G}}_\mu - \mathscr{D}_\mu \bar{\mathscr{G}} + i\bar{\mathscr{C}} \times \bar{\mathscr{G}}_\mu = 0, \\
\partial_\theta \bar{\mathscr{G}}_\mu + \partial_{\bar\theta} \mathscr{G}_\mu - \mathscr{D}_\mu \mathscr{K} + i\mathscr{C} \times \bar{G}_\mu + i\bar{\mathscr{C}} \times \mathscr{G}_\mu = 0, \\
\partial_\theta \mathscr{G} + i\mathscr{C} \times \mathscr{G} = 0, \\
\partial_{\bar\theta} \bar{\mathscr{G}} + i\bar{\mathscr{C}} \times \bar{\mathscr{G}} = 0, \\
\partial_\theta \bar{\mathscr{G}} + \partial_{\bar\theta} \mathscr{K} + i\mathscr{C} \times \bar{\mathscr{G}} + i\bar{\mathscr{C}} \times \mathscr{K} = 0, \\
\partial_{\bar\theta} \mathscr{G} + \partial_\theta \mathscr{K} + i\bar{\mathscr{C}} \times \mathscr{G} + i\mathscr{C} \times \mathscr{K} = 0.
\end{gathered}
\tag{V.3}
$$

We reinforce the fact that we are making the coupling constants equal to one. Making similar developments as in the previous section, we obtain similar relations also involving the component fields plus other equations. But here an interesting fact occurs. These last equations are not all consistency relations as in the Abelian case. Instead, they permit us to conclude that the entire superfields $\mathscr{G}$, $\bar{\mathscr{G}}$, and $\mathscr{K}$ are zero (see Appendix B). This shows the consistency of the formalism we are using because the non-Abelian version of the theory we are dealing with is not reducible, and it is not necessary with the presence of these terms here.

The final form of the superfields for the non-Abelian case reads

$$
\begin{aligned}
\mathscr{B}_{\mu\nu} = {} & B_{\mu\nu} + \theta(\tfrac{1}{2} D_\mu g_\nu - \tfrac{1}{2} D_\nu g_\mu - ic \times B_{\mu\nu}) + \bar\theta(\tfrac{1}{2} D_\mu \bar g_\nu - \tfrac{1}{2} D_\nu \bar g_\mu - i\bar c \times B_{\mu\nu}) \\
& + \bar\theta\theta\Big[-\frac{1}{2} D_\mu e_\nu + \frac{1}{2} D_\nu e_\mu - \frac{i}{2} c \times (D_\mu \bar g_\nu - D_\nu \bar g_\mu) - \frac{i}{2} (D_\mu \bar c) \times g_\nu \\
& + \frac{i}{2} (D_\nu \bar c) \times g_\mu - ib \times B_{\mu\nu} - \bar c \times (c \times B_{\mu\nu}) \Big],
\end{aligned}
\tag{V.4}
$$

$$
\mathscr{G}_\mu = g_\mu - i\theta c \times g_\mu + \bar\theta e_\mu + \bar\theta\theta[(c \times \bar c) \times g_\mu - ic \times e_\mu - ib \times g_\mu],
\tag{V.5}
$$

$$
\begin{aligned}
\bar{\mathscr{G}}_\mu = {} & \bar g_\mu - \theta(e_\mu + ic \times \bar g_\mu + i\bar c \times g_\mu) - i\bar\theta\bar c \times \bar g_\mu \\
& + \bar\theta\theta[\bar c \times (\bar c \times g_\mu) + \bar c \times (c \times \bar g_\mu) - ib \times \bar g_\mu - i\bar c \times e_\mu].
\end{aligned}
\tag{V.6}
$$

We stress the fact that, as can be seen in Appendix B, to arrive at the solution (V.4)–(V.6) above, one must use the previous results for the one-form gauge field (II.8). The BRST and anti-BRST transformations for the non-Abelian theory read

$$
\begin{gathered}
\delta_\lambda B_{\mu\nu} = \lambda(\tfrac{1}{2} D_\mu g_\nu - \tfrac{1}{2} D_\nu g_\mu - ic \times B_{\mu\nu}), \\
\delta_\lambda g_\mu = -i\lambda c \times g_\mu, \\
\delta_\lambda e_\mu = \lambda[(c \times \bar c) \times g_\mu - i\bar c \times e_\mu - ib \times g_\mu], \\
\delta_\lambda \bar g_\mu = -\lambda(e_\mu + ic \times \bar g_\mu + i\bar c \times g_\mu),
\end{gathered}
\tag{V.7}
$$

and

$$\begin{aligned}
\delta_{\bar\lambda} B_{\mu\nu} &= \bar\lambda\left(\tfrac{1}{2} D_\mu \bar g_\nu - \tfrac{1}{2} D_\nu \bar g_\mu - i\bar c \times B_{\mu\nu}\right),\\
\delta_{\bar\lambda} g_\mu &= \bar\lambda e_\mu,\\
\delta_{\bar\lambda} e_\mu &= 0,\\
\delta_{\bar\lambda} \bar g_\mu &= -i\bar\lambda \bar c \times \bar g_\mu .
\end{aligned} \tag{V.8}$$

Let us finally discuss the obtainment of invariant Lagrangians under BRST and anti-BRST transformations for the non-Abelian tensor theory. First we have that a term that would correspond to $\mathscr{L}_I$ of the Abelian case, namely tr $\mathscr{H}_{\mu\nu\rho}\mathscr{H}^{\mu\nu\rho}$ is not a singlet here. So, it cannot be directly used as an invariant Lagrangian. We shall discuss this term at the end of the section. Let us consider the other terms first.

The gauge-fixing Lagrangians are

$$\begin{aligned}
\mathscr{L}_{II} &= \tfrac{1}{2}\,\partial_\theta \partial_{\bar\theta}\,\mathrm{tr}\,\mathscr{B}_{\mu\nu}\mathscr{B}^{\mu\nu}\\
&= -\,\mathrm{tr}\,B_{\mu\nu} D^\mu (e^\nu + i\bar c \times g^\nu) - \tfrac{1}{2}\,\mathrm{tr}(D_\mu \bar g_\nu - D_\nu \bar g_\mu) D^\mu \bar g^\nu,
\end{aligned} \tag{V.9}$$

$$\begin{aligned}
\mathscr{L}_{III} &= \beta\,\partial_\theta \partial_{\bar\theta} \bar{\mathscr{G}}_\mu \mathscr{G}^\mu\\
&= \beta\,\mathrm{tr}(e_\mu + i\bar c \times g_\mu)(e^\mu + i\bar c \times g^\mu).
\end{aligned} \tag{V.10}$$

Concerning the topological Lagrangian, we have that the quantity $\epsilon^{\mu\nu\rho\kappa}\mathscr{F}_{\mu\nu}\mathscr{B}_{\rho\kappa}$ is a singlet, in a sense that the components along θ and $\bar\theta$ are total derivatives. Thus the topological Lagrangian reads

$$\begin{aligned}
\mathscr{L}_{IV} &= -\,m\,\epsilon^{\mu\nu\rho\kappa}\,\mathrm{tr}\,\mathscr{F}_{\mu\nu}\mathscr{B}_{\rho\kappa}\\
&= -\,m\,\epsilon^{\mu\nu\rho\kappa}\,\mathrm{tr}\,F_{\mu\nu}B_{\rho\kappa}.
\end{aligned} \tag{V.11}$$

Let us finally consider the $\mathscr{L}_I$ Lagrangian. As it was told in the beginning, the quantity tr $\mathscr{H}_{\mu\nu\rho}\mathscr{H}^{\mu\nu\rho}$ is not a singlet and consequently, it cannot be directly considered as an invariant Lagrangian. Considering what was developed in Sec. III, the way we have to obtain an invariant Lagrangian is introducing a kind of Stuckelberg field. Here we consider the superfield $\hat{\mathscr{H}}_{\mu\nu\rho}$ defined by

$$\tfrac{1}{3}\hat{\mathscr{H}} = \mathscr{D}_{[\mu}\mathscr{B}_{\nu\rho]} + \mathscr{D}_{[\mu}\mathscr{D}_\nu \mathscr{S}_{\rho]}, \tag{V.12}$$

where in order to simplify the notation we are using the subscript $[\cdots]$ to denote antisymmetry among the indices. Here $\mathscr{S}_\mu$ is a (Stuckelberg) superfield that has the purpose to make $\hat{\mathscr{H}}_{\mu\nu\rho}\hat{\mathscr{H}}^{\mu\nu\rho}$ a singlet. This is achieved after a long algebraic calculation and we conclude that the superfield $\mathscr{S}_\mu$ must be

$$\begin{aligned}
\mathscr{S}_\mu &= \Omega_\mu - \theta(g_\mu + ic \times \Omega_\mu) - \bar\theta(\bar g_\mu + i\bar c \times \Omega_\mu)\\
&\quad + \bar\theta\theta[e_\mu + c \times (i\bar g_\mu - \bar c \times \Omega_\mu) - i(b + c \times \bar c) \times \Omega_\mu].
\end{aligned} \tag{V.13}$$

The BRST and anti-BRST invariant $\mathscr{L}_I$ Lagrangian then reads

$$\begin{aligned}
\mathscr{L}_I &= \tfrac{1}{12}\,\mathrm{tr}\,\hat{\mathscr{H}}_{\mu\nu\rho}\hat{\mathscr{H}}^{\mu\nu\rho}\\
&= \tfrac{3}{4}\,\mathrm{tr}(D_{[\mu}B_{\nu\rho]} + D_{[\mu}D_\nu \Omega_{\rho]})^2.
\end{aligned} \tag{V.14}$$

VI. THE FIELD–ANTIFIELD FORMALISM

In this section we are going to use the field–antifield formalism of Batalin–Vilkowisky to deal with one- and two-form gauge fields in the superfield language. To do this, we have to introduce

collective fields,[7] from where the antifields[8,9] are identified. Since the set of fields in the Abelian and non-Abelian cases are different, due to their different reducibility characteristics, we consider both cases separately.

Let us start from the Abelian case. The coupling of the tensor gauge field $B_{\mu\nu}$ and the ghosts with the vector gauge one is a trivial matter. To fix the superfields given at Eq. (IV.7), we introduce the collective fields

$$\mathscr{B}^1_{\mu\nu},\ \mathscr{G}^1_\mu,\ \overline{\mathscr{G}}^1_\mu,\ \mathscr{G}^1,\ \overline{\mathscr{G}}^1,\ \mathscr{K}^1. \tag{VI.1}$$

The index 1 stands for the BRST symmetry which we have privileged in the BV formalism. If we were interested in maintaining both symmetries at the same level we would introduce also collective fields with indices 2 and arrive at a Batalin–Lavranov–Tyutin (BLT) action.[29] The next step is to define the shifted two-form $\tilde{\Lambda}$ as in Eq. (IV.1) but here written in terms of the shifted superfields

$$\begin{aligned}
\tilde{\mathscr{B}}_{\mu\nu} &= \mathscr{B}_{\mu\nu} - \mathscr{B}^1_{\mu\nu},\\
\tilde{\mathscr{G}}_\mu &= \mathscr{G}_\mu - \mathscr{G}^1_\mu,\\
\tilde{\bar{\mathscr{G}}}_\mu &= \overline{\mathscr{G}}_\mu - \overline{\mathscr{G}}^1_\mu,\\
\tilde{\mathscr{G}} &= \mathscr{G} - \mathscr{G}^1,\\
\tilde{\bar{\mathscr{G}}} &= \overline{\mathscr{G}} - \overline{\mathscr{G}}^1,\\
\tilde{\mathscr{K}} &= \mathscr{K} - \mathscr{K}^1.
\end{aligned} \tag{VI.2}$$

We impose again the horizontal condition $\tilde{H} = d\tilde{\Lambda}$, that is to say, its components along the θ and $\overline{\theta}$ directions must vanish. We naturally obtain the same conditions (IV.5) with the shifted superfields in place of the original superfields. Now we have an ambiguity in determining the components of the individual superfields. As an example, for the superfield $\tilde{\mathscr{G}}_\mu$ we obtain from Eq. (IV.7)

$$\tilde{\mathscr{G}}_\mu = \tilde{g}_\mu + \theta\partial_\mu\tilde{G} + \overline{\theta} e_\mu + i\overline{\theta}\partial_\mu f, \tag{VI.3}$$

and a possible choice for $\mathscr{G}_\mu$ and $\mathscr{G}^1_\mu$ is

$$\begin{aligned}
\mathscr{G}_\mu &= g_\mu + \theta\Pi_\mu + \overline{\theta}(\overline{g}^*_\mu + e_\mu) + i\overline{\theta}\theta(N_\mu + \partial_\mu f\ ),\\
\mathscr{G}^1_\mu &= g^1_\mu + \theta(\Pi_\mu - \partial_\mu\tilde{G}) + \overline{\theta}\overline{g}^*_\mu + i\overline{\theta}\theta N_\mu,
\end{aligned} \tag{VI.4}$$

where Π_μ, $\overline{g}^*_\mu$, and N_μ are new fields which arise from the additional shift symmetry. Observe that it is not necessary to introduce fields like f^1 or e^1_μ since f and e_μ are already auxiliary fields.

The remaining set of fields is chosen to be

$$\begin{aligned}
\mathscr{B}_{\mu\nu} &= B_{\mu\nu} + \theta\Pi_{\mu\nu} + \overline{\theta}(B^*_{\mu\nu} + \partial_{[\mu}\tilde{\bar{g}}_{\nu]}) + \overline{\theta}\theta(N_{\mu\nu} - \partial_{[\mu}e_{\nu]}),\\
\mathscr{B}^1_{\mu\nu} &= B^1_{\mu\nu} + \theta(\Pi_{\mu\nu} - \partial_{[\mu}\tilde{g}_{\nu]}) + \overline{\theta}B^*_{\mu\nu} + \overline{\theta}\theta N_{\mu\nu},\\
\overline{\mathscr{G}}_\mu &= \overline{g}_\mu + \theta\overline{\Pi}_\mu + \overline{\theta}(g^*_\mu + \partial_\mu\tilde{\bar{G}}) + i\overline{\theta}\theta(\overline{N}_\mu - \partial_\mu\overline{f}\ ),\\
\overline{\mathscr{G}}^1_\mu &= \overline{g}^1_\mu + \theta(\overline{\Pi}_\mu - \partial_\mu\tilde{K} + e_\mu) + \overline{\theta}g^*_\mu + i\overline{\theta}\theta\overline{N}_\mu,\\
\mathscr{G} &= G + \theta\Pi + \overline{\theta}(\overline{G}^* - f\ ) + \overline{\theta}\theta N,\\
\mathscr{G}^1 &= G^1 + \theta\Pi + \overline{\theta\overline{G}}^* + \overline{\theta}\theta N,
\end{aligned} \tag{VI.5}$$

$$\bar{\mathscr{G}}=\bar{G}+\theta\bar{\Pi}+\bar{\theta}G^*+\bar{\theta}\theta\bar{N},$$

$$\bar{\mathscr{G}}^1=\bar{G}^1+\theta(\bar{\Pi}+\bar{f})+\bar{\theta}G^*+\bar{\theta}\theta\bar{N},$$

$$\mathscr{K}=K+i\theta\pi+i\bar{\theta}(K^*+\bar{f})+\bar{\theta}\theta M,$$

$$\mathscr{K}^1=K^1+i\theta(\pi-f)+i\bar{\theta}K^*+\bar{\theta}\theta M.$$

The natural interpretation for the new fields appearing in (VI.4) and (VI.5) is the following. The quantum action describing the two-form gauge fields has an additional trivial shift symmetry with respect to the tilde fields defined in Eq. (VI.2). Consequently we have to introduce the ghosts: $\Pi_{\mu\nu}$, Π_μ, $\bar{\Pi}_\mu$, Π, $\bar{\Pi}$, and π; the antighosts: $B^*_{\mu\nu}$, g^*_μ, $\bar{g}^*_\mu$, G^*, $\bar{G}^*$, and K^*, and auxiliary Nakanish–Lautrup fields $N_{\mu\nu}$, N_μ, $\bar{N}_\mu$, N, $\bar{N}$, and M.

We shall see that with the choice given by Eqs. (VI.4) and (VI.5), these antighosts will play the role of the antifields in the BV formalism. In order to fix this shift symmetry we impose that all indices 1 fields vanish. This can be done with the aid of the following BRST and anti-BRST invariant terms

$$\begin{aligned}
&\tfrac{1}{2}\,\partial_\theta\partial_{\bar{\theta}}(\mathscr{B}^1_{\mu\nu}\mathscr{B}^{1\mu\nu})=B^1_{\mu\nu}N^{\mu\nu}+(\Pi_{\mu\nu}-\partial_{[\mu}\tilde{g}_{\nu]})B^{*\mu\nu},\\
&\partial_\theta\partial_{\bar{\theta}}(\mathscr{G}^1_\mu\bar{\mathscr{G}}^{1\mu})=iN_\mu\bar{g}^{1\mu}+ig^1_\mu\bar{N}^\mu-(\Pi_\mu-\partial_\mu\tilde{G})g^{*\mu}+\bar{g}^*_\mu(\bar{\Pi}^\mu-\partial^\mu\tilde{K}+e^\mu),\\
&\partial_\theta\partial_{\bar{\theta}}(\mathscr{G}^1\bar{\mathscr{G}}^1)=G^1\bar{N}+N\bar{G}^1+\Pi G^*-\bar{G}^*(\bar{\Pi}+\bar{f}),\\
&\tfrac{1}{2}\,\partial_\theta\partial_{\bar{\theta}}(\mathscr{K}^1\mathscr{K}^1)=K^1M-(\pi-f)K^*.
\end{aligned}\tag{VI.6}$$

To fix the original gauge symmetry of the theory, we choose a gauge-fixing superboson

$$\Phi=\phi+\theta\delta\phi+\bar{\theta}\psi+\bar{\theta}\theta\delta\psi,\tag{VI.7}$$

with $\psi=\bar{\delta}\phi$. Then we have

$$\begin{aligned}
\partial_\theta\partial_{\bar{\theta}}\Phi&=\delta\psi\\
&=\delta B_{\mu\nu}\frac{\delta\psi}{\delta B_{\mu\nu}}+\delta g_\mu\frac{\delta\psi}{\delta g_\mu}+\delta\bar{g}_\mu\frac{\delta\psi}{\delta\bar{g}_\mu}\\
&\quad+\delta G\frac{\delta\psi}{\delta G}+\delta\bar{G}\frac{\delta\psi}{\delta\bar{G}}+\delta K\frac{\delta\psi}{\delta K},
\end{aligned}\tag{VI.8}$$

where we have considered $\psi=\psi(B_{\mu\nu},g_\mu,\bar{g}_\mu,G,\bar{G},K)$. The δ variations of the fields are obtained from the θ components of (VI.4) and (VI.5) and we have, for example,

$$\begin{aligned}
\delta B_{\mu\nu}&=\Pi_{\mu\nu},\\
\delta K&=i\pi.
\end{aligned}\tag{VI.9}$$

The use of the equations of motion for the fields $N_{\mu\nu}$, N_μ, $\bar{N}_\mu$, N, $\bar{N}$, and M, as well as for the ones with indices 1, makes these last ones vanish. This corresponds to a functional integration over the same fields. Once this is done, the sum of Eqs. (VI.6) and (VI.8), and the singlet $\mathscr{S}_I$ in Eq. (IV.12) give us the two-form field-dependent part of the quantum action

$$S_B \equiv \int dx^\mu \Bigg[\frac{1}{12} H_{\mu\nu\rho} H^{\mu\nu\rho} + B^*_{\mu\nu} \partial^{[\mu} g^{\nu]} + g^{*\mu} \partial_\mu G + \overline{g}^*_\mu (e^\mu - \partial^\mu K) - G^* f - \overline{G}^* \overline{f} + K^* \pi$$
$$+ \Pi_{\mu\nu} \left(B^{*\mu\nu} + \frac{\delta\psi}{\delta B_{\mu\nu}} \right) + \Pi_\mu \left(- g^{*\mu} + \frac{\delta\psi}{\delta g_\mu} \right) + \overline{\Pi}_\mu \left(\overline{g}^{*\mu} + \frac{\delta\psi}{\delta \overline{g}_\mu} \right) + \Pi \left(G^* + \frac{\delta\psi}{\delta G} \right)$$
$$+ \overline{\Pi} \left(\overline{G}^* + \frac{\delta\psi}{\delta \overline{G}} \right) + \pi \left(- K^* + i \frac{\delta\psi}{\delta K} \right) \Bigg]. \tag{VI.10}$$

If we add the action

$$S_A = \int dx^\mu \left[- \frac{1}{4} F_{\mu\nu} F^{\mu\nu} + i A^*_\mu \partial^\mu c + \overline{c}^* b \right], \tag{VI.11}$$

with a convenient gauge choice for A^*_μ, and $\overline{c}^*$, and the interacting singlet term $\mathscr{L}_{IV}$ of Eq. (IV.17), to S_B, we obtain the full BV action which agrees with the one obtained in Ref. 15.

We now turn our attention to the non-Abelian theory described in Secs. III and V. The procedure is quite similar but now the schedule of superfields is different since we do not have ghosts-for-ghosts and we have to introduce the Stuckelberg superfield. Another point is that the coupling of the one-form gauge field with its corresponding ghosts is not so trivial as in the Abelian case. Let us start from the one-form Yang–Mills fields by introducing new index 1 superfields through the following shift

$$\tilde{\mathscr{A}}_\mu \equiv \mathscr{A}_\mu - \mathscr{A}^1_\mu,$$
$$\tilde{\mathscr{C}} \equiv \mathscr{C} - \mathscr{C}^1, \tag{VI.12}$$
$$\tilde{\overline{\mathscr{C}}} \equiv \overline{\mathscr{C}} - \overline{\mathscr{C}}^1.$$

Imposing the horizontal condition on the shifted curvature, we arrive at expressions similar to (II.9)–(II.11) for the shifted superfields (VI.12), but written in terms of the shifted components

$$\tilde{A}_\mu \equiv A_\mu - A^1_\mu,$$
$$\tilde{c} \equiv c - c^1, \tag{VI.13}$$
$$\tilde{\overline{c}} \equiv \overline{c} - \overline{c}^1.$$

A field like b^1 does not need to be introduced here since b is already an auxiliary field. The solution for the individual superfields contains some arbitrariness and we choose

$$\mathscr{A}_\mu = A_\mu + i\theta \Pi^A_\mu + i\overline{\theta}(A^*_\mu + D^{A-A^1}_\mu (\overline{c} - \overline{c}^1)) + i\overline{\theta}\theta [N^A_\mu + D^{A-A^1}_\mu b + i D^{A-A^1}_\mu (c - c^1) \times (\overline{c} - \overline{c}^1)],$$
$$\mathscr{A}^1_\mu = A^1_\mu + i\theta [\Pi^A_\mu - D^{A-A_1}_\mu (c - c^1)] + i\overline{\theta} A^*_\mu + i\overline{\theta}\theta N^A_\mu,$$
$$\mathscr{C} = C + i\theta \Pi^c + i\overline{\theta}[\overline{c}^* - b + (c - c^1) \times (\overline{c} - \overline{c}^1)] + i\overline{\theta}\theta [N^c + (c - c^1) \times (b + i(c - c^1) \times (\overline{c} - \overline{c}^1))], \tag{VI.14}$$
$$\mathscr{C}^1 = c^1 + i\theta [\Pi^c + \tfrac{1}{2} g (c - c^1) \times (c - c^1)] + i\overline{\theta} c^* + i\overline{\theta}\theta N^c,$$
$$\overline{\mathscr{C}} = \overline{c} + i\theta \Pi^{\overline{c}} + i\overline{\theta}[c^* - \tfrac{1}{2} (\overline{c} - \overline{c}^1) \times (\overline{c} - \overline{c}^1)] + i\overline{\theta}\theta [N^{\overline{c}} - b \times (\overline{c} - \overline{c}^1)],$$
$$\overline{\mathscr{C}}^1 = \overline{c}^1 + i\theta (\Pi^c + ib) + i\overline{\theta}\overline{c}^* + i\overline{\theta}\theta N^{\overline{c}}.$$

Concerning the two-form gauge fields sector, we introduce four index 1 superfields corresponding to $\mathscr{B}_{\mu\nu}$, $\mathscr{S}_\mu$, $\mathscr{G}_\mu$, $\bar{\mathscr{G}}_\mu$ and impose the horizontal condition on $\tilde{H}=\tilde{\mathscr{D}}\Gamma$ defined through (V.2). One of the possible solutions that is in agreement with Eqs. (V.4)–(V.6) and (V.13), is given by (this one leads to the familiar BV action)

$$
\begin{aligned}
\mathscr{B}_{\mu\nu}&=B_{\mu\nu}+\theta\Pi_{\mu\nu}+\bar{\theta}(B^*_{\mu\nu}+\tilde{B}^{\bar{\theta}}_{\mu\nu})+\bar{\theta}\theta(N_{\mu\nu}+\tilde{B}^{\bar{\theta}\theta}_{\mu\nu}),\\
\mathscr{B}^1_{\mu\nu}&=B^1_{\mu\nu}+\theta(\Pi_{\mu\nu}-\tilde{B}^{\theta}_{\mu\nu})+\bar{\theta}B^*_{\mu\nu}+\bar{\theta}\theta N_{\mu\nu},\\
\mathscr{S}_\mu&=\Omega_\mu+\theta s_\mu+\bar{\theta}(\Omega^*_\mu+\tilde{\Omega}^{\bar{\theta}}_\mu)+\bar{\theta}\theta(M_\mu+\tilde{\Omega}^{\bar{\theta}\theta}_\mu),\\
\mathscr{S}^1_\mu&=\Omega^1_\mu+\theta(s_\mu-\tilde{\Omega}^{\theta}_\mu)+\bar{\theta}\Omega^*_\mu+\bar{\theta}\theta M_\mu,\\
\mathscr{G}_\mu&=g_\mu+\theta\Pi_\mu+\bar{\theta}(\bar{g}^*_\mu+\tilde{g}^{\bar{\theta}}_\mu)+\bar{\theta}\theta(N_\mu+\tilde{g}^{\bar{\theta}\theta}_\mu),\\
\mathscr{G}^1_\mu&=g^1_\mu+\theta(\Pi_\mu-\tilde{g}^{\theta}_\mu)+\bar{\theta}\bar{g}^*_\mu+\bar{\theta}\theta N_\mu,\\
\bar{\mathscr{G}}_\mu&=\bar{g}_\mu+\theta\bar{\Pi}_\mu+\bar{\theta}(g^*_\mu+\tilde{g}^{\bar{\theta}}_\mu)+\bar{\theta}\theta(\bar{N}_\mu+\tilde{\bar{g}}^{\bar{\theta}}_\mu),\\
\bar{\mathscr{G}}^1_\mu&=\bar{g}^1_\mu+\theta(\bar{\Pi}_\mu-\tilde{\bar{g}}^{\theta}_\mu)+\bar{\theta}g^*_\mu+\bar{\theta}\theta\bar{N}_\mu,
\end{aligned}
\tag{VI.15}
$$

where

$$
\begin{aligned}
\tilde{B}^{\theta}_{\mu\nu}&=\tilde{D}_{[\mu}\tilde{g}_{\nu]}-i\tilde{c}\times\tilde{B}_{\mu\nu},\\
\tilde{B}^{\bar{\theta}}_{\mu\nu}&=\tilde{D}_{[\mu}\tilde{\bar{g}}_{\nu]}-i\tilde{\bar{c}}\times\tilde{B}_{\mu\nu},\\
\tilde{B}^{\bar{\theta}\theta}_{\mu\nu}&=-\tilde{D}_{[\mu}e_{\nu]}-i\tilde{c}\times\tilde{D}_{[\mu}\tilde{\bar{g}}_{\nu]}-i(\tilde{D}_{[\mu}\tilde{\bar{c}})\times\tilde{g}_{\nu]}-ib\times\tilde{B}_{\mu\nu}-\tilde{\bar{c}}\times(\tilde{c}\times\tilde{B}_{\mu\nu}),\\
\tilde{\Omega}^{\theta}_\mu&=-\tilde{g}_\mu-i\tilde{c}\times\tilde{\Omega}_\mu,\\
\tilde{\Omega}^{\bar{\theta}}_\mu&=-\tilde{\bar{g}}_\mu-i\tilde{\bar{c}}\times\tilde{\Omega}_\mu,\\
\tilde{\Omega}^{\bar{\theta}\theta}_\mu&=e_\mu+\tilde{c}\times(i\tilde{\bar{g}}_\mu-\tilde{\bar{c}}\times\tilde{\Omega}_\mu)-i(b+\tilde{c}\times\tilde{\bar{c}})\times\tilde{\Omega}_\mu,\\
\tilde{g}^{\theta}_\mu&=-i\tilde{c}\times\tilde{g}_\mu,\\
\tilde{g}^{\bar{\theta}}_\mu&=e_\mu,\\
\tilde{g}^{\bar{\theta}\theta}_\mu&=(\tilde{c}\times\tilde{\bar{c}})\times\tilde{g}_\mu-ic\times e_\mu-ib\times\tilde{g}_\mu,\\
\tilde{\bar{g}}^{\theta}_\mu&=-e_\mu-i\tilde{c}\times\tilde{\bar{g}}_\mu-i\tilde{\bar{c}}\times\tilde{g}_\mu,\\
\tilde{\bar{g}}^{\bar{\theta}}_\mu&=-i\tilde{\bar{c}}\times\tilde{\bar{g}}_\mu,\\
\tilde{\bar{g}}^{\bar{\theta}\theta}_\mu&=\tilde{\bar{c}}\times(\tilde{\bar{c}}\times\tilde{g}_\mu)+\tilde{\bar{c}}\times(\tilde{c}\times\tilde{\bar{g}}_\mu)-ib\times\tilde{\bar{g}}_\mu-i\tilde{\bar{c}}\times e_\mu.
\end{aligned}
\tag{VI.16}
$$

In Eqs. (VI.14) and (VI.15) some new auxiliary fields have appeared which may be interpreted as ghosts ($\Pi^A_\mu,\Pi^c,\Pi^c,\Pi_{\mu\nu},s_\mu,\Pi_\mu,\bar{\Pi}_\mu$), antighosts ($\underline{A}^*_\mu,c^*,\bar{c}^*,B^*_{\mu\nu},\Omega^*_\mu,\bar{g}^*_\mu,g^*_\mu$), and Nakanish–Lautrup fields (N^A_μ, N^c, N^c, $N_{\mu\nu}$, M_μ, N_μ, and $\bar{N}_\mu$).

As in the Abelian case, the antighosts above will play the role of the BV antifields. At this point we can fix the shift symmetry using the following (anti-) BRST invariant terms:

$$\tfrac{1}{2}\ \mathrm{tr}\ \partial_\theta\partial_{\overline{\theta}}(\mathscr{A}^1_\mu\mathscr{A}^{1\mu})=\mathrm{tr}\{iA^1_\mu B^\mu+(D^{A-A^1}_\mu(c-c^1)-\Pi^A_\mu)A^{*\mu}\},$$

$$\mathrm{tr}\ \partial_\theta\partial_{\overline{\theta}}(\mathscr{C}^1\overline{\mathscr{C}}^1)=\mathrm{tr}\{iN^c\overline{c}^1+[\Pi^c+\tfrac{1}{2}\ (c-c^1)\times(c-c^1)]c^*-\overline{c}^*(\Pi^{\overline{c}}+ib)+ic^1N^{\overline{c}}\},$$

$$\tfrac{1}{2}\ \mathrm{tr}\ \partial_\theta\partial_{\overline{\theta}}(\mathscr{B}^1_{\mu\nu}\mathscr{B}^{1\mu\nu})=\mathrm{tr}\{B^1_{\mu\nu}N^{\mu\nu}+(\Pi_{\mu\nu}-\tilde{B}^\theta_{\mu\nu})B^{*\mu\nu}\},\tag{VI.17}$$

$$\tfrac{1}{2}\ \mathrm{tr}\ \partial_\theta\partial_{\overline{\theta}}(\mathscr{S}^1_\mu\mathscr{S}^{1\mu})=\mathrm{tr}\{\Omega^1_\mu M^\mu+(s_\mu-\tilde{\Omega}^\theta_\mu)\Omega^{*\mu}\},$$

$$\mathrm{tr}\ \partial_\theta\partial_{\overline{\theta}}(\mathscr{G}^1_\mu\overline{\mathscr{G}}^{1\mu})=\mathrm{tr}\{N_\mu\overline{g}^{1\mu}+g^1_\mu\overline{N}^\mu-(\Pi_\mu-\tilde{g}^\theta_\mu)g^{*\mu}+\overline{g}^*_\mu(\overline{\Pi}^\mu-\tilde{\bar{g}}^{\theta\mu})\}.$$

In order to fix the original gauge symmetry we choose a superboson

$$\Phi=\phi+\theta\delta\phi+\overline{\theta\delta}\phi+\overline{\theta}\theta\delta\overline{\delta}\phi,\tag{VI.18}$$

which generates the invariant term

$$\begin{aligned}\mathrm{tr}\ \partial_\theta\partial_{\overline{\theta}}\Phi&=\mathrm{tr}\ \delta\overline{\delta}\phi\\&=\mathrm{tr}\Bigg[\delta A_\mu\frac{\delta(\overline{\delta}\phi)}{\delta A_\mu}+\delta c\ \frac{\delta(\overline{\delta}\phi)}{\delta c}+\delta\overline{c}\frac{\delta(\overline{\delta}\phi)}{\delta\overline{c}}\\&\quad+\delta B_{\mu\nu}\frac{\delta(\overline{\delta}\phi)}{\delta B_{\mu\nu}}+\delta\Omega_\mu\frac{\delta(\overline{\delta}\phi)}{\delta\Omega_\mu}+\delta g_\mu\frac{\delta(\overline{\phi})}{\delta g_\mu}+\delta\overline{g}_\mu\frac{\delta(\overline{\delta}\phi)}{\delta\overline{g}_\mu}\Bigg],\end{aligned}\tag{VI.19}$$

provided that $\overline{\delta}\phi=\overline{\delta}\phi(A_\mu,B_{\mu\nu},\Omega_\mu,c,\overline{c},g_\mu,\overline{g}_\mu)$. The BV gauge-fixing fermion is naturally identified with $\overline{\delta}\phi$. With this choice, the gauge-fixed Lagrangian density reads

$$\begin{aligned}\mathscr{L}_{\mathrm{gf}}=\mathrm{tr}\Bigg[&iA^1_\mu B^\mu+iN^c\overline{c}^1+ic^1N^{\overline{c}}-A^{*\mu}D^{A-A_1}(c-c_1)+\overline{c}^*[(c-c^1)\times(c-c^1)]-ic^*b\\&+\Pi^A_\mu\Bigg(-A^{*\mu}+i\ \frac{\delta(\overline{\delta}\phi)}{\delta A_\mu}\Bigg)+\Pi^c\Bigg(c^*+i\ \frac{\delta(\overline{\delta}\phi)}{\delta c}\Bigg)+\Pi^{\overline{c}}\Bigg(-\overline{c}^*+i\ \frac{\delta(\overline{\delta}\phi)}{\delta\overline{c}}\Bigg)+\Omega^1_\mu M^\mu+B^1_{\mu\nu}N^{\mu\nu}\\&+N_\mu\overline{g}^{1\mu}+g^1_\mu\overline{N}^\mu+B^{*\mu\nu}\tilde{B}^\theta_{\mu\nu}+\Omega^{*\mu}\tilde{\Omega}^\theta_\mu+g^{*\mu}\tilde{g}^\theta_\mu-\overline{g}^*_\mu\tilde{\bar{g}}^{\theta\mu}+s_\mu\Bigg(\Omega^{*\mu}+\frac{\delta(\overline{\delta}\phi)}{\delta\Omega_\mu}\Bigg)\\&+\Pi_{\mu\nu}\Bigg(B^{*\mu\nu}+\frac{\delta(\overline{\delta}\phi)}{\delta B_{\mu\nu}}\Bigg)+\Pi_\mu\Bigg(-g^{*\mu}+\frac{\delta(\overline{\delta}\phi)}{\delta g_\mu}\Bigg)+\overline{\Pi}_\mu\Bigg(\overline{g}^{*\mu}+\frac{\delta(\overline{\delta}\phi)}{\delta\overline{g}_\mu}\Bigg)\Bigg].\end{aligned}\tag{VI.20}$$

The replacement of the equations of motion for $N_{\mu\nu}$, M_μ, N_μ, $\overline{N}_\mu$, and the index 1 fields leads to the action

$$\begin{aligned}S=S_0+\mathrm{tr}\int dx^\mu\Bigg[&B^*_{\mu\nu}(D^{[\mu}g^{\nu]}-ic\times B_{\mu\nu})+\Omega^*_\mu(-g^\mu-ic\times B^{\mu\nu})-g^*_\mu(ic\times g^\mu)\\&+\overline{g}^*_\mu(e^\mu+ic\times\overline{g}^\mu+i\overline{c}\times g^\mu)+s_\mu\Bigg(\Omega^{*\mu}+\frac{\delta(\overline{\delta}\phi)}{\delta\Omega_\mu}\Bigg)+\Pi_{\mu\nu}\Bigg(B^{*\mu\nu}+\frac{\delta(\overline{\delta}\phi)}{\delta B_{\mu\nu}}\Bigg)\\&+\Pi_\mu\Bigg(-g^{*\mu}+\frac{\delta(\overline{\delta}\phi)}{\delta g_\mu}\Bigg)+\overline{\Pi}_\mu\Bigg(\overline{g}^{*\mu}+\frac{\delta(\overline{\delta}\phi)}{\delta\overline{g}_\mu}\Bigg)\Bigg],\end{aligned}\tag{VI.21}$$

where the classical part S_0 is given by Eqs. (II.19), (V.11), and (V.14), namely

$$S_0=\int dx\Bigg[-\frac{1}{4}F_{\mu\nu}F^{\mu\nu}-m\epsilon^{\mu\nu\rho\kappa}\ \mathrm{tr}\ F_{\mu\nu}B_{\rho\kappa}+\frac{3}{4}\ \mathrm{tr}(D_{[\mu}B_{\nu\rho]}+D_{[\mu}D_\nu\Omega_{\rho]})^2\Bigg].\tag{VI.22}$$

Action S is exactly the Batalin–Vilkovisky one with gauge-fixing fermion $\overline{\delta}\phi$.

VII. CONCLUSION

We have used the BRST superspace formalism for two-form gauge fields. We have considered the Abelian and the non-Abelian cases. The first one is of course much simpler algebraically, but has a richer structure by virtue of the reducibility condition. We have shown that the treatment in the BRST superspace language naturally contains all the ingredients of the theory and has permitted us to obtain a deeper comprehension of the theory where both BRST and anti-BRST symmetries are present. In the non-Abelian case, we have considered an off-shell treatment, compatible with the Abelian limit where both vector and tensor fields are coupled in a topological manner. This was achieved by the introduction of a kind of a Stuckelberg field which we believe is the only way we can make the non-Abelian formalism compatible with this Abelian limit. We have also explicitly shown that the superfield treatment of one- and two-form gauge fields leads directly to the field–antifield BV action.

APPENDIX A

The superfield equations given by (IV.5) and the superfield expressions given by (IV.3) lead, in components, to the following set of equations [each set corresponds to one of the equations (IV.5)]

$$
\begin{aligned}
&B^{\theta}_{\mu\nu}+\frac{i}{2}\,(\partial_\mu g_\nu-\partial_\nu g_\mu)=0,\\
&B^{\bar\theta\theta}_{\mu\nu}-\frac{i}{2}\,(\partial_\mu e_\nu-\partial_\nu e_\mu)=0,\\
&\partial_\mu \bar e_\nu-\partial_\nu \bar e_\mu=0,\\
&\partial_\mu G^{\bar\theta\theta}_{\nu}-\partial_\nu G^{\bar\theta\theta}_{\mu}=0,
\end{aligned}
\tag{A1}
$$

$$
\begin{aligned}
&B^{\bar\theta}_{\mu\nu}+\frac{i}{2}\,(\partial_\mu \bar g_\nu-\partial_\nu \bar g_\mu)=0,\\
&B^{\bar\theta\theta}_{\mu\nu}+\frac{i}{2}\,(\partial_\mu \bar G^{\theta}_{\nu}-\partial_\nu \bar G^{\theta}_{\mu})=0,\\
&\partial_\mu \bar G^{\bar\theta}_{\nu}-\partial_\nu \bar G^{\bar\theta\theta}_{\mu}=0,\\
&\partial_\mu \bar G^{\bar\theta}_{\nu}-\partial_\nu \bar G^{\bar\theta\theta}_{\mu}=0,
\end{aligned}
\tag{A2}
$$

$$
\begin{aligned}
&\bar e_\mu-\partial_\mu G=0,\\
&G^{\bar\theta\theta}_{\mu}+\partial_\mu G^{\bar\theta}=0,\\
&\partial_\mu G^{\bar\theta}=0,\\
&\partial_\mu G^{\bar\theta\theta}=0,
\end{aligned}
\tag{A3}
$$

$$\begin{gathered}\overline{\overline{G}^{\theta}_{\mu}}-\partial_{\mu}\overline{G}=0,\\ \overline{\overline{G}^{\theta}_{\mu}}-\partial_{\mu}\overline{G}^{\theta}=0,\\ \partial_{\mu}\overline{\overline{G}^{\theta}}=0,\\ \partial_{\mu}\overline{\overline{G}^{\theta\theta}}=0,\end{gathered}\tag{A4}$$

$$\begin{gathered}\overline{G}^{\theta}_{\mu}+e_{\mu}-\partial_{\mu}K=0,\\ G^{\overline{\theta\theta}}_{\mu}-\partial_{\mu}f=0,\\ \overline{G}^{\overline{\theta\theta}}_{\mu}+\partial_{\mu}\overline{f}=0,\\ \partial_{\mu}K^{\overline{\theta\theta}}=0,\end{gathered}\tag{A5}$$

$$\begin{gathered}G^{\theta}=0,\\ G^{\overline{\theta\theta}}=0,\end{gathered}\tag{A6}$$

$$\begin{gathered}\overline{\overline{G}^{\theta}}=0,\\ \overline{\overline{G}^{\theta\theta}}=0,\end{gathered}\tag{A7}$$

$$\begin{gathered}\overline{G}^{\theta}+\overline{f}=0,\\ \overline{\overline{G}^{\theta\theta}}=0,\\ K^{\overline{\theta\theta}}=0,\end{gathered}\tag{A8}$$

$$\begin{gathered}G^{\overline{\theta}}+f=0,\\ G^{\overline{\theta\theta}}=0,\\ K^{\overline{\theta\theta}}=0.\end{gathered}\tag{A9}$$

As one observes, some of the equations above correspond to the relations already displayed in (IV.6). One can also verify that the remaining ones do not lead to any new result besides what is shown in (IV.6). For example, the third of Eqs. (A1) is in agreement with the fourth Eq. (IV.6). The same occurs with respect the fourth Eq. (A1) and the sixth Eq. (IV.6), and so on.

APPENDIX B

Each one of the equations (V.3) leads, respectively, to the following sets below

$$\begin{gathered}B^{\theta}_{\mu\nu}+iD_{[\mu}g_{\nu]}+c\times B_{\mu\nu}=0,\\ D_{[\mu}\overline{e}_{\nu]}+iA^{\theta}_{[\mu}\times g_{\nu]}-c\times B^{\theta}_{\mu\nu}-iC^{\theta}\times B_{\mu\nu}=0,\\ \overline{B}^{\theta\theta}_{\mu\nu}-iD_{[\mu}e_{\nu]}+\overline{A}^{\theta}_{[\mu}\times g_{\nu]}-c\times\overline{B}^{\theta}_{\mu\nu}-\overline{c}^{\theta}\times B_{\mu\nu}=0,\end{gathered}\tag{B1}$$

$$D_{[\mu}\bar{G}^{\theta\theta}_{\nu]}+A^{\theta}_{[\mu}\times e_{\nu]}-\bar{A}^{\theta}_{[\mu}\times\bar{e}_{\nu]}+\bar{A}^{\theta\theta}_{[\mu}\times g_{\nu]}-ic\times\bar{B}^{\theta\theta}_{\mu\nu}+ic^{\theta}\times\bar{B}^{\theta}_{\mu\nu}-i\bar{c}^{\theta}\times B^{\theta}_{\mu\nu}-i\bar{c}^{\theta\theta}\times B_{\mu\nu}=0,$$

$$\bar{B}^{\theta}_{\mu\nu}+iD_{[\mu}\bar{g}_{\nu]}+\bar{c}\times B_{\mu\nu}=0,$$

$$D_{[\mu}\bar{G}^{\theta}_{\nu]}+i\bar{A}^{\theta}_{[\mu}\times\bar{g}_{\nu]}-\bar{c}\times\bar{B}^{\theta}_{\mu\nu}-i\bar{b}\times B_{\mu\nu}=0,$$

$$\bar{B}^{\theta\theta}_{\mu\nu}+iD_{[\mu}\bar{G}^{\theta}_{\nu]}-A^{\theta}_{[\mu}\times\bar{g}_{\nu]}-i\bar{c}\times B^{\theta}_{\mu\nu}+b\times B_{\mu\nu}=0,\tag{B2}$$

$$D_{[\mu}\bar{G}^{\theta\theta}_{\nu]}+A^{\theta}_{[\mu}\times\bar{G}^{\theta}_{\nu]}-\bar{A}^{\theta}_{[\mu}\times\bar{G}^{\theta}_{\nu]}+\bar{A}^{\theta\theta}_{[\mu}\times\bar{g}_{\nu]}-i\bar{c}\times\bar{B}^{\theta\theta}_{\mu\nu}+ib\times\bar{B}^{\theta}_{\mu\nu}-i\bar{b}\times B^{\theta}_{\mu\nu}-i\bar{C}^{\theta\theta}\times B_{\mu\nu}=0,$$

$$D_{\mu}G-\bar{e}_{\mu}-ic\times g_{\mu}=0,$$

$$D_{\mu}G^{\theta}+A^{\theta}_{\mu}\times G+c\times\bar{e}_{\mu}-C^{\theta}\times g_{\mu}=0,$$

$$G^{\theta\theta}_{\mu}+D_{\mu}\bar{G}^{\theta}+\bar{A}^{\theta}_{\mu}\times G+c\times e_{\mu}-\bar{C}^{\theta}\times g_{\mu}=0,\tag{B3}$$

$$D_{\mu}\bar{G}^{\theta\theta}+iA^{\theta}_{\mu}\times\bar{G}^{\theta}-iA^{\theta}_{\mu}\times G^{\theta}-\bar{A}^{\theta\theta}_{\mu}\times G+ic\times\bar{G}^{\theta\theta}_{\mu}-C^{\theta}\times e_{\mu}+\bar{C}^{\theta}\times\bar{e}_{\mu}+iC^{\theta\theta}\times g_{\mu}=0,$$

$$D_{\mu}\bar{G}-\bar{G}^{\theta}_{\mu}-i\bar{c}\times\bar{g}_{\mu}=0,$$

$$D_{\mu}\bar{G}^{\theta}+A^{\theta}_{\mu}\times\bar{G}+\bar{c}\times\bar{g}^{\theta}_{\mu}-\bar{b}\times\bar{G}_{\mu}=0,$$

$$\bar{G}^{\theta\theta}_{\mu}-D_{\mu}\bar{G}^{\theta}-A^{\theta}_{\mu}\times\bar{G}-\bar{c}\times\bar{G}^{\theta}_{\mu}-b\times\bar{g}_{\mu}=0,\tag{B4}$$

$$D_{\mu}\bar{G}^{\theta\theta}-iA^{\theta}_{\mu}\times\bar{G}^{\theta}+iA^{\theta}_{\mu}\times\bar{G}^{\theta}+\bar{A}^{\theta\theta}_{\mu}\times\bar{G}-i\bar{c}\times\bar{G}^{\theta\theta}_{\mu}-\bar{b}\times\bar{G}^{\theta}_{\mu}+b\times\bar{G}^{\theta}_{\mu}-i\bar{C}^{\theta\theta}\times\bar{g}_{\mu}=0,$$

$$D_{\mu}K-\bar{G}^{\theta}_{\mu}-e_{\mu}-ic\times\bar{g}_{\mu}-i\bar{c}\times g_{\mu}=0,$$

$$D_{\mu}f-G^{\theta\theta}_{\mu}+c\times\bar{G}^{\theta}_{\mu}-C^{\theta}\times\bar{g}_{\mu}+\bar{c}\times\bar{e}_{\mu}-b\times g_{\mu}+A^{\theta}_{\mu}\times K=0,$$

$$D_{\mu}\bar{f}+\bar{G}^{\theta\theta}_{\mu}+c\times\bar{G}^{\theta}_{\mu}-\bar{C}^{\theta}\times\bar{g}_{\mu}+\bar{c}\times e_{\mu}-\bar{b}\times g_{\mu}+\bar{A}^{\theta}_{\mu}\times K=0,\tag{B5}$$

$$D_{\mu}K^{\theta\theta}-ic\times\bar{G}^{\theta\theta}_{\mu}+C^{\theta}\times\bar{G}^{\theta}_{\mu}-\bar{C}^{\theta}\times\bar{G}^{\theta}_{\mu}-iC^{\theta\theta}\times\bar{g}_{\mu}-i\bar{c}\times G^{\theta\theta}_{\mu}+b\times e_{\mu}-\bar{b}\times\bar{e}_{\mu}-i\bar{C}^{\theta\theta}\times g_{\mu}+iA^{\theta}_{\mu}\times\bar{f}-i\bar{A}^{\theta}_{\mu}\times f+\bar{A}^{\theta\theta}_{\mu}\times K=0,$$

$$\bar{G}^{\theta}+f+\bar{c}\times G+c\times K=0,$$

$$\bar{G}^{\theta\theta}-i\bar{c}\times G^{\theta}+b\times G-ic\times f+C^{\theta}\times K=0,$$

$$K^{\theta\theta}+i\bar{c}\times\bar{G}^{\theta}-\bar{b}\times G+ic\times\bar{f}-\bar{C}^{\theta}\times K=0,\tag{B6}$$

$$\bar{c}\times G^{\theta\theta}+b\times\bar{G}^{\theta}-\bar{b}\times G^{\theta}+\bar{C}^{\theta\theta}\times G+c\times K^{\theta\theta}-C^{\theta}\times\bar{f}+\bar{C}^{\theta}\times f+C^{\theta\theta}\times K=0,$$

$$\bar{G}^{\theta}+\bar{f}+c\times\bar{G}+\bar{c}\times K=0,$$

$$K^{\theta\theta}-ic\times\bar{G}^{\theta}+C^{\theta}\times\bar{G}-i\bar{c}\times f+b\times K=0,$$

$$\bar{G}^{\bar{\theta\theta}}+ic\times\bar{G}^{\bar{\theta}}-C^{\bar{\theta}}\times\bar{G}+i\bar{c}\times\bar{f}-\bar{b}\times K=0, \tag{B7}$$

$$c\times\bar{G}^{\bar{\theta\theta}}-C^{\theta}\times\bar{G}^{\bar{\theta}}+C^{\bar{\theta}}\times\bar{G}^{\theta}+C^{\bar{\theta\theta}}\times\bar{G}+\bar{c}\times K^{\bar{\theta\theta}}-b\times\bar{f}+\bar{b}\times f+\bar{C}^{\bar{\theta\theta}}\times K=0,$$

$$\begin{gathered}
G^{\theta}+c\times G=0,\\
c\times G^{\theta}+iC^{\theta}\times G=0,\\
G^{\bar{\theta\theta}}+ic\times G^{\bar{\theta}}-C^{\bar{\theta}}\times G=0,\\
c\times G^{\bar{\theta\theta}}-C^{\theta}\times G^{\bar{\theta}}-iC^{\bar{\theta}}\times G^{\theta}+C^{\bar{\theta\theta}}\times G=0,
\end{gathered} \tag{B8}$$

$$\begin{gathered}
\bar{G}^{\bar{\theta}}+\bar{c}\times\bar{G}=0,\\
\bar{c}\times\bar{G}^{\bar{\theta}}+i\bar{b}\times\bar{G}=0,\\
\bar{G}^{\bar{\theta\theta}}-i\bar{c}\times\bar{G}^{\theta}-b\times\bar{G}=0,\\
\bar{c}\times\bar{d}^{\bar{\theta\theta}}-b\times\bar{G}^{\bar{\theta}}+\bar{b}\times\bar{G}^{\theta}+\bar{C}^{\bar{\theta\theta}}\times\bar{G}=0.
\end{gathered} \tag{B9}$$

We observe that the component relations that permitted us to write the superfield expressions (V4)–(V6) are contained in the first expressions of the set (B1)–(B9). As usual in this formalism, some of the remaining expressions are consistency relations. As an example, we mention the second and fourth equations of (B3) and (B4), the last three equations of (B5), and others. The new fact here is that it is possible to show that the superfields related to ghost-for-ghost are zero. For example, the combination of (II.8) and the two first equation (B1) and (B2) leads to $D_{[\mu}D_{\nu]}G=0$ and $D_{[\mu}D_{\nu]}G=0$. Since our formulation is not on-shell, one concludes that $G=0$ and $G=0$. Similarly, after hard algebraic work, one obtains that all components of the superfields related to ghost-for-ghosts are zero.

Expansion of the hydrogen-like wave functions in the inverse principal quantum number, for the discrete and continuous spectra

Bruno Blaive[a] and Michel Cadilhac
CNRS, Ecole Nat. Sup. Chimie, Faculty of St-Jerome, 13397 Marseille Cedex 20, France

(Received 29 April 1998; accepted for publication 12 August 1998)

An expansion with respect to the inverse principal quantum number n^{-1} has been derived recently for the hydrogen-like wave functions of the discrete spectrum. The basic functions of this expansion were Bessel functions multiplied by a power r^k of the distance r to the origin. We show that this expansion remains valid for the continuous spectrum, with minor changes. For the wave function corresponding to the energy $E=+1/(2n^2)$ a.u. of the continuum, the pure imaginary number $-in$ (positive real n) must be substituted for the integer n in the expansion for the discrete spectrum, and a normalizing factor must be introduced. © *1998 American Institute of Physics.* [S0022-2488(98)03811-0]

I. INTRODUCTION

The energy $E=0$ is an upper limit for the eigenenergy corresponding to the atomic electronic Schrödinger wave functions of the hydrogen discrete spectrum ($E=-1/(2n^2)\rightarrow 0^-$), and a lower limit for those of the continuous spectrum ($E=+1/(2n^2)\rightarrow 0^+$). In a recent paper,[1] we derived an expansion of the discrete hydrogen-like wave functions $\psi_{nlm}(r,\theta,\varphi)=R_{nl}(r)Y_l^m(\theta,\varphi)$ in the vicinity of $E=0^-$, with respect to the inverse principal quantum number n^{-1}, for fixed quantum numbers l,m:

$$R_{nl}(r)=\frac{2}{n^{3/2}}\left[\prod_{k=1}^{l}\left(1-\frac{k^2}{n^2}\right)^{-1/2}\right]e^{-x/(2n)} \times\left[x^{-1/2}J_{2l+1}(2\sqrt{x})-\sum_{q=1}^{\infty}\frac{1}{n^q}\sum_{k=q}^{2q}s_{q,k}(l)x^{(k-1)/2}J_{k-2l-1}(2\sqrt{x})\right], \tag{1}$$

where

$$x=2r. \tag{2}$$

The coefficients $s_{q,k}(l)$ $(q\leqslant k\leqslant 2q)$ of the expansion are polynomials of l that satisfy the recursion formula,

$$s_{1,1}=-l, \quad s_{1,2}=-\tfrac{1}{2}, \tag{3}$$

$$s_{q,k}=\left(1-\frac{l+1}{k}\right)s_{q-1,k-1}-\frac{1}{k}s_{q-1,k-2}. \tag{4}$$

Equation (1), which has no connection with previous expansions involving Bessel functions,[2–5] is founded on a development of the Laguerre polynomial $L_n^{\alpha}(x/n)$ with respect to n^{-1}. The idea of the expansion (1) originated from the calculation of quantum integrals involving discrete atomic wave functions. However, one also finds in the literature cases where such an expansion would be useful for the continuous spectrum, as in the theory of collisions, where a zeroth order expansion is used.[6,7] In the present article we shall examine how to obtain an equation analogous to Eq. (1) for the wave functions of the continuum.

II. RECALL: THE RADIAL WAVE FUNCTION OF THE CONTINUUM, AND THE CORRESPONDENCE WITH THE DISCRETE SPECTRUM

The Schrödinger radial equation is a second-order linear differential equation, whose complex solutions $R(r)$ belong to a two-dimensional complex space. Since the wave functions are also submitted to a regularity condition,[8] they must be proportional to a particular solution R_{El}:

$$R(r)=cR_{El}(r), \tag{5}$$

where c is any complex number. Being real, the Schrödinger radial equation has a real normalized solution (the real part, or the imaginary part, of a solution is a solution), which is unique if it is chosen to be positive for small r. This solution can be expressed as [Ref. 9, Eq. (4.23)]

$$R_{El}(r)=\frac{2}{\sqrt{1-e^{-2\pi|n|}}}\prod_{q=1}^{l}(n^2+q^2)^{1/2}\frac{(2r/n)^l}{(2l+1)!}e^{-ir/n}F(in+l+1,2l+2,2ir/n), \tag{6}$$

where $n=(2E)^{-1/2}$, and all the other complex radial wave functions differ from $R_{El}(r)$ by a uniform phase factor $c=e^{i\alpha}$.

A correspondence can be established[2] with the discrete wave functions,[8]

$$R_{nl}(r)=N_{nl}\left(\frac{2r}{n}\right)^l e^{-r/n}(n+l)!L_{n-l-1}^{2l+1}\left(\frac{2r}{n}\right), \tag{7}$$

$$=\frac{2}{(2l+1)!}n^{-3/2}\prod_{q=1}^{l}(n^2-q^2)^{1/2}\left(\frac{2r}{n}\right)^l e^{-r/n}F\left(-n+l+1,2l+2,\frac{2r}{n}\right). \tag{8}$$

Equation (8) devolves from the proportionality between the Laguerre polynomial L and a finite confluent hypergeometric series F, and from the identity

$$\binom{n+l}{2l+1}\frac{2}{n^2}\sqrt{\frac{(n-l-1)!}{(n+l)!}}=\frac{2}{(2l+1)!}n^{-3/2}\prod_{q=1}^{l}(n^2-q^2)^{1/2}. \tag{9}$$

When we perform in Eq. (8), the change of variable,

$$n(n\text{natural integer})\mapsto -in(n\text{positive real number}),$$

the coefficients i^l arising from different factors cancel, yielding the function

$$R_{-in,l}(r)=e^{-i\pi/4}n^{-3/2}\sqrt{1-e^{-2\pi n}}R_{El}(r). \tag{10}$$

In the following we consider only positive real numbers n, since opposite values of n correspond to the same energy E. R_{El} is normalized with respect to the energy $E=+1/(2n^2)$; let R'_{El} be the same function renormalized with respect to n. R'_{El} is defined in such a way that the integral over the spectrum,

$$\int_0^\infty dE\, R_{El}^* R_{El}=\int_0^\infty \frac{dn}{n^3}R_{El}^* R_{El}, \tag{11}$$

is written in the form

$$\int_0^\infty dn\, R_{El}^{\prime *} R'_{El}, \tag{12}$$

i.e.,

$$R'_{El}(r)=R_{El}(r)/n^{3/2}. \tag{13}$$

Equations (10) and (13) show that the change of variable $n \mapsto -in$ made in the discrete wave function yields the continuous wave function R'_{El} multiplied by the coefficient

$$e^{-i\pi/4}\sqrt{1-e^{-2\pi n}}. \tag{14}$$

This correspondence between the two spectra suggests that expansion (1) could remain valid for the continuum when n is replaced by $-in$, apart from a factor equal to (14).

III. EXPANSION OF THE CONFLUENT HYPERGEOMETRIC FUNCTION $F(in+l+1,2l+2,2ir/n)$

In the case of the discrete spectrum, the expansion of ψ_{nlm} with respect to n^{-1} has been obtained by using a Laplace transform, applied to the Laguerre polynomial of Eq. (7). In this section, the same method will be generalized to the confluent hypergeometric function of Eq. (6). We shall refer to Ref. 1 for the steps of the derivation that will remain unchanged. Several additional difficulties due to infinite series and complex variables will be described.

The hypergeometric function F involved in Eq. (6) is defined by

$$F\left(in+l+1,2l+2,\frac{ix}{n}\right)=\frac{\Gamma(2l+2)}{\Gamma(in+l+1)}\sum_{k=0}^{\infty}\frac{\Gamma(in+l+k+1)}{\Gamma(2l+k+2)k!}\left(\frac{ix}{n}\right)^k. \tag{15}$$

The Laplace transform of (15), with respect to the variable x, is given by

$$(\mathcal{L}F)(p)=\frac{\Gamma(2l+2)}{\Gamma(in+l+1)}\sum_{k=0}^{\infty}\frac{\Gamma(in+l+k+1)}{\Gamma(2l+k+2)}\left(\frac{i}{n}\right)^k\frac{1}{p^{k+1}}. \tag{16}$$

The p domain of convergence of the series (16) is given by

$$\left|\frac{i}{np}\right|<1, \tag{17}$$

i.e., $|p|>1/n$, a domain that will allow us to define the incoming inverse Laplace transform. Inequality (17) is deduced easily from the Sterling formula, which gives an equivalent of the series coefficient when k tends to infinity:

$$\Gamma(k+\alpha)/\Gamma(k+\gamma)\sim k^{\alpha-\gamma}. \tag{18}$$

Using the identity

$$\Gamma(x)\Gamma(1-x)=(-1)^{x-y}\Gamma(y)\Gamma(1-y), \tag{19}$$

which is valid for complex numbers x and y whose difference $x-y$ is an integer, we obtain

$$(\mathcal{L}F)(p)=\Gamma(2l+2)p^{2l}(in)^{2l+1}\sum_{k=0}^{\infty}\frac{\Gamma(-in-l)}{\Gamma(-in-l-k)\Gamma(2l+k+2)}\left(\frac{-i}{np}\right)^{2l+1+k}. \tag{20}$$

In Eq. (20), let us set $q=2l+1+k$, and insert the identity

$$\frac{\Gamma(-in+l+1)}{\Gamma(-in-l)}=(-1)^{l+1}in\prod_{j=1}^{l}(n^2+j^2). \tag{21}$$

We then obtain

$$(\mathcal{L}F)(p)=Cp^{2l}\sum_{q=2l+1}^{\infty}\frac{\Gamma(-in+l+1)}{\Gamma(-in+l+1-q)q!}\left(\frac{-i}{np}\right)^q, \tag{22}$$

where C represents the constant

$$C \equiv -(2l+1)!\, n^{2l} \prod_{j=1}^{l} (n^2+j^2)^{-1}. \tag{23}$$

Equation (22) can be rewritten in the form

$$(\mathcal{L}F)(p) = Cp^{2l} D(p) - \sum_{q=0}^{2l} b_q p^{2l-q}, \tag{24}$$

with

$$D(p) = \sum_{q=0}^{\infty} \frac{\Gamma(-in+l+1)}{\Gamma(-in+l+1-q)q!} \left(\frac{-i}{np}\right)^q; \tag{25}$$

hence

$$D(p) = \exp\left[(-in+l)\mathrm{Log}\left(1-\frac{i}{np}\right)\right], \tag{26}$$

where Log represents the principal determination of the complex logarithm (the imaginary part comprised between $-\pi$ and π). Equation (26), which generalizes the Newton binomial formula to a nonreal power $-in+l$, can be readily verified in the following manner: if we consider expression (26) as a function $f(z)$ of the variable $z=1-i/(np)$, its nth derivatives give the coefficients of the series (25). This property, together with the limit $D(p)\to 1$ when $p\to+\infty$, shows that the series (25) is merely the Taylor series of $f(z)$.

The constants b_q in the second term of (24) are unimportant. In fact, in the inverse Laplace transform that will be performed later, the second term of (24) will bring only a delta distribution and its derivatives $\delta^{(k)}$. Since F is a function, these terms must be compensated for in the final result by terms arising from $p^{2l}D(p)$.

With the view to expanding $D(p)$ into powers of n^{-1}, we first expand its complex logarithm,

$$\mathrm{Log}\, D(p) = (-in+l)\mathrm{Log}\left(1-\frac{i}{np}\right) + 2iK\pi \tag{27}$$

(K integer). We have

$$\mathrm{Log}\, D(p) = i\sum_{k=1}^{\infty} \frac{1}{kn^{k-1}} \left(\frac{i}{p}\right)^k - l\sum_{k=1}^{\infty} \frac{1}{kn^k} \left(\frac{i}{p}\right)^k + 2iK\pi, \tag{28}$$

$$= -\frac{1}{p} - \sum_{k=1}^{\infty} \frac{1}{n^k} i^k a_k(p) + 2iK\pi, \tag{29}$$

where we have introduced the same coefficients,

$$a_k(p) \equiv \frac{l}{kp^k} + \frac{1}{(k+1)p^{k+1}}, \tag{30}$$

as in Ref. 1. Apart from the coefficient i^k, Eqs (29), (30) coincide with those obtained for the discrete spectrum. The derivation can, therefore, be ended in a similar manner. Let us expose only the differences due to the new coefficient i^k: in the equation,

$$D(p) = e^{-1/p}\left(1 + \sum_{q=1}^{\infty} \frac{1}{n^q} \sum_{k=q}^{2q} \frac{s_{q,k}(l)}{p^k}\right) \quad (q \geqslant 1), \tag{31}$$

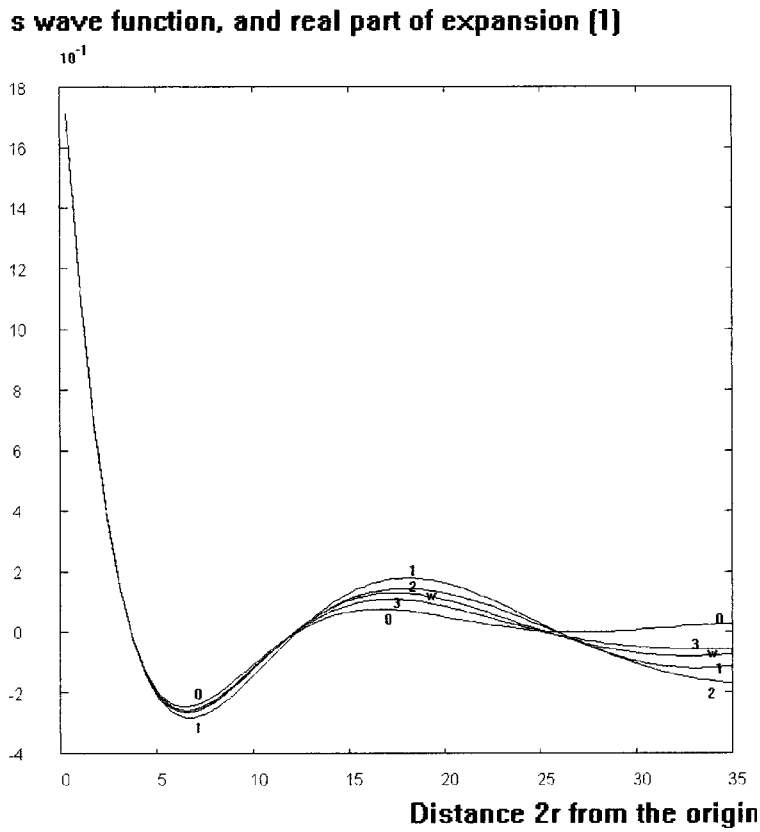

FIG. 1. A comparison between the R_{Es} $(n=9,\ l=0)$ radial wave function of the continuous spectrum of the hydrogen atom, and its expansion (1) to order 0, 1, 2, 3. The following radial functions are drawn: Curve 0: zeroth-order expansion (term $q=0$), $\mathrm{Re}[2e^{-ix/(2n)}J_1(2\sqrt{x})/\sqrt{x}]=2\cos(x/(2n))\,J_1(2\sqrt{x})/\sqrt{x}$. Curve 1: first-order expansion $(q=0,1)$, $\mathrm{Re}[2e^{-ix/(2n)}\times[1/\sqrt{x}+(i/2n)\sqrt{x}]J_1(2\sqrt{x})]$. Curve 2: second-order expansion $(q=0,1,2)$, $idem+\mathrm{Re}[2/n^2e^{-ix/(2n)}[-(x/3)J_2(2\sqrt{x})+x^{3/2}J_3(2\sqrt{x})/8]]$. Curve 3: third-order. Curve w: wave function, $2e^{-ix/(2n)}F(in+1,2,ix/n)$.

which has been derived formerly for the discrete spectrum, the polynomials $s_{q,k}(l)$ should now be replaced by $i^q s_{q,k}(l)$. This means that Eq. (31) remains valid unchanged, provided that n is replaced by $-in$. Like in Ref. 1, the inverse Laplace transform of $p^{2l}D(p)$ in Eq. (24) is a sum of terms of the type

$$\mathcal{L}^{-1}(e^{-1/p}p^k)=(-1)^{k+1}\left[x^{-(k+1)/2}J_{k+1}(2\sqrt{x})\Upsilon(x)-\sum_{q=0}^{k}(-1)^q\frac{\delta^{(q)}}{(k-q)!}\right], \tag{32}$$

and this leads to Eq. (1).

IV. CONCLUSION

We have shown that expansion (1) can be used to compute the wave function R'_{El} of the continuum, corresponding to the energy $E=+1/(2n^2)$, normalized with respect to n, provided that the following changes are made. First, all the occurrences of the integer n in Eq. (1) must be replaced by $-in$, where $n=1/\sqrt{2E}$ now is a positive real number. Second, the rhs of Eq. (1) must be multiplied by the coefficient

$$c_n=e^{i\pi/4}(1-e^{-2\pi n})^{-1/2}, \tag{33}$$

i.e.,

$$R'_{El}(r)=c_nR_{-in,l}(r). \tag{34}$$

The wave function R_{El} normalized with respect to the energy E is related to R'_{El} by Eq. (13).

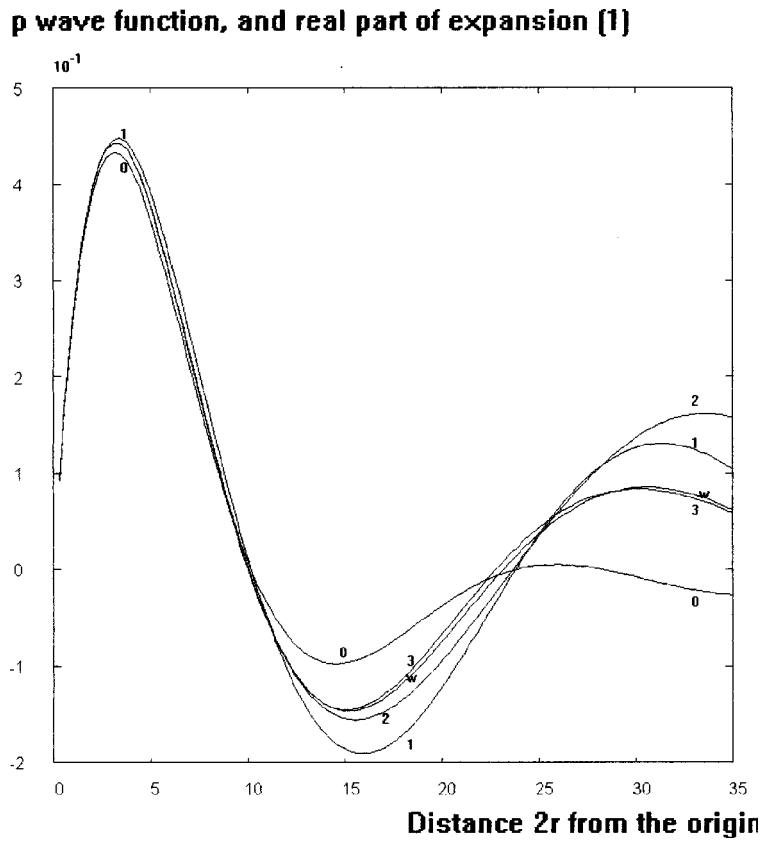

FIG. 2. A comparison between the R_{Ep} $(n=9,l=1)$ radial wave function and its expansion (1) to order 0, 1, 2, 3. The following radial functions are drawn: Curve 0: zeroth-order expansion (term $q=0$), $\mathrm{Re}[2e^{-ix/(2n)}(1+1/n^2)^{-1/2}J_3(2\sqrt{x})/\sqrt{x}]$. Curve 1: first-order expansion $(q=0,1)$, $\mathrm{Re}[2e^{-ix/(2n)}(1+1/n^2)^{-1/2}[1/\sqrt{x}+i/(2n)\sqrt{x}]J_3(2\sqrt{x})]$. Curve 2: second-order expansion $(q=0,1,2)$, $idem+\mathrm{Re}[(2/n^2)e^{-ix/(2n)}(1+1/n^2)^{-1/2}[(x/6)J_0(2\sqrt{x})+x^{3/2}J_1(2\sqrt{x})/8]]$. Curve 3: third-order. Curve w: wave function, $e^{-ix/(2n)}\sqrt{1+n^2}x/(3n)F(in+2,4,ix/n)$.

For practical physical calculations, $R'_{El}(r)$, given by (34) and the series (1), will always be approximated by $R'_{El,Q}(r)$, its partial sum truncated at $q=Q$. The partial sums are real for the discrete spectrum, and complex for the continuous spectrum. In the latter case, their limit is real, thanks to the phase factor chosen in (33). One can use either expansion (1) itself, or its real part, both of them being equal to R'_{El}. We have shown that

$$\lim_{Q\to+\infty}[\mathrm{Re}\,R'_{El,Q}(r)+i\,\mathrm{Im}\,R'_{El,Q}(r)]=R'_{El}(r), \tag{35}$$

which implies

$$\lim_{Q\to+\infty}[\mathrm{Im}\,R'_{El,Q}(r)]=0, \tag{36}$$

since R'_{El} is real. The order of magnitude of the imaginary part is a clue to estimate the error made in the real part of the expansion.

The convergence of expansion (1) is uniform on a bounded interval $0<r<r_{\max}$. Practically, this means that the order Q of the expansion that is necessary for a good approximation of $R'_{El}(r)$ increases with $r_{\max}$. Conversely, for a given order Q, arbitrarily large discrepancies between $R'_{El}(r)$ and its approximation $R'_{El,Q}(r)$ are observed for large radii r. This is exemplified for the third-order approximation $(Q=3)$ of s and p states, for level $n=9$ (Figs. 1–3).

In this study, we also verify that the wave functions are analytical functions of the parameter $\zeta=1/n$ (discrete spectrum) or $\zeta=i/n$ (continuous spectrum). Therefore, the transition between the two types of spectra $(\zeta=0)$ is completely regular.

Equation (1) suggests interesting mathematical properties of expansions on the family of complex functions,

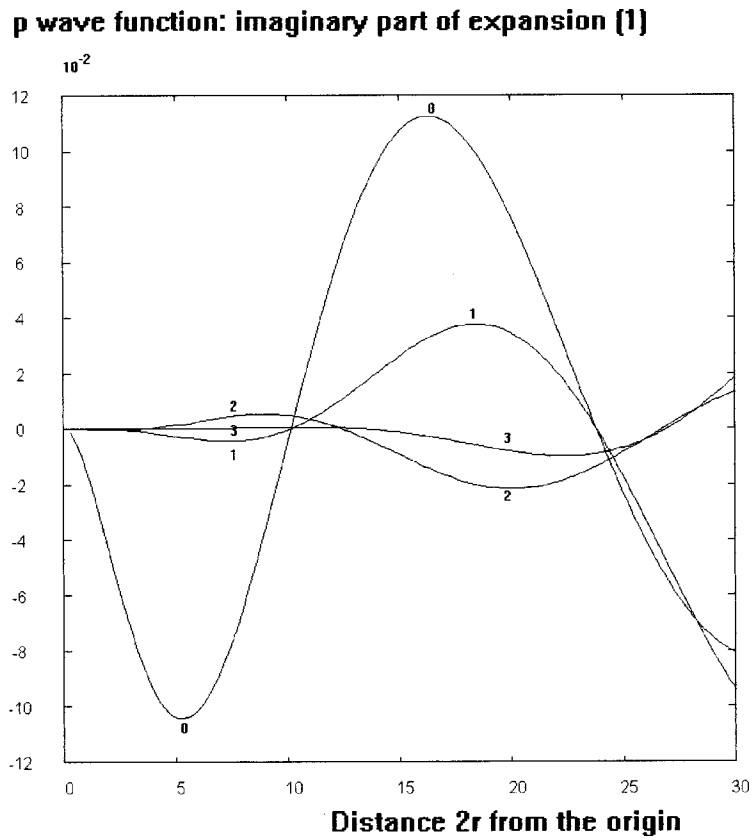

FIG. 3. Imaginary part of expansion (1) for R_{Ep} $(n=9,l=1)$. The same functions as in Fig. 2, with Im instead of Re. Curves 0, 1, 2, 3 correspond to zeroth, first, second, and third order expansions.

$$z^{n/2}J_n(2\sqrt{z}), \tag{37}$$

in connection with the Nielsen series.[10,11] These properties will be dealt with separately.

APPENDIX: GLOSSARY

$F(a,b,z)=\Gamma(b)/\Gamma(a)\Sigma_{k=0}^{\infty}\Gamma(a+k)/(\Gamma(b+k)k!)z^k$, confluent hypergeometric or Kummer function ${}_1F_1$

$J_n(z)=(z/2)^n\Sigma_{k=0}^{\infty}(-1)^k(z/2)^{2k}/(k!(n+k)!)$, Bessel function

$L_n^{\alpha}(x)=\Sigma_{k=0}^{n}(-1)^k\binom{n+\alpha}{n-k}x^k/k!$, Laguerre polynomial [this definition[12] is the definition of Ref. 8 divided by $(n+\alpha)!$].

$\mathcal{L}$, Laplace transform $(\mathcal{L}f)(p)=\int_0^{\infty}dx\,e^{-px}f(x)$

$Y_l^m(\theta,\varphi)$, spherical harmonics

$\delta^{(k)}$, kth derivative of the Dirac distribution δ

$\Gamma(z)$, Euler Gamma function

$\Upsilon(x)$, Heaviside function [$\Upsilon(x)=0$ for $x<0$, 1 for $\geqslant 0$].

Complex Hamiltonian evolution equations and field theory

Theodore Bodurov[a)]
Eugene, Oregon 97405

(Received 22 August 1997; accepted for publication 23 July 1998)

The form of the complex Hamiltonian evolution equations (linear and nonlinear) is deduced here from that of the classical Hamiltonian systems. Their properties and those of the associated continuous Poisson bracket are studied. It is shown that if any space-localized solution of the above type equations is expanded in any Hilbert space basis the expansion coefficients are canonically conjugate variables and obey Hamiltonian systems of complex equations. The last is proved also for sets of ''canonically conjugate'' functionals of general type. As an application, commutation relations which are equivalent in form to Dirac's quantization rules (the constant in place of $\hbar$ is undetermined) are obtained. The question of how a nonlinear field theory may contain quantum mechanics as a special case is discussed in view of this paper's results. © *1998 American Institute of Physics.*
[S0022-2488(98)03211-3]

I. INTRODUCTION

Since the time of quantum mechanics' first successes many physicists, led by diverse motivations, have proposed nonlinear extensions for quantum mechanics and quantum field theory. Among the most prominent were de Broglie[1] and Heisenberg.[2] A more recent contribution which has attracted much attention is from Weinberg.[3]

The underlying idea in Weinberg[3] may be stated as follows: *To study the role of possible nonlinearities in quantum mechanics, and field theory in general, one should study the mathematical properties of those nonlinear field equations whose form is as close as possible to that of the currently accepted fundamental equations, and which form contains the latter as special cases*. This is also the guiding principle for the present work. However, unlike Weinberg, we do not assume that the nonlinearities are small. Instead, we assume that the nonlinear field equations are such that they possess *space-localized* solutions. By doing this we not only extend the validity of Weinberg's general formalism, but we also find other results which would have been inaccessible otherwise.

Just as the physics motivations of the various contributors differ substantially, the nonlinear field equations or the formalisms which are assumed in the respective contributions also differ. Illustrations for this state of affairs are the following samples from the pertinent literature: Finkelstein and Fronsdal,[4] Soler,[5] Bialynicki-Birula and Mycielski,[6] Freidberg and Lee,[7] Cooperstock and Rosen,[8] Enz,[9] Reinisch,[10] Bodurov,[11] Schwartz,[12] in addition to the references given earlier. It is apparent, even from this short list, that many physicists share the view that it makes a lot of sense to represent particles by self-localized solutions of nonlinear field equations, although no one is sure what these equations should be beyond the model-making stage.

The work of Berestycki and Lions,[13] which does not seem to be well known, is cited as an illustration of how rich the nonlinear field equations are. There it is proved that even simple field equations like some of the free nonlinear Schrödinger equations (NLS), in three space dimensions, possess infinitely many space-localized solutions starting from a ground-state solution, all of which have finite Hermitian norms and are singularity free. Thus, there is a complete analogy with the solutions of the Schrödinger equation proper for a particle trapped in some potential well. But while the solutions of the fundamental equations in quantum mechanics (QM), due to their linearity, are space-localized (bound states) only if an appropriate external potential is present, the above NLS equations admit solutions which are space-localized (or self-localized) solely by the field's self-interaction.

A generalization of Ehrenfest's theorem which applies to the self-localized solutions of all nonlinear Schrödinger equations, and a corollary of it (pertaining to the motion of the region of

a)Electronic mail: bodt@efn.org

 © 1998 American Institute of Physics

localization) are proved and discussed in a recent paper, Bodurov.[14] The generalized Ehrenfest theorem establishes a link between those field equations and classical mechanics/electrodynamics, just as the Ehrenfest theorem proper establishes the relation of quantum mechanics to classical physics. The question now arises: *What is the generic form of the field equations for which such results apply?* One objective of the present paper is to offer a possible answer and to discuss its implications.

In this paper, the term ''field'' will mean exclusively a function of the space coordinates and the time whose components are complex-valued, in general, and obey certain transformation rules. That is, the fields considered here are not quantized.

The organization of the paper is as follows. Section II introduces the form of a family of field equations, here called *complex Hamiltonian evolution* (CHE) equations, by deducing it from the form of the classical Hamiltonian systems and shows that it contains Schrödinger and Dirac equations. Section III defines the *continuous complex Poisson bracket* and uses it to derive some of the general properties of the complex Hamiltonian evolution equations. Section IV proves that the expansion coefficients of *any* space-localized solution of a CHE equation in terms of *any* Hilbert space basis satisfy complex Hamiltonian systems of equations. The expansion coefficients and their conjugates, treated as linear functionals, obey canonical Poisson bracket relations. Further, it is found that any set of ''canonically conjugate'' functionals also satisfies a Hamiltonian systems of equations, thus providing an equivalent description for the time evolution of space-localized fields. Section V shows, as an application of the previous results, that the same lead to commutation relations whose form is that of Dirac's quantization rules. Consequently, the *complementarity* of the classical canonical variables with the operators of quantum mechanics may be seen as a property of the field dynamics which is given by the complex Hamiltonian evolution equations. Section VI discusses the following: ''Can a QM extension which assumes the presence of only small nonlinearities be compatible with a nonlinear field theory based on equations which possess self-localized solutions?'' This inquiry leads to the key question: ''When may a nonlinear field theory be said to contain QM as a special case?'' and to its possible answer. This new, and rather unexpected, answer may be seen as the conclusion of the entire paper.

Notation: Here, all functionals will be denoted with Roman capital letters, all densities (the integrands of functionals) with script capital letters, all operators with bold roman capital letters, all fields with the Greek letters: $\boldsymbol{\psi}$, $\boldsymbol{\varphi}$, $\boldsymbol{\eta}$, and $\boldsymbol{\pi}$. The rest of the symbols will be defined at their first appearance. The summation convention of repeated indexes is assumed for the entire paper. All integrals' domains are $\mathbb{R}^n$.

II. COMPLEX HAMILTONIAN EVOLUTION EQUATIONS FROM CLASSICAL HAMILTONIAN SYSTEMS

It is known that any Hamiltonian system

$$\frac{dq_i}{dt}=\frac{\partial}{\partial p_i}H(q,p,t),\quad \frac{dp_i}{dt}=-\frac{\partial}{\partial q_i}H(q,p,t), \tag{2.1}$$

with $i=1,2,...,s$ may be transformed into a system of complex equations

$$\frac{dz_i}{dt}=-i\frac{\partial}{\partial z_i^*}H(z^*,z,t)\quad \text{where}\quad \frac{\partial}{\partial z_i^*}=\frac{1}{\sqrt{2}}\left(\frac{\partial}{\partial q_i}+i\frac{\partial}{\partial p_i}\right)\quad \text{or} \tag{2.2}$$

$$\frac{dz_i^*}{dt}=i\frac{\partial}{\partial z_i}H(z^*,z,t)\quad \text{where}\quad \frac{\partial}{\partial z_i}=\frac{1}{\sqrt{2}}\left(\frac{\partial}{\partial q_i}-i\frac{\partial}{\partial p_i}\right), \tag{2.3}$$

whose form is the same as that of the original system, when the Hamiltonian function is expressed in terms of the complex variables

$$z_i=\frac{1}{\sqrt{2}}(q_i+ip_i)\quad \text{and}\quad z_i^*=\frac{1}{\sqrt{2}}(q_i-ip_i). \tag{2.4}$$

Thus, (2.4) may be considered to be a type of *canonical* transformation. For real-valued Hamiltonian functions $H=H(z^*,z,t)$ the systems (2.2) and (2.3) are equivalent. Then, one of them may be dropped without loss of information.

The first to point out the significance of the transformation (2.4) and its properties for quantum mechanics appears to be Strocchi.[15]

Actually, this transformation is permissible only if the *dimensionalities* of the variables q_i and p_i are the same. Otherwise, they cannot be combined into the complex variables z_i and z_i^*. Hence, the following simple canonical transformation must be applied first:

$$q_i'=c_i q_i \quad \text{and} \quad p_i'=\frac{p_i}{c_i} \quad (i=1,2,...,s, \quad \text{no summation}) \tag{2.5}$$

which will make the dimensionalities of q_i' and p_i' the same, if the dimensionalities of the constants c_i are chosen according to: $\mathrm{dms}(c_i)=\sqrt{\mathrm{dms}(p_i)/\mathrm{dms}(q_i)}$.

The transformation (2.5) together with (2.4) erase all distinctions between the two types of canonical variables. Since (2.5) does not alter the form of the Hamiltonian system (2.1), we may assume that it has already been applied when the complex transformation (2.4) is performed. Consequently, the dimensionalities of the squared magnitudes of all variables $z_i^*z_i=(q_i^2+p_i^2)/2$ are [*action*], in all complex Hamiltonian systems. The significance of this observation will become apparent at the end of Sec. V.

One finds easily that the transformation (2.4) preserves, within a multiplication constant, the Poisson bracket of any two real or complex-valued functions *R* and *S*, that is

$$\{R,S\}=\frac{\partial R}{\partial q_i}\frac{\partial S}{\partial p_i}-\frac{\partial S}{\partial q_i}\frac{\partial R}{\partial p_i}=\frac{1}{i}\left(\frac{\partial R}{\partial z_i}\frac{\partial S}{\partial z_i^*}-\frac{\partial S}{\partial z_i}\frac{\partial R}{\partial z_i^*}\right). \tag{2.6}$$

(The summation convention of repeated indexes is assumed for the entire paper.)

The next step, from where Strocchi[15] left, is to convert the complex system (2.2) into an evolution equation by letting the number of variables *s* in (2.2) become infinitely large. Then, in place of a system of infinitely many ordinary differential equations one will have a system of finitely many partial differential equations, which will describe the evolution of a multicomponent field.

A discussion of how to perform this transition, may be found in Olver[16] (Chap. 7). There it is shown that (in this paper notation)

$$\frac{\partial \eta_j}{\partial t}=\sum_k \mathbf{D}_{jk}\frac{\delta}{\delta \eta_k}\mathrm{H}[\boldsymbol{\eta};t] \tag{2.7}$$

is the most general form of the Hamiltonian evolution equations which are obtained from Hamiltonian systems with real variables. In this expression $\eta_j=\eta_j(x,t)$ are the components of the real field $\boldsymbol{\eta}$, $\mathbf{D}_{jk}$ are the entries of a skew-adjoint matrix-differential operator which may depend on $\boldsymbol{\eta}$, $\mathrm{H}[\boldsymbol{\eta};t]$ is the Hamiltonian functional for the field $\boldsymbol{\eta}$, and $\delta/\delta\eta_k$ is the variational derivative with respect to η_k.

Clearly, the Hamiltonian functional must remain finite during the entire time interval of interest, which necessitates the following

Definition 2.1: A scalar, vector or spinor-valued function $\boldsymbol{\psi}=\boldsymbol{\psi}(x)$ *of the coordinates* $x\in\mathbb{R}^n$ *will be called space-localized, or* $\boldsymbol{\psi}$*-field, if it is smooth* (C^∞), *hence singularity-free, and if its norm*

$$\mathrm{N}=\langle\boldsymbol{\psi},\boldsymbol{\psi}\rangle=\int_{\mathbb{R}^n}\psi_k^*\psi_k\,d^nx, \tag{2.8}$$

with the integral taken over all space, is finite.

Definition 2.2: A $\boldsymbol{\psi}$ *field will be called self-localized if it is a solution of a free (no interaction with external fields) field equation and if it remains space-localized for all time.*

Definition 2.3: All functionals considered in this paper (admissible functionals) are assumed to be finite when evaluated with a space-localized field.

Note that, the linear free field equations do not have space-localized solutions. The physics aspect of Definition 2.1 requires some comments, which are included in Sec. VI.

The form (2.7) is too general for the purposes of this paper. We would like to have a form which is as specific as possible, and yet, is general enough to contain as special cases the fundamental equations of quantum mechanics, together with the nonlinear equations which in some respect are related to the QM equations. Since the former are complex, such a form then has to represent a class of complex Hamiltonian evolution equations, both linear and nonlinear. It turns out that, the desired equation form may easily be deduced from the complex Hamiltonian system (2.2) by following the same process with which (2.7) was deduced. This is done by replacing (Olver,[16] Chap. 7) the set of all variables z_i with the $\boldsymbol{\psi}$ field, and the z_i^* with the $\boldsymbol{\psi}^*$ field; the Hamiltonian function $H(z^*,z,t)$ with the Hamiltonian functional $\mathrm{H}[\boldsymbol{\psi}^*,\boldsymbol{\psi};t]$; the ordinary time derivative d/dt with the partial time derivative $\partial/\partial t$; and the partial derivatives $\partial/\partial z_i$, $\partial/\partial z_i^*$ with the variational derivatives $\delta/\delta\psi_k$, $\delta/\delta\psi_k^*$, where $\boldsymbol{\psi}=(\psi_1,\ldots,\psi_r)$ is an r-component field and $\boldsymbol{\psi}^*$ is its complex conjugate.

The result is the form of the *complex Hamiltonian evolution* (CHE) equations

$$\frac{\partial\psi_k}{\partial t}=-i\,\frac{\delta}{\delta\psi_k^*}\,\mathrm{H}[\boldsymbol{\psi}^*,\boldsymbol{\psi};t],\quad k=1,2,\ldots,r \tag{2.9}$$

for $\boldsymbol{\psi}=\boldsymbol{\psi}(x,t)$ which may be a *scalar, vector*, or *spinor* field. Here, the Hamiltonian functional H is an integral of some real-valued *Hamiltonian* density $\mathscr{H}$ over all space

$$\mathrm{H}[\boldsymbol{\psi}^*,\boldsymbol{\psi};t]=\int_{\mathbb{R}^n}\mathscr{H}(x,t,\boldsymbol{\psi}^*,\boldsymbol{\psi},\partial\boldsymbol{\psi}^*,\partial\boldsymbol{\psi},\ldots)d^nx.$$

$\partial\boldsymbol{\psi}$ and $\partial\boldsymbol{\psi}^*$ stand for derivatives with respect to the space-coordinates x_i, $i=1,\ldots,n$. The latter are assumed to be Cartesian in order to avoid complications, unnecessary for the present purposes. The dimension of the space on which the fields are defined is n. Generally, $\mathscr{H}$ may contain derivatives of orders higher than the first. The variational derivative of H with respect to ψ_k^* is given with the *Euler–Lagrange expressions*

$$\frac{\delta\mathrm{H}}{\delta\psi_k^*}=\frac{\partial\mathscr{H}}{\partial\psi_k^*}-\frac{d}{dx_i}\,\frac{\partial\mathscr{H}}{\partial(\partial_i\psi_k^*)}+\frac{d^2}{dx_idx_j}\,\frac{\partial\mathscr{H}}{\partial(\partial_{ij}\psi_k^*)}-\cdots=\mathbf{H}_k(\boldsymbol{\psi}^*,\boldsymbol{\psi}), \tag{2.10}$$

where $\mathbf{H}_k(\boldsymbol{\psi}^*,\boldsymbol{\psi})$ denotes operators which may depend on x and t, and which act on $\boldsymbol{\psi}$, $\boldsymbol{\psi}^*$ nonlinearly in general.

Unlike the multiparticle wave functions of quantum mechanics, here, the $\boldsymbol{\psi}$ fields will never depend on more than three space coordinates, that is $n=1$, 2, or 3. This departure from the QM description of multiparticle systems is briefly discussed in Sec. VI.

Schrödinger and Dirac equations, written as evolution equations, have the forms

$$i\,\frac{\partial\psi}{\partial t}=\mathbf{H}\psi,\quad\text{and}\quad i\,\frac{\partial\psi_k}{\partial t}=\mathbf{H}_{kj}\,\psi_j,\quad k,j=1,\ldots,r, \tag{2.11}$$

with $\mathbf{H}$ being a scalar Hermitian operator and $\mathbf{H}_{kj}$ denoting the entries of a matrix-differential Hermitian operator. Then, we see immediately that the two fundamental equations of quantum mechanics are CHE equations, since the forms (2.11) are special cases of the form (2.9) obtained with the real-valued bilinear Hamiltonian functionals

$$\mathrm{H}=\int\psi^*\mathbf{H}\psi\,d^nx\quad\text{and}\quad\mathrm{H}=\int\psi_k^*\mathbf{H}_{kj}\,\psi_j\,d^nx, \tag{2.12}$$

respectively. This shows that the generic form (2.9) is of the desired type.

It is simple to verify that, Eq. (2.9) are the necessary conditions, i.e., the Euler–Lagrange equations, for the extremums of the real-valued functional

$$\int \mathrm{L}[\boldsymbol{\psi}^*,\boldsymbol{\psi}]\,dt=\iint \mathscr{L}\,d^nx\,dt=\iint\left(\frac{i}{2}\left(\psi_k^*\,\frac{\partial\psi_k}{\partial t}-\frac{\partial\psi_k^*}{\partial t}\,\psi_k\right)-\mathscr{H}\right)d^nx\,dt.$$

This establishes that $\mathrm{L}[\boldsymbol{\psi}^*,\boldsymbol{\psi}]$ is the *Lagrangian functional*, and that the relation of the *Lagrangian density* $\mathscr{L}$ of the $\boldsymbol{\psi}$ field to its *Hamiltonian* density $\mathscr{H}$ is

$$\mathscr{L}=\frac{i}{2}\left(\psi_k^*\,\frac{\partial\psi_k}{\partial t}-\frac{\partial\psi_k^*}{\partial t}\,\psi_k\right)-\mathscr{H}. \tag{2.13}$$

With this relation it is very simple to show that the *$\boldsymbol{\psi}$-field energy density*, i.e., *the $\mathscr{T}_{00}$ component of the stress-energy 4-tensor is equal to the Hamiltonian density $\mathscr{H}$* as follows:

$$\mathscr{T}_{00}=\frac{\partial\pi_i}{\partial t}\,\frac{\partial\mathscr{L}}{\partial(\partial_t\pi_i)}-\mathscr{L}=\frac{i}{2}\left(\psi_k^*\,\frac{\partial\psi_k}{\partial t}-\frac{\partial\psi_k^*}{\partial t}\,\psi_k\right)-\mathscr{L}=\mathscr{H}. \tag{2.14}$$

Here, the field $\boldsymbol{\pi}=(\pi_1,\ldots,\pi_{2r})=(\psi_1,\ldots,\psi_r,\psi_1^*,\ldots,\psi_r^*)$ with $i=1,2,...,2r$ and $k=1,2,...,r$ is only a notational device.

The physics interpretation of an important result at the end of Sec. V depends on the validity of identifying the $\boldsymbol{\psi}$-field total energy with the value of the Hamiltonian functional. Equation (2.14) assures us that such an identification is well justified.

III. THE COMPLEX CONTINUOUS POISSON BRACKET

Now, we apply the same transition $s\to\infty$ (a finite to a continuous set of variables) on the complex Poison bracket (2.6) and obtain

$$\{\mathrm{R},\mathrm{S}\}=\frac{1}{i}\int_{\mathbb{R}^n}\left(\frac{\delta\mathrm{R}}{\delta\psi_k}\,\frac{\delta\mathrm{S}}{\delta\psi_k^*}-\frac{\delta\mathrm{S}}{\delta\psi_k}\,\frac{\delta\mathrm{R}}{\delta\psi_k^*}\right)d^nx, \tag{3.1}$$

which defines the *continuous complex Poisson bracket* of two real or complex-valued functionals $\mathrm{R}=\mathrm{R}[\boldsymbol{\psi}^*,\boldsymbol{\psi};t]$ and $\mathrm{S}=\mathrm{S}[\boldsymbol{\psi}^*,\boldsymbol{\psi};t]$. Both the discrete and the continuous Poisson brackets will be denoted by the same symbol $\{\cdot,\cdot\}$, unless noted otherwise, since it will be clear from the context to which type it refers.

Just as for the finite-dimensional Poisson bracket (2.6), so also for (3.1) it is straightforward but tedious to verify that it satisfies *Jacobi's identity*. Of course, the second variations of the functionals R and S are assumed to exist. The rest of the properties which qualify (3.1) to be a Poisson bracket are obvious.

The formalism proposed in Weinberg[3] is based on an expressly assumed product of homogeneous functions of degree one in their arguments ψ_k and ψ_k^*. Since this product is noncommutative it defines a bracket which is essentially the discrete counterpart of (3.1) and structurally the same as (2.6). The difference is that neither the functions $R(z^*,z)$ and $S(z^*,z)$ in (2.6) nor the functionals $\mathrm{R}[\boldsymbol{\psi}^*,\boldsymbol{\psi}]$ and $\mathrm{S}[\boldsymbol{\psi}^*,\boldsymbol{\psi}]$ in (3.1) are required to be homogeneous in their arguments. The physics implications of dropping or retaining this *homogeneity condition* will be discussed in Sec. VI.

Expression (3.1) is an exact form-replica of the ''classical'' continuous Poisson bracket

$$\{\mathrm{R},\mathrm{S}\}_{\mathrm{cl}}=\int\left(\frac{\delta\mathrm{R}}{\delta\eta_k}\,\frac{\delta\mathrm{S}}{\delta\pi_k}-\frac{\delta\mathrm{S}}{\delta\eta_k}\,\frac{\delta\mathrm{R}}{\delta\pi_k}\right)d^nx, \tag{3.2}$$

where η_k and $\pi_k=\partial\mathscr{L}/\partial\dot{\eta}_k$ are the components of two ''canonically conjugate'' fields. However, the complex Poisson bracket (3.1) and the one proposed in Weinberg[3] have an important advantage over the ''classical'' bracket. The problem with (3.2) is that its properties under Lorentz transformations are not well defined since the fields $\boldsymbol{\eta}$ and $\boldsymbol{\pi}$ behave differently under change of reference frame. This criticism does not apply to the brackets discussed here because $\boldsymbol{\psi}$ and $\boldsymbol{\psi}^*$ transform, of course, as the same entity regardless of whether they are scalars, vectors, or spinors. Some details and a discussion of the difficulties with (3.2) may be found in Goldstein[17] (Sec. 12.14).

The time-derivative of any functional $\mathrm{R}=\mathrm{R}[\boldsymbol{\psi}^*,\boldsymbol{\psi};t]$ is given in terms of the complex Poisson bracket by

$$\frac{d\mathrm{R}}{dt}=\int\left(\frac{\delta\mathrm{R}}{\delta\psi_k}\frac{\partial\psi_k}{\partial t}+\frac{\delta\mathrm{R}}{\delta\psi_k^*}\frac{\partial\psi_k^*}{\partial t}\right)d^nx+\frac{\partial\mathrm{R}}{\partial t}$$

$$=\frac{1}{i}\int\left(\frac{\partial\mathrm{R}}{\partial\psi_k}\frac{\delta\mathrm{H}}{\delta\psi_k^*}-\frac{\delta\mathrm{H}}{\delta\psi_k}\frac{\delta\mathrm{R}}{\delta\psi_k^*}\right)d^nx+\frac{\partial\mathrm{R}}{\partial t}=\{\mathrm{R},\mathrm{H}\}+\frac{\partial\mathrm{R}}{\partial t},\tag{3.3}$$

which is a direct consequence of (2.9). If the Hamiltonian functional $\mathrm{H}[\boldsymbol{\psi}^*,\boldsymbol{\psi}]$ does not depend explicitly on the time, then its value is constant, as seen from (3.3).

All bilinear functionals (and trivially, all linear field equations) share a common property, that is, they are invariant under the *gauge type I* transformation:

$$\psi_k'=\psi_k\mathbf{e}^{i\epsilon}\quad\text{and}\quad\psi_k'^*=\psi_k^*\mathbf{e}^{-i\epsilon},\tag{3.4}$$

with ϵ its parameter. Then, the nonlinear CHE equations whose Hamiltonian functionals are gauge type I invariant should have properties which are similar to those of the linear CHE equations. The rest of this section will show that, indeed, this is the case.

Theorem 3.1: *Let* $\boldsymbol{\psi}=(\psi_1,\ldots,\psi_r)$ *be a field on a n-dimensional space, whose components* $\psi_k=\psi_k(x_1,\ldots,x_n,t)$ *are complex-valued and may depend on the time t. The continuous Poisson bracket (3.1) of the Hermitian norm* N *(2.8) of* $\boldsymbol{\psi}$ *with any real or complex-valued functional*

$$\mathrm{F}=\int\mathscr{F}(x,t,\boldsymbol{\psi},\boldsymbol{\psi}^*,\partial\boldsymbol{\psi},\partial\boldsymbol{\psi}^*,\ldots)d^nx$$

is zero if F *is invariant under the gauge type I transformation (3.4).*

Proof: Since N is also a functional its continuous Poisson bracket (3.1) with F is

$$\{\mathrm{N},\mathrm{F}\}=\frac{1}{i}\int\left(\frac{\delta\mathrm{N}}{\delta\psi_k}\frac{\delta\mathrm{F}}{\delta\psi_k^*}-\frac{\delta\mathrm{F}}{\delta\psi_k}\frac{\delta\mathrm{N}}{\delta\psi_k^*}\right)d^nx$$

$$=\frac{1}{i}\int\left(\psi_k^*\left(\frac{\partial\mathscr{F}}{\partial\psi_k^*}-\frac{d}{dx_i}\frac{\partial\mathscr{F}}{\partial(\partial_i\psi_k^*)}+\cdots\right)-\left(\frac{\partial\mathscr{F}}{\partial\psi_k}-\frac{d}{dx_i}\frac{\partial\mathscr{F}}{\partial(\partial_i\psi_k)}+\cdots\right)\psi_k\right)d^nx$$

$$=\frac{1}{i}\int\left(\psi_k^*\frac{\partial\mathscr{F}}{\partial\psi_k^*}-\psi_k\frac{\partial\mathscr{F}}{\partial\psi_k}+\partial_i\psi_k^*\frac{\partial\mathscr{F}}{\partial(\partial_i\psi_k^*)}-\partial_i\psi_k\frac{\partial\mathscr{F}}{\partial(\partial_i\psi_k)}+\cdots\right)d^nx,\tag{3.5}$$

where all terms with total derivatives were integrated by parts. The invariance condition for F, with $\mathscr{F}'=\mathscr{F}(x,t,\boldsymbol{\psi}',\boldsymbol{\psi}'^*,\partial\boldsymbol{\psi}',\partial\boldsymbol{\psi}'^*,\ldots)$ being its transformed density, is

$$\frac{d}{d\epsilon}\mathscr{F}'\bigg|_{\epsilon=0}=\boldsymbol{\nabla}\cdot\mathscr{C}$$

where $\mathscr{C}$ is an undetermined vector-valued density which becomes constant at infinity. Performing the differentiation and setting $\epsilon=0$ into the resulting expression we obtain

$$\frac{d}{d\epsilon}\mathscr{F}'\bigg|_{\epsilon=0}=i\left(\psi_k\frac{\partial\mathscr{F}}{\partial\psi_k}-\psi_k^*\frac{\partial\mathscr{F}}{\partial\psi_k^*}\right)+i\left(\partial_i\psi_k\frac{\partial\mathscr{F}}{\partial(\partial_i\psi_k)}-\partial_i\psi_k^*\frac{\partial\mathscr{F}}{\partial(\partial_i\psi_k^*)}\right)+\cdots=\boldsymbol{\nabla}\cdot\mathscr{C},$$

which when inserted into (3.5) concludes the proof by showing that

$$\{\mathrm{N},\mathrm{F}\}=\int\boldsymbol{\nabla}\cdot\mathscr{C}\,d^nx=0.\qquad\square$$

A result, structurally the same as the above, is obtained in Weinberg[3] but under a much more restrictive condition—there F is required to be homogeneous of degree one in its arguments (instead of gauge type I invariant).

The *stationary solutions* of the CHE equations (2.9) are, just as in QM, those whose components absolute values $|\psi_k(x)|$ are time independent. Hence, a solution is stationary when it can be written as $\boldsymbol{\psi}(t,x)=\boldsymbol{\varphi}(x)\exp(-i\omega t)$, where ω is a real constant. It is simple to verify that this is the case if the Hamiltonian functional in (2.9) is gauge type I (3.4) invariant. Then, the components $\varphi_k=\varphi_k(x)$ of $\boldsymbol{\varphi}(x)$ are solutions of

$$\frac{\delta}{\delta\varphi_k^*}\,\mathrm{H}[\boldsymbol{\varphi}^*,\boldsymbol{\varphi}]=\omega\varphi_k, \quad k=1,2,...,r, \tag{3.6}$$

where $\mathrm{H}[\boldsymbol{\varphi}^*,\boldsymbol{\varphi}]=\mathrm{H}[\boldsymbol{\psi}^*,\boldsymbol{\psi}]$ by the invariance assumption. Again, there is an equivalent result in Weinberg[3] which, however, is derived from the homogeneity assumption.

The form (3.6) is structurally equivalent to that of the *time-independent* Schrödinger and Dirac equations, although it is nonlinear in general.

The following corollary, to Theorem 3.1, extends a fundamental property of the QM equations to the gauge type I invariant nonlinear CHE equations:

Corollary 3.2: The Hermitian norm $\mathrm{N}=\langle\boldsymbol{\psi},\boldsymbol{\psi}\rangle$ *of any space-localized solution of a nonlinear CHE equation is constant in time if the equation is gauge type I invariant.*

Proof: A CHE equation is gauge type I invariant if its associated Hamiltonian functional H is gauge type I invariant. Hence, by Theorem 3.1 we have $\{\mathrm{N},\mathrm{H}\}=0$. Then from the relation (3.3) the corollary follows. □

IV. COMPLEX POISSON BRACKETS IN HILBERT SPACE

In quantum field theory the Fourier expansion of the fields plays, of course, a key role. This fact together with the previous results raises the question: ''If we expand a space-localized solution of a complex Hamiltonian evolution equation in terms of *a Hilbert space basis* defined on $\mathbb{R}^n$ then what system of equations do the expansion coefficients satisfy?'' In its answer and those of several other associated questions are encountered some new mathematical relations.

Let $\eta_\mu=\eta_\mu(x)$ be a set of scalar complex-valued functions on $\mathbb{R}^n$ which define an orthonormal basis in the Hilbert space $\mathbb{H}(\mathbb{R}^n)$, that is

$$\langle\eta_\mu,\eta_\nu\rangle=\int_{\mathbb{R}^n}\eta_\mu^*(x)\,\eta_\nu(x)\,d^nx=\delta_{\mu\nu}, \quad \mu,\nu=1,2,...,\infty, \tag{4.1}$$

where $x\in\mathbb{R}^n$. (Lower case Greek indices will be used for numbering the elements of all *infinite* sets and their subsets.) Any space-localized $\boldsymbol{\psi}$ field belongs to $\mathbb{H}(\mathbb{R}^n)$ by Definition 2.1. Hence, its components ψ_k may be expressed as linear combinations of the basis functions:

$$\psi_k(x,t)=\sum_{\mu=1}^{\infty}\mathrm{A}_{k\mu}(t)\,\eta_\mu(x). \tag{4.2}$$

The expansion coefficients $\mathrm{A}_{k\mu}$ are given by

$$\mathrm{A}_{k\mu}(t)=\int_{\mathbb{R}^n}\psi_k(x,t)\,\eta_\mu^*(x)\,d^nx. \tag{4.3}$$

Clearly, (4.3) and its complex conjugate $\mathrm{A}_{k\mu}^*(t)$ are linear functionals of $\psi_k(x,t)$ and $\psi_k^*(x,t)$. The following theorem shows that they provide an equivalent description of the time evolution of a space-localized field

Theorem 4.1: *Let* $\boldsymbol{\psi}=(\psi_1,\ldots,\psi_r)$ *be a space-localized solution of a complex Hamiltonian evolution equation with the form (2.9). Then its expansion coefficients* $\mathrm{A}_{k\mu}$ *and* $\mathrm{A}_{k\mu}^*$, *given by (4.3), satisfy the infinite-dimensional Hamiltonian system of equations*

$$\frac{d\mathrm{A}_{k\mu}}{dt}=-i\,\frac{\partial}{\partial A_{k\mu}^*}\,\mathrm{H}(\mathrm{A}^*,\mathrm{A},t) \tag{4.4}$$

with $k=1,2,...,r$ and $\mu=1,2,...,\infty$. $H=H(A^*,A,t)$ *is the Hamiltonian function of the system obtained by inserting (4.2) and its complex conjugate into the functional* $H[\boldsymbol{\psi}^*,\boldsymbol{\psi};t]$ *and performing the integration. The converse is true with any set of* $A_{k\mu}$ *provided the series* $\Sigma_\mu A_{k\mu}^* A_{k\mu}$ *converges for all* $k=1,2,...,r$.

Proof: Since $H(A^*,A,t)$ is a function of functionals its variational derivatives $\delta H/\delta\psi_j$ and $\delta H/\delta\psi_j^*$ are well defined. From the definition of the variational derivative and with the use of (4.2) we get

$$\frac{\partial H}{\partial A_{k\mu}^*}=\int\left(\frac{\delta H}{\delta\psi_j}\frac{\partial\psi_j}{\partial A_{k\mu}^*}+\frac{\delta H}{\delta\psi_j^*}\frac{\partial\psi_j^*}{\partial A_{k\mu}^*}\right)d^nx=\int\eta_\mu^*\delta_{jk}\frac{\delta H}{\delta\psi_j^*}\,d^nx.$$

Then, applying (2.9) and taking the time-derivative of (4.2) gives the desired result:

$$\frac{\partial H}{\partial A_{k\mu}^*}=i\int\eta_\mu^*\frac{\partial\psi_k}{\partial t}\,d^nx=i\,\frac{dA_{k\nu}}{dt}\int\eta_\mu^*\eta_\nu\,d^nx=i\,\frac{dA_{k\mu}}{dt}.$$

To prove the converse observe that the convergence of the series $\Sigma_\mu A_{k\mu}^* A_{k\mu}$ ensures that the field $\boldsymbol{\psi}$, given by (4.2), is space-localized. Then, with the use of (4.4) we have

$$\frac{\partial\psi_k}{\partial t}=\frac{dA_{k\mu}}{dt}\,\eta_\mu=-i\,\frac{\partial H(A^*,A,t)}{\partial A_{k\mu}^*}\,\eta_\mu=-i\,\frac{\partial H(A^*,A,t)}{\partial A_{k\mu}^*}\frac{\delta A_{k\mu}^*}{\delta\psi_k^*}=-i\,\frac{\delta}{\delta\psi_k^*}H[\boldsymbol{\psi}^*,\boldsymbol{\psi};t].$$

□

A corollary of Theorem 4.1, which does not require any further proofs, is: *All unitary transformations which perform change of basis in the Hilbert space* $\mathbb{H}(\mathbb{R}^n)$ *are canonical transformations since they preserve the form (4.4) of the Hamiltonian systems.*

Theorem 4.1 implies that the expansion coefficients $A_{k\mu}$ and $A_{k\nu}^*$ constitute an infinite set of complex canonical variables. To show that this is so we need to distinguish between the continuous complex Poisson bracket $\{\cdot,\cdot\}^c$ (3.1) and the *discrete* complex Poisson bracket $\{\cdot,\cdot\}^d$ defined by (2.6) in which for the summation index, now, we use $\alpha=1,2,...,\infty$. $R=R(z^*,z,t)$ and $S=S(z^*,z,t)$ are real or complex-valued functions of z_α, z_α^* and possibly t. With these definitions the next result is stated as:

Theorem 4.2: *The continuous Poisson bracket (3.1) is identically equal to the discrete Poisson bracket (2.6) when* $z_\alpha=A_{k\mu}$ *are the expansion coefficients of the space-localized* $\boldsymbol{\psi}$ *field in any Hilbert space basis.*

Proof: By inserting (4.2) into a functional $F=F[\boldsymbol{\psi}^*,\boldsymbol{\psi};t]$ and performing the required integration one obtains its value $F=F(A^*,A,t)$ as a function of the functionals $A_{k\mu}[\boldsymbol{\psi}]$ and $A_{k\mu}^*[\boldsymbol{\psi}^*]$. Then, the identity

$$\frac{\delta F[\boldsymbol{\psi}^*,\boldsymbol{\psi};t]}{\delta\psi_k}=\frac{\partial F(A^*,A,t)}{\partial A_{j\mu}}\frac{\delta A_{j\mu}[\boldsymbol{\psi}]}{\delta\psi_k}=\frac{\partial F(A^*,A,t)}{\partial A_{k\mu}}\,\eta_\mu^* \tag{4.5}$$

is the result of taking the variational derivative of a function of functionals. An alternative derivation of the same identity is

$$\begin{aligned}\frac{\partial F(A^*,A,t)}{\partial A_{k\mu}}\,\eta_\mu^*(x)&=\int\frac{\delta F[\boldsymbol{\psi}^*,\boldsymbol{\psi};t]}{\delta\psi_k(x')}\frac{\partial\psi_k(x')}{\partial A_{k\mu}}\,\eta_\mu^*(x)\,d^nx'\\&=\int\frac{\delta F[\boldsymbol{\psi}^*,\boldsymbol{\psi};t]}{\delta\psi_k(x')}\,\delta(x'-x)\,d^nx'=\frac{\delta F[\boldsymbol{\psi}^*,\boldsymbol{\psi};t]}{\delta\psi_k(x)},\end{aligned}$$

where use was made of the *closure* relation $\eta_\mu^*(x)\,\eta_\mu(x')=\delta(x'-x)$. With the identity (4.5) the continuous Poisson bracket is transformed into the discrete one as follows:

$$\{\mathrm{R},\mathrm{S}\}^c=\frac{1}{i}\int\left(\frac{\delta \mathrm{R}}{\delta\psi_k}\frac{\delta \mathrm{S}}{\delta\psi_k^*}-\frac{\delta \mathrm{S}}{\delta\psi_k}\frac{\delta \mathrm{R}}{\delta\psi_k^*}\right)d^nx$$
$$=\frac{1}{i}\left(\frac{\partial \mathrm{R}}{\partial \mathrm{A}_{k\mu}}\frac{\partial \mathrm{S}}{\partial \mathrm{A}_{k\nu}^*}-\frac{\partial \mathrm{S}}{\partial \mathrm{A}_{k\mu}}\frac{\partial \mathrm{R}}{\partial \mathrm{A}_{k\nu}^*}\right)\int \eta_\mu^*\eta_\nu\, d^nx$$
$$=\frac{1}{i}\left(\frac{\partial \mathrm{R}}{\partial \mathrm{A}_{k\mu}}\frac{\partial \mathrm{S}}{\partial \mathrm{A}_{k\mu}^*}-\frac{\partial \mathrm{S}}{\partial \mathrm{A}_{k\mu}}\frac{\partial \mathrm{R}}{\partial \mathrm{A}_{k\mu}^*}\right)=\{\mathrm{R},\mathrm{S}\}^d. \qquad \square$$

Now, if the discrete bracket form (4.5) is used the canonical relations

$$\{\mathrm{A}_{j\mu}^*,\mathrm{A}_{k\nu}\}=i\,\delta_{jk}\delta_{\mu\nu},\quad \{\mathrm{A}_{j\mu}^*,\mathrm{A}_{k\nu}\}=0,\quad \{\mathrm{A}_{j\mu},\mathrm{A}_{k\nu}\}=0 \tag{4.6}$$

follow trivially. To see that they hold also with the continuous bracket forms (without relying on Theorem 4.2) note that $\mathrm{A}_{k\mu}$ and $\mathrm{A}_{k\mu}^*$ are functionals, and hence

$$\{\mathrm{A}_{j\mu}^*,\mathrm{A}_{k\nu}\}=\frac{1}{i}\int\left(\frac{\delta \mathrm{A}_{j\mu}^*}{\delta\psi_i}\frac{\delta \mathrm{A}_{k\nu}}{\delta\psi_i^*}-\frac{\delta \mathrm{A}_{k\nu}}{\delta\psi_i}\frac{\delta \mathrm{A}_{j\mu}^*}{\delta\psi_i^*}\right)d^nx=i\,\delta_{ij}\delta_{ik}\int \eta_\nu^*\eta_\mu\, d^nx=i\,\delta_{jk}\delta_{\mu\nu}.$$

Similarly, one finds that $\{\mathrm{A}_{j\mu},\mathrm{A}_{k\nu}\}=\{\mathrm{A}_{j\mu}^*,\mathrm{A}_{k\nu}^*\}=0$.

With the expansion coefficients $\mathrm{A}_{k\mu}$ one can define real-valued functionals as follows:

$$\mathrm{X}_{k\mu}=\frac{1}{\sqrt{2}}\,(\mathrm{A}_{k\mu}^*+\mathrm{A}_{k\mu})=\frac{1}{\sqrt{2}}\int(\psi_k^*\eta_\mu+\psi_k\eta_\mu^*)\,d^nx, \tag{4.7}$$

$$\mathrm{Y}_{k\mu}=\frac{i}{\sqrt{2}}\,(\mathrm{A}_{k\mu}^*-\mathrm{A}_{k\mu})=\frac{i}{\sqrt{2}}\int(\psi_k^*\eta_\mu-\psi_k\eta_\mu^*)\,d^nx. \tag{4.8}$$

Proposition 4.3: The values $\mathrm{X}_{k\mu}(t)$ *and* $\mathrm{Y}_{k\mu}(t)$ *of the functionals (4.7) and (4.8) are real canonical variables which satisfy a classical Hamiltonian system if the* $\boldsymbol{\psi}$ *field is a solution of a complex Hamiltonian evolution equation of the form (2.9).*

Proof: Use the Poisson bracket relations (4.6) to see that

$$\{\mathrm{X}_{j\mu},\mathrm{Y}_{k\nu}\}=i\{\mathrm{A}_{j\mu}^*,\mathrm{A}_{k\nu}\}=\delta_{jk}\delta_{\mu\nu},\quad \{\mathrm{X}_{j\mu},\mathrm{X}_{k\nu}\}=0,\quad \{\mathrm{Y}_{j\mu},\mathrm{Y}_{k\nu}\}=0,$$

which shows that $\mathrm{X}_{k\mu}(t)$ and $\mathrm{Y}_{k\mu}(t)$ are canonical variables. To show that they are solutions of a Hamiltonian system of equations take the time derivative of $\mathrm{X}_{k\mu}(t)$ and use (2.9) with $\mathrm{H}=\mathrm{H}[\boldsymbol{\psi}^*,\boldsymbol{\psi};t]=\mathrm{H}(\mathrm{A}^*,\mathrm{A},t)$. Then

$$\frac{d\mathrm{X}_{k\mu}}{dt}=\frac{1}{\sqrt{2}}\left(\frac{d\mathrm{A}_{k\mu}}{dt}+\frac{d\mathrm{A}_{k\mu}^*}{dt}\right)=\frac{i}{\sqrt{2}}\left(\frac{\partial \mathrm{H}}{\partial A_{k\mu}}-\frac{\partial \mathrm{H}}{\partial \mathrm{A}_{k\mu}^*}\right)=\frac{\partial \mathrm{H}(\mathrm{X},\mathrm{Y},t)}{\partial \mathrm{Y}_{k\mu}}.$$

The Hamiltonian $\mathrm{H}(\mathrm{X},\mathrm{Y},t)$ is obtained by inserting (4.7) and (4.8) into $\mathrm{H}(\mathrm{A}^*,\mathrm{A},t)$. A similar derivation produces

$$\frac{d\mathrm{Y}_{k\mu}}{dt}=-\frac{\partial \mathrm{H}(\mathrm{X},\mathrm{Y},t)}{\partial \mathrm{X}_{k\mu}}. \qquad \square$$

Proposition 4.3 shows that there is at least one class of real-valued functionals which contains infinitely many sets of *canonically conjugate functionals* and that any well behaved functional can be expressed as their function. But more important, one observes that according to Theorem 4.2 the functionals (4.7) and (4.8) define a transformation from the *continuous set* of variables $\boldsymbol{\psi}(x,t)$ to the *discrete set* of variables $\mathrm{X}_{k\mu}(t)$ and $\mathrm{Y}_{k\mu}(t)$ which preserves the value of the Poisson bracket, while changing only its type. Its inverse, of course, is given by

$$\psi_k=\frac{1}{\sqrt{2}}\sum_{\alpha=1}^{\infty}(X_{k\alpha}+iY_{k\alpha})\eta_\alpha. \tag{4.9}$$

Thus, one arrives at the following natural extension of the well known classical definition:

Definition 4.1: An invertible transformation between a continuous and a discrete sets of variables will be called infinite-dimensional canonical transformation if it preserves the value of the Poisson bracket (while changing its type) of any two admissible functionals.

Once the above link, between the expansions of functions in orthonormal basis and the canonical transformations, is established we become aware that while the classical canonical transformations are nonlinear, in general, the infinite-dimensional canonical transformations whose form is given by (4.7) and (4.8) are linear. Hence, we are led to inquire: Are there infinite-dimensional canonical transformations which are nonlinear?

The remaining portion of this section presents the answer and some of its implications. Before we state the next result we note that a set of functionals is called *independent* if no one of its members can be expressed as a function of the rest of its members.

Theorem 4.4: *Let the countably infinite set of real-valued functionals*

$$\mathrm{Q}_\mu=\mathrm{Q}_\mu[\boldsymbol{\psi}^*,\boldsymbol{\psi}] \quad \text{and} \quad \mathrm{P}_\mu=\mathrm{P}_\mu[\boldsymbol{\psi}^*,\boldsymbol{\psi}] \tag{4.10}$$

(not necessarily linear or bilinear) be independent. If the relations

$$\{\mathrm{Q}_\mu,\mathrm{P}_\nu\}^c=\delta_{\mu\nu}, \quad \{\mathrm{Q}_\mu,\mathrm{Q}_\nu\}^c=0, \quad \{\mathrm{P}_\mu,\mathrm{P}_\nu\}^c=0, \quad \mu,\nu=1,2,...,\infty \tag{4.11}$$

hold when evaluated with any space-localized function $\boldsymbol{\psi}$ then, the transformation (4.10), from the continuous set of variables $\boldsymbol{\psi}(x,t)$ to the discrete set of variables Q_μ and P_μ, is an infinite-dimensional canonical transformation.

Proof: First, we will show that the transformation (4.10) is invertible by expanding the components ψ_k of the localized field $\boldsymbol{\psi}(x,t)$ in an orthonormal Hilbert space basis $\eta_\alpha(x)$, according to (4.2), with the complex expansion coefficients $\mathrm{A}_{k\alpha}$ given by (4.3). When the series (4.2) and its complex conjugate are inserted into the functionals Q_μ, P_μ and the integrations are performed the resulting expressions give the functionals values

$$\mathrm{Q}_\mu=\mathrm{Q}_\mu(\mathrm{A}^*,\mathrm{A}), \quad \mathrm{P}_\mu=\mathrm{P}_\mu(\mathrm{A}^*,\mathrm{A}) \tag{4.12}$$

as functions of the variables $\mathrm{A}_{k\alpha}$ and $\mathrm{A}^*_{k\alpha}$.

Consider, now, the finite-dimensional case when $\alpha=1,2,...,\rho$ and denote by ψ_k^ρ the field obtained by truncating the expansion series for ψ_k (4.2) to ρ terms

$$\psi_k^\rho=\sum_{\alpha=1}^{\rho}\mathrm{A}_{k\alpha}\eta_\alpha. \tag{4.13}$$

By inserting (4.13) into the set of independent functionals (4.10) one finds that the last splits into infinitely many subsets each containing $2r\rho$ independent functions

$$\mathrm{Q}_\mu^\rho=\mathrm{Q}_\mu^\rho(\mathrm{A}^{\rho *},\mathrm{A}^\rho) \quad \text{and} \quad \mathrm{P}_\mu^\rho=\mathrm{P}_\mu^\rho(\mathrm{A}^{\rho *},\mathrm{A}^\rho), \quad \mu=1,2,...,r\rho,$$

where the collection of $r\rho$ expansion coefficients $\mathrm{A}_{11},...,\mathrm{A}_{r\rho}$ is denoted by A^ρ and that of their complex conjugates—by $\mathrm{A}^{\rho *}$. Consequently, each subset determines a solution which expresses the coefficients $\mathrm{A}_{k\alpha}(\mathrm{Q}^\rho,\mathrm{P}^\rho)$ as functions of Q_μ^ρ and P_μ^ρ with $\mu=1,2,...,r\rho$. For a finite ρ these solutions are distinct, in general.

However, we are concerned only with the limits when $\rho\to\infty$. And these limits must all consist of the same set of functions

$$\mathrm{A}_{k\alpha}=\mathrm{A}_{k\alpha}(Q,P), \quad \alpha=1,2,...,\infty, \tag{4.14}$$

since otherwise the original set of functionals $\mathrm{Q}_\mu^\rho\to\mathrm{Q}_\mu$ and $\mathrm{P}_\mu^\rho\to\mathrm{P}_\mu$ which obtains as a result of $\rho\to\infty$ will not be independent, contradicting the theorem's assumption.

The *uniqueness* of the set of functions (4.14) as a solution of the system (4.12) will be demonstrated by an alternative argument, as follows: Consider the identities

$$\{Q_\mu, A_{k\alpha}\}^c = \frac{\partial A_{k\alpha}}{\partial Q_\nu}\{Q_\mu, Q_\nu\}^c + \frac{\partial A_{k\alpha}}{\partial P_\nu}\{Q_\mu, P_\nu\}^c = \frac{\partial A_{k\alpha}(Q,P)}{\partial P_\mu}, \tag{4.15}$$

$$\{P_\mu, A_{k\alpha}\}^c = \frac{\partial A_{k\alpha}}{\partial Q_\nu}\{P_\mu, Q_\nu\}^c + \frac{\partial A_{k\alpha}}{\partial P_\nu}\{P_\mu, P_\nu\}^c = -\frac{\partial A_{k\alpha}(Q,P)}{\partial Q_\mu}, \tag{4.16}$$

which are derived by regarding $A_{k\alpha}(Q,P)$ as functions of independent functionals and applying the canonical relations (4.11). For a given space-localized $\boldsymbol{\psi}$ field the values of the functionals $\{Q_\mu, A_{k\alpha}\}^c$, $\{P_\mu, A_{k\alpha}\}^c$, Q_μ and P_μ are well defined and unique. Then, the identities (4.15) and (4.16) show that all partial derivatives of all functions $A_{k\alpha}(Q,P)$ are well defined and unique which, in turn, shows that the functions themselves are unique.

The inverse of the transformation (4.10) is determined by inserting the so obtained functions $A_{k\alpha}(Q,P)$ into (4.2) which becomes

$$\psi_k = \sum_{\mu=1}^{\infty} A_{k\mu}(Q,P)\,\eta_\mu(x) = \psi_k(Q,P,x). \tag{4.17}$$

This series is convergent since the series (4.2) is convergent and the expansion coefficients remain the same in value, while they are being expressed as functions of Q_μ and P_μ.

In (4.17) we have the most general form of the infinite-dimensional canonical transformations from a discrete set of real variables Q_μ, P_μ to a continuous set of complex variables $\boldsymbol{\psi}$. Accordingly, when the field is given with this form its time-dependence is determined only by the time-dependence of $Q_\mu(t)$ and $P_\mu(t)$. If complex discrete variables Z_μ are used in place of the real ones the form of the inverse transformation will be $\psi_k = \psi_k(Z^*,Z,x)$ according to the relevant relations in Sec. II.

It remains to show that the transformations (4.10) preserve the Poisson bracket of any two admissible functionals R and S. For this purpose we substitute their arguments with the inverse transformation functions $\psi_k = \psi_k(Q,P,x)$ and perform the integrations. The results are functions which give the functionals values

$$R = R[\boldsymbol{\psi}^*, \boldsymbol{\psi}] = R(Q,P) \quad \text{and} \quad S = S[\boldsymbol{\psi}^*, \boldsymbol{\psi}] = S(Q,P)$$

in terms of the discrete variables. Now, both the continuous Poisson bracket (3.1) and the discrete Poisson bracket

$$\{R,S\}^d = \frac{\partial R}{\partial Q_\mu}\frac{\partial S}{\partial P_\mu} - \frac{\partial S}{\partial Q_\mu}\frac{\partial R}{\partial P_\mu} \tag{4.18}$$

are well defined. Then, as a consequence of (4.11) we have

$$\begin{aligned}
\{R,S\}^c &= \frac{1}{i}\int\left(\frac{\delta R}{\delta\psi_k}\frac{\delta S}{\delta\psi_k^*} - \frac{\delta R}{\delta\psi_k}\frac{\delta S}{\delta\psi_k^*}\right)d^n x \\
&= \frac{1}{i}\int\left(\frac{\partial R}{\partial Q_\mu}\frac{\delta Q_\mu}{\delta\psi_k} + \frac{\partial R}{\partial P_\mu}\frac{\delta P_\mu}{\delta\psi_k}\right)\left(\frac{\partial S}{\partial Q_\nu}\frac{\delta Q_\nu}{\delta\psi_k^*} + \frac{\partial S}{\partial P_\nu}\frac{\delta P_\nu}{\delta\psi_k^*}\right)d^n x \\
&\quad - \frac{1}{i}\int\left(\frac{\partial S}{\partial Q_\mu}\frac{\delta Q_\mu}{\delta\psi_k} + \frac{\partial S}{\partial P_\mu}\frac{\delta P_\mu}{\delta\psi_k}\right)\left(\frac{\partial R}{\partial Q_\nu}\frac{\delta Q_\nu}{\delta\psi_k^*} + \frac{\partial R}{\partial P_\nu}\frac{\delta P_\nu}{\delta\psi_k^*}\right)d^n x \\
&= \frac{\partial R}{\partial Q_\mu}\frac{\partial S}{\partial Q_\nu}\{Q_\mu,Q_\nu\}^c + \frac{\partial R}{\partial Q_\mu}\frac{\partial S}{\partial P_\nu}\{Q_\mu,P_\nu\}^c + \frac{\partial R}{\partial P_\mu}\frac{\partial S}{\partial P_\nu}\{P_\mu,P_\nu\}^c + \frac{\partial R}{\partial P_\mu}\frac{\partial S}{\partial Q_\nu}\{P_\mu,Q_\nu\}^c \\
&= \frac{\partial R}{\partial Q_\mu}\frac{\partial S}{\partial P_\mu} - \frac{\partial S}{\partial Q_\mu}\frac{\partial R}{\partial P_\mu} = \{R,S\}^d.
\end{aligned}$$

This establishes that $\{R,S\}^c=\{R,S\}^d$ is an identity, since it holds for all space-localized ψ fields, completing the proof. □

In the finite-dimensional case a canonical transformation of $2s$ variables preserves the form of any Hamiltonian system with the same number of variables. In a complete correspondence, we have as a consequence from the above theorem the following:

Corollary 4.5: An infinite-dimensional canonical transformation of the general type (4.10) converts any Hamiltonian evolution equation of the form (2.9) for the ψ field into a Hamiltonian system of infinitely many equations for the variables Q_μ, P_μ. *The converse holds for the inverse transformation (4.17).*

Proof: Express the Hamiltonian functional $H[\psi^*,\psi;t]=H(Q,P,t)$ of the evolution equation as a function of Q_μ and P_μ using the inverse transformation functions $\psi=\psi(Q,P,x)$ (which exist according to Theorem 4.4). Then, the desired result follows from (3.3) for the time-derivative of a functional and from the identity of Theorem 4.4:

$$\frac{dQ_\mu}{dt}=\{Q_\mu,H\}^c=\{Q_\mu,H\}^d=\frac{\partial H}{\partial P_\mu},$$

$$\frac{dP_\mu}{dt}=\{P_\mu,H\}^c=\{P_\mu,H\}^d=-\frac{\partial H}{\partial Q_\mu}.$$

To establish the converse, represent $\psi_k(x)$ with the functional $\int\psi_k(x')\,\delta(x'-x)d^nx'$ and denote $\psi_k'=\psi(x')$. Then, we have

$$\frac{\partial\psi_k}{\partial t}=\frac{\partial\psi_k}{\partial Q_\mu}\frac{dQ_\mu}{dt}+\frac{\partial\psi_k}{\partial P_\mu}\frac{dP_\mu}{dt}=\{\psi_k,H\}^d.$$

Applying the same identity completes the proof by showing that

$$\frac{\partial\psi_k}{\partial t}=\{\psi_k,H\}^c=\frac{1}{i}\int\frac{\delta H}{\delta\psi_j'^*}\,\delta_{jk}\,\delta(x'-x)\,d^nx'=-i\,\frac{\delta H}{\delta\psi_k^*}.$$ □

V. ON THE QUANTIZATION RULES

This section is an application of the previous results.

By very general physics arguments, one expects that the characteristics of a localized ψ field *as a whole*, like its position, velocity, linear, and angular momentum, etc., are to be given with real-valued bilinear functionals even when the ψ field is assumed to obey some nonlinear evolution equation. Or, to use the QM term, the *observables* are to remain linear Hermitian operators and their values are to be given with bilinear functionals (except for the Hamiltonian) even if the wave function was to obey a nonlinear equation. Assuming that this is true, then these functionals must be *normalized bifunctionals*, that is, divided by N from (2.8). For, the function ψ cannot be normalized, as done in quantum mechanics, since by the above assumption it is a solution of a nonlinear evolution equation.

In place of ''normalized bilinear functional'' one could use, of course, the QM term ''expectation value'' of the associated linear operator. But no probabilistic interpretation should be attached to it since, here, such an interpretation would be entirely unnecessary, and the controversies accompanying it may distract us from the subject at hand.

After these preliminaries we pose the question: ''What can be said for the Poisson bracket of the expectation values of two linear operators if they are evaluated with a space-localized solution of a *nonlinear* field equation?'' There is at least one statement which, as we will see, is surprisingly similar to the quantum mechanics' answer in the linear case, namely:

Theorem 5.1: *The continuous Poisson bracket of two normalized bilinear real or complex-valued functionals* R *and* S *which are associated with the linear matrix-differential operators* **R** *and* **S** *according to the ''rule''*

$$\mathrm{R}=\frac{1}{\mathrm{N}}\int \psi_j^*\mathbf{R}_{jk}\psi_k\,d^nx=\frac{1}{\mathrm{N}}\int \boldsymbol{\psi}^\dagger\mathbf{R}\boldsymbol{\psi}\,d^nx \quad \text{and}$$

$$\mathrm{S}=\frac{1}{\mathrm{N}}\int \psi_j^*\mathbf{S}_{jk}\,\psi_k\,d^nx=\frac{1}{\mathrm{N}}\int \boldsymbol{\psi}^\dagger\mathbf{S}\boldsymbol{\psi}\,d^nx$$

is equal to the normalized bilinear functional which is associated, precisely by the same ''rule,'' with the linear matrix-differential operator

$$[\mathbf{R},\mathbf{S}]_{\mathrm{QM}}=\frac{1}{i\mathrm{N}}\,(\mathbf{RS}-\mathbf{SR}). \tag{5.1}$$

($\mathrm{N}=\langle\boldsymbol{\psi},\boldsymbol{\psi}\rangle$ and $\boldsymbol{\psi}^\dagger=(\boldsymbol{\psi}^*)^t$ denotes the transpose of $\boldsymbol{\psi}^*$.)

Proof: First, we observe that any bilinear functional is gauge-type I invariant. Then, from Theorem 3.1 it follows that $\{\mathrm{N},\mathrm{R}\}=\{\mathrm{N},\mathrm{S}\}=0$ since for any functional F, not necessarily bilinear, which is gauge type I invariant we have

$$\left\{\mathrm{N},\frac{\mathrm{F}}{\mathrm{N}}\right\}=\frac{1}{i}\int\left(\frac{\delta\mathrm{N}}{\delta\psi_k}\frac{\delta}{\delta\psi_k^*}\left(\frac{\mathrm{F}}{\mathrm{N}}\right)-\frac{\delta}{\delta\psi_k}\left(\frac{\mathrm{F}}{\mathrm{N}}\right)\frac{\delta\mathrm{N}}{\delta\psi_k^*}\right)d^nx=\frac{1}{\mathrm{N}}\{\mathrm{N},\mathrm{F}\}-\frac{\mathrm{F}}{\mathrm{N}^2}\{\mathrm{N},\mathrm{N}\}=0,$$

where $\{\mathrm{N},\mathrm{F}\}=0$ according to Theorem 3.1. Hence, it follows that

$$\begin{aligned}\{\mathrm{R},\mathrm{S}\}&=\frac{1}{i}\int\left(\frac{\delta\mathrm{R}}{\delta\psi_k}\frac{\delta\mathrm{S}}{\delta\psi_k^*}-\frac{\delta\mathrm{S}}{\delta\psi_k}\frac{\delta\mathrm{R}}{\delta\psi_k^*}\right)d^nx\\&=\frac{1}{i\mathrm{N}^2}\int\psi_i^*(\mathbf{R}_{ik}\mathbf{S}_{kj}-\mathbf{S}_{ik}\mathbf{R}_{kj})\psi_j\,d^nx\\&\quad+\frac{\{\mathrm{N},\mathrm{R}\}}{\mathrm{N}^2}\int\boldsymbol{\psi}^\dagger\mathbf{S}\boldsymbol{\psi}\,d^nx-\frac{\{\mathrm{N},\mathrm{S}\}}{\mathrm{N}^2}\int\boldsymbol{\psi}^\dagger\mathbf{R}\boldsymbol{\psi}\,d^nx=\frac{1}{\mathrm{N}}\int\boldsymbol{\psi}^\dagger[\mathbf{R},\mathbf{S}]_{\mathrm{QM}}\,\boldsymbol{\psi}\,d^nx\end{aligned}\qquad\square$$

which completes the proof.

The above result deserves a discussion, and this is what follows:

Theorem 5.1 holds regardless of what the nonlinear equation for $\boldsymbol{\psi}$ is. Moreover, N is not required to be constant in time, as long as it remains finite and nonzero.

We also see that when the operators **R** and **S** are Hermitian the operator $[\mathbf{R},\mathbf{S}]_{\mathrm{QM}}$ in (5.1) not only plays the role of, but also has the form of the *quantum commutator* or the ''quantum Poisson bracket,'' as P. M. Dirac[18] called it. The single, and remarkable, difference is that the Hermitian norm N appears in (5.1) in place of Planck's constant $\hbar$.

But first, we must make sure that the *dimensionality* of N is right. Certainly, N is not dimensionless, as it is in quantum mechanics, since $\boldsymbol{\psi}$ is not normalized. From the identity (2.14) it follows that the dimensionality of any Hamiltonian functional for a CHE equation is always [*energy*]. Then, the form (2.9) together with expression (2.10) tell us that the dimensionality of all the products $\psi_k^*\psi_k$ is [*action*] per unit volume. Referring to the definition (2.8) we conclude that the dimensionality of the Hermitian norm N is always [*action*] which, of course, is the dimensionality of Planck's constant. The only condition for the validity of the above is that $\boldsymbol{\psi}$ must be a solution of a CHE equation.

The same conclusion is reached by recalling, from the beginning of Sec. II, that the dimensionality of $\Sigma_{i=1}^{s}\,z_i^*z_i$ is always [*action*] if z_i are solutions of a complex Hamiltonian system. Obviously, the transition $s\to\infty$ cannot change the dimensionality of the sum, whose limit is precisely N.

There is an entirely different argument discussed in Bodurov[11] which shows that if $\boldsymbol{\psi}$ is a solution of a *Galilei-invariant* nonlinear CHE equation then, again, N plays the role of Planck's constant when $\boldsymbol{\psi}$ is Galilei transformed.

Next, let us assume that we have found a set of Hermitian operators $\mathbf{Q}_\mu$ and $\mathbf{P}_\mu$ for whose commutators the following conditions hold:

$$[\mathbf{Q}_\mu,\mathbf{P}_\nu]=i\mathrm{N}\delta_{\mu\nu},\quad [\mathbf{Q}_\mu,\mathbf{Q}_\nu]=0,\quad [\mathbf{P}_\mu,\mathbf{P}_\nu]=0 \tag{5.2}$$

and whose expectation values Q_μ and P_μ are defined by the ''rule'' of Theorem 5.1. Then, by the same theorem their continuous Poisson brackets are

$$\{\mathrm{Q}_\mu,\mathrm{P}_\nu\}=\delta_{\mu\nu},\quad \{\mathrm{Q}_\mu,\mathrm{Q}_\nu\}=0,\quad \{\mathrm{P}_\mu,\mathrm{P}_\nu\}=0. \tag{5.3}$$

The last relations allow us to apply Theorem 4.4 and Corollary 4.5 which, in turn, tell us *that the time development of the expectation values* Q_μ *and* P_μ *is governed by a classical Hamiltonian system of equations*.

The preceeding sequence of arguments demonstrates that the form of the *fundamental quantization rules* which where postulated by P. M. Dirac,[18] and which are equivalent to the commutation relations (5.2) with $\mathrm{N}=\hbar$, are obtainable without any ''external'' assumptions. This claim is made only with respect to the form of the quantization rules because the value of N in (5.1) is left undetermined by the field equation. The investigation of a possible condition with which the value of N can be ''fixed'' will be the subject of a forthcoming paper.

The commutation relations (5.2) and the canonical relations (5.3) are not equivalent: (5.2) obtains uniquely from (5.2), but (5.2) does not follow uniquely from (5.3). The most general commutation relations which follow from (5.3) contain (5.2) as a special case. This observation may be taken as an evidence that there is a nonlinear field theory which contains quantum mechanics as a special case.

We remark that the results of this section allow us to view the *complementarity* between classical variables and the operators of quantum mechanics as a manifestation of infinite-dimensional canonical transformations between discrete and continuous variables.

VI. A CONCLUDING DISCUSSION

The previous sections were intended to be as free of speculative arguments as possible. This section, on the other hand, is free of such restrictions. The history of QM, alone, is evidence that speculative physics arguments may be essential in finding key questions and nonspeculative answers. To those who share this view the following may be of interest.

It is natural to assume, as done in Weinberg[3] and in other publications, that if any nonlinearities exist in the equations of quantum mechanics they must be only small perturbations. Could it be otherwise, without having been known already? But then, all the proposed models which are based on nonlinear self-localized fields would be no more than futile exercises, including the work of W. Heisenberg[2] (and the references there).

These two approaches, the one critically relying on the assumption of *perturbationally small* nonlinearity and the other exploiting the possibilities of self-localized fields, seem to be mutually excluding. Indeed, only particular types of nonlinear field equation may possess self-localized solutions, and certainly none if the degree of their nonlinearity is arbitrarily small. (See, for example, Berestycki and Lions.[13])

Yet, a third alternative is possible, and the following will explain what it is.

But first, we need to define the meaning of the ''*linearized version*'' of a ψ-field equation, which is the equation obtained by letting $|\psi|\to 0$ and retaining only the terms linear in ψ.

Now, consider a self-localized solution $\psi(x,t)$ of a particular nonlinear *free field* CHE equation, and let ρ_1 be an appropriately defined radius of the localization region which, of course, will depend only on the equation parameters. Next, assume that the initially free moving localization region enters a domain in space where it interacts with an external potential $U(x)$ according to the QM prescription:

$$\frac{\partial}{\partial t}\to\frac{\partial}{\partial t}+igU(x) \tag{6.1}$$

where g is a suitably chosen interaction constant. Then, as long as the variation of $|U(x)|$ *within the localization region* is sufficiently small the motion of the ψ field *as a whole* will be identical to the motion of a point-mass in the same potential. This is a rigorous result, and it is derived in Bodurov[19] for a large class of *gauge I invariant nonlinear* field equations, including the CHE.

When the external field $-\nabla U$ reach sufficiently high intensity the initial ψ-field configuration, of course, will become unstable. Consequently, ψ will expand in space (rather than contract to a point), because otherwise either N would vanish, or ψ would become singular. However, for certain potential wells space-localization (that is, bound state) may occur again, but this time, due to the presence of $U(x)$, and not because of nonlinearity.

This can happen if the following three conditions are met: First, the ''linearized version'' of the initial CHE equation possesses a bound state solution with a suitably defined radius ρ_2. Second (this is the only speculative part in this argument), the norm N of the ψ field remains the same, or at least within the same order of magnitude, in both cases of localization. And third, ρ_2 is sufficiently larger than ρ_1.

One way to satisfy the first condition is to assume that the ''linearized version'' is an equation of the Schrödinger or of the Dirac-type. The second condition is easy to justify as long as the ''linearized version'' provides a sufficiently accurate description of the bound state, since then we may chose N to have any real value we like. Then, the ratio of the maximum field magnitudes $|\psi_2|_{\max}$ and $|\psi_1|_{\max}$ in the respective cases is

$$\frac{|\psi_2|_{\max}}{|\psi_1|_{\max}}=\left(\frac{\rho_1}{\rho_2}\right)^{3/2}, \tag{6.2}$$

where ρ_1 and ρ_2 are defined by (for $n=3$)

$$\rho_i^3=\frac{3\mathrm{N}}{4\pi|\psi_i|^2_{\max}} \quad \text{with} \quad i=1,2. \tag{6.3}$$

According to (6.2) the effect of nonlinearity will necessarily become perturbationally small when the ratio ρ_2/ρ_1 is sufficiently large, that is, when the third condition is satisfied. Then, the ψ-field equation will become essentially the same as its ''linearized version.'' Hence, at least when the last is a Schrödinger or a Dirac-type equation, we are assured that, indeed, there are potential wells for which the assumed bound state does exist.

Thus, the assumption that the field equations contain only *small nonlinearity*, and the assumption of *strongly nonlinear* field equations are not necessarily incompatible. On the contrary, we see that the two approaches must be linked together if each of them is to meet the expectations of its proponents.

Let us illustrate these arguments by an example. Any nonlinear field theory ''X'' which represents, say, the electron with a self-localized field must give for the radius ρ_1 a number which is much smaller than the *the classical electron radius*, according to the experimental results. But, as a ''worst case'' assumption let us take $\rho\approx 10^{-13}$ cm. On the other hand, *Bohr radius* provides a good estimate $\rho_2\approx 10^{-8}$ cm of what the radius of localization is when the electron (or more precisely, its wave function) is trapped in a potential well. Even this very conservative estimate gives the ratio $\rho_2/\rho_1\approx 10^5$. Then, (6.2) tells us that the ratio of the maximum magnitude of the externally localized field to that of the self-localized field is $|\psi_2|_{\max}/|\psi_1|_{\max}\approx 3\times 10^{-8}$. Certainly, this is enough to make any (physically meaningful) nonlinearity perturbationally small and to allow a linear treatment of the trapped electron by the same theory ''X.''

This discussion was intended also to illustrate how a ''strongly'' nonlinear field theory may reduce to quantum mechanics, and thus contain it as a special case.

Next, the reasons for limiting n to three space-dimensions (Sec. II) are briefly discussed: Quantum mechanics represents systems consisting of i particles with wave functions which depend on $3i$ space-coordinates. The resulting equations, then, are solved by perturbation methods because there are no known methods for obtaining exact solutions.

In a nonlinear field theory there is a natural alternative, not available to quantum mechanics, which is: If we assume that a region of localization in a ψ field represents a particle, then a system of i particles should be represented by a ψ field with i regions of localization. For, if a nonlinear field equation admits a solution with a single localization region, then it admits solutions with any number of localization regions. In this approach the field equation which describes a system of

particles is the same equation which describes one particle, only the initial conditions differ. If such a unification in the treatment of single and multiparticle systems is accepted as correct, then the *homogeneity assumption* (Sec. III) becomes unnecessary.

As remarked in Sec. II Definition 2.1 requires a few comments: If a space-localized field is to represent a particle then we expect, on the basis of physics considerations, that the field localization should be much ''sharper'' than what is demanded by Definition 2.1, alone. It is very satisfying that this expectation is met (without any additional assumptions or restrictions) by all pertinent results which are known to me. For example: It was shown by Berestycki and Lions[13] that all space-localized solutions of all nonlinear Schrödinger and of all nonlinear Klein–Gordon equations (which admit such solutions) *decay exponentially* as $|x|\to\infty$. The localization of the solutions (''gaussons'') to the logarithmic NLS equation[6] is even sharper, that is, they *decay exponentially* as $|x|^2\to\infty$.

Thus, even for the purposes of representing particles with localized fields there is no need for more restrictive definition. On the other hand, we do want Definition 2.1 to give *as generally as possible* the mathematical meaning of a term which is needed both for the preciseness and for the clarity of the preceeding discussions.

It is hoped that this paper will contribute toward the development of a nonlinear field theory whose compatibility with the principles of quantum mechanics will be ensured not by inventing ''quantization rules for nonlinear fields,'' but by the theory's ability to reduce to conventional quantum mechanics as a special case. Accordingly, this paper's results are to be seen not as arrived-at destinations, but rather as destination pointers.

(Received 1 April 1998; accepted for publication 27 May 1998)

Canonical and quasi-canonical realizations of the osp($D|d$) superalgebra are presented. In these realizations there is only one independent Casimir operator: The quadratic one C, the eigenvalues of which allow specification of the involved representations. Pauli's method for solving the spectrum of the Coulomb problem through quantization of the Runge–Lenz vector is extended to an arbitrary dimension superspace $E(D|d)$ with D bosonic coordinates and d (even) fermionic coordinates. The symmetry algebra of the Hamiltonian is the superalgebra osp($D+1|d$). It is shown how the energy spectrum is related to the Casimir operator C' of osp($D+1|d$) in its quasicanonical realization. Then the energy levels are given in terms of the eigenvalues of the operator C'. © *1998 American Institute of Physics.* [S0022-2488(98)02210-5]

I. INTRODUCTION

It is well-known that a few months before the event of Schrödinger equation, Pauli[1,2] solved the quantum-mechanical hydrogen atom in the framework of Born, Heisenberg, Jordan matrix mechanics, by a purely algebraic method through quantization of the Runge–Lenz vector. Very soon, it appeared that Schrödinger wave mechanics is much more efficient than Heisenberg matrix mechanics for solving many problems in atomic physics, especially through perturbation theory. And this explains why, with the exception of some work by Fock,[3] Pauli's method was completely forgotten for about 40 years, and was not even mentioned in the classical textbooks on quantum mechanics and atomic physics. However, Pauli's technique was revived in the mid 1960's with the discovery[4] of the so(4,2) dynamical symmetry of the Coulomb problem. Since then, numerous articles[5,6] and books[7,8] have reviewed the original work of Pauli and the more recent developments of the algebraic method. Before proceeding, let us also recall that the spectrum of the Coulomb problem in arbitrary dimension Euclidean space had been obtained a long time ago by solving the Schrödinger equation in D dimensions and that more recently it has been found very fruitful to consider the reciprocal dimension $1/D$ as a perturbation parameter for solving some problems in $D=3$ quantum mechanics.[9] Finally it should also be mentioned that recently, Horwitz[10] has generalized Pauli's method to the relativistic Kepler problem.

In this paper, we show that Pauli's method can be generalized to arbitrary dimension superspaces. More precisely we show that besides the generalized angular momentum that is a constant of motion for the Coulomb problem whatever the dimension of the superspace, one can define another set of constants of motion in the form of a supervector that generalizes the Runge–Lenz vector. In addition, it is shown that, exactly as in the three-dimensional case, the whole set of constants of motion forms an orthosymplectic algebra and that the Hamiltonian of the Coulomb problem can be written in terms of the quadratic Casimir operator of this symmetry algebra, which provides an algebraic solution to the problem.

In order to generalize Pauli's method, we consider an arbitrary dimension superspace $E(D|d)$ with D bosonic coordinates and d (even) fermionic coordinates. To each position coordinate we associate a conjugate momentum that is realized as a differential operator acting on functions defined on the superspace $E(D|d)$. Then, by means of the antisupersymmetric tensor product of the coordinates and the momenta, we build the canonical realization of the superalgebra

osp$(D|d)$. Next, we define the Runge–Lenz supervector, constant of motion for the Coulomb problem, and we show that this supervector allows us to construct the quasicanonical realization of the superalgebra osp$(D+1|d)$. Finally, we derive the energy spectrum for the Coulomb problem from the eigenvalues of the Casimir operators of the osp$(D+1|d)$ superalgebra. Note that the general case of a (bosonic) D-dimensional space is obtained by setting $d=0$.

The organization of the paper is the following. In Sec. II, we review the original work of Pauli for the three-dimensional Euclidean space $E(3)$ and we write it in a tensorial form that is more suitable for generalization. Section III is devoted to the construction of the canonical and quasicanonical realizations of the osp$(D|d)$ superalgebra. Finally, in Sec. IV we generalize the Pauli's method to an arbitrary dimension orthosymplectic superspace $E(D|d)$.

II. THE COULOMB PROBLEM IN THREE-DIMENSIONS

A. Pauli's method

Let us first recall the basics and results of Pauli's method for the three-dimensional Coulomb problem.[1,5] The Hamiltonian of the Hydrogen atom (in units with $m=e^2=\hbar=1$) is

$$H=\frac{1}{2}\,\mathbf{p}^2-\frac{1}{r}, \tag{2.1}$$

where $r=|\mathbf{r}|$. From the canonical commutation relation $[r_i,p_j]=i\,\delta_{ij}$, it is easy to verify that the angular momentum vector operator $\mathbf{L}=\mathbf{r}\times\mathbf{p}$ satisfies the commutation relations

$$[L_i,L_j]=i\,\epsilon_{ijk}L_k, \tag{2.2}$$

and is a constant of motion

$$[H,\mathbf{L}]=0. \tag{2.3}$$

Pauli introduced another constant of motion, the quantum-mechanical Runge–Lenz vector operator, defined by

$$\mathbf{A}=\frac{1}{2}\,(\mathbf{p}\times\mathbf{L}-\mathbf{L}\times\mathbf{p})-\frac{\mathbf{r}}{r}. \tag{2.4}$$

Use of the commutation relations for $\mathbf{r}$, $\mathbf{p}$, and $\mathbf{L}$ leads to

$$[H,\mathbf{A}]=0. \tag{2.5}$$

Furthermore, one derives the constraints

$$\mathbf{A}\cdot\mathbf{L}=\mathbf{L}\cdot\mathbf{A}=0, \tag{2.6}$$

and the commutation relations between the angular momentum and the Runge–Lenz vector components

$$[L_i,A_j]=i\,\epsilon_{ijk}A_k, \tag{2.7}$$

$$[A_i,A_j]=i(-2H)\,\epsilon_{ijk}L_k. \tag{2.8}$$

The clue to an algebraic solution of the problem is the remark that, in the quantum case as well as in the classical case, the Hamiltonian can be written in terms of the constants of motion $\mathbf{L}^2$ and $\mathbf{A}^2$. Indeed, one has the relation

$$\mathbf{A}^2=1+(2H)(\mathbf{L}^2+1), \tag{2.9}$$

and, therefore, the spectrum of H is related to the eigenvalues of $\mathbf{A}^2$ and $\mathbf{L}^2$. In order to exhibit more precisely this relation, it is interesting to define two new vector operators $\mathbf{M}$ and $\mathbf{N}$, through the combinations (assuming $H<0$)

$$\mathbf{M}=\frac{1}{2}\left(\mathbf{L}+\frac{\mathbf{A}}{\sqrt{-2H}}\right), \tag{2.10}$$

$$\mathbf{N}=\frac{1}{2}\left(\mathbf{L}-\frac{\mathbf{A}}{\sqrt{-2H}}\right). \tag{2.11}$$

They are constants of motion

$$[H,\mathbf{M}]=[H,\mathbf{N}]=0, \tag{2.12}$$

and from Eqs. (2.3), (2.7), and (2.8), it is easy to show that they satisfy the commutation relations of su(2)⊕su(2)=so(4)

$$[M_i,N_j]=0, \tag{2.13}$$

$$[M_i,M_j]=i\epsilon_{ijk}M_k, \tag{2.14}$$

$$[N_i,N_j]=i\epsilon_{ijk}N_k. \tag{2.15}$$

From Eq. (2.9), the expression of the Hamiltonian in terms of these new operators is

$$H=-\frac{1}{2}\frac{1}{2(\mathbf{M}^2+\mathbf{N}^2)+1}. \tag{2.16}$$

But, because of Eq. (2.6), one has the constraint

$$\mathbf{M}^2=\mathbf{N}^2, \tag{2.17}$$

and since **M** satisfies the commutation relations (2.14) of an angular momentum, the eigenvalues of $\mathbf{M}^2$ are $j(j+1)$ with j integer or half-integer, and therefore, the eigenvalues of H are

$$E_n=-\frac{1}{2}\frac{1}{4j(j+1)+1}=-\frac{1}{2}\frac{1}{n^2}, \tag{2.18}$$

with $n=2j+1=1,2,\ldots$. This is the well-known spectrum of the hydrogen atom.

The main result of Pauli's method is Eq. (2.16) that relates the Hamiltonian H of the three-dimensional problem to the quadratic Casimir operator $C_4=2(\mathbf{M}^2+\mathbf{N}^2)$ of the so(4) algebra.

Let us finally recall that the method provides not only the spectrum but also the degeneracy of each level. Indeed, for fixed n, i.e., for fixed j, the number of eigenstates for each of the angular momentum operators **M** and **N** is $2j+1$; therefore, the total degeneracy is $(2j+1)^2=n^2$.

B. Tensorial form of Pauli's method

Instead of the vectorial form recalled in the previous section, Pauli's method can be rewritten in a tensorial form[11] that is more suitable for generalizations. Let us associate to the angular momentum operator **L** the skew symmetric tensor M_{ij} defined by

$$M_{ij}=\epsilon_{ijk}L_k=r_ip_j-r_jp_i \quad (i,j=1,2,3). \tag{2.19}$$

The components of this tensor satisfy the SO(3) commutation relations

$$[M_{ij},M_{kl}]=\frac{1}{i}(\delta_{jk}M_{il}+\delta_{il}M_{jk}-\delta_{jl}M_{ik}-\delta_{ik}M_{jl}), \tag{2.20}$$

and are constants of motion

$$[H,M_{ij}]=0. \tag{2.21}$$

The Runge–Lenz vector **A** is built with the tensor M_{ij} and the vectors r_i and p_j as follows:

$$A_i=\frac{1}{2}\{M_{ij},p_j\}-\frac{r_i}{r}, \tag{2.22}$$

where {,} is set for the usual anticommutator. Using the definitions and the commutation relations, one verifies that this vector is a constant of motion

$$[H,A_i]=0, \tag{2.23}$$

and that the commutation relations between the M_{ij} and the A_i components are

$$[M_{ij},A_k]=\frac{1}{i}(\delta_{jk}A_i-\delta_{ik}A_j), \tag{2.24}$$

$$[A_i,A_j]=i(-2H)M_{ij}. \tag{2.25}$$

In addition, the vector A_i satisfies constraints that result from the orthogonality relations (2.6), namely

$$M_{ij}A_k+M_{jk}A_i+M_{ki}A_j=A_iM_{jk}+A_jM_{ki}+A_kM_{ij}=0. \tag{2.26}$$

Equation (2.16) yields the following relation between the Hamiltonian H and the constants of motion $\mathrm{Tr}(M^2)$ and $\mathbf{A}^2$:

$$\mathbf{A}^2=1+(2H)(1-\tfrac{1}{2}\mathrm{Tr}(M^2)). \tag{2.27}$$

Then, to define the so(4) algebra, we introduce the skew symmetric tensor operators $M'_{ij}=-M'_{ji}$, $(i,j=1,2,3,4)$, such that

$$M'_{ij}=M_{ij}, \quad \text{for } i,j=1,2,3, \tag{2.28}$$

$$M'_{k,4}=-M'_{4,k}=\frac{A_k}{\sqrt{-2H}}, \quad \text{for } k=1,2,3. \tag{2.29}$$

One readily verifies that these six independent operators M'_{ij} satisfy the commutation relations of the so(4) algebra

$$[M'_{ij},M'_{kl}]=\frac{1}{i}(\delta_{jk}M'_{il}+\delta_{il}M'_{jk}-\delta_{jl}M'_{ik}-\delta_{ik}M'_{jl}). \tag{2.30}$$

The quadratic Casimir operator of this algebra reads

$$C'=-\frac{1}{2}\mathrm{Tr}(M'^2)=-\frac{1}{2}\left(\mathrm{Tr}(M^2)+\frac{A^2}{H}\right), \tag{2.31}$$

and Eq. (2.27) implies that the Hamiltonian H can be written

$$H=-\frac{1}{2}\frac{1}{C'+1}. \tag{2.32}$$

In the particular realization of the so(4) algebra represented by the expressions (2.19) and (2.29), because of the relations between traces of the powers of M'

$$\mathrm{Tr}(M'^3)=\frac{1}{2i}\mathrm{Tr}(M'^2), \quad \mathrm{Tr}(M'^4)=\frac{1}{2}[\mathrm{Tr}(M'^2)]^2, \tag{2.33}$$

there is only one algebraically independent Casimir operator, namely the quadratic operator C'. The eigenvalues of C' are

$$C' = k(k+2), \quad k = 0,1,\ldots . \tag{2.34}$$

By substitution of this value in Eq. (2.32) and setting $k = n-1$, we find again the energy spectrum (2.18).

The realization (2.19) of the so(3) algebra is called the canonical realization because the generators M_{ij} are functions of the operators r_i and p_j that satisfy the canonical commutation relations $[r_i, p_j] = i\delta_{ij}$. By analogy, we call quasicanonical realization, the realization of the so(4) algebra that is given by Eqs. (2.28) and (2.29). Indeed, it is built from the canonical realization of the so(3) subalgebra completed with a set of three generators A_i that are also functions of the operators r_i and p_j.

In the following section, we shall generalize this construction of canonical and quasicanonical realizations to orthosymplectic superalgebras and this will provide us a way to generalize Pauli's method for the resolution of the Coulomb problem in arbitrary dimension spaces.

III. CANONICAL AND QUASICANONICAL REALIZATIONS OF ORTHOSYMPLECTIC SUPERALGEBRAS

A. The superspace $E(D|d)$

The elements of the orthosymplectic superspace $E(D|d)$ (d even) are called supervectors. The position and the momentum supervector are denoted, respectively, by $R_a = (r_i \equiv \mathbf{r}, \chi_\alpha)$ and $P_a = (p_i \equiv \mathbf{p}, \pi_\alpha)$. The range of the collective index a is: $a = \{i = 1,\ldots,D; \alpha = 1,\ldots,d\}$. The components r_i (or p_i) are bosonic, i.e., they commute, while the components χ_α (or π_α) are fermionic, i.e., they anticommute: $\{\chi_\alpha, \chi_\beta\} = 0$ (or $\{\pi_\alpha, \pi_\beta\} = 0$).

The contravariant components of the metric tensor are $g^{ab} = (-1)^{ab} g^{ba} = (\delta^{ij}, \Gamma^{\alpha\beta})$ where Γ is the $d \times d$ antisymmetric matrix with $(1, -1, 1, -1, \ldots, -1)$ on the second diagonal. The covariant components are $g_{ab} = (\delta_{ij}, -\Gamma_{\alpha\beta})$. The scalar product $R \cdot P$ of the supervectors R and P is defined by

$$R \cdot P = g^{ab} R_a P_b = \mathbf{r} \cdot \mathbf{p} + \Gamma^{\alpha\beta} \chi_\alpha \pi_\beta . \tag{3.1}$$

The square R^2 of the position supervector, and its norm R are

$$R^2 = \mathbf{r}^2 + \Gamma^{\alpha\beta} \chi_\alpha \chi_\beta , \quad R = r + \frac{1}{2r} \Gamma^{\alpha\beta} \chi_\alpha \chi_\beta , \tag{3.2}$$

In order to define a quantum mechanics in the orthosymplectic superspace $E(D|d)$, we define canonical supercommutation relations (CSR) between the position and the momentum components as

$$[R_a, P_b]_s \equiv R_a P_b - (-1)^{ab} P_b R_a = i g_{ab} , \tag{3.3}$$

i.e., one has $[r_i, p_j] = i\delta_{ij}$ and $\{\chi_\alpha, \pi_\beta\} = -i\Gamma_{\alpha\beta}$.

These CSR can be realized in terms of operators acting on functions defined on the $E(D|d)$ superspace. The components of the position supervector act as multiplication by r_i or χ_α and the components of the momentum supervector are represented by differential operators

$$p_i = \frac{1}{i} \frac{\partial}{\partial r_i}, \quad \pi_\alpha = \frac{1}{i} \frac{\partial}{\partial \chi^\alpha}. \tag{3.4}$$

The Laplace operator on the superspace $E(D|d)$ is defined by $\Delta \equiv -P^2$ and it writes

$$\Delta = \frac{\partial^2}{\partial R^2} + (D - d - 1) \frac{1}{R} \frac{\partial}{\partial R} - \frac{C}{R^2}, \tag{3.5}$$

where C is a positive operator, involving the nonradial variables. The eigenvalues of this operator are determined in the following way. Let $Z_l(R_a)$ be a degree l homogeneous polynomial, solution of the Laplace equation, i.e.,

$$Z_l(\lambda R_a)=\lambda^l Z_l(R_a), \quad \Delta Z_l=0. \tag{3.6}$$

We define reduced variables by $\rho_a=R_a/R$ so that $Z_l(R_a)=R^l Z_l(\rho_a)$. Then, the functions $Z_l(\rho_a)$ are eigenfunctions of the operator C with eigenvalues $l(l+D-d-2)$

$$CZ_l(\rho_a)=l(l+D-d-2)Z_l(\rho_a). \tag{3.7}$$

B. Canonical realization of the osp($D|d$) superalgebra

In the superspace $E(D|d)$, the super angular momentum M is built with the position and momentum supervectors in the following way:

$$M_{ab}=R_aP_b-(-1)^{ab}R_bP_a. \tag{3.8}$$

From the canonical supercommutation relations (3.3), it is easy to verify that the operator M is a super antisymmetric tensor

$$M_{ab}=-(-1)^{ab}M_{ba}, \tag{3.9}$$

and that its components satisfy the super commutation relations of the orthosymplectic superalgebra osp($D|d$)

$$\begin{aligned}[M_{ab},M_{cd}]_s &\equiv M_{ab}M_{cd}-(-1)^{(a+b)(c+d)}M_{cd}M_{ab}\\ &=\frac{1}{i}\,(g_{bc}M_{ad}-(-1)^{cd}g_{bd}M_{ac}\\ &\quad -(-1)^{ab}g_{ac}M_{bd}+(-1)^{ab+cd}g_{ad}M_{bc}).\end{aligned} \tag{3.10}$$

This realization of the superalgebra osp($D|d$) is called the canonical realization. Its essential characteristic is to have only one independent Casimir operator. This fact can be proved as follows. First, it is well known that for any representation of osp($D|d$), the traces of the odd powers of M depend linearly on the traces of the even powers,[12,13] for example

$$\mathrm{Tr}(M^3)=-\tfrac{1}{2}(D-d-2)\mathrm{Tr}(M^2). \tag{3.11}$$

Then, in the canonical realization, one has the relation

$$(M^4)_{ab}=\tfrac{1}{2}\mathrm{Tr}(M^2)(M^2)_{ab}+(\mathrm{td}\leqslant 3), \tag{3.12}$$

where (td$\leqslant$3) means ''terms of degree less than or equal to 3.'' By taking the trace of this relation, we get precisely

$$\mathrm{Tr}(M^4)=\tfrac{1}{2}\mathrm{Tr}(M^2)[\mathrm{Tr}(M^2)-(D-d-2)(D-d-3)]. \tag{3.13}$$

By induction, we find

$$\mathrm{Tr}(M^{2n})=\frac{1}{2^{2n-1}}\,\mathrm{Tr}(M^2)^n+Q_{n-1}(\mathrm{Tr}\,M^2), \tag{3.14}$$

where Q_{n-1} is a polynomial of degree $n-1$.

Hence, we can choose as the unique algebraically independent Casimir operator, the quadratic one

$$\begin{aligned}C&=-\tfrac{1}{2}\mathrm{Tr}(M^2)\equiv-\tfrac{1}{2}g^{ab}M_{ac}g^{cd}M_{db},\\ &=R^2P^2-(R\cdot P)^2+i(D-d-2)R\cdot P.\end{aligned} \tag{3.15}$$

This equation is equivalent to Eq. (3.5) that gives the form of the Laplace operator. The eigenvalues of the operator C were determined in the previous subsection. By using the fact that C is the square of a super-Hermitian operator and must be positive definite, these eigenvalues can be written as

$$\text{for } D \geqslant d+2: \quad C = l(l+D-d-2), \tag{3.16}$$

$$\text{for } D < d+2: \quad C = l(l-D+d+2). \tag{3.17}$$

with $l = 0,1,2...$, and where for the second relation we have performed a change of integer variable.

C. Quasicanonical realization of the osp($D+1|d$) superalgebra

Let us consider a supervector K belonging to the $E(D|d)$ superspace and that satisfies the following relations:

$$[M_{ab}, K_b]_s = \frac{1}{i}(g_{bc}K_a - (-1)^{ab} g_{ac}K_b), \tag{3.18}$$

$$[K_a, K_b]_s = iM_{ab}, \tag{3.19}$$

$$M_{ab}K_c + (-1)^{a(b+c)}M_{bc}K_a + (-1)^{c(a+b)}M_{ca}K_b = 0,$$

$$K_a M_{bc} + (-1)^{a(b+c)}K_b M_{ca} + (-1)^{c(a+b)}K_c M_{ab} = 0, \tag{3.20}$$

where M is the canonical realization of osp($D|d$).

It is possible to gather the operators K_a and M_{bc} into a new super antisymmetric tensor operator $M'_{ab} = -(-1)^{ab}M'_{ba}$, the indices of which take their values in $E(D+1|d)$, i.e., $a = \{i = 1,2,...,D+1; \alpha = 1,...,d\}$. The tensor M'_{ab} is defined by

$$M'_{ab} = M_{ab} \quad \text{for} \quad a,b \in E(D|d),$$

$$M'_{a,D+1} = -M'_{D+1,a} = K_a. \tag{3.21}$$

The components of this tensor satisfy the super commutation relations of the osp($D+1|d$) superalgebra. We call it quasicanonical realization of osp($D+1|d$) because the same relations exist between the traces of the powers as for the canonical realization. Indeed, conditions (3.18)–(3.20) imply the identities

$$(K \cdot M^2)_a = -\tfrac{1}{2}\mathrm{Tr}(M^2)K_a + (\mathrm{td} \leqslant 2), \tag{3.22}$$

$$(M^2 \cdot K)_a = -\tfrac{1}{2}\mathrm{Tr}(M^2)K_a + (\mathrm{td} \leqslant 2), \tag{3.23}$$

$$(M \cdot K)_a (K \cdot M)_b = K^2 (M^2)_{ab} - \tfrac{1}{2}\mathrm{Tr}(M^2)K_a K_b + (\mathrm{td} \leqslant 3). \tag{3.24}$$

These identities allow us to prove the following relation:

$$(M'^4)_{ab} = \tfrac{1}{2}\mathrm{Tr}(M'^2)(M'^2)_{ab} + (\mathrm{td} \leqslant 3), \tag{3.25}$$

that is similar to Eq. (3.12) for the canonical realization. Then, by the same method, one proves that there is only one algebraically independent Casimir operator, the quadratic one

$$C' = -\tfrac{1}{2}\mathrm{Tr}(M'^2). \tag{3.26}$$

Its eigenvalues are denoted by

$$\text{for } D \geqslant d+1: \quad C' = k(k+D-d-1), \tag{3.27}$$

$$\text{for } D < d+1: \quad C' = k(k-D+d+1), \tag{3.28}$$

with $k=0,1,2...$. Note that the relation

$$C'=C+K^2, \tag{3.29}$$

where K^2 is positive definite, implies the inequality $k \geqslant l$ between the eigenvalues of C' and C.

IV. THE COULOMB PROBLEM IN SUPERSPACE $E(D|d)$

In this section we show that Pauli's method can be extended to an arbitrary superspace in the form of the quasicanonical realization of the superalgebra $\mathrm{osp}(D+1|d)$. The Coulomb problem in this superspace is defined by the Hamiltonian

$$H=\frac{1}{2}P^2-\frac{1}{R}, \tag{4.1}$$

where the inverse $1/R$ of the norm of R is

$$\frac{1}{R}=\frac{1}{r}-\frac{1}{2r^3}\Gamma^{\alpha\beta}\chi_\alpha\chi_\beta, \quad \text{where } r=|\mathbf{r}|. \tag{4.2}$$

The super angular momentum operator M in this superspace defined by

$$M_{ab}=R_aP_b-(-1)^{ab}R_bP_a, \tag{4.3}$$

forms the canonical realization of the $\mathrm{osp}(D|d)$ superalgebra. One can show that it is a constant of motion: $[H,M_{ab}]=0$, which means that the Coulomb problem has an $\mathrm{osp}(D|d)$ symmetry.

The extension of Pauli's method is made possible because of the existence of another constant of motion, namely the Runge–Lenz supervector defined by[14]

$$A_a=\frac{1}{2}\{M_{ab},P^b\}_s-\frac{R_a}{R}, \tag{4.4}$$

where $\{,\}_s$ is the super anticommutator. Use of the canonical supercommutation relation leads to $[H,A_a]=0$. Furthermore, one derives the supercommutation relations between the super angular momentum and the Runge–Lenz supervector components, namely

$$[M_{ab},A_c]_s=\frac{1}{i}(g_{bc}A_a-(-1)^{ab}g_{ac}A_b), \tag{4.5}$$

$$[A_a,A_b]_s=i(-2H)M_{ab}, \tag{4.6}$$

and the following relations that generalize the classical orthogonality condition:

$$\begin{aligned} &M_{ab}A_c+(-1)^{a(b+c)}M_{bc}A_a+(-1)^{c(a+b)}M_{ca}A_b=0,\\ &A_aM_{bc}+(-1)^{a(b+c)}A_bM_{ca}+(-1)^{c(a+b)}A_cM_{ab}=0. \end{aligned} \tag{4.7}$$

As in the classical case, there exists a relation between H and the constants of motion. A long calculation yields

$$A^2=1+(2H)(C+\tfrac{1}{4}(D-d-1)^2), \tag{4.8}$$

where C is the quadratic Casimir operator of $\mathrm{osp}(D|d)$ superalgebra. This expression relates the spectrum of H to the dimensions of the superspace and to the eigenvalues of A^2 and C. It is the generalization of Eq. (2.27).

It is now interesting to gather A_a and M_{ab} into a new super antisymmetric tensor operator $M'_{ab}=-(-1)^{ab}M'_{ba}$ the indices of which take their values in $E(D+1|d)$, i.e., $a=\{i=1,2,...,D+1;\alpha=1,...,d\}$. Assuming $H<0$, the tensor M'_{ab} is defined by

$$M'_{ab}=M_{ab} \quad \text{for} \quad a,b\in E(D|d),$$
$$M'_{a,D+1}=-M'_{D+1,a}=\frac{A_a}{\sqrt{-2H}}. \tag{4.9}$$

The tensor M'_{ab} forms the quasicanonical realization of the osp$(D+1|d)$ superalgebra described in the previous section and it is a constant of motion: $[H,M'_{ab}]=0$. The quadratic Casimir operator C' of this algebra is

$$C'=-\frac{1}{2}\,\mathrm{Tr}(M'^2)=C-\frac{A^2}{2H}. \tag{4.10}$$

Finally, relation (4.8) between H and the constants of motion yields the expression

$$H=-\frac{1}{2}\,\frac{1}{C'+(1/4)(D-d-1)^2}, \tag{4.11}$$

This relation is the direct generalization of Eq. (2.32). It yields the spectrum of H, when the Casimir operator C' is replaced by its eigenvalues given by Eqs. (3.27) and (3.28).

For $D\neq d+1$, in order to obtain expressions similar to the usual ones, we set $n=k+1$, with $n=1,2,...$ and we get

(i) for $D>d+1$

$$H=-\frac{1}{2}\,\frac{1}{(n+(1/2)(D-d-3))^2}, \tag{4.12}$$

and the eigenvalues of the square of the angular momentum operator are

$$C=l(l+D-d-2), \quad l=0,...,n-1. \tag{4.13}$$

(ii) for $D<d+1$

$$H=-\frac{1}{2}\,\frac{1}{(n+(1/2)(d-D-1))^2}, \tag{4.14}$$

and the eigenvalues of the square of the angular momentum operator are

$$C=l(l+2+d-D), \quad l=0,...,n-1. \tag{4.15}$$

For $D=d+1$, we set $n=k$ and we get

$$H=-\frac{1}{2}\,\frac{1}{n^2}, \tag{4.16}$$

and the eigenvalues of the square of the angular momentum operator are

$$C=l(l+1), \quad l=0,...,n-1. \tag{4.17}$$

For $d=0$, Eq. (4.12) yields the energy spectrum of the Coulomb problem in an ordinary D dimensional space.

V. CONCLUSION

In this paper we have shown how Pauli's method for the resolution of Coulomb problem can be extended to an arbitrary dimensional superspace. First we have written Pauli's method in a tensorial form suitable for generalization. Then, the canonical realization of the osp$(D|d)$ superalgebra has been built by means of differential operators and the quasicanonical realization of the osp$(D+1|d)$ superalgebra has been constructed by extension of the previous realization by a supervector operator. For the Coulomb problem, this supervector is the generalization of the

Runge–Lenz vector for the hydrogen atom. Finally, we have deduced the energy spectrum of the Coulomb problem in terms of the eigenvalues of the quadratic operator C' of the $\mathrm{osp}(D+1|d)$ superalgebra. This result is valid for spaces and superspaces with arbitrary dimension.

It is interesting to note that for the particular cases $D=d-1$, $d+1$, $d+3$ the energy spectrum is identical to that of the hydrogen atom. For superspaces, this last result has been confirmed by a direct calculation for the simplest superspace $E(1|2)$,[15] and for the smallest superspace that contains the ordinary $E(3)$ space, namely the superspace $E(3|2)$.[16]

(Received 4 February 1998; accepted for publication 1 July 1998)

We consider arbitrary splits of field operators into two parts; $\psi=\psi^{+}+\psi^{-}$, and use the corresponding definition of normal ordering introduced earlier [T. S. Evans and D. A. Steer, Nucl. Phys. B **474**, 481 (1996)]. In this case the normal ordered products and contractions have none of the special symmetry properties assumed in existing proofs of Wick's theorem. Despite this, we prove that Wick's theorem still holds in its usual form as long as the contraction is a *c*-number. Wick's theorem is thus shown to be much more general than existing derivations suggest, and we discuss possible simplifying applications of this result. © *1998 American Institute of Physics.* [S0022-2488(98)01911-2]

I. INTRODUCTION

Wick's theorem is at the core of perturbative calculations in the canonical operator approach to quantum field theory: on expansion of the *S*-matrix, it is used to relate time ordered products of field operators to normal ordered products and contractions.[1] Within the traditional definition of normal ordered products, the interaction picture field operators, $\psi(x)$, are split into positive $\psi^{(0+)}$ and negative $\psi^{(0-)}$ energy waves containing annihilation and creation operators, respectively:

$$\psi(x)=\psi^{(0+)}(x)+\psi^{(0-)}(x). \tag{1.1}$$

Normal ordering, $N^{(0)}[\bullet]$, then places the annihilation (creation) operators to the right (left), otherwise leaving the order of the operators unchanged. Hence the vacuum expectation values of normal ordered products are guaranteed to vanish,

$$\langle 0|N^{(0)}[\bullet]|0\rangle=0. \tag{1.2}$$

Calculations therefore proceed in a straightforward manner by simply taking the vacuum expectation value of the operator identity called Wick's theorem.

In the literature, Wick's theorem has been proved either through the use of a generating functional,[2–4] or by the manipulation of products of operators.[1,5–7] In both cases, an essential ingredient of the proof is the fact that the normal ordered products defined above are *symmetric* in the following sense. Let us denote the normal ordered product of n (possibly different) field operators $\psi_i:=\psi(x_i)$ evaluated at different space time points x_i by

$$N^{(0)}_{1,2,\ldots,n}:=N^{(0)}[\psi_1\psi_2\ldots\psi_n]. \tag{1.3}$$

Then since $[\psi^{(0+)}(x),\psi^{(0+)}(x')]_\sigma=[\psi^{(0-)}(x),\psi^{(0-)}(x')]_\sigma=0 \quad \forall x,x'$ (where $\sigma=+1$ for bosonic operators, and $\sigma=-1$ for fermionic ones), it follows that

$$N^{(0)}_{1,2,\ldots,n}=(-1)^p N^{(0)}_{a,b,\ldots,t}\forall n>0. \tag{1.4}$$

Here $a,b,\ldots,t$ is any permutation of 1,2,$\ldots,n$ and p is the number of times pairs of fermionic fields are interchanged in moving from an order 1,2,$\ldots,n$ to an $a,b,\ldots,t$ order of fields. Normal ordered products satisfying (1.4) are said to be *symmetric*. The reason why this symmetry is central to the existing derivations of Wick's theorem will be explained in detail in Sec. III below where we work with the generating functional approach. However, the following comments may help illustrate the reason. Recall that Wick's theorem relates time ordered products, normal ordered products and contractions. One way to prove this theorem[1,6] is to begin by considering a given order of times. The resulting (single) contribution from the time ordered product may then be shown to be equivalent to a combination of normal ordered products and contractions. *If* these normal ordered products and contractions are symmetric, then each contribution to the time ordered product takes the same form, and thus Wick's theorem is proved.[1,6] However, if they are *not symmetric*, this is no longer the case (see Sec. III).

In general, however, normal ordering with respect to annihilation and creation operators does *not* simplify calculations. As an example, consider how, in the presence of symmetry breaking, one must normal order with respect to new annihilation and creation operators related by a Bogoliubov transformation to the ones appearing in the field.[5,6]. This is equivalent to choosing to split the field in a different way from (1.1). A more recent example[8] was provided by a system in thermal equilibrium at a temperature T. There the thermal expectation value of a normal ordered product of creation and annihilation operators ($\hat{a}^\dagger$ and $\hat{a}$, respectively) no longer vanishes in the way that it did at $T=0$:

$$\langle\langle N^{(0)}[\hat{a},\hat{a}^\dagger]\rangle\rangle = n_{be}, \quad n_{fd} \neq 0. \tag{1.5}$$

(Here n_{be}, n_{fd} are the Bose–Einstein and Fermi–Dirac distributions, respectively.) As a result, perturbative calculations at finite T would not seem to be simplified by the use of Wick's theorem. This point has caused some confusion in the literature[6,9,10] and it was addressed in Ref. 8. There it was shown that Wick's theorem could be used in the usual way at finite temperature provided one split the field in a different way from the usual one into creation and annihilation operators (1.1).

Thus, in general, one must consider arbitrary splits of the field operators. The precise split used will reflect the physical environment of the problem if it is to simplify practical calculations in the usual way. We denote the arbitrary split by

$$\psi(x) = \psi^+(x) + \psi^-(x), \tag{1.6}$$

where $\psi^+(x)$ and $\psi^-(x)$ are unspecified in this paper, so that we can accommodate any physical problem. We still call the two parts ''positive'' and ''negative'' even though the split is general and no longer necessarily into positive and negative energy waves. The corresponding (natural) generalization of normal ordering is then expressed in terms of $\psi^+(x)$ and $\psi^-(x)$, and is defined as follows:

Normal ordering of products of fields, $N[\bullet]$, places all the ''positive'' parts to the right and the ''negative'' parts to the left, otherwise leaving the order of the fields unchanged. A sign change occurs whenever two fermion field operators are interchanged.

Note that this reduces to the usual definition, $N^{(0)}[\bullet]$, when the split is into the annihilation and creation operators appearing in the field. We have used the (0) superscript to denote this traditional and very special case. So, for example, in the two-point case one has

$$N[\psi_1\psi_2] := N_{1,2} = \psi_1^+\psi_2^+ + \psi_1^-\psi_2^+ + \sigma\psi_2^-\psi_1^+ + \psi_1^-\psi_2^-. \tag{1.7}$$

Such a generalization of normal ordering was successfully used for thermal field theory in Ref. 8, and is equivalent to discussions of normal ordering involving Bogoliubov transformations and symmetry breaking.[5,6] Contractions are then defined in the usual way through the two-point time ordered products which, being independent of the split, take the canonical form

$$T_{1,2} := T[\psi_1\psi_2] = \psi_1\psi_2\theta(t_1-t_2) + \sigma\psi_2\psi_1\theta(t_2-t_1). \tag{1.8}$$

(In general the θ functions may be defined for complex times and hence be contour dependent—as, for example, in Euclidean quantum field theory and thermal field theory.[2,11] Thus the time ordered products are also contour dependent. However, the analysis presented here holds regardless of contour.) Using (1.7) and (1.8) the contraction $D_{1,2}$ is

$$D_{1,2}=D[\psi_1,\psi_2]:=T_{1,2}-N_{1,2}=\theta(t_1-t_2)[\psi_1^+,\psi_2^-]_\sigma \tag{1.9}$$

$$-\theta(t_2-t_1)\{[\psi_1^+,\psi_2^+]_\sigma+[\psi_1^-,\psi_2^+]_\sigma+[\psi_1^-,\psi_2^-]_\sigma\}. \tag{1.10}$$

Now the key point is that for such arbitrary splits, the contraction and normal product are *not* generally symmetric: from (1.7) and (1.10) the condition for symmetry is

$$D_{1,2}=\sigma D_{2,1}, N_{1,2}=\sigma N_{2,1}\Leftrightarrow[\psi_1^+,\psi_2^+]_\sigma+[\psi_1^-,\psi_2^-]_\sigma=0, \tag{1.11}$$

which is not necessarily satisfied. If these two-point relations are true, then all higher order normal ordered products are symmetric in the sense of (1.4). This is only easy to prove if one has already proved that Wick's theorem holds independent of the symmetry of all normal ordered products!

It is conceivable that in some situations, for example systems out of equilibrium, calculations may be simplified by the use of a split for which the normal ordered products are not symmetric [i.e., (1.11) is not satisfied]. Indeed, out of equilibrium it may be possible to find a split such that (1.11) is true for specific times, but without time-translation symmetry it is doubtful that this split will ensure (1.11) will be true for all times. Wick's theorem, which relates normal ordered products (1.7), time ordered products (1.8), and contractions (1.10), has only been proved for the special case where the normal ordered products and contractions are symmetric. The question this paper asks then is: Does the usual form of Wick's theorem still hold when normal ordered products are not symmetric?

Our answer is yes. Wick's theorem is, in fact, more general than the existing proofs suggest, namely: *if the contraction is a c-number (and hence the split is linear in creation and annihilation operators), Wick's theorem holds for both symmetric and nonsymmetric normal ordered products.* Possible practical applications of this result, in particular to time dependent nonequilibrium systems, are discussed in the conclusions.

In Sec. II we derive the generating functional for Wick's theorem in terms of the generalized definition of normal ordering. We stress the places in which the nonsymmetry of products means that our derivation differs from others existing in the literature. In Sec. III we use the generating functional to obtain Wick's theorem. For symmetric products the proof is immediate—for nonsymmetric ones it is considerably more complicated. We finally summarize our work and also comment on a claim made in the original paper on thermal field theory by Matsubara.[9] Applications for our work are then discussed.

II. THE GENERATING FUNCTIONAL FOR WICK'S THEOREM

In this section we derive the generating functional for Wick's Theorem – that is, we prove the identity

$$T\left[\exp\left\{-i\int d^4x j(x)\psi(x)\right\}\right]=N\left[\exp\left\{-i\int d^4x j(x)\psi(x)\right\}\right]$$
$$\times\exp\left\{-\frac{1}{2}\int d^4x d^4y j(x)D[\psi(x)\psi(y)]j(y)\right\}. \tag{2.1}$$

Here $\int d^4x=\int dt\int d^3\mathbf{x}$, and the precise range of integration does not affect our arguments. For simplicity, we just consider bosonic fields. (Comments regarding fermionic fields will be made later.) Thus the $j(x)$'s are *c*-number sources and since Wick's theorem is used in perturbation theory, the field operators $\psi(x)$ are in the interaction picture. The normal ordered products $N[\bullet]$ and contraction $D[\psi(x)\psi(y)]$ have been defined above in terms of the arbitrary split of the fields into positive and negative parts; $\psi(x)=\psi^+(x)+\psi^-(x)$. Following the discussion in the previous section, we therefore make no assumptions about their symmetry properties. The first part of the proof presented here follows closely that of Refs. 2 and 3.

Recall that for two operators A and B

$$e^{A+B}=e^{A}e^{B}e^{(1/2)[B,A]} \tag{2.2}$$

if and only if

$$[A,[A,B]]=[B,[A,B]]=0. \tag{2.3}$$

Recall, too, that time ordering puts the larger times to the left, and so, for example, in the case of two operators $A(t_1)$ and $A(t_2)$ with $t_2>t_1$,

$$T[e^{A(t_1)+A(t_2)}]=e^{A(t_2)}e^{A(t_1)}=T[e^{A(t_1)}e^{A(t_2)}]. \tag{2.4}$$

We comment that a similar relation holds for any operation which places the two operators in a given order. This will be used for normal ordered products below in Eq. (2.11).

Consider the lhs of (2.1),

$$T[e^{-i\int dt\int d^3x j(x)\psi(x)}]:=T[e^{-i\int dt O(t)}]. \tag{2.5}$$

Let t_i and t_f denote the initial and final time. Divide the total time interval into N equal intervals with $\Delta t=(t_f-t_i)/N$ and

$$t_f=t_N>t_{N-1}>\cdots>t_1>t_0=t_i\,. \tag{2.6}$$

By definition,

$$\int_{t_i}^{t_f}dt\,O(t)=\lim_{N\to\infty}\Delta t\sum_{j=1}^{N}O(t_j). \tag{2.7}$$

So here,

$$\begin{aligned}T[e^{-i\int_{t_i}^{t_f}dtO(t)}]&=\lim_{N\to\infty}T[e^{-i\Delta t\Sigma_{j=1}^{N}O(t_j)}]\\&=\lim_{N\to\infty}[e^{-i\Delta tO(t_N)}e^{-i\Delta tO(t_{N-1})}\cdots e^{-i\Delta tO(t_1)}] \qquad (2.8)\\&=\lim_{N\to\infty}[e^{-i\Delta t\Sigma_{k=1}^{N}O(t_k)}e^{-(1/2)(\Delta t)^2\Sigma_{1<k<l<N}[O(t_l),O(t_k)]}]. \qquad (2.9)\end{aligned}$$

In going from (2.8) to (2.9) we have used (2.2), which is legitimate since $[O(t_l),O(t_k)]$ is a c-number. Note also that in this exponential $t_l>t_k$. Thus using the definition of $O(t)$, (2.9) gives

$$T[e^{-i\int d^4x j(x)\psi(x)}]=e^{-i\int d^4x j(x)\psi(x)}e^{-(1/2)\int d^4x\int d^4y\,\theta(x_0-y_0)j(x)[\psi(x),\psi(y)]j(y)}. \tag{2.10}$$

In order to relate the time ordered product in (2.10) to a normal ordered product, consider an arbitrary split of the fields into ''positive'' and ''negative'' parts introduced in (1.6) and the corresponding definition of normal ordering given in the previous section. Using (2.2), the first exponential on the rhs of (2.10) may be rewritten as

$$\begin{aligned}e^{-i\int d^4x j(x)\psi(x)}&=e^{-i\int d^4x j(x)\{\psi^-(x)+\psi^+(x)\}}\\&=e^{-i\int d^4x j(x)\psi^-(x)}e^{-i\int d^4x j(x)\psi^+(x)}e^{(1/2)\int d^4x\int d^4y j(x)[\psi^-(x),\psi^+(y)]j(y)}\\&=N[e^{-i\int d^4x j(x)\psi(x)}]e^{1/2\int d^4x\int d^4y j(x)[\psi^-(x),\psi^+(y)]j(y)}. \qquad (2.11)\end{aligned}$$

In obtaining (2.11) we have used (2.4) for normal ordered products, and (2.2), which requires that

$$[\psi^{\pm},[\psi^+,\psi^-]]=0. \tag{2.12}$$

This condition is satisfied if ψ^+ and ψ^- are linear in annihilation and creation operators, and in turn it ensures that the contraction is a *c*-number. Substituting (2.11) into (2.10) gives

$$T[e^{-i\int d^4x j(x)\psi(x)}]=N[e^{-i\int d^4x j(x)\psi(x)}]e^{-(1/2)\int d^4x\int d^4y j(x)\{\theta(x_0-y_0)[\psi(x),\psi(y)]-[\psi^-(x),\psi^+(y)]\}j(y)}. \tag{2.13}$$

Our proof now diverges from that given in the usual texts[2,3] since we are considering the possibility of having an *arbitrary* (unsymmetric) split of the fields rather than a (symmetric) one into annihilation and creation operators. Look at the part in curly brackets in the second exponential of (2.13); it is

$$\begin{aligned}
&\theta(x_0-y_0)[\psi(x),\psi(y)]-[\psi^-(x),\psi^+(y)]\\
&\quad=[\psi^+(y),\psi^-(x)]+\theta(x_0-y_0)\{[\psi^+(x),\psi^+(y)]+[\psi^-(x),\psi^+(y)]\\
&\qquad+[\psi^+(x),\psi^-(y)]+[\psi^-(x),\psi^-(y)]\}\\
&\quad=\theta(y_0-x_0)[\psi^+(y),\psi^-(x)]-\theta(x_0-y_0)\\
&\qquad\times\{[\psi^+(y),\psi^+(x)]+[\psi^-(y),\psi^+(x)]+[\psi^-(y),\psi^-(x)]\}\\
&\quad=D[\psi(y)\psi(x)],
\end{aligned} \tag{2.14}$$

where we have used the definition of the contraction in (1.10).

Thus, now substitute (2.14) into the final exponential of (2.13), relabel $x\leftrightarrow y$ and use the fact that the $j(x),j(y)$ are *c*-numbers to switch their positions. This enables (2.13) to be rewritten as

$$\begin{aligned}
T\left[\exp\left\{-i\int d^4x j(x)\psi(x)\right\}\right]&=N\left[\exp\left\{-i\int d^4x j(x)\psi(x)\right\}\right]\\
&\quad\times\exp\left\{-\frac{1}{2}\int d^4x d^4y j(x)D[\psi(x)\psi(y)]j(y)\right\},
\end{aligned} \tag{2.15}$$

thus proving (2.1). This equation is also true for fermionic operators. There the sources are Grassmann variables, and the contraction, defined in (1.10), contains anticommutators.

III. WICK'S THEOREM FOR NONSYMMETRIC PRODUCTS

Wick's theorem is obtained by functionally differentiating (2.15) with respect to the sources $j(x)$. Observe that we need only work with an even number of fields as the perturbation is about the expectation value of the fields, and hence the expectation value of an odd number of fields will always vanish.

Functionally differentiate (2.15) with respect to the sources $2n$ times and then set every $j(x_a)=j_a$ to zero. Since time-ordered products of fields evaluated at the same time points are undefined, the indices *a* refer to different space–time points and are therefore all different. The lhs of (2.15) gives

$$T\left[\frac{\delta}{\delta j_1\cdots\delta j_{2n}}\exp\{-ij\psi\}\right]\Big|_{j_a=0}=T\left[\frac{\delta}{\delta j_1\cdots\delta j_{2n}}\frac{(-ij\psi)^{2n}}{(2n)!}\right] \tag{3.1}$$

$$=\sum_{\text{perm}\{a\}}(-1)^p\frac{T_{a_1,a_2,\ldots,a_{2n}}}{(2n)!} \tag{3.2}$$

$$=T_{1,2,3,\ldots,2n}. \tag{3.3}$$

In (3.2) the sum takes $a_1,\ldots,a_{2n}$ through all permutations of 1,…,2*n*;

$$\text{perm}\{a\}=\begin{pmatrix}1&2&3&\cdots&2n\\a_1&a_2&a_3&\cdots&a_{2n}\end{pmatrix} \tag{3.4}$$

and p is the number of times one has to interchange pairs of fermions in moving from 1,…,2n to $a_1,\ldots,a_{2n}$ order. The last identity [going from (3.2) to (3.3)] follows from the fact that by definition time ordered products are symmetric in their indices, and that there are $(2n)!$ permutations of the numbers 1,2,…,2n. This type of manipulation will *not* hold for normal ordered products and contractions since they are *not*, in general, symmetric in their indices.

Carrying out a similar operation for the rhs of (2.15) gives a general form of Wick's theorem for nonsymmetric products:

$$T_{1,2,\ldots,2n}=\sum_{m=0}^{n}\sum_{\mathrm{perm\{a\}}}(-1)^p\left[\frac{N_{a_1,a_2,\ldots,a_{2m}}}{(2m)!}\cdot\frac{1}{(n-m)!}\left(\prod_{j=m+1}^{n}\frac{1}{2}D_{a_{2j-1},a_{2j}}\right)\right]. \tag{3.5}$$

In the traditional split of the fields into annihilation and creation operators, the normal ordered products $N^{(0)}_{1,2,\ldots}$ and contraction $D^{(0)}_{1,2}$ are *symmetric* as was discussed in Sec. I. As a result, the sum over permutations on the rhs of (3.5) can easily be evaluated and thus (3.5) rapidly reduces to the well known form of Wick's theorem. For two bosonic fields this is

$$T_{1,2}=N^{(0)}_{1,2}+D^{(0)}_{1,2}, \tag{3.6}$$

and for four bosonic fields

$$\begin{aligned}T_{1,2,3,4}=&N^{(0)}_{1,2,3,4}+D^{(0)}_{1,2}N^{(0)}_{3,4}+D^{(0)}_{1,3}N^{(0)}_{2,4}+D^{(0)}_{1,4}N^{(0)}_{2,3}+D^{(0)}_{2,3}N^{(0)}_{1,4}+D^{(0)}_{2,4}N^{(0)}_{1,3}\\&+D^{(0)}_{3,4}N^{(0)}_{1,2}+D^{(0)}_{1,2}D^{(0)}_{3,4}+D^{(0)}_{1,3}D^{(0)}_{2,4}+D^{(0)}_{1,4}D^{(0)}_{2,3}.\end{aligned} \tag{3.7}$$

Higher order relations follow the same pattern. Note that in the above expressions we have *chosen* to arrange the indices on any one given normal ordered product and contraction such that the smaller indices are to the left of the larger ones. In the case of symmetric products, this ordering is, of course, not important. However, it will also be used below where, starting from (3.5), we show that the above expressions [Eqs. (3.6) and (3.7)] hold even for *nonsymmetric* products N and D, *as long as the contraction is a c-number*. We again consider bosonic fields. The results below can be extended to fermionic fields by inserting a minus sign every time the positions of two fermionic fields are interchanged. The following relations and lemmas are useful for the proof.

A. Lemmas and relations

Lemma 1: Two-point normal ordered products and contractions are related by

$$N_{2,1}-N_{1,2}=D_{1,2}-D_{2,1}. \tag{3.8}$$

Proof: By definition of the contraction (1.9)

$$\begin{aligned}D_{1,2}-D_{2,1}=&\theta_{1,2}[\psi_1^+,\psi_2^-]-\theta_{2,1}\{[\psi_1^+,\psi_2^+]+[\psi_1^-,\psi_2^+]+[\psi_1^-,\psi_2^-]\}-\theta_{2,1}[\psi_2^+,\psi_1^-]\\&+\theta_{1,2}\{[\psi_2^+,\psi_1^+]+[\psi_2^-,\psi_1^+]+[\psi_2^-,\psi_1^-]\}\\=&[\psi_2^+,\psi_1^+]+[\psi_2^-,\psi_1^-]=N_{2,1}-N_{1,2},\end{aligned} \tag{3.9}$$

where $\theta_{1,2}=\theta(t_1-t_2)$ and where the last line follows directly from the definition of normal ordering (1.7).

Lemma 2: Let X and Y be arbitrary operators. Then if the contraction is a c-number,

$$N[X\psi_1\psi_2Y]=N[X\psi_2\psi_1Y]+(D_{2,1}-D_{1,2})N[XY]. \tag{3.10}$$

Proof: By definition

$$N[X\psi_1^+\psi_2^-Y]=N[X\psi_2^-\psi_1^+Y]\forall X,Y. \tag{3.11}$$

Therefore

$$
\begin{aligned}
N[X\psi_1\psi_2Y] &= N[X\psi_1^+\psi_2^+Y]+N[X\psi_1^+\psi_2^-Y]+N[X\psi_1^-\psi_2^+Y]+N[X\psi_1^-\psi_2^-Y] \\
&= N[X\psi_2^+\psi_1^+Y]+N[X\psi_2^-\psi_1^+Y]+N[X\psi_2^+\psi_1^-Y] \\
&\quad +N[X\psi_2^-\psi_1^-Y]+N[X[\psi_1^+,\psi_2^+]Y]+N[X[\psi_1^-,\psi_2^-]Y] \\
&= N[X\psi_2\psi_1Y]+(D_{2,1}-D_{1,2})N[XY], \qquad (3.12)
\end{aligned}
$$

provided $[\psi_1^+,\psi_2^+]$ and $[\psi_1^-,\psi_2^-]$ are *c*-numbers. This implies that both ψ^+ and ψ^- are linear in the creation and annihilation operators, and hence that *the contraction is a c-number*.

Relation 3: The number of ways of filling p indistinguishable bags each with exactly two marbles labeled $1,2,\ldots,2q$ *is precisely*

$$
[(2q)(2q-1)][(2q-2)(2q-3)]\cdots[(2q-2p+2)(2q-2p+1)]\frac{1}{p!}\frac{1}{2^p}=\frac{(2q)!}{(2q-2p)!2^p p!}. \qquad (3.13)
$$

Consequence 3.1: Let labels a_i's take values from $1,2,3,\ldots,2q$. The number of distinct configurations of p contractions $D_{a_1,a_2}D_{a_3,a_4}\cdots D_{a_{2p-1},a_{2p}}$ with unordered indices is given by (3.13).

Consequence 3.2: For a product of p contractions and one normal ordered product, with a total number of $2q$ indices; $N_{a_1,a_2,\ldots,a_{2q-2p}}D_{a_{2q-2p+1},a_{2q-2p+2}}\cdots D_{a_{2q-1},a_{2q}}$, the number of distinct configurations with unordered indices is again given by (3.13).

Using these, we now show that (3.6), (3.7) and the usual higher order version of Wick's theorem holds even for nonsymmetric normal ordered products and contractions, as long as the contraction is a *c*-number.

B. Proof for $n=1$

This is the easiest case. For $n=1$, (3.5) gives

$$
T_{1,2}=\tfrac{1}{2}(N_{1,2}+N_{2,1}+D_{1,2}+D_{2,1}). \qquad (3.14)
$$

Substituting (3.8) into (3.14) gives

$$
T_{1,2}=N_{1,2}+D_{1,2}, \qquad (3.15)
$$

showing that for $n=1$ (3.6) holds even for nonsymmetric normal ordered products and contractions. [This result is, of course, consistent with the definition of the contraction; from (1.9), $D_{1,2}:=T_{1,2}-N_{1,2}$ and similarly $D_{2,1}:=T_{2,1}-N_{2,1}=T_{1,2}-N_{2,1}$. Adding these two equations gives (3.14).]

C. Proof for $n=2$

For $n=2$, (3.5) gives

$$
\begin{aligned}
T_{1,2,3,4} &= \sum_{\text{perm}\{a\}}\sum_{m=0}^{2}\left[\frac{N_{a_1,a_2,\ldots,a_{2m}}}{(2m)!}\cdot\frac{1}{(2-m)!}\left(\prod_{j=m+1}^{2}\frac{1}{2}D_{a_{2j-1},a_{2j}}\right)\right] \\
&= \sum_{\text{perm}\{a\}}\left(\frac{1}{4!}N_{a_1,a_2,a_3,a_4}+\frac{1}{2!}\frac{1}{2}N_{a_1,a_2}D_{a_3,a_4}+\frac{1}{2!}\frac{1}{2}\frac{1}{2}D_{a_1,a_2}D_{a_3,a_4}\right) \\
&= \sum_{\text{perm}\{a\}}\frac{1}{4!}(N_{a_1,a_2,a_3,a_4}+6N_{a_1,a_2}D_{a_3,a_4}+3D_{a_1,a_2}D_{a_3,a_4}) \qquad (3.16) \\
&= \sum_{\text{perm}\{a\}}\frac{1}{4!}S_{a_1,a_2,a_3,a_4}, \qquad (3.17)
\end{aligned}
$$

where in (3.16) the first term corresponds to $m=2$, the second to $m=1$, and the third to $m=0$, and in (3.17) S_{a_1,a_2,a_3,a_4} will be defined later. Provided we choose S_{a_1,a_2,a_3,a_4} correctly (see below),

proof that $T_{1,2,3,4}$ is given by the usual expression [i.e., (3.7)] even for nonsymmetric N and D will then follow directly from (3.17) if we can show that the chosen S_{a_1,a_2,a_3,a_4} is symmetric under interchange of any two indices.

To do that, consider initially the second term of (3.16); $\Sigma_{\text{perm}\{a\}} 6N_{a_1,a_2}D_{a_3,a_4}$. The first important point to notice is that because of the sum over permutations, the order in which the a_i indices are written is irrelevant; for example,

$$\sum_{\text{perm}\{a\}} N_{a_1,a_2}D_{a_3,a_4} = \sum_{\text{perm}\{a\}} N_{a_1,a_3}D_{a_2,a_4}. \tag{3.18}$$

Second, the factor of 6 can be understood in the following way. From Consequence 3.2 we know that for a product of one normal ordered product and one contraction with a total of $2q=4$ indices, there are $4!/2!2=6$ distinct configurations with unordered indices. Thus we can rewrite the second term of (3.16) as a sum over the six distinct configurations with unordered indices:

$$\begin{aligned}\sum_{\text{perm}\{a\}} 6N_{a_1,a_2}D_{a_3,a_4} = \sum_{\text{perm}\{a\}} [&D_{a_1,a_2}N_{a_3,a_4}+D_{a_1,a_3}N_{a_2,a_4}+D_{a_1,a_4}N_{a_2,a_3}\\ &+D_{a_2,a_3}N_{a_1,a_4}+D_{a_2,a_4}N_{a_1,a_3}+D_{a_3,a_4}N_{a_1,a_2}].\end{aligned} \tag{3.19}$$

Note that since the indices on the contractions and normal ordered products are unordered, there was still some freedom in writing down the above expression. We have made the particular choice to write the a_i indices on each individual N and each individual D with the smallest value of i to the left. The reason for this will become clear later.

Now carry out a similar procedure for the third term of (3.16) involving the product of two contractions: the three terms arise from the three distinct configurations of two contractions with unordered indices (see Consequence 3.1), and we then chose to write the indices on each individual contraction such that the smallest value of i is to the left. Thus S_{a_1,a_2,a_3,a_4} in (3.17) is defined by

$$\begin{aligned}S_{a_1,a_2,a_3,a_4} := &N_{a_1,a_2,a_3,a_4}+D_{a_1,a_2}N_{a_3,a_4}+D_{a_1,a_3}N_{a_2,a_4}+D_{a_1,a_4}N_{a_2,a_3}\\ &+D_{a_2,a_3}N_{a_1,a_4}+D_{a_2,a_4}N_{a_1,a_3}+D_{a_3,a_4}N_{a_1,a_2}+D_{a_1,a_2}D_{a_3,a_4}\\ &+D_{a_1,a_3}D_{a_2,a_4}+D_{a_1,4}D_{a_2,a_3}.\end{aligned} \tag{3.20}$$

Hence we see that S_{a_1,a_2,a_3,a_4} is given by the rhs of (3.7), where instead of the symmetric normal ordered products and contractions one uses the more general nonsymmetric normal ordered products and contractions: this was the reason why (3.16) was decomposed as above.

To show that S_{a_1,a_2,a_3,a_4} is symmetric under the interchange of any two indices, consider a particular order of the indices, say, a,b,c,d, and then the effect of $a\leftrightarrow b$ say. Now

$$\begin{aligned}S_{a,b,c,d} = &N_{a,b,c,d}+D_{a,b}N_{c,d}+D_{c,d}(N_{a,b}+D_{a,b})+[D_{a,c}N_{b,d}+D_{b,c}N_{a,d}]\\ &+[D_{a,d}N_{b,c}+D_{b,d}N_{a,c}]+[D_{a,c}D_{b,d}+D_{a,d}D_{b,c}].\end{aligned} \tag{3.21}$$

The pairs of terms in square brackets are invariant under interchange $a\leftrightarrow b$. Now use (3.8) and (3.10) to show that the first line of (3.21) is also invariant under $a\leftrightarrow b$:

$$\begin{aligned}&N_{a,b,c,d}+D_{a,b}N_{c,d}+D_{c,d}(N_{a,b}+D_{a,b})\\ &\quad=N_{b,a,c,d}+(D_{b,a}-D_{a,b})N_{c,d}+D_{a,b}N_{c,d}+D_{c,d}(N_{b,a}+D_{b,a})\\ &\quad=N_{b,a,c,d}+D_{b,a}N_{c,d}+D_{c,d}(N_{b,a}+D_{b,a}).\end{aligned} \tag{3.22}$$

Thus $S_{a,b,c,d}=S_{b,a,c,d}$. One can prove more generally that $S_{a,b,c,d}$ is invariant under the interchange of any two adjacent indices and hence under any of the 4! permutations of the indices. Thus from (3.18) and (3.21) it follows that

$$T_{1,2,3,4}=N_{1,2,3,4}+D_{1,2}N_{3,4}+D_{1,3}N_{2,4}+D_{1,4}N_{2,3}+D_{2,3}N_{1,4}+D_{2,4}N_{1,3}$$
$$+D_{3,4}N_{1,2}+D_{1,2}D_{3,4}+D_{1,3}D_{2,4}+D_{1,4}D_{2,3}. \tag{3.23}$$

Hence, both at the two- and four-point levels, the usual form of Wick's theorem holds even if the contraction and normal ordered product are not symmetric.

D. Proof for arbitrary *n*

At the *n*th order, the proof is a generalization of that given above for $n=2$. However, before proceeding, we use some of the expressions encountered in the previous subsection to motivate the introduction of two new pieces of notation.

The first enables us to write the terms appearing in square brackets on the rhs of (3.19) in a much more compact way. Recall that in this square bracket (which we now denote by Q), the i subscript on *each* normal ordered product and on each contraction is arranged in increasing order going from left to right. The simplest case is when $a_1=1$, $a_2=2$, $a_3=3$ and $a_4=4$. Then Q is given by

$$Q=D_{1,2}N_{3,4}+D_{1,3}N_{2,4}+D_{1,4}N_{2,3}+D_{2,3}N_{1,4}+D_{2,4}N_{1,3}+D_{3,4}N_{1,2}. \tag{3.24}$$

However, we can rewrite this as

$$Q=\sum_{\mathrm{perm}\{b\}\in B} D_{b_1,b_2}N_{b_3,b_4}, \tag{3.25}$$

where the sum over permutations of $\{b\}$ is *restricted* to include only those permutations which are an element of the set B defined by

$$B=\{\mathrm{perm}\{b\}:b_1<b_2,b_3<b_4\}. \tag{3.26}$$

[It is possible to check that (3.25) indeed reduces to (3.24).] If we now return to the case in which the a_i's are arbitrary, then Q is given by

$$Q=\sum_{\mathrm{perm}\{b\}\in B} D_{a_{b_1},a_{b_2}}N_{a_{b_3},a_{b_4}}, \tag{3.27}$$

where B is defined as in (3.26).

We now introduce the second piece of notation whose aim is to enable one to rewrite expressions such as (3.27) in a slightly simpler way (with fewer subscripts). Define

$$N(a_1,a_2,\ldots,a_{2n}):=N_{a_1,a_2,\ldots,a_{2n}},$$
$$D(a_1,a_2):=D_{a_1,a_2}. \tag{3.28}$$

As an example of the use of this notation, use (3.27) and (3.28) to rewrite (3.19) as

$$\sum_{\mathrm{perm}\{a\}} 6D(a_1,a_2)N(a_3,a_4)=\sum_{\mathrm{perm}\{a\}}\sum_{\mathrm{perm}\{b\}\in B} D(a_{b_1},a_{b_2})N(a_{b_3},a_{b_4}). \tag{3.29}$$

We now continue with the proof of Wick's theorem to *n*th order.

Step 1. For a given value of *m*, the rhs of (3.5) can be rewritten as a sum over distinct configurations of *N*'s and *D*'s, with the indices on each individual *N* and each individual *D* arranged in increasing order going from left to right [compare with (3.29)]. To do that, use Lemma 4.

Lemma 4: The following identity holds,

$$\frac{(2n)!}{(2m)!(n-m)!2^{n-m}}\sum_{\mathrm{perm}\{a\}} N(a_1,a_2,\ldots,a_{2m})\prod_{j=m+1}^{n} D(a_{2j-1},a_{2j})$$

$$=\sum_{\mathrm{perm}\{a\}}\sum_{\mathrm{perm}\{b\}\in B} N(a_{b_1},a_{b_2},\ldots,a_{b_{2m}})\prod_{j=m+1}^{n} D(a_{b_{2j-1}},a_{b_{2j}}), \tag{3.30}$$

where

$$\mathrm{perm}\{b\}=\begin{pmatrix}1 & 2 & 3 & \ldots & 2n\\ b_1 & b_2 & b_3 & \ldots & b_{2n}\end{pmatrix}, \tag{3.31}$$

and the restriction on the sum of permutations of $\{b\}$ *is such that (1) it arranges the indices on each individual normal ordered product and on each individual contraction in increasing order going from left to right, and (2) it orders the contractions by size of the leading element so as to avoid repetition of* $D_{1,2}D_{3,4}\cdots$ *as* $D_{3,4}D_{1,2}\cdots$:

$$B=\left\{\mathrm{perm}\{b\}:\begin{bmatrix} b_1<b_2<\cdots<b_{2m}\\ b_{2m+1}<b_{2m+2}\\ b_{2m+3}<b_{2m+4}\\ \ldots\\ b_{2n-1}<b_{2n}\end{bmatrix};b_{2m+1}<b_{2m+3}<\ldots<b_{2n-1}\right\}. \tag{3.32}$$

Proof: From Relation 3, for a product of $n-m$ contractions and one normal ordered product with a total of $2n$ indices, there are $(2n)!/(2m)!(n-m)!2^{n-m}$ distinct configurations with unordered indices. These distinct configurations are represented by the sum over permutations of the b labels. On a given contraction or normal ordered product, the order of the indices is arbitrary, but above the choice has been made by the restriction.

Step 2. Using Lemma 4, rewrite the rhs of (3.5) as

$$T_{1,2,\ldots,2n}=\frac{1}{(2n)!}\sum_{\mathrm{perm}\{a\}}\left[\sum_{m=0}^{n}\sum_{\mathrm{perm}\{b\}\in B} N(a_{b_1},a_{b_2},\ldots,a_{b_{2m}})\prod_{j=m+1}^{n} D(a_{b_{2j-1}},a_{b_{2j}})\right]$$

$$=:\frac{1}{(2n)!}\sum_{\mathrm{perm}\{a\}} S(\{a\}). \tag{3.33}$$

This is a generalization of (3.20) to arbitrary n.

Step 3. Use Lemmas 1 and 2 to show the following lemma.

Lemma 5: For any two permutations, $\{a\}$ *and* $\{a'\}$

$$S(\{a\})=S(\{a'\}). \tag{3.34}$$

Proof: Consider two permutations related by $\{a\}\to\{a'\}$ with

$$a_i=a'_{i+1},\quad a_{i+1}=a'_i,\quad a_j=a'_j\,\forall\, j\neq i,i+1. \tag{3.35}$$

The only nonzero contributions to $\Delta:=S(\{a\})-S(\{a'\})$ arise when *both* the indices a_i and a_{i+1} are *either* on the same normal ordered product, or on the *same* contraction. The reason is that when these indices occur on different normal ordered products or contractions, the restriction on the sum of permutations of $\{b\}$ orders the terms in exactly the same way in both the $\{a\}$ and $\{a'\}$ permutation thus making Δ vanish. [These terms are the generalization of those in square brackets in (3.21).]

Thus we may write

$$S(\{a\})-S(\{a'\})=\sum_{m=0}^{n}{\sum_{\mathrm{perm}\{b\}\in B}}'[N(a_{b_1},a_{b_2},\ldots,a_{b_{2m}})$$

$$-N(a'_{b_1},a'_{b_2},\ldots,a'_{b_{2m}})]\prod_{j=m+1}^{n}D(a_{b_{2j-1}},a_{b_{2j}}) \tag{3.36}$$

$$+\sum_{m=0}^{n}{\sum_{\mathrm{perm}\{b\}\in B}}''N(a_{b_1},a_{b_2},\ldots,a_{b_{2m}})[D(a_i,a_{i+1})$$

$$-D(a'_i,a'_{i+1})]\prod_{\substack{j=m+1\\ j\neq k}}^{n}D(a_{b_{2j-1}},a_{b_{2j}}). \tag{3.37}$$

Here the prime on the sum in (3.36) means that the sum over permutations of $\{b\}$ is further restricted by the condition that $(i,i+1)\in\{b_1,b_2,\ldots,b_{2m}\}$. (Thus it guarantees that the indices a_i and a_{i+1} only occur on the N and *not* on the D's.) In (3.37), the double prime means that this sum is further restricted to have $\{i,i+1\}=\{b_{2k-1},b_{2k}\}$ for some $k>m$, and this is the reason for which the contribution with $(j=k)$ is excluded in the product. (Hence the double prime on the sum ensures that the indices a_i and a_{i+1} both occur on a single D.)

Noting that when $m=0$ there are no contributions to (3.36) (since it involves no normal ordered products), and using Lemma 2, (3.36) may be rewritten as

$$\begin{aligned}
&\sum_{m=0}^{n}{\sum_{\mathrm{perm}\{b\}\in B}}'[N(a_{b_1},a_{b_2},\ldots,a_i,a_{i+1},\ldots,a_{b_{2m}})\\
&\quad-N(a'_{b_1},a'_{b_2},\ldots,a'_i,a'_{i+1},\ldots,a'_{b_{2m}})]\prod_{j=m+1}^{n}D(a_{b_{2j-1}},a_{b_{2j}})\\
&\quad=\sum_{m=1}^{n}\sum_{\mathrm{perm}\{c\}\in B}N(a_{c_1},a_{c_2},\ldots,a_{c_{2m-2}})[D(a_{i+1},a_i)-D(a_i,a_{i+1})]\prod_{j=m}^{n-1}D(a_{c_{2j-1}},a_{c_{2j}})\\
&\quad=\sum_{p=0}^{n-1}\sum_{\mathrm{perm}\{c\}\in B}N(a_{c_1},\ldots,a_{c_{2p}})[D(a_{i+1},a_i)-D(a_i,a_{i+1})]\prod_{j=p+1}^{n-1}D(a_{c_{2j-1}},a_{c_{2j}}),
\end{aligned} \tag{3.38}$$

where $p=m-1$, $c_j=b_j$ for $j<i$ and $c_j=b_{j+2}$ for $j\geqslant i$.

The second term of Eq. (3.37) vanishes for $m=n$ (as then it contains no contractions) and thus it can be rewritten as

$$\begin{aligned}
&\sum_{m=0}^{n}{\sum_{\mathrm{perm}\{b\}\in B}}''N(a_{b_1},a_{b_2},\ldots,a_{b_{2m}})[D(a_i,a_{i+1})-D(a'_i,a'_{i+1})]\prod_{\substack{j=m+1\\ j\neq k}}^{n}D(a_{b_{2j-1}},a_{b_{2j}})\\
&\quad=\sum_{m=0}^{n-1}{\sum_{\mathrm{perm}\{b\}\in B}}''N(a_{b_1},\ldots,a_{b_{2m}})[D(a_i,a_{i+1})-D(a_{i+1},a_i)]\prod_{\substack{j=m+1\\ j\neq k}}^{n}D(a_{b_{2j-1}},a_{b_{2j}}).
\end{aligned} \tag{3.39}$$

Recalling the definition of the c's, it is now possible to see that (3.38) and (3.39) just differ by a sign, and thus from (3.37) we have proved that $\Delta=S(\{a\})-S(\{a'\})=0$. Hence Δ vanishes for *any* two permutations.

Step 4. Since $S(\{a\})=S(\{a'\})$ for any two permutations $\{a\}$ and $\{a'\}$, then from (3.33) one has

$$T_{1,2,\ldots,2n}=\frac{1}{(2n)!}\sum_{\mathrm{perm}\{a\}} S(\{a\})=S(\{a\}), \tag{3.40}$$

where $S(\{a\})$ is just given by the usual form of Wick's theorem with the ordered indices. This finishes the proof that Wick's theorem holds in its usual form for nonsymmetric normal ordered products and contractions, *provided* the contraction is a *c*-number.

IV. CONCLUSIONS

In this paper we have worked with a general split of the field operators into two parts and the corresponding nonsymmetric normal ordered products and contractions. We have shown that, somewhat surprisingly, Wick's theorem still holds in its usual form for such nonsymmetric products as long as the contraction is a *c*-number. As a result, Wick's theorem—an important calculational tool in field theory—is more general than was originally thought.

We now comment on another interesting idea inspired by the discussion of Wick's theorem in the original paper on thermal field theory by Matsubara.[9] There, the definition of the contraction given for bosonic relativistic phonon field is *always symmetric* for all splits, and consistent with another definition of normal ordering $N^{(T)}[\bullet]$;

$$N^{(T)}[\psi_1\psi_2\ldots\psi_n]=N[T[\psi_1\psi_2\ldots\psi_n]]. \tag{4.1}$$

Note that $N^{(T)}[\bullet]$ is distinct from $N[\bullet]$, the definition of normal ordering which was given in Sec. I and was used throughout this paper: by definition $N^{(T)}$ is always symmetric in the sense of (1.4) because of the way it is built out of the time-ordered product [hence our designation with a (T) superscript[12]]. It therefore gives a corresponding symmetric contraction

$$D^{(T)}[\psi_1,\psi_2]=T_{12}-N^{(T)}_{12}=\theta(t_1-t_2)[\psi_1^+,\psi_2^-]_\sigma+\sigma\theta(t_2-t_1)[\psi_2^+,\psi_1^-]_\sigma. \tag{4.2}$$

It is clear that there are, in fact, many possible splits of the field which may be used to define normal ordering, and even then the definition of $N^{(T)}$ shows that one can think of other definitions of normal ordering different from the N given in Sec. I. Whichever definition is used, we have shown that even if the normal ordered product is not symmetric and the contraction is a *c*-number, Wick's theorem can be used so that calculations are not too cumbersome.

In practice the only definite cases we know of have symmetric normal ordered products. Symmetry breaking problems expressed in terms of Bogoliubov transformations[5,6] and equilibrium thermal field theory, whether using path-ordered methods[8] or thermo field dynamics,[13] all use our definition of N but have symmetric products. It is easy to see why symmetric products are so common; it is because the most useful normal ordered product is one which has zero expectation value. Thus taking the expectation value of Wick's theorem implies that the *c*-number contraction must then be symmetric (since it is then equal to the expectation value of the two-point time ordered function). In turn the operator version of Wick's theorem now shows that the normal ordered operator must itself be symmetric.

However, there is at least one situation where we might envisage the appearance of nonsymmetric products, and that is nonequilibrium field theory. In this case the environment is changing with time so we should expect the split, and hence the normal ordered products, also to change in time. It is then not at all obvious whether one can ever define normal ordered products of fields at different times which have zero physical expectation values. Thus, reversing the argument of the previous paragraph, it is not at all clear that symmetric products will simplify the calculations, and therefore it is reasonable that nonsymmetric products may prove to be a useful tool.

[12] Only by using $N^{(T)}$ rather than our N for the normal ordering can the derivation of Wick's theorem given in the appendix of Matsubara (Ref. 9) be of use, as it is only given for a particular time ordering and requires symmetry arguments if one is to apply it for all possible time orderings. However, the definition of normal ordering for phonons given in the main text of Ref. 9 is, in fact, our $N[\bullet]$! Thus it is *not* consistent with the definition of the contraction in the main text, nor with the proof of Wick theorem proof in the appendix, whereas the $N^{(T)}$ definition (4.1) is consistent.

A group-theoretical description of N identical harmonic oscillators on a line is presented. It provides a scheme for labeling the energy eigenstates that are invariant under the permutation group S_N and for obtaining the symmetric operators that transform these degenerate eigenfunctions among themselves. The symmetry algebra that these generators form is in general polynomial. The 2- and 3-particle cases are considered in detail. For the simple 2-body problem the invariance algebra is found to be the cubic SU(2) algebra: $[J_0,J_\pm]=\pm J_\pm$, $[J_+,J_-]=2J_0-\alpha J_0^3$. In the 3-body case, the permutational invariant states are characterized with the help of the subgroup chain $U(3)\supset U(2)\supset O(2)$. The labeling and step operators are obtained from determining an integrity basis for the S_3 scalar in $\mathcal{U}(U(3))$. Generating functions techniques are used to that end; an eight-dimensional basis is found whose elements span the symmetry algebra of the three identical oscillator problem. These constants of motion are seen to generate a nonlinear algebra whose representation on the symmetric states is provided. © *1998 American Institute of Physics.* [S0022-2488(98)02007-6]

I. INTRODUCTION

There is sustained interest for integrable N-particle systems, in particular because of the light they throw on quantum many-body physics. In such models, the statistical properties of the systems are accounted for by the transformation laws of the wave functions under permutations of the N-particle coordinates. In the case of bosons for instance, these functions should be invariant under all the elements of the symmetric group S_N of permutations of N objects.

Quite often, the Hamiltonians of such integrable models admit a fairly large invariance algebra. It is then natural to ask how can this dynamical algebra be used on the one hand, to obtain quantum numbers that characterize those states of the system behaving appropriately under S_N and, how can it be exploited on the other hand, to find operators that transform those states among themselves. This is the problem that we consider here in a most simple and fundamental context, namely, that of a system of N-identical Bose oscillators on the line. As is well known, the Hamiltonian for a collection of independent harmonic oscillators is invariant under SU(N). We shall only consider the case of bosonic quantum excitations. The physical wave functions of the system will therefore be those that are completely symmetric under the exchange of the N-particle coordinates. Now, it so happens that the generators of the SU(N) invariance group (except for one) do not transform the symmetric states onto themselves. These states thus cannot be adequately labeled by the eigenvalues of a subset of the SU(N) algebra elements, say the Cartan generators, as is customarily done to identify the basis vectors of SU(N) representation spaces. Here one turns instead to the enveloping algebra $\mathcal{U}(SU(N))$ of SU(N) to find, as we shall show, a complete set of commuting S_N-invariant operators whose eigenvalues provide the desired quantum numbers. We shall see in addition that $\mathcal{U}(SU(N))$ also contains S_N-invariant ladder operators that transform irreducibly among themselves the symmetric wave functions with common eigenenergies. These operators are moreover found to generate polynomial algebras; for instance, when $N=2$, they realize the following SU(2) polynomial algebra:[1–6]

$$[J_0,J_\pm]=\pm J_\pm, \quad [J_+,J_-]=2J_0-\alpha J_0^3. \tag{1.1}$$

 © 1998 American Institute of Physics

Owing to the ubiquity of harmonic oscillators in the description of physical phenomena, these basic results should prove useful.

Analyses bearing some connection with the one presented here have been carried out in the past. Some 30 years ago, the kinematics of nonrelativistic free particles was studied[7–9] in a fashion close to the approach used here for oscillators. The aim was to construct complete sets of observables that would lead to a classification of states where all the N particles are treated on an equal footing. The key observation there is that in d dimensions, after separation of the center of mass, the reduced Hamiltonian is invariant under $\mathrm{SO}(dN-d)$. This was then exploited to obtain labeling operators with definite transformation laws under S_N and such that their common eigenvectors enjoy simple symmetry properties under permutations. In the case of three particles, this has led[7] to a classification of states according to SU(3) which proved most useful to perform harmonic analyses on the Dalitz plot and to describe 3-body decays such as $K^+ \to \pi^+ \pi^+ \pi^-$. An important difference that distinguishes these studies from the one presented in this paper is that the dynamical group of a collection of oscillators is much larger than the kinematical group of a set of free particles.

Closer to our analysis are the extensive studies by nuclear theorists of the group theory of harmonic oscillators in the context of the shell, collective, and cluster model. In Ref. 10 for instance, the problem of constructing N-particle oscillator states with permutational symmetry is reviewed. The authors discuss the physical situation where the states of N three-dimensional oscillators are characterized by irreducible representations of $\mathrm{U}(3)\times\mathrm{U}(N)$. In the case where the particles interact via 2-body harmonic forces, they use the chain of groups $\mathrm{U}(N)\supset\mathrm{U}(N-1)\supset\mathrm{O}(N-1)$ to classify the states with permutational symmetry. While this chain will also arise in our work, the context is rather different: We do not consider the translational invariant system of N 3-D oscillators but instead, the one consisting of N 1-D particles in harmonic potentials. More importantly, the focus is not the same as we aim to find the ladder operators that transform the symmetric N-oscillator states among themselves in order to identify the dynamical algebra of these N-identical bosons on the line.

The paper is organized as follows. In Sec. II, we provide a general presentation of how the symmetric states of N-harmonic oscillators on the line can be described with the help of $\mathrm{SU}(N)$. Sections III and IV are, respectively, devoted to the specifics of the 2- and 3-particle special cases. The paper ends with a discussion of how the present work could be extended and generalized.

II. THE GENERAL SCHEME

A. *N*-harmonic oscillators on the line and SU(*N*)

We shall consider systems consisting of N-identical harmonic oscillators with coordinate x_i, $i=1,...,N$ in one dimension whose quantum Hamiltonians are given by

$$H^{(N)}=\frac{1}{2}\sum_{i=1}^{N}\left[-\frac{\partial^2}{\partial x_i^2}+x_i^2\right]. \tag{2.1}$$

Their masses and frequencies have been set to one (the superscript on H specify the number of oscillators). Upon introducing the creation and annihilation operators a_i^+ and a_i, $i=1,...,N$, respectively

$$a_i=\frac{1}{\sqrt{2}}\left(x_i+\frac{\partial}{\partial x_i}\right), \quad a_i^+=\frac{1}{\sqrt{2}}\left(x_i-\frac{\partial}{\partial x_i}\right). \tag{2.2}$$

$H^{(N)}$ is rewritten in the familiar quadratic form

$$H^{(N)}=\sum_{i=1}^{N} a_i^+ a_i+\frac{N}{2}. \tag{2.3}$$

The operators a_i and a_i^+, $i=1,...,N$, obey the commutation relations

$$[a_i,a_j^+]=\delta_{ij}, \quad [a_i,a_j]=[a_i^+,a_j^+]=0 \tag{2.4}$$

and verify

$$[H^{(N)},a_i]=-a_i, \quad [H^{(N)},a_i^+]=a_i^+ . \tag{2.5}$$

The invariance algebra of $H^{(N)}$ is readily identified as follows. Let

$$J_{ij}=a_i^+ a_j, \quad i,j=1,...,N. \tag{2.6}$$

Owing to the equations of motion (2.5), these N^2 operators are immediately seen to be constants of motion

$$[H^{(N)},J_{ij}]=0, \tag{2.7}$$

and they are found to realize the commutation relations of the U(N) algebra

$$[J_{ij},J_{kl}]=\delta_{jk}J_{il}-\delta_{il}J_{kj}. \tag{2.8}$$

Apart from the Hamiltonian $H^{(N)}=\Sigma_{i=1}^N J_{ii}+N/2$ which is central, we thus have N^2-1 independent operators generating a SU(N) invariance group. The eigenstates of $H^{(N)}$ are built through repeated action of the creation operators on the ground state wave function ϕ_0 which satisfy

$$a_i\phi_0=0; \quad i=1,...,N; \quad H^{(N)}\phi_0=\frac{N}{2}\,\phi_0. \tag{2.9}$$

They read

$$\phi(n_1,\ldots,n_N)=\prod_{i=1}^N \frac{(a_i^+)^{n_i}}{\sqrt{n_i!}}\,\phi_0 \tag{2.10}$$

and in view of (2.5) obey

$$H^{(N)}\phi(n_1,\ldots,n_N)=\left[|n|_N+\frac{N}{2}\right]\phi(n_1,\ldots,n_N) \tag{2.11}$$

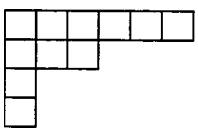
with

$$|n|_N=n_1+\cdots+n_N. \tag{2.12}$$

Clearly, the U(N) generators transform the eigenstates with the same energy among themselves and thus account for the degeneracies:

$$J_{kl}\phi(n_1,\ldots,n_k,\ldots,n_l,\ldots,n_N)=\sqrt{(n_k+1)n_l}\,\phi(n_1,\ldots,n_k+1,...,n_l-1,...,n_N). \tag{2.13}$$

The irreducible representations of U(N) (like those of the symmetric group S_N) are labeled by partitions, that is sets $\lambda=(\lambda_1,\lambda_2,\ldots,)$ of ordered non-negative integers: $\lambda_1\geqslant\lambda_2\geqslant\cdots$. It is customary to represent partitions by Young diagrams which are of the form



with λ_1 boxes in the first row, λ_2 boxes in the second, etc. The representations of U(N) that the oscillators realize are the fully symmetrized tensor products of the fundamental representation. These irreducible representations are associated to partitions $\lambda=(|n|_N)$ with only one part, or to diagrams of the form

 (2.14)

The vectors of the canonical bases for U(N) modules are eigenfunctions of the Casimir operators of U(N) and of all the Casimir operators of the following chain of subgroups:

$$\mathrm{U}(N)\supset \mathrm{U}(N-1)\supset\cdots\supset \mathrm{U}(1). \tag{2.15}$$

This ensures that the basis vectors also span representation spaces for all the subgroups in the chain. In the case of the oscillators, since the representation of U(N) is specified by only one number $|n|_N$, it is superfluous to diagonalize all Casimir operators. The reduction to subgroups is characterized by diagonalizing the Hamiltonians $H^{(N-1)},H^{(N-2)},\ldots$ which specify through the partitions $|n|_{N-1},|n|_{N-2},\ldots$, the irreducible representations of U($N-1$), U($N-2$),… that are contained in the original U(N) representation. Note that this is tantamount to giving the occupation numbers $n_1,n_2,\ldots,n_N$ since $n_1=|n|_1$, $n_2=|n|_2-|n|_1$, $n_3=|n|_3-|n|_2$, etc., and that this does therefore characterize the states (2.11).

It should be stressed immediately though, that the wave functions (2.10) are not appropriate for a system of N indistinguishable bosons since most of these do not have the required symmetry property under the exchange of the particle coordinates.

At times, we shall use the Bargmann–Fock representation in which the creation and annihilation operators act on holomorphic functions of the variables z_i, $i=1,...,N$ and are realized by

$$a_i=\frac{\partial}{\partial z_i},\quad a_i^+=z_i. \tag{2.16}$$

In this realization, $H^{(N)}$ takes the form of the Euler operator

$$H^{(N)}=\sum_{i=1}^{N} z_i\,\frac{\partial}{\partial z_i}+\frac{N}{2}, \tag{2.17}$$

its eigenvalues are monomials

$$\phi(n_1,\ldots,n_N)=\prod_{i=1}^{N}\frac{z_i^{n_i}}{\sqrt{n_i!}} \tag{2.18}$$

and the U(N) generators read $J_{ij}=z_i(\partial/\partial z_j)$.

B. S_N-invariant oscillator states

The symmetric group S_N acts in a natural way on the dynamical variables; under the transpositions $\sigma_{ij}=\sigma_{ji}$, $(\sigma_{ij})^2=1$, which generate S_N, a_i and a_i^+ transform as follows:

$$\sigma_{ij}a_i=a_j\sigma_{ij},\quad \sigma_{ij}a_i^+=a_j^+\sigma_{ij}. \tag{2.19}$$

In the framework of the bosonic realization of U(N), this entails a representation of S_N on this algebra. Clearly, the Hamiltonian is invariant under S_N: $\sigma_{ij}H=H\sigma_{ij}\forall i,j$, and hence, the Hilbert space of state vectors decomposes into irreducible S_N modules. We are interested in the eigensubspaces consisting of states that are totally symmetric under the exchanges of particle coordinates and have the same energy. We want to find the symmetry generators that transform these degenerate symmetric states among themselves and for that, wish to exploit the fact that SU(N) is the symmetry algebra of the Hamiltonian when no symmetry restrictions are imposed.

We first need to label the eigenstates conveniently. A standard characterization is achieved by arranging the occupation numbers $n_1,\ldots,n_N$ in a nondecreasing sequence $n_{\kappa_1}\geqslant n_{\kappa_2}\geqslant\cdots\geqslant n_{\kappa_N}$, that is, in a partition of $|n|_N=n_{\kappa_1}+\cdots+n_{\kappa_N}$. The partitions $n=(n_{\kappa_1},\ldots,n_{\kappa_N})$ of $|n|_N$ (or their associated diagrams) can then be used to enumerate the vectors of a basis for the symmetric N-oscillators states as follows:

$$\phi_n=\sum_{\substack{\text{distinct}\\ \text{permutations}}}\prod_{i=1}^{N}\frac{(a_i^+)^{n_{\kappa_i}}}{\sqrt{n_{\kappa_i}!}}\,\phi_0. \tag{2.20}$$

Let $I_l=\Sigma_i(J_{ii})^l$, $l=1,...,N$. The symmetric functions ϕ_n are characterized by the fact that they are the simultaneous eigenstates of these operators

$$I_l\phi_n=\left(\sum_i n_{\kappa_i}^l\right)\phi_n. \tag{2.21}$$

Natural as it might be, this basis does not, nevertheless, lend itself easily to the algebraic analysis that we want to perform since the transformation properties under U(N) of the vectors ϕ_n are not well known. In fact, representations of U(N) are typically constructed using basis states that are labeled by the eigenvalues of the Casimir operators associated with chains of continuous subgroups of U(N). The functions ϕ_n are not of that type. We shall therefore use another basis and a different set of quantum numbers for the S_N-invariant oscillator states.

What follows is a general description of how a basis which is convenient for our purposes can be characterized, and of how the corresponding ladder operators can be obtained. (The cases $N=2,3$ will be worked out in detail in Secs. III and IV, respectively.) We need a complete set of commuting symmetric operators to label the basis states. The first place to look is in the U(N) algebra itself. Usually, one diagonalizes the Cartan generators, this will not do here, however, since these operators are not symmetric. In fact, there are only two S_N-invariant operators in the bosonic realization of U(N): the Hamiltonian $H^{(N)}$ and

$$K=\sum_{\substack{i,j\\ i\neq j}} J_{ij}. \tag{2.22}$$

We shall demand that the basis states be eigenfunctions of this Hermitian operator. Given the symmetry requirements, this choice will pretty much determine the set of labeling operators. To supplement K with operators that commute with it, we consider the centralizer $C_K(\mathrm{U}(N))$ of K in U(N), in other words, the set of U(N) elements that commute with K. None of these operators are symmetric though (excluding of course H and K), so we turn to the enveloping algebra $\mathscr{U}(C_K(\mathrm{U}(N)))$ of C_K and look there for the required S_N-invariant elements (which are guaranteed to commute with K). The labeling generators that we will obtain in this way will provide quantum numbers related to those of familiar U(N) modules. As for the ladder operators, they will be taken among the S_N-invariant operators in $\mathscr{U}(\mathrm{U}(N))$ that do not lie in $\mathscr{U}(C_K)$.

In order to describe C_K, it is best to perform a change of variables so as to isolate the center of mass (CM) excitations from the relative ones. Let $\{O_{ij}\}$ be an $N\times N$ orthogonal matrix with the property

$$O_{Ni}=N^{-1/2},\quad i=1,...,N \tag{2.23}$$

implying that $\Sigma_{j=1}^N O_{ij}=0$ for $i\neq N$. We define the new variables as well as new creation and annihilation operators by

$$\hat{x}_i=\sum_j O_{ij}x_j,\quad \hat{a}_i=\sum_j O_{ij}a_j,\quad \hat{a}_i^+=\sum_j O_{ij}a_j^+. \tag{2.24}$$

Owing to (2.23)

$$\hat{a}_N=N^{-1/2}\sum_i a_i,\quad \hat{a}_N^+=N^{-1/2}\sum_i a_i^+, \tag{2.25}$$

$\hat{a}_N$ and $\hat{a}_N^+$ are the annihilation and the creation operators of the CM oscillator excitations. Obviously, the operators $\hat{J}_{ij}=\hat{a}_i^+\hat{a}_j$ obey the same commutation relations as the operators J_{ij} and thus generate also the U(N) algebra. The Jacobi variables are a special case of (2.23) with

$$O_{ji}=\begin{cases} -1/[j(j+1)]^{1/2} & i\leqslant j\\ j/[j(j+1)]^{1/2} & i=j+1\\ 0 & i>j+1\end{cases} \tag{2.26}$$

for $j=1,...,N-1$.

