$$\times\left(\prod_{j=q}^N\prod_{k=1}^{N-n}\sigma_\mu(z_{jk})\sigma_\mu(z_j+z_k)\right)\left(\prod_{j=q}^N\prod_{k=N-n+1}^{q-1}\sigma_\mu(z_j+z_k)\right)\prod_{j=q}^N T_j(2\beta). \tag{4.29}$$

By Lemma 4.3 and 4.4, we can pick up the zeroth power terms in $\mathscr{R}_{N-n+1}^{q-1}.\mathscr{K}_{N-n+1}^{q-1}.\bar{\mathscr{R}}_{N-n+1}^{q-1}$ and $\bar{\mathscr{K}}_{N-n+1}^{q-1}$. Then we have the explicit forms

$$U_{\{1,\ldots,q-1\},q-N+n-1}\left(\prod_{j=q}^N H(z_j)\bar{H}(z_j+\beta)\right)\left(\prod_{q\leqslant j<j'\leqslant N}\sigma_\mu(z_j+z_{j'})\sigma_\mu(z_j+z_{j'}+2\beta)\right)$$
$$\times\left(\prod_{j=q}^N\prod_{k=1}^{q-1}\sigma_\mu(z_{jk})\sigma_\mu(z_j+z_k)\right)\prod_{j=q}^N T_j(2\beta). \tag{4.30}$$

The W_B-invariance of operator $\mathscr{W}_n$ implies Theorem 4.2. □

V. CONCLUSION

We have constructed two sets of commutative difference operators associated with the Weyl group of type-*A* and type-*B*. By use of a pictorial interpretation, we have shown that they possess the Weyl group invariance, and that the higher conserved operators can be constructed in terms of the operator-valued solutions of the YBE and the RE. We have also computed the explicit forms of all the conserved operators. It has been shown that the conserved operators of type-*A* coincide with the elliptic Macdonald operators, which are gauge equivalent with the Hamiltonians of the Ruijsenaars models. We note that our *D*-type Hamiltonian (4.1) is the most general integrable

Hamiltonian, which contains ten arbitrary parameters. One sees[4] that, in a certain limit, it reduces to the so-called Macdonald–Koornwinder operator i.e., the multivariable Askey–Wilson operator. Contrary to the case of the Askey–Wilson polynomial, a unity is not an eigenfunction of our operator $\mathscr{W}_1$ (4.1) except the case, $\overline{\nu}+\nu=-(N-1)\mu$. It is a challenging problem to determine how we diagonalize the elliptic difference operators $\mathscr{M}_n$ (3.1) and $\mathscr{W}_n$ (4.10) by use of the ''symmetric'' and ''nonsymmetric'' elliptic functions.

APPENDIX: FUNDAMENTAL FUNCTIONS AND IDENTITIES

We shall establish notations and useful identities on the theta functions[27,28] used in this paper. The Jacobi theta functions are defined for $\Im\tau>0$ as

$$\vartheta_1(z)=-\mathrm{i}\sum_{n\in\mathbb{Z}}\exp\left(\mathrm{i}\pi\left(n+\frac{1}{2}\right)^2\tau+2\pi\mathrm{i}\left(n+\frac{1}{2}\right)z+\mathrm{i}\pi n\right), \tag{A1a}$$

$$\vartheta_2(z)=\sum_{n\in\mathbb{Z}}\exp\left(\mathrm{i}\pi\left(n+\frac{1}{2}\right)^2\tau+2\pi\mathrm{i}\left(n+\frac{1}{2}\right)z\right), \tag{A1b}$$

$$\vartheta_3(z)=\sum_{n\in\mathbb{Z}}\exp(1\pi n^2\tau+2\pi\mathrm{i}nz), \tag{A1c}$$

$$\vartheta_0(z)=\sum_{n\in\mathbb{Z}}\exp(\mathrm{i}\pi n^2\tau+2\pi\mathrm{i}nz+\mathrm{i}\pi n), \tag{A1d}$$

and $\vartheta_4(z)=\vartheta_0(z)$. These functions have a kind of periodic behavior under the translation generated by 1 and τ. Note that $\vartheta_1(z)$ is odd while the other three are even.

Let us define functions $\sigma_\mu^r(z)$ for $r=0,1,2,3$ in terms of the Jacobi theta functions by

$$\sigma_\mu^r(z)=\frac{\vartheta_{r+1}(z-\mu)\vartheta_1'(0)}{\vartheta_{r+1}(z)\vartheta_1(-\mu)}, \tag{A2}$$

where $\vartheta_1'(z)$ denotes a derivative of $\vartheta_1(z)$ with respect to z. In this paper we often refer to $\sigma_\mu^0(z)$ as $\sigma_\mu(z)$ for brevity. We remark that the elliptic functions $\sigma_\mu^r(z)$ satisfy[27,28]

$$\sigma_{-\mu}^r(-z)=-\sigma_\mu^r(z), \tag{A3}$$

$$\sigma_\mu^r(z)\sigma_\mu^r(-z)=\wp(\mu)-\wp(z+\omega_r), \tag{A4}$$

$$\sum_{i=1}^{q}\left(\prod_{\substack{k=1\\k\neq i}}^{q}\sigma_{\mu_k}(z_{ki})\right)\sigma_{\Sigma_{j=1}^q\mu_j}(z_i)=\prod_{k=1}^{q}\sigma_{\mu_k}(z_k), \tag{A5}$$

where $\wp(z)$ is Weierstrass's $\wp$-function with periods 1 and τ.

Discrete spectral triples and their symmetries

Mario Paschke[a] and Andrzej Sitarz[b]
Institut für Physik, Johannes-Gutenberg Universität, 55130 Mainz, Germany

(Received 28 February 1997; accepted for publication 24 September 1997)

We classify zero-dimensional spectral triples over complex and real algebras and provide some general statements about their differential structure. We investigate also whether such spectral triples admit a symmetry arising from the Hopf algebra structure of the finite algebra. We discuss examples of commutative algebras and group algebras. © *1998 American Institute of Physics.* [S0022-2488(98)01603-X]

I. INTRODUCTION

Recently Connes[1] has proposed a definition of *spectral triples*, which is supposed to extend the notion of the Riemannian geometry to a noncommutative setup. This could be a natural geometrical framework for theories of fundamental interactions and gravity at a small distance scale and could possibly open a way towards quantum gravity.

One of the promising applications to fundamental particle physics is an attempt to explain the particle contents and interaction pattern in the Standard Model. A finite algebra $M_3(\mathbb{C})\oplus\mathbb{H}\oplus\mathbb{C}$ plays a significant role in the spectral triple in question. In this paper we shall not discuss this particular physical application. (For a more detailed discussion of the Standard Model spectral triple see Ref. 2.)

We derive here the general structure of zero-dimensional spectral triples and of the Dirac operator for complex and real semisimple algebras. Moreover, assuming that such algebras are Hopf algebras, we discuss possible symmetry structures. As examples we present $\mathbb{C}^n$ commutative algebra with discrete group structure as well as group algebras, particularly $\mathbb{C}S_3$ for the permutation group S_3.

II. COMPLEX SPECTRAL TRIPLES

Let $\mathcal{A}_F$ be a finite-dimensional semi-simple algebra over the field of complex numbers $\mathbb{C}$. (C^* algebras are semisimple, thus we consider only them. Of course, nonsemisimple algebras (Grassman variables, for instance) may also appear in physical models. Whether one can successfully construct a corresponding theory for them remains an interesting problem.) Such an algebra is isomorphic to $M_{n_1}(\mathbb{C})\oplus\cdots\oplus M_{n_k}(\mathbb{C})$ for some nonzero integers $n_1,\ldots,n_k$ (see Ref. 3, pp. 29–36).

A *spectral triple* for a finite algebra means a finite Hilbert space $\mathcal{H}$, a faithful representation $\pi:\mathcal{A}\to B(\mathcal{H})$ over the field $\mathbb{C}$, a reality structure J, such that J is an antilinear isometry of $\mathcal{H}$, $J^2=1$, and $\pi^0=J\circ\pi^*\circ J$ is a representation of the opposite algebra $\mathcal{A}^0$, which commutes with π:

$$[\pi^0(a),\pi(b)]=0 \quad \forall a,b\in\mathcal{A}.$$

We assume that there exists a grading $\gamma\in B(\mathcal{H})$, such that $\gamma^*=\gamma$, $\gamma^2=1$, $J\gamma=\gamma J$, $\gamma\pi(a)=\pi(a)\gamma$, and γ is equal to $\pi(c)$ for some Hochschild cocycle $c\in Z_0(\mathcal{A},\mathcal{A}\otimes\mathcal{A}^0)$.

We begin with some simple observations.

Observation 1: $\mathcal{H}$ is a bimodule over $\mathcal{A}$. If $\xi\in\mathcal{H}$, then we have $a\xi=\pi(a)\xi$ and $\xi a=\pi^0(a)\xi$.

We can now use the structure of the finite algebra $\mathcal{A}$ to learn more about the Hilbert space of the spectral triple.

Lemma 1: Let P_i be the element of $\mathcal{A}$ with identity matrix in the ith entry and zeroes elsewhere. Let H_{ij} be $P_i\mathcal{H}P_j$. Then $\mathcal{H}$ is a direct sum of all H_{ij},

$$\mathscr{H}=\oplus_{i,j} H_{ij},$$

and if for every $a\in\mathscr{A}$ *we denote* $P_i a = a P_i$ as a_i *we have*

$$(a\xi)_{ij}=a_i\xi_{ij},\quad (\xi a)_{ij}=\xi_{ij}a_j.$$

The proof is a simple calculation and we skip it.

Lemma 2: The Hilbert subspace H_{ij} *has the following form:*

$$H_{ij}=\mathbb{C}^{n_i}\otimes\mathbb{C}^{r_{ij}}\otimes\mathbb{C}^{n_j},$$

where r_{ij} *are some integers,* $r_{ij}\geqslant 0$. *We take* $H_{ij}=0$ *iff* $r_{ij}=0$. *An element* a *acts on* H_{ij} *from the left as* $a_i\otimes 1\otimes 1$ *and from the right as* $1\otimes 1\otimes a_j^T$, *where* ^{T} *denotes the matrix transposition.*

From the previous lemma we know that H_{ij} is the representation space for $M_{n_i}(\mathbb{C})$ and for the opposite algebra of $M_{n_j}(\mathbb{C})$. Because these representations commute, the structure of H_{ij} must have the above form.

Lemma 3: The grading operator γ *is* ± 1 *when restricted to the subspace* H_{ij}.

Proof: Since γ commutes with both the elements of $\mathscr{A}$ and J, and is self-adjoint, we conclude that it also commutes with the right multiplication on $\mathscr{H}$:

$$a(\gamma\xi)b=\gamma(a\xi b).$$

Hence, $\gamma H_{ij}\subset H_{ij}$. When restricted to H_{ij}, γ is an isometry, which commutes with the left multiplication by matrices from $M_{n_i}(\mathbb{C})$ and right multiplication by matrices from $M_{n_j}(\mathbb{C})$. Therefore it must be of the form

$$\gamma_{ij}: H_{ij}\to H_{ij},\quad \gamma=1_{n_i}\otimes\Gamma_{ij}\otimes 1_{n_j},$$

where Γ_{ij} is an arbitrary self-adjoint matrix, such that $\Gamma_{ij}^2=1$ acting on $\mathbb{C}^{r_{ij}}$. However, if we take into account that γ is an image of a Hochschild cocycle, i.e., there exists an element c of $\mathscr{A}\otimes\mathscr{A}^0$ such that $\pi(c)=\gamma$, we see that Γ_{ij} must be proportional to the identity matrix, so it leaves only the possibility for $+1$ or -1. ■

Lemma 4: The reality J *maps* H_{ij} *onto* H_{ji}, *therefore* r_{ij} *must be equal to* r_{ji}.

Proof: Let us take $\xi\in H_{ij}$. There exists $\nu\in\mathscr{H}$ such that $\xi=P_i\nu P_j$. Next, we calculate $J\xi$, writing all the expressions carefully:

$$J\xi=JP_i\nu P_j=J\pi(P_i)(J\pi(P_j)J)\nu=(JP_iJ)P_j(J\nu)=P_j(J\nu)P_i\in H_{ji}.$$

Of course, since $J^2=\mathrm{id}$ we must have $r_{ij}=r_{ji}$ so that the dimensions of both Hilbert spaces are equal. ■

Observation 2: If we denote by γ_{ij} *the sign of the grading on* H_{ij}, *then* $\gamma_{ij}=\gamma_{ji}$.

This is a trivial consequence of the commutation relation $[J,\gamma]=0$.

We can now introduce $q_{ij}=r_{ij}\gamma_{ij}$, which, later on, could be identified as the intersection form for our spectral triple. So far, we know that q_{ij} is a symmetric matrix with integer entries.

Lemma 5: There exists a basis of H_{ij}, H_{ji} *of the form* $H_{ij}\ni\nu=\nu_i\otimes\nu_{ij}\otimes\nu_j$ *such that*

$$J\nu=\nu_j\otimes\nu_{ji}\otimes\nu_i\in H_{ji}. \tag{1}$$

Proof: We begin with the $i\neq j$ case. First of all, let us fix an orthonormal basis of the spaces H_{ij} and H_{ji} of the form $e_1\otimes e_2\otimes e_3$ and define $\tilde{J}$ as an antilinear isometry operator, which exchanges the first and the third element of the tensor product:

$$\tilde{J}(e_1\otimes e_2\otimes e_3)=e\otimes e_2\otimes e_1.$$

Then $\tilde{J}$ satisfies all the axioms for the spectral triple, i.e., $\tilde{J}^2=1$ and $a^0=\tilde{J}a^\dagger\tilde{J}$. Next, observe that $J\circ\tilde{J}$ is a linear invertible map, such that

$$J\circ\tilde{J}a = aJ\circ\tilde{J}$$

and

$$J\circ\tilde{J}a^0 = a^0 J\circ\tilde{J}.$$

We prove only the first of the two:

$$J\circ\tilde{J}a = J\circ\tilde{J}a\tilde{J}^2 = J(a^\dagger)^0\tilde{J} = J^2 aJ\circ\tilde{J} = aJ\circ\tilde{J}.$$

Therefore $J\circ\tilde{J}$ commutes both with the left and the right multiplication, so it has to be of the form $1\otimes\tilde{l}\otimes 1$, where $\tilde{l}$ is a linear isometry $l:\mathbb{C}^{r_{ij}}\to\mathbb{C}^{r_{ji}}$. Thus $J=(1\otimes\tilde{l}^{-1}\otimes 1)\circ\tilde{J}$ and the only possible nontrivial part of J comes from $\tilde{l}$.

In the last step we have to consider the cases $j=i$ and $j\neq i$ separately. The latter one is simpler, we just chose any orthonormal basis e_s of $C^{r_{ij}}$ (same as in the definition of $\tilde{J}$) and then $\tilde{l}^{-1}e_s$ constitutes a basis of $C^{r_{ji}}$. Take as ν_{ij} just the vectors of the chosen basis and ν_{ji} their image under $\tilde{l}^{-1}$. Then the property (1) follows immediately.

A more subtle situation occurs in the $i=j$ case. Here, however, we can use another simple argument. Take $\nu\in C^{r_{ii}}$. Then either $\tilde{l}^{-1}\nu$ is proportional to ν or is linearly independent from it. In the latter case it is sufficient to consider ν_{ii} to be $\nu+\tilde{l}^{-1}\nu$ and $i(\nu-\tilde{l}^{-1}\nu)$. In the first case $\tilde{l}^{-1}\nu=e^{i\phi}\nu$ and then $e^{i\phi/2}\nu$ will do as ν_{ii}. Since our space is finite dimensional and l is an isometry we can carry on with this procedure until we find a complete basis of H_{ii} satisfying our requirement. ■

A. The Dirac operator

Up to this point we have constructed the basic geometry of a finite spectral triple and in the next step we shall introduce the Dirac operator, which gives the differential and metric structures.

The Dirac operator D of a finite spectral triple is a self-adjoint linear operator on $\mathscr{H}$, which commutes with J: $DJ=JD$, anticommutes with γ: $D\gamma=-\gamma D$, and satisfies the following relation:

$$[[D,\pi(a)],\ \pi^0(b)]=0 \quad \forall a,b\in\mathscr{A}. \tag{2}$$

Observation 3: Let $D_{ij,kl}=P_{ij}DP_{kl}$, where P_{ij} is the projection operator on H_{ij}: ($P_{ij}\nu=P_i\nu P_j$). Then the following is true:

(1) *$D_{ij,kl}:H_{kl}\to H_{ij}$ is a linear map, which is zero unless $\gamma_{ij}\gamma_{kl}<0$ (i.e., they are of opposite sign).*
(2) *$D^\dagger_{ij,kl}=D_{kl,ij}$. This follows easily from the requirement $D=D^\dagger$.*
(3) *$D_{ij,kl}=JD_{ji,lk}J$. This follows from the relation $[D,\ J]=0$ and $J^2=\mathrm{id}$. If we choose the basis of the spaces H_{ij} so that the operator J has a preferred form $J\nu=\pm\nu$, the above condition can be simplified to $D_{ij,kl}=D^*_{ji,lk}$, where $*$ means the complex conjugation of matrix elements of $D_{ji,lk}$ in the preferred basis.*

The strongest restriction for the Dirac operator follows from the commutation property (2).

Lemma 6: The Dirac operator component $D_{ij,kl}$ vanishes unless $i=k$ or $j=l$. In either of these cases D must commute with the corresponding action of the $\mathscr{A}$ or $\mathscr{A}^0$, respectively.

Proof: Let us rewrite the condition (2) for $\nu\in H_{kl}$:

$$D_{ij,kl}(a_k\nu b_l)-a_iD_{ij,kl}(\nu b_l)-(D_{ij,kl}(a_k\nu))b_j+a_i(D_{ij,kl}\nu)b_j=0.$$

Choosing $b=P_j$, $j\neq l$, we get that $D_{ij,kl}=0$ unless $i=k$ and, for $i=k$, $D_{ij,il}a_i=a_iD_{ij,il}$ for every $a\in\mathscr{A}$.

Similarly, if we choose $a=P_i$, $i\neq k$, we get that $D_{ij,kl}=0$ unless $j=l$ and additionally $D_{ij,kj}(\nu b_j)=(D_{ij,kj}\nu)b_j$.

Of course, the case $i=k$ and $j=l$ is excluded by the requirement that D acts only between spaces of different grading. ■

B. Differential algebra

The Dirac operator D provides us with both the metric and the differential properties on the finite space corresponding to the algebra $\mathcal{A}$. We shall now concentrate on some general properties of the differential structure.

Observation 4: The representation π of $\mathcal{A}$ extends to the universal differential algebra $\Omega_u\mathcal{A}$, by

$$\pi(a_0 da_1 d_2 \cdots da_n) = \pi(a_0)[D,\pi(a_1)]\cdots[D,\pi(a_n)].$$

The differential calculus is usually constructed as follows: first, $\Omega^1(\mathcal{A})$ is the quotient of $\Omega^1_u\mathcal{A}$ by the kernel of π. Therefore the bimodule $\Omega^1(\mathcal{A})$ is isomorphic to $\pi(\Omega^1_u(\mathcal{A}))$. Higher-order forms are obtained by taking the quotient of the universal forms of a given order by the ideal $\Omega^n_u\mathcal{A}\cap(\ker\pi\cup d\ \ker\pi)$.

Let us state some general results.

Lemma 7: The first-order differential calculus is inner; there exists a one-form

$$\xi=\sum_{i\neq j} P_i dP_j, \tag{3}$$

such that for every $a\in\mathcal{A}$ one has $da=[\xi,\ a]$. The Dirac operator $D=\pi(\xi)+J\pi(\xi)J$.

Proof: Of course, from the definition we have $\pi(da)=[D,\ \pi(a)]$, so one has to show

$$\sum_{i\neq j}[\pi(P_i)[D,\ \pi(P_j)],\ \pi(a)]=[D,\ \pi(a)].$$

Let us compute $\xi_{ij,kl}=P_{ij}\pi(\xi)P_{kl}$. For any $h\in H_{kl}$ we have

$$(\pi(\xi)h)_{ij}=\left(\sum_{s\neq t} P_s[D,\ P_t]h\right)_{ij}=\sum_{s\neq t}(P_sDP_th)_{ij}=(P_iDP_kh)_{ij}=\delta_{jl}D_{ij,kj}h.$$

Note that

$$\xi=\sum_{i\neq j} P_i dP_j=-\sum_i P_i dP_i.$$

The relation $D=\pi(\xi)+J\pi(\xi)J$ follows immediately from the properties of J and D, additionally $[J\xi J,\ a]=0$ for every element $a\in\mathcal{A}$, so that the property $da=[D,\ a]=[\xi,\ a]$ holds.■

Observation 5: $\pi(\xi)$ is a self-adjoint operator, thus the first-order calculus has a natural involution map such that $d\circ *=-(*\circ d)$ if we define $\xi^*=\xi$.

The one-form ξ has some more interesting properties, which make the task of determining the differential structure easier. Before we discuss the construction of $\Omega^2(\mathcal{A})$ let us make another useful remark.

Observation 6: The bimodule $\Omega^1(\mathcal{A})$ has no center. If $a\omega=\omega a$ for every element $a\in\mathcal{A}$, then $\omega=0$.

Proof: First, let us observe that for every idempotent $e=e^2$, we have $edee=0$. This follows from differentiating $0=e^2-e$ and multiplying it from the left and from the right by e. Therefore $P_idP_iP_i=P_i\xi P_i=0$.

Every element of $\Omega^1(\mathcal{A})$ could be written as a finite sum of the type $\omega=\Sigma_\alpha b_\alpha\xi c_\alpha$. Suppose that it commutes with every $a\in\mathcal{A}$, in particular with P_i. Then if we multiply both sides by P_i, since $P_i^2=P_i$ we get $P_i\omega P_i=P_i\omega$. However, $P_i\omega P_i=0$ as P_i commute with elements of the algebra and $P_i\xi P_i=0$. So $P_i\omega=0$ for every i, and therefore $\omega=0$. ■

Lemma 8: $d\xi=\xi\xi-\Sigma P_i\xi\xi P_i$.

Proof:

$$d\xi=-\sum_i dP_i dP_i=-\sum_i[\xi,\ P_i][\xi,\ P_i]=\xi\xi+\sum_i P_i\xi\xi P_i.$$

■

The above equality holds only within the differential algebra, which means that all products of one-forms in the line above must be calculated using the product in $\Omega^2(\mathcal{A})$. We have not determined it yet (in a general situation it is a difficult technical calculation), however, using the above relations we will be able to say something about it.

Lemma 9: Let $\Omega^1(\mathcal{A})\otimes_{\mathcal{A}}\Omega^1(\mathcal{A})\ni\Xi=\Sigma_i P_i\xi\otimes_{\mathcal{A}}\xi P_i$. *Let* $\mathcal{J}_1=\ker\pi$ [*where* π *on* $\Omega^1(\mathcal{A})\otimes_{\mathcal{A}}\Omega^1(\mathcal{A})$ *is defined in the usual way*: $\pi(\omega_1\otimes_{\mathcal{A}}\omega_2)=\pi(\omega_1)\pi(\omega_2)$], $\mathcal{J}_2$ *be the subbimodule generated by commutators* $[a,\Xi]$ *for all* $a\in\mathcal{A}$, *and finally let* $\mathcal{J}_3$ *be the subbimodule generated by all elements of the form* $\Sigma_i a_i(\xi\otimes_{\mathcal{A}}\xi-\Xi)b_i$ *for all* a_i, b_i *such that* $\Sigma_i a_i\xi b_i=0$. *Then* $\mathcal{J}=\mathcal{J}_1\oplus\mathcal{J}_2\oplus\mathcal{J}_3$ *is a subbimodule of* $\Omega^1(\mathcal{A})\otimes_{\mathcal{A}}\Omega^1(\mathcal{A})$ *and* $\Omega^2(\mathcal{A})=\Omega^1(\mathcal{A})\otimes_{\mathcal{A}}\Omega^1(\mathcal{A})/\mathcal{J}$.

Proof: We know that every element of $\Omega^1(\mathcal{A})$ can be written as a finite sum of $\omega=a\xi b$. One easily finds $d\omega$,

$$d\omega=\xi\omega-\omega\xi+a(\tilde{\Xi}-\xi\xi)b, \tag{4}$$

and, in a special case, when ω is of the form $da=\xi a-a\xi$, we obtain

$$d^2a=\tilde{\Xi}a-a\tilde{\Xi}, \tag{5}$$

where $\tilde{\Xi}$ denotes an element in $\Omega^2(\mathcal{A})$ which is the image of Ξ. Now, we clearly see that division by $\mathcal{J}_2$ guarantees that d is well defined ($d0=0$) and $d^2\equiv 0$ if and only if we quotient out $\mathcal{J}_3$. Note that in order to obtain a differential algebra we do not need to include $\mathcal{J}_1$ as the quotient; however, we proceed so in order to be in agreement with the *standard* definition of the differential algebra for spectral triples. ■

Before we start considering an interesting simplification, let us say a bit more about the interpretation of $\xi\xi$ and Ξ. The image of the latter (under π) is an operator which links pairs of subspaces of $\mathcal{H}$, which have the same first index i. Clearly, it means that the Dirac operator ''connects'' $H_{ik}\to H_{pk}\to H_{ik}$, which is always the case, as ξ is self-adjoint (for every map $H_{ik}\to H_{pk}$ there exists a conjugate map $H_{pk}\to H_{ik}$). Now, $\pi(\Xi-\xi\xi)$ is a set of maps between subspaces of $\mathcal{H}$ with different first index, so it does not vanish if and only if ξ connects $H_{ij}\to H_{kj}\to H_{pj}$ for some $p\neq i$ and the composition of these maps does not vanish.

An interesting situation occurs when $\pi(\xi\otimes_{\mathcal{A}}\xi)=\pi(\Xi)$, so that $\mathcal{J}_2\subset\mathcal{J}_1$.

1. Inner calculi for spectral triples

Lemma 10: When $\pi(\xi\otimes_{\mathcal{A}}\xi)=\pi(\Xi)$, *then* $\tilde{\Xi}=\xi\xi$ *and the calculus remains inner in* $\Omega^2(\mathcal{A})$:

$$d\omega=\xi\omega+\omega\xi, \tag{6}$$

for any one-form ω. *The subbimodule* $\mathcal{J}$ *contains the kernel of* π *and all commutators* $[a,\ \xi\otimes_{\mathcal{A}}\xi]$.

This happens, for instance, if $\pi(\xi)\pi(\xi)$ is in $\pi(\mathcal{A})$; additionally, if it commutes with $\pi(\mathcal{A})$, then $\mathcal{J}=\ker\pi$ and the structure of $\Omega^2(\mathcal{A})$ simplifies considerably.

The next lemma makes these observations more precise:

Lemma 11: If $\pi(\xi)\pi(\xi)$ *commutes with* $\pi(Z(\mathcal{A}))$, *where* $Z(\mathcal{A})$ *is the center of* $\mathcal{A}$, *then* $\pi(\xi)\pi(\xi)=\pi(\Xi)$. *The converse is also true.*

Proof: Of course, if $\pi(\xi)\pi(\xi)$ commutes with $\pi(Z(\mathcal{A}))$ it commutes with every $\pi(P_i)$. Using $\Sigma_i P_i\equiv 1$ we get the required identity. For the converse, let us assume that there exists i such that $\pi(P_i)$ does not commute with $\pi(\xi)\pi(\xi)$ and let the commutator be ρ. Then it is easy to verify that $\pi(\xi)\pi(\xi)-\pi(\Xi)=\rho$. ■

It is quite interesting to characterize the space in which $\pi(\xi)\pi(\xi)$ takes value for this particular situation. We already know that it commutes with $\pi(\mathcal{A}^0)$. Since additionally it has to commute with the center of $\pi(\mathcal{A})$, the only possibility is that it is diagonal (i.e., when restricted to H_{ij} maps it to itself), and using the decomposition into tensor products presented in Sec. II, we find that it is $T_{ij}\otimes\mathrm{id}$ on each of the subspaces H_{ij}.

If the calculus [at least up to $\Omega^2(\mathcal{A})$] is inner, we can immediately make an interesting observation about the gauge potentials.

Observation 7: If H is a self-adjoint one-form and $F(H)=dH+HH$ is its curvature form, then for the inner calculus, as described above, $F(-2\xi)=0$.

This follows from a simple calculation. Of course, we have presented here only the *formal* solution of the $F(H)=0$ equation in $\Omega^2(\mathcal{A})$. It does not guarantee that this solution is unique; it could happen (for instance, if we take a tensor product of the spectral triple in question with a triple corresponding to a manifold) that there are far more solutions or even the whole subbimodule $\Omega^2(\mathcal{A})$ for the discrete part vanishes.

2. Commutative discrete spectral triples

A lot more can be said about the commutative case $\mathcal{A}=\mathbb{C}^n$. The generators of the algebra could be identified with the earlier introduced projection operators P_i. The structure of $\Omega^1(\mathcal{A})$ is completely determined by the elements $P_i dP_j$, $i\neq j$ (using $\Sigma_i dP_i=0$). In our representation we have

$$\pi(P_i dP_j)h=P_i DP_j h-P_i\delta_{ij}Dh,$$

which for the kl-component becomes

$$(\pi(P_i dP_j)h)_{kl}=\delta_{ik}D_{kljp}h_{jp}-\delta_{ik}\delta_{ij}D_{klps}h_{ps}=\cdots,$$

which, after taking into account the properties of D, becomes

$$\cdots=\delta_{ik}D_{iljl}h_{jl}-\delta_{ik}\delta_{ij}D_{klpl}h_{pl}.$$

Since we are interested in the case $i\neq j$ we obtain that for $P_i dP_j\neq 0$ it is sufficient that there exists l such that $D_{iljl}\neq 0$.

Let us now investigate $\Omega^2(\mathcal{A})$, which would be composed out of the bimodule $\Omega_u^2(\mathcal{A})$ after we quotient out the subbimodule generated by $\ker\pi\cup d\ker\pi$.

First, we show the representation action of the basis of $\Omega_u^2(\mathcal{A})$, $e_{kij}=P_k dP_i dP_j$, $k\neq i$ and $i\neq j$ (again, to see that this is the basis we use the identity $\Sigma_i dP_i=0$).

Observation 8: For i,j,k such that $k\neq i$ and $i\neq j$, $\pi(e_{kij})$ is a collection of maps $H_{jl}\mapsto H_{kl}$, each of the form

$$\pi(e_{kij})=D_{klil}D_{iljl}.$$

Next we shall show the structure of $d\ker\pi$.

Let us take a one-form ρ in $\ker\pi$. Of course, it is sufficient to take a generator: $\pi(P_i dP_j)=0$ for some $i\neq j$.

Let us calculate $\pi(dP_i dP_j)$. After little calculation we get the following result:

$$\pi(dP_i dP_j)h=-P_i D^2 P_j h \quad \text{if } P_i dP_j\in\ker\pi,\quad i\neq j. \tag{7}$$

Rewriting all that in terms of the basis of Ω_u^2 we obtain that for each $i\neq j$ if $\pi(P_i dP_j)=0$, we have the following generator added to the *junk*:

$$\sum_{i\neq s\neq j} P_i dP_s dP_j.$$

An easy way to visualize the construction of the differential structure coming from the commutative spectral triple is by the way of graphs. Imagine we have n vertices, and each vertex is *split* into n points. The nonzero entries of the Dirac operator shall correspond to arrows linking two points of two different vertices or within the same vertex (of course, due to the reality structure there exists a link between both).

If we look at the differential forms, the *fine* structure of the vertices becomes not so important.

Now, as for the one-forms, we know that $P_i dP_j$, $i\neq j$, exists if there is at least one arrow connecting vertex j with i. For a two-form $P_k dP_i dP_j$ there must exist links $j\to i\to k$. However, if there is no direct link $j\to k$, then the sum of all forms $\Sigma P_k dP_i dP_j$ over $i\neq k$ and $i\neq j$, vanishes. This bears a resemblance to a general structure of differential geometry on graphs.[4]

3. The metric

On the algebra $\mathscr{A}$ we have a natural trace coming from the representation on the Hilbert space $\mathscr{H}$. Since our representation extends naturally to the differential algebra, such a trace gives a *generic* scalar product on the space of one-forms. In particular, for the generators of the commutative algebra (which is the easiest example) we have

$$(P_i dP_j, P_k dP_l) = \mathrm{Tr}\,(\pi^*(P_i dP_j)\pi(P_k dP_l)) = \delta_{ik}\delta_{jl}\sum_p \mathrm{Tr}\,(D_{lpkp}D_{kplp}).$$

The last term of the expression is a self-adjoint map from H_{lp} into itself, therefore the scalar product is positive. All generating one-forms $P_i dP_j$ are orthogonal to each other and the norm of each is fixed by the elements of the Dirac operator. Of course, should the norm be zero then it is obvious that $\forall p\ D_{ipjp}=0$ and hence the one-form $P_i dP_j$ vanishes.

The above choice is not unique, and one may consider its deformation of the following type:

$$(\omega,\rho)z = \mathrm{Tr}\,(Z\pi(\omega)\pi(\rho)^\dagger),$$

where Z is an operator, for which it is sufficient to assume that Z is self-adjoint, and to keep the gauge invariance we need $\pi(U)Z\pi(U)^\dagger = Z$ for any unitary U from the algebra.

The reason for introducing such scaling may follow from the requirement that the trace has some additional symmetry (for instance, we might fix it to recover the Haar measure on the algebra, when it has a Hopf algebra structure).

Of course, changing the trace would have significant physical consequences (for details of the construction and application to the Standard Model, see the forthcoming Ref. 2).

C. Finite spectral triples with real algebras

So far we have discussed finite spectral triples with algebras over $\mathbb{C}$. Since the possible high-energy physics application of noncommutative geometry uses rather a real algebra, we shall now briefly discuss the above construction assuming that $\mathscr{A}$ is over the field of real numbers.

Lemma 12 (See Ref. 3): The simple finite algebras over $\mathbb{R}$ *are of the type* $M_n(F)$*, where* F *could be* $\mathbb{R}$, $\mathbb{C}$, *or* $\mathbb{H}$.

Therefore every semi-simple algebra over $\mathbb{R}$ could be decomposed as

$$\mathscr{A} = \bigoplus_i M_{n_i}(F_i), \tag{8}$$

where each F_i could be the field of real, complex, or quaternionic numbers.

We shall now investigate irreducible representations of $\mathscr{A}$ on a *complex* Hilbert space. Consider $M_n(\mathbb{R})$ and $M_n(\mathbb{H})$ as real algebras. Then each has only one irreducible representation on $\mathbb{C}$ (for quaternions the conjugate representation is equivalent to the fundamental one). As for $M_n(\mathbb{C})$ we have two inequivalent irreducible representations:

$$\pi(a) = a, \quad \overline{\pi}(a) = \overline{a},$$

where $\overline{a}$ means the involution of matrix elements.

How does the description of our spectral triple change? Apparently for $M_n(\mathbb{R})$ and $M_n(\mathbb{H})$ there is no change at all, whereas for $M_n(\mathbb{C})$ we have to take into account the existence of these two inequivalent representations:

Lemma 13: If $F_i=\mathbb{C}$*, then the Hilbert subspace* H_{ij} *decomposes into* H_{ij} *and* $H_{\bar{\imath}j}$*, with the representation of* $M_{n_i}(F_i)$ *by* m *and* $\overline{m}$*, respectively.*

Of course, an analogous decomposition takes place if one takes into account the right action of the algebra on $\mathscr{H}$.

Until now, there has not been much change apart from the additional splitting of the Hilbert space. All other results remain unchanged, in particular, γ cannot be different for H_{ij} and $H_{\bar{\imath}j}$.

If we look at the restrictions for the Dirac operator, which come from (2) we see that the constraints on allowed values of D also remain unchanged; however, one should add some more,

which arise from the fact that one cannot mix the fundamental and the conjugated representation. To see this explicitly one should replace in the proof of Lemma 6 $b=P_j$ by $b=zP_j$ for any complex number z.

Generally speaking, the derivation of the constraint, which we had for the complex case, could be repeated separately for each of the real situations. Therefore, we may summarize the result by stating that D does not mix two inequivalent representations of the same algebra.

D. The intersection form

The intersection form in K-theory is a map $K_*(\mathcal{A})\times K_*(\mathcal{A})\to\mathbb{Z}$ and its invertibility (Poincaré duality) is fundamental for a characterization of homotopy types of spaces, which possess the structure of a smooth manifold.

For finite complex spectral triples the intersection form, evaluated on generators of the K_0-group, e,f, is[1]

$$\langle e,f\rangle=\langle D,e\otimes f^o\rangle,$$

and, generally, the pairing $\langle D,E\rangle$ for a projector E means

$$\langle D,E\rangle=\dim\,\mathrm{coker}_{E\mathcal{H}_R}(ED^+E)-\dim\,\ker(ED^+E),$$

where $\mathcal{H}_L=\frac{1}{2}(1+\gamma).\mathcal{H}$, $\mathcal{H}_R=\frac{1}{2}(1-\gamma).\mathcal{H}$, and $D^+=\frac{1}{4}(1-\gamma)D(1+\gamma)$.

Since for matrix algebras the group K_1 is trivial (any element can be deformed to 1), the only nontrivial part is K_0. For $M_n(\mathbb{C})$ all projectors are equivalent [within $M_\infty(M_n(\mathbb{C}))$] to a diagonal matrix with 1 at the first diagonal entry and zeroes elsewhere, which we shall call e. Of course, for a direct sum of N simple algebras the corresponding K-theory will have N independent generators, each coming from the simple component of the sum.

Let us calculate the $\langle e_i,e_j\rangle$ entry. First, we have to determine the dimensions of Hilbert subspaces appearing in the above formulas:

$$\dim\,e_ie_j^0.\mathcal{H}_L=\begin{cases}r_{ij}, & \text{if } \gamma_{ij}=-1,\\ 0, & \text{if } \gamma_{ij}=1,\end{cases}\tag{9}$$

$$\dim\,e_ie_j^0.\mathcal{H}_R=\begin{cases}r_{ij}, & \text{if } \gamma_{ij}=1,\\ 0, & \text{if } \gamma_{ij}=-1.\end{cases}\tag{10}$$

Now, observe out of $e_ie_j^0.\mathcal{H}_L$ and $e_ie_j^0.\mathcal{H}_R$ one must always be empty, so the $e_ie_j^0D^+e_ie_j^0$ operator, which acts between them, has either domain or target space empty. Thus, the index is independent of D and reads

$$\langle e_i,e_j\rangle=\gamma_{ij}r_{ij}=q_{ij},$$

so we recover the matrix q as our intersection form.

For real algebras the calculation is slightly more complicated. First, one has to take into account the form of projectors for quaternions, which results in the doubling of the corresponding entries in the intersection form. Moreover, for real algebras the group K_1 is nontrivial, as $K_1(M_n(\mathbb{R}))=\mathbb{Z}_2$; however, this still does not change the intersection form if one does not take into account torsion in K-theory.

III. HOPF ALGEBRA SYMMETRIES

Spectral triples are expected to be an extension of the notion of Riemannian manifolds to noncommutative geometry. Similarly as in the standard differential geometry we may attempt to explore symmetries of such manifolds. We expect, however, that the correct idea of a symmetry should be extended from a group to a Hopf algebra (for a good introduction to Hopf algebras and quantum groups we refer the reader to Ref. 5). Another potentially interesting point is the speculation[1,6,7] that the finite algebra of the Standard Model originates from the q-deformation of the Spin structure and may possess some Hopf algebra symmetry (for details see also Ref. 8).

We shall try to answer the question of whether spectral triples admit (and if so, to what extent) a symmetry understood as a Hopf algebra symmetry. Of course, the natural thing is to use the Haar measure as a trace on the algebra and to extend it to the whole representation space. Another possibility is to demand that differential structures of the spectral triple are also symmetric, for instance, that they are left-covariant or bicovariant. Furthermore, the Hilbert space may be investigated for the existence of a comodule structure. Last but not least, we may turn our attention to the tensor product of representations (this is allowed only if a coproduct on the algebra exists), which physically has the meaning of constructing composite states. In this paper we concentrate our efforts on the first two aspects of symmetries, leaving the others for future investigations.

A. Discrete group structure on $\mathbb{C}^n$ algebra

One of the simplest examples of real spectral triples are those based on a finite-dimensional commutative algebra $\mathbb{C}^n$ understood as function algebras on a discrete n-point space. The general construction scheme was presented by Connes[1] and falls into the general classification of complex spectral triples presented in the previous section.

Suppose that we assume the discrete space to have the structure of a finite group and demand that the first-order differential calculus generated by D is bicovariant.

First, let us recall the basics of the bicovariant differential structure for finite groups (details in Ref. 9). The calculus is generated by left-covariant forms:

$$\chi^g=\sum_h e_{gh}de_g,$$

where e_g is a delta-Kronecker function: 1 at g and 0, elsewhere. The right coaction on them is

$$\Delta_R\chi^g=\sum_h \chi^{hgh^{-1}}\otimes e_h.$$

Using the spectral triple approach, we may calculate the χ^g forms as operators on our Hilbert space. It appears that

$$(\chi^g h)_{ij}=D_{ij,(ig^{-1})l}h_{(ig^{-1})l}.$$

Because of the properties of D we see that it is only possible that $j=l$ and therefore finally

$$(\chi^g h)_{ij}=D_{ij,(ig^{-1})j}h_{(ig^{-1})j},$$

so it is a collection of operators from $H_{(ig^{-1})j}\to H_{ij}$. Of course, if $\gamma_{ij}\gamma_{(ig^{-1})j}=1$ they all vanish because D acts only between spaces of different chirality.

What we have obtained so far is the representation of left-invariant forms as operators on our Hilbert space. We see that all χ^g which do not vanish are linearly independent (since they act between different Hilbert subspaces).

If we demand that the calculus is bicovariant, we immediately see that if for any g, χ^g vanishes, then for every h, $\chi^{hgh^{-1}}$ must vanish as well. Of course, for commutative groups such a condition is void; however, for non-Abelian ones it leads to certain restrictions on possible forms of D, which we make precise in the following lemma:

Lemma 14: If the spectral-triple calculus on $\mathbb{C}^n$ with a structure of the discrete group G is bicovariant, then

$$\text{if } \chi^g\neq 0, \quad \text{then } \forall i\in G\,\exists j\in G: D_{ij,(ig)j}\neq 0,$$

$$\text{if } \chi^g=0, \quad \text{then } \forall i\in G\,\forall j\in G: D_{ij,(ig)j}=0.$$

The proof is an immediate consequence of previous observations.

1. Function algebra on S_3

Consider as an example the six-dimensional space S_3. We shall check what restrictions on the spectral triple and the Dirac operator are set by the requirements that the corresponding calculus is bicovariant.

First, let us take the universal calculus. It appears that there exists a spectral triple which gives such a calculus. The simplest example is given by the following intersection form,

$$\begin{pmatrix} -1 & 1 & 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & 1 & 1 & 1 \\ 1 & 1 & 1 & -1 & 1 & 1 \\ 1 & 1 & 1 & 1 & -1 & 1 \\ 1 & 1 & 1 & 1 & 1 & -1 \end{pmatrix},$$

and is 36-dimensional! It is quite easy to see that this must be the case—for each χ^g not to vanish, the Dirac operator must link (for every i) some $H_{(ig^{-1})j}$ with H_{ij}. For the intersection matrix it means that for every row there always exists an entry which has an opposite sign to an entry in the same column of another row. It is easy to verify that such a matrix is nondegenerate so that the Poincaré duality axiom is fulfilled. Of course, to get the universal calculus, all possible Dirac operator elements must not vanish.

A more interesting case is when we require that the calculus is the lowest-dimensional bicovariant. For S_3 such a calculus is generated by χ^{ab} and χ^{ba}, where a and b denote the generators of S_3.

If we order the elements of S_3 as $a,b,c,1,ab,ba$, the example of a spectral triple which gives the desired calculus is defined by

$$\begin{pmatrix} 1 & 1 & -1 & 0 & 0 & 0 \\ 1 & -1 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & -1 \\ 0 & 0 & 0 & 1 & -1 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 \end{pmatrix}.$$

Again, all the possible elements of the Dirac operator (components which act between spaces of different chirality) must not vanish. Of course if we slightly change the intersection form (introduce, for instance, other nonzero entries in the intersection matrix) the bicovariance (two-dimensional) shall also be preserved provided that the additional allowed Dirac operator components vanish!

For physical interpretation this would mean that the symmetry requires some of the fermion particles in the model to be massless, whereas in the spectral triple presented above all mass matrices must be nonzero.

Noncommutative finite algebras cannot carry such a simple group structure and therefore we have to look for non-Abelian Hopf algebras. This itself is an interesting topic and very little is known about the general classification of such (semisimple) objects. The easiest examples come from group algebras and as we try to make our examples comprehensible, we shall use the simplest one of them, the group algebra $\mathbb{C}S_3$.

B. Group algebra S_3

We shall begin here with some generalities on Hopf and bicovariant differential structures on group algebras and then we shall present the interesting example of S_3.

1. Generalities on group algebras

The group algebra $\mathbb{C}G$ has a natural structure of a Hopf algebra with the following coproduct, counit, and antipode:

$$\Delta g = g \otimes g, \quad \varepsilon(g) = 1, \quad Sg = g^{-1}.$$

The adjoint coaction is trivial:

$$\mathrm{ad}(g) = g \otimes 1.$$

The Haar invariant measure μ is just $\mu(g) = 0$ for g different from the neutral element of the group.

Finally let us state some observations on the differential calculi.

Observation 9: The differential calculi on group algebras are always inner, i.e., there exists a one-form χ such that $dg = [g, \chi]$.

It is sufficient to take

$$\chi = -\frac{1}{N_G}\left(\sum_h h^{-1} dh\right).$$

Then

$$\begin{aligned}[g, \chi] &= -\frac{1}{N_G}\sum_h (gh^{-1}dh - h^{-1}dhg) \\ &= -\frac{1}{N_G}\sum_h (gh^{-1}dh - h^{-1}d(hg) - dg) \\ &= \frac{1}{N_G}\sum_h dg = dg.\end{aligned}$$

Observation 10: Since $\mathbb{C}G$ is cocommutative, every left-covariant calculus is bicovariant. There exists a 1:1 correspondence between bicovariant calculi and representations of the group G.

The first remark is obvious, so let us concentrate on the latter. Suppose we have a representation of G on some vector space V. We may define Ω_1 as a right-module $\mathbb{C}G \otimes V$, with the multiplication from the right by elements of $\mathscr{A}$ only on the first component of the tensor product. Then the following rule (it is sufficient to define it only for the generators) makes Ω_1 a bimodule:

$$h(g \otimes \nu) = (hg) \otimes (\pi(h)\nu).$$

Of course, Ω_1 is a bicovariant bimodule, with all the elements of type $1 \otimes \nu$ being left and right invariant. We already know that every differential calculus is inner and, moreover, it is easy to check that the one-form χ is left and right invariant. Therefore, to construct the calculus, it is sufficient to choose a $\chi = 1 \otimes \nu \in 1 \otimes V$ and define $dg = [g, \chi]$. It remains to show that $\mathrm{lm}\, d$ generates Ω_1. This is equivalent to verifying whether $\{\nu - \pi(h)\nu\}$, $h \in G$, generates the whole space V. Note that the representation π could be linearly extended on the whole group algebra $\mathbb{C}G$. Then the latter requirement tells us that the kernel of the counit acting on ν spans the whole space V.

The proof of the converse (every bicovariant calculus provides us with a representation of the group) is obvious.

Observation 11: The central part of $\Omega^1(\mathscr{A})$ consists of all one-forms of the type $\omega = \Sigma_g g \otimes \nu_g$, where $\nu_g \in V$ are vectors satisfying for every $g, h \in G$:

$$\pi(h)\nu_g = \nu_{hgh^{-1}}. \tag{11}$$

Of course, this condition may be void for some representation of the group G (in particular for a nontrivial one-dimensional representation).

Proof: Every one-form can be written as $\omega=\Sigma_g g\otimes\nu_g$ for some $\nu_g\in V$. If we require that $h\omega=\omega h$ for every $h\in G$, then it is easy to verify that (11) follows. ■

As an example we shall consider the smallest noncommutative group algebra $\mathbb{C}S_3$.

2. The group algebra $\mathbb{C}S_3$

The group S_3 has two generators a,b with the following multiplication rules:

$$a^2=e, b^2=e, aba=bab.$$

It is convenient to name the element $aba=c$, $c^2=e$ and use the rules for multiplication between a,b,c:

$$ab=bc,\quad ac=ba,\quad bc=ca.$$

As an algebra $\mathbb{C}S_3$ is isomorphic to the algebra $M_2(C)\oplus\mathbb{C}\oplus\mathbb{C}$. We shall present the form of this isomorphism i for the generators a,b:

$$i(a)=\begin{pmatrix} 1 & 0 & & \\ 0 & -1 & & \\ & & 1 & \\ & & & -1 \end{pmatrix},\quad i(b)=\begin{pmatrix} -\frac{1}{2} & \frac{\sqrt{3}}{2} & & \\ \frac{\sqrt{3}}{2} & \frac{1}{2} & & \\ & & 1 & \\ & & & -1 \end{pmatrix}.$$

The Haar measure on the Hopf algebra is defined as a linear map which satisfies

$$1\mu(f)=(\mathrm{id}\otimes\mu)\Delta f=(\mu\otimes\mathrm{id})\Delta f.$$

On any group algebra there exists only one such measure, which is $\mu(g)=0$, $g\neq 0$ and $\mu(1)=1$ (normalized). For our four-dimensional representation $[M\in M_2(C), p,q\in C]$ it is given by

$$\mu\begin{pmatrix} M & & \\ & p & \\ & & q \end{pmatrix}=\frac{1}{3}\,\mathrm{Tr}\,M+\frac{1}{6}\,p+\frac{1}{6}\,q.$$

Before we start constructing spectral triples let us have a look at the covariant differential calculi, constructed according to the general scheme. Therefore, first we have to give the representations of the group S_3:

dimension	$\pi(a)$	$\pi(b)$
1^*	1	1
1	-1	-1
2	$\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$	$\begin{pmatrix} -\frac{1}{2} & \frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & \frac{1}{2} \end{pmatrix}$

where 1^* is the trivial representation. Every representation of higher dimension is a direct sum of them.

(i) One-dimensional calculus: For the one-dimensional calculus we take the representation 1 (the trivial one gives $d\equiv 0$).

There is only one generating form χ and the bimodule rules follow from the one-dimensional representation of S_3. Since there is only one such representation $a=b=-1$, we obtain

$$a\chi = -\chi a, \quad b\chi = -\chi b,$$

and the external derivative is

$$da = a\chi, \quad db = b\chi, \quad dc = c\chi.$$

Notice that

$$d(ab) = 0, \quad d(ba) = 0.$$

Such a calculus is extendible to a higher-order calculus with $d^2 = 0$ provided that we set $d\chi = -\chi\chi$.

This calculus has an interesting splitting property:

Observation 12: Let $A = M_2(C)$ and $B = C \oplus C$, $\mathbb{C}S_3 = A \oplus B$. Then the split short exact sequence of algebras,

$$0 \to A \to \mathbb{C}S_3 \to B \to 0,$$

extends to a split short exact sequence of differential modules,

$$0 \to \Omega(A) \to \Omega(\mathbb{C}S_3) \to \Omega(B) \to 0,$$

where $\Omega(\mathbb{C}S_3)$ is the one-dimensional bicovariant calculus, and $\Omega(A)$ and $\Omega(B)$ are its restriction to the corresponding subalgebras.

This tells us immediately that no spectral triple data could generate this calculus. Indeed, since the Dirac operator D can act only between spaces of different left (or right) representation of the algebra, such a splitting of differential bimodules is not possible.

(ii) Two-dimensional calculus: As we have pointed out there exists only one nontrivial two-dimensional representation of S_3 (here nontrivial means that there exists a vector ν such that (ker ε) ν spans the whole representation space, which, for instance, does not hold for $1 \oplus 1$). Various possibilities for the choice of ν would correspond to differential calculi related by automorphism of the group algebra.

If we choose the above presented matrix form of a and b and $\nu = (1, -\sqrt{3})$ we arrive at the following relations:

$$\chi^1 a = -a\chi^1, \quad \chi^2 b = -b\chi^2,$$

$$\chi^1 b = b(\chi^1 - \chi^2), \quad \chi^2 a = a(\chi^2 - \chi^1),$$

where $\chi^1 = ada$ and $\chi^2 = bdb$.

The same relations expressed in terms of dg become

$$(da)b = c(da) - a(db), \quad (db)a = c(db) - b(da).$$

Then $dc = (da)ba + a(da)b + ab(da) = 0$.

All other two-dimensional differential calculi could be obtained through an automorphism of the algebra.

Note that for this calculus we may construct a one-form in the center of $\Omega^1(\mathcal{A})$. For instance, the vector $a\nu_a + b\nu_b - c(\nu_a + \nu_b)$, where ν_a and ν_b are eigenvectors (to eigenvalue 1) of $\pi(a)$ and $\pi(b)$, respectively, gives such a form. Using χ^a and χ^b we can write it as

$$(2a - b - c)\chi^2 + (2b - a - c)\chi^1,$$

so, again this rules out the compatibility between bicovariance and spectral-triple calculus for $\mathbb{C}S_3$.

Our result extends also for higher-dimensional calculi, as all higher-order representations of S_3 contain the two-dimensional part (and, if not, they must be composed out of 1 and 1*) and therefore one may repeat the arguments.

Thus, we may state a simple no-go lemma:

Lemma 15: For $\mathbb{C}S_3$ the differential structure from spectral triple construction cannot carry a bicovariance symmetry.

Knowing that we may now concentrate on spectral triples and the symmetry of the measure.

C. Spectral triples for $\mathbb{C}S_3$

Following the general construction scheme presented earlier we shall now turn our attention to an example of low-dimensional spectral triples for the algebra $\mathbb{C}S_3$. We will be interested in the nontrivial case, which admits a nonzero Dirac operator.

It is easy to verify that the lowest-dimensional spectral triple is given by the intersection form:

$$\begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & -1 \\ 0 & -1 & 1 \end{pmatrix}.$$

The Hilbert space has the dimension 7 (it is odd, as it contains a vector in the subspace H_{33} such that $J\nu=\nu$!).

Instead of the Dirac operator it is more convenient to use the one-form ξ. Since the Dirac operator D can only have nonzero entries $D_{12,32}$ and $D_{23,33}$ (and, respectively, their Hermitian conjugates and J-conjugates) we have the following ξ (where the Hilbert spaces on which ξ acts are ordered as follows: $H_{12},H_{32},H_{23},H_{33}$):

$$\pi(\xi)=\begin{pmatrix} 0 & 0 & x & 0 & 0 \\ 0 & 0 & y & 0 & 0 \\ x^* & y^* & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & z \\ 0 & 0 & 0 & z^* & 0 \end{pmatrix}.$$

Observation 13: The operator $\pi(\xi)\pi(\xi)$ is in $\pi(\mathcal{A})$ provided that $xx^*+yy^*=zz^*$. In any case it commutes with the image of the center of the algebra and therefore it follows from Lemma 11 that $\pi(\xi)^2=\pi(\Xi)$ and the calculus is inner:

$$\pi(\xi)^2=\begin{pmatrix} xx^* & xy^* & 0 & 0 & 0 \\ yx^* & yy^* & 0 & 0 & 0 \\ 0 & 0 & xx^*+yy^* & 0 & 0 \\ 0 & 0 & 0 & zz^* & 0 \\ 0 & 0 & 0 & 0 & zz^* \end{pmatrix}.$$

We shall finish the investigation by writing the *measure operator*, which gives the Haar measure on $\mathbb{C}S_3$.

Observation 14: If $Z=\frac{1}{3}P_1+\frac{1}{18}P_2+\frac{1}{12}P_3$, where P_i denote the corresponding projections in the algebra, then, for every $a\in\mathcal{A}$,

$$\mathrm{Tr}_Z\pi(a)=\mathrm{Tr}\,(\pi(Z)\pi(a))$$

is the Haar measure on $\mathbb{C}S_3$.

One may now use this deformed scalar product on forms to calculate the Yang–Mills action. Note that $[D,\pi(Z)]\neq 0$ and the results would differ from the ones obtained using the *generic* scalar product. For physical models this would result in different mass relations between the gauge bosons in the theory based upon such a triple.

IV. CONCLUSIONS

The world of noncommutative geometry is much bigger than that of classical geometry. In the classical differential geometry, once given a smooth manifold we already know its differential

bundle. Given a Lie group we have a natural notion of the Lie group action on differential structures. All this seems to be lost when we enter the noncommutative world. For a single algebra we have many choices of differential structures and there is no universal rule to tell us which one to choose. Symmetries, or at least group symmetries, are in many cases no longer present or drastically reduced.

The notion of spectral triples is an attempt to bring some order into our understanding of noncommutative differential geometry, by specifying what structures must appear in the models to make them a real *geometry*.

What we have tried to investigate in this paper are the restrictions, which are introduced by this order to the realms of zero-dimensional geometry. We have tried even more to answer the question whether the proposed structures admit and restrict the possible zero-dimensional noncommutative symmetries.

We have classified finite spectral triples and the allowed Dirac operators. This, for instance, enables us to state that the Standard Model Dirac operator is not the most general one, and in fact one may consider an identical spectral triple with some additional components of the Dirac operator, which would link left-handed antileptons with right-handed quarks. Of course, the assumption that such a component exists might have some deep consequences for the model, as it could potentially lead to the breaking of the SU(3) strong symmetry. Another consequence (mentioned originally by D. Testard, see Ref. 10) is that Poincaré duality enforces that there are no right-handed neutrinos. This is correct provided that we add a pair of them (particle and antiparticle). However, it is easy to verify that adding only one right-handed Majorana particle (we doubt whether the name *neutrino* would be justified) still does preserve the Poincaré duality. These and other observations concerning the standard model will be the topic of our forthcoming paper.[2]

The symmetries of spectral triples are a far more complicated problem. We have seen that only in some cases there exists an extension (on the differential level at least) of the Hopf algebra structure into the spectral triple theory. Whether this is a general pattern is difficult to say; however, we believe that symmetries can also be realized in the zero-dimensional case. The examples we have analyzed do not give a conclusive answer; what they suggest, however, is that the symmetry restrictions would be much stronger and of different type than in classical geometry.

ACKNOWLEDGMENTS

We would like thank Florian Scheck for valuable discussions and J. M. Warzecha for remarks on the manuscript.

While preparing a final version of this paper we learned that similar results were obtained by T. Krajewski,[11] whom we would also like to thank for comments and remarks.

(Received 12 May 1998; accepted for publication 8 July 1998)

It is a well-known fact that the first and last nontrivial coefficients of the characteristic polynomial of a linear operator are, respectively, its trace and its determinant. This work shows how to compute recursively all the coefficients as polynomial functions in the traces of the successive powers of the operator. With the aid of Cayley–Hamilton's theorem the trace formulas provide a rational formula for the resolvent kernel and an operator-valued null identity for each finite dimension of the underlying vector space. The four-dimensional resolvent formula allows an algebraic solution of the inverse metric problem in general relativity. © *1998 American Institute of Physics.* [S0022-2488(98)01311-5]

I. INTRODUCTION

The eigenvalue problem arises in a variety of different branches of mathematical physics. For instance, it is well-known that quantum systems reach stationary states that are the eigenvectors of a suitable linear operator defined throughout a complex vector space representing the physical quantum states.

In the infinite dimensional case real and complex analytical methods have been developed to compute the eigenvalues of a linear operator. We mention, for instance, global variational methods, which consist of investigating stationary levels of a suitable energy functional, and local perturbative methods by means of complex analytic continuation.

On the other hand, if the underlying vector space is finite dimensional the eigenvalue problem becomes an algebraically well-posed problem by means of the characteristic polynomial. It is exactly this feature that justifies the algebraic approach in this work. Following this general device, the algebraic environment is set by the complex number field. After working out a few tools, the most important of these being Newton's identities, and setting very fundamental concepts and basic results in complex linear algebra, we succeed in achieving the mathematical core of this work: a recursive algorithm to compute the coefficients of the characteristic polynomial as algebraic functions in the traces of the successive powers of the linear operator.

With the aid of Cayley–Hamilton's theorem the trace formulas already obtained provide an operator-valued null identity for each finite dimension of the underlying vector space. As a by-product it sheds light on the algebraic structure of the associative algebra of complex linear operators. The computational skill just attained is enough to yield an operator-valued polynomial with rational coefficients for the finite-dimensional resolvent kernel, which improves a known result by revealing its rational dependence with respect to the spectral variable, as well as with respect to the linear operator.

In the context of general relativity, the four-dimensional characteristic formula endows a polynomial expression for the volume scalar density. Furthermore, the four-dimensional resolvent formula yields a tensor-valued third-degree polynomial for the inverse metric, thus avoiding the computational and formal drawbacks of the Neumann series.

II. NEWTON'S IDENTITIES

The fundamental theorem of algebra[1] together with Euclid's division algorithm imply algebraic closure[2] of the complex number field; this basic result is encompassed without proof by

[a)]Electronic mail: ronaldor@cat.cbpf.br

Theorem 0: *If* $p(z)=z^n+D_1z^{n-1}+\cdots+D_{n-1}z+D_n$ *is a polynomial with complex coefficients* D_k *then there exist complex numbers* $\lambda_1,\lambda_2,\ldots,\lambda_n$, *called roots of p, such that* $p(z)=(z-\lambda_1)(z-\lambda_2)\cdots(z-\lambda_n)$.

As a consequence of the identity principle, the following relations between coefficients and roots hold:

$$\begin{aligned}
-D_1&=\lambda_1+\lambda_2+\cdots+\lambda_n,\\
+D_2&=\lambda_1\lambda_2+\cdots+\lambda_{n-1}\lambda_n,\\
&\vdots,\\
(-)^kD_k&=\sum\ k\text{-products of }\lambda\text{'s},\\
&\vdots,\\
(-)^nD_n&=\lambda_1\lambda_2\cdots\lambda_n.
\end{aligned}\tag{1}$$

The right-hand side of (1) defines the elementary symmetric functions[3] in the variables $\lambda_1,\lambda_2,\ldots,\lambda_n$. Next to them, the most important symmetric functions are the sums of like powers:

$$\begin{aligned}
T_1&=\lambda_1+\lambda_2+\cdots+\lambda_n,\\
T_2&=\lambda_1^2+\lambda_2^2+\cdots+\lambda_n^2,\\
&\vdots,\\
T_k&=\lambda_1^k+\lambda_2^k+\cdots+\lambda_n^k,\\
&\vdots
\end{aligned}\tag{2}$$

D_k and T_k, besides being symmetric, are homogeneous functions of degree k in the variables $\lambda_1,\lambda_2,\ldots,\lambda_n$. We shall derive a set of recursive relations connecting D's and T's by which the λ's are eliminated from (1) and (2).

To pursue this goal we need two lemmas. The first one is an improved version of the remainder theorem.

Proposition 1: If $p(z)=z^n+D_1z^{n-1}+\cdots+D_{n-1}z+D_n$ *is a polynomial with complex coefficients* D_k *and* λ *is a complex number then*

$$\frac{p(z)-p(\lambda)}{z-\lambda}=z^{n-1}+(\lambda+D_1)z^{n-2}+(\lambda^2+D_1\lambda+D_2)z^{n-3}+\cdots+(\lambda^{n-1}+D_1\lambda^{n-2}+\cdots+D_{n-1}).$$

Proof: By induction on the degree. For $n=1$, $p(z)-p(\lambda)=(z+D_1)-(\lambda+D_1)=z-\lambda$. *For generic n,*

$$\begin{aligned}
p(z)-p(\lambda)&=(z^n+D_1z^{n-1}+\cdots+D_{n-1}z+D_n)-(\lambda^n+D_1\lambda^{n-1}+\cdots+D_{n-1}\lambda+D_n)\\
&=z(z^{n-1}+D_1z^{n-2}+\cdots+D_{n-1})-\lambda(\lambda^{n-1}+D_1\lambda^{n-2}+\cdots+D_{n-1})\\
&=z((z^{n-1}+D_1z^{n-2}+\cdots+D_{n-1})-(\lambda^{n-1}+D_1\lambda^{n-2}+\cdots+D_{n-1}))\\
&\quad+(z-\lambda)(\lambda^{n-1}+D_1\lambda^{n-2}+\cdots+D_{n-1}).
\end{aligned}$$

From the inductive hypothesis the last expression reads

$$
\begin{aligned}
&z(z-\lambda)(z^{n-2}+(\lambda+D_1)z^{n-3}+\cdots+(\lambda^{n-2}+D_1\lambda^{n-3}+\cdots+D_{n-2}))\\
&\quad+(z-\lambda)(\lambda^{n-1}+D_1\lambda^{n-2}+\cdots+D_{n-1})\\
&\quad=(z-\lambda)(z^{n-1}+(\lambda+D_1)z^{n-2}+\cdots+(\lambda^{n-2}+D_1\lambda^{n-3}+\cdots+D_{n-2})z\\
&\qquad+(\lambda^{n-1}+D_1\lambda^{n-2}+\cdots+D_{n-1})).
\end{aligned}
$$

The second lemma is a contribution of differential calculus to algebra.

Proposition 2: If $\lambda_1,\lambda_2,\ldots,\lambda_n$ are the complex roots of the nth-degree polynomial p and p' is its derivative polynomial, then

$$
p'(z)=\sum_{k=1}^{n}\frac{p(z)}{z-\lambda_k}.
$$

Proof: From $p(z)=d_0(z-\lambda_1)(z-\lambda_2)\cdots(z-\lambda_n)$, it follows

$$
\begin{aligned}
p'(z)&=d_0(z-\lambda_2)(z-\lambda_3)\cdots(z-\lambda_n)+d_0(z-\lambda_1)(z-\lambda_3)\cdots(z-\lambda_n)\\
&\quad+\cdots+d_0(z-\lambda_1)(z-\lambda_2)\cdots(z-\lambda_{n-1})\\
&=\frac{p(z)}{z-\lambda_1}+\frac{p(z)}{z-\lambda_2}+\cdots+\frac{p(z)}{z-\lambda_n}.
\end{aligned}
$$

Thus, we are able to get

Theorem 1: *(Newton's formulas[4]) If $\lambda_1,\lambda_2,\ldots,\lambda_n$ are the complex roots of the polynomial $p(z)=z^n+D_1z^{n-1}+D_2z^{n-2}+\cdots+D_{n-1}z+D_n$ with complex coefficients D_k and $T_k=\lambda_1^k+\lambda_2^k+\cdots+\lambda_n^k$ then*

$$
T_k+D_1T_{k-1}+\cdots+D_{k-1}T_1+kD_k=0,\quad k=1,2,\ldots,n.
$$

Proof: Propositions 1 and 2 yield

$$
\begin{aligned}
&nz^{n-1}+(n-1)D_1z^{n-2}+(n-2)D_2z^{n-3}+\cdots+D_{n-1}\\
&\quad=\sum_{k=1}^{n}\{z^{n-1}+(\lambda_k+D_1)z^{n-2}+(\lambda_k^2+D_1\lambda_k+D_2)z^{n-3}\\
&\qquad+\cdots+(\lambda_k^{n-1}+D_1\lambda_k^{n-2}+\cdots+D_{n-2}\lambda_k+D_{n-1})\}\\
&\quad=nz^{n-1}+(T_1+nD_1)z^{n-2}+(T_2+D_1T_1+nD_2)z^{n-3}\\
&\qquad+\cdots+(T_{n-1}+D_1T_{n-2}+\cdots+D_{n-2}T_1+nD_{n-1}).
\end{aligned}
$$

Equating coefficients we obtain

$$
\begin{aligned}
(n-1)D_1&=T_1+nD_1,\\
(n-2)D_2&=T_2+D_1T_1+nD_2,\\
&\vdots,\\
D_{n-1}&=T_{n-1}+D_1T_{n-2}+\cdots+D_{n-2}T_1+nD_{n-1},
\end{aligned}
$$

from which follow the $(n-1)$ first relations to be shown. Since each λ_k is a root of p it verifies $0=\lambda_k^n+D_1\lambda_k^{n-1}+\cdots+D_{n-1}\lambda_k+D_n$. The addition of these relations yields

$$
0=\sum_{k=1}^{n}\{\lambda_k^n+D_1\lambda_k^{n-1}+\cdots+D_{n-1}\lambda_k+D_n\}=T_n+D_1T_{n-1}+\cdots+D_{n-1}T_1+nD_n,
$$

which is the remaining formula to be proved.

III. THE TRACE FORMULAS

The characteristic polynomial[5] of a complex linear operator $\mathbf{T}$ in a finite dimensional complex vector space $\mathbb{V}$ is defined by $p(z)=\det(z\mathbf{I}-\mathbf{T})$, where $\mathbf{I}$ is the identity operator in $\mathbb{V}$. The degree of p as a polynomial in the complex variable z equals the dimension of $\mathbb{V}$ as a complex vector space; its roots are called the characteristic values of $\mathbf{T}$ and the set of characteristic values is called the spectrum of $\mathbf{T}$.

These definitions and properties lead to

Proposition 3: The trace of a complex linear operator $\mathbf{T}$ *equals the sum of its characteristic values counted with multiplicities.*

Proof: $\det(z\mathbf{I}-\mathbf{T})=(z-\lambda_1)(z-\lambda_2)\cdots(z-\lambda_n)$. *By the matrix representation* T_j^i *of* $\mathbf{T}$ *we cast the left-hand side as* $z^n-(T_1^1+T_2^2+\cdots+T_n^n)z^{n-1}+$ *terms of order* $\leqslant n-2$. *In the right-hand side we have* $z^n-(\lambda_1+\lambda_2+\cdots+\lambda_n)z^{n-1}+$ *terms of order* $\leqslant n-2$. *Equating coefficients we obtain*

$$T_1^1+T_2^2+\cdots+T_n^n=\lambda_1+\lambda_2+\cdots+\lambda_n.$$

The roots of unity in the complex field yield the following factorization lemma in the associative algebra of complex linear operators.

Proposition 4: If $\mathbf{T}$ *and* $\mathbf{W}$ *are commuting complex linear operators and* $\theta=e^{i2\pi/k}=\cos(2\pi/k)+i\sin(2\pi/k)$ *with* k *a positive integer, then*

$$\mathbf{T}^k-\mathbf{W}^k=(\mathbf{T}-\mathbf{W})(\mathbf{T}-\theta\mathbf{W})(\mathbf{T}-\theta^2\mathbf{W})\cdots(\mathbf{T}-\theta^{k-1}\mathbf{W}).$$

Proof: As $\mathbf{T}$ *and* $\mathbf{W}$ *commute we collect terms as*

$$\begin{aligned}&(\mathbf{T}-\mathbf{W})(\mathbf{T}-\theta\mathbf{W})(\mathbf{T}-\theta^2\mathbf{W})\cdots(\mathbf{T}-\theta^{k-1}\mathbf{W})\\&\quad=\mathbf{T}^k+d_1\mathbf{W}\mathbf{T}^{k-1}+d_2\mathbf{W}^2\mathbf{T}^{k-2}+\cdots+d_{k-1}\mathbf{W}^{k-1}\mathbf{T}+d_k\mathbf{W}^k,\end{aligned}$$

where the complex numbers $d_1,d_2,\ldots,d_k$ *are the coefficients of the polynomial* $(z-1)(z-\theta)\times(z-\theta^2)\cdots(z-\theta^{k-1})=z^k-1$, *since* $(\theta^j)^k=((e^{i2\pi/k})^j)^k=1$ *for each* $j=0,1,\ldots,k-1$. *Therefore* $d_1=d_2=\cdots=d_{k-1}=0$ *and* $d_k=-1$.

From the multiplicative and homogeneity properties of determinants we get

Proposition 5: If $\lambda_1,\lambda_2,\ldots,\lambda_n$ *are the characteristic values of the complex linear operator* $\mathbf{T}$ *then* $\lambda_1^k,\lambda_2^k,\ldots,\lambda_n^k$ *are the characteristic values of the linear operator* $\mathbf{T}^k$.

Proof: For the particular case where $\mathbf{W}=w\mathbf{I}$, *proposition 4 yields*

$$\begin{aligned}\det(\mathbf{T}^k-w^k\mathbf{I})&=\det(\mathbf{T}-w\mathbf{I})\det(\mathbf{T}-\theta w\mathbf{I})\cdots\det(\mathbf{T}-\theta^{k-1}w\mathbf{I})\\&=(\lambda_1-w)\cdots(\lambda_n-w)(\lambda_1-\theta w)\cdots(\lambda_n-\theta w)\cdots(\lambda_1-\theta^{k-1}w)\cdots(\lambda_n-\theta^{k-1}w)\\&=(\lambda_1-w)(\lambda_1-\theta w)\cdots(\lambda_1-\theta^{k-1}w)\cdots(\lambda_n-w)(\lambda_n-\theta w)\cdots(\lambda_n\theta^{k-1}w)\\&=(\lambda_1{}^k-w^k)\cdots(\lambda_n{}^k-w^k).\end{aligned}$$

Thus $\det(z\mathbf{I}-\mathbf{T}^k)=(z-\lambda_1{}^k)\cdots(z-\lambda_n{}^k)$.

Collecting the former results we are ready to achieve the *recursive formulas* enclosed by

Theorem 2: *If* $p(z)=z^n+D_1z^{n-1}+\cdots+D_{n-1}z+D_n$ *is the characteristic polynomial of the complex linear operator* $\mathbf{T}$ *and* $T_k=\mathrm{trace}\,(\mathbf{T}^k)$ *then*

$$T_k+D_1T_{k-1}+\cdots+D_{k-1}T_1+kD_k=0,\quad k=1,2,\ldots,n.$$

Proof: It is a straightforward consequence of theorem 1 together with propositions 3 and 5.

The key content of theorem 2 shall be emphasized by the following *trace formulas statement: The coefficients of the characteristic polynomial of a linear operator can be recursively computed as polynomial functions in the traces of its successive powers.*

The *trace formulas* $D_k=D_k(T_1,T_2,\ldots,T_{k-1},T_k)$ for the coefficients of the characteristic polynomial are listed below for k up to 8.

$$
\begin{aligned}
D_1 &= -T_1,\\
D_2 &= \tfrac{1}{2}T_1^2-\tfrac{1}{2}T_2,\\
D_3 &= -\tfrac{1}{6}T_1^3+\tfrac{1}{2}T_1T_2-\tfrac{1}{3}T_3,\\
D_4 &= \tfrac{1}{24}T_1^4-\tfrac{1}{4}T_1^2T_2+\tfrac{1}{3}T_1T_3+\tfrac{1}{8}T_2^2-\tfrac{1}{4}T_4,\\
D_5 &= -\tfrac{1}{120}T_1^5+\tfrac{1}{12}T_1^3T_2-\tfrac{1}{6}T_1^2T_3-\tfrac{1}{8}T_1T_2^2+\tfrac{1}{4}T_1T_4+\tfrac{1}{6}T_2T_3-\tfrac{1}{5}T_5,
\end{aligned}
\tag{3}
$$

$$
D_6=\tfrac{1}{720}T_1^6-\tfrac{1}{48}T_1^4T_2+\tfrac{1}{18}T_1^3T_3+\tfrac{1}{16}T_1^2T_2^2-\tfrac{1}{8}T_1^2T_4-\tfrac{1}{6}T_1T_2T_3+\tfrac{1}{5}T_1T_5-\tfrac{1}{48}T_2^3+\tfrac{1}{8}T_2T_4+\tfrac{1}{18}T_3^2-\tfrac{1}{6}T_6,
$$

$$
\begin{aligned}
D_7=&-\tfrac{1}{5040}T_1^7+\tfrac{1}{240}T_1^5T_2-\tfrac{1}{72}T_1^4T_3-\tfrac{1}{48}T_1^3T_2^2+\tfrac{1}{24}T_1^3T_4+\tfrac{1}{12}T_1^2T_2T_3-\tfrac{1}{10}T_1^2T_5+\tfrac{1}{48}T_1T_2^3-\tfrac{1}{8}T_1T_2T_4\\
&-\tfrac{1}{18}T_1T_3^2+\tfrac{1}{6}T_1T_6-\tfrac{1}{24}T_2^2T_3+\tfrac{1}{10}T_2T_5+\tfrac{1}{12}T_3T_4-\tfrac{1}{7}T_7,
\end{aligned}
$$

$$
\begin{aligned}
D_8=&\tfrac{1}{40\,320}T_1^8-\tfrac{1}{1440}T_1^6T_2+\tfrac{1}{360}T_1^5T_3+\tfrac{1}{192}T_1^4T_2^2-\tfrac{1}{96}T_1^4T_4-\tfrac{1}{36}T_1^3T_2T_3+\tfrac{1}{30}T_1^3T_5-\tfrac{1}{96}T_1^2T_2^3+\tfrac{1}{16}T_1^2T_2T_4\\
&+\tfrac{1}{36}T_1^2T_3^2-\tfrac{1}{12}T_1^2T_6+\tfrac{1}{24}T_1T_2^2T_3-\tfrac{1}{10}T_1T_2T_5-\tfrac{1}{12}T_1T_3T_4+\tfrac{1}{7}T_1T_7+\tfrac{1}{384}T_2^4-\tfrac{1}{32}T_2^2T_4-\tfrac{1}{36}T_2T_3^2\\
&+\tfrac{1}{12}T_2T_6+\tfrac{1}{15}T_3T_5+\tfrac{1}{32}T_4^2-\tfrac{1}{8}T_8.
\end{aligned}
$$

The *characteristic formulas* for dimensions up to four are written down:

$$
\begin{aligned}
\det(z\mathbf{I}-\mathbf{T}) &= z-T_1,\\
\det(z\mathbf{I}-\mathbf{T}) &= z^2-T_1z+\tfrac{1}{2}(T_1^2-T_2),\\
\det(z\mathbf{I}-\mathbf{T}) &= z^3-T_1z^2+\tfrac{1}{2}(T_1^2-T_2)z-\tfrac{1}{6}(T_1^3-3T_1T_2+2T_3),\\
\det(z\mathbf{I}-\mathbf{T}) &= z^4-T_1z^3+\tfrac{1}{2}(T_1^2-T_2)z^2-\tfrac{1}{6}(T_1^3-3T_1T_2+2T_3)z\\
&\quad+\tfrac{1}{24}(T_1^4-6T_1^2T_2+8T_1T_3+3T_2^2-6T_4).
\end{aligned}
\tag{4}
$$

IV. NULL IDENTITIES

The polynomial $p(z)=d_0z^n+d_1z^{n-1}+\cdots+d_{n-1}z+d_n$ with complex coefficients d_k is said to annihilate the complex linear operator $\mathbf{T}$ if $p(\mathbf{T})=d_0\mathbf{T}^n+d_1\mathbf{T}^{n-1}+\cdots+d_{n-1}\mathbf{T}+d_n\mathbf{I}=\mathbf{0}$, the identically null operator.

The knowledge of the principal ideal[6] of polynomials that annihilate a linear operator $\mathbf{T}$ is essential to attaining computational skill in the associative algebra generated by $\mathbf{T}$. To ensure this goal we state without proof one of the fundamental results in linear algebra.

Theorem 3: *(Cayley–Hamilton[7]) The characteristic polynomial of a linear operator annihilates it.*

Joining Cayley–Hamilton's theorem with the trace formulas statement we conclude that *for each finite dimension of the underlying vector space there is a fundamental null identity in the associative algebra of linear operators*. For instance, in dimensions up to four, the characteristic formulas (4) yield the following *null identities*:

$$
\begin{aligned}
&\mathbf{T}-T_1\mathbf{I}=\mathbf{0},\\
&\mathbf{T}^2-T_1\mathbf{T}+\tfrac{1}{2}(T_1^2-T_2)\mathbf{I}=\mathbf{0},\\
&\mathbf{T}^3-T_1\mathbf{T}^2+\tfrac{1}{2}(T_1^2-T_2)\mathbf{T}-\tfrac{1}{6}(T_1^3-3T_1T_2+2T_3)\mathbf{I}=\mathbf{0},\\
&\mathbf{T}^4-T_1\mathbf{T}^3+\tfrac{1}{2}(T_1^2-T_2)\mathbf{T}^2-\tfrac{1}{6}(T_1^3-3T_1T_2+2T_3)\mathbf{T}+\tfrac{1}{24}(T_1^4-6T_1^2T_2+8T_1T_3+3T_2^2-6T_4)\mathbf{I}=\mathbf{0}.
\end{aligned}
$$

V. THE FINITE-DIMENSIONAL RESOLVENT KERNEL

The resolvent of a complex linear operator $\mathbf{T}$ is the operator-valued function $\mathbf{R}$ defined by $\mathbf{R}(z)=(z\mathbf{I}-\mathbf{T})^{-1}$. It is a well-known fact that $\mathbf{R}$ is an operator-valued analytic function outside the spectrum of $\mathbf{T}$. We shall refine such a result showing that in the finite dimensional case $\mathbf{R}$ is an operator-valued rational function completely tied by a finite set of complex-valued rational functions, whose coefficients are exactly the trace formulas.

In this vein we need an improved version of the remainder theorem in the associative algebra of complex linear operators, whose content is the extension of proposition 1 to operator-valued polynomials.

Proposition 6: If $p(w)=w^n+D_1w^{n-1}+\cdots+D_{n-1}w+D_n$ *is a polynomial with complex coefficients* D_k *and* $\mathbf{T}$ *and* $\mathbf{W}$ *are commuting complex linear operators then*

$$p(\mathbf{W})-p(\mathbf{T})=(\mathbf{W}-\mathbf{T})[\mathbf{T}^{n-1}+(\mathbf{W}+D_1\mathbf{I})\mathbf{T}^{n-2}+(\mathbf{W}^2+D_1\mathbf{W}+D_2\mathbf{I})\mathbf{T}^{n-3}+\cdots+(\mathbf{W}^{n-1}+D_1\mathbf{W}^{n-2}+\cdots+D_{n-1}\mathbf{I})\mathbf{I}].$$

Proof: By induction on the degree. For $n=1$, $p(\mathbf{W})-p(\mathbf{T})=(\mathbf{W}+D_1\mathbf{I})-(\mathbf{T}+D_1\mathbf{I})=\mathbf{W}-\mathbf{T}$. *For generic n,*

$$\begin{aligned}p(\mathbf{W})-p(\mathbf{T})&=\mathbf{W}(\mathbf{W}^{n-1}+D_1\mathbf{W}^{n-2}+\cdots+D_{n-1}\mathbf{I})+D_n\mathbf{I}\\&\quad-\mathbf{T}(\mathbf{T}^{n-1}+D_1\mathbf{T}^{n-2}+\cdots+D_{n-1}\mathbf{I})-D_n\mathbf{I}\\&=(\mathbf{W}-\mathbf{T})(\mathbf{W}^{n-1}+D_1\mathbf{W}^{n-2}+\cdots+D_{n-1}\mathbf{I})+\mathbf{T}[(\mathbf{W}^{n-1}+D_1\mathbf{W}^{n-2}\\&\quad+\cdots+D_{n-1}\mathbf{I})-(\mathbf{T}^{n-1}+D_1\mathbf{T}^{n-2}+\cdots+D_{n-1}\mathbf{I})].\end{aligned}$$

From the inductive hypothesis the last expression reads

$$\begin{aligned}&(\mathbf{W}-\mathbf{T})(\mathbf{W}^{n-1}+D_1\mathbf{W}^{n-2}+\cdots+D_{n-1}\mathbf{I})+\mathbf{T}(\mathbf{W}-\mathbf{T})[\mathbf{T}^{n-2}+(\mathbf{W}+D_1\mathbf{I})\mathbf{T}^{n-3}\\&\quad+\cdots+(\mathbf{W}^{n-2}+D_1\mathbf{W}^{n-3}+\cdots+D_{n-2}\mathbf{I})\mathbf{I}]\\&=(\mathbf{W}-\mathbf{T})[\mathbf{T}^{n-1}+(\mathbf{W}+D_1\mathbf{I})\mathbf{T}^{n-2}\\&\quad+\cdots+(\mathbf{W}^{n-2}+D_1\mathbf{W}^{n-3}+\cdots+D_{n-2}\mathbf{I})\mathbf{T}\\&\quad+(\mathbf{W}^{n-1}+D_1\mathbf{W}^{n-2}+\cdots+D_{n-1}\mathbf{I})\mathbf{I}].\end{aligned}$$

We are ready to achieve a *rational formula* for the resolvent kernel.

Theorem 4: *If* $p(w)=w^n+D_1w^{n-1}+\cdots+D_{n-1}w+D_n$ *is the characteristic polynomial of the complex linear operator* $\mathbf{T}$ *and z is any complex number not belonging to the spectrum of* $\mathbf{T}$ *then*

$$(z\mathbf{I}-\mathbf{T})^{-1}=\frac{1}{p(z)}\,\mathbf{T}^{n-1}+\frac{z+D_1}{p(z)}\,\mathbf{T}^{n-2}+\frac{z^2+D_1z+D_2}{p(z)}\,\mathbf{T}^{n-3}+\cdots+\frac{z^{n-1}+D_1z^{n-2}+\cdots+D_{n-1}}{p(z)}\,\mathbf{I}.$$

Proof: It is enough to consider Cayley–Hamilton's theorem for the linear operator $\mathbf{T}$ *and set* $\mathbf{W}=z\mathbf{I}$ *in proposition 6; notice that in such case* $\mathbf{W}^k+D_1\mathbf{W}^{k-1}+\cdots+D_k\mathbf{I}=(z^k+D_1z^{k-1}+\cdots+D_k)\mathbf{I}$ *for each* $k=1,2,...,n$.

The joint content of theorem 4 and the trace formulas statement shall be pointed out as follows: *For each finite dimension of the underlying vector space there is a fundamental rational formula for the resolvent kernel of a linear operator*. For instance, in dimensions up to four, the trace formulas (3) provide the following *resolvent formulas*:

$$
\begin{aligned}
(z\mathbf{I}-\mathbf{T})^{-1} &= (z-T_1)^{-1}\mathbf{I},\\
(z\mathbf{I}-\mathbf{T})^{-1} &= (z^2-T_1z+\tfrac{1}{2}(T_1^2-T_2))^{-1}[\mathbf{T}+(z-T_1)\mathbf{I}],\\
(z\mathbf{I}-\mathbf{T})^{-1} &= (z^3-T_1z^2+\tfrac{1}{2}(T_1^2-T_2)z-\tfrac{1}{6}(T_1^3-3T_1T_2+2T_3))^{-1}[\mathbf{T}^2+(z-T_1)\mathbf{T}\\
&\quad +(z^2-T_1z+\tfrac{1}{2}(T_1^2-T_2))\mathbf{I}],\\
(z\mathbf{I}-\mathbf{T})^{-1} &= (z^4-T_1z^3+\tfrac{1}{2}(T_1^2-T_2)z^2-\tfrac{1}{6}(T_1^3-3T_1T_2+2T_3)z+\tfrac{1}{24}(T_1^4-6T_1^2T_2+8T_1T_3+3T_2^2\\
&\quad -6T_4))^{-1}[\mathbf{T}^3+(z-T_1)\mathbf{T}^2+(z^2-T_1z+\tfrac{1}{2}(T_1^2-T_2))\mathbf{T}+(z^3-T_1z^2+\tfrac{1}{2}(T_1^2-T_2)z\\
&\quad -\tfrac{1}{6}(T_1^3-3T_1T_2+2T_3))\mathbf{I}].
\end{aligned}
\tag{5}
$$

VI. APPLICATIONS TO GENERAL RELATIVITY

In general relativity the fundamental physical object is an effective geometry, mathematically represented by a second-rank covariant tensor field $\mathbf{g}$, defined throughout a suitable four-dimensional manifold. In a local coordinate system $\mathbf{x}=(x^\alpha)$ the metric tensor can be written as $\mathbf{g}=g_{\mu\nu}dx^\mu\otimes dx^\nu$.

Investigations on general relativity are frequently carried out under the assumption that there exists some background geometry $\mathring{\mathbf{g}}=\mathring{g}_{\mu\nu}dx^\mu\otimes dx^\nu$. The metric properties to be assumed on $\mathring{\mathbf{g}}$ vary depending on the gravitational scenario. In order to perform calculations it suffices to set $\mathring{\mathbf{g}}$ a Ricci-flat metric. However, to interpret the results as physically meaningful it is generally agreed that one should require $\mathring{\mathbf{g}}$ to be a flat metric. Even this case is sometimes thought to be too broad, as some authors claim to set harmonic coordinates[8] or even Cartesian coordinates.[9] We do not take into account here any suplementary conditions on the background geometry $\mathring{\mathbf{g}}$.

The effective and background geometries are related by a tensor field $\mathbf{h}=h_{\mu\nu}dx^\mu\otimes dx^\nu$ by a connecting equation, the generally accepted form of which is $\mathbf{g}=\mathring{\mathbf{g}}+\mathbf{h}$. The scalar density $\sqrt{-g}d^4x$ associated with $\mathbf{g}$ requires us to compute $\det(\mathbf{g})=\det(\mathring{\mathbf{g}}+\mathbf{h})$. This can be achieved by means of

Proposition 7: If $\mathbf{g}=\mathring{\mathbf{g}}+\mathbf{h}$, $\mathbf{H}=\mathring{\mathbf{g}}^{-1}\mathbf{h}$, $H_k=\mathrm{trace}\,(\mathbf{H}^k)$ *and the underlying manifold is four-dimensional then*

$$
\begin{aligned}
\frac{\det(\mathbf{g})}{\det(\mathring{\mathbf{g}})} &= 1+H_1+\frac{1}{2}(H_1^2-H_2)+\frac{1}{6}(H_1^3-3H_1H_2+2H_3)\\
&\quad +\frac{1}{24}(H_1^4-6H_1^2H_2+8H_1H_3+3H_2^2-6H_4).
\end{aligned}
$$

Proof: From $\mathbf{g}=\mathring{\mathbf{g}}+\mathbf{h}=\mathring{\mathbf{g}}(\mathbf{I}+\mathbf{H})$ *it follows that* $\det(\mathbf{g})=\det(\mathring{\mathbf{g}})\det(\mathbf{I}+\mathbf{H})$. *Now it is enough to consider the four-dimensional characteristic formula in (4) with* $z=1$ *and* $\mathbf{T}=-\mathbf{H}$; *notice that* $\mathbf{T}^k=(-)^k\mathbf{H}^k$ *implies* $T_k=(-)^kH_k$.

The Levi-Civita connection associated with $\mathbf{g}$ requires us to compute $\mathbf{g}^{-1}=(\mathring{\mathbf{g}}+\mathbf{h})^{-1}=(\mathbf{I}+\mathbf{H})^{-1}\mathring{\mathbf{g}}^{-1}$. The known explicit form is given by the Neumann series[10]

$$
(\mathbf{I}+\mathbf{H})^{-1}=\mathbf{I}-\mathbf{H}+\mathbf{H}^2-\mathbf{H}^3+\cdots .
$$

In local coordinates it reads

$$
g^{\mu\nu}=(\delta^\mu_\beta-\mathring{g}^{\mu\alpha}h_{\alpha\beta}+\mathring{g}^{\mu\alpha}h_{\alpha\lambda}\mathring{g}^{\lambda\epsilon}h_{\epsilon\beta}-\mathring{g}^{\mu\alpha}h_{\alpha\lambda}\mathring{g}^{\lambda\epsilon}h_{\epsilon\rho}\mathring{g}^{\rho\sigma}h_{\sigma\beta}+\cdots)\mathring{g}^{\beta\nu},
$$

where $g^{\mu\nu}$ and $\mathring{g}^{\mu\nu}$ are well-defined by $g^{\mu\alpha}g_{\alpha\nu}=\delta^\mu_\nu=\mathring{g}^{\mu\beta}\mathring{g}_{\beta\nu}$.

Besides convergence requirements on the above series, we stress that such expression leads to technical difficulties when developing the Lagrangian variational formalism. These problems were already dealt with in the literature, the proposed solution being to modify the above form of the connecting equation.[11] We show how to overcome such drawbacks by means of

Proposition 8: If $\mathbf{g}=\mathring{\mathbf{g}}+\mathbf{h}$, $\mathbf{H}=\mathring{\mathbf{g}}^{-1}\mathbf{h}$, $H_k=\mathrm{trace}\,(\mathbf{H}^k)$ *and the underlying manifold is four-dimensional then*

$$\mathbf{g}^{-1}=(1+H_1+\tfrac{1}{2}(H_1^2-H_2)+\tfrac{1}{6}(H_1^3-3H_1H_2+2H_3)+\tfrac{1}{24}(H_1^4-6H_1^2H_2+8H_1H_3+3H_2^2-6H_4))^{-1}[-\mathbf{H}^3+(1+H_1)\mathbf{H}^2-(1+H_1+\tfrac{1}{2}(H_1^2-H_2))\mathbf{H}+(1+H_1+\tfrac{1}{2}(H_1^2-H_2)+\tfrac{1}{6}(H_1^3-3H_1H_2+2H_3))\mathbf{I}]\mathring{\mathbf{g}}^{-1}.$$

Proof: From $\mathbf{g}=\mathring{\mathbf{g}}+\mathbf{h}=\mathring{\mathbf{g}}(\mathbf{I}+\mathbf{H})$ *it follows that* $\mathbf{g}^{-1}=(\mathbf{I}+\mathbf{H})^{-1}\mathring{\mathbf{g}}^{-1}$. *Now it is enough to consider the four-dimensional resolvent formula in (5) with* $z=1$ *and* $\mathbf{T}=-\mathbf{H}$; *notice that* $\mathbf{T}^k=(-)^k\mathbf{H}^k$ *implies* $T_k=(-)^kH_k$.

ACKNOWLEDGMENTS

The author thanks Dr. Renato Klippert Barcellos for having collaborated with him on this work, for valuable discussions, and for the implementation of the computer algebra algorithm. The author owes special thanks to Dr. Nelson Pinto Neto and Dr. Vitorio Alberto De Lorenci for encouragement, and for having drawn his attention to the relevance of the subject of the present work. The author is also indebted to Carla da Fonseca-Bernetti for helpful corrections of the manuscript. This work was financially supported by CNPq.

Branching rules for restriction of the Weil representations of Sp($n,\mathbb{R}$) to its maximal parabolic subgroup CM(n)

(Received 3 March 1998; accepted for publication 8 July 1998)

The symplectic group $\mathrm{Sp}(n,\mathbb{R})$ is the group of linear canonical transformations of a real $2n$-dimensional phase space and $\mathrm{CM}(n)\subset\mathrm{Sp}(n,\mathbb{R})$ is a maximal parabolic subgroup. The symplectic groups are the fundamental dynamical groups of classical and quantal Hamiltonian mechanics. In particular, $\mathrm{Sp}(3,\mathbb{R})$ is the dynamical group of the spherical harmonic oscillator and its Weil (harmonic series) representations are important for the microscopic (shell model) description of the collective motions of many-particle systems. The subgroup $\mathrm{CM}(3)\subset\mathrm{Sp}(3,\mathbb{R})$ also appears in the microscopic theory of nuclear collective motion as the dynamical group of a hydrodynamic model of quadrupole vibrations and rotations of a nucleus. Thus, the $\mathrm{Sp}(3,\mathbb{R})\rightarrow\mathrm{CM}(3)$ branching rules are needed in finding the embedding of the hydrodynamic collective model in the microscopic shell model. Some new developments are made in the vector-coherent-state theory of induced representations. © *1998 American Institute of Physics.* [S0022-2488(98)01211-0]

I. INTRODUCTION

The symplectic group $\mathrm{Sp}(n,\mathbb{R})$ is the group of linear transformations of a real $2n$-dimensional phase space, $\mathbb{R}^{2n}$, that leave the antisymmetric biform

$$(\tilde{p},\tilde{x})\begin{pmatrix}0 & I_n\\ -I_n & 0\end{pmatrix}\begin{pmatrix}p\\ x\end{pmatrix}=(\tilde{p}x-\tilde{x}p),\quad x\in\mathbb{R}^n,\quad p\in\mathbb{R}^n, \tag{1}$$

invariant; $\tilde{x}$ denotes the transpose (row vector) of x (a column vector). Thus, $\mathrm{Sp}(n,\mathbb{R})$ is the group of $2n\times 2n$ real matrices

$$\mathrm{Sp}(n,\mathbb{R})=\left\{\begin{pmatrix}A & B\\ C & D\end{pmatrix}\middle|\begin{pmatrix}\tilde{A} & \tilde{C}\\ \tilde{B} & \tilde{D}\end{pmatrix}\begin{pmatrix}0 & I_n\\ -I_n & 0\end{pmatrix}\begin{pmatrix}A & B\\ C & D\end{pmatrix}=\begin{pmatrix}0 & I_n\\ -I_n & 0\end{pmatrix}\right\}. \tag{2}$$

The symplectic groups are the fundamental dynamical groups of classical and quantal Hamiltonian mechanics. In quantum mechanics, one is interested, for example, in their unitary representations on many-particle Hilbert spaces. The latter are spaces of square integrable wave functions $\mathscr{L}^2(\mathbb{R}^{Nn})$ for N-particles in n dimensions. The corresponding representations are known as Weil or Segal–Shale–Weil representations.[1] They are also known as harmonic oscillator or harmonic series representations.

It is known (cf. Gelbart[2]) that the space $\mathscr{L}^2(\mathbb{R}^{Nn})$, with $N=2n$, carries all the holomorphic discrete series representations of $\mathrm{Sp}(n,\mathbb{R})$. For other N, some of the discrete series representations are missing and, for $N<2n$, other irreps (irreducible representations) which are limits of discrete series appear. The harmonic series comprise all representations with lowest weights; for N even these representations are true representations of $\mathrm{Sp}(n,\mathbb{R})$ while for N odd they are projective representations, i.e., true representations of the double covering metaplectic group $\mathrm{Mp}(n,\mathbb{R})$. [For the remainder of this paper we shall mean by a representation of $\mathrm{Sp}(n,\mathbb{R})$ either a true or a projective representation according as N is even or odd.]

$\mathrm{CM}(n)$ (a mnemonic for ''collective motion in n dimensions'') is the maximal parabolic subgroup of matrices of the form

 © 1998 American Institute of Physics

$$\mathrm{CM}(n)=\left\{\begin{pmatrix} A & B \\ 0 & D \end{pmatrix}\in \mathrm{Sp}(n,\mathbb{R})\right\}\subset \mathrm{Sp}(n,\mathbb{R}). \tag{3}$$

It is generated by the matrices

$$\begin{aligned} M_1(g)&=\begin{pmatrix} g & 0 \\ 0 & \tilde{g}^{-1} \end{pmatrix}, \quad g\in \mathrm{GL}(n,\mathbb{R}),\\ M_2(B)&=\begin{pmatrix} I_n & B \\ 0 & I_n \end{pmatrix}, \quad B=\tilde{B}\in \mathbb{R}^{n\times n}, \end{aligned} \tag{4}$$

where $\mathbb{R}^{n\times n}$ is the set of $n\times n$ real matrices. Thus, $\mathrm{CM}(n)$ is isomorphic to the semidirect product group $[\mathbb{R}^{(1/2)n(n+1)}]\mathrm{GL}(n,\mathbb{R})$ of which the normal subgroup $\mathbb{R}^{(1/2)n(n+1)}$ is the additive Abelian group of real $n\times n$ symmetric matrices. The isomorphism is given by the map

$$M_2(B)M_1(g)\rightarrow(B,g), \tag{5}$$

from which one infers the group product

$$(B,g)\circ(B',g')=(B+gB'\tilde{g},gg'). \tag{6}$$

To generate the group $\mathrm{Sp}(n,\mathbb{R})$, one needs, in addition to the generators of $\mathrm{CM}(n)$, the matrix

$$J=\begin{pmatrix} 0 & I_n \\ -I_n & 0 \end{pmatrix}. \tag{7}$$

The group CM(3) appears, for example, in the microscopic theory of nuclear collective motion as the dynamical group of a hydrodynamic model of quadrupole vibrations and rotations of a nucleus.[3] The shape and orientation of a nucleus in this model are characterized by a 3×3 real symmetric matrix Q whose entries are the quadrupole moments

$$Q_{ij}=\int x_i x_j \rho(x)\mathrm{d}v, \tag{8}$$

of the nuclear matter density distribution ρ, where (x_1,x_2,x_3) are Cartesian coordinates of a point $x\in\mathbb{R}^3$. The momentum observables of the model are infinitesimal generators $\{S_{ij}\}$ of the general linear transformations

$$Q\rightarrow\tilde{g}Qg, \quad g\in\mathrm{GL}(3,\mathbb{R}). \tag{9}$$

Together, the set $\{Q_{ij},S_{ij}\}$ comprise an algebra of observables for the CM(3) model. Note that the algebra $\mathbb{R}^6$ spanned by the quadrupole moments $\{Q_{ij}\}$ is both an Abelian Lie algebra and an Abelian Lie group with product given by addition. Moreover, an arbitrary element $B=\Sigma_{ij}\,B_{ij}Q_{ij}\in\mathbb{R}^6$ transforms under $\mathrm{GL}(3,\mathbb{R})$ according to

$$g{:}B\rightarrow\sum_{ij}\,B_{ij}(\tilde{g}Qg)_{ij}=\sum_{ij}\,(gB\tilde{g})_{ij}Q_{ij}, \quad g\in\mathrm{GL}(3,\mathbb{R}), \tag{10}$$

consistent with Eq. (6). The representations of CM(3) that have a microscopic interpretation for an N-nucleon nucleus are the ones carried by subspaces of $\mathscr{S}^2(\mathbb{R}^{3N})$.[4] We construct these representations in the following. Moreover, we determine which $\mathrm{CM}(n)$ irreps are contained within the harmonic series of $\mathrm{Sp}(3,\mathbb{R})$ irreps.

In addition to its CM(3) subgroup, the symplectic group $\mathrm{Sp}(3,\mathbb{R})$ contains the unitary group U(3) as a subgroup. This is significant because U(3) is the symmetry group of the spherical harmonic oscillator; a fact which makes it particularly easy to construct the irreps of $\mathrm{Sp}(3,\mathbb{R})$ in a basis which reduces the subgroup chain

$$\mathrm{Sp}(3,\mathbb{R})\supset \mathrm{U}(3)\supset \mathrm{SO}(3). \tag{11}$$

For this reason, microscopic collective model calculations[5] have been carried out in such a basis. However, to interpret the results of such calculations, one would like to express the wave functions in a basis that reduces the subgroup chain

$$\mathrm{Sp}(3,\mathbb{R})\supset \mathrm{CM}(3)\supset \mathrm{SO}(3). \tag{12}$$

The $\mathrm{Sp}(n,\mathbb{R})\to\mathrm{U}(n)$ branching rules have been long known for the holomorphic discrete series representations. They were derived for all the harmonic series by Rowe, Wybourne, and Butler.[6] The $\mathrm{Sp}(n,\mathbb{R})\to\mathrm{CM}(n)$ branching rules were given for the holomorphic discrete series by Rosensteel and Rowe.[7] We give them herein for the whole harmonic series.

II. THE WEIL REPRESENTATIONS

The Weil (harmonic series) representations of $\mathrm{Sp}(n,\mathbb{R})$ on $\mathscr{L}^2(\mathbb{R}^{Nn})$, with $N=1,2,3,...$, are defined [1,2] by

$$\begin{aligned} M_1(e^a)&\to W(M_1(e^a))=\exp\left[\frac{i}{2}\sum_{ij} a_{ij}\hat{S}_{ij}\right],\\ M_2(B)&\to W(M_2(B))=\exp\left[-\frac{i}{2}\sum_{ij} B_{ij}\hat{Q}_{ij}\right],\\ J&\to W(J)=\exp\left[-\frac{i\pi}{2}\hat{H}\right] \end{aligned} \tag{13}$$

where

$$\begin{aligned} [\hat{S}_{ij}\psi](X)&=\sum_{s=1}^{N}(X_{si}P_{sj}+P_{sj}X_{si})\psi(X),\\ [\hat{Q}_{ij}\psi](X)&=\sum_{s=1}^{N}X_{si}X_{sj}\psi(X),\\ [\hat{H}\psi](X)&=\frac{1}{2}\sum_{s=1}^{N}(X_{si}^2+P_{si}^2)\psi(X); \end{aligned} \tag{14}$$

$X=\{X_{si}\}$ is an element of $\mathbb{R}^{Nn}$ and $P_{si}=-i\partial/\partial X_{si}$. Equivalently, one can show that

$$\begin{aligned} [W(M_1(g))\psi](X)&=[R(g)\psi](X)=[\det g]^{N/2}\psi(Xg),\\ [W(M_2(B))\psi](X)&=\exp\left[-\frac{i}{2}\,\mathrm{Tr}(XB\tilde{X})\right]\psi(X),\\ [W(J)\psi](X)&=(-i)^{Nn/2}\phi(X), \end{aligned} \tag{15}$$

where ϕ is the Fourier transform of ψ. As already noted, the Weil representations are projective, for N odd, i.e., they are true representations of the double covering metaplectic group $\mathrm{Mp}(n,\mathbb{R})$.

A Weil representation of $\mathrm{Sp}(n,\mathbb{R})$ can be combined with the corresponding representation of $\mathrm{O}(N)$

$$\omega\to\rho(\omega),\quad [\rho(\omega)\psi](X)=\psi(\omega^{-1}X),\quad \omega\in\mathrm{O}(N), \tag{16}$$

to give a representation T of the direct product group $\mathrm{O}(N)\times\mathrm{Sp}(n,\mathbb{R})$ for which

$$T(\omega,\alpha)\psi=\rho(\omega)W(\alpha)\psi,\quad \omega\in\mathrm{O}(N),\quad \alpha\in\mathrm{Sp}(n,\mathbb{R}). \tag{17}$$

The decomposition of T is then given by the following theorem.

Theorem: (Kashiwara and Vergne)[1] Let ρ^σ denote an irreducible $O(N)$ representation of highest weight σ and let $\mathscr{L}^2_\sigma(\mathbb{R}^{Nn})$ denote the sum of the $O(N)$-invariant subspaces of $\mathscr{L}^2(\mathbb{R}^{Nn})$ on which the action of $O(N)$ is equivalent to ρ^σ. Then, $\mathscr{L}^2_\sigma(\mathbb{R}^{Nn})$ is the carrier space for an irreducible representation T^σ (projective when N is odd) of $O(N)\times Sp(n,\mathbb{R})$. Moreover, $T=\Sigma_\sigma T^\sigma$ is the direct sum of such irreps.

III. GENERIC REPRESENTATIONS OF THE MAXIMAL PARABOLIC SUBGROUP

First we consider the case where $N>n$. Let S denote the surface of all points in $\mathbb{R}^{Nn}$ for which the matrix of quadrupole moments $Q(X)=\tilde{X}X$ is equal to the $n\times n$ identity matrix, i.e.,

$$S=\{\xi\in\mathbb{R}^{Nn}|\tilde{\xi}\xi=I_n\}. \tag{18}$$

This surface is invariant under both the left action of $O(N)$ and the right action of $O(n)$. Moreover, the measure on S inherited from the Euclidean measure on $\mathbb{R}^{Nn}$ is also invariant under these $O(N)$ and $O(n)$ actions. It follows that the space $U=\mathscr{L}^2(S)$ of square integrable functions on S, relative to this $O(n)$-invariant measure, carries a unitary representation ρ of $O(n)$ with

$$[\rho(\Omega)\varphi](\xi)=\varphi(\xi\Omega),\quad \Omega\in O(n),\quad \varphi\in U. \tag{19}$$

Furthermore, an irreducible right $O(n)$-invariant subspace $\mathscr{U}^v\subset U$ is the carrier space for both an irreducible $O(n)$ subrepresentation ρ^v of ρ and a unitary irrep $\mathscr{R}^v$ of the semidirect product group $[\mathbb{R}^{(1/2)n(n+1)}]O(n)$ with

$$[\mathscr{R}^v(B,\Omega)\varphi](\xi)=e^{-(i/2)\mathrm{Tr}[B]}\varphi(\xi\Omega),\quad (B,\Omega)\in[\mathbb{R}^{(1/2)n(n+1)}]O(n),\quad \varphi\in\mathscr{U}^v. \tag{20}$$

The objective is now to induce a unitary irrep of $CM(n)$, on a subspace of $\mathscr{L}^2(\mathbb{R}^{Nn})$, from the irrep $\mathscr{R}^v$ of $[\mathbb{R}^{(1/2)n(n+1)}]O(n)\subset CM(n)$ on $\mathscr{U}^v$. This would be straightforward if $\mathscr{U}^v$ were a closed subspace of $\mathscr{L}^2(\mathbb{R}^{Nn})$, which it is not. Instead, we make use of the fact that the functionals on $\mathscr{U}^v$ are naturally extended to functionals on the dense subspace $\mathbb{H}_D$ of Schwartz functions[8] in $\mathscr{L}^2(\mathbb{R}^{Nn})$. This enables us to map $\mathscr{U}^v$ into the dual space $\mathbb{H}_D^*$.

An element $\langle\varphi_U|$ of the dual space U^* of functionals on U can be seen as an element $\langle\varphi|$ of the dual $\mathbb{H}_D^*$ of the dense subspace $\mathbb{H}_D$ of Schwartz functions in $\mathscr{L}^2(\mathbb{R}^{Nn})$ as follows. Let $\psi_{|S}$ denote the restriction of the function $\psi\in\mathbb{H}_D$ to the subset $S\subset\mathbb{R}^{Nn}$. The function $\psi_{|S}$ is an element of $\mathscr{L}^2(S)$ (because it is continuous and therefore bounded on the compact set S). Therefore, given a linear functional $\langle\varphi_U|\in U^*$, we can define $\langle\varphi|\in\mathbb{H}_D^*$ by

$$\langle\varphi|\psi\rangle=\langle\varphi_U|\psi_{|S}\rangle. \tag{21}$$

Combined with the standard map $U\to U^*;\varphi\mapsto\langle\varphi_U|$, defined by the Hermitian inner product of $U=\mathscr{L}^2(S)$, we then have a map $U\to\mathbb{H}_D^*$ defined by the sequence $U\to U^*\to\mathbb{H}_D^*;\varphi\mapsto\langle\varphi_U|\mapsto\langle\varphi|$.

The $U\to\mathbb{H}_D^*$ map can be constructed explicitly as follows. Recall that there is a natural map from $\mathbb{R}^{Nn}$ to $\mathbb{H}_D^*$ in which an element $X\in\mathbb{R}^{Nn}$ maps to the functional $\langle X|$ for which

$$\langle X|\psi\rangle=\psi(X),\quad \psi\in\mathbb{H}_D. \tag{22}$$

Thus, for $\varphi\in U$, we define the functional on $\mathbb{H}_D$,

$$\langle\varphi|=\int_S d\xi\ \varphi^*(\xi)\langle\xi|, \tag{23}$$

where $d\xi$ is the $O(N)$-invariant measure on S.

Let $\{\langle vK|\}$ in $\mathbb{H}_D^*$ denote the images under the above map of a set of orthonormal basis functions $\{\varphi_K^v\}$ for $\mathscr{U}^v$. We then have a map $\Pi^v:\mathscr{L}^2(\mathbb{R}^{Nn})\to\mathscr{U}^v$ defined on the dense subspace $\mathbb{H}_D\subset\mathscr{L}^2(\mathbb{R}^{Nn})$ by

$$\Pi^{\upsilon}=\sum_{K}\ \varphi_{K}^{\upsilon}\langle \upsilon K|. \tag{24}$$

Claim: Π^{υ} is an $[\mathbb{R}^{(1/2)n(n+1)}]\mathrm{O}(n)$-intertwining operator for which

$$\Pi^{\upsilon}W(M_2(B)M_1(\Omega))=\mathscr{R}^{\upsilon}(B,\Omega)\Pi^{\upsilon},\quad (B,\Omega)\in[\mathbb{R}^{(1/2)n(n+1)}]\mathrm{O}(n). \tag{25}$$

Proof: The group $[\mathbb{R}^{(1/2)n(n+1)}]\mathrm{O}(n)$ is a subgroup of $\mathrm{Sp}(n,\mathbb{R})$. Thus, it has a (reducible) representation on $\mathbb{H}_D$ given by the restriction of the Weil representation W of $\mathrm{Sp}(n,\mathbb{R})$. For this representation, we have, for any $|\psi\rangle\in\mathbb{H}_D$

$$\sum_{K}\ \varphi_{K}^{\upsilon}\langle \upsilon K|W(M_2(B))|\psi\rangle=\sum_{K}\ \varphi_{K}^{\upsilon}\int_{S}d\xi\ \varphi_{K}^{\upsilon}(\xi)^{*}\langle\xi|W(M_2(B))|\psi\rangle$$

$$=e^{-(i/2)\mathrm{Tr}[B]}\sum_{K}\ \varphi_{K}^{\upsilon}\langle \upsilon K|\psi\rangle, \tag{26}$$

implying that

$$\Pi^{\upsilon}W(M_2(B))=e^{-(i/2)\mathrm{Tr}[B]}\Pi^{\upsilon}. \tag{27}$$

We also have

$$\Pi^{\upsilon}W(M_1(\Omega))=\rho^{\upsilon}(\Omega)\Pi^{\upsilon}. \tag{28}$$

Therefore

$$\Pi^{\upsilon}W(M_2(B)M_1(\Omega))=e^{-(i/2)\mathrm{Tr}[B]}\rho^{\upsilon}(\Omega)\Pi^{\upsilon} \tag{29}$$

and the claim follows.

Claim: The VCS (vector-coherent-state) wave functions [9,10]

$$\mathscr{F}^{\upsilon}=\{\psi:\mathrm{GL}(n,\mathbb{R})\to\mathscr{C}^{\upsilon}\,|\,\psi(g)=\Pi^{\upsilon}W(M_1(g))|\psi\rangle;\ \ g\in\mathrm{GL}(n,\mathbb{R}),\ \ |\psi\rangle\in\mathbb{H}_D\} \tag{30}$$

satisfy the identity

$$\psi(\Omega g)=\rho^{\upsilon}(\Omega)\psi(g),\quad \Omega\in\mathrm{O}(n),\quad g\in\mathrm{GL}(n,\mathbb{R}), \tag{31}$$

and carry a unitary representation, $\overline{\Gamma}^{\upsilon}$, of $\mathrm{CM}(n)$ defined by

$$[\overline{\Gamma}^{\upsilon}(B,g)\psi](g')=e^{-(i/2)\mathrm{Tr}[g'B\tilde{g}']}\psi(g'g). \tag{32}$$

This representation is irreducible.

Proof: The identity (31) follows directly from Eq. (28). Under restriction of the Weil representation to $\mathrm{CM}(n)$, an element $(B,g)\in\mathrm{CM}(n)$ maps

$$|\psi\rangle\to W(M_2(B)M_1(g))|\psi\rangle. \tag{33}$$

The corresponding map $\psi\to\overline{\Gamma}^{\upsilon}(B,g)\psi$ of the VCS wave function ψ for $|\psi\rangle$ is therefore given by

$$[\overline{\Gamma}^{\upsilon}(B,g)\psi](g')=\Pi^{\upsilon}W(M_1(g'))W(M_2(B)M_1(g))|\psi\rangle$$

$$=\Pi^{\upsilon}W(M_2(g'B\tilde{g}')M_1(g'g))|\psi\rangle$$

$$=e^{-(i/2)\mathrm{Tr}[g'B\tilde{g}']}\psi(g'g). \tag{34}$$

Thus, $\overline{\Gamma}^{\upsilon}$ is equivalent to a subrepresentation of the unitary Weil representation restricted to $\mathrm{CM}(n)$. The representation $\overline{\Gamma}^{\upsilon}$ is irreducible by Mackey's theory of induced representations.[11]

Note, that there is a close similarity, but also important differences, between the representations of $\mathrm{CM}(n)$ obtained in this way and those constructed[4] by Mackey induction.[11] In Mackey's

construction, one starts with the set of square integrable $\mathrm{GL}(n,\mathbb{R})\to\mathscr{C}^v$ functions that satisfy Eq. (31). One then defines a representation on this space in accord with Eq. (32). An advantage of Mackey's approach is that the Hilbert space of the representation is equipped with an inner product from the start. In contrast, more work is required to infer the inner product in the VCS method. The advantage of the VCS construction is that it tells us which representations of $\mathrm{CM}(n)$, equivalent to Mackey representations, exist within a given reducible representation on some completely different space (in our case $\mathscr{L}^2(\mathbb{R}^{Nn})$). Moreover, having found such a representation, we can make use of Mackey's theory to infer that it is irreducible.

IV. BRANCHING RULES

Determination of the $\mathrm{CM}(n)$ irreps contained in the restriction to $\mathrm{CM}(n)$ of an irreducible harmonic series (Weil) representation of $\mathrm{Sp}(n,\mathbb{R})$ is simple in a VCS representation.

Observation: The surface S, defined by Eq. (18) for $N>n$, is diffeomorphic to the Stiefel manifold $\mathrm{O}(N)/\mathrm{O}(N-n)$.

Proof: The $\mathrm{O}(N)$ action on $\mathbb{R}^{Nn}$, in which an element $\omega\in\mathrm{O}(N)$ sends X to ωX, leaves S invariant. Furthermore, an $N\times n$ matrix is in S if and only if its columns are orthonormal; such a matrix is of the form $\omega\dot{I}$, where $\dot{I}$ is the matrix with entries $\dot{I}_{si}=\delta_{si}$ and $\omega\in\mathrm{O}(N)$. Thus, S is an $\mathrm{O}(N)$ orbit in $\mathbb{R}^{Nn}$ containing $\dot{I}$. The stability subgroup at $\dot{I}$ is $\mathrm{O}(N-n)$.

By the Peter–Weyl theorem, an orthonormal basis for $U=\mathscr{L}^2(\mathrm{O}(N)/\mathrm{O}(N-n))$ is given by the $\mathrm{O}(N)/\mathrm{O}(N-n)\to\mathbb{C}$ functions $\{\phi^\sigma_{\nu r}\}$, where

$$\phi^\sigma_{\nu r}(\xi)=\sqrt{d_\sigma}\;D^\sigma_{\nu,r}(\xi)^*,\quad \xi\in\mathrm{O}(N)/\mathrm{O}(N-n); \tag{35}$$

$D^\sigma_{\nu,r}$ is a matrix coefficient function for an $\mathrm{O}(N)$ irrep of highest weight σ and dimension d_σ; ν indexes an orthonormal basis for the carrier space V^σ of this irrep and r indexes an orthonormal basis for the $\mathrm{O}(N-n)$-invariant subspace of V^σ. For each σ and r, the functions $\{\phi^\sigma_{\nu r}\}$ are a basis for a representation ρ^σ of $\mathrm{O}(N)$ defined by

$$[\rho^\sigma(\omega)\phi^\sigma_{\nu r}](\xi)=\phi^\sigma_{\nu r}(\omega^{-1}\xi),\quad \omega\in\mathrm{O}(N). \tag{36}$$

Let $\{\langle\nu\sigma r|\}$ in $\mathbb{H}_D^*$ denote the images under the $U\to\mathbb{H}_D^*$ map (defined in Sec. III) of the orthonormal basis functions $\{\phi^\sigma_{\nu r}\}$. And let U^σ denote the subspace of U spanned by the functions $\{\phi^\sigma_{\nu r}\}$ of a given σ. Then, for each σ, we have a map $\Pi^\sigma:\mathscr{L}^2(\mathbb{R}^{Nn})\to U^\sigma$ defined on the dense subspace $\mathbb{H}_D\subset\mathscr{L}^2(\mathbb{R}^{Nn})$ by

$$\Pi^\sigma=\sum_{\nu r}\phi^\sigma_{\nu r}\langle\nu\sigma r|. \tag{37}$$

Claim: The VCS wave functions

$$F^\sigma=\{\Psi:\mathrm{GL}(n,\mathbb{R})\to U^\sigma\,|\,\Psi(g)=\Pi^\sigma W(M_1(g))|\psi\rangle;\ \ g\in\mathrm{GL}(n,\mathbb{R}),\ \ |\psi\rangle\in\mathbb{H}_D\} \tag{38}$$

carry a representation Γ^σ of $\mathrm{O}(N)\times\mathrm{Sp}(n,\mathbb{R})$ defined by

$$[\Gamma^\sigma(\omega,\alpha)\Psi](g)=\Pi^\sigma W(M_1(g))T(\omega,\alpha)|\psi\rangle,\quad (\omega,\alpha)\in\mathrm{O}(N)\times\mathrm{Sp}(n,\mathbb{R}), \tag{39}$$

where T is the representation of $\mathrm{O}(N)\times\mathrm{Sp}(n,\mathbb{R})$ defined by Eq. (17). This representation is equivalent to the irreducible subrepresentation T^σ of the representation T.

Proof: Let $\mathscr{L}^2_\sigma(\mathbb{R}^{Nn})$ be the sum of $\mathrm{O}(N)$-invariant subspaces of $\mathscr{L}^2(\mathbb{R}^{Nn})$ on which the action of $\mathrm{O}(N)$ is equivalent to ρ^σ; as in the Kashiwara–Vergne theorem. Then, by the Kashiwara–Vergne theorem, $\mathscr{L}^2_\sigma(\mathbb{R}^{Nn})$ is a Hilbert space for an irreducible subrepresentation T^σ of the representation T of $\mathrm{O}(N)\times\mathrm{Sp}(n,\mathbb{R})$. Moreover, the dense subspace $\mathbb{H}^\sigma_D=\mathbb{H}_D\cap\mathscr{L}^2_\sigma(\mathbb{R}^{Nn})$ is invariant under T^σ. To prove the claim, we now show that F^σ is isomorphic to $\mathbb{H}^\sigma_D=\mathbb{H}_D\cap\mathscr{L}^2_\sigma(\mathbb{R}^{Nn})$.

First observe that a vector-valued function $\Psi\in F^\sigma$ is uniquely characterized by the set of $\mathrm{GL}(n,\mathbb{R})\to\mathbb{C}$ functions $\{\Psi^\sigma_{\nu r}\}$ defined by

$$\Psi^{\sigma}_{\nu r}(g)=\langle \nu\sigma r|W(M_1(g))|\psi\rangle, \quad g\in \mathrm{GL}(n,\mathbb{R}), \tag{40}$$

for some $|\psi\rangle\in\mathbb{H}_D$. These functions remain the same if $|\psi\rangle$ is replaced by its projection onto $\mathscr{L}^2_\sigma(\mathbb{R}^{Nn})$. So we can assume that $|\psi\rangle\in\mathbb{H}_D\cap\mathscr{L}^2_\sigma(\mathbb{R}^{Nn})$.

Any continuous function $\psi\in\mathscr{L}^2_\sigma(\mathbb{R}^{Nn})$ is uniquely defined by its restriction to the dense set of matrices $X\in\mathbb{R}^{Nn}$ that have maximal rank, i.e., rank equal to n. For such an X, performing a Gram–Schmidt orthonormalization on the columns amounts to finding $g\in\mathrm{GL}(n,\mathbb{R})$ so that $Xg\in S$ (after all, being in S is equivalent to having orthonormal columns). This implies that any continuous function $\psi\in\mathscr{L}^2_\sigma(\mathbb{R}^{Nn})$ is uniquely defined by the restrictions to S of its $\mathrm{GL}(n,\mathbb{R})$-translates. In turn, this implies that ψ is determined by the overlaps $\{\langle \nu\sigma r|W(M_1(g))|\psi\rangle; g\in\mathrm{GL}(n,\mathbb{R})\}$. Thus, F^σ is isomorphic to $\mathbb{H}^\sigma_D=\mathbb{H}_D\cap\mathscr{L}^2_\sigma(\mathbb{R}^{Nn})$ and the claim is proved.

Irreps of $\mathrm{Sp}(n,\mathbb{R})$ are constructed on subspaces of F^σ as follows. First observe that the operator Π^σ satisfies the identity

$$\Pi^\sigma T(\omega,\alpha)=\rho^\sigma(\omega)\Pi^\sigma W(\alpha), \quad \omega\in\mathrm{O}(N), \quad \alpha\in\mathrm{Sp}(n,\mathbb{R}). \tag{41}$$

It follows that the action of the $\mathrm{O}(N)\times\mathrm{Sp}(n,\mathbb{R})$ representation Γ^σ is given by

$$[\Gamma^\sigma(\omega,\alpha)\Psi](g)=\rho^\sigma(\omega)\Pi^\sigma W(M_1(g)\alpha)|\psi\rangle, \quad (\omega,\alpha)\in\mathrm{O}(N)\times\mathrm{Sp}(n,\mathbb{R}). \tag{42}$$

Now F^σ is a direct sum $F^\sigma=\Sigma_\nu F^\sigma_\nu$, where

$$F^\sigma_\nu=\{\Psi:\mathrm{GL}(n,\mathbb{R})\to U^\sigma_\nu|\Psi(g)=\Pi^\sigma_\nu W(M_1(g))|\psi\rangle;\ g\in\mathrm{GL}(n,\mathbb{R}),\ |\psi\rangle\in\mathbb{H}_D\}, \tag{43}$$

U^σ_ν is the subspace of U^σ spanned by the basis wave functions $\{\phi^\sigma_{\nu r}\}$ with both σ and ν held fixed, and

$$\Pi^\sigma_\nu=\sum_r \phi^\sigma_{\nu r}\langle \nu\sigma r|. \tag{44}$$

From the Kashiwara–Vergne theorem, we know that each subspace F^σ_ν is invariant and irreducible under the restriction of Γ^σ to $\mathrm{Sp}(n,\mathbb{R})$. Thus, F^σ_ν is the carrier space for an $\mathrm{Sp}(n,\mathbb{R})$ irrep Γ^σ_ν for which

$$[\Gamma^\sigma_\nu(\alpha)\Psi](g)=\Pi^\sigma_\nu W(M_1(g)\alpha)|\psi\rangle, \quad \alpha\in\mathrm{Sp}(n,\mathbb{R}), \quad \Psi(g)=\Pi^\sigma_\nu W(M_1(g))|\psi\rangle. \tag{45}$$

We now obtain the $\mathrm{Sp}(n,\mathbb{R})\to\mathrm{CM}(n)$ branching rules by expanding the $\mathrm{Sp}(n,\mathbb{R})$ intertwining operator Π^σ_ν as a sum of intertwining operators for $\mathrm{CM}(n)$ irreps. Recall that the label r of the U basis wave functions $\{\phi^\sigma_{\nu r}\}$ indexes a basis for the $\mathrm{O}(N-n)$-invariant subspace of the carrier space V^σ for an $\mathrm{O}(N)$ irrep equivalent to ρ^σ. Let us choose a basis for this subspace of V^σ that reduces the subgroup chain

$$\begin{array}{ccccc}\mathrm{O}(N) & \supset & \mathrm{O}(n)\times\mathrm{O}(N-n),\\ \sigma & & \delta\ \upsilon K & & 0\end{array} \tag{46}$$

where K labels a basis for an $\mathrm{O}(n)$ irrep υ, 0 labels an identity representation of $\mathrm{O}(N-n)$ and δ is a multiplicity index. The index r is then replaced by the set of indices $(\delta\upsilon K)$. It follows that Π^σ_ν can be expanded

$$\Pi^\sigma_\nu=\sum_{\delta\upsilon K}\Pi^\sigma_{\nu\delta\upsilon K}. \tag{47}$$

Moreover, we can identify the $\mathrm{CM}(n)$ intertwining operator Π^υ with any one of the $\Pi^\sigma_{\nu\delta\upsilon K}$ operators of the same υ.

Thus, $\mathrm{Sp}(n,\mathbb{R})\to\mathrm{CM}(n)$ branching rules for the $N\geqslant n$ harmonic series irreps are given by the following claim:

Theorem 1(A): If $N>n$ and an $O(n)$ irrep ρ^v occurs κ times in combination with the identity irrep of $O(N-n)$ in the restriction of the irrep ρ^σ of $O(N)$ to its $O(n)\times O(N-n)$ subgroup, then the irrep Γ^v of $CM(n)$ occurs κ times in the restriction of the $N>n$ harmonic series irrep Γ^σ_ν of $Sp(n,\mathbb{R})$ to $CM(n)$.

An equivalent, and more useful, form of this branching rule is given by equating it with a corresponding $U(n)\to O(n)$ branching rule. Let $U(n)$ be the maximal compact subgroup of $Sp(n,\mathbb{R})$. On restriction to this subgroup, a harmonic series irrep of $Sp(n,\mathbb{R})$ restricts to an infinite sum of $U(n)$ irreps each of which is labeled by a highest weight. Let σ denote the $U(n)$ highest weight having lowest value in this sum. With σ interpreted in this way, the $Sp(n,\mathbb{R})\to CM(n)$ branching rules are given for the $N>n$ harmonic series irreps by the following claim.

Theorem 1(B): If an $O(n)$ irrep ρ^v occurs κ times in the restriction of the irrep of highest weight σ of $U(n)$ to its $O(n)$ subgroup, then the irrep Γ^v of $CM(n)$ occurs κ times in the restriction of an $N>n$ harmonic series irrep Γ^σ_ν of $Sp(n,\mathbb{R})$ to $CM(n)$.

Proof: The claim is proved by comparing the known $U(n)\to O(n)$ and $O(N)\to O(n)\times O(N-n)$ branching rules both of which are given by King.[12]

V. BRANCHING RULES FOR THE REMAINING HARMONIC SERIES REPRESENTATIONS

Now we consider the harmonic representations for which $N\leqslant n$. When $N\leqslant n$, we define the surface S in $\mathbb{R}^{Nn}$ to be the subset of matrices

$$S=\{\xi\in\mathbb{R}^{Nn}\,|\,\tilde{\xi}\xi=I^n_N\}, \tag{48}$$

where I^n_N is the $n\times n$ diagonal rank-N matrix with elements

$$(I^n_N)_{ij}=\delta_{ij}\times\begin{cases}1 & \text{if } i\leqslant N\\ 0 & \text{if } i>N.\end{cases} \tag{49}$$

S is generated by the right action of the subgroup $O(N)\subset O(n)$ on the matrix $\dot{I}\in\mathbb{R}^{Nn}$, where $\dot{I}$ is the matrix with entries $I_{si}=\delta_{si}$ and an element $\Omega\in O(n)$ acts on $\mathbb{R}^{Nn}$ in the usual way by sending $X\in\mathbb{R}^{Nn}$ to $X\tilde{\Omega}$. The stability subgroup of this $O(N)$ action at $\dot{I}$ is the identity subgroup. Thus, S is diffeomorphic to $O(N)$.

The square integrable functions $U=\mathscr{L}^2(O(N))$ on $O(N)\sim S$, relative to the $O(N)$-invariant measure, carry a right representation ρ_R of $O(N)$ with

$$[\rho_R(\omega)\phi](\omega')=\phi(\omega'\omega). \tag{50}$$

It follows that an irreducible right $O(N)$-invariant subspace $\mathscr{U}^\sigma\subset U$ is the carrier space for both an irrep of $O(N)$ and a unitary irrep $\mathscr{R}^\sigma$ of $[\mathbb{R}^{(1/2)n(n+1)}]O(N)$ with

$$[\mathscr{R}^\sigma(B,\omega)\phi](\omega')=e^{-(i/2)\mathrm{Tr}[BI^n_N]}\phi(\omega'\omega),\quad (B,\omega)\in[\mathbb{R}^{(1/2)n(n+1)}]O(N),\quad \phi\in\mathscr{U}^\sigma. \tag{51}$$

We now induce a representation of $CM(n)$ from the representation $\mathscr{R}^\sigma$.

By the Peter–Weyl theorem, an orthonormal basis for $U=\mathscr{L}^2(O(N))$ is given by the functions $\{\phi^\sigma_{\mu\nu}\}$, where

$$\phi^\sigma_{\mu\nu}(\omega)=\sqrt{d_\sigma}\;D^\sigma_{\mu,\nu}(\omega),\quad \omega\in O(N), \tag{52}$$

and $D^\sigma_{\mu,\nu}$ is a matrix coefficient function for an $O(N)$ irrep ρ^σ of dimension d_σ. Let U^σ_μ denote the subspace of U^σ spanned by the subset of functions $\{\phi^\sigma_{\mu\nu}\}$ with σ and μ fixed. The $U^\sigma_\mu\subset U^\sigma$ subspaces are invariant and irreducible under the right $O(N)$ action ρ_R; they carry equivalent $O(N)$ irreps given by

$$\rho^\sigma_R(\omega)\phi^\sigma_{\mu\nu}=\sum_{\nu'}\phi^\sigma_{\mu\nu'}D^\sigma_{\nu',\nu}(\omega),\quad \omega\in O(N). \tag{53}$$

One sees that the irreducible right $O(N)$-invariant subspace $\mathscr{U}^\sigma\subset U$ can be identified with any one of the U^σ_μ of the same σ.

Let $\{\langle\mu\sigma\nu|\}$ in $\mathbb{H}_D^*$ denote the images under the $U\to\mathbb{H}_D^*$ map (defined in Sec. III) of the orthonormal basis functions $\{\phi^\sigma_{\mu\nu}\}$ and let

$$\Pi^\sigma_\mu=\sum_\nu \phi^\sigma_{\mu\nu}\langle\mu\sigma\nu|. \tag{54}$$

Claim: The VCS wave functions

$$F^\sigma_\mu=\{\Psi:\mathrm{GL}(n,\mathbb{R})\to U^\sigma_\mu|\Psi(g)=\Pi^\sigma_\mu W(M_1(g))|\psi\rangle;\ \ g\in\mathrm{GL}(n,\mathbb{R}),\ \ |\psi\rangle\in\mathbb{H}_D\} \tag{55}$$

satisfy the identity

$$\Psi(\omega g)=\rho^\sigma_R(\omega)\Psi(g),\quad \omega\in\mathrm{O}(N)\subset\mathrm{O}(n),\quad g\in\mathrm{GL}(n,\mathbb{R}), \tag{56}$$

and carry an irreducible representation, $\overline{\Gamma}^\sigma_\mu$, of $\mathrm{CM}(n)$, for which

$$[\overline{\Gamma}^\sigma_\mu(B,g)\Psi](g')=e^{-(i/2)\mathrm{Tr}[g'B\tilde{g}'I^n_N]}\Psi(g'g). \tag{57}$$

Proof: Equation (56) follows from the identity

$$\Pi^\sigma_\mu W(M_1(\omega))=\rho^\sigma_R(\omega)\Pi^\sigma_\mu,\quad \omega\in\mathrm{O}(N)\subset\mathrm{O}(n). \tag{58}$$

Under restriction of the Weil representation to $\mathrm{CM}(n)$, an element $(B,g)\in\mathrm{CM}(n)$ maps $|\psi\rangle\to W(M_2(B)M_1(g))|\psi\rangle$. The corresponding map $\Psi\to\overline{\Gamma}^\sigma_\mu(B,g)\Psi$ of the VCS wave function Ψ for $|\psi\rangle$ is given therefore by

$$\begin{aligned}[\overline{\Gamma}^\sigma_\mu(B,g)\Psi](g')&=\Pi^\sigma_\mu W(M_1(g')M_2(B)M_1(g))|\psi\rangle\\&=\Pi^\sigma_\mu W(M_2(g'B\tilde{g}')M_1(g'g))|\psi\rangle\\&=e^{-(i/2)\mathrm{Tr}[g'B\tilde{g}'I^n_N]}\Psi(g'g).\end{aligned} \tag{59}$$

This representation $\overline{\Gamma}^\sigma_\mu$ is the representation of $\mathrm{CM}(n)$ induced from the representation $\mathscr{R}^\sigma$. It is known, from Mackey's theory,[11] to be irreducible.

We now show that F^σ_μ also carries an $\mathrm{Sp}(n,\mathbb{R})$ irrep.

Theorem 2: Let σ label an irrep of $\mathrm{O}(N)$. The Kashiwara–Vergne theorem associates to σ a harmonic series irrep of $\mathrm{Sp}(n,\mathbb{R})$. On restriction to its maximal parabolic subgroup, $\mathrm{CM}(n)$, this irrep of $\mathrm{Sp}(n,\mathbb{R})$ remains irreducible when $N<n$. The $\mathrm{CM}(n)$ representation obtained by the restriction is the representation induced from the irrep $\mathscr{R}^\sigma$ of the $[\mathbb{R}^{(1/2)n(n+1)}]\mathrm{O}(N)\subset\mathrm{CM}(n)$ subgroup.

Proof: Let $\mathscr{L}^2_\sigma(\mathbb{R}^{Nn})$ denote the sum of $\mathrm{O}(N)$-invariant subspaces of $\mathscr{L}^2(\mathbb{R}^{Nn})$ on which the action of $\mathrm{O}(N)$ is equivalent to ρ^σ. Then, as shown in Sec. IV, $F^\sigma=\Sigma_\mu F^\sigma_\mu$ is isomorphic to a dense subspace of $\mathscr{L}^2_\sigma(\mathbb{R}^{Nn})$. It follows from the Kashiwara–Vergne theorem that F^σ carries a unitary irrep Γ^σ of $\mathrm{O}(N)\times\mathrm{Sp}(n,\mathbb{R})$ for which

$$\begin{aligned}\Gamma^\sigma(\omega,\alpha)\Psi](g)&=\sum_\mu \Pi^\sigma_\mu W(M_1(g))T(\omega,\alpha)|\psi\rangle,\\&=\sum_\mu \Pi^\sigma_\mu T(\omega,M_1(g)\alpha)|\psi\rangle.\end{aligned} \tag{60}$$

The restriction of this irrep, Γ^σ, to $\mathrm{Sp}(n,\mathbb{R})$ is reducible but, again by the Kashiwara–Vergne theorem, each subspace $F^\sigma_\mu\subset F^\sigma$ is invariant and irreducible.

VI. COMMENTS ON VCS INDUCTION

In deriving the above branching rules, we have relied on the VCS inducing construction and introduced some new techniques. Since these techniques are more generally useful, we conclude with some brief comments on VCS theory in the context of general inducing constructions.

The essential ingredients of all inducing constructions are as follows. Let G be a group and $H \subset G$ a subgroup. Let ρ be a representation of H on a vector space U and let $\mathscr{F}$ be a G-invariant space of $G \to U$ (vector-valued) functions for which the G action is expressed

$$G \times \mathscr{F} \to \mathscr{F}; \quad g \times \psi \mapsto \psi_g, \quad \text{where} \quad \psi_g(g') = \psi(g'g). \tag{61}$$

The space $\mathscr{F}$ carries a (generally reducible) representation of G. A subrepresentation carried by the G-invariant subset of functions

$$\overline{\mathscr{F}} = \{\psi \in \mathscr{F} \,|\, \psi(hg) = \rho(h)\psi(g), \ \forall h \in H\}, \tag{62}$$

is then said to be induced from the representation ρ of H. Different choices of $\mathscr{F}$ give rise to different inducing constructions. In Mackey's theory,[11] for example, $\mathscr{F}$ is usually set equal to $\mathscr{L}^2(G)$, relative to a G-invariant or quasi-invariant measure.

The VCS construction starts with a representation T of G on some space (e.g., a Hilbert space) $\mathbb{H}$ and seeks an intertwining operator Π which maps $\mathbb{H}$ to the carrier space U of a representation ρ of a subgroup $H \subset G$, i.e., Π satisfies

$$\Pi T(h) = \rho(h)\Pi, \quad h \in H. \tag{63}$$

This ensures that the VCS wave functions

$$\overline{\mathscr{F}} = \{\psi \,|\, \psi(g) = \Pi T(g)\Psi; \Psi \in \mathbb{H}, g \in G\} \tag{64}$$

satisfy the identity $\psi(hg) = \rho(h)\psi(g)$, for all $h \in H$, and carry a representation Γ for which

$$[\Gamma(g)\psi](\alpha) = \Pi T(\alpha)T(g)\Psi = \psi(\alpha g), \quad g \in G. \tag{65}$$

The VCS representation Γ is seen to be isomorphic to a subrepresentation of T.

The standard (i.e., Mackey) construction has the advantage that the Hilbert space $\mathscr{L}^2(G)$ is automatically equipped with an inner product, whereas the inner product for a VCS representation has to be inferred from that of the Hilbert space $\mathbb{H}$ in which it is embedded. This can be an advantage, e.g., for representations for which the $\mathscr{L}^2(G)$ inner product diverges, as for nondiscrete series representations of $\mathrm{Sp}(n, \mathbb{R})$. Moreover, even when defined, the $\mathscr{L}^2(G)$ integrals can be much harder to evaluate than the corresponding expressions of the VCS construction. For present purposes, the special property of the VCS induction that we have exploited is that it gives the representations contained within a (generally reducible) representation T on an arbitrary space $\mathbb{H}$ [not necessarily $\mathscr{L}^2(G)$ or even a Hilbert space].

In the special case that $\mathbb{H}$ is set equal to $\mathscr{L}^2(G)$ and T is the regular representation, VCS induction may or may not be equivalent to that of Mackey, depending on the choice of Π. For some choices of Π it may be possible to induce irreducible VCS representation of G whereas the standard induced representation is reducible. The space $\mathbb{H}$ might also be a space of holomorphic sections of a G/H bundle or a Hilbert space of many-particle wave functions, as in this paper. There are many possibilities. Thus, VCS theory provides tools for finding the subrepresentations of a group within a particular space of interest. The practicality of the VCS construction relies on the existence of systematic ways of choosing the representation ρ to achieve some desired purpose and for determining the corresponding space $\overline{\mathscr{F}}$ of wave functions. Moreover, by means of the so-called K-matrix theory,[9,10] there are systematic ways of determining the inner product for $\overline{\mathscr{F}}$ inherited from $\mathbb{H}$.

In the first applications of VCS theory, the carrier space U for the representation ρ of H was taken to be a subspace of $\mathbb{H}$ and Π was an $\mathbb{H} \to U$ projection operator. The projection operator was constructed explicitly by choosing an orthonormal basis $\{\varphi_\alpha\}$ for U and identifying the wave functions of this basis with corresponding vectors $\{|\alpha\rangle\}$ in $\mathbb{H}$ (in which U is embedded as a subspace). The $\mathbb{H} \to U$ projection operator Π is then defined

$$\Pi = \sum_\alpha \varphi_\alpha \langle \alpha|. \tag{66}$$

The only problem with Π defined in this way is that it limits the construction to induction from a representation ρ of the subgroup H that occurs in a direct sum decomposition of $T|_H$, the restriction of T to H. However, as shown explicitly in this paper, this limitation can be relaxed and the VCS construction also applied with representations that occur in a direct integral decomposition of $T|_H$. We have shown that there is a natural embedding of the dual U^* of U in the space of functionals $\mathbb{H}_D^*$ on a dense subspace $\mathbb{H}_D$ of $\mathbb{H}$. Thus, if $\{\varphi_\alpha\}$ is an orthonormal basis for U we obtain a sequence of maps $U \to U^* \to \mathbb{H}_D^*$ in which the basis functions $\{\varphi_\alpha\}$ map to functionals $\{\langle\alpha|\}$ in $\mathbb{H}_D^*$. We then again have an intertwining operator $\Pi = \Sigma_\alpha \varphi_\alpha \langle\alpha|$. The only difference is that now Π is only defined on the dense subspace $\mathbb{H}_D$ but that is sufficient.

ACKNOWLEDGMENTS

(Received 20 May 1998; accepted for publication 24 June 1998)

In this paper the algebraic expressions for SO(N) Racah coefficients involving the coupling of three irreducible representations $(1\,\dot{0})$, $(m_1\,m_2\,m_3\,\dot{0})$ and $(1\,\dot{0})$ are given by using the building-up process. Their properties are discussed in detail. © *1998 American Institute of Physics.* [S0022-2488(98)01811-8]

I. INTRODUCTION

Racah coefficients[1] (or the highly symmetrical $6j$ symbols[2]) for SO(N) are very useful in calculating energy levels and transition rates in atomic, molecular and nuclear structure theory. They appear in the calculation of the matrix element of any coupled tensor operator when the Wigner–Eckart theorem is applied. In fact, Racah coefficients are the transformation coefficients between different coupling schemes of three angular momenta in quantum mechanics, where the underlying group is SO(3). This concept and the cases of the coupling of more than three angular momenta (or $3nj$ symbols) have been discussed widely[3–6] and been generalized to various groups such as point groups,[7,8] symmetry groups,[9] classical Lie groups SU(N),[10–12] SO(N),[13–16] Sp($2N$),[17] and exceptional Lie group G_2.[14,18]

There are many approaches to the Racah coefficients. Usually, a basic and direct approach is to use the Biedenharn–Elliott sum rule (including the Racah backcoupling formula and the orthonormality relations of Racah coefficients).[3–6] The other methods are the use of the bootstrap procedure,[15,19,20] the generating functions method,[17] the building-up process using the known reduction factors (reduced Wigner factors),[13,21,22] the diagrammatic method[23,24] and so on.

Besides the well-known SO(3), the algebraic expressions for some special Racah coefficients of SO(N) were discussed by Judd *et al.*[14,15] and Ališauskas.[16] Judd *et al.* considered the cases of single-parameter irreducible representations for SO(N) (so only one parameter w in $6j$ symbol), and of all six irreducible representations having the type $(1^a\,0^{l-a})$ for SO($2l+1$). Ališauskas considered the semistretched case of the symmetry irreducible representations $(l\,\dot{0})$ for SO(N) ($N>5$) and gave the polynomial-type expressions for $6j$ symbol, namely, they are expressed by the sums over a series of $6j$ symbols of SU(2).

Recently, Sun *et al.*[25,26] obtained the algebraic expressions for SO(N)$\supset$SO($N-1$) reduction factors for $(m_1\,m_2\,m_3\,\dot{0})\times(1\,\dot{0})$ by use of the irreducible tensor basis method.[27,28] Therefore, it allows us, using the building-up process, to derive algebraic expressions for all SO(N) Racah coefficients for $(1\,\dot{0})\times(m_1\,m_2\,m_3\,\dot{0})\times(1\,\dot{0})$.

This paper is arranged as follows. In Sec. II, the definitions of Racah coefficient and the corresponding $6j$ symbol for an arbitrary group and the building-up equation we will utilize are reviewed simply. In Sec. III, the algebraic expressions for SO(N) Racah coefficients are calculated and given in convenient tabular forms. A simple discussion is given in the final section.

II. DEFINITIONS AND BUILDING-UP EQUATION

Let Γ label the irreducible representations of group G and Λ label those of the subgroup G'. Then $|\Gamma\,\Lambda\,\lambda\rangle$ are the basis vectors carrying the irreducible representations Γ, where λ, as the

a)Electronic mail: gllong@mail.tsinghua.edu.cn

components of Λ, distinguishes the individual basis vectors. When we consider the coupling of products of the basis states of three irreducible representations Γ_1, Γ_2 and Γ_3 for the definitive resultant coupled states $|\Gamma\,\Lambda\,\lambda\rangle$, there are two coupling sequences: one is first coupling $|\Gamma_1\,\Lambda_1\,\lambda_1\rangle$ with $|\Gamma_2\,\Lambda_2\,\lambda_2\rangle$ to $|\Gamma_{12}\,\Lambda_{12}\,\lambda_{12}\rangle$, then coupling $|\Gamma_{12}\,\Lambda_{12}\,\lambda_{12}\rangle$ with $|\Gamma_3\,\Lambda_3\,\lambda_3\rangle$ to $|\Gamma\,\Lambda\,\lambda\rangle$; another is first coupling $|\Gamma_2\,\Lambda_2\,\lambda_2\rangle$ with $|\Gamma_3\,\Lambda_3\,\lambda_3\rangle$ to $|\Gamma_{23}\,\Lambda_{23}\,\lambda_{23}\rangle$, then coupling $|\Gamma_1\,\Lambda_1\,\lambda_1\rangle$ with $|\Gamma_{23}\,\Lambda_{23}\,\lambda_{23}\rangle$ to $|\Gamma\,\Lambda\,\lambda\rangle$. (Note that here and afterwards, i.e., in Eqs. (1) and (4) and in the definitions of Racah coefficient (2), $6j$ symbol (3) and reduction factor (5), we have dropped the additional labels because in our case they are multiplicity-free.) The two resultant coupled states $|(\Gamma_1\Gamma_2)\,\Gamma_{12},\Gamma_3;\Gamma\,\Lambda\,\lambda\rangle$ and $|\Gamma_1,(\Gamma_2\,\Gamma_3)\,\Gamma_{23};\Gamma\,\Lambda\,\lambda\rangle$ must be related by a unitary transformation matrix $\mathrm{U}(\Gamma)$, such that

$$|(\Gamma_1\Gamma_2)\Gamma_{12},\Gamma_3;\Gamma\Lambda\lambda\rangle=\sum_{\Gamma_{23}}\mathrm{U}_{\Gamma_{12}\Gamma_{23}}(\Gamma)|\Gamma_1,(\Gamma_2\Gamma_3)\Gamma_{23};\Gamma\Lambda\lambda\rangle \tag{1}$$

where matrix element $\mathrm{U}_{\Gamma_{12}\,\Gamma_{23}}(\Gamma)$, which is independent of Λ and λ,

$$\mathrm{U}_{\Gamma_{12}\,\Gamma_{23}}(\Gamma)\equiv W\begin{pmatrix}\Gamma_1 & \Gamma_2 & \Gamma_{12}\\ \Gamma_3 & \Gamma & \Gamma_{23}\end{pmatrix}, \tag{2}$$

is called a normalized Racah coefficient of group G. Its corresponding $6j$ symbol, which may display better symmetries, is[15]

$$\begin{Bmatrix}\Gamma_1 & \Gamma_2 & \Gamma_{12}\\ \Gamma_3 & \Gamma & \Gamma_{23}\end{Bmatrix}=[\mathrm{Dim}(\Gamma_{12})\,\mathrm{Dim}(\Gamma_{23})]^{-1/2}W\begin{pmatrix}\Gamma_1 & \Gamma_2 & \Gamma_{12}\\ \Gamma_3 & \Gamma & \Gamma_{23}\end{pmatrix}, \tag{3}$$

where $\mathrm{Dim}(\Gamma_i)$ is the dimension of the irreducible representation Γ_i. Equation (3) is analogous to the definition of Jahn[29] for SO(3).

By standard recoupling theory, the ket in Eq. (1) may be expressed in terms of sums of products of coupling coefficients. Then, multiplying this equation on both sides by $\langle\,\Gamma_1\,\Lambda_1,(\Gamma_2\,\Gamma_3)\,\Gamma_{23}\Lambda_{23}|\Gamma\,\Lambda\,\rangle$, and using the Racah factorization lemma together with the unitarity properties of the coupling coefficients, we can obtain the following very useful relationship[13,22,28]

$$\begin{aligned}W\begin{pmatrix}\Gamma_1 & \Gamma_2 & \Gamma_{12}\\ \Gamma_3 & \Gamma & \Gamma_{23}\end{pmatrix}\begin{bmatrix}\Gamma_1 & \Gamma_{23}\\ \Lambda_1 & \Lambda_{23}\end{bmatrix}\Gamma\Lambda\Big]=&\sum_{\Lambda_2,\,\Lambda_{12},\,\Lambda_3}W\begin{pmatrix}\Lambda_1 & \Lambda_2 & \Lambda_{12}\\ \Lambda_3 & \Lambda & \Lambda_{23}\end{pmatrix}\begin{bmatrix}\Gamma_1 & \Gamma_2\\ \Lambda_1 & \Lambda_2\end{bmatrix}\Gamma_{12}\Lambda_{12}\Big]\\ &\times\begin{bmatrix}\Gamma_3 & \Gamma_{12}\\ \Lambda_3 & \Lambda_{12}\end{bmatrix}\Gamma\Lambda\Big]\begin{bmatrix}\Gamma_2 & \Gamma_3\\ \Lambda_2 & \Lambda_3\end{bmatrix}\Gamma_{23}\Lambda_{23}\Big]\end{aligned} \tag{4}$$

where

$$W\begin{pmatrix}\Gamma_1 & \Gamma_2 & \Gamma_{12}\\ \Gamma_3 & \Gamma & \Gamma_{23}\end{pmatrix}\quad\text{and}\quad W\begin{pmatrix}\Lambda_1 & \Lambda_2 & \Lambda_{12}\\ \Lambda_3 & \Lambda & \Lambda_{23}\end{pmatrix}$$

are the normalized Racah coefficients of G and of its subgroup G', respectively, and the remaining factors, like

$$\begin{bmatrix}\Gamma_1 & \Gamma_{23}\\ \Lambda_1 & \Lambda_{23}\end{bmatrix}\Gamma\Lambda\Big], \tag{5}$$

stand for the $G\supset G'$ reduction factors. Equation (4) is the so-called building-up equation, which relates the Racah coefficients of G with those of its subgroup G' by the $G\supset G'$ reduction factors. It is a straightforward generalization of the relationships between SO(3) Racah coefficients and the Clebsch–Gordan coefficients of SO(3) [i.e., the $\mathrm{SO}(3)\supset\mathrm{SO}(2)$ reduction factors].[3]

TABLE I. SO(3) Racah coefficients $W\begin{pmatrix} 1 & j & j_{12} \\ 1 & j' & j_{23} \end{pmatrix}$

(a) $j'=j+1$

$j_{12}\backslash j_{23}$	j	$j+1$
j	$\frac{1}{j+1}$	$\frac{\sqrt{j(j+2)}}{j+1}$
$j+1$	$\frac{\sqrt{j(j+2)}}{j+1}$	$-\frac{1}{j+1}$

(b) $j'=j-1$

$j_{12}\backslash j_{23}$	$j-1$	j
$j-1$	$\frac{1}{j}$	$\frac{\sqrt{(j-1)(j+1)}}{j}$
j	$\frac{\sqrt{(j-1)(j+1)}}{j}$	$-\frac{1}{j}$

(c) $j'=j$

$j_{12}\backslash j_{23}$	$j-1$	j	$j+1$
$j-1$	$\frac{1}{j(2j+1)}$	$-\frac{\sqrt{2j-1}}{j\sqrt{2j+1}}$	$\frac{\sqrt{(2j-1)(2j+3)}}{2j+1}$
j	$-\frac{\sqrt{2j-1}}{j\sqrt{2j+1}}$	$\frac{j^2+j-1}{j(j+1)}$	$\frac{\sqrt{(2j-1)(2j+3)}}{(j+1)(2j+1)}$
$j+1$	$\frac{\sqrt{(2j-1)(2j+3)}}{2j+1}$	$\frac{\sqrt{(2j-1)(2j+3)}}{(j+1)(2j+1)}$	$\frac{1}{(j+1)(2j+1)}$

III. CALCULATIONS OF RACAH COEFFICIENTS

We have observed that Eq. (4) is a kind of recursion relationship. This equation makes it possible that the Racah coefficients, to within an overall phase convention, of groups of higher ranks may be obtained step by step from those of their subgroups through a suitable group chain provided that the corresponding reduction factors have been known.