Let us clarify at this point the nature of the N-dimensional representation of S_N under which the variables a_i and a_i^+ $i=1,...,N$ transform when the particles are permuted. This representation is reducible since the CM operator $\hat{a}_N$ (or $\hat{a}_N^+$) is invariant and thus associated to the one-dimensional identity representation. It can be shown, however, that the remaining relative operators $\hat{a}_i$, $i=1,...,N-1$ (or $\hat{a}_i^+$) transform irreducibly under the $N-1$ dimensional representation

$$(N-1,1) \rightarrow \begin{array}{|c|c|c|c|c|}\hline \multicolumn{1}{|c|}{} & & & & \\ \hline & & & & \\ \cline{2-2}\end{array}\cdots \square \tag{2.27}$$

of S_N. This can be done, for instance, by computing explicitly the characters or comparing directly the transformation matrices with the Yamanouchi symbols[11] of the representation (2.27). Let us also remark that the matrices representing the permutations of the relative operators can be viewed as improper rotations and thus embedded in $O(N-1)$.

The generators of C_K are readily identified when K is expressed in terms of the operators $\hat{J}_{ij}$. First note that $H^{(N)}=\Sigma_{i=1}^N J_{ii}=\Sigma_{i=1}^N \hat{J}_{ii}=\hat{H}^{(N)}$. For K we have,

$$\begin{aligned} K&=\sum_{\substack{i,j\\ i\neq j}}\left(\sum_{k,l\neq N} O_{ki}O_{lj}\hat{J}_{kl}+\frac{1}{N}\hat{J}_{NN}\right)\\ &=-\sum_{k,l\neq N}\sum_{i=1}^{N} O_{ki}O_{li}\hat{J}_{kl}+(N-1)\hat{J}_{NN}=-\sum_{k=1}^{N-1}\hat{J}_{kk}+(N-1)\hat{J}_{NN} \end{aligned} \tag{2.28}$$

in other words,

$$K=-\hat{H}^{(N-1)}+(N-1)\hat{J}_{NN}. \tag{2.29}$$

Upon performing the change of coordinate (2.24)–(2.25) we see that K is a combination of the CM phonon number operator and of the $(N-1)$-dimensional Hamiltonian for the relative oscillators. From (2.29), the centralizer of K is immediately recognized to be

$$C_K \simeq U(N-1)\times U(1)_{CM} \tag{2.30}$$

with $U(1)_{CM}$ generated by $\hat{J}_{NN}$ and $U(N-1)$ by the symmetries $\hat{J}_{ij}$ $i,j=1,...,N-1$ of $\hat{H}^{(N-1)}$. Note first that we can equivalently diagonalize $\hat{H}^{(N-1)}$ and $\hat{J}_{NN}$ instead of $H^{(N)}$ and K. This is what we shall do in the following. In order to find the complementary labeling operators, we shall therefore be looking for S_N-invariant operators in $\mathcal{U}(U(N-1)\otimes U(1)_{CM})$. We already remarked that the action of S_N on the relative variables is by $O(N-1)$ matrices of S_N, hence the Casimir operators of the $O(N-1)$ subgroup of $U(N-1)$ will *a fortiori* be permutational invariant and admissible labeling operators. We are thus led naturally to the following chain of subgroups:

$$U(N)\supset U(N-1)\supset O(N-1)\supset\cdots. \tag{2.31}$$

Basis vectors for representations of $U(N)$ corresponding to the reduction (2.31) have been relatively well studied. They are eigenstates of various Casimir operators of all the groups in the chain. It is known, however, that in general this does not suffice because irreducible representations of $O(N-1)$ can occur with multiplicities bigger than one in irreducible representations of $U(N-1)$. One thus faces a notorious missing label problem. This degeneracy can be resolved in various ways. It will not be our concern here, however, since this problem does not arise when one deals with the $U(N-1)$ representations that the oscillators realize i.e., the completely symmetrized tensor products of the fundamental representation. In such cases the representations of $O(N-1)$ all have multiplicity 0 or 1.

Once a complete set of commuting symmetric operators has been found, it will thus be useful to start from the $U(N)$ representation space bases associated to the chain (2.31) in order to diagonalize the labeling operators. This done, there remains the task of finding among these joint

eigenfunctions those that are actually invariant under S_N. This requires restricting the range of the quantum numbers and taking appropriate linear combination. (This will be worked out in detail for $N=2$ and $N=3$ in the next two sections.)

C. Raising and lowering operators

The above group theoretical characterization of the symmetric wave functions sets up nicely the problem of determining the dynamical algebra of this system of N identical bosonic oscillators. To proceed we need the ladder operators that transform the symmetric degenerate eigenstates among themselves. As already mentioned, the symmetric polynomials involving the generators associated with the coset $\mathrm{U}(N)/\mathrm{U}(N-1)$ will do that job. A fundamental fact about the space of these invariant polynomials is that it is finitely generated. It will thus suffice to consider a minimal set whose elements generate all the symmetric ladder operators. Such a minimal set is called an integrity basis. At this point, the task that remains in order to specify the dynamical algebra, is to understand the structure of the algebra that the labeling operators form with the integrity basis of ladder operators. We would also want ideally, to construct the representations of this algebra. It is clear that it is of polynomial type: The commutators of the generators will be polynomial expressions in the algebra elements.

We have not found it possible to proceed from here in full generality, that is, for arbitrary N. On the one hand, the study of polynomial algebras has just begun and not much is known of them yet. On the other hand, although the dimension of the integrity basis for the S_N-invariant operators in $\mathrm{U}(N)$ is finite, its cardinality grows very quickly with N. In the following sections therefore we shall focus the discussion on the interesting $N=2$ and 3 cases. This will illustrate the procedure that one could follow to work out the cases involving larger numbers of particles.

An essential part of the program is to obtain an integrity basis for the set $\mathscr{I}$ of the polynomials in the generators of $\mathrm{U}(N)$ that are invariant under S_N. The elements of this basis that belong to $\mathrm{U}(N-1)$ are used as labeling operators and the others act as ladder operators. Let $p(\{J_{kl}\})$ denote a homogeneous polynomial in the N^2 $\mathrm{U}(N)$ generators J_{kl}, $k,l=1,...,N$. To be precise, a S_N-invariant polynomial is one which is such that $p(\{J_{kl}\})=p(\{\sigma_{ij}J_{kl}\sigma_{ij}\})$ for all transpositions σ_{ij}, $i,j=1,...,N$. The procedure for finding an integrity basis for these polynomial operators is the following.[12] One first assumes that the J_{kl} are ''classical'' quantities and obtain an integrity basis $I=p_1(\{J_{kl}\}),\ldots,p_q(\{J_{kl}\})$ in the variables J_{kl} momentarily taken to commute. Upon restoring the noncommutative character of the J_{kl}, one sees that the set $\{p_1,\ldots,p_q\}$ is not an integrity basis of $\mathscr{I}$ but rather that a subset of it is. This is because there may be algebraic relations between the polynomials $p_1,\ldots,p_q$ with operator arguments that do not exist when the variables are c-numbers. Indeed if p_1 and p_2 do not commute, then $p=[p_1,p_2]$ is also an invariant. This invariant p could belong to the integrity basis for functions of the commuting variables, if so, it should be discarded when the group generators are reinstated as noncommuting variables since $p=p_1p_2-p_2p_1$. (Classically of course this relation could not be obtained.) Therefore, in order to avoid this overcounting, one should form all the possible commutators $[p_s,p_t]$ out of the set $\{p_1,\ldots,p_q\}$ so as to determine a minimal set of independent p_κ.

In the situation of interest here there is another cause for possible overcounting which has to do with the specific bosonic realization of the $\mathrm{U}(N)$-algebra we are using, namely, $J_{ij}=a_i^+a_j$ and the fact that there are in this case quadratic relations of the form

$$J_{ij}J_{kl}=J_{il}J_{kj}-\delta_{kl}J_{ij}+\delta_{jk}J_{il} \tag{2.32}$$

between the generators. These could be responsible for the fact that two apparently distinct generators only differ by a lower degree invariant (already included in the basis).

D. Generating functions

When facing the problem of obtaining a minimal set $\{p_1,\ldots,p_q\}$ of invariants in the classical J_{kl} or an integrity basis for these, it is extremely useful to know how many basis elements there are and their degree. This information is provided by a generating function. (Much of what follows is taken from Ref. 13.)

Let Γ and Γ' be representations of a group G (for us G will be S_N). We shall call (Γ,Γ') tensors those tensors whose components transform according to the representation Γ and are polynomials in the components of another tensor transforming according to the representation Γ'. We know that the generators of U(N) transform according to the representation $\Gamma'=[(N-1,1)+(N)]\times[(N-1,1)+(N)]$ which admits the following Clebsch–Gordan series:

$$\Gamma'=2\Gamma_1+\Gamma_2+3\Gamma_3+\Gamma_4, \tag{2.33}$$

where

$$\Gamma_1=(N), \quad \Gamma_2=(N-2,1^2), \quad \Gamma_3=(N-1,1), \quad \Gamma_4=(N-2,2). \tag{2.34}$$

Our problem thus amounts to finding an integrity basis for the (Γ_1,Γ') tensor with Γ_1 the identity representation and Γ' given by (2.33). With Γ_m the irreducible representations of G, the generating function for the multiplicities of the (Γ_r,Γ') tensors of given degree is denoted by $B(\Gamma_r,\Gamma';\lambda)$. We shall first give formulas for $B(\Gamma_r,\Gamma_m;\lambda)$ when both representations Γ_r and Γ_m are irreducible. We shall then provide a composition rule that will allow us to find $B(\Gamma_r,\Gamma_m+\Gamma_{m'};\lambda,\lambda')$ from $B(\Gamma_r,\Gamma_m;\lambda)$ and $B(\Gamma_r,\Gamma_{m'};\lambda')$. A general expression for $B(\Gamma_r,\Gamma_m;\lambda)$ is

$$B(\Gamma_r,\Gamma_m;\lambda)=\frac{1}{N}\sum_s \frac{N_s\chi^*_{sr}}{\det(1-\lambda A_s)}, \tag{2.35}$$

where the sum runs over the classes s of G, N is the order of the group G, N_s is the order of the class s of G, A_s the matrix in the representation Γ_m of an element of G belonging to the class s and χ^*_{sr} the complex conjugate of the character χ_{sr} of s in Γ_r. Upon expanding the right-hand side of (2.35) as a power series in λ

$$B(\Gamma_r,\Gamma_m;\lambda)=\sum_{n=0}^{\infty} c_n\lambda^n, \tag{2.36}$$

the coefficients c_n are seen to count the number of times the irreducible representation Γ_r occurs in the symmetrized product $\{\Gamma_m\}$.

The generating functions for reducible representations can be derived with the help of the following formula:

$$B(\Gamma_r,\Gamma_{m_1}+\Gamma_{m_2};\lambda_1,\lambda_2)=\sum_{r_1,r_2} B(\Gamma_{r_1},\Gamma_{m_1};\lambda_1)B(\Gamma_{r_2},\Gamma_{m_2};\lambda_2)C^r_{r_1r_2}, \tag{2.37}$$

where the constants $C^r_{r_1r_2}$ are defined by the Clebsch–Gordan series

$$\Gamma_{r_1}\times\Gamma_{r_2}=\sum C^r_{r_1r_2}\Gamma_r. \tag{2.38}$$

The coefficient of $\lambda_1^{n_1}\lambda_2^{n_2}$ in the expansion of $B(\Gamma_r,\Gamma_{m_1}+\Gamma_{m_2};\lambda_1,\lambda_2)$ is the number of linearly independent $(\Gamma_r,\Gamma_{m_1}+\Gamma_{m_2})$ tensors of degree n_1 and n_2, respectively, in the components of two tensors transforming, respectively, according to Γ_{m_1} and Γ_{m_2}. When $\Gamma_r=\Gamma_1$, the identity representation, (2.37) reduces to

$$B(\Gamma_1,\Gamma_{m_1}+\Gamma_{m_2};\lambda_1,\lambda_2)=\sum_r B(\Gamma_r,\Gamma_{m_1};\lambda_1)B(\Gamma^*_r,\Gamma_{m_2};\lambda_2), \tag{2.39}$$

where Γ^*_r denotes the representation which is the complex conjugate of Γ_r. One obtains the generating function $B(\Gamma_r,\Gamma';\lambda_1,\lambda_2,\ldots)$ for any reducible representation Γ' by iterating formula (2.38).

The generating function $B(\Gamma_r,\Gamma';\lambda)$ contains more than just the multiplicities of the (Γ_r,Γ') tensors of given degree, it in fact allows one to find the dimensions of the integrity basis for the (Γ_r,Γ') tensors. To see this, the finite sum in (2.35) has to be performed and the result expressed as a ratio of two polynomials in λ

$$B(\Gamma_r,\Gamma_m;\lambda)=\frac{N_{rm}(\lambda)}{D_m(\lambda)}. \tag{2.40}$$

It turns out that

$$N_{rm}(\lambda)=\sum_{\alpha} k_\alpha \lambda^\alpha, \quad D_m(\lambda)=\prod_{\beta}(1-\lambda^\beta), \tag{2.41}$$

where the coefficients k_α are positive integers and the sum and product taken over finite sets of integers $\alpha_1,\alpha_2,\ldots,$ and $\beta_1,\beta_2,\ldots,$ respectively. The denominator $D_m(\lambda)$ is common to all generating functions with the same Γ_m and G. In view of (2.38), the generating function $B(\Gamma_r,\Gamma';\lambda)$ associated with the reducible representation $\Gamma'=\Sigma\Gamma_i$ will have a similar form

$$B(\Gamma_r,\Gamma';\{\lambda_i\})=\frac{N_r'(\lambda_i)}{D'(\lambda_i)} \tag{2.42}$$

with

$$N_r'(\lambda_i)=\sum_{\{\alpha_i\}} k_{\{\alpha_i\}}\prod_i \lambda_i^{\alpha_i}, \quad D'(\lambda_i)=\prod_i\prod_{\beta_i}(1-\lambda_i^{\beta_i}). \tag{2.43}$$

The number of elements in an integrity basis for the invariants or the (Γ_1,Γ') tensors can now be determined as follows. To each factor $(1-\lambda_i^{\beta_i})$ of $D'(\lambda_i)$ corresponds one invariant of degree β_i in the components of the Γ_i tensor. To each term $k_{\{\alpha_i\}}\Pi_i\lambda_i^{\alpha_i}$ of $N_1'(\lambda_i)$ corresponds $k_{\{\alpha_i\}}$ independent invariants of degree α_1 in the components of the Γ_1 tensor, α_2 in the components of the Γ_2 tensor and so on, as long as the monomials $\Pi_i\,\lambda_i^{\alpha_i}$ cannot be formed (in equal number) out of the monomials $\Pi_i\,\lambda_i^{\beta_i}$ and of monomials $\Pi_i\,\lambda_i^{\alpha_i'}$ of lower degree already considered.

The generating function $B(\Gamma_1,\Gamma';\lambda_1,\ldots,\lambda_7)$ with Γ' as in (2.33)–(2.34) thus provides the number of elements in a minimal set of invariants in the classical J_{kl}; it also gives the degree of the elements in the set. To construct all these invariants one first assumes that they are arbitrary polynomials of the given degree in various irreducible components of the tensor J_{kl}, then impose that they remain unchanged when the components on which these polynomials depend are transformed according to their respective representation. After that, one should not forget to model out the realization dependent relations (2.32) and to compute the commutators between these invariants in order to eliminate them from the set the symmetric polynomials that are no longer independent from the others when the functions are made to depend on the U(N) generators. A concrete illustration of how all this works will be found in Sec. IV.

III. THE $N=2$ CASE

We shall now apply the program that we described in the previous section to the simplest possible situation: the $N=2$ case. We shall find, remarkably, that the invariance algebra of two identical bosonic harmonic oscillators on the line is the cubic deformation of SU(2) whose defining commutation relations were given in (1.1). We shall show that the symmetric eigenstates of the 2-oscillator system belong, depending on the energy, to irreducible modules of this algebra that are of two types and shall thus explain the spectrum degeneracies.

A. The symmetry algebra

In accordance with the general discussion, we shall characterize the states of the system as the joint eigenfunctions of the Hamiltonian $H^{(2)}=a_1^+a_1+a_2^+a_2$ and the symmetric observable K

$=J_{12}+J_{21}$. [The reader will recall that the operators $J_{ij}=a_i^+ a_j$, $i,j=1,2$, generate the U(2) invariance algebra of $H^{(2)}$.] In order to diagonalize these operators simultaneously, it is best to pass to the relative and center of mass coordinates

$$\hat{x}_i=\sum_{j=1}^{2} M_{ij}x_j, \quad M=\frac{1}{\sqrt{2}}\begin{pmatrix} -1 & 1 \\ 1 & 1 \end{pmatrix}, \tag{3.1}$$

and to use correspondingly, the creation and annihilation operators

$$\hat{a}_i=\sum_{j=1}^{2} M_{ij}a_j, \quad \hat{a}_i^+=\sum_{j=1}^{2} M_{ij}a_j^+ . \tag{3.2}$$

In terms of these, $H^{(2)}$ and K read

$$H^{(2)}=\hat{a}_1^+\hat{a}_1+\hat{a}_2^+\hat{a}_2, \quad K=-\hat{a}_1^+\hat{a}_1+\hat{a}_2^+\hat{a}_2. \tag{3.3}$$

It is then manifest that they are diagonal on the states

$$|n_1,n_2\rangle=\frac{(\hat{a}_1^+)^{n_1}}{\sqrt{n_1!}}\frac{(\hat{a}_2^+)^{n_2}}{\sqrt{n_2!}}|0\rangle \quad n_1,n_2\in\mathbb{N}, \tag{3.4}$$

and in fact

$$H^{(2)}|n_1,n_2\rangle=(n_1+n_2)|n_1,n_2\rangle, \quad K|n_1,n_2\rangle=(n_2-n_1)|n_1,n_2\rangle. \tag{3.5}$$

Of these eigenstates we want to retain only those that are invariant under the exchange of the oscillators. The group S_2 is generated by the transposition $\sigma_{12}\equiv\sigma$. Under this operation, the creation and annihilation operators transform as follows:

$$\begin{aligned} &\sigma\hat{a}_1\sigma=-\hat{a}_1, \quad \sigma\hat{a}_2\sigma=\hat{a}_2, \\ &\sigma\hat{a}_1^+\sigma=-\hat{a}_1^+, \quad \sigma\hat{a}_2^+\sigma=\hat{a}_2^+ . \end{aligned} \tag{3.6}$$

The ground state moreover, is symmetric $\sigma|0\rangle=|0\rangle$. Hence the S_2-invariant states are $|2n_1,n_2\rangle$, that is, the states (3.4) with n_1 even. The energy spectrum is thus

$$E_{n_1,n_2}=2n_1+n_2\equiv n \tag{3.7}$$

and shows at level n a degeneracy of degree $[n/2]+1$ with $[n/2]$ standing for the integer part of $n/2$.

In this simple case and in view of (3.6), an integrity basis for the S_2 scalars in $\mathscr{U}(\mathrm{U}(2))$ is readily found by inspection. One indeed checks that the set $\{H^{(2)},K,(\hat{J}_{12})^2,(\hat{J}_{21})^2\}$ forms such a basis. The elements $(\hat{J}_{12})^2$ and $(\hat{J}_{21})^2$ must thus be the ladder operators for the eigenvalues of K and a short computation confirms that this is indeed the case

$$[K,(\hat{J}_{12})^2]=8(\hat{J}_{12})^2, \quad [K,(\hat{J}_{21})^2]=-8(\hat{J}_{21})^2. \tag{3.8}$$

The question now is to identify the algebra that the constants K, $(\hat{J}_{12})^2$, and $(\hat{J}_{21})^2$ realize. In this connection note that the commutator of $(\hat{J}_{12})^2$ and $(\hat{J}_{21})^2$ is a cubic expression in $H^{(2)}$ and K

$$[(\hat{J}_{12})^2,(\hat{J}_{21})^2]=K^3-K[(H^{(2)})^2+2H^{(2)}-2]. \tag{3.9}$$

Let

$$\alpha=\frac{32}{[(H^{(2)})^2+2H^{(2)}-2]} \tag{3.10}$$

and redefine the symmetry generators as follows:

$$J_0 = -\tfrac{1}{4}K = \tfrac{1}{4}(\hat{a}_1^+\hat{a}_1 - \hat{a}_2^+\hat{a}_2),$$

$$J_+ = \frac{\sqrt{\alpha}}{8}(\hat{J}_{12})^2 = \frac{\sqrt{\alpha}}{8}(\hat{a}_1^+)^2(\hat{a}_2)^2, \tag{3.11}$$

$$J_- = \frac{\sqrt{\alpha}}{8}(\hat{J}_{21})^2 = \frac{\sqrt{\alpha}}{8}(\hat{a}_2^+)^2(\hat{a}_1)^2 = (J_+)^\dagger.$$

It is straightforward to verify that these operators satisfy the commutation relations

$$[J_0, J_\pm] = \pm J_\pm, \tag{3.12a}$$

$$[J_+, J_-] = 2J_0 - \alpha J_0^3 \equiv f(J_0), \tag{3.12b}$$

and thus generate a cubic deformation of the SU(2) Lie algebra if we treat α as a constant which can always be done on energy eigensubspaces. This generalized algebra is the symmetry algebra of the two identical oscillator systems. It remains to determine the irreducible representations according to which the degenerate eigenstates of $H^{(2)}$ transform.

B. Physical representations

Since there are finitely many degenerate levels, we are interested in highest-weight irreducible representations of dimension $d+1<\infty$. Let m be the eigenvalues of J_0 and j denote the highest value that m takes in one such representation. We shall use these numbers j and m to label the basis states. In view of (3.12a), we can posit that J_0, J_+ and J_- act as follows on the vectors $|j,m\rangle$:

$$J_0|j,m\rangle = m|j,m\rangle, \tag{3.13a}$$

$$J_+|j,m\rangle = c^*(j,m+1)|j,m+1\rangle, \tag{3.13b}$$

$$J_-|j,m\rangle = c(j,m)|j,m-1\rangle, \tag{3.13c}$$

if we request that the representation be unitary, in other words that $J_+ = (J_-)^\dagger$. Here $c^*(j,m+1)$ is the complex conjugate of the coefficient $c(j,m+1)$. From the definition of j, we must have

$$c(j,j+1) = 0. \tag{3.14}$$

We now define the function $h(J_0)$ through [see (3.12b)]

$$f(J_0) = h(J_0) - h(J_0 - 1). \tag{3.15}$$

From (3.12b) we have

$$[J_+, J_-]|j,m\rangle = f(J_0)|j,m\rangle \tag{3.16}$$

which gives, using (3.13) and (3.15),

$$|c(j,m)|^2 - |c(j,m+1)|^2 = h(m) - h(m-1). \tag{3.17}$$

With the help of (3.14), it is easily seen that this entails the relation

$$|c(j,m)|^2 = h(j) - h(m-1). \tag{3.18}$$

Without loss of generality, the phases of the vectors $|j,m\rangle$ can be chosen so that $c(j,m)=[h(j)-h(m-1)]^{1/2}$ and these coefficients therefore are real and non-negative for all m. As a matter of fact, for this representation to be $(d+1)$-dimensional, we must also have

$$c(j,j-d)=0, \tag{3.19}$$

implying that m takes the values $j,j-1,...,j-d+1$. The Casimir operator of the algebra (3.12) is given by

$$C=J_-J_++h(J_0). \tag{3.20}$$

It is readily checked that this element is central. It is found moreover from (3.18) that the basis vectors $|j,m\rangle$ are all eigenvectors of C with eigenvalues $h(j)$. This confirms that j properly labels the irreducible representations of this polynomial algebra.

We now want to determine which of these modules are realized by the symmetric oscillator states $\{|2n_1,n_2\rangle;n_1,n_2\in\mathbb{N}\}$. In this context, the irreducible subspaces are identified by the total energy, in other words by the integers

$$n=2n_1+n_2. \tag{3.21}$$

To identify the irreducible representations of the symmetry algebra, one needs to obtain the relation between n and the highest eigenvalue j of J_0 on the states $|2n_1,n_2\rangle$. This is easily achieved. From $J_0|2n_1,n_2\rangle=\frac{1}{4}(2n_1-n_2)|2n_1,n_2\rangle$ we see that

$$m=\tfrac{1}{4}(2n_1-n_2)=\tfrac{1}{4}(n-2n_2). \tag{3.22}$$

From the last equality we see that for a given n, the maximum value j of m is attained when n_2 takes its minimum value. Since n_1 and n_2 are non-negative integers, this minimum value is 0 when n is even and 1 when n is odd. Thus

$$j(n)=\begin{cases} n/4 & \text{for } n \text{ even} \\ (n-2)/4 & \text{for } n \text{ odd.} \end{cases} \tag{3.23}$$

These values of j can also be obtained by looking at the action of $J_-=\sqrt{\alpha}/8(\hat{a}_2^+)^2(\hat{a}_1)^2$ on the oscillator states

$$|2n_1,n_2\rangle=|j(n),m\rangle=\frac{(\hat{a}_1^+)^{(n/2)+2m}(\hat{a}_2^+)^{(n/2)-2m}}{\sqrt{((n/2)+2m)!((n/2)-2m)!}}\,|0\rangle. \tag{3.24}$$

An easy computation shows that

$$J_-|j(n),m\rangle=\frac{\sqrt{\alpha}}{8}\left\{\left(\frac{n}{2}-2m+1\right)\left(\frac{n}{2}-2m+2\right)\left(\frac{n}{2}+2m\right)\left(\frac{n}{2}+2m-1\right)\right\}|j(n),m-1\rangle. \tag{3.25}$$

From the representation theory we know [see (3.13c)] that $J_-|j,m\rangle=c(j,m)|j,m-1\rangle$, where [see (3.18)] $c(j,m)=[h(j)-h(m-1)]^{1/2}$. In the specific case at hand, $f(J_0)=2J_0-\alpha J_0^3$ [see (3.12b)], and the function $h(J_0)$ which solves (3.15) is found to be

$$h(J_0)=J_0(J_0+1)\left[1-\frac{\alpha}{4}J_0(J_0+1)\right]. \tag{3.26}$$

Combining (3.18), (3.24), and (3.26), one thus gets the following relation:

$$\frac{\alpha}{64}\left(\frac{n}{2}-2m+1\right)\left(\frac{n}{2}-2m+2\right)\left(\frac{n}{2}+2m\right)\left(\frac{n}{2}+2m-1\right)$$
$$=j(j+1)\left[1-\frac{\alpha}{4}j(j+1)\right]-m(m-1)\left[1-\frac{\alpha}{4}m(m-1)\right], \tag{3.27}$$

which connects n and j. Of course, when $m=j+1$, the right-hand side of (3.27) vanishes and for the equality to be valid j must take either one of the values given in (3.23), that is $n/4$ or $(n-2)/4$. Upon replacing α by $32/(n^2+2n-2)$ according to (3.10), one may check that (3.27) is satisfied for arbitrary m provided that j is as specified above.

We may now determine the dimensions $(=d+1)$ of the representations from the condition $J_-|j(n),j(n)-d\rangle=0$. This equation is immediately found from (3.25) to possess the two solutions $d=n/2$ and $d=(n-1)/2$ for each of the two values of j. Of these solutions, in each case, only one will be admissible since d must be an integer. The situation will be the following:

$$n \text{ even: } j=n/4, \quad d+1=2j+1=\frac{n}{2}+1,$$
$$n \text{ odd: } j=(n-2)/4, \quad d+1=2j+\frac{3}{2}=\frac{1}{2}(n-1)+1. \tag{3.28}$$

In summary we found that the degenerate symmetric energy eigenstates of the 2-oscillator system fall into irreducible representations of the cubic deformation (3.12) of SU(2) that are of two types. The dimensions of these representations are $[n/2]+1$ and we have thus algebraically explained the observed degeneracies of the spectrum.

It is instructive to write down explicitely a few wave functions $\phi_{n,m}(z_1,z_2)=\langle z_1,z_2|n,m\rangle$ in the holomorphic realization where

$$\hat{a}_i=\frac{\partial}{\partial z_i}, \quad \hat{a}_i^+=z_i, \quad i=1,2. \tag{3.29}$$

For the two-dimensional representation we have

$$\phi_{2,-1/2}=\frac{z_2^2}{\sqrt{2}}, \quad \phi_{2,1/2}=\frac{z_1^2}{\sqrt{2}},$$
$$\phi_{3,-3/4}=\frac{z_2^3}{\sqrt{3!}}, \quad \phi_{3,1/4}=\frac{z_1^2 z_2}{\sqrt{2}}. \tag{3.30}$$

In this realization the symmetry algebra generators take the form

$$J_0=\frac{1}{4}\left(z_1\frac{\partial}{\partial z_1}-z_2\frac{\partial}{\partial z_2}\right),$$
$$J_+=\frac{\sqrt{\alpha}}{8}z_1^2\frac{\partial^2}{\partial z_2^2}, \tag{3.31}$$
$$J_-=\frac{\sqrt{\alpha}}{8}z_2^2\frac{\partial^2}{\partial z_1^2}.$$

These operators are easily seen to transform the wave functions (3.21) with the same n among themselves and according to (3.13). Note that since α depends on n, the normalizations of J_+ and J_- change in each irreducible representation. Since the dimension of the representations is given by $[n/2]+1$, it increases by one with every even number. The three-dimensional representations, for instance, are obtained when $n=4$ and $n=5$. The corresponding normalized basis functions are

$$\phi_{4,-1}=\frac{z_2^4}{\sqrt{4!}},\quad \phi_{4,0}=\frac{z_1^2z_2^2}{2},\quad \phi_{4,1}=\frac{z_1^4}{2\sqrt{3!}},$$
$$\phi_{5,-5/4}=\frac{z_2^5}{\sqrt{5!}},\quad \phi_{5,-1/4}=\frac{z_1^2z_2^3}{2\sqrt{3}},\quad \phi_{5,3/4}=\frac{z_1^4z_2}{2\sqrt{3!}}, \tag{3.32}$$

and one may again check that the action of the operators (3.22) on these functions is in agreement with the formulas obtained from the abstract representation theory.

IV. THE $N=3$ CASE

We now present the $N=3$ case. Although the 2-particle problem proved surprisingly interesting, it remains somewhat special. The system consisting of three identical oscillators on the line is more generic and its analysis will require all the tools introduced in Sec. II.

We are dealing here with the Hamiltonian $H^{(3)}=\Sigma_{i=1}^3 a_i^+ a_i$ whose U(3) invariance algebra is generated by the operators $J_{ij}=a_i^+ a_j$, $i,j=1,2,3$. Our goal is to characterize the symmetric eigenstates of $H^{(3)}$ and to find the operators that will transform these degenerate states among themselves. In order to accomplish the first part of this task, we shall (i) obtain a complete set of commuting observables that are symmetric, (ii) diagonalize these operators simultaneously, and (iii) impose that the joint eigenfunctions be invariant under permutations. As for the ladder operators, we shall compute the generating function from which they can be enumerated, provide their action on the basis vectors, and give the commutation relations for a minimal generating set.

A. The symmetric 3-oscillator states

Following the plan of Sec. II, we shall take

$$K=J_{12}+J_{13}+J_{21}+J_{23}+J_{31}+J_{32} \tag{4.1}$$

as one of the labeling operators. As already explained, it will also be best to use relative and CM coordinates and we shall choose those of Jacobi

$$\hat{x}_1=\frac{1}{\sqrt{2}}(x_1-x_2),$$
$$\hat{x}_2=-\frac{1}{\sqrt{6}}(x_1+x_2-2x_3), \tag{4.2}$$
$$\hat{x}_3=\frac{1}{\sqrt{3}}(x_1+x_2+x_3).$$

The corresponding annihilation and creation operators are $\hat{a}_i=\Sigma_{j=1}^3 O_{ij}a_j$, $\hat{a}_i^+=\Sigma_{j=1}^3 O_{ij}a_j^+$ with the orthogonal matrix O given by (2.23) and (2.26) for $i,j=1,2,3$. The operators $\hat{J}_{ij}=\hat{a}_i^+\hat{a}_j=\Sigma_{k,l=1}^3 O_{ik}O_{jl}J_{kl}$ form an equivalent basis for the symmetry algebra of $H^{(3)}=\hat{H}^{(3)}$ whose eigenvalues we shall denote by $|n|_3$. Moreover, K reads

$$K=-\hat{H}^{(2)}+2\hat{J}_{33}+1 \tag{4.3}$$

with $\hat{H}^{(2)}=\hat{a}_1^+\hat{a}_1+\hat{a}_2^+\hat{a}_2+1$. Instead of using the eigenvalues of $H^{(3)}=\hat{H}^{(2)}+\hat{J}_{33}+1/2$ and K as labels for the state vectors, we shall use equivalently those of $\hat{H}^{(2)}$ and $\hat{J}_{33}$ to which a third quantum number has to be added. The operators that commute with K and $H^{(3)}$ (or $\hat{H}^{(2)}$ and $\hat{J}_{33}$) are $\hat{J}_{ij}$ $i,j=1,2$; they generate the U(2) invariance algebra of the two-dimensional oscillator in the relative coordinates with Hamiltonian $\hat{H}^{(2)}$. In terms of

$$\hat{J}_x=-\frac{1}{2}(\hat{J}_{12}+\hat{J}_{21}),\quad \hat{J}_y=-\frac{1}{2i}(\hat{J}_{12}-\hat{J}_{21}),\quad \hat{J}_z=-\frac{1}{2}(\hat{J}_{11}-\hat{J}_{22}), \tag{4.4}$$

we have $[\hat{J}_x,\hat{J}_y]=i\hat{J}_z$ and the other cyclic combinations. Note also that since

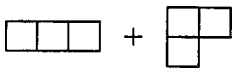
$$\hat{J}^2=\hat{J}_x^2+\hat{J}_y^2+\hat{J}_z^2=\left(\frac{\hat{H}^{(2)}-1}{2}\right)\left(\frac{\hat{H}^{(2)}-1}{2}+1\right), \tag{4.5}$$

the eigenvalues of $\hat{H}^{(2)}$ could also be replaced by those of $\hat{J}^2$. In addition to commuting with $\hat{H}^{(2)}$ and $\hat{J}_{33}$, the additional labeling operator we are looking for must have the property of being invariant under the permutations of the three oscillators. We must therefore find a polynomial in $\hat{J}_x$, $\hat{J}_y$, and $\hat{J}_z$ with this feature. To that end, we shall now examine how the symmetry generators $\hat{J}_{ij}$ $i,j=1,2,3$ transform under S_3.

The symmetric group S_3 is generated by the transposition σ_{12} and the cyclic permutation σ_{123} whose action on the coordinates x_i, $i=1,2,3$ are

$$\begin{aligned}&\sigma_{12}: \quad x_1\to x_2 \quad x_2\to x_1 \quad x_3\to x_3,\\ &\sigma_{123}: \quad x_1\to x_2 \quad x_2\to x_3 \quad x_3\to x_1.\end{aligned} \tag{4.6}$$

The irreducible content of the corresponding 3-dimensional representation of S_3 is



and the decomposition effected by passing to the Jacobi coordinates:

$$\sigma_{12}: \quad \hat{x}_3\to\hat{x}_3, \quad \sigma_{123}: \ \hat{x}_3\to\hat{x}_3, \tag{4.7}$$

$$\sigma_{12}: \ \hat{x}_i\to\hat{x}_i^I=\sum_{j=1}^{2} I_{ij}\hat{x}_j, \quad \sigma_{123}: \ \hat{x}_i\to\hat{x}_i^R=\sum_{j=1}^{2} R_{ij}\hat{x}_j, \tag{4.8}$$

where

$$I=\begin{pmatrix}-1 & 0\\ 0 & 1\end{pmatrix}, \quad R=\begin{pmatrix}-1/2 & \sqrt{3}/2\\ -\sqrt{3}/2 & -1/2\end{pmatrix}. \tag{4.9}$$

The operators $\hat{J}_{ij}$ behave as a second-rank tensor and their transformation properties under σ_{12} and σ_{123} are easily obtained. We introduce the following basis for U(3):

$$\{\hat{H}^{(2)}, \quad \hat{J}_{33}, \quad \hat{J}_y, \quad \hat{J}_\pm=\hat{J}_x\pm i\hat{J}_z, \quad \hat{J}_{\pm 3}=\hat{J}_{13}\pm i\hat{J}_{23}, \quad \hat{J}_{3\pm}=\hat{J}_{31}\pm i\hat{J}_{32}\}. \tag{4.10}$$

Its elements are seen to transform as follows:

$$\begin{array}{lll}\sigma_{12}: & \hat{H}^{(2)}\to\hat{H}^{(2)} & \sigma_{123}: \quad \check{H}^{(2)}\to\check{H}^{(2)}\\ & \hat{J}_{33}\to\hat{J}_{33} & \hat{J}_{33}\to\hat{J}_{33}\\ & \hat{J}_y\to-\hat{J}_y & \hat{J}_y\to\hat{J}_y\\ & \hat{J}_\pm\to-\hat{J}_\mp & \hat{J}_\pm\to e^{\pm i4\pi/3}\hat{J}_\pm\\ & \hat{J}_{\pm 3}\to-\hat{J}_{\mp 3} & \hat{J}_{\pm 3}\to e^{\pm i4\pi/3}\hat{J}_{\pm 3}\\ & \hat{J}_{3\pm}\to-\hat{J}_{3\mp} & \hat{J}_{3\pm}\to e^{i4\pi/3}\hat{J}_{3\pm}.\end{array} \tag{4.11}$$

In order to obtain an extra labeling operator, we set out to find an S_3-invariant polynomial in $\hat{J}_x$, $\hat{J}_y$, and $\hat{J}_z$. From (4.11), it is readily seen that the lowest order invariant is $\hat{J}_y^2$. The operator $\hat{J}_+\hat{J}_-+\hat{J}_-\hat{J}_+$ is also invariant but in view of (4.5) can be expressed in terms of $\hat{H}^{(2)}$ and $\hat{J}_y^2$. The operators $\hat{H}^{(2)}$, $\hat{J}_y^2$, and $\hat{J}_{33}$ will thus form a natural set of commuting and symmetric observables for labeling the permutational invariant 3-oscillator states

$$\hat{H}^{(2)}|j,l,n_3\rangle=(2j+1)|j,l,n_3\rangle,$$

$$\hat{J}_y^2|j,l,n_3\rangle=l^2|j,l,n_3\rangle, \tag{4.12}$$

$$\hat{J}_{33}|j,l,n_3\rangle=n_3|j,l,n_3\rangle.$$

It proves convenient to set $|n|_2=2j$.

The eigenstates $|j,l,n_3\rangle$ are straightforwardly expressed in terms of the vectors $\hat{\phi}(n_1,n_2,n_3)=\Pi_{i=1}^3((\hat{a}_i^+)^{n_i}/\sqrt{n_i!})\phi_0$. One first observes that $\hat{\phi}(j-l,j+l,n_3)$ is an eigenvector of $\hat{H}^{(2)}$, $\hat{J}_z$ and $\hat{J}_{33}$ with eigenvalue $2j+1$, l, and n_3, respectively. Let $U(\alpha,\beta,\gamma)=e^{-i\alpha\hat{J}_z}e^{-i\beta\hat{J}_y}e^{-i\gamma\hat{J}_z}$; one further notes that $\hat{J}_y=U(\pi/2,\pi/2,0)\hat{J}_zU^{-1}(\pi/2,\pi/2,0)$. It thus follows that the states $e^{i\pi j/2}U(\pi/2,\pi/2,0)\hat{\phi}(j-l,j+l,n_3)$ are eigenvectors of $\hat{J}_y$ with eigenvalue l. The phase $e^{i\pi j/2}$ is introduced for convenience. We shall denote by $|\widetilde{j,l,n_3}\rangle$ the eigenstates of $\hat{H}^{(2)}$, $\hat{J}_y$ and $\hat{J}_{33}$.

In terms of the Wigner matrix elements, we have

$$|\widetilde{j,l,n_3}\rangle=e^{i\pi j/2}\sum_{m=-j}^{j}D_{m,l}^j\left(\frac{\pi}{2},\frac{\pi}{2},0\right)\phi(j-m,j+m,n_3), \tag{4.13}$$

where for m, $l=-j,\ldots,j$

$$\begin{aligned}D_{m,l}^j\left(\frac{\pi}{2},\frac{\pi}{2},0\right)&=e^{-(1/2)i\pi m}d_{m,l}^j\left(\frac{\pi}{2}\right)\\&=e^{-(1/2)i\pi m}\sqrt{\frac{(j+l)!(j-l)!}{(j+m)!(j-m)!}}\left(\frac{1}{2}\right)^j\sum_{\substack{0\le s\le j-m\\0\le s\le j-l}}(-)^{j-l+s}\binom{j-m}{s}\binom{j+m}{j-l-s},\end{aligned} \tag{4.14}$$

with $\binom{m}{s}$, the binomial coefficient. The eigenvectors of $\hat{J}_y^2$ with eigenvalue l^2 will thus be of the form

$$|j,l,n_3\rangle=\frac{1}{\sqrt{2}}\,(|\widetilde{j,l,n_3}\rangle+e^{i\alpha}|\widetilde{j,-l,n_3}\rangle) \tag{4.15}$$

with $e^{i\alpha}$ an arbitrary phase at this point. There remains to characterize the states that are invariant under the permutations of the oscillators and this is easily carried out with our choice of quantum numbers. We must determine which of the states $|j,l,n_3\rangle$ are stable against the action of σ_{12} and σ_{123}. From the transformations it induces on the observables (4.10), we see that the cyclic permutation is realized by the $4\pi/3$ rotations generated by $\hat{J}_y$. The symmetric states must satisfy

$$e^{-i(4\pi/3)\hat{J}_y}|j,l,n_3\rangle=|j,l,n_3\rangle. \tag{4.16}$$

Clearly, this imposes that l be a multiple of 3/2

$$l=\pm 3k/2,\quad k\in\mathbb{N}. \tag{4.17}$$

Similarly, the transposition σ_{12} is seen to correspond to the inversion $\mathscr{P}$ which acts as follows on the states $\hat{\phi}$: $\mathscr{P}\hat{\phi}(j-m,j+m,n_3)=(-1)^{j-m}\hat{\phi}(j-m,j+m,n_3)$. Hence, using the fact that

$$d_{m,-l}^j\left(\frac{\pi}{2}\right)=(-1)^{j+m}d_{m,l}^j\left(\frac{\pi}{2}\right), \tag{4.18}$$

we have

$$\mathscr{P}\widetilde{|j,l,n_3\rangle} = e^{i\pi j/2}\sum_{m=-j}^{j} D^{i}_{m,l}\left(\frac{\pi}{2},\frac{\pi}{2},0\right)(-1)^{j-m}\phi(j-m,j+m,n_3) = (-1)^{2j}\widetilde{|j,-l,n_3\rangle}. \tag{4.19}$$

Therefore, upon demanding the invariance of the states $|j,l,n_3\rangle$ under σ_{12}, i.e.,

$$\mathscr{P}|j,l,n_3\rangle = |j,l,n_3\rangle, \tag{4.20}$$

we find that the relative phase $e^{i\alpha}$ in (4.15) is $(-1)^{2j}$. This leads to the following formula for the symmetric 3-oscillator states:

$$\begin{aligned}|j,l,n_3\rangle &= \frac{1}{\sqrt{2}}\left(\widetilde{|j,l,n_3\rangle} + (-1)^{2j}\widetilde{|j,-l,n_3\rangle}\right)\\ &= \frac{e^{i\pi j/2}}{\sqrt{2}}\sum_{m=-j}^{j}(1+(-1)^{j-m})e^{-(1/2)i\pi m}d^{j}_{m,l}\left(\frac{\pi}{2}\right)\hat{\phi}(j-m,j+m,n_3)\end{aligned} \tag{4.21}$$

with l a multiple of 3. [We used the fact that $(-1)^{4j}=1$.] Note that the vectors $|j,l,n_3\rangle$ and $|j,-l,n_3\rangle$ only differ by a phase

$$|j,-l,n_3\rangle = (-1)^{2j}|j,l,n_3\rangle; \tag{4.22}$$

they hence describe the same physical state and should be identified. Furthermore, notice that the vectors $|j,l,n_3\rangle$ are normalized to one except when $l=0$; in this case, $\langle j,0,n_3|j,0,n_3\rangle = 2$.

B. The raising and lowering operators

We now aim to find raising and lowering operators that transform the degenerate eigenstates (4.21) of $H^{(3)}$ among themselves; ultimately we want to characterize the algebra that these constants of motion generate. The procedure that we shall follow has been outlined in Sec. II and amounts to obtaining an integrity basis for S_3 scalars in the envelopping algebra $\mathscr{U}(\mathrm{U}(3))$.

We shall denote by

$\Gamma_1 =$  $\Gamma_2 =$ $\Gamma_3 =$ (4.23)

the three irreducible representations of S_3 of dimension 1, 1, and 2, respectively. The coefficients C^{c}_{ab} entering in the Clebsch–Gordan series $\Gamma_a\times\Gamma_b = \Sigma C^{c}_{ab}\Gamma_c$, $a,b,c=1,2,3$, are[11]

$$\begin{array}{lll} C^{c}_{1b}=C^{c}_{b1}=\delta^{c}_{b} & & \\ C^{1}_{22}=1 & C^{2}_{22}=C^{3}_{22}=0 & \\ C^{a}_{33}=1 & C^{3}_{23}=1 & C^{1}_{23}=C^{2}_{23}=0. \end{array} \tag{4.24}$$

The generators of U(3) transform under S_3 according to the representation $\Gamma' = (\Gamma_1+\Gamma_3)\times(\Gamma_1+\Gamma_3)$ whose irreducible content, according to (4.24), is

$$\Gamma' = \Gamma_1+\Gamma_1+\Gamma_2+\Gamma_3+\Gamma_3+\Gamma_3. \tag{4.25}$$

This decomposition is in effect exhibited in the basis (4.10) of U(3) which we shall keep using: the two scalars are $\hat{H}^{(2)}$ and $\hat{J}_{33}$, the pseudoscalar is $\hat{J}^{2}_{\gamma}$, and the 3 Γ_3 doublets, respectively, formed by $\hat{J}_{\pm}$, $\hat{J}_{\pm 3}$, $\hat{J}_{3\pm}$. We now wish to find a ''minimal'' basis for polynomials in the components of this Γ' tensor [i.e., elements of $\mathscr{U}(\mathrm{U}(3))$] that are invariant under S_3 (i.e., that transform according to Γ_1). We shall first determine the maximum number of polynomials in this basis by computing the generating function $B(\Gamma_1,\Gamma')$. One proceeds using formulas (2.36) and (2.38) repeatedly. The generating functions involving the irreducible representations are evaluated straightforwardly from the definition (2.35) and then cast in the form (2.39). One finds

$$
\begin{aligned}
&B(\Gamma_1,\Gamma_1)=\frac{1}{1-\lambda}, \quad B(\Gamma_1,\Gamma_2)=\frac{1}{1-\lambda^2},\\
&B(\Gamma_2,\Gamma_2)=\frac{\lambda}{1-\lambda^2}, \quad B(\Gamma_1,\Gamma_3)=\frac{1}{(1-\lambda^2)(1-\lambda^3)},\\
&B(\Gamma_2,\Gamma_3)=\frac{\lambda^3}{(1-\lambda^2)(1-\lambda^3)}, \quad B(\Gamma_3,\Gamma_3)=\frac{\lambda+\lambda^2}{(1-\lambda^2)(1-\lambda^3)}.
\end{aligned}
\tag{4.26}
$$

(Recall that S_3 has 1 cycle of length 1, 3 of length 2, and 2 of length 3. Γ_1 is the identity representation and Γ_2 the alternating one in which the transpositions are represented by -1. As for Γ_3, I and R given in (4.9) can be taken to play the role of A_s in (2.35) for transpositions and cyclic permutations, respectively.) Combining everything, we find that $B(\Gamma_1,\Gamma')$ takes the form

$$
B(\Gamma_1,\Gamma_1+\Gamma_1+\Gamma_2+\Gamma_3+\Gamma_3+\Gamma_3;\lambda_1,\lambda_2,\ldots,\lambda_6)=\frac{N(\lambda_1,\ldots,\lambda_6)}{D(\lambda_1,\ldots,\lambda_6)},
\tag{4.27}
$$

where

$$
D(\lambda_1,\ldots,\lambda_6)=(1-\lambda_1)(1-\lambda_2)(1-\lambda_3^2)(1-\lambda_4^2)(1-\lambda_4^3)(1-\lambda_5^2)(1-\lambda_5^3)(1-\lambda_6^2)(1-\lambda_6^3)
\tag{4.28}
$$

and

$$
\begin{aligned}
N(\lambda_1,\ldots,\lambda_6)=1&+\lambda_4\lambda_5+\lambda_4\lambda_6+\lambda_5\lambda_6+\lambda_4^2\lambda_5+\lambda_4\lambda_5^2+\lambda_4^2\lambda_6+\lambda_4\lambda_6^2+\lambda_5^2\lambda_6\\
&+\lambda_5\lambda_6^2+\lambda_4\lambda_5\lambda_6+\lambda_4^2\lambda_5^2+\lambda_4^2\lambda_6^2+\lambda_5^2\lambda_6^2+\lambda_4^2\lambda_5\lambda_6+\lambda_4\lambda_5^2\lambda_6\\
&+\lambda_4\lambda_5\lambda_6^2+\lambda_4^3\lambda_5\lambda_6+\lambda_4\lambda_5^3\lambda_5+\lambda_4\lambda_5\lambda_6^3+\lambda_4^2\lambda_5^2\lambda_6+\lambda_4^2\lambda_5\lambda_6^2\\
&+\lambda_4\lambda_5^2\lambda_6^2+\lambda_4^3\lambda_5^3+\lambda_4^3\lambda_6^3+\lambda_5^3\lambda_6^3+\lambda_4^3\lambda_5^2\lambda_6+\lambda_4^3\lambda_5\lambda_6^2+\lambda_4^2\lambda_5^3\lambda_6\\
&+\lambda_4^2\lambda_5\lambda_6^3+\lambda_4\lambda_5^3\lambda_6^2+\lambda_4\lambda_5^2\lambda_6^3+\lambda_4^2\lambda_5^2\lambda_6^2+\lambda_4^3\lambda_5^2\lambda_6^2+\lambda_4^2\lambda_5^3\lambda_6^2\\
&+\lambda_4^2\lambda_5^2\lambda_6^3+\lambda_3\lambda_4\lambda_5+\lambda_3\lambda_4\lambda_6+\lambda_3\lambda_5\lambda_6+\lambda_3\lambda_4^3\\
&+\lambda_3\lambda_5^3+\lambda_3\lambda_6^3+\lambda_3\lambda_4^2\lambda_5+\lambda_3\lambda_4\lambda_5^2+\lambda_3\lambda_4^2\lambda_6+\lambda_3\lambda_4\lambda_6^2\\
&+\lambda_3\lambda_5^2\lambda_6+\lambda_3\lambda_5\lambda_6^2+\lambda_3\lambda_4\lambda_5\lambda_6+\lambda_3\lambda_4^2\lambda_5^2+\lambda_3\lambda_4^2\lambda_6^2+\lambda_3\lambda_5^2\lambda_6^2\\
&+\lambda_3\lambda_4^2\lambda_5\lambda_6+\lambda_3\lambda_4\lambda_5^2\lambda_6+\lambda_3\lambda_4\lambda_5\lambda_6^2+\lambda_3\lambda_4^3\lambda_5\lambda_6+\lambda_3\lambda_4\lambda_5^3\lambda_6\\
&+\lambda_3\lambda_4\lambda_5\lambda_6^3+\lambda_3\lambda_4^2\lambda_5^2\lambda_6+\lambda_3\lambda_4^2\lambda_5\lambda_6^2+\lambda_3\lambda_4\lambda_5^2\lambda_6^2+\lambda_3\lambda_4^3\lambda_5^2\lambda_6\\
&+\lambda_3\lambda_4^3\lambda_5\lambda_6^2+\lambda_3\lambda_4^2\lambda_5^3\lambda_6+\lambda_3\lambda_4^2\lambda_5\lambda_6^3+\lambda_3\lambda_4\lambda_5^3\lambda_6^2+\lambda_3\lambda_4\lambda_5^2\lambda_6^3\\
&+\lambda_3\lambda_4^2\lambda_5^2\lambda_6^2+\lambda_3\lambda_4^3\lambda_5^2\lambda_6^2+\lambda_3\lambda_4^2\lambda_5^3\lambda_6^2+\lambda_3\lambda_4^2\lambda_5^2\lambda_6^3.
\end{aligned}
\tag{4.29}
$$

We can now count directly the number of elements that we would have in our integrity basis if the components of the Γ' tensor were classical objects with no further properties. The denominator reflects the invariants that can be formed by mixing together components that belong to the same irreducible modules only. For each factor $(1-\lambda_i^{\beta_i})$ there is one such invariant giving, in the present case, a total of nine. These invariants are

$$
\begin{aligned}
&\hat{H}^{(2)}, \quad \hat{J}_{33}, \quad \hat{J}_y^2, \quad \hat{J}_+\hat{J}_-+\hat{J}_-\hat{J}_+, \quad \hat{J}_{+3}\hat{J}_{-3}+\hat{J}_{-3}\hat{J}_{+3}, \quad \hat{J}_{3+}\hat{J}_{3-}+\hat{J}_{3-}\hat{J}_{3+},\\
&\qquad \hat{J}_+^3-\hat{J}_-^3, \quad \hat{J}_{+3}^3-\hat{J}_{-3}^3, \quad \hat{J}_{3+}^3-\hat{J}_{3-}^3.
\end{aligned}
\tag{4.30}
$$

The numerator $N(\lambda_1,\ldots,\lambda_6)$ shows the number of invariants that can be constructed by multiplying components belonging to different irreducible singlets or doublets. It also allows us to determine the number of elements in the integrity basis. In the case of reducible representations there is in general some overcounting in N in this respect.

Consider an example: The presence of $\lambda_4\lambda_5$ in (4.29), indicates that there exists a quadratic invariant in both sets of components $\hat{J}_\pm$ and $\hat{J}_{\pm 3}$, call it $Y_6^{(2)}=-2(\hat{J}_+\hat{J}_{-3}+\hat{J}_-\hat{J}_{-3})$. Meanwhile, the terms λ_4^2 and λ_5^2 in the denominator have already told us that there are two quadratic invariants say $Y_4^{(2)}=2(\hat{J}_+\hat{J}_-+\hat{J}_-\hat{J}_+)$ and $Y_2^{(2)}=(\hat{J}_{+3}\hat{J}_{-3}+\hat{J}_{-3}\hat{J}_{+3})/2$ that can be formed using separately the 2 Γ_3-doublets $\hat{J}_\pm$ and $\hat{J}_{3\pm}$. It is then checked that the quartic invariant associated with the term $\lambda_4^2\lambda_5^2$ in N can be built out of the invariants $Y_6^{(2)}$, $Y_4^{(2)}$, and $Y_2^{(2)}$ already included in the integrity basis. It thus follows, as a rule, that in counting the number of elements in the integrity basis, one should discard from N the monomials that can be formed from those of the form $\lambda_i^{\beta_i}$ occuring in the factors of D and those of lower degree in N. When this is done in (4.29) we are left with the following 23 terms:

$$\begin{aligned}&1+\lambda_4\lambda_5+\lambda_4\lambda_6+\lambda_5\lambda_6+\lambda_4^2\lambda_5+\lambda_4\lambda_5^2+\lambda_4^2\lambda_6+\lambda_4\lambda_6^2+\lambda_5^2\lambda_6+\lambda_5\lambda_6^2\\&\quad+\lambda_4\lambda_5\lambda_6+\lambda_3\lambda_4\lambda_5+\lambda_3\lambda_4\lambda_6+\lambda_3\lambda_5\lambda_6+\lambda_3\lambda_4^3+\lambda_3\lambda_5^3+\lambda_3\lambda_6^3\\&\quad+\lambda_3\lambda_4^2\lambda_5+\lambda_3\lambda_4\lambda_5^2+\lambda_3\lambda_4^2\lambda_6+\lambda_3\lambda_4\lambda_6^2+\lambda_3\lambda_5^2\lambda_6+\lambda_3\lambda_5\lambda_6^2+\lambda_3\lambda_4\lambda_5\lambda_6.\end{aligned}\tag{4.31}$$

We thus have a total of 32 invariants. In terms of the basis elements (4.10), they read

$$\begin{aligned}
&Y_1^{(1)}=\hat{J}_{33}, && Y_2^{(1)}=\hat{H}^{(2)}-1\\
&Y_1^{(2)}=4\hat{J}_y^2, && Y_2^{(2)}=\tfrac{1}{2}\,(\hat{J}_{+3}\hat{J}_{-3}+\hat{J}_{-3}\hat{J}_{+3}),\\
&Y_3^{(2)}=\tfrac{1}{2}\,(\hat{J}_{3+}\hat{J}_{3-}+\hat{J}_{3-}\hat{J}_{3+}), && Y_4^{(2)}=2(\hat{J}_+\hat{J}_-+\hat{J}_-\hat{J}_+),\\
&Y_5^{(2)}=\hat{J}_{3+}\hat{J}_{-3}+\hat{J}_{3-}\hat{J}_{+3}, && Y_6^{(2)}=-2(\hat{J}_+\hat{J}_{-3}+\hat{J}_-\hat{J}_{+3})\\
&Y_7^{(2)}=-2(\hat{J}_{3-}\hat{J}_++\hat{J}_{3+}\hat{J}_-), && Y_1^{(3)}=4\hat{J}_y(\hat{J}_+\hat{J}_{3-}-\hat{J}_-\hat{J}_{3+}),\\
&Y_2^{(3)}=4\hat{J}_y(\hat{J}_+\hat{J}_{-3}-\hat{J}_-\hat{J}_{+3}), && Y_3^{(3)}=-2\hat{J}_y(\hat{J}_{3+}\hat{J}_{-3}-\hat{J}_{3-}\hat{J}_{+3}),\\
&Y_4^{(3)}=4i(\hat{J}_+^2\hat{J}_{3+}-\hat{J}_-^2\hat{J}_{3-}), && Y_5^{(3)}=4i(\hat{J}_+^2\hat{J}_{+3}-\hat{J}_-^2\hat{J}_{-3}),\\
&Y_6^{(3)}=i(\hat{J}_{3+}^2\hat{J}_{+3}-\hat{J}_{3-}^2\hat{J}_{-3}), && Y_7^{(3)}=-2i(\hat{J}_+\hat{J}_{3+}^2-\hat{J}_-\hat{J}_{3-}^2),\\
&Y_8^{(3)}=-2i(\hat{J}_+\hat{J}_{+3}^2-\hat{J}_-\hat{J}_{-3}^2), && Y_9^{(3)}=i(\hat{J}_{3+}\hat{J}_{+3}^2-\hat{J}_{3-}\hat{J}_{-3}^2),\\
&Y_{10}^{(3)}=-2i(\hat{J}_+\hat{J}_{3+}\hat{J}_{+3}-\hat{J}_-\hat{J}_{3-}\hat{J}_{-3}), && Y_{11}^{(3)}=-8i(\hat{J}_+^3-\hat{J}_-^3),\\
&Y_{12}^{(3)}=i(\hat{J}_{3+}^3-\hat{J}_{3-}^3), && Y_{13}^{(3)}=i(\hat{J}_{+3}^3-\hat{J}_{-3}^3),\\
&Y_1^{(4)}=-8i\hat{J}_y(\hat{J}_+^2\hat{J}_{3+}+\hat{J}_-^2\hat{J}_{3-}), && Y_2^{(4)}=-8i\hat{J}_y(\hat{J}_+^2\hat{J}_{+3}+\hat{J}_-^2\hat{J}_{-3}),\\
&Y_3^{(4)}=-2i\hat{J}_y(\hat{J}_{3+}^2\hat{J}_{+3}+\hat{J}_{3-}^2\hat{J}_{-3}), && Y_4^{(4)}=4i\hat{J}_y(\hat{J}_+\hat{J}_{3+}^2+\hat{J}_-\hat{J}_{3-}^2),\\
&Y_5^{(4)}=4i\hat{J}_y(\hat{J}_+\hat{J}_{+3}^2+\hat{J}_-\hat{J}_{-3}^2), && Y_6^{(4)}=-2i\hat{J}_y(\hat{J}_{3+}\hat{J}_{+3}^2+\hat{J}_{3-}\hat{J}_{-3}^2),\\
&Y_7^{(4)}=4i\hat{J}_y(\hat{J}_+\hat{J}_{3+}\hat{J}_{+3}+\hat{J}_-\hat{J}_{3-}\hat{J}_{-3}), && Y_8^{(4)}=16i\hat{J}_y(\hat{J}_+^3+\hat{J}_-^3),\\
&Y_9^{(4)}=-2i\hat{J}_y(\hat{J}_{3+}^3+\hat{J}_{3-}^3), && Y_{10}^{(4)}=-2i\hat{J}_y(\hat{J}_{+3}^3+\hat{J}_{-3}^3).
\end{aligned}$$

This is the point at which we must take into account the special nature of the realization we are using and the fact that there are various relations of the type (2.32) among the generators. This

leads one to the observation that of the 32 invariants given in (4.32) only 9 (actually 8) are functionally independent in the particular problem we are considering. Let us denote these nine invariants as follows:

$$\begin{aligned}
&\hat{J}_{33}=Y_1^{(1)}, \quad \hat{J}=Y_2^{(1)}/2, \quad \hat{J}_y^2=Y_1^{(2)}/4,\\
&X_1=-2Y_2^{(2)}, \quad X_{3/2}=Y_{13}^{(3)}, \quad X_{1/2}=Y_6^{(2)},\\
&X_{-1}=-2Y_3^{(2)}, \quad X_{-(3/2)}=Y_{12}^{(3)}, \quad X_{-(1/2)}=Y_7^{(2)}.
\end{aligned} \tag{4.32}$$

The remaining 23 invariants are expressed in terms of the above operators in the following manner: One first straightforwardly obtains the 19 relations below which give 19 of the 32 invariants as polynomials in the remaining ones

$$\begin{aligned}
&Y_4^{(2)}=4(\hat{J}(\hat{J}+1)-\hat{J}_y^2),\\
&Y_5^{(2)}=4\hat{J}_{33}(\hat{J}+1),\\
&Y_1^{(3)}=-Y_4^{(3)}-X_{-(1/2)}(2\hat{J}-3),\\
&Y_2^{(3)}=Y_5^{(3)}+X_{1/2}(2\hat{J}+5),\\
&Y_3^{(3)}=8\hat{J}_{33}\hat{J}_y^2,\\
&Y_6^{(3)}=-X_{-(1/2)}\hat{J}_{33},\\
&Y_7^{(3)}=2\hat{J}X_{-1},\\
&Y_8^{(3)}=2(\hat{J}+1)X_1,\\
&Y_9^{(3)}=-\hat{J}_{33}X_{1/2},\\
&Y_{10}^{(3)}=-8\hat{J}_{33}(\hat{J}(\hat{J}+1)-\hat{J}_y^2),\\
&Y_1^{(4)}=-4\hat{J}_y^2X_{-(1/2)}+X_{-(1/2)}(2\hat{J}-3)^2+Y_4^{(3)}(2\hat{J}-3),\\
&Y_2^{(4)}=4\hat{J}_y^2X_{1/2}-X_{1/2}(2\hat{J}+5)^2-Y_5^{(3)}(2\hat{J}+5),\\
&Y_3^{(4)}=-(X_{-(1/2)}(2\hat{J}-3)+Y_4^{(3)})\hat{J}_{33},\\
&Y_4^{(4)}=4\hat{J}_y^2X_{-1},\\
&Y_5^{(4)}=-4\hat{J}_y^2X_1,\\
&Y_6^{(4)}=\hat{J}_{33}(Y_5^{(3)}+X_{1/2}(2\hat{J}+5)),\\
&Y_7^{(4)}=-16\hat{J}_y^2\hat{J}_{33},\\
&Y_9^{(4)}=-\tfrac{1}{2}X_{-1}X_{-(1/2)}+X_{-(3/2)}(2\hat{J}-1),\\
&Y_{10}^{(4)}=-X_{3/2}(2\hat{J}+3)+\tfrac{1}{2}X_1X_{1/2}.
\end{aligned} \tag{4.33}$$

Allowing division by diagonal operators further permits us to write $Y_4^{(3)}$, $Y_5^{(3)}$, $Y_{11}^{(3)}$, and $Y_8^{(4)}$ as functions of operators (4.33)

$$\begin{aligned}
Y_4^{(3)}&=\frac{1}{2}X_{1/2}X_{-1}\frac{1}{(\hat{J}_{33}+2)},\\
Y_5^{(3)}&=-4X_{1/2}+\frac{1}{2}X_1X_{-(1/2)}\frac{1}{(\hat{J}_{33}+1)},\\
Y_{11}^{(3)}&=-X_{1/2}X_{-(1/2)}\frac{1}{(\hat{J}_{33}+1)}-16[\hat{J}-\hat{J}^3+\hat{J}_y^2(\hat{J}-2)],\\
Y_8^{(4)}&=-32[\hat{J}_y^2(\hat{J}^2+5\hat{J}-7-\hat{J}_y^2)+3\hat{J}(1-\hat{J}^2)]+2X_{1/2}X_{-(1/2)}\frac{\hat{J}-3}{(\hat{J}_{33}+1)}\\
&\quad+\frac{1}{2}X_{1/2}^2X_{-1}\frac{1}{(\hat{J}_{33}+1)(\hat{J}_{33}+2)}.
\end{aligned} \tag{4.34}$$

We may also remark that $\hat{J}_y^2$ could be eliminated in this fashion

$$\left(\hat{J}_y^2 = \hat{J}^2 - \frac{1}{16} X_1 X_{-1} \frac{1}{(\hat{J}_{33}+1)(\hat{J}_{33}+2)} \right)$$

but since it is a labeling operator we have chosen to keep it in the basis set (4.33).

In principle, a further reduction in the number of independent invariants could be expected from the noncommuting nature of the Γ'-tensor component $\hat{J}_{ij}$ as was explained in Sec. II. However since we shall give below the commutation relations between operators (4.33), there is no use in pursuing this question.

Note that set (4.33) includes the diagonal operators $\hat{H}^{(2)}$, $\hat{J}_{33}$, and $\hat{J}_y^2$; leaving six raising and lowering operators: $X_{\pm(3/2)}, X_{\pm(3/2)}, X_{\pm 1}$. Observe further that

$$X_s^\dagger = X_{-s}, \quad s = \tfrac{3}{2}, \tfrac{1}{2}, 1. \tag{4.35}$$

C. The symmetry algebra: Representation and commuting relations

We now wish to present the action of these operators X_s, $s = \pm(3/2), \pm(1/2), \pm 1$ on the symmetric 3-oscillator states $|j,l,n_3\rangle$ to show that they indeed transform these vectors irreducibly among themselves. This action reads as follows:

$$\hat{J}_{33}|j,l,n_3\rangle = n_3|j,l,n_3\rangle, \tag{4.36}$$

$$\hat{J}|j,l,n_3\rangle = j|j,l,n_3\rangle, \tag{4.37}$$

$$\hat{J}_y^2|j,l,n_3\rangle = l^2|j,l,n_3\rangle, \tag{4.38}$$

$$X_{-1}|j,l,n_3\rangle = 4\sqrt{(j+l)(j-l)(n_3+1)(n_3+2)}\,|j-1,l,n_3+2\rangle, \tag{4.39}$$

$$\begin{aligned} X_{-(3/2)}|j,l,n_3\rangle = &-\sqrt{8(j-l-2)(j-l-1)(j-l)(n_3+1)(n_3+2)(n_3+3)}\,|j-\tfrac{3}{2},l+\tfrac{3}{2},n_3+3\rangle \\ &+\sqrt{8(j+l-2)(j+l-1)(j+l)(n_3+1)(n_3+2)(n_3+3)}\,|j-\tfrac{3}{2},l-\tfrac{3}{2},n_3+3\rangle, \end{aligned} \tag{4.40}$$

$$\begin{aligned} X_{-(1/2)}|j,l,n_3\rangle = &-\sqrt{8(j-l-1)(j-l)(j+l+1)(n_3+1)}\,|j-\tfrac{1}{2},l+\tfrac{3}{2},n_3+1\rangle \\ &+\sqrt{8(j+l-1)(j+l)(j-l+1)(n_3+1)}\,|j-\tfrac{1}{2},l-\tfrac{3}{2},n_3+1\rangle, \end{aligned} \tag{4.41}$$

$$\begin{aligned} X_{1/2}|j,l,n_3\rangle = &\sqrt{8(j-l)(j+l+1)(j+l+2)n_3}\,|j+\tfrac{1}{2},l+\tfrac{3}{2},n_3-1\rangle \\ &-\sqrt{8(j+l)(j-l+1)(j-l+2)n_3}\,|j+\tfrac{1}{2},l-\tfrac{3}{2},n_3-1\rangle, \end{aligned} \tag{4.42}$$

$$\begin{aligned} X_{3/2}|j,l,n_3\rangle = &\sqrt{8(j+l+1)(j+l+2)(j+l+3)n_3(n_3-1)(n_3-2)}\,|j+\tfrac{3}{2},l+\tfrac{3}{2},n_3-3\rangle \\ &-\sqrt{8(j-l+1)(j-l+2)(j-l+3)n_3(n_3-1)(n_3-2)}\,|j+\tfrac{3}{2},l-\tfrac{3}{2},n_3-3\rangle, \end{aligned} \tag{4.43}$$

$$X_1|j,l,n_3\rangle = 4\sqrt{(j+l+1)(j-l+1)n_3(n_3-1)}\,|j+1,l,n_3-2\rangle. \tag{4.44}$$

Notice that in these expressions, formula (4.22) has to be used whenever l becomes negative.

Finally, we give the commutation relations among the eight independent generators of (4.33) [excluding $\hat{J}_y^2$ and taking (4.35) into account]

$$[X_1, X_{3/2}] = 0,$$

$$[X_1, X_{1/2}] = -4X_{3/2},$$

$$[X_1, X_{-(1/2)}] = 2X_1 X_{-(1/2)} \frac{1}{(\hat{J}_{33}+1)} + 8X_{1/2}(\hat{J}_{33}-1),$$

$$[X_1, X_{-(3/2)}] = 6X_{1/2}X_{-1} \frac{(\hat{J}_{33}+1)}{(\hat{J}_{33}+2)} + 12X_{-(1/2)}(4\hat{J}+4\hat{J}\hat{J}_{33}-3\hat{J}_{33}-\hat{J}_{33}^2-4),$$

$$[X_1, X_{-1}] = 16[\hat{J}_{33}(1+2\hat{J}-\hat{J}_{33}(1+2\hat{J})+4(\hat{J}^2-\hat{J}_y^2))] + 32(\hat{J}^2-\hat{J}_y^2), \tag{4.45}$$

$$[X_{3/2}, X_{1/2}] = 3X_1^2,$$

$$[X_{3/2}, X_{-(1/2)}] = -3X_{1/2}^2 - 12X_1(2\hat{J}_{33}(1+\hat{J})-\hat{J}-2\hat{J}_y^2-4),$$

$$[X_{3/2}, X_{-(3/2)}] = X_{1/2}X_{-(1/2)} \frac{(9\hat{J}_{33}^2+9\hat{J}_{33}+6)}{(\hat{J}_{33}+1)} - 96(3\hat{J}^2-4\hat{J}\hat{J}_y^2+5\hat{J}_y^2-3\hat{J}) - 48\hat{J}_{33}(15\hat{J}^2+21\hat{J}_y^2$$
$$+4-12\hat{J}\hat{J}_y^2-3\hat{J}) - 288\hat{J}_{33}^2(\hat{J}_y^2-2\hat{J}_y^2\hat{J}-3\hat{J}-1) - 48\hat{J}_{33}^3(2+3\hat{J}+3\hat{J}^2+3\hat{J}_y^2),$$

$$[X_{1/2}, X_{\cdot(1/2)}] = X_{1/2}X_{-(1/2)} \frac{1}{(\hat{J}_{33}+1)} - \hat{J}_{33}(48\hat{J}^2-80\hat{J}_y^2+48\hat{J}).$$

V. CONCLUSIONS

How the general description of S_N-invariant oscillator states given in Sec. II applies to specific cases should be clear from the discussions in Secs. III and IV. If we wished to work out the case $N=4$ with $H^{(4)}=\Sigma_{i=1}^4 a_i^+ a_i$, for instance, the analysis would proceed as in the last section. The cycles σ_{12}, σ_{123}, and σ_{1234} of length 2, 3, and 4, respectively, can now be used to generate S_4. It remains convenient to pass to relative and CM coordinates and one might again take those of Jacobi. It proves in fact more practical to introduce the set

$$\begin{aligned} \hat{x}_1 &= \tfrac{1}{2}(x_1+x_2-x_3-x_4), \quad \hat{x}_2 = \tfrac{1}{2}(x_2+x_3-x_1-x_4), \\ \hat{x}_3 &= \tfrac{1}{2}(x_1+x_3-x_2-x_4), \quad \hat{x}_4 = \tfrac{1}{2}(x_1+x_2+x_3+x_4), \end{aligned} \tag{5.1}$$

which is such that σ_{12}: $\hat{x}_1 \to \hat{x}_1$, σ_{1234}: $\hat{x}_3 \to -\hat{x}_3$. The Hamiltonian $H^{(4)}$ is U(4) invariant. The operators $H^{(3)}$ and $\hat{J}_{44}$ are taken to be diagonal on the state vectors thus subducing to U(3) representations. Two more S_4-invariant labeling operators are to be found in $\mathcal{U}(\mathrm{U}(3))$. Since S_4 acts by improper three-dimensional rotations on the coordinates $\hat{x}_1$, $\hat{x}_2$, $\hat{x}_3$, we are led to the following chain of subgroups $\mathrm{U}(4)\supset\mathrm{U}(3)\supset\mathrm{O}(3)\supset\mathrm{O}(2)$.

The case $N=5$ admits of course a similar treatment with the Wigner supermultiplet scheme underlying it: $\mathrm{U}(5)\supset\mathrm{U}(4)\supset\mathrm{U}(2)\times\mathrm{U}(2)$.

The situation obviously becomes more and more complicated as the number of oscillators is increased, and while the formalism applies in general we do not have explicit formulas for arbitrary N. This requires further investigation.

We have been concerned in this paper with the invariance algebra of N-identical oscillators. It could be interesting to examine in the same spirit the spectrum-generating algebras of these systems. Instead of starting from $\mathrm{SU}(N)$, one would base the analysis on $\mathrm{Sp}(2N)$ or even the superalgebra $\mathrm{OSp}(N,2N)$. In this connection, let us remark that the nonlinear algebras of identical oscillators are embedded in the (completion of) universal Heisenberg algebra $\mathcal{U}(\mathcal{H}(N))$ generated by the creation and annihilation operators a_i, a_i^+ $i=1,...,N$. It could prove instructive to study directly the quotient of this algebra under S_N.

Our study raises a number of challenging issues. Noteworthy is the problem of understanding the structure of the nonlinear symmetry algebras and developing their representation theory. This could be done of course in the special case $N=2$ where the symmetries form a cubic SU(2) algebra with three generators. The case $N=3$, has brought a rare example of a dynamical nonlinear algebra of higher dimension. A representation of it could be obtained from the physical problem; this should be of help towards understanding these nonlinear algebras and their representations more abstractly. It is tantalizing that many polynomial algebras of physical interest can be identified as finite W algebras.[14] Whether this is the case in the present problem should be examined.

Finally, we plan to extend the results presented here to systems of the Calogero–Moser type so as to develop the algebraic treatment of these models. We should point out that this has already been done for the special case $N=2$[15] and $N=3$.[16] We hope to report on some of these interesting questions in the near future.

Rational conformal field theory extensions of $W_{1+\infty}$ in terms of bilocal fields

L. S. Georgiev and I. T. Todorov
Institute for Nuclear Research and Nuclear Energy,
Tsarigradsko Chaussee 72, BG-1784 Sofia, Bulgaria

(Received 29 October 1997; accepted for publication 25 March 1998)

The rational conformal field theory extensions of $W_{1+\infty}$ at $c=1$ are in one-to-one correspondence with one-dimensional integral lattices $L(m)$. Each extension is associated with a pair of oppositely charged ''vertex operators'' of charge square $m \in \mathbf{N}$. Their product defines a bilocal field $V_m(z_1,z_2)$ whose expansion in powers of $z_{12}=z_1-z_2$ gives rise to a series of (neutral) local quasiprimary fields $V^l(z,m)$ (of dimension $l+1$). The associated bilocal exponential of a normalized current generates the $W_{1+\infty}$ algebra spanned by the $V^l(z,1)$ (and the unit operator). The extension of this construction to higher (integer) values of the central charge c is also considered. Applications to a quantum Hall system require computing characters (i.e., chiral partition functions) depending not just on the modular parameter τ, but also on a chemical potential ζ. We compute such a ζ dependence of orbifold characters, thus extending the range of applications of a recent study of affine orbifolds. © *1998 American Institute of Physics.* [S0022-2488(98)01011-1]

I. INTRODUCTION

The unitary positive energy representations of $W_{1+\infty}$ (Ref. 1) correspond to positive integer central charges $c \in \mathbf{N}$. A standard tool in their study[1–4] is the embedding of all irreducible modules for a given c into the Fock space of c pairs of free Weyl fermion fields $\psi_i^*(z)$. It has been used in Ref. 5 to develop a conformal (quantum) field theory (CFT) approach to $W_{1+\infty}$ based on the expansion of the bilocal field

$$V_1(z_1,z_2)=\sum_{i=1}^{c}\left(\psi_i^*(z_1)\psi_i(z_2)-\frac{1}{z_{12}}\right), \quad z_{12}=z_1-z_2 \tag{1.1}$$

into local quasiprimary fields. V_1 is invariant under $\mathrm{SO}(2c)(\supset \mathrm{U}(1)^{\times c})$ gauge transformations in the $2c$-dimensional space of ψ_i and ψ_i^* [it is, in particular, $\mathrm{U}(1)^{\times c}$ neutral]. The index 1 on V indicates the charge square of ψ_i (and ψ_i^*) which coincides with the (total) conformal dimension of V_1: there is a representation $U(\rho)$ of the multiplicative group of positive reals ($\rho>0$) in the state space of our CFT such that

$$U(\rho)V_1(z_1,z_2)U(\rho)^{-1}=\rho V_1(\rho z_1,\rho z_2) \quad (\text{and } U(\rho)|0\rangle=|0\rangle) \tag{1.2}$$

($|0\rangle$ representing the unique zero-energy state, the *vacuum* of the theory). The chiral algebra W_c of c Weyl fermions (and their conjugates) corresponds to the simplest orthogonal lattice, $\mathbf{Z}^c$, of admissible charges: $W_c=\mathscr{A}(\mathbf{Z}^c)$. In general, the abelian compact Lie group $\mathrm{U}(1)^{\times c}$ defines a lattice in $\mathrm{u}(1)^{\otimes c}$ of elements ω satisfying $e^{2\pi i\omega}=1$ (where 1 stands for the group unit). Equipped with a positive definite integral quadratic form, $(\omega|\omega') \in \mathbf{Z}$ $|\omega|^2=(\omega|\omega) \in \mathbf{N}$ for $\omega \neq 0$, L gives rise to a chiral algebra $\mathscr{A}(L)$ whose positive energy (localizable) representations give rise to a rational conformal field theory (RCFT) (see, e.g., Sec. 1 of Ref. 6). Singling out a current $H(z)$ in the Kac–Moody algebra $\hat{\mathrm{u}}(1)^{\otimes c}$ we can view $\mathscr{A}(L)$ as a RCFT extension of the level c $W_{1+\infty}$ algebra which contains H. We define a bilocal field $V_m(z_1,z_2)$, expressed as a bilocal exponential in H—see (2.17) [generalizing (1.1) to any positive integer charge square m] and establish for it

 © 1998 American Institute of Physics

an *operator product expansion* (OPE) of quasiprimary fields $V^l(z,m)$ of dimension $l+1$ ($l=0,1,\ldots$). We prove, however, that only for $m=1$, in which case the fields $V^i(z)=V^l(z,1)$ are expressed in terms of an orthonormal set of u(1) currents J^i,

$$\langle J^i(z_1)J^j(z_2)\rangle=\delta_{ij}z_{12}^{-2},\quad i,j=1,\ldots,c, \tag{1.3}$$

do the V^l (and the unit operator) close an infinite dimensional Lie algebra (which coincides with the level c $W_{1+\infty}$). We work out the details, establishing exact OPE formulas, in Sec. II for the case $c=1$ and indicate the extension to arbitrary $c\in\mathbf{N}$ in Sec. III.

II. RATIONAL EXTENSIONS OF $W_{1+\infty}$ FOR $C=1$. OPE OF QUASIPRIMARY BILOCAL FIELDS

A. Local field basis for $W_{1+\infty}$ in terms of Schur polynomials of a u(1) current and its derivatives

The product of two oppositely charged fields $\phi^{\pm}(z)$ of charge square m can be expressed as a normal ordered exponential of a U(1) current:[7]

$$\phi^+(z_1)\phi^-(z_2)=z_{12}^{-m}:\exp\left\{\int_{z_2}^{z_1}H(z)\mathrm{d}z\right\}:,\quad z_{12}=z_1-z_2. \tag{2.1}$$

(The subtractions involved in the definition of normal ordering can be formally described by dividing the exponential by its vacuum expectation value.) The normalization of the ''Cartan current'' H can be read off the singular terms of the OPE:

$$H(z_1)H(z_2)\sim\frac{m}{z_{12}^2},\quad H(z_1)\phi^{\pm}(z_2)\sim\frac{\pm m}{z_{12}}\phi^{\pm}(z_2). \tag{2.2}$$

For a $c=1$ theory the stress energy tensor $T(z)$ is expressed in terms of H by the Sugawara formula:

$$T(z)=\frac{1}{2m}:H^2(z):\quad\left(:H(z_1)H(z_2):\equiv H(z_1)H(z_2)-\frac{m}{z_{12}^2}\right). \tag{2.3}$$

Its Laurent modes L_n generate the Virasoro algebra:

$$T(z)=\sum_{n\in\mathbf{Z}}L_nz^{-n-2}\left([L_n,L_{n'}]=(n-n')L_{n+n'}+\frac{c}{12}(n^3-n)\delta_{n,-n'},\quad c=1\right). \tag{2.4}$$

A central result in Ref. 5 says that the bilocal field (2.1) is, for $m=1$, a generating functional for a local field basis of the $W_{1+\infty}$ algebra. In fact, it then coincides (up to a c-number term) with (1.1) for central charge $c=1$. We shall reformulate this result using the U(1) current alone (without reference to the free Weyl field ψ) thus extending it to the more general current algebra framework.

Denote the normalized U(1) current $(1/\sqrt{m})H(z)$ by $J^0(z)$. Using the Taylor expansion of the integral in the exponential in (2.1),

$$\int_{z_2}^{z_1}J^0(z)\mathrm{d}z=\sum_{l=0}^{\infty}\frac{z_{12}^{l+1}}{(l+1)!}\partial_2^lJ^0(z_2)\quad\left(\partial_2=\frac{\partial}{\partial z_2};\quad\langle J^0(z_1)J^0(z_2)\rangle_0=z_{12}^{-2}\right) \tag{2.5}$$

we introduce the *Schur polynomials* (in the terminology of Refs. 8 and 9) of J^0 and its derivatives,

$$J^l(z)=l!:S_{l+1}\left(J^0(z),\frac{\partial J^0(z)}{2!},\ldots,\frac{\partial^lJ^0(z)}{(l+1)!}\right):, \tag{2.6}$$

setting

$$V_1(z_1,z_2)=\frac{1}{z_{12}}\left(:\exp\left\{\int_{z_2}^{z_1}J^0(z)\mathrm{dz}\right\}:-1\right)=\sum_{l=0}^{\infty}\frac{z_{12}^l}{l!}J^l(z_2). \tag{2.7}$$

In general, a Schur polynomial of N variables is defined by

$$S_N(t_1,t_2,\ldots,t_k,\ldots)=\sum_{n_1+2n_2+\cdots+kn_k+\cdots=N}\frac{t_1^{n_1}t_2^{n_2}\cdots t_k^{n_k}\cdots}{n_1!n_2!\cdots n_k!\cdots}. \tag{2.8}$$

The series of all Schur polynomials (of an increasing number of variables) is generated by

$$\exp\left(\sum_{k=1}^{\infty}t_kz^k\right)=\sum_{N=0}^{\infty}z^NS_N(t_1,t_2,\ldots,t_k,\ldots). \tag{2.9}$$

$J^l(z)$, as computed from (2.5) and (2.7), satisfy the recurrence relation

$$(l+1)J^l(z)=(J^0+\partial)lJ^{l-1}=\cdots=(J^0+\partial)^lJ^0\left(\equiv(l+1)!S_{l+1}(J^0,\ldots),\partial\equiv\frac{\mathrm{d}}{\mathrm{dz}}\right); \tag{2.10}$$

we have: $2J^1=(J^0)^2+\partial J^0$, $3J^2=(J^0)^3+3J^0\partial J^0+\partial^2J^0$, $4J^3=(J^0)^4+6(J^0)^2\partial J^0+3(\partial J^0)^2+4J^0\partial^2J^0+\partial^3J^0$, etc. (Viewed as quantum operators these expressions should be understood as normal products.) The local fields J^l (which, together with the unit operator span the infinite dimensional Lie algebra $W_{1+\infty}$) are singled for their simple commutation relations (Ref. 5, Lemma 1.2) which are coded in the (singular terms of the) OPE

$$J^k(z_1)J^l(z_2)\simeq\sum_{\nu\geqslant1}\left\{\frac{l!}{(l-\nu)!}J^{k+l-\nu}(z_2)-(-1)^\nu\frac{k!}{(k-\nu)!}J^{k+l-\nu}(z_1)\right\}z_{12}^{-\nu-1}$$
$$+(-1)^kl!k!z_{12}^{-k-l-2}. \tag{2.11}$$

As we shall see shortly, the bilocal field (2.7) can also be expanded in a basis of local *quasiprimary* fields $V^l(z)$ of dimension $l+1$ which are expressed in terms of J^l (Ref. 5, Lemma 1.3) by

$$V^l(z)=\frac{(l!)^2}{(2l)!}\sum_{k=0}^{\infty}(-1)^k\binom{l}{k}\binom{2l-k}{l}\partial^kJ^{l-k}(z). \tag{2.12}$$

A characteristic feature of quasiprimary fields is their orthogonality; indeed, the two-point function of a pair of V^l's is

$$\langle V^l(z_1)V^{l'}(z_2)\rangle_0=\frac{(l!)^2}{(2l)!}z_{12}^{-2l-2}\delta_{l,l'} \tag{2.13}$$

($\langle\cdots\rangle_0$ being a shorthand for the vacuum expectation value $\langle0|\cdots|0\rangle_0$).

According to Ref. 1 each positive energy unitary irreducible representation of $W_{1+\infty}$ for $c=1$ is characterized by a single real number r, the J^0 charge, and the existence of a unique ground state $|r\rangle$ such that

$$(J_0^0-r)|r\rangle=0=(L_0-\tfrac{1}{2}r^2)|r\rangle,\quad J_n^0|r\rangle=0(=L_n|r\rangle)\quad\text{for } n>0. \tag{2.14}$$

Here J_n^0 are the $J^0(z)$ Laurent modes, such that

$$J^0(z)=\sum_{n\in\mathbf{Z}}J_n^0z^{-n-1},\quad[J_n^0,J_{n'}^0]=n\delta_{n,-n'}. \tag{2.15}$$

The *minimal quantum field theory* whose state space includes the irreducible $W_{1+\infty}$ modules $\mathscr{H}$ and $\mathscr{H}_r$ (the *vacuum module* and the charge $r\neq0$ module $\mathscr{H}_r$) is generated by a pair of oppositely charged fields $\phi(z,\pm r)$. Its OPE algebra contains (the $W_{1+\infty}$ currents and) an infinite series of

charged fields $\phi(z,nr)$, $n\in\mathbf{Z}$ (relatively local to J^0—see Ref. 10). For $r^2=m\in\mathbf{N}$ they are also local among themselves Bose or Fermi fields; more precisely, they satisfy

$$z_{12}^{r_1r_2}\phi(z_1,r_1)\phi(z_2,r_2)=z_{21}^{r_1r_2}\phi(z_2,r_2)\phi(z_1,r_1)\quad \text{for } r_{1,2}\in\mathbf{Z}\sqrt{m}\quad (m=1,2,\ldots\text{fixed}). \tag{2.16}$$

In this case we recover the algebra $\mathscr{A}_m$ generated by the fields $\phi^{\pm}(z)=\phi(z,\pm\sqrt{m})$ satisfying (2.1), which provides a RCFT extension of $W_{1+\infty}$. Moreover, as noted in Ref. 5 (Sec. 3) any RCFT extension of $W_{1+\infty}$ for $c=1$ is of this type.

B. Expansion of the dipole field (2.1) into local quasiprimary fields $V^l(z,m)$

We introduce for arbitrary $m(=1,2,\ldots)$ and $c=1$ the counterpart of (1.1), the *bilocal field*

$$V_m(z_1,z_2)=z_{12}^{m-1}\phi^+(z_1)\phi^-(z_2)-z_{12}^{-1}=\frac{1}{z_{12}}\left(:\exp\left\{\int_{z_2}^{z_1}H(z)\mathrm{d}z\right\}:-1\right); \tag{2.17}$$

it is *quasiprimary* of total dimension 1 in the sense that it satisfies

$$[L_n,V_m(z_1,z_2)]=\sum_{i=1}^{2}z_i^n\left(z_i\frac{\partial}{\partial z_i}+\frac{n+1}{2}\right)V_m(z_1,z_2)\quad \text{for } n=0,\pm1. \tag{2.18}$$

(It is easily verified, in particular, that the differential operators on the right-hand side annihilate, for $n=0,\pm1$, the two-point function z_{12}^{-1}.) Equation (2.17) [with the current H satisfying (2.2)] provides a version of the vertex operator construction, thus allowing one to compute the correlation functions of V_m. We have, in particular, $\langle V_m(z_1,z_2)\rangle_0=0$,

$$\begin{aligned}\langle V_m(z_1,z_2)V_m(z_3,z_4)\rangle_0&=\frac{1}{z_{12}z_{34}}\{(1-\eta)^{-m}-1\}\\&=\frac{m}{z_{13}z_{24}}\sum_{n=0}^{\infty}\binom{m+n}{m}\frac{\eta^n}{n+1},\qquad \eta=\frac{z_{12}z_{34}}{z_{13}z_{24}};\end{aligned} \tag{2.19}$$

$$\begin{aligned}&\langle V_m(z_1,z_2)V_m(z_3,z_4)V_m(z_5,z_6)\rangle_0\\&=(z_{12}z_{34}z_{56})^{-m}\left\{2-\left(\frac{z_{13}z_{24}}{z_{23}z_{14}}\right)^m-\left(\frac{z_{35}z_{46}}{z_{36}z_{45}}\right)^m-\left(\frac{z_{15}z_{26}}{z_{16}z_{25}}\right)^m+\left(\frac{z_{13}z_{24}z_{35}z_{46}z_{15}z_{26}}{z_{23}z_{14}z_{36}z_{45}z_{16}z_{25}}\right)^m\right\}.\end{aligned} \tag{2.20}$$

We shall describe the complete OPE of (2.17) into local Bose fields thus extending to arbitrary $m\in\mathbf{N}$ an earlier result about V_1 (cf. Theorem 2.1 of Ref. 5).

Theoorem 2.1: *The bilocal field (2.17) admits an expansion in integrals over local quasiprimary fields V^l (of dimension $l+1$):*

$$V_m(z_1,z_2)=\sum_{l=0}^{\infty}\frac{z_{12}^l}{l!}\int_{z_2}^{z_1}p_l(z;z_1,z_2)V^l(z,m)\mathrm{d}z, \tag{2.21}$$

where p_l is the (normalized) weight function

$$p_l(z;z_1,z_2)=\frac{(2l+1)!}{(l!)^2z_{12}^{2l+1}}(z_1-z)^l(z-z_2)^l\quad \left(\int_{z_2}^{z_1}p_l(z;z_1,z_2)\mathrm{d}z=1\right). \tag{2.22}$$

The two-point functions of V^l (which display their orthogonality),

$$\frac{l+1}{l!}\langle V^l(z_1,m)V^{l'}(z_2,m)\rangle_0=C_{lm}z_{12}^{-2l-2}\delta_{l,l'}, \tag{2.23}$$

involve the same normalization constant as the three-point function

$$(l+1)\langle V_m(z_1,z_2)V^l(z_3,m)\rangle_0 = C_{lm}\frac{z_{12}^l}{(z_{13}z_{23})^{l+1}}. \tag{2.24}$$

The (positive) constants C_{lm} are uniquely determined by the four-point function (2.19). Conversely, $V^l(z,m)$ are computed from $V_m(z_1,z_2)$ by differentiation:

$$V^l(z,m) = \frac{l!}{(2l)!}\lim_{z_1,z_2\to z}\{\partial_1^l(-\partial_2)^l(z_{12}^l V_m(z_1,z_2))\}. \tag{2.25}$$

Furthermore, V^l are again related to the Schur polynomials $S_n(H,\partial H/2!,\ldots,(\partial^{n-1}H)/n!)$ by (the counterpart of) Eq. (2.12).

The *proof* follows, for the most part the argument in Ref. 5 and we shall only sketch it emphasizing the new points.

The weight function (2.22) satisfies the identity

$$\int_{z_2}^{z_1} p_l(z;z_1,z_2)(z-z_3)^{-2l-2}dz = z_{13}^{-l-1}z_{23}^{-l-1}. \tag{2.26}$$

Since, on the other hand, two- and three-point functions of quasiprimary fields are determined (up to normalization constants) by Möbius (conformal) invariance, this implies

$$\langle V_m(z_1,z_2)V^l(z_3,m)\rangle_0 = \frac{z_{12}^l}{l!}\int_{z_2}^{z_1} p_l(z;z_1,z_2)\langle V^l(z,m)V^l(z_3,m)\rangle_0 \mathrm{dz}. \tag{2.27}$$

Orthogonality of V^l [reflected in (2.23)] is a general property of quasiprimary fields of different dimensions. Inserting the expansion (2.21) for $V_m(z_3,z_4)$ into (2.19) and using (2.24) we end up with a triangular set of linear equations for C_{lm}:

$$(1-\eta)^{-m} = 1+\sum_{l=0}^{\infty} C_{lm}\frac{\eta^{l+1}}{(l+1)!}F(l+1,l+1;2l+2;\eta). \tag{2.28}$$

Here we have used the following representation for the Gauss hypergeometric function

$$F(n,n;2n;\eta) = z_{13}^n z_{24}^n\int_{z_4}^{z_3}\frac{p_{n-1}(z;z_3,z_4)\mathrm{dz}}{(z_1-z)^n(z_2-z)^n} \quad \left(\eta = \frac{z_{12}z_{34}}{z_{13}z_{24}}\right). \tag{2.29}$$

We thus have

$$\sum_{l=0}^{\infty} C_{lm}\frac{\eta^{l+1}}{(l+1)!}\sum_{n=0}^{\infty}\binom{l+n}{n}^2\binom{2l+1+n}{n}^{-1}\eta^n = \sum_{l=0}^{\infty}\binom{m+l}{l+1}\eta^{l+1}. \tag{2.30}$$

The first seven C_{lm} are captured by

$$C_{lm} = m^{l+1}+\binom{l+1}{4}\frac{m^{l-1}}{2l-1}+\binom{l+1}{6}\frac{5l^2-7l+6}{8(2l-1)(2l-3)}m^{l-3} \quad \text{for } 0\leqslant l\leqslant 6. \tag{2.31}$$

On the other hand, for $m=1$, we recover the expression $C_{l1}=(l+1)!\binom{2l}{l}^{-1}$ of Ref. 5. The important point is the existence of a unique solution of the (infinite) system (2.30) $C_{lm}>0$.

Finally, Lemma 1.3 of Ref. 5 holds in this case, too, and we can write

$$V^l(z,m) = \frac{(l!)^2}{(2l)!}\sum_{k=0}^{l}(-1)^k\binom{l}{k}\binom{2l-k}{l}(l-k)!\,\partial^k S_{l-k+1}\left(H,\frac{\partial H}{2!},\ldots,\frac{\partial^{l-k}H}{(l-k+1)!}\right), \tag{2.32}$$

where $S_{n+1}(H,\partial H/2!,\ldots,\partial^n H/(n+1)!)=(H+\partial)^n H$ [cf. Eq. (2.10)] and we omit (here and in the following remark) the normal product sign.

Remark 2.1: In spite of the fact that $V^l(z)=V^l(z,1)$ is expressed by the same Schur polynomials as $V^l(z,m)$—only the argument H is substituted by the normalized current J^0 in $V^l(z,1)$—the quasiprimary fields $V^l(z,m)$ do not close under commutation among themselves (and the unit operator) for $m\geqslant 2$. In effect the fields $V^l(z,m)=m^{(l+1/2)}V^l(z)$ for $l=0,1,2$ generate the whole $W_{1+\infty}$ algebra spanned by $V^l(z)$ (and 1). On the other hand, the fields $V^l(z,m)$ and $V^l(z)$ are linearly independent for $l\geqslant 3$, $m\geqslant 2$. Indeed, we have

$$V^3(z,m)=\frac{H^4(z)}{4}+\frac{1}{20}P_1(H,H',H'')=\frac{m^2}{4}J^4(z)+\frac{m}{20}(2JJ''-3J'^2)(z)(\text{for } H=\sqrt{m}J);$$

$$V^4(z,m)=\frac{1}{5}H^5+\frac{1}{7}HP_1,\ \text{etc.} \tag{2.33}$$

Here P_1 is the first of a series of quasiprimary fields that are quadratic forms P_n of H and its derivatives (each term having dimension $2n+2$):

$$P_n(H,H',\ldots,H^{(2n)})=2\sum_{l=0}^{n-1}(-1)^l a_l H^{(l)}H^{(2n-l)}+(-1)^n a_n (H^{(n)})^2,$$

$$a_l=\prod_{k=0}^{l-1}\binom{2n-1+k}{2}\prod_{k=l}^{n-1}\binom{k+2}{2}. \tag{2.34}$$

III. EXTENSION TO ARBITRARY $C\in$ N: DISCUSSION

A. Additive bilocal fields and lattice RCFT extensions

The construction of Sec. II extends to arbitrary positive integer c due to the following simple observation.

Proposition 3.1: (Ref. 5, Lemma 2.2) *Let $V_i(z_1,z_2)$,$1\leqslant i\leqslant c$ be a commuting set of bilocal fields with the properties of $V_1(z_1,z_2)$* (2.7). *Then their sum generates the $W_{1+\infty}$ algebra for central charge c*:

$$\sum_{i=1}^{c}V_i(z_1,z_2)=\sum_{l=0}^{\infty}\frac{z_{12}^l}{l!}J^l(z_2)\Rightarrow[J^k(z_1),J^l(z_2)]=\sum_{\nu\geqslant 1}\left\{(-1)^\nu\binom{l}{\nu}J^{k+l-\nu}(z_2)\right.$$
$$\left.-\binom{k}{\nu}J^{k+l-\nu}(z_1)\}\,\delta^{(\nu)}(z_{12})\right\}-(-1)^l\frac{k!l!c}{(k+l+1)!}\delta^{(k+l+1)}(z_{12}). \tag{3.1}$$

If we use the bosonized expressions

$$V_i(z_1,z_2)=\frac{1}{z_{12}}\left(:\exp\left\{\int_{z_2}^{z_1}J_i^0(z)\mathrm{d}z\right\}:-1\right)\text{with}[J_i^0(z_1),J_j^0(z_2)]=-\delta'(z_{12})\delta_{ij}, \tag{3.2}$$

then $J^l(z)=\Sigma_{i=1}^c J_i^l(z)$ where J_i^l is expressed as a Schur polynomial of $J_i^0(z)$ and its derivatives

$$J_i^l(z)=l!S_{l+1}\left(J_i^0(z),\frac{\partial J_i^0(z)}{2!},\ldots,\frac{\partial^l J_i^0(z)}{(l+1)!}\right). \tag{3.3}$$

Similarly, the basic quasiprimary fields $V^l(z)$ appear as sums of mutually commuting $c=1$ fields $V_i^l(z,1)$.

Let $W^{(c)}$ be the chiral algebra corresponding to the vacuum representation of $W_{1+\infty}$ of central charge c; it is spanned by (normal ordered) polynomials of $V^l(z)$. The set of RCFT extensions is much richer for $c>1$. It includes, in particular, local charged fields' algebras $\mathscr{A}(L)$ associated with a c-dimensional integral Euclidean charge lattice L. In other words, there is a basis $(\mathbf{q}^1,\ldots,\mathbf{q}^c)$ in the space of $\mathrm{U}(1)^{\times c}$ charges such that the (symmetric) positive definite Gram matrix

$(\mathbf{q}^i|\mathbf{q}^j)$ of inner products has integer entries. To each such lattice corresponds a vertex algebra (for a recent review—see Ref. 11) spanned by charged vertex operators $Y(\mathbf{q},z)$ and ''Cartan currents'' $H^{\mathbf{q}}(z)$ satisfying OPE of the type

$$Y(\mathbf{q},z_1)Y(-\mathbf{q},z_2)=\frac{1}{z_{12}^{|\mathbf{q}|^2}}:\exp\left\{\int_{z_2}^{z_1}H^{\mathbf{q}}(z)\mathrm{d}z\right\}:,\quad H^{\mathbf{q}}(z_1)H^{\mathbf{q}'}(z_2)\sim\frac{(\mathbf{q}|\mathbf{q}')}{z_{12}^2},\tag{3.4}$$

$$Y(\mathbf{q},z_1)Y(\mathbf{q}',z_2)\sim\varepsilon(\mathbf{q},\mathbf{q}')z_{12}^{(\mathbf{q}|\mathbf{q}')}Y(\mathbf{q}+\mathbf{q}',z_2)\quad(\text{for }\ \mathbf{q}+\mathbf{q}'\neq 0),\tag{3.5}$$

where ε is a (± 1) valued cocycle that ensures the correct spin-statistics relation between different vertex operators. If the charge lattice is odd, i.e., if there are vectors $\mathbf{q}\in L$ such that $|\mathbf{q}|^2\equiv(\mathbf{q}|\mathbf{q})$ is odd (which is the case of interest in applications to a quantum Hall system—see Refs. 12–14 and references therein) then the resulting chiral algebra $\mathscr{A}(L)$ is a local $\mathbf{Z}_2$ graded superalgebra. In order to identify a $W^{(c)}$ subalgebra we should choose a one-dimensional subspace in the c-dimensional space of currents, thus singling out the current $J^0(z)=\Sigma_{i=1}^c J_i^0(z)$. This is achieved, in particular, by selecting an ''electron charge'' vector $\mathbf{Q}$ in the dual lattice L^* (whose square $|\mathbf{Q}|^2$ gives the quantum Hall filling fraction[12,13]).

The positive energy representations of the RCFT so obtained, in which all vertex operators $Y(\mathbf{q},z)$, $\mathbf{q}\in L$ are single valued, are in one-to-one correspondence with the elements of the (finite) Abelian group L^*/L of order

$$|L^*/L|=\det((\mathbf{q}^i|\mathbf{q}^j)).$$

Let Γ be any finite group of automorphisms of the chiral algebra $\mathscr{A}(L)$ which leaves each element of its $W^{(c)}$ subalgebra invariant. [It is enough to demand the invariance of the first three ''tensor currents'' $V^l(z), l=0,1,2$ which generate the entire $W_{1+\infty}$ algebra.] There is a wealth of such inner automorphism groups in the case when L is a semisimple Lie group lattice (for integer c it may only correspond to a lattice of the A-D-E type, the basis $\mathbf{q}^i$ being identified with a basis of simple roots). Viewing Γ as a *gauge group* we define the *observable algebra* as the subalgebra $\mathscr{A}(L)^\Gamma$ of Γ invariant elements of $\mathscr{A}(L)$. The resulting chiral algebra $\mathscr{A}(L)^\Gamma$ provides another RCFT extension of $W^{(c)}$ (see Ref. 6).

The characters of positive energy irreducible representations of a lattice current algebra span, in general, a finite dimensional representation of the subgroup of the modular group $\mathrm{SL}(2,\mathbf{Z})$ generated by the matrices

$$S=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\quad\text{and}\quad T^2=\begin{pmatrix}1 & 2\\ 0 & 1\end{pmatrix}.\tag{3.6}$$

[If L is an even lattice then they span a representation of the full $\mathrm{SL}(2,\mathbf{Z})$.] Recently, all weak modular invariants [i.e., invariants under the group generated by (3.6) have been classified—see Ref. 15). On the other hand, given a *nonexceptional gauge group* of inner automorphisms Γ [such is, in particular, any finite subgroup of U(n) or SU(n)], it has been demonstrated in Ref. 6 how to construct the specialized characters (that only capture the energy distribution) of the corresponding $\mathscr{A}(L)^\Gamma$ *orbifold modules* and to exhibit their modular transformation properties.

Remark 3.1: Albeit we thus arrive at a rich family of manageable RCFT extensions of $W_{1+\infty}$, the set of such extensions is not exhaustive—even if we admit outer automorphisms in Γ, for which no general construction of orbifold modules is known. RCFT extensions of a different type are obtained through the so-called conformal embedding.[16–21] A simple example of this type is provided by the level 5 su(3)-current algebra $\mathscr{A}_5(\mathrm{su}(3))$ of Virasoro central charge $c_k=8k/(3+k)=5$ for $k=5$, which can be viewed as the *observable subalgebra* of the rank 5 lattice chiral algebra $\mathscr{A}_1(\mathrm{su}(6))$. Indeed, the vacuum space of $\mathscr{A}_1(\mathrm{su}(6))$ splits into a direct sum of two $\mathscr{A}_5(\mathrm{su}(3))$ modules (with the same central charge $c=5$, and hence, the same Virasoro subalgebra): one with su(3) weight $\Lambda_0=(0,0)$ and ground state energy $\Delta_0=0$ and a second one with $\Lambda_1=(2,2)$ and a degenerate 27-dimensional ground state of energy (=conformal weight) $\Delta_1=\frac{1}{24}\{\lambda_1(\lambda_1+3)+\lambda_2(\lambda_2+3)+\lambda_1\lambda_2\}=1$ for $\lambda_1=\lambda_2=2$. Thus $\mathscr{A}_5(\mathrm{su}(3))$ can be viewed as a RCFT extension of either $W^{(5)}$ or the part of $W^{(6)}$ orthogonal to the u(1) current J^0. It cannot be

viewed as the gauge invariant part of the lattice algebra $\mathscr{A}_1(\mathrm{su}(6))$ with respect to a finite gauge group Γ since then the $\mathscr{A}_5(\mathrm{su}(3))$ module of highest weight Λ_1 should have an integer quantum dimension (equal to the dimension of the associated irreducible representation of Γ—see Ref. 21 and references therein) while it is, in fact, irrational:

$$d_q(\Lambda)=\frac{[3]^2[6]}{[2]}=(1+\sqrt{2})^2 \quad \text{for } q^8=-1.$$

Only for $c=1$ we have listed all RCFT extensions of the u(1) current algebra—cf. Ref. 22—and hence all extensions of $W^{(1)}$.

B. Computing character dependence on chemical potential for orbifold models

It is important, as far as applications to the quantum Hall effect are concerned, to compute the character dependence on the chemical and electric potentials combined in a complex variable ζ (see Ref. 14; the ζ dependence carries information about charge distribution and the so-called spectral flow). In the case of lattice orbifolds this requires the following simple (but important) complement of the algorithm presented in Ref. 6.

To set the stage we reformulate briefly some notions and results of Ref. 6 adapted to the present context.

Let L be an integral Euclidean lattice and let $\mathbf{Q}$ be a fixed vector in the dual lattice L^*, the ''electric charge'' [such a pair $(L,\mathbf{Q})$, satisfying some additional requirements, is called a *chiral quantum Hall lattice* in Ref. 12]. We shall assume, for the sake of convenience, that L is *maximal*, i.e., there is no sublattice of L^* that is a proper extension of L. (This assumption does not restrict the generality of the orbifold chiral algebra we shall end up with.) Let G be a connected compact Lie group whose Lie algebra is generated by the zero-components of all (dimension 1) currents in the chiral algebra $\mathscr{A}(L)$. It can hence be assumed acting by unitary operators in each irreducible (positive energy) $\mathscr{A}(L)$ module. G is a rank $l=\dim L$ Lie group: it has a maximal Abelian subgroup $\mathrm{U}(1)^{\times l}$ where $l=\mathrm{rank}\, L$; the center $\mathbf{Z}_G(\subset \mathrm{U}(1)^{\times l})$ of G is nontrivial: it contains a (finite) subgroup isomorphic to $|L^*/L|$. To any $\mathbf{q}\in L^*$ there corresponds a pair of charged vertex operators $Y(\pm\mathbf{q},z)$ [which intertwine the vacuum representation of $\mathscr{A}(L)$ with the charge $\pm\mathbf{q}$ representations] and hence a u(1) current $H^{\mathbf{q}}(z)$ satisfying (3.4) whose zero-component $H_0^{\mathbf{q}}$-belongs to the Lie algebra $\mathscr{G}$ of G. ($\mathscr{G}$ may also involve raising and lowering operators $E^{\pm\alpha}$ for $\underline{\alpha}\in L$, $|\underline{\alpha}|^2=2$ whenever L contains such vectors $\underline{\alpha}$. Let Γ be a (nonexceptional) finite subgroup of G acting by inner automorphisms on $\mathscr{A}(L)$ and leaving the current $H^{\mathbf{Q}}(z)$ invariant. To each inner automorphism $\rho\in \mathrm{Ad}\,\Gamma$ of $\mathscr{A}(L)$ we make correspond a $\beta=\underline{\beta_\rho}\in i\mathscr{G}$ such that

$$\rho(V)=bVb^{-1}, \quad b=e^{2\pi i\beta}, \quad \Gamma_b=\Gamma_\beta, \tag{3.7}$$

where $\Gamma_b(\Gamma_\beta)$ is the centralizer of $b(\beta)$ in Γ. (We identify vectors $\beta\in L$ with corresponding Lie algebra element H_0^β.)

Let $\mathscr{H}_{\underline{\lambda}}, \underline{\lambda}\in L^*/L$ be an irreducible positive energy $\mathscr{A}(L)$ module. Define its character $\chi_{\underline{\lambda}}$

$$\chi_{\underline{\lambda}}(\tau,\underline{\alpha})=\mathrm{tr}_{\mathscr{H}_{\underline{\lambda}}}(q^{L_0-c/24}e^{2\pi i\underline{\alpha}}), \quad q=e^{2\pi i\tau}, \quad \mathrm{Im}\,\tau>0; \quad i\underline{\alpha}\in\mathscr{G}. \tag{3.8}$$

It follows that

$$\chi_{\underline{\lambda}}(\tau,\underline{\alpha})=\frac{1}{[\eta(\tau)]^l}\sum_{\gamma\in L+\underline{\lambda}} q^{(1/2)(\underline{\gamma}|\underline{\gamma})}e^{2\pi i(\underline{\gamma}|\underline{\alpha})} \quad \left(\eta=q^{1/24}\prod_{n=1}^{\infty}(1-q^n),\ \ l=\mathrm{rank}\, L\right). \tag{3.9}$$

The character of a *β-twisted module* $\mathscr{H}_{\underline{\lambda}}^{\beta}$ is [see Eq. (3.18) of Ref. 6]

$$\chi_{\underline{\lambda}}^{\underline{\alpha},\beta}(\tau)=q^{(1/2)|\underline{\beta}|^2}\chi_{\underline{\lambda}}(\tau,\underline{\alpha}-\tau\beta), \quad [\underline{\alpha},\beta]=0. \tag{3.10}$$

Proposition 3:2: Let σ be (the character of) an irreducible representation of the centralizer $\Gamma_{\underline{\beta}}(=\Gamma_b)$ of β in Γ. Then the projected module $\mathscr{H}^{\beta}_{\underline{\lambda},\sigma}$ is only nontrivial if σ and $\underline{\lambda}$ agree on L^*/L and then the character is

$$\chi^{\beta}_{\underline{\lambda},\sigma}(\tau,\zeta)=\frac{1}{|\Gamma_{\underline{\beta}}|}\sum_{h=e^{2\pi i\alpha}\in\Gamma_{\underline{\beta}}} e^{-2\pi i\zeta(\mathbf{Q}|\beta)}\chi^{\zeta\mathbf{Q}+\alpha,\beta}_{\underline{\lambda}}(\tau)\sigma^*(h) \tag{3.11}$$

$|\Gamma_{\underline{\beta}}|$ *standing for the number of elements of* $\Gamma_{\underline{\beta}}$.

Indeed, defining $\mathscr{H}^{\beta}_{\underline{\lambda},\sigma}$ by

$$\mathscr{H}^{\beta}_{\underline{\lambda},\sigma}=P_{\sigma}\mathscr{H}^{\beta}_{\underline{\lambda}} \quad \text{where} \quad P_{\sigma}=\frac{\sigma(1)}{|\Gamma_{\underline{\beta}}|}\sum_{h\in\Gamma_{\underline{\beta}}}\sigma^*(h)h\,(=P_{\sigma}^2) \tag{3.12}$$

one proves by a simple extension of the argument of Sec. 4.1 of Ref. 6 that

$$\chi^{\beta}_{\underline{\lambda},\sigma}(\tau,\zeta)=\mathrm{tr}_{\mathscr{H}^{\beta}_{\underline{\lambda},\sigma}}(q^{L_0-H_0^{\beta}+(1/2)|\beta|^2-c/24}e^{2\pi i\zeta(H_0^{\mathbf{Q}}-(\mathbf{Q}|\beta))}). \tag{3.13}$$

Instead of reproducing the details we shall work out an example of physical interest (cf., Ref. 23).

Example 3.1: Let L be a two-dimensional orthogonal lattice with basis $\mathbf{e}^1,\mathbf{e}^2$ and Gram matrix

$$((\mathbf{e}^i|\mathbf{e}^j))=\begin{pmatrix}(\mathbf{e}^1|\mathbf{e}^1) & (\mathbf{e}^1|\mathbf{e}^2)\\ (\mathbf{e}^2|\mathbf{e}^1) & (\mathbf{e}^2|\mathbf{e}^2)\end{pmatrix}=\begin{pmatrix}m & 0\\ 0 & 1\end{pmatrix},\quad m\in\mathbf{N}, \tag{3.14}$$

and let $\mathbf{Q}=\mathbf{e}_1^*$ (where $\{\mathbf{e}_i^*\}$ stands for the dual basis in L^* satisfying $(\mathbf{e}_i^*|\mathbf{e}^j)=\delta_i^j$). Consider a $\mathbf{Z}_M$ gauge group in $\mathscr{A}(L)$ generated by an automorphism of type (3.7) with

$$\underline{\beta}=\underline{\beta}_M=\frac{1}{M}(\mu\mathbf{e}_1^*+\mathbf{e}_2^*),\quad 0<\mu<M. \tag{3.15}$$

$\mathscr{A}(L)$ has m (untwisted) representations with partition functions

$$\chi_l(\tau,\underline{\alpha})=K_l(\tau,\alpha^1;m)K_0(\tau,\alpha^2;1)\quad \text{for}\ \ \underline{\alpha}=\alpha^i\mathbf{e}_i^*, \tag{3.16}$$

where K_l are the one-dimensional lattice characters (see, e.g., Ref. 22)

$$K_l(\tau,\alpha;m)=\frac{1}{\eta(\tau)}\sum_{n\in\mathbf{Z}} q^{m/2(n+l/m)^2}e^{2\pi i\alpha(n+l/m)} \tag{3.17}$$

l mod m (for m even a canonical choice is $1-m/2\leqslant l\leqslant m/2$).

The lift $b=e^{2\pi iH_0^{\beta}}$ $(H_0^{\beta}=1/M(\mu H_0^{\mathbf{e}_1^*}+H_0^{\mathbf{e}_2^*}))$ of the automorphism group $\mathbf{Z}_M$ to the $\mathscr{A}(L)$ modules $\mathscr{H}_l$ is $\mathbf{Z}_{mM}$. Setting

$$\begin{gathered}\sigma^*(e^{2\pi i\underline{\alpha}})=e^{-2\pi i(\alpha/m)\sigma}\quad (\text{for}\ \ \underline{\alpha}=\alpha(\mu\mathbf{e}_1^*+\mathbf{e}_2^*)),\\ \underline{\beta}=\beta(\mu\mathbf{e}_1^*+\mathbf{e}_2^*);\quad e^{2\pi i(\alpha/m)},\ e^{2\pi i(\beta/m)}\in\mathbf{Z}_{mM},\quad |\Gamma_{\beta}|=mM\end{gathered} \tag{3.18}$$

we can evaluate the finite sum in (3.11) with the result

$$\chi^{\beta}_{l,\sigma}(\tau,\zeta)=\frac{1}{\eta^2(\tau)}\sum_{n_1,n_2\in\mathbf{Z}} \mathrm{e}^{2\pi i(n_1+(l-\mu\beta)/m)\zeta}\mathbf{q}^{(m/2)(n_1+(l-\mu\beta/m)^2+(1/2)(n_2-\beta)}\delta^{\sigma \bmod mM}_{m(\mu n_1+n_2)+\mu l}. \tag{3.19}$$

It follows that $\sigma-\mu l=0$ mod m, in accord with the first statement in Proposition 3.2, and we can take the Kronecker δ into account setting (for M,μ coprime)

$$n_1=\frac{\sigma-\mu l}{m}+r+Mn,\quad n_2=\frac{\mu l-\sigma}{m}(\mu-1)-\mu r+mn',$$
$$r=0,1,\ldots,M-1\quad (n,n'\in\mathbf{Z}). \tag{3.20}$$

Inserting in (3.19) and using once more (3.17) we find

$$\chi_{l,\sigma}^{\nu/M}(\tau,\zeta)=\sum_{r=0}^{M-1} K_{M[\sigma-(\mu-1)l]-\mu\nu+mMr}(\tau,M\zeta;mM^2)K_{M[(l\mu-\sigma)/m](\mu-1)-\nu-\mu Mr}(\tau,0;M^2). \tag{3.21}$$

Remark 3.2: A nonanalytic factor, $e^{-(\pi/m)(\mathrm{Im}\,\zeta)^2/\mathrm{Im}\,\tau}$, is to be assigned to the character in order to ensure its $V:\zeta\to\zeta+\tau$ covariance (see Ref. 14).

Remark 3.3: Given the automorphism ρ there is a ''gauge'' freedom in the choice of b and β in (3.11) [in the example (3.15) it amounts to adding to β an arbitrary vector of L^*] Theorem 4.2 of Ref. 6 guarantees that the resulting orbifold models do not depend on this choice.

To sum up: Quantum field theory realization of $W_{1+\infty}$ are provided by $U(1)^{\times c}$ current algebras which also allow the construction of a large family of RCFT extensions of such algebras. These leave room for additional physical requirements having in mind specific applications, e.g., to quantum Hall systems.

A histories approach to quantum mechanics

Stanley Gudder
Department of Mathematics and Computer Science, University of Denver, Denver, Colorado 80208

(Received 8 June 1998; accepted for publication 14 July 1998)

A histories approach to quantum mechanics is formulated without the consistency requirement. Plausible, physically motivated axioms for a history structure are presented. In this structure, the consistency requirement is unnecessary because the joint sequential distributions are already probability measures. It is shown that the logic of a history structure is a temporal effect algebra and conversely, any temporal effect algebra is isomorphic to the logic of a history structure. When this general framework is specialized to a Hilbert space context, it reduces to a previously studied formalism. © *1998 American Institute of Physics.*

I. INTRODUCTION

The consistent histories approach to quantum mechanics has been extensively studied in recent years.[1–8] In this article we shall delete the adjective ''consistent'' and refer to our framework as a histories approach to quantum mechanics. This is because we believe that consistent sets of histories are too restrictive and rarely occur. Even when they do occur, we question their usefulness for describing quantum situations. However, in the absence of the consistency requirement, this approach may provide an important method for formulating and interpreting quantum mechanics. Besides their emphasis on consistency and decoherence, some of these previous works have studied temporal and logical structures in the histories framework.[1,4,5,7,8] Most recently this approach has been extended to include generalized observables given by POV measures and the generalized logics of effect algebras.[7,8] The goal of the present article is to provide a simplification and unification of these previous works without the consistency requirement. Moreover, we argue that consistent sets of histories are unnecessary in a certain sense. Unlike previous works in which the ''logic'' of a history structure is essentially postulated, we shall derive the ''logic'' from more basic principles.

In Sec. II we first present some plausible and physically motivated axioms for a history structure. Although the axioms are completely different, they are motivated by Mackey's quantum logic approach.[9] The general framework and two of the axioms were first introduced by Medina.[10] The existence of sequential joint distributions and distributions of observables follow from the axioms. Conditional probabilities and conditional sequential joint distributions are then defined. Various manifestations of quantum interference are discussed.

The fundamentals of σ-effect algebras and their associated states and observables are reviewed in Sec. III. A temporal effect algebra is a σ-effect algebra that possesses a temporal product that satisfies certain conditions. The basic properties of temporal effect algebras and their automorphism groups are discussed.

Section IV derives the quantum logic associated with a history structure $\mathscr{H}$. Histories that occur with the same probability for every state of the system form an equivalence class that we call a history effect and the set of history effects $\mathscr{E}$ is called the logic of $\mathscr{H}$. It is shown that $\mathscr{E}$ has the algebraic structure of a temporal effect algebra. Conversely, it is shown that any temporal effect algebra is isomorphic to the logic of a history structure. We also prove that states and observables in a history structure $\mathscr{H}$ are represented by corresponding states and observables on the logic of $\mathscr{H}$. Conditional probabilities and quantum stochastic processes on a temporal effect algebra are discussed.

Section V considers Hilbert space history structures. If H is a complex Hilbert space and $\mathscr{E}(H)$ is the set of Hilbert space effects on H, then a natural temporal product can be defined on $\mathscr{E}(H)$ so that $\mathscr{E}(H)$ becomes a temporal effect algebra. We then carry over the concepts developed

 © 1998 American Institute of Physics

in Sec. IV and show that they reduce to a familiar form in $\mathcal{E}(H)$. Decoherence functions are briefly discussed and some observations about them are given.

II. HISTORY STRUCTURES

Denote the σ-algebra of Borel subsets of $\mathbb{R}^n$ by $\mathcal{B}(\mathbb{R}^n)$. A *countable Borel partition* of $\mathbb{R}^n$ is a sequence $A_i \in \mathcal{B}(\mathbb{R}^n)$ such that $A_i \cap A_j = \varnothing$ for $i \neq j$ and $\cup A_i = \mathbb{R}^n$. We denote the set of countable Borel partitions of $\mathbb{R}^n$ by $\mathcal{P}(\mathbb{R}^n)$. If $\mathcal{N} \in \mathcal{P}(\mathbb{R}^n)$, then the σ-algebra generated by $\mathcal{N}$ is denoted by $\mathcal{A}(\mathcal{N})$. Notice that $\mathcal{A}(\mathcal{N})$ consists of all unions of sets in $\mathcal{N}$ and that $\mathcal{A}(\mathcal{N}) \subseteq \mathcal{B}(\mathbb{R}^n)$. It is easy to check that if $\mathcal{N}_i \in \mathcal{P}(\mathbb{R})$, $i=1,...,n$, then

$$\mathcal{M} = \{A_1 \times \cdots \times A_n : \quad A_i \in \mathcal{N}_i, i=1,...,n\} \in \mathcal{P}(\mathbb{R}^n)$$

and we use the notation $\mathcal{A}(\mathcal{M}) = \mathcal{A}(\mathcal{N}_1, \ldots, \mathcal{N}_n)$. We denote the set of probability measures on $(\mathbb{R}^n, \mathcal{A}(\mathcal{N}))$, $\mathcal{N} \in \mathcal{P}(\mathbb{R}^n)$, by $M_1^+(\mathbb{R}^n, \mathcal{A}(\mathcal{N}))$ and use the notation

$$M_1^+ = \cup \{M_1^+(\mathbb{R}^n, \mathcal{A}(\mathcal{N})) : n \in \mathbb{N}, \mathcal{N} \in \mathcal{P}(\mathbb{R}^n)\}.$$

Let $\mathcal{O}$ be a set of observables for a physical system. For $X \in \mathcal{O}$, $A \in \mathcal{B}(\mathbb{R})$, we may view (X,A) as the event for which X has a value in the set A. We do not assume that this event is sharp. It may be unsharp due to an imprecision in a measurement apparatus or in the case of a closed system in which no measurement is performed, the unsharpness may be due to an intrinsic property of the observable X. If $\mathcal{N} \in \mathcal{P}(\mathbb{R})$, we may view $(X, \mathcal{N})$ as a set of possible alternative events that can occur. One interpretation is that $(X, \mathcal{N})$ represents an apparatus for measuring X and the discrete alternatives result from the dial readings of the apparatus. In the absence of a measurement, we may interpret $(X, \mathcal{N})$ as a course-grained set of alternative events.

For $X_i \in \mathcal{O}$, $A_i \in \mathcal{B}(\mathbb{R})$, $i=1,...,n$, we call $h = ((X_1, A_1), \ldots, (X_n, A_n))$ a *history* or *temporal event* and interpret h as an ordered temporal sequence in which X_i has a value in A_i at time τ_i where $\tau_1 < \tau_2 < \cdots < \tau_n$. Alternatively, no specific times may be involved and we regard h as a sequential event in which (X_1, A_1) occurs first, (X_2, A_2) occurs second,..., and (X_n, A_n) occurs last. Notice that the A_i could be singleton sets $A_i = \{a_i\}$ in which case $((X_1, \{a_1\}), \ldots, (X_n, \{a_n\}))$ would be a ''path'' in which X_i has value a_i, $i=1,...,n$. We denote the set of all histories of length n by $\mathcal{H}^n = (\mathcal{O} \times \mathcal{B}(\mathbb{R}))^n$ and the set of all histories by $\mathcal{H} = \cup \{\mathcal{H}^n : n \in \mathbb{N}\}$.

A *history set* is an element of $\hat{\mathcal{H}}^n = (\mathcal{O} \times \mathcal{P}(\mathbb{R}))^n$ for some $n \in \mathbb{N}$ and an $s \in \hat{\mathcal{H}}^n$ has the form $s = ((X_1, \mathcal{N}_1), \ldots, (X_n, \mathcal{N}_n))$ where $X_i \in \mathcal{O}$, $\mathcal{N}_i \in \mathcal{P}(\mathbb{R})$, $i=1,...,n$. We interpret s as a temporal sequence with partitions $\mathcal{N}_i$ in the temporal order $\tau_1 < \tau_2 < \cdots < \tau_n$ or as ordered successive measurements of observables X_i with partitions $\mathcal{N}_i$, $i=1...,n$. We use the notation $\mathcal{A}_s = \mathcal{A}(\mathcal{N}_1, \ldots, \mathcal{N}_n)$ and denote the collection of all history sets by $\hat{\mathcal{H}} = \cup \{\hat{\mathcal{H}}^n : n \in \mathbb{N}\}$. If $h = ((X_1, A_1), \ldots, (X_n, A_n))$ and $s = ((X_1, \mathcal{N}_1), \ldots, (X_n, \mathcal{N}_n))$ with $A_i \in \mathcal{N}_i$, $i=1,...,n$, we write $h \in s$ and say that the history h is an element of the history set s. Our history corresponds to a history filter or homogeneous history and our history set corresponds to a complete set of histories in the literature. We call $(X,A) \in \mathcal{H}^1$ a *one-time event* and $(X, \mathcal{N}) \in \hat{\mathcal{H}}^1$ a *one-time history set*. If $s = ((X_1, \mathcal{N}_1), \ldots, (X_n, \mathcal{N}_n))$, $t = ((Y_1, \mathcal{M}_1), \ldots, (Y_n, \mathcal{M}_n))$ are history sets, we define their *sequential product* by

$$st = ((X_1, \mathcal{N}_1), \ldots, (X_n, \mathcal{N}_n), (Y_1, \mathcal{M}_1), \ldots, (Y_n, \mathcal{M}_n)).$$

Of course, $st \in \hat{\mathcal{H}}$. Notice that $\hat{\mathcal{H}}$ becomes a semigroup under this product and by convention we assume that $\varnothing \in \hat{\mathcal{H}}$ and that $s\varnothing = \varnothing s = s$.

If the system is in a state α and $h = ((X_1, A_1), \ldots, (X_n, A_n)) \in \mathcal{H}$ with $h \in s$, $s \in \hat{\mathcal{H}}$, then the probability that h occurs within s is denoted by $P_{\alpha,s}(A_1 \times \cdots \times A_n)$. We now propose an axiomatic framework for a statistical theory of histories. All of the axioms will concern properties of the probabilities $P_{\alpha,s}$.

Let $\mathcal{S}$ be the set of states and $\mathcal{O}$ the set of observables for a physical system. A *history structure* is a triple $(\mathcal{S}, \mathcal{O}, P)$ where $P : \mathcal{S} \times \hat{\mathcal{H}} \to M_1^+$, $(\alpha, s) \mapsto P_{\alpha,s}$ and $P_{\alpha,s} \in M_1^+(\mathbb{R}^n, \mathcal{A}_s)$ when $s \in \hat{\mathcal{H}}^n$. We postulate that $(\mathcal{S}, \mathcal{O}, P)$ satisfies the following axioms.

(H1) If $s_i \in \hat{\mathscr{H}}^1$ and $P_{\alpha,s_i}(A_i) \leq P_{\alpha,s_{i+1}}(A_{i+1})$ for every $\alpha \in \mathscr{S}$, then there exists an $s \in \hat{\mathscr{H}}^1$ and $B_i \in \mathscr{A}_s$ with $B_i \subseteq B_{i+1}$ such that $P_{\alpha,s_i}(A_i) = P_{\alpha,s}(B_i)$, $i = 1,2,...$, for every $\alpha \in \mathscr{S}$.

(H2) Let $s_1, s_2, t_1, t_2 \in \hat{\mathscr{H}}^1$. If $P_{\alpha,s_1}(A_1) = P_{\alpha,s_2}(A_2)$ and $P_{\alpha,t_1}(B_1) = P_{\alpha,t_2}(B_2)$ for every $\alpha \in \mathscr{S}$, then

$$P_{\alpha,s_1t_1}(A_1 \times B_1) = P_{\alpha,s_2t_2}(A_2 \times B_2)$$

for every $\alpha \in \mathscr{S}$.

(H3) If $s = ((X_1, \mathscr{N}_1), \ldots, (X_n, \mathscr{N}_n)) \in \hat{\mathscr{H}}$ and $A_i \in \mathscr{N}_i$ $i = 1,...,n$, then there exists a $t = (X, \mathscr{N}) \in \hat{\mathscr{H}}^1$ and an $A \in \mathscr{N}$ such that

$$P_{\alpha,t}(A) = P_{\alpha,s}(A_1 \times \cdots \times A_n)$$

for every $\alpha \in \mathscr{S}$.

(H4) If $s \in \hat{\mathscr{H}}$, $t = (X, \mathscr{N}) \in \hat{\mathscr{H}}^1$, $u = (X, \mathscr{M}) \in \hat{\mathscr{H}}^1$, $A \in \mathscr{A}_s$, $B \in \mathscr{A}_t \cap \mathscr{A}_u$, then $P_{\alpha,st}(A \times B) = P_{\alpha,su}(A \times B)$ for every $\alpha \in \mathscr{S}$. Moreover, $P_{\alpha,st}(A \times \mathbb{R}) = P_{\alpha,s}(A)$ for every $\alpha \in \mathscr{S}$.

(H5) If $s = ((X_1, \mathscr{N}_1), \ldots, (X_n, \mathscr{N}_n)) \in \hat{\mathscr{H}}$, $t = ((X_1, \mathscr{M}_1), \ldots, (X_n, \mathscr{M}_n)) \in \hat{\mathscr{H}}$ and $A_i \in \mathscr{N}_i \cap \mathscr{M}_i$, then

$$P_{\alpha,s}(A_1 \times \cdots \times A_n) = P_{\alpha,t}(A_1 \times \cdots \times A_n)$$

for every $\alpha \in \mathscr{S}$.

If $s = ((X_1, \mathscr{N}_1), \ldots, (X_n, \mathscr{N}_n)) \in \hat{\mathscr{H}}$ and $\alpha \in \mathscr{S}$, we call $P_{\alpha,s} \in M_1^+(\mathbb{R}^n, \mathscr{A}_s)$ the *sequential joint distribution of* $X_1, \ldots, X_n$ *with partitions* $\mathscr{N}_1, \ldots, \mathscr{N}_n$ *in the state* α. The main reason for requiring a consistent set of histories in the usual approach is to ensure that $P_{\alpha,s}$ is indeed a probability measure. In the present approach this is not necessary because we are already guaranteed that $P_{\alpha,s}$ is a probability measure. This may appear to be circumventing a problem by decree. However, the point here is that a histories approach with proper statistical properties can be developed without the need for decoherence functions and a consistency requirement.

We now give physical interpretations for the history structure axioms. Axiom (H1) says that an increasing sequence of one-time events can be described by a single observable. In this sense, one-time events in an increasing sequence are compatible. Axiom (H2) says that if pairs of one-time events have the same probabilities of occurrence for every state, then so do the corresponding two-time histories. Our interpretation of (H3) is that any history can be described by a one-time event. This is in accordance with the following statement:[7] ''All meaningful propositions about a physical system specify that the value of some observable lies in some set $A \in \mathscr{B}(\mathbb{R})$.'' The first part of (H4) means that the partition of the last measurement is irrelevant and the second part means that the last measurement does not affect the previous ones. This axiom as well as parts of this general framework were given in Ref. 10. Axiom (H5) says that the probability of a history does not depend on the partitions and hence is unambiguous. However, if s and t are as in (H5) and $A \in \mathscr{A}_s \cap \mathscr{A}_t$, then in general $P_{\alpha,s}(A) \neq P_{\alpha,t}(A)$. This is an unavoidable manifestation of quantum interference and we shall mention other such manifestations in the sequel. (Section V discusses examples in Hilbert space.)

It follows from (H4) by letting $s = \varnothing$ that if $t = (X, \mathscr{N})$, $u = (X, \mathscr{M})$ and $B \in \mathscr{A}(\mathscr{N}) \cap \mathscr{A}(\mathscr{M})$, then $P_{\alpha,t}(B) = P_{\alpha,u}(B)$ for every $\alpha \in \mathscr{S}$. Hence, the probability that X has a value in B is independent of the partition that generates B. The next lemma is stated without proof in Ref. 10.

Lemma 2.1: If $\alpha \in \mathscr{S}$, $X \in \mathscr{O}$, then there exists a unique probability measure $P_{\alpha,X}$ on $(\mathbb{R}, \mathscr{B}(\mathbb{R}))$ such that $P_{\alpha,X}(A) = P_{\alpha,s}(A)$ for every $s = (X, \mathscr{N})$ and $A \in \mathscr{A}(\mathscr{N})$.

Proof: For $A \in \mathscr{B}(\mathbb{R})$, define $P_{\alpha,X}(A) = P_{\alpha,s}(A)$, where $s = (X, \mathscr{N})$ with $A \in \mathscr{A}(\mathscr{N})$. Our previous observation shows that $P_{\alpha,X}$ is well defined. Then $P_{\alpha,X}(A) \geqslant 0$ for every $A \in \mathscr{B}(\mathbb{R})$ and $P_{\alpha,X}(\mathbb{R}) = 1$. If $A_i \in \mathscr{B}(\mathbb{R})$ are mutually disjoint, $i = 1,2,...$, let $\mathscr{N} \in \mathscr{P}(\mathbb{R})$ contain each A_i, $i = 1,2,...$. If $s = (X, \mathscr{N})$, then

$$P_{\alpha,X}(\cup A_i) = P_{\alpha,s}(\cup A_i) = \sum P_{\alpha,s}(A_i) = \sum P_{\alpha,X}(A_i).$$

Hence, $P_{\alpha,X}$ is a probability measure on $(\mathbb{R},\mathscr{B}(\mathbb{R}))$ and it is clear that $P_{\alpha,X}$ is unique. □

We call $P_{\alpha,X}$ the *distribution of X in the state* α. The proof of the following result is similar to that of Lemma 2.1.

Corollary 2.2: If $\alpha\in\mathscr{S}$, $s\in\hat{\mathscr{H}}$, $A\in\mathscr{A}_s$, $X\in\mathscr{O}$, then there exists a unique probability measure $P_{\alpha,s,X}$ such that $P_{\alpha,s,X}(A\times B)=P_{\alpha,s,t}(A\times B)$ for every $t=(X,\mathscr{N})$ and $B\in\mathscr{A}(\mathscr{N})$.

The next lemma follows directly from (H1).

Lemma 2.3: If $P_{\alpha,X_i}(A_i)\leqslant P_{\alpha,X_{i+1}}(A_{i+1})$ for every $\alpha\in\mathscr{S}$, then there exists an $X\in\mathscr{O}$ and $B_i\in\mathscr{B}(\mathbb{R})$ with $B_i\subseteq B_{i+1}$ such that $P_{\alpha,X}(B_i)=P_{\alpha,X_i}(A_i)$ for every $\alpha\in\mathscr{S}$, $i=1,2,\ldots$.

By iterating (H4) we have the following result:[10]

Lemma 2.4: If $\alpha\in\mathscr{S}$, $s\in((X_1,\mathscr{N}_1),\ldots,(X_n,\mathscr{N}))\in\hat{\mathscr{H}}$ and $A\in\mathscr{A}(\mathscr{N}_1)$, then $P_{\alpha,s}(A\times\mathbb{R}^{n-1})=P_{\alpha,X_1}(A)$.

In general, the other marginal distributions are not equal to the one-variable distributions. That is, in general for $k>1$, $s=((X_1,\mathscr{N}_1),\ldots,(X_n,\mathscr{N}_n))$ and $A\in\mathscr{A}(\mathscr{N}_k)$,

$$P_{\alpha,s}(\mathbb{R}^{k-1}\times A\times\mathbb{R}^{n-k})\neq P_{\alpha,X_k}(A).$$

This is another manifestation of quantum interference.

If $s,t\in\hat{\mathscr{H}}$, $A\in\mathscr{A}_s$, $B\in\mathscr{A}_t$ with $P_{\alpha,s}(A)\neq 0$, we defined the *conditional probability of B given A for st in the state* α by

$$P_{\alpha,t|s}(B|A)=\frac{P_{\alpha,st}(A\times B)}{P_{\alpha,s}(A)}.$$

It is clear that if $t\in\hat{\mathscr{H}}^m$, then $P_{\alpha,t|s}(\cdot\,|A)$ is a probability measure on $(\mathbb{R}^m,\mathscr{A}_t)$ which we call a *conditional sequential joint distribution*. The next lemma shows that these distributions have the fundamental properties possessed by sequential joint distributions.

Lemma 2.5: For every $\alpha\in\mathscr{S}$, $s\in\hat{\mathscr{H}}$, $P_{\alpha,\cdot|s}(\cdot\,|A)$ satisfies (H4) and (H5).

Proof: Applying (H4) we have

$$P_{\alpha,tu|s}(B\times C|A)=\frac{P_{\alpha,stu}(A\times B\times C)}{P_{\alpha,s}(A)}=\frac{P_{\alpha,stv}(A\times B\times C)}{P_{\alpha,s}(A)}=P_{\alpha,tv|s}(B\times C|A).$$

Thus, $P_{\alpha,\cdot|s}(\cdot\,|A)$ satisfies the first part of (H4). For the second part of (H4) we have

$$P_{\alpha,tu|s}(B\times\mathbb{R}|A)=\frac{P_{\alpha,stu}(A\times B\times\mathbb{R})}{P_{\alpha,s}(A)}=\frac{P_{\alpha,st}(A\times B)}{P_{\alpha,s}(A)}=P_{\alpha,t|s}(B|A).$$

The proof of (H5) is similar. □

The next result which follows from Corollary 2.2 shows that observables have conditional distributions on $(\mathbb{R},\mathscr{B}(\mathbb{R}))$.

Corollary 2.6: If $\alpha\in\mathscr{S}$, $X\in\mathscr{O}$ and $P_{\alpha,s}(A)\neq 0$, then there exists a unique probability measure $P_{\alpha,X}(\cdot\,|A)$ on $(\mathbb{R},\mathscr{B}(\mathbb{R}))$ such that $P_{\alpha,X}(B|A)=P_{\alpha,t|s}(B|A)$ for every $t=(X,\mathscr{N})$ and $B\in\mathscr{A}(\mathscr{N})$.

Another manifestation of quantum interference is the fact that Bayes' formula need not hold,

$$P_{\alpha,t|s}(B|A)P_{\alpha,s}(A)\neq P_{\alpha,s|t}(A|B)P_{\alpha,t}(B).$$

This is because the left-hand side is $P_{\alpha,st}(A\times B)$ and the right-hand side is $P_{\alpha,ts}(B\times A)$ so the order of the measurements or the order of the occurrences is changed. Also the other Bayes' formula need not hold,

$$\sum_{i=1}^{r}P_{\alpha,s}(A_i)P_{\alpha,t|s}(B|A_i)\neq P_{\alpha,t}(B),$$

where $\{A_1,\ldots,A_r\}\in\mathscr{P}(\mathbb{R}^n)$, $s\in\hat{\mathscr{H}}^n$. This is because the left-hand side is

$$\sum_{i=1}^{r} P_{\alpha,st}(A_i\times B)=P_{\alpha,st}(\cup A_i\times B)=P_{\alpha,st}(\mathbb{R}^n\times B)$$

and $P_{\alpha,st}(\mathbb{R}^n\times B)\neq P_{\alpha,t}(B)$ in general. The last inequality comes from the fact that past measurements can affect future ones.

For $h=((X_1,A_1),\ldots,(X_n,A_n))\in\mathscr{H}$ and $\alpha\in\mathscr{S}$, we define $P_\alpha(h)=P_{\alpha,s}(A_1\times\cdots\times A_n)$ for any $s\in\hat{\mathscr{H}}$ with $h\in s$ and (H5) ensures that $P_\alpha(h)$ is well defined. An *automorphism* on $\mathscr{O}$ is a bijection $\psi\colon\mathscr{O}\to\mathscr{O}$ that satisfies

$$P_\alpha((\psi X,A))=P_\alpha((\psi Y,B),(\psi Z,C))$$

and

$$P_\alpha((\psi^{-1}X,A))=P_\alpha((\psi^{-1}Y,B),(\psi^{-1}Z,C))$$

for all $\alpha\in\mathscr{S}$ whenever $P_\alpha((X,A))=P_\alpha((Y,B),(Z,C))$ for all $\alpha\in\mathscr{S}$. Thus, if a two-time history is described by a one-time event, then ψ and ψ^{-1} preserve this relationship. Denoting the set of automorphisms on $\mathscr{O}$ by aut($\mathscr{O}$), it is clear that aut($\mathscr{O}$) is a group under composition. A *dynamical group* on $\mathscr{O}$ is a group homomorphism $\tau\mapsto\psi(\tau)$ from the additive group $\mathbb{R}$ into aut($\mathscr{O}$). We thus have $\psi(\tau_1+\tau_2)=\psi(\tau_1)\circ\psi(\tau_2)$ for all $\tau_1,\tau_2\in\mathbb{R}$ and $\psi(0)=I$, where I is the identity automorphism. We interpret $\psi(\tau)X$ as the evolution of the observable X. If $X_1,\ldots,X_n$ are observables at time $\tau=0$ and $\tau_1<\ldots<\tau_n$, we interpret

$$((\psi(\tau_1)X_1,A_1),\ldots,(\psi(\tau_n)X_n,A_n))$$

as a history in which X_1 has a value in A_1 at time $\tau_1,\ldots,X_n$ has a value in A_n at time τ_n.

III. TEMPORAL EFFECT ALGEBRAS

An *effect algebra*[8,11–16] is an algebraic system $(E,0,1,\oplus)$ where $0,1\in E$ and $\oplus$ is a partial binary operation on E that satisfies

(E1) if $a\oplus b$ is defined, then $b\oplus a$ is defined and $b\oplus a=a\oplus b$;
(E2) if $a\oplus b$ and $(a\oplus b)\oplus c$ are defined, then $b\oplus c$ and $a\oplus(b\oplus c)$ are defined and $a\oplus(b\oplus c)=(a\oplus b)\oplus c$;
(E3) for every $a\in E$, there exists a unique $a'\in E$ such that $a\oplus a'$ is defined and $a\oplus a'=1$;
(E4) if $a\oplus 1$ is defined, then $a=0$.

We call $a\oplus b$ an *orthogonal sum*. It follows from (E2) that existing orthogonal sums do not require parentheses and we write $a\oplus b\oplus c$ for $(a\oplus b)\oplus c$. More generally, we write $a_1\oplus\cdots\oplus a_n$ if this orthogonal sum is defined. We define $a\leqslant b$ if there exists a $c\in E$ such that $a\oplus c=b$. It can be shown[13] that $(E,0,1,\leqslant)$ is a bounded poset and $a\oplus b$ is defined if and only if $a\leqslant b'$. If $a\leqslant b'$, we write $a\perp b$. If $a\leqslant b$, then the unique c that satisfies $a\oplus c=b$ is denoted by $c=b\ominus a$. If the least upper bound $\vee a_i$ exists whenever $a_1\leqslant a_2\leqslant\cdots$, then E is called a *σ-effect algebra*.[8] Suppose $b_i=a_i\oplus\cdots\oplus a_i$ is defined for all $i\in\mathbb{N}$. If $\vee b_i$ exists then we say that $\oplus a_i$ exists and we define $\oplus a_i$ to be $\vee b_i$.

Lemma 3.1: An effect algebra E is a σ-effect algebra if and only if $\oplus a_i$ exists whenever $a_1\oplus\cdots\oplus a_i$ is defined for all $i\in\mathbb{N}$.

Proof: If E is a σ-effect algebra and $b_i=a_1\oplus\cdots\oplus a_i$ is defined for all $i\in\mathbb{N}$, then $b_1\leqslant b_2\leqslant\ldots$, so $\vee b_i$ exists. Conversely, suppose $\oplus a_i$ exists whenever $a_1\oplus\cdots\oplus a_i$ is defined for all $i\in\mathbb{N}$ and let $b_1\leqslant b_2\leqslant\cdots$. Defining $a_1=b_1$, $a_i=b_i\ominus b_{i-1}$, $i=2,3,\ldots$, it easily follows that $a_1\oplus\cdots\oplus a_i=b_i$ exists for all $i\in\mathbb{N}$. Hence, $\vee b_i=\oplus a_i$, exists so E is a σ-effect algebra. □

Let E and F be σ-effect algebras. A map $\phi\colon E\to F$ is *additive* if $a\perp b$ implies $\phi(a)\perp\phi(b)$ and $\phi(a\oplus b)=\phi(a)\oplus(b)$. If ϕ is additive, then ϕ is *monotone* in the sense that $a\leqslant b$ implies $\phi(a)\leqslant\phi(b)$. Indeed, if $a\leqslant b$ then $b=a\oplus c$ for some $c\in E$ so that

$$\phi(a)\leqslant\phi(a)\oplus\phi(c)=\phi(a\oplus c)=\phi(b).$$

An additive map $\phi\colon E\to F$ is *σ-additive* if $a_1\leqslant a_2\leqslant\cdots$ implies that $\phi(\vee a_i)=\vee\phi(a_i)$. The proof of the next result is similar to that of Lemma 3.1.

Lemma 3.2: A map $\phi\colon E\to F$ is σ-additive if and only if $\phi(\oplus a_i)=\oplus\phi(a_i)$ whenever $\oplus a_i$ exists.

A σ-additive map $\phi\colon E\to F$ is a *σ-morphism* if $\phi(1)=1$. It is clear that a σ-morphism satisfies $\phi(a')=\phi(a)'$. If $\phi\colon E\to F$ is a bijective σ-morphism and ϕ^{-1} is a σ-morphism, then ϕ is a *σ-isomorphism*.

An important example of a σ-effect algebra is the unit interval $[0,1]\subseteq\mathbb{R}$. For $a,b\in[0,1]$ we say that $a\oplus b$ is defined if $a+b\leqslant 1$ and in this case $a\oplus b=a+b$. We then have $a'=1-a$, 0 is the zero element and 1 is the one element. A σ-morphism from a σ-effect algebra E into $[0,1]$ is called a *state* on E. We denote the set of states on E by $\mathscr{S}(E)$. We say that $S\subseteq\mathscr{S}(E)$ is *order determining* if $\alpha(a)\leqslant\alpha(b)$ for all $\alpha\in S$ implies that $a\leqslant b$.

Another example of a σ-effect algebra is a measurable space $(\Omega,\mathscr{A})$. For $A,B\in\mathscr{A}$ we say that $A\oplus B$ is defined if $A\cap B=\varnothing$ and in this case $A\oplus B=A\cup B$. We then have A' equal to the complement of A and $0=\varnothing$, $1=\Omega$. A σ-morphism from $(\Omega,\mathscr{A})$ into a σ-effect algebra E is called an *observable* on E with *value space* $(\Omega,\mathscr{A})$. We denote the set of such observables by $\mathscr{O}_{\mathscr{A}}(E)$. Notice that $\mathscr{S}(\Omega,\mathscr{A})$ is precisely the set of probability measures on $(\Omega,\mathscr{A})$. If $X\in\mathscr{O}_{\mathscr{A}}(E)$ and $\alpha\in\mathscr{S}(E)$, then $\alpha\circ X\in\mathscr{S}(\Omega,\mathscr{A})$ is called the *distribution* of X in the state α.

The elements of a σ-effect algebra are called *effects*. If $\alpha\in\mathscr{S}(E)$, then $\alpha(a)$ is the probability that a occurs when the system is in the state α. For $X\in\mathscr{O}_{\mathscr{A}}(E)$, $X(A)$ is the effect that X has a value in A and $\alpha\circ X(A)$ is the probability that $X(A)$ occurs in the state α. We interpret $a\oplus b$ as a statistical sum in the sense that $a\oplus b$ is the effect that satisfies $\alpha(a\oplus b)=\alpha(a)+\alpha(b)$ for every state α.

A *temporal product* on a σ-effect algebra E is a binary operation $(a,b)\mapsto a\circ b$ on E such that $b\mapsto a\circ b$ is σ-additive and $0\circ a=a$, $a\circ 1=a$ for every $a\in E$. Notice that $a\circ 0=0$ for every $a\in E$ because

$$a=a\circ 1=a\circ(0\oplus 1)=a\circ 0\oplus a\circ 1=a\circ 0\oplus a.$$

Hence, by cancellation[13] $a\circ 0=0$. We interpret $a\circ b$ as the effect in which a first occurs and then b occurs. A natural temporal product on the σ-effect algebra $(\Omega,\mathscr{A})$ is given by $A\circ B=A\cap B$. The next lemma shows that there is only one temporal product on $[0,1]$.

Lemma 3.3: The unique temporal product on $[0,1]$ has the form $a\circ b=ab$.

Proof: It is clear that $a\circ b=ab$ is a temporal product on $[0,1]$. Conversely, suppose $a\circ b$ is a temporal product on $[0,1]$. Let $a\in[0,1]$ with $a\neq 0$ and define $\phi_a\colon[0,1]\to[0,1]$ by $\phi_a(b)=(a\circ b)/a$. Then $\phi_a\in\mathscr{S}([0,1])$ and it follows[14] that $\phi_a(b)=b$ for all $b\in[0,1]$. Hence, $a\circ b=ab$. □

In general, a temporal product is not associative. When we write $a_1\circ a_2\circ\cdots\circ a_n$ we mean that the operations are performed from right to left. That is, first $a_{n-1}\circ a_n$ is performed, then $a_{n-2}\circ(a_{n-1}\circ a_n)$ is performed,..., and finally $a_1\circ(a_2\circ\cdots\circ a_n)$ is performed. For example, $a\circ b\circ c$ means $a\circ(b\circ c)$.

Lemma 3.4: Let $\circ$ be a temporal product on E. (i) $a\circ b\leqslant a$ for all $a,b\in E$. (ii) $a\circ b'=a\ominus a\circ b$ for all $a,b\in E$. (iii) If $a\leqslant b$ then $c\circ a\leqslant c\circ b$ for all $c\in E$. (iv) If $a\leqslant b$, then $c\circ(b\ominus a)=c\circ b\ominus c\circ a$ for all $c\in E$.

Proof: (i) For $a,b\in E$ we have

$$a=a\circ 1=a\circ(b\oplus b')=a\circ b\oplus a\circ b'\geqslant a\circ b.$$

(ii) This follows from the proof of (i). (iii) The function $a\mapsto c\circ a$ is additive so it is monotone. (iv) Since $b=a\oplus(b\ominus a)$ we have

$$c\circ a\oplus c\circ(b\ominus a)=c\circ(a\oplus(b\ominus a))=c\circ b.$$

□

A *temporal effect algebra* is a σ-effect algebra that possesses an order determining set of states and a temporal product. For the remainder of this section, E will be a temporal effect algebra with temporal product $\circ$. For $\alpha\in\mathscr{S}(E)$ and $a,b\in E$ with $\alpha(a)\neq 0$, the *conditional probability of b given a in the state α* is defined as $\alpha(b|a)=\alpha(a\circ b)/\alpha(a)$. Notice that $\alpha(\cdot\,|a)\in\mathscr{S}(E)$ and we denote this state by $\alpha|a$. Thus, $(\alpha|a)(b)=\alpha(a\circ b)/\alpha(a)$. By employing the temporal product

$A\circ B=A\cap B$ on $(\Omega,\mathscr{A})$ we see that this definition of conditional probability reduces to the usual concept. Also, it is easy to check that $(\Omega,\mathscr{A})$ and $[0,1]$ are temporal effect algebras.

Temporal effect algebras also give a convenient framework for discussing dynamics. An *automorphism* on E is a σ-isomorphism ϕ: $E\to E$ such that $\phi(a\circ b)=\phi(a)\circ\phi(b)$ for all $a,b\in E$. Notice that the set of automorphisms aut(E) on E forms a group under composition. Indeed, it is clear that if $\phi,\psi\in\text{aut}(E)$, then $\phi\psi\in\text{aut}(E)$. Moreover, if $\phi\in\text{aut}(E)$, then ϕ^{-1} is a σ-isomorphism and

$$\phi[\phi^{-1}(a)\circ\phi^{-1}(b)]=a\circ b$$

so that

$$\phi^{-1}(a)\circ\phi^{-1}(b)=\phi^{-1}(a\circ b).$$

Hence, $\phi^{-1}\in\text{aut}(E)$. If $\phi_1,\ldots,\phi_n\in\text{aut}(E)$, $a_1,\ldots,a_n\in E$, we use the notation $\phi_1\circ a_1\circ\phi_2\circ a_2\circ\cdots\circ\phi_n\circ a_n$ to mean that each ϕ_i operates on the expression to its right. For example,

$$\phi_1\circ a_1\circ\phi_2\circ a_2=\phi_1[a_1\circ(\phi_2(a_2))].$$

A *dynamical group* on E is a one-parameter group of automorphisms on E. That is, a dynamical group on E is a group homomorphism $\tau\mapsto\phi(\tau)$ from the additive group $\mathbb{R}$ into aut(E). We thus have $\phi(\tau_1+\tau_2)=\phi(\tau_2)\circ\phi(\tau_2)$ for all $\tau_1,\tau_2\in\mathbb{R}$ and $\phi(0)=I$ where I is the identity automorphism. It follows that $\phi(-\tau)=\phi(\tau)^{-1}$ for all $\tau\in\mathbb{R}$. If $a\in E$ is an effect at time $\tau=0$, we interpret $\phi(\tau)a$ as the evolution of a at time τ. If $a_1,\ldots,a_n\in E$ correspond to effects at time $\tau=0$ and $\tau_1<\cdots<\tau_n$, we interpret $\phi(\tau_1)a_1\circ\cdots\circ\phi(\tau_n)a_n$ as the effect in which a_1 occurs at time τ_1, a_2 at time $\tau_2,\ldots,a_n$ at time τ_n.

Lemma 3.5: If $\phi(\tau)$ is a dynamical group, then

$$\phi(\tau_1)a_1\circ\cdots\circ\phi(\tau_n)a_n=\phi(\tau_1)\circ a_1\circ\phi(\tau_2-\tau_1)\circ a_2\circ\cdots\circ\phi(\tau_n-\tau_{n-1})\circ a_n.$$

Proof: We proceed by induction on n. The result clearly holds for $n=1$. For $n=2$ we have

$$\begin{aligned}\phi(\tau_1)a_1\circ\phi(\tau_2)a_2&=\phi(\tau_1)a_1\circ\phi(\tau_1)\phi(\tau_2-\tau_1)a_2\\&=\phi(\tau_1)[a_1\circ\phi(\tau_2-\tau_1)a_2]=\phi(\tau_1)\circ a_1\circ\phi(\tau_2-\tau_1)\circ a_2.\end{aligned}$$

Now suppose the result holds for $n\geqslant 1$. Then

$$\begin{aligned}\phi(\tau_1)a_1\circ\cdots\circ\phi(\tau_{n+1})a_{n+1}&=\phi(\tau_1)a_1\circ\phi(\tau_2)[a_2\circ\phi(\tau_3-\tau_2)\circ a_3\circ\cdots\circ\phi(\tau_{n+1}-\tau_n)\circ a_{n+1}]\\&=\phi(\tau_1)\circ a_1\circ\phi(\tau_2-\tau_1)\circ a_2\circ\cdots\circ\phi(\tau_{n+1}-\tau_n)a_{n+1}.\end{aligned}$$

The result follows by induction. □

If $\tau_1<\cdots<\tau_n$, we can interpret Lemma 3.5 as saying that the system evolves until time τ_1 and a_1 occurs, then the system evolves from time τ_1 until time τ_2 and a_2 occurs,..., then the system evolves from time τ_{n-1} until time τ_n and a_n occurs.

If $\phi\in\text{aut}(E)$, we define $\hat{\phi}$: $\mathscr{S}(E)\to\mathscr{S}(E)$ by $\hat{\phi}\alpha(a)=\alpha(\phi^{-1}a)$. Then $\hat{\phi}$ is a bijection on $\mathscr{S}(E)$. Moreover, $(\phi_1\phi_2)\hat{}=\hat{\phi}_1\hat{\phi}_2$ because

$$(\phi_1\phi_2)\hat{}\,\alpha(a)=\alpha((\phi_1\phi_2)^{-1}a)=\alpha(\phi_2^{-1}\phi_1^{-1}a)=\hat{\phi}_2\alpha(\phi_1^{-1}a)=\hat{\phi}_1\hat{\phi}_2\alpha(a).$$

Hence, aut$(E)\hat{}$ is a group and $\phi\mapsto\hat{\phi}$ is a group isomorphism from aut(E) onto aut$(E)\hat{}$. If $\phi(\tau)$ is a dynamical group on E and $\alpha\in\mathscr{S}(E)$ is the state of the system at time $\tau=0$, then we interpret $\hat{\phi}(\tau_0)\alpha$ as the state at time τ_0. If $0<\tau_0<\tau_1<\cdots<\tau_n$, by Lemma 3.5, the probability of the temporal effect $\phi(\tau_1)a_1\circ\cdots\circ\phi(\tau_n)a_n$ in the state $\hat{\phi}(\tau_0)\alpha$ becomes

$$\hat{\phi}(\tau_0)\alpha[\phi(\tau_1)\circ a_1\circ\cdots\circ\phi(\tau_n-\tau_{n-a})\circ a_n]=\alpha[\phi(\tau_1-\tau_0)\circ a_1\circ\cdots\circ\phi(\tau_n-\tau_{n-1})\circ a_n].$$

We can also transfer an automorphism on E into a bijection on $\mathcal{O}(E)=\mathcal{O}_{\mathcal{B}(\mathbb{R})}(E)$. An *observable automorphism* is a bijection $\psi\colon \mathcal{O}(E)\to\mathcal{O}(E)$ such that $(\psi X)(A)=(\psi Y)(B)\circ(\psi Z)(C)$ and $(\psi^{-1}X)(A)=(\psi^{-1}Y)(B)\circ(\psi^{-1}Z)(C)$ whenever $X(A)=Y(B)\circ Z(C)$. It is clear that the set of observable automorphisms $\mathrm{aut}_{\mathcal{O}}(E)$ is a group under composition. If $\phi\in\mathrm{aut}(E)$, define $\tilde{\phi}\colon \mathcal{O}(E)\to\mathcal{O}(E)$ by $(\tilde{\phi}X)(A)=\phi[X(A)]$.

Theorem 3.6: The map $\phi\mapsto\tilde{\phi}$ is a group isomorphism from $\mathrm{aut}(E)$ onto $\mathrm{aut}_{\mathcal{O}}(E)$.

Proof: Letting $\phi\in\mathrm{aut}(E)$, it is straightforward to show that $\tilde{\phi}\colon \mathcal{O}(E)\to\mathcal{O}(E)$ is a bijection. To show that $\tilde{\phi}\in\mathrm{aut}_{\mathcal{O}}(E)$ suppose $X(A)=Y(B)\circ Z(C)$. We then have

$$(\tilde{\phi}X)(A)=\phi[X(A)]=\phi[Y(B)\circ Z(C)]=\phi[Y(B)]\circ\phi[Z(C)]=(\tilde{\phi}Y)(B)\circ(\tilde{\phi}Z)(C).$$

Also, since $(\tilde{\phi})^{-1}=(\phi^{-1})\tilde{}$ we have

$$((\tilde{\phi})^{-1}X)(A)=((\tilde{\phi})^{-1}Y)(B)\circ((\tilde{\phi})^{-1}Z)(C)$$

so $\tilde{\phi}\in\mathrm{aut}_{\mathcal{O}}(E)$. If $\phi_1,\phi_2\in\mathrm{aut}(E)$, then

$$[(\phi_1\phi_2)\tilde{}X](A)=\phi_1\phi_2[X(A)]=\phi_1(\tilde{\phi}_2X)(A)=(\tilde{\phi}_1\tilde{\phi}_2X)(A).$$

Hence, $(\phi_1\phi_2)\tilde{}=\tilde{\phi}_1\tilde{\phi}_2$ so $\phi\mapsto\tilde{\phi}$ is a group homomorphism. To show that $\phi\mapsto\tilde{\phi}$ is injective suppose that $\tilde{\phi}_1=\tilde{\phi}_2$ and $a\in E$. Let $\lambda_1,\lambda_2\in\mathbb{R}$ with $\lambda_1\neq\lambda_2$ and define $X\in\mathcal{O}(E)$ by $X(\lambda_1)=a$, $X(\lambda_2)=a'$ and for $A\in\mathcal{B}(\mathbb{R})$

$$X(A)=\oplus\{X(\lambda_i):\lambda_i\in A,i=1,2\}.$$

We then have

$$\phi_1(a)=\phi_1[X(\lambda_1)]=(\tilde{\phi}_1X)(\lambda_1)=(\tilde{\phi}_2X)(\lambda_1)=\phi_2[X(\lambda_1)]=\phi_2(a).$$

Hence, $\phi_1=\phi_2$ so $\phi\mapsto\tilde{\phi}$ is injective. Finally, to show that $\phi\mapsto\tilde{\phi}$ is surjective, suppose $\psi\in\mathrm{aut}_{\mathcal{O}}(E)$. We have previously shown that for $a\in E$ there exists an $X\in\mathcal{O}(E)$ and an $A\in\mathcal{B}(\mathbb{R})$ such that $X(A)=a$. Define $\phi\colon E\to E$ by $\phi(a)=(\psi X)(A)$. Now ϕ is well defined because if $Y(B)=a$ we have $X(A)=Y(B)\circ Y(\mathbb{R})$ so that

$$(\psi X)(A)=(\psi Y)(B)\circ(\psi Y)(\mathbb{R})=(\psi Y)(B).$$

To show that ϕ is injective, suppose $\phi(a)=\phi(b)$. As before there exists $X,Y\in\mathcal{O}(E),\lambda_1,\lambda_2\in\mathbb{R}$ such that $X(\lambda_1)=a$, $X(\lambda_2)=a'$, $Y(\lambda_1)=b$, $Y(\lambda_2)=b'$. Since

$$X(\{\lambda_1,\lambda_2\})=1=X(\mathbb{R})\circ X(\mathbb{R}),$$

we have

$$(\psi X)(\lambda_1)\oplus(\psi X)(\lambda_2)=(\psi X)(\{\lambda_1,\lambda_2\})=(\psi X)(\mathbb{R})\circ(\psi X)(\mathbb{R})=1,$$

and similarly, $(\psi Y)(\lambda_1)\oplus(\psi Y)(\lambda_2)=1$. Moreover,

$$(\psi X)(\lambda_1)=\phi(a)=\phi(b)=(\psi Y)(\lambda_1)$$

and

$$(\psi X)(\lambda_2)=(\psi X)(\lambda_1)'=(\psi Y)(\lambda_1)'=(\psi Y)(\lambda_2).$$

It follows that $\psi X=\psi Y$ and since ψ is injective, we have $X=Y$. Hence, $a=b$ so ϕ is injective. To show that ϕ is surjective, suppose $b\in E$. Then there exist $Y\in\mathcal{O}(E)$, $\lambda\in\mathbb{R}$ such that $Y(\lambda)=b$. Since ψ is surjective, there exists an $X\in\mathcal{O}(E)$ such that $\psi X=Y$. Letting $a=X(\lambda)$ we have

$$\phi(a)=(\psi X)(\lambda)=Y(\lambda)=b,$$

so ϕ is surjective. Since $X(\mathbb{R})=1$ for $X\in\mathcal{O}(E)$ we have

$$\phi(1)=(\psi X)(\mathbb{R})=1.$$

Assume that $a_i\in E$, $i=1,2,...$, and $\oplus a_i$ exists. Let $\lambda_0,\lambda_1,\ldots\in\mathbb{R}$ be distinct and define $X\in\mathcal{O}(E)$ by $X(\lambda_0)=(\oplus a_i)'$, $X(\lambda_i)=a_i$, $i=1,2,...$, and for $A\in\mathcal{B}(\mathbb{R})$,

$$X(A)=\oplus\{X(\lambda_i):\lambda_i\in A\}.$$

We then have

$$\phi(\oplus a_i)=(\psi X)(\cup\{\lambda_i\})=\oplus(\psi X)(\lambda_i)=\oplus\phi(a_i),$$

and it follows from Lemma 3.2 that ϕ is σ-additive. Define $\phi_1: E\to E$ by $\phi_1(a)=(\psi^{-1}X)(A)$ where $X(A)=a$. As before, ϕ_1 is a well defined σ-morphism and we have

$$\phi\phi_1(a)=(\psi\psi^{-1}X)(A)=X(A)=a.$$

Hence, $\phi\phi_1=I$ and similarly, $\phi_1\phi=I$. It follows that ϕ is a σ-isomorphism. For $a,b\in E$ there exists $X,Y,Z\in\mathcal{O}(E)$, $A,B,C\in\mathcal{B}(\mathbb{R})$ such that $X(A)=a$, $Y(B)=b$, $Z(C)=a\circ b$. Since $Z(C)=X(A)\circ Y(B)$ we have

$$\phi(a\circ b)=\phi(Z(C))=(\psi Z)(C)=(\psi X)(A)\circ(\psi Y)(B)=\phi(a)\circ\phi(b).$$

Hence, $\phi\in\mathrm{aut}(E)$ and for any $X\in\mathcal{O}(E)$, $A\in\mathcal{B}(\mathbb{R})$ we have

$$(\psi X)(A)=\phi[X(A)]=(\tilde{\phi}X)(A).$$

We conclude that $\psi=\tilde{\phi}$ so $\phi\mapsto\tilde{\phi}$ is surjective. □

A *quantum stochastic process* on E is a set of observables X_τ, $\tau\in\mathbb{R}$. If $\phi(\tau)$ is a dynamical group on E and $X\in\mathcal{O}(E)$ then $X_\tau=\phi(\tau)\tilde{}(X)$ is an example of a quantum stochastic process. We then interpret X_τ as the evolution of the observable X.

IV. HISTORY EFFECTS

This section shows that there is a close connection between a history structure and a temporal effect algebra. In this section $(\mathcal{S},\mathcal{O},P)$ will denote a fixed history structure with set of histories $\mathcal{H}$. We have seen that for $h\in\mathcal{H}$, $\alpha\in\mathcal{S}$, the probability $P_\alpha(h)$ is well defined. Moreover, by (H3) there exists a one-time event (X,A) such that

$$P_\alpha(h)=P_{\alpha,X}(A)=P_\alpha((X,A))$$

for every $\alpha\in\mathcal{S}$. For $h_1,h_2\in\mathcal{H}$ we define $h_1\sim h_2$ if $P_\alpha(h_1)=P_\alpha(h_2)$ for every $\alpha\in\mathcal{S}$. In this case h_1 and h_2 are statistically indistinguishable. Clearly, $\sim$ is an equivalence relation on $\mathcal{H}$ and we denote the equivalence class containing h by $[h]$. We call the elements of $\mathcal{E}=\mathcal{H}/\sim=\{[h]:h\in\mathcal{H}\}$ *history effects* and we call $\mathcal{E}$ the *logic* for $(\mathcal{S},\mathcal{O},P)$. Notice that for every $[h]\in\mathcal{E}$ there exists a *one-time effect* $[(X,A)]$ such that $[h]=[(X,A)]$. For $\alpha\in\mathcal{S}$, $[h]\in\mathcal{E}$, we define $P_\alpha([h])=P_\alpha(h)$. We also define $O\in\mathcal{E}$ by $O=[(X,\varnothing)]$ and $1\in\mathcal{E}$ by $1=[(X,\mathbb{R})]$ for any $X\in\mathcal{O}$.

Lemma 4.1: (i) For $a,b\in\mathcal{E}$, if $P_\alpha(a)=P_\alpha(b)$ for every $\alpha\in\mathcal{S}$, then $a=b$. (ii) For $a,b\in\mathcal{E}$, if $P_\alpha(a)+P_\alpha(b)\leqslant 1$ for every $\alpha\in\mathcal{S}$, then there exists a unique $c\in\mathcal{E}$ such that $P_\alpha(c)=P_\alpha(a)+P_\alpha(b)$ for every $\alpha\in\mathcal{S}$.

Proof: (i) Letting $a=[h_1]$, $b=[h_2]$ we have $P_\alpha(h_1)=P_\alpha(h_2)$ for every $\alpha\in\mathcal{S}$. Hence, $h_1\sim h_2$ so $a=b$. (ii) Let $a=[(X,A)]$, $b=[(Y,B)]$. Then for every $\alpha\in\mathcal{S}$ we have

$$P_{\alpha,X}(A)=P_\alpha(a)\leqslant 1-P_\alpha(b)=1-P_{\alpha,Y}(B)=P_{\alpha,Y}(B').$$

By Lemma 2.3, there exists a $Z\in\mathcal{O}$ and C, $D\in\mathcal{B}(\mathbb{R})$ with $C\subseteq D$ such that $P_{\alpha,Z}(C)=P_{\alpha,X}(A)$ and $P_{\alpha,Z}(D)=P_{\alpha,Y}(B')$ for every $\alpha\in\mathcal{S}$. Since $C\cap D'=\varnothing$, letting $c=[(Z,C\cup D')]$ we have

$$P_\alpha(c)=P_{\alpha,Z}(C\cup D')=P_{\alpha,Z}(C)+P_{\alpha,Z}(D')=P_{\alpha,X}(A)+P_{\alpha,Y}(B)=P_\alpha(a)+P_\alpha(b)$$

for every $\alpha\in\mathscr{S}$. The uniqueness of c follows from (i). □

For $a,b\in\mathscr{E}$, we write $a\perp b$ if $P_\alpha(a)+P_\alpha(b)\leqslant 1$ for every $\alpha\in\mathscr{S}$. If $a\perp b$ we define $a\oplus b=c$, where c is the unique element of $\mathscr{E}$ given by Lemma 4.1(ii). We interpret c as the statistical sum of a and b in the sense that c is the unique element of $\mathscr{E}$ such that $P_\alpha(c)=P_\alpha(a)+P_\alpha(b)$ for every $\alpha\in\mathscr{S}$. We define the temporal product of $[(X,A)],[(Y,B)]\in\mathscr{E}$ by

$$[(X,A)]\circ[(Y,B)]=[((X,A),(Y,B))].$$

The temporal product is well defined by (H2). For $a,b\in\mathscr{E}$ we have $a=[(X,A)]$, $b=[(Y,B)]$ for some $X,Y\in\mathscr{O}$ and $A,B\in\mathscr{B}(\mathbb{R})$ and we define $a\circ b=[(X,A)]\circ[(Y,B)]$. The next result shows that the logic of a history structure is a temporal effect algebra.

Theorem 4.2: The algebraic system $(\mathscr{E},0,1,\oplus,\circ)$ is a temporal effect algebra and $\{P_\alpha:\alpha\in\mathscr{S}\}$ is an order determining set of states on $\mathscr{E}$.

Proof: It is clear that if $a\perp b$, then $b\perp a$ and $b\oplus a=a\oplus b$. Now suppose that $a\perp b$ and $a\oplus b\perp c$. Then for every $\alpha\in\mathscr{S}$ we have

$$P_\alpha(a)+P_\alpha(b)+P_\alpha(c)=P_\alpha(a\oplus b)+P_\alpha(c)\leqslant 1$$

so $b\perp c$. Since $P_\alpha(a)+P_\alpha(b\oplus c)\leqslant 1$ for every $\alpha\in\mathscr{S}$, we have $a\perp b\oplus c$. For every $\alpha\in\mathscr{S}$ we have

$$P_\alpha(a\oplus(b\oplus c))=P_\alpha(a)+P_\alpha(b)+P_\alpha(c)=P_\alpha((a\oplus b)\oplus c)$$

so by Lemma 4.1(i), $a\oplus(b\oplus c)=(a\oplus b)\oplus c$. For $a=[(X,A)]\in\mathscr{E}$, let $a'=[(X,A')]$. Then for every $\alpha\in\mathscr{S}$ we have

$$P_\alpha(a)+P_\alpha(a')=P_{\alpha,X}(A)+P_{\alpha,X}(A')=1=P_\alpha(1).$$

Hence, $a\perp a'$ and by Lemma 4.1(i), $a\oplus a'=1$ and a' is unique. If $a\perp 1$, then for every $\alpha\in\mathscr{S}$ we have

$$P_\alpha(a)+1=P_\alpha(a)+P_\alpha(1)\leqslant 1.$$

Hence, $P_\alpha(a)=0$ for every $\alpha\in\mathscr{S}$ so $a=0$. We conclude that $(\mathscr{E},0,1,\oplus)$ is an effect algebra. For $\alpha\in\mathscr{S}$, we have $P_\alpha(1)=1$ and P_α is additive because $a\perp b$ implies that $P_\alpha(a\oplus b)=P_\alpha(a)+P_\alpha(b)$. To show that $\{P_\alpha:\alpha\in\mathscr{S}\}$ is order determining suppose that $P_\alpha(a)\leqslant P_\alpha(b)$ for every $\alpha\in\mathscr{S}$. Then $P_\alpha(a)+P_\alpha(b')\leqslant 1$ for every $\alpha\in\mathscr{S}$ so $a\perp b'$. Since

$$P_\alpha(a)+P_\alpha((a\oplus b')')=P_\alpha(a)+1-P_\alpha(a\oplus b')=P_\alpha(a)+1-P_\alpha(a)-P_\alpha(b')=P_\alpha(b)$$

for every $\alpha\in\mathscr{S}$ we have $a\oplus(a\oplus b')'=b$ so $a\leqslant b$. To show that $\mathscr{E}$ is a σ-effect algebra, suppose that $a_i\in\mathscr{E}$, $i=1,2,...$, with $a_1\leqslant a_2\leqslant\cdots$. Then $a_i=[(X_i,A_i)]$ and since $P_\alpha(a_i)\leqslant P_\alpha(a_{i+1})$ we have $P_{\alpha,X_i}(A_i)\leqslant P_{\alpha,X_{i+1}}(A_{i+1})$, $i=1,2,...$, for every $\alpha\in\mathscr{S}$. Applying Lemma 2.3, there exists an $X\in\mathscr{O}$ and $B_i\in\mathscr{B}(\mathbb{R})$ with $B_i\subseteq B_{i+1}$ such that $P_{\alpha,X}(B_i)=P_{\alpha,X_i}(A_i)$, $i=1,2,...$, for every $\alpha\in\mathscr{S}$. Letting $a=[(X,\cup B_i)]$ we have

$$\lim P_\alpha(a_i)=\lim P_{\alpha,X_i}(A_i)=\lim P_{\alpha,X}(B_i)=P_{\alpha,X}(\cup B_i)=P_\alpha(a)$$

for every $\alpha\in\mathscr{S}$. Since $P_\alpha(a_i)\leqslant P_\alpha(a)$ for every $\alpha\in\mathscr{S}$, we conclude that $a_i\leqslant a$, $i=1,2,...$. If $a_i\leqslant b$, $i=1,2,...$, then $P_\alpha(a_i)\leqslant P_\alpha(b)$ for every $\alpha\in\mathscr{S}$, $i=1,2,...$. Hence, $P_\alpha(a)\leqslant P_\alpha(b)$ for every $\alpha\in\mathscr{S}$ so $a\leqslant b$. Hence, $a=\vee a_i$ so $\mathscr{E}$ is a σ-effect algebra. Also P_α is a state for every $\alpha\in\mathscr{S}$ because we have just shown that if $a_1\leqslant a_2\leqslant\cdots$, then $P_\alpha(\vee a_i)=\lim P_\alpha(a_i)$.

To complete the proof, we must show that $\circ$ is indeed a temporal product. Letting $a=[(X,A)]\in\mathscr{E}$, then for every $\alpha\in\mathscr{S}$ we have by (H4) that

$$P_\alpha(a\circ 1)=P_\alpha([(X,A),(X,\mathbb{R})])=P_{\alpha,s}(A\times\mathbb{R})=P_{\alpha,X}(A)=P_\alpha(a).$$

Hence, $a\circ 1=a$ for every $a\in\mathscr{E}$. Moreover,

$$P_\alpha(0\circ a)=P_\alpha([(X,\varnothing),(X,A)])=P_{\alpha,s}(\varnothing\times A)=P_{\alpha,s}(\varnothing)=0$$

for every $\alpha\in\mathscr{S}$, so $0\circ a=0$. To show that $\circ$ is additive, let $b\perp c$ so that $b\leqslant c'$. Since $P_\alpha(b)\leqslant P_\alpha(c')$ for every $\alpha\in\mathscr{S}$, by Lemma 2.3 there exists an $X\in\mathscr{O}$ and $B, D\in\mathscr{B}(\mathbb{R})$ with $B\subseteq D$ such that $P_{\alpha,X}(B)=P_\alpha(b)$, $P_{\alpha,X}(D)=P_\alpha(c')$ for every $\alpha\in\mathscr{S}$. Then,

$$P_{\alpha,X}(B\cup D')=P_{\alpha,X}(B)+P_{\alpha,X}(D')=P_\alpha(b)+P_\alpha(c)=P_\alpha(b\oplus c)$$

for every $\alpha\in\mathscr{S}$. Hence, $[(X,B\cup D')]=b\oplus c$. For $a=[(Y,A)]\in\mathscr{E}$, by Corollary 2.2 we have

$$\begin{aligned}P_\alpha(a\circ(b\oplus c))&=P_{\alpha,s,X}([((Y,A),(X,B\cup D'))])\\&=P_{\alpha,s,X}([((Y,A),(X,B))])+P_{\alpha,s,X}([((Y,A),(X,D'))])\\&=P_\alpha(a\circ b)+P_\alpha(a\circ c)\end{aligned}$$

for every $\alpha\in\mathscr{S}$. We conclude that $a\circ b\perp a\circ c$ and $a\circ(b\oplus c)=a\circ b\oplus a\circ c$. To show that $\circ$ is σ-additive, suppose that $b_1\leqslant b_2\leqslant\cdots$. By Lemma 3.4(iii) we have that $a\circ b_1\leqslant a\circ b_2\leqslant\cdots$. Applying (H1) there exists $Y\in\mathscr{O}$ and $B_i\in\mathscr{B}(\mathbb{R})$ with $B_i\subseteq B_{i+1}$ such that $P_{\alpha,Y}(B_i)=P_\alpha(b_i)$, $i=1,2,...$, for every $\alpha\in\mathscr{S}$. As in the previous paragraph, we have $[(Y,\cup B_i)]=\vee b_i$. Letting $a=[(X,A)]$ we have by Corollary 2.2 that

$$\begin{aligned}P_\alpha(\vee a\circ b_i)&=\lim P_\alpha(a\circ b_i)=\lim P_{\alpha,s,Y}([((X,A),(Y,B_i))])\\&=P_{\alpha,s,Y}([((X,A),(Y,\cup B_i))])=P_\alpha(a\circ\vee b_i)\end{aligned}$$

for every $\alpha\in\mathscr{S}$. Hence, $\vee a\circ b_i=a\circ\vee b_i$. □

For $X\in\mathscr{O}$, define $\hat{X}:\mathscr{B}(\mathbb{R})\to\mathscr{E}$ by $\hat{X}(A)=[(X,A)]$.

Theorem 4.3: The map $\hat{X}:\mathscr{B}(\mathbb{R})\to\mathscr{E}$ is an observable on $\mathscr{E}$ and the distribution $P_{\alpha,X}$ of X coincides with the distribution $P_\alpha\circ\hat{X}$ of $\hat{X}$ for every $\alpha\in\mathscr{S}$.

Proof: Notice that $\hat{X}(\mathbb{R})=[(X,\mathbb{R})]=1$. If $A, B\in\mathscr{B}(\mathbb{R})$ with $A\cap B=\varnothing$, then

$$P_{\alpha,X}(A)+P_{\alpha,X}(B)=P_{\alpha,X}(A\cup B)\leqslant 1$$

for every $\alpha\in\mathscr{S}$. Hence, $[(X,A)]\perp[(X,B)]$ and

$$P_\alpha([(X,A)])+P_\alpha([(X,B)])=P_\alpha([(X,A\cup B)])$$

for every $\alpha\in\mathscr{S}$ so that $\hat{X}(A\cup B)=\hat{X}(A)\oplus\hat{X}(B)$. Suppose that $A_i\in\mathscr{B}(\mathbb{R})$ with $A_i\cap A_j=\varnothing$, $i\neq j$. Then for $n\in\mathbb{N}$ we have

$$\hat{X}\left(\bigcup_{i=1}^{\infty}A_i\right)\geqslant\hat{X}\left(\bigcup_{i=1}^{n}A_i\right)=\bigoplus_{i=1}^{n}\hat{X}(A_i).$$

Suppose that $a\geqslant\oplus_{i=1}^{n}\hat{X}(A_i)$ for all $n\in\mathbb{N}$. Then

$$P_\alpha(a)\geqslant\sum_{i=1}^{n}P_{\alpha,X}(A_i)$$

for all $n\in\mathbb{N}$ so that

$$P_\alpha(a)\geqslant\sum_{i=1}^{\infty}P_{\alpha,X}(A_i)=P_{\alpha,X}\left(\bigcup_{i=1}^{\infty}A_i\right)=P_\alpha\left(\hat{X}\left(\bigcup_{i=1}^{\infty}A_i\right)\right)$$

for every $\alpha\in\mathscr{S}$. Hence, $a\geqslant\hat{X}(\cup A_i)$ so that

$$\hat{X}(\cup A_i)=\vee\bigoplus_{i=1}^{n}\hat{X}(A_i)=\bigoplus_{i=1}^{\infty}\hat{X}(A_i).$$

It follows from Lemma 3.2 that $\hat{X}\in\mathcal{O}(\mathcal{E})$. Finally, for $\alpha\in\mathcal{S}$, $A\in\mathcal{B}(\mathbb{R})$ we have

$$(P_\alpha\circ\hat{X})(A)=P_\alpha([(X,A)])=P_\alpha((X,A))=P_{\alpha,X}(A). \qquad \square$$

It follows from Theorem 4.2 that any state $\alpha\in\mathcal{S}$ can be represented by a state $P_\alpha\in\mathcal{S}(\mathcal{E})$. Moreover, by Theorem 4.3, any observable $X\in\mathcal{O}$ can be represented by an observable $\hat{X}\in\mathcal{O}(\mathcal{E})$. We can also represent history sets in $\hat{\mathcal{H}}$ by observables on $\mathcal{E}$. If $s=((X_1,\mathcal{N}_1),\ldots,(X_n,\mathcal{N}_n))\in\hat{\mathcal{H}}$ and $A_i\in\mathcal{N}_i$, $i=1,\ldots,n$, define

$$\hat{s}(A_1\times\cdots\times A_n)=[((X_1,A_1),\ldots,(X_n,A_n))]\in\mathcal{E}.$$

Then as in the proof of Theorem 4.3, $\hat{s}$ extends to a unique observable on $\mathcal{E}$ with value space $(\mathbb{R}^n,\mathcal{A}_s)$. Moreover, the joint sequential distribution $P_{\alpha,s}$ of s coincides with the distribution $P_\alpha\circ\hat{s}$ of $\hat{s}$ for every $\alpha\in\mathcal{S}$.

We have shown that the logic of a history structure is a temporal effect algebra. We now prove the converse statement. That is, any temporal effect algebra is σ-isomorphic to the logic of a history structure.

Theorem 4.4: If $(E,0,1,\oplus,\circ)$ is a temporal effect algebra, then there exists a history structure $(\mathcal{S},\mathcal{O},P)$ such that E is σ-isomorphic to the logic of $(\mathcal{S},\mathcal{O},P)$.

Proof: Let $\mathcal{H}$, $\hat{\mathcal{H}}$ be the families of histories and history sets, respectively, for $\mathcal{O}(E)$. That is,

$$\mathcal{H}=\cup\{(\mathcal{O}(E)\times\mathcal{B}(\mathbb{R}))^n:n\in\mathbb{N}\},$$

$$\hat{\mathcal{H}}=\cup\{(\mathcal{O}(E)\times\mathcal{P}(\mathbb{R}))^n:n\in\mathbb{N}\}.$$

For $s=((X_1,\mathcal{N}_1),\ldots,(X_n,\mathcal{N}_n))\in\hat{\mathcal{H}}$, $\alpha\in\mathcal{S}(E)$ and $A_i\in\mathcal{N}_i$, $i=1,\ldots,n$, define

$$P_{\alpha,s}(A_1\times\cdots\times A_n)=\alpha(X_1(A_1)\circ\cdots\circ X_n(A_n)).$$

We now show that $P_{\alpha,s}$ extends uniquely to an element of $M_1^+(\mathbb{R}^n,\mathcal{A}_s)$. Suppose that $\mathcal{N}_i=\{A_i^j:j=1,2,\ldots\}$, $i=1,\ldots,n$. By the σ-additivity of $\circ$ we have

$$\begin{aligned}\bigoplus_{j_n}X_1(A_1^{j_1})\circ\cdots\circ X_n(A_n^{j_n})&=X_1(A_1^{j_1})\circ\cdots\circ X_{n-1}(A_{n-1}^{j_{n-1}})\circ\bigoplus_{j_n}X_n(A_n^{j_n})\\&=X_1(A_1^{j_1})\circ\cdots\circ X_{n-1}(A_{n-1}^{j_{n-1}})\circ X_n\left(\cup_{j_n}A_n^{j_n}\right)=X_1(A_1^{j_1})\circ\cdots\circ X_{n-1}(A_{n-1}^{j_{n-1}}).\end{aligned}$$

Proceeding by induction, we conclude that

$$\bigoplus_{j_1,\ldots,j_n}X_1(A_1^{j_1})\circ\cdots\circ X_n(A_n^{j_n})=1.$$

Hence,

$$\sum_{j_1,\ldots,j_n}P_{\alpha,s}(A_1^{j_1}\times\cdots\times A_n^{j_n})=1.$$

Now any $A\in\mathcal{A}_s$ has the form

$$A=\cup\{A_1^{j_1}\times\cdots\times A_n^{j_n}:j_1\in I_1,\ldots,j_n\in I_n\},$$

where $I_i\subseteq\mathbb{N}$ is an index set depending on A, $i=1,\ldots,n$. We then define $P_{\alpha,s}\in M_1^+(\mathbb{R}^n,\mathcal{A}_s)$ by

$$P_{\alpha,s}(A)=\sum\{P_{\alpha,s}(A_1^{j_1}\times\cdots\times A_n^{j_n}):j_1\in I_1,\ldots,j_n\in I_n\}.$$

We now show that $(\mathscr{S}(E),\mathscr{O}(E),P)$ is a history structure. To verify (H1), suppose that $s_i=(X_i,\mathscr{N}_i)\in\hat{\mathscr{H}}^1$ and $P_{\alpha,s_i}(A_i)\leqslant P_{\alpha,s_{i+1}}(A_{i+1})$ for every $\alpha\in\mathscr{S}(S)$, $i=1,2,\ldots$. Letting $a_i=X_i(A_i)$ we have

$$\alpha(a_i)=\alpha(X_i(A_i))=P_{\alpha,s_i}(A_i)\leqslant P_{\alpha,s_{i+1}}(A_{i+1})=\alpha(X_{i+1}(A_{i+1}))=\alpha(a_{i+1})$$

for every $\alpha\in\mathscr{S}(E)$, $i=1,2,\ldots$. Since $\mathscr{S}(E)$ is order determining, we have $a_i\leqslant a_{i+1}$, $i=1,2,\ldots$. Let $a=\vee a_i$, $b_1=a_1$, $b_i=a_i\ominus a_{i-1}$, $i=2,3,\ldots$, and we have $\oplus b_i=a$. Letting $b_0=a'$, we have $\oplus_{i=0}^{\infty}b_i=1$. Now let $\{\lambda_i:i=0,1,\ldots\}\subseteq\mathbb{R}$, define $X(\lambda_i)=b_i$, $i=0,1,\ldots$, and for $B\in\mathscr{B}(\mathbb{R})$ define

$$X(B)=\bigoplus\{X(\lambda_i):\lambda_i\in B\}.$$

Then $X\in\mathscr{O}(E)$ and for $B_i=\{\lambda_1,\ldots,\lambda_i\}$, $i=1,2,\ldots$, we have $B_i\subseteq B_{i+1}$ and

$$X(B_i)=\bigoplus_{j=1}^{i}X(\lambda_j)=\bigoplus_{j=1}^{i}b=a_i.$$

Letting $\mathscr{N}$ be a partition generated by $\{\lambda_i\}$ $i=1,2,\ldots$, and $s=(X,\mathscr{N})$ we have

$$P_{\alpha,s_i}(A_i)=\alpha(a_i)=\alpha(X(B_i))=P_{\alpha,s}(B_i)$$

for every $\alpha\in\mathscr{S}(E)$. The verifications of (H2)–(H5) are straightforward. Moreover, it is easy to show that the logic of $(\mathscr{S}(E),\mathscr{O}(E),P)$ is σ-isomorphic to E. □

It follows from Theorem 4.4 that a temporal effect algebra E generates a history structure $(\mathscr{S}(E),\mathscr{O}(E),P)$ in a natural way. For $X_i\in\mathscr{O}(E)$, $A_i\in\mathscr{B}(\mathbb{R})$, we call $X_1(A_1)\circ\cdots\circ X_n(A_n)$ a *history effect* and this corresponds to the history $((X_1,A_1),\ldots,(X_n,A_n))$ of the history structure $(\mathscr{S}(E),\mathscr{O}(E),P)$. For $\mathscr{N}_i\in\mathscr{P}(\mathbb{R})$, the observable on E with value space $(\mathbb{R}^n,\mathscr{A}(\mathscr{N}_1,\ldots,\mathscr{N}_n))$ induced by $X_1(A_1)\circ\cdots\circ X_n(A_n)$, $A_i\in\mathscr{N}_i$, $i=1,\ldots,n$, is called a *history observable* and is denoted by $X_s=X_1\circ\cdots\circ X_n$. This observable corresponds to the history set $s=((X_1,\mathscr{N}_1),\ldots,(X_n,\mathscr{N}_n))$ on $(\mathscr{S}(E),\mathscr{O}(E),P)$. If $\alpha\in\mathscr{S}(E)$, then $\alpha(X_1(A_1)\circ\cdots\circ X_n(A_n))$ is the probability of the corresponding history in the state α and the distribution of X_s gives the joint sequential distribution for the history set s in the state α. It is also clear that an observable automorphism $\psi\in\mathrm{aut}_{\mathscr{O}}(E)$ induces an automorphism on the history structure $(\mathscr{S}(E),\mathscr{O}(E),P)$. Moreover, a dynamical group on E induces a dynamical group on $(\mathscr{S}(E),\mathscr{O}(E),P)$.

It is of interest to note that a fixed history set s corresponds to a classical logic in the sense that the range $R(X_s)\subseteq E$ of X_s is a Boolean algebra.[7] In this Boolean algebra, the operations $\vee$ and $\wedge$ are computed within $R(X_s)$ and not relative to the total effect algebra E. (In general E is not even a lattice.) In fact, if $X_s(A),X_s(B)\in R(X_s)$, then $X_s(A)'=X_s(A')$ and

$$X_s(A)\vee X_s(B)=X_s(A\cup B),$$

$$X_s(A)\wedge X_s(B)=X_s(A\cap B).$$

The ''local'' Boolean algebra $R(X_s)$ is contextual in the sense that it depends on s. If t is another history set then there is no relationship between $R(X_s)$ and $R(X_t)$ in general even when s and t both involve the same observables.

V. HILBERT SPACE HISTORIES

Let H be a complex Hilbert space. A linear operator T on H that satisfies $O\leqslant T\leqslant I$ is called a *Hilbert space effect*[17,18] and the set of Hilbert space effects on H is denoted $\mathscr{E}(H)$. For $S,T\in\mathscr{E}(H)$ we write $S\perp T$ if $S+T\in\mathscr{E}(H)$ and in this case we define $S\oplus T=S+T$.

Lemma 5.1: The system $(\mathscr{E}(H),O,I,\oplus)$ is a σ-effect algebra and every state α on $\mathscr{E}(H)$ has the form $\alpha(T)=\mathrm{tr}(WT)$ where W is a unique density operator on H.

Proof: It is easy to show that $(\mathscr{E}(H),O,I,\oplus)$ is an effect algebra. To show that $\mathscr{E}(H)$ is a σ-effect algebra, suppose that $T_i\in\mathscr{E}(H)$ with $T_1\leqslant T_2\leqslant\cdots$. A standard result[19] shows that there exists a $T\in\mathscr{E}(H)$ such that

$$\langle Tx,x\rangle=\lim\langle T_ix,x\rangle$$

for every $x\in H$. That is $\lim T_i=T$ in the weak operator topology. Since $\langle T_ix,x\rangle\leqslant\langle Tx,x\rangle$ for every $x\in H$, we conclude that $T_i\leqslant T$, $i=1,2,...$. Moreover, if $S\in\mathscr{E}(H)$ with $T_i\leqslant S$, $i=1,2,...$, then $\langle T_ix,x\rangle\leqslant\langle Sx,x\rangle$ for every $x\in H$, $i\in\mathbb{N}$. Hence, $\langle Tx,x\rangle\leqslant\langle Sx,x\rangle$ for every $x\in H$ so $T\leqslant S$. Thus, $S=\vee T_i$ so $\mathscr{E}(H)$ is a σ-effect algebra. It is well known that every state on $\mathscr{E}(H)$ has the given form.[17,18] □

Because of Lemma 5.1, we can identify the set $\mathscr{S}(H)$ of density operators on H with the set of states on $\mathscr{E}(H)$ and it is clear that $\mathscr{S}(H)$ is order determining. Moreover, the observables on $\mathscr{E}(H)$ are given by positive operator valued (POV) measures[17,18] on H and we denote the set of observables by $\mathscr{O}(H)$. For $S,T\in\mathscr{E}(H)$ define $S\circ T=S^{1/2}TS^{1/2}$. Since

$$\langle S^{1/2}TS^{1/2}x,x\rangle=\langle TS^{1/2}x,S^{1/2}x\rangle\leqslant\langle S^{1/2}x,S^{1/2}x\rangle=\langle Sx,x\rangle\leqslant\langle x,x\rangle$$

for every $x\in H$, we conclude that $S\circ T\in\mathscr{E}(H)$.

Theorem 5.2: The system $(\mathscr{E}(H),O,I,\oplus,\circ)$ is a temporal effect algebra.

Proof: We only need to show that $\circ$ is a temporal product. It is clear that $O\circ T=O$ and $T\circ I=T$ for all $T\in\mathscr{E}(H)$. If $T_1,T_2\in\mathscr{E}(H)$ with $T_1\perp T_2$, then

$$S\circ(T_1\oplus T_2)=S\circ(T_1+T_2)=S^{1/2}(T_1+T_2)S^{1/2}=S^{1/2}T_1S^{1/2}\oplus S^{1/2}T_2S^{1/2}=S\circ T_1\oplus S\circ T_2.$$

Now suppose that $T_i\in\mathscr{E}(H)$ with $T_1\leqslant T_2\leqslant\cdots$. As in the proof of Lemma 5.1, $\lim T_i=\vee T_i$ in the weak operator topology. Moreover, since $S\circ T_1\leqslant S\circ T_2\leqslant\cdots$, $\lim S\circ T_i=\vee(S\circ T_i)$ in the weak operator topology. Hence, for every $x\in H$, we have

$$\lim\langle S\circ T_ix,x\rangle=\lim\langle T_iS^{1/2}x,S^{1/2}x\rangle=\langle(\vee T_i)S^{1/2}x,S^{1/2}x\rangle=\langle S\circ\vee T_ix,x\rangle.$$

Thus,

$$S\circ\vee T_i=\lim S\circ T_i=\vee(S\circ T_i)$$

so $T\mapsto S\circ T$ is countably additive. □

Since $\mathscr{E}(H)$ is a temporal effect algebra, we can form the corresponding history structure $(\mathscr{S}(H),\mathscr{O}(H),P)$ as in Sec. IV. For $X_i\in\mathscr{O}(H)$, $A_i\in\mathscr{B}(\mathbb{R})$, $i=1,...,n$, we have the history effect

$$h=X_1(A_1)\circ\cdots\circ X_n(A_n)=X_1(A_1)^{1/2}\cdots X_{n-1}(A_{n-1})^{1/2}X_n(A_n)X_{n-1}(A_{n-1})^{1/2}\cdots X_1(A_1)^{1/2}$$

and for a state $W\in\mathscr{S}(H)$ the probability of h becomes

$$P_W(h)=\operatorname{tr}(WX_1(A_1)\circ\cdots\circ X_n(A_n))=\operatorname{tr}(X_n(A_n)^{1/2}\cdots X_1(A_1)^{1/2}WX_1(A_1)^{1/2}\cdots X_n(A_n)^{1/2}).$$

These expressions are given in Ref. 7. For

$$s=((X_1,\mathscr{N}_1),\ldots,(X_n,\mathscr{N}_n))\in\hat{\mathscr{H}}$$

we have the history observable $X_s=X_1\circ\cdots\circ X_n$ with value space $(\mathbb{R}^n,\mathscr{A}_s)$ and for $W\in\mathscr{S}(H)$ the joint sequential distribution of $X_1,\ldots,X_n$ with partitions $\mathscr{N}_1,\ldots,\mathscr{N}_n$ is the probability measure on $(\mathbb{R}^n,\mathscr{A}_s)$ given by $P_{W,s}(X_s(\cdot))=\operatorname{tr}(WX_s(\cdot))$. If $S,T\in\mathscr{E}(H)$ and $W\in\mathscr{S}(H)$ with $\operatorname{tr}(WS)\neq0$, then the conditional probability of T given S is

$$P_W(T|S)=\frac{\operatorname{tr}(WS\circ T)}{\operatorname{tr}(WS)}=\frac{\operatorname{tr}(S^{1/2}WS^{1/2}T)}{\operatorname{tr}(WS)}.$$

Hence, the conditional state $W|S\in\mathscr{S}(H)$ is given by

$$W|S=\frac{S^{1/2}WS^{1/2}}{\mathrm{tr}(WS)}.$$

We now illustrate some manifestations of quantum interference discussed in Sec. II. Let $s=((X_1,\mathcal{N}),(X_2,\mathcal{N}))\in\hat{\mathcal{H}}$ where $\mathcal{N}=\{A_1,A_2\}$, $A_2=A_1'$. The possible alternatives in this history set are the four history effects

$$X_s(A_i\times A_j)=X_1(A_i)\circ X_2(A_j)\quad i,j=1,2.$$

In general

$$\begin{aligned}X_1\circ X_2(\mathbb{R}\times A_1)&=X_s(\mathbb{R}\times A_1)=X_s(A_1\times A_1\cup A_2\times A_1)=X_s(A_1\times A_1)+X_s(A_2\times A_1)\\&=X_1(A_1)\circ X_2(A_1)+X_1(A_2)\circ X_2(A_1)\\&=X_1(A_1)^{1/2}X_2(A_1)X_1(A_1)^{1/2}+X_1(A_2)^{1/2}X_2(A_1)X_1(A_2)^{1/2}\neq X_2(A_1).\end{aligned}$$

Thus, the marginal distribution need not coincide with the one-variable distribution. Of course, this is just an illustration of the nonadditivity in the first argument $(a\oplus b)\circ c\neq a\circ c\oplus b\circ c$.

As another example, let $s=((X_1,\mathcal{N}_1),(X_2,\mathcal{N}_2))$, $t=((X_1,\mathcal{M}_1),(X_2,\mathcal{M}_2))$ and suppose that $A,B\in\mathcal{N}_1$, $A\cup B\in\mathcal{M}_1$, $C\in\mathcal{N}_2\cap\mathcal{M}_2$. Then

$$X_s(A\cup B\times C)=X_s(A\times C\cup B\times C)=X_s(A\times C)\oplus X_s(B\times C)=X_1(A)\circ X_2(C)\oplus X_1(B)\circ X_2(C)$$

$$X_t(A\cup B\times C)=X_1\circ X_2(A\cup B\times C)=X_1(A\cup B)\circ X_2(C)=[X_1(A)\oplus X_1(B)]\circ X_2(C).$$

These two expressions need not coincide. Hence, if $W\in\mathcal{S}(H)$ in general we have

$$P_{W,s}(A\cup B\times C)\neq P_{W,t}(A\cup B\times C).$$

We thus see that refining a partition can change the probability of measurement results. Finally, the fact that Bayes' formula

$$P_W(T|S)P_W(S)=P_W(S|T)P_W(T)$$

does not hold in general follows from the fact that $S\circ T=T\circ S$ need not hold. That is, in general $S^{1/2}TS^{1/2}\neq T^{1/2}ST^{1/2}$.

This framework encompasses the formalism of quantum evolution. Let U: $H\to H$ be a unitary operator and define ϕ: $\mathcal{E}(H)\to\mathcal{E}(H)$ by $\phi(T)=U^*TU$. Then ϕ is an automorphism on $\mathcal{E}(H)$. Indeed, it is straightforward to show that ϕ is a σ-isomorphism and to show that ϕ preserves the temporal product we have

$$\begin{aligned}\phi(S\circ T)&=U^*S^{1/2}TS^{1/2}U=U^*S^{1/2}UU^*TUU^*S^{1/2}U\\&=(U^*SU)^{1/2}U^*TU(U^*SU)^{1/2}=\phi(S)\circ\phi(T).\end{aligned}$$

Let $U(\tau)=e^{-i\tau K/h}$ be a unitary evolution on H where K is the Hamiltonian of the system. It is clear that $U(\tau)$ is a dynamical group on $\mathcal{E}(H)$. If $X\in\mathcal{O}(H)$ is an observable at time zero, then the corresponding observable at time τ is

$$X_\tau(\cdot)=\phi_\tau(X(\cdot))=U(\tau)^*X(\cdot)U(\tau).$$

Thus, X_τ, $\tau\in\mathbb{R}$, is a quantum stochastic process. For times $\tau_1<\tau_2<\cdots<\tau_n$ and $A_1,\ldots,A_n\in\mathcal{B}(\mathbb{R})$ a temporal history effect is given by $h=X_{\tau_1}(A_1)\circ\cdots\circ X_{\tau_n}(A_n)$. To simplify the notation, let $U_i=U(\tau_i)$ and $U_{i,j}=U(\tau_j-\tau_i)$ for $i<j$. We then have

$$\begin{aligned}h&=U_1^*X(A_1)^{1/2}U_1\cdots U_{n-1}^*X(A_{n-1})^{1/2}U_{n-1}U_n^*X(A_n)U_nU_{n-1}^*X(A_{n-1})^{1/2}U_{n-1}\cdots U_1^*X(A_1)^{1/2}U_1\\&=U_1^*X(A_1)^{1/2}U_{2,1}^*\cdots U_{n-1,n-2}^*X(A_{n-1})^{1/2}U_{n,n-1}^*X(A_n)U_{n,n-1}X(A_{n-1})^{1/2}\\&\quad\times U_{n-1,n-2}\cdots U_{2,1}X(A_1)^{1/2}U_1.\end{aligned}$$

If $W\in\mathcal{S}(H)$ is the state at time zero and $\tau_0<\tau_1$ is the initial time under consideration, then the corresponding state at time τ_0 is $W_{\tau_0}=U(\tau_0)^*WU(\tau_0)$. The probability of h for the state W becomes

$$P_{W_{\tau_0}}(h)=\operatorname{tr}(U(\tau_0)^*WU(\tau_0)h)$$
$$=\operatorname{tr}(WU_{1,0}^*X(A_1)^{1/2}U_{2,1}^*\cdots U_{n-1,n-2}^*X(A_{n-1})^{1/2}\cdots U_{2,1}X(A_1)^{1/2}U_{1,0})$$

and this is the form given previously in Ref. 7.

In order to compare our formalism to those given previously, we can reformulate it in the following way. For

$$s=((X_1,\mathcal{N}_1),\ldots,(X_n,\mathcal{N}_n))\in\hat{\mathcal{H}}$$

we use the notation $\mathcal{N}=(\mathcal{N}_1,\ldots,\mathcal{N}_n)$ and for $A_i\in\mathcal{N}_i$, $i=1,...,n$, we write $A=(A_1,\ldots,A_n)\in\mathcal{N}$. For $A\in\mathcal{N}$ we define the *class operator*

$$C_s(A)=X_n(A_n)^{1/2}X_{n-1}(A_{n-1})^{1/2}\cdots X_1(A_1)^{1/2}.$$

Notice that

$$C_s(A)^*C_s(A)=X_1(A_1)\circ\cdots\circ X_n(A_n),$$

which is a history effect. For $W\in\mathcal{S}(H)$, we define the *decoherence function* $D_s^W:\mathcal{N}\times\mathcal{N}\to\mathbb{C}$ by

$$D_s^W(A,B)=\operatorname{tr}(WC_s(A)^*C_s(B)).$$

Then the following properties are easy to check.

(D1) $D_s^W(A,A)=P_W(X_1(A_1)\circ\cdots\circ X_n(A_n))\geqslant 0$;

(D2) $D_s^W(A,B)=D_s^W(B,A)^*$;

(D3) $\Sigma_{A\in\mathcal{N}}D_s^W(A,A)=1$.

We say that s is a *consistent history set relative to* W if $\operatorname{Re}D_s^W(A,B)=0$ for $A\neq B$.

We shall not pursue consistent history sets here because they have been thoroughly studied in the literature. Moreover, the decoherence function D_s^W is a specific Hilbert space construct and its physical significance is not completely clear. For this reason, it is not a natural concept to introduce into our axiomatic framework for a history structure or a temporal effect algebra. Nevertheless, we shall make some observations about D_s^W that do not seem to have been previously considered.

For simplicity, assume that $\mathcal{N}=(\mathcal{N}_1,\ldots,\mathcal{N}_n)$ consists of finite partitions $\mathcal{N}_i$, $i=1,...,n$ (which is frequently done in this formalism) and form the Hilbert space $\ell_2(\mathcal{N})=\{\psi:\mathcal{N}\to\mathbb{C}\}$ with inner product

$$\langle\psi,\phi\rangle=\sum_{A\in\mathcal{N}}\psi(A)\phi(A)^*.$$

Now D_s^W induces a linear operator (which we also denote by D_s^W) on $\ell_2(\mathcal{N})$ given by

$$(D_s^W\psi)(A)=\sum_{B\in\mathcal{N}}D_s^W(A,B)\psi(B).$$

Applying (D2) we have

$$\langle D_s^W\psi,\psi\rangle=\sum_{A,B\in\mathcal{N}} D_s^W(A,B)\psi(B)\psi(A)^*$$

$$=\sum_{A,B\in\mathcal{N}} \operatorname{tr}(WC_s^*(A)C_s(B))\psi(B)\psi(A)^*$$

$$=\operatorname{tr}\left[W\sum_{A\in\mathcal{N}}(\psi(A)C_s(A))^*\sum_{B\in\mathcal{N}}\psi(B)C_s(B)\right]\geqslant 0.$$

Hence, D_s^W is a positive operator on $\ell_2(\mathcal{N})$. It follows from (D3) that the trace of D_s^W is 1. Hence, D_s^W is a density matrix so $D_s^W\in\mathcal{S}(\ell_2(\mathcal{N}))$. It is easy to check that $W\mapsto D_s^W$ is a continuous affine map from $\mathcal{S}(H)$ to $\mathcal{S}(\ell_2(\mathcal{N}))$ so it has a unique continuous linear extension L from the trace class operators on H to the trace class operators on $\ell_2(\mathcal{N})$. The adjoint transformation L^* is a continuous linear transformation from $\mathcal{O}(\ell_2(\mathcal{N}))$ into $\mathcal{O}(H)$. With a little care, these ideas can be generalized to the case in which $\mathcal{N}$ is not finite ($\mathcal{N}$ is always countable). We conclude that each history set s possesses its own Hilbert space $\ell_2(\mathcal{N})$ and observables on $\ell_2(\mathcal{N})$ can be transferred in a natural way to observables on H. In a dual manner, states on H can be transferred to states on $\ell_2(\mathcal{N})$ by employing the decoherence function. This may be a useful physical interpretation for the decoherence function.

(Received 26 March 1998; accepted for publication 20 April 1998)

We present several examples of quasiexactly solvable *N*-body problems in one, two, and higher dimensions. We study various aspects of these problems in some detail. In particular, we show that in some of these examples the corresponding polynomials form an orthogonal set, and many of their properties are similar to those of the Bender–Dunne polynomials. We also discuss QES problems where the polynomials do not form an orthogonal set. © *1998 American Institute of Physics.* [S0022-2488(98)04510-1]

I. INTRODUCTION

In last few years, the quasiexactly solvable (QES) problems have attracted a lot of attention.[1] In particular, by now a detailed study has been made of several QES problems in (one-particle) nonrelativistic quantum mechanics in one dimension, and several interesting features have been uncovered. However, very few QES problems in multidimensions or *N*-body problems in one dimension[2,3] have been discussed so far. Further, to the best of our knowledge, no QES *N*-body problem in two and higher dimensions has been discussed so far. The purpose of this paper is to initiate a systematic study of the various aspects of the *N*-body QES problems in multidimensions. In particular, one would first like to discover several *N*-body QES problems in two and higher dimensions. Further, one would like to know if the corresponding polynomials form an orthogonal set or not. Besides, one would like to know if there is an underlying hidden algebra. In this context, it is worth recalling that in the case of the one-body problem in one dimension, it is known that in most QES cases (though not all[4]), there is an underlying hidden algebra $Sl(2)$. Further, the polynomials form an orthogonal set provided the Hamiltonian can be written in terms of the quadratic generators of this Sl(2) algebra,[5] and that in this case one has one[6] or two sets[7] of Bender–Dunne polynomials.

In this paper we discuss in some detail three different *N*-body QES problems namely, Calogero–Marchioro-type *N*-body problem in *D* dimensions[8,9] in Sec. II ($D \geqslant 2$), *N*-body systems exhibiting novel correlations in two dimensions[10] in Sec. III A, and the Calogero–Sutherland-type *N*-body problem in one dimension[11] in Sec. III B. In each case we discuss the QES problem in case the potential is either of the sextic type or is a sum of the oscillator plus Coulomb-type potential. We show that whereas in the former case, the polynomials form an orthogonal set, in the latter case they do not. We discuss the various properties of the orthogonal polynomials in these problems and show that they are similar to those of the Bender–Dunne polynomials in the one-body case. As a special case, we also discuss a self-dual system[12] in which case we can obtain several more QES levels analytically. Further, in this case we obtain a novel relation between the weight functions of the system. Finally, in Sec. IV we summarize our conclusions and point out some of the open problems.

II. CALOGERO–MARCHIORO-TYPE PROBLEM IN *D* DIMENSIONS

The *N*-body Hamiltonian corresponding to the Calogero–Marchioro model in *D* dimensions for arbitrary potential *V* can be written as[9]

 © 1998 American Institute of Physics

$$H=-\frac{\hbar^2}{2m}\sum_{i=1}^{N}\nabla_i^2+g\sum_{i<j}^{N}\frac{1}{r_{ij}^2}+G\sum_{i<j,i,j\neq k}\frac{\mathbf{r}_{ki}^2\cdot\mathbf{r}_{kj}^2}{r_{ki}^2 r_{kj}^2}+V\left(\sum_{i<j}^{N}r_{ij}^2\right), \tag{2.1}$$

where $\mathbf{r}_{ij}=(\mathbf{r}_i-\mathbf{r}_j)$ and $\mathbf{r}_i$ is the D-dimensional position vector for the ith particle.

On substituting the ansatz,

$$\psi=\left(\prod_{i<j}\mathbf{r}_{ij}^2\right)^{\Lambda_D/2}\phi(\rho), \tag{2.2}$$

in the Schrödinger equation ($H\psi=\epsilon\psi$) corresponding to the above system (with $\hbar=m=1$), it is easily shown that the equation satisfied by $\phi(\rho)$ is[9]

$$\phi''(\rho)+\frac{2\Gamma_D+1}{\rho}\phi'(\rho)-2V(\rho)\phi(\rho)+E\phi(\rho)=0. \tag{2.3}$$

Here $E=2\epsilon$ while

$$\rho^2=\frac{1}{N}\sum_{i<j}^{N}r_{ij}^2,$$

$$\Gamma_D=\tfrac{1}{2}[D(N-1)-2+\Lambda_D N(N-1)], \tag{2.4}$$

$$\Lambda_D=\sqrt{G}=\tfrac{1}{2}[\sqrt{(D-2)^2+4g}-(D-2)].$$

We now consider two different forms of $V(\rho)$ and obtain QES solutions in each case.

A. Sextic potential and QES problem

Let us first consider $V(\rho)$, as given by

$$V(\rho)=\frac{1}{2}\left[B\rho^2+C\rho^4+H\rho^6+\frac{F}{\rho^2}\right]. \tag{2.5}$$

In the special case when $C=0=H$, an infinite class of exact solutions including the bosonic ground state have already been obtained.[9,13]

On substituting

$$\phi(\rho)=\rho^a\exp(-\alpha\rho^2-\beta\rho^4)\eta(\rho), \tag{2.6}$$

in Eq. (2.3), we obtain

$$\eta''(\rho)+\left(\frac{2a+2\Gamma_D+1}{\rho}-[4\alpha\rho+8\beta\rho^3]\right)\eta'(\rho)$$
$$+(E-4\alpha(a+\Gamma_D+1)+\rho^2[4\alpha^2-B-8\beta(a+\Gamma_D+2)])\eta(\rho)=0, \tag{2.7}$$

where we have chosen, $\alpha=C/4\sqrt{H}$, $\beta=\sqrt{H}/4$, and $F=a^2+2a\Gamma_D$. Thus, a is zero or nonzero depending on if F is zero or nonzero. Finally, on substituting

$$\eta(\rho)=\sum_n\frac{P_n(E)\rho^{2n}}{4^n n!(n+a+\Gamma_D)!}, \tag{2.8}$$

in Eq. (2.7), we obtain the recursion relation satisfied by $P_n(E)$ as

$$P_n(E)+[E-4\alpha(2n-1+a+\Gamma_D)]P_{n-1}(E)+4(n-1)(n-1+a+\Gamma_D)$$
$$\times[4\alpha^2-B-8\beta(2n+a+\Gamma_D-2)]P_{n-2}(E)=0, \tag{2.9}$$

with initial conditions $P_{-1}=0$ and $P_0=1$. Using the well-known theorem,[14,15] ''the *necessary and sufficient* condition for a family of polynomials $\{P_n\}$ (with degree $P_n=n$) to form an orthogonal polynomial system is that $\{P_n\}$ satisfy a three-term recursion relation of the form

$$P_n(E)=(A_nE+B_n)P_{n-1}(E)+C_nP_{n-2}(E), \quad n\geqslant 1, \tag{2.10}$$

where the coefficients A_n, B_n, and C_n are independent of E, $A_n\neq 0$, $C_1=0$, $C_n\neq 0$ for $n\geqslant 1$,'' it then follows that $\{P_n(E)\}$ for this problem forms an orthogonal set of polynomials with respect to some weight function, $\omega(E)$.

Let us write B in the form $B=4\alpha^2-8\beta(2J+a+\Gamma_D)$, where J is any arbitrary number. We shall see that when J is a positive integer, then this represents a QES system. In terms of J, Eq. (2.9) then can be rewritten as

$$\begin{aligned} &P_n(E)+[E-4\alpha(2n-1+a+\Gamma_D)]P_{n-1}(E)-64\beta(n-1)\\ &\quad\times(n-1+a+\Gamma_D)(n-J-1)P_{n-2}(E)=0, \end{aligned} \tag{2.11}$$

from where it is clear that as long as J is a positive integer, this recursion relation will reduce to a two-term recursion relation. Thus, when J is a positive integer, we have a QES system. These recursion relations generate a set of orthogonal polynomials of which the first few are

$$\begin{aligned} P_1&=-E+4\alpha(a+\Gamma_D+1),\\ P_2&=E^2-E[8\alpha(a+\Gamma_D+2)]+16\alpha^2(a+\Gamma_D+1)\\ &\quad\times(a+\Gamma_D+3)-64\beta(a+\Gamma_D+1)(J-1). \end{aligned} \tag{2.12}$$

It is easily seen that when J is a positive integer, exact energy eigenvalues for the first J levels are known. Further, when J is a positive integer, these polynomials exhibit the factorization property, as given by

$$P_{n+J}(E)=P_J(E)Q_n(E), \tag{2.13}$$

where the polynomial set $Q_n(E)$ corresponds to the nonexact spectrum for this problem with $Q_0(E)=1$. For example, for $J=1$, P_{n+1} will be factorized into P_1 and Q_n and the corresponding QES energy level (which in this case is the ground state) is obtained by putting $P_1=0$, i.e.,

$$E_1=4\alpha(a+\Gamma_D+1). \tag{2.14}$$

Similarly for $J=2$, P_{n+2} will be factorized into P_2 and Q_n and the corresponding energy levels are

$$\begin{aligned} E_1&=4\alpha(a+\Gamma_D+2)-4\sqrt{\alpha^2+4\beta(a+\Gamma_D+1)},\\ E_2&=4\alpha(a+\Gamma_D+2)+4\sqrt{\alpha^2+4\beta(a+\Gamma_D+1)}. \end{aligned} \tag{2.15}$$

The quotient polynomials $Q_n(E)$ also form an orthogonal set as they satisfy the recursion relation

$$\begin{aligned} &Q_n(E)+[E-4\alpha\{2(n+J)-1+a+\Gamma_D\}]Q_{n-1}(E)\\ &\quad-64\beta(n+J-1)(n+J-1+a+\Gamma_D)(n-1)Q_{n-2}(E)=0, \end{aligned} \tag{2.16}$$

with $Q_0(E)=1$ and $Q_{-1}(E)=0$.

The square norm of both P_n and Q_n polynomials can be calculated from the recursion relations in Eqs. (2.11) and (2.16), respectively. We obtain

$$\gamma_n^P = 64\beta \prod_{k=1}^{n} k(k+a+\Gamma_D)(J-n),$$
$$\gamma_n^Q = 64\beta \prod_{k=1}^{n} (k+J)(k+J+a+\Gamma_D). \tag{2.17}$$

Note that à la the Bender–Dunne case,[6] the norm for the P_n polynomials vanish for $n \geqslant J$ while it is positive definite for $n<J$. This is an alternative characterization of the QES system. On the other hand, the norm for the Q_n polynomials is always nonvanishing and positive definite.

One can also calculate the weight functions ω_k for the set $P_n(E)$ by using the relations[16]

$$\sum_{k=1}^{J} P_n(E_k)\omega_k = \delta_{n0}, \quad n=0,1,...,J-1. \tag{2.18}$$

For example, for $J=2$ we obtain

$$\omega_1 = \frac{1}{2} + \frac{\alpha}{2\sqrt{\alpha^2+4\beta(a+\Gamma_D+1)}},$$
$$\omega_2 = \frac{1}{2} - \frac{\alpha}{2\sqrt{\alpha^2+4\beta(a+\Gamma_D+1)}}. \tag{2.19}$$

Notice that to the leading order, the weight functions are inversely proportional to the particle number N for a fixed D, while they are inversely proportional to the square root of the space dimension D, when the particle number N remains unchanged. It may also be noted that both the weight functions ω_1 and ω_2 are positive definite. Actually, one can prove on very general grounds that for any J, the weight functions in this case will always be positive. As has been shown by Finkel *et al.*,[15] if the three-term recursion relation is of the form

$$P_{k+1} = (E-b_k)P_k - a_k P_{k-1}, \quad k \geqslant 0, \tag{2.20}$$

with $a_0=0$ and $a_{n+1}=0$, then (i) the weight functions are all positive, (ii) the norm of the polynomials (γ_n^p) is positive for $n<J$, provided b_k is real for $0 \leqslant k \leqslant n$ and $a_k>0$ for $1 \leqslant k \leqslant n$. Using Eq. (2.11) it is then easy to see that for any J, the weight functions and γ_n^p (for $n<J$) will be positive.

One can also calculate the moments $\mu_n = \int dE\ E^n \omega(E)$ of the weight functions. It is easily shown that both the odd and the even moments are nonzero. Further, to the leading order,

$$\mu_n = [4\alpha(a+\Gamma_D+1)]^n + \cdots . \tag{2.21}$$

Thus, to the leading order, the growth rate is proportional to N^{2n} for fixed D and proportional to D^n for fixed N.

Finally, let us discuss the consequences of the anti-isospectral transformation (also termed the duality transformation)[12] in the context of our QES problem. It is easily seen that because of the duality transformation ($x \to ix$), the QES levels of the potential in Eq. (2.5) are related to that of a similar potential (say $\hat{V}$), where C (and hence α) has been replaced by $-C$. In particular, if J levels of the potential in Eq. (2.5) are QES levels with energy eigenvalues and eigenfunctions E_k and ψ_k, respectively ($k=1,2,...,J$), then the corresponding QES eigenvalues and eigenfunctions of $\hat{V}$ are given by

$$\hat{E}_k = -E_{J+1-k}, \quad \hat{\psi}_k(x) = \psi_{J+1-k}(ix). \tag{2.22}$$

For example, for $J=2$, the QES energy eigenvalues of $\hat{V}$ are same as those given by Eq. (2.15), with the precise relationship being $\hat{E}_{1,2} = -E_{2,1}$. The other properties of the dual potential are also similarly related and can be easily worked out.

B. Self-dual potential

Let us now discuss the special case of $C=0$ in Eq. (2.5), in which case we have a self-dual QES potential which has remarkably simple properties. For example, the recursion relation (2.11) now takes the simpler form (note that now $\alpha=C/4\sqrt{H}=0$),

$$P_n(E)+EP_{n-1}(E)-64\beta(n-1)(n-1+a+\Gamma_D)(n-J-1)P_{n-2}(E)=0, \tag{2.23}$$

and similarly the set Q_n satisfy Eq. (2.16) with $\alpha=0$. As a result, both $P_n(E)$ and $Q_n(E)$ are eigenfunctions of parity. First, few polynomials generated by this recursion relation are given by ($s\equiv 1+a+\Gamma_D$)

$$\begin{aligned} P_1&=-E,\\ P_2&=E^2-64\beta s(J-1),\\ P_3&=-E^3+E[64\beta s(J-1)+128\beta(s+1)(J-2)],\\ P_4&=E^4-E^2[64\beta s(J-1)+128\beta(s+1)(J-2)\\ &\quad+192\beta(s+2)(J-3)]+(64\beta)^2 3s(s+2)(J-1)(J-3). \end{aligned} \tag{2.24}$$

From the duality relation (2.22), it follows that for this self-dual system, all the energy eigenvalues must be symmetrically distributed around $E=0$. Further, in this case QES eigenvalues can be analytically calculated very simply for $J=1,2,...,5$. For example, the eigenvalues for $J=3$ and $J=4$ are given as follows: $J=3$,

$$\begin{aligned} E_1&=-8\sqrt{2\beta(2s+1)},\\ E_2&=0,\\ E_3&=8\sqrt{2\beta(2s+1)}, \end{aligned} \tag{2.25}$$

and $J=4$,

$$\begin{aligned} E_1&=-\sqrt{320\beta(s+1)+64\beta\sqrt{16s(s+2)+25}},\\ E_2&=-\sqrt{320\beta(s+1)-64\beta\sqrt{16s(s+2)+25}},\\ E_3&=\sqrt{320\beta(s+1)-64\beta\sqrt{16s(s+2)+25}},\\ E_4&=-\sqrt{320\beta(s+1)+64\beta\sqrt{16s(s+2)+25}}. \end{aligned} \tag{2.26}$$

The square norms of the polynomial sets P_n and $Q_n s$ are again given by Eq. (2.17). Since the polynomials have definite parity, the odd moments vanish. The even moments of the weight functions in the leading order are given by

$$\mu_{2n}\sim[(1+a+\Gamma_D)]^n+\cdots . \tag{2.27}$$

This means μ_{2n} is proportional to N^{2n} for fixed D and proportional to D^n for fixed N. It is worth noting that in the limit $C=0$ (and hence $\alpha=0$), the leading term in the expansion of μ_n in Eq. (2.21) vanishes, and that is why the leading behavior of μ_n as a function of $(1+a+\Gamma)$ when C (and hence α) is nonzero is the same as that of μ_{2n} when C (and hence α)$=0$.

The weight functions in this self-dual QES model are related through a nice relation,

$$\omega_k=\omega_{J+1-k}. \tag{2.28}$$

This can be proved explicitly using relation (2.18) as follows.

We consider n to be odd in Eq. (2.18), i.e.,

$$\sum_k P_{2m+1}(E_k)\omega_k=0, \quad \text{for} \quad k=1,2,...,J. \tag{2.29}$$

Now, since the $P_n(E)$ are of definite parity of E, we can write

$$P_{2m+1}(E_k)=\sum_{n=0}^{m} a_n E_k^{2n+1}, \qquad m=0,1,2,\ldots, \tag{2.30}$$

when a_n are (E-independent) constants and $a_m=-1$.

Putting (2.30) in (2.29), we obtain

$$\sum_{k=1}^{J}\sum_{n=0}^{m} a_n E_k^{2n+1}\omega_k=0. \tag{2.31}$$

This implies that

$$\sum_{k=1}^{J} E_k^{2m+1}\omega_k=0. \tag{2.32}$$

Now in Eq. (2.32), we use the duality relation between the eigenvalues of the self-dual system, i.e., $E_k=-E_{J+1-k}$, to obtain

$$\sum_{k=1}^{J} E_{J+1-k}^{2m+1}\omega_k=0. \tag{2.33}$$

Next, we make a change of variable $k=J+1-j$ in Eq. (2.33) to obtain

$$\sum_{j=1}^{J} E_j^{2m+1}\omega_{J+1-j}=0. \tag{2.34}$$

Subtracting Eq. (2.34) from Eq. (2.32),

$$\sum_{k=1}^{J} E_k^{2m+1}[\omega_k-\omega_{J+1-k}]=0. \tag{2.35}$$

This is true for arbitrary E_k, and hence the result, $\omega_k=\omega_{J+1-k}$.

We now explicitly calculate the weight functions for the case of $J=3$ and $J=4$. We find, for $J=3$,

$$\omega_1=\omega_3=\frac{s}{2(2s+1)}, \qquad \omega_2=\frac{s+1}{2s+2}, \tag{26}$$

and for $J=4$,

$$\omega_1=\omega_4=\frac{1}{4}\left[1-\frac{2s+5}{\sqrt{16s(s+2)+25}}\right], \qquad \omega_2=\omega_3=\frac{1}{4}\left[1+\frac{2s+5}{\sqrt{16s(s+2)+25}}\right]. \tag{2.37}$$

Not surprisingly, the weight function satisfies relation (2.28) and $\Sigma_{k=1}^{J}\ \omega_k=1$.

C. An unusual QES problem

Let us now discuss an unusual QES problem. To that end consider the following potential:

$$V(\rho)=\frac{1}{2}\left[B^2\rho^2-\frac{C}{\rho}+\frac{F}{\rho^2}\right]. \tag{2.38}$$

It is worth noting that for $C=0$ as well as for $B=0$, a class of energy levels can be analytically obtained.[9,13] The special case of $N=2$, i.e., 2-anyons in a magnetic field and experiencing Coulomb potential has been discussed by Myrheim *et al.*[17] We want to show that when both of them are nonzero, it is an example of an unusual QES system, in the sense that for a one-parameter family of potentials (when there is a specific relation between B, C, and F), one always obtains one QES eigenvalue.

On substituting

$$\phi(\rho)=\rho^a\ \exp(-B\rho^2/2)\,\eta(\rho), \tag{2.39}$$

in Eq. (2.3), we obtain

$$\eta''(\rho)+\left[\frac{2a+2\Gamma_D+1}{\rho}-(2B\rho)\right]\eta'(\rho)+\left[E-2(a+\Gamma_D+1)B+\frac{C}{\rho}\right]\eta(\rho)=0, \tag{2.40}$$

where we have chosen $F=a^2+2a\Gamma_D$. Next, we substitute

$$\eta(\rho)=\sum_n\ P_n(E)\rho^n \tag{2.41}$$

in Eq. (2.40) and obtain the recursion relation satisfied by $P_n(E)$ as

$$n(2a+2\Gamma_D+n)P_n(E)+CP_{n-1}(E)+[E-2(n-1+a+\Gamma_D)]P_{n-2}(E)=0, \tag{2.42}$$

with initial conditions $P_{-1}=0$ and $P_0=1$.

From the recursion relation, it follows that the QES levels are obtained in case the coefficient of $P_{n-2}(E)$ vanishes, i.e., the energy of the QES levels is given by $E=2(a+\Gamma_D+n+1)$, where $n=1,2,\ldots$. Further, in that case B, C, and F are not independent. For example, for $n=1$, the relation is $C^2=2(2a+2\Gamma_D+1)B$, while for $n=2$ the relation is $C^2=4(4a+4\Gamma_D+3)B$. The QES level corresponds to an excited (ground) state depending on if $C>(<)0$. On comparing Eq. (2.42) with Eq. (2.10), we conclude that the polynomials in this case do not correspond to orthogonal polynomials.

III. OTHER *N*-BODY PROBLEMS

In this section we briefly discuss two other many-body problems and we will see that in both of these cases we have two QES problems which are very similar to those discussed in the last section.

A. Novel correlations for *N* particles

Recently, a class of exact solutions including the bosonic ground state has been obtained for a many-body Hamiltonian in two dimensions, such that the wave functions have a novel correlation (of the form $X_{ij}=x_iy_j-x_jy_i$) built into them.[10] Here we would like to show that QES states with novel correlations can also be obtained in this case. To that purpose we start from the Hamiltonian,

$$H=-\frac{\hbar^2}{2m}\sum_i \nabla_i^2+\frac{\hbar^2}{2m}\,g_1\sum_{i,j}\ \frac{\mathbf{r}_{ij}^2}{X_{ij}^2}+\frac{\hbar^2}{2m}\,g_2\sum\ \frac{\mathbf{r}_j\cdot\mathbf{r}_k}{X_{ij}\cdot X_{ik}}$$
$$+\frac{\hbar^2}{2m}\left[2\left\{B\sum_i\ r_i^2+C\left(\sum_i\ r_i^2\right)^2+H\left(\sum_i\ r_i^2\right)^3+\frac{F}{\Sigma_i r_i^2}\right\}\right]. \tag{3.1}$$

On substituting the ansatz,

$$\psi=\prod_{i<j}^{N}\ |X_{ij}|^g\phi(\rho), \tag{3.2}$$

in the Schrödinger equation $H\psi=\epsilon\psi$ $(m=\hbar=1)$, one can show that ϕ satisfies the equation

$$\phi''+\frac{2\Delta+1}{\rho}\ \phi'+\left[E-B\rho^2-C\rho^4-H\rho^6-\frac{F}{\rho^2}\right]\phi=0, \tag{3.3}$$

where

$$2\Delta+1=2N-1+2gN(N-1),$$
$$\rho^2=\sum_i\ r_i^2;\quad E=2\epsilon;\quad g_1=g(g-1),\quad g_2=g^2. \tag{3.4}$$

On substituting

$$\phi(\rho)=\rho^a\ \exp(-\alpha\rho^2-\beta\rho^4)\,\eta(\rho), \tag{3.5}$$

in Eq. (3.3), we obtain

$$\eta''(\rho)+\left[\frac{2a+2\Delta+1}{\rho}-(4\alpha\rho+8\beta\rho^3)\right]\eta'(\rho)$$
$$+[E-4\alpha(a+\Delta+1)+\rho^2(4\alpha^2-B-8\beta(a+\Delta+2))]\,\eta(\rho)=0, \tag{3.6}$$

where we have chosen $\alpha=C/4\sqrt{H}$; $\beta=\sqrt{H}/4$; and $F=a^2+2a\Delta$. Now notice that this equation is similar to the corresponding equation in the last section, and hence the rest of the analysis of that section will be considered step by step in this case. Thus, this is another example of a QES N-body problem in two dimensions, where the polynomials satisfy most of the properties of the Bender–Dunne polynomials. Similarly, one can also consider the admixture of the oscillator and Coulomb-type potentials and, as in the last section, again obtain similar QES solutions. In particular, in this case the polynomials do not form an orthogonal set.

B. *N*-body QES problem in one-dimension

Finally, we would like to briefly discuss the Calogero–Sutherland-type N-body QES problems in one dimension.[2,3]

The Hamiltonian corresponding to the N-body QES problem in one-dimension is given by

$$H=-\frac{\hbar^2}{2m}\sum_i\ \nabla_i^2+\sum_{i<j}\ \frac{g}{(x_i-x_j)^2}+B\sum_i\ x_i^2+C\left[\sum\ x_i^2\right]^2 H\left[\sum\ x_i^2\right]^3+\frac{F}{\Sigma x_i^2}. \tag{3.7}$$

We substitute the standard ansatz for the wave function ψ,

$$\psi=Z^{\lambda+1/2}\phi(\rho), \tag{3.8}$$

where $Z=\Pi_{i<j}(x_i-x_j)$, $\rho^2=\Sigma x_i^2$, $\lambda=\frac{1}{2}\sqrt{1+4g}$ in $H\psi=\epsilon\psi$ $(\hbar=m=1)$, and obtain the ϕ equation,

$$\phi''+\frac{2\Delta+1}{\rho}\ \phi'+\left[E-B\rho^2-C\rho^4-H\rho^6-\frac{F}{\rho^2}\right]\phi=0, \tag{3.9}$$

where $E=2\epsilon$ and

$$2\Delta+1=N-1+N(N-1)\lambda. \tag{3.10}$$

This equation is very similar to the Eq. (3.3), and hence the rest of the analysis goes through as in the last section, i.e., the polynomials of the QES problem indeed form an orthogonal set and share most of the properties of the Bender–Dunne polynomials. Similarly, we can show that even in this case the other QES solution corresponding to the admixture of the oscillator and Coulomb potential also exists, and in this case, the polynomials do not form an orthogonal set.

IV. SUMMARY AND OPEN PROBLEMS

In this paper we have obtained QES solutions of a number of N-body problems in one, two, and higher dimensions. We have shown that with a sextic-type potential, in all these cases one has a set of orthogonal polynomials which satisfy almost all the properties, as satisfied by the Bender–Dunne polynomials. However, the hidden algebra is not clear in these cases. In this context, recall that for the case of one particle in one dimension experiencing the sextic potential, the underlying symmetry algebra is $Sl(2)$. In particular, in that case one can express the Hamiltonian in terms of the quadratic (and linear) generators of $Sl(2)$. Further, it will be nice to discover some other QES many-body problems. Finally, it would be most interesting if one can find some application of these QES N-body problems. In this context it is worth noting that one application has already been found by one of the present authors (AK) and Jatkar.[18] In particular, they have considered the model discussed in Sec. III B (with $F=0$) and have shown that the square of the ground state wave function of this model is related to the matrix model corresponding to branched polymers. It will really be interesting if one can find some other application of the N-body QES problems in two and higher dimensions.

SU(2) quantum kinematics: Rotation-observable versus angular-momentum generalized commutation relations

J. Krause[a)]
Facultad de Física, Pontificia Universidad Católica de Chile, Casilla 306, Santiago 22, Chile

(Received 21 January 1998; accepted for publication 27 July 1998)

The canonical commutation relations of quantum mechanics are generalized to the case where appropriate dynamical variables are angular-momentum, rotation-angle, and rotation-axis observables. To this end, SU(2) is ''quantized'' on the compact group manifold, according to the standard procedure of non-Abelian quantum kinematics. Quantum-kinematic invariant operators are introduced, and their commutation relations with the rotation variables are found in an explicit manner. The quantum-kinematic invariants yield superselection rules in the form of eigenvalue equations of an isotopic structure (which one should solve in the applications, in order to get multiplets that carry the irreducible representations of the underlying quantum kinematic models). A wide range of applicability of SU(2) quantum kinematics is suggested. © *1998 American Institute of Physics.*

I. INTRODUCTION

The problem of extending the canonical commutation relations to non-Cartesian dynamical variables is a long-standing question in the general setting of quantum mechanics.[1] Most attempts to solve this problem have been focused on the search of new quantization methods for obtaining generalized minimum-uncertainty states of systems which are primarily described by non-Abelian dynamical variables.[2] However, important as it is, this particular purpose may be too narrow a motivation for such an ambitious endeavor.[3] Indeed, it is quite conceivable that some unknown general constraints should be taken into account for extending the conventional (i.e., Heisenberg) commutation relations to the appropriate ones. Kinematic constraints follow, for instance, from the superselection rules due to the symmetry group that characterizes a system.[4] Likewise, the search for generalized coherent states would be unable by itself to disclose such constraints. Other important motivations for having generalized canonical commutation relations in quantum mechanics appear in the current literature, as well.[5] As a matter of fact, this question has been already so amply discussed in the literature, for so many years, that it seems unnecessary to repeat here the sound physical motivation behind this issue.[6] This paper addresses this fundamental problem for the particular case of rotation configuration variables and angular momenta. Let us here remark that this is a problem in quantum kinematics.[7]

Much progress has been achieved during the last several years on the subject of group-*quantization* and non-Abelian quantum kinematics as used in this paper.[8] Here we shall follow a new group-theoretic approach to quantum kinematics which is quite consistent with the formalism of unitary symmetries used in ordinary quantum mechanics.[9] The new formalism, however, is enhanced by quantizing the parameters of the group (cf. below). In this way, quantum kinematics appears as a self-contained theory which can yield interesting models evolving on the arena of the group manifold. These abstract models can be projected on the configuration states of a physical system (on which the quantized group acts as a symmetry group), and thus a quantal model of the system arises (for details, see Ref. 8). Quantum kinematic theory yields a self-contained formalism of quantum mechanics, for it relinquished the use of ''prequantized'' classical analogs, and everything stems from the assumed symmetry group. Therefore, quantum kinematic models become

a)Electronic mail: jkrause@chopin.fis.puc.cl

 © 1998 American Institute of Physics

interesting in themselves if the quantized group is a physically relevant symmetry group.[10,11]

The analysis of rotational symmetry, and the behavior of physical quantities under rotations, is one of the most common problems in the study of the symmetries of physical systems. In addition, the theory of angular momentum is the prototype of continuous symmetry groups of many types now found useful in the classification of the internal symmetries of elementary particle physics. So it was an important contribution of Wigner[12] to note that SU(2) is the group that enters quantum physics. Of course, the main consequences of this fact are well known and have been studied in the literature for a long time.[13] Nevertheless, some SU(2) quantal features will be considered here under the wide perspective offered by quantum kinematics. In fact, the main point dealt with in this paper is to obtain *generalized Heisenberg commutation relations* for *angular-momenta* and *rotation-angle* operators. (As far as we know, all the fundamental commutation relations presented in this paper are new.) To this end, we use the Euler–Rodrigues parameters[13] for describing the elements of the group, we then introduce the regular representation and we quantize SU(2) on the group manifold. This means that we replace the rotation-angle and the rotation-axis parameters (which are *c*-numbers that label the elements of the group) by a complete set of commuting Hermitian operators, acting as *generalized* position operators of the group manifold, which admit the parameters for spectra. In this approach, the generators of the representation afford the *generalized* momentum operators (i.e., angular momenta) of the model.[4] [The angular momenta and rotation variables mentioned here need not be taken literally, but may be understood in a wide sense. However, it will do just as well if the intuitive example of SO(3), acting in ordinary space, is kept in mind.] As we shall see, according to this formalism one is in a position to introduce a generalized SU(2) Weyl–Heisenberg algebra, and one obtains three quantum-kinematic invariant operators;[14] i.e., superselection rules follow, which reduce the model.