In order to obtain SO(N) Racah coefficients, we choose a canonical group chain $\mathrm{SO}(N)\supset\mathrm{SO}(N-1)\supset\cdots\supset\mathrm{SO}(3)\supset\mathrm{SO}(2)$. Due to the trivial SO(2), whose Racah coefficients only take either 1 when the ordinary weight addition rules are satisfied or 0 otherwise, we first need to derive the algebraic expressions for Racah coefficients of the lowest but nontrivial subgroup, SO(3). Fortunately, as mentioned in Sec. I, the case of SO(3) has been treated very well in the quantum theory of angular momentum.[3,5,6] The algebraic expressions for SO(3) Racah coefficients for $1\times j\times 1$ considered in this paper, cast into the corresponding unitary matrices, are given in Table I. It is worth reminding readers to note the differences between the phase conventions of SO(3) Racah coefficients in Table I and the usual ones of the Racah coefficients of the angular momenta[3] because the phase conventions of the coupling coefficients of SO(3) we used[25] are different from those of the coupling coefficients of the angular momenta.[3] The convenient phase conventions of SO(3) Racah coefficients in Table I have been adopted in order to be consistent with the phase conventions of SO(N) ($N>3$) Racah coefficients calculated later.

Then, using the SO(3) Racah coefficients (Table I) and the $\mathrm{SO}(4)\supset\mathrm{SO}(3)$ reduction factors for $(m_{14}m_{24})\times(1\ 0)$,[25] we can obtain all SO(4) Racah coefficients for $(1\ 0)\times(m_{14}\ m_{24})\times(1\ 0)$ by the standard technique, that is, in the building-up equation (4) Λ_{23} and Λ taking their highest weights respectively while Λ_2, Λ_{12} and Λ_3 are running their range of allowed values. This method may go further to SO(5), SO(6), ... We have calculated up to SO(7), and obtained SO(7) Racah coefficients, however, here the procedure is no longer repeated for economy of

pages. From the obtained results of SO(4), SO(5), SO(6) and SO(7), we have found that there exists a very simple relation depending on rank N $(=4,\ldots,7)$ in the corresponding Racah coefficients—the factors involving $m_{iN}+m_{jN}$ contain rank N whereas the factors involving $m_{iN}-m_{jN}$ do not contain rank N. This result is not surprising because a similar property occurred in the $\mathrm{SO}(N)\supset\mathrm{SO}(N-1)$ reduction factors.[25] Therefore, we can extend easily the SO(7) Racah coefficients for $(1\ 0\ 0)\times(m_{17}\ m_{27}\ m_{37})\times(1\ 0\ 0)$ to the case of SO(N) of the arbitrary rank N for $(1\ \dot{0})\times(m_1\ m_2\ m_3\ \dot{0})\times(1\ \dot{0})$, where the three entries m_1, m_2 and m_3 in the irreducible representation $(m_1\ m_2\ m_3\ \dot{0})$ of SO(N) must be integer and obey the betweenness relation $m_1\geqslant m_2\geqslant m_3\geqslant 0$. (Here for simplicity, the subscript N of m_{iN} has been omitted, i.e., $m_{iN}\equiv m_i$, and a dot over a number implies that this number is repeated as often as necessary.) Thus using Eq. (4) and the $\mathrm{SO}(N)\supset\mathrm{SO}(N-1)$ reduction factors,[25,26] we can gain by mathematical induction all SO(N) Racah coefficients of the type

$$W\begin{pmatrix}(1\ \dot{0}) & (m_1\,m_2\,m_3\,\dot{0}) & \Gamma_{12}\\ (1\,\dot{0}) & \Gamma & \Gamma_{23}\end{pmatrix}.$$

Correspondingly, in Eq. (4), we have to choose $\Gamma_1=\Gamma_3=(1\ \dot{0})$ and $\Gamma_2=(m_1m_2\ m_3\dot{0})$. Then Γ_{12} and Γ_{23} may be different for different Γ's. They can be gained by the method of weight decomposition or Shur function method,[22,28] and are listed in Table II.

Hence eighty-six Racah coefficients in all needed calculating. Furthermore, they may be put into twenty-six unitary matrices, i.e., seven 1×1 matrices, eighteen 2×2 matrices and one 7×7 matrix. For the first seven cases in Table II, the normalized Racah coefficients are

$$W\begin{pmatrix}(1\,\dot{0}) & (m_1\,m_2\,m_3\,\dot{0}) & (m_1\pm1\,m_2\,m_3\,\dot{0})\\ (1\,\dot{0}) & (m_1\pm2\,m_2\,m_3\,\dot{0}) & (m_1\pm1\,m_2\,m_3\,\dot{0})\end{pmatrix}=1,$$

$$W\begin{pmatrix}(1\,\dot{0}) & (m_1\,m_2\,m_3\,\dot{0}) & (m_1\,m_2\pm1\,m_3\,\dot{0})\\ (1\,\dot{0}) & (m_1\,m_2\pm2\,m_3\,\dot{0}) & (m_1\,m_2\pm1\,m_3\,\dot{0})\end{pmatrix}=1,$$

$$W\begin{pmatrix}(1\,\dot{0}) & (m_1\,m_2\,m_3\,\dot{0}) & (m_1\,m_2\,m_3\pm1\,\dot{0})\\ (1\,\dot{0}) & (m_1\,m_2\,m_3\pm2\,\dot{0}) & (m_1\,m_2\,m_3\pm1\,\dot{0})\end{pmatrix}=1,$$

$$W\begin{pmatrix}(1\,\dot{0}) & (m_1\,m_2\,m_3\,\dot{0}) & (m_1\,m_2\,m_3\,1\,\dot{0})\\ (1\,\dot{0}) & (m_1\,m_2\,m_3\,2\,\dot{0}) & (m_1\,m_2\,m_3\,1\,\dot{0})\end{pmatrix}=1\,, \tag{6}$$

owing to the fact that for a fixed Γ there is only one coupling scheme (i.e., only one Γ_{12} and one Γ_{23}). The other SO(N) Racah coefficients for $\Gamma=(m_1\pm1\,m_2\pm1\,m_3\,\dot{0})$, $\Gamma=(m_1\pm1\,m_2\,m_3\pm1\,\dot{0})$ and $\Gamma=(m_1\,m_2\pm1\,m_3\pm1\,\dot{0})$ are given in Table III(a)–III(c), respectively; those for $\Gamma=(m_1+1\,m_2\,m_3\,1\,\dot{0})$, $\Gamma=(m_1\,m_2+1\,m_3\,1\,\dot{0})$ and $\Gamma=(m_1\,m_2\,m_3+1\,1\,\dot{0})$ are given in Table III(d)–III(f), respectively; those for $\Gamma=(m_1\pm1\,m_2\mp1\,m_3\,\dot{0})$, $\Gamma=(m_1\pm1\,m_2\,m_3\mp1\,\dot{0})$ and $\Gamma=(m_1\,m_2\pm1\,m_3\mp1\,\dot{0})$ are given in Table III(g)–III(i), respectively; those for $\Gamma=(m_1-1\,m_2\,m_3\,1\,\dot{0})$, $\Gamma=(m_1\,m_2-1\,m_3\,1\,\dot{0})$ and $\Gamma=(m_1\,m_2\,m_3-1\,1\,\dot{0})$ are given in Table III(j)–III(l), respectively, and, finally, those for $\Gamma=(m_1\,m_2\,m_3\,\dot{0})$ are given in Table III(m).

However, the $6j$ symbol forms of SO(N) Racah coefficients for $(1\,\dot{0})\times(m_1\ m_2\ m_3\,\dot{0})\times(1\,\dot{0})$ are not given here because they may be obtained easily by Eq. (3) together with the dimension formula of the irreducible representation $(m_1\ m_2\ m_3\,\dot{0})$ of SO(N),[26,28]

$$\begin{aligned}\mathrm{Dim}(m_1\,m_2\,m_3\,\dot{0})=\ & \frac{(2m_1+N-2)(2m_2+N-4)(2m_3+N-6)}{(N-2)(N-3)(N-4)^2(N-5)^2(N-6)^3}\\ &\times(m_1-m_2+1)(m_1+m_2+N-3)(m_1-m_3+2)\\ &\times(m_1+m_3+N-4)(m_2-m_3+1)(m_2+m_3+N-5)\\ &\times\begin{pmatrix}m_1+N-5\\ m_1+2\end{pmatrix}\begin{pmatrix}m_2+N-6\\ m_2+1\end{pmatrix}\begin{pmatrix}m_3+N-7\\ m_3\end{pmatrix},\end{aligned} \tag{7}$$

where the binomal symbol $\binom{n}{k}=n!/k!\,(n-k)!$ has been used.

We have observed the following properties for the SO(N) Racah coefficients.

(1) Like the Racah coefficients of SO(3), SO(N) Racah coefficients depend on the irreducible representations of SO(N) only, and do not depend on those of SO($N-1$).

(2) There exist two types of Racah coefficients. The first type of Racah coefficients are rank N-independent [see Table III(a)–III(f)] because they are no trace contractions for the irreducible representations in the coupling, and the second type of Racah coefficients are rank N-dependent [see Table III(g)–III(m)].[30] This property of SO(N) Racah coefficients is little different from that of SU(N) Racah coefficients, in which all SU(N) Racah coefficients are rank N-independent.[10,11,31]

From the obtained SO(N) Racah coefficients (Table III), we can gain the following simple rules: compared with $\Gamma_2=(m_1\ m_2\ m_3\,\dot{0})$, if any two entries in a Γ (see Table II), say m_i and m_j $(i\neq j)$, change by the same interval, i.e., $+1$ or -1, simultaneously, then all Racah coefficients in the corresponding unitary matrix U(Γ) only contain the factors involving m_i-m_j, and hence

TABLE III. SO(N) Racah coefficients $W\begin{pmatrix}(1\,\dot{0}) & (m_1\,m_2\,m_3\,\dot{0}) & \Gamma_{12}\\ (1\,\dot{0}) & \Gamma & \Gamma_{23}\end{pmatrix}$.

$(m_1\ m_2\ m_3\ 1\ \dot{0})$	$\frac{[m_1(m_1-2+N)+(2N-9)]m_2(m_2-4+N)m_3(m_3-6+N)-(m_1+3)(m_1-5+N)(m_2+2)(m_2-6+N)+(N-6)[(m_1+2)(m_1-5+N)+m_1]m_3(m_3-6+N)}{(m_1+3)(m_1-5+N)(m_2+2)(m_2-6+N)(m_3+1)(m_3-7+N)}$

belong to the first type. If the two entries change by the opposite interval, i.e., one $+1$ and another -1, then the corresponding Racah coefficients only contain the factors involving m_i+m_j, and hence belong to the second type. Furthermore, all of them are independent of the remaining entries [see Table III(a)–III(l)].

However, compared with Γ_2, if Γ does not change, i.e., $\Gamma=\Gamma_2$, then all Racah coefficients in the corresponding unitary matrix U(Γ) include both the factors involving m_i-m_j and the factors involving m_i+m_j, and hence belong to the second type [see Table III(m)].

(3) Each unitary matrix U(Γ) is symmetric and its matrix elements, SO(N) Racah coefficients, are real. They satisfy the orthonormality relations

$$\sum_{\Gamma_{12}} W\begin{pmatrix} \Gamma_1 & \Gamma_2 & \Gamma_{12} \\ \Gamma_3 & \Gamma & \Gamma_{23} \end{pmatrix} W\begin{pmatrix} \Gamma_1 & \Gamma_2 & \Gamma_{12} \\ \Gamma_3 & \Gamma & \overline{\Gamma}_{23} \end{pmatrix} = \delta(\Gamma_{23},\overline{\Gamma}_{23}). \tag{8}$$

The orthonormality of Racah coefficients in Table III have been checked by software ''MATHEMATICA.'' It is worth reminding readers that when $N=7$, in Table III(d)–III(f), III(j)–III(l) and III(m) the values of the type ($\bullet\bullet\bullet$ 1 $\dot{0}$) taken by Γ_{12} and Γ_{23} should be replaced by ($\bullet\bullet\bullet$).

(4) Similar to the symmetries of SO(3) Racah coefficients in angular momentum theory under the substitution $l\rightarrow -l-1$, SO(N) ($N>3$) Racah coefficients hold the kind of so-called weight-space symmetries[32] as well. For the case in this paper, any number of the independent substitutions

$$m_i\rightarrow -m_i-N+2i, \qquad i=1,2,3, \tag{9}$$

are allowed. They leave the algebraic expressions for SO(N) Racah coefficients untouched, but merely change the relative phases among them and the appearance of the irreducible representations occurring in $W(\cdots)$. When combined with the substitutions (9), the irreducible representations occurring in $W(\cdots)$ are transformed as follows:

$$(m_1\, m_2\, m_3\, \dot{0})\rightarrow(m_1\, m_2\, m_3\, \dot{0}),$$

$$(m_1\, m_2\, m_3 1\, \dot{0})\rightarrow(m_1\, m_2\, m_3 1\, \dot{0}),$$

$$(m_1\pm 2\, m_2\, m_3\, \dot{0})\rightarrow(m_1\mp 2\, m_2\, m_3\, \dot{0}),$$

$$(m_1\, m_2\pm 2\, m_3\, \dot{0})\rightarrow(m_1\, m_2\mp 2\, m_3\, \dot{0}),$$

$$(m_1\, m_2\, m_3\pm 2\, \dot{0})\rightarrow(m_1\, m_2\, m_3\mp 2\, \dot{0}),$$

$$(m_1\pm 1\, m_2\, m_3\, \dot{0})\rightarrow(m_1\mp 1\, m_2\, m_3\, \dot{0}),$$

$$(m_1\, m_2\pm 1\, m_3\, \dot{0})\rightarrow(m_1\, m_2\mp 1\, m_3\, \dot{0}),$$

$$(m_1\, m_2\, m_3\pm 1\, \dot{0})\rightarrow(m_1\, m_2\, m_3\mp 1\, \dot{0}),$$

$$(m_1\pm 1\, m_2\, m_3 1\, \dot{0})\rightarrow(m_1\mp 1\, m_2\, m_3 1\, \dot{0}),$$

$$(m_1\, m_2\pm 1\, m_3 1\, \dot{0})\rightarrow(m_1\, m_2\mp 1\, m_3 1\, \dot{0}),$$

$$(m_1\, m_2\, m_3\pm 1\, 1\, \dot{0})\rightarrow(m_1\, m_2\, m_3\mp 1\, 1\, \dot{0}),$$

$$(m_1\pm 1\, m_2\pm 1\, m_3\, \dot{0})\rightarrow(m_1\mp 1\, m_2\mp 1\, m_3\, \dot{0}),$$

$$(m_1 \pm 1\ m_2\ m_3 \pm 1\ \dot{0}) \rightarrow (m_1 \mp 1\ m_2\ m_3 \mp 1\ \dot{0}),$$

$$(m_1\ m_2 \pm 1\ m_3 \pm 1\ \dot{0}) \rightarrow (m_1\ m_2 \mp 1\ m_3 \mp 1\ \dot{0}),$$

$$(m_1 \mp 1\ m_2\ m_3 \pm 1\ \dot{0}) \rightarrow (m_1 \pm 1\ m_2\ m_3 \mp 1\ \dot{0}),$$

$$(m_1\ m_2 \mp 1\ m_3 \pm 1\ \dot{0}) \rightarrow (m_1\ m_2 \pm 1\ m_3 \mp 1\ \dot{0}).$$

IV. CONCLUSIONS

In this paper, the explicit algebraic expressions for a class of multiplicity-free SO(N) Racah coefficients for $(1\ \dot{0}) \times (m_1\ m_2\ m_3\ \dot{0}) \times (1\ \dot{0})$ are given. These results take on the stronger regularity, therefore, as the base of mathematical induction, they may be extended to the more general case of SO(N) for $(1\ \dot{0}) \times (m_1 m_2 \ldots m_{[N/2]}) \times (1\ \dot{0})$. They, and SO($N$) Racah coefficients of the spinor type for $(\frac{1}{2} \pm \dot{\frac{1}{2}}) \times (m_1 m_2 \ldots m_{[N/2]}) \times (\frac{1}{2} \pm \dot{\frac{1}{2}})$, are being studied.

[S0022-2488(98)01711-3]

Three vacuum metrics have been obtained in the paper. In the third metric, given in Eq. (62), the y factors were misplaced. Here is how the metric should read:

$$ds^2=-(f^0y^2/f)(r^{1-\gamma^0}dx^2+r^{1+\gamma^0}dy^2)+2dr[dt-\gamma^0x^2ydy]+f[dt-\gamma^0x^2ydy]^2.$$

Wigner distribution function for finite systems

Natig M. Atakishiyev,[a),b)] Sergey M. Chumakov, and Kurt Bernardo Wolf

(Received 9 May 1997; accepted for publication 11 August 1998)

We construct a Wigner distribution function for finite data sets. It is based on a finite optical system; a linear wave guide where the finite number of discrete sensors is equal to the number of modes which the guide can carry. The dynamical group for this model is SU(2) and the wave functions are sets of $N=2l+1$ data points. The Wigner distribution function assigns classical *c*-numbers to the operators of position, momentum, and wave guide mode. © *1998 American Institute of Physics.* [S0022-2488(98)00312-0]

I. CONTINUOUS AND FINITE SIGNAL ANALYSIS

The phase-space representation of data sets can be analyzed with the aid of the Wigner distribution function. This was introduced originally in quantum mechanics, where the ''signal'' is a wave function $\psi(q)$, and its Wigner function (for $\hbar=1$) is defined as[1]

$$W_\psi(q,p)=\frac{1}{2\pi}\int_{\mathfrak{R}} dx[\,\psi(q-\tfrac{1}{2}x)]^* e^{-ixp}\psi(q+\tfrac{1}{2}x). \tag{1.1}$$

When (q,p) are understood as canonically conjugate coordinates of a phase-space plane, the value of $W_\psi(q,p)$ mirrors closely the intuitive objects in the model. They can be ''particles'' in quantum mechanics, with position q and canonically conjugate momentum p; in quantum optics these objects may be the coherent states of the radiation field; in monochromatic paraxial wave optics they are often beams with Gaussian position and inclination distributions. The Heisenberg uncertainty relation is built into the Wigner picture by the Fourier transform between the position and momentum representations.

The importance of the Wigner distribution function on finite data sets can be explained in terms of Lohmann's rendering of the Wigner function in music,[2] whereas the graphs of the acoustic signal or the frequency spectrum of a performance are meaningless to visual inspection, the Wigner function will exhibit peaks at positions that are the notes in a pentagram. In effect, the Wigner function is a musical score—*partitura* of the data set $\{\psi(q)\}$, $q\in\mathfrak{R}$, which also contains the information of its Fourier transform function $\{\tilde{\psi}(p)\}$, $p\in\mathfrak{R}$. Lohmann also presents optical devices to produce essentially a photograph of the Wigner function of a line segment of data on a slide.[3]

In this paper we analyze specifically the phase-space representation of finite data sets. We are interested in the features specific to finite systems. They include the discreteness of measurement and operator spectra, and the fact that these operators are realizations of a compact Lie algebra of *difference* operators. Physicists using Lie-theoretical methods are much more familiar with algebras of *differential* operators. We should stress that the domain of difference operators are functions on the complex plane; in the same way as the difference equation $\Gamma(x+1)=x\Gamma(x)$ generalizes the factorial product of the nonnegative integers to any $x\in\mathfrak{R}$, difference operators will generally relate three neighboring points of x separated by unity. Moreover, finite difference equations have a recognizedly richer structure of solutions than their limit differential equations.[4] When the interval and density of data points approach infinity, the results obtained will match with those of the standard formalism for continuous signals.

We consider $2l+1$ complex data values

$$\mathbf{f}=\{f_m | m=-l,-l+1,...,l\}, \quad f_m \in \mathcal{C}, \tag{1.2a}$$

where $2l+1$ is a non-negative integer. These can be thought of as complex light amplitude values measured on an array of $2l+1$ points on a screen, equidistant by $\lambda>0$ and centered at the origin, i.e.,

$$f_m=f(q_m), \quad q_m=m\lambda, \quad m=-l,-l+1,...,l. \tag{1.2b}$$

In ordinary finite Fourier analysis one asks for the exponential Fourier transform to provide the wave number content $\tilde{\mathbf{f}}$ of the signal $\mathbf{f}$ in the $2l+1=N$-dimensional orthonormal basis $N^{-1/2}\exp(2\pi nm/N)$, $n=1,...,N$, consisting of Brillouin waves in a periodic lattice. This basis is adequate for a model of a finite system if the system is homogeneous under (dihedral) rotations of the lattice, so the points q_{-l} and q_l are first neighbors. When the two points q_{-l} and q_l are poles apart of an array where the middle portion carries the most significant part of the information, a different basis and transform are called for. Moreover, since the spectrum of the finite second-difference matrix is not equally spaced, the finite Fourier-exponential transform[5] is a poor basis for Lie-theoretical classification and evolution treatment of finite data in a system.

In Sec. II we present the finite wave guide model.[6] This is a physical system which embodies well the mathematical developments we present below; it is a *finite oscillator*. As will become clear at the end of the paper, the wave guide model serves as a working definition of *finite optics*. We start with Newton's equation for the classical harmonic oscillator, and show that both the usual infinite-spectrum quantum mechanical oscillator and the present finite-spectrum oscillator satisfy that equation; the former with the Heisenberg–Weyl algebra, the latter with the su(2) compact algebra. We stress that our approach uses the group of 2×2 unimodular unitary matrices (twofold cover of the rotation group in three dimensions), rather than the usual Heisenberg–Weyl group, as an arena for the Wigner function. In this way, we are assured of the existence of a *position* operator whose spectrum, $m=-l,-l+1,...,l$, is discrete and finite.

Section III defines the Wigner operator in the group ring,[7] and the Wigner distribution function as a bilinear form of the data values, which depend on the classical position, momentum, and energy variables. Section IV examines the SU(2) covariance of the Wigner function and addresses its computation by using group theoretical properties. It is clarified that for each fixed number of sensors $N=2l+1$, the essential information can be plotted and inspected visually on the surface of a two-sphere. Coherent SU(2) states are examined in Sec. V, where we also plot other interesting data sets, such as Schrödinger-cat states with their concomitant interference phenomenon. The concluding Sec. VI recapitulates our construction and indicates other finite systems with various dynamical laws, which can be analyzed by the same mathematical tools and physical concepts.

II. FINITE WAVE GUIDE MODEL AND THE SU(2) GROUP

Finite data sets and their parallel processing by optical means will be based on a planar multimodal wave guide, such as would be part of photonic devices fabricated by doping a strip on a transparent substratum.[6] The *finite* wave guide model has a refractive index whose profile is parabolic (i.e., of the form $n(q)=n_0-\nu q^2+\cdots$ in a neighborhood of its axis); it acts as a harmonic oscillator on the input wave field (signal) produced by a linear array of N coherent light sources; the output is received by the same number of wave field sensors. We stress that our wave guide model is capable of carrying only a *finite* number of modes, and corresponds to a quantum system with finite number of bound states equidistant in energy (see Fig. 1).

A. Newton equation for the finite oscillator

A unit mass in the classical one-dimensional harmonic oscillator potential $V(q)=\frac{1}{2}\omega^2 q^2$ obeys Newton's equation $\ddot{q}=-\omega^2 q$ (the dots indicate time derivatives); the same equation applies in geometric optics to the transverse ray coordinate within a wave guide. As in the quantization (or *wavization*) of geometric to paraxial wave (Fourier) optics,[8] we assume that there exists a *position* operator Q, and time derivatives of the classical observables are replaced by Lie brackets (commutators) of the corresponding operators with a Hamiltonian evolution operator H (times i). For the systems at hand, Newton's equation thereby becomes the *Lie–Newton equation*

$$[H,\,[H,\,Q]]=\omega^2 Q. \tag{2.1a}$$

By definition, the commutator of the Hamiltonian and position operators yields the *momentum* operator

$$P=i[H,\,Q], \tag{2.1b}$$

so the Lie–Newton equation (2.1a) becomes

$$[H,\,P]=i\omega^2 Q. \tag{2.1c}$$

The three operators Q, P, and H satisfy two commutation relations, (2.1b) and (2.1c), which embody the *Hamilton* equations of oscillator/wave guide systems; their geometry and dynamics, respectively. Notice that the third commutator, $[P, Q]$, is so far unspecified; for the three operators to close into a Lie algebra, their Jacobi identity requires that $[H,\,[P,\,Q]]=0$. This implies that $[P, Q]$ is constant under evolution by H, and has the form

$$[P,\,Q]=i(\sigma H+C), \tag{2.2}$$

where $\sigma\in\{+1,0,-1\}$, and C is any operator that commutes with the original three, i.e., is in the center of the Lie algebra. [We placed the i in (2.2) to use self-adjoint operators below.] The values of the coefficient σ determine the *dynamical* Lie algebra to be su(2), iso(2) or su(1,1), respectively, and C may be a function of the Casimir invariant plus/or the generator of a central extension, plus/or a constant. [If a nonlinear function of H is placed in (2.2), other algebraic structures may arise; we will not examine them here.]

In the familiar formulation of quantum phase space with operators Q and P, one sets $\sigma=0$ and $C=\hbar\mathbf{1}$; this defines the Heisenberg–Weyl–Lie algebra, and Eqs. (2.1) are satisfied when $H=\frac{1}{2}(P^2+\omega^2Q^2)$, in accordance with the classical Hamiltonian formulation.[9] In Fourier polychromatic optics, the natural constant $\hbar$ is replaced by the reduced wavelength $\lambda/2\pi$, $\lambda\in\Re-\{0\}$.[7] In Ref. 10 we examined the case when in (2.1a) and (2.1c) the oscillator frequency ω is zero, and in (2.2) $\sigma=-1$, $C=0$; we have then a Euclidean dynamical Lie algebra, iso(2). In this article we shall examine the su(2) structure that fits the finite wave guide model.

B. Difference operators for finite systems

In finite systems, the position coordinate ranges over a finite (discrete) set of integer (or half-integer) values, $q_m=m$, $m=-l,-l+1,...,l$. This set of values we here interpret as the *spectrum* of the position operator Q of the model, in a $(2l+1)$-dimensional vector space $\Re^{2l+1}$ of signals (1.2).

Denoting by $q\in\Re$ the continuous coordinate whose integer (or half-integer) values are the normalized sensor positions m, and using the right- and left-shift operators $e^{\pm\partial_q}f(q)=f(q\pm1)$, we recall from Refs. 6 and 11 the *difference* operators

$$J_1=Q=q, \tag{2.3a}$$

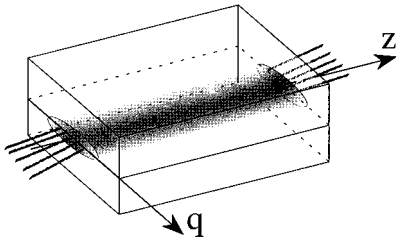

FIG. 1. Finite wave guide model. A shallow, planar wave guide doped into a transparent substrate, capable of confining only $2l+1$ transverse modes, transmits in parallel at most that number of signals to the same number of sensors.

$$J_2 = -P = -i\tfrac{1}{2}[\alpha_l(-q)e^{\partial_q} - \alpha_l(q)e^{-\partial_q}], \quad \alpha_l(q) = \sqrt{(l+q)(l-q+1)}, \tag{2.3b}$$

$$J_3 = H - l - \tfrac{1}{2} = -\tfrac{1}{2}[\alpha_l(q)e^{-\partial_q} + \alpha_l(-q)e^{\partial_q}]. \tag{2.3c}$$

These operators satisfy the Lie–Hamilton commutation relations (2.1) and (2.2) with $\sigma = +1$ and $C = -(l+\frac{1}{2})\mathbf{1}$, as generators of a Lie algebra su(2),

$$[J_1, J_2] = iJ_3, \quad [J_2, J_3] = iJ_1, \quad [J_3, J_1] = iJ_2. \tag{2.4}$$

Since the Casimir operator in this realization is $J^2 = J_1^2 + J_2^2 + J_3^2 = l(l+1)\mathbf{1}$, it is equivalent to the SU(2) unitary irreducible representation familiar from quantum angular momentum theory, but with J_1 identified as the position operator.

In this way the angular momentum algebra su(2) is woven into the foundation of finite systems, i.e., systems with a finite number of independent states, and in particular of the multimodal planar wave guide model. The spectra of positions, momenta, and energies are intrinsically discrete, finite, and equally-spaced. When we change the basis (2.3), so that the Hamiltonian $H = J_3 + l + \frac{1}{2}$ be diagonal, we find the eigenvalue equation

$$H(q)\phi_n(q,2l) = (n+\tfrac{1}{2})\phi_n(q,2l), \quad n = 0,1,...,2l, \tag{2.5}$$

that governs the wave field normal modes in the finite wave guide. The eigenfunctions $\phi_n(q,2l)$ can be written in terms of Kravchuk polynomials,[12] which satisfy a discrete orthogonality relation with a binomial weight function. Multiplying the polynomials with the square root of the latter defines the Kravchuk *functions*,[6,13] which are continuously defined in the interval $-l-1 \leqslant q \leqslant l+1$ and satisfy the discrete orthogonality relation $\Sigma_{m=-1}^{l} \phi_n'(m,2l)\phi_{n'}(m,2l) = \delta_{n,n'}$. In Ref. 13 we showed that when $l \to \infty$ and the spacing between points vanishes as l^{-1}, they become the usual quantum harmonic oscillator wave functions.

C. Polar parametrization of SU(2)

Exponentiation of the Lie algebra of operators (2.3) yields the elements of the SU(2) group, whose generic element can be parametrized by a three-vector $\mathbf{y}$, whose unit direction vector $\mathbf{v} = \mathbf{y}/|\mathbf{y}|$ is the rotation axis, and whose length $\eta = |\mathbf{y}|$ is the rotation angle around that axis, namely,

$$g[\mathbf{y}] = g[\eta\mathbf{v}] = \exp(-i\mathbf{y}\cdot\mathbf{J}) = \exp[-i\eta(v_1J_1 + v_2J_2 + v_3J_3)]. \tag{2.6}$$

$$\mathbf{y} = \eta\mathbf{v}(\theta,\phi), \quad \mathbf{v} = \begin{pmatrix} \sin\theta\sin\phi \\ \sin\theta\cos\phi \\ \cos\theta \end{pmatrix}, \quad \begin{cases} 0 \leqslant \eta < 4\pi, \\ 0 \leqslant \theta \leqslant \pi, \\ 0 \leqslant \phi < 2\pi. \end{cases} \tag{2.7}$$

This is the *polar* parametrization of the group, indicated hereafter by the square brackets; it provides an $\mathfrak{R}^3$ coordinate system where the unit element is at the origin, $g[\mathbf{0}]$, for all directions (θ,ϕ) and the SU(2) ''minus unit,'' also in the center (commutant) of the group, is the element $g[2\pi\mathbf{v}(\theta,\phi)]$, also for all directions. The vanishing of the Haar measure at $\eta = 0,2\pi$ in Eq. (2.10) below, indicates that each of these element counts for a single point of the manifold. In polar coordinates, the nth power is simply expressed as $(g[\mathbf{y}])^n = g[n\mathbf{y}]$; this defines fractional powers and yields the inverse element for $n = -1$. The angle η is counted modulo 4π and labels the conjugation classes of the group; the group elements within each class are distinguished by the axis $\mathbf{v}(\theta,\phi) \in \mathcal{S}_2$ on the two-sphere. (Relations with the more commonly used Euler angle parametrization $g(\phi,\theta,\psi)$ (Refs. 14, 15), indicated by round brackets, will appear below.)

The three generators $\mathbf{J} = (J_1, J_2, J_3)$ transform under the action of the SU(2) group as the components a row vector under the *adjoint* representation $\mathbf{R}$ by 3×3 orthogonal matrices

$$g[\mathbf{z}]\mathbf{J}(g[\mathbf{z}])^{-1} = \mathbf{J}\mathbf{R}[\mathbf{z}]. \tag{2.8}$$

The generic operator in the su(2) algebra has the form $\mathbf{y}\cdot\mathbf{J} = \Sigma_{i=1}^{3} y_i J_i$; therefore, from (2.6) and writing $\mathbf{y} = \eta\mathbf{v}(\theta,\phi)$, it follows that in polar parametrization,

$$g[\mathbf{z}]g[\mathbf{y}](g[\mathbf{z}])^{-1}=g[\mathbf{R}[\mathbf{z}]\mathbf{y}]=g[\,\eta\mathbf{R}[\mathbf{z}]\mathbf{v}]. \tag{2.9}$$

In these coordinates, the invariant measure [for which $\int_{SU(2)} dg\ f(g)=\int_{SU(2)} dg\ f(gg_0)=\int_{SU(2)} dg\ f(g^{-1})$] is[14,15]

$$dg[\mathbf{y}]=\gamma(\eta)d\mathbf{y}=\tfrac{1}{2}\sin^2\tfrac{1}{2}\eta d\,\eta d\mathbf{v},\quad d\mathbf{v}(\vartheta,\varphi)=\sin\vartheta d\vartheta d\varphi, \tag{2.10a}$$

where $d\mathbf{y}=dy_1\,dy_2\,dy_3$ is the Cartesian measure in $\mathfrak{R}^3$, the weight function is

$$\gamma(\eta)=\frac{\frac{1}{2}\sin^2\frac{1}{2}\eta}{\eta^2}=\tfrac{1}{8}\,\mathrm{sinc}\,\tfrac{1}{2}\eta, \tag{2.10b}$$

and $\mathrm{sinc}\,x=x^{-1}\sin x$ is the *sinus cardinalis* function. Finally, we recall that the SU(2) manifold is the three-sphere $\mathcal{S}_3$ and $\mathrm{vol\,SU(2)}=\int_{SU(2)}dg=2\pi^2=\mathrm{vol}\,\mathcal{S}_3$.

On the su(2) algebra, the Hamiltonian generates evolution through $g[z,\mathbf{k}]=\exp(-izH)$, i.e., a rotation by the angle z around the unit vector $\mathbf{k}$ along the three-axis. In the finite wave guide model defined by (2.3), it represents evolution of the $\mathfrak{R}^{2l+1}$ wave fields along the optical z-axis of the wave guide (times a common phase $\exp[-iz(l+\frac{1}{2})]$). Other useful optical elements are also contained in this su(2) model; a thin *wedge* (prism) of distinct refracting index in the wave guide, of small angle ω, multiplies the signal along the sensor array by $e^{-i\omega m}$; this is generated by Q and is a rotation by ω around the one-axis of the group. A tilted plate of such material *translates* signal positions at the center of the guide; it is a rotation around the two-axis of the group generated by P.

III. WIGNER OPERATOR AND DISTRIBUTION FUNCTION

In this section we define the Wigner operator on a Lie group[7] and examine the SU(2) Wigner function associated with the finite wave guide model.

A. Wigner operator and its covariance

Consider a d-parameter Lie group $\mathcal{G}$ with generators $\mathbf{J}=\{J_i\}_{i=1}^d$, whose elements in polar parametrization are $g[\mathbf{y}]=\exp(-i\mathbf{y}\cdot\mathbf{J})$, where $\mathbf{y}\cdot\mathbf{J}:=\Sigma_{j=1}^D y_jJ_j$. We define the *Wigner operator* as the family of formal operators, function of $\mathbf{x}\in\mathfrak{R}^d$, given by

$$\mathcal{W}(\mathbf{x})=\int_{\mathcal{G}}dg[\mathbf{y}]\exp[i\mathbf{y}\cdot(\mathbf{x}-\mathbf{J})]=\int_{\mathcal{G}}dg[\mathbf{y}]\exp(i\mathbf{x}\cdot\mathbf{y})g[\mathbf{y}]. \tag{3.1}$$

In the case of the unitary group SU(2), $d=3$ and the dot product is the rotation-invariant scalar product between three-vectors, $\mathbf{x}\cdot\mathbf{y}=\Sigma_{i=1}^3 x_iy_i$. The direct integral of group elements is well defined when the operator acts on functions over a homogeneous space under the group; the SU(2)-invariant measure is (2.10).

Note first that the Wigner operator at the coordinate origin, $\mathcal{W}(\mathbf{0})=\mathcal{I}$, is the unit element in the SU(2) group ring of formal operators $\mathcal{A}=\int_{\mathcal{G}} dg\ A(g)g$ (i.e., $\mathcal{I}\mathcal{A}=\mathcal{A}\mathcal{I}=\mathcal{A}$). Next, observe that the range of the polar parameters $\mathbf{y}$ is the compact SU(2) manifold, while the space $\mathbf{x}$ in the argument of the Wigner operator is $\mathfrak{R}^3$. Moreover, the function $\exp(i\mathbf{x}\cdot\mathbf{y})$ in (3.1) is not periodic over the group; for general $\mathbf{x}$ it has different values at $g[\,\eta\mathbf{v}]$ and at $g[(\eta+4\pi)\mathbf{v}]$, which represent the same element $g[\mathbf{y}]$. We must therefore fix the definition of the Wigner operator (3.1) by imposing an otherwise natural condition for operators in Lie group rings, self-adjointness. We consider the group elements $g[\mathbf{y}]$ in (3.1) acting as unitary operators on an appropriate Hilbert space, so their operator adjoint is their inverse, $(g[\mathbf{y}])^\dagger=g[-\mathbf{y}]$. Then, we obtain the adjoint of $\mathcal{W}(\mathbf{x})$ through complex conjugation of the exponential function; changing integration variables by $\mathbf{y}\mapsto-\mathbf{y}$, we reproduce (3.1) only if $\int_{SU(2)} dg[-\mathbf{y}]\cdots=\int_{SU(2)} dg[\mathbf{y}]\cdots$. The range of $\mathbf{y}=\eta\mathbf{v}(\theta,\phi)$ will be the same as that of its inverse $-\mathbf{y}$ if we agree that η, naturally ranging in $[0,4\pi)$ in accordance with (2.6)–(2.7) and counted modulo 4π, will be integrated over $(-2\pi,2\pi]$. Only in this way the Wigner operator will be self-adjoint (in the same Hilbert space): $[\mathcal{W}(\mathbf{x})]^\dagger=\mathcal{W}(\mathbf{x})$ for all $\mathbf{x}\in\mathfrak{R}^3$.

The Wigner operator (3.1) satisfies the important property of SU(2)-*covariance*,

$$g[\mathbf{y}]\mathcal{W}(\mathbf{x})(g[\mathbf{y}])^{-1}=\mathcal{W}(\mathbf{R}[\mathbf{y}]\mathbf{x}). \tag{3.2a}$$

This is a consequence of the bilateral invariance of $dg[\mathbf{y}]$ and the property (2.9) of the adjoint representation; it follows from rewriting the left-hand side of (3.2a) as

$$\int_{\mathrm{SU}(2)} dg[\mathbf{y}]\exp(i\mathbf{y}'\cdot\mathbf{x})g[\mathbf{R}\mathbf{y}']=\int_{\mathrm{SU}(2)} dg[\mathbf{y}'']\exp(i\mathbf{y}''\cdot\mathbf{R}\mathbf{x})g[\mathbf{y}''], \tag{3.2b}$$

where $\mathbf{R}=\mathbf{R}[\mathbf{y}]$ and $\mathbf{y}''=\mathbf{R}\mathbf{y}'$, to obtain the right-hand side of the equation.

B. Wigner matrix

The action of the Wigner operator (3.1) on column vectors $\mathbf{f}\in\mathfrak{R}^{2l+1}$ [whose vector components are the observed wave field values (1.2)], is

$$\mathcal{W}(\mathbf{x})\mathbf{f}=\int_{\mathrm{SU}(2)} dg[\mathbf{y}]\exp(i\mathbf{x}\cdot\mathbf{y})\mathbf{D}^l[\mathbf{y}]\mathbf{f}=\mathbf{W}^l(\mathbf{x})\mathbf{f}, \tag{3.3}$$

where $\mathbf{D}^l[\mathbf{y}]$ are the spin-l unitary irreducible representation matrices of SU(2) in polar coordinates, well known as the *Wigner D-matrices* in angular momentum theory.[14,15] We call $\mathbf{W}^l(\mathbf{x})$ the SU(2) *Wigner W-matrices*; they are the *matrix representation* of the SU(2) Wigner operator on $\mathfrak{R}^{2l+1}$.

The Wigner *D*- and *W*-matrices are essentially Fourier conjugates of each other; the integral in Eq. (3.3) can be inverted because it has the transform kernel $\exp(i\mathbf{x}\cdot\mathbf{y})$. Thus, the transform pair is

$$\mathbf{W}^l(\mathbf{x})=\int_{\mathrm{SU}(2)} \gamma(|\mathbf{y}|)d\mathbf{y}\ \exp(i\mathbf{x}\cdot\mathbf{y})\mathbf{D}^l[\mathbf{y}], \tag{3.4a}$$

$$\mathbf{D}^l[\mathbf{y}]=\frac{1}{(2\pi^3)\gamma(|\mathbf{y}|)}\int_{\mathfrak{R}^3} d\mathbf{x}\ \exp(-i\mathbf{x}\cdot\mathbf{y})\mathbf{W}^l(\mathbf{x}). \tag{3.4b}$$

From (3.4) we see that since the Wigner *D*-matrices are unitary, $(\mathbf{D}^l[\mathbf{y}])^\dagger=\mathbf{D}^l[-\mathbf{y}]$, and since we have chosen the integration range to be invariant under inversions, it follows that $\mathbf{W}^l(\mathbf{x})^\dagger=\mathbf{W}^l(\mathbf{x})$, i.e., the Wigner *W*-matrices are self-adjoint. Therefore, their eigenvalues, determinant and trace, are real. Also from (3.4), the known integral and a special value of the *D*-matrices imply

$$\mathbf{W}^l(\mathbf{0})=\int_{\mathrm{SU}(2)} dg[\mathbf{y}]\mathbf{D}^l[\mathbf{y}]=2\pi^2\delta_{l,0}, \tag{3.5a}$$

$$\int_{\mathfrak{R}^3} d\mathbf{x}\mathbf{W}^l(\mathbf{x})=(2\pi)^3\gamma(\mathbf{0})\mathbf{D}^l[\mathbf{0}]=\pi^3\mathbf{1}. \tag{3.5b}$$

The unitarity of the *D*-matrices in (3.4a) further determines the integral

$$\int_{\mathfrak{R}^3} d\mathbf{x}[\mathbf{W}^l(\mathbf{x})]^\dagger\mathbf{W}^l(\mathbf{x})=(2\pi)^3\int_{\mathrm{SU}(2)}[\gamma(|\mathbf{y}|)]^2d\mathbf{y}\mathbf{1}=\pi^4 s_4\mathbf{1}, \tag{3.6}$$

where $s_4=\int_0^{2\pi}\mathrm{sinc}^4\ z\ dz=1.0467...$ is a constant. Finally, notice that (3.4) is a transform pair between functions W of $\mathbf{x}\in\mathfrak{R}^3$ and functions D of $g[\mathbf{y}]\in\mathrm{SU}(2)$ with support inside a sphere of radius 2π in $\mathfrak{R}^3$. Payley–Wiener theorems should yield analiticity properties of the Wigner *W*-matrices that will be explored elsewhere.

C. Wigner function and its covariance

We define the *Wigner distribution function* of the finite signals $\mathbf{f}=\{f_m\}_{m=-l}^l$ and $\mathbf{g}=\{g_m\}_{m=-l}^l$ as the sesquilinear form

$$W^l(\mathbf{f},\mathbf{g}|\mathbf{x}) = \mathbf{f}^\dagger \mathbf{W}^l(\mathbf{x})\mathbf{g} = \sum_{m,m'=-l}^{l} [f_m]^* W^l_{m,m'}(\mathbf{x}) g_{m'}. \tag{3.7}$$

The Wigner matrix elements are, from (2.7), (2.10), and (3.4a),

$$W^l_{m,m'}(\chi\mathbf{u}) = \int_{-2\pi}^{2\pi} \tfrac{1}{2}\sin^2\tfrac{1}{2}\eta d\eta \int_{\mathcal{S}_2} d\mathbf{v}\, \exp(i\chi\eta\mathbf{u}\cdot\mathbf{v}) D^l_{m,m'}[\eta\mathbf{v}]. \tag{3.8}$$

In Dirac's notation one can usefully write $W^l_{m,m'}(\mathbf{x}) = \langle l,m|\mathcal{W}(\mathbf{x})|l,m'\rangle$. When $\mathbf{f}=\mathbf{g}$, we indicate the Wigner function simply by $W^l(\mathbf{f}|\mathbf{x})$; this is the expectation value of the Wigner operator in the state $\mathbf{f}$.

From the SU(2)-covariance of the Wigner operator (3.2) follows the SU(2)-covariance of the Wigner matrix and of the Wigner function,

$$\mathbf{D}^l[\mathbf{y}]\mathbf{W}^l(\mathbf{x})\mathbf{D}^l[-\mathbf{y}] = \mathbf{W}^l(\mathbf{R}[\mathbf{y}]\mathbf{x}), \tag{3.9}$$

$$W^l(\mathbf{D}^l[-\mathbf{y}]\mathbf{f},\mathbf{D}^l[-\mathbf{y}]\mathbf{g}|\mathbf{x}) = W^l(\mathbf{f},\mathbf{g}|\mathbf{R}[\mathbf{y}]\mathbf{x}). \tag{3.10}$$

One consequence is that a signal vector $\boldsymbol{\alpha}^\mu = \{\alpha^\mu_m\}^l_{m=-l}$ which is an eigenvector of any operator $J_a = \mathbf{a}\cdot\mathbf{J}$ in the su(2) algebra and with the eigenvalue μ, will have a Wigner function that will be invariant under rotations of $\mathbf{x}$ around the axis $\mathbf{a}$. This is so because rotation by $\exp(-i\omega J_a)$ will multiply its eigenvector $\boldsymbol{\alpha}^\mu$ by $\exp(-i\omega\mu)$; but in (3.3)–(3.7) we see that the Wigner function is insensitive to common signal phase factors, $W^l(e^{i\phi}\mathbf{f}|\mathbf{x}) = W^l(\mathbf{f}|\mathbf{x})$. Such is the eigenbasis of *normal modes* of the finite wave guide, which are the eigenfunctions of the Hamiltonian H and given by the Kravchuk functions (2.5).

D. Meta-phase space

The definition, properties, and use of the common Wigner distribution function (1.1) were briefly discussed in the Introduction. We propose (3.7) as the proper Wigner function for finite signals $\mathbf{f}$ in a planar multimode wave guide. Equations (2.3)–(2.6) establish a correspondence between the (c-number) arguments of $W^l(\mathbf{f}|\mathbf{x})$ and the physical observables of a wave field in a shallow waveguide, namely,

$$\mathbf{x} = \chi\boldsymbol{\mu}(\vartheta,\varphi) = \begin{pmatrix} q \\ -p \\ E-l-\frac{1}{2} \end{pmatrix} = \begin{pmatrix} \text{position} \\ -\text{momentum} \\ \text{energy}-l-\frac{1}{2} \end{pmatrix}. \tag{3.11}$$

Because the first two coordinates are of ordinary phase space, let us call the three-dimensional space of $\mathbf{x}\in\mathfrak{R}^3$ the *metaphase space* of the finite wave guide model. When l is large and E is small, in a neighborhood of the South pole we can approximate the sphere $|\mathbf{x}|^2 = q^2+p^2+(e-l-\frac{1}{2})^2 \approx l^2$, by the osculating paraboloid $E \approx (p^2+q^2)/2l$, which corresponds to the classical energy in an oscillator. We should thus expect the values of the Wigner function to peak in $\chi = |\mathbf{x}|$ between l and $l+1$. This will be borne out below.

IV. WIGNER MATRIX AND PROJECTIONS

With the aim of computing the Wigner function of finite signals, we now find expressions for the D- and W-matrix elements and some of their main properties. To understand the results in three-dimensional space, we examine spherical slices and projections.

A. D^l matrix elements in polar coordinates

For analytic and computational work it is convenient to use both polar and Euler angle coordinate systems in SU(2). Their relation is

$$g[\mathbf{y}] = g(\phi,\theta,0)g(0,0,\eta)[g(\phi,\theta,0)]^{-1}, \quad \mathbf{y} = \eta\mathbf{v}(\theta,\phi), \tag{4.1}$$

where (θ,ϕ) determine the direction of the unit vector **v**. This also holds for any matrix representation. The *D*-matrix elements are commonly written in terms of Euler angles as

$$D^l_{m,m'}(\phi,\theta,\psi)=e^{im\phi}d^l_{m,m'}(\theta)e^{im'\psi}, \tag{4.2}$$

where ϕ and ψ are rotations around the three-axis, $e^{im\phi}=\langle lm|e^{i\phi J_3}|lm\rangle$, and the *little-d*'s represent rotations around the one-axis, $d^l_{m,m'}(\theta)=\langle lm|e^{i\theta J_1}|lm'\rangle$, noting that we follow the convention of Vilenkin and Klymik[14] in rotating the second Euler angle around the one-axis; this is a form preferred for SO(N) systematics and is slightly different from that of Biedenharn and Louck in Ref. 15, Sec. 3.6, who rotate around the two-axis. The *D*-matrix elements in polar parametrization are thus bilinear in the *d*-functions,

$$\begin{aligned} D^l_{m,m'}[\eta\mathbf{v}(\theta,\phi)]&=\sum_{n=-l}^{l} D^l_{m,n}(\phi,\theta,0)e^{-in\eta}[D^l_{m',n}(\phi,\theta,0)]^* \\ &=e^{i(m'-m)\phi}\sum_{n=-l}^{l} d^l_{m,n}(\theta)e^{-in\eta}[d^l_{m',n}(\theta)]^*. \end{aligned} \tag{4.3}$$

B. W^l matrix elements on the two-sphere

Any point $\mathbf{x}=\chi\mathbf{u}(\vartheta,\varphi)\in\mathfrak{R}^3$ [cf. Eq. (2.7)] can be obtained by rotating $\chi\mathbf{k}=(0,0,\chi)$ from the North pole to $(\vartheta,\varphi)\in\mathcal{S}_2$, through

$$\mathbf{u}(\vartheta,\varphi)=\mathbf{R}(\varphi,\vartheta,0)\mathbf{k}. \tag{4.4}$$

Because of SU(2)-covariance (3.2a)–(3.9), we can write the Wigner W^l-matrix over the sphere in terms of its values at the North pole, where it is diagonal, $W^l_{m,m'}(\chi\mathbf{k})=\delta_{m,m'}W^l_m(\chi)$. Thus we have

$$W^l_{m,m'}(\chi\mathbf{u}(\vartheta,\varphi))=e^{-i(m-m')\varphi}\sum_{n=-l}^{l} d^l_{m,n}(\vartheta)W^l_n(\chi)[d^l_{m',n}(\vartheta)]^*, \tag{4.5}$$

which separates the angular dependence from the radial coordinate $\chi=|\mathbf{x}|\in\mathfrak{R}^+$, and

$$\begin{aligned} W^l_m(\chi)&=2\pi\sum_{n=-l}^{l}\int_{-1}^{1} d\,\cos\,\theta|d^l_{m,n}(\theta)|^2\int_{-2\pi}^{2\pi}\frac{1}{2}\sin^2\frac{1}{2}\,\psi d\psi\,\exp(i\psi[\chi\,\cos\,\theta-n]) \\ &=(-1)^{2l}\frac{\pi}{4}\sum_{n=-l}^{l}\int_{-1}^{1} ds|d^l_{m,n}(\arccos s)|^2 \\ &\quad\times\sin(2\pi\chi s)\left[\frac{-1}{\chi s-n+1}+\frac{2}{\chi s-n}+\frac{-1}{\chi s-n-1}\right], \end{aligned} \tag{4.6}$$

where in the last expression we have used $s:=\cos\,\theta$. Note that the integral we performed in ψ is the second difference in n of $\mathrm{sinc}\,2\pi(\chi s-n)$, and that the poles within the brackets cancel the zeros of the sine function. The eigenvalues of the self-adjoint Wigner matrix $\mathbf{W}^l(\chi\mathbf{u})$ are $\{W^l_m(\chi)\}^l_{m=-l}$. The Wigner matrix elements $W^l_{m,m'}(\mathbf{x})$ merit a deeper group-theoretical analysis; this will be done elsewhere, but it suffices to point out here that by virtue of their covariance properties, they are the *transform kernel* between functions of the continuous space coordinates $\mathbf{x}\in\mathfrak{R}^3$ and functions of the discrete space of irreducible representation indices (l,m,m'). They intertwine the angular momentum operators in their well-known differential form with their form (2.3) as difference operators.

C. Radial projection

The *radial marginal distribution* of the SU(2)-Wigner function $W^l(\mathbf{f},\mathbf{g}|\mathbf{x})$, $\mathbf{x}=\chi\mathbf{u}$, is its projection on the radius χ by integration over the spherical coordinates of $\mathbf{u}(\vartheta,\varphi)$,

$$M^l_{\text{radial}}(\mathbf{f},\mathbf{g}|\chi)=\int_{\mathcal{S}_2} d\mathbf{u}\,W^l(\mathbf{f},\mathbf{g}|\chi\mathbf{u}). \tag{4.7}$$

When we evaluate the integral (4.7) over $\mathbf{u}\in\mathcal{S}_2$, the exponential factor $\exp(i\chi\eta\mathbf{u}\cdot\mathbf{v})$ yields 4π sinc $\chi\eta$. Next, the $\mathcal{S}_2$-integral over the group parameters $\mathbf{v}(\theta,\phi)$ is computed by using

$$\int_{\mathcal{S}_2} d\mathbf{v}D^l_{m,m'}[\eta\mathbf{v}]=\frac{4\pi}{2l+1}\,\delta_{m,m'}\,\frac{\sin(l+\frac{1}{2})\eta}{\sin\frac{1}{2}\eta}. \tag{4.8}$$

Substituting, we obtain the radial projection of the Wigner function in the form

$$M^l_{\text{radial}}(\mathbf{f},\mathbf{g}|\chi)=(\mathbf{f},\mathbf{g})R^l(\chi), \tag{4.9}$$

where $(\mathbf{f},\mathbf{g})=\Sigma^l_{m=-l} f^*_m g_m$ is the inner product of the two signals (or the squared norm $|\mathbf{f}|^2$ of one signal when $\mathbf{f}=\mathbf{g}$). All radial dependence is contained in the factor

$$\begin{aligned}R^l(\chi)&=\frac{8\pi^2}{2l+1}\int_{-2\pi}^{2\pi} d\eta\,\sin\frac{1}{2}\,\eta\,\text{sinc}\,\chi\eta\,\sin\left(l+\frac{1}{2}\right)\eta\\&=\frac{4\pi^2}{(2l+1)\chi}\,[\text{Si}\,2\pi(\chi+l)+\text{Si}\,2\pi(\chi-l)-\text{Si}\,2\pi(\chi+l+1)-\text{Si}\,2\pi(\chi-l-1)],\end{aligned} \tag{4.10}$$

given in terms of the sine integral functions $\text{Si}\,x=\int_0^x \text{sinc}\,y\,dy$ (Ref. 16, Eq. 3.7632). Finally, the integral of the Wigner function over $\mathbf{x}\in\mathfrak{R}^3$ is proportional to the signal inner product (or squared norm),

$$M^l(\mathbf{f},\mathbf{g})=\int_{\mathfrak{R}^3} d\mathbf{x}W^l(\mathbf{f},\mathbf{g}|\mathbf{x})=\pi^3(\mathbf{f},\mathbf{g}). \tag{4.11}$$

In Fig. 2 we plot $R^l(\chi)$, the radial factor (4.10); taking into account (4.11) it shows that the Wigner function is concentrated in a spherical shell between radii $\chi=l$ and $l+1$. It is not difficult to show that the function $\chi R^l(\chi)$ has extremal points at every integer and half-integer $\chi\geqslant 0$, except for $\chi=l$ and $\chi=l+1$; the largest maximum of $\chi R^l(\chi)$ is at $\chi=l+\frac{1}{2}$, and $R^0(0)=2(2\pi)^3$. We emphasize that in $R^l(\chi)$ or $\chi^2R^l(\chi)$ (with the radial measure $\chi^2d\chi$), the position of this maximum shifts right or left (respectively) by small amounts but stays well within the interval $(l,l+1)$.

The number of sensors in the wave guide is fixed, so the Wigner function corresponds to a single value of l. In searching for convenient ways to plot this function of $\mathbf{x}\in\mathfrak{R}^3$, we have chosen to show its level curves on a *spherical slice* of $\mathfrak{R}^3$, for the standard value $\chi=l+\frac{1}{2}$. We have checked that similar plots at various radii near $l+\frac{1}{2}$ produce very similar figures, only with smaller maxima and curves somewhat more rounded. (Another graphing strategy for the Wigner function would be to project it by integration over χ with the radial measure $\chi^2d\chi$, or with any special or convenient measure; we leave this possibility open for future work.)

V. COHERENT STATES, ELEMENTARY STATES, CAT STATES

In this section we present the Wigner function of some signals of interest suggested by our group-theoretical treatment; they are concepts taken from the quantum theory of angular momentum. We direct our attention to coherent states and spherical harmonics.

A. Vacuum coherent state

The *vacuum* coherent state is the lowest-energy state (signal) of the system. For SU(2) and in the eigenbasis of J_3 it is the $(2l+1)$-dimensional column vector indicated

$$\boldsymbol{\alpha}(-\mathbf{k})=(0,\ldots,0,1)^{\mathsf{T}}, \tag{5.1}$$

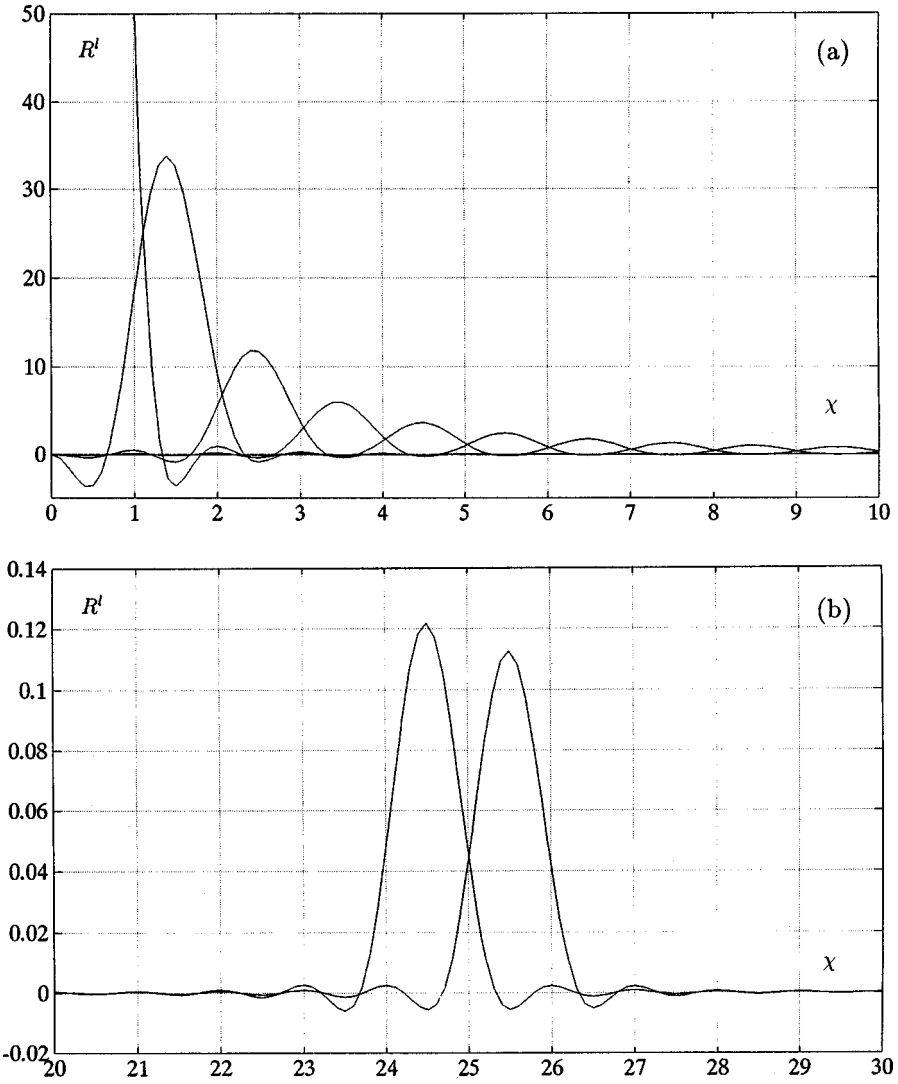

FIG. 2. Radial factor $R^l(\chi)$ in Eq. (4.10). (a) For $l=0,1,2,...,10$ in $0\leqslant\chi\leqslant 10$; the $l=0$ curve has its maximum value $2(2\pi)^3=496.10...$ at $\chi=0$. (b) Amplification of $l=24$ and $l=25$ in $20\leqslant\chi\leqslant 30$.

where T is the transpose and $-\mathbf{k}$ is a unit vector pointing to the South pole of the sphere.

In the basis where the position operator $Q=J_1$ is diagonal, the same state (5.1) represents the $(2l+1)$-point signal

$$\tilde{\boldsymbol{\alpha}}(-\mathbf{k})=\exp(-i\tfrac{1}{2}\pi J_2)\,\boldsymbol{\alpha}(-\mathbf{k})=\mathbf{D}^l(-\tfrac{1}{2}\pi,-\tfrac{1}{2}\pi,0)\,\boldsymbol{\alpha}(-\mathbf{k}), \tag{5.2a}$$

$$\tilde{\alpha}_m(-\mathbf{k})=e^{-i\pi m/2}d^l_{m,-l}(-\tfrac{1}{2}\pi)=\frac{e^{-i\pi m/2}}{2^l}\sqrt{\binom{2l}{l-m}}=e^{-i\pi m/2}\phi_0(m,2l). \tag{5.2b}$$

Here we recognize the Kravchuk function of order zero, $\phi_0(m,2l)$ in (2.5).[13] At the integers m, this function is the square root of the binomial distribution. In the limit when $l\to\infty$, $\phi_0(q,2l)$ becomes the Gaussian function of lowest oscillator state of quantum mechanics. In Fig. 3, the Wigner function (3.7) of the signal (5.2) is plotted on the sphere of radius $|\mathbf{x}|=l+\frac{1}{2}$,

$$W^l_{\text{sphere}}(\boldsymbol{\alpha}(-\mathbf{k}))|\,\vartheta,\varphi)=W^l_{-l,-l}(\chi\mathbf{u}(\vartheta,\varphi))\big|_{\chi=l+1/2}=\sum_{m=-l}^{l}W^l_m[d^l_{-l,m}(\vartheta)]^2, \tag{5.3}$$

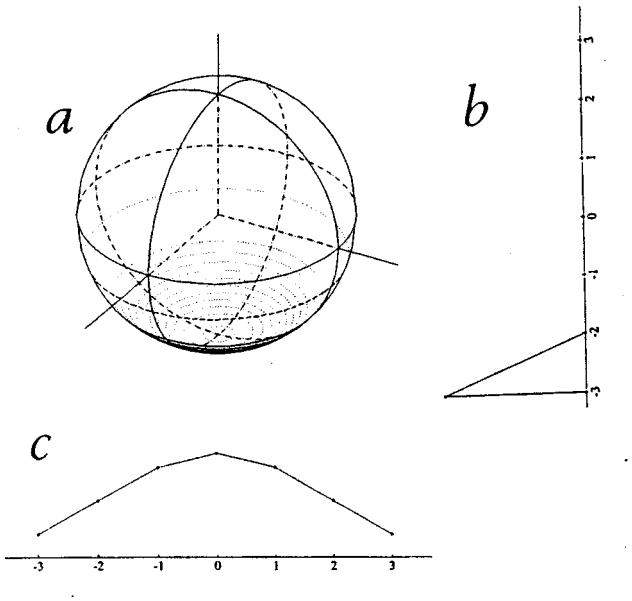

FIG. 3. Faces of the vacuum coherent state $\boldsymbol{\alpha}(-\mathbf{k})$ for $l=3$ and 7 ''sensor'' points: (a) Wigner function (5.3). Positive level contours are indicated with unbroken lines for function values 0.35, 0.7,...; zero and negative levels are indicated with broken lines. (b) Energy (mode) content. (c) The signal in the ''position'' ($Q=J_1$) basis of sensors; it is a Kravchuk function of order zero which is also the root of the binomial distribution.

where $W_m^l = W_m^l(l+\frac{1}{2})$ are constants obtained from (4.6) for the chosen value of the radius χ. Figure 3 shows the signal, its mode (energy) content, and the level curves of the Wigner function on the sphere; it shows the *partitura* of the vacuum coherent state, the ''fundamental note'' of the system. Evolution along the z-axis of the wave guide is generated by the Hamiltonian H in (2.3c), and appears as a rotation of the Wigner function around the three-axis of the sphere. Under this transformation, the vacuum state is simply multiplied by the phase $e^{-iz/2}$; hence its Wigner function is invariant.

B. SU(2) coherent states

The Wigner function of the vacuum coherent state can be rotated to any new position on the sphere (ϑ,φ) by means of SU(2)-optical transformations of the signal, i.e., by free propagation along a waveguide, with refracting wedges and tilted plates. One thus generalizes the concept of coherent states to $\boldsymbol{\alpha}(\mathbf{a})$ for any and all directions $\mathbf{a}(\vartheta,\varphi)\in\mathcal{S}_2$. If

$$\mathbf{a}=e^{i\vartheta J_1}e^{i\varphi J_3}\mathbf{k}, \quad \text{then} \quad \alpha_m(\mathbf{a}(\vartheta,\varphi))=D^l_{m,-l}(-\varphi,-\vartheta,0)=e^{im\varphi}d^l_{-l,m}(\vartheta) \tag{5.4}$$

are the components of the coherent state along **a**. In Figs. 4 we show the *antivacuum coherent* state $\boldsymbol{\alpha}(\mathbf{k})$, which is the highest energy mode in the finite planar wave guide. This is obtained from the vacuum state $\boldsymbol{\alpha}(-\mathbf{k})$ by a rotation of the sphere around the one-axis; such rotation can be physically produced with a refracting wedge that impresses a phase $e^{i\pi m}=(-1)^m$ on the input signal values; the output signal for continuous q is the Kravchuk function $\phi_{2l}(q,2l)$. For integer values m of q, this signal has the envelope of the vacuum coherent state $\phi_0(m,2l)$, but with values alternating in sign.

C. Elementary states

When the unit vector **a** is along the one-axis **i**, the coherent state $\boldsymbol{\alpha}(\mathbf{i})$ is the signal (1,0,...,0). When this signal propagates along the wave guide, the vector **a** will move around the equator; the signal will undergo the fractional Fourier–Kravchuk transformation cycle.[6] We call *elementary*

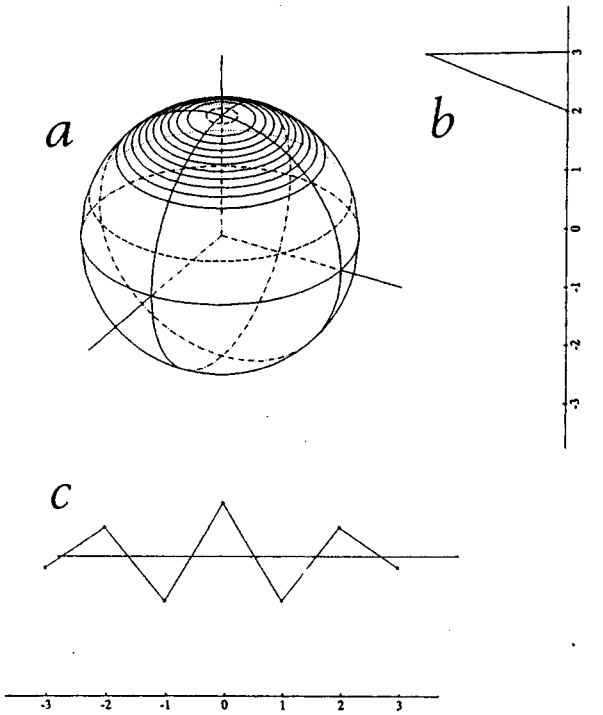

FIG. 4. Antivacuum coherent state $\boldsymbol{\alpha}(\mathbf{k})$ for $l=3$, with the parameters of the previous figure. (a) Wigner function. (b) Energy (mode) content. (c) Signal at the sensors ($Q=J_1$ basis) as in the previous figure but with alternating signs.

states (in an array of $2l+1$ sensors) to those signals with single 1 at some position ν ($l-\nu$ integer) and zeros on the rest. They are the eigenfunctions of J_1 with eigenvalues $\nu\in\{l,l-1,...,-l\}$ and will be indicated by $\boldsymbol{\alpha}^{\nu}(\mathbf{i})$.

The Wigner function (3.7) of elementary states can be then written in polar coordinates $\mathbf{u}_1(\vartheta_1,\varphi_1)$, referred to the one-axis [so $\mathbf{u}_1(0,\varphi_1)=\mathbf{i}$],

$$W^l_{\text{sphere}}(\boldsymbol{\alpha}^{\nu}(\mathbf{i})|\vartheta_1,\varphi_1)=W^l_{\nu,\nu}(\chi\mathbf{u}_1(\vartheta_1,\varphi_1))|_{\chi=l+1/2}=\sum_{m=-l}^{l} W^l_m[d^l_{\nu,m}(\vartheta_1)]^2. \tag{5.5}$$

[cf. Eq. (5.3).] The Wigner functions of elementary signals are independent of φ_1, and thus invariant under rotations of the sphere around the one-axis. Conversely, when the Wigner function of a signal $\mathbf{f}$ is invariant under rotations around some axis $\mathbf{a}$, $\mathbf{f}$ can be multiplied only by an overall phase when acted upon by $\exp(i\omega\mathbf{a}\cdot\mathbf{J})$; therefore $\mathbf{f}$ will be an eigenfunction of $\mathbf{a}\cdot\mathbf{J}$. From the plot of the Wigner function one can determine readily whether or not an output signal $\mathbf{f}=\{f_m\}^l_{m=-l}$ derives from the input of an elementary signal (0,...,0,1,0,...,0) through an SU(2)-optical system.

D. Schrödinger-cat signals and their smile function

The sum of two signals is a *Schrödinger-cat signal*. The original Schrödinger ''paradox'' of coherently superposing one dead and one live cat states applies fruitfully to signal analysis.

Consider two signals $\mathbf{f}$ and $\mathbf{g}$; the Wigner function of their linear combination $c_f\mathbf{f}+c_g\mathbf{g}$ is

$$W(c_f\mathbf{f}+c_g\mathbf{g}|\mathbf{x})=|c_f|^2W(\mathbf{f}|\mathbf{x})+|c_g|^2W(\mathbf{g}|\mathbf{x})+2\,\text{Re}\,c_f^*c_gW(\mathbf{f},\mathbf{g}|\mathbf{x}). \tag{5.6}$$

The Wigner functions of the two signals thus not only add, but *interfere*. The cross term $S(\mathbf{f},\mathbf{g}|\mathbf{x})=2\,\text{Re}\,\mathbf{f}^{\dagger}\mathbf{W}(\mathbf{x})\mathbf{g}$ has been called the *smile* function of the Schrödinger-cat state; it is a most prominent feature of the Wigner function of cat states that carries the holographic information of the object signal $\mathbf{g}$ with the reference signal $\mathbf{f}$.[17]

In Fig. 5 we plot Schrödinger cat states composed of two normal modes of the wave guide, for $l=3$ and 7 sensors. If we place the one-axis along the three-axes of the figures, the Schrödinger

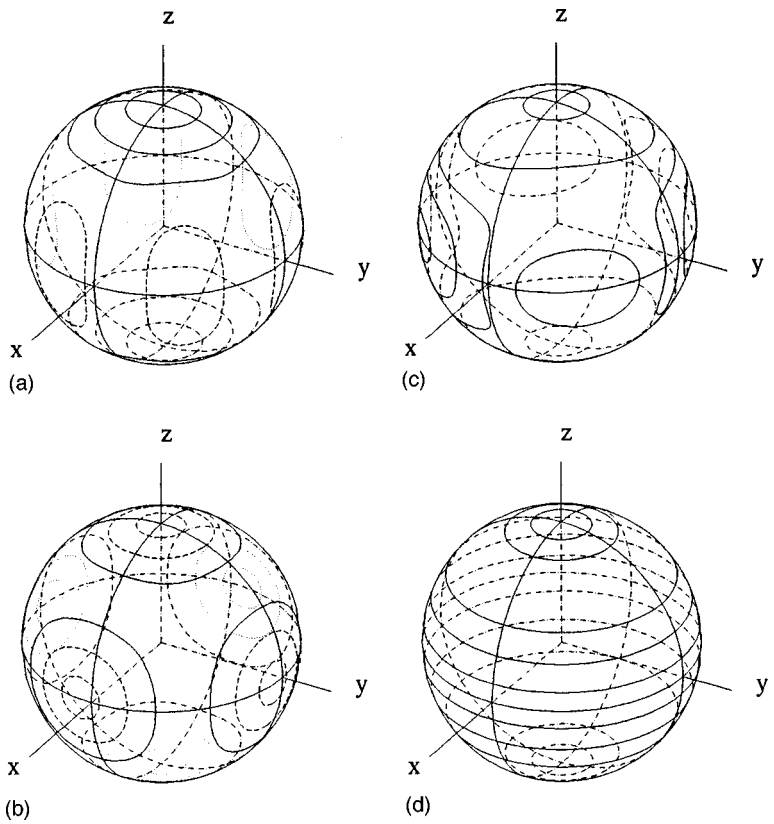

FIG. 5. Schrödinger-cat states of two normal modes or elementary seven-point signals ($l=3$). (a) ($1/\sqrt{2}$, 0, 0, 0, 0, 0, $1/\sqrt{2}$), (b) (0, $1/\sqrt{2}$, 0, 0, 0, $1/\sqrt{2}$, 0), (c) (0, 0, $1/\sqrt{2}$, 0, $1/\sqrt{2}$, 0, 0), and (d) (0,0,0,1,0,0,0).

cats are ''bilocalized'' states and the last is an elementary state. Compare Fig. 5(a) with Figs. 3 and 4, noticing the six oscillations (*teeth*) of the smile across the equator; Fig. 5(b) exhibits four, Fig. 5(c) shows two, and Fig. 5(d) has axial symmetry.

VI. CONCLUDING REMARKS

We represented finite data sets by their Wigner function in an optical model of planar multimodal wave guides. Position, momentum, and energy (mode number) are *c*-number coordinates which are associated to the generators of su(2) algebra; the latter are self-adjoint difference operators with discrete, equally-spaced, and finite spectra. The *partitura* of a signal is drawn on a sphere. The vacuum coherent state is analogous to the ground harmonic oscillator wave function; from it, all other coherent states can be produced by SU(2)-optical elements, wave guide, wedge, and slab. These transformations are the counterpart of rotation and translation of classical phase space.

The applicability of our construction extends to other mechanical and optical systems, also based on finite data sets but with different dynamics. For instance, the quantum *point rotor* (a mass point constrained to move on $\mathcal{S}_2$) has symmetry group SO(3), which is covered twice by SU(2). This system is isomorphic to the mechanical vibrating sphere and, by stereographic projection, to the two-dimensional Maxwell fisheye wave-optical medium.[18] In both of these cases, wave functions are on the sphere and generally contain *all* spherical harmonics,

$$\Psi(\beta,\gamma)=\sum_{l=0}^{\infty}\sum_{m=-l}^{l}\Psi_m^l Y_m^l(\beta,\gamma). \tag{6.1}$$

The data set is now infinite and given by the tower of coefficients $\mathbf{\Psi}=\{\mathbf{\Psi}^l\}_{l=0}^{\infty}$, $\mathbf{\Psi}^l=\{\Psi_m^l\}_{m=-l}^{l}$.

The SU(2) Wigner function (3.7) was built for a single value of l corresponding to a fixed number of sensors of the model, and the radial factor (4.10) indicated that it is concentrated in a spherical shell of mean radius $l+\frac{1}{2}$. If now the data vector is (6.1), the Wigner operator (3.1) will act irreducibly on each subvector $\mathbf{\Psi}^l$, and the Wigner function of $\mathbf{\Psi}$ will be the sum of the Wigner functions in the irreducible subspaces, i.e.,

$$W(\mathbf{\Psi}|\mathbf{x})=\sum_{l=0}^{\infty} W^l(\mathbf{\Psi}^l|\mathbf{x})=\sum_{l=0}^{\infty} \mathbf{\Psi}^{l\dagger}\mathbf{W}^l(\mathbf{x})\mathbf{\Psi}^l. \tag{6.2}$$

Such a function must be plotted in $\mathfrak{R}^3$-space $\mathbf{x}$ and will show the quasiprobability distribution of the angular momentum vector $\mathbf{J}$ in the mechanical model, and of the beam parameters in the Maxwell fisheye. As drawn in elementary texts, the extreme spherical harmonic (coherent state) $Y_l^l(\beta,\gamma)$ has a minimal uncertainty cone around the three-axis, $Y_{l-1}^l(\beta,\gamma)$ has a larger cone, etc., until $Y_0^l(\beta,\gamma)$ opens the cone into the equator. Thus, while the wave function on the sphere $Y_l^l(\beta,\gamma)$ have their square maximum on the equator $\beta=\frac{1}{2}\pi$ (where the classical particle is), the Wigner function is concentrated in the North polar cap around $\mathbf{x}=(l+\frac{1}{2})\mathbf{k}$ (where the angular momentum is). On the other hand, strongly localized rotor wave functions, containing a wide spread of l's, will have Wigner functions (6.2) widely spread in $|\mathbf{x}|$.

The dynamics of the rotor models (vibrating sphere and Maxwell fisheye) are different from the wave guide, however; their Hamiltonian is proportional to the Casimir operator of so(3)=su(2), rather than to one of its generators. Since under the corresponding ''time'' evolution τ, each component $\mathbf{\Psi}^l$ is multiplied by the phase $\exp[i\tau l(l+1)]$, it follows that the Wigner function (6.2) is invariant under rotor dynamics.

Nonlinear processes on discrete, finite systems, can also be analyzed with the SU(2) Wigner function (3.7) when the Hamiltonian belongs to the su(2) *enveloping* algebra. This is the case of the finite analog of the optical Kerr medium studied in Ref. 19, whose Hamiltonian is $\sim J_3+\alpha J_3^2$. It also applies for Hamiltonians contrieved to have the form $\frac{1}{2}J_2^2+V(J_1)$, to mimic the classical form of mechanics $\frac{1}{2}p^2+V(q)$, but restricted to a finite number of bound states. Natural applications for SU(2)-Wigner functions will also include spin and pseudo-spin systems, as they appear, e.g., in quantum optics, when a collection of two-level atoms interact with the radiation field under small-volume approximation, as in the Dicke model.[20,21] Time evolution in these cases deforms the shape of the initial coherent state on the sphere; in the Kerr medium, the SU(2) Wigner function gives a transparent picture of the nature of fractional-period resonances.[19] Covariance does not hold beyond SU(2), so we can expect purely quantum effects (including squeezing) to show up in the Wigner function on the sphere.

ACKNOWLEDGMENTS

We are very grateful to the referee for carefully reading the original manuscript and his critical remarks which have helped us greatly to improve the presentation of our results. We thank Guillermo Krötzsch for his kind help with the figures. This work was performed under the support of Project DGAPA-UNAM 106595 *Optica Matemática.*

Resolution of some mathematical problems arising in the relativistic treatment of the *S* states of three-electron systems

D. Matthew Feldmann, Paul J. Pelzl, and Frederick W. King

(Received 16 April 1998; accepted for publication 27 August 1998)

Some of the mathematical difficulties that arise in the evaluation of the Breit–Pauli relativistic energy corrections for the *S* states of three-electron systems are resolved. Evaluation of the expectation value of the Breit–Pauli Hamiltonian using explicitly correlated wave functions leads to sets of integrals that diverge individually. By appropriately combining these integrals, and using some judicious series expansions, all the integration problems are resolved in terms of well-known auxiliary functions. © *1998 American Institute of Physics.* [S0022-2488(98)02512-2]

I. INTRODUCTION

There has been considerable progress over the past ten years on the calculation of high-precision properties of the lithium atom and other members of the Li isoelectronic series (for a recent summary of this progress see Refs. 1 and 2). A large part of this effort has been achieved using Hylleraas (or configuration interaction (CI)-Hylleraas) type wave functions.

One important property that has received limited theoretical attention is the high-precision calculation of the relativistic correction to the energy, ΔE_{REL}. This is a key contribution in determining a precise theoretical estimate of the first ionization potential. At present, the only calculations of the relativistic correction to the ground state energy for the lithium atom are due to Chung,[3] who used the CI technique, the very recent paper of Yan and Drake using the Hylleraas technique,[4] and the work of King *et al.*,[5] who also employed the Hylleraas method. Chung's calculation required a significant core correction, determined by first computing the relativistic correction for Li^+, and then comparing with precise calculations for Li^+ using Hylleraas-type wave functions.[6,7] This core correction was then applied directly to the Li calculation. A very effective approach to obtaining high-precision estimates of ΔE_{REL} is to make use of large-scale Hylleraas-type expansions. Progress in this area has been hampered by the mathematical difficulties which arise for the operators

$$H_{\mathrm{mass}}=-\frac{\alpha^2}{8}\sum_{i=1}^{3}\nabla_i^4, \tag{1a}$$

$$H_{\mathrm{oo}}=\frac{\alpha^2}{2}\sum_{i=1}^{3}\sum_{j>i}^{3}\frac{1}{r_{ij}}\left(\nabla_i\cdot\nabla_j+\frac{\mathbf{r}_{ij}\cdot(\mathbf{r}_{ij}\cdot\nabla_i)\nabla_j}{r_{ij}^2}\right), \tag{1b}$$

where α is the fine structure constant and r_{ij} is the interelectronic separation. For the three-electron problem, evaluation of the matrix elements of H_{mass} or H_{oo} [in the form displayed in Eqs. (1a) and (1b)] using a general Hylleraas expansion can be shown to involve the following integrals:

$$I(i,j,k,l,m,n,\alpha,\beta,\gamma)\equiv\int r_1^i r_2^j r_3^k r_{23}^l r_{31}^m r_{12}^n e^{-\alpha r_1-\beta r_2-\gamma r_3}\,d\mathbf{r}_1\,d\mathbf{r}_2\,d\mathbf{r}_3, \tag{2}$$

where $i,j,k\geqslant -2$, $l\geqslant -2$, $m\geqslant -2$, and $n\geqslant -1$;

 © 1998 American Institute of Physics

$$I_1(i,j,k,l,m,\alpha,\beta,\gamma) \equiv \int r_1^i r_2^j r_3^k \left(\frac{r_1^2 - r_2^2}{r_{12}^3} \right) r_{23}^l r_{31}^m e^{-\alpha r_1 - \beta r_2 - \gamma r_3} \, d\mathbf{r}_1 \, d\mathbf{r}_2 \, d\mathbf{r}_3, \tag{3}$$

$$I_2(i,j,k,l,m,\alpha,\beta,\gamma) \equiv \int r_1^i r_2^j r_3^k \left(\frac{r_{31}^2 - r_{23}^2}{r_{12}^3} \right) r_{23}^l r_{31}^m e^{-\alpha r_1 - \beta r_2 - \gamma r_3} \, d\mathbf{r}_1 \, d\mathbf{r}_2 \, d\mathbf{r}_3, \tag{4}$$

and

$$I_3(i,j,k,l,m,\alpha,\beta,\gamma) \equiv \int r_1^i r_2^j r_3^k \left(\frac{r_1^2 - r_2^2}{r_{12}^2} \right) r_{23}^l r_{31}^m e^{-\alpha r_1 - \beta r_2 - \gamma r_3} \, d\mathbf{r}_1 \, d\mathbf{r}_2 \, d\mathbf{r}_3, \tag{5}$$

where $i,j,k \geqslant -2$, $l \geqslant -1$, and $m \geqslant 1$. The combination of terms displayed in Eqs. (3) and (4) is essential, if a finite value of the expectation value of the Breit–Pauli Hamiltonian is to be obtained using a first-order perturbation theory approach. For Eq. (2) and some related generalizations, several evaluation approaches exist in the literature for the case where l, m, and n are $\geqslant -1$,[8–18] and for the more difficult cases involving $l = -2$ (and $m = -2$).[19–24] Some of the published techniques could be applied to evaluate I_3.

The purpose of this paper is to present an efficient method for the evaluation of the integrals I_1, I_2, and I_3. The integrals are evaluated for the cases $i,j,k \geqslant -2$, $l \geqslant -1$, and $m \geqslant -1$. The obvious reduction of the I_1 and I_2 integrals into a difference of I integrals is not possible, because the separate I integrals both diverge. This is discussed further in Appendix A. While I_3 could be calculated by taking a difference of I integrals, a computationally superior approach is discussed in Sec. IV. The solution method is to reduce each of the integrals to a series of well-known auxiliary functions.

II. EVALUATION OF I_1

To evaluate I_1, the following expansions are employed:[25–27]

$$r_{23}^l = \sum_{w_2=0}^{\infty} R_{l w_2}(r_2, r_3) P_{w_2}(\cos \theta_{23}), \tag{6}$$

$$r_{31}^m = \sum_{w_3=0}^{\infty} R_{m w_3}(r_1, r_3) P_{w_3}(\cos \theta_{31}), \tag{7}$$

and

$$\frac{1}{r_{12}^3} = \frac{1}{r_{12>}^2 - r_{12<}^2} \sum_{w_1=0}^{\infty} (2w_1 + 1) \frac{r_{12<}^{w_1}}{r_{12>}^{w_1+1}} P_{w_1}(\cos \theta_{12}). \tag{8}$$

Equations (6) and (7) are the Sack expansions for the interelectron coordinates.[25] Equation (8) is discussed in Appendix B. Here $r_{12<}$ denotes the lesser of (r_1, r_2), $r_{12>}$ represents the greater of (r_1, r_2), and $P_n(x)$ designates a Legendre polynomial throughout this work.

Substituting Eqs. (6), (7), and (8) into Eq. (3) gives

$$I_1 = \sum_{w_1=0}^{\infty} \sum_{w_2=0}^{\infty} \sum_{w_3=0}^{\infty} (2w_1 + 1) I_R(w_1, w_2, w_3) I_\Omega(w_1, w_2, w_3), \tag{9}$$

where I_R is the integral over the radial coordinates,

$$I_R(w_1, w_2, w_3) = \int r_1^{i+2} r_2^{j+2} r_3^{k+2} r_{12<}^{w_1} r_{12>}^{-w_1-1} \left(\frac{r_1^2 - r_2^2}{r_{12>}^2 - r_{12<}^2} \right) R_{l w_2}(r_2, r_3) \times R_{m w_3}(r_1, r_3) e^{-\alpha r_1 - \beta r_2 - \gamma r_3} \, dr_1 \, dr_2 \, dr_3, \tag{10}$$

and I_Ω is the integral over the angular variables,

$$I_\Omega(w_1,w_2,w_3)=\int P_{w_1}(\cos\,\theta_{12})P_{w_2}(\cos\,\theta_{23})P_{w_3}(\cos\,\theta_{31})d\Omega_1\,d\Omega_2\,d\Omega_3. \tag{11}$$

The functional dependence of I_R on $\{i,j,k,l,m,\alpha,\beta,\gamma\}$ is suppressed to simplify the notation. Expanding the Legendre polynomials in terms of spherical harmonics, the angular integral simplifies to

$$I_\Omega(w_1,w_2,w_3)=\frac{64\pi^3}{(2w_1+1)^2}\,\delta_{w_1w_2}\delta_{w_2w_3}, \tag{12}$$

where δ_{ij} denotes a Kronecker delta. Equation (9) now becomes

$$I_1=64\pi^3\sum_{w_1=0}^{\infty}\frac{I_R(w_1)}{(2w_1+1)}, \tag{13}$$

where $I_R(w_1)\equiv I_R(w_1,w_1,w_1)$.

To evaluate the radial integral the formulas for the Sack radial functions are employed:[25]

$$R_{lw_1}(r_2,r_3)=\sum_{p=0}^{\infty}a_{w_1lp}r_{23<}^{w_1+2p}r_{23>}^{l-w_1-2p} \tag{14}$$

and

$$R_{mw_1}(r_1,r_3)=\sum_{q=0}^{\infty}a_{w_1mq}r_{31<}^{w_1+2q}r_{31>}^{m-w_1-2q}, \tag{15}$$

where

$$a_{tuv}=\frac{(-u/2)_t(t-u/2)_v(-1/2-u/2)_v}{(1/2)_t v!(t+3/2)_v} \tag{16}$$

and $(z)_n$ denotes a Pochhammer symbol. Inserting Eqs. (14) and (15) into Eq. (10) gives

$$\begin{aligned}I_R(w_1)=\sum_{p=0}^{\infty}\sum_{q=0}^{\infty}a_{w_1lp}a_{w_1mq}\int r_1^{i+2}r_2^{j+2}r_3^{k+2}r_{12<}^{w_1}r_{12>}^{-w_1-1}\left(\frac{r_1^2-r_2^2}{r_{12>}^2-r_{12<}^2}\right)\\ \times r_{23<}^{w_1+2p}r_{23>}^{l-w_1-2p}r_{31<}^{w_1+2q}r_{31>}^{m-w_1-2q}e^{-\alpha r_1-\beta r_2-\gamma r_3}\,dr_1\,dr_2\,dr_3.\end{aligned} \tag{17}$$

If the integration in Eq. (17) is broken up into the six regions $r_i\leqslant r_j\leqslant r_k$, then I_1 can be written as

$$\begin{aligned}I_1(i,j,k,l,m,\alpha,\beta,\gamma)=64\pi^3\sum_{w=0}^{\infty}\frac{1}{(2w+1)}\sum_{p=0}^{\infty}\sum_{q=0}^{\infty}a_{wlp}a_{wmq}\\ \times\{W(k+2+2p+2q+2w,j+2+l-2p,i+m+1-2q-2w,\gamma,\beta,\alpha)\\ +W(j+2+2w+2p,k+2+2q+l-2p,i+m+1-2q-2w,\beta,\gamma,\alpha)\\ +W(j+2+2w+2p,i+1+2q,k+m+l+2-2w-2p-2q,\beta,\alpha,\gamma)\\ -W(i+2+2w+2q,j+1+2p,k+m+l+2-2w-2p-2q,\alpha,\beta,\gamma)\\ -W(i+2+2w+2q,k+2+m-2q+2p,j+1+l-2w-2p,\alpha,\gamma,\beta)\\ -W(k+2+2p+2q+2w,i+2+m-2q,j+1+l-2w-2p,\gamma,\alpha,\beta)\},\end{aligned} \tag{18}$$

where

$$W(L,M,N,a,b,c)=\int_0^\infty x^L e^{-ax}\,dx\int_x^\infty y^M e^{-by}\,dy\int_y^\infty z^N e^{-cz}\,dz. \tag{19}$$

The W integrals have been well studied in the literature,[8,9,13,16,28–30] and efficient algorithms exist for the evaluation of these auxiliary functions.

We now examine the summation limits of the w, p, and q sums of Eq. (18). Because of the following property of the Pochhammer symbol,

$$(-k)_l=0, \quad l>k \text{ for positive integer } k, \tag{20}$$

the p summation terminates at $(l+1)/2$ for odd l, and $(l/2)-w$ for even l. Similarly, the q summation terminates at $(m+1)/2$ for odd m, and $(m/2)-w$ for even m. These conditions follow from the definition of a_{tuv} given in Eq. (16). This leads to the following termination conditions for the w sum:

$$\frac{m}{2}, \quad m \text{ even and } n \text{ odd},$$

$$\frac{n}{2}, \quad n \text{ even and } m \text{ odd},$$

$$\min\left\{\frac{m}{2},\frac{n}{2}\right\}, \quad m \text{ and } n \text{ both even}.$$

For m and n both odd, the w sum is nonterminating.

In addition to the individual constraints on i, j, k, l, and m mentioned in the Introduction, it is also necessary that

$$i+j+k+l+m\geqslant -7. \tag{21}$$

This follows directly from a known constraint on the arguments of the W integrals, namely

$$L+M+N\geqslant -2. \tag{22}$$

Yan and Drake[23] give a reduction formula [see their Eq. (128)] for a radial integral which is related to I_1. This radial integral is part of a nested sum, which for the general case would involve a double infinite sum.

III. EVALUATION OF I_2

For this integral, the coordinate system of choice is a three-dimensional analog of the one used by Hylleraas,[31] where the directions of the vectors $\mathbf{r}_1$ and $\mathbf{r}_2$ are given relative to $\mathbf{r}_3$. This method has been previously employed to consider other three-electron integration problems.[10] In this coordinate system the volume element becomes

$$d\mathbf{r}_1\,d\mathbf{r}_2\,d\mathbf{r}_3=r_1^2r_2^2r_3^2\,dr_1\,dr_2\,dr_3\sin\theta_3\,d\theta_3\,d\phi_3\sin\theta_{23}\,d\theta_{23}\,d\phi_{23}\sin\theta_{31}\,d\theta_{31}\,d\phi_{31}. \tag{23}$$

If $r_{31}^2-r_{23}^2$ is written as

$$r_{31}^2-r_{23}^2=r_1^2-r_2^2-2r_1r_3\cos\theta_{31}+2r_2r_3\cos\theta_{23}, \tag{24}$$

then I_2 may be expressed as

$$I_2(i,j,k,l,m,\alpha,\beta,\gamma)=I_1(i,j,k,l,m,\alpha,\beta,\gamma)-2J_1(i,j,k,l,m,\alpha,\beta,\gamma), \tag{25}$$

where

$$J_1(i,j,k,l,m,\alpha,\beta,\gamma)=\int r_1^i r_2^j r_3^{k+1}\left(\frac{r_1\cos\theta_{31}-r_2\cos\theta_{23}}{r_{12}^3}\right) r_{23}^l r_{31}^m e^{-\alpha r_1-\beta r_2-\gamma r_3}\, d\mathbf{r}_1\, d\mathbf{r}_2\, d\mathbf{r}_3. \tag{26}$$

J_1 is simplified by substituting Eqs. (6), (7), (8), (14), and (15) into Eq. (26) and integrating over θ_3 and ϕ_3 to obtain

$$J_1=4\pi\sum_{w_1=0}^{\infty}(2w_1+1)\sum_{w_2=0}^{\infty}\sum_{w_3=0}^{\infty}\sum_{p=0}^{\infty}\sum_{q=0}^{\infty}a_{w_2lp}a_{w_3mq}\int r_1^{i+2}r_2^{j+2}r_3^{k+3}r_{23<}^{w_2+2p}r_{23>}^{l-w_2-2p}$$
$$\times r_{31<}^{w_3+2q}r_{31>}^{m-w_3-2q}r_{12<}^{w_1}r_{12>}^{-w_1-1}\left(\frac{r_1\Phi_1-r_2\Phi_2}{r_{12>}^2-r_{12<}^2}\right)e^{-\alpha r_1-\beta r_2-\gamma r_3}\, dr_1\, dr_2\, dr_3, \tag{27}$$

where

$$\Phi_1=\int_0^{2\pi}d\phi_{23}\int_0^{2\pi}d\phi_{31}\int_0^{\pi}d\theta_{31}\sin\theta_{31}\int_0^{\pi}d\theta_{23}\sin\theta_{23}\cos\theta_{31}$$
$$\times P_{w_1}(\cos\theta_{12})P_{w_2}(\cos\theta_{23})P_{w_3}(\cos\theta_{31}) \tag{28}$$

and

$$\Phi_2=\int_0^{2\pi}d\phi_{23}\int_0^{2\pi}d\phi_{31}\int_0^{\pi}d\theta_{31}\sin\theta_{31}\int_0^{\pi}d\theta_{23}\sin\theta_{23}\cos\theta_{23}$$
$$\times P_{w_1}(\cos\theta_{12})P_{w_2}(\cos\theta_{23})P_{w_3}(\cos\theta_{31}). \tag{29}$$

Evaluation of the integrals Φ_1 and Φ_2 leads to

$$\Phi_1=\frac{16\pi^2\delta_{w_1w_2}}{2w_1+1}\left\{\frac{w_2}{4w_2^2-1}\,\delta_{w_2,w_3+1}+\frac{w_3}{4w_3^2-1}\,\delta_{w_3,w_2+1}\right\} \tag{30}$$

and

$$\Phi_2=\frac{16\pi^2\delta_{w_1w_3}}{2w_1+1}\left\{\frac{w_2}{4w_2^2-1}\,\delta_{w_2,w_3+1}+\frac{w_3}{4w_3^2-1}\,\delta_{w_3,w_2+1}\right\}. \tag{31}$$

The solution of these integrals is discussed in Appendix C. Substituting Eqs. (30) and (31) into Eq. (27) leads to

$$J_1=64\pi^3\sum_{w_2=0}^{\infty}\sum_{w_3=0}^{\infty}\sum_{p=0}^{\infty}\sum_{q=0}^{\infty}a_{w_2lp}a_{w_3mq}\int r_1^{i+2}r_2^{j+2}r_3^{k+3}r_{23<}^{w_2+2p}r_{23>}^{l-w_2-2p}r_{31<}^{w_3+2q}$$
$$\times r_{31>}^{m-w_3-2q}e^{-\alpha r_1-\beta r_2-\gamma r_3}\left(\frac{r_1r_{12<}^{w_2}r_{12>}^{-w_2-1}-r_2r_{12<}^{w_3}r_{12>}^{-w_3-1}}{r_{12>}^2-r_{12<}^2}\right)$$
$$\times\left[\frac{w_2}{4w_2^2-1}\,\delta_{w_2,w_3+1}+\frac{w_3}{4w_3^2-1}\,\delta_{w_3,w_2+1}\right]dr_1\, dr_2\, dr_3. \tag{32}$$

Using the fact that

$$a_{(t+1)uv}=\left(\frac{2t+3}{2t+1}\right)\left(\frac{2t+2v-u}{2t+2v+3}\right)a_{tuv} \tag{33}$$

allows I_2 to be simplified to

$$
\begin{aligned}
I_2(i,j,k,l,m,\alpha,\beta,\gamma) &= I_1(i,j,k,l,m,\alpha,\beta,\gamma) \\
&+ 128\pi^3 \sum_{w=0}^{\infty} \frac{(w+1)}{(2w+1)^2} \sum_{q=0}^{\infty} \sum_{p=0}^{\infty} a_{wmq} a_{wlp} \left[\left(\frac{2w+2p-l}{2w+2p+3} \right) \right. \\
&\times \{ W(i+2+2w+2q, j+1+2p, k+m+l+2-2w-2p-2q, \alpha, \beta, \gamma) \\
&+ W(i+2+2w+2q, k+m+4+2p-2q, j+l-1-2w-2p, \alpha, \gamma, \beta) \\
&+ W(k+4+2w+2p+2q, i+m+2-2q, j+l-1-2w-2p, \gamma, \alpha, \beta) \} \\
&- \left(\frac{2w+2q-m}{2w+2q+3} \right) \{ W(j+2+2w+2p, i+1+2q, k+m \\
&+ l+2-2w-2p-2q, \beta, \alpha, \gamma) \\
&+ W(j+2+2w+2p, k+4+l-2p+2q, i+m-1-2w-2q, \beta, \gamma, \alpha) \\
&\left. + W(k+4+2w+2p+2q, j+2+l-2p, i+m-1-2w-2q, \gamma, \beta, \alpha) \} \right].
\end{aligned} \tag{34}
$$

Equation (34) represents the solution to I_2. The summation limits of the w, p, and q sums are the same as those for the I_1 integral. The constraint given in Eq. (21) also applies for Eq. (34).

VI. EVALUATION OF I_3

The generating function for the Chebyshev polynomials of the first kind is

$$
\frac{1-r^2}{1-2rx+r^2} = 1 + 2 \sum_{w_1=1}^{\infty} r^{w_1} T_{w_1}(x). \tag{35}
$$

Letting $r = r_{12<}/r_{12>}$ and $x = \cos\theta_{12}$ in Eq. (35) yields

$$
\frac{1}{r_{12}^2} = \frac{1}{r_{12>}^2 - r_{12<}^2} \left[1 + 2 \sum_{w_1=1}^{\infty} \left(\frac{r_{12<}}{r_{12>}} \right)^{w_1} T_{w_1}(\cos\theta_{12}) \right]. \tag{36}
$$

Substituting Eqs. (6), (7), and (36) into Eq. (5) leads to the result

$$
I_3 = F(i,j,k,l,m,\alpha,\beta,\gamma) + 2 \sum_{w_1=1}^{\infty} \sum_{w_2=0}^{\infty} \sum_{w_3=0}^{\infty} I_\Omega(w_1,w_2,w_3) I_R(w_1,w_2,w_3), \tag{37}
$$

where

$$
\begin{aligned}
F(i,j,k,l,m,\alpha,\beta,\gamma) = \sum_{w_2=0}^{\infty} \sum_{w_3=0}^{\infty} \int r_1^i r_2^j r_3^k \left(\frac{r_1^2 - r_2^2}{r_{12>}^2 - r_{12<}^2} \right) R_{lw_2}(r_2,r_3) R_{mw_3}(r_3,r_1) \\
\times P_{w_2}(\cos\theta_{23}) P_{w_3}(\cos\theta_{31}) d\mathbf{r}_1\, d\mathbf{r}_2\, d\mathbf{r}_3,
\end{aligned} \tag{38}
$$

$$
I_\Omega = \int T_{w_1}(\cos\theta_{12}) P_{w_2}(\cos\theta_{23}) P_{w_3}(\cos\theta_{31}) d\Omega_1\, d\Omega_2\, d\Omega_3 \tag{39}
$$

and

$$
I_R = \int r_1^{i+2} r_2^{j+2} r_3^{k+2} r_{12<}^{w_1} r_{12>}^{-w_1} \left(\frac{r_1^2 - r_2^2}{r_{12>}^2 - r_{12<}^2} \right) R_{lw_2}(r_2,r_3) R_{mw_3}(r_3,r_1) dr_1\, dr_2\, dr_3. \tag{40}
$$

Employing Eqs. (14) and (15), and expanding the Legendre polynomials in terms of spherical harmonics, Eq. (38) may be easily evaluated to yield

$$
\begin{aligned}
F(i,j,k,l,m,\alpha,\beta,\gamma) = 64\pi^3 \sum_{p=0}^{\infty} \sum_{q=0}^{\infty} a_{0lp} a_{0mq} \\
&\times \{ W(k+2+2p+2q, j+2+l-2p, i+m+2-2q, \gamma, \beta, \alpha) \\
&+ W(j+2+2p, k+2+l-2p+2q, i+m+2-2q, \beta, \gamma, \alpha) \\
&+ W(j+2+2p, i+2+2q, k+m+l+2-2p-2q, \beta, \alpha, \gamma) \\
&- W(i+2+2q, j+2+2p, k+m+l+2-2p-2q, \alpha, \beta, \gamma) \\
&- W(i+2+2q, k+m+2+2p-2q, j+l+2-2p, \alpha, \gamma, \beta) \\
&- W(k+2+2p+2q, i+m+2-2q, j+l+2-2p, \gamma, \alpha, \beta) \}. \qquad (41)
\end{aligned}
$$

Due to the property of the Pochhammer symbol given in Eq. (20), the p summation in Eq. (41) will terminate at $l/2$ for even l, and $(l+1)/2$ for odd l. Similarly, the q summation will terminate at $m/2$ for even m, and $(m+1)/2$ for odd m.

The integral I_Ω can be evaluated to give

$$
I_\Omega = \frac{32\pi^3}{2w_2+1}\, \delta_{w_2 w_3} \times \begin{cases} \dfrac{\sqrt{\pi}\,\Gamma(w_1+1)}{2\Gamma(w_1+\frac{3}{2})}, & w_1 = w_2, \\ \dfrac{-w_1}{(w_1-w_2)(w_1+w_2+1)} \dfrac{\Gamma\left(\dfrac{w_1-w_2-1}{2}\right)\Gamma\left(\dfrac{w_1+w_2}{2}\right)}{\Gamma\left(\dfrac{w_1-w_2}{2}\right)\Gamma\left(\dfrac{w_1+w_2+1}{2}\right)}, & w_1 \geqslant w_2+2, \quad w_1+w_2 \text{ even}, \\ 0, & \text{elsewhere}, \end{cases} \qquad (42)
$$

where $\Gamma(n)$ denotes the Gamma function. The evaluation of this integral is discussed in Appendix D. Since I_Ω is independent of $\{i,j,k,l,m,\alpha,\beta,\gamma\}$, it can be stored in table form to increase the computational speed of the integral evaluation. Equation (37) may now be written

$$
I_3 = F(i,j,k,l,m,\alpha,\beta,\gamma) + 2 \sum_{w_1=1}^{\infty} \sum_{w_2=0}^{w_1} I_\Omega(w_1,w_2) I_R(w_1,w_2), \qquad (43)
$$

where

$$
I_\Omega(w_1,w_2) \equiv I_\Omega(w_1,w_2,w_2) \qquad (44)
$$

and

$$
I_R(w_1,w_2) \equiv I_R(w_1,w_2,w_2). \qquad (45)
$$

Inserting Eqs. (14) and (15) into Eq. (43), then breaking up the region of integration as $r_i \leqslant r_j \leqslant r_k$, allows us to write Eq. (43) as

$$
\begin{aligned}
&I_3(i,j,k,l,m,\alpha,\beta,\gamma)\\
&\quad = F(i,j,k,l,m,\alpha,\beta,\gamma) + 2 \sum_{\substack{w_1=1 \\ (w_1+w_2 \text{ even})}}^{\infty} \sum_{w_2=0}^{w_1} I_\Omega(w_1,w_2) \sum_{p=0}^{\infty} \sum_{q=0}^{\infty} a_{w_2 lp} a_{w_2 mq}\\
&\qquad \times \{ W(j+2+w_1+w_2+2p, i+2-w_1+w_2+2q, k+2+l+m-2w_2-2p-2q, \beta,\alpha,\gamma)\\
&\qquad + W(j+2+w_1+w_2+2p, k+2+l-2p+2q, i+2-w_1+m-w_2-2q, \beta,\gamma,\alpha)\\
&\qquad + W(k+2+2w_2+2p+2q, j+2+l+w_1-2p-w_2, i+2+m-w_1-w_2-2q, \gamma,\beta,\alpha)\\
&\qquad - W(k+2+2w_2+2p+2q, i+2+w_1+m-w_2-2q, j+2-w_1+l-w_2-2p, \gamma,\alpha,\beta)\\
&\qquad - W(i+2+w_1+w_2+2q, j+2-w_1+w_2+2p, k+2+l+m-2w_2-2p-2q, \alpha,\beta,\gamma)\\
&\qquad - W(i+2+w_1+w_2+2q, k+2+m-2q+2p, j+2-w_1-w_2+l-2p, \alpha,\gamma,\beta) \}. \quad (46)
\end{aligned}
$$

Due to properties of the Pochhammer symbol, the p summation in Eq. (46) will terminate at $l/2$ for even l, and $(l+1)/2$ for odd l. Similarly, the q summation will terminate at $m/2$ for even m, and $(m+1)/2$ for odd m. Also, due to the Pochhammer symbols in Eq. (46) and the restriction on w_2 given in Eq. (42), the w_2 sum has the following termination conditions:

$$
\begin{aligned}
&\min\left\{ w_1, \frac{l}{2} \right\}, \quad l \text{ even and } m \text{ odd},\\
&\min\left\{ w_1, \frac{m}{2} \right\}, \quad m \text{ even and } l \text{ odd},\\
&\min\left\{ w_1, \frac{l}{2}, \frac{m}{2} \right\}, \quad l \text{ and } m \text{ both even},\\
&w_1, \quad l \text{ and } m \text{ both odd}.
\end{aligned}
$$

The w_1 sum is always nonterminating.

In addition to the individual constraints on i, j, k, l, and m mentioned in the Introduction, Eq. (46) requires that

$$
i+j+k+l+m \geqslant -8, \quad (47)
$$

which follows from Eq. (22).

V. NUMERICAL EVALUATION

For even l or m, the evaluation of I_1 and I_2 reduces to a finite sum of terms. For l and m both odd, it is useful to examine the asymptotic behavior of the series. I_1 is considered first.

The asymptotic behavior of a single W integral appearing in Eq. (18) is[32]

$$
W \sim \frac{1}{w^2}. \quad (48)
$$

However, if the W integrals are taken in the appropriate pairs, it can be shown that the set of six W integrals in Eq. (18) behaves like

$$
\text{set of six } W \sim \frac{1}{w^3}, \quad (49)
$$

due to the difference in signs. The product of the a_{tuv} coefficients in Eq. (17) exhibits the asymptotic behavior[32]

TABLE I. Values of $I_1(i,j,k,l,m,n,\alpha,\beta,\gamma)$.

i	j	k	l	m	α	β	γ	$I_1(i,j,k,l,m,n,\alpha,\beta,\gamma)$
0	0	0	−1	1	2.7	2.9	0.65	8.947 959 925 047 512 835 052 492
2	−1	1	3	−1	2.7	2.9	0.65	$3.066\,249\,710\,874\,801\,140\,638\,611\times10^{4}$
1	2	3	1	3	2.7	2.9	0.65	$-7.127\,529\,951\,937\,274\,842\,240\,935\times10^{7}$
0	2	0	2	1	2.7	2.9	0.65	$-1.155\,955\,548\,991\,711\,453\,287\,647\times10^{4}$
−1	3	2	0	4	2.7	2.9	0.65	$-4.898\,965\,561\,162\,249\,945\,560\,093\times10^{7}$
1	2	−1	3	4	2.7	2.9	0.65	$-5.595\,918\,656\,196\,395\,007\,062\,751\times10^{6}$

$$\frac{(-m/2)_w(-l/2)_w}{[(\frac{1}{2})_w]^2}\sim\frac{1}{w^{(l+m+2)/2}}. \tag{50}$$

Combining Eqs. (49) and (50) with the factor $1/(2w+1)$ from Eq. (18) leads to

$$I_1\sim\sum_w \frac{1}{w^{(l+m+10)/2}}. \tag{51}$$

The worst case that arises in the evaluation of the matrix elements of H_{oo} is $l=-1$ and $m=1$, where

$$I_1\sim\sum_w \frac{1}{w^5}, \tag{52}$$

which is suitable for direct numerical evaluation.

The asymptotic form for I_2 can be determined in a similar manner to that described for I_1. The result is

$$I_2\sim\sum_w \frac{1}{w^{(l+m+10)/2}}. \tag{53}$$

The worst case asymptotic behavior for I_2 is the same as that of I_1.

While the series representations of I_1 and I_2 are suitable for direct summation, such a process is rather time consuming for the most slowly converging cases. An improved approach is to apply the techniques discussed in Ref. 18. By first converting these monotonic series into equivalent alternating series, then applying convergence accelerators to the transformed series, a high-precision evaluation scheme is produced which is far more rapid for the most slowly converging integrals.

The sign differences on the coefficients of the W integrals in Eqs. (18) and (34) might be suggestive of possible numerical precision problems. However, both equations have been tested and found to be numerically stable. Tables I and II present some representative values for the I_1 and I_2 integrals, respectively.

A useful check for I_1 and I_2 can be derived by considering the integral

TABLE II. Values of $I_2(i,j,k,l,m,n,\alpha,\beta,\gamma)$.

i	j	k	l	m	α	β	γ	$I_2(i,j,k,l,m,n,\alpha,\beta,\gamma)$
0	2	0	−1	−1	2.7	2.9	0.65	−2.943 608 978 543 536 288 422 283
1	4	3	−1	3	2.7	2.9	0.65	$2.755\,380\,752\,419\,424\,787\,112\,100\times10^{6}$
2	1	1	1	−1	2.7	2.9	0.65	$-1.874\,264\,201\,450\,095\,466\,617\,095\times10^{2}$
1	3	2	0	2	2.7	2.9	0.65	$6.929\,145\,321\,870\,892\,125\,904\,854\times10^{3}$
0	4	0	2	−1	2.7	2.9	0.65	$-2.953\,164\,176\,902\,131\,531\,016\,592\times10^{3}$
3	2	−1	3	2	2.7	2.9	0.65	$2.411\,321\,913\,805\,718\,749\,043\,867\times10^{5}$

$$I_4(i,j,k,l,m,\alpha,\beta,\gamma)=\int r_1^i r_2^j r_3^k \frac{(r_1^2-r_2^2)(r_{31}^2-r_{23}^2)}{r_{12}^3} r_{23}^l r_{31}^m e^{-\alpha r_1-\beta r_2-\gamma r_3}\, d\mathbf{r}_1\, d\mathbf{r}_2\, d\mathbf{r}_3. \tag{54}$$

Equation (54) can be evaluated using either I_1 or I_2, resulting in the following relationship:

$$\begin{aligned} &I_1(i,j,k,l,m+2,\alpha,\beta,\gamma)-I_1(i,j,k,l+2,m,\alpha,\beta,\gamma)\\ &\quad=I_2(i+2,j,k,l,m,\alpha,\beta,\gamma)-I_2(i,j+2,k,l,m,\alpha,\beta,\gamma). \end{aligned} \tag{55}$$

Hence, Eqs. (18) and (34) may checked against each other. Also, if $l=m=0$ in Eq. (26), $J_1=0$, and therefore

$$I_1(i,j,k,0,0,\alpha,\beta,\gamma)=I_2(i,j,k,0,0,\alpha,\beta,\gamma). \tag{56}$$

The asymptotic behavior of I_3 is the most difficult to estimate, due to the nested w_2 sum in Eq. (46). Let us define K to be the infinite series portion of the I_3 integral. The technique used to analyze the asymptotic behavior of K will be to divide the w_1, w_2 plane into three regions:

$$w_2=0,$$

$$0<w_2<w_1,$$

$$w_2=w_1.$$

Making these simplifications, it is possible to arrive at upper and lower bound estimates on the convergence rate for the w_1 summation.

First we examine the region where $w_2=0$. From Eq. (42), it can easily be shown that

$$I_\Omega\sim\frac{1}{w_1^2}. \tag{57}$$

If taken in the appropriate pairs, the sum of the W integrals in Eq. (46) behaves like

$$\text{set of six } W\sim\frac{1}{w_1^2}. \tag{58}$$

For the case $w_2=0$, the a_{tuv} coefficients in Eq. (46) lead to

$$\frac{(-m/2)_0(-l/2)_0}{[(\frac{1}{2})_0]^2}\sim 1. \tag{59}$$

Combining Eqs. (57), (58), and (59) gives the result

$$K\sim\sum_{w_1}\frac{1}{w_1^4}. \tag{60}$$

The asymptotic behavior of K in the other two regions may be obtained by similar methods. The results are

$$K\sim\sum_{w_1}\frac{1}{w_1^4} \quad\text{to}\quad \sum_{w_1}\frac{1}{w_1^{(l+m+14)/2}} \tag{61}$$

and

$$K\sim\sum_{w_1}\frac{1}{w_1^{(l+m+11)/2}}, \tag{62}$$

TABLE III. Values of $I_3(i,j,k,l,m,\alpha,\beta,\gamma)$.

i	j	k	l	m	α	β	γ	$I_3(i,j,k,l,m,\alpha,\beta,\gamma)$
1	−1	0	−1	1	2.7	2.9	0.65	$1.356\,087\,352\,189\,092\,17\times10^{2}$
1	2	2	1	1	2.7	2.9	0.65	$-6.371\,117\,492\,583\,756\times10^{4}$
3	1	2	3	1	2.7	2.9	0.65	$4.870\,134\,178\,451\,231\,6\times10^{7}$
2	2	3	−1	3	2.7	2.9	0.65	$6.471\,807\,181\,649\,945\times10^{5}$
4	1	2	3	3	2.7	2.9	0.65	$3.203\,917\,521\,846\,703\,1\times10^{10}$
3	1	−1	1	5	2.7	2.9	0.65	$5.849\,805\,492\,834\,822\,33\times10^{6}$

respectively. The second of the two results given in Eq. (61) was obtained using $w_2=w_1/2$. If instead we employ $w_2\approx w_1$ (with $w_2<w_1$), the same asymptotic behavior given in Eq. (62) would be obtained.

The convergence of the entire sum will be determined by the most slowly converging portion of that sum, which was found at $w_2=0$. So the entire sum behaves asymptotically like

$$K\sim\sum_{w_1}\frac{1}{w_1^4}. \tag{63}$$

It should be clear from this result that a large number of terms are needed to obtain an accurate result for K. Rather than directly summing the series, a convergence acceleration technique was applied to the infinite series portion of Eq. (46). The acceleration method employed was the Richardson extrapolation,[33] which has been used previously in the evaluation of other three-electron integration problems.[22] The Richardson extrapolation is given by

$$S_0=\sum_{k=0}^{N}\frac{S_{n+k}(n+k)^N(-1)^{k+N}}{k!(N-k)!}, \tag{64}$$

where S_0 is an approximation to the total sum in Eq. (46). A well-known difficulty associated with the application of Eq. (64) is that it is subject to numerical precision loss for higher values of N.

Careful examination of Eq. (46) shows it to be composed of two monotonically decreasing series, one for w_1 even and one for w_1 odd. Because the individual terms of the two series differ significantly in magnitude, a direct application of the Richardson extrapolation produces quite poor results. However, if Eq. (64) is applied individually to these two series, then a significant improvement in convergence is obtained. For both of these series, choosing $n=1$, the optimal value of N appears to be at about $N=23$. At this value, approximately 17 digits of precision may be obtained using 30 digit arithmetic. As was found for I_1 and I_2, the sign differences on the coefficients of the W integrals in Eq. (46) do not appear to be problematic. Some representative values of I_3 are presented in Table III.

For the case l and m both odd, evaluation of Eq. (5) via the approach developed in Sec. IV requires about half the computational time of previously published methods. For a number of test cases investigated, several more significant digits were obtained using the present approach. The increased speed of evaluation is directly tied to the much simpler formula that results in the present work, in comparison with what is obtained by breaking the integral into two separate parts. For l and m not both odd, evaluation methods may be employed which are both computationally faster and produce higher-precision results.[19]

VI. DISCUSSION

In this work, some key integrals are solved which are needed for the evaluation of ΔE_{REL} (the non-fine-structure contributions) for the ^2S states of three-electron systems. The basic approach employed in this work is to treat each of the integrand factors $(r_1^2-r_2^2)r_{12}^{-3}$, $(r_{31}^2-r_{23}^2)r_{12}^{-3}$, and $(r_1^2-r_2^2)r_{12}^{-2}$ as single expansions. For the I_1 and I_2 integrals investigated, the option of splitting these factors into separate parts does not exist, as each of the separate integrals diverge. A recursive scheme for an integral related to I_1 is developed by Yan and Drake.[23]

With the evaluation of I_1, I_2, and I_3, the difficulties associated with the evaluation of the matrix elements of the Breit–Pauli relativistic operators now lie elsewhere. Integrals of the form shown in Eq. (2) with $l=-2$ also arise in the evaluation of H_{oo} and H_{mass}, and these have known computational difficulties.[19] While several methods exist for their evaluation,[19–24] they are relatively slow for some choices of the arguments and are subject to precision loss. Development of better methods for handling integrals of this form would be useful.

ACKNOWLEDGMENTS

APPENDIX A: DIVERGENCE OF *I* INTEGRAL WHEN $n=-3$

This appendix illustrates that Eq. (2) diverges for at least one of l, m and $n=-3$. Consequently, Eqs. (3) and (4) cannot be broken into separate integrals of the form of Eq. (2).

Let

$$I(i,j,k,l,m,-3,\alpha,\beta,\gamma)\equiv\int r_1^i r_2^j r_3^k r_{23}^l r_{31}^m r_{12}^{-3} e^{-\alpha r_1-\beta r_2-\gamma r_3}\, d\mathbf{r}_1\, d\mathbf{r}_2\, d\mathbf{r}_3. \tag{A1}$$

Because the integrand is everywhere positive,

$$I\geqslant\int_{(r_3-\varepsilon)\geqslant r_p} r_1^i r_2^j r_3^k r_{23}^l r_{31}^m r_{12}^{-3} e^{-\alpha r_1-\beta r_2-\gamma r_3}\, d\mathbf{r}_1\, d\mathbf{r}_2\, d\mathbf{r}_3, \tag{A2}$$

where $(r_3-\varepsilon)>0$ and $p=1,2$.

Furthermore,

$$I\geqslant \min_{\substack{\mathbb{R}^9\\(r_3-\varepsilon)\geqslant r_p}}\{r_{23}^l\}\ \min_{\substack{\mathbb{R}^9\\(r_3-\varepsilon)\geqslant r_p}}\{r_{31}^m\}\int_{(r_3-\varepsilon)\geqslant r_p} r_1^i r_2^j r_3^k r_{12}^{-3} e^{-\alpha r_1-\beta r_2-\gamma r_3}\, d\mathbf{r}_1\, d\mathbf{r}_2\, d\mathbf{r}_3. \tag{A3}$$

Due to the restrictions placed on the region of integration,

$$\min_{\substack{\mathbb{R}^9\\(r_3-\varepsilon)\geqslant r_p}}\{r_{23}^l\}\ \min_{\substack{\mathbb{R}^9\\(r_3-\varepsilon)\geqslant r_l}}\{r_{31}^m\}=\varepsilon^{l+m}. \tag{A4}$$

Substituting Eq. (A4) into Eq. (A3) yields,

$$I\geqslant\varepsilon^{l+m}\times\int_{(r_3-\varepsilon)\geqslant r_p} r_1^i r_2^j r_3^k r_{12}^{-3} e^{-\alpha r_1-\beta r_2-\gamma r_3}\, d\mathbf{r}_1\, d\mathbf{r}_2\, d\mathbf{r}_3. \tag{A5}$$

Integration over $\mathbf{r}_3$ produces a finite sum of positive terms involving integrals of the form

$$\int r_1^s r_2^t r_{12}^{-3} e^{-ar_1-br_2}\, d\mathbf{r}_1\, d\mathbf{r}_2. \tag{A6}$$

Choosing perimetric coordinates[6] it can easily be shown that Eq. (A6) diverges irrespective of the values of s, t, a, and b. Therefore Eq. (A5) must be divergent, and so Eq. (A1) must also diverge.

The extension to N-electron systems is obvious.

APPENDIX B: EXPANSION FOR r_{12}^{-3}

The generating function for the Legendre polynomials is[34]

$$\frac{1}{\sqrt{1-2rx+r^2}}=\sum_{n=0}^{\infty} r^n P_n(x). \tag{B1}$$

If the operator $\hat{O}\equiv 1+2r\ \partial/\partial r$ is applied to both sides of Eq. (B1)[26] one obtains

$$\frac{1-r^2}{(1-2rx+r^2)^{3/2}}=\sum_{n=0}^{\infty} (2n+1)r^n P_n(x). \tag{B2}$$

Making the substitutions $r=r_{12<}/r_{12>}$, $x=\cos\theta_{12}$, and $n=w_1$ in Eq. (B2) results in Eq. (8).

APPENDIX C: SOLUTION OF ANGULAR INTEGRALS FOR I_2

This appendix discusses the evaluation of the angular integrals Φ_1 and Φ_2 which arise in Eq. (27). If the addition theorem for Legendre polynomials,[26]

$$P_{w_1}(\cos\ \theta_{12})=P_{w_1}(\cos\ \theta_{23})P_{w_1}(\cos\ \theta_{31}) + 2\sum_{n=1}^{w_1} \frac{(w_1-n)!}{(w_1+n)!} P_{w_1}^n(\cos\ \theta_{23})P_{w_1}^n(\cos\ \theta_{31})\cos(n(\phi_{23}-\phi_{31})), \tag{C1}$$

is applied to $P_{w_1}(\cos\theta_{12})$ in Eq. (28), and the integration over ϕ_{23} and ϕ_{31} is performed, then the finite sum in Eq. (C1) vanishes. Thus Φ_1 simplifies to

$$\Phi_1=4\pi^2\int_{-1}^{1} xP_{w_1}(x)P_{w_3}(x)dx\int_{-1}^{1} P_{w_1}(x)P_{w_2}(x)dx. \tag{C2}$$

Using the standard recurrence relationship

$$(2v+1)xP_v(x)=(v+1)P_{v+1}(x)+vP_{v-1}(x), \tag{C3}$$

and the orthogonality property of the Legendre polynomials, allows Eq. (C2) to be simplified to Eq. (30). The result for Φ_2 can be obtained by symmetry [switch $1\leftrightarrow 2$ and $w_2\leftrightarrow w_3$ in Eq. (28), thereby obtaining Eq. (31)].

APPENDIX D: SOLUTION OF ANGULAR INTEGRAL FOR I_3

This appendix discusses the evaluation of the angular integral I_Ω, Eq. (39), which occurs in I_3. We choose our coordinate system such that

$$d\Omega_1\ d\Omega_2\ d\Omega_3=\sin\ \theta_{12}\ d\theta_{12}\ d\phi_{12}\ \sin\ \theta_{31}\ d\theta_{31}\ d\phi_{31}\ \sin\ \theta_1\ d\theta_1\ d\phi_1. \tag{D1}$$

Expanding $P_{w_2}(\cos\theta_{23})$ by the addition theorem for Legendre polynomials, then integrating over θ_1, ϕ_1, ϕ_{12}, ϕ_{31}, and θ_{31}, yields

$$I_\Omega(w_1,w_2,w_3)=\frac{32\pi^3}{2w_2+1}\ \delta_{w_2w_3}\int_0^{\pi} T_{w_1}(\cos\ \theta_{12})P_{w_2}(\cos\ \theta_{12})\sin\ \theta_{12}\ d\theta_{12}. \tag{D2}$$

Expanding $P_{w_2}(\cos\theta_{12})$ in a Fourier sine series,[34] and using the identity

$$T_{w_1}(\cos\ \theta_{12})=\cos(w_1\theta_{12}), \tag{D3}$$

produces

$$I_\Omega = \frac{64\pi^{5/2}}{2w_2+1}\,\delta_{w_2 w_3}\sum_{k=0}^{\infty}\frac{(\frac{1}{2})_k\Gamma(w_2+k+1)}{k!\,\Gamma(w_2+k+\frac{3}{2})}\int_0^{\pi}\cos(w_1\theta_{12})\sin[(w_2+2k+1)\theta_{12}]\sin\,\theta_{12}\,d\theta_{12}. \tag{D4}$$

Evaluation of this integral, followed by some straightforward simplification, leads to Eq. (42).

Local $U(2,2)$ symmetry in relativistic quantum mechanics

Felix Finster
Department of Mathematics, Harvard University, Cambridge, Massachusetts 02138

(Received 15 May 1998; accepted for publication 9 June 1998)

Local gauge freedom in relativistic quantum mechanics is derived from a measurement principle for space and time. For the Dirac equation, one obtains local $U(2,2)$ gauge transformations acting on the spinor index of the wave functions. This local $U(2,2)$ symmetry allows a unified description of electrodynamics and general relativity as a classical gauge theory. © *1998 American Institute of Physics.* [S0022-2488(98)03012-6]

I. CONNECTION BETWEEN LOCAL GAUGE FREEDOM AND POSITION MEASUREMENTS

In Ref. 1, it was suggested to link the physical gauge principle with quantum mechanical measurements of the position variable. In the present paper, we will extend this concept to relativistic quantum mechanics and apply it to the Dirac equation. For Dirac spinors, we obtain local $U(2,2)$ gauge freedom. Our main result is that this $U(2,2)$ symmetry allows a natural description of both electrodynamics and general relativity as a classical gauge theory. This is shown by deriving a $U(2,2)$ spin connection from the Dirac operator and analyzing the geometry of this connection. Although we develop the subject from a particular point of view, this paper can be used as an introduction to the Dirac theory in curved space–time.

In contrast to Ref. 1, where the point of interest is the measure theoretic derivation of local gauge transformations, here we will concentrate on the differential geometry of the Dirac operator. In order to keep measure theory out of this paper, we will use a bra/ket notation in position space. This allows us to explain the basic ideas and results of Ref. 1 in a simple, nontechnical way, which will be sufficient for the purpose of this paper. Nevertheless, one should keep in mind that the bra/ket symbols and the δ normalizations are only a formal notation; the mathematical justification for this formalism is given in Ref. 1.

We begin with the example of a scalar particle in nonrelativistic quantum mechanics. The particle is described by a wave function $\Psi(\mathbf{x})$, which is a vector of the Hilbert space $H = L^2(\mathbb{R}^3)$. The physical observables correspond to self-adjoint operators on H. The position operators $\mathbf{X}$, for example, are given as multiplication operators with the coordinate functions, X^i: $\Psi(\mathbf{x}) \to x^i \Psi(\mathbf{x})$, $i = 1,...,3$. Our definition of the Hilbert space as a space of functions in the position variable was only a matter of convenience; e.g., we could just as well have introduced H as functions in momentum space. Therefore it seems reasonable to forget about the fact that H is a function space and consider it merely as an abstract Hilbert space. After this generalization, which is often implicitly assumed in quantum mechanics, we must construct the representation of H as wave functions. For this purpose, we choose an ''eigenvector basis'' $|\mathbf{x}\rangle$ of the position operators,

$$X^i|\mathbf{x}\rangle = x^i|\mathbf{x}\rangle, \quad \langle \mathbf{x}|\mathbf{y}\rangle = \delta^3(\mathbf{x}-\mathbf{y}), \tag{1}$$

and define the wave function of a vector $\Psi \in H$ by $\Psi(\mathbf{x}) = \langle \mathbf{x}|\Psi\rangle$.

This ''position representation'' of the Hilbert space is quite elementary and is currently used in physics. We point out that it is not unique, because the ''eigenvectors'' $|\mathbf{x}\rangle$ are only determined up to a phase. Namely, we can transform $|\mathbf{x}\rangle$ according to

$$|\mathbf{x}\rangle \to e^{ie\Lambda(\mathbf{x})}|\mathbf{x}\rangle, \tag{2}$$

with a real function $\Lambda(\mathbf{x})$. This corresponds to a local phase transformation,

 © 1998 American Institute of Physics

$$\Psi(\mathbf{x}) \rightarrow e^{-ie\Lambda(\mathbf{x})} \Psi(\mathbf{x}), \tag{3}$$

of the wave functions. The arbitrariness of the local phase of the wave functions can also be understood directly from the fact that the wave function itself is not observable, only its absolute square $|\Psi|^2$ has a physical interpretation as probability density. It is important for the following that the local phase transformations (2), (3) can be interpreted as $U(1)$ gauge transformations. To see this, we consider the canonical momentum operator $\boldsymbol{\pi} = -i\nabla - e\mathbf{A}$ with magnetic vector potential $\mathbf{A}$. Under the transformation (2), the canonical momentum behaves like

$$\boldsymbol{\pi} \rightarrow e^{-ie\Lambda(\mathbf{x})} \boldsymbol{\pi} e^{ie\Lambda(\mathbf{x})} = -i\nabla - e(\mathbf{A} - \nabla\Lambda),$$

which corresponds to the gauge transformation $\mathbf{A} \rightarrow \mathbf{A} - \nabla\Lambda$ of the vector potential.

In this way, we have explained the local $U(1)$ gauge symmetry of the magnetic field from the fact that space is a quantum mechanical observable. Unfortunately, this natural explanation of local $U(1)$ gauge freedom only works for scalar particles. In the general case with spin, the wave functions have several components, $\Psi \in H = L^2(\mathbb{R}^3)^m$ (i.e., $m = 2s+1$ for particles with spin s). We again consider H as an abstract Hilbert space. In order to construct the representation of a vector $\Psi \in H$ as a function, we choose an ''orthonormal basis'' $|\mathbf{x}\alpha\rangle$, $\mathbf{x} \in \mathbb{R}^3$, $\alpha = 1,...,m$ of the position operators,

$$X^i |\mathbf{x}\alpha\rangle = x^i |\mathbf{x}\alpha\rangle, \quad \langle \mathbf{x}\alpha | \mathbf{y}\beta \rangle = \delta_{\alpha\beta} \delta^3(\mathbf{x}-\mathbf{y}), \tag{4}$$

and define the wave function by $\Psi^\alpha(\mathbf{x}) = \langle \mathbf{x}\alpha | \Psi \rangle$. The basis $|\mathbf{x}\alpha\rangle$ is only unique up to local unitary transformations,

$$|\mathbf{x}\alpha\rangle \rightarrow \sum_{\beta=1}^{m} (U^{-1})^\alpha_\beta(\mathbf{x}) |\mathbf{x}\beta\rangle, \quad \text{with} \quad U(\mathbf{x}) \in U(m), \tag{5}$$

as is verified by substituting into (4). Thus the wave functions can be transformed according to

$$\Psi(\mathbf{x}) \rightarrow U(\mathbf{x}) \Psi(\mathbf{x}). \tag{6}$$

It would be nice if we could again identify the local $U(m)$ transformations (5), (6) with physical gauge transformations. Then the local gauge principle would no longer be an *a priori* principle in physics. It would be a consequence of a quantum mechanical ''measurement principle,'' namely the description of space with observables X^i on an abstract Hilbert space. Notice that the local $U(m)$ transformations (6) are a generalization of the phase transformations (3). Our idea is that the additional degrees of freedom of the larger gauge group in (6) might make it possible to describe additional interactions (like gravitation or the weak and strong forces). Notice that, as a great advantage of our procedure, the local gauge group could no longer be chosen arbitrarily; it would be determined by the configuration of the spinors. Thus, we could hope to get into the position to explain the gauge groups observed in physics. At the moment, however, it is not clear if the interpretation of (5), (6) as gauge transformations really makes physical sense. We will in the following simply assume it as a postulate and want to study its further consequences.

In view of our later generalization to curved space (and curved space–time), it is convenient to introduce the spectral measure $dE_\mathbf{x}$ of the position operators: We form the ''projectors'' $E_\mathbf{x}$ on the ''eigenspaces'' of $\mathbf{X}$,

$$E_\mathbf{x} = \sum_{\alpha=1}^{m} |\mathbf{x}\alpha\rangle\langle\mathbf{x}\alpha|. \tag{7}$$

The $E_\mathbf{x}$ do not depend on the choice of $|\mathbf{x}\alpha\rangle$; we can characterize them by the operator relations,

$$X^i E_\mathbf{x} = x^i E_\mathbf{x}, \quad E_\mathbf{x} E_\mathbf{y} = \delta^3(\mathbf{x}-\mathbf{y}) E_\mathbf{x}. \tag{8}$$

The δ^3 normalization in (8) leads to difficulties as soon as curved coordinate systems are considered. To avoid these problems, it is useful to combine $E_{\mathbf{x}}$ with the integration measure by introducing the spectral measure $dE_{\mathbf{x}} := E_{\mathbf{x}}\, d\mathbf{x}$. Integrating over the spectral measure yields an operator on the Hilbert space. For example, we have

$$X^i = \int_{\mathbb{R}^3} x^i \, dE_{\mathbf{x}}, \quad \chi_V = \int_V dE_x, \tag{9}$$

where χ_V is the multiplication operator with the characteristic function [i.e., $(\chi_V \Psi)(\mathbf{x})$ is equal to $\Psi(\mathbf{x})$ if $\mathbf{x} \in V$ and vanishes otherwise]. These relations can be verified directly with the help of (4) and (7). Actually, the spectral measure is completely characterized by (9). In the mathematical paper,[1] spectral measures on a manifold are used as the starting point. In this more general approach, the number of components of the wave functions $m = m(\mathbf{x})$ may vary in space. We call it the *spin dimension*.

II. GENERALIZATION TO DIRAC SPINORS, $U(2,2)$ GAUGE SYMMETRY

If our explanation of local gauge freedom shall have general significance, it must be possible to extend it to the relativistic setting. We start the analysis with Dirac wave functions in Minkowski space. [We mention for completeness that *Minkowski space* is a four-dimensional real vector space with a scalar product of signature $(+---)$. A coordinate system where this scalar product coincides with the Minkowski metric η_{ij} is called *reference frame*. We will mainly work in a fixed reference frame and can then identify Minkowski space with $\mathbb{R}^4$.] Since we do not yet want to introduce Dirac matrices and the Dirac operator, we consider the wave functions $\Psi, \Phi, \ldots$, just as four-component functions. We define a scalar product on the spinors,

$$\prec \Psi, \Phi \succ (x) = \sum_{\alpha=1}^{4} s_\alpha (\Psi^\alpha(x))^* \Phi^\alpha(x), \quad \text{with } s_1 = s_2 = 1, \quad s_3 = s_4 = -1, \tag{10}$$

which is called *spin scalar product*. It is indefinite of signature (2,2). Later, after the introduction of the Dirac matrices in Dirac representation, the spin scalar product will coincide with $\overline{\Psi}\Phi$, where $\overline{\Psi} = \Psi^* \gamma^0$ is the adjoint spinor. Our definition without referring to Dirac matrices will clarify the relation between coordinate and gauge transformations in Sec. III.

The basic question is how we want to describe space–time. At the moment, position and time are merely parameters of the wave functions. This is the usual description in relativistic quantum mechanics. In the previous section, however, it was essential for the explanation of local gauge transformations that space corresponds to some operators on the wave functions. In order to generalize this ''measurement principle'' to the relativistic setting, we introduce ''observables'' for space and time as multiplication operators with the coordinate functions,

$$X^i : \Psi(x) \to x^i \Psi(x), \quad i = 0, \ldots, 3. \tag{11}$$

We point out that these operators, especially the time operator X^0, are commonly not used in relativistic quantum mechanics. Nevertheless, our description of Minkowski space makes sense, as we will see in the following.

The next step is the introduction of a scalar product on the wave functions. Usually one considers the positive product,

$$(\Psi | \Phi) = \int_{\mathbb{R}^3} \Psi^*(t, \mathbf{x}) \Phi(t, \mathbf{x}) \, d\mathbf{x}, \tag{12}$$

where the spinors are integrated over a space-like hypersurface $t = \text{const}$ (we avoid the notation $\Psi^* \Phi = \overline{\Psi} \gamma^0 \Phi$ with the adjoint spinor because we have no Dirac matrices at the moment). The integrand of $(\Psi | \Psi)$ can be interpreted as the probability density of the particle. For solutions of the Dirac equation, current conservation implies that (12) is independent of t. As an apparent problem of this scalar product, time measurements do not make sense, because expectations $(\Psi | X^0 | \Psi)$

$=t(\Psi|\Psi)$ depend on the choice of the hypersurface. The only way out is to introduce a different scalar product where the spinors are also integrated over the time variable, namely,

$$\langle \Psi | \Phi \rangle = \int_{\mathbb{R}^4} <\Psi|\Phi> d^4x. \tag{13}$$

In contrast to (12), the scalar product (13) has no immediate physical interpretation. Nevertheless, it causes no problem to consider (13) as the fundamental scalar product on the spinors, for the following reason: The scalar product does not enter in the physical equations (i.e., the Dirac equation and the classical field equations), we only need it for the probabilistic interpretation of the wave functions. For this final interpretation, we can just introduce (12) by an additional mathematical construction [see Eq. (27)].

We choose (13) as the fundamental scalar product on the wave functions. We denote the corresponding function space by $(H, \langle \cdot | \cdot \rangle)$ and consider it together with the position/time operators (11) as an abstract scalar product space. In order to represent the vectors of H as wave functions, we choose an ''eigenvector basis'' $|x\alpha\rangle$, $x \in \mathbb{R}^4$, $\alpha = 1,...,4$ of the position/time operators,

$$X^i |x\alpha\rangle = x^i |x\alpha\rangle, \quad \langle x\alpha | y\beta \rangle = s_\alpha \delta_{\alpha\beta} \delta^4(x-y), \tag{14}$$

and define for $\Psi \in H$ the corresponding wave function by $\Psi^\alpha(x) = \langle x\alpha | \Psi \rangle$. This is a relativistic analog of (4). The additional factors $s_\alpha = \pm 1$ occur as a consequence of the indefinite spin scalar product. The arbitrariness of the choice of $|x\alpha\rangle$ leads to the transformations

$$|x\alpha\rangle \rightarrow \sum_{\beta=1}^{4} (U^{-1})^\alpha_\beta(x) |x\beta\rangle$$

$$\Psi(x) \rightarrow U(x)\Psi(x), \quad \text{with } U(x) \in U(2,2), \tag{15}$$

which we interpret as local $U(2,2)$ gauge transformations. According to this interpretation, we call $|x\alpha\rangle$ a *gauge*. Notice that the gauge group is noncompact, which is directly related to the indefiniteness of the spin scalar product. Similar to the nonrelativistic case, the spectral measure is given by

$$dE_x = \sum_{\beta=1}^{4} s_\beta |x\beta\rangle\langle x\beta| d^4x.$$

We say that the spin dimension is (2,2).

We remark that the indefiniteness of the scalar product $\langle \cdot | \cdot \rangle$ leads to mathematical problems in the rigorous derivation of gauge transformations. A first, but not fully convincing attempt toward a satisfying mathematical formulation was made in Ref. 2 (which also contains a preliminary version of Ref. 1).

III. THE FREE DIRAC OPERATOR, LORENTZIAN TRANSFORMATIONS

Having introduced the Dirac wave functions in Minkowski space, we can now define the free Dirac operator: We fix the reference frame, choose a special gauge, and introduce the partial differential operator $i\partial\!\!\!/ := i\gamma^j \partial_j$ on the wave functions, where γ^j denote the usual (4×4)-matrices in the Dirac representation acting on the spinor index,

$$\gamma^0 = \begin{pmatrix} \mathbb{1} & 0 \\ 0 & -\mathbb{1} \end{pmatrix}, \quad \gamma^i = \begin{pmatrix} 0 & \sigma^i \\ -\sigma^i & 0 \end{pmatrix}, \quad i = 1,2,3$$

($\sigma^1, \sigma^2, \sigma^3$ are the Pauli matrices). Now we forget about the fact that the free Dirac operator was defined in a special gauge and a special reference frame and consider it as an operator on H. We denote this operator by G and write the free Dirac equation in the coordinate and gauge invariant form $(G-m)\Psi = 0$.

The Dirac operator is Hermitian (with respect to the scalar product $\langle \cdot | \cdot \rangle$). This is most conveniently verified in the original gauge and reference frame where $G = i\partial\!\!\!/$: For simplicity, we rewrite the factors s_α in (10) with the matrix γ^0 and obtain

$$\langle G\Psi | \Phi \rangle = \int_{\mathbb{R}^4} <G\Psi | \Phi>_{|x} \, d^4x = \int_{\mathbb{R}^4} (i\gamma^j \, \partial_j \Psi)(x)^* \gamma^0 \Phi(x) d^4x = -i \int_{\mathbb{R}^4} (\partial_j \Psi)^* (\gamma^j)^* \gamma^0 \Phi \; d^4x$$

$$= i \int_{\mathbb{R}^4} \Psi^* \gamma^0 (\gamma^0 (\gamma^j)^* \gamma^0) \partial_j \Phi = i \int_{\mathbb{R}^4} \Psi^* \gamma^0 \gamma^j \, \partial_j \Phi = \int_{\mathbb{R}^4} <\Psi | G\Phi>_{|x} d^4x = \langle \Psi | G\Phi \rangle .$$

Note that the γ-matrices are not Hermitian [more precisely, $(\gamma^0)^* = \gamma^0$ and $(\gamma^j)^* = -\gamma^j$ for $j = 1,2,3$], but they are self-adjoint with respect to the spin scalar product, $<\gamma^j \Psi | \Phi> = <\Psi | \gamma^j \Phi>$.

We point out that G is as operator on H a coordinate- and gauge-independent mathematical object (although its definition might depend on the special gauge and reference frame chosen at the beginning). Both coordinate and gauge transformations are merely passive transformations and lead to equivalent representations of G. Especially, transformations of the space–time coordinates and of the spinors are independent of each other. This is a major difference to the usual description of the Dirac equation. Therefore we will now discuss coordinate and gauge transformations and explain what ''Lorentzian invariance'' of the free Dirac operator exactly means in our setting.

We first look at the Dirac operator in a general gauge, but still in the original reference frame. The gauge transformation (15) leads to

$$i\partial\!\!\!/ \rightarrow G = U i\partial\!\!\!/ U^{-1} = iG^j \frac{\partial}{\partial x^j} + B,$$

with

$$G^j(x) = U(x) \gamma^j U(x)^{-1}, \quad B(x) = U(x) \gamma^j (\partial_j U(x)^{-1}).$$

As explained before, all these operators are equivalent; of course, it is most convenient to work in the original gauge with $G = i\partial\!\!\!/$.

Next we look at a Lorentzian transformation. The transformation of the space–time variables is described by a coordinate transformation $x^j \rightarrow \Lambda^j_k x^k$, where Λ is an isometry of Minkowski space. The Dirac operator transforms like

$$i\partial\!\!\!/ \rightarrow G = i\gamma^j \Lambda^k_j \partial_k . \tag{16}$$

Thus, in the new reference frame, the Dirac operator no longer has the original form. This might seem to contradict Lorentzian invariance, but we must keep in mind that all operators related to each other by gauge transformations are equivalent. Thus we must look for a gauge transformation such that the Dirac operator in the new reference frame again coincides with $i\partial\!\!\!/$. As is shown in standard textbooks on relativistic quantum mechanics (see, e.g., Ref. 3), there is a (4×4)-matrix $U(\Lambda)$ with

$$U(\Lambda) \gamma^j \Lambda^k_j U(\Lambda)^{-1} = \gamma^k .$$

It is important for our purpose that this matrix is unitary with respect to the spin scalar product, $U(\Lambda) \in U(2,2)$. Therefore we can perform a gauge transformation with $U(x) \equiv U(\Lambda)$. In the new gauge we again have $G = i\partial\!\!\!/$, which shows Lorentzian invariance of G. To summarize, we describe a Lorentzian transformation in two steps. The first step is a coordinate; the second a gauge transformation. If both steps are performed at once, the transformation of the space–time coordinates and of the spinors are related in the usual way. Notice, however, that the second step is only a matter of convenience; we could just as well work in the new reference frame in any other gauge. This splitting of the space–time and spinor transformation becomes possible because the conditions $G^j = \gamma^j$ give a link between coordinate and gauge transformations.

We remark that it is not trivial that a spinorial equation can be described with passive coordinate and gauge transformations. As a counterexample, we consider the Weyl equation: Chiral fermions are usually described by two-component spinors χ satisfying the equation

$$i\sigma^j \frac{\partial}{\partial x^j} \chi = 0, \tag{17}$$

with Pauli matrices $\sigma^0 = \mathbb{1}, \boldsymbol{\sigma}$. This equation is Lorentzian invariant in the sense that there is a one-to-one correspondence between the solutions of (17) in different reference frames (see, e.g., Ref. 3). We assume that the Weyl operator $W := i\sigma^j \partial_j$ were given as a coordinate- and gauge-independent object (we will not specify the scalar product on the wave functions). After a Lorentzian transformation $x^j \to \Lambda^j_k x^k$, the Weyl operator has the form $W = i\sigma^k \Lambda^j_k \partial_j$. If W was Lorentzian invariant, it should be possible to perform a gauge transformation such that $W = i\sigma^j \partial_j$. Thus there should be a matrix $U(\Lambda)$ with

$$U(\Lambda) \sigma^k \Lambda^j_k U(\Lambda)^{-1} = \sigma^j.$$

Taking the trace on both sides, however, yields the equation $\Lambda^j_0 = \delta^j_0$, which is only satisfied for $\Lambda = \mathbb{1}$. We conclude that the Weyl operator cannot be described as a Lorentz invariant operator in our setting (this is not a serious problem because the Weyl equation can always be obtained as the left- or right-handed component of the massless Dirac equation).

IV. GENERAL DEFINITION OF THE DIRAC OPERATOR

In the previous section, we introduced the free Dirac operator as an operator on the wave functions in Minkowski space. We point out that this definition involved some global assumptions on space–time. First of all, the reference frames gave global coordinate systems. Furthermore, we chose a special gauge at the beginning and described Lorentzian transformations using global gauge transformations (i.e., transformations independent of x). According to the principle of general relativity, however, global conditions do not make sense. In this section, we replace them by corresponding local conditions, which will yield the general definition of the Dirac operator.

We start with the observation that the Minkowski metric can be derived from the Dirac matrices by $\eta^{ij}\mathbb{1} = \frac{1}{2}\{G^i, G^j\}$. This allows us to forget about the Minkowski metric and view Minkowski space simply as a four-dimensional vector space. For the generalization to curved coordinate systems, we replace this vector space by a four-dimensional (smooth) manifold M. Notice that M has no Lorentzian structure; we will later recover the Lorentzian metric from the Dirac operator.

Next we must generalize the scalar product space $(H, \langle \cdot | \cdot \rangle)$ and the position/time operators to the setting of a space–time manifold. This can be most easily done with the help of spectral measures: We consider an indefinite scalar product space $(H, \langle \cdot | \cdot \rangle)$ and introduce a spectral measure $(dE_x)_{x \in M}$ on M of spin dimension (2,2). For any chart (x^i, U), we define corresponding position/time operators by

$$X^i = \int_U x^i \, dE_x. \tag{18}$$

We choose an ''eigenvector basis'' $|x\alpha\rangle$, $x \in U$, $\alpha = 1,...,4$ of the X^i,

$$X^i |x\alpha\rangle = x^i |x\alpha\rangle, \quad \langle x\alpha | y\beta \rangle = s_\alpha \delta_{\alpha\beta} \delta^4(x-y), \tag{19}$$

and represent a vector $\Psi \in H$ as the wave function $\Psi^\alpha(x) = \langle x\alpha | \Psi \rangle$, $x \in U$. This construction generalizes (9), (14) to curved coordinate systems. The spectral measure in (18) allows us to extend the usual changes of charts to the level of a calculus of operators.

After these preparations, we can introduce the Dirac operator G. First of all, it shall be a Hermitian operator on H. In a representation of H as wave functions, we assume it to be a partial differential operator of first order, i.e.,

$$G = iG^j \frac{\partial}{\partial x^j} + B, \tag{20}$$

with (4×4)-matrices $G^j(x)$, $B(x)$. Since G is (as an operator on H) a coordinate- and gauge-independent object, the matrices $G^j(x)$ and $B(x)$ have a well-defined behavior under coordinate and gauge transformations. As an additional condition, we demand that the matrices G^j shall coincide locally with the usual Dirac matrices:

Definition IV.1: A partial differential operator G on H is called a **Dirac operator**, *if, for any* $p \in M$, *there is a chart* (x^i, U) *around p and a gauge* $|x\alpha\rangle$ *such that G has the form (20) with*

$$G^j(p) = \gamma^j. \tag{21}$$

This definition can also be understood in more physical terms: Let us assume that an observer (e.g., a spacecraft passing through the space–time point p) chooses a coordinate system and gauge satisfying (21). Since the Dirac matrices at p coincide with those of the free Dirac operator, the observer at p has the impression that space–time locally resembles Minkowski space. Thus, we expect that the Dirac operator gives a Lorentz metric g_{jk}, which coincides with the Minkowski metric at p, $g_{jk}(p) = \eta_{jk}$. We can really derive this Lorentz metric from G; it is most conveniently given by

$$g^{jk}(x)\mathbb{1} = \tfrac{1}{2}\{G^j(x), G^k(x)\}. \tag{22}$$

In this way, our definition of the Dirac operator incorporates the principle of general relativity; the coordinate and gauge satisfying (21) gives a local reference frame. If the partial derivatives $\partial_j g_{kl}(p)$ of the metric also vanish (which can be arranged by choosing a so-called ''normal coordinate system''), the reference frame is a ''local system of inertia,'' where the observer feels no gravitational force at p. It might happen that $\partial_j G^k(p) \neq 0$, although $\partial_j g_{kl}(p)$ vanishes. This corresponds to a ''spin-mixing force'' which is related to our $U(2,2)$ symmetry. The matrix $B(x)$ can be used for the description of additional interactions, especially of electromagnetism $G = i\partial\!\!\!/ + eA\!\!\!/$. Note that $B(x)$ was not at all specified in our definition of the Dirac operator. This will turn out to be too general for physical applications. We postpone the discussion and specification of $B(x)$ to Sec. VI.