We wish to emphasize that this paper has only an introductory character, since the quantum kinematic theory of SU(2) discussed in the space allotted here is by no means complete. Given the relevance of this group, the endeavor of SU(2) quantum kinematics is so conspicuous, that each of its main features deserves a separate study by itself. Physical applications of SU(2) quantum kinematic theory are many. [Some applications will be given in some forthcoming papers. (For more comments, cf. Sec. IV, below.)] For instance, in the current literature (concerning ordinary rotations in quantum mechanics) the Euler-angle parametrization is predominantly used for describing the elements of SO(3), of which SU(2) is the universal covering group. Thus, in particular, we wish to remark that the introduction of SO(3) quantum kinematics (in terms of fundamental commutation relations for Euler-angle versus angular-momentum operators) follows from the theory presented in this paper, since (of course) the Euler-angles are related with the Euler–Rodrigues parameters in a well-defined way.[13] Strictly speaking, however, this subject belongs to the applications of the present theory, and thus it will be considered elsewhere. Here we are interested exclusively in the SU(2) quantum kinematic theory, for which the discussion in terms of the Euler–Rodrigues variables is the simplest one.[13]

The plan of the paper is the following. Section II deals with group quantization. For quantizing SU(2) we use an embedding approach that describes the group manifold as the surface $\mathcal{S}_3$ of the unit sphere in $\mathcal{E}_4$, in which SU(2) appears as a subgroup of the four-dimensional group of real quaternions.[13] [With this aim, in this paper we adopt the Euler–Rodrigues parameters,[13] which are best suited to this end (cf. Appendix A).] We then deduce the associated quantum kinematic commutation relations within the left regular representation, which is the basic working frame adopted in this article. [For the sake of completeness, both (left and right) regular representations of SU(2) are briefly dealt with in Appendix B.] Section III contains an overview of quantum kinematic invariant operators, which play a central role in this theory. Thus, in Secs. II and III, our discussion will be focused on the most general kinematic features of SU(2)-quantized-group models (although we do not solve for any concrete model in the present paper). Finally, Sec. IV contains our concluding remarks and some perspectives for future work.

II. QUANTUM KINEMATIC COMMUTATION RELATIONS

We begin our work by introducing generalized position operators in the group manifold $\mathcal{S}_3$ of SU(2). Here, $\mathcal{S}_3$ denotes the three-dimensional surface of the unit sphere in four-dimensional Euclidean space $\mathcal{E}_4$, defined by $q^\mu q^\mu = 1$. The four Cartesian variables $q^\mu = (\mathbf{q}, q^4) \in \mathcal{E}_4$, when

TABLE I. Synopsis of the left regular representation formalism on $\mathcal{S}_3$, within the carrier Hilbert space $\mathcal{H}[\mathrm{SU}(2)]$. (For details, see Appendix B.)

$\langle q'\|q\rangle=\mu_0^{-}L(q)\delta^{(3)}(q'-q), \quad \oint_{\mathcal{S}_3} d\mu(q)\|q\rangle\langle q\|=I$	(I.1)
$U(q')\|q\rangle=\|g(q';q)\rangle, \quad U(q)=\oint_{\mathcal{S}_3} d\mu(q')\|g(q;q')\rangle\langle q'\|$	(I.2)
$U(q')U(q)=U[(g(q';q)], \quad U^{\dagger}(q)=U^{-1}(q)=U(\overline{q})$	(I.3)
$U(e+\delta q)=I-\frac{i}{\hbar}\,\delta q^j L_j, \quad U^{\dagger}(q)L_jU(q)=A_{jk}(q)L_k$	(I.4)
$L_j\|q\rangle=i\hbar X_j(q)\|q\rangle, \quad [L_j,L_k]=-2i\hbar\epsilon_{jk\ell}L_{\ell}$	(I.5)

restricted to $q\in\mathcal{S}_3\subset\mathcal{E}_4$, play the role of the Euler–Rodrigues parameters which label the elements of the group in a faithful way.[13] (See Appendix A for some useful details.) We then focus our attention on the regular representation,[15] since this is the paramount structure in the kinematic quantization method. [The regular representation of SU(2) is reviewed in Appendix B.]

Now, given the resolution of the identity stated in Eq. (I.1) (cf. Table I), we define a set of operators Q^{μ} by means of the following spectral integrals:

$$Q^{\mu}=\oint_{\mathcal{S}_3} d\mu(q)\|q\rangle q^{\mu}\langle q\|, \tag{2.1}$$

where $d\mu(q)$ denotes the Hurwitz invariant measure on $\mathcal{S}_3$ defined in Eq. (A17). This is elementary, but fundamental. In general, this means that in Lie group theory one can consider integrals over the group manifold, like (2.1), as a basic geometric definition of quantization. One borrows this definition from standard quantum mechanics. As we will see through the chosen example, in this way one achieves a consistent and fruitful generalized setting for quantum theory. The Q's are generalized position operators on the group manifold $\mathcal{S}_3$, since they satisfy the following demands for such qualification:

$$Q^{\mu\dagger}=Q^{\mu}, \quad [Q^{\mu},Q^{\nu}]=0, \quad Q^{\mu}\|q\rangle=q^{\mu}\|q\rangle. \tag{2.2}$$

In particular, we observe that these operators satisfy the required constraint:

$$Q^{\mu}Q^{\mu}=I. \tag{2.3}$$

So we quantize the group.

In this article we adopt the left-regular representation as the working frame for developing the theory (cf. Appendix B); namely, we here consider exclusively the left unitary group-operators $\mathrm{U}(q)$ defined in Eq. (B7). (See also Table I.)

We next show that the Q's are interesting mathematical objects. We first look for the kinematic law [under SU(2) transformations] obeyed by the position operators of the group. According to their definition, it turns out that the position operators defined in Eq. (2.1) obey the same quaternion kinematic law (A2) that characterizes the parameters of the group SU(2) on $\mathcal{S}_3$:

$$U^{\dagger}(q)Q^{\mu}U(q)=g^{\mu}(q;Q)=\sigma^{\mu}_{\nu\lambda}q^{\nu}Q^{\lambda}. \tag{2.4}$$

$U(q)$ denotes the group operators [cf. Table I, Eq. (I.2)], and the group coefficients $\sigma^{\mu}_{\nu\lambda}$ are those used in Eq. (A2). It must be borne in mind that, in the present theory, Eq. (2.4) is *not* an assumption. As a matter of fact, this analytic identity is a general result of group-theoretic quantum kinematics,[6] whose proof does not demand an explicit realization of the operators involved. One proves Eq. (2.4) in a few lines. Since one adopts the regular representation of the quantized group as the working frame of the formalism, from definition (2.1), using Eqs. (I.2a) and (I.3b) of Table I, and recalling that $d\mu(q)$ is an invariant SU(2) measure on $\mathcal{S}_3$, it follows:

$$U^{\dagger}(q)Q^{\mu}U(q) = \oint_{\mathcal{S}_3} d\mu(q')U^{\dagger}(q)|q'\rangle q'^{\mu}\langle q'|U(q)$$

$$= \oint_{\mathcal{S}_3} d\mu(q')|g(\overline{q};q')\rangle q'^{\mu}\langle g(\overline{q};q')|$$

$$= \oint_{\mathcal{S}_3} d\mu[g(q;q'')]|q''\rangle g^{\mu}(q;q'')\langle q''|$$

$$= \oint_{\mathcal{S}_3} d\mu(q'')|q''\rangle g^{\mu}(q;q'')\langle q''| = g^{\mu}(q;Q), \tag{2.5}$$

which according to (A2) is precisely Eq. (2.4). This is one of the most important results provided by the Lie group quantization technique.

If we now consider the infinitesimal transformation $U^{\dagger}(e+\delta q)Q^{\mu}U(e+\delta q)$, Eq. (I.4) (Table I) and Eq. (2.4) lead us immediately to a set of generalized Heisenberg commutation relations for the position operators on $\mathcal{S}_3$ with the non-Abelian momenta represented by the SU(2) generators. Indeed, a typical group-theoretic calculation yields the desired commutation rules, which read

$$[Q^{\mu},L_j] = i\hbar R_j^{\mu}(Q) = i\hbar\sigma_{j\nu}^{\mu}Q^{\nu} = i\hbar\begin{bmatrix} Q^4 & Q^3 & -Q^2 & -Q^1 \\ -Q^3 & Q^4 & Q^1 & -Q^2 \\ Q^2 & -Q^1 & Q^2 & -Q^3 \end{bmatrix}. \tag{2.6}$$

Here we have written L_j $(j=1,2,3)$ to denote the generators of the left regular representation [see Appendix B, Eqs. (B10) and (B11)]. The entries $R_j^{\mu}(q)$ of the right transport matrix are given in Eq. (A4.1). It is important to note that the σ-coefficients satisfy

$$\sigma_{j\nu}^{\mu}\sigma_{k\lambda}^{\nu} - \sigma_{k\nu}^{\mu}\sigma_{j\lambda}^{\nu} + 2\epsilon_{jk\ell}\sigma_{\ell\lambda}^{\mu} = 0, \tag{2.7}$$

for these imply that the commutation relations (2.6) are consistent with the Lie algebra (B11), in the sense of the Jacobi identity. Furthermore, Eq. (2.6) is also consistent with the constraint $Q^{\mu}Q^{\mu}=I$, because on $\mathcal{S}_3$ one has: $\sigma_{j\nu}^{\mu}q^{\mu}q^{\nu}=0$. (These features are not trivial at all.)

This is the point where the quantum principle begins to emerge from the traditional (i.e., classical) theory of SU(2). Notice that, since $\mu=1,2,3,4$ and $j=1,2,3$, the generalized closed commutation relations shown in Eq. (2.6) do not correspond to a quantized symplectic structure, as do the canonical commutation relations (in the traditional Heisenberg form) of ordinary quantum mechanics. In this sense, considering future applications, let us here remark that it not necessary to redefine Eq. (2.6) in order to get some more conventional 3×3 matrix forms, instead of the 3×4 matrix form obtained here, because *all* four operators Q^{μ} stand on a same footing (see, below) and satisfy the constraint $Q^{\mu}Q^{\mu}=I$. Indeed, as we have discussed in our previous work, non-Abelian quantum kinematics leads us beyond the traditional canonical quantization methods.[8] Much of what follows is a consequence of the generalized commutation relations (2.6).

We now have the kinematic model. Let us proceed to examine the Q's more closely. In general, we define functions of the commuting position operators by means of their spectral integrals:

$$F(Q) = \oint_{\mathcal{S}_3} d\mu(q)|q\rangle F(q)\langle q| \tag{2.8}$$

(see Table I). Then it is worth noting that Eq. (2.6) yields the general commutation rule

$$[F(Q),L_j] = i\hbar R_j^{\mu}(Q)F_{,\mu}(Q) = i\hbar X_j(Q)F(Q), \tag{2.9}$$

where $F_{,\mu}(q)$ is a vector field in $\mathcal{E}_4$, defined by $F_{,\mu}(q)=(\partial/\partial q^{\mu})F(q)$, and where $X_j(q)$ denotes Lie's right vector fields on $\mathcal{S}_3$ [defined in Eq. (A10)]. [Certainly, the fact that the q's are not independent variables on $\mathcal{S}_3$ does not preclude the existence of $F_{,\mu}(q)$ when $q\in\mathcal{S}_3\subset\mathcal{E}_4$. See also the discussion in Appendix A, concerning Eqs. (A11) and (A12).]

Equation (2.9) is a very useful expression. For instance, let us define the rotation axis as follows: $F^j(q)=q^j/\sin\phi=q^j/\sqrt{1-(q^4)^2}\equiv\hat{n}^j$. In quantum kinematics, the rotation axis $\hat{\mathbf{n}}$ becomes a self-adjoint operator $\hat{\mathbf{N}}$: $\hat{\mathbf{n}}\to\hat{\mathbf{N}}$. Using Eq. (2.9), we easily find the generalized commutation relations obeyed by the Cartesian components $\hat{N}^j$ of the rotation-axis-operator with the generators L_j, which read

$$[\hat{N}^j,L_k]=i\hbar[\cot\Phi(\delta^j_k-\hat{N}^j\hat{N}^k)-\epsilon_{jk\not}\hat{N}^{\not}]. \tag{2.10}$$

[In fact, one has $X_k(q)F^j(q)=\cot\phi(\delta^j_k-\hat{n}^j\hat{n}^k)-\epsilon_{jk\not}\hat{n}^{\not}$. If one defines instead $G^j(q)=q^j/\sqrt{q^kq^k}\equiv\hat{n}^j$ (say) one obtains the same result (2.10). Indeed, Eq. (2.10) does not depend on how one defines the unit vector $\hat{\mathbf{n}}$ in terms of the q's. For the operator $\cot\Phi$, see Eq. (2.12), below.] The constraint $\hat{N}^j\hat{N}^j=I$ follows, since the rotation-axis operator $\hat{\mathbf{N}}=(\hat{N}^1,\hat{N}^2,\hat{N}^3)$ is a bounded operator given by

$$\hat{\mathbf{N}}=\mu_0\oint_{\mathcal{S}_3}d\Omega(\phi,\hat{\mathbf{n}})|\phi,\hat{\mathbf{n}}\rangle\hat{\mathbf{n}}\langle\phi,\hat{\mathbf{n}}|, \tag{2.11}$$

so that $\hat{\mathbf{N}}|\phi,\hat{\mathbf{n}}\rangle=\hat{\mathbf{n}}|\phi,\hat{\mathbf{n}}\rangle$ holds. [Concerning the $(\phi,\hat{\mathbf{n}})$ notation, see Appendix B].

In the same manner, we define two bounded operators $\cos\Phi$ and $\sin\Phi$ on $\mathcal{S}_3$:

$$\cos\Phi=\mu_0\oint_{\mathcal{S}_3}d\Omega(\phi,\hat{\mathbf{n}})|\phi,\hat{\mathbf{n}}\rangle\cos\phi\langle\phi,\hat{\mathbf{n}}|, \tag{2.12a}$$

$$\sin\Phi=\mu_0\oint_{\mathcal{S}_3}d\Omega(\phi,\hat{\mathbf{n}})|\phi\cdot\hat{\mathbf{n}}\rangle\sin\phi\langle\phi,\hat{\mathbf{n}}|, \tag{2.12b}$$

which satisfy the rather natural constraint $\cos^2\Phi+\sin^2\Phi=I$ and do not cause difficulties related to periodicity. As the reader can prove, for these operators we obtain the following commutation relations with the L's:

$$[\cos\Phi,L_j]=-i\hbar\hat{N}^j\sin\Phi,\quad[\sin\Phi,L_j]=i\hbar\hat{N}^j\cos\Phi, \tag{2.13}$$

which have a very suggestive form. [See also Eq. (2.17), below.] Similar commutation relations are well known for the (trivial) case of U(1) Abelian quantum kinematics.[1,2] Indeed, from Eq. (2.13) one obtains

$$[\cos\Phi,L]=-i\hbar\sin\Phi,\quad[\sin\Phi,L]=i\hbar\cos\Phi, \tag{2.14}$$

where the Hermitian operator $L=\frac{1}{2}(\hat{\mathbf{N}}\cdot\mathbf{L}+\mathbf{L}\cdot\hat{\mathbf{N}})$ may be interpreted as the U(1) angular-momentum generator in the direction of $\hat{\mathbf{N}}$. [Compare with Ref. 1, and with the references given in Ref. 2.] Equation (2.14) is quite familiar. However, to our best knowledge, Eqs. (2.10) and (2.13) do not figure in the literature, because in order to obtain the SU(2) position operators $(\Phi,\hat{\mathbf{N}})$ one has to quantize the group.

If now one considers the Euler–Rodrigues operators, i.e.,

$$Q^j=\hat{N}^j\sin\Phi,\quad Q^4=\cos\Phi \tag{2.15}$$

(cf. Appendix A), recalling the definition of the σ-coefficients, one can use Eq. (2.6) directly to obtain other basic commutation relations. For example, in this way, the commutators

$$[\hat{N}^j\sin\Phi,L_k]=i\hbar(\delta^j_k\cos\Phi-\epsilon_{jk\not}\hat{N}^{\not}\sin\Phi), \tag{2.16}$$

follow immediately from (2.6). [Of course, these commutators are consistent with Eqs. (2.10) and (2.13).]

Of particular interest are the following commutation relations:

$$[\cos 2\Phi,J_j]=-2i\hbar\hat{N}^j\sin 2\Phi,\quad[\sin 2\Phi,J_j]=2i\hbar\hat{N}^j\cos 2\Phi, \tag{2.17}$$

where we have written $2J_j = L_j$. [The reader will have no difficulty verifying Eq. (2.17), after a short calculation.] These commutation relations are called on to play an important role in the quantum kinematic theory of proper rotations, since the operators J_j are the standard angular-momentum operators in ordinary space, and 2Φ is the SO(3) rotation-angle operator about the axis-operator $\hat{\mathbf{N}}$. [See also Eq. (A9).]

All required generalized commutation relations can be obtained in this fashion, one way or another, from Eqs. (2.6) and (2.9). We have been unable to find such generalized Heisenberg commutation relations in the extensive literature devoted to SU(2).

III. QUANTUM KINEMATIC INVARIANT OPERATORS

We next take advantage of this technique, from a very general point of view. Let us first introduce the following matrix-operator [cf. Eq. (A7)]:

$$A_{jk}(Q) = Q^{\mu} Q_{\mu} \delta_{jk} + 2Q^j Q^k - 2Q^4 \epsilon_{jk\ell} Q^{\ell}, \tag{3.1}$$

which will be referred to as the antiadjoint operator. Since $U^{\dagger}(q)F(Q)U(q) = F[g(q;Q)]$ holds in general, from the discussion presented in Appendix A we conclude that the antiadjoint operator obeys the kinematic law given by the unitary transformation

$$U^{\dagger}(q)\overline{A}_{jk}(Q)U(q) = \overline{A}_{j\ell}(Q)\overline{A}_{\ell k}(q). \tag{3.2}$$

Hence a closed algebra follows immediately:

$$[\overline{A}_{jk}(Q), L_{\ell}] = -2i\hbar \epsilon_{k\ell m}\overline{A}_{jm}(Q). \tag{3.3}$$

Equation (3.3), together with the Lie algebra (B11) and the fact $[\overline{A}_{jk}(Q), \overline{A}_{\ell m}(Q)] = 0$, define the generalized Weyl–Heisenberg algebra of SU(2) quantum kinematics, which is analogous to the Weyl–Heisenberg algebra of the canonical commutation relations of ordinary quantum mechanics. This algebra is interesting, because it produces new invariant operators of the theory, as we shall see presently.

The main reason for introducing the antiadjoint operator of a Lie group, in general, is that it allows the definition of the following operators:[14]

$$\begin{aligned} R_j(Q;L) &= \overline{A}_{jk}(Q)L_k \\ &= (\cos^2\Phi - \sin^2\Phi)L_j + 2\sin^2\Phi \hat{N}^j \hat{N}^k L_k + 2\cos\Phi \sin\Phi \epsilon_{jk\ell}\hat{N}^k L_{\ell}, \end{aligned} \tag{3.4}$$

for which Eq. (3.2) together with (B12) imply the SU(2) invariant property:

$$U^{\dagger}(q)R_j(Q;L)U(q) = R_j(Q;L). \tag{3.5}$$

Thus one has

$$[R_j(Q;L), L_k] = 0, \tag{3.6}$$

for $j,k = 1,2,3$. Moreover, a rather lengthy but straightforward calculation, using the antiadjoint representation, yields $X_k(q)\overline{A}_{jk}(q) = 0$, which means that the invariant operators defined in (3.4) are Hermitian: $R_j^{\dagger}(Q;L) = R_j(Q;L)$, notwithstanding the fact that the Q's and the L's do not commute. Hence, in the kinematic theory of SU(2), besides the familiar Casimir operator $\mathbf{L}^2$, the group acquires three basic Hermitian invariant operators: R_1, R_2, R_3, which stem from the group-quantization procedure.[16]

Furthermore, using well-known properties of the adjoint representation, one proves that the basic invariant operators (3.4) satisfy the right SU(2) Lie algebra:

$$[R_j(Q;L), R_k(Q;L)] = 2i\hbar \epsilon_{jk\ell} R_{\ell}(Q;L) \tag{3.7}$$

TABLE II. Synopsis of the right regular representation formalism on $\mathcal{S}_3$, within the carrier Hilbert space $\mathcal{H}[\mathrm{SU}(2)]$.

$\langle q'\|q\rangle=\mu_0^{-1}R(q)\delta^{3)}(q'-q), \quad \oint_{\mathcal{S}_3} d\mu(q)\|q\rangle\langle q\|=I$	(II.1)
$V(q')\|q\rangle=\|g(q;q')\rangle, \quad V(q)=\oint_{\mathcal{S}_3} d\mu(q')\|g(q';q)\rangle\langle q'\|$	(II.2)
$V(q')V(q)=V[g(q;q')], \quad V^{\dagger}(q)=V^{-1}(q)=V(\overline{q})$	(II.3)
$V(e+\delta q)=I-\frac{i}{\hbar}\delta q^j R_j, \quad V^{\dagger}(q)R_jV(q)=\overline{A}_{jk}(q)R_k$	(II.4)
$R_j\|q\rangle=i\hbar Y_j(q)\|q\rangle, \quad [R_j,R_k]=2i\hbar\epsilon_{jk\not}R_{\not}$	(II.5)

[see Table II, Eq. (II.5)]. For the Casimir operator one has $\mathbf{L}^2=\mathbf{R}^2$. Therefore, we identify the operators $R_j(Q;L)$ as the generators of the right regular representation acting as invariant operators within the left representation of the group.[14] [See also, Eq. (A15).]

To end up this brief study, we consider the following commutation rules:

$$[F(Q),R_j]=i\hbar L_j^{\mu}(Q)F_{,\mu}(Q)=i\hbar Y_j(Q)F(Q), \tag{3.8}$$

where $Y_j(q)$ denotes Lie's left vector fields on $\mathcal{S}_3$ [defined in Eq. (A10)]. These rules yield, for instance,

$$[N^j \sin\Phi,R_k]=i\hbar(\delta_k^j\cos\Phi+\epsilon_{jk\not}N^{\not}\sin\Phi), \tag{3.9}$$

$$[\cos\Phi,R_j]=-i\hbar N^j\sin\Phi, \quad [\sin\Phi,R_j]=i\hbar N_j\cos\Phi. \tag{3.10}$$

Indeed, the kinematic calculus of generalized Heisenberg commutation relations for SU(2) can be applied easily to the kinematic invariant operators.

We here omit the calculations leading to these results. It is important to note, however, that one does not arrive at these results if one does not quantize the group.

IV. CONCLUDING REMARKS AND PERSPECTIVES

In our opinion, the quantum-kinematic operator calculus obtained in this paper bears a great potential value for physics, in general, because it stems from a standard procedure for handling symmetries in quantum theory. In our previous work, a group-quantization program has been developed for the case of noncompact non-Abelian Lie groups (cf. Ref. 8 and references quoted therein). The attained formalism has been applied to some models for which the Schrödinger equation, as well as the corresponding propagation kernel, have been deduced on a strict group-theoretic fashion.[10,11,17,18] It is rather clear, however, that further progress in quantum kinematics requires the consideration of symmetries described by compact Lie groups.

In particular, SU(2) symmetry must be examined upon this new perspective, as we have done in this introductory paper. Quantization of this fundamental symmetry is needed, for instance, for the development of the quantum kinematic theory of the complete Kepler group (recently introduced in the literature[19]), of the Poincaré group and the Galileo group in four-dimensional space–time, and of many other relevant Lie groups which contain SU(2) as a proper subgroup. Work is in progress concerning a companion paper to the present one, devoted to the quantum kinematic theory of the three-dimensional isotropic harmonic oscillator, in which SU(2) quantum kinematics (as introduced here) plays a central role. In fact, the piece of work presented in this paper is ripe for many physical applications.

In light of the previous results, the first point we want to note is that several uncertainty correlations (of the mean-square deviations between rotation observables and angular momentum), which appear in quantum kinematics, are worthy of a detailed study in every application of SU(2) in quantum theory. Maybe there are problems in which new physical predictions can be found by considering SU(2) quantum kinematic models in this sense.

We also have to remark that SU(2) quantum kinematics is quite different from the quantum theory of rotation angles of Barnett and Pegg.[20] As we have shown, the group-quantization approach goes much further into the very roots of the problem set by angle observables in quantum mechanics, than any other attempt considered previously.

We are now in position to use a maximal set of superselection rule operators, as given for instance by $\{\mathbf{R}^2, R_3\}$, in order to obtain full reduction (i.e., maximal diagonalization) of the regular representation. In other words, we can diagonalize the incoherent Hilbert space $\mathcal{H}[\mathrm{SU}(2)]$ into invariant subspaces $\mathcal{H}_{JM}[\mathrm{SU}(2)]$, each carrying an irreducible representation of the group, which corresponds to a SU(2) elementary system.[21] To this end, one must search for a complete orthogonal basis $\{|JMN\rangle\}$ within the left regular representation, associated with the complete set of commuting operators $\{\mathbf{R}^2, R_3, L_3\}$. That is, one looks for vectors satisfying the basic conditions

$$\langle JMN|J'M'N'\rangle = \delta_{JJ'}\delta_{MM'}\delta_{NN'}, \tag{4.1.1}$$

$$\sum_{J=0}^{\infty}\sum_{M=-J}^{J}\sum_{N=-J}^{J}|JMN\rangle\langle JMN| = I, \tag{4.1.2}$$

where the multiplets $|JMN\rangle$ are solutions to the following system of simultaneous eigenvalue equations:

$$\mathbf{R}^2|JMN\rangle = \hbar^2 J(J+2)|JMN\rangle. \tag{4.2.1}$$

$$R_3|JMN\rangle = \hbar M|JMN\rangle, \tag{4.2.2}$$

$$L_3|JMN\rangle = \hbar N|JMN\rangle. \tag{4.2.3}$$

Here: $J = 0,1,2,...$ and $M, N = -J, -J+2, ..., J-2, J$. This problem will be examined in a forthcoming paper.

Here we wish to remark only that, if one considers SU(2) [i.e., the universal covering group of SO(3)] acting as an external symmetry group of a system, then Eqs. (4.2.1) and (4.2.2) define automatically an isotopic angular momentum problem for that system, because both $\mathbf{R}^2$ and R_3 are invariant operators of SU(2). (N is not a good quantum number because L_3 is not an invariant operator.) This result is peculiar to quantum kinematics. It is a very reassuring feature, for it means that quantum kinematics brings into the fore an isotopic structure as a necessary theoretical construct, in a rather natural way indeed.

ACKNOWLEDGMENTS

This paper is devoted to the memory of Professor Lawrence C. Biedenharn, whose wise criticism and encouragement prompted much of the thoughts behind this work. The author acknowledges the referee for many remarks that have improved the presentation of this paper. This research was partially supported by FONDECYT, through Grant No. 1960256.

APPENDIX A: THE REAL-QUATERNION GROUP

It is well known that there is a one-to-one relation between points on the three-dimensional surface $\mathcal{S}_3$ (of the unit sphere in four-dimensional Euclidean space $\mathcal{E}_4$) and elements of SU(2): $\mathcal{S}_3 \ni q \leftrightarrow u(q) \in \mathrm{SU}(2)$, which is preserved by the group law;[13] briefly, the group manifold of SU(2) is the unit spherical surface $\mathcal{S}_3$. Since this is the basic framework adopted in this paper, a compact geometric notation for handling SU(2) on $\mathcal{S}_3$ will be introduced in this appendix, which is a very useful tool for quantum kinematics.

For simplicity and definiteness we label the group elements by means of the Euler–Rodrigues parameters:[13] $\mathbf{q} = \hat{\mathbf{n}} \sin\phi$ and $q^4 = \cos\phi$, with $0 \leqslant \phi \leqslant \pi$ and $\hat{\mathbf{n}}\cdot\hat{\mathbf{n}} = 1$. Thus we write the 2×2 matrices

$$u(q) = u(\mathbf{q}, q^4) = q^4\sigma_4 + iq^k\sigma_k = e^{i\phi\hat{\mathbf{n}}\cdot\sigma} \in \mathrm{SU}(2), \tag{A1}$$

which meaning is clear. One obtains the group law for SU(2) from the so-called quaternionic composition rule,[13] which can be written in a compact manner as follows:

$$q''^{\mu}=g^{\mu}(q';q)=\sigma^{\mu}_{\nu\lambda}q'^{\nu}q^{\lambda}. \tag{A2}$$

One defines the group coefficients $\sigma^{\mu}_{\nu\lambda}$ using well-known properties of the Pauli matrices. Thus one sets: $\sigma^{j}_{k\not4}=-\epsilon_{jk\not4}$, $\sigma^{\mu}_{4\nu}=\sigma^{\mu}_{\nu4}=\delta^{\mu}_{\nu}$, and $\sigma^{4}_{\mu\nu}=\eta_{\mu\nu}$, where the matrix $\eta_{\mu\nu}=\mathrm{diag}(---+)$ denotes the Minkowski metric. Using this notation, the inversion law for the Euler–Rodrigues parameters reads $\overline{q^{\mu}}=\eta_{\mu}=\eta_{\mu\nu}q^{\nu}$, since the identity point is at the ''north pole;'' i.e., $e^{\mu}=\delta^{\mu}_{4}=(0,0,0,1)\in\mathcal{S}_3$.

Useful relations obeyed by the group-coefficients follow from the group property. Especially, we note a remarkable feature of the quaternionic composition law:

$$q''^{\mu}q''^{\mu}=(q'^{\nu}q'^{\nu})(q^{\lambda}q^{\lambda}), \tag{A3}$$

from which the implication $(q';q)\in\mathcal{S}_3\times\mathcal{S}_3\Rightarrow q''\in\mathcal{S}_3$ follows. The Euler–Rodrigues variables are not essential parameters of the group, to be sure, for they do not correspond to independent variables. They are faithful parameters, however, because $q=(\mathbf{q},q^4)=(\hat{\mathbf{n}}\sin\phi,\cos\phi)$ covers the whole group manifold $\mathcal{S}_3$ in a strictly one-to-one way. [So we see that there is indeed a one-to-one relation between points on $\mathcal{S}_3$ and elements of SU(2), which is preserved by the group law.]

By means of the same group-coefficients $\sigma^{\mu}_{\nu\lambda}$ one defines another four-dimensional Lie group in $\mathcal{E}_4$. With this aim, all one needs to modify is the inversion law of the parameters, to read $\overline{q^{\mu}}=\rho^{-2}\eta_{\mu\nu}q^{\nu}$, where $\rho=\sqrt{q^{\mu}q^{\mu}}$, and one identifies the points $\overline{0}=\infty$ and $\overline{\infty}=0$. This group is the real-quaternion group;[13] we denote it by $\Sigma(4)$. The noncompact group $\Sigma(4)$ is isomorphic to $\mathcal{R}_x\otimes\mathrm{SU}(2)$, has the whole Euclidean space $\mathcal{E}_4$ for group manifold, and corresponds to the analytic continuation of SU(2) along the radius $0<p<\infty$. In fact, in this construct, SU(2) appears simply as that subgroup which arises from restricting the action of the quaternion group $\Sigma(4)$ to the locus $\mathcal{S}_3\subset\mathcal{E}_4$.

Since $\Sigma(4)$ is a noncompact (connected and simply connected) Lie group, right and left transport matrices are defined in the usual manner: $R^{\mu}_{\nu}(q)=\lim_{q'\to e}(\partial/\partial q'^{\nu})g^{\mu}(q';q)$ and $L^{\mu}_{\nu}(q)=\lim_{q'\to e}(\partial/\partial q'^{\nu})g^{\mu}(q;q')$, respectively. Expressions for these transport matrices in $\mathcal{E}_4$ are then obtained as follows:

$$R^{\mu}_{\nu}(q)=\sigma^{\mu}_{\nu\lambda}q^{\lambda}=\begin{bmatrix}\delta^{k}_{j}q^4+\epsilon_{jk\not4}q^{\not4} & -q^{j}\\ q^{k} & q^4\end{bmatrix}, \tag{A4.1}$$

$$L^{\mu}_{\nu}(q)=\sigma^{\mu}_{\lambda\nu}q^{\lambda}=\begin{bmatrix}\delta^{k}_{j}q^4-\epsilon_{jk\not4}q^{\not4} & -q^{j}\\ q^{k} & q^4\end{bmatrix}. \tag{A4.2}$$

By the same token, one gets the corresponding inverse transport matrices of $\Sigma(4)$, which are given by $\rho^{-2}\overline{R^{\mu}_{\nu}}(q)$ and $\rho^{-2}\overline{L^{\mu}_{\nu}}(q)$, where

$$\overline{R^{\mu}_{\nu}}(q)=\sigma^{\mu}_{\nu\lambda}\overline{q^{\lambda}}=\begin{bmatrix}\delta^{k}_{j}q^4-\epsilon_{jk\not4}q^{\not4} & q^{j}\\ -q^{k} & q^4\end{bmatrix}, \tag{A5.1}$$

$$\overline{L^{\mu}_{\nu}}(q)=\sigma^{\mu}_{\lambda\nu}\overline{q^{\lambda}}=\begin{bmatrix}\delta^{k}_{j}q^4+\epsilon_{jk\not4}q^{\not4} & q^{j}\\ -q^{k} & q^4\end{bmatrix}. \tag{A5.2}$$

[Here, the superscripts (μ) label the columns, and the subscripts (ν) label the rows.] One checks these matrices against the required property: $R^{\lambda}_{\mu}(q)\overline{R^{\nu}_{\lambda}}(q)=L^{\lambda}_{\mu}(q)\overline{L^{\nu}_{\lambda}}(q)=\rho^2\delta^{\nu}_{\mu}$, for all $q\in\mathcal{E}_4$. Also $R(q)=\det[R^{\mu}_{\nu}(q)]=L(q)=\det[L^{\mu}_{\nu}(q)]=(q^{\mu}q^{\mu})^2=\rho^4$ can be shown rather easily. Moreover, a detailed analysis shows that, if $q\in\mathcal{S}_3$, these matrices transport vectors which are tangent to $\mathcal{S}_3$ into tangent vectors to $\mathcal{S}_3$. Therefore, fixing $q^{\mu}q^{\mu}=1$, Eqs. (A4) and (A5) yield precisely the transport matrices of SU(2) on $\mathcal{S}_3$.

The transport matrices are affine connections on the group manifold. Furthermore, for the noncompact Lie group $\Sigma(4)$ it follows that the mixed transport matrix given by $\rho^{-2}R^{\lambda}_{\nu}(q)L^{\mu}_{\lambda}(q)$ carries the *adjoint representation* of the group.[14] Hence, in the present instance, using Eqs. (A4.1) and (A5.2), for the action of SU(2) on $\mathcal{S}_3$ we get

$$A^{\mu}_{\nu}(q)=\begin{bmatrix} A_{jk}(q) & 0 \\ 0 & 1 \end{bmatrix}. \tag{A6}$$

The 3×3 matrix $A_{jk}(q)$ in Eq. (A6), has entries given by

$$A_{jk}(q)=q^{\mu}q_{\mu}\delta_{jk}+2q^{j}q^{k}+2q^{4}\epsilon_{jk\ell}q^{\ell}, \tag{A7}$$

and carries the adjoint representation of SU(2). In fact, one easily finds

$$u^{\dagger}(q)\sigma_{j}u(q)=A_{jk}(q)\sigma_{k}, \tag{A8}$$

and therefore the A's satisfy the group law $A_{j\ell}(q')A_{\ell k}(q)=A_{jk}[g(q';q)]$. We can further analyze this construct recalling that proper rotations in ordinary space $\mathcal{E}_3$ are characterized by an angle of rotation $\vartheta(0\leqslant\vartheta\leqslant 2\pi)$ about an axis of rotation $\hat{\mathbf{n}}(\hat{\mathbf{n}}\cdot\hat{\mathbf{n}}=1)$, and are represented by the group SO(3) of real orthogonal matrices of the form:

$$R_{jk}(\vartheta,\hat{\mathbf{n}})=\delta_{jk}\cos\vartheta+\hat{n}^{j}\hat{n}^{k}(1-\cos\vartheta)+\epsilon_{jk\ell}\hat{n}^{\ell}\sin\vartheta. \tag{A9}$$

One identifies $2\phi=\vartheta$ and one obtains: $A_{jk}(q)=R_{jk}(\vartheta,\hat{\mathbf{n}})\in \mathrm{SO}(3)$. Also, defining $\mathbf{x}=x^{k}\sigma_{k}$, the unitary transformation $\mathbf{x}'=u^{\dagger}(q)\mathbf{x}u(q)$ yields $x'^{j}=x^{k}R_{jk}(\vartheta,\hat{\mathbf{n}})$. Hence, the double covering of SU(2) onto SO(3) becomes manifest. (These things are, of course, well known.[13])

We next define right and left vector fields for $\Sigma(4)$ in $\mathcal{E}_4$ by means of the transport matrices, as usual: $X_{\mu}(q)=R^{\nu}_{\mu}(q)\partial_{\nu}=\sigma^{\nu}_{\mu\lambda}q^{\lambda}\partial_{\nu}$, and $Y_{\mu}(q)=L^{\nu}_{\mu}(q)\partial_{\nu}=\sigma^{\nu}_{\lambda\mu}q^{\lambda}\partial_{\nu}$. Writing them more explicitly, one sees that these operators correspond to SU(2) right and left generators acting on $\mathcal{S}_3$, which in the Euler–Rodrigues parametrization read:

$$X_{j}(q)=q^{4}\partial_{j}-q^{j}\partial_{4}-\epsilon_{jk\ell}q^{k}\partial_{\ell},\quad Y_{j}(q)=q^{4}\partial_{j}-q^{j}\partial_{4}+\epsilon_{jk\ell}q^{k}\partial_{\ell}, \tag{A10}$$

respectively, as well as to the dilation generator of $\Sigma(4)$ acting along the radius ρ in $\mathcal{E}_4$, which is given by $X_4(q)=Y_4(q)=q^{\mu}\partial_{\mu}=\rho(\partial/\partial\rho)$.

Using (θ,φ,ϕ) as the independent variables of the SU(2) theory [where $\hat{\mathbf{n}}$ is a unit 3-vector corresponding to $\hat{\mathbf{n}}=(\theta,\varphi)$], given any function $\psi(q)$ defined on $\mathcal{S}_3$, the displacement $q\rightarrow(q+dq)\in\mathcal{S}_3$ produces the differential

$$d\psi(q)=\frac{\partial\psi}{\partial q^{j}}\sin\phi d\hat{n}^{j}+\left(\frac{\partial\psi}{\partial q^{j}}\hat{n}^{j}\cos\phi-\frac{\partial\psi}{\partial q^{4}}\sin\phi\right)d\phi, \tag{A11}$$

with $d\hat{n}^{j}=(\partial\hat{n}^{j}/\partial\theta)d\theta+(\partial\hat{n}^{j}/\partial\varphi)d\varphi$. On the other hand, defining $\delta q^{\mu}_{R}=\overline{R^{\mu}_{\nu}}(q)dq^{\nu}$, a straightforward calculation shows that $d\psi(q)=\delta q^{j}_{R}X_{j}(q)\psi(q)$ is given by

$$d\psi(q)=\delta\phi\hat{n}^{j}_{R}\left(\cos\phi\frac{\partial\psi}{\partial q^{j}}-\sin\phi\hat{n}^{j}\frac{\partial\psi}{\partial q^{4}}-\sin\phi\epsilon_{jk\ell}\hat{n}^{k}\frac{\partial\psi}{\partial q^{\ell}}\right). \tag{A12}$$

Hence, consistency demands: $d\phi\hat{n}^{j}=\delta\phi\hat{n}^{j}_{R}$ and $d\hat{n}^{j}=\delta\phi\epsilon_{jk\ell}\hat{n}^{k}\hat{n}^{\ell}_{R}$ [which follow from the transport formula $dq^{\mu}=R^{\mu}_{\nu}(q)\delta q^{\nu}_{R}$], as the reader can prove in a few lines. Furthermore, one also proves that $X_4(q)\psi(q)=0$ follows if $q\in\mathcal{S}_3$. (We left this as an exercise for the reader.) In this fashion we conclude that the action of the four operators [either $X_{\mu}(q)$ or $Y_{\mu}(q)$], on functions $\psi(q)$ defined on the three-dimensional surface $\mathcal{S}_3$, is consistent with the three degrees of freedom of the group SU(2).

As operators in $\mathcal{E}_4$, the generators of $\Sigma(4)$ satisfy the following Lie algebra:

$$[X_{j}(q),X_{k}(q)]=2\epsilon_{jk\ell}X_{\ell}(q),\quad [Y_{j}(q),Y_{k}(q)]=-2\epsilon_{jk\ell}Y_{\ell}(q), \tag{A13}$$

$$[X_j(q),X_4(q)]=0, \quad [Y_j(q),Y_4(q)]=0, \tag{A14}$$

and moreover

$$[X_\mu(q),Y_\nu(q)]=0. \tag{A15}$$

Equation (A13) corresponds to the (right and left) realizations of the SU(2) Lie algebra, whereas Eq. (A14) assures a consistent result (for our purposes here). Equation (A15) is of fundamental importance in quantum kinematics [i.e., see Eq. (3.6)].

Finally, since $\Sigma(4)$ is a noncompact Lie group, an invariant measure in $\mathcal{E}_4$ follows immediately:

$$d\mu(q)=\mu_0\rho^{-4}\, dq^1\, dq^2\, dq^3\, dq^4=\mu_0\,\frac{\sin\,\theta\,\sin^2\,\phi}{\rho}\, d\rho\, d\theta\, d\varphi\, d\phi=\mu_0\,\frac{d\rho}{\rho}\, d\Omega(\phi,\hat{\mathbf{n}}), \tag{A16}$$

where μ_0 denotes an arbitrary normalization constant and $d\Omega(\phi,\hat{\mathbf{n}})$ is the element of solid angle in $\mathcal{E}_4$. The direct-product structure of the quaternion group $\Sigma(4)\sim\mathcal{R}\times\otimes\mathrm{SU}(2)$ means that (if we fix $\rho=1$) we obtain an invariant measure on $\mathcal{S}_3$ as well, which is given by

$$d\mu(q)=\mu_0\,\sin\,\theta\,\sin^2\,\phi\, d\theta\, d\varphi\, d\phi=\mu_0\, d\Omega(\phi,\hat{\mathbf{n}}). \tag{A17}$$

This well-known measure is indeed (right and left) SU(2)-invariant.

APPENDIX B: SU(2) REGULAR REPRESENTATION REVISITED

We here append a brief description of the regular representation of SU(2) as it follows from the embedding scheme $\mathcal{S}_3\subset\mathcal{E}_4$ presented in Appendix A. Henceforth we use a shorthand notation for handling the Euler–Rodrigues parameters $q=(\mathbf{q},q^4)$ in terms of the angle parameters $(\phi,\hat{\mathbf{n}})$. Thus we set: $q=(\hat{\mathbf{n}}\,\sin\,\phi,\cos\,\phi)\equiv(\phi,\hat{\mathbf{n}})\in\mathcal{S}_3$.

As one knows, the regular representation[15] of SU(2) is carried by functions $\psi(q)=\psi(\phi,\hat{\mathbf{n}})$, which have a finite norm with respect to the invariant measure on $\mathcal{S}_3$ defined in Eq. (A17):

$$\langle\psi|\psi\rangle=\mu_0\oint_{\mathcal{S}_3} d\Omega(\phi,\hat{\mathbf{n}})|\psi(\phi,\hat{\mathbf{n}})|^2<\infty. \tag{B1}$$

To proceed, one introduces a Hilbert space $\mathcal{H}[\mathrm{SU}(2)]$ such that $|\psi\rangle\in\mathcal{H}[\mathrm{SU}(2)]\Leftrightarrow\langle\psi|\psi\rangle<\infty$. In order to have a one-to-one mapping between wave functions $\psi(q)$ and vectors $|\psi\rangle$, one considers the associated rigged Hilbert space $\tilde{\mathcal{H}}[\mathrm{SU}(2)]$, which is spanned by continuous basic vectors $|q\rangle$ satisfying the one-to-one correspondence $\mathcal{S}_3\ni q\leftrightarrow|q\rangle\in\tilde{\mathcal{H}}[\mathrm{SU}(2)]$. The basic vectors obey the orthogonal relation:

$$\langle\phi',\hat{\mathbf{n}}'|\phi,\hat{\mathbf{n}}\rangle=\mu_0^{-1}\,\frac{\delta(\phi'-\phi)\,\delta(\theta'-\theta)\,\delta(\varphi'-\varphi)}{\sin^2\,\phi\,\sin\,\theta}, \tag{B2}$$

and yield the following resolution of the identity:

$$\mu_0\oint_{\mathcal{S}_3} d\Omega(\phi,\hat{\mathbf{n}})|\phi,\hat{\mathbf{n}}\rangle\langle\phi,\hat{\mathbf{n}}|=I. \tag{B3}$$

Wave functions are then defined on the group manifold in the usual manner; namely, one writes $\psi(q)=\langle q|\psi\rangle\equiv\psi(\phi,\hat{\mathbf{n}})=\langle\phi,\hat{\mathbf{n}}|\psi\rangle$, whenever $|\psi\rangle\in\mathcal{H}[\mathrm{SU}(2)]$ and $q=(\phi,\hat{\mathbf{n}})\in\mathcal{S}_3$.

Using this notation, the quaternion group law (A2) can be cast in terms of the angle variables $(\phi,\hat{\mathbf{n}})$. In fact, (A2) corresponds to the well-known combination formulas:[13]

$$\hat{\mathbf{n}}''\,\sin\,\phi''=\hat{\mathbf{n}}'\,\sin\,\phi'\,\cos\,\phi+\hat{\mathbf{n}}\,\sin\,\phi\,\cos\,\phi'-\hat{\mathbf{n}}\times\hat{\mathbf{n}}\,\sin\,\phi'\,\sin\,\phi, \tag{B4a}$$

$$\cos\,\phi''=\cos\,\phi'\,\cos\,\phi-\hat{\mathbf{n}}\cdot\hat{\mathbf{n}}\,\sin\,\phi'\,\sin\,\phi. \tag{B4b}$$

At times it is useful to write this law in a compact symbolic way:

$$(\phi'',\hat{\mathbf{n}}'')=(\phi',\hat{\mathbf{n}}')\circ(\phi,\hat{\mathbf{n}}). \tag{B5}$$

For instance, if we consider a point $q=(\phi,\hat{\mathbf{n}})\in\mathcal{S}_3$ which is left-transported by means of $e+\delta q'=(\delta\phi,\hat{\mathbf{n}}')\in\mathcal{S}_3$, Eq. (B4) allows us to express Lie's left-differentials as follows:

$$\delta_L(\hat{\mathbf{n}}\sin\phi)=\delta\phi(\hat{\mathbf{n}}'\cos\phi-\hat{\mathbf{n}}'\times\hat{\mathbf{n}}\sin\phi),\quad \delta_L(\cos\phi)=-\delta\phi\hat{\mathbf{n}}'\cdot\hat{\mathbf{n}}\sin\phi, \tag{B6}$$

where $\hat{\mathbf{n}}''\sin\phi''=\hat{\mathbf{n}}\sin\phi+\delta_L(\hat{\mathbf{n}}\sin\phi)$ and $\cos\phi''=\cos\phi+\delta_L(\cos\phi)$ give us the angle coordinates of the image point, i.e., $(\phi'',\hat{\mathbf{n}})=(\delta\phi,\hat{\mathbf{n}}')\circ(\phi,\hat{\mathbf{n}})$.

A sensible definition of the unitary group-operators $U(q)\equiv U(\phi,\hat{\mathbf{n}})$, of the left regular representation, can then be given in the following manner:

$$U(\phi,\hat{\mathbf{n}})=e^{-(i/\hbar)\phi\hat{\mathbf{n}}\cdot\mathbf{L}}=\mu_0\int_0^{\pi}\mathbf{d}\phi'\ \sin^2\phi'\oint_{\mathcal{S}_2}d\Omega(\hat{\mathbf{n}}')|(\phi,\hat{\mathbf{n}})\circ(\phi',\hat{\mathbf{n}}')\rangle\langle\phi',\hat{\mathbf{n}}'|. \tag{B7}$$

$\mathbf{L}$ denotes the generators of this representation: $\mathbf{L}=(L_1,L_2,L_3)$. In fact, a straightforward calculation yields the unitary representation property obeyed by these operators:

$$U(\phi',\hat{\mathbf{n}}')U(\phi,\hat{\mathbf{n}})=U[(\phi',\hat{\mathbf{n}}')\circ(\phi,\hat{\mathbf{n}})],\quad U^{\dagger}(\phi,\hat{\mathbf{n}})=U^{-1}(\phi,\hat{\mathbf{n}}), \tag{B8}$$

as well as

$$U(\phi',\hat{\mathbf{n}}')|\phi,\hat{\mathbf{n}}\rangle=|(\phi',\hat{\mathbf{n}}')\circ(\phi,\hat{\mathbf{n}})\rangle, \tag{B9}$$

As we see, the operators (B7) realize the left regular representation of SU(2) on $\mathcal{S}_3$. The infinitesimal operators are given by $U(\delta\phi,\hat{\mathbf{n}})=I-(i/\hbar)\delta\phi\hat{\mathbf{n}}\cdot\mathbf{L}$. Therefore, using Eq. (A10), we obtain

$$L_j|\phi,\hat{\mathbf{n}}\rangle=i\hbar X_j(q)|q\rangle=i\hbar(\cos\phi\partial_j-\sin\phi\hat{n}^j\partial_4-\sin\phi\epsilon_{jk\ell}\hat{n}^k\partial_{\ell})|\phi,\hat{\mathbf{n}}\rangle, \tag{B10}$$

for $q=(\phi,\hat{\mathbf{n}})\in\mathcal{S}_3$, as consistency demands. This expression yields the familiar Lie Algebra in terms of the left-regular representation's generators [cf., Eq. (A13)]:

$$[L_j,L_k]=-2i\hbar\epsilon_{jk\ell}L_{\ell}. \tag{B11}$$

[Notice that the generators L_j equal twice the standard physical operators of angular momentum J_j. See, for instance, Eq. (2.17). The reader can change to the conventional scale if he likes.]

Within the left regular representation, the adjoint representation is obtained from $U^{\dagger}(\phi,\hat{\mathbf{n}})U(\delta\phi,\hat{\mathbf{n}}')U(\phi,\hat{\mathbf{n}})$. This yields [see Eq. (A7)]

$$U^{\dagger}(\phi,\hat{\mathbf{n}})L_jU(\phi,\hat{\mathbf{n}})=[(\cos^2\phi-\sin^2\phi)\delta_{jk}+2\sin^2\phi\hat{n}^j\hat{n}^k+2\cos\phi\sin\phi\epsilon_{jk\ell}\hat{n}^{\ell}]L_k \tag{B12}$$

[which leads also to the Lie Algebra (B11)].

To end up this brief revision, let us finally observe that $X_4(q)\psi^*(q)=\langle\psi|X_4(q)|q\rangle=0$ holds for all $|\psi>\in\mathcal{H}[\mathrm{SU}(2)]$ and $q\in\mathcal{S}_3$. So we have

$$q\in\mathcal{S}_3\Rightarrow X_4(q)|q\rangle=0. \tag{B13}$$

In fact, the dilation operator $X_4(q)=Y_4(q)$ is the sole generator of the embedding quaternion group $\Sigma(4)$ not represented in SU(2) quantum kinematics.

Table I summarizes these features. One introduces the right regular representation of SU(2) in a similar manner, defining appropriate group-operators $V(q)$, which act ''from the right'' in the following sense $V(q')|q\rangle=|g(q;q')\rangle$. For the sake of completeness, Table II presents a synoptic setting of the right regular representation. Let us here recall that in the left quantum kinematic formalism, as considered in this article, the right generators R_j presented in Table II play an important role, because they correspond to the basic invariant operators of the theory (cf., Sec. III).

(Received 9 February 1998; accepted for publication 9 June 1998)

Quantum mechanical models and practical calculations often rely on some exactly solvable models like the Coulomb and the harmonic oscillator potentials. The *D* dimensional generalized Coulomb potential contains these potentials as limiting cases, thus it establishes a continuous link between the Coulomb and harmonic oscillator potentials in various dimensions. We present results which are necessary for the utilization of this potential as a model and practical reference problem for quantum mechanical calculations. We define a Hilbert space basis, the generalized Coulomb–Sturmian basis, and calculate the Green's operator on this basis and also present an SU(1,1) algebra associated with it. We formulate the problem for the one-dimensional case, too, and point out that the complications arising due to the singularity of the one-dimensional Coulomb problem can be avoided with the use of the generalized Coulomb potential. © *1998 American Institute of Physics.* [S0022-2488(98)02311-1]

I. INTRODUCTION

Local potentials have been used to model the interactions of the subatomic world ever since the introduction of quantum mechanics. Some of these (like the Coulomb potential) do not differ essentially from the forces observed in nature, while most of them (like the harmonic oscillator, for example) represent approximations of the actual physical situation. The potential shape, defined by the potential type and the parameters in it, is usually chosen in a way that reflects the physical picture our intuition associates with the problem; therefore we can define attractive or repulsive, short-range or long-range potentials, etc.

Some of the potentials used in quantum mechanics are exactly solvable. This means that the energy eigenvalues, the bound-state wave functions and the scattering matrix can be determined in closed analytical form. The range of these potentials has been extended considerably in the recent years by investigations inspired by supersymmetric quantum mechanics (SUSYQM), for example. (See Ref. 1 for recent reviews.) Most of the solvable potentials are one-dimensional problems, which means that they are defined on the $(-\infty,\infty)$ domain (or on some finite interval of it), or they can be reduced to radial problems in higher spatial dimensions, in which case they are confined to the positive real axis. The simplest exactly solvable potentials are those belonging to the so-called shape-invariant class.[2] Many of the most well-known potentials, like the Coulomb, harmonic oscillator, Morse, Pöschl–Teller, etc. potentials, belong to this class. Usually 12 potentials are mentioned to have the property of shape-invariance,[3] although two of them are just alternative forms of other shape-invariant potentials.

A rather more general potential type is that of the Natanzon potentials,[4] the solutions of which can be reduced to a single hypergeometric or confluent hypergeometric function. These potentials are written as complicated six-parameter expressions of the coordinate, and their energy eigenvalues are given by an implicit formula. Although these problems are solvable exactly in principle, only some specific Natanzon potentials have been studied in detail,[5–8] because the formalism is getting more and more complicated with the increasing number of parameters handled. Some of the Natanzon potentials contain certain shape-invariant potentials as special cases: the Ginocchio potential[6] can be considered as a generalization of the Pöschl–Teller potential, while the gener-

[b]Electronic mail: pz@indigo.atomki.hu

 © 1998 American Institute of Physics

alized Coulomb potential[8] is a simultaneous extension of the Coulomb and the harmonic oscillator potentials. There are also further potentials beyond the Natanzon class. These include, for example, quasi-exactly solvable (QES) potentials,[9] conditionally exactly solvable (CES) potentials[10] and the SUSYQM partners of Natanzon-class potentials,[11] of which certain CES potentials form a subclass.[12]

The study of exactly solvable potentials represents an interesting field of mathematical physics in itself, but results from this area are also essential for the description of realistic physical problems. More and more interactions can be modeled by taking advantage of the rather flexible potential shapes offered by exactly solvable potentials. The solutions of these can be applied directly, or they can be combined with numerical calculations. In the simplest case analytical calculations can aid numerical studies in areas where numerical techniques might not be safely controlled. This is the case, for example, when bound-state wave functions with arbitrary node numbers are required, for certain singular potentials, or for complex potentials.[13] As the next level of complexity, analytical solutions can supply a basis for numerical calculations.

Virtually all quantum mechanical methods rely in some respect on analytically solvable potentials. Very often their wave function solutions are used as a Hilbert-space basis. More powerful methods can be constructed if we select a basis which allows the exact analytical calculation of the Green's operator of an analytically solvable potential. Some time ago, by utilizing the Coulomb–Sturmian functions as basis functions, the Coulomb Green's operator was calculated analytically and a quantum mechanical approximation method was developed.[14] Recently this method was extended for approaching the really challenging three-body Coulomb problem.[15] We note here that in this work the exact analytical representation of the Coulomb Green's operator on the Coulomb–Sturmian basis was essential. In our recent work[16] we showed that if on some basis representation the Hamiltonian possesses an infinite tridiagonal matrix (J-matrix) form, then its resolvent can be given in terms of continued fractions which can be continued analytically to the whole complex plane. This theorem was exemplified by the Coulomb and harmonic oscillator Green's operators.

The aim of the present work is to demonstrate that various techniques developed for the simple shape-invariant potentials, like the Coulomb and harmonic oscillator potentials, can be generalized for certain Natanzon-class potentials, too, without making the formalism significantly more involved, and that these more general potentials can help our understanding of both practical and theoretical problems. The actual example we consider here is the generalized Coulomb potential,[8] which is the member of the Natanzon confluent potential class.[17] This potential is Coulomb-like asymptotically, while its short-range behavior depends on the parameters: it can be finite or singular as well at the origin. Its shape therefore can approximate various realistic problems, such as nuclear potentials with relatively flat central part, or atomic potentials that incorporate the effect of inner closed shells by a phenomenological repulsive core.

An advantageous feature of the generalized Coulomb problem is that the equivalent of the Coulomb–Sturmian basis can be defined for it, together with all its implications. For example, the method of calculating the matrix elements of the Green's operator as described in Ref. 16 for the Coulomb and the harmonic oscillator potentials can be extended to this case, too, so that the above two problems appear in the present treatment as special cases.

Using a particular differential realization, an SU(1,1) algebra can also be associated with this potential, which reduces to known SU(1,1) algebras in the Coulomb and harmonic oscillator limits.

Another important feature of this potential is that it can be formulated as a one-dimensional problem, but it can avoid the pathologic features of the one-dimensional Coulomb problem, which arise due to the $|x|^{-1}$-like singularity. Since this potential can be chosen to be finite at $x=0$, it offers a convenient basis for calculations which require the use of a one-dimensional Coulomb-like problem.

The arrangement of this paper is the following. In Sec. II we give the basic formalism for the generalized Coulomb problem by recapitulating and extending former results. Section III contains the main results of the paper: *(i)* the discussion of the Coulomb–oscillator connection using the two limiting cases of the potential, *(ii)* the determination of the matrix elements of the Green's operator, *(iii)* the description of an SU(1,1) algebra associated with the problem and *(iv)* discussion on the one-dimensional case, which elucidates the complications related to the singularity of the

one-dimensional Coulomb problem. Finally, we summarize the results and discuss further possibilities in Sec. IV.

II. THE GENERALIZED COULOMB POTENTIAL IN *D* DIMENSIONS

Let us consider the Schrödinger equation in D spatial dimensions with a potential that depends only on the radial variable r. Separating the angular variables from the wave function we obtain the radial Schrödinger equation

$$\hat{H}_0\psi(r)\equiv\left(-\frac{d^2}{dr^2}+\frac{1}{r^2}\left(l+\frac{D-3}{2}\right)\left(l+\frac{D-1}{2}\right)+v(r)\right)\psi(r)=\epsilon\psi(r), \tag{1}$$

where $v(r)\equiv 2m\hbar^{-2}V(r)$ and $\epsilon\equiv 2m\hbar^{-2}E$. The centrifugal term, which depends on the angular momentum l, originates from the kinetic term, i.e., from the D-dimensional Laplace operator after separating the angular variables. The bound-state wave functions solving (1) are normalized as

$$\int_0^\infty |\psi(r)|^2\,dr=1. \tag{2}$$

Here we recapitulate the results obtained for the generalized Coulomb potential in Ref. 8 by adapting it to the D-dimensional case. Changing slightly the notation used in Ref. 8 we define the generalized Coulomb potential as

$$v(r)=-\frac{1}{r^2}\left(l+\frac{D-3}{2}\right)\left(l+\frac{D-1}{2}\right)+\left(\beta-\frac{1}{2}\right)\left(\beta-\frac{3}{2}\right)\frac{C}{4h(r)(h(r)+\theta)}$$
$$-\frac{q}{h(r)+\theta}-\frac{3C}{16(h(r)+\theta)^2}+\frac{5C\theta}{16(h(r)+\theta)^3}, \tag{3}$$

where $h(r)$ is defined in terms of its inverse function

$$r=r(h)=C^{-1/2}\left[\theta\tanh^{-1}\left(\left(\frac{h}{h+\theta}\right)^{1/2}\right)+(h(h+\theta))^{1/2}\right]. \tag{4}$$

The $h(r)$ function maps the $[0,\infty)$ half-axis onto itself and can be approximated with $h(r)\simeq C^{1/2}r$ and $h(r)\simeq Cr^2/(4\theta)$ in the $r\to\infty$ and $r\to 0$ limits, respectively.

Bound states are located at

$$\epsilon_n=-\frac{C}{4}\rho_n^2, \tag{5}$$

where

$$\rho_n=\frac{2}{\theta}\left[\left((n+\beta/2)^2+\frac{q\theta}{C}\right)^{1/2}-(n+\beta/2)\right]. \tag{6}$$

The bound-state wave functions can be written in terms of associated Laguerre polynomials as

$$\psi_n(r)=C^{1/4}\rho_n^{(\beta+1)/2}\left(\frac{\Gamma(n+1)}{\Gamma(n+\beta)(2n+\beta+\rho_n\theta)}\right)^{1/2}$$
$$\times(h(r)+\theta)^{1/4}(h(r))^{(2\beta-1)/4}\exp\left(-\frac{\rho_n}{2}h(r)\right)L_n^{(\beta-1)}(\rho_n h(r)). \tag{7}$$

Potential (3) clearly carries angular momentum dependence: its first term merely compensates the centrifugal term arising from the kinetic term of the Hamiltonian. Its second term also has r^{-2}-like singularity (due to $h^{-1}(r)$), and, as it will be demonstrated later, it cancels the angular

momentum dependent term in the two important limiting cases that recover the D-dimensional Coulomb and the harmonic oscillator potentials. The third term of (3) represents an asymptotically Coulomb-like interaction, while the remaining two terms behave like r^{-2} and r^{-3} for large values of r.

In the remaining part of this section we consider the specific case of $D=3$ and $l=0$. The S matrix of the generalized Coulomb potential can be derived in complete analogy with that of the Coulomb problem for $D=3$. Although this can only be done exactly for $l=0$, the singular term imitating the centrifugal term in Eq. (3) can be defined to be part of the potential. Using the notation of Ref. 18 the equivalents of the general regular and irregular solutions are

$$\varphi^{(G)}(k,r)=C^{-\beta/4}(h(r)+\theta)^{1/4}(h(r))^{(2\beta-1)/4}\exp\left(-\frac{\rho}{2}h(r)\right)\Phi\left(\frac{\beta}{2}+i\nu,\beta;\rho h(r)\right) \tag{8}$$

and

$$f^{(G)}(k,r)=\rho^{-\beta/4}e^{\nu\pi/2}(h(r)+\theta)^{1/4}(h(r))^{(2\beta-1)/4}\exp\left(-\frac{\rho}{2}h(r)\right)\Psi\left(\frac{\beta}{2}+\mathrm{i}\nu,\beta;\rho h(r)\right), \tag{9}$$

where $\Phi(a,c;z)$ and $\Psi(a,c;z)$ are the regular and the irregular confluent hypergeometric functions,[19] and ρ and ν have to be chosen as

$$\rho\equiv\rho(k)=-\frac{2ik}{C^{1/2}},\quad i\nu\equiv i\nu(k)=\frac{\rho\theta}{4}-\frac{q}{C\rho}. \tag{10}$$

The functions (8) and (9) reduce to $\varphi^{(c)}(k,r)$ and $f^{(c)}(k,r)$ of Ref. 18 in the $\theta\to 0$ Coulomb limit. The S matrix for $l=0$ is expressed as

$$S_0(k)=(-1)^{\beta/2+1}\frac{\Gamma(\beta/2+i\nu)}{\Gamma(\beta/2-i\nu)}. \tag{11}$$

The extra phase factor appears because of the r^{-2}-type singular term, which is now defined to be part of the potential. In the Coulomb limit this expression becomes part of the centrifugal term, which is dealt with separately.

The long-range behavior of potential (3) suggests its use in problems associated with the electrostatic field of some charge distribution. The deviation from the Coulomb potential close to the origin can be viewed as replacing the pointlike charge with an extended charged object. The relevant charge density is readily obtained from the potential using

$$\rho(r)=-\frac{\hbar^2}{8\pi me}\Delta v(r). \tag{12}$$

Choosing $D=3$ and neglecting the terms singular at the origin by making the choice $l=0$ and $\beta=1/2$ or $3/2$ we get

$$\rho(r)=-\frac{\hbar^2}{8\pi me}\left[-\frac{2qC}{(h(r)+\theta)^3}+\frac{20qC\theta-9C^2}{8(h(r)+\theta)^4}+\frac{81C^2\theta}{16(h(r)+\theta)^5}-\frac{135C^2\theta^2}{32(h(r)+\theta)^6}\right.$$
$$\left.+\frac{2C^{1/2}}{r}\left(\frac{h(r)}{h(r)+\theta}\right)^{1/2}\left(\frac{q}{(h(r)+\theta)^2}+\frac{3C}{8(h(r)+\theta)^3}-\frac{15C\theta}{16(h(r)+\theta)^4}\right)\right]. \tag{13}$$

In Figs. 1 and 2 we present examples for the actual shape of potential (3) and the corresponding charge distribution (13) for various values of the parameters. It can be seen that this potential is suitable for describing the Coulomb field of extended objects. It is a general feature of potential (3) that for small values of θ a (finite) positive peak appears near the origin, which also manifests itself in a repulsive ''hard core,'' corresponding to a region with positive charge density (see Fig. 2).

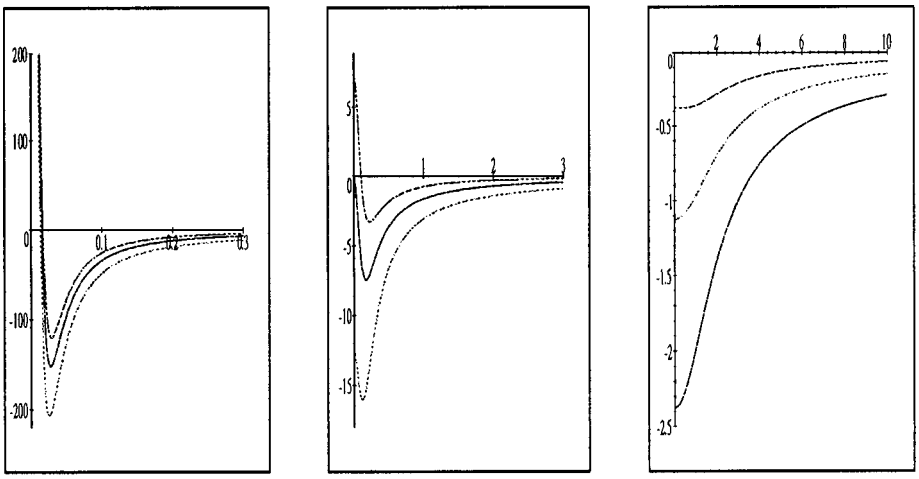

FIG. 1. The generalized Coulomb potential for $q=0.5$, 1.25, 2.5; $\theta=0.01$, 0.1, 1; $C=1$ and $\beta=3/2$. $l=0$ and $D=3$ is also implied. In each panel the largest q corresponds to the lowest curve. Note the different scales of the horizontal (r) and the vertical $(v(r))$ axes.

III. DISCUSSION

A. The Coulomb and harmonic oscillator limits

As described in Ref. 8, the introduction of the generalized Coulomb problem was inspired by a simple method of transforming the Schrödinger equation into the differential equation of the confluent hypergeometric function. The bound-state solutions of these problems contain associated Laguerre polynomials. The three most well-known examples of this type are the Coulomb, the harmonic oscillator and the Morse potentials, which are all members of the shape-invariant potential class.[2] These three potentials are recovered by specific choices of the variable transformation reducing the Schrödinger equation to the differential equation of the associated Laguerre polynomials. This is also reflected by the structure of the function $h(r)$ in Eq. (4): when $h(r)$ is proportional to r and r^2, one obtains the Coulomb problem and the harmonic oscillator potential, respectively. These limits can readily be realized by specific choices of the parameters in Eq. (4): the first one follows from the $\theta\to 0$ limit,[8] while the second one is reached by taking $\theta\to\infty$, while keeping $C/\theta\equiv\tilde{C}$ constant.[20]

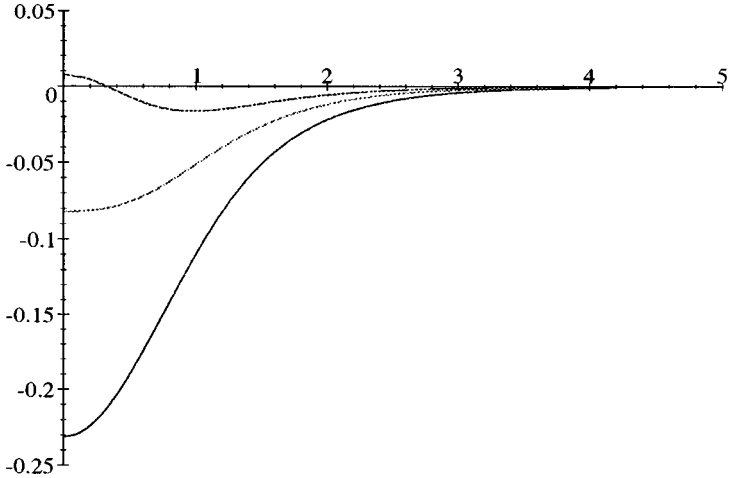

FIG. 2. The charge distributions corresponding to the potentials displayed in Fig. 1 for $\theta=1$ and $q=0.5$, 1.25, 2.5. (The largest q corresponds to the lowest curve.)

Besides taking the $\theta\to 0$ limit, the Coulomb problem in D-dimensions is recovered from Eq. (3) by the $\beta=2l+D-1$ and $C^{-1/2}q=2mZe^2/\hbar^2$ choices: the third term of (3) becomes the Coulomb term, the fifth one vanishes, while the other three all become proportional with r^{-2} and cancel out completely.

In order to reach the oscillator limit one also has to redefine the potential (3) and the energy eigenvalues by adding q/θ to both. (This is equivalent to $\tilde{C}\tilde{D}\theta$ in the notation of Ref. 20.) This choice simply represents resetting the energy scale: $\epsilon=0$ corresponds to $v(r\to\infty)$ for the Coulomb problem, and to $v(r=0)$ for the harmonic oscillator. (Note that the energy eigenvalues also have different signs in the two cases.) Besides $C/\theta=\tilde{C}$, the $\tilde{q}\equiv q/\theta^2$ parameter also has to remain constant in the $\theta\to\infty$ transition here. The potential thus adapted to the harmonic oscillator limit reads

$$\tilde{v}(r)\equiv v(r)+q\theta=-\frac{1}{r^2}\left(l+\frac{D-3}{2}\right)\left(l+\frac{D-1}{2}\right)+\left(\beta-\frac{1}{2}\right)\left(\beta-\frac{3}{2}\right)\frac{\tilde{C}}{4h(r)(1+h(r)/\theta)}$$
$$-\frac{\tilde{q}h(r)}{1+h(r)/\theta}-\frac{3\tilde{C}}{16\theta}\frac{1}{(1+h(r)/\theta)^2}+\frac{5\tilde{C}}{16\theta}\frac{1}{(1+h(r)/\theta)^3}. \tag{14}$$

The harmonic oscillator potential is recovered from (14) by the $\beta=l+D/2$ and $\tilde{C}\tilde{q}=(2m\omega/\hbar)^2$ choice. The two last terms in (14) vanish, the first and the second cancel out, while the third one reproduces the harmonic oscillator potential. The new form of the energy eigenvalues is

$$\tilde{\epsilon}_n\equiv\epsilon_n+q/\theta=\tilde{C}(2n+\beta)\left[\left(\frac{1}{\theta^2}\left(n+\frac{\beta}{2}\right)^2+\frac{\tilde{q}}{\tilde{C}}\right)^{1/2}-\frac{1}{\theta}\left(n+\frac{\beta}{2}\right)\right], \tag{15}$$

which, indeed, reduces to the $\tilde{\epsilon}_n=(2m\omega/\hbar)(2n+l+D/2)$ oscillator spectrum in the $\theta\to\infty$ limit. The wave functions (7) are unchanged, except for the redefinition of the parameters.

Note that the generalized Coulomb problem establishes a link between the Coulomb problem and the harmonic oscillator potential in different spatial dimensions. This is best seen by inspecting the wave functions (7). If the $\beta-1$ parameter of the associated Laguerre polynomial is required to be the same in the two limits, we get an interrelation between the value of the angular momentum and the spatial dimension to be used for the Coulomb and the harmonic oscillator case:

$$l^O+\frac{D^O}{2}=2l^C+D^C-1. \tag{16}$$

Considering $l^O=2l^C$, Eq. (16) implies $D^O=2D^C-2$ which establishes link between the $(D^C,D^O)=(2,2)$, (3,4), (4,6), (5,8), ..., etc. pairs. [Of these the (3,4) pair corresponds to the Kustaanheimo–Stiefel transformation.[21]] This case is called the ''direct map'' between the Coulombic and oscillator solutions in Ref. 22, while with the $l^O=2l^C+\lambda$ choice the ''general map'' can be recovered. These results suggest that the generalized Coulomb potential can be used to formulate a continuous transition between the Coulomb and harmonic oscillator potentials, as opposed to the usual procedure that employs a unique variable and parameter transformation to reach this goal.

B. The generalized Coulomb–Sturmian basis and the matrix elements of the Green's operator

The generalized Coulomb–Sturmian equation, which depends on n as a parameter, has similar structure to the eigenvalue equation in Eq. (1) with potential (3),

$$\hat{X}\phi(\rho,r)\equiv\Bigg[-\frac{d^2}{dr^2}-\frac{3C}{16(h(r)+\theta)^2}+\frac{5C\theta}{16(h(r)+\theta)^3}+\frac{C(\beta-1/2)(\beta-3/2)}{4h(r)(h(r)+\theta)}$$
$$-\left(\frac{\rho^2\theta}{4}+\rho\left(n+\frac{\beta}{2}\right)\right)\frac{C}{h(r)+\theta}+\frac{C}{4}\rho^2\Bigg]\phi(\rho,r)=0, \tag{17}$$

and is solved by the generalized Coulomb–Sturmian (GCS) functions

$$\langle r|n\rangle\equiv\phi_n(\rho,r)=\left(\frac{\Gamma(n+1)}{\Gamma(n+\beta)}\right)^{1/2}(\rho h(r)+\rho\theta)^{1/4}(\rho h(r))^{(2\beta-1)/4}$$
$$\times\exp\left(-\frac{\rho}{2}h(r)\right)L_n^{(\beta-1)}(\rho h(r)). \tag{18}$$

Here ρ is a parameter characterizing the generalized Coulomb–Sturmian basis. The GCS functions, being solutions of a Sturm–Liouville problem, have the property of being orthonormal with respect to the weight function $C^{1/2}(h(r)+\theta)^{-1}$. Introducing the notation $\langle r|\tilde{n}\rangle \equiv \phi_n(\rho,r)C^{1/2}(h(r)+\theta)^{-1}$ the orthogonality and completeness relation of the GCS functions can be expressed as

$$\langle n|\tilde{n}\rangle=\delta_{nn'} \tag{19}$$

and

$$1=\sum_{n=0}^{\infty}|\tilde{n}\rangle\langle n|=\sum_{n=0}^{\infty}|n\rangle\langle\tilde{n}|. \tag{20}$$

Straightforward calculation shows that both the overlap of two GCS functions and the $\langle n'|\hat{H}_0|n\rangle$ matrix element can be expressed as a tridiagonal matrix, therefore the matrix elements of the $\epsilon-\hat{H}_0$ operator also have this feature:

$$\langle n|\epsilon-\hat{H}_0|n'\rangle=\delta_{nn'}\left[\frac{\epsilon}{C^{1/2}\rho}(2n+\beta-\rho\theta)-\frac{C^{1/2}\rho}{4}\left(-\frac{4q}{C\rho}+(2n+\beta)\right)\right]$$
$$-\delta_{nn'+1}(n(n+\beta-1))^{1/2}\left(\frac{\epsilon}{C^{1/2}\rho}+\frac{C^{1/2}\rho}{4}\right)$$
$$-\delta_{nn'-1}((n+1)(n+\beta))^{1/2}\left(\frac{\epsilon}{C^{1/2}\rho}+\frac{C^{1/2}\rho}{4}\right). \tag{21}$$

This means that, similar to the *D*-dimensional Coulomb and harmonic oscillator potential, the matrix elements of the Green's operator can be determined by using continued fractions, as described in Ref. 16. The present results, therefore, extend the applicability of this method to a new potential problem. The formulas presented here reduce to those in Ref. 16 in the appropriate limits discussed in Sec. III A. The role of the Coulomb–Sturm parameter *b* used in Ref. 16 is now played by $C^{1/2}\rho/2$.

C. Algebraic aspects

Here we show that an SU(1,1) algebra can be associated with the generalized Coulomb problem. The generators of this algebra are

$$\hat{J}_3=\frac{h+\theta}{C\rho}\hat{X}+\left(n+\frac{\beta}{2}\right), \quad \hat{J}_1=\hat{J}_3-\frac{\rho}{2}h,$$
$$\hat{J}_2=-\frac{i}{C^{1/2}}(h(h+\theta))^{1/2}\frac{d}{dr}-\frac{i\theta}{4(h+\theta)}, \tag{22}$$

and they satisfy the commutation relations

$$[\hat{J}_1,\hat{J}_2]=-i\hat{J}_3, \quad [\hat{J}_2,\hat{J}_3]=i\hat{J}_1, \quad [\hat{J}_3,\hat{J}_1]=i\hat{J}_2. \tag{23}$$

As can be seen from Eq. (17), $\hat{J}_3$ is diagonal in the basis (18) with eigenvalues $m=n+\beta/2$. The elements of this basis can then be associated with the infinite-dimensional discrete unitary irreducible representation of SU(1,1) called[23] discrete principal series D_j^+, for which the allowed values of m are

$$m=-j,-j+1,-j+2,\ldots, \tag{24}$$

with j being negative. It is natural then to identify j as $j=-\beta/2$. Direct calculations show that the ladder operators connect the neighboring members of this basis:

$$\hat{J}_+\phi_n(\rho,r)\equiv(\hat{J}_1+i\hat{J}_2)\phi_n(\rho,r)=[(n+1)(n+\beta)]^{1/2}\phi_{n+1}(\rho,r), \tag{25}$$

$$\hat{J}_-\phi_n(\rho,r)\equiv(\hat{J}_1-i\hat{J}_2)\phi_n(\rho,r)=[n(n+\beta-1)]^{1/2}\phi_{n-1}(\rho,r). \tag{26}$$

We find that the eigenvalues of the Casimir invariant

$$\hat{C}_2=\hat{J}_3^2-\hat{J}_1^2-\hat{J}_2^2 \tag{27}$$

are $(\beta/2)(\beta/2-1)=j(j+1)$, as expected, and that they set the strength of the fourth term in (17). For $\theta\neq 0$ this is the only singular term and it behaves like γr^{-2} with $\gamma=(\beta-\frac{1}{2})(\beta-\frac{3}{2})=4j(j+1)+\frac{3}{4}$. It is interesting to inspect the allowed values of γ for the different unitary irreducible representations of SU(1,1). For the discrete principal series D_j^+ $\beta>1$ holds, which always secures $-\frac{1}{4}<\gamma$, i.e., the potential has repulsive or ''weakly attractive''[24] r^{-2}-type singularity. For the supplementary series[23] $-\frac{1}{2}<j<0$ holds, which results in $-\frac{1}{4}<\gamma<\frac{3}{4}$. This is exactly the domain where both independent solutions are square integrable at the origin:[24] for $0<\gamma<\frac{3}{4}$ one of these vanishes at $r=0$ and the other one is infinite there, while for $-\frac{1}{4}<\gamma<0$ both solutions vanish at $r=0$. From (18) it is seen that solutions regular and irregular at the origin correspond to $\beta>\frac{1}{2}$ and $\beta<\frac{1}{2}$. This seems to indicate that one regular solution (with $\beta>1$) is associated with D_j^+, while the second square integrable solution, which is either regular or infinite at the origin (depending on β), might be related to the supplementary series, for which $0<\beta<1$ holds. For the sake of completeness we note that for the continuous series[23] C_k^0 and $C_k^{1/2}$, $j=-\frac{1}{2}+ik$ ($k>0$, real) is valid, which results in the strongly singular $\gamma<-\frac{1}{4}$ case. The solutions then oscillate infinitely near the origin and are unbounded from below,[24] which can be interpreted as the falling of the particle into the center of attraction.[25] The situation is similar to that described in Ref. 26 for the $v(x)=\gamma\sin^{-2}x$ potential: the various unitary irreducible representations of the SU(1,1) spectrum generating group there also corresponded to different types of singularities.

We note that we analyzed the singularities of the generalized Coulomb–Sturmian equation (17) and its solutions (18), but similar considerations of the physical potential (3) and its solutions can also be performed taking $D=3$ and $l=0$. The algebraic construction, however, does not apply to this latter problem. This is because the bound-state solutions (7) pick up extra n-dependence through ρ_n, which is not accessible for the ladder operators otherwise changing n as in Eqs. (25) and (26).

The present realization of the SU(1,1) algebra is a special case of that described in Ref. 17 in relation with the Natanzon confluent potentials. Considering the Coulomb and harmonic oscillator limits discussed in Sec. III A and setting the dimension to $D=3$, the generators reduce to the forms presented for the two problems separately in Ref. 27. We note that the spectrum generating

algebra associated this way with the radial harmonic oscillator problem in three dimensions is different from the two-parameter realization of the SU(1,1) algebra discussed in Refs. 28 and 29, because the ladder operators there are linear differential operators and the Hamiltonian is related to the Casimir invariant, while here the ladder operators are second-order differential operators and the Hamiltonian is essentially a linear function of generator $\hat{J}_3$.

Finally, we note that similar limiting cases of other Natanzon-class potentials can also be treated in terms of SU(1,1) algebras. In Ref. 29 an SU(1,1) algebra associated with the Ginocchio potential[5] was analyzed, and it was shown that in two different limiting cases, which both result in the Pöschl–Teller potential, two different algebras can be recovered from the original one: the first being a spectrum generating algebra and the second a potential algebra.

D. The one-dimensional case

The formalism developed previously is valid for $D=1$, too; nevertheless, some particular properties of one-dimensional problems justify a separate treatment of this case. First, the implicit definition of the $h(r)$ function in Eq. (4) has to be extended to negative values of r, which we now denote with x. Using the notation of (4), we can write that $x=r(h)$ for $x\geqslant 0$ and $x=-r(h)$ for $x<0$. The normalization of the wave functions in (7) also has to be modified with a factor of $2^{-1/2}$, accounting for the fact that the integration now runs from $-\infty$ to ∞, but since the potential is symmetric, the bound-state wave functions are either even or odd, therefore $|\psi(x)|^2$ is an even function of x.

For one-dimensional problems it is natural to set l to 0 besides $D=1$, which eliminates the centrifugal term in (3). Furthermore, in order to avoid r^{-2}-like singularities at $x=0$, the second term in (3) also has to be canceled by setting β to either $\frac{1}{2}$ or to $\frac{3}{2}$. Elementary calculations show that the latter choice corresponds to bound-state wave functions that vanish at $x=0$, and essentially represent physical solutions of the problem in higher dimensions as well, while the former choice recovers solutions that do not vanish in general at $x=0$. These two possibilities can naturally be interpreted as odd and even solutions of the one-dimensional potential problem. Furthermore, for $x\geqslant 0$ the two types of wave functions can be rewritten into a common notation (up to a sign) by making use of the relation of associated Laguerre and Hermite polynomials, when the former ones have $\alpha=\frac{1}{2}$ or $\alpha=-\frac{1}{2}$ as parameters:[30]

$$\psi_N^{(D=1)}(x)=C^{1/4}\tilde{\rho}_N^{3/4}2^{-N}\left(\Gamma\left(\frac{N+1}{2}\right)\Gamma\left(\frac{N}{2}+1\right)\left(N+\frac{1}{2}+\theta\tilde{\rho}_N\right)\right)^{-1/2}$$
$$\times(h(x)+\theta)^{1/4}\exp\left(-\frac{\tilde{\rho}_N}{2}h(x)\right)H_N((\tilde{\rho}_N h(x))^{1/2}). \tag{28}$$

For $x\leqslant 0$ the bound-state wave functions satisfy

$$\psi_N^{(D=1)}(-x)=\begin{cases}\psi_N^{(D=1)}(x) & \text{for } N=2n;(\beta=\frac{1}{2}),\\ -\psi_N^{(D=1)}(x) & \text{for } N=2n+1;(\beta=\frac{3}{2}).\end{cases} \tag{29}$$

In (28) we defined $\tilde{\rho}_N$ as

$$\tilde{\rho}_N\equiv\frac{1}{\theta}\left[\left((N+1/2)^2+4\frac{q\theta}{C}\right)^{1/2}-\left(N+1/2\right)\right], \tag{30}$$

which reduces to $\rho_{[N/2]}$, where even and odd values of N have to be chosen with $\beta=\frac{1}{2}$ and $\beta=\frac{3}{2}$, respectively, and the integer part of $N/2$ corresponds to n used in ρ_n in Eq. (6).

An interesting aspect of this potential is that it remains finite at $x=0$ $(v(0)=-q/\theta+C/(8\theta^2))$ for any finite value of θ; however, a narrow, finite peak appears in the $\theta\to 0$ limit, which then becomes an attractive $-3/(16r^2)$-like singularity in the Coulomb limit. This is due to the fourth term in (3) and it corresponds to a ''weak'' singularity in the sense that the center of attraction is not strong enough for the particle to become infinitely bound.[25] This finite barrier

arising for small, but finite θ values also introduces the possibility of studying tunneling effects in symmetric potential wells. We also note that besides being finite at $x=0$, potential (3) has continuous derivative there, as can directly be verified.

Based on these features the $D=1$ version of potential (3) can be used to analyze the peculiarities of the one-dimensional Coulomb potential defined as $v^{(c)}=-e^2/|x|$. This problem has been the subject of intensive studies in the past couple of decades, but there is still some controversy in the interpretation of the results (see, e.g., Ref. 31 for a recent review). The unusual features attributed to this singular problem include degenerate eigenvalues[32] interpreted in terms of a hidden O(2) symmetry,[33] an infinitely bound ground state[32] and continuous bound-state spectrum.[34] The last two of these were later found to be based on unacceptable solutions of the Schrödinger equation,[35,36] while the unexpected degeneracy was explained by an impenetrable barrier at $x=0$, which separates the problem into two disjoint, noncommunicating systems with identical energy spectra[36] and makes even the concept of parity obsolete here.[37] Most authors discussing the one-dimensional Coulomb problem agree that the usual techniques of quantum mechanics alone in dealing with potentials are not sufficient in this case. In Ref. 38, for example, self-adjoint extension of the relevant differential operator has been discussed.

The one-dimensional version of potential (3) can be chosen such that it becomes close to nonsingular potentials used in the approximation of the true one-dimensional Coulomb potential. In fact, with appropriate choice of q and θ, any desired Coulomb asymptotics and $v(x=0)$ value can be generated. Figure 1 shows potentials with rounded-off shape near $x=0$ ($\theta=1$, $q=0.5$) and also ones close to the Coulomb potential with a cutoff $-e^2/(|x|+a)$ ($\theta=1$, $q=2.5$). In contrast with these modified Coulomb potentials, all calculations can be performed exactly with (3). In the $\theta\to 0$ limit the generalized Coulomb potential recovers the one-dimensional Coulomb potential supplemented with the $-\frac{3}{16}x^{-2}$ term. This means that the one-dimensional Coulomb potential cannot be reached exactly, nevertheless, reasonable approximations of it can be given, as it will be demonstrated below.

The odd solutions, of course, vanish at $x=0$, while the even solutions have nonzero value there as long as $\theta>0$ holds. In the $\theta\to 0$ limit $\psi^{(D=1)}_{N=2n}(0)$ varies with $\theta^{1/4}$, so the even solutions also tend to zero at $x=0$. This is in accordance with the discussion in Sec. III C on weakly attractive γr^{-2}-type singular potentials on the half line: for $-\frac{1}{4}<\gamma<0$ both independent solutions vanish at the origin, so the wave functions are necessarily zero at $r=0$. If we try to extend the $N=2n$ solutions (28) in the $\theta=0$ Coulomb limit to the $(-\infty,0)$ domain, we find that, due to its $x^{1/4}$-type behavior at the origin, the derivative of an even wave function would not be continuous anymore.

It is also interesting to compare the Coulomb limit of the one-dimensional generalized Coulomb potential with the true one-dimensional Coulomb potential. Switching off gradually the γr^{-2} term we find that the two types of solutions contain confluent hypergeometric functions of the type $\Phi(-n,c;z)$ with $c=1+(1+4\gamma)^{1/2}$ and $c=1-(1+4\gamma)^{1/2}$. Starting with $\gamma=-\frac{3}{16}$ we recover the $c=\frac{3}{2}$ and $\frac{1}{2}$ corresponding to the two $c=\beta$ values assigned to the allowed solutions of the one-dimensional generalized Coulomb potential and its Coulomb limit. Taking the $\gamma\to 0$ limit results in $c=2$ and $c=0$. The first one of these corresponds to the allowed solutions of the one-dimensional Coulomb potential (see, e.g., Ref. 39), while the latter one has to be rejected, because the confluent hypergeometric function $\Phi(a,c;z)$ is not defined for $c=0$. This shows that even solutions which are allowed for the generalized Coulomb potential in one dimension do not have equivalents in the true one-dimensional Coulomb case.

We also note that the true one-dimensional Coulomb potential can be reached in the $\theta\to 0$ limit, setting β to 2 from the beginning. In this case, however, a repulsive $3/(16r^2)$-type singularity appears, which cancels out only for $\theta=0$. This repulsive singularity then separates the problem into two parts (with $x>0$ and $x<0$) from the beginning, so the potential is not a real one-dimensional one. The $\beta=0$ choice, in principle, also gives the same potential; however, the solutions associated with $\beta=0$ are not defined, as we have shown previously. Using $\beta=\varepsilon$ or $2-\varepsilon$ with ε being small we can get as close to the true one-dimensional Coulomb potential as we wish, but the repulsive singularity is then present for all θ values.

The reflection and transmission coefficients can be analyzed using the asymptotic behavior of the general solutions of the one-dimensional problem. These can be chosen to be even and odd functions of x. Making use of Eq. (8) the even and the odd solutions can be defined for $x\geqslant 0$ in

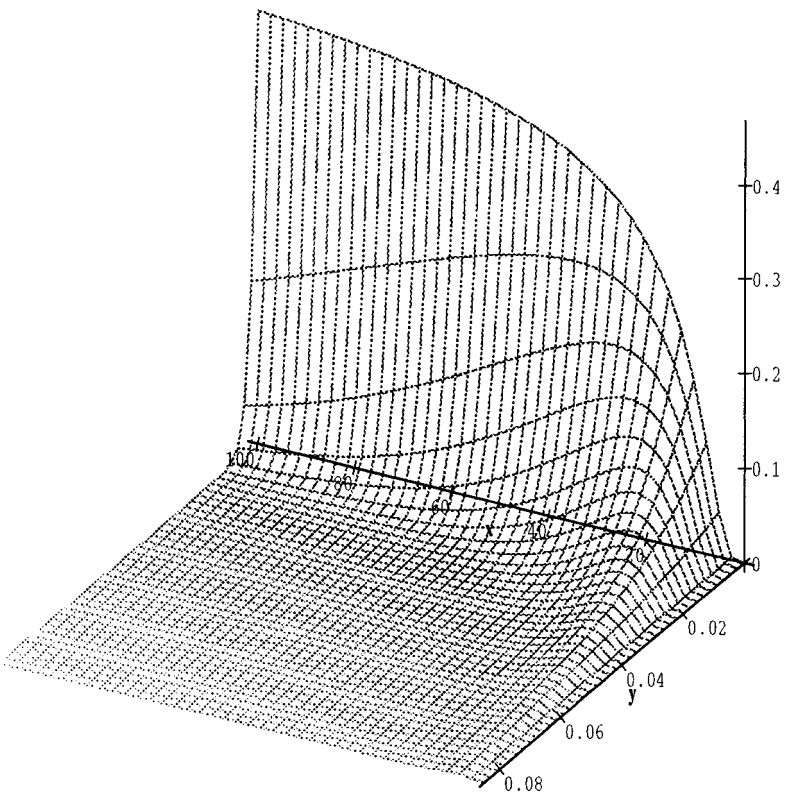

FIG. 3. $|R(k)|^2$ plotted as a function of θ. The notation $x=k$ and $y=\theta$ is used. For technical reasons the plot is made only from $\theta=10^{-5}$ instead of 0.

terms of $\varphi^{(G)}(k,x)$ for $x\geqslant 0$, setting $\beta=\frac{1}{2}$ and $\frac{3}{2}$, respectively; and their extension to $x\leqslant 0$ can be given using a formula similar to Eq. (29). The two solutions are interrelated by Eq. 6.3(3) of Ref. 19. Due to the symmetric nature of the one-dimensional potential $(v(x)=v(-x))$, it is enough to analyze the asymptotic behavior of the solutions for $x\to\infty$: the $x\to-\infty$ case follows naturally. Straightforward calculations show that the reflection coefficient is

$$R(k)=\frac{e^{-i\pi/4}}{2}\left(\frac{\Gamma(\frac{1}{4}+i\nu)}{\Gamma(\frac{1}{4}-i\nu)}-i\frac{\Gamma(\frac{3}{4}+i\nu)}{\Gamma(\frac{3}{4}-i\nu)}\right). \tag{31}$$

Strong reflection is found for potentials having a (finite) barrier in $x=0$ (like those in Fig. 1 with $\theta=0.01$), while more regular shapes (like that in Fig. 1 with $\theta=1$ and $q=2.5$, for example) give weak reflection. The k corresponding to maximal reflection increases as θ gets closer to 0 (i.e., as the barrier at $x=0$ gets higher). $|R(k)|$ is small for very large and very small values of k. Figure 3 presents illustration for $|R(k)|^2$ for various values of θ. Our findings on the reflection coefficient of the one-dimensional generalized Coulomb potential seem to support the existence of the space splitting effect[37] valid for the Coulomb potential on one dimension: in situations close to the true Coulomb case (e.g., $\theta\to 0$) $|R(k)|^2$ is close to 1, which corresponds to a nearly impenetrable barrier at $x=0$. This is also confirmed by our analysis on other approximations of the one-dimensional Coulomb potential, i.e., those with $\beta=\varepsilon$ or $2-\varepsilon$ above.

Besides its mathematical aspects the one-dimensional Coulomb potential has physical relevance, too, in the description of the hydrogen atom in strong magnetic field,[40] for example. In such practical calculations it is reasonable to use a nonsingular Coulomb-like potential instead of the true one-dimensional Coulomb potential: the finite size of the nucleus can be a justification for this. This means that the one-dimensional Coulomb potential might not be sufficient in such calculations: the basis defined with it simply does not contain even-parity states. In practical calculations, therefore, the use of bases like that assigned to the generalized Coulomb potential is necessary.

IV. SUMMARY AND OUTLOOK

We analyzed the generalized Coulomb potential and extended results for the D-dimensional Coulomb and harmonic oscillator potentials to this potential, too, which includes these two simple problems as special cases. The results presented here have both theoretical and practical significance. The theoretical aspects concern the treatment of Coulomb-like problems in one dimension. Due to the singular nature of the one-dimensional Coulomb potential, the usual methods of defining a physically relevant basis are not sufficient in this case. The generalized Coulomb potential avoids these complications and it supplies a basis (including both even and odd functions) which can be used instead of the Coulomb–Sturmian basis, which is otherwise a rather helpful tool in higher dimensions, e.g., the three-body Coulomb problem has been approached this way.[15] We also gave a unification of the SU(1,1) algebras associated with the Coulomb and harmonic oscillator problems separately.

The practical aspects of our work include the introduction of the generalized Coulomb–Sturmian basis, which we used as a basis for analytic representation of the Green's operator. The generalized Coulomb potential (being the member of the rather general Natanzon potential class) offers potential shapes that can approximate various physical problems more accurately than the conventional textbook potentials. In particular, its long-range Coulomb-like behavior makes it a good candidate for describing the Coulomb field of extended (non-point-like) charge distributions. It can be applied either directly, or as a basis for numerical calculations. Its direct applications can be envisaged in describing muonic atoms, where it can model the Coulomb field of the nucleus. It can also be combined with short-range potentials in the potential separable expansion formalism,[14,15] for example. Then the Coulombic asymptotics of the interaction between the strongly interacting charged objects could be taken care of by the Green's operator and only the short-range (nuclear) interaction would have to be approximated.

Similar extensions of other relatively simple (shape-invariant) potentials also seem possible. The example of the generalized Coulomb potential shows that the techniques developed for these well-known potentials can be extended to more general potentials without much technical difficulty. The generalized potentials ''inherit'' many important features of the simple potentials, of which they are extensions, and, at the same time, they can be adapted to more complex physical situations, due to their more flexible shape. There are other examples confirming the expectations that seemingly complicated formulas can be evaluated analytically even for highly nontrivial potentials. In Ref. 41, for example, potentials phase equivalent with the Ginocchio potential[6] have been determined analytically, using the transformations of supersymmetric quantum mechanics.

Based on the present results we believe that the Natanzon-class potentials, which have been analyzed almost exclusively in theoretical studies until now, can be used in practical applications too.

(Received 9 February 1998; accepted for publication 8 July 1998)

Two distinct Skyrme terms for the $\mathbb{C}P^1$ model are defined, only one of which preserves the equivalence with the corresponding O(3) model. A gauging prescription in which the composite connection of the $\mathbb{C}P^1$ model is replaced by the U(1) gauge connection is defined. A U(1) gauged $\mathbb{C}P^1$ model and two distinct U(1) gauged $\mathbb{C}P^1$ models with Skyrme terms are defined. The existence of topologically stable vortices in each of the three U(1) gauged models is proved analytically. © *1998 American Institute of Physics.* [S0022-2488(98)02211-7]

I. INTRODUCTION

Abelian gauge theories in $2+1$ dimensions which support topologically stable vortex solutions have proved to be useful models in various areas of theoretical physics; for example, the Abelian Higgs model[1] has been employed in superconductivity and cosmology. More recently, Abelian gauge theories in which the matter field is either $\mathbb{C}P^1$ valued or S^2 (two-sphere) valued, instead of the complex Higgs field of the Abelian Higgs model, have been introduced.[2,3] These are the various two dimensional gauged sigma models, which describe the static vortices of the corresponding $2+1$ dimensional theories. The study of certain Maxwell gauged sigma models in two dimensions is the purpose of this work.

While there are some qualitative and quantitative differences between these U(1) gauged sigma models and the well known Abelian Higgs model, we will not concentrate on this interesting area of comparisons here. We suffice to mention the most obvious of these differences, namely that in the limit of the gauge field decoupling the soliton of the gauged sigma model persists, while the soliton of the Abelian Higgs model collapses.

The two dimensional sigma models under consideration are the $\mathbb{C}P^1$ and the O(3) models. There are *two* distinct U(1) gauging prescriptions for these models.

The *first* gauging prescription[2] involves replacing the composite Abelian connection[4] which is defined in terms of the $\mathbb{C}P^1$ valued field, with the U(1) gauge connection. Using this prescription the ungauged $\mathbb{C}P^1$ models and the O(3) models [obtained from the well known equivalence (4) given below, of the $\mathbb{C}P^1$ valued and the S^2 valued fields] can be gauged. These include both the scale invariant $\mathbb{C}P^1$ model,[4] and the $\mathbb{C}P^1$ model with Skyrme terms. This is the gauging prescription that will be employed in the present work.

The *second* gauging prescription,[3] which applies to the O(3) models only, involves the gauging of an SO(2) subgroup of the global SO(3) group under which these models are invariant. These include both the scale invariant $\mathbb{C}P^1$ model,[4] and the $\mathbb{C}P^1$ model with Skyrme terms.

The most important difference between the two gauging prescriptions is that in the *first* case,[2] the solutions of the resultant gauged models do not saturate the topological lower bound, while in the *second* case,[3] there are gauged models in which the Bogomol'nyi equations support nontrivial

solutions. In the case of the $\mathbb{C}P^1$ or O(3) sigma models being gauged according to the *first* prescription, the Bogomol'nyi equations are overdetermined,[5] and as a consequence they have only trivial solitons. We do not give details of the demonstration here since that is given already in Section II of Ref. 5. Inasfar as the existence of self-dual solutions saturating the topological lower bound is concerned, the *second* gauging prescription is mathematically more interesting.

It is nevertheless worthwhile to investigate both the models with and without and Skyrme terms arising from the *first* gauging prescription because they are, in principle, just as relevant to physical applications as the models arising from the second gauging prescription, and in some ways even more interesting physically. Indeed the $\mathbb{C}P^1$ models gauged according to the first[2] prescription, which do not support self-dual solutions, have a distinctive physical quality contrasting with the O(3) model gauged according to the second prescription.[3] This concerns the dual properties of spontaneous symmetry breaking and quantized magnetic flux which are absent in the O(3) models (with or without Skyrme terms) gauged according to the *second* prescription,[3] and which is present in the gauged $\mathbb{C}P^1$ models or their equivalent O(3) models gauged according to the *first* prescription.[2] We can easily see this by noticing that the asymptotic (vacuum) value of the S^2 valued field ϕ^a is $\phi_0^a=(0,0,1)$, which completely preserves the local SO(2) symmetry acting on its first two components, leading to no symmetry breaking. By contrast, the local Abelian U(1) symmetry acts on both of the two components of the $\mathbb{C}P^1$ valued field z^α, with vacuum configuration $z_0^\alpha=(e^{-in\theta},0)$. Hence the symmetry in the latter case is broken and the U(1) gauge field receives a mass proportional to $z^\dagger z=1$. In this sense, the first gauging prescription[2] gives rise to models which have a physically richer particle spectrum. Concerning the arbitrary values of the magnetic flux in the models of the *second* type, this is a consequence of the conditions for the finiteness of energy, yielding topologically significant boundary conditions.

In this paper we employ the *first* gauging prescription, namely that used in Ref. 2, in which the composite connection

$$B_i=iz^\dagger\partial_i z=iz_\alpha^*\partial_i z^\alpha \tag{1}$$

is replaced by a dynamical (independent) U(1) connection. The $\mathbb{C}P^1$ valued field z^α, $\alpha=1,2$ is subject to the constraint $z^\dagger z=z_\alpha^* z^\alpha=1$, and the covariant derivative defined in terms of the composite connection B_i is

$$D_i^{(B)}z=\partial_i z+iB_i z. \tag{2}$$

In Sec. II we introduce the action densities, or in the context of soliton physics the static Hamiltonian densities, and subject them to radial symmetry. In Sec. II A we present the $\mathbb{C}P_1$ models, in their ungauged forms, and then in Sec. II B we give the corresponding gauged models. In Sec. II C we subject the static Hamiltonian densities to radial symmetry. In Sec. III, we give the existence proofs for the vortices in each of these models.

II. THE MODELS

After presenting the ungauged $\mathbb{C}P^1$ models, we will gauge these with a U(1) gauge field described by Maxwell dynamics according to the *first* gauging prescription described above. Then we will impose radial symmetry.

It is equally possible to consider the U(1) gauging with a Chern–Simons (CS) rather than a Maxwell term, as for example in Refs. 6 and 2. There will be no need to do this, however, since the static Hamiltonian density pertaining to the CS-$\mathbb{C}P^1$ model turns out to be identical with the corresponding quantity for the Maxwell–$\mathbb{C}P^1$ model. Hence the corresponding proof given in Sec. III holds for both these systems. It is interesting to note that this coincidence occurs only for the U(1) gauged $\mathbb{C}P^1$ model [or the equivalent O(3) model] subject to the *first* gauging prescription. By contrast, when one employs CS dynamics to gauge the Abelian Higgs model,[7] or to gauge the O(3) model[8,9,5] applying the *second* prescription, one finds that the static Hamiltonian densities of the CS gauged models are quite different from the corresponding quantities of the Maxwell gauged models.[1,3]

A. The ungauged models

In terms of the covariant derivative (2), the action density of the $\mathbb{C}P^1$ model is defined as

$$\mathscr{L}^{(z)} = D_i^{(B)} z^\dagger D_i^{(B)} z = D_i^{(B)} z_\alpha^* D_i^{(B)} z^\alpha. \tag{3}$$

Clearly the system (3) exhibits a local U(1) symmetry given by the composite gauge connection (1).

Since there is a natural isomorphism between the two symmetric coset spaces $\mathbb{C}P^1$ and S^2, the S^2 valued field ϕ^a, $a=1,2,3$, subject to the constraint $|\phi^a|^2=1$ can be expressed in terms of the Pauli matrices σ^a as follows:

$$\phi^a = z^\dagger \sigma^a z = z_\alpha^* (\sigma^a)^\alpha{}_\beta z^\beta. \tag{4}$$

The action density of the O(3) sigma model is defined as

$$\mathscr{L}^{(\phi)} = |\partial_i \phi^a|^2, \tag{5}$$

which can be shown to be equal to the action density (3) of the $\mathbb{C}P^1$ model by substituting (4) in (5). Formally, we have

$$\mathscr{L}^{(\phi)} = 4\mathscr{L}^{(z)}. \tag{6}$$

This equivalence between the densities of the $\mathbb{C}P^1$ model and the O(3) model does not persist when Skyrme (kinetic) terms are introduced.

The Skyrme term of the O(3) sigma model[10] is $|\partial_{[i}\phi^a \partial_{j]}\phi^b|^2$ and it can be expressed in terms of the covariant derivatives (2) and using (4) as follows,

$$|\partial_{[i}\phi^a \partial_{j]}\phi^b|^2 = 2((|\partial_i \phi^a|^2)^2 - |\partial_{(i}\phi^a \partial_{j)}\phi^a|^2) = 2(4|D_i^{(B)} z^\dagger D_i^{(B)} z|^2 - |D_{(i}^{(B)} z^\dagger D_{j)}^{(B)} z|^2, \tag{7}$$

where the $a_{(i}b_{j)}$ denotes the *symmetrization* of the indices i and j, and $a_{[i}b_{j]}$ denotes *antisymmetrization*.

The Skyrme term of the $\mathbb{C}P^1$ sigma model can be chosen in *two* different ways. In the first case, one simply defines the Skyrme term of the $\mathbb{C}P^1$ sigma model to be the Skyrme term (7) of the O(3) model, and so the equivalence of the O(3) model with Skyrme term and $\mathbb{C}P^1$ model with Skyrme term is maintained.

In the second case, a Skyrme term subject to the usual criteria is defined. These criteria are that a kinetic term should feature only the second power of the velocity fields and, in the present case, exhibit the local U(1) gauge invariance characterized by the composite connection B_i in (1). This Skyrme term, denoted, which is simpler and perhaps more natural, is

$$|D_{[i}^{(B)} z^\dagger D_{j]}^{(B)} z|^2 = |D_{[i}^{(B)} z_\alpha^* D_{j]}^{(B)} z^\alpha|^2. \tag{8}$$

The $\mathbb{C}P^1$ model with this Skyrme term is *not* equivalent to the O(3) model with Skyrme term.

The action density of the O(3) model with Skyrme term[10] is

$$\mathscr{L}_{Sk}^{(\phi)} = \kappa_2^4 |\partial_{[i}\phi^a \partial_{j]}\phi^b|^2 + \kappa_2^2 |\partial_i \phi^a|^2 + \lambda_0(1-\phi^3). \tag{9}$$

The action density of the $\mathbb{C}P^1$ model with Skyrme term which is equivalent to the O(3) model with Skyrme term (9) is

$$\mathscr{L}_{Sk1}^{(z)} = 2\kappa_2^4 (4|D_i^{(B)} z^\dagger D_i^{(B)} z|^2 - |D_{(i}^{(B)} z^\dagger D_{j)}^{(B)} z|^2) + \kappa_1^2 D_i^{(B)} z^\dagger D_i^{(B)} z + \lambda_0(1 - z^\dagger \sigma^3 z). \tag{10}$$

The action density of the alternative $\mathbb{C}P^1$ model with Skyrme term which is not equivalent to the O(3) model with Skyrme term (9) is

$$\mathscr{L}_{Sk2}^{(z)} = \kappa_2^4 |D_{[i}^{(B)} z^\dagger D_{j]}^{(B)} z|^2 + \kappa_1^2 D_i^{(B)} z^\dagger D_i^{(B)} z + \lambda_0(1 - z^\dagger \sigma^3 z). \tag{11}$$

The constants κ_1 and κ_2 have the dimensions of length, while the constant λ_0 is dimensionless. Equations (10) and (11) are the two sigma models with Skyrme terms which will be gauged using Maxwell dynamics.

B. U(1) Maxwell gauging prescription

We now subject the $\mathbb{C}P^1$ models with Skyrme terms (10) and (11) to our U(1) Maxwell gauging prescription which consists of replacing the composite connection B_i by the Maxwell U(1) connection A_i, i.e., by replacing the covariant derivatives defined by (2) with

$$D_i^{(A)}z=\partial_i z+iA_i z. \tag{12}$$

We also add the usual Maxwell term F_{ij}^2, where F_{ij} is the curvature of the connection in (12), to the action density. This results in the following two gauged $\mathbb{C}P^1$ models with Skyrme terms

$${}^g\mathscr{L}_{Sk1}^{(z)}=\kappa_3^4F_{ij}^2+2\kappa_2^4(4|D_i^{(A)}z^\dagger D_i^{(A)}z|^2-|D_{(i}^{(A)}z^\dagger D_{j)}^{(A)}z|^2)+\kappa_1^2D_i^{(A)}z^\dagger D_i^{(A)}z+\lambda_0(1-z^\dagger\sigma^3z). \tag{13}$$

$${}^g\mathscr{L}_{Sk2}^{(z)}=\kappa_3^4F_{ij}^2+\kappa_2^4|D_{[i}^{(A)}z^\dagger D_{j]}^{(A)}z|^2+\kappa_1^2D_i^{(A)}z^\dagger D_i^{(A)}z+\lambda_0(1-z^\dagger\sigma^3z). \tag{14}$$

In (13) and (14), κ_3 is a coupling constant which has the dimension of length. If $\kappa_2=0$, then ${}^g\mathscr{L}_{Sk1}^{(z)}={}^g\mathscr{L}_{Sk2}^{(z)}$. We note that ${}^g\mathscr{L}_{Sk1}^{(z)}$ with $\kappa_2=0$, which is the Maxwell–U(1) gauged $\mathbb{C}P^1$ model (without Skyrme term), when subjected to radial symmetry coincides with the Chern–Simons-U(1) gauged $\mathbb{C}P^1$ model studied in Ref. 6 as will be seen in the next section.

C. Radial symmetry

We employ the following radially symmetric ansätze:

$$A_i=\frac{a(r)-n}{r}\varepsilon_{ij}\hat{x}_j, \tag{15}$$

$$\phi^a=(\phi^\alpha,\phi^3)=(\sin f(r)n^\alpha,\cos f(r)); \quad n^\alpha=(\cos n\theta,\sin n\theta), \tag{16}$$

$$z^\alpha=\left(\cos\frac{f(r)}{2}\,e^{-in\theta},\sin\frac{f(r)}{2}\right). \tag{17}$$

Under these ansätze we find that the radially symmetric restrictions of the $\mathbb{C}P^1$ models with Skyrme terms (10) and (11), as well as the U(1) gauged $\mathbb{C}P^1$ models with Skyrme terms (13) and (14), reduce to the following one dimensional Lagrangian densities:

$$L_{Sk}^{(\phi)}=L_{Sk1}^{(z)}=\lambda_2n^2\frac{\sin^2 f}{\rho}f_\rho^2+\lambda_1\left(\rho f_\rho^2+n^2\,\frac{\sin^2 f}{\rho}\right)+\lambda_0 r(1-\cos f\,), \tag{18}$$

$$L_{Sk2}^{(z)}=\lambda_2n^2\frac{\sin^2 2f}{\rho}f_\rho^2+\lambda_1\left(\rho f_\rho^2+n^2\,\frac{\sin^2 f}{\rho}\right)+\lambda_0 r(1-\cos f\,), \tag{19}$$

$$\begin{aligned}{}^gL_{Sk}^{(\phi)}={}^gL_{Sk1}^{(z)}=&\frac{\lambda_3}{\rho}a_\rho^2+2\,\frac{\lambda_2}{\rho}\left[a^2\,\cos^2\frac{f}{2}+(a-n)^2\,\sin^2\frac{f}{2}\right]f_\rho^2\\&+\lambda_1\left(\frac{\rho}{4}f_\rho^2+\frac{1}{\rho}\left[a^2\,\cos^2\frac{f}{2}+(a-n)^2\,\sin^2\frac{f}{2}\right]\right)+\lambda_0\rho(1-\cos f\,),\end{aligned} \tag{20}$$

$${}^gL_{Sk2}^{(z)}=\frac{\lambda_3}{\rho}a_\rho^2+\frac{\lambda_2}{2}n^2\frac{\sin^2 2f}{\rho}f_\rho^2+\lambda_1\left(\frac{\rho}{4}f_\rho^2+\frac{1}{\rho}\left[a^2\,\cos^2\frac{f}{2}+(a-n)^2\,\sin^2\frac{f}{2}\right]\right)+\lambda_0\rho(1-\cos f\,). \tag{21}$$

When $\lambda_2=0$, ${}^gL^{(z)}_{Sk1}={}^gL^{(z)}_{Sk2}$. Let ${}^gL^{(z)}_0$ denote ${}^gL^{(z)}_{Sk1}$ with $\lambda_2=0$. ${}^gL^{(z)}_0$, which is the radially symmetric restriction of the action density of the $\mathbb{C}P^1$ sigma model gauged with Maxwell dynamics, coincides with the corresponding quantity for the $\mathbb{C}P^1$ sigma model gauged with Chern–Simons dynamics of Ref. 6.

$$ {}^gL^{(z)}_0=\frac{\lambda_3}{\rho}a_\rho^2+\lambda_1\left(\frac{\rho}{4}f_\rho^2+\frac{1}{\rho}\left[a^2\,\cos^2\frac{f}{2}+(a-n)^2\,\sin^2\frac{f}{2}\right]\right)+\lambda_0\rho(1-\cos\,f\,). \tag{22}$$

In (18)–(22), we have used a dimensionless radial variable $\rho=\kappa r$ and the dimensionless coupling constants there are defined by $\lambda_1=(\kappa_1/\kappa)^2$, $\lambda_2=(\kappa_2/\kappa)^4$ and $\lambda_3=(\kappa_3/\kappa)^4$.

We note that after the imposition of radial symmetry the Skyrme term in (21) does not exhibit the gauge field function $a(\rho)$.

In the next section we present the proofs of existence for the solitons in the models described above, *analytically*. In connection with this, we emphasize that the existence of these solitons was verified *numerically* for several values of the vorticity n, in Refs. 10, 6, and 2.

III. EXISTENCE OF SOLITONS

A proof of the existence of smooth finite-energy solutions with winding number n of the variational equation of (18) was given in Ref. 11. It is clear that the existence of solutions with winding number n of the variational equation of (19) can be proved in a similar manner to the proof given in Ref. 11 so we do not concern ourselves with it here. We proceed therefore to give the proofs of existence for the gauged Skyrme-Sigma models (20)–(22).

Consider the energy density functionals ${}^gL^{(z)}_0$, ${}^gL^{(z)}_{Sk1}$, ${}^gL^{(z)}_{Sk2}$ and their associated energies. The boundary conditions for solutions of the variational equations with finite energy and with topological charge n given in Refs. 6 and 2 are

$$\lim_{\rho\to 0}\,a(\rho)=n,\quad \lim_{\rho\to\infty}\,a(\rho)=0,\quad \lim_{\rho\to 0}\,f(\rho)=\pi,\quad \lim_{\rho\to\infty}\,f(\rho)=0. \tag{23}$$

Theorem: *The Euler-Lagrange equations of each of the three functionals* ${}^gL^{(z)}_0$, ${}^gL^{(z)}_{Sk1}$ *and* ${}^gL^{(z)}_{Sk2}$ *have finite energy solutions with winding number n satisfying (23).*

To prove the theorem it suffices to find minimizers of each of the energies which satisfy the boundary conditions (23).

To each of the three energies we associate the space of admissible functions:

$$\begin{aligned}\mathscr{A}=\{(a(\rho),f(\rho)):\ & a(\rho)\ \text{and}\ f(\rho)\ \text{are continuous functions on}\ [0,\infty)\ \text{and}\\ & \text{absolutely continuous on every compact subinterval of}\ (0,\infty)\\ & \text{and}\ \lim_{\rho\to 0}\,a(\rho)=n,\quad \lim_{\rho\to 0}\,f(\rho)=\pi,\quad \lim_{\rho\to\infty}\,f(\rho)=0\},\end{aligned}$$

and we consider the optimization problems

$$m\equiv\inf_{(a,f\,)\in\mathscr{A}}\,E(a,f\,), \tag{24}$$

where $E(a,f\,)$ denotes the energy of the respective model which is proportional to

$$\int_0^\infty L\,d\rho,\quad L={}^gL^{(z)}_0,\ {}^gL^{(z)}_{Sk1},\ \text{or}\ {}^gL^{(z)}_{Sk2}.$$

Lemma 1: Let $\{(a_k,f_k)\}$ be a minimizing sequence for any of the three optimization problems (24). Then

$$0\leqslant a_k\leqslant n,\quad 0\leqslant f_k\leqslant\pi,\quad k=1,2,\ldots. \tag{25}$$

Proof: Let $\{(a_k,f_k)\}$ be a minimizing sequence for any of the three optimization problems (24). Define

$$g_k(\rho)=\begin{cases} -f_k(\rho), & \text{if } f_k(\rho)<0,\\ 2\pi-f_k(\rho), & \text{if } f_k(\rho)>\pi,\\ f_k(\rho), & \text{otherwise,}\end{cases}$$

$$b_k(\rho)=\begin{cases} 0, & \text{if } a_k(\rho)<0,\\ n, & \text{if } a_k(\rho)>n,\\ a_k(\rho), & \text{otherwise.}\end{cases}$$

The sequence $\{(b_k,g_k)\}$ lies in $\mathscr{A}$ for any of the three optimization problems, (24). Since $E(b_k,g_k)\leqslant E(a_k,f_k)$ for each of the three energies, $k=1,2,\ldots,$ it follows that $\{(b_k,g_k)\}$ is also a minimizing sequence for any of the three optimization problems (24) which satisfies (25).

Let $\{(a_k,f_k)\}$ be a minimizing sequence for (24) which satisfies (25). Then for any pair of numbers $0<\rho_1<\rho_2$, $\{(a_k,f_k)\}$ is a bounded minimizing sequence in the space $W^{1,2}(\rho_1,\rho_2)$. Hence there exists a pair of functions (a,f) and a subsequence of $\{(a_k,f_k)\}$ [which we also denote by $\{(a_k,f_k)\}$], such that $a_k\to a$ and $f_k\to f$ weakly in $W^{1,2}(\rho_1,\rho_2)$ (as $k\to\infty$) for any ρ_1 and ρ_2 with $0<\rho_1<\rho_2$.

Since there is a compact embedding $W^{1,2}(\rho_1,\rho_2)\to C[\rho_1,\rho_2]$, it follows that $a_k\to a$ and $f_k\to f$ strongly in $C[\rho_1,\rho_2]$ (as $k\to\infty$) for any $0<\rho_1<\rho_2$.

Hence

$$E(a,f)=\lim_{\rho_1\to 0,\rho_2\to\infty}\sup\ \lim_{k\to\infty}\inf\int_{\rho_1}^{\rho_2}\mathscr{E}(a_k,f_k)d\rho\leqslant\lim_{k\to\infty}E(a_k,f_k)=m$$

for any of the three optimization problems (24).

Lemma 2: Let (a,f) be the field configuration pair obtained above in the limit of the sequence $\{(a_k,f_k)\}$. Then (a,f) is a solution of the minimization problem (24).

Proof: It remains to show that (a,f) satisfies the boundary conditions stated in the definition of the admissible space $\mathscr{A}$.

Let $\{(a_k,f_k)\}$ be a minimizing sequence for any of the three optimization problems (24). Since

$$|a_k(\rho)-n|\leqslant\int_0^\rho\left|\frac{da_k}{d\rho'}\right|d\rho'\leqslant\rho\left(\int_0^\infty\frac{1}{\rho'}\left[\frac{da_k}{d\rho'}\right]^2d\rho'\right)^{1/2}\leqslant\rho E^{1/2}(a_k,f_k)\to 0\quad\text{as}\quad\rho\to 0,$$

uniformly for $k=1,2,\ldots,$ for each of the three energies E, so the limit $a(\rho)\to n$ as $\rho\to 0$ follows.

Furthermore, since

$$\begin{aligned}1-\cos f_k&=\frac{f_k^2}{2!}\left(1-\frac{f_k^2}{3\cdot 4}\right)+\frac{f_k^6}{6!}\left(1-\frac{f_k^2}{7\cdot 8}\right)+\cdots\\&\geqslant\frac{f_k^2}{2!}\left(1-\frac{\pi^2}{3\cdot 4}\right)+\frac{f_k^6}{6!}\left(1-\frac{\pi^2}{7\cdot 8}\right)+\cdots>\frac{12-\pi^2}{4!}f_k^2,\end{aligned}$$

then it follows from the respective energy functionals that $\{f_k\}$ satisfies

$$\sup_k\int_0^\infty\rho\left(f_k^2+\left[\frac{df_k}{d\rho}\right]^2\right)d\rho<C$$

for some constant $C>0$. Since $f_k(\rho)\to 0$ as $\rho\to\infty$, then

$$f_k^2(\rho)=-2\int_\rho^\infty f_k\frac{df_k}{d\rho'}\,d\rho'\leqslant\frac{2}{\rho}\left(\int_0^\infty\rho' f_k^2(\rho')d\rho'\right)^{1/2}\left(\int_0^\infty\rho'\left[\frac{df_k}{d\rho'}\right]^2d\rho'\right)^{1/2}\leqslant\frac{2C}{\rho},\quad\rho>0.$$

Hence $f_k(\rho)\to 0$ as $\rho\to\infty$ uniformly for $k=1,2,\ldots$ for each of the energy E. Thus it follows that $f(\rho)\to 0$ as $\rho\to\infty$.

To obtain the boundary condition for f at $\rho=0$, we use the uniform limit $a_k(\rho)\to n\neq 0$ as $\rho\to 0$ to find a number $\delta>0$ so that

$$a_k^2(\rho)>\tfrac{1}{2},\quad k=1,2,\ldots,\quad 0<\rho<\delta.$$

For the energy defined by ${}^gL_{Sk1}^{(z)}$, we have from (23), for all $k=1,2,\ldots$, that

$${}^gL_{Sk1}^{(z)}(a_k,f_k)\geqslant C\frac{1}{\rho}\cos^2\left(\frac{f_k}{2}\right)\left(\frac{df_k}{d\rho}\right)^2,\quad 0<\rho<\delta.$$

Therefore, we see from the estimate

$$\begin{aligned}\left|\sin^2\left(\frac{f_k(\rho)}{2}\right)-1\right|&\leqslant\int_0^\rho\left|\sin\ \text{frac}\ \ f_k 2\cos\frac{f_k}{2}\frac{df_k}{d\rho'}\right|d\rho'\\&\leqslant\rho\left(\int_0^\rho\frac{1}{\rho'}\cos^2\frac{f_k}{2}\left[\frac{df_k}{d\rho'}\right]^2d\rho'\right)^{1/2}\\&\leqslant C\rho E^{1/2}(a_k,f_k),\quad k=1,2,\ldots,\quad 0<\rho<\delta\end{aligned}$$

that $f_k(\rho)\to\pi$ as $\rho\to 0$ uniformly for all k. Hence $f(\rho)\to\pi$ as $\rho\to 0$ as well.

Similarly, we consider the energy defined by ${}^gL_{Sk2}^{(z)}$. Since

$$|\cos\ f_k(\rho)+1|\leqslant\int_0^\rho\left|\sin\ f_k\frac{df_k}{d\rho'}\right|d\rho'\leqslant\rho\left(\int_0^\rho\frac{1}{\rho'}\sin^2\ f_k\left[\frac{df_k}{d\rho'}\right]^2d\rho'\right)^{1/2}\leqslant C\rho E^{1/2}(a_k,f_k)\to 0$$

$$\text{as}\ \ \rho\to 0$$

uniformly for $k=1,2,\ldots$, it follows that $f(\rho)\to\pi$ as $\rho\to 0$.

Using the established fact that $a(\rho)\to 0$ as $\rho\to 0$ and finite energy for the model defined by ${}^gL_0^{(z)}$, we have the convergent integral

$$\int_0^1\frac{1}{\rho}\cos^2\left(\frac{f}{2}\right)d\rho<\infty.$$

Consequently, we obtain

$$\left|\sin^2\left(\frac{f_k(\rho)}{2}\right)-1\right|\leqslant\int_0^\rho\left|\cos\frac{f_k}{2}\frac{df_k}{d\rho'}\right|d\rho'\leqslant C\left(\int_0^\rho\frac{1}{\rho'}\cos^2\frac{f_k}{2}\,d\rho'\right)^{1/2}\sup_k E^{1/2}(a_k,f_k).$$

Applying the Schwarz inequality first and then taking the limit $k\to\infty$, we get

$$\left|\sin^2\left(\frac{f(\rho)}{2}\right)-1\right|\leqslant C_1\left(\int_0^\rho\frac{1}{\rho'}\cos^2\frac{f}{2}\,d\rho'\right)^{1/2}.$$

Letting $\rho\to 0$ we have $f(\rho)\to\pi$ as desired and the proof of Lemma 2 is complete.

It remains to establish the boundary condition $a(\rho)\to 0$ as $\rho\to\infty$. As a preparation, we prove the following.

Lemma 3: Let (a,f) be a minimizer of the energy of any of the three models. Then there hold

$$0<a(\rho)<n,\quad 0<f(\rho)<\pi,\quad \rho>0. \tag{26}$$

Proof: For the model ${}^gL_0^{(z)}$, the Euler–Lagrange equations are

$$\lambda_1\frac{d}{d\rho}\left(\rho\frac{df}{d\rho}\right)=\frac{n}{\rho}\lambda_1(n-2a)\sin\ f+2\lambda_0\rho\ \sin\ f, \tag{27}$$

$$\lambda_3 \frac{d}{d\rho}\left(\frac{1}{\rho}\frac{da}{d\rho}\right)=\frac{\lambda_1}{\rho}\left(a-n\,\sin^2\frac{f}{2}\right). \tag{28}$$

From Lemma 1, we have $0\leqslant a(\rho)\leqslant n$, $0\leqslant f(\rho)\leqslant\pi$. On the other hand, since $f=0,\pi$ are the equilibrium solutions of (27), an easy application of the uniqueness theorem for the solutions of ordinary differential equations shows that $0<f(\rho)<\pi$ for all $\rho>0$.

If there is a $\rho_0>0$ so that $a(\rho_0)=0$, then $a(\rho_0)$ is the minimum of a and $a_\rho=0$ at $\rho=\rho_0$. Inserting this information into (28), we have $a_{\rho\rho}(\rho_0)<0$ which is a contradiction. Similarly, if $a(\rho_0)=n$, then $a_\rho=0$ and $a_{\rho\rho}\leqslant 0$ at $\rho=\rho_0$ which violates again (28).

For a model defined either by ${}^gL^{(z)}_{Sk1}$ or ${}^gL^{(z)}_{Sk2}$, we may use the same argument. Hence the lemma is proved.

Lemma 4: We have the boundary behavior $a(\rho)\to 0$ as $\rho\to\infty$.

Proof: The structure of each of the energy densities implies that there is a sequence $\{\rho_j\}$, $\rho_j\to\infty$ as $j\to\infty$ so that

$$\lim_{j\to\infty} a(\rho_j)=0 \tag{29}$$

because $f(\rho)\to 0$ as $\rho\to\infty$. Suppose otherwise that $a(\rho)\not\to 0$ as $\rho\to\infty$. Then there is some $\varepsilon_0>0$ and a sequence $\{\rho_j'\}$, $\rho_j'\to\infty$ as $j\to\infty$ so that

$$a(\rho_j')\geqslant\varepsilon_0,\quad j=1,2,\ldots. \tag{30}$$

From (26) and (28) it follows that there is a sequence $\{\rho_j^0\}$, $\rho_j^0\to\infty$ as $j\to\infty$ such that $a(\rho_j^0)\geqslant\varepsilon_0$ and ρ_j^0 are local maximum points of $a(\rho)$. Inserting $a_\rho(\rho_j^0)=0$ and $a_{\rho\rho}(\rho_j^0)\leqslant 0$ in the Euler–Lagrange equations of any of the three models, we arrive at a contradiction. For example, for the model defined by ${}^gL^{(z)}_0$, we would get $a_{\rho\rho}(\rho_j^0)>0$ for any sufficiently large j because $f(\rho)\to 0$ as $\rho\to\infty$. This proves the lemma.

In summary, our existence theorem is proved.

Note added. After completing this work it came to our attention that some new[12] Maxwell[13,14] and Chern–Simons[15] gauged O(3) models subject to the *second* gauging prescription which exhibit both symmetry breaking and quantized magnetic flux have been proposed. The vortices of these models, however, are not stabilized by the usual degree of the map, but instead by a partial map which we have not discussed in the present work.

(Received 2 April 1998; accepted for publication 9 July 1998)

A class of highest-weight irreducible representations of the algebra $U_h(A_\infty)$, the quantum analog of the completion and central extension A_∞ of the Lie algebra gl_∞, is constructed. It is considerably larger than the class of representations known so far. Within each module a basis is introduced and the transformation relations of the basis under the action of the Chevalley generators are explicitly given. The verification of the quantum algebra relations is shown to reduce to a set of nontrivial q-number identities. All representations are restricted in the terminology of S. Levendorskii and Y. Soibelman [Commun. Math. Phys. **140**, 399–414 (1991)].

I. INTRODUCTION

We construct a class of highest-weight irreducible representations (irreps) of the algebra $U_h(A_\infty)$,[1] the quantum analog of the completion and central extension A_∞ of the Lie algebra gl_∞.[2,3] Our interest in the subject stems from the observation that certain representations of $gl(n)$ (including $n=\infty$)[4] and of A_∞ (see *Example 2* in Ref. 5 and the references therein) are related to a new quantum statistics, the A-statistics. The latter, as it is clear now, is a particular case of the Haldane exclusion statistics,[6] a subject of considerable interest in condensed matter physics (see Sec. 4 in Ref. 7 for more discussions on the subject). It turns out that some of the representations of the deformed algebra $U_h(A_\infty)$ satisfy also the requirements of the Haldane statistics. More precisely, they lead to new solutions for the microscopic statistics of Karabali and Nair[8] directly in the case of infinitely many degrees of freedom. These results will be published elsewhere. We mention them here only in order to justify our motivation for the work we are going to present. One may expect certainly that similar to A_∞[9,10] the representations of $U_h(A_\infty)$ may prove useful also in other branches of physics and mathematics.

The quantum analogs of gl_∞ and A_∞ in the sense of Drinfeld,[11] namely $U_h(gl_\infty)$ and $U_h(A_\infty)$, were worked out by Levendorskii and Soibelman.[1] These authors have constructed a class of highest-weight irreducible representations, writing down explicit expressions for the transformations of the basis under the action of the algebra generators.

The $U_h(A_\infty)$-modules, which we study, are labeled by all possible sequences (see the end of the Introduction for the notation) $\{M\}\equiv\{M_i\}_{i\in\mathbf{Z}}\in\mathbf{C}[h]^\infty$, subject to the conditions:

(a) There exists $m\leqslant n\in\mathbf{Z}$, such that $M_m=M_{m-k}$ and $M_n=M_{n+k}$ for all $k\in\mathbf{N}$;
(b) $M_i-M_j\in\mathbf{Z}_+$ for all $i<j\in\mathbf{Z}$.

Representations, corresponding to two different sequences, $\{M^1\}\neq\{M^2\}$, are inequivalent. The $U_h(A_\infty)$-modules of Levendorskii and Soibelman[1] are labeled by all those sequences $\{M^{(s)}\}$, for which $s=m=n\in\mathbf{Z}$ and $M_i^{(s)}=1$, if $i<s$ and $M_i^{(s)}=0$ for $i\geqslant s$.

The transformation relations of the $U_h(A_\infty)$-modules are given in terms of a basis, which we called a C basis [see Ref. 11]. This basis was initially introduced for a description of the finite-

signature representations of gl_∞ [12,13] and A_∞ .[14,15] We recall that the *C* basis is different from the known Gel'fand-Zetlin basis (GZ basis)[16] even for $\mathrm{gl}(n)$. The GZ-basis is introduced through a ''left to right'' and ''up to down'' embedding in the chain of subalgebras (see Ref. 13 for the notation)

$$\mathrm{gl}_0(1)\subset\mathrm{gl}_0(2)\subset\cdots\subset\mathrm{gl}_0(n-1)\subset\mathrm{gl}_0(n)\equiv\mathrm{gl}(n), \tag{1}$$

whereas the *C* basis corresponds to a ''central'' embedding

$$\mathrm{gl}_1\subset\mathrm{gl}_2\subset\cdots\subset\mathrm{gl}_{n-1}\subset\mathrm{gl}_n\equiv\mathrm{gl}(n). \tag{2}$$

In the finite-dimensional case the GZ basis and the C basis describe certainly one and the same representation. This is no more the case for gl_∞. The representations obtained through the GZ basis (GZ representations) are not equivalent to the *C* representations. These are different classes of representations. In particular the GZ representations are not highest-weight representations of gl_∞ (with respect to the natural order of the Cartan generators). This is the reason why the GZ representations of gl_∞ are not so interesting in the physical applications.

In the present paper we generalize to the quantum case the C representations. In Ref. 13 we have derived the transformations of the C basis from the results of Gel'fand and Zetlin.[16] This possibility was based on a map φ of gl_n onto $\mathrm{gl}_0(n)$, defined there. Its main property (see *Proposition 3* in Ref. 13) is that φ maps isomorphically the chain (2) onto the chain (1). We were unable to formulate an analog of *Proposition 3* in the quantum case. As a result we were unable to derive the transformation relations [see Eqs. (19)–(22)] from the results of Jimbo.[17] The very idea of Jimbo, however, to replace certain multiples in the transformation relations of the $\mathrm{gl}(n)$ modules by *q* numbers in order to obtain representations in the quantum case turned to work also for the transformation relations of the gl_∞ *modules*. This was certainly only a working hypothesis, because the matrix elements in the GZ basis were too different from those in the C basis. We knew a similar hypothesis worked in the case of the superalgebra $\mathrm{U}_q[\mathrm{gl}(n/m)]$,[18,19] but it did not work in other cases.[20] Therefore our proof of *Proposition 1* [namely of the transformation relations (19)–(22) of the C basis] is based on a direct verification of the Cartan and the Serre relations (3)–(5).

From our results it follows that each A_∞ module with a signature $\{M\}$ can be deformed to a $\mathrm{U}_h(A_\infty)$ module with the same signature. The class of the finite-signature representations of $\mathrm{U}_h(A_\infty)$ is, however, larger, which is due to the fact that the coordinates of the $\mathrm{U}_h(A_\infty)$ signatures take values in $\mathbf{C}[h]$. All representations we obtain are restricted in the sense of Ref. 1, Definition 4.1.

In Sec. II we construct a class of highest-weight irreps of the subalgebra $\mathrm{U}_h(a_\infty)$ of $\mathrm{U}_h(A_\infty)$. Some of these representations, namely the finite-signature representations (*Definition 2*), are extended to representations of $\mathrm{U}_h(A_\infty)$ in Sec. III.

Throughout the paper we use the notation (most of them standard):

N—all positive integers;
$\mathbf{Z}_+$—all non-negative integers;
Z—all integers;
Q—all rational numbers;
C—all complex numbers;
$\mathbf{C}[h]$—the ring of all polynomials in h over **C**;
$\mathbf{C}[[h]]$—the ring of all formal power series in h over **C**;
$X^n=\{(a_1,a_2,\ldots,a_n)|a_i\in X\}$, (including $n=\infty$);
$[a;b]=\{x|a\leqslant x\leqslant b,x\in\mathbf{Z}\}$, $(a;b)=\{x|a<x<b,x\in\mathbf{Z}\}$;
$\Gamma(\{M\})$—the *C*-basis of a module with a signature $\{M\}$;

$$\theta(i)=\begin{cases}1, & \text{for } i\geqslant 0,\\ 0, & \text{for } i<0;\end{cases}$$

$q=e^{h/2}\in\mathbf{C}[[h]]$;
$[x]=(q^x-q^{-x})/(q-q^{-1})\in\mathbf{C}[[h]]$;
$[x,y]_q=xy-qyx$.

II. REPRESENTATIONS OF THE ALGEBRA $U_h(a_\infty)$

The algebra $U_h(a_\infty)$ was defined in Ref. 1. The authors denote it as $U_h(g'(A_\infty))_f$. It is a Hopf algebra, which is a topologically free module over $\mathbf{C}[[h]]$ (complete in h-adic topology), with generators $\{e_i, f_i, h_i, c\}_{i\in\mathbf{Z}}$, and

(1) Cartan relations:

$$[c,\ a]=0, \quad a\in\{h_i, e_i, f_i\}_{i\in\mathbf{Z}}, \tag{3a}$$

$$[h_i,\ h_j]=0, \tag{3b}$$

$$[h_i,\ e_j]-(\delta_{ij}-\delta_{i,j+1})e_j=0, \tag{3c}$$

$$[h_i,\ f_j]+(\delta_{ij}-\delta_{i,j+1})f_j=0, \tag{3d}$$

$$[e_i,\ f_i]-[h_i-h_{i+1}+(\theta(-i)-\theta(-i-1))c]=0, \tag{3e}$$

$$[e_i,\ f_j]=0, \quad i\neq j; \tag{3f}$$

(2) *e*-Serre relations:

$$[e_i,\ e_j]=0, \quad \text{if } |i-j|\neq 1, \tag{4a}$$

$$e_i^2 e_{i+1}-(q+q^{-1})e_i e_{i+1} e_i+e_{i+1}e_i^2=0, \tag{4b}$$

$$e_{i+1}^2 e_i-(q+q^{-1})e_{i+1} e_i e_{i+1}+e_i e_{i+1}^2=0; \tag{4c}$$

(3) *f*-Serre relations:

$$[f_i,\ f_j]=0, \quad \text{if } |i-j|\neq 1. \tag{5a}$$

$$f_i^2 f_{i+1}-(q+q^{-1})f_i f_{i+1} f_i+f_{i+1}f_i^2=0, \tag{5b}$$

$$f_{i+1}^2 f_i-(q+q^{-1})f_{i+1} f_i f_{i+1}+f_i f_{i+1}^2=0. \tag{5c}$$

We do not write the other Hopf algebra maps (Δ,ε,S),[1] since we will not use them. They are certainly also a part of the definition of $U_h(a_\infty)$.

Replacing throughout in the above relations $\{e_i, f_i, h_i, c\}_{i\in\mathbf{Z}}$ with $\{E_i, F_i, H_i, 0\}_{i\in\mathbf{Z}}$, one obtains the definition of $U_h(gl_\infty)$.

In terms of an equivalent set of generating elements $\{\hat{e}_i, \hat{f}_i, h_i, c\}_{i\in\mathbf{Z}}$, with

$$\hat{e}_i=e_i q^{(h_{i+1}-h_i)/2}, \quad \hat{f}_i=f_i q^{(h_i-h_{i+1})/2},$$

one writes the quantum analogs of the Weyl generators $\{e_{ij}\}_{(i,j)\in\mathbf{Z}^2}$:

$$e_{ii}=h_i, \quad e_{i,i+1}=\hat{e}_i, \quad e_{i+1,i}=\hat{f}_i,$$

$$e_{ij}=[\hat{e}_i,[\hat{e}_{i+1},[\ldots,[\hat{e}_{j-2},\hat{e}_{j-1}]_q\ldots]_q]_q]_q, \quad i+1<j,$$

$$e_{ji}=[\hat{f}_i,[\hat{f}_{i+1},[\ldots,[\hat{f}_{j-2},\hat{f}_{j-1}]_q\ldots]_q]_q]_q, \quad i+1<j.$$

The ''commutation relations'' between these generators follow from (3)–(5) and are given in Ref. 1. The relevance of the generators $\{e_{ij}\}_{(i,j)\in\mathbf{Z}^2}$ stems from the observation that the set of ordered monomials (see Ref. 1 for the ordering)

$$c^l \prod_{(i,j)\in\mathbf{Z}^2} e_{ij}^{n_{ij}} \tag{6}$$

with finitely many nonzero exponents $n_{ij}\in\mathbf{Z}_+$, $l\in\mathbf{Z}_+$ forms a (topological) basis in $U_h(a_\infty)$.

Set $H=\oplus_i \mathbf{C}h_i$. Define linear functionals $\varepsilon_i: H\to\mathbf{C}$ by $\varepsilon_i(h_j)=\delta_{ij}$ and set $\alpha_i=\varepsilon_i-\varepsilon_{i+1}$, $Q'_+=\oplus_i \mathbf{Z}_+\alpha_i$. Denote by $\mathrm{U}_h(n_+)$ [respectively $\mathrm{U}_h(n_-)$] the unital subalgebra in $\mathrm{U}_h(a_\infty)$ generated by $\{e_i\}_{i\in\mathbf{Z}}$ (respectively $\{f_i\}_{i\in\mathbf{Z}}$). Then

$$\mathrm{U}_h(n_\pm)=\bigoplus_{\alpha\in Q'_+}\mathrm{U}_h(n_\pm)_{\pm\alpha}, \tag{7}$$

where

$$\mathrm{U}_h(n_\pm)_{\pm\alpha}=\{x\in\mathrm{U}_h(n_\pm)\,|\,[h',x]=\pm\alpha(h')x,\quad \forall h'\in H\} \tag{8}$$

for $\alpha\neq 0$, and $\mathrm{U}_h(n_\pm)_0=\mathbf{C}[[h]]$. Any element $u\in\mathrm{U}_h(a_\infty)$ can be represented as

$$u=\sum_{k=0}^{\infty}h^k\sum_{l=0}^{l(k)}c^l\sum_{\alpha,\beta\in Q'_+}\sum_{\gamma(k,l)\in\mathbf{Z}_+^\infty}\sum_{t=1}^{t(\alpha,\beta)}\mathscr{F}_{\alpha,k,l,t}\prod_{i\in\mathbf{Z}}h_i^{\gamma(k,l)_i}\mathscr{E}_{\beta,k,l,t},\quad \text{finite sums over } \alpha,\beta,\gamma, \tag{9}$$

where $\mathscr{F}_{\alpha,k,l,t}\in\mathrm{U}_h(n_-)_{-\alpha}$, $\mathscr{E}_{\beta,k,l,t}\in\mathrm{U}_h(n_+)_{+\beta}$ and finitely many exponents $\gamma(k,l)_i$ are different from zero. The words ''finite sums over α, β, γ'' have been added in order to indicate that for a fixed k only finitely many summands in (9) are different from zero.

The set $\hat{\mathrm{U}}_h(a_\infty)$, consisting of all $\mathbf{C}[[h]]$-polynomials of the Chevalley generators $\{e_i,f_i,h_i,c\}_{i\in\mathbf{Z}}$, is dense in $\mathrm{U}_h(a_\infty)$ with a basis (6). In particular $\mathscr{F}_{\alpha,k,l,t}$, $\mathscr{E}_{\beta,k,l,t}$ and $\Pi_{i\in\mathbf{Z}}h_i^{\gamma(k,l)_i}$ are in $\hat{\mathrm{U}}_h(a_\infty)$. Then according to (9) any element $u\in\mathrm{U}_h(a_\infty)$ is of the form

$$u=\sum_{k=0}^{\infty}u_kh^k,\quad u_k=\sum_{l=0}^{l(k)}c^l\sum_{\alpha,\beta\in Q'_+}\sum_{\gamma(k,l)\in\mathbf{Z}_+^\infty}\sum_{t=1}^{t(\alpha,\beta)}\mathscr{F}_{\alpha,k,l,t}\prod_{i\in\mathbf{Z}}h_i^{\gamma(k,l)_i}\mathscr{E}_{\beta,k,l,t}\in\hat{\mathrm{U}}_h(a_\infty). \tag{10}$$

We pass to construct a class of highest-weight irreps of $\mathrm{U}_h(a_\infty)$. In the following Propositions 1 and 2 we define the $\mathrm{U}_h(a_\infty)$-modules $V(\{M\};\xi_0,\xi_1)$, each one labeled by ξ_0, $\xi_1\in\mathbf{C}[h]$ and by a sequence $\{M\}\equiv\{M_i\}_{i\in\mathbf{Z}}\in\mathbf{C}[h]^\infty$ such that

$$M_i-M_j\in\mathbf{Z}_+,\quad \forall i<j\in\mathbf{Z}.$$

The basis $\Gamma(\{M\})$ in $V(\{M\};\xi_0,\xi_1)$, called a central basis (C basis), is independent of ξ_0,ξ_1. It is formally the same as the one introduced in Refs. 14 and 15 for a description of representations of a_∞. $\Gamma(\{M\})$ consists of all C patterns

$$|M)\equiv\begin{bmatrix}
.., & M_{1-\theta-k}, & ..., & M_{-1}, & M_0, & M_1, & ..., & M_{k-1},... \\
.., & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
 & M_{1-\theta-k,2k+\theta-1}, & ..., & M_{-1,2k+\theta-1}, & M_{0,2k+\theta-1}, & M_{1,2k+\theta-1}, & ..., & M_{k-1,2k+\theta-1} \\
 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \\
 & & & M_{-1,3}, & M_{03}, & M_{13} & & \\
 & & & M_{-1,2}, & M_{02} & & & \\
 & & & & M_{01} & & &
\end{bmatrix}, \tag{11}$$

where $k\in\mathbf{N}$, $\theta=0,1$. Each such pattern is an ordered collection of formal polynomials in h,

$$M_{i,2k+\theta-1}\in\mathbf{C}[h],\quad \forall k\in\mathbf{N},\quad \theta=0,1,\quad i\in[-\theta-k+1;k-1], \tag{12}$$

which satisfy the conditions:

(i) there exists a positive integer $N_{|M)}>1$, depending on $|M)$, such that

$$M_{i,2k+\theta-1}=M_i,\quad \forall 2k+\theta-1\geqslant N_{|M)},\quad \theta=0,1,\quad i\in[1-\theta-k;k-1]; \tag{13a}$$

(ii) for each $k\in\mathbf{N}$, $\theta=0$, 1, and $i\in[1-\theta-k;k-1]$,

$$M_{i+\theta-1,2k+\theta}-M_{i,2k+\theta-1}\in\mathbf{Z}_+,\quad M_{i,2k+\theta-1}-M_{i+\theta,2k+\theta}\in\mathbf{Z}_+. \tag{13b}$$

Denote by $\hat{V}(\{M\};\xi_0,\xi_1)$ the free $\mathbf{C}[[h]]$-module with generators $\Gamma(\{M\})$ and let $V(\{M\};\xi_0,\xi_1)$ be its completion in the h-adic topology. $V(\{M\};\xi_0,\xi_1)$ is a topologically free $\mathbf{C}[[h]]$ module with a (topological) basis $\Gamma(\{M\})$ and $\hat{V}(\{M\};\xi_0,\xi_1)$ is dense in it (in the h-adic topology). $V(\{M\};\xi_0,\xi_1)$ consists of all formal power series in h with coefficients in $\hat{V}(\{M\};\xi_0,\xi_1)$:

$$v=\sum_{i=0}^{\infty} v_i h^i, \quad v_0,v_1,v_2,\ldots\in\hat{V}(\{M\};\xi_0,\xi_1). \tag{14}$$

If a is a $\mathbf{C}[[h]]$-linear map in $\hat{V}(\{M\};\xi_0,\xi_1)$, $a\in\mathrm{End}\,\hat{V}(\{M\};\xi_0,\xi_1)$, extend it to a continuous linear map on $V(\{M\};\xi_0,\xi_1)$ setting

$$av=\sum_{i=0}^{\infty}(av_i)h^i. \tag{15}$$

Therefore the transformation of $V(\{M\};\xi_0,\xi_1)$ under the action of a is completely defined, if a is defined on $\Gamma(\{M\})$.

We proceed to turn $V(\{M\};\xi_0,\xi_1)$ into a $\mathrm{U}_h(a_\infty)$ module. Denote by

$$|M)_{\pm k_1\{j_1,p_1\},\pm k_2\{j_2,p_2\},\ldots}\equiv|M)^{\pm k_1\{j_1,p_1\},\ldots}_{\pm k_2\{j_2,p_2\},\ldots}\equiv|M)^{\pm k_1\{j_1,p_1\},\pm k_2\{j_2,p_2\},\ldots}, \quad k_1,k_2,\ldots=1,2,..., \tag{16}$$

the pattern obtained from the C pattern $|M)$ in (11) after the replacements

$$M_{j_1,p_1}\to M_{j_1,p_1}\pm k_1, \quad M_{j_2,p_2}\to M_{j_2,p_2}\pm k_2,\ldots,$$

correspondingly, and let

$$S(j,l;\nu)=\begin{cases}(-1)^\nu & \text{for } j=l,\\ 1 & \text{for } j<l,\\ -1 & \text{for } j>l\end{cases} \qquad \theta(i)=\begin{cases}1 & \text{for } i\geqslant 0\\ 0 & \text{for } i<0,\end{cases} \quad L_{ij}=M_{ij}-i. \tag{17}$$

Set, moreover,

$$e_i^0=f_i, \quad e_i^1=e_i \quad i\in\mathbf{Z}. \tag{18}$$

Let $\{\rho(e_i),\rho(f_i),\rho(h_i),\rho(c)\}_{i\in\mathbf{Z}}$ be a collection of $\mathbf{C}[[h]]$ endomorphisms of $V(\{M\};\xi_0,\xi_1)$, defined on any C pattern $|M)\in\Gamma(\{M\})$, as follows [see also (46), (47), (50) and (51)]:

$$\rho(e_{-1}^{1-\mu})|M)=([L_{-1,2}-L_{0,1}-\mu][L_{0,1}-L_{0,2}+\mu])^{1/2}|M)_{-(-1)^\mu\{0,1\}}, \quad \mu=0,1, \tag{19}$$

$$\begin{aligned}\rho(e^\mu_{(-1)^\nu i-1})|M)=&-\sum_{j=1-i-\nu}^{i-1}\sum_{l=-i}^{i+\nu-1}S(j,l;\nu)\\ &\times\Bigg(-\frac{\Pi_{k\neq l=-i}^{i+\nu-1}[L_{k,2i+\nu}-L_{j,2i+\nu-1}-(-1)^\nu\mu]\Pi_{k=1-i}^{i+\nu-2}[L_{k,2i+\nu-2}-L_{j,2i+\nu-1}-(-1)^\nu\mu]}{\Pi_{k\neq j=1-i-\nu}^{i-1}[L_{k,2i+\nu-1}-L_{j,2i+\nu-1}][L_{k,2i+\nu-1}-L_{j,2i+\nu-1}+(-1)^{\mu+\nu}]}\\ &\times\frac{\Pi_{k=-i-\nu}^{i}[L_{k,2i+\nu+1}-L_{l,2i+\nu}+(-1)^\nu(1-\mu)]\Pi_{k\neq j=1-i-\nu}^{i-1}[L_{k,2i+\nu-1}-L_{l,2i+\nu}+(-1)^\nu(1-\mu)]}{\Pi_{k\neq l=-i}^{i+\nu-1}[L_{k,2i+\nu}-L_{l,2i+\nu}][L_{k,2i+\nu}-L_{l,2i+\nu}+(-1)^{\mu+\nu}]}\Bigg)^{1/2}\\ &\times|M)^{-(-1)^{\mu+\nu}\{l,2i+\nu\}}_{-(-1)^{\mu+\nu}\{j,2i-1+\nu\}}, \quad i\in\mathbf{N}, \quad \mu,\nu=0,1,\end{aligned} \tag{20}$$

$$\rho(h_i)|M)=\Bigg(\sum_{j=-|i|}^{|i|+\theta(i)-1}M_{j,2|i|+\theta(i)}-\sum_{j=-|i|+1-\theta(i)}^{|i|-1}M_{j,2|i|+\theta(i)-1}+(\xi_1-\xi_0)\,\theta(-i)-\xi_1\Bigg)|M),$$

$$i\in\mathbf{Z}, \tag{21}$$

$$\rho(c)|M)=(\xi_0-\xi_1)|M). \tag{22}$$

Above and throughout $[x]=(q^x-q^{-x})/(q-q^{-1})\in\mathbf{C}[[h]]$. If a pattern from the right-hand side of (20) does not belong to $\Gamma(\{M\})$, i.e., it is not a C pattern, then the corresponding term has to be deleted. (The coefficients in front of all such patterns are undefined; they contain zero multiples in the denominators. Therefore an equivalent statement is that all terms with zeros in the denominators have to be removed.) With this convention all coefficients in front of the C patterns on the rhs of (19)–(22) are well defined as elements from $\mathbf{C}[[h]]$.

Proposition 1: The endomorphisms $\{\rho(e_i),\rho(f_i),\rho(h_i),\rho(c)\}_{i\in\mathbf{Z}}$ *satisfy Eqs. (3)–(5) with* $\rho(e_i)$, $\rho(f_i)$, $\rho(h_i)$, *and* $\rho(c)$ *substituted for* e_i, f_i, h_i, *and* c, *respectively.*

The proof is based on a direct verification of the relations (3)–(5). The most difficult to check is the Cartan relation (3e). In order to show that it holds, one has to prove as an intermediate step that the following identities hold ($k\in\mathbf{N}$):

$$\sum_{s=0}^{1}\sum_{j=1-k}^{k-1}\sum_{l=-k}^{k-1}(-1)^s\frac{\Pi_{i\neq l=-k}^{k-1}[L_{i,2k}-L_{j,2k-1}+s-1]\Pi_{i=1-k}^{k-2}[L_{i,2k-2}-L_{j,2k-1}+s-1]}{\Pi_{i\neq j=1-k}^{k-1}[L_{i,2k-1}-L_{j,2k-1}+s][L_{i,2k-1}-L_{j,2k-1}+s-1]}$$
$$\times\frac{\Pi_{i=-k}^{k}[L_{i,2k+1}-L_{l,2k}+s]\Pi_{i\neq j=1-k}^{k-1}[L_{i,2k-1}-L_{l,2k}+s]}{\Pi_{i\neq l=-k}^{k-1}[L_{i,2k}-L_{l,2k}+s][L_{i,2k}-L_{l,2k}+s-1]}$$
$$=\left[\sum_{j=-k+1}^{k-1}L_{j,2k-1}-\sum_{j=-k+1}^{k-2}L_{j,2k-2}-\sum_{j=-k}^{k}L_{j,2k+1}+\sum_{j=-k}^{k-1}L_{j,2k}-1\right], \tag{23a}$$

$$\sum_{s=0}^{1}\sum_{j=-k}^{k-1}\sum_{l=-k}^{k}(-1)^s\frac{\Pi_{i\neq l=-k}^{k}[L_{i,2k+1}-L_{j,2k}-s+1]\Pi_{i=1-k}^{k-1}[L_{i,2k-1}-L_{j,2k}-s+1]}{\Pi_{i\neq j=-k}^{k-1}[L_{i,2k}-L_{j,2k}-s][L_{i,2k}-L_{j,2k}-s+1]}$$
$$\times\frac{\Pi_{i=-k-1}^{k}[L_{i,2k+2}-L_{l,2k+1}-s]\Pi_{i\neq j=-k}^{k-1}[L_{i,2k}-L_{l,2k+1}-s]}{\Pi_{i\neq l=-k}^{k}[L_{i,2k+1}-L_{l,2k+1}-s][L_{i,2k+1}-L_{l,2k+1}-s+1]}$$
$$=\left[\sum_{j=-k-1}^{k}L_{j,2k+2}-\sum_{j=-k}^{k}L_{j,2k+1}-\sum_{j=-k}^{k-1}L_{j,2k}+\sum_{j=-k+1}^{k-1}L_{j,2k-1}-1\right], \tag{23b}$$

$$\sum_{s=0}^{1}\sum_{l=-k}^{k-1}(-1)^s\frac{\Pi_{i=-k}^{k}[L_{i,2k+1}-L_{l,2k}+s]\Pi_{i=1-k;i\neq j,m}^{k-1}[L_{i,2k-1}-L_{l,2k}+s]}{\Pi_{i\neq l=-k}^{k-1}[L_{i,2k}-L_{l,2k}+s][L_{i,2k}-L_{l,2k}+s-1]}=0, \tag{24a}$$

$$\sum_{s'=0}^{1}\sum_{l=-k}^{k}(-1)^{s'}\frac{\Pi_{i=-k-1}^{k}[L_{i,2k+2}-L_{l,2k+1}-s']\Pi_{i=-k;i\neq j,m}^{k-1}[L_{i,2k}-L_{l,2k+1}-s']}{\Pi_{i\neq l=-k}^{k}[L_{i,2k+1}-L_{l,2k+1}-s'][L_{i,2k+1}-L_{l,2k+1}-s'+1]}=0, \tag{24b}$$

$$\sum_{s'=0}^{1}\sum_{j=1-k}^{k-1}(-1)^{s'}\frac{\Pi_{r=1-k}^{k-2}[L_{r,2k-2}-L_{j,2k-1}-s']\Pi_{r=-k;r\neq l,q}^{k-1}[L_{r,2k}-L_{j,2k-1}-s']}{\Pi_{r\neq j=1-k}^{k-1}[L_{r,2k-1}-L_{j,2k-1}-s'][L_{r,2k-1}-L_{j,2k-1}-s'+1]}=0, \tag{24c}$$

$$\sum_{s=0}^{1}\sum_{j=-k}^{k-1}(-1)^s\frac{\Pi_{i=-k;i\neq l,q}^{k}[L_{i,2k+1}-L_{j,2k}+s]\Pi_{i=1-k}^{k-1}[L_{i,2k-1}-L_{j,2k}+s]}{\Pi_{i\neq j=-k}^{k-1}[L_{i,2k}-L_{j,2k}+s][L_{i,2k}-L_{j,2k}+s-1]}=0. \tag{24d}$$

The identities (24) are relevant also for the proof of the Serre relations (4a) and (5a). Another set of simpler identities, namely,

$$([a-b-1][c-b-1]-[2][a-b]][c-b-1]+[a-b][c-b])\left(\frac{[a-d][c-e-1]}{[d-e-1][c-a-1]}\right.$$

$$\left.+\frac{[c-d-1][a-e]}{[d-e+1][c-a-1]}\right)+\left(\frac{[a-e-1][c-d]}{[d-e-1][c-a+1]}+\frac{[a-d-1][c-e]}{[d-e+1][c-a+1]}\right)([a-b-1]$$

$$\times[c-b-1]-[2][a-b-1][c-b]+[a-b][c-b])=0, \tag{25}$$

$$\frac{[a-1][b-1]-[2][a][b-1]+[a][b]}{[a-b+1]}+\frac{[a-1][b-1]-[2][a-1][b]+[a][b]}{[a-b-1]}=0, \tag{26}$$

$$[a-1]-[2][a]+[a+1]=0. \tag{27}$$

are used in the proof of the Serre relations (4b), (4c), (5b), and (5c).

The proof is lengthy. The main steps of it are outlined in the Appendix. There we prove also the identities (23) and (24), which, we believe, are of independent interest. The approach is similar to the one used in Ref. 19, where a method for proving such q identities was first considered.

Remark: We may have constructed the endomorphisms $\{\rho(e_i),\rho(f_i),\rho(h_i),\rho(c)\}_{i\in\mathbf{Z}}$ from the results on the representations of $\mathrm{U}_h(gl_\infty)$, announced in Ref. 21, and, more precisely, from the endomorphisms $\{\rho(E_i),\rho(F_i),\rho(H_i)\}_{i\in\mathbf{Z}}$ of the $\mathbf{C}[[h]]$ module $V(\{M\})$, which satisfy the Cartan and the Serre relations for $\mathrm{U}_h(gl_\infty)$ [Ref. 21, Eqs. (16)–(18)]. This possibility is based on the observation that the $C[[h]]$ linear map φ, defined on the generators as

$$\begin{gathered}\varphi(E_i)=e_i, \quad \varphi(F_i)=f_i, \quad \varphi(c)=c,\\ \varphi(H_i)=h_i+(\theta(-i)+\alpha)c, \quad \alpha\in\mathbf{C}[h],\end{gathered} \tag{28}$$

and extended by associativity is an (algebra) isomorphism of $\mathrm{U}_h(gl_\infty)\oplus\mathbf{C}[[h]]c$ onto $\mathrm{U}_h(a_\infty)$. Then the endomorphisms $\{\rho(e_i),\rho(f_i),\rho(h_i),\rho(c)\}_{i\in\mathbf{Z}}$ defined according to (28) [with $\alpha(\xi_0-\xi_1)=\xi_1$] as

$$\begin{gathered}\rho(e_i)=\rho(E_i), \quad \rho(f_i)=\rho(F_i), \quad \rho(c)=\xi_0-\xi_1,\\ \rho(h_i)=\rho(H_i)-((\xi_0-\xi_1)\theta(-i)+\xi_1),\end{gathered} \tag{29}$$

lead to the transformation relations (19)–(22). Here we give a direct proof of *Proposition 1*, since the corresponding *Proposition 1* in Ref. 21 was only stated. Its proof would have been based again on the identities (23)–(27).

Consider ρ as a $\mathbf{C}[[h]]$ linear operator from $\mathrm{U}_h(a_\infty)$ into End $V(\{M\};\xi_0,\xi_1)$. So far ρ is defined only on the Chevalley generators $\{e_i,f_i,h_i,c\}_{i\in\mathbf{Z}}$. Extend the domain of its definition on $\hat{\mathrm{U}}_h(a_\infty)$: if ρ has already been defined on $a,b\in\hat{\mathrm{U}}_h(a_\infty)$, then set

$$\rho(\alpha a+\beta b)=\alpha\rho(a)+\beta\rho(b), \quad \rho(ab)=\rho(a)\rho(b), \quad a,b\in\hat{\mathrm{U}}_h(a_\infty), \quad \alpha,\beta\in\mathbf{C}[[h]]. \tag{30}$$

As we know from (10), any element $u\in\mathrm{U}_h(a_\infty)$ can be represented as a sum $u=\Sigma_{i=0}^{\infty}u_ih^i$, $u_i\in\hat{\mathrm{U}}_h(a_\infty)$. Then for an arbitrary $v\in V(\{M\};\xi_0,\xi_1)$, writing it as in (14), we have

$$\left(\sum_{i=0}^{\infty}\rho(u_i)h^i\right)v=\left(\sum_{i=0}^{\infty}\rho(u_i)h^i\right)\left(\sum_{j=0}^{\infty}v_jh^j\right)=\sum_{n=0}^{\infty}\left(\sum_{m=0}^{n}\rho(u_{n-m})v_m\right)h^n\in V(\{M\};\xi_0,\xi_1), \tag{31}$$

since

$$\sum_{m=0}^{n}\rho(u_{n-m})v_m\in\hat{V}(\{M\};\xi_0,\xi_1).$$

Using (31), we extend ρ on $U_h(a_\infty)$:

$$\rho(u)=\sum_{i=0}^{\infty}\rho(u_i)h^i\in \text{End } V(\{M\};\xi_0,\xi_1) \quad \forall u\in \mathrm{U}_h(a_\infty). \tag{32}$$

Hence ρ is a well-defined map from $\mathrm{U}_h(a_\infty)$ into End $V(\{M\};\xi_0,\xi_1)$,

$$\rho:\mathrm{U}_h(a_\infty)\to \text{End } V(\{M\};\xi_0,\xi_1). \tag{33}$$

Proposition 2: The map (33), acting on the C basis according to Eqs. (19)–(22), defines a highest-weight irreducible representation of $\mathrm{U}_h(a_\infty)$ *in* $V(\{M\};\xi_0,\xi_1)$).

Proof: According to *Proposition 1*, (30), and (32), ρ is a $\mathbf{C}[[h]]$ homomorphism of $\mathrm{U}_h(a_\infty)$ in End $V(\{M\};\xi_0,\xi_1)$. It is continuous in the h-adic topology. Indeed, let $u\in \mathrm{U}_h(a_\infty)$. Then any neighborhood $W(\rho(u))$ of $\rho(u)$ contains a basic neighborhood $\rho(u)+h^n$ End $V(\{M\};\xi_0,\xi_1)\subset W(\rho(u))$. Evidently

$$\rho(u+h^n\mathrm{U}_h(a_\infty))\subset\rho(u)+h^n \text{ End } V(\{M\};\xi_0,\xi_1)\subset W(\rho(u)) \tag{34}$$

and therefore ρ is continuous in u for any $u\in \mathrm{U}_h(a_\infty)$. Hence $V(\{M\};\xi_0,\xi_1)$ is a $\mathrm{U}_h(a_\infty)$ module. It is a highest-weight module with respect to the ''Borel'' subalgebra $\mathrm{U}_h(n_+)$. The highest-weight vector $|\hat{M})$, which by definition satisfies the condition $\rho(\mathrm{U}_h(n_+))|\hat{M})=0$ and is an eigenvector of $\rho(H)$, corresponds to the one from (11) with

$$\hat{M}_{i,2k+\theta-1}=M_i, \quad \forall k\in\mathbf{N}, \quad \theta=0,1, \quad i\in[-\theta-k+1;k-1]. \tag{35}$$

The irreducibility of the $\mathrm{U}_h(a_\infty)$ module $V(\{M\};\xi_0,\xi_1)$ follows from the statement that $V(\{M\};\xi_0,\xi_1)$ is an irreducible module also of the non-deformed algebra $\mathrm{U}(A_\infty)$.[15] Let x and y be any two nonzero vectors from $V(\{M\};\xi_0,\xi_1)$. Then there exists a polynomial P of the non-deformed generators such that

$$\rho(P)x=cy, \quad 0\neq c\in\mathbf{C}. \tag{36}$$

Let $\hat{P}$ be the same polynomial, but of the deformed generators. From the non-deformed transformation relations {see Ref. 15, or simply replace the ''quantum'' brackets [ ] with ordinary brackets throughout in Eqs. (19)–(22)} one concludes that $\rho(\hat{P})x=\hat{c}y$, where

$$\hat{c}=c+d, \quad d\in h\mathbf{C}[[h]]. \tag{37}$$

Since $c\neq 0$, then also $\hat{c}\neq 0$. Therefore the representation of $\mathrm{U}_h(a_\infty)$ in $V(\{M\},\xi_0,\xi_1)$ is irreducible.

III. REPRESENTATIONS OF THE ALGEBRA $\mathrm{U}_h(A_\infty)$

In this section we show that some of the $\mathrm{U}_h(a_\infty)$ modules $V(\{M\};\xi_0,\xi_1)$ can be turned into irreducible highest-weight $\mathrm{U}_h(A_\infty)$ modules. First, following Ref. 1, we recall the definition of the quantum algebra $\mathrm{U}_h(A_\infty)$ [denoted by the authors as $\mathrm{U}_h(g'(A_\infty))$] only within the algebra sector (for the other Hopf algebra maps see Ref. 1). $\mathrm{U}_h(A_\infty)$ consists of all elements

$$u=\sum_{k=0}^{\infty}h^k\sum_{l=0}^{l(k)}c^l\sum_{\alpha,\beta\in Q'_+}\sum_{\gamma(k,l)\in\mathbf{Z}_+^\infty}\sum_{t=1}^{t(\alpha,\beta)}\mathscr{F}_{\alpha,k,l,t}\prod_{i\in\mathbf{Z}}h_i^{\gamma(k,l)_i}\mathscr{E}_{\beta,k,l,t}, \quad \text{infinite sums over } \alpha,\beta,\gamma, \tag{38}$$

however certain conditions on the pairs (α,γ) corresponding to the nonzero summands are imposed. In order to state them, set for $\alpha=\Sigma_i m_i\alpha_i\in\mathbf{Q}'_+$, $\gamma=\{\gamma_i\}_{i\in\mathbf{Z}}\in\mathbf{Z}_+^\infty$,

$$S(\alpha)=\{i|m_i\neq 0\}, \quad S(\gamma)=\{i|\gamma_i\neq 0\}, \quad S(\alpha,\gamma)=S(\alpha)\cup S(\gamma). \tag{39}$$

Connecting i and j with a line, if $|i-j|=1$, one can view $S(\alpha,\gamma)$ as a graph. Denote by $\mathscr{T}(\alpha,\gamma)$ the collection of its connected components. For any $u=\Sigma_{k=0}^{\infty}h^k u_k$ as given in (38) consider the series

$$u_k=\sum_{l=0}^{l(k)} c^l \sum_{\alpha,\beta\in Q'_+} \sum_{\gamma(k,l)\in \mathbf{Z}_+^\infty} \sum_{t=1}^{t(\alpha,\beta)} \mathscr{T}_{\alpha,k,l,t}\prod_{i\in\mathbf{Z}} h_i^{\gamma(k,l)_i}\mathscr{E}_{\beta,k,l,t}, \tag{40}$$

and let

$$\mathscr{F}(u,k)=\cup\mathscr{F}(\alpha,\gamma), \tag{41}$$

where the union is taken over all α and γ, which appear in the nonzero summands of (40). For $i\in\mathbf{Z}$ and $k\in\mathbf{Z}_+$ set

$$\text{Int}\,(u,k,i)=\{I\in\mathscr{F}(u,k)|\, i\in I\}. \tag{42}$$

For $r\in\mathbf{N}$ define the series $u(r)$, corresponding to u, by substituting 0 for all h_i ($i\leqslant -r$ or $i>r$) and for all e_i, f_i ($|i|\geqslant r$).

Definition 1:[1] *The series u of the form (38) is said to belong to* $\mathrm{U}_h(A_\infty)$, *provided*

(i) *for any* $k\in\mathbf{Z}_+$ *and any* $i\in\mathbf{Z}$ *the set* Int (u,k,i) *is finite*;

(ii) $u(r)\in\mathrm{U}_h(a_\infty)$ *for all* $r\in\mathbf{N}$.

We turn to construct a class of representations of $\mathrm{U}_h(A_\infty)$. The idea is to show that within certain $V(\{M\};\xi_0,\xi_1)$ the domain of the definition of the operator ρ: $\mathrm{U}_h(a_\infty)\to\text{End}\,V(\{M\};\xi_0,\xi_1)$ [see (33)] can be extended from $\mathrm{U}_h(a_\infty)$ to $\mathrm{U}_h(A_\infty)$, so that ρ is a representation of $\mathrm{U}_h(A_\infty)$ in $V(\{M\};\xi_0,\xi_1)$. The construction is a natural one. We assume that $\rho(u)$ is a continuous $\mathbf{C}[[h]]$ linear operator in $V(\{M\};\xi_0,\xi_1)$ for any $u\in\mathrm{U}_h(A_\infty)$. Then for any $v=\Sigma_{j=0}^\infty v_j h^j\in V(\{M\};\xi_0,\xi_1)$, $v_j\in\hat{V}(\{M\};\xi_0,\xi_1)$

$$\rho(u)v=\sum_{j=0}^{\infty}(\rho(u)v_j)h^j. \tag{43}$$

The above series is well defined, if $\rho(u)v_j\in V(\{M\};\xi_0,\xi_1)$. Since v_j is a (finite) $\mathbf{C}[[h]]$ linear combination of C basis vectors the latter holds, and hence $\rho(u)$ is defined as an operator in $V(\{M\};\xi_0,\xi_1)$, if $\rho(u)|M)\in V(\{M\};\xi_0,\xi_1)$ for any C pattern $|M)$. Thus, the first step is to clarify which are the $\mathrm{U}_h(a_\infty)$ modules $V(\{M\};\xi_0,\xi_1)$, for which $\rho(u)|M)\in V(\{M\};\xi_0,\xi_1)$ holds.

Definition 2: We say that $V(\{M\};\xi_0,\xi_1)$ *is of finite signature or, more precisely, of (m,n) signature and write* $\{M\}=\{M\}_{m,n}$ *if there exist integers* $m\leqslant n\in\mathbf{Z}$, *such that* $M_m=M_{m-k}$ *and* $M_n=M_{n+k}$ *for all* $k\in\mathbf{N}$.

We now proceed to show that each finite signature $\mathrm{U}_h(a_\infty)$ module $V(\{M\}_{m,n};M_m,M_n)$ can be turned into a $\mathrm{U}_h(A_\infty)$ module. To this end we prove first a few preliminary propositions.

Denote by $V(\{M\};\xi_0,\xi_1)_N$, $1<N\in\mathbf{N}$, the subspace of $V(\{M\};\xi_0,\xi_1)$, which is a $\mathbf{C}[[h]]$ linear envelope of all C basis vectors $|M)$, for which

$$M_{i,2k+\theta-1}=M_i \quad \forall 2k+\theta-1\geqslant N, \quad \theta=0,1, \quad i\in[1-\theta-k;k-1]. \tag{44}$$

Note that $V(\{M\};\xi_0,\xi_1)_N$ is a finite-dimensional subspace.

Proposition 3:

$$\rho(e_k)V(\{M\};\xi_0,\xi_1)_N=0, \quad \text{if } k\notin(-\tfrac{1}{2}(N+1);\tfrac{1}{2}(N-2)). \tag{45}$$

Proof: From (20) one obtains

$$\begin{aligned}\rho(e_k)|M)=&-\sum_{j=-k}^{k}\sum_{l=-k-1}^{k} S(j,l;0)\\ &\times\left|\frac{\Pi_{i\neq l=-k-1}^{k}[L_{i,2k+2}-L_{j,2k+1}-1]\Pi_{i=-k}^{k-1}[L_{i,2k}-L_{j,2k+1}-1]}{\Pi_{i\neq j=-k}^{k}[L_{i,2k+1}-L_{j,2k+1}][L_{i,2k+1}-L_{j,2k+1}-1]}\right|^{1/2}\\ &\times\left|\frac{\Pi_{i=-k-1}^{k+1}[L_{i,2k+3}-L_{l,2k+2}]\Pi_{i\neq j=-k}^{k}[L_{i,2k+1}-L_{l,2k+2}]}{\Pi_{i\neq l=-k-1}^{k}[L_{i,2k+2}-L_{l,2k+2}][L_{i,2k+2}-L_{l,2k+2}-1]}\right|^{1/2}|M)^{\{l,2k+2\}}_{\{j,2k+1\}}, \quad k\geqslant 0,\end{aligned} \tag{46}$$

$$\rho(e_{-k})|M)=-\sum_{j=-k+1}^{k-2}\sum_{l=-k+1}^{k-1}S(j,l;1)\times\left|\frac{\Pi_{i\neq l=-k+1}^{k-1}[L_{i,2k-1}-L_{j,2k-2}+1]\Pi_{i=2-k}^{k-2}[L_{i,2k-3}-L_{j,2k-2}+1]}{\Pi_{i\neq j=-k+1}^{k-2}[L_{i,2k-2}-L_{j,2k-2}][L_{i,2k-2}-L_{j,2k-2}+1]}\right|^{1/2}\times\left|\frac{\Pi_{i=-k}^{k-1}[L_{i,2k}-L_{l,2k-1}]\Pi_{i\neq j=-k+1}^{k-2}[L_{i,2k-2}-L_{l,2k-1}]}{\Pi_{i\neq l=-k+1}^{k-1}[L_{i,2k-1}-L_{l,2k-1}][L_{i,2k-1}-L_{l,2k-1}+1]}\right|^{1/2}|M)_{-\{j,2k-2\}}^{-\{l,2k-1\}},\quad k>1. \tag{47}$$

If $|M)\in V(\{M\};\xi_0,\xi_1)_N$ and

$$\begin{aligned}&\text{if } k\geqslant\tfrac{1}{2}(N-2),\quad \text{then } L_{i,2k+3}=L_{i,2k+2}=L_i=M_i-i,\\&\text{if } k\leqslant-\tfrac{1}{2}(N+1),\quad \text{then } L_{i,2k-1}=L_{i,2k}=L_i=M_i-i.\end{aligned} \tag{48}$$

In both cases the rhs of (46) and (47) contain zero multiples (L_l-L_l) and therefore vanish.

Proposition 4:

$$\rho(f_k)V(\{M\}_{m,n};M_m,M_n)_N=0,\quad \text{if } k\notin(\min\{-\tfrac{1}{2}(N+3),m-1\};\max\{\tfrac{1}{2}N,n\}). \tag{49}$$

Proof: Let $|M)\in V(\{M\}_{m,n};M_m,M_n)_N$. The relations that follow from (20) in this case are

$$\rho(f_k)|M)=-\sum_{j=-k}^{k}\sum_{l=-k-1}^{k}S(j,l;0)\left|\frac{\Pi_{i\neq l=-k-1}^{k}[L_{i,2k+2}-L_{j,2k+1}]\Pi_{i=-k}^{k-1}[L_{i,2k}-L_{j,2k+1}]}{\Pi_{i\neq j=-k}^{k}[L_{i,2k+1}-L_{j,2k+1}][L_{i,2k+1}-L_{j,2k+1}+1]}\right|^{1/2}\times\left|\frac{\Pi_{i=-k-1}^{k+1}[L_{i,2k+3}-L_{l,2k+2}+1]\Pi_{i\neq j=-k}^{k}[L_{i,2k+1}-L_{l,2k+2}+1]}{\Pi_{i\neq l=-k-1}^{k}[L_{i,2k+2}-L_{l,2k+2}][L_{i,2k+2}-L_{l,2k+2}+1]}\right|^{1/2}\times|M)_{-\{j,2k+1\}}^{-\{l,2k+2\}},\quad k\in\mathbf{Z}_+, \tag{50}$$

$$\rho(f_{-k})|M)=-\sum_{j=-k+1}^{k-2}\sum_{l=-k+1}^{k-1}S(j,l;1)\times\left|\frac{\Pi_{i\neq l=-k+1}^{k-1}[L_{i,2k-1}-L_{j,2k-2}]\Pi_{i=2-k}^{k-2}[L_{i,2k-3}-L_{j,2k-2}]}{\Pi_{i\neq j=-k+1}^{k-2}[L_{i,2k-2}-L_{j,2k-2}][L_{i,2k-2}-L_{j,2k-2}-1]}\right|^{1/2}\times\left|\frac{\Pi_{i=-k}^{k-1}[L_{i,2k}-L_{l,2k-1}-1]\Pi_{i\neq j=-k+1}^{k-2}[L_{i,2k-2}-L_{l,2k-1}-1]}{\Pi_{i\neq l=-k+1}^{k-1}[L_{i,2k-1}-L_{l,2k-1}][L_{i,2k-1}-L_{l,2k-1}-1]}\right|^{1/2}\times|M)_{\{j,2k-2\}}^{\{l,2k-1\}},\quad k>1. \tag{51}$$

If $k\geqslant N/2$, then $L_{i,2k+3}=L_{i,2k+2}=L_{i,2k+1}=L_{i,2k}=L_i=M_i-i$ and therefore (50) reads

$$\rho(f_k)|M)=-\sum_{j=-k}^{k}\sum_{l=-k-1}^{k}S(j,l;0)\left|\frac{\Pi_{i\neq l=-k-1}^{k}[L_i-L_j]\Pi_{i=-k}^{k-1}[L_i-L_j]}{\Pi_{i\neq j=-k}^{k}[L_i-L_j][L_i-L_j+1]}\right|^{1/2}\times\left|\frac{\Pi_{i=-k-1}^{k+1}[L_i-L_l+1]\Pi_{i\neq j=-k}^{k}[L_i-L_l+1]}{\Pi_{i\neq l=-k-1}^{k}[L_i-L_l][L_i-L_l+1]}\right|^{1/2}|M)_{-\{j,2k+1\}}^{-\{l,2k+2\}}.$$

Above only the term with $j=k$ survives:

$$\rho(f_k)|M\rangle = -\sum_{l=-k-1}^{k} S(k,l;0)\left|\frac{\Pi_{i\neq l=-k-1}^{k}[L_i-L_k]\Pi_{i=-k}^{k-1}[L_i-L_k]}{\Pi_{i=-k}^{k-1}[L_i-L_k][L_i-L_k+1]}\right|^{1/2}$$
$$\times\left|\frac{\Pi_{i=-k-1}^{k+1}[L_i-L_l+1]\Pi_{i=-k}^{k-1}[L_i-L_l+1]}{\Pi_{i\neq l=-k-1}^{k}[L_i-L_l][L_i-L_l+1]}\right|^{1/2}|M\rangle_{-\{k,2k+1\}}^{-\{l,2k+2\}}$$
$$= -S(k,k;0)$$
$$\times\left|\frac{\Pi_{i=-k-1}^{k-1}[L_i-L_k]\Pi_{i=-k-1}^{k+1}[L_i-L_k+1]\Pi_{i=-k}^{k-1}[L_i-L_k+1]}{\Pi_{i=-k}^{k-1}[L_i-L_k+1]\Pi_{i=-k-1}^{k-1}[L_i-L_k][L_i-L_k+1]}\right|^{1/2}|M\rangle_{-\{k,2k+1\}}^{-\{k,2k+2\}}$$
$$-\sum_{l=-k-1}^{k-1} S(k,l;0)$$
$$\times\left|\frac{\Pi_{i\neq l=-k-1}^{k}[L_i-L_k]\Pi_{i=-k-1}^{k+1}[L_i-L_l+1]\Pi_{i=-k}^{k-1}[L_i-L_l+1]}{\Pi_{i=-k}^{k-1}[L_i-L_k+1]\Pi_{i\neq l=-k-1}^{k}[L_i-L_l][L_i-L_l+1]}\right|^{1/2}|M\rangle_{-\{k,2k+1\}}^{-\{l,2k+2\}}.$$

In the last term $l\neq k$. Hence

$$\prod_{i\neq l=-k-1}^{k}[L_i-L_k]=[L_k-L_k]\prod_{i\neq l=-k-1}^{k-1}[L_i-L_k]=0$$

and therefore it vanishes. Then

$$\rho(f_k)|M\rangle = -\left|\frac{\Pi_{i=-k-1}^{k+1}[L_i-L_k+1]}{\Pi_{i=-k-1}^{k-1}[L_i-L_k+1]}\right|^{1/2}|M\rangle_{-\{k,2k+1\}}^{-\{k,2k+2\}} = -|[L_{k+1}-L_k+1]|^{1/2}|M\rangle_{-\{k,2k+1\}}^{-\{k,2k+2\}},$$

i.e.,

$$\rho(f_k)|M\rangle = -|[M_{k+1}-M_k]|^{1/2}|M\rangle_{-\{k,2k+1\}}^{-\{k,2k+2\}}. \tag{52}$$

If $k\geqslant n$, then $M_{k+1}=M_k$ and $\rho(f_k)|M\rangle=0$. In a similar way one derives from (51) that $\rho(f_k)|M\rangle=0$ if $k\leqslant\min\{-\frac{1}{2}(N+3),m-1\}$, which proves (49). □

Proposition 5:

$$\rho(h_k)V(\{M\}_{m,n};M_m,M_n)_N=0, \quad \text{if } k\notin(\min\{-\tfrac{1}{2}(N+1),m\};\max\{\tfrac{1}{2}N,n\}). \tag{53}$$

The proof follows easily from (21).

Set

$$r_N=\max\{\tfrac{1}{2}(N+3),1-m,n\}. \tag{54}$$

From the last three propositions one concludes the following.

Corollary 1: If $k\notin(-r_N;r_N)$, then

$$\rho(h_k)V(\{M\}_{m,n};M_m,M_n)_N=\rho(e_k)V(\{M\}_{m,n};M_m,M_n)_N=\rho(f_k)V(\{M\}_{m,n};M_m,M_n)_N=0. \tag{55}$$

Proposition 6: $\rho(\mathrm{U}_h(n_+)_\beta)V(\{M\};\xi_0,\xi_1)_N\subset V(\{M\};\xi_0,\xi_1)_N$ for any $N\in\mathbf{N}$. More precisely,

$$\text{if } S(\beta)\subset\left(-\frac{(N+1)}{2};\frac{(N-2)}{2}\right)\equiv I_N, \text{ then } \rho(U_h(n_+)_{+\beta})V(\{M\};\xi_0,\xi_1)_N\subset V(\{M\};\xi_0,\xi_1)_N. \tag{56}$$

$$\text{If } S(\beta)\not\subset I_N, \text{ then } \rho(\mathrm{U}_h(n_+)_\beta)V(\{M\};\xi_0,\xi_1)_N=0. \tag{57}$$

Proof: From (20) [or directly from (46) and (47)] one concludes that

$$\rho(e_j)|M\rangle \in V(\{M\};\xi_0,\xi_1)_N, \quad \forall j \in \left(-\frac{(N+1)}{2};\frac{(N-2)}{2}\right) \quad \text{and} \quad \forall |M\rangle \in V(\{M\};\xi_0,\xi_1)_N. \tag{58}$$

Hence (56) holds.

Assume $S(\beta) \not\subset I_N$ and let P_β be a monomial of the generators e_i, $i \in S(\beta)$. P_β can be represented as $P_\beta = Q' e_n Q$, where Q depends only on the generators e_j with $j \in S(\beta) \cap I_N$ and $n \notin I_N$. Then (58) yields that $\rho(Q)|M\rangle \in V(\{M\};\xi_0,\xi_1)_N$ and therefore (*Proposition 3*) $\rho(P_\beta)|M\rangle = \rho(Q')\rho(e_n)\rho(Q)|M\rangle = 0$. □

Proposition 7: Let u be any element from $\mathrm{U}_h(A_\infty)$*, represented as in (38). Then*

$$\sum_{k=0}^{\infty} h^k \sum_{l=0}^{l(k)} \rho(c)^l \sum_{\alpha,\beta \in Q'_+} \sum_{\gamma(k,l) \in \mathbf{Z}_+^\infty} \sum_{t=1}^{t(\alpha,\beta)} \rho(\mathscr{T}_{\alpha,k,l,t}) \prod_{i \in \mathbf{Z}} \rho(h_i)^{\gamma(k,l)_i} \rho(\mathscr{E}_{\beta,k,l,t})|M\rangle$$
$$\in V(\{M\}_{m,n};M_m,M_n) \tag{59}$$

for any $|M\rangle$ *from the basis* $\Gamma(\{M\})$ *of* $V(\{M\}_{m,n};M_m,M_n)$*. For a fixed k the number of the nonzero summands in (59) is finite.*

Proof: In order to prove the proposition it suffices to show that

$$\sum_{\alpha,\beta \in Q'_+} \sum_{\gamma(k,l) \in \mathbf{Z}_+^\infty} \sum_{t=1}^{t(\alpha,\beta)} \rho(\mathscr{T}_{\alpha,k,l,t}) \prod_{i \in \mathbf{Z}} \rho(h_i)^{\gamma(k,l)_i} \rho(\mathscr{E}_{\beta,k,l,t})|M\rangle \in \hat{V}(\{M\}_{m,n};M_m,M_n). \tag{60}$$

Assume that $|M\rangle \in V(\{M\}_{m,n};M_m,M_n)_N$ and let β_0 be the weight of $|M\rangle$. Since $\mathscr{E}_{\beta,k,l,t} \in U_h(n_+)_\beta$, $\rho(\mathscr{E}_{\beta,k,l,t})|M\rangle \in V(\{M\}_{m,n};M_m,M_n)_N$ *(Proposition 6).* Each $\rho(\mathscr{E}_{\beta,k,l,t})|M\rangle$ has a weight $\beta+\beta_0$ and the nonzero vectors $\rho(\mathscr{E}_{\beta,k,l,t})|M\rangle$, corresponding to different $\beta \in \mathbf{Q}'_+$, are linearly independent (over $\mathbf{C}[[h]]$). Since $V(\{M\}_{m,n};M_m,M_n)_N$ is a finite-dimensional subspace, $\rho(\mathscr{E}_{\beta,k,l,t})|M\rangle \neq 0$ only for a finite number of $\beta \in \mathbf{Q}'_+$. Hence the sum over β in (60) is finite. Setting $\rho(\mathscr{E}_{\beta,k,l,t})|M\rangle = v_{\beta,k,l,t} \in \hat{V}(\{M\}_{m,n};M_m,M_n)_N$, we obtain for the lhs of (60)

$$\sum_{\alpha,\beta \in Q'_+} \sum_{\gamma(k,l) \in \mathbf{Z}_+^\infty} \sum_{t=1}^{t(\alpha,\beta)} \rho(\mathscr{T}_{\alpha,k,l,t}) \prod_{i \in \mathbf{Z}} \rho(h_i)^{\gamma(k,l)_i} v_{\beta,k,l,t}. \tag{61}$$

We proceed to show that the sum over α and γ in (61) is finite, too. Without loss of generality we assume that every $\mathscr{T}_{\alpha,k,l,t} \Pi_{i \in \mathbf{Z}} h_i^{\gamma(k,l)i}$ is a monomial of $\{f_i,h_i\}_{i \in \mathbf{Z}}$. Consider any term from (61), corresponding to a particular pair (α,γ):

$$\rho(\mathscr{T}_{\alpha,k,l,t}) \prod_{i \in \mathbf{Z}_+} \rho(h_i)^{\gamma(k,l)_i} v_{\beta,k,l,t}. \tag{62}$$

Let $\mathscr{I}(\alpha,\gamma)$ be the connected components of $S(\alpha,\gamma)$:

$$\mathscr{I}(\alpha,\gamma) = \{I_{a_i,b_i} \equiv [a_i;b_i] | i = 1,2,...,n\}, \quad a_i \leqslant b_i \in \mathbf{Z}, \quad |a_i - b_j| > 1, \quad \text{if } i \neq j. \tag{63}$$

In (63) we do not distinguish between a connected component I_{a_i,b_i} (beginning in a_i and ending in b_i) and the corresponding finite integer interval $[a_i;b_i]$. Then

$$\mathscr{T}_{\alpha,k,l,t} \prod_{i \in \mathbf{Z}_+} (h_i)^{\gamma(k,l)_i} = \prod_{i=1}^{n} \mathscr{T}_i, \tag{64}$$

where $\mathscr{T}_i$ is a monomial of f_j,h_j, $j \in [a_i;b_i]$. From (3) and (5) it follows that the multiples $\mathscr{T}_i$ in (64) commute. If $[a_i;b_i] \subset (-\infty;-r_N]$ or $[a_i;b_i] \subset [r_N;\infty)$, then *Corollary 1* yields that $\rho(\mathscr{T}_i)v_{\beta,k,l,t} = 0$. Hence also $\rho(\mathscr{T}_{\alpha,k,l,t}) \Pi_{i \in \mathbf{Z}_+} \rho(h_i)^{\gamma(k,l)_i} v_{\beta,k,l,t} = 0$. Thus, the sum in (60) is over

such pairs (α,γ), for which all connected components of $S(\alpha,\gamma)$, namely the elements from $\mathscr{F}(\alpha,\gamma)$, have nonzero intersection with $(-r_N;r_N)$. There is only a finite number of pairs (α,γ) with this property, for which $\mathrm{Int}(u,k,i)$ is finite.

The conclusion is that the lhs of the series (60) contains a finite number of nonzero summands. Since the generators of $\mathrm{U}_h(A_\infty)$ [see (19)–(22)] transform $\hat{V}(\{M\}_{m,n};M_m,M_n)$ into itself, (60) holds. Hence (59) holds, too. □

Based on *Proposition 7,* we extend the domain of the operator ρ on $\mathrm{U}_h(A_\infty)$, setting for any $u\in \mathrm{U}_h(A_\infty)$ [see (38)]

$$\rho(u)=\sum_{k=0}^{\infty} h^k \sum_{l=0}^{l(k)} \rho(c)^l \sum_{\alpha,\beta\in Q'_+} \sum_{\gamma(k,l)\in \mathbf{Z}_+^\infty} \sum_{t=1}^{t(\alpha,\beta)} \rho(\mathscr{F}_{\alpha,k,l,t}) \prod_{i\in\mathbf{Z}} \rho(h_i)^{\gamma(k,l)_i} \rho(\mathscr{E}_{\beta,k,l,t})$$

$$\in \mathrm{End}\ V(\{M\}_{m,n};M_m,M_n). \tag{65}$$

The map ρ is a homomorphism of $\mathrm{U}_h(A_\infty)$ in $\mathrm{End}\ V(\{M\}_{m,n};M_m,M_n)$. It is continuous in the h-adic topology. Hence ρ defines a representation of $\mathrm{U}_h(A_\infty)$ in $V(\{M\}_{m,n};M_m,M_n)$, which is a highest-weight irreducible representation [since it is a highest weight irrep with respect to the subalgebra $U_h(a_\infty)$].

Let $v=\Sigma_{k\in\mathbf{Z}_+} h^k v_k$, $v_k\in\hat{V}(\{M\}_{m,n};M_m,M_n)$ be an arbitrary element from $V(\{M\}_{m,n};M_m,M_n)$. Since each v_k is a finite linear combination of C vectors, for any $k\in\mathbf{Z}_+$ there exists an integer $N_k>1$ such that $v_k\in V(\{M\}_{m,n};M_m,M_n)_{N_k}$. Then from (55) and (57) one concludes that the following properties hold:

$$(1)\quad \rho(\mathrm{U}_h(n_+)_\beta)v_k=0,\quad \text{if } S(\beta)\not\subset(-r_{N_k};r_{N_k}),$$

$$(2)\quad \rho(\mathrm{U}_h(n_-)_{-\alpha})v_k=0,\quad \text{if } S(\alpha)\subset(-\infty;-r_{N_k}] \text{ or } S(\alpha)\subset[r_{N_k};\infty),$$

$$(3)\quad \rho(h_i)v_k=0,\quad \text{if } |i|\geqslant r_{N_k}. \tag{66}$$

Therefore each finite-signature representation of $\mathrm{U}_h(A_\infty)$ in $V(\{M\}_{m,n};M_m,M_n)$ is a restricted representation (see *Definition 4.1* in Ref. 1).

Let us mention in conclusion that the $\mathrm{U}_h(a_\infty)$ modules $V(\{M\};\xi_0,\xi_1)$, which are not of a finite (m,n) signature and for which $\xi_0\neq M_m$, $\xi_1\neq M_n$, cannot be turned into $\mathrm{U}_h(A_\infty)$ modules. In order to see this consider the transformation of the highest-weight vector $|\hat{M})$ under the action of the operator $I=\Sigma_{i\in\mathbf{Z}}h_i\in\mathrm{U}_h(A_\infty)$. From (21) and (35) one obtains

$$\rho(I)|\hat{M})=\left(\sum_{i=-\infty}^{0}(M_i-\xi_0)+\sum_{i=1}^{\infty}(M_i-\xi_1)\right)|\hat{M}). \tag{67}$$

Only in the finite-signature modules $V(\{M\}_{m,n};M_m,M_n)$ is the rhs of (67) not divergent.

We were dealing with algebras and modules over $\mathbf{C}[[h]]$. The algebra $\mathrm{U}_h(A_\infty)$ is, however, well-defined also for h being a fixed complex number h_c, such that $h_c\notin i\pi\mathbf{Q}$, namely in the case $q=e^{h_c}$ is not a root of 1.[1] In that case the representations we have obtained remain highest-weight irreps of $\mathrm{U}_{h_c}(A_\infty)$ realized in infinite-dimensional complex linear spaces.

APPENDIX: PROOF OF PROPOSITION 1

Here we outline the main steps in the proof of Proposition 1.

(1) The equations

$$[\rho(c),\rho(a)]|M)=0, \quad a\in\{h_i,e_i,f_i\}_{i\in\mathbf{Z}}, \tag{A1}$$

$$[\rho(h_i),\rho(h_j)]|M)=0 \tag{A2}$$

are evident.

(2) The validity of

$$([\rho(h_i),\rho(e_j)]-(\delta_{ij}-\delta_{i,j+1})\rho(e_j))|M)=0, \tag{A3}$$

$$([\rho(h_i),\rho(f_j)]+(\delta_{ij}-\delta_{i,j+1})\rho(f_j))|M)=0 \tag{A4}$$

follows easily from (19)–(22).

(3) We proceed to show that

$$([\rho(e_i),\rho(f_i)]-[\rho(h_i)-\rho(h_{i+1})+(\theta(-i)-\theta(-i-1))\rho(c)])|M)=0, \quad i\in\mathbf{Z}. \tag{A5}$$

(3a) The case in (A5) with $i\in\mathbf{Z}_+$. Applying the transformation relations (20) and (21) and rearranging the terms in an appropriate way, we obtain

$$\begin{aligned}
&([\rho(e_{k-1}),\rho(f_{k-1})]-[\rho(h_{k-1})-\rho(h_k)+(\theta(-k+1)-\theta(-k))\rho(c)])|M)\\
&\quad=\mathscr{A}_{2k}|M)+\sum_{j=-k+1}^{k-1}\sum_{m=-k+1;m\neq j}^{k-1}\mathscr{B}_{2k,j,m}|M)^{\{m,2k-1\}}_{-\{j,2k-1\}}\\
&\qquad+\sum_{l=-k}^{k-1}\sum_{p=-k;p\neq l}^{k-1}\mathscr{C}_{2k-1,p,l}|M)^{\{p,2k\}}_{-\{l,2k\}}, \quad \forall k\in\mathbf{N},
\end{aligned} \tag{A6}$$

where

$$\begin{aligned}
\mathscr{A}_{2k}=&\sum_{s=0}^{1}\sum_{j=1-k}^{k-1}\sum_{l=-k}^{k-1}(-1)^s\frac{\Pi_{i\neq l=-k}^{k-1}[L_{i,2k}-L_{j,2k-1}+s-1]\Pi_{i=1-k}^{k-2}[L_{i,2k-2}-L_{j,2k-1}+s-1]}{\Pi_{i\neq j=1-k}^{k-1}[L_{i,2k-1}-L_{j,2k-1}+s][L_{i,2k-1}-L_{j,2k-1}+s-1]}\\
&\times\frac{\Pi_{i=-k}^{k}[L_{i,2k+1}-L_{l,2k}+s]\Pi_{i\neq j=1-k}^{k-1}[L_{i,2k-1}-L_{l,2k}+s]}{\Pi_{i\neq l=-k}^{k-1}[L_{i,2k}-L_{l,2k}+s][L_{i,2k}-L_{l,2k}+s-1]}\\
&-\left[\sum_{j=-k+1}^{k-1}L_{j,2k-1}-\sum_{j=-k+1}^{k-2}L_{j,2k-2}-\sum_{j=-k}^{k}L_{j,2k+1}+\sum_{j=-k}^{k-1}L_{j,2k}-1\right],
\end{aligned} \tag{A7}$$

$$\mathscr{B}_{2k,j,m}=-\sum_{s=0}^{1}\sum_{l=-k}^{k-1}(-1)^s\frac{\Pi_{i=-k}^{k}[L_{i,2k+1}-L_{l,2k}+s]\Pi_{i=1-k;i\neq j,m}^{k-1}[L_{i,2k-1}-L_{l,2k}+s]}{\Pi_{i\neq l=-k}^{k-1}[L_{i,2k}-L_{l,2k}+s][L_{i,2k}-L_{l,2k}+s-1]}, \tag{A8}$$

$$\mathscr{C}_{2k-1,p,l}=\sum_{s'=0}^{1}\sum_{j=1-k}^{k-1}(-1)^{s'}\frac{\Pi_{r=1-k}^{k-2}[L_{r,2k-2}-L_{j,2k-1}-s']\Pi_{r=-k;r\neq l,p}^{k-1}[L_{r,2k}-L_{j,2k-1}-s']}{\Pi_{r\neq j=1-k}^{k-1}[L_{r,2k-1}-L_{j,2k-1}-s'][L_{r,2k-1}-L_{j,2k-1}-s'+1]}. \tag{A9}$$

The rhs of (A6) does not contain all terms, which would appear immediately after applying the transformation relations (20) and (21). The terms, which cancel out in a straightforward way, have already been removed.

We proceed to show that $\mathscr{A}_{2k}=\mathscr{B}_{2k,j,m}=\mathscr{C}_{2k-1,p,l}=0$ or, which is the same, we prove the identities (23a), (24a), and (24c).

(1^0) We begin with $\mathscr{A}_{2k}=0$. Each such coefficient is a formal power series in h, $\mathscr{A}_{2k}=\Sigma_{i=0}^{\infty}a_{ki}h^i$. In order to prove that $\mathscr{A}_{2k}=0$ we have to show that $a_{ki}=0$ for any k and i. To this

end replace h in (A7) by a complex variable $h\in\mathbf{C}$, so that h takes values on any curve $\gamma\subset\mathbf{C}$ and $h\notin i\pi\mathbf{Q}$. Then the complex function $\mathscr{A}_{2k}$ is well defined for any $h\in\gamma$ and $\mathscr{A}_{2k}=\Sigma_{i=0}^{\infty}a_{ki}h^i$. Therefore, $a_{ki}=0$ if the function $\mathscr{A}_{2k}$ of $h\in\gamma$ vanishes. Since $h\in\mathbf{C}$ appears in $\mathscr{A}_{2k}$ only through $q=e^{h/2}$, it suffices to show that the function $\mathscr{A}_{2k}=0$ for q being a number, which is not a root of 1.

Let $q\in\mathbf{C}$ be not a root of unity. Setting

$$\begin{gathered}q^{2L_{i-k,2k-1}}=A_i,\quad i=1,...,2k-1,\\ q^{2L_{i-k-1,2k}}=B_i,\quad i=1,...,2k,\\ q^{2L_{i-k-1,2k+1}}=C_i,\quad i=1,...,2k+1,\\ q^{2L_{i-k,2k-2}}=D_i,\quad i=1,...,2k-2,\\ 2k=n,\end{gathered}\tag{A10}$$

one represents $\mathscr{A}_{2k}\equiv\mathscr{A}_n$ in the form

$$\begin{aligned}\mathscr{A}_n=&\sum_{j=1}^{n-1}\sum_{l=1}^{n}\frac{q\Pi_{i\neq l=1}^{n}(A_j-q^{-2}B_i)\Pi_{i=1}^{n-2}(A_j-q^{-2}D_i)\Pi_{i=1}^{n+1}(B_l-C_i)\Pi_{i\neq j=1}^{n-1}(B_l-A_i)}{A_jB_l\Pi_{i\neq j=1}^{n-1}(A_j-A_i)(A_j-q^{-2}A_i)\Pi_{i\neq l=1}^{n}(B_l-B_i)(B_l-q^{-2}B_i)}\\ &-\sum_{j=1}^{n-1}\sum_{l=1}^{n}\frac{q^{-1}\Pi_{i\neq l=1}^{n}(A_j-B_i)\Pi_{i=1}^{n-2}(A_j-D_i)\Pi_{i=1}^{n+1}(B_l-q^2C_i)\Pi_{i\neq j=1}^{n-1}(B_l-q^2A_i)}{A_jB_l\Pi_{i\neq j=1}^{n-1}(A_j-A_i)(A_j-q^2A_i)\Pi_{i\neq l=1}^{n}(B_l-B_i)(B_l-q^2B_i)}\\ &-(q-q^{-1})\left(1-q^2\frac{\Pi_{i=1}^{n-2}D_i\Pi_{i=1}^{n+1}C_i}{\Pi_{i=1}^{n-1}A_i\Pi_{i=1}^{n}B_i}\right),\end{aligned}\tag{A11}$$

which can be written also as

$$\begin{aligned}\mathscr{A}_n=&\sum_{j=1}^{n-1}\frac{q\Pi_{i=1}^{n}(A_j-q^{-2}B_i)\Pi_{i=1}^{n-2}(A_j-q^{-2}D_i)}{A_j\Pi_{i\neq j=1}^{n-1}(A_j-A_i)(A_j-q^{-2}A_i)}F_{n,j}\\ &-\sum_{l=1}^{n}\frac{q^{-1}\Pi_{i=1}^{n+1}(B_l-q^2C_i)\Pi_{i=1}^{n-1}(B_l-q^2A_i)}{B_l\Pi_{i\neq l=1}^{n}(B_l-B_i)(B_l-q^2B_i)}G_{n,l}-(q-q^{-1})\left(1-q^2\frac{\Pi_{i=1}^{n-2}D_i\Pi_{i=1}^{n+1}C_i}{\Pi_{i=1}^{n-1}A_i\Pi_{i=1}^{n}B_i}\right),\end{aligned}\tag{A12}$$

where

$$F_{n,j}=\sum_{l=1}^{n}\frac{\Pi_{i=1}^{n+1}(B_l-C_i)\Pi_{i\neq j=1}^{n-1}(B_l-A_i)}{(A_j-q^{-2}B_l)B_l\Pi_{i\neq l=1}^{n}(B_l-B_i)(B_l-q^{-2}B_i)}\tag{A13}$$

and

$$G_{n,l}=\sum_{j=1}^{n-1}\frac{\Pi_{i\neq l=1}^{n}(A_j-B_i)\Pi_{i=1}^{n-2}(A_j-D_i)}{A_j(B_l-q^2A_j)\Pi_{i\neq j=1}^{n-1}(A_j-A_i)(A_j-q^2A_i)}.\tag{A14}$$

Consider the complex functions

$$f_1(z)=\frac{\Pi_{i=1}^{n+1}(z-C_i)\Pi_{i\neq j=1}^{n-1}(z-A_i)}{(z-q^2A_j)\Pi_{i=1}^{n}(z-B_i)(z-q^{-2}B_i)},\quad f_2(z)=\frac{\Pi_{i\neq l=1}^{n}(z-B_i)\Pi_{i=1}^{n-2}(z-D_i)}{(z-q^{-2}B_l)\Pi_{i=1}^{n-1}(z-A_i)(z-q^2A_i)}.\tag{A15}$$

The function $f_1(z)$ [resp. $f_2(z)$] is analytic in the extended complex plane $\mathbf{C}\cup\infty$ except in its simple poles q^2A_j, $B_1,...,B_n$, $q^{-2}B_1,...,q^{-2}B_n$ (resp. $q^{-2}B_l$, $A_1,...,A_{n-1}$, $q^2A_1,...,q^2A_{n-1}$). Let C be a closed curve whose interior contains all poles of $f_1(z)$ [resp. $f_2(z)$]. The Residue

theorem of complex analysis implies that $\oint_{\mathbf{C}} f_j(z)dz = 2\pi i \Sigma \mathrm{Res}(f_j(z))$, $j=1,2$. On the other hand $f_1(z)$ [resp. $f_2(z)$] has no poles at infinity, Res $f_j(\infty)=0$. Therefore $\oint_{\mathbf{C}} f_j(z)dz=0$, $j=1,2$. Hence

$$\sum_{\text{all residues}} \mathrm{Res}(f_j(z))=0, \quad j=1,2. \tag{A16}$$

From (A16) we obtain

$$F_{n,j}=(q^2-1)\,\frac{\Pi_{i=1}^{n+1}(q^2A_j-C_i)\Pi_{i\neq j=1}^{n-1}(q^2A_j-A_i)}{\Pi_{i=1}^{n}(q^2A_j-B_i)(q^2A_j-q^{-2}B_i)} - \sum_{l=1}^{n} \frac{\Pi_{i=1}^{n+1}(B_l-q^2C_i)\Pi_{i\neq j=1}^{n-1}(B_l-q^2A_i)}{B_l(q^{-2}B_l-q^2A_j)\Pi_{i\neq l=1}^{n}(B_l-B_i)(B_l-q^2B_i)}, \tag{A17}$$

$$G_{n,l}=(q^{-2}-1)\,\frac{\Pi_{i\neq l=1}^{n}(B_l-q^2B_i)\Pi_{i=1}^{n-2}(q^{-2}B_l-D_i)}{\Pi_{i=1}^{n-1}(B_l-q^2A_i)(q^{-2}B_l-q^2A_i)} - \sum_{j=1}^{n-1} \frac{\Pi_{i\neq l=1}^{n}(A_j-q^{-2}B_i)\Pi_{i=1}^{n-2}(A_j-q^{-2}D_i)}{A_j(q^2A_j-q^{-2}B_l)\Pi_{i\neq j=1}^{n-1}(A_j-A_i)(A_j-q^{-2}A_i)}. \tag{A18}$$

Inserting (A17) and (A18) into the rhs of (A12) one ends with an expression for A_n, which contains only simple sums:

$$\frac{\mathscr{A}_n}{q-q^{-1}}=\sum_{j=1}^{n-1} \frac{\Pi_{i=1}^{n-2}(A_j-q^{-2}D_i)\Pi_{i=1}^{n+1}(A_j-q^{-2}C_i)}{A_j\Pi_{i\neq j=1}^{n-1}(A_j-A_i)\Pi_{i=1}^{n}(A_j-q^{-4}B_i)} + \sum_{l=1}^{n} \frac{\Pi_{i=1}^{n+1}(B_l-q^2C_i)\Pi_{i=1}^{n-2}(B_l-q^2D_i)}{B_l\Pi_{i\neq l=1}^{n}(B_l-B_i)\Pi_{i=1}^{n-1}(B_l-q^4A_i)} + q^2\,\frac{\Pi_{i=1}^{n-2}D_i\Pi_{i=1}^{n+1}C_i}{\Pi_{i=1}^{n-1}A_i\Pi_{i=1}^{n}B_i}-1. \tag{A19}$$

In order to show that the rhs of (A19) vanishes, consider the function

$$f(z)=\frac{\Pi_{i=1}^{n-2}(z-q^{-2}D_i)\Pi_{i=1}^{n+1}(z-q^{-2}C_i)}{z\Pi_{i=1}^{n-1}(z-A_i)\Pi_{i=1}^{n}(z-q^{-4}B_i)}. \tag{A20}$$

This function is a meromorphic function in the extended complex plane, having a simple pole also at infinity. Then the residue theorem, applied to $f(z)$, yields that the rhs of (A19) vanishes.

For further reference we write down the identity, which we have proved:

$$\sum_{j=1}^{n-1}\sum_{l=1}^{n} \frac{q\Pi_{i\neq l=1}^{n}(A_j-q^{-2}B_i)\Pi_{i=1}^{n-2}(A_j-q^{-2}D_i)\Pi_{i=1}^{n+1}(B_l-C_i)\Pi_{i\neq j=1}^{n-1}(B_l-A_i)}{A_jB_l\Pi_{i\neq j=1}^{n-1}(A_j-A_i)(A_j-q^{-2}A_i)\Pi_{i\neq l=1}^{n}(B_l-B_i)(B_l-q^{-2}B_i)} - \sum_{j=1}^{n-1}\sum_{l=1}^{n} \frac{q^{-1}\Pi_{i\neq l=1}^{n}(A_j-B_i)\Pi_{i=1}^{n-2}(A_j-D_i)\Pi_{i=1}^{n+1}(B_l-q^2C_i)\Pi_{i\neq j=1}^{n-1}(B_l-q^2A_i)}{A_jB_l\Pi_{i\neq j=1}^{n-1}(A_j-A_i)(A_j-q^2A_i)\Pi_{i\neq l=1}^{n}(B_l-B_i)(B_l-q^2B_i)} - (q-q^{-1})\left(1-q^2\,\frac{\Pi_{i=1}^{n-2}D_i\Pi_{i=1}^{n+1}C_i}{\Pi_{i=1}^{n-1}A_i\Pi_{i=1}^{n}B_i}\right)=0. \tag{A21}$$

In particular [see (A11)], $\mathscr{A}_n=\mathscr{A}_{2k}=0$.

(2^0) We pass to show that $\mathscr{B}_{2k,j,m}=0$ [see (A8)]. Without loss of generality we may write it as

$$\mathscr{B}_{2k,j,m}=-\sum_{s=0}^{1}\sum_{l=-k}^{k-1}(-1)^s\,\frac{\Pi_{r=-k}^{k}[L_{r,2k+1}-L_{l,2k}+s]\Pi_{r=-k}^{k-4}[L'_{r,2k-1}-L_{l,2k}+s]}{\Pi_{r\neq l=-k}^{k-1}[L_{r,2k}-L_{l,2k}+s][L_{r,2k}-L_{l,2k}+s-1]}. \tag{A22}$$

In order to obtain (A22) we have relabeled the indices of $L_{i,2k-1}$:

$$\{L_{i,2k-1}\}_{i\in\{1-k;k-1\},i\neq j\neq m}=\{L'_{i,2k-1}\}_{i\in\{-k;k-4\}}. \tag{A23}$$

Setting in (A22) $i=l+k+1$ and $t=r+k+1$ and introducing the notation

$$\begin{gathered}L_{t-k-1,2k}=a_t,\quad t=1,...,2k,\\ L_{t-k-1,2k+1}=b_t,\quad t=1,...,2k-1,\\ L_{k,2k+1}=c_{2k-1},\quad L_{k-1,2k+1}=c_{2k-2},\quad L'_{t-k-1,2k-1}=c_t,\quad t=1,...,2k-3,\\ 2k=n,\end{gathered} \tag{A24}$$

we rewrite $\mathscr{B}_{n,j,m}$ in the following form:

$$\mathscr{B}_{n,j,m}=-\sum_{s=0}^{1}\sum_{i=1}^{n}(-1)^s\frac{\Pi_{t=1}^{n-1}[a_i-b_t-s]\Pi_{t=1}^{n-1}[a_i-c_t-s]}{\Pi_{t\neq i=1}^{n}[a_i-a_t-s][a_i-a_t-s+1]}. \tag{A25}$$

In order to prove that $\mathscr{B}_{n,j,m}=0$, it suffices to show that

$$\sum_{s=0}^{1}\sum_{i=1}^{n}(-1)^s\frac{\Pi_{t=1}^{n-1}[a_i-b_t-s]\Pi_{t=1}^{n-1}[a_i-c_t-s]}{\Pi_{t\neq i=1}^{n}[a_i-a_t-s][a_i-a_t-s+1]}=0 \tag{A26}$$

for $q\in\mathbf{C}$ not being a root of 1. Assume this is the case and set $q^{2a_i}=A_i$, $q^{2b_i}=B_i$, $q^{2c_i}=C_i$. Then the lhs of (A26) becomes

$$\frac{\Pi_{t=1}^{n}A_t}{q^{n-1}\Pi_{t=1}^{n-1}B_t^{1/2}C_t^{1/2}}\sum_{i=1}^{n}\frac{1}{A_i}\left(\frac{\Pi_{t=1}^{n-1}(A_i-q^2B_t)(A_i-q^2C_t)}{\Pi_{t\neq i=1}^{n}(A_i-A_t)(A_i-q^2A_t)}-\frac{\Pi_{t=1}^{n-1}(A_i-B_t)(A_i-C_t)}{\Pi_{t\neq i=1}^{n}(A_i-A_t)(A_i-q^{-2}A_t)}\right). \tag{A27}$$

Consider the complex function

$$f(z)=\frac{\Pi_{t=1}^{n-1}(z-q^2B_t)(z-q^2C_t)}{\Pi_{t=1}^{n}(z-A_t)(z-q^2A_t)}. \tag{A28}$$

This function is analytic in the extended complex plane except in its simple poles A_t, q^2A_t, $t=1,2,...,n$. Therefore the sum over all residues of $f(z)$ vanishes. It is a simple calculation to see that

$$\begin{aligned}\sum_{i=1}^{n}\mathrm{Res}(f(A_i))+\sum_{i=1}^{n}\mathrm{Res}(f(q^2A_i))=\frac{1}{1-q^2}\sum_{i=1}^{n}\frac{1}{A_i}\Bigg(&\frac{\Pi_{t=1}^{n-1}(A_i-q^2B_t)(A_i-q^2C_t)}{\Pi_{t\neq i=1}^{n}(A_i-A_t)(A_i-q^2A_t)}\\ &-\frac{\Pi_{t=1}^{n-1}(A_i-B_t)(A_i-C_t)}{\Pi_{t\neq i=1}^{n}(A_i-A_t)(A_i-q^{-2}A_t)}\Bigg)=0.\end{aligned} \tag{A29}$$

Hence (A26) holds and therefore $\mathscr{B}_{n,j,m}\equiv\mathscr{B}_{2k,j,m}=0$ for any k, j and m.

(3^0) The proof of $\mathscr{C}_{2k-1,p,l}=0$ is similar to the previous case. Relabeling the indices of $L_{i,2k}$, one writes (A9) as

$$\begin{aligned}\mathscr{C}_{2k-1,p,l}=&\sum_{s'=0}^{1}\sum_{j=1-k}^{k-1}(-1)^{s'}\\ &\times\frac{\Pi_{r=1-k}^{k-2}[L_{r,2k-2}-L_{j,2k-1}-s']\Pi_{r=1-k}^{k-2}[L'_{r,2k}-L_{j,2k-1}-s']}{\Pi_{r\neq j=1-k}^{k-1}[L_{r,2k-1}-L_{j,2k-1}-s'][L_{r,2k-1}-L_{j,2k-1}-s'+1]}.\end{aligned} \tag{A30}$$

Setting in (A30) $i=j+k$ and $t=r+k$ and introducing the notation

$$a_t=L_{t-k,2k-1}+1,\quad t=1,...,2k-1,$$

$$b_t = L_{t-k,2k-2}, \quad t = 1,...,2k-2,$$

$$c_t = L'_{t-k,2k}, \quad t = 1,...,2k-2, \tag{A31}$$

$$s = 1 - s',$$

$$n = 2k-1,$$

we obtain for $\mathscr{C}_{2k-1,p,l} \equiv \mathscr{C}_{n,p,l}$

$$\mathscr{C}_{n,p,l} = -\sum_{s=0}^{1} \sum_{i=1}^{n} (-1)^s \frac{\Pi_{t=1}^{n-1}[a_i - b_t - s]\Pi_{t=1}^{n-1}[a_i - c_t - s]}{\Pi_{t\neq i=1}^{n}[a_i - a_t - s][a_i - a_t - s + 1]}. \tag{A32}$$

It has already been shown [see (A26)] that the rhs of (A32) vanishes. Hence $\mathscr{C}_{2k-1,p,l} = 0$.

The conclusion so far is that the rhs of (A6) is also equal to zero, i.e., Eq. (A5) holds for any $i \in \mathbf{Z}_+$. It remains to prove (A5) for $i \notin \mathbf{Z}_+$.

(3b) The verification of (A5) corresponding to $i = -1$ is based on Eqs. (19) and (21) and is very simple.

(3c) The proof of (A5), corresponding to $i < -1$, is based essentially on the identities (23b), (24b) and (24d). The latter are proved similarly as (23a), (24a) and (24c).

(4) The verification of last Cartan relation

$$[\rho(e_i), \rho(f_j)]|M) = 0, \quad i \neq j, \tag{A33}$$

as well as of the Serre relations is lengthy but straightforward. It is based on the identities (24)–(27).

Symmetries of history quantum theories and decoherence functionals

Oliver Rudolph[a)]
Theoretical Physics Group, Blackett Laboratory, Imperial College of Science, Technology and Medicine, Prince Consort Road, London SW7 2BZ, United Kingdom

(Received 2 May 1998; accepted for publication 8 July 1998)

Recently, Schreckenberg investigated symmetries in the context of *history quantum theories*. In the case that the space of histories is given by the set of projectors on some finite dimensional Hilbert space he obtained, first, a complete characterization of all physical symmetries of history quantum theories — an analog of Wigner's theorem — and, second, a complete mathematical characterization of symmetries of single decoherence functionals. In this paper we extend Schreckenberg's results to the case where the underlying space of histories is given by the set of projectors on some infinite dimensional Hilbert space. © *1998 American Institute of Physics.* [S0022-2488(98)02011-8]

I. INTRODUCTION

History quantum theories are an interesting candidate for quantum theories in which space and time are treated more symmetrically than in standard Hamiltonian quantum mechanics and in which there is no *a priori* external notion of time. They have been introduced by Isham[1] based on ideas of the so called consistent histories approach (see Refs. 2–7). Isham's approach has subsequently been studied by several authors.[8–24] In Isham's approach a history quantum theory is characterized by the space of histories on the one hand, which correspond to the general temporal properties of the quantum system, and by the space of decoherence functionals on the other hand, which correspond to the generalized quantum state of a quantum system in a history theory. To get deeper insight into the structural content of general history quantum theories it is worthwhile to study the mathematical structure of history quantum theories in some detail. In the present paper we will restrict ourselves to the mathematical study of history quantum theories. For a lucid account of the physical motivation for studying history quantum theories the reader is referred to the original works by Isham and co-workers.[1,8–17]

In the present note we study the notion of *symmetry* in history quantum theories. Symmetries in history quantum theories have first been studied by Schreckenberg.[8,9] In these works Schreckenberg considered the situation where the space of histories is given by the set of projection operators on some finite dimensional Hilbert space and, generalizing Wigner's symmetry theorem[25] to history theories, proved that there exists a one-to-one correspondence between physical symmetries of history quantum theories and operators $U\otimes U$ on $\mathfrak{H}\otimes\mathfrak{H}$ where U is a unitary or anti-unitary operator on $\mathfrak{H}$.[8] In Ref. 9 Schreckenberg studied symmetries of decoherence functionals in the finite dimensional case and proved that the symmetries of a given decoherence functional d are in a one-to-one correspondence with operators $U\otimes U$ on $\mathfrak{H}\otimes\mathfrak{H}$ such that $[\mathfrak{X}_d, U\otimes U]=0$, where $\mathfrak{X}_d$ denotes the unique trace class operator associated with d [see Ref. 16 and below, Eq. (1)].

Our aim here is to investigate to what extent Schreckenberg's two main results remain valid when the underlying Hilbert space is infinite dimensional. To this end we use recent results in the representation theory of decoherence functionals in the infinite dimensional case.[21] We shall show in the present note that Schreckenberg's first theorem classifying the physical symmetries of a history quantum theory is valid also in the infinite dimensional case. We shall also investigate to what extent Schreckenberg's second theorem characterizing the symmetries of a decoherence

functional remains valid and give a complete characterization of symmetries of bounded decoherence functionals in the infinite dimensional case.

This paper is organized as follows: in the next section the necessary mathematical preliminaries are presented. In Sec. III we discuss physical symmetries of history quantum theories and in the fourth section we investigate symmetries of decoherence functionals.

II. MATHEMATICAL PRELIMINARIES

Consider a history quantum theory in which the space of histories is given by the set of projection operators on some in general infinite dimensional Hilbert space. In this case decoherence functionals are defined as follows: let $\mathcal{B}(\mathfrak{H})$ be the space of all bounded operators on a Hilbert space $\mathfrak{H}$ and let $\mathcal{P}(\mathfrak{H})$ be the lattice of projections in $\mathcal{B}(\mathfrak{H})$ which is interpreted as the set of histories. Then a *decoherence functional for* $\mathfrak{H}$ is a complex valued function $d:\mathcal{P}(\mathfrak{H})\times\mathcal{P}(\mathfrak{H})\to\mathbb{C}$, defined on all ordered pairs of projections in $\mathcal{P}(\mathfrak{H})$, for which the following conditions are satisfied:

(i) *Hermiticity:* $d(p,q)=d(q,p)^*$ for each p and q in $\mathcal{P}(\mathfrak{H})$. (Here * denotes complex conjugation.)
(ii) *Positivity:* $d(p,p)\geqslant 0$ for each $p\in\mathcal{P}(\mathfrak{H})$.
(iii) *Normalization:* $d(1,1)=1$.
(iv) *Orthoadditivity:* $d(p_1+p_2,q)=d(p_1,q)+d(p_2,q)$ whenever $p_1\in\mathcal{P}(\mathfrak{H})$ and $p_2\in\mathcal{P}(\mathfrak{H})$ are perpendicular and $q\in\mathcal{P}(\mathfrak{H})$ is an arbitrary projection.

Moreover, in the infinite dimensional case, a decoherence functional is said to be *completely additive* if, whenever $\{p_i\}_{i\in I}$ is an infinite collection of pairwise orthogonal projections, $d(\Sigma_{i\in I}p_i,q)=\Sigma_{i\in I}d(p_i,q)$, for each $q\in\mathcal{P}(\mathfrak{H})$. Here the convergence is always absolute. In this note we denote the set of all decoherence functionals on the Hilbert space $\mathfrak{H}$ by $\mathcal{D}(\mathfrak{H})$.

When $\mathfrak{H}$ is finite dimensional and of dimension greater than 2, it follows from Isham, Linden and Schreckenberg[16] that there is a one-to-one correspondence between bounded decoherence functionals d on $\mathcal{P}(\mathfrak{H})\times\mathcal{P}(\mathfrak{H})$ and trace class operators $\mathfrak{X}$ on $\mathfrak{H}\otimes\mathfrak{H}$ according to the rule

$$d(p,q)=\mathrm{tr}_{\mathfrak{H}\otimes\mathfrak{H}}((p\otimes q)\mathfrak{X}), \tag{1}$$

for all $p,q\in\mathcal{P}(\mathfrak{H})$, where

(i) $\mathrm{tr}_{\mathfrak{H}\otimes\mathfrak{H}}((p\otimes q)\mathfrak{X})=\mathrm{tr}_{\mathfrak{H}\otimes\mathfrak{H}}((q\otimes p)\mathfrak{X}^\dagger)$;
(ii) $\mathrm{tr}_{\mathfrak{H}\otimes\mathfrak{H}}((p\otimes p)\mathfrak{X})\geqslant 0$;
(iii) $\mathrm{tr}_{\mathfrak{H}\otimes\mathfrak{H}}(\mathfrak{X})=1$.

In contrast to the finite dimensional case where all bounded decoherence functionals admit an *Isham–Linden–Schreckenberg (ILS) representation* as in Eq. (1), in the infinite dimensional case only those decoherence functionals satisfying an additional so-called *tensor boundedness* condition[21] admit an ILS representation.

Denote by $\mathcal{K}(\mathfrak{H})$ the set of compact operators on $\mathfrak{H}$, and by $\mathcal{K}(\mathfrak{H})\bullet\mathcal{K}(\mathfrak{H})$ the algebraic tensor product of $\mathcal{K}(\mathfrak{H})$ with itself. We recall from Ref. 21 that for every bounded decoherence functional there exists a unique bounded bilinear form $\mathcal{D}:\mathcal{B}(\mathfrak{H})\times\mathcal{B}(\mathfrak{H})\to\mathbb{C}$ which extends d and a unique linear functional $\beta:\mathcal{K}(\mathfrak{H})\bullet\mathcal{K}(\mathfrak{H})\to\mathbb{C}$ such that $\beta(x\otimes y)=\mathcal{D}(x,y)$ for all $x,y\in\mathcal{K}(\mathfrak{H})$. A bounded decoherence functional is said to be *tensor bounded* if the associated functional β is bounded on $\mathcal{K}(\mathfrak{H})\bullet\mathcal{K}(\mathfrak{H})$, when $\mathcal{K}(\mathfrak{H})\bullet\mathcal{K}(\mathfrak{H})$ is equipped with the norm induced from $\mathcal{B}(\mathfrak{H}\otimes\mathfrak{H})$. We denote the projection operator from $\mathfrak{H}\otimes\mathfrak{H}$ onto the one dimensional subspace spanned by $\xi\in\mathfrak{H}\otimes\mathfrak{H}$ by p_ξ. A bounded decoherence functional is said to be *tracially bounded* if there exists a constant C such that for every unit vector $\xi\in\mathfrak{H}\otimes_{alg}\mathfrak{H}$ the associated functional β satisfies $|\beta(p_\xi)|\leqslant C$, where $\mathfrak{H}\otimes_{alg}\mathfrak{H}$ denotes the algebraic tensor product of $\mathfrak{H}$ by itself.

In Ref. 21 it has been shown that a bounded decoherence functional is ILS representable if and only if it is tensor bounded (provided the underlying Hilbert space is of dimension greater than two). Moreover, it has been shown that for a tracially bounded decoherence functional d there exists a unique bounded operator $\mathfrak{M}_d$ on $\mathfrak{H}\otimes\mathfrak{H}$ such that $d(p,q)=\mathrm{tr}_{\mathfrak{H}\otimes\mathfrak{H}}(p\otimes q\mathfrak{M}_d)$, for all finite rank projections p,q on $\mathfrak{H}$ (provided $\mathfrak{H}$ is of dimension greater than two).

The structure of the space of decoherence functionals has been studied in detail in Ref. 21. We shall need the following result from Ref. 21 in the sequel.

Proposition 2.1: Let $\mathfrak{H}$ be a Hilbert space of dimension greater than two and let $d:\mathcal{P}(\mathfrak{H})\times\mathcal{P}(\mathfrak{H})\to\mathbb{C}$ be a bounded decoherence functional for $\mathfrak{H}$. Then there exist families of trace class operators $\{\mathfrak{X}_i\}_{i\in I}$, and $\{\mathfrak{Y}_i\}_{i\in I}$ on $\mathfrak{H}$, where, for each x and y in $\mathcal{K}(\mathfrak{H})$, $\Sigma_{i\in I}|\mathrm{tr}_{\mathfrak{H}}(x\mathfrak{X}_i)|^2$ and $\Sigma_{i\in I}|\mathrm{tr}_{\mathfrak{H}}(y\mathfrak{Y}_i)|^2$ are convergent, such that, for all $p,q\in\mathcal{P}(\mathfrak{H})$,

$$d(p,q)=\sum_{i\in I}\mathrm{tr}_{\mathfrak{H}\otimes\mathfrak{H}}\{p\otimes q(\mathfrak{X}_i\otimes\mathfrak{X}_i^\dagger-\mathfrak{Y}_i\otimes\mathfrak{Y}_i^\dagger)\},\tag{2}$$

where the infinite series is absolutely convergent.

III. SYMMETRIES OF HISTORY QUANTUM THEORIES

Wigner's symmetry theorem in ordinary quantum mechanics is discussed in detail in Refs. 8, 25, and 26. We denote the single-time Hilbert space of standard quantum mechanics by $\mathcal{H}$ and the set of rays in $\mathcal{H}$ by $\mathcal{R}(\mathcal{H})$.

Then, in short, a physical symmetry is an affine bijective map $\xi:\mathcal{R}(\mathcal{H})\to\mathcal{R}(\mathcal{H})$ such that the transition probability between the physical states corresponding to the rays in $\mathcal{H}$ remains unchanged under ξ. Wigner's theorem now states that there is a bijective correspondence between physical symmetries and unitary and antiunitary operators on $\mathcal{H}$.

Considering the histories formulation of standard quantum mechanics[1,16] we see that every physical symmetry ξ in standard quantum mechanics induces an affine orthogonality preserving map $\Xi:\mathcal{R}(\mathfrak{H})\to\mathcal{R}(\mathfrak{H})$ on the rays of the history Hilbert space $\mathfrak{H}$ which in turn induces a map $d\mapsto d^{\Xi}$ on the space of decoherence functionals. Explicitly, if the (anti)unitary operator on $\mathcal{H}$ corresponding to ξ is given by U, then Ξ acts on an n-time history h as $h\mapsto(U\otimes\cdots\otimes U)h(U^\dagger\otimes\cdots\otimes U^\dagger)$, where $U\otimes\cdots\otimes U$ denotes the n-fold tensor product of U by itself. Details can be found in Ref. 9.

The above considerations about symmetries in ordinary quantum mechanics and in the history formulation of standard quantum mechanics motivate the ansatz that in a general history quantum theory a symmetry is still given by an affine one-to-one and onto mapping $\mathcal{Q}:\mathcal{R}(\mathfrak{H})\to\mathcal{R}(\mathfrak{H})$ on the history Hilbert space $\mathfrak{H}$.

The families $\{\mathfrak{X}_i\}_{i\in I}$, and $\{\mathfrak{Y}_i\}_{i\in I}$ on $\mathfrak{H}$ appearing in Eq. (2) in Proposition 2.1 are not unique. For every trace class operator T on $\mathfrak{H}$ there exist two orthonormal families $\{|\psi_k\rangle\}_{k\in K}$ and $\{|\phi_k\rangle\}_{k\in K}$ of vectors in $\mathfrak{H}$ and a family of real positive numbers $\{\lambda_k\}_{k\in K}$ with $\Sigma_{k\in K}\lambda_k<\infty$ such that $T=\Sigma_{k\in K}\lambda_k|\psi_k\rangle\langle\phi_k|$.

Thus, given a representation (2) of a bounded decoherence functional by families of trace class operators $\{\mathfrak{X}_i\}_{i\in I}$ and $\{\mathfrak{Y}_i\}_{i\in I}$, every affine one-to-one map $\mathcal{Q}:\mathcal{R}(\mathfrak{H})\to\mathcal{R}(\mathfrak{H})$ induces a map $\{\mathfrak{X}_i\}_{i\in I}\mapsto\{\mathfrak{X}_i^{\mathcal{Q}}\}_{i\in I}$ and $\{\mathfrak{Y}_i\}_{i\in I}\mapsto\{\mathfrak{Y}_i^{\mathcal{Q}}\}_{i\in I}$. This map, however, depends, in general, obviously on the choice of the representations for the $\mathfrak{X}_i$ and $\mathfrak{Y}_i$. Different choices may lead to different sets of operators $\{\mathfrak{X}_i^{\mathcal{Q}}\}_{i\in I}$ and $\{\mathfrak{Y}_i^{\mathcal{Q}}\}_{i\in I}$. Moreover, the map $\mathcal{Q}$ is, in general, not preserving orthogonality between rays. Nevertheless, it is easy to check that the transformed operators are also compact operators, but *a priori* not necessarily of trace class. The sets of transformed operators may or may not define via Eq. (2) a transformed bounded decoherence functional. Since the representation in the form (2) is not unique, *a priori* we have to take into account the possibilities that the image of d under $\mathcal{Q}$ depends upon the representation (2) chosen and, even worse, that the series defining the image of d under $\mathcal{Q}$ may be not convergent for all $p,q\in\mathcal{P}(\mathfrak{H})$. The well-defined bounded decoherence functionals which can be obtained from a representation (2) of d through the application of $\mathcal{Q}$ will be denoted by $d_s^{\mathcal{Q}}$ where the index s distinguishes the possibly different decoherence functionals arising from different representations of d and of the $\{\mathfrak{X}_i\}_{i\in I}$ and $\{\mathfrak{Y}_i\}_{i\in I}$.

So far, the situation is clearly unsatisfactory from a physical point of view. From a *physical symmetry* $\mathcal{Q}$ of a history theory one would reasonably expect that $\mathcal{Q}$ induces a well-defined map $d\mapsto d^{\mathcal{Q}}$ on the space of decoherence functionals.

This motivates the following definition in the spirit of Ref. 8.

Definition 3.1: Consider a history quantum theory with underlying Hilbert space $\mathfrak{H}$. A physical symmetry *of the history quantum theory is a pair $(\mathcal{Q}_1,\mathcal{Q}_2)$ consisting of an affine bijection*

$\mathcal{Q}_1:\mathcal{R}(\mathfrak{H})\to\mathcal{R}(\mathfrak{H})$ such that $\mathcal{Q}_1$ induces a map $\mathcal{Q}_2:\mathcal{D}(\mathfrak{H})\to\mathcal{D}(\mathfrak{H}), d\mapsto d^{\mathcal{Q}_2}$ on the space of decoherence functionals such that the value of the decoherence functional is preserved, i.e.,

$$d(p,q)=d^{\mathcal{Q}_2}(p^{\mathcal{Q}_1},q^{\mathcal{Q}_1})$$

for all $d\in\mathcal{D}(\mathfrak{H})$ and all $p,q\in\mathcal{R}(\mathfrak{H})$.

The following theorem depends crucially on the choice of the space of decoherence functionals. We assume that the set of all physical decoherence functionals contains as a subset all bounded decoherence functionals.

Theorem 3.2: *Consider a history quantum theory with underlying Hilbert space $\mathfrak{H}$. Then there exists a bijective correspondence between physical symmetries of the history quantum theory and unitary or anti-unitary operators on $\mathfrak{H}$. The physical symmetry $\mathcal{Q}^U=(\mathcal{Q}_1^U,\mathcal{Q}_2^U)$ corresponding to U is explicitly given by*

$$\mathcal{Q}^U:\mathcal{P}(\mathfrak{H})\times\mathcal{D}(\mathfrak{H})\to\mathcal{P}(\mathfrak{H})\times\mathcal{D}(\mathfrak{H}),\mathcal{Q}^U(p,d)=(p^{\mathcal{Q}^U},d^{\mathcal{Q}^U})=(UpU^\dagger,d_U),$$

where d_U is the decoherence functional defined by $d_U(p,q):=d(U^\dagger pU,U^\dagger qU)$, for all $p,q\in\mathcal{P}(\mathfrak{H})$.

Proof: Obviously, $\mathcal{Q}^U$ defines a physical symmetry of the history quantum theory for every unitary or anti-unitary operator U. Conversely, let $(\mathcal{Q}_1,\mathcal{Q}_2)$ be a physical symmetry. We proceed in analogy with Ref. 8. Since the invariance requirement must hold for all physical decoherence functionals, it has particularly to be true for all tensor bounded decoherence functionals whose associated trace class operator [via Eq. (1)] is of finite rank. Consider, for instance, the decoherence functional $d_P(p,q):=\mathrm{tr}_{\mathfrak{H}\otimes\mathfrak{H}}(p\otimes qP\otimes P)$ where P is some one dimensional projector on $\mathfrak{H}$. The invariance requirement amounts to $d_P^{\mathcal{Q}_2}(p^{\mathcal{Q}_1},q^{\mathcal{Q}_1})=d_P(p,q)$. Applying Wigner's theorem and using the fact that $\mathcal{Q}_2$ is induced by $\mathcal{Q}_1$ shows that the transformations leaving the values of the decoherence functional invariant are of the form $\mathcal{Q}^U$ for some unitary or anti-unitary operator on $\mathfrak{H}$. Particularly, it follows that $\mathcal{Q}_2$ is, in fact, single valued. □

Notice that the requirement that $\mathcal{Q}_2$ is a map in Definition 3.1 is redundant and actually follows from the requirement that the value of the decoherence functional is invariant. As shown in the proof of Theorem 3.2, the latter requirement already fixes $\mathcal{Q}_1$ to be equal to $\mathcal{Q}^U$ for some unitary or anti-unitary U. However, the relation $\mathcal{Q}_2$ induced by $\mathcal{Q}^U$ is the map $d\mapsto d_U$.

IV. SYMMETRIES OF DECOHERENCE FUNCTIONALS

Definition 4.1: Let $\mathfrak{H}$ be a Hilbert space and let $d:\mathcal{P}(\mathfrak{H})\times\mathcal{P}(\mathfrak{H})\to\mathbb{C}$ be a decoherence functional. A symmetry of *d is a unitary or anti-unitary operator U on $\mathfrak{H}$ such that $d(p,q)=d(UpU^\dagger,UqU^\dagger)$, for all $p,q\in\mathcal{P}(\mathfrak{H})$.*

Proposition 4.2: Let $\mathfrak{H}$ be a Hilbert space and let $d:\mathcal{P}(\mathfrak{H})\times\mathcal{P}(\mathfrak{H})\to\mathbb{C}$ be a decoherence functional. The set $\mathcal{S}[d]$ of symmetries of d carries the structure of a group.

Proof: The unit element of $\mathcal{S}[d]$ is given by the unit operator **1** and the group multiplication is given by multiplication of operators. We show that $U\in\mathcal{S}[d]$ implies $U^\dagger\in\mathcal{S}[d]$. Since U is a symmetry of d, we have $d(p,q)=d(UU^\dagger pUU^\dagger,UU^\dagger qUU^\dagger)=d(U^\dagger pU,U^\dagger qU)$, for all $p,q\in\mathcal{P}(\mathfrak{H})$. This implies $U^\dagger\in\mathcal{S}[d]$. □

Schreckenberg[9] has shown that if $\mathfrak{H}$ is finite dimensional and of dimension greater than 2, then the set $\mathcal{S}[d]$ of all symmetries of a decoherence functional d is given by

$$\mathcal{S}[d]=\{U\in\mathrm{Aut}(\mathfrak{H}):[\mathfrak{X}_d,U\otimes U]=0\},$$

where $\mathrm{Aut}(\mathfrak{H})$ denotes the set of all unitary and anti-unitary operators on $\mathfrak{H}$ and where $\mathfrak{X}_d$ denotes the ILS operator from Eq. (1) associated with d.

We shall need the following lemma.

Lemma 4.3: Let $\mathcal{L}$ be a bounded operator on $\mathfrak{H}\otimes\mathfrak{H}$ such that, for all $\alpha,\beta\in\mathfrak{H}$,

$$\langle\mathcal{L}(\alpha\otimes\beta),\alpha\otimes\beta\rangle=0.$$

Then $\mathcal{L}=0$.

A proof can be found, for instance, in Ref. 21.

Theorem 4.4: *Let $\mathfrak{H}$ be a Hilbert space of dimension greater than 2 and let $d:\mathcal{P}(\mathfrak{H})\times\mathcal{P}(\mathfrak{H})\to\mathbb{C}$ be a tracially bounded, completely additive decoherence functional and denote by $\mathfrak{M}_d$ the bounded operator on $\mathfrak{H}\otimes\mathfrak{H}$ associated with d. The set $\mathcal{S}[d]$ of symmetries of d is given by*

$$\mathcal{S}[d]=\{U\in\mathrm{Aut}(\mathfrak{H}):[\mathfrak{M}_d,U\otimes U]=0\},$$

where $\mathrm{Aut}(\mathfrak{H})$ *denotes the set of all unitary and anti-unitary operators on* $\mathfrak{H}$.

Proof: It is well known that every projection operator P on $\mathfrak{H}$ can be written as a sum over projection operators of rank one, $P=\Sigma_i P_i$. Thus, according to Theorem 4.4 in Ref. 21, whenever p and q are projections in $\mathcal{P}(\mathfrak{H})$ and $\{p_j\}_{j\in J}$ and $\{q_i\}_{i\in I}$ are, respectively, orthogonal families of rank one projections with $p=\Sigma_{j\in J}p_j$ and $q=\Sigma_{i\in I}q_i$, then

$$d(p,q)=\sum_{j\in J}\sum_{i\in I}\mathrm{tr}_{\mathfrak{H}\otimes\mathfrak{H}}((p_j\otimes q_i)\mathfrak{M}_d). \tag{3}$$

Let $U\in\{U\in\mathrm{Aut}(\mathfrak{H}):[\mathfrak{M}_d,U\otimes U]=0\}$, then it follows from Eq. (3) that U is a symmetry of d. Conversely, let U by a symmetry of d. Then, by Lemma 4.3, $\mathfrak{M}_d=(U\otimes U)\mathfrak{M}_d(U^\dagger\otimes U^\dagger)$, i.e., $U\in\{U\in\mathrm{Aut}(\mathfrak{H}):[\mathfrak{M}_d,U\otimes U]=0\}$. □

Corollary 4.5: Let $\mathfrak{H}$ be a Hilbert space of dimension greater than 2 and let $d:\mathcal{P}(\mathfrak{H})\times\mathcal{P}(\mathfrak{H})\to\mathbb{C}$ be a tracially bounded decoherence functional and denote by $\mathfrak{M}_d$ the bounded operator on $\mathfrak{H}\otimes\mathfrak{H}$ associated with d. Then the set $\mathcal{S}[d]$ of symmetries of d satisfies

$$\mathcal{S}[d]\subseteq\{U\in\mathrm{Aut}(\mathfrak{H}):[\mathfrak{M}_d,U\otimes U]=0\}.$$

Remarks: (i) In the case of a tensor bounded decoherence functional the requirement of complete additivity can be dropped from the theorem.

(ii) A *weak symmetry* of a decoherence functional d is a unitary or anti-unitary operator $U\in\mathrm{Aut}(\mathfrak{H})$ such that the diagonal values of the decoherence functional (which are interpreted as the physical probabilities) are invariant, i.e.,

$$d(p,p)=d(UpU^\dagger,UpU^\dagger),\forall p\in\mathcal{P}(\mathfrak{H}).$$

For the weak symmetries of a tracially bounded, completely additive decoherence functional d we find, in general, only $\mathfrak{M}_d-(U\otimes U)\mathfrak{M}_d(U^\dagger\otimes U^\dagger)=\Delta_U$, where $\mathrm{tr}_{\mathfrak{H}\otimes\mathfrak{H}}(p\otimes p\Delta_U)=0$ for all $p\in\mathcal{P}(\mathfrak{H})$. A detailed discussion about weak symmetries can be found in Ref. 9 and need not be repeated here.

A bounded decoherence functional (not necessarily tracially bounded), according to Proposition 2.1, can be represented as a series of trace class operators, which, in general, converges only in a weak sense. Thus we obtain the following.

Theorem 4.6: *Let $\mathfrak{H}$ be a Hilbert space of dimension greater than 2 and let $d:\mathcal{P}(\mathfrak{H})\times\mathcal{P}(\mathfrak{H})\to\mathbb{C}$ be a completely additive, bounded decoherence functional. Let $\{\mathfrak{X}_i\}_{i\in I}$ and $\{\mathfrak{Y}_i\}_{i\in I}$ be families of trace class operators forming a representation of d as in Eq. (2). Then, the set $\mathcal{S}[d]$ of symmetries of d is given by*

$$\mathcal{S}[d]=\left\{U\in\mathrm{Aut}(\mathfrak{H}):\sum_{i\in I}\langle[(\mathfrak{X}_i\otimes\mathfrak{X}_i^\dagger-\mathfrak{Y}_i\otimes\mathfrak{Y}_i^\dagger)U^\dagger\otimes U^\dagger,U\otimes U]\xi\otimes\eta,\xi\otimes\eta\rangle=0,\forall\xi,\eta\in\mathfrak{H}\right\}.$$

The proof is analogous to the proof of Theorem 4.4. The representation of d in Proposition 2.1 is not unique. Theorem 4.6 is independent of the choice of the representation in Eq. (2).

A version of Thirring's approach to the Kolmogorov–Arnold–Moser theorem for quadratic Hamiltonians with degenerate twist

C. Chandre[a] and H. R. Jauslin
Laboratoire de Physique, CNRS, Université de Bourgogne, BP 400, F-21011 Dijon, France

(Received 23 February 1998; accepted for publication 8 July 1998)

We give a proof of the Kolmogorov–Arnold–Moser (KAM) theorem on the existence of invariant tori for weakly perturbed Hamiltonian systems, based on Thirring's approach for Hamiltonians that are quadratic in the action variables. The main point of this approach is that the iteration of canonical transformations on which the proof is based stays within the space of quadratic Hamiltonians. We show that Thirring's proof for nondegenerate Hamiltonians can be adapted to Hamiltonians with degenerate twist. This case, in fact, drastically simplifies Thirring's proof. © *1998 American Institute of Physics.*

I. INTRODUCTION

Regular Hamiltonian dynamics is characterized by the existence of as many independent conserved quantities as degrees of freedom d. As a consequence, each trajectory is confined to evolve on an invariant torus of dimension d. The Kolmogorov–Arnold–Moser (KAM) technique was developed to prove the stability under small perturbations of a large fraction of these invariant tori. The KAM theorem[1–4] states that if the frequency satisfies a diophantine condition, and the size of the perturbation ε is sufficiently small, then a torus of that frequency will be stable. The proof is based on an iterative algorithm to construct the invariant tori. Each step of the KAM iteration consists of a coordinate transformation that reduces the size of the perturbation from order ε to ε^2.

In this paper, we derive a KAM theorem for a family of Hamiltonians that has been used in Refs. 5–7 within the setup of a renormalization-group approach to the breakup of invariant tori.

We consider the following class of Hamiltonians with d degrees of freedom, that are quadratic in the action variables $\mathbf{A}=(A_1,A_2,\ldots,A_d)\in\mathbb{R}^d$ and described by three scalar functions of the angles $\boldsymbol{\varphi}=(\varphi_1,\varphi_2,\ldots,\varphi_d)\in\mathbb{T}^d$ (the d-dimensional torus parametrized, e.g., by $[0,2\pi]^d$):

$$H(\mathbf{A},\boldsymbol{\varphi})=\frac{1}{2}m(\boldsymbol{\varphi})(\boldsymbol{\Omega}\cdot\mathbf{A})^2+[\boldsymbol{\omega}_0+g(\boldsymbol{\varphi})\boldsymbol{\Omega}]\cdot\mathbf{A}+f(\boldsymbol{\varphi}), \tag{1.1}$$

where $\boldsymbol{\omega}_0\in\mathbb{R}^d$ is the frequency vector of the considered torus, and $\boldsymbol{\Omega}$ is some other constant vector. Without loss of generality, we assume that $\boldsymbol{\Omega}=(\Omega_1,\ldots,\Omega_d)$ is of norm one, i.e., $|\boldsymbol{\Omega}|=\Sigma_{i=1}^d|\Omega_i|=1$. The functions m, g, and f are real analytic on $\mathbb{T}^d$, i.e., they are holomorphic functions on some complex neighborhood of $\mathbb{T}^d$.

We consider $\boldsymbol{\omega}_0$ verifying a diophantine condition

$$|\boldsymbol{\omega}_0\cdot\boldsymbol{\nu}|^{-1}\leqslant\sigma|\boldsymbol{\nu}|^{\tau},\quad \forall\,\boldsymbol{\nu}=(\nu_1,\ldots,\nu_d)\in\mathbb{Z}^d\backslash\{0\}, \tag{1.2}$$

for some $\tau>d-1$ and $\sigma>0$.

The aim is to prove the existence of a torus with frequency vector $\boldsymbol{\omega}_0$ for Hamiltonian systems described by Eq. (1.1). The method is to find a canonical transformation such that the equations of

[a]Electronic mail: cchandre@jupiter.u-bourgogne.fr

 © 1998 American Institute of Physics

motion expressed in the new coordinates show trivially the existence of this torus. For Hamiltonians of type (1.1), if one takes g and f equal to zero, then the resulting equations of motion are

$$\frac{d\mathbf{A}}{dt} = -\frac{1}{2}\frac{\partial m}{\partial \boldsymbol{\varphi}}(\boldsymbol{\Omega}\cdot\mathbf{A})^2, \tag{1.3}$$

$$\frac{d\boldsymbol{\varphi}}{dt} = m(\boldsymbol{\varphi})(\boldsymbol{\Omega}\cdot\mathbf{A})\boldsymbol{\Omega} + \boldsymbol{\omega}_0. \tag{1.4}$$

Thus there exists a torus with frequency vector $\boldsymbol{\omega}_0$ located at $\mathbf{A}=0$ (even if the resulting Hamiltonian is not globally integrable, i.e., for $\mathbf{A}\neq 0$). This canonical transformation cannot be defined directly, because the formal expressions that appear in the classical perturbation theory do not converge due to the presence of small denominators. The construction is done via an iterative algorithm. We iterate a canonical change of coordinates that maps a Hamiltonian of the form (1.1) with a perturbation (g,f) of order $\mathcal{O}(\varepsilon)$, into a Hamiltonian with (g',f') of order $\mathcal{O}(\varepsilon^2)$. When the iteration converges, the perturbation (g,f) is completely eliminated.

The fact that m does not need to be eliminated to prove the existence of the torus with frequency vector $\boldsymbol{\omega}_0$, allows us to stay with Hamiltonians that are quadratic in the actions at each step of the iteration. This approach has been developed by Thirring.[8,9] In fact, Thirring considered a nondegenerate family of Hamiltonians quadratic in the actions, of the form

$$H(\mathbf{A},\boldsymbol{\varphi}) = \tfrac{1}{2}\,\mathbf{A}\cdot M(\boldsymbol{\varphi})\mathbf{A} + [\boldsymbol{\omega}_0 + \mathbf{g}(\boldsymbol{\varphi})]\cdot\mathbf{A} + f(\boldsymbol{\varphi}), \tag{1.5}$$

where M is a $d\times d$ matrix such that $\det M\neq 0$, and $\mathbf{g}$ a vector. This implies that Thirring's Hamiltonian (1.5) satisfies the ''twist condition''

$$\det\left|\frac{\partial^2 H}{\partial\mathbf{A}\partial\mathbf{A}}\right| = \det M \neq 0. \tag{1.6}$$

The Hamiltonian (1.1) does not satisfy the twist condition for any $\boldsymbol{\varphi}$. The extension of the KAM theorem for degenerate systems was done by Arnold[10] (see also Refs. 11–15). In the case we consider here, the rank of the matrix in (1.6) is one. Thus there is a twist in a particular direction, which is the only relevant one for the considered perturbation.

Condition (1.6) is also called the (standard) nondegeneracy condition. KAM theorems were also proven for Hamiltonians which satisfy the isoenergetic nondegeneracy condition,[16,17] for which the following determinant of order $d+1$ does not vanish

$$\det\begin{vmatrix} \dfrac{\partial^2 H}{\partial\mathbf{A}\partial\mathbf{A}} & \dfrac{\partial H}{\partial\mathbf{A}} \\ \left(\dfrac{\partial H}{\partial\mathbf{A}}\right)^T & 0 \end{vmatrix} \neq 0. \tag{1.7}$$

For $d=2$, the determinant (1.7) is equal to $-m(\boldsymbol{\varphi})[\det(\boldsymbol{\Omega},\boldsymbol{\omega}_0)]^2$. Thus the isoenergetic nondegeneracy condition is not satisfied if $m(\boldsymbol{\varphi})$ has zeroes.

For $d>2$, the model (1.1) is isoenergetically degenerate. The present result is thus not a direct consequence of the ones in Refs. 16 and 17. We notice that in the case where $\boldsymbol{\Omega}$ is parallel to $\boldsymbol{\omega}_0$, the Hamiltonian (1.1) is integrable (because of the existence of d integrals of motion in involution: H and $\boldsymbol{\omega}_0^{\perp}\cdot\boldsymbol{\varphi}$, where $\boldsymbol{\omega}_0^{\perp}$ denotes a vector perpendicular to $\boldsymbol{\omega}_0$, and there are $d-1$ such independant vectors).

In this article, we present a self-contained proof of the KAM theorem for Hamiltonian (1.1) based on Thirring's proof for Hamiltonian (1.5). The advantages are twofold: On one hand, we show that Thirring's proof can be adapted to degenerate twist Hamiltonians, and on the other hand, the resulting proof becomes even simpler than Thirring's. The fact that the iteration stays within the space of Hamiltonians quadratic in the actions is very useful, e.g., for numerical implementations to study the breakup of invariant tori.[5,6]

Before entering into details of the theorem, we give basic definitions and notations: We denote $\mathscr{D}_\rho$ a complex neighborhood of $\mathbb{T}^d$ defined by

$$\mathscr{D}_\rho=\{\boldsymbol{\varphi}\in\mathbb{C}^d \,|\, \|\mathrm{Im}\ \boldsymbol{\varphi}\|\leqslant\rho\}, \tag{1.8}$$

where $\|z\|=\max_i(|z_i|)$, for any $z\in\mathbb{C}^d$. We will consider, in the following calculations, scalar functions defined in $\mathscr{D}_\rho$. More precisely, we define $\mathscr{A}_\rho$ as the set of complex functions $f(\boldsymbol{\varphi})$ defined on $\mathscr{D}_\rho$, analytic in the interior of $\mathscr{D}_\rho$, of period 2π in the variables φ_i, and which have real values when $\boldsymbol{\varphi}\in\mathbb{R}^d$. We define a norm on $\mathscr{A}_\rho$: $\|f\|_\rho=\sup_{\varphi\in\mathscr{D}_\rho}|f(\boldsymbol{\varphi})|$. We define $\langle f\rangle$, the mean value of f by

$$\langle f\rangle=\int_{\mathbb{T}^d}\frac{d^d\boldsymbol{\varphi}}{(2\pi)^d}f(\boldsymbol{\varphi}). \tag{1.9}$$

In the following sections, we will use the notation $\boldsymbol{\partial} f=\partial f/\partial\boldsymbol{\varphi}$ for any function of the angles. In Sec. II, we define the KAM iteration. In Sec. III, we give estimates on the transformed functions. Finally, in Sec. IV, we iterate the transformation, and prove the following KAM theorem for the family of Hamiltonians (1.1):

Theorem 1: *For* $H(\mathbf{A},\boldsymbol{\varphi})=1/2\ m(\boldsymbol{\varphi})(\boldsymbol{\Omega}\cdot\mathbf{A})^2+[\boldsymbol{\omega}_0+g(\boldsymbol{\varphi})\boldsymbol{\Omega}]\cdot\mathbf{A}+f(\boldsymbol{\varphi})$, *suppose that*

(*i*) $|\boldsymbol{\omega}_0\cdot\boldsymbol{\nu}|^{-1}\leqslant\sigma|\boldsymbol{\nu}|^\tau, \forall\,\boldsymbol{\nu}\in\mathbb{Z}^d\backslash\{0\}$, *for some* $\sigma>0$ *and* $\tau>d-1$;

(*ii*) m, g, *and* f *are analytic in* $\mathscr{D}_\rho$, *and* $|\boldsymbol{\Omega}|=1$;

(*iii*) $\max(\|g\|_\rho,\|f\|_\rho)\leqslant\beta_0$, *where*

$$\beta_0=2^{-10}\Gamma^{-6}c^{-3}(h/3)^{3(\tau+d+1)},$$

$$c=2^{3d}\sigma[2e^{-1}(\tau+1)]^{\tau+1},$$

$$\Gamma=\max(1,\|m\|_\rho,|\langle m\rangle|^{-1}),$$

$$h<\inf(2\rho/9,c^{1/(\tau+d+1)}).$$

Then, there exists a canonical transformation, analytic in $\mathscr{D}_{\rho-9h/2}$, *such that the Hamiltonian expressed in the new coordinates is*

$$H^{(\infty)}=\tfrac{1}{2}m^{(\infty)}(\boldsymbol{\varphi}^{(\infty)})(\boldsymbol{\Omega}\cdot\mathbf{A}^{(\infty)})^2+\boldsymbol{\omega}_0\cdot\mathbf{A}^{(\infty)},$$

where $m^{(\infty)}$ *is analytic in* $\mathscr{D}_{\rho-9h/2}$. *As a consequence, the system has an analytic invariant torus of frequency* $\boldsymbol{\omega}_0$.

Remark: If the constant part $\langle m\rangle$ of the quadratic term is zero, the maximal amplitude of the perturbation β_0 given by the theorem becomes zero. Thus in order to have a nontrivial result, we require that $\langle m\rangle$ is nonzero.

II. EXPRESSIONS OF THE GENERATING FUNCTION AND OF THE NEW HAMILTONIAN

We perform a canonical transformation $\mathscr{U}_F:(\boldsymbol{\varphi},\mathbf{A})\mapsto(\boldsymbol{\varphi}',\mathbf{A}')$ defined by a generating function[18,19] linear in the action variables, and characterized by two scalar functions Y, Z, of the angles, and a constant a, of the form

$$F(\mathbf{A}',\boldsymbol{\varphi})=(\mathbf{A}'+a\boldsymbol{\Omega})\cdot\boldsymbol{\varphi}+Y(\boldsymbol{\varphi})\boldsymbol{\Omega}\cdot\mathbf{A}'+Z(\boldsymbol{\varphi}), \tag{2.1}$$

leading to

$$\mathbf{A}=\frac{\partial F}{\partial\boldsymbol{\varphi}}=\mathbf{A}'+(\boldsymbol{\Omega}\cdot\mathbf{A}')\boldsymbol{\partial}Y+a\boldsymbol{\Omega}+\boldsymbol{\partial}Z, \tag{2.2}$$

$$\boldsymbol{\varphi}'=\frac{\partial F}{\partial\mathbf{A}'}=\boldsymbol{\varphi}+Y(\boldsymbol{\varphi})\boldsymbol{\Omega}. \tag{2.3}$$

Inserting Eq. (2.2) into the Hamiltonian (1.1), we obtain the expression of the Hamiltonian in the mixed representation of new action variables and old angle variables

$$\tilde{H}(\mathbf{A}',\boldsymbol{\varphi}) = \tfrac{1}{2}\,\tilde{m}(\boldsymbol{\varphi})(\boldsymbol{\Omega}\cdot\mathbf{A}')^2 + [\boldsymbol{\omega}_0 + \tilde{g}(\boldsymbol{\varphi})\boldsymbol{\Omega}]\cdot\mathbf{A}' + \tilde{f}(\boldsymbol{\varphi}), \tag{2.4}$$

with

$$\tilde{m} = (1+\boldsymbol{\Omega}\cdot\boldsymbol{\partial} Y)^2 m, \tag{2.5}$$

$$\tilde{g} = g + \boldsymbol{\omega}_0\cdot\boldsymbol{\partial} Y + mb + \boldsymbol{\Omega}\cdot\boldsymbol{\partial} Y(g+mb), \tag{2.6}$$

$$\tilde{f} = f + \boldsymbol{\omega}_0\cdot\boldsymbol{\partial} Z + \tfrac{1}{2}mb^2 + gb, \tag{2.7}$$

where $b(\boldsymbol{\varphi}) = a\Omega^2 + \boldsymbol{\Omega}\cdot\boldsymbol{\partial} Z$. As the new angles do not depend on the actions, the Hamiltonian (1.1) expressed in the new variables is also quadratic in the actions, and of the same form as (1.1). We notice that this transformation does not change $\boldsymbol{\Omega}$.

We determine the generating function (2.1) such that the new functions $\tilde{g}$, $\tilde{f}$ in $H\circ\mathscr{U}_F$ vanish to the first order in ε. This leads to the conditions

$$\boldsymbol{\omega}_0\cdot\boldsymbol{\partial} Z + f = \text{const}, \tag{2.8}$$

$$\boldsymbol{\omega}_0\cdot\boldsymbol{\partial} Y + g + m(a\Omega^2 + \boldsymbol{\Omega}\cdot\boldsymbol{\partial} Z) = 0. \tag{2.9}$$

The constant a allows us to have $\langle\tilde{g}\rangle = \mathscr{O}(\varepsilon^2)$, in order to keep the frequency $\boldsymbol{\omega}_0$ at the chosen value. We recall that the functions g and f are of order $\mathscr{O}(\varepsilon)$ and m is of order one; as a consequence Y, Z and a are of order $\mathscr{O}(\varepsilon)$. Equations (2.8) and (2.9) are solved by representing them in Fourier space. They define the generating function F as

$$Z(\boldsymbol{\varphi}) = \sum_{\nu\neq 0} \frac{i}{\boldsymbol{\omega}_0\cdot\boldsymbol{\nu}} f_\nu e^{i\nu\cdot\varphi}, \tag{2.10}$$

$$a = -\frac{\langle g\rangle + \langle m\boldsymbol{\Omega}\cdot\boldsymbol{\partial} Z\rangle}{\Omega^2\langle m\rangle}, \tag{2.11}$$

$$Y(\boldsymbol{\varphi}) = \sum_{\nu\neq 0} \frac{i}{\boldsymbol{\omega}_0\cdot\boldsymbol{\nu}} (g_\nu + (m\boldsymbol{\Omega}\cdot\boldsymbol{\partial} Z)_\nu + m_\nu a\Omega^2) e^{i\nu\cdot\varphi}, \tag{2.12}$$

where the scalar functions m, g, f are represented by their Fourier series, e.g.,

$$f(\boldsymbol{\varphi}) = \sum_{\nu\in\mathbb{Z}^d} f_\nu e^{i\nu\cdot\varphi}. \tag{2.13}$$

Thus the scalar functions in $\tilde{H}$ become

$$\tilde{m} = (1+\boldsymbol{\Omega}\cdot\boldsymbol{\partial} Y)^2 m, \tag{2.14}$$

$$\tilde{g} = -(\boldsymbol{\omega}_0\cdot\boldsymbol{\partial} Y)(\boldsymbol{\Omega}\cdot\boldsymbol{\partial} Y), \tag{2.15}$$

$$\tilde{f} = \tfrac{1}{2}(g - \boldsymbol{\omega}_0\cdot\boldsymbol{\partial} Y)(a\Omega^2 + \boldsymbol{\Omega}\cdot\boldsymbol{\partial} Z). \tag{2.16}$$

The expression of $\tilde{H}$ in the new angles requires the inversion of Eq. (2.3). We denote H' the Hamiltonian expressed in the new variables $H'(\mathbf{A}',\boldsymbol{\varphi}') = \tilde{H}(\mathbf{A}',\boldsymbol{\varphi})$:

$$H'(\mathbf{A}',\boldsymbol{\varphi}') = \tfrac{1}{2}m'(\boldsymbol{\varphi}')(\boldsymbol{\Omega}\cdot\mathbf{A}')^2 + [\boldsymbol{\omega}_0 + g'(\boldsymbol{\varphi}')\boldsymbol{\Omega}]\cdot\mathbf{A}' + f'(\boldsymbol{\varphi}'). \tag{2.17}$$

In the following section, we give estimates on Z, Y and a, in order to derive estimates on m', g' and f'.

III. ESTIMATES ON THE GENERATING FUNCTION AND ON THE NEW HAMILTONIAN

A. Estimate on the generating function

Lemma 1: Let f be an element of $\mathscr{A}_\rho$, and $\boldsymbol{\omega}_0$ satisfy Eq. (1.2), then $Z(\boldsymbol{\varphi})$ given by Eq. (2.10) is analytic on $\mathscr{D}_{\rho-h}$ (for any choice of h with $0<h<\rho<2$), and satisfies the following estimates

$$\|Z\|_{\rho-h}\leqslant \overline{c}h^{-\tau-d}\|f\|_\rho, \tag{3.1}$$

$$\|\boldsymbol{\omega}_0\cdot\boldsymbol{\partial}Z\|_{\rho-h}\leqslant\|f\|_\rho, \tag{3.2}$$

$$\|\boldsymbol{\Omega}\cdot\boldsymbol{\partial}Z\|_{\rho-h}\leqslant ch^{-\tau-d-1}\|f\|_\rho, \tag{3.3}$$

where $\overline{c}=2^{3d}\sigma(2e^{-1}\tau)^\tau$ and $c=2^{3d}\sigma[2e^{-1}(\tau+1)]^{\tau+1}$.

Proof: This lemma is proved, for instance, in Refs. 10 and 20. First, we estimate the Fourier coefficients of f expressed as integrals of f over the torus,

$$f_\nu=\int_{\mathbb{T}^d}\frac{d^d\boldsymbol{\varphi}}{(2\pi)^d}f(\boldsymbol{\varphi})e^{-i\nu\cdot\varphi}. \tag{3.4}$$

By a shift of the angles $\boldsymbol{\varphi}\mapsto\boldsymbol{\varphi}+i\boldsymbol{\eta}$, where $\eta_i=-\rho\nu_i/|\nu_i|$,

$$f_\nu=\int_{\mathbb{T}^d}\frac{d^d\boldsymbol{\varphi}}{(2\pi)^d}f(\boldsymbol{\varphi}+i\boldsymbol{\eta})e^{-i\nu\cdot\varphi}e^{-\rho|\nu|}. \tag{3.5}$$

Then $|f_\nu|\leqslant\|f\|_\rho e^{-\rho|\nu|}$, for all $\boldsymbol{\nu}\in\mathbb{Z}^d$.

To estimate Z given by Eq. (2.10), we use the diophantine property (1.2),

$$|Z(\boldsymbol{\varphi})|\leqslant\sigma\sum_{\nu\neq0}|\boldsymbol{\nu}|^\tau|f_\nu|e^{-\nu\cdot\mathrm{Im}\,\varphi}. \tag{3.6}$$

Then, for all $\boldsymbol{\varphi}\in\mathscr{D}_{\rho-h}$, we have

$$|Z(\boldsymbol{\varphi})|\leqslant\sigma\|f\|_\rho\sum_{\nu\neq0}|\boldsymbol{\nu}|^\tau e^{-h|\nu|}. \tag{3.7}$$

To estimate the sum, we use the following property which is easy to check (see Ref. 2):

$$|\boldsymbol{\nu}|^\tau\leqslant\left(\frac{2\tau}{eh}\right)^\tau e^{|\nu|h/2},\quad\forall\,\tau,h>0. \tag{3.8}$$

From the fact that $1/(1-e^{-x})<2/x$, for all $x\in]0,1[$, we have

$$\sum_{\nu\neq0}e^{-|\nu|h/2}<\left(\frac{8}{h}\right)^d, \tag{3.9}$$

which gives the estimate (3.1). The estimate (3.3) is obtained by the same calculations, and the estimate (3.2) is straightforward from Eq. (2.8). □

Lemma 2: Let m, g, and f be elements of $\mathscr{A}_\rho$, and $\boldsymbol{\omega}_0$ satisfy Eq. (1.2), then $Y(\boldsymbol{\varphi})$ given by Eq. (2.12) is analytic on $\mathscr{D}_{\rho-2h}$. The constant a and the function Y satisfy the following estimates

$$\|Y\|_{\rho-2h}\leqslant\overline{c}h^{-\tau-d}(1+|\langle m\rangle|^{-1}\|m\|_\rho)\times(\|g\|_\rho+ch^{-\tau-d-1}\|f\|_\rho\|m\|_\rho), \tag{3.10}$$

$$\|\boldsymbol{\omega}_0\cdot\boldsymbol{\partial}Y\|_{\rho-2h}\leqslant(1+|\langle m\rangle|^{-1}\|m\|_\rho)\times(\|g\|_\rho+ch^{-\tau-d-1}\|f\|_\rho\|m\|_\rho), \tag{3.11}$$

$$\|\boldsymbol{\Omega}\cdot\boldsymbol{\partial}Y\|_{\rho-2h}\leqslant ch^{-\tau-d-1}(1+|\langle m\rangle|^{-1}\|m\|_\rho)\times(\|g\|_\rho+ch^{-\tau-d-1}\|f\|_\rho\|m\|_\rho), \tag{3.12}$$

$$|a|\Omega^2\leqslant|\langle m\rangle|^{-1}(\|g\|_\rho+ch^{-\tau-d-1}\|f\|_\rho\|m\|_\rho). \tag{3.13}$$

The proof is the same as the one for the estimates on Z.

B. Estimate on the new Hamiltonian

The expression of the scalar functions of the Hamiltonian expressed in the new actions and old angles are explicitly known, and estimates on these functions are easy to obtain from the estimates on the generating function. One has then to invert Eq. (2.3) in order to obtain the estimate on the Hamiltonian expressed in the new angle variables. The Jacobian of this transformation is

$$\det\left|\frac{\partial\varphi_j'}{\partial\varphi_k}\right|=1+\boldsymbol{\Omega}\cdot\boldsymbol{\partial}Y. \tag{3.14}$$

In this section, we denote $V_\rho=\max(\|f\|_\rho,\|g\|_\rho)$ and $\Gamma=\max(1,\|m\|_\rho,|\langle m\rangle|^{-1})$.

From Eq. (2.3) and estimate (3.10), one has the following inequality:

$$|\boldsymbol{\varphi}'-\boldsymbol{\varphi}|\leqslant 2\Gamma^3ch^{-\tau-d}(1+ch^{-\tau-d-1})V_\rho, \tag{3.15}$$

for all $\boldsymbol{\varphi}\in\mathscr{D}_{\rho-2h}$ (we recall that $\Gamma\geqslant 1$). If we assume that V_ρ and h are sufficiently small, one has an estimate on the new angles. More precisely, we assume the following inequalities:

$$\Gamma^3c^2h^{-2(\tau+d+1)}V_\rho\leqslant\tfrac{1}{4}, \tag{3.16}$$

$$ch^{-\tau-d-1}\geqslant 1. \tag{3.17}$$

Then, for all $\boldsymbol{\varphi}\in\mathscr{D}_{\rho-2h}$, we have

$$|\boldsymbol{\varphi}'-\boldsymbol{\varphi}(\boldsymbol{\varphi}')|\leqslant h. \tag{3.18}$$

As a consequence, $\mathscr{D}_{\rho-2h}\subset\Phi(\mathscr{D}_{\rho-3h})$ by the map $\boldsymbol{\varphi}'\mapsto\boldsymbol{\varphi}=\Phi(\boldsymbol{\varphi}')$ given by Eq. (2.3). In order to express the estimates with respect to $\boldsymbol{\varphi}'$, it suffices thus to restrict the width of the strip $\mathscr{D}$ from $\rho-2h$ to $\rho-3h$, e.g., $\|f'\|_{\rho-3h}\leqslant\|\tilde{f}\|_{\rho-2h}$. Then, the estimates on the new perturbation (g',f') are obtained from Eqs. (2.15) and (2.16) and from the estimates on the generating function:

$$\|g'\|_{\rho-3h}\leqslant 2^4\Gamma^6c^3h^{-3(\tau+d+1)}V_\rho^2, \tag{3.19}$$

$$\|f'\|_{\rho-3h}\leqslant 2^3\Gamma^5c^2h^{-2(\tau+d+1)}V_\rho^2. \tag{3.20}$$

Taking into account condition (3.17), we obtain the estimate on $V'_{\rho-3h}=\max(\|g'\|_{\rho-3h},\|f'\|_{\rho-3h})$:

$$V'_{\rho-3h}\leqslant 2^4\Gamma^6c^3h^{-3(\tau+d+1)}V_\rho^2. \tag{3.21}$$

Concerning the quadratic term, we deduce from Eqs. (3.12) and (2.14) that

$$\|m'\|_{\rho-3h}\leqslant\|m\|_\rho(1+4\Gamma^3c^2h^{-2(\tau+d+1)}V_\rho)^2. \tag{3.22}$$

Then using Hypothesis (*iii*) of the theorem, we obtain $\|m'\|_{\rho-3h}\leqslant 2\Gamma$.

The mean value of m' is determined by the integral

$$\langle m'\rangle=\int_{\mathbb{T}^d}\frac{d^d\boldsymbol{\varphi}'}{(2\pi)^d}m'(\boldsymbol{\varphi}'). \tag{3.23}$$

With the change of variable $\boldsymbol{\varphi}' \mapsto \boldsymbol{\varphi}$ given by Eqs. (2.3) and (3.14) and using Eq. (2.14), we rewrite the integral

$$\langle m' \rangle = \int_{\mathbb{T}^d} \frac{d^d\boldsymbol{\varphi}}{(2\pi)^d} |1+\boldsymbol{\Omega}\cdot\boldsymbol{\partial} Y| \tilde{m}(\boldsymbol{\varphi}) = \int_{\mathbb{T}^d} \frac{d^d\boldsymbol{\varphi}}{(2\pi)^d} |1+\boldsymbol{\Omega}\cdot\boldsymbol{\partial} Y|^3 m(\boldsymbol{\varphi}). \tag{3.24}$$

To estimate $|\langle m' \rangle|^{-1}$, we first estimate the difference $|\langle m' \rangle - \langle m \rangle|$ using Eq. (3.24), and we obtain

$$|\langle m' \rangle - \langle m \rangle| \leqslant \|m\|_\rho (3\|\boldsymbol{\Omega}\cdot\boldsymbol{\partial} Y\|_{\rho-2h} + 3\|\boldsymbol{\Omega}\cdot\boldsymbol{\partial} Y\|^2_{\rho-2h} + \|\boldsymbol{\Omega}\cdot\boldsymbol{\partial} Y\|^3_{\rho-2h}). \tag{3.25}$$

From Eq. (3.12) and condition (3.16), we have the estimate

$$\|\boldsymbol{\Omega}\cdot\boldsymbol{\partial} Y\|_{\rho-2h} \leqslant 4\Gamma^3 c^2 h^{-2(\tau+d+1)} V_\rho \leqslant 1, \tag{3.26}$$

which leads to

$$|\langle m' \rangle - \langle m \rangle| \leqslant 28\Gamma^4 c^2 h^{-2(\tau+d+1)} V_\rho . \tag{3.27}$$

One can easily check that from Hypothesis (*iii*), it follows that

$$|\langle m' \rangle - \langle m \rangle| \leqslant \frac{1}{2\Gamma}. \tag{3.28}$$

Writing that $\langle m' \rangle = \langle m \rangle + \langle m' \rangle - \langle m \rangle$, we have the following estimate on $|\langle m' \rangle|^{-1}$:

$$|\langle m' \rangle|^{-1} \leqslant \frac{|\langle m \rangle|^{-1}}{|1-|\langle m \rangle|^{-1}|\langle m' \rangle - \langle m \rangle||}. \tag{3.29}$$

From Eq. (3.28), we deduce that $|\langle m' \rangle|^{-1} \leqslant 2\Gamma$. Therefore we have proved that $\Gamma' \equiv \max(1, \|m'\|_{\rho-3h}, |\langle m' \rangle|^{-1}) \leqslant 2\Gamma$.

IV. CONVERGENCE OF THE ITERATION: KAM THEOREM

The estimate (3.21) gives a precise meaning to the statement that the perturbation is reduced from V to V^2: we see that the actual reduction is somewhat smaller, since h depends on V_ρ through the condition (3.16) [the actual rate of reduction that takes this into account will be expressed by Eq. (4.11) below]. The counterpart is that the width of the domain of analyticity of the new functions is reduced from ρ to $\rho - 3h$; for this reason, h is called the ''analyticity loss parameter.'' At the n th step of the iteration, we choose h_n as the analyticity loss parameter such that the final domain of analyticity (after an infinite number of iterations) does not shrink to zero. For instance, we choose

$$h_n = h 3^{-n+1}, \quad \text{with} \quad h < \inf(2\rho/9, c^{1/(\tau+d+1)}). \tag{4.1}$$

The second term in the inf is to guarantee also the condition (3.17). We denote $\Gamma_n = \max(1, \|m^{(n)}\|_{\rho_n}, |\langle m^{(n)} \rangle|^{-1})$ and $V_n = \max(\|g^{(n)}\|_{\rho_n}, \|f^{(n)}\|_{\rho_n})$, where $m^{(n)}$, $g^{(n)}$ and $f^{(n)}$ denote the three scalar functions defining the Hamiltonian (1.1) after n iterations, and

$$\rho_n = \rho_{n-1} - 3h_n = \rho - 3\sum_{k=1}^{n} h_k . \tag{4.2}$$

The previous section gave the following estimates

$$V_n \leqslant 2^4 \Gamma^6_{n-1} c^3 h_n^{-3(\tau+d+1)} V^2_{n-1}, \tag{4.3}$$

$$\|m^{(n)}\|_{\rho_n} \leqslant \|m^{(n-1)}\|_{\rho_{n-1}} \times (1 + 4\Gamma^3_{n-1} c^2 h_n^{-2(\tau+d+1)} V_{n-1})^2. \tag{4.4}$$

We now prove that Γ_n is bounded, and that V_n tends to zero faster than geometrically as n goes to infinity.

Denoting

$$V_0=\max(\|g\|_\rho,\|f\|_\rho), \tag{4.5}$$

$$\Gamma=\max(1,\|m\|_\rho,|\langle m\rangle|^{-1}), \tag{4.6}$$

$$\gamma=2^{10}\Gamma^6c^3h^{-3(\tau+d+1)}, \tag{4.7}$$

$$\delta=3^{3(\tau+d+1)}, \tag{4.8}$$

we define the sequence of values

$$\varepsilon_n=\gamma\delta^{n-1}\varepsilon_{n-1}^2=\frac{(\gamma\delta V_0)^{2^n}}{\gamma\delta^{n+1}}. \tag{4.9}$$

We will show by induction that

$$\Gamma_k\leqslant 2\Gamma, \tag{4.10}$$

$$V_k\leqslant\varepsilon_k, \tag{4.11}$$

for all k. If we assume V_0 to be sufficiently small, such that $\gamma\delta V_0<1$, i.e.,

$$2^{10}\Gamma^6c^3h^{-3(\tau+d+1)}3^{3(\tau+d+1)}V_0<1, \tag{4.12}$$

which is the hypothesis (*iii*) of the theorem, then V_n tends to zero faster than $\delta^{-n}=3^{-3n(\tau+d+1)}$ as n goes to infinity. The bounds (4.10) and (4.11) are satisfied for $k=0$, since $\Gamma_0=\Gamma>0$ and $V_0=\varepsilon_0$. Suppose that for all $k<n$, these bounds are satisfied. From Eqs. (4.3) and (4.10), we deduce that

$$V_n\leqslant\gamma\delta^{n-1}V_{n-1}^2. \tag{4.13}$$

Then using Eq. (4.11), we have $V_n\leqslant\varepsilon_n$. Concerning Γ_n, Eq. (4.4) leads to

$$\|m^{(n)}\|_{\rho_n}\leqslant\|m\|_\rho\times\prod_{k=0}^{n-1}(1+2^5\Gamma^3c^2h^{-2(\tau+d+1)}3^{2k(\tau+d+1)}V_k)^2. \tag{4.14}$$

Using Eq. (4.11) and Hypothesis (*iii*), we obtain

$$2^5\Gamma^3c^2h^{-2(\tau+d+1)}3^{2k(\tau+d+1)}V_k\leqslant 3^{-(k+3)(\tau+d+1)}. \tag{4.15}$$

Then we have

$$\|m^{(n)}\|_{\rho_n}\leqslant\Gamma\prod_{k=0}^{\infty}(1+3^{-(k+3)(\tau+d+1)})^2. \tag{4.16}$$

Using the fact that $\Pi(1+x_k)^2\leqslant\exp(2\Sigma x_k)$, we show that the infinite product converges, and that it is smaller than 2. Thus $\|m^{(n)}\|_{\rho_n}\leqslant 2\Gamma$.

For $|\langle m^{(n)}\rangle|^{-1}$, we use estimate (3.29):

$$\frac{|\langle m^{(n)}\rangle|^{-1}}{|\langle m^{(n-1)}\rangle|^{-1}}\leqslant\frac{1}{|1-|\langle m^{(n-1)}\rangle|^{-1}|\langle m^{(n)}\rangle-\langle m^{(n-1)}\rangle||}. \tag{4.17}$$

The difference $|\langle m^{(n)}\rangle-\langle m^{(n-1)}\rangle|$ is evaluated as in the first step (3.27):

$$|\langle m^{(n)}\rangle-\langle m^{(n-1)}\rangle|\leqslant 28\cdot 2^4\Gamma^4c^2h^{-2(\tau+d+1)}\times 3^{2(n-1)(\tau+d+1)}V_{n-1}. \tag{4.18}$$

Using Eq. (4.11), Hypothesis (*iii*), and the fact that Γ and $ch^{-(\tau+d+1)}$ are greater than one,

$$|\langle m^{(n)}\rangle - \langle m^{(n-1)}\rangle| \leqslant 2^{-1}\Gamma^{-1}3^{-(n+2)(\tau+d+1)}. \tag{4.19}$$

Then,

$$|\langle m^{(n)}\rangle|^{-1} \leqslant \Gamma \prod_{k=0}^{\infty} (1-3^{-(k+2)(\tau+d+1)})^{-1}. \tag{4.20}$$

Using the fact that $\Pi(1-x_k)^{-1}=\exp(-\Sigma \ln(1-x_k))$, and that $-\ln(1-x)\leqslant x2\ln 2$, $\forall x\in[0,1/2]$, we show by straightforward calculations that $|\langle m^{(n)}\rangle|^{-1}\leqslant 2\Gamma$.

Thus we have proved (4.10) and (4.11) for all k.

We finally have to verify that with the choices (4.1) and (4.2), the conditions (3.16) and (3.17) are satisfied at each step of the iteration. Equation (3.17) is guaranteed by Eq. (4.1): $ch_n^{-(\tau+d+1)}\geqslant ch^{-(\tau+d+1)}\geqslant 1$. For Eq. (3.16), we first notice that, since $\Gamma\geqslant 1$, $\Gamma_n\leqslant 2\Gamma$, and $ch^{-(\tau+d+1)}>1$, we can write

$$\Gamma_{n-1}^3 c^2 h_n^{-2(\tau+d+1)} < 2^{-7}\gamma\delta^n.$$

Therefore using Eq. (4.11) and Hypothesis (*iii*), we have

$$\Gamma_{n-1}^3 c^2 h_n^{-2(\tau+d+1)} V_{n-1} < 2^{-7}(\gamma\delta V_0)^{2^{n-1}} < \tfrac{1}{4}.$$

We have shown that, for sufficiently small initial perturbation, the Hamiltonian converges under successive iterations of the transformation to a Hamiltonian of the form (1.1) with $g=f=0$. In order to complete the proof, we have still to verify that the composition of the infinitely many canonical transformations is a well-defined finite canonical transformation. It suffices to verify that $|\boldsymbol{\varphi}^{(\infty)}-\boldsymbol{\varphi}|$ and $|\mathbf{A}^{(\infty)}-\mathbf{A}|$ are finite. This is an immediate consequence of the fast convergence of the iteration. From Eq. (3.15), we deduce, e.g., that

$$|\boldsymbol{\varphi}^{(\infty)}-\boldsymbol{\varphi}| \leqslant \sum_{n=1}^{\infty} h_n = 3h/2. \tag{4.21}$$

Analogously, using Eqs. (2.2), (3.3), (3.11), (3.12), and (4.11), for $|\mathbf{A}|\leqslant A_0$, we can bound

$$|\mathbf{A}^{(\infty)}-\mathbf{A}| < \text{const}\times \sum_{n=1}^{\infty} h_n. \tag{4.22}$$

I. INTRODUCTION

Poncelet's theorem[1,2] is one of most beautiful and most important claims in projective geometry. Suppose we have two conics given in the plane, and a polygon inscribed in one and circumscribed about another conic. Poncelet's theorem states that there exist infinitely many such polygons. Even more, every point of the outer conic is a vertex of some polygonal line with this property, and all these polygons have the same number of sides.

A natural question arises: Is it possible to find an analytical condition for determination if there existed a polygon inscribed in one and circumscribed about another conic? Such a condition was established by Cayley. This result, in a nice geometrical form, can be found in Ref. 2. Griffiths and Harris derived Cayley's theorem using the analytical condition on a point to be of finite order in an elliptic curve group structure.[3] They also gave a generalization of Poncelet's theorem, considering polyhedra inscribed in two quadrics in three-dimensional space.[4]

Poncelet's theorem can be applied in mechanics. Trajectories of the billiard inside an ellipse have an interesting property: every segment of a given trajectory is tangent to the same conic, confocal with the boundary.[5] One can consider the billiard system inside an ellipsoid in the space of any dimension. Any trajectory of that mechanical system in R^d is tangent to $d-1$ quadrics confocal with the outer hypersurface.[6,7] The generalization of Poncelet's theorem (which is made in a different direction than Griffiths and Harris') is valid in the d-dimensional case also: There exists a closed trajectory with $d-1$ given confocal caustics if and only if infinitely many such trajectories exist, and all of them have the same period.[6,7]

The aim of our investigation was to find the corresponding generalization of Cayley's theorem, i.e., the analytical condition on a billiard trajectory within an ellipsoid in R^d to be periodic. Modifying Griffiths and Harris' ideas and applying them to the isospectral curves of Veselov and Moser, we established such a condition in three-dimensional space.[8]

In this paper, we are going to give similar conditions for the ellipsoidal billiard in any dimension. One of the consequences of the obtained result can be restated in a simple manner—there are no periodic billiard trajectories within an ellipsoid in d-dimensional space with nondegenerate caustics, with period less than d. If a trajectory is closed after k bounces, $k<d$, then it is placed in one of the coordinate k-planes and can be examined as in k-dimensional case. Let us note that in the planar case, the obtained condition is not identical to the classical Cayley's formula, although they are similar by their form.

II. ISOSPECTRAL CURVES AND PERIODICAL BILLIARD TRAJECTORIES

Veselov and Moser in Ref. 9 considered the ellipsoidal billiard as a system with discrete time. Let us give a brief account of the algebro-geometric way of its integration, necessary for further exposition. After that, the connection between periodical billiard trajectories and divisors of finite order, established in Ref. 8, will be also demonstrated.

Let an ellipsoid in R^d be given by the equation $(Ax,x)=1$, where A is a diagonal matrix, with different eigenvalues. Let $x_0,x_1,x_2,\ldots,$ be the points of consecutive bounces of the billiard inside that ellipsoid, and $y_k=(x_k-x_{k-1})/|x_k-x_{k-1}|$ be the momenta.

The sequence (x_k,y_k) can be transformed to a sequence which represents a flow of the discrete Heisenberg XYZ model,[9] given by

$$q_{k+1}+q_{k-1}=\nu_k J^{-1}q_k, \tag{1}$$

where ν_k is such that $|q_k|=1$. Namely, using the mapping $\phi:(\underline{x},\underline{y})\to(x',\underline{y'})$ given by $x'_k=J\underline{y}_{k+1}$, $y'_k=-J^{-1}\underline{x}_k$, $J=A^{-1/2}$, and defining the sequence $(\underline{x}_k,\underline{y}_k)$ by $(\underline{x}_0,\underline{y}_0)=(x_0,y_0)$, $(\underline{x}_{k+1},\underline{y}_{k+1})=\phi(\underline{x}_k,\underline{y}_k)$, we obtain $q_k=J^{-1}\underline{x}_k$. The sequence q_k satisfies Eq. (1). Conversely, if q_k is the solution of the Heisenberg system, then the sequence $x_k=(-1)^k Jq_{2k}$ represents a trajectory of a discrete ellipsoidal billiard system.[9]

The isospectral curve, a basic tool of algebro-geometric integration, related to the Heisenberg system is found in[9]

$$\Gamma:\nu^2=\prod_{i=1}^{d-1}(\mu-\mu_i)\prod_{j=1}^{d}(\mu-J_j^2), \tag{2}$$

where $J=\mathrm{diag}(J_1,...,J_d)$, and $\mu_1,\ldots,\mu_{d-1}$ are the roots of the function

$$\phi_\mu(x,Jy)=\sum_{i=1}^{N}\frac{F_i(x,y)}{\mu-J_i^2},\quad F_i=x_i^2+\sum_{j\neq i}\frac{(x\wedge Jy)_{ij}^2}{J_i^2-J_j^2}, \tag{3}$$

with $x=q_{k-1}$, $y=q_k$. The sequence q_k can be uniquely recovered from the divisor sequence $D_{k+1}=D_k+P_\infty-P_0$ on the Jacobian variety of the curve Γ, where P_∞ corresponds to the value $\mu=\infty$, and P_0 to $\mu=0$, $\lambda=(q_k,J^{-1}q_{k+1})^{-1}$.

The connection between periodical billiard trajectories and periodic sequences of the divisors is described in following lemma.

Lemma 1: (Reference 8) If the billiard is periodic with the period n, then the divisor sequence D_k joined to the corresponding Heisenberg XYZ system is also periodic, with period 2n.

By this lemma, we need to investigate when $2n(P_\infty-P_0)=0$ on the Jacobian variety of the spectral curve Γ.

III. POINTS OF FINITE ORDER ON THE JACOBIAN VARIETY OF A HYPERELLIPTIC CURVE

The following discussion is motivated by Eq. (2) of curve Γ and the fact that P_∞ is a branch point of Γ.

Let the curve $\mathscr{C}$ be given by

$$y^2=(x-x_1)\cdots(x-x_{2g+1}),\quad x_i\neq x_j \text{ when } i\neq j.$$

It is a hyperelliptic curve of genus g. Here, we are going to find an analytic characterization of points $P\in\mathscr{C}$ which satisfy $nu(P)=0$, where $u:\mathrm{Div}(\mathscr{C})\to\mathscr{J}(\mathscr{C})$ is the Abel–Jacobi map.

Take E to be the point which corresponds to the value $x=\infty$, and choose $u(E)$ to be the neutral in $\mathscr{J}(\mathscr{C})$. According to the Abel's theorem,[10] $u(P_1)+\cdots+u(P_n)=0$ if and only if there exists a meromorphic function f with zeroes $P_1,\ldots,P_n$ and a pole of order n at the point E. Let $\mathscr{L}(nE)$ be the vector space of meromorphic functions on $\mathscr{C}$ with a unique pole E of order at most n, and $f_1,\ldots,f_k$ a basis of $\mathscr{L}(nE)$. The mapping

$$F:\mathscr{C}\to P^{k-1},\quad X\mapsto[f_1(X),\ldots,f_k(X)]$$

is a projective embedding whose image is a smooth algebraic curve of degree n. Hyperplane sections of this curve are zeroes of functions from $\mathscr{L}(nE)$. Thus, the equality $nu(P)=0$ is equivalent to

$$\operatorname{rank}\begin{bmatrix} f_1(P) & f_2(P) & \cdots & f_k(P) \\ f_1'(P) & f_2'(P) & \cdots & f_k'(P) \\ \cdots\cdots & \cdots\cdots & \cdots & \cdots\cdots \\ f_1^{(n-1)}(P) & f_2^{(n-1)}(P) & \cdots & f_k^{(n-1)}(P) \end{bmatrix} < k. \tag{4}$$

Lemma 2: For $n \leqslant 2g$, there does not exist a point P on the curve $\mathscr{C}$, such that $nu(P)=0$ and $P \neq E$.

Proof: Let P be a point on $\mathscr{C}$, $P \neq E$, and $x=x_0$ its corresponding value.

Consider the case of n even. Since E is a branch point of a hyperelliptic curve, its Weietstrass gap sequence is $1,3,5,\ldots,2g-1$.[10] Now applying the Riemann–Roch theorem,[10] we obtain $\dim \mathscr{L}(nE)=n/2+1$. Choosing a basis $1,x,\ldots,x^{n/2}$ for $\mathscr{L}(nE)$, and substituting in (4), we come to a contradiction. □

Lemma 3: Let $P(x_0,y_0)$ be a nonbranching point on the curve $\mathscr{C}$. For $n>2g$, equality $nu(P)=0$ is equivalent to

$$\operatorname{rank}\begin{bmatrix} B_{m+1} & B_m & \cdots & B_{g+2} \\ B_{m+2} & B_{m+1} & \cdots & B_{g+3} \\ \cdots\cdots & \cdots\cdots & \cdots & \cdots\cdots \\ B_{2m-1} & B_{2m-2} & \cdots & B_{m+g} \end{bmatrix} < m-g \quad \textit{when} \quad n=2m$$

and $\sqrt{(x-x_1)\cdots(x-x_{2g+1})}=B_0+B_1(x-x_0)+B_2(x-x_0)^2+B_3(x-x_0)^3+\cdots$. The similar condition can be written for n odd.

Proof: This claim follows from previous results by choosing a basis for $\mathscr{L}(nE)$: $1,x,\ldots,x^m,y,xy,\ldots,x^{m-g-1}y$, $n=2m$, similarly as in Ref. 2. □

IV. ANALYTICAL CHARACTERIZATION OF PERIODICAL BILLIARD TRAJECTORIES

Using the connection between periodical billiard trajectories and divisors of finite order on the spectral curve Γ, we can apply the results of Sec. III whenever Γ is a nonsingular curve.

Let the equation of the boundary be

$$\frac{x_1^2}{J_1^2}+\cdots+\frac{x_d^2}{J_d^2}=1. \tag{5}$$

Every segment of a given billiard trajectory is tangent to the same $d-1$ quadrics, confocal with the outer ellipsoid. Suppose their equations are:

$$\frac{x_1^2}{J_1^2-\alpha_i}+\cdots+\frac{x_d^2}{J_d^2-\alpha_i}=1 \quad (1 \leqslant i \leqslant d-1). \tag{6}$$

Functions F_i defined by (3) are integrals of the billiard. Moreover, they have the same values for all trajectories which share the same caustic hypersufaces.[11] The roots of ϕ_μ are equal to $\alpha_1,\ldots,\alpha_{d-1}$,[12] which can be obtained by direct calculation choosing a line parallel to one of the coordinate axes to be the first segment of the trajectory.

Proposition: The curve Γ is singular if and only if the billiard trajectory is placed in one of coordinate hyperplanes.

Proof: By assumption, $J_1^2,\ldots,J_d^2$ are mutually different. Chasles' theorem[13] states that every line in d-dimensional space is tangent to $d-1$ quadrics from a given confocal family. Thus $\alpha_1,\ldots,\alpha_{d-1}$ are also all different.

Γ is singular if and only if $\alpha_i=J_j^2$ for some i,j, i.e., if some of the caustic quadrics is degenerate. This takes place if the first segment of the trajectory is in one of the coordinate hyperplanes (because of symmetry, then the whole trajectory has to be placed in this hyperplane). □

Summarize the obtained results as follows.

Theorem 1. The condition on a billiard trajectory inside ellipsoid (5) in R^d, with nondegenerate caustics (6), to be perodic with period $n \geqslant d$ is

$$\operatorname{rank}\begin{bmatrix} B_{n+1} & B_n & \cdots & B_{d+1} \\ B_{n+2} & B_{n+1} & \cdots & B_{d+2} \\ \cdots\cdots & \cdots\cdots & \cdots\cdots & \cdots\cdots \\ B_{2n-1} & B_{2n-2} & \cdots & B_{n+d-1} \end{bmatrix} < n-d+1,$$

where $\sqrt{(x-\alpha_1)\cdots(x-\alpha_{d-1})(x-J_1^2)\cdots(x-J_d^2)} = B_0 + B_1 x + B_2 x^2 + \cdots$ *. There are no such trajectories with period less than d.*

Proof: The trajectory is periodic with period n if, by lemma 1, the corresponding divisor sequence on the curve Γ has the period $2n$, i.e., $2n(P_\infty - P_0) = 0$ on $\mathscr{J}(\mathscr{C})$. Curve Γ is hyperelliptic with genus $g = d-1$. Taking $u(P_\infty)$ to be the neutral on $\mathscr{J}(\mathscr{C})$ we get desired results by applying lemmas 2 and 3. □

This is a sort of generalization of Cayley's condition. It is very similar, but even in the case $d=2$, not exactly the same as Cayley's formula. Theorem 1 does not give a complete description of periodical billiard trajectories. For example, it is obvious that there always exists a trajectory with period 2—with both bounces on the same coordinate axis.

Theorem 2: *If the billiard trajectory inside the ellipsoid (5) is periodic with period $n<d$, then all the bounces are placed in one of the coordinate n-dimensional planes.*

Proof: This follows immediately from the proposition, theorem 1, and the fact that the section of the confocal family of quadrics with a coordinate hyperplane is again a confocal family. □

All periodic trajectories of the billiard system either satisfy the condition from Theorem 1 and have at least d bounces, or they are placed in a coordinate k-plane. The analytic condition in the latter case can be obtained by appropriate application of Theorem 1.

Electromagnetic fields in air of traveling-wave currents above the earth

Dionisios Margetis[a)]
Gordon McKay Laboratory, Harvard University, Cambridge, Massachusetts 02138-2901

(Received 12 November 1996; accepted for publication 10 July 1998)

The problem of the electromagnetic field created by a thin, straight conductor of infinite length carrying a forward traveling-wave current with a complex propagation constant γ above a homogeneous and isotropic planar earth of wave number k_1 is formulated in terms of contour integrals. In the limit where γ becomes equal to the free-space wave number k_0, the component of the magnetic field in air normal to both conductor and interface is evaluated in closed form in terms of known special functions while the remaining components of the field in air are expressed as series expansions in $\delta=k_0^2(k_1^4-k_0^4)^{-1/2}$ via the application of a contour integration technique. The new analytical formulas involve familiar transcendental functions and are valid at any distance from the source. The analysis sheds light on the intricate nature of low-frequency electromagnetic fields generated by transmission lines in the presence of a conducting or a dielectric half-space. © *1998 American Institute of Physics.* [S0022-2488(98)02811-4]

I. INTRODUCTION

The determination of the propagation modes for the current and evaluation of the ensuing electromagnetic field of a thin, infinitely long straight wire immersed in a stratified medium is a fundamental and fairly old problem in electromagnetic theory. Of particular interest is the case in which the conductor is placed parallel to an isotropic, homogeneous half-space. In the thin-wire approximation, the field is computed with the assumption that the current is axial and concentrated in a line at the center of the cross section of the wire. Early investigations[1,2] employed approximate transmission-line theory and were essentially limited to a relatively dense neighboring medium and to distances from the source that are short compared to the medium's wavelength. In later analyses[3–6] the field components of a conductor carrying an exponential current were expressed in terms of Fourier integrals in the direction normal to the conductor and parallel to the interface, with the tacit or explicit assumption that the field tends to zero when the distance perpendicular to the wire approaches infinity. In these studies, it has not been possible to evaluate all requisite integrals of the so-called Sommerfeld type, even for special values of the propagation constant γ for the current.

Coleman[7] was probably the first to point out that in the limit $a/d\to 0$, where a is the radius of the wire and d is the distance from the interface, the modal equation yields a solution for γ which approaches the wave number k_0 of the ambient medium. Approximate analytical derivations through disparate mathematical methods by Chang and Wait[4] and by King *et al.*[8] with the condition $0<k_0d\ll 1$ and for a relatively dense neighboring medium have corroborated and refined Coleman's[7] findings when $a\ll d$. For the air-earth configuration, deviations from the value $\gamma=k_0$ result then in negligible deviations of the fields in air for all distances of interest at extremely low frequencies. In the case of two or more thin, parallel conductors the condition of a vanishing total current reinforces the reasoning for the assumption $\gamma=k_0$ because of the confinement of the field closer to the source.[9,10] Notably, γ changes drastically when the wire approaches the vicinity of the boundary ($d\sim a$) because of the proximity effect of the earth's surface.[4,7,9] Investigation of the modal equation for a wide range of frequencies is a formidable task.[11,12]

In a recent paper by King and Wu[10] simple approximate formulas for the field were derived under the condition $k_0^2\ll|k_1^2|$ via integration of the approximate lateral-wave formulas for the field

a)Electronic mail: margetis@huhepl.harvard.edu

 © 1998 American Institute of Physics

of a horizontal electric dipole,[13] where k_1 is the wave number of the earth. However, as pointed out in Ref. 10, the violation of the requisite condition $|k_1 r'|>1$ at extremely low frequencies, where r' is the distance from the dipole, introduced an inaccuracy for the axial component of the electric field.

This paper has a twofold purpose. The first is to outline a procedure for obtaining integral representations for all components of the electromagnetic field under the thin-wire approximation in the general case when the current in the x-directed conductor at a fixed frequency ω is of the form $e^{i\gamma x - i\omega t}$, where Re $\gamma>0$, Im $\gamma\geqslant 0$, by invoking the condition that the field be described as a superposition of outgoing waves in the direction normal to both conductor and interface. This in turn leads to a radiation field which is exponentially increasing in the direction normal to the wire when Im $\gamma>0$ and the surrounding medium is a perfect dielectric, such as air, in agreement with the studies on the theory of the microstrip.[14–17] This point is discussed further in Sec. IV.

The second purpose is to evaluate exactly the requisite integrals for the field in air at any distance from the source in the limit $\gamma\to k_0$ by relaxing the condition $k_0^2\ll|k_1^2|$, where k_1 is the wave number of the adjacent medium. This is achieved by applying a contour integration technique. The new integrated formulas involve series expansions in δ^2 for $|\delta|<1$, where δ is expressed as $\delta=\eta_S/k$, η_S being the limit as $\gamma\to k_0$ of the Sommerfeld pole and $k=\sqrt{k_1^2-k_0^2}$, with series coefficients that depend on known special functions. These series are shown to converge uniformly in distance. In certain limiting cases the formulas in question reduce to simplified expressions, such as the well known Carson's series,[1] that have been previously derived by different approximate means. It is emphasized that the proposed treatment is not intended to serve as a substitute for previous simple approximate results; it rather aims at demonstrating rigorously exact solubility of the model in question with the removal of certain restrictions on the physical parameters. Consequently, stringent conditions for the validity of practically appealing simplifications can follow.

Compared with actual current-carrying wires the main idealizations involved here are (1) the current-carrying conductor in air is infinitely long and thin ($a\ll d$); (2) the air-earth interface is planar; (3) the source current has the dependence $e^{i\gamma x}$ with the distance x along the wire. The limit $\gamma\to k_0$ corresponds to the transverse electromagnetic (TEM) mode in air in the absence of the earth. This propagation constant reasonably describes the slow-wave currents in actual multiphase transmission lines above the earth.[9,10] The $e^{-i\omega t}$ time dependence is suppressed throughout the analysis.

II. FORMULATION

The geometry of the problem is shown in Fig. 1. It consists of an infinitely long x-directed conductor lying in the vertical plane $y=0$ in the air (region 0, $z>0$) at height d above the surface ($z=0$) of an isotropic, homogeneous and nonmagnetic earth (region 1, $z<0$). The associated current density is assumed to be

$$\mathbf{J}(\mathbf{r})=e^{i\gamma x}\delta(y)\,\delta(z-d)\hat{\mathbf{x}},\quad \text{Re }\gamma>0,\quad \text{Im }\gamma>0, \tag{1}$$

where $\mathbf{r}=(x,y,z)$. At this point, it is not advisable to employ the usual spatial Fourier transform in y of the field since the requisite integrability condition for $|y|\to\infty$ is not necessarily met. A remedy to this problem is to seek a meaningful integral representation of the form

$$\mathbf{F}_j(x,y,z)=\frac{1}{2\pi}\int_\Gamma d\eta\,\overline{\mathbf{F}}_j(x,\eta,z)e^{i\eta y}, \tag{2}$$

where $\mathbf{F}_j=\mathbf{E}_j$, $\mathbf{B}_j$ $(j=0,1)$ denote the electric and magnetic field, respectively, in each region 0, 1 and Γ is a properly chosen infinite integration path with horizontal asymptotes in the η-plane. Specifically, when a scalar integral coefficient becomes 1, the respective integral yields the Dirac delta function $\delta(y)$. Conventional inversion of the integral formula of Eq. (2) is not generally possible.

Formally, with a dependence of the form

$$\mathbf{F}_j(\mathbf{r})=e^{i\gamma x}\mathbf{f}_j(y,z), \tag{3}$$

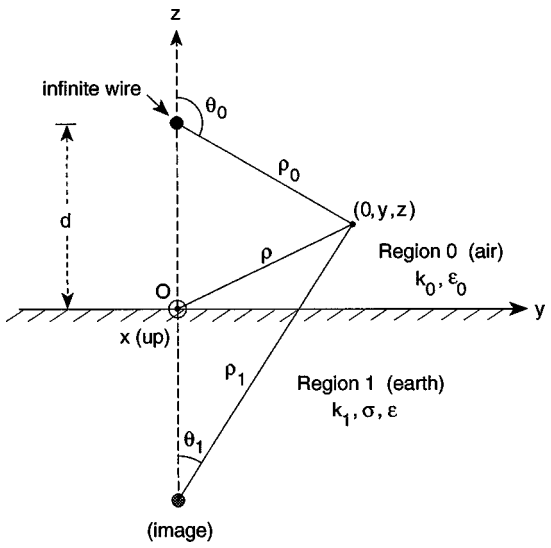

FIG. 1. Cross section of an infinitely thin, infinitely long conductor above the earth.

$\mathbf{E}_j$ and $\mathbf{B}_j$ satisfy Maxwell's equations if the coefficients $\overline{\mathbf{f}}_j=\overline{\mathbf{e}}_j$, $\overline{\mathbf{b}}_j$ $(j=0,1)$ obey the following equations:

$$\overline{e}_{jy}=\frac{i}{k_j^2-\gamma^2}\left[i\eta\gamma\overline{e}_{jx}+\omega\frac{\partial\overline{b}_{jx}}{\partial z}\right], \tag{4}$$

$$\overline{e}_{jz}=\frac{i}{k_j^2-\gamma^2}\left[\gamma\frac{\partial\overline{e}_{jx}}{\partial z}-i\eta\omega\overline{b}_{jx}\right], \tag{5}$$

$$\overline{b}_{jy}=-\frac{1}{k_j^2-\gamma^2}\left[\eta\gamma\overline{b}_{jx}+\frac{ik_j^2}{\omega}\frac{\partial\overline{e}_{jx}}{\partial z}\right], \tag{6}$$

$$\overline{b}_{jz}=\frac{1}{k_j^2-\gamma^2}\left[i\gamma\frac{\partial\overline{b}_{jx}}{\partial z}-\frac{\eta k_j^2}{\omega}\overline{e}_{jx}\right], \tag{7}$$

$$\frac{\partial^2\overline{e}_{jx}}{\partial z^2}+\gamma_j^2\overline{e}_{jx}=-\frac{i\omega\mu_0}{k_j^2}(k_j^2-\gamma^2)\,\delta(z-d), \tag{8}$$

$$\frac{\partial^2\overline{b}_{jx}}{\partial z^2}+\gamma_j^2\overline{b}_{jx}=0, \tag{9}$$

where

$$\gamma_j^2=k_j^2-\gamma^2-\eta^2. \tag{10}$$

The η-Riemann surface for $\overline{\mathbf{e}}_j$, $\overline{\mathbf{b}}_j$ consists of four sheets. For definiteness, the first Riemann sheet $\mathscr{R}_1$ is defined as

$$\forall\,\eta\in\mathscr{R}_1,\quad -\pi/2<\arg\,\gamma_j\leqslant\pi/2. \tag{11}$$

The corresponding branch cuts are parts of hyperbolas, as depicted in Fig. 2. Final expressions for $\overline{\mathbf{e}}_j$, $\overline{\mathbf{b}}_j$ are uniquely determined by imposition of:

(1) Outgoing waves in z; this excludes solutions of the form $e^{-i\gamma_0 z}$ for $z>d$ and $e^{i\gamma_1 z}$ for $z<0$ in Eqs. (8) and (9).

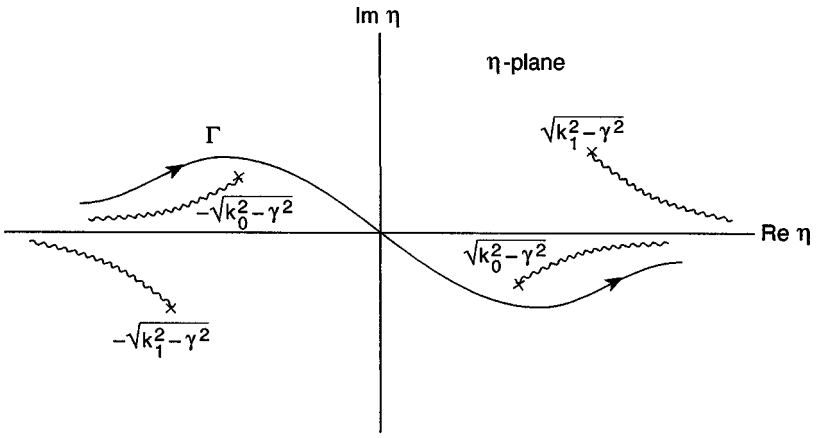

FIG. 2. Integration path Γ in the complex η-plane for the electric and magnetic field of an infinitely long wire in air (wave number k_0) carrying an $e^{i\gamma x}$, Re $\gamma>0$, Im $\gamma>0$, current over the earth (wave number k_1).

(2) Continuity of $\overline{e}_{jx}$, $\overline{b}_{jx}$, $\overline{e}_{jy}$, $\overline{b}_{jy}$ at $z=0$.

Accordingly, for $z>0$ the axial components read

$$\overline{e}_{0x}=-\omega\mu_0\frac{\gamma_1(k_0^2-\gamma^2)+\gamma_0(k_1^2-\gamma^2)}{K(\eta)L(\eta)}e^{i\gamma_0(z+d)}+\frac{i\omega\mu_0}{\gamma_0 k_0^2}(k_0^2-\gamma^2)e^{i\gamma_0 z_>}\sin(\gamma_0 z_<), \tag{12}$$

$$\overline{b}_{0x}=\mu_0\frac{\eta\gamma(k_1^2-k_0^2)}{K(\eta)L(\eta)}e^{i\gamma_0(z+d)}, \tag{13}$$

while for $z<0$

$$\overline{e}_{1x}=-\omega\mu_0\frac{\gamma_1(k_0^2-\gamma^2)+\gamma_0(k_1^2-\gamma^2)}{K(\eta)L(\eta)}e^{i\gamma_0 d}e^{-i\gamma_1 z}, \tag{14}$$

$$\overline{b}_{1x}=\mu_0\frac{\eta\gamma(k_1^2-k_0^2)}{K(\eta)L(\eta)}e^{i\gamma_0 d}e^{-i\gamma_1 z}, \tag{15}$$

where

$$K(\eta)=\gamma_0+\gamma_1, \tag{16a}$$

$$L(\eta)=k_1^2\gamma_0+k_0^2\gamma_1. \tag{16b}$$

In the above, $z_>$ is the larger one of z and d and $z_<$ is the smaller one. Similar formulas for the remaining components are obtained directly from Eqs. (4)–(7). If γ is considered to be real, $\overline{\mathbf{e}}_j$ and $\overline{\mathbf{b}}_j$ designate the two-dimensional spatial Fourier transforms in x,y of the projections in x of the tensor Green's functions for the electric and magnetic field. From Eq. (16b) it is inferred that when $\gamma\neq k_0k_1/\sqrt{k_0^2+k_1^2}$, $L(\eta)$ has four simple zeros in the η-Riemann surface which are the Sommerfeld poles:

$$\eta=\pm\eta_S=\pm\sqrt{\frac{k_0^2k_1^2}{k_0^2+k_1^2}-\gamma^2}. \tag{17}$$

In contrast, $K(\eta)$ is free of zeros in any finite region of this surface. It is noteworthy that the $\overline{b}_{jz}$ are free of the $L(\eta)$ denominator.

An integration path Γ which is symmetric under inversion through the origin is subsequently chosen so that: (1) It lies entirely in $\mathscr{R}_1$. (2) All integrals are absolutely convergent. (3) The positive and negative real axes are asymptotes of the path. Among these requirements, (1) and (2)

suffice to determine the field. The chosen contour is shown in Fig. 2. Integral representations for the field follow from Eq. (2). These satisfy Maxwell's equations in each region 0, 1 along with the prescribed boundary conditions at $z=0$ and are expressed as a Fourier superposition of outgoing waves in z.

In the limit $z\to\infty$, the principal contribution to integration arises from the vicinity of $\eta=0$, yielding a leading term that is exponentially growing in z. Similar asymptotic behavior can be found via the method of steepest descents[18] when $\sqrt{y^2+z^2}\to\infty$ for $z>0$, as outlined in Appendix A.

Evidently, the integral representations may be continued to $\gamma=k_0$. The respective field tends to zero when $\sqrt{y^2+z^2}\to\infty$.

III. THE CASE $\gamma=k_0$

A. Integral representations for the field in air

In the limit $\gamma\to k_0$, the integration path Γ in Eq. (2) can be deformed to coincide with the entire real axis. By use of Eqs. (2)–(7), (12) and (13), and evaluation of the elementary integrals, it is straightforward to arrive at the following expressions for the fields $\mathbf{E}_0$, $\mathbf{B}_0$:

$$E_{0x}=-\frac{\omega\mu_0}{2\pi}\,e^{ik_0x}\int_{-\infty}^{\infty}d\eta e^{i\eta y}e^{-|\eta|(z+d)}\left[\frac{1}{i|\eta|+\sqrt{k^2-\eta^2}}-\frac{k_0^2}{k_0^2\sqrt{k^2-\eta^2}+ik_1^2|\eta|}\right] \tag{18a}$$

$$=\frac{i\omega\mu_0}{2\pi}\,e^{ik_0x}[\Phi_+(y,z;1)-(k_0^2/k_1^2)\Phi_+(y,z;k_0^2/k_1^2)], \tag{18b}$$

$$E_{0y}=\frac{\omega\mu_0k_0}{2\pi}\,e^{ik_0x}\int_{-\infty}^{\infty}d\eta e^{i\eta y}e^{-|\eta|d}\eta\left[\frac{-i\,\sinh(\eta z)}{\eta k_0^2}+\frac{e^{-|\eta|z}}{ik_1^2|\eta|+k_0^2\sqrt{k^2-\eta^2}}\right],\quad 0<z<d \tag{19a}$$

$$=\frac{\mu_0c}{2\pi}\,e^{ik_0x}\left[\left(\frac{y}{\rho_0^2}-\frac{y}{\rho_1^2}\right)+k\,\frac{k_0^2}{k_1^2}\,\Psi_-(y,z;k_0^2/k_1^2)\right], \tag{19b}$$

$$E_{0z}=\frac{\omega\mu_0k_0}{2\pi}\,e^{ik_0x}\int_{-\infty}^{\infty}d\eta e^{i\eta y}e^{-|\eta|d}\left[-\frac{\cosh(\eta z)}{k_0^2}+\frac{\sqrt{k^2-\eta^2}}{ik_1^2|\eta|+k_0^2\sqrt{k^2-\eta^2}}\,e^{-|\eta|z}\right],\quad 0<z<d \tag{20a}$$

$$=\frac{\mu_0c}{2\pi}\,e^{ik_0x}\left[\left(\frac{z-d}{\rho_0^2}-\frac{z+d}{\rho_1^2}\right)-ik\,\frac{k_0^2}{k_1^2}\,U(y,z;k_0^2/k_1^2)\right], \tag{20b}$$

$$B_{0x}=-i\,\frac{\mu_0k_0}{2\pi}\,e^{ik_0x}\int_{-\infty}^{\infty}d\eta e^{i\eta y}e^{-|\eta|(z+d)}\,\mathrm{sgn}(\eta)\left[\frac{1}{\sqrt{k^2-\eta^2}+i|\eta|}-\frac{k_0^2}{ik_1^2|\eta|+k_0^2\sqrt{k^2-\eta^2}}\right] \tag{21a}$$

$$=\frac{\mu_0\omega}{2\pi c}\,e^{ik_0x}[\Phi_-(y,z;1)-(k_0^2/k_1^2)\Phi_-(y,z;k_0^2/k_1^2)], \tag{21b}$$

$$B_{0y}=\frac{\mu_0}{2\pi}\,e^{ik_0x}\int_{-\infty}^{\infty}d\eta e^{i\eta y}e^{-|\eta|d}\left[\cosh(\eta z)+\frac{k_1^2\eta^2-k_0^2(k^2+i|\eta|\sqrt{k^2-\eta^2})}{(i|\eta|+\sqrt{k^2-\eta^2})(ik_1^2|\eta|+k_0^2\sqrt{k^2-\eta^2})}\,e^{-|\eta|z}\right],\quad 0<z<d \tag{22a}$$

$$= -\frac{\mu_0}{2\pi} e^{ik_0x}\left[\left(\frac{z-d}{\rho_0^2} - \frac{z+d}{\rho_1^2}\right) - ikW(y,z;k_0^2/k_1^2)\right], \tag{22b}$$

$$B_{0z} = \frac{\mu_0}{2\pi} e^{ik_0x}\int_{-\infty}^{\infty} d\eta e^{i\eta y} e^{-|\eta|d}\eta\left[\frac{-i\ \sinh(\eta z)}{\eta} + \frac{e^{-|\eta|z}}{i|\eta| + \sqrt{k^2-\eta^2}}\right], \quad 0<z<d \tag{23a}$$

$$= \frac{\mu_0}{2\pi} e^{ik_0x}\left[\left(\frac{y}{\rho_0^2} - \frac{y}{\rho_1^2}\right) + k\Psi_-(y,z;1)\right], \tag{23b}$$

where

$$k = \sqrt{k_1^2 - k_0^2}, \quad \text{Im } k \geqslant 0, \tag{24}$$

$c = (\epsilon_0\mu_0)^{-1/2}$ is the velocity of light, $\text{sgn}(\eta)$ is the sign function

$$\text{sgn}(\eta) = \begin{cases} 1, & \eta > 0 \\ 0, & \eta = 0 \\ -1, & \eta < 0, \end{cases}$$

and, with the introduction of a new variable $s = ik^{-1}|\eta|$,

$$\Phi_\pm(y,z;\beta) = \varphi(\alpha_+;\beta) \pm \varphi(\alpha_-;\beta), \quad \Psi_\pm(y,z;\beta) = \psi(\alpha_+;\beta) \pm \psi(\alpha_-;\beta), \tag{25}$$

$$U(y,z;\beta) = u(\alpha_+;\beta) + u(\alpha_-;\beta) = \frac{1}{\beta}\left(\frac{1}{\alpha_+} + \frac{1}{\alpha_-}\right) - \frac{1}{\beta}\Psi_+(y,z;\beta), \tag{26}$$

$$W(y,z;\beta) = w(\alpha_+;\beta) + w(\alpha_-;\beta) = \Psi_+(y,z;1) - (1+\beta)\Psi_+(y,z;\beta) + \left(\frac{1}{\alpha_+} + \frac{1}{\alpha_-}\right), \tag{27}$$

$$\varphi(\alpha;\beta) = \int_0^{\infty e^{i\tau}} ds e^{-\alpha s}\frac{1}{s + \beta\sqrt{s^2+1}}, \tag{28}$$

$$\psi(\alpha;\beta) = \int_0^{\infty e^{i\tau}} ds e^{-\alpha s}\frac{s}{s + \beta\sqrt{s^2+1}} = -\frac{\partial}{\partial\alpha}\varphi(\alpha;\beta), \tag{29}$$

$$u(\alpha;\beta) = \int_0^{\infty e^{i\tau}} ds e^{-\alpha s}\frac{\sqrt{s^2+1}}{s + \beta\sqrt{s^2+1}} = \frac{1}{\beta}\left[\frac{1}{\alpha} - \psi(\alpha;\beta)\right], \tag{30}$$

$$w(\alpha;\beta) = \int_0^{\infty e^{i\tau}} ds e^{-\alpha s}\frac{s^2 + \beta(1 + s\sqrt{1+s^2})}{(s+\sqrt{1+s^2})(s+\beta\sqrt{1+s^2})} = \psi(\alpha;1) - (1+\beta)\psi(\alpha;\beta) + \frac{1}{\alpha}, \tag{31}$$

$$\alpha_\pm = -ik(z+d\pm iy) = -ik\rho_1 e^{\pm i\theta_1}, \quad -\pi/2 < \theta_1 < \pi/2,$$

$$\rho_0 = \sqrt{(z-d)^2+y^2}, \quad \rho_1 = \sqrt{(z+d)^2+y^2}, \quad \sin\theta_{0,1} = y/\rho_{0,1}, \quad z>0, \tag{32}$$

$$\tau = \frac{\pi}{2} - \arg(k). \tag{33}$$

The integral formulas in the first expressions, Eqs. (18a)–(23a), are invertible.[19] The restriction $0<z<d$ has been removed in the second expressions, Eqs. (18b)–(23b), since the singular term $1/\rho_0^2$ is extracted by direct integration and the ensuing representations may be continued to $z \geqslant d$. In Eq. (29), the interchange of the order of differentiation and integration is legitimate because the integrals are absolutely and uniformly convergent.

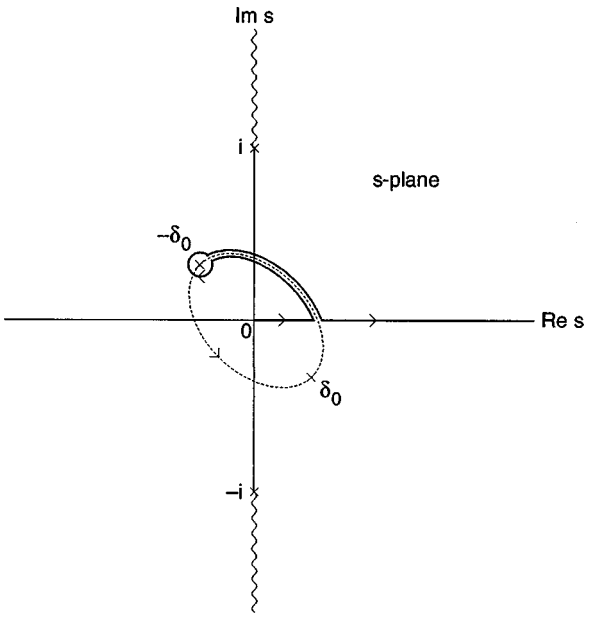

FIG. 3. Branch-cut configuration in the s-plane for the integral of Eq. (34). The modified path serves the analytic continuation of $\varphi(\alpha;\beta)$ along the respective contour enclosing the origin in the β-plane.

The quantities $\Phi_{\pm}$, $\Psi_{\pm}$, U, W introduced above designate solely the corrections to the solution for a perfectly conducting earth ($k_1 \to \infty$). The form of the solution above verifies that for a current supporting a TEM mode in air the x-components of the field satisfy Laplace's equation in y,z in the simply connected region $\{(y,z): z>0\}$ whereas the rest of the components satisfy the Poisson equation in the same region.

An examination of Eqs. (25)–(31) indicates that only the integrations for $\varphi(\alpha;\beta)$, where $\beta = 1$ and k_0^2/k_1^2, need to be carried out.

B. Evaluation of φ, ψ, u, w

For mathematical convenience it is assumed that $\alpha>0$. The extension over the range of complex values of α for which $|\arg \alpha|<\pi$ is attained via analytic continuation. The principal integral reads

$$\varphi(\alpha;\beta)=\int_0^{+\infty} ds e^{-\alpha s} \frac{1}{s+\beta\sqrt{s^2+1}}, \tag{34}$$

where the integration path coincides with the entire positive real axis. The integrand in Eq. (34) has two branch points at $s=\pm i$. A branch of the square root is chosen such that $\sqrt{1+s^2}>0$ for $s>0$. The first Riemann sheet is subsequently defined by taking the branch cuts along the positive and negative imaginary axis, as shown in Fig. 3. A study of the cases $\beta=1$ and $\beta=k_0^2/k_1^2$ essentially evinces the differences introduced by the denominators $K(\eta)$ and $L(\eta)$ of Eqs. (16a) and (16b), respectively. These two possibilities need to be considered separately.

(i) $\beta=1$. In this case, $\varphi(\alpha;\beta)$ is cast in the form

$$\varphi(\alpha;1)=\int_0^{+\infty} ds e^{-\alpha s}(\sqrt{1+s^2}-s)=\frac{1}{\alpha} S_{1,1}(\alpha)-\frac{1}{\alpha^2}. \tag{35}$$

In the above, $S_{\nu,\nu}(\alpha)$ $(\nu=1)$ denotes Lommel's function

$$S_{\nu,\nu}(\alpha)=2^{\nu-1}\pi^{1/2}\Gamma\left(\nu+\frac{1}{2}\right)[\mathbf{H}_\nu(\alpha)-Y_\nu(\alpha)], \tag{36}$$

where $\mathbf{H}_\nu(\alpha)$ and $Y_\nu(\alpha)$ are Struve's function and Neumann's function, respectively, from p. 18 of Ref. 20.

(ii) $\beta=k_0^2/k_1^2$. In this case, it has not been possible to obtain similar expressions in closed form. In particular, in the limit $\beta\to 0$ the integral of Eq. (34) becomes divergent. For $\beta\neq 0$, the denominator of the integrand vanishes to first order at

$$s=\pm\delta, \quad \delta=\beta/(1-\beta^2)^{1/2}=k_0^2/(k_1^4-k_0^4)^{1/2}, \tag{37}$$

which implies the existence of two simple poles in the s-Riemann surface. For definiteness, it is assumed that $\delta>0$ for $0<\beta<1$. Accordingly, the pole $s=-\delta$ alone is present in the selected Riemann sheet.

The analytic continuation of $\varphi(\alpha;\beta)$, qua function of β, along any simple closed curve $\beta=\beta(t)$ enclosing the origin in the β-plane is carried out through deformation of the integration path in the s-plane in order that the pole $s=-\delta(\beta(t))$ does not cross the modified path. In particular, when the initial point is $\beta=\beta_0$ and the contour is described once in the counterclockwise sense in the β-plane, the s-integration picks up the residue at $s=-\delta(\beta_0)\equiv-\delta_0$, as shown in Fig. 3:

$$\varphi(\alpha;\beta_0 e^{i2\pi})-\varphi(\alpha;\beta_0)=-2\pi i\,\mathrm{Res}_{s=-\delta_0}\left[\frac{e^{-\alpha s}}{s+\beta_0\sqrt{s^2+1}}\right]=-2\pi i(1+\delta_0^2)e^{\alpha\delta_0}. \tag{38}$$

This calculation indicates the existence of a logarithmic singularity at $\beta=0$. Accordingly, the task is assigned of expanding the regular part of $\varphi(\alpha;\beta(\delta))$ in powers of δ in the unit disc $\mathscr{D}=\{\delta\in\mathbb{C}:|\delta|<1\}$.

In order to extract the singular contribution, it is desirable to write

$$\frac{1}{s+\beta\sqrt{s^2+1}}=\frac{1+\delta^2}{s+\delta}-\delta\sqrt{1+\delta^2}\,\frac{1}{\sqrt{s^2+1}+\sqrt{1+\delta^2}}, \tag{39}$$

which in turn leads to

$$\varphi(\alpha;\beta)=-(1+\delta^2)e^{\delta\alpha}\mathrm{Ei}(-\delta\alpha)-\delta\sqrt{1+\delta^2}\,\varphi_1(\alpha;\delta), \tag{40}$$

where

$$\varphi_1(\alpha;\delta)=\int_0^\infty ds e^{-\alpha s}\,\frac{1}{\sqrt{s^2+1}+\sqrt{1+\delta^2}}, \tag{41}$$

and $\mathrm{Ei}(-z)$ is the exponential integral defined on p. 267 of Ref. 21 as

$$\mathrm{Ei}(-z)=-\int_z^\infty dt e^{-t}t^{-1}. \tag{42}$$

The integrand in Eq. (41) no longer admits any pole in the first Riemann sheet. By inspection, $\varphi_1(\alpha;\delta)$ is holomorphic in $\mathscr{D}$. It is noted in passing that

$$e^z\mathrm{Ei}(-z)=\sum_{n=0}^{N-1}\frac{(-1)^{n+1}}{n!}z^{-1-n}+\mathrm{O}(|z|^{-N-1}) \quad \text{for } z\to\infty, \quad N=1,2,\ldots,|\arg(z)|<3\pi/2, \tag{43}$$

$$\mathrm{Ei}(-z)=\gamma+\ln z+\sum_{n=1}^{\infty}\frac{(-1)^n z^n}{n!n}, \quad \mathrm{Ei}(-ze^{i2\pi})=\mathrm{Ei}(-z)+2\pi i, \tag{44}$$

where $\gamma=0.5772\ldots$ is Euler's constant.

For the purpose of obtaining a series expansion of $\varphi_1(\alpha;\delta)$ in δ^2, $\varphi_1(\alpha;\delta)$ is expressed as a contour integral, namely,

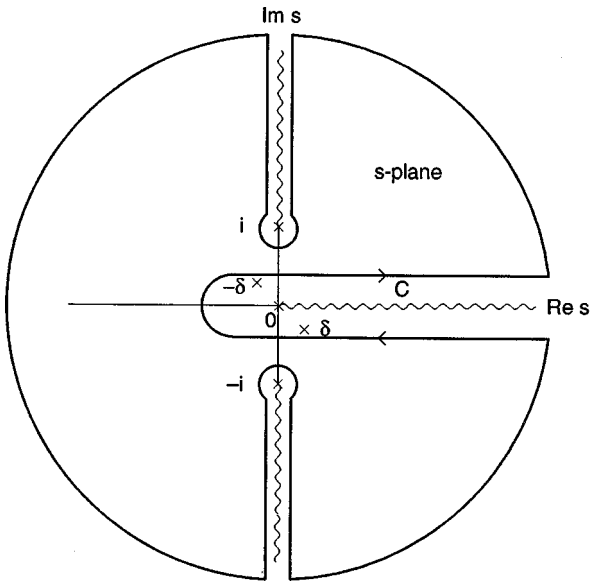

FIG. 4. Branch-cut configuration and contour of integration C in the s-plane for the integral of Eq. (45).

$$\varphi_1(\alpha;\delta)=-\frac{1}{2\pi i}\int_C ds e^{-\alpha s}\mathrm{Ei}(-\alpha s e^{-i\pi})\,\frac{\sqrt{s^2+1}-\sqrt{1+\delta^2}}{s^2-\delta^2}, \tag{45}$$

in view of Eq. (44). A branch of $\mathrm{Ei}(-\alpha s e^{-i\pi})$ is chosen such that $0\leqslant \arg(s)<2\pi$. Contour C is traversed in the clockwise sense and its interior contains the points $s=\pm\delta$, as depicted in Fig. 4. By virtue of

$$\frac{1}{s^2-\delta^2}=\sum_{l=0}^{L-1}\delta^{2l}s^{-2l-2}+\delta^{2L}\,\frac{s^{-2L}}{s^2-\delta^2}, \tag{46}$$

where L is any fixed positive integer, Eq. (45) is rearranged to give

$$\begin{aligned}\varphi_1(\alpha;\delta)=&\sum_{l=0}^{L-1}\delta^{2l}\left(-\frac{1}{2\pi i}\right)\int_C ds e^{-\alpha s}\mathrm{Ei}(-\alpha s e^{-i\pi})s^{-2l-2}\left[\sqrt{1+s^2}-\sum_{m=0}^{l}\binom{\frac{1}{2}}{m}s^{2m}\right]\\&+\sum_{l=0}^{L-1}\sum_{m=0}^{l}\binom{\frac{1}{2}}{m}\delta^{2l}\left(-\frac{1}{2\pi i}\right)\int_C ds e^{-\alpha s}\mathrm{Ei}(-\alpha s e^{-i\pi})s^{2m-2l-2}\\&+\sqrt{1+\delta^2}\,\frac{1}{2\pi i}\int_C ds e^{-\alpha s}\mathrm{Ei}(-\alpha s e^{-i\pi})\,\frac{1}{s^2-\delta^2}\\&-\delta^{2L}\,\frac{1}{2\pi i}\int_C ds e^{-\alpha s}\mathrm{Ei}(-\alpha s e^{-i\pi})s^{-2L}\,\frac{\sqrt{s^2+1}}{s^2-\delta^2}.\end{aligned} \tag{47}$$

In regard to the first sum of the preceding expression, the integration may be performed using the positive real axis since the integrands are all integrable at $s=0,\infty$. The double sum and the third term are zero because the respective integrals can be indented at infinity and no singularity lies within the resulting contour. The fourth term represents the remainder of the summation and is evaluated by folding the contour around the branch cuts in the imaginary axis, as shown in Fig. 4. Accordingly, $\varphi_1(\alpha;\delta)$ reads

$$\varphi_1(\alpha;\delta)=\sum_{l=0}^{L-1}\delta^{2l}q_{2l+2}(\alpha)+R_L(\alpha;\delta), \tag{48}$$

where

$$q_{2l+2}(\alpha)=\int_0^\infty ds e^{-\alpha s}s^{-2l-2}\left[\sqrt{1+s^2}-\sum_{m=0}^{l}\binom{\frac{1}{2}}{m}s^{2m}\right] \tag{49a}$$

$$=(-1)^l\frac{1}{i\pi}\int_1^\infty d\xi[e^{i\alpha\xi}\mathrm{Ei}(-i\alpha\xi)-e^{-i\alpha\xi}\mathrm{Ei}(i\alpha\xi)]\xi^{-2l-2}\sqrt{\xi^2-1}, \tag{49b}$$

and

$$R_L(\alpha;\delta)=(-1)^L\delta^{2L}\frac{1}{i\pi}\int_1^\infty d\xi[e^{i\alpha\xi}\mathrm{Ei}(-i\alpha\xi)-e^{-i\alpha\xi}\mathrm{Ei}(i\alpha\xi)]\xi^{-2L}\frac{\sqrt{\xi^2-1}}{\xi^2+\delta^2}. \tag{50a}$$

When $2L\gg 1$,

$$R_L(\alpha;\delta)=(-1)^L\delta^{2L}\frac{\pi^{-1/2}}{4i}\left\{\frac{1}{1+\delta^2}[e^{i\alpha}\mathrm{Ei}(-i\alpha)-e^{-i\alpha}\mathrm{Ei}(i\alpha)]L^{-3/2}+\mathrm{O}(L^{-5/2})\right\} \tag{50b}$$

for any α, δ ($|\delta|<1$). In the limit $L\to\infty$, $R_L(\alpha;\delta)\to 0$ uniformly in α, δ. Furthermore,

$$\frac{q_{2l+4}(\alpha)}{q_{2l+2}(\alpha)}=-\frac{\int_1^\infty d\xi[e^{i\alpha\xi}\mathrm{Ei}(-i\alpha\xi)-e^{-i\alpha\xi}\mathrm{Ei}(i\alpha\xi)]\xi^{-2l-4}\sqrt{\xi^2-1}}{\int_1^\infty d\xi[e^{i\alpha\xi}\mathrm{Ei}(-i\alpha\xi)-e^{-i\alpha\xi}\mathrm{Ei}(i\alpha\xi)]\xi^{-2l-2}\sqrt{\xi^2-1}}=\mathrm{O}(1) \tag{51a}$$

to all orders in α. Specifically,

$$\frac{q_{2l+4}(\alpha)}{q_{2l+2}(\alpha)}\sim-\frac{\int_1^\infty d\xi\,\xi^{-2l-4}\sqrt{\xi^2-1}}{\int_1^\infty d\xi\,\xi^{-2l-2}\sqrt{\xi^2-1}}=-\frac{2l}{2l+3}\quad(2l\gg 1) \tag{51b}$$

uniformly in α. The preceding expressions are suggestive of the efficiency of the expansion in question when $|\delta|\ll 1$.

The final formula for $\varphi(\alpha;\beta)$ is

$$\varphi(\alpha;\beta(\delta))=-(1+\delta^2)e^{\delta\alpha}\mathrm{Ei}(-\delta\alpha)-\delta\sqrt{1+\delta^2}\sum_{l=0}^{\infty}\delta^{2l}q_{2l+2}(\alpha),\quad\text{for }|\delta|<1, \tag{52}$$

where the $q_{2l+2}(\alpha)$ are given by Eqs. (49a) and (49b) and can be expressed in terms of known special functions for any finite l. An outline of the procedure along with the first six coefficients are provided in Appendix B. A straightforward, yet tedious, alternative derivation of Eq. (52) is carried out in Appendix C by invoking the Mellin transform technique. A strong indication of the validity of Eq. (52) is provided in Tables I and II which display values of the principal quantity $\varphi_1(\alpha;\delta)$ obtained both numerically through the integral of Eq. (41) and from the series of Eq. (48), for selected positive values of δ and α as well as for negative imaginary values of α. As verified analytically, the rate of convergence of the series is essentially independent of α.

Once $\varphi(\alpha;\beta)$ is evaluated, $\psi(\alpha;\beta)$ is obtained by direct differentiation. In particular, for $|\delta|<1$, term-by-term differentiation of the right-hand side of Eq. (52) is justified on grounds of uniform convergence of the resulting series when $|\alpha|>0$. Consequently,

$$\psi(\alpha;1)=-\frac{2}{\alpha^3}-\frac{1}{3}+\frac{1}{3\alpha}S_{2,2}(\alpha), \tag{53}$$

$$\psi(\alpha;\beta(\delta))=\frac{1+\delta^2}{\alpha}+\delta(1+\delta^2)e^{\delta\alpha}\mathrm{Ei}(-\delta\alpha)-\delta\sqrt{1+\delta^2}\sum_{l=0}^{\infty}\delta^{2l}q_{2l+1}(\alpha),\quad\text{for }|\delta|<1, \tag{54}$$

TABLE I. Values for $\varphi_1(\alpha;\delta)$obtained for positive α, δ ($\delta<1$)by numerical integration according to Eq. (41) and by evaluation of series on right-hand side of Eq. (48). The coefficients $q_n(\alpha)$,$n=2$, 4, 6, 8, are evaluated both by numerical integration from Eq. (49a) and by use of the results of Appendix B.

10	4.9640×10^{-2}	4.9763×10^{-2}	4.9639×10^{-2}	4.9640×10^{-2}	4.9640×10^{-2}
100	4.9873×10^{-3}	$4.999\,75\times10^{-3}$	$4.987\,25\times10^{-3}$	4.9873×10^{-3}	4.9873×10^{-3}
10^4	4.9876×10^{-5}	5.0000×10^{-5}	4.9875×10^{-5}	4.9876×10^{-5}	4.9876×10^{-5}

where

$$q_{2l+1}(\alpha)=-\frac{d}{d\alpha}\,q_{2l+2}(\alpha)=\int_0^\infty ds e^{-\alpha s}s^{-2l-1}\left[\sqrt{1+s^2}-\sum_{m=0}^{l}\binom{\frac{1}{2}}{m}s^{2m}\right] \tag{55a}$$

$$=(-1)^{l+1}\,\frac{1}{\pi}\int_1^\infty d\xi[e^{i\alpha\xi}\mathrm{Ei}(-i\alpha\xi)+e^{-i\alpha\xi}\mathrm{Ei}(i\alpha\xi)]\xi^{-2l-1}\sqrt{\xi^2-1}. \tag{55b}$$

The first six coefficients $q_{2l+1}(\alpha)$ of the above series are tabulated in Appendix B. The remainder of this expansion when L terms are summed equals

$$Q_L(\alpha;\delta)=-\frac{\partial}{\partial\alpha}\,R_L(\alpha;\delta)=(-1)^{L+1}\delta^{2L}\,\frac{1}{\pi}\int_1^\infty d\xi[e^{i\alpha\xi}\mathrm{Ei}(-i\alpha\xi)$$
$$+e^{-i\alpha\xi}\mathrm{Ei}(i\alpha\xi)]\xi^{-2L+1}\,\frac{\sqrt{\xi^2-1}}{\xi^2+\delta^2}, \tag{56}$$

which is $O(\ln\alpha)$ as $\alpha\to0$ and $O(1/\alpha^2)$ as $\alpha\to\infty$, i.e., integrable at $\alpha=0,\infty$. In the limit $L\to\infty$, $Q_L(\alpha;\delta)\to0$ uniformly in $|\delta|<1$, $|\alpha|>0$. The preceding expansion preserves the same interesting features as those implied by Eqs. (51a) and (51b).

Substitution for $\psi(\alpha;\beta)$ into Eqs. (30) and (31) yields

$$u(\alpha;\beta(\delta))=-(1+\delta^2)^{3/2}e^{\delta\alpha}\mathrm{Ei}(-\delta\alpha)-\frac{\delta\sqrt{1+\delta^2}}{\alpha}+(1+\delta^2)\sum_{l=0}^{\infty}\delta^{2l}q_{2l+1}(\alpha), \tag{57}$$

TABLE II. Complex values of $\varphi_1(\alpha;\delta)$ obtained for positive δ and pure imaginary α by numerical integration according to Eq. (41) and by evaluation of series on right-hand side of Eq. (48). These integrals arise, for example, over a very dry earth (conductivity $\sigma\simeq 0$) at $y=0$.

$$w(\alpha;\beta(\delta))=-\frac{2}{\alpha^3}-\frac{1}{3}+\frac{1}{3\alpha}S_{2,2}(\alpha)-\frac{\delta[\delta+(1+\delta^2)^{1/2}]}{\alpha}$$
$$-\delta(1+\delta^2)^{1/2}[\delta+(1+\delta^2)^{1/2}]e^{\delta\alpha}\mathrm{Ei}(-\delta\alpha)$$
$$+\delta[\delta+(1+\delta^2)^{1/2}]\sum_{l=0}^{\infty}\delta^{2l}q_{2l+1}(\alpha),\quad \text{for } |\delta|<1. \tag{58}$$

The analytic continuation to complex values of α can be carried out through the appropriate rotation of both contour C and the enclosed branch cut in the right half s-plane. The condition $|\delta|<1$ holds when the surrounding medium is air and the adjacent medium is earth, being dictated on mathematical grounds by the use of a power series representation in δ along with the existence of branch points at $\delta=\pm i$. A physical situation corresponding to these points arises when the ambient medium becomes perfectly conducting and the field is identically zero.

C. The *z*-component of the magnetic field in air

The field is easily evaluated with Eqs. (18b)–(27). Only the z-component of the magnetic field B_{0z} is calculable in simple closed form:

$$B_{0z}=\frac{\mu_0}{2\pi}e^{ik_0x}\left[y\left(\frac{1}{\rho_0^2}-\frac{1}{\rho_1^2}\right)-\frac{4y}{k^2}\frac{y^2-3(z+d)^2}{\rho_1^6}+\frac{1}{3i(z+d-iy)}S_{2,2}(-ky-ik(z+d))\right.$$
$$\left.-\frac{1}{3i(z+d+iy)}S_{2,2}(ky-ik(z+d))\right]. \tag{59}$$

This relatively simple structure is not surprising since it originates from the absence of any pole in the integrand of Eq. (29) when $\beta=1$.

D. Approximate expressions for the field when $k_0^2 \ll |k_1^2|$, $|k_0 k_1^{-1}(k_0\rho_1)| \ll 1$

Clearly, the critical parameters of the problem are $\alpha_\pm = -ik(z+d\pm iy)$ and k_0^2/k_1^2. When $k_0^2 \ll |k_1^2|$, at most only the first term of the associated series expansions needs to be retained essentially regardless of the magnitude of $|\alpha_\pm|$, while the condition $|\delta\alpha_\pm| \sim |k_0 k_1^{-1}(k_0\rho_1)| \ll 1$ enables approximation of the exponential integral $\mathrm{Ei}(-\alpha_\pm\delta)$ according to Eq. (44).

In particular, the exact integrated formulas may be greatly simplified under the condition $|k_1\rho_1|^2 \ll 1$ as, for instance, when the earth is highly conducting and the vertical distance from the image is much shorter than the wavelength in earth. Indeed, then $|\alpha_\pm| \ll 1$ in Eqs. (25)–(27) and small-argument approximations become effective. The resulting approximate expressions are

$$E_{0x} \sim -\frac{i\omega\mu_0}{2\pi} e^{ik_0 x}\left\{ \gamma - \frac{1}{2} - \frac{i\pi}{2} + \frac{2i}{3} k(z+d) + \left[1 + \frac{1}{8} k^2(z+d)^2 - \frac{1}{8} k^2 y^2\right] \ln\left(\frac{1}{2} k\rho_1\right) \right.$$
$$- \frac{1}{32}(5 - 4\gamma + 2\pi i) k^2[(z+d)^2 - y^2] - \frac{1}{4} k^2 (z+d) y \tan^{-1}\left(\frac{y}{z+d}\right)$$
$$\left. - \frac{2k_0^2}{k_1^2}\left[\gamma - \frac{i\pi}{2} + \ln\left(\frac{k_0^2}{k_1^2} k\rho_1\right)\right]\right\}, \tag{60}$$

$$E_{0y} \sim \frac{\mu_0 c}{2\pi} e^{ik_0 x} y\left[\frac{1}{\rho_0^2} - \frac{1 - 2k_0^2/k_1^2}{\rho_1^2}\right], \tag{61}$$

$$E_{0z} \sim \frac{\mu_0 c}{2\pi} e^{ik_0 x}\left[\frac{z-d}{\rho_0^2} - \frac{(1 - 2k_0^2/k_1^2)(z+d)}{\rho_1^2}\right], \tag{62}$$

$$B_{0x} \sim -i \frac{\mu_0 \omega}{2\pi c} e^{ik_0 x}\left\{\left[1 + \frac{1}{8} k^2(z+d)^2 - \frac{1}{8} k^2 y^2\right] \tan^{-1}\left(\frac{y}{z+d}\right) + \frac{2i}{3} ky \right.$$
$$\left. + \frac{1}{4} k^2 (z+d) y \ln\left(\frac{1}{2} k\rho_1\right) - \frac{1}{16}(5 - 4\gamma + 2\pi i) k^2 (z+d) y - \frac{k_0^2}{k_1^2} \tan^{-1}\left(\frac{y}{z+d}\right)\right\}, \tag{63}$$

$$B_{0y} \sim -\frac{\mu_0}{2\pi} e^{ik_0 x}\left\{\frac{z-d}{\rho_0^2} + \frac{1}{4} k^2 (z+d) \ln\left(\frac{1}{2} k\rho_1\right) + \frac{2ik}{3} - \frac{1}{16}(3 - 4\gamma + 2\pi i) k^2 (z+d) \right.$$
$$- \frac{1}{4} k^2 y \tan^{-1}\left(\frac{y}{z+d}\right) + \frac{2i}{15} k^3[(z+d)^2 - y^2] - 2ik \frac{k_0^2}{k_1^2}\left[\ln\left(\frac{2k_1^2}{k_0^2}\right) - 1\right]\Bigg\}, \tag{64}$$

$$B_{0z} \sim \frac{\mu_0}{2\pi} e^{ik_0 x}\left\{ y\left[\frac{1}{\rho_0^2} + \frac{1}{16}(3 - 4\gamma + 2\pi i) k^2 - \frac{1}{4} k^2 \ln\left(\frac{1}{2} k\rho_1\right) - \frac{4}{15} ik^3 (z+d)\right]\right.$$
$$\left. - \frac{1}{4} k^2 (z+d) \tan^{-1}\left(\frac{y}{z+d}\right)\right\}. \tag{65}$$

Equation (60) gives the first few terms of Carson's series[1,3,9] if k is approximated by k_1, with the exception of the correction term proportional to k_0^2/k_1^2. This discrepancy is due to the neglect of the Sommerfeld-pole contribution in Carson's formulation. Equations (60)–(65) agree with the findings of image theory in the static limit $\omega \to 0^+$. In this limit, the exact integrated formulas (18)–(23) reduce to the results of image theory without any restriction on k_0 and k_1. In particular, when the earth has zero conductivity and $\omega \to 0^+$, only the first term in the series expansion of Eq. (54) is nonzero. Only the approximate formula in Eq. (61) and the zeroth-order terms in Eq. (62) for the y- and z-components of the electric field are in accord with the application of the lateral-wave formulas of Ref. 10. No $1/\rho_1^2$ term of the reflected field is involved in the y- and z-components of the magnetic field because the earth was assumed to be nonmagnetic.

Another limiting case involves $|k_1\rho_1| \sim |\alpha_\pm| \gg 1$. Then large-argument approximations apply and the integrated formulas simplify to

$$E_{0x}\sim -\frac{\omega\mu_0}{\pi}\,e^{ik_0x}\left\{\frac{z+d}{k\rho_1^2}-i\frac{(z+d)^2-y^2}{k^2\rho_1^4}-i\frac{k_0^2}{k_1^2}\left[\gamma-\frac{i\pi}{2}+\ln\left(\frac{k_0^2}{k_1^2}\,k\rho_1\right)\right]\right\}, \tag{66}$$

$$E_{0y}\sim \frac{\mu_0 c}{2\pi}\,e^{ik_0x}y\left\{\frac{1}{\rho_0^2}-\frac{1-2k_0^2/k_1^2}{\rho_1^2}\right\}, \tag{67}$$

$$E_{0z}\sim \frac{\mu_0 c}{2\pi}\,e^{ik_0x}\left\{\frac{z-d}{\rho_0^2}-\frac{z+d}{\rho_1^2}+i\frac{k_0^2}{k_1^2}\frac{(z+d)^2-y^2}{k\rho_1^4}+2ik\,\frac{k_0^2}{k_1^2}\left[\gamma-\frac{i\pi}{2}+\ln\left(\frac{k_0^2}{k_1^2}\,k\rho_1\right)\right]\right\}, \tag{68}$$

$$B_{0x}\sim \frac{\mu_0\omega}{\pi c}\,e^{ik_0x}\left\{\frac{y}{k\rho_1^2}-\frac{2iy(z+d)}{k^2\rho_1^4}+i\frac{k_0^2}{k_1^2}\tan^{-1}\left(\frac{y}{z+d}\right)\right\}, \tag{69}$$

$$B_{0y}\sim -\frac{\mu_0}{2\pi}\,e^{ik_0x}\left\{\frac{z-d}{\rho_0^2}-\frac{(1+2k_0^2/k_1^2)(z+d)}{\rho_1^2}+2ik\,\frac{k_0^2}{k_1^2}\left[\gamma-\frac{i\pi}{2}+\ln\left(\frac{k_0^2}{k_1^2}\,k\rho_1\right)\right]\right\}, \tag{70}$$

$$B_{0z}\sim \frac{\mu_0}{2\pi}\,e^{ik_0x}y\left\{\frac{1}{\rho_0^2}-\frac{1}{\rho_1^2}+\frac{4i(z+d)}{k\rho_1^4}\right\}. \tag{71}$$

Only the y-component of the electric field preserves its static character to first order in k_0^2/k_1^2. The correction terms $O(k_0^2/k_1^2)$ become significant over a very dry earth. These either stem from the vicinity of the Sommerfeld pole (logarithm and inverse-tangent terms) or are due to secondary imperfect reflections from the image inside the earth (terms proportional to $1/\rho_1^2$, $1/\rho_1^4$).

IV. CONCLUSIONS AND DISCUSSION

The problem of the field created by an infinitely long and infinitely thin conductor carrying a traveling-wave current above a planar earth is revisited, but with a perspective different from previous analyses. Integral representations for the field in terms of contour integrals are derived in a physically meaningful way. It is shown that, as a direct consequence of this formulation, an exponentially decreasing outgoing current along the conductor (in the positive x direction) causes exponential increase of the radiation field in any direction perpendicular to the line source. This result is in accord with preliminary studies on the theory of the microstrip[14] that seem to have escaped attention in a considerable part of the recent literature.

In the limit where the propagation constant γ for the current becomes equal to the free-space wave number, all integrals for the field in air are, for the first time, evaluated *exactly* in terms of series expansions in the Sommerfeld pole. A prominent feature of the new series representations is the essential independence of their rates of convergence from distance. These series describe corrective contributions for the reflected (secondary) field to take account of the fact that it is not actually the field of an ideal image, and involve coefficients of nontrivial, yet calculable, form in terms of incomplete integrals of cylindrical functions. Finally, the component of the magnetic field normal to both conductor and interface is evaluated in simple closed form in terms of Lommel functions.

It should be borne in mind that the method of solution here crucially depends on the fact that the radiative structure is planar, and therefore is restricted in its applicability. Nevertheless, the present exposition for $\gamma=k_0$ reveals the nature of the field produced by multiphase transmission lines operating at sufficiently low frequencies above the earth, where the total field, trivially obtained via superposition, is spatially confined near the wires.

In the case of a complex propagation constant γ with Im $\gamma>0$, the usual radiation condition in three dimensions[22,23] is not explicitly invoked because the line has infinite length. This point is also discussed in Ref. 14. Heuristically speaking, the field growth in the radial distance $\sqrt{y^2+z^2}$ characterizes an asymptotic region in space where the assumed exponential increase along the *negative x* direction dominates over the free-space radiation decrease inversely proportional with distance. This region extends to infinity, in some sense, when the line becomes infinitely long.

Application of a limiting procedure that, starting with a localized source and the usual boundary condition at infinity, may lead to Eq. (2) and the accompanying assumptions in full mathematical rigor remains an open question for future work.

APPENDIX A: ON THE ASYMPTOTIC BEHAVIOR OF THE RADIATION FIELD IN AIR

For definiteness, consider $y \geqslant 0$. The phase associated with Eqs. (12) and (13) reads

$$\Phi_{\mp}(\eta) = \sqrt{k_0^2 - \gamma^2 - \eta^2}(z \mp d) + \eta y, \quad z > d. \tag{A1}$$

The corresponding saddle point, $\eta = \eta_{\mp}^{(\mathrm{sp})}$, is

$$\eta_{\mp}^{(\mathrm{sp})} = \sqrt{k_0^2 - \gamma^2}\ \sin\ \theta_{0,1}, \quad 0 \leqslant \theta_{0,1} < \pi/2, \tag{A2}$$

where $-\pi/2 < \arg\sqrt{k_0^2 - \gamma^2} \leqslant 0$, yielding

$$\Phi_{\mp}(\eta^{(\mathrm{sp})}) = \sqrt{k_0^2 - \gamma^2}\rho_{0,1}, \quad \mathrm{Im}\ \Phi_{\mp}(\eta^{(\mathrm{sp})}) < 0, \tag{A3}$$

$$\left.\frac{d^2\Phi_{\mp}}{d\eta^2}\right|_{\eta = \eta^{(\mathrm{sp})}} = -\frac{\rho_1^3}{(z \mp d)^2}\ (k_0^2 - \gamma^2)^{-1/2}. \tag{A4}$$

$\rho_{0,1}$ and $\theta_{0,1}$ are defined by Eqs. (32). For $|\sqrt{k_0^2 - \gamma^2}|\rho_{0,1} \gg 1$ and fixed $\theta_{0,1}$, the steepest descents path is determined by the conditions

$$\mathrm{Re}[\Phi_{\mp}(\eta) - \Phi_{\mp}(\eta^{(\mathrm{sp})})] = 0, \tag{A5}$$

$$\mathrm{Im}[\Phi_{\mp}(\eta) - \Phi_{\mp}(\eta^{(\mathrm{sp})})] > 0. \tag{A6}$$

Once the integration path Γ is properly deformed to pick up the saddle-point contribution, the exponential growth in $\sqrt{y^2 + z^2}$ of the field follows easily from (A3).

Under the usual substitution

$$\eta = \eta(\chi) = \sqrt{k_0^2 - \gamma^2}\ \sin\ \chi, \tag{A7}$$

each $\Phi_{\mp}(\eta)$ is recast in the form

$$\Phi_{\mp}(\eta(\chi)) = \sqrt{k_0^2 - \gamma^2}\rho_{0,1}\ \cos(\theta_{0,1} - \chi). \tag{A8}$$

A branch of $\chi = \chi(\eta)$ can be chosen so that $\chi(0) = 0$. In the χ-plane, the saddle point is $\chi_{\mp}^{(\mathrm{sp})} = \theta_{0,1}$, while the steepest descents path is now described by the relations

$$A\ \cos(\chi_r - \theta_{0,1})\cosh\ \chi_i - D\ \sinh\ \chi_i\ \sin(\chi_r - \theta_{0,1}) = A, \tag{A9}$$

$$A\ \sinh\ \chi_i\ \sin(\chi_r - \theta_{0,1}) + D\ \cos(\chi_r - \theta_{0,1})\cosh\ \chi_i < D, \tag{A10}$$

where $A = \mathrm{Re}\sqrt{k_0^2 - \gamma^2} > 0$, $D = -\mathrm{Im}\sqrt{k_0^2 - \gamma^2} > 0$, and $\chi_r = \mathrm{Re}\ \chi$, $\chi_i = \mathrm{Im}\ \chi$. The path configuration in the χ-plane is depicted in Fig. 5. Note that

$$\tan\ \overline{\theta} = A/D. \tag{A11}$$

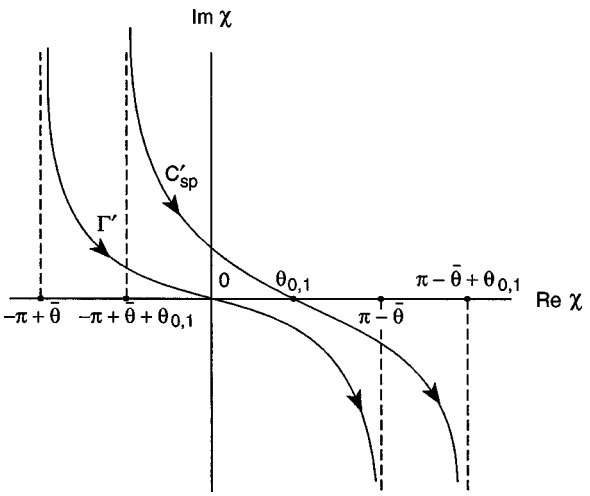

FIG. 5. A sketch of the integration-path configuration in the χ-plane under (A7). Γ' is the image of Γ of Fig. 2 and C'_{sp} is the steepest descents path. For simplicity, the branch points corresponding to $\eta=\pm\sqrt{k_1^2-\gamma^2}$ are not shown here. The dashed lines are vertical asymptotes ($\bar{\theta}=\pi/2-\arg\sqrt{k_0^2-\gamma^2}$).

Possible contribution from a Sommerfeld pole is recognized as exponentially recessive.

APPENDIX B: EVALUATION OF $q_n(\alpha)$

From Eqs. (49a) and (55a), the $q_n(\alpha)$ read

$$q_n(\alpha)=\int_0^{+\infty} ds e^{-\alpha s} s^{-n}\left[\sqrt{1+s^2}-\sum_{m=0}^{[(n-1)/2]}\binom{\frac{1}{2}}{m} s^{2m}\right], \tag{B1}$$

where $\alpha>0$, $n=0,1,\ldots,$ and $[x]$ denotes the integral part of the real number x. These satisfy the following equations:

$$\frac{d}{d\alpha} q_{2l+2}(\alpha)=-q_{2l+1}(\alpha), \tag{B2}$$

$$\frac{d}{d\alpha}\left[q_{2l+1}(\alpha)-\binom{\frac{1}{2}}{l}\ln\alpha\right]=-q_{2l}(\alpha), \tag{B3}$$

where $l\geqslant 0$ and

$$q_0(\alpha)=\int_0^{+\infty} ds e^{-\alpha s}\sqrt{1+s^2}=\frac{1}{\alpha} S_{1,1}(\alpha). \tag{B4}$$

$S_{\nu,\nu}(\alpha)$ is given by Eq. (36).

The application of Lebesgue's dominated convergence theorem to Eq. (49b) when $\alpha\to 0$, $l\geqslant 1$ entails:

$$c_l\equiv\lim_{\alpha\to 0} q_{2l+2}(\alpha)=(-1)^l\int_1^{\infty} d\xi \xi^{-2l-2}\sqrt{\xi^2-1}=\frac{(-1)^l}{2}\frac{\Gamma(3/2)\Gamma(l)}{\Gamma((3/2)+l)}. \tag{B5}$$

For $l\geqslant 1$, the integral of Eq. (55b) is recast in the form

$$q_{2l+1}(\alpha)-\binom{\frac{1}{2}}{l}\ln\alpha=\frac{(-1)^{l-1}}{\pi}\int_1^{\infty} d\xi[e^{i\alpha\xi}\mathrm{Ei}(-i\alpha\xi)+e^{-i\alpha\xi}\mathrm{Ei}(i\alpha\xi)-2\ln\alpha]\xi^{-2l-1}\sqrt{\xi^2-1}. \tag{B6}$$

For $0<\alpha\ll 1$, the preceding integral may be rewritten as

$$\int_1^\infty = \int_1^{O(\alpha^{-\lambda})} + \int_{O(\alpha^{-\lambda})}^\infty,$$

where $0<\lambda<1$. In the limit $\alpha\to 0$, the second term tends to zero because absolute convergence obtains. In regard to the first term, the integrand in brackets is properly expanded according to Eq. (44). This in turn leads to

$$d_l \equiv \lim_{\alpha\to 0}\left\{ q_{2l+1}(\alpha) - \binom{\frac{1}{2}}{l} \ln\,\alpha \right\} = 2\frac{(-1)^{l-1}}{\pi}\int_1^\infty d\xi(\gamma+\ln\,\xi)\xi^{-2l-1}\sqrt{\xi^2-1}$$

$$= 2^{-1}\binom{\frac{1}{2}}{l}\left[2\gamma+\psi(1+l)-\psi\left(-\frac{1}{2}+l\right)\right], \tag{B7}$$

where $l\geqslant 1$ and

$$\psi(z)=\frac{d}{dz}\ln\,\Gamma(z), \quad \psi(1)=-\gamma, \quad \psi(\tfrac{1}{2})=-\gamma-2\ln\,2,$$

$$\psi(z+l)=\frac{1}{z}+\cdots+\frac{1}{z+l-1}+\psi(z).$$

Note that $q_2(\alpha)$ and $q_1(\alpha)-\ln\,\alpha$ exhibit different behavior from that described in Eqs. (B5) and (B7), respectively. By use of Eq. (B1),

$$q_1(\alpha)=\ln\,\alpha+\frac{1}{\alpha}+\gamma+\ln\,2-1+O(\alpha\,\ln\,\alpha) \quad \text{for } \alpha\to 0. \tag{B8}$$

Likewise,

$$q_2(\alpha)=-\ln\,\alpha-\gamma+\ln\,2-1+O(\alpha\,\ln\,\alpha). \tag{B9}$$

Equations (B2)–(B5) and (B7)–(B9) suffice to determine $q_n(\alpha)$ for any $n\geqslant 1$.

In consideration of the following formulas:[20]

$$\frac{d}{dt}[tS_{1,1}(t)]=tS_{0,0}(t), \quad S_{1,1}(t)=1-\frac{d}{dt}S_{0,0}(t), \tag{B10}$$

along with Eqs. (B8) and (B9), Eqs. (B3) and (B2) are properly integrated for $l=0$ to give

$$q_1(\alpha)=\frac{1}{\alpha}+\ln\,\alpha+(\gamma+\ln\,2-1)+\lim_{\delta_1\to 0^+}\int_{\delta_1}^\alpha dt\left\{\frac{1}{t^2}-\frac{1}{t}S_{1,1}(t)\right\}$$

$$=-1+\gamma+\ln(2\alpha)-D(\alpha)+S_{1,1}(\alpha), \tag{B11}$$

$$q_2(\alpha)=-\ln\,\alpha-\gamma+\ln\,2-1-\lim_{\delta_1\to 0^+}\int_{\delta_1}^\alpha dt\left\{\ln\,t+\gamma+\ln\,2-1+S_{1,1}(t)-D(t)-\frac{1}{t}\right\}$$

$$=-\alpha[-1+\gamma+\ln(2\alpha)-D(\alpha)]+S_{0,0}(\alpha)-\alpha S_{1,1}(\alpha). \tag{B12}$$

In the above, use is made of the small-argument approximations for $\mathbf{H}_{0,1}(\alpha)$ and $Y_{0,1}(\alpha)$, and $D(\alpha)$ is defined as

$$D(\alpha)=\int_0^\alpha dtS_{0,0}(t). \tag{B13}$$

This function was initially studied in connection with a problem in acoustic radiation.[24] Despite the fact that[20]

$$\int_0^\alpha dt Y_0(t)=\frac{\pi\alpha}{2}\left[Y_0(\alpha)\mathbf{H}_{-1}(\alpha)+\mathbf{H}_0(\alpha)Y_1(\alpha)\right],\quad \mathbf{H}_{-1}(\alpha)=\frac{2}{\pi}-\mathbf{H}_1(\alpha), \tag{B14}$$

$$\int_0^\alpha dt\mathbf{H}_0(t)=\frac{\alpha^2}{\pi}\,{}_2F_3(1,1;\tfrac{3}{2},\tfrac{3}{2},2;-\alpha^2/4), \tag{B15}$$

the form of Eq. (B13) is more advantageous to employ here. $D(\alpha)$ cannot be expressed in terms of simpler transcendental functions. It is noted in passing that the integral in Eq. (B15) is a special case of the incomplete Lipschitz-Hankel integral of the Struve type.[25]

For $l\geqslant 1$, it is permissible to integrate Eqs. (B2) and (B3) explicitly over the range $[0,\alpha]$ subject to the conditions of Eqs. (B5) and (B7):

$$q_{2l+2}(\alpha)=c_l-\int_0^\alpha dt q_{2l+1}(t),\quad q_{2l+1}(\alpha)=\binom{\frac{1}{2}}{l}\ln\alpha+d_l-\int_0^\alpha dt q_{2l}(t). \tag{B16}$$

Successive integrations by parts according to the recursive scheme

$$\int^t dt t^\nu D(t)=\frac{t^{\nu+1}}{\nu+1}D(t)-\frac{1}{\nu+1}\int^t dt t^{\nu+1}S_{0,0}(t), \tag{B17}$$

$$\int^t dt t^\nu S_{0,0}(t)=t^\nu S_{1,1}(t)-(\nu-1)\int^t dt t^{\nu-1}S_{1,1}(t), \tag{B18}$$

$$\int^t dt t^\nu S_{1,1}(t)=\frac{t^{\nu+1}}{\nu+1}-t^\nu S_{0,0}(t)+\nu\int^t dt t^{\nu-1}S_{0,0}(t) \tag{B19}$$

provide a routine procedure for the evaluation of $q_n(\alpha)$ for any finite $n\geqslant 3$. For all reasonable purposes, the first 13 integrals $q_n(\alpha)$ $(n=0,1,\ldots,12)$ are sufficient. It is readily found that $q_n(\alpha)$ $(n\geqslant 3)$ can be expressed as

$$\begin{aligned}q_n(\alpha)=\frac{(-1)^{n-1}}{(n-1)!}\{&\mathscr{P}^{(1)}_{n-1}(\alpha)[\gamma+\ln(2\alpha)-D(\alpha)]\\&-\mathscr{P}^{(2)}_{n-1}(\alpha)-\mathscr{P}^{(3)}_{n-2}(\alpha)S_{0,0}(\alpha)+\mathscr{P}^{(4)}_{n-1}(\alpha)S_{1,1}(\alpha)\},\end{aligned} \tag{B20}$$

where the $\mathscr{P}^{(j)}_m(\alpha)$ $(j=1,2,3,4)$ denote even or odd mth-degree polynomials in α, $\mathscr{P}^{(j)}_m(-\alpha)=(-1)^m\mathscr{P}^{(j)}_m(\alpha)$. For $n=3,\ldots,12$, the $\mathscr{P}^{(j=1,2,4)}_{n-1}(\alpha)$ and $\mathscr{P}^{(j=3)}_{n-2}(\alpha)$ read

$$\begin{gathered}\mathscr{P}^{(1)}_2(\alpha)=\alpha^2+1,\quad \mathscr{P}^{(1)}_3(\alpha)=\alpha^3+3\alpha,\quad \mathscr{P}^{(1)}_4(\alpha)=\alpha^4+6\alpha^2-3,\\ \mathscr{P}^{(1)}_5(\alpha)=\alpha^5+10\alpha^3-15\alpha,\quad \mathscr{P}^{(1)}_6(\alpha)=\alpha^6+15\alpha^4-45\alpha^2+45,\\ \mathscr{P}^{(1)}_7(\alpha)=\alpha^7+21\alpha^5-105\alpha^3+315\alpha,\\ \mathscr{P}^{(1)}_8(\alpha)=\alpha^8+28\alpha^6-210\alpha^4+1260\alpha^2-1575,\\ \mathscr{P}^{(1)}_9(\alpha)=\alpha^9+36\alpha^7-378\alpha^5+3780\alpha^3-14\,175\alpha,\\ \mathscr{P}^{(1)}_{10}(\alpha)=\alpha^{10}+45\alpha^8-630\alpha^6+9450\alpha^4-70\,875\alpha^2+99\,225,\\ \mathscr{P}^{(1)}_{11}(\alpha)=\alpha^{11}+55\alpha^9-990\alpha^7+20\,790\alpha^5-259\,875\alpha^3+1\,091\,475\alpha;\end{gathered} \tag{B21}$$

$$\mathscr{P}_2^{(2)}(\alpha)=\alpha^2-\frac{1}{2},\quad \mathscr{P}_3^{(2)}(\alpha)=\alpha^3+\frac{3}{2}\alpha,\quad \mathscr{P}_4^{(2)}(\alpha)=\alpha^4+\frac{9}{2}\alpha^2-\frac{3}{4},$$

$$\mathscr{P}_5^{(2)}(\alpha)=\alpha^5+\frac{17}{2}\alpha^3-\frac{75}{4}\alpha,\quad \mathscr{P}_6^{(2)}(\alpha)=\alpha^6+\frac{27}{2}\alpha^4-\frac{225}{4}\alpha^2+\frac{75}{4},$$

$$\mathscr{P}_7^{(2)}(\alpha)=\alpha^7+\frac{39}{2}\alpha^5-\frac{501}{4}\alpha^3+\frac{1785}{4}\alpha,$$

$$\mathscr{P}_8^{(2)}(\alpha)=\alpha^8+\frac{53}{2}\alpha^6-\frac{963}{4}\alpha^4+\frac{3255}{2}\alpha^2-\frac{6195}{8},\tag{B22}$$

$$\mathscr{P}_9^{(2)}(\alpha)=\alpha^9+\frac{69}{2}\alpha^7-\frac{1683}{4}\alpha^5+\frac{8979}{2}\alpha^3-\frac{169\,155}{8}\alpha,$$

$$\mathscr{P}_{10}^{(2)}(\alpha)=\alpha^{10}+\frac{87}{2}\alpha^8-\frac{2745}{4}\alpha^6+\frac{42\,555}{4}\alpha^4-\frac{732\,375}{8}\alpha^2+\frac{424\,305}{8},$$

$$\mathscr{P}_{11}^{(2)}(\alpha)=\alpha^{11}+\frac{107}{2}\alpha^9-\frac{4245}{4}\alpha^7+\frac{90\,525}{4}\alpha^5-\frac{2\,433\,855}{8}\alpha^3+\frac{13\,399\,155}{8}\alpha;$$

$$\mathscr{P}_1^{(3)}(\alpha)=\alpha,\quad \mathscr{P}_2^{(3)}(\alpha)=\alpha^2,\quad \mathscr{P}_3^{(3)}(\alpha)=\alpha^3+3\alpha,\quad \mathscr{P}_4^{(3)}(\alpha)=\alpha^4+7\alpha^2,$$

$$\mathscr{P}_5^{(3)}(\alpha)=\alpha^5+12\alpha^3-45\alpha,\quad \mathscr{P}_6^{(3)}(\alpha)=\alpha^6+18\alpha^4-123\alpha^2,$$

$$\mathscr{P}_7^{(3)}(\alpha)=\alpha^7+25\alpha^5-249\alpha^3+1575\alpha,$$

$$\mathscr{P}_8^{(3)}(\alpha)=\alpha^8+33\alpha^6-441\alpha^4+4959\alpha^2,\tag{B23}$$

$$\mathscr{P}_9^{(3)}(\alpha)=\alpha^9+42\alpha^7-720\alpha^5+11\,790\alpha^3-99\,225\alpha,$$

$$\mathscr{P}_{10}^{(3)}(\alpha)=\alpha^{10}+52\alpha^8-1110\alpha^6+24\,660\alpha^4-354\,195\alpha^2;$$

$$\mathscr{P}_2^{(4)}(\alpha)=\alpha^2,\quad \mathscr{P}_3^{(4)}(\alpha)=\alpha^3+2\alpha,\quad \mathscr{P}_4^{(4)}(\alpha)=\alpha^4+5\alpha^2,$$

$$\mathscr{P}_5^{(4)}(\alpha)=\alpha^5+9\alpha^3-16\alpha,\quad \mathscr{P}_6^{(4)}(\alpha)=\alpha^6+14\alpha^4-51\alpha^2,$$

$$\mathscr{P}_7^{(4)}(\alpha)=\alpha^7+20\alpha^5-117\alpha^3+384\alpha,$$

$$\mathscr{P}_8^{(4)}(\alpha)=\alpha^8+27\alpha^6-229\alpha^4+1497\alpha^2,\tag{B24}$$

$$\mathscr{P}_9^{(4)}(\alpha)=\alpha^9+35\alpha^7-405\alpha^5+4257\alpha^3-18\,432\alpha,$$

$$\mathscr{P}_{10}^{(4)}(\alpha)=\alpha^{10}+44\alpha^8-666\alpha^6+10\,260\alpha^4-85\,095\alpha^2,$$

$$\mathscr{P}_{11}^{(4)}(\alpha)=\alpha^{11}+54\alpha^9-1036\alpha^7+22\,050\alpha^5-290\,925\alpha^3+1\,474\,560\alpha.$$

As explained in Sec. III, the final formulas for $q_n(\alpha)$ may be extended over complex values of α for which $|\arg\alpha|<\pi$. Small-argument approximations for $q_n(\alpha)$ follow from Eqs. (B11)–(B15) and (B20)–(B24) if the series expansions in α for $\mathbf{H}_{0,1}(\alpha)$, $Y_{0,1}(\alpha)$, and ${}_2F_3(1,1;\frac{3}{2},\frac{3}{2},2;-\alpha^2/4)$ are taken into account. Large-argument approximations when $|\alpha|\to\infty$, $|\arg\alpha|<\pi$ can be readily obtained either from Eq. (B1) via Laplace's method[18] or by use of the asymptotic expansions of the related transcendental functions.[20,26]

APPENDIX C: EVALUATION OF $\varphi(\alpha;\beta)$ BY THE MELLIN TRANSFORM TECHNIQUE

In this appendix, Eq. (52) is derived formally via application of the Mellin transform technique.[27,28] For mathematical convenience, let $\beta=i\tilde{\beta}$ and take $\tilde{\beta}>0$. Then,

$$\varphi(\alpha;\beta(\delta))=\int_0^\infty ds\ \frac{e^{-\alpha s}}{s+i\tilde{\beta}\sqrt{1+s^2}}=(1-\tilde{\delta}^2)I_1(\alpha;\tilde{\delta})-i\tilde{\delta}\sqrt{1-\tilde{\delta}^2}I_2(\alpha;\tilde{\delta}), \tag{C1}$$

where

$$\tilde{\delta}=\frac{\tilde{\beta}}{\sqrt{1+\tilde{\beta}^2}}=-i\delta,\quad \delta=\frac{\beta}{\sqrt{1-\beta^2}}, \tag{C2}$$

$$I_1(\alpha;\tilde{\delta})=\int_0^\infty ds\ \frac{se^{-\alpha s}}{s^2+\tilde{\delta}^2}=-\frac{1}{2}\left[e^{i\tilde{\delta}\alpha}\mathrm{Ei}(-i\tilde{\delta}\alpha)+e^{-i\tilde{\delta}\alpha}\mathrm{Ei}(i\tilde{\delta}\alpha)\right], \tag{C3}$$

$$I_2(\alpha;\tilde{\delta})=\int_0^\infty ds\ \frac{\sqrt{1+s^2}}{s^2+\tilde{\delta}^2}\,e^{-\alpha s}. \tag{C4}$$

When $\alpha=\mathrm{O}(1)>0$, Eq. (38) implies that an expansion of $I_2(\alpha;\tilde{\delta})$ in powers of $\tilde{\delta}$ can be obtained quite straightforwardly by invoking its Mellin transform $\overline{I}_2(\alpha;\zeta)$. Avoiding elaboration on mathematical subtleties, such as issues related to convergence of any of the resulting series, consider

$$\overline{I}_2(\alpha;\zeta)=\int_0^\infty d\tilde{\delta}^2(\tilde{\delta}^2)^{-\zeta}I_2(\alpha;\tilde{\delta})=\frac{\pi}{\sin\ \pi\zeta}\int_0^\infty ds e^{-\alpha s}s^{-2\zeta}\sqrt{1+s^2},\quad 0<\mathrm{Re}\ \zeta<\frac{1}{2}, \tag{C5}$$

by interchanging the order of integration. Inversion of the above formula is studied initially according to the formula

$$I_2(\alpha;\tilde{\delta})=\frac{1}{2\pi i}\int_{c'-i\infty}^{c'+i\infty}d\zeta\overline{I}_2(\alpha;\zeta)(\tilde{\delta}^2)^{\zeta-1},\quad 0<c'<\frac{1}{2}. \tag{C6}$$

Of course, $\overline{I}_2(\alpha;\zeta)$ defined by (C5) can be analytically continued into $\mathrm{Re}\ \zeta\leqslant 0$, $\mathrm{Re}\ \zeta\geqslant 1/2$, as shown below. It is noteworthy that

$$\begin{aligned}\overline{I}_2(\alpha;\zeta)&\sim\frac{\pi}{\sin\ \pi\zeta}\int_0^\infty ds e^{-\alpha s}s^{-2\zeta}\\ &=\frac{\pi}{\sin\ \pi\zeta}\,\alpha^{2\zeta-1}\Gamma(1-2\zeta)\\ &=\frac{\pi^2}{\sin\ \pi\zeta\ \sin 2\pi\zeta}\,\frac{\alpha^{2\zeta-1}}{\Gamma(2\zeta)}\\ &\sim-(2\pi)^{3/2}(2\zeta)^{1/2}e^{-2\zeta\ \ln 2\zeta+(2\pm 3i\pi)\zeta+(2\zeta-1)\ln\ \alpha},\\ &\qquad |\zeta|\to\infty,\quad 0<|\arg\ \zeta|<\pi/2,\end{aligned} \tag{C7}$$

where the upper sign holds for $\mathrm{Re}\ \zeta>0$ and the lower sign for $\mathrm{Re}\ \zeta<0$, and use was made of the Stirling formula

$$\Gamma(z)\sim\sqrt{2\pi}e^{-z+(z-1/2)\ln z},\quad |z|\to\infty,\quad |\arg\ z|<\pi.$$

In view of

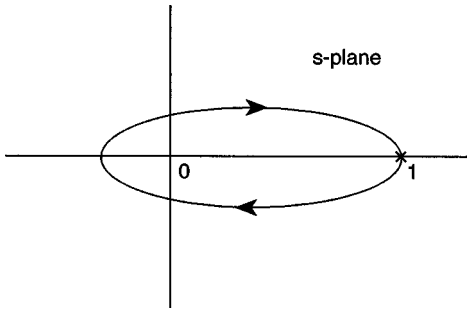

FIG. 6. Contour C_0 that serves the analytic continuation of the integral formula (C5) into the right and left ζ-plane according to (C8).

$$\int_0^1 ds e^{-\alpha s} s^{-2\zeta}\sqrt{1+s^2} = \frac{e^{i2\pi\zeta}}{2i\,\sin 2\pi\zeta}\int_{C_0} ds e^{-\alpha s} s^{-2\zeta}\sqrt{1+s^2}, \tag{C8}$$

where the upper limit $s=1$ is chosen arbitrarily and C_0 is a closed contour passing through 1 and encircling 0 clockwise without enclosing any of the branch points $s=\pm i$ (as shown in Fig. 6), it is not difficult to deduce that $\overline{I}_2(\alpha;\zeta)$ is a meromorphic function of ζ. For Re $\zeta>0$, its poles are located at $\zeta=l$ and $\zeta=l-1/2$, where l is any positive integer. By writing

$$\overline{I}_2(\alpha;\zeta) = \frac{\pi}{\sin\,\pi\zeta}\left\{\int_0^\infty ds\; e^{-\alpha s} s^{-2\zeta}\sum_{m=0}^{l-1}\binom{\frac{1}{2}}{m} s^{2m} + \int_0^\infty ds e^{-\alpha s} s^{-2\zeta} \times\left[\sqrt{1+s^2} - \sum_{m=0}^{l-1}\binom{\frac{1}{2}}{m} s^{2m}\right]\right\}, \tag{C9}$$

the singular behavior of $\overline{I}_2(\alpha;\zeta)(\tilde{\delta}^2)^{\zeta-1}$ in the vicinity of $\zeta=l$ is singled out as

$$\begin{aligned}\overline{I}_2(\alpha;\zeta)(\tilde{\delta}^2)^{\zeta-1} \sim (\tilde{\delta}^2)^{l-1}\Bigg\{&\frac{(-1)^{l+1}}{2(\zeta-l)^2}\sum_{m=0}^{l-1}\binom{\frac{1}{2}}{m}\frac{\alpha^{2(l-m)-1}}{(2l-2m-1)!} \\ &+\frac{(-1)^{l+1}}{\zeta-l}\sum_{m=0}^{l-1}\binom{\frac{1}{2}}{m}\frac{\alpha^{2(l-m)-1}}{(2l-2m-1)!}\left[\gamma - h_{2l-2m-1} + \ln(\tilde{\delta}\alpha)\right] \\ &+\frac{(-1)^{l+1}}{\zeta-l}\int_0^\infty ds e^{-\alpha s} s^{-2l}\left[\sqrt{1+s^2} - \sum_{m=0}^{l-1}\binom{\frac{1}{2}}{m} s^{2m}\right]\Bigg\} \quad (l=1,2,\ldots),\end{aligned} \tag{C10}$$

where

$$h_n = 1 + 2^{-1} + \cdots + n^{-1}, \quad n \geqslant 1. \tag{C11}$$

In the vicinity of $\zeta=l-1/2$,

$$\overline{I}_2(\alpha;\zeta)(\tilde{\delta}^2)^{\zeta-1} \sim \frac{\pi}{2}\frac{(-1)^l}{\zeta-l+1/2}\,\tilde{\delta}^{2l-3}\sum_{m=0}^{l-1}\binom{\frac{1}{2}}{m}\frac{\alpha^{2(l-m-1)}}{(2l-2m-2)!}. \tag{C12}$$

Equation (C7) suggests that deformation of the original inversion path $\mathscr{C}_1$ so that it finally coincides with $\mathscr{C}_2$, which wraps around the positive real axis (see Fig. 7), is legitimate. Subsequent summation of the residues from all pole contributions there yields

$$I_2(\alpha;\tilde{\delta}) = \frac{1}{2\pi i} \oint_{\mathscr{C}_2} d\zeta \overline{I_2}(\alpha;\zeta)(\overline{\delta^2})^{\zeta-1}$$

$$= \frac{\pi}{2}\mathscr{S}_{21}(\alpha;\tilde{\delta}) + [\gamma + \ln(\tilde{\delta}\alpha)]\mathscr{S}_{22}(\alpha;\tilde{\delta}) - \mathscr{S}_{23}(\alpha;\tilde{\delta}) + \lim_{L\to\infty}\sum_{l=0}^{L}(-1)^l\tilde{\delta}^{2l}q_{2l+2}(\alpha), \tag{C13}$$

where $\tilde{\delta}$ is sufficiently small, $q_{2l+2}(\alpha)$ is given by Eq. (49a), and

$$\mathscr{S}_{21}(\alpha;\tilde{\delta}) \equiv \sum_{l=0}^{\infty}(-1)^l\tilde{\delta}^{2l-1}\sum_{m=0}^{l}\binom{\frac{1}{2}}{m}\frac{\alpha^{2(l-m)}}{(2l-2m)!}$$

$$= \sum_{m=0}^{\infty}\sum_{p=0}^{\infty}(-1)^{p+m}\binom{\frac{1}{2}}{m}\tilde{\delta}^{2(p+m)-1}\frac{\alpha^{2p}}{(2p)!}$$

$$= \frac{1}{\tilde{\delta}}\sqrt{1-\tilde{\delta}^2}\cos\tilde{\delta}\alpha, \tag{C14}$$

$$\mathscr{S}_{22}(\alpha;\tilde{\delta}) \equiv \sum_{l=0}^{\infty}(-1)^l\tilde{\delta}^{2l}\sum_{m=0}^{l}\binom{\frac{1}{2}}{m}\frac{\alpha^{2(l-m)+1}}{(2l-2m+1)!}$$

$$= \sum_{m=0}^{\infty}\sum_{p=0}^{\infty}(-1)^{p+m}\binom{\frac{1}{2}}{m}\tilde{\delta}^{2(p+m)}\frac{\alpha^{2p+1}}{(2p+1)!}$$

$$= \frac{\sqrt{1-\tilde{\delta}^2}}{\tilde{\delta}}\sin\tilde{\delta}\alpha, \tag{C15}$$

$$\mathscr{S}_{23}(\alpha;\tilde{\delta}) \equiv \sum_{l=0}^{\infty}(-1)^l\tilde{\delta}^{2l}\sum_{m=0}^{l}\binom{\frac{1}{2}}{m}\frac{\alpha^{2(l-m)+1}}{(2l-2m+1)!}h_{2l-2m+1}$$

$$= \sum_{p=0}^{\infty}\sum_{m=0}^{\infty}(-1)^{p+m}\binom{\frac{1}{2}}{m}\tilde{\delta}^{2(p+m)}\frac{\alpha^{2p+1}}{(2p+1)!}h_{2p+1}$$

$$= \frac{1}{\tilde{\delta}}\sqrt{1-\tilde{\delta}^2}\sum_{p=0}^{\infty}(-1)^p\frac{(\tilde{\delta}\alpha)^{2p+1}}{(2p+1)!}h_{2p+1}. \tag{C16}$$

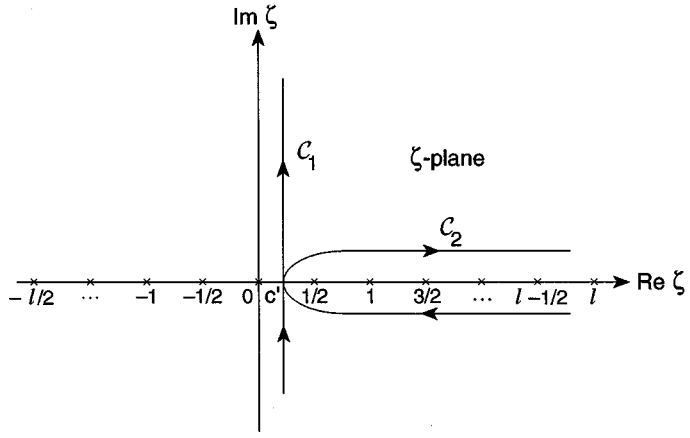

FIG. 7. Inversion paths for the Mellin transform $\overline{I_2}(\alpha;\zeta)$ of (C5). $\mathscr{C}_1$ is the original inversion path and $\mathscr{C}_2$ serves the expansion of $I_2(\alpha;\delta)$ in powers of δ. l is any positive integer.

The last series is easily evaluated by noting that

$$h_m = -\sum_{l=1}^{m} \frac{(-1)^l}{l} \binom{m}{l}. \tag{C17}$$

Therefore

$$\begin{aligned}\sum_{p=0}^{\infty} (-1)^p \frac{z^{2p+1}}{(2p+1)!}\, h_{2p+1} &= \sum_{p=0}^{\infty} \sum_{l=0}^{2p} (-1)^{p+l} \frac{z^{2p+1}}{(l+1)!(l+1)} \frac{1}{(2p-l)!} \\ &= \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} (-1)^{m+n} \frac{z^{2m+2n+1}}{(2n+1)!(2n+1)} \frac{1}{(2m)!} \\ &\quad + \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} (-1)^{m+n} \frac{z^{2m+2n+3}}{(2n+2)!(2n+2)} \frac{1}{(2m+1)!} \\ &= z\, \cos z\, F(z) + \sin z\, G(z), \end{aligned} \tag{C18}$$

where

$$F(z) = \sum_{n=0}^{\infty} (-1)^n \frac{z^{2n}}{(2n+1)!(2n+1)}, \tag{C19}$$

$$G(z) = \sum_{n=0}^{\infty} (-1)^n \frac{z^{2n+2}}{(2n+2)!(2n+2)}. \tag{C20}$$

$F(z)$ satisfies

$$\frac{d}{dz}(zF) = \frac{1}{z} \sin z, \quad F(0) = 1, \tag{C21}$$

with the solution

$$F(z) = \frac{1}{z} \int_0^z dt\, \frac{\sin t}{t} = \frac{\pi}{2z} - \frac{1}{2iz} [\mathrm{Ei}(-iz) - \mathrm{Ei}(iz)]. \tag{C22}$$

By inspection of (C20),

$$\begin{aligned} G(z) &= \int_0^z dt\, \frac{1-\cos t}{t} = \int_0^{\infty} \frac{dt}{t} \left(\frac{1}{1+t^2} - \cos t \right) + \int_0^z dt\, \frac{t}{1+t^2} - \int_z^{\infty} \frac{dt}{t(1+t^2)} + \int_z^{\infty} dt\, \frac{\cos t}{t} \\ &= \gamma + \ln z - \tfrac{1}{2} [\mathrm{Ei}(-iz) + \mathrm{Ei}(iz)]. \end{aligned} \tag{C23}$$

Equations (C18), (C22), and (C23), along with (C16), lead to

$$\begin{aligned} \mathscr{S}_{23}(\alpha;\tilde{\delta}) = \tilde{\delta}^{-1} \sqrt{1-\tilde{\delta}^2} \Bigg\{ &\frac{\pi}{2} \cos \tilde{\delta}\alpha + [\gamma + \ln(\tilde{\delta}\alpha)] \sin \tilde{\delta}\alpha \\ &+ \frac{i}{2} [e^{i\tilde{\delta}\alpha} \mathrm{Ei}(-i\tilde{\delta}\alpha) - e^{-i\tilde{\delta}\alpha} \mathrm{Ei}(i\tilde{\delta}\alpha)] \Bigg\}. \end{aligned} \tag{C24}$$

Substitution of (C14), (C15), and (C24) into (C13) yields

$$I_2(\alpha;\tilde{\delta}) = \frac{\sqrt{1-\tilde{\delta}^2}}{2i\tilde{\delta}} [e^{i\tilde{\delta}\alpha} \mathrm{Ei}(-i\tilde{\delta}\alpha) - e^{-i\tilde{\delta}\alpha} \mathrm{Ei}(i\tilde{\delta}\alpha)] + \sum_{l=0}^{\infty} (-1)^l \tilde{\delta}^{2l} q_{2l+2}(\alpha). \tag{C25}$$

By virtue of (C1) and (C3),

$$\varphi(\alpha;\beta)=-(1-\tilde{\delta}^2)e^{i\tilde{\delta}\alpha}\mathrm{Ei}(-i\tilde{\delta}\alpha)-i\tilde{\delta}\sqrt{1-\tilde{\delta}^2}\sum_{l=0}^{\infty}(-1)^l\tilde{\delta}^{2l}q_{2l+2}(\alpha), \tag{C26}$$

which is Eq. (52). This result can be analytically continued to complex values of $\tilde{\delta}=-i\delta$ and α ($|\arg\alpha|<\pi$).

Point vortices on a sphere: Stability of relative equilibria

Sergey Pekarsky[a] and Jerrold E. Marsden[b]
Control and Dynamical Systems 107-81, California Institute of Technology, Pasadena, California 91125

(Received 27 January 1998; accepted for publication 10 March 1998)

In this paper we analyze the dynamics of N point vortices moving on a sphere from the point of view of geometric mechanics. The formalism is developed for the general case of N vortices, and the details are worked out for the (integrable) case of three vortices. The system under consideration is SO(3) invariant; the associated momentum map generated by this SO(3) symmetry is equivariant and corresponds to the moment of vorticity. Poisson reduction corresponding to this symmetry is performed; the quotient space is constructed and its Poisson bracket structure and symplectic leaves are found explicitly. The stability of relative equilibria is analyzed by the energy–momentum method. Explicit criteria for stability of different configurations with generic and nongeneric momenta are obtained. In each case a group of transformations is specified, modulo which one has stability in the original (unreduced) phase space. Special attention is given to the distinction between the cases when the relative equilibrium is a nongreat circle equilateral triangle and when the vortices line up on a great circle. © *1998 American Institute of Physics.* [S0022-2488(98)01906-9]

I. INTRODUCTION

The problem of vortex motion has a long and interesting history. It was Helmholtz[1] who introduced the model that is referred to today as point vortices. Several of Helmholtz' contemporaries immediately seized upon and developed the treasures in his paper, such as Kirchhoff[2] and his student Gröbli. An account of some of the history of this problem can be found in Aref, Rott and Thomann[3] and Kidambi and Newton.[4]

We mention a few more historical facts relevant to the present paper. The problem of configurations of vortices that could move without change of shape, namely *relative equilibria* in the language of Poincaré, was analyzed by Thomson,[5] the later Lord Kelvin, and stability aspects of this motion were studied in his later paper, Thomson.[6] The geometric construction was rediscovered, updated and added to by Novikov[7] a century later for the case of equal strength vortices. Synge[8] developed a qualitative classification of all possible motions of three planar vortices and was the first to introduce trilinear coordinates. Aref[9] also treats the case of three vortices of general strength.

The paper by Bogomolov[10] contains the first systematic and thorough derivation of the equations of motion for point vortices on both rotating and nonrotating spheres. A later paper of Bogomolov[11] contains an analysis of the motion of three identical point vortices on the sphere, generalizing the planar result by Novikov.[7] The paper by Kidambi and Newton[4] treats the case of three vortices on a sphere for general vortex strengths, thus generalizing the planar results of Synge[8] and Aref.[9]

The topology of the problem of vortices moving on a sphere is considered by Kirwan,[12] though this paper mainly deals with the symplectic reduction (in the sense of Marsden and Weinstein[13]) of the problem and the study of the topology of the symplectically reduced phase spaces and the number of equilibria, by computing, in the spirit of Smale,[14] some topological invariants, such as Betti numbers.

The dynamics of N vortices on a sphere is a Hamiltonian system (see, e.g., Kidambi and Newton[4] and references therein). This Hamiltonian structure can be obtained using general reduc-

tion techniques starting with the geometrical description of ideal hydrodynamics in terms of diffeomorphism groups; see Marsden and Weinstein[13] and Arnold and Khesin.[15]

In this paper we explicitly carry out Poisson reduction for the 3-vortex problem on a sphere. We calculate the induced Poisson structure on the Poisson reduced space and analyze the associated symplectic stratification. Furthermore, relative equilibria are classified and their stability is determined by the energy–momentum method (see Marsden[16] and references therein). The use of the energy–momentum method for the stability of vortices was studied for certain planar cases by Lewis and Ratiu.[17] As in the basic example of the rigid body, stability in the reduced space can also be studied by considering intersections of the energy levels with the symplectic leaves.

A. The phase space and its Poisson structure

The phase space of the dynamical system of N-vortices moving on the two sphere consists of N copies of a sphere, namely $P=S^2\times\cdots\times S^2$ regarded as being embedded in N copies of three space $\mathbb{R}^{3N}$ as the set defined by $\|\mathbf{x}_n\|=R$, where R is the radius of the sphere and $n=1,\ldots,N$ labels the location of the nth vortex. There are nonzero vortex strengths Γ_n ascribed to each vortex; i.e., to each S^2. The Poisson structure on P is given by

$$\{\cdot,\cdot\}=\sum_{n=1}^{N}\frac{R}{\Gamma_n}\{\cdot,\cdot\}_n, \tag{1}$$

where $\{\ ,\ \}_n$ is the Poisson structure on the nth copy of S^2 corresponding to the natural area symplectic form on S^2; that is, the Poisson structure in each copy of $\mathbb{R}^3$ is the standard Lie–Poisson structure on $\mathbb{R}^3$ considered as $\mathfrak{so}(3)^*$, the dual of the Lie algebra of the rotation group SO(3). (See, for example, Marsden and Ratiu[18] for the basic definitions used here.) The restriction of the Lie–Poisson bracket operation on $\mathbb{R}^3$ to a sphere [which is a symplectic leaf in $\mathfrak{so}(3)^*$] defines an area form. For two functions F,H on the nth copy of $\mathbb{R}^3$, the Lie–Poisson structure is

$$\{F,H\}_n(\mathbf{x}_n)=-\mathbf{x}_n\cdot(\nabla_n F\times\nabla_n H), \tag{2}$$

where $\times$ denotes the vector cross product.

B. The symmetry group and momentum map

Consider the diagonal action of the group SO(3) on P defined by rotations in each $\mathbb{R}^3$. This action is canonical with respect to the Poisson structure (1). The corresponding Lie algebra is naturally identified with $\mathbb{R}^3$ (having the vector product as its Lie bracket operation) and we write $\boldsymbol{\xi}$ for the vector in $\mathbb{R}^3$ corresponding to the matrix $\xi\in\mathfrak{so}(3)$; thus,

$$\mathfrak{so}(3)\simeq(\mathbb{R}^3,\times),\quad \text{i.e.,}\quad [\xi,\eta]=\boldsymbol{\xi}\times\boldsymbol{\eta},\quad \text{for any}\quad \xi,\eta\in\mathfrak{so}(3). \tag{3}$$

The vector field of infinitesimal transformations corresponding to an element ξ in the Lie algebra is given by

$$\xi_P(\mathbf{x}):=\frac{d}{dt}\exp(\xi t)\cdot\mathbf{x}\Big|_{t=0}=(\boldsymbol{\xi}\times\mathbf{x}_1,\ldots,\boldsymbol{\xi}\times\mathbf{x}_N). \tag{4}$$

The space $\mathfrak{so}(3)^*$, which, as mentioned above, is the dual of the Lie algebra $\mathfrak{so}(3)$, is equipped with the natural Lie–Poisson structure given by (2) (after identifying the dual of $\mathbb{R}^3$ with itself using the standard dot product on $\mathbb{R}^3$).

Recall that a *momentum map* $\mathbf{J}:P\to\mathfrak{so}(3)^*\simeq\mathbb{R}^3$ for this action is defined in terms of the Poisson bracket of an arbitrary function F on P by

$$\{F,J(\xi)\}=\xi_P[F],$$

where $J:\mathfrak{so}(3)\to C^\infty(P)$ is related to $\mathbf{J}$ by

$$J(\xi)(z)=\langle\mathbf{J}(z),\xi\rangle,$$

for all $\mathbf{x}\in\mathbf{P}$, $\xi\in\mathfrak{so}(3)$, and where $\langle\cdot,\cdot\rangle$ is the natural paring between the Lie algebra and its dual.

It is readily checked that the momentum map is proportional to the moment of vorticity and is given by

$$\mathbf{J}(\mathbf{x})=-\frac{1}{R}\sum_{n=1}^{N}\Gamma_n\mathbf{x}_n. \tag{5}$$

Denote its components by $\mathbf{J}=(\mathscr{Q},\mathscr{P},\mathscr{S})$. The momentum map is *not surjective* since

$$\max_n|\Gamma_n|-\sum_{m\neq n}|\Gamma_m|<\|\mathbf{J}\|<\sum_n|\Gamma_m|. \tag{6}$$

Denote the range of $\mathbf{J}$ by $\mathscr{R}$.

The momentum map is *equivariant*, that is,

$$\mathrm{Ad}^*_{g^{-1}}(\mathbf{J}(\mathbf{x}))=\mathbf{J}(g(\mathbf{x})), \tag{7}$$

for all $g\in\mathrm{SO}(3)$. Here, the map $\mathrm{Ad}^*_k:\mathfrak{so}(3)^*\to\mathfrak{so}(3)^*$, defined for each $k\in\mathrm{SO}(3)$, denotes the coadjoint action of SO(3) on $\mathfrak{so}(3)^*$. That one can find an *equivariant* momentum map is consistent with general theorems for compact or semisimple groups. In our case, this can be seen directly from (5) as the coadjoint action corresponds simply to rotations in the dual space $\mathfrak{so}(3)^*\simeq\mathbb{R}^3$.

It follows from equivariance of $\mathbf{J}$ or directly, that $\|\mathbf{J}\|^2$ is invariant under the coadjoint action. Hence, smooth functions of $\|\mathbf{J}\|^2$ are also invariant. Thus, if $\mathbf{b}=(b_1,b_2,b_3)\in\mathbb{R}^3$ are coordinates in the dual $\mathfrak{so}(3)^*$, then any smooth function of $\|\mathbf{b}\|^2$ is a Casimir function. Correspondingly, the generic symplectic leaves of $\mathfrak{so}(3)^*$ are spheres defined by the level sets $\|\mathbf{J}\|^2=\mathrm{const}\neq 0$. Note that as SO(3) is compact, the action of it on both P and $\mathfrak{so}(3)^*$ is proper.

C. The Hamiltonian

The Hamiltonian describing the motion of N vortices on the surface of a sphere of radius R is given by (see, e.g., Kidambi and Newton[4])

$$H=\frac{1}{4\pi R^2}\sum_{m<n}\Gamma_m\Gamma_n\ln(l^2_{mn}), \tag{8}$$

where $l^2_{mn}=2(R^2-\mathbf{x}_m\cdot\mathbf{x}_n)$ is the square of the chord distance between two vortices with positions $\mathbf{x}_m$ and $\mathbf{x}_n$. The constraints $\|\mathbf{x}_n\|=R$ are assumed. Notice that the Hamiltonian is invariant with respect to the diagonal action of SO(3) on P described above. Hence, the momentum map $\mathbf{J}$ defined by (5) is constant along the flow of this Hamiltonian.

II. POISSON AND SYMPLECTIC REDUCTION

A. Poisson quotients

In performing Poisson reduction, one normally constructs the quotient space by the symmetry group and calculates its naturally induced Poisson bracket. As is well known, singularities in the quotient space may arise if the group action on the phase space is not free. Strictly speaking, the phase space of the problem is not $S^2\times\cdots\times S^2$ but rather

$$S^2\times\cdots\times S^2\ \Big\backslash\ \sum_k\ \cup_{i_n\neq i_m}\Delta_{i_1\cdots i_k},$$

where $\Delta_{i_1\cdots i_k}=\{\mathbf{x}|$ any two or more of $\mathbf{x}_{i_n}$ coincide$\}$. This is because the self-interaction and collision of vortices (which lead to infinite energy) have been excluded from consideration. This restriction guarantees that the diagonal action of SO(3) on P is free provided $N\geqslant 3$, i.e., there are 3 or more vortices. The action is also proper, as was mentioned above.

Thus, *the quotient* $T=P/\mathrm{SO}(3)$ *is a smooth* $2N-3$ *dimensional Poisson manifold*. In coordinatizing this quotient we shall use the quantities l_{mn}^2, which are functions on P that are invariant with respect to the SO(3) action, with the conditions $l_{mn}^2\neq 0$. In general, there are $1+2(N-2)=2N-3$ independent functions l_{mn}^2, and other invariant functions can be expressed in terms of them.

To describe a configuration of N vortices on a sphere (up to a global rotation), it is sufficient to specify the chord distance between some two vortices and the chord distances from the remaining $N-2$ to those two (to remove the ambiguity of reflection consider, for example, a stereographic projection and choose two vortices such that all the rest lie to one side of the line connecting those two).

When 3 or more vortices are aligned on a great circle, this coordinate system is degenerate, i.e., there are less than $2N-3$ independent functions l_{mn}^2, and so we shall introduce other coordinates in the neighborhood of such points in the quotient space. Specifically, it is easy to see that the differentials of the three square distances associated to three vortices are linearly dependent when the three vortices lie on a great circle. This analysis, obviously, agrees with the dimension of the Poisson quotient. Also, the variables l_{mn}^2 naturally appear in the Hamiltonian for the N-vortex problem on the sphere, which makes the calculation of the reduced Hamiltonian h easy.

It follows from (5) that the square of the momentum map is given by

$$\mathbf{J}^2=:\|\mathbf{J}\|^2=\left(\sum\ \Gamma_n\right)^2-\frac{1}{R^2}\sum_{n<m}\Gamma_n\Gamma_m l_{nm}^2, \tag{9}$$

which, as we mentioned, is invariant under the SO(3) action. Other invariants are given by l_{nm}^2. Denote $\Gamma=\Sigma\Gamma_n$ and define a map $\Phi_\mu: T\to\mathbb{R}$ by

$$\Phi_\mu=(\mu-\Gamma)(\mu+\Gamma)+\frac{1}{R^2}\sum_{n<m}\Gamma_n\Gamma_m l_{nm}^2. \tag{10}$$

Notice that the relation (9) between the variables l_{nm}^2 and $\mathbf{J}$ can be expressed as $\Phi_J(l_{nm^2})=0$.

B. Reduction for the 3-vortex problem

Now we consider the 3-vortex problem and the structure of the corresponding Poisson reduced space in more detail. The phase space of the 3-vortex problem is trivial in a sense that it is diffeomorphic to a product of SO(3) with a ''shape-phase space'' U; that is, $P\cong\mathrm{SO}(3)\times U$, where

$$U=\{(a,\alpha_1,\alpha_2)\,|\,-R<a<R, 0<\alpha_1+\alpha_2<2\pi, \alpha_1<\alpha_2\}\subset\mathbb{R}^3. \tag{11}$$

Here, a can be interpreted as the height of the triangle of the vortices with respect to the sphere and α_n corresponds to an angle opposite the nth vortex. For the computations we will use another atlas which consists of three charts, two of which are nearly identical—they differ only in the orientation and are connected by a $\mathbb{Z}_2$ reflection. That is, for the same chord distances vectors $\mathbf{x}_1,\mathbf{x}_2,\mathbf{x}_3$ can form a right-handed or left-handed coordinate system, corresponding to different orientations and thus defining two different configurations, one in each of these two charts.

Denote the coordinates on these charts by $a_1=l_{23}^2, a_2=l_{13}^2, a_3=l_{12}^2$, so that the a_n are the squares of the sides of the triangle inscribed in a circle of radius $r<R$. Thus, all admissible values of a_n can be parameterized by any two angles α_n,α_m. The chart can be given parametrically by an open set $\mathcal{T}\subset\mathbb{R}^3$ defined as the set of triples (a_1,a_2,a_3) given by

$$a_1=2r^2(1-\cos\,\alpha_1),\qquad a_2=2r^2(1-\cos\,\alpha_2),\qquad a_3=2r^2(1-\cos(\alpha_1+\alpha_2)), \tag{12}$$

where $0<\alpha_1+\alpha_2<2\pi$, $0<r<R$. The third chart contains an open neighborhood of the set of great circles and smoothly connects different orientations. Indeed, for great circles $\mathbf{x}_n$ become linearly dependent, and $\mathbf{x}_1,\mathbf{x}_2,\mathbf{x}_3$ fail to define either the right- or left-handed coordinate system. The chart can be coordinatized by $V=\mathbf{x}_1\cdot(\mathbf{x}_2\times\mathbf{x}_3)$, i.e., the orientable volume of the parallelepiped formed by the vectors $\mathbf{x}_1,\mathbf{x}_2,\mathbf{x}_3$, and any two chord distances a_n,a_m. The sign of V deter-

mines the orientation (by distinguishing between right- and left-handed coordinate systems) and thus specifies one of the above two charts, while $V=0$ corresponds to the great circles. The change of coordinates is checked to be nondegenerate in the open intersections of the charts.

We summarize our results on Poisson reduction for the 3-vortex problem in the following.

Proposition II.1 (Poisson reduction for the 3-vortex problem): The quotient $T=P/\mathrm{SO}(3)$ is a smooth 3 dimensional manifold diffeomorphic to the shape phase space U defined by (11). The natural projection of P to T is a surjective submersion with fibers being the SO(3)-orbits on P.

The manifold T carries the quotient Poisson structure given as follows in the coordinate charts described above. Let f and h be given functions defined on the set $\mathscr{T}\subset T$ and let (a_1,a_2,a_3) lie in the set $\Phi_\mu(a_1,a_2,a_3)=0$. Then

$$\{f,h\}_T(a_1,a_2,a_3)=\frac{4R^3V}{\Gamma_1\Gamma_2\Gamma_3}\nabla\Phi_\mu\cdot(\nabla f\times\nabla h), \tag{13}$$

where V is regarded as a function of **a**; *its sign, which corresponds to different orientations, distinguishes between the two charts $\mathscr{T}$. The Poisson bracket along the set of great circles is given by the following expression:*

$$\{f,h\}_T(V,a_2,a_3)=B_2\left(\frac{\partial f}{\partial a_2}\frac{\partial h}{\partial V}-\frac{\partial f}{\partial V}\frac{\partial h}{\partial a_2}\right)+B_3\left(\frac{\partial f}{\partial a_3}\frac{\partial h}{\partial V}-\frac{\partial f}{\partial V}\frac{\partial h}{\partial a_3}\right). \tag{14}$$

Here

$$B_2=4R\left(\frac{2(a_1+a_2-a_3)R^2-a_1a_2}{\Gamma_1}-\frac{2(a_2+a_3-a_1)R^2-a_2a_3}{\Gamma_3}\right)$$

and

$$B_3=4R\left(\frac{2(a_2+a_3-a_1)R^2-a_2a_3}{\Gamma_2}-\frac{2(a_1+a_3-a_2)R^2-a_1a_3}{\Gamma_1}\right),$$

in which a_1 is regarded as a function of a_2,a_3 (since they are dependent when $V=0$).

Casimir functions on T are generated by Φ_μ; that is, any function of Φ_μ is a Casimir function. The level sets, $\Phi_\mu=0$, determine the symplectic leaves; these leaves are isomorphic to the symplectic-reduced spaces $P_\mu=\mathbf{J}^{-1}(\mu)/\mathrm{SO}(3)_\mu$. The generic leaves are those not containing the great circle equilibria with $\mathbf{J}=\mathbf{0}$ and are open planes that foliate $\mathscr{T}$. For every fixed choice of Γ_n they are parallel to each other and none of them contains the central line $a_1=a_2=a_3$. If $0\in Range\ \mathbf{J}$, then there is a unique nongeneric zero dimensional symplectic leaf that corresponds to a great circle configuration with $\mathbf{J}=0$.

Proof: Define $F=f\circ\pi$, where $\pi:P\to T$ is the projection. The Poisson bracket on P is given by (1) and (2). One computes, in a straightforward way, $\{F,H\}$ using the chain rule to get (13). Then (14) is obtained upon change of coordinates in the chart intersections and setting $V=0$ afterwards; we omit here the required simple but tedious calculations.

The structure of generic symplectic leaves follows from the linearity of the Casimir function (10). □

A Hamiltonian H on P that is invariant under the diagonal action of SO(3) induces a reduced Hamiltonian h on $T=P/\mathrm{SO}(3)$. The corresponding reduced equations on the leaves $\Phi_\mu=0$ in $\mathscr{T}$ are checked to be given by the following (Euler-like) equations (see Kummer[19] and Kirk and Marsden and Silber[20]):

$$\dot{\mathbf{a}}=\frac{4R^3V}{\Gamma_1\Gamma_2\Gamma_3}\nabla h\times\nabla\Phi_\mu, \tag{15}$$

where $\mathbf{a}=(a_1,a_2,a_3)$.

For the Hamiltonian (8) the reduced equations are

$$\dot{a}_i = \frac{V}{\pi R}\Gamma_i\left(\frac{1}{a_j}-\frac{1}{a_k}\right), \tag{16}$$

where (i,j,k) is a cyclic permutation of (1,2,3). Along the set of great circles the equations are represented in a different way, as is the Poisson bracket; in fact, they are given by

$$\dot{V} = \frac{1}{8\pi}\left(2R\left(\frac{a_3-a_1}{a_2}(\Gamma_1+\Gamma_3)+\frac{a_1-a_2}{a_3}(\Gamma_2+\Gamma_1)+\frac{a_2-a_3}{a_1}(\Gamma_3+\Gamma_2)\right)\right.$$
$$\left.-\frac{1}{R}(a_3(\Gamma_1-\Gamma_2)+a_2(\Gamma_3-\Gamma_1)+a_1(\Gamma_2-\Gamma_3))\right), \tag{17}$$

together with $\dot{a}_2=0$ and $\dot{a}_3=0$.

These results reproduce, in the spirit of geometric mechanics, some of the results of Kidambi and Newton.[4] For instance, the second invariant in this reference is interpreted as a linear function of the square of the momentum map, $\|\mathbf{J}\|^2$. They differ only in an overall factor and an additive constant. As it was mentioned above, $\|\mathbf{J}\|^2$ determines the symplectic leaves in $\mathfrak{so}(3)^*$ and naturally leads to conserved quantities.

III. STABILITY OF RELATIVE EQUILIBRIA

A. The energy–momentum method

We will now utilize the energy–momentum method (see Marsden[16] for a summary and references) for the analysis of the stability of *relative equilibria*, i.e., dynamical orbits with initial conditions $\mathbf{x}_e$ such that $\mathbf{x}(t)=\exp(\xi_e t)\mathbf{x}_e$ for some Lie algebra element ξ_e and any time t. As is well known for relative equilibria, the *augmented energy* function $H_{\xi_e}:=H-\langle \mathbf{J}-\mu_e,\xi_e\rangle$ has a critical point at $\mathbf{x}_e$, where $\mu_e=\mathbf{J}(\mathbf{x}_e)$ is the value of the momentum at the relative equilibrium. For notational convenience we will occasionally omit the subscript e.

The orbital stability of a relative equilibrium is equivalent to the stability of the corresponding equilibrium of the reduced system that is induced on the symplectic leaves P_μ of the quotient manifold $P/\mathrm{SO}(3)$. The energy momentum method is designed to enable one to test for orbital stability directly on the unreduced manifold P by constructing a subspace $\mathscr{G}\subset T_{\mathbf{x}_e}P$ which is isomorphic to $T_{\mathbf{x}_e}P_{\mu_e}$. This is done by considering a tangent space to the level set of constant momentum $\mathbf{J}^{-1}(\mu_e)$ and eliminating the neutrally stable directions associated to the isotropy subgroup,

$$\mathrm{SO}(3)_{\mu_e}:=\{g\in \mathrm{SO}(3)\,|\,\mathrm{Ad}^*_g\mu_e=\mu_e\}.$$

The energy–momentum method determines stability by examining definiteness of the second variation of H_{ξ_e} restricted to the subspace $\mathscr{G}$. A detailed description of this method can be found in Simo, Lewis and Marsden.[21]

If one has a definite second variation, then Patrick's theorem (see Patrick[22]) guarantees stability modulo the isotropy subgroup, provided its action on P is proper and the Lie algebra admits an inner product invariant under the adjoint action of the isotropy subgroup. Note that as SO(3) is compact, the assumptions of Patrick's theorem are automatically satisfied for our applications.

As was mentioned above, relative equilibria are critical points of the augmented Hamiltonian H_ξ. For variational calculations, we extend all functions on P to functions on the ambient space $\mathbb{R}^{3N}$, and then restrict variations to the tangent space to P by requiring

$$\delta F(\mathbf{x})\cdot\boldsymbol{\eta}=0,$$

for all $\boldsymbol{\eta}\in T_{\mathbf{x}}P$. For the augmented Hamiltonian corresponding to (8), this results in the following conditions on $\mathbf{x}$:

$$\frac{\Gamma_r}{R}\left(\boldsymbol{\xi}(\mathbf{x})-\frac{1}{2\pi R}\sum_{n\neq r}\Gamma_n\frac{\mathbf{x}_n}{l_{nr}^2}\right)=\kappa_r\frac{\Gamma_r}{R^2}\mathbf{x}_r, \tag{18}$$

where κ_r are constants to be determined.

B. Equidistant relative equilibria

An ***equidistant configuration*** is, by definition, one that satisfies $l_{mn}^2 = l^2$ for all $m \neq n$. Whatever its dynamics, such a configuration is possible only for $N = 2,3,4$ (this follows by geometric arguments similar to those used for the study of regular polytopes in three space); we exclude the simple case $N = 2$ from our considerations.

To verify that an equidistant configuration is a relative equilibrium, one need only check that conditions (18) are satisfied. It is easy to see that

$$\boldsymbol{\xi}(\mathbf{x}) = \frac{1}{2\pi R l^2} \sum_n \Gamma_n \mathbf{x}_n = -\frac{1}{2\pi l^2} \mathbf{J}(\mathbf{x}) \tag{19}$$

solves (18) with $\kappa_r = \Gamma_r / 2\pi l^2$. Notice, that in (19) the vectors $\boldsymbol{\xi}$ and $\mathbf{J}$ have opposite directions. These observations prove the following.

Proposition III.1: Equidistant configurations of relative equilibria satisfying $\mathbf{J}(\mathbf{x}_e) \neq 0$ *are possible only for* $N = 3$ *and* 4 *and are given by equilateral triangles and a tetrahedron, respectively; the associated values of the momentum and the Lie algebra element for these relative equilibria satisfy (19).*

Condition (18) together with $\boldsymbol{\xi} = 0$ defines ***static equilibria***. It follows from (19) that equidistant static equilibria are possible only in the degenerate case of zero momentum. This necessarily implies for $N = 3$ that the vortices lie on a great circle, and for both $N = 3$ and $N = 4$ that all Γ_n are equal, i.e., $\Gamma_n = \Gamma$. Moreover, a tetrahedral configuration with zero momentum $\mathbf{J} = 0$ is necessarily a static equilibrium.

C. Great circle relative equilibria

For $N = 3$ vortices, we have the following classification of ***great circle equilibria*** (see Kidambi and Newton[4]); recall the notations $a_1 = l_{23}^2, a_2 = l_{13}^2, a_3 = l_{12}^2$.

1. Generic momentum, $\mathbf{J}(\mathbf{x}_e) \neq 0$

General relative equilibria correspond to vortices lying on a great circle (and thus satisfying $V = 0$) and also satisfying the following condition:

$$2R\left(\frac{a_3 - a_1}{a_2}(\Gamma_1 + \Gamma_3) + \frac{a_1 - a_2}{a_3}(\Gamma_2 + \Gamma_1) + \frac{a_2 - a_3}{a_1}(\Gamma_3 + \Gamma_2)\right)$$
$$-\frac{1}{R}(a_3(\Gamma_1 - \Gamma_2) + a_2(\Gamma_3 - \Gamma_1) + a_1(\Gamma_2 - \Gamma_3)) = 0, \tag{20}$$

obtained by setting $\dot{V} = 0$ in (17). This implicit formula determines another relation (in addition to $V = 0$), between a_1, a_2 and a_3 for each fixed set of Γ's. This is a nonlinear equation and thus can have multiple solutions.

(a) Isosceles triangular great circle equilibria. A particular family of ***isosceles triangular relative equilibria*** *for arbitrary values of* Γ*'s is given by the following configuration:*

$$a_1 = a_2 = 2R^2, \quad a_3 = 4R^2, \tag{21}$$

or, equivalently, $\alpha_1 = \alpha_2 = \pi/2$, $\alpha_3 = \pi$, as well as configurations obtained from it by cyclic permutations of indices. The whole configuration rotates around the vector

$$\boldsymbol{\xi}(\mathbf{x}) = -\frac{1}{4\pi R^2} \mathbf{J}(\mathbf{x}) \tag{22}$$

and the constants κ_n in (18) are given by

$$\kappa_1=\frac{\Gamma_1}{4\pi R^2}-\frac{\Gamma_2}{8\pi R^2},\quad \kappa_2=\frac{\Gamma_2}{4\pi R^2}-\frac{\Gamma_1}{8\pi R^2},\quad \kappa_3=\frac{\Gamma_3}{4\pi R^2}.$$

(b) Equilateral triangular great circle equilibria. A ***great circle equilateral triangle relative equilibrium*** with $l_{mn}^2=l^2=3R^2$ and ξ given by (19).

Note: When the term *equilateral triangle relative equilibrium* is used, and we do not append ''great circle,'' we will mean that it is a *nongreat circle equilateral triangle relative equilibrium.*

2. Degenerate momentum, $\mathbf{J}(\mathbf{x}_e)=\mathbf{0}$

In this case, the vortices again lie on a great circle, and the whole configuration rotates around the vector

$$\boldsymbol{\xi}(\mathbf{x})=-\frac{1}{2\pi R}\left(\frac{\Gamma_1\mathbf{x}_1}{l_{23}^2}+\frac{\Gamma_2\mathbf{x}_2}{l_{13}^2}+\frac{\Gamma_3\mathbf{x}_3}{l_{12}^2}\right). \tag{23}$$

Remarks.

(1) Another specific family of great circle solutions can be found in case two of the Γ's are equal; for instance, $\Gamma_1=\Gamma_2$. In fact, any isosceles triangle with the corresponding sides of the triangle being also equal, that is, $a_1=a_2$ for $\Gamma_1=\Gamma_2$, solves to (20) and hence is a relative equilibrium for any value of Γ_3.

(2) If we consider the ''inverse'' problem, namely, given a configuration on a great circle find Γ_n satisfying (20) so that this configuration is a relative equilibrium, then condition (20) becomes a linear equation in Γ_n of the form
$$\beta_1\Gamma_1+\beta_2\Gamma_2+\beta_3\Gamma_3=0,$$
where $\beta_n=\beta_n(a_1,a_2,a_3)$ are functions of a great circle configuration. One would expect this to have a two parameter family of solutions.

The structure of the symplectic leaves sheds light on the stability of relative equilibria of the system. In particular, generically, great circle configurations satisfying (20) form a family of one dimensional curves in the Poisson manifold T that intersect symplectic leaves in a point. Similarly, equilateral configurations are isolated points within the symplectic leaves, and stability analysis is done by restricting a proper second variation to the tangent space to these leaves.

D. Geometry of the tangent space of phase space

Following the outline in the beginning of this section, consider a generic *regular* relative equilibrium $\mathbf{x}_e$, that is, its symmetry subgroup is finite, i.e., for each nonzero element $\boldsymbol{\xi}$ of the Lie algebra, the corresponding infinitesimal generator evaluated at $\mathbf{x}_e$, denoted $\boldsymbol{\xi}_P(\mathbf{x}_e)$, is nonzero. Then, the isotropy subgroup of the corresponding nonzero momentum value $\mu_e=\mathbf{J}(\mathbf{x}_e)$ is the group SO(2) of rotations around the vector $\mathbf{J}$. For $\mu_e=0$ the isotropy subgroup is SO(3) itself; (the stability in this is case is simple and will be considered in the end of the section). The isotropy Lie subalgebra is defined by

$$\mathfrak{so}(3)_{\mu_e}=\left\{\boldsymbol{\xi}\in\mathbb{R}^3\,\middle|\,\boldsymbol{\xi}=\varrho\,\mathbf{J}(\mathbf{x}_e)=-\frac{\varrho}{R}\sum_n\Gamma_n\mathbf{x}_{e,n},\ \ \varrho\ \text{ a constant}\right\}. \tag{24}$$

Hence, the tangent space to the $\mathrm{SO}(3)_\mu$ orbit at $\mathbf{x}_e$, which corresponds to the neutrally stable direction, is given by

$$T_{\mathbf{x}_e}(\mathrm{SO}(3)_{\mu_e}\cdot\mathbf{x}_e)=\{\boldsymbol{\xi}\times\mathbf{x}_e\,|\,\boldsymbol{\xi}=\varrho\,\mathbf{J}(\mathbf{x}_e)\}, \tag{25}$$

where again ϱ is a constant. For regular relative equilibria, $\mathrm{Ker}D\mathbf{J}(\mathbf{x}_e)=T_{\mathbf{x}_e}\mathbf{J}^{-1}(\mu_e)$. The derivative of the momentum map $D\mathbf{J}$ as a mapping from TP to $T\mathbb{R}^3$ can be easily computed from (5) to produce

$$D\mathbf{J}(\mathbf{x})\cdot\mathbf{y}=-\frac{1}{R}\sum_n \Gamma_n\mathbf{y}_n,$$

where $\mathbf{y}:=(\mathbf{y}_1,\ldots,\mathbf{y}_N)\in T_{\mathbf{x}}P$ and $\mathbf{y}_n\in T_{\mathbf{x}_n}S^2$ is a tangent vector to the sphere S^2 at the point $\mathbf{x}_n$. Thus, the kernel is determined by the following condition:

$$\mathrm{Ker}D\mathbf{J}(\mathbf{x})=\left\{\mathbf{y}\in T_{\mathbf{x}}P\,\middle|\,\sum_n \Gamma_n\mathbf{y}_n=0\right\}, \tag{26}$$

and is $2N-3$ dimensional.

Using Eqs. (25) and (26) it is easy to see that

$$T_{\mathbf{x}_e}(\mathrm{SO}(3)_\mu\cdot\mathbf{x}_e)\subset\mathrm{Ker}D\mathbf{J}(\mathbf{x}_e).$$

Indeed,

$$\sum_n \Gamma_n\mathbf{y}_n=\sum_n \Gamma_n\varrho\,\mathbf{J}\times\mathbf{x}_n=\varrho\,\mathbf{J}\times\mathbf{J}=0.$$

We proceed to find a subspace $\mathcal{G}\subset\mathrm{Ker}D\mathbf{J}(\mathbf{x}_e)$ that is transversal to the tangent space to the $\mathrm{SO}(3)_\mu$ orbit at $\mathbf{x}_e$. It is done in the following way. Chose two arbitrary vectors $\mathbf{D}^{(1)}$ and $\mathbf{D}^{(2)}$ such that the plane through them contains no vortices. Then, tangent vectors at each of the vortices,

$$\mathbf{y}_n^{(1)}:=\gamma_n^{(1)}\mathbf{D}^{(1)}\times\mathbf{x}_n,\quad \mathbf{y}_n^{(2)}:=\gamma_n^{(2)}\mathbf{D}^{(2)}\times\mathbf{x}_n \tag{27}$$

span $T_{\mathbf{x}}P$. Notice that (27) guarantees that all $\mathbf{y}_n^{(i)}$ lie in a plane perpendicular to $\mathbf{D}^{(i)}$. Thus, for each $\mathbf{D}^{(i)}$ there are $N-2$ independent zero linear combinations of $\mathbf{y}_n$'s. Also, it follows from (26) that if the coefficients $\gamma_n^{(i)}$ are chosen to satisfy

$$\sum_n \Gamma_n\gamma_n^{(i)}\mathbf{x}_n=\mathbf{D}^{(i)}\quad\text{or}\quad\sum_n \Gamma_n\gamma_n^{(i)}\mathbf{x}_n=0,\quad i=1,2, \tag{28}$$

then the corresponding tangent vectors belong to the Ker$D\mathbf{J}$.

Any of the equalities in (28) has $N-3+1=N-2$ linearly independent solutions for each $\mathbf{D}^{(i)}$, and, hence, a transversal subspace $\mathcal{G}$ is defined by

$$\mathcal{G}=\mathrm{span}\{\mathbf{y}^{(1)}:=(\gamma_n^{(1)}\mathbf{D}^{(1)}\times\mathbf{x}_n),\ \mathbf{y}^{(2)}:=(\gamma_n^{(2)}\mathbf{D}^{(2)}\times\mathbf{x}_n)\}, \tag{29}$$

and $\dim\mathcal{G}=2N-4$. The isotropy subgroup transformations, i.e., rotations around the axis $\mathbf{J}$, is determined by tangent vectors

$$\mathbf{y}_n:=-\frac{1}{R}\,\mathbf{J}\times\mathbf{x}_n$$

and corresponds to an additional one-dimensional neutrally stable subspace in Ker$D\mathbf{J}$.

We note that special choice of $\mathbf{D}^{(i)}$ would result in a diagonal structure of the second variation of H_ξ. We shall see an instance of this below.

E. Definiteness of the second variation

For the calculation of the second variation the Lagrange multiplier method is used. Define the *extended Hamiltonian* $\tilde{H}_\xi$,

$$\tilde{H}_\xi:=H_\xi+\sum_n \lambda_n(\mathbf{x}_n^2-R^2),$$

where $(\mathbf{x}_n^2 - R^2) = 0$ constrains the motion of vortices to the sphere S^2. The Lagrange multipliers λ_n are determined by the condition $\delta \tilde{H}_\xi(\mathbf{x}_e) = 0$ and are given by

$$\lambda_n = -\frac{\kappa_n \Gamma_n}{2R^2},$$

where κ_n are determined from (18). Then the second variation at $\mathbf{x}_e$ is well-defined as a bilinear form on $T_{\mathbf{x}_e} P$. It is given by the following expression:

$$\frac{\partial^2 \tilde{H}_\xi}{\partial x_s^j \partial x_r^i} = \begin{cases} 2\lambda_r \delta^{ij} - \dfrac{\Gamma_r}{\pi R^2} \displaystyle\sum_{n \neq r} \Gamma_n \frac{x_n^i x_n^j}{l_{nr}^4}, & r = s, \\ -\dfrac{\Gamma_r \Gamma_s}{2\pi R^2 l_{rs}^2} \left(\delta^{ij} + 2 \dfrac{x_s^i x_r^j}{l_{rs}^2} \right), & r \neq s. \end{cases} \tag{30}$$

In the case of an equilateral triangle configuration, when $l_{rs}^2 = l^2$, one can choose

$$\mathbf{D}^{(1)} = \mathbf{x}_1 + \mathbf{x}_2 \quad \text{and} \quad \mathbf{D}^{(2)} = \mathbf{x}_2 + \mathbf{x}_3,$$

as a set of vectors defining a basis of the transversal subspace $\mathcal{G}$ according to (27) with the constants $\gamma_n^{(i)}$ that satisfy conditions (28) being given by $\gamma_1^{(1)} = 1/\Gamma_1, \gamma_2^{(1)} = 1/\Gamma_2, \gamma_3^{(1)} = 0$ and $\gamma_1^{(2)} = 0$, $\gamma_2^{(2)} = 1/\Gamma_2, \gamma_3^{(2)} = 1/\Gamma_3$. Then, the restriction of the second variation to it is given by the following expression:

$$\delta^2 \tilde{H}_\xi \big|_{\mathcal{G}} = \frac{V^2}{\pi R^2 l^4} \begin{pmatrix} -\dfrac{\Gamma_3}{\Gamma_1} - \dfrac{\Gamma_3}{\Gamma_2} & 1 \\ 1 & -\dfrac{\Gamma_1}{\Gamma_2} - \dfrac{\Gamma_1}{\Gamma_3} \end{pmatrix}. \tag{31}$$

The second variation is definite provided $\det(\delta^2 \tilde{H}_\xi)$ is positive. Hence, the following.

Theorem III.2 (stability of nongreat circle equilateral triangles): *An equilateral triangle configuration of nongreat circle relative equilibria* $\mathbf{x}_e$ *is stable modulo* SO(2) *rotations around the vector* $\mathbf{J}(\mathbf{x}_e)$ *if*

$$\sum_{n<m} \Gamma_n \Gamma_m > 0, \tag{32}$$

and unstable if

$$\sum_{n<m} \Gamma_n \Gamma_m < 0. \tag{33}$$

This theorem generalizes the known results of Synge[8] for the stability of equilateral relative equilibria of 3 vortices on a plane. Indeed, conditions (32) and (33) are independent of the radius R. Thus, in the limit $R \to \infty$ the spherical stability conditions agree with those for the planar case.

Conjecture: The condition $\Sigma_{n<m} \Gamma_n \Gamma_m = 0$ *corresponds to a (degenerate) Hamiltonian bifurcation.*

Next we analyze stability for the family of great circle relative equilibria given by (21). Choose

$$\mathbf{D}^{(1)} = \mathbf{x}_1 + \mathbf{x}_3 \quad \text{and} \quad \mathbf{D}^{(2)} : (\mathbf{D}^{(2)}, \mathbf{x}_n) = 0, \ \|\mathbf{D}^{(2)}\| = R,$$

as a set of vectors defining a basis of the transversal subspace $\mathcal{G}$ according to (27) with the constants $\gamma_n^{(i)}$ satisfying conditions (28) being given by $\gamma_1^{(1)} = 1/\Gamma_1, \gamma_2^{(1)} = 0$, $\gamma_3^{(1)} = 1/\Gamma_3$ and $\gamma_1^{(2)} = 1/\Gamma_1, \gamma_2^{(2)} = 1/\Gamma_2, \gamma_3^{(2)} = 0$. Then we obtain the following expression for the restriction of the second variation:

$$\delta^2\tilde{H}_\xi|_{\mathscr{S}}=\frac{1}{8\pi}\begin{pmatrix}\dfrac{\Gamma_2}{\Gamma_1} & 0\\ 0 & \left(\dfrac{\Gamma_2}{\Gamma_1}+\dfrac{\Gamma_1}{\Gamma_2}\right)-2\left(1+\dfrac{\Gamma_3}{\Gamma_1}+\dfrac{\Gamma_3}{\Gamma_2}\right)\end{pmatrix}.$$

Stability then follows from a direct analysis of its definiteness; that is, whether or not the two diagonal entries have the same sign or not. In other words, one has stability if the determinant is positive and instability if it is negative. Carrying out this simple calculation gives the following result.

Theorem III.3 (stability of isosceles triangle great circle equilibria): *A great circle configuration of relative equilibrium* $\mathbf{x}_e$ *given by (21) is* stable *if*

$$\Gamma_1^2+\Gamma_2^2>\sum_{n\neq m}\Gamma_n\Gamma_m \tag{34}$$

and unstable *if*

$$\Gamma_1^2+\Gamma_2^2<\sum_{n\neq m}\Gamma_n\Gamma_m. \tag{35}$$

The stability is modulo SO(2) *rotations around* $\mathbf{J}(\mathbf{x}_e)$.

F. Stability of great circle equilateral triangle relative equilibria

The stability analysis of a GCET, a great circle equilateral triangle relative equilibrium is different from the nongreat circle equilateral triangle case. The reason is that the two-dimensional subspace to which the second variation of the augmented Hamiltonian is restricted in the general case fails to be a transversal subspace to the G_μ orbit (rotations around $\mathbf{J}$) within Ker$D\mathbf{J}$ but rather degenerates to a one-dimensional subspace. A complimentary direction transversal to the plane of the triangle has to be taken into account similar to the case of other great circle relative equilibria. Using the notations developed in the section on the geometry of the tangent space, we choose $\mathbf{D}^{(1)}=n\mathbf{x}_1+m\mathbf{x}_2$ and $\mathbf{D}^{(2)}:(\mathbf{D}^{(2)},\mathbf{x}_n)=0$, $\|\mathbf{D}^{(2)}\|=R$ as a set of vectors defining a basis of the transversal subspace $\mathscr{S}$ according to (27) with the constants $\gamma_n^{(i)}$ satisfying conditions (28) being given by $\gamma_1^{(1)}=n/\Gamma_1, \gamma_2^{(1)}=m/\Gamma_2, \gamma_3^{(1)}=0$ and $\gamma_1^{(2)}=1/\Gamma_1, \gamma_2^{(2)}=1/\Gamma_2, \gamma_3^{(2)}=1/\Gamma_3$.

Using this basis, a straightforward computation gives the following expression for the restriction of the second variation:

$$\delta^2\tilde{H}_\xi|_{\mathscr{S}}=\frac{1}{12\pi}\begin{pmatrix}0 & 0\\ 0 & 9-(\Gamma_1+\Gamma_2+\Gamma_3)\left(\dfrac{1}{\Gamma_1}+\dfrac{1}{\Gamma_2}+\dfrac{1}{\Gamma_3}\right)\end{pmatrix}.$$

One concludes from this that *these GCET equilibria are at best, neutrally stable.*

In the paragraphs below, we explore this in a little more detail and identify the source of the zero eigenvector. Compute the gradient of the Casimir function Φ_μ, given by equation (10), which gives the normal direction to the symplectic leaf:

$$\nabla\Phi_\mu=\left(\frac{\partial\Phi_\mu}{\partial\mathbf{x}_n}\right)=-\frac{2}{R^2}\begin{pmatrix}\Gamma_1\Gamma_2\mathbf{x}_2+\Gamma_1\Gamma_3\mathbf{x}_3\\ \Gamma_1\Gamma_2\mathbf{x}_1+\Gamma_2\Gamma_3\mathbf{x}_3\\ \Gamma_1\Gamma_3\mathbf{x}_1+\Gamma_2\Gamma_3\mathbf{x}_2\end{pmatrix}.$$

Evaluate this gradient at the point corresponding to the GCET, and take the gradient in the direction corresponding to the family of equilateral triangles. To determine such a direction, recall that in the coordinates of the trivialization this family is defined by the following curve: $a=a, \alpha_1=\alpha_2=2\pi/3$, where a is the curve parameter. The tangent vector to this curve is (1,0,0) and so in coordinates of the ambient space, the variation of the GCET configuration along the family of equilateral triangles is given by the following expression:

$$w_{\text{gcet}} := \begin{pmatrix} \mathbf{x}_1 \times \mathbf{x}_2 \\ \mathbf{x}_1 \times \mathbf{x}_2 \\ \mathbf{x}_1 \times \mathbf{x}_2 \end{pmatrix} \in T_x P,$$

i.e., the same tangent vector $\mathbf{x}_1 \times \mathbf{x}_2$ is attached at each vortex position.

Intuitively, one can understand this in the following way. Fix a horizontal plane going through the center of the sphere, intersecting it along a great circle. Inscribe an equilateral triangle giving us precisely the GCET configuration. Constrain each vortex to move along a great circle going through its original position and the North Pole. Then, shifting the plane vertically up and down and keeping track on its cross-section with the sphere, defines a family of equilateral triangles. Obviously, the vector of infinitesimal translation at the GCET configuration is given by w_{GCET} above, i.e., at each vortex the vector points strictly vertically.

The gradient $\nabla \Phi_\mu$ evaluated on w_{GCET} at GCET is zero; the volume function V, being the mixed vector product, vanishes at the great circle. This means that such a direction, i.e., the equilateral triangle family of equilibria, is tangential to the leaf at this point. In this sense the GCET is a nonisolated equilibrium within its symplectic leaf. Thus, further analysis of the stability of the GCET equilibrium requires applications of some other, nonstandard techniques.

The preceding considerations are not applicable to a nongreat circle equilateral triangle configuration, for which one shows that in the coordinates given by chord distances l_{nm}, the family of equilateral triangles given by $l_{nm} = l$ for all n, m intersects symplectic leaves, which are planes [see equation (10), Φ_μ is linear], *transversally*.

G. The degenerate case $\mathbf{J}(\mathbf{x}_e) = \mathbf{0}$

Stability in this case is a simple task and can be done by a dimension count. This results in the following theorem.

Theorem III.4 (stability of great circle equilibria with $\mathbf{J} = 0$): *A relative equilibrium with zero vorticity momentum* $\mathbf{J}(\mathbf{x}_e) = 0$, *which necessarily lies on a great circle, is* stable modulo SO(3).

Proof: The isotropy subgroup $\mathrm{SO}(3)_{\mu=0}$ is, in this case, the whole group SO(3) and hence the dimension of $\mathbf{J}^{-1}(0)/\mathrm{SO}(3)_{\mu=0}$ is zero. This implies that

$$\mathrm{Ker} D\mathbf{J}(\mathbf{x}) = T_{\mathbf{x}}(\mathrm{SO}(3)_{\mu=0} \cdot \mathbf{x}).$$

The assumptions of Patrick's theorem are satisfied as SO(3) is compact, and so this proves the theorem. □

H. Stability in the reduced space

One can also study the stability of equidistant configurations of fixed equilibria in the reduced space by analyzing level sets of the integrals of motion. In general, each such integral defines a codimension 1 surface, and trajectories are confined to lie in the intersection of these surfaces. In our case, the flow lines are given by intersecting the 2d energy levels $h = \text{const}$ with the coadjoint orbits which are planes. This is analogous to the rigid body flow on the angular momentum spheres, where the orbits are given by the intersection of the energy ellipsoids $h = \text{const}$ with the coadjoint orbits that are two-spheres (see, e.g., Marsden and Ratiu[18]). Similar to the Energy–Casimir method, this approach, while defining stability conditions, does not specify the transformations in the unreduced space modulo which the stability is understood.

The equidistant fixed equilibria in T are determined by the central line $a_1 = a_2 = a_3 = a$. In the neighborhood of such an equilibrium $a_i = a(1 + \epsilon_i)$, where ϵ_i are small, and the energy levels are given by

$$h = \frac{1}{4\pi R^2}\left(\ln a \sum_{n<m} \Gamma_n \Gamma_m + \Gamma_1 \Gamma_2 \epsilon_3 + \Gamma_1 \Gamma_3 \epsilon_2 + \Gamma_2 \Gamma_3 \epsilon_1 \right)$$

$$- \frac{1}{4\pi R^2} \frac{1}{2} (\Gamma_1 \Gamma_2 \epsilon_3^2 + \Gamma_1 \Gamma_3 \epsilon_2^2 + \Gamma_2 \Gamma_3 \epsilon_1^2) + \ldots . \tag{36}$$

The symplectic leaves are planes; up to a constant they are given by a linear part in (36). Thus, in a small enough neighborhood of an equilibrium, trajectories are determined by the intersections of these planes with the surfaces defined by the quadratic part in (36). Depending on the mutual signs of Γ's these surfaces are either ellipsoids or hyperboloids of one sheet or hyperboloids of two sheets. For instance, if all Γ_n have the same sign, then the quadratic surface is an ellipsoid, and its intersection with any plane is an ellipse. Hence, the fixed point is surrounded by closed planar orbits and is therefore stable. Note that the condition (32) is satisfied. On the contrary, if the signs of Γ_n are different, the quadratic surface is an hyperboloid, and its intersections with a plane are either ellipses or hyperbolas, depending on the position of the plane. This results in either stable or unstable fixed point, respectively, and is determined precisely by the conditions (32) and (33).

IV. CONCLUSIONS

A simple physical system of 3 point vortices on a sphere reveals a surprisingly rich geometrical structure. In this paper we have explicitly constructed the quotient manifold $T=P/\mathrm{SO}(3)$ of the problem and calculated its inherited Poisson bracket.

An analysis of the symplectic structure of the symplectic leaves in this quotient manifold sheds light on the classification of relative equilibria and their stability. By applying the energy–momentum method, we have found explicit criteria for the stability of different configurations of relative equilibria with generic and nongeneric momenta. In each case we have specified a group of transformations modulo which stability in the unreduced space is understood.

In work in progress, we shall explore the link with dual pairs (see Marsden and Weinstein[13] and Weinstein[23]) more thoroughly. Indeed, $P/\mathrm{SO}(3)\overset{\pi}{\leftarrow}P\overset{J}{\rightarrow}\mathscr{R}$ is a full dual pair. This duality is also one way of viewing noncommutative complete integrability of the 3-vortex problem on a sphere.

We also will be exploring the geometric phase (in the sense of Marsden, Montgomery and Ratiu[24]) for the three-vortex problem on a sphere.

ACKNOWLEDGMENTS

We would like to thank Paul Newton for helpful discussions and for insightful remarks on vortex dynamics. We also thank Anthony Blaom, Serge Preston and Tudor Ratiu for their helpful comments and advice on this and related work.

(Received 13 April 1998; accepted for publication 20 July 1998)

In order to clarify certain misconceptions in the literature, we discuss the details of the way determining equations for general symmetries of a Lagrangian system differ from determining equations for Noether symmetries, and establish the minimal set of extra conditions which have to be imposed in practical situations for the former to reduce to the latter. We further derive properties by which, in situations where the system is integrable through quadratic integrals in involution, the components of the corresponding Noether symmetries themselves can be used to compute the separation variables, if they exist, for the Hamilton–Jacobi equation. © *1998 American Institute of Physics.* [S0022-2488(98)02711-X]

I. INTRODUCTION

The role and importance of Noether's theorem in the study of Lagrangian systems is widely recognized. It is the vehicle by which, from a physical perspective, the duality is established between symmetries and conservation laws. The mathematical interest of knowing symmetries and/or first integrals of a dynamical system is that they provide means for a reduction of the integration process; knowledge of a sufficient number of such elements may eventually lead to a form of complete integrability of the system.

Many authors have discussed ways of generating, if possible, first integrals also from general symmetries of the Lagrangian (or Hamiltonian) differential equations, i.e., symmetries of non-Noether type. The general mechanisms behind all such constructions are fairly easy to grasp if one makes use of some elementary concepts from the differential geometric description of (Lagrangian) mechanics. Indeed, leaving aside certain slight variations or generalizations, one can roughly capture the full picture in the following scheme. Noether symmetries of a Lagrangian system are symmetries of the Cartan two-form $d\theta$ and the corresponding integral originates from the closedness of the contraction of $d\theta$ with the symmetry generator (see, e.g., Ref. 1). In the case of non-Noether symmetries, there is usually one of two mechanisms at work: if a corresponding first integral has a divergence part, then we are essentially looking at the invariance of the volume form $(d\theta)^n$, where n is the number of degrees of freedom (see, e.g., Ref. 2); alternatively, the invariant object is a type (1,1) tensor field, constructed from $d\theta$ and its Lie derivative under the action of the symmetry generator, and the first integrals then essentially come from the Lax-type equation which expresses this invariance.[3–5]

Unfortunately, there is still a lot of confusion about such issues in the current literature, probably because a number of authors are still not aware or convinced of the benefits and the generality of coordinate free descriptions. To cite one (of many possible) example where this leads to unfruitful efforts Lutzky recently discussed ''generalizations'' of his earlier work on non-Noether symmetries,[6,7] in which a class of velocity-dependent symmetry generators is considered. His new results,[8,9] however, are merely particular cases of the above cited construction of an invariant type (1,1) tensor field, which is valid for all velocity-dependent symmetries.

The need for correcting some inaccurate or misleading statements lies partly at the origin of the present paper. In some of the publications of Lakshmanan and co-workers about integrability aspects of mechanical systems,[10,11] consistent use of Noether's theorem was made to construct the

invariants. In other papers,[12–14] however, the emphasis is much more on a methodology which starts from a systematic construction of (generalized) symmetries of the differential equations (except that in the review paper,[14] a large part deals with Painlevé analysis as well). The adjective generalized refers to the fact that the spirit is much in the line of the Lie approach to differential equations, but nonpoint symmetries are being considered. From the point of view of symmetries of the vector field generating second-order dynamics, however, there is no need to talk about anything generalized here. This is of course not the point of criticism. The point is that the authors believe that they are making use of a wider class of symmetries than just Noether symmetries, as is illustrated by the explicit statement[12,13] that a first integral is being constructed without recourse to Noether's theorem. Yet, the calculations are manifestly not about some volume form or some type (1,1) tensor field. Instead, a certain *ad hoc* ansatz is imposed on the construction of (generalized) Lie symmetries, which apparently has the effect that an invariant of the symmetry generator itself becomes a first integral of the given differential equations. Another, potentially interesting, but in the presentation of the authors rather peculiar story, is about the way separation variables (in the sense of Hamilton-Jacobi theory) can be constructed directly from the components of the symmetry generator. The claim is that such variables follow from a process of ''integration of part of the characteristic equations related to the symmetry vector field.'' However, no justification whatsoever is given concerning reasons why the manipulations which are being carried out should have anything to do with the construction of separation variables.

In Sec. II we will show first of all that the extra anzats which is assumed in Refs. 12 and 13 to find symmetries which lead to a corresponding first integral, is exactly a condition which forces these symmetries to be of Noether type. In Sec. III we will take the opportunity to add new insights into the way Noether symmetries, from a computational point of view, make up a subset of the set of all dynamical symmetries of a class of autonomous Lagrangian systems. Roughly speaking, for symmetries whose leading components are polynomial functions of the velocities of a certain degree, we will prove that the restriction to be a Noether symmetry is equivalent to the requirement that: (i) the coefficients of the terms of nonzero degree in the velocities are totally symmetric; (ii) the symmetry generator preserves energy (a necessary condition for all Noether symmetries of autonomous Lagrangian systems); (iii) the lowest order part (only) is imposed of the determining equations for arbitrary symmetry vector fields.

In Sec. IV we investigate the way the Noether symmetries, corresponding to a set of n quadratic integrals in involution, might be directly related to the construction of separation variables in the sense of Hamilton-Jacobi. For a start, the calculations presented in Refs. 12–14 appear to have little to do with ''integration of characteristic equations'' related to the first-order partial differential operator which comes from the symmetry vector field. Instead, they are merely a set of formal manipulations which, at least in the case of two degrees of freedom[12] and for the examples under consideration, seem to produce the right answers. We will provide an explanation for this feature, which is based on Eisenhart's theorem about the intrinsic characterization of Stäckel systems (see, e.g., Ref. 15), and show that the manipulations under consideration can be given a theoretical backing from a factorization property of the action of the natural volume form on the vector fields corresponding to all quadratic integrals in involution. From this point of view, it would seem that for an extension to more than two degrees of freedom, a similar manipulation of characteristic equations, as attempted in Refs. 13 and 14, has no meaning whatsoever; instead, one is led to compute a determinant from the components of the symmetries and look at a factorization property again. Sec. V contains illustrative examples.

II. COMPUTATIONAL ASPECTS OF NOETHER'S THEOREM

For convenience, we will stick to the framework of autonomous second-order differential equations (as is the case in the papers we wish to clarify).

Let $L(x^i,\dot{x}^i)$, $i=1,\ldots,n$ be the regular Lagrangian of a given second-order dynamical system $\ddot{x}^i=f^i(x,\dot{x})$, with corresponding vector field

$$\Gamma=\dot{x}^i\frac{\partial}{\partial x^i}+f^i(x,\dot{x})\frac{\partial}{\partial \dot{x}^i}, \tag{1}$$

living on the tangent bundle TM of some manifold M. With $\Delta=\dot{x}^i\partial/\partial\dot{x}^i$ representing the Liouville vector field, $E=\Delta(L)-L$ the ''energy function'' associated to L, and $\theta=(\partial L/\partial\dot{x}^i)\,dx^i$ the Poincaré-Cartan one-form, we know that Γ is defined by

$$i_\Gamma d\theta=-dE. \tag{2}$$

If, for simplicity, we restrict ourselves to symmetry vector fields which are time-independent as well, Noether's theorem says: let $Y\in\mathscr{X}(TM)$ be a vector field with the properties

$$\mathscr{L}_Y\theta=df \quad \text{and} \quad Y(E)=0, \tag{3}$$

for some function f on TM, then $F=f-\langle Y,\theta\rangle$ is a first integral, i.e., $\Gamma(F)=0$. The function f is usually referred to as the gauge term in Noether's theorem. Every such Noether symmetry Y is effectively a symmetry of the given differential equations, i.e., we have $[\Gamma,Y]=0$. Recall further that the first condition can equivalently be written as

$$i_Y d\theta=dF, \tag{4}$$

from which in fact it trivially follows that $\Gamma(F)=0$ in view of (2) and $Y(E)=0$. Conversely, if F is a first integral, the relation (4) uniquely defines a vector field Y which will automatically leave the energy function invariant. This way, we obtain a one to one correspondence between Noether symmetries and first integrals (which depends on the Lagrangian). Note in passing that (4) trivially implies that $Y(F)=0$, but needless to say, if for a given symmetry vector field Y of Γ one searches for invariants of Y, there is no reason why these would at the same time be first integrals of the given dynamics as well.

In coordinates, the symmetry generator Y will be of the form

$$Y=\xi^i\frac{\partial}{\partial x^i}+\Gamma(\xi^i)\frac{\partial}{\partial\dot{x}^i}, \tag{5}$$

where the leading components ξ^i are of course functions on TM, i.e., we are talking in general about more than point symmetries.

Let us first link this up with the original version of Noether's theorem, which has to do with invariance of the action integral (up to a gauge term). In that approach, again restricting ourselves to transformations which do not change the time variable, one arrives at the following necessary and sufficient conditions for a Noether symmetry:

$$\xi^i\frac{\partial L}{\partial x^i}+\dot{\xi}^i\frac{\partial L}{\partial\dot{x}^i}=\dot{f}. \tag{6}$$

This is often referred to as the Noether identity. A good reference in this respect is the book by Logan.[16] The right way to look at the conditions (6), from the point of view of writing down determining equations for the construction of Noether symmetries, is that (6) has to be identically satisfied for all values of the independent variables $x^i,\dot{x}^i,\ddot{x}^i$. The terms $\dot{\xi}^i$ and $\dot{f}$ stand for total time derivatives of functions of $x^i,\dot{x}^i$ and hence depend linearly on $\ddot{x}^i$. As a result, Eq. (6) immediately splits and is equivalent with the $n+1$ requirements:

$$\frac{\partial\xi^i}{\partial\dot{x}^j}\frac{\partial L}{\partial\dot{x}^i}=\frac{\partial f}{\partial\dot{x}^j}, \quad j=1,\ldots,n, \tag{7}$$

$$\xi^k\frac{\partial L}{\partial x^k}+\dot{x}^k\frac{\partial\xi^i}{\partial x^k}\frac{\partial L}{\partial\dot{x}^i}=\dot{x}^k\frac{\partial f}{\partial x^k}. \tag{8}$$

The full equivalence between these partial differential equations for the unknown ξ^i, f and the ones which come out of the requirements (3) has been established (also more generally for

time-dependent situations) in Ref. 1. It may be helpful, however, to make a few more observations around this point here. Multiplying Eqs. (7) by f^j, summing over j and adding the result to (8), we see right away that the system [(7) and (8)] is equivalent with

$$\frac{\partial \xi^i}{\partial \dot{x}^j}\frac{\partial L}{\partial \dot{x}^i}=\frac{\partial f}{\partial \dot{x}^j}, \quad j=1,\ldots,n, \tag{9}$$

$$Y(L)=\Gamma(f\ ), \tag{10}$$

with Y as defined in (5). Recalling the identity

$$\mathscr{L}_\Gamma i_Y\theta=i_Y\mathscr{L}_\Gamma\theta+i_{[\Gamma,Y]}\theta$$

(which is valid for arbitrary vector fields Y,Γ and arbitrary θ), we observe that for a vector field of type (5), $[\Gamma,Y]$ is vertical, so that its contraction with the semibasic one-form θ is zero. We thus obtain,

$$\mathscr{L}_\Gamma i_Y\theta=i_Y(i_\Gamma d\theta+di_\Gamma\theta)=i_Y(-dE+d(\Delta L))=Y(L).$$

Putting $F=f-i_Y\theta$, we conclude that (10) is further equivalent to $\Gamma(F)=0$. The point about this remark is the following. Part of the folklore in the literature is that for the explicit calculations involved in the construction of first integrals of Lagrangian systems, one can either follow Darboux' direct approach,[17] i.e., try to solve directly the partial differential equation $\Gamma(F)=0$, or use Noether's method to construct symmetries first, and that these are different methods from the practical point of view. Of course, Noether's theorem expresses that one will lead to the other, but the above remark shows that in fact the calculations are, roughly speaking, the same.

A computation which is different, in principle, but more or less of the same complexity, is the search for solutions of the determining equations for arbitrary symmetries of Γ, i.e., vector fields Y for which $[\Gamma,Y]=0$. Such vector fields will be of the form (5), where the ξ^i have to solve the second-order partial differential equations

$$\Gamma^2(\xi^i)=Y(f^i). \tag{11}$$

If more than just point symmetries are hoped for, an ansatz will be needed about the polynomial dependence of the ξ^i on the velocities, to make such calculations feasible. The set of solutions will always be larger than the solutions of the corresponding search for Noether symmetries with the same ansatz. The construction of general symmetries (11) is the line of approach followed in Refs. 12 and 13, where the authors study Lagrangian systems with 2 and 3 degrees of freedom, for some specific cases of standard Lagrangians of the form

$$L=\frac{1}{2}\sum\ (\dot{x}^i)^2-V(x). \tag{12}$$

The ansatz is that the ξ^i are linear in the velocities and the claim is somehow that with all the symmetries which are obtained ''one can find, without recourse to Noether's theorem, and almost by inspection, a set of involutive first integrals by looking for invariants of the symmetry generator itself.'' Close inspection of their analysis reveals for a start, that in the process of solving Eqs. (11), the authors must have taken for granted certain simplifications, because all the symmetries they obtain will turn out to be Noether symmetries anyway. Moreover, the impression is given that first integrals should follow from ''integrating the equation $Y(F)=0$.'' The fact that the energy integral every time appears to be one of such functions F, points in the direction of Noether symmetries [see the second condition in (3)]. Finally, the rule of thumb by which the other integrals are said to appear is that we ought to expect that our symmetries are such that (in more correct notations):

$$\xi^i=\frac{\partial U}{\partial \dot{x}^i} \quad \text{and} \quad \Gamma(\xi^i)=-\frac{\partial U}{\partial x^i}, \tag{13}$$

for some function U [cf. Eqs. (2.7) and (2.9) in Ref. 12 and (2.6), (2.8), and (2.9) in Ref. 13].

Now, for a Lagrangian of type (12), we have $\theta=\dot{x}^i dx^i$ and hence, with a vector field Y of type (5)

$$i_Y(d\dot{x}^i\wedge dx^i)=\Gamma(\xi^i)dx^i-\xi^i d\dot{x}^i.$$

It follows that the requirements (13) precisely express the condition (4) with $F=-U$, so that the whole idea is bound to be just an application of Noether's theorem, as expected.

In Refs. 11 and 14 no claim is made that the construction of first integrals follows without recourse to Noether's theorem. Symmetry generators are constructed from the general requirement (11), with ξ^i which are of degree 1 or of degree 3 in the velocities. But also here, in the course of the calculations, a number of unspecified simplifications must have been imposed for the ease of finding solutions, because it turns out in the end that again all the symmetries which are found are of Noether type. In the next section, therefore, we will analyze in detail and in some generality what the minimal set of requirements is that one has to impose on general symmetries in order for them to become Noether symmetries.

III. NOETHER VERSUS GENERAL SYMMETRIES

We wish to clarify the situation about conditions which force symmetries to fall into the Noether class from the very practical point of view of actually solving determining equations. For that purpose, we will limit ourselves to purely analytical considerations and a case study for arbitrary n, which covers all the examples of symmetries mentioned in the above cited papers.

The systems under consideration are the Lagrangian ones with a Lagrangian of the form (12). It is known[18,19] that first integrals of such a system, which polynomially depend on the velocities, can be taken to have only terms which are either all of odd or all of even degree in the velocities. We consider the even degree case and assume, to be concrete, that the degree is at most four. The leading coefficients ξ^i of corresponding Noether symmetries will thus contain only terms of odd degree in the velocities and the maximal degree is three. These will then, of course, also be the restrictions we impose on the search for general symmetries. Writing all the indices of undetermined coefficients as bottom indices for easy legibility, we look for functions ξ^i of the following form:

$$\xi^i=a_{ijkl}(x)\dot{x}^j\dot{x}^k\dot{x}^l+b_{ij}(x)\dot{x}^j. \tag{14}$$

Obviously, a_{ijkl} is assumed to be symmetric in its last three indices, but no further symmetry conditions for the coefficients in (14) must hold *a priori* if the search is for general symmetries. The conditions (11) for symmetries, here more specifically of the form

$$\Gamma^2(\xi^i)+Y\left(\frac{\partial V}{\partial x^i}\right)=0, \tag{15}$$

explicitly become

$$\begin{aligned}&\frac{1}{10}a_{i(jkl,mn)}\dot{x}^j\dot{x}^k\dot{x}^l\dot{x}^m\dot{x}^n-a_{i(mkl,j)}\frac{\partial V}{\partial x^j}\,\dot{x}^k\dot{x}^l\dot{x}^m-a_{ij(kl,m)}\frac{\partial V}{\partial x^j}\,\dot{x}^k\dot{x}^l\dot{x}^m-a_{ij(kl}\frac{\partial^2 V}{\partial x^{m)}\partial x^j}\,\dot{x}^k\dot{x}^l\dot{x}^m\\&\quad+a_{jklm}\frac{\partial^2 V}{\partial x^i\partial x^j}\,\dot{x}^k\dot{x}^l\dot{x}^m+\frac{1}{3}b_{i(k,lm)}\dot{x}^k\dot{x}^l\dot{x}^m+6a_{ijkl}\frac{\partial V}{\partial x^j}\,\frac{\partial V}{\partial x^k}\,\dot{x}^l-b_{i(k,l)}\frac{\partial V}{\partial x^k}\,\dot{x}^l-b_{ik,l}\frac{\partial V}{\partial x^k}\,\dot{x}^l\\&\quad-b_{ik}\frac{\partial^2 V}{\partial x^k\partial x^l}\,\dot{x}^l+b_{kl}\frac{\partial^2 V}{\partial x^i\partial x^k}\,\dot{x}^l=0.\end{aligned} \tag{16}$$

As customary, brackets around indices refer to symmetrization. Let us, however, be precise about this to avoid confusion concerning numerical factors: the convention here is that in an expression like $a_{i(mkl,j)}$, where the object is already symmetric in k,l,m by assumption, symmetrization simply means taking a cyclic sum over all indices inside the brackets. The determining equations

for constructing all symmetries with leading components of the form (14) are obtained by putting the coefficients of the terms of degree 5, 3 and 1 in the above expression separately equal to zero.

If the symmetry is of Noether type, the ξ^i will be related to a first integral F via the relations $\xi^i = \partial F/\partial \dot{x}^i$ [strictly speaking, this is minus the F of (4)]. In other words, and in agreement with our analysis in the previous section, Y will be a Noether symmetry if and only if

$$F = \tfrac{1}{4} a_{ijkl} \dot{x}^i \dot{x}^j \dot{x}^k \dot{x}^l + \tfrac{1}{2} b_{ij} \dot{x}^i \dot{x}^j + g(x) \tag{17}$$

is a first integral of Γ for some function g. This implies for a start that we have to take the functions a_{ijkl} and b_{ij} to be symmetric in all indices. Note in passing that these symmetry properties are the integrability conditions for existence of a function f which satisfies (9) and that $\Gamma(F) = 0$, as argued before, is another way of writing (10), which again shows explicitly that we are expressing here the Noether identity (6). Now, $\Gamma(F) = 0$ also gives rise to a relation of degree 5 in the velocities and the terms of order 5, 3 and 1 produce the requirements

$$a_{(ijkl,m)} = 0, \tag{18}$$

$$b_{(ij,k)} = 6 a_{ijkl} \frac{\partial V}{\partial x^l}, \tag{19}$$

$$\frac{\partial g}{\partial x^j} = b_{jk} \frac{\partial V}{\partial x^k}. \tag{20}$$

In summary, functions of the form (14) are the leading components of a Noether symmetry if and only if the a_{ijkl} and b_{ij} are completely symmetric and satisfy (18)–(20) for some function g. The last of the requirements will then give rise to further integrability conditions which read

$$(b_{jk,l} - b_{lk,j}) \frac{\partial V}{\partial x^k} + b_{jk} \frac{\partial^2 V}{\partial x^k \partial x^l} - b_{lk} \frac{\partial^2 V}{\partial x^k \partial x^j} = 0. \tag{21}$$

Clearly, the requirements for Noether symmetries are quite different from those for arbitrary symmetries, if only because in the general case the undetermined functions in (14) need not be totally symmetric. If one wants to pin down a minimal set of extra assumptions which will force symmetries to fall into the subcategory of Noether symmetries, imposing symmetry in all indices is obviously inevitable. Since all Noether symmetries will further preserve the energy function, we wish to investigate now to what extent $Y(E) = 0$ can count for these extra assumptions.

With $E = \frac{1}{2}\Sigma(\dot{x}^i)^2 + V$, we have

$$Y(E) = \dot{x}^i \Gamma(\xi^i) + \xi^i \frac{\partial V}{\partial x^i}$$

and for general ξ^i of the form (14), this becomes

$$Y(E) = \dot{x}^i \left[\frac{1}{4} a_{i(jkl,m)} \dot{x}^j \dot{x}^k \dot{x}^l \dot{x}^m - 3 a_{ijkl} \frac{\partial V}{\partial x^j} \dot{x}^k \dot{x}^l + \frac{1}{2} b_{i(j,k)} \dot{x}^j \dot{x}^k - b_{ij} \frac{\partial V}{\partial x^j} \right]$$
$$+ a_{ijkl} \frac{\partial V}{\partial x^i} \dot{x}^j \dot{x}^k \dot{x}^l + b_{ij} \frac{\partial V}{\partial x^i} \dot{x}^j.$$

Under the assumption of fully symmetric a_{ijkl} and b_{ij}, the terms of order 1 cancel out, whereas the terms of order 5 and 3 can easily be seen to produce exactly (18) and (19). Obviously, we need one further condition to produce the remaining requirement (20) or equivalently (21). For that purpose, we look at the lowest order terms in the general symmetry requirement (16). Originally, they produce the condition:

$$6 a_{ijkl} \frac{\partial V}{\partial x^j} \frac{\partial V}{\partial x^k} - b_{i(l,k)} \frac{\partial V}{\partial x^k} - b_{ij,l} \frac{\partial V}{\partial x^j} - b_{ij} \frac{\partial^2 V}{\partial x^j \partial x^l} + b_{jl} \frac{\partial^2 V}{\partial x^i \partial x^j} = 0. \tag{22}$$

Making use of the symmetry assumption on the a and b functions and condition (19) which already followed from $Y(E)=0$, one readily verifies that (22) becomes identical to (21). The results can be summarized as follows.

Proposition: Consider a vector field Y of the form (5), where the functions $\xi^i(x,\dot{x})$ *have the structure (14), then the following three conditions imply that Y will be a Noether symmetry of the Lagrangian second-order system* Γ *derived from the function L in (12):*

(1) *the coefficients in the expression (14) for* ξ^i *are symmetric in all indices,*
(2) $Y(E)=0$ *(where E is the energy function associated to L),*
(3) *the lowest-order terms (i.e., terms of degree 1) in the nonzero components of the vector field* $[Y,\Gamma]$ *cancel out.*

Remark: Since Noether symmetries are symmetries, the above requirements will guarantee that the terms of degree 5 and 3 in the complicated expression (16) will automatically be zero as well.

Needless to say, the proposition is equally valid for the case of symmetry components ξ^i which are linear in the velocities, with corresponding quadratic first integrals: it suffices to put $a_{ijkl}=0$ in all calculations above. It would not be too difficult to extend it, on the other hand, to higher-degree polynomials and to Lagrangians with a more general metric in the kinetic energy term than the standard Euclidean metric in (12). We finally point to a few other well known facts. The condition (18) in the Noether approach, which comes from the terms of highest degree does not involve the potential and hence expresses that the terms of highest degree in (17) (quartic in our case) will constitute a first integral of the pure geodesic motion produced by the kinetic energy term in L. What the structure of Eqs. (18) further tells us is that we are looking at the components of a Killing tensor: in the present situation, the comma of course refers to taking partial derivates; if the kinetic energy metric would not be Euclidean, covariant derivatives would make their appearance there instead. To name just a few references which deal with the relation between first integrals and Killing tensors, see Refs. 20, 21, 15, and 22. As some of these references indicate, Killing tensors play a key role also in the theory about separation of variables in the Hamilton-Jacobi equation, which we discuss in the next section.

IV. SYMMETRIES AND SEPARABILITY

Separation of variables in the Hamilton-Jacobi equation is a problem with a long history. It is not our intention to even attempt a short survey of the history here. For that we refer to specialists in the field, like Benenti and Kalnins and Miller, who have contributed to the subject with numerous publications of which we cite just a few here.[23,24,15] Probably the best known classical result is Stäckel's theorem about orthogonally separable systems. It is a key result which tells you how separable systems look in the coordinates in which indeed the separation works (generalizations by Benenti cover a similar characterization for the nonorthogonal case). It does not tell you, however, how to construct such coordinates, or in fact whether such coordinates exist (see also Ref. 25). The first fundamental result about existence of separation variables is Eisenhart's theorem,[26] which is in the first place an existence theorem, but also has constructive features which are perhaps underestimated. Eisenhart's theorem essentially gives an intrinsic characterization of the existence of a point transformation which will transform a Hamiltonian system into Stäckel form. Very little is known about the existence of more general canonical transformations which have such effect. A remarkable example of a nonpoint transformation which transforms a Hamiltonian system into separable form is contained in Ref. 27. In Ref. 28, this example is put into a more general framework by the introduction of what the authors call quasipoint transformations. An equivalent result for the same example, by the way, has been obtained through techniques of algebraic geometry. See in that respect Ref. 29 and references therein. In any event, even in the case of point transformations, there is still room for new insights about tests which can tell whether a given system is separable and how one can find the right coordinates explicitly. As a preliminary remark, although Hamilton-Jacobi is of course, strictly speaking, about Hamiltonian systems, we will continue to describe the situation for the corresponding Lagrangian setting. This is certainly justified for systems with a Lagrangian of type (12), for which velocities and momenta are the same.

In Refs. 12–14 it is claimed that a direct calculation on the components of symmetry vector fields can produce separation variables, at least in the case of functions ξ^i which are linear in the velocities. In a program in which one starts the analysis of a given system by constructing symmetries, in particular Noether symmetries and the corresponding first integrals, it is certainly a good idea to investigate whether the symmetries contain by themselves information about the construction of separation variables. Roughly, what the authors do goes as follows. Consider the characteristic equations for the partial differential equation $Y(F)=0$, which read, for the case $n=2$ say,

$$\frac{dx^1}{\xi^1}=\frac{dx^2}{\xi^2}=\frac{d\dot{x}^1}{\Gamma(\xi^1)}=\frac{d\dot{x}^2}{\Gamma(\xi^2)}, \tag{23}$$

and assume that the functions ξ^i are of the form

$$\xi^i=a_{ij}(x)\dot{x}^j, \quad \text{with} \quad a_{ij}=a_{ji}. \tag{24}$$

Then, the first equality can be written in the form

$$a_{2j}\dot{x}^j dx^1-a_{1j}\dot{x}^j dx^2=0.$$

Thinking of $\dot{x}^j$ as standing for dx^j/dt and multiplying by dt, the formal quadratic expression

$$a_{2j}dx^j dx^1-a_{1j}dx^j dx^2=0 \tag{25}$$

is obtained. Solving this, for example, algebraically for dx^2/dx^1 and treating these as first-order differential equations, it so happens that their integration seems to produce the separation variables. The authors call this procedure ''integrating part of the characteristic equations.'' However, when integrating characteristic equations such as (23), the x^i and $\dot{x}^i$ ought to be treated as independent variables, so the formal manipulation we just sketched has nothing to do with that. In any event, the authors do not give any reason why this manipulation should have something to do with the construction of separation variables. The lack of a supporting theory puts the authors on even more shaky ground when they attempt similar manipulations on some three-dimensional systems because there is then more than one symmetry involved and it is in general not clear how one could, even in principle, handle a set of such formal quadratic expressions.

We will develop arguments here to show first that the formal manipulations mentioned above are indeed bound to produce separation variables for $n=2$. These arguments will show at the same time that the route to generalizations to more than two degrees of freedom is quite different from the calculations performed in Refs. 13 and 14. As a preliminary remark, observe that in manipulating the quadratic expression (25), it makes no difference whether one writes dx^i or $\dot{x}^i$, and in fact it will be more appropriate for the developments below to think of it as

$$a_{2j}\dot{x}^j\dot{x}^1-a_{1j}\dot{x}^j\dot{x}^2=0. \tag{26}$$

Since Eisenhart's theorem concerning separability is about Killing tensors, and such objects are related to first integrals which in turn correspond to Noether symmetries, it should not come as a surprise that we will seek an explanation which starts from Eisenhart. We first state the theorem more or less in the form in which it is cited in Ref. 15.

Eisenhart's theorem: *A necessary and sufficient condition that a kinetic energy Lagrangian* $L=\frac{1}{2}g_{ij}(x)\dot{x}^i\dot{x}^j$ *(or better its corresponding Hamiltonian) can be given the Stäckel form is that there exist* $n-1$ *Killing tensors* a^γ_{ij}, $\gamma=1,\ldots,n-1$, *such that:*

(1) *the tensors* $\{g_{ij},a^\gamma_{ij}\}$ *are linearly independent,*
(2) *all roots of the (generalized) eigenvalue problem* $\det(a^\gamma-\lambda^\gamma g)=0$ *are distinct for all* γ *(*a^γ *stands for the matrix with components* a^γ_{ij}*),*
(3) *there exist new coordinates* y^i *such that the vectors* $X_{(k)}$, *with components* $X^j_{(k)}=\partial x^j/\partial y^k$, *are common eigenvectors of all* a^γ, *i.e., we have*

$$(a_{ij}^{\gamma}-\lambda_{(k)}^{\gamma}g_{ij})X_{(k)}^{j}=0, \quad k=1,\ldots,n, \quad \gamma=1,\ldots,n-1. \tag{27}$$

A dual version of this theorem is mentioned by Benenti.[30] If (g^{kl}) denotes the inverse of the matrix of the given metric tensor and a_{γ}^{ij} the contravariant version of the Killing tensors obtained by raising indices in the usual way, then the contravariant version of the third requirement in the theorem says that there are n common orthogonal closed eigenforms $\alpha^{(k)}$:

$$(a_{\gamma}^{ij}-\lambda_{\gamma}^{(k)}g^{ij})\alpha_{j}^{(k)}=0, \quad \text{with} \quad d\alpha^{(k)}=0. \tag{28}$$

Locally then, $\alpha^{(k)}=dy^{k}$ for some functions y^{k}, which define, as in the other version, separation coordinates. It is worth mentioning in this context that Benenti now even has a theorem about the characterization of separable systems in which only one Killing tensor is needed,[23] but this result will not be directly relevant to our further discussion.

Naturally, for the standard metric we are considering in Lagrangians of type (12), the covariant and contravariant versions of the Killing tensors are the same, so if we construct eigenvectors in the algebraic sense, we have the freedom of interpreting them either as vector fields or as one-forms. Strictly speaking, Eisenhart's theorem is about geodesic motions or, in other words, about Lagrangians without potential term. However, it is well known since Levi-Civita that for a Hamiltonian of type $T+V$ to be separable, it is necessary that the kinetic energy part by itself is separable. Moreover, if the full Lagrangian or Hamiltonian has a quadratic first integral, which is the sum of a quadratic part and terms of degree zero, it is the quadratic part only which defines the corresponding symmetry as in (24) and, as said before, this quadratic part determines a Killing tensor for the geodesic motion coming from the kinetic energy term. As a result, for the sake of identifying separation variables and trying to relate them to symmetries, we can, without loss of generality, omit the potential term all together. There are simple criteria then (see again Ref. 23, for example, or even the original theorem of Stäckel) to check, once separation variables have been detected, whether the potential term has a structure which is compatible with the separation.

We now start examining what the implications are of the conditions on the a_{ij}^{γ} in Eisenhart's theorem for the symmetry components ξ^{i} which correspond to these via (24). It is clear that a symmetry vector field Y as in (5) is completely determined by its first term

$$X=\xi^{i}\frac{\partial}{\partial x^{i}}, \tag{29}$$

which looks like a vector field on the base manifold M, whose components, however, are functions on TM. This is called a vector field along the projection $\tau:TM\to M$. So-called semibasic forms on TM likewise can be regarded as differential forms along τ. For an adapted calculus about forms and fields along τ and an application to separability of second-order equations, we refer to Refs. 31–33. We will, however, not really need that sophisticated machinery here. Recall though, that there exists a canonically defined vector field along τ, namely the ''total time derivative operator''

$$\mathbf{T}=\dot{x}^{i}\frac{\partial}{\partial x^{i}} \tag{30}$$

which, in the present context of Lagrangians of type (12), is in fact precisely the vector field along τ determining the Noether symmetry corresponding to the energy integral.

For simplicity, we first discuss the case $n=2$ in some detail, for which there is just one Killing tensor a_{ij} with distinct eigenvalues. It is perhaps instructive to show via Eisenhart's theorem why in such a case separability always works. Using the covariant version, for example, we have two one-dimensional, integrable eigendistributions and their sum is also integrable by dimension. It follows from the Frobenius theorem that there exist coordinates y^{i} such that $\partial/\partial y^{1}$ spans the first distribution and $\partial/\partial y^{2}$ the second. This in turn means that in each of the original eigendistributions, one can find an element such that the two selected eigenvectors commute and hence can simultaneously be straightened out. These elements are of course the eigenvectors with components of the form $\partial x^{j}/\partial y^{k}$ featured in Eisenhart's theorem. Likewise, referring to the contravariant version, one-forms in dimension 2 always have an integrating factor, so that we can always make

the $\alpha^{(k)}$ locally exact, yielding again the desired separation variables. Note that these ideas can in fact be used constructively to find the separation variables for two degrees of freedom systems with a known second quadratic integral (see next section).

Now, if $\alpha^{(k)}=\alpha_i^{(k)}dx^i$, $k=1,2$ are the eigenforms and we consider their formal product to produce a quadratic expression in the dx^i, we know that this expression will become (up to a factor) the formal product dy^1dy^2 when expressed in the right coordinates. Hence if there is any truth in the expectation that the manipulations described about the quadratic expression (25) should indeed lead to the identification of separation variables y^i, there should be a link between (25) and the formal product of the $\alpha^{(k)}$ (to be interpreted properly, for example, as the symmetric tensor product). This is what we shall establish now, taking account of the earlier remark that one can write just as well a quadratic expression in $\dot{x}^i$ instead of dx^i, meaning that we then think of

$$\alpha_i^{(1)}\alpha_j^{(2)}\dot{x}^i\dot{x}^j. \tag{31}$$

Expressing that the $\alpha^{(k)}$ are eigenforms of the matrix a_{ij}, we have

$$a_{ij}\alpha_j^{(k)}=\lambda^{(k)}\alpha_i^{(k)}, \quad k=1,2, \quad i=1,2,$$

or equivalently, since these are functions of the coordinates only,

$$\dot{x}^i a_{ij}\alpha_j^{(k)}=\lambda^{(k)}\alpha_i^{(k)}\dot{x}^i, \quad k=1,2. \tag{32}$$

In the left-hand side, we recognize the contraction of the basic one-form $\alpha^{(k)}$, regarded as one-form along τ, with the vector field X along τ, determined by (29) and (24). The right-hand side contains the contraction of $\alpha^{(k)}$ with $\mathbf{T}$. In other words, the equality (32) has the intrinsic interpretation:

$$\langle X,\alpha^{(k)}\rangle=\lambda^{(k)}\langle \mathbf{T},\alpha^{(k)}\rangle, \quad k=1,2, \tag{33}$$

from which it follows that

$$(\alpha^{(1)}\wedge\alpha^{(2)})(\mathbf{T},X)=(\lambda^{(2)}-\lambda^{(1)})\langle \mathbf{T},\alpha^{(1)}\rangle\langle \mathbf{T},\alpha^{(2)}\rangle. \tag{34}$$

The final point to observe now is that $\alpha^{(1)}\wedge\alpha^{(2)}$, being a volume form (on an open set), is proportional to the standard volume form $dx^1\wedge dx^2$, and

$$(dx^1\wedge dx^2)(\mathbf{T},X)=\xi^2\dot{x}^1-\xi^1\dot{x}^2=a_{2j}\dot{x}^j\dot{x}^1-a_{1j}\dot{x}^j\dot{x}^2. \tag{35}$$

Collecting the results we thus conclude: (35) shows that the quadratic expression (26) (which was obtained through manipulation of characteristic equations in Ref. 12) can be interpreted as coming from the action of a volume form on the symmetry generators $(\mathbf{T},X)$; as such, it is bound to be proportional to the right-hand side of (34) when one thinks of the eigenforms of the matrix (a_{ij}) to construct a volume form; since the eigenvalues $\lambda^{(k)}$ are further assumed to be different in Eisenhart's theorem, this right-hand side is in turn proportional to the expression (31); finally, Eisenhart's theorem guarantees that separation coordinates exist, in which (31) will simply factorize as $\dot{y}^1\dot{y}^2$ (always up to a multiplicative function).

From a practical point of view, once a second quadratic integral has been found (or its corresponding linear Noether symmetry) and the eigenvalues of the matrix (a_{ij}) are different, the above result somehow provides an indirect way of making use, constructively, of Eisenhart's theorem: without bothering about computing eigenforms, we compute a determinant, namely the function $(dx^1\wedge dx^2)(\mathbf{T},X)$ which gives rise to a quadratic form in the $\dot{x}^i$ and one can try to find separation variables by factorizing this expression into the product of two linear expressions. For two degrees of freedom, in fact, this idea can be made stronger because there is a converse result: any such factorization, with factors which are linearly independent, will give rise to separation variables. Indeed, suppose we can write the determinant in question as follows

$$a_{2j}\dot{x}^j\dot{x}^1-a_{1j}\dot{x}^j\dot{x}^2=(\alpha_i^{(1)}\dot{x}^i)(\alpha_j^{(2)}\dot{x}^j).$$

Identification of the coefficients of corresponding terms in both sides then gives:

$$a_{21}=\alpha_1^{(1)}\alpha_1^{(2)}, \quad a_{22}-a_{11}=\alpha_1^{(1)}\alpha_2^{(2)}+\alpha_2^{(1)}\alpha_1^{(2)}, \quad a_{12}=-\alpha_2^{(1)}\alpha_2^{(2)}.$$

Remembering of course that $a_{12}=a_{21}$ it follows that

$$a_{11}\alpha_1^{(1)}+a_{12}\alpha_2^{(1)}=(a_{11}+\alpha_1^{(2)}\alpha_2^{(1)})\alpha_1^{(1)},$$

$$a_{21}\alpha_1^{(1)}+a_{22}\alpha_2^{(1)}=(a_{22}-\alpha_2^{(2)}\alpha_1^{(1)})\alpha_2^{(1)},$$

$$a_{11}\alpha_1^{(2)}+a_{12}\alpha_2^{(2)}=(a_{11}+\alpha_1^{(1)}\alpha_2^{(2)})\alpha_1^{(2)},$$

$$a_{21}\alpha_1^{(2)}+a_{22}\alpha_2^{(2)}=(a_{22}-\alpha_2^{(1)}\alpha_1^{(2)})\alpha_2^{(2)}.$$

This proves that, with

$$\lambda^{(1)}=a_{11}+\alpha_1^{(2)}\alpha_2^{(1)}=a_{22}-\alpha_2^{(2)}\alpha_1^{(1)},$$

$$\lambda^{(2)}=a_{11}+\alpha_1^{(1)}\alpha_2^{(2)}=a_{22}-\alpha_2^{(1)}\alpha_1^{(2)},$$

the $\alpha_i^{(1)}$ and $\alpha_i^{(2)}$ give the components of an eigenform, and we have $\lambda^{(1)}\neq\lambda^{(2)}$ in view of the assumed linear independence. The two eigenforms have an integrating factor by dimension and the resulting new variables will be separation variables by Eisenhart's theorem.

Let us now move on to the case $n=3$. Clearly, if we follow the same line of thought the generalization will not lead to a set of quadratic expressions but rather to one cubic expression, obtained from the computation of a determinant again and having a factorization property as before. A sketch of the reasoning goes as follows. Assume we have obtained two extra quadratic integrals in involution or, equivalently, their corresponding Noether symmetries which are determined by vector fields along τ, say

$$X_\gamma=\xi_\gamma^k\frac{\partial}{\partial x^k}, \quad \text{with} \quad \xi_\gamma^k=a_{\gamma kl}\dot{x}^l, \quad \gamma=1,2. \tag{36}$$

In case of separability, following Eisenhart, there must be closed one-forms $\alpha^{(i)}$, $i=1,2,3$, which are common eigenforms of both matrices a_γ. Denoting the eigenvalues of a_γ, which are assumed to be different, by $\lambda_\gamma^{(k)}$, we thus have, in the same way as (32) was derived and rewritten in the form (33):

$$\langle X_\gamma,\alpha^{(k)}\rangle=\lambda_\gamma^{(k)}\langle\mathbf{T},\alpha^{(k)}\rangle, \quad k=1,2,3, \quad \gamma=1,2. \tag{37}$$

It follows that

$$(\alpha^{(1)}\wedge\alpha^{(2)}\wedge\alpha^{(3)})(\mathbf{T},X_1,X_2)=\rho\langle\mathbf{T},\alpha^{(1)}\rangle\langle\mathbf{T},\alpha^{(2)}\rangle\langle\mathbf{T},\alpha^{(3)}\rangle, \tag{38}$$

with

$$\rho=\lambda_1^{(1)}(\lambda_2^{(2)}-\lambda_2^{(3)})+\lambda_1^{(2)}(\lambda_2^{(3)}-\lambda_2^{(1)})+\lambda_1^{(3)}(\lambda_2^{(1)}-\lambda_2^{(2)}). \tag{39}$$

The function ρ is nonzero because of the first assumption in Eisenhart's theorem. The left-hand side of (38), coming from a volume form, is proportional to the determinant $(dx^1\wedge dx^2\wedge dx^3)\times(\mathbf{T},X_1,X_2)$ which can be computed directly from the symmetry components. The right-hand side of (38) then expresses that this cubic expression in the $\dot{x}^i$ can be factorized as the product of three linear expressions and even in such a way that this product becomes simply $\dot{y}^1\dot{y}^2\dot{y}^3$ in a set of separation variables. For $n>2$ there is no converse in the sense that the existence of a factorization of the determinant by itself does not necessarily imply that each of the factors will be integrable. The results of our analysis can be summarized as follows.