Unfortunately, the equation (19) for the ''eigenvector basis'' is too simple and must be modified. This is only a minor technical point, but, nevertheless, we give it in detail: The δ^4-distribution in (19) is useful in combination with the integration measure d^4x, because integrations can be easily carried out using the relation $\int f(x)\,\delta^4(x)\,d^4x = f(0)$. On a manifold, however, one works with the invariant measure $d\mu := \sqrt{|g|}\,d^4x$ instead of d^4x. In order to compensate the factor $\sqrt{|g|}$ of the integration measure in the integral over the δ-distribution, we must view the combination $|g(y)|^{-1/2}\delta^4(x-y)$ as the ''invariant δ-distribution'' at a point y of the manifold. Thus, we are led to replace (19) by

$$X^i|x\alpha\rangle = x^i|x\alpha\rangle, \quad \langle x\alpha|y\beta\rangle = s_\alpha \delta_{\alpha\beta} \frac{1}{\sqrt{|g|}}\,\delta^4(x-y). \tag{23}$$

This definition of a gauge is much better than (19) because $|x\alpha\rangle$ now behaves under coordinate transformations $x \to x'(x)$ simply like $|x\alpha\rangle \to |x'\alpha\rangle$. We again introduce the wave functions by $\Psi^\alpha(x) = \langle x\alpha|\Psi\rangle$ and obtain a representation of G as the differential operator (20). Notice that this indirect definition of a gauge by first introducing (19) and then replacing it by (23) was necessary because we had no invariant measure at the beginning. We must check that this procedure is consistent: The transition from (19) to (23) is described by the transformation $|x\alpha\rangle \to |g(x)|^{-1/4}|x\alpha\rangle$. Consequently, the Dirac operator transforms as $G \to |g(x)|^{-1/4} G |g(x)|^{1/4}$, and thus $G^j \to G^j$, $B \to B + (i/4)G^j(\partial_j \log|g|)$. We conclude that the definition of the Dirac operator and the Lorentz metric (22) are independent of whether (19) or (23) are used.

We will in the following always work with (23) as the definition of a *gauge*. The freedom in the choice of the gauge again describes local $U(2,2)$ transformations of the wave functions

$$\Psi \to U(x)\Psi(x), \quad \text{with } U(x) \in U(2,2). \tag{24}$$

We define the spin scalar product by (10). According to (23), the scalar product is obtained by integrating over the spin scalar product,

$$\langle \Psi | \Phi \rangle = \int_M < \Psi | \Phi > d\mu. \tag{25}$$

The Dirac equation is again introduced as the operator equation

$$(G - m)\Psi = 0. \tag{26}$$

On solutions of the Dirac equation, we finally define a generalization of the scalar product (12): We choose a space-like hypersurface $\mathcal{H}$ with normal vector field ν and set

$$(\Psi | \Phi)_{\mathcal{H}} = \int_{\mathcal{H}} < \Psi | G^j | \Phi > \nu_j \, d\mu_{\mathcal{H}}, \tag{27}$$

where $d\mu_{\mathcal{H}}$ is the measure on $\mathcal{H}$ induced by the Lorentzian metric.

V. CONSTRUCTION OF THE SPIN DERIVATIVE

We just introduced the Dirac operator on a manifold by combining the principle of general relativity with our $U(2,2)$ gauge symmetry. Although this definition was very natural, it is not clear what it precisely means: The Dirac operator is characterized by the matrices $G^j(x)$ and $B(x)$ in (20). We saw that $G^j(x)$ induces a Lorentzian structure and that $B(x)$ is composed of potentials that might be identified with usual gauge potentials. The precise physical interpretation of the degrees of freedom of $G^j(x)$, $B(x)$ is not clear, however. Furthermore, we expect in analogy to the discussion of Lorentzian transformations in Sec. III that coordinate and gauge transformations can be linked by imposing some conditions on the Dirac matrices. This would imply that the freedom in choosing the coordinate system is related to the $U(2,2)$ gauge symmetry. But this relation is also very vague at the moment.

In order to clarify the situation, we proceed in this section with some differential geometry. We will try to avoid abstract formalisms and prefer calculations in explicit coordinate systems and gauges. This is less elegant than a coordinate-free formulation, but it leads to a more elementary and direct approach. Our constructions are helpful for the physical interpretation, as will be explained in Sec. VI. In nontechnical terms, our aim is to rewrite the Dirac operator in a form which gives a better geometrical understanding of the matrices $G^j(x)$, $B(x)$.

Before starting the mathematical analysis, we point out that we consider the Dirac operator (apart from the wave functions of the physical particles) as the only *a priori* given object on the manifold. This means that all additional structure (like the metric, curvature, classical potentials, and field tensors) must be constructed from G. It might seem unusual to take only the Dirac operator as the starting point of a classical gauge theory. The motivation for this very restrictive procedure is the following: A physical theory is more convincing if it is developed from few objects, which are given from the very beginning and are considered as the ''fundamental'' objects of the theory. In relativistic quantum mechanics, the Dirac operator is needed in any case for the formulation of the Dirac equation. The objects of classical field theory, however, either enter directly in the Dirac operator or can be expressed in terms of derivatives of potentials occurring in G. We conclude that it is both desirable and might be possible to consider them as derived objects, which are only constructed from the Dirac operator for a convenient formulation of the classical interactions.

The Lorentzian metric (22) induces the Levi-Civita connection ∇, which gives a parallel transport of vector and tensor fields along geodesics. The geometry of space–time can be described as usual with the Riemannian curvature tensor R^i_{jkl}, and we could thus formulate general relativity by writing down Einstein's field equations. This procedure only tells about part of the geometry, however. We did not at all use the matrix $B(x)$ and did not take into account the $U(2,2)$ gauge symmetry. If we want to understand all the degrees of freedom of the Dirac operator geometrically, it is a better idea to study the parallel transport of spinors (instead of tensor fields). In the infinitesimal version, this parallel transport is given by a $U(2,2)$ gauge covariant derivative

D on the wave functions, which we call a *spin derivative*. It is characterized by the condition that the derivative $D_j \Psi$ of a wave function shall again behave under gauge transformations according to (24). The basic question is if the Dirac operator induces a spin derivative.

For the construction of the spin derivative, we will analyze gauge transformations explicitly. In a special gauge and coordinate system, D shall have the representation

$$D_j = \frac{\partial}{\partial x^j} - iC_j(x), \tag{28}$$

with suitable (4×4)-matrices $C_j(x)$. Under a gauge transformation (24), it transforms like

$$D_j \to U D_j U^{-1} = \partial_j - iUC_j U^{-1} + U(\partial_j U^{-1}). \tag{29}$$

Thus, our aim is to find matrices $C_j(x)$ satisfying the transformation rule,

$$C_j \to UC_j U^{-1} + iU(\partial_j U^{-1}). \tag{30}$$

These matrices must be formed out of $G^j(x)$, $B(x)$, which behave under gauge transformations like

$$G^j \to UG^j U^{-1}, \quad B \to UBU^{-1} + iUG^j(\partial_j U^{-1}). \tag{31}$$

It is far from being obvious how an explicit formula for the matrices C_j should look like. But we can already say something about its general structure: since only first derivatives of U occur in (30), we will only use G^j, B, and first derivatives of the Dirac matrices $\partial_k G^l$ for the construction. As a consequence, we need not care about second derivatives of U; they will not enter in our calculations. Constant gauge transformations (i.e., transformations U with $\partial_j U = 0$) are also irrelevant, because they only describe a common unitary transformation$\to U$. U^{-1} of all matrices. The point of interest is the first-order term $iU(\partial_j U^{-1})$ in (30).

We introduce some notation: In analogy to the bilinear and pseudoscalar covariants of the Dirac theory, we define the matrices

$$\sigma^{jk}(x) = \frac{i}{2}\,[G^j, G^k], \quad \rho(x) = \frac{i}{4!}\,\epsilon_{jklm} G^j G^k G^l G^m.$$

In a local reference frame (21), they coincide with the usual matrices σ^{jk}, γ^5 in the Dirac representation (we use the notation ρ instead of γ^5, because the ''tensor index'' [5] might be confusing on a manifold). A (4×4)-matrix is called *even* or *odd* if it commutes, resp. anticommutes, with ρ. The matrices

$$G^j, \quad \rho G^j, \quad \mathbb{1}, \quad i\rho, \quad \sigma^{jk}, \tag{32}$$

form a basis of the 16-dimensional (real) vector space of self-adjoint matrices (with respect to $<\cdot|\cdot>$). G^j, ρG^j are odd; $\mathbb{1}$, $i\rho$, and σ^{jk} are even.

Since we must expect the matrices C_j to be complicated expressions in G^j and B, it is useful to first consider special gauges where these expressions *should have* a simple form. For this purpose, we study the term $\nabla_k G^j = \partial_k G^j + \Gamma^j_{kl} G^l$. Under coordinate transformations, it behaves like a tensor. Under gauge transformations, however, first derivatives of U occur,

$$\begin{aligned} \nabla_k G^j \to \nabla_k (UG^j U^{-1}) &= U(\nabla_k G^j) U^{-1} + (\partial_k U) G^j U^{-1} + UG^j (\partial_k U^{-1}) \\ &= U(\nabla_k G^j) U^{-1} - [U(\partial_k U^{-1}), UG^j U^{-1}]. \end{aligned} \tag{33}$$

We can use the second summand in (33) for a partial gauge fixing.

Lemma V.1: For any space–time point $p \in M$ there is a gauge such that

$$\nabla_k G^j(p) = 0. \tag{34}$$

Proof: Notice that the matrix $\partial_j \rho$ is odd, because

$$0 = \partial_j \mathbb{1} = \partial_j(\rho\rho) = (\partial_j\rho)\rho + \rho(\partial_j\rho). \tag{35}$$

We start with an arbitrary gauge and construct the desired gauge with two subsequent gauge transformations.

(1) According to (35), the matrix $i\rho(\partial_j\rho)$ is self-adjoint. We can thus perform a gauge transformation U with $U(p)=\mathbb{1}$, $\partial_j U(p) = 1/2\rho(\partial_j\rho)$. The matrix $\partial_j\rho(p)$ vanishes in the new gauge, since

$$\partial_j\rho_{|p} \to \partial_j(U\rho U^{-1})_{|p} = \partial_j\rho_{|p} + \tfrac{1}{2}[\rho(\partial_j\rho),\rho]_{|p} = \partial_j\rho_{|p} - \rho^2(\partial_j\rho)_{|p} = 0.$$

By differentiating the relation $\{\rho, G^j\}=0$, we conclude that the matrix $\nabla_k G^j_{|p}$ is odd. We can thus represent it in the form

$$\nabla_k G^j_{|p} = \Lambda^j_{km} G^m_{|p} + \Theta^j_{km}\rho G^m, \tag{36}$$

with suitable coefficients Λ^j_{km}, Θ^j_{km}.

This representation can be further simplified: According to Ricci's Lemma, we have at p,

$$0 = 2\nabla_n g^{jk} = \{\nabla_n G^j, G^k\} + \{G^j, \nabla_n G^k\} = 2\Lambda^j_{nm} g^{mk} - \Theta^j_{nm} 2i\rho\sigma^{mk} + 2\Lambda^k_{nm} g^{mj} - \Theta^k_{nm} 2i\rho\sigma^{mj}, \tag{37}$$

and thus

$$\Lambda^j_{nm} g^{mk}_{|p} = -\Lambda^k_{nm} g^{mj}_{|p}. \tag{38}$$

In the case $j=k\neq m$, (37) yields that $\Theta^j_{nm}=0$. For $j\neq k$, we obtain $\Theta^j_{nj}\sigma^{jk} + \Theta^k_{nk}\sigma^{kj} = 0$ and thus $\Theta^j_{nj} = \Theta^k_{nk}$ (j and k denote fixed indices; no summation is performed). We conclude that there are coefficients Θ_k with

$$\Theta^j_{km} = \Theta_k \delta^j_m. \tag{39}$$

(2) We perform a gauge transformation U with $U(p)=\mathbb{1}$ and

$$\partial_k U = -\frac{1}{2}\,\Theta_k\rho - \frac{i}{4}\,\Lambda^m_{kn} g^{nl}\sigma_{ml}.$$

Using the representation (36) together with (38),(39), the matrix $\nabla_k G^j$ transforms like

$$\nabla_k G^j \to \nabla_k G^j + [\partial_k U, G^j] = \Lambda^j_{km} G^m + \Theta_k \rho G^j - \Theta_k \rho G^j - \frac{i}{4}\,\Lambda^m_{kn} g^{nl}[\sigma_{ml}, G^j]$$

$$= \Lambda^j_{km} G^m - \frac{i}{4}\,\Lambda^m_{kn} g^{nl} 2i(G_m \delta^j_l - G_l \delta^j_m)$$

$$= \Lambda^j_{km} G^m + \tfrac{1}{2}\Lambda^m_{kn} g^{nj} G_m - \tfrac{1}{2}\Lambda^j_{km} G^m = 0. \qquad \blacksquare$$

In general, the condition $\nabla_k G^j$ can only be satisfied ''locally'' in one point $p \in M$. We call a gauge satisfying (34) a *normal gauge* around p.

Now we look to which extent the gauge is fixed by Lemma V.1. According to (33), a transformation between normal gauges must satisfy the condition

$$[U(\partial_j U^{-1}), U G^j U^{-1}]_{|p} = 0.$$

As a consequence, the matrix $iU(\partial_j U^{-1})_{|p}$ must be a multiple of the identity, as is verified in the basis (32) using the commutation relations between the Dirac matrices. Since constant gauge transformations and higher than first-order derivatives of U are irrelevant, we can assume that $U(x)$ itself is a multiple of the identity. In other words, we can restrict ourselves to $U(1)$ gauge transformations. This is very helpful because in this special case there is a simple expression showing the transformation law (30), namely,

$$\tfrac{1}{4}\,\mathrm{Re}\,\mathrm{Tr}(G_j B)\mathbb{1} \to \tfrac{1}{4}\,\mathrm{Re}\,\mathrm{Tr}(G_j B)\mathbb{1} + \tfrac{1}{4}\,\mathrm{Re}\,\mathrm{Tr}(G_j G^k i U(\partial_j U^{-1})\mathbb{1}) = \tfrac{1}{4}\,\mathrm{Re}\,\mathrm{Tr}(G_j B)\mathbb{1} + iU(\partial_j U^{-1}).$$

We can identify this expression with C_j and use (28) as the definition for a spin derivative.

Definition V.2: We define the **canonical spin derivative** *D by the condition that it has in normal gauges around p the form*

$$D_j(p) = \frac{\partial}{\partial x^j} - \frac{i}{4}\,\mathrm{Re}\,\mathrm{Tr}(G_j B)_{|p}\mathbb{1}. \tag{40}$$

In general gauges, the canonical spin derivative can be written as

$$D_j = \frac{\partial}{\partial x^j} - iE_j - \frac{i}{4}\,\mathrm{Re}\,\mathrm{Tr}(G_j B)\mathbb{1}, \tag{41}$$

with additional matrices $E_j(x)$. These matrices are characterized by the condition that $E_j(p)$ vanishes in normal gauges around p and behaves according to (30) under $SU(2,2)$ gauge transformations. They are given by the formula

$$E_j = \frac{i}{2}\,\rho(\partial_j \rho) - \frac{i}{16}\,\mathrm{Tr}(G^m \nabla_j G^n) G_m G_n + \frac{i}{8}\,\mathrm{Tr}(\rho G_j \nabla_m G^m)\rho, \tag{42}$$

as can be verified by a straightforward calculation. Unfortunately, this expression is rather complicated. We will in the following always avoid working with E_j explicitly.

The canonical spin derivative has some nice properties. We first collect them in a theorem and discuss them afterward.

Theorem V.3: *The canonical spin derivative satisfies the equation*

$$[D_k, G^j] + \Gamma^j_{kl} G^l = 0. \tag{43}$$

It is compatible with the spin scalar product,

$$\partial_j \langle \Psi | \Phi \rangle = \langle D_j \Psi | \Phi \rangle + \langle \Psi | D_j \Phi \rangle. \tag{44}$$

The operator $iG^j D_j$ is a well-defined Hermitian operator on H. Furthermore,

$$-i\nabla_j \langle G^j \Psi | \Phi \rangle = \langle iG^j D_j \Psi | \Phi \rangle - \langle \Psi | iG^j D_j \Phi \rangle. \tag{45}$$

Proof: The left side of (43) behaves under gauge transformations according to the adjoint representation. $i \to U \cdot U^{-1}$ of the gauge group. Thus it suffices to check (43) in a normal gauge, where

$$[D_k, G^j] + \Gamma^j_{kl} G^l = \nabla_k G^j - \frac{i}{4}\,\mathrm{Re}\,\mathrm{Tr}(G_j B)[\mathbb{1}, G^j] = 0.$$

For the canonical spin derivative, the matrix C_j in (28) is self-adjoint, as can be verified with (41), (42). This immediately implies (44).

According to its behavior under coordinate and gauge transformations, we can view $iG^j D_j$ as an operator on H. Relation (44) yields the equation

$$\nabla_j \langle G^j \Psi | \Phi \rangle = \langle D_j G^j \Psi | \Phi \rangle + \langle G^j \Psi | D_j \Phi \rangle + \Gamma^j_{jk} \langle G^k \Psi | \Phi \rangle.$$

Applying (43) and the self-adjointness of the Dirac matrices, we obtain (45). If we integrate this equation with respect to the invariant measure $d\mu = \sqrt{|g|}\,d^4x$, the left side vanishes with Gauss' theorem. On the right side, we substitute (25) and conclude that the operator $iG^j D_j$ is Hermitian. ∎

Generally speaking, this theorem shows that the connections ∇, D, the Dirac matrices G^j, and the scalar products $g_{jk}, \langle \cdot | \cdot \rangle$ can be consistently used in combination with each other, if all

expressions are written in a coordinate and gauge invariant form (by appropriately using ∇_j, D_j, and Γ^j_{kl}). We can leave out the derivatives of G^j and may use the product rule inside the spin scalar product. Relation (44) formally corresponds to Ricci's Lemma in Riemannian geometry if we replace the metric by the spin scalar product and ∇ by D.

Since the operators G and iG^jD_j are both Hermitian and coincide up to zeroth-order contributions, we can represent the Dirac operator in the form

$$G = iG^jD_j + H, \tag{46}$$

with a self-adjoint matrix $H(x)$. Under gauge transformations, H simply behaves according to the adjoint representation. This is an advantage over the formula (20), where the transformation of B involves derivatives of U.

Equation (45) implies a general version of current conservation: Assume that Ψ and Φ are eigenvectors of G with real eigenvalue m. Then the vector field $<G^j\Psi|\Phi>$ is divergence-free,

$$-i\nabla_j <G^j\Psi|\Phi> = <(G-H)\Psi|\Phi> - <\Psi|(G-H)\Phi> = 0.$$

It is a natural generalization of the electromagnetic current $\overline{\Psi}\gamma^j\Psi$ of the Dirac theory. According to Gauss' law, the current conservation implies that the scalar product (27) is independent of the choice of the hypersurface $\mathcal{H}$. The integrand of the scalar product $(\Psi|\Psi)$ has the interpretation as the probability density of the particle.

The Christoffel symbol in (43) indicates that the spin derivative in some way includes the Levi-Civita connection ∇. The following bundle construction makes this relation more precise: We denote the sections of a vector bundle N over M by $\Gamma(N)$ [e.g., $\Gamma(TM)$ are the vector fields on M]. The Levi-Civita connection is a connection on the tangent bundle TM,

$$\nabla : T_pM \times \Gamma(TM) \to T_pM : (X,Y) \to \nabla_X Y.$$

We can view the wave functions as sections of a vector bundle SM with fiber $(\mathbb{C}^4, <\cdot|\cdot>)$. In order to describe the $U(2,2)$ gauge symmetry, we make this *spin bundle* to a principal bundle with structure group $U(2,2)$, which acts on the fiber in the fundamental representation. $\to U$. . The spin derivative is a connection on the spin bundle,

$$D : T_pM \times \Gamma(SM) \to S_pM : (X,\Psi) \to D_X\Psi.$$

We define L_pM as the vector space of self-adjoint transformations of S_pM. In a special gauge, L_pM can be represented as (4×4)-matrices; (32) gives an explicit basis. The gauge transformations act on the matrices according to the adjoint representation. $\to U_{|p} . U_{|p}^{-1}$. We denote the corresponding principal bundle by LM. The spin derivative induces a connection on LM by

$$D : T_pM \times \Gamma(LM) \to L_pM : (X,A) \to [D_X, A]. \tag{47}$$

We can view the tangent bundle as a subspace of LM, because there are canonical embeddings and projections,

$$\iota_p : T_pM \hookrightarrow L_pM : X \to X^i G_i,$$

$$\pi_p : L_pM \to T_pM : A \to \frac{1}{4}\,\mathrm{Tr}(G^jA)\,\frac{\partial}{\partial x^j},$$

with $\pi\iota = id$. By restricting the connection (47) to the tangent bundle, we can form a connection $\tilde{\nabla}$ on TM,

$$\tilde{\nabla} : T_pM \times S(TM) \to T_pM : (X,Y) \to \pi[D_X, \iota Y].$$

Equation (43) states that this connection coincides with the Levi-Civita connection, since

$$[D_X, \iota Y] = X^j[D_j, G^kY_k] = X^j((\partial_j Y_k)G^k - \Gamma^k_{jl}Y_kG^l) = X^j(\nabla_j Y_k)G^k = \iota\,\nabla_X Y, \tag{48}$$

and thus

$$\tilde{\nabla}_X Y = \pi[D_X, \iota Y] = \pi \iota\, \nabla_X Y = \nabla_X Y.$$

In this way, the Levi-Civita connection is recovered as a suitable restriction of the spin connection. The geometry of the spin bundle generalizes the Lorentzian geometry of the manifold.

It remains to construct the geometrical invariants of the spin connection. On an elementary level, one can look for expressions in D_k, G^j, which transform both like a tensor and according to a local representation of the gauge group. This leads to the definition of the 2-forms,

$$T_{jk} = \frac{i}{2}\,([D_j, G_k] - [D_k, G_j]),$$

$$R_{jk} = \frac{i}{2}\,[D_j, D_k],$$

which are called *torsion* and *curvature*.

Theorem V.4: *The canonical spin connection is torsion-free. Curvature has the form*

$$R_{jk} = \tfrac{1}{8} R_{mnjk} \sigma^{mn} + \tfrac{1}{2}(\partial_j a_k - \partial_k a_j)\mathbb{1}, \tag{49}$$

with the Riemannian curvature tensor R_{mnjk} and the potential

$$a_j = \tfrac{1}{4}\,\mathrm{Re}\,\mathrm{Tr}(G_j B). \tag{50}$$

Proof: Relation (43) yields

$$[D_j, G_k] = [D_j, g_{kl} G^l] = (\partial_j g_{kl}) G^l - g_{kl} \Gamma^l_{jm} G^m = \Gamma^m_{jk} G_m,$$

and thus, using that the Levi-Civita connection is torsion-free,

$$T_{jk} = \frac{i}{2}\,(\Gamma^m_{jk} - \Gamma^m_{kj}) G_m = 0.$$

We iterate formula (48) and express the Riemannian curvature tensor in terms of the curvature of the spin connection,

$$\begin{aligned} G_i R^i_{jkl} Z^l = \iota(\nabla_j \nabla_k Z - \nabla_k \nabla_j Z) &= [D_j, [D_k, \iota Z]] - [D_k, [D_j, \iota Z]] \\ &= [[D_j, D_k], \iota Z] = -2i[R_{jk}, \iota Z]. \end{aligned}$$

This equation determines curvature up to a multiple of the identity matrix,

$$R_{jk}(x) = \tfrac{1}{8} R_{mnjk} \sigma^{mn} + \lambda_{jk}\mathbb{1}.$$

Thus, it remains to calculate the trace of curvature,

$$\tfrac{1}{4}\,\mathrm{Tr}(R_{jk}) = \tfrac{1}{8}\mathrm{Tr}(\partial_j C_k - \partial_k C_j) = \tfrac{1}{2}(\partial_j a_k - \partial_k a_j),$$

where we used (41) and the fact that the matrices E_j are trace-free. ∎

We remark that the canonical spin derivative is not the only spin derivative, which can be constructed from the Dirac operator. A general spin derivative $\overline{D}$ differs from the canonical spin derivative by matrices $F_j = D_j - D_j$, which transform according to the adjoint representation of the gauge group. It is no loss of generality to work with the canonical spin derivative because the matrices F_j can also be dealt as additional potentials. Because of the useful properties of Theorem V.4, it is most convenient to use the canonical spin derivative.

VI. INTERPRETATION, THE PHYSICAL DIRAC OPERATOR

For the physical interpretation of the previous constructions, we return to the discussion of the moving observer on page 9. We saw that the coordinate system and gauge satisfying (21) give a local reference frame for the observer. The gravitational field can be compensated locally by choosing a normal coordinate system. According to Lemma V.1, we can further compensate the dynamics of the Dirac matrices: in a normal gauge even the derivatives of the Dirac matrices vanish, $\partial_k G^j(p) = \nabla_k G^j(p) = 0$. This means that the above-mentioned ''spin-mixing force'' can also be compensated locally by choosing an appropriate coordinate system and gauge. We cannot do even better because second-order derivatives of the metric and the Dirac matrices involve the Riemannian curvature tensor. We call a coordinate system and gauge satisfying the conditions $G^j(p) = \gamma^j$, $\partial_k G^j(p) = 0$ a *normal reference frame* around p.

We come to the discussion of the matrix $B(x)$, which was not at all specified in Definition IV.1. The strongest local condition is to impose that $B(p)$ vanishes in a suitable normal reference frame around p. This condition turns out to be of physical interest, and we use it as the definition for the physical Dirac operator:

Definition VI.1: A Dirac operator G is called a **physical Dirac operator** *if for any $p \in M$ there is a normal reference frame around p such that $B(p) = 0$.*

In other words, the physical Dirac operator is characterized by the condition that it locally coincides with the free Dirac operator, which means more precisely that there is a coordinate system and a gauge with $G^j(p) = \gamma^j$, $\partial_k G^j(p) = 0$, and $B(p) = 0$.

We again consider the physical Dirac operator as the only *a priori* given object on the manifold and construct the metric and the canonical spin derivative from G. In a normal reference frame with $G = iG^j \partial_j$, the canonical spin derivative (40) coincides with the partial derivatives, $D_j = \partial_j$. Thus, the physical Dirac operator has the representation

$$G = iG^j D_j, \tag{51}$$

which is also valid in a general gauge and coordinate system. In comparison to the representation (20), the degrees of freedom of the matrix $B(x)$ now occur in the canonical spin derivative. This has the advantage that they can be immediately identified with the $U(2,2)$ gauge potentials in (41). The last summand in (41) describes the $U(1)$ phase transformations of electrodynamics. We define the electromagnetic potential by

$$A_j = \frac{1}{4e} \text{ Re Tr}(G_j B),$$

and rewrite the canonical spin derivative in the more familiar form

$$D_j = \frac{\partial}{\partial x^j} - iE_j - ieA_j.$$

The matrices E_j take into account the gravitational field. According to Theorem V.4, the curvature of the spin connection is formed of the Riemannian curvature tensor and the electromagnetic field tensor $F_{jk} = \partial_j A_k - \partial_k A_j$. We can write down the classical action in terms of these tensor fields. The classical variational principle yields a unified description of general relativity and electromagnetism as a $U(2,2)$ gauge symmetry.

The definition of the physical Dirac operator can also be understood in more technical terms with the canonical spin derivative: The Dirac operator of Definition IV.1 has the representation (46) with a self-adjoint matrix $H(x)$. According to the construction of the spin derivative, the matrices $G^j H$ are trace-free. Thus $H(x)$ is characterized by 12 degrees of freedom, which correspond to additional potentials (more precisely, one scalar, one pseudoscalar, four pseudovector, and six bilinear potentials). These potentials are not gauge potentials. They do not seem to occur in nature. Therefore it is a reasonable physical condition to assume that H vanishes. This leads to the representation (51) of the physical Dirac operator.

Our definition of the Dirac operator introduces the gauge potentials and in this way replaces the usual minimal coupling procedure. We explain for clarity why simple minimal coupling does

not make sense in the context of our $U(2,2)$ symmetry: Assume that we had (instead of constructing the spin derivative from the Dirac operator) introduced a $U(2,2)$ gauge covariant derivative D of the form (28) with gauge potentials C_j. According to minimal coupling, we must replace the partial derivatives in the free Dirac operator by gauge covariant derivatives, which gives the operator $i\gamma^j D_j$. This operator does not make sense, however. First of all, it is not Hermitian (with respect to $<\cdot|\cdot>$). Furthermore, the current $<\gamma^j\Psi|\Psi>$ is, in general, not divergence-free, so that the probabilistic interpretation of the Dirac wave function breaks down. The basic reason why minimal coupling does not work is that the $U(2,2)$ gauge potentials C_j do, in general, not commute with the Dirac matrices γ^j. In order to bypass these problems, we must replace the γ-matrices by dynamical Dirac matrices $G^j(x)$. The two replacements $\partial_j \rightarrow D_j$ and $\gamma^j \rightarrow G^j$ must be coordinated in such a way that the Dirac operator iG^jD_j is Hermitian and allows a reasonable definition of a conserved current. This is accomplished by our definition of the Dirac operator and the subsequent construction of the spin derivative.

Our description of gravitation differs considerably from the usual formulation of general relativity as a gauge theory (see, e.g., Ref. 4). As one of the major differences, we avoid the principal bundle of orthonormal frames (with the Lorentz group as structure group); instead, we are working with the spin bundle and local $U(2,2)$ transformations. This replacement is possible because the subgroup of $U(2,2)$ generated by the bilinear covariants σ^{ij} is locally isomorphic to the Lorentz group. In contrast to the connection on the bundle of orthonormal frames, the canonical spin connection is torsion-free. Remember that the $U(2,2)$ spin bundle arose as a consequence of our measurement principle for space and time. Thus, as an advantage of our procedure, the usual bundle constructions for the definition of gauge fields and of spinors in curved space–time are no longer necessary.

VII. CONCLUSION

We saw that the adaptation of the ideas in Ref. 1 to the relativistic context yields a local $U(2,2)$ gauge symmetry of the Dirac equation. In order to describe the physical interactions with this gauge symmetry, it is necessary to consider the Dirac operator as the basic object on the manifold. The gauge potentials are implicitly contained in the Dirac operator. By constructing the spin derivative, they are recovered as describing the electromagnetic and gravitational field. In this way, we conclude that the local $U(2,2)$ symmetry in relativistic quantum mechanics makes physical sense. The concept of measurability of space–time gives a fundamental explanation for this gauge symmetry.

Our description has the advantage that both the Dirac theory and classical field theory are developed from few *a priori* given objects: The fermionic particles correspond to vectors of the indefinite scalar product space $(H,\langle\cdot|\cdot\rangle)$. Space–time is described by the spectral measure dE_x on the manifold M. The Dirac operator gives the gauge potentials and determines the interaction between the fermions and the gauge fields. This description is conceptually simple. It is the starting point for further constructions which finally lead to the ''Principle of the Fermionic Projector'' as introduced in Ref. 5.

Stochastically positive structures on Weyl algebras. The case of quasi-free states

R. Gielerak,[a] L. Jakóbczyk,[b] and R. Olkiewicz[c]
Institute of Theoretical Physics, University of Wroclaw, Wroclaw, Poland

(Received 20 May 1997; accepted for publication 21 August 1998)

We consider quasi-free stochastically positive ground and thermal states on Weyl algebras in the imaginary time formulation. In particular, we obtain a new derivation of a general form of thermal quasi-free state and give conditions when such a state is stochastically positive, i.e., when it defines a periodic stochastic process with respect to imaginary time, a so-called thermal process. Then we show that the thermal process completely determines modular structure canonically associated with the quasi-free thermal state on Weyl algebra. We discuss a variety of examples connected with free quantum field theories on globally hyperbolic stationary space–times and models of quantum statistical mechanics. © *1998 American Institute of Physics.* [S0022-2488(98)01712-5]

I. INTRODUCTION

It is well known that the idea of analytic continuation to the imaginary time (Euclidean) variables is very fruitful for studying several quantum systems, especially Wightman quantum field theories on a flat space–time. From the general properties of Wightman distributions follows the possibility of analytic continuation to the Euclidean region, which gives an alternative, purely Euclidean description in terms of so-called Schwinger functions.[1–4] In the context of bosonic fields, we obtain commutative objects, which are much easier to analyze.[5] A particulary nice situation occurs in the case of free scalar fields. As was noticed by Nelson[6] (see also Ref. 7), the corresponding Euclidean structure is given by a Gaussian Markov generalized random field. This observation and the general reconstruction theorem,[8] gave powerful input for the development of the constructive quantum field theory on a flat space–time (Refs. 9 and 10 and references therein).

One of the main objectives of the present paper is to develop systematically the rigorous imaginary time formalism in the context of equilibrium states given by the Kubo–Martin–Schwinger (KMS) condition. As an interesting application of general results, we consider imaginary time approach to quantum field theories at nonzero temperature on globally hyperbolic stationary space–times.[11,12] Some aspects of imaginary time formalism in this context were discussed in the literature at various levels of mathematical rigor (see, e.g., Refs. 13–16), but, to our knowledge, there is still the lack of a systematic and mathematically rigorous approach to these problems. In the context of quantum statistical mechanics, the imaginary time approach developed in Refs. 17–27 also appears to be very useful. In particular, for a class of quantum systems with so-called stochastic positivity, which are described by some stochastic processes, methods of classical statistical mechanics can be applied to study several questions like the existence and properties of the limiting thermal states, phase transitions, etc.[20,21,24–27]

In the present paper a general conceptual framework for stochastically positive structures on Weyl algebras is introduced (Sec. II). As a starting point for further development, we analyze in detail the case of quasi-free states (Sec. III). Although basic structural results characterizing quasi-free thermal states were obtained a long time ago,[28–30] we present a new (in our opinion, simpler) proof of the theorem giving the general form of a quasi-free state satisfying the KMS condition (see Theorems 3.1 and 3.7). Section III D contains complete characterizations of stochastically positive quasi-free KMS states and corresponding periodic stochastic processes. The

important problem of the equivalence of the modular structure given by a stochastic process (Theorem 3.3) with the canonical modular structure associated with a quasi-free KMS state is solved in full generality in Sec. III E. This result shows that in the case of quasi-free stochastically positive states, all relevant information about KMS structure is contained in the commutative sector given by a thermal stochastic process. Similar results are true also for the ground state case (Sec. III G). Let us emphasize that it gives new possibilities for the description of KMS structures in the case when interaction is present. Having described quasi-free systems in terms of stochastic processes, one may perturb them with multiplicativelike functionals, thereby creating some new non-Gaussian thermal process. Furthermore, given such a process, we can reproduce its KMS structure. Some results in this direction were obtained in Ref. 24 for gentle perturbations of the free Bose gas in the noncritical region of densities and in Ref. 25 for the critical case. Essentially equivalent (via the Feynman–Kac formula) types of perturbations which can be studied using this method are central perturbations of a quasi-free state, by which we mean the perturbations of the form ''$H_\omega + V$,'' where H_ω is the generator of the free evolution in the thermal representation, and V is an operator affiliated with the von Neumann algebra $\pi_\omega(\mathfrak{U})''$, for an appropriate Abelian subalgebra $\mathfrak{U}$ of the Weyl algebra. That kind of perturbation will be discussed in the second part of the present work. Section IV contains several examples to which our general arguments can be applied. In the particular case of the scalar quantum field theory on a globally hyperbolic stationary space–time, we give a general result on the existence of Markov thermal process, which determines the whole modular structure of the theory. Similar arguments are also valid for ground state structure. In the case of a static space–time, we obtain much more explicit description of the arising process and we are able to discuss its continuity properties. In particular, in the case of the Rindler wedge (Example 4.1.2), we show stochastic positivity of the KMS structure arising in the context of the Bisognano–Wichmann theorem.[31] These results can be used to develop a rigorous constructive approach to nonlinear quantum field theories by adopting the tools worked out in constructive quantum field theory on a flat space–time. A detailed study of the perturbed Euclidean quantum fields on stationary globally hyperbolic space–times will be presented in our forthcoming publication. In this section we discuss the models of quantum statistical mechanics, including the model of nonrelativistic Bose matter and infinite harmonic crystal, and describe the corresponding stochastic processes.

II. WEYL ALGEBRA. VACUUM AND TEMPERATURE GREEN FUNCTIONS

A. Weyl algebra

Let $\mathcal{D}$ be a real vector space with a locally convex topology τ. If σ is a τ-continuous symplectic form on $\mathcal{D}$ (i.e., σ is a bilinear, antisymmetric and nondegenerate mapping from $\mathcal{D}\times\mathcal{D}$ into $\mathbb{R}$), then $((\mathcal{D},\tau),\sigma)$ is called a vector symplectic space. Let W_f be the real function on $\mathcal{D}$ defined by

$$W_f(g)=\begin{cases}1, & \text{if } f=g,\\ 0, & \text{if } f\neq g.\end{cases}$$

With the product

$$W_f W_g = e^{-i\sigma(f,g)/2} W_{f+g}$$

and involution

$$W_f^* = W_{-f},$$

the complex algebra generated by W_f, $f\in\mathcal{D}$ becomes a*-algebra $\mathfrak{W}_0(\mathcal{D},\sigma)$. We define $\mathfrak{W}(\mathcal{D},\sigma)$ [the Weyl algebra over $((\mathcal{D},\sigma))$] in the following way. Let

$$\left\| \sum_{k=1}^{N} z_k W_{f_k} \right\|_1 = \sum_{k=1}^{N} |z_k|.$$

Here $\|\cdot\|_1$ is a $*$-norm on $\mathfrak{W}_0(\mathcal{D},\sigma)$ and let the completion $\overline{\mathfrak{W}(\mathcal{D},\sigma)}^{\|\cdot\|_1}$ be a $*$-Banach algebra with unit. Let $\mathcal{F}$ be the set of states on $\overline{\mathfrak{W}(\mathcal{D},\sigma)}^{\|\cdot\|_1}$. Then we define a C^*-algebra norm as follows:[32]

$$\|W\| = \sup_{\rho \in \mathcal{F}} \sqrt{\rho(W^*W)},$$

then $\mathfrak{W}(\mathcal{D},\sigma)$ is the completion of $\overline{\mathfrak{W}_0(\mathcal{D},\sigma)}^{\|\cdot\|_1}$ with respect to this norm.

A state ω on $\mathfrak{W}(\mathcal{D},\sigma)$ is called regular if it is τ-continuous, i.e., the function

$$f \to \omega(W_f)$$

is τ-continuous.

Remark: Usually, the weaker form of continuity is assumed, namely the map

$$\mathbb{R} \ni t \to \omega(W_{tf})$$

should be continuous, for every $f \in \mathcal{D}$.

The set of all regular states on $\mathfrak{W}(\mathcal{D},\sigma)$ will be denoted by $E(\mathfrak{W})$. For a given $\omega \in E(\mathfrak{W})$, $(\mathfrak{h}_\omega, \pi_\omega, \Omega_\omega)$ will be the corresponding Gel'fand–Nalmark–Segal (GNS) representation.

Let $\{T_t\}_{t \in \mathbb{R}}$ be a one-parameter group of τ-continuous symplectic mappings from $\mathcal{D}$ onto $\mathcal{D}$. In the following, $(\mathcal{D},\sigma,\{T_t\})$ will be called a linear dynamical system. If we put

$$\alpha_t(W_f) = W_{T_t f},$$

we obtain a one-parameter group of *-automorphisms of the Weyl algebra $\mathfrak{W}(\mathcal{D},\sigma)$. For a given linear dynamical system $(\mathcal{D},\sigma,\{T_t\})$, let $E^\alpha(\mathfrak{W})$ be the set of all regular α_t-invariant states on $\mathfrak{W}(\mathcal{D},\sigma)$. If $\omega \in E^\alpha(\mathfrak{W})$, then on the GNS space $\mathfrak{h}_\omega$, the evolution α_t is represented by a unitary group $U_\omega(t)$ with a self-adjoint generator H_ω.

Definition 2.1:

(1) $\omega \in E^\alpha(\mathfrak{W})$ is *a ground state* iff $H_\omega \geqslant 0$.

(2) Let $0 < \beta < \infty$ be given. A faithful state $\omega \in E^\alpha(\mathfrak{W})$ is *an α_t-KMS state at the inverse temperature β* iff in the corresponding GNS representation the unitary group e^{itH_ω} defines a weakly continuous group of *-automorphisms of $\pi_\omega(\mathfrak{W}(\mathcal{D},\sigma))''$ such that

$$\langle e^{-(\beta/2)H_\omega} \pi_\omega(W_f)\Omega_\omega, e^{-(\beta/2)H_\omega} \pi_\omega(W_g)\Omega_\omega \rangle = \langle \pi_\omega(W_g)^*\Omega_\omega, \pi_\omega(W_f)^*\Omega_\omega \rangle$$

for all $f,g \in \mathcal{D}$. In this case Ω_ω is cyclic and separating for $\pi_\omega(\mathfrak{W}(\mathcal{D},\sigma))''$ and the modular operator associated with Ω_ω coincides with $e^{-(\beta/2)H_\omega}$.

B. Imaginary time Green's functions

For any $\omega \in E^\alpha(\mathfrak{W})$ define *multi-time Green's functions*

$$\begin{aligned} G(f_1,\ldots,f_n;t_1,\ldots,t_n) &= \omega(\alpha_{t_1}(W_{f_1}) \cdots \alpha_{t_n}(W_{f_n})) \\ &= \langle \Omega_\omega, U_\omega(t_1)\pi_\omega(W_{f_1})U_\omega(-t_1) \\ &\quad \cdots U_\omega(t_n)\pi_\omega(W_{f_n})U_\omega(-t_n)\Omega_\omega \rangle \end{aligned}$$

for $t_1,\ldots,t_n \in \mathbb{R}$. If $\omega_\infty \in E^\alpha(\mathfrak{W})$ is a ground state, then it can be shown that the corresponding Green's functions $G_\infty(f_1,\ldots,f_n;t_1,\ldots,t_n)$ can be analytically continued to the functions denoted by $G_\infty(f_1,\ldots,f_n;z_1,\ldots,z_n)$, holomorphic in the region

$$\mathfrak{T}_n^\infty = \{(z_1,\ldots,z_n) \in \mathbb{C}^n : -\infty < \mathrm{Im}\ z_1 < \mathrm{Im}\ z_2 < \ldots < \mathrm{Im}\ z_n < \infty\}$$

and continuous on the boundary of $\overline{\mathfrak{T}_n^{\infty}}$. Similarly, if $\omega_\beta \in E^\alpha(\mathfrak{W})$ is a strongly β-KMS state, then by the theorem of Araki,[33] the corresponding Green's functions $G_\beta(f_1,\ldots,f_n;t_1,\ldots,t_n)$ can be analytically continued to the functions denoted by $G_\beta(f_1,\ldots,f_n;z_1,\ldots,z_n)$, holomorphic in the region

$$\mathfrak{T}_n^\beta=\{(z_1,\ldots,z_n)\in\mathbb{C}^n: -\beta/2<\mathrm{Im}\ z_1<\cdots<\mathrm{Im}\ z_n<\beta/2\}$$

and continuous on the boundary of $\overline{\mathfrak{T}_n^\beta}$. Let

$$\mathfrak{E}_n^\infty=\{(s_1,\ldots,s_n)\in\mathbb{R}^n: s_1\leqslant\cdots\leqslant s_n\}$$

and

$$\mathfrak{E}_n^\beta=\{(s_1,\ldots,s_n): -\beta/2\leqslant s_1\leqslant\cdots\leqslant s_n\leqslant\beta/2\}.$$

Definition 2.2:

(1) The restrictions of $G_\infty(f_1,\ldots,f_n;z_1,\ldots,z_n)$ to the purely imaginary points

$$(is_1,\ldots,is_n),\quad (s_1,\ldots,s_n)\in\mathfrak{E}_n^\infty$$

will be called *imaginary time* (*or Euclidean*) Green's functions corresponding to the ground state ω_∞, and will be denoted by $G_\infty^E(f_1,\ldots,f_n;s_1,\ldots,s_n)$.

(2) Similarly, the restrictions of $G_\beta(f_1,\ldots,f_n;z_1,\ldots,z_n)$ to the points

$$(is_1,\ldots,is_n),\quad (s_1,\ldots,s_n)\in\mathfrak{E}_n^\beta$$

will be called *imaginary time* (*or Euclidean*) Green's functions corresponding to the KMS state ω_β, and will be denoted by $G_\beta^E(f_1,\ldots,f_n;s_1,\ldots,s_n)$.

Remark: By linearity and continuity, we extend $G_{\infty(\beta)}^E(f_1,\ldots,f_n;s_1,\ldots,s_n)$ to the whole Weyl algebra and obtain

$$G_{\infty(\beta)}^E(W_1,\ldots,W_n;s_1,\ldots,s_n),\quad W_1,\ldots,W_n\in\mathfrak{W}(\mathcal{D},\sigma).$$

The properties of imaginary time Green's functions corresponding to the KMS state ω_β were studied in Ref. 23. Similarly we can obtain the properties of ground state imaginary time Green's functions. In the formulation of these properties, the following notation will be used: for $W_1,\ldots,W_k\in\mathfrak{W}(\mathcal{D},\sigma)$,

$$\underline{W}^k=(W_1,\ldots,W_k)\quad\text{and}\quad \underline{W}^{k*}=(W_k^*,\ldots,W_1^*)$$

for $f_1,\ldots,f_k\in\mathcal{D}$, $\underline{f}^k=(f_1,\ldots,f_k)$. Similarly

$$\underline{s}^k=(s_1,\ldots,s_k)\quad\text{and}\quad \underline{s}^{k*}=(-s_k,\ldots,-s_1).$$

Moreover,

$$G_{\infty(\beta)}^E(\underline{f}^k;\underline{s}^k)=G_{\infty(\beta)}^E(f_1,\ldots,f_k;s_1,\ldots,s_k),$$

$$G_{\infty(\beta)}^E(\underline{W}^k;\underline{s}^k)=G_{\infty(\beta)}^E(W_1,\ldots,W_k;s_1,\ldots,s_k),$$

and

$$\underline{W}^{k-1}(i)=(W_1,\ldots,W_{i-1},W_iW_{i+1},W_{i+2},\ldots,W_k),$$

$$\underline{W}^{k-1}([i])=(W_1,\ldots,W_{i-1},W_{i+1},\ldots,W_k),$$

$$\underline{s}^{k-1}([i])=(s_1,\ldots,s_{i-1},s_{i+1},\ldots,s_k).$$

For the ground state $\omega_\infty \in E^\alpha(\mathfrak{W})$ the set of imaginary time Green's functions $\mathbb{G}^E_\infty = \{G^E_\infty(\underline{W}^k;\underline{s}^k)\}$ has the following properties.

(EG1)$_\infty$: (1) For each $\underline{W}^k$ the map

$$\underline{s}^k \to G^E_\infty(\underline{W}^k;\underline{s}^k)$$

is continuous.

(2) For a fixed $\underline{s}^k \in \mathfrak{E}^\infty_k$, the map

$$\underline{W}^k \to G^E_\infty(\underline{W}^k;\underline{s}^k)$$

is multilinear and bounded, i.e.,

$$|G^E_\infty(\underline{W}^k;\underline{s}^k)| \leqslant \prod_{i=1}^{k} \|W_i\|.$$

Moreover, the map

$$\underline{f}^k \to G^E_\infty(\underline{f}^k;\underline{s}^k)$$

is τ-continuous.

(3) For any $s \in [0,\infty)$

$$G^E_\infty(\underline{W}^k;\underline{s}^k + s) = G^E_\infty(\underline{W}^k;\underline{s}^k).$$

(4) For any $\underline{W}^k$ and $\underline{s}^k \in \mathfrak{E}^\infty_k$ such that $s_i = s_{i+1}$, $1 \leqslant i \leqslant k-1$,

$$G^E_\infty(\underline{W}^k;\underline{s}^k) = G^E_\infty(\underline{W}^{k-1}(i),\underline{s}^{k-1}([i+1])).$$

(5) For any $\underline{W}^k$ such that $W_i = \mathbb{I}$: $1 \leqslant i \leqslant k$,

$$G^E_\infty(\underline{W}^k;\underline{s}^k) = G^E_\infty(\underline{W}^{k-1}([i]);\underline{s}^{k-1}([i])).$$

(6)

$$G^E_\infty(\mathbb{I};0) = 1.$$

(EG2)$_\infty$ (OS-positivity): For every terminating sequences

$$(\underline{W}^0,\underline{W}^1,\ldots,\underline{W}^k,\ldots), \quad (\underline{s}^0,\underline{s}^1,\ldots,\underline{s}^k,\ldots), \quad \underline{s}^k \in \mathfrak{E}^{\infty,+}_k = \{\underline{s}^k \in \mathfrak{E}^\infty_k : s_1 \geqslant 0\}.$$

we have

$$\sum_{k,l} G^E_\infty(\underline{W}^{k*},\underline{W}^l;\underline{s}^{k*},\underline{s}^l) \geqslant 0.$$

(EG3)$_\infty$: For every terminating sequences

$$(\underline{W}^0,\underline{W}^1,\ldots,\underline{W}^k,\ldots), \quad (\underline{s}^0,\underline{s}^1,\ldots,\underline{s}^k,\ldots), \quad \underline{s}^k \in \mathfrak{E}^{\infty,+}_k = \{\underline{s}^k \in \mathfrak{E}^\infty_k : s_1 \geqslant 0\}$$

and every $W \in \mathfrak{W}(\mathcal{D},\sigma)$ we have

$$\sum_{k,l} G^E_\infty(\underline{W}^{k*},W^*,W,\underline{W}^l\underline{s}^{k*},0,0\underline{s}^l) \leqslant \|W\|^2 \sum_{k,l} G^E_\infty(\underline{W}^{k*},\underline{W}^l;\underline{s}^{k*},\underline{s}^l).$$

Similarly, for the β-KMS state ω_β the set $\mathbb{G}^E_\beta = \{G^E_\beta(\underline{W}^k;\underline{s}^k)\}$ of imaginary time Green's functions has the following properties.

(EG1)$_\beta$: (1) For each $\underline{W}^k$ the map

$$\underline{s}^k \to G^E_\beta(\underline{W}^k;\underline{s}^k)$$

is continuous.

(2) For a fixed $\underline{s}^k \in \mathfrak{E}^\beta_k$ the map

$$\underline{W}^k \to G^E_\beta(\underline{W}^k;\underline{s}^k)$$

is multilinear, and bounded

$$|G^E_\beta(\underline{W}^k;\underline{s}^k)| \leqslant \prod_{i=1}^{k} \|W_i\|.$$

Moreover, the map

$$\underline{f}^k \to G^E_\beta(\underline{f}^k;\underline{s}^k)$$

is τ-continuous,

(3) For any $\underline{s}^k \in \mathfrak{E}^\beta_k$ and $s \in [-\beta/2,\beta/2]$ such that $s_k + s \leqslant \beta/2$, the imaginary time Green's functions are locally shift invariant, i.e.,

$$G^E_\beta(\underline{W}^k;\underline{s}^k + s) = G^E_\beta(\underline{W}^k;\underline{s}^k).$$

(4) For any $\underline{W}^k$ and $\underline{s}^k \in \mathfrak{E}^\beta_k$ such that $s_i = s_{i+1}$, $1 \leqslant i \leqslant k-1$,

$$G^E_\beta(\underline{W}^k;\underline{s}^k) = G^E_\beta(\underline{W}^{k-1}(i);\underline{s}^{k-1}([i+1])).$$

(5) For any $\underline{W}^k$ such that $W_i = 1$: $1 \leqslant i \leqslant k$,

$$G^E_\beta(\underline{W}^k;\underline{s}^k) = G^E_\beta(\underline{W}^{k-1}([i]);\underline{s}^{k-1}([i])).$$

(6)

$$G^E_\beta(\mathbb{I};0) = 1.$$

(EG2)$_\beta$ [Osterwalder–Schrader (OS-positivity)]: For every terminating sequences

$$(\underline{W}^0,\underline{W}^1,\ldots,\underline{W}^k,\ldots), \quad (\underline{s}^0,\underline{s}^1,\ldots,\underline{s}^k,\ldots), \quad \underline{s}^k \in \mathfrak{E}^{\beta,+}_k = \{\underline{s}^k \in \mathfrak{E}^\beta_k : s_1 \geqslant 0\}$$

we have

$$\sum_{k,l} G^E_\beta(\underline{W}^{k*},\underline{W}^l;\underline{s}^{k*},\underline{s}^l) \geqslant 0.$$

(EG3)$_\beta$: For every terminating sequences

$$(\underline{W}^0,\underline{W}^1,\ldots,\underline{W}^k,\ldots), \quad (\underline{s}^0,\underline{s}^1,\ldots,\underline{s}^k,\ldots), \quad \underline{s}^k \in \mathfrak{E}^{\beta,+}_k = \{\underline{s}^k \in \mathfrak{E}^\beta_k : s_1 \geqslant 0\}$$

and every $W \in \mathfrak{W}(\mathcal{D},\sigma)$ we have

$$\sum_{k,l} G^E_\beta(\underline{W}^{k*},W^*,W,\underline{W}^l;\underline{s}^{k*},0,0,\underline{s}^l) \leqslant \|W\|^2 \sum_{k,l} G^E_\beta(\underline{W}^{k*},\underline{W}^l;\underline{s}^{k*},\underline{s}^l).$$

(EG4)$_\beta$ (weak form of KMS condition): Let us define for $0 \leqslant s_1 \leqslant \cdots \leqslant s_n \leqslant \beta$

$$\hat{G}^E_\beta(W_0,\ldots,W_n;s_1,\ldots,s_n) := G^E_\beta(W_0,\ldots,W_n;-\beta/2,s_1-\beta/2,\ldots,s_n-\beta/2).$$

Then for each n

$$\hat{G}^E_\beta(W_0,\ldots,W_n;s_1,\ldots,s_n) = \hat{G}^E_\beta(W_n,W_0,W_1,\ldots,W_{n-1};\beta-s_n,\beta-s_n+s_1,\ldots,\beta-s_n+s_{n-1}).$$

On the other hand, starting with imaginary time Green's functions and proceeding similarly as in Ref. 23 (see also Ref. 18), we can obtain the following reconstruction theorems. Thus for ground state case we have the following.

Theorem 2.1: *Let $\mathbb{G}^E_\infty$ be an abstract set of imaginary time Green's functions on the Weyl algebra $\mathfrak{W}(\mathcal{D},\sigma)$ with properties* $(\mathrm{EG1})_\infty - (\mathrm{EG3})_\infty$. *Then there exist*

(1) *the Hilbert space $\mathfrak{H}_\infty$,*
(2) *the vector $\Omega_\infty \in \mathfrak{H}_\infty$,*
(3) *the*-representation π_∞ of $\mathfrak{W}(\mathcal{D},\sigma)$ in $\mathbb{B}(\mathfrak{H}_\infty)$, and*
(4) *the weakly continuous one-parameter group of unitary operators $U_\infty(t)=e^{itH_\infty}$ with $H_\infty \geqslant 0$*

such that

$$G^E_\infty(f^k;\underline{s}^k)=\langle \Omega_\infty, e^{-s_1 H_\infty}\pi_\infty(W_{f_1})\cdots e^{-(s_k-s_{k-1})H_\infty}\pi_\infty(W_{f_k})\Omega_\infty\rangle.$$

Moreover, the vector Ω_∞ is cyclic for the algebra $\mathfrak{M}^\infty_0$ generated by

$$e^{it_1 H_\infty}\pi_\infty(W_{f_1})e^{-it_1 H_\infty}\cdots e^{it_n H_\infty}\pi_\infty(W_{f_n})e^{-it_n H_\infty}, \quad t_1,\ldots,t_n\in\mathbb{R},$$

and the linear space spanned by vectors

$$e^{-s_1 H_\infty}\pi_\infty(W_{f_1})\cdots e^{-(s_k-s_{k-1})H_\infty}\pi_\infty(W_{f_k})\Omega_\infty$$

is dense in $\mathfrak{H}_\infty$. Additionally, $\alpha^\infty_t(W)=e^{itH_\infty}We^{-itH_\infty}$ is σ-weakly continuous group of automorphisms of $\mathfrak{M}^\infty=(\mathfrak{M}^\infty_0)''$.

And similarly, for temperature case, we have the following.

Theorem 2.2: *Let $\mathbb{G}^E_\beta$ be an abstract set of imaginary time Green's functions on the Weyl algebra $\mathfrak{W}(\mathcal{D},\sigma)$ with properties* $(\mathrm{EG1})_\beta - (\mathrm{EG4})_\beta$. *Then there exist*

(1) *the Hilbert space $\mathfrak{H}_\beta$,*
(2) *the vector $\Omega_\beta \in \mathfrak{H}_\beta$,*
(3) *the *-representation π_β of $\mathfrak{W}(\mathcal{D},\sigma)$ in $\mathbb{B}(\mathfrak{H}_\beta)$, and*
(4) *the weakly continuous one-parameter group of unitary operators $U_\beta(t)=e^{itH_\beta}$*

such that if $-\beta/2\leqslant s_1\leqslant s_2\leqslant\cdots\leqslant s_j\leqslant 0\leqslant s_{j+1}\leqslant\cdots\leqslant s_k\leqslant\beta/2$, then

$$G^E_\beta(f^k;\underline{s}^k)=\langle e^{s_j H_\beta}\pi_\beta(W_{f_j})^* e^{-(s_j-s_{j-1})H_\beta}\pi_\beta(W_{f_{j-1}})^*\cdots e^{-(s_2-s_1)H_\beta}\pi_\beta(W_{f_1})^*\Omega_\beta,$$
$$e^{-s_{j+1}H_\beta}\pi_\beta(W_{f_{j+1}})e^{-(s_{j+2}-s_{j+1})H_\beta}\pi_\beta(W_{f_{j+2}})\cdots e^{-(s_k-s_{k-1})H_\beta}\pi_\beta(W_{f_k})\Omega_\beta.$$

Moreover, the vector Ω_β is cyclic for the algebra $\mathfrak{M}^\beta_0$ generated by operators of the form

$$e^{it_1 H_\beta}\pi_\beta(W_{f_1})e^{-it_1 H_\beta}\cdots e^{it_n H_\beta}\pi_\beta(W_{f_n})e^{-it_n H_\beta}, \quad t_1,\ldots,t_n\in\mathbb{R},$$

and the state $\omega(M)=\langle\Omega_\beta, M\Omega_\beta\rangle$ is a β-KMS state on $\mathfrak{M}^\beta=(\mathfrak{M}^\beta_0)''$ with respect to the unitary group e^{itH_β}.

In the following, the $W^*-\beta$-KMS system constructed in Theorem 2.2 will be denoted as

$$\mathfrak{C}=(\mathfrak{H}_\beta,\Omega_\beta,\pi_\beta,e^{itH_\beta},\mathfrak{M}^\beta).$$

C. Stochastic positivity

For a general KMS state ω on an abstract C^*-algebra $\mathfrak{A}$, Klein and Landau[18] discussed the problem of construction of a stochastic process corresponding to ω. As they showed, such a process can be constructed using some Abelian sub-C^*-algebra $\mathfrak{B}$ of $\mathfrak{A}$ on which imaginary time Green's functions corresponding to ω are positive in some special sense. In such a case, the process has values in the spectrum of the Abelian algebra $\mathfrak{B}$. To study the existence of a stochastic process in the case of Weyl algebra $\mathfrak{W}(\mathcal{D},\sigma)$, we consider Abelian subalgebras of $\mathfrak{W}(\mathcal{D},\sigma)$ defined in terms of so-called *A*belian splitting of the symplectic space $(\mathcal{D},\sigma)$.

Definition 2.3: A pair $(\mathcal{D}_+,\mathcal{D}_-)$ of linear subspaces of the symplectic space $(\mathcal{D},\sigma)$ is called an Abelian splitting if $\mathcal{D}=\mathcal{D}_+ + \mathcal{D}_-$ and $\sigma(\mathcal{D}_\pm,\mathcal{D}_\pm)=0$. For the Abelian splitting $(\mathcal{D}_+,\mathcal{D}_-)$, let $\mathfrak{W}_+$ and $\mathfrak{W}_-$ be the Abelian subalgebras of the Weyl algebra $\mathfrak{W}(\mathcal{D},\sigma)$ generated by W_f with $f\in\mathcal{D}_+$ and $\mathcal{D}_-$, respectively.

Now the desired positivity condition is the following:

Definition 2.4:

(1) The set of imaginary time Green's functions $\mathbb{G}^E_\beta$ on the Weyl algebra $\mathfrak{W}(\mathcal{D},\sigma)$ with the given Abelian splitting is $\mathfrak{W}_\pm$-stochastically positive if for every positive element $W_1,\ldots,W_n \in \mathfrak{W}_\pm$ and every $(s_1,\ldots,s_n)\in\mathfrak{E}^\beta_n$

$$G^E_\beta(W_1,\ldots,W_n;s_1,\ldots,s_n)\geqslant 0.$$

(2) In the case of ground state system $\mathbb{G}^E_\infty$ the definition is analogous.

In the following discussion we will use the notions of thermal and ground state processes with values in some Hausdorff topological space $\mathbb{V}$.

Definition 2.5:

(1) Let $\mathbb{V}$ be a Hausdorff space. A stochastic process ξ_t taking values in $\mathbb{V}$ will be called a *thermal process* (with the inverse temperature β) if

TP1$_\beta$: ξ_t is stochastically continuous and faithful, i.e., for any $f\in C_b(\mathbb{V})$, $f>0$, we have $\mathbb{E}f(\xi_t)\neq 0$.

TP2$_\beta$: ξ_t is periodic with period β, i.e., for all $t\in\mathbb{R}$, $\xi_t=\xi_{t+\beta}$ in law (if K_β is the circle with length β parametrized as $[-\beta/2,\beta/2]$ with end points glued, then ξ_t can be indexed by $t\in K_\beta$).

TP3$_\beta$: ξ_t is OS-positive on K_β, i.e., for every $F\in C_b(\mathbb{V}^n)$ and $t_1,\ldots,t_n\in[0,\beta/2]$,

$$\mathbb{E}\overline{F}(\xi_{-t_1},\ldots,\xi_{-t_n})F(\xi_{t_1},\ldots,\xi_{t_n})\geqslant 0.$$

TP4$_\beta$: ξ_t is shift invariant on K_β, i.e., $\xi_{t+\tau}=\xi_t$ for all $t,\tau\in K_\beta$, and $t+\tau$ is defined modulo β.

TP5$_\beta$: ξ_t is reflection invariant, i.e., for every $F\in C_b(\mathbb{V}^n)$ and $t_1,\ldots,t_n\in K_\beta$,

$$\mathbb{E}F(\xi_{t_1},\ldots,\xi_{t_n})=\mathbb{E}F(\xi_{-t_1},\ldots,\xi_{-t_n}).$$

(2) Similarly, the process ξ_t is called a *ground state process* if it is stochastically continuous and faithful, shift and reflection invariant on $\mathbb{R}$ and OS-positive on $\mathbb{R}$.

Let ξ_t be the thermal process with values in $\mathcal{D}^*_+$, where $\mathcal{D}^*_+$ is an algebraic dual to $\mathcal{D}_+$. Define

$$G^\xi(\underline{f}^k;\underline{s}^k)=\mathbb{E}\left(\prod_{l=1}^k e^{i\langle\xi_{s_l},f_l\rangle}\right),$$

where $\underline{f}^k\in\mathcal{D}^k_+$ and $\underline{s}^k\in K^k_\beta$. It can be shown that $\mathbb{G}^\xi=\{G^\xi(\underline{f}^k;\underline{s}^k)\}$ satisfy conditions $(\mathrm{EG1})_\beta-(\mathrm{EG4})_\beta$ for the Abelian algebra $\mathfrak{W}_+$. Thus from Theorem 2.2, there exists the unique (up to the unitary equivalence) $W^*-\beta$-KMS system

$$\mathfrak{C}^\xi=(\mathfrak{H}^\xi,\Omega^\xi,\pi^\xi,e^{itH^\xi},\mathfrak{M}^\xi)$$

such that for every $\underline{f}^k\in\mathcal{D}^k_+$ and $-\beta/2\leqslant s_1\leqslant s_2\leqslant\cdots\leqslant s_j\leqslant 0\leqslant s_{j+1}\leqslant\cdots\leqslant s_k\leqslant\beta/2$,

$$G^E_\xi(\underline{f}^k;\underline{s}^k)=\langle e^{s_jH^\xi}\pi^\xi(W_{f_j})^* e^{-(s_j-s_{j-1})H^\xi}\pi^\xi(W_{f_{j-1}})^*\cdots e^{-(s_2s_1)H^\xi}\pi^\xi(W_{f_1})^*\Omega^\xi,$$
$$e^{-s_{j+1}H^\xi}\pi^\xi(W_{f_{j+1}})e^{-(s_{j+2}-s_{j+1})H^\xi}\pi^\xi(W_{f_{j+2}})\cdots e^{-(s_k-s_{k-1})H^\xi}\pi^\xi(W_{f_k})\Omega^\xi\rangle.$$

Now we show the converse:

Theorem 2.3:

(1) *Let $(\mathcal{D}_+,\mathcal{D}_-)$ be the Abelian splitting of the symplectic space $(\mathcal{D},\sigma)$. If $\mathbb{G}^E_\beta$ is the set of $\mathfrak{W}_+$-stochastically positive imaginary time Green's functions on $\mathfrak{W}(\mathcal{D},\sigma)$, there exists the unique (up to the stochastic equivalence) thermal process ξ^β_t with values in $\mathcal{D}^*_+$ such that, for every $f_1,\ldots,f_k\in\mathcal{D}_+$ and $\underline{s}^k\in K^k_\beta$,*

$$G^E_\beta(\underline{f}^k;\underline{s}^k)=\mathbb{E}\left(\prod_{l=1}^{k} e^{i\langle \xi^\beta_{s_1}, f_l\rangle}\right). \tag{2.1}$$

(2) *Similarly, if* $\mathbb{G}^E_\infty$ *is the set of* $\mathfrak{W}_+$*-stochastically positive ground state imaginary time Green's functions, there exists the unique (up to the stochastic equivalence) ground state process* ξ^∞_t *with values in* $\mathcal{D}^*_+$ *such that, for every* $f_1,\ldots,f_k\in\mathcal{D}_+$ *and* $-\infty<s_1\leqslant\ldots\leqslant s_k<\infty$,

$$G^E_\infty(\underline{f}^k;\underline{s}^k)=\mathbb{E}\left(\prod_{l=1}^{k} e^{i\langle \xi^\infty_{s_l}, f_l\rangle}\right). \tag{2.2}$$

Proof: Let $\mathbb{C}^+$ be the $W^*-\beta$-KMS system generated by the set $\mathbb{G}^+$ of imaginary time Green's functions $G^E(\underline{f}^k;\underline{s}^k)$ restricted to $\underline{f}^k\in\mathcal{D}^k_+$. Then, using the result of Ref. 18, we conclude that there exists the thermal process ξ^{KL}_t with values in the spectrum of the von Neumann algebra $(\pi_+(\mathfrak{W}_+))''$ (where π_+ denotes the representation defined by the set $\mathbb{G}^+$) and such that

$$G^E_\beta(\underline{f}^k;\underline{s}^k)=\int_{Q_\beta}\prod_{l=1}^{k}\widehat{\pi_+(W_{f_l})}(q(s_l))\,d\mu^{\xi^{KL}}(q),$$

where Q_β is the path space of the process ξ^{KL} and $\widehat{\pi_+(W_f)}$ is the Gel'fand transformation of $\pi_+(W_f)$.

For fixed $\underline{f}^k$ and $\underline{s}^k$ define the map

$$\underline{\alpha}\to\Gamma_{\underline{f}^k,\underline{s}^k}(\underline{\alpha}),$$

where $\underline{\alpha}=(\alpha_1,\ldots,\alpha_k)\in\mathbb{R}^k$, by

$$\Gamma_{\underline{f}^k,\underline{s}^k}(\underline{\alpha})=G^E(\alpha_1 f_1,\ldots,\alpha_k f_k;s_1,\ldots,s_k).$$

Here Γ is positive definite on $\mathbb{R}^k$ since for every $c_l\in\mathbb{C}$, $\underline{\alpha}^l\in\mathbb{R}^k$, $l=1,\ldots,M$,

$$\sum_{l,m=1}^{M} c_l\overline{c_m}\Gamma_{\underline{f}^k,\underline{s}^k}(\underline{\alpha}^l-\underline{\alpha}^m)=\int_{Q_\beta}\left|\sum_{l=1}^{M}\prod_{i=1}^{k}\widehat{\pi_+(W_{\alpha'_i f_i})}(q(s_i))\right|^2 d\mu^{\xi^{KL}}(q)\geqslant 0.$$

By the Bochner theorem, there exists Borel probability measure $d\nu^{\underline{f}^k,\underline{s}^k}$ on $\mathbb{R}^k$ such that

$$\Gamma_{\underline{f}^k,\underline{s}^k}(\underline{\alpha})=\int e^{i\langle\underline{\alpha},\underline{\gamma}\rangle}d\nu^{\underline{f}^k,\underline{s}^k}.$$

The system of finite-dimensional measures $d\nu^{\underline{f}^k,\underline{s}^k}$ forms a compatible system of measures on the cylindrical sets of $\mathcal{D}^{*K_\beta}_+$ as it follows from $(\mathrm{EG1})_\beta$ (5). Thus, by the theorem of Kolmogorov, there exists unique, up to the stochastic equivalence stochastic process, ξ^β_t with values in $\mathcal{D}^*_+$ such that (2.1) is satisfied. Similar arguments can be used in the ground state case.

Remarks:

(1) It is worthwhile to stress that the process corresponding to stochastically positive imaginary time Green's functions on the Weyl algebra $\mathfrak{W}(\mathcal{D},\sigma)$ can be realized as a process with values not in an abstract spectrum of Abelian algebra, but in the dual space to $\mathcal{D}_+$. In particular situations, the space of values of the process ξ^β_t can be localized in a much smaller subspace of $\mathcal{D}^*_+$ (see, i.e., Sec. IV and Refs. 24 and 25).

(2) In order to reconstruct all relevant informations about KMS structure (or ground state structure) from the stochastic process, it is important to take the Abelian subalgebra in such a way that the W^*-systems $\mathfrak{C}$ and $\mathfrak{C}^\xi$ (or analogous in the ground state case) are unitarily equivalent. It is interesting that in the quasi-free case discussed in the next section, Abelian subalgebras defined by some natural splitting always have this property.

III. QUASI-FREE STOCHASTICALLY POSITIVE STATES

A. Quasi-free states

To discuss the properties of quasi-free stochastically positive systems, assume that $\mathcal{D}$ has a structure of complex pre-Hilbert space with a scalar product $\langle\cdot,\cdot\rangle$ and $\sigma(f,g)=\mathrm{Im}\langle f,g\rangle$. Moreover, assume that T_t is a group of unitary operators with respect to $\langle\cdot,\cdot\rangle$ which leaves $\mathcal{D}$ invariant and has a self-adjoint generator $\mathbf{h}$. Let $\mathbb{B}(f,g)$ be a positive, sesqulinear form on $\mathcal{D}$ which is T_t-invariant and such that

$$|\sigma(f,g)|^2 \leqslant \mathbb{B}(f,f)\mathbb{B}(g,q).$$

Then ω defined by

$$\omega(W_f)=e^{-(1/4)\mathbb{B}(f,f)} \tag{3.1}$$

and extended by linearity and continuity to the whole $\mathfrak{W}(\mathcal{D},\sigma)$ is a so-called *gauge invariant quasi-free state*[34] on the Weyl algebra $\mathfrak{W}(\mathcal{D},\sigma)$.

For quasi-free states, two-point Green's functions

$$G^{(2)}(f,g:t)=\omega(W_f W_{T_t g})$$

can be calculated, and have the form

$$G^{(2)}(f,g;t)=e^{-(1/4)\mathbb{B}(f,f)-(1/4)\mathbb{B}(g,g)}e^{-(1/2)F(f,g;t)}, \tag{3.2}$$

where

$$F(f,g;t)=\mathrm{Re}\ \mathbb{B}(f,T_t,g)+i\sigma(f,T_t g).$$

B. KMS quasi-free states

Now we consider a quasi-free state ω which is α_t-KMS state at the inverse temperature β for α_t defined by $T_t=e^{it\mathbf{h}}$. Then for every $f,g\in\mathcal{D}$ there exists a function $\Phi(f,g;z)$, analytic in the strip $0<\mathrm{Im}\, z<\beta$ and continuous on the boundary, such that

$$\Phi(f,g;t+i0)=F(f,g;t)$$

and

$$\Phi(f,g;t+i\beta)=F(g,f;-t).$$

Then

$$G^{(2)}(f,g;t)=e^{-(1/4)(\mathbb{B}(f,f)+\mathbb{B}(g,g))}e^{-(1/2)\Phi(f,g;t+i0)}$$

and

$$G^{(2)}(g,f;-t)=e^{-(1/4)(\mathbb{B}(f,f)+\mathbb{B}(g,g))}e^{-(1/2)\Phi(f,g;t+i\beta)}.$$

To find the explicit form of $\mathbb{B}(f,g)$ let us first consider the case when $\mathcal{D}$ is a Hilbert space and $\mathbb{B}(f,g)$ is bounded on $\mathcal{D}$, hence defined by some bounded operator B such that $B\geqslant 1$.