Proposition: Assume that X_1 and X_2 of the form (36) define Noether symmetries of a Lagrangian system (12) with three degrees of freedom. Then, if we are in a situation where corresponding separation variables for the Hamilton-Jacobi equation exist, they can be obtained from factorizing the determinant

$$\begin{vmatrix} \dot{x}^1 & \dot{x}^2 & \dot{x}^3 \\ \xi_1^1 & \xi_1^2 & \xi_1^3 \\ \xi_2^1 & \xi_2^2 & \xi_2^3 \end{vmatrix} \tag{40}$$

into the product of three factors which are linear in the velocities and integrable.

Observe that the potential energy function V is not present in this statement: we repeat that the potential is irrelevant as long as one wants to find out the nature of separation variables if they exist; having found them, one is assured of separability of the kinetic energy part and then it is relatively easy to check whether the form of the potential is such that also the full system will be separable (see next section).

We have proved above a similar result for $n=2$ and it is obvious that it can actually be done for arbitrary n. But beyond $n=3$, it is doubtful that this procedure (as perhaps any other) could be implementable in practice. We will show in the next section, however, that up to three degrees of freedom, there are indeed different ways of making constructive use of this proposition. Our point of view in this respect is that this amounts to making constructive use of the existence theorem by Eisenhart.

On the theoretical side, it looks worthwhile for a future study to go more deeply into the potential role and relevance of volume forms for the characterization of separability. A generalization of the present considerations to nonstandard metrics looks fairly straightforward. A more difficult issue is the question whether anything similar could be done related to nonquadratic integrals, where a transformation to separation variables will not be a point transformation (cf. the already cited example[27]).

Before closing this section, let us make clear why one should not expect any meaningful conclusion from manipulations of quadratic expressions such as (26) when n is greater than 2. Indeed, thinking of the case $n=3$, for example, and the matrix a_{ij} related to one of the symmetry generators, (26) can still be generated by a computation as in (35), and the related computation (34) will still produce a quadratic expression which factorizes in the new variables guaranteed by Eisenhart's theorem. The point then is, however, that $\alpha^{(1)}\wedge\alpha^{(2)}$ will in general contain terms in all $dx^i\wedge dx^j$, or alternatively, $dx^1\wedge dx^2$ will be a combination of all $\alpha^{(i)}\wedge\alpha^{(j)}$ and hence will by itself not factorize.

V. ILLUSTRATIVE EXAMPLES

An example of an integrable and separable system with two degrees of freedom which can be found, e.g., in one of the tables in Ref. 14 is the Lagrangian system (12) with potential (we will write here x,y for the coordinates instead of x^1,x^2)

$$V(x,y)=a(x^2+4y^2)+b(x^4+12x^2y^2+16y^4), \tag{41}$$

for which a second quadratic integral is of the form

$$F=(x\dot{y}-y\dot{x})\dot{x}+2(a+4by^2+2bx^2)x^2y. \tag{42}$$

For the sake of illustrating a number of points discussed in the previous section, we will first of all limit ourselves to quartic potentials ($a=0$) and in fact assume that the class of admissible quartic potentials, in the sense that there exists a first integral with $(x\dot{y}-y\dot{x})\dot{x}$ as quadratic part in the velocities, has as yet to be discovered. Let us say, for example, that we aim at finding potentials of the form

$$V=c_1x^4+c_2x^2y^2+c_3y^4, \tag{43}$$

with c_i to be determined.

When we think of quadratic integrals, the Noether requirements [(18)–(20)] reduce to

$$a_{(ij,k)}=0, \quad \frac{\partial g}{\partial x^j}=a_{jk}\frac{\partial V}{\partial x^k}. \tag{44}$$

Our starting point is the assumption that we have found from the highest-order terms the quadratic part of the above first integral F as a particular solution, or in other words, the symmetry generator (as vector field along τ):

$$X=(x\dot{y}-2y\dot{x})\frac{\partial}{\partial x}+x\dot{x}\frac{\partial}{\partial y}. \tag{45}$$

The potential V plays no role in obtaining this part, which determines a Killing tensor with components

$$A=(a_{ij})=\begin{pmatrix} -2y & x \\ x & 0 \end{pmatrix}. \tag{46}$$

Our objective is not only to find potentials for which a second quadratic integral exists, but also to construct separation coordinates. The determination of the potential can then further be suspended and separation variables, if they exist, should follow from the following procedure. According to Eisenhart's theorem, we construct a set of eigenvectors of the matrix A; they read:

$$(x,y+r) \quad \text{and} \quad (x,y-r) \quad \text{with} \quad r=(x^2+y^2)^{1/2}.$$

If we treat these as components of eigenvector fields, say

$$X_1=x\frac{\partial}{\partial x}+(y+r)\frac{\partial}{\partial y}, \quad X_2=x\frac{\partial}{\partial x}+(y-r)\frac{\partial}{\partial y}, \tag{47}$$

then it is easy to verify that this happens to be a basis of commuting vector fields for the eigendistributions, so that they can simultaneously be straightened out. A coordinate transformation which does this is and therefore defines separation variables reads:

$$u=\ln\frac{x}{\sqrt{r-y}}, \quad v=\ln\sqrt{r-y}.$$

However, any further transformation which does not couple these coordinates will preserve separability. We may, therefore, just as well take

$$u=\sqrt{r+y}, \quad v=\sqrt{r-y}. \tag{48}$$

In agreement with the theoretical discussion of the previous section, we could here also treat the eigenvectors of A as components of eigenforms, and one then readily finds integrating factors which bring these into the form du and dv, with u and v as defined by (48). Finally, the new idea which we have introduced with regard to separation variables, namely as coming from a factorization of the determinant $\dot{x}\xi^2-\dot{y}\xi^1$, can be seen to work as follows. The quadratic expression (35) here becomes:

$$x\dot{x}^2-2y\dot{x}\dot{y}-x\dot{y}^2=\frac{1}{x}(x\dot{x}+(y+r)\dot{y})(x\dot{x}+(y-r)\dot{y}).$$

Again, one can see that the potential is irrelevant in this process of detecting possible separation variables. One way of determining subsequently whether the potential has an appropriate form for separability could go as follows: having found separation variables already, one could first express the given system in these new coordinates and then verify for what values of the parameters the potential satisfies the criteria of Stäckel's theorem. Alternatively, there is an intrinsic character-

ization of the condition which the potential should satisfy, which therefore can be verified directly in the original coordinates. This characterization can be found in Ref. 23, and says that the one-form $K\cdot dV$ should be closed (for all of the Killing tensors K entering Eisenhart's theorem). For the present example, this reduces to the requirement that the functions $a_{ij}\partial V/\partial x^j$ should be the components (locally) of an exact one-form. Not surprisingly, this is exactly the remaining Noether condition in (44), or equivalently, the condition (21). For the Killing tensor A given in (46), we have

$$A\cdot dV=\left(-2y\frac{\partial V}{\partial x}+x\frac{\partial V}{\partial y}\right)dx+x\frac{\partial V}{\partial x}\,dy,$$

and expressing that $d(A\cdot dV)$ should be zero, for a V of the form (43), reduces to the condition

$$(12c_1-c_2)x^3+(8c_2-6c_3)xy^2=0.$$

It follows that we must have $c_2=12c_1$ and $c_3=16c_1$, which is in agreement with the quartic part in the potential function (41).

It is worth mentioning that another, in fact well-known, admissible potential could have been discovered along the lines of this example. Indeed, the quadratic part $(x\dot{y}-y\dot{x})\dot{x}$ of the function F in (42) is the velocity-dependent part of one of the components of the Runge-Lenz vector in the reduced (planar) Kepler problem. One easily verifies that the Kepler potential also satisfies the above requirement $d(A\cdot dV)=0$ and we further conclude that (48) defines separation variables for the Kepler problem as well. A good reference where this example is encountered in the context of linking symmetries to Killing tensors is Ref. 34.

For three degrees of freedom it is not so obvious how one could use in practice the factorization property of the determinant (40) to find separation variables. We will nevertheless illustrate two ways in which one could make use of this result for constructive purposes. We shall write x,y,z for the coordinates x^i now.

Looking once more at the rich collection of examples which is contained in Ref. 14, assume we have a Lagrangian of type (12) which has an angular momentum type first integral, the square of which provides a first quadratic integral, say

$$F_1=(y\dot{z}-z\dot{y})^2. \tag{49}$$

Assume another integral is of the form

$$F_2=(y\dot{x}-x\dot{y})\dot{y}+(z\dot{x}-x\dot{z})\dot{z}+\cdots. \tag{50}$$

As before, we leave the terms of degree zero, both in the Lagrangian and in F_2, out of the discussion for the time being. For the corresponding Noether symmetries, we have

$$\xi_1^1=0,\quad \xi_1^2=-2z(y\dot{z}-z\dot{y}),\quad \xi_1^3=2y(y\dot{z}-z\dot{y}), \tag{51}$$

$$\xi_2^1=y\dot{y}+z\dot{z},\quad \xi_2^2=y\dot{x}-2x\dot{y},\quad \xi_2^3=z\dot{x}-2x\dot{z}. \tag{52}$$

It is obvious from the second row (51) in the determinant (40) that there will be factor $y\dot{z}-z\dot{y}$. The remaining quadratic factor then is

$$(y\dot{y}+z\dot{z})^2+2x(y\dot{y}+z\dot{z})\dot{x}-(y^2+z^2)\dot{x}^2,$$

and it is not too hard to see that this factorizes as

$$(y\dot{y}+z\dot{z}+(x+r)\dot{x})(y\dot{y}+z\dot{z}+(x-r)\dot{x}),$$

with $r=(x^2+y^2+z^2)^{1/2}$. It turns out that these three factors are integrable and identify separation variables u,v,w, defined by

$$u=\sqrt{r+x},\quad v=\sqrt{r-x},\quad w=\arctan\left(\frac{y}{z}\right).$$

However, we should emphasize that our theoretical arguments in Sec. IV do not allow us to draw this conclusion at all. Indeed, it is easy to see that the matrix corresponding to F_1 has a double eigenvalue zero, so that we are not in the situation of Eisenhart's theorem from which our results were derived. The reason is that the essential first integral behind F_1 is the linear expression $y\dot{z}-z\dot{y}$, which corresponds to a Killing vector (not a Killing two-tensor). A rudimentary explanation about the reasons why the above determinant calculation happens to produce the right answers anyway, is that the Killing vectors for a separable Hamiltonian in the end correspond to ignorable coordinates (see Ref. 30). As a result, the system will immediately reduce to a lower dimensional one, and the remaining quadratic expression which we factorized above can then be expected to be in direct correspondence with the quadratic form coming from this lower dimensional system. Note in passing that this situation should not be confused with the well-known property (see, e.g., Ref. 20) that in spaces of constant curvature, every Killing two-tensor is trivial, in the sense of being expressible as a linear combination of symmetrized tensor products of Killing vectors. From the point of view of the present analysis, there is no problem with this form of ''triviality'' as long as the regularity assumptions of Eisenhart's theorem are satisfied. For now, let us again sketch how one can subsequently find appropriate potentials which preserve the separability.

Assume we want to find suitable potentials again in the class of homogeneous functions of degree 4 and, to simplify matters, more particularly of the form

$$V=c_1x^4+c_2y^4+c_3z^4+d_1x^2y^2+d_2x^2z^2+d_3y^2z^2. \tag{53}$$

The one-form $A\cdot dV$ which comes from the Killing tensor related to F_2 reads

$$(yV_y+zV_z)dx+(yV_x-2xV_y)dy+(zV_x-2xV_z)dz.$$

Expressing its closure for a V of type (53), we find restrictions on the undetermined constants which reduce to $c_1=16c_2$, $c_3=c_2$, $d_1=d_2=12c_2$, $d_3=2c_2$. This way, up to a constant factor c_2, the potential is bound to be of the form

$$V=16x^4+(y^2+z^2)^2+12x^2(y^2+z^2). \tag{54}$$

We observe then that this potential is already invariant under the action of the Killing vector $y\partial/\partial z-z\partial/\partial y$ related to F_1. It follows that F_1 will be a quadratic integral for the full system as well.

Let us finally illustrate how one can now further determine the terms in F_2 which are indicated by dots. With the potential (54), the one-form $A\cdot dV$ becomes

$$4(y^2+z^2)(6x^2+y^2+z^2)dx+16x(x^2+y^2+z^2)(ydy+zdz).$$

In agreement with the Noether condition (20), putting this expression equal to dg should produce the remaining function in the quadratic integral. We thus find

$$g=4x(y^2+z^2)^2+8x^3(y^2+z^2). \tag{55}$$

For a third illustration now, assume we start from the following two Killing tensors of the standard metric in dimension 3,

$$F_1=(x\dot{y}-y\dot{x})^2+(x\dot{z}-z\dot{x})^2+(y\dot{z}-z\dot{y})^2+(\dot{x}^2-\dot{z}^2), \tag{56}$$

$$F_2=(y\dot{z}-z\dot{y})^2-(x\dot{y}-y\dot{x})^2-(\dot{x}^2+\dot{z}^2). \tag{57}$$

Also this case is inspired by an example in Ref. 14 and fits as well into the category of systems described in Ref. 35. The idea again is that these should become the leading parts of quadratic integrals of a Lagrangian system of type (12) for some suitable potential. If we first want to verify whether the ultimate system and its integrals will correspond to a case of separability in the

Hamilton-Jacobi sense, then we could try our luck with the factorization property of the determinant (40). Needless to say, we could also try to address directly the conditions of Eisenhart's theorem. The determinant (40) for this case gives rise to a fairly complicated cubic expression in $\dot{x},\dot{y},\dot{z}$ and it is not obvious at first sight how one could think of a way to write it as a product of three linear factors. Nevertheless, we know that there are only a finite number of coordinate systems in $\mathbb{R}^3$ in which the standard metric is separable (the 11 types first derived by Eisenhart[26] and reconstructed also by Benenti[23]). With some experience in the field one can readily rule out a number of these possibilities and then a direct computation on the determinant (40) does become feasible, as we shall now illustrate. One of the more difficult types of coordinates to work with is, for example, the class (IV_1) of Eisenhart.[26] If we denote the new coordinates by u,v,w again, they are defined by relations of the following type

$$x^2=\frac{(\alpha-u)(\alpha-v)(\alpha-w)}{(\alpha-\beta)(\alpha-\gamma)}, \tag{58}$$

$$y^2=\frac{(\beta-u)(\beta-v)(\beta-w)}{(\beta-\alpha)(\beta-\gamma)}, \tag{59}$$

$$z^2=\frac{(\gamma-u)(\gamma-v)(\gamma-w)}{(\gamma-\alpha)(\gamma-\beta)}, \tag{60}$$

for some constants α,β,γ, and the domain of definition is determined by the requirement $\alpha>u>\beta>v>\gamma>w$. It is then a fairly straightforward exercise to transform the cubic polynomial in $\dot{x},\dot{y},\dot{z}$ into a corresponding cubic expression in $\dot{u},\dot{v},\dot{w}$ via the derivatives of (58)–(60). If there indeed exists a transformation of this type which will give rise to separation variables, the new cubic polynomial should reduce to just one term, namely the monomial $\dot{u}\dot{v}\dot{w}$. Doing such a calculation is not as formidable as it may at first sound: first of all, it is typically a symbolic calculation which computer algebra packages can handle; second, to see whether there is any chance for this to work, it suffices to test first just one term, i.e., to check, for example, whether the coefficient of $\dot{u}^3$ can be made to vanish. We have done this for the above situation and found that (58)–(60) does produce a factorization of the determinant (40), provided we choose α,β,γ in such a way that

$$\alpha-\beta=1, \quad \gamma-\beta=-1. \tag{61}$$

As before, one can separately compute what kind of potentials are acceptable and in that process one will find at the same time what extra functions then have to be added to the expressions (56) and (57) in order to obtain quadratic integrals for the full Lagrangian. The procedure works exactly as in the preceding case. We limit ourselves to the observation that it is not possible for this case to find an acceptable potential which is homogeneous of degree four in the coordinates. One does obtain, however, the following class of potentials (with A an arbitrary constant):

$$V=A(x^2+y^2+z^2)+(y^2+2z^2)+(x^2+y^2+z^2)^2. \tag{62}$$

We use Kepler's eccentric anomaly in order to get explicit equations for the planetary orbits in a solar system. By successively modifying the corresponding Lagrangian, we build a Lagrangian for a relativistic two-body problem, the trajectories of which are conics in Minkowski space. The equations of these trajectories, projected on a three-space, exhibit new anomalies.

I. INTRODUCTION

The eccentric anomaly α was introduced by Kepler in order to obtain the relationship between the variables r and t appearing in the equations of a planetary motion. Explicitly, one gets [see Ref. 1, formulas (106) and (107) and Ref. 2, p. 83]

$$r=a(1-e\ \cos\ \alpha),\quad t-t_0=\frac{T}{2\pi}\,(\alpha-e\ \sin\ \alpha).$$

In this paper we show briefly the way one can use α in order to get the explicit equations for the planetary orbits. However, our main goal is to obtain a relativistic version of those equations. We solve this problem by successively modifying the Lagrangian of the Newtonian two-body problem, until we get a Poincaré-invariant two-particle Lagrangian, whose trajectories are conics in Minkowski space. The equations of these trajectories are very close to those corresponding to the Newtonian case. However, when we project these on three-space, some new anomalies arise.

We note that in our discussion of both classical and relativistic cases, the eccentric anomaly α and also the Bernoulli–Laplace eccentricity vector A play an essential role (see Ref. 3). This is because the use of α as a parameter on each trajectory leads to linear differential equations and $-A/2E$ gives the centers of the trajectories, when E is the relative energy. Moreover, α plays the role of a relativistic proper time.

We shall also use a modified version of Maupertuis' theorem, which we named **Maupertuis 2000**, since we suppose it is well known and since we cannot give any quotation.

The relativistic two-particle Lagrangians studied in this Note have been obtained in our endeavor to get a link between a similar Lagrangian, introduced in Ref. 4, and the relativistic theory of gravitation.

II. THE NEWTONIAN TWO-BODY PROBLEM

The Lagrangian of the two-body problem in Newtonian mechanics has the form

$$N=\frac{1}{2}\,(m_x\dot{x}^2+m_y\dot{y}^2)+Cm_xm_y\,\frac{1}{r},\quad r=[(x-y)^2]^{1/2}.$$

Hoping to find a realistic relativistic version, we shall first integrate the Euler–Lagrange equations for N, following a nonstandard but possibly already invented method. To this end, we make the notations

$$u=x-y,\quad M=m_x+m_y,\quad v=M^{-1}(m_xx+m_yy),\quad k=CM.$$

Note that v represents the *center of gravity*; we can write

$$N=\frac{M}{2}\,\dot{v}^2+\frac{m_xm_y}{2M}\left(\dot{u}^2+\frac{2k}{r}\right)$$

a)Electronic mail: kostake@math.math.unibuc.ro

 © 1998 American Institute of Physics

and the Euler–Lagrange equations take the form $\ddot{v}=0$, $\ddot{u}=-ku/r^3$.

In order to integrate the second of these equations, we introduce, along each trajectory, s as a new parameter, so that $dt/ds=t'=r$ and then

$$u'=\frac{du}{ds}=r\dot{u},\quad u''=\frac{d^2u}{ds^2}=r^2\ddot{u}+r\dot{r}\dot{u},\quad r'=r\dot{r},\quad r''=r^2\ddot{r}+r\dot{r}^2.$$

The second Euler–Lagrange equation becomes

$$ru''=r'u'-ku,$$

and the quantities

$$E=\frac{\dot{u}^2}{2}-\frac{k}{r}=\frac{u'^2}{2r^2}-\frac{k}{r},\quad L=u\times\dot{u}=\frac{u\times u'}{r}.$$

$$A=u''-2Eu=r\dot{r}\dot{u}+\left(\frac{k}{r}-\dot{u}^2\right)u,\quad L^2=2Er^2+2kr-r'^2=u'^2-r'^2$$

are conserved. Moreover, we have

$$A^2=k^2+2EL^2,\quad r''-2Er=r^2\ddot{r}+r\dot{r}^2-r\dot{u}^2+2k=ru\ddot{u}+2k=k.$$

In the nonparabolic case $E\neq 0$, the equations thus obtained,

$$\text{(I)}\quad u''-2Eu=A,\quad r''-2Er=k,$$

have the general solution

$$u=-\frac{A}{2E}+u_1,\quad r=-\frac{k}{2E}+r_1,\quad u_1''=2Eu_1,\quad r_1''=2Er.$$

If $kE<0$, there are solutions with $u^2=r^2$ which define conic sections with centers $u_0=-A/2E$, foci $u_1=0$, $u_2=-A/E$, and parameters

$$L^2=-2Eb^2,\quad a=-\frac{k\varepsilon}{2E},\quad \varepsilon=\pm 1,$$

$$c=\sqrt{a^2-b^2}=-\frac{|A|}{2E}\,\varepsilon,\quad e=\frac{c}{a}=\frac{|A|}{k}\,\varepsilon.$$

When $E<0$, we have $\varepsilon=1$ and the motion will have the period

$$T=\int_0^\tau r\,ds=\frac{\pi k}{\sqrt{-2E^3}}=\pi\sqrt{\frac{a^3}{2k}},\quad \tau=\frac{2\pi}{\sqrt{-2E}}.$$

The quantity a is *the major semi-axis* of the relative orbit.

As a consequence of the equations above, we have the following.

Theorem: *The Kepler–Newton trajectories are geodesic paths of the hyperplane sections of the light-cone in Minkowski space, in which the time coordinate was replaced by the radial coordinate r.*

An elliptic Kepler–Newton trajectory is defined by the equations

$$u=[c-a\,\cos(hs)]v_1-b\,\sin(hs)v_2,$$

$$t-t_0=as-h^{-1}c\,\sin(hs),\quad r=a-c\,\cos(hs).$$

where v_1, v_2 are constant vectors, a, b, c, h are positive numbers, and

$$v_1 \perp v_2, \quad |v_1| = |v_2| = 1, \quad b^2 = a^2 - c^2, \quad h = 2\pi a T^{-1},$$

$$h^2 = -2E, \quad 2a = -kE^{-1}, \quad 2T^2 = -\pi^2 k^2 E^{-3}.$$

Introducing *the eccentric anomaly* $\alpha = hs$, we obtain

$$u = (c - a\ \cos\ \alpha)v_1 - (b\ \sin\ \alpha)v_2, \quad r = a - c\ \cos\ \alpha,$$

$$t - t_0 = \frac{T}{2\pi}\,(\alpha - e\ \sin\ \alpha), \quad e = \frac{c}{a}.$$

It follows that an increase of α by 2π induces an increase of t by T and

$$\left| t - t_0 - \frac{T\alpha}{2\pi} \right| \leqslant \frac{Te}{2\pi}.$$

III. ALTERNATIVE LAGRANGIANS

The differential equations (I) can also be obtained from the Lagrangian

$$L = \tfrac{1}{2}(\|u'\|^2 - r'^2) + E(\|u\|^2 - r^2) + (\langle A, u\rangle - kr)$$

and have the following consequences:

$$F := ru'' - r'u' + ku = -r'u' + (2Er + k)u + rA = \text{const},$$

$$f := rr'' - r'^2 + kr = -r'^2 + 2Er^2 + 2kr = \text{const},$$

$$\|u'\|^2 - r'^2 - 2E(\|u\|^2 - r^2) - 2(\langle A, u\rangle - kr) = \text{const}.$$

The equations

$$ru'' - r'u' + ku = 0, \quad \ddot{u} + \frac{ku}{r^3} = 0$$

can be obtained as Euler–Lagrange equations of

$$L_1 = \frac{\|u'\|^2}{r} + 2Er, \quad L_2 = \|\dot{u}\|^2 - 2\varepsilon r\dot{s}^2, \quad \varepsilon = \pm 1$$

when we add the constraints

$$\|u\|^2 = r^2, \quad \frac{\|u'\|^2}{r} - 2Er = 2k, \quad r\dot{s} = h, \quad \varepsilon h^2 = k.$$

The trajectories associated with the Lagrangians L_1, L_2 are related to each other according to the following version of Maupertuis' theorem.

The version we give will allow us to get a Lagrangian for a relativistic two-body problem, generalizing the classical two-body problem.

Maupertuis 2000. Suppose we have three Lagrangians such as

$$M_0 = \sum_{i,j=1}^{n} g_{ij}\,\frac{du^i}{ds}\,\frac{du^j}{ds}, \quad M_1 = \sum_{i',j'=n+1}^{n+m} g_{i'j'}\,\frac{du^{i'}}{ds}\,\frac{du^{j'}}{ds}, \quad L = U(M_0 + M_1),$$

where U, $g_{ij} = g_{ji}$ *are functions of* $u^1, \ldots, u^n$ *and* $g_{i'j'} = g_{j'i'}$ *are functions of separate variables* $u^{n+1}, \ldots, u^{n+m}$.

Then the relations

$$\frac{dt}{ds}=U^{-1},\quad M_0^*=U^2M_0,\quad M_1^*=U^2M_1,\quad L^*=M_0^*+fU,\quad f\in\mathbb{R}$$

allow us to associate with each geodesic path of L verifying $L=f$ a trajectory of $L^*=M_0^*+fU$ and a geodesic path of M_1^* verifying

$$M_0^*-fU=-M_1^*.$$

The proof is straightforward.

We give some examples which will guide us towards a relativistic version of the classical two-body problem and which could lead to a proper formulation of the relativistic n-body problem.

Defining

$$r=\|u\|,\quad U=\frac{1}{r},\quad x'=\frac{dx}{ds},\quad \dot{x}=\frac{dx}{dt},$$

we consider the Lagrangians

$$L=\frac{u'^2+v'^2+\lambda t'^2+\lambda_1\tau'^2}{r},\quad L^*=\dot{u}^2+\dot{v}^2+\frac{2k}{r},\quad \lambda\in\mathbb{R},\ \lambda_1\in\mathbb{R},\ k\in\mathbb{R},$$

and it follows that, modulo the constraint $t'=dt/ds=r$, *the trajectories of L verifying*

$$\frac{u'^2+v'^2+\lambda t'^2+\lambda_1\tau'^2}{r}=2k$$

correspond bijectively to the trajectories of L^* verifying

$$L^*-\frac{4k}{r}=\dot{u}^2+\dot{v}^2-\frac{2k}{r}=-(\lambda+\lambda_1C_1^2),$$

where $C_1=\dot{\tau}$ is a conserved quantity.

We make now another choice, by taking

$$U=r,\quad \nu\in\mathbb{R},\quad \nu_1\in\mathbb{R},$$

and replacing τ by σ, t by s, and s by t. We then consider the Lagrangians

$$L_1^*=r^{-1}(u'^2+v'^2)+2Er,\quad L_1=(\dot{u}^2+\dot{v}^2)+\nu r\left(\frac{ds}{dt}\right)^2+\nu_1 r\left(\frac{d\sigma}{dt}\right)^2.$$

According to Maupertuis 2000, the trajectories of L_1^* with

$$r^{-1}(u'^2+v'^2)-2Er=-(\nu+\nu_1C^2)$$

are transformed into geodesic paths of the metric L_1 with $L_1=2E$, when we impose the constraints

$$\frac{ds}{dt}=r^{-1},\quad \frac{d\sigma}{dt}=Cr^{-1},\quad C\in\mathbb{R}.$$

We resume:

The Lagrangians

$$L=r^{-1}(u'^2+v'^2+\lambda t'^2+\lambda_1\tau'^2),\ \lambda\in\mathbb{R},\ \lambda_1\in\mathbb{R},$$

$$L^*=\dot{u}^2+\dot{v}^2+2kr^{-1},\ k\in\mathbb{R},$$

$$L_1=\dot{u}^2+\dot{v}^2+\nu r\dot{s}^2+\nu_1 r\dot{\sigma}^2,\quad \nu\in\mathbb{R},\quad \nu_1\in\mathbb{R},$$

$$L_1^*=r^{-1}(u'^2+v'^2)+2Er,\quad E\in\mathbb{R},$$

give rise to (modulo reparametrizations) equivalent trajectories (u,v) in $\mathbb{R}^3\times\mathbb{R}^3$, *provided we impose the following constraints*:

$$t'=r,\quad \dot{s}=r^{-1},\quad \tau'=C_1 r,\quad \sigma'=C.$$

IV. INVARIANT LAGRANGIANS IN MINKOWSKI SPACE

The previous considerations suggest for us to study the Lagrangians

$$K=\frac{\varepsilon|m_X X'+m_Y Y'|^2+m_X m_Y|X'-Y'|^2}{2G(m_X+m_Y)R},$$

where ε^2, G, m_X, and m_Y are positive numbers and $X=(x,t_x)$, $Y=(y,t_y)$ are trajectories in Minkowski space with a common parameter s, playing the role of a *proper time*. Primes indicate derivatives with respect to s and

$$|X'|^2=x'^2-t_x'^2,\quad |Y'|^2=y'^2-t_y'^2,\quad R^2=(x-y)^2-(t_x-t_y)^2.$$

We shall suppose that $R^2>0$, **i.e.**, $X-Y$ *is spacelike*.

Inspired by classical manipulations, we introduce the four-vectors

$$U=(u,\tau)=X-Y,\quad V=(v,t_V)=m_X^*X+m_Y^*Y,$$

where $m_X^*=M^{-1}m_X$, $m_Y^*=M^{-1}m_Y$, and $M=m_X+m_Y$. Then we have

$$X=V+m_Y^*U,\quad Y=V-m_X^*U,\quad R^2=|U|^2,$$

$$K=\frac{\varepsilon M^2|V'|^2+m_X m_Y|U'|^2}{2GMR}.$$

The Euler–Lagrange equations for the Lagrangian K are

$$(R^{-1}V')'=0,\quad (R^{-1}U')'=-kR^{-2}U,\quad k=GM\,\frac{K}{m_X m_Y}.$$

The first of these equations shows that there is a constant four-vector $W=(w,t_W)$ such that

$$\text{(II)}\quad V'=RW,\quad v'=Rw,\quad t_V'=Rt_W,$$

and the second Euler–Lagrange equation writes

$$\text{(III)}\quad RU''=R'U'-kU.$$

The equation (III) shows that $\langle U,U''\rangle=R'^2-kR$ and the expressions

$$\text{(IV)}\quad E=\frac{|U'|^2}{2R^2}-\frac{k}{R},\quad A=U''-2EU,$$

$$R^{-1}U\wedge U'=R^{-1}(u\times u',\tau' u-\tau u'),\quad U''\wedge U'=A\wedge U'+2EU\wedge U'$$

are constant. In fact,

$$E=-\frac{\varepsilon M^2|W|^2}{2m_X m_Y}$$

so that W and V' are *timelike* when $\varepsilon E>0$.

These relations combined with

$$\langle U,U'\rangle = RR', \quad \langle U,U''\rangle + U'^2 = RR'' + R'^2$$

will imply

$$R''-2ER=k, \quad U'^2=2ER^2+2kR$$

and

$$\frac{|U\wedge U'|^2}{-R^2}=R'^2-2ER^2-2kR=\langle A,U\rangle - kR = R'^2-U'^2=\text{const.}$$

When we introduce *the relative time of the center of gravity*,

$$t=\frac{t_V}{t_W}=\int R\ ds,$$

we get from equations (II) and (III) the astonishing relativistic equation

$$\text{(V)} \quad \frac{d^2U}{dt^2}=-\frac{kU}{R^3}.$$

We will also have, since $t'=R$,

$$R^{-1}U\wedge U' = U\wedge\frac{dU}{dt}=\text{angular } 4-\text{momentum.}$$

The general solution of the differential equations

$$U''=2EU+A, \quad R''=2ER+k$$

writes, for $E<0$ and $\varepsilon<0$,

$$U(s)=-\frac{A}{2E}+U_1\cos(hs)+U_2\sin(hs),$$

$$R(s)=-\frac{k}{2E}+R_1\cos(hs)+R_2\sin(hs),$$

where $h^2=-2E$, U_1 and U_2 are constant four-vectors, and R_1 and R_2 are real numbers.

The image of U in Minkowski space is an ellipse with center $A^*=-A/2E$ and semi-major axis $k^*=-k/2E=(G/M)K/\varepsilon|W|^2$.

The relations established above imply

$$R^{-1}U\wedge U'=\frac{h}{k^*}U_1\wedge U_2, \quad k^*A^*=R_1U_1+R_2U_2,$$

$$kR_1=\langle A,U_1\rangle, \quad kR_2=\langle A,U_2\rangle, \quad \langle U_1,U_2\rangle=R_1R_2,$$

$$|U_1|^2=R_1^2+\frac{k^2-|A|^2}{4E^2}, \quad |U_2|^2=R_2^2+\frac{k^2-|A|^2}{4E^2}, \quad R_1^2+R_2^2=\frac{|A|^2}{4E^2}.$$

We can suppose that $R_1\geqslant 0$ and $R_2=0$. Then

$$kA=4E^2R_1U_1, \quad k^*A^*=R_1U_1, \quad \langle U_1,U_2\rangle=0$$

and

$$|A^*|=R_1, \quad |U_1|^2=\frac{k^2}{4E^2}=k^{*2}, \quad |U_2|^2=\frac{k^2-|A|^2}{4E^2}=k^{*2}-|A^*|^2.$$

As a consequence, we have

$$|A|^2\geqslant 0, \quad |U_1|^2>0,$$

so that U_1 *is a spacelike vector* and $A=(4E^2/k)R_1U_1$ either vanishes (when $R_1=0$, i.e., when $R=-k/2E=k^*$ is constant) or is also spacelike.

The solutions thus obtained generalize the solutions to the Kepler–Newton problem and we obtain those solutions when we select the four-vectors $U_1=(u_1,t_1)$ and $U_2=(u_2,t_2)$ inside $\mathbb{R}^3\times\{0\}$, i.e., when

$$t_1=t_2=0, \quad U_1=(u_1,0), \quad U_2=(u_2,0).$$

Disregarding these conditions, our solutions in Minkowski space can be written in the form $U=(u,\tau)$ with

$$x-y=u=-\frac{a}{2E}+u_1\cos(hs)+u_2\sin(hs),$$

$$A=(a,t_A)=\frac{4E^2}{k}R_1(u_1,t_1), \quad h=\sqrt{-2E},$$

$$t_X-t_Y=\tau=-\frac{t_A}{2E}+t_1\cos(hs)+t_2\sin(hs),$$

and, without restricting the generality, we can add the formulas

$$R=\sqrt{r^2-\tau^2}=-\frac{k}{2E}-\frac{|A|}{2E}\cos(hs), \quad r=\sqrt{u^2}, \quad |A|=-2ER_1,$$

$$V=W\int R\,ds=\left(-\frac{ks}{2E}-\frac{|A|}{2Eh}\sin(hs)\right)W+\text{constant four-vector},$$

where

$$V=(v,t_V)=m_X^*X+m_Y^*Y, \quad W=(w,t_W)=\text{constant four-vector}.$$

When we compare Eq. (V) with the similar equation of Newtonian theory of Gravitation, *we are lead to assimilate the Newtonian time (of the pair (X,Y)) with the variable* $t=\int R\,ds=t_V/t_W$, where t_V is the fourth component of the vector V, which represents the *center of gravity*.

Note that an increase of s by $2\pi/h$ produces an increase of V by

$$\Delta V=-\frac{\pi k}{Eh}W=\frac{2\pi k^*}{h}W.$$

In the frame of center of gravity, $dV/dt=(0,t_W)$; when $E<0$, one obtains for the *period* T of the motion the expression

$$T=\Delta t=-\frac{\pi k}{Eh}=\frac{2\pi k^*}{h}.$$

For $E<0$, the solutions described previously define elliptic trajectories in Minkowski space

$$X=V+m_Y^*U, \quad Y=V-m_X^*U,$$

with centers

$$S_X=-\frac{m_Y^*}{2E}A+V=m_Y^*A^*+V,\quad S_Y=\frac{m_X^*}{2E}A+V=-m_X^*A^*+V$$

moving with constant velocity four-vector

$$\dot{S}_X=\dot{S}_Y=\dot{V}=\frac{dV}{dt}=W=(w,t_W).$$

We have introduced the notations

$$A^*=-\frac{A}{2E}=-\frac{2E}{k}R_1U_1,\quad k^*=-\frac{k}{2E}.$$

Thus we have, for $\lambda=R_1/k^*$: $A^*=\lambda U_1$ and

$$|U_1|^2=k^{*2},\quad |A^*|^2=\lambda^2k^{*2},\quad |U_2|^2=k^{*2}(1-\lambda^2),\quad \langle U_1,U_2\rangle=0.$$

For $\lambda^2\neq 1$, we obtain the following solutions:

$$U(s)=k^*(\lambda+\cos(hs))U_1^*+k^*\sqrt{\varepsilon'(1-\lambda^2)}\,\sin(hs)U_2^*,$$

$$R(s)=k^*(1+\lambda\,\cos(hs)),\quad V(s)=k^*W(s+\lambda h^{-1}\,\sin(hs))+\text{const},$$

where U_1^*, U_2^* are constant four-vectors verifying the conditions:

$$\langle U_1^*,U_2^*\rangle=0,\quad |U_1^*|^2=1,$$

$$|U_2^*|^2=\varepsilon',\quad \varepsilon'^2=1,\quad \varepsilon'(1-\lambda^2)\geqslant 0.$$

We shall suppose, without losing generality, that $\lambda\geqslant 0$.

The formula which defines U implies the identity

$$|U(s)|+|U(s)-2k^*\lambda U_1^*|=2|k^*|;$$

when $U_2\neq 0$, the image of U in Minkowski space is an affine ellipse. Then we interpret the last formula saying that:

When $U_2\neq 0$, the image of U is a Minkowskian ellipse with *focuses* $F_1=0$ and $F_2=2k^*\lambda U_1^*$, *center* $A^*=k^*\lambda U_1^*$, *major axis* $2k^*$, *and Minkowskian eccentricity* $e=\lambda$.

The case $e=\lambda=1$ arrives when the four-vector U_2 is on the light cone; in contrast to properties of conic sections in Euclidean spaces, where eccentricity 1 characterizes parabolas, we see that a Minkowskian ellipse can have $e=1$.

Supposing again that $\lambda^2\neq 1$. Let us now consider the orthogonal projections $u(s)$, u_1^*, u_2^* of the four-vectors

$$U(s)=(u(s),\tau(s)),\quad U_1^*=(u_1^*,t_1^*),\quad U_2^*=(u_2^*,t_2^*)$$

on $\mathbb{R}^3\times\{0\}$. Then we have

$$u(s)=k^*(\lambda+\cos(hs))u_1^*+k^*\sqrt{\varepsilon'(1-\lambda^2)}\,\sin(hs)u_2^*$$

and

$$\|u_1^*\|^2=t_1^{*2}+1,\quad \|u_2^*\|^2=t_2^{*2}+\varepsilon',\quad \langle\langle u_1^*,u_2^*\rangle\rangle=t_1^*t_2^*.$$

The image of u is an ellipse in $\mathbb{R}^3$ with center $a^*=k^*\lambda u_1^*$. When $t_2^*t_1^*\neq 0$, *the foci of this ellipse are not even colinear with the origin; this new anomaly never arises in Newton's theory*, according to which the attractive origin is always in one of the foci.

We get three canonical solutions when we take

$$\varepsilon' = 1, \quad \lambda^2 < 1, \quad U_1^* = (0,1,0,0), \quad U_2^* = (0,0,1,0),$$

$$\varepsilon' = -1, \quad \lambda^2 > 1, \quad U_1^* = (1,0,0,0), \quad U_2^* = (0,0,0,1),$$

$$\lambda = 1, \quad U_1^* = (1,0,0,0), \quad U_2 = (0,0,1,1).$$

All other solutions are obtained from these three particular solutions by applying Lorentz transformations.

The case $\varepsilon' = -1$, $\lambda^2 > 1$, contains the following example:

$$u_\mu(s) = k^*(\lambda + \cos(hs), \ \mu\sqrt{\lambda^2 - 1}\ \sin(hs), 0), \quad \mu \in \mathbb{R},$$

$$\tau_\mu(s) = k^*\sqrt{(\lambda^2 - 1)(\mu^2 + 1)}\ \sin(hs),$$

which is Lorentz equivalent to the solution

$$u_0(s) = k^*(\lambda + \cos(hs), 0, 0), \quad \tau_0(s) = k^*\sqrt{\lambda^2 - 1}\ \sin(hs).$$

This example shows that *an elliptic trajectory in space* $\mathbb{R}^3 \times \{0\}$ *can be Lorentz equivalent to a rectilinear trajectory in three-space*.

The image of the path u_μ is an ellipse in $\mathbb{R}^3$ with center $(k^*\lambda, 0, 0)$. When $\mu^2(\lambda^2 - 1) < 1$, the major axis and the foci are respectively $2|k^*|$ and $(k^*\lambda + c, 0, 0), (k^*\lambda - c, 0, 0)$ with $c^2 = k^{*2}(1 - \mu^2(\lambda^2 - 1))$. However, when $\mu^2(\lambda^2 - 1) > 1$, the major axis and the foci will be $2|k^*|\sqrt{\mu^2(\lambda^2 - 1)}$, respectively, $(k^*\lambda, d, 0), (k^*\lambda, -d, 0)$ with $d^2 = k^{*2}(\mu^2(\lambda^2 - 1) - 1)$.

Notes. This work has been partially inspired by the discussion given at page 11 in Ref. 5.

Maxwell fields in anisotropic space–times

Matthias Wollensak,[a)]
Theoretisch-Physikalisches Institut, Friedrich-Schiller-Universität Jena, Max-Wien-Platz 1, D-07743 Jena, Germany

(Received 9 December 1997; accepted for publication 16 June 1998)

Maxwell's equations are rewritten with respect to anholonomic orthonormal frames and applied to the case when the background is described by a diagonal Bianchi-type I universe. It is shown that solutions analogous to plane wave solutions in flat space–time must obey *two* transversality conditions when the space–time is anisotropic. Analytic solutions are presented for propagation along the respective coordinate axes and a special stiff fluid model. Furthermore, by use of a generally applicable ansatz the long- and short-time behavior of waves traveling in the axisymmetric Kasner universe have been investigated. © *1998 American Institute of Physics.* [S0022-2488(98)03010-2]

I. INTRODUCTION

Electromagnetic–gravitational interactions have been studied in numerous investigations and there exists a considerable amount of exact solutions of Einstein–Maxwell systems.[1] In many cases, however, it is sensible and sufficient to treat electromagnetic backreactions on space–time geometry only perturbatively[2,3] or to neglect these effects altogether.[4,5] Hence, provided that the influence of the electromagnetic stress-energy-tensor on the underlying geometry can be assumed to be small enough the situation simplifies considerably. The problem then reduces to the determination of solutions of Maxwell's equations in a given background metric. In the ensuing calculations we adopt this point of view.

If one is interested in effects of electromagnetic-gravitational interactions only, then it is sufficient to compute the Faraday tensor $F_{\mu\nu}$. However, when additional (matter) fields are involved it is even on the classical level necessary to calculate the Maxwell fields A_μ explicitly because the corresponding interaction term is usually written as a bilinear expression of matter and Maxwell fields.[6]

In order to treat Maxwell fields in curved spaces we propose the use of an orthonormal frame instead of the usually employed coordinate frame. This approach puts the treatment of Maxwell fields in a curved background on the same geometric footing as that of Dirac fields[7,8,9] and therefore facilitates in a natural way the coupling of spin-$\frac{1}{2}$ and spin-1-fields. It also has the advantage that the field components with respect to an orthonormal frame represent the physical components.[8,9] Moreover, calculations can be easier performed due to the particularly simple metric tensor.

The paper is organized as follows: In Sec. II we present Maxwell's equations and the Lorenz gauge with respect to orthonormal frames. In Sec. III attention is focused on Maxwell fields in diagonal Bianchi-type I cosmologies. We specialize to the sourcefree case and derive the corresponding differential equations. For solutions analogous to plane waves in Minkowskian space–time we find in addition to the usual transversality condition a second one which has no counterpart in flat space–time. We then develop general expressions for the long- and short-time behavior of those Maxwell fields. In Sec. IV we consider first the special case of waves propagating along coordinate axes. Exact solutions are calculated which confirm our asymptotic expressions. Next we study a universe filled with a perfect stiff fluid. We obtain exact solutions of the corresponding Maxwell system and determine again their asymptotic behavior. In the third model the long- and short-time behavior of Maxwell fields propagating in the axisymmetric Kasner universe are computed.

A final remark on notation: Greek indices run from 0 to 3, Latin indices from 1 to 3, and repeated Greek indices are summed over. Throughout this paper we use metric signature $(+---)$.

II. ORTHONORMAL FRAMES AND MAXWELL FIELDS

We give a brief derivation of Maxwell's equations with respect to orthonormal frames which will be used later on. In the following the notion frame will be synonymously used for cobasis, i.e., it stands for a set of (orthonormal) covectors spanning the cotangent space $T_p^*(M)$ of a differentiable manifold M. Our starting point is the frame independent formulation of the Maxwell system,

$$dF=0, \quad \delta F=-J \tag{1}$$

together with Lorenz gauge

$$\delta A=0, \tag{2}$$

where F denotes the electromagnetic field two-form and J, A the four-current, and Maxwell field 1-forms, respectively. Here, δ is the codifferential which is up to a sign identical with $*d*$, where $*$ is the well-known Hodge operator. In general an orthonormal basis is not holonomic so that the commutators of basis vectors e_ν and equivalently the exterior derivative of covectors Θ^μ are not necessarily vanishing any more,[8–10] $[e_\mu,e_\nu]=C^\alpha{}_{\mu\nu}e_\alpha$ and $d\Theta^\mu=-\frac{1}{2}C^\mu{}_{\alpha\beta}\Theta^\alpha\wedge\Theta^\beta$. The commutation (or anholonomic) coefficients $C^\mu{}_{\nu\lambda}$ which take the place of the Christoffel fields are obviously antisymmetric in the second and third indices.

The Maxwell field 1-form, the four-current 1-form and the electromagnetic field 2-form are given by

$$A=A_\mu\Theta^\mu, \quad J=J_\mu\Theta^\mu, \quad F=\tfrac{1}{2}F_{\mu\nu}\Theta^\mu\wedge\Theta^\nu,$$

with

$$F_{\mu\nu}=e_\mu(A_\nu)-e_\nu(A_\mu)-A_\alpha C^\alpha{}_{\mu\nu}.$$

Now since

$$d*F=\frac{1}{3!}\,\epsilon_{\alpha\beta\gamma\delta}\Theta^\alpha\wedge\Theta^\beta\wedge\Theta^\gamma\left\{C^\mu{}_{\mu\nu}F^{\nu\delta}+\frac{1}{2}\,C^\delta{}_{\mu\nu}F^{\mu\nu}+e_\mu(F^{\mu\delta})\right\}$$

and $d*F=*J=(1/3!)\epsilon_{\alpha\beta\gamma\delta}J^\delta\Theta^\alpha\wedge\Theta^\beta\wedge\Theta^\gamma$ one arrives at

$$C^\mu{}_{\mu\nu}F^{\nu\lambda}+\tfrac{1}{2}C^\lambda{}_{\mu\nu}F^{\mu\nu}+e_\mu(F^{\mu\lambda})=J^\lambda. \tag{3}$$

Analogously one finds for the first of Eqs. (1),

$$H_{(\mu\nu\lambda)}=0, \quad \mu<\nu<\lambda, \quad H_{\mu\nu\lambda}=e_\mu(F_{\nu\lambda})+C^\alpha{}_{\mu\nu}F_{\lambda\alpha}, \tag{4}$$

where the brackets denote even permutation of the indices. (3) and (4) represent Maxwell's equations with respect to an *orthonormal* frame.

It remains for us to derive the analogous expression for the Lorenz gauge (2). To this end one calculates the exterior derivative of the 3-form $*A$,

$$d*A=-\Theta^0\wedge\Theta^1\wedge\Theta^2\wedge\Theta^3\{e_\mu(A^\mu)+C^\mu{}_{\mu\nu}A^\nu\},$$

and by use of (2) the Lorenz condition can be read off immediately,

$$e_\mu(A^\mu)+C^\mu{}_{\mu\nu}A^\nu=0. \tag{5}$$

Lorenz gauge is *not* invariant under conformal transformations. Hence, the application of (5) to a term like

$$e_\mu(F^{\mu\lambda})=\eta^{\lambda\kappa}\{e_\mu e^\mu(A_\kappa)+e_\kappa(C^\mu{}_{\mu\nu}A^\nu)+C^\rho{}_{\kappa\mu}e_\rho(A^\mu)+e^\rho(A_\mu C^\mu{}_{\kappa\rho})\}, \tag{6}$$

necessarily spoils conformal invariance of Eq. (3).

III. MAXWELL FIELDS IN BIANCHI-TYPE I UNIVERSES

The general line element of diagonal Bianchi-type I space–times (henceforth abbreviated by BS) is defined by

$$ds^2=dt^2-\sum_{j=1}^{3}\alpha_j^2(t)(dx^j)^2.$$

A natural choice of the orthonormal frame is given by $\Theta^0=dx^0=dt$, $\Theta^j=\alpha_j dx^j$ while the tangent vectors read $e_0=\partial_0=\partial_t$, $e_j=(1/\alpha_j)\partial_j$ satisfying $\Theta^\mu(e_\nu)=\delta^\mu_\nu$. The metric coefficients are given by $\eta_{\mu\nu}=\mathrm{diag}(+1,-1,-1,-1)$. There are three nonzero commutation coefficients

$$C^j{}_{0j}=-\frac{\dot\alpha_j}{\alpha_j}=-C^j{}_{j0}. \tag{7}$$

Overdot means derivation with respect to t ($e_0=\partial_t=\dot{}$). Hence, the field equations (3) take the form

$$e_\mu(F^\mu{}_0)=J_0, \tag{8}$$

$$e_\mu(F^\mu{}_j)=(\mathscr{C}-C_j)F_{0j}+J_j, \tag{9}$$

with $C_j=C^j{}_{0j}$ and $\mathscr{C}=\Sigma_{j=1}^3 C_j=-\partial_t \ln\sqrt{|g|}$, where $|g|=\alpha_1\alpha_2\alpha_3$ denotes the absolute value of $\det g_{\mu\nu}$. On substituting (6) into (8), (9) one gets

$$J_0=e_\mu e^\mu(A_0)-e_0e^\nu(A_\nu)-2\sum_{j=1}^{3}C_j e_j(A_j), \tag{10}$$

$$J_j=e_\mu e^\mu(A_j)-\mathscr{C}\dot A_j+(C_j\mathscr{C}-C_j^2-\dot C_j)A_j-2C_j e_j(A_0). \tag{11}$$

Spatial translation invariance of BS suggests ansatz,

$$A_\mu(t,\mathbf{x})=\int d^3k f_\mu(t,\mathbf{k})e^{i\mathbf{kx}} \tag{12}$$

for the Maxwell fields (bold letters denote 3-vectors). Restricting ourselves from now on to the sourceless case $J_\mu=0$ we find from (10) and (11), resp.,

$$f_0=\frac{i}{p^2}(\dot{\mathbf{p}}\mathbf{f}-\mathbf{p}\dot{\mathbf{f}}) \tag{13}$$

and

$$\partial_t\left(\frac{\sqrt{|g|}}{\alpha_j^2}\partial_t(\alpha_j f_j)\right)+\frac{\sqrt{|g|}}{\alpha_j^2}p^2(\alpha_j f_j)=i\frac{\sqrt{|g|}}{k_j}(\partial_t p_j)^2 f_0, \tag{14}$$

where

$$p_j(t)=\frac{k_j}{\alpha_j(t)} \tag{15}$$

denotes the jth component of the *physical* 3-momentum[11] and $p\equiv|\mathbf{p}|$. Equation (13) is the BS analog of the Minkowskian equation of constraint in the Maxwell theory.

Insertion of ansatz (12) into (5) yields

$$\dot{f}_0 - \mathscr{C} f_0 = \frac{1}{\sqrt{|g|}}\,\partial_t(\sqrt{|g|} f_0) = i\mathbf{pf}, \tag{16}$$

which resembles constraint (13) in that the time-like component f_0 couples to all space-like components f_j.

In what follows we are now seeking solutions of the Maxwell system (13), (14) analogous to plane wave solutions in flat space–time. To this end we consider those fields whose scalaric component vanishes,

$$f_0 \equiv 0. \tag{17}$$

This ansatz is consistent with the Lorenz gauge (16) if the generalized transversality condition

$$\mathbf{pf} = 0 \tag{18}$$

holds. It implies that with increasing t a wave with an arbitrary wave vector will tilt toward that direction with the smallest Hubble constant $H_j = \dot{\alpha}_j / \alpha_j$.

The absence of scalaric photons is established by an additional *second* transversality condition

$$\dot{\mathbf{p}}\mathbf{f} = 0, \tag{19}$$

following from (17), (18) together with constraint (13). (19) enforces orthogonality between the spatial part **f** of the spectral components of the Maxwell fields and the change of momentum **p** with time t. It has no counterpart in flat space. To summarize, ansatz (17) leads to the following (sourcefree) Maxwell system describing transversal fields traveling in a BS background,

$$F_0(t,\mathbf{k}) = 0, \quad \{\partial_t^2 + \Omega_j^2(t)\} F_j(t,\mathbf{k}) = 0, \tag{20}$$

with $F_\mu = |g|^{1/4} f_\mu$ and time-dependent frequency $\Omega_j = \sqrt{\dot{b}_j - b_j^2 + p^2}$, where $b_j = \dot{B}_j / 2B_j$ and $B_j = \alpha_j^2 / \sqrt{|g|}$. The transversality constraints read $\mathbf{pF} = 0 = \dot{\mathbf{p}}\mathbf{F}$. We introduce now a transformation defined by

$$F_j^{\pm}(t,\mathbf{k}) = V_j^{\pm} \exp\left\{ \int_{t_0}^{t} dx [-b_j(x) + ip(x) H_j^{\pm}(x)] \right\}, \quad H_j^{\pm}(x) = \frac{\sqrt{1 + [h_j^{\pm}(x)]^2} \pm 1}{h_j^{\mp}(x)}, \tag{21}$$

where the two functions $F_j^{\pm}$ constitute the fundamental system of solutions of (20). By virtue of (21) Eq. (20) can be cast into a nonlinear first order differential equation for the functions $h_j^{\pm}$,

$$\frac{\partial_x h_j^{\mp}(x)}{\sqrt{1 + [h_j^{\pm}(x)]^2}} \pm h_j^{\mp}(x) \partial_x \ln \beta_j(x) - 2ip(x) = 0, \tag{22}$$

with

$$\beta_j(x) = \frac{\alpha_j^2(x)}{p(x)\sqrt{|g(x)|}}. \tag{23}$$

It turns out that here and in the following one need not care about discontinuities in the interval $(-\infty, 0)$ so that the principal branch of the square root can always be taken.

The form of (21) suggests that $|h_j^{\pm}| \to \infty$ is equivalent to the long-time (or high-frequency) limit. In this case $F_j^{\pm}$ exhibits the typical WKB phase factor because $|H_j^{\pm}|$ tends to unity. Analogously, it will be shown below that $|h_j^{\pm}| \to 0$ corresponds to the short-time limit. For $|h_j^{\pm}| \ll 1$ the square root in (22) can be replaced by unity neglecting terms of order $[h_j^{\pm}]^2$. One obtains a linear first order differential equation with solutions

$$h_j^{\pm}(t) = \beta_j^{\mp 1}(t) \left\{ 2i \int_{t_0}^{t} dx p(x) \beta_j^{\pm 1}(x) + \beta_j^{\pm 1}(t_0) h_j^{\pm}(t_0) \right\}. \tag{24}$$

For $|h_j^{\pm}| \gg 1$ one encounters a nonlinear differential equation of Bernoulli-type where terms of the order $[h_j^{\pm}]^{-2}$ have been discarded. Again, the integration is feasible yielding

$$\frac{1}{h_j^{\pm}(t)} = \pm \int_{t_0}^{t} d\mu_j(x) P(t;x) + \frac{P(t;t_0)}{h_j^{\pm}(t_0)}, \tag{25}$$

with $\mu_j = \ln \beta_j$ and $P(t;x) = \exp\{-2i\int_x^t d\tau p(\tau)\}$. Taking then the expansion of $H_j^{\pm}$ for small $|h_j^{\pm}|$ and inserting the result into (21) one finds

$$F_j^{+}(t,\mathbf{k}) = \tilde{V}_j^{+} \sqrt{\frac{B_j(t_0)}{B_j(t)}} \exp\left\{ i \int_{t_0}^{t} dx p(x) \left[\frac{2}{h_j^{+}(x)} + \lambda_{j,1}^{+}(x) \frac{h_j^{+}(x)}{2} - \lambda_{j,2}^{+}(x) \left(\frac{h_j^{+}(x)}{2} \right)^3 + \cdots \right] \right\}, \tag{26}$$

$$F_j^{-}(t,\mathbf{k}) = \tilde{V}_j^{-} \sqrt{\frac{B_j(t_0)}{B_j(t)}} \exp\left\{ i \int_{t_0}^{t} dx p(x) \left[\frac{h_j^{-}(x)}{2} - \lambda_{j,1}^{-}(x) \left(\frac{h_j^{-}(x)}{2} \right)^3 + \cdots \right] \right\}. \tag{27}$$

Note that the $h_j^{\pm}$ as given by (24) are correct only to the *lowest* order! The higher order corrections are described by the coefficients $\lambda_{j,n}^{\pm}(x)$ which relate the nth order expression ${}^{(n)}h_j^{\pm}$ to the lowest order result $h_j^{\pm}$. For $n=1$ holds, e.g.,

$${}^{(1)}h_j^{\pm}(x) = h_j^{\pm}(x) \left(1 + \frac{1 - \lambda_{j,1}^{\pm}(x)}{4} [h_j^{\pm}(x)]^2 \right). \tag{28}$$

Insertion of (28) into (22) yields after some algebra

$$\lambda_{j,1}^{\pm}(x) = 1 - \frac{\int^x dz I_j^{\pm}(z) \partial_z [h_j^{\pm}(z)]^2}{I_j^{\pm}(x) [h_j^{\pm}(x)]^2}, \tag{29}$$

where

$$I_j^{\pm}(x) = \int^x dy p(y) \beta_j^{\pm 1}(y). \tag{30}$$

For $|h_j^{\pm}| \gg 1$ the procedure can be analogously carried out.

Of particular interest are anisotropically expanding universes with $\alpha_j(t) = t^{q_j}$ subject to constraint $\Sigma_{j=1}^{3} q_j = 1$, $|q_j| < 1$. From (15) and (23) follows $p_j(t) = k_j t^{-q_j}$ and $\beta_j(t) = t^{3q_j - 1}/k_j$. The lowest order expressions for the functions $h^{\pm}(t)$ simplify then to

$$h_j^{+}(t) = \frac{i}{q_j} t p(t), \tag{31}$$

$$h_j^{-}(t) = \frac{i}{p(t)} \sum_{n=1}^{3} \frac{k_n^2}{1 - q_n - q_j} t^{1 - 2q_n}. \tag{32}$$

An additional logarithmic factor appears in (31) when $q_j = 0$ and similarly in (32) if $q_n + q_j = 1$. Note that Eqs. (31), (32) are only sensible in the case $|h_j^{\pm}| \to 0$. This is equivalent to the short-time limit if $p(t)$ diverges slower than t^{-1}. For exponents $|q_j| < 1$ as demanded above this condition is always fulfilled.

IV. EXACT AND ASYMPTOTIC SOLUTIONS

Exact solutions can be easily found if one restricts his attention to fields propagating along the respective coordinate axes. But there exists no ''superposition'' principle which would allow the construction of general results by use of those special results. These solutions are nonetheless interesting as limiting cases of the general situation with arbitrary wave vectors. Below we will present exact solutions for BS with $\alpha_j(t) = t^{q_j}$.

One faces a more complicated situation if one considers fields propagating with an arbitrary wave vector **k** in an axially symmetrical BS. In most cases there are no analytic solutions at disposal. We investigate here two models, an exactly solvable stiff fluid model and a Kasner space–time. Before doing so we note that the transversality conditions (18), (19) together with restriction $\alpha_1(t)=\alpha_2(t)$ lead to

$$f_0(t,\mathbf{k})=f_3(t,\mathbf{k})=0, \quad k_1 f_1(t,\mathbf{k})=-k_2 f_2(t,\mathbf{k}), \tag{33}$$

i.e., linear polarization.

A. Propagation along the coordinate axes

In the ensuing calculation we set without loss of generality $k_1\equiv k$, $k_2=0=k_3$, i.e., we consider propagation along the x^1-axis.[3,4] It follows from (18) that a wave propagating along a special coordinate axis will keep propagating along this axis. But this motion is only stable when the propagation originally started along that axis with the smallest Hubble constant. Otherwise small deviations off the axis will increase with time and cause the wave to tilt toward that axis with the smallest Hubble constant.

The differential equations pertaining to the spatial components $f_j=t^{-1/2}F_j$ read according to (20)

$$\{\partial_t^2+\Omega_j^2(t)\}F_j(t)=0, \tag{34}$$

$$\Omega_j^2(t)=\frac{1-4q_j^2}{4t^2}+k^2t^{-2q_1} \tag{35}$$

$(j\neq 1)$ while the time-like component vanishes. The general solution of (34) may be written as

$$F_j^{\pm}(t)=\sqrt{t}\mathscr{Q}_{\pm\nu_j}(\gamma(t)/2) \quad (j\neq 1), \quad F_0^{\pm}(t)=0=F_1^{\pm}(t), \tag{36}$$

with $\nu_j=q_j/(1-q_1)$ and $\gamma(t)=2kt^{1-q_1}/(1-q_1)$, where $\mathscr{Q}_\nu(z)$ denotes Bessel functions of the first kind J_ν and Y_ν or any linear combination thereof, e.g., Hankel's functions.[12] As is well known J_ν, $J_{-\nu}$ represent a fundamental system of solutions of (34) for noninteger ν while in the case of integer indices a fundamental system is given by J_ν and Y_ν.

We now derive the corresponding expressions in the short- and long-time limit using ansatz (21). Beginning with case $t\to\infty$ one finds upon insertion of $p_j=k_jt^{-q_j}$ and $\beta_j=t^{3q_j-1}/k_j$ into (25)

$$\frac{1}{h_j^{\pm}(t)}\sim\pm\frac{1-q_1-2q_j}{1-q_1}\frac{i}{\gamma(t)}+\mathscr{O}(\gamma^{-2}). \tag{37}$$

On expanding $H_j^{\pm}$ in terms of $1/h_j^{\pm}$ and inserting the result into (21) one arrives at $(j\neq 1)$

$$F_j^{\pm}(t,\mathbf{k})\sim V_j^{\pm}(t_0)t^{q_1/2}\exp\left\{\pm\frac{ik}{1-q_1}t^{1-q_1}\right\} \quad (t\to\infty). \tag{38}$$

(38) exhibits the correct long-time behavior of the exact solutions (36).

The short-time limit coincides with case $|h_j^{\pm}(t)|\to 0$. This has already been shown in Sec. III. One gets from (31), (32),

$$h_j^{+}(t)=\frac{ik}{q_j}t^{1-q_1}, \tag{39}$$

$$h_j^{-}(t)=\frac{ik}{1-q_1-q_j}t^{1-q_1}. \tag{40}$$

The cases $q_j=0$ and $q_j+q_1=1$ have been omitted here because they can be carried out in an entirely analogous way. On calculating the first order corrections

$$\lambda_{j,1}^{+}(0)=\frac{\nu_j}{1+\nu_j},\quad \lambda_{j,1}^{-}(0)=\frac{\nu_j-1}{\nu_j-2},$$

and substituting (39), (40) into (26) and (27), respectively, one obtains in the small-t limit ($j\neq 1$),

$$F_j^{+}(t)=\tilde{V}_j^{+}(t_0)t^{1/2+q_j}\left\{1-\frac{1}{1+\nu_j}\left(\frac{\gamma(t)}{4}\right)^2+\mathcal{O}(\gamma^4)\right\} \tag{41}$$

and

$$F_j^{-}(t)=\tilde{V}_j^{-}(t_0)t^{1/2-q_j}\left\{1-\frac{1}{1-\nu_j}\left(\frac{\gamma(t)}{4}\right)^2+\frac{1}{2}\frac{1}{(1-\nu_j)(2-\nu_j)}\left(\frac{\gamma(t)}{4}\right)^4-\mathcal{O}(\gamma^6)\right\}. \tag{42}$$

These are the short-time expansions up to the order γ^2 and γ^4, respectively, of the exact solutions (36).

B. Stiff-fluid model

We consider exact solutions of Einstein's field equations when the material content is described by the ''perfect-fluid'' stress tensor $T_{\alpha\beta}=(\mu+\mathcal{P})u_\alpha u_\beta+\mathcal{P}g_{\alpha\beta}$, where $\mathcal{P}$ denotes pressure, μ the energy density consisting of the rest mass density plus total internal energy, and u_α the 4-velocity. The equation of state reads $\mathcal{P}=(\zeta-1)\mu$ with ζ a constant. The special case $\zeta=2$ is often referred to as the ''stiff matter'' case. The line element pertaining to it is given by $ds^2=dt^2-\Sigma_{j=1}^{3}(t^{q_j}dx^j)^2$, where $q_1=q_2=q$, $q_3=1-2q$. In the following we are going to study Maxwell fields in a curved space–time described by this model for $q=1/2$, i.e.,

$$q_1=q_2=\tfrac{1}{2},\quad q_3=0. \tag{43}$$

The corresponding differential equation assumes according to (20) the simple form

$$\{\partial_t^2+p^2(t)\}F_j(t,\mathbf{k})=0 \tag{44}$$

with $p^2(t)=k_3^2+\kappa^2/t$, where $\kappa^2=k_1^2+k_2^2$. Here, one must only consider the cases $j=1,2$ because (33) enforces $F_0=F_3=0$. Solutions of (44) are

$$F_j^{+}(t,\mathbf{k})=M_{\eta,1/2}(-2ik_3t), \tag{45}$$

$$F_j^{-}(t,\mathbf{k})=W_{\eta,1/2}(-2ik_3t), \tag{46}$$

where M and W are Whittaker's functions[12] and $\eta=i\kappa^2/2k_3$. The complete set of solutions satisfying constraint (33) reads

$$F_0^{\pm}(t,\mathbf{k})=0=F_3^{\pm}(t,\mathbf{k}),\quad \tilde{F}_1^{\pm}(t,\mathbf{k})=D^{\pm}k_2F_1^{\pm}(t,\mathbf{k}),\quad \tilde{F}_2^{\pm}(t,\mathbf{k})=-D^{\pm}k_1F_2^{\pm}(t,\mathbf{k}), \tag{47}$$

with constant prefactors $D^{\pm}$. We compare these exact results with the corresponding outcome based on our asymptotic expressions. In the long-time limit follows for $k_3\neq 0$,[13]

$$\frac{1}{h_j^{\pm}(t)}=\mp\frac{1-2q_j}{2i|k_3|t}\left\{1+\mathcal{O}\left(\frac{1}{2i|k_3|t};\frac{1}{at}\right)\right\} \tag{48}$$

with $a=k_3^2/\kappa^2$, $\kappa^2=k_1^2+k_2^2$. Expansion of ansatz (21) for large $|h_j^{\pm}|$ eventually gives

$$F_j^{\pm}(t,\mathbf{k})=V_j^{\pm}(t_0,\mathbf{k})t^{\pm i|\eta|}e^{\pm i|k_3|t[1+\mathcal{O}(t^{-2})]}\quad (t\to\infty), \tag{49}$$

where terms of order $(|k_3|t)^{-1}$, $(at)^{-1}$ have been neglected. For the short-time limit we use again (26), (27). After some manipulations one arrives at

$$h_j^+(x)=2ix\sqrt{\frac{\kappa^2}{x}+k_3^2}, \tag{50}$$

$$h_j^-(x)=2i\,\frac{\kappa^2\,\ln(x)+k_3^2}{\sqrt{\frac{\kappa^2}{x}+k_3^2}}, \tag{51}$$

and

$$\lambda_{j,1}^+(x)=\tfrac{1}{2}-\tfrac{1}{6}ax+\mathcal{O}(\kappa^2x)+\mathcal{O}(a^2x^2), \tag{52}$$

$$\lambda_{j,1}^-(x)=\frac{1}{\ln(x)}\left\{1-\frac{2}{\ln(x)}+\frac{2}{[\ln(x)]^2}+\cdots+ax+\mathcal{O}\left(\frac{ax}{\ln(x)}\right)\right\}, \tag{53}$$

where the dots in (53) indicate that there are still terms present that are decaying slower than x for $x\to 0$. But these terms can be omitted here because they do not depend on $a\equiv k_3^2/\kappa^2$ and therefore do not contribute to the ''interaction'' terms. With the interaction the following is meant here: As has been discussed in detail in Sec. IV A one can study propagation along the axes (or within planes in axisymmetric models), i.e., the wave vector has two (or one) vanishing components. One gets exact results depending in the present model on either κ, namely (apart from a constant factor)

$$F_j^+(t,\kappa)=\sqrt{t}J_1(2\kappa\sqrt{t}), \tag{54}$$

$$F_j^-(t,\kappa)=\sqrt{t}\left\{Y_1(2\kappa\sqrt{t})-\frac{2}{\pi}\,[\ln(\kappa)-\psi(1)]J_1(2\kappa\sqrt{t})\right\} \tag{55}$$

(where J_1, Y_1 are the Bessel functions introduced earlier and ψ denotes the Digamma function), or on k_3, namely,

$$F_j^+(t,k_3)=\sin(k_3t), \tag{56}$$

$$F_j^-(t,k_3)=\cos(k_3t). \tag{57}$$

The explicit determination of all *a-independent* terms in (52), (53) can be much easier accomplished by directly using (54), (55). But for an arbitrary wave vector there are additional terms of the form $\kappa^pk_3^q$ which ''couple'' the motions along the x^3-axis ($\kappa=0$) and in the x^1–x^2-plane ($k_3=0$). It is those interaction terms we are after which cannot be obtained from the decoupled results (54)–(57).

Upon insertion of (50), (52) into (26) one finds for small t ($j=1,2$),

$$F_j^+(t,\mathbf{k})=\tilde{V}_j^+(t_0,\mathbf{k})t\{1-\tfrac{1}{2}\kappa^2t-\tfrac{1}{6}k_3^2t^2+\mathcal{O}(\kappa^4t^2)+\mathcal{O}(\kappa^2k_3^2t^3)\}. \tag{58}$$

This is the correct expansion of (45). Here, the lowest order interaction term is proportional to $\kappa^2k_3^2t^3$. For times $t<\min(\kappa^{-2},k_3^{-1})$ one can neglect all interaction terms, but even then (58) is not simply a superposition of (54) and (56).

The short-time limit of F_j^- can be treated in the same way and one gets

$$F_j^-(t,\mathbf{k})=\tilde{V}_j^-(t_0,\mathbf{k})\{1+\mathscr{D}_\kappa^-(t)+\mathscr{D}_{k_3}^-(t)+\mathscr{D}_I^-(t)\} \tag{59}$$

with

$$\mathscr{D}_{\kappa}^{-}(t)=\ln(t)[-\kappa^2 t+\tfrac{1}{2}\kappa^4 t^2+\mathscr{O}(\kappa^6 t^3)]+\kappa^2 t-\tfrac{5}{4}\kappa^4 t^2+\mathscr{O}(\kappa^6 t^3),$$

$$\mathscr{D}_{k_3}^{-}(t)=-\tfrac{1}{2}k_3^2 t^2+\mathscr{O}(k_3^4 t^4), \quad \mathscr{D}_{I}^{-}(t)=\tfrac{1}{6}\kappa^2 k_3^2 t^3[\ln(t)+\mathscr{O}(1)]+\cdots .$$

$\mathscr{D}_{I}^{-}$ denotes the interaction term while $\mathscr{D}_{\kappa}^{-}$, $\mathscr{D}_{k_3}^{-}$ pertain to the special cases of propagation in the x^1–x^2-plane and along the x^3-axis. Since $\mathscr{D}_{\kappa}^{-}$, $\mathscr{D}_{k_3}^{-}$, and $\mathscr{D}_{I}^{-}$ are real, our result (59) is not the small-t expansion of solution (46) but actually belongs to

$$F_j^{-}(t,\mathbf{k})=\tfrac{1}{2}[\Gamma(1-\eta)W_{\eta,1/2}(z)+\Gamma(1+\eta)W_{-\eta,1/2}(-z)]+2\eta[\ln(\kappa)-\psi(1)]M_{\eta,1/2}(z)$$

with $z=-2ik_3 t$ and Γ the gamma and ψ the digamma function. This solution together with (45) represent another possible fundamental system of solutions of Eq. (44).

C. Axially symmetrical Kasner universe

Metrics of the Kasner-type are vacuum solutions of Einstein's field equations.[10] They are special cases of BS with coefficients $\alpha_j=t^{q_j}$ obeying constraints $\Sigma_{j=1}^{3}q_j=1=\Sigma_{j=1}^{3}q_j^2$. The axisymmetric Kasner solution is given by $q_1=2/3=q_2$, $q_3=-1/3$. The differential equations describing the behavior of transversal Maxwell fields in this model read according to (20),

$$\{\partial_t^2+\Omega_j^2(t)\}F_j(t,\mathbf{k})=0 \quad (j=1,2), \quad F_0(t,\mathbf{k})=0=F_3(t,\mathbf{k}) \tag{60}$$

with $\Omega_j^2(t)=p^2(t)+(1-4q_j^2)/4t^2$ and $p(t)=\kappa t^{-2/3}\sqrt{1+at^2}$. There are no nontrivial analytic solutions at disposal but it is not difficult to determine the long- and short-time limits using the results derived in Sec. III. The calculation proceeds along the lines of Sec. IV B. Since

$$\int p(\tau)d\tau=\frac{3}{4}|k_3|\tau^{4/3}\left\{1-\frac{1}{a\tau^2}+\mathscr{O}\left(\frac{1}{a^2\tau^4}\right)\right\},$$

$$\partial_x \ln \beta_j=\frac{2q_j-\frac{1}{3}}{x}-\frac{ax}{1+ax^2},$$

one obtains in the long-time limit with (25)

$$\frac{1}{h_j^{\pm}(t)}=\pm\frac{i\left(\frac{2}{3}-q_j\right)}{|k_3|}t^{-4/3}\left\{1-\frac{2i}{3|k_3|}t^{-4/3}+\mathscr{O}(t^{-2})\right\}\mp\frac{i\kappa^2}{2|k_3|^3}t^{-10/3}+\cdots ,$$

where $k_3\neq 0$.[13] Upon insertion of

$$\int_{t_0}^{t}dx\,\frac{p(x)}{h_j^{\pm}(x)}=\pm i\left(\frac{2}{3}-q_j\right)\left\{\ln\frac{t}{t_0}+\cdots\right\}\pm\frac{i}{4}\frac{\kappa^2}{k_3^2}[t^{-2}-t_0^{-2}]+\cdots$$

into the large-$|h_j^{\pm}|$-expansion of (21) one arrives at the desired long-time limit

$$F_j^{\pm}(t,\mathbf{k})=\epsilon_j(\mathbf{k})V^{\pm}(t_0,\mathbf{k})t^{-1/6}\exp\left\{\pm\frac{3i}{4}|k_3|t^{4/3}\left(1-\frac{\kappa^2}{k_3^2t^2}+\mathscr{O}(t^{-10/3})\right)\right\}, \tag{61}$$

where according to (33) the components ϵ_j of the polarization vectors satisfy $\epsilon_1=k_2$, $\epsilon_2=-k_1$, $\epsilon_3=0$.

Starting point for the determination of the short-time limit are Eqs. (26), (27), where $I_j^{+}(x)=\frac{3}{4}x^{4/3}$, $I_j^{-}(x)=-\frac{3}{2}\kappa^2x^{-2/3}(1+\frac{1}{2}ax^2)$. Equations (31) and (32) lead to

$$h_j^{+}(x)=\frac{3i}{2}\kappa x^{1/3}\sqrt{1+ax^2}, \tag{62}$$

$$h_j^-(x) = -3i\kappa x^{1/3}\frac{1-\frac{1}{2}ax^2}{\sqrt{1+ax^2}}, \tag{63}$$

and via (29) to

$$\lambda_{j,1}^+(x) = \tfrac{2}{3} - \tfrac{1}{3}ax^2 + \mathcal{O}(a^2x^4), \tag{64}$$

$$\lambda_{j,1}^-(x) = -\tfrac{2}{3}\{\ln(x) + \cdots + 5ax^2\ \ln(x) + \mathcal{O}(ax^2)\}. \tag{65}$$

Again, terms of lower order in x than those being kept have been neglected in (65). Because these terms do not contribute to the interaction terms they are not of interest here. From (26) together with (62), (64) follows in the limit $t \to 0 (j = 1,2)$,

$$F_j^+(t,\mathbf{k}) = \epsilon_j(\mathbf{k})\tilde{V}^+(t_0,\mathbf{k})t^{7/6}\{1 + \mathscr{D}_\kappa^+(t) + \mathscr{D}_{k_3}^+(t) + \mathscr{D}_I^+(t)\}, \tag{66}$$

with

$$\mathscr{D}_\kappa^+(t) = -\frac{1}{3}\left(\frac{3\kappa}{2}\right)^2 t^{2/3} + \frac{1}{24}\left(\frac{3\kappa}{2}\right)^4 t^{4/3} + \mathcal{O}(\kappa^6 t^2),$$

$$\mathscr{D}_{k_3}^+(t) = -\frac{1}{6}\left(\frac{3k_3}{4}\right)^2 t^{8/3} + \mathcal{O}(k_3^4 t^{16/3}), \quad \mathscr{D}_I^+(t) = \mathcal{O}(\kappa^2 k_3^2 t^{10/3}). \tag{67}$$

Mode F_j^- given by (27) together with (63) and (65) can be expanded as

$$F_j^-(t,\mathbf{k}) = \epsilon_j(\mathbf{k})\tilde{V}^-(t_0,\mathbf{k})t^{-1/6}\{1 + \mathscr{D}_\kappa^-(t) + \mathscr{D}_{k_3}^-(t) + \mathscr{D}_I^-(t)\} \tag{68}$$

(with $j = 1,2$) where

$$\mathscr{D}_\kappa^-(t) = \left(\frac{3\kappa}{2}\right)^2 t^{2/3} + \frac{3}{4}\left(\frac{3\kappa}{2}\right)^4 t^{4/3} + \mathcal{O}(\kappa^6 t^2) - \ln(t)\left\{\frac{1}{3}\left(\frac{3\kappa}{2}\right)^4 t^{4/3} + \mathcal{O}(\kappa^6 t^2)\right\},$$

$$\mathscr{D}_{k_3}^-(t) = -\frac{1}{2}\left(\frac{3k_3}{4}\right)^2 t^{8/3} + \mathcal{O}(k_3^4 t^{16/3}), \tag{69}$$

$$\mathscr{D}_I^-(t) = -\frac{27}{16}\kappa^2 k_3^2 t^{10/3}[\ln(t) + \mathcal{O}(1)],$$

and as before $\epsilon_1 = k_2$, $\epsilon_2 = -k_1$, $\epsilon_3 = 0$ in (68) and (66) as well. It turns out that $\mathscr{D}_\kappa^\pm$ and $\mathscr{D}_{k_3}^\pm$ can be exactly determined and one finds eventually

$$\mathscr{D}_\kappa^+(t) = \frac{8}{9\kappa^2}\, t^{-2/3} J_2(3\kappa t^{1/3}) - 1,$$

$$\mathscr{D}_{k_3}^+(t) = \sqrt{\frac{2\pi}{3k_3}}\, t^{-2/3} J_{1/2}\left(\frac{3}{4}\, k_3 t^{4/3}\right) - 1,$$

$$\mathscr{D}_\kappa^-(t) = -\frac{9\kappa^2}{4}\, t^{2/3}\left\{\pi Y_2(3\kappa t^{1/3}) - 2\left[\ln\frac{3\kappa}{2} - \psi(1)\right] J_2(3\kappa t^{1/3})\right\} - 1, \tag{70}$$

$$\mathscr{D}_{k_3}^-(t) = \sqrt{\frac{3\pi k_3}{8}}\, t^{2/3} J_{-(1/2)}\left(\frac{3}{4}\, k_3 t^{4/3}\right) - 1.$$

V. CONCLUSION

In this paper we studied the behavior of Maxwell fields in a Bianchi-type I background. Starting with the frame-independent formulation (1), (2) we derived in Sec. II Maxwell's equations and the Lorenz condition with respect to an anholonomic orthonormal frame. In Sec. III we specialized in the sourcefree case and to solutions analogous to plane waves in flat space–time. We found that the spectral components $f_j(t,\mathbf{k})\equiv|g(t)|^{-1/4}F_j(t,\mathbf{k})$ of the spatial Maxwell fields A_j as given in (12) must be perpendicular to the time-dependent 3-momentum $\mathbf{p}$ *and* also to the change $d\mathbf{p}$. As a consequence, the structure of the system of differential equations (20) is in fact complicated since the spatial components F_j are coupled to each other on account of these transversality conditions. However, the coupling becomes trivial in all axisymmetric space–times owing to (33).

We explicitly considered-first the special case of propagation along coordinate axes which has the obvious advantage that the second transversality constraint (19) becomes equivalent to the first one, Eq. (18). This case has also been investigated by Goorjian[3] who treated Maxwell fields with only one nonvanishing component A_j. He obtained a second order partial differential equation of the Euler–Poisson–Darboux-type with solutions which have the structure of decaying standing waves. In contrast, our approach yields decaying traveling waves. This outcome is compatible with the results of Sagnotti and Zwiebach[4] (see also the Appendix) who considered $F_{\mu\nu}$ and the corresponding *E*- and *B*-fields. In the second case we treated a so-called stiff fluid space–time and determined exact general solutions. The corresponding Faraday tensor agrees with the result found earlier by Lotze.[5] Furthermore, we showed that the formalism developed in Sec. III reproduces the correct short- and long-time asymptotics of those exact solutions. In the third model which deals with Maxwell fields in the axially symmetrical Kasner universe we determined the long- and short-time behavior of the two linearly independent solutions.

In all cases we found that the nonvanishing spectral components $f_j^{\pm}$ behave like

$$f_j^{\pm}(t,\mathbf{k})\sim t^{\pm q_j} \tag{71}$$

when t tends to zero. For $t\to\infty$ we showed that the $f_j^{\pm}$ behave like traveling waves with decaying amplitudes, i.e.,

$$|f_j^{\pm}(t,\mathbf{k})|\sim t^{-q_j}. \tag{72}$$

In the coordinate frame $\{dx^{\mu}\}_{\mu}$ one gets instead of (71) $f_j^{\pm}\sim t^{q_j\pm q_j}$ and (72) must be replaced by $|f_j^{\pm}|\sim$ const.[14]

APPENDIX: FARADAY TENSOR IN BIANCHI-TYPE I SPACE–TIMES

In order to determine the components of the Faraday tensor in a BS one conveniently starts with field equations (8) and (9). Upon insertion of the ansatz,

$$F_{\mu\nu}(t,\mathbf{x})=\int d^3k f_{\mu\nu}(t,\mathbf{k})e^{i\mathbf{kx}} \tag{A1}$$

into (8) ($J_{\mu}\equiv 0$) one obtains the orthogonality condition $\mathbf{k}\mathbf{\Lambda}=0$. The components of $\mathbf{\Lambda}$ are given by $\Lambda_j=\sqrt{|g|}f_{j0}/\alpha_j$. (A1) together with (9) yields

$$\sum_{l=1}^{3} p_l f_{jl}=-i\,\frac{\alpha_j}{\sqrt{|g|}}\,\dot{\Lambda}_j, \tag{A2}$$

where $p_l=k_l/\alpha_l$. From the second part (4) of Maxwell's equations follows

$$\partial_t(\alpha_m\alpha_n f_{mn})+i\alpha_m\alpha_n(p_m f_{n0}-p_n f_{m0})=0 \tag{A3}$$

and a second orthogonality condition $\mathbf{k\Gamma}=0$ with $\Gamma_j=\sqrt{|g|}\epsilon_{jlm}f_{lm}/\alpha_j$. Note that Λ_j and Γ_j are in flat space–time and just the spatial Fourier transforms of the electric and magnetic field components, respectively. It is useful to introduce a vector $\mathbf{D}^{(\xi)}$ with components

$$D_j^{(\xi)}=\alpha_j^2\Delta_j^{(\xi)},\quad \Delta_j^{(\xi)}=\Gamma_j+i\xi\Lambda_j\quad(\xi=\pm 1), \tag{A4}$$

by use of which Eqs. (A2) and (A3) can be combined to

$$\sqrt{|g|}\dot{\Delta}_j^{(\xi)}+\xi(\mathbf{k}\times\mathbf{D}^{(\xi)})_j=0,\quad \mathbf{k\Delta}^{(\xi)}=0. \tag{A5}$$

If one projects (A5) onto the respective axes of the standard dreibein consisting of $\mathbf{w}_1=(1/k\kappa)\times(k_1k_3,k_2k_3,-\kappa^2)^T$, $\mathbf{w}_2=(1/\kappa)(-k_2,k_1,0)^T$, $\mathbf{w}_3=(1/k)\mathbf{k}$ and then uses $\mathbf{1}\equiv\Sigma_j\mathbf{w}_j\mathbf{w}_j^T$ one recovers Eqs. (1.9)–(1.11) of Ref. 4.

We will now determine $F_{\mu\nu}$ for the stiff-fluid model treated in Sec. IV B. On using (12) and comparing the outcome with (A1) one obtains $f_{0j}=(1/\alpha_j)\partial_t(\alpha_jf_j)$, $f_{mn}=i(p_mf_n-p_nf_m)$, and by use of (47) one gets

$$\begin{aligned}
&f_{12}=-i\,\frac{\kappa^2}{k_2}\,\frac{F_1}{t}=-f_{21},\quad f_{01}=\frac{1}{\sqrt{t}}\,\dot{F}_1=-f_{10},\\
&f_{13}=-ik_3\,\frac{F_1}{\sqrt{t}}=-f_{31},\quad f_{02}=-\frac{1}{\sqrt{t}}\,\frac{k_1}{k_2}\,\dot{F}_1=-f_{20},\\
&f_{23}=i\,\frac{k_1k_3}{k_2}\,\frac{F_1}{\sqrt{t}}=-f_{32},\quad f_{\mu\nu}=0\ \text{ otherwise.}
\end{aligned} \tag{A6}$$

It is then easy to infer from (A4) with the help of (A6),

$$\Delta_1^{(\xi)}\equiv\frac{\sqrt{|g|}}{\alpha_1^2}\,(f_{23}+i\xi f_{10})=i\left(\frac{k_1k_3}{k_2}-\xi\partial_t\right)F_1,$$

$$\Delta_2^{(\xi)}=i\left(k_3+\xi\,\frac{k_1}{k_2}\,\partial_t\right)F_1,\quad \Delta_3^{(\xi)}=-i\,\frac{\kappa^2}{k_2}\,F_1,$$

and hence[5] $\mathbf{w}_1\mathbf{\Delta}^{(\xi)}=i(k\kappa/k_2)F_1$, $\mathbf{w}_2\mathbf{\Delta}^{(\xi)}=i\xi(\kappa/k_2)\dot{F}_1$.

Using the quantum inverse scattering method for the XXZ model with open boundary conditions, we obtained the determinant formula for the six-vertex model with reflecting end. © *1998 American Institute of Physics.* [S0022-2488(98)01511-4]

I. INTRODUCTION

Determinant representations of correlation functions of one-dimensional quantum integrable models were studied extensively.[1] In particular, Essler *et al.* studied the correlation functions of the XXZ model with periodic boundary conditions.[2,3] In the calculation of scalar products of the XXZ model, the relation between the scalar products of the model and the partition function of the six-vertex with domain wall boundary conditions is essential.[4] Izergin *et al.* used this relation to obtain the determinant formula for the six-vertex model with domain wall boundary conditions.[5]

On the other hand, integrable models with open boundary conditions are interesting. Integrable models with open boundary conditions are related to the B_N type Weyl group[6] and in condenced matter physics they are related to the impurity problems in the Luttinger liquid.[7]

Correlation function of the $1+1$ dimensional delta function interacting Bose gas with open boundary conditions were studied in Ref. 8.

For the XXZ model with open boundary conditions, the algebraic Bethe ansatz of the model can be used to calculate the six-vertex model with a reflecting boundary condition at one boundary and domain wall boundary conditions at the other three boundaries. (In this paper we call a six-vertex model with these types of boundary conditions *six-vertex model with reflecting end*.) In this paper, we obtain the determinant formula for the above six-vertex model using the above relation.

The paper is organized as follows: In Sec. II we give a brief review of the algebraic Bethe ansatz for the open XXZ model. An inhomogeneous six-vertex model with a reflecting end is studied in Sec. III. The determinant formula for the partition function of the six-vertex model with a reflecting end are given in Sec. IV.

II. QUANTUM INVERSE SCATTERING METHOD FOR THE OPEN XXZ MODEL

Let us start with a brief review of the quantum inverse scattering method for the XXZ model with open boundary conditions.[9] The trigonometrical solution of the Yang–Baxter equation is given by

$$R_{00'}(\lambda)=\frac{1}{2}\left\{\left[\frac{\sinh(\lambda-2i\eta)-\sinh(2i\eta)}{\sinh(\lambda)}\right]1_0\otimes 1_{0'}+\sigma_0^x\otimes\sigma_{0'}^x+\sigma_0^y\otimes\sigma_{0'}^y\right.$$
$$\left.+\left[\frac{\sinh(\lambda-2i\eta)+\sinh(2i\eta)}{\sinh(\lambda)}\right]\sigma_0^z\otimes\sigma_{0'}^z\right\}, \tag{1}$$

where $R_{00'}(\mu)$ acts as a linear operator on the tensor product of two auxiliary spaces. The L operators are given by $L_n(\lambda)=\sinh(\lambda)R_{0n}(\lambda)P_{0n}$ where 0 denotes the auxiliary space, n denotes the nth quantum space, and $P_{0n}=(1/2)(1_0\otimes 1_n+\sigma_0^x\otimes\sigma_n^x+\sigma_0^y\otimes\sigma_n^y+\sigma_0^z\otimes\sigma_n^z)$ is a permutation operator. Thus

a)Electronic mail: otutiya@hep1.c.u-tokyo.ac.jp

 © 1998 American Institute of Physics

$$L_n(\lambda)=\tfrac{1}{2}\{[\sinh(\lambda-2i\eta)+\sinh(\lambda)]1_0\otimes 1_n-\sinh(2i\eta)[\sigma_0^x\otimes\sigma_n^x+\sigma_0^y\otimes\sigma_n^y]$$
$$+[\sinh(\lambda-2i\eta)-\sinh(\lambda)]\sigma_0^z\otimes\sigma_n^z\}. \tag{2}$$

As a consequence of the Yang–Baxter equation, the L operators satisfy the fundamental commutation relations

$$R(\lambda-\mu)(L_n(\lambda)\otimes L_n(\mu))=(L_n(\mu)\otimes L_n(\lambda))R(\lambda-\mu). \tag{3}$$

The monodromy matrix of the inhomogeneous XXZ model is constructed from the L operators as

$$T(\lambda,\boldsymbol{\omega})=L_L(\lambda-\omega_L)L_{L-1}(\lambda-\omega_{L-1})\cdots L_1(\lambda-\omega_1). \tag{4}$$

This matrix satisfies fundamental commutation relations similar to (4)

$$R(\lambda-\mu)(T(\lambda,\boldsymbol{\omega})\otimes T(\mu,\boldsymbol{\omega}))=(T(\mu,\boldsymbol{\omega})\otimes T(\lambda,\boldsymbol{\omega}))R(\lambda-\mu). \tag{5}$$

For the model with open boundary conditions, in addition to the Yang–Baxter equation, the reflection equation[9] plays an important role,

$$R_{12}(\lambda-\mu)K_1(\lambda)R_{12}(\lambda+\mu)K_1(\mu)=K_1(\mu)R_{12}(\lambda+\mu)K_1(\lambda)R_{12}(\lambda-\mu), \tag{6}$$

where $K_j(\lambda)$ is the 2×2 matrix which acts to the jth auxiliary space and is related to the reflection of the particle with rapidity λ at the boundaries. In the present paper, we concentrate to the diagonal solution of the reflection equation

$$K(\lambda,\xi)=\frac{1}{\sinh(\xi)}\begin{pmatrix}\sinh(\xi+\lambda) & 0\\ 0 & \sinh(\xi-\lambda)\end{pmatrix}. \tag{7}$$

For the model with open boundary conditions, Sklyanin's monodromy matrix

$$U(\lambda,\boldsymbol{\omega})=T(\lambda,\boldsymbol{\omega})K(\lambda,\xi_-)\grave{T}(\lambda,\boldsymbol{\omega})=\begin{pmatrix}\mathscr{A}(\lambda,\boldsymbol{\omega}) & \mathscr{B}(\lambda,\boldsymbol{\omega})\\ \mathscr{C}(\lambda,\boldsymbol{\omega}) & \mathscr{D}(\lambda,\boldsymbol{\omega})\end{pmatrix}, \tag{8}$$

where

$$\grave{T}(\lambda,\boldsymbol{\omega})=L_1(\lambda+\omega_1)L_2(\lambda+\omega_2)\cdots L_L(\lambda+\omega_L)\propto T^{-1}(-\lambda,\boldsymbol{\omega}) \tag{9}$$

is fundamental, where $\mathscr{A}(\lambda,\boldsymbol{\omega})$, $\mathscr{B}(\lambda,\boldsymbol{\omega})$, $\mathscr{C}(\lambda,\boldsymbol{\omega})$, $\mathscr{D}(\lambda,\boldsymbol{\omega})$ are operators which act on the quantum spaces.

$U(\lambda,\boldsymbol{\omega})$ also satisfies the reflection equation

$$R_{12}(\lambda-\mu)U_1(\lambda,\boldsymbol{\omega})R_{12}(\lambda+\mu)U_1(\mu,\boldsymbol{\omega})=U_1(\mu,\boldsymbol{\omega})R_{12}(\lambda+\mu)U_1(\lambda,\boldsymbol{\omega})R_{12}(\lambda-\mu). \tag{10}$$

The reflection equation is rewritten as the commutation relations of the matrix elements $\mathscr{A}$, $\mathscr{B}$, $\mathscr{C}$, $\mathscr{D}$,

$$[\mathscr{A}(\lambda),\mathscr{A}(\mu)]=-[\mathscr{D}(\lambda),\mathscr{D}(\mu)]=\frac{\sinh(2i\eta)}{\sinh(\lambda+\mu-2i\eta)}\{\mathscr{B}(\lambda)\mathscr{C}(\mu)-\mathscr{B}(\mu)\mathscr{C}(\lambda)\}$$
$$=-\frac{\sinh(2i\eta)}{\sinh(\lambda+\mu-2i\eta)}\{\mathscr{C}(\lambda).\mathscr{B}(\mu)-\mathscr{C}(\mu).\mathscr{B}(\lambda)\}$$
$$=\frac{\sinh(\lambda-\mu)\sinh(\lambda+\mu)}{\sinh^2(2i\eta)-\sinh(\lambda+\mu-2i\eta)}[\mathscr{A}(\lambda),\mathscr{D}(\mu)], \tag{11}$$

$$[\mathscr{B}(\lambda),\mathscr{B}(\mu)]=[\mathscr{C}(\lambda),\mathscr{C}(\mu)]=0, \tag{12}$$

$$[\mathscr{B}(\lambda),\mathscr{C}(\mu)]=\frac{\sinh(2i\eta)}{\sinh(\lambda-\mu)\sinh(\lambda+\mu-2i\eta)}$$
$$\times\{\sinh(\lambda+\mu)[\mathscr{D}(\lambda).\mathscr{A}(\mu)-\mathscr{D}(\mu).\mathscr{A}(\lambda)]$$
$$+\sinh(\lambda-\mu)[.\mathscr{A}(\lambda).\mathscr{A}(\mu)-\mathscr{D}(\mu)\mathscr{D}(\lambda)]\}. \tag{13}$$

From the above commutation relations (13) Sklyanin's transfer matrices

$$\tau(\lambda,\boldsymbol{\omega})=\mathrm{tr}_0(K(-\lambda+2i\eta)U(\lambda,\boldsymbol{\omega}))$$
$$=(1/\sinh(\xi_+))[\sinh(\xi_+-\lambda+2i\eta).\mathscr{A}(\lambda,\boldsymbol{\omega})+\sinh(\xi_++\lambda-2i\eta)\mathscr{D}(\lambda,\boldsymbol{\omega})] \tag{14}$$

are commutative for any values of spectral parameter $[\tau(\lambda),\tau(\mu)]$.

Consequently, $\tau(\lambda,\boldsymbol{\omega})$ generate the infinite number of conserved quantities. For example the Hamiltonian is given by

$$\frac{d}{d\lambda}\,\tau(\lambda,0)|_{\lambda=0}=-\frac{1}{\sinh(2i\eta)}\sum_{n=1}^{L-1}\{\sigma_n^x\sigma_{n+1}^x+\sigma_n^y\sigma_{n+1}^y+\cosh(2i\eta)\sigma_n^z\sigma_{n+1}^z\}$$
$$+\coth(\xi_-)\sigma_1^z-\coth(\xi_+)\sigma_L^z+\text{const.} \tag{15}$$

In the algebraic Bethe ansatz, we construct the simultaneous eigenstates of the conserved quantities by applying the nondiagonal elements (creation operator) of the monodromy matrix to the pseudovacuum. We choose as a pseudovacuum the state whose spins are all up

$$|0\rangle=\otimes_{j=1}^{L}|+\rangle_j. \tag{16}$$

This pseudovacuum is the eigenstate of $\mathscr{A}$ and $\mathscr{D}$ and is annihilated by $\mathscr{C}$

$$\mathscr{A}(\lambda,\boldsymbol{\omega})|0\rangle=a(\lambda,\boldsymbol{\omega})|0\rangle,\quad \mathscr{D}(\lambda,\boldsymbol{\omega})|0\rangle=d(\lambda,\boldsymbol{\omega})|0\rangle,\quad \mathscr{C}(\lambda,\boldsymbol{\omega})|0\rangle=0, \tag{17}$$

where

$$a(\lambda,\boldsymbol{\omega})=\sinh(\xi_-+\lambda)\prod_{n=1}^{L}\{\sinh(\lambda-\omega_n-2i\eta)\sinh(\lambda+\omega_n-2i\eta)\},$$
$$d(\lambda)=\sinh(\xi_--\lambda)\prod_{n=1}^{L}\{\sinh(\lambda-\omega_n)\sinh(\lambda+\omega_n)\}. \tag{18}$$

In other words $\mathscr{B}$ has the role of the creation operator and the eigenstates of the Hamiltonian are of the form $\Pi_{n=1}^{N}.\mathscr{B}(\lambda_n,\boldsymbol{\omega})|0\rangle$ if rapidities λ_n satisfy the Bethe ansatz equations.

In the algebraic Bethe ansatz eigenstates and dual states of eigenstates are, respectively, given by

$$\mathscr{B}(\lambda_L)\cdots\mathscr{B}(\lambda_1)|0\rangle \tag{19}$$

and

$$\langle 0|\mathscr{C}(\mu_1)\cdots\mathscr{C}(\mu_L). \tag{20}$$

III. INHOMOGENEOUS SIX-VERTEX MODEL WITH REFLECTING END

For the scalar products between the eigenstates the following relation holds

$$\langle 0|\mathscr{C}(\mu_1)\cdots\mathscr{C}(\mu_L).\mathscr{B}(\lambda_L)\cdots\mathscr{B}(\lambda_1)|0\rangle=\langle 0|\mathscr{C}(\mu_1)\cdots\mathscr{C}(\mu_L)|\overline{0}\rangle\langle\overline{0}|.\mathscr{B}(\lambda_L)\cdots\mathscr{B}(\lambda_1)|0\rangle, \tag{21}$$

where $|\overline{0}\rangle$ is the quantum state with all spins down $\Pi_{n=1}^{L}|-\rangle$. Note that

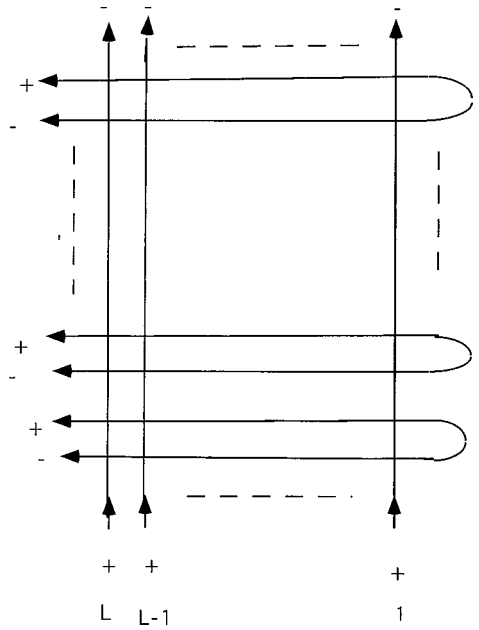

FIG. 1. A six-vertex model with reflecting end: Quantum inverse scattering method formulation. Boundary conditions are all spins: + for the bottom of the lattice, all spins − for the top of the lattice, and + alternate with − for the left of the latlice. The right boundary corresponds to diagonal boundary K matrices.

$$Z_L(\{\lambda\},\{\omega\})=\langle\overline{0}|\mathscr{B}(\lambda_L)\cdots\mathscr{B}(\lambda_1)|0\rangle, \tag{22}$$

is nothing but the partition function of the inhomogeneous six-vertex model on a $L\times 2L$ lattice with domain wall boundary condition for the lower, upper, and left boundaries and reflecting end for the right boundary (see Fig. 1). $\mathscr{B}(\lambda_n)={}_n^0(+|U(\lambda,\omega)|-)_n^0$ where $|+)_n^0$ and $|-)_n^0$ are the nth auxiliary states with spins + and −, respectively, $[{}_n^0(+|$ and ${}_{n(-|}^0$ are dual states with spins + and −, respectively]. Here we assign the auxiliary space to each $B(\lambda_n)$.

Now we derive the recursion relations to the partition function $Z_L(\{\lambda\},\{\omega\})$.

If the inhomogenuity ω_L is choosen to be $\omega_L=-\lambda_1$ then the partition function of the $L\times 2L$ lattice is related to the partiton function of the $L-1\times 2(L-1)$ lattice.

The L operators are regular, i.e.,

$$L_L(0)=-\sinh(2i\eta)P_{0L}\,. \tag{23}$$

Thus

$$\begin{aligned}\mathscr{B}(\lambda_1)\prod_{j=1}^{L}|+\rangle_j\Big|_{\omega_L=-\lambda_1}&=-\sinh(2i\eta)\,{}_1^0(+|L_L(\lambda_1-\omega_L)\cdots L_{L-1}(\lambda_1+\omega_{L-1})P_{0L}|-)_1^0\prod_{j=1}^{L}|+\rangle_j\\&=-\sinh(2i\eta)\,{}_1^0(+|L_L(\lambda_1-\omega_L)\cdots L_{L-1}(\lambda_1+\omega_{L-1})|+)_1^0|-\rangle_L\prod_{j=1}^{L-1}|+\rangle_j\,.\end{aligned} \tag{24}$$

Noting that $|+)_1|+\rangle_n$ is the eigenstate of $L_n(\lambda_1)$

$$L_n(\lambda_1)|+)_1|+\rangle_n=\sinh(\lambda_1-2i\eta)|+)_1|+\rangle_n\,, \tag{25}$$

$$K(\lambda_1,\xi_-)|+)_1=\frac{\sinh(\xi_-+\lambda_1)}{\sinh(\xi_-)}|+)_1\,, \tag{26}$$

and

$$ {}_1\langle +|L_L(\lambda_n-\omega_L)|-\rangle_L = 2\sinh(\lambda_n-\omega_L)\,{}_1\langle +\|-\rangle_L . \tag{27} $$

We obtain

$$ \begin{aligned} \mathscr{B}(\lambda_1)\prod_{j=1}^{L}|+\rangle_j\Big|_{\omega_L=-\lambda_1} &= -\frac{\sinh(\xi_1+\lambda_1)}{\sinh(\xi_-)}\sinh(2i\eta)\sinh(2\lambda_1) \\ &\quad\times\prod_{j=1}^{L-1}\sinh(\lambda_1-\omega_j-2i\eta)\sinh(\lambda_1+\omega_j-2i\eta) \\ &\quad\times|-\rangle_L\prod_{j=1}^{L-1}|+\rangle_j . \end{aligned} \tag{28} $$

Using

$$ L_L(\lambda_n+\omega_L)|-)_n|-\rangle_L = \sinh(\lambda_n+\omega_L-2i\eta)|-)_n|-\rangle_L , \tag{29} $$

together with Eq. (30) and the locality of the L operators we find the relation

$$ \mathscr{B}(\lambda_n)|-\rangle_L = \sinh(\lambda_n+\omega_L-2i\eta)\sinh(\lambda_n-\omega_L)|-\rangle_L\mathscr{B}_{L-1}(\lambda_n), \tag{30} $$

where

$$ \begin{aligned} \mathscr{B}_{L-1}(\lambda_n) &= {}_n\langle +|L_{L-1}(\lambda_n-\omega_{L-1})\cdots L_1(\lambda_n-\omega_1)K(\lambda_n,\xi_-) \\ &\quad\times L_1(\lambda_n+\omega_1)\cdots L_{L-1}(\lambda_n+\omega_{L-1})|-)_n . \end{aligned} \tag{31} $$

Lemma 1-a: The partition function of the model on the $L\times 2L$ lattice is related to the one on the $L-1\times 2(L-1)$ lattice

$$ \begin{aligned} Z_L(\{\lambda\},\{\omega\})|_{\omega_L=-\lambda_1} &= -\frac{\sinh(\xi_-+\lambda_L)}{\sinh(\xi_-)}\sinh(2i\eta)\sinh(2\lambda_L) \\ &\quad\times\prod_{j=1}^{L-1}\sinh(\lambda_L-\omega_j-2i\eta)\sinh(\lambda_L+\omega_j-2i\eta) \\ &\quad\times\prod_{n=1}^{L-1}\sinh(\lambda_n+\omega_L-2i\eta)\sinh(\lambda_n-\omega_L)Z_{L-1}(\{\lambda\},\{\omega\}). \end{aligned} \tag{32} $$

Here $Z_M(\{\lambda\},\{\omega\})$ is the partition function for the model on the $M\times 2M$ lattice

$$ Z_M(\{\lambda\},\{\omega\}) = \prod_{j=1}^{M}{}_j\langle -|\prod_{n=1}^{M}\mathscr{B}_M(\lambda_n,\omega)\prod_{j=1}^{M}|+\rangle_j , \tag{33} $$

which depend on $\lambda_1\sim\lambda_M$ and $\omega_1\sim\omega_M$.

Lemma 1-b: Folowing the same line of argument as above we have other types of recursion relations

$$ \begin{aligned} Z_L(\{\lambda\},\{\omega\})|_{\omega_L=\lambda_1} &= -\frac{\sinh(\xi_--\lambda_L)}{\sinh(\xi_-)}\sinh(2i\eta)\sinh(2\lambda_L) \\ &\quad\times\prod_{j=1}^{L-1}\sinh(\lambda_L-\omega_j-2i\eta)\sinh(\lambda_L+\omega_j-2i\eta) \\ &\quad\times\prod_{n=1}^{L-1}\sinh(\lambda_n-\omega_L-2i\eta)\sinh(\lambda_n+\omega_L)Z_{L-1}(\{\lambda\},\{\omega\}). \end{aligned} \tag{34} $$

Lemma 2:

$$Z_1(\{\lambda\},\{\omega\}) = {}_1\langle \overline{0}| \mathscr{B}(\lambda)|0\rangle_1 \tag{35}$$

is explicitly calculated as

$$Z_1(\{\lambda\},\{\omega\}) = -\frac{\sinh(2i\eta)}{\sinh(\xi_-)}[\sinh(\xi+\lambda)\sinh(\lambda-\omega)+\sinh(\xi-\lambda)\sinh(\lambda+\omega)]. \tag{36}$$

Lemma 3: $\langle \overline{0}| \mathscr{B}(\lambda_L)\cdots\mathscr{B}(\lambda_1)|0\rangle$ depend on each λ_n as

$$\langle \overline{0}| \mathscr{B}(\lambda_L)\cdots\mathscr{B}(\lambda_1)|0\rangle = e^{-2L\lambda_n} P_{2L}(e^{2\lambda_n}), \tag{37}$$

where $P_{2L}(x)$ is the polynomial of degree $2L$.

Proof: This can be proved by straightforward calculations.

IV. DETERMINANT FORMULA FOR THE SIX-VERTEX MODEL WITH REFLECTING END

The lemmas in the last section determine the partition function of the model uniquely.

Theorem: The partition function of the six-vertex model with reflecting end is given by

$$\begin{aligned} Z_L(\{\lambda\},\{\omega\}) = & \prod_{j=1}^{L}\prod_{n=1}^{L} \sinh(\lambda_j-\omega_n-2i\eta)\sinh(\lambda_j-\omega_n)\sinh(\lambda_j+\omega_n-2i\eta)\sinh(\lambda_j+\omega_n) \\ & \times\left[\prod_{j>k}\sinh(\lambda_j-\lambda_k)\sinh(\lambda_j+\lambda_k-2i\eta)\prod_{n>m}\sinh(\omega_n-\omega_m)\sinh(\omega_n+\omega_m)\right]^{-1} \\ & \times \det M, \end{aligned} \tag{38}$$

where

$$M_{jn} = \frac{\sinh(2i\eta)}{\sinh(\xi)\sinh(\lambda_j-\omega_n-2i\eta)\sinh(\lambda_j+\omega_n-2i\eta)} \times \left\{\frac{\sinh(\xi_-+\lambda_j)}{\sinh(\lambda_j+\omega_n)}+\frac{\sinh(\xi_--\lambda_j)}{\sinh(\lambda_j-\omega_n)}\right\}. \tag{39}$$

Proof: This is proved along the same line of argument as in Ref. 5.

V. CONCLUSION

In this paper the determinant formula for the partition function of the six-vertex model with reflecting end is given. It is the determinant formula corresponding to the quantum inverse scattering method with open boundary conditions.

In the model with open boundary conditions, as opposed to the model with periodic boundary conditions, one cannot determine the scalar product from the six-vertex model with reflecting end. To calculate the scalar products and correlation functions for the open XXZ model is interesting.

Transition to criticality in circle maps at the golden mean

Tony W. Dixon[a] and Brian G. Kenny[b]
Department of Physics, University of Western Australia, Western Australia 6907, Australia

(Received 3 February 1998; accepted for publication 12 August 1998)

The one-dimensional circle map is frequently used to model the quasiperiodic route to chaos. In this paper we study the transition to criticality for circle maps with a golden mean winding number in the limit as the order of the map inflection point $N=1+\epsilon$ approaches unity. The solution to the relevant pair of functional equations consists of the subcritical solution together with a perturbative correction of order ϵ. We derive functional relations that the perturbative correction must satisfy and produce numerical evidence that these equations are indeed satisfied. A similar analysis is performed for the golden mean eigenvalue equations. Power law conjugacy of the subcritical solution to order $N=1+\epsilon$ enables us to obtain a closed form solution for the perturbative correction that satisfies the constraint relations exactly. This is compared with the more interesting critical case associated with a circle map whose inflection point is infinitesimally close to unity. © *1998 American Institute of Physics.* [S0022-2488(98)03611-1]

I. INTRODUCTION

Shenker[1] has argued that the main features of the quasiperiodic route to chaos can be modeled by the sine circle map,

$$\theta_{n+1}=f(\theta_n)=\theta_n+\Omega-\frac{k}{2\pi}\sin(2\pi\theta_n).$$

In particular, he showed that Feigenbaum scaling occurred at the golden mean winding number. For $0\leqslant k<1$ the sine map demonstrates *subcritical* behavior due to the leading linear term for small θ. At $k=1$ (*critical*) the map develops a cubic point of inflection at $\theta=0$ and can demonstrate chaotic behavior.

Associated with this universal scaling at the golden mean is a universal function $g(\theta)$ and an associated universal scaling parameter $\alpha(N)$ that satisfy a pair of equivalent functional equations:

$$g(\theta)=\alpha g[g(\alpha^{-2}\theta)], \tag{1a}$$

$$g(\theta)=\alpha^2 g[\alpha^{-2}g(\alpha^{-1}\theta)], \tag{1b}$$

where we follow the notation of Feigenbaum *et al.*[2] If we set the scale so that $g(0)=1$ and assume a power series expansion of the form

$$g(\theta)=1+g_1\theta^N+g_2\theta^{2N}+\cdots, \quad \theta^N\equiv\theta|\theta|^{N-1}, \tag{2}$$

then one can determine the universal function g and its associated constant α for a critical point of order N.[3,4] Rand *et al.*[5,6] have given an equivalent formulation involving two separate analytic functions on different domains.

Linearizing Eqs. (1) about the fixed point $g(\theta)$ (see Ref. 2), one can obtain two equivalent eigenvalue equations for which the largest eigenvalue is the parameter scaling constant $\delta(N)$, and its associated eigenfunction is denoted as $h(\theta)$. In a similar fashion to $g(\theta)$ and α, $h(\theta)$ and δ are also universal, depending only on the order N of the point of inflection.

There is a subcritical solution of Eqs. (1) corresponding to diffeomorphisms of the circle. The equation,

$$g(\theta)=1-\frac{1}{\rho}\,\theta, \tag{3}$$

solves both equations (1a) and (1b) [that is, $N=1$ in the power series expansion (2)] with $\alpha=-1/\rho$; ρ is the golden mean $(\sqrt{5}-1)/2$.

One can generate a family of exact *noncritical* solutions by applying the power conjugacy transformation $g(\theta)\to[g(\theta^N)]^{1/N}$ to the subcritical solution

$$g(\theta)=\left(1-\frac{1}{\rho}\,\theta^N\right)^{1/N}, \quad \theta^N\equiv\theta|\theta|^{N-1}, \tag{4}$$

with associated constant

$$\alpha=-\left(\frac{1}{\rho}\right)^{1/N} \quad \text{or} \quad \alpha^N=-\frac{1}{\rho}. \tag{5}$$

We intend to compare results from these solutions with those obtained for the critical solutions.

Collet *et al.*[7] studied the solution of the period-doubling equation[8,9] in the space of analytic functions of $|x|^{1+\epsilon}$, $\epsilon\geqslant 0$. In a similar fashion, Jonker and Rand[10] used perturbation methods to show that the functional equations associated with the circle map at the golden mean have a solution on the space of analytic functions of $\theta|\theta|^{\epsilon}$, using the formulation of Rand *et al.*[5,6] The existence of a fixed point at $\epsilon=0$ $(N=1)$ greatly simplifies the proof for the golden mean compared to the period-doubling case. We may therefore consider solutions of Eqs. (1) near $N=1$.

This paper is mainly concerned with solutions of Eqs. (1) for small ϵ. We carefully examine the singular transition from subcritical $(\epsilon=0)$ to critical $(\epsilon>0)$ behavior at the golden mean. We derive new functional relations (which characterize this transition) that the first-order corrections to the universal functions g and h must satisfy. The properties of these critical solutions are investigated numerically and compared with those of the class of noncritical functions (4) above.

II. DEVIATION FROM SUBCRITICAL SOLUTION FOR $N=1+\epsilon$

Let us denote an arbitrary solution (noncritical or critical) by $g(N,\theta)$. We want to examine this solution in the case where $N\to 1$ in the infinitesimal limit. If $N=1+\epsilon$, then let us suppose that for small ϵ,

$$g(N,\theta)=g(1+\epsilon,\theta)=g(1,\theta)+\epsilon\mathcal{G}(\theta), \tag{6}$$

where $g(1,\theta)$ is given by (3). If we assume that the normalization is such that $g(N,0)=1$ for all N, then $\mathcal{G}(0)=0$. We do not *a priori* know how α depends on N; numerically we find that the deviation of $\alpha(N)$ from its subcritical value is dependent on ϵ to first order always. If we assume then that

$$\alpha\approx-\frac{1}{\rho}\,(1-c\epsilon), \tag{7a}$$

it follows that

$$\frac{1}{\alpha}\approx-\rho(1+c\epsilon) \tag{7b}$$

to leading order. We expect $c>0$ since $|\alpha|$ decreases as N increases above 1.

For the noncritical functions (4) we know $\alpha=-(1/\rho)^{1/N}$. If $N=1+\epsilon$, for small ϵ,

$$\alpha=-\left(\frac{1}{\rho}\right)^{1/(1+\epsilon)}\approx-\left(\frac{1}{\rho}\right)^{1-\epsilon}\approx-\frac{1}{\rho}\left(1-\epsilon\,\log\frac{1}{\rho}\right).$$

Equating this expression with our first-order approximation (7a) gives

$$c=\log\frac{1}{\rho}. \tag{8}$$

Arneodo and Holschneider[11] have derived the relation

$$\alpha^N(N)=\alpha(1/N), \tag{9}$$

for critical circle maps. We can use this expression to determine the critical value of c as follows. For $N=1+\epsilon$, the LHS of (9) gives

$$\alpha^N(N)\approx-\left(\frac{1}{\rho}\right)^{1+\epsilon}(1-c\epsilon)^{1+\epsilon}\approx-\frac{1}{\rho}\left(1+\epsilon\,\log\frac{1}{\rho}\right)(1-c\epsilon)[1+\epsilon\,\log(1-c\epsilon)]$$
$$\approx-\frac{1}{\rho}\left(1+\epsilon\,\log\frac{1}{\rho}-c\epsilon\right),$$

and the RHS of (9) gives

$$\alpha(1/N)=\alpha(1/(1+\epsilon))\approx\alpha(1-\epsilon)=-\frac{1}{\rho}\,(1+c\epsilon).$$

Equating and rearranging, we find

$$c=\frac{1}{2}\,\log\frac{1}{\rho}. \tag{10}$$

This is the value of the constant c governing the correction to the critical α near $N=1$, a different result to that found for the noncritical α, that is, expression (8).

We note here that by assuming an expansion of the form (2), the following conditions will hold:

$$g(N,1)=1/\alpha,\quad g(N,1/\alpha^2)=1/\alpha^2,$$

$$g'(N,1)=\alpha^{2N-1},\quad g'(N,1/\alpha^2)=\alpha^N.$$

A. Functional equations for $\mathcal{G}(\theta)$

We now proceed to derive constraint equations on $\mathcal{G}(\theta)$ from each of the functional equations (1). In this section, we use the symbol g for the subcritical solution $g(1,\theta)$ and G for the general solutions $g(N,\theta)$.

1. First functional equation

Let $\beta=-1/\rho$, that is, the subcritical value of α at $\epsilon=0$. From (1a) and (7a) we now have

$$G[G(\theta)]=\alpha^{-1}G(\alpha^2\theta), \tag{11a}$$

$$g[g(\theta)]=\beta^{-1}g(\beta^2\theta), \tag{11b}$$

$$\alpha\approx\beta(1-c\epsilon). \tag{11c}$$

To first order in ϵ, the LHS of (11a) is

$$G[G(\theta)]=g[g(\theta)]+\epsilon\mathcal{G}[g(\theta)]+\epsilon\mathcal{G}(\theta)g'[g(\theta)]$$
$$=\beta^{-1}g(\beta^2\theta)+\epsilon\{\mathcal{G}[g(\theta)]+\mathcal{G}(\theta)g'[g(\theta)]\}.$$

As $g(\theta)=1+\beta\theta$, this expression becomes

$$G[G(\theta)]=\beta^{-1}g(\beta^2\theta)+\epsilon[\mathcal{G}(1-\rho^{-1}\theta)-\rho^{-1}\mathcal{G}(\theta)].$$

Also, the RHS of (11a) gives to $O(\epsilon)$

$$\alpha^{-1}G(\alpha^2\theta)=\alpha^{-1}g(\alpha^2\theta)+\alpha^{-1}\epsilon\mathcal{G}(\alpha^2\theta)=\alpha^{-1}g(\alpha^2\theta)+\beta^{-1}\epsilon\mathcal{G}(\beta^2\theta).$$

Equating and rearranging we find

$$\epsilon[\mathcal{G}(1-\rho^{-1}\theta)-\rho^{-1}\mathcal{G}(\theta)+\rho\mathcal{G}(\rho^{-2}\theta)]$$
$$=\alpha^{-1}g(\alpha^2\theta)-\beta^{-1}g(\beta^2\theta)=\alpha^{-1}[1+\alpha^2\beta\theta]-\beta^{-1}[1+\beta^3\theta]=(\alpha^{-1}-\beta^{-1})+\beta\theta(\alpha-\beta)$$
$$=-\rho(1+c\epsilon)+\rho-\rho^{-1}\theta[\rho^{-1}-\rho^{-1}(1-c\epsilon)]=-\epsilon[c\rho+c\rho^{-2}\theta].$$

Therefore, the first-order correction term $\mathcal{G}(\theta)$ must satisfy

$$\mathcal{G}(1-\theta/\rho)-\rho^{-1}\mathcal{G}(\theta)+\rho\mathcal{G}(\rho^{-2}\theta)=-c(\rho+\rho^{-2}\theta). \tag{12}$$

2. Second functional equation

Following the same notation as above, we have, from Eq. (1b),

$$G[\alpha^{-2}G(\theta)]=\alpha^{-2}G(\alpha\theta), \tag{13a}$$

$$g[\beta^{-2}g(\theta)]=\beta^{-2}g(\beta\theta). \tag{13b}$$

To first order in ϵ, (13a) gives, for the LHS and RHS, respectively,

$$G[\alpha^{-2}G(\theta)]=g[\alpha^{-2}g(\theta)]+\epsilon\mathcal{G}[\beta^{-2}g(\theta)]+\epsilon\beta^{-2}\mathcal{G}(\theta)g'[\beta^{-2}g(\theta)],$$

$$\alpha^{-2}G(\alpha\theta)=\alpha^{-2}g(\alpha\theta)+\beta^{-2}\epsilon\mathcal{G}(\beta\theta).$$

Equating these and rearranging, we have

$$-\epsilon\{\mathcal{G}[\beta^{-2}g(\theta)]+\beta^{-2}\mathcal{G}(\theta)g'[\beta^{-2}g(\theta)]-\beta^{-2}\mathcal{G}(\beta\theta)\}=-\alpha^{-2}g(\alpha\theta)+g[\alpha^{-2}g(\theta)]. \tag{14}$$

Again using $g(\theta)=1+\beta\theta$, the quantity in square brackets on the LHS of (14) may be written as

$$\mathcal{G}(\beta^{-2}+\theta\beta^{-1})+\beta^{-1}\mathcal{G}(\theta)-\beta^{-2}\mathcal{G}(\beta\theta)=\mathcal{G}(\rho^2-\rho\theta)-\rho\mathcal{G}(\theta)-\rho^2\mathcal{G}(-\rho^{-1}\theta).$$

Also,

$$\text{RHS of (14)}=-(\alpha^{-2}+\beta\alpha^{-1}\theta)+(1+\beta\alpha^{-2}+\beta^2\alpha^{-2}\theta)$$
$$=-(\alpha^{-2}-1-\beta\alpha^{-2})-\theta(\beta\alpha^{-1}-\beta^2\alpha^{-2})$$
$$=-[-1+\alpha^{-2}(1-\beta)]-\theta[\beta\alpha^{-1}-(\beta/\alpha)^2]$$
$$=-[-1+\rho^2\rho^{-2}(1+2c\epsilon)]-\theta[(1+c\epsilon)-(1+c\epsilon)^2]$$
$$=-2c\epsilon+\theta c\epsilon=-c\epsilon(2-\theta).$$

We have, therefore, a second constraint equation that $\mathcal{G}$ must satisfy:

$$\mathcal{G}(\rho^2-\rho\theta)-\rho\mathcal{G}(\theta)-\rho^2\mathcal{G}(-\rho^{-1}\theta)=c(2-\theta). \tag{15}$$

We anticipate that the equations (12) and (15) are equivalent to the extent that the functional equations (1) are equivalent. The results presented here hold for small $\epsilon<0$ as well.

Jonker and Rand[10] have derived an equation analogous to our first equation (12), using the formulation of Rand *et al.*[5,6] Feigenbaum *et al.*[2] have also studied this transition. They derived constraint equations in what they called the ''standard form,'' where the application of a power conjugacy transformation gives a function g that behaves like $g(\theta)=a+b\theta^{\nu}+\cdots$ at $\theta=0$ and $g(\theta)=c(\theta-1)^{\mu}+\cdots$ at $\theta=1$, with $\mu=\nu=\sqrt{N}$. Our formulation corresponds to the normally encountered situation where g behaves like (2) at $\theta=0$ and is linear at its zero.

3. Evaluation of $\mathcal{G}$ and $\mathcal{G}'$ at special points

Noting again that $\mathcal{G}(0)=0$, substituting $\theta=0$ in Eq. (12) gives $\mathcal{G}(1)=-c\rho$. If we now set $\theta=\rho^2$ in Eq. (12) and use the identity $1-\rho=\rho^2$, then

$$\text{LHS of (12)}=\mathcal{G}(\rho^2)-\rho^{-1}\mathcal{G}(\rho^2)+\rho\mathcal{G}(1)=\rho[\mathcal{G}(1)-\mathcal{G}(\rho^2)],$$

$$\text{RHS of (12)}=-c(\rho+1)=-c/\rho.$$

Therefore, $\mathcal{G}(1)-\mathcal{G}(\rho^2)=-c\rho^{-2}$, or $\mathcal{G}(\rho^2)=c\rho^{-2}+\mathcal{G}(1)=c(\rho^{-2}-\rho)=2c$. Thus

$$\mathcal{G}(\rho^2)=2c, \tag{16a}$$

$$\mathcal{G}(1)=-c\rho. \tag{16b}$$

If we substitute $\theta=0$ in Eq. (15), we again obtain (16a).

It is possible to determine relations involving the derivatives of $\mathcal{G}(\theta)$ at certain points in this way too. However, it is easier to return to the source of these relations, Eq. (6). Differentiating this expression with respect to θ gives

$$g'(1+\epsilon,\theta)-g'(1,\theta)=\epsilon\mathcal{G}'(\theta). \tag{17}$$

At $\theta=1$ we have

$$\begin{aligned}\epsilon\mathcal{G}'(1)&=g'(1+\epsilon,1)-\beta\\&=\alpha^{2N-1}-\beta=-|\alpha|^{1+2\epsilon}+\rho^{-1}=-[\rho^{-1}(1-c\epsilon)]^{1+2\epsilon}+\rho^{-1}\\&=-\rho^{-1}(1-2\epsilon\log\rho^{-1})(1-c\epsilon)+\rho^{-1}=-\rho^{-1}(2\epsilon\log\rho^{-1}-c\epsilon)\\\Rightarrow\mathcal{G}'(1)&=\rho^{-1}[c-2\log\rho^{-1}].\end{aligned} \tag{18}$$

At $\theta=\alpha^{-2}$ (which approaches ρ^2 as $\epsilon\to0$), we have

$$\begin{aligned}\epsilon\mathcal{G}'(\alpha^{-2})&=g'(1+\epsilon,\alpha^{-2})-\beta\\&=\alpha^{N}-\beta=-[\rho^{-1}(1-c\epsilon)]^{1+\epsilon}+\rho^{-1}=-\rho^{-1}(1-\epsilon\log\rho^{-1})(1-c\epsilon)+\rho^{-1}\\&=-\rho^{-1}(\epsilon\log\rho^{-1}-c\epsilon)\\\Rightarrow\mathcal{G}'(\rho^2)&=\rho^{-1}[c-\log\rho^{-1}].\end{aligned} \tag{19}$$

As $g'(N,0)=0$ for all $N>1$, we can see from Eq. (17) that

$$\mathcal{G}'(0)=\frac{1}{\rho\epsilon}\to\infty,\quad\text{as}\quad\epsilon\to0.$$

The correction function $\mathcal{G}$ is thus singular at $\theta=0$. In this sense, the onset of criticality is singular.

B. Exact solution for $\mathcal{G}(\theta)$

Using the exact function $g(N,\theta)$ given by Eq. (4), the $\mathcal{G}(\theta)$ function can be expressed in the form

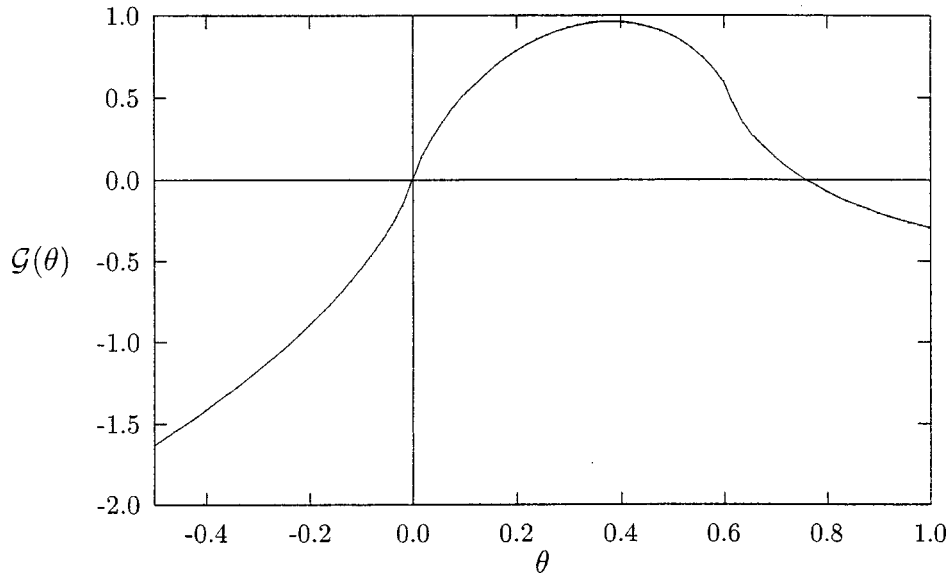

FIG. 1. The exact first-order correction to the subcritical solution for a noncritical function $g(\theta)$ of order N infinitesimally greater than unity.

$$\mathcal{G}(\theta)=\lim_{N\to 1}\frac{\left(1-\frac{1}{\rho}\,\theta^N\right)^{1/N}-\left(1-\frac{1}{\rho}\,\theta\right)}{N-1}=\frac{d}{dN}\,g(N,\theta)\bigg|_{N=1}=\lim_{N\to 1}\frac{d}{dN}\left(1-\frac{1}{\rho}\,\theta^N\right)^{1/N}.$$

Writing

$$F(N,\theta)=\left(1-\frac{1}{\rho}\,\theta^N\right)$$

and

$$\log g(N,\theta)=\frac{1}{N}\log F(N,\theta),$$

we can differentiate $\log g(N,\theta)$ with respect to N, giving

$$\frac{g'(N,\theta)}{g(N,\theta)}=\frac{1}{N}\,\frac{F'(N,\theta)}{F(N,\theta)}-\frac{1}{N^2}\log F(N,\theta)$$

$$\Leftrightarrow g'(N,\theta)=-\frac{1}{\rho N}\left(\frac{d}{dN}\,\theta^N\right)\frac{F(N,\theta)^{1/N}}{F(N,\theta)}-\frac{1}{N^2}\,F(N,\theta)^{1/N}\log F(N,\theta)$$

$$=-\frac{1}{\rho N}\,\theta^N\log\theta\,\frac{F(N,\theta)^{1/N}}{F(N,\theta)}-\frac{1}{N^2}\,F(N,\theta)^{1/N}\log F(N,\theta).$$

Letting $N\to 1$ gives us the solution

$$\mathcal{G}(\theta)=-(\theta/\rho)\log|\theta|-(1-\theta/\rho)\log|1-\theta/\rho|. \tag{20}$$

This solution for $\mathcal{G}(\theta)$ satisfies both of the functional relations (12) and (15) exactly, when c is given by (8). A plot of this noncritical solution is given in Fig. 1. The function values and derivatives at $\theta=\rho^2$ and $\theta=1$ agree with the expected results (16), (18), and (19). One can see from (20) that $\mathcal{G}'(\theta)\approx-(1/\rho)\log|\theta|$ as $\theta\to 0$; that is, the slope of $\mathcal{G}$ is infinite at zero. The logarithmic behavior explains why the singularity is not immediately apparent to the human eye.

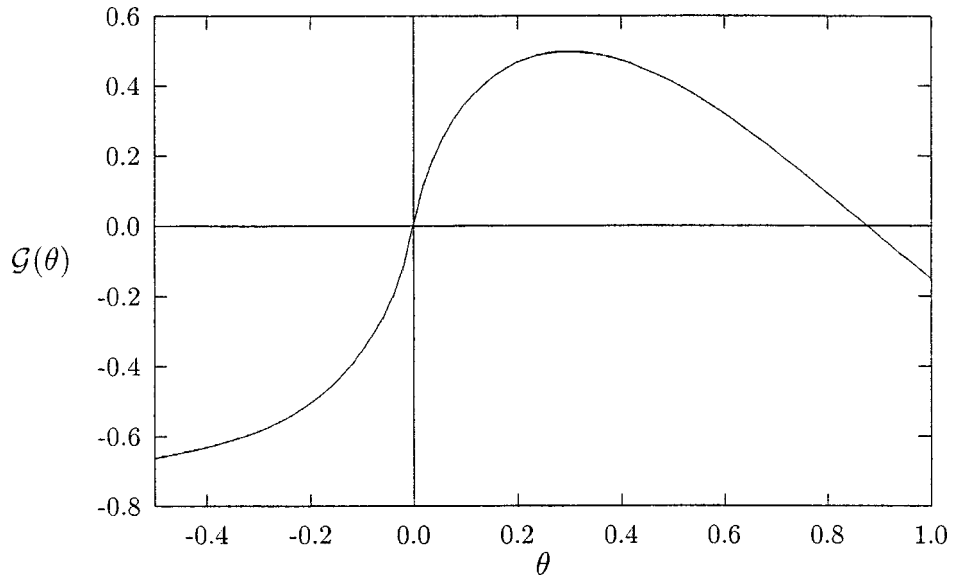

FIG. 2. The first-order correction to the subcritical solution for a critical function $g(\theta)$ with critical point order N infinitesimally greater than unity.

C. Critical $\mathcal{G}(\theta)$

To obtain the critical correction function, we can numerically solve the functional equation (1a) for small ϵ with an expansion of the form (2), and rearrange Eq. (6) to give

$$\mathcal{G}(\theta)=[g(1+\epsilon,\theta)-g(1,\theta)]/\epsilon.$$

A plot of the critical $\mathcal{G}(\theta)$ for $\epsilon=10^{-4}$ is given in Fig. 2, where c is given by (10). Numerical investigations with critical functions of order $N=1+\epsilon$ with ϵ small, have verified that both Eqs. (12) and (15) are satisfied to $O(\epsilon)$. Similarly, the numerical function values are in agreement with predicted results. Comparing the critical and noncritical functions $\mathcal{G}(\theta)$, we see that they are qualitatively similar. The singularity at zero is more apparent in the critical case, though. Also, the critical correction function is regular at $\theta=\rho$, unlike the noncritical plot.

D. Iteration of circle maps

Hu *et al.*[3] and Delbourgo and Kenny[12] have studied the dependence of the critical golden mean scaling constants using the nonanalytic circle map,

$$\theta_{n+1}=f(\theta_n)=\Omega+\theta_n|2\theta_n|^{N-1},\quad -1/2\leqslant\theta<1/2.$$

Reexpressing this map as

$$\theta_{n+1}=f(\theta_n)=\Omega+\theta_n|2\theta_n|^{\epsilon},\quad -1/2\leqslant\theta<1/2, \tag{21}$$

we can find the critical $\mathcal{G}(\theta)$ directly from circle maps.

Shenker[1] showed that one can define a sequence of approximations $\overline{f}_n(\theta)$ to the golden mean universal function, given by

$$\overline{f}_n(\theta)=\alpha^n[f_{K,\Omega}^{F_n}(\alpha^{-n}\theta)-F_{n-1}],$$

where F_n is the nth Fibonacci number. By redefining these universal function approximants in terms of $g_n(\theta)=\alpha\overline{f}_n(\theta)$, and rescaling to get $g_n(0)=1$, we are then able to use Eq. (6) to generate a sequence of $\mathcal{G}_n(\theta)$ that converges to the critical $\mathcal{G}(\theta)$ derived from the functional equations (1) for small ϵ. A plot of $\mathcal{G}(\theta)$ derived from circle maps is exactly the same as Fig. 2; the critical function generated via the circle map (21) is exactly the same as the critical function

generated from the functional equation (1a) using the approach described in the previous section, as one would expect due to the universality arguments developed by Feigenbaum *et al.*[2]

III. DEVIATION FROM SUBCRITICAL EIGENFUNCTION FOR $N=1+\epsilon$

We now focus on the behavior of the linearized function $h(\theta)$ associated with δ at the transition to criticality. This eigenfunction is found by linearizing Eqs. (1) about the fixed point $g(\theta)$:

$$\lambda h[g(\theta)]+h(\theta)g'[g(\theta)]=\frac{\lambda^2}{\alpha}h(\alpha^2\theta), \tag{22a}$$

$$h[\alpha^{-2}g(\theta)]+\frac{\lambda}{\alpha^2}h(\theta)g'[\alpha^{-2}g(\theta)]=\frac{\lambda^2}{\alpha^2}h(\alpha\theta). \tag{22b}$$

The largest eigenvalue $|\lambda|>1$ is δ, the universal constant governing scaling of the parameter space.

Jonker and Rand[10] have shown analytically that for small ϵ, $\delta(N)$ behaves no worse than

$$\delta(1+\epsilon)=\delta(1)+O(\epsilon).$$

Numerically one finds[6]

$$\delta(1+\epsilon)=\delta(1)+O(\epsilon^2).$$

Our numerical studies[13,14] have shown, however, that the following stronger relation appears to hold for all N:

$$\delta(N)=\delta(1/N). \tag{23}$$

Using this conjectured relation, we can illustrate the second-order dependence of δ on ϵ.

We may assume that for small ϵ, $\delta(N)$ deviates from its subcritical value as follows:

$$\delta(1+\epsilon)=-\frac{1}{\rho^2}(1+d\epsilon+e\epsilon^2).$$

Substituting $1/N\approx 1-\epsilon$ into this equation and using the relation (23) above to equate terms gives $d=0$, and therefore $\delta(N)$ depends on ϵ to second order near $N=1$, in agreement with other numerical findings.

We note that recently Briggs *et al.*[4] have shown numerically that, as $N\to\infty$,

$$\delta(N)\to -4.121\,326(\pm 4).$$

For the class of noncritical functions, however,

$$\delta(N)=-\alpha^{2N}=-\frac{1}{\rho^2},$$

which is independent of N or ϵ.

A. Functional equations for $\mathscr{H}(\theta)$

To determine the behavior of $h(\theta)$ as $N\to 1$, we can treat each of the linearized equations (22) in a similar manner to our treatment of Eqs. (1) above. If we assume that

$$h(N,\theta)=h(1,\theta)+\epsilon\mathscr{H}(\theta), \tag{24}$$

where

$$h(1,\theta)=1 \quad \text{and} \quad \mathscr{H}(0)=0,$$

we can show that the following equations are satisfied to $O(\epsilon)$:

$$\rho^2 \mathscr{H}(\theta) + \rho \mathscr{H}\left(1 - \frac{\theta}{\rho}\right) - \mathscr{H}\left(\frac{\theta}{\rho^2}\right) = c + \rho^3 \mathscr{G}'\left(1 - \frac{\theta}{\rho}\right), \tag{25}$$

$$\mathscr{H}(\rho^2 - \rho\theta) + \frac{1}{\rho}\,\mathscr{H}(\theta) - \frac{1}{\rho^2}\,\mathscr{H}\left(-\frac{\theta}{\rho}\right) = 2c + \mathscr{G}'(\rho^2 - \rho\theta). \tag{26}$$

Again, we expect that these relations are equivalent to the extent that the linearized equations (22) are equivalent.

B. Evaluation of $\mathscr{H}$ at special points

Substituting $\theta = 0$ and $\theta = \rho^2$ into Eq. (25), we can show

$$\mathscr{H}(1) = c + \rho^3 \mathscr{G}'(1), \tag{27a}$$

$$\mathscr{H}(\rho^2) = 2c + \mathscr{G}'(\rho^2), \tag{27b}$$

where $\mathscr{G}'(1)$ and $\mathscr{G}'(\rho^2)$ are given by (18) and (19), respectively.

C. Exact solution for $\mathscr{H}(\theta)$

Quite generally, there is a class of solutions to the eigenvalue equations (22) of the form[2]

$$h_n(\theta) = [g(\theta)]^n - \alpha^{n-1}\theta^n g'(\theta), \tag{28}$$

which result from the invariance of the renormalization group functional equations under power conjugacy transformations. These (smooth) coordinate changes generate perturbations that are eigenfunctions of both equations (22). (See Feigenbaum[8,9] or Feigenbaum and Kenway[15] for a treatment of the analogous period-doubling case.) We can use these exact eigenfunctions to derive an exact correction function $\mathscr{H}(\theta)$.

First note that for our noncritical family we have

$$g'(N,\theta) = \alpha^N \theta^{N-1}[1 + \alpha^N \theta^N]^{(1-N)/N} = \alpha^N \theta^{N-1}[g(N,\theta)]^{1-N}. \tag{29}$$

Substituting this expression into (28) gives

$$h_n(N,\theta) = [g(N,\theta)]^n - (\alpha\theta)^{n-1}\alpha^N \theta^N [g(N,\theta)]^{1-N}.$$

If we now choose $n = 1$ (to retain the θ^N dependence of h) and omit the subscript, then

$$h(N,\theta) = g(N,\theta) - \alpha^N \theta^N [g(N,\theta)]^{1-N} = \frac{[g(N,\theta)]^N - \alpha^N \theta^N}{[g(N,\theta)]^{N-1}} = [g(N,\theta)]^{1-N} = \left[1 - \frac{1}{\rho}\,\theta^N\right]^{(1-N)/N}.$$

As we did with the exact $\mathscr{G}(\theta)$ function, we can now proceed to derive an exact solution for $\mathscr{H}(\theta)$, using the equation above for $h(N,\theta)$. Note that $h(N,\theta)$ is singular at $\theta = \rho^{1/N}$. We can express $\mathscr{H}(\theta)$ in the form

$$\mathscr{H}(\theta) = \lim_{N \to 1} \frac{h(N,\theta) - h(1,\theta)}{N-1} = \frac{d}{dN}\, h(N,\theta)\bigg|_{N=1}.$$

Again, defining

$$F(N,\theta) = \left(1 - \frac{1}{\rho}\,\theta^N\right)$$

and

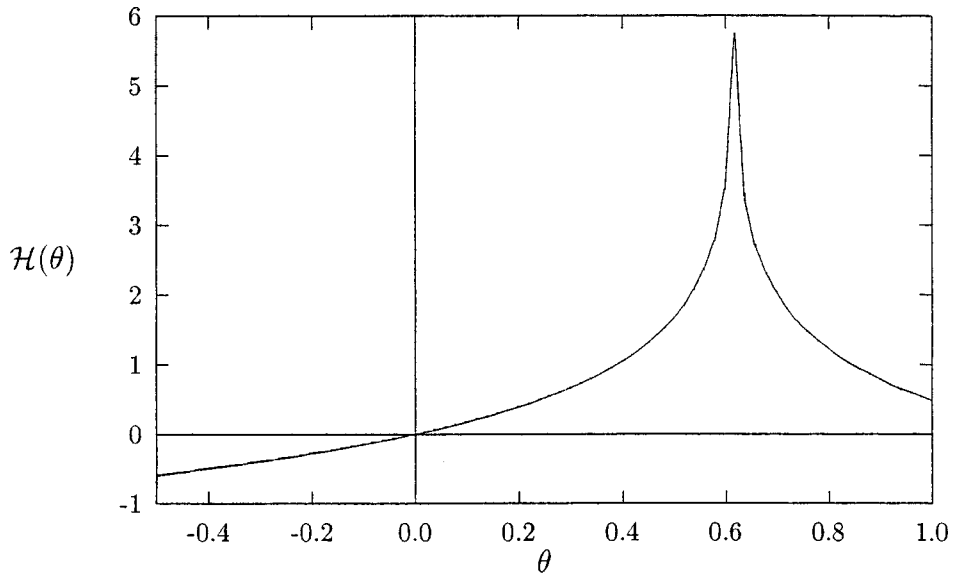

FIG. 3. The exact first-order correction to the subcritical solution for a noncritical $h(\theta)$ of order N infinitesimally greater than unity.

$$\log h(N,\theta)=\frac{1-N}{N}\log F(N,\theta),$$

we can differentiate $\log h(N,\theta)$ with respect to N to get

$$\frac{h'(N,\theta)}{h(N,\theta)}=\frac{1-N}{N}\frac{F'(N,\theta)}{F(N,\theta)}-\frac{1}{N^2}\log F(N,\theta)$$

$$\Leftrightarrow h'(N,\theta)=-\frac{1-N}{\rho N}\left(\frac{d}{dN}\,\theta^N\right)\frac{F(N,\theta)^{(1-N)/N}}{F(N,\theta)}-\frac{1}{N^2}F(N,\theta)^{(1-N)/N}\log F(N,\theta)$$

$$=\frac{N-1}{\rho N}\,\theta^N\log\theta\,\frac{F(N,\theta)^{(1-N)/N}}{F(N,\theta)}-\frac{1}{N^2}F(N,\theta)^{(1-N)/N}\log F(N,\theta)$$

$$=\frac{N-1}{\rho N}\,\theta^N\log\theta\left(1-\frac{1}{\rho}\,\theta^N\right)^{(1-2N)/N}-\frac{1}{N^2}F(N,\theta)^{(1-N)/N}\log F(N,\theta).$$

Letting $N\to 1$ gives

$$\mathcal{H}(\theta)=-\log|1-\theta/\rho|.$$

This exact expression for $\mathcal{H}(\theta)$ satisfies both of the functional equations (25) and (26), when c is given by (8). A plot of this function is given in Fig. 3. Note that the exact $\mathcal{H}(\theta)$ is singular at $\theta=\rho$. The function values at $\theta=1$ and $\theta=\rho^2$ agree with the predicted results (27).

D. Critical $\mathcal{H}(\theta)$

In order to numerically determine the critical $\mathcal{H}$, we first solve for the eigenfunction h for small ϵ using (22a). We then simply rearrange Eq. (24) in terms of $\mathcal{H}$. A plot of the critical $\mathcal{H}(\theta)$ for $\epsilon=10^{-4}$ is given in Fig. 4 when c is given by (10). Numerical investigations verify that the relations (25) and (26) are satisfied by critical functions to $O(\epsilon)$. Similarly, the numerical function values satisfy (27). However, unlike the noncritical case in Fig. 3, the critical $\mathcal{H}$ is not singular. In fact, the functions are quite dissimilar, unlike those for the correction function $\mathcal{G}$.

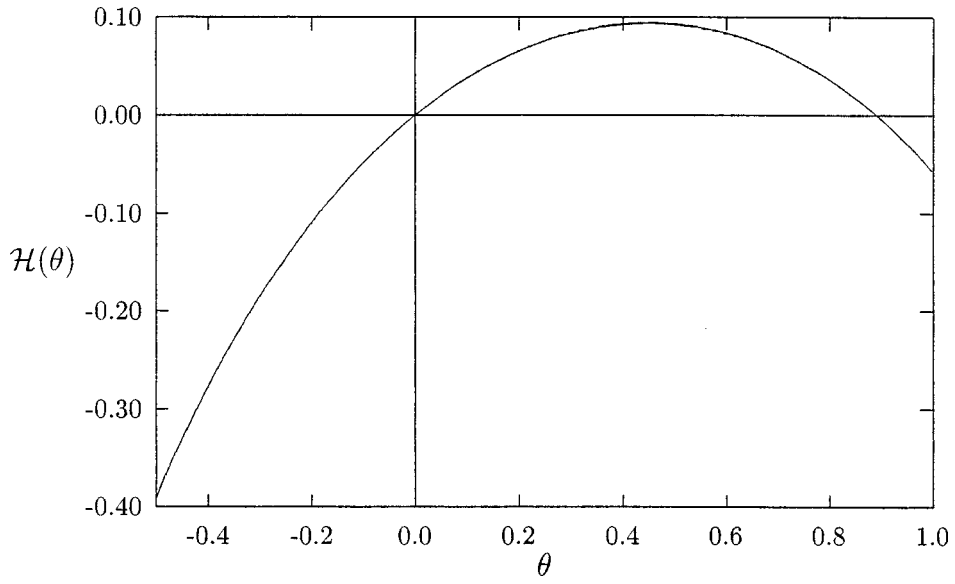

FIG. 4. The first-order correction to the subcritical solution for a critical eigenfunction $h(\theta)$ of order N infinitesimally greater than unity.

IV. CONCLUSION

We have shown that the transition from subcritical to critical dynamics in quasiperiodic systems is a singular phenomenon. We have derived a pair of functional relations, which, together with their respective linearizations, characterize this transition at the golden mean. We have compared the properties of the critical functions with those of the power conjugacy class of the subcritical solution, and in doing so, we have analytically derived the first-order corrections to the subcritical α for both critical and noncritical functions.

An analogous analysis of other quadratic irrationals could be carried out; for example, the silver mean, where three functional equations characterize the transition to chaos. A similar analysis would also describe the behavior near a Siegel boundary.[16,17]

(Received 9 December 1997; accepted for publication 26 May 1998)

Three families of dynamical *r*-matrices are explicitly constructed by means of constrained flows of nonlinear evolution equations (NLEE) associated with polynomial second-order spectral problems. The dynamical classical Yang–Baxter equations for the three linear *r*-matrix algebras are presented with explicit expression for the extra term. The separation variables and the Jacobi inversion problems for the x- and t_n-constrained flow of the NLEEs are found. The factorization of NLEE allows us to obtain the Jacobi inversion problem for the NLEE by combining the above two Jacobi inversion problems. This provides a method of separation of variables to solve the NLEEs. © *1998 American Institute of Physics.* [S0022-2488(98)01611-9]

I. INTRODUCTION

In recent years the study of completely integrable systems admitting a classical *r*-matrix Poisson structure with dynamical *r*-matrix has attracted some attention.[1–7] A family of systems with parabolic separable potentials and parabolic dynamical *r*-matrices has been presented by recurrence relation in Ref. 3. An approach of additive deformation to a quite general family of dynamical *r*-matrices including parabolic and elliptic *r*-matrices is described in Refs. 5 and 6. The stimulus for considering such recurrence relation and additive deformation was inspired by constrained flows of Korteweg–de Vries (KdV) and coupled KdV equations. However, explicit expressions for the family both of integrable systems and of parabolic and elliptic dynamical *r*-matrices have not been carried out. It was pointed out in Refs. 7 and 8 that various constrained flows of soliton equations can be directly used to construct some kinds of dynamical *r*-matrices, since their Lax representations can always be deduced from the adjoint representation of the spectral problem.[9] The first and primary aim of this paper is to construct explicit expressions for three families of integrable systems and their dynamical *r*-matrices directly from the constrained flows of nonlinear evolution equations (NLEEs) associated with two polynomial second-order spectral problems considered in Ref. 10. The first and third families of integrable systems possess elliptic but different dynamical *r*-matrices; the second one has the parabolic dynamical *r*-matrices. We also discuss the dynamical classical Yang–Baxter equations satisfied by the three dynamical *r*-matrix algebras and present a general way to find the explicit expressions for the extra term.[4]

The second aim of this paper is to establish the Jacobi inversion problem for the NLEEs. For the Lax matrices satisfying *r*-matrix algebra with the *r*-matrix of *XXX*, *XXZ*, and *XYZ* type, the problem of determining variables of separation has been essentially solved.[11–14] By using the Lax representation, the separation variables and Jacobi inversion problems for the x- and t_n-constrained flows are found. It was shown in Refs. 15–17 that the soliton equation can always be factorized by x- and t_n-constrained flow. The factorization of the NLEEs together with a combination of the above two Jacobi inversion problems gives rise to the Jacobi inversion problem for the NLEE. The standard Jacobi inversion techniques allow us to find the solution of the NLEE in terms of the Riemann theta function.[18] Therefore, this provides a method of separation of variables to solve the NLEE. The paper is organized as follows.

 © 1998 American Institute of Physics

In Sec. II, for our purposes we reproduce two hierarchies of NLEEs associated with the polynomial second-order spectral problem and its modification, which were considered in Ref. 17, in the framework of zero-curvature representation. In Sec. III we study the first x-constrained flow and t_n-constrained flow and obtain x-finite-dimensional integrable Hamiltonian systems (FDIHS) and t_n-FDIHS. The NLEE is factorized by these two commuting x- and t_n-FDIHSs. In fact we obtain a family of x-FDIHSs depending on the order m of the polynomial. We deduce the Lax representation for the x- and t_n-FDIHSs from the adjoint representation of the spectral problem. Then we construct the classical Poisson structure for the family of x-FDIHSs and obtain explicitly a family of elliptic dynamical r-matrices. Finally we introduce the dynamical classical Yang–Baxter equations which are valid for the dynamical r-matrix algebra. We present a general way to obtain the explicit form for the extra term in the Yang–Baxter equations. In Sec. IV we determine canonically conjugated separation variables and the Jacobi inversion problem for the x- and t_n-FDIHSs by means of their Lax representation. By combining these two Jacobi inversion problems the factorization of the NLEE allows us to find the Jacobi inversion problem for the NLEE. In Secs. V and VI we consider the second x-constrained flow for the first hierarchy of the NLEEs and first x-constrained flow for the second hierarchy of the NLEEs, and present explicit expressions for the second and third families of x-FDIHSs and parabolic and elliptic dynamical r-matrices, respectively. Then we apply the same procedure as in Secs. III and IV to them. In Sec. VII a summary is presented.

II. TWO HIERARCHIES OF NONLINEAR EVOLUTION EQUATIONS

In this section we recall two hierarchies of nonlinear evolution equations (NLEEs) associated with the polynomial second-order spectral problem and its modification. These NLEEs have been described in Ref. 10. For our purpose we rederive these NLEEs in the framework of zero-curvature representation and present some formulas in different form.

A. The first hierarchy of NLEEs

Consider the following polynomial second-order spectral problem,[10]

$$\psi_x = U(u,\lambda)\psi, \quad U(u,\lambda) = \begin{pmatrix} 0 & 1 \\ -\sum_{i=0}^{m} u_i \lambda^i & 0 \end{pmatrix}, \quad \psi = \begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix}, \tag{2.1}$$

where $u_m = -1$, $u = (u_{m-1},\ldots,u_0)^T$. The adjoint representation of (2.1) is[19]

$$V_x = [U,V] \equiv UV - VU. \tag{2.2}$$

Set

$$V = \sum_{i=0}^{\infty} V_i \lambda^{-i}, \quad V_i = \begin{pmatrix} a_i & b_i \\ c_i & -a_i \end{pmatrix}. \tag{2.3}$$

Equation (2.2) yields

$$a_0 = \cdots = a_m = b_0 = \cdots = b_{m-1} = 0, \quad b_m = 1, \quad b_{m+1} = \tfrac{1}{2} u_{m-1},$$

$$a_{m+1} = -\tfrac{1}{4} u_{m-1,x}, \quad c_0 = 1, \quad c_1 = -\tfrac{1}{2} u_{m-1},\ldots,$$

and, in general,

$$\begin{pmatrix} b_{k+m} \\ \vdots \\ b_{k+1} \end{pmatrix} = L \begin{pmatrix} b_{k+m-1} \\ \vdots \\ b_k \end{pmatrix}, \tag{2.4a}$$

$$a_k = -\frac{1}{2} b_{k,x}, \quad c_k = -\frac{1}{2} b_{k,xx} - \sum_{i=0}^{m} u_i b_{k+i}, \quad k = 1,2,\ldots, \tag{2.4b}$$

where

$$L=\begin{pmatrix} L_{m-1} & L_{m-2} & \cdots & L_1 & L_0 \\ 1 & 0 & \cdots & 0 & 0 \\ 0 & 1 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 1 & 0 \end{pmatrix},$$

$$L_0=\tfrac{1}{4}D^2+u_0-\tfrac{1}{2}D^{-1}u_{0,x}, \quad L_i=u_i-\tfrac{1}{2}D^{-1}u_{i,x}, \quad i=1,\ldots,m-1,$$

$$D=\frac{\partial}{\partial x}, \quad DD^{-1}=D^{-1}D=1. \tag{2.5}$$

Take

$$V^{(n)}(u,\lambda)=\sum_{i=0}^{n} V_i\lambda^{n-i}+\begin{pmatrix} 0 & 0 \\ -\sum_{k=1}^{m}\lambda^{m-k}\sum_{i=1}^{k} b_{n+i}u_{m-k+i} & 0 \end{pmatrix}, \tag{2.6}$$

and define

$$\psi_{t_n}=V^{(n)}(u,\lambda)\psi. \tag{2.7}$$

Then the compatibility condition of (2.1) and (2.7) gives rise to the zero-curvature representation[19]

$$U_{t_n}-V_x^{(n)}+[U,\ V^{(n)}]=0, \quad n=1,2,\ldots. \tag{2.8}$$

Equation (2.8) leads to the following hierarchy of NLEEs which can be written as an infinite-dimensional Hamiltonian system,

$$u_{t_n}=\begin{pmatrix} u_{m-1} \\ \vdots \\ u_0 \end{pmatrix}_{t_n}=J\begin{pmatrix} b_{n+m} \\ \vdots \\ b_{n+1} \end{pmatrix}=J\,\frac{\delta H_n}{\delta u}, \quad n=1,2,\ldots, \tag{2.9}$$

where the Hamiltonian H_n and Hamiltonian operator J are given by

$$J=\begin{pmatrix} 0 & 0 & \cdots & 0 & 2D \\ 0 & 0 & \cdots & 2D & J_{m-1} \\ 0 & 0 & \cdots & J_{m-1} & J_{m-2} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 2D & J_{m-1} & \cdots & J_1 & J_0 \end{pmatrix},$$

$$J_i=-u_{i,x}-2u_iD, \quad i=0,1,\ldots,m-1, \quad H_n=\frac{2}{m-2n-2}\sum_{i=1}^{m} iu_ib_{n+i+1}.$$

Furthermore V satisfies the adjoint representation of (2.7):[19]

$$V_{t_n}=[V^{(n)},\ V], \quad n=1,2,\ldots. \tag{2.10}$$

Under zero boundary condition we have

$$\frac{\delta\lambda}{\delta u}=(\lambda^{m-1}\psi_1^2,\ldots,\psi_1^2)^T, \quad L\,\frac{\delta\lambda}{\delta u}=\lambda\,\frac{\delta\lambda}{\delta u}. \tag{2.11}$$

B. The second hierarchy of NLEEs

Consider the following modified polynomial second-order spectral problem:[10]

$$\psi_x = U(u,\lambda)\psi, \quad U(u,\lambda) = \begin{pmatrix} u_0 & \lambda \\ -\sum_{i=1}^{m} u_i \lambda^{i-1} & -u_0 \end{pmatrix}, \quad \psi = \begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix}, \tag{2.12}$$

where $u_m = -1$, $u = (u_0,\ldots,u_{m-1})^T$. Equations (2.2) and (2.3) yield

$$a_0 = \cdots = a_{m-2} = b_0 = \cdots = b_{m-3} = 0, \quad b_{m-2} = 1, \quad b_{m-1} = \tfrac{1}{2}u_{m-1},$$

$$a_{m-1} = u_0, \quad c_0 = 1, \quad c_1 = -\tfrac{1}{2}u_{m-1},\ldots,$$

and, in general,

$$\begin{pmatrix} 2a_{k+1} \\ -b_{k+1} \\ \vdots \\ -b_{k+m-1} \end{pmatrix} = L \begin{pmatrix} 2a_k \\ -b_k \\ \vdots \\ -b_{k+m-2} \end{pmatrix}, \tag{2.13a}$$

$$c_{k+1} = a_{k,x} - \sum_{i=1}^{m} u_i b_{k+i-1}, \quad k = 1,2,..., \tag{2.13b}$$

where

$$L = \begin{pmatrix} 0 & -2u_0 + D & 0 & \ldots & 0 & 0 \\ 0 & 0 & 1 & \ldots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \ldots & 0 & 1 \\ L_0 & L_1 & L_2 & \ldots & L_{m-2} & L_{m-1} \end{pmatrix},$$

$$L_0 = \tfrac{1}{4}D + \tfrac{1}{2}D^{-1}u_0 D, \quad L_i = \tfrac{1}{2}u_i + \tfrac{1}{2}D^{-1}u_i D, \quad i = 1,...,m-1.$$

Take

$$V^{(n)}(u,\lambda) = \sum_{i=0}^{n} V_i \lambda^{n-i} + \begin{pmatrix} 0 & -b_n \\ \sum_{j=1}^{m-1} \lambda^{j-1} \sum_{i=j+1}^{m} b_{n+i-j-1} u_i & 0 \end{pmatrix}, \tag{2.14}$$

and define

$$\psi_{t_n} = V^{(n)}(u,\lambda)\psi. \tag{2.15}$$

Then the zero-curvature representation (2.8) leads to the following hierarchy of NLEEs which can also be written as an infinite-dimensional Hamiltonian system

$$u_{t_n} = \begin{pmatrix} u_0 \\ \vdots \\ u_{m-1} \end{pmatrix}_{t_n} = J \begin{pmatrix} 2a_n \\ -b_n \\ \vdots \\ -b_{n+m-2} \end{pmatrix} = J \frac{\delta H_n}{\delta u}, \quad n = 1,2,..., \tag{2.16}$$

where the Hamiltonian H_n and Hamiltonian operator J are given by

$$J=\begin{pmatrix} \frac{1}{2}D & 0 & 0 & \cdots & 0 & 0 \\ 0 & J_2 & J_3 & \cdots & J_{m-1} & -2D \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & J_{m-1} & -2D & \cdots & 0 & 0 \\ 0 & -2D & 0 & \cdots & 0 & 0 \end{pmatrix},$$

$$J_i=u_{i,x}+2u_iD, \quad i=0,1,...,m-1, \quad H_n=\frac{2}{m-2n-2}\left[a_{n,x}-\sum_{i=1}^{m} iu_ib_{n+i-1}\right].$$

Also we have

$$\frac{\delta\lambda}{\delta u}=(2\psi_1\psi_2,\psi_1^2,\ldots,\lambda^{m-2}\psi_1^2)^T, \quad L\,\frac{\delta\lambda}{\delta u}=\lambda\,\frac{\delta\lambda}{\delta u}. \tag{2.17}$$

III. THE FIRST FAMILY OF DYNAMICAL *r*-MATRICES

A. The factorization of the NLEEs (2.9)

We first recall the constrained flows and factorization of the NLEEs. The *x*-constrained flow of NLEEs consists of the equations obtained from the spectral problem for N distinct λ_j and of restriction of the variational derivatives for conserved quantities H_k (for any fixed k) and λ_j:[15,16,20]

$$\begin{pmatrix}\psi_{1j}\\ \psi_{2j}\end{pmatrix}_x=U(u,\lambda_j)\begin{pmatrix}\psi_{1j}\\ \psi_{2j}\end{pmatrix}, \quad j=1,...,N, \tag{3.1a}$$

$$\frac{\delta H_k}{\delta u}-\frac{1}{2}\sum_{j=1}^{N}\frac{\delta\lambda_j}{\delta u}=0. \tag{3.1b}$$

The t_n-constrained flow of NLEEs consists of the equations obtained from the evolution equation of the eigenfunction for N distinct λ_j and of the NLEE itself:[15,16]

$$\begin{pmatrix}\psi_{1j}\\ \psi_{2j}\end{pmatrix}_{t_n}=V^{(n)}(u,\lambda_j)\begin{pmatrix}\psi_{1j}\\ \psi_{2j}\end{pmatrix}, \quad j=1,...,N, \tag{3.2a}$$

$$u_{t_n}=J\,\frac{\delta H_n}{\delta u}. \tag{3.2b}$$

Hereafter we denote the inner product in $\mathbf{R}^N$ by $\langle .,. \rangle$ and $\Psi_i=(\psi_{i1},\ldots,\psi_{iN})^T$, $i=1,2$, $\Lambda=\mathrm{diag}\,(\lambda_1,...,\lambda_N)$. By means of (2.11), (3.1) for NLEE (2.9) can be written as

$$\Psi_{1,x}=\Psi_2, \quad \Psi_{2,x}=\Lambda^m\Psi_1-\sum_{i=0}^{m-1}u_i\Lambda^i\Psi_2, \tag{3.3a}$$

$$\begin{pmatrix}b_{m+k}\\ \vdots\\ b_{k+1}\end{pmatrix}=\frac{1}{2}\begin{pmatrix}\langle\Lambda^{m-1}\Psi_1,\Psi_1\rangle\\ \vdots\\ \langle\Psi_1,\Psi_1\rangle\end{pmatrix}. \tag{3.3b}$$

For $k=m$, (3.3b) reads

$$\begin{pmatrix} b_{2m} \\ \vdots \\ b_{m+k} \\ \vdots \\ b_{m+1} \end{pmatrix} = \begin{pmatrix} \frac{1}{2}u_0 + \sum_{i=1}^{m-1} L_i b_{m+i} \\ \vdots \\ \frac{1}{2}u_{m-k} + \sum_{i=1}^{k-1} L_{m-k+i} b_{m+i} \\ \vdots \\ \frac{1}{2}u_{m-1} \end{pmatrix} = \frac{1}{2}\begin{pmatrix} \langle \Lambda^{m-1}\Psi_1, \Psi_1 \rangle \\ \vdots \\ \langle \Lambda^{k-1}\Psi_1, \Psi_1 \rangle \\ \vdots \\ \langle \Psi_1, \Psi_1 \rangle \end{pmatrix}, \tag{3.4a}$$

which leads to

$$u_{m-k} = \langle \Lambda^{k-1}\Psi_1, \Psi_1 \rangle - \sum_{i=1}^{k-1} L_{m-k+i} \langle \Lambda^{i-1}\Psi_1, \Psi_1 \rangle. \tag{3.4b}$$

Then, using the following kind of equality,

$$\sum_{j=l}^{k} A_{k-j} \sum_{i=l}^{j} B_i C_{j,i} = \sum_{i=l}^{k} B_i \sum_{j=0}^{k-i} A_j C_{k-j,i}, \quad l = 0,1, \tag{3.5}$$

it is found from (3.4) and (3.3a) by a direct computation and induction that

$$u_{m-k} = \sum_{j=1}^{k} (-1)^{j-1} \frac{j+1}{2^j} \sum_{l_1+\cdots+l_j=k-j} \langle \Lambda^{l_1}\Psi_1, \Psi_1 \rangle \cdots \langle \Lambda^{l_j}\Psi_1, \Psi_1 \rangle,$$

$$k = 1,...,m, \tag{3.6}$$

where $l_1 \geqslant 0,...,l_j \geqslant 0$. By substituting (3.6) into (3.3a), the first x-constrained flow of (2.9) can be written in canonical finite-dimensional Hamiltonian system (FDHS)

$$\Psi_{1,x} = \frac{\partial F_0}{\partial \Psi_2}, \quad \Psi_{2,x} = -\frac{\partial F_0}{\partial \Psi_1}, \tag{3.7}$$

with the Hamiltonian F_0 given by

$$F_0 = \frac{1}{2}\langle \Psi_2, \Psi_2 \rangle + \sum_{j=0}^{m} \frac{(-1)^{j-1}}{2^{j+1}} \sum_{l_1+\cdots+l_{j+1}=m-j} \langle \Lambda^{l_1}\Psi_1, \Psi_1 \rangle \cdots \langle \Lambda^{l_{j+1}}\Psi_1, \Psi_1 \rangle.$$

The integrals of motion for (3.7) are

$$F_k = \frac{1}{2}\langle \Lambda^k \Psi_2, \Psi_2 \rangle + \frac{1}{4}\sum_{j=0}^{k-1} [\langle \Lambda^j \Psi_2, \Psi_2 \rangle \langle \Lambda^{k-1-j}\Psi_1, \Psi_1 \rangle - \langle \Lambda^j \Psi_1, \Psi_2 \rangle \langle \Lambda^{k-1-j}\Psi_1, \Psi_2 \rangle]$$

$$+ \sum_{j=0}^{m} \frac{(-1)^{j-1}}{2^{j+1}} \sum_{l_1+\cdots+l_{j+1}=m-j} \langle \Lambda^{l_1}\Psi_1, \Psi_1 \rangle \cdots \langle \Lambda^{l_j}\Psi_1, \Psi_1 \rangle \langle \Lambda^{l_{j+1}+k}\Psi_1, \Psi_1 \rangle,$$

$$k = 0,1,... . \tag{3.8}$$

The FDHS (3.7) was first presented in Ref. 21. However, the Lax representation, r-matrix, and separability for (3.7) have not been studied.

Under (3.6) and (3.7), t_{m+1}-constrained flow (3.2) of NLEE (2.9) can be written as a FDHS,

$$\Psi_{1,t_{m+1}} = \frac{\partial F_1}{\partial \Psi_2}, \quad \Psi_{2,t_{m+1}} = -\frac{\partial F_1}{\partial \Psi_1}, \tag{3.9}$$

and t_{m+2}-constrained flow (3.2) of NLEE (2.9) becomes a FDHS:

$$\Psi_{1,t_{m+2}}=\frac{\partial F_2}{\partial \Psi_2},\quad \Psi_{2,t_{m+2}}=-\frac{\partial F_2}{\partial \Psi_1}. \tag{3.10}$$

We will show in Sec. III C that FDHSs (3.7), (3.9), and (3.10) are a finite-dimensional integrable Hamiltonian system (FDIHS) with the integrals of motion given by (3.8). The construction of the x- and t_n-constrained flow ensures that if (Ψ_1,Ψ_2) satisfies two commuting FDIHSs (3.7) and (3.9) [(3.10)] simultaneously, then u given by (3.6) is a solution of the NLEE (2.9) with $n=m+1(n=m+2)$.

In general, the x-constrained flow (3.1) and t_n-constrained flow (3.2) under (3.1) can be transformed into an x-FDIHS and t_n-FDIHS. Then the NLEE is factorized into these two commuting x-FDIHS and t_n-FDIHS, namely if (Ψ_1,Ψ_2,u) satisfies these two commuting FDIHSs simultaneously, then u is a solution of the NLEE. Therefore, some kind of solution, such as finite-gap solution, for NLEE can be obtained through solving two commuting x- and t_n-FDIHS. We shall find the Jacobi inversion problem for these x- and t_n-FDIHSs later, and combine them to obtain the Jacobi inversion problem for the NLEE, which is solvable in terms of Riemann theta function.

B. Lax representation

By following the method in Ref. 9, the Lax representation for FDHS (3.7) can be deduced from the adjoint representation (2.2). First we have to find the expression of a_i, b_i, c_i under the constraint (3.6) and (2.11), which are denoted by $\tilde{a}_i$, $\tilde{b}_i$, $\tilde{c}_i$. According to (2.4), (2.11), (3.6), and (3.7), it is found by a direct calculation and using (3.5):

$$\tilde{a}_0=\cdots=\tilde{a}_m=\tilde{b}_0=\cdots=\tilde{b}_{m-1}=0,\quad \tilde{b}_m=1,\quad \tilde{c}_0=1,$$

$$\tilde{b}_{m+1+k}=\tfrac{1}{2}\langle\Lambda^k\Psi_1,\Psi_1\rangle,\quad k=0,1,..., \tag{3.11a}$$

$$\tilde{a}_{m+1+k}=-\tfrac{1}{2}\tilde{b}_{m+1+k,x}=-\tfrac{1}{2}\langle\Lambda^k\Psi_1,\Psi_2\rangle,\quad k=0,1,..., \tag{3.11b}$$

$$\tilde{c}_k=-\sum_{i=m-k}^{m}u_i\tilde{b}_{k+i}=\sum_{j=1}^{k}\left(-\frac{1}{2}\right)^j\sum_{l_1+\cdots+l_j=k-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle,$$

$$k=1,...,m,$$

$$\tilde{c}_{m+1+k}=-\frac{1}{2}\tilde{b}_{m+1+k,xx}-\sum_{i=0}^{m}u_i\tilde{b}_{m+1+k+i}=-\frac{1}{2}\langle\Lambda^k\Psi_2,\Psi_2\rangle,\quad k=0,1,... . \tag{3.11c}$$

The construction of $\tilde{a}_i$, $\tilde{b}_i$, $\tilde{c}_i$ guarantees that under (3.7)

$$\tilde{V}=\sum_{m=0}^{\infty}\begin{pmatrix}\tilde{a}_i & \tilde{b}_i\\ \tilde{c}_i & -\tilde{a}_i\end{pmatrix}\lambda^{-i}$$

satisfies (2.2). Set

$$M\equiv\lambda^m\tilde{V}=\begin{pmatrix}A(\lambda) & B(\lambda)\\ C(\lambda) & -A(\lambda)\end{pmatrix}. \tag{3.12}$$

We have

$$A(\lambda)=-\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\psi_{2j}}{\lambda-\lambda_j},\quad B(\lambda)=1+\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}^2}{\lambda-\lambda_j}, \tag{3.13a}$$

$$C(\lambda)=\lambda^m+\sum_{k=1}^{m}\lambda^{m-k}\sum_{j=1}^{k}\left(-\frac{1}{2}\right)^j\sum_{l_1+\cdots+l_j=k-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle-\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{2j}^2}{\lambda-\lambda_j}. \tag{3.13b}$$

The construction of M ensures the following proposition.

Proposition 1: The Lax representation for the FDHS (3.7) is given by

$$M_x=[\overline{U},\ M], \tag{3.14}$$

where $\overline{U}$ is obtained by inserting (3.6) into U in (2.1).

Similarly, $\tilde{V}$ under (3.9) [(3.10)] satisfies the adjoint representation (2.10). Thus the Lax representation for (3.9) $(n=m+1)$ [(3.10) $(n=m+2)$] is given by

$$M_{t_n}=[\overline{V}^{(n)},\ M], \tag{3.15}$$

where $\overline{V}^{(n)}$ is obtained by inserting (3.6) into $V^{(n)}$ in (2.6).

The equations (3.14) and (3.15) implies that $\mathrm{Tr}\ M^2(\lambda)=A^2(\lambda)+B(\lambda)C(\lambda)$ is the generating function of the integrals of motion for (3.7), (3.9), and (3.10). We have

$$A(\lambda)^2+B(\lambda)C(\lambda)=\lambda^m+\sum_{i=1}^{N}\frac{F^{(i)}}{\lambda-\lambda_i}, \tag{3.16}$$

$$F^{(i)}=-\frac{1}{2}\psi_{2i}^2+\frac{1}{2}\left[\lambda_i^m+\sum_{k=1}^{m}\lambda_i^{m-k}\sum_{j=1}^{k}\left(-\frac{1}{2}\right)^j\sum_{l_1+\cdots+l_j=k-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle\right]\psi_{1i}^2$$
$$-\frac{1}{4}\sum_{k\neq i}\frac{(\psi_{1i}\psi_{2k}-\psi_{1k}\psi_{2i})^2}{\lambda_k-\lambda_i},\quad i=1,...,N,$$

where $F^{(i)}$, $i=1,...,N$, are independent integrals of motion for (3.7), (3.9), and (3.10). In fact, we have

$$F_k=\sum_{i=0}^{N}\lambda_i^k F^{(i)},\quad k=0,1,\ldots .$$

C. The first family of dynamical *r*-matrices

In this section we describe the classical Poisson structure associated with the Lax representation for (3.7), (3.9), and (3.10).

With respect to the standard Poisson bracket, it is found by a straightforward but lengthy calculation and using (3.5) that

$$\{A(\lambda),A(\mu)\}=\{B(\lambda),B(\mu)\}=0,\quad \{C(\lambda),C(\mu)\}=2g_1(\lambda,\mu)[A(\lambda)-A([\mu)], \tag{3.17a}$$

$$\{A(\lambda),B(\mu)\}=\frac{1}{\mu-\lambda}[B(\lambda)-B(\mu)],\quad \{B(\lambda),C(\mu)\}=\frac{2}{\mu-\lambda}[A(\lambda)-A(\mu)], \tag{3.17b}$$

$$\{A(\lambda),C(\mu)\}=\frac{1}{\mu-\lambda}[C(\mu)-C(\lambda)]-g_1(\lambda,\mu)B(\lambda), \tag{3.17c}$$

where

$$g_1(\lambda,\mu)=\sum_{k=0}^{m-1}\lambda^k\mu^{m-1-k}+\sum_{l=1}^{m-1}\sum_{k=0}^{m-1-l}\lambda^k\mu^{m-1-l-k}\sum_{j=1}^{l}\left(-\frac{1}{2}\right)^j$$

$$\times(j+1)\sum_{l_1+\cdots+l_j=l-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle. \tag{3.18}$$

We use the standard notation σ_k, $k=0,1,2,3$, for the Pauli matrices and $\sigma_\pm=\frac{1}{2}(\sigma_1\pm i\sigma_2)$. Denote

$$M_1(\lambda)=M(\lambda)\otimes I,\quad M_2(\mu)=I\otimes M(\mu),$$

where I is the 2×2 unit matrix. Let P be the permutation matrix. Then (3.17) gives rise to the the following proposition.

Proposition 2: The classical Poisson structure for (3.7), (3.9), and (3.10) is given in the following linear r-matrix form:[1]

$$\{M_1(\lambda),M_2(\mu)\}=[r_{12}(\lambda,\mu),M_1(\lambda)]-[r_{21}(\lambda,\mu),M_2(\mu)], \tag{3.19}$$

where the r-matrix is of the form

$$r_{12}(\lambda,\mu)=\frac{1}{\lambda-\mu}P+g_1(\lambda,\mu)S,\quad P=\frac{1}{2}\sum_{k=0}^{3}\sigma_k\otimes\sigma_k,\quad S=\sigma_-\otimes\sigma_-,$$
$$r_{21}(\lambda,\mu)=Pr_{12}(\lambda,\mu)P=r_{12}(\mu,\lambda). \tag{3.20}$$

Proof: The proof is a direct computation.

The family of r-matrices $r_{12}(\lambda,\mu)$ for $m=2,3,...$ is of the dynamical type which depends not only on the spectral parameter but also on the dynamical variables.

According to a remarkable theorem proved in Ref. 1, the involutivity of the integrals of motion

$$\{F^{(i)},F^{(j)}\}=0,\quad i,j=1,...,N, \tag{3.21}$$

is a consequence of (3.19). Therefore (3.7), (3.9), and (3.10) are FDIHSs.[22]

Let us denote

$$M_1(\lambda)=M(\lambda)\otimes I\otimes I,\quad M_2(\mu)=I\otimes M(\mu)\otimes I,\quad M_3(\nu)=I\otimes I\otimes M(\nu),$$

$$P_{12}=P\otimes I,\quad P_{23}=I\otimes P,\quad P_{13}=\frac{1}{2}\sum_{k=0}^{3}\sigma_k\otimes I\otimes\sigma_k,$$

$$S_{12}=S\otimes I,\quad S_{23}=I\otimes S,\quad S_{13}=\sigma_-\otimes I\otimes\sigma_-.$$

It is known that the r-bracket is a Poisson bracket if r-matrix obeys some classical dynamical Yang–Baxter equations. In the following we introduce dynamical Yang–Baxter equations for this family of dynamical r-matrices.

Proposition 3: For the linear r-matrix algebra (3.19) and (3.20), the following dynamical Yang–Baxter equations are valid:

$$[d_{12}(\lambda,\mu),d_{13}(\lambda,\nu)]+[d_{12}(\lambda,\mu),d_{23}(\mu,\nu)]+[d_{32}(\nu,\mu),d_{13}(\lambda,\nu)]+\{M_2(\mu),d_{13}(\lambda,\nu)\}$$
$$-\{M_3(\nu),d_{12}(\lambda,\mu)\}+f(\lambda,\mu,\nu)[S_0,M_2(\mu)-M_3(\nu)], \tag{3.22}$$

plus cyclic permutations, where

$$d_{ij}(\lambda,\mu)=\frac{1}{\lambda-\mu}P_{ij}+g_1(\lambda,\mu)S_{ij},$$

$$d_{ji}(\lambda,\mu)=d_{ij}(\lambda,\mu),\quad i<j,\quad i,j=1,2,3,\quad S_0=\sigma_-\otimes\sigma_-\otimes\sigma_-,$$

$$f(\lambda,\mu,\nu)=-2\sum_{k=0}^{m-2}\sum_{l=0}^{m-2-k}\lambda^k\mu^l\nu^{m-2-l-k}-2\sum_{l=1}^{m-2}\sum_{k=0}^{m-2-l}\sum_{i=0}^{m-2-l-k}\lambda^k\mu^i\nu^{m-2-l-k-i}$$
$$\times\sum_{j=1}^{l}\left(-\frac{1}{2}\right)^j(j+1)^2\sum_{l_1+\cdots+l_j=l-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle. \tag{3.23}$$

Proof: A direct calculation shows that the validity of (3.22) is due to the following equality

$$2\{A(\mu),g_1(\lambda,\nu)\}+\frac{2}{\lambda-\mu}[g_1(\mu,\nu)-g_1(\lambda,\nu)]-f(\lambda,\mu,\nu)B(\mu)=0, \tag{3.24}$$

where λ,μ are treated as spectral parameters. Notice that if (3.24) holds and $g_1(\lambda,\nu)$ is replaced by $g_1(\lambda,\nu)-\frac{1}{2}\Sigma_{j=1}^{N}\psi_{2j}^2/(\lambda-\lambda_j)$, then (3.24) still holds. Comparing (3.24) with (3.17c), we find that the relation between $g_1(\lambda,\mu)$ and $f(\lambda,\mu,\nu)$ is the same as the relation between $C(\mu)$ and $g_1(\lambda,\mu)$. Thus we may obtain $f(\lambda,\mu,\nu)$ from $-2g_1(\lambda,\mu)$ by replacing m by $m-1$ and μ^k by $\Sigma_{l=0}^{k}\mu^l\nu^{k-l}$. This completes the proof.

The proof provides a general way to obtain $f(\lambda,\mu,\nu)$ from $g(\lambda,\mu)$, namely, $f(\lambda,\mu,\nu)$ can be deduced from $-2g(\lambda,\mu)$ by the same relation as that between $g(\lambda,\mu)$ and $C(\mu)$. The dynamical Yang–Baxter equations (3.22) take the general form introduced in Ref. 4.

IV. THE JACOBI INVERSION PROBLEM FOR NLEE (2.9)

We introduce separation variables w_k,v_k, $k=1,...,N$ for (3.7), (3.9), and (3.10) by zeros of $B(\lambda)$ (Refs. 11–14):

$$B(\lambda)=1+\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}^2}{\lambda-\lambda_j}=\frac{R(\lambda)}{K(\lambda)}, \tag{4.1a}$$

and

$$v_k=A(w_k)=\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\psi_{2j}}{w_k-\lambda_j},\quad k=1,...,N, \tag{4.1b}$$

where

$$K(\lambda)\equiv\prod_{j=1}^{N}(\lambda-\lambda_j)=\sum_{i=0}^{N}\alpha_i\lambda^{N-i},\quad R(\lambda)\equiv\prod_{j=1}^{N}(\lambda-w_j)=\sum_{i=0}^{N}\beta_i\lambda^{N-i},$$

$$\alpha_0=1,\quad \alpha_1=-\sum_{j=1}^{N}\lambda_j,\quad \alpha_2=\sum_{j=1}^{N}\sum_{k=j+1}^{N}\lambda_j\lambda_k,\ldots,\quad \alpha_N=(-1)^N\lambda_1\cdots\lambda_N,$$

$$\beta_0=1,\quad \beta_1=-\sum_{j=1}^{N}w_j,\quad \beta_2=\sum_{j=1}^{N}\sum_{k=j+1}^{N}w_jw_k,\ldots,\quad \beta_N=(-1)^Nw_1\cdots w_N. \tag{4.1c}$$

It follows from (4.1a) that the w_k, $k=1,...,N$, define elliptic coordinates given by the formula

$$\psi_{1j}^2=2\frac{R(\lambda_j)}{K'(\lambda_j)},\quad j=1,...,N, \tag{4.2}$$

where the prime denotes differentiation with respect to λ. Then we obtain from (4.2)

$$\sum_{j=1}^{N}\psi_{2j}d\psi_{1j}=\sum_{j=1}^{N}v_kdw_k,$$

which implies that the coordinates w_k, v_k are canonically conjugated.[22] From (4.1a) we find

$$\langle \Lambda^k \Psi_1, \Psi_1 \rangle = 2\beta_{k+1} + 2\sum_{i=0}^{N} \beta_i \sum_{l=1}^{k+1-i} (-1)^l \prod_{j_1+\cdots+j_l=k+1-i} \alpha_{j_1} \cdots \alpha_{j_l}, \tag{4.3}$$

where $j_i \geqslant 1$, $\alpha_k = \beta_k = 0$ for $k > N$. Combining (3.6) and (4.3) gives rise to the expression of u_k in terms of w_k, which are the symmetric functions of w_k, $k = 1,...,N$. Let

$$A^2(\lambda) + B(\lambda)C(\lambda) = \frac{P(\lambda)}{K(\lambda)}, \quad P(\lambda) = \sum_{i=1}^{N+m+1} P_i \lambda^{i-1}, \tag{4.4}$$

where P_i, $i = 1,...,N$, are also the integrals of motion for (3.7), (3.9), and (3.10). By substituting (3.13) we find

$$P_{N+m+1} = 1, \quad P_{N+m} = \alpha_1, \quad \ldots, \quad P_{N+1} = \alpha_m, \tag{4.5}$$

$$F_0 = -P_N + \alpha_{m+1}, \quad F_1 = -P_{N-1} + \alpha_1 P_N - \alpha_1 \alpha_{m+1} + \alpha_{m+2}, \tag{4.6a}$$

$$F_2 = -P_{N-2} + \alpha_1 P_{N-1} - (\alpha_1^2 - \alpha_2) P_N + \alpha_1^2 \alpha_{m+1} - \alpha_1 \alpha_{m+2} - \alpha_2 \alpha_{m+1} + \alpha_{m+3}, \quad \ldots . \tag{4.6b}$$

In order to write the Hamilton–Jacobi equation from (4.4), we must reinterpret the P_i as integration constants and replace v_k by the partial derivatives $\partial W / \partial w_k$ of the generating function W of canonical transformation.[22] Inserting $\lambda = w_k$, we find from (4.4)

$$v_k = \sqrt{\frac{P(w_k)}{K(w_k)}}, \quad k = 1,...,N, \tag{4.7}$$

which implies that variables in the Hamilton–Jacobi equation are completely separable. Here W can be expressed in the separation form $W(w_1,\ldots,w_N) = \Sigma_{k=1}^{N} W_k(w_k)$. By replacing $v_k = \partial W_k / \partial w_k$ and interpreting P_i as integration constants, (4.4) may be integrated to give the completely separated solution

$$W(w_1,\ldots,w_N) = \sum_{k=1}^{N} \int^{w_k} \sqrt{\frac{P(\lambda)}{K(\lambda)}}\, d\lambda. \tag{4.8}$$

The linearizing coordinates are then

$$Q_i \equiv \frac{\partial W}{\partial P_i} = \frac{1}{2} \sum_{k=1}^{N} \int^{w_k} \frac{\lambda^{i-1}}{\sqrt{P(\lambda)K(\lambda)}}\, d\lambda, \quad i = 1,...,N. \tag{4.9}$$

This equality provides a map, called the Abel map, from the old coordinates w_k, $k = 1,...,N$, which live on the Riemann surface, to new coordinates Q_k, $k = 1,...,N$, which live on its Jacobi variety. The linear flow induced by (3.7) is then given by [using (4.6a)]

$$Q_i = \gamma_i + \frac{\partial F_0}{\partial P_i} x = \gamma_i - x\,\delta_{i,N}, \quad i = 1,...,N, \tag{4.10}$$

where γ_i are constants.

The linear flow induced by (3.9) is of the form [using (4.6a)]

$$Q_i = \overline{\gamma_i} + \frac{\partial F_1}{\partial P_i} t_{m+1} = \overline{\gamma_i} - [\,\delta_{i,N-1} - \alpha_1 \delta_{i,N}] t_{m+1}, \quad i = 1,...,N. \tag{4.11}$$

The factorization of NLEE (2.9) and combining of Eqs. (4.9), (4.10), and (4.11) give rise to the following proposition.

Proposition 4: The Jacobi inversion problem for FDHS (3.7) is given by

$$\frac{1}{2}\sum_{k=1}^{N}\int^{w_k}\frac{\lambda^{i-1}}{\sqrt{P(\lambda)K(\lambda)}}\,d\lambda=\gamma_i-\delta_{i,N}x,\quad i=1,...,N, \tag{4.12}$$

the Jacobi inversion problem for FDHS (3.9) is given by

$$\frac{1}{2}\sum_{k=1}^{N}\int^{w_k}\frac{\lambda^{i-1}}{\sqrt{P(\lambda)K(\lambda)}}\,d\lambda=\gamma_i+(\delta_{i,N}\alpha_1-\delta_{i,N-1})t_{m+1},\quad i=1,...,N, \tag{4.13}$$

and the Jacobi inversion problem for NLEE (2.9) with $n=m+1$ is of the form

$$\frac{1}{2}\sum_{k=1}^{N}\int^{w_k}\frac{\lambda^{i-1}}{\sqrt{P(\lambda)K(\lambda)}}\,d\lambda=\gamma_i-\delta_{i,N}(x-\alpha_1 t_{m+1})-\delta_{i,N-1}t_{m+1},\quad i=1,...,N. \tag{4.14}$$

The linear flow induced by (3.10) is given by [using (4.6b)]

$$Q_i=\overline{\gamma}_i+\frac{\partial F_2}{\partial P_i}\,t_{m+2}=\overline{\gamma}_i-[\delta_{i,N-2}-\alpha_1\delta_{i,N-1}+(\alpha_1^2-\alpha_2)\delta_{i,N}]t_{m+2},\quad i=1,...,N. \tag{4.15}$$

The factorization of NLEE (2.9) and the combining of Eqs. (4.9), (4.10), and (4.15) lead to the Jacobi inversion problem for FDHS (3.10),

$$\frac{1}{2}\sum_{k=1}^{N}\int^{w_k}\frac{\lambda^{i-1}}{\sqrt{P(\lambda)K(\lambda)}}\,d\lambda=\gamma_i-[\delta_{i,N-2}-\alpha_1\delta_{i,N-1}+(\alpha_1^2-\alpha_2)\delta_{i,N}]t_{m+2},\quad i=1,...,N, \tag{4.16}$$

and the Jacobi inversion problem for NLEE (2.9) with $n=m+2$:

$$\frac{1}{2}\sum_{k=1}^{N}\int^{w_k}\frac{\lambda^{i-1}}{\sqrt{P(\lambda)K(\lambda)}}\,d\lambda=\gamma_i-[\delta_{i,N-2}-\alpha_1\delta_{i,N-1}]t_{m+2}-[x+(\alpha_1^2-\alpha_2)t_{m+2}]\delta_{i,N},$$
$$i=1,...,N. \tag{4.17}$$

By using standard Jacobi inversion techniques,[18] the solutions u of NLEE (2.9), which are the symmetric functions of w_k, $k=1,...,N$, determined by (3.6) and (4.3), can be given an explicit form in terms of Riemann theta functions. This provides a method of separation of variables to solve NLEE (2.9) for $n=m+1$, $m+2$. The above presented method can be applied to the whole hierarchy (2.9).

V. THE SECOND FAMILY OF DYNAMICAL *r*-MATRICES

We now consider the second x-constrained flow of NLEE (2.9) and its Lax representation, dynamical r-matrix, and Jacobi inversion problem.

A. The second *x*-constrained flow of the NLEE (2.9)

The second x-constrained flow of NLEE (2.9) is obtained from (3.3) for $k=m+1$. Equation (3.3b) with $k=m+1$ reads

$$\begin{pmatrix} b_{2m+1}\\ \vdots\\ b_{m+k}\\ \vdots\\ b_{m+2}\end{pmatrix}=\begin{pmatrix} \Sigma_{i=0}^{m-1}L_i b_{m+i+1}\\ \vdots\\ \frac{1}{2}u_{m-k}+\Sigma_{i=1}^{k-1}L_{m-k+i}b_{m+i}\\ \vdots\\ \frac{1}{2}u_{m-2}+\frac{1}{2}L_{m-1}u_{m-1}\end{pmatrix}=\frac{1}{2}\begin{pmatrix}\langle\Lambda^{m-1}\Psi_1,\Psi_1\rangle\\ \vdots\\ \langle\Lambda^{k-2}\Psi_1,\Psi_1\rangle\\ \vdots\\ \langle\Psi_1,\Psi_1\rangle\end{pmatrix}, \tag{5.1a}$$

which leads to

$$u_{m-k}=\langle\Lambda^{k-2}\Psi_1,\Psi_1\rangle-L_{m-k+1}u_{m-1}-\sum_{i=2}^{k-1}L_{m-k+i}\langle\Lambda^{i-2}\Psi_1,\Psi_1\rangle,\quad k=2,...,m,\tag{5.1b}$$

$$L_0u_{m-1}=\langle\Lambda^{m-1}\Psi_1,\Psi_1\rangle-\sum_{i=1}^{m-1}L_i\langle\Lambda^{i-1}\Psi_1,\Psi_1\rangle.\tag{5.1c}$$

By using (3.5) and the following kind of equality,

$$\sum_{j=2l}^{k}A_{k-j}\sum_{i=l}^{[j/2]}B_iC_{j,2i}=\sum_{i=l}^{[k/2]}B_i\sum_{j=0}^{k-2i}A_jC_{k-j,2i},\quad l=0,1,\tag{5.2}$$

it is found from (5.1b) and (3.3a) by a direct but lengthy computation that

$$u_{m-k}=E_{k,0}u_{m-1}^k+\sum_{i=0}^{k-2}u_{m-1}^i\sum_{j=1}^{[(k-i)/2]}E_{i,j}\sum_{l_1+\cdots+l_j=k-i-2j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle,$$
$$k=2,...,m,\tag{5.3a}$$

where

$$E_{i,j}=-\left(-\frac{1}{2}\right)^{i+j}\frac{(i+j+1)!}{i!j!}=-(i+j+1)\beta_{i,j},\quad \beta_{i,j}=\left(-\frac{1}{2}\right)^{i+j}\frac{(i+j)!}{i!j!}.\tag{5.3b}$$

Denote

$$q=u_{m-1},\quad p=-\tfrac{1}{8}u_{m-1,x}.\tag{5.4}$$

By substituting (5.3) into (3.3a) and (5.1c), the second x-constrained flow of (2.9) can be written as a canonical FDHS with the extended phase space (Ψ_1,q,Ψ_2,p):

$$\Psi_{1,x}=\frac{\partial F_0}{\partial\Psi_2},\quad \Psi_{2,x}=-\frac{\partial F_0}{\partial\Psi_1},\quad q_x=\frac{\partial F_0}{\partial p},\quad p_x=-\frac{\partial F_0}{\partial q},\tag{5.5}$$

with the Hamiltonian F_0 given by

$$F_0=\frac{1}{2}\langle\Psi_2,\Psi_2\rangle+\beta_{m+2,0}q^{m+2}-4p^2$$
$$+\sum_{i=0}^{m}q^i\sum_{j=1}^{[(m+2-i)/2]}\beta_{i,j}\sum_{l_1+\cdots+l_j=m+2-i-2j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle.$$

B. Lax representation

We now derive the Lax representation for the family of FDHS (5.5) from the adjoint representation (2.2) in the same way as for (3.7). According to (2.4), (2.11), (5.1), and (5.5), it is found by a direct calculation

$$\tilde a_0=\cdots=\tilde a_m=\tilde b_0=\cdots=\tilde b_{m-1}=0,\quad \tilde b_m=1,$$
$$\tilde b_{m+1}=\tfrac{1}{2}q,\quad \tilde a_{m+1}=-\tfrac{1}{2}\tilde b_{m+1,x}=2p,\quad \tilde c_0=1\tag{5.6a}$$
$$\tilde b_{m+2+k}=\tfrac{1}{2}\langle\Lambda^k\Psi_1,\Psi_1\rangle,\quad k=0,1,...,$$
$$\tilde a_{m+2+k}=-\tfrac{1}{2}\tilde b_{m+2+k,x}=-\tfrac{1}{2}\langle\Lambda^k\Psi_1,\Psi_2\rangle,\quad k=0,1,...,\tag{5.6b}$$

$$\tilde{c}_k=-\frac{1}{2}\tilde{b}_{k,xx}-\sum_{i=m-k}^{m}u_i\tilde{b}_{k+i}=\beta_{k,0}q^k$$
$$+\sum_{i=0}^{k-2}q^i\sum_{j=1}^{[(k-i)/2]}\beta_{i,j}\sum_{l_1+\cdots+l_j=k-i-2j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle,\quad k=1,\ldots,m+1,$$
$$\tilde{c}_{m+2+k}=-\frac{1}{2}\tilde{b}_{m+2+k,xx}-\sum_{i=0}^{m}u_i\tilde{b}_{m+k+2+i}=-\frac{1}{2}\langle\Lambda^k\Psi_2,\Psi_2\rangle,\quad k=0,1,\ldots. \tag{5.6c}$$

Set

$$M\equiv\lambda^{m+1}\tilde{V}=\begin{pmatrix}A(\lambda) & B(\lambda)\\ C(\lambda) & -A(\lambda)\end{pmatrix}.$$

Then we have

$$A(\lambda)=2p-\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\psi_{2j}}{\lambda-\lambda_j},\quad B(\lambda)=\lambda+\frac{1}{2}q+\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}^2}{\lambda-\lambda_j}, \tag{5.7a}$$

$$C(\lambda)=\lambda^{m+1}+\sum_{k=1}^{m+1}\lambda^{m+1-k}\tilde{c}_k-\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{2j}^2}{\lambda-\lambda_j}. \tag{5.7b}$$

The construction of M gives rise to the following proposition.

Proposition 5: The Lax representation for the FDHS (5.5) is given by (3.14) with $\bar{U}$ obtained by inserting (5.3) and (5.4) into U in (2.1).

Similarly, the equality

$$A^2(\lambda)+B(\lambda)C(\lambda)=\lambda^{m+2}+F_0+\sum_{i=1}^{N}\frac{F^{(i)}}{\lambda-\lambda_i} \tag{5.8}$$

determines $N+1$ independent integrals of motion $F_0,F^{(i)}$, $i=1,\ldots,N$, for FDHS (5.5). We omit the expression for $F^{(i)}$.

C. The second family of dynamical *r*-matrices

By a straightforward but lengthy calculation and using (5.2), it is found that $A(\lambda),B(\lambda),C(\lambda)$ satisfies the same formulas as (3.17) with $g_1(\lambda,\mu)$ replaced by the following $g_2(\lambda,\mu)$:

$$g_2(\lambda,\mu)=-\sum_{l=0}^{m-1}E_{l,0}q^l\sum_{k=0}^{m-1-l}\mu^{m-1-l-k}\lambda^k-\sum_{n=0}^{m-3}\sum_{k=0}^{m-3-n}\lambda^k\mu^{m-3-n-k}\sum_{l=0}^{n}q^l\sum_{j=1}^{[(n+2-l)/2]}E_{l,j}$$
$$\times\sum_{l_1+\cdots+l_j=n+2-l-2j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle. \tag{5.9}$$

Then we have the following proposition.

Proposition 6: The classical Poisson structure for FDHS (5.5) is given in the linear r-matrix form (3.19) with

$$r_{12}(\lambda,\mu)=\frac{1}{\lambda-\mu}P+g_2(\lambda,\mu)S,\quad r_{21}(\lambda,\mu)=Pr_{12}(\lambda,\mu)P=r_{12}(\mu,\lambda). \tag{5.10}$$

This gives the second family of dynamical *r*-matrices $r_{12}(\lambda,\mu)$ for $m=2,3,\ldots$. The involutivity of the integrals of motion $F_0,F^{(i)}$, $i=1,\ldots,N$, is a consequence of (3.9) and (5.10). Therefore (5.5) is a FDIHS.

As shown in the proof of Proposition 3, the following proposition is valid.

Proposition 7: For the linear r-matrix algebra (3.19) and (5.10) the dynamical Yang–Baxter equations (3.22) with $d_{i,j}(\lambda,\mu)$ and f given by following formulas are valid:

$$d_{ij}(\lambda,\mu)=\frac{1}{\lambda-\mu}P_{ij}+g_2(\lambda,\mu)S_{ij},\quad d_{ji}(\lambda,\mu)=d_{ij}(\lambda,\mu),\quad i<j,\quad i,j=1,2,3,$$

$$\begin{aligned}f(\lambda,\mu,\nu)=&2\sum_{l=0}^{m-3}\tilde{E}_{l,0}q^l\sum_{k=0}^{m-3-l}\sum_{i=0}^{m-3-l-k}\lambda^k\mu^i\nu^{m-3-l-k-i}\\&+2\sum_{n=0}^{m-5}\sum_{k=0}^{m-5-n}\sum_{i=0}^{m-5-n-k}\lambda^k\mu^i\nu^{m-5-n-k-i}\\&\times\sum_{l=0}^{n}q^l\sum_{j=2}^{[(n+2-l)/2]}\tilde{E}_{l,j}\sum_{l_1+\cdots+l_j=n+2-l-2j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle,\end{aligned}$$

where

$$\tilde{E}_{i,j}=(i+j+1)^2\beta_{i,j}.$$

D. The Jacobi inversion problem for FDHS (5.5)

We introduce separation variables w_k,v_k, $k=1,...,N+1$, for (5.5) as

$$B(\lambda)=\lambda+\frac{1}{2}q+\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}^2}{\lambda-\lambda_j}=\frac{R(\lambda)}{K(\lambda)},\tag{5.11a}$$

and

$$v_k=A(w_k)=2p-\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\psi_{2j}}{w_k-\lambda_j},\quad k=1,...,N+1,\tag{5.11b}$$

where $K(\lambda)$ is given by (4.1c); $R(\lambda)$ and β_k are also given by (4.1c) but with N replaced by $N+1$. It follows from (5.11a) that w_k, $k=1,...,N+1$, define parabolic coordinates given by the formula

$$\psi_{1j}^2=2\frac{R(\lambda_j)}{K'(\lambda_j)},\quad j=1,...,N,\quad q=2\beta_1-2\alpha_1.\tag{5.12}$$

The equation (5.12) leads to

$$\sum_{j=1}^{N}\psi_{2j}d\psi_{1j}+pdq=\sum_{j=1}^{N+1}v_k dw_k.$$

Therefore the coordinates w_k,v_k are canonically conjugated. From (4.1a) we find

$$\langle\Lambda^k\Psi_1,\Psi_1\rangle=2\beta_{k+1}+2\sum_{i=0}^{N+1}\beta_i\sum_{l=1}^{k+1-i}(-1)^l\prod_{j_1+\cdots+j_l=k+1-i}\alpha_{j_1}\cdots\alpha_{j_l},\tag{5.13}$$

where $j_i\geqslant 1$, $\alpha_k=0$, for $k>N$, and $\beta_k=0$ for $k>N+1$. Combining (5.3), (5.12), and (5.13) gives rise to the expression of u_k in terms of w_k, which are the symmetric functions of w_k, $k=1,...,N+1$. Let

$$A^2(\lambda)+B(\lambda)C(\lambda)=\frac{P(\lambda)}{K(\lambda)},\quad P(\lambda)=\sum_{i=1}^{N+m+3}P_i\lambda^{i-1},\tag{5.14}$$

where P_i, $i=1,...,N+1$, are the integrals of motion for FDHS (5.5). By substituting (5.7) into (5.14), one obtains

$$P_{N+m+3}=1, \quad P_{N+m+2}=\alpha_1, \quad \ldots, \quad P_{N+2}=\alpha_{m+1}, \quad P_{N+1}=\alpha_{m+2}-F_0, \quad \ldots . \tag{5.15}$$

In the exact same way as we did in Sec. IV, we can arrive at the following proposition.

Proposition 8: The Jacobi inversion problem for FDHS (5.5) is of the form

$$\frac{1}{2}\sum_{k=1}^{N+1}\int^{w_k}\frac{\lambda^{i-1}}{\sqrt{P(\lambda)K(\lambda)}}\,d\lambda=\gamma_i-\delta_{i,N+1}x, \quad i=1,...,N+1.$$

VI. THE THIRD FAMILY OF DYNAMICAL *r*-MATRIX

We now apply the same procedure in Sec. III and IV to the NLEEs (2.16).

A. The factorization of the NLEEs (2.16)

The first x-constrained flow (3.1) for $k=m-1$ of NLEE (2.16) reads

$$\Psi_{1,x}=u_0\Psi_1+\Lambda\Psi_2, \quad \Psi_{2,x}=\left(\Lambda^{m-1}-\sum_{i=1}^{m-1}u_i\Lambda^{i-1}\right)\Psi_1-u_0\Psi_2, \tag{6.1a}$$

$$\begin{pmatrix} 2a_{m-1} \\ -b_{m-1} \\ \vdots \\ -b_{2m-3} \end{pmatrix}=\frac{1}{2}\begin{pmatrix} 2\langle\Psi_1,\Psi_2\rangle \\ \langle\Psi_1,\Psi_1\rangle \\ \vdots \\ \langle\Lambda^{m-2}\Psi_1,\Psi_1\rangle \end{pmatrix}, \tag{6.1b}$$

which leads to

$$u_0=\tfrac{1}{2}\langle\Psi_1,\Psi_2\rangle, \tag{6.2a}$$

$$u_{m-k}=-\langle\Lambda^{k-1}\Psi_1,\Psi_1\rangle+\sum_{i=1}^{k-1}L_{m-i}\langle\Lambda^{k-i-1}\Psi_1,\Psi_1\rangle, \quad k=1,...,m-1. \tag{6.2b}$$

Then it is found by a direct but lengthy computation that

$$u_0=\tfrac{1}{2}\langle\Psi_1,\Psi_2\rangle, \tag{6.3a}$$

$$u_{m-k}=-\sum_{j=1}^{k}\frac{j+1}{2^j}\sum_{l_1+\cdots+l_j=k-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle, \quad k=1,...,m-1. \tag{6.3b}$$

By substituting (6.3) into (6.1a), the first x-constrained flow of NLEE (2.16) can be written in canonical FDHS

$$\Psi_{1,x}=\frac{\partial F_0}{\partial\Psi_2}, \quad \Psi_{2,x}=-\frac{\partial F_0}{\partial\Psi_1}, \tag{6.4a}$$

with the Hamiltonian F_0 given by

$$F_0=\frac{1}{2}\langle\Lambda\Psi_2,\Psi_2\rangle+\frac{1}{4}\langle\Psi_1,\Psi_2\rangle^2-\sum_{j=1}^{m}\left(\frac{1}{2}\right)^j\sum_{l_1+\cdots+l_j=m-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle. \tag{6.4b}$$

Under (6.3) and (6.4), the t_m-constrained flow (3.2) of NLEE (2.16) can be written as a FDHS

$$\Psi_{1,t_m}=\frac{\partial F_1}{\partial\Psi_2}, \quad \Psi_{2,t_m}=-\frac{\partial F_1}{\partial\Psi_1}, \tag{6.5a}$$

with the Hamiltonian F_1 given by

$$F_1=\frac{1}{2}\langle\Lambda^2\Psi_2,\Psi_2\rangle+\frac{1}{2}\langle\Psi_1,\Psi_2\rangle\langle\Lambda\Psi_1,\Psi_2\rangle-\frac{1}{4}\langle\Psi_1,\Psi_1\rangle\langle\Lambda\Psi_2,\Psi_2\rangle$$
$$-\sum_{j=1}^{m}\left(\frac{1}{2}\right)^j\sum_{l_1+\cdots+l_j=m-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_{j-1}}\Psi_1,\Psi_1\rangle\langle\Lambda^{l_j+1}\Psi_1,\Psi_1\rangle. \quad (6.5b)$$

We will show later that both (6.4) and (6.5) are FDIHS. The construction of the x- and t_m-constrained flow ensures that if (Ψ_1,Ψ_2) satisfies two commuting FDIHSs (6.4) and (6.5) simultaneously, then u given by (6.3) is a solution of the NLEE (2.16) with $n=m$, namely the NLEE (2.16) with $n=m$ is factorized into two commuting x-FDIHS (6.4) and t_m-FDIHS (6.5).

B. Lax representation for (6.4) and (6.5)

It is found by a direct calculation

$$\tilde{a}_0=\cdots=\tilde{a}_{m-2}=\tilde{b}_0=\cdots=\tilde{b}_{m-3}=0,\quad \tilde{b}_{m-2}=1,\quad \tilde{c}_0=1,$$
$$\tilde{b}_{m-1+k}=-\tfrac{1}{2}\langle\Lambda^k\Psi_1,\Psi_1\rangle,\quad k=0,1,...,$$
$$\tilde{a}_{m-1+k}=(u_0-\tfrac{1}{2}D)\tilde{b}_{m-2+k}=\tfrac{1}{2}\langle\Lambda^k\Psi_1,\Psi_2\rangle,\quad k=0,1,...,$$
$$\tilde{c}_k=-\sum_{i=m-k}^{m}u_i\tilde{b}_{k+i-2}=\sum_{j=1}^{k}\left(\frac{1}{2}\right)^j\sum_{l_1+\cdots+l_j=k-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle,\quad k=1,...,m-1,$$
$$\tilde{c}_{m-1+k}=\tilde{a}_{m-2+k,x}-\sum_{i=1}^{m}u_i\tilde{b}_{m+k+i-3}=\frac{1}{2}\langle\Lambda^k\Psi_2,\Psi_2\rangle,\quad k=1,\ldots.$$

Set

$$M\equiv\lambda^{m-1}\tilde{V}=\begin{pmatrix}A(\lambda) & B(\lambda)\\ C(\lambda) & -A(\lambda)\end{pmatrix}, \quad (6.6a)$$

we have

$$A(\lambda)=\frac{1}{2}\lambda\sum_{j=1}^{N}\frac{\psi_{1j}\psi_{2j}}{\lambda-\lambda_j},\quad B(\lambda)=\lambda-\frac{1}{2}\lambda\sum_{j=1}^{N}\frac{\psi_{1j}^2}{\lambda-\lambda_j}, \quad (6.6b)$$

$$C(\lambda)=\lambda^{m-1}+\sum_{k=1}^{m-1}\lambda^{m-1-k}\sum_{j=1}^{k}\left(\frac{1}{2}\right)^j\sum_{l_1+\cdots+l_j=k-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle+\frac{1}{2}\sum_{j=1}^{N}\frac{\lambda_j\psi_{2j}^2}{\lambda-\lambda_j}. \quad (6.6c)$$

Proposition 9: The Lax representation for the FDHS (6.4) is given by (3.14) with $\bar{U}$ obtained by inserting (6.3) into U in (2.12) and M defined by (6.6). The Lax representation for the FDHS (6.5) is given by (3.15) with $\bar{V}^{(m)}$ obtained by inserting (6.3) into $V^{(m)}$ in (2.14).

C. The third family of dynamical *r*-matrices

With respect to the standard Poisson bracket one obtains

$$\{A(\lambda)A(\mu)\}=\{B(\lambda),B(\mu)\}=0,\quad \{C(\lambda),C(\mu)\}=2g_3(\lambda,\mu)[A(\mu)-A(\lambda)],$$
$$\{A(\lambda),B(\mu)\}=\frac{1}{\mu-\lambda}[\lambda B(\mu)-\mu B(\lambda)],\quad \{B(\lambda),C(\mu)\}=\frac{2\lambda}{\mu-\lambda}[A(\mu)-A(\lambda)],$$

$$\{A(\lambda),C(\mu)\}=\frac{\lambda}{\mu-\lambda}\,[C(\lambda)-C(\mu)]+g_3(\lambda,\mu)B(\lambda), \tag{6.7a}$$

where

$$g_3(\lambda,\mu)=\sum_{k=0}^{m-2}\mu^{m-2-k}\lambda^k+\sum_{l=1}^{m-2}\sum_{k=0}^{m-2-l}\lambda^k\mu^{m-2-l-k}\times\sum_{j=1}^{l}\left(\frac{1}{2}\right)^j(j+1)$$

$$\times\sum_{l_1+\cdots+l_j=l-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle. \tag{6.7b}$$

Then (6.7) gives rise to the following proposition.

Proposition 10: The classical Poisson structure for FDHS (6.4) and (6.5) is given by the linear r-matrix form (3.19) with the following r-matrix:

$$r_{12}(\lambda,\mu)=\frac{\mu}{\mu-\lambda}\,P-G-g_3(\lambda,\mu)S,\quad G=\sigma_+\otimes\sigma_-,\quad S=\sigma_-\otimes\sigma_-,$$

$$r_{21}(\lambda,\mu)=Pr_{12}(\lambda,\mu)P=r_{12}(\mu,\lambda). \tag{6.8}$$

The equation (6.8) presents the third family of dynamical r-matrices $r_{12}(\lambda,\mu)$ for $m=3,4,\ldots$. We have

$$A^2(\lambda)+B(\lambda)C(\lambda)=\lambda^m+\lambda\sum_{i=1}^{N}\frac{F^{(i)}}{\lambda-\lambda_i}, \tag{6.9}$$

where

$$F^{(i)}=\frac{1}{2}\,\lambda_i\psi_{2i}^2-\frac{1}{2}\,\lambda_i^{m-1}\psi_{1i}^2+\frac{1}{2}\,\psi_{1i}\psi_{2i}\langle\Psi_1,\Psi_2\rangle-\frac{1}{4}\,\psi_{2i}^2\langle\Psi_1,\Psi_1\rangle$$

$$-\sum_{k=1}^{m-1}\lambda_i^{m-k-1}\sum_{j=1}^{k}\left(\frac{1}{2}\right)^{j+1}\sum_{l_1+\cdots+l_j=k-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle\psi_{1i}^2$$

$$+\frac{1}{4}\sum_{k\neq i}\frac{\lambda_k(\psi_{1i}\psi_{2k}-\psi_{1k}\psi_{2i})^2}{\lambda_k-\lambda_i},\quad i=1,\ldots,N.$$

The classical Poisson structure (3.19) and (6.8) guarantees that independent integrals of motion for (6.4) and (6.5) $F^{(i)}$, $i=1,\ldots,N$ are in involution. Therefore (6.4) and (6.5) are FDIHSs.

In the similar way as for Proposition 3, we can prove the following proposition.

Proposition 11: For the linear r-matrix algebra (3.19) and (6.8) the dynamical Yang–Baxter equations (3.22) with the $d_{i,j}$ and f given by following formulas are valid:

$$d_{ij}(\lambda,\mu)=\frac{\mu}{\mu-\lambda}\,P_{ij}-G_{ij}-g_3(\lambda,\mu)S_{ij},\quad d_{ji}(\lambda,\mu)=d_{ij}(\lambda,\mu),\quad j>i,\quad i,j=1,2,3,$$

$$f(\lambda,\mu,\nu)=-2\sum_{k=0}^{m-3}\sum_{l=0}^{m-3-k}\lambda^k\mu^l\nu^{m-3-l-k}-2\sum_{l=1}^{m-3}\sum_{k=0}^{m-3-l}\sum_{i=0}^{m-3-l-k}\lambda^k\mu^i\nu^{m-3-l-k-i}$$

$$\times\sum_{j=1}^{l}\left(\frac{1}{2}\right)^j(j+1)^2\sum_{l_1+\cdots+l_j=l-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle.$$

D. The Jacobi inversion problem for NLEE (2.16)

We introduce canonically conjugated separation variables w_k, v_k, $k=1,...,N$ as

$$B(\lambda)=\lambda\left[1-\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}^2}{\lambda-\lambda_j}\right]=\lambda\frac{R(\lambda)}{K(\lambda)}, \tag{6.10a}$$

and

$$v_k=\frac{A(w_k)}{w_k}=\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\psi_{2j}}{w_k-\lambda_j}, \quad k=1,...,N, \tag{6.10b}$$

where $K(\lambda)$, $R(\lambda)$ are given by (4.1c). It follows from (6.10a) that w_k, $k=1,...,N$, define elliptic coordinates given by the formula

$$\psi_{1j}^2=-2\frac{R(\lambda_j)}{K'(\lambda_j)}, \quad j=1,...,N. \tag{6.11}$$

We have from (6.10) that

$$\langle\Lambda^k\Psi_1,\Psi_1\rangle=-2\beta_{k+1}-2\sum_{i=0}^{N}\beta_i\sum_{l=1}^{k+1-i}(-1)^l\prod_{j_1+\cdots+j_l=k+1-i}\alpha_{j_1}\cdots\alpha_{j_l}. \tag{6.12}$$

One obtains from (6.3a), (6.4), and (6.10a) that

$$u_0=\frac{\beta_{N,x}}{2\beta_N}. \tag{6.13}$$

Equations (6.3b), (6.12), and (6.13) imply that the expression of u_k, $k=0,...,m-1$, in terms of w_k are the symmetric functions of w_k, $k=1,...,N$.

Then in the same way as in Sec. IV, we obtain the following proposition.

Proposition 12: The Jacobi inversion problem for FDHS (6.4) is of the form

$$\sum_{k=1}^{N}\int^{w_k}\frac{\lambda^{i-1}}{\sqrt{P(\lambda)K(\lambda)}}d\lambda=\gamma_i+2\delta_{i,N}x, \quad i=1,...,N, \tag{6.14}$$

the Jacobi inversion problem for FDHS (6.5) is

$$\sum_{k=1}^{N}\int^{w_k}\frac{\lambda^{i-1}}{\sqrt{P(\lambda)K(\lambda)}}d\lambda=\gamma_i-2\delta_{i,N}\alpha_1 t_m+2\delta_{i,N-1}t_m, \quad i=1,...,N, \tag{6.15}$$

and the Jacobi inversion problem for NLEE (2.16) with $n=m$ is of the form

$$\sum_{k=1}^{N}\int^{w_k}\frac{\lambda^{i-1}}{\sqrt{P(\lambda)K(\lambda)}}d\lambda=\gamma_i+2\delta_{i,N}(x-\alpha_1 t_m)+2\delta_{i,N-1}t_m, \quad i=1,...,N. \tag{6.16}$$

The Jacobi inversion problem (4.14) and (6.16) are almost the same; however, the u of (2.9) and u of (2.16) are in terms of w_k, $k=1,...,N$, in different way.

VII. CONCLUSION

By directly using the constrained flows of soliton equations, we have constructed three families of FDIHSs and their dynamical r-matrices. In this way explicit expressions for the FDIHSs and for the dynamical r-matrices as well as for the dynamical Yang–Baxter equations arise naturally.

Since Lax representation for x- and t_n-constrained flow of soliton equation are naturally deduced from the adjoint representation of the spectral problem, the Jacobi inversion problem for

x- and t_n-constrained flow can always be found by means of the Lax representation. The factorization of soliton equation by x- and t_n-constrained flow allows us to obtain the Jacobi inversion problem for soliton equation by combining the Jacobi inversion problems for x- and t_n-constrained flow. This implies that some kind of solution for soliton equation can be found by the method of separation of variables.

Timelike geodesic motions within the general relativistic gravitational field of the rigidly rotating disk of dust

M. Ansorg[a)]
Friedrich-Schiller-Universität Jena, Theoretisch-Physikalisches Institut, Max-Wien-Platz 1, D-07743 Jena, Germany

(Received 15 June 1998; accepted for publication 3 August 1998)

The general relativistic motion of a test particle near a rigidly rotating disk of dust is investigated. Circular orbits within the plane of the disk (centered on the rotation axis) are special cases of the geodesic motion. One finds that there is always a (stable or unstable) circular orbit for positive angular momentum and a given radius. However, for sufficiently relativistic disks there are regions within the plane of the disk in which a particle with negative angular momentum cannot follow a circular path. If the disk is still more strongly relativistic, then one finds circular orbits with negative energies of arbitrary magnitude. Within the theoretical construction of the Penrose effect, this property can be used to produce arbitrarily high amounts of energy. The study of Hamiltonian mechanics forms another topic of this article. It turns out that the stochastic behavior of the geodesics is related to the position of the region containing all the crossing points of the particle through the plane of the disk. If this region contains points lying inside the disk as well as points outside, the geodesic motion shows highly stochastic behavior. However, if the crossing region is completely inside or outside the disk, the motion proves to be nearly integrable. In these cases the corresponding Hamiltonian system is close to an integrable system of the so-called Liouville class. © *1998 American Institute of Physics.* [S0022-2488(98)03711-6]

I. INTRODUCTION

Einstein's general theory of relativity describes gravitation as a geometric property of the four-dimensional manifold of space and time. Particles moving merely under the influence of gravitation follow the so-called timelike geodesic paths. The investigation of these curves helps in the understanding of the geometrical structure of the manifold in question. Furthermore, accretion processes in which matter is drawn into a central object (e.g., a black hole or a disklike formation) may be approximated by the assumption that the inflowing matter follows the timelike geodesics.

The famous Kerr black hole was the first rotating object for which the relativistic field equations were solved. The timelike geodesic motions near a Kerr black hole have been studied in detail (see, e.g., Ref. 1). For them the corresponding Hamiltonian–Jacobi equation is separable,[2] and the equations of motions are integrable by quadratures. As a consequence, in phase space the trajectories lie within surfaces diffeomorphic to tori.

The general relativistic gravitational field created by a rigidly rotating disk of dust was first studied numerically in 1971 by Bardeen and Wagoner.[3] The global analytic solution of Einstein's field equations for this object was found in 1995 by Neugebauer and Meinel.[4] Their explicit expressions for the metric coefficients allow a direct numerical implementation of the geodesic equations.

In this paper the bounded motions around a rigidly rotating disk of dust are investigated. It turned out that these motions are not integrable by quadratures. In phase space they occupy regions of more complicated structure. However, for a considerable fraction of the set of all bounded timelike geodesic motions, particular properties can be found.

A. The metric

Einstein's field equations for a rigidly rotating disk of dust can be reduced to a single nonlinear complex partial differential equation—the so-called Ernst equation—for which a boundary value problem has to be solved.[5,6] Neugebauer and Meinel succeeded in solving this problem by means of the inverse scattering method which is a technique from the soliton theory.

Writing the metric in Weyl–Papapetrou coordinates (ρ,ζ,φ,t) in the form (a comma in an index represents a partial derivative, a semicolon stands for a covariant derivative)

$$(g_{ij})=\begin{pmatrix} e^{2(k-U)} & 0 & 0 & 0 \\ 0 & e^{2(k-U)} & 0 & 0 \\ 0 & 0 & -a^2e^{2U}+\rho^2e^{-2U} & -ae^{2U} \\ 0 & 0 & -ae^{2U} & -e^{2U} \end{pmatrix} \quad \text{with} \quad g_{ij,\varphi}=0=g_{ij,t},$$

the field equations turn out to be equivalent to the Ernst equation

$$\Re f\left(f_{,\rho\rho}+f_{,\zeta\zeta}+\frac{f_{,\rho}}{\rho}\right)=f_{,\rho}^2+f_{,\zeta}^2$$

for the Ernst potential f which is defined by

$$f=e^{2U}+ib \quad \text{with} \quad b_{,\zeta}=\frac{e^{4U}}{\rho}\,a_{,\rho}, \quad b_{,\rho}=-\frac{e^{4U}}{\rho}\,a_{,\zeta}.$$

The remaining metric function k can be calculated from the functions U and a by quadratures.

Neugebauer and Meinel found the Ernst potential for the rigidly rotating disk of dust in terms of ultraelliptic functions.[4] In their expressions, the Ernst potential depends on a parameter μ, which is related to the angular velocity Ω and the radius ρ_0 of the disk by

$$\mu=2\Omega^2\rho_0^2e^{-2V_0} \quad \text{with} \quad V_0(\mu)=U(\rho=0,\zeta=0;\mu).$$

The parameter μ lies within the interval $(0,\mu_0)$ with $\mu_0=4.629\,66...$. For $\mu\ll1$, one obtains the Newtonian limit of the Maclaurin disk; $\mu\to\mu_0$ and $\rho_0\to0$ yield the extreme Kerr solution. The disk creates an ergosphere [i.e., a region within which the metric function $(-e^{2U})$ is positive] for $\mu>\mu_e\approx1.69$.

In what follows, units are used where the radius ρ_0 as well as the velocity of light c are equal to 1.

B. The Hamiltonian system of the geodesic equations

For axisymmetric stationary space–times the general Hamiltonian system

$$\mathscr{H}=\frac{1}{2}\,g^{ij}p_ip_j \quad \text{with} \quad p_i=g_{ij}\dot{x}^i, \quad \left(=\frac{d}{d\tau}, \quad \tau\text{:proper time}\right)$$

for the timelike geodesic equations

$$\ddot{x}^i+\Gamma^i_{kl}\dot{x}^k\dot{x}^l=0, \quad \dot{x}_k\dot{x}^k=-1$$

can be reduced to a conservative Hamiltonian of two degrees of freedom of the following form:

$$\mathscr{H}=\frac{1}{2}\,e^{2(U-k)}(p_\rho^2+p_\zeta^2)+\frac{1}{2}\left[1-\frac{1}{\rho^2}\,(L^2g_{tt}+2LEg_{\varphi t}+E^2g_{\varphi\varphi})\right]. \tag{1}$$

Here, $L=p_\varphi=\text{const}$ is called the (ζ component of the) angular momentum of the particle and $E=-p_t=\text{const}$ its energy.

The above Hamiltonian is invariant under a simultaneous change of the signs of L and E. Now, these signs are fixed by the condition $\dot{t}>0$ and this condition is then satisfied along the whole trajectory.

The Hamiltonian (1) is arranged such that $\mathscr{H}=0$ holds along the trajectory of the considered test particle. Therefore a restricting condition for the region in which the motion takes place is given by

$$0\leqslant e^{2(U-k)}(p_\rho^2+p_\zeta^2)=\left[\frac{1}{\rho^2}\,(L^2 g_{tt}+2LEg_{\varphi t}+E^2 g_{\varphi\varphi})-1\right]. \tag{2}$$

This region of motion has the following properties:

(1) The region is bounded for $E^2<1$. For $E^2\geqslant 1$ there are unbounded areas allowing an escape of the test particle to infinity. But also, in the case of $E^2\geqslant 1$, there may be additional bounded regions which force the particle to stay inside.
(2) Particles with $L\neq 0$ may not cross the rotation axis.
(3) The momenta p_ρ and p_ζ as well as the velocities $\dot{\rho}$ and $\dot{\zeta}$ vanish at the rim of the considered region. Furthermore, at the boundary of the region the acceleration vector $(\ddot{\rho},\ddot{\zeta})$ is perpendicular to the curve of the boundary and points inwards.
(4) Because of the property $g_{ij}(\rho,-\zeta)=g_{ij}(\rho,\zeta)$, the regions of motion are symmetric with respect to reflection in the plane of the disk.

Illustrative examples for bounded regions of motion can be seen in Figs. 9, 10, 18, and 20.

II. CIRCULAR ORBITS

Motions within the plane of the disk are described by a Hamiltonian with merely one degree of freedom. By the conditions $\dot{\rho}=0=\ddot{\rho}$, circular orbits with centers on the rotation axis are fixed. The following numerical results about circular orbits contain in particular Meinel's and Kleinwächter's analytic results about circular orbits at the rim of the disk.[7] The above conditions $\dot{\rho}=0=\ddot{\rho}$ lead to the equations

$$\begin{aligned} L^2 g_{tt}(\rho,0)+2LEg_{\varphi t}(\rho,0)+E^2 g_{\varphi\varphi}(\rho,0)&=\rho^2,\\ L^2 g_{tt,\rho}(\rho,0)+2LEg_{\varphi t,\rho}(\rho,0)+E^2 g_{\varphi\varphi,\rho}(\rho,0)&=2\rho, \end{aligned} \tag{3}$$

which serve to determine the parameter functions $L_\pm=L_\pm(\rho)$ and $E_\pm=E_\pm(\rho)$. These functions yield for a circular orbit of given radius ρ, the associated pairs of angular momentum and energy. In general, there are two such pairs, denoted by $(L_+(\rho),E_+(\rho))$ and $(L_-(\rho),E_-(\rho))$ where (L_+,E_+) refers to an orbit of positive angular momentum and similarly (L_-,E_-) to an orbit with negative angular momentum. It turns out that the functions $L_+(\rho)$ and $E_+(\rho)$ exist for arbitrary choice of $\rho\geqslant 0$. However, for sufficiently large values of the parameter μ there are no corresponding (L_-,E_-) pairs for ρ values within a certain interval $(\tilde{\rho}_1,\tilde{\rho}_2)$.

In Figs. 1–5, the functions $L_\pm=L_\pm(\rho)$ and $E_\pm=E_\pm(\rho)$ can be seen for different values of the parameter μ. A discussion of these pictures follows.

(1) The pictures for (L_+,E_+) are similar for all values of μ (see Fig. 1). There is a monotonous growth of the functions L_+ and E_+ for $\rho<1$. At $\rho=1$ (here $E_+=1$) both functions turn back and decrease monotonously until they reach another turning point at $\rho=\rho'$. For still greater values of the parameter ρ, the functions L_+ and E_+ grow monotonously again. The turning points are characterized by the conditions $dL_+/d\rho=0=dE_+/d\rho$. As the radius $\rho\to\infty$, E_+ tends to 1 and L_+ to $+\infty$.

Circular orbits with a radius $\rho\in(1,\rho')$ are unstable. Stable circular orbits are those with a radius $\rho\in[0,1)$ or $\rho\in(\rho',\infty)$; the remaining circular orbits with radius 1 or ρ' are marginally unstable.

For circular orbits, the condition

$$\dot{\varphi}=\frac{dE}{dL}\,\dot{t} \tag{4}$$

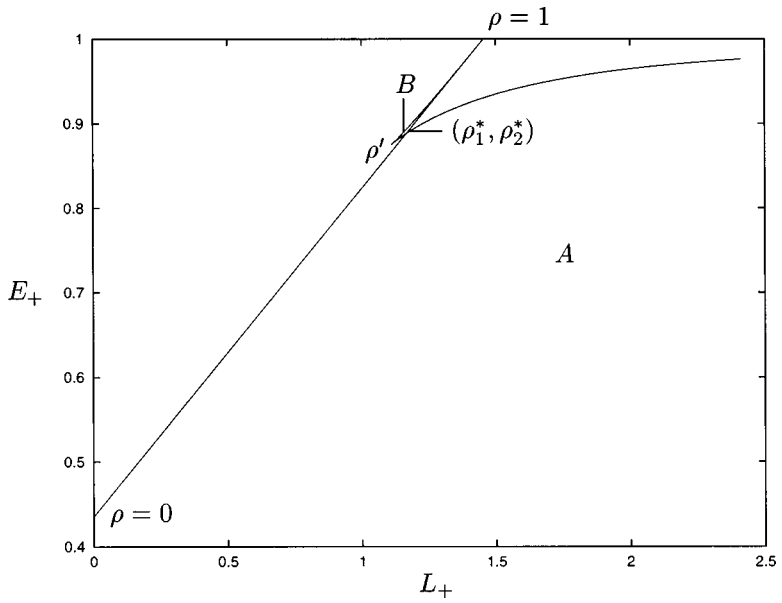

FIG. 1. The functions $L_+(\rho)$ and $E_+(\rho)$ for $\mu = 1.61$.

holds. In all sections of the graphs of the functions L_+ and E_+, the function $E_+ = E_+(L_+)$ grows monotonously. Hence, all circular orbits with positive angular momenta possess positive angular velocity. Furthermore, circular orbits with radii $\rho < 1$ are just those paths along which the dust particles of the disk move. Their four velocity (u^i) is given by $(u^i) = (0,0,\dot{\varphi},\dot{t}) = e^{-V_0}(0,0,\Omega,1)$ (see Ref. 8) from which $dE/dL = \Omega = \text{const}$ follows. Thus, the graph $E_+(L_+)$ is a straight line for $\rho \in [0,1]$.

The region A contains all (L,E) pairs for which no motion of a particle is possible, i.e., either the restricting condition (2) cannot be satisfied or the motion possesses a negative $\dot{t}$. If one chooses for a (not necessarily circular) motion, an (L,E) pair inside the small region B, then there exist two separate compact regions in which bounded motions are possible. At the intersection point of the stable and unstable parts of the (L_+, E_+) graphs these regions degenerate into two

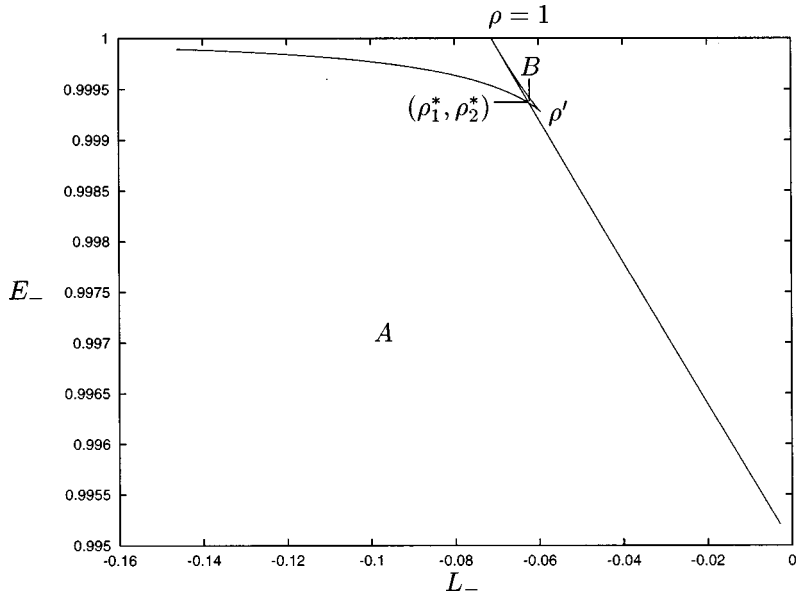

FIG. 2. The functions $L_-(\rho)$ and $E_-(\rho)$ for $\mu = 0.01$.

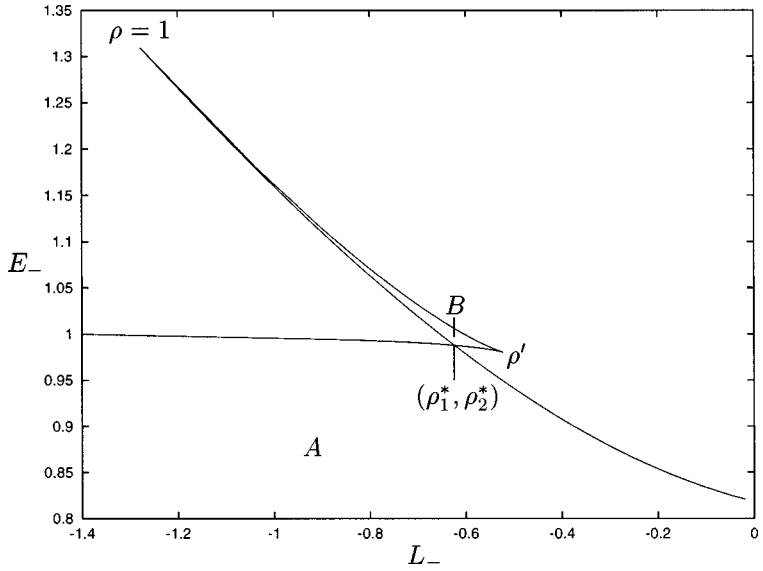

FIG. 3. The functions $L_-(\rho)$ and $E_-(\rho)$ for $\mu = 0.4$.

separate stable circular orbits with radii $\rho_1^* < 1$ and $\rho_2^* > 1$. In Fig. 6, it can be seen how the radii ρ_1^*, ρ_2^*, and ρ' depend on the parameter μ.

(2) In Figs. 2–5, the parameter functions $L_-(\rho)$ and $E_-(\rho)$ are displayed for different values of the parameter μ. For $0 < \mu < 1/2$, the pictures are similar to the graphs of the functions L_+ and E_+. The region B extends now to E_--values greater than 1. Thus, there are stable as well as unstable circular orbits, and furthermore, extended compact regions of motions with energies greater than 1 and corresponding negative angular momenta. From Eq. (4) and the slopes of the functions $E_- = E_-(L_-)$ in Figs. 2 and 3, one concludes that all particles moving along circular orbits with negative angular momenta have negative angular velocity.

(3) As μ approaches the value $\frac{1}{2}$, the region B grows and is unbounded for $\mu \geqslant 1/2$. For radii $\rho \in (\tilde{\rho}_1, \tilde{\rho}_2)$ there are no circular orbits with negative angular momentum. As can be seen in Fig. 4, for sufficiently large values of μ ($\mu > \mu_{\dot{\varphi}} \approx 0.7088$) there are small intervals $[0, \rho_{\dot{\varphi}})$ in which the functions $E_-(L_-)$ grow monotonously. Hence, circular orbits with radii $\rho < \rho_{\dot{\varphi}}$ possess positive

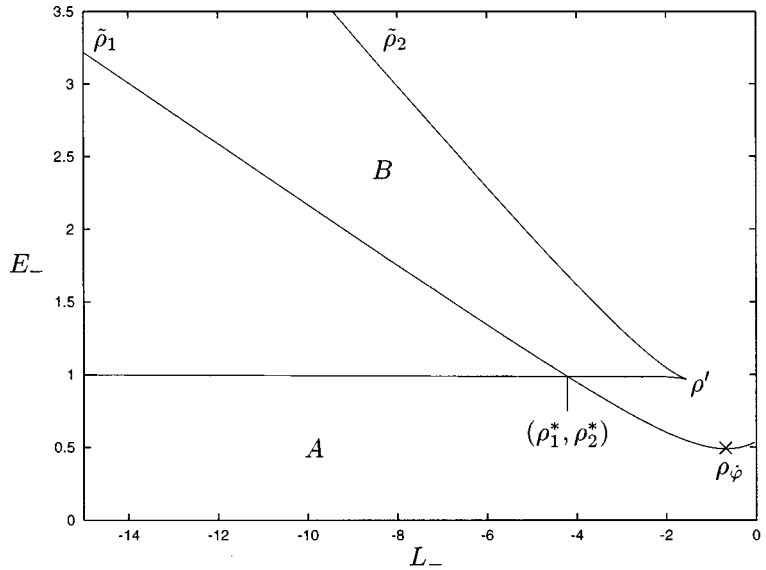

FIG. 4. The functions $L_-(\rho)$ and $E_-(\rho)$ for $\mu = 1.21$.

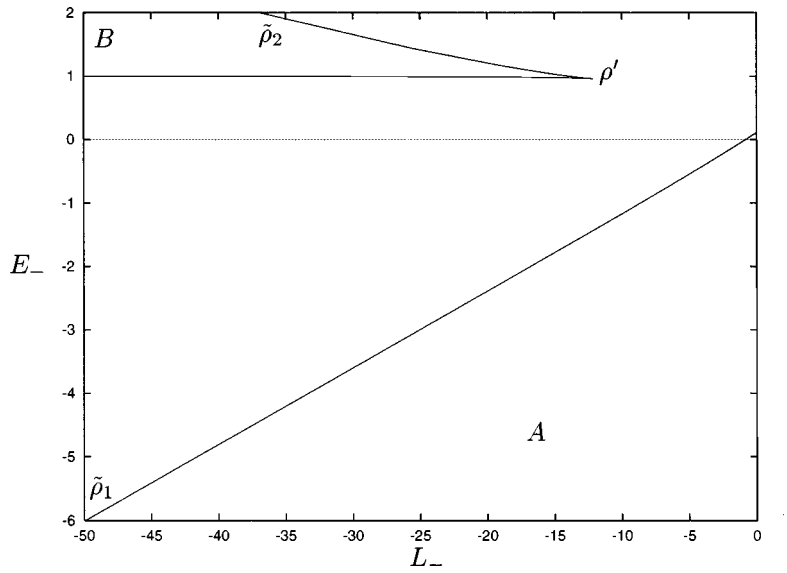

FIG. 5. The functions $L_-(\rho)$ and $E_-(\rho)$ for $\mu=3.5$.

angular velocities in spite of having negative angular momenta. At the radius $\rho_{\dot{\varphi}}$ a particle may remain at rest (in the chosen coordinate system). Such a particle has the smallest energy possible of all motions around the disk.

(4) Finally, in the range $\mu_e<\mu<\mu_0$ (see Fig. 5), there are stable circular orbits with negative energies. As the slope of $E_-(L_-)$ is positive for $\rho<\tilde{\rho}_1$, circular orbits with radii in this range have positive angular velocities. The μ dependencies of the radii $\{\rho_1^*,\rho_2^*,\rho',\tilde{\rho}_1,\tilde{\rho}_2,\rho_{\dot{\varphi}}\}$ as well as those of the radii $\rho_1^{(E)}$ and $\rho_2^{(E)}$, at which the function $E_-=E_-(\rho)$ reaches the value $E_-(\rho_i^{(E)})=1$, are displayed in Fig. 7.

(5) As $\mu\to 0$, the curves $L_\pm(\rho)$ and $E_\pm(\rho)$ tend to the corresponding graphs for the Maclaurin disk (the Newtonian limit of the relativistic disk). Since negative and positive angular momenta are equivalent in Newtonian theory, these graphs possess a reflectional symmetry with respect to the axis $L=0$.

Circular orbits around a Kerr black hole are characterized by the functions (see, e.g., Ref. 1)

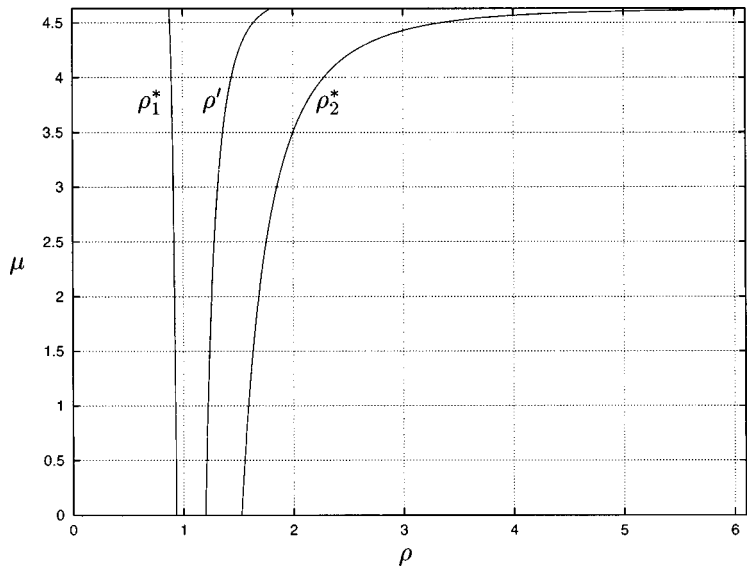

FIG. 6. The μ dependency of the radii ρ_1^*, ρ_2^*, and ρ' for the functions L_+ and E_+.

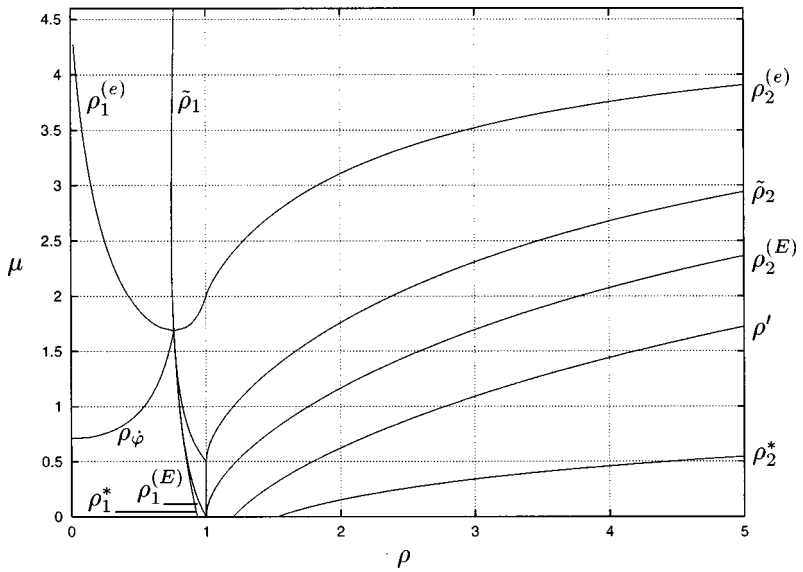

FIG. 7. The μ dependency of the radii $\{\rho_1^*,\rho_2^*,\rho',\tilde{\rho}_1,\tilde{\rho}_2,\rho_{\dot{\varphi}},\rho_1^{(E)},\rho_2^{(E)}\}$ for the functions L_- and E_-. Additionally, the radii $\rho_1^{(e)}$ and $\rho_2^{(e)}$, at which the ergosphere intersects the plane of the disk, are plotted.

$$E_\pm=\frac{r^{3/2}-2mr^{1/2}\pm am^{1/2}}{r^{3/4}(r^{3/2}-3mr^{1/2}\pm 2am^{1/2})^{1/2}},\quad L_\pm=\pm\frac{m^{1/2}[r^2\mp 2a(mr)^{1/2}+a^2]}{r^{3/4}(r^{3/2}-3mr^{1/2}\pm 2am^{1/2})^{1/2}},$$

where $\rho=\sqrt{r^2-2mr+a^2}$, m denotes the mass, and a the specific angular momentum of the black hole. For vanishing denominator in the above expressions (this may happen as ρ reaches the value $\tilde{\rho}$), $L_\pm\to\pm\infty$ and $E_\pm\to+\infty$. Circular orbits with radii less than $\tilde{\rho}$ do not exist. For $\rho>\tilde{\rho}$, the $(L_\pm,E_\pm)$ curves are similar to those of Fig. 5 for $\rho>\tilde{\rho}_2$. Again there is a ρ' which separates unstable (for $\rho<\rho'$) and stable orbits (for $\rho>\rho'$). Furthermore, for circular orbits within the Kerr metric, the signs of angular momentum and velocity always coincide.

Generally one finds that the qualitative behavior of circular motions at sufficiently large radii is similar for the Kerr black hole and the disk. However, circular motions at small radii are quite different.

III. THE PENROSE EFFECT

The Penrose effect is a theoretical construction to produce energy. A test particle (with angular momentum L_0 and energy E_0) is allowed to fall from infinity (hence $E_0>1$) into the ergosphere of the disk. There, it splits into two particles with angular momenta L_1,L_2 and energies E_1,E_2. The total angular momentum and energy are preserved, i.e.,

$$L_0=L_1+L_2,\quad E_0+E_1+E_2.$$

If one of the created particles possesses negative energy (say $E_1<0$), then the other one has an energy $E_2>E_0$. The latter particle escapes to infinity where its higher energy can be utilized.

If a large amount of energy were to be drawn from the disk by this method, the particles remaining within the ergosphere would have a considerable repercussion on the disk. Hence, in the following considerations, when one speaks about arbitrarily high energies, one still means that these energies are negligible compared to the energy of the disk.

A simple way to produce energy would seem to be the following. A particle with an energy E_0 which is slightly larger than 1 falls from infinity into the ergosphere to the point $(\tilde{\rho}_1,0)$ (see Figs. 5 and 7), where it separates into two particles. After the separation, one of the created particles follows the stable circular orbit at $\tilde{\rho}_1$ and has the energy $E_1=E_-(\tilde{\rho}_1)=-\infty$. Hence, the escaping particle possesses an energy $E_2=\infty$. But this does not work since the outgoing particle cannot satisfy the condition (2) at $(\tilde{\rho}_1,0)$, i.e., it never reaches this point. However, it turns out that

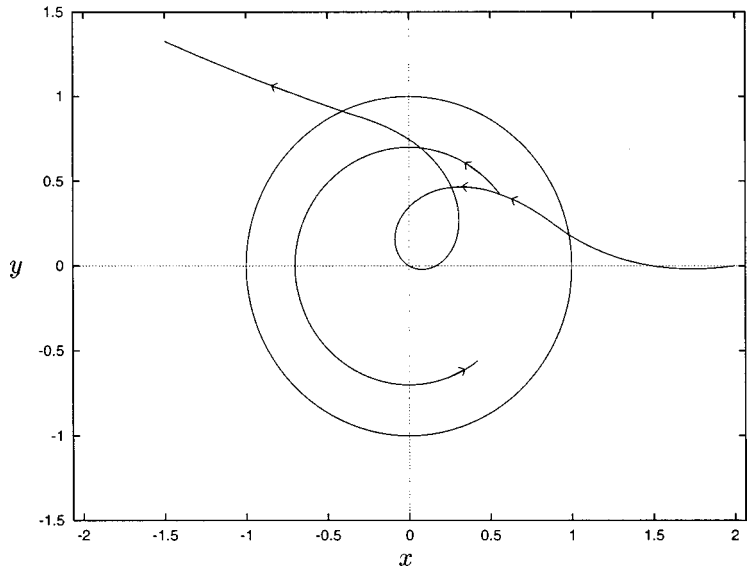

FIG. 8. The Penrose effect. At a value $\mu=2.2$, the parameters $E_0=1.1$ and $\rho_C=0.7$ have been chosen. The energy of the escaping particle is 0.16 greater than the energy of the infalling particle. The curves of the particles can be seen, as the particles move within the plane of the disk (the disk is represented by a circle).

an arbitrary profit of energy can be obtained by giving the infalling particle a high energy $E_0>1$. In the following example, the pair (L_0,E_0) should be chosen above the curve of unstable circular orbits with negative angular momenta (see Fig. 5).

(1) It turns out that it is possible for a particle with an angular momentum L_0 to fall inward toward $(\rho_C,0)$, at which point the corresponding circular orbit has angular momentum $L_-(\rho_C)=L_0$. If the infalling particle remains within the plane of the disk, it suffices to check that (2) holds at $(\rho_C,0)$. In the diagram (E,h), the graph of the function

$$h(E)=\frac{1}{2}\left(1-\frac{1}{\rho_C^2}\left[L_0^2 g_{tt}(\rho_C,0)+2L_0 E g_{\varphi t}(\rho_C,0)+E^2 g_{\varphi\varphi}(\rho_C,0)\right]\right)$$

shows a parabola with negative curvature (since $g_{\varphi\varphi}>0$). Furthermore, $h[E_-(\rho_C)]=0$ since this just represents the first of the conditions (3) for the circular orbit at ρ_C with negative angular momentum. Another conclusion is

$$\frac{dh}{dE}[E_-(\rho_C)]=-\frac{1}{\rho_C^2}\left[L_0 g_{\varphi t}(\rho_C,0)+E_-(\rho_C)g_{\varphi\varphi}(\rho_C,0)\right]=-\dot{t}_C<0,$$

where $\dot{t}_C$ denotes the fourth component of the four velocity of the circular orbit at ρ_C. Thus, h is negative for $E>E_-(\rho_C)$ and hence in particular for $E=E_0$. The infalling particle reaches the point $(\rho_C,0)$.

(2) At the point $(\rho_C,0)$ the particle splits. One of the created particles follows the circular path at ρ_C with negative angular momentum. Hence, it possesses the energy $E_1=E_-(\rho_K)$. The angular momentum of the escaping particle vanishes, whereas its energy $E_2=E_0-E_1$ is greater than E_0 if $E_-(\rho_C)$ is negative. Again, it can be shown that the escaping particle indeed reaches the point $(\rho_C,0)$.

If one goes along the curve of unstable circular orbits (Fig. 5) to higher and higher energies, the corresponding $E_-(\rho_C)$ will be of higher and higher magnitude. Hence, an arbitrary high amount of energy can be obtained if the infalling particle carries a high energy (and a corresponding angular momentum L_0). An example of the described Penrose effect is displayed in Fig. 8.

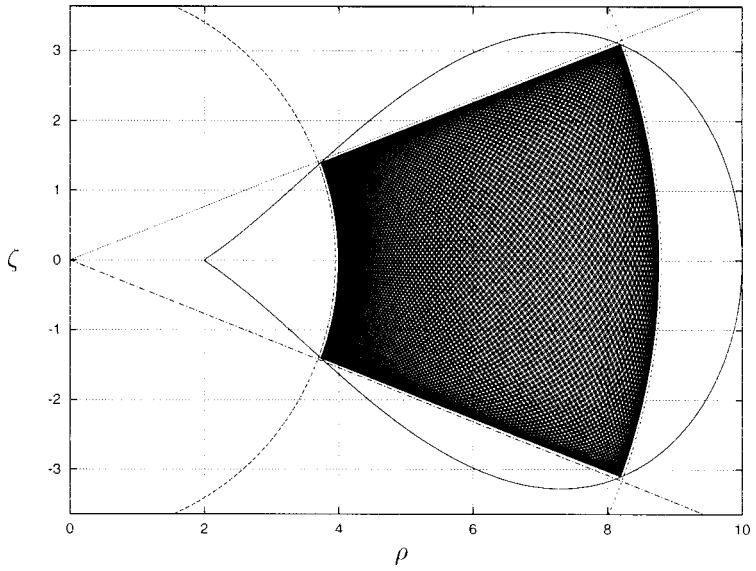

FIG. 9. Example of a geodesic motion in the (ρ,ζ) space with the values $\mu=1$, $L=-1.32$, $E=0.8$, $\rho_1=2$, $\rho_2=10$.

IV. HAMILTONIAN MECHANICS FOR THE GEODESICS

In this section the dynamical properties of bounded geodesics in phase space are investigated. Section IV A treats integrable motions. The regions in phase space occupied by the trajectories are discussed. Furthermore, a class of integrable Hamiltonians—the so-called Liouville class (see, e.g., Ref. 9)—is introduced. In Sec. IV B, this class will turn out to be relevant for the discussion of the nearly integrable geodesics and their properties. Finally, Sec. IV C treats the remaining geodesics which show highly stochastic behavior.

A. Integrable Hamiltonian systems

A famous theorem by Liouville states that in phase space, the bounded trajectories of an integrable Hamiltonian run on geometrical objects diffeomorphic to tori (for a proof see, e.g., Ref. 10). By means of a canonical transformation, it is possible to introduce angle and action variables (ϕ_j, I_j) in which the Hamiltonian merely depends on the action variables I_j. The corresponding Hamiltonian equations

$$\frac{dI_i}{d\tau}=-\frac{\partial \mathscr{H}(I_j)}{\partial \phi_i}=0, \quad \frac{d\phi_i}{d\tau}=\frac{\partial \mathscr{H}(I_j)}{\partial I_i}=\text{const}$$

are easily integrated; one gets $I_j=\text{const}$ and $\phi_j=\omega_j\tau+\phi_{j0}$, where ω_j and ϕ_{j0} are constants.

For an integrable Hamiltonian with two degrees of freedom, one can describe the situation as follows. In the four-dimensional phase space, the action variables $I_j (j=1,2)$ determine a set of surfaces diffeomorphic to two-dimensional tori. Each bounded motion of the considered integrable Hamiltonian runs on one of these surfaces. The angle variables yield a coordinate net on this surface, and the motion within this net proceeds linearly in time. If the ratio ω_1/ω_2 is chosen to be rational, the motion is periodic on the surface; for a ratio $\omega_1/\omega_2=m/n$ $(m,n\in\mathbb{N}$; relatively prime), the path returns to its initial point after a time period of $\tau=2\pi m/\omega_1$. Since the rational numbers are dense in the set of real numbers, the surfaces $I_j=\text{const}$ on which the motion is periodic form a dense subset in the set of all surfaces $I_j=\text{const}$. For the nonperiodic motions with an irrational ratio of the frequencies ω_1 and ω_2, the trajectory fills uniquely the whole surface.

Trajectories in phase space are studied by means of the so-called Poincaré surfaces of section. One chooses a two-dimensional surface in the phase space and labels its two sides (say left and right). Then, the set of crossing points of the trajectory through this surface is investigated. Only intersections are considered for which the trajectory runs through the surface in a particular sense (say from left to right). For integrable Hamiltonians, one gets a closed curve if the ratio of the frequencies is irrational. Otherwise, the Poincaré surfaces of section contain a finite number of

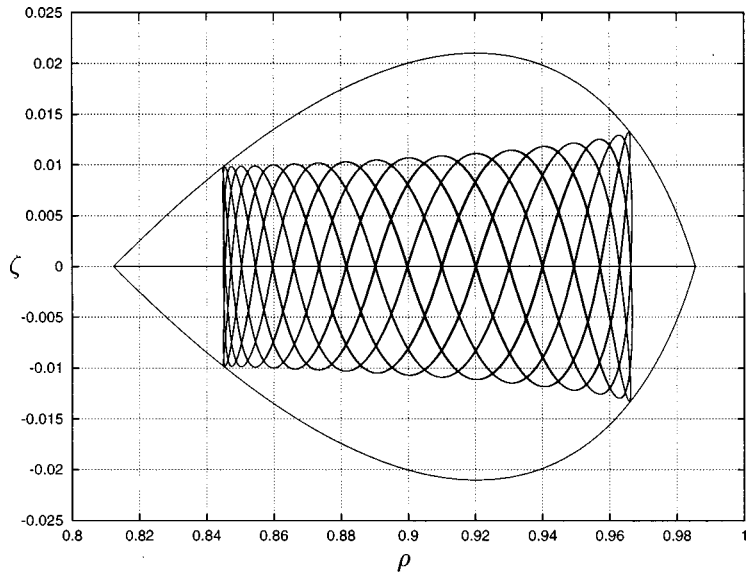

FIG. 10. Example of a geodesic motion in the (ρ,ζ) space with the values $\mu=3$, $L=2.78$, $E=0.77$, $\rho_1=0.81$, $\rho_2=0.986$.

intersection points. For continuously chosen initial conditions of the action variables I_j, the resulting picture consists of closed curves lying inside one another. Lying densely between them, are the finitely many intersection points corresponding to periodic motions.

An important family of integrable Hamiltonian is the so-called Liouville class. In Sec. IV B it will turn out to be the class to which the Hamiltonians for the geodesics are close.

(1) A conformal coordinate transformation $\rho'=\rho'(\rho,\zeta)$ and $\zeta'=\zeta'(\rho,\zeta)$ is defined such that the complex function $z'=z'(\rho,\zeta)=\rho'(\rho,\zeta)+i\zeta'(\rho,\zeta)$ can be expressed only in terms of the variable $z=\rho+i\zeta$, i.e., $z'=z'(z)$. In these coordinates, Hamiltonian systems of the form (1), i.e.,

$$\mathscr{H}=\tfrac{1}{2}e^{\alpha(\rho,\zeta)}(p_\rho^2+p_\zeta^2)+h(\rho,\zeta;L,E), \tag{5}$$

assume the form

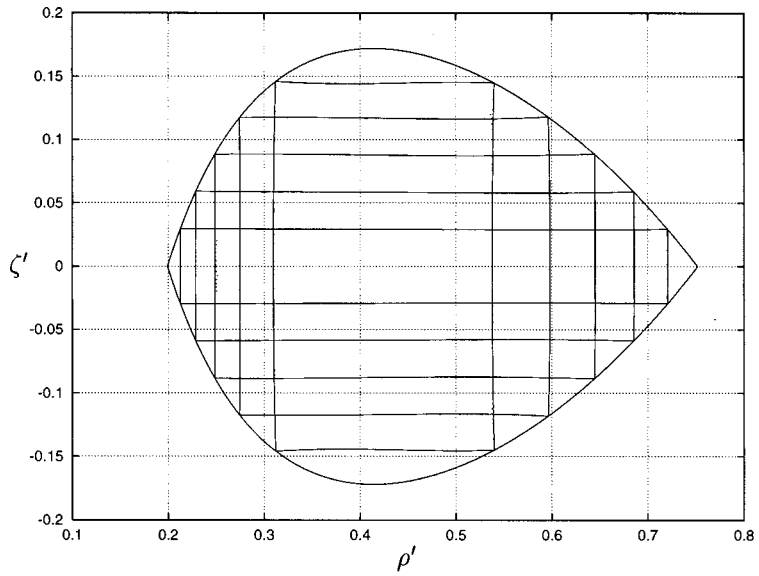

FIG. 11. Boundaries of regions that are filled by Newtonian geodesics in the conformal coordinates (ρ',ζ') introduced by $z'=10z/(10+z^2)$ (the values $\rho_1=0.2$, $\rho_2=0.75$ have been taken).

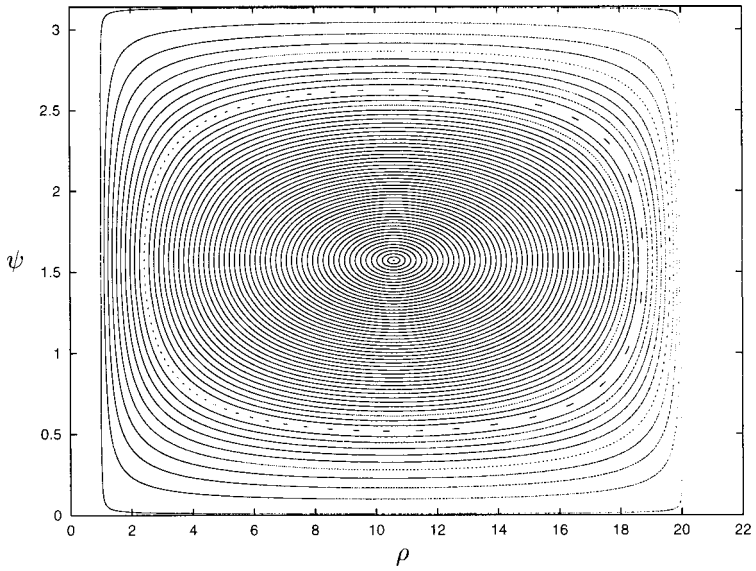

FIG. 12. Poincaré section of surface with $\rho_1 = 1.0001$, $\rho_2 = 20$ (Maclaurin disk).

$$\mathscr{H} = \tfrac{1}{2} e^{\alpha'(\rho',\zeta')}(p_{\rho'}^2 + p_{\zeta'}^2) + h'(\rho',\zeta';L,E)$$

with

$$e^{\alpha'} = e^{\alpha}\left|\frac{dz'}{dz}\right|^2, \quad h'(\rho',\zeta';L,E) = h[\rho(\rho',\zeta'),\zeta(\rho',\zeta');L,E].$$

(2) A Hamiltonian system of the form (5) turns out to be integrable if there are conformal coordinates $z' = z'(z)$ in which the functions α' and h' read

$$e^{\alpha'(\rho',\zeta')} = \frac{1}{R_1(\rho') + Z_1(\zeta')},$$

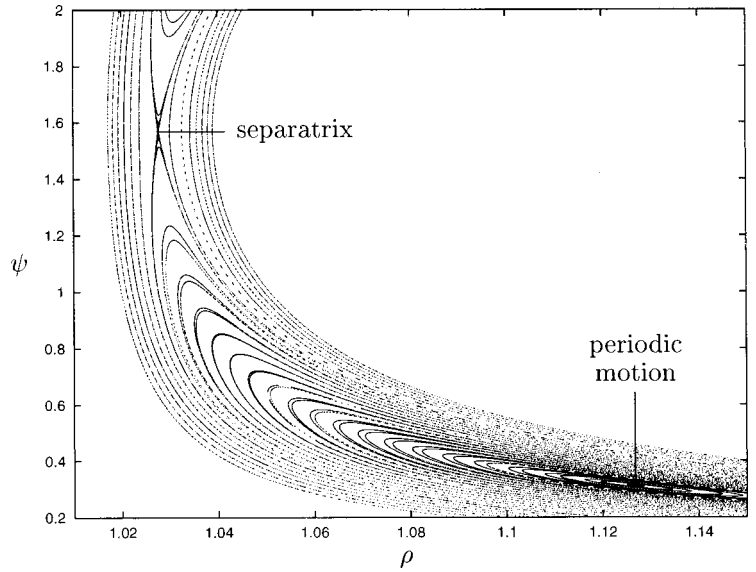

FIG. 13. Magnified extract from Fig. 12.

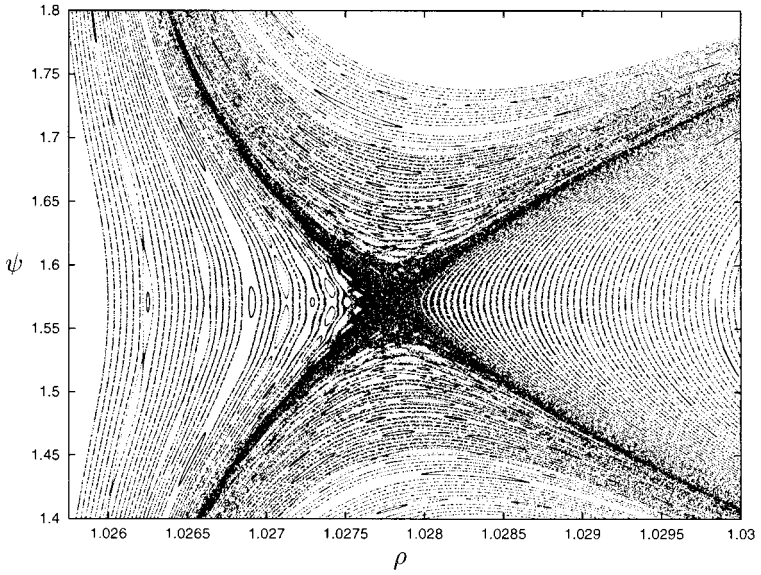

FIG. 14. Still more strongly magnified extract from Fig. 12.

$$h'(\rho',\zeta')=\frac{1}{2}\,e^{\alpha'(\rho',\zeta')}[R_2(\rho')+Z_2(\zeta')]=\frac{1}{2}\cdot\frac{R_2(\rho')+Z_2(\zeta')}{R_1(\rho')+Z_1(\zeta')},$$

where the functions R_i only depend on ρ' and the functions Z_i only on ζ'. Hamiltonians possessing this property belong to the Liouville class of integrable systems. From their first integrals, one concludes

$$\frac{\dot\rho'^2}{\dot\zeta'^2}=\frac{\nu+2\lambda R_1-R_2}{-\nu+2\lambda Z_1-Z_2}=\frac{R_3(\rho';\lambda,\nu)}{Z_3(\zeta';\lambda,\nu)}.$$

If the constants of integration, λ and ν, are fixed by the conditions $R_3(\rho_1';\lambda,\nu)=0=R_3(\rho_2';\lambda,\nu)$, then $\dot\rho'$ vanishes whenever the coordinate ρ' reaches the values ρ_1' or ρ_2'. Simi-

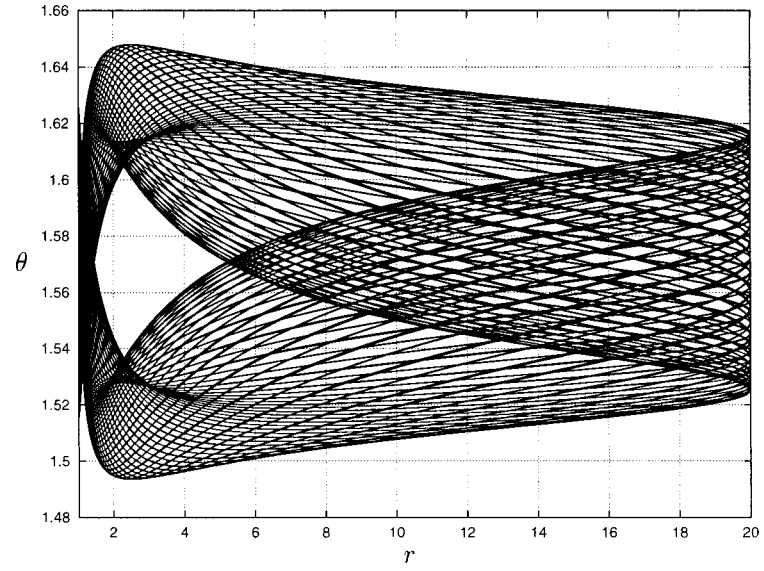

FIG. 15. Trajectory whose intersection points on the Poincaré surface of section fall into the regions of islands displayed in Fig. 13. The curve is presented in spherical polar coordinates ($\rho=r\sin\theta$; $\zeta=r\cos\theta$).

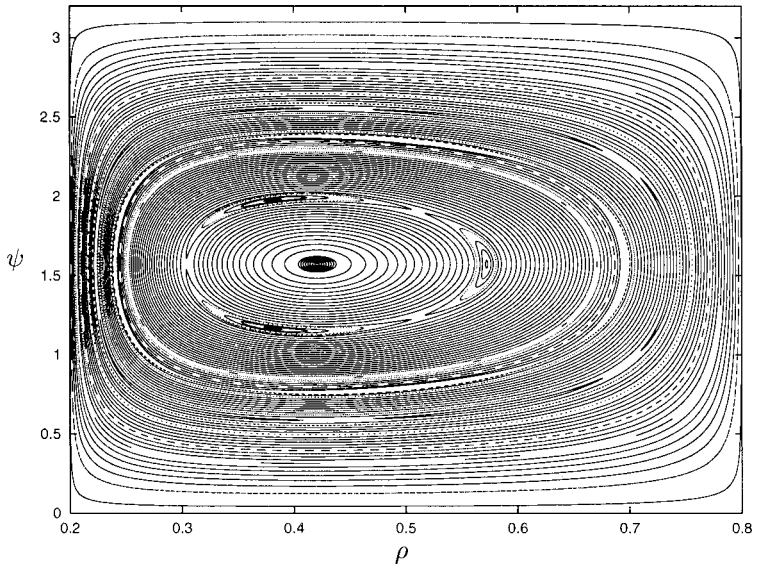

FIG. 16. Poincaré section of surface with $\rho_1=0.2$, $\rho_2=0.8$ (Maclaurin disk).

larly, $\dot{\zeta}'$ vanishes whenever the coordinate ζ' assumes the value of a zero of the function $Z_3(\zeta';\lambda,\nu)$, of which there are at least two for bounded motions. Thus, any bounded nonperiodic motion will gradually fill a region which is spanned by the coordinate axes $\rho'=\text{const}$ and $\zeta'=\text{const}$.

It can be shown that the geodesics within the Kerr metric (the integrability of which was proved by Carter[10]) belong to this class. One gets another important special case by introducing the conformal coordinates $z'=z'(z)=\ln z$, which are closely connected with spherical polar coordinates. Thus, there is a class of integrable Hamiltonians whose (nonperiodic) trajectories in the (ρ,ζ) space densely fill circular segments.

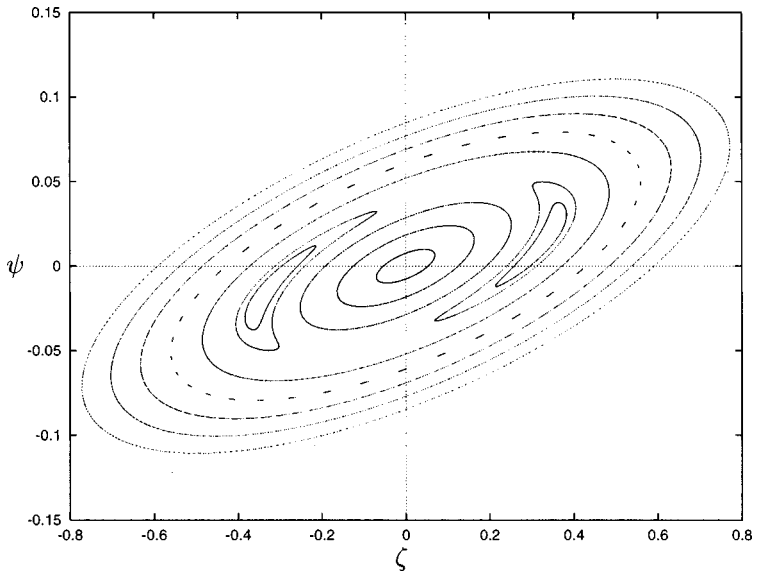

FIG. 17. Poincaré section of surface with $\mu=3.5$, $\rho_1=1.01$, $\rho_2=20$ (relativistic disk). The plane $\rho=\frac{1}{2}(\rho_1+\rho_2)$ and the crossing direction $\dot{\rho}>0$ have been taken.

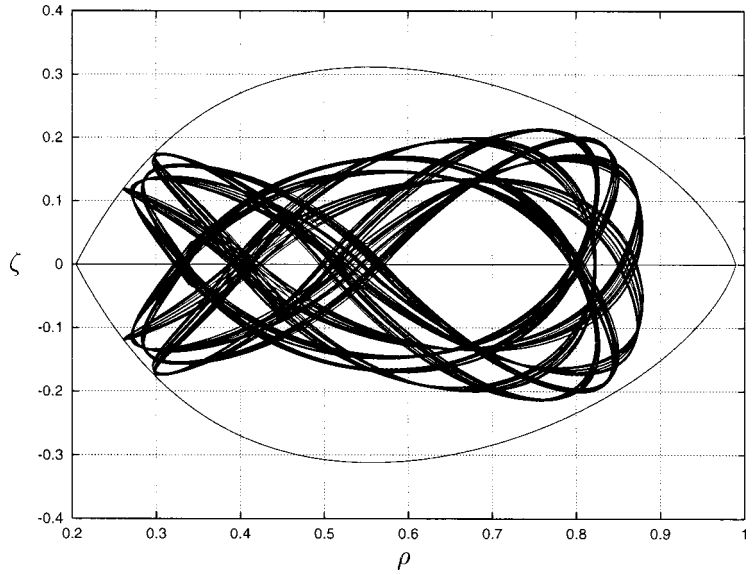

FIG. 18. Example of clearly irregular relativistic geodesic ($\mu=1$, $\rho_1=0.205$, $\rho_2=0.99$).

B. Nearly integrable Hamiltonian systems

Figures 9 and 10 show examples of bounded geodesic motions. In the (ρ,ζ) space, the paths remain within a certain region determined by the formula (2). In Fig. 9, both intersection points (with ρ coordinates ρ_1 and ρ_2) of this region with the disk of the plane are outside the disk, whereas in Fig. 10 both of them are placed inside.

One notices a high regularity of the resulting geodesics. From Fig. 9, one gets the impression that the corresponding Hamiltonian possesses, in spherical polar coordinates, the separation property discussed in Sec. IV A. Also the geodesic shown in Fig. 10 seems to belong to an integrable system of the Liouville class. In Fig. 11, the boundaries of the regions that are gradually filled by the geodesics can be seen in conformal coordinates which are introduced by the transformation $z'=10z/(10+z^2)$.

However, these systems turned out to be clearly nonintegrable. But their deviations from

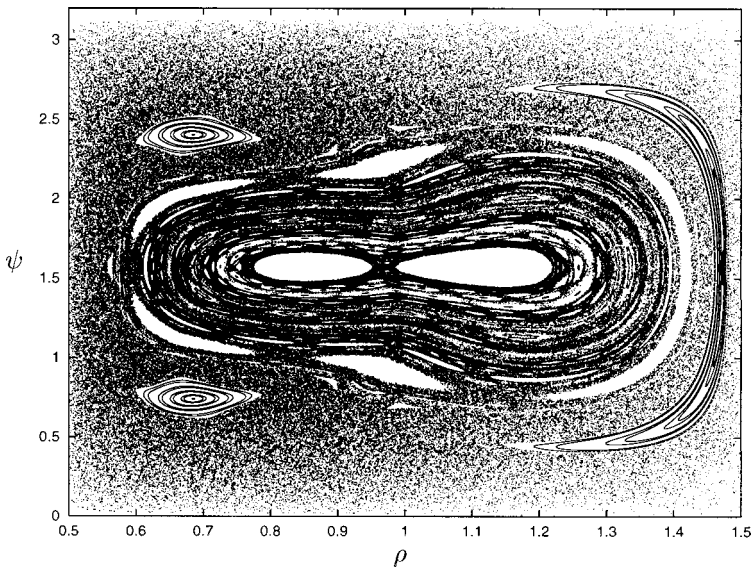

FIG. 19. Poincaré section of surface with $\rho_1=0.5$, $\rho_2=1.5$ (Maclaurin disk).

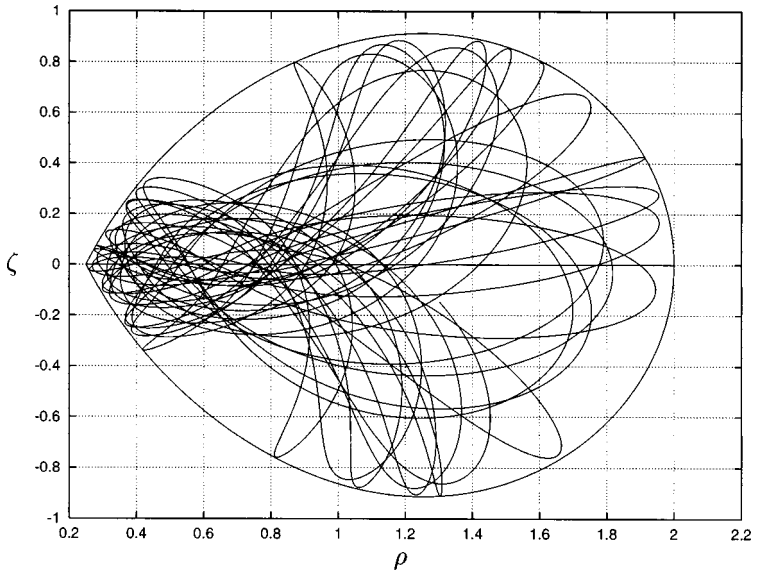

FIG. 20. Example of a geodesic motion in the (ρ,ζ) space with the values $\mu=1$, $L=-0.57$, $E=0.89$, $\rho_1=0.25$, $\rho_2=2$.

integrable systems of the Liouville class are so small that the so-called KAM (Kolmogorov, Arnold, Moser) theorem (see, e.g., Ref. 11) for nearly integrable systems applies.

According to this theorem, the qualitative characteristics of the trajectories of a weakly disturbed integrable Hamiltonian do not change drastically. Most of the curves are still regular, i.e., they are associated with first integrals of motion. Some of the trajectories still lie on tori which now are slightly deformed compared to the integrable case. However, the most regular motions occur on more complicated surfaces. Insight into the topological structure of these surfaces is given by the Poincaré sections of surface. The remaining geodesics show irregular behavior and are not associated with first integrals of motion.

The situation is illustrated by the Poincaré sections of surface displayed in Figs. 12–14. The trajectories are considered in the three-dimensional hypersurface $\mathscr{H}=0$. A coordinate net in this space is given by the coordinates ρ, ζ, and ψ where the angle ψ is defined by $\tan\psi=\dot{\zeta}/\dot{\rho}$. For the Poincaré sections of surface, the intersection plane $\zeta=0$ and the crossing direction $\dot{\zeta}>0$ have

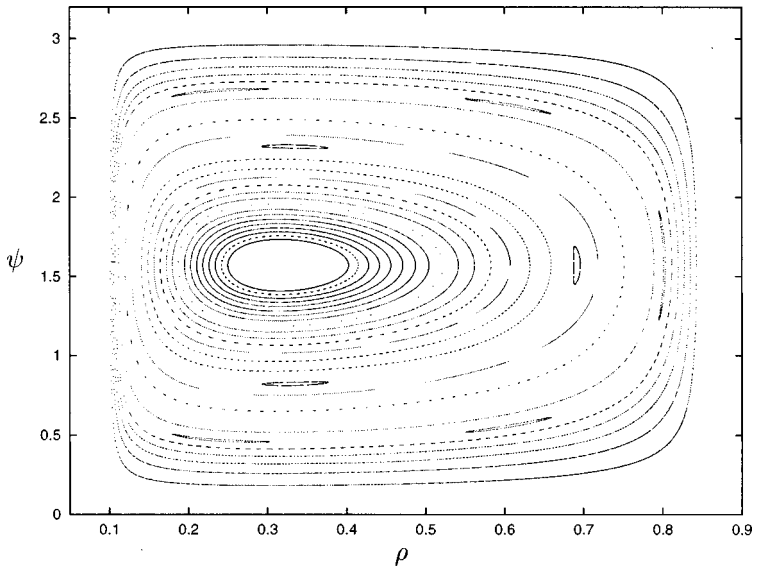

FIG. 21. Poincaré section of surface with $\rho_1=0.1$, $\rho_2=0.85$ (Maclaurin disk).

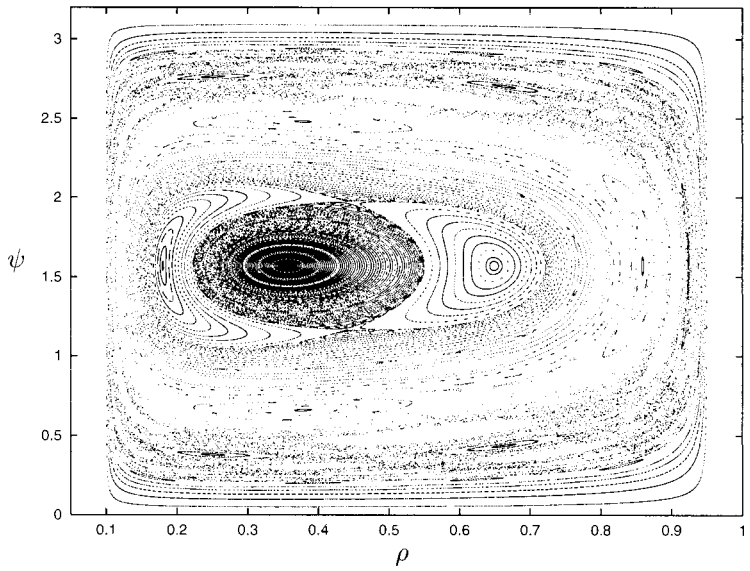

FIG. 22. Poincaré section of surface with $\rho_1 = 0.1$, $\rho_2 = 0.95$ (Maclaurin disk). The distances between the KAM tori have clearly enlarged. The irregular trajectories fill a considerable part of the phase space.

been taken. [The sections of surfaces were created by taking fixed values ρ_1 and ρ_2 and varying the initial conditions $(\rho(0),\zeta(0))$ of the trajectories continuously along the boundary of the region described by formula (2).]

At first glance, one sees as depicted in Fig. 12, what seems to simply be a series of curves lying inside one another, as described in Sec. IV A for integrable motions. But if one enlarges an extract, a more complicated structure becomes evident (Fig. 13). The periodic motions are encircled by islands which lie inside one another. Furthermore, there are so-called separatrices encircling different groups of these islands. In the vicinity of an apex between two of these groups of islands, one recognizes a still more complicated structure (Fig. 14). New groups of islands can be found, and at every new level of magnification, the same qualitative picture emerges. The separatrices represent irregular motions. However, each of the islands belongs to a regular one

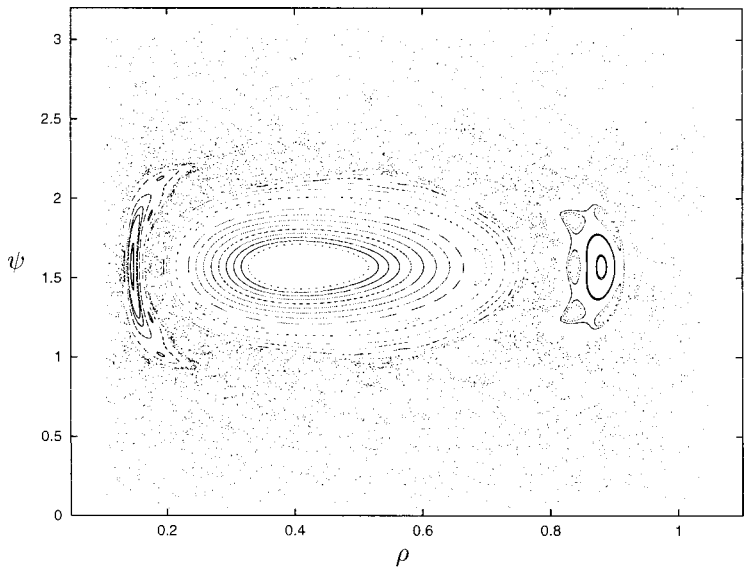

FIG. 23. Poincaré section of surface with $\rho_1 = 0.1$, $\rho_2 = 1.05$ (Maclaurin disk). The characteristical KAM tori have disappeared. Now, there are islands of regular motions within a region of globally stochastic motions.

(with a complicated topological structure of the surface on which the trajectory is trapped). An example for a such a geodesic motion is to be seen in Fig. 15.

Also the geodesics, for which the corresponding region of motion given by formula (2) intersects the plane of the disk at the ρ values $\rho_1<\rho_2<1$, prove to be nearly integrable. As to be seen in Fig. 16, they are not as close to integrable systems as those for the case $1<\rho_1<\rho_2$. But one gets the same qualitative pictures.

The qualitative properties discussed above can be found for the Maclaurin disk (i.e., the Newtonian limit) as well as for the relativistic disk. In general, the relativistic motions show a somewhat stronger deviation from integrable systems, but they still can be regarded as nearly integrable motions. A Poincaré section of surface for the relativistic disk can be seen in Fig. 17. A clearly irregular motion is displayed in Fig. 18.

From these investigations one concludes that the regions in the (ρ,ζ) space that are gradually filled by the nonperiodic geodesics are not spanned by the coordinate axis $\rho'=\text{const}$ and $\zeta'=\text{const}$ of a conformal coordinate system. Rather one finds that the trajectories are trapped by neighboring regions of this form. The distance between these neighboring regions is determined by the deviation of the geodesic in question from an integrable motion.

C. Global stochastic motions

As the departures from an integrable Hamiltonian grow, the distances between the regular curves in phase space become larger and larger. If the disturbance is large enough, then there are no longer any KAM tori, which previously encircled the irregular trajectories. In a global stochastic region, smaller subregions occur, containing groups of islands similar to those described in Sec. IV B. Again, these islands correspond to regular motions.

The remaining bounded geodesic motions, for which the boundary of the region described by formula (2) intersects the plane of the disk at the ρ coordinates $\rho_1<1<\rho_2$, show just this stochastic behavior (as can be seen in Figs. 19 and 20).

The transition from nearly integrable systems to the global stochastic ones is indicated in Figs. 21–23. Here, while keeping the value $\rho_1<1$ fixed, the coordinate ρ_2 is gradually enlarged, which eventually leads to the global stochastic picture in which the KAM tori have disappeared.

Global stochastic motions possess a rather unpredictable behavior. In general, the trajectories are not necessarily trapped into a subregion of the region described by (2) (as was the case for nearly integrable motions). However, if one restricts oneself to motions which lie in a region of islands, one has again nearly integrable motions with particular properties. (For a detailed introduction into the theory of regular and stochastic motions, see, e.g., Ref. 12.)

Cauchy horizons are shown to be differentiable at end points where only a single null generator leaves the horizon. A Cauchy horizon fails to have any null generator end points on a given open subset iff it is differentiable on the open subset and also iff the horizon is (at least) of class C^1 on the open subset. Given the null convergence condition, a compact horizon which is of class C^2 almost everywhere has no end points and is (at least) of class C^1 at all points. © *1998 American Institute of Physics.* [S0022-2488(98)00911-6]

I. INTRODUCTION

Cauchy horizons and black hole event horizons have been extensively studied and used in relativity.[1–12] For general space–times, horizons may fail to be stable under small metric perturbations, however, some sufficiency conditions for various stability questions have been obtained.[13,14] In the present paper, we will consider some differentiability questions for Cauchy horizons.

Let (M,g) be a space–time with a partial Cauchy surface S. The future Cauchy development $D^+(S)$ is the set of points of the space–time where, in theory, one may calculate everything in terms of initial data on S. The future Cauchy horizon $H^+(S)$ is the future boundary of S. We state our results in terms of the future horizon $H^+(S)$, but similar results hold for any past Cauchy horizon $H^-(S)$.

Cauchy horizons are *achronal* (i.e., no two points on the horizon may be joined by a timelike curve) and this implies that Cauchy horizons (locally) satisfy a Lipschitz condition. This, in turn, implies that Cauchy horizons are differentiable almost everywhere. Because they are differentiable except for a set of (three dimensional) measure zero, it seems that they have often been assumed to be smooth except for a set which may be more or less neglected. However, one must remember in the above that (1) differentiable only refers to being differentiable at a single point and (2) sets of measure zero may be quite widely distributed. In fact, Chruściel and Galloway[5] have constructed examples of both a Cauchy horizon and a black hole event horizon where the horizons fail to be differentiable on dense subsets. Thus, they have constructed examples of horizons which contain no open subsets on which they are differentiable at all points. They point out that these examples raise definite questions concerning some major arguments that have been given in the past where smoothness assumptions have been implicitly assumed.[5] In light of these new examples, it is clear that there is a real need for a deeper understanding of the differentiability properties of horizons.

Each point p of a Cauchy horizon $H^+(S)$ lies on at least one null generator.[8] Since partial Cauchy surfaces are edgeless, a null generator continues to lie on the horizon when it is extended in the past. However, null generators may or may not stay on the horizon when they are extended in the future direction. If a null generator leaves the horizon, then there is a last point where it remains on the horizon. This last point is said to be an *end point* of the horizon.

End points where two or more null generators leave the horizon are points where the horizon must fail to be differentiable.[5,7] In addition, Chruściel and Galloway[5] have shown that Cauchy

horizons are differentiable at points which are not end points. Furthermore, Chruściel and Galloway pointed out the need to resolve the differentiability issue for end points where only one generator leaves the horizon. In the present paper, we show that Cauchy horizons are differentiable at these end points. This completes the classification of (pointwise) differentiability for Cauchy horizons in terms of null generators and their end points. However, this result raises the following question. Is it always true that the entire set of end points of a Cauchy horizon will have measure zero? We conjecture that the answer should be affirmative based on known examples. Also, some support for our conjecture is given by our proof that the set of end points with only one generator is in the closure of the set of end points with more than one generator.

Restricting our attention to an open subset W of the Cauchy horizon $H^+(S)$ and assuming that the horizon has no end points on the open set W, we find the horizon must be differentiable at each point of W and, in fact, that the horizon must be at least of class C^1 on W. Conversely, we find differentiability on an open set W implies there are no end points on W. In general, (pointwise) differentiability on an open set yields class C^1, but not necessarily class C^2. We give an example to demonstrate that one may not conclude that either differentiability or lack of end points on an open set W imply class C^2 on W. We also include a very simple example of a Cauchy horizon with an end point where only one null generator leaves the horizon.

Hawking[7] has argued that under certain conditions there should be no compactly generated Cauchy horizons. These are horizons with a compact set K such that all null generators eventually enter and remain in this set K when extended in the past direction. Hawking was interested in establishing arguments against the possibility of having closed timelike curves in physical space–times and, as he mentions, most of his arguments apply to the special case of compact horizons. A key part of Hawking's paper involves flowing the horizon back along null generators to get a contradiction. We use his notation and technique to find sufficient conditions for a compact horizon to have no end points and to be at least of class C^1 at all points. More precisely, we show that if one has the null convergence condition and a compact horizon which is of class C^2 on an open set G with complement of measure zero, then the horizon has no end points and is (at least) of class C^1 at all points.

II. PRELIMINARIES

Let (M,g) be a space–time. Although our results hold for n-dimensional space–times, we will only give the proofs in the four-dimensional case since similar proofs hold in other dimensions. Thus, we will take M to be a smooth, connected, four-dimensional, Hausdorff manifold with a Lorentzian metric, a countable basis, and a time orientation. The Lorentzian metric g will have signature $(-,+,+,+)$. A *partial Cauchy surface* S will be a connected, acausal, edgeless three-dimensional submanifold of (M,g).[2,7,8] The *future Cauchy development* $D^+(S)$ consists of all points $p \in M$ such that each past endless and past directed causal curve from p intersects the set S. The *future Cauchy horizon* is $H^+(S)=\overline{(D^+(S))}-I^-(D^+(S))$. Let p be a point of the Cauchy horizon. It is well known, that there is at least one null generator of $H^+(S)$ containing p. Each null generator is at least part of a null geodesic of M. When a null generator of $H^+(S)$ is extended into the past, it continues to lie on the horizon.[8] However, if a null generator is extended into the future it may have a last point on the horizon which is then said to be an *end point* the horizon. We will define the *multiplicity* of a point p in $H^+(S)$ to be the number of null generators containing p. Points of the horizon which are not end points must have multiplicity one. The multiplicity of an end point may be any positive integer or infinite. We will call the set of end points of multiplicity two or higher the *crease set*.[5]

Consider any fixed point p of the Cauchy horizon $H^+(S)$ and let x^0,x^1,x^2,x^3 be local coordinates defined on an open set about $p=(p^0,p^1,p^2,p^3)$. Let $H^+(S)$ be given near p by an equation of the form

$$x^0=f_H(x^1,x^2,x^3).$$

The horizon $H^+(S)$ is *differentiable* at the point p iff the function f_H is differentiable at the point (p^1,p^2,p^3) using the advanced calculus definition of differentiability.[15] In particular, if $p=(0,0,0,0)$ corresponds to the origin in the given local coordinates and if

$$\Delta x=(x^1,x^2,x^3)$$

represents a small displacement from p in the $x^0=0$ plane, then $H^+(S)$ is differentiable at p iff one has

$$f_H(\Delta x)=f_H(0)+\sum a_i x^i+R_H(\Delta x)=0+\sum a_i x^i+R_H(\Delta x),$$

where the ratio $R_H(\Delta x)/|\Delta x|$ converges to zero as $|\Delta x|$ goes to zero. Here we use

$$|\Delta x|=\sqrt{(x^1)^2+(x^2)^2+(x^3)^2}.$$

Note that even though $|\Delta x|$ represents a coordinate dependent length, the Cauchy surface $H^+(S)$ will be differentiable or not differentiable at p independent of the particular choice of local coordinates. Of course, when $H^+(S)$ is differentiable at p, one has $a_i=\partial f_H/\partial x^i$ evaluated at the origin for $i=1,2,3$. The surface $H^+(S)$ is of class C^r on an open neighborhood of p iff f_H is of class C^r on an open neighborhood of the origin.

If $H^+(S)$ is differentiable at the point p, then there is a well-defined three-dimensional linear subspace N_0 in the tangent space $T_p(M)$ such that N_0 is tangent to the three-dimensional surface $H^+(S)$ at p. In the above notation a basis for N_0 is given by $\{a_i\partial/\partial x^0+\partial/\partial x^i|i=1,2,3\}$. It is clear that if local coordinates x^0,x^1,x^2,x^3 have been chosen as above, then the partials $a_i=\partial f_H/\partial x^i$ at p are determined by N_0 assuming, of course, that $H^+(S)$ is differentiable at p and is given by $x^0=f_H(\Delta x)$ near p. Notice that the given tangent plane N_0 cannot be spacelike since there is at least one null generator containing p. Also, the tangent plane N_0 cannot be timelike since otherwise p would be in chronological past of some points of $H^+(S)$. Thus, N_0 is null [i.e., of signature $(0,+,+)$] and it follows that there is a one-dimensional linear subspace L_0 in N_0 such that L_0 is null. In fact, $N_0=L_0^\perp$ is the orthogonal space to L_0 and is thus uniquely determined by L_0. Given a tangent vector X at p with $X\in N_0$, then X belongs to L_0 iff $g(X,Y)=0$ for all $Y\in N_0$.

At a point p where $H^+(S)$ is differentiable there can only be one null generator through p since two different null generators through p would yield a two-dimensional timelike plane lying in the (three-dimensional) tangent plane to the horizon and this would imply the existence of a timelike plane tangent to $H^+(S)$ at p in contradiction to the above. Thus at points with two or more null generators of $H^+(S)$, the horizon $H^+(S)$ cannot be differentiable.[5] In fact, if p is a point of the horizon having two or more null generators, then all null generators through p must leave the horizon at p when traversed in the future direction. This follows since if $\gamma_1(t)$ and $\gamma_2(t)$ are future directed null generators with $\gamma_1(0)=\gamma_2(0)=p$ and if $\gamma_1(t)$ remains on $H^+(S)$ for some $\gamma_1(t_1)$ with $t_1>0$, one has that all points of $\gamma_2(t)$ with $t<0$ are in the chronological past of $\gamma_1(t_1)$ since one can traverse $\gamma_1(t)$ backward to p, make a corner at p to head in the past direction of the null geodesic $\gamma_2(t)$, and then traverse this null geodesic backward. This would imply the points $\gamma_2(t)$ for $t<0$ are in the set $D^+(S)$ and not on the horizon, in contradiction.

We now give an example of an end point p of multiplicity one.

Example 2.1: Let $M_0=L^3$ be three-dimensional Minkowski space–time with coordinates (t,x,y) and $g=-dt^2+dx^2+dy^2$. Remove the parabola $y=x^2$ from the $t=0$ plane to obtain the space–time M. Let the partial Cauchy surface S be the portion of the $x-y$ plane which is interior to the parabola $y=x^2$ (i.e., $S=\{(0,x,y)|y>x^2\}$). The curvature k of the curve $y=x^2$ has a maximum value of 2 at $x=0$ and is always less than 2 for points on the parabola other than the origin. The osculating circle at the origin to the curve $y=x^2$ is a circle in the $x-y$ plane of radius $1/k=1/2$ and center at $y=1/2$ on the y-axis. The chronological past of the point $(1/2,0,1/2)$ intersected with the $x-y$ plane is the interior of this osculating circle and lies in the set S. It follows that the null geodesic $x=0$, $y=t$ contains a null generator of $H^+(S)$. In particular, the curve $c(t)=(t,0,t)$ for $0<t<\infty$ is a null geodesic which lies on the horizon for $0<t\leqslant 1/2$. Notice that if one intersects the $x-y$ plane with the chronological past of $(t,0,t)$ for $t>1/2$, then one obtains some points outside of the above partial Cauchy surface S. Thus, the null generator $c(t)=(t,0,t)$ must leave the horizon at $t=1/2$ and one finds that $(1/2,0,1/2)$ is an end point of the horizon. However, the end point $p=(1/2,0,1/2)$ has no other null generators since all other null geodesics through

this point intersect the set S. Thus, p is an end point of multiplicity one as desired. In this example one may directly check that $H^+(S)$ is differentiable at the point p. The crease set is a curve which lies above the points on the y-axis for which $1/2<y<\infty$.

In the next example we obtain a horizon which has an open set W where the horizon is of class C^1, but where there are some points in this open set W where the horizon fails to be of class C^2. In particular, there is a certain null generator and the horizon fails to be of class C^2 along this null generator.

Example 2.2: Let $M_0=L^3$. The space–time M will be obtained by removing two half lines and one-fourth of a circle. From M_0 remove the set in the $t=0$ plane given by $y=-1$ and $0\leqslant x$. Then remove the part of the circle $x^2+y^2=1$ for which $x<0$ and $y<0$. Finally, remove the half line in the $t=0$ plane given by $x=-1$ and $0\leqslant y$. The partial Cauchy surface S will be the open set in the $x-y$ plane corresponding to the interior of the convex hull of the deleted set. The null generators corresponding to the quarter circle focus at the point (1,0,0). The null generators corresponding to points on the line $y=-1$ for sufficiently small values of t lie on lines of the form $c(t)=(t,x,t-1)$ where $0\leqslant x$. It follows that for values of x and y near $x=0$ and $y=-1/2$ the height t of the Cauchy horizon is given by $t=f_H(x,y)$ where $f_H(x,y)=1+y$ for $0\leqslant x$ and also $f_H(x,y)=1-(x^2+y^2)^{1/2}$ for $x<0$. It is easily checked that f_H is of class C^1 near $(0,-1/2)$, but that f_H fails to be of class C^2 along the y-axis near $(0,-1/2)$. It follows that there is an open set W in $H^+(S)$ about the point $(1/2,0,-1/2)$ where the horizon is of class C^1, but not of class C^2. In this example there are no end points of multiplicity one. The crease set consists of the closed half line $t=y+1=x+1$ for $0\leqslant y<\infty$ and is a space–like curve.

Both examples 2.1 and 2.2 may be changed to four-dimensional examples using a Cartesian product with a positive definite R^1 corresponding to the z-axis. In particular, to modify example 2.1, one may take $M_0=L^4$, delete the two-dimensional set $\{(0,x,y,z)|y=x^2\}$, and use the three-dimensional partial Cauchy surface $S=\{(0,x,y,z)|y>x^2\}$. This generates a horizon $H^+(S)$ with an end point $p=(1/2,0,1/2,0)$ of multiplicity one. To modify example 2.2, one may take $M_0=L^4$ and delete the set formed by the Cartesian product of the originally deleted set with the z-axis. Of course, in this four-dimensional example, one takes the new partial Cauchy surface to be the Cartesian product of the original Cauchy surface with the z-axis.

III. DIFFERENTIABILITY OF CAUCHY HORIZONS

One may always represent tangent null directions using a normalization based on an auxiliary positive definite metric $g_{\rm pos}$. Given a fixed point p on a null geodesic γ, choose the uniquely defined tangent vector V to γ at p which is future pointing and satisfies $g_{\rm pos}(V,V)=1$. With this normalization, it is clear that the null directions at p form a compact set homeomorphic to S^2. Of course, we are identifying the null direction given by a null vector V as the same as that given by αV for nonzero values of α. Thus, in particular, the null direction represented by V is the same as the null direction represented by $-V$. Note that if one is given any compact subset K of M, the set of null directions attached at points of K forms a compact set.

Let γ_n be a sequence of null generators of $H^+(S)$ and let $p_n\in\gamma_n$ for each n. Assume the sequence $\{p_n\}$ converges to p and let γ be a null generator at p. We will say the sequence γ_n converges to γ if there is a sequence of null vectors $\{V_n\}$ converging to the null vector V such that each V_n is tangent to the corresponding generator γ_n at p_n and V is tangent to γ at p. Notice that in this definition we do not assume that the points $\{p_n\}$ have unique null generators and we do not assume that the point p has a unique null generator. In particular, we allow for the possibility that some (or all) of $\{p_n\}$ and p may be end points.

We now show that if p is a point of multiplicity one, then any point on the horizon sufficiently close to p must have all of its null generators close to the unique null generator containing p.

Lemma 3.1: Let p be a point of multiplicity one on the horizon $H^+(S)$. If $\{p_n\}$ is a sequence of points on the horizon converging to p and if for each n a null generator γ_n containing the point p_n has been chosen, then the sequence γ_n converges to the null generator γ containing p.

Proof: Assume by way of contradiction that the sequence $\{p_n\}$ converges to p, but that the null directions defined by the generators γ_n do not converge to the null direction defined by γ. Using compactness, it follows that there must be a subsequence $\{j\}$ of the sequence $\{n\}$ with the γ_j directions converging to a null direction at p different from that defined by γ. This yields a second null generator at p, in contradiction to the assumption that p was of multiplicity one. □

Clearly, Lemma 3.1 implies that if W is an open subset of the horizon and if each point of W has multiplicity one, then the null generators move in a continuous fashion on W. More precisely, we have the following result.

Lemma 3.2: Let W be an open subset of the future Cauchy horizon $H^+(S)$. If each point of W has multiplicity one, then there is a (nonvanishing) null vector field V tangent to null generators and defined on W such that V is continuous. Furthermore, the vector field V may be taken to be future pointing.

We are now able to show that for open subsets of the horizon, differentiability implies (at least) class C^1. Example 2.2 shows that differentiability on an open set does not, in general, imply class C^2 and hence the following is the best possible result one may obtain without additional assumptions. Recall that if a surface is of class C^r for $r>1$, then it is also of class C^1.

Proposition 3.3: If W is an open subset of $H^+(S)$ and if $H^+(S)$ is differentiable at all points of W, then $H^+(S)$ is of class C^r on W for some $r\geqslant 1$.

Proof: A point where the horizon is differentiable must be a point of multiplicity one. Hence Lemma 3.2 yields the existence of a null vector field V on W which is continuous, tangent to $H^+(S)$ and serves to define the generator directions on W. Let $p\in W$ and, as in Sec. II, introduce local coordinates x^0,x^1,x^2,x^3 near p with $\partial/\partial x^0$ future timelike. Let $H^+(S)$ be given locally by $x^0=f_H(\Delta x)$. The partial derivatives of f_H exist near p since $H^+(S)$ is differentiable near p. Notice that the null vector field V determines the orthogonal space $V^\perp$ which is the null tangent plane to $H^+(S)$ at each point near p. Furthermore, the tangent plane $V^\perp$ determines the first-order partial derivatives of f_H. The continuity of V yields the continuity of $V^\perp$ and hence the continuity of the first-order partial derivatives of f_H. Thus, f_H is at least of class C^1 which is equivalent to $H^+(S)$ being at least of class C^1, as desired. □

Fix a point p on $H^+(S)$ of multiplicity one. Choose normal coordinates x^0,x^1,x^2,x^3 with p corresponding to the origin, with $\partial/\partial x^0$ future timelike at p, and with the future direction of the unique null generator at p corresponding to the direction of $\partial/\partial x^0+\partial/\partial x^1$. Assume also that the natural basis is orthonormal at p. As before, let $H^+(S)$ be given near p by $x^0=f_H(\Delta x)$. If $H^+(S)$ is differentiable at p one has $\partial f_H/\partial x^1=1$ and $\partial f_H/\partial x^2=\partial f_H/\partial x^3=0$ at p. Assuming that f_H is of class C^r for $r\geqslant 1$ near p, define new coordinates z^0,z^1,z^2,z^3 by $z^0=x^0-f_H(\Delta x)$, and $z^i=x^i$ for $i=1,2,3$. Locally $H^+(S)$ corresponds to the set $z^0=0$. Note that z^0,z^1,z^2,z^3 are local coordinates of class C^r in terms of the original x coordinates.

Proposition 3.4: If a Cauchy horizon $H^+(S)$ is differentiable on an open subset W, then the horizon has no end points on W.

Proof: The horizon must be (at least) of class C^1 on W by Proposition 3.3. Fixing $p\in W$, we may use the above local coordinates z^0,z^1,z^2,z^3 which are at least of class C^1 and the horizon is given near p by $z^0=0$. From Lemma 3.2 it follows that there is a continuous future directed null vector field V tangent to $H^+(S)$ near p. Then $V=\Sigma y^i(z^1,z^2,z^3)\partial/\partial z^i$ where $y^i=y^i(z^1,z^2,z^3)$ are continuous functions for $i=1,2,3$. Consider the system

$$dz^i/dt=y^i(z^1,z^2,z^3)$$

for $i=1,2,3$. This is a system which we may regard as being defined on the coordinate plane $z^0=0$ (i.e., on the horizon) and solving the system corresponds to finding integral curves of the vector field V. However, the above system does not necessarily satisfy a Lipschitz condition and thus, in principle, might fail to have unique solutions. Nevertheless, because of the continuity of the functions y^i, one may apply the Cauchy–Peano existence theorem[16] to obtain a class C^1 solution $c(t)$ with $c(0)=p$. Notice that $c(t)$ is a null curve always tangent to $H^+(S)$ because $c'(t)$ is always equal to the vector field V at the corresponding point $c(t)$. Moving along the curve c a little to the past, one obtains a point $r=c(t_1)\in H^+(S)$ with $t_1<0$. Similarly, moving along c a little to the future one obtains $q=c(t_2)\in H^+(S)$ with $t_2>0$. Traversing the curve c backward from q to r one finds it must be a null geodesic lying on the horizon since if it were not, then r would be in the chronological past of q and this would yield a contradiction to the achronality of $H^+(S)$. Since there is a unique null direction tangent to $H^+(S)$ at p, the curve c (at least) restricted to the domain $[t_1,t_2]$ must lie on the generator containing p and it follows that p is not an end point, as desired. □

We note in passing that the proof of Proposition 3.4 shows that, in fact, the system $dz^i/dt = y^i(z^1,z^2,z^3)$ has unique solutions given an initial point $p \in W$ and that each solution $c(t)$ lies on (part of) a null generator.

Fix a point p of multiplicity one on $H^+(S)$ with null direction L_0 tangent to the unique null generator at p. Let Y_0,Y_1,Y_2,Y_3 be an orthonormal basis at p with Y_0 future pointing timelike and with Y_0+Y_1 future pointing null in the direction of L_0. Then Y_2 and Y_3 lie in the orthogonal space to L_0. Let X_0,X_1,X_2,X_3 be a new basis of T_pM given by $X_0=Y_0$, $X_1=Y_0+Y_1$, $X_2=Y_2$, and $X_3=Y_3$. Take normal coordinates x^0,x^1,x^2,x^3 centered at p determined by the basis X_0,X_1,X_2,X_3. Then $\partial/\partial x^0$ is timelike future pointing, $\partial/\partial x^1$ future pointing in the null direction L_0, and both $\partial/\partial x^2$ and $\partial/\partial x^3$ are in the orthogonal space to L_0. Of course, these normal coordinates fail to be orthonormal at p since, in particular, $\partial/\partial x^1$ is null. Notice that the metric tensor g has components (in the x coordinates) which at p have all zero values except for $g_{00}(p)=g_{01}(p)=g_{10}(p)=-1$ and $g_{22}(p)=g_{33}(p)=1$. The x^1 axis is a geodesic which corresponds to a null generator of $H^+(S)$ and (at least) the origin and negative x^1 axis lie on the horizon. The point p is an end point iff points on the positive x^1 axis do not lie on the horizon. In the following we allow p to be either an end point or a non-end-point. Fix a point $r=(0,t_1,0,0)$ on the negative x^1 axis and lying in a convex normal neighborhood of p. Thus, $t_1<0$. Since we have used normal coordinates, we have $p=\exp_r(V_0)$ where $V_0=|t_1|\partial/\partial x^1$ and V_0 is a null vector attached at r. If one considers the exponential map at r restricted to all null vectors at r in some small neighborhood of V_0, then one obtains a smooth null surface which passes through $p=(0,0,0,0)$. Since $\partial/\partial x^1$ at the origin is a null vector tangent to this null surface, it follows that the tangent plane to this null surface at the point p is the orthogonal plane to $\partial/\partial x^1$, which is also the tangent plane to the coordinate plane $x^0=0$ at $p=(0,0,0,0)$. Let $N(V_0)$ be a sufficiently small neighborhood of V_0 in the tangent bundle TM and let $U(r)$ be a (small) three-dimensional neighborhood of r in the coordinate plane $x^1=t_1$. Then points of $U(r)$ are of the form $u=(u^0,t_1,u^2,u^3)$ where the values of of u^0, u^2, and u^3 are all close to zero. For each fixed $u \in U(r)$ one generates a smooth null surface $S(u^0,u^2,u^3)$ defined near the origin by using the exponential map at u and restricting $\exp_u$ to null vectors in the set $N(V_0)$ attached at u. An element $V \in N(V_0)$ attached at $u \in U(r)$ may be represented in local coordinates as $V=V^0\partial/\partial x^0 + \Sigma V^i \partial/\partial x^i$. Thus, using $g(V,V)=0$ to determine the V^0 component in terms of the V^1,V^2,V^3 components, one may parametrize our six-dimensional domain space by u^0,u^2,u^3,V^1,V^2,V^3. Here the values of u^0, u^2, u^3, V^2, and V^3 are close to zero and the value of V^1 is close to $|t_1|$. Note that tangent vectors to this six-dimensional space may be expressed in terms of a basis of the form $\partial/\partial u^0,\partial/\partial u^2,\partial/\partial u^3,\partial/\partial V^1,\partial/\partial V^2,\partial/\partial V^3$. Consider the map

$$E(u,V)=\exp_u(V)$$

taking elements of the domain space to points of M near p. This map may be written as $E(u,V)=(E^0,E^1,E^2,E^3)$ where each component $E^\mu(u^0,u^2,u^3,V^1,V^2,V^3)$ is a real valued function of six variables. The reader will note a slight abuse of notation in the above. For example, we will use u to denote both the point (u^0,t_1,u^2,u^3) in M and also the corresponding coordinates u^0,u^2,u^3 in our domain space. A similar comment holds for our use of V. Notice that if u is chosen to be the point r, then the map $E(r,-)$ takes the null vectors attached at r to the null surface $S(0,0,0)$ which we noted above is tangent to the coordinate plane $x^0=0$ at p. In our domain space the vector V_0 in T_rM corresponds to $(0,0,0|t_1|,0,0)$. Notice that the derivative of the exponential map for $u=r$ (i.e., $(\exp_r)_*$) is nondegenerate at V_0 since r was chosen close to p. Furthermore, $(\exp_r)_*$ takes the null hyperplane at V_0 tangent to the null vectors at r to the null plane tangent to $x^0=0$ at $p=(0,0,0,0)$. Thus, for fixed $u=r$ and $V=V_0$, E_* takes the three-dimensional space with basis $\partial/\partial V^1,\partial/\partial V^2,\partial/\partial V^2$ corresponding to certain vectors tangent to our six-dimensional domain space and attached to this domain space at $V_0=(0,0,0,|t_1|,0,0)$ in a nonsingular fashion to the three-dimensional space with basis $\partial/\partial x^1,\partial/\partial x^2,\partial/\partial x^3$ of vectors tangent to M and attached at p. Thus, using $x^i=E^i(u^0,u^2,u^3,V^1,V^2,V^3)$ one finds that the three by three matrix $[\partial x^i/\partial V^j]$ is nonsingular when evaluated at the point $(0,0,0,|t_1|,0,0)$ of our domain space. Using the implicit function theorem,[17] we may thus solve for the V^1,V^2,V^3 variables in terms of the u^0,u^2,u^3,x^1,x^2,x^3 variables. Hence, one obtains three C^∞ functions V^i

$=V^i(u^0,u^2,u^3,x^1,x^2,x^3)=V^i(u,\Delta x)$. We will let F be the x^0 component of E using the u^0,u^2,u^3,x^1,x^2,x^3 variables. In other words, we define F to be the real valued function

$$F(u^0,u^2,u^3,x^1,x^2,x^3)=E^0(u,V^1(u,\Delta x),V^2(u,\Delta x),V^3(u,\Delta x)).$$

Then, for fixed u, the surface $S(u^0,u^2,u^3)$ is given near the origin by $x^0=F_u(x^1,x^2,x^3)$ where $F_u(\Delta x)=F(u^0,u^2,u^3,x^1,x^2,x^3)$ is a smooth function of six variables. Still holding $u\in U(r)$ fixed, select a point $q=(q^0,q^1,q^2,q^3)$ near the origin on the surface $S(u^0,u^2,u^3)$. Then one has $q^0=F_u(q^1,q^2,q^3)=F_u(\Delta q)$. Now expand F_u about this point (holding the u coordinates fixed) to obtain

$$F_u(x^1,x^2,x^3)=q^0+\sum\ (\partial F_u/\partial x^i)(x^i-q^i)+R(u,q,\Delta(x-q)),$$

where $\Delta(x-q)=(x^1-q^1,x^2-q^2,x^3-q^3)$ and the partials of F_u are evaluated at Δq. Using the smoothness of F, it follows that the remainder term $R(u,q,\Delta(x-q))$ may be bounded on some compact set in the domain space of six variables using the size of the second partial derivatives of F and the magnitude of $|\Delta(x-q)|^2$. Of course the bound will depend on the mixed second partials of F involving the u^0,u^2,u^3 variables as well as the x^1,x^2,x^3 variables.[18] In particular, one may obtain an inequality of the form

$$|R(u,q,\Delta(x-q))|<M|\Delta(x-q)|^2, \tag{3.1}$$

where M is a constant which holds for u near r, q near p, and all sufficiently small $|\Delta(x-q)|$. We will use this bound on the size of the remainder term in the proof of Theorem 3.5 below. We remark in passing that points of any sufficiently small neighborhood $W(p)$ of $p=(0,0,0,0)$ will lie on many of the null surfaces $S(u^0,u^2,u^3)$. In fact, the null cone from each point of a sufficiently small $W(p)$ will intersect the coordinate plane $x^1=t_1$ in a two-dimensional surface and thus through a point of $W(p)$ there will be a two parameter family of null surfaces in the collection $S(u^0,u^1,u^2)$.

The next result answers a question raised by Chruściel and Galloway.[5] They proved that Cauchy horizons fail to be differentiable at end points with more than one null generator and that Cauchy horizons are differentiable at points which are not end points.[5] They mentioned that these results left open the question of the differentiability of Cauchy horizons at end points where there is only null generator (i.e., end points of multiplicity one in our terminology). As Chruściel and Galloway noted, it is of interest to resolve this remaining differentiability question. In Theorem 3.5, we obtain a positive answer to this question. We show that a Cauchy horizon is always differentiable at points of multiplicity one.

Theorem 3.5: *A Cauchy horizon is differentiable at all points of multiplicity one. In particular, a Cauchy horizon is differentiable at an end point where only one null generator leaves the horizon.*

Proof: Let p be a point of multiplicity one. We will use the above-described coordinates x^0,x^1,x^2,x^3, neighborhoods $U(r)$, $N(V_0)$, $W(p)$, null surfaces $S(u^0,u^2,u^3)$, functions $F_u(x^1,x^2,x^3)$ and inequality (3.1).

Assume that the Cauchy horizon $H^+(S)$ is given near p by $x^0=f_H(\Delta x)$. We will show that f_H must be differentiable at the origin and have all of its first-order partials equal to zero at the origin. This will prove that $H^+(S)$ is differentiable at the origin and that it has its tangent plane at the origin tangent to the coordinate plane $x^0=0$. To show the desired properties of f_H are true, it is sufficient to show that $f_H(\Delta x)/|\Delta x|$ converges to zero as $|\Delta x|$ converges to zero. Hence, by way of contradiction, we assume that there is a sequence of points $\{q_k=(q_k^0,q_k^1,q_k^2,q_k^3)\}$ on $H^+(S)$ and converging to p with

$$|f_H(\Delta q_k)|/|\Delta q_k|>c>0$$

for all k. Here

$$\Delta q_k=(q_k^1,q_k^2,q_k^3),\quad |\Delta q_k|=\sqrt{(q_k^1)^2+(q_k^2)^2+(q_k^3)^2}.$$

The surface $S(0,0,0)$ is tangent at the origin to the coordinate plane $x^0=0$ and represents (part of) the null cone from the point $r=(0,t_1,0,0)$. Note that points in the chronological future of r must lie above the Cauchy horizon and that $\partial/\partial x^0$ is future pointing timelike at the origin. It follows that points of the horizon lie on or below the surface $S(0,0,0)$ and hence

$$q_k^0=f_H(\Delta q_k)\leqslant F(0,0,0,q_k^1,q_k^2,q_k^3)$$

for all k. Expanding $F(0,0,0,x^1,x^2,x^3)$ about the origin in the x variables, one has $F(0,0,0,q_k^1,q_k^2,q_k^3)=0+0+R(\Delta q_k)$ where $R(\Delta q_k)/|\Delta q_k|$ converges to zero as k increases. Using $q_k^0=f_H(\Delta q_k)\leqslant F(0,0,0,\Delta q_k)$ and $|f_H(\Delta q_k)|/|\Delta q_k|>c$, one finds that for all large k one must have $f_H(\Delta q_k)<0$. Also, one obtains the inequality $f_H(\Delta q_k)<-c|\Delta q_k|$ for all large k. For each k, choose a null generator γ_k containing q_k. Lemma 3.1 guarantees that the sequence $\{\gamma_k\}$ converges to the unique null generator γ ($=x^1$ axis) containing p. Thus, for sufficiently large k, each γ_k contains points close to r and has tangent directions for these points close to that of γ at r (i.e., close to the direction of the x^1 axis). It follows that for each large k there will be a well-defined point u_k on γ_k with $u_k=(u_k^0,t_1,u_k^2,u_k^3)\in U(r)$ and the sequence u_k will converge to r. Furthermore, we may parametrize γ_k such that $\gamma_k(0)=u_k$ and $\gamma_k(1)=q_k$. Then $V_k=\gamma_k'(0)$ converges to V_0. The null surface $S(u_k^0,u_k^2,u_k^3)$ contains q_k and is given by $x^0=F_k(\Delta x)$ where $F_k(\Delta x)=F(u_k^0,u_k^2,u_k^3,x^1,x^2,x^3)$. We will show that for large k one has $F_k(0,0,0)<0$ and thus that the surface $S(u_k^0,u_k^2,u_k^3)$ cuts the x^0 axis below the origin. To this end, expand F_k about the point q_k in the x variables to obtain

$$F_k(\Delta x)=q_k^0+\sum\ a_{ki}(x^i-q_k^i)+R_k(\Delta(x-q_k)),$$

where $\Delta(x-q_k)=(x^1-q_k^1,x^2-q_k^2,x^3-q_k^3)$, $R_k(\Delta(x-q_k))=R(u_k,q_k,\Delta(x-q_k))=R(u_k^0,u_k^2,u_k^3,q^1,q^2,q^3,\Delta(x-q_k))$ and a_{ki} represents the partial of F_k with respect to x^i evaluated at the point q_k for $i=1,2,3$. Using $x^1=x^2=x^3=0$ and $q_k^0=f_H(\Delta q_k)<-c|\Delta q_k|$, one obtains the following inequality for large k:

$$F_k(0,0,0)<-c|\Delta q_k|+\sum\ a_{ki}(0-q_k^i)+R_k(-q_k^1,-q_k^2,-q_k^3)$$

Recall that as k increases, the tangent direction to γ_k converges to the tangent direction to γ. Thus, the null tangent plane to $x^0=F_k(\Delta x)$ at q_k must converge to the null plane tangent to $x^0=0$ at the origin. It follows that the coefficients a_{ki} converge to zero for $i=1,2,3$ and thus for large k one has an inequality of the form

$$\left|\sum\ a_{ki}(0-q_k^i)\right|<(c/3)|\Delta q_k|.$$

Also, using inequality (3.1) one has $|R_k(-q_k^1,-q_k^3,-q_k^3)|<M|\Delta q_k|^2$ which implies that for large k

$$|R_k(-q_k^1,-q_k^2,-q_k^3)|<(c/3)|\Delta q_k|.$$

Consequently, we find

$$F_k(0,0,0)<-c|\Delta q_k|+(c/3)|\Delta q_k|+(c/3)|\Delta q_k|,$$

which yields $F_k(0,0,0)<0$ for large k since $|\Delta q_k|\neq 0$. Using the fact that the x^0 axis is timelike future directed, one finds that $F_k(0,0,0)$ is in the chronological past of $p=(0,0,0,0)$ for large k. Using the fact that u_k is in the causal past of $F_k(0,0,0)$, one finds that u_k must be in the chronological past of $p=(0,0,0,0)$ for large k. Since p and u_k must lie on $H^+(S)$, this contradicts the achronality of the horizon. We conclude that f_H is differentiable at the origin and all of its partials with respect to x^i are zero at the origin. It follows that $H^+(S)$ is differentiable at the origin, as desired. □

Recall that the *crease* set is the set of points in the horizon having multiplicity at least two and that the horizon fails to be differentiable at any such point. Clearly, Theorem 3.5 is equivalent to the statement *that the crease set consists precisely of those points on the Cauchy horizon where the horizon fails to be differentiable*.

Combining Propositions 3.3 and 3.4 with Theorem 3.5, one obtains the following result.

Proposition 3.6: Let W be an open subset of the Cauchy horizon $H^+(S)$. *Then the following are equivalent:*

(1) $H^+(S)$ *is differentiable on W.*
(2) $H^+(S)$ *is of class* C^r *on W for some* $r \geqslant 1$.
(3) $H^+(S)$ *has no end points on W.*
(4) All points of W have multiplicity one.

Note that the four parts of Proposition 3.6 are logically equivalent for an *open* set *W*, but that, in general, they are not necessarily equivalent for sets which fail to be open. Using the equivalence of parts (1) and (3) of Proposition 3.6, it now follows that near each end point of multiplicity one there must be points where the horizon fails to be differentiable. Hence, each neighborhood of an end point of multiplicity one must contain end points of higher multiplicity. This yields the following corollary.

Corollary 3.7: If p is an end point of multiplicity one on a Cauchy horizon $H^+(S)$, then each neighborhood $W(p)$ of p on $H^+(S)$ contains points where the horizon fails to be differentiable. Hence, the set of end points of multiplicity one is in the closure of the crease set.

We know that the nondifferentiable set (i.e., the crease set) has (three-dimensional) measure zero since the horizon satisfies a Lipschitz condition. On the other hand, since a Cauchy horizon is differentiable at an end point of multiplicity one, the fact that $H^+(S)$ satisfies a Lipschitz condition does not give us any direct information on the measure of the set of end points of multiplicity one. Based on known examples it seems likely that this set should be a relatively small set. Thus, we conjecture that the set of end points of multiplicity one is of measure zero for all Cauchy horizons. Clearly, this is equivalent to the following end point conjecture.

Conjecture: The set of all end points of a Cauchy horizon must have measure zero.

An affirmative or negative answer to the above conjecture would certainly help in the understanding of Cauchy horizons and in future studies of these horizons.

IV. COMPACT HORIZONS

In the previous sections we have not made any curvature assumptions. In this section we will assume $\mathrm{Ric}(V,V) \geqslant 0$ for all null V which is the *null convergence condition*. We will also assume that we have a Cauchy horizon $H^+(S)$ which is compact and of class C^2 on an open subset G such that the complement of G is of three-dimensional measure zero.

Theorem 4.1: *Let (M,g) be a space–time and assume that (M,g) satisfies the null convergence condition (i.e.,* $\mathrm{Ric}(V,V) \geqslant 0$ *for all null V). Let S be a partial Cauchy surface. Assume that the future horizon* $H^+(S)$ *is compact and contains an open set G where it is* C^2 *and is such that the complement of G in* $H^+(S)$ *has three-dimensional measure zero. Then,* $H^+(S)$ *has no end points and hence is differentiable of (at least) class* C^1 *for all points.*

Proof: The compactness of $H^+(S)$ yields the past completeness of all null generators.[8] We use the notation of Hawking[7] to obtain a map $u_t : G \to G$ and[7]

$$d/dt \int_{u_t(G)} dA = 2 \int_{u_t(G)} \rho dA. \tag{4.1}$$

Notice that since $H^+(S)$ is compact we find that $\int_{u_t(G)} dA$ is finite. However, the derivative of $\int_{u_t(G)} dA$ cannot be positive since the set G is mapped into itself. Thus, the left-hand side of Eq. (4.1) is nonpositive. On the other hand, the right-hand side of Eq. (4.1) must be non-negative since $\rho \geqslant 0$. Assume now that $H^+(S)$ has an end point p of a null generator γ. Even if γ does not lie in G, the horizon will be differentiable on the part of γ in the past of p. Choose some q on γ in the past of p and some u on γ in the future of p. Then for some small neighborhood $W(q)$ of q on $H^+(S)$, all null generators though points r of $W(q)$ will have directions close to the direction of

γ at q. Recall that given a compact domain set in the t-axis, geodesics with close initial conditions remain close on the compact domain set. Thus, by choosing $W(q)$ sufficiently small we may get all null generators though points of $W(q)$ come arbitrarily close to u. Thus for sufficiently small $W(q)$ all null generators intersecting $W(q)$ must leave $H^+(S)$ in the future. Since $W(q)$ is open in $H^+(S)$ it must have a nontrivial intersection with the set G. Thus, $u_t(G)$ cannot be all of G for some positive values of t and this yields a negative for some values of t on the left-hand side of Eq. (4.1), in contradiction. Thus, $H^+(S)$ has no end points and by Proposition 3.6 must be (at least) of class C^1 at all points.

Symmetries of asymptotically flat electrovacuum space–times and radiation

J. Bičák[a] and A. Pravdová[b]
Department of Theoretical Physics, Faculty of Mathematics and Physics, Charles University, V Holešovičkách 2, 180 00 Prague 8, Czech Republic

(Received 24 June 1998; accepted for publication 8 July 1998)

Symmetries compatible with asymptotic flatness and admitting gravitational and electromagnetic radiation are studied by using the Bondi–Sachs–van der Burg formalism. It is shown that in axially symmetric electrovacuum space–times in which at least locally a smooth null infinity in the sense of Penrose exists, the only second allowable symmetry is either the translational symmetry or the boost symmetry. Translationally invariant space–times with, in general, a straight ''cosmic string'' along the axis of symmetry are nonradiative although they can have a nonvanishing news function. The boost-rotation symmetric space–times are radiative. They describe ''uniformly accelerated charged particles'' or black holes which in general may also be rotating—the axial and an additional Killing vector are not assumed to be hypersurface orthogonal. The general functional forms of both gravitational and electromagnetic news functions, and of the mass aspect and total mass of asymptotically flat boost-rotation symmetric space–times at null infinity are obtained. The expressions for the mass are new even in the case of vacuum boost-rotation symmetric space–times with hypersurface orthogonal Killing vectors. In the Appendices some errors appearing in previous works are corrected. © *1998 American Institute of Physics.* [S0022-2488(98)00311-9]

I. INTRODUCTION AND SUMMARY

There is only one class of explicitly known radiative solutions which are asymptotically flat in the sense that null infinity is global, i.e., admits spherical sections, though its generators are not complete: boost-rotation symmetric space–times describing ''uniformly accelerated particles'' of various kinds.[1] A unique role of these solutions is exhibited by a theorem which roughly states that in axially symmetric, asymptotically flat space–times (in the sense that at least a local null infinity exists) the only additional symmetry that does not exclude radiation is the boost symmetry.[2]

The boost-rotation symmetric space–times have been used in various contexts. From a mathematical point of view, these solutions contain the only known space–times in which *arbitrarily strong initial data* with the given symmetry can be chosen on a hyperboloidal hypersurface which lead to the complete, smooth null infinity and regular timelike infinity in future. From a more physical point of view these are—and most probably will long remain—the only exact solutions of Einstein's equations for which one can find such quantities as angular distribution of gravitational radiation emitted by particles (represented by singularities) or by uniformly accelerated black holes.[3] In numerical calculations these space–times have been employed as important test beds in the null cone version of numerical relativity,[4,5] and, most recently, also in the standard approach based on a spacelike initial hypersurface.[6] In the context of quantum gravity the boost-rotation symmetric space–times (as ''generalized C-metric'') have been used to describe production of black-hole pairs in strong background fields (see, e.g., Ref. 7). We refer to the recent review[8] of exact radiative space–times and to the comprehensive analysis of the general structure of the boost-rotation symmetric space–times[1] for more details and references on both the history and recent developments in these issues.

Until now all work on the general properties of the boost-rotation symmetric space–times has

concentrated on the vacuum case with two non-null, hypersurface orthogonal Killing vectors—the rotational (axial) Killing vector and the boost Killing vector. The metric of such space–times, in suitable coordinates, contains just two functions. It can be constructed starting from the appropriately behaved boost-rotation symmetric solution of the flat-space wave equation with sources which is satisfied by one of the functions. The other metric function can then be determined by a quadrature (see Ref. 1). In the present paper we start the systematic study of more general boost-rotation symmetric space–times. We assume that an *electromagnetic field* coupled to gravity may also be present; and we consider *Killing vectors* which need *not* be *hypersurface orthogonal*. Even if only one of these extensions is taken into account, the field equations become fully nonlinear—there is no flat-space wave equation available. The inclusion of an electromagnetic field is also of interest because there exist the analogous features of gravitational fields due to uniformly accelerated masses in general relativity and of electromagnetic fields due to uniformly accelerated charges in special relativity. The study of boost-rotation symmetric fields within the Einstein–Maxwell theory treats both gravitational and electromagnetic fields from a unified point of view.

It is known that the example of a boost-rotation symmetric electrovacuum solution with Killing vectors which are not hypersurface orthogonal exists—this is the charged ''rotating'' C-metric.[9] Here we consider general solutions. Our main result is the theorem which roughly states that even under the presence of electromagnetic field and ''rotating sources,'' the boost symmetry is the only one which can be combined with axial symmetry and radiation exists. However, we shall also obtain other results (e.g., for the news function and total mass) some of which are new even in the vacuum case with hypersurface orthogonal Killing vectors.

In Sec. II we start out from the general form of axially symmetric metric and electromagnetic field in Bondi–Sachs coordinates $\{u,r,\theta,\phi\}$, where $u=\text{const}$ labels null hypersurfaces (in flat space $u=t-r$ is the usual retarded time), r is a luminosity distance along null rays $u=\text{const}$, $\theta=\text{const}$, $\phi=\text{const}$, and θ, ϕ are standard spherical angles. We consider their asymptotic expansions at $r\to\infty$ as they follow from the Einstein–Maxwell equations under the assumption of asymptotic flatness. Since we wish to study space–times in which the axial Killing vector is in general not hypersurface orthogonal we cannot employ the original work of Bondi *et al.*[10] but have to start from its generalization by Sachs[10] or, rather, from van der Burg's[11] explicit treatment of the asymptotic behavior of the coupled Einstein–Maxwell fields in the Bondi–Sachs coordinates. Now van der Burg's work involves complicated equations in which many errors and misprints appear. These do not change basic conclusions of his paper but we need correct forms. Therefore, in Appendix A we first summarize all Einstein–Maxwell equations in the Bondi–Sachs coordinates in general space–time and then give asymptotic forms of their solutions under the assumption of axial symmetry. (All equations were checked by using MAPLE V.) The structure of the field equations (the splitting into twelve main equations and five supplementary conditions), the total quantities (the mass and the charge) and their fluxes given in terms of two gravitational and two electromagnetic news functions are also briefly reviewed in Appendix A. The resulting formulas are used extensively in Sec. II to prove the theorem which states the following:

Suppose that an axially symmetric electrovacuum space–time admits a ''piece'' of null infinity. If this space–time admits an additional Killing vector forming with the axial Killing vector a two-dimensional Lie algebra, then the additional Killing vector either generates a supertranslation or it is the boost Killing vector.

The theorem is proven by first decomposing the additional Killing vector field η^α in the null (Sachs) tetrad and then solving the Killing equations asymptotically in the leading terms. In order to illustrate the form of the Killing equations, the lengthiest among them, $\mathscr{L}_\eta g_{00}=0$, is written down in Appendix B.

In Sec. III the case of the supertranslational Killing field is considered further. By solving Killing equations in the higher orders in r^{-k} and considering also asymptotic solutions of equations $\mathscr{L}_\eta F_{\mu\nu}=0$ (assuming thus that the electromagnetic field shares the same symmetry), we show that the supertranslational Killing field in fact has to be the generator either of translations along the axis of axial symmetry (z-axis) or time translations. The resulting space–times are nonradiative. Somewhat surprisingly perhaps, the news functions of the system need not necessarily be vanishing. This is not because of cylindrical waves, which of course are symmetric under translations along the z-axis. Cylindrical waves are excluded from our analysis if we assume that

the local null infinity exists at $\theta=\pi/2$; there are no cylindrical space–times which admit a regular cross section of null infinity. (We refer to Refs. 12 and 13 for the study of null infinity of cylindrically symmetric space–times and to our forthcoming work in which the Killing equations will be considered in greater detail in further orders in r^{-k} for translational Killing vectors.) Here we consider space–times with a straight cosmic string along the z-axis which, as shown by Bičák and Schmidt,[14] have a nonvanishing news function independent of time. If we assume that the electromagnetic field is regular at the axis of symmetry, only the gravitational news function is nonvanishing. We give the explicit form of the translational Killing vector in this case. This translational Killing vector in the case of the string has not been given in Ref. 2 because of a sign error. The error and misprints appearing in Ref. 2 are corrected in Appendix C. In Appendix D the translations in Bondi's coordinates in a space–time with a straight, nonrotating cosmic string are analyzed in detail. At the end of Sec. III we give explicitly the asymptotic form of both gravitational and electromagnetic fields in the Bondi–Sachs coordinates for stationary space–times without a string.

Section IV is devoted to the case when the additional Killing vector is the boost Killing vector. By analyzing the Killing equations in further orders in r^{-k} and considering also equations $\mathscr{L}_\eta F_{\mu\nu}=0$, we discover that both gravitational and electromagnetic news functions must have the same functional form—they depend on u and θ so that the news function $=f(\sin\theta/u)u^{-2}$, where f is an arbitrary function of its argument. We also derive the general form of the mass aspect and total (Bondi) mass for boost-rotation symmetric space–times. The mass aspect is given by

$$M(u,\theta)=\frac{1}{2\sin\theta}(w^2\mathscr{K}_{,w})_{,w}+\frac{\mathscr{L}}{u^3}, \tag{1}$$

where $w=\sin\theta/u$, $\mathscr{K}(w)$ is an arbitrary function, and $\mathscr{L}(w)=\lambda(w)/w^3$, where $\lambda(w)$ satisfies the simple equation (120) in the main text. $\lambda(w)$ can be determined if the news functions are known. The total Bondi mass is then given by

$$m(u)=\frac{1}{4}\int_0^\pi (w^2\mathscr{K}_{,w})_{,w}\,d\theta+\frac{1}{2}\int_0^\pi \frac{\mathscr{L}w}{u^2}d\theta. \tag{2}$$

The formulas for the mass aspect and total mass are new even in the case of hypersurface orthogonal Killing vectors studied in Ref. 2. Also, the boost Killing vector is here expanded to further orders than in Ref. 2 [see Eq. (122)].

Let us note that in general Bondi's news function has an invariant meaning only if null infinity is topologically $S^2\times\mathrm{R}$. However, as shown in Ref. 14, in axially symmetric space–time relative to a chosen $\partial/\partial\phi$ Killing vector Bondi news and translations have an invariant meaning even locally.

Our conventions for the Riemann and Ricci tensors follow those of Ref. 15 but our signature is -2.

II. AXIALLY SYMMETRIC SPACE–TIMES WITH ANOTHER SYMMETRY

Consider an axially symmetric electrovacuum space–time with circular group orbits; denote the corresponding Killing vector field by $\partial/\partial\phi$. Assume that at least the ''piece of $\mathscr{I}^+$'' exists in the sense of Ref. 16. Then one can introduce the Bondi–Sachs coordinate system $\{u,r,\theta,\phi\}\equiv\{x^0,x^1,x^2,x^3\}$ in which the metric satisfying the Einstein–Maxwell equations has the form[10,11]

$$\begin{aligned}ds^2=&\left(\frac{V}{r}e^{2\beta}-r^2e^{2\gamma}U^2\cosh 2\delta-r^2e^{-2\gamma}W^2\cosh 2\delta-2r^2UW\sinh 2\delta\right)du^2\\&+2e^{2\beta}\,du\,dr+2r^2(e^{2\gamma}U\cosh 2\delta+W\sinh 2\delta)du\,d\theta\\&+2r^2(e^{-2\gamma}W\cosh 2\delta+U\sinh 2\delta)\sin\theta\,du\,d\phi\\&-r^2[\cosh 2\delta(e^{2\gamma}d\theta^2+e^{-2\gamma}\sin^2\theta\,d\phi^2)+2\sinh 2\delta\sin\theta\,d\theta\,d\phi],\end{aligned} \tag{3}$$

where six metric functions U, V, W, β, γ, δ and the Maxwell field $F_{\mu\nu}$ do not depend on ϕ because of axial symmetry.

The complete set of the Einstein–Maxwell equations and the asymptotic expansions of the metric functions and electromagnetic field components at large r are given in Appendix A. We shall need these expansions, in which also the field equations are used, up to the following orders (all ''coefficients'' c, d, M, e, f, ... below being in general functions of u and θ):

$$\begin{aligned}
\gamma &= \frac{c}{r} + O(r^{-3}), \\
\delta &= \frac{d}{r} + O(r^{-3}), \\
\beta &= -\frac{1}{4}(c^2+d^2)\frac{1}{r^2} + O(r^{-4}), \\
U &= -(c_{,\theta} + 2c\cot\theta)\frac{1}{r^2} + O(r^{-3}), \\
W &= -(d_{,\theta} + 2d\cot\theta)\frac{1}{r^2} + O(r^{-3}), \\
V &= r - 2M + O(r^{-1}).
\end{aligned} \tag{4}$$

The leading terms in the electromagnetic field tensor are given by

$$\begin{aligned}
F_{12} &= \frac{e}{r^2} + (2E + ec + fd)\frac{1}{r^3} + O(r^{-4}), \\
F_{13} &= \left(\frac{f}{r^2} + (2F + ed - fc)\frac{1}{r^3} + O(r^{-4})\right)\sin\theta, \\
F_{01} &= -\frac{\epsilon}{r^2} + (e_{,\theta} + e\cot\theta)\frac{1}{r^3} + O(r^{-4}), \\
F_{23} &= \left(-\mu - (f_{,\theta} + f\cot\theta)\frac{1}{r} + O(r^{-2})\right)\sin\theta, \\
F_{02} &= X + (\epsilon_{,\theta} - e_{,u})\frac{1}{r} + O(r^{-2}), \\
F_{03} &= \left(Y - \frac{f_{,u}}{r} + O(r^{-2})\right)\sin\theta.
\end{aligned} \tag{5}$$

The mass aspect $M(u,\theta)$ is connected with the two gravitational news functions $c_{,u}$ and $d_{,u}$, and with the electromagnetic news functions X and Y by the relation

$$M_{,u} = -(c_{,u}^2 + d_{,u}^2) - (X^2+Y^2) + \tfrac{1}{2}(c_{,\theta\theta} + 3c_{,\theta}\cot\theta - 2c)_{,u}. \tag{6}$$

As a consequence of the Einstein–Maxwell equations the electromagnetic functions e, f, ϵ, μ and X, Y are connected by the relations

$$e_{,u} = \tfrac{1}{2}\epsilon_{,\theta} - (cX + dY), \tag{7}$$

$$f_{,u} = -\tfrac{1}{2}\mu_{,\theta} - (-cY + dX), \tag{8}$$

$$\epsilon_{,u} = -X_{,\theta} - X\cot\theta, \tag{9}$$

$$\mu_{,u} = -Y_{,\theta} - Y\cot\theta. \tag{10}$$

The gravitational news functions enter the evolution equations for e and f. The evolution equations for functions E, F are given in Appendix A. There the evolution of the whole Einstein–Maxwell system is summarized and the interpretation of the mass and the charges of the system is recalled. Here let us only notice that both the gravitational news functions $c_{,u}$, $d_{,u}$ and the electromagnetic news functions X, Y are freely specifiable functions.

Now we wish to emphasize that we assume that Eqs. (3)–(10) are valid for all $\phi\in[0,2\pi)$, however, they need *not* be true for all $\theta\in[0,\pi]$. Since we want to admit space–times with only ''local'' $\mathscr{I}^+$, we assume Eqs. (3)–(10) to be satisfied in some open interval of θ, i.e., not necessarily on the whole sphere. In particular, the ''axis of symmetry'' ($\theta=0,\pi$) may contain some nodal singularities and thus need not be regular. The regularity conditions on the axis [which can be obtained by transforming (3) into local Minkowskian coordinates] on functions γ, V, β ... need not be satisfied for any u. If the axis is singular then at least two generators of $\mathscr{I}^+$ would be missing so that $\mathscr{I}^+$ would not be topologically $S^2\times R$ (this is exactly the case which can occur in the boost-rotation symmetric space–times discussed in Sec. IV).

Let us now assume that another Killing vector field η exists which forms together with $\xi=\partial/\partial\phi$ a two-parameter group. In Ref. 2 it is proved (see the Lemma in Sec. 2) that in the case of ξ with circles as integral curves, ξ and η determine an Abelian Lie algebra so that we can assume $[\eta,\xi]=0$. Hence, the components of η^α are independent of ϕ.

Introduce the standard null tetrad field[17] $\{k^\alpha,m^\alpha,t^\alpha,\bar{t}^\alpha\}$, with the overbar denoting the complex conjugation, where $k_\alpha=\partial_\alpha u$, $m^\alpha k_\alpha=1$, $m^\alpha m_\alpha=0$, and the complex vector $t^\alpha=t^\alpha_R+it^\alpha_I$ (the subscripts R and I denoting the real and imaginary parts) obeys $t^\alpha\bar{t}_\alpha=-1$, $t^\alpha t_\alpha=t^\alpha k_\alpha=t^\alpha m_\alpha=0$. A convenient choice of the tetrad reads

$$k_\alpha=[1,0,0,0],\quad m_\alpha=[\tfrac{1}{2}Vr^{-1}e^{2\beta},e^{2\beta},0,0],$$

$$t_\alpha=\tfrac{1}{2}r(\cosh 2\delta)^{-1/2}[(1+\sinh 2\delta)e^{\gamma}U+\cosh 2\delta e^{-\gamma}W+i[(1-\sinh 2\delta)e^{\gamma}U-\cosh 2\delta e^{-\gamma}W], \tag{11}$$

$$0,\quad -(1+\sinh 2\delta+i(1-\sinh 2\delta))e^{\gamma},\quad -(1-i)\cosh 2\delta\sin\theta e^{-\gamma}].$$

This choice indeed implies $g_{\mu\nu}=2k_{(\mu}m_{\nu)}-2\bar{t}_{(\mu}t_{\nu)}$, with $g_{\mu\nu}$ given by (3).

We now decompose the Killing vector field η^α in the null tetrad,

$$\eta^\alpha=Ak^\alpha+Bm^\alpha+Ct^\alpha+\bar{C}\bar{t}^\alpha, \tag{12}$$

or

$$\eta^\alpha=Ak^\alpha+Bm^\alpha+\tilde{f}(t^\alpha_R+t^\alpha_I)+\tilde{g}(t^\alpha_R-t^\alpha_I), \tag{13}$$

where A, B, $C=C_R+iC_I$, $\tilde{f}=C_R-C_I$, $\tilde{g}=C_R+C_I$ are general functions of u, r, θ. The Killing equations

$$\mathscr{L}_\eta g_{\alpha\beta}=0 \tag{14}$$

can then be rewritten in the form

$$\begin{aligned}0=\mathscr{L}_\eta g_{\alpha\beta}=&A\mathscr{L}_k g_{\alpha\beta}+B\mathscr{L}_m g_{\alpha\beta}+2A_{,(\alpha}k_{\beta)}+2B_{,(\alpha}m_{\beta)}\\&+\tilde{f}[(\mathscr{L}_t g_{\alpha\beta})_R+(\mathscr{L}_t g_{\alpha\beta})_I]+2\tilde{f}_{,(\alpha}[t_{R\beta)}+t_{I\beta)}]\\&+\tilde{g}[(\mathscr{L}_t g_{\alpha\beta})_R-(\mathscr{L}_t g_{\alpha\beta})_I]+2\tilde{g}_{,(\alpha}[t_{R\beta)}-t_{I\beta)}].\end{aligned} \tag{15}$$

The easiest is the equation

$$\mathscr{L}_\eta g_{11}=2e^{2\beta}B_{,r}=0, \tag{16}$$

which implies

$$B=B(u,\theta). \tag{17}$$

In the hypersurface orthogonal case, analyzed in Ref. 2, also the equations $\mathscr{L}_\eta g_{03}=\mathscr{L}_\eta g_{13}=\mathscr{L}_\eta g_{23}=0$ can easily be solved. This is not so if $\partial/\partial\phi$ is not hypersurface orthogonal. All Killing equations other than $\mathscr{L}_\eta g_{11}=0$ now become complicated. For illustration, the equation $\mathscr{L}_\eta g_{00}=0$ is written down in Appendix B; the other equations can be found in Ref. 18.

We assume that the coefficients A, $\tilde{f}$, $\tilde{g}$ can be expanded in powers of r^{-k} and solve the Killing equations asymptotically. Denoting by $A^{(k)}$, $f^{(k)}$, $g^{(k)}$ the coefficients of r^{-k} in the expansions, we first notice that $\mathscr{L}_\eta g_{22}=0$, $\mathscr{L}_\eta g_{12}=0$, $\mathscr{L}_\eta g_{13}=0$ imply

$$\begin{aligned} A&=A^{(-1)}r+A^{(0)}+\frac{A^{(1)}}{r}+O(r^{-2}),\\ \tilde{f}&=f^{(-1)}r+f^{(0)}+\frac{f^{(1)}}{r}+O(r^{-2}),\\ \tilde{g}&=g^{(-1)}r+g^{(0)}+\frac{g^{(1)}}{r}+O(r^{-2}), \end{aligned} \tag{18}$$

where $A^{(k)}$, $f^{(k)}$, $g^{(k)}$ are functions of u and θ. The remaining nine Killing equations imply the conditions on functions B, $A^{(k)}$, $f^{(k)}$, $g^{(k)}$. The procedure of their solutions is similar to that in Ref. 2 (cf. Eqs. (20)–(24) therein). However, the equations are now more complicated and there are three additional equations to be satisfied.

In the leading orders in r^{-k} the Killing equations can be written down easily (we omit equations $\mathscr{L}_\eta g_{12}=0$, $\mathscr{L}_\eta g_{13}=0$ since they do not restrict the leading terms in η^α):

$$\mathscr{L}_\eta g_{00}=0 \quad (r^1): \quad A^{(-1)}{}_{,u}=0, \tag{19}$$

$$\mathscr{L}_\eta g_{01}=0 \quad (r^0): \quad B_{,u}+A^{(-1)}=0, \tag{20}$$

$$\mathscr{L}_\eta g_{02}=0 \quad (r^2): \quad f^{(-1)}{}_{,u}=0, \tag{21}$$

$$\mathscr{L}_\eta g_{03}=0 \quad (r^2): \quad g^{(-1)}{}_{,u}=0, \tag{22}$$

$$\mathscr{L}_\eta g_{22}=0 \quad (r^2): \quad f^{(-1)}{}_{,\theta}+A^{(-1)}=0, \tag{23}$$

$$\mathscr{L}_\eta g_{23}=0 \quad (r^2): \quad -g^{(-1)}{}_{,\theta}+g^{(-1)}\cot\theta=0, \tag{24}$$

$$\mathscr{L}_\eta g_{33}=0 \quad (r^2): \quad f^{(-1)}\cot\theta+A^{(-1)}=0. \tag{25}$$

The system of equations (19)–(21), (23), (25) is, at this order, identical to Eqs. (20)–(24) in Ref. 2. The solutions are thus identical, reading

$$\begin{aligned} A^{(-1)}&=k\cos\theta,\\ f^{(-1)}&=-k\sin\theta,\\ B&=-ku\cos\theta+\alpha(\theta), \end{aligned} \tag{26}$$

where $k=\text{const}$ and α is an arbitrary function of θ. Equations (22) and (24) imply

$$g^{(-1)}=h\sin\theta, \tag{27}$$

where $h=\text{const}$.

Regarding Eqs. (11), (13) and (18) we find $\eta^{\phi}=h+O(r^{-1})$. Since the contribution of h to the vector field η^{α} is just $\eta^{\phi}=\text{const}$, which is a constant multiple of the axial Killing vector $\partial/\partial\phi$, we may, without loss of generality, put $h=0$. Therefore, in the lowest order in r^{-1} the general asymptotic form of the Killing vector η turns out to be

$$\eta^{\alpha}=[-ku\cos\theta+\alpha(\theta),\quad kr\cos\theta+O(r^0),\quad -k\sin\theta+O(r^{-1}),\quad O(r^{-1})], \tag{28}$$

where k is a constant, α – an arbitrary function of θ. Thus, in the leading order of the asymptotic expansion the presence of an electromagnetic field satisfying the boundary conditions (5) and the fact that the axial Killing vector need not be hypersurface orthogonal do not change the conclusion obtained in Ref. 2 in the vacuum case with hypersurface orthogonal $\partial/\partial\phi$. When $k=0$, the vector field (28) generates supertranslations. We shall see in Sec. III that the resulting space–times are then nonradiative.

Assuming $k\neq 0$, it is then easy to find a Bondi–Sachs coordinate system with $\alpha=0$ by making a supertranslation $\tilde{u}=u+\hat{\alpha}(\theta)$, $\tilde{r}=r$, $\tilde{\theta}=\theta$, $\tilde{\phi}=\phi$, where $\hat{\alpha}$ satisfies the equation $-\hat{\alpha}_{,\theta}\ k\sin\theta+\hat{\alpha}k\cos\theta=-\alpha$ (cf. Ref. 2). [Notice that no singularity arises for $\hat{\alpha}$ even if $\alpha(0)\neq 0$.] We then obtain $\eta^{\tilde{u}}=-k\tilde{u}\cos\theta$. Hence, we put $\alpha=0$ in Eq. (28) and without loss of generality (buno) we choose $k=1$. Then $B=-u\cos\theta$, $A^{(-1)}=\cos\theta$, $f^{(-1)}=-\sin\theta$ and $g^{(-1)}=0$. The asymptotic form of the Killing vector field η is

$$\eta^{\alpha}=[-u\cos\theta,\quad r\cos\theta+O(r^0),\quad -\sin\theta+O(r^{-1}),\quad O(r^{-1})], \tag{29}$$

which is the *boost Killing vector*. It generates the Lorentz transformations along the axis of axial symmetry.

We have thus proven the following:

Theorem: Suppose that an axially symmetric electrovacuum space–time admits a ''piece'' of $\mathscr{I}^+$ in the sense that the Bondi–Sachs coordinates can be introduced in which the metric takes the form (3)–(4) and the asymptotic form of the electromagnetic field is given by (5). If this space–time admits an additional Killing vector forming with the axial Killing vector a two-dimensional Lie algebra, then the additional Killing vector has asymptotically the form (28). For $k=0$ it generates a supertranslation; for $k\neq 0$ it is the boost Killing field.

On $\mathscr{I}^+$ in the coordinates u, $l=r^{-1}$, θ, and ϕ the boost Killing vector reads (cf. Ref. 2)

$$\eta^{\alpha}_{|\mathscr{I}^+}=[-u\cos\theta,\ \ 0,\ \ -\sin\theta,\ \ 0]. \tag{30}$$

III. THE SUPERTRANSLATIONAL KILLING FIELD

In this section we shall show that if the Killing field (28) for $k=0$ is the supertranslational Killing field, it has, in fact, to be the generator of translations and the resulting space–time is thus nonradiative.

Assuming $k=0$, and considering the Killing equations (14) in the higher orders in r^{-k} than in Eqs. (19)–(25), and taking into account the metric expansions (4), we find the following restrictions on the expansion coefficients of functions A, $\tilde{f}$ and $\tilde{g}$:

$$\mathscr{L}_{\eta}g_{00}=0\quad (r^0):\quad A^{(0)}{}_{,u}=0, \tag{31}$$

$$(r^{-1}):\quad A^{(1)}{}_{,u}-f^{(0)}{}_{,u}(c_{,\theta}+2c\cot\theta)-g^{(0)}{}_{,u}(d_{,\theta}+2d\cot\theta)=0, \tag{32}$$

$$\mathscr{L}_{\eta}g_{01}=0\quad (r^{-1}):\quad \text{satisfied automatically}, \tag{33}$$

$$(r^{-2}):\quad -B(cc_{,u}+dd_{,u})-BM-A^{(1)}+f^{(0)}(c_{,\theta}+2c\cot\theta)+g^{(0)}(d_{,\theta}+2d\cot\theta)=0, \tag{34}$$

$$\mathscr{L}_{\eta}g_{02}=0\quad (r^1):\quad f^{(0)}{}_{,u}=0, \tag{35}$$

$$(r^0):\ (A^{(0)}+\tfrac{1}{2}B)_{,\theta}+f^{(0)}c_{,u}-cf^{(0)}{}_{,u}-f^{(1)}{}_{,u}-2g^{(0)}{}_{,u}\,d=0, \tag{36}$$

$\mathscr{L}_\eta g_{03}=0$ $(r^1):\ g^{(0)}{}_{,u}=0,$ (37)

$$(r^0):\ -g^{(0)}c_{,u}+g^{(0)}{}_{,u}c-g^{(1)}{}_{,u}+2f^{(0)}d_{,u}=0, \tag{38}$$

$\mathscr{L}_\eta g_{12}=0$ $(r^0):\ f^{(0)}+B_{,\theta}=0,$ (39)

$$(r^{-1}):\ f^{(1)}-B(c_{,\theta}+2c\cot\theta)+g^{(0)}d=0, \tag{40}$$

$\mathscr{L}_\eta g_{13}=0$ $(r^0):\ g^{(0)}=0,$ (41)

$$(r^{-1}):\ g^{(1)}-B(d_{,\theta}+2d\cot\theta)-f^{(0)}d=0, \tag{42}$$

$\mathscr{L}_\eta g_{22}=0$ $(r^1):\ f^{(0)}{}_{,\theta}+Bc_{,u}+A^{(0)}-\tfrac{1}{2}B=0,$ (43)

$$(r^0):\ f^{(1)}{}_{,\theta}+B(cc_{,u}+2dd_{,u})-B(c_{,\theta}+2c\cot\theta)_{,\theta}+A^{(1)}+BM+2d(g^{(0)}{}_{,\theta}-g^{(0)}\cot\theta)=0, \tag{44}$$

$\mathscr{L}_\eta g_{23}=0$ $(r^1):\ 2Bd_{,u}+g^{(0)}{}_{,\theta}-g^{(0)}\cot\theta=0,$ (45)

$$(r^0):\ -2A^{(0)}d-4f^{(0)}d\cot\theta+B(d_{,\theta}+2d\cot\theta)_{,\theta}-B(d_{,\theta}+2d\cot\theta)\cot\theta+Bd+g^{(0)}{}_{,\theta}c-g^{(0)}(c_{,\theta}+c\cot\theta)-g^{(1)}{}_{,\theta}+g^{(1)}\cot\theta=0, \tag{46}$$

$\mathscr{L}_\eta g_{33}=0$ $(r^1):\ f^{(0)}\cot\theta-Bc_{,u}+A^{(0)}-\tfrac{1}{2}B=0,$ (47)

$$(r^0):\ \cot\theta[-B(c_{,\theta}+2c\cot\theta)+f^{(1)}-f^{(0)}c]-c_{,\theta}f^{(0)}+c(A^{(0)}-\tfrac{1}{2}B)+A^{(1)}+2Bdd_{,u}+BM=0. \tag{48}$$

First notice that Eqs. (31), (35), (37), (39), (41) and (45) imply

$$A^{(0)}=A^{(0)}(\theta),\quad f^{(0)}=f^{(0)}(\theta)=-B_{,\theta},\quad g^{(0)}=0,\quad d=d(\theta). \tag{49}$$

Using these results in the remaining equations we find

$$A^{(0)}=\tfrac{1}{2}(B_{,\theta\theta}+B_{,\theta}\cot\theta+B), \tag{50}$$

$$c_{,u}=\frac{1}{2B}(B_{,\theta\theta}-B_{,\theta}\cot\theta), \tag{51}$$

$$c=\frac{u}{2B}(B_{,\theta\theta}-B_{,\theta}\cot\theta)+\omega(\theta), \tag{52}$$

$$A^{(1)}=A^{(1)}(\theta), \tag{53}$$

$$f^{(1)}=B(c_{,\theta}+2c\cot\theta), \tag{54}$$

$$g^{(1)}=B(d_{,\theta}+2d\cot\theta)-B_{,\theta}d, \tag{55}$$

where $\omega(\theta)$ is an arbitrary function of θ; ω can be transformed away by a supertranslation $u=\overline{u}+\hat{\alpha}(\theta)$ with $\hat{\alpha}$ satisfying $\omega+(-\hat{\alpha}_{,\theta\theta}+\hat{\alpha}_{,\theta}\cot\theta)/2=0$. Equations (36) and (46) are now satisfied identically. Equations (34), (44) and (48) lead to only one further independent condition:

$$M=-cc_{,u}-B^{-1}[A^{(1)}+B_{,\theta}(c_{,\theta}+2c\cot\theta)]. \tag{56}$$

Important results follow from Eqs. (49) and (51). Equation (49) shows that the news function $d_{,u}=0$. Since $B=B(\theta)$, Eq. (51) implies that the time derivative of the news function $c_{,u}$ must vanish. Therefore, with the supertranslational Killing field, we arrive at the Weyl tensor (see, e.g., Ref. 11)

$$C_{\alpha\beta\gamma\delta}m^{\alpha}t^{\beta}m^{\gamma}t^{\delta}=[(c+id)_{,uu}]\frac{1}{r}+O(r^{-2}), \tag{57}$$

which is nonradiative since the first term proportional to r^{-1} vanishes.

Substituting the expansion of the metric functions (4) into the null tetrad (11) and coefficients A, B, $\tilde{f}$ and $\tilde{g}$ [given by Eqs. (49)–(56)] into Eq. (13), we find the expansion of the supertranslational Killing vector to be

$$\begin{aligned}\eta^{\mu}=\Bigg[&B(\theta),\tfrac{1}{2}(B_{,\theta\theta}+B_{,\theta}\cot\theta)\\&+\Bigg[-B_{,\theta\theta}-2B_{,\theta}B_{,\theta\theta\theta}+2B_{,\theta}{}^{2}B_{,\theta\theta}B^{-1}-2B_{,\theta}{}^{3}\cot\theta B^{-1}+B_{,\theta}{}^{2}\left(3\cot^{2}\theta-\frac{2}{\sin^{2}\theta}\right)\Bigg]\\&\times B^{-1}\frac{u}{4r}+O(r^{-2}),\ \ -B_{,\theta}\frac{1}{r}+B_{,\theta}\frac{c}{r^{2}}+O(r^{-3}),\ \ B_{,\theta}\frac{d}{r^{2}}\sin\theta+O(r^{-3})\Bigg].\end{aligned} \tag{58}$$

Let us now turn to the asymptotic properties of electromagnetic field. We assume $\mathcal{L}_{\eta}F_{\alpha\beta}=0$ where η is now the supertranslational Killing field (58). From the general expression of the Lie derivative of $F_{\mu\nu}$ with respect to general η^{α} decomposed into the null tetrad according to Eq. (13),

$$\begin{aligned}\mathcal{L}_{\eta}F_{\alpha\beta}=&A\mathcal{L}_{k}F_{\alpha\beta}+A_{,\alpha}k^{\gamma}F_{\gamma\beta}+A_{,\beta}k^{\gamma}F_{\alpha\gamma}+B\mathcal{L}_{m}F_{\alpha\beta}+B_{,\alpha}m^{\gamma}F_{\gamma\beta}+B_{,\beta}m^{\gamma}F_{\alpha\gamma}\\&+\tilde{f}[(\mathcal{L}_{l}F_{\alpha\beta})_{R}+(\mathcal{L}_{l}F_{\alpha\beta})_{I}]+\tilde{g}[(\mathcal{L}_{l}F_{\alpha\beta})_{R}-(\mathcal{L}_{l}F_{\alpha\beta})_{I}]\\&+\tilde{f}_{,\alpha}(t_{R}^{\gamma}+t_{I}^{\gamma})F_{\gamma\beta}+\tilde{f}_{,\beta}(t_{R}^{\gamma}+t_{I}^{\gamma})F_{\alpha\gamma}+\tilde{g}_{,\alpha}(t_{R}^{\gamma}-t_{I}^{\gamma})F_{\gamma\beta}+\tilde{g}_{,\beta}(t_{R}^{\gamma}-t_{I}^{\gamma})F_{\alpha\gamma},\end{aligned} \tag{59}$$

and after substituting for A, B, $\tilde{f}$, and $\tilde{g}$ in accordance with Eq. (58), we find that in the first orders in r^{-k} the Lie equations imply

$$\mathcal{L}_{\eta}F_{01}=0\ \ (r^{-2}):\ \ -\epsilon_{,u}B+XB_{,\theta}=0, \tag{60}$$

$$\mathcal{L}_{\eta}F_{02}=0\ \ (r^{0}):\ \ X_{,u}B=0, \tag{61}$$

$$\mathcal{L}_{\eta}F_{03}=0\ \ (r^{0}):\ \ (Y\sin\theta)_{,u}B=0, \tag{62}$$

$$\mathcal{L}_{\eta}F_{12}=0\ \ (r^{-2}):\ \ e_{,u}B+\epsilon B_{,\theta}=0, \tag{63}$$

$$\mathcal{L}_{\eta}F_{13}=0\ \ (r^{-2}):\ \ (f\sin\theta)_{,u}B-\mu\sin\theta B_{,\theta}=0, \tag{64}$$

$$\mathcal{L}_{\eta}F_{23}=0\ \ (r^{0}):\ \ -(\mu\sin\theta)_{,u}B+Y\sin\theta B_{,\theta}=0. \tag{65}$$

From Eq. (61) we get $X=X(\theta)$. Combining Eq. (60) and Maxwell equation (9) we get the equation for X, $(XB\sin\theta)_{,\theta}=0$, the solution being

$$X=\frac{x_{0}}{B\sin\theta},\quad x_{0}=\text{const.} \tag{66}$$

Regarding the last result and integrating Eq. (60), we obtain

$$\epsilon = \frac{x_0 B_{,\theta}}{B^2 \sin\theta} u + \epsilon_1(\theta), \tag{67}$$

where $\epsilon_1(\theta)$ is an arbitrary integration function. Equation (63) then implies

$$e = -\frac{x_0 B_{,\theta}^2}{2B^3 \sin\theta} u^2 - \frac{\epsilon_1 B_{,\theta}}{B} u + e_1(\theta), \tag{68}$$

where $e_1(\theta)$ is again an integration function.

Analogously, using Eqs. (62), (64), (65) and Maxwell equation (10) we find

$$Y = \frac{y_0}{B \sin\theta}, \quad y_0 = \text{const}, \tag{69}$$

$$\mu = \frac{y_0 B_{,\theta}}{B^2 \sin\theta} u + \mu_1(\theta), \tag{70}$$

$$f = \frac{y_0 B_{,\theta}^2}{2B^3 \sin\theta} u^2 + \frac{\mu_1 B_{,\theta}}{B} u + f_1(\theta), \tag{71}$$

where μ_1, f_1 are arbitrary functions of θ.

Comparing Eqs. (68) and (71) with Maxwell equations (7) and (8) we obtain restrictions on ϵ_1 and μ_1:

$$\epsilon_{1,\theta} + \frac{2\epsilon_1 B_{,\theta}}{B} - \frac{2y_0 d}{B \sin\theta} = 0, \tag{72}$$

$$\mu_{1,\theta} + \frac{2\mu_1 B_{,\theta}}{B} + \frac{2x_0 d}{B \sin\theta} = 0. \tag{73}$$

Now we assume that the Killing field η is bounded at the axis, i.e., $B(\theta)$ is bounded for $\theta = 0, \pi$ and the electromagnetic field (5), i.e., X and Y have to be bounded there, too. Therefore constants entering X and Y must vanish:

$$x_0 = y_0 = 0. \tag{74}$$

Taking the time derivative of Eq. (56), regarding Eqs. (49), (51), (53), and comparing with Eq. (6), we arrive at the following equation for function B:

$$\left[\frac{\sin^3\theta}{2B} \left(\frac{B_{,\theta}}{\sin\theta} \right)_{,\theta} \right]_{,\theta} = 0. \tag{75}$$

The general solution can be seen to be

$$B = a \sin\theta \left(\frac{\sin\theta}{\cos\theta + 1} \right)^C + b \sin\theta \left(\frac{\sin\theta}{\cos\theta + 1} \right)^{-C}, \tag{76}$$

where a, b, $C > 0$ are constants. If we assume $C \in [0,1]$ then B is bounded at the axis.

The news function is obtained from (51): $c_{,u} = (C^2 - 1)/(2 \sin^2\theta)$. As described in Ref. 14 and in Appendix D it corresponds to the news function of a string; we exclude $C = 0$. Function B given in Eq. (76) corresponds to translations along the z-axis and t-axis in the space–time of an infinite thin cosmic string described by the deficit angle $2\pi(1 - C)$, $C \in (0,1]$; in the weak-field limit, $C = 1 - 4\mu$, where μ is the mass per unit length of the string. (Notice that $\mu \geqslant 0$ for $C \in (0,1]$.) See Appendix D for details.

In Appendix E, part 1, the explicit form of electromagnetic field for general B, Eq. (76), representing translations in asymptotically flat space–times with a straight string is given.

If $C=1$, there is no string extending to infinity. Equation (76) gives

$$B=(b-a)\cos\theta+(b+a). \tag{77}$$

Then $c_{,u}=0$ and from Eqs. (49) and (50) we get

$$f^{(0)}=(b-a)\sin\theta, \quad A^{(0)}=\tfrac{1}{2}[-(b-a)\cos\theta+b+a]. \tag{78}$$

Consequently, regarding Eqs. (11), (13) and (18), we find the Killing vector field η^α to be asymptotically of the form

$$\eta^\alpha=\left[(b-a)\cos\theta+b+a,\quad -(b-a)\cos\theta+O(r^{-2}),\quad (b-a)\sin\theta\frac{1}{r}+O(r^{-3}),\quad O(r^{-3})\right]. \tag{79}$$

We thus see that the Killing vector field generates translations: with $b-a=0$ this is the time translation, with $a+b=0$ the translation along the z-axis.

Since there is no string extending to infinity, both functions $c=c(\theta)$ and $d=d(\theta)$ are independent of time and both news functions thus vanish; there is no radiation. By employing two transformations from the Bondi–Metzner–Sachs group, functions c and d can be transformed away.

For an illustration let us write down the asymptotic form of both gravitational and electromagnetic fields in the case of the Killing vector representing timelike translations in asymptotically flat space–time without a string; we thus assume $B=\text{const}$ and $c=d=0$. The resulting axially symmetric stationary metric and electromagnetic field then have the asymptotic form

$$\begin{aligned}ds^2=&\left(1-\frac{2M(\theta)}{r}+O(r^{-2})\right)du^2+2(1+O(r^{-4}))du\,dr+2O(r^{-1})du\,d\theta+2O(r^{-1})\sin\theta\,du\,d\phi\\&-r^2[(1+O(r^{-3}))d\theta^2+(1+O(r^{-3}))\sin^2\theta d\phi^2+2O(r^{-3})\sin\theta\,d\theta\,d\phi],\end{aligned}$$

$$F_{01}=-\frac{\epsilon_1}{r^2}+(e_{1,\theta}+e_1\cot\theta)\frac{1}{r^3}+O(r^{-4}),$$

$$F_{02}=O(r^{-2}),$$

$$F_{03}=O(r^{-2}), \tag{80}$$

$$F_{12}=\frac{e_1}{r^2}+O(r^{-3}),$$

$$F_{13}=f_1\sin\theta\frac{1}{r^2}+O(r^{-3}),$$

$$F_{23}=-\mu_1\sin\theta-(f_1\sin\theta)_{,\theta}\frac{1}{r}+O(r^{-2}).$$

Using the consequence of Einstein's equations (A46) and assuming $N_{,u}=0$ (which, as will be proven in our forthcoming publication, follows from further terms in r^{-k} in the Killing equations), we see that $M_{,\theta}=0$, i.e., $A^{(1)}(\theta)=\text{const}$. Constants M, ϵ_1 and μ_1 represent the total mass, electric charge and magnetic charge, respectively.

IV. THE BOOST KILLING VECTOR

In this section we shall find the form of the gravitational news functions $c_{,u}$ and $d_{,u}$ for the case of the boost Killing vector by expanding the Killing equations in further orders in r^{-1}. We shall also obtain the form of the electromagnetic news functions X and Y.

We thus assume the asymptotic form of the Killing vector to be given by Eq. (29). Expanding now the Killing equations (14) in higher orders of r^{-1} we obtain

$$\mathscr{L}_\eta g_{00}=0 \quad (r^0): \quad 2A^{(0)}{}_{,u}+B_{,u}=2A^{(0)}{}_{,u}-\cos\theta=0, \tag{81}$$

$$\mathscr{L}_\eta g_{01}=0 \quad (r^{-1}): \quad \text{satisfied automatically}, \tag{82}$$

$$\mathscr{L}_\eta g_{02}=0 \quad (r^1): \quad f^{(-1)}c_{,u}-f^{(0)}{}_{,u}+A^{(-1)}{}_{,\theta}=-\sin\theta\, c_{,u}-f^{(0)}{}_{,u}-\sin\theta=0, \tag{83}$$

$$\mathscr{L}_\eta g_{03}=0 \quad (r^1): \quad -g^{(0)}{}_{,u}+2f^{(-1)}d_{,u}=-g^{(0)}{}_{,u}-2\sin\theta\, d_{,u}=0, \tag{84}$$

$$\mathscr{L}_\eta g_{12}=0 \quad (r^0): \quad f^{(0)}-f^{(-1)}c+B_{,\theta}=f^{(0)}+\sin\theta\, c+u\sin\theta=0, \tag{85}$$

$$\mathscr{L}_\eta g_{13}=0 \quad (r^0): \quad 2f^{(-1)}d-g^{(0)}=-2\sin\theta\, d-g^{(0)}=0, \tag{86}$$

$$\begin{aligned}\mathscr{L}_\eta g_{22}=0 \quad (r^1): \quad & f^{(0)}{}_{,\theta}+Bc_{,u}+A^{(0)}-\tfrac{1}{2}B \\ & =f^{(0)}{}_{,\theta}-u\cos\theta\, c_{,u}+A^{(0)}+\tfrac{1}{2}u\cos\theta=0,\end{aligned} \tag{87}$$

$$\begin{aligned}\mathscr{L}_\eta g_{23}=0 \quad (r^1): \quad & -g^{(0)}{}_{,\theta}+g^{(0)}\cot\theta-2Bd_{,u}-2df^{(-1)}\cot\theta \\ & =-g^{(0)}{}_{,\theta}+g^{(0)}\cot\theta+2u\cos\theta\, d_{,u}+2d\cos\theta=0,\end{aligned} \tag{88}$$

$$\begin{aligned}\mathscr{L}_\eta g_{33}=0 \quad (r^1): \quad & \tfrac{1}{2}B-A^{(0)}+f^{(-1)}(c_{,\theta}+2c\cot\theta)-f^{(0)}\cot\theta+Bc_{,u} \\ & =-\frac{u}{2}\cos\theta-A^{(0)}-\sin\theta(c_{,\theta}+2c\cot\theta)-f^{(0)}\cot\theta-u\cos\theta\, c_{,u}=0.\end{aligned} \tag{89}$$

From Eqs. (81) and (85) we immediately get

$$A^{(0)}=\frac{u}{2}\cos\theta+\rho(\theta), \tag{90}$$

$$c=-u-\frac{f^{(0)}}{\sin\theta}, \tag{91}$$

where $\rho(\theta)$ is an arbitrary function of θ. Equation (83) is just the u-derivative of Eq. (85). Equation (87) implies

$$c_{,u}=\frac{1}{u\cos\theta}\left(f^{(0)}{}_{,\theta}+A^{(0)}+\frac{u}{2}\cos\theta\right). \tag{92}$$

Using now Eqs. (90)–(92) in Eq. (89) we find that additive function $\rho(\theta)$ in Eq. (90) must vanish, i.e.,

$$A^{(0)}=\frac{u}{2}\cos\theta. \tag{93}$$

Comparing Eqs. (83) and (87) we obtain an equation for $f^{(0)}$,

$$uf^{(0)}{}_{,u}+\tan\theta\, f^{(0)}{}_{,\theta}+2u\sin\theta=0. \tag{94}$$

This equation can be solved by introducing a new variable

$$w=\frac{\sin\theta}{u}. \tag{95}$$

Equation (94) then becomes

$$\partial_u f^{(0)}(u,w)+2uw=0, \tag{96}$$

so that the general solution is

$$f^{(0)}=-u^2w+\mathscr{K}(w)=-u\sin\theta+\mathscr{K}(\sin\theta/u), \tag{97}$$

where $\mathscr{K}(w)$ is an arbitrary function of w. Consequently, Eq. (91) leads to

$$c(u,\theta)=-\frac{\mathscr{K}(w)}{uw}, \tag{98}$$

where w is given by Eq. (95). The news function thus reads

$$c_{,u}(u,\theta)=\frac{\mathscr{K}(w)_{,w}}{u^2}. \tag{99}$$

Before writing down the result for the second news function, let us compare expression (99) with the news function given for the case of the vacuum boost-rotation symmetric space–times with the hypersurface orthogonal Killing vectors in Ref. 2. There the news function is obtained in the form $c_{,u}=F(\tilde{U}/\sin\theta)/\sin^2\theta$, where F is an arbitrary function of $\tilde{U}/\sin\theta$ and the flat-space retarded time $\tilde{U}$ satisfies the equation $\tilde{U}_{,u}u\cot\theta=\tilde{U}\cot\theta-\tilde{U}_{,\theta}$. This equation can be rewritten as the equation $u\tilde{U}_{,u}+\tan\theta\,\tilde{U}_{,\theta}-\tilde{U}=0$, the solution of which is $\tilde{U}=\mathscr{A}(w)u$, $\mathscr{A}$ being function of $w=\sin\theta/u$. We can write $c_{,u}=F(\mathscr{A}(w)/w)/\sin^2\theta=F(\mathscr{A}(w)/w)/(w^2u^2)=\mathscr{K}_{,w}(w)/u^2$, where $\mathscr{K}_{,w}=F(\mathscr{A}(w)/w)/w^2$. Therefore, our result (99) for the general form of the news function is in agreement with Eq. (59) given in Ref. 2.

The second news function, $d_{,u}$, can be found analogously. Equation (84) is the u-derivative of Eq. (86) which gives

$$d=-\frac{g^{(0)}}{2\sin\theta}. \tag{100}$$

Substituting this result and $d_{,u}$ from Eq. (84) into Eq. (88), we obtain the equation for $g^{(0)}$,

$$ug^{(0)}_{,u}+\tan\theta g^{(0)}_{,\theta}=0, \tag{101}$$

which in terms of variables u and w simply yields

$$g^{(0)}=g^{(0)}(w). \tag{102}$$

The second news function is thus given by

$$d_{,u}(u,\theta)=\frac{g^{(0)}(w)_{,w}}{2u^2}, \tag{103}$$

where $g^{(0)}$ is an arbitrary function of $w=\sin\theta/u$.

In order to obtain the mass aspect and the total mass at null infinity we have to expand the Killing equations in higher orders in r^{-1}. Straightforward though rather lengthy calculations lead to the following system of equations (in which $A^{(-1)}$, $A^{(0)}$, B, $f^{(-1)}$, $f^{(0)}$, $g^{(0)}$, c and d are already known but are left unspecified for the sake of compactness):

$$\mathscr{L}_\eta g_{00}=0 \quad (r^{-1}): \quad A^{(1)}{}_{,u}-B_{,u}M+A^{(-1)}(cc_{,u}+dd_{,u}+M)-f^{(-1)}M_{,\theta}$$
$$-(d_{,\theta}+2d\cot\theta)(g^{(0)}{}_{,u}-2f^{(-1)}d_{,u})-(c_{,\theta}+2c\cot\theta)(f^{(0)}{}_{,u}$$
$$-f^{(-1)}c_{,u})=0, \tag{104}$$

$$\mathscr{L}_\eta g_{01}=0 \quad (r^{-2}): \quad (c_{,\theta}+2c\cot\theta)(f^{(0)}-f^{(-1)}c)-f^{(-1)}(dd_{,\theta}+cc_{,\theta})$$
$$-\tfrac{1}{2}B_{,u}(c^2+d^2)-A^{(1)}-BM-B(dd_{,u}+cc_{,u})=0, \tag{105}$$

$$\mathscr{L}_\eta g_{02}=0 \quad (r^{0}): \quad f^{(-1)}(cc_{,u}+2dd_{,u})-f^{(-1)}(c_{,\theta}+2c\cot\theta)_{,\theta}-f^{(-1)}{}_{,\theta}(c_{,\theta}+2c\cot\theta)$$
$$+A^{(0)}{}_{,\theta}+\tfrac{1}{2}B_{,\theta}-f^{(0)}{}_{,u}c+f^{(0)}c_{,u}-f^{(1)}{}_{,u}-2dg^{(0)}{}_{,u}=0, \tag{106}$$

$$\mathscr{L}_\eta g_{03}=0 \quad (r^{0}): \quad -g^{(0)}c_{,u}+g^{(0)}{}_{,u}c-g^{(1)}{}_{,u}+2f^{(0)}d_{,u}+2f^{(-1)}(2dc_{,u}-cd_{,u})$$
$$-f^{(-1)}(d_{,\theta}+2d\cot\theta)_{,\theta}-f^{(-1)}(d_{,\theta}+2d\cot\theta)\cot\theta=0, \tag{107}$$

$$\mathscr{L}_\eta g_{12}=0 \quad (r^{-1}): \quad 2f^{(1)}-2B(c_{,\theta}+2c\cot\theta)-f^{(-1)}(c^2+2d^2)+2dg^{(0)}=0, \tag{108}$$

$$\mathscr{L}_\eta g_{13}=0 \quad (r^{-1}): \quad g^{(1)}-B(d_{,\theta}+2d\cot\theta)-d(f^{(0)}+f^{(-1)}c)=0, \tag{109}$$

$$\mathscr{L}_\eta g_{22}=0 \quad (r^{0}): \quad 2d(g^{(0)}{}_{,\theta}-g^{(0)}\cot\theta)+A^{(-1)}\frac{3d^2}{2}+4f^{(-1)}d^2\cot\theta+A^{(1)}$$
$$+BM+f^{(1)}{}_{,\theta}+B(2dd_{,u}+cc_{,u})-B(c_{,\theta}+2c\cot\theta)_{,\theta}=0, \tag{110}$$

$$\mathscr{L}_\eta g_{23}=0 \quad (r^{0}): \quad -2A^{(0)}d+Bd+4f^{(-1)}d(c_{,\theta}+c\cot\theta)$$
$$-4f^{(0)}d\cot\theta+g^{(0)}{}_{,\theta}c-g^{(0)}(c_{,\theta}+c\cot\theta)-g^{(1)}{}_{,\theta}+g^{(1)}\cot\theta$$
$$+B(d_{,\theta}+2d\cot\theta)_{,\theta}-B(d_{,\theta}+2d\cot\theta)\cot\theta=0, \tag{111}$$

$$\mathscr{L}_\eta g_{33}=0 \quad (r^{0}): \quad A^{(1)}-A^{(0)}c+\tfrac{1}{2}Bc+\tfrac{1}{2}A^{(-1)}(c^2+d^2)+BM-f^{(-1)}d^2\cot\theta$$
$$+2f^{(-1)}d(d_{,\theta}+2d\cot\theta)-B\cot\theta(c_{,\theta}+2c\cot\theta)+2B(cc_{,u}+dd_{,u})$$
$$+f^{(1)}\cot\theta+(c_{,\theta}+2c\cot\theta)(-f^{(0)}+3f^{(-1)}c)$$
$$-c\cot\theta(f^{(0)}+\tfrac{3}{2}f^{(-1)}c)=0. \tag{112}$$

Substituting for c, d and $g^{(0)}$ from Eqs. (98), (100) and (102) into Eqs. (108) and (109) we obtain

$$f^{(1)}=\frac{1}{4\sin\theta}(-2\mathscr{K}^2+g^{(0)2})+u\cot^2\theta(\mathscr{K}_{,w}w+\mathscr{K}), \tag{113}$$

and

$$g^{(1)}=\frac{u}{2}g^{(0)}-\frac{g^{(0)}\mathscr{K}}{\sin\theta}+\frac{u}{2}\cot^2\theta(g^{(0)}{}_{,w}w+g^{(0)}). \tag{114}$$

Using the results for $f^{(-1)}$, $f^{(0)}$, B, ... already obtained, we find that Eqs. (106), (107) and (111) are just identities; Eqs. (110) and (112) also become identities if Eq. (105) is used.

Comparing the remaining Eq. (104) with the u-derivative of Eq. (105), we finally arrive at the equation for the mass aspect M:

$$uM_{,u}+\tan\theta M_{,\theta}+3M-u\tan\theta(c_{,\theta}+2c\cot\theta)_{,u}=0, \tag{115}$$

where $c_{,u}$ is given by Eq. (99). This equation can be solved by the substitution (95) to yield

$$M(u,\theta)=\frac{1}{2u}(\mathcal{K}_{,ww}w+2\mathcal{K}_{,w})+\frac{\mathcal{L}(w)}{u^3}, \tag{116}$$

where $\mathcal{L}(w)$ is an arbitrary function of w. Substituting M into Eq. (105) we obtain function $A^{(1)}$ in the form

$$A^{(1)}=\cos\theta\left(\frac{1}{2}\mathcal{K}_{,ww}w+2\mathcal{K}_{,w}+\frac{\mathcal{K}}{w}\right)-\frac{\cos\theta}{8\sin^2\theta}(4\mathcal{K}^2+g^{(0)2})+\frac{\cos\theta}{u^2}\mathcal{L}(w). \tag{117}$$

The last expression for M can be written as

$$M(u,\theta)=\frac{1}{2\sin\theta}(w^2\mathcal{K}_{,w})_{,w}+\frac{\mathcal{L}}{u^3}. \tag{118}$$

Comparing this form of $M(u,\theta)$ with the consequence of Einstein's equations (6), we find

$$\mathcal{L}(w)=\frac{\lambda(w)}{w^3}, \tag{119}$$

where λ has to satisfy the equation

$$\lambda(w)_{,w}=w^2\left(\mathcal{K}_{,w}^{\,2}+\frac{1}{4}g^{(0)}{}_{,w}^{\,2}+\mathcal{E}^2+\tilde{\mathcal{B}}^2\right)-\frac{1}{2w}(w^3\mathcal{K}_{,ww})_{,w}. \tag{120}$$

Here, $\mathcal{K}$ and $g^{(0)}$ determine the gravitational news functions, $c_{,u}$ and $d_{,u}$, by relations (99) and (103), $\mathcal{E}$ and $\tilde{\mathcal{B}}$ determine the electromagnetic news functions, X and Y, given below by relations (129) and (130). Hence, solving the last equation for λ for *given* $\mathcal{K}$, $g^{(0)}$, $\mathcal{E}$ and $\tilde{\mathcal{B}}$, we find $\mathcal{L}(w)$ and thus the mass aspect $M(u,\theta)$ in the form of Eq. (118). The total mass at $\mathcal{I}^+$ is then given by integrating Eq. (118) over the sphere:

$$m(u)=\frac{1}{2}\int_0^\pi M(u,\theta)\sin\theta\,d\theta=\frac{1}{4}\int_0^\pi(w^2\mathcal{K}_{,w})_{,w}\,d\theta+\frac{1}{2}\int_0^\pi\frac{w\mathcal{L}}{u^2}d\theta. \tag{121}$$

Substituting the expansions of the metric functions, Eq. (4), into the null tetrad, Eq. (11), and coefficients A, B, $\tilde{f}$ and $\tilde{g}$, Eqs. (93), (97), (98), (100), (102), (113), (114), (116), (117), into Eq. (13), we find the expansion of the boost Killing vector to be

$$\begin{aligned}\eta^\mu=\Bigg[&-u\cos\theta,\quad r\cos\theta+u\cos\theta+\cos\theta\left(\mathcal{K}_{,w}+\frac{\mathcal{K}}{w}\right)\frac{1}{r}+O(r^{-2}),\\ &-\sin\theta-u\sin\theta\frac{1}{r}+uc\sin\theta\frac{1}{r^2}+O(r^{-3}),\quad ud\frac{1}{r^2}+O(r^{-3})\Bigg].\end{aligned} \tag{122}$$

It can easily be seen that the boost Killing vector generating Lorentz transformations along the z-axis in Minkowski space, $\eta^\alpha_M=[z,0,t,0]$, in $\{u,\ r,\ \theta,\ \phi\}$ coordinates reads $\eta^\alpha_M=[-u\cos\theta,\ r(1+u/r)\cos\theta,\ -\sin\theta(1+u/r),\ 0]$ so that both vectors differ only in terms proportional to $\mathcal{K}$, c and d.

Let us finally turn to the asymptotic properties of the electromagnetic field which now is assumed to satisfy $\mathcal{L}_\eta F_{\alpha\beta}=0$, Eq. (59), where η is the boost Killing field (122). The first orders of these equations read

$$\mathscr{L}_\eta F_{01}=0 \quad (r^{-2}): \quad \cos\theta \ (\tan\theta \ \ \epsilon_{,\theta}+u\epsilon_{,u}+2\epsilon+u\tan\theta \ \ X)=0, \tag{123}$$

$$\mathscr{L}_\eta F_{02}=0 \quad (r^{0}): \quad -\cos\theta \ (\tan\theta \ \ X_{,\theta}+uX_{,u}+2X)=0, \tag{124}$$

$$\mathscr{L}_\eta F_{03}=0 \quad (r^{0}): \quad -\cos\theta \ [\tan\theta \ \ (Y\sin\theta)_{,\theta}+u(Y\sin\theta)_{,u}+Y\sin\theta]=0, \tag{125}$$

$$\mathscr{L}_\eta F_{12}=0 \quad (r^{-2}): \quad -\cos\theta(\tan\theta \ \ e_{,\theta}+ue_{,u}+2e-u\tan\theta \ \ \epsilon)=0, \tag{126}$$

$$\mathscr{L}_\eta F_{13}=0 \quad (r^{-2}): \quad -\cos\theta \ [\tan\theta \ \ (f\sin\theta)_{,\theta}+u(f\sin\theta)_{,u}+f\sin\theta+u\tan\theta \ \ (\mu\sin\theta)]=0, \tag{127}$$

$$\mathscr{L}_\eta F_{23}=0 \quad (r^{0}): \quad \cos\theta \ [\tan\theta \ \ (\mu\sin\theta)_{,\theta}+u(\mu\sin\theta)_{,u}+\mu\sin\theta+u\tan\theta \ \ (Y\sin\theta)]=0. \tag{128}$$

Using again variable w given by Eq. (95), Eqs. (124) and (125) can easily be solved to yield

$$X(u,\theta)=\frac{\mathscr{E}(w)}{u^2}, \tag{129}$$

$$Y(u,\theta)=\frac{\mathscr{B}(w)}{u\sin\theta}=\frac{\mathscr{B}(w)}{wu^2}=\frac{\tilde{\mathscr{B}}(w)}{u^2}, \tag{130}$$

where functions $\mathscr{E}(w)$ and $\mathscr{B}(w)$ are arbitrary integration functions and $\tilde{\mathscr{B}}(w)=\mathscr{B}(w)/w$. Substituting these results into Eqs. (123) and (128) we find

$$\epsilon=\frac{\mathscr{E}(w)}{u}\cot\theta+\frac{\mathscr{F}(w)}{u^2}, \tag{131}$$

$$\mu=\frac{\mathscr{B}(w)}{\sin\theta}\cot\theta+\frac{\mathscr{C}(w)}{u\sin\theta}=\frac{\tilde{\mathscr{B}}(w)}{u}\cot\theta+\frac{\tilde{\mathscr{C}}(w)}{u^2}, \tag{132}$$

where functions $\mathscr{F}(w)$ and $\mathscr{C}(w)$ are arbitrary integration functions and $\tilde{\mathscr{C}}(w)=\mathscr{C}(w)/w$. Then the solution of Eqs. (126) and (127) reads

$$e=\frac{\mathscr{E}(w)}{2}-\frac{\mathscr{F}(w)}{u}\cot\theta+\frac{\mathscr{G}(w)}{u^2}, \tag{133}$$

$$f=-\frac{\mathscr{B}(w)u}{2\sin\theta}+\frac{\mathscr{C}(w)}{\sin\theta}\cot\theta+\frac{\mathscr{D}(w)}{u\sin\theta}=-\frac{\tilde{\mathscr{B}}(w)}{2}+\frac{\tilde{\mathscr{C}}(w)}{u}\cot\theta+\frac{\tilde{\mathscr{D}}(w)}{u^2}, \tag{134}$$

where $\mathscr{G}(w)$ and $\mathscr{D}(w)$ are again integration functions and $\tilde{\mathscr{D}}(w)=\mathscr{D}(w)/w$. Comparing Eqs. (123) and (128) with Maxwell equations (9) and (10), and using previous results, we get equations for $\mathscr{F}(w)$ and $\mathscr{C}(w)$: $\mathscr{F}_{,w}w+2\mathscr{F}=0$ and $\mathscr{C}_{,w}w+\mathscr{C}=0$. Their solutions are

$$\mathscr{F}=\frac{l}{w^2}, \quad l=\text{const}, \tag{135}$$

$$\mathscr{C}=\frac{p}{w},\quad p=\text{const.} \tag{136}$$

Since $w=\sin\theta/u$, the regularity of the electromagnetic field implies $l=p=0$.

Finally, comparing Maxwell equations (7) and (8) with Eqs. (126) and (127), we get restrictions on functions $\mathscr{D}(w)$ and $\mathscr{G}(w)$ in the form

$$\mathscr{E}_{,w}w-\mathscr{E}+2w^2(\mathscr{G}_{,w}w+2\mathscr{G})+2w\mathscr{E}\mathscr{K}+\mathscr{B}g^{(0)}=0, \tag{137}$$

$$-(\mathscr{B}_{,w}w-2.\mathscr{B})+2w^2(\mathscr{D}_{,w}w+\mathscr{D})-2w.\mathscr{B}\mathscr{K}+w^2g^{(0)}\mathscr{E}=0. \tag{138}$$

ACKNOWLEDGMENTS

We thank Vojtěch Pravda for discussions and help with calculations. We are grateful to Piotr Chruściel for reading the manuscript and making helpful suggestions. We also acknowledge support from Grant Nos. GACR-202/96/0206 of the Czech Republic and GAUK-230/96 of the Charles University, and the hospitality of the Albert Einstein Institute, Potsdam.

APPENDIX A: THE EINSTEIN–MAXWELL EQUATIONS IN THE BONDI–SACHS COORDINATES

In our convention (see the end of Sec. I) the Einstein–Maxwell equations read

$$K_{\mu\nu}\equiv R_{\mu\nu}+8\pi T_{\mu\nu}=0, \tag{A1}$$

where the electromagnetic stress tensor is given by

$$T_{\mu\nu}=\frac{1}{4\pi}\left(F_{\mu\sigma}F_{\nu}{}^{\sigma}-\frac{1}{4}g_{\mu\nu}F_{\sigma\rho}F^{\sigma\rho}\right), \tag{A2}$$

and $T^{\mu}_{\mu}=R=0$; the Maxwell equations are

$$G_{\mu\nu\lambda}\equiv F_{[\mu\nu,\lambda]cykl.}=0, \tag{A3}$$

$$J^{\mu}\equiv F^{\mu\nu}{}_{;\nu}=0. \tag{A4}$$

In Ref. 11 the tensor $E_{\mu\nu}=4\pi T_{\mu\nu}$ is introduced; however, the field equations (A1) are erroneously written without the factor 2 at $E_{\mu\nu}$. This can be ''cured'' by considering $F_{\mu\nu(\text{Burg})}=\sqrt{2}F_{\mu\nu(\text{real})}$. Following Ref. 11, eighteen equations (A1), (A3) and (A4) can be divided into twelve main equations, one trivial equation, and five supplementary conditions. The main equations are

$$\begin{gathered}K_{11}=K_{12}=K_{13}=K_{22}=K_{23}=K_{33}=0,\\ G_{123}=G_{012}=G_{013}=0,\quad J^0=J^2=J^3=0.\end{gathered} \tag{A5}$$

If these are satisfied, then also

$$K_{01}=0. \tag{A6}$$

The only further equations to be satisfied are the supplementary conditions

$$(r^2K_{00})_{,r}=(r^2K_{02})_{,r}=(r^2K_{03})_{,r}=0, \tag{A7}$$

$$G_{023},_r=0, \quad J^1,_r=0,$$

which imply that $r^2(K_{00},K_{02},K_{03})$, G_{023}, and J^1 are functions of u, θ, ϕ only.

Since in Ref. 11 all Einstein equations contain errors due to the factor 2 mentioned above, and Eqs. (5), (6), (7), (14), (15), (17), (18), (19) in Ref. 11 contain additional errors, we write all field equations explicitly here (we checked them by using MAPLE V). Starting from the metric of the form (3) we find that the main field equations are (denoting $\mathrm{ch}=\cosh 2\delta$, $\mathrm{sh}=\sinh 2\delta$)

$$\frac{r}{4}K_{11}=0: \quad \beta,_r=\frac{r}{2}(\gamma,_r^2 \mathrm{ch}^2+\delta,_r^2)$$
$$+\frac{1}{2r}(e^{-2\gamma}\mathrm{ch}\,F_{12}^2+e^{2\gamma}\mathrm{ch}\,F_{13}^2\csc^2\theta-2\,\mathrm{sh}\,F_{12}F_{13}\csc\theta), \tag{A8}$$

$$2r^2K_{12}=0: \quad \{r^4e^{-2\beta}(e^{2\gamma}U,_r\,\mathrm{ch}+W,_r\,\mathrm{sh})\},_r$$
$$=2r^2\left\{\beta,_{r\theta}-\frac{2}{r}\beta,_\theta+2\delta,_r\delta,_\theta-4\gamma,_r\delta,_\theta\,\mathrm{sh}\,\mathrm{ch}-(\gamma,_{r\theta}+2\gamma,_r\cot\theta-2\gamma,_r\gamma,_\theta)\mathrm{ch}^2\right\}$$
$$+2r^2e^{2\gamma}\csc\theta\{-\delta,_{r\phi}-2\delta,_r\gamma,_\phi+2\gamma,_r\delta,_\phi(1+2\,\mathrm{sh}^2)+(\gamma,_{r\phi}+2\gamma,_r\gamma,_\phi)\,\mathrm{sh}\,\mathrm{ch}\}$$
$$-4r^2e^{-2\beta}(F_{01}-UF_{12}-WF_{13}\csc\theta)F_{12}-4(\mathrm{sh}\,F_{12}-e^{2\gamma}\mathrm{ch}\,F_{13}\csc\theta)F_{23}\csc\theta, \tag{A9}$$

$$\frac{2r^2}{\sin\theta}K_{13}=0: \quad \{r^4e^{-2\beta}(e^{-2\gamma}W,_r\,\mathrm{ch}+U,_r\,\mathrm{sh})\},_r$$
$$=2r^2e^{-2\gamma}\{-\delta,_{r\theta}+2\delta,_r\gamma,_\theta-2\delta,_r\cot\theta-(\gamma,_{r\theta}+2\gamma,_r\cot\theta-2\gamma,_r\gamma,_\theta)\mathrm{sh}\,\mathrm{ch}$$
$$-2\gamma,_r\delta,_\theta(1+2\,\mathrm{sh}^2)\}+2r^2\csc\theta\left\{\beta,_{r\phi}-\frac{2}{r}\beta,_\phi+2\delta,_r\delta,_\phi+4\gamma,_r\delta,_\phi\,\mathrm{sh}\,\mathrm{ch}\right.$$

$$-(e^{2\gamma}\,\mathrm{ch}\,U+\mathrm{sh}\,W)F_{23}\csc\theta\Big\}_{,r} \tag{A19}$$

Since we assume the axial symmetry, hereafter we put all derivatives $\partial/\partial\phi$ equal to zero.

Now following Ref. 11, we assume functions γ, δ, F_{12} and F_{13} to have the expansions at large r on a hypersurface $u=u_0$ of the form

$$\gamma=\frac{c}{r}+\left(C-\frac{1}{6}c^3-\frac{3}{2}cd^2\right)\frac{1}{r^3}+\frac{D}{r^4}+O(r^{-5}), \tag{A20}$$

$$\delta=\frac{d}{r}+\left(H-\frac{1}{6}d^3+\frac{1}{2}c^2d\right)\frac{1}{r^3}+\frac{K}{r^4}+O(r^{-5}), \tag{A21}$$

$$F_{12}=\frac{e}{r^2}+(2E+ec+fd)\frac{1}{r^3}+O(r^{-4}), \tag{A22}$$

$$F_{13}=\left(\frac{f}{r^2}+(2F+ed-fc)\frac{1}{r^3}+O(r^{-4})\right)\sin\theta, \tag{A23}$$

where c, C, d, ... are prescribed functions of θ on $u=u_0$. This corresponds to the outgoing radiation condition and the absence of logarithmic terms. (We thus do not consider polyhomogeneous null infinity of Ref. 19.) Then twelve main equations determine the other eight functions β, U, V, W, F_{01}, F_{02}, F_{03} and u-derivatives of the four prescribed functions γ, δ, F_{12} and F_{13} on the hypersurface $u=u_0$. Denoting by N, P, M, ϵ, μ, X and Y arbitrary functions of θ on $u=u_0$, we find

$$\beta=-\frac{1}{4}(c^2+d^2)\frac{1}{r^2}+O(r^{-4}), \tag{A24}$$

$$\begin{aligned}U=&-(c_{,\theta}+2c\cot\theta)\frac{1}{r^2}+(2N+3(cc_{,\theta}+dd_{,\theta})+4(c^2+d^2)\cot\theta)\frac{1}{r^3}\\&+\frac{1}{2}(3(C_{,\theta}+2C\cot\theta)-6(cN+dP)-4(2c^2c_{,\theta}+cdd_{,\theta}+c_{,\theta}d^2))\frac{1}{r^4}\\&+\frac{1}{2}(-8c(c^2+d^2)\cot\theta+2(\epsilon e-f\mu))\frac{1}{r^4}+O(r^{-5}),\end{aligned} \tag{A25}$$

$$\begin{aligned}W=&-(d_{,\theta}+2d\cot\theta)\frac{1}{r^2}+(2P+2(c_{,\theta}d-cd_{,\theta}))\frac{1}{r^3}\\&+\frac{1}{2}(3(H_{,\theta}+2H\cot\theta)+(cP-dN)-4(2d^2d_{,\theta}+cdc_{,\theta}+c^2d_{,\theta}))\frac{1}{r^4}\\&+\frac{1}{2}(-8d(c^2+d^2)\cot\theta+2(\mu e+\epsilon f))\frac{1}{r^4}+O(r^{-5}),\end{aligned} \tag{A26}$$

$$\begin{aligned}V=&r-2M-(N_{,\theta}+N\cot\theta-\tfrac{1}{2}(c^2+d^2))\frac{1}{r}\\&-(-(c_{,\theta}+2c\cot\theta)^2-(d_{,\theta}+2d\cot\theta)^2-(\epsilon^2+\mu^2))\frac{1}{r}\\&-\frac{1}{2}(C_{,\theta\theta}+3C_{,\theta}\cot\theta-2C+6N(c_{,\theta}+2c\cot\theta)+6P(d_{,\theta}+2d\cot\theta))\frac{1}{r^2}\\&-\frac{1}{2}(4(2cc_{,\theta}^2+3c_{,\theta}dd_{,\theta}-cd_{,\theta}^2)+8(2c_{,\theta}d^2+3c^2c_{,\theta}+cdd_{,\theta})\cot\theta)\frac{1}{r^2}\\&-\frac{1}{2}(16c(c^2+d^2)\cot^2\theta+2\epsilon(e_{,\theta}+e\cot\theta)-2\mu(f_{,\theta}+f\cot\theta))\frac{1}{r^2}+O(r^{-3}),\end{aligned} \tag{A27}$$

$$F_{01}=-\frac{\epsilon}{r^2}+(e_{,\theta}+e\cot\theta)\frac{1}{r^3}+O(r^{-4}), \tag{A28}$$

$$\mathrm{F}_{23}=\left(-\mu-(f,_\theta+f\cot\theta)\frac{1}{r}+O(r^{-2})\right)\sin\theta, \tag{A29}$$

$$F_{02}=X+(\epsilon,_\theta-e,_u)\frac{1}{r}-\left(\left[E+\frac{1}{2}(ec+fd)\right],_u+\frac{1}{2}(e,_\theta+e\cot\theta),_\theta\right)\frac{1}{r^2}+O(r^{-3}), \tag{A30}$$

$$F_{03}=\left(Y-\frac{f,_u}{r}-\left(\left[F+\frac{1}{2}(ed-fc)\right],_u\right)\frac{1}{r^2}+O(r^{-3})\right)\sin\theta, \tag{A31}$$

and

$$2e,_u=\epsilon,_\theta-2(cX+dY), \tag{A32}$$

$$2f,_u=-\mu,_\theta-2(-cY+dX), \tag{A33}$$

$$4E,_u=-\left(\frac{\partial}{\partial\theta}+2\cot\theta\right)\left[\left(\frac{\partial}{\partial\theta}-\cot\theta\right)e+2(c\epsilon+d\mu)\right], \tag{A34}$$

$$4F,_u=-\left(\frac{\partial}{\partial\theta}+2\cot\theta\right)\left[\left(\frac{\partial}{\partial\theta}-\cot\theta\right)f+2(d\epsilon-c\mu)\right], \tag{A35}$$

$$\begin{aligned}4C,_u=&\,2(c^2-d^2)c,_u+4dcd,_u+2cM+d\left(\frac{\partial}{\partial\theta}+\cot\theta\right)(d,_\theta+2d\cot\theta)\\&-\left(\frac{\partial}{\partial\theta}-\cot\theta\right)N+2(eX-fY),\end{aligned} \tag{A36}$$

$$\begin{aligned}4H,_u=&-2(c^2-d^2)d,_u+4dcc,_u+2dM-c\left(\frac{\partial}{\partial\theta}+\cot\theta\right)(d,_\theta+2d\cot\theta)\\&-\left(\frac{\partial}{\partial\theta}-\cot\theta\right)P+2(eY+fX),\end{aligned} \tag{A37}$$

$$\begin{aligned}4D,_u=&\left(\frac{\partial}{\partial\theta}+3\cot\theta\right)\left[-\left(\frac{\partial}{\partial\theta}-2\cot\theta\right)C+2(cN-dP)\right]-\frac{2}{3}\epsilon\left(\frac{\partial}{\partial\theta}-\cot\theta\right)e\\&+\frac{2}{3}\mu\left(\frac{\partial}{\partial\theta}-\cot\theta\right)f-\frac{4}{3}c(\epsilon^2+\mu^2)+\frac{8}{3}(EX-YF),\end{aligned} \tag{A38}$$

$$\begin{aligned}4K,_u=&\left(\frac{\partial}{\partial\theta}+3\cot\theta\right)\left[-\left(\frac{\partial}{\partial\theta}-2\cot\theta\right)H+2(cP+dN)\right]-\frac{2}{3}\epsilon\left(\frac{\partial}{\partial\theta}-\cot\theta\right)f\\&-\frac{2}{3}\mu\left(\frac{\partial}{\partial\theta}-\cot\theta\right)e-\frac{4}{3}d(\epsilon^2+\mu^2)+\frac{8}{3}(FX+YE).\end{aligned} \tag{A39}$$

In order to simplify the last equations one can, following Ref. 11, introduce ten new quantities

$$\begin{aligned}&c^*=c+id, \quad X^*=X+iY,\\&C^*=C+iH, \quad e^*=e+if,\\&D^*=D+iK, \quad E^*=E+iF,\\&N^*=N+iP, \quad \epsilon^*=\epsilon+i\mu,\\&M^*=M+i\frac{1}{2}\left(\frac{\partial}{\partial\theta}+\cot\theta\right)(d,_\theta+2d\cot\theta),\end{aligned} \tag{A40}$$

$$\mathscr{L}_p=-\left(\frac{\partial}{\partial\theta}-p\cot\theta\right),\quad p=-3,-2\ldots 2,$$

in terms of which Eqs. (A32)–(A39) become

$$2e^*{}_{,u}=-\mathscr{L}_0\overline{\epsilon}^*-2c^*\overline{X}^*, \tag{A41}$$

$$4E^*{}_{,u}=-\mathscr{L}_{-2}(\mathscr{L}_1e^*-2c^*\overline{\epsilon}^*), \tag{A42}$$

$$4C^*{}_{,u}=2c^{*2}\overline{c}^*{}_{,u}+2c^*\overline{M}^*+\mathscr{L}_1N^*+2e^*X^*, \tag{A43}$$

$$4D^*{}_{,u}=-\mathscr{L}_{-3}(\mathscr{L}_2C^*+2c^*N^*)+\tfrac{2}{3}\epsilon^*\mathscr{L}_1e^*-\tfrac{4}{3}c^*\epsilon^*\overline{\epsilon}^*+\tfrac{8}{3}E^*X^*. \tag{A44}$$

The supplementary conditions (A7) have the form

$$M_{,u}=-(c_{,u}^2+d_{,u}^2)-(X^2+Y^2)+\tfrac{1}{2}(c_{,\theta\theta}+3c_{,\theta}\cot\theta-2c)_{,u}, \tag{A45}$$

$$\begin{aligned}3N_{,u}=&-M_{,\theta}-2c\left(\frac{\partial}{\partial\theta}+2\cot\theta\right)c_{,u}-2d\left(\frac{\partial}{\partial\theta}+2\cot\theta\right)d_{,u}\\&-(cc_{,u})_{,\theta}-(dd_{,u})_{,\theta}-2(\epsilon X+\mu Y),\end{aligned} \tag{A46}$$

$$\begin{aligned}3P_{,u}=&\frac{1}{2}\,\frac{\partial}{\partial\theta}\left(\frac{\partial}{\partial\theta}+\cot\theta\right)(d_{,\theta}+2d\cot\theta)+2c\left(\frac{\partial}{\partial\theta}+2\cot\theta\right)d_{,u}\\&-2d\left(\frac{\partial}{\partial\theta}+2\cot\theta\right)c_{,u}+(cd_{,u})_{,\theta}-(dc_{,u})_{,\theta}-2(\epsilon Y-\mu X),\end{aligned} \tag{A47}$$

$$\epsilon_{,u}=-X_{,\theta}-X\cot\theta, \tag{A48}$$

$$\mu_{,u}=-Y_{,\theta}-Y\cot\theta, \tag{A49}$$

which in terms of quantities (A40) simplify to

$$M^*{}_{,u}=-c^*{}_{,u}\overline{c}^*{}_{,u}-X^*\overline{X}^*+\tfrac{1}{2}\mathscr{L}_{-1}\mathscr{L}_{-2}c^*{}_{,u}, \tag{A50}$$

$$3N^*{}_{,u}=\mathscr{L}_0\overline{M}^*+2c^*\mathscr{L}_{-2}\overline{c}^*{}_{,u}+\mathscr{L}_0(c^*\overline{c}^*{}_{,u})-2\overline{\epsilon}^*X^*, \tag{A51}$$

$$\epsilon^*{}_{,u}=\mathscr{L}_{-1}X^*. \tag{A52}$$

The structure of the field equations is thus as follows. Nine functions γ, δ, F_{12}, F_{13}, M, N, P, ϵ and μ are prescribed on an ''initial'' hypersurface $u=u_0$, and four functions $c_{,u}$, $d_{,u}$, X and Y have to be prescribed for all u. Then the time evolution of gravitational and electromagnetic fields is fully determined. Functions $c_{,u}$ and $d_{,u}$ are the well-known *gravitational news functions*, functions X and Y–the *electromagnetic news functions*. Nonvanishing news functions $d_{,u}$ and Y correspond to a ''rotation'' of a radiating source. In vacuum space–times with hypersurface orthogonal Killing vector $\partial/\partial\phi$ we find $d=0$.

The total mass of the system at a given retarded time u is defined by

$$m(u)=\frac{1}{2}\int_0^\pi M(u,\theta)\sin\theta\,d\theta. \tag{A53}$$

(Notice that the definition of the total mass given in Ref. 11 is different; for example, in the Schwarzschild case it gives $4\pi m_{\text{Schw.}}$.) The time derivative of the total mass is equal to

$$m_{,u} = -\frac{1}{2}\int_0^\pi (c^*{}_{,u}\bar{c}^*{}_{,u} + X^*\bar{X}^*)\sin\theta\, d\theta$$
$$= -\frac{1}{2}\int_0^\pi (c_{,u}^2 + d_{,u}^2 + X^2 + Y^2)\sin\theta\, d\theta \leqslant 0. \tag{A54}$$

Hence, if any of the news functions is nonvanishing, the waves are radiated out and the mass of the system necessarily decreases.

There exist two quantities which are always conserved:

$$\frac{\partial}{\partial u}\int_0^\pi \tfrac{1}{2}\epsilon^* \sin\theta\, d\theta = 0. \tag{A55}$$

These are the ''electric'' and ''magnetic'' charges of the source.

The rate of loss of the electromagnetic energy radiated out from the system is given by

$$\frac{1}{2}\,\frac{\partial}{\partial u}\int_0^\pi X^*\bar{X}^* \sin\theta\, d\theta, \tag{A56}$$

which also implies the loss of mass as seen from Eq. (A54).

APPENDIX B: THE KILLING EQUATION

For an illustration we write down the expression for the Lie derivative component $\mathcal{L}_\eta g_{00} = 0$, where the metric has the form (3) and the vector η is given by Eqs. (11) and (13):

$$\begin{aligned}
\mathcal{L}_\eta g_{00} = & -\frac{1}{2r^3(2\,\mathrm{ch}^2-1)^{3/2}} e^{-3\gamma-2\beta} \\
& \times \Big\{ 2r^2(2\,\mathrm{ch}^2-1)e^{2(\beta+\gamma)}[-\sqrt{2\,\mathrm{ch}^2-1}\,e^{\gamma}(2A_{,u}r + B_{,u}Ve^{2\beta}) \\
& -2e^{2\gamma}(2\tilde{g}_{,u}\,\mathrm{sh}\,\mathrm{ch} + \tilde{f}_{,u})Ur^2 - (2\,\mathrm{ch}^2-1)2r^2\tilde{g}_{,u}W] \\
& +\tilde{g}4r^4e^{2(\beta+\gamma)}[W(2\,\mathrm{ch}^2-1) + 2U\,\mathrm{sh}\,\mathrm{ch}\,e^{2\gamma}][2\delta_{,u}\,\mathrm{sh}\,\mathrm{ch} - (2\,\mathrm{ch}^2-1)\gamma_{,u}] \\
& +\tilde{f}2re^{2\beta}[2r^3W(2\,\mathrm{ch}^2-1)^2(2W\delta_{,\theta}\,\mathrm{sh}\,\mathrm{ch} + (2\,\mathrm{ch}^2-1)(W_{,\theta} + \gamma_{,\theta}W)) \\
& -e^{2(\beta+\gamma)}(2\,\mathrm{ch}^2-1)^2(V_{,\theta} + 2\beta_{,\theta}V) \\
& +4r^3e^{2\gamma}(2\,\mathrm{ch}^2-1)((2\,\mathrm{ch}^2-1)^2UW\delta_{,\theta} + (2\,\mathrm{ch}^2-1)\mathrm{sh}\,\mathrm{ch}(U_{,\theta}W + UW_{,\theta} + 2W\gamma_{,u}) \\
& +W\delta_{,u}) + 2Ur^3e^{4\gamma}((2\,\mathrm{ch}^2-1)^3(U_{,\theta} + U\gamma_{,\theta}) + (2\,\mathrm{ch}^2-1)(2(2\,\mathrm{ch}^2-1)^2-1)\gamma_{,u} \\
& +2U\delta_{,\theta}\,\mathrm{sh}\,\mathrm{ch}(2\mathrm{ch}^2-1)^2 + 2\delta_{,u}\,\mathrm{sh}\,\mathrm{ch})] \\
& +A2r^2e^{\gamma}(2\,\mathrm{ch}^2-1)^{3/2}\Big[2r^2W((2\,\mathrm{ch}^2-1)(-rW\gamma_{,r} + W + rW_{,r}) \\
& +2rW\delta_{,r}\,\mathrm{sh}\,\mathrm{ch}) + 2r^2Ue^{4\gamma}((2\,\mathrm{ch}^2-1)(rU\gamma_{,r} + U + rU_{,r}) + 2rU\delta_{,r}\,\mathrm{sh}\,\mathrm{ch}) \\
& +e^{2(\beta+\gamma)}\Big(-V_{,r} + \frac{V}{r} - 2V\beta_{,r} + 4r\beta_{,u}\Big) \\
& +4r^2e^{2\gamma}((2\,\mathrm{ch}^2-1)rUW\delta_{,r} + \mathrm{sh}\,\mathrm{ch}(rU_{,r}W + 2UW + rUW_{,r}))\Big]
\end{aligned}$$

$$+Be^{2\beta+\gamma}(2\,\mathrm{ch}^2-1)^{3/2}\Big\{e^{2(\beta+\gamma)}\Big(Vr\Big(V_{,r}-\frac{1}{r}V+2V\beta_{,r}\Big)$$

$$-4Vr^2\beta_{,u}-2Ur^2(2\beta_{,\theta}V+V_{,\theta})\Big)$$

$$+2r^4e^{4\gamma}\Big((2\,\mathrm{ch}^2-1)\Big(2U^2r(U_{,\theta}+U\gamma_{,\theta}+\gamma_{,u})-VU\Big(\frac{1}{r}U+U_{,r}+U\gamma_{,r}\Big)\Big)$$

$$+2U^2r\,\mathrm{sh\,ch}\Big(2U\delta_{,\theta}-\frac{V}{r}\delta_{,r}+2\delta_{,u}\Big)\Big)$$

$$+4r^4e^{2\gamma}\Big(UW(2\,\mathrm{ch}^2-1)(-V\delta_{,r}+2Ur\delta_{,\theta}+2r\delta_{,u})$$

$$+\mathrm{sh\,ch}\Big(-V\Big(U_{,r}W+UW_{,r}+\frac{2}{r}UW\Big)+2Ur(U_{,\theta}W+UW_{,\theta})\Big)\Big)$$

$$+r^4\Big((2\,\mathrm{ch}^2-1)2W\Big(-2r\gamma_{,u}W-\frac{V}{r}(W+W_{,r}r-W\gamma_{,r}r)+2Ur(W_{,\theta}-\gamma_{,\theta}W)\Big)$$

$$+4W^2\,\mathrm{sh\,ch}(2Ur\delta_{,\theta}-V\delta_{,r}+2r\delta_{,u})\Big)\Big]\Big\}=0.$$

The Killing equation $\mathscr{L}_\eta g_{00}$ is the lengthiest among all Killing equations $\mathscr{L}_\eta g_{\mu\nu}=0$.

APPENDIX C: CORRECTIONS OF KILLING EQUATIONS GIVEN IN REF. 2

In Ref. 2 a number of misprints appear, and there is also a sign error which does not change the conclusions of the paper but makes wrong Eqs. (53)–(57), including the pathological solution given by Eq. (57) for η^u. Below we give the correct forms of all equations from Ref. 2 in which a misprint appears. First we give the correct forms of erroneous Killing equations from the Appendix in Ref. 2. These are (notice that functions f, g in Ref. 2 are denoted as $\tilde f$, $\tilde g$ in the present paper):

$$\mathscr{L}_\eta g_{01}=e^{2\beta}\beta_{,\theta}(2\tilde f r^{-1}e^{-\gamma}+2BU)+(Be^{2\beta})_{,u}+Ue^{\gamma}(r\tilde f_{,r}-\tilde f-\tilde f r\gamma_{,r})$$
$$+Ur^2e^{2\gamma}BU_{,r}+\Big(A-\frac{1}{2r}BVe^{2\beta}\Big)_{,r}+\frac{1}{r}B_{,r}Ve^{2\beta}, \tag{C1}$$

$$\mathscr{L}_\eta g_{11}=2e^{2\beta}B_{,r}, \tag{C2}$$

$$\mathscr{L}_\eta g_{13}=e^{-\gamma}\sin\theta(\tilde g-\tilde g r\gamma_{,r}-r\tilde g_{,r})+e^{2\beta}B_{,\phi}, \tag{C3}$$

$$\mathscr{L}_\eta g_{22}=-2re^{\gamma}\Big[\tilde f_{,\theta}+rBe^{\gamma}\gamma_{,u}+BUre^{\gamma}\gamma_{,\theta}+Bre^{\gamma}U_{,\theta}+e^{\gamma}\Big(Ae^{-2\beta}-\frac{1}{2r}BV\Big)(1+r\gamma_{,r})\Big]. \tag{C4}$$

In the main text in Ref. 2 the following equations contain misprints and are here corrected:

$$\text{Eq. (34):}\quad B_{,u}+2A^{(0)}{}_{,u}=0, \tag{C5}$$

$$\text{Eq. (46):}\quad f^{(1)}{}_{,\theta}+B_{,\theta\theta}c+A^{(1)}-c(A^{(0)}-\tfrac{1}{2}B)+BM-B(c_{,\theta}+2c\cot\theta)_{,\theta}=0, \tag{C6}$$

$$\text{Eq. (47):}\quad f^{(1)}\cot\theta+B_{,\theta}(c_{,\theta}+c\cot\theta)+c(A^{(0)}-\tfrac{1}{2}B)+A^{(1)}+BM-B\cot\theta(c_{,\theta}+2c\cot\theta), \tag{C7}$$

$$\text{Eq. (48):}\quad [B,_\theta \cot\theta + Bc,_u - (A^{(0)} - \tfrac{1}{2}B)]c = 0. \tag{C8}$$

As with Eq. (48) in Ref. 2 (which contains a sign error), the correct equation (C8) implies that either $c=0$ or the expression in the square brackets has to vanish. The first possibility gives vanishing news function and leads to translations. The second possibility leads to

$$A^{(0)} = \tfrac{1}{2}(B,_{\theta\theta} + B,_\theta \cot\theta + B), \tag{C9}$$

i.e., to Eq. (50) of the present paper. As it is shown below Eq. (50) in the main text, this case corresponds to the translational Killing vector under the presence of a straight cosmic string along the z-axis.

APPENDIX D: TRANSLATIONS IN SPACE–TIMES WITH A STRAIGHT COSMIC STRING

In this Appendix we show that function B in Eq. (76) corresponds to translations along the z-axis and t-axis in the space–time of an infinite thin cosmic string. Let us first recall some results from Ref. 14. The metric outside a straight nonrotating cosmic string along the z-axis can be written in cylindrical coordinates as

$$ds^2 = dt^2 - d\rho^2 - dz^2 - C^2\rho^2\, d\phi^2, \tag{D1}$$

where $\phi \in [0, 2\pi)$ and $C \in (0,1]$ is a constant. [Equation (D1) represents also the asymptotic form of the metric corresponding to a spatially bounded system and the cosmic string along the z-axis.] Introducing spherical flat-space coordinates $\{R, \vartheta, \phi\}$ by $\rho = R\sin\vartheta$, $z = R\cos\vartheta$, $\phi = \phi$, and flat-space retarded time $U = t - R$, we get

$$ds^2 = dU^2 + 2dUdR - R^2(d\vartheta^2 + C^2\sin^2\vartheta\, d\phi^2). \tag{D2}$$

We can now go over to Bondi's coordinates $\{u, r, \theta, \phi\}$—in which the metric has asymptotically Bondi's form—by assuming expansions

$$\begin{aligned} U &= \mathring{\pi}(u,\theta) + O(r^{-1}), \\ R &= q(u,\theta)r + O(r^0), \\ \vartheta &= \mathring{\tau}(u,\theta) + O(r^{-1}). \end{aligned} \tag{D3}$$

Comparing then the resulting metric with the general form of Bondi's metric one obtains the expressions for functions $\mathring{\pi}$, q, $\mathring{\tau}$, ... (see Ref. 14 for details) and the expression for the news function $c,_u$. Here we need only the following results:

$$q(\theta) = \frac{\sin\theta}{C\sin\vartheta}, \qquad \mathring{\tau},_\theta = \pm\frac{1}{q}, \tag{D4}$$

and the news function is

$$c,_u = \frac{C^2 - 1}{2\sin^2\theta}. \tag{D5}$$

Taking the θ-derivative of q, using $\mathring{\tau},_\theta = \pm 1/q$, and excluding the original flat-space ϑ, we obtain the equation

$$q,_\theta^2 - 2qq,_\theta \cot\theta + q^2\left(\cot^2\theta - \frac{C^2}{\sin^2\theta}\right) + 1 = 0, \tag{D6}$$

which implies

$$q_{,\theta}=q\cot\theta\pm\sqrt{\frac{q^2C^2}{\sin^2\theta}-1}. \tag{D7}$$

The solution is

$$q=\frac{\sin\theta}{2C}\left[\left(\chi\frac{\sin\theta}{\cos\theta+1}\right)^C+\left(\chi\frac{\sin\theta}{\cos\theta+1}\right)^{-C}\right],\quad \chi=\text{const.} \tag{D8}$$

Consider now translations along the z-axis and t-axis. In coordinates $\{t,\rho,z,\phi\}$ they have the form $\zeta^\mu_{(z)}=[0,0,a_0,0]$ and $\zeta^\mu_{(t)}=[b_0,0,0,0]$, with a_0 and b_0 constant, so that their general combination is just $\zeta^\mu_{(z)}+\zeta^\mu_{(t)}$.

The asymptotic form of this linear combination in Bondi's coordinates reads

$$\begin{aligned}
\zeta^u_{(z)}+\zeta^u_{(t)}&=b_0q+\frac{a_0}{C}\sin^2\theta\left(\frac{q}{\sin\theta}\right)_{,\theta}+O(r^{-1}),\\
\zeta^r_{(z)}+\zeta^r_{(t)}&=\frac{b_0}{2q}(q_{,\theta}{}^2-q^2+1)\\
&\quad+\frac{a_0}{2Cq^2}[(-q_{,\theta}{}^2+q^2+1)(q\cos\theta-q_{,\theta}\sin\theta)+2q_{,\theta}\sin\theta]+O(r^{-1}),\\
\zeta^\theta_{(z)}+\zeta^\theta_{(t)}&=-\frac{b_0q_{,\theta}}{r}+\frac{a_0}{Cqr}[q_{,\theta}\ (q\cos\theta-q_{,\theta}\sin\theta)-\sin\theta]+O(r^{-2}),\\
\zeta^\phi_{(z)}+\zeta^\phi_{(t)}&=0.
\end{aligned} \tag{D9}$$

Substituting for q from Eq. (D8) we obtain

$$\begin{aligned}
\zeta^u_{(z)}+\zeta^u_{(t)}&=\frac{\sin\theta}{2C}\left(\chi\frac{\sin\theta}{\cos\theta+1}\right)^C(b_0+a_0)+\frac{\sin\theta}{2C}\left(\chi\frac{\sin\theta}{\cos\theta+1}\right)^{-C}(b_0-a_0)\\
&=\sin\theta\left(\frac{\sin\theta}{\cos\theta+1}\right)^C\frac{(b_0+a_0)\chi^C}{2C}+\sin\theta\left(\frac{\sin\theta}{\cos\theta+1}\right)^{-C}\frac{(b_0-a_0)\chi^{-C}}{2C},
\end{aligned} \tag{D10}$$

and similar expressions for $\zeta^r_{(z)}+\zeta^r_{(t)}$ and $\zeta^\theta_{(z)}+\zeta^\theta_{(t)}$; these are somewhat lengthy and are thus not written here explicitly. Comparing now the last results (including those for $\zeta^r_{(z)}+\zeta^r_{(t)}$ and $\zeta^\theta_{(z)}+\zeta^\theta_{(t)}$) with a general asymptotic form of the Killing vector representing a supertranslation, i.e., with Eq. (58) with B given by Eq. (76), we find that this Killing vector is just equal to $\zeta^\mu_{(z)}+\zeta^\mu_{(t)}$ if the constant parameters are related by

$$a=\frac{(b_0+a_0)\chi^C}{2C}, \tag{D11}$$

$$b=\frac{(b_0-a_0)\chi^{-C}}{2C}. \tag{D12}$$

Therefore the supertranslational Killing vector is in fact the translational Killing vector in the asymptotically flat space–time with an infinite cosmic string along the z-axis; $b_0=0$ corresponds to a translation along the z-axis, and $a_0=0$—along the t-axis.

For the special case $C=1$ (no string) the space–time is asymptotically flat, and

$$q=\cos\theta\left(\frac{1}{2\chi}-\frac{\chi}{2}\right)+\frac{1}{2\chi}+\frac{\chi}{2} \tag{D13}$$

corresponds to a standard translation where B is given by Eq. (77).

APPENDIX E: ELECTROMAGNETIC FIELD

1. Translational case

The electromagnetic tensor reads:

$$F_{01}=-\epsilon_1(\theta)\frac{1}{r^2}+[uB^{-2}(-\epsilon_1 BB_{,\theta\theta}+\epsilon_1 B_{,\theta}^2-\epsilon_1 BB_{,\theta}\cot\theta-\epsilon_{1,\theta}BB_{,\theta}) + e_{1,\theta}+e_1\cot\theta]\frac{1}{r^3}+O(r^{-4}), \tag{E1}$$

$$F_{02}=[\epsilon_{1,\theta}+\epsilon_1 B_{,\theta}B^{-1}]\frac{1}{r}+O(r^{-2}), \tag{E2}$$

$$F_{03}=-\mu_1\sin\theta\, B_{,\theta}B^{-1}\frac{1}{r}+O(r^{-2}), \tag{E3}$$

$$F_{12}=[-\epsilon_1 B_{,\theta}B^{-1}u+e_1]\frac{1}{r^2}+O(r^{-3}), \tag{E4}$$

$$F_{13}=[\mu_1\sin\theta\, B_{,\theta}B^{-1}u+f_1\sin\theta]\frac{1}{r^2}+O(r^{-3}), \tag{E5}$$

$$F_{23}=-\mu_1\sin\theta-\{B^{-2}[(\mu_1\sin\theta)_{,\theta}BB_{,\theta} + \mu_1\sin\theta\, BB_{,\theta\theta}-\mu_1\sin\theta\, B_{,\theta}^2]u+(f_1\sin\theta)_{,\theta}\}\frac{1}{r}+O(r^{-2}). \tag{E6}$$

2. Boost case

Assuming the boost-rotation symmetry, the electromagnetic tensor has the form:

$$F_{01}=-\frac{\mathscr{E}}{u}\cot\theta\frac{1}{r^2}+\left[\frac{\cot\theta}{2}(\mathscr{E}_{,w}w+\mathscr{E})+\frac{\cot\theta}{u^2}(\mathscr{G}_{,w}w+\mathscr{G})\right]\frac{1}{r^3}+O(r^{-4}), \tag{E7}$$

$$F_{02}=\frac{\mathscr{E}}{u^2}+\left[\frac{1}{u\sin^2\theta}(\mathscr{E}_{,w}w-\mathscr{E})-\frac{\mathscr{E}_{,w}\sin\theta}{2u^2}+\frac{1}{u^3}(\mathscr{G}_{,w}w+2\mathscr{G})\right]\frac{1}{r}+O(r^{-2}), \tag{E8}$$

$$F_{03}=\frac{\mathscr{B}}{u}+\left[-\frac{1}{2}(\mathscr{B}_{,w}w-\mathscr{B})+\frac{1}{u^2}(\mathscr{D}_{,w}w+\mathscr{D})\right]\frac{1}{r}+O(r^{-2}), \tag{E9}$$

$$F_{12}=\left[\frac{1}{2}\mathscr{E}+\frac{\mathscr{G}}{u^2}\right]\frac{1}{r^2}+O(r^{-3}), \tag{E10}$$

$$F_{13}=\left[-\frac{1}{2}\mathscr{B}u+\frac{\mathscr{D}}{u}\right]\frac{1}{r^2}+O(r^{-3}), \tag{E11}$$

$$F_{23}=-\mathscr{B}\cot\theta+\cos\theta\left(\frac{1}{2}\mathscr{B}_{,w}-\frac{\mathscr{D}_{,w}}{u^2}\right)\frac{1}{r}+O(r^{-2}). \tag{E12}$$

Let us yet illustrate the general asymptotic forms (E8), (E9) for boost-rotation symmetric electromagnetic fields by specific examples. As follows from Eqs. (E8) and (E9), the first nonvanishing terms are given by $F_{02}=\mathscr{E}(w)/u^2$, $F_{03}=\mathscr{B}(w)/u$, with $w=\sin\theta/u$. Denote by e, p, m electric charge, electric dipole and magnetic dipole moments, respectively, and by α^{-1} the magnitude of acceleration. For a uniformly accelerated electric monopole (producing Born's solution), we find $\mathscr{E}(w)=e\alpha^2w/(1+\alpha^2w^2)^{3/2}$, $\mathscr{B}(w)=0$. For a uniformly accelerated electric dipole (see Ref. 20 for the complete field), we get $\mathscr{E}(w)=p\alpha w(2-\alpha^2w^2)/(1+\alpha^2w^2)^{5/2}$, $\mathscr{B}(w)=0$, whereas for a magnetic dipole (see Ref. 21 for the complete field), one finds $\mathscr{E}(w)=0$, $\mathscr{B}(w)=-\alpha mw^2(2-\alpha^2w^2)/(1+\alpha^2w^2)^{5/2}$. We can easily check that $\int(\mathscr{E}\cos\theta/u)d\theta=0$ in the case of electric dipole and $\int\mathscr{B}\cot\theta\,d\theta=0$ in the magnetic case—total charges indeed vanish.

Chaos in Robertson–Walker cosmological models where gravity is coupled to one or more scalar fields has been studied by a few authors, mostly using numerical simulations. In this paper we begin a systematic study of the analytical aspect. We consider one conformally coupled scalar field and, using the fact that the model is integrable when the field is massless, we show in detail how homoclinic chaos arises for nonzero masses using a perturbative method. © *1998 American Institute of Physics.* [S0022-2488(98)00511-8]

I. INTRODUCTION

In Ref. 1, Calzetta and El Hasi presented an argument, supported by numerical evidence, for the appearance of chaotic behavior in a spatially closed Robertson–Walker (RW) cosmological model, filled with a conformally coupled massive scalar field. Because cosmological models of this type are practically the simplest possible ones, but give in some sense a rough, smoothed out indication of the average properties of a more realistic cosmology, they have frequently been used as a first testing ground on which to try out approaches to both classical and quantum problems in cosmology. In addition, because of their kinematical simplicity, one would expect the dynamics of these models to be equally simple. It thus may come somewhat as a surprise that chaos should appear at this level, although it is known that it can appear in a nonlinear dynamical system with two degrees of freedom, and one may suspect that it is in fact generic for relativistic systems.

The study of chaos in relativistic cosmology began more than 20 years ago with the study by the Russian school[2] and Misner's group[3] on diagonal Bianchi type IX (mixmaster) vacuum cosmologies. This research is, by itself, very interesting and still active,[4] but the hopes initially placed in these models, essentially the solution of the horizon problem from the mixing effect associated with chaos, could not be sustained, and the Bianchi IX cosmologies have been mostly used as toy models, rather than first approximations from which to extract estimates of physical quantities. On the other hand, although the question of which RW model best approximates our inhomogeneous, anisotropic universe is not yet settled, there is agreement on the relevance of RW models both for classical and quantum cosmology,[5] and physical predictions are often made based on them. Therefore the presence of chaos, in this kind of cosmologies, enlarges the avenues of research in fundamental subjects such as the arrow of time and the issue of irreversibility in the evolution of the universe, or the transition from the quantum regime to the classical one, with the corresponding appearance of decoherence and correlations and related phenomena like particle creation, and has been used in considerations related to physical phenomena in inflationary universes.[6–8]

In their work, Calzetta and El Hasi used mostly a numerical method to investigate the chaotic behavior of the model, but also sketched an analytical, perturbative method by which they considered the model as a perturbation of the integrable one obtained with a vanishing mass for the

scalar field, and split the Hamiltonian of the system into an integrable part and a coupling term. With a perturbative argument commonly used in the treatment of near-integrable systems, based on the Melnikov criterion for homoclinic chaos and Chirikov's resonance overlap criterion,[9] they argued qualitatively that the Kolmogorov-Arnold-Moser (KAM) tori of the integrable part are destroyed and replaced by stochastic layers under the effect of the perturbation. The resulting strong indications of chaotic behavior were confirmed by the numerical analysis, which allowed them to go beyond perturbation theory.

The generic transition to chaos in a perturbed integrable Hamiltonian system (''soft chaos'') can be seen as taking place in two steps.[9,10] In the first one, a perturbation of the Hamiltonian, with a nonvanishing Fourier component in resonance with one of the tori of the unperturbed system, modifies the dynamics in a neighborhood of this torus to give a new integrable system, which, however, has heteroclinic orbits even if before there were none. These orbits are separatrices, which act as seeds of chaos when in the second step one takes into account the effect of the remaining components of the perturbation on the new integrable dynamics; it is here that one may use the Melnikov method to determine whether in effect the dynamics becomes chaotic. What this method provides is a topological criterion for detecting a chaotic ''tangle'' in the orbits near the separatrices, and is therefore free of the coordinate ambiguities that have arisen, e.g., in the study of the chaotic nature of Bianchi models by other methods; for a quick introduction to the Melnikov method see, e.g., Refs. 11 or 12, and Ref. 13 for a more technical exposition.

The goal of this paper is to continue the work in Ref. 1 by starting to examine in detail the analytical treatment of the model; in future work, we will systematically extend our work to more general models. We will use a different perturbative expansion of the Hamiltonian, and show the onset of chaotic behavior by an explicit computation of the Melnikov integral. Other recent work on chaos in Robertson–Walker models coupled to scalar fields has focused on their application to inflation,[7] again using mostly numerical methods, and an analysis based on the Painlevé analysis of differential equations,[14] which confirmed the nonintegability of the models. The main advantage of our work is the amount of information it can give us regarding the resonances responsible for the onset of chaos and the chaotic region of phase space.

The paper is organized as follows: in Sec. II, we set up the perturbative method we will use, by choosing appropriate variables to describe the cosmological model and separating the corresponding Hamiltonian into an ''unperturbed'' term and a ''perturbation;'' in Sec. III we analyze the first step above for our example, i.e., we discuss the local dynamics in the vicinity of one of the resonant tori, while in Sec. IV we develop the second step, discussing the effect of other perturbation terms on the local dynamics, which becomes chaotic as Melnikov's method shows; Sec. V contains concluding remarks on possible future developments.

II. DYNAMICAL VARIABLES AND HAMILTONIAN: SETUP FOR THE PERTURBATIVE TREATMENT

Let us consider the closed Robertson–Walker (RW) metric for a homogeneous and isotropic universe, written in the form

$$ds^2 = a^2(t)[-dt^2 + d\chi^2 + \sin^2\chi(d\theta^2 + \sin^2\theta d\varphi^2)], \tag{2.1}$$

where $0 \leqslant \varphi \leqslant 2\pi$, $0 \leqslant \theta \leqslant \pi$, $0 \leqslant \chi \leqslant \pi$ are the angular coordinates on S^3, and t is the usual ''conformal time'' (see, e.g., Ref. 15). We shall consider only models possessing a cosmic singularity $a=0$, chosen for convenience to occur at $t=0$. We shall also assume that after the big crunch a new cosmological cycle begins, but a changes sign, in such a way that the evolution is smooth, and this process is repeated an infinite number of times. This well-known possibility of extending the evolution beyond the $a=0$ singularity is an artifact of the symmetry possessed by the RW models (we have no grounds for believing that it can be generalized), but it is convenient for us because it allows us to assume that time runs up to $t=+\infty$, and thus to use techniques for detecting chaos, including its very definition, that would otherwise be inapplicable. Any conclusion we draw from the model would of course not have to rely on this extension; the time scale for any chaotic behavior to set in must be shorter than one cycle for its physical consequences to be meaningful.

We start with the Einstein–Hilbert action for the gravitational field,

$$S_{\mathrm{g}}[g]=\frac{1}{16\pi G}\int d^4x\sqrt{-g}R, \tag{2.2}$$

and the action

$$S_{\mathrm{f}}[\Phi,g]=-\frac{1}{2}\int d^4x\sqrt{-g}\left[g^{ab}\nabla_a\Phi\nabla_b\Phi+\left(\mu^2+\frac{1}{6}R\right)\Phi^2\right] \tag{2.3}$$

for a real, conformally coupled scalar field of mass μ. To write down the Hamiltonian, use the fact that the square root of the determinant of the metric (2.1) and its scalar curvature are, respectively,

$$\sqrt{-g}=a^4\sin^2\chi\sin\theta,\quad R=6\left(\frac{\ddot{a}}{a^3}+\frac{1}{a^2}\right), \tag{2.4}$$

where an overdot denotes a t-derivative, and reparametrize the scalar field (which must be homogeneous for consistency) by $\Phi\mapsto\phi:=\sqrt{4\pi G/3}a\Phi$. Then we obtain, up to a constant overall factor,

$$H(a,\phi;\pi,p)=\tfrac{1}{2}[-(\pi^2+a^2)+(p^2+\phi^2)+\mu^2a^2\phi^2], \tag{2.5}$$

where π and p are the momenta conjugate to a and ϕ, respectively. Here, as usual with general relativistic systems, time reparametrization invariance requires that we impose that all solutions satisfy the constraint

$$H=0, \tag{2.6}$$

which is just the (0,0)-component of the Einstein equation.

The system described by the Hamiltonian (2.5) consists of two harmonic oscillators (of which one is ''inverted,'' as is to be expected from any degree of freedom related to the spatial volume element), coupled through a term proportional to μ^2. For $\mu^2=0$, the system is trivially integrable; our main goal is to analyze the effect of the coupling term, at least for small values of μ^2. However, in view of the perturbative treatment to be carried out, the form (2.5) has two disadvantages: the ''perturbation'' term $\mu^2a^2\phi^2$ is not always small, in the sense that for a fixed value of μ^2 it cannot be uniformly bounded for all orbits of the unperturbed system; and the latter system is degenerate, in the sense that the frequencies of both oscillators are constant. We will not attempt to deal directly with the first inconvenience, which at any rate is not really a problem for perturbations of a fixed orbit; we will instead perform a change of variables that will allow us to isolate a different integrable Hamiltonian from H, with enough of the degeneracy removed for us to be able to use the Melnikov method of detecting homoclinic chaos. Regarding the perturbation, it will be sufficient for us to know that it is a well-behaved function on each trajectory.

Following Ref. 1, we first replace the dynamical variables p and ϕ by new variables j and φ, respectively, defined as

$$\phi=\sqrt{\frac{2j}{\omega}}\sin\varphi,\quad p=\sqrt{2\omega j}\cos\varphi, \tag{2.7}$$

where $\omega=\sqrt{1+\mu^2a^2}$ is the instantaneous frequency of the field; thus, this is a first approximation to action-angle variables for the scalar field, which takes into account the coupling term, but not the fact that a is a dynamical variable, and it is a key trick in this treatment of the model. To complete the canonical transformation, we must introduce a new momentum variable conjugate to a, given by

$$P:=\pi-\frac{\mu^2aj}{2\omega^2}\sin 2\varphi, \tag{2.8}$$

and arising from the fact that ω is a-dependent. Now the Hamiltonian in terms of the new variables can be written as a sum $H=\hat{H}_0+\delta\hat{H}$, of an unperturbed Hamiltonian

$$\hat{H}_0(a,\varphi;P,j) = -\tfrac{1}{2}(P^2+a^2) + j\sqrt{1+\mu^2 a^2}, \tag{2.9}$$

which is obviously integrable, since it has the two commuting constants of the motion $\hat{H}_0$ and j, and a perturbation

$$\delta\hat{H}(a,\varphi;P,j) = -\frac{\mu^2 aPj}{2(1+\mu^2 a^2)}\sin 2\varphi - \left[\frac{\mu^2 aj}{4(1+\mu^2 a^2)}\right]^2 (1-\cos 4\varphi). \tag{2.10}$$

However, the system (2.9) is not easy to integrate; since we will need to perform explicit calculations, and in particular to write it in terms of action-angle variables, we find it convenient to simplify it somewhat.

In Ref. 1, this simplification was achieved by noticing that for most of the unperturbed motion, the value of ω is very large, and using the $\omega \gg 1$ approximation to $\hat{H}_0$. In addition, because the treatment was a perturbative one in the parameter μ^2, or more precisely $\mu^2 j$, the second term in the Hamiltonian perturbation (2.10) was dropped, since it contains higher powers of μ^2 than the first one. Notice that, implicit in this way of proceeding is the idea that one considers the μ^2 in $\hat{H}_0$ as a fixed parameter, while in $\delta\hat{H}$, $\mu^2 =: \epsilon$ is rendered temporarily independent of the first one for the sake of the perturbative treatment, and allowed to vary in a neighborhood of $\mu^2 = \epsilon = 0$. (One may be able to set up a perturbation theory for Hamiltonians of the type $H_0(q,p;\epsilon) + \epsilon\delta H(q,p)$, where $H_0(q,p;\epsilon)$ is integrable for all ϵ, but to our knowledge such a theory is not available yet.)

Here we will follow a different path. Since we are going to expand the perturbation in powers of μ^2 and neglect terms higher than μ^4, we will do the same for $\hat{H}_0$, and retain there only the terms up to order μ^2 while we will put in the perturbation the higher order ones. The new unperturbed system obtained in this way will be explicitly integrable. As the perturbation parameter, we will use μ^2, rather than the dimensionless $\mu^2 j$; this is mainly to avoid having to explain already at this stage what values of the variable j we are interested in. At any rate, strictly speaking we will not have to talk about $\epsilon = \mu^2$ being ''small'' (if we did, we might say that $\mu/\mu_{\mathrm{P}} \ll 1$, where μ_{P} is the Planck mass); the perturbative results we will obtain are valid for ϵ in some interval near zero, and such topological statements are ''dimensionless.'' Expanding $\sqrt{1+\mu^2 a^2} = 1 + (1/2)\mu^2 a^2 - (1/4)\mu^4 a^4 + o(\mu^4)$, we obtain a new breakup of the Hamiltonian into

$$H = H_0 + \delta H, \tag{2.11}$$

where the unperturbed part is now

$$H_0(a,\varphi;P,j) = -\tfrac{1}{2}(P^2+a^2) + j\left(1 + \tfrac{1}{2}\mu^2 a^2\right), \tag{2.12}$$

and the perturbation differs from (2.10) by terms proportional to $\mu^4 a^4$ and of higher order in μ^2, namely,

$$\delta H = -\tfrac{1}{2}\mu^2 aPj\,\sin 2\varphi + \mu^4\left[\tfrac{1}{2}a^3 Pj\,\sin 2\varphi - \tfrac{1}{4}a^4 j - \tfrac{1}{16}a^2 j^2(1-\cos 4\varphi)\right] + \mathrm{o}(\mu^4). \tag{2.13}$$

One of the action variables of the new unperturbed system is j itself; to find the other one, we compute the integral $k := (2\pi)^{-1}\int P\,da$, along the trajectory specified by the values of the conserved quantities j and $H_0 = \mathrm{const} := h_0$ (ultimately, we will be interested only in trajectories near $h_0 = 0$, in order to satisfy the constraint $H_0 + \delta H = 0$, but for now we keep the treatment more general), for which

$$P(a) = \pm\sqrt{2(j-h_0) - (1-\mu^2 j)a^2}. \tag{2.14}$$

The integration yields

$$k = \frac{j-h_0}{\sqrt{1-\mu^2 j}}, \tag{2.15}$$

and the angle variables canonically conjugate to k and j, respectively, are given by

$$\theta = \arctan(\sqrt{1-\mu^2 j}\, a/P), \tag{2.16}$$

$$\delta = \varphi - \frac{\mu^2 a P}{4(1-\mu^2 j)}, \tag{2.17}$$

as can be checked by direct computation of the Poisson brackets. Notice that μ^2 here is not the infinitesimal ϵ, but we do want to consider it as being small, so for j not too big $1-\mu^2 j > 0$. With these new variables we can now write down our final expression for the unperturbed Hamiltonian,

$$H_0(k,j) = j - k\sqrt{1-\mu^2 j}. \tag{2.18}$$

Choosing a value for h_0 will then impose a relationship between j and k; in particular, for $h_0 \approx 0$, since j is positive, see (2.12), k must be positive as well. For the perturbation, we invert the transformation (2.15)–(2.17), and substitute in (2.13), which, keeping only the lowest order terms in $\epsilon = \mu^2$, gives

$$\begin{aligned}\delta H = {} & \frac{1}{4}\epsilon kj[\cos(2\theta+2\delta) - \cos(2\theta-2\delta)] + \frac{1}{4}\epsilon^2\Bigg[-\frac{3}{2}k^2 j - \frac{1}{4}kj^2 \\ & + \left(2k^2 j + \frac{1}{4}kj^2\right)\cos 2\theta - \frac{1}{2}k^2 j\,\cos 4\theta - \frac{1}{2}k^2 j\,\cos(2\delta - \pi/2) + \frac{1}{4}kj^2\,\cos 4\delta \\ & + k^2 j\,\cos(2\theta - 2\delta) - k^2 j\,\cos(2\theta + 2\delta) - \frac{1}{8}kj^2\,\cos(2\theta + 4\delta) \\ & - \frac{1}{8}kj^2\,\cos(2\theta - 4\delta) + \frac{\sqrt{5}}{4}k^2 j\,\cos(4\theta + 2\delta + \psi) - \frac{\sqrt{5}}{4}k^2 j\,\cos(4\theta - 2\delta + \psi)\Bigg] \\ & + O(\epsilon^3),\end{aligned} \tag{2.19}$$

where $\psi := -\arcsin(1/\sqrt{5})$, and we have chosen to write the various terms in the form that will be most useful in the following. This completes the setup for the perturbative treatment of the model. The dynamics of the unperturbed Hamiltonian H_0 is trivial, and gives a conditionally periodic motion $\theta = \theta_0 + \omega_k t$, $\delta = \delta_0 + \omega_j t$, with frequencies given by

$$\omega_k = \frac{\partial H_0}{\partial k} = -\sqrt{1-\mu^2 j},$$

$$\omega_j = \frac{\partial H_0}{\partial j} = \frac{\mu^2 k + 2\sqrt{1-\mu^2 j}}{2\sqrt{1-\mu^2 j}}. \tag{2.20}$$

In the next section we will start to take a look at the perturbed dynamics.

III. EFFECT OF THE RESONANT TERMS IN THE PERTURBATION

The effect of the perturbation δH is felt in particular on the rational tori of the unperturbed dynamics, the ones where the motion becomes periodic, because the frequencies (2.20) associated with the two degrees of freedom are related by the resonance condition

$$n_0\omega_k + m_0\omega_j = 0, \tag{3.1}$$

for some integer numbers n_0 and m_0. Using the explicit form of the frequencies in the resonance condition, we obtain a relationship between the action variables k and j, namely, that

$$\frac{2(1-\mu^2 j)}{\mu^2 k + 2\sqrt{1-\mu^2 j}} = \frac{m_0}{n_0} \tag{3.2}$$

must be a rational number. The latter equation can be expressed as

$$\mu^2 k = 2\frac{n_0}{m_0}(1-\mu^2 j) - 2\sqrt{1-\mu^2 j}, \tag{3.3}$$

and, since k must be positive in order for $h_0 \approx 0$, we see that a necessary condition is that n_0 and m_0 have the same sign (we can take them to be positive) with n_0 strictly greater than m_0.

To find out which of the resonant tori of the unperturbed system are affected by δH, we must consider the perturbation (2.19) as a Fourier series with respect to the angular variables θ and δ, of the form

$$\begin{aligned} \delta H(\theta,\delta;k,j) &= \sum_{i=1}^{\infty} \delta H^{(i)}(\theta,\delta;k,j), \\ \delta H^{(i)}(\theta,\delta;k,j) &= \epsilon^i \sum_{n,m} V_{nm}^{(i)}(k,j)\cos(n\theta + m\delta + \psi_{nm}^{(i)}), \end{aligned} \tag{3.4}$$

and check which of the Fourier coefficients $V_{nm}^{(1)}(k,j)$ are nonvanishing. The order ϵ terms in (2.19) are

$$\delta H^{(1)} = \tfrac{1}{4}\,\epsilon kj[\cos(2\theta+2\delta) - \cos(2\theta-2\delta)]. \tag{3.5}$$

Therefore to order μ^2 in the perturbation, the resonant tori which are broken by the perturbation are those for which

$$n_0 = \pm m_0 = 2.$$

However, neither of these pairs satisfies the conditions given below (3.3), which means that these resonant tori are not present in the physically relevant region near $h_0 = 0$.

This forces us to consider the Fourier components of order ϵ^2 in the perturbation (2.19). In order to look at their effect on the dynamics, however, we must somehow consider them as perturbations of a system which includes the order ϵ terms. The dynamical behavior of such a system is qualitatively similar to that of the unperturbed one in the region near $h_0 = 0$, because H_0 has no tori there which resonate with the order ϵ terms, and to set up the system we can use the normal techniques for nonresonant perturbations of integrable systems.

The method (see, e.g., Ref. 16) consists in performing an ϵ-dependent canonical transformation to new coordinates $(\theta',\delta';k',j')$, in which the new Hamiltonian has no perturbation terms of order ϵ, and is obtained by using $k'\theta + j'\delta + \Phi(\theta,\delta;k',j')$ as a generating function, where

$$\Phi(\theta,\delta;k',j') = -\epsilon \sum_{n,m} \frac{V_{nm}^{(1)}(k',j')}{n\omega_k(k',j') + m\omega_j(k',j')} \sin(n\theta + m\delta + \psi_{nm}). \tag{3.6}$$

While the new canonical coordinates cannot be explicitly expressed in terms of the old ones, they differ by a series of powers of ϵ, and for our purposes it will be sufficient to calculate the term of order ϵ. A calculation shows that the new unperturbed Hamiltonian $H_0'(k',j') = H_0(k',j')$, i.e., it is given by the same function (2.18) as in the previous variables, while the perturbation is now of the form

$$\begin{aligned} \delta H' = \epsilon^2 [& V_{00}'^{(2)}(k',j') + V_{20}'^{(2)}(k',j')\cos 2\theta' + V_{02}'^{(2)}(k',j')\cos(2\delta' - \pi/2) + V_{40}'^{(2)}(k',j') \\ & \times \cos 4\theta' + V_{04}'^{(2)}(k',j')\cos 4\delta' + V_{22}'^{(2)}(k',j')\cos(2\theta' + 2\delta') + V_{2-2}'^{(2)}(k',j') \\ & \times \cos(2\theta' - 2\delta') + V_{24}'^{(2)}(k',j')\cos(2\theta' + 4\delta') + V_{2-4}'^{(2)}(k',j')\cos(2\theta' - 4\delta') \\ & + V_{42}'^{(2)}(k',j')\cos(4\theta' + 2\delta' + \psi) + V_{4-2}'^{(2)}(k',j')\cos(4\theta' - 2\delta' + \psi) + V_{44}'^{(2)}(k',j') \\ & \times \cos(4\theta' + 4\delta') + V_{4-4}'^{(2)}(k',j')\cos(4\theta' - 4\delta')] + O(\epsilon^3). \end{aligned} \tag{3.7}$$

Since the unperturbed Hamiltonian is the same as before, the condition for a resonance at $h_0 \approx 0$ is still $n_0 > m_0 > 0$, and the only term in (3.7) satisfying this condition has

$$n_0 = 4, \quad m_0 = 2,$$

in which case

$$\mu^2 k_0 = 2\sqrt{1-\mu^2 j_0}\,(2\sqrt{1-\mu^2 j_0} - 1) \tag{3.8}$$

is positive if $\mu^2 j_0 < 3/4$. We thus choose to study the motion near the resonant torus with action variables (j_0, k_0) characterized by the integer numbers $(n_0, m_0) = (4,2)$, and for which the perturbation coefficient is

$$V'^{(2)}_{42}(k', j') = V^{(2)}_{42}(k', j') = \frac{\sqrt{5}}{16}\, k'^2 j'. \tag{3.9}$$

[It is not necessary for us to write down explicitly all the functions $V'^{(2)}_{mn}(k', j')$ here, but some of them coincide with the $V^{(2)}_{mn}(k', j')$ in (2.19).] As far as this local dynamics is concerned, then, we could have used directly the Hamiltonian $H_0(k, j)$ with perturbation $\delta H^{(2)}(\theta, \delta; k, j)$ as in (2.19), without worrying about the presence of the ϵ term. From now on, we will drop the primes on the variables just introduced.

Since the perturbation with coefficient (3.9) is resonant, it does change the local dynamics qualitatively near the chosen torus. Following the standard procedure for such a case (see, e.g., Ref. 9), we go over to a set of canonical variables $(\gamma, \delta; K, J)$ adapted to the resonant torus, chosen so that one of the momenta will still be a constant of the motion under the resonant term in the perturbation:

$$\begin{gathered} K := \frac{k - k_0}{n_0} = \frac{1}{4}\,(k - k_0), \quad \gamma := n_0\theta + m_0\delta + \psi_0 = 4\theta + 2\delta + \psi_0, \\ J := -\frac{m_0}{n_0}\, k + j = -\frac{1}{2}\, k + j, \end{gathered} \tag{3.10}$$

where ψ_0 is some arbitrary, fixed angle.

If we suppose that $K \ll 1$ is a small increment of the variable k around the resonant value k_0, then we can expand the Hamiltonian, written in the new variables, in powers of K, and study the dynamics generated by the leading terms. We begin with the resonant part of the perturbation,

$$\begin{aligned} \delta H^{(2)} &= \epsilon^2 V^{(2)}_{42}(k, j)\cos(4\theta + 2\delta + \psi) + (\text{terms with different } n \text{ and } m) \\ &= \frac{\sqrt{5}}{16}\, \epsilon^2 k_0^2 j\, \cos(\gamma + \psi - \psi_0) + (\text{terms with different } n \text{ and } m). \end{aligned} \tag{3.11}$$

Here j is to be thought of as $j(K = 0, J)$, with J arbitrary. Since this term in the perturbation depends only on γ and not on δ, J is still a constant of the motion; for simplicity we fix its value at the resonant one, J_0. Then for the unperturbed Hamiltonian we obtain

$$H_0(K, J_0) = H_0(k_0, j_0) + \tfrac{1}{2}\,\Omega K^2 + O(K^3), \tag{3.12}$$

where

$$\Omega := \frac{\partial^2 H_0}{\partial k^2}\, n_0^2 + 2\,\frac{\partial^2 H_0}{\partial j\,\partial k}\, n_0 m_0 + \frac{\partial^2 H_0}{\partial j^2}\, m_0^2 = \frac{8\mu^2}{\sqrt{1-\mu^2 j_0}} + \frac{\mu^4 k_0}{(1-\mu^2 j_0)^{3/2}}. \tag{3.13}$$

So, to the lowest order in K and ϵ, the K dynamics near the resonant torus is generated by

$$H_{\rm loc}(\gamma,K)=H_0(k_0,j_0)+\frac{1}{2}\,\Omega K^2+\frac{\sqrt{5}}{16}\,\epsilon^2 k_0^2 j_0\,\cos(\gamma+\psi-\psi_0), \tag{3.14}$$

which is the Hamiltonian of a well-known system, the nonlinear pendulum.

Let us now find the homoclinic orbits. If we call $h_0=H_0(k_0,j_0)$, as before, and fix some value $H_{\rm loc}=h_{\rm loc}$ for the local Hamiltonian, we can compute from Eq. (3.14)

$$K=\pm\left\{\frac{2}{\Omega}\left[h_{\rm loc}-h_0-\frac{\sqrt{5}}{16}\,\epsilon^2 k_0^2 j_0\,\cos(\gamma+\psi-\psi_0)\right]\right\}^{1/2}.$$

To simplify calculations, we set $\psi_0=\psi+\pi$. Then, for the homoclinic orbit, at the maximum $\gamma=\pi$ of the potential we must have $K=0$, from which we find that $h_{\rm loc}-h_0=(\sqrt{5}/16)\epsilon^2 k_0^2 j_0$, and

$$K=\pm\left\{\frac{\sqrt{5}}{8}\,\Omega^{-1}\epsilon^2 k_0^2 j_0(1+\cos\,\gamma)\right\}^{1/2}=\pm\left(\frac{\sqrt{5}}{4}\,\Omega^{-1}\epsilon^2 k_0^2 j_0\right)^{1/2}\cos\frac{\gamma}{2}. \tag{3.15}$$

Finally, we can compute the evolution of γ by integrating the Hamilton equation $\dot{\gamma}=\partial H_{\rm loc}/\partial K=\Omega K$, and we obtain

$$\gamma(t)=4\,\arctan\,\exp\left\{\left(\frac{\sqrt{5}}{16}\,\epsilon^2\Omega k_0^2 j_0\right)^{1/2}t\right\}-\pi. \tag{3.16}$$

We will use all of these results in the next section.

IV. THE MELNIKOV METHOD

We are now going to study the effect of the other terms of the perturbation

$$\begin{aligned}\delta H'^{(2)}(\gamma,\delta;K,J)&=\epsilon^2\sum_{nm}\,V'^{(2)}_{nm}(k,j)\cos(n\theta+m\delta+\psi_{nm})\\&=\epsilon^2\sum_{nm}\,V'^{(2)}_{nm}(k,j)\cos\left(\frac{n}{4}\,\gamma+\frac{2m-n}{2}\,\delta-\frac{n}{4}\,\psi_0+\psi_{nm}\right),\end{aligned} \tag{4.1}$$

in particular of the terms with $(n,m)\neq(n_0,m_0)$, on the dynamics of the integrable system with Hamiltonian $H_{\rm loc}$, near the homoclinic orbit. We will use the Melnikov method to show that a stochastic layer forms in the vicinity of this destroyed separatrix, which acts as a seed for chaos.

We thus want to show[13] that the Melnikov function of the local K dynamics has a contribution

$$M_{nm}(\psi_{nm}):=\int_{\rm ho}dt\{H_{\rm loc},\delta H'^{(2)}_{nm}\} \tag{4.2}$$

which is an oscillating function of ψ_{nm} and has therefore isolated, transverse zeroes, for some values of (n,m); here the integral in (4.2) is taken over the homoclinic orbit, given by $\gamma(t)$ in (3.16), $\delta(t)=\omega_j t+O(\epsilon^2)$ from $\dot{\delta}=\partial H/\partial j'$, $k=k_0+4K=k_0+O(\epsilon)$, and $j=j_0+O(\epsilon)$.

In the calculation of the Melnikov integral we will keep only the leading order terms in ϵ and K. Then, approximating the Poisson bracket

$$\begin{aligned}\{H_{\rm loc},\delta H'^{(2)}_{nm}\}&\approx\left\{\frac{1}{2}\,\Omega K^2,\epsilon^2 V'^{(2)}_{nm}\,\cos\left(\frac{n}{4}\,\gamma+\frac{2m-n}{2}\,\delta-\frac{n}{4}\,\psi_0+\psi_{nm}\right)\right\}\\&=\frac{1}{4}\,\epsilon^2\Omega K n V'^{(2)}_{nm}(k_0,j_0)\sin\left(\frac{n}{4}\,\gamma+\frac{2m-n}{2}\,\delta-\frac{n}{4}\,\psi_0+\psi_{nm}\right),\end{aligned} \tag{4.3}$$

and using $\dot{\gamma}=\Omega K$, we get

$$M_{nm}(\psi_{nm}) = \int_{-\pi}^{\pi} d\gamma \dot{\gamma}^{-1} \{H_{\rm loc}, \delta H'^{(2)}_{nm}\} = \frac{1}{4}\,\epsilon^2 n V'^{(2)}_{nm}(k_0, j_0)(A_{nm}\,\sin\,\psi'_{nm} + B_{nm}\,\cos\,\psi'_{nm}), \tag{4.4}$$

where we have defined $\psi'_{nm} := \psi_{nm} - (n/4)\psi_0$, and

$$A_{nm} := \int_{-\pi}^{\pi} d\gamma\,\cos\left(\frac{n}{4}\,\gamma + \frac{2m-n}{2}\,\delta(\gamma)\right)$$

$$B_{nm} := \int_{-\pi}^{\pi} d\gamma\,\sin\left(\frac{n}{4}\,\gamma + \frac{2m-n}{2}\,\delta(\gamma)\right), \tag{4.5}$$

and $\delta(\gamma)$ is obtained from (3.16) and $\delta \approx \omega_j t$,

$$\delta(\gamma) = \eta\,\ln\,\tan\frac{\gamma+\pi}{4}, \quad \eta := \omega_j\left(\frac{\sqrt{5}}{16}\,\epsilon^2 \Omega k_0^2 j_0\right)^{-1/2}. \tag{4.6}$$

The function M_{nm} in (4.4) is clearly oscillating whenever $nV'^{(2)}_{nm}A_{nm}$ and/or $nV'^{(2)}_{nm}B_{nm}$ are not zero. We thus have to show that, for some (n,m) in the set $\{(2,0), (2,\pm 2), (2,\pm 4), (4,0), (4,-2), (4,\pm 4)\}$, A_{nm} or B_{nm} do not vanish.

Perhaps surprisingly, the integrals in (4.5) can be calculated analytically, at least for half of the cases of interest, the ones with $n=2$. To do this, notice that A_{nm} and B_{nm} are, respectively, the real and imaginary parts of the complex function

$$Z_{nm} := \int_{-\pi}^{\pi} d\gamma e^{{\rm i}n\gamma/4}\left(\tan\frac{\gamma+\pi}{4}\right)^{{\rm i}(2m-n)\eta/2} = 4e^{-{\rm i}n\pi/4}\int_0^{\pi/2} dx e^{{\rm i}nx}(\tan x)^{{\rm i}(2m-n)\eta/2}, \tag{4.7}$$

where we have defined $x := (1/4)(\gamma+\pi)$. Therefore for $n=2$, we have[17]

$$\begin{aligned} Z_{2m} &= -4{\rm i}\left[\int_0^{\pi/2} dx\,\cos 2x\,\tan^{{\rm i}(m-1)\eta} x + {\rm i}\int_0^{\pi/2} dx\,\sin 2x\,\tan^{{\rm i}(m-1)\eta} x\right] \\ &= -4{\rm i}\left[-\frac{{\rm i}(m-1)\eta\pi}{2}\,\sec\frac{{\rm i}(m-1)\eta\pi}{2} + \frac{{\rm i}(m-1)\eta\pi}{2}\,{\rm cosec}\,\frac{{\rm i}(m-1)\eta\pi}{2}\right] \\ &= -2(m-1)\eta\pi\left[{\rm sech}\,\frac{(m-1)\eta\pi}{2} + {\rm i}\,{\rm cosech}\,\frac{(m-1)\eta\pi}{2}\right], \end{aligned} \tag{4.8}$$

in other words,

$$A_{2m} = -2(m-1)\eta\pi\,{\rm sech}\,\frac{(m-1)\eta\pi}{2}, \quad B_{2m} = -2(m-1)\eta\pi\,{\rm cosech}\,\frac{(m-1)\eta\pi}{2}, \tag{4.9}$$

which do not vanish for any of the values of m listed above.

V. CONCLUSIONS

We have shown analytically that a RW universe, filled with a massive conformally coupled scalar field, has a chaotic behavior, at least for a sufficiently small value of the mass, confirming the numerical results of Ref. 1. This is just the first step in our program to analyze the dynamics of RW models with various types of matter content, in order to relate this to numerical results, and make more precise statements about physical consequences. Among the purely theoretical aspects of this work, on the one hand, some possible generalizations to cosmological models differing by the addition of a cosmological constant and/or other parameters are being currently studied,[18] as well as the possibility of adding a second matter field; on the other hand, we are working on extending the results obtained for the model in this paper to an estimation of the size of the stochastic region in phase space and of the time scale for the manifestation of the chaos we

predict. The latter point is an important one since, as we mentioned in Sec. II, this time scale must be smaller than the lifetime of the universe in our model. Although the simulations in Ref. 1 covered many cycles for the universe, it was stated there that chaos would show up on much smaller time scales, and therefore has, in principle, observable consequences; in Ref. 7, however, the authors argued qualitatively that they expect the time scale to be much larger than the lifetime of the universe, and used this to motivate the use of two different scalar fields in their model. We believe that the issue should be resolved by an actual, quantitative estimate of the time scale.

We will conclude with some comments on possible avenues for future research, concerning other aspects of the relationship between chaos and the physics of the early universe. At a classical level already, chaos opens up ways of explaining the origin of the arrow of time,[19] and in our cosmological setting therefore, of improving our knowledge of cosmological statistical mechanics and thermodynamics. Furthermore, just as nonintegrability and dynamical instability are, at the classical level, the causes of chaos, they are also, at the quantum level, the causes of the instability of quantum states and particles; one therefore expects, for example, classical chaos and semiclassical particle production to be related.[20] At the semiclassical level,[21] one can prove the presence of decoherence and correlations, which cause the transition to the classical regime; stable and unstable scalar field quanta are created during this process. The study of this passage, that leads from particle creation to chaos is, therefore, imperative. In a model very similar to ours,[22] a Lyapunov variable was used to define a growing entropy in the universe; this could be adapted, with minor changes, to the present model, and looks promising since, for example, growth of entropy, particle creation, decoherence and isotropization (a tendency to some kind of equilibrium) are related in semiclassical cosmological models.[23]

The relevance of chaos in the transition to the semiclassical limit of quantum cosmology, for RW models, was studied in Ref. 24. At the complete quantum level, let us recall only that RW models have been used to study the relation between the cosmological and thermodynamical arrows of time;[25] but many other results related to these subjects can be found in the literature. Ultimately, a very interesting goal for future work, and possibly a formidable task even in our simple RW model with chaotic behavior, is to relate all these fundamental features of the universe in a unified theoretical framework.

ACKNOWLEDGMENTS

Part of this work was done when the authors were in the RGGR group at the Université Libre de Bruxelles in Brussels, Belgium, where it was partially supported by the Commission of the European Communities, under Contract No. ECRU002 (DG-III); we are grateful to Edgard Gunzig for making this possible, and for the working atmosphere in the group. (Received 23 April 1998; accepted for publication 17 June 1998)

We present a general class of noncollinear colliding wave solutions of the Einstein–Maxwell equations given in terms of fourth order polynomials, which in turn can be expressed through Jacobi functions depending on generalized advanced and retarded time coordinates. The solutions are characterized by six free parameters. The parameters can be chosen in such a way as to avoid the generic focusing singularity. © *1998 American Institute of Physics.* [S0022-2488(98)02611-5]

I. INTRODUCTION

Recently, the collision of plane-fronted gravitational waves possibly coupled with electromagnetic waves, has been extensively studied.[1–4] Because gravity is always attractive, it was expected that focusing of the waves would occur and one of the interesting questions is: how much focusing does general relativity predict? Within this framework, strong focusing would appear by the development of space–time curvature singularities. Many solutions have been presented so far, describing collisions of plane-fronted gravitational and electromagnetic waves. And quite a few of them do develop Cauchy horizons. It is important to stress the fact that all of these solutions contain *only second degree* polynomials and that until now no one has gone ahead to *higher degree polynomials* in the sense we are going to explain below.

All known colliding wave solutions are characterized, in null coordinates, by the line element

$$ds^2 = e^{-M} du dv + g_{ab} dx^a dx^b, \quad a,b = 1,2, \tag{1.1}$$

where x^1, x^2 are ignorable coordinates and metric functions depending on (u,v).[5] When written in (η,μ) coordinates,[3] where η is a measure of the time from the instant of collision and μ is a measure of the distance between the plane wavefronts, the metric becomes

$$ds^2 = e^{2\gamma(\eta^2-\mu^2)}\left(\frac{d\eta^2}{P(\eta)} - \frac{d\mu^2}{Q(\mu)}\right) + g_{ab} dx^a dx^b, \tag{1.2}$$

where the polynomials $P(\eta)$, $Q(\mu)$ are at most of the second degree in their respective variables. Generating techniques and other methods have allowed a great deal of generalizations in relation

with the metric components g_{ab} (sometimes called Killing sector).[6–13] The generated solutions preserve the seed's structure of the polynomials $P(\eta)$, $Q(\mu)$, changing in general the form of the metric function γ.

In this paper, we further pursue this and present solutions with $P(\eta)$ and $Q(\mu)$ being polynomials of fourth degree, by means of a generalization of the advanced and retarded coordinates concept. This generalization endows the corresponding space–times with a geometric structure for the time and independently for the spatial coordinate richer than the already known colliding wave solutions. In the limit of polynomials of second degree one recovers the widely used retarded and advanced time coordinates (u,v). The main purpose of this paper is to give the formulation of the most general class presently known of colliding waves with fourth degree polynomials. As usual, it is assumed that in the corresponding space–time, the two waves approach each other from opposite sides in flat Minkowski background; after the collision, a new gravitational field evolves, which satisfies certain continuity conditions. The colliding plane waves posses five symmetries, while the geometry resulting after the collision has two spacelike Killing vectors.

The plan of the paper is as follows: In Sec. II we revisited some generalities on colliding waves concept. In Sec. III the general representation through advanced and retarded time coordinates for fourth degree polynomials is introduced. In Sec. IV the class of colliding waves with fourth degree polynomials is presented. In Sec. V the results are discussed.

II. COLLIDING WAVES

As was stated previously, in this section we review briefly some generalities on electrovacuum colliding waves, introduced by Ernst *et al.*[8]

The set of colliding waves solutions is described by the line element

$$g=2g(u,v)dudv+g_{ab}(u,v)dx^a dx^b, \quad a,b=1,2, \tag{2.1}$$

where $x^1=x$, $x^2=y$ are ignorable coordinates. The domain of the coordinate charts consists of $(x,y)\in\mathbf{R}^2$ and $(u,v)\in\mathbf{R}^2$; it is the union of four continuous regions: $\mathrm{I}:=\{(u,v):0\leqslant u<1,0\leqslant v<1\}$, $\mathrm{II}:=\{(u,v):u\leqslant 0,0\leqslant v<1\}$, $\mathrm{III}:=\{(u,v):0\leqslant u<1,v<0\}$, $\mathrm{IV}:=\{(u,v):u\leqslant 0,v\leqslant 0\}$.

In region IV, a closed subregion of the Minkowski space, it is required that

$$g_{\mu\nu}(u,v)=g_{\mu\nu}(0,0), \quad A_\mu(u,v)=A_\mu(0,0), \tag{2.2}$$

where A_μ is the electromagnetic vector potential. By scaling–shifting transformations the metric can be brought to standard Minkowski metric. In region II, the metric components and the electromagnetic vector potential depend only on v, i.e., $g_{\mu\nu}=g_{\mu\nu}(0,v)$, $A_\mu=A_\mu(0,v)$. In region III these fields are functions of the coordinate u, i.e., $g_{\mu\nu}=g_{\mu\nu}(u,0)$, $A_\mu=A_\mu(u,0)$. In region I, which is occupied by the scattered null fields, the metric components and the electromagnetic field are functions of both u and v coordinates. In this way, the problem is reduced to know the metric (coframe) and the electromagnetic vector function A_μ.

A. Newman–Penrose tetrad

We introduce a complex null frame according to the conventional description:

$$e_\alpha=(\mathbf{l},\mathbf{n},\mathbf{m},\overline{\mathbf{m}}) \tag{2.3}$$

with

$$\mathbf{l}^2=\mathbf{n}^2=\mathbf{m}^2=\overline{\mathbf{m}}^2=\mathbf{l}\cdot\mathbf{m}=\mathbf{n}\cdot\mathbf{m}=\mathbf{l}\cdot\overline{\mathbf{m}}=\mathbf{n}\cdot\overline{\mathbf{m}}=0, \tag{2.4}$$

$$\mathbf{l}\cdot\mathbf{n}=1, \quad \mathbf{m}\cdot\overline{\mathbf{m}}=-1. \tag{2.5}$$

The basis of the corresponding 1-forms, the coframe, is denoted by ϑ^α. If we lower the coframe index, then we use the same letters as with the frame: $\vartheta_\alpha=(\mathbf{l},\mathbf{n},\mathbf{m},\overline{\mathbf{m}})$. Then the coframe reads

$$\vartheta^\alpha=(\mathbf{n},\mathbf{l},-\overline{\mathbf{m}},-\mathbf{m}). \tag{2.6}$$

According to (2.4) and (2.5), we have

$$g=2(\hat{\vartheta^0}\otimes\hat{\vartheta^1}-\hat{\vartheta^2}\otimes\hat{\vartheta^3})=n_{\alpha\beta}\vartheta^\alpha\otimes\vartheta^\beta, \tag{2.7}$$

with

$$n_{\alpha\beta}=\begin{pmatrix}0&1&0&0\\1&0&0&0\\0&0&0&-1\\0&0&-1&0\end{pmatrix}. \tag{2.8}$$

B. Self-dual part of the complex Weyl 2-form

Quite independently from the type of coframe we are using, we can consider some properties of the Weyl 2-form. Let us denote the Weyl curvature 2-form by

$$C_{\alpha\beta}=\tfrac{1}{2}C_{\mu\nu\alpha\beta}\vartheta^\mu\wedge\vartheta^\nu. \tag{2.9}$$

If, in four dimensions, an arbitrary complex 2-form ω is given, then its Hodge dual ${}^\star\omega$ is again a 2-form. Therefore we can build linear combinations of both:

$$\omega^\pm:=\tfrac{1}{2}(\omega\pm i{}^\star\omega). \tag{2.10}$$

Here i is the imaginary unit. We call ω^+ the self-dual and ω^- the antiself-dual part of the 2-form ω. Clearly,

$$\omega=\omega^+ +\omega^-. \tag{2.11}$$

A form ω is called self-dual, if its antiself-dual piece vanishes, i.e., if $\omega=i{}^\star\omega$, it is called antiself-dual, if $\omega=-i{}^\star\omega$.

Let us now assume that the form ω is real, that is, $\omega=\overline{\omega}$, where the bar denotes complex conjugation. Then, according to (2.10), they fulfill the relations:

$$\overline{\omega^+}=\omega^-, \quad \text{and} \quad \overline{\omega^-}=\omega^+. \tag{2.12}$$

Consequently, a real 2-form $\omega=\overline{\omega}$ can be alternatively encoded into its self-dual part ω^+. Incidentally, the same is true for its antiself-dual part.

The Weyl 2-form is a real quantity. Accordingly, we can also take its self-dual part

$$C^+_{\alpha\beta}:=\tfrac{1}{2}(C_{\alpha\beta}+i{}^\star C_{\alpha\beta}). \tag{2.13}$$

Expanding the Weyl 2-form $C^+_{\alpha\beta}$ in terms of the basis $\vartheta^\mu\wedge\vartheta^\nu$ we have

$$C^+_{\alpha\beta}=\tfrac{1}{2}C^+_{\mu\nu\alpha\beta}\vartheta^\mu\wedge\vartheta^\nu, \tag{2.14}$$

which we will assume to be in the standard 2-form self-dual basis [**U,V,W**]. The most general form of our Weyl field components, compatible with colliding wave space–time structure is given by[14]

$$\begin{aligned}
&A_\mu=A_\mu(u,v),\ \ C^+_{abcd}=2\Psi_0U_{ab}U_{cd}+2\Psi_2(U_{ab}V_{cd}+V_{ab}U_{cd}+W_{ab}W_{cd})\\
&\qquad\qquad +2\Psi_4V_{ab}V_{cd},\ \text{region I},\\
&A_\mu=A_\mu(v),\quad C^+_{abcd}=2\Psi_0U_{ab}U_{cd},\quad \text{region II},\\
&A_\mu=A_\mu(u),\quad C^+_{abcd}=2\Psi_4V_{ab}V_{cd},\quad \text{region III},
\end{aligned} \tag{2.15}$$

with

$$W_{ab}=m_a\tilde{m}_b-m_b\tilde{m}_a-k_al_b+k_bl_a,$$

$$V_{ab}=k_a m_b-k_b m_a, \quad U_{ab}=-l_a\tilde{m}_b+l_b\tilde{m}_a \tag{2.16}$$

where m_a, $\tilde{m}_b$, k_a and l_a are null tetrads.

III. GENERALIZED ADVANCED AND RETARDED TIME COORDINATES

We shall consider a metric of the form

$$g=e^{-2\gamma}\left(\frac{dp^2}{P(p)}-\frac{dq^2}{Q(q)}\right)+g_{ab}dx^a dx^b, \tag{3.1}$$

where P,Q are fourth degree polynomials in their respective variable, and γ depending on both (p,q) coordinates.

Since we have real polynomials of fourth degree, when looking for advanced and retarded time variables one has to deal with elliptic integrals, i.e., we shall use the Legendre first kind integrals:

$$\int \frac{dr}{\sqrt{G_4(r)}}=\mu\int \frac{d\phi}{\sqrt{1-k^2\sin^2\phi}}=\mu F(\phi,k), \tag{3.2}$$

where the fourth degree polynomial $G_4(r)$, is represented by the product of four monomials containing the corresponding roots, the coefficient of the higher degree (fourth), denoted by a_4, is assumed to be $a_4=\pm 1$; if this were not the case, i.e., $a_4=\pm\alpha_4$, $\alpha_4>0$, then dividing by α_4 one arrives at the above equation where now μ has to be interpreted as $\mu/\sqrt{\alpha_4}$; in what follows we shall adopt these conventions when needed. The real roots are denoted by r_j, with $j=1,...,4$ and $r_1>r_2>r_3>r_4$, while the complex roots by $s_1\pm it_1$, $s_2\pm it_2$, with $s_1\geqslant s_2$, $t_1>t_2>0$. We also introduce the following useful notation

$$\begin{gathered}
r_{ik}=r_k-r_i, \quad (i,k=1,2,3,4),\\
(r,\beta,\gamma,\delta)=\frac{r-\gamma}{r-\delta}\frac{\beta-\delta}{\beta-\gamma},\\
\tan\theta_1=\frac{r_1-s_1}{t_1}, \quad \tan\theta_2=\frac{r_2-s_1}{t_1},\\
\tan\theta_3=\frac{t_1+t_2}{s_1-s_2}, \quad \tan\theta_4=\frac{t_1-t_2}{s_1-s_2},\\
\tan[(\theta_5/2)^2]=\frac{\cos\theta_3}{\cos\theta_4},\\
\nu=\tan[(\theta_2-\theta_1)/2]\tan[(\theta_2+\theta_1)/2].
\end{gathered} \tag{3.3}$$

The elliptic integral $F(\phi,k)$ is the Legendre integral of the first kind. As is well known, the standard form for writing this function is

$$z=\int^{\phi}\frac{d\phi}{\sqrt{1-k^2\sin^2\phi}}=F(\phi,k), \quad \phi=\text{am } z, \tag{3.4}$$

where am z denotes the function amplitude of z. Replacing ϕ through ω according to

$$\omega=\sin\phi=\sin(\text{am } z):=\text{sn } z, \quad z=\int_0^{\omega}\frac{d\omega}{\sqrt{(1-\omega^2)(1-k^2\omega^2)}}=\tilde{F}(\omega,k), \tag{3.5}$$

where sn z belongs to the Jacobi family of elliptic functions (sn z, cn z, dn z), with well established analytical properties. The values and main properties of these functions can be found in Ref. 15.

Going back to the line element (3.1) and assuming that $P(p)$ and $Q(q)$ are polynomials up to fourth degree on p and q, respectively, then the two dimensional line element [first two terms in (3.1)] can be written in terms of the retarded and advanced time coordinates $\tilde{u}$ and $\tilde{v}$, respectively, as follows

$$e^{-2\gamma(p,q)}\left(\frac{dp^2}{P(p)}-\frac{dq^2}{Q(q)}\right)=e^{-\gamma(\tilde{u},\tilde{v})}d\tilde{u}d\tilde{v}, \tag{3.6}$$

with

$$\left.\begin{matrix}d\tilde{u}\\ d\tilde{v}\end{matrix}\right\}=\frac{dp}{\sqrt{P_4(p)}}\pm\frac{dq}{\sqrt{Q_4(q)}}=\frac{\mu_\phi}{\sqrt{\alpha_4}}\frac{d\phi}{\sqrt{1-k_\phi^2\sin^2\phi}}\pm\frac{\mu_\theta}{\sqrt{\beta_4}}\frac{d\theta}{\sqrt{1-k_\theta^2\sin^2\theta}}, \tag{3.7}$$

where μ_ϕ, μ_θ are constants and α_4, β_4 are the moduli of the coefficients of the higher power in the polynomials P and Q, correspondingly. The variables $\tilde{u}$ and $\tilde{v}$ range the values from $-\infty$ to $+\infty$.