Theorem 3.1: *Suppose that ω defined by (3.1) is an α_t-*KMS *state at the inverse temperature β. Then*

(1) *there exists $\epsilon>0$ such that $\mathbf{h}\geqslant\epsilon$, and*

(2)

$$B=\frac{\mathbb{I}+e^{-\beta\mathbf{h}}}{\mathbb{I}-e^{-\beta\mathbf{h}}}.$$

Proof: Since ω is α_t-KMS state, it is α_t-invariant. Thus B commutes with $T_t=e^{it\mathbf{h}}$, hence B commutes with spectral projectors $E(\lambda)$ of $\mathbf{h}$. First we show that 0 is not an eigenvalue of $\mathbf{h}$. Suppose that there exists $f_0\in\mathcal{D}$ such that $\mathbf{h}f_0=0$. Then for every $t\in\mathbb{R}$, $T_tf_0=f_0$. Because

$$F(f,f_0;t)=\mathrm{Re}\ \mathbb{B}(f,T_tf_0)+i\mathrm{Im}\langle f,T_tf_0\rangle=F(f,f_0;0),$$

$\Phi(f,f_0,z)$ is identically constant. Hence

$$F(f,f_0;0)=F(f_0,f;0).$$

On the other hand, $F(f,f_0;0)=\overline{F(f_0,f;0)}$, which implies $\sigma(f,f_0)=0$. But σ is nondegenerate, so $f_0=0$. Because $\Phi(f,f;z)$ is the analytic continuation of $F(f,f;t)$ and $F(f,f;-t)$, so[22]

$$\mathcal{F}(\mathbb{T}_F)(-p)=e^{-\beta p}\mathcal{F}(\mathbb{T}_F)(p),$$

where $\mathbb{T}_F$ is a distribution from $\mathcal{S}'$ given by

$$\langle\mathbb{T}_F,\varphi\rangle=\int_{-\infty}^{\infty}F(f,f,t)\varphi(t)\ dt,\quad \varphi\in\mathcal{S},$$

and $\mathcal{F}$ is the Fourier transform in $\mathcal{S}'$. Because

$$\begin{aligned}F(f,f;t)&=\mathrm{Re}\langle f,Be^{it\mathbf{h}}f\rangle+i\mathrm{Im}\langle f,e^{it\mathbf{h}}f\rangle\\&=\mathrm{Re}\int_{\mathbb{R}\setminus\{0\}}e^{it\lambda}d\langle Bf,E(\lambda)f\rangle+i\mathrm{Im}\int_{\mathbb{R}\setminus\{0\}}e^{it\lambda}d\langle f,E(\lambda)f\rangle\\&=\frac{1}{2}\int_{\mathbb{R}\setminus\{0\}}e^{it\lambda}\ d\langle(B+\mathbb{I})f,E(\lambda)f\rangle+\frac{1}{2}\int_{\mathbb{R}\setminus\{0\}}e^{it\lambda}\ d\langle(B-\mathbb{I})f,E(\lambda)f\rangle\end{aligned}$$

for any $\varphi\in\mathcal{S}$ we have

$$\begin{aligned}\langle\mathcal{F}(\mathbb{T}_F),\varphi_{\mathrm{inv}}\rangle&=\frac{1}{2}\int_{-\infty}^{\infty}dt\int_{\mathbb{R}\setminus\{0\}}d\langle(B+\mathbb{I})f,E(\lambda)f\rangle e^{it\lambda}\mathcal{F}(\sigma_{\mathrm{inv}})(t)\\&\quad+\frac{1}{2}\int_{-\infty}^{\infty}dt\int_{\mathbb{R}\setminus\{0\}}d\langle(B-\mathbb{I})f,E(\lambda)f\rangle e^{-it\lambda}\mathcal{F}(\varphi_{\mathrm{inv}})(t)\\&=\frac{\sqrt{2\pi}}{2}\int_{\mathbb{R}\setminus\{0\}}d\langle(B+\mathbb{I})f,E(\lambda)f\rangle\varphi(-\lambda)+\frac{\sqrt{2\pi}}{2}\int_{\mathbb{R}\setminus\{0\}}d\langle(B-\mathbb{I})f,E(\lambda)f\rangle\varphi(\lambda).\end{aligned}$$

On the other hand, it is equal to

$$\begin{aligned}\langle e^{-\beta\cdot}\mathcal{F}(\mathbb{T}_F),\varphi\rangle&=\frac{\sqrt{2\pi}}{2}\int_{\mathbb{R}\setminus\{0\}}d\langle(B+\mathbb{I})f,E(\lambda)f\rangle e^{-\beta\lambda}\varphi(\lambda)\\&\quad+\frac{\sqrt{2\pi}}{2}\int_{\mathbb{R}\setminus\{0\}}d\langle(B-\mathbb{I})f,E(\lambda)f\rangle e^{\beta\lambda}\varphi(-\lambda).\end{aligned}$$

Because Ker $\mathbf{h}=0$,

$$\mathbf{h}=\int_{-\infty}^{0^-}\lambda\ dE(\lambda)+\int_{0^+}^{\infty}\lambda\ dE(\lambda).$$

Assume that $E((-\infty,0))\neq 0$ and take $f\neq 0$, $f\in\tilde{\mathcal{D}}=E((-\infty,0))\mathcal{D}$. Suppose also that $\varphi\geqslant 0$ and supp $\varphi=[0,\infty)$. Then

$$\int_{-\infty}^{0} d\langle (B+\mathbb{I})f, E(\lambda)f\rangle \varphi(-\lambda) = \int_{-\infty}^{0} d\langle (B-\mathbb{I})f, E(\lambda)f\rangle e^{\beta\lambda}\varphi(-\lambda),$$

thus

$$\langle f, (B+\mathbb{I})\varphi(\mathbf{h}^{-1})f\rangle = \langle f, (B-\mathbb{I})e^{-\beta\mathbf{h}^{-}}\varphi(\mathbf{h}^{-})f\rangle,$$

where

$$\mathbf{h}^{-} = \int_{-\infty}^{0} (-\lambda)\, dE(\lambda).$$

Because $B:\tilde{\mathcal{D}}\to\tilde{\mathcal{D}}$, so by polarization we obtain that

$$(B+\mathbb{I})\varphi(\mathbf{h}^{-}) = (B-\mathbb{I})e^{-\beta\mathbf{h}^{-}}\varphi(\mathbf{h}^{-}).$$

But φ is arbitrary, so

$$B|_{\tilde{\mathcal{D}}} = \frac{\mathbb{I}+e^{-\beta\mathbf{h}^{-}}}{e^{-\beta\mathbf{h}^{-}}-\mathbb{I}} < -\mathbb{I}.$$

Thus we get the contradiction. Hence $\mathbf{h}>0$ and using similar arguments we show that

$$B = \frac{\mathbb{I}+e^{-\beta\mathbf{h}}}{\mathbb{I}-e^{-\beta\mathbf{h}}}.$$

Suppose now that for every $n\in\mathbb{N}$ the projector $E((0,1/n))$ is nonzero. Take $f_n\in E((0,1/n))\mathcal{D}$ such that $\|f_n\|=1$. Then

$$\|B^{1/2}f_n\|^2 = \int_0^{1/n} a(\lambda)\, d\rho_n(\lambda),$$

where $a(\lambda)=(1+e^{-\beta\lambda})^{-1}(1-e^{-\beta\lambda})$ and $d\rho_n(\lambda)=d\langle f_n, E(\lambda)f_n\rangle$. But for every $n\in\mathbb{N}$ the measure $d\rho_n$ is normed to 1 on $(0,1/n)$, so

$$\|B^{1/2}f_n\|^2 \geqslant a\left(\frac{1}{n}\right)\to\infty.$$

It contradicts the assumption that B is bounded.

C. Analytic continuation

Starting with the functions $\Phi(f,g;z)$ we can define a two-point imaginary time Green's function in terms of

$$S(f,g;s) = \Phi(f,g;is) \tag{3.3}$$

for $s\in[0,\beta]$. Then

$$G^{E,2}(f,g;s) = e^{-(1/4)(\mathbb{B}(f,f)+\mathbb{B}(g,g))}e^{-(1/2)S(f,g;s)}. \tag{3.4}$$

Proposition 3.1: $S(f,g;s)$ defined by (3.3) satisfies the following.
(1) For every $f,g\in\mathcal{D}$ and $s\in[0,\beta]$

$$S(f,g;s) = S(g,f;\beta-s).$$

(2) For every $f\in\mathcal{D}$ the mapping $s\to S(f,f;s)$ is OS-positive, i.e., for every sequence $\{s_k\}$, $s_k\in[0,\beta/2]$; $\{c_k\}$, $c_k\in\mathbb{C}$.

$$\sum_{k,l} \overline{c_k} c_l S(f,f;s_k+s_l) \geqslant 0.$$

More generally, for every terminating sequence $\{f_k\}$, $f_k \in \mathcal{D}$; $\{s_k\}$, $s_k \in [0,\beta/2]$, and $\{c_k\}$, $c_k \in \mathbb{C}$,

$$\sum_{k,l} \overline{c_k} c_l S(f_k,f_l;s_k+s_l) \geqslant 0.$$

Proof: The function $S(f,g;s)$ can be represented by the following integral formula,[22]

$$S(f,g;s) = \int_{-\infty}^{\infty} [\mathfrak{B}(\rho,s)F(f,g;\rho) + \mathfrak{B}(\rho,\beta-s)F(g,f;-\rho)]\, d\rho, \tag{3.5}$$

with the kernel

$$\mathfrak{B}(\rho,s) = \frac{1}{2\beta} \sin \frac{\pi s}{\beta} \left(\cosh \frac{\pi \rho}{\beta} - \cos \frac{\pi s}{\beta} \right)^{-1}.$$

From this formula, we see that $S(f,g;s) = S(g,f;\beta-s)$. On the other hand, the function $t \to F(f,f;t)$ is positive definite since

$$F(f,g;t) = F_+(f,g;t) + F_-(f,g;t),$$

where

$$F_+(f,g;t) = \tfrac{1}{2}\langle f, (B+\mathbb{I})e^{it\mathbf{h}} g\rangle, \quad F_-(f,g;t) = \tfrac{1}{2}\langle g, (B-\mathbb{I})e^{-it\mathbf{h}} f\rangle,$$

and the functions $F_+(f,f;t), F_-(f,f;t)$ are obviously positive definite. Thus $S(f,f;s)$ is OS-positive as a Laplace transform of positive measure. By polarization

$$\sum_{k,l} \overline{c_k} c_l F_{\pm}(f_k,f_l;t_k-t_l) \geqslant 0$$

and

$$F_{\pm}(f,g;t) = \int_{-\infty}^{\infty} e^{it\lambda}\, d\mu_{f,g}^{\pm}(\lambda)$$

for complex-valued measure $\mu_{f,g}^{\pm}$. Thus

$$\sum_{k,l} \overline{c_k} c_l F(f_k,f_l;t_k-t_l) \geqslant 0$$

and

$$F(f,q;t) = \int_{-\infty}^{\infty} e^{it\lambda}\, d\mu_{f,g}(\lambda)$$

for $\mu_{f,g} = \mu_{f,g}^{+} + \mu_{f,g}^{-}$.

Hence the matrix of measures (μ_{f_k,f_l}) is positive definite, and the matrix

$$(S(f_k,f_l;s_k+s_l)) = \left(\int_{-\infty}^{\infty} e^{-s(s_k+s_l)\lambda}\, d\mu_{f_k,f_l}(\lambda) \right)$$

is also positive definite.

Corollary 3.1:

$$G^{E,2}(f,g;s)$$

satisfies

(1) $$G^{E,2}(f,g;s)=G^{E,2}(g,f;\beta-s), \quad s\in[0,\beta];$$

(2) $$\sum_{k,l}\overline{c}_k c_l G^{E,2}(-f_k,f_l,s_k+s_l)\geqslant 0, \quad s_k\in[0,\beta/2].$$

Remark: Multi-time Green's functions corresponding to the quasi-free KMS state can be obtained as follows. By a direct computation we show that

$$G(f_1,\ldots,f_n;t_1,\ldots,t_n)=\omega(W_{T_{t_1}f_1}\cdots W_{T_{t_n}f_n})=\prod_{l=1}^{n} e^{[(n-2)/4]\mathbb{B}(f_l,f_l)}\prod_{(j_n,k_n)} G^{(2)}(f_{j_n},f_{k_n};t_{k_n}-t_{j_n}),$$

where the second product is taken over all pairs of different indices (j_n,k_n) such that $j_n,\ k_n \in\{1,\ldots,n\},\ t_{j_n}<t_{k_n}$. Analytic continuation of the right-hand side of this expression gives after restriction to imaginary times the formula

$$G^{E}(f_1,\ldots,f_n;s_1,\ldots,s_n)=\prod_{l=1}^{n} e^{[(n-2)/4]\mathbb{B}(f_l,f_l)}\prod_{(j_n,k_n)} G^{E,2}(f_{j_n},f_{k_n};s_{k_n}-s_{j_n}),$$

which can be rewritten in the following way:

$$G^{E}(f_1,\ldots,f_n;s_1,\ldots,s_n)=\prod_{k=1}^{n} e^{-(1/4)\mathbb{B}(f_k,f_k)}\prod_{(j_k,l_k)} e^{-(1/2)S(f_{j_k},f_{l_k};s_{l_k}-s_{j_k})}.$$

It can be checked that $G^{E}(f_1,\ldots,f_n;s_1,\ldots,s_n)$ satisfy all conditions of Theorem 2.1.

D. Stochastic positivity and thermal process

Now we can pass to the question of stochastic positivity of quasi-free imaginary time Green's functions. This property can be naturally formulated in terms of the functions $S(f,g;s)$.

Let C be an abstract complex conjugation on $\mathcal{D}$, i.e., C is antiunitary and $C^2=1$. The mapping C naturally defines the Abelian splitting $(\mathcal{D}_+,\mathcal{D}_-)$ of $\mathcal{D}$:

$$\mathcal{D}_+=\{f\in\mathcal{D}:Cf=f\}, \quad \mathcal{D}_-=\{f\in\mathcal{D}:Cf=-f\}.$$

Lemma 3.1: The functions $S(f,g;s)$ restricted to $\mathcal{D}_+$ satisfy

$$S(f,g;s)=S(g,f,;s), \quad s\in[0,\beta], \tag{3.6}$$

if $\mathbf{h}$ is C-real, i.e., C leaves the domain $D(\mathbf{h})$ invariant and

$$C\mathbf{h}f=\mathbf{h}Cf$$

for every $f\in D(\mathbf{h})$.

Proof: By analytic continuation, the property (3.6) is equivalent to

$$F(f,g;t)=F(g,f;t)$$

for $f,g\in\mathcal{D}_+$ and $t\in\mathbb{R}$. So we have to show that

$$\mathrm{Re}\langle f,(T_t-T_{-t})Bg\rangle=0 \tag{3.7}$$

and

$$\mathrm{Im}\langle f,(T_t+T_{-t})g\rangle=0 \tag{3.8}$$

for all $f,g\in\mathcal{D}_+$. Because $\mathbf{h}$ is C-real, C commutes with spectral projectors of $\mathbf{h}$ and

$$CT_t = T_{-t}C,$$

thus

$$T_t + T_{-t} : \mathcal{D}_+ \to \mathcal{D}_+ ,$$

$$T_t - T_{-t} : \mathcal{D}_+ \to \mathcal{D}_- .$$

Hence (3.8) is satisfied. B as a real function of $\mathbf{h}$ is C-real, too, and so B: $\mathcal{D}_+ \to \mathcal{D}_+$. But

$$\mathrm{Re}\langle f_+ , g_- \rangle = 0$$

for all $f_+ \in \mathcal{D}_+$, $g_- \in \mathcal{D}_-$, so (3.7) follows.

Combining this result with that of Proposition 3.1 we get

$$S(f,g;s) = S(f,g;\beta - s), \quad s \in [0,\beta].$$

This allows us to extend the function $S(f,g;s)$ (for the fixed $f,g \in \mathcal{D}_+$) to the periodic function of s with the period β, defined for all $s \in \mathbb{R}$. The extended functions will also be denoted by $S(f,g;s)$.

Proposition 3.2: For every fixed $f,g \in \mathcal{D}_+$ there exists a finite, real-valued measure $\nu_{f,g}$ on $[0,\infty)$ such that

$$S(f,g;s) = \int_0^\infty (e^{-sp} + e^{-(\beta - s)p})\, d\nu_{f,g} . \tag{3.9}$$

Proof: For a fixed $f \in \mathcal{D}_+$, the function $S(f,f,s)$ is OS-positive, thus by the Widder theorem there exists a finite measure $\tilde{\nu}_{f,f}$ on $\mathbb{R}$ such that

$$S(f,f;s) = \int_{-\infty}^\infty e^{-sp}\, d\tilde{\nu}_{f,f}$$

for $s \in [0,\beta]$. Since $S(f,f;s) = S(f,f;\beta - s)$,

$$d\tilde{\nu}_{f,f}(-p) = e^{-\beta p} d\tilde{\nu}_{f,f}(p).$$

Thus there exists a unique finite measure $\nu_{f,f}$ with support on $[0,\infty)$ such that

$$S(f,f;s) = \int_0^\infty (e^{-sp} + e^{-(\beta - s)p})\, d\nu_{f,f} .$$

By polarization, this gives the integral representation of $S(f,g;s)$ in terms of real-valued measure $\nu_{f,g}$.

Proposition 3.3: $S(f,g;s)$ is positive definite, i.e.,

$$\sum_{k,l=1}^n \overline{c_k} c_l S(f_k, f_l; s_k - s_l) \geqslant 0, \tag{3.10}$$

for all terminating sequences $f_1,\ldots,f_n \in \mathcal{D}_+$; $s_1,\ldots,s_n \in \mathbb{R}$ and $c_1,\ldots,c_n \in \mathbb{C}$.

Proof: Since

$$e^{-sp} + e^{-(\beta - s)p} = \sum_{n \in \mathbb{Z}} c_n(p) e^{i2\pi n s/\beta} \tag{3.11}$$

for all $s \in [0,\beta]$, where

$$c_n(p) = ((p\beta)^2 + (2\pi n)^2)^{-1} (2\beta p (1 - e^{-\beta p})) \geqslant 0,$$

the right-hand side of (3.11) defines a periodic function for all $s \in \mathbb{R}$.[35] Combining this with (3.9) we get

$$S(f,f;s)=\sum_{n\in\mathbb{Z}} e^{i2\pi ns/\beta}\int_0^\infty c_n(p)\,d\nu_{f,f}(p),$$

so for a fixed $f\in\mathcal{D}_+$, $S(f,f;s)$ is a real-valued positive-definite function as a function of s. Thus, it is a Fourier transform of a positive measure $m_{f,f}$ on $\mathbb{R}$. Using the polarization formula for $S(f,g;s)$ we obtain that $S(f,g;s)$ is a Fourier transform of real-valued measure $m_{f,g}$ with finite variation. Let

$$m=(m_{f_k,f_l})$$

be an $n\times n$ matrix of such measures. We show that m is positive definite, i.e., for every Borel subset $E\subset\mathbb{R}$, the matrix $(m_{f_k,f_l}(E))$ is positive definite. Let $\varphi\in\mathcal{S}$ be non-negative. For $g_k=r_kf_k$, $r_k\in\mathbb{R}$, we have

$$\sum_{k,l} r_k r_l m_{f_k,f_l}(\varphi)=\sum_{k,l} m_{g_k,g_l}(\varphi)=m_{(\Sigma_k g_k),(\Sigma_k g_k)}(\varphi)\geqslant 0.$$

It implies that the matrix

$$(S(f_k,f_l;s_k-s_l))=\left(\int_{-\infty}^{\infty} e^{i(s_k-s_l)p}\,dm_{f_k,f_l}(p)\right) \tag{3.12}$$

is also positive definite. To show this, notice that the integral on the right-hand side of (3.12) can be approximated by the sum

$$\sum_{j=0}^{N} e^{i(s_k-s_l)p_j}m_{f_k,f_l}(E_j).$$

Because $(e^{i(s_k-s_l)p_j})$ and $(m_{f_k,f_l}(E_j))$ are positive-definite matrices, from the Schur lemma the matrix

$$(e^{i(s_k-s_l)p_j}m_{f_k,f_l}(E_j))$$

is positive definite for each j, so the matrix (3.12) is positive definite. Thus $S(f_k,f_l;s_k-f_l)$ is a real-valued positive-definite matrix in real vector space. It follows that it is also positive definite as a matrix in complex vector space.

Theorem 3.2: *$S(f,g;s)$ defines an operator-valued covariance function $R_\beta(s)$ of a periodic Gaussian OS-positive stochastic process indexed by $\mathcal{D}_+$. Thus $R_\beta(s)$ is an operator-valued positive-definite function on $\mathcal{D}_+$ which is periodic and OS-positive. Moreover,*

$$S(f,g;s)=\langle f,R_\beta(s)g\rangle.$$

Proof: From the positive definiteness of $S(f,g;s)$ we have

$$|S(f,g;s)|^2\leqslant S(f,f;0)S(g,g;0)\leqslant\|B\|^2\|f\|^2\|g\|^2.$$

Since $S(f,g;s)$ is bilinear and symmetric, there exists a bounded and positive operator $R_\beta(s)$ on $\mathcal{D}_+$ such that

$$S(f,g;s)=\langle f,R_\beta(s)g\rangle.$$

Moreover, the function

$$s\to R_\beta(s)$$

is positive definite, OS-positive and weakly periodic.

Corollary 3.2: Let ξ_s^β be the Gaussian process indexed by $\mathcal{D}_+$ defined by

$$\mathbb{E}(\langle \xi_s^\beta, f\rangle)=0$$

and

$$\mathbb{E}(\langle \xi_{s_1}^\beta, f_1\rangle\langle \xi_{s_2}^\beta, f_2\rangle)=\tfrac{1}{2}\langle f_1, R_\beta(s_2-s_1)f_2\rangle.$$

Then, for $f_1, f_2 \in \mathcal{D}_+$,

$$G^{E,2}(f_1,f_2;s_2-s_1)=\mathbb{E}(e^{i\langle \xi_{s_1}^\beta, f_1\rangle}e^{i\langle \xi_{s_2}^\beta, f_2\rangle}).$$

Similarly, for $f_1,\ldots,f_n \in \mathcal{D}_+$,

$$G^E(f_1,\ldots,f_n;s_1,\ldots,s_n)=\mathbb{E}(e^{i\Sigma_{k=1}^n\langle \xi_{s_k}^\beta, f_k\rangle}).$$

Proposition 3.4: If $f \in \mathcal{D}_+$ is such that $m(f)=\int_0^\infty p\, d\nu_{f,f}(p)<\infty$, then the coordinate process $\xi_s^f := \langle \xi_s^\beta, f\rangle$ has a version (denoted by the same symbol) with Hölder continuous paths. More precisely, for any $0<\gamma<\frac{1}{2}$ there exists an integrable random variable $d(f,\gamma)$ such that

$$|\xi_s^f-\xi_{s'}^f|\leqslant d(f,\gamma)|s-s'|^\gamma$$

with probability one.

Proof: Since

$$|S(f,f;h)-S(f,f;0)|=\left|\int_0^\infty ((e^{-hp}-1)+(e^{-(\beta-h)p}-e^{-\beta p}))\,d\nu_{f,f}(p)\right|$$

$$\leqslant 2|h|\int_0^\infty p\,d\nu_{f,f}(p)=2m(f)|h|,$$

it follows that

$$|\mathbb{E}e^{z|\xi^f_{s+h}-\xi^f_s|}|\leqslant \mathbb{E}e^{|z|(\xi^f_{s+h}-\xi^f_s)}+\mathbb{E}e^{-|z|(\xi^f_{s+h}-\xi^f_s)}=2e^{(|z|^2/2)\mathbb{E}(\xi^f_{s+h}-\xi^f_s)^2}$$

$$\leqslant 2e^{|z||S(f,f;0)-S(f,f;h)|}\leqslant 2e^{2|z|h|m(f)}.$$

On the other hand, by the Cauchy integral formula,

$$|\xi^f_{s+h}-\xi^f_s|^n=\frac{n!}{2\pi i}\int_{C_r}\frac{e^{z|\xi^f_{s+h}-\xi^f_s|}}{z^{n+1}}\,dz.$$

Thus

$$\mathbb{E}|\xi^f_{s+h}-\xi^f_s|^n\leqslant 2n!\,\frac{e^{2r^2|h|m(f)}}{r^n}.$$

Now taking $r=|h|^{-1/2}$ we obtain

$$\mathbb{E}|\xi^f_{s+h}-\xi^f_s|^n\leqslant c_n|h|^{n/2}.$$

The assertion follows by the application of the Kolmogorov continuity test.

Definition 3.1: A periodic stochastic process ξ_s indexed by $\mathcal{D}_+$ has the *two-sided Markov property on the circle* K_β iff for all $r,s \in K_\beta$,

$$E_{[s,r]}E_{[r,s]}=E_{\{r,s\}}E_{[r,s]},$$

where for $I \subset K_\beta$, E_I denotes conditional expectation with respect to the σ-algebra generated by $\{\xi_s, s \in I\}$, and $\{r,s\}=\{s,r\}$ is the set consisting of the two elements r,s.

Proposition 3.5: ξ_s^β has a version with the two-sided Markov property on the circle K_β.

Proof: The covariance operator $R_\beta(s)$ has the form

$$R_\beta(s)=\frac{e^{-s\mathbf{h}}+e^{-(\beta-s)\mathbf{h}}}{1-e^{-\beta\mathbf{h}}}.$$

Let us introduce the new scalar product in $\mathcal{D}_+$ given by

$$\langle f,g\rangle_\beta := \langle f,(1-e^{-\beta\mathbf{h}})^{-1}g\rangle.$$

The norms $\|\cdot\|$ and $\|\cdot\|_\beta$ are obviously equivalent. Let $\tilde{\xi}_s$ be the Gaussian process indexed by $(\mathcal{D}_+,\langle\cdot,\cdot\rangle_\beta)$ with zero mean and covariance operator

$$\tilde{R}_\beta(s)=e^{-s\mathbf{h}}+e^{-(\beta-s)\mathbf{h}}.$$

Here $\tilde{\xi}_s$ is stochastically equivalent to ξ_s^β and by the result of Ref. 35 it satisfies the two-sided Markov property on the circle K_β.

E. KMS structure generated by thermal process

Let ξ_s^β be a Gaussian process constructed above and let (Q,Σ,μ) be its underlying probability space. Since the process is stationary, $u(t)$ defined by

$$u(t)(e^{i\langle\xi^\beta_{s_1},f_1\rangle}\cdots e^{i\langle\xi^\beta_{s_n},f_n\rangle})=e^{i\langle\xi^\beta_{s_1+t},f_1\rangle}\cdots e^{i\langle\xi^\beta_{s_n+t},f_n\rangle}$$

extends to a one-parameter group of unitary operators on $L^2(Q,\Sigma,\mu)$. By periodicity, $u(\beta)=\mathbb{I}$. Since the process is symmetric, Θ defined by

$$\Theta(e^{i\langle\xi^\beta_{s_1},f_1\rangle}\cdots e^{i\langle\xi^\beta_{s_n},f_n\rangle})=e^{i\langle\xi^\beta_{-s_1},f_1\rangle}\cdots e^{i\langle\xi^\beta_{-s_n},f_n\rangle}$$

extends to a unitary operator on $L^2(Q,\Sigma,\mu)$ such that $\Theta^2=\mathbb{I}$. Finally, since the process is OS-positive,

$$\langle\Theta F,F\rangle_{L^2}\geqslant 0$$

for all $F\in L^2(Q,\Sigma_{[0,\beta/2]},\mu)$, where for $S\subset\mathbb{R},\Sigma_S$ denotes the σ-algebra generated by $\{\xi_s^\beta : s \in S\}$.

Theorem 3.3: *Let ξ_s^β be a Gaussian, periodic (with period β), OS-positive stochastic process indexed by $\mathcal{D}_+$. Then there exist a Hilbert space $\mathfrak{H}_\xi$ with a unit vector Ω_ξ, a weakly continuous one-parameter group of unitary operators $U_\xi(t)=e^{itH_\xi}$, and a von Neumann algebra $\mathfrak{M}_\xi$ of operators acting on $\mathfrak{H}_\xi$ such that Ω_ξ is cyclic and separating for $\mathfrak{M}_\xi$ and $\alpha_t^\xi(M)=e^{itH_\xi}Me^{-itH_\xi}$ is the modular automorphisms group associated with Ω_ξ.*

Proof: On the space $L^2(Q,\Sigma_{[0,\beta/2]},\mu)$ define a sesquilinear form by

$$\langle F,G\rangle=\langle\Theta F,G\rangle_{L^2}.$$

By OS-positivity, it is positive semi-definite. Let

$$\mathcal{N}=\{F\in L^2(Q,\Sigma_{[0,\beta/2]},\mu):\langle F,F\rangle=0\}.$$

Then

$$\mathfrak{D}=L^2(Q,\Sigma_{[0,\beta/2]},\mu)/\mathcal{N}$$

is a pre-Hilbert space with respect to the inner product

$$\langle[F],[G]\rangle=\langle F,G\rangle,$$

where $[F]$ denotes the class containing F. Here $\mathfrak{H}_\xi$ is defined as a Hilbert space completion of $\mathcal{D}$ and $\Omega_\xi=[1]$. Let $\mathcal{D}_t$ be the linear space generated by vectors $[F]$ for $F\in L^2(Q,\Sigma_{[0,\beta/2-t]},\mu)$, $t\in[0,\beta/2]$. For every $t\in[0,\beta/2]$ we can define the linear operator $p(t)$ with domain $\mathfrak{D}_t$ by

$$p(t)[F]=[u(t)F],$$

and we can show that $(p(t),\mathfrak{D}_t)$ form a symmetric local semigroup.[36] Hence there exists a unique self-adjoint operator H_ξ on $\mathfrak{H}_\xi$ such that $p(t)=e^{-tH_\xi}$. Here $U_\xi(t)$ is defined by $U_\xi(t)=e^{itH_\xi}$. Now let $F_0\in L^\infty(Q,\Sigma_0,\mu)$. Then

$$\pi_0(F_0)[F]=[F_0F]$$

defines a bounded operator on $\mathfrak{H}_\xi$ and

$$\mathfrak{M}_0=\{\pi_0(F_0):F_0\in L^\infty(Q,\Sigma_0,\mu)\}$$

is a von Neumann algebra of operators on $\mathfrak{H}_\xi$. Let $\mathfrak{M}_\xi$ be the von Neumann algebra generated by elements

$$e^{it_1H_\xi}B_1e^{-it_1H_\xi}\cdots e^{it_nH_\xi}B_ne^{-it_nH_\xi}$$

with $t_j\in\mathbb{R}$, $B_j\in\mathfrak{M}_0$. Then Ω_ξ is cyclic and separating for $\mathfrak{M}_\xi$.[23] Using the properties of the process ξ_s^β we can now define the modular conjugation and modular group corresponding to Ω_ξ. Let

$$\Theta_{\beta/4}=u(\beta/4)\Theta u(-\beta/4)$$

and

$$J_\xi[F]=[\overline{\Theta_{\beta/4}F}].$$

Then

$$\langle J_\xi[F],J_\xi[G]\rangle=\langle\Theta\overline{\Theta_{\beta/4}F},\overline{\Theta_{\beta/4}G}\rangle_{L^2}=\langle G,\Theta F\rangle_{L^2}=\langle[G],[F]\rangle$$

since $\Theta_{\beta/4}$ commutes with Θ by periodicity. Hence J_ξ can be extended to an antiunitary operator on $\mathfrak{H}_\xi$ such that $J_\xi^2=\mathbb{I}$. Computing the action of J_ξ on $\mathfrak{M}_\xi\Omega_\xi$, $M\in\mathfrak{M}_\xi$, we can show that

$$J_\xi M^*\Omega_\xi=e^{(-\beta/2)H_\xi}M\Omega_\xi.$$

Now since $\mathfrak{M}_\xi\Omega_\xi$ is a core for $e^{(-\beta/2)H_\xi}$,[18] J_ξ defined above is the modular conjugation operator and the corresponding modular operator Δ_ξ can be identified with $e^{(-\beta/2)H_\xi}$. For more details see Ref. 18.

Let $(\mathfrak{H}_\omega,\pi_\omega,\Omega_\omega)$ be the GNS representation defined by quasi-free KMS state ω. Then Ω_ω is cyclic and separating for $\pi_\omega(\mathfrak{W}(\mathcal{D},\sigma))''$. Let J_ω and Δ_ω be the corresponding modular conjugation and modular operator. We are going to show that in the case of the quasi-free state the modular structure constructed from the process ξ_s^β is unitarily equivalent to the canonical modular structure defined by KMS state ω. Thus all relevant information about KMS structure is contained in the (commutative) stochastic process ξ_s^β. To obtain this result we need the following property of the dynamics $e^{it\mathbf{h}}$.

Theorem 3.4: *Let* $\mathbf{h}$ *be C-real on* $\mathcal{D}$ *and let* $E(\{0\})=0$, *where* $dE(\lambda)$ *is the spectral measure of* $\mathbf{h}$. *Then the family*

$$\left\{\sum_{k=1}^n e^{it_k\mathbf{h}}f_k:n\in\mathbb{N},t_k\in\mathbb{R},f_k\in\mathcal{D}_+\right\}$$

is dense in $\mathcal{D}$.

Proof: Because C commutes with spectral projectors of $\mathbf{h}$ and 0 is not an eigenvalue of $\mathbf{h}$, so

$$\mathbf{h}=\mathbf{h}_1\oplus\mathbf{h}_2, \quad \mathcal{D}=\mathcal{D}_1\oplus\mathcal{D}_2 \quad \text{and} \quad \mathcal{D}_+=\mathcal{D}_{+,1}\oplus\mathcal{D}_{+,2},$$

where

$$\mathcal{D}_1=E((0,\infty))\mathcal{D}, \quad \mathcal{D}_2=E((-\infty,0))\mathcal{D}, \quad \mathcal{D}_{+,1}=\mathcal{D}_+\cap\mathcal{D}_1, \quad \mathcal{D}_{+,2}=\mathcal{D}_+\cap\mathcal{D}_2.$$

Hence it is enough to consider a positive operator $\mathbf{h}$ such that $\operatorname{Ker}\mathbf{h}=\{0\}$. Because $\mathcal{D}$ is separable, $\mathbf{h}$ can be written as

$$\mathbf{h}=\oplus_{l=1}^{\infty}\mathbf{h}_l, \quad \mathcal{D}=\bigoplus_{l=1}^{\infty}\mathcal{D}_l,$$

where each $\mathbf{h}_l$ is a positive operator with a simple spectrum. Moreover, each generating vector g_l for a Hilbert space $\mathcal{D}_l$ can be taken from $\mathcal{D}_+$ and normalized. Indeed, let us take arbitrary $g_1\in\mathcal{D}_+$ with $\|g_1\|=1$ and define

$$\mathcal{D}_1=\overline{\operatorname{Lin}_{\mathbb{C}}\{E(\sigma)g_1\}}, \quad \sigma\in\mathcal{B}(0,\infty).$$

Because C commutes with all $E(\sigma)$, so $C:\mathcal{D}_1\to\mathcal{D}_1$ and hence $C:\mathcal{D}_1^{\perp}\to\mathcal{D}_1^{\perp}$. In the second step we take $g_2\in\mathcal{D}_1^{\perp}\cap\mathcal{D}_+$, $\|g_2\|=1$ and define

$$\mathcal{D}_2=\overline{\operatorname{Lin}_{\mathbb{C}}\{E(\sigma)g_2\}}.$$

It is clear that $\mathcal{D}_1\perp\mathcal{D}_2$. The total decomposition follows from the Kuratowski–Zorn lemma. Because every $\mathcal{D}_l$ reduces $\mathbf{h}$, $\mathbf{h}=\bigoplus_{l=1}^{\infty}\mathbf{h}_l$ where $\mathbf{h}_l:D(\mathbf{h})\cap\mathcal{D}_l\to\mathcal{D}_l$. Moreover, each $\mathbf{h}_l$ is $C|_{\mathcal{D}_l}$-real.

Let us assume that we have proved that for every $n\in\mathbb{N}$ the set

$$\left\{\sum_{k=1}^{m} e^{it_k\mathbf{h}_k}f_n^k : m\in\mathbb{N}, t_k\in\mathbb{R}, f_n^k\in\mathcal{D}_{+,n}\right\}$$

is dense in $\mathcal{D}_n$. Then for any $\epsilon>0$ and for any $f\in\mathcal{D}$ we can find $n_0\in\mathbb{N}$ such that

$$\left\|\bigoplus_{n=1}^{n_0} f_n-f\right\|<\epsilon/3$$

and for these $f_n\in\mathcal{D}_n$ there are $f_n^k\in\mathcal{D}_{+,n}$ such that

$$\left\|f_n-\sum_{k=1}^{m_n} e^{it_k(n)\mathbf{h}_n}f_n^k\right\|\leqslant\epsilon/2^n.$$

It follows that

$$\left\|f-\bigoplus_{n=1}^{n_0}\sum_{k=1}^{m_n} e^{it_k(n)\mathbf{h}_n}f_n^k\right\|\leqslant\left\|f-\bigoplus_{n=1}^{n_0}f_n\right\|+\left\|\bigoplus_{n=1}^{n_0}f_n-\bigoplus_{n=1}^{n_0}\sum_{k=1}^{m_n} e^{it_k(n)\mathbf{h}_n}f_n^k\right\|$$

$$\leqslant\epsilon/3+\left[\sum_{n=1}^{n_0}\left\|f_n-\sum_{k=1}^{m_n} e^{it_k(n)\mathbf{h}_n}f_n^k\right\|^2\right]^{1/2}\leqslant\epsilon/3+\left[\sum_{n=1}^{n_0}(\epsilon^2/4^n)\right]^{1/2}<\epsilon.$$

Because every f_n^k is an element of $\mathcal{D}_+$ and we can write

$$e^{it_k(n)\mathbf{h}_n}f_n^k=e^{it_k(n)\mathbf{h}}f_n^k,$$

we obtain

$$\left\| f-\sum_{n=1}^{n_0}\sum_{k=1}^{m_n} e^{it_k(n)\mathbf{h}} f_n^k \right\| < \epsilon.$$

Hence to finish the proof we need only the following Lemma.

Lemma 3.2: Suppose that $\mathbf{h}$ *is C-real and positive on* $\mathcal{D}$. *If* Ker $\mathbf{h}=\{0\}$ *and* $\mathbf{h}$ *is simple with a generating vector* $g\in\mathcal{D}_+$, $\|g\|=1$, *then the family*

$$\left\{ \sum_{k=1}^{n} e^{it_k\mathbf{h}} f_k : n\in\mathbb{N}, t_k\in\mathbb{R}, f_k\in\mathcal{D}_+ \right\}$$

is dense in $\mathcal{D}$.

Proof: By the spectral theorem, $\mathbf{h}$ is unitarily isomorphic to the multiplication operator $\hat{x}$ in $L^2(\mathbb{R}_+,\mathcal{B},\rho)$, where $\rho(\sigma)=\langle g,E(\sigma)g\rangle$. This means that the unitary operator U given by

$$Ua=\int_0^\infty a(\lambda)\, dE(\lambda)g$$

maps $D(\hat{x})$ onto $D(\mathbf{h})$ and $U^*\mathbf{h}U=\hat{x}$. Because C commutes with $E(\sigma)$ and $Cg=g$, we also have that $U(L_r^2)=\mathcal{D}_+$ where

$$L_r^2=\{a\in L^2(\mathbb{R}_+,\mathcal{B},\rho): \overline{a}=a\}.$$

Thus for $a_k\in L_r^2$

$$U\left(\sum_{k=1}^{n} e^{it_k\hat{x}} a_k\right)=\sum_{k=1}^{n} e^{it_kU\hat{x}U^*}(Ua_k)=\sum_{k=1}^{n} e^{it_k\mathbf{h}} f_k,$$

where $f_k=Ua_k$. So it is enough to prove the statement for $\hat{x}$.

Let K be an arbitrary compact set $K\subset(0,\infty)$. Let us consider the family of continuous, real-valued functions on K given by

$$\left\{ a: a=\sum_{k=1}^{n} \sin(t_k\hat{x})a_k, n\in\mathbb{N}, a_k\in C_r(K) \right\}.$$

It is clear that this family is an algebra which separates points in K and does not vanish identically on some point in K. By Stone–Weierstrass theorem this family is dense in $C_r(K)$. Now let $f\in C(K)$. Then $f=f_1+if_2, f_1,f_2\in C_r(K)$. At first we find a finite sum $\Sigma_{k=1}^n \sin(t_k\hat{x})a_k, a_k\in C_r(K)$, such that

$$\left\| f_2-\sum_{k=1}^{n} \sin(t_k\hat{x})a_k \right\|_{\sup} < \epsilon.$$

Next put $t_0=0$, and $a_0=f_1-\Sigma_{k=1}^n \cos(t_k\hat{x})a_k$. Then

$$\left\| f-\sum_{k=0}^{n} e^{it_k\hat{x}} a_k \right\|_{\sup} = \left\| f_2-\sum_{k=1}^{n} \sin(t_k\hat{x})a_k \right\|_{\sup} < \epsilon.$$

Because ρ is a probability measure on $\mathbb{R}_+$, we have also that

$$\left\| f-\sum_{k=0}^{n} e^{it_k\hat{x}} a_k \right\|_{L^2} < \epsilon.$$

But $\mathbb{R}_+$ is locally compact and ρ is a Borel measure, so for every $\varphi\in L^2(\mathbb{R}_+,\mathcal{B},\rho)$ there is a compact set $K\subset\mathbb{R}_+$ and a function $f\in C(K)$ such that $\|\varphi-f\|_{L^2}<\epsilon$. Thus the proof of Lemma 3.2 is finished.

Theorem 3.5: *For quasi-free KMS state ω defined on the Weyl algebra $\mathfrak{W}(\mathcal{D},\sigma)$ the canonical modular structure $(\pi_\omega(\mathfrak{W}(\mathcal{D},\sigma))'',\Delta_\omega,J_\omega)$ is unitarily equivalent to the modular structure $(\mathfrak{M}_\xi,\Delta_\xi,J_\xi)$ constructed from the stochastic process ξ_s^β.*

Proof: Let $w(f)$ denote the following elements of $L^\infty(Q,\Sigma_0,\mu)$:

$$w(f)=e^{i\langle\xi_0^\beta,f\rangle}.$$

On a dense set of vectors in $\mathfrak{H}_\xi$ generated by elements

$$e^{it_1H_\xi}\pi_0(w(f_1))e^{-it_1H_\xi}\cdots e^{it_nH_\xi}\pi_0(w(f_n))e^{-t_nH_\xi}\Omega_\xi,\quad t_1,\ldots,t_n\in\mathbb{R},f_1,\ldots,f_n\in\mathcal{D}_+,$$

we define a map V by

$$\begin{aligned}&V(e^{it_1H_\xi}\pi_0(w(f_1))e^{-it_1H_\xi}\cdots e^{it_nH_\xi}\pi_0(w(f_n))e^{-it_nH_\xi}\Omega_\xi)\\&\quad=e^{it_1H_\omega}\pi_\omega(W_{f_1})e^{-it_1H_\omega}\cdots e^{it_nH_\omega}\pi_\omega(W_{f_n})e^{-it_nH_\omega}\Omega_\omega.\end{aligned}$$

Since the functions

$$\phi_\xi(t_1,\ldots,t_n)=\langle\Omega_\xi,e^{it_1H_\xi}\pi_0(w(f_1))e^{-it_1H_\xi}\cdots e^{it_nH_\xi}\pi_0(w(f_n))e^{-it_nH_\xi}\Omega_\xi\rangle$$

and

$$\phi_\omega(t_1,\ldots,t_n)=\langle\Omega_\omega,e^{it_1H_\omega}\pi_\omega(W_{f_1})e^{-it_1H_\omega}\cdots e^{it_nH_\omega}\pi_\omega(W_{f_n})e^{-it_nH_\omega}\Omega_\omega\rangle$$

can be analytically continued to $\mathfrak{T}_n^\beta$ and coincide on imaginary times, they are equal for all $t_1,\ldots,t_n\in\mathbb{R}$. Thus V is an isometry with dense domain in $\mathfrak{H}_\xi$. But

$$e^{it_1H_\omega}\pi_\omega(W_{f_1})e^{-it_1H_\omega}\cdots e^{it_nH_\omega}\pi_\omega(W_{f_n})e^{-it_nH_\omega}=\pi_\omega(W_{\Sigma_{k=1}^n e^{it_k\mathbf{h}}f_k})\prod_{l\leqslant k<l\leqslant n}e^{-(i/2)\sigma(f_k,e^{i(t_l-t_k)\mathbf{h}}f_l)},$$

hence the range of V is dense in $\mathfrak{H}_\omega$ by Theorem 3.4 and continuity of $f\to\omega(W_f)$ with respect to the Hilbert space norm on $\mathcal{D}$. Moreover, $V\Omega_\xi=\Omega_\omega$. By direct computation we show that

$$V\pi_0(w(f))V^*=\pi_\omega(W_f),\quad f\in\mathcal{D}_+;\quad Ve^{itH_\xi}V^*=e^{itH_\omega}$$

and

$$V\left(\prod_{k=1}^m e^{it_kH_\xi}\pi_0(w(f_k))e^{-it_kH_\xi}\right)V^*=\prod_{k=1}^m e^{it_kH_\omega}\pi_\omega(W_{f_k})e^{i-it_kH_\omega}.$$

Thus

$$V\mathfrak{M}_\xi V^*=\pi_\omega(\mathfrak{W}(\mathcal{D},\sigma))''$$

and

$$VJ_\xi V^*=J_\omega,\quad V\Delta_\xi V^*=\Delta_\omega.$$

F. General case

If the operator **h** is only bounded from below, that is

$$\mathbf{h}\geqslant\mu\mathbb{I},\quad \mu<0,$$

then we can still obtain a quasi-free KMS state on the whole algebra $\mathfrak{W}(\mathcal{D},\sigma)$ if we replace **h** by $\tilde{\mathbf{h}}=\mathbf{h}-(\mu-1)\mathbb{I}$, for example. Then the operator B will be equal to

$$B=\frac{\mathbb{I}+ze^{-\beta\mathbf{h}}}{\mathbb{I}-ze^{-\beta\mathbf{h}}},$$

where $z=e^{\beta(\mu-1)}$ and B will be bounded. But at the same time the dynamics α_t have to be replaced by $\tilde{\alpha}_t$ given by

$$\tilde{\alpha}_t(W_f)=W_{e^{it\tilde{\mathbf{h}}}f}=W_{z^{-it/\beta}T_tf}.$$

In some cases it is necessary to consider the operator $\mathbf{h}$ itself. Then we have to restrict $\mathfrak{W}(\mathcal{D},\sigma)$ to a Weyl algebra over a suitable subspace of the Hilbert space $\mathcal{D}$.

Theorem 3.6: *Suppose that* $\mathbf{h}\geqslant 0$ *and* Ker $\mathbf{h}=0$. *Let* $B=(\mathbb{I}+e^{-\beta\mathbf{h}})^{-1}(\mathbb{I}+e^{-\beta\mathbf{h}})$ *and*

$$\mathbb{B}(f,g)=\langle B^{1/2}f,B^{1/2}g\rangle \quad with \quad D(\mathbb{B})=D(B^{1/2}).$$

Let us define

$$\omega(W_f)=e^{-(1/4)\mathbb{B}(f,f)} \quad \text{for} \quad f\in D(\mathbb{B})$$

and extend it onto the Weyl algebra $\mathfrak{W}(D(\mathbb{B}),\sigma)$. *Then* ω *is an* α_t*-KMS state at the inverse temperature* β *for the dynamics* α_t *given by* $T_t=e^{it\mathbf{h}}$.

Proof: First let us check that α_t maps $\mathfrak{W}(D(\mathbb{B}),\sigma)$ into itself. But since T_t commutes with spectral projectors of $\mathbf{h}$,

$$T_t:D(B^{1/2})\to D(B^{1/2}),$$

hence α_t leaves $\mathfrak{W}(D(\mathbb{B}),\sigma)$ invariant. Now consider two-point Green's function $G^{(2)}(f,g;t)$ given by (3.2) for $f,g\in D(\mathbb{B})$. It is clear that this function is continuous and bounded. Hence to show the existence of an analytic function interpolating between $G^{(2)}(f,g;t)$ and $G^{(2)}(g,f;-t)$ in the strip $\mathbb{R}\times i[0,\beta]$ it is enough to check that

$$\mathcal{F}(\mathbb{T}_{F(f,g;\cdot)})=e^{-\beta p}\mathcal{F}(\mathbb{T}_{F(g,f;\cdot)}).$$

For $f=g$ it can be done by direct calculations similarly as in the proof of Theorem 3.1. The general result follows from the polarization formula. It is clear that such an analytic function exists for any

$$a_n=\sum_{k=1}^{n}c_kW_{f_k},\quad b_n=\sum_{k=1}^{n}d_kW_{g_k}$$

in $\mathfrak{W}(D(\mathbb{B}),\sigma)$. Now for arbitrary $a,b\in\mathfrak{W}(D(\mathbb{B}),\sigma)$

$$G^{(2)}(a,b;t)=\lim_{n\to\infty}G^{(2)}(a_n,b_n;t)$$

and this function is continuous and bounded, so

$$\mathbb{T}_{G^{(2)}(a,b;\cdot)}=\lim_{n\to+\infty}\mathbb{T}_{G^{(2)}(a_n,b_n;\cdot)}$$

in $\mathcal{S}'$. But since $\mathcal{F}$ is a homeomorphism of $\mathcal{S}'$

$$\mathcal{F}(\mathbb{T}_{G^{(2)}(a,b;\cdot)})(-p)=e^{-p\beta}\mathcal{F}(\mathbb{T}_{G^{(2)}(b,a;\cdot)})(p).$$

Remark: In the above case the state ω is not $\mathcal{D}$-continuous in the Hilbert space topology.

Conversely, we show that among quasi-free gauge-invariant states this is the only possibility.

Theorem 3.7: *Suppose that* $\mathbb{B}$ *is a positive, closed sesquilinear form on* $\mathcal{D}$ *with domain* $D(\mathbb{B})$. *Let* $\mathbf{h}\geqslant 0$ *and* Ker $\mathbf{h}=0$. *If* $e^{it\mathbf{h}}$: $D(\mathbb{B})\to D(\mathbb{B})$ *and a state* ω *determined by* $\mathbb{B}$ *by formula* (4.1) *is an* α_t*-KMS state at inverse temperature* β, *defined on the Weyl algebra* $\mathcal{W}(D(\mathbb{B}),\sigma)$, *then*

$$\mathbb{B}(f,g)=\langle B^{1/2}f,B^{1/2}g\rangle \quad \text{where } B=\frac{\mathbb{I}+e^{-\beta\mathbf{h}}}{\mathbb{I}-e^{-\beta\mathbf{h}}}.$$

Proof: Let $f\in D(\mathbb{B})$. Then

$$\int_0^\infty d\langle (B+\mathbb{I})f,E(\lambda)f\rangle\varphi(-\lambda)+\int_0^\infty d\langle (B-\mathbb{I})f,E(\lambda)f\rangle\varphi(\lambda)$$
$$=\int_0^\infty d\langle (B+\mathbb{I})f,E(\lambda)f\rangle e^{-\beta\lambda}\varphi(\lambda)+\int_0^\infty d\langle (B-\mathbb{I})f,E(\lambda)f\rangle e^{\beta\lambda}\varphi(-\lambda),$$

where $E(\lambda)$ are spectral projectors of $\mathbf{h}$. Suppose that $\varphi>0$ for every $x\in\mathbb{R}$. Then

$$\langle (B-\mathbb{I})f,\varphi(\mathbf{h})f\rangle=\langle (B+\mathbb{I})f,e^{-\beta\mathbf{h}}\varphi(\mathbf{h})f\rangle.$$

By polarization we get

$$\varphi(\mathbf{h})(B-\mathbb{I})f=\varphi(\mathbf{h})e^{-\beta\mathbf{h}}(B+\mathbb{I})f.$$

But $\varphi(\mathbf{h})$ is injective, hence

$$(B-\mathbb{I})f=e^{-\beta\mathbf{h}}(B+\mathbb{I})f.$$

So

$$(\mathbb{I}-e^{-\beta\mathbf{h}})Bf=(\mathbb{I}=e^{-\beta\mathbf{h}})f.$$

It implies that $f\in D((\mathbb{I}-e^{-\beta\mathbf{h}})^{-1}(\mathbb{I}+e^{-\beta\mathbf{h}}))$ and

$$\frac{\mathbb{I}+e^{-\beta\mathbf{h}}}{\mathbb{I}-e^{-\beta\mathbf{h}}}f=Bf.$$

Thus

$$B\subset\frac{\mathbb{I}+e^{-\beta\mathbf{h}}}{\mathbb{I}-e^{-\beta\mathbf{h}}}.$$

Because both of them are self-adjoint, $D(B)=D((\mathbb{I}+e^{-\beta\mathbf{h}})^{-1}(\mathbb{I}-e^{-\beta\mathbf{h}}))$ and

$$B=\frac{\mathbb{I}+e^{-\beta\mathbf{h}}}{\mathbb{I}-e^{-\beta\mathbf{h}}}.$$

Remark: The results of Secs. III C and D can also be extended to this case. In particular, the functions $S(f,g;s)$ restricted to $D(\mathbb{B})_+=\{f\in D(\mathbb{B}):Cf=f\}$ define periodic Gaussian OS-positive stochastic process indexed by $D(\mathbb{B})_+$, where $D(\mathbb{B})_+$ is the real Hilbert space with respect to the inner product

$$\langle f,g\rangle_B=\langle B^{1/2}f,B^{1/2}g\rangle.$$

Similarly, since $e^{it\mathbf{h}}$ is unitary with respect to the inner product $\langle\cdot,\cdot\rangle_B$, Theorem 3.5 can be applied to this case. Moreover, the mapping

$$f\to\omega(W_f)$$

is continuous with respect to the norm $\|\cdot\|_B=\langle\cdot,\cdot\rangle_B^{1/2}$. Thus also in this case the process ξ_s^β determines the modular structure associated with the state ω. Similarly, one can show that ξ_s^β has a version with two-sided Markov property on K_β.

G. Ground state process

Now consider a quasi-free state ω_0 which is a ground state with respect to the evolution α_t defined by $T_t=e^{it\mathbf{h}}$. Then, for every $f,g\in\mathcal{D}$ there exists a function $\Phi_0(f,g;z)$, analytic and bounded for Im $z>0$, continuous on Im $z\geqslant 0$ and such that

$$\Phi_0(f,g;t)=F(f,g;t)$$

for all $t\in\mathbb{R}$. We know that for the ground state case, supp $\mathcal{F}(\mathbb{T}_F)\subseteqq[0,\infty)$. Similar arguments as used in the proof of Theorem 3.1 lead to the conclusion that for ω_0,

$$F(f,g;t)=\langle f,e^{it\mathbf{h}}g\rangle$$

and $\mathbf{h}\geqslant 0$. By analytic continuation to the imaginary times we obtain the functions

$$S_0(f,g;s)=\Phi_0(f,g;is) \tag{3.13}$$

defined for $s\geqslant 0$. Two-point imaginary time Green's functions are now given by

$$G_0^{E,2}(f,g;s)=e^{-(1/4)(\mathbb{B}(f,f)+\mathbb{B}(g,g)-(1/2)S_0(f,g;s)}.$$

Proposition 3.6: $S_0(f,g;s)$ defined by (3.13) satisfies the following.

(1) For every $f\in\mathcal{D}$ and $s\in[0,\infty)$, $S(f,f;s)$ is OS-positive.
(2) More generally, for every terminating sequences $f_k\in\mathcal{D}$, $s_k\in[0,\infty)$, $c_k\in\mathbb{C}$,

$$\sum_{k,l}\overline{c_k}c_lS_0(f_k,f_l;s_k+s_l)\geqslant 0.$$

Proof: Since the function

$$t\to F(f,f;t)=\langle f,e^{it\mathbf{h}}f\rangle$$

is positive definite, $S_0(f,f;s)$ is OS-positive as a Laplace transform of positive measure. The general positivity condition follows by polarization.

Similarly as in the nonzero temperature case, the existence of complex conjugation C defining the Abelian splitting $(\mathcal{D}_+,\mathcal{D}_-)$ of $\mathcal{D}$, commuting with $\mathbf{h}$ is necessary for stochastic positivity of $S_0(f,g;s)$ restricted to $\mathcal{D}_+$. Adopting the arguments from Sec. III C to the ground state case we can also prove the following Proposition.

Proposition 3.7: Let $\mathbf{h}$ be C-real. Then functions $S_0(f,g;s)$ restricted to $\mathcal{D}_+$ satisfy the following.

(1) $S_0(f,g;s)=S_0(g,f;s)$, $s\in[0,\infty)$.

(2) $S_0(f,g;s)$ can be extended to the function of $s\in\mathbb{R}$ (denoted by the same symbol) such that for all terminating sequences $f_1,\ldots,f_n\in\mathcal{D}_+$; $s_1,\ldots,s_n\in\mathbb{R}$ and $c_1,\ldots,c_n\in\mathbb{C}$,

$$\sum_{k,l=1}^{n}\overline{c_k}c_lS_0(f_k,f_l;s_k-s_l)\geqslant 0.$$

(3) $S_0(f,g;s)$ defines an operator-valued covariance function $R_\infty(s)$ of Gaussian OS-positive stochastic process indexed by $\mathcal{D}_+$.

Let ξ_t^∞ be the Gaussian process indexed by $\mathcal{D}_+$ defined by

$$\mathbb{E}(\langle\xi_t^\infty,f\rangle)=0;\quad \mathbb{E}(\langle\xi_{t_1}^\infty,f_1\rangle\langle\xi_{t_2}^\infty,f_2\rangle)=\tfrac{1}{2}\langle f_1,R_\infty(t_2-t_1)f_2\rangle.$$

If, in addition, Ker $\mathbf{h}=\{0\}$, then as in the KMS state case, the process ξ_t^∞ corresponding to the ground state completely determines the ground state structure.

Theorem 3.8: *Let ξ_t^∞ be a Gaussian, OS-positive stochastic process indexed by $\mathcal{D}_+\times\mathbb{R}$. Then there exists a Hilbert space $\mathfrak{H}_\xi^\infty$ with a unit vector Ω_ξ^∞, a weakly continuous one-parameter group of unitary operators $U_\xi^\infty(t)=e^{itH_\xi^\infty}$ with $H_\xi^\infty\geqslant 0$, Ker $H_\xi^\infty=\{0\}$ and a von Neumann algebra $\mathfrak{M}_\xi^\infty$ of*

operators acting on $\mathfrak{H}_\xi^\infty$ *such that* Ω_ξ^∞ *is cyclic for* $\mathfrak{M}_\xi^\infty$. *Moreover, the canonical ground state structure* $(\pi_{\omega_0}(\mathfrak{W}(\mathcal{D},\sigma))'', e^{itH_{\omega_0}}, \Omega_{\omega_0})$ *reconstructed from the state* ω_0 *is unitarily equivalent to the ground state structure* $(\mathfrak{M}_\xi^\infty, e^{itH_\xi^\infty}, \Omega_\xi^\infty)$.

Remark: In the case $\mathbf{h}>0$, there is the following relation between covariance R_β and R_∞. If $\beta\to\infty$, then

$$R_\beta(s)\to R_\infty(s)$$

weakly. On the other hand,

$$R_\beta(s)=\sum_{n\in\mathbb{Z}} R_\infty(s+n\beta),$$

where the series on the right-hand side is weakly convergent.

IV. EXAMPLES

A. Ground states and KMS states for quantum fields on a stationary space–time

Let $(\mathcal{M},g)$ be a stationary space–time, i.e., $(\mathcal{M},g)$ is space and time orientable with a global timelike Killing vector field X. Thus, $(\mathcal{M},g)$ can always be realized as $(\mathbb{R}\times\mathcal{C},g)$ where $(\mathcal{C},\hat{g})$ is a Riemannian three-manifold and

$$g=\begin{pmatrix} a^2-b^ib_i & -b_i \\ -b_i & -\hat{g}_{ij}\end{pmatrix}$$

with a scalar field a (laps field) and a vector field b (shift field) satisfying

$$a>0,\quad a^2-\hat{g}(b,b)>0,$$

and with the Killing vector field

$$X:=\frac{\partial}{\partial t}=aN(\mathcal{C})+b,$$

where $N(\mathcal{C})$ is a unit future-pointing normal vector field to $\mathcal{C}$. If $(\mathcal{M},g)$ is globally hyperbolic, then $\mathcal{C}$ can be chosen to be a global Cauchy surface. On $(\mathcal{M},g)$ we consider the covariant Klein–Gordon equation

$$(g^{\mu\nu}\nabla_\mu\nabla_\nu+m^2+V)\varphi=0.$$

Given some Cauchy surface $\mathcal{C}$, let

$$D(\mathcal{C})=C_0^\infty(\mathcal{C})+C_0^\infty(\mathcal{C})$$

be the space of real smooth Cauchy data of compact support. Then, by the Leray theorem,[37] the Cauchy data $\Phi\in D(\mathcal{C})$ given by

$$\Phi=\begin{pmatrix} f \\ p\end{pmatrix}$$

define a unique solution φ of the Klein–Gordon equation having compact support on every other Cauchy surface and such that

$$\varphi|c=f,\quad N(\mathcal{C})\varphi|c=p.$$

Thus, we may view time evolution as a one-parameter group

$$T_t: D(\mathcal{C})\to D(\mathcal{C}).$$

Moreover, T_t preserves the symplectic form

$$\hat{\sigma}(\Phi_1,\Phi_2)=\int_{\mathcal{C}}(f_1p_2-p_1f_2)\ d\eta(\mathcal{C}),$$

where $\eta(\mathcal{C})$ is the Riemannian volume element on $(\mathcal{C},\hat{g})$ and

$$\frac{d}{dt}\,T_t\Phi|_{t=0}=-\hat{h}\Phi$$

with $\hat{h}=-\mathbf{gA}$ and

$$\mathbf{A}=\begin{pmatrix}-(\partial^i a)\partial_i+a(m^2-\Delta(\mathcal{C})+V) & -(\nabla_i b^i+b^i\partial_i)\\ b^i\partial_i & a\end{pmatrix},\quad \mathbf{g}=\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix},$$

where $\Delta(\mathcal{C})$ is the Laplace–Beltrami operator on $(\mathcal{C},\hat{g})$ and ∇_i is the covariant derivative on $(\mathcal{C},\hat{g})$.

In order to apply the results of Sec. III we need a Hilbert space $(\mathcal{D},\langle,\rangle_{\mathcal{D}})$ containing $D(\mathcal{C})$, such that $\hat{\sigma}(\cdot,\cdot)=\mathrm{Im}\langle\cdot,\cdot\rangle_{\mathcal{D}}$ and $T_t=e^{it\mathbf{h}}$, where $\mathbf{h}$ is self-adjoint on $\mathcal{D}$. The result of Kay[38] shows that such *a one-particle Hilbert space structure* exists under the following (mass gap) assumptions:

(1) V is stationary and $\inf V(x)+m^2>0$,
(2) $\inf a>0$ on $\mathcal{C}$, and
(3) $\inf(a-b^ib_i/a)>0$ on $\mathcal{C}$.

The above assumptions also imply that the generator $\mathbf{h}$ has a bounded inverse.

Proposition 4.1: Let $(\mathcal{D},e^{it\mathbf{h}})$ be the one-particle Hilbert space structure corresponding to the Klein–Gordon equation on a globally hyperbolic stationary space–time $(\mathcal{M},g)$. There exists a complex conjugation C on $\mathcal{D}$ such that $\mathbf{h}$ is C-real.

Proof: To show the existence of complex conjugation C we quote basic steps of the Kay construction. Since

$$\langle\Phi,\mathbf{A}\Phi\rangle_{L^2+L^2}>\epsilon\|\Phi\|^2_{L^2+L^2}$$

for some $\epsilon>0$, we define the $\mathbf{A}$-norm

$$\|\Phi\|^2_{\mathbf{A}}=\langle\Phi,\mathbf{A}\Phi\rangle_{L^2+L^2}$$

and $D_{\mathbf{A}}$ as the completion of $D(\mathcal{C})$ in this norm. Then, it can be shown that $\hat{h}$ is essentially skew-adjoint and $(\overline{\hat{h}})^{-1}$ exists and is bounded. Since $\hat{\sigma}$ is continuous in $\mathbf{A}$-norm, it can be extended to $\hat{\sigma}'$ on $D_{\mathbf{A}}$ and

$$\hat{\sigma}'(\Phi,\Psi)=\langle\Phi,(\overline{\hat{h}})^{-1}\Psi\rangle_{\mathbf{A}}.$$

Let $D^{\mathbb{C}}_{\mathbf{A}}$ be the natural complexification of the real Hilbert space $D_{\mathbf{A}}$. We change the inner product in $D^{\mathbb{C}}_{\mathbf{A}}$ by modifying the complex structure on $D^{\mathbb{C}}_{\mathbf{A}}$. To do this we introduce a unitary operator I satisfying $I^2=-1$ and $\hat{\sigma}'(\Phi,I\Phi)>0$. Since $i\overline{\hat{h}}$ is self-adjoint on $D^{\mathbb{C}}_{\mathbf{A}}$ we can define

$$I=i(P_+-P_-)=|\overline{\hat{h}}|^{-1}\overline{\hat{h}},$$

where P_+,P_- are projectors onto positive and negative parts of its spectrum. Now we define the new inner product by

$$\langle\Phi,\Psi\rangle_{\mathcal{D}}=\hat{\sigma}'(\Phi,I\Psi)+i\hat{\sigma}'(\Phi,\Psi).$$

Let $\mathcal{D}$ be the Hilbert space completion of $D_{\mathbf{A}}^{\mathbb{C}}$ with respect to $\langle,\rangle_{\mathcal{D}}$. From the construction of $\mathcal{D}$ we see that T_t is the unitary group with respect to the inner product $\langle,\rangle$, and the generator $\mathbf{h}$ of it is strictly positive. The complex conjugation C in $\mathcal{D}$ is defined as follows. Let C_0 be the complex conjugation in $D_{\mathbf{A}}^{\mathbb{C}}$ with respect to the complex structure given by multiplication by i. Then

$$C = C_0(P_+ - P_-)$$

is the complex conjugation in $\mathcal{D}$ such that $\mathbf{h}$ is C-real.

Applying the results of Sec. III we have the following.

Corollary 4.1:

(1) Let ω be the KMS state at the inverse temperature β, defined on $\mathfrak{W}(\mathcal{D},\sigma)$ as in Theorem 3.1, and let ξ_t^β be the corresponding Gaussian Markov thermal process indexed by $\mathcal{D}_+$ (where $\mathcal{D}_+$ is defined by the complex conjugation C). The modular structure defined by ω is unitarily equivalent to the modular structure reconstructed from ξ_t^β as in Theorem 3.5.

(2) Similarly, let ω_0 be the ground state on $\mathfrak{W}(\mathcal{D},\sigma)$ and let ξ_t^∞ be the corresponding ground state process. The ground state structure defined by ω_0 is unitarily equivalent to the ground state structure reconstructed from the process ξ_t^∞ as in Theorem 3.8.

In the case of *a static* space–time, we can realize $(\mathcal{M},g)$ as above, but with the vector field $b=0$. Then the matrix $\mathbf{A}$ becomes diagonal

$$\mathbf{A} = \begin{pmatrix} A & 0 \\ 0 & a \end{pmatrix}$$

with

$$A = -(\partial^i a)\partial_i + a(m^2 - \Delta(\mathcal{C}) + V.$$

In this case the one-particle structure can be described in a more explicit way. As was shown by Kay,[38] $\mathcal{D}$ can be identified with $L^2(\mathcal{C},d\eta)$ and the space $D(\mathcal{C})$ of Cauchy data is mapped into $L^2(\mathcal{C},d\eta)$ by

$$(f,p) \to Yf + IY^{*-1}p,$$

where

$$Y = (\overline{a}^{1/2}\overline{A}\overline{a}^{1/2})^{-1/4}\overline{a}^{1/2}$$

and $\overline{B}$ means closure of operator B. The one-particle Hamiltonian $\mathbf{h}$ is now given by

$$\mathbf{h} = (\overline{a}^{1/2}\overline{A}\overline{a}^{1/2})^{1/2},$$

and the complex conjugation C is the natural one in $L^2(\mathcal{C},d\eta)$. Then $\mathcal{D}_+$ is defined as a Hilbert space completion in $L^2(\mathcal{C},d\eta)$ of the linear space generated by vectors

$$Yf, \quad f \in C^\infty_{0,\mathbb{R}}(\mathcal{C}),$$

and, similarly, $\mathcal{D}_-$ is the completion in $L^2(\mathcal{C},d\eta)$ of linear space generated by

$$Y^{*-1}p, \quad p \in C^\infty_{0,\mathbb{R}}(\mathcal{C}).$$

From the general results of Sec. III it follows that there exist thermal (respectively, ground state) processes indexed by $\mathcal{D}_+$ and $\mathcal{D}_-$. The former we call *field thermal* (respectively, *ground state*) *process* and denote by ξ_t^β (respectively ξ_t^∞) and the latter we call *momentum thermal* (respectively *ground state*) *process* and denote by π_t^β (respectively π_t^∞). It is enough to consider the covariances of these processes for the indexes of the form Yf or $Y^{*-1}p$ with $f,p \in C_0^\infty(\mathcal{C})$. Thus for thermal processes we obtain

$$\mathbb{E}(\langle \xi_t^\beta, f\rangle\langle \xi_s^\beta, g\rangle) = \int_{\mathcal{C}\times\mathcal{C}} (Yf)(x) R^\beta(t,s;x,y)(Yg)(y)\, d\eta(x)\, d\eta(y),$$

$$\mathbb{E}(\langle \pi_t^\beta, f\rangle\langle \pi_s^\beta, g\rangle) = \int_{\mathcal{C}\times\mathcal{C}} (Y^{*-1}f)(x) R^\beta(t,s;x,y)(Y^{*-1}g)(y)\, d\eta(x)\, d\eta(y),$$

where

$$R^\beta(t,s;x,y) = \frac{e^{-|t-s|\mathbf{h}} + e^{-(\beta-|t-s|)\mathbf{h}}}{1-e^{-\beta\mathbf{h}}}(x,y)$$

for $|t-s| \leqslant \beta$. Similarly, for the ground state processes,

$$\mathbb{E}(\langle \xi_t^\infty, f\rangle\langle \xi_s^\infty, g\rangle) = \int_{\mathcal{C}\times\mathcal{C}} (Yf)(x) R^\infty(t,s;x,y)(Yg)(y)\, d\eta(x)\, d\eta(y),$$

$$\mathbb{E}(\langle \pi_i^\infty, f\rangle\langle \pi_s^\infty, g\rangle) = \int_{\mathcal{C}\times\mathcal{C}} (Y^{*-1}f)(x) R^\infty(t,s;x,y)(Y^{*-1}g)(y)\, d\eta(x)\, d\eta(y),$$

where

$$R^\infty(t,s;x,y) = e^{-|t-s|\mathbf{h}}(x,y).$$

Let $dE_{\mathbf{h}}(\lambda)$ be the spectral resolution of the operator $\mathbf{h}$ in the Hilbert space $L^2(\mathcal{C}, d\eta)$. Then

$$\mathbb{E}(\langle \xi_l^\beta, f\rangle\langle \xi_0^\beta, g\rangle) = \int_0^\infty \frac{e^{-t\lambda} + e^{-(\beta-t)\lambda}}{\lambda(1-e^{-\beta\lambda})}\, d\langle \overline{a}^{1/2} f, E_{\mathbf{h}}(\lambda)\overline{a}^{1/2} g\rangle.$$

Therefore, if f is such that $\overline{a}^{1/2} f \in L^2(\mathcal{C}, d\eta)$, then

$$m(f) = \int_0^\infty \frac{e^{-t\lambda} + e^{-(\beta-t)\lambda}}{1-e^{-\beta\lambda}}\, d\langle \overline{a}^{1/2} f, E_{\mathbf{h}}(\lambda)\overline{a}^{1/2} f\rangle < \text{const} \|\overline{a} f\|^2_{L^2(\mathcal{C}, d\eta)},$$

and we can apply Proposition 3.6 to conclude that for every such f there exists a version of the coordinate process $\langle \xi_t^\beta, f\rangle$ with Hölder continuous paths. Similar arguments work also for the ground state (field) process and momentum processes. Thus we obtain the following.

Corollary 4.2: Let $(\mathcal{M}, g)$ be a static, globally hyperbolic space–time with the laps field a. Then

(1) For any $f \in C^\infty_{0,\mathbb{R}}(\mathcal{C})$ such that $\overline{a}^{1/2} f \in L^2(\mathcal{C}, d\eta)$ and $\beta \in (0,\infty]$ there exists a version of the coordinate process $\langle \xi_t^\beta, f\rangle$ such that for every $\gamma \in (0,1/2)$ there is an integrable random variable $d(f,\gamma)$ such that

$$|\langle \xi_t^\beta, f\rangle - \langle f_s^\beta, f\rangle| \leqslant d(f,\gamma)|t-s|^\gamma$$

with probability one.

(2) For any $f \in C^\infty_{0,\mathbb{R}}(\mathcal{C})$ such that $\overline{a}^{1/2} f \in H_{1/2}(\mathcal{C}, d\eta)$ where

$$H_{1/2}(\mathcal{C}, d\eta) = \text{metric completion of } C^\infty_{0,\mathbb{R}}(\mathcal{C}) \text{ with respect to (Sobolev-like) norm,}$$

$$\|f\|^2_{1/2} = \int_{\mathcal{C}\times\mathcal{C}} (\mathbf{h}^{1/2} f)(x)(\mathbf{h}^{1/2} f)(y)\, d\eta(x)\, d\eta(y),$$

the coordinate process $\langle \pi_t^\beta, f\rangle$ for $\beta \in (0,\infty]$ has a version with Hölder continuous paths similarly as in (1).

Example 4.1.1: Let $\mathcal{M}_d$ be a flat d-dimensional Minkowski space–time with the metric tensor

$$(g_{\mu\nu})=\begin{pmatrix}1 & 0\\ 0 & -\mathbb{I}_{d-1}\end{pmatrix}.$$

Taking

$$\mathcal{C}=\{(x^0,\mathbf{x})\in\mathcal{M}_d : x^0=0\}$$

and $V=0$, we obtain the following covariances of thermal and ground state (field) processes:

$$\mathbb{E}(\langle\xi_t^\beta,f\rangle\langle\xi_s^\beta,g\rangle)=\int_{\mathbb{R}^{d-1}}\frac{d\mathbf{p}}{\sqrt{\mathbf{p}^2+m^2}}\,\hat f(\mathbf{p})\hat g(\mathbf{p})\,\frac{e^{-|t-s|\sqrt{\mathbf{p}^2+m^2}}+e^{-(\beta-|t-s|)\sqrt{\mathbf{p}^2+m^2}}}{1-e^{-\beta\sqrt{\mathbf{p}^2+m^2}}}$$

for $|t-s|\leqslant\beta$ and

$$\mathbb{E}(\langle\xi_t^\infty,f\rangle\langle\xi^{\infty}{}_s,g\rangle)=\int_{\mathbb{R}^{d-1}}\frac{d\mathbf{p}}{\sqrt{\mathbf{p}^2+m^2}}\,\hat f(\mathbf{p})\hat g(\mathbf{p})e^{-|t-s|\sqrt{\mathbf{p}^2+m^2}},$$

where $f,g\in C_0^\infty(\mathbb{R}^{d-1})$. And similarly for momentum processes:

$$\mathbb{E}(\langle\pi_t^\beta,f\rangle\langle\pi_s^\beta,g\rangle)=\int_{\mathbb{R}^{d-1}}d\mathbf{p}\sqrt{\mathbf{p}^2+m^2}\hat f(\mathbf{p})\hat g(\mathbf{p})\,\frac{e^{-|t-s|\sqrt{\mathbf{p}^2+m^2}}+e^{-(\beta-|t-s|)\sqrt{\mathbf{p}^2+m^2}}}{1-e^{-\beta\sqrt{\mathbf{p}^2+m^2}}},$$

$$\mathbb{E}(\langle\pi_t^\infty,f\rangle\langle\pi_s^\infty,g\rangle)=\int_{\mathbb{R}^{d-1}}d\mathbf{p}\sqrt{\mathbf{p}^2+m^2}\hat f(\mathbf{p})\hat g(\mathbf{p})e^{-|t-s|\sqrt{\mathbf{p}^2+m^2}}.$$

The law of the process ξ_t^β is given by the Gaussian random field μ_0^β indexed by $\mathcal{S}(K_\beta\times\mathbb{R}^{d-1})$ and defined by

$$\mathbb{E}^{\mu_0^\beta}(\langle\varphi,f\rangle)=0\quad\text{and}\quad\mathbb{E}^{\mu_0^\beta}(\langle\varphi,f\rangle\langle\varphi,g\rangle)=\langle f,(-\Delta_d^\beta+m^2)^{-1}g\rangle,$$

where $-\Delta_d^\beta$ denotes the d-dimensional Laplace operator with periodic boundary conditions in the time direction [$-\Delta_d^\infty$ is defined as the Friedrichs extension of $-\Delta$ in $L^2(\mathbb{R}^d)$]. The law of the momentum process π_t^β is given by the Gaussian random field ν_0^β indexed by $\mathcal{S}(K_\beta\times\mathbb{R}^{d-1})$ and defined by

$$\mathbb{E}^{\nu_0^\beta}(\langle\psi,f\rangle)=0\quad\text{and}\quad\mathbb{E}^{\nu_0^\beta}(\langle\psi,f\rangle\langle\psi,g\rangle)=\langle f,(-\Delta_{d-1}+m^2)(-\Delta_d^\beta+m^2)^{-1}g\rangle.$$

In the present case we are able to analyze the properties of continuity of the processes in more detail.

Proposition 4.2: Let $\rho\in L^2(\mathbb{R}^{d-1})\cap C(\mathbb{R}^{d-1})$, $\alpha>(d-2)/2$. Then the field process ξ_t^β has a version realized in the space

$$\bigcap_{\alpha>(d-2)/2}H^\rho_{-\alpha}(\mathbb{R}^{d-1}),$$

where

$$H^\rho_{-\alpha}(\mathbb{R}^{d-1})=\text{metric completion of } C_0^\infty(\mathbb{R}^{d-1}) \text{ in the norm,}$$

$$\|f\|^\rho_{-\alpha}=\left[\int\frac{|\hat f(p)|^2}{(p^2+m^2)^\alpha}\,\rho^2(p)dp\right]^{1/2},$$

and such that for any $\alpha>(d-1)/2$:

(1) If $\beta<\infty$, there exists a Borel measurable function $\Theta_\beta:\mathcal{S}'(K_\beta\times\mathbb{R}^{d-1})\to\mathbb{R}_+$ such that for all $t,s\in K_\beta$ such that $|t-s|<1$

$$\|\xi_t^\beta - \xi_s^\beta\|_{-\alpha}^\rho \leqslant \Theta_\beta\left(\frac{|t-s|}{\ln(1/|t-s|)}\right)^{1/2}.$$

(2) If $\beta=\infty$, then for any $n\in\mathbb{N}$ there exists a Borel measurable function $\Theta_n:\mathcal{S}'(\mathbb{R}^d)\to\mathbb{R}_+$ such that for any $t,s\in[-n,n]$ such that $|t-s|<e^{-1}$

$$\|\xi_t^\infty - \xi_s^\infty\|_{-\alpha}^\rho \leqslant \Theta_n\left(\frac{|t-s|}{\ln(1/|t-s|)}\right)^{1/2}.$$

In the case of momentum process π_t^∞, let ρ be as above. Then the process π_t^∞ is realized in the space

$$\bigcap_{\alpha>d/2} H_{-\alpha}^\rho(\mathbb{R}^{d-1}).$$

Moreover, for any $\alpha>(d+1)/2$, π_t^β has a version with Hölder continuous [in $H_{-\alpha}^\rho(\mathbb{R}^{d-1})$] paths and obeys inequalities similar to (1) and (2).