The integration of (3.7) yields

$$\left.\begin{matrix}\tilde{u}\\ \tilde{v}\end{matrix}\right\}=\frac{\mu_\phi}{\sqrt{\alpha_4}}F(\phi,k_\phi)\pm\frac{\mu_\theta}{\sqrt{\beta_4}}F(\theta,k_\theta), \tag{3.8}$$

where $-\infty<\tilde{u}<\infty$, $-\infty<\tilde{v}<\infty$. Hence, one has relations between the Legendre elliptic integrals and the null coordinates $\tilde{u}$, $\tilde{v}$, i.e.,

$$F(\phi,k_\phi)=\frac{\sqrt{\alpha_4}}{2\mu_\phi}(\tilde{u}+\tilde{v}),\quad F(\theta,k_\theta)=\frac{\sqrt{\beta_4}}{2\mu_\theta}(\tilde{u}-\tilde{v}). \tag{3.9}$$

Consequently, the inversion formulas bring the following functional dependence upon the generalized advanced and retarded time coordinates

$$\phi=\mathrm{am}\left[\frac{\sqrt{\alpha_4}}{2\mu_\phi}(\tilde{u}+\tilde{v})\right],\quad \omega=\sin\phi=\mathrm{sn}\left[\frac{\sqrt{\alpha_4}}{2\mu_\phi}(\tilde{u}+\tilde{v})\right], \tag{3.10}$$

$$\theta=\mathrm{am}\left[\frac{\sqrt{\beta_4}}{2\mu_\theta}(\tilde{u}-\tilde{v})\right],\quad \Omega=\sin\theta=\mathrm{sn}\left[\frac{\sqrt{\beta_4}}{2\mu_\theta}(\tilde{u}-\tilde{v})\right], \tag{3.11}$$

which allow us to give the original p and q coordinates, initially expressed through ϕ and θ, in terms of $\tilde{u}$ and $\tilde{v}$ null coordinates, i.e.,

$$p=p(\tilde{u},\tilde{v}),\quad \text{and}\quad q=q(\tilde{u},\tilde{v}). \tag{3.12}$$

Moreover, one can introduce a new set of variables (u,v)

$$u=\sin\left(\frac{\tilde{u}}{2}\right),\quad \text{and}\quad v=\sin\left(\frac{\tilde{v}}{2}\right) \tag{3.13}$$

where the ranges of the variables are $-\infty<\tilde{u}<\infty$, $-\infty<\tilde{v}<\infty$ and $-1<u<1$, $-1<v<1$. These variables are such that

$$d\tilde{u}=2\frac{du}{U},\quad d\tilde{v}=2\frac{dv}{V}, \tag{3.14}$$

and

$$\frac{\tilde{u}\pm\tilde{v}}{2}=\arcsin u\pm\arcsin v=\arcsin[uV\pm vU], \tag{3.15}$$

where $U=\sqrt{1-u^2}$, $V=\sqrt{1-v^2}$ and the corresponding term in the line element

$$d\tilde{u}\otimes d\tilde{v}=4\frac{du}{U}\otimes\frac{dv}{V}. \tag{3.16}$$

Having in mind colliding wave interpretations of the results, one restricts u and v to the range $0\leqslant u<1$, $0\leqslant v<1$ to be closed to the standard colliding wave approach. Depending on the character, real or complex, of the roots of the fourth degree polynomials, one may encounter, in general, combinations of different possible cases. It is always possible to introduce the retarded and advanced time coordinates u and v. However, only certain solutions satisfy the Ernst[8] requirements for colliding waves. We shall restrict ourselves to metrics which can support a colliding wave interpretation.

It may occur that several mixed cases depend on the degree of the polynomials appearing in the non-Killing sector, for instance,

$$\frac{dp^2}{P_4}-\frac{dq^2}{Q_2},\quad \frac{dp^2}{P_3}-\frac{dq^2}{Q_2}, \tag{3.17}$$

where the subindice indicates the degree of the polynomial we are dealing with; the possibility of interchanging P by Q and p by q and vice versa also has to be taken into account. The case $(dp^2/P_3)-(dq^2/Q_3)$ can be treated in the manner we did with the fourth degree polynomial.

Let us consider the case of $(dp^2/P_4)-(dq^2/Q_2)$. Introducing the null variables $(\tilde{u},\tilde{v})$,

$$\left.\begin{matrix}d\tilde{u}\\ d\tilde{v}\end{matrix}\right\}=\frac{dp}{\sqrt{P_4(p)}}\pm\frac{dq}{\sqrt{Q_2(q)}}, \tag{3.18}$$

in the case when Q_2 can be brought to the form $1-q^2$. They become

$$\left.\begin{matrix}\tilde{u}\\ \tilde{v}\end{matrix}\right\}=\mu_\phi F(\phi,k_\phi)\pm\arcsin\, q, \tag{3.19}$$

therefore

$$\frac{\tilde{u}-\tilde{v}}{2}=\arcsin\, q, \tag{3.20}$$

$$\frac{\tilde{u}+\tilde{v}}{2}=\mu_\phi F(\phi,k_\phi)=\mu_\phi\int^{\phi}\frac{dx}{\sqrt{1-k_\phi^2\sin^2 x}}=\mu_\phi z,\quad \phi=\mathrm{am}\, z, \tag{3.21}$$

hence

$$q=\sin\left(\frac{\tilde{u}-\tilde{v}}{2}\right),\quad p=p\left(\frac{\tilde{u}+\tilde{v}}{2}\right), \tag{3.22}$$

where the relation of p in terms of $\tilde{u}$, $\tilde{v}$ depend on the roots of the polynomial P_4. The other case with P_3, Q_2 can be treated in a similar way.

For completeness, we also briefly comment on the following cases

(i)

$$\frac{dp^2}{P_{4,3}(p)}-\frac{dq^2}{Q_1(q)}\rightarrow\frac{dp^2}{P_{4,3}(p)}-\beta(dq^{1/2})^2,\quad q>0,\beta>0. \tag{3.23}$$

The corresponding $\tilde{u}$, $\tilde{v}$ are

$$\left.\begin{matrix}\tilde{u}\\ \tilde{v}\end{matrix}\right\}=\mu_\phi F(\phi,k_\phi)\pm\beta q^{1/2}, \tag{3.24}$$

thus

$$p=p\left(\frac{\tilde{u}+\tilde{v}}{2}\right),\quad q=\left(\frac{\tilde{u}-\tilde{v}}{2\beta}\right)^2, \tag{3.25}$$

(ii)

$$\frac{dp^2}{P_2(p)}-\frac{dq^2}{Q_2(q)}\to\frac{dp^2}{1-p^2}-\frac{dq^2}{1-q^2}. \tag{3.26}$$

The corresponding $\tilde{u}$, $\tilde{v}$ are

$$\left.\begin{matrix}\tilde{u}\\ \tilde{v}\end{matrix}\right\}=\arcsin\, p\pm\arcsin\, q, \tag{3.27}$$

hence

$$p=\sin\left(\frac{\tilde{u}+\tilde{v}}{2}\right),\quad q=\sin\left(\frac{\tilde{u}-\tilde{v}}{2}\right), \tag{3.28}$$

(iii)

$$\frac{dp^2}{P_{4,3}(p)}-dq^2. \tag{3.29}$$

The corresponding $\tilde{u}$, $\tilde{v}$ are

$$\left.\begin{matrix}\tilde{u}\\ \tilde{v}\end{matrix}\right\}=\mu_\phi F(\phi,k_\phi)\pm q, \tag{3.30}$$

hence

$$p=p\left(\frac{\tilde{u}+\tilde{v}}{2}\right),\quad q=\frac{\tilde{u}-\tilde{v}}{2}, \tag{3.31}$$

(iv)

$$\frac{dp^2}{P_2(p)}-\frac{dq^2}{Q_1}\to\frac{dp^2}{1-p^2}-\beta(dq^{1/2})^2,\quad \beta>0,q>0. \tag{3.32}$$

The corresponding $\tilde{u}$, $\tilde{v}$ are

$$\left.\begin{matrix}\tilde{u}\\ \tilde{v}\end{matrix}\right\}=\arcsin\, p\pm\beta q^{1/2}, \tag{3.33}$$

hence

$$p=\sin\left(\frac{\tilde{u}+\tilde{v}}{2}\right),\quad q=\left(\frac{\tilde{u}-\tilde{v}}{2\beta}\right)^2, \tag{3.34}$$

(v)

$$\frac{dp^2}{P_1(p)}-\frac{dq^2}{Q_1(q)}\to(dp^{1/2})^2-(dq^{1/2})^2,\quad p>0,q>0. \tag{3.35}$$

The corresponding $\tilde{u}$, $\tilde{v}$ are

$$\left.\begin{matrix}\tilde{u}\\ \tilde{v}\end{matrix}\right\}=p^{1/2}\pm q^{1/2}, \tag{3.36}$$

thus

$$p=\left(\frac{\tilde{u}+\tilde{v}}{2}\right)^2,\quad q=\left(\frac{\tilde{u}-\tilde{v}}{2}\right)^2, \tag{3.37}$$

A. Different transformations of $p(\tilde{u},\tilde{v})$ and $q(\tilde{u},\tilde{v})$

In this subsection, we present all possible cases depending upon the roots of the polynomials $P(p)$ and $Q(q)$ and the corresponding transformation.

(1) For P and Q with all real and different roots, i.e.,

$$P=\alpha_4\epsilon_{\pm}[p-p_1][p-p_2][p-p_3][p-p_4],\quad \epsilon_{\pm}=\pm 1,\alpha_4>0, \tag{3.38}$$

$$Q=\beta_4\nu_{\pm}[q-q_1][q-q_2][q-q_3][q-q_4],\quad \nu_{\pm}=\pm 1,\beta_4>0. \tag{3.39}$$

The corresponding transformations read as follows

$P_4(p)$	$\epsilon_{\pm}$	Interval	$p(\tilde{u},\tilde{v})=$	k^2
four	ϵ_+	$p_1\leqslant p$ or $p\leqslant p_4$	$\dfrac{p_1p_{42}-p_2p_{41}(\mathrm{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2}{p_{42}-p_{41}(\mathrm{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2}$	
real	ϵ_+	$p_3\leqslant p\leqslant p_2$	$\dfrac{p_3p_{42}-p_4p_{32}(\mathrm{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2}{p_{42}-p_{32}(\mathrm{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2}$	$(\alpha_1,\alpha_2,\alpha_4,\alpha_3)$
roots	ϵ_-	$p_4\leqslant p\leqslant p_3$	$\dfrac{p_4p_{31}+p_1p_{43}(\mathrm{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2}{p_{31}+p_{43}(\mathrm{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2}$	
	ϵ_-	$p_2\leqslant p\leqslant p_1$	$\dfrac{p_2p_{31}-p_3p_{21}(\mathrm{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2}{p_{31}-p_{21}(\mathrm{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2}$	$(\alpha_3,\alpha_2,\alpha_4,\alpha_1)$

In the transformations given above we must understand that $\tilde{u}=2\arcsin u$ and $\tilde{v}=2\arcsin v$, such that $\tilde{u}\pm\tilde{v}=2\arcsin(uV\pm vU)$ and μ_ϕ has to be understood as $\mu_\phi/\sqrt{\alpha_4}$ when $\alpha_4\neq 1$. For $Q(q)$ the same table is valid making the changes: $p\to q$, $p_i\to q_i$, $\epsilon_{\pm}\to\nu_{\pm}$, $\mu_\phi\to\mu_\theta$ and $\tilde{u}+\tilde{v}\to\tilde{u}-\tilde{v}$, $s_i\to\sigma_i$ and $t_i\to\tau_i$. The same applies in the following cases.

(2) For the case in which P and Q possess two real and different roots, and two complex roots, i.e.,

$$P=\alpha_4\epsilon_{\pm}[p-p_1][p-p_2][p-(s_1+it_1)][p-(s_1-it_1)],\quad \alpha_4>0, \tag{3.40}$$

$$Q=\beta_4\nu_{\pm}[q-q_1][q-q_2][q-(\tilde{\sigma}_1+i\tilde{\tau}_1)][q-(\tilde{\sigma}_1-i\tilde{\tau}_1)],\quad \beta_4>0, \tag{3.41}$$

the transformations are given by

$P_4(p)$	$\epsilon_{\pm}$	Interval	$p(\tilde{u},\tilde{v})=$	k^2
two complex and two real roots	ϵ_+	$-\infty<p<\infty$	$\dfrac{p_1+p_2}{2}-\dfrac{p_1-p_2}{2}\left(\dfrac{\nu_\theta-\mathrm{cn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})]}{1-\nu_\theta\mathrm{cn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})]}\right)$	$\left(\sin\left(\dfrac{\theta_1-\theta_2}{2}\right)\right)^2$

(3) In the case P and Q with four complex roots, respectively, i.e.,

$$P=\alpha_4[p-(s_1+it_1)][p-(s_1-it_1)][p-(s_2+it_2)][p-(s_2-it_2)], \tag{3.42}$$

$$Q=\beta_4[q-(\tilde{\sigma}_1+i\tilde{\tau}_1)][q-(\tilde{\sigma}_1-i\tilde{\tau}_1)][q-(\tilde{\sigma}_2+i\tilde{\tau}_2)][q-(\tilde{\sigma}_2-i\tilde{\tau}_2)], \tag{3.43}$$

the transformations are now

$P_4(p)$	$\epsilon_\pm$	Interval	$p(\tilde{u},\tilde{v})=$	k^2
$s_1>s_2$			$s_1 + t_1\left[\frac{\text{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})]\cos((\theta_3/2)+(\theta_4/2))+\text{cn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})]\sin((\theta_3/2)+(\theta_4/2))}{\text{cn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})]\cos((\theta_3/2)+(\theta_4/2))-\text{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})]\sin((\theta_3/2)+(\theta_4/2))}\right]$	$\sin^2\theta_5$
	ϵ_+	$-\infty<p<\infty$		
$s_1=s_2$			$s_1 - t_1\left[\frac{\text{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})]\cos((\theta_3/2)+(\theta_4/2))+\text{cn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})]\sin((\theta_3/2)+(\theta_4/2))}{\text{cn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})]\cos((\theta_3/2)+(\theta_4/2))-\text{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})]\sin((\theta_3/2)+(\theta_4/2))}\right]$	
B $t_1>t_2$				

We include the transformations for the case of polynomials of third degree:

$P_3(p)$	$\epsilon_\pm$	Interval	$p(\tilde{u},\tilde{v})=$	k^2
three	ϵ_+	$p_3\leqslant p\leqslant p_2$	$\frac{p_{32}}{p_3}\left(\text{sn}\,\frac{1}{2\mu_\phi}(\tilde{u}+\tilde{v})\right)^2$	$\frac{p_{32}}{p_{31}}$
real		$p_1\leqslant p$	$\frac{p_1-p_2(\text{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2}{1-(\text{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2}$	
roots	ϵ_-	$p\leqslant p_1$	$\frac{p_1(\text{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2-p_{31}}{(\text{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2}$	$\frac{p_{21}}{p_{31}}$
		$p_2\leqslant p\leqslant p_1$	$\frac{p_2p_{31}-p_3p_{21}(\text{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2}{p_{31}-p_{21}(\text{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2}$	
two	ϵ_+	$p_1\leqslant p$	$p_1-\frac{c_1(1-\text{cn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])}{\cos\theta_1(1-\text{cn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])}$	
complex and				$\left(\sin\left[\frac{\theta_1}{2}+\frac{\pi}{4}\right]\right)^2$
one real	ϵ_-	$p\leqslant p_1$		

For the polynomial Q the same tables are valid making the changes: $p\to q$, $p_i\to q_i$, $\epsilon_\pm\to\nu_\pm$, $\mu_\phi\to\mu_\theta$ and $\tilde{u}+\tilde{v}\to\tilde{u}-\tilde{v}$, $s_i\to\sigma_i$ and $t_i\to\tau_i$.

All possible combinations between the transformations corresponding to the different possible ranges of p and q should be taken into account. Moreover, it is straightforward to perform such combinations by using the explicit transformations in the tables given above.

B. Limiting transition

For completeness we include the limiting procedure to obtain from the fourth order polynomials and the third and second degree ones,

$$\begin{aligned} P&=\epsilon_\pm a_4(p-p_1)(p-p_2)(p-p_3)(p-p_4)\\ &=a_4p_1\left(\frac{p}{p_1}-1\right)(p-p_2)(p-p_3)(p-p_4)\\ &=\alpha_4\left(\frac{p}{p_1}-1\right)(p-p_2)(p-p_3)(p-p_4). \end{aligned} \tag{3.44}$$

Taking the limit when $p_1\to\infty$ we recover a third degree polynomial:

$$\lim_{p_1\to\infty} P_4=\epsilon_\pm\alpha_4(p-p_2)(p-p_3)(p-p_4)=\epsilon_\pm\alpha_4P_3. \tag{3.45}$$

Analogously we take the limit on P_3 when $p_2\to\infty$ to get a second order polynomial:

$$\lim_{p_2\to\infty} P_3 = \lim_{p_2\to\infty}\left\{\epsilon_\pm a_4 p_2\left(\frac{p}{p_2}-1\right)(p-p_3)(p-p_4)\right\}$$
$$= \lim_{p_2\to\infty}\left\{\epsilon_\pm \alpha_3\left(\frac{p}{p_2}-1\right)(p-p_3)(p-p_4)\right\}$$
$$= \epsilon_\pm \alpha_3 (p-p_3)(p-p_4) = \epsilon_\pm \alpha_3 P_2 . \tag{3.46}$$

The corresponding procedure can be achieved for Q_4 to obtain a second order polynomial.

C. Concrete example

As a concrete example let us consider, for instance, the case P with four real and different roots and Q also with four real and different roots, in which the coefficients of the higher degree are 1, and the roots of P and Q are denoted by p_i and q_i respectively. For the elliptic integral depending on the p-coordinate, with $P(p)=(p-p_1)(p-p_2)(p-p_3)(p-p_4)$, $(\epsilon_\pm=1)$, one has the relation

$$\int \frac{dx}{\sqrt{P(p)}} = \mu_\phi \int \frac{d\phi}{\sqrt{1-k_\phi^2 \sin^2\phi}} = \mu_\phi F(\phi,k), \tag{3.47}$$

where the explicit relation between p and ϕ reads

$$p = \frac{p_1 p_{42} - p_2 p_{41}\sin^2\phi}{p_{42} - p_{41}\sin^2\phi},$$
$$\sin^2\phi = \frac{p_{42}}{p_{41}}\left(\frac{p-p_1}{p-p_2}\right), \quad \rightarrow \quad \phi = \arcsin\left(\pm\sqrt{\frac{p_{42}}{p_{41}}\left(\frac{p-p_1}{p-p_2}\right)}\right). \tag{3.48}$$

The parameter k_ϕ, $0<k_\phi^2<1$, is given by

$$k^2 = (p_1,p_2,p_4,p_3) = \left(\frac{p_1-p_4}{p_1-p_3}\right)\left(\frac{p_2-p_3}{p_2-p_4}\right), \quad \text{and} \quad \mu = \frac{\mu_\phi}{\sqrt{\alpha_4}} = \frac{2}{\sqrt{p_{31}p_{42}}}. \tag{3.49}$$

It is straightforward to find the analogous expression for the elliptic integral depending on the q-coordinate. The explicit expression of the coordinates p and q through $\tilde{u}$ and $\tilde{v}$ is the following

$$p(\tilde{u},\tilde{v}) = \frac{p_1 p_{42} - p_2 p_{41}(\mathrm{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2}{p_{42} - p_{41}(\mathrm{sn}\,[(1/2\mu_\phi)\,(\tilde{u}+\tilde{v})])^2}, \tag{3.50}$$

$$q(\tilde{u},\tilde{v}) = \frac{q_1 q_{42} - q_2 q_{41}(\mathrm{sn}\,[(1/2\mu_\theta)(\tilde{u}-\tilde{v})])^2}{q_{42} - q_{41}(\mathrm{sn}\,[(1/2\mu_\phi)\,(\tilde{u}-\tilde{v})])^2}. \tag{3.51}$$

In terms of the null variables u and v which bring the line element to the form

$$\frac{dp^2}{P_4} - \frac{dq^2}{Q_4} = d\tilde{u}d\tilde{v} = 4\frac{dudv}{UV} \tag{3.52}$$

the p and q variables amount to

$$p(u,v) = \frac{p_1 p_{42} - p_2 p_{41}(\mathrm{sn}\,[(1/\mu_\phi)\,(\arcsin(uV+vU))])^2}{p_{42} - p_{41}(\mathrm{sn}\,[(1/2\mu_\phi)\,(\arcsin(uV+vU))])^2}, \tag{3.53}$$

$$q(u,v) = \frac{q_1 q_{42} - q_2 q_{41}(\mathrm{sn}\,[(1/2\mu_\theta)\,(\arcsin(uV-vU))])^2}{q_{42} - q_{41}(\mathrm{sn}\,[(1/2\mu_\theta)\,(\arcsin(uV-vU))])^2}. \tag{3.54}$$

On the other hand, the relations between ϕ and θ with p and q are

$$\phi \pm \theta = \arcsin\ \sqrt{\frac{p_{42}}{p_{41}}\left(\frac{p-p_1}{p-p_2}\right)} \pm \arcsin\ \sqrt{\frac{q_{42}}{q_{41}}\left(\frac{q-q_1}{q-q_2}\right)}, \tag{3.55}$$

where ϕ and θ stand correspondingly for the arguments of the elliptical Legendre integrals related with the integration of P and Q. We define the auxiliary non-null variables u' and v' as

$$u' = \sin\left(\frac{\phi+\theta}{2}\right), \quad v' = \sin\left(\frac{\phi-\theta}{2}\right), \tag{3.56}$$

with

$$\left.\begin{matrix}\phi\\ \theta\end{matrix}\right\} = \arcsin\ u' \pm \arcsin\ v' = \arcsin[u'\sqrt{1-v'^2} \pm v'\sqrt{1-u'^2}] = \arcsin[u'V' \pm v'U'], \tag{3.57}$$

where

$$V' = \sqrt{1-v'^2}, \quad \text{and} \quad U' = \sqrt{1-u'^2}. \tag{3.58}$$

Thus, when we substitute (3.57) and (3.58) into (3.50) and (3.51) it is straightforward to find

$$p(u',v') = \frac{p_1 p_{42} - p_2 p_{41}(u'V' + v'U')^2}{p_{42} - p_{41}(u'V' + v'U')^2}, \tag{3.59}$$

$$q(u',v') = \frac{q_1 q_{42} - q_2 q_{41}(u'V' - v'U')^2}{q_{42} - q_{41}(u'V' - v'U')^2}. \tag{3.60}$$

Moreover, from (3.7) and (3.57), the advanced and retarded time coordinates $\tilde{u}$ and $\tilde{v}$ are related with the variables u' and v' through

$$\begin{aligned}\left.\begin{matrix}d\tilde{u}\\ d\tilde{v}\end{matrix}\right\} = &\left[\frac{\mu_\phi}{\sqrt{1-k_\phi^2(u'V'+v'U')^2}} \mp \frac{\mu_\theta}{\sqrt{1-k_\theta^2(u'V'-v'U')^2}}\right]\frac{du'}{U'}\\ &+\left[\frac{\mu_\phi}{\sqrt{1-k_\phi^2(u'V'+v'U')^2}} \mp \frac{\mu_\theta}{\sqrt{1-k_\theta^2(u'V'-v'U')^2}}\right]\frac{dv'}{V'}.\end{aligned} \tag{3.61}$$

According to our general procedure (3.61) can be inverted, yielding $u' = u'(\tilde{u},\tilde{v})$ and $v' = v'(\tilde{u},\tilde{v})$.

In the limit of polynomials of second degree, i.e., P_2, Q_2, one has $k_\phi = k_\theta = 0$, and μ_ϕ, $\mu_\theta \to 1$, hence one recovers from (3.61) the widely used retarded and advanced time coordinates

$$d\tilde{u} = 2\frac{du'}{U'}, \quad d\tilde{v} = 2\frac{dv'}{V'}. \tag{3.62}$$

In the next section we present an explicit class of colliding wave solutions.

IV. A CLASS OF COLLIDING WAVES

Let us consider an explicit solution of the Einstein–Maxwell equations in region I, given by the following coframe in coordinates (x,p,q,y):

$$\begin{aligned}\vartheta^{\hat{0}} &= \frac{1}{H}\sqrt{\frac{\Delta}{Q}}\,dq, \quad \vartheta^{\hat{1}} = \frac{1}{H}\sqrt{\frac{Q}{\Delta}}\,(dx + p^2 dy),\\ \vartheta^{\hat{2}} &= \frac{1}{H}\sqrt{\frac{\Delta}{P}}\,dp, \quad \vartheta^{\hat{3}} = \frac{1}{H}\sqrt{\frac{P}{\Delta}}\,(dx - q^2 dy).\end{aligned} \tag{4.1}$$

Here we have the functions $H=H(p,q)$, $P=P(p)$, $Q=Q(q)$, and $\Delta=\Delta(p,q)$. The coframe is assumed to be orthonormal

$$g=o_{\alpha\beta}\vartheta^{\alpha}\otimes\vartheta^{b}. \tag{4.2}$$

Then the metric explicitly reads

$$g=\frac{1}{H^2}\left\{\frac{Q}{\Delta}\,(dx+p^2dy)^2-\frac{\Delta}{Q}\,dq^2+\frac{\Delta}{P}\,dp^2+\frac{P}{\Delta}\,(dx-q^2dy)^2\right\}, \tag{4.3}$$

with

$$\begin{aligned}
H(p,q)&:=1-\mu pq,\\
P(p)&:=b-g^2+2np-\epsilon p^2+2m\mu p^3+\left(-\frac{\lambda}{3}-\mu^2b-\mu^2e^2\right)p^4,\\
Q(q)&:=-(b+e^2)+2mq-\epsilon q^2+2n\mu q^3+\left(\frac{\lambda}{3}+\mu^2b-\mu^2g^2\right)q^4,\\
\Delta(p,q)&:=p^2+q^2,
\end{aligned} \tag{4.4}$$

while the nonvanishing electromagnetic field components are given by

$$\begin{aligned}
F_{xq}&:=\frac{(p^2-q^2)e-2gpq}{2\Delta^2}, \quad F_{yq}:=p^2F_{xq},\\
F_{xp}&:=\frac{g(q^2-p^2)-2epq}{\Delta^2}, \quad F_{yp}:=-q^2F_{xp}.
\end{aligned} \tag{4.5}$$

In order to express our solutions (4.4) and (4.5) in terms of the advanced and retarded time coordinates $\tilde{u}$, $\tilde{v}$, one has to use the inversion procedure, presented in the previous section, yielding $p=p(u,v)$ and $q=q(u,v)$. The explicit representation requires the use of tables for the sn function.

Our class of solutions, defined in region I, can be extended to the full space–time by introducing the Heaviside step function

$$\Theta(x)=\begin{cases}1, & x\geqslant 0\\ 0, & x<0\end{cases}, \tag{4.6}$$

with $\Theta^2(x)=\Theta(x)$, and performing the following transformation

$$u\to\Theta(u)u, \quad \text{and} \quad v\to\Theta(v)v. \tag{4.7}$$

For the case of real roots of the polynomials, treated extensively in Sec. III B, we obtain for region II

$$p(u,v)=\frac{p_1p_{42}-p_2p_{41}(\mathrm{sn}\,[(1/2\mu_\phi)\,\tilde{v}])^2}{p_{42}-p_{41}(\mathrm{sn}\,[(1/2\mu_\phi)\,\tilde{v}])^2}, \tag{4.8}$$

$$q(u,v)=\frac{q_1q_{42}-q_2q_{41}(\mathrm{sn}\,[(1/2\mu_\theta)\,\tilde{v}])^2}{q_{42}-q_{41}(\mathrm{sn}\,[(1/2\mu_\theta)\,\tilde{v}])^2}, \tag{4.9}$$

where

$$\mathrm{sn}\,\frac{\tilde{v}}{2\mu}=\mathrm{sn}\left[\frac{1}{\mu}\,\arcsin\,v\right]. \tag{4.10}$$

For region III

$$p(u,v)=\frac{p_1p_{42}-p_2p_{41}(\mathrm{sn}\,[(1/2\mu_\phi)\,\tilde{u}])^2}{p_{42}-p_{41}(\mathrm{sn}\,[(1/2\mu_\phi)\,\tilde{u}])^2}, \tag{4.11}$$

$$q(u,v)=\frac{q_1q_{42}-q_2q_{41}(\mathrm{sn}\,[(1/2\mu_\phi)\,\tilde{u}])^2}{q_{42}-q_{41}(\mathrm{sn}\,[(1/2\mu_\phi)\,\tilde{u}])^2}, \tag{4.12}$$

where

$$\mathrm{sn}\,\frac{\tilde{u}}{2\mu}=\mathrm{sn}\left[\frac{1}{\mu}\,\arcsin\,u\right]. \tag{4.13}$$

At this point it is important to mention that not every cylindrically symmetric space–time, even in vacuum, satisfies the requirements of Ernst[8] for being interpreted as colliding waves, only certain classes of cylindrically symmetric solutions can be thought of as solutions generated by collision of waves.

Moreover, until now our analysis has been concerned mostly with metrical aspects, leaving aside the task of having suitable field and matter energy-momentum tensors. As is well known, each participating wave in the head-on collision is assumed to be plane fronted, i.e., it is characterized by a covariantly constant null eigenvector k, i.e., $k_{\mu;\nu}=0$, of the Weyl–Petrov-type N conformal tensor. This condition implies a null energy-momentum tensor for the electromagnetic field, i.e., a radiation field or electrovacuum, let us call it null field for short, into the Einstein field equations, cf. Kramer *et al.*,[16] Sec. 21.5. Therefore, the existence of colliding wave solutions with nonvanishing cosmological λ term is thus forbidden.

Usually one derives colliding wave solutions using the backward procedure, namely, one starts with a cylindrically symmetric solution and an energy-momentum tensor in terms of fields depending on the usual two null variables, say u and v, restricted to a closed interaction region, region I in our approach. Furthermore, by accomplishing on it the transformations (4.7) with Heaviside functions one obtains the space–times prior to the collision. These space–times occur as type N solutions to the Einstein equations in vacuum or coupled with null fields—regions II and III in our approach, where the gravitational and null fields depend solely on a single variable (u or v). At this level, the colliding wave condition allows only for fields which can be matched to the flat Minkowski space–time (region IV) background where the wavefronts propagate. (We appreciate the referee's comment which drew our attention to this characteristic.) In other words, if the cylindrically symmetric space–time is endowed with a cosmological λ term, one has to set it equal to zero in order to connect smoothly the different regions of the collision and in order to avoid meaningless jumps of the cosmological constant across the null lines.

On the other hand, it is worthwhile to mention the results by Chandrasekhar and Xanthopoulos[17] concerning colliding wave solutions with a perfect fluid (stiff matter, fluid pressure=fluid energy density). They found that after the collision takes place, the incoming plane waves supporting radiative fields give rise to solutions with stiff matter perfect fluid tensor. It is an example of the transformation of massless particles describing null trajectories into a perfect fluid in which the stream lines describe timelike trajectories.

In full, in order to interpret our class of cylindrically symmetric solutions (4.4) as a colliding waves class of solutions, it is compulsory to set $\lambda=0$ on it.[16]

V. DISCUSSION

In this paper we present the formulation of the most general class, currently, of colliding waves with fourth degree polynomials determining the non-Killing sector, by means of a generalization of the advanced and retarded coordinates concept. As has been pointed out, after setting the cosmological λ term equal to zero, this class of solutions describes the scattering of two noncollinear polarized gravitation plane waves, having a null electromagnetic field as a source. At the leading edge of each colliding type-N gravitational wave, the curvature tensor exhibits delta and jump discontinuities. The former is interpreted as a gravitational impulsive wave, whereas the latter is attributed to a gravitational shock wave.

As stated above, this class of solutions, defined again in region I, can also be extended to the full space–time by introducing the Heaviside step function Θ.

The electromagnetic field presents delta singularities and jump discontinuities. However, the Bianchi identities hold in a distributional sense, see Ref. 18.

There are no problems on the right-hand side because the delta type singularities of the curvature are multiplied by the smooth distributions $\sqrt{1-\Theta(u)u^2}$ and $\sqrt{1-\Theta(v)v^2}$, respectively.

On the other hand (with respect to the singularities of the solution) we have in region I that the solution is of type *D* in the classification of Petrov. This is so because the only nonvanishing Weyl scalar is Ψ_2, and explicitly, it is given by

$$\Psi_2=\frac{H^3}{2\Delta^3}\,[2(e^2+g^2)(1+\mu pq)(p-iq)^2+q(q^2-3p^2)(a_3-ia_1)-p(p^2-3q^2)(a_1+ia_3)], \tag{5.1}$$

where the parameters $a_1=2n$, $a_3=2m$. The parameters ϵ and b do not appear in the curvature scalar, however the properties of the solution depend on them, as we shall see. The complex structure of Ψ_2 is due to the noncollinear polarization of the incoming waves (nondiagonal metric, see Ref. 19). Since we have the explicit expression for the Weyl scalar, Eq. (5.1), we can study the behavior of the invariants of the space–time and determine if the solution develops a curvature singularity a finite time after the instant of collision. Penrose attributed the development of the singularity in most colliding wave solutions to the self-focusing of the gravitational waves on scattering. In this case the invariants are given by $I=3\Psi_2^2$ and $J=\Psi_2^3$. Then the singularities of Ψ_2 are clearly the same for the invariants. A singularity occurs when $\Delta=p^2+q^2=0$, i.e., when simultaneously $p=0$ and $q=0$. The interesting question is whether there is any case in which the nature of the roots do not permit that $p=0$ and $q=0$ simultaneously. If this is the case, then the solution is free of the focusing singularity. A brief analysis shows that this occurrence can be avoided for certain values of the parameters of the solution.

Let us consider the expressions given in Sec. III C for the case of *P* and *Q*, both with four real roots. In this case (3.53) and (3.54) express p and q in terms of (u,v). Analyzing those expressions we see that $p=0$ and $q=0$ simultaneously if, for instance, $p_{42}=0$, $p_{41}=0$ and $q_{42}=0$, $q_{41}=0$, i.e., when at least three of the four roots coincide: $p_4=p_2=p_1$ and also $q_4=q_2=q_1$. The assumption of the occurrence of three equal roots for *P* and for *Q* leads to algebraic conditions that must be satisfied by the parameters of the solution, *b*, g, n, m, ϵ, *e* and μ. Some of these conditions are incompatible. For instance, in the case considered, the following condition must be valid: $\mu^2(b+e^2)=\mu^2(b-g^2)$. This is only true in the case if $e^2+g^2=0$; i.e., if $e^2+g^2\neq 0$ we do not have that $p=0$ and $q=0$ simultaneously and then the singularity fails to occur. Then we conclude that in some cases the existence of the electromagnetic field permits us to tune the parameters in such a way as to avoid the focusing singularity. A related result was obtained already by Chandrasekhar for a colliding wave solution with a scalar field[20] and by García *et al.* in the framework of metric-affine gauge theories of gravity.[21,22]

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 39, NUMBER 11 NOVEMBER 1998

A harmonic space approach to quantum gravity of stationary space–times with SO(3) symmetry

Helia Hollmann[a)]
Max-Planck-Institut für Physik, Werner-Heisenberg-Institut, Föhringer Ring 6, 80805 Munich, Germany

(Received 14 April 1997; accepted for publication 6 November 1997)

After dimensional reduction the stationary sector of SO(3) symmetric Einstein's gravity is identified with an $SL(2,\mathbb{R})/SO(2)$ Sigma model coupled to a one-dimensional gravitational remnant. The space of classical solutions consists of the Schwarzschild and Taub–NUT family. A Dirac quantization of this system is performed and the observables—the mass and the charge operator—are shown to be self-adjoint operators with a continuous spectrum ranging from $-\infty$ to ∞. The Hilbert space is constructed explicitly using a harmonic space approach. © *1998 American Institute of Physics.* [S0022-2488(98)03004-7]

I. INTRODUCTION

The quantization of Einstein's gravity is one of the outstanding and most challenging areas in theoretical physics. There have been many attempts at a solution of this problem classified by Isham in his articles about quantum gravity.[1,2] One can start with the classical theory of general relativity and apply some kind of quantization algorithm. General relativity may be considered as a low-energy limit of another theory, for example, superstring theory. One can either try to force some principal ideas of a quantum field theory to be compatible with general relativity or the fundament of quantum gravity is seen to be some radically new perspective which leads to the classical theory of general relativity in certain limiting situations. Attempts in this direction are quantum groups or the noncommutative geometry invented by Connes. Nonperturbative approaches to the problem became of great importance since it is known that quantum gravity is non-renormalizable.

This paper originates in a conservative point of view. Starting from the classical theory of general relativity one achieves a quantization via a canonical scheme, the ADM quantization. For full general relativity this is still an unsolved problem, but freezing all but a few of the infinitely many degrees of freedom of the gravitational field solutions for special sectors of Einstein's vacuum theory are within reach. It is hoped that at least some relevant features of the quantum theory are preserved. Even restricting oneself to a particularly symmetric case, that is spherical symmetry (as it is done here), the space of classical solutions contains a black hole, the Schwarzschild solution, whose special importance is explained now. There are no particles in the sense of ordinary field theory. Even the concept of solitons has to be modified as shown in Refs. 3 and 4. One has to allow singularities in the solutions, leading to the suggestion that black holes are the proper particles of general relativity: coupling a point particle to its own gravitational field turns it into a black hole.[5] Furthermore, classical black holes are stable under local perturbations,[6] and they have remarkable uniqueness properties. This is why they are considered to be the fundamental pieces of a quantum theory of gravitation and the investigation of the spherically symmetric and the SO(3) symmetric sector of Einstein's theory of gravitation is seen in a different light.[3,4,7] As in conventional gauge theory, where one tries to keep manifest Poincaré invariance even in the process of gauge fixing, this sector of Einstein's gravity has a global symmetry group, the $SL(2,\mathbb{R})$, which will be preserved even at a quantum level. The unitary irreducible representations play a key role in the process of quantization. The major advantage of this model is that the quantum theory is explicitly known.

One of the most important developments in field theory during the last two decades was the

[a)]Electronic mail:hollmann@mppmu.mpg.de

 © 1998 American Institute of Physics

discovery of the quantum mechanical instability of black holes due to Hawking radiation. Most of the calculations of black hole radiation involve matter fields quantized in front of a classical background. After the coupling of matter fields this model opens the possibility to take a closer look at Hawking radiation quantum mechanically. However, this is considered to be a project of future research.

This paper mainly splits into a classical and a quantum part. In the beginning the SO(3) symmetric sector of Einstein's gravity is introduced and a Kaluza–Klein-like reduction is performed.[8] This treatment is rather concise, but a more comprehensive and more general exposition can be found in Ref. 8. Gravity reduced from four to three dimensions in its dual representation is equivalent to a $SL(2,\mathbb{R})/SO(2)$ nonlinear coset sigma model coupled to three-dimensional gravity.[9] Using this coset space structure all stationary solutions of Einstein's equations with SO(3) symmetry are constructed in Ref. 10: there are the Schwarzschild solution labeled by a mass parameter and the Taub–NUT family characterized by a charge parameter in addition.[11] The mass parameter m and the charge parameter l labeling the space–time are hidden in the sigma model currents. In the following the problem is treated as a constraint system. The Hamiltonian is the only constraint which survives the process of dimensional reduction. The components of the sigma model currents consequently turn out to be observables in the sense of Dirac and form an $sl(2,\mathbb{R})$ algebra.

During quantization the classical phase space is turned into a Hilbert space on which the operators—the former functions on phase space—act. In general it is a difficult problem to identify the Hilbert space. On the other hand, it is the Hilbert space, which is of fundamental importance to make assertions about the operators to be considered physical. The implementation of the classical $SL(2,\mathbb{R})$ symmetry at a quantum level leads to a solution of this problem. The eigenfunctions of the invariant differential operator on the group span the Hilbert space as is shown by the application of a generalized Plancherel theorem. The measure on the Hilbert space is derived quite naturally from the Haar measure on the group. Once knowing the Hilbert space explicitly one can investigate the self-adjointness and the spectrum of certain differential operators. Both the mass operator and the charge operator are self-adjoint and their spectra are purely continuous. Neither the spectrum of the mass operator nor the spectrum of the charge operator are bounded, that is, negative charges as well as negative masses belong to the spectrum, too.

The most challenging feature of this model is that bases of the Hilbert space are at hand. Therefore the model serves as a kind of test laboratory for several aspects of quantum gravity. However, these topics will be reserved for a forthcoming publication.

This method is not limited to the situation here. It is applicable to various other models occurring in conformal field theory, string theory, quantum cosmology, or supergravity.

II. THE CLASSICAL THEORY

This classical part starts with the application of a Kaluza–Klein reduction[9,12] to a four-dimensional Einstein space M_4 with signature $(+,+,+,-)$ having a one-parameter Abelian isometry group[10] which acts freely and corresponds to time translations; that is there exists a timelike Killing vector field K^M describing the action of the Lie algebra of the isometry group. In a coordinate basis the metric g_{MN} of M_4 decomposes into a metric h_{mn} on the remaining three spatial dimensions, a scalar field τ and the vector field B_m:

$$g_{MN}=\begin{pmatrix} \frac{1}{\tau}\,h_{mn}+\tau B_m B_n & \tau B_n \\ \tau B_m & -\tau \end{pmatrix}.$$

The extra factor τ assures that diffeomorphisms of the special form $t\mapsto t+\Lambda(x^m)$ act as gauge transformations $B_m\mapsto B_m+\partial_m\Lambda$ on the vector field B_m.[3] Capital letters M and N vary from 1 to 4 and small ones from 1 to 3. Plugging this Ansatz for the four-dimensional metric into the Einstein Hilbert action

$$S=-\frac{1}{2}\int d^4\,\sqrt{-g}R \tag{1}$$

leads to the Lagrangian

$$\mathscr{L}^{(4,3)}=-\frac{1}{2}\sqrt{-g}R=\sqrt{h}\left(-\frac{1}{2}{}^{(3)}R-\frac{\tau^2}{8}F^{mn}F_{mn}+\frac{1}{4\tau^2}\partial^m\tau\partial_m\tau\right). \tag{2}$$

Here F_{mn} defined by $F_{mn}=\partial_m B_n-\partial_n B_m$ denotes the field strength of B_m, R and ${}^{(3)}R$ are the scalar curvatures corresponding to the four-dimensional metric g_{MN} and the three dimensional metric h_{mn}, respectively, and $\sqrt{-g}$ and $\sqrt{h}$ are the square roots of the determinants of the metrics as usual.

Under the specified conditions dimensional reduction of four-dimensional pure gravity to three dimensions leads to gravity coupled to an Abelian vector field and a scalar.

The equations of motion derived from (2) can be interpreted as an integrability condition for the vector field B_m:

$$\tau^2F_{mn}=\epsilon_{mnp}\,\partial^p\omega.$$

Elimination of the field strength in terms of the gravito-magnetic potential ω leads to a dual Lagrangian density

$$\mathscr{L}^D=\sqrt{h}\left(\frac{1}{2}{}^{(3)}R-\frac{h^{mn}}{4\tau^2}(\partial_m\tau\partial_n\tau+\partial_m\omega\partial_n\omega)\right),$$

which can be rewritten as

$$\mathscr{L}^D=\sqrt{h}\left(\frac{1}{2}{}^{(3)}R-\frac{h^{mn}}{8}\,\mathrm{Tr}\,(\chi^{-1}\partial_m\chi\chi^{-1}\partial_n\chi)\right), \tag{3}$$

where

$$\chi=\begin{pmatrix}\tau+\dfrac{\omega^2}{\tau} & \dfrac{\omega}{\tau}\\ \dfrac{\omega}{\tau} & \dfrac{1}{\tau}\end{pmatrix},$$

that is four-dimensional reduced gravity in its dual representation is equivalent to an $\mathrm{SL}(2,\mathbb{R})/\mathrm{SO}(2)$ sigma model coupled to three-dimensional gravity. The matrix χ is an element of the Riemannian symmetric space $\mathrm{SL}(2,\mathbb{R})/\mathrm{SO}(2)$. The fields contained in χ have a physical interpretation. The norm τ of the Killing vector plays the role of a gravitational potential, and ω is the so-called gravito-magnetic or NUT potential. In the stationary sector the NUT potential can be considered as a kind ''magnetic potential'' in analogy to Maxwell's theory.

For the derivation of the equations of motion one starts from (3). Here $R_{MN}=0$ is equivalent to the set of equations

$${}^{(3)}R_{mn}=\tfrac{1}{2}\,\mathrm{Tr}\,(\chi^{-1}\partial_m\chi\chi^{-1}\partial_n\chi), \tag{4a}$$

$$D^m(\chi^{-1}\partial_m\chi)=0. \tag{4b}$$

Now an additional SO(3) symmetry with S^2 orbits is imposed. Coordinates ρ, ϕ, and θ are introduced such that ρ is constant on the orbits; ϕ and θ are the usual angles.

The three-dimensional metric is then parametrized by

$$h_{mn}=\begin{pmatrix}N^2(\rho) & 0 & \\ & f^2(\rho) & \\ 0 & & f^2(\rho)\,\sin^2\theta\end{pmatrix},\quad m,n=\rho,\theta,\phi. \tag{5}$$

After substitution of this metric into the Lagrangian one obtains

$$\mathscr{L}^{(D)}=N\left[\frac{f'^2}{N^2}+1-\frac{f^2}{4N^2\tau^2}\,(\tau'^2+\omega'^2)\right]. \tag{6}$$

The prime $'$ denotes the derivative with respect to ρ, N is the ''lapse'' function, and ''lapse'' is set in quotation marks because it usually refers to a timelike direction whereas the lapse indicates spacelike propagation.

For SO(3) symmetric gravity $\chi^{-1}\chi'$ is unequal to zero and (4) simplifies to

$${}^{(3)}R_{22}={}^{(3)}R_{33}=\left[\frac{f''}{f}+\left(\frac{f'}{f}\right)^2-\frac{1}{f^2}\right]=0, \tag{7a}$$

$${}^{(3)}R_{11}=-\frac{2f''}{f}=\frac{1}{4}\,\mathrm{Tr}\,(\chi^{-1}\chi')^2, \tag{7b}$$

$$(f^2\chi^{-1}\chi')'=0. \tag{7c}$$

The lapse function refers to a gauge degree of freedom and was set equal to one meanwhile. Dobiasch and Maison[10] calculated the solution of these equations of motion. To show the unique correspondence between the observables and the initial data it is indicated briefly how the structure of the homogeneous space may be used to determine ω and τ classically (see Ref. 10). Using the transformation

$$\rho\mapsto\sigma(\rho)=-\int_\rho^\infty f^{-2}(s)\,ds,$$

(7c) become the geodesic equation in the homogeneous space

$$\frac{d^2\Phi^i}{d\sigma^2}+\Gamma^i_{jk}\frac{d\Phi^j}{d\sigma}\frac{d\Phi^k}{d\sigma}=0.$$

whose invariant line element is given by

$$ds^2=\frac{1}{4}\,\mathrm{Tr}\,(\chi^{-1}d\chi)^2=\frac{1}{2\tau^2}\,(d\tau^2+d\omega^2). \tag{8}$$

The Φ^i are the coordinates ω and τ. This yields the following system of differential equations:

$$\ddot{\tau}-\frac{\dot{\tau}^2}{\tau}+\frac{\dot{\omega}^2}{\tau}=0,\quad \ddot{\omega}-\frac{2\dot{\tau}\dot{\omega}}{\tau}=0. \tag{9}$$

The overdot $\dot{}$ denotes the derivative with respect to σ. The solutions are assumed to be asymptotically flat. From this one derives the boundary conditions $\tau(\sigma=0)=1$ for the gravitational potential τ and $\omega(\sigma=0)=0$ for the gravito-magnetic potential. To better understand the connection between the geodesic coordinate σ and the coordinate ρ one now cites the solutions for $a^2>0$ and $a=0$ from Ref. 10. Here a^2 is defined by $\mathrm{Tr}\,(\chi'\chi^{-1})^2=2a^2/f^4$. For $a^2>0$ the function [Eq. (7a) yields $f^2(\rho)=R^2-a^2$ with $R=\rho-b$] has two simple zeros at $\rho=b\pm a$. This leads to

$$\sigma(\rho)=\frac{1}{a}\,\ln\left(\frac{\rho-b-a}{\rho-b+a}\right).$$

For $\rho=b-a$ the geodesic coordinate σ tends to ∞. At $\sigma=0$ there starts a geodesic in (τ_0,ω_0) and assumes the value (τ_h,ω_h) at $\sigma=\infty$, which determines the position of the horizon of a black hole. The value $a=0$ corresponds to a solution with vanishing mass and charge. For this reason it belongs to flat space. The system of differential equations (9) has the solutions

$$\omega(\sigma)=\cosh\,\beta\,\tanh\,(a\sigma+\beta)-\sinh\,\beta, \tag{10}$$

$$\tau(\sigma)=\frac{\cosh\,\beta}{\cosh\,(a\sigma+\beta)}. \tag{11}$$

To summarize: For each geodesic there is a solution with an asymptotic behavior as demanded, i.e., $(\tau_0,\omega_0)=(1,0)$. It is uniquely determined by its tangent vector

$$(\dot\tau_0,\dot\omega_0)=\left(-a\,\tanh\,\beta,\,\frac{a}{\cosh\,\beta}\right)=(m,l).$$

The parameters m and l range from $-\infty$ to ∞. For the sake of completeness we also give the four-dimensional metric in terms of the one-dimensional data:

$$g_{MN}=\begin{pmatrix} \frac{1}{\tau} & & & & \\ & \frac{f^2}{\tau} & & 0 & \\ & & \frac{f^2}{\tau}\sin^2\,\theta+\frac{f^4}{\tau^3}\cos^2\,\theta\omega'^2 & \frac{f^2}{\tau}\cos\,\theta\omega' & \\ & 0 & & & \\ & & \frac{f^2}{\tau}\cos\,\theta\omega' & -\tau & \end{pmatrix},$$

$M,N=\rho,\theta,\phi,t$. The solution corresponding to $\sin\,\psi=0$ turns out to be the Schwarzschild solution, which is the gravitational field outside a spherically symmetric mass distribution. It is a static solution of Einstein's equations. For $\cos\,\psi=0$ only the μ_1 part remains and it is a Taub–NUT solution with mass parameter equal to zero. For any other value of ψ one obtains a Taub–NUT solution, labeled by a mass and a charge parameter. The geometrical difference between the Schwarzschild and the Taub–NUT solution is that the latter admits an isometry group whose orbits are on three-spheres, whereas in the case of the Schwarzschild solution they are on two-spheres. The ''result'' is the Taub–NUT time being a circle. Another interpretation is given in terms of the difference between staticity and stationarity: In the static case there are two symmetries: a time translation symmetry and a time reflection symmetry. For Taub–NUT the fields being time translation invariant fail to be time reflection invariant: the neighboring orbits of the Killing vector fields twist around each other!

Although it should be clear from the structure of the Lagrangian (3), it is stressed at this point once more that the space of solutions contains more than the Schwarzschild solution. The attempts to quantize spherically symmetric gravity[13–17] can be understood to be the static truncation GL(1) of this SL(2,$\mathbb{R}$)/SO(2) sigma model. The authors do not assume staticity, but the classical solutions turn out to have a hypersurface-orthogonal Killing vector that is timelike in certain regions of space–time.

After this excursion the Lagrangian (3) or (6), respectively, is investigated once more. It is invariant under SL(2,$\mathbb{R}$) transformations $z\mapsto(az+b)/(cz+d)$, $z=\omega+i\tau$, $ad-bc=1$. The corresponding Noether currents J are

$$J=\begin{pmatrix} -J^0 & J^+ \\ J^- & J^0 \end{pmatrix}:=\frac{f^2}{2N}\,\chi^{-1}\chi'=\frac{f^2}{2N}\begin{pmatrix} -\frac{\tau'}{\tau}-\frac{\omega\omega'}{\tau^2} & \frac{\omega'}{\tau^2} \\ \omega'-\frac{2\omega\tau'}{\tau}-\frac{\omega^2\omega'}{\tau^2} & \frac{\omega\omega'}{\tau^2}+\frac{\tau'}{\tau} \end{pmatrix}. \tag{12}$$

As χ is a symmetric matrix only two components of the current matrix are linearly independent. Imposing proper boundary conditions at infinity on the sigma model fields there exists an asymptotic multipole expansion of χ:

$$\chi \sim \sum_{n=0}^{\infty} \rho^{-n} \chi_n(\theta, \phi).$$

A suitable choice of coordinates asymptotically leads to

$$\omega = \frac{l}{\rho} + O\left(\frac{1}{\rho^2}\right) \quad \text{and} \quad \tau = 1 - \frac{2m}{\rho} + O\left(\frac{1}{\rho^2}\right).$$

In particular one is interested in the $1/\rho$ term in the expansion of χ because it contains the mass and the charge parameters m and l, which are the entries of the matrix of global charges

$$Q = \frac{1}{4\pi} \int_{\partial S^2} J_\rho \, d\Sigma^\rho = \chi_0^{-1} \chi_1 .$$

By integration over an infinitely large sphere Q is calculated to be

$$Q = \begin{pmatrix} -2m & l \\ l & 2m \end{pmatrix}.$$

The identification of the mass parameter m and the charge parameter l is obtained by comparison with the standard form of the Schwarzschild and the Taub–NUT solution in the literature.[9] Evaluation of the currents J^0 and J^+ at a classical solution yield m and l, respectively. The J^0 component of the current is related to the mass parameter m, and the J^+ and J^- components lead to the charge parameter l.

So far the space of classical solutions is understood completely. Now one turns to the ADM approach to Einstein's gravity. General relativity is invariant with respect to space–time diffeomorphisms. This local symmetry relates part of the solutions stemming from the same initial conditions. In the Lagrangian formalism this results in the fact that out of ten field equations there are only six independent ones: The reparametrization invariance leads to Noether currents, the so-called Bianchi identities, and in the sequel to the presence of an arbitrary function of time in the general solution of the equations of motion. A solution is mapped to a solution by a gauge transformation. Performing a Hamiltonian formalism the local symmetry transformations yield a system with constraints. This means that there are conditions on the allowed initial data which must be preserved during time evolution. This consistency requirement can lead to secondary and higher-order constraints. The gauge degrees of freedom are hidden in the system of first class constraints (these are those whose Poisson brackets vanish weakly, that is on-shell).

Here a modified Hamiltonian formalism is implemented. The slicing is performed according to the ρ, that is a spacelike, coordinate. How to proceed in this case can be found in Refs. 13 and 18. Due to spherical symmetry the lapse function is the only Lagrange multiplier which survives. In other words, it expresses the invariance under ρ-reparametrization and this leads to the only primary first class constraint of the theory, the Hamiltonian constraint, which generates the gauge transformations

$$H = \frac{1}{4} \pi_f^2 - 1 - \frac{\tau^2}{f^2} (\pi_\tau^2 + \pi_\omega^2).$$

In terms of the fields and their conjugate momenta J reads

$$J = \begin{pmatrix} -\tau\pi_\tau - \omega\pi_\omega & \pi_\omega \\ \tau^2\pi_\omega - 2\omega\tau\pi_\tau - \omega^2\pi_\omega & \tau\pi_\tau + \omega\pi_\omega \end{pmatrix}. \tag{13}$$

By definition an observable is a function on the constraint surface that is gauge invariant. As explained above it has weakly, i.e., on-shell, vanishing brackets with the first class constraints. Observables do not evolve in ''time'' and therefore there is a one-to-one correspondence between the observables and the initial data here: They can be identified with the space of solutions. Here

the classical solutions are parametrized by the mass m and the charge l. Therefore one expects the existence of two observables, which turn out to be ''hidden'' in the current matrix J:

$$\{H,J^0\}=0, \quad \{H,J^+\}=0, \quad \{H,J^-\}=0.$$

On the other hand they generate an $\mathrm{sl}(2,\mathbb{R})$ algebra:

$$\{J^+,J^0\}=-J^+, \quad \{J^+,J^-\}=2J^0, \quad \{J^0,J^-\}=-J^-.$$

The observable J^0 measures the mass, and J^+ and J^- lead to the charge l. Because $\mathrm{Tr}\, J^2$ commutes with all the currents

$$\{H,\mathrm{Tr}\, J^2\}=0, \quad \{\mathrm{Tr}\, J^2,J^+\}=0, \quad \{\mathrm{Tr}\, J^2,J^-\}=0, \quad \{\mathrm{Tr}\, J^2,J^0\}=0,$$

these observables can be ''measured simultaneously'' (simultaneously diagonalized). A ''simultaneous measurement'' of the mass and the charge parameter m and l is not possible.

III. QUANTIZATION

Concerning the canonical approach to quantum gravity there are two main streams to handle the problem:[19] the reduced phase space quantization and the Dirac quantization. From a ''Hamiltonian point of view'' the former deals with the problem by eliminating the first class constraints at an early stage. This amounts to quantizing gauge invariant functions only, i.e., constants of motion. To carry out the reduced phase space quantization one must find a complete set of gauge invariant functions, which is a difficult task in general. Therefore often canonical gauge conditions are imposed to obtain the reduced phase space. After completely fixing the gauge any function of the canonical variables can be viewed as the restriction of a gauge invariant function in that gauge. Hence, once the gauge is fixed one is effectively working with gauge invariant functions. A complete set of independent gauge fixed functions provides a complete set of gauge invariant functions.

Problems of that quantization scheme are that an early elimination of the gauge degrees of freedom may spoil the manifest invariance under important symmetries and in general it destroys locality in space. Furthermore, it might happen that the brackets of the observables are complicated functions and the question arises of how to realize them quantum mechanically. The main advantage is that only the physical degrees of freedom are quantized. Every state in the Hilbert space is a physical one.

In the so-called Dirac quantization one keeps the gauge degrees of freedom. The classical phase space functions become operators acting in the Dirac representation space, which carries nonphysical information. Hence, one has to select a physical subspace of gauge invariant states.

This paper proceeds along the Dirac approach. The $\mathrm{SL}(2,\mathbb{R})$ symmetry of the theory provides the key to quantize this sector of Einstein's gravity. An outline of what happens next is given: The former phase space functions become operators. After this step a naive approach is followed: the Wheeler–DeWitt equation is solved formally. For the investigation of the self-adjointness and the spectra of the physical operators it is necessary to specify the Hilbert space employing group theoretical arguments. Then, to justify the choice of the Hilbert space or to obtain a basis, harmonic analysis is heavily used. That is what is done finally in this quantum part of the paper.

During the process of quantization the functions J^+, J^-, J^0, $\mathrm{Tr}\, J^2$, and H on the phase space become operators on an appropriate Hilbert space. In the Schrödinger representation the fields are turned into multiplication operators and the momenta become differentiation operators $\pi_\Phi \mapsto -i\partial_\Phi$, where ∂_Φ is an abbreviation for ∂/∂_Φ. The operators $\widehat{J^0}$, $\widehat{J^+}$, and $\widehat{J^-}$ turn out to be the differential operators one obtains calculating the Lie derivatives with respect to a suitable basis of the Lie algebra $\mathrm{sl}(2,\mathbb{R})$. This yields an algorithm of how to calculate the Casimir operator $\widehat{\mathrm{Tr}\, J^2}$: one squares the matrix J (12) with entries J^0, J^+, and J^- now in operator form and takes the trace. Therefore, by implementing the symmetry at the quantum level, no ambiguities in the operator ordering arise. The generators of the currents J^0, J^+, J^-, the Casimir $\mathrm{Tr}\, J^2$, and the Hamiltonian H become

$$\widehat{J^0} = -i\tau\partial_\tau - i\omega\partial_\omega,$$

$$\widehat{J^+} = i\partial_\omega,$$

$$\widehat{J^-} = i(\tau^2-\omega^2)\partial_\omega - 2i\omega\tau\partial_\tau,$$

$$\mathrm{Tr}\ J^2 = -\tau^2(\partial_\tau^2+\partial_\omega^2),$$

$$\hat{H} = -\frac{\partial_f^2}{4} + \frac{1}{2f^2}\widehat{\mathrm{Tr}\ J^2} - 1.$$

Applied to a wave function ψ the Hamiltonian defines the so-called Wheeler–DeWitt equation $\hat{H}\psi = 0$. The following commutation relations hold:

$$[\hat{H},\ \widehat{J^0}] = 0, \quad [\hat{H},\ \widehat{J^+}] = 0, \quad [\hat{H}, \widehat{J^-}] = 0,$$

i.e., the current operators are observables. The Casimir operator $\widehat{\mathrm{Tr}\ J^2}$ commutes with the Hamiltonian and the currents

$$[\widehat{\mathrm{Tr}\ J^2},\ \hat{H}] = 0, \quad [\widehat{\mathrm{Tr}\ J^2},\ \widehat{J^0}] = 0, \quad [\widehat{\mathrm{Tr}\ J^2},\ \widehat{J^+}] = 0, \quad [\widehat{\mathrm{Tr}\ J^2}, \widehat{J^{-1}}] = 0,$$

and $\widehat{J^0}$, $\widehat{J^+}$, and $\widehat{J^-}$ form an sl(2,$\mathbb{R}$) algebra:

$$[\widehat{J^+},\ \widehat{J^0}] = -i\widehat{J^+}, \quad [\widehat{J^+},\ \widehat{J^-}] = 2i\widehat{J^0}, \quad [\widehat{J^0},\ \widehat{J^-}] = -i\widehat{J^-}.$$

The Casimir operator $\widehat{\mathrm{Tr}\ J^2}$ is an essential part of the Wheeler–DeWitt equation. As it commutes with the current operators, $\widehat{\mathrm{Tr}\ J^2}$ and any one of the $\hat{J}$'s can be ''measured simultaneously,'' i.e., they can be simultaneously diagonalized. $\widehat{J^0}$, $\widehat{J^+}$, and $\widehat{J^-}$ do not commute with each other. Therefore, even formally a direct ''measurement'' of the mass M and the charge L is not possible.

The interpretation of the current operators as observables of the theory strongly suggests to preserve the SL(2,$\mathbb{R}$) symmetry at the quantum level: $\widehat{J^0}$, $\widehat{J^-}$, $\widehat{J^+}$, and the Casimir operator $\widehat{\mathrm{Tr}\ J^2}$ are forced to become self-adjoint operators during the process of quantization. That is, the quantum mechanical Hilbert space is built from the unitary irreducible representations of the group SL(2,$\mathbb{R}$). Finding a solution of the Wheeler–DeWitt equation therefore basically becomes a group theoretical problem as the equation splits into an f-dependent and an f-independent part, which is the Casimir operator on the group up to a constant term.

There are two particularly useful possibilities to diagonalize the Casimir operator $\widehat{\mathrm{Tr}\ J^2}$. On one hand, one solves the differential equations for $\widehat{\mathrm{Tr}\ J^2}$ and the charge operator $\widehat{J^+}$ simultaneously. The other possibility is to diagonalize the mass operator $\widehat{J^0}$ and the Casimir operator $\widehat{\mathrm{Tr}\ J^2}$.

The former case is investigated first, i.e., the formal solutions of the following system of differential equations,

$$-\tau^2(\partial_\tau^2+\partial_\omega^2)\psi_{\lambda L}(\omega,\tau) = \lambda\psi_{\lambda L}(\omega_r\tau), \tag{14a}$$

$$i\partial_\omega\psi_{\lambda L}(\omega,\tau) = L\psi_{\lambda L}(\omega,\tau), \tag{14b}$$

are obtained. The second equation, (14b), is considered first. The solution is

$$\psi_{\lambda L}(\omega,\tau) = C(\tau)\mathrm{e}^{-iL\omega}.$$

Substitution of this solution into the first equation yields

$$\tau^2\partial_\tau^2 C(\tau) + (\lambda - \tau^2 L^2)C(\tau) = 0.$$

This is a differential equation of Bessel type. If $L^2 \neq 0$, it follows that

$$\psi_{\lambda L}(\omega,\tau) = \psi^1_{\lambda L}(\omega,\tau) + \psi^2_{\lambda L}(\omega,\tau)$$

with

$$\psi^1_{\lambda L}(\omega,\tau) = C_1 \mathrm{e}^{-iL\omega}\sqrt{\tau}\mathrm{I}_k(|L|\tau), \tag{15a}$$

$$\psi^2_{\lambda L}(\omega,\tau) = C_2 \mathrm{e}^{-iL\omega}\sqrt{\tau}\mathrm{K}_k(|L|\tau). \tag{15b}$$

Here I_k and K_k denote the Bessel functions of imaginary argument. For $L^2 = 0$ it follows that

$$C(\tau) = \hat{C}_1 \tau^{1/2+k} + \hat{C}_2 \tau^{1/2-k}, \quad \text{for } k \neq 0,$$

$$C(\tau) = \sqrt{\tau}(\hat{C}_1 + \hat{C}_2 \log \tau, \quad \text{for } k = 0.$$

Now the simultaneous diagonalization of the Casimir operator $\widehat{\mathrm{Tr}\, J^2}$ and the mass operator $\widehat{J^0}$ is carried out. As in the former case the system of differential equations

$$-\tau^2(\partial^2_\tau + \partial^2_\omega)\psi_{\lambda M}(\omega,\tau) = \lambda \psi_{\lambda M}(\omega,\tau), \tag{16a}$$

$$-i(\tau\partial_\tau + \omega\partial_\omega)\psi_{\lambda M}(\omega,\tau) = M\psi_{\lambda M}(\omega,\tau) \tag{16b}$$

has to be solved. The solution of (16b) is

$$\psi_{\lambda M}(\omega,\tau) = C(v)\omega^{iM}, \tag{17}$$

where $v = \tau/\omega$. Alternatively $1/v$ could be used as an independent variable. This seems to be more natural at first sight, but leads to differential equations which are more complicated to handle later on. It turns out that (17) leads to a nice representation in terms of the associated Legendre functions. Substituting (17) into (16a) yields

$$-v^2(v^2+1)C'' + 2mv^3C' - (m(m+1)v^2 - \lambda)C = 0.$$

Here the prime $'$ denotes differentiation with respect to v and m is defined to be $m := iM - 1$. This differential equation is of hypergeometric type and transformed into the hypergeometric differential equation by

$$C(v) = v^{1/2+k}\eta(-v^2),$$

where $\eta(\xi)$ is the solution of

$$\xi(\xi-1)\eta'' + [(\alpha+\beta+1)\xi - \gamma]\eta' + \alpha\beta\eta = 0.$$

The prime $'$ denotes differentiation with respect to ξ, and α, β, and γ are equal to

$$\alpha = \tfrac{1}{4}(1+2k-2m), \quad \beta = -\tfrac{1}{4}(1-2k+2m), \quad \gamma = 1+k.$$

If $\lambda \neq -n^2 + \frac{1}{4}$, $n \in \mathbb{Z}$, $\eta(\xi)$ is calculated to be

$$\eta(\xi) = C_1 F(\alpha,\beta;\gamma;\xi) + C_2 \xi^{1-\gamma} F(\alpha-\gamma+1, \beta-\gamma+1; 2-\gamma; \xi). \tag{18}$$

Equation (18) can be expressed by associated Legendre functions so that one finally obtains

$$\psi_{\lambda M}(\omega,v) = \psi^1_{\lambda M}(\omega,v) + \psi^2_{\lambda M}(\omega,v)$$

with

$$\psi^1_{\lambda M}(\omega,v)=C_1\omega^{iM}\sqrt{v}(1+v^2)^{iM/2-1/4}\mathrm{P}^{-k}_{-iM-1/2}\left(\frac{1}{\sqrt{1+v^2}}\right), \tag{19a}$$

$$\psi^2_{\lambda M}(\omega,\tau)=C_2\omega^{iM}v^{2k+1/2}|v|^{-2k}(1+v^2)^{iM/2-1/4}\mathrm{P}^{k}_{-iM-1/2}\left(\frac{1}{\sqrt{1+v^2}}\right), \tag{19b}$$

where $\lambda\neq\frac{1}{4}-n^2$, $n\in\mathbb{Z}$. For the definition of P see Refs. 20 and 21.

In the coordinates ω and v the differential operators can be written in the following manner:

$$\widehat{J^0}=-i\omega\partial_\omega, \tag{20a}$$

$$\widehat{\mathrm{Tr}\,J^2}=v^2(1+v^2)\partial_v^2+\omega^2v^2\partial_\omega^2-2v\omega^3\partial_\omega\partial_v+2v^3\partial_v. \tag{20b}$$

To solve (20) means seeking solutions of $\widehat{\mathrm{Tr}\,J^2}\psi=\lambda\psi$ of the form $f(\omega)C(v)$.

Of course, the formal solutions of the differential equations do not yield enough structural elements to solve the problem. For a deeper understanding a Hilbert space structure is needed to single out part of the solutions of the differential equations and to show self-adjointness of the physical operators. For this one applies various techniques from functional analysis, the representation theory of SL(2,$\mathbb{R}$), the Plancherel theorem, and its version on the coset space SL(2,$\mathbb{R}$)/SO(2).

The natural choice of the Hilbert space is to take the closure of the functions on the coset space SL(2,$\mathbb{R}$)/SO(2) on which the physical operators can be shown to be essentially self-adjoint. One would also like to have a subset of functions which uniformly approximate all functions on compact subsets of the coset space. This is the content of the theorem by Stone and Weierstrass. It states that, given a compact metric space E, which is constructed below, any subalgebra of continuous functions on that space which contains the unity and separates the points of E is dense in the Banach space of functions E. One immediately recognizes that the space of L^2-functions over the coset space measurable with respect to the Haar measure on the group SL(2,$\mathbb{R}$) is too small: it does not contain the constants. Furthermore, the coset space SL(2,$\mathbb{R}$)/SO(2) is noncompact. This problem is solved by exhausting the coset space by a sequence of compact subsets. The restriction of the solutions on each compact subset of SL(2,$\mathbb{R}$)/SO(2) form (by group theoretical arguments) the required subalgebra of the Stone–Weierstrass theorem. The sequence of compact subsets converges towards SL(2,$\mathbb{R}$)/SO(2).

This paragraph is to motivate the further construction. The Hilbert space $\mathscr{H}$ is defined to be the closure with respect to the scalar product (21) (to follow) of the linear span of the finite norm solutions of the eigenvalue equations corresponding to $\widehat{\mathrm{Tr}\,J^2}$, $\widehat{J^+}$ or $\widehat{\mathrm{Tr}\,J^2}$, $\widehat{J^0}$, respectively. It turns out that the K-Bessel functions (15b) constitute a basis in the case of the diagonalization of $\widehat{\mathrm{Tr}\,J^2}$, $\widehat{J^+}$, and the Hilbert space is the closure of the span of these functions. For the diagonalization of $\widehat{\mathrm{Tr}\,J^2}$, $\widehat{J^0}$ the functions (19a) provide a basis. It can be shown that the Hilbert spaces are isomorphic. The scalar product is defined employing the Haar measure on the coset space dressed with a suitable damping factor, which is chosen such that the constants and enough functions to separate the points on SL(2,$\mathbb{R}$)/SO(2) belong to the Hilbert space. That is, from a technical point of view the Hilbert space theory of the continuation of symmetric operators to their closure is applied.

One realization of the coset space SL(2,$\mathbb{R}$)/SO(2) is the Poincaré upper half-plane $\mathbb{H}$. The details are given in the Appendix.

As motivated above, the Hilbert space $\mathscr{H}(\mathbb{H},d\mu_n)$ is the space of square integrable functions on the upper half-plane, which are measurable with respect to the SL(2,$\mathbb{R}$) invariant measure $d\mu$,

$$d\mu=\frac{d\omega d\tau}{\tau^2},$$

dressed with the damping factor

$$d_n(\omega,\tau)=\frac{\tau^n}{(\omega^2+(1+\tau)^2)^n},\quad \in\mathbb{N}.$$

The Hilbert space measure is defined by $d\mu_n=d_n(\omega,\tau)d\mu$. It is shown below that $\mathscr{H}(\mathbb{H},d\mu_n)$ contains solutions of the differential equations as long as $n>1$. It turns out that they constitute a dense subset of $\mathscr{H}(\mathbb{H},d\mu_n)$. With $d_{n_1}(\omega,\tau)<d_{n_2}(\omega,\tau)$ for $n_1>n_2$ there exists a natural embedding of the L^2 spaces with a smaller n into those with a greater n. In particular $\mathscr{H}(\mathbb{H},d\mu_0)=L^2(\mathbb{H})$. The scalar product $(,)_n$ is defined by

$$(f(\omega,\tau),g(\omega,\tau))_n=\int_{-\infty}^{\infty}d\omega\int_0^{\infty}d\tau\,\frac{d_n(\omega,\tau)}{\tau^2}\,f(\omega,\tau)g^*(\omega,\tau). \tag{21}$$

As to (14) the following lemma holds:

Lemma 1: For $1-4\lambda>0$ *neither* $\psi^1_{\lambda L}$ *nor* $\psi^2_{\lambda L}$ *belong to* $\mathscr{H}(\mathbb{H},d\mu_n)$. *For* $1-4\leqslant 0$ *the* $\psi^2_{\lambda L}$ *are elements of* $\mathscr{H}(\mathbb{H},d\mu_n)$, $n>1$.

It is sufficient to show that

$$(\psi^1_{\lambda L},\psi^1_{\lambda L})_n=\int_{-\infty}^{\infty}d\omega\int_0^{\infty}d\tau\,\frac{d_n(\omega,\tau)}{\tau^2}\,|\psi^1_{\lambda L}(\omega,\tau)|^2$$

and $(\psi^2_{\lambda L},\psi^2_{\lambda L})_n$ are finite. This is essentially proven by splitting the integrals into three parts with respect to τ, namely the asymptotic region near zero, a singularity-free part having ''compact support,'' and the asymptotic region near infinity.

At first the case $1-4\lambda>0$ is studied more closely. Near infinity $|\mathrm{I}_\kappa(|L|\tau)|\sim \mathrm{e}^{\tau}$ holds and therefore the integral does not exist. On the other hand, for small arguments $|\mathrm{K}_k(|L|\tau)|\geqslant k_0\tau^{-k/2}$, which lets the norm of $\psi^2_{\lambda L}$ tend to infinity, too.

For $1-4\lambda=0$ it is clear that I_0 is not bounded and therefore $\psi^1_{\lambda L}$ is not either. Near zero one can approximate $\mathrm{K}_0(x)$ by $\ln 2/x$ and near infinity by $\sqrt{\pi/2x}\mathrm{e}^{-x}$. Splitting the integrals into the three parts mentioned above it can be shown that the norm of $\psi^2_{\lambda L}$ is finite. That the integral over $\psi^2_{\lambda L}$ remains finite for $1-4\lambda<0$, too, is due to the fact that $\mathrm{K}_0(|L|\tau)$ can be used as an upper bound for the function K_k. The easiest way to see this is to use the integral representation for K_k.

To prove the divergence of $(\psi^1_{\lambda L},\psi^1_{\lambda L})$ for $1-4\lambda<0$ the asymptotic expansion of $\mathrm{I}_\nu(z)$ is employed.

Now one answers the question concerning which norm of which part of the solutions $\psi_{\lambda M}$ of the system of differential equations (16) is finite. The parameter κ assumes values on the positive real line $\mathbb{R}_+$ or on the positive imaginary line $i\mathbb{R}_+$.

Lemma 2: For $\lambda\in i\mathbb{R}$ *the functions* $\psi^1_{\lambda M}$ *belong to* $\mathscr{H}(\mathbb{H},d\mu_n)$ *with* $n>1$.

This lemma is proven by rather tricky estimates of the integrals $(\psi^1_{\lambda M},\psi^1_{\lambda M})_n$. The first integral is reduced to one over the damping factor d_n using that by holomorphy there exists an upper bound for the hypergeometric function on the interval $[0,\frac{1}{2}]$. Concerning the second integral, the existence of a lower bound in the neighborhood of 0 is quite useful to prove divergence of the integral.

The Hilbert space is spanned by the solutions of the systems of differential equations (14) or (16), respectively. In particular they form a dense subspace of the Hilbert space. Therefore the symmetry of the operators has to be proven for the solutions of these differential equations only where the operators are diagonal. That is, by construction of the Hilbert space the current operators $\widehat{J^0}$, $\widehat{J^+}$, and the Casimir operator $\widehat{\mathrm{Tr}\,J^2}$ are already symmetric. The self-adjointness of the operators is discussed with the technique of the deficiency indices n_+ and n_-. Given a symmetric operator A, the deficiency index $n_\pm$ is defined to be the dimension of the space $\ker(i\pm A^*)$. The operator is essentially self-adjoint iff the deficiency indices are zero. It has self-adjoint extensions, iff the deficiency indices are equal. Therefore the dimensions n_- of the kernel of $i-\widehat{J^+}^*$ and n_+ of $i+\widehat{J^+}^*$ are calculated next.

Lemma 3: The deficiency indices n_+ *and* n_- *are equal to zero, i.e., the operator* $\widehat{J^+}$ *is already essentially self-adjoint in* $L^2(\mathbb{H},d\mu)$.

The kernel, the dimension n_+ of which is calculated, consists of the functions $\psi_{\lambda L}$ with $\lambda = i$ and $L = -i$ and the ones corresponding to n_- consists of $\psi_{\lambda L}$ with $\lambda = -i$ and $L = i$. The techniques to prove the preceeding Lemma 2 are applied to show the divergence of all the integrals involved.

In an analogous manner one calculates the dimensions n_- of the kernel and $i - \widehat{J^0}$ and n_+ of $i + \widehat{J^0}^*$.

Lemma 4: The deficiency indices n_+ and n_- of the spaces $\ker(i \pm \widehat{J^0}^*)$ *are equal to zero. That is, the operator $\widehat{J^0}$ is already essentially self-adjoint in $L^2(\mathbb{H}, d\mu)$.*

Here $\widehat{\mathrm{Tr}\, J^2}$ is shown to be essentially self-adjoint, too. With the solutions of the differential equations (14) and (16) we have the following.

Lemma 5: The spectrum of the operators $\widehat{J^0}$ and $\widehat{J^+}$ consists of the whole real line.

Lemma 6: The spectrum of the Casimir operator is continuous and consists of a part of the positive real line, i.e., $[\frac{1}{4}, \infty)$.

To summarize: part of the formal simultaneous eigendistributions of the invariant differential operator $\widehat{\mathrm{Tr}\, J^2}$ and the charge operator $\widehat{J^+}$ as well as of $\widehat{\mathrm{Tr}\, J^2}$ and the physical ''mass-operator'' $\widehat{J^0}$ are shown to belong to $\mathscr{H}(\mathbb{H}, d\mu_n)$. They are exactly the functions which are needed to decompose a function on the Poincaré upper half-plane into irreducible parts. This is discussed in the group theoretical context below. The operators $\hat{J}^+$ and $\hat{J}^0$ are shown to be essentially self-adjoint. Finally, no constraints on the spectra of the operators $\widehat{J^+}$ and $\widehat{J^0}$ arise: they consist of the whole real line. Negative charges as well as negative masses belong to the spectrum, too.

Now one switches to the group theoretical point of view. There exists a canonical Hilbert space associated to the group $\mathrm{SL}(2,\mathbb{R})$. The unitary irreducible characters provide a basis of this Hilbert space. There are sufficiently many of them to separate the points of the group which means that a function on the group can be approximated by its characters: one obtains a generalized Fourier transform. This is the reason why the construction of the Hilbert space above makes sense. The property that the characters separate the points of the group reminds one of the assumption of the Stone–Weierstrass theorem mentioned above. The generalized inverse Fourier transform, which is called Plancherel theorem in the mathematical literature, yields an expansion of an arbitrary function on the group into a series or an integral of functions which occur as matrix elements of unitary irreducible representations on the group.[22–25] It contains the characters of the continuous and the discrete series. The formula can then be applied to elements of $\mathrm{SL}(2,\mathbb{R})/\mathrm{SO}(2)$ with the result that only one part of the continuous series survives. The eigendistributions of the invariant differential operators are shown to appear explicitly in the inverse Fourier transform. That is the deeper reason why the spectra of the mass and the charge operator are purely continuous.

For the classifications of the unitary irreducible representations of $\mathrm{SL}(2,\mathbb{R})$ and the notations used below the author refers to the Appendix.

This approach is similar to the one needed for the investigation of the hydrogen atom. There the coset space $\mathrm{SO}(3)/\mathrm{SO}(2)$, which is isomorphic to the two-sphere S^2, plays the key role. The generalized Fourier transform of $\mathrm{SO}(3)$ represented on S^2 leads to the spherical harmonics. The main difference arises from the fact that the group $\mathrm{SL}(2,\mathbb{R})$ is no longer compact, therefore the unitary irreducible representations are no longer finite dimensional, and apart from a discrete sum there further appears a direct integral in the decomposition formula.

The generalized Fourier transform[22] establishes a topological isomorphism between the C^∞ functions and the space of rapidly decreasing function on the dual of the group $\hat{G}$. ($\hat{G}$ is defined to be the set of all equivalence classes of unitary irreducible representations of the group.)

Theorem 1: *For each function $f \in \mathscr{S}(G)$,*

$$f(g) = \frac{1}{2\pi} \int_0^\infty dt\ \mathrm{Tr}\,[\hat{f}(0, \tfrac{1}{2} + it) V_g^{0,1/2+it}]\, t \tanh \pi t + \frac{1}{2\pi} \int_0^\infty dt\ \mathrm{Tr}\,[\hat{f}(\tfrac{1}{2}, \tfrac{1}{2} + it) V_g^{1/2,1/2+it}]\, t$$

$$\times \coth \pi t + \frac{1}{4\pi} \sum_{\substack{n \in 1/2\mathbb{Z} \\ n \geqslant 1}} (2n-1)\{\mathrm{Tr}\,[\hat{f}(n) U_g^n] + \mathrm{Tr}\,[\hat{f}(-n) U_g^{-n}]\}. \tag{22}$$

In particular

$$f(1)=\frac{1}{2\pi}\int_0^\infty dt(\Theta^{0,1/2+it}(f\,)t\,\tanh\,\pi t+\Theta^{1/2,1/2+it}(f\,)t\,\coth\,\pi t)$$

$$+\frac{1}{4\pi}\sum_{\substack{n\in 1/2\mathbb{Z}\\ n\geqslant 1}}(2n-1)[\Theta^{n}(f\,)+\Theta^{-n}(f\,)]$$

with

$$\Theta^{0,1/2+it}(f\,)=\int_G dg\;f(g^{-1})\Theta^{0,1/2+it}(g).$$

Here $\Theta^{0,1/2+it}$ and $\Theta^{1/2,1/2+it}$ denote the characters of the principal continuous series and Θ^{n} and Θ^{-n} those of the discrete series. Only the discrete and the principal continuous series contribute to the support of the Plancherel measure in $\hat{G}$ in the Plancherel theorem for a general group element g of SL(2,$\mathbb{R}$).

In Einstein's gravity a parametrization of the coset space is given: the upper half-plane. Therefore the formula has to be applied to $\mathbb{H}$. One starts with a function $f\in\mathscr{S}(\mathbb{H})$, which is left and right invariant under the action of the elliptic part K of the group. This leads to the conclusion that the irreducible characters associated with K do not contribute to the Fourier inversion formula for such functions. Without loss of generality g can be taken to be a regular element of the hyperbolic part of the group G'_{hyp}. One calculates

$$\mathrm{Tr}\;\hat{f}(n)U_g^n=\mathrm{Tr}\left(\int_G dl\;f_g(l)U_{l^{-1}}^n\right).$$

Here f_g is both left and right invariant under the action of K, too. The representation $U_{l^{-1}}^n$ is explicitly known. It acts on holomorphic functions s on $\mathbb{H}$ in the following manner:[23]

$$U_{l^{-1}}^n s(z)=\frac{1}{(cz+a)^{2n}}\,s\left(\frac{az+b}{cz+d}\right),\quad l^{-1}=\begin{pmatrix}a & b\\ c & d\end{pmatrix}.$$

For a rotation matrix l the action reads

$$U_{l^{-1}}^n s(z)=\frac{1}{(\sin(\theta/2)z+\cos(\theta/2))^{2n}}\,s\left(\frac{\cos(\theta/2)z-\sin(\theta/2)}{\sin(\theta/2)z+\cos(\theta/2)}\right).$$

The integrand is a holomorphic function on $\mathbb{H}$ and the path of integration is a closed circle around zero. Therefore the integral vanishes and the discrete series does not contribute to the Plancherel formula on $\mathbb{H}$.

The characters of the continuous series enter into the formula in two places.

Due to the symmetry the coth-part denoted by $f_2(g)$ does not contribute to the formula either. By translation all group elements are obtained from unity and

$$\mathrm{Tr}\,[\hat{f}(\tfrac{1}{2},\tfrac{1}{2}+it)V_g^{1/2,1/2+it}]=\Theta^{1/2,1/2+it}(f_g);\tag{23}$$

f_g is two-sided K-invariant leading to $f_g(g)=f_g(-g)$. The character $\Theta^{1/2,1/2+it}$ is[22]

$$\Theta^{1/2,1/2+it}(g)=\begin{cases}\dfrac{\cos\,t\tau}{|\sinh\,\tau|}, & g=g_0a_\tau g_0^{-1}\in G'_{\mathrm{hyp}},\\ -\dfrac{\cos\,t\tau}{|\sinh\,\tau|}, & g=-g_0a_\tau g_0^{-1}\in G'_{\mathrm{hyp}},\\ 0, & g\in G'_{\mathrm{ell}}\cup G_{\mathrm{par}}.\end{cases}$$

It follows that $\Theta^{1/2,1/2+it}(g)=\Theta^{1/2,1/2+it}(-g)$, i.e., the character is point symmetric in τ and (23) vanishes. That is, the coth-part does not contribute to the Plancherel theorem on the upper half-plane, either.

Given a representation space, which is the Poincaré upper half-plane here, it is now possible to prove that the Plancherel theorem on $\mathrm{SL}(2,\mathbb{R})/\mathrm{SO}(2)$ can be written such that the eigendistributions of the Casimir operator appear as integrand in the formula! This is an application of the known Fourier inversion theorem of zonal functions to this situation.

Theorem 2: *For* $f\in\mathscr{S}(\mathbb{H})$,

$$f(\omega,\tau)=\frac{1}{\pi^2}\int_{L\in\mathbb{R}}dL\int_{t\in\mathbb{R}}dt\ \hat{f}(L,t)e_{L,t}(\omega,\tau)t\ \sinh\ \pi t$$

where

$$e_{L,t}(\omega,\tau)=\exp\ (-iL\omega)\sqrt{\tau}K_{it}(|L|\tau),\quad \text{if } L\neq 0,$$

and

$$\hat{f}(L,t)=\int_{\mathbb{H}}d\omega d\tau\ \frac{f(\omega,\tau)\overline{e_{L,t}(\omega,\tau)}}{\tau^2}.$$

Proof: It is sufficient to show that the tanh part of the Plancherel formula (22), denoted by $f_1(g)$, is equivalent to this lemma. The nuclear spectral theorem[24] yields

$$\begin{aligned}f(\omega,\tau)&=2\pi\int_{L\in\mathbb{R}}dL\int d\lambda(t)\ \hat{f}(L,t)e_{L,t}(\omega,\tau)\\&=2\pi\int d\lambda(t)\int_{\tilde{\omega}\in\mathbb{R}}d\tilde{\omega}\int_{\tilde{\tau}\in\mathbb{R}_+}d\tilde{\tau}\,\frac{f(\tilde{\omega},\tilde{\tau})}{\tilde{\tau}^2}\left(\int_{L\in\mathbb{R}}dL\ \overline{e_{L,t}(\tilde{\omega},\tilde{\tau})}e_{L,t}(\omega,\tau)\right).\end{aligned}\tag{24}$$

The inner integral can be evaluated using the calculus of residues, which leads to an orthogonality relation for the K–Bessel functions:

$$\int_{L\in\mathbb{R}}dL\ \overline{e_{L,t}(\tilde{\omega},\tilde{\tau})}e_{L,t}(\omega,\tau)=\delta(\omega-\tilde{\omega})\,\delta(\tau-\tilde{\tau})\ \frac{\pi}{4\cosh\ t\pi}.\tag{25}$$

Substitution of (25) into (24) yields

$$f(\omega,\tau)=\frac{\pi^2}{2}\int_{t\in\mathbb{R}}d\lambda(t)\int_{\tilde{\omega}\in\mathbb{R}}d\tilde{\omega}\ \frac{f(\tilde{\omega},\tilde{\tau})}{\tilde{\tau}^2}\delta(\omega-\tilde{\omega})\,\delta(\tau-\tilde{\tau})\ \frac{1}{\coth\ \pi t}.\tag{26}$$

On the other hand $f_1(g)=f_{1,g}(1)$. Therefore, and because $\mathrm{SL}(2,\mathbb{R})$ is unimodular, $f_1(g)$ is transformed into

$$f_1(g)=\frac{1}{2\pi}\int_0^\infty dt\Theta^{0,1/2+it}(f_g)t\ \tanh\ \pi t=\frac{1}{2\pi}\int_0^\infty dt\int_G d\tilde{g}\,f_g(\tilde{g}^{-1})\Theta^{0,1/2+it}(\tilde{g})t\ \tanh\ \pi t.$$

The character is symmetric with respect to t (Ref. 22) and the $\mathrm{SL}(2,\mathbb{R})$ acts on the upper half-plane leading to

$$f_1(h)=\frac{1}{4\pi}\int_{-\infty}^{\infty}dt\int_{\mathbb{H}}d\tilde{h}\,f_h(\tilde{h}^{-1})\Theta^{0,1/2+it}(\tilde{h})t\,\tanh\,\pi t$$

$$=\frac{1}{4\pi}\int_{-\infty}^{\infty}dt\int_{\mathbb{H}}d\tilde{h}\,f_h(\tilde{h})\Theta^{0,1/2+it}(\tilde{h}^{-1})t\,\tanh\,\pi t$$

$$=\frac{1}{4\pi}\int_{-\infty}^{\infty}dt\int_{\mathbb{H}}d\tilde{h}\,f(\tilde{h})\Theta_h^{0,1/2+it}(\tilde{h}^{-1})t\,\tanh\,\pi t. \tag{27}$$

The normed character ($\Phi^{0,1/2+it}(e)=1$) is

$$\Theta^{0,1/2+it}(g)=\begin{cases}\cos\,t\tau, & g=g_0a_\tau g_0^{-1}\in G'_{\mathrm{hyp}},\\ 0, & \text{otherwise.}\end{cases}$$

Equations (26) and (27) yield

$$\lambda'(t)=\frac{1}{4\pi}\,\Theta^{0,1/2+it}(e)t\,\tanh\,\pi t\,\frac{2}{\pi^2}\cosh\,\pi t=\frac{t\,\sinh\,\pi t}{2\pi^3}\,\Theta^{0,1/2+it}(e),$$

and therefore

$$\lambda'(t)=\frac{1}{2\pi^3}\,t\,\sinh\,\pi t.$$

This concludes the proof. □

This Fourier inversion formula corresponds to a simultaneous diagonalization of the Casimir operator and the differential operator corresponding to the generator of the Lie algebra, which has a 1 in the upper right corner and 0's elsewhere. The charge L appears explicitly.

On the algebraic level $\widehat{J^0}$ belongs to the generator diag $(1,-1)$. The representation most suitable for the mass M yields another Plancherel inversion formula. Given a $f\in\mathscr{S}(\mathbb{H})$, this function can be written as

$$f(\omega,v)=C\int_{M\in\mathbb{R}}dM\int_{t\in\mathbb{R}}dt\;\hat{f}(M,t)g_{M,t}(\omega,v)d\lambda(M,t),$$

where

$$g_{M,t}(\omega,\tau)=\omega^{iM}\sqrt{v}(1+v^2)^{iM/2-1/4}\mathrm{P}^{-\kappa/2}_{-iM-1/2}\left(\frac{1}{\sqrt{1+v^2}}\right),\quad\text{if } M\neq 0,$$

and

$$\hat{f}(M,t)=\int_{\mathbb{H}}d\omega dv\;\frac{f(\omega,v)\overline{g_{M,t}(\omega,v)}}{v^2\omega}.$$

After the diagonalization of the Casimir operator the Wheeler–DeWitt equation is transformed into

$$\psi''+\left(4-\frac{2\lambda}{f^2}\right)\psi=0. \tag{28}$$

Here λ denotes the eigenvalue of the Casimir operator. Equation (28) can be interpreted as an evolution equation in the coordinate f. In contrast to ρ, f has a physical meaning as $1/f$ is the curvature of the two-spheres. Hence it is also a physical parameter. Equation (28) is a second-order differential equation and therefore there does not exist a positive semi-definite probability density which is invariant under SL(2,$\mathbb{R}$) transformations and conserved during evolution. This

situation is comparable with the one in the case of the Klein–Gordon equation: a conserved current can be associated to the Klein–Gordon equation, but the zero component of the current is not positive definite. Feshbach and Villar[26] interpreted j_0 as a charge density which measures the difference between the numbers of positive and negative charges. In the one-particle case, they showed that the density carries either a positive or a negative sign and that the two degrees of freedom of the second-order differential equation are identified as two possible but equivalent charge states. In Ref. 26 it is outlined that although the nonrelativistic equation only admits charges of one sign, in the relativistic generalization two signs of the charge happen to appear. The two equivalent charge states are basically obtained by transforming the Klein–Gordon equation into a symmetrized Schrödinger equation, i.e., a system of first-order differential equations. Now Eq. (28) is investigated in two steps. At first, the summand $-(2\lambda/f^2)$, is considered to be an f-dependent perturbation and is neglected. This ''free'' equation can easily be solved and two equivalent states are found. The second step consists of the investigation of the ''perturbed'' system. For λ given and finite the solution approaches the free solution in the limit $f\to\infty$. This fixes the asymptotic behavior of the solution. The two linear independent solutions can then again be shown to form two equivalent but independent states.

The ''free'' differential equation $\psi_0''+4\psi_0=0$ has the solution $\psi_0(f)=C_1e^{2if}+C_2e^{-2if}$. It follows that

$$\psi_0^*\partial_f\psi_0-\psi_0\partial_f\psi_0^*=\frac{i}{4}(\chi_0^*\chi_0-\phi_0^*\phi_0)=\frac{i}{4}(|C_1|^2-|C_2|^2)$$

with $\phi_0=C_1e^{2if}$ and $\chi_0=C_2e^{-2if}$. It is not difficult to solve the differential equation (28). The solutions with the proper asymptotic behavior turn out to be the Bessel functions of third kind $H_\nu^{(1)}$ and $H_\nu^{(2)}$:

$$\psi(f)=C_1\sqrt{f}H_\nu^{(1)}(2f)+C_2\sqrt{f}H_\nu^{(2)}(2f),\quad \nu=\tfrac{1}{2}\sqrt{1+8\lambda}.$$

Using that the complex conjugate of $H_\nu^{(1)}$ is $H_\nu^{(2)}$, the density is calculated to be

$$\begin{aligned}\psi\partial_f\psi-\psi\partial_f\psi&=2C_1^2f[H_\nu^{(2)}(2f)\partial_fH_\nu^{(1)}(2f)-H_\nu^{(1)}(2f)\partial_fH_\nu^{(2)}(2f)]\\&\quad+2C_2^2f[H_\nu^{(1)}(2f)\partial_fH_\nu^{(2)}(2f)-H_\nu^{(2)}(2f)\partial_fH_\nu^{(1)}(2f)]\\&=\frac{8i}{\pi}(|C_1|^2-|C_2|^2).\end{aligned}\tag{29}$$

The last equality uses the Wronskian of $H_\nu^{(1)}$ and $H_\nu^{(2)}$. The choice of the equivalent states is not unique as the scalar product is only defined up to phase. With the scalar product given the states are fixed in the evolution of f. Here one finds

$$\phi=\tfrac{1}{2}(\partial_f\psi+i\psi)\quad\text{and}\quad\chi=\tfrac{1}{2}(\partial_f\psi-i\psi).$$

In these new variables the density ρ reads $\rho=2i(\chi\chi^*-\phi\phi^*)$, yet the physical meaning of this discrete symmetry (''charge conjugation'') is not clear.

There is a nice relation between the quantization of the four-dimensional reduced SO(3) symmetric gravity in its dual representation and a WZNW model in the point particle version, which is further reduced to a Liouville theory.[27] There are also some important differences which lead to a deeper understanding of the quantization of the system dealt with in this paper. Performing the reduction to Liouville theory Fülöp ended with a Hamiltonian system with constraints, which correspond to initial values. Choosing these initial values the Hamiltonian of the latter system has exactly the form of the remaining part of the Wheeler–DeWitt equation (28), where the initial values take the place of the eigenvalue of the Casimir operator. The Liouville Hamiltonian is interpreted to be the Hamiltonian of a relativistic particle which moves in a potential. Formally, there are three cases to be distinguished depending on the sign of the constant λ for the initial values. If $\lambda>0$, the particle is repelled by an infinitely high potential barrier, when it travels in the negative f direction. For $\lambda=0$ the particle is free, and for $\lambda<0$ an infinitely deep potential

valley attracts the particle towards the negative f direction. This interpretation is in agreement with the group theoretical facts. $\lambda>0$ corresponds to $\lambda=s(1-s)=\frac{1}{4}+t^2$ and these are the values of the continuous series, which lead to ''scattering states''. $\lambda<0$ means $\lambda=n(1-n)$, $n\in\mathbb{Z}/2$, $n>1$, that is, it is an element of the discrete series of representation theory. Bound states are obtained. Here $\lambda\geqslant 0$ holds, because the Casimir operator can be shown to be the square of the charge and the mass operator. If the Casimir operator on the group would no longer be positive semi-definite, one would expect the discrete series of representations to play a role. The spectra of the physical operators would have a discrete part. However, in the case of stationary SO(3) symmetric gravity this argumentation is certainly not more than a consistency check: here the coordinate f has no intrinsic group theoretical meaning, contrary to the situation which occurs in the Liouville model. It is a ''gravitational remnant.''

Another important difference is that Fülöp considers the momenta of the particle to be fundamental. In particular they become Hermitian operators. Here, as the physical meaning is contained in the currents, there is no reason for the momenta to become Hermitian operators. Moreover, it turns out that starting with Hermitian momenta the currents are non-Hermitian. On the other hand, the conditions that $\widehat{J^0}$, $\widehat{J^+}$, and $\widehat{J^-}$ are Hermitian defines these operators to be Lie derivatives. This also fixes the operator ordering of the Laplacian and therefore of the Hamiltonian, too.

IV. RESULTS AND DISCUSSION

After proper dimensional reduction the SO(3) symmetric sector of Einstein's vacuum theory can be identified with an $\mathrm{SL}(2,\mathbb{R})/\mathrm{SO}(2)$ sigma model coupled to a gravitational remnant which belongs to a gauge degree of freedom. The gravitative part describes an evolution in the radius of the two-spheres. The ''true'' dynamical degrees of freedom are entirely hidden in the sigma model. In addition to the mass m another parameter of the classical space of solutions—the charge l—shows up. The invariance of the Lagrangian under the group $\mathrm{SL}(2,\mathbb{R})$ offers the key to quantize this part of gravity. The Hilbert space measure is given by the Haar measure of the group. The physical operators are self-adjoint due to the unitarity of the representations of $\mathrm{SL}(2,\mathbb{R})$ used here. The spectra of the mass and the charge operators are purely continuous and consist of the whole real axis. The spectrum of the Casimir operator is $[\frac{1}{4},\infty]$. In a modified Hamiltonian formalism the invariant differential operator on the group—the Casimir operator—appears quite naturally in the Hamiltonian constraint known as the Wheeler–DeWitt equation at the quantum level. After the diagonalization of the Casimir operator the Wheeler–DeWitt equation is reduced to an ordinary differential equation of second order which can be interpreted as Schrödinger equation for two equivalent states. Although this differential equation is of second order a positive definite scalar product on a not uniquely determined subspace can be defined. It is possible to diagonalize the Casimir operator and the mass operator or the charge operator simultaneously. The part of the eigendistributions not increasing more rapidly than a polynomial yields a spectral decomposition of the Laplacian. In the case of the mass operator one finds essentially associated Legendre functions, and in the case of the charge operator there appear K-Bessel functions. The Plancherel formula of $\mathrm{SL}(2,\mathbb{R})$, which allows us to decompose each function on the group into irreducible parts, can be applied to the coset space $\mathrm{SL}(2,\mathbb{R})/\mathrm{SO}(2)$. In the case of group $\mathrm{SL}(2,\mathbb{R})$ the continuous and the discrete series support the Plancherel measure whereas on the coset space one is left with one part of the continuous series.

The group theoretical methods are not limited to the situation here. They are applicable to various other stationary and static sectors of models in string theory and supergravity as well as to cosmological models. A list of models can be found in Ref. 3.

APPENDIX:

1. The isomorphism between SL(2,$\mathbb{R}$)/SO(2) and $\mathbb{H}$

One realization of the coset space SL(2,$\mathbb{R}$)/SO(2) is the Poincaré upper half-plane $\mathbb{H}$. The isomorphism is established now.[28] Each element g of the group SL(2,$\mathbb{R}$) can be represented by a 2×2 matrix with real entries and determinant equal to one:

$$\mathrm{SL}(2,\mathbb{R}) := \left\{ g=\begin{pmatrix} a & b \\ c & d \end{pmatrix}, \quad ad-bc=1 \right\};$$

$\mathbb{H}$ is defined to be

$$\mathbb{H} := \{ z=\omega+i\tau\in\mathbb{C}, \tau>0 \}.$$

Let the SL(2,$\mathbb{R}$) act on $\mathbb{H}$ in the following manner:

$$g\circ z=\frac{az+b}{cz+d}.$$

It is easy to see that the mapping $g\mapsto g\circ i$ from SL(2,$\mathbb{R}$) into $\mathbb{H}$ induces a bijection SL(2,$\mathbb{R}$)/SO(2)$\rightarrow\mathbb{H}$.

2. The representations of SL(2,$\mathbb{R}$)

The classification of the unitary irreducible representations of SL(2,$\mathbb{R}$) is due to Bargman:[23]

(1) the principal continuous series $V^{j,s}$, $j=0,\ \frac{1}{2}$, $s=\frac{1}{2}+it$, $t\in\mathbb{R}$ (if $j=0$, then $t>0$, and if $j=\frac{1}{2}$, then $t\geqslant 0$),
(2) the limit of the discrete series $U^{1/2}$, $U^{-1/2}$,
(3) the discrete series U^{n}, U^{-n}, $n\in\mathbb{Z}/2$, $n>\frac{1}{2}$,
(4) the complementary series V^{σ}, $\frac{1}{2}<\sigma<1$, and
(5) the trivial representation.

Let λ denote the eigenvalue of the Casimir operator. To the five cases listed above there correspond the following eigenvalues:

(1) $\lambda=s(1-s)$,
(2) $\lambda=\frac{1}{4}$,
(3) $\lambda=n(1-n)$,
(4) $\lambda=\sigma(1-\sigma)$, and
(5) $\lambda=0$.

That is, group theory yields a restriction of the eigenvalues of the Casimir operator and some formal solutions of the differential equations are excluded from the Hilbert space by group theoretical arguments, namely the case $1-4\lambda>0$ mentioned above. To the representations there correspond characters, which are class functions. To evaluate and to apply them it is quite natural to factor the group by the Iwasawa decomposition into an elliptic, a hyperbolic, and a parabolic part, which are denoted by G_{ell}, G_{hyp}, and G_{par}, respectively. Now it is outlined how to proceed.

3. The Iwasawa decomposition of SL(2,$\mathbb{R}$)

Each 2×2 matrix of SL(2,$\mathbb{R}$) can be written as a product of a rotation matrix, the elliptic part of SL(2,$\mathbb{R}$), a diagonal matrix with entries either both positive or both negative, the hyperbolic part of the group, and one matrix with a Jacobi-like upper triangular form, which parametrizes the parabolic part of the group:

$$\mathrm{SL}(2,\mathbb{R})=KAN, \quad g=u_{\theta}a_{\tau}\eta_{\omega},$$

with

$$u_\theta = \begin{pmatrix} \cos\frac{\theta}{2} & \sin\frac{\theta}{2} \\ -\sin\frac{\theta}{2} & \cos\frac{\theta}{2} \end{pmatrix}, \quad a_\tau = \begin{pmatrix} \tau & 0 \\ 0 & \tau^{-1} \end{pmatrix}, \quad \eta_\omega = \begin{pmatrix} 1 & \omega \\ 0 & 1 \end{pmatrix},$$

where τ is assumed to be positive. Denote $H := A \cup (-1)A$. Then G_{hyp}, G_{ell}, and G_{par} are defined by

$$G_{\text{hyp}} := \bigcup_{g \in G} gHg^{-1}, \quad G_{\text{ell}} := \bigcup_{g \in G} gKg^{-1}, \quad G_{\text{par}} := \bigcup_{g \in G} g(\pm N)g^{-1}.$$

Furthermore, the group $\mathrm{SL}(2,\mathbb{R})$ can be decomposed into disjoint parts of classes of regular elements, i.e., elements with distinct eigenvalues, G''_{ell}, G''_{hyp}, and G''_{par}. G''_{par} is the empty set. G may be represented as the product of G''_{ell}, G''_{hyp}, and G_{par}. The series of the unitary irreducible representations correspond in a one-to-one manner to the factors of the Iwasawa decomposition: the discrete series to the elliptic part, the continuous one to the hyperbolic factor, and the complementary series to the parabolic one.

4. Some relevant spaces

Before dealing with the decomposition of a function on $\mathrm{SL}(2,\mathbb{R})$ into its irreducible parts, the space of rapidly decreasing functions $\mathscr{S}(G), G = \mathrm{SL}(2,\mathbb{R})$ has to be introduced (see Ref. 24):

$$\mathscr{S}(G) := \left\{ f \in C^\infty(G) : \sup_{g \in G} \frac{(\omega^2(1+\tau)^2)^N}{\tau^N} |(D^\alpha f)(g)| < \infty, \quad \forall N \right\}.$$

The tempered distributions $\mathscr{S}'(G)$ are the dual space of the space of the rapidly decreasing functions. They are called slowly increasing. The triplet $\mathscr{S}(G), L^2(G, d\mu_G)$, and $\mathscr{S}'(G)$ is called a Gel'fand triplet. $d\mu_G$ denotes the Haar measure on $\mathrm{SL}(2,\mathbb{R})$. It holds

$$\mathscr{S}(G) \subset L^2(G, d\mu_G) \subset \mathscr{S}'(G).$$

As already mentioned above, $\mathscr{H}(G, d\mu_G) = L^2(G, d\mu_G)$. $\mathscr{S}'(G)$ contains all of the spaces $\mathscr{H}(G, d\mu_n)$. $\mathscr{H}(G, d\mu_G)$ denotes the Hilbert space of functions on G, which are measurable with respect to the Haar measure of G.

The complete Schwarzschild interior and exterior solution in the harmonic coordinate system

Quan-Hui Liu[a)]
Department of Physics, Hunan University, Changsha 410082, People's Republic of China, and Institute of Theoretical Physics, Academia Sinica, P.O. Box 2735, Beijing 100080, People's Republic of China[b)]

(Received 12 January 1998; accepted for publication 23 July 1998)

An exact solution of Schwarzschild interior and exterior solution for a star which has a uniform density and whose center pressure approaches infinite, in the harmonic coordinate system, is given. This solution enables us to demonstrate that in known literatures, a term in the Schwarzschild exterior solution is usually ignored in such a system. Neglect of the term directly leads to contradiction of the continuity of the Schwarzschild interior and exterior solution expressed in the system. © *1998 American Institute of Physics.* [S0022-2488(98)02911-9]

The Harmonic coordinate system (HCS) is an important coordinate system in general relativity. It can be used in studying, e.g., the gravitational fields produced by stable stars,[1–3] black holes,[4,5] gravitational waves,[6] supergravity,[7] quantum gravity,[8] etc. The most fundamental result of HCS is the usual Schwarzschild exterior solution (ES) under HCS.[1] In this paper, we are going to point out that the fundamental ES is not complete indeed if both the Schwarzschild interior solution (IS) and ES are transformed into those in the HCS and then examine their continuity at the boundary.

For simplicity, we will use the rational units in which gravitational constant G and light velocity c are unity.

At first let us examine the general Schwarzschild type solution in the so-called standard coordinate system (SCS)[1] as

$$d\tau^2=E(r)dt^2-G(r)dr^2-r^2(d\theta^2+\sin^2\theta\, d\phi^2). \tag{1}$$

This solution can be expressed in the following coordinates X_μ ($\mu=0,1,2,3$):

$$X_0=t, \tag{2}$$

$$X_1=R(r)\sin\theta\cos\phi, \tag{3}$$

$$X_2=R(r)\sin\theta\sin\phi, \tag{4}$$

$$X_3=R(r)\cos\theta. \tag{5}$$

In these coordinates, the proper time (1) becomes:[1]

$$d\tau^2=E(r)dt^2-\frac{r^2}{R^2}d\mathbf{X}^2-\left(\frac{G}{R^2R_r'^2}-\frac{r^2}{R^4}\right)(\mathbf{X}\cdot d\mathbf{X}), \tag{6}$$

where $R_r'=dR/dr$.

In the new coordinates, the continuity of the solution at the surface of a spherically symmetrical star of radius a is that the metric components and the so-called extrinsic curvature[9] are continuous at $r=a$, respectively. For metric (6) they are

a)Electronic mail: liuqh@itp.ac.cn
b)Mailing address.

 © 1998 American Institute of Physics

$$E_{\rm in}(a)=E_{\rm ex}(a),\quad G_{\rm in}(a)=G_{\rm ex}(a),$$
$$R_{\rm in}(a)=R_{\rm ex}(a),\quad R'_{\rm in}(a)=R'_{\rm ex}(a). \tag{7}$$

where subscripts ''in'' and ''ex'' denote the interior and exterior solution of E, G and R in Eq. (6) respectively.

The coordinates X_μ are to be harmonic if and only if they satisfy the harmonic condition:

$$\Box^2 X_\mu \equiv g^{\lambda\nu}\left[\frac{\partial^2 X_\mu}{\partial x^\nu \partial x^\lambda}-\Gamma^\gamma_{\lambda\nu}\frac{\partial X_\mu}{\partial x^\gamma}\right]=0. \tag{8}$$

It leads to that $R(r)$ must satisfy the differential equation:[1]

$$\frac{d}{dr}\left[r^2\sqrt{\frac{E(r)}{G(r)}}\frac{dR}{dr}\right]-2\sqrt{E(r)G(r)}R=0. \tag{9}$$

Evidently, only after $R(r)$ is solved can we say the metric (6) in HCS is obtained. So, it is necessary to solve ES $R_{\rm ex}(r)$ and IS $R_{\rm in}(r)$, respectively. For ES, $R_{\rm ex}(r)$ is easily available. We have known ES in the SCS for a long time as[1,2,10]

$$E_{\rm ex}(r)=1-\frac{2M}{r}, \tag{10}$$

$$G_{\rm ex}(r)=\frac{1}{1-2M/r}, \tag{11}$$

in which M is a constant of integration. Substituting these relations into Eq. (9), we have

$$\left(1-\frac{2M}{r}\right)R''_{rr}+\frac{2}{r^2}(r-M)R'_r-\frac{2R}{r^2}=0. \tag{12}$$

The general form of the ES $R_{\rm ex}(r)$ is in the interval $0<|r-2M|<\infty$:

$$R_{\rm ex}(r)=C(r-M)+C_1\left[\frac{r-M}{2M}\ln\left(1-\frac{2M}{r}\right)+1\right], \tag{13}$$

where C and C_1 are two arbitrary constants and the constant C can be conveniently chosen to be 1. It is evident in mathematics that the second term cannot be discarded, or say, we cannot put $C_1=0$, when the solution applying to physics objects with $r>2m$. Note that for all spherically symmetrical stable stars, uniform or not, $r\geqslant 9M/4>2M$ always holds.[1] It means that this term probably plays a role for all stars, otherwise the last two equations in continuity equations (7) are not compatible. Surprisingly, in known literature, for example, Refs. 1–5 and 8, C_1 is made zero. In the rest of this paper, an exact solvable star model is given to demonstrate $C_1\neq 0$.

As is well-known, solving IS $R_{\rm in}(r)$ from Eq. (9) is not so simple because the explicit forms of ISs depend on the structure of the stars. For some stars, solving Eq. (9) is mathematically formidable. Fortunately, for a uniform density star whose center pressure approaches infinity, Eq. (9) can be solve analytically. The explicit form of IS for this star will be presented.

First, we need to know the metric components $E_{\rm in}(r), G_{\rm in}(r)$ of IS in the SCS. For an arbitrary uniform density star in the SCS they are in general:[10]

$$E_{\rm in}(r)=\left[A-B\sqrt{1-\frac{r^2}{R_0^2}}\right]^2, \tag{14}$$

$$G_{\rm in}(r)=\frac{1}{1-r^2/R_0^2}, \tag{15}$$

where $R_0^2=3/(8\pi\rho_0)$,[10] A and B are two constants of integration. The above IS can be simplified by considering the internal pressure $p(r)$ of the star, which is[10]

$$8\pi p(r)=\frac{1}{R_0}\left(\frac{3B\xi(r)-A}{A-B\xi(r)}\right), \tag{16}$$

where $\xi(r)=\sqrt{1-r^2/R_0^2}$. Since the pressure equals zero at the surface of the sphere $r=a$, we have

$$3B\xi(a)-A=0, \tag{17}$$

which shows that constants A and B are not independent. And since the star we are interested in has infinite pressure at $r=0$, we have from Eqs. (16) and (17) two relations:

$$A=B, \quad a=\sqrt{\frac{8}{9}}R_0. \tag{18}$$

Substituting these relations into Eqs. (14) and (15) we have the simplified forms of $E_{\text{in}}(r)$ and $G_{\text{in}}(r)$ as

$$E_{\text{in}}(r)=A^2\left[1-\sqrt{1-\frac{8r^2}{9a^2}}\right]^2, \tag{19}$$

$$G_{\text{in}}(r)=\frac{1}{1-8r^2/9a^2}. \tag{20}$$

There are still two arbitrary constants A in IS (19) and M in ES [(10) and (11)]. We can fix them by utilizing the first two equations in (7). And they give:

$$M=\frac{4}{3}\pi\rho_0 a^3, \quad A=\frac{1}{2}, \quad a=\frac{9M}{4}. \tag{21}$$

So far, both the ES [(10) and (11)] and the IS [(19) and (20)] in the SCS for the special uniform density star are complete.

Second, we need to know the IS $R_{\text{in}}(r)$ in the HCS. From Eq. (9) and the above results the equation determining the IS $R_{\text{in}}(r)$ can be established as

$$R''_{rr}+R'_r\left[\frac{2}{r}+\frac{r}{R_0^2}\frac{1}{[1-\xi(r)]\xi(r)}-\frac{r}{R_0^2}\frac{1}{\xi^2(r)}\right]-\frac{2R}{r^2\xi^2(r)}=0. \tag{22}$$

After lengthy and delicate work, we obtain the following general solution of Eq. (22):

$$R_{\text{in}}(r)=C_2 z^{n/2}(1-z)^{m/2}F(\alpha,\beta,\gamma;z)+C_3 z^{n/2}(1-z)^{m/2}z^{1-\gamma}F(\alpha-\gamma+1,\beta-\gamma+1,2-\gamma;z), \tag{23}$$

in which

$$n=\frac{-3+\sqrt{17}}{2}, \tag{24}$$

$$m=1, \tag{25}$$

$$\alpha=\frac{m+n}{2}=\frac{-1+\sqrt{17}}{4}, \tag{26}$$

$$\beta=\frac{m+n+6}{2}=\frac{11+\sqrt{17}}{4}, \tag{27}$$

$$\gamma=\frac{2n+5}{2}=\frac{2+\sqrt{17}}{2}, \tag{28}$$

$$z=\tfrac{1}{2}(1-\xi(r)), \tag{29}$$

$$F(\alpha,\beta,\gamma;z)=1+\sum_{k=1}^{\infty}\frac{(\alpha)_k(\beta)_k}{(\gamma)_k}\frac{z^k}{k!}, \tag{30}$$

$$(\alpha)_k=\alpha(\alpha+1)(\alpha+2)\cdots(\alpha+k-1), \tag{31}$$

C_2 *and* C_3 *are two arbitrary constants.* (32)

Thus the general ES $R_{\rm ex}(r)$ and IS $R_{\rm in}(r)$ for the special uniform density star are all obtained. Now we are in a position to discuss the constants C_1, C_2, C_3 in Eqs. (13) and (23). Evidently we must set $C_3=0$ for $z^{n/2+1-\gamma}\sim r^{-1/4(3+\sqrt{17})}\to\infty$ at the vicinity $r=0$. And importantly, we cannot set $C_1=0$ again. Otherwise the mathematical consistency of the last two equations in continuity equations (7) will be violated. In fact the constants C_1 and C_2 are

$$C_1=\frac{(a-M)g'(a)-g(a)}{g(a)f'(a)-g'(a)f(a)}, \tag{33}$$

$$C_2=\frac{(a-M)f'(a)-f(a)}{g(a)f'(a)-g'(a)f(a)}, \tag{34}$$

where

$$f(r)=\frac{r-M}{2M}\ln\left(1-\frac{2M}{r}\right)+1, \tag{35}$$

$$g(r)=z^{n/2}(1-z)^{m/2}F(\alpha,\beta,\gamma;z). \tag{36}$$

Substituting the results (21) into C_1 and C_2, they are simply:

$$C_1=0.060\,498a, \tag{37}$$

$$C_2=0.594\,473a. \tag{38}$$

Now the complete forms of the IS $R_{\rm in}(r)$ and ES $R_{\rm ex}(r)$ in HCS are obtained as

$$R_{\rm ex}(r)=(r-M)+0.060\,498a\left[\frac{r-M}{2M}\ln\left(1-\frac{2M}{r}\right)+1\right], \tag{39}$$

$$R_{\rm in}(r)=0.594\,473az^{n/2}(1-z)^{m/2}F(\alpha,\beta,\gamma;z). \tag{40}$$

In other words, from Eqs. (2)–(6), the complete Schwarzschild interior and exterior solution in the HCS for the star is obtained. As we expected, the constant C_1 has a nonvanishing value. The curve showing $R(r)$ versus r is plotted in Fig. 1, in which we can see the curve at point $r=a$ is smoothly connected indeed.

In summary, we can conclude that the usual ES in HCS is not complete in mathematics, or strictly speaking, is not the correct mathematical solution in HCS corresponding to the ES in the SCS, for a term is neglected as $C_1=0$. The neglected term reflects how the presence of the mass distribution affects the HCS in the surrounding empty space; it is a purely general-relativistic consequence. However, this does not mean that the usual ES are not a correct solution of the Einstein field equation. In fact they are. In light of the principles in general relativity which permits us to use arbitrary coordinate systems, the usual ES in HCS is an exterior solution in a new coordinate system X_μ (2)–(5) with $R(r)=r-M$. But the new coordinate system is not the

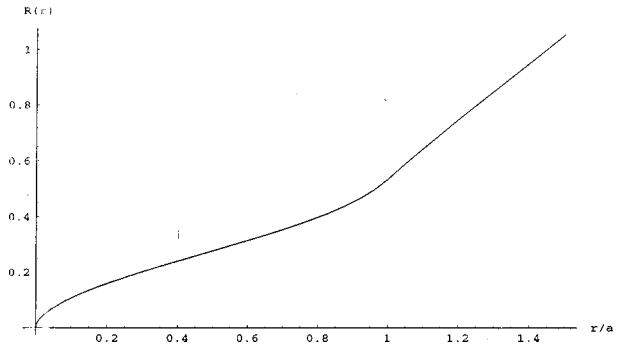

FIG. 1. The curve showing the function relation between $R(r)$ and r in the interval [0,1.5a].

complete HCS at all; and surprisingly, all literature used the HCS in this incomplete sense when an explicit form of HCS was needed.[1–5,8] Finally, we would like to point out that sometimes the neglect of the term may not have a significant influence in physics. Even at the surface of our simplified uniform density star model, only in a percentage point of the results can this term play a role, and the proportion of the second term to the first is approximately 0.04.

ACKNOWLEDGMENTS

I am grateful to Professor Huan-Wu Peng for drawing my attention to the importance of the second term in Eq. (13) and for his encouragement. I also thank Professors Ou-Yang Zhongcan, Yuan-Zhong Zhang, Chao-Guang Huang, Yong-Qiang Yu and Shang-Wu Qian for their helpful discussions. JOURNAL OF MATHEMATICAL PHYSICS VOLUME 39, NUMBER 11 NOVEMBER 1998

Applications of topological *-algebras of unbounded operators

F. Bagarello[a)]
Dipartimento di Matematica ed Applicazioni, Facoltà di Ingegneria, Università di Palermo, I-90128 Palermo, Italy

(Received 6 April 1998; accepted for publication 4 June 1998)

In this paper we discuss some physical applications of topological *-algebras of unbounded operators. The first example is a simple system of free bosons. Then we consider other models related to this one. Finally, we discuss the time evolution of two interacting models of matter and bosons. We show that for all these systems it is possible to build up a common mathematical framework where the existence of the thermodynamical limit of the algebraic dynamics can be conveniently analyzed.
© *1998 American Institute of Physics.* [S0022-2488(98)00111-X]

I. INTRODUCTION

Since the first appearance of the algebraic approach to the quantum field theory,[1] many new results have been found and discussed in the literature showing that the structure of C^*-algebras is not rich enough in many relevant physical situations. Difficulties arise already in ordinary quantum mechanics, since the commutation rule $[x,p]=i$ implies that the operators x and p cannot be both bounded as operators on $\mathscr{L}^2(\mathbf{R})$. Obviously, even more involved is the situation for models with infinite degrees of freedom. These physical difficulties have originated much literature about unbounded operators and possible extensions of C^*-algebras: Lassner's quasi *-algebras,[2] partial *-algebras introduced by Antoine and Karwowsky,[3] CQ^*-algebras recently introduced by Trapani and the author,[4] etc. Most of these results are collected, in particular, in two books: the first, essentially mathematically oriented, was written in 1989 by Schmüdgen;[5] the second, which also contains some links with physics, was published one year later by Dubin and Hennings.[6]

These works, however, with few exceptions are mostly concerned with purely mathematical aspects of the problem, while physical applications are missing. In other words, over the years many powerful tools have been proposed, constructed, and refined, but not many relevant physical problems have been solved or even considered using these tools. The present paper tries to make a step to fill this gap. We use topological *-algebras of unbounded operators, of the kind introduced first by Lassner,[2] to show the existence of the algebraic dynamics of several physical models. We begin with an apparently innocuous model of free bosons, where the difficulty of dealing with unbounded operators already appears, and we show how this model can be regularized, using a certain cutoff, and then we prove the existence of the algebraic dynamics of the model when this cutoff is *cleverly* removed. This is the content of the first part of Sec. III. In the second part of the same section we analyze different models which are related to the free bosons by simple transformations. In Sec. IV we first consider an interacting model of single mode bosons interacting with the matter, mimicked by spin observables localized at different lattice sites, and we show again the possibility of regularizing the unbounded Hamiltonian and of finding a limit of the time evolution in a natural topology, similar to that introduced by Lassner.[2] Then we extend our procedure to a generalized version of the same model, where different kinds of bosons are considered. Section V contains the outcome of the paper. We begin, in the following section, with fixing the mathematical structure of our approach. Some of the mathematical details will be analyzed in more detail also in the Appendices.

Before starting a remark is in order: the topological structure of the algebra of the unbounded operators is not always essential. In fact, depending on the approach used for removing the cutoff,

a)Electronic mail: Bagarello@ipamat.math.unipa.it

 © 1998 American Institute of Physics

it can be sufficient to work in an algebra without making reference to any topology. This has been done, for instance, in Refs. 7 and 8, where the limit of several correlation functions of the time evolution of local and delocalized observables has been considered.

II. THE MATHEMATICAL FRAMEWORK

In this paper we will mainly consider a single mode boson oscillator. Here a and $a^\dagger$ are, respectively, the annihilation and the creation operators, satisfying the canonical commutation relation (CCR)

$$[a,a^\dagger]=\mathbb{1}. \tag{2.1}$$

We introduce in a canonical way the Hilbert space of the radiation: we consider a vector Φ_0 which is annihilated by a, and then we build up the linear span of the vectors $\{(a^\dagger)^n\Phi_0, n\in\mathbf{N}\}$, $\mathscr{D}_0$. Taking the completion of this set, we obtain the Fock space of the bosons, $\mathscr{H}$.

Let $N_0\equiv a^\dagger a$. This is a symmetric operator on $\mathscr{D}_0$ which can be uniquely extended to a self-adjoint operator N. Let $D(N^k)$ be the domain of the operator N^k, $k\in\mathbf{N}$, and $\mathscr{D}$ the domain of all the powers of N:

$$\mathscr{D}\equiv D^\infty(N)=\cap_{k\geqslant 0}D(N^k). \tag{2.2}$$

This set is dense in $\mathscr{H}$. Starting from $\mathscr{D}$ we can define, following Lassner,[2] the *-algebra $\mathscr{L}^+(\mathscr{D})$ of all the closable operators defined on $\mathscr{D}$ which, together with their adjoints, map $\mathscr{D}$ into itself. It is clear that all powers of a and $a^\dagger$ belong to this set.

In Ref. 2, the topological structures of both $\mathscr{D}$ and $\mathscr{L}^+(\mathscr{D})$ are discussed in detail; in particular, in $\mathscr{D}$ the topology is defined by the following N-depending seminorms:

$$\phi\in\mathscr{D}\rightarrow\|\phi\|_n\equiv\|N^n\phi\|, \tag{2.3}$$

where n is a natural integer, while $\|\ \|$ is the norm of $\mathscr{H}$. The topology in $\mathscr{L}^+(\mathscr{D})$ is introduced in the following way. We start defining the set $\mathscr{C}$ of all the positive, bounded and continuous functions $f(x)$ on $\mathbf{R}_+$, which are decreasing faster than any inverse power of x. The seminorms on $\mathscr{L}^+(\mathscr{D})$ are labeled by functions in $\mathscr{C}$ and by the integers $\mathbf{N}$. We have

$$X\in\mathscr{L}^+(\mathscr{D})\rightarrow\|X\|^{f,k}\equiv\max\{\|f(N)XN^k\|,\|N^kXf(N)\|\}. \tag{2.4}$$

Here $\|\ \|$ is the usual norm in $B(\mathscr{H})$. We use for this norm the same notation as in Eq. (2.3) since there is no possibility of confusion. Incidentally, we see that a possible way to look at $\mathscr{L}^+(\mathscr{D})$ is as the set of operators such that both $f(N)XN^k$ and $N^kXf(N)$ are bounded for all integers k and for all functions f in $\mathscr{C}$. Moreover, we observe that definition (2.4) easily implies the following invariance property: $\|X\|^{f,k}=\|X^\dagger\|^{f,k}$. We call τ the topology on $\mathscr{L}^+(\mathscr{D})$ defined by the seminorms (2.4). In Ref. 2 it has been proved that $\mathscr{L}^+(\mathscr{D})[\tau]$ is a complete locally convex topological *-algebra.

In the following sections a useful role will be played by some subspaces of $\mathscr{H}$ that we now introduce. We start by defining the one-dimensional spaces $\mathscr{E}_l$ as the set of all the vectors which are proportional to $(a^\dagger)^l\Phi_0$. Then we introduce the $(L+1)$-dimensional space $\mathscr{F}_L\equiv\mathscr{E}_0\oplus\mathscr{E}_1\oplus\cdots\oplus\mathscr{E}_L$, as the direct sum of the first $L+1$ spaces $\mathscr{E}_l$.

These spaces are in one-to-one correspondence with some projection operators. Let $N=\Sigma_{l=0}^\infty l\Pi_l$ be the spectral decomposition of the number operator N. The operators Π_l are projection operators, as well as the operators $Q_L=\Sigma_{l=0}^L\Pi_l$. The following properties are obvious:

$$\Pi_k\Pi_l=\delta_{kl}\Pi_l,\quad \Pi_k^\dagger=\Pi_k, \tag{2.5}$$

and

$$Q_LQ_M=Q_L\quad \text{if } L\leqslant M,\quad Q_L^\dagger=Q_L. \tag{2.6}$$

We see that $\Pi_k:\mathscr{H}\rightarrow\mathscr{E}_k$, while $Q_L:\mathscr{H}\rightarrow\mathscr{F}_L$. From Eqs. (2.5) and (2.6), or alternatively from the definitions of $\mathscr{E}_k$ and $\mathscr{F}_L$, we deduce that the spaces $\mathscr{E}_k$ are mutually orthogonal, while the $\mathscr{F}_L$ are not. Of course, the following inclusions of spaces hold:

$$\mathscr{E}_l \subset \mathscr{F}_L \subset \mathscr{F}_{L+1} \subset \mathscr{D} \subset \mathscr{H}, \tag{2.7}$$

whenever $l \leqslant L$.

In this paper we will not use another possibility which sometimes can be of a certain interest: this consists of considering, instead of $\mathscr{L}^+(\mathscr{D})$, the set $\mathscr{L}(\mathscr{D},\mathscr{D}')$ of the continuous linear maps from $\mathscr{D}$ into its dual $\mathscr{D}'$. Also in this set a topology can be defined,[2] which makes it a complete locally convex space, but the lack of a convenient algebraic structure makes this space of little use to us. In other words, while the problem of finding the time evolution of the product AB when both A and B belong to $\mathscr{L}^+(\mathscr{D})$ is well posed, this is not so in general if A and B are both elements of $\mathscr{L}(\mathscr{D},\mathscr{D}')$. As it is well known, in this case only partial multiplications could be defined, between elements in $\mathscr{L}^+(\mathscr{D})$ and elements of $\mathscr{L}(\mathscr{D},\mathscr{D}')$. A rather complete review on this and related subjects can be found in Ref. 9.

Some final comments concerning the seminorms in (2.4). The first remark is that the two contributions in the definition are exactly of the same form. The estimate of $\|f(N)XN^k\|$ is very similar to the estimate of $\|N^kXf(N)\|$. This is why in the following we will only consider the first of these contributions, identifying from now on $\|X\|^{f,k}$ simply with $\|f(N)XN^k\|$.

With this in mind, we came to the second remark, which is a consequence of the spectral decomposition for N. Using $N=\Sigma_{l=0}^{\infty} l\Pi_l$, we see that the seminorms can be written as follows:

$$X \in \mathscr{L}^+(\mathscr{D}) \to \|X\|^{f,k} = \sum_{l,s=0}^{\infty} f(l)s^k \|\Pi_l X \Pi_s\|. \tag{2.8}$$

We will denote by *physical* the topology τ generated by these seminorms, following, with some freedom, the language usually adopted in the literature.

Since in Sec. IV we will discuss an interacting model with bosons and spins, we introduce here some more relevant spaces and topologies. We refer to Ref. 10 for further details.

Let $\mathbb{Z}^d$ be a d-dimensional infinite lattice, $V \subset \mathbb{Z}^d$, and $|V|$ the number of the points of V. We call $\mathscr{A}_V$ the C^*-algebra generated by the spin operators σ_α^i, $i \in V$ and $\alpha = x,y,z$, and $\mathscr{A}_0$ the norm closure of $\cup_V \mathscr{A}_V$.

We call *relevant* a state ω over $\mathscr{A}_0$ if, denoting by $\mathscr{H}_\omega$ the Hilbert space defined by the Gel'fand–Naimark–Segal (GNS) construction on $\mathscr{A}_0$ and ω, and by Ψ_ω the vector which represents ω in $\mathscr{H}_\omega$ [$\omega(A) = \langle \Psi_\omega, \pi_\omega(A)\Psi_\omega \rangle$, for all $A \in \mathscr{A}_0$], then Ψ_ω belongs to the following set $\mathscr{F}$:

$$\mathscr{F} = \left\{ \Psi \in \mathscr{H}_\omega : \lim_{|V|,\infty} \frac{1}{|V|} \sum_{p \in V} \Pi_\omega(\sigma_3^p)\Psi = \Pi_\omega(\sigma_3^\infty)\Psi, \quad \|\Pi_\omega(\sigma_3^\infty)\| \leqslant 1 \right\}, \tag{2.9}$$

where σ_3^∞ belongs to the center of the algebra $\mathscr{A}_0$ and π_ω is the canonical representation for the spin algebra.[10]

The relevance of this set has been discussed in Ref. 10, where it has been proven, among other things, that all the powers of σ_3^V converge in the $\mathscr{F}$-strong topology (the strong topology ''restricted'' to those vectors which belong to $\mathscr{F}$), as well as the analytic functions of σ_3^V. This reflects the well known fact that σ_3^V does not converge in norm for $|V|$ increasing.[11] The topology is therefore defined by the following seminorms:

$$X \in \mathscr{A}_0 \simeq B(\mathscr{H}_{\text{spin}}) \to \|X\|^\Psi \equiv \|X\Psi\|, \tag{2.10}$$

where $\Psi \in \mathscr{F}$, X is identified with its ''canonical'' representative in $B(\mathscr{H}_{\text{spin}})$, $\mathscr{H}_{\text{spin}}$ being the infinite tensor product of two-dimensional complex spaces $\mathbf{C}_i^2$, $i \in \mathbb{Z}^d$. In this way $\mathscr{A}_0$ is canonically identified with its representative $B(\mathscr{H}_{\text{spin}})$. This identification will be used all throughout this paper in order to simplify the notation.

III. THE FREE BOSONS AND RELATED MODELS

A. The free model

In this section we propose a possible rigorous algebraic treatment of the existence of the time evolution of a single mode of radiation described by the following free Hamiltonian:

$$H=a^{\dagger}a, \tag{3.1}$$

where a and $a^{\dagger}$ are the boson operators introduced in Sec. II. Throughout this paper we will follow the general strategy usually adopted in the literature, whenever a certain mathematical rigor is required: first we regularize the Hamiltonian introducing a certain cutoff; then we obtain the equations of motion which are solved keeping this cutoff fixed, and finally we remove the cutoff. If all these steps can be performed, we define the dynamics for the ''infinite'' model as the limit of these cutoff dynamics.

The first nontrivial problem is the way of implementing this cutoff. As it is obvious from the expression of H, which is nothing but the number operator N, H is unbounded. Nevertheless, if we consider N as acting not on the whole $\mathscr{H}$ but only on some (cleverly chosen) subspaces of the Hilbert space, the unboundedness can be controlled. In fact, it is easily seen that $\|N\varphi\|<c_{\varphi}$ whenever φ is taken in any of the spaces $\mathscr{E}_l$ or $\mathscr{F}_L$, where c_{φ} is a positive constant depending on φ (and therefore on l and L). This fact suggests one consider the following regularization:

$$H_L=Q_LHQ_L\,. \tag{3.2}$$

This choice preserves the Hermitianness of the Hamiltonian and gives the following property: $\forall\varphi\in\mathscr{H}\Rightarrow H_L\varphi=Q_LH\varphi_L$, where $\varphi_L\in\mathscr{F}_L$. Therefore $\forall\varphi\in\mathscr{H}$, $\|H_L\varphi\|<c_{\varphi_L}$. However, this regularization has an unpleasant drawback already evident for the model we will discuss in some detail in Sec. IV, and which is described by the following Hamiltonian,

$$H_V=\frac{1}{|V|}\sum_{i,j\in V}\sigma_3^i\sigma_3^j+a^{\dagger}a+\gamma(a+a^{\dagger})\sigma_3^V,$$

where $\sigma_3^V=(1/|V|)\Sigma_{i\in V}\sigma_3^i$. In fact, it is clear that, after the regularization procedure (3.2), the following term would appear: $(1/|V|)\Sigma_{i,j\in V}\sigma_3^i\sigma_3^jQ_L$. This contribution is not certainly natural, and it is also technically difficult to be properly considered, since the boson and spin variables appear together already in the free spin Hamiltonian.

All these considerations suggest the use of another regularization, defined starting from the boson operators themselves. We perform the following substitutions:

$$a\to a_L\equiv Q_LaQ_L\,,\quad a^{\dagger}\to a_L^{\dagger}\equiv Q_La^{\dagger}Q_L\,, \tag{3.3}$$

and then we define, for the model (3.1),

$$H_L=a_L^{\dagger}a_L\,. \tag{3.4}$$

This procedure has a natural generalization: if H is a given function χ of certain nonbosonic (bounded) operators $X_1,\ldots,X_n$, as well as of a and $a^{\dagger}$, possibly already depending on some cutoff as the Hamiltonian H_V above, we can consider the *regularized* Hamiltonian H_L as the same function of the same variables $X_1,\ldots,X_n$ and of the regularized boson operators a_L and of $a_L^{\dagger}$:

$$H=\chi(X_1,\ldots,X_n,a,a^{\dagger})\to H_L=\chi(X_1,\ldots,X_n,a_L,a_L^{\dagger}). \tag{3.5}$$

Remark: Using the results of Appendix A it is easy to show that for the free Hamiltonian $H=N$ the above regularizations coincide. Indeed, by Eqs. (A2) and (2.6), we have

$$a_L^{\dagger}a_L=Q_La^{\dagger}Q_LQ_LaQ_L=Q_La^{\dagger}Q_LaQ_L=Q_La^{\dagger}aQ_{L+1}Q_L=Q_LNQ_L\,.$$

This is not true for general models, as the spin-bosons Hamiltonian above explicitly shows.

Once we have fixed the regularization procedure, we come to the main problem of this section, that is to prove the existence of the limit, for L going to infinity, of the following algebraic dynamics:

$$\alpha_L^t(X)=e^{iH_Lt}Xe^{-iH_Lt},$$

where X is an element of $\mathscr{L}^+(\mathscr{D})$. The topology in which this limit will be considered is the physical one defined in the previous section, which makes $\mathscr{L}^+(\mathscr{D})$ a complete topological *-algebra.

Proposition 3.1: The limits of $\alpha_L^t(a^n)$ and $\alpha_L^t((a^\dagger)^n)$ exist in $\mathscr{L}^+(\mathscr{D})[\tau]$ for all natural n.

Proof: We prove the Proposition only for the annihilation operator a. The proof for $a^\dagger$ is essentially the same. We proceed by induction on n. We start therefore by proving the statement for $n=1$.

The first step is to observe that:

$$[H_L,a]_m=(L\Pi_L-Q_{L-1})^m a=(L^m\Pi_L+(-1)^m Q_{L-1})a. \tag{3.6}$$

Again, the proof of these formulas goes on by induction on m, and is a simple consequence of the commutation relations proved in Appendix A. The equality $(L\Pi_L-Q_{L-1})^m=(L^m\Pi_L+(-1)^m Q_{L-1})$ is a consequence of the properties of the projection operators Π_l and Q_L. In particular, we use the equality $\Pi_L Q_{L-1}=0$, which follows from Eq. (2.5) and from the definition of Q_L.

By means of (3.6) we can prove that

$$\alpha_L^t(a)=e^{iH_Lt}ae^{-iH_Lt}=(1-Q_L+e^{itL}\Pi_L+e^{-it}Q_{L-1})a. \tag{3.7}$$

In fact, since H_L is bounded, we have

$$\alpha_L^t(a)=\sum_{m=0}^{\infty}\frac{(it)^m}{m!}[H_L,a]_m=\sum_{m=0}^{\infty}\frac{(it)^m(L^m\Pi_L+(-1)^m Q_{L-1})a}{m!},$$

so that Eq. (3.7) follows.

Now we are ready to prove the τ-Cauchy nature of $\alpha_L^t(a)$. Using the seminorms (2.8) we have

$$Q_{L,M}(t)\equiv\|\alpha_L^t(a)-\alpha_M^t(a)\|^{f,k}=\sum_{l,s=0}^{\infty}f(l)s^k\|\Pi_l(\alpha_L^t(a)-\alpha_M^t(a))\Pi_s\|.$$

We are not making explicit here the dependence of $Q_{L,M}(t)$ from the seminorm, that is from f and k. Using the explicit expression (3.7) for $\alpha_L^t(a)$ we get the following inequality:

$$\begin{aligned}Q_{L,M}(t)\leqslant\sum_{l,s=0}^{\infty}f(l)s^k[&\|\Pi_l(Q_M-Q_L)a\Pi_s\|+|e^{-it}|\|\Pi_l(Q_{L-1}-Q_{M-1})a\Pi_s\|\\&+|e^{itL}|\|\Pi_l\Pi_L a\Pi_s\|+|e^{itM}|\|\Pi_l\Pi_M a\Pi_s\|].\end{aligned}$$

To conclude we use Eq. (2.5) and formula (A4):

$$\|\Pi_l a\Pi_s\|=\delta_{l,s-1}\sqrt{s}, \tag{3.8}$$

which give the following estimate for $Q_{L,M}(t)$:

$$Q_{L,M}(t)\leqslant 2\sum_{s=M+1}^{L}f(s-1)s^{k+1/2}\to 0, \tag{3.9}$$

when L and M both diverge, due to the nature of the functions of the set $\mathscr{C}$. Since $\mathscr{L}^+(\mathscr{D})$ is τ-complete, the above result implies the existence of the limit of $\alpha_L^t(a)$ in $\mathscr{L}^+(\mathscr{D})[\tau]$.

Remark: As announced in Sec. II, we have focused our attention on the seminorm $\|f(N)\cdots N^k\|$. From the above computations, it appears clear how to extend the same estimates to $\|N^k\cdots f(N)\|$: it goes to zero essentially for the same reasons. This implies, due the invariance of the ''complete'' physical topology, given by the seminorms (2.4), with respect to the adjoint, that also $\alpha_L^t(a^\dagger)$ is τ-Cauchy and therefore τ-convergent in $\mathscr{L}^+(\mathscr{D})[\tau]$.

At this point we can prove the second step of the induction. Hence we suppose that $\alpha_L^t(a^{n-1})$ is τ-Cauchy and we also prove that $\alpha_L^t(a^n)$ is τ-Cauchy. The proof goes as follows:

$$Q^n_{L,M}(t)=\|\alpha^t_L(a^n)-\alpha^t_M(a^n)\|^{f,k}\leqslant\|\alpha^t_L(a)((\alpha^t_L(a))^{n-1}-(\alpha^t_M(a))^{n-1})\|^{f,k}$$
$$+\|(\alpha^t_L(a)-\alpha^t_M(a))(\alpha^t_M(a))^{n-1}\|^{f,k}. \tag{3.10}$$

The first contribution can be estimated by the seminorm $\|(\alpha^t_L(a^{n-1})-\alpha^t_M(a^{n-1}))\|^{xf,k}$, which we know by the induction hypothesis to be converging to zero since, if $f(x)\in\mathscr{C}$, then $xf(x)\in\mathscr{C}$ as well. To show this, we call $F_L(t)\equiv 1-Q_L+e^{itL}\Pi_L+e^{-it}Q_{L-1}$, so that $\alpha^t_L(a)=F_L(t)a$. We see that $\|F_L(t)\|\leqslant 3$ and that $F_L(t)$ commutes with Π_l (and Q_L). Therefore the first contribution in (3.10) can be estimated with

$$3\sum_{l,s=0}^{\infty} f(l)s^k\|a\Pi_{l+1}\|\|\Pi_{l+1}((\alpha^t_L(a))^{n-1}-(\alpha^t_M(a))^{n-1})\Pi_s\|,$$

and our claim follows resumming over s and l.

The second contribution in (3.10) can be estimated with similar techniques. Using formula (2.8) for the seminorms, $[F_L(t),\Pi_l]=0$ and formula (A1), we get

$$\begin{aligned}
&\|\Pi_l(\alpha^t_L(a)-\alpha^t_M(a))(F_M(t)a)^{n-1}\Pi_s\|\\
&\quad=\|\Pi_l(\alpha^t_L(a)-\alpha^t_M(a))\Pi_{s-(n-1)}F_M(t)a\Pi_{s-(n-2)}F_M(t)a\cdots\Pi_{s-1}F_M(t)a\Pi_s\|\\
&\quad\leqslant\|\Pi_l(\alpha^t_L(a)-\alpha^t_M(a))\Pi_{s-n+1}\|3^{n-1}\sqrt{(s-n+2)(s-n+3)\ldots(s-2)(s-1)s}\\
&\quad\leqslant(3\sqrt{s})^{n-1}\|\Pi_l(\alpha^t_L(a)-\alpha^t_M(a))\Pi_{s-n+1}\|.
\end{aligned}$$

Here we have also used the estimate $\|a\Pi_l\|\leqslant\sqrt{l}$. After some more easy steps, we finally find

$$\|(\alpha^t_L(a)-\alpha^t_M(a))(\alpha^t_M(a))^{n-1}\|^{f,k}\leqslant 2\sum_{l=M}^{L} f(l)(l+n)^k\sqrt{l+1}(3\sqrt{l+n})^{n-1},$$

which, again, goes to zero for any fixed n when L and M go to infinity, due to the decay properties of the function $f\in\mathscr{C}$. □

B. Variations on the same theme

In this section we briefly discuss two more models which can be easily ''transformed'' into the model (3.1).

The first model is simply a linear perturbation of the original one, and is described by the following Hamiltonian:

$$H=a^\dagger a+\gamma(a+a^\dagger),$$

where γ is real. As it is well known, the above model can be rewritten as a free model in terms of the different boson operators

$$b\equiv a+\gamma.$$

The operator b and its adjoint $b^\dagger$ satisfy the canonical commutation relation, as well as a and $a^\dagger$. Furthermore, in terms of b, we can write $H=b^\dagger b-\gamma^2$. This suggests how to proceed: We introduce the number operator for b, $N_b=b^\dagger b$, and then we consider its spectral decomposition, instead of that of $N_a=a^\dagger a$. Now we can proceed as in the previous section. Every step can be repeated also in this case, so that, again, it is possible to define rigorously the model first introducing, and then removing, the cutoff $b\to b_L=Q_L bQ_L$.

The second model we are going to analyze presents some more interesting aspects. It is a model of two modes of radiation coupled to each other. We assume for it the following Hamiltonian

$$H=a^\dagger a+b^\dagger b+(a^\dagger b+b^\dagger a).$$

Here a and b both satisfy the CCR as well as $[a^\sharp,b^\sharp]=0$, where with $X^\sharp$ we denote X or $X^\dagger$.

Again, the Hamiltonian can be mapped into something very similar to a number operator. We introduce the linear combinations

$$A=\frac{a+b}{\sqrt{2}}, \quad B=\frac{a-b}{\sqrt{2}}. \tag{3.11}$$

With these definitions we get $H=2A^\dagger A$. The commutation relations are

$$[A,A^\dagger]=1, \quad [B,B^\dagger]=1, \quad [A^\sharp,B^\sharp]=0.$$

We can consider now the spectral decomposition of the operator $N_A=A^\dagger A=\Sigma_{l=0}^{\infty} l\Pi_l$, and from the above commutation relations it is clear that Π_l also commutes with B and $B^\dagger$. At this point, with the usual regularization $H\to H_L=2A_L^\dagger A_L$, where $A_L=Q_L A Q_L$ and $Q_L=\Pi_0+\Pi_1+\cdots+\Pi_L$, the limit for $L\to\infty$ of $\alpha_L^t(A^n)$ exists in its natural physical topology τ. Furthermore, it is easily checked that $\alpha_L^t(B^n)=B^n$ for all integers n, so that its limit for L diverging exists as well. Therefore inverting Eqs. (3.11), we also find that $\alpha_L^t(a^n)$ and $\alpha_L^t(b^n)$ do converge in $\mathscr{L}^+(\mathscr{D})[\tau]$, for all integers n.

IV. TWO INTERACTING MODELS

A. Single mode bosons

In this section we will show how to use the framework introduced in Sec. II to discuss the existence of the algebraic dynamics for the model described by the following finite-volume Hamiltonian, already introduced in Sec. III:

$$H_V'=\frac{J}{|V|}\sum_{i,j\in V}\sigma_3^i\sigma_3^j+a^\dagger a+\gamma(a+a^\dagger)\sigma_3^V. \tag{4.1}$$

Here $\sigma_3^V=(1/|V|)\Sigma_{i\in V}\sigma_3^i$. This is a prototype model of an interaction between the matter, considered as a family of two levels atoms, and conveniently mimicked using spin matrices, with a single boson mode.

We take γ as a ''small'' real parameter, in a sense which will appear clear in the following, and V as a subset of the infinite lattice $\mathbb{Z}^d$. We remind the reader that the Pauli spin matrices satisfy the following commutation rules:

$$[\sigma_\alpha^i,\sigma_\beta^j]=2i\epsilon_{\alpha\beta\gamma}\delta_{i,j}\sigma_\gamma^i. \tag{4.2}$$

A consequence of this commutation relation, together with the definition of σ_3^V, is that

$$[\sigma_3^V,\sigma_\beta^j]=\frac{2i\epsilon_{3\beta\gamma}}{|V|}\sigma_\gamma^i, \tag{4.3}$$

which shows already that, in the limit $|V|\to\infty$, σ_3^V commutes with all the other observables.

It is worth remarking that a volume cutoff appears in H_V'. The necessity of this cutoff in a rigorous treatment of the mean field version of the BCS model for the high temperature superconductivity has been discussed, for instance, in Ref. 11.

Assuming that the perturbation $\gamma(a+a^\dagger)\sigma_3^V$ is small compared with the energy difference between the energy levels of the harmonic oscillator, we can consider ''frozen'' the boson kinetic contribution in H_V'. In this approximation we consider

$$H_V=\frac{J}{|V|}\sum_{i,j\in V}\sigma_3^i\sigma_3^j+\gamma(a+a^\dagger)\sigma_3^V. \tag{4.4}$$

What we have done is the same kind of approximation which leads to the Hamiltonian for the fractional quantum hall effect (FQHE) starting with an interacting two-dimensional electron gas in the presence of a strong magnetic field. In that system, the Coulomb interaction between the

electrons is considered as a small perturbation of the Hamiltonian of the free model, which consists in a gas of noninteracting electrons localized in the plane $(0;x,y)$ and subjected to a strong constant magnetic field directed along z. The free Hamiltonian of each electron is, in convenient variables, the Hamiltonian of an harmonic oscillator, and the free Hamiltonian of the system is the sum of all these contributions, one for each electron. The assumption on the Coulomb interaction suggests that, without other interactions, all the electrons are in the lowest Landau level (ground state of the oscillators) so that the kinetic part of the complete Hamiltonian (free Hamiltonian plus Coulomb interaction) can be replaced by its mean value in the ground state of the system. The idea of considering only the lowest Landau level in the description of the FQHE is now very common in the literature and was originally proposed by Yoshioka and Fukuyama in Ref. 12.

Before describing our treatment of the dynamics, it is worth remarking on the likeness of this model with the dissipative laser model introduced in Ref. 7. Of course, the present model is quite a simplified version of that one, first for its conservative nature, which allows a Hamiltonian approach, second for the presence of only one mode for the bosons (a condition which will be relaxed in the next section), and finally for the simplified form of the interaction Hamiltonian. As it has been shown in Refs. 7 and 8, a complete analysis of the Alli-Sewell model can be carried out already in a nontopological *-algebra of unbounded operators. In this paper we want to play a similar game with rather different rules, that is we want to introduce a topology related in some way to the model itself.

The way of doing this is suggested by the results contained in Sec. III and in Ref. 10: the algebra $\mathscr{A}$ should reflect the composite nature of the model, and is therefore reasonable to take $\mathscr{A}$ as the tensor product of the bounded spin algebra, $B(\mathscr{H}_{\rm spin})$, and the Lassner boson algebra, $\mathscr{L}^+(\mathscr{D})$: $\mathscr{A}=B(\mathscr{H}_{\rm spin})\otimes\mathscr{L}^+(\mathscr{D})$. The topology on $\mathscr{A}$, τ, is generated by seminorms which deal separately with the spin and the boson variables. Obviously, in view of the results in Sec. III for the free bosons and what is known about the mean field spin models,[10] we take these seminorms essentially as the ones in (2.8) for the boson operators and as the strong ones in (2.10) for the spin observables. We give here the definition of these seminorms which will be discussed in more detail in Appendix B. First of all, following Refs. 10 and 13, we give the definition of what we will call relevant vectors in the present contest. It may be worthwhile to observe that the set below is slightly different from the one introduced in Sec. II:

$$\mathscr{T}=\left\{\Psi\in\mathscr{H}_{\rm spin}:\lim_{|V|,\infty}\frac{1}{|V|}\sum_{p\in V}\sigma_3^p\Psi=\sigma_3^\infty\Psi,\|\sigma_3^\infty\|\leqslant 1\right\},\tag{4.5}$$

σ_3^∞ being an element of the center of the C^*-spin algebra. The usefulness of this set relies on the fact that σ_3^V (together with its powers and its analytical functions) converges strongly only on the vectors of $\mathscr{T}$, not on general vectors of $\mathscr{H}_{\rm spin}$ (and, of course, not in norm).

For future convenience, it is better to introduce the unbounded operator

$$M\equiv N+\mathbb{1}=a^\dagger a+\mathbb{1}=\sum_{l=1}^{\infty} l\Pi_l.\tag{4.6}$$

The only difference between the operators M and N is in the lower value of l in their spectral decompositions. With these considerations we define, for each $X\in\mathscr{L}^+(\mathscr{D})$ and for each $A\in B(\mathscr{H}_{\rm spin})$,

$$\|XA\|^{f,k,\Psi}\equiv\|X\|^{f,k}\|A\|^\Psi=\|f(M)XM^k\|\|A\Psi\|,\tag{4.7}$$

where $f\in\mathscr{C}$, $k\in\mathbf{N}$, $\Psi\in\mathscr{T}$. The final remark is that, again, we are considering only one contribution in the Lassner seminorm; a complete definition should also include $\|M^kXf(M)\|$, see (2.4).

Now we proceed to a complete regularization of the Hamiltonian H_V. The approach we follow is the one already discussed in Sec. III. Therefore we consider the following operator

$$H_{V,L}=J|V|(\sigma_3^V)^2+\gamma(a_L+a_L^\dagger)\sigma_3^V,\tag{4.8}$$

where, as before, $a_L = Q_L a Q_L = a Q_L$, see (A2). Then we define the cutoff algebraic dynamics $\alpha^t_{V,L}$ in a canonical way:

$$\alpha^t_{V,L}(X) = e^{iH_{V,L}t} X e^{-iH_{V,L}t}, \tag{4.9}$$

where $X \in \mathscr{A}$.

For technical convenience it is useful to introduce here a relation between the two different cutoffs. It will be used in the second part of Proposition 5.1, where we will assume that

$$|V| = L^r. \tag{4.10}$$

Here r is an integer bigger than 1. This condition essentially restricts the subspaces $V \subset \mathbb{Z}^d$ which are to be used in the regularization procedure: they are those finite lattices whose number of sites is the rth power of the integers.

We can now state the main result of this section:

Proposition 5.1: The limit of $\alpha^t_{V,L}(a)$ for $|V|$ and L both diverging exists in $\mathscr{A}[\tau]$. In the hypothesis (4.10) the same holds true also for $\alpha^t_{V,L}(\sigma^i_\alpha)$.

Proof: We begin with the proof of the first statement above. Since $[J|V|(\sigma^V_3)^2,\ \gamma(a_L + a_L^\dagger)\sigma^V_3]] = 0$, we can write

$$\begin{aligned}\alpha^t_{V,L}(a) &= e^{i\gamma(a_L + a_L^\dagger)\sigma^V_3 t}(e^{iJ|V|(\sigma^V_3)^2 t} a e^{-i,J|V|(\sigma^V_3)^2 t}) e^{-i\gamma(a_L + a_L^\dagger)\sigma^V_3 t} \\ &= e^{i\gamma(a_L + a_L^\dagger)\sigma^V_3 t} a e^{-i\gamma(a_L + a_L^\dagger)\sigma^V_3 t} = \sum_{n=0}^{\infty} \frac{(i\gamma t \sigma^V_3)^n}{n!} [a_L + a_L^\dagger, a]_n, \end{aligned} \tag{4.11}$$

due to the commutation relation $[a, \sigma^i_\alpha] = 0$. Here $[a_L + a_L^\dagger, a]_n$ is the usual multiple commutator defined as

$$[a_L + a_L^\dagger, a]_0 = a, \quad [a_L + a_L^\dagger, a]_n = [(a_L + a_L^\dagger), [a_L + a_L^\dagger, a]_{n-1}], n \geq 1.$$

We divide the infinite sum in the right-hand side of (4.11) in two contributions:

$$\alpha^t_{V,L}(a) = \sum_{n=0}^{1} \frac{(i\gamma t \sigma^V_3)^n}{n!} [a_L + a_L^\dagger, a]_n + \sum_{n=2}^{\infty} \frac{(i\gamma t \sigma^V_3)^n}{n!} [a_L + a_L^\dagger, a]_n, \tag{4.12}$$

and we show that the last term, $\Sigma_{n=2}^{\infty} \ldots$, converges to zero in τ when L goes to infinity, for any $|V|$.

The proof of this convergence goes as follows:

(a) First we compute, using the formulas in Appendix A, the following multiple commutators:

$$\begin{aligned}&[a_L + a_L^\dagger, a]_0 = a, \quad [a_L + a_L^\dagger, a]_1 = a^2 \Pi_{L+1} + a a^\dagger \Pi_L - Q_L, \\ &[a_L + a_L^\dagger, a]_2 = a^3 \Pi_{L+1} + a^2 a^\dagger (\Pi_L + \Pi_{L+1}) - 2a\Pi_{L+1} - a(a^\dagger)^2 \Pi_{L-1}. \end{aligned} \tag{4.13}$$

(b) Then we observe that $\|f(M)[a_L + a_L^\dagger, a]_2 M^k\| \to 0$ when $L \to \infty$, for any $f \in \mathscr{C}$ and any $k \in \mathbb{N}$. The proof of this convergence is a bit long. Here we only show the convergence to zero of the first contribution in (4.13). We have

$$\|f(M) a^3 \Pi_{L+1} M^k\| = \sum_{l,s=1}^{\infty} f(l) s^k \|\Pi_l a^3 \Pi_{L+1} \Pi_s\| = \sum_{l,s=1}^{\infty} f(l) s^k \delta_{s,L+1} \|\Pi_l a^3 \Pi_s\|.$$

But, since $\|\Pi_l a \Pi_s\| = \sqrt{s}\,\delta_{l,s-1}$, we deduce that, using the idempotence of Π_l, $\Pi_l = \Pi_l^2$ together with formula (A2),

$$\|\Pi_l a^3 \Pi_s\| \leq \|\Pi_l a \Pi_{l+1}\| \|\Pi_{l+1} a \Pi_{l+2}\| \|\Pi_{l+2} a \Pi_s\| \leq \sqrt{(l+1)(l+2)(l+3)}\,\delta_{s,l+3}.$$

Therefore after some algebraic computations,

$$\|f(M)a^3\Pi_{L+1}M^k\| \leqslant f(L-2)(L+1)^k\sqrt{L(L-1)(L-2)},$$

which, of course, goes to zero for $L\to\infty$. Analogous estimates work for the other contributions in $\|f(M)[a_L+a_L^\dagger,a]_2M^k\|$ in (4.13).

(c) In the third step we show how the previous estimate can be extended to the other multiple commutators $[a_L+a_L^\dagger,a]_n$, $n>2$. The estimate goes as follows: first we observe that $[a_L+a_L^\dagger,a]_2$ is essentially the sum of six monomials (we consider two contributions from $-2a\Pi_{L+1}$) in a and $a^\dagger$, each at most raised to the power 3. Since we are interested in very large values of L, it is not very important that sometimes we find Π_L and somewhere else $\Pi_{L\pm1}$. The structure of this commutator is therefore $[a_L+a_L^\dagger,a]_2\simeq 6m_2(a,a^\dagger)\Pi_L$, where m_2 is a monomial of degree $2+1=3$. Analogously we find $[a_L+a_L^\dagger,a]_3\simeq 24m_3(a,a^\dagger)\Pi_L$ where m_3 is of degree 4. The number 24 is the maximum possible number of contributions following from the commutation between $a_L+a_L^\dagger$ and $6m_2(a,a^\dagger)\Pi_L$. This procedure can be extended to each n, and we find that, for $L\gg 1$,

$$[a_L+a_L^\dagger,a]_n\simeq 6\cdot 4^{n-2}m_n(a,a^\dagger)\Pi_L. \tag{4.14}$$

Using this formula in the expression of $\|[a_L+a_L^\dagger,a]_n\|^{f,k}$, together with the $\Pi_L\Pi_s=\Pi_s\delta_{s,L}$ we obtain the following:

$$\|[a_L+a_L^\dagger,a]_n\|^{f,k}\simeq 6L^k4^{n-2}\sum_{l=1}^{\infty}\|\Pi_l m_n(a,a^\dagger)\Pi_L\|.$$

By similar estimates to those used in point (b) above, we see that $\|\Pi_l m_n(a,a^\dagger)\Pi_L\|$ is essentially a polynomial p_n in l and L, times a delta function $\delta_{l,\varphi_{m_n}}$, where φ_{m_n} is an increasing function related to the explicit expression of m_n. Therefore we get

$$\|[a_L+a_L^\dagger,a]_n\|^{f,k}\simeq 6\cdot 4^{n-2}L^k f(\varphi_{m_n}(L))p_n(\varphi_{m_n}(L),L).$$

Due to the nature of f, the right-hand side is bounded by the supremum on n of the same quantity:

$$L^k f(\varphi_{m_n}(L))p_n(\varphi_{m_n}(L),L)\leqslant\sup_n[L^k f(\varphi_{m_n}(L))p_n(\varphi_{m_n}(L),L)]=:F_k(L),$$

where the function $F_k(L)$ goes to zero when $L\to\infty$. We conclude that

$$\|[a_L+a_L^\dagger,a]_n\|^{f,k}\leqslant 6\cdot 4^{n-2}F_k(L). \tag{4.15}$$

(d) At this point we have at hand all the ingredients to prove that the last contribution in (4.12) converges to zero for any V when L diverges. In fact we have, using the definition (4.7) of the seminorms $\|\ \|^{f,k,\Psi}$, the inequality (4.15), and the uniform bound on σ_3^V, $\|(\sigma_3^V)^n\|\leqslant 1$,

$$\left\|\sum_{n=2}^{\infty}\frac{(i\gamma t\sigma_3^V)^n}{n!}[a_L+a_L^\dagger,a]_n\right\|^{f,k,\Psi}\leqslant\sum_{n=2}^{\infty}\frac{|\gamma t|^n}{n!}\|(\sigma_3^V)^n\Psi\|\|[a_L+a_L^\dagger,a]_n\|^{f,k}$$
$$\leqslant\frac{3}{2}\left(\sum_{n=2}^{\infty}\frac{|4\gamma t|^n}{n!}\right)F_k(L)\leqslant\frac{3}{2}e^{|4t\gamma|}F_k(L)\to 0,$$

when $L\to\infty$.

Now, the first statement of the Proposition, that is the τ-convergence of $\alpha_{V,L}^t(a)$, easily follows. In fact, in view of the above result, we can write equality (4.12) as

$$\alpha_{V,L}^t(a)=a+i\gamma\sigma_3^V t(a^2\Pi_{L+1}+aa^\dagger\Pi_L-Q_L)+\tilde{\alpha}_{V,L}^t(a), \tag{4.16}$$

where $\tilde{\alpha}_{V,L}^t(a)\equiv\Sigma_{n=2}^{\infty}[(i\gamma t\sigma_3^V)^n/n!][a_L+a_L^\dagger,a]_n$ is τ-converging to zero with L, and uniformly bounded in $|V|$, so that

$$\|\|\alpha^t_{V,L}(a)-\alpha^t_{V',L'}(a)\|\|^{f,k,\Psi}\leqslant|\gamma t|\|\|\sigma_3^V t(a^2\Pi_{L+1}+aa^\dagger\Pi_L-Q_L)$$
$$-\sigma_3^{V'}t(a^2\Pi_{L'+1}+aa^\dagger\Pi_{L'}-Q_{L'})\|\|^{f,k,\Psi}+O_L,$$

where $O_L\to 0$ when $L\to\infty$.

In this estimate we can handle very easily all the contributions containing any projection operator Π_n, such as $\|\|\sigma_3^V t a^2\Pi_{L+1}\|\|^{f,k,\Psi}$. In fact, they go to zero, and can be seen following essentially the same steps as in point (b) above. What is to be controlled is only the term $\|\|\sigma_3^V Q_L-\sigma_3^{V'}Q_{L'}\|\|^{f,k,\Psi}$. This can be estimated adding and subtracting first the same quantity $\sigma_3^V Q_{L'}$ and observing that, if $L>L'$, then

$$\|Q_L-Q_{L'}\|^{f,k}=\sum_{l=L'+1}^{L}f(l)l^k\to 0,$$

when both L and L' diverge. We have

$$\|\|\sigma_3^V Q_L-\sigma_3^{V'}Q_{L'}\|\|^{f,k,\Psi}\leqslant\|\|\sigma_3^V(Q_L-Q_{L'})\|\|^{f,k,\Psi}+\|\|(\sigma_3^V-\sigma_3^{V'})Q_{L'}\|\|^{f,k,\Psi}$$
$$=\|\sigma_3^V\Psi\|\|Q_L-Q_{L'}\|^{f,k}+\|(\sigma_3^V-\sigma_3^{V'})\Psi\|\|Q_{L'}\|^{f,k}\to O\quad\text{for } L,|V|\to\infty.$$

The existence of $\alpha^t(a)$ finally follows from the completeness of the algebra $\mathscr{A}$.

Remarks: (1) It is clear from the above procedure that the order of the limits ($|V|\to\infty$ or $L\to\infty$) has no importance. (2) It is worthwhile to observe that hypothesis (4.10) has not been used so far. We will use this condition in the second part of the proof.

Let us now discuss the convergence of $\alpha^t_{V,L}(\sigma^i_\alpha)$. Using the commutativity of the two pieces of the Hamiltonian, formula (2.3) of Ref. 13, and the obvious commutation relation $[\sigma_3^V,\sigma_3^i]=0$, we have

$$\begin{aligned}\alpha^t_{V,L}(\sigma^i_\alpha)&=e^{iH_{V,L}t}\sigma^i_\alpha e^{-iH_{V,L}t}\\&=e^{i\gamma(a_L+a_L^\dagger)\sigma_3^V t}(e^{iJ|V|(\sigma_3^V)^2t}\sigma^i_\alpha e^{-iJ|V|(\sigma_3^V)^2t})e^{-i\gamma(a_L+a_L^\dagger)\sigma_3^V t}\\&=\beta^t_{V,L}(\sigma^i_\alpha)\cos^2(S_3^V)-2\epsilon_{3\alpha\beta}\beta^t_{V,L}(\sigma^i_\beta)\sin(S_3^V)\cos(S_3^V)\\&\quad+\sigma_3^i\beta^t_{V,L}(\sigma^i_\alpha)\sigma_3^i\sin^2(S_3^V)+O(|V|^{-1}),\end{aligned}\tag{4.17}$$

where $S_3^V=2Jt\sigma_3^V$, $O(|V|^{-1})$ is norm converging to zero and we have introduced the notation

$$\beta^t_{V,L}(\sigma^i_\alpha)=e^{i\gamma(a_L+a_L^\dagger)\sigma_3^V t}\sigma^i_\alpha e^{-i\gamma(a_L+a_L^\dagger)\sigma_3^V t}.\tag{4.18}$$

The next step consists in proving that

$$\beta^t_{V,L}(\sigma^i_\alpha)=\sigma^i_\alpha+\tilde\beta^t_{V,L},\tag{4.19}$$

where $\tilde\beta^t_{V,L}$ τ-converges to zero when $|V|$ diverges, under the technical assumption (4.10). This result is reasonable, since $[\sigma_3^V,\sigma^i_\alpha]=O(|V|^{-1})$, so that in definition (4.18) we can commute $e^{i\gamma(a_L+a_L^\dagger)\sigma_3^V t}$ with σ^i_α only within an error going to zero when $|V|$ is sent to infinity. We are going to prove (4.19) rigorously. We begin splitting

$$\beta^t_{V,L}(\sigma^i_\alpha)=\sum_{l=0}^{\infty}\frac{(it\gamma(a_L+a_L^\dagger))^l}{l!}[\sigma_3^V,\sigma^i_\alpha]_l=\sigma^i_\alpha+\sum_{l=1}^{\infty}\frac{(it\gamma(a_L+a_L^\dagger))^l}{l!}[\sigma_3^V,\sigma^i_a]_l.\tag{4.20}$$

We will show that the last term, which is exactly what we have called $\tilde\beta^t_{V,L}$, τ-converges to zero, at least under the assumption (4.10). Since

$$\left\|\left|\sum_{l=1}^{\infty}\frac{(it\gamma(a_L+a_L^\dagger))^l}{l!}[\sigma_3^V,\sigma^i_\alpha]_l\right|\right\|^{f,k,\Psi}\leqslant\sum_{l=1}^{\infty}\frac{|t\gamma|^l}{l!}\|(a_L+a_L^\dagger)^l\|^{f,k}\|[\sigma_3^V,\sigma^i_\alpha]_l\Psi\|,$$

we need to estimate $\|(a_L+a_L^\dagger)^l\|^{f,k}$ and $\|[\sigma_3^V,\sigma_\alpha^i]_l\Psi\|$. This last term is easily seen to be bounded by powers of $2/|V|$:

$$\|[\sigma_3^V,\sigma_\alpha^i]_l\Psi\|\leq\left(\frac{2}{|V|}\right)^l. \tag{4.21}$$

As for the estimate of $\|(a_L+a_L^\dagger)^l\|^{f,k}$, the situation is a bit more difficult. In fact, it is possible to prove the following inequality

$$\|(a_L+a_L^\dagger)^l\|^{f,k}\leq c_k((2^k+1)(L+1)^{3/2})^l, \tag{4.22}$$

where $c_k\equiv\Sigma_{l=1}^\infty f(l)l^k$ is certainly finite for any integer k. The proof of the estimate above goes as follows:

$$\|(a_L+a_L^\dagger)^l\|^{f,k}=\|f(M)(a_L+a_L^\dagger)^lM^k\|\leq\|f(M)M^k\|\|M^{-k}(a_L+a_L^\dagger)M^k\|^l.$$

Now, $\|f(M)M^k\|=c_k$ and, using the spectral decomposition for M and formula (A4),

$$\|M^{-k}(a_L+a_L^\dagger)M^k\|=\sum_{l,s=1}^{L}\left(\frac{s}{l}\right)^k\|\Pi_l(a+a^\dagger)\Pi_s\|\leq(2^k+1)L\sqrt{L+1}.$$

Putting it all together, inequality (4.22) follows. Now we can use this inequality and the one in (4.21) to prove our claim on $\tilde{\beta}_{V,L}^t$. Indeed, we have

$$\left\|\left|\sum_{l=1}^{\infty}\frac{(it\gamma(a_L+a_L^\dagger))^l}{l!}[\sigma_3^V,\sigma_a^i]_l\right|\right\|^{f,k,\Psi}\leq c_k\sum_{l=1}^{\infty}\left(\frac{(|2t\gamma|(2^k+1)(L+1)^{3/2})}{|V|}\right)^l\frac{1}{l!}$$
$$=c_k\left(\exp\left\{\frac{(|2t\gamma|(2^k+1)(L+1)^{3/2})}{|V|}\right\}-1\right),$$

which, of course, goes to zero for $L\to\infty$, at least if the hypothesis (4.10) is satisfied. This concludes the proof of Eq. (4.19). Taking into account condition (4.10) we will write

$$\|\|\beta_L^t(\sigma_\alpha^i)-\sigma_\alpha^i\|\|^{f,k,\Psi}=O(L^{-\mu}), \tag{4.23}$$

where μ is a strictly positive number. Inserting (4.23) in (4.18), with $|V|=L^r$, we get

$$\alpha_L^t(\sigma_\alpha^i)=\sigma_\alpha^i\cos^2(S_3^{L^r})-2\epsilon_{3\alpha\beta}\sigma_\beta^i\sin(S_3^{L^r})\cos(S_3^{L^r})$$
$$+\sigma_3^i\sigma_\alpha^i\sigma_3^i\sin^2(S_3^{L^r})+O(L^{-r})+O(L^{-\mu}). \tag{4.24}$$

Here we have written explicitly the two terms going to zero with L, the reason being that while the first goes to zero in the usual norm of the operators, see Ref. 13, the second one goes to zero in the topology τ. Using now the expression above for $\alpha_L^t(\sigma_\alpha^i)$ and the results in Ref. 10, we conclude that the sequence $\alpha_L^t(\sigma_\alpha^i)$ is τ-Cauchy, so that its limit exists in the algebra $\mathscr{A}$. □

Remarks: (a) Our first remark is about condition (4.10): we do believe that this is only a technical requirement, without any physical meaning, and that a refinement of our estimates can be found which does not make use of (4.10). But it is not worth going in this direction.

(b) Even if the approach we are following in this paper is somehow more in line with Refs. 13 and 14, nevertheless it is in Ref. 10 that we find the information we need about what we have called ''$\mathscr{T}$-strong convergence'' of σ_3^V and of its *good*, i.e., analytical, functions. In particular, in Ref. 13 we were forced not to use the strong topology because of the appearance of variables, like $(1/|V|^\gamma)\Sigma_{i\in V}\sigma_3^i$, which, in general, are not uniformly bounded in V for $\gamma<1$. Of course, the algebraic structure for the spin variables of this model could also be constructed using the results in Ref. 13 which, for $\gamma=1$, is nothing but a mean field model, like the present one. This would imply, however, that the strong seminorms (2.10) should be replaced by the Lassner seminorms constructed starting with a certain ''number'' operator which can be introduced also in the spin

algebra.[2,13] Also, the algebra $B(\mathscr{H}_{\rm spin})$ should be replaced by a certain $\mathscr{L}^+(\tilde{\mathscr{D}})$, where $\tilde{\mathscr{D}}$ is the domain of all the powers of this new number operator, and is a subspace of $\mathscr{H}_{\rm spin}$. Since σ_3^V is uniformly bounded, this is not necessary here, so we have used the simpler framework discussed in Ref. 10.

(c) With the same kind of estimates considered above, it is also possible to prove the existence, among the others, of the limits of the following quantities: $\alpha_L^t(a\sigma_\alpha^i)$, $\alpha_L^t(\sigma_{\alpha_1}^{i_1}\cdots\sigma_{\alpha_n}^{i_n})$, $\alpha_L^t(a^n)$. Here n is an arbitrary integer. The proof essentially follows from the explicit expressions (4.16) and (4.24) for the cutoff dynamics and from the algebraic nature of α_L^t.

We can conclude, therefore, that the algebraic dynamics for the model (4.4) can be rigorously defined using the regularization (3.5) and that a natural topological *-algebra considering the model is $\mathscr{A}[\tau]=B(\mathscr{H}_{\rm spin})\otimes\mathscr{L}^+(\mathscr{D})$, $B(\mathscr{H}_{\rm spin})$ taken with its strong topology and $\mathscr{L}^+(\mathscr{D})$ with the physical one.

B. Many mode bosons

The last model we will discuss in this paper is an extension of the interacting model (4.1):

$$H_V'=\frac{J}{|V|}\sum_{i,j\in V}\sigma_3^i\sigma_3^j+\sum_{l=1}^n a_l^\dagger a_l+\sum_{l=1}^n \gamma_l(a_l+a_l^\dagger)\sigma_3^V. \tag{4.25}$$

In this generalization, n different modes of bosons are introduced, satisfying the CCR

$$[a_l,a_n^\dagger]=\delta_{ln}\mathbb{1},$$

while γ_l are n small real numbers such that, again, the kinetic boson Hamiltonian $\Sigma_{l=1}^n a_l^\dagger a_l$ can be considered frozen in a given level. Again, therefore, we consider the following simplified Hamiltonian

$$H_V=\frac{J}{|V|}\sum_{i,j\in V}\sigma_3^i\sigma_3^j+\sum_{l=1}^n \gamma_l(a_l+a_l^\dagger)\sigma_3^V. \tag{4.26}$$

The regularization of H_V can be performed in the following way: for each mode we consider the number operator $N_k=a_k^\dagger a_k$, its spectral decomposition $N_k=\Sigma_{l=0}^\infty l\Pi_{k,l}$ and the projection operators $Q_{k,L}\equiv\Sigma_{l=0}^L\Pi_{k,l}$ (also for this model it is convenient to introduce $M_k=N_k+\mathbb{1}$). We also define the Hilbert spaces $\mathscr{H}_k$, one for each mode, and $\mathscr{D}_k\equiv D^\infty(N_k)\subset\mathscr{H}_k$ as in Sec. II. Finally we take $\mathscr{D}\equiv\mathscr{D}_1\otimes\mathscr{D}_2\otimes\cdots\otimes\mathscr{D}_n$ which is dense in the Hilbert space $\mathscr{H}$ of the tensor product of all the $\mathscr{H}_k$. Other useful spaces are $\mathscr{E}_{k,l}=\{(a_k^\dagger)^l\Phi_0\}$ and $\mathscr{F}_{k,L}=\mathscr{E}_{k,0}+\mathscr{E}_{k,1}+\cdots+\mathscr{E}_{k,L}$. Of course, projections corresponding to different modes commute. The algebra is the usual $\mathscr{A}=B(\mathscr{H}_{\rm spin})\otimes\mathscr{L}^+(\mathscr{D})$.

At this point we define the regularized Hamiltonian $H_{V,L}$ as

$$H_{V,L}=\frac{J}{|V|}\sum_{i,j\in V}\sigma_3^i\sigma_3^j+\sum_{l=1}^n \gamma_l(a_{l,L}+a_{l,L}^\dagger)\sigma_3^V, \tag{4.27}$$

where $a_{l,L}=Q_{l,L}a_lQ_{l,L}$.

The existence of the limit of $\alpha_{V,L}^t(a_j)$ is a simple consequence of the results in the first section. In fact, with the same arguments as for the single mode bosons model, we find that

$$\alpha_{V,L}^t(a_j)=e^{i\gamma(a_{j,L}+a_{j,L}^\dagger)\sigma_3^V t}a_j e^{-i\gamma(a_{j,L}+a_{j,L}^\dagger)\sigma_3^V t}.$$

This has exactly the same expression as in Eq. (4.11), so that its convergence in the physical topology can be proven in the same way.

A bit different is the proof of the existence of the limit of $\alpha_{V,L}^t(\sigma_\alpha^i)$. Without going too much into detail, we just observe that the main difference is that in formula (4.18) $\beta_{V,L}^t(\sigma_\alpha^i)$ must be replaced with

$$\varphi^t_{V,L}(\sigma^i_\alpha)=e^{i\Sigma_{l=1}^n \gamma_l(a_{l,L}+a^\dagger_{l,L})\sigma_3^V t}\sigma^i_\alpha e^{-i\Sigma_{l=1}^n \gamma_l(a_{l,L}+a^\dagger_{l,L})\sigma_3^V t}$$
$$=e^{i\gamma_n(a_{n,L}+a^\dagger_{n,L})\sigma_3^V t}(\cdots(e^{i\gamma_1(a_{1,L}+a^\dagger_{1,L})\sigma_3^V t}\sigma^i_\alpha e^{-i\gamma_1(a_{1,L}+a^\dagger_{1,L})\sigma_3^V t})\cdots)e^{-i\gamma_n(a_{n,L}+a^\dagger_{n,L})\sigma_3^V t}.$$

This can still be estimated as in (4.19), $\varphi^t_{V,L}(\sigma^i_\alpha)\simeq\sigma^i_\alpha$, simply by noticing that the contribution τ-converging to zero appears now n times, n being the fixed number of boson modes. We conclude that (4.24) still holds for this multimodes model, and therefore that the limit of $\alpha^t_{V,L}(\sigma^i_\alpha)$ exists in $\mathscr{A}$.

V. OUTCOME AND FUTURE PROJECTS

In this paper some physically relevant models have been analyzed making use of the algebras of unbounded operators of Lassner type. In particular, we have shown that for the free bosons, and for other models related to this one, it is possible to introduce an ''occupation number'' cutoff, whose removal can be performed in the complete topological *-algebra $\mathscr{L}^+(\mathscr{D})$, where $\mathscr{D}$ is the domain of all powers of the number operator N.

Moreover, for an interacting model of spins and bosons, the same kind of regularization allows a rigorous definition of the cutoff Hamiltonian. Again, this cutoff can be removed, together with its other volume cutoff, working in a large topological *-algebra $\mathscr{A}[\tau]=B(\mathscr{H}_{\text{spin}})\otimes\mathscr{L}^+(\mathscr{D})$, where $B(\mathscr{H}_{\text{spin}})$ and $\mathscr{L}^+(\mathscr{D})$ are endowed, respectively, with the strong and with the physical topologies.

For what concerns our future projects, our main goal is to analyze, within the mathematical structure proposed here, some more physically realistic models like the original conservative Dicke model,[15] or its nonconservative generalization proposed by Alli and Sewell.[7]

ACKNOWLEDGMENTS

It is a pleasure to thank Professor G. L. Sewell for many stimulating discussions about the interactions between matter and radiation and for his comments. I also would like to thank Dr. D. Dubin for an interesting discussion concerning topological algebras of unbounded operators, and Dr. C. Trapani for his careful reading of the manuscript and for his comments. This work has been supported by M.U.R.S.T.

APPENDIX A: SOME USEFUL FORMULAS

In this Appendix we will obtain some useful relations concerning the projection operators Π_l and Q_L. We start by proving the following relation:

$$\Pi_{l-1}a=a\Pi_l,\quad l=1,2,3,\ldots. \tag{A1}$$

The proof is the following. First, we observe that $\varphi\in\mathscr{H}$ is such that $\Pi_{l-1}a\varphi=0$ if, and only if, $a\Pi_l\varphi=0$. In fact, if $\Pi_{l-1}a\varphi=0$ then $a\varphi$ must be orthogonal to $\mathscr{E}_{l-1}$ or, that is to say, φ must be orthogonal to $\mathscr{E}_l$, which implies that $\Pi_l\varphi=0$. The converse implication is proved in the same way. This implies that if Ψ is such that $\Pi_{l-1}a\Psi\neq0$ then necessarily also $a\Pi_l\Psi\neq0$. Let Ψ be such a vector. Then $\Pi_l\Psi\in\mathscr{E}_l$ and $a\Pi_l\Psi\in\mathscr{E}_{l-1}$. Analogously $\Pi_{l-1}a\Psi\in\mathscr{E}_{l-1}$. Therefore the two vectors must be necessarily proportional to each other. In other words, a nonzero constant α_l must exist such that $\Pi_{l-1}a\Psi=\alpha_l a\Pi_l\Psi$. Taking the scalar product of both sides of this equality with the vector $(a^\dagger)^{l-1}\Phi_0$ we deduce that $\alpha_l=1$, from which Eq. (A1) follows.

The following relations are now easy consequences of formula (A1):

$$a^\dagger\Pi_{l-1}=\Pi_l a^\dagger,\quad Q_L a=aQ_{L+1},\quad Q_L a^\dagger=a^\dagger Q_{L-1}, \tag{A2}$$

$$[Q_L,a]=\Pi_L a,\quad [Q_L,a^\dagger]=-a^\dagger\Pi_L, \tag{A3}$$

where l and L take integer values.

Let us finally prove the following useful formula:

$$\|\Pi_l a\Pi_s\|=\sqrt{s}\,\delta_{l,s-1}. \tag{A4}$$

This is a consequence of the following equalities:

$$\|\Pi_l a \Pi_s\|^2 = \|a\Pi_{l+1}\Pi_s\|^2 = \delta_{l,s-1}\|a\Pi_s\|^2 = \delta_{l,s-1}\sup_{\|\varphi\|\leqslant 1}|\langle a\Pi_s\varphi, a\Pi_s\varphi\rangle|$$

$$= \delta_{l,s-1}\sup_{\|\varphi\|\leqslant 1}|\langle \Pi_s\varphi, N\Pi_s\varphi\rangle| = s\,\delta_{l,s-1}.$$

APPENDIX B: THE TOPOLOGY τ FOR THE INTERACTING MODELS

Let $\mathscr{H}$ and $\mathscr{H}_{\rm spin}$ be the Hilbert spaces, respectively, of the bosons and the spin. $\mathscr{D}$ is the subset of $\mathscr{H}$ defined as in Sec. II and $\mathscr{A}=B(\mathscr{H}_{\rm spin})\otimes\mathscr{L}^+(\mathscr{D})$ is the relevant *-algebra for the model in Sec. IV.

We start defining, for $X=X_1\otimes X_2\in B(\mathscr{H}_{\rm spin})\otimes B(\mathscr{H})$, and for $\Psi\in\mathscr{T}$ given in (4.5), the following ''strong'' seminorms:

$$\|X\|^{\Psi} = \sup_{\|\chi_1\|\leqslant 1,\|\chi_2\|\leqslant 1,\|\phi_2\|\leqslant 1}|\langle \chi_1\otimes\chi_2, (X_1\otimes X_2)\Psi\otimes\phi_2\rangle| = \|X_1\Psi\|\|X_2\| \tag{B1}$$

(obviously in $\|X_1\Psi\|$ the norm is the one in $\mathscr{H}_{\rm spin}$, while in $\|X_2\|$ is the one in $B(\mathscr{H})$. It is straightforwardly proven that these are really seminorms. The meaning of the above definition is also evident: we are considering the $(\mathscr{T}-)$ strong topology on $B(\mathscr{H}_{\rm spin})$ and the usual norm topology on $B(\mathscr{H})$. At this point, since if $A\in\mathscr{L}^+(\mathscr{D})$ then both $f(M)AM^k$ and $M^kAf(M)$ are bounded operators on $\mathscr{H}$, the following definition appears as the most natural: for any $X\in\mathscr{A}$ we define the following seminorms

$$|||X|||^{f,k,\Psi} \equiv \max\{\|f(M)XM^k\|^{\Psi}, \|M^kXf(M)\|^{\Psi}\}. \tag{B2}$$

Again, it is not difficult to prove that $\{|||\cdots|||^{f,k,\Psi}\}$ is a system of seminorms which define a topology τ and this topology makes of $\mathscr{A}$ a complete topological *-algebra.

Calculus on the multivector manifold spin$^+(p,q)$

Stephen Blake
Machine Tool Vision Limited, 53 Lawrence Street, Blackburn, Lancashire, BB2 1QF, England

(Received 13 January 1998; accepted for publication 27 May 1998)

Coordinate-free differential and integral calculus is formulated on the spin groups, regarded as multivector manifolds embedded in Geometric Algebra. The derivative with respect to a point on the manifold is shown to be in the tangent algebra at the inverse point. The curvature of spin(p,q) is calculated and related to the structure constants of its Lie algebra. Volume elements on spin(p,q) are introduced naturally as completely antisymmetrized geometric products of bivectors. They are left invariant like Haar measure and are elements of a multivector-valued Grassman algebra. It is shown that integration in this sense is forbidden for many spin groups. A version of Stokes's theorem is formulated on spin(p,q). © *1998 American Institute of Physics.* [S0022-2488(98)03311-8]

I. INTRODUCTION

This article is concerned with a development of the Geometric Calculus of references Refs. 1–5. Calculus on manifolds is formulated in a coordinate-free way, in the principal reference, Ref. 1, by taking the points of a manifold as vectors in the Geometric Algebra. The notation of Ref. 1 is used in this article. The Geometric Algebra is a graded linear space, whose elements are called multivectors. The grade-0 elements are scalars and the grade-1 elements are vectors. It is reasonable to try to generalize the existing calculus on vector manifolds by formulating differential and integral calculus on manifolds whose points are the higher grade multivectors.

The motivation for this generalization arose from problems involving rotations. In Geometric Algebra, rotations are multivectors R of even grades, called rotors, which satisfy the following constraint:

$$R^\dagger R = 1. \tag{1}$$

Equation (1) picks out a set of points which form a multivector manifold. In applications, one often encounters the need to evaluate the derivative, in the rotor manifold, of a function of a rotation. This led the writer to work on the differential and integral calculus of general multivector manifolds. Guided by the vector manifold theory of Ref. 1, it was necessary to find a projection operator that sends any multivector in the embedding Geometric Algebra into a multivector in the tangent algebra at a point on a multivector manifold. The difficulty is that, on a general multivector manifold, there does not appear to be anything analogous to a pseudoscalar or volume element on a vector manifold. In order to make progress, the scope of the work was confined to the general rotor manifold.

Rotors form the group spin$^+(p,q)$ and Refs. 3 and 2 show that every Lie group can be represented as a spin group spin(p,q). Therefore the restriction to the rotor manifold spin$^+(p,q)$ still encompasses Lie groups as multivector manifolds. Spin(p,q) has the interesting property that the elements of its Lie algebra are bivectors (grade-2 elements of the Geometric Algebra). This fact, and the notion of left and right translation on a group, permit the construction of a projection operator into the tangent algebra of spin$^+(p,q)$ in Sec. III A.

Armed with the projection operator, the differential calculus on the multivector manifold spin$^+(p,q)$ is developed. Two interesting results are obtained. First, the derivative with respect to a point on the multivector manifold is shown, in Sec. III C, to live in the tangent algebra at the inverse point on the manifold. Second, the curvature tensor on the manifold is evaluated in Sec. III G and shown to be related to the structure constants of spin(p,q).

Integration on spin$^+(p,q)$ is formulated in a natural way by defining volume elements as completely antisymmetrized geometric products of bivectors. These volume elements are left

 © 1998 American Institute of Physics

invariant, just like Haar measure Ref. 6 and are shown to form a multivector-valued Grassman algebra in Sec. IV B. The interaction between the multivector grade and the Grassman grade of the volume elements gives rise to the interesting property (Sec. IV C) that not every spin group permits integration. Finally, a version of Stokes's theorem on $\text{spin}^+(p,q)$ is obtained in Sec. IV E and it is used to quickly obtain the curvature formula of Sec. III G.

Lie groups are thoroughly treated as vector manifolds in Ref. 1, so that it is necessary to consider what precisely is gained by the notion of a multivector manifold. In the author's opinion, a multivector can actually be an element of a Lie group because the grading endows it with a rich enough structure. One has no need to construct a representation of the group out of some other mathematical objects which lack the required spectrum of properties. For example, consider the case of spin(3,0). In Chap. 8 of Ref. 1, this group is represented as a vector manifold by the 3-sphere S^3. This is the set of vectors x in four-dimensional (4D) Euclidean space with constraint $x^2=1$. Let x, x', and x'' be three points of the vector manifold which are related by the group multiplication rule. The group multiplication rule on the representative vector manifold is

$$x''=\tfrac{1}{2}(xex'+x'ex)+\tfrac{1}{2}(xex'-x'ex)I, \tag{2}$$

where e is the vector corresponding to the group identity element and I is the unit pseudoscalar of the Geometric Algebra constructed from the 4D Euclidean space. Let rotors R, R', and R'' be elements of spin(3,0). In contrast to Eq. (2), the group multiplication rule is simply $R''=R'R$. This takes the form that is used for the group elements underlying the representation.

Furthermore, a key property of the spin groups is that their Lie algebras are bivectors. Consequently, the tangent algebra of the multivector manifold $\text{spin}(p,q)$ at the identity is distinguished by being the particularly simple space of bivectors. The representation of spin(3,0) as the vector manifold S^3 fails to capture this property because the lack of grading on a vector manifold means that all the tangent spaces must be copies of a linear vector space.

In summary, in order to make progress in physics one needs geometric objects that match the underlying physical reality. The spin groups seem to be an important constituent of this underlying reality. It seems that the grading associated with a multivector makes the notion of a multivector manifold the appropriate geometric object to use when treating the spin groups. For these reasons, the writer thinks that the notion of a multivector manifold might become a fruitful contribution to the program of geometrization of physics.

II. BASIC DEFINITIONS

The Geometric Algebra generated by p vectors of positive norm and q of negative norm is denoted $G_{p,q}$. The grade-r subspace of this algebra is denoted $G^r_{p,q}$.

Orthogonal transformations in $G_{p,q}$ are isometries of the inner product

$$f(x)\cdot f(y)=x\cdot y.$$

The simplest orthogonal transformation in $G_{p,q}$ is the reflection

$$f(x)=-u^{-1}xu,$$

where u is a vector. The most general isometry of the inner product is formed by k reflections

$$f(x)=(-1)^k u_k^{-1}\cdots u_1^{-1}xu_1\cdots u_k.$$

The inverse factors are $u_i^{-1}=u_i/u_i^2$ so nothing is lost by using unit vectors $u_i^2=\pm 1$. A rotation is the result of a pair of reflections so that a general rotation is obtained when k is even. The isometry is now

$$f(x)=U^{\dagger}xU,$$

where the multivector U is

$$U=u_1\cdots u_k$$

with k even and

$$U^\dagger U = u_k \cdots u_1 u_1 \cdots u_k = \pm 1.$$

The group of all products of an even number of unit vector factors is the group spin(p,q). The term *rotor* is used for elements of spin(p,q) satisfying $R^\dagger R = +1$, which has already been encountered as Eq. (1). The subgroup of spin(p,q) just containing the rotors is called the rotor group spin$^+(p,q)$. The reason for specifying rotors to obey Eq. (1) is because rotations are continuously connected to the identity, which is the rotor $R=1$, and $1^\dagger 1 = 1$.

III. DIFFERENTIAL CALCULUS ON THE ROTOR MANIFOLD

Chapter 2 of Ref. 1 shows how to differentiate a function of a multivector variable defined on a linear multivector subspace of $G_{p,q}$. The current section extends this to the case of functions defined on the rotor manifold.

A. The projection operator

The rotor manifold is the set of multivector points in $G_{p,q}$ that belong to spin$^+(p,q)$. It is embedded in $G_{p,q}$. Consider a function $A(R)$, defined on the rotor manifold, that takes values in $G_{p,q}$. For example, suppose that $A(R) = uRv$, where R is a point on the rotor manifold and u and v are arbitrary vectors. The example function uRv sticks out of the tangent algebra of the rotor manifold. In order to verify this, note that the points of the rotor manifold obey Eq. (1). Therefore, a small displacement δR in the rotor manifold obeys

$$(\delta R)^\dagger R + R^\dagger \delta R = 0$$

and a multivector-valued function $A(R)$ sticks out of the tangent algebra of the rotor manifold at point R if it violates the constraint

$$A^\dagger R + R^\dagger A = 0. \tag{3}$$

On substituting the example function $A = uRv$ into the left-hand side of Eq. (3), one obtains the expression $(R^\dagger uR)\cdot v/2$. The example function does indeed stick out of the tangent algebra since the expression is not zero. One needs an operator $P(R,A)$ that will project such a multivector A into the tangent algebra at point R.

The projection operator will be made by using the fact that each multivector defines a map of the geometric algebra into itself. Let L,X,Y be multivectors in $G_{p,q}$ and write $Y = LX$. This defines a left translation by L of the points X of $G_{p,q}$ into points Y. Consider a pair of neighboring points X and $X+\delta X$. Under left translation by L, the small displacement δX at X is mapped to a small displacement $\delta Y = L\,\delta X$ at $Y = LX$. In this way, a multivector-valued function $A(X)$ at X can be transformed, or left translated, into a multivector-valued function taking value $LA(X)$ at $Y = LX$. The next paragraph defines the projection operator by left translating a function to the identity element of the rotor manifold, manipulating it in the tangent algebra at the identity, then left translating it back to its starting point on the rotor manifold.

Let $A(R)$ be a multivector-valued function defined on the rotor manifold. The function is left translated back to the identity as $R^{-1}A(R)$. The Lie algebra of spin(p,q) is the linear space $G^2_{p,q}$ of bivectors. Consequently, taking the grade-2 part of the left-translated function gives a bivector $\langle R^{-1}A(R)\rangle_2$ in the tangent algebra of spin(p,q) at the identity. Left translation of this element of the Lie algebra to the original point R of the rotor manifold gives a multivector $R\langle R^{-1}A(R)\rangle_2$ in the tangent algebra of the rotor manifold at point R. The projection operator is therefore defined by

$$P(R,A) \overset{\text{def}}{=} R\langle R^{-1}A\rangle_2. \tag{4}$$

It is easily verified that the projection obeys the constraint of Eq. (3). The projection of the example function $A = uRv$ into the tangent algebra of the rotor manifold at R is $P(R,A) = R((R^\dagger uR)\wedge v)$.

The projection could also be defined using right translation as

$$P(R,A)=\langle AR^{-1}\rangle_2 R \tag{5}$$

and these alternative definitions turn out to be identical. In order to see this use, the general result $\langle R^\dagger AR\rangle_r=R^\dagger\langle A\rangle_r R$, which is easily obtained by writing A as a sum of blades of anticommuting vectors and using the property that R is an orthogonal transformation. Starting from the right-translated Eq. (5), the left-translated Eq. (4) is obtained as follows:

$$\begin{aligned}P(R,A)&=\langle AR^{-1}\rangle_2 R=\langle AR^\dagger\rangle_2 R=\langle RR^\dagger AR^\dagger\rangle_2 R=\langle R(R^\dagger A)R^\dagger\rangle_2 R\\&=R\langle R^\dagger A\rangle_2 R^\dagger R=R\langle R^\dagger A\rangle_2=R\langle R^{-1}A\rangle_2.\end{aligned}$$

B. Basis and dual basis multivector fields

Let $\{E_i\}$ be a bivector basis for the tangent space $G^2_{p,q}$ of the rotor manifold at the identity. Let $\{E^i\}$ be the dual bivector basis so that $\langle E^iE_j\rangle_0=\delta^i_j$. Expand the bivector part of the projection operator in equation (4) in terms of the basis bivectors. The summation convention is in force from this point onwards.

$$P(R,A)=R\langle R^{-1}A\rangle_2=R\langle\langle R^{-1}A\rangle_2E^i\rangle_0E_i=\langle\langle R^{-1}A\rangle_2E^i\rangle_0RE_i=\langle R^{-1}AE^i\rangle_0RE_i.$$

An application of the cyclic property of the scalar product in the final line gives the following formula for the projection:

$$P(R,A)=\langle AE^iR^{-1}\rangle_0RE_i. \tag{6}$$

The multivector fields RE_i in Eq. (6) are the left invariant fields of the rotor manifold which form a multivector basis for the tangent algebra at R. The form of Eq. (6) also shows that the multivector fields E^iR^{-1} are the dual basis fields. They are also right invariant multivector fields spanning the tangent algebra at the inverse point R^{-1} of the rotor manifold. These multivector fields are a basis and its dual basis because $\langle E^iR^{-1}RE_j\rangle_0=\delta^i_j$.

It is interesting that expansion (6) of a multivector-valued field on the rotor manifold in terms of a set of basis fields at a point should involve the dual basis fields which live at the inverse point on the manifold. On a vector manifold, both the basis and dual basis vector fields span the tangent vector space at the point on the vector manifold. In contrast, on the multivector manifold, the basis multivector fields RE_i span the tangent algebra at point R, while the dual basis multivector fields span the tangent algebra at point R^{-1}, and these tangent algebras are different from one another. This is illustrated in the simple case of spin(2,0). The rotor manifold spin(2,0) is one-dimensional so that a single bivector spans its tangent algebra at the identity. Take $E_1=-E^1=i$ with $i^2=-1$ and consider a point $R=\exp(i\theta/2)$ on the rotor manifold. This point is a rotation by a scalar angle θ. The basis multivector for the tangent algebra at R is

$$RE_1=-\sin(\theta/2)+i\cos(\theta/2),$$

while the basis multivector for the tangent algebra at the inverse point R^{-1} is

$$E^1R^{-1}=-\sin(\theta/2)-i\cos(\theta/2)$$

and it is clear these tangent algebras are different because one cannot write $RE_1=\alpha E^1R^{-1}$ for any scalar α.

C. Differentiation in the rotor manifold

Following Ref. 1, the directed derivative of a multivector-valued function $A(R)$ in the direction δR in the tangent algebra of the rotor manifold at point R is

$$\langle\delta R\partial_R\rangle_0A(R)\overset{\text{def}}{=}A(R+\delta R)-A(R). \tag{7}$$

The meaning of the derivative ∂_R with respect to a point on the rotor manifold can be found by expanding the displacement δR in (7) using (6).

$$\langle \delta R \partial_R \rangle_0 = \langle \langle \delta R E^i R^{-1} \rangle_0 R E_i \partial_R \rangle_0 = \langle \delta R E^i R^{-1} \rangle_0 \langle R E_i \partial_R \rangle_0 = \langle \delta R E^i R^{-1} \langle R E_i \partial_R \rangle_0 \rangle_0 .$$

The final line shows that the derivative with respect to a point is

$$\partial_R = E^i R^{-1} \langle R E_i \partial_R \rangle_0 . \tag{8}$$

The meaning of (8) is that the derivative with respect to a point R on the rotor manifold is a multivector-valued operator in the tangent algebra at the inverse point R^{-1}.

D. Example of differentiation

In applications, it is useful to have a formula for $\partial_R \langle MR \rangle_0$, where M is a constant multivector in $G_{p,q}$.

$$\partial_R \langle MR \rangle_0 = E^i R^\dagger \langle R E_i \dot{\partial}_R \rangle_0 \langle M \dot{R} \rangle_0 = E^i R^\dagger \langle M R E_i \rangle_0 .$$

When one compares the above result with (6), it is clear that

$$\partial_R \langle MR \rangle_0 = P(R^{-1}, M). \tag{9}$$

Similarly,

$$\partial_R \langle R^\dagger M \rangle_0 = \partial_R \langle M^\dagger R \rangle_0 = P(R^{-1}, M^\dagger). \tag{10}$$

As an example of the use of these formulas, the stationary points of the scalar-valued function $\langle v R^\dagger u R \rangle_0$ on spin$^+(p,q)$ are determined. Here, u and v are vectors in $G^1_{p,q}$,

$$\begin{aligned} \partial_R \langle v R^\dagger u R \rangle_0 &= \dot{\partial}_R \langle v \dot{R}^\dagger u R \rangle_0 + \dot{\partial}_R \langle v R^\dagger u \dot{R} \rangle_0 \\ &= \dot{\partial}_R \langle \dot{R}^\dagger u R v \rangle_0 + \dot{\partial}_R \langle v R^\dagger u \dot{R} \rangle_0 \\ &= 2 P(R^\dagger, v R^\dagger u) \\ &= 2 \langle v R^\dagger u R \rangle_2 R^\dagger . \end{aligned} \tag{11}$$

The last line follows from (5). Using (11), the condition for a stationary point is

$$\langle v R^\dagger u R \rangle_2 = v \wedge (R^\dagger u R) = 0. \tag{12}$$

Condition (12) can also be written as an eigenrotor equation

$$v R^\dagger u R = v \cdot (R^\dagger u R) + v \wedge (R^\dagger u R) = \langle v R^\dagger u R \rangle_0 . \tag{13}$$

Multiplying on the right by $R^\dagger$ gives the equivalent eigenrotor equation

$$v R^\dagger u = \langle v R^\dagger u R \rangle_0 R^\dagger \tag{14}$$

with eigenrotors $R^\dagger$ and eigenvalues $\langle v R^\dagger u R \rangle_0$.

E. Lie brackets and commutators

Let A and B be multivector fields in the rotor manifold. Figure 1 shows some integral curves of A and B with parameters α and β, respectively. The multivectors R, S, T, U, and V are points in the rotor manifold that are used to approximate the fields. For example, R and S are separated by a parameter distance α

$$A(R) = \frac{dR}{d\alpha} \approx \frac{S - R}{\alpha}, \tag{15}$$

$$B(R) = \frac{dR}{d\beta} \approx \frac{V - R}{\beta}. \tag{16}$$

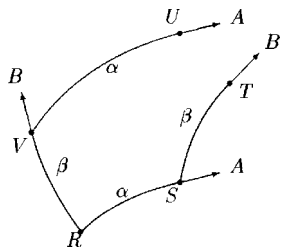

FIG. 1. Gap construction of the Lie bracket.

The conventional *Lie bracket* is extended to the rotor manifold by

$$[B,A] \overset{\text{def}}{=} \langle B\dot{\partial}_R\rangle_0 A(\dot{R}) - \langle A\dot{\partial}_R\rangle_0 B(\dot{R}). \tag{17}$$

Using definition (17) in conjunction with the approximations to the fields, the Lie bracket is shown to be, in essence, the gap in Fig. 1

$$\alpha\beta[B,A] = U - T. \tag{18}$$

Now consider the gap construction to be placed at the identity in the rotor manifold by setting $R=1$. Also, suppose that the multivector fields are no longer arbitrary, but are generators on $\text{spin}^+(p,q)$. This means, for example, that the multivector field $A(V)$ can be obtained by left translation from the field value at the identity as $A(V)=VA(1)$. In other words, when the multivector fields are generators, the points in the gap construction at the identity are not independent since $U=VS$ and $T=SV$. These relations show that the Lie bracket and the commutator are identical for the generators on $\text{spin}^+(p,q)$ at the identity because

$$[B,A] = \frac{1}{\alpha\beta}(VS-SV) = \frac{1}{\alpha\beta}((1+\beta B)(1+\alpha A)-(1+\alpha A)(1+\beta B)) = BA-AB. \tag{19}$$

Reference 1 defines the *commutator product* of a pair of *arbitrary* multivectors by

$$B\times A \overset{\text{def}}{=} \frac{1}{2}(BA-AB)$$

and proves that for A and B *bivectors*,

$$B\times A = \langle BA\rangle_2 .$$

Therefore, the following useful relations hold between bivectors, which are the elements of the tangent algebra $G^2_{p,q}$ at the identity of the rotor manifold $\text{spin}^+(p,q)$:

$$B\times A = \langle BA\rangle_2 = \tfrac{1}{2}(BA-AB) = \tfrac{1}{2}[B,A]. \tag{20}$$

F. Parallel transport on the rotor manifold

The notion of parallel transport on the rotor manifold can be defined with the aid of the projection operator that was introduced in Sec. III A. Let $A(R)$ be a multivector in the tangent algebra of the rotor manifold at R. The result of parallel transport of $A(R)$ to the point $R+\delta R$ on the rotor manifold is the multivector $P(R+\delta R, A(R))$. The change δA under parallel transport by δR is therefore,

$$\delta A = \langle \delta R\dot{\partial}_R\rangle_0 P(\dot{R},A(R)) \overset{\text{def}}{=} P_{\delta R}(R,A(R)) = \langle \delta R\dot{\partial}_R\rangle_0 \dot{R}\langle \dot{R}^{-1}A\rangle_2 = \delta R R^{-1}A - R\langle R^{-1}\delta R R^{-1}A\rangle_2 . \tag{21}$$

In obtaining Eq. (21), the relation $\langle R^{-1}A\rangle_2 = R^{-1}A$ was used since A is in the tangent algebra of the rotor manifold at R and therefore $R^{-1}A$ is the left translation into the tangent algebra $G^2_{p,q}$ at the identity.

Instead of the change δA, which is a multivector that sticks out of the rotor manifold into the embedding algebra $G_{p,q}$, it is more helpful to keep track of the bivector-valued change $\delta(R^{-1}A)$ in the tangent algebra $G^2_{p,q}$ at the identity. This is

$$\delta(R^{-1}A) = -\langle R^{-1}\delta R R^{-1}A\rangle_2 = (R^{-1}A)\times(R^{-1}\delta R). \tag{22}$$

The geodesic equation in $\mathrm{Spin}^+(p,q)$ is obtained by replacing A in Eq. (22) by the tangent multivector $(dR/d\lambda)$ to a path with parameter λ. It is

$$\frac{d}{d\lambda}\left(R^{-1}\frac{dR}{d\lambda}\right) = 0 \tag{23}$$

which has the solution,

$$R(\lambda) = R(0)e^{\lambda B}, \tag{24}$$

where B is a bivector, so that the geodesics are also the one-parameter Abelian subgroups (compare exercise 10.17 of Ref. 7).

The covariant derivative of a multivector-valued function $A(R)$ in the direction δR of the rotor manifold is

$$\langle \delta R\nabla_R\rangle_0 A(R) \overset{\text{def}}{=} P(R,A(R+\delta R)) - P(R,A(R)) = P(R,\langle \delta R\dot{\partial}_R\rangle_0 A(\dot{R})). \tag{25}$$

G. Intrinsic curvature of the rotor manifold

Some results for vector manifolds in Ref. 1 are easily adapted to give the change δA in a multivector A after parallel transport around an infinitesimal parallelogram with sides δR_1 and δR_2 in a general multivector manifold

$$\begin{aligned}\delta A &= P_{\delta R2}(R,P_{\delta R1}(R,A)) - P_{\delta R1}(R,P_{\delta R2}(R,A))\\ &= (\langle \delta R_2\nabla_R\rangle_0\langle \delta R_1\nabla_R\rangle_0 - \langle \delta R_1\nabla_R\rangle_0\langle \delta R_2\nabla_R\rangle_0 - \langle[\delta R_2,\delta R_1]\nabla_R\rangle_0)A.\end{aligned} \tag{26}$$

The case of the rotor manifold can be obtained by replacing the derivatives of the projection operator, $P_{\delta R}(R,A)$, that occur in Eq. (26) with the result in Eq. (21)

$$R^{-1}\delta A = -(R^{-1}A)\times((R^{-1}\delta R_1)\times(R^{-1}\delta R_2)). \tag{27}$$

The details of the calculation of Eq. (27) from the general formula (26) are omitted because the result is most easily obtained by following the derivation of the Riemann curvature tensor in Ref. 8. For this reason, the calculation must be postponed until Stokes's theorem on $\mathrm{spin}^+(p,q)$ is available in Sec. IV E.

The curvature tensor is hidden inside Eq. (27), but it can be made explicit by expressing everything in components with respect to the basis and dual basis multivectors RE_i and E^iR^{-1} of Sec. III B. For example, the multivector A at point R on the rotor manifold is expanded as in Eq. (6),

$$A = \langle AE^iR^{-1}\rangle_0 RE_i = A^iRE_i,$$

where the components of a multivector are distinguished because they carry superscripts. Expanding δA, A, δR_1, and δR_2 in this way in Eq. (27) gives

$$\delta A^l = -E^l\cdot(E_i\times(E_j\times E_k))A^i\delta R_1^j\delta R_2^k$$

and the components B^l_{ijk} of the curvature tensor are

$$B^l_{ijk} = -E^l \cdot (E_i \times (E_j \times E_k)). \tag{28}$$

The structure constants c^k_{ij} of the Lie algebra of spin(p,q) in this basis are obtained from

$$[E_i, E_j] = c^k_{ij} E_k \tag{29}$$

and using Eqs. (20), (29), and (28), the following relation (compare exercise 11.12 of Ref. 7) between the structure constants and the components of the curvature tensor on spin(p,q) is obtained:

$$B^l_{ijk} = -\tfrac{1}{4} c^l_{im} c^m_{jk}. \tag{30}$$

In the standard texts on Lie groups, the Jacobi identity is used to prove the following relation among the structure constants:

$$c^l_{im} c^m_{jk} + c^l_{jm} c^m_{ki} + c^l_{km} c^m_{ij} = 0.$$

The curvature tensor also has the symmetry,

$$B^l_{ijk} + B^l_{jki} + B^l_{kij} = 0$$

and the relation between these two facts is clear from Eq. (30).

IV. INTEGRAL CALCULUS ON THE ROTOR MANIFOLD

Consider Eq. (27) that gives the change in a multivector under parallel transport around a closed contour in the rotor manifold. The comparison of (27) with the analogous equation on a Riemannian manifold Ref. 8 suggests that the bivector $(R^{-1}\delta R_1) \times (R^{-1}\delta R_2)$ is the area of the infinitesimal parallelogram whose edges are the multivector displacements δR_1 and δR_2 on the rotor manifold at R. Equation (20) shows that the key point about this area is that it is a completely antisymmetrized geometric product of bivectors. It seems reasonable to generalize this notion, by defining a k-dimensional volume element on spin$^+(p,q)$ as a completely antisymmetrized geometric product of bivectors, and to formulate integration on spin$^+(p,q)$ in terms of such geometric objects.

A. Directed Haar measure

An infinitesimal k-dimensional volume element $d\mathscr{V}(R)$, at multivector point R on spin$^+(p,q)$, is a completely antisymmetrized geometric product of bivectors

$$d\mathscr{V}(R) = [R^{-1}dR_1, \ldots, R^{-1}dR_k] \overset{\text{def}}{=} \sum_\sigma \ \text{sgn}(\sigma) R^{-1}dR_{\sigma(1)} \cdots R^{-1}dR_{\sigma(k)}. \tag{31}$$

In Eq. (31), σ denotes a permutation of the indices $1,\ldots,k$ and a generalized Lie bracket notation is used to denote a completely antisymmetrized geometric product of bivectors.

If a left translation $T = SR^{-1}$ is made from R to S then a typical dR of the volume element at R is left-translated to $dS = SR^{-1}dR$ and so $S^{-1}dS = R^{-1}dR$. Therefore $d\mathscr{V}(TR) = d\mathscr{V}(R)$ and so the volume elements are a left invariant measure on spin$^+(p,q)$ similar to Haar measure Ref. 6.

B. Grassman algebra of the volume elements

The generators of the Grassman algebra Ref. 9 are the bivectors of $G^2_{p,q}$. A grade-k element of the Grassman algebra is a completely antisymmetrized geometric product of k bivectors $B_1, \ldots, B_k$

$$\mathscr{A} = [B_1, \ldots, B_k] \overset{\text{def}}{=} \sum_\sigma \ \text{sgn}(\sigma) B_{\sigma(1)} \cdots B_{\sigma(k)}. \tag{32}$$

Clearly,

$$[B_{\sigma(1)},\ldots,B_{\sigma(k)}]=\mathrm{sgn}(\sigma)[B_1,\ldots,B_k] \tag{33}$$

so that the brackets can be multiplied by scalars and hence arbitrary elements of the Grassman algebra can be made using linear combinations of the brackets with scalar coefficients.

It is important to note that *grade* now has two meanings. One may refer to the grade of a Grassman element or to its multivector grade. The first is simply the number of bivector generators in the square bracket, the second is the grade of the right-hand side of Eq. (32), considered as a multivector in $G_{p,q}$. The interaction between these two notions of grade is the subject of Sec. IV C.

Elements of the Grassman algebra are multiplied by simply putting the bivector generators together in a geometric product and antisymmetrizing

$$\mathscr{A}\mathscr{B}=[B_1,\ldots,B_k][B_{k+1},\ldots,B_{k+l}]\overset{\text{def}}{=}[B_1,\ldots,B_k,B_{k+1},\ldots,B_{k+l}]. \tag{34}$$

This amounts to just removing the internal square brackets. It is then obvious that multiplication of the Grassman elements is associative. Using Eq. (33), the commutation rule for a pair of elements of Grassman grades k and l is

$$\mathscr{B}\mathscr{A}=(-1)^{kl}\mathscr{A}\mathscr{B}. \tag{35}$$

In Eq. (34), the product of a pair of elements of Grassman grades k and l is of Grassman grade $k+l$. There is also a need for an inner product, written $\mathscr{A}\circ\mathscr{B}$, which reduces the Grassman grade. Using Eq. (32), collect the terms which lead with $B_1,B_2,\ldots,B_k$. The result is a left expansion

$$\mathscr{A}=\sum_{j=1}^{k}(-1)^{j-1}B_j[B_1,\ldots,\check{B}_j,\ldots,B_k] \tag{36}$$

and similarly, a right expansion,

$$\mathscr{A}=\sum_{j=1}^{k}(-1)^{k-j}[B_1,\ldots,\check{B}_j,\ldots,B_k]B_j \tag{37}$$

where the vee means the jth bivector is omitted from the bracket. The rule for constructing the inner product $\mathscr{A}\circ\mathscr{B}$ is to make a right expansion of $\mathscr{A}$ and a left expansion of $\mathscr{B}$. The inner product of Geometric Algebra is then employed to reduce every pair of adjacent bivectors outside the brackets to scalars. The recursive definition is thus,

$$\mathscr{A}\circ\mathscr{B}=[B_1,\ldots,B_k]\circ[B'_1,\ldots,B'_l]$$

$$\overset{\text{def}}{=}\sum_{r=1}^{k}\sum_{s=1}^{l}(-1)^{k-r+s-1}B_r\cdot B'_s[B_1,\ldots,\check{B}_r,\ldots,B_k]\circ[B'_1,\ldots,\check{B}'_s,\ldots,B'_l]. \tag{38}$$

This rule is consistent, because it can be shown that the right-hand side of Eq. (38) preserves the antisymmetry of the elements $\mathscr{A}$ and $\mathscr{B}$. Repeated application of Eq. (38) shows that the Grassman grade of $\mathscr{A}\circ\mathscr{B}$ is $|k-l|$. It can also be shown that the commutation rule for the inner product of elements of Grassman grades k and l with $k\leqslant l$ is

$$\mathscr{B}\circ\mathscr{A}=(-1)^{k(l-k)}\mathscr{A}\circ\mathscr{B}. \tag{39}$$

C. Multivector values of the volume elements

This section studies the interaction between the Grassman grade and the multivector grades of the volume elements that was mentioned in Sec. IV B.

1. Multivector grades of a Grassman element

Consider a Grassman grade-k element $\mathscr{A}$ as a completely antisymmetrized geometric product of bivectors [see Eq. (32) so that it is a multivector in $G_{p,q}$]. Apply the reversion operation of Ref. 1 to this multivector

$$\mathscr{A}^\dagger=[B_1,\ldots,B_k]^\dagger=\sum_\sigma \ \mathrm{sgn}(\sigma)B^\dagger_{\sigma(k)}\cdots B^\dagger_{\sigma(1)}\,.$$

The reverse of a bivector is $B^\dagger=-B$ and each permutation in the sum has also been reversed so that each term gets a sign change $(-1)^{k(k-1)/2}$. Therefore,

$$\mathscr{A}^\dagger=[B_1,\ldots,B_k]^\dagger=(-1)^{k(k+1)/2}[B_1,\ldots,B_k]=(-1)^{k(k+1)/2}\mathscr{A}. \tag{40}$$

Formula (1-1.19) of Ref. 1 can also be used to find the reversion-symmetry of the multivector grade-r part of $\mathscr{A}$

$$\langle\mathscr{A}^\dagger\rangle_r=(-1)^{r(r-1)/2}\langle\mathscr{A}\rangle_r\,. \tag{41}$$

Equations (40) and (41) impose a restriction on the allowable multivector grades of a volume element of Grassman grade-k because

$$\langle\mathscr{A}\rangle_r=0 \ \text{ if } \ (-1)^{r(r-1)/2}\neq(-1)^{k(k+1)/2}. \tag{42}$$

As an example, consider the commutator $[B_1,B_2]$, which, by Eq. (20), is known to be a pure bivector in spite of the fact that it could be of multivector grades $r=0,2,4$ since it is made from geometric products of pairs of bivectors. Setting $k=2$ in Eq. (42) shows that multivector grades $r=0,4$ cannot exist so that the commutator is a pure bivector.

2. Rotor manifolds with nonvanishing volume elements

Let $p+q=n$. The dimension of spin(p,q) is the dimension of its Lie algebra $G^2_{p,q}$ which is $N=n(n-1)/2$. Let $e_1,\ldots,e_n$ be an anticommuting set of basis vectors for $G^1_{p,q}$ with $e_j^2=\pm1$. A bivector basis for the tangent algebra of spin$^+(p,q)$ at the identity is $E_1=e_1e_2,\ldots,E_N=e_{n-1}e_n$. A volume element $d\mathscr{V}$ on spin$^+(p,q)$ is a Grassman grade-N element which, by expanding its bivector factors in terms of the basis bivectors, is shown to be simply proportional to the element $[E_1,\ldots,E_N]$. There are $(n-1)$ copies of e_j for $j=1,\ldots,n$ in each geometric product that forms $[E_1,\ldots,E_N]$. The anticommuting property can be used to bring the vectors together. There is no need to keep track of the sign changes. Each geometric product is of the form $\pm e_1^{n-1}\cdots e_n^{n-1}$. There are two cases to be considered.

If n is odd then each factor e_j^{n-1} contains an even number of vectors and therefore $[E_1,\ldots,E_N]$ must be a pure scalar. Now check that the restriction (42) is compatible with this statement by setting the Grassman grade $k=N$ and the multivector grade $r=0$. The restriction implies that

$$\begin{aligned} d\mathscr{V}&=\langle d\mathscr{V}\rangle_0 \ \text{ for } \ n \ \text{ odd and } \ \frac{n(n-1)(n(n-1)+2)}{8} \ \text{ even},\\ d\mathscr{V}&=0 \ \text{ for } \ n \ \text{ odd and } \ \frac{n(n-1)(n(n-1)+2)}{8} \ \text{ odd}. \end{aligned} \tag{43}$$

If n is even then each factor e_j^{n-1} contains an odd number of vectors and therefore $[E_1,\ldots,E_N]$ must be a pure pseudoscalar. This time, the compatibility of the restriction (42) is checked by setting the Grassman grade $k=N$ and the multivector grade $r=n$. The restriction implies that

$$d\mathscr{V}=\langle d\mathscr{V}\rangle_n \ \text{ for } \ n \ \text{ even and } \ \frac{n(n-1)(n(n-1)-2)}{8} \ \text{ even}, \tag{44}$$

$$d\mathscr{V}=0 \quad \text{for } n \text{ even and } \frac{n(n-1)(n(n-1)-2)}{8} \text{ odd.}$$

Applying these conditions for the low dimensional rotor manifolds, one finds that integration is possible on $\text{spin}^+(p,q)$ for $p+q=2,3,8,9,10,11$, while integration is forbidden for $p+q=4,5,6,7,12,13,14,15$.

D. Example of integration

The volume of spin(3,0),

$$\mathscr{V}=\int d\mathscr{V}=\int [R^{-1}dR_1,R^{-1}dR_2,R^{-1}dR_3]$$

is calculated as an example of integration on a rotor manifold. Introduce basis bivectors E_1,E_2,E_2 for $G^2_{3,0}$ with the properties $E_1^2=E_2^2=E_3^2=-1$ and $E_3E_2=E_1$, $E_1E_3=E_2$, $E_2E_1=E_3$. Coordinates are needed to evaluate the integral. A point on the rotor manifold is $R=\alpha+A$ where α is a scalar and A is a bivector. The components A^1,A^2,A^3 of A in the bivector basis are used as coordinates. The constraint (1) means that

$$\alpha^2=1-(A^1)^2-(A^2)^2-(A^3)^2.$$

The bivector generators turn out to be

$$R^{-1}dR_j=\left(E_j\times A+\alpha E_j+\frac{A^jA}{\alpha}\right)dA^j$$

for $j=1,2,3$ and no summation. A straightforward calculation gives

$$\mathscr{V}=3!\int \frac{dA^1dA^2dA^3}{\alpha}=3!\int \frac{dA^1dA^2dA^3}{\pm\sqrt{1-(A^1)^2-(A^2)^2-(A^3)^2}}.$$

The coordinates range over the unit ball in three dimensions. The integral is therefore over two unit balls because of the sign ambiguity of the square root. The volume elements defined in Sec. IV A are a *directed measure* Ref. 1 and so the integral over the whole of spin(3,0) vanishes because of the sign ambiguity. In accordance with Eq. (43), the volume elements $d\mathscr{V}$ on spin(3,0) are scalar-valued, so a positive result for the volume is obtained by integrating the absolute values of the volume elements

$$V=3!\int \frac{dA^1dA^2dA^3}{|\alpha|}=2\cdot 3!\,\pi^2=12\pi^2.$$

The volumes for SO(3) and SU(2) are stated in Ref. 10 as being $8\pi^2$ and $4\pi^2$, respectively. The different numerical factors are not significant. The volume of spin(3,0) of $12\pi^2$ can also be calculated using Euler angle coordinates, more commonly used for SO(3). When this is done it becomes clear that the different numerical factors are due to a factor of 3! that might be included in the definition of a volume element and a factor of 2^3, caused by the three generators because of the half-angle nature of spin(3,0).

E. Stokes's theorem

Stokes's theorem relates an integral over a k-dimensional region to an integral over its $(k-1)$-dimensional boundary. The integral over the k-dimensional region of $\text{spin}^+(p,q)$ will be

$$\int \mathscr{L}(R,(\partial_R R)\circ[R^{-1}dR_1,\ldots,R^{-1}dR_k])$$

where $\mathscr{L}(\cdot,\cdot)$ is a Grassman-valued function on the rotor manifold (first slot) and is a linear function of a Grassman element (second slot). The second slot is filled with the Grassman inner

product $(\partial_R R)\circ d\mathscr{V}$ where ∂_R is the derivative with respect to a point R on the rotor manifold [Eq. (8)] and $d\mathscr{V}$ is the directed Haar measure [Eq. (31)]. Section III C has shown that ∂_R lives in the tangent algebra at the inverse point R^{-1}. Therefore, it must be right translated, as $\partial_R R$, to the tangent space at the identity of spin$^+(p,q)$, where it is a bivector or generator of the Grassman algebra and it can take part in the Grassman inner product. The derivative ∂_R operates on *all* the R variables in the integral including those in the directed Haar measure.

Stokes's theorem is a straightforward calculation using the definition of the Grassman inner product [Eq. (38)]. The result is

$$\int_{\mathscr{V}} \mathscr{L}(R,(\partial_R R)\circ d\mathscr{V}(R)) = \int_{\partial\mathscr{V}} \mathscr{L}(R,d\mathscr{S}(R)), \tag{45}$$

where $d\mathscr{S}$ is the Grassman grade-$(k-1)$ measure of the boundary of the integration region.

The derivation of formula (27) for the change δA in a multivector A after parallel transport around a closed contour in spin$^+(p,q)$, that was promised in Sec. III G, is now obtained by application of Stokes's theorem. Consider the following integral over a two-dimensional patch of spin$^+(p,q)$ which is converted to an integral around a closed contour by Stokes's theorem:

$$\int (R^{-1}A)\times(\partial_R R\circ[R^{-1}dR_1, R^{-1}dR_2]) = \oint (R^{-1}A)\times(R^{-1}dR). \tag{46}$$

Equation (22) shows that the right-hand side of Eq. (46) is the cumulative change in the bivector that has been left translated to the identity as the loop is traversed

$$\oint d(R^{-1}A) = \int (R^{-1}A)\times(\partial_R R\circ[R^{-1}dR_1, R^{-1}dR_2]). \tag{47}$$

Now evaluate the right-hand side using the definition (38) of the Grassman inner product

$$\oint d(R^{-1}A) = \int \langle dR_1\partial_R\rangle_0((R^{-1}A)\times(R^{-1}dR_2)) - \langle dR_2\partial_R\rangle_0((R^{-1}A)\times(R^{-1}dR_1)).$$

Differentiate by parts, use Eq. (22) for the $R^{-1}A$ terms, use the Jacobi identity for commutator products and the definition (20) of the commutator product, and the result is

$$\oint d(R^{-1}A) = -\int (R^{-1}A)\times(R^{-1}dR_1\times R^{-1}dR_2). \tag{48}$$

This is a bivector change. Multiply by R in order to get the change δA at R on the rotor manifold for an infinitesimal loop. The result,

$$\delta A = -R((R^{-1}A)\times(R^{-1}dR_1\times R^{-1}dR_2))$$

is Eq. (27) of Sec. III G.

Foliation of a dynamically homogeneous neutral manifold

Novica Blažić, Neda Bokan,[a] and Zoran Rakić

(Received 8 August 1997; accepted for publication 8 July 1998)

It is known that Riemannian and Lorentzian four-dimensional dynamically homogeneous manifolds are two-point homogeneous spaces. This is not true for signature $(--++)$ (neutral or Kleinian signature). In order to better understand their rich structure we study the geometry of nonsymmetric dynamically homogeneous spaces (types II and III): they admit autoparallel distributions and they are locally foliated by totally geodesic, flat, isotropic two-dimensional submanifolds. Moreover we characterize them locally in terms of the existence of an appropriate coordinate system (in the sense of A. G. Walker [Q. J. Math. **1**, 69–79 (1950)]).

I. INTRODUCTION

The Jacobi operator is important in pseudo-Riemannian geometry as shown in the following examples. A family of free falling particles along a geodesic γ in a Lorentz manifold (M,g), is described by the normal variational Jacobi vector field V along γ. The Jacobi operator plays the role of the tidal force and V satisfies Newton's second law: $V''=R_{V\gamma'}(\gamma')=\mathcal{K}_{\gamma'}V$.[1] The Jacobi operator $\mathcal{K}_{\gamma'}$ is a symmetric operator on the tangent space and from the dynamical point of view the simpliest case to consider is when the algebraic structure of $\mathcal{K}_X$ does not depend on the choice of the unit spacelike or timelike vector X. In other words local dynamics of these spaces is the same in all points and all non-null directions.

Pseudo-Riemannian manifolds with a metric of signature (2,2) have a very interesting geometry. They are also important for physisists. Geometry of these manifolds has been studied, for example, in Refs. 2–4, etc. Spaces with more than one time component have been studied before in Kaluza–Klein theories and a string context (see, Refs. 5–7). $N=2$ string theory is one of the simplest and the most interesting types of string theories. The heterotic version of $N=2$ strings is more intricate than the symmetric one as the dimension for target space is four and its signature (2,2). Its correspondence with self-dual Yang–Mills configuration and a notion of integrability for field theories is studied in Ref. 8. Some other results related to metrics of signature (2,2) one can find, for example, in Refs. 9 and 10, etc.

Let $S^+(p)$ and $S^-(p)$ be the sets of all unit non-null vectors, respectively, at a point $p\in M$. The Jacobi operator $R:Y\mapsto R(Y,X)X$ is a symmetric endomorphism of the tangent space. Its restriction to $X^\perp$ is denoted by $\mathcal{K}_X$. We say that (M,g) is *dynamically homogeneous* or *Osserman manifold* if the Jordan form of $\mathcal{K}_X$ is independent of the choice $X\in S^+(p)\cup S^-(p)$ for arbitrary point $p\in M$.

Now we can state the following question: What is the local and global structure of dynamically homogeneous pseudo-Riemannian manifolds? In a special case of positive definite metric Osserman[11] conjectured that dynamically homogeneous manifolds have to be two-point homogeneous, i.e., rank-one locally symmetric or flat. The conjecture was confirmed by Chi[12] for $\dim M\neq 4k$, $k>1$ (see also Refs. 13, 14 as well as 15 for more details). Also, Lorentzian dynamically homogeneous manifolds have to be of constant sectional curvature (see Ref. 16). But in $(--++)$ signature there are nonsymmetric examples of dynamically homogeneous manifolds ([Ref. 3, examples 8.6–8.8] and Refs. 17 and 18).

If M is a manifold with the diagonalizable Jacobi operator $\mathcal{K}_X$ or if its characteristic polynomial has no triple root then in Ref. 3 it was proved that M is rank-one symmetric space or flat. But

[a]Electronic mail: neda@matf.bg.ac.yu

 © 1998 American Institute of Physics

for $\mathcal{K}_X$ with triple eigenvalue α and the minimal polynomial of the degree 2 or 3 it is not true. These are especially type II and type III dynamically homogeneous manifolds.

We are particularly interested in the neutral signature $(--++)$ and this condition is reduced to the constancy of the minimal polynomial of the Jacobi operator $\mathcal{K}_X$.

The main goal of this paper is to establish some important properties of Osserman manifolds of types II and III. It is known that dynamically homogeneous neutral manifolds have to be self-dual.[19] As we mentioned before self-dual neutral manifolds are broadly studied in Refs. 9 and 10. Here we show that Osserman manifolds of types II and III admit an integrable, autoparallel isotropic two-dimensional distribution in $T_p(M)$, $p \in M$. These distributions have been studied also in the framework of the conformal structure CO(2,2) of four-dimensional manifold M (see Refs. 20 and 2, etc.). We study also some coordinate systems for type II and III dynamically homogeneous manifolds such that the metric has a simpler form. Let us mention that the Walker metric,[21] corresponding to the parallel distributions, belongs to this class and the existence of this type of metric was one of the most important facts in the proof that type II dynamically homogeneous manifolds have to have $\mathcal{K}_X$ with all equal eigenvalues.

II. PRELIMINARIES

Let M be a pseudo-Riemannian manifold of dimension 4 with the metric $\langle \cdot,\cdot \rangle$ of signature (2,2). We also use the notation g for the metric because of convenience reasons. Let $\epsilon_i = -1$, $i=1,2$, and $\epsilon_i = 1$, $i=3,4$. Let e_1, e_2, e_3, e_4 denote an orthonormal basis of T_pM, $\langle e_i, e_j \rangle = \epsilon_i \delta_{ij}$.

ω and Ω are the connection one-form and the curvature two-form, respectively. Then

$$\nabla e_i = \sum \omega_i^s e_s,$$

$$\Omega_j^i = \frac{1}{2} \sum R_{klj}{}^i \theta^k \wedge \theta^l = \frac{1}{2} R_{klj}{}^i \theta^{kl},$$

where θ^i are the dual forms of e_i, i.e., $\theta^i(e_j) = \delta^i_j$ and $\theta^{kl} = \theta^k \wedge \theta^l$. The Cartan structural equations are given as

$$d\theta^i = -\sum \omega_j^i \wedge \theta^j,$$

$$d\omega_j^i = -\sum (\omega_k^i \wedge \omega_j^k + \Omega_j^i) \quad \text{(the second Bianchi identity)}.$$

Let us mention also the symmetry properties of the connection forms as well as the curvature forms

$$\omega_j^i = -\epsilon_i \epsilon_j \omega_i^j, \quad \Omega_j^i = -\epsilon_i \epsilon_j \Omega_i^j.$$

III. TYPE II DYNAMICALLY HOMOGENEOUS MANIFOLDS

In this section we will consider the case when the Jacobi operator $\mathcal{K}_X$ has a characteristic polynomial with triple zero α and the minimal polynomial of degree two. We recall there exists a pseudo-orthonormal basis e_1, e_2, e_3, e_4 such that the matrix of $\mathcal{K}_{e_1}$ has the form

$$\begin{pmatrix} \alpha - \frac{1}{2} & \frac{1}{2} & 0 \\ -\frac{1}{2} & \alpha + \frac{1}{2} & 0 \\ 0 & 0 & \beta \end{pmatrix} \quad \text{or} \quad \begin{pmatrix} -\alpha + \frac{1}{2} & -\frac{1}{2} & 0 \\ \frac{1}{2} & -\alpha - \frac{1}{2} & 0 \\ 0 & 0 & \beta \end{pmatrix}, \tag{3.1}$$

with respect to this basis.

The following one-forms can help us to better understand the structure of these manifolds

$$A=\omega_1^2-\omega_3^4, \quad B=\omega_1^3+\omega_2^4, \quad C=\omega_1^4-\omega_2^3, \quad \tilde{A}=\tfrac{1}{2}(A-B).$$

These one-forms are the linear combinations of the basic forms θ^i, i.e.,

$$A=\sum A_i\theta^i, \quad B=\sum B_i\theta^i, \quad C=\sum C_i\theta^i, \quad \tilde{A}=\sum \tilde{A}_i\theta^i.$$

The coefficients are not independent. More precisely, the following lemma holds.

3.1 Lemma: (Ref. 3) The coefficients $\tilde{A}_i$, $i=1,...,4$ *satisfy the following relations*

$$\tilde{A}_1=\tilde{A}_4=-C_2-C_3 \quad \textit{and} \quad \tilde{A}_2=-\tilde{A}_3=C_1-C_4.$$

We have proved that $\beta=\alpha$ in (3.1) (see [Ref. 3, Corollary 7.7]). Also the nonvanishing generic components of the curvature tensor are the following ones:

$$\begin{gathered} R_{1221}=R_{4334}=\tfrac{1}{2}-\alpha, \quad R_{1331}=R_{4224}=\alpha+\tfrac{1}{2}, \quad R_{1441}=R_{3223}=\beta, \\ R_{2113}=R_{2443}=R_{1234}=-\tfrac{1}{2}, \quad R_{1224}=R_{1334}=R_{1342}=\tfrac{1}{2}. \end{gathered} \tag{3.2}$$

Notice that the scalar curvature is given by $\tau=-12\alpha$.

It is now convenient to consider the components of the curvature tensor in the following isotropic frame

$$F_1=\frac{1}{\sqrt{2}}(e_1-e_4), \quad F_2=\frac{1}{\sqrt{2}}(e_2+e_3), \quad F_3=\frac{1}{\sqrt{2}}(e_2-e_3), \quad F_4=\frac{1}{\sqrt{2}}(e_1+e_4), \tag{3.3}$$

and let ξ^i be the corresponding dual basis and φ_j^i be the corresponding connection forms, so $\nabla F_i=\varphi_i^j F_j$.

Symmetries of the connection forms φ_i^j are the following

$$\begin{gathered} \varphi_1^3+\varphi_2^4=\varphi_3^1+\varphi_4^2=0, \quad \varphi_1^4=\varphi_4^1=0, \\ \varphi_1^2+\varphi_3^4=\varphi_2^1+\varphi_4^3=0, \quad \varphi_2^3=\varphi_3^2=0, \\ \varphi_1^1+\varphi_4^4=\varphi_2^2+\varphi_3^3=0. \end{gathered} \tag{3.4}$$

For type II Osserman manifolds in Ref. 22 it was proved that there exists an isotropic basis F_i, $i=1,...,4$, such that

(i) $\varphi_1^3(F_1)=\varphi_1^3(F_2)=0$.
(ii) $\varphi_1^3(F_3)=-2(\varphi_1^1+\varphi_2^2)(F_2)$ and $\varphi_1^3(F_4)=2(\varphi_1^1+\varphi_2^2)(F_1)$.

Now we are ready to state the theorem.

3.2 Theorem: Let (M,g) be an Osserman manifold of type II. Then, there exists an integrable, autoparallel, isotropic two-dimensional distribution on M.

Proof: Let F_i, $i=1,...,4$ be an already introduced isotropic frame. We will check that the distribution $D=\mathcal{L}(F_1,F_2)$ generated by F_1 and F_2 is autoparallel. We have

$$\nabla_X F_1=\varphi_1^i(X)F_i=\varphi_1^1(X)F_1+\varphi_1^2(X)F_2+\varphi_1^3(X)F_3+\varphi_1^4(X)F_4.$$

Because of symmetries (3.4) we have $\varphi_1^4(X)=0$, and because of (i) it follows $\varphi_1^3(X)=0$ for $X\in D$. This is a consequence of the Osserman condition. Thus $\nabla_X F_1\in D$ for $X\in D$ and similarly $\nabla_X F_2\in D$. Consequently, D is an autoparallel distribution. Since D is autoparallel it is an integrable distribution. □

Remark: Other isotropic two-dimensional distributions $\mathcal{L}(F_i,F_j)$, $\{i,j\}\neq\{1,2\}$ *are not necessarily integrable.*

Remark: The distribution $D=\mathcal{L}(F_1,F_2)$ is parallel if and only if $\varphi_1^3\equiv 0$. In Ref. 3 the possible eigenvalues α and β of the type II manifold were studied. In this context one interesting case was $\beta=4\alpha\neq 0$. It was shown in a few steps that this case is impossible. First, we noticed that $\varphi_1^3\equiv A-B\equiv 0$, consequently D is parallel. Then we introduced the coordinate system where the metric is given by (6.3) for $g_{13}=g_{31}=g_{24}=g_{42}=1$, $g_{14}=g_{41}=g_{23}=g_{32}=0$. The existence of this metric was garanted by Walker.[21] *Studying the Osserman condition in this coordinate system we obtained the contradiction.*

Let us state the following corollary.

3.3 Corollary: An Osserman manifold (M,g) of type II is locally foliated by totally geodesic, flat, isotropic two-dimensional submanifolds.

Proof: First of all notice that the nonzero components of the curvature tensor with respect to the isotropic frame F_i, $i=1,...,4$, are determined by

$$R_{1441}=R_{2332}=R_{1243}=R_{1342}=\alpha \quad \text{and} \quad R_{4334}=2.$$

Since the distribution D is an integrable one, through an arbitrary point $x\in M$ there exists two-dimensional submanifold N defined by D. Since D is autoparallel, N is totally geodesic. The curvature of N is determined by $R_{1221}=0$. □

IV. TYPE III DYNAMICALLY HOMOGENEOUS MANIFOLDS

In this section we will prove the existence of an integrable autoparallel distribution when M is a type III Osserman manifold, i.e., the minimal polynomial has triple zero α.

Similarly to the double zero case we introduce some one-forms

$$A=\omega_1^2+\omega_3^4, \quad B=\omega_2^4-\omega_1^3, \quad C=\omega_2^3+\omega_1^4,$$

$$\tilde{A}=2(A+B), \quad \tilde{B}=2(B-A).$$

Some relations between the forms C, $\tilde{A}$ and $\tilde{B}$ are given by the following lemma.

4.1 Lemma: Let M be a dynamically homogeneous manifold of type III (the minimal polynomial of the Jacobi operator has triple zero). Then, with respect to the pseudoorthonormal basis e_1, e_2, e_3, e_4, we have

(1) $\tilde{A}_1=-\tilde{A}_4=C_2+C_3$, $\tilde{A}_2=-\tilde{A}_3=-(C_1+C_4)$.
(2) $\tilde{B}_1=B_1$, $\tilde{B}_2=B_2$, $\tilde{B}_3=C_1-C_4-B_2$, $\tilde{B}_4=C_3-C_2-B_1$.

Proof: There exists a pseudo-orthonormal frame e_1, e_2, e_3, e_4 (see Ref. 3) such that the nonvanishing generic components of the curvature tensor are determined by

$$R_{1331}=R_{4224}=R_{1441}=R_{3223}=-\alpha, \quad R_{1221}=R_{4334}=\alpha,$$

$$R_{3114}=-R_{3224}=-R_{2114}=-R_{2334}=k,$$

$$R_{1223}=R_{1443}=R_{1332}=-R_{1442}=k.$$

We differentiate the second Bianchi identity to see

$$d\Omega_p^1=\Omega_i^1\wedge\omega_p^i-\omega_i^1\wedge\Omega_p^i,$$

and consequently for $p=2,3,4$ this relation implies

$$\tfrac{1}{2}\tilde{B}(\theta^{13}-\theta^{24})-2B(\theta^{12}-\theta^{34})+C(\theta^{14}+\theta^{23})=0,$$

$$\tfrac{1}{2}\tilde{B}(\theta^{12}-\theta^{34})+2A(\theta^{13}-\theta^{24})-C(\theta^{14}+\theta^{23})=0,$$

$$C(\theta^{12}-\theta^{34}-\theta^{13}+\theta^{24})-\tilde{A}(\theta^{14}+\theta^{23})=0.$$

Comparing coefficients of $\theta^i\wedge\theta^j\wedge\theta^k$ in these three-forms we obtain the system of linear equations, which implies the statement of Lemma. □

We will now change the frame e_i to the isotropic one F_i introduced by (3.3).

As in Sec. III ξ^i is the corresponding dual basis and φ^i_j are the connection one-forms and $\nabla F_i=\varphi^j_i F_j$.