Sketch of the proof: Let

$$C_0^\beta(x,y)=(-\Delta_d^\beta+m^2)^{-1}(x,y)$$

be the covariance of the Gaussian random field μ_0^β. Let $\{\chi_\epsilon\}$ be the net of functions satisfying: $\chi_\epsilon\in C_0^\infty(\mathbb{R}^{d-1})$, $\chi_\epsilon>0$, $\int_{\mathbb{R}^{d-1}}\chi_\epsilon(x)dx=1$, i.e., $\chi_\epsilon\to\delta$ in $\mathcal{D}'(\mathbb{R}^{d-1})$. Define

$$C_{0,\epsilon}^\beta = C_0^\beta * (\chi_\epsilon\otimes\chi_\epsilon)$$

and let $\mu_{0,\epsilon}^\beta$ be the corresponding Gaussian measure on $(\mathcal{S}'(K_\beta\times\mathbb{R}^{d-1}),\mathcal{B})$, where $\mathcal{B}$ is the Borel σ-algebra of sets in $\mathcal{S}'(K_\beta\times\mathbb{R}^{d-1})$. For every $t>0$ and $\mu_{0,\epsilon}^\beta$-almost every $\varphi\in\mathcal{S}'(K_\beta\times\mathbb{R}^{d-1})$ we can define the map

$$x\to X_t^\epsilon(x)=\varphi(t,x).$$

Moreover, it can be shown that $X_t^\epsilon(x)$ takes values in the space $H_{-\alpha}^\rho(\mathbb{R}^{d-1})$.[39] Suitable modification of X_t^ϵ gives rise to $L^2(\mathcal{S}'(K_\beta\times\mathbb{R}^{d-1}),\mu_0^\beta|_{H_{-\alpha}^\rho(\mathbb{R}^{d-1})})$ stochastic process and its L^2 limit is easily seen to be the process ξ_t^β. Thus, there exists a version of ξ_t^β (denoted by the same symbol) which is $L^2(\mathcal{S}'(K_\beta\times\mathbb{R}^{d-1}),\mu_0^\beta|_{H_{-\alpha}^\rho(\mathbb{R}^{d-1})})$ stochastic process and which takes values in $H_{-\alpha}^\rho(\mathbb{R}^{d-1})$ for all $\alpha>(d-2)/2$. Notice that for $\alpha>(d-1)/2$

$$\sup_{|t-s|\leqslant r}(\mathbb{E}(\|\xi_t^\beta-\xi_s^\beta\|_{-\alpha}^\rho)^2)^{1/2}\leqslant \text{const}|t-s|^{1/2}$$

and

$$\lim_{t\to s}\mathbb{E}(\|\xi_t^\beta-\xi_s^\beta\|_{-\alpha}^\rho)^2=0.$$

Thus we can apply the continuity criterion due to Preston and Garsia[40,41] as formulated in Theorem 5.1 in Ref. 42. This leads to the Hölder continuity of ξ_t^β in $H_{-\alpha}^\rho(\mathbb{R}^{d-1})$ for all $\alpha>(d-1)/2$ and ρ as above. Similarly, we can prove the analogous properties of the momentum processes.

Remark: For more refined continuity properties and additional references to other continuity properties of the process ξ_t^∞ we refer to Ref. 42. Other aspects of the process ξ_t^β are discussed in Refs. 43 and 35. It is interesting to note the essential difference between Markov properties of the field and momentum processes. For example, if $\beta=\infty$, then the law of ξ_t^∞ fulfills the so-called sharp Markov property,[6] while the law of π_t^∞ satisfies another kind of Markov property discussed in Ref. 44.

Example 4.1.2:

Let

$$W_{\mathrm{R}}=\{(T,X)\in\mathcal{M}_2: T^2-X^2<0,\ X>0\}$$

be the right wedge in two-dimensional Minkowski space–time. In the hyperbolic coordinates (τ,x) defined by

$$T=e^x \sinh\,\tau,\quad X=e^x\cosh\,\tau,$$

the action of the Lorentz boost

$$\Lambda(t)=\begin{pmatrix}\cosh\,t & \sinh\,t\\ \sinh\,t & \cosh\,t\end{pmatrix}$$

becomes

$$\Lambda(t)(\tau,x)=(\tau+t,x).$$

Let

$$\mathcal{C}=\{(\tau,x):\tau=0\}=\mathbb{R}.$$

Then, on

$$\hat{D}_{\mathcal{C}}=\{(f,\hat{p}): f\in C_0^\infty(\mathcal{C}),\hat{p}=e^x p, p\in C_0^\infty(\mathcal{C})\},$$

the symplectic form

$$\hat{\sigma}((f,\hat{p}),(f',\tilde{p}'))=\int_{\mathcal{C}}(f\hat{p}'-\hat{p}f')\,dx$$

is invariant under the induced action of

$$\hat{\Lambda}(t)=e^{-t\mathcal{L}},\quad \text{where}\quad \mathcal{L}=\begin{pmatrix}0 & -1\\ A & 0\end{pmatrix}\quad\text{and}\quad A=-\frac{\partial^2}{\partial x^2}+e^{2x}m^2.$$

Although in this case the mass gap conditions are not fulfilled, a one-particle Hilbert space can also be constructed.[45] $\mathcal{D}$ can be identified with $L^2(\mathbb{R},dx)$ and $\mathbf{h}=A^{1/2}$. The space $\hat{D}(\mathcal{C})$ of Cauchy data is mapped in $L^2(\mathbb{R},dx)$ by

$$(f,\hat{p})\to A^{-1/4}f+iA^{1/4}\hat{p}.$$

As was shown in Sec. III F we can define the thermal state (for any $\beta>0$) on the Weyl algebra over $D(B^{1/2})\subset L^2(\mathbb{R},dx)$, where

$$B=\frac{\mathbb{I}+e^{-\beta\mathbf{h}}}{\mathbb{I}-e^{-\beta\mathbf{h}}}.$$

Using the natural complex conjugation on $L^2(\mathbb{R},dx)$ we obtain thermal processes indexed by $D(B^{1/2})_{\pm}$. On a suitable domain in $C_0^\infty(\mathbb{R})$ we can compute the covariance of the field process, denoted now by l_τ^β, for the indexes of the form $A^{-1/4}f$, $f\in C_0^\infty(\mathbb{R})$, and we obtain

$$\mathbb{E}(\langle l_\tau^\beta,f\rangle\langle l_{\tau'}^\beta,g\rangle)=\left\langle f,\ \frac{e^{-|\tau-\tau'|A^{1/2}}+e^{-(\beta-|\tau-\tau'|)A^{1/2}}}{A^{1/2}(\mathbb{I}-e^{-\beta A^{1/2}})}\,g\right\rangle_{L^2(\mathbb{R})}.$$

Let φ be a free scalar massive quantum field on $\mathcal{M}_2$. It is well known that for f real, the field operator $\varphi(f)$ is essentially self-adjoint on D^φ defined by

$$D^\varphi=\mathrm{lh}\{\varphi(f_1)\cdots\varphi(f_n)\Omega_0: f_1,\ldots,f_n\in C_0^\infty(\mathcal{M}_2), n\in\mathbb{N}\},$$

where Ω_0 is the Fock vacuum. For any open $G\subset\mathcal{M}_2$, let $\mathfrak{N}_G$ be the von Neumann algebra generated by

$$e(f)=e^{\overline{i\varphi(f)}} \quad \text{with supp } f\subset G.$$

If $G\subset\mathcal{M}_2$ is such that its causal complement is nonempty, then by the Reeh–Schlieder theorem, Ω_0 is cyclic and separating for $\mathfrak{N}_G$. In particular, we can put $G=W_{\mathrm{R}}$ and, using the Bisognano–Wichmann theorem,[31] we conclude that $(\mathfrak{N}_{W_{\mathrm{R}}},\Omega_0,\Lambda(\tau))$ forms a W^*-KMS system at $\beta=2\pi$. On the other hand, for any $f\in C_0^\infty(\mathbb{R})$, $t\in\mathbb{R}$, the operator $\varphi(\delta_t\otimes f)$ is also essentially self-adjoint on D^φ. Thus we can define the Abelian von Neumann algebra $\mathfrak{U}_R$ generated by

$$e^{\overline{i\varphi(\delta_l\otimes f)}}, \quad \text{with } f=\overline{f} \text{ supp } f\subset\{(x,0):x>0\}.$$

By the direct computation we also obtain

$$\langle\Omega_0,e^{i\varphi(\delta_0\otimes f)}\Lambda(i\tau)e^{i\varphi(\delta_0\otimes g)}\Omega_0\rangle=\mathbb{E}(e^{i\langle l_0^{2\pi},f\rangle}e^{i\langle l_\tau^{2\pi},g\rangle})$$

for $\tau\in[0,2\pi]$, supp f,supp $g\subset\{(x,0):x>0\}$. Moreover, it is easy to show that the modular structure reconstructed from the thermal (boost) process $l_\tau^{2\pi}$ is unitarily equivalent to $(\mathfrak{N}_{W_{\mathrm{R}}},\Omega_0,\Lambda(\tau))$.

Remark: Similar construction of the thermal process can be done in the case of the exterior Schwarzschild right wedge region in the Kruskal space–time $\mathcal{M}\simeq\mathbb{R}^2\times\Omega$ where Ω is some $d-2$-dimensional Riemann manifold with the metric dl_Ω^2. The metric on $\mathcal{M}$ is given by

$$ds^2=32M^3r^{-1}e^{-r/(2M)}(dT^2-dX^2)-r^2dl_\Omega^2,$$

where M is the mass of the black hole and r is the Schwarzschild radius defined by

$$T^2-X^2=(1-r/(2M))e^{r/(2M)}.$$

The exterior Schwarzschild right wedge is defined as

$$\mathcal{R}=\{(T,X,\zeta):X>|T|,r>2M,\zeta\in\Omega\}.$$

The corresponding thermal process has the covariance defined as above, but in terms of the operator A given by

$$A=-\frac{\partial^2}{\partial x^2}+(1-2M/r)(2M/r^3-\Delta_\Omega/r^2+m^2),$$

where Δ_Ω is the Laplace operator on Ω. Detailed analysis of this process together with the construction corresponding to the de Sitter case will be discussed in a separate paper.

B. Nonrelativistic Bose matter

Let $\mathcal{D}=L^2(\mathbb{R}^d)$ and $T_t=e^{it\mathbf{h}}$ where $\mathbf{h}\geqslant 0$, Ker $\mathbf{h}=\{0\}$, commutes with the natural complex conjugation on $L^2(\mathbb{R}^d)$. Then there exist thermal (and ground state) processes indexed by a suitable subspaces of $L^2_{\mathbb{R}}(\mathbb{R}^d)$. In particular, then the covariance operator of the thermal process ξ_τ^β is given by

$$R^\beta(\tau)=\frac{e^{-|\tau|\mathbf{h}}+e^{-(\beta-|\tau|)\mathbf{h}}}{\mathbb{I}-e^{-\beta\mathbf{h}}}$$

for $|\tau|\leqslant\beta$. As in the previous examples the modular structure defined by the canonical KMS state at the inverse temperature β coincides with the modular structure obtained from the thermal process ξ_τ^β. If additionally inf $\sigma(\mathbf{h})>0$, it is easy to see that for any $f\in L^2_{\mathbb{R}}(\mathbb{R}^d)$ the assumption of Proposition 3.4 is satisfied, hence each coordinate process $\langle\xi^\beta,f\rangle$ has a version with Hölder continuous paths.

The case when the operator **h** (called a kinetic energy) is of the form $\mathbf{h}=\mathcal{E}(-i\nabla)$, where $\mathcal{E}$ is some locally bounded, measurable function satisfying $\mathcal{E}(p)\geqslant 0$, is of particular interest to physics. The choice $\mathcal{E}(p)=p^2+\mu,\ \mu>0$, corresponds to the standard kinetic energy,[24] whereas $\mathcal{E}(p)=\sqrt{p^2+m^2}$ corresponds to the semirelativistic kinetic energy. For a given $\mathcal{E}\in\mathcal{B}_0(\mathbb{R}^d)$ where

$$\mathcal{B}_0(\mathbb{R}^d)=\{\text{the set of locally bounded, measurable functions on } \mathbb{R}^d \text{ satisfying } \inf \mathcal{E}(p)=\epsilon>0\},$$

we denote

$$\hat{C}^\beta(p)=\frac{1+e^{-\beta\mathcal{E}(p)}}{1-e^{-\beta\mathcal{E}(p)}},\quad \hat{S}^\beta(\tau,p)=\frac{e^{-|\tau|\mathcal{E}(p)}+e^{-(\beta-|\tau|)\mathcal{E}(p)}}{1-e^{-\beta\mathcal{E}(p)}}.$$

Since

$$\hat{C}^\beta(p)=1+\frac{2e^{-\beta\mathcal{E}(p)}}{1-e^{-\beta\mathcal{E}(p)}},$$

the corresponding expression in x space has a δ singularity at $x=0$. If we assume that $\mathcal{E}\in C(\mathbb{R}^d)$ and

$$\mathcal{E}(p)\sim|p|^\eta \quad \text{for} \quad |p|\to\infty,\quad \eta>0,$$

we obtain

$$C^\beta(x)=\delta(x)+\mathcal{R}^\beta(x),$$

where $\mathcal{R}^\beta$ is continuous and

$$\mathcal{R}^\beta\in\bigcap_{p\geqslant 1}L^p(\mathbb{R}^d).$$

The kernel $\hat{S}^\beta(\tau,p)$ has similar properties.

Remark: The technical difficulties arise only in the case when the set

$$\mathcal{N}_\mathcal{E}=\{p\in\mathcal{R}^d:\mathcal{E}(p)=0\}$$

is nonempty. In that case, we have to restrict the index space of the process ξ_τ^β. For example, if $\mathcal{E}$ is continuous and

$$\mathcal{E}(p)\sim|p|^\nu \quad \text{as} \quad |p|\to+0,$$

we can take as the index space $C^\infty_{\eta^*}(\mathbb{R}^d)$ defined as follows:

$$C^\infty_{\eta^*}(\mathbb{R}^d)=\left\{f\in\mathcal{S}(\mathbb{R}^d):\ \frac{\partial^{|\mathbf{i}|}}{\partial x_1^{i_1}\cdots\partial x_n^{i_n}}f\Big|_{x=0}=0,\quad \text{for all } \left|\mathbf{i}\right|\leqslant\eta^*\right\},$$

where $\eta^*\geqslant d-1-\nu$.

Using similar arguments as in the proof of Proposition 4.2, we obtain the following:

Proposition 4.3:

(1) Let $\mathcal{E}\in\mathcal{B}_0(\mathbb{R}^d)$. Then for any $\alpha>d/2$, there exists a version of the process ξ_τ^β with values in the space

$$H^\rho_{-\alpha}(\mathbb{R}^d)=\left\{f\in\mathcal{S}'(\mathbb{R}^d):\int_{\mathbb{R}^d}\frac{|\hat{f}(p)|^2}{(p^2+1)^\alpha}\,\rho^2(p)dp<\infty\right\}.$$

If, in addition, $\mathcal{E}(p)\sim|p|^\eta$ for $|p|\to\infty$, then for any $\alpha>(d+\eta)/2$ there exists a version of ξ_τ^β such that with probability one

$$\|\xi_\tau^\beta - \xi_{\tau'}^\beta\|_{-\alpha}^2 \leqslant \Theta_\beta \left(\frac{|\tau-\tau'|}{\ln(1/|\tau-\tau'|)} \right)^{1/2}.$$

for sufficiently small $|\tau-\tau'|$ and some integrable random variable Θ_β.

(2) Let $\mathcal{E}$ be such that $\mathcal{E}(p)\sim|p|^\eta$ as $|p|\to+0$ and $\mathcal{E}(p)\sim|p|^\nu$ as $|p|\to\infty$. Let

$$H^\rho_{-\alpha,\eta}(\mathbb{R}^d) = \Big\{ \text{metric completion of } C_0^\infty(\mathbb{R}^d) \text{ with the norm } \|f\|^{\rho 2}_{-\alpha,\eta}$$
$$= \int_{\mathbb{R}^d} \frac{|p|^\eta |f(p)|^2}{(p^2+1)^\alpha}\, \rho^2(p)dp \Big\}.$$

Then for any $\alpha>(d+\eta)/2$ there exists a version of the process ξ_τ^β with values in $H^\rho_{-\alpha,\eta}(\mathbb{R}^d)$ and for any $\alpha>(d+\eta+\nu)/2$ there exists a version of ξ_τ^β with Hölder continuous paths as in (1).

Remark: The case of critical (standard) Bose gas defined by the thermal state ω_{cr} on the Weyl algebra over $\mathcal{S}(\mathbb{R}^d)$ given by

$$\omega_{\mathrm{cr}}(W_f) = \exp\, c|\hat f(0)|^2) \exp\left[-\frac{1}{4} \int_{\mathbb{R}^d} \frac{1+e^{-\beta p^2}}{1-e^{-\beta p^2}} |\hat f(p)|^2\, dp \right],$$

where $c>0$ is a constant and $d\geqslant 3$, was discussed in Ref. 25. Here we quote only some continuity results.

Let $d\geqslant 3$ and $\xi_\tau^{\beta,\mathrm{cr}}$ be the thermal process indexed by $\mathcal{S}(\mathbb{R}^d)$ with the covariance given by the density

$$S^{\beta,\mathrm{cr}}(\tau,p) = c\,\delta(p) + \frac{e^{-|\tau|p^2} + e^{-(\beta-|g t|)p^2}}{1-e^{-\beta p^2}}.$$

For any $\alpha>d/2$ there exists a version of $\xi_\tau^{\beta,cr}$ with values in $H_{-\alpha}(\mathbb{R}^d)$ and for any $\alpha>(d+1)/2$ there exists a version of $\xi_\tau^{\beta,cr}$ with Hölder continuous paths.

C. Quantum lattice models

Let $\mathbb{L}$ be a countable set with elements denoted by $\mathbf{l}$. Assume that for any $\mathbf{l}\in\mathbb{L}$ there is a separable Hilbert space $\mathcal{D}_\mathbf{l}$ with a unitary group $T_{\mathbf{l},t}=e^{it\mathbf{h}_\mathbf{l}}$, where $\mathbf{h}_\mathbf{l}$ is self-adjoint and $\sigma(\mathbf{h}_\mathbf{l})\subset[\epsilon,\infty)$, $\epsilon>0$. Assume also that there is a complex conjugation $C_\mathbf{l}$ on $\mathcal{D}_\mathbf{l}$ such that $\mathbf{h}_\mathbf{l}$ is $C_\mathbf{l}$-real. Let us define

$$\mathcal{D}=\bigoplus_{\mathbf{l}\in\mathbb{L}} \mathcal{D}_\mathbf{l}, \quad T_t=\bigoplus_{\mathbf{l}\in\mathbb{L}} T_{\mathbf{l},t}, \quad C=\bigoplus_{\mathbf{l}\in\mathbb{L}} C_\mathbf{l}.$$

On $\mathcal{D}$ we define a symplectic form

$$\sigma(\varphi,\psi)=\sum_{\mathbf{l}\in\mathbb{L}} \mathrm{Im}\langle \varphi_\mathbf{l}, \psi_\mathbf{l}\rangle_{\mathcal{D}_\mathbf{l}},$$

where $\varphi=(\varphi_\mathbf{l})_\mathbf{l}\in\mathbb{L}\in\mathcal{D}$. Consider a state ω defined on the Weyl algebra $\mathfrak{M}(\mathcal{D},\sigma)$ by

$$\omega(W_\varphi)=\prod_{\mathbf{l}\in\mathbb{L}} \exp\left[-\frac{1}{4} \left\langle \varphi_\mathbf{l}, \coth\frac{\beta}{2}\mathbf{h}_\mathbf{l}\varphi_\mathbf{l} \right\rangle_{\mathcal{D}_l} \right]. \tag{4.1}$$

The state (4.1) is an α_t-KMS state (for α_t defined by T_t) at the inverse temperature β. The corresponding thermal process indexed by $\mathcal{D}_+=\bigoplus \mathbf{l}\in\mathbb{L}\mathcal{D}_{+,l}$ will be denoted by $\xi_\tau^{\beta,\mathbb{L}}$. The process $\xi_\tau^{\beta,\mathbb{L}}$ is a direct sum of the site processes $\xi_\tau^{\beta,\mathbf{l}}$, indexed by $\mathcal{D}_{+,\mathbf{l}}$, and its covariance is given by

$$\mathbb{E}\langle \xi_\tau^{\beta,\mathbb{L}},\varphi\rangle\langle \xi_\tau^{\beta,\mathbb{L}},\psi\rangle=\sum_{\mathbf{l}\in\mathbb{L}} \mathbb{E}\langle \xi_\tau^{\beta,\mathbf{l}},\varphi_\mathbf{l}\rangle\langle \xi_{\tau'}^{\beta,\mathbf{l}},\psi_\mathbf{l}\rangle. \tag{4.2}$$

From Proposition 3.4 and Eq. (4.2) follows that for $\varphi=(\varphi_l)_{l\in\mathbb{L}}$ such that

$$m(\varphi)=\sum_{\mathbf{l}\in\mathbb{L}} m_{\mathbf{l}}(\varphi_{\mathbf{l}})\leqslant\infty,$$

where $m_{\mathbf{l}}(\varphi_{\mathbf{l}})$ is the moment of the measure corresponding to the covariance of $\xi^{\beta,\mathbf{l}}$ (see Proposition 3.4), there exists a Hölder continuous version of the coordinate process $\langle\xi_\tau^{\beta,\mathbb{L}},\varphi\rangle = \sum_{\mathbf{l}\in\mathbb{L}}\langle\xi_\tau^{\beta,\mathbf{l}},\varphi_{\mathbf{l}}\rangle$.

Let A be a self-adjoint, non-negative operator on $\mathcal{D}$ such that $\oplus_{\mathbf{l}\in\mathbb{L}}\mathbf{h}_{\mathbf{l}}+A$ is essentially self-adjoint on $D(\oplus_{\mathbf{l}\in\mathbb{L}}\mathbf{h}_{\mathbf{l}})$. Define $\mathbf{h}_A=\overline{\oplus_{\mathbf{l}\in\mathbb{L}}\mathbf{h}_{\mathbf{l}}+A}$. The state

$$\omega_A(W_\varphi)=\exp\left[-\frac{1}{4}\left\langle\varphi,\frac{\mathbb{I}+e^{-\beta\mathbf{h}_A}}{\mathbb{I}-e^{-\beta\mathbf{h}_A}}\,\varphi\right\rangle\right]$$

is a KMS state with respect to the evolution defined by $T_t^A=e^{it\mathbf{h}_A}$. If $\mathbf{h}_A$ is C-real, there exists a thermal process $\xi_\tau^{\beta,A}$ indexed by $\mathcal{D}_+=\oplus_{\mathbf{l}\in\mathbb{L}}\mathcal{D}_{+,\mathbf{l}}$, with the covariance

$$\mathbb{E}\langle\xi_\tau^{\beta,A},\varphi\rangle\langle\xi_{\tau'}^{\beta,A},\psi\rangle=\left\langle\varphi,\frac{e^{-|\tau-\tau'|\mathbf{h}_A}+e^{-(\beta-|\tau-\tau'|)\mathbf{h}_A}}{\mathbb{I}-e^{-\beta\mathbf{h}_A}}\,\psi\right\rangle.$$

The law of this process is given by a centered Gaussian random field μ_A^β with covariance

$$\mathbb{E}^{\mu_A^\beta}\langle\Phi,\varphi\otimes f\rangle\langle\Phi,\psi\otimes g\rangle=\left\langle\varphi\otimes f,\left[\left(-\frac{d^2}{d\tau^2}\right)_{\text{per}}+\mathbf{h}_A\right]^{-1}\psi\otimes g\right\rangle,$$

where $(-d^2/d\tau^2)_{\text{per}}$ is a periodized version of the operator $-d^2/d\tau^2$. A similar conclusion is true for the ground state process.

Harmonic crystal model. Let $\mathbb{L}=\mathbb{Z}^d$ be a lattice consisting of points in $\mathbb{R}^d$ with all coordinates integer. To each $\mathbf{l}\in\mathbb{Z}^d$ we associate a copy of the complex plane $\mathbb{C}$ with a natural complex conjugation $z\to\overline{z}$ and a copy of an unitary group $u_1(t)=\exp(i/2)t$. By the direct sum construction we obtain the Hilbert space $\mathcal{D}=l^2(\mathbb{Z}^d)$ with the complex conjugation $C(z_{\mathbf{l}})_{\mathbf{l}\in\mathbb{Z}^d}=(\overline{z_{\mathbf{l}}})_{\mathbf{l}\in\mathbb{Z}^d}$ and the unitary group $T_t=\oplus_{\mathbf{l}\in\mathbb{Z}^d}u_l(t)$. Defining the KMS state by (4.1) and proceeding as above, we obtain a thermal process $\xi_\tau^{\beta,\mathbb{Z}^d}$ which is a direct sum of the periodized Ornstein–Uhlenbeck processes $\xi_\tau^{\beta,\mathbf{l}}$ with covariances

$$\mathbb{E}\xi_\tau^{\beta,\mathbf{l}}\xi_0^{\beta,\mathbf{l}'}=\frac{1}{2}\,\frac{e^{-|\tau|/2}+e^{-(\beta-|\tau|)/2}}{1-e^{-\beta/2}}\,\delta_{\mathbf{l}\mathbf{l}'},$$

where $|\tau|\leqslant\beta$

Now let A be a self-adjoint and non-negative operator on $l^2(\mathbb{Z}^d)$ with real matrix coefficients. Since A is C-real, $\mathbf{h}_A=1/2\mathbb{I}+A$ is also C-real, and we obtain a thermal process $\xi_\tau^{\beta,A}$ indexed by $l^2_{\mathbb{R}}(\mathbb{Z}^d)$. Its covariance is given by

$$\mathbb{E}\langle\xi_\tau^{\beta,A},(z_{\mathbf{l}})\rangle\langle\xi_0^{\beta,A},(z'_{\mathbf{l}})\rangle=\left\langle(z_{\mathbf{l}}),\frac{e^{-|\tau|\mathbf{h}_A}+e^{-(\beta-|r|)\mathbf{h}_A}}{\mathbb{I}-e^{-\beta\mathbf{h}_A}}\,(z'_{\mathbf{l}})\right\rangle_{l^2(\mathbb{Z}^d)}. \tag{4.3}$$

In the Gibbs state approach discussed in Refs. 46–49, the process $\xi_\tau^{\beta,A}$ can be obtained as a perturbation of the process $\xi_\tau^{\beta,\mathbb{Z}^d}$. The perturbation is defined as follows. Let

$$d\mu_0^\beta=\bigotimes_{\mathbf{l}\in\mathbb{Z}^d} d\mu_0^{\beta,\mathbf{l}},$$

where $d\mu_0^{\beta,\mathbf{l}}$ is the measure on trajectories of the periodic Ornstein–Uhlenbeck process $\xi_\tau^{\beta,\mathbf{l}}$. Then

$$d\mu^{\beta,A}((\omega_{\mathbf{l}})_{\mathbf{l}\in\mathbb{Z}^d}) = \lim_{\Lambda\uparrow\mathbb{Z}^d} \frac{1}{Z_A} \exp\left[-\int_{-\beta/2}^{\beta/2} \sum_{\mathbf{l},\mathbf{k}\in\Lambda} A_{\mathbf{lk}}\omega_{\mathbf{l}}(\tau)\omega_{\mathbf{k}}(\tau)\, d\tau \right] \cdot d\mu_0^{\beta}((\omega_{\mathbf{l}})_{\mathbf{l}\in\mathbb{Z}^d}),$$

$$Z_{\Lambda} = \int d\mu_0^{\beta}((\omega_{\mathbf{l}})_{\mathbf{l}\in\mathbb{Z}^d}) \exp\left[-\int_{-\beta/2}^{\beta/2} \sum_{\mathbf{l},\mathbf{k}\in\Lambda} A_{\mathbf{lk}}\omega_{\mathbf{l}}(\tau)\omega_{\mathbf{k}}(\tau) d\tau \right],$$

where Λ is a finite subset of $\mathbb{Z}^d$ and the limit is taken in the sense of Dobrushin–Landford–Rueke (DLR) equations.[50,51] Clearly it defines a measure on trajectories of the process $\xi_{\tau}^{\beta,A}$. In fact, the set of limiting Gibbs measures can contain also some nontranslationary invariant solutions,[52] which differ from those chosen above only by nonzero means. This is connected with the nontrivial kernel of the operator $d^2/d\tau^2+\mathbf{h}_A$. Using this and general results of Sec. III E we obtain the following:

Proposition 4.4: The modular structure of the KMS state corresponding to the harmonic crystal model with the Fock space Hamiltonian $d\Gamma(\mathbf{h}_A)$ formally given by

$$d\Gamma(\mathbf{h}_A) = '' \sum_{\mathbf{l}\in\mathbb{Z}^d} \left(-\frac{1}{2}\frac{d^2}{dx_{\mathbf{l}}^2} + \frac{1}{2} x_{\mathbf{l}}^2 \right) + \sum_{\mathbf{l},\mathbf{k}\in\mathbb{Z}^d} A_{\mathbf{lk}} x_{\mathbf{l}} x_{\mathbf{k}} '',$$

where $(A_{\mathbf{lk}}) = A \geqslant 0$, is determined by the thermal process $\xi_{\tau}^{\beta,A}$ with the covariance (4.3).

Remark: The result that the modular structure of the harmonic crystal model is stochastically determined seems to be new. For other aspects of this model, we refer to Ref. 53. Gibbsian perturbations of the Abelian sector were discussed recently in Refs. 48 and 49.

(Received 13 February 1998; accepted for publication 17 June 1998)

We consider a special class of C^*-systems containing asymptotically Abelian binary shifts and shifts of Temperley–Lieb algebras. We study Gibbs states for these systems corresponding to potentials with finite range interaction, and obtain the same results as the well-known Araki's results for a one-dimensional quantum lattice. In particular, it is proved that a Gibbs state in the infinite volume is a translation invariant KMS state having the exponential uniform clustering property. Entropic properties of the Gibbs states are also discussed. This allows us, in particular, to construct new examples of quantum K-systems. © *1998 American Institute of Physics.* [S0022-2488(98)01112-8]

I. INTRODUCTION

In Ref. 1, Araki studied a one-dimensional infinite quantum spin lattice system with a finite range interaction. He showed that the Gibbs state ϕ of the system in the infinite volume is a limit of local Gibbs states, is a factor state of the UHF algebra A corresponding to the quantum spin lattice system, is invariant under time and lattice translation, satisfies the KMS boundary condition, and has the exponential uniform clustering property.

Developing the transfer matrix technique in a fashion analogous to Ref. 2, Araki introduced an auxiliary operator $\mathcal{L}$ acting on A, and found an eigenstate ν for $\mathcal{L}$. It turned out that the Gibbs state ϕ is a perturbation of the state ν. To realize this approach, Araki developed the Tomonaga–Shwinger–Dyson perturbation theory to the case of UHF algebras (see Refs. 3 and 4 for a more detailed exposition and applications).

It is a natural problem to extend Araki's theory to a more general class of AF algebras. We would like to include in this class such important algebras as Temperley–Lieb algebras and asymptotically Abelian binary shifts. So we will consider quadruples $(A,\{A_{[n,m]}\},\tau,\gamma)$, where A is a unital C^*-algebra, $A_{[n,m]}$, $n,m\in\mathbb{Z}$, $n\leqslant m$, is a finite-dimensional subalgebra of A such that $A_{[n,m]}\subset A_{[n',m']}$ for $n'\leqslant n\leqslant m\leqslant m'$, $\cup_n A_{[-n,n]}$ is dense in A, τ is a faithful trace on A, and γ is a τ-preserving automorphism of A such that $\gamma(A_{[n,m]})=A_{[n+1,m+1]}$. Moreover, we suppose that the trace τ has some multiplicativity property, and the local algebras satisfy Popa's commuting square condition (see Sec. II). Nevertheless, there are difficulties in this way. For example, we cannot define an analog of Araki's operator $\mathcal{L}$ on the whole algebra A, since, in general, the algebra cannot be ''cut'' into two commuting pieces as in Ref. 1. Fortunately, it is possible to define such an operator on the subalgebra $A_{[0,\infty)}$ as in Ruelle's paper.[2] Then, basing on Araki's perturbation technique we can prove the existence of an eigenstate ν on $A_{[0,\infty)}$. The Gibbs state ϕ on A can be restored from this state ν. Again, as in Ref. 1, the Gibbs state is the limit of local Gibbs states, invariant under γ, satisfies the KMS boundary condition and has the exponential uniform clustering property. These results are proved in Sec. III.

The constructed Gibbs state is a σ_t-KMS state ($\beta=1$), where σ_t is the time evolution. For a one-dimensional quantum lattice it is a unique σ_t-KMS state (see Refs. 5 and 4). The same result holds for binary shifts, or for the C^*-tensor product of a binary shift and a quantum spin lattice system. To prove this, one can apply the same arguments as in Ref. 5, or Ref. 4 (see Remark III.13), but, in general, this problem apparently requires new arguments.

The present research has been undertaken to construct new examples of quantum Kolmogorov systems in the sense of Narnhofer and Thirring.[6] Indeed, let ϕ be a Gibbs state, π_ϕ the GNS

representation of A corresponding to ϕ. Then (M, ϕ, γ), where $M=\pi_\phi(A)''$, is a quantum K-system. We deduce this result in Sec. IV from the proved clustering property and from the sufficient condition for the K-property in our paper.[7]

In Sec. IV we also compute the mean entropy of a Gibbs state for certain C^*-dynamical systems. In particular, for a binary shift and for a Temperley–Lieb algebra of index $\leqslant 4$. It is a very interesting problem to investigate when this mean entropy is equal to the dynamical entropy $h_\phi(\gamma)$. But this problem has not been solved, even for a quantum spin lattice system[8] (see also Remark IV.7 below).

It is important to note that Hiai and Petz[9] considered quantum statistical thermodynamics in AF C^*-systems. They studied, in particular, such problems as the Gibbs conditions, the variational principle for states, their relations with the KMS conditions, and presented a lot of interesting examples. But Araki's approach to Gibbs states was not considered.

II. NOTATIONS AND EXAMPLES

We consider quadruples $(A,\{A_{[n,m]}\}_{n\leqslant m},\tau,\gamma)$, $n,m\in\mathbb{Z}$, where A is a unital C^*-algebra, $A_{[n,m]}$ is a finite-dimensional C^*-subalgebra of A such that $A_{[n',m']}\subset A_{[n'',m'']}$ for $n''\leqslant n'\leqslant m'\leqslant m''$, and $\cup_n A_{[-n,n]}$ is dense in A, τ a faithful trace of A, γ a τ-preserving automorphism of A such that $\gamma(A_{[n,m]})=A_{[n+1,m+1]}$. For any subset Λ of $\mathbb{Z}$, we denote by A_Λ the C^*-subalgebra of A generated by $A_{[k,n]}$, $[k,n]\subset\Lambda$, and write A_n instead of $A_{[n,n]}$.

Throughout the paper we suppose that the following conditions are satisfied.

Assumptions II.1:

(i) There exists $n_0\geqslant 0$ such that $A_{(-\infty,0]}$ and $A_{[n_0+1,\infty)}$ commute.

(ii) $\tau(xy)=\tau(x)\tau(y)$ for $x\in A_{(-\infty,0]}$, $y\in A_{[n_0+1,\infty)}$.

(iii) There exists a τ-preserving conditional expectation $\mathcal{E}:A_{[0,\infty)}\to A_{[1,\infty)}$, and $\mathcal{E}(A_{[0,n]})=A_{[1,n]}$ for any $n\geqslant 1$. Equivalently,

$$\begin{array}{ccc} A_{[0,n]} & \subset & A_{[0,n+1]} \\ \cup & & \cup \\ A_{[1,n]} & \subset & A_{[1,n+1]} \end{array}$$

is a commuting square[10,11] for any n.

Besides a one-dimensional quantum spin lattice system we have the following standard examples.

Example II.2. Automorphism θ_λ:[11]

Let $\lambda\in\{(4\cos^2(\pi/n))^{-1}\}_{n>3}\cup(0,\frac{1}{4}]$, A the C^*-algebra generated by projections e_n, $n\in\mathbb{Z}$, satisfying $e_ie_j=e_je_i$ for $|i-j|\geqslant 2$, and $e_ie_{i\pm1}e_i=\lambda e_i$, $A_{[n,m]}=C^*(e_n,e_{n+1},\ldots,e_m)$, τ the λ-Markov trace on A, i.e., $\tau(we_n)=\lambda\tau(w)$ for any $w\in A_{(-\infty,n-1]}$, $\gamma(e_n)=e_{n+1}$.

Example II.3. Canonical shift on the tower of relative commutants:[12]

Let M be a II_1 factor, $N\subset M$ its subfactor of finite index, $N\subset M\subset^{e_1}M_1\subset^{e_2}M_2\subset\cdots$ the Jones tower, $\cdots\subset^{e_{-2}}M_{-2}\subset^{e_{-1}}M_{-1}=N\subset^{e_0}M_0=M$ a tunnel, $A_{[n,m]}=M'_{2n}\cap M_{2m}$, $A=\overline{\cup_n A_{[-n,n]}}$, τ the restriction of the trace on $\cup_n M_n$. For any $n\in\mathbb{N}$, the triple $M_{-n}\subset M_n\subset M_{3n}$ is a basic construction in a canonical way. In particular, a (not necessarily τ-preserving) antiautomorphism $\gamma_n(x)=J_nx^*J_n$ of $M'_{-n}\cap M_{3n}$ is defined, where J_n is the canonical conjugation on $L^2(M_n)$. Then $\gamma(x)=\gamma_{n+1}(\gamma_n(x))$ for $x\in M'_{-n}\cap M_{3n}$.

Example II.4. Asymptotically Abelian binary shift:[13,14]

Let X be a nonempty finite subset of $\mathbb{N}$, $a(x)$ the characteristic function of X, A the C^*-algebra with unit generated by symmetries s_n, $n\in\mathbb{Z}$, satisfying $s_is_j=(-1)^{a(|i-j|)}s_js_i$, $A_{[n,m]}=C^*(s_n,s_{n+1},\ldots,s_m)$, $\tau(w)=0$ for any nonempty word w in s_n's, $\gamma(s_n)=s_{n+1}$.

It is worth noting that the C^*-tensor product of systems satisfying Assumptions II.1 also satisfies these assumptions.

By an interaction potential we mean a mapping $X\mapsto\Phi(X)\in A_X$ defined on finite subsets X of $\mathbb{Z}$ such that $\Phi(X)=\Phi(X)^*$, $\Phi(X+n)=\gamma^n(\Phi(X))$. We suppose that $\Phi(X)=0$ if X is not within an interval of length $r>0$. Following Araki, we denote by $U(\Lambda)$ the Hamiltonian for a finite interval Λ,

$$U(\Lambda)=\sum_{X\subset\Lambda}\Phi(X).$$

We write $U(a,b)$ instead of $U([a,b])$.

For a finite interval Λ, the local Gibbs state is

$$\phi_\Lambda(Q)=\frac{\tau(Qe^{-U(\Lambda)})}{\tau(e^{-U(\Lambda)})}.$$

III. EXISTENCE AND CLUSTERING PROPERTIES OF GIBBS STATES

Our main results in this section are as follows.

Theorem III.1:

(i) The limit $P(\Phi)=\lim_{b-a\to\infty}[1/(b-a)]\log\tau(e^{-U(a,b)})$ *exists and is finite.*

(ii) For any $Q\in A$, *there exists the limit* $\phi(Q)=\lim_{\substack{a\to-\infty\\ b\to+\infty}}\phi_{[a,b]}(Q)$. *Moreover, there exist* $C,q>0$ *such that*

$$|\phi_{[-n+a,b+n]}(Q)-\phi(Q)|\leqslant Ce^{-qn}\|Q\|,\quad for\quad Q\in A_{[a,b]},\quad n\in\mathbb{N}.$$

Theorem III.2: *The state* ϕ *is uniformly exponentially clustering, i.e., there exist* $C,q>0$, *such that*

$$|\phi(Q_1Q_2)-\phi(Q_1)\phi(Q_2)|\leqslant Ce^{-qn}\|Q_1\|\|Q_2\|,$$

for $Q_1\in A_{(-\infty,-n)}$, $Q_2\in A_{[n,\infty)}$, $n\in\mathbb{N}$.

We shall call the state ϕ the Gibbs state corresponding to the interaction potential $\Phi(X)$.

The proofs of Theorems follow closely the work by Araki.[1] We introduce an auxiliary operator $\mathcal{L}$ and found an eigenstate ν for this operator. Then the Gibbs state can be restored from ν. The main difference of our work from Araki's one is that the operator $\mathcal{L}$ cannot be defined on the whole algebra A, but only on $A_{[0,\infty)}$. So ν is a state on $A_{[0,\infty)}$, and the perturbation argument by Araki cannot be applied. Our arguments are closer to Ruelle's work[2] (see also Ref. 15).

Following Araki, for $Q\in A_{[0,\infty)}$, we define

$$\|Q\|_l=\inf_{Q_l\in A_{[0,l]}}\|Q-Q_l\|,$$

$$|||Q|||_{N,x}=\|Q\|+\sum_{n=N}^{\infty}\|Q\|_n x^n\quad(x>1,\ N\in\mathbb{N}),$$

$$A(x)=\{Q\in A_{[0,\infty)}|\,|||Q|||_{1,x}<\infty\}.$$

Then $A(x)$ is a Banach space with respect to the norm $|||\ |||_{1,x}$. Every $|||\ |||_{N,x}$ is an equivalent norm on $A(x)$. For $Q>0$, we also define

$$\alpha_l(Q)=\inf_{Q_l\in A_{[0,l]},Q_l>0}\|Q-Q_l\|\|Q_l^{-1}\|,$$

$$\alpha(Q)=\|Q\|\|Q^{-1}\|=\frac{\text{l.u.b. Spec }Q}{\text{g.l.b. Spec }Q}.$$

Lemma III.3: For $Q>0$, *we have the following:*

(i) $\alpha_l(Q)\leqslant[\alpha(Q)-1]/[\alpha(Q)+1]<1$;

(ii) there exists $Q_l\in A_{[0,l]}$, $Q_l>0$, *such that* $\alpha_l(Q)=\|Q-Q_l\|\|Q_l^{-1}\|$, *then*

$$(1-\alpha_l(Q))\alpha(Q)\leqslant\|Q\|\|Q_l^{-1}\|\leqslant(1+\alpha_l(Q))\alpha(Q);$$

(iii) if $\|Q\|_l\|Q^{-1}\|<1$, *then* $\alpha_l(Q)\leqslant\|Q\|_l\|Q^{-1}\|/(1-\|Q\|_l\|Q^{-1}\|)$;
(iv) $\|Q\|_l\|Q^{-1}\|\leqslant\alpha_l(Q)/[1-\alpha_l(Q)]$.

Proof: See Ref. 1, Lemma 3.9: It is worth only to note that if $\|Q\|_l\|Q^{-1}\|<1$, then, for $Q_l=Q_l^*\in A_{[0,l]}$, $\|Q-Q_l\|=\|Q\|_l$, we have $Q_l>0$. Indeed,

$$\|\|Q\|1-Q_l\|\leqslant\|\|Q\|1-Q\|+\|Q\|_l=\|Q\|-\|Q^{-1}\|^{-1}+\|Q\|_l<\|Q\|.$$

□

Let us also define

$$\Phi=\sum_{I\subset[0,r]}\frac{\Phi(I)}{n(I)}\quad\text{and}\quad H(I)=\sum_{n:[n,n+r]\subset I}\gamma^n(\Phi),$$

where $n(I)$ is the number of translates $I+a$ of I that are still in $[0,r]$. $H(a,b)=H([a,b])$ and $U(a,b)$ differ only near the two ends. More precisely, there exist $\Delta^-\in A_{[0,r]}$ and $\Delta^+\in A_{[-r,0]}$ such that, for $b-a>2r$, we have

$$U(a,b)=H(a,b)+\gamma^a(\Delta^-)+\gamma^b(\Delta^+).$$

For any subset $I\subset\mathbb{Z}$, the sequence $\mathrm{Ad}\exp(itH(I\cap[-n,n]))$ pointwise converges to a strongly continuous one-parameter automorphism group σ_t^I on A, and every $Q\in\cup_nA_{[-n,n]}$ is a σ_t^I-analytic element (see Ref. 1, Theorem 4.2, or Ref. 4, Theorem 6.2.4). We write σ_t instead of $\sigma_t^{\mathbb{Z}}$. For $Q\in\cup_nA_{[-n,n]}$, $\lambda\in\mathbb{R}$, let us also consider the perturbed dynamics $(\sigma_t^I)^Q$ (see Ref. 4, Section 5.4.1). These dynamics are related via a σ_t^I-cocycle Γ_t^Q. Following Araki, an analytic continuation of this cocycle at the point $t=-i\lambda$ is denoted by $E(\lambda Q;\lambda H(I))$,

$$E(\lambda Q;\lambda H(I))=1+\sum_{n=1}^{\infty}\int_0^1ds_1\int_0^{s_1}ds_2\cdots\int_0^{s_{n-1}}ds_n\;\sigma^I_{-i\lambda s_n}(\lambda Q)\cdots\sigma^I_{-i\lambda s_1}(\lambda Q),$$

(see Ref. 1, Definition 5.1, or Ref. 4, p. 149). If I is finite, then

$$E(\lambda Q;\lambda H(I))=e^{\lambda Q+\lambda H(I)}e^{-\lambda H(I)}.$$

Lemma III.4: There exist constants $q>0$ *and* $C_n>0$, $n\in\mathbb{N}$, *such that*

$$\|E(Q;\lambda H(I))\|\leqslant e^{C_n\|Q\|}$$

and

$$\|E(Q;\lambda H(I))-E(Q;\lambda H(I\cap[-N,n+N]))\|\leqslant C_n\frac{q^{[N/(r+n_0)]}}{(1+[N/(r+n_0)])!}e^{C_n\|Q\|},$$

for $Q\in A_{[0,n]}$, $n\geqslant r$, $N>0$, $|\lambda|\leqslant1$, $I\subset\mathbb{Z}$, *where* n_0 *is defined in Assumptions II.1.*

Proof: See Ref. 1, Theorem 4.2 and Lemma 5.2. We would only mention that if $[\gamma^{j_m}(\Phi),[\ldots,[\gamma^{j_1}(\Phi),Q]\cdots]]\neq\varnothing$ then $[j_k,j_k+r]$ has a nonempty intersection with

$$[-n_0,n+n_0]\cup\bigcup_{1\leqslant l<k}[j_l-n_0,j_l+r+n_0],$$

for $k=1,\ldots,m$. But $[j_k,j_k+r]\cap[a-n_0,b+n_0]\neq\varnothing$ iff $[j_k,j_k+r+n_0]\cap[a,b+n_0]\neq\varnothing$. So the estimates by Araki hold with the replacement of r by $r+n_0$. □

We define the transfer operator $\mathcal{L}:A_{[0,\infty)}\to A_{[0,\infty)}$ as follows: $\mathcal{L}(Q)=\gamma^{-1}\mathcal{E}(K^*QK)$, where $K=E(-\frac{1}{2}\Phi;-\frac{1}{2}H(1,\infty))$ and $\mathcal{E}:A_{[0,\infty)}\to A_{[1,\infty)}$ is the τ-preserving conditional expectation.

Lemma III.5:

(i) $\mathcal{L}$ *is a faithful completely positive mapping. Moreover, if* $Q\geqslant0$ *is invertible,* $\mathcal{L}(Q)$ *is invertible too.*

(ii) $\mathcal{L}^n(Q)=\gamma^{-n}\mathcal{E}_n(K_n^*QK_ne^{-H(0,n-n_0-1)})$, *where* $\mathcal{E}_n:A_{[0,\infty)}\to A_{[n,\infty)}$ *is the* τ*-preserving conditional expectation,*

$$K_n=\begin{cases} E\left(-\frac{1}{2}\sum_{j=0}^{n-1}\gamma^j(\Phi);-\frac{1}{2}H(n,\infty)\right), & n\leqslant r+n_0,\\ E(-\frac{1}{2}\gamma^{n-1}(\Psi);-\frac{1}{2}[H(0,n-n_0-1)+H(n,\infty)]), & n>r+n_0; \end{cases}$$

$$\Psi=\sum_{j=1-r-n_0}^{0}\gamma^j(\Phi).$$

Proof: We follow the proof of Lemma 6.3 in Ref. 1.

(i) is trivial, since $\mathcal{E}$ is faithful and K is invertible ($K^{-1}=E(\frac{1}{2}\Phi;\frac{1}{2}H(1,\infty))^*$).

(ii) Define $K_n'=K\gamma(K)\cdots\gamma^{n-1}(K)$. Then $\mathcal{L}^n(Q)=\gamma^{-n}\mathcal{E}_n(K_n'^*QK_n')$. Indeed, for $n=1$ it is true by definition. By induction,

$$\begin{aligned}\mathcal{L}^n(Q)&=\gamma^{-n+1}\mathcal{E}_{n-1}(K_{n-1}'^*\mathcal{L}(Q)K_{n-1}')\\&=\gamma^{-n+1}\mathcal{E}_{n-1}\gamma^{-1}\mathcal{E}((K\gamma(K_{n-1}'))^*QK\gamma(K_{n-1}'))\\&=\gamma^{-n}\mathcal{E}_n(K_n'^*QK_n'),\end{aligned}$$

since $\mathcal{E}_n|_{A_{[1,\infty)}}=\gamma\mathcal{E}_{n-1}\gamma^{-1}$ and $\mathcal{E}_n\mathcal{E}=\mathcal{E}_n$.

Using the identity $E(Q_1;Q_2+R)E(Q_2;R)=E(Q_1+Q_2;R)$, we obtain

$$K_n'=E\left(-\frac{1}{2}\sum_{j=0}^{n-1}\gamma^j(\Phi);-\frac{1}{2}H(n,\infty)\right)$$

$$\begin{aligned}(\text{for } n>r+n_0)&=E\left(-\frac{1}{2}\sum_{j=n-r-n_0}^{n-1}\gamma^j(\Phi);-\frac{1}{2}\left[\sum_{j=0}^{n-r-n_0-1}\gamma^j(\Phi)+H(n,\infty)\right]\right)\\&\quad\times E\left(-\frac{1}{2}\sum_{j=0}^{n-r-n_0-1}\gamma^j(\Phi);-\frac{1}{2}H(n,\infty)\right)\\&=E\left(-\frac{1}{2}\gamma^{n-1}(\Psi);-\frac{1}{2}[H(0,n-n_0-1)+H(n,\infty)]\right)\\&\quad\times E\left(-\frac{1}{2}H(0,n-n_0-1);-\frac{1}{2}H(n,\infty)\right)\\&=E\left(-\frac{1}{2}\gamma^{n-1}(\Psi);-\frac{1}{2}[H(0,n-n_0-1)+H(n,\infty)]\right)\\&\quad\times e^{-(1/2)H(0,n-n_0-1)},\end{aligned}$$

since $H(0,n-n_0-1)$ commute with $A_{[n,\infty)}$. It remains to note that $\mathcal{E}_n(xy)=\mathcal{E}_n(yx)$ for any $x\in A_{[0,n-n_0-1]}$ and $y\in A_{[0,\infty)}$ by Assumption II.1 (i). □

Lemma III.6: There exist constants $C,q>0$ such that, for $Q>0$,

(i) $\alpha(\mathcal{L}^n(Q))\leqslant C\alpha(Q)$;

(ii) $\alpha_l(\mathcal{L}^n(Q))\leqslant C(\alpha(Q)\delta_{l-r}+\alpha_{n+l}(Q))$, for $l\geqslant r$, where $\delta_{l-r}=q^{[(l-r+1)/(n_0+r)]}/(1+[(l-r+1)/(n_0+r)])!$ (see Lemma III.4);

(iii) if $|||Q|||_{M,x}\|Q^{-1}\|\leqslant a$, then $\alpha(\mathcal{L}^n(Q))\leqslant C$ for any $n\geqslant N(a,M,x)$ for a constant $N(a,M,x)$, depending on $a>0$, $x>1$, $M\in\mathbb{N}$.

Proof: See Ref. 1, Lemma 6.4. We give a proof to demonstrate that all the Assumptions II.1 are applied.

(i) Let K_n be as in Lemma III.5. By Lemma III.4, there exists a constant C such that $\|K_n\|$, $\|K_n^{-1}\|\leqslant C$.

Let $p_n=\tau(e^{-H(0,n-n_0-1)})$. Then, by Assumption II.1(ii), $\mathcal{E}_n(e^{-H(0,n-n_0-1)})=p_n1$, so that

$$\|(K_n^*QK_n)^{-1}\|^{-1}\leqslant\frac{1}{p_n}\,\mathcal{L}^n(Q)\leqslant\|K_n^*QK_n\|,$$

hence $\alpha(\mathcal{L}^n(Q))\leqslant C^4\alpha(Q)$.

(ii) Let $Q_{n+l}\in A_{[0,n+l]}$, $Q_{n+l}>0$, $\alpha_{n+l}(Q)=\|Q-Q_{n+l}\|\,\|Q_{n+l}^{-1}\|$ [Lemma III.3(ii)],

$$K_{(n,l)}=E(-\tfrac{1}{2}\gamma^{n-1}(\Psi);-\tfrac{1}{2}[H(0,n-n_0-1)+H(n,n+l)]),$$

$Q_l'=\gamma^{-n}\mathcal{E}_n(K_{(n,l)}^*Q_{n+l}K_{(n,l)}e^{-H(0,n-n_0-1)})$. By Assumption II.1(iii), $Q_l'\in A_{[0,l]}$. Let us compute $\|\mathcal{L}^n(Q)-Q_l'\|\,\|(Q_l')^{-1}\|$.

By Lemma III.4,

$$\|K_{(n,l)}\|,\|K_{(n,l)}^{-1}\|\leqslant C\quad\text{and}\quad\|K_n-K_{(n,l)}\|\leqslant C\delta_{l-r}.$$

Hence,

$$\|K_n^*QK_n-K_{(n,l)}^*QK_{(n,l)}\|\leqslant 2C^2\delta_{l-r}\|Q\|\quad\text{and}\quad\|K_{(n,l)}^*(Q-Q_{n+l})K_{(n,l)}\|\leqslant C^2\|Q-Q_{n+l}\|.$$

Being a completely positive unital mapping, $A_{[0,\infty)}\ni x\mapsto(1/p_n)\mathcal{E}_n(xe^{-H(0,n-n_0-1)})$ has norm one, so that

$$\|\mathcal{L}^n(Q)-Q_l'\|\leqslant p_nC^2(2\,\delta_{l-r}\|Q\|+\|Q-Q_{n+l}\|).\tag{1}$$

On the other hand, $K_{(n,l)}^*Q_{n+l}K_{(n,l)}\geqslant\|(K_{(n,l)}^*Q_{n+l}K_{(n,l)})^{-1}\|^{-1}\geqslant C^{-2}\|Q_{n+l}^{-1}\|^{-1}$. Hence

$$Q_l'\geqslant\frac{p_n}{C^2}\,\|Q_{n+l}^{-1}\|^{-1}.\tag{2}$$

Using (1) and (2), we obtain

$$\alpha_l(\mathcal{L}^n(Q))\leqslant\|\mathcal{L}^n(Q)-Q_l'\|\,\|(Q_l')^{-1}\|\leqslant C^4(2\,\delta_{l-r}\|Q\|\,\|Q_{n+l}^{-1}\|+\alpha_{n+l}(Q)).$$

Since $\|Q\|\,\|Q_{n+l}^{-1}\|\leqslant 2\alpha(Q)$ by Lemma III.3(i), (ii), the proof of (ii) is complete.

(iii) Let $Q_k\in A_{[0,k]}$, $Q_k>0$, $\|Q-Q_k\|\,\|Q_k^{-1}\|=\alpha_k(Q)$,

$$K_{n,l}=E(-\tfrac{1}{2}\gamma^{n-1}(\Psi);-\tfrac{1}{2}[H(n-l,n-n_0-1)+H(n,\infty)]),$$

$Q'=\gamma^{-n}\mathcal{E}_n(K_{n,l}^*Q_kK_{n,l}e^{-H(0,n-n_0-1)})$. Then, as in the proof of (ii), we conclude that, for a constant C depending only on the potential, we have $\|K_{n,l}\|$, $\|K_{n,l}^{-1}\|\leqslant C$ and

$$\|\mathcal{L}^n(Q)-Q'\|\,\|(Q')^{-1}\|\leqslant C(\alpha(Q)\,\delta_{l-r-n_0}+\alpha_k(Q)).\tag{3}$$

We denote the right-hand part of (3) by Δ. Then

$$\mathcal{L}^n(Q)\leqslant Q'+\|\mathcal{L}^n(Q)-Q'\|\leqslant Q'+\|\mathcal{L}^n(Q)-Q'\|\,\|(Q')^{-1}\|Q'\leqslant(1+\Delta)Q',$$

$$\mathcal{L}^n(Q)\geqslant Q'-\|\mathcal{L}^n(Q)-Q'\|\geqslant Q'-\|\mathcal{L}^n(Q)-Q'\|\,\|(Q')^{-1}\|Q'\geqslant(1-\Delta)Q',$$

so that

$$\alpha(\mathcal{L}^n(Q))\leqslant\frac{1+\Delta}{1-\Delta}\,\alpha(Q'),\quad\text{whenever }\Delta<1.\tag{4}$$

Since $|||Q|||_{M,x}\|Q^{-1}\|\leqslant a$, we have $\alpha(Q)\leqslant a$ and $\|Q\|_k\|Q^{-1}\|\leqslant ax^{-k}$ for $k\geqslant M$, hence [Lemma III.3(iii)] $\alpha_k(Q)\leqslant ax^{-k}/(1-ax^{-k})$. We see that we can choose $l\geqslant r+n_0$ and k such that $\Delta\leqslant\frac{1}{2}$ independently of Q. Let $N(a,M,x)=k+l+n_0+1$. Then, for $n\geqslant N$, $K_{n,l}$ and Q_k commute. If $p=\tau(Q_ke^{-H(0,n-n_0-1)})$, the mapping $y\mapsto(1/p)\mathcal{E}_n(Q_k^{1/2}yQ_k^{1/2}e^{-H(0,n-n_0-1)})$ is completely positive and unital, so that

$$\frac{1}{C^2}\leqslant\|(K_{n,l}^*K_{n,l})^{-1}\|^{-1}\leqslant\frac{1}{p}\,\mathcal{E}_n(K_{n,l}^*K_{n,l}Q_ke^{-H(0,n-n_0-1)})\leqslant\|K_{n,l}^*K_{n,l}\|\leqslant C^2,$$

hence $\alpha(Q')\leqslant C^4$. By virtue of this inequality, the inequality (4) and the choice of N, we obtain $\alpha(\mathcal{L}^n(Q))\leqslant 3C^4$. □

The operator $\psi\mapsto\psi(\mathcal{L}(1))^{-1}\psi\mathcal{L}$ is defined on the state space of $A_{[0,\infty)}$. By the Schauder theorem, there exists a state ν of $A_{[0,\infty)}$ such that $\nu\mathcal{L}=\lambda\nu$ with $\lambda=\nu(\mathcal{L}(1))>0$.

Let $L=\lambda^{-1}\mathcal{L}$.

Corollary III.7: The sequence $\{L^n\}_{n=1}^{\infty}$ is bounded.

Proof: First let $Q>0$ and $\alpha(Q)\leqslant 2$. By Lemma III.6(i), $\alpha(L^n(Q))=\alpha(\mathcal{L}^n(Q))\leqslant 2C$ for a constant C independent of Q. Then

$$\|L^n(Q)\|=\alpha(L^n(Q))\|L^n(Q)^{-1}\|^{-1}\leqslant 2C\nu(L^n(Q))=2C\nu(Q)\leqslant 2C\|Q\|.$$

For arbitrary $Q\geqslant 0$, let $Q'=Q+\|Q\|1$. Then $\alpha(Q')\leqslant 2$. Hence

$$\|L^n(Q)\|\leqslant\|L^n(Q')\|+\|Q\|\,\|L^n(1)\|\leqslant 6C\|Q\|.$$

So for any $Q\in A_{[0,\infty)}$, we have $\|L^n(Q)\|\leqslant 24C\|Q\|$. □

Proposition III.8: There exists an element $h\in\cap_{x>1}A(x)$ such that $h>0$, $\nu(h)=1$, $Lh=h$. Then

$$|||L^n(Q)-\nu(Q)h|||_{1,x}\leqslant C_xe^{-q_xn}|||Q|||_{1,x},\quad \textit{for any } Q\in A(x)$$

for constants C_x, $q_x>0$ depending on x.

Proof: See Lemmas 6.5, 7.5, 7.6 in Ref. 1.

Step 1. Existence of h.

Let C be chosen as in the formulation of Lemma III.6, and δ_l be as defined there. Let X be the norm closure of the convex hull of $\{L^n(1)\}_{n=1}^{\infty}$. The set X is L-invariant. We prove that X is compact.

Let $Y=\{Q\in A_{[0,\infty)}|\ \|Q\|\leqslant C,\ \|Q\|_l\leqslant C\delta_{l-r}/(1-C\delta_{l-r}),\ l\geqslant r\}$. The set Y is compact, since the compact ball of radius C in $A_{[0,l]}$ is a $2C\delta_{l-r}/(1-C\delta_{l-r})$-net for Y. X is a subset of Y. Indeed, it is enough to show that $L^n(1)\in Y$ for any n. We have

$$\|L^n(1)\|=\alpha(L^n(1))\|L^n(1)^{-1}\|^{-1}\leqslant\alpha(L^n(1))\nu(L^n(1))=\alpha(L^n(1))\leqslant C$$

and

$$\|L^n(1)\|_l\leqslant\frac{\alpha_l(L^N(1))}{1-\alpha_l(L^n(1))}\,\|L^n(1)^{-1}\|^{-1}\leqslant\frac{\alpha_l(L^n(1))}{1-\alpha_l(L^n(1))}\leqslant\frac{C\delta_{l-r}}{1-C\delta_{l-r}},$$

by Lemma III.6(i), (ii) and Lemma III.3(iv).

By the Schauder theorem, there exists $h\in X$ such that $Lh=h$. We have $h\geqslant 0$, $\nu(h)=1$, and $h\in\cap_{x>1}A(x)$, since $Y\subset\cap_{x>1}A(x)$. Since

$$L^n(1)\geqslant\frac{\|L^n(1)\|}{\alpha(L^n(1))}\geqslant\frac{\nu(L^n(1))}{C}=\frac{1}{C},$$

we have $h\geqslant C^{-1}$.

Step 2. Continuity of $L|_{A(x)}$.

Consider $Q=Q^*$, $|||Q|||_{1,x}\leqslant 1$. Let $Q'=2+Q$. Then $1\leqslant Q'\leqslant 3$ and $\|Q'\|_l=\|Q\|_l$ for any l. By Lemma III.6(i) we obtain $\alpha(L(Q'))\leqslant 3C$, and, as in Step 1, we have

$$\|L(Q')\|_l\leqslant\frac{\alpha_l(L(Q'))}{1-\alpha_l(L(Q'))}\,\nu(Q')\leqslant\frac{3}{2}\,(3C+1)\alpha_l(L(Q')),\tag{5}$$

where the latter inequality follows from Lemma III.3(i). By Lemma III.6(ii), for $l\geqslant r$,

$$\alpha_l(L(Q'))\leqslant C(3\delta_{l-r}+\alpha_{l+1}(Q')),$$

and by Lemma III.3(iii),

$$\alpha_{l+1}(Q')\leqslant\frac{\|Q'\|_{l+1}\|(Q')^{-1}\|}{1-\|Q'\|_{l+1}\|(Q')^{-1}\|}\leqslant\frac{\|Q'\|_{l+1}}{1-\|Q'\|_{l+1}}\leqslant\frac{\|Q'\|_{l+1}}{1-x^{-1}},$$

so that

$$\alpha_l(L(Q'))\leqslant C\left(3\delta_{l-r}+\frac{\|Q'\|_{l+1}}{1-x^{-1}}\right). \tag{6}$$

Using (5), (6), and $\Sigma_l\|Q'\|_l x^l\leqslant 1$, we obtain

$$\begin{aligned}|||L(Q')|||_{r,x}&=\|L(Q')\|+\sum_{l=r}^{\infty}\|L(Q')\|_l x^l\\&\leqslant 3\|L(1)\|+\frac{3}{2}(3C+1)\sum_{l=r}^{\infty}C\left(3\delta_{l-r}+\frac{\|Q'\|_{l+1}}{1-x^{-1}}\right)x^l\\&\leqslant 3\|L(1)\|+\frac{9C(3C+1)}{2}\sum_{l=r}^{\infty}\delta_{l-r}x^l+\frac{3C(3C+1)}{2(x-1)}.\end{aligned}$$

In particular, $|||L(1)|||_{r,x}<\infty$. Since $|||L(Q)|||_{r,x}\leqslant 2|||L(1)|||_{r,x}+|||L(Q')|||_{r,x}$, the continuity of $L|_{A(x)}$ is proved.

Step 3. Convergence proof.

Let C be chosen as in the formulation of Lemma III.6. Then we take

$$a\geqslant 4C,$$

and choose $M\in\mathbb{N}$ such that

$$2Cax^{-M}\leqslant\frac{1}{4},\quad Ca\delta_{l-r}\leqslant\frac{1}{4},\quad\text{for}\quad l\geqslant M,\quad 4C\sum_{l=M}^{\infty}\delta_{l-r}x^l\leqslant\frac{1}{4}.$$

Finally, we fix $N\in\mathbb{N}$ such that

$$8Cx^{-N}\leqslant\tfrac{1}{4}\quad\text{and}\quad N\geqslant N(a,M,x),$$

where $N(a,M,x)$ is as in the formulation of Lemma III.6(iii).

We define an auxiliary operator Λ on $A(x)$,

$$\Lambda(Q)=L^N(Q)-\frac{\nu(Q)}{2C}.$$

We state that

$$\text{if}\ \ Q>0,|||Q|||_{M,x}\|Q^{-1}\|\leqslant a,\quad\text{then}\ \ \Lambda(Q)>0,\quad |||\Lambda(Q)|||_{M,x}\|\Lambda(Q)^{-1}\|\leqslant a. \tag{7}$$

Suppose the statement is proved. Let $q_x=-(1/N)\log(1-1/2C)>0$. Then $\nu(\Lambda(Q))=(1-1/2C)\nu(Q)=e^{-q_xN}\nu(Q)$. In particular, for $\nu(Q)=0$, we have $\Lambda^n(Q)=L^{Nn}(Q)$.

Consider $Q=Q^*\in A(x)$, $|||Q|||_{M,x}\leqslant 1$, $\nu(Q)=0$. Define $Q_1=2+Q$, $Q_2=2$. Then $1\leqslant Q_1\leqslant 3$, $|||Q_1|||_{M,x}\|Q_1^{-1}\|\leqslant|||Q_1|||_{M,x}\leqslant 3\leqslant a$. By (7),

$$|||\Lambda^n(Q_1)|||_{M,x}\leqslant a\|\Lambda^n(Q_1)^{-1}\|^{-1}\leqslant a\,\nu(\Lambda^n(Q_1))=ae^{-q_xNn}\nu(Q_1)=2ae^{-q_xNn},$$

analogously $|||\Lambda^n(2)|||_{M,x}\leqslant 2ae^{-q_xNn}$, so that

$$|||L^{Nn}(Q)|||_{M,x}=|||\Lambda^n(Q)|||_{M,x}=|||\Lambda^n(Q_1)-\Lambda^n(Q_2)|||_{M,x}\leqslant 4ae^{-q_xNn}.$$

For arbitrary $k\in\mathbb{N}$ we obtain

$$|||L^k(Q)|||_{M,x}\leqslant|||L|||_{M,x}^{k-[k/N]N}4ae^{-q_x[k/N]N}\leqslant 4ae^{q_xN}(1+|||L|||_{M,x})^Ne^{-q_xk},$$

where $|||L|||_{M,x}$ is the norm of the operator L on the Banach space $(A(x),|||\ |||_{M,x})$ that is finite by Step 2. Let $\tilde{C}_x=4ae^{q_xN}(1+|||L|||_{M,x})^N$. Then, for $Q=Q^*\in A(x)$, we have

$$\begin{aligned}|||L^k(Q)-\nu(Q)h|||_{M,x}&=|||L^k(Q-\nu(Q)h)|||_{M,x}\\&\leqslant\tilde{C}_xe^{-q_xk}|||Q-\nu(Q)h|||_{M,x}\\&\leqslant\tilde{C}_x(1+|||h|||_{M,x})e^{-q_xk}|||Q|||_{M,x},\end{aligned}$$

so that, for arbitrary $Q\in A(x)$,

$$|||L^k(Q)-\nu(Q)h|||_{M,x}\leqslant 2\tilde{C}_x(1+|||h|||_{M,x})e^{-q_xk}|||Q|||_{M,x}.$$

It remains to prove (7). We have $\alpha(L^N(Q))\leqslant C$ by Lemma III.6(iii) and the choice of N. Hence

$$L^N(Q)\geqslant\frac{\|L^N(Q)\|}{\alpha(L^N(Q))}\geqslant\frac{\|L^N(Q)\|}{C}\geqslant\frac{\nu(Q)}{C}.$$

In particular, $\Lambda(Q)\geqslant\nu(Q)/2C>0$ and $[\nu(Q)/C]\|L^N(Q)^{-1}\|\leqslant 1$. Further,

$$\begin{aligned}\alpha(\Lambda(Q))&=\frac{\|L^N(Q)\|-\dfrac{\nu(Q)}{2C}}{\|L^N(Q)^{-1}\|^{-1}-\dfrac{\nu(Q)}{2C}}=\frac{\alpha(L^N(Q))-\dfrac{\nu(Q)}{2C}\|L^N(Q)^{-1}\|}{1-\dfrac{\nu(Q)}{2C}\|L^N(Q)^{-1}\|}\\&\leqslant\frac{\alpha(L^N(Q))}{1-\dfrac{1}{2}}=2\alpha(L^N(Q))\leqslant 2C\leqslant\frac{a}{2}\end{aligned}\tag{8}$$

and

$$\begin{aligned}\|\Lambda(Q)\|_l\|\Lambda(Q)^{-1}\|&=\|L^N(Q)\|_l\|\Lambda(Q)^{-1}\|\\&=\|L^N(Q)\|_l\left(\|L^N(Q)^{-1}\|^{-1}-\frac{\nu(Q)}{2C}\right)^{-1}\\&\leqslant 2\|L^N(Q)\|_l\|L^N(Q)^{-1}\|\leqslant\frac{2\alpha_l(L^N(Q))}{1-\alpha_l(L^N(Q))},\end{aligned}\tag{9}$$

where we have used Lemma III.3(iv) in the latter inequality. By Lemma III.6(ii),

$$\alpha_l(L^N(Q))\leqslant C(\alpha(Q)\delta_{l-r}+\alpha_{l+N}(Q)).\tag{10}$$

Since $\|Q\|_{l+N}\|Q^{-1}\|\leqslant ax^{-l-N}$ and $\alpha_{l+N}(Q)\leqslant\|Q\|_{l+N}\|Q^{-1}\|/(1-\|Q\|_{l+N}\|Q^{-1}\|)$ by Lemma III.3(iii), $C\alpha_{l+N}(Q)\leqslant C[ax^{-M}/(1-ax^{-M})]\leqslant\frac{1}{4}$. We also have $C\alpha(Q)\delta_{l-r}\leqslant Ca\,\delta_{l-r}\leqslant\frac{1}{4}$ for $l\geqslant M$, so that $\alpha_l(L^N(Q))\leqslant\frac{1}{2}$ for any $l\geqslant M$. Together with (9), this gives

$$\|\Lambda(Q)\|_l\|\Lambda(Q)^{-1}\|\leqslant 4\alpha_l(L^N(Q)).$$

Now it follows from (10) again that

$$\|\Lambda(Q)\|_l\|\Lambda(Q)^{-1}\|\leqslant 4C(\alpha(Q)\delta_{l-r}+\alpha_{l+N}(Q))$$
$$\leqslant 4Ca\,\delta_{l-r}+4C\,\frac{\|Q\|_{l+N}\|Q^{-1}\|}{1-ax^{-M}}\leqslant 4Ca\,\delta_{l-r}+8C\|Q\|_{l+N}\|Q^{-1}\|. \quad (11)$$

Finally, using (8), (11), and the choice of M and N, we obtain

$$|||\Lambda(Q)|||_{M,x}\|\Lambda(Q)^{-1}\|=\alpha(\Lambda(Q))+\sum_{l=M}^{\infty}\|\Lambda(Q)\|_l\|\Lambda(Q)^{-1}\|x^l$$
$$\leqslant\frac{a}{2}+4Ca\sum_{l=M}^{\infty}\delta_{l-r}x^l+8C\sum_{l=M}^{\infty}\|Q\|_{l+N}\|Q^{-1}\|x^l$$
$$\leqslant\frac{a}{2}+\frac{a}{4}+8Cax^{-N}\leqslant a.$$

□

Corollary III.9: For any $x>1$, there exist C_x, $q_x>0$, such that

$$|||L^{N+n}(Q)-\nu(Q)h|||_{1,x}\leqslant C_xe^{-q_xn}\|Q\|, \quad \forall Q\in A_{[0,N]}, \quad \forall n,N.$$

Proof: It is enough to prove that there exists a constant C_x independent of N such that $|||L^N(Q)|||_{1,x}\leqslant C_x\|Q\|$, $\forall Q\in A_{[0,N]}$. As in the proof of Proposition III.8, Step 2, it suffices to consider $Q\in A_{[0,N]}$, $1\leqslant Q\leqslant 3$. By the same arguments as given there, we have $\alpha(L^N(Q))\leqslant 3C$ and, for $l\geqslant r$,

$$\|L^N(Q)\|_l\leqslant\frac{3C(3C+1)}{2}\,(3\,\delta_{l-r}+\alpha_{l+N}(Q)).$$

But $\alpha_{l+N}(Q)=0$ for any $Q\in A_{[0,N]}$, $Q>0$, and we obtain

$$|||L^N(Q)|||_{1,x}\leqslant rx^{r-1}\|L^N(Q)\|+\sum_{l=r}^{\infty}\|L^N(Q)\|_lx^l\leqslant 3rx^{r-1}\|L^N\|+\frac{9C(3C+1)}{2}\sum_{l=r}^{\infty}\delta_{l-r}x^l.$$

From Corollary III.7, we conclude that the latter expression is bounded by a constant $\widetilde{C}_x$ independent of Q and N. □

Lemma III.10: The sequence $\{\nu\gamma^n\}_{n=1}^{\infty}$ converges to a state ϕ on $A_{[0,\infty)}$ in norm. Moreover, there exist C, $q>0$ such that $\|\phi-\nu\gamma^n\|\leqslant Ce^{-qn}$.

Proof: For n and N, $N+n_0<n$, let

$$K_{n-N,n}=E(-\tfrac{1}{2}\gamma^{n-N-1}(\Psi);-\tfrac{1}{2}[H(0,n-N-n_0-1)+H(n-N,n-n_0-1)]).$$

According to Lemma III.4, Corollary III.7, and Proposition III.8, there exist C, $q>0$ such that

$$\|K_{n-N,n}K_{n-N}^{-1}-1\|\leqslant Ce^{-qN},$$
$$\|L^n\|\leqslant C,$$
$$\|L^n(1)-h\|\leqslant Ce^{-qn},$$

where K_{n-N}'s are defined in Lemma III.5.

Since $\gamma^n(Q)$ and $K_{n-N,n}$ commute for any $Q\in A_{[0,\infty)}$, we have

$$L^{n-N}((K_{n-N,n}K_{n-N}^{-1})*\gamma^n(Q)K_{n-N,n}K_{n-N}^{-1})=\gamma^N(Q)L^{n-N}((K_{n-N,n}K_{n-N}^{-1})*K_{n-N,n}K_{n-N}^{-1}).$$

So

$$\|L^{n-N}(\gamma^n(Q))-\gamma^N(Q)L^{n-N}(1)\|\leqslant C\|\gamma^n(Q)-(K_{n-N,n}K_{n-N}^{-1})^*\gamma^n(Q)K_{n-N,n}K_{n-N}^{-1}\|$$
$$+C\|(K_{n-N,n}K_{n-N}^{-1})^*K_{n-N,n}K_{n-N}^{-1}-1\|\ \|Q\|\leqslant C'e^{-qN}\|Q\|,$$

where $C'=2C^2(2+C)$ (note that $\|K_{n-N,n}K_{n-N}^{-1}\|\leqslant 1+C$). Then

$$\|L^{n-N}(\gamma^n(Q))-\gamma^N(Q)h\|\leqslant C'e^{-qN}\|Q\|+\|L^{n-N}(1)-h\|\ \|Q\|\leqslant(C'e^{-qN}+Ce^{-q(n-N)})\|Q\|,$$

hence $|\nu(\gamma^n(Q))-\nu(\gamma^N(Q)h)|\leqslant(C'e^{-qN}+Ce^{-q(n-N)})\|Q\|$, and

$$\|\nu\gamma^n-\nu\gamma^m\|\leqslant 2C'e^{-qN}+Ce^{-q(n-N)}+Ce^{-q(m-N)},$$

for n, $m>N+n_0$. We see that the sequence $\{\nu\gamma^n\}_n$ converges. Denoting its limit by ϕ and letting $m\to\infty$ in the latter inequality, we obtain

$$\|\nu\gamma^n-\phi\|\leqslant 2C'e^{-qN}+Ce^{-q(n-N)}.$$

Taking $N=[\frac{1}{2}n]$, we obtain the desired. □

The state ϕ of $A_{[0,\infty)}$ is obviously γ-invariant. Hence there exists a unique γ-invariant state of A that, being restricted to $A_{[0,\infty)}$, coincides with ϕ. We denote this state by the same letter ϕ, and our aim is to prove that ϕ is the required Gibbs state.