Connection one-forms φ^j_i satisfy the symmetry relations (3.4). Following Ref. 23 we have

$$\widetilde{A}=-4\varphi^1_2,\quad \widetilde{B}=-4\varphi^2_1,\quad C=-\varphi^1_1+\varphi^2_2 \tag{4.1}$$

and

$$\begin{aligned}&\varphi^1_2(F_2)=\varphi^1_2(F_4)=0,\\ &\varphi^1_2(F_1)=2(-\varphi^1_1+\varphi^2_2)(F_2),\\ &\varphi^1_2(F_3)=-2(-\varphi^1_1+\varphi^2_2)(F_4).\end{aligned} \tag{4.2}$$

Now we are able to consider two-dimensional distribution on T_pM. More precisely, one can use (3.3), (4.1) and (4.2) and the same method as in Theorem 3.2 to prove the following theorem.

4.2 Theorem: Let (M,g) be a type III dynamically homogeneous manifold. Then there exists an integrable, autoparallel, isotropic two-dimensional distribution on M.

V. SOME COORDINATE SYSTEM FOR TYPE II AND III DYNAMICALLY HOMOGENEOUS MANIFOLDS

In this section we study some coordinate systems for type II and III dynamically homogeneous manifolds such that the metric has the simplest form as much as possible. We use some results from Sec. III to prove the technical lemma. Then we consider the existence of a coordinate system in Proposition 5.2.

5.1 Lemma: There exist an open set U and functions $A,B\in C^\infty_+(U)$, such that the vector fields $\widetilde{F}_1=AF_1$ and $\widetilde{F}_2=BF_2$ commute, i.e., $[\widetilde{F}_1,\widetilde{F}_2]=0$.

Proof: We use Theorem 3.2 to see that the distribution generated by vectors F_1 and F_2 is integrable and autoparallel. Applying this result we get

$$[F_1,F_2]=\mu_1F_1+\mu_2F_2. \tag{5.1}$$

The straightforward computation gives

$$\begin{aligned}[\widetilde{F}_1,\widetilde{F}_2]=[AF_1,BF_2]&=AB[F_1,F_2]+AF_1(B)F_2-BF_2(A)F_1\\ &=B(A\mu_1-F_2(A))F_1+A(B\mu_2+F_1(B))F_2.\end{aligned}$$

Now the proof follows from the standard fact: for a smooth function μ there exists a smooth solution of the equation

$$\frac{\partial a}{\partial x_1}=\mu_1 a, \tag{5.2}$$

for the appropriate coordinate system (x^1,x^2,x^3,x^4). □

5.2 Proposition: Let (M,g) be a four-dimensional pseudo-Riemannian manifold of signature (2,2) which satisfies the dynamically homogeneous condition. Assume now, that the Jacobi operator is of type II or III. Then there exists a coordinate system $u=(u^1,u^2,u^3,u^4):U\subseteq\mathbb{R}^4\to M$ and an null basis F_1, F_2, F_3, F_4 such that

(i)

$$g=\begin{bmatrix} 0 & 0 & g_{13} & g_{14} \\ 0 & 0 & g_{23} & g_{24} \\ g_{13} & g_{23} & 0 & g_{34} \\ g_{14} & g_{24} & g_{34} & 0 \end{bmatrix}, \quad with \ \det\begin{bmatrix} g_{13} & g_{14} \\ g_{23} & g_{24} \end{bmatrix}=1 \tag{5.3}$$

and

(ii)

$$F_1=\frac{\partial}{\partial u^1}, \quad F_2=\frac{1}{C}\frac{\partial}{\partial u^2}, \quad F_3=CP_i\frac{\partial}{\partial u^i}, \quad F_4=Q_i\frac{\partial}{\partial u^i}, \tag{5.4}$$

where P_i, Q_i, $C\in C^\infty(U)$ *and* C *are nonvanishing on* U.

Proof: We prove Proposition for type II dynamically homogeneous manifolds with all the details. We mention that the proof for type III is the same. Let $\hat{E}_i$ be an arbitrary pseudo-orthonormal basis such that the components of the curvature tensor are given by (3.2) and $\hat{F}_i$ is the corresponding isotropic basis given by (3.3). We already established

$$\hat{\varphi}_1^3(\hat{F}_1)=\hat{\varphi}_1^3(\hat{F}_2)=0, \tag{5.5}$$

$$\hat{\varphi}_1^3(\hat{F}_3)=2(\hat{\varphi}_1^1+\hat{\varphi}_2^2)(\hat{F}_1), \tag{5.6}$$

$$\hat{\varphi}_1^4(\hat{F}_4)=-2(\hat{\varphi}_1^1+\hat{\varphi}_2^2)(\hat{F}_2), \tag{5.7}$$

where $\hat{\varphi}_j^i$ is the corresponding connection form, i.e., $\nabla\hat{F}_i=\hat{\varphi}_i^j\hat{F}_j$.

Now, let $\tilde{F}=(\tilde{F}_1,\tilde{F}_2,\tilde{F}_3,\tilde{F}_4)$ be the following moving frame:

$$\tilde{F}_1=a\hat{F}_1, \quad \tilde{F}_2=b\hat{F}_2, \quad \tilde{F}_3=\frac{1}{b}\hat{F}_3, \quad \tilde{F}_4=\frac{1}{a}\hat{F}_4. \tag{5.8}$$

Notice that $\langle\hat{F}_i,\hat{F}_j\rangle=\langle\tilde{F}_i,\tilde{F}_j\rangle$. The corresponding pseudo-orthonormal frame is

$$\tilde{E}_1=\frac{1}{\sqrt{2}}(\tilde{F}_1+\tilde{F}_4), \quad \tilde{E}_2=\frac{1}{\sqrt{2}}(\tilde{F}_2+\tilde{F}_3), \quad \tilde{E}_3=\frac{1}{\sqrt{2}}(\tilde{F}_2-\tilde{F}_3), \quad \tilde{E}_1=\frac{1}{\sqrt{2}}(\tilde{F}_4-\tilde{F}_1). \tag{5.9}$$

Nonvanishing generic components of the curvature tensor with respect to this frame agree with those given by (3.2) but $\frac{1}{2}$ is replaced by $\frac{1}{2}a^2b^2$. Now we consider Jacobi operator $\mathcal{K}_{\tilde{E}_1}$ and the corresponding frame, i.e., a basis $E_1=\tilde{E}_1,E_2,E_3,E_4$ which satisfies formulas (3.2). Since we assume the Jacobi operator is of type II, then there exists unique two-dimensional invariant subspace generated by $\tilde{E}_2$ and $\tilde{E}_3$, and because of the structure of the curvature tensor follows $\tilde{E}_4=E_4$. There is a hyperbolic rotation which fixes E_1 and E_4 and moves $\tilde{E}_2$ and $\tilde{E}_3$ into E_2 and E_3. Once again, we consider the corresponding null frame defined by (3.3). Clearly,

$$F_1=\tilde{F}_1, \quad F_2=C\tilde{F}_2, \quad F_3=\frac{1}{C}\tilde{F}_3, \quad F_4=\tilde{F}_4, \tag{5.10}$$

where a function C is determined by the above-mentioned hyperbolic rotation.

Since $[\tilde{F}_1,\tilde{F}_2]=0$, Frobenius theorem implies the existence of the coordinate system $\tilde{u}=(\tilde{u}^1,\tilde{u}^2,\tilde{u}^3,\tilde{u}^4)$ in $U\subset M\to\mathbb{R}^4$ such that $\tilde{F}_1=\partial/\partial\tilde{u}^1$ and $\tilde{F}_2=\partial/\partial\tilde{u}^2$.

To complete the proof we will modify slightly this coordinate system to control the determinant condition. Let $u^i=\tilde{u}^i$, $1\leqslant i\leqslant 3$ and

$$\tilde{u}^4=f(u^1,u^2,u^3,u^4).$$

Then the second condition in (5.3) is reduced to

$$\frac{\partial f}{\partial u^4} = \frac{1}{\det(g_{13}g_{24} - g_{14}g_{23})}. \tag{5.11}$$

The solution of (5.11) exists and the proof of Proposition is completed. □

ACKNOWLEDGMENTS

We are very grateful to the referee for suggestions on how to improve and clarify the exposition, particularly the proof of Proposition 5.2. This research was partially supported by SFS, Project No. 04M03.

Differential geometry on SU(3) with applications to three state systems

Mark Byrd[a)]
Center for Particle Physics, University of Texas at Austin, Austin, Texas 78712-1081

(Received 22 August 1997; accepted for publication 17 July 1998)

The left and right invariant vector fields are calculated in an ''Euler angle''-type parametrization for the group manifold of SU(3), referred to here as Euler coordinates. The corresponding left and right invariant one-forms are then calculated. This enables the calculation of the invariant volume element or Haar measure. These are then used to describe the density matrix of a pure state and geometric phases for three state systems. © *1998 American Institute of Physics.* [S0022-2488(98)04111-5]

I. INTRODUCTION

In this paper we have two main goals: the first is to construct the invariant vector fields and one-forms on SU(3) in Euler coordinates that are similar to the Euler angle parameters of SU(2); the second is the application of these structures to the description of the geometric phases of three state systems.

The Euler coordinates along with the left and right invariant vector fields and one-forms are constructed here for several reasons. One, the Euler decomposition of a group element is achieved by a method that is very general and could, in principle, be applied to SU(n). Two, this particular parametrization is convenient for many calculations, as will be shown. Three, there will be advantages to having a set of invariant vector fields and corresponding one-forms in the same parametrization of the group.

Color,[1] flavor,[2] and nuclear models[3] use the group SU(3). However, geometric aspects of the group manifold are not emphasized. That is not to say that the differential geometric structures are not relevant to these models; indeed they are! However, as shown in Refs. 4, and 5, the differential geometry of SU(3) is an integral part of the description of three state systems. The Euler coordinates[6] and differential forms provide a complete description of the differential geometry needed to describe the pure state density matrix and geometric phase[7] of three state systems.

II. THE LIE ALGEBRA

The Lie Algebra of a Lie group is a set of left invariant vector fields on the group manifold. These can be constructed by a method that has been applied to SU(2) (see, for example, Ref. 8). The method for decomposing a group element into Euler coordinates and the method for constructing the left invariant vector fields can, in principle, be applied to SU(n). Here we provide the details for SU(3).

A. Euler decomposition

To parametrize the group into the ''Euler angle''-type parametrization, or Euler coordinates, we first consider the Lie algebra of the group. The algebra obeys the following commutation relations:

$$[\lambda_i,\lambda_j]=iC_{ij}^k\lambda_k.$$

The structure constants, C_{ij}^k, can be chosen totally antisymmetric in the three indices. Then the distinction between upper and lower indices is not relevant. (One may also use the Killing metric to lower the index.) In the usual, Gell–Mann basis, the nonzero structure constants are given by

[a)]Electronic mail: mbyrd@physics.utexas.edu

 © 1998 American Institute of Physics

$$C_{123}=2, \quad C_{458}=C_{678}=\sqrt{3},$$

$$C_{147}=C_{246}=C_{257}=C_{345}=C_{516}=C_{637}=1.$$

We can use the Cartan decomposition and split the Lie algebra of SU(3), denoted here $\mathcal{L}(\mathrm{SU}(3))$, into a Lie subalgebra $\mathcal{L}(K)$ and the set of all other SU(3) Lie algebra elements $\mathcal{U}(P)$. The Lie algebra may then be expressed as a (semi-)direct sum,

$$\mathcal{L}(G)=\mathcal{L}(K)\oplus\mathcal{U}(P).$$

To this, there corresponds a decomposition of the group,

$$G=K\cdot P.$$

Here $\mathcal{L}(K)=\{\lambda_1,\lambda_2,\lambda_3,\lambda_8\}$, and $\mathcal{U}(P)=\{\lambda_4,\lambda_5,\lambda_6,\lambda_7\}$, and according to the Cartan decomposition, they obey, for $k_1,\ k_2\in\mathcal{L}(K)$, and $p_1,p_2\in\mathcal{U}(P)$, the following Lie brackets:

$$[k_1,k_2]\in\mathcal{L}(K), \quad [p_1,p_2]\in\mathcal{L}(K),$$

and

$$[k_1,p_1]\in\mathcal{U}(P).$$

Thus K is the U(2) subgroup obtained by exponentiating the corresponding algebra $\{\lambda_1,\lambda_2,\lambda_3\}$ plus λ_8. Since λ_8 commutes with this SU(2) subgroup, an element of K can be written as

$$K=e^{(i\lambda_3\alpha)}e^{(i\lambda_2\beta)}e^{(i\lambda_3\gamma)}e^{(i\lambda_8\phi)},$$

by the Euler angle parametrization of SU(2).

Next, P may be parametrized. Of the four elements of P, we can pick one, say λ_5, and write any element of P as

$$P=Ke^{(i\lambda_5\theta)}K.$$

Dropping the redundancies, we arrive at the following product for SU(3). (This method was adapted from the book by Hermann[9] and first pointed out to me by Biedenharn.[10])

$$D(\alpha,\beta,\gamma,\theta,a,b,c,\phi)=e^{(i\lambda_3\alpha)}e^{(i\lambda_2\beta)}e^{(i\lambda_3\gamma)}e^{(i\lambda_5\theta)}e^{(i\lambda_3\alpha)}e^{(i\lambda_2 b)}e^{(i\lambda_3 c)}e^{(i\lambda_8\phi)}, \tag{1}$$

where D is an arbitrary element of SU(3). This can be written as

$$D(\alpha,\beta,\gamma,\theta,a,b,c,\phi)=D^{(2)}(\alpha,\beta,\gamma)e^{(i\lambda_5\theta)}D^{(2)}(a,b,c)e^{(i\lambda_8\phi)},$$

where the D denotes an arbitrary element of SU(3) and $D^{(2)}$ is an arbitrary element of SU(2) as a subset of SU(3). Since SU(3) is semisimple, it has only one connected component (see, for instance, Ref. 11). Thus, the given parametrization covers the group.

B. A set of invariant vector fields

To find the differential operators corresponding to the Lie algebra elements, one takes derivatives of $D(\alpha,\beta,\gamma,\theta,a,b,c,\phi)$ in (1) with respect to each of its parameters. (For brevity, this will be called D, dropping the explicit dependence on the parameters.) Writing the result of differentiation in the form

$$e^{A}Be^{-A}D,$$

and using the Campbell–Baker–Hausdorff relation to expand this as

$$e^{A}Be^{-A}=B+[A,B]+\tfrac{1}{2}[A,[A,B]]+\cdots,$$

the series can be resummed. Thus, linear combinations of the Lie algebra elements with coefficients given by sines and cosines of the parameters are obtained. The following is an example of such a calculation:

$$\begin{aligned}\frac{\partial D}{\partial \gamma} &= e^{(i\lambda_3\alpha)}e^{(i\lambda_2\beta)}i\lambda_3 e^{(i\lambda_3\gamma)}e^{(i\lambda_5\theta)}e^{(i\lambda_3 a)}e^{(i\lambda_2 b)}e^{(i\lambda_3 c)}e^{(i\lambda_8\phi)}\\ &= e^{(i\lambda_3\alpha)}e^{(i\lambda_2\beta)}(i\lambda_3)e^{(-i\lambda_2\beta)}e^{(-i\lambda_3\alpha)}D\\ &= i(\lambda_1 \cos 2\alpha \sin 2\beta + \lambda_2 \sin 2\alpha \sin \beta + \lambda_3 \cos 2\beta)D.\end{aligned}$$

There are eight such derivatives. These linear combinations may then be expressed as

$$\partial_j = b_j^i \lambda_i , \tag{2}$$

where the parameters have been labeled sequentially as they appear in (1), i.e.,

$$\partial_1 \equiv \frac{\partial}{\partial \alpha}, \quad \partial_2 \equiv \frac{\partial}{\partial \beta}, \quad \partial_3 \equiv \frac{\partial}{\partial \gamma},$$

$$\partial_5 \equiv \frac{\partial}{\partial a}, \quad \partial_6 \equiv \frac{\partial}{\partial b}, \quad \partial_7 \equiv \frac{\partial}{\partial c},$$

$$\partial_4 \equiv \frac{\partial}{\partial \theta}, \quad \partial_8 \equiv \frac{\partial}{\partial \phi}.$$

The matrix b_j^i is then inverted to obtain the representation of the Lie algebra of SU(3) as left invariant vector fields on the group manifold in the Euler parametrization. Note that this calculation relies only on the commutation relations and not on any particular representation of the algebra.

The left invariant vector fields are differential operators on smooth functions D^* on SU(3); they satisfy[12]

$$\Lambda_i D^* = -\lambda^i D^*. \tag{3}$$

Explicit forms of these operators are given in Appendix A. The operators acting from the right are found similarly by taking right derivatives. Note, however, that the right operators obey the commutation relation $[\Lambda_i^r, \Lambda_j^r] = -C_{ij}^k \Lambda_k^r$ since a left translation by a group element is directly related to the right translation of the inverse of this element (see, for example, Refs. 13, 14 or 15).

The calculation of the left invariant vector fields acting on the D matrices was first attempted by Nelson.[16] However, no attempt was made to calculate the right invariant vector fields or the corresponding forms.

As stated above, the right differential operators (the differential operators that correspond to this action when acting *from* the right) are different and are denoted as Λ_i^r. One may find these ''right'' differential operators in two ways. First, one may use the relation

$$D^* \lambda_i = -\Lambda_i^r D^*,$$

and do the same calculation as with the left ones. Second, one may use the fact that

$$\Lambda_i^r = R_i^j \Lambda_j , \tag{4}$$

where the $R_i^j \in \mathrm{SO}(8)$ is an element of the adjoint representation of SU(3). It is therefore a function of the eight parameters above. The matrix R does not cover SO(8), as is clear from the fact that SU(3) has only eight parameters whereas SO(8) has twenty eight.

The right invariant vector fields are also given in Appendix A and the matrix R_i^j has been calculated explicitly in the Euler coordinates as well (see Ref. 17).

III. INVARIANT INTEGRATION

A. Invariant forms

The left invariant forms for the manifold are dual to the left invariant vector fields. This duality between the tangent and cotangent vectors may be used to construct left invariant one-forms from the left invariant vector fields. If the left invariant vector fields are written as

$$\lambda_i = a_i^j \partial_j$$

and the left invariant forms are expressed as

$$\omega^l = b_k^l \, dx^k, \tag{5}$$

then

$$\delta_i^l = \langle \omega^l, \lambda_i \rangle = b_k^l a_i^j \langle dx^k, \partial_j \rangle = b_k^l a_i^j \delta_j^k . \tag{6}$$

Therefore, the matrices b and a are inverse transposes of each other. This is, in fact, the same b given in (2). In this way, we obtain left (and analogously right) invariant forms on the group manifold. Thus, one may now use these to integrate over the whole space or any subspace of the group manifold by the appropriate wedge product of these forms. The explicit left and right invariant one-forms are given in Appendix B.

B. Invariant volume element

The group invariant volume element, or Haar measure, may now be computed, using the invariant forms. To do this, compute the wedge product of the invariant one-forms or, equivalently, take the determinant of the matrix b above. The result is

$$dV = \sin 2\beta \, \sin 2b \, \sin 2\theta \, \sin^2 \theta \, d\alpha \, d\beta \, d\gamma \, d\theta \, da \, db \, dc \, d\phi .$$

This agrees with the result of Holland[18] but is determined only up to normalization. The normalization is determined by having $\int dV = 1$.

With the explicit left and right invariant forms one can check that the left invariant volume element is equal, as expected, to the right invariant volume element by direct computation (see, for instance Ref. 11).

The determination of the ranges of the angles in the Euler coordinates is not a trivial matter. This is related to determining the group invariant volume that would set the normalization of the volume integral. The determination of this group invariant volume has been attempted by many authors (see Ref. 19 and references therein). Taking the products of states in the fundamental irreducible representations and enforcing the orthogonality relations among them, one may infer the minimum ranges for which these orthogonality relations hold. This implies the following ranges of the angles:

$$0 \leqslant \alpha, \gamma, a, c < \pi,$$

$$0 \leqslant \beta, b, \theta \leqslant \frac{\pi}{2}, \quad 0 \leqslant \phi < \sqrt{3}\pi .$$

A further discussion of this is given in Ref. 17.

IV. THREE STATE SYSTEMS

Before discussing the geometric phase, some preliminary remarks are in order. (For a review of geometric phases see Refs. 20, 7, or the review article.[21])

The general pure state density matrices for three-level systems can be represented in the following way:[4,5] Let ψ be a state in a three-dimensional complex Hilbert space $\mathcal{H}^{(3)}$. The density matrix is the matrix ρ described by

$$\rho=\psi\psi^{\dagger}=\tfrac{1}{3}(\mathbb{1}+\sqrt{3}\mathbf{n}\cdot\boldsymbol{\lambda}),$$

$$\psi\in\mathcal{H}^{(3)},\quad(\psi,\psi)=1. \tag{7}$$

Here the dagger denotes the Hermitian conjugate and $\mathbb{1}$ is the 3×3 unit matrix. The dot product of $\mathbf{n}$, and $\boldsymbol{\lambda}$, is the ordinary sum over repeated indices $n^r\lambda_r$. The eight-dimensional unit vector, $\mathbf{n}$, of real functions is restricted to a four-dimensional subspace, as discussed below. The brackets $(\cdot,\cdot)$ denote the inner product on the space $\mathcal{H}^{(3)}$. The $\boldsymbol{\lambda}$ represents the eight Gell–Mann matrices,

$$\lambda_1=\begin{pmatrix}0&1&0\\1&0&0\\0&0&0\end{pmatrix},\quad \lambda_2=\begin{pmatrix}0&-i&0\\i&0&0\\0&0&0\end{pmatrix},\quad \lambda_3=\begin{pmatrix}1&0&0\\0&-1&0\\0&0&0\end{pmatrix},$$

$$\lambda_4=\begin{pmatrix}0&0&1\\0&0&0\\1&0&0\end{pmatrix},\quad \lambda_5=\begin{pmatrix}0&0&-i\\0&0&0\\i&0&0\end{pmatrix},\quad \lambda_6=\begin{pmatrix}0&0&0\\0&0&1\\0&1&0\end{pmatrix},$$

$$\lambda_7=\begin{pmatrix}0&0&0\\0&0&-i\\0&i&0\end{pmatrix},\quad \lambda_8=\frac{1}{\sqrt{3}}\begin{pmatrix}1&0&0\\0&1&0\\0&0&-2\end{pmatrix}.$$

These matrices obey the anticommutation relations,

$$\{\lambda_i,\lambda_j\}=\tfrac{4}{3}\mathbb{1}\delta_{ij}+2d_{ijk}\lambda_k.$$

The nonzero components of the completely symmetric tensor d_{ijk} are

$$d_{118}=d_{228}=d_{338}=-d_{888}=\frac{1}{\sqrt{3}},\quad d_{448}=d_{558}=d_{668}=d_{778}=-\frac{1}{2\sqrt{3}},$$

$$d_{146}=d_{157}=-d_{247}=d_{256}=d_{344}=d_{355}=-d_{366}=-d_{377}=\tfrac{1}{2}.$$

Using the d_{ijk}, the following symmetric product between two elements in the algebra may be defined:

$$(\mathbf{a}\star\mathbf{b})_i=\sqrt{3}d_{ijk}a_jb_k. \tag{8}$$

Now the restrictions on the density matrix:

$$\rho^{\dagger}=\rho=\rho^2\geqslant0,\quad\text{and}\quad \mathrm{Tr}\ \rho=1,$$

are equivalent to the following conditions on n:

$$\mathbf{n}^*=\mathbf{n},\quad \mathbf{n}\cdot\mathbf{n}=1,\quad \mathbf{n}\star\mathbf{n}=\mathbf{n}. \tag{9}$$

A. Pure state density matrices

The density matrix for a pure state, e.g.,

$$\rho_0=\tfrac{1}{3}(\mathbb{1}-\sqrt{3}\lambda_8)=\begin{pmatrix}0&0&0\\0&0&0\\0&0&1\end{pmatrix}, \tag{10}$$

can be mapped into an arbitrary pure state density matrix, ρ, by an SU(3) transformation:

$$\rho=D\rho_0D^{-1},\quad D\in\mathrm{SU}(3).$$

This mapping can be seen as a projection from SU(3) to SU(3)/SU(2) since the upper left 2×2 block of this matrix is invariant under a U(2) subgroup of SU(3). This subgroup is spanned by the parameters a, b, c, and ϕ. This is clear from the fact that the subalgebra K, defined in Sec. II A, commutes with λ_8. Thus, an arbitrary pure state density matrix for a three state system is an element of the coset space SU(3)/U(2). Moreover, this is expressed in a very natural way in terms of the Euler coordinates of the group manifold coordinates.

It may also be reexpressed in terms of the adjoint representation of the group, viz.,

$$\rho=\tfrac{1}{3}(\mathbb{1}-\sqrt{3}D\lambda_8 D^{-1})=\tfrac{1}{3}(\mathbb{1}-\sqrt{3}R_8^i\lambda_i).$$

This enables the identification of the matrix elements $-R_8^i$ with the vector $\mathbf{n}$ in (7) and one can show by direct computation that this vector satisfies the requirements (9).

B. Geometric phases for three state systems

Using the Euler coordinates for SU(3), in which

$$D=e^{(i\lambda_3\alpha)}e^{(i\lambda_2\beta)}e^{(i\lambda_3\gamma)}e^{(i\lambda_5\theta)}e^{(i\lambda_3 a)}e^{(i\lambda_2 b)}e^{(i\lambda_3 c)}e^{(i\lambda_8\phi)},$$

one can write down explicit coordinates for ψ. This is done by first calculating $\rho=|\psi\rangle\langle\psi|=\psi\psi^\dagger$ by the method above then, and then using $n_i=(\sqrt{3}/2)\psi^\dagger\lambda_i\psi$ to find ψ. The result is

$$\psi=e^{-2i\phi/\sqrt{3}}\begin{pmatrix} e^{i(\alpha+\gamma)}\cos\beta\sin\theta \\ e^{-i(\alpha-\gamma)}\sin\beta\sin\theta \\ \cos\theta \end{pmatrix}.$$

Using this, one can calculate the connection one-form and curvature two-form. The connection one-form for the geometric phase is

$$\mathcal{A}=\psi\, d\psi^\dagger. \tag{11}$$

From this, the connection one-form for the three state system is

$$\begin{aligned}\mathcal{A}&=\frac{2}{\sqrt{3}}\,d\phi+\sin^2\theta[\cos^2\beta(d\alpha+d\gamma)-\sin^2\beta(d\alpha-d\gamma)]\\ &=-\frac{2}{\sqrt{3}}\,d\phi+\sin^2\theta\cos 2\beta d\alpha+\sin^2\theta\, d\gamma,\end{aligned} \tag{12}$$

and the curvature two-form is given by

$$\begin{aligned}F=d\mathcal{A}&=-id\psi^\dagger\wedge d\psi=\sin 2\theta\cos^2\beta\, d\theta\wedge d(\alpha+\gamma)-\sin^2\theta\sin 2\beta\, d\beta\wedge d(\alpha+\gamma)\\ &\quad-\sin 2\theta\sin^2\beta\, d\theta\wedge d(\alpha-\gamma)-\sin^2\theta\sin 2\beta\, d\beta\wedge d(\alpha-\gamma)\\ &=\sin 2\theta\cos 2\beta\, d\theta\wedge d\alpha\\ &\quad-2\sin^2\theta\sin 2\beta\, d\beta\wedge d\alpha+\sin 2\theta\, d\theta\wedge d\gamma.\end{aligned} \tag{13}$$

The geometric phase around a closed loop is given, in general, by

$$\varphi_g=\int\mathcal{A},$$

and specifically for the three state systems by

$$\varphi_g=\int\sin^2\theta[\cos_2\beta(d\alpha+d\gamma)-\sin^2\beta(d\alpha-d\gamma)]=\int[\sin^2\theta\cos 2\beta\, d\alpha+\sin^2\theta\, d\gamma], \tag{14}$$

or by the integral of the curvature over the corresponding surface enclosed by this loop. The pull-back from SU(3)/U(2) to SU(3) of the connection one-form, $\mathscr{A}$, is expressible in terms of linear combinations of the one-forms on the group manifold. Let D be a point in SU(3) as above, and ρ a point in SU(3)/U(2). The push-forward (or derivative mapping) and pull-back maps denoted as ρ^*, and ρ_*, respectively, give the relationship between the vector fields and one-forms on the group manifold and coset space.

V. CONCLUSIONS/COMMENTS

The left and right invariant vector fields on SU(3) in an Euler angle parametrization were displayed explicitly. This enables the calculation of tensor products by direct computation (see, for instance, Ref. 22). In the case of three state systems there is a natural projection map from SU(3) to the coset space SU(3)/U(2) that describes the density matrix of pure states. Having a natural projection map one may use all of the fiber bundle techniques for computing the explicit structures in terms of the Euler coordinates. This enables the calculation of vector fields and forms on the coset space. It also provides a means of calculating geometric phases for the three state systems.

It was stated earlier that the methods for calculating the invariant vector fields and forms for SU(3) are generalizable to SU(n). Though this is true, the left invariant one-forms given here were calculated by hand. This is obviously not an enviable task for an SU(n) group since the dimension of these groups is n^2-1. It is possible to calculate the invariant vector fields with MATHEMATICA.[23] However, this program has some difficulty simplifying products of trigonometric functions of the form found in this calculation. As such programs become more proficient at symbolic manipulations of this sort, the calculations and analyses of such structures for higher-dimensional Lie groups will become more manageable.

ACKNOWLEDGMENTS

I would, first and foremost, like to thank Professor L. C. Biedenharn (now deceased) who, as my advisor, first started me on the construction of these structures. I could not give him too much credit here. I would also like to thank Professor E. C. G. Sudarshan for many helpful comments along with Professor Duane Dicus, whose help and support enabled the completion of this paper. I would like to thank David Cook for deriving the vector fields independently. This provided a check for the results below. This research was supported in part by the U.S. Department of Energy under Contract No. DE-EG013-93ER40757.

APPENDIX A: INVARIANT VECTOR FIELDS

The left invariant vector fields are as follows:

$$\Lambda_1 = i\cos 2\alpha\cot 2\beta\partial_1 + i\sin 2\alpha\partial_2 - i\frac{\cos 2\alpha}{\sin 2\beta}\partial_3, \tag{A1}$$

$$\Lambda_2 = -i\sin 2\alpha\cot 2\beta\partial_1 + i\cos 2\alpha\partial_2 + i\frac{\sin 2\alpha}{\sin 2\beta}\partial_3, \tag{A2}$$

$$\Lambda_3 = i\partial_1, \tag{A3}$$

$$\Lambda_8 = i\sqrt{3}\partial_3 - i\sqrt{3}\partial_5 + i\partial_8, \tag{A4}$$

$$\begin{aligned}\lambda_4 = {} & i\frac{\sin\beta}{\sin 2\beta}\cot\theta\cos(\alpha+\gamma)\partial_1 - i\sin\beta\cot\theta\sin(\alpha+\gamma)\partial_2 \\ & - i\cot 2\beta\sin\beta\cot\theta\cos(\alpha+\gamma)\partial_3 + i\frac{(2-\sin^2\theta)}{\sin 2\theta}\cos\beta\cos(\alpha+\gamma)\partial_3 \\ & + i\cos\beta\sin(\alpha+\gamma)\partial_4 - i2\frac{\cos\beta}{\sin 2\theta}\cos(\alpha+\gamma)\partial_5\end{aligned}$$

$$-i\,\frac{\cot 2b}{\sin\theta}\sin\beta\cos(\alpha-\gamma-2a)\partial_5+i\,\frac{\sin\beta}{\sin\theta}\sin(\alpha-\gamma-2a)\partial_6$$
$$+i\,\frac{\sin\beta}{\sin\theta\sin 2b}\cos(\alpha-\gamma-2a)\partial_7-\frac{\sqrt{3}}{2}\tan\theta\cos\beta\cos(\alpha+\gamma)\Lambda_8, \tag{A5}$$

$$\Lambda_5=-i\,\frac{\sin\beta}{\sin 2\beta}\cos\theta\sin(\alpha+\gamma)\partial_1-\sin\beta\cot\theta\cos(\alpha+\gamma)\partial_2$$
$$+i\cot 2\beta\sin\beta\cot\theta\sin(\alpha+\gamma)\partial_3-i\,\frac{(2-\sin^2\theta)}{\sin 2\theta}\cos\beta\sin(\alpha+\gamma)\partial_3$$
$$+i\cos\beta\cos(\alpha+\gamma)\partial_4+i2\,\frac{\cos\beta}{\sin 2\theta}\sin(\alpha+\gamma)\partial_5+i\,\frac{\cot 2b}{\sin\theta}\sin\beta\sin(\alpha-\gamma-2a)\partial_5$$
$$+i\,\frac{\sin\beta}{\sin\theta}\cos(\alpha-\gamma-2a)\partial_6$$
$$-i\,\frac{\sin\beta}{\sin\theta\sin 2b}\sin(\alpha-\gamma-2a)\partial_7+\frac{\sqrt{3}}{2}\tan\theta\cos\beta\sin(\alpha+\gamma)\Lambda_8, \tag{A6}$$

$$\Lambda_6=i\,\frac{\cos\beta}{\sin 2\beta}\cot\theta\cos(\alpha-\gamma)\partial_1+i\cos\beta\cot\theta\sin(\alpha-\gamma)\partial_2$$
$$-i\cot 2\beta\cos\beta\cot\theta\cos(\alpha-\gamma)\partial_3-i\,\frac{(2-\sin^2\theta)}{\sin 2\theta}\sin\beta\cos(\alpha-\gamma)\partial_3$$
$$+i\sin\beta\sin(\alpha-\gamma)\partial_4+i2\,\frac{\sin\beta}{\sin 2\theta}\cos(\alpha-\gamma)\partial_5-i\,\frac{\cot 2b}{\sin\theta}\cos\beta\cos(\alpha+\gamma+2a)\partial_5$$
$$-i\,\frac{\cos\beta}{\sin\theta}\sin(\alpha+\gamma+2a)\partial_6+i\,\frac{\cos\beta}{\sin\theta\sin 2b}\cos(\alpha+\gamma+2a)\partial_7$$
$$+\frac{\sqrt{3}}{2}\tan\theta\sin\beta\cos(\alpha-\gamma)\Lambda_8, \tag{A7}$$

$$\Lambda_7=i\,\frac{\cos\beta}{\sin 2\beta}\cot\theta\sin(\alpha-\gamma)\partial_1-i\cos\beta\cot\theta\cos(\alpha-\gamma)\partial_2-i\cot 2\beta\cos\beta\cot\sin(\alpha-\gamma)\partial_3$$
$$-i\,\frac{(2-\sin^2\theta)}{\sin 2\theta}\sin\beta\sin(\alpha-\gamma)\partial_3-i\sin\beta\cos(\alpha-\gamma)\partial_4+i2\,\frac{\sin\beta}{\sin 2\theta}\sin(\alpha-\gamma)\partial_5$$
$$-i\,\frac{\cot 2b}{\sin\theta}\cos\beta\sin(\alpha+\gamma+2a)\partial_5+i\,\frac{\cos\beta}{\sin\theta}\cos(\alpha+\gamma+2a)\partial_6$$
$$+i\,\frac{\cos\beta}{\sin\theta\sin 2b}\sin(\alpha+\gamma+2a)\partial_7+\frac{\sqrt{3}}{2}\tan\theta\sin\beta\sin(\alpha-\gamma)\Lambda_8, \tag{A8}$$

where $\eta=\phi/\sqrt{3}$. The right invariant vector fields are given by the following equations:

$$\Lambda_1^r=-i\cos 2c\cot 2b\partial_7-i\sin 2c\partial_6+i\,\frac{\cos 2c}{\sin 2b}\partial_5, \tag{A9}$$

$$\Lambda_2^r=-i\sin 2c\cot 2b\partial_7+i\cos 2c\partial_6+i\,\frac{\sin 2c}{\sin 2b}\partial_5, \tag{A10}$$

$$\Lambda_3^r = i\partial_7, \tag{A11}$$

$$\Lambda_8^r = i\partial_8, \tag{A12}$$

$$\begin{aligned}\Lambda_4^r = &-i\,\frac{\sin b}{\sin 2b}\cot\theta\cos(c+a+3\eta)\partial_7 + i\sin b\cot\theta\sin(c+a+3\eta)\partial_6\\ &+i\cot 2b\sin b\cot\theta\cos(c+a+3\eta)\partial_5 - i\,\frac{(2-\sin^2\theta)}{\sin 2\theta}\cos b\cos(c+a+3\eta)\partial_5\\ &-i\cos b\sin(c+a+3\eta)\partial_4 + i2\,\frac{\cos b}{\sin 2\theta}\cos(c+a+3\eta)\partial_3\\ &+i\,\frac{\cot 2\beta}{\sin\theta}\sin b\cos(c-a-2\gamma+3\eta)\partial_3 - i\,\frac{\sin b}{\sin\theta}\sin(c-a-2\gamma+3\eta)\partial_2\\ &-i\,\frac{\sin b}{\sin\theta\sin 2\beta}\cos(c-a-2\gamma+3\eta)\partial_1 - \frac{\sqrt{3}}{2}\tan\theta\cos b\cos(c+a+3\eta)\Lambda_8^r,\end{aligned} \tag{A13}$$

$$\begin{aligned}\Lambda_5^r = &-i\,\frac{\sin b}{\sin 2b}\cot\theta\sin(c+a+3\eta)\partial_7 - i\sin b\cot\theta\cos(c+a+3\eta)\partial_6\\ &+i\cot 2b\sin b\cot\theta\sin(c+a+3\eta)\partial_5 - i\,\frac{(2-\sin^2\theta)}{\sin 2\theta}\cos b\sin(c+a+3\eta)\partial_5\\ &+i\cos b\cos(c+a+3\eta)\partial_4 + i2\,\frac{\cos b}{\sin 2\theta}\sin(c+a+3\eta)\partial_3\\ &+i\,\frac{\cot 2\beta}{\sin\theta}\sin b\sin(c-a-2\gamma+3\eta)\partial_3 + i\,\frac{\sin b}{\sin\theta}\cos(c-a-2\gamma+3\eta)\partial_2\\ &-i\,\frac{\sin b}{\sin\theta\sin 2\beta}\sin(c-a-2\gamma+3\eta)\partial_1 - \frac{\sqrt{3}}{2}\tan\theta\cos b\sin(c+a+3\eta)\Lambda_8^r,\end{aligned} \tag{A14}$$

$$\begin{aligned}\Lambda_6^r = &\,i\,\frac{\cos b}{\sin 2b}\cot\theta\cos(c-a-3\eta)\partial_7 + i\cos b\cot\theta\sin(c-a-3\eta)\partial_6\\ &-i\cot 2b\cos b\cot\theta\cos(c-a-3\eta)\partial_5 - \frac{(2-\sin^2\theta)}{\sin 2\theta}\sin b\cos(c-a-3\eta)\partial_5\\ &+i\sin b\sin(c-a-3\eta)\partial_4 + i2\,\frac{\sin b}{\sin 2\theta}\cos(c-a-3\eta)\partial_3\\ &-i\,\frac{\cot 2\beta}{\sin\theta}\cos b\cos(c+a+2\gamma-3\eta)\partial_3 - i\,\frac{\cos b}{\sin\theta}\sin(c+a+2\gamma-3\eta)\partial_2\\ &+i\,\frac{\cos b}{\sin\theta\sin 2\beta}\cos(c+a+2\gamma-3\eta)\partial_1 - \frac{\sqrt{3}}{2}\tan\theta\sin b\cos(c-a-3\eta)\Lambda_8^r,\end{aligned} \tag{A15}$$

$$\begin{aligned}\Lambda_7^r = &-i\,\frac{\cos b}{\sin 2b}\cot\theta\sin(c-a-3\eta)\partial_7 + i\cos b\cot\theta\cos(c-a-3\eta)\partial_6\\ &+i\cot 2b\cos b\cot\theta\sin(c-a-3\eta)\partial_5 + i\,\frac{(2-\sin^2\theta)}{\sin 2\theta}\sin b\sin(c-a-3\eta)\partial_5\\ &+i\sin b\cos(c-a-3\eta)\partial_4 - i2\,\frac{\sin b}{\sin 2\theta}\sin(c-a-3\eta)\partial_3\end{aligned}$$

$$+i\,\frac{\cot 2\beta}{\sin\,\theta}\cos\,b\,\sin(c+a+2\gamma-3\eta)\partial_3-i\,\frac{\cos\,b}{\sin\,\theta}\cos(c+a+2\gamma-3\eta)\partial_2$$

$$-i\,\frac{\cos\,b}{\sin\,\theta\,\sin 2\beta}\sin(c+a+2\gamma-3\eta)\partial_1+\frac{\sqrt{3}}{2}\tan\,\theta\,\sin\,b\,\sin(c-a-3\eta)\Lambda_8^r. \quad \text{(A16)}$$

APPENDIX B: INVARIANT FORMS

The invariant forms on the manifold are given by the following equations:

$$\begin{aligned}\omega^1=&-i\,\sin(2\alpha)d\beta+i\,\cos(2\alpha)\sin(2\beta)d\gamma+i\,\cos(2\alpha)\sin(2\beta)(1-\tfrac{1}{2}\sin^2(\theta))da\\&-i\,\cos(2a+2\gamma)\cos(\theta)\sin(2\alpha)db-i\,\cos(2\alpha)\cos(2\beta)\cos(\theta)\sin(2a+2\gamma)db\\&+i[\cos(2\alpha)\cos(2\beta)\cos(2a+2\gamma)\cos(\theta)\sin(2b)]dc\\&-i\,\cos(\theta)\sin(2\alpha)\sin(2b)\sin(2a+2\gamma)dc+i\,\cos(2\alpha)\cos(2b)\sin(2\beta)(1-\tfrac{1}{2}\sin^2(\theta))dc\\&-i\,\frac{\sqrt{3}}{2}\cos(2\alpha)\sin(2\beta)\sin^2\,\theta d\phi,\end{aligned} \quad \text{(B1)}$$

$$\begin{aligned}\omega^2=&-i\,\cos(2\alpha)d\beta-i\,\sin(2\alpha)\sin(2\beta)d\gamma-i\,\sin(2\alpha)\sin(2\beta)(1-\tfrac{1}{2}\sin^2(\theta))da\\&-i\,\cos(2\alpha)\cos(2a+2\gamma)\cos(\theta)db+i\,\cos(2\beta)\cos(\theta)\sin(2\alpha)\sin(2a+2\gamma)db\\&-i\,\cos(2\beta)\cos(2a+2\gamma)\cos(\theta)\sin(2\alpha)\sin(2b)dc\\&-i\,\cos(2\alpha)\cos(\theta)\sin(2b)\sin(2a+2\gamma)dc-i\,\cos(2b)\sin(2\alpha)\sin(2\beta)\\&\times(1-\tfrac{1}{2}\sin^2(\theta))dc+i\,\frac{\sqrt{3}}{2}\sin(2\alpha)\sin(2\beta)\sin^2(\theta)d\phi,\end{aligned} \quad \text{(B2)}$$

$$\begin{aligned}\omega^3=&-i\,d\alpha-i\,\cos(2\beta)d\gamma-i\,\cos(2\beta)(1-\tfrac{1}{2}\sin^2(\theta))da-i\,\cos(\theta)\sin(2\beta)\sin(2a+2\gamma)db\\&+i\,\cos(2a+2\gamma)\cos(\theta)\sin(2b)\sin(2\beta)dc-i\,\cos(2b)\cos(2\beta)(1-\tfrac{1}{2}\sin^2(\theta))dc\\&+i\,\frac{\sqrt{3}}{2}\cos(2\beta)\,\frac{1}{2}\sin^2(\theta)d\phi,\end{aligned} \quad \text{(B3)}$$

$$\begin{aligned}\omega^4=&-i\,\cos(\beta)\sin(\alpha+\gamma)d\theta+i\tfrac{1}{2}\cos(\beta)\cos(\alpha+\gamma)\sin(2\theta)da\\&+i\,\sin(\beta)\sin(2a-\alpha+\gamma)\sin(\theta)db-i\,\cos(2a-\alpha+\gamma)\sin(2b)\sin(\beta)\sin(\theta)dc\\&+i\tfrac{1}{2}\cos(2b)\cos(\beta)\cos(\alpha+\gamma)\sin(2\theta)dc+i\,\frac{\sqrt{3}}{2}\cos(\beta)\cos(\alpha+\gamma)\sin(2\theta)d\phi,\end{aligned} \quad \text{(B4)}$$

An existence theory for relativistic brachistochrones in stationary space–times

Fabio Giannoni
Dipartimento di Energetica, Universitá de L'Aquila, Italy

Paolo Piccione
Departamento de Matemática, Universidade de São Paulo, São Paulo, Brazil

(Received 16 March 1998; accepted for publication 11 May 1998)

We use a variational principle proven by Giannoni *et al.* [J. Math. Phys. **38**, 6367–6381 (1997)] for relativistic brachistochrones and techniques of global analysis to develop an existence theory for brachistochrones in stationary space–times. We also develop a Ljusternik–Schnirelman theory for brachistochrones, obtaining multiplicity results depending on the topology of the space–time. © *1998 American Institute of Physics.* [S0022-2488(98)01111-6]

I. INTRODUCTION

The classical formulation of the brachistochrone problem is to determine the shape of a frictionless slide between two points in space in such a way that a particle, if released from rest at the first point and driven by a homogeneous gravitational field, would reach the second point in the shortest time. This problem has several generalizations, e.g., the homogeneous gravitational field could be replaced with an arbitrary Newtonian potential, and, instead of releasing the particle from rest, one could prescribe an arbitrary value for the initial speed, leaving the initial direction of the velocity undetermined. Moreover, the brachistochrone problem can also be formulated in the context of general relativity.

The first relativistic versions of the brachistochrone problem appear in Refs. 1 and 2. Perlick (Ref. 3; see also Kamath) has determined the brachistochrone equation in a *regular* stationary Lorentzian manifold, i.e., in a time-independent gravitational field according to general relativity, and the two authors, together with Verderesi, in Ref. 4 have generalized Perlick's result to the case of an arbitrary stationary manifold by reformulating the brachistochrone problem in the context of sub-Riemannian geometry.

If one drops the stationarity assumption for the Lorentzian manifold, the brachistochrone problem can still be formulated in a physically meaningful way (see Ref. 5) and, also in the general case, using the Lagrange multiplier technique one is able to derive a system of differential equations for the brachistochrones and for the Lagrange multipliers. Unfortunately, it does not seem possible to eliminate the Lagrange multipliers from this system without introducing integrals, unless in the stationary case. Thus, it looks as if the brachistochrones in the nonstationary case are not determined by a second-order differential equation, but rather by an integro-differential equation.

The aim of this paper is to use the variational principle for brachistochrones in a stationary space–time proven in Ref. 4 and techniques from critical point theory to develop an existence theory for brachistochrones of fixed energy between an event p and an observer γ.

In order to make the paper self-contained and for the reader's convenience, in Sec. II we will recall the main results of Ref. 4, together with a few other remarks needed in the rest of the paper.

To make our statements precise, we introduce some notation and terminology.

We will denote by $\mathscr{M}$ an $(n+1)$-dimensional smooth manifold, $n \geqslant 1$, and by g a Lorentzian metric on $\mathscr{M}$. More precisely, we assume that $\mathscr{M}$ is a finite-dimensional real C^∞ manifold of dimension greater than two whose topology satisfies the second countability axiom and the Hausdorff separation axiom, and we assume that g is a pseudo-Riemannian C^∞ metric of signature $(+,\ldots,+,-)$ on $\mathscr{M}$. The physically interesting case is, of course, $\dim(\mathscr{M})=4$.

We will also denote by $\langle \cdot,\cdot \rangle$ the bilinear form induced on the tangent space $T_q\mathscr{M}$ by $g(q)$.

Let Y be a smooth timelike Killing vector field on $\mathscr{M}$, i.e., $\langle Y,Y\rangle<0$ everywhere, and the

 © 1998 American Institute of Physics

metric tensor g is invariant by the flow of Y. A Lorentzian manifold endowed with such a vector field is said to be *stationary*.

We will also assume that $\mathscr{M}$ is *causal*, i.e., there exists no closed causal curve in $\mathscr{M}$. We recall that a smooth curve γ is causal if the tangent vector $\dot{\gamma}(s)$ is causal ($\langle \dot{\gamma}(s), \dot{\gamma}(s)\rangle \leqslant 0$) everywhere. Physically, the causality condition on $\mathscr{M}$ means that the possibility that any object, massive or massless, in the universe, traveling at speed less than or equal to the speed of light (in vacuum), may encounter itself at an earlier stage of its life is excluded.

For the main properties of Lorentzian geometry and the basics of general relativity we refer to the classical textbooks, like Refs. 6–8.

Let $\gamma:]a,b[\mapsto \mathscr{M}$ be a *maximal* integral curve of Y and $p \notin \gamma$ be an event of $\mathscr{M}$ (we will also denote by γ the image $\gamma(]a,b[)$ in $\mathscr{M}$). By the causality assumption on $\mathscr{M}$, the curve γ is a *closed embedding* of $]a,b[$ into $\mathscr{M}$, i.e., the relative topology of γ in $\mathscr{M}$ coincides with the topology of $]a,b[$. Moreover, the maximality of γ implies that γ has no *end points* in $\mathscr{M}$, i.e., $\gamma(s)$ is eventually outside of any compact subset of $\mathscr{M}$ for $s \to a,b$.

Let $k \in \mathbb{R}^+$ be a fixed constant. We consider the space $\mathscr{B}^+_{p,\gamma}(k)$ of all piecewise smooth future pointing, timelike curves z from p to γ, parametrized by proper time, and satisfying the conservation law $-\langle \dot{z}, Y\rangle \equiv k > 0$:

$$\mathscr{B}^+_{p,\gamma}(k) = \{z:[0,T_z] \mapsto \mathscr{M} : z \text{ of class } C^1,$$

$$z(0) = p, z(T_z) \in \gamma, \langle \dot{z}, \dot{z}\rangle \equiv -1,$$

$$-\langle \dot{z}, Y\rangle \equiv k > 0 (\text{constant})\}. \tag{1}$$

The curve γ is interpreted as the world line of an observer; the curves z in $\mathscr{B}^+_{p,\gamma}(k)$ represent the world line of massive particles starting at the event p and eventually reaching the observer γ. The condition $\langle \dot{z}, \dot{z}\rangle = -1$ means that z is parametrized by proper time, so that T_z is the *travel time* of z measured on the particle. The quantity $\langle \dot{z}, Y\rangle$ is the component along Y of the four-momentum of the particle z; observe that, since Y is Killing, then it is constant on geodesics. The condition $-\langle \dot{z}, Y\rangle \equiv k$ is the analog of the conservation law of the energy in the Newtonian case.

The positivity of the constant k says that z is future pointing with respect to the time orientation induced on $\mathscr{M}$ by Y. A perfectly similar theory may be developed considering past pointing curves. If one modifies properly the definitions, it is easily checked that all the results proven in this paper work equally well in this case.

Let us consider the open subset $U_k \subset \mathscr{M}$:

$$U_k = \{q \in \mathscr{M} : \langle Y(q), Y(q)\rangle + k^2 > 0\}. \tag{2}$$

Observe that, since Y is Killing, then $\langle Y, Y\rangle$ is constant on the flow lines of Y, and so U_k is invariant by the flow of Y. Observe that, by the wrong way Schwartz's inequality, if $z \in \mathscr{B}^+_{p,\gamma}(k)$ then z is contained in the closure of U_k. Indeed, $-\langle Y, Y\rangle = \langle \dot{z}, \dot{z}\rangle \langle Y, Y\rangle \leqslant \langle \dot{z}, Y\rangle^2$. Moreover, if $-\langle \dot{z}, Y\rangle \equiv k$, then z is entirely contained in U_k if and only if the tangent vector $\dot{z}$ is never a multiple of Y.

We will assume that γ is a maximal integral curve of Y. For all q in $\mathscr{M}$, γ_q will denote the maximal integral line of Y such that $\gamma_q(0) = q$.

Definition I.1: A curve $z \in \mathscr{B}^+_{p,\gamma}(k)$ is said to be a *minimal brachistochrone of energy k* between p and γ if z is a minimal point for the *travel time* functional $F: \mathscr{B}^+_{p,\gamma}(k) \to \mathbb{R}^+$ given by

$$F(z) = T_z.$$

A curve $z \in \mathscr{B}^+_{p,\gamma}(k)$ is a *brachistochrone of energy k* if it minimizes locally its travel time, i.e., if for all $r \in [0,T_z[$ and for $\varepsilon \in]0,T_z - r[$ small enough, the curve $\overline{z}(s) = z(s-r)$, defined on the interval $[0,\varepsilon]$, is a minimal brachistochrone between $z(s)$ and $\gamma_{z(s+\varepsilon)}$.

It is proven in Ref. 4 that the brachistochrones are smooth curves in $\mathscr{M}$ that satisfy the following differential equation:

$$\nabla_{\dot z}\dot z+\frac{2k}{\langle Y,Y\rangle}\nabla_{\dot z}Y+2k^2\frac{\langle\nabla_z Y,Y\rangle}{\langle Y,Y\rangle(k^2+\langle Y,Y\rangle)}\dot z+-2k\frac{\langle\nabla_{\dot z}Y,Y\rangle}{\langle Y,Y\rangle(k^2+\langle Y,Y\rangle)}Y=0, \tag{3}$$

where ∇ is the covariant derivative with respect to the Levi-Civita connection of the Lorentzian metric g.

If Y is a complete vector field on $\mathscr{M}$, then, using the flow of Y, the brachistochrones having fixed energy k are deformed into geodesics with respect to a suitable (sub-)Riemannian structure defined on $\mathscr{M}$.

Our definition of brachistochrones extends the definition of the *τ-brachistochrones* given in Ref. 3 in the case of a regular stationary manifold. In Ref. 3 it is also defined a different brachistochrone problem (in Perlick's terminology: the *t-brachistochrones*), which are curves $z\in\mathscr{B}^+_{p,\gamma}(k)$ minimizing the *arrival time* functional:

$$AT(z)=\gamma^{-1}(z(T_z)),\quad z\in\mathscr{B}^+_{p,\gamma}(k), \tag{4}$$

where γ is assumed to be injective.

The two variational problems are essentially different; as it was shown in Ref. 3, the *t*-brachistochrone problem is also reduced to a Riemannian variational problem consisting of the sum of a length functional and a linear functional in the derivative, representing a sort of *Coriolis* force. In this paper we will only deal with the variational problem of Definition I.1, while the second brachistochrone problem is the subject of a forthcoming paper.

As it is natural to expect, in order to obtain existence results for brachistochrones, one needs to assume the completeness of $\mathscr{M}$ with respect to some Riemannian structure. In the statements of our results we assume the completeness of $\mathscr{M}$ with respect to the Riemannian metric g_R, defined by $g_R[v,v]=g[v,v]$ for v orthogonal to Y, and $g_R[Y,Y]=-g[Y,Y]$ [see formula (7)].

Theorem I.2: *Let $\mathscr{M}$ be a stationary Lorentzian manifold, Y a timelike Killing vector field on $\mathscr{M}$ and $k\in\mathbb{R}^+$ a fixed real constant.*

Suppose that Y is complete, k^2 is a regular value for the function $-\langle Y,Y\rangle$, and assume that Y is bounded from below in U_k, i.e., there exists a positive constant $\nu>0$ such that:

$$-\langle Y(q),Y(q)\rangle\geqslant\nu>0,\quad\forall q\in U_k. \tag{5}$$

Let p be a point in U_k and γ a maximal integral line of Y inside U_k.

Then, if $\overline{U_k}=U_k\cup\partial U_k$ is complete with respect to the Riemannian metric g_R, there exists at least one brachistochrone z of energy k joining p and γ in U_k.

Under the extra assumption that the closed set $\overline{U_k}$ be noncontractible, we also have the following multiplicity result for brachistochrones of fixed energy:

Theorem I.3: *Under the hypotheses of Theorem I.2, if $\overline{U_k}$ is not contractible, then there exists a sequence $\{z_n\}_{n\in\mathbb{N}}$ of brachistochrones of energy k between p and γ such that:*

$$\lim_{n\to\infty}T_{z_n}=+\infty. \tag{6}$$

Theorem I.3 is the analog of Serre's Theorem (see Ref. 9) concerning the multiplicity of geodesics joining two fixed points in a noncontractible Riemannian manifold.

Theorems I.2 and I.3 will be proven in the paper, which is organized as follows. In Sec. II we recall the variational principle for brachistochrones in stationary space–times, relating the brachistochrone curves (with fixed energy) to geodesics in suitable Riemannian and sub-Riemannian structures. In particular, we point out that, using the flow of the vector field Y, the brachistochrones of fixed energy k in $\mathscr{M}$ are deformed into geodesics with respect to the Riemannian metric $\phi_k\cdot g_R$ of $\mathscr{M}$, where $\phi_k=-\langle Y,Y\rangle(k^2+\langle Y,Y\rangle)^{-1}$, hence they are critical points for the Riemannian energy functional E_k associated with this metric.

In Sec. III, using a classical approach to the study of geodesics in Riemannian manifolds with convex boundary, we introduce a *penalized* functional $E_{k,\varepsilon}$, which is a perturbation of E_k. We

prove that, under our hypotheses, the functional $E_{k,\varepsilon}$ satisfies good compactness properties, like the Palais–Smale condition. Such property is essential to obtain existence results for critical points for $E_{k,\varepsilon}$.

In Sec. IV we prove some estimates on the critical points of $E_{k,\varepsilon}$ which do not depend on the parameter ε. These estimates are then used to pass to the limit as $\varepsilon \to 0$, obtaining the proof of Theorem I.2.

Finally, in Sec. V we develop a Ljusternik–Schnirelman theory for the critical points of the penalized functional $E_{k,\varepsilon}$ that, using the estimates proven in Sec. IV, allow us to prove the multiplicity result of Theorem I.3.

We will assume henceforth that the hypotheses of Theorem I.2 are satisfied.

II. THE VARIATIONAL PRINCIPLE FOR BRACHISTOCHRONES

In this section we present our functional framework and we recall the variational principle for brachistochrones and the main results of Ref. 4. The reader will find in Ref. 4 all the details and the proofs of the claims made in this section.

First of all, we define an auxiliary Riemannian structure on $\mathscr{M}$. We denote by Δ the orthogonal distribution to the vector field Y. Since Y is timelike, the wrong-way Schwartz's inequality implies that the restriction of the Lorentzian metric g is positive definite. We consider the following (0,2)-tensor on $\mathscr{M}$:

$$g_R[v,v] = \langle v,v \rangle_{(R)} = \langle v,v \rangle - 2\frac{\langle v, Y(q)\rangle^2}{\langle Y(q), Y(q)\rangle}, \tag{7}$$

where $q \in \mathscr{M}$ and $v \in T_q\mathscr{M}$. The wrong-way Schwartz's inequality implies that $g_R[v,v]$ defines a positive definite, symmetric tensor on $\mathscr{M}$. It is easily checked that the flow of Y preserves g_R, so that Y is Killing with respect to g_R also.

Let $\nabla^{(R)}$ be the covariant derivative with respect to the Levi-Civita connection of g_R. Using standard notation, for a smooth function $\phi: \mathscr{M} \mapsto \mathbb{R}$ we also denote by $\nabla\phi$ ($\nabla_{(R)}\phi$) the *Lorentzian (Riemannian) gradient* of ϕ with respect to g (g_R), which is the vector field defined by $d\phi(q)[\,\cdot\,] = \langle \nabla\phi(q), \cdot \rangle$ ($d\phi(q)[\,\cdot\,] = \langle \nabla_{(R)}\phi(q), \cdot \rangle_{(R)}$), for all $q \in \mathscr{M}$.

Since Y is Killing with respect to g, then for every pair v_1, v_2 of smooth vector fields on $\mathscr{M}$, it is (see Ref. 8):

$$\langle \nabla_{v_1} Y, v_2 \rangle + \langle \nabla_{v_2} Y, v_1 \rangle = 0. \tag{8}$$

The characterization (8) of the Killing property of Y will be used implicitly or explicitly throughout the paper.

We introduce the following functions on U_k:

$$\psi_k(q) = \langle Y(q), Y(q)\rangle + k^2, \quad \text{and} \quad \phi_k(q) = -\frac{\langle Y(q), Y(q)\rangle}{\langle Y(q), Y(q)\rangle + k^2}. \tag{9}$$

Observe that ϕ_k and ψ_k are positive and smooth; moreover, by definition of U_k, they are positive in U_k. Note also that:

$$\partial U_k = \psi_k^{-1}(0), \tag{10}$$

and the condition that k^2 is a regular value for the function $-\langle Y, Y\rangle$ says that the derivative ψ_k' is nonzero on ∂U_k:

$$\psi_k' \neq 0 \quad \text{on} \quad \partial U_k. \tag{11}$$

By the implicit function theorem, (11) implies that ∂U_k is a smooth submanifold of $\mathscr{M}$.

Using the Riemannian metric, we define the space $L^2([0,1], T\mathscr{M})$, consisting of all measurable maps $\zeta: [0,1] \mapsto T\mathscr{M}$ such that $\langle \zeta, \zeta \rangle_{(R)}$ is Lebesgue integrable on $[0,1]$.

The Sobolev space $H^{1,2}([0,1],\mathscr{M})$ is defined as the set of all absolutely continuous curves $z:[0,1]\mapsto\mathscr{M}$ such that $\dot{z}$ is in $L^2([0,1],T\mathscr{M})$. By a classical result of global analysis on manifolds, the spaces $L^2([0,1],T\mathscr{M})$ and $H^{1,2}([0,1],\mathscr{M})$ actually do not depend on the choice of the Riemannian metric on $\mathscr{M}$ (see Ref. 10).

We will also use the spaces $L^p([0,1],T\mathscr{M})$, defined in an obvious way using the Riemannian metric of $\mathscr{M}$, and the Sobolev spaces $H^{m,p}([0,1],\mathscr{M})$, with $m\in\mathbb{N}$ and $p\in[1,+\infty]$. These can be defined as the set of curves of class C^{m-1} in $\mathscr{M}$ possessing a weak mth derivative that belongs to $L^p([0,1],T\mathscr{M})$.

Our functional framework consists of the following spaces:

$$\Omega_{p,\gamma}=\{w\in H^{1,2}([0,1],U_k)\,:\,w(0)=p,w(1)\in\gamma\},\tag{12}$$

$$\Omega_{p,\gamma}(\Delta)=\{w\in\Omega_{p,\gamma}\,:\,\dot{w}(s)\in\Delta\text{ a.e. on}[0,1]\}.\tag{13}$$

Moreover, for $q\in\gamma$, we denote by $\Omega_{p,q}$ the space of all curves $w\in\Omega_{p,\gamma}$ such that $w(1)=q$.

It is well known (see Ref. 10) that $\Omega_{p,\gamma}$ has the structure of a smooth Hilbertian manifold; for $w\in\Omega_{p,\gamma}$ the tangent space $T_w\Omega_{p,\gamma}$ is identified with the Hilbert space:

$$T_w\Omega_{p,\gamma}=\{\zeta:[0,1]\mapsto T\mathscr{M}:\zeta\text{absolutely continuous},$$
$$\zeta(0)=0,\zeta(1)\|Y(w(1)),\quad \nabla_{\dot{w}}\zeta\in L^2([0,1],T\mathscr{M}),\quad \zeta(s)\in T_{w(s)}\mathscr{M}\forall s\},\tag{14}$$

endowed with the Hilbert norm:

$$\|\zeta\|_w=\left(\int_0^1\langle\nabla_{\dot{w}}\zeta,\nabla_{\dot{w}}\zeta\rangle_{(R)}\,ds\right)^{1/2}.$$

Observe that, due to the presence of the boundary ∂U_k, the manifold $\Omega_{p,\gamma}$ (and consequently of $\Omega_{p,\gamma}(\Delta)$) is *not* complete. Namely, if z_n is a Cauchy sequence of curves in $\Omega_{p,\gamma}$, then z_n may converge to a curve z whose image contain points of ∂U_k.

For all $q\in\gamma$, $\Omega_{p,q}$ is a closed submanifold of $\Omega_{p,\gamma}$, and for $w\in\Omega_{p,q}$ the tangent space $T_w\Omega_{p,q}$ is given by

$$T_w\Omega_{p,q}=\{\zeta\in T_w\Omega_{p,\gamma}:\zeta(1)=0\}.\tag{15}$$

In Ref. 4, it is also proven that $\Omega_{p,\gamma}(\Delta)$ is a smooth submanifold of $\Omega_{p,\gamma}$ and that, for $w\in\Omega_{p,\gamma}(\Delta)$, the tangent space $T_w\Omega_{p,\gamma}(\Delta)$ is given by

$$T_w\Omega_{p,\gamma}(\Delta)=\{\zeta\in T_w\Omega_{p,\gamma}:\langle\nabla_{\dot{w}}\zeta,Y\rangle+\langle\dot{w},\nabla_\zeta Y\rangle\equiv 0\}.\tag{16}$$

We can define the following functional E_k on $\Omega_{p,\gamma}(\Delta)$:

$$E_k(w)=\frac{1}{2}\int_0^1\phi_k(w)\cdot\langle\dot{w},\dot{w}\rangle_{(R)}ds.\tag{17}$$

It is easy to see that E_k is smooth on $\Omega_{p,\gamma}$, and so is its restriction to $\Omega_{p,\gamma}(\Delta)$, and, for $\zeta\in T_w\Omega_{p,\gamma}$, its Gateaux derivative $E_k'(w)[\zeta]$ is given by:

$$E_k'(w)[\zeta]=\frac{1}{2}\int_0^1\langle\nabla_{\dot{w}}^{(R)}\phi_k(w),\zeta\rangle_{(R)}\cdot\langle\dot{w},\dot{w}\rangle_{(R)}ds+\int_0^1\phi_k(w)\cdot\langle\nabla_{\dot{w}}^{(R)}\zeta,\dot{w}\rangle_{(R)}ds.\tag{18}$$

We have the following result concerning the critical points of E_k in $\Omega_{p,\gamma}$:

Proposition II.1: Let w be a curve in $\Omega_{p,\gamma}$. *Then,* $E_k'(w)=0$ *if and only if* $w\in\Omega_{p,\gamma}(\Delta)$ *and w is a critical point of the restriction of* E_k *to* $\Omega_{p,\gamma}(\Delta)$. *Such critical points are precisely the geodesics with respect to the Riemannian metric* $\phi_k\cdot g_R$ *on* $\mathscr{M}$ *that join p and* γ *and that are orthogonal to* γ.

Proof: It is an easy observation that, since ϕ_k is constant along the flow lines of Y, then Y is Killing also with respect to the Riemannian metric $\phi_k\cdot g_R$. Since E_k is the energy functional

associated to the Riemannian metric $\phi_k \cdot g_R$, by a well-known result in Riemannian geometry, the set of its critical points in $\Omega_{p,\gamma}$ are precisely the $(\phi_k \cdot g_R)$-geodesics w in $\mathscr{M}$ that arrive orthogonally to γ: $g_R[\dot{w}(1), \dot{\gamma}(w(1))] = 0$. Since γ is the flow line of the Killing vector field Y, then, $\dot{w}$ is orthogonal to Y everywhere, and so $w \in \Omega_{p,\gamma}(\Delta)$. The rest of the proof is easily obtained from Lemma 2.6 of Ref. 4. □

A critical point of E_k in $\Omega_{p,\gamma}$ will be called a *normal* $(\phi_k \cdot g_R)$*-geodesic* between p and γ.

Let's assume now that Y is complete on $\mathscr{M}$, i.e., its integral lines are curves defined on the entire real line. We denote by $\psi: \mathscr{M} \times \mathbb{R} \mapsto \mathscr{M}$ the flow of Y.

We use the flow of Y to define a map from the space $\mathscr{B}^+_{p,\gamma}(k)$ to the space $\Omega_{p,\gamma}(\Delta)$ as follows. First of all, we introduce the space $\tilde{\mathscr{B}}^+_{p,\gamma}(k)$ consisting of all curves in $\mathscr{B}^+_{p,\gamma}(k)$ suitably reparametrized on the interval $[0,1]$:

$$\tilde{\mathscr{B}}^+_{p,\gamma}(k) = \left\{ \sigma:[0,1] \mapsto \mathscr{M} \text{ of class } C^1 \;\middle|\; \sigma(0) = p, \sigma(1) \in \gamma, \exists T_\sigma, \text{ such that} \langle \dot{\sigma}, \dot{\sigma} \rangle \equiv -T_\sigma^2, \frac{\langle \dot{\sigma}, Y(\sigma) \rangle}{T_\sigma} \equiv -k. \right\}. \tag{19}$$

Clearly, the map $R: \mathscr{B}^+_{p,\gamma}(k) \mapsto \tilde{\mathscr{B}}^+_{p,\gamma}(k)$ defined by $R(z) = \sigma$, where $\sigma(s) = z(T_z \cdot s)$, gives a bijection between $\mathscr{B}^+_{p,\gamma}(k)$ and $\tilde{\mathscr{B}}^+_{p,\gamma}(k)$.

The map R is used to identify the spaces $\mathscr{B}^+_{p,\gamma}(k)$ and $\tilde{\mathscr{B}}^+_{p,\gamma}(k)$; a curve $\sigma \in \tilde{\mathscr{B}}^+_{p,\gamma}(k)$ will be called a brachistochrone of energy k if $R^{-1}(\sigma)$ is a brachistochrone of energy k.

We introduce the following map $\mathscr{F}: \tilde{\mathscr{B}}^+_{p,\gamma}(k) \mapsto \Omega_{p,\gamma}(\Delta)$:

$$\mathscr{F}(\sigma)(s) = w_\sigma(s) = \psi(\sigma(s), t_\sigma(s)), \tag{20}$$

where

$$t_\sigma(s) = -\int_0^s \frac{\langle \dot{\sigma}, Y(\sigma) \rangle}{\langle Y(\sigma), Y(\sigma) \rangle} dr = k \cdot T_\sigma \int_0^s \frac{dr}{\langle Y(\sigma), Y(\sigma) \rangle}. \tag{21}$$

The curve w_σ is of class C^1, moreover, it is easy to see that w_σ is in $\Omega_{p,\gamma}(\Delta)$.

Observe that, if for some positive k the curve $\sigma \in \tilde{\mathscr{B}}^+_{p,\gamma}(k)$ has image in the open set U_k of (2), then, since U_k is Y-invariant, also $\mathscr{F}(\sigma)$ has image in U_k.

Our variational principle states that the map $\mathscr{F}$ is a bijection between the set of brachistochrones of fixed energy k joining p with γ and the set of normal $(\phi_k \cdot g_R)$-geodesics.

We can state the variational principle for brachistochrones proven in Ref. 4:

Proposition II.2: Let k be a fixed positive number. If σ is a brachistochrone of energy k between p and γ, then $w_\sigma = \mathscr{F}(\sigma)$ is a normal geodesic joining p and γ in U_k with respect to the metric $\phi_k \cdot g_{\mathrm{sr}}$.

Conversely, if w is a normal geodesic in U_k between p and γ with respect to $\phi_k \cdot g_R$, then there exists a unique brachistochrone σ of energy k between p and γ such that $w = \mathscr{F}(\sigma)$. Moreover, in either case, w is minimal if and only of σ is minimal. □

It is also proven in Ref. 4 that, if $\sigma \in \tilde{\mathscr{B}}^+_{p,\gamma}$ is a brachistochrone of energy k and $w_\sigma = \mathscr{F}(\sigma)$ is the corresponding $(\phi_k \cdot g_R)$-geodesic in $\Omega_{p,\gamma}$, then the quantity $\phi_k(w_\sigma)\langle \dot{w}_\sigma, \dot{w}_\sigma \rangle$ is constant, and

$$2\, E_k(w_\sigma) = \phi_k(w_\sigma)\langle \dot{w}_\sigma, \dot{w}_\sigma \rangle = T_\sigma^2 \equiv -\langle \dot{\sigma}, \dot{\sigma} \rangle. \tag{22}$$

Hence, the proof of Theorem I.2 and Theorem I.3 is reduced to the proof of existence and multiplicity of critical points for the functional E_k in $\Omega_{p,\gamma}$.

III. THE PENALIZED FUNCTIONAL $E_{k,\varepsilon}$ AND THE PALAIS–SMALE CONDITION

The presence of the boundary ∂U_k is the main obstruction for the functional E_k to satisfy good compactness properties on $\Omega_{p,\gamma}$. Moreover, as we have already observed, the manifold $\Omega_{p,\gamma}$ is not complete.

To overcome this problem, we introduce a *penalization* argument, which has been used systematically in the study of geodesics in convex subsets of (semi) Riemannian manifolds.

Recalling the definition (9) of the function ψ_k, for all $\varepsilon \in [0,1]$ we introduce the *penalized* functional $E_{k,\varepsilon}:\Omega_{p,\gamma} \mapsto \mathbb{R}^+$ given by

$$E_{k,\varepsilon}(w) = E_k(w) + \varepsilon \int_0^1 \frac{ds}{\psi_k(w)^2}. \tag{23}$$

Observe that $E_{k,0} = E_k$.

Since ψ_k is smooth, then $E_{k,\varepsilon}$ is a smooth functional on $\Omega_{p,\gamma}$, and its Gateaux derivative is easily computed as

$$E'_{k,\varepsilon}(w)[\zeta] = E'_k(w)[\zeta] - 2\varepsilon \int_0^1 \frac{\langle \nabla_{(R)}\psi_k(w), \zeta\rangle_{(R)}}{\psi_k(w)^3} ds. \tag{24}$$

For all $\varepsilon \in\,]0,1]$, the sublevels of the penalized functional are complete. In order to prove this, we use the following result, known as *Gordon's Lemma*, whose proof can be found, e.g., in Ref. 11 and it is based on the fact that $\psi'_k \neq 0$ on ∂U_k.

We denote by $\mathrm{dist}(\cdot,\cdot)$ the distance function on $\mathscr{M}$ induced by the Riemannian structure g_R.

Lemma III.1: Let $\{w_n\}_n$ be a bounded sequence in $\Omega_{p,\gamma}$ such that:

$$\sup_n \int_0^1 \frac{ds}{\psi_k(w_n)^2} < +\infty.$$

Then, there exists $\rho > 0$ such that $\mathrm{dist}(w_n(s), \partial U_k) \geqslant \rho$ *for all $s \in [0,1]$ and all $n \in \mathbb{N}$.* □

We have the following immediate Corollary:

Corollary III.2: For all $\varepsilon \in\,]0,1]$ and all $c > 0$, the sublevel

$$E^c_{k,\varepsilon} = \{w \in \Omega_{p,\gamma} : E_{k,\varepsilon}(w) \leqslant c\}$$

is a (possibly empty) complete metric subspace of $\Omega_{p,\gamma}$.

Proof: Let w_n be a Cauchy sequence in $\Omega_{p,\gamma}$. Then, w_n is convergent in the $H^{1,2}$-norm to a curve w with image in $\overline{U_k} = U_k \cap \partial U_k$. Since w_n is bounded in $\Omega_{p,\gamma}$ and $E_{k,\varepsilon}(w_n)$ is bounded, from Lemma III.1 it follows that w_n, and hence w, is uniformly far from the boundary ∂U_k. Then, since γ is a maximal integral line of Y, then $w(1) \in \gamma$, so $w \in \Omega_{p,\gamma}$ and w_n converges to w in $\Omega_{p,\gamma}$; moreover, by the continuity of $E_{k,\varepsilon}$, it is $E_{k,\varepsilon}(w) \leqslant c$ and $E^c_{k,\varepsilon}$ is complete. □

We recall that if (X,h) is an Hilbert manifold and $F:X \mapsto \mathbb{R}$ is a C^1-functional on X, then F is said to satisfy the *Palais–Smale* condition at level $c \in \mathbb{R}$ if every sequence $\{x_n\}_{n\in\mathbb{N}} \subset X$ satisfying

$$(\mathrm{PS1})_c \quad \lim_{n\to\infty} F(x_n) = c,$$

$$(\mathrm{PS2})_c \quad \lim_{n\to\infty} \|F'(x_n)\| = 0,$$

has a subsequence converging in X. The norm considered in (PS2) is the operator norm in the Hilbert space $T_{x_n}X$.

A sequence x_n in X that satisfies $(\mathrm{PS1})_c$ and $(\mathrm{PS2})_c$ will be called a *Palais–Smale* sequence at level c for the functional F.

Proposition III.3: For all $\varepsilon \in\,]0,1]$, the penalized functional $E_{k,\varepsilon}$ satisfies the Palais–Smale condition at every level $c \in \mathbb{R}$.

Proof: Let $\varepsilon \in]0,1]$ and $c \in \mathbb{R}$ be fixed; let $\{w_n\}_n$ be a Palais–Smale sequence at the level c for $E_{k,\varepsilon}$.

Since $\{w_n\}_n$ is bounded in $\Omega_{p,\gamma}$, from Lemma III.1 it follows that w_n stays uniformly far from the boundary ∂U_k. Moreover, the boundedness in the Hilbert manifold $H^{1,2}([0,1],U_k)$ implies the existence of a subsequence, still denoted by w_n, which is weakly convergent to a curve $w \in H^{1,2}([0,1],U_k)$. In particular, w_n is uniformly convergent to w, and since γ is a maximal integral line of Y, then $w \in \Omega_{p,\gamma}$.

Hence, since w_n and w have image which is uniformly far from ∂U_k, then we can assume that w_n and w have image in a compact subset K of U_k.

Since ϕ_k is uniformly far from zero in U_k, the set K is complete with respect to the Riemannian metric $\phi_k \cdot g_R$.

We now use the fact that $E_{k,\varepsilon}(w_n)$ goes to 0 to prove that the convergence of w_n to w is strong. We argue as follows.

We assume, by the Nash embedding theorem (see Ref. 12), that $\mathscr{M}$ is embedded in some Euclidean space $\mathbb{R}^N$ isometrically with respect to g_R. For all $q \in \mathscr{M}$, we denote by P_q the orthogonal projection of $\mathbb{R}^N$ onto the tangent space $T_q\mathscr{M}$.

If we consider the vector field ζ_n along w_n given by:

$$\zeta_n(s) = P_{w_n(s)}(w_n(s) - w(s) - c_n(s)),$$

where $c_n(s) = s(w_n(1) - w(1))$, then clearly ζ_n is bounded in $T_{w_n}\Omega_{p,\gamma}$ and ζ_n tends weakly to 0 in the Sobolev space $H^{1,2}([0,1],\mathbb{R}^N)$.

Since w_n is uniformly convergent to w, then the vector field:

$$\frac{\nabla_{(R)}\phi_k(w_n)}{\phi_k(w_n)^3}$$

is uniformly convergent. It follows that:

$$\lim_{n\to\infty} \int_0^1 \frac{\langle \nabla_{(R)}\phi_k(w_n), \zeta_n\rangle}{\phi_k(w_n)^3} ds = 0. \tag{25}$$

From (18), (24) and (25) it follows that:

$$\lim_{n\to\infty} E_k'(w_n)[\zeta_n] = \lim_{n\to\infty} \left(\frac{1}{2}\int_0^1 \langle \nabla_{(R)}\phi_k(w_n), \zeta_n\rangle_{(R)} \langle \dot{w}_n, \dot{w}_n\rangle_{(R)} ds + \int_0^1 \phi_k(w_n) \langle \dot{w}_n, \nabla^{(R)}_{\dot{w}_n}\zeta_n\rangle_{(R)} ds \right) = 0. \tag{26}$$

If we consider the first integral on the right-hand side of equality (26), by the weak convergence in $H^{1,2}$ of w_n, we have that the vector field $\nabla_{(R)}\phi_k(w_n)$ is bounded in $L^\infty([0,1],T\mathscr{M})$, ζ_n tends to zero in $L^\infty([0,1],T\mathscr{M})$, and $\langle \dot{w}_n, \dot{w}_n\rangle_{(R)}$ is bounded in $L^1([0,1],\mathbb{R})$. It follows:

$$\lim_{n\to\infty} \int_0^1 \langle \nabla_{(R)}\phi_k(w_n), \zeta_n\rangle_{(R)} \langle \dot{w}_n, \dot{w}_n\rangle_{(R)} ds = 0. \tag{27}$$

Now, we can write:

$$\int_0^1 \phi_k(w_n) \langle \dot{w}_n, \nabla^{(R)}_{\dot{w}_n}\zeta_n\rangle_{(R)} ds = \int_0^1 \phi_k(w_n) \langle \dot{w}_n, (dP_{w_n}[\dot{w}_n])(w_n - w - c_n)\rangle_{(R)} ds + \int_0^1 \phi_k(w_n) \langle \dot{w}_n, P_{w_n}(\dot{w}_n - \bar{w} - \dot{c}_n)\rangle_{(R)} ds, \tag{28}$$

where $dP_{w_n}[\dot{w}_n]$ denotes the linear operator given by the derivative of P_{w_n} in the direction of $\dot{w}_n$.

Once again, the weak convergence of w_n in $\Omega_{p,\gamma}$ implies that the first integral on the right-hand side of (28) is infinitesimal:

$$\lim_{n\to\infty}\int_0^1 \phi_k(w_n)\langle \dot{w}_n, (dP_{w_n}[\dot{w}_n])(w_n - w - c_n)\rangle_{(R)} ds = 0,$$

hence, considering that $\dot{c}_n$ converges to zero uniformly, we have:

$$\lim_{n\to\infty}\int_0^1 \phi_k(w_n)\langle \dot{w}_n, P_{w_n}(\dot{w}_n - \dot{w} - \dot{c}_n)\rangle_{(R)} ds = \lim_{n\to\infty}\int_0^1 \phi_k(w_n)\langle \dot{w}_n, \dot{w}_n - \dot{w}\rangle_{(R)} ds = 0. \quad (29)$$

In (29) we have used the fact that P_{w_n} is symmetric and that $P_{w_n}(\dot{w}_n) = \dot{w}_n$. We also have

$$\lim_{n\to\infty}\int_0^1 \phi_k(w_n)\langle \dot{w}, \dot{w}_n - \dot{w}\rangle_{(R)} ds = 0. \quad (30)$$

To see this, we consider that

$$\lim_{n\to\infty}\left(\int_0^1 \phi_k(w_n)\langle \dot{w}_n - \dot{w}, \dot{w}\rangle_{(R)} ds - \int_0^1 \phi_k(w)\langle \dot{w}_n - \dot{w}, \dot{w}\rangle_{(R)} ds \right) = 0, \quad (31)$$

because $(\phi_k(w_n) - \phi_k(w))$ tends to zero uniformly and $\langle \dot{w}_n - \dot{w}, \dot{w}\rangle_{(R)}$ is bounded in $L^1([0,1], T\mathscr{M})$. Also, by the weak L^2-convergence of $\dot{w}_n$ to $\dot{w}$, it follows immediately that

$$\lim_{n\to\infty}\int_0^1 \phi_k(w)\langle \dot{w}_n - \dot{w}, \dot{w}\rangle_{(R)} ds = 0. \quad (32)$$

Equations (31) and (32) imply immediately (30).

Subtracting (30) from (29), we obtain

$$\lim_{n\to\infty}\int_0^1 \phi_k(w_n)\langle \dot{w}_n - \dot{w}, \dot{w}_n - \dot{w}\rangle_{(R)} ds = 0; \quad (33)$$

finally, since $\inf \phi_k(w_n) > 0$, we get

$$\lim_{n\to\infty}\int_0^1 \langle \dot{w}_n - \dot{w}, \dot{w}_n - \dot{w}\rangle_{(R)} ds = 0, \quad (34)$$

which gives the strong convergence of w_n to w in $\Omega_{p,\gamma}$, concluding the proof. □

Standard techniques in critical point theory are then used to prove the existence of minima for the penalized functionals $E_{k,\varepsilon}$:

Corollary III..4: For all $\varepsilon \in]0,1]$ *the penalized functional* $E_{k,\varepsilon}$ *attains its minimum in* $\Omega_{p,\gamma}$.

Proof: It is a classical argument in critical point theory. Let us fix $\varepsilon \in]0,1]$. Thanks to the Palais–Smale condition and the completeness of the sublevels of the functionals $E_{k,\varepsilon}$, if the infimum i_ε of $E_{k,\varepsilon}$ on $\Omega_{p,\gamma}$ were not a critical value, then it would be possible to find a homotopy between the sublevels $E_{k,\varepsilon}^{i-\eta}$ and $E_{k,\varepsilon}^{i+\eta}$, where $\eta > 0$ is sufficiently small. This is clearly impossible, because, for every $\eta > 0$, $E_{k,\varepsilon}^{i-\eta} = \varnothing$ while $E_{k,\varepsilon}^{i+\eta} \neq \varnothing$. Hence, $E_{k,\varepsilon}$ attains its minimum on $\Omega_{p,\gamma}$. □

IV. *A PRIORI* ESTIMATES FOR THE PENALIZED FUNCTIONAL

The goal of this section is to prove that, given a family w_ε of stationary points for the penalized functionals $E_{k,\varepsilon}$, with $\varepsilon \in]0,1]$, there exists a sequence $\varepsilon_n \downarrow 0$ such that the corresponding sequence w_{ε_n} tends to a curve w which is a critical point for E_k in $\Omega_{p,\gamma}$.

From Corollary III.4, throughout this section we will assume that $\{w_\varepsilon\}$ is a family of critical points for $E_{k,\varepsilon}$ in $\Omega_{p,\gamma}$, with $\varepsilon \in]0,1]$, and that D is a fixed positive constant such that

$$E_{k,\varepsilon}(w_\varepsilon) \leqslant D < +\infty, \forall \varepsilon]0,1]. \tag{35}$$

Since $\varepsilon \mapsto E_{k,\varepsilon}(w)$ is an increasing function for all $w \in \Omega_{p,\gamma}$, then the inequality (35) is satisfied, for instance, if we take w_ε to be a minimum point for $E_{k,\varepsilon}$ and $D = E_{k,1}(w)$, for any fixed $w \in \Omega_{p,\gamma}$.

Observe that, since $\langle Y, Y \rangle_{(R)}$ is bounded away from zero, then (35) implies that the integrals:

$$\int_0^1 \langle \dot{w}_\varepsilon, \dot{w}_\varepsilon \rangle_{(R)} ds$$

are bounded. By the completeness of $\overline{U_k}$, it follows that there exists a compact subset $\mathscr{K}$ of $\overline{U_k}$ such that

$$w_\varepsilon(s) \in \mathscr{K}, \quad \forall \varepsilon \in]0,1], \quad s \in [0,1].$$

In the course of this section, it will be useful to have the following formulas for the derivatives of the functions ϕ_k and ψ_k. They are easily computed using the fact that Y is a Killing vector field with respect to g_R:

$$\nabla_{(R)} \psi_k = 2 \nabla^{(R)}_Y Y, \tag{36}$$

$$\nabla_{(R)} \phi_k = -\frac{2k^2}{(k^2 - \langle Y, Y \rangle_{(R)})^2} \nabla^{(R)}_Y Y = -\frac{k^2}{\psi_k^2} \nabla_{(R)} \psi_k . \tag{37}$$

We start by exhibiting the differential equation satisfied by the w_ε's.

Proposition IV.1: For all $\varepsilon \in]0,1]$, the curve w_ε is smooth, and it satisfies the differential equation:

$$\nabla^{(R)}_{\dot{w}_\varepsilon} \dot{w}_\varepsilon + \left\langle \frac{\nabla_{(R)} \phi_k(w_\varepsilon)}{\phi_k(w_\varepsilon)}, \dot{w}_\varepsilon \right\rangle_{(R)} \dot{w}_\varepsilon + 2\varepsilon \frac{\nabla_{(R)} \psi_k(w_\varepsilon)}{\phi_k(w_\varepsilon) \cdot \psi_k(w_\varepsilon)^3} + -\frac{1}{2} \langle \dot{w}_\varepsilon, \dot{w}_\varepsilon \rangle_{(R)} \frac{\nabla_{(R)} \phi_k(w_\varepsilon)}{\phi_k(w_\varepsilon)} = 0. \tag{38}$$

Proof: The proof of the smoothness of w_ε is carried out by standard *boot-strap* techniques, and it is omitted.

The differential equation (38) is obtained from the Euler–Lagrange equation for the functional $E_{k,\varepsilon}$. Namely, from (18) and (24), the curve w_ε satisfies:

$$E'_{k,\varepsilon}(w_\varepsilon)[\zeta] = \int_0^1 \left(-2\varepsilon \frac{\langle \nabla_{(R)} \psi_k(w_\varepsilon), \zeta \rangle_{(R)}}{\psi_k(w_\varepsilon)^3} + \phi_k(w_\varepsilon) \langle \nabla^{(R)}_{\dot{w}_\varepsilon} \zeta, \dot{w}_\varepsilon \rangle_{(R)} \right) ds$$
$$+ \frac{1}{2} \int_0^1 \langle \nabla_{(R)} \phi_k(w_\varepsilon), \zeta \rangle_{(R)} \langle \dot{w}_\varepsilon, \dot{w}_\varepsilon \rangle_{(R)} ds = 0, \tag{39}$$

for all $\zeta \in T_{w_\varepsilon} \Omega_{p,\gamma}$. If we integrate by parts the term in (39) that contain the covariant derivative $\nabla^{(R)}_{\dot{w}_\varepsilon} \zeta$, considering that $\zeta(0) = \zeta(1) = 0$, we obtain

$$0 = \int_0^1 \langle \zeta, -\phi_k(w_\varepsilon) \nabla^{(R)}_{\dot{w}_\varepsilon} \dot{w}_\varepsilon - \langle \nabla_{(R)} \phi_k(w_\varepsilon), \dot{w}_\varepsilon \rangle_{(R)} \dot{w}_\varepsilon \rangle_{(R)} ds$$
$$+ \int_0^1 \left\langle \zeta, \frac{1}{2} \langle \dot{w}_\varepsilon, \dot{w}_\varepsilon \rangle_{(R)} - 2\varepsilon \frac{\nabla_{(R)} \psi_k(w_\varepsilon)}{\psi_k(w_\varepsilon)^3} \right\rangle_{(R)} ds, \tag{40}$$

for all $\zeta \in T_{w_\varepsilon}\Omega_{p,\gamma}$. From the fundamental Lemma of calculus of variations, we have the Euler–Lagrange equations for the functional $E_{k,\varepsilon}$:

$$0 = -\phi_k(w_\varepsilon)\nabla^{(R)}_{\dot{w}_\varepsilon}\dot{w}_\varepsilon - \langle \nabla_{(R)}\phi_k(w_\varepsilon), \dot{w}_\varepsilon\rangle_{(R)}\dot{w}_\varepsilon + \frac{1}{2}\langle \dot{w}_\varepsilon, \dot{w}_\varepsilon\rangle_{(R)}\nabla_{(R)}\phi_k(w_\varepsilon) - 2\varepsilon\frac{\nabla_{(R)}\psi_k(w_\varepsilon)}{\psi_k(w_\varepsilon)^3}. \tag{41}$$

Equation (38) is obtained by dividing (41) by $-\phi_k(w_\varepsilon)$. □

Remark IV.2: Observe that, using the same argument of the first part of the proof of Proposition IV.1, it is easily seen that the critical points for the functional E_k are smooth curves that satisfy the differential equation obtained from (38) by setting $\varepsilon = 0$.

We now prove that the images of the curves w_ε stay uniformly far from the boundary ∂U_k. The distance from the boundary ∂U_k is measured by the function ψ_k.

Lemma IV.3: There exists $\delta = \delta(D) > 0$ such that $\psi_k(w_\varepsilon(s)) \geqslant \delta$ for all $\varepsilon \in]0,1]$ and all $s \in [0,1]$.

Proof: For all $\varepsilon \in]0,1]$, we consider the smooth function $\rho_\varepsilon(s) = \psi_k(w_\varepsilon(s))$; let $s_\varepsilon \in [0,1]$ be a minimum point for ρ. By contradiction, we assume that

$$\liminf_{\varepsilon\to 0} \rho_\varepsilon(s_\varepsilon) = 0, \tag{42}$$

and thus we can assume that $s_\varepsilon \in]0,1[$. Therefore, we have

$$\rho'_\varepsilon(s_\varepsilon) = \langle \nabla_{(R)}\psi_k(w_\varepsilon(s_\varepsilon)), \dot{w}_\varepsilon(s_\varepsilon)\rangle_{(R)} = 0, \tag{43}$$

and

$$\rho''_\varepsilon(s_\varepsilon) = \langle H^{\psi_k}_{(R)}(w_\varepsilon(s_\varepsilon))\,\dot{w}_\varepsilon, \dot{w}_\varepsilon\rangle_{(R)} + \langle \nabla_{(R)}\psi_k(w_\varepsilon(s_\varepsilon)), \nabla^{(R)}_{\dot{w}_\varepsilon}\dot{w}_\varepsilon(s_\varepsilon)\rangle_{(R)} \geqslant 0, \tag{44}$$

where $H^{\psi_k}_{(R)}$ denote the Hessian operator of ψ_k with respect to the Riemannian metric g_R.

For the sake of shortness, in the computations that follow we will omit the argument s_ε.

Since $H^{\psi_k}_{(R)}$ is continuous in $\mathscr{M}$ and w_ε has image in a compact subset of $\overline{U}_k$, then there exists a positive constant ν_0 such that

$$|\langle H^{\psi_k}_{(R)}(w_\varepsilon)\dot{w}_\varepsilon, \dot{w}_\varepsilon\rangle_{(R)}| \leqslant \nu_0 \cdot \langle \dot{w}_\varepsilon, \dot{w}_\varepsilon\rangle_{(R)}, \quad \forall \varepsilon \in]0,1]. \tag{45}$$

Using the differential equation (38), the formula (36) and the fact that $\langle \nabla_{(R)}\psi_k(w_\varepsilon), \dot{w}_\varepsilon\rangle_{(R)} = 0$, from (44) and (45) we obtain

$$\begin{aligned}
\rho''_\varepsilon(s_\varepsilon) &= \frac{1}{2}\frac{\langle \dot{w}_\varepsilon, \dot{w}_\varepsilon\rangle_{(R)}}{\phi_k(w_\varepsilon)} \cdot \langle \nabla_{(R)}\phi_k(w_\varepsilon), \nabla_{(R)}\psi_k(w_\varepsilon)\rangle_{(R)} \\
&\quad - \frac{2\varepsilon}{\phi_k(w_\varepsilon)\cdot\psi_k(w_\varepsilon)^3}\langle \nabla_{(R)}\psi_k(w_\varepsilon), \nabla_{(R)}\psi_k(w_\varepsilon)\rangle_{(R)} + \langle H^{\psi_k}_{(R)}(w_\varepsilon)\dot{w}_\varepsilon, \dot{w}_\varepsilon\rangle_{(R)} \\
&\leqslant \left(\nu_0 - \frac{k^2\langle \nabla_{(R)}\psi_k(w_\varepsilon), \nabla_{(R)}\psi_k(w_\varepsilon)\rangle_{(R)}}{2\phi_k(w_\varepsilon)\cdot\psi_k(w_\varepsilon)^2} \right) \cdot \langle \dot{w}_\varepsilon, \dot{w}_\varepsilon\rangle_{(R)} \\
&\quad - \frac{2\varepsilon}{\phi_k(w_\varepsilon)\cdot\psi_k(w_\varepsilon)^3}\langle \nabla_{(R)}\psi_k(w_\varepsilon), \nabla_{(R)}\psi_k(w_\varepsilon)\rangle_{(R)}.
\end{aligned} \tag{46}$$

Since $\nabla_{(R)}\psi_k$ does not vanish near ∂U_k and the image of the w_ε's lie in a compact subset of $\overline{U}_k$, then

$$\langle \nabla_{(R)}\psi_k(w_\varepsilon), \nabla_{(R)}\psi_k(w_\varepsilon)\rangle_{(R)} \geqslant \mu_0 > 0$$

for some suitable constant μ_0; moreover, the function $(\phi_k \cdot \psi_k^2)$ is infinitesimal near the boundary ∂U_k.

Then, if (42) holds, then it would be possible to find $\varepsilon > 0$ small enough so that:

$$\left(\nu_0 - \frac{k^2 \langle \nabla_{(R)} \psi_k(w_\varepsilon), \nabla_{(R)} \psi_k(w_\varepsilon) \rangle_{(R)}}{2\, \phi_k(w_\varepsilon) \cdot \psi_k(w_\varepsilon)^2} \right) \cdot \langle \dot{w}_\varepsilon, \dot{w}_\varepsilon \rangle_{(R)} \leqslant 0. \tag{47}$$

Since

$$-\frac{2\,\varepsilon}{\phi_k(w_\varepsilon) \cdot \psi_k(w_\varepsilon)^3} \langle \nabla_{(R)} \psi_k(w_\varepsilon), \nabla_{(R)} \psi_k(w_\varepsilon) \rangle_{(R)} < 0, \tag{48}$$

from (46), (47), and (48) it would follow:

$$\rho_\varepsilon''(s_\varepsilon) < 0, \tag{49}$$

which contradicts (44) and concludes the proof. □

From Lemma IV.3, it follows that the function $\psi_k(w_\varepsilon)$ is uniformly bounded away from zero.

We are now ready to prove the main result of the section:

Proposition IV.4: There exists a sequence $\{\varepsilon_n\}$ *tending to zero as* $n \to \infty$ *and a smooth curve* $w \in \Omega_{p,\gamma}$ *such that* w_{ε_n} *tends to* w in $C^2([0,1], \mathscr{M})$. *Moreover, such a curve* w *is a critical point for the functional* E_k in $\Omega_{p,\gamma}$.

Proof: From (35), we have that the family $\{w_\varepsilon\}$ is bounded in $\Omega_{p,\gamma}$ and, from Lemma IV.3, the images of the curves w_ε stay uniformly far from the boundary ∂U_k.

We consider Eq. (38) satisfied by the w_ε's. Since $\psi_k(w_\varepsilon)$ is bounded away from zero, and w_ε is uniformly bounded, then the term:

$$\frac{\nabla_{(R)} \psi_k(w_\varepsilon)}{\phi_k(w_\varepsilon) \psi_k(w_\varepsilon)^3} \tag{50}$$

is bounded in $L^\infty([0,1], T\mathscr{M})$.

Moreover, since $\dot{w}_\varepsilon$ is bounded in $L^2([0,1], T\mathscr{M})$, then the term

$$\left\langle \frac{\nabla_{(R)} \phi_k(w_\varepsilon)}{\phi_k(w_\varepsilon)}, \dot{w}_\varepsilon \right\rangle_{(R)} \dot{w}_\varepsilon \tag{51}$$

is bounded in $L^1([0,1], T\mathscr{M})$.

Also the term:

$$\langle \dot{w}_\varepsilon, \dot{w}_\varepsilon \rangle_{(R)} \frac{\nabla_{(R)} \phi_k(w_\varepsilon)}{\phi_k(w_\varepsilon)} \tag{52}$$

is bounded in $L^1([0,1], T\mathscr{M})$.

Then, from (38), we have that $\nabla^{(R)}_{\dot{w}_\varepsilon} \dot{w}_\varepsilon$ is bounded in $L^1([0,1], T\mathscr{M})$. This implies that $\dot{w}_\varepsilon$ is bounded in $L^\infty([0,1], T\mathscr{M})$.

Repeating the same argument, we have now that the terms (50)–(52) are bounded in $L^\infty([0,1], T\mathscr{M})$, and this implies that $\nabla^{(R)}_{\dot{w}_\varepsilon} \dot{w}_\varepsilon$ is bounded in $L^\infty([0,1], T\mathscr{M})$, so w_ε is bounded in $H^{1,\infty}([0,1], \mathscr{M})$.

Proceeding similarly, we obtain that w_ε is bounded in $H^{2,2}([0,1], \mathscr{M})$. Then, up to subsequences, w_n is convergent in $C^1([0,1], \mathscr{M})$. Hence, by (41), the convergence is in $C^2([0,1], \mathscr{M})$.

Since the convergence of w_{ε_n} to w is C^2, we can pass to the limit as $\varepsilon \to 0$ in the differential equation (38), obtaining that w satisfies

$$\nabla^{(R)}_{\dot{w}}\dot{w}+\left\langle \frac{\nabla_{(R)}\phi_k(w)}{\phi_k(w)},\dot{w}\right\rangle_{(R)}\dot{w}-\frac{1}{2}\langle \dot{w},\dot{w}\rangle_{(R)}\nabla_{(R)}\phi_k(w)=0. \tag{53}$$

Such equation is the Euler–Lagrange equation for the functional E_k on $\Omega_{p,\gamma}$ (see Remark IV.2), thus w is a critical point for E_k and we are done. □

Observe that, as a consequence of Proposition IV.4, we have proved Theorem I.2.

V. LJUSTERNIK–SCHNIRELMAN THEORY AND MULTIPLICITY OF BRACHISTOCHRONES

The goal of this section is to give a proof of Theorem I.3 by means of the Ljusternik–Schnirelman theory for Palais–Smale functionals. Observe that, by Proposition II.2 and formula (22), if $\sigma\in\tilde{\mathscr{B}}^+_{p,\gamma}$ is a brachistochrone of energy k and w is the corresponding $\phi_k\cdot g_R$ normal geodesic in $\Omega_{p,\gamma}$, then the travel time T_σ of σ and the value of the functional $E_k(w)$ is

$$T_\sigma=\sqrt{2\,E_k(w)}. \tag{54}$$

We recall the following definition:

Definition V.1: If X is a topological space and B any subset of X, the Ljusternik–Schnirelman category $\mathrm{cat}_X(B)$ of B in X is the minimal number (possibly infinite) of closed, contractible subsets of X that cover B. We denote by $\mathrm{cat}(X)=\mathrm{cat}_X(X)$.

Clearly, the Ljusternik–Schnirelman category is increasing with respect to the inclusion, i.e., if A and B are subsets of X, then

$$A\subseteq B\ \Rightarrow\ \mathrm{cat}_X(A)\leqslant\mathrm{cat}_X(B). \tag{55}$$

Moreover, the Ljusternik–Schnirelman category is a homotopical invariant, i.e., if A and B are homotopical subsets of X, then $\mathrm{cat}_X(A)=\mathrm{cat}_X(B)$.

It is easy to see that, since Y is complete and γ is contractible in $\mathscr{M}$, then, for any fixed point $q\in\gamma$, the spaces $\Omega_{p,q}$ and $\Omega_{p,\gamma}$ have the same homotopy type. Namely, given any curve $z\in\Omega_{p,\gamma}$, one can consider the curve $\tilde{z}\in\Omega_{p,q}$ given by

$$\tilde{z}(s)=\psi(z(s),\phi_z(s)),$$

where

$$\phi_z(s)=(\gamma^{-1}(q)-\gamma^{-1}(z(1)))\cdot s.$$

Observe that the map γ^{-1} is well defined and continuous on $\gamma(\mathbb{R})$ because γ is injective, due to the causality of $\mathscr{M}$. Moreover, the evaluation map $z\mapsto z(1)$ is continuous in $\Omega_{p,\gamma}$, and so the map $z\mapsto\phi_z\in C^1([0,1],\mathbb{R})$ is continuous in $\Omega_{p,\gamma}$.

The map $\mathscr{H}:\Omega_{p,\gamma}\times[0,1]\mapsto\Omega_{p,\gamma}$ given by

$$\mathscr{H}(z,\sigma)(s)=\psi(z(s),\phi_z(s)\cdot\sigma)$$

is clearly continuous; moreover it satisfies $\mathscr{H}(z,0)=z$, $\mathscr{H}(z,\sigma)=z$ for all $z\in\Omega_{p,q}$ and all $\sigma\in[0,1]$, and $\mathscr{H}(z,1)=\tilde{z}$, and so it is a *strong deformation retract* of $\Omega_{p,\gamma}$ onto $\Omega_{p,q}$. In particular, the map $\mathscr{H}(\cdot,1)$ is a homotopy equivalence between $\Omega_{p,\gamma}$ and $\Omega_{p,q}$ and the two spaces have the same homotopy type.

A well known result by Fadell and Husseini (see Ref. 13) states that, if $\overline{U_k}$ is not contractible, then the category of the space $\Omega_{p,q}$, and so also the category of $\Omega_{p,\gamma}$, is infinite:

$$\mathrm{cat}(\Omega_{p,\gamma})=\mathrm{cat}(\Omega_{p,q})=+\infty;$$

moreover, there exists a sequence K_n of compact subsets of $\Omega_{p,\gamma}$ such that

$$\lim_{n\to\infty}\mathrm{cat}_{\Omega_{p,\gamma}}(K_n)=+\infty. \tag{56}$$

For all $n \in \mathbb{N}$, we denote by Γ_n the collection of all compact subsets of $\Omega_{p,\gamma}$ having category strictly larger than to n:

$$\Gamma_n = \{B \text{ compact subset of } \Omega_{p,\gamma} : \mathrm{cat}_{\Omega_{p,\gamma}}(B) \geqslant n+1\}. \tag{57}$$

Observe that, by (56), $\Gamma_n \neq \varnothing$ for all $n \in \mathbb{N}$.

For all $c \in \mathbb{R}$ and $\varepsilon \in [0,1]$, we denote by $E^c_{k,\varepsilon}$ the closed c-sublevel of the functional $E_{k,\varepsilon}$ in $\Omega_{p,\gamma}$:

$$E^c_{k,\varepsilon} = \{w \in \Omega_{p,\gamma} : E_{k,\varepsilon}(w) \leqslant c\};$$

clearly

$$E^c_{k,\varepsilon} \subseteq E^c_k, \quad \forall c \in \mathbb{R}, \quad \forall \varepsilon \in [0,1].$$

A well known argument in critical point theory shows that, if $F: X \mapsto \mathbb{R}$ is a C^1-functional defined on the Banach manifold X, satisfying the Palais–Smale condition at the level $c' \in \mathbb{R}$ and such that the sublevel $F^{c'}$ is complete, then, the category $\mathrm{cat}_X(F^{c'})$ is finite.

In the following preliminary Lemma we show that, for all $c \in \mathbb{R}$, the category $\mathrm{cat}_{\Omega_{p,\gamma}}(E^c_{k,\varepsilon})$ is bounded *uniformly* with respect to ε.

Lemma V.2: For all $c \in \mathbb{R}$ there exists $N = N(c) \in \mathbb{N}$ such that

$$\mathrm{cat}_{\Omega_{p,\gamma}}(E^c_{k,\varepsilon}) \leqslant N(c), \tag{58}$$

for all $\varepsilon \in [0,1]$.

Proof: We will show that, for all $c \in \mathbb{R}$, there exists $c' \in \mathbb{R}$ and, for all $\varepsilon \in [0,1]$, a homotopy between the sublevel $E^c_{k,\varepsilon}$ and a subset of the sublevel $F^{c'}$, where F is a suitable smooth functional satisfying the properties described above.

By the completeness of $\overline{U_k}$, for all $c \in \mathbb{R}$ there exists a compact subset $K_c \subset \overline{U_k}$ containing the images of all the curves in $E^c_{k,\varepsilon}$, for all $\varepsilon \in [0,1]$. Indeed, as we have already observed at the beginning of Sec. IV, all such curves w have bounded energy:

$$\int_0^1 \langle \dot{w}, \dot{w} \rangle_{(R)} ds \leqslant d_0 < +\infty.$$

For $\delta > 0$, we denote by V_δ the closed subset of U_k given by

$$V_\delta = \{x \in U_k : \psi_k(x) \geqslant \delta\}. \tag{59}$$

Let now $\delta > 0$ be small enough and $H: [0,1] \times (\overline{U_k} \cap K_c) \mapsto K_c$ be a map of class C^1 satisfying:

(1) $H(0,x) = x$ for all $x \in \overline{U_k} \cap K_c$;
(2) $H(\sigma, V_\delta) \subset V_\delta$ for all $\sigma \in [0,1]$;
(3) $H(1, \overline{U_k} \cap K_c) \subset V_\delta$.

Such a map is built using the flow of the vector field $\nabla_{(R)} \psi_k$, which is bounded away from 0 in the compact set $K_c \cap \partial U_k$.

Finally, we consider the map $\mathscr{H}: [0,1] \times E^c_k \mapsto \Omega_{p,\gamma}$ defined by

$$\mathscr{H}(\sigma, w)(s) = H(\sigma \cdot s, w(s)), \quad \forall \sigma, s \in [0,1]. \tag{60}$$

Clearly, $\mathscr{H}$ is continuous; moreover, by the construction of H, the map $\mathscr{H}(0,\cdot)$ is the identity on E^c_k. By construction, the curves in $\mathscr{H}(1, E^c_k)$ have image in the set V_δ, and so they stay uniformly far from ∂U_k.

Since the curves in E^c_k have image in a fixed compact set, it is easy to see by a direct computation that the map H has bounded partial derivatives, and so the map $\mathscr{H}(1,\cdot)$ is Lipschitz continuous on E^c_k. It follows that there exists a real number c' such that

$$\sup_{w \in \mathscr{H}(1,E_k^c)} E_k(w) \leqslant c'.$$

We denote by $A_{k,\delta,c'}$ the set of curves in $E_k^{c'}$ having image in V_δ:

$$A_{k,\delta,c'} = \{w \in E_k^{c'} : w(s) \in V_\delta, \forall s\};$$

we have just proven that

$$\mathscr{H}(1,E_k^c) \subseteq A_{k,\delta,c'}.$$

Let us consider the functional $F:\Omega_{p,\gamma} \mapsto \mathbb{R}$ given by

$$F(w) = E_k(w) + \int_0^1 \frac{ds}{G(\psi_k(w))^2}, \tag{61}$$

where $G:[0,+\infty[\mapsto \mathbb{R}^+$ is a smooth function satisfying

$$G(0) = 0,\ G'(0) > 0, \quad \text{and } G(r) \equiv 0 \quad \text{if } x \in \left[\frac{\delta}{2}, +\infty\right[.$$

Now, the same proofs of Corollary III.2 and of Proposition III.3 can be repeated *verbatim* to show that F is a smooth functional on $\Omega_{p,\gamma}$ that satisfies the Palais–Smale condition, and whose sublevels are complete. It follows that, for all $c' \in \mathbb{R}$, there exists a natural number $N(c')$ such that:

$$\mathrm{cat}_{\Omega_{p,\gamma}}(F^{c'}) = N(c') < +\infty. \tag{62}$$

Since the function G vanishes identically on the images of the curves in $A_{k,\delta,c'}$, then $A_{k,\delta,c'} \subseteq F^{c'}$, and, in particular,

$$\mathrm{cat}_{\Omega_{p,\gamma}}(A_{k,\delta,c'}) \leqslant \mathrm{cat}_{\Omega_{p,\gamma}}(F^{c'}) = N(c'). \tag{63}$$

Thus, by the homotopical invariance and the monotonicity of the Ljusternik–Schnirelman category, it is:

$$\mathrm{cat}_{\Omega_{p,\gamma}}(E_{k,\varepsilon}^c) \leqslant \mathrm{cat}_{\Omega_{p,\gamma}}(E_k^c) = \mathrm{cat}_{\Omega_{p,\gamma}}(\mathscr{H}(1,E_k^c)) \leqslant \mathrm{cat}_{\Omega_{p,\gamma}}(A_{k,\delta,c'}), \tag{64}$$

which concludes the proof. □

A well known *minimax* argument in critical point theory shows that the numbers:

$$c_m^\varepsilon = \inf_{B \in \Gamma_m} \sup_{x \in B} E_{k,\varepsilon}(x) \tag{65}$$

are critical values for the functional $E_{k,\varepsilon}$ for all $m \in \mathbb{N}$ and all $\varepsilon \in]0,1]$. Observe that, by the definition (57) of Γ_n, each c_m^ε is well defined and finite. Also, since $\varepsilon \mapsto E_{k,\varepsilon}(w)$ is increasing on $[0,1]$ for all $w \in \Omega_{p,\gamma}$, it follows easily that

$$0 \leqslant c_m^\varepsilon \leqslant c_m^1, \quad \forall \varepsilon \in [0,1], \quad \forall m \in \mathbb{N}. \tag{66}$$

Since Γ_n is nonempty for all n, from (65) it follows that $E_{k,\varepsilon}$ has arbitrarily large critical values for all $\varepsilon \in]0,1]$; in order to prove Theorem I.3, we need to prove that the same claim is true for the functional $E_k = E_{k,0}$.

Lemma V.3: In the notations of Lemma V.2, for all $c \in \mathbb{R}$, if $m \geqslant N(c)$ then

$$c_m^\varepsilon \geqslant c, \quad \forall \varepsilon \in]0,1]. \tag{67}$$

Proof: Let $\varepsilon \in]0,1]$ and $c \in \mathbb{R}$ be fixed. By contradiction, suppose that there exists $m \geqslant N(c)$ and $B \in \Gamma_m$ such that:

$$\sup_{x \in B} E_{k,\varepsilon}(x) \leqslant c.$$

Then, it would be:

$$B \subseteq E^c_{k,\varepsilon} \subseteq E^c_k,$$

and, by the monotonicity of the Ljusternik–Schnirelman category, it would be

$$\mathrm{cat}_{\Omega_{p,\gamma}}(B) \leqslant \mathrm{cat}_{\Omega_{p,\gamma}}(E^c_k) \leqslant N(c). \tag{68}$$

The inequality (68) contradicts the fact that $B \in \Gamma_m$ and concludes the proof. □

We are ready for the proof of Theorem I.3:

Proof of Theorem I.3 Let $\{\varepsilon_n\}_n \subset]0,1]$ be any decreasing sequence converging to 0 and let E_{k,ε_n} be the corresponding sequence of functionals on $\Omega_{p,\gamma}$.

For all $m \in \mathbb{N}$, we define:

$$\overline{c}_m = \lim_{n \to \infty} \inf c^{\varepsilon_n}_m. \tag{69}$$

By (66), the $\overline{c}_m$ are well defined (finite), and they form a nondecreasing sequence.

By Proposition IV.4, for all $m \in \mathbb{N}$, $\overline{c}_m$ is a critical value for E_k.

Finally, by Lemma V.3, the sequence $\overline{c}_m$ is unbounded, hence E_k has arbitrarily large critical values. The conclusion follows immediately from Proposition II.2 and formula (54). □

Modified real structures for quantum groups and applications

G. Grensing[a)]
Institut für Theoretische Physik und Astrophysik, Universität Kiel, D-24118 Kiel, Germany

(Received 28 October 1997; accepted for publication 28 July 1998)

A modification of the standard $*$-structure on a quasitriangular Hopf algebra is introduced by means of which, in particular, the quantum deformation $U_q(su_2)$ can be endowed with a real structure for q a pure phase. As opposed to the standard definition, its modified version not only works for the quantum group regarded as an algebra, but as a quasitriangular Hopf algebra if q is of modulus one. Applications to two relevant examples are given, which are known to require quantum symmetries: the anisotropic Heisenberg chain and the Landau theory on the torus, thus solving some unitarity problems that have always resisted a satisfactory solution. © *1998 American Institute of Physics.* [S0022-2488(98)03511-7]

I. INTRODUCTION

More than half a century was needed to realize that some quantum mechanical models do not admit conventional symmetries in the form of Lie groups, but instead require symmetries which have come to be known as quantum groups. Their underlying algebraic structure was revealed by Drinfeld;[1] they may all be subsumed under the class of quasitriangular Hopf algebras. The deformations of the classical Lie algebras, the q-deformed quantum enveloping algebras, are main examples of these constructs (see, e.g., Ref. 2).

The case of interest in many applications, both in mathematics and physics, is the one for which the deformation parameter q is a pure phase, or even a root of unity. On the mathematical side, this occurs for invariants of three-manifolds.[3] On the physical side, what we have in mind are examples such as the anisotropic spin chain,[4] living in one dimension, and the Landau theory of two-dimensional electrons,[5,6] which underlies the quantum Hall effect.

Despite its relevance, the case q a pure phase, or even a root of unity, is also the most difficult to handle. One reason is that no real structure that extends to the quantum enveloping algebra as a whole is known, because the standard definition[7] is not compatible with the coalgebra structure. Since a real structure dictates what is to be called a unitary or Hermitian operator, one thus gets confronted with severe unitarity problems. As for the Heisenberg spin chain, unitarity seems to be violated for $|q|=1$ because the Hamiltonian is not Hermitian; for the Landau theory of two-dimensional electrons, the quantum group which acts on the lowest Landau level wave functions carries the wrong real structure $U_q(su_{1,1})$, if one relies on the results given in the literature.

It is the purpose of the present paper to contribute to the solution of these problems. Related ideas have appeared in Refs. 8 and 9, but our approach is rather different; the treatment given in Ref. 8, which employs category-theoretic ideas, seems to be closest to ours.

The paper may roughly be divided into two parts: the first is concerned with the mathematical aspects of the problem. In Sec. II the standard definition of a real structure on a Hopf algebra is modified and extended for the quasitriangular case to the universal $\mathcal{R}$-matrix. The applications to the basic example $U_q(sl_2)$ are given in Sec. III, and it is shown that the number of its real structures is simply doubled; in particular, the case $|q|=1$, which has always played a singular role, is now included for the ''compact'' real form. Furthermore, the modified $*$-structure is applied to representations of the real form $U_q(su_2)$ with q a pure phase, which are now representations of the quasitriangular Hopf algebra, and not of the algebra only.

The second part is concerned with some physical aspects of the problem. In Sec. IV we deal with the applications to the XXZ-spin chain which, for open boundary conditions, admits a global

$U_q(su_2)$ symmetry. The Hamilton operator is not hermitian in the naive sense, but the appropriate definition of hermiticity, derived from the modified real structure, will guarantee the eigenvalues to be real. We end this Section with a short discussion of closed boundary conditions, which are considerably more difficult to treat.[4] Recent work[10] has given hints that in this case a two-parameter deformation of gl_2 gets involved. We take another route to demonstrate this on invoking a generalization of the Wigner–Jordan transformation, which will turn out to be intimately connected with the notion of anyons.[11] The resulting two-parameter deformation $U_{q,t}(gl_2)$ is then shown to constitute the symmetry group of this system; but what we have not been able to resolve is the unitarity problem for closed boundary conditions. In Sec. V we deal with the Landau theory on the torus[6] with twisted boundary conditions, and it is shown that there is a residual symmetry, resulting from a discrete subgroup of the magnetic translation group, which gives rise to a unitary and irreducible representation of the finite-dimensional restriction of the quantum group $U_q(su_2)$ at a primitive root of unity. Section VI ends with some concluding remarks.

II. STANDARD AND MODIFIED REAL STRUCTURES ON QUASITRIANGULAR HOPF ALGEBRAS

To begin with, we briefly review the standard definition of a $*$-structure on a Hopf algebra. Let $\mathcal{A}$ be an associative algebra with unit over the field $k=\mathbb{C}$; then a $*$-structure is a conjugate-linear antimorphism $*:\mathcal{A}\to\mathcal{A}$ with $*^2=id_{\mathcal{A}}$. If, in addition, $\mathcal{A}$ is a bialgebra, the compatibility requirements for the comultiplication Δ and the count ε are usually taken to be

$$*\otimes *\circ\Delta=\Delta\circ *, \quad *\circ\varepsilon=\varepsilon\circ *, \tag{1}$$

where $*\circ\varepsilon(a)=\overline{\varepsilon(a)}$ with $a\in\mathcal{A}$ is the complex conjugate. Furthermore, if $\mathcal{A}$ is also a Hopf algebra with antipode σ, which we always assume to be invertible, there is no need to impose $*\circ\sigma=\sigma^{-1}\circ *$ as a further axiom, since this property follows from the conditions stated above.

There is another option to define the $*$-structure of a bialgebra, as we now explain. In order to motivate this modification, let us show the defining properties of a $*$-structure on an algebra $\mathcal{A}$ in the form of commutative diagrams. The $*$-involution is chosen so as to make the following diagrams commute:

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{*} & \mathcal{A} \\ {\scriptstyle \mu_{op}}\uparrow & & \uparrow{\scriptstyle \mu} \\ \mathcal{A}\otimes\mathcal{A} & \xrightarrow[*\otimes *]{} & \mathcal{A}\otimes\mathcal{A} \end{array} \qquad \begin{array}{ccc} k & \xrightarrow{*} & k \\ {\scriptstyle \iota}\downarrow & & \downarrow{\scriptstyle \iota} \\ \mathcal{A} & \xrightarrow[*]{} & \mathcal{A} \end{array}$$

where ι is the identity, μ the multiplication, and μ_{op} its opposite.

For the standard choice of a $*$-structure on a bialgebra, the comultiplication and the count are $*$-morphisms of $\mathcal{A}$ as a coalgebra. A rather obvious modification is to define a $*$-structure for a coalgebra such that it is dual to the one for an algebra, i.e., in the form of commuting diagrams,

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{*} & \mathcal{A} \\ {\scriptstyle \Delta}\downarrow & & \downarrow{\scriptstyle \Delta^{op}} \\ \mathcal{A}\otimes\mathcal{A} & \xrightarrow[*\otimes *]{} & \mathcal{A}\otimes\mathcal{A} \end{array} \qquad \begin{array}{ccc} k & \xrightarrow{*} & k \\ {\scriptstyle \epsilon}\uparrow & & \uparrow{\scriptstyle \epsilon} \\ \mathcal{A} & \xrightarrow[*]{} & \mathcal{A} \end{array}$$

with $\Delta^{op}=\tau\circ\Delta$ and τ the transposition in $\mathcal{A}\otimes\mathcal{A}$. We thus see that the defining properties for the standard case are replaced by

$$*\otimes *\circ\Delta=\Delta^{op}\circ *, \quad *\circ\varepsilon=\varepsilon\circ *. \tag{2}$$

This is the case which we call modified in the sequel. That such modified $*$-structures indeed exist will be shown in Sec. III on the basic example $U_q(sl_2)$. Furthermore, if $\mathcal{A}$ is also a Hopf algebra, the antipode obeys $*\circ\sigma=\sigma\circ *$ for the modified $*$- structure, the proof being rather similar to the corresponding statement for the standard case.

We now assume that $\mathcal{A}$ is also endowed with a quasitriangular structure; what one needs is the behavior of the universal $\mathcal{R}$-matrix under the tensor product map $*\otimes *$. We find the two possi-

bilities: $*\otimes *(\mathcal{R})=\check{\mathcal{R}}$ and $*\otimes *(\mathcal{R})=\mathcal{R}^{-1}$ with $\check{\mathcal{R}}=\tau\mathcal{R}$ for the standard case, whereas $*\otimes *(\mathcal{R})=\check{\mathcal{R}}^{-1}$ and $*\otimes *(\mathcal{R})=\mathcal{R}$ for the modified case. It is straightforward to prove that all these possibilities are indeed compatible with the quasitriangular structure.

Finally, let us briefly discuss tensor product representations of quasitriangular Hopf algebras with standard and modified real structures.[12] If $\rho_V:\mathcal{A}\to End(V)$ is a $*$-representation of $\mathcal{A}$ on a finite-dimensional vector space V over $\mathbb{C}$ with a nondegenerate Hermitian form, then the Hermitian adjoint of the representation $\rho_{V,W}(a)=\rho_V\otimes\rho_W\circ\Delta(a)$ of $\mathcal{A}$ on $V\otimes W$ reads as $\rho^{\dagger}_{V,W}(a)=\rho_V\otimes\rho_W\circ *\otimes *\circ\Delta(a)$. This can be rewritten in terms of the adjoint $*(a)$ of $a\in A$. For the standard $*$-structure, the result is

$$\rho^{\dagger}_{V,W}(a)=\rho_{V,W}(*(a)), \tag{3}$$

and so the tensor product representation is again a $*$-representation; for the modified $*$-structure, we find

$$\rho^{\dagger}_{V,W}(a)=R_{V,W}\rho_{V,W}(*(a))R^{-1}_{V,W}. \tag{4}$$

In Sec. IV to come, we will have an occasion to discuss this result.

III. REAL STRUCTURES OF $U_q(sl_2)$ AND $*$-REPRESENTATIONS

Let us apply the above results to the quantum enveloping algebra $U_q(sl_2)$ with generators X_+, X_-, and H and relations

$$q^{H/2}X_{\pm}q^{-H/2}=q^{\pm 1}X_{\pm}, \quad [X_+,X_-]=\frac{q^H-q^{-H}}{q-q^{-1}}. \tag{5}$$

For the sake of brevity, the additional properties needed to endow this deformation with a quasitriangular Hopf structure are omitted.[2]

For the discussion of the $*$-structures of $U_q(sl_2)$, we rely on the known fact that real forms exist for q real, a pure phase, and purely imaginary; since in the latter case no classical limit exists, we confine ourselves to the first two possibilities. Furthermore, it is known that there are three nonequivalent real forms for the standard $*$-structure.[7] The modified $*$-structure adds three additional real forms, which just cover the alternative possibility, i.e., if $q\in\mathbb{R}$ is realized in the standard case (i), then the modified case (ii) realizes $|q|=1$, and vice versa. For the compact case $U_q(su_2)$ with $*(H)=H$ and $*(X_{\pm})=X_{\mp}$ the result is

$$\text{(i)}\quad q\in\mathbb{R}:*\otimes *(\mathcal{R})=\check{\mathcal{R}}, \quad \text{(ii)}\quad |q|=1:*\otimes *(\mathcal{R})=\check{\mathcal{R}}^{-1}. \tag{6}$$

For the two noncompact cases, we find for $U_q(su_{1,1})$ with $*(H)=H$ and $*(X_{\pm})=-X_{\mp}$:

$$\text{(i)}\quad q\in\mathbb{R}:*\otimes *(\mathcal{R})=\check{\mathcal{R}}, \quad \text{(ii)}\quad |q|=1:*\otimes *(\mathcal{R})=\check{\mathcal{R}}^{-1}, \tag{7}$$

and for $U_q(sl_2,\mathbb{R})$ with $*(H)=-H$ and $*(X_{\pm})=-X_{\pm}$]:

$$\text{(i)}\quad |q|=1:*\otimes *(\mathcal{R})=\mathcal{R}^{-1}, \quad \text{(ii)}\quad q\in\mathbb{R}:*\otimes *(\mathcal{R})=\mathcal{R}. \tag{8}$$

The proof (cf. also Ref. 2), which may be greatly simplified by using basic elements of q-analysis, is rather straightforward. As a rule, $K=e^H$ obeys $*(K)=K$ for the standard real structures, and $*(K)=K^{-1}$ for the modified real structures.

We thus see that all four possibilities for $*\otimes *(\mathcal{R})$, having been encountered in Sec. II, really do appear. Furthermore, we are now entitled to discuss $*$-representations of the ''compact'' real form $U_q(su_2)$ for q a pure phase, which are compatible with the structure of $U_q(su_2)$ as a Hopf algebra, and not as an algebra only.

So let us give a brief review of the known representation theory of the quantum deformation $U_q(su_2)$,[13] where we restrict ourselves to the case with $q=e^{2\pi i/p}$ a primitive root of unity. Since

the representations with dimension $n+1>p$ are reducible but not completely reducible,[2] we choose $n+1\leqslant p$. The irreducible highest weight representations take the form

$$X_+ w_r = \epsilon[n-r+1][r]w_{r-1}, \quad X_- w_r = w_{r+1}, \quad K w_r = \epsilon q^{n-2r} w_r, \tag{9}$$

with $0\leqslant r\leqslant n$, $\epsilon=\pm 1$, and $[x]=(q^x-q^{-x})/(q-q^{-1})$; this result holds as well for $q\in\mathbb{R}$ and $n\geqslant 0$. For q a root of unity, the generators obey the additional restrictions $K^{2p}-1=0$ and $X_\pm^p=0$. If q is an odd root of unity and $\epsilon=+1$, we even have the stronger restriction $K^p=1$; but, as will be seen, we shall have a need for the weaker version.

Since these restrictions are obeyed on all irreducible representations, one can as well impose them on the algebra level as additional relations. This is achieved on passing from K to the square root $L=K^{1/2}$ and, with the obvious changes in the defining properties of $U_q(sl_2)$, it is straightforward to prove that the two-sided ideal I, generated by the elements $L^{4p}-1$ and $X_\pm^p$, is a Hopf ideal. Hence, $U_q(sl_2)'=U_q(sl_2)/I$ is again a Hopf algebra. This finite-dimensional restriction[2] is even quasitriangular with a universal $\mathcal{R}$-matrix,

$$\mathcal{R}=\mathcal{R}_L \sum_{m=0}^{p-1} r_m (X_+ L^{+1}\otimes L^{-1} X_-)^m, \tag{10}$$

where $\mathcal{R}_L=(1/4p)\,\Sigma_{k,l=0}^{4p-1} q^{-(1/2)kl} L^k\otimes L^l$ and $r_m=q^{(1/2)m(m-1)}(q-q^{-1})^m/[m]!$; furthermore, we have $*\otimes *(\mathcal{R})=\check{\mathcal{R}}^{-1}$. For q an even root of unity, this is a known result;[3] the proof for q an odd root of unity is rather similar.

A nondegenerate Hermitian form can be constructed on the $n+1$-dimensional vector space, with respect to which the representations are $*$-representations. For $q\in\mathbb{R}$, they read

$$X_\pm e^j{}_m = (\epsilon[j\mp m][j\pm m+1])^{1/2} e^j{}_{m\pm 1}, \quad K e^j{}_m = \epsilon q^{2m} e^j{}_m, \tag{11}$$

with $n=2j$ and $+j\geqslant m\geqslant -j$; they are well-known for $\epsilon=+1$.[14] For q an even root of unity and $\epsilon=+1$, it is easy to prove that the irreducible representations with $n+1\leqslant p$ are unitary and take the same form; this result is related to Jones' work on subfactors.[15]

If q is an odd root of unity, no general statement can be made. Of special importance are those representations which are on the verge of getting reducible and indecomposable, i.e., those with $n+1=p$. For $\epsilon=-1$, they are unitary and can be shown to read

$$X_\pm e^j{}_m = [m\pm\tfrac{1}{2}] e^j_{m\pm 1}, \quad K e^j{}_m = -q^{2m} e^j{}_m. \tag{12}$$

This result, which may also formally be obtained from (11) on choosing $q=e^{2\pi i/p}$ with p odd and $\epsilon=-1$, will be referred to in Sec. V below.

IV. SPIN CHAINS AND UNITARITY

Let us apply the above results to the anisotropic XXZ-spin chain, which is described by the Hamiltonian,[16,4,17]

$$\hat{H}=-\frac{J}{4}\sum_{i=1}^{N-1}\{2(\sigma_i^+\sigma_{i+1}^- + \sigma_i^-\sigma_{i+1}^+) + \gamma\sigma_i^3\sigma_{i+1}^3 + \delta(\sigma_i^3-\sigma_{i+1}^3) + \varepsilon\}. \tag{13}$$

Here, the σ_i are local spin-$\frac{1}{2}$ operators, living on the sites $i=1,\ldots,N-1$ of a one-dimensional finite lattice with boundary conditions which, for the present, we assume to be open. The local symmetry is the quantum algebra $U_q(su_2)$ since its fundamental representation coincides with the undeformed version. The constants appearing in (13) are given in terms of the deformation parameter q as $\gamma=(q+q^{-1})/2$, $\delta=-(q-q^{-1})/2$, and $\epsilon=-\delta$. They are designed so as to render the Hamiltonian invariant under a global $U_q(su_2)$, the generators of which are determined by the $(N-1)$-fold coproduct. There are two routes to prove the global invariance, both of which will be made use of in the subsequent development.

The first proof relies on the observation that one can read the Hamiltonian as[4] $\hat{H}=(J/2)\,\Sigma_{i=1}^{N-1}E_i$, where the operators $E_i=(\overset{i-1}{\otimes}1)\otimes E\otimes(\overset{N-i-1}{\otimes}1)$ with

$$E=-\tfrac{1}{2}(2(\sigma^+\otimes\sigma^-+\sigma^-\otimes\sigma^+)+\gamma\sigma^3\otimes\sigma^3+\delta(\sigma^3\otimes 1-1\otimes\sigma^3)+\epsilon 1\otimes 1) \tag{14}$$

form a Temperley–Lieb–Jones (TLJ) algebra;[18] our conventions are fixed by $E_i^2=2\gamma E_i$. Hence, the operators[15] $S_i=qE_i-1$ obey the braid group relations; furthermore, the global generators commute with $\hat{H}$, since they commute with each single TLJ operator.

The second proof relies on the observation that the Hamiltonian is built from the coproduct of the Casimir operator $C=J^+J^-+[J^3][J^3-1]$, where the J's are now understood to denote the generators of $U_q(su_2)$ in an arbitrary representation. Indeed, in the fundamental representation, we have $\Delta^\natural(C)=-E+2\gamma 1\otimes 1$. On introducing $\Delta^\natural_{i,i+1}(C)=(\overset{i-1}{\otimes}1)\otimes\Delta^\natural(C)\otimes(\overset{N-i-1}{\otimes}1)$, the Hamiltonian can be expressed as a sum of such terms. So the proof is complete if we can show that

$$\Delta_{i,i+1}(C)\Delta^{N-1}(a)=\Delta^{N-1}(a)\Delta_{i,i+1}(C), \tag{15}$$

for all $i=1,\ldots,N-1$ and a in $U_q(su_2)$. But this property follows by induction, using coassociativity and the fact that the Casimir operator is central.

However, what has always been something of a mystery is that, for q a pure phase, the Hamiltonian is not self-adjoint because the boundary term in (13) (the one proportional to ε) is purely imaginary; so one would not expect the eigenvalues to be real.

This intriguing contradiction is resolved by means of the modified real structure of $U_q(su_2)$. Again, we make use of the fact that $\hat{H}$ may be written as a sum of Casimir operators, where it is essential that the prefactor γ of the additional term is a real number and thus does not affect the conclusions to follow.

For the discussion of the hermiticity properties of $\hat{H}$, we may thus restrict ourselves to the investigation of $\Delta(C)$, and for this purpose we go back to Sec. II. The naive Hermitian conjugation of

$$\Delta(C)=\Delta(J^+)\Delta(J^-)+[\Delta(J^3)][\Delta(J^3)-1], \tag{16}$$

with $*(J^\pm)=J^\mp$ amounts to Eq. (1) with $a=C$, i.e., $*\otimes *\cdot\Delta(C)=\Delta(*(C))=\Delta(C)$ since C is self-adjoint; but for $|q|=1$ this is the wrong result. The reason is, of course, that Eq. (1) only holds for q real. For q a pure phase, we must use instead Eq. (2), i.e., $*\otimes *\cdot\Delta(C)=\Delta^{op}(C)$, and this is indeed the correct result.

Turning to representations, we know that for q an even root of unity, the representations are $*$-representations with a positive definite Hermitian form. In particular, we can thus resort to [see (4)] $\Delta^\natural(C)^\dagger=R^\natural\Delta^\natural(C)R^{\natural\,-1}$, where $R^\natural$ denotes the representation of $\mathcal{R}$ in the tensor product of two fundamental representations. As can easily be shown now, although $\Delta^\natural(C)$ is only ''almost'' Hermitian, it nevertheless has real eigenvalues.

In summary, the spin chain Hamiltonian with open boundary conditions is not Hermitian in the naive sense, but the generalized hermiticity property (4) at least guarantees its eigenvalues to be real. This property holds without qualification only if q is an even root of unity.

We want to conclude this section with some comments on the spin chain with closed boundary conditions. These amount to the replacement $N\to N+1$ and, for the term with $i=N$ in (13), one defines $\sigma^\pm_{N+1}=e^{\pm i\varphi}\sigma^\pm_1$ and $\sigma^3_{N+1}=\sigma^3_1$, where the angle φ describes the twisting. It is advantageous to remove the exceptional role of σ_{N+1} by means of the substitution $\sigma_i^\pm\to t^{\pm i}\sigma_i^\pm$ and $\sigma_i^3\to\sigma_i^3$ with $t^N=e^{i\varphi}$, which does not change the local algebra; the boundary conditions then become periodic in the usual sense. The Hamiltonian now takes the form as above, with N replaced by $N+1$, and

$$E(q,t)=-\tfrac{1}{2}(2(t^{-1}\sigma^+\otimes\sigma^-+t\sigma^-\otimes\sigma^+)+\gamma\sigma^3\otimes\sigma^3+\delta(\sigma^3\otimes 1-1\otimes\sigma^3)+\epsilon 1\otimes 1). \tag{17}$$

Remarkably, the operators $E_i(q,t)$ still obey a TLJ algebra for t arbitrary.[19]

In order to motivate what follows, let us consider the following generalization of the Jordan–Wigner transformation:

$$S_i^- = e^{i\pi\kappa\sum_{j=1}^{N}\theta(i-j)c_j^\dagger c_j} c_i, \quad S_i^3 = c_i^\dagger c_i - \frac{1}{2}, \tag{18}$$

where the c_i are fermionic operators with $\{c_i, c_j^\dagger\} = \delta_{ij}$ and θ is the ''lattice angle'' in one dimension with $\theta(j)$ equal to 0 for $j \leqslant 0$ and 1 for $j > 0$; the original case[20] is recovered for $\kappa = 1$. This generalization leads to anyons,[11,21] usually considered in two dimensions only, but this concept works in one dimension as well. Indeed, the operators $S_i^\pm$ and S_i^3 obey relations such as $S_i^+ S_j^- + e^{-i\pi\kappa} S_j^- S_i^+ = 0$ for $i \neq j$, being characteristic of anyons. This relation guides us to introduce the deformed commutator,

$$[S_i^+, S_j^-]_t = t^{-1} S_i^+ S_j^- - t S_j^- S_i^+ = t^{-2S_i^3} [2S_i^3]_q \delta_{ij}, \tag{19}$$

with $t^2 = -e^{-i\pi\kappa}$, where the last equality is easily verified; the other relations remain undeformed. Hence, the anyonization of one-dimensional fermions on a lattice leads to a two-parameter deformation of sl_2, q being a measure of the anisotropy, and t is related to the boundary conditions.

We thus have obtained a two-parameter deformation $U_{q,t}(sl_2)$,[22] but what is still missing is the global invariance of the Hamiltonian. This can be achieved on supplementing the generators $S^\pm$ and S^3 by a central element Z. Then the coproduct must be modified as follows:

$$\Delta(S^\pm) = S^\pm \otimes q^{+S^3} t^{-(S^3 \pm Z)} + q^{-S^3} t^{-(S^3 \mp Z)} \otimes S^\pm, \quad \Delta(S^3) = S^3 \otimes 1 + 1 \otimes S^3, \tag{20}$$

and for the count we choose $\epsilon(Z) = 0$; a Hopf algebra is obtained on defining the antipode as

$$\sigma(S^3) = -S^3, \quad \sigma(S^\pm) = -(qt)^{\pm 1} S^\pm t^{2S^3}, \quad \sigma(Z) = -Z. \tag{21}$$

This is a deformation $U_{q,t}(gl_2)$ of the general linear group in two dimensions (Ref. 10); see also Ref. 23). As can now be shown by explicit computation, the generalized TLJ operators $E_i(q,t)$ commute with the generators,

$$J^\pm = \sum_{i=1}^{N+1} \left(\overset{i-1}{\otimes} q^{-1/2\,\sigma^3} t^{-(1/2)(\sigma^3 \mp 1)} \right) \otimes \sigma^\pm \otimes \left(\overset{N-i+1}{\otimes} q^{+(1/2)\sigma^3} t^{-(1/2)(\sigma^3 \pm 1)} \right), \tag{22}$$

$$J^3 = \sum_{i=1}^{N+1} (\overset{i-1}{\otimes} 1) \otimes \frac{1}{2}\sigma^3 \otimes (\overset{N-i+1}{\otimes} 1),$$

of the global $U_{q,t}(gl_2)$, which thus constitutes the quantum symmetry of the spin chain with closed boundary conditions.[24]

V. LANDAU THEORY AND QUANTUM SYMMETRY

Another respectable problem where quantum symmetries make their appearance is the quantum Hall effect.[25] Recently, the deformation $U_q(su_2)$ has been shown to be the spectrum generating algebra for odd filling fractions $\nu = 1/p$.[26] Here, we are concerned with the underlying Landau theory of two-dimensional electrons, confined to a rectangular sample of extensions L_x and L_y, and subjected to a strong constant magnetic field B in the third direction. Hence, boundary conditions will again play a crucial role.

Thus, the point of departure is the Hamilton operator,

$$\hat{H} = \frac{1}{2m}(\pi_x{}^2 + \pi_y{}^2), \tag{23}$$

with $\pi_i = p_i + (e/c)A_i$ and $i = x,y$. The magnetic translations[27] $T(\alpha,\beta) = \exp((1/2)(\alpha Y - \beta X))$, where $X = x - (1/\omega B)\pi_y$ and $Y = y + (1/\omega B)\pi_x$, commute with the Hamiltonian and yield a Heisenberg–Weyl group; here $l = \sqrt{\hbar c/eB}$ denotes the magnetic length and $\omega = eB/mc$ the cyclotron frequency. On wave functions they act as

$$T(\alpha,\beta)\psi(x,y) = \exp\left(-\frac{i}{l^2}\left(\frac{1}{2}\alpha\beta + \beta x \right) \right) \psi(x+\alpha, y+\beta), \tag{24}$$

and choosing the Landau gauge[28] $A_x = -By, A_y = 0$, we impose twisted boundary conditions, which are compatible with the symmetries of the system, by requiring

$$T(L_x,0)\psi_0(x,y) = e^{2\pi i\mu}\psi_0(x,y), \quad T(0,L_y)\psi_0(x,y) = e^{2\pi i\nu}\psi_0(x,y), \tag{25}$$

with $\mu, \nu \in [0,1]$. The ground state solutions can be expressed in terms of θ-functions with characteristics[29] as

$$\psi_{o;m}(x,y) = \langle x,y|m\rangle = c_0 \exp\left(-\frac{1}{2l^2}y^2 \right) \theta\begin{bmatrix} \dfrac{m+\mu}{N} \\ \nu \end{bmatrix} (N\overline{v}|N\tau), \tag{26}$$

with $v = (x+iy)/L_x$, and $\tau = iL_y/L_x$ the modular parameter of the torus; furthermore, $N = L_xL_y/2\pi l^2$ is the degree of degeneracy, and m takes values $(N-1)/2 \geqslant m \geqslant -(N-1)/2$. These ground state wave functions are orthonormal for $c_0 = (1/\pi l^2 L_x^2)^{1/4}$, where the integration extends over the fundamental domain of the torus only.

There remains a discrete subgroup of the Weyl group, which arises as follows. The ''latticized'' magnetic translations $T = T(L_x/N,0)$ and $S = T(0,L_y/N)$ obey the relation $TS = qST$, where $q = e^{2\pi i(1/N)}$. They act on the ground state wave functions as

$$S|m\rangle = q^{m+\mu}|m\rangle, \quad T|m\rangle = q^{\nu}|m-1\rangle, \tag{27}$$

with $S^N = e^{2\pi i\mu}$ and $T^N = e^{2\pi i\nu}$ in this representation. As a consequence, the discrete subgroup, which is generated by S and T, subject to the above relation, acts unitarily and irreducibly on the N-dimensional Hilbert space, being built from the lowest Landau level wave functions on the torus.

On passing from the discrete subgroup to the corresponding group algebra, it is legitimate to take linear combinations of products of its generating elements. In particular, it is easy to guess the form of the operators,

$$J^{\pm} = \frac{q^{\mp 1/2}S - q^{\pm 1/2}S^{-1}}{q - q^{-1}} T^{\mp 1}, \quad K = -S^2, \tag{28}$$

being designed so as to act on the basis as

$$J^{\pm}|m\rangle = \left[m \pm \frac{1}{2} \right] |m \pm 1\rangle, \quad K|m\rangle = -q^{2m}|m\rangle, \tag{29}$$

for $\mu = \nu = 0$.[30] This is recognized as the irreducible and unitary representation (12) of Sec. III, and so the operators (28) are the generators of the finite-dimensional restriction $U_q(su_2)'$; furthermore, the degeneracy number N must necessarily be an odd[31] integer. Remarkably, they belong to the class of representations with quantum dimension zero, which are regarded as ''unphysical'' in another context.[32]

The final result, Eq. (29), looks similar to what is reported in Refs. 6,33, but differs in at least one essential aspect, since the action of the generators J^+ and J^- does not contain a relative minus sign. This makes a big difference because we then had the wrong real structure $U_q(su_{1,1})$, and it is known that this ''noncompact'' real form does not admit any finite-dimensional irreducible and unitary representations.

To collect what we have shown, the (modular invariant) wave functions of the lowest Landau level on the torus constitute the representation space of an irreducible and unitary representation of the finite-dimensional quantum group $U_q(su_2)'$ for q an odd root of unity, the generators being built from the discrete subgroup of the Weyl group. To put it differently,[34] theta functions are intimately related to representations of quantum groups at the roots of unity.

VI. CONCLUSION

Having provided for a real structure that makes sense of the quantum deformation $U_q(su_2)$ as a quasitriangular Hopf algebra for q a pure phase, nevertheless, there remains some work to be done.

On the mathematical side, we have left open the application to quantum enveloping algebras of the form $U_q(\mathcal{G})$ with $\mathcal{G}$ an element of the Cartan list, as well as their affine generalizations; the standard case is solved in Ref. 35. We also have not touched upon the implications for the Faddeev–Reshetikhin–Takhtadjian construction.

On the physical side, as for the applications to quantum spin chains, for closed boundary conditions we have proven the invariance under a two-parameter deformation, but unitarity remains an issue. As for the Landau theory, we have not gone very far since what one aims at is the transition to the many-particle problem. The simplest kind of approach would be to pass to the N_e-fold tensor product. Since we know now that the finite-dimensional restriction $U_q(su_2)'$ for q an odd root of unity acts irreducibly and unitarily on the Hilbert space of the lowest Landau level with quantum dimension zero, the braiding of the electrons is then determined by the $\mathcal{R}$-matrix. A more ambitious program would be to take the Laughlin ground state[36] as the vacuum, and to perform second quantization over this new ground state. But the Laughlin ground state is not appropriate since it is not even a singlet under the quantum symmetry; the trivial representation $\varepsilon: U_q(su_2) \to \mathbb{C}$ is not realized because $\varepsilon(K)=1$ is violated. What one needs instead is the analog of the Laughlin ground state on the torus. This was given soon after the advent of Laughlin's theory in an important paper by Haldane and Rezayi.[37] But we have reasons[26] to believe that this degenerate ground state is restricted to the sector with total charge zero, and so is hardly related to the quantum Hall effect.

[22] This approach is rather different from the one given by A. Lerda and S. Sciuto, Nucl. Phys. B **401**, 613 (1993), where it is essential that two Schwinger fermions are needed to connect the anyonic operators with the generators of the one-parameter deformation $U_q(sl_2)$. The approach given here can also be generalized to two dimensions on replacing

the step function θ by the two-dimensional lattice angle function, as given from Chern–Simons theory.

[30] For nonzero values of the phases μ and ν, the representations generally belong to the cyclic series. However, there is one special case for which, again, a highest weight representation is obtained. Namely, if the ground state wave functions are required to be modular invariant, one can show that this requirement is met if the phases take the values $\mu=-\nu=\frac{1}{2}$; hence, there are no spin structures. It is straightforward to prove that the resulting representation is equivalent to (29).
[31] For q an even root of unity, the representations with $n+1=p$ cannot be brought into the form (12); the best that can be achieved is $X_{\pm}e^j_m=[j\mp m]e^j_{m\pm1}$ and $Ke^j_m=q^{2m}e^j_m$ in the notation of Sec. III. Also note the crucial role of the choice $\epsilon=-1$ in (12).

Hamiltonian structure and Darboux theorem for families of generalized Lotka–Volterra systems

Benito Hernández-Bermejo and Víctor Fairén[a)]

(Received 3 November 1997; accepted for publication 16 July 1998)

This work is devoted to the establishment of a Poisson structure for a format of equations known as generalized Lotka–Volterra systems. These equations, which include the classical Lotka–Volterra systems as a particular case, have been deeply studied in the literature. They have been shown to constitute a whole hierarchy of systems, the characterization of which is made in the context of simple algebra. Our main result is to show that this algebraic structure is completely translatable into the Poisson domain. Important Poisson structures features, such as the symplectic foliation and the Darboux canonical representation, rise as a result of rather simple matrix manipulations. © *1998 American Institute of Physics.* [S0022-2488(98)02411-6]

I. INTRODUCTION

Poisson structures[1,2] (sometimes named *generalized Hamiltonian structures* in the literature) are ubiquitous in all fields of mathematical physics, from finite-dimensional dynamical systems[3–7] to field theories:[8,9] Fluid dynamics,[10,11] magnetohydrodynamics,[11,12] plasmas,[13–15] continuous media,[15] condensed matter,[16] etc. Reformulating a given problem in terms of a Poisson structure provides fruitful insight into the behavior of the system, which may take the form of perturbative solutions,[17] nonlinear stability analysis through the energy-Casimir algorithm[7,18] or the energy-momentum method,[19] bifurcation properties and characterization of chaotic dynamics,[20] integrability results,[21] application of reduction of order procedures[2,22] or explicit determination of new solutions.[14,23]

In the present work, we shall restrict ourselves to finite-dimensional Poisson structures. In terms of local coordinates, a Poisson system defined on an n-dimensional manifold takes the following form:

$$\dot{x}_i = \sum_{j=1}^{n} J_{ij}\partial_j H, \quad i=1,...,n. \tag{1}$$

The smooth, real-valued function $H(x)$ in (1) is a constant of motion of the system, which plays the role of Hamiltonian, and the $J_{ij}(x)$ are also smooth and real-valued, being the entries of a $n \times n$ skew-symmetric structure matrix $\mathscr{J}$ which verifies the Jacobi equations:

$$\sum_{l=1}^{n} (J_{li}\partial_l J_{jk} + J_{lj}\partial_l J_{ki} + J_{lk}\partial_l J_{ij}) = 0. \tag{2}$$

Here ∂_l means $\partial/\partial x_l$ and indices i,j,k run from 1 to n. The flow (1) can then be expressed as $\dot{x}_i = [x_i, H]$, in terms of the Poisson bracket defined by

$$[F,G] = \sum_{i,j=1}^{n} \frac{\partial F}{\partial x_i} J_{ij} \frac{\partial G}{\partial x_j},$$

where F and G are smooth real-valued functions defined on the Poisson manifold. Consequently, Poisson structures generalize classical Hamiltonian systems, for which $\mathscr{J}$ is the well-known symplectic matrix. In particular, the classical restriction to even-dimensional manifolds is not present in Poisson systems. However, Poisson dynamics preserves the Hamiltonian character of the motion. This is proven by Darboux theorem,[2] which states that there exist local coordinates in the neighborhood of every point of the Poisson manifold, such that the equations of motion take essentially the classical Hamiltonian form. The practical construction of Darboux coordinates is, however, a complicated task in general, which has been carried out only for a limited sample of systems.[2,24,25]

An important question is that of characterizing a given vector field not in form (1), as an actual Poisson system. In the finite-dimensional case the problem amounts to giving a procedure for decomposing (whenever possible) a smooth function $f(x):\Omega\subset R^n\to R^n$, where Ω is open, as $f(x)=\mathscr{J}(x)\cdot\nabla H(x)$, where $\mathscr{J}$ is a solution of the nonlinear PDE (2) and $H(x)$ is a real-valued function. This is a nontrivial problem to which important efforts have been devoted in past years in a variety of approaches.[3–8,25–28] The question is well understood in the simplest cases—two and three dimensions—and the existence and determination of at least one Poisson structure is ensured if a first integral is known for the system.[25,28] In higher dimensions the situation is by no means so clear, and comparable results are still lacking.

The main exception to this absence of results in n-dimensional systems is, to our knowledge, given by the Lotka–Volterra equations (LV from now on). They were introduced by Lotka[29] and Volterra[30] in chemical and biological contexts, respectively, and Volterra himself was already aware of the (classical) Hamiltonian nature of some LV systems. However, the main and more systematic advances are due to Kerner,[31] who developed a biological analog of classical statistical mechanics for predator-prey systems. More recently, the attention has turned to the search of Poisson structures for more general LV models, since Poisson structures generalize classical Hamiltonian systems while retaining the Hamiltonian nature of the dynamics—in this sense, the Poisson structure of many two and three-dimensional LV systems has been established,[3,25,27,28] and all three-dimensional biHamiltonian LV systems have been classified by Plank.[5] Also, in the domain of n-dimensional LV flows, a first tentative classification of Poisson structures has been carried out.[6]

Both the relevance of LV equations and the importance of finding their Hamiltonian or Poisson representations, transcends the fact that LV models are appropriate in describing many problems in Biology, Chemistry or Physics. Cairó and Feix,[32] for example, refer to a fairly long list of systems modeled by LV equations—their ubiquity has even prompted Peschel and Mende[33] to head their book on the issue with the title: *Do we live in a Volterra World?*

Actually, the significance of LV equations goes beyond a strict modeling context, because they have been shown to be canonical representatives of infinite families, or classes, of very general flows,[33,34] to which, following Brenig, we shall refer as Generalized Lotka–Volterra (GLV) systems. There is a whole formalism associated to the GLV equations.[33–36] As we shall see later, the most relevant feature of this formalism is that of permitting the analysis and interpretation of certain properties of the vector field in purely algebraic terms.

Our purpose in this article is to demonstrate how these algebraic properties are of fundamental importance in understanding the Poisson structure of LV and GLV models. We shall investigate Poisson structures for GLV families of systems. They include as particular elements all LV models which have been the object of interest in the literature in relation to Poisson structures (in works of Volterra, Kerner and Plank). We shall show that the algebraic GLV matrix properties can be translated into the Poisson context and acquire a new significance. The reverse is also true, thus defining a close connection between GLV algebraic properties and the Poisson structure of the system.

Implementing the structure of the GLV formalism on its Poisson counterpart has very interesting consequences. First of all, we are able to include in our scheme systems which are more general than the LV ones. Second, we can take into account larger sets of LV flows than those studied by previous approaches. For example, we are neither limited to LV systems of even dimension, nor cases with a unique fixed point. These are two common restrictions often imposed in the literature,[6,37] which we obviate at once. Third, we are able to capture important phase-space features in terms of simple properties of constant matrices. Finally, our approach leads to an

algorithmic reduction to the Darboux form for the equations. And last but not least, our construction is always global.

II. OVERVIEW OF THE GLV FORMALISM

We proceed now to briefly summarize the main features of the GLV formalism. We refer the reader interested in a more detailed exposition to the original references.[33–36]

Definition 2.1: A GLV system is a set of ordinary differential equations which is defined in the real positive orthant and complies to the form:

$$\dot{x}_i = x_i\left(\lambda_i + \sum_{j=1}^{m} A_{ij}\prod_{k=1}^{n} x_k^{B_{jk}}\right), \quad i=1...n, \tag{3}$$

where n and m are positive integers, $m \geqslant n$, and A, B and λ are $n\times m$, $m\times n$ and $n\times 1$ real matrices, respectively.

The m nonlinear terms of the right-hand side of (3) are usually known as *quasimonomials*. Sometimes we shall group all the coefficients of A and λ in a single, composite matrix, $M=(\lambda|A)$. We shall assume that matrix B is of maximal rank. This is a standard case to which every GLV system can be reduced.[36] Notice also that the well-known LV equations

$$\dot{x}_i = x_i\left(\lambda_i + \sum_{j=1}^{n} A_{ij}x_j\right), \quad i=1...n$$

are a particular case of (3) where $m=n$ and B is the $n\times n$ identity matrix.

System (3) is form-invariant under quasimonomial transformations (or QMTs from now on):

$$x_i = \prod_{k=1}^{n} y_k^{C_{ik}}, \quad i=1,...,n, \quad |C|\neq 0. \tag{4}$$

Under (4), matrices B, A, λ and M change to $B'=B\cdot C$, $A'=C^{-1}\cdot A$, $\lambda'=C^{-1}\cdot\lambda$ and $M'=C^{-1}\cdot M$, respectively, but the GLV format is preserved. Obviously, all GLV systems which can be connected through QMTs share the value of the product $B\cdot M$. These families of systems are, in fact, classes of equivalence, the product $B\cdot M$ being a class invariant. The QMTs are diffeomorphisms defined in the positive orthant, and are orientation-preserving iff $|C|>0$. Consequently, QMTs preserve the topology of the phase portrait modulo an inversion.

Definition 2.2: A GLV class of equivalence for which rank $(M)=r$, and whose members are n-dimensional and have m quasimonomials, is denoted as an (r,n,m)-class.

The kind of manipulations in which we shall be interested later will transform a GLV system into another one belonging to the same or, eventually, to a different class. However, these manipulations will affect neither r nor m, but may change n. We shall always operate, however, in the range $r\leqslant n\leqslant m$. Obviously, a QMT does not modify anyone of these three indexes.

If $m=n$, we can perform a QMT of matrix $C=B^{-1}$. The result is another flow for which $B'=I_n$, that is, a LV system. Such a system can be taken as the canonical representative of the GLV class of equivalence.

In the complementary case $m>n$, there is no LV system inside the class of equivalence. However, the reduction to the LV form is possible if we perform an embedding, just by adding new variables to system (3).

Definition 2.3: We define a p-embedding as the result of adding to a GLV system p new variables in the following way:

$$\dot{x}_i = 0, \quad x_i(0)=\alpha_i>0, \quad i=n+1,...,n+p, \quad 1\leqslant p\leqslant m-n.$$

Let A, B, and λ be the matrices of the original GLV system. The p-embedded system is also GLV, and its characteristic matrices are:

$$\tilde{B}=(B|B^{*}_{m\times p}), \quad \tilde{\lambda}=\begin{pmatrix}\lambda\\ O_{p\times 1}\end{pmatrix}, \quad \tilde{A}=\begin{pmatrix}A\cdot E\\ O_{p\times m}\end{pmatrix}, \tag{5}$$

where

$$E=\mathrm{diag}(e_1,\ldots,e_m),\quad e_j=\left(\prod_{k=n+1}^{n+p}\alpha_k^{\tilde{B}_{jk}}\right)^{-1},\quad j=1,\ldots,m. \tag{6}$$

In (5), O denotes a submatrix of null entries, while $B^*_{m\times p}$ has arbitrary real entries appropriately chosen for $\tilde{B}$ to be of maximal rank. The subscripts such as $m\times p$ indicate the size of the corresponding submatrix (B^* in this case); we shall maintain this notation henceforth.

Notice how the previous operation transforms a GLV system from an (r,n,m)-class, with $m>n$, into a GLV system belonging to an $(r,n+p,m)$-class, with $1\leqslant p\leqslant m-n$. The embedded system is topologically equivalent to the original one in the manifold $x_i=\alpha_i$, $i=n+1,\ldots,n+p$.

For fixed p, infinitely many different $(r,n+p,m)$-classes can be reached by means of an embedding, depending on the entries of matrix E. Also, in the particular case $p=m-n$ the target system belongs to an (r,m,m)-class, in which a LV representative can be reached by a QMT of matrix $C=\tilde{B}^{-1}$ (since $\mathrm{rank}(\tilde{B})=m$). Thus, the recasting of the original GLV flow into the LV form is always possible. For this m-dimensional LV system, however, $\mathrm{rank}(\tilde{M}_{\mathrm{LV}})<m$, and is not maximum. Whenever this happens in a GLV system, it indicates the existence of quasimonomial constants of motion, as the following proposition shows:

Proposition 2.4: In a GLV system (3), $\mathrm{rank}(M)=r<n$ if and only if there exist $(n-r)$ functionally independent constants of the motion which are time-independent and have quasimonomial form.

Proof: We can assume, without loss of generality, that the r first rows of M are the linearly independent ones. Then, there exist real constants γ_{ki}, with $i=1,\ldots,r$, and $k=r+1,\ldots,n$, such that:

$$M_{kl}=\sum_{i=1}^{r}\gamma_{ki}M_{il},\quad \forall l=1,\ldots,m+1.$$

From (3), we arrive at:

$$\frac{\dot{x}_k}{x_k}=\sum_{i=1}^{r}\gamma_{ki}\frac{\dot{x}_i}{x_i}.$$

After a simple integration this leads to the set of $(n-r)$ constants of motion:

$$x_k^{-1}\prod_{i=1}^{r}x_i^{\gamma_{ki}}=c_k,$$

where the c_k are real constants given by the initial conditions. The functional independence holds immediately from simple evaluation of the Jacobian. The proof in the opposite sense is straightforward after this. Q.E.D.

Therefore, a p-embedding in the $m>n$ case introduces p quasimonomial constants of motion, which are obviously form-invariant under QMTs. This invariance implies that the quasimonomial constants of motion can always be decoupled from a GLV system by means of an appropriate QMT. When this is done, what we are doing is to reverse the p-embedding procedure, actually. The first step to show this is the following result:

Proposition 2.5: Let A^*, B^* and λ^* be the matrices of a GLV system belonging to an $(r,n+p,m)$-class, where $r\leqslant n$ and $0<p\leqslant m-n$. Then there exists a quasimonomial transformation that leads to an $(n+p)$-dimensional GLV system of matrices

$$\lambda=\begin{pmatrix}\overline{\lambda}\\ O_{p\times 1}\end{pmatrix},\quad A=\begin{pmatrix}\overline{A}\\ O_{p\times m}\end{pmatrix}. \tag{7}$$

Proof: We shall omit it, since it is based on simple matrix algebra properties.

In (7), we have decoupled the final p components of the vector field: Let $x_1,\ldots,x_{n+p}$ be the variables of the system of matrices (7), and let $x_{n+i}(0)=\alpha_{n+i}>0$, $i=1,\ldots,p$, be the initial condi-

tions of the decoupled variables. Let us also write $B=(\overline{B}|\overline{B}'_{m\times p})$ for the matrix of exponents of this system. Then, when we restrict the dynamics to an n-dimensional flow, the result is another GLV system from an (r,n,m)-class, which is characterized by three matrices $\hat{B}$, $\hat{\lambda}$ and $\hat{A}$, given by:

$$\hat{B}=\overline{B}, \quad \hat{\lambda}=\overline{\lambda}, \quad \hat{A}=\overline{A}\cdot E^{-1},$$

where again

$$E=\mathrm{diag}(e_1,\ldots,e_m), \quad e_j=\left(\prod_{k=n+1}^{n+p}\alpha_k^{B_{jk}}\right)^{-1}, \quad j=1,\ldots,m. \tag{8}$$

Definition 2.6: The previous operation transforming a GLV system in an $(r,n+p,m)$-class, with $r\leqslant n$ and $0<p\leqslant m-n$, into a GLV system belonging to an (r,n,m)-class, is called a p-decoupling.

Even for fixed n, there are again infinite possible target classes, due to the arbitrariness in the initial conditions represented by E. In any case, there is obviously a conservation of the topological properties of the flow in the process. It is also clear that, in the especial case in which we choose $n=r$, we have the maximum reduction possible by means of this method; otherwise the decoupling is partial. In either case, the simplification is possible because we are, in fact, restricting the dynamics to the level surfaces of quasimonomial constants of motion.

To summarize, we have a multilevel structure of (r,n,m)-classes of equivalence, with n ranging in the interval $r\leqslant n\leqslant m$. We can transform freely every GLV system inside this scheme by means of the QMTs and the two basic—and opposite—operations: p-embeddings and p-decouplings, which proceed by the introduction of quasimonomial first integrals, or by the restriction of the system dynamics to their level surfaces, respectively.

III. GLV FAMILIES OF POISSON SYSTEMS

We start by characterizing the systems of interest. In what follows, the superscript T denotes the transpose of a matrix.

Theorem 3.1: Let us consider a GLV system of the form (3) such that

$$\lambda=K\cdot L, \quad A=K\cdot B^T\cdot D, \tag{9}$$

with K, L and D matrices of real entries, where K is $n\times n$ and skew-symmetric; L is $n\times 1$; and D is $m\times m$, diagonal and of maximal rank. Then the system has a constant of motion of the form:

$$H=\sum_{i=1}^{m} D_{ii}\prod_{k=1}^{n} x_k^{B_{ik}}+\sum_{j=1}^{n} L_j\,\ln(x_j). \tag{10}$$

Moreover, the system is Poisson with Hamiltonian H.

Proof: The GLV flow complies with the format $\dot{x}=\mathscr{J}\cdot\nabla H$, where the Hamiltonian is smooth in the positive orthant and given by H in (10), while $\mathscr{J}$ is the smooth matrix

$$\mathscr{J}=X\cdot K\cdot X, \quad X=\mathrm{diag}(x_1,\ldots,x_n). \tag{11}$$

That H is the Hamiltonian implies that it is a constant of motion. Q.E.D.

Notice that the first part of the Hamiltonian is associated to the m quasimonomials of the GLV vector field (in fact, it is a linear combination of them), while the logarithmic terms are closely connected to the linear contributions. The observation that a matrix of the form $X\cdot K\cdot X$ is a structure matrix iff $K^T=-K$ is due to Plank.[6] From now on, we shall denote the systems described by Theorem 3.1 as the GLV-Poisson (GLVP).

Proposition 3.2: The Poisson structure of GLVP systems is form-invariant under a QMT. After a QMT of matrix C, the characteristic matrices of the transformed Poisson structure are:

$$K'=C^{-1}\cdot K\cdot (C^{-1})^T, \quad L'=C^T\cdot L, \quad D'=D.$$

In particular, both the Hamiltonian and the structure matrix are form-invariant under QMTs.

Proof: The simplest proof is the algebraic one. After a QMT we have:

$$\lambda' = C^{-1}\cdot K\cdot L = C^{-1}\cdot K\cdot (C^{-1})^T\cdot C^T\cdot L = K'\cdot L'$$

$$A' = C^{-1}\cdot K\cdot B^T\cdot D = K'\cdot (B')^T\cdot D'$$

and $D' = D$. Then, from Theorem 3.1 the new system is also GLVP, and its structure matrix and Hamiltonian are, respectively, $\mathscr{T}' = Y\cdot K'\cdot Y$, and

$$H' = \sum_{i=1}^{m} D'_{ii}\prod_{k=1}^{n} y_k^{B'_{ik}} + \sum_{j=1}^{n} L'_j \ln(y_j).$$

This demonstrates the result. Q.E.D.

Corollary 3.3: The Poisson bracket of a GLVP system is form-invariant under QMTs.

There is an important degree of freedom in the Poisson structure: Let $N\in \mathrm{Ker}\{K\}$. Then, the GLVP system we obtain does not change if we replace L by $L+N$, since from (9) we have $\lambda = K\cdot L = K\cdot (L+N)$. This is, in fact, a source of ambiguity in the Hamiltonian itself, because the flow is unaltered if we add to H an extra term of the form:

$$\phi_N = \sum_{j=1}^{n} N_j \ln(x_j), \quad N\in \mathrm{Ker}\{K\}. \tag{12}$$

This degree of freedom is precisely the one associated to the well-known Casimir functions:

Proposition 3.4: Let $r = \mathrm{rank}(K)$ in a given GLVP structure. There is a complete set of $n-r$ functionally independent Casimir functions of the form (12).

Proof: Evidently, $\mathrm{rank}(\mathscr{T}) = \mathrm{rank}(K) = \text{constant}$ everywhere in the positive orthant. Then there are exactly $n-\mathrm{rank}(K)$ functionally independent Casimirs. If $N\in \mathrm{Ker}\{K\}$ we have $\mathscr{T}\cdot\nabla\phi_N = 0$, and all such ϕ_N are Casimirs. But $\dim(\mathrm{Ker}\{K\}) = n-r$: Then we can get a maximal set of independent Casimirs by choosing $n-r$ linearly independent vectors of $\mathrm{Ker}\{K\}$, i.e., a basis of $\mathrm{Ker}\{K\}$. The functional independence can be readily verified in this case. Q.E.D.

Moreover, under a QMT of matrix C, ϕ_N is form-invariant and changes to $\phi_{N'}$, where $N' = C^T\cdot N$ and $N'\in \mathrm{Ker}\{K'\}$. Thus $\phi_{N'}$ is a Casimir of the transformed system. Let $\{N^{(1)},\ldots,N^{(n-r)}\}$ be a basis of $\mathrm{Ker}\{K\}$, where $r = \mathrm{rank}(K)$ as before. Then $\{\phi_{N^{(1)}},\ldots,\phi_{N^{(n-r)}}\}$ is a complete set of Casimirs of the initial system. After a QMT of matrix C, the Casimirs are transformed into a new family of Casimirs $\{\phi_{N'^{(1)}},\ldots,\phi_{N'^{(n-r)}}\}$, where $N'^{(i)} = C^T\cdot N^{(i)}$ for all i. In fact, the new set $\{N'^{(1)},\ldots,N'^{(n-r)}\}$ is also a basis of $\mathrm{Ker}\{K'\}$. Therefore, every QMT carries a complete set of independent Casimirs of the form (12) into its counterpart for the target system. In other words, the symplectic foliation of a GLVP system is a class property.

We can equivalently express the Casimir functions (12) in quasimonomial form as:

$$\phi_N = \prod_{j=1}^{n} x_j^{N_j}, \quad N\in \mathrm{Ker}\{K\}.$$

However, we have seen in Proposition 2.4 that the quasimonomial first integrals arise in a purely GLV context, independently of the existence of a Poisson structure of the system. We saw that they are associated to a degeneracy in the rank of M. Clearly, there must be a close relationship between quasimonomial Casimirs and quasimonomial first integrals in general. We shall now demonstrate that both sets do coincide:

Theorem 3.5: Every quasimonomial constant of motion of a GLVP system is a Casimir function.

Proof: Notice that a quasimonomial constant of motion can be expressed as:

$$\prod_{j=1}^{n} x_j^{N_j} = \text{constant}, \quad N\in \mathrm{Ker}\{M^T\}.$$

Therefore, our statement will be automatically demonstrated if we show that $\mathrm{Ker}\{M^T\} = \mathrm{Ker}\{K\}$.

First, we demonstrate that $\mathrm{rank}(A) = \mathrm{rank}(M)$ for GLVP systems, where $M = (\lambda | A)$. From (9), we can write symbolically $M = K \cdot (L | B^T \cdot D)$. Expressed in this form, it is immediate to see that $\mathrm{rank}(A) = \mathrm{rank}(M)$ by simple inspection. Consequently, $\mathrm{Ker}\{M^T\} = \mathrm{Ker}\{A^T\}$ for GLVP systems, and the theorem will be demonstrated if $\mathrm{Ker}\{A^T\} = \mathrm{Ker}\{K\}$.

It is evident that $\mathrm{Ker}\{K\} \subset \mathrm{Ker}\{A^T\}$. To show that $\mathrm{Ker}\{A^T\} \subset \mathrm{Ker}\{K\}$, note that $\mathrm{rank}(D \cdot B) = n$, and therefore $\mathrm{Ker}(D \cdot B) = \{0\}$. The result is then straightforward, and the theorem is demonstrated. Q.E.D.

Corollary 3.6: In every GLVP system, $\mathrm{rank}(M) = \mathrm{rank}(A) = \mathrm{rank}(\mathscr{J}) = \mathrm{rank}(K)$.

Theorem 3.5 will be of fundamental importance in what follows. It summarizes very well the interplay between algebraic and Poisson properties, which is present in GLVP systems. The level surfaces of the Casimir functions yield the global structure of the Poisson system—they constitute the symplectic foliation of the phase-space. We are now able to reconstruct this important feature in terms of a very simple and purely algebraic scheme, which is summarized in the proof of Proposition 2.4. More concisely, we can say that the symplectic foliation of the system is condensed in the rank properties of the GLV matrix M. Conversely, purely algebraic properties of the system in the GLV context now assume a completely new role. This is the case of the quasimonomial first integrals, which now become Casimir functions. Moreover, this parallelism is not only valid for a single system, but it is a class property. Obviously, some logical consequences arise from this interplay: For example, $\mathrm{rank}(M)$ may take any value between 0 and n in a general GLV system. However, from Corollary 3.6 this must be an even number for GLVP systems, an evident restriction if the level surfaces of the quasimonomial first integrals are to be a symplectic foliation.

In Sec. II, we elaborated in some detail on the techniques for the manipulation of the quasimonomial constants of motion in a pure GLV context. These procedures involved inter-class transformations which might, if desired, eliminate all such first integrals. These ideas acquire completely new implications in the light of the last results: Such manipulations give now the key for restricting the dynamics to the symplectic leaves or, in the opposite sense, to embed the system in Poisson structures of higher dimensionality. We shall devote the next section to give a systematic treatment of these issues.

IV. TRANSFORMATIONS ON THE SYMPLECTIC FOLIATION

According to Sec. II, three basic procedures are those which allow the manipulation of GLV systems: QMTs, embeddings, and decouplings. In Sec. III, we have seen how QMTs preserve the GLVP structure. That is, we have demonstrated that the GLVP structure is a class property. In this section, our aim will be to show that the inter-class operations do also preserve in an appropriate way the same GLVP character. This will complete the Poisson description of these systems and reinforce the parallelism between algebraic and Poisson properties.

We shall first establish the result for the embeddings:

Proposition 4.1: If a GLVP system which belongs to an (r,n,m)-class, with $m > n$, is subjected to a p-embedding, with $1 \leqslant p \leqslant m - n$, then the resulting system is also GLVP.

Proof: Relations $A = K \cdot B^T \cdot D$ and $\lambda = K \cdot L$ in the original system, imply that $\tilde{A} = \tilde{K} \cdot \tilde{B}^T \cdot \tilde{D}$ and $\tilde{\lambda} = \tilde{K} \cdot \tilde{L}$ in the embedded vector field, where:

$$\tilde{K} = \begin{pmatrix} K & O_{n\times p} \\ O_{p\times n} & O_{p\times p} \end{pmatrix}, \quad \tilde{L} = \begin{pmatrix} L \\ L^*_{p\times 1} \end{pmatrix}, \quad \tilde{D} = D \cdot E.$$

Here, L^* is composed of arbitrary entries, E is given by (6), and $\tilde{A}$, $\tilde{B}$, and $\tilde{\lambda}$ are those in (5). With the help of Theorem 3.1, this proves the result. Q.E.D.

Corollary 4.2: Under the same hypotheses of Proposition 4.1, all the members of the $(r, n+p, m)$-class to which the expanded system belongs, are GLVP systems.

Corollary 4.3: Given a GLVP flow belonging to an (r,n,m)-class, every m-dimensional LV representative of the system is also GLVP.

We shall demonstrate now that we have an analogous situation in the case of the decouplings. For this we need a preliminary result:

Proposition 4.4: Given a GLVP system of matrices M^* and K^*, which belongs to an $(r,n+p,m)$-class, with $r\leqslant n$ and $0<p\leqslant m-n$, then there exists at least one QMT such that the transformed flow has matrices of the form:

$$M=\begin{pmatrix} \overline{M} \\ O_{p\times(m+1)} \end{pmatrix}, \quad K=\begin{pmatrix} \overline{K} & O_{n\times p} \\ O_{p\times n} & O_{p\times p} \end{pmatrix}. \tag{13}$$

Proof: Let C be the matrix of the QMT. From the transformation rule $K=C^{-1}\cdot K^*\cdot (C^{-1})^T$ and the skew-symmetry of K, it is clear that there exists an invertible C which recasts K^* in the desired way. The form of M is a consequence of the form of K, since from (9) we have $\lambda=K\cdot L$ and $A=K\cdot B^T\cdot D$. Q.E.D.

This leads to the main result for reductions:

Proposition 4.5: If a GLVP system belonging to an $(r,n+p,m)$-class, with $r\leqslant n$ and $0<p\leqslant m-n$, is subjected to a p-decoupling, then the resulting system is also GLVP.

Proof: From Proposition 4.4, we can first transform the GLVP system into another one in the same $(r,n+p,m)$-class, with matrices like those in (13). We shall denote the rest of matrices of the latter as A, B, λ, L and D (A and λ being given by Eq. (7)). We shall also, for convenience, express B and L as composed of submatrices in the usual form $B=(\overline{B}|\underline{B}'_{m\times p})$, and $L=(\overline{L}|\underline{L}'_{p\times 1})^T$. As we know from Sec. II, the matrices of the restricted system are $\hat{B}=B$, $\hat{\lambda}=\overline{\lambda}$, and $\hat{A}=A\cdot E^{-1}$, where E is given by (8). It is not difficult to check that the relations $A=K\cdot B^T\cdot D$ and $\lambda=K\cdot L$, imply that $\hat{A}=\hat{K}\cdot\hat{B}^T\cdot\hat{D}$ and $\hat{\lambda}=\hat{K}\cdot\hat{L}$ in the reduced flow, where:

$$\hat{K}=\overline{K}, \quad \hat{L}=\overline{L}, \quad \hat{D}=D\cdot E^{-1}.$$

This proves the result. Q.E.D.

Therefore, not only the GLV format itself, but also the proper GLVP structure is preserved when a reduction is carried out. This is consistent with the fact that quasimonomial constants of motion are Casimirs of the Poisson structure. We can then state:

Corollary 4.6: If a GLV system of an (r,n,m)-class is GLVP, then all the (r,k,m)-classes, for $k=r,\ldots,m$, which can be reached by means of successive embeddings and/or decouplings, are composed of GLVP systems.

Consequently, all the transformations that we have defined within and among the classes preserve both the algebraic GLV properties of the equations and the Poisson format. A decoupling amounts to restricting the system totally or partially to the level surfaces of the Casimirs. An embedding adds new Casimirs to the system, thus increasing its dimensionality. The dynamics on the symplectic leaves remains, on the other hand, always intact. Knowing how to increase the dimension by means of embeddings is important, because it connects every class with the LV format—and vice versa in the case of decouplings. In particular, this tells us how an LV system can be simplified.

In the case in which we perform a maximal decoupling, we obviously arrive at an (r,r,m)-class of GLVP systems, with r even: The members of this class are symplectic systems, since all the Casimirs have been removed. The previous results not only allow, however, the mere transformation of the vector field into symplectic form: They can also be used to reach the full reduction to the canonical forms of Darboux or Hamilton. This is the issue of the next section.

V. REDUCTION TO DARBOUX CANONICAL FORM

We detail here three ways for constructing the Darboux canonical form. We shall first address the more general approach, and then comment on two more specific possibilities.

A. General method

Proposition 5.1: Given a GLVP system belonging to an (r,n,m)-class, there exists a quasimonomial transformation such that for the transformed system:

$$K'=\mathscr{S}(r,n-r)=\mathrm{diag}(S_1,S_2,\ldots,S_{r/2},\overbrace{0,\ldots,0}^{(n-r)}), \tag{14}$$

where

$$S_i = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad \forall i = 1,...,r/2.$$

Proof: From Corollary 3.6, $\mathrm{rank}(K) = r$ for the original system. After a QMT of matrix C, we have from Proposition 3.2 that $K' = C^{-1} \cdot K \cdot (C^{-1})^T$, which is a congruence transformation over K. But, since K is skew-symmetric and of rank r, it is congruent[38] to a matrix of the form (14). Then, the QMT exists. Q.E.D.

We can now state the following result:

Theorem 5.2: Every GLVP system belonging to an (r,n,m)-class can be globally reduced to Darboux canonical form inside the positive orthant.

Proof: The proof is constructive. We shall assume that the system has been already transformed in such a way that its matrix K complies to format (14). We can then introduce the following transformation, which is a global orientation-preserving diffeomorphism inside the positive orthant:

$$y_i = \ln(x_i), \quad i = 1,...,n. \tag{15}$$

We now take into account the equation for the transformation of the structure matrix under general diffeomorphisms, $y_i = y_i(x)$:

$$(\mathscr{J}')_{ij}(y) = \sum_{k,l=1}^{n} \frac{\partial y_i}{\partial x_k} \mathscr{J}_{kl}(x) \frac{\partial y_j}{\partial x_l}. \tag{16}$$

The result, upon applying (15), is:

$$(\mathscr{J}')_{ij} = (\mathscr{S}(r,n-r))_{ij}, \quad \forall i,j = 1,...,n.$$

This transforms the original GLVP into a non-GLVP system that conforms, however, to Darboux form: There are obviously $r/2$ pairs of canonically conjugate variables, and $(n-r)$ trivial Casimirs. The transformation of the Hamiltonian is straightforward. This proves the result. Q.E.D.

B. Decoupling method

Notice that in the case $r < n$, i.e., when the GLVP system is not symplectic, we can make use of the reduction procedure of the previous section, instead of applying Theorem 5.2 from the very beginning. The result would be another GLVP system, now symplectic, which belongs to an (r,r,m)-class. Making use of Theorem 5.2 on the reduced flow, would lead to a purely Hamiltonian system, since

$$\mathscr{J}' = \mathscr{S}(r,0),$$

which is the classical symplectic matrix of dimension r.

C. Linear transformation method

Assume that we first subject the initial system of an (r,n,m)-class and matrix K, to transformation (15). From (16), we find:

$$\mathscr{J}' = K.$$

The resulting system $\dot{y} = K \cdot \nabla H'(y)$ is not GLVP, though it is Poisson. A linear change of variables $w = C \cdot y$, where C is an invertible $n \times n$ matrix, leads to another Poisson system of constant structure matrix,

$$\dot{w} = (C \cdot K \cdot C^T) \cdot \nabla H''(w).$$

Finally, there exists a C such that $C \cdot K \cdot C^T = \mathscr{S}(r,n-r)$, and Darboux form is achieved. This procedure has already been applied in the literature to certain symplectic LV systems, of even-dimension and with a single fixed point.[37]

VI. EXAMPLE: 3D LOTKA–VOLTERRA EQUATIONS

A. Poisson structure

As an illustration of the previous results, we shall look upon the 3D LV Poisson structure first characterized by Nutku.[27] The flow is given by the equations:

$$\dot{x}_1 = x_1(\rho + cx_2 + x_3),$$

$$\dot{x}_2 = x_2(\mu + x_1 + ax_3),$$

$$\dot{x}_3 = x_3(\nu + bx_1 + x_2).$$

As Nutku has pointed out, this is a Poisson system if

$$abc = -1, \quad \nu = \mu b - \rho ab.$$

In this case, the structure matrix and the Hamiltonian are, respectively:

$$\mathscr{J} = \begin{pmatrix} 0 & cx_1x_2 & bcx_1x_3 \\ -cx_1x_2 & 0 & -x_2x_3 \\ -bcx_1x_3 & x_2x_3 & 0 \end{pmatrix},$$

obeying to form (11), and

$$H = abx_1 + x_2 - ax_3 + \nu \ln(x_2) - \mu \ln(x_3),$$

which is of the form (10). The system is thus GLVP with characteristic matrices:

$$B = I_{3\times 3}, \quad M = \begin{pmatrix} \rho & 0 & c & 1 \\ \mu & 1 & 0 & a \\ \nu & b & 1 & 0 \end{pmatrix},$$

$$K = \begin{pmatrix} 0 & c & bc \\ -c & 0 & -1 \\ -bc & 1 & 0 \end{pmatrix}, \quad D = \begin{pmatrix} ab & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -a \end{pmatrix}, \quad L = \begin{pmatrix} 0 \\ \nu \\ -\mu \end{pmatrix}.$$

Notice that $\mathrm{rank}(M) = \mathrm{rank}(A) = \mathrm{rank}(K) = \mathrm{rank}(\mathscr{J}) = 2$ inside the positive orthant of R^3. There is then one independent Casimir function. By noting that, in M, $\mathrm{row}(3) = (1/c) \times \mathrm{row}(1) + b \times \mathrm{row}(2)$, we immediately find the quasimonomial first integral:

$$x_1^{ab} x_2^{-b} x_3 = \text{constant},$$

which is also a Casimir of the Poisson structure from Theorem 3.5. This way of recovering Casimir functions of the system is certainly more economic than solving the PDE $\mathscr{J} \cdot \nabla \phi = 0$, which is the usual approach.

B. Darboux form: General method

Let us now subject the system to a QMT of matrix:

$$C = \begin{pmatrix} c & 0 & 0 \\ 0 & 1 & 0 \\ 1 & b & -1 \end{pmatrix}.$$

We arrive to a new GLVP of matrices:

$$B'=\begin{pmatrix} c & 0 & 0 \\ 0 & 1 & 0 \\ 1 & b & -1 \end{pmatrix}, \quad M'=\begin{pmatrix} \rho/c & 0 & 1 & 1/c \\ \mu & 1 & 0 & a \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

$$K'=\begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad D'=\begin{pmatrix} ab & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -a \end{pmatrix}, \quad L'=\begin{pmatrix} -\mu \\ \rho/c \\ \mu \end{pmatrix}.$$

The Casimir function has been decoupled, and now is just x_3'. A change of variables $y_i=\ln(x_i')$, $i=1,2,3$ yields Darboux's form, with:

$$\mathscr{J}(y)=\begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \tag{17}$$

and

$$H(y)=abe^{cy_1}+e^{y_2}-ae^{y_1+by_2-y_3}-\mu y_1+(\rho/c)y_2+\mu y_3. \tag{18}$$

C. Darboux form: Decoupling method

Although the previous one is the shortest way to achieve the transformation into Darboux form, it may be sometimes more convenient to proceed in a two-step alternative: The first step is the transformation of the system into a symplectic flow. This might be more appropriate in systems of higher dimensions, in which an initial reduction of the dimensionality of the problem may produce the most manageable system. We shall briefly display it for the sake of illustration.

We can first make a QMT of matrix:

$$C_1=\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 1/c & b & -1 \end{pmatrix}.$$

If we then decouple the third variable, assuming for simplicity that its initial condition is $x_3'(0)=1$, the reduced GLVP system is given by:

$$\hat{B}'=\begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 1/c & b \end{pmatrix}, \quad \hat{M}'=\begin{pmatrix} \rho & 0 & c & 1 \\ \mu & 1 & 0 & a \end{pmatrix},$$

$$\hat{K}'=\begin{pmatrix} 0 & c \\ -c & 0 \end{pmatrix}, \quad \hat{D}'=\begin{pmatrix} ab & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -a \end{pmatrix}, \quad \hat{L}'=\begin{pmatrix} -\mu/c \\ \nu-\mu b \end{pmatrix}.$$

We now perform a second QMT, this time acting on the reduced (2,2,3)-class:

$$C_2=\begin{pmatrix} c & 0 \\ 0 & 1 \end{pmatrix}.$$

In the resulting flow, we have:

$$\hat{K}''=S(2,0)=\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

After the final change of variables $y_i=\ln(x_i'')$, $i=1,2$, we arrive at a Hamiltonian system in which:

$$H(y)=abe^{cy_1}+e^{y_2}-ae^{y_1+by_2}-\mu y_1+(\rho/c)y_2.$$

Notice that this Hamiltonian can be obtained from (18) with $y_3=0$. This is due to the initial condition we have assumed for x_3' in the 1-decoupling. We obviously retrieve, up to trivial differences in form, the Darboux system (17–18).

VII. FINAL REMARKS

We have seen that there is a close parallelism between the Poisson structure of GLVP flows and the algebraic properties of GLV equations. The deep and unexpected interplay between both aspects of the systems results in an economy in their description. It also establishes an operational framework for their manipulation and simplification. This is, to our knowledge, a novel approach to the treatment of finite-dimensional Poisson structures.

We end this work by giving an evaluation in relation to what has been done previously in the literature. Unfortunately, the only way for doing this is by particularizing the comparison to LV models, for which earlier results are available. We shall only consider previous approaches which are valid for n-dimensional LV models, for arbitrary n. We can then say that most Hamiltonian and Poisson LV systems treated in the literature have a matrix A which is of maximal rank, i.e., they have a single fixed point.[6,30,37] Also, they are often restricted to even dimensionality,[30,37] which usually entails that the system is symplectic (these are, of course, two requirements which are implicit in the classical Hamiltonian studies). None of these restrictions are present, as we have seen, in our models. On the other hand, our treatment joins previous works in what concerns certain requirements on matrix A: For a GLVP Lotka–Volterra system, we have that $A=K\cdot D$, where K is skew-symmetric. This implies, as it can be readily seen, that $D_{ii}A_{ij}=-D_{jj}A_{ji}$, which is exactly the same kind of generalized skew-symmetry which can be found in the works of Kerner[37] and some cases from Plank,[6] for example. Therefore, the scope of our treatment does not differ, in this sense, to that of previous ones. Notice also how our Hamiltonian (10) reduces, in the case of LV systems, to a generalization of the classical Volterra's constant of the motion:

$$H_V=\sum_{i=1}^{n}\beta_i(x_i-p_i\ln(x_i)),$$

where p_i are the coordinates of the (unique) fixed point of Volterra's systems.

Another interesting issue which we would like to comment on here concerns the use of an arbitrary Hamiltonian, while retaining the form (11) for the structure matrix. This leads, of course, to the generation of a wide range of Poisson systems. This procedure can be found, for example, in Plank's work.[6] We may mention that many of our previous results still hold in this Hamiltonian-independent situation. This is the case, for instance, in the reduction of the system to the Darboux form. The reason is that the criterion to decide whether a system complies to Darboux format or not, relies on the form of the structure matrix, exclusively. Consequently, the manipulations to which the system is to be subjected concern the recasting of $\mathscr{T}$ in the desired form, H being irrelevant for that case—which is the situation in Sec. V.

(Received 2 July 1997; accepted for publication 1 June 1998)

We construct the integrable families of the generalized elliptic Ruijsenaars models by use of the Yang–Baxter equation and the reflection equation. The higher order conserved operators of these models are explicitly presented. © *1998 American Institute of Physics.* [S0022-2488(98)00811-1]

I. INTRODUCTION

Since a relativistic analog of the Calogero–Sutherland–Moser (CSM) model was first introduced by Ruijsenaars,[1] this model has been studied extensively in both classical and quantum cases.[2–6] In his studies Ruijsenaars defined the ''relativistic'' Hamiltonian $\mathscr{H}_A$ as

$$\mathscr{H}_A=\sum_{j=1}^{N}\left(\prod_{\substack{k=1\\k\neq j}}^{N}\sqrt{\frac{\vartheta_1(z_{jk}-\mu)}{\vartheta_1(z_{jk})}}\right)\exp\left(\beta\,\frac{\partial}{\partial z_j}\right)\left(\prod_{\substack{k=1\\k\neq j}}^{N}\sqrt{\frac{\vartheta_1(z_{kj}-\mu)}{\vartheta_1(z_{kj})}}\right)$$
$$+\sum_{j=1}^{N}\left(\prod_{\substack{k=1\\k\neq j}}^{N}\sqrt{\frac{\vartheta_1(z_{kj}-\mu)}{\vartheta_1(z_{kj})}}\right)\exp\left(-\beta\,\frac{\partial}{\partial z_j}\right)\left(\prod_{\substack{k=1\\k\neq j}}^{N}\sqrt{\frac{\vartheta_1(z_{jk}-\mu)}{\vartheta_1(z_{jk})}}\right). \tag{1.1}$$

Here z_{jk} denotes z_j-z_k, and β and μ are arbitrary parameters. The function $\vartheta_r(z)$ is the Jacobi theta function (see the Appendix for detail). One sees that the Hamiltonian $\mathscr{H}_A$ is invariant under permutations of variables $z_j\leftrightarrow z_k$, and is called the *A*-type Ruijsenaars model. As a generalization of the *A*-type model, also considered is a *D*-type analog of the Ruijsenaars model,[6–8] i.e., a model invariant not only under permutations $z_j\leftrightarrow z_k$ but sign flips of variables $z_j\leftrightarrow -z_j$. The *D*-type Hamiltonian $\mathscr{H}_D$ reads as

$$\mathscr{H}_D=\sum_{j=1}^{N}\Psi_j(z)^{1/2}\exp\left(2\beta\,\frac{\partial}{\partial z_j}\right)\Psi_j(-z)^{1/2}$$
$$+\sum_{j=1}^{N}\Psi_j(-z)^{1/2}\exp\left(-2\beta\,\frac{\partial}{\partial z_j}\right)\Psi_j(z)^{1/2}+\Psi_0(z), \tag{1.2}$$

where functions $\Psi_j(z)$ and $\Psi_0(z)$ are

$$\Psi_j(z)=\left(\prod_{\substack{k=1\\k\neq j}}^{N}\frac{\vartheta_1(z_{jk}-\mu)}{\vartheta_1(z_{jk})}\,\frac{\vartheta_1(z_j+z_k-\mu)}{\vartheta_1(z_j+z_k)}\right)\left(\prod_{r=0}^{3}\frac{\vartheta_{r+1}(z_j-\nu_r)}{\vartheta_{r+1}(z_j)}\,\frac{\vartheta_{r+1}(z_j+\beta-\overline{\nu_r})}{\vartheta_{r+1}(z_j+\beta)}\right), \tag{1.3a}$$

[b]Electronic mail: hikami@phys.s.u-tokyo.ac.jp

 © 1998 American Institute of Physics

$$\Psi_0(z)=-\sum_{p=0}^{3}\left(\frac{\pi}{\vartheta_1'(0)}\right)^2\frac{2}{\vartheta_1(-\mu)\vartheta_1(-2\beta-\mu)}\left(\prod_{r=0}^{3}\vartheta_{r+1}(-\beta-\nu_{\pi_p r})\vartheta_{r+1}(-\overline{\nu}_{\pi_p r})\right)$$
$$\times\left(\prod_{j=1}^{N}\frac{\vartheta_{p+1}(z_j-\beta-\mu)}{\vartheta_{p+1}(z_j-\beta)}\frac{\vartheta_{p+1}(-z_j-\beta-\mu)}{\vartheta_{p+1}(-z_j-\beta)}\right). \tag{1.3b}$$

Here π_p for $p=0,1,2,3$ denote permutations; $\pi_0=\mathbb{1}$, $\pi_1=(01)(23)$, $\pi_2=(02)(13)$, and $\pi_3=(03)(12)$. Parameters β, μ, ν_r and $\overline{\nu}_r$ $(r=0,1,2,3)$ are arbitrary constants. We note that the *A*-type model and the *D*-type model contain two and ten parameters, respectively. Mathematically the trigonometric limits of these operators are related to the Macdonald operators (or, for the case of *D* type, the Macdonald–Koornwinder operator), and their eigenfunctions are much investigated in *q*-orthogonal polynomial theory.[9–11] There the affine Hecke algebra plays an important role.[12–16]

In this paper, we define two families of commutative difference operators in terms of solutions of both the Yang–Baxter equation (YBE) and the reflection equation (RE). Here we regard these solutions as operators acting on function spaces. While these elliptic difference operators were constructed in the form of an infinite sum or product of trigonometric solution,[17,18] our method deals only with finite products since the solutions of the YBE and the RE are elliptic. We prove that the difference operators possess the Weyl group invariance. This fact follows from the quasi-classical properties of the YBE and the RE. Owing to these symmetries, we present the explicit forms of all the conserved operators for both *A*-type and *D*-type models.

This paper is organized as follows. In Sec. II, we briefly review the operator-valued solutions of the YBE and the RE. We also mention characteristic properties used in later discussions. In Sec. III, we define a family of commutative difference operators in terms of the solution of the YBE. These operators are supposed to act on symmetric space in coordinates. When we assign a proper figure to each operator, the symmetry of the difference operators becomes manifest. We see that the higher conserved operators are explicitly calculated and reduce to the elliptic Macdonald operators. We show in Sec. IV that a similar discussion can be applied to the *D*-type model. As in the previous sections, we construct a set of difference operators using solutions of the YBE and the RE. The symmetry is also clarified by a pictorial analysis. Though the calculation is not straightforward and needs several steps in contrast to the *A*-type, we obtain the explicit forms of the *D*-type operators. Section V is devoted to the conclusion.

II. YANG–BAXTER EQUATION AND THE REFLECTION EQUATION

We shall review operator-valued solutions[19–23] of the YBE and the RE.[25,26] The YBE and the RE are, respectively, defined by

$$R^{12}(\xi_{12})R^{13}(\xi_{13})R^{23}(\xi_{23})=R^{23}(\xi_{23})R^{13}(\xi_{13})R^{12}(\xi_{12}), \tag{2.1}$$

$$R^{12}(\xi_{12})\overset{1}{K}(\xi_1)R^{21}(\xi_1+\xi_2)\overset{2}{K}(\xi_2)=\overset{2}{K}(\xi_2)R^{12}(\xi_1+\xi_2)\overset{1}{K}(\xi_1)R^{21}(\xi_{12}). \tag{2.2}$$

Here ξ_j is called the spectral parameter, and ξ_{jk} denotes $\xi_{jk}=\xi_j-\xi_k$. The operator $R^{jk}(\xi)$ acts nontrivially on the jth and the kth variables, and $\overset{j}{K}(\xi)$ acts as $K(\xi)$ only on the jth variable.

We regard solutions of both the YBE and RE as operators acting on the functional space of z_j. We use operators $\hat{s}_{jk}$ and $\hat{t}_j$ as a permutation and a sign flip of variables, respectively;

$$z_j\hat{s}_{jk}=\hat{s}_{jk}z_k, \quad z_j\hat{t}_j=-\hat{t}_jz_j. \tag{2.3}$$

As shown in Refs. 4, 23, and 24, we have the following theorems:

Theorem 2.1: *The elliptic R-operator, defined by*

$$R^{jk}(\xi)=\sigma_\mu(z_{jk})-\sigma_\xi(z_{jk})\cdot\hat{s}_{jk}, \tag{2.4}$$

with arbitrary constant μ, satisfies the YBE (2.1). This R-operator possesses the unitarity,

$$R^{12}(\xi)R^{21}(-\xi)=c(\xi)\cdot\mathbb{1}, \tag{2.5}$$

where function $c(\xi)$ *is given by* $c(\xi)=\wp(\mu)-\wp(\xi)$.

Theorem 2.2: *With the elliptic R-operator (2.4), the elliptic K-operator defined by*

$$K(\xi)=\sum_{r=0}^{3} g_r\sigma^r_{2\xi}(z)-\sum_{r=0}^{3} g_r\sigma^r_{2\nu}(z)\cdot\hat{t}, \tag{2.6}$$

satisfies the RE (2.2). Here parameters ν, g_r $(r=0,1,2,3)$ *are arbitrary. This K-operator (2.6) has the unitarity,*

$$K(\xi)K(-\xi)=d(\xi)\cdot\mathbb{1}, \tag{2.7}$$

where function $d(\xi)$ *is given by*

$$d(\xi)=\mathbf{g}^{\mathrm{T}}\mathbf{S}\mathbf{\Lambda}(\xi)\mathbf{S}\mathbf{g},$$

$$\mathbf{S}=\frac{1}{2}\begin{pmatrix}1&1&1&1\\1&1&-1&-1\\1&-1&1&-1\\1&-1&-1&1\end{pmatrix},\quad \mathbf{g}=\begin{pmatrix}g_0\\g_1\\g_2\\g_3\end{pmatrix},$$

$$\mathbf{\Lambda}(\xi)=\mathrm{diag}_{r=0,1,2,3}(\wp(\nu+\omega_r)-\wp(\xi+\omega_r)).$$

We remark that the *R*- and *K*-operators satisfy the quasiclassical conditions as follows;

$$R^{12}(\mu)=\sigma_\mu(z_{12})(1-\hat{s}_{12}), \tag{2.8a}$$

$$R^{12}(-\mu)=(1+\hat{s}_{12})\sigma_\mu(z_{12}), \tag{2.8b}$$

$$K(\nu)=\left(\sum_{r=0}^{3} g_r\sigma^r_{2\nu}(z)\right)(1-\hat{t}), \tag{2.8c}$$

$$K(-\nu)=(1+\hat{t})\left(\sum_{r=0}^{3} g_r\sigma^r_{-2\nu}(z)\right). \tag{2.8d}$$

It should also be noted that (2.5) and (2.7) include identities

$$R^{12}(\mu)R^{21}(-\mu)=0, \tag{2.9a}$$

$$K(\nu)K(-\nu)=0. \tag{2.9b}$$

III. ELLIPTIC RUIJSENAARS MODEL OF TYPE-*A*

We shall study the elliptic Ruijsenaars model $\mathscr{H}_A$ (1.1) of type-*A*. We begin with a family of difference operators called the elliptic Macdonald operators,

$$\mathscr{M}_n=\sum_{\substack{J\subset\{1,\ldots,N\}\\|J|=n}}\left(\prod_{\substack{j\in J\\k\in J^c}}\sigma_\mu(z_{jk})\right)\prod_{j\in J}T_j(\beta), \tag{3.1}$$

where $T_j(\beta)$ is a shift operator and is defined by $T_j(\beta)=\exp(-\beta\partial/\partial z_j)$. Throughout this section, we denote $T_j(\beta)$ as T_j. The Macdonald operators are supposed to act on a symmetric space in coordinates $z_1,z_2,\ldots,z_N$, i.e., an invariant space under the action of the Weyl group $W_A\simeq S_N$. Thus hereafter we restrict our discussions to such a space. These operators are connected with the Hamiltonian (1.1) of the elliptic Ruijsenaars model of type-*A* by a gauge transformation.[6]

In our previous paper,[6] we proved that the Ruijsenaars model, or the elliptic Macdonald operator $\mathscr{M}_n$ (3.1), is integrable, and that the operators $\mathscr{M}_n$ are related to the elliptic R-operator (2.4) as follows.

(1) the difference operators $\mathscr{D}_n(\xi)=\mathscr{D}_n(\xi_1,\ldots,\xi_N)$ defined by

$$\mathscr{D}_n(\xi)=\mathscr{R}^N_{N-n+1}(\xi)\prod_{m=N-n+1}^{N} T_m, \tag{3.2}$$

commute each other for arbitrary ξ,

$$[\mathscr{D}_n(\xi),\mathscr{D}_m(\xi)]=0. \tag{3.3}$$

Here the operator $\mathscr{R}^n_m(\xi)$ corresponds to a fused R-operator[4] given by

$$\mathscr{R}^n_m(\xi)=\prod_{j=m}^{n}\left(\prod_{k=1}^{\overset{\frown}{m-1}} R^{jk}(\xi_{jk})\right). \tag{3.4}$$

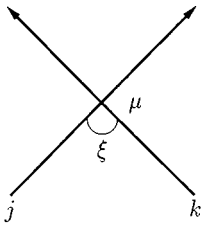
(2) The difference operator $\mathscr{D}_n(\xi)$ reduces to the elliptic Macdonald operator with a specific choice of the spectral parameters,

$$\mathscr{M}_n=\mathscr{D}_n(\xi)|_{\xi_{jk}=(k-j)\mu}, \tag{3.5}$$

where the spectral parameters are set to be $\xi_{jk}=(k-j)\mu$.

Though we have proved the equality (3.5) after a lengthy computation,[6] we shall take another simple method. To clarify the structure of our difference operators, we assign a figure for each operator. The R-operator and the shift operator T can be represented pictorially as

$R^{jk}(\xi)$ =

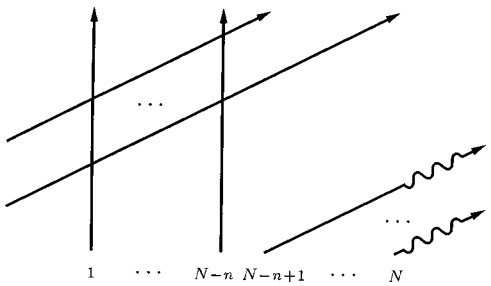


$T_j(\beta)$ = j

(3.6)

Using these figures, the difference operators $\mathscr{D}_n(\xi)$ are depicted as follows:

$\mathscr{D}_n(\xi)$ =



(3.7)

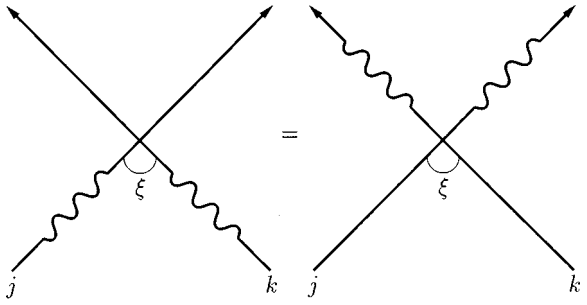
Note that both ends of the figures are supposed to be connected.

Theorem 3.1: *The difference operators $\mathscr{D}_n(\xi)$ preserve the W_A-invariant space when the spectral parameters are set to be $\xi_{jk}=(k-j)\mu$.*

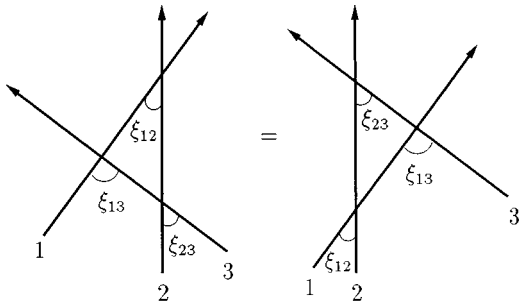
Proof: It is easy to see that the elliptic R-operator (2.4) commutes with T_jT_k;

$$R^{jk}(\xi)T_jT_k=T_jT_kR^{jk}(\xi), \tag{3.8}$$

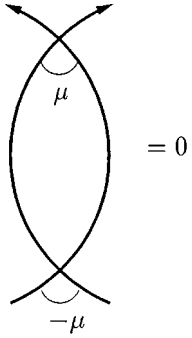
since the R-operator (2.4) depends only on the difference of variables. We depict some relations as follows:



$$R^{jk}(\xi)\,T_j\,T_k \quad = \quad T_j\,T_k\,R^{jk}(\xi) \tag{3.8$'$}$$

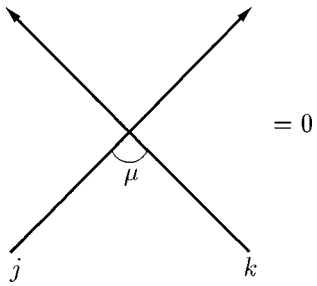


$$R^{12}(\xi_{12})R^{13}(\xi_{13})R^{23}(\xi_{23}) \;=\; R^{23}(\xi_{23})R^{13}(\xi_{13})R^{12}(\xi_{12}) \tag{2.1$'$}$$



$$R^{jk}(\mu)R^{kj}(-\mu) = 0 \tag{2.9a$'$}$$

We also note that, by the quasiclassical condition (2.8), the operator $R^{jk}(\mu)$ vanishes when it acts on symmetric space in z_j, z_k;



(3.9)

To prove the statement of Theorem 3.1, we only need to check it for the generators of W_A, i.e.,

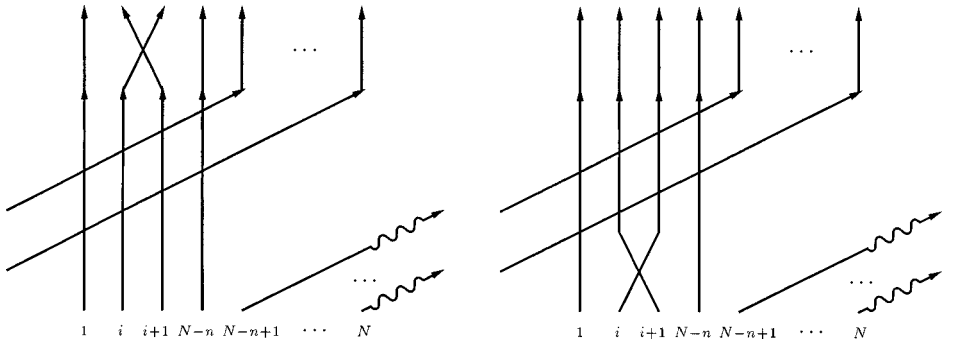
$$R_{ii+1}(\xi_{ii+1})\mathscr{D}_n(\xi)\big|_{\xi_{jk}=(k-j)\mu}=\sigma_\mu(z_{ii+1})(1-\hat{s}_{ii+1})\mathscr{D}_n(\xi)\big|_{\xi_{jk}=(k-j)\mu}=0. \tag{3.10}$$

This equation can be shown as follows.

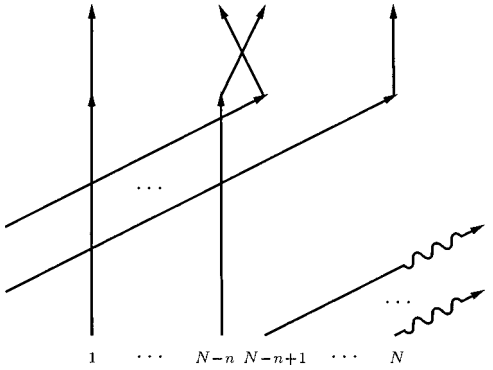
(1) $1\leqslant i\leqslant N-n-1$: By using the YBE (2.1′), one finds that the left-hand side of (3.11) is equivalent to the right-hand side of (3.11), which vanishes when it acts on the W_A-invariant space due to (3.9).

(2) $i=N-n$: (3.12) vanishes immediately due to (2.9a′).

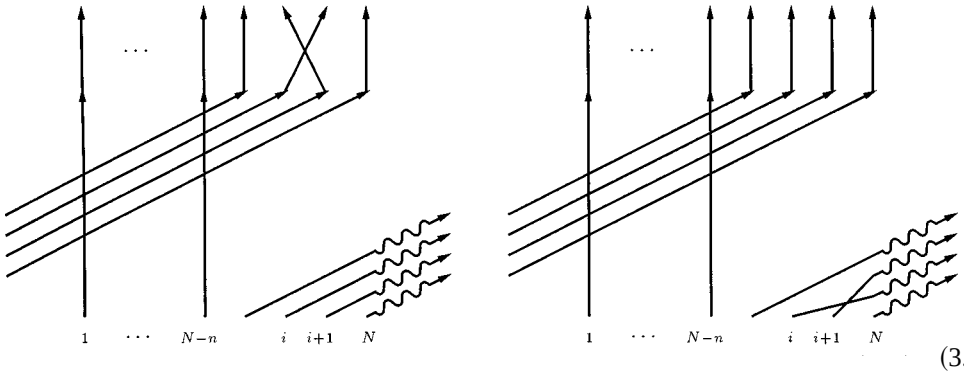
(3) $N-n+1\leqslant i\leqslant N-1$: By use of the YBE (2.1′) and the relation (3.8′), one finds that the left-hand side of (3.13) is equivalent to the right-hand side of (3.13), which vanishes if it acts on the W_A-invariant space due to (3.9),



(3.11)



(3.12)



(3.13)

□

Now it is straightforward to calculate the explicit forms of the difference operators $\mathscr{D}_n(\xi)$ with $\xi_{jk}=(k-j)\mu$.

Theorem 3.2: *We have*

$$\mathscr{D}_n(\xi)\big|_{\xi_{jk}=(k-j)\mu}=\mathscr{M}_n, \tag{3.14}$$

where operators $\mathscr{M}_n$ are the elliptic Macdonald operators (3.1).

Proof: When we expand the operators $\mathscr{D}_n(\xi)$ by substituting the elliptic R-operator (2.4) into (3.2), we see that the term $\Pi_{j=N-n+1}^{N} T_j$ is computed simply as

$$\prod_{j=N-n+1}^{N}\left(\prod_{k=1}^{N-n}\sigma_\mu(z_{jk})\right)\prod_{j=N-n+1}^{N} T_j. \tag{3.15}$$

Due to the W_A-invariance of the operators $\mathscr{D}_n(\xi)$ with $\xi_{jk}=(k-j)\mu$, we obtain the result by symmetrizing (3.15). □

IV. ELLIPTIC RUIJSENAARS MODEL OF TYPE-*D*

We introduced the *D*-type Ruijsenaars operators $\mathscr{W}_n$,[6] which form a commutative family of difference operators. The explicit form of the lowest order operator is given by

$$\begin{aligned}\mathscr{W}_1=&\sum_{j=1}^{N}\left(\prod_{\substack{k=1\\k\neq j}}^{N}\sigma_\mu(z_{jk})\sigma_\mu(z_j+z_k)\right)\left(\sum_{r=0}^{3} g_r\sigma_{2\nu}^{r}(z_j)\right)\\&\times\left(\sum_{r=0}^{3}\overline{g}_r\sigma_{2\nu}^{r}(z_j+\beta)T_j(2\beta)-\sum_{r=0}^{3}\overline{g}_r\sigma^{r}_{-2(N-1)\mu-2\nu}(z_j+\beta)\right)\\&+\sum_{j=1}^{N}\left(\prod_{\substack{k=1\\k\neq j}}^{N}\sigma_\mu(z_{kj})\sigma_\mu(-z_j-z_k)\right)\left(\sum_{r=0}^{3} g_r\sigma_{2\nu}^{r}(-z_j)\right)\\&\times\left(\sum_{r=0}^{3}\overline{g}_r\sigma_{2\nu}^{r}(-z_j+\beta)T_j(-2\beta)-\sum_{r=0}^{3}\overline{g}_r\sigma^{r}_{-2(N-1)\mu-2\nu}(-z_j+\beta)\right).\end{aligned} \tag{4.1}$$

The operators $\mathscr{W}_n$ are supposed to act on a symmetric space under permutations and sign flips, i.e., the Weyl group $W_B\simeq S_N\ltimes\{\mathbb{Z}_2\}^N$. We impose such restriction on the space in what follows.

In this section, we shall give the explicit forms of the higher order operators $\mathscr{W}_n$ by a similar technique discussed for the *A*-type operator. To define the operators $\mathscr{W}_n$, we introduce a set of integrable difference operators $\mathscr{Y}_n(\xi)$ for $\xi=\{\xi_1,\ldots,\xi_N\}$ as[6]

$$\mathscr{Y}_n(\xi)=\mathscr{R}^{N}_{N-n+1}(\xi)\mathscr{K}^{N}_{N-n+1}(\xi)\overline{\mathscr{R}}^{N}_{N-n+1}(\xi)\overline{\mathscr{K}}^{N}_{N-n+1}(\xi), \tag{4.2}$$

where $\mathscr{R}^{n}_{m}(\xi)$ is the same as (3.4), and the others are given by

$$\overline{\mathscr{R}}^{n}_{m}(\xi)=\prod_{j=m}^{n}\left(\prod_{k=1}^{m-1}R^{kj}(\xi_k+\xi_j)\right), \tag{4.3}$$

$$\mathscr{K}^{n}_{m}(\xi)=\prod_{j=m}^{n}{}^{j}K(\xi_j)\left(\prod_{k=j+1}^{n}R^{kj}(\xi_k+\xi_j)\right), \tag{4.4}$$

$$\overline{\mathscr{K}}^{n}_{m}(\xi)=\prod_{j=m}^{n}\left(\prod_{k=m}^{j-1}R^{kj}(\xi_k+\xi_j)\right)\overline{{}^{j}K}(\xi_j). \tag{4.5}$$

In this expression, we have used a ''conjugate'' boundary operator $\overline{K}(\xi)$ as

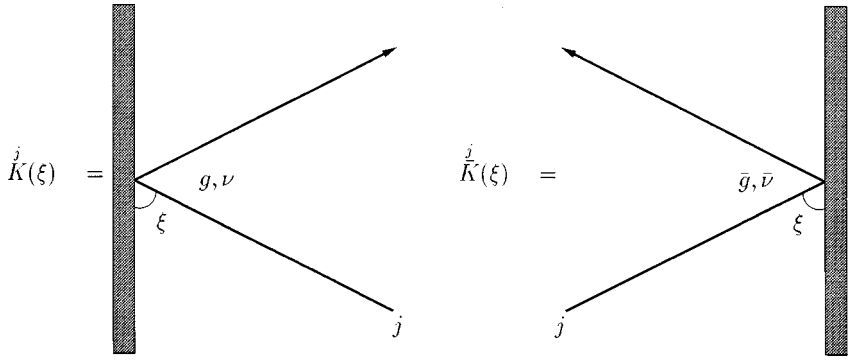
$$\overline{K}(\xi)=T(-\beta)\cdot\hat{t}\cdot K(\xi)\cdot\hat{t}\cdot T(\beta), \tag{4.6}$$

where parameters in the elliptic K-operator (2.6) are replaced as $g_r \to \overline{g_r}$ and $\underline{\nu} \to \overline{\nu}$. As the boundary K-operator (2.6) satisfies the RE (2.2), the conjugate boundary operator $\underline{K}(\xi)$ defined in (4.6) is proved to satisfy the ''conjugate'' RE;

$$\underline{\overset{2}{K}}(\xi_2)R^{21}(\xi_1+\xi_2)\underline{\overset{1}{K}}(\xi_1)R^{12}(\xi_{12}) = R^{21}(\xi_{12})\underline{\overset{1}{K}}(\xi_1)R^{12}(\xi_1+\xi_2)\underline{\overset{2}{K}}(\xi_2). \tag{4.7}$$

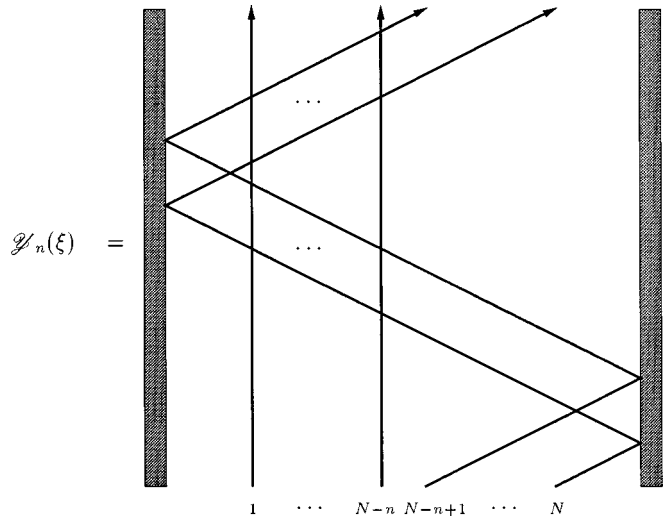
It should be noted that (3.4) and (4.3)–(4.5) are closely related to the fusion procedure and they also satisfy the YBE and the RE.

The operators K and $\underline{K}$ are, respectively, depicted as follows:



(4.8)

Using the above interpretations, the difference operators $\mathscr{Y}_n(\xi)$ defined in (4.2) can be depicted as



(4.9)

It should be noted that the difference operators $\mathscr{Y}_n(\xi)$ are proved[6] to constitute a commutative family for arbitrary spectral parameters, by applying the YBE and the RE.

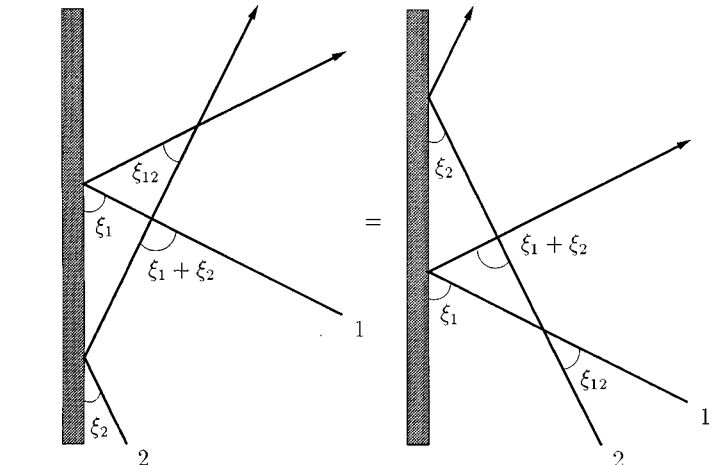
In terms of the integrable operators $\mathscr{Y}_n(\xi)$, we define[6] the D-type Ruijsenaars operators $\mathscr{W}_n$ by fixing the spectral parameters as

$$\mathscr{W}_n = \mathscr{Y}_n(\xi)|_{\xi_j = -\nu-(j-1)\mu}. \tag{4.10}$$

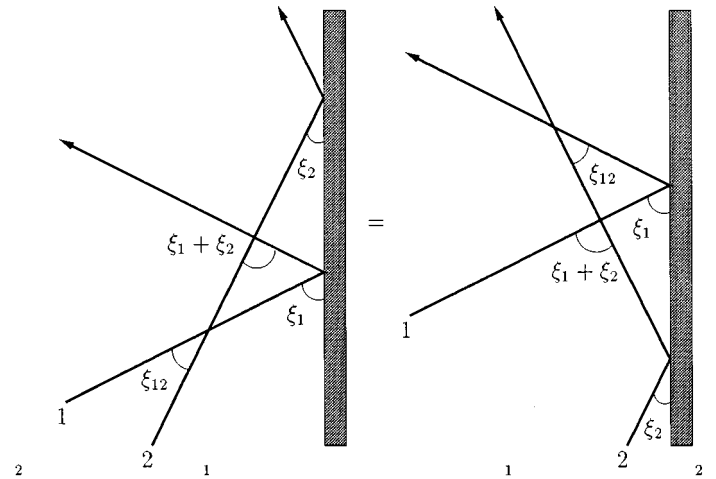
The meaning of this definition is clarified by the following theorem.

Theorem 4.1: *The difference operators $\mathscr{Y}_n(\xi)$ preserve the W_B-invariant space when each spectral parameter is set to be $\xi_j = -\nu-(j-1)\mu$.*

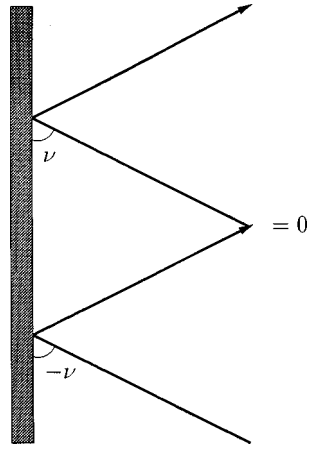
Proof: We apply the similar discussion in Theorem 3.1 to prove this theorem. Note that the RE (2.2), the conjugate RE (4.7), and the unitarity condition (2.9b) can be graphically interpreted as follows:



$$R^{12}(\xi_{12})\overset{1}{K}(\xi_1)R^{21}(\xi_1+\xi_2)\overset{2}{K}(\xi_2) = \overset{2}{K}(\xi_2)R^{12}(\xi_1+\xi_2)\overset{1}{K}(\xi_1)R^{21}(\xi_{12}) \tag{2.2′}$$

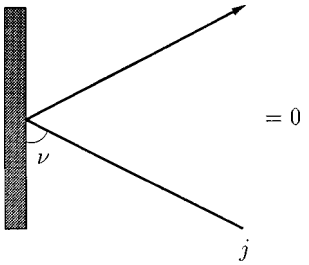


$$\overset{2}{K}(\xi_2)R^{21}(\xi_1+\xi_2)\overset{1}{K}(\xi_1)R^{12}(\xi_{12}) = R^{21}(\xi_{12})\overset{1}{K}(\xi_1)R^{12}(\xi_1+\xi_2)\overset{2}{K}(\xi_2) \tag{4.7′}$$



(2.9b′)

We also depict the quasiclassical condition of the boundary operator $K(\nu)$ acting on a invariant space in a sign flip $z_j \leftrightarrow -z_j$;



(4.11)

In the following, we fix the spectral parameters ξ as $\xi_j=-\nu-(j-1)\mu$. By noting that the Weyl group W_B is generated by $\hat{t}_1$ and $\hat{s}_{ii+1}$, it is sufficient to show that the following equalities hold:

$$R_{ii+1}(\xi_{ii+1})\mathscr{Y}_n(\xi)=\sigma_\mu(z_{ii+1})(1-\hat{s}_{ii+1})\mathscr{Y}_n(\xi)=0, \tag{4.12}$$

$$\overset{1}{K}(-\xi_1)\mathscr{Y}_n(\xi)=\left(\sum_{r=0}^{3} g_r\sigma^r_{2\nu}(z)\right)(1-\hat{t}_1)\mathscr{Y}_n(\xi)=0. \tag{4.13}$$

These equations are proved pictorially. Equation (4.12) is proved as

(1) $1\leqslant i\leqslant N-n-1$: By using the YBE (2.1′), one finds that the left-hand side of (4.14) is equivalent to the right-hand side of (4.14), which vanishes when it acts on the W_B-invariant space due to (3.9).

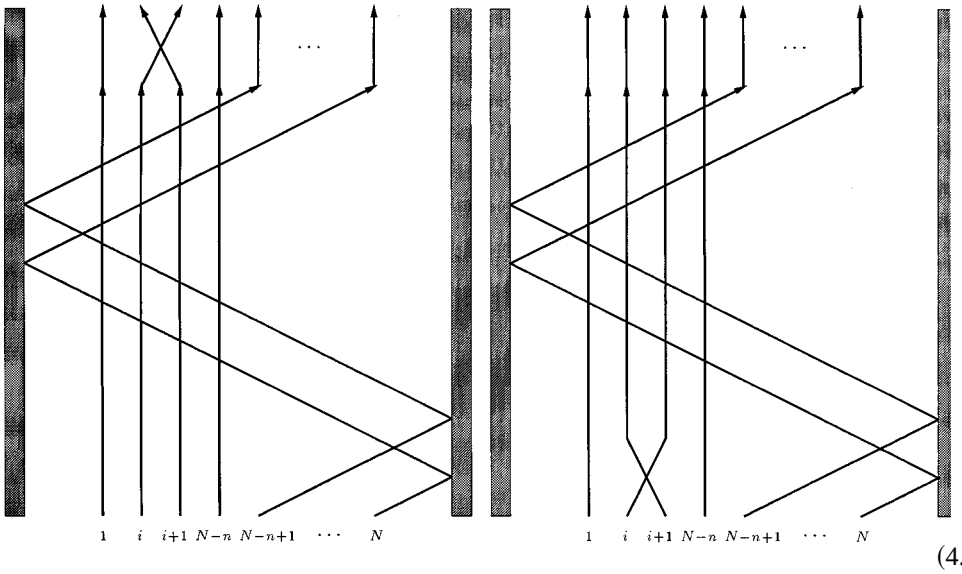
(2) $i=N-n$: Equation (4.15) vanishes immediately due to (2.9a′).

(3) $N-n+1\leqslant i\leqslant N-1$: By use of the YBE (2.1′), the RE (2.2′), and the conjugate RE (4.7′), one finds that the left-hand side of (4.16) is equivalent to the right-hand side of (4.16), which vanishes if it acts on the W_B-invariant space due to (3.9).

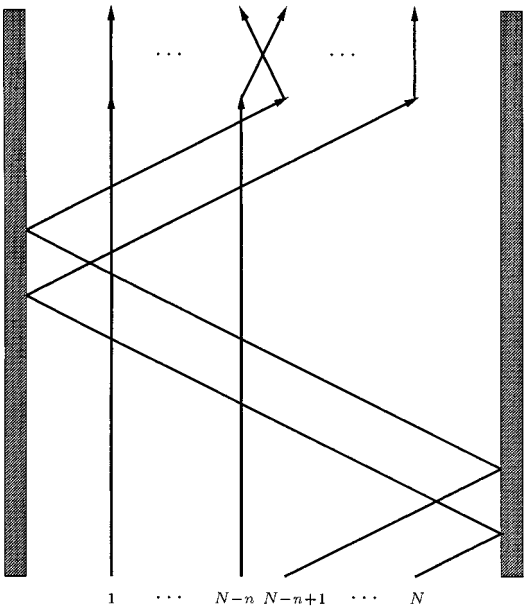
Equation (4.13) is proved in the same way as

(1) $n\neq N$: By use of the YBE (2.1′) and the RE (2.2′), one finds that the left-hand side of (4.17) is equivalent to the right-hand side of (4.17), which vanishes if it acts on the W_B-invariant space due to (4.11).

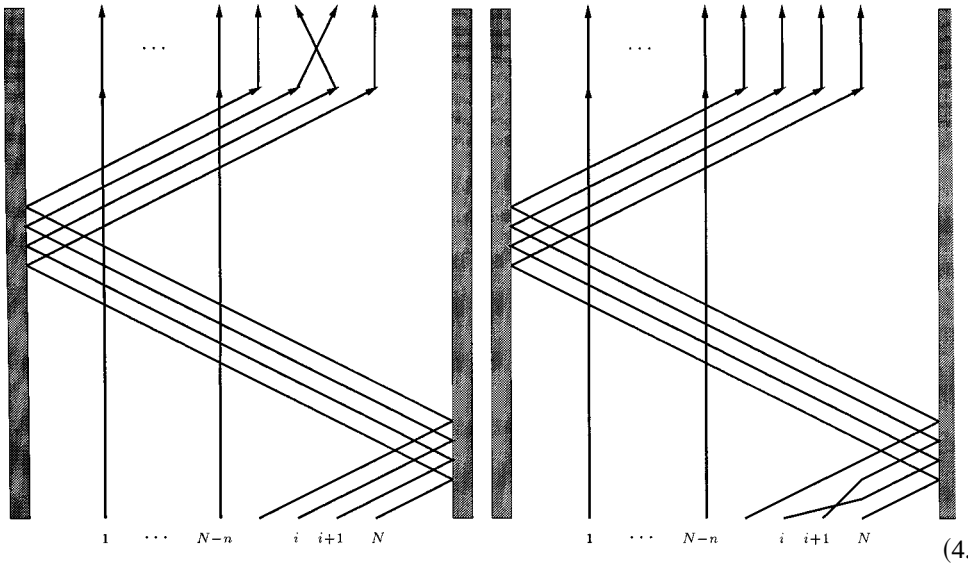
(2) $n=N$: Equation (4.18) vanishes immediately due to (2.9b′).



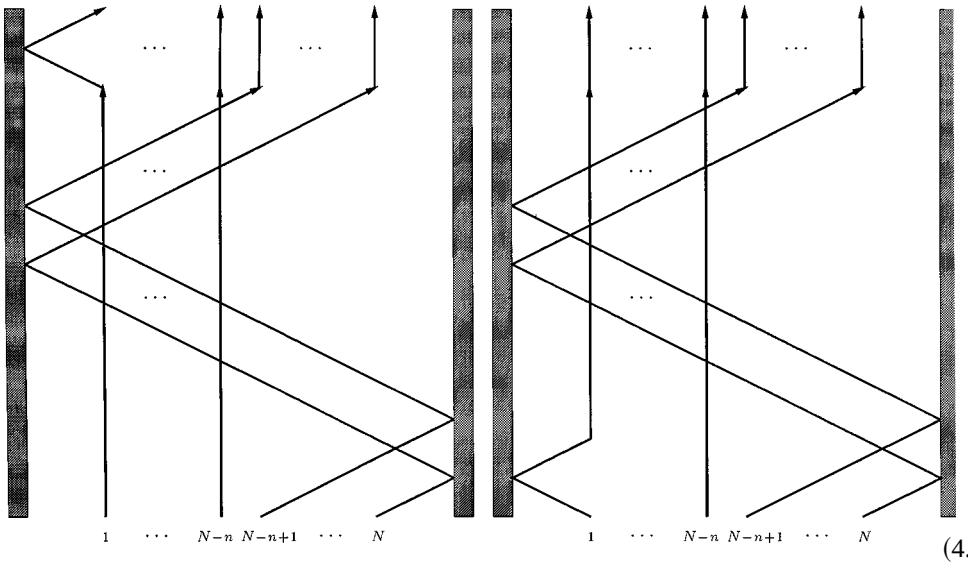
(4.14)



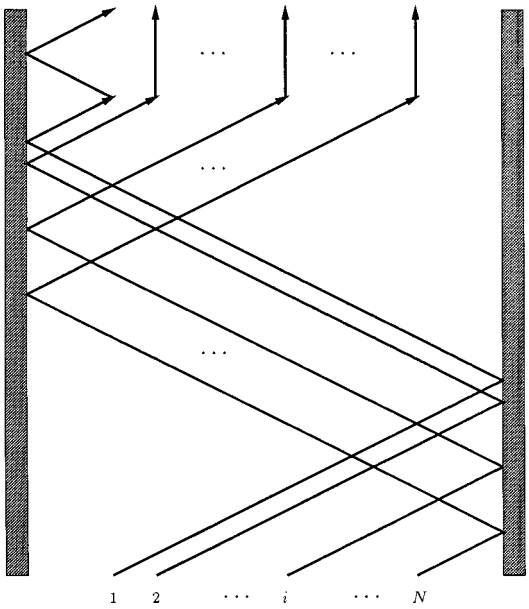
(4.15)



(4.16)



(4.17)



(4.18)

□

Based on Theorem 4.1 we now compute the explicit forms of the conserved operators $\mathscr{W}_n = \mathscr{Y}_n(\xi)|_{\xi_j=-\nu-(j-1)\mu}$. Explicit forms of these operators are given by the following theorem.

Theorem 4.2: *The Ruijsenaars operators $\mathscr{W}_n$ (4.10) are explicitly given by*

$$\mathscr{W}_n = \sum_{\substack{J\subset\{1,\ldots,N\},|J|\leqslant n \\ \epsilon_j=\pm 1, j\in J}} U_{J^c,n-|J|} V_{\epsilon J;J^c} T_{\epsilon J}, \quad \text{for } 1\leqslant n\leqslant N. \tag{4.19}$$

Here the shift operator $T_{\epsilon J}$ and functions $U_{K,m}$ and $V_{\epsilon J;K}$ are, respectively, defined as

$$T_{\epsilon J} = \prod_{j\in J} T_j(2\epsilon_j\beta), \tag{4.20a}$$

$$V_{\epsilon J;K} = \prod_{j\in J} H(\epsilon_j z_j)\overline{H}(\epsilon_j z_j+\beta) \prod_{\substack{j,j'\in J \\ j<j'}} \sigma_\mu(\epsilon_j z_j+\epsilon_{j'} z_{j'})\sigma_\mu(\epsilon_j z_j+\epsilon_{j'} z_{j'}+2\beta)$$

$$\times \prod_{\substack{j\in J \\ k\in K}} \sigma_\mu(\epsilon_j z_j+z_k)\sigma_\mu(\epsilon_j z_j-z_k), \tag{4.20b}$$

$$U_{K,m} = (-1)^m \sum_{\substack{J\subset K,|J|=m \\ \epsilon_j=\pm 1, j\in J}} w_{m,|K|-m}(-\epsilon_{j_1} z_{j_1},\ldots,-\epsilon_{j_m} z_{j_m}) \prod_{j\in J} H(\epsilon_j z_j)$$

$$\times \prod_{\substack{j,j'\in J \\ j<j'}} \sigma_\mu(\epsilon_j z_j+\epsilon_{j'} z_{j'}) \prod_{\substack{j\in J \\ k\in K\setminus J}} \sigma_\mu(\epsilon_j z_j+z_k)\sigma_\mu(\epsilon_j z_j-z_k), \tag{4.20c}$$

where

$$G(\xi,z) = \sum_{r=0}^{3} g_r \sigma_{2\xi}^r(z), \quad H(z) = G(\nu,z), \tag{4.21a}$$

$$\overline{G}(\xi,z) = \sum_{r=0}^{3} \overline{g}_r \sigma_{2\xi}^r(z), \quad \overline{H}(z) = \overline{G}(\overline{\nu},z). \tag{4.21b}$$

The function $w_{p,q}(z_1,\ldots,z_p)$ is a symmetric function of p variables, and recursively defined as

$$
\begin{aligned}
w_{p+1,q}(z_1,\ldots,z_{p+1}) = w_{p,q}(z_1,\ldots,z_p)\Bigg(&\Bigg(\prod_{k=1}^{p}\sigma_\mu(z_{kp+1})\Bigg)\overline{G}(-\nu-(p+q)\mu,-z_{p+1}+\beta)\\
&-\sum_{j=1}^{p}\sigma_{-2\nu-(p+2q)\mu}(z_{jp+1})\Bigg(\prod_{\substack{k=1\\k\neq j}}^{p}\sigma_\mu(z_{kj})\Bigg)\overline{G}(-\nu-(p+q)\mu,-z_j+\beta)\Bigg)\\
&-\sum_{j=1}^{p}w_{p-1,q}(z_1,\ldots,z_{j-1},z_{j+1},\ldots,z_p)\Bigg(\prod_{\substack{k=1\\k\neq j}}^{p}\sigma_\mu(z_{kj})\Bigg)\\
&\times\Bigg(\prod_{\substack{k=1\\k\neq j}}^{p}\sigma_\mu(z_k+z_j-2\beta)\Bigg)\overline{H}(-z_j+\beta)\\
&\times\overline{H}(z_j-\beta)\sigma_{-2\nu-(p+2q)\mu}(-z_j-z_{p+1}+2\beta),
\end{aligned}
\tag{4.22}
$$

where the first two functions are given by

$$
w_{1,q}(z_1)=\overline{G}(-\nu-q\mu,-z_1+\beta),
\tag{4.23a}
$$

$$
\begin{aligned}
w_{2,q}(z_1,z_2)=&\overline{G}(-\nu-q\mu,-z_1+\beta)\overline{G}(-\nu-q\mu,-z_2+\beta)\sigma_\mu(z_1+z_2-2\beta)\\
&-\overline{d}(-\nu-q\mu)\sigma_{-2\nu-(2q+1)\mu}(-z_1-z_2+2\beta).
\end{aligned}
\tag{4.23b}
$$

The function $w_{p,q}(z_1,\ldots,z_p)$ is indeed a symmetric function as will be shown in Lemma 4.3. We have not found a simple expression for a symmetric function $w_{p,q}$ in the case of $p\geqslant 3$. We remark that the function $w_{p,q}(z_1,\ldots,z_p)$ can be rewritten as

$$
\begin{aligned}
w_{p,q}(z_1,\ldots,z_p)=&\prod_{k=1}^{p}\overline{G}(-\nu-q\mu,-z_k+\beta)\prod_{1\leqslant k<k'\leqslant p}\sigma_\mu(z_k+z_{k'}-2\beta)\\
&+\overline{d}(-\nu-q\mu)f_{p,q}(z_1,\ldots,z_p),
\end{aligned}
\tag{4.24}
$$

for some symmetric function $f_{p,q}(z_1,\ldots,z_p)$. By using this expression, one sees, in the case of $\nu+\overline{\nu}=0$, that the highest conserved operator $\mathscr{W}_N$ takes a simple form since $\overline{d}(\overline{\nu})=0$ and that it reduces to the operator proposed in Ref. 7 (see also Ref. 6).

To prove Theorem 4.2, we use the following two lemmas.

Lemma 4.3: The zeroth power term of the shift operator in $\overline{\mathscr{K}}_m^n$ (4.5) *is given by function $w_{n-m+1,m-1}(z_m,\ldots,z_n)$, which satisfies* (4.22) *and* (4.23).

Proof: We show this lemma by mathematical induction for n. For $n=m$ and $n=m+1$ cases, Eq. (4.23) can be shown by a direct calculation. We check the $n+1$ case. Since the operator $\overline{\mathscr{K}}_m^{n+1}$ can be rewritten by use of $\overline{\mathscr{K}}_m^n$ as

$$
\overline{\mathscr{K}}_m^{n+1}=\overline{\mathscr{K}}_m^n\Bigg(\prod_{k=m}^{n}\sigma_\mu(z_{kn+1})-\sum_{l=m}^{n}\sigma_{\xi_m+\xi_{n+1}}(z_{ln+1})\prod_{\substack{k=m\\k\neq l}}^{n}\sigma_\mu(z_{kl})\hat{s}_{ln+1}\Bigg)\overline{K}^{n+1}(\xi_{n+1}),
\tag{4.25}
$$

one finds that the zeroth power term and the $T_j(-2\beta)$ term in $\overline{\mathscr{K}}_m^n$ only contribute to the zeroth power term in $\overline{\mathscr{K}}_m^{n+1}$. As the $T_n(-2\beta)$ term in $\overline{\mathscr{K}}_m^n$ is easily given by

$$
w_{n-m,m}(z_m,\ldots,z_{n-1})\prod_{k=m}^{n-1}\sigma_\mu(z_{kn})(-\overline{H}(-z_n+\beta))T_n(-2\beta)\hat{t}_n,
\tag{4.26}
$$

the $T_j(-2\beta)$ terms in $\bar{\mathscr{K}}_m^n$ are given by symmetrizing (4.26). Substituting these expressions into (4.25) and gathering the zeroth power terms, we obtain the recursive equations for functions $w_{p,q}$ (4.22).

The fact that the function $w_{p,q}$ is symmetric is trivial by construction. □

Lemma 4.4: On the space both W_A-invariant in $z_m,\ldots,z_n$ and W_B-invariant in $z_1,\ldots,z_{m-1}$, the operator $\mathscr{R}_m^n.\mathscr{K}_m^n.\bar{\mathscr{R}}_m^n$ is explicitly given by

$$\mathscr{R}_m^n.\mathscr{K}_m^n.\bar{\mathscr{R}}_m^n=(-1)^{n-m+1}\sum_{\substack{J\subset\{1,\ldots,n\},|J|=n-m+1\\ \epsilon_j=\pm 1,j\in J}}\prod_{j\in J}H(\epsilon_j z_j)\prod_{\substack{j,j'\in J\\ j<j'}}\sigma_\mu(\epsilon_j z_j+\epsilon_{j'}z_{j'})$$
$$\times\prod_{\substack{j\in J\\ k\in\{1,\ldots,n\}\setminus J}}\sigma_\mu(\epsilon_j z_j+z_k)\sigma_\mu(\epsilon_j z_j-z_k)\left(\prod_{j\in J,\epsilon_j=1}\hat{t}_j\right)\hat{s}_{\{m,\ldots,n\},J}. \tag{4.27}$$

Proof: First we note that this operator maps the above space to W_B-invariant space in $z_1,\ldots,z_n$. Hence it is sufficient to calculate the $\Pi_{j=m}^n\hat{t}_j$ term, which is simply computed as

$$\left(\prod_{j=m}^n(-H(z_j))\right)\left(\prod_{m\leqslant j<j'\leqslant n}\sigma_\mu(z_j+z_{j'})\right)\left(\prod_{j=m}^n\prod_{k=1}^{m-1}\sigma_\mu(z_{jk})\sigma_\mu(z_j+z_k)\right)\prod_{j=m}^n\hat{t}_j. \tag{4.28}$$

By the W_B-invariance, we obtain the result. □

Now we are in position to show Theorem 4.2.

Proof: We shall calculate terms $\Pi_{j=q}^N T_j(2\beta)$ for $N-n+1\leqslant q\leqslant N$ in operators $\mathscr{W}_n$, which appear only in the following form:

$$\mathscr{R}_{N-n+1}^{q-1}.\mathscr{K}_{N-n+1}^{q-1}.\bar{\mathscr{R}}_{N-n+1}^{q-1}\left(\prod_{j=q}^N\prod_{k=N-n+1}^{q-1}\sigma_\mu(z_{jk})\right)\bar{\mathscr{K}}_{N-n+1}^{q-1}$$
$$\times\left(\prod_{j=q}^N H(z_j)\bar{H}(z_j+\beta)\right)\left(\prod_{q\leqslant j<j'\leqslant N}\sigma_\mu(z_j+z_{j'})\sigma_\mu(z_j+z_{j'}+2\beta)\right)$$