First, we shall prove that ϕ satisfies the conclusion of Theorem III.2.

Proposition III.11: There exist C, $q>0$, such that

$$|\nu(Q_1Q_2)-\nu(Q_1)\nu(Q_2)|\leqslant Ce^{-qn}\|Q_1\|\ \|Q_2\|,$$

for $Q_1\in A_{[0,N]}$ and $Q_2\in A_{[N+n,\infty)}$ for any N, n.

Proof: Replacing Q_1 by $Q_1-\nu(Q_1)1$ we can suppose that $\nu(Q_1)=0$.

By the same arguments as in Lemma III.10, we can find C, q such that

$$\|L^{N+m}(Q_1Q_2)-\gamma^{-N-m}(Q_2)L^{N+m}(Q_1)\|\leqslant Ce^{-q(n-m)}\|Q_1\|\ \|Q_2\|,$$

for $m<n-n_0$. On the other hand, $\|L^{N+m}(Q_1)\|\leqslant Ce^{-qm}\|Q_1\|$ by Corollary III.9. Hence

$$\|L^{N+m}(Q_1Q_2)\|\leqslant C(e^{-qm}+e^{-q(n-m)})\|Q_1\|\ \|Q_2\|,$$

so that

$$|\nu(Q_1Q_2)|\leqslant C(e^{-qm}+e^{-q(n-m)})\|Q_1\|\ \|Q_2\|.$$

Taking $m=[\frac{1}{2}n]$ we obtain the required. □

Now we can prove that ϕ is uniformly exponentially clustering in the sense of Theorem III.2:

If C, q are chosen according to Proposition III.11 then, for $m>N>n$, $Q_1\in A_{[-N,-n]}$, $Q_2\in A_{[n,N]}$, we have

$$|\nu(\gamma^m(Q_1Q_2)-\nu(\gamma^m(Q_1))\nu(\gamma^m(Q_2))|\leqslant Ce^{-2qn}\|Q_1\|\ \|Q_2\|.$$

Letting $m\to\infty$, we obtain

$$|\phi(Q_1Q_2)-\phi(Q_1)\phi(Q_2)|\leqslant Ce^{-2qn}\|Q_1\|\ \|Q_2\|.$$

Lemma III.12: Let $\overline{Z}_n=\tau(e^{-H(0,n)-\gamma^n(\Delta^+)})$ and $\overline{\phi}_n(Q)=\overline{Z}_n^{-1}\tau(Qe^{-H(0,n)-\gamma^n(\Delta^+)})$ for $Q\in A_{[0,\infty)}$. Then

(i) $\lim_{n\to\infty}(1/n)\ \log\overline{Z}_n=\log\lambda$;

(ii) there exist C, $q>0$ such that

$$|\nu(Q)-\overline{\phi}_{n+N}(Q)|\leqslant Ce^{-qn}\|Q\|,\quad \forall Q\in A_{[0,N]},\quad \forall N,n.$$

Proof: See Lemma 8.1 in Ref. 1.

Let $Q\in A_{[0,N]}$. Proving (ii) we can suppose that $Q>0$ and $\alpha(Q)\leqslant 2$ as in Corollary III.7. For $n>m+r$, let

$$K_{N+m,N+n}=E(-\tfrac{1}{2}\gamma^{N+m-1}(\Psi);-\tfrac{1}{2}[H(0,N+m-n_0-1)+H(N+m,N+n)+\gamma^{N+n}(\Delta^+)]).$$

Then

$$e^{-(1/2)H(0,N+n)-(1/2)\gamma^{N+n}(\Delta^+)}=K_{N+m,N+n}e^{-(1/2)H(0,N+m-n_0-1)-(1/2)H(N+m,N+n)-(1/2)\gamma^{N+n}(\Delta^+)},$$

so that

$$\begin{aligned}\overline{\phi}_{N+n}(Q)&=\overline{Z}_{N+n}^{-1}\tau(K_{N+m,N+n}^*QK_{N+m,N+n}e^{-H(0,N+m-n_0-1)-H(N+m,N+n)-\gamma^{N+n}(\Delta^+)})\\&=\overline{Z}_{N+n}^{-1}\tau(\gamma^{-N-m}\mathcal{E}_{N+m}(K_{N+m,N+n}^*QK_{N+m,N+n}e^{-H(0,N+m-n_0-1)})e^{-H(0,n-m)-\gamma^{n-m}(\Delta^+)})\\&=\overline{Z}_{N+n}^{-1}\overline{Z}_{n-m}\overline{\phi}_{n-m}(\gamma^{-N-m}\mathcal{E}_{N+m}(K_{N+m,N+n}^*QK_{N+m,N+n}e^{-H(0,N+m-n_0-1)})).\end{aligned}$$

By Corollary III.9 and a version of Lemma III.4, there exist C, $q>0$ such that

$$\|K_{N+m,N+n}\|,\ \|K_{N+m}\|,\ \|K_{N+m}^{-1}\|\leqslant C,$$

$$\|L^{N+m}(Q)-\nu(Q)h\|\leqslant Ce^{-qm}\|Q\|,$$

$$\|K_{N+m}-K_{N+m,N+n}\|\leqslant Ce^{-q(n-m)}.$$

Let $p_{N+m}=\tau(e^{-H(0,N+m-n_0-1)})$. Then $x\mapsto p_{N+m}^{-1}\mathcal{E}_{N+m}(xe^{-H(0,N+m-n_0-1)})$, being a unital completely positive mapping, has norm one. From this observation, the choice of C, and Lemma III.5, we infer

$$\begin{aligned}&\|\gamma^{-N-m}\mathcal{E}_{N+m}(K_{N+m,N+n}^*QK_{N+m,N+n}e^{-H(0,N+m-n_0-1)})-\mathcal{L}^{N+m}(Q)\|\\&\quad\leqslant p_{N+m}\|K_{N+m,N+n}^*QK_{N+m,N+n}-K_{N+m}^*QK_{N+m}\|\leqslant p_{N+m}2C^2e^{-q(n-m)}\|Q\|,\end{aligned}$$

and $\mathcal{L}^{N+m}(Q)\geqslant p_{N+m}\|K_{N+m}^{-1}\|^{-2}\|Q^{-1}\|^{-1}$, so that $\|\mathcal{L}^{N+m}(Q)^{-1}\|\leqslant p_{N+m}^{-1}C^2\|Q^{-1}\|$.

Hence

$$\begin{aligned}&\|\lambda^{-N-m}\gamma^{-N-m}\mathcal{E}_{N+m}(K_{N+m,N+n}^*QK_{N+m,N+n}e^{-H(0,N+m-n_0-1)})-L^{N+m}(Q)\|\|L^{N+m}(Q)^{-1}\|\\&\quad\leqslant 2C^4e^{-q(n-m)}\alpha(Q)\leqslant 4C^4e^{-q(n-m)}.\end{aligned}$$

Applying $\overline{\phi}_{n-m}$, we obtain

$$\begin{aligned}&|\lambda^{-N-m}\overline{Z}_{N+n}\overline{Z}_{n-m}^{-1}\overline{\phi}_{N+n}(Q)-\overline{\phi}_{n-m}(L^{N+m}(Q))|\\&\quad\leqslant 4C^4e^{-q(n-m)}\|L^{N+m}(Q)^{-1}\|^{-1}\leqslant 4C^4e^{-q(n-m)}\nu(L^{N+m}(Q))\leqslant 4C^4e^{-q(n-m)}\|Q\|.\end{aligned}$$

Hence

$$|\lambda^{-N-m}\overline{Z}_{N+n}\overline{Z}_{n-m}^{-1}\overline{\phi}_{N+n}(Q)-\nu(Q)\overline{\phi}_{n-m}(h)|\leqslant(4C^4e^{-q(n-m)}+Ce^{-qm})\|Q\|. \tag{12}$$

In particular,

$$|\lambda^{-N-m}\overline{Z}_{N+n}\overline{Z}_{n-m}^{-1}-\overline{\phi}_{n-m}(h)|\leqslant 4C^4e^{-q(n-m)}+Ce^{-qm}. \tag{13}$$

Having fixed $n-m$ sufficiently large, we see from $\|\underline{h}^{-1}\|^{-1}\leqslant\overline{\phi}_{n-m}(h)\leqslant\|h\|$ and the latter inequality that the sequence $\{-(N+n)\log\lambda+\log Z_{N+n}\}_n$ is bounded. In particular, $\lim_{n\to\infty}n^{-1}\log Z_n=\log\underline{\lambda}$. So we have proved (i).

Multiplying (13) by $\phi_{N+n}(Q)$ we also deduce from (12) and (13) that

$$|\overline{\phi}_{N+n}(Q)-\nu(Q)|\leqslant 2(4C^4e^{-q(n-m)}+Ce^{-qm})\|Q\|\|h^{-1}\|.$$

Taking $m=[\frac{1}{2}n]$, we obtain (ii). □

Proof of Theorem III.1: Let $Q\in A_{[a,b]}$,

$$\begin{aligned}\phi_{[-n+a,b+n]}(Q)&=\frac{\tau(Qe^{-U(-n+a,b+n)})}{\tau(e^{-U(-n+a,b+n)})}\\&=\frac{\tau(\gamma^{n-a}(Q)e^{-U(0,b-a+2n)})}{\tau(e^{-U(0,b-a+2n)})}\\&=\frac{\overline{\phi}_{b-a+2n}(\Delta^*_{b-a+2n}\gamma^{n-a}(Q)\Delta_{b-a+2n})}{\overline{\phi}_{b-a+2n}(\Delta^*_{b-a+2n}\Delta_{b-a+2n})},\end{aligned}$$

where $\overline{\phi}_{b-a+2n}$ is introduced in Lemma III.12,

$$\Delta_{b-a+2n}=E(-\tfrac{1}{2}\Delta^-;-\tfrac{1}{2}[H(0,b-a+2n)+\gamma^{b-a+2n}(\Delta^+)]).$$

Let C, q be chosen as in Lemma III.10, Proposition III.11 and Lemma III.12. By a version of Lemma III.4, we can also suppose that

$$\|\Delta_m\|,\|\Delta_m^{-1}\|\leqslant C \quad\text{and}\quad \|\Delta_m-\Delta_k\|\leqslant Ce^{-q\,\min\{m,k\}}.$$

We have the following inequalities ($m<n-n_0$):

$$|\overline{\phi}_{b-a+2n}(\Delta^*_{b-a+2n}\gamma^{n-a}(Q)\Delta_{b-a+2n})-\overline{\phi}_{b-a+2n}(\gamma^{n-a}(Q)\Delta^*_m\Delta_m)|\leqslant 2C^2e^{-qm}\|Q\|, \quad (14)$$

since $\gamma^{n-a}(Q)$ and Δ_m commute;

$$|\overline{\phi}_{b-a+2n}(\gamma^{n-a}(Q)\Delta^*_m\Delta_m)-\nu(\gamma^{n-a}(Q)\Delta^*_m\Delta_m)|\leqslant C^3e^{-qn}\|Q\|, \quad (15)$$

by Lemma III.12,

$$|\nu(\gamma^{n-a}(Q)\Delta^*_m\Delta_m)-\nu(\gamma^{n-a}(Q))\nu(\Delta^*_m\Delta_m)|\leqslant C^3e^{-q(n-m)}\|Q\|, \quad (16)$$

by Proposition III.11,

$$|\nu(\gamma^{n-a}(Q))\nu(\Delta^*_m\Delta_m)-\phi(Q)\nu(\Delta^*_m\Delta_m)|\leqslant C^3e^{-qn}\|Q\|, \quad (17)$$

by Lemma III.10,

$$|\phi(Q)\nu(\Delta^*_m\Delta_m)-\phi(Q)\overline{\phi}_{b-a+2n}(\Delta^*_m\Delta_m)|\leqslant C^3e^{-q(b-a+2n-m)}\|Q\|\leqslant C^3e^{-qn}\|Q\|, \quad (18)$$

by Lemma III.12. Finally,

$$|\phi(Q)\overline{\phi}_{b-a+2n}(\Delta^*_m\Delta_m)-\phi(Q)\overline{\phi}_{b-a+2n}(\Delta^*_{b-a+2n}\Delta_{b-a+2n})|\leqslant 2C^2e^{-qm}\|Q\|, \quad (19)$$

by the property of Δ_m's. Summing the inequalities (14)–(19), we obtain

$$\begin{aligned}&|\overline{\phi}_{b-a+2n}(\Delta^*_{b-a+2n}\gamma^{n-a}(Q)\Delta_{b-a+2n})-\phi(Q)\overline{\phi}_{b-a+2n}(\Delta^*_{b-a+2n}\Delta_{b-a+2n})|\\&\quad\leqslant\tilde{C}(e^{-qn}+e^{-qm}+e^{-q(n-m)}),\end{aligned}$$

for a constant $\tilde{C}$, depending only on the potential.

Since

$$|\overline{\phi}_{b-a+2n}(\Delta^*_{b-a+2n}\Delta_{b-a+2n})|\geqslant\|(\Delta^*_{b-a+2n}\Delta_{b-a+2n})^{-1}\|^{-1}\geqslant\frac{1}{C^2},$$

we have

$$|\phi_{[-n+a,b+n]}(Q)-\phi(Q)|\leqslant\tilde{C}C^2(e^{-qn}+e^{-qm}+e^{-q(n-m)}).$$

Taking $m=[\frac{1}{2}n]$, we obtain (ii). Since

$$\tau(e^{-U(a,b)})=\overline{Z}_{b-a}\overline{\phi}_{b-a}(\Delta^*_{b-a}\Delta_{b-a}),$$

$1/C^2\leqslant\overline{\phi}_{b-a}(\Delta^*_{b-a}\Delta_{b-a})\leqslant C^2$ and $(1/n)\log\overline{Z}_n\to\log\lambda$, we have (i). □

Remark III.13: The Gibbs state ϕ is a σ_t-KMS state ($\beta=1$). It is known that for a one-dimensional quantum lattice this is a unique σ_t-KMS state (see Ref. 5, or Ref. 4). The same result holds for binary shifts (Example II.4). Indeed, by Refs. 16 and 17, there exist $p,k\in\mathbb{N}$ such that $A_{[0,k+pn]}$ is a full matrix algebra for any $n\in\mathbb{N}$. Then one can apply Ref. 5.

IV. ENTROPIC PROPERTIES OF GIBBS STATES

In the sequel, ϕ denotes a Gibbs state on $(A,\{A_{\{n,m\}}\}_{n\leqslant m},\tau,\gamma)$ corresponding to an interaction, $\Phi(X)$.

Theorem IV.1: *Let $M=\pi_\phi(A)''$. Then (M,ϕ,γ) is an entropic K-system.*

Proof: Let M_0 be the W^*-subalgebra of M generated by $\pi_\phi(A_{(-\infty,0]})$. Using Theorem III.2, one concludes that $\cap_n\gamma^n(M_0)=\mathbb{C}1$. Hence (M,ϕ,γ) is an entropic K system by Ref. 7, Theorem 3.1. □

Corollary IV.2: If $\pi_\phi(A)\neq\mathbb{C}1$, then $h_\phi(\gamma)>0$. □

Corollary IV.3: For all the examples of Sec. II we have $0<h_\phi(\gamma)<\infty$.

Proof: Let d_n be the tracial dimension of $A_{[1,n]}$, i.e., the dimension of a maximal Abelian subalgebra in $A_{[1,n]}$. Then

$$h_\phi(\gamma)\leqslant\liminf_{n\to\infty}\frac{S(\phi|_{A_{[1,n]}})}{n}\leqslant\sup_n\frac{\log d_n}{n}.$$

So to prove the finiteness it suffices to show that $\sup_n(1/n)\log d_n<\infty$.

It is obvious for binary shifts (Example II.4), since $\dim A_{[1,n]}=2^n$. For the automorphism θ_λ (Example II.2) and for the canonical shift on the tower of relative commutants (Example II.3) we note that the tracial dimension of $M'\cap M_n$ does not exceed $[M_n:M]=[M:N]^n$.[18]

To prove that the entropy is nonzero, we have to show that each of the algebras under consideration has no ideals of codimension one. The algebra of a binary shift is simple as well as the algebra of relative commutants corresponding to a finite depth inclusion. In general, an algebra of higher relative commutants can be nonsimple. Nevertheless, it always contains a Temperley–Lieb algebra that has no ideals of codimension one. □

Next, we shall discuss mean entropy. First we need a form of the Gibbs condition (called the Gibbs condition in the strong sense in Ref. 9).

Proposition IV.4: For a finite interval $\Lambda=[k,l]\subset\mathbb{Z}$, let $W(\Lambda)$ denote the surface energy, i.e.,

$$W(\Lambda)=\sum_{\substack{X:\\ X\cap\Lambda\neq\varnothing\\ X\cap\Lambda^c\neq\varnothing}}\Phi(X)+\sum_{\substack{X\subset\Lambda^c:\\ X\cap([k-n_0,k-1]\cup[l+1,l+n_0])\neq\varnothing}}\Phi(X).$$

Then, for the perturbed state $\phi^{W(\Lambda)}$ (see, for example, Ref. 4, Section 5.4.1), we have

$$\phi^{W(\Lambda)}(ab)=\phi_\Lambda(a)\phi^{W(\Lambda)}(b),\quad\forall a\in A_\Lambda,\quad\forall b\in A_{(-\infty,k-n_0)\cup(l+n_0,\infty)}.$$

Proof: Let $K=E(\frac{1}{2}W(\Lambda);-\frac{1}{2}U(\mathbb{Z}))$,

$$K_n=E(\tfrac{1}{2}W(\Lambda);-\tfrac{1}{2}U(-n,n))=e^{(1/2)W(\Lambda)-(1/2)U(-n,n)}e^{(1/2)U(-n,n)}.$$

Then K and K_n are invertible, K_n converges to K in norm, and

$$\phi^{W(\Lambda)}=\frac{\phi(K^*\cdot K)}{\phi(K^*K)},\quad \phi^{W(\Lambda)}_{[-n,n]}=\frac{\phi_{[-n,n]}(K_n^*\cdot K_n)}{\phi_{[-n,n]}(K_n^*K_n)}.$$

Since $\phi_{[-n,n]}$ pointwise converges to ϕ, we see that $\phi^{W(\Lambda)}_{[-n,n]}$ pointwise converges to $\phi^{W(\Lambda)}$. For n sufficiently large, we have

$$\begin{aligned}\phi^{W(\Lambda)}_{[-n,n]}(ab)&=\frac{\tau(abe^{-U(-n,n)+W(\Lambda)})}{\tau(e^{-U(-n,n)+W(\Lambda)})}\\&=\frac{\tau(abe^{-U(\Lambda)}e^{-U([-n,k-n_0-1]\cup[l+n_0+1,n])})}{\tau(e^{-U(-n,n)+W(\Lambda)})}\\&=\frac{\tau(ae^{-U(\Lambda)})\tau(be^{-U([-n,k-n_0-1]\cup[l+n_0+1,n])})}{\tau(e^{-U(-n,n)+W(\Lambda)})}\\&=\frac{\tau(ae^{-U(\Lambda)})}{\tau(e^{-U(\Lambda)})}\cdot\frac{\tau(be^{-U(\Lambda)}e^{-U([-n,k-n_0-1]\cup[l+n_0+1,n])})}{\tau(e^{-U(-n,n)+W(\Lambda)})}\\&=\phi_\Lambda(a)\phi^{W(\Lambda)}_{[-n,n]}(b).\end{aligned}$$

□

With the help of the Gibbs condition the mean entropy is computed in a standard way (see Refs. 4 and 9). Namely, we have the following.

Corollary IV.5: Let P_n be the density operator for $\tau|_{A_{[1,n]}}$. Then

$$\lim_{n\to\infty}\frac{1}{n}\,(\phi(\log P_n)+S(\phi|_{A_{[1,n]}}))=\phi(\Phi)+P(\Phi)=\phi(E_\Phi)+P(\Phi),$$

where $E_\Phi=\Sigma_{X\ni 0}\Phi(X)/|X|$. In particular, the mean entropy $s(\phi)=\lim_n(1/n)S(\phi|_{A_{[1,n]}})$ exists iff the limit $\lim_n(1/n)\phi(\log P_n)$ exists.

Proof: Let Q_n be the density operator for $\phi|_{A_{[1,n]}}$. The operator $[e^{-U(1,n)}/\tau(e^{-U(1,n)})]P_n$ is the density operator for $\phi_{[1,n]}|_{A_{[1,n]}}=\phi^{W(1,n)}|_{A_{[1,n]}}$. Then by Ref. 4, p. 278,

$$0\leqslant \mathrm{Tr}_{A_{[1,n]}}\left(Q_n\left(\log Q_n-\log\left(\frac{e^{-U(1,n)}}{\tau(e^{-U(1,n)})}\,P_n\right)\right)\right)\leqslant S(\phi^{W(1,n)},\phi)\leqslant 2\|W(1,n)\|,$$

so that

$$0\leqslant -S(\phi|_{A_{[1,n]}})-\phi(\log P_n)+\phi(U(1,n))+\log\,\tau(e^{-U(1,n)})\leqslant 2\|W(1,n)\|.$$

Since $(1/n)\phi(U(1,n))\to\phi(\Phi)=\phi(E_\Phi)$, $(1/n)\log\tau(e^{-U(1,n)})\to P(\Phi)$, and the sequence $\{W(1,n)\}_n$ is bounded, we obtain the desired. □

Corollary IV.6: The mean entropy exists for each of the following cases:

(1) the automorphism θ_λ, $\lambda\geqslant\frac{1}{4}$,

$$s(\phi)=\phi(E_\Phi)+P(\Phi)-\tfrac{1}{2}\log\lambda;$$

(2) the canonical shift on the tower of relative commutants corresponding to a subfactor of finite depth,

$$s(\phi)=\phi(E_\Phi)+P(\Phi)+\log[M:N];$$

(3) a binary shift,

$$s(\phi)=\phi(E_\Phi)+P(\Phi)+\tfrac{1}{2}\log 2.$$

Proof: For all these systems the limit $\lim_n(1/n)\log P_n$ exists in norm. The result is well known for the systems in (1) and (2) (see, e.g., Ref. 9, Examples 1.3, 1.4). Concerning binary shifts the sequence $\{A_{[1,n]}\}_n$ is periodic.[17] Hence, the limit $\lim_n -(1/n)\log P_n$ exists, is scalar, and equals the entropy $h_\tau(\gamma)$ of γ with respect to τ.[19] This entropy is equal to $\frac{1}{2}\log 2$.[19] □

Remark IV.7: It is not known whether the mean entropy equals the dynamical entropy, even for a quantum spin lattice system. But such an equality is possible. This is the case when an interaction potential lies in the diagonal (then, by the general theory,[8] the dynamical entropy coincides with entropy of the restriction of the automorphism to the diagonal). A bit less trivial example can be obtained as follows.

Suppose an interaction potential on a one-dimensional quantum lattice has the property $\sigma_t(A_0)\subset A_{[-n,n]}$ for some $n\in\mathbb{N}$. Then it is easy to see that $h_\phi(\gamma)=s(\phi)$ (in fact, the state ϕ is n-Markov, i.e., it would be Markov if we consider A as a quantum lattice system with the one-site algebra $A_{[0,n-1]}$,[20] and we can refer to Ref. 21; see also Ref. 7). One can construct potentials with such a property, but that do not lie in the diagonal. For example, we can choose self-adjoint a_0, a_1, $b\in \mathrm{Mat}_d(\mathbb{C})$, $d\geqslant 3$, such that a_0 commutes with a_1 and b, but a_1 and b do not commute. Define $\Phi(\{0\})=b$, $\Phi(\{0,1\})=a_0\otimes a_1$, $\Phi(X)=0$ for $|X|\geqslant 3$. Then $\sigma_t(A_0)\subset A_{[-1,1]}$, but the centralizer A^σ does not contain any diagonal of A_0.

Matrix elements for a generalized spiked harmonic oscillator

Richard L. Hall, Nasser Saad,[a] and Attila B. von Keviczky
Department of Mathematics and Statistics, Concordia University, 1455 de Maisonneuve Boulevard West, Montréal, Québec H3G 1M8, Canada

(Received 12 June 1998; accepted for publication 8 July 1998)

Closed form expressions for the singular-potential integrals $\langle m|x^{-\alpha}|n\rangle$ are obtained with respect to the Gol'dman and Krivchenkov eigenfunctions for the singular potential Bx^2+A/x^2, $B>0$, $A\geqslant 0$. The formulas obtained are generalizations of those found earlier by use of the odd solutions of the Schrödinger equation with the harmonic oscillator potential [Aguilera-Navarro *et al.*, J. Math. Phys. **31**, 99 (1990)]. © *1998 American Institute of Physics.* [S0022-2488(98)00812-3]

I. INTRODUCTION

In 1990 Aguilera-Navarro *et al.*[1] employed a perturbative scheme to provide a variational analysis for the lowest eigenvalue of the Schrödinger operator,

$$H=-\frac{d^2}{dx^2}+x^2+\frac{\lambda}{x^\alpha},\quad 0\leqslant x<\infty,$$

where α is a positive constant. Writing $H\equiv H_0+\lambda V$ with H_0 standing for the harmonic oscillator Hamiltonian and $V=x^{-\alpha}$, Aguilera-Navarro *et al.*[1] used the basis set

$$\psi_n(x)=A_n e^{-x^2/2}H_{2n+1}(x),\quad A_n^{-2}=4^n(2n+1)\Gamma(1/2),\quad n=0,1,2,..., \tag{1}$$

constructed from the normalized solutions of $H_0\psi=E\psi$ to evaluate the matrix elements of H. They found that

$$H_{m+1,n+1}\equiv(3+4n)\,\delta_{m,n}+\lambda\langle m|x^{-\alpha}|n\rangle,\quad m,n=0,1,2,...,N-1, \tag{2}$$

where

$$\langle m|x^{-\alpha}|n\rangle=(-1)^{n+m}\,\frac{\sqrt{(2n+1)!(2m+1)!}}{2^{n+m}n!m!}\sum_{k=0}^{m}(-1)^k\binom{m}{k}\,\frac{\Gamma(k+(3-\alpha)/2)\Gamma(n-k+\alpha/2)}{\Gamma(k+3/2)\Gamma(-k+\alpha/2)}. \tag{3}$$

Our aim in this article is to extend these results to treat the more general spiked harmonic oscillator Hamiltonian,

$$H=-\frac{d^2}{dx^2}+Bx^2+\frac{A}{x^2}+\frac{\lambda}{x^\alpha},\quad B>0,\quad A\geqslant 0. \tag{4}$$

The particular case of $A=0$ and $B=1$ allows us, of course, to recover the results of Aguilera-Navarro *et al.*[1] as a special case. The existence of all the exact eigenfunctions for a problem with a singular potential is the principal motivation for the present work: we expect that such a set of functions will be more effective for the analysis of other singular problems than are the Hermite functions generated, as they are, by the nonsingular harmonic-oscillator potential x^2.

The article is organized as follows. In Sec. II we provide an orthonormal set of functions that we use to compute the matrix elements of the Hamiltonian (4). In Sec. III we prove that this set of

[a]Present address: Department of Mathematics, Faculty of Science, Notre Dame University, Beirut, Lebanon.

 © 1998 American Institute of Physics

functions is complete in the sense that it is a basis for $L^2(0,\infty)$. We then compute the matrix elements using this basis in Sec. IV. In Sec. V the comparison with the result of Aguilera-Navarro *et al.*[1] are presented for the special case $B=1$ and $A=0$, where we shall point out some errors in their value for the matrix element $\langle \psi_3|x^{-\alpha}|\psi_3\rangle$ as quoted in the appendix of Ref. 1.

II. AN ORTHONORMAL BASIS

Gol'dman and Krivchenkov[2] have provided a clear description of the exact solutions of the following one dimensional Schrödinger equation (in units $\hbar=2m=1$),

$$-\psi''+V_0\left(\frac{a}{x}-\frac{x}{a}\right)^2\psi=E_n\psi, \quad x\in[0,\infty), \tag{5}$$

with ψ satisfying the Dirichlet boundary condition $\psi(0)=0$. They showed that the energy spectrum in terms of the parameters V_0 and a is given by

$$E_n=\frac{4}{a}\sqrt{V_0}\left\{n+\frac{1}{2}+\frac{1}{4}\left(\sqrt{1+4V_0a^2}-2a\sqrt{V_0}\right)\right\}. \tag{6}$$

To simplify notation we introduce the parameters $B=V_0a^{-2}$ and $A=V_0a^2$, and obtain thereby an exact solution to the Schrödinger equation with the singular potential

$$V(x)=Bx^2+\frac{A}{x^2}, \quad B>0, \quad A\geqslant 0, \tag{7}$$

where the energy spectrum is now given in terms of the parameters A and B by

$$E_n=\sqrt{B}(4n+2+\sqrt{1+4A}), \quad n=0,1,2,\ldots. \tag{8}$$

The wave functions have the form

$$\langle x|n\rangle\equiv\psi_n(x)=C_nx^{(1/2)(1+\sqrt{1+4A})}e^{-(1/2)\sqrt{B}x^2}\,{}_1F_1(-n,1+\tfrac{1}{2}\sqrt{1+4A};\sqrt{B}x^2), \tag{9}$$

where $n=0,1,2,\ldots$, and ${}_1F_1$ is the confluent hypergeometric function[3]

$${}_1F_1(a,b;z)=\sum_k\frac{(a)_kz^k}{(b)_kk!}.$$

The Pochhammer symbols $(a)_k$ are defined as

$$(a)_k=a(a+1)(a+2)\cdots(a+k-1)=\frac{\Gamma(a+k)}{\Gamma(a)}, \quad k=1,2,\ldots, \tag{10}$$

where $\Gamma(a)$ is the gamma function. Note that we have corrected the misprint of Ref. 4 for the power of x in the wave functions (9). The constant C_n is determined from the normalization condition

$$\int_0^\infty\psi_n^2(x)dx=1,$$

which requires use of the identity[4]

$$\int_0^\infty e^{-\lambda x}x^{\nu-1}[{}_1F_1(-n,\gamma;kx)]^2dx$$

$$=\frac{n!\Gamma(\nu)}{k^\nu\gamma(\gamma+1)\cdots(\gamma+n-1)}$$

$$\times\left\{1+\sum_{s=0}^{n-1}\frac{n(n-1)\cdots(n-s)(\gamma-\nu-s-1)(\gamma-\nu-s)\cdots(\gamma-\nu+s)}{[(s+1)!]^2\gamma(\gamma+1)\cdots(\gamma+s)}\right\}, \quad (11)$$

thereby yielding

$$C_n^2=\frac{2B^{1/2+1/4\sqrt{1+4A}}\Gamma(n+1+\frac{1}{2}\sqrt{1+4A})}{n![\Gamma(1+\frac{1}{2}\sqrt{1+4A})]^2}. \quad (12)$$

In order to prove that the $\psi_n(x)$, $n=0,1,2,...$, defined by (9) are orthonormal, we have to demonstrate

$$\int_0^\infty \psi_n(x)\psi_m(x)dx=0 \quad (n\neq m). \quad (13)$$

We know, however, that $\psi_n(x)$ and $\psi_m(x)$ satisfy the Schrödinger equations,

$$\psi_n''+\left(E_n-Bx^2-\frac{A}{x^2}\right)\psi_n=0, \quad E_n=\sqrt{B}(4n+2+\sqrt{1+4A}), \quad (14)$$

$$\psi_m''+\left(E_m-Bx^2-\frac{A}{x^2}\right)\psi_m=0, \quad E_m=\sqrt{B}(4m+2+\sqrt{1+4A}). \quad (15)$$

Multiplying (14) by ψ_m and (15) by ψ_n and then subtracting the resulting equations, we obtain

$$\frac{d}{dx}(\psi_m\psi_n'-\psi_n\psi_m')+\sqrt{B}(n-m)\psi_n\psi_m=0.$$

After integrating this equation over $[0,\infty)$ and using $\psi_n(0)=\psi_m(0)=0$ and $\psi_n(\infty)=\psi_m(\infty)=0$, we get

$$(n-m)\int_0^\infty \psi_n(x)\psi_m(x)dx=0,$$

which proves (13). Thus we obtain the following identity:

$$\int_0^\infty e^{-\lambda x^2}x^{2\gamma-1}\,{}_1F_1(-n,\gamma;\lambda x^2){}_1F_1(-m,\gamma;\lambda x^2)dx=\begin{cases}0, & \text{if } n\neq m,\\ \dfrac{1}{2}\dfrac{n!\Gamma(\gamma)}{\lambda^\gamma(\gamma)_n}, & \text{if } n=m,\end{cases}$$

wherein the confluent hypergeometric functions ${}_1F_1$ are defined as follows:[3]

$${}_1F_1(-n,\gamma;r)\equiv-\frac{1}{2\pi i}\frac{\Gamma(n+1)\Gamma(\gamma)}{\Gamma(n+\gamma)}\oint_{C'}e^{tr}(-t)^{-n-1}(1-t)^{\gamma-n-1}dt$$

$$=\frac{\Gamma(\gamma)}{\Gamma(\gamma+n)}r^{1-\gamma}e^rD^n(r^{\gamma+n-1}e^{-r})=\frac{\Gamma(\gamma)}{\Gamma(\gamma+n)}r^{1-\gamma}(D-1)^n(r^{\gamma+n-1}), \quad (16)$$

for any simply closed rectifiable contour C' starting at 1 and enclosing the straight line segment from 0 to 1 in the complex plane, as illustrated in Fig. 1. With $\gamma=1+\frac{1}{2}\sqrt{1+4A}$ and $\lambda=\sqrt{B}$, the set of $L^2(0,\infty)$-functions,

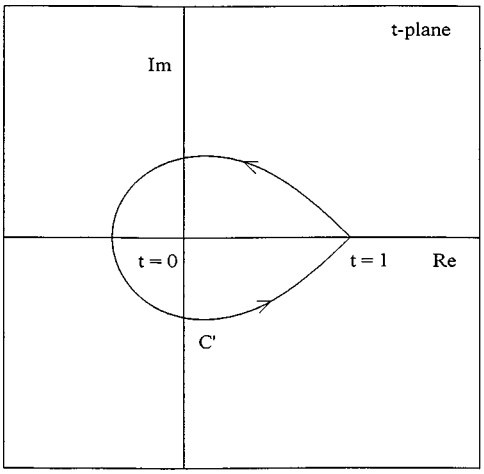

FIG. 1. The contour C' in the t-plane starting at 1 and enclosing the line segment from 0 to 1.

$$\psi_n(x)=C_n x^{\gamma-1/2}e^{-(1/2)\lambda x^2}\,{}_1F_1(-n,\gamma;\lambda x^2),\quad n=0,1,2,..., \tag{17}$$

constitutes an orthonormal system of the Hilbert space $L^2(0,\infty)$.

III. PROOF OF COMPLETENESS

For the orthonormal functions $\{\psi_n\}$ to qualify as a basis for $L^2(0,\infty)$, we must demonstrate the density of the linear manifold generated by these functions in the topology induced by the norm determined by the inner product $\langle\cdot|\cdot\rangle$. This is equivalent to showing that if $\langle\psi_n|f\rangle=0$ for all $n=0,1,2,...$, then $f=0$ a.e. on $(0,\infty)$. To this end we note that out of the fourth expression of (16) follows:

$${}_1F_1(-n,\gamma;\lambda x^2)=\sum_{k=0}^{n}\binom{n}{k}\frac{(-\lambda)^{n-k}\Gamma(\gamma)}{\Gamma(\gamma+n-k)}\,x^{2(n-k)}. \tag{18}$$

Hence the basis representation of the functions (vectors),

$$\{{}_1F_1(-n,\gamma;\lambda x^2),\ {}_1F_1(-(n-1),\gamma;\lambda x^2),\ldots,\ {}_1F_1(-1,\gamma;\lambda x^2),\ {}_1F_1(-0,\gamma;\lambda x^2)\},$$

in terms of the basis

$$\{x^{2n},x^{2(n-1)},\ldots,x^2,1\},$$

is achieved by a lower triangular $(n+1)\times(n+1)$ matrix, whose diagonal entries are $(-\lambda)^{n-k}\Gamma(\gamma)/\Gamma(\gamma+n-k)$ for $k=0,1,2,...,n$—i.e., this matrix is invertible provided $\lambda\neq 0$. Thus each x^{2n} is a unique linear combination of the $n+1$ functions ${}_1F_1(-(n-k),\gamma;\lambda x^2)$ for $k=0,1,2,...,n$, which conclusion carries over to the $2n$-th degree Taylor polynomial,

$$e_n\left(-\frac{\mu x^2}{2}\right)=\sum_{k=0}^{n}\frac{1}{k!}\left(-\frac{\mu x^2}{2}\right)^k,$$

of $e^{-\mu x^2/2}$ about the point 0, where μ is an arbitrary parameter.

Let f be an $L^2(0,\infty)$-function orthogonal to each of the ψ_n, which is equivalent to saying

$$\left\langle e_n\left(-\frac{\mu\cdot^2}{2}\right)\middle|f\right\rangle=\int_0^\infty x^{\gamma-1/2}e_n\left(-\frac{\mu x^2}{2}\right)f(x)\,dx=0, \tag{19}$$

for all $n=0,1,2,...$. Here we note that

$$x^{\gamma-1/2}e^{-\lambda x^2/4}f(x),$$

is an $L^1(0,\infty)$-function whose absolute value majorizes $x^{\gamma-1/2}e^{-\lambda x^2/4}e^{|\mu|x^2/4}f(x)$ for $|\mu|\leqslant\lambda/4$ and consequently also $x^{\gamma-1/2}e^{-\lambda x^2/4}e_n(-\mu x^2/4)f(x)$. Because $x^{\gamma-1/2}e^{-\lambda x^2/4}e_n(-\mu x^2/4)f(x)$ converges to $x^{\gamma-1/2}e^{-\lambda x^2/2}f(x)$ a.e. on $(0,\infty)$ as $n\to\infty$, we conclude by means of the Lebesgue dominated convergence theorem[5] that we may replace $e_n(-\mu x^2/2)$ by $e^{-\mu x^2/2}$ in Eq. (19) for all complex numbers μ such that $|\mu|\leqslant\lambda/4$, which, after setting $x=\sqrt{2t}$, yields the Laplace-Transform expression

$$\mathscr{L}\{F\}(z)=\int_0^\infty e^{-zt}(\sqrt{2t})^{\gamma-3/2}f(\sqrt{2t})\,dt=0, \quad |z-\lambda|\leqslant\frac{\lambda}{4}. \tag{20}$$

However, the Laplace transform of the measurable Laplace-transformable function $F(t)=e^{-zt}(\sqrt{2t})^{\gamma-3/2}f(\sqrt{2t})$ defines a holomorphic function of variable z in the right half plane $\Re(z)>0$ vanishing in the disc $|z-\lambda|\leqslant\lambda/4$. By uniqueness of the analytic function[6] the Laplace transform of the function must vanish in the right half plane, specifically $\mathscr{L}\{F\}(s)=0$ for all s on the interval $(0,\infty)$. Further, the Laplace transform determines $F(t)$ uniquely[7] a.e. in t on $(0,\infty)$, hence $F(t)=0$ a.e. in t or f is the zero $L^2(0,\infty)$-function. Consequently, $\{\psi_n:\ n=0,1,2,...\}$ is an orthonormal basis of $L^2(0,\infty)$.

IV. THE MATRIX ELEMENTS $\langle m|x^{-\alpha}|n\rangle$

Let us now split the Hamiltonian (5) into an H_0 part,

$$H_0=-\frac{d^2}{dx^2}+Bx^2+\frac{A}{x^2}, \quad x\geqslant 0, \tag{21}$$

and a perturbation,

$$H_I=\lambda/x^\alpha.$$

The eigenstates of H_0 are now given by (9) and their unperturbed energy is given by (8). All we need to do is to evaluate the matrix elements $\langle m|x^{-\alpha}|n\rangle$ using the basis (9), namely,

$$\langle m|x^{-\alpha}|n\rangle=C_nC_m\int_0^\infty e^{-\sqrt{B}x^2}x^{-\alpha+1+\sqrt{1+4A}}\ {}_1F_1\left(-n,1+\frac{1}{2}\sqrt{1+4A};\sqrt{B}x^2\right)$$
$$\times\ {}_1F_1\left(-m,1+\frac{1}{2}\sqrt{1+4A};\sqrt{B}x^2\right)dx, \quad \alpha<2+\sqrt{1+4A}\,. \tag{22}$$

This is equivalent to

$$\langle m|x^{-\alpha}|n\rangle=\frac{C_nC_m}{2}\,B^{-(1/2)(-\alpha+2+\sqrt{1+4A})}\times I, \tag{23}$$

where

$$I=\int_0^\infty e^{-r}r^{\gamma-s}\ {}_1F_1(-n,\gamma;r)\ {}_1F_1(-m,\gamma;r)\,dr, \tag{24}$$

with $r=\sqrt{B}x^2$, $\gamma=1+\frac{1}{2}\sqrt{1+4A}$, and $s=1+\alpha/2$.

From the Fubini–Tonneli theorem[5] combined with the Leibniz formula for differentiating the product of two functions, as well as exponential shift from the third expression to the fourth in Eq. (16), with n replaced by m, we find that I is given by the expression

$$I=(-1)^n\frac{n![\Gamma(\gamma)]^2}{\Gamma(n+\gamma)\Gamma(m+\gamma)}(2\pi i)^{-1}\oint_{C'}t^{-n-1}(1-t)^{\gamma-n-1}\int_0^\infty e^{-(1-t)r}r^{1-s}$$
$$\times\left[\sum_{k=0}^{m}(-1)^k\binom{m}{k}(\gamma+m-1)(\gamma+m-2)\cdots(\gamma+k)r^{\gamma+m-1-(m-k)}\right]dr\,dt.$$

Further, owing to the fact that the simply closed rectifiable contour C' lies to the left of the complex number 1, Fig. 1, we have

$$\int_0^\infty e^{-(1-t)r}r^{\gamma-s+k}\,dr=\Gamma(\gamma-s+k+1)(1-t)^{-\gamma+s-k-1},$$

and our expression for I thereby reduces to

$$I=(-1)^n\frac{n![\Gamma(\gamma)]^2}{\Gamma(n+\gamma)\Gamma(m+\gamma)}\sum_{k=0}^{m}(-1)^k\binom{m}{k}\frac{\Gamma(m+\gamma)\Gamma(\gamma-s+k+1)}{\Gamma(k+\gamma)}(2\pi i)^{-1}$$
$$\times\oint_{C'}t^{-n-1}(1-t)^{s+n-k-2}\,dt. \tag{25}$$

Since the contour C' has 0 in its inside, Fig. 1, and the integrand has a weak singularity at 1 [in consequence of $\Re(s+n-k-2)>-1$], the Cauchy integral formula lets us write the contour integral multiplied by $(2\pi i)^{-1}$ as the n-th derivatives of $(1-t)^{s+n-k-2}$ evaluated at $t=0$. Utilizing thereafter the Pochhammer symbol in the Gamma function format, Eq. (10), we arrive at

$$I=\frac{[\Gamma(\gamma)]^2}{\Gamma(n+\gamma)}\sum_{k=0}^{m}(-1)^k\binom{m}{k}\frac{\Gamma(\gamma-s+k+1)\Gamma(s+n-k-1)}{\Gamma(\gamma+k)\Gamma(s-k-1)}. \tag{26}$$

Therefore, the matrix elements are given by

$$\langle m|x^{-\alpha}|n\rangle=(-1)^{n+m}\frac{C_nC_m}{2}B^{-(1/4)(-\alpha+2+\sqrt{1+4A})}\frac{[\Gamma(1+\frac{1}{2}\sqrt{1+4A})]^2}{\Gamma(n+1+\frac{1}{2}\sqrt{1+4A})}$$
$$\times\sum_{k=0}^{m}(-1)^k\binom{m}{k}\frac{\Gamma\left(k+1+\frac{1}{2}\sqrt{1+4A}-\frac{\alpha}{2}\right)\Gamma(\alpha/2+n-k)}{\Gamma(k+1+\frac{1}{2}\sqrt{1+4A})\Gamma(\alpha/2-k)},\alpha<2+\sqrt{1+4A}, \tag{27}$$

with normalization coefficients C_n given in Eq. (12). In case $\alpha/2-k$ is a negative integer; then[3] $1/\Gamma(\alpha/2-k)=0$ for such k and the terms involving these k's shall not appear in the summation of Eq. (27). Further, by expressing the confluent hypergeometric functions ${}_1F_1(-n,\gamma;r)$ and ${}_1F_1(-m,\gamma;r)$ by means of the fourth formula in Eq. (19) and substituting these into Eq. (18), we immediately see that the sum appearing in Eq. (27) is a polynomial of degree $m+n$ in α.

With Eq. (27) we have therefore computed the matrix elements of the operator $x^{-\alpha}$ in the complete basis given by the Gol'dman and Krivchenkov eigenfunctions (9). Concomitant to our result, the matrix elements,

$$\langle 0|x^{-\alpha}|n\rangle=(-1)^nB^{\alpha/4}\sqrt{\frac{\Gamma(1+\frac{1}{2}\sqrt{1+4A})}{n!\Gamma(n+1+\frac{1}{2}\sqrt{1+4A})}}\frac{\Gamma(1+\frac{1}{2}\sqrt{1+4A}-\alpha/2)\Gamma(\alpha/2+n)}{\Gamma(1+\frac{1}{2}\sqrt{1+4A})\Gamma(\alpha/2)}, \tag{28}$$

are of special interest.

V. EXPLICIT FORMS OF THE MATRIX ELEMENTS

In terms of the parameter $\gamma=1+\frac{1}{2}\sqrt{1+4A}$, the explicit forms of the first ten matrix elements of $x^{-\alpha}$ with $\alpha<2\gamma$ are

$$x_{00}^{-\alpha}=B^{\alpha/4}\frac{\Gamma(-\alpha/2+\gamma)}{\Gamma(\gamma)},$$

$$x_{01}^{-\alpha}=-\frac{B^{\alpha/4}}{2}\frac{\Gamma(-\alpha/2+\gamma)}{\sqrt{\gamma}\Gamma(\gamma)}\,\alpha,$$

$$x_{02}^{-\alpha}=\frac{B^{\alpha/4}}{2^2}\frac{\Gamma(-\alpha/2+\gamma)}{\sqrt{2!\,\gamma(\gamma+1)}\Gamma(\gamma)}\,\alpha(\alpha+2),$$

$$x_{03}^{-\alpha}=-\frac{B^{\alpha/4}}{2^3}\frac{\Gamma(-\alpha/2+\gamma)}{\sqrt{3!\,\gamma(\gamma+1)(\gamma+2)}\Gamma(\gamma)}\,\alpha(\alpha^2+6\alpha+8),$$

$$x_{11}^{-\alpha}=B^{\alpha/4}\frac{\Gamma(-\alpha/2+\gamma)}{4\Gamma(\gamma+1)}\,(\alpha^2-2\alpha+4\gamma),$$

$$x_{12}^{-\alpha}=-B^{\alpha/4}\frac{\Gamma(-\alpha/2+\gamma)}{8\sqrt{2}\sqrt{\gamma+1}\Gamma(\gamma+1)}\,\alpha(\alpha^2-2\alpha+8\gamma),$$

$$x_{13}^{-\alpha}=B^{\alpha/4}\frac{\Gamma(-\alpha/2+\gamma)}{16\sqrt{3!(\gamma+2)(\gamma+1)}\Gamma(\gamma+1)}\,\alpha(\alpha^3+(12\gamma-4)\alpha+24\gamma),$$

$$x_{22}^{-\alpha}=B^{\alpha/4}\frac{\Gamma(-\alpha/2+\gamma)}{32\Gamma(\gamma+2)}\,(\alpha^4-4\alpha^3-16(1+2\gamma)\alpha+4(3+4\gamma)\alpha^2+32\gamma(1+\gamma)),$$

$$x_{23}^{-\alpha}=B^{\alpha/4}\frac{\Gamma(-\alpha/2+\gamma)}{32\sqrt{3!2!(\gamma+2)}\Gamma(\gamma+2)}\,\alpha(\alpha^4-4\alpha^3+4(5+6\gamma)\alpha^2-16(2+3\gamma)\alpha+96\gamma(1+\gamma)),$$

$$x_{33}^{-\alpha}=B^{\alpha/4}\frac{\Gamma(-\alpha/2+\gamma)}{384\Gamma(\gamma+3)}\,(\alpha^6-8\alpha^5+(72+36\gamma)\alpha^4-(208+144\gamma)\alpha^3$$
$$+(272+720\gamma+288\gamma^2)\alpha^2-(192+1152\gamma+576\gamma^2)\alpha+384\gamma(1+\gamma)(2+\gamma)).$$

These matrix elements can be compared for the special case $(A,B)=(0,1)$ with the matrix elements computed by the simple harmonic oscillator representation supplemented by the Dirichlet boundary condition.[1] We have found an error in the value of the matrix element $x_{33}^{-\alpha}$ as given by Ref. 1; this error is confirmed by a re-computation according to the matrix element expression given by them. Indeed, the matrix element $x_{33}^{-\alpha}$ should read as

$$x_{33}^{-\alpha}=\frac{\Gamma((3-\alpha)/2)}{7!\,\Gamma(3/2)}\,(\alpha^6-6\alpha^5+106\alpha^4-384\alpha^3+2080\alpha^2-3408\alpha+5040),$$

instead of

$$x_{33}^{-\alpha}=\frac{\Gamma((3-\alpha)/2)}{7!\,\Gamma(3/2)}\,(\alpha^6-6\alpha^5+106\alpha^4-454\alpha^3+1660\alpha^2-3968\alpha+5040),$$

as quoted by Aguilera-Navarro *et al.*[1]

In this work we have proved that the Gol'dman–Krivchenkov wave functions constitute an orthonormal basis for the Hilbert space $L^2(0,\infty)$. Using this orthonormal basis, we are able to construct the matrix elements of $x^{-\alpha}$: the general result [Eq. (27)] is convenient for use in any practical application which involves such singular potential terms. It is also interesting that, with minor changes,[8] essentially involving only the value of the coefficient A, the same formulas apply

immediately to the corresponding problems with nonzero angular momentum and in arbitrary spatial dimension $N \geqslant 2$. A detailed variational analysis of the spiked harmonic Hamiltonian operator based on these matrix elements is presently in progress.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 39, NUMBER 12 DECEMBER 1998

On infravacua and the localization of sectors

Walter Kunhardt[a)]
Institut für Theoretische Physik der Universität Göttingen, Bunsenstraße 9, 37073 Göttingen, Germany

(Received 24 June 1998; accepted for publication 27 August 1998)

A certain class of superselection sectors of the free massless scalar field in three space dimensions is considered. It is shown that these sectors, which cannot be localized with respect to the vacuum, acquire a much better localization, namely in spacelike cones, when viewed in front of suitable ''infravacuum'' backgrounds. These background states coincide, essentially, with a class of states introduced by Kraus, Polley, and Reents as models for clouds of infrared radiation. © *1998 American Institute of Physics.* [S0022-2488(98)02412-8]

I. INTRODUCTION

In the analysis of superselection sectors, the localizability properties of charges are crucial for defining notions as charge composition and conjugation, statistics or a (global) gauge group. In a classical work,[1] Doplicher, Haag, and Roberts carried through such a program for charges which fulfill what is now called the DHR criterion, i.e., which are compactly localized. Now this criterion is very restrictive, and Buchholz and Fredenhagen[2] established that sectors of theories in three space dimensions without massless particles in general only comply with the so-called BF criterion, i.e., they are localized in spacelike cones. Still, these authors could extend the analysis of Ref. 1 to charges with such a weaker localization behavior.

The situation is more difficult for theories with massless particles. Typically, these theories possess sectors whose localization is too poor for the DHR framework to be applicable. Motivated by what is expected to happen in quantum electrodynamics (QED), it has been proposed by Buchholz in Ref. 3 to improve the localization by viewing the charges in front of some suitable background field instead of the vacuum. In QED, such background fields should correspond to clouds of infrared radiation. An appropriate mathematical description of such infrared clouds has been introduced by Kraus, Polley, and Reents (KPR).[4]

Here, we want to verify this mechanism in a simpler model, namely in the theory of the free massless scalar field in three space dimensions.[5] More precisely, we will consider a certain class of (non-Lorentz invariant) sectors described by automorphisms of the observable algebra and analyze their localization properties in terms of the BF criterion. In particular, we will show that the sectors under consideration do satisfy this criterion with respect to a KPR-like background but do not satisfy it with respect to the vacuum. (Calling the background fields ''KPR-like'' should indicate that they are very similar, yet not identical, to those of Ref. 4.)

As to the consistency of such an approach, it should be kept in mind that, in a theory whose charges are compactly localized, the superselection structure can be described without any difference with respect to the vacuum as well as with respect to so-called infravacua, the latter being generalizations of the KPR-like background states considered here. As has been shown in Ref. 6, when viewed in front of such an infravacuum, the charges remain compactly localized and have the same fusion structure and statistics as in front of the vacuum. Moreover, positivity of the energy in a sector does not depend on the background chosen, nor do the masses of massive particles possibly contained in such a theory.

The above-mentioned class of sectors of the free massless field has been studied recently by Buchholz *et al.*[5] with the purpose of modeling charges of electromagnetic type. In the following, we will stick very closely to the notations introduced there, but we should emphasize that our point of view is slightly different from that adopted in Ref. 5: Buchholz *et al.* achieved a better

localization of the sectors by restricting them to a (non-Lorentz invariant) subnet $\mathcal{A}_0 \subset \mathcal{A}$ of the observable net. The sectors then even became localized in the DHR sense, which permitted them to carry through a DHR-like analysis, even though the net $\mathcal{A}_0$ does not fulfill Haag duality. Here, in contrast, the subnet $\mathcal{A}_0$ will play no role, and the localization obtained will be in a weaker sense.

We end this Introduction by recalling the definition of the model under consideration. The observable algebra of the free massless scalar field is defined in its vacuum representation. More precisely, let $\mathcal{K} := L^2(\mathbf{R}^3, d^3k)$ be the Hilbert space of momentum space wave functions, $\omega(\vec{k}) := |\vec{k}|$ the one-particle energy and $U(t,\vec{x}) = e^{i(\omega(\hat{k})t - \vec{k}\vec{x})}$ the usual representation of the space–time translations. The vacuum Hilbert space of our model will be the bosonic Fock space $\mathcal{H}$ over $\mathcal{K}$; the induced unitary representation of the space–time translations will still be denoted by $U(t,\vec{x})$ without any risk of confusion. For any $v \in \mathcal{K}$, $W(v) \in \mathcal{B}(\mathcal{H})$ will denote the corresponding Weyl operator. The normalization is chosen such that the Weyl relations read $W(u)W(v) = e^{-(i/2)\mathrm{Im}\langle u,v\rangle} W(u+v)$. For any real linear subspace $\mathcal{L} \subset \mathcal{K}$, $\mathcal{W}(\mathcal{L})$ denotes the C*-subalgebra of $\mathcal{B}(\mathcal{H})$ generated by the operators $W(f)$, $f \in \mathcal{L}$. The net of observables now is given as

$$\mathcal{O} \mapsto \mathcal{A}(\mathcal{O}) := \mathcal{W}(\mathcal{L}(\mathcal{O}))'',$$

where $\mathcal{O} \mapsto \mathcal{L}(\mathcal{O})$ is the isotonous, local and covariant net of symplectic subspaces in $\mathcal{K}$ (indexed by the set of open double cones in Minkowski space) defined as follows: If $\mathcal{O} := (\{0\} \times O)''$ is the causal completion of an open ball $O \subset \mathbf{R}^3$ at time $t = 0$, one has

$$\mathcal{L}(\mathcal{O}) := \omega^{-1/2} \widehat{\mathcal{D}_{\mathbf{R}}(O)} + i\omega^{+1/2} \widehat{\mathcal{D}_{\mathbf{R}}(O)},$$

where $\mathcal{D}_{\mathbf{R}}(O)$ is the set of all real-valued smooth functions with support in O and $\hat{}$ denotes the Fourier transform. For other double cones $\mathcal{O}$, the space $\mathcal{L}(\mathcal{O})$ is defined by translation covariance and additivity. The symplectic form σ on $\mathcal{L} := \cup_{\mathcal{O}} \mathcal{L}(\mathcal{O}) \subset \mathcal{K}$ reads

$$\sigma(f_1, f_2) := -\mathrm{Im}\langle f_1, f_2\rangle,$$

and locality for the net $\mathcal{L}(\cdot)$ just means $\sigma(\mathcal{L}(\mathcal{O}_1), \mathcal{L}(\mathcal{O}_2)) = 0$ whenever $\mathcal{O}_1$ and $\mathcal{O}_2$ are spacelike to each other. As usual, we also associate symplectic subspaces of $\mathcal{L}$ (resp. C*-subalgebras of $\mathcal{B}(\mathcal{H})$) to *un*bounded regions in $\mathbf{R}^{1+3}$ by additivity (resp. additivity and norm closure) and simply denote by $\mathcal{A}$ the quasilocal algebra $\mathcal{A}(\mathbf{R}^{1+3})$.

The charges under consideration are given in terms of net automorphisms $\gamma \in \mathrm{Aut}\,\mathcal{A}$ which are labeled uniquely by elements of the (additive) Abelian group

$$\mathcal{L}_\Gamma := \omega^{-1/2} \widehat{\mathcal{D}_{\mathbf{R}}(\mathbf{R}^3)} + i\omega^{-3/2} \widehat{\mathcal{D}_{\mathbf{R}}(\mathbf{R}^3)}.$$

Any element $\gamma \in \mathcal{L}_\Gamma$ gives rise to a linear form $l_\gamma : \mathcal{L} \to \mathbf{C}$,

$$l_\gamma(f) := -\mathrm{Im} \int d^3k\, \overline{\gamma(\vec{k})} f(\vec{k}),$$

and hence to an automorphism, again denoted by γ, of $\mathcal{A}$ by

$$\gamma(W(f)) := e^{i l_\gamma(f)} W(f).$$

As explained in Ref. 5, γ is indeed a well-defined automorphism of the quasi-local algebra $\mathcal{A}$ since, by Huygens' principle, it turns out to be locally normal; as a consequence, it can be extended by weak continuity from the local Weyl algebras $\mathcal{W}(\mathcal{L}(\mathcal{O}))$ to the local von Neumann algebras $\mathcal{A}(\mathcal{O})$.

There will be no risk of confusion in viewing the real vector space $\mathcal{L}_\Gamma$ as an Abelian subgroup of $\mathrm{Aut}\,\mathcal{A}$. In particular, a sum $\gamma_1 + \gamma_2$ in $\mathcal{L}_\Gamma$ corresponds to the composition $\gamma_1 \circ \gamma_2$ in $\mathrm{Aut}\,\mathcal{A}$. Moreover, γ_1 and γ_2 define the same sector of $\mathcal{A}$, i.e., they are unitarily equivalent in $\mathcal{B}(\mathcal{H})$, iff $\gamma_1 - \gamma_2 \in \mathcal{L}_\Gamma \cap \mathcal{K}$. In this case, the Weyl operator $W(\gamma_1 - \gamma_2)$ is well defined and implements the unitary equivalence $\gamma_1 \cong \gamma_2$ on $\mathcal{A}$.

Any $\gamma \in \mathscr{S}_\Gamma$ can be written uniquely in the form $\gamma = \omega^{-1/2}\hat{\sigma} + i\omega^{-3/2}\hat{\rho}$ with functions $\sigma, \rho \in \mathscr{D}_{\mathbf{R}}(\mathbf{R}^3)$. Since $\hat{\sigma}$ and $\hat{\rho}$ are analytic, it is obvious that γ is square integrable, i.e., $\gamma \in \mathscr{K}$, iff $\hat{\rho}(0) = 0$. As a consequence, the sectors considered are labeled by a single real parameter

$$q_\gamma := \hat{\rho}(0) = \int d^3x \rho(\vec{x})$$

which is interpreted as the charge of the sector $[\gamma]$. In particular, this shows that the sectors are transportable; as a matter of fact, they even have positive energy.[5]

II. BAD LOCALIZATION OF THE SECTORS IN FRONT OF THE VACUUM

It has been shown in Ref. 5 that the automorphisms $\gamma \in \mathscr{S}_\Gamma$ do not satisfy the DHR localization criterion. Here, we want to strengthen this result and show with closely related methods that they do not even satisfy the BF criterion, that is, that they are not localizable in spacelike cones. To this end, it is sufficient to prove the following

Proposition 2.1: Let $C \subset \mathbf{R}^3$ be an open convex cone having 0 as its apex and denote with $\mathscr{C} := (\{0\} \times C)''$ its causal completion. Then, for any $\gamma \in \mathscr{S}_\Gamma$,

$$\gamma|_{\mathscr{A}(\mathscr{C})} \cong \mathrm{id}|_{\mathscr{A}(\mathscr{C})} \quad \text{iff} \quad q_\gamma = 0.$$

The ''if'' part of this proposition is trivial, and before proving the ''only if'' part, we recall some facts about the dilation covariance of the model. The dilation group $\mathbf{R}_{>0}$ acts unitarily on $\mathscr{K}$ and leaves the space $\mathscr{S}$ invariant. More precisely, $f \in \mathscr{S}(\mathscr{O})$ is mapped onto $f_\lambda \in \mathscr{S}(\lambda\mathscr{O})$, where $f_\lambda(\vec{k}) := \lambda^{3/2} f(\lambda\vec{k})$. Writing $f = \omega^{-1/2}\hat{h} + i\omega^{+1/2}\hat{g}$, it is verified by a straightforward computation that this entails for the linear form l_γ, $\gamma \in \mathscr{S}_\Gamma$:

$$l_\gamma(f_\lambda) = \int \frac{d^3k}{\omega^2} \overline{\hat{\rho}(\vec{k}/\lambda)}\hat{h}(\vec{k}) - \frac{1}{\lambda}\int d^3k \overline{\hat{\sigma}(\vec{k}/\lambda)}\hat{g}(\vec{k}).$$

In the limit $\lambda \to \infty$, $\vec{k} \mapsto \overline{\hat{\rho}(\vec{k}/\lambda)}\hat{h}(\vec{k})$ converges to $\hat{\rho}(0)\hat{h}$ in the space of test functions, and since $2\pi^2/r$ is the Fourier transform of $1/\omega^2$ in the sense of distributions, one obtains

$$\lim_{\lambda\to\infty} l_\gamma(f_\lambda) = q_\gamma \kappa_f \quad \text{with} \quad \kappa_f := 2\pi^2 \int \frac{d^3x}{|\vec{x}|} h(\vec{x}).$$

This allows us to prove the following

Lemma 2.2: Let $f \in \mathscr{S}(\mathscr{O}')$, where $\mathscr{O} \subset \mathbf{R}^{1+3}$ is a neighborhood of 0. For any $\gamma \in \mathscr{S}_\Gamma$, one then has

$$\text{w-}\lim_{\lambda\to\infty} \gamma(W(f_\lambda)) = e^{iq_\gamma\kappa_f} e^{-(1/4)\|f\|^2}\mathbf{1}.$$

Proof: Since the dilations act geometrically, it follows by locality from the special form of the localization region of f that $\lim_{\lambda\to\infty} \sigma(f_\lambda, f') = 0$ for any $f' \in \mathscr{S}$. Hence, $(W(f_\lambda))_{\lambda>0}$ is a central sequence of unitaries in $\mathscr{W}(\mathscr{S})$ whose set of weak limits is, by the irreducibility of the vacuum representation, a (nonempty) subset of $\mathbf{C1}$. On the other hand, unitarity of the dilations permits us to evaluate this limit in the vacuum state: $\omega_0(W(f_\lambda)) \xrightarrow{\lambda\to\infty} e^{-(1/4)\|f\|^2}$. But this means that $W(f_\lambda)$ has $e^{-(1/4)\|f\|^2}\mathbf{1}$ as its *unique* weak limit for $\lambda \to \infty$, establishing thus the assertion for $\gamma = 0$. For arbitrary $\gamma \in \mathscr{S}_\Gamma$, it now follows easily in view of the discussion in the preceding paragraph. ∎

Physically, the sequence $(W(f_\lambda))_{\lambda\to\infty}$ is interpreted as a measurement of the asymptotic behavior (in the spatial directions determined by the smearing function h) of the ''Coulomb potential'' of the ''charge density'' ρ. In QED, one expects that operators measuring the

asymptotic electric flux distribution play a similar role.[3] In the present case, the leading $1/r$ behavior of the Coulomb potential is isotropic in all sectors $[\gamma]$. This fact, reflected by the factorizing of $\lim l_\gamma(f_\lambda)$ as seen above, is relevant in the following.

Proof of Proposition 2.1: Let $\gamma \in \mathscr{G}_\Gamma$ with $q_\gamma \neq 0$. Choose a nonvanishing, non-negative test function $h \in \mathscr{D}_{\mathbf{R}}(C)$. Letting $f := \omega^{-1/2}\hat{h}$, this implies $\kappa_f \neq 0$ and $f \in \mathscr{S}(\mathscr{O} \cap \mathscr{O}')$ for some neighborhood $\mathscr{O} \subset \mathbf{R}^{1+3}$ of 0. Since $e^{iq_\gamma \kappa_f} \neq 1$ can always be achieved by a mere rescaling of h, Lemma 2.2 shows that the weak limits (as $\lambda \to \infty$) of $W(f_\lambda)$ and $\gamma(W(f_\lambda))$ are different scalar multiples of the unit operator. But since $W(f_\lambda) \in \mathscr{A}(\mathscr{O})$ for all $\lambda > 0$, this implies $\gamma|_{\mathscr{A}(\mathscr{O})} \neq \mathrm{id}|_{\mathscr{A}(\mathscr{O})}$. ■

III. INFRAVACUUM BACKGROUND STATES

In this section we introduce a class of background states in front of which the automorphisms γ will be shown (in Sec. IV) to have better localization properties. Apart from two modifications necessitated by the present model, these background states are of the same type as those introduced by Kraus, Polley, and Reents[4] as a model for infrared clouds in QED or, more generally, in any theory containing massless particles.

A. Preliminaries on quasifree states

First, we recall that a *quasifree state* on $\mathscr{A}$ is a locally normal state ω_T which is, on the Weyl operators $W(f) \in \mathscr{A}$, $f \in \mathscr{S}$, of the form

$$\omega_T(W(f)) = e^{-(1/4)\|Tf\|^2}.$$

Here, $T: D_T \to \mathscr{K}$ is a real linear, symplectic (i.e., fulfilling $\mathrm{Im}\langle Tv, Tw\rangle = \mathrm{Im}\langle v, w\rangle, v, w \in D_T$) operator defined on a dense, real linear subspace D_T which contains $\mathscr{S}$. In the case at hand, we will have in addition $\overline{T\mathscr{S}} = \mathscr{K}$, which entails that ω_T is a pure state. Its Gel'fand–Naimark–Segal (GNS) representation π_T acts irreducibly on the vacuum Hilbert space $\mathscr{H}$ as $\pi_T(W(f)) = W(Tf)$, $f \in \mathscr{S}$.

Next, we describe the *real linear* operator T in terms of a pair of *complex linear* operators T_1, T_2 defined on complex linear subspaces D_{T_j}, $j = 1,2$.

Lemma 3.1: Let $\Gamma: \mathscr{K} \to \mathscr{K}$ *be an antiunitary involution. Then, the formulas*

$$T := T_2 \frac{1+\Gamma}{2} + T_1 \frac{1-\Gamma}{2},$$

$$D_T := \left\{ v \in \mathscr{K} \,\middle|\, \frac{1+\Gamma}{2} v \in D_{T_2},\ \frac{1-\Gamma}{2} v \in D_{T_1} \right\}$$

establish a bijection between

(i) *densely defined,* Γ*-invariant* **R***-linear operators* $T: D_T \to \mathscr{K}$ *and*
(ii) *densely defined,* Γ*-invariant* **C***-linear operators* $T_j: D_{T_j} \to \mathscr{K}$, $j = 1,2$

(*where* $T: D_T \to \mathscr{K}$ *being* Γ*-invariant means* $\Gamma D_T = D_T$ *and* $[\Gamma, T] = 0$ *on* D_T). *Moreover,* T *is symplectic iff* $\langle T_1 u_1, T_2 u_2\rangle = \langle u_1, u_2\rangle$ *for all* $u_j \in D_{T_j}$.

Since all assertions can be checked by simple calculations, we omit the formal proof of this Lemma and merely point out that the converse formulas expressing T_1 and T_2 in terms of T read

$$D_{T_2} = \left\{ v \in \mathscr{K} \,\middle|\, \frac{1+\Gamma}{2} \mathbf{C} v \subset D_T \right\}, \quad T_2 = T \frac{1+\Gamma}{2} - iT \frac{1+\Gamma}{2}\, i,$$

$$D_{T_1} = \left\{ v \in \mathscr{K} \,\middle|\, \frac{1-\Gamma}{2} \mathbf{C} v \subset D_T \right\}, \quad T_1 = T \frac{1-\Gamma}{2} + iT \frac{1-\Gamma}{2}\, i.$$

Remark: The involution Γ induces the notion of real and imaginary parts of vectors $v \in \mathscr{K}$: $\mathrm{Re}\, v = [(1+\Gamma)/2]v$, $\mathrm{Im}\, v = [(1-\Gamma)/2i]v$. Then, T_2 acts on the real and T_1 on the imaginary parts:

$$\mathrm{Re}\ Tv = T_2\ \mathrm{Re}\ v, \quad \mathrm{Im}\ Tv = T_1\ \mathrm{Im}\ v, \quad v \in D_T.$$

From now on, we will fix Γ to be pointwise complex conjugation in position space. In terms of momentum space wave functions $v \in \mathscr{K}$, this means

$$(\Gamma v)(\vec{k}) := \overline{v(-\vec{k})}.$$

(For the sake of completeness, we point out that Kraus *et al.* used pointwise conjugation in *momentum space* for defining their background states in Ref. 4. In their case as well as in ours, the choice of the involution Γ is dictated by the set of sectors under consideration.)

B. Quasifree states with positive energy

Before describing in detail the operators T_1 and T_2, we introduce some notation: for any $\epsilon > 0$, let $P_\epsilon : \mathscr{K} \to \mathscr{K}$ be the projector onto the subspace $P_\epsilon \mathscr{K} = \{v \in \mathscr{K} \mid v(\vec{k}) = 0 \text{ if } |\vec{k}| < \epsilon\}$ and denote by

$$D_0 := \bigcup_{\epsilon > 0} P_\epsilon \mathscr{K}$$

the dense subspace of functions vanishing in some neighborhood of $\vec{k} = 0$. Note that $[P_\epsilon, \Gamma] = 0$ and $\Gamma D_0 = D_0$. The subspace D_0 will serve as a provisional domain for T_1 and T_2.

Now we follow Ref. 4 and choose

(i) a sequence $(\epsilon_i)_{i \in \mathbf{N}}$ in $\mathbf{R}_{>0}$ satisfying $\epsilon_{i+1} < \epsilon_i$ and $\epsilon_i \xrightarrow{i \to \infty} 0$. This sequence induces a decomposition of momentum space into concentric spherical shells. The projections onto the associated spectral subspaces of $\mathscr{K}$ will be denoted by $P_i := P_{\epsilon_{i+1}} - P_{\epsilon_i}$. For notational convenience, we also put $P_0 := P_{\epsilon_1}$.

(ii) a sequence $(Q_i)_{i \in \mathbf{N}}$ of orthogonal projections in $\mathscr{K}$ with finite rank $\mathrm{rk} Q_i$ satisfying $Q_i \Gamma = \Gamma Q_i$, $Q_i P_i = Q_i$.

(iii) a sequence $(b_i)_{i \in \mathbf{N}}$ in $]0,1[$ satisfying $b_i \xrightarrow{i \to \infty} 0$ and $\Sigma_i (\epsilon_i / b_i^2) \mathrm{rk} Q_i < \infty$. If, e.g., the ϵ_i decrease exponentially and $\mathrm{rk} Q_i$ is polynomially bounded, this can be satisfied by $b_i \propto i^{-\alpha}$, $\alpha > 0$.

With these data, define $\mathbf{C}$-linear operators T_1 and T_2 on the subspace D_0 by

$$T_1 := 1 + \text{s-lim}_{n \to \infty} \sum_{i=1}^{n} (b_i - 1) Q_i, \quad T_2 := 1 + \text{s-lim}_{n \to \infty} \sum_{i=1}^{n} \left(\frac{1}{b_i} - 1 \right) Q_i.$$

Since, on every $v \in D_0$, the number of terms which contribute on the right-hand side is finite, these operators are well defined and map D_0 into itself. Moreover, the relations

$$T_1 P_i = ((1 - Q_i) + b_i Q_i) P_i, \quad T_2 P_i = ((1 - Q_i) + (1/b_i) Q_i) P_i$$

show that the subspace $P_i \mathscr{K}$ decomposes into a subspace $(1 - Q_i) P_i \mathscr{K}$ where both T_1 and T_2 act trivially and an orthogonal subspace $Q_i P_i \mathscr{K} = Q_i \mathscr{K}$ where they act as multiplications with the scalars b_i and $1/b_i$, respectively. As a consequence, T_1 and T_2 are inverses of each other. Because of $\lim_{i \to \infty} b_i = 0$, T_1 is bounded ($\|T_1\| = 1$), whereas T_2 is not. Also, it is clear that T_1 and T_2 are Γ-invariant and symmetric. In particular, it follows that $\langle T_1 u_1, T_2 u_2 \rangle = \langle u_1, T_1 T_2 u_2 \rangle = \langle u_1, u_2 \rangle$ for any $u_1, u_2 \in D_0$. We are thus in the situation of Lemma 3.1 and obtain an unbounded symplectic operator

$$T : D_0 \to \mathscr{K}, \quad T = T_2 \frac{1 + \Gamma}{2} + T_1 \frac{1 - \Gamma}{2}.$$

In the next step, T has to be extended to a larger domain $D_T \supset \mathscr{L}$. To this end, we analyze its singular behavior for $|\vec{k}| \to 0$ by comparing it with powers of (a regularized version ω_r of) the one-particle Hamiltonian ω. Setting

$$\omega_r := \omega(1-P_0) + \epsilon_1 P_0 = \begin{cases} \omega & \text{on } (1-P_0)\mathscr{K}, \\ \epsilon_1 \mathbf{1} & \text{on } P_0\mathscr{K}, \end{cases}$$

and noting that $\omega_r^{1/2} D_0 \subset D_0$, we obtain the following Lemma:

Lemma 3.2: $T_2 \omega_r^{1/2}$ is bounded.

Proof: Making use of $\|\omega_r P_i\| = \epsilon_i$ for $i \in \mathbf{N}$, one obtains for $v \in D_0$

$$\|(T_2-1)\omega_r^{1/2} v\|^2 = \left\| \sum_i \left(\frac{1}{b_i}-1\right) Q_i \omega_r^{1/2} v \right\|^2 = \sum_i \left(\frac{1}{b_i}-1\right)^2 \langle \omega_r^{1/2} v, Q_i \omega_r^{1/2} v \rangle$$

$$\leqslant \sum_i \left(\frac{1}{b_i}-1\right)^2 \mathrm{rk} Q_i \langle \omega_r^{1/2} v, P_i \omega_r^{1/2} v \rangle \leqslant \sum_i \left(\frac{1}{b_i}-1\right)^2 \mathrm{rk} Q_i \epsilon_i \|v\|^2.$$

From the conditions imposed on the b_i, it follows that $\Sigma_i (1/b_i - 1)^2 \,\mathrm{rk} Q_i \epsilon_i$ is finite. Thus $(T_2 - 1)\omega_r^{1/2}$ is bounded, hence also $T_2 \omega_r^{1/2}$. ∎

We now can extend T_1 by continuity to all of $\mathscr{K} =: D_{T_1}$ and T_2 by the formula

$$T_2 v := T_2 \omega_r^{1/2} \omega_r^{-1/2} v, \quad v \in \omega_r^{1/2} \mathscr{K}$$

to the dense subspace $\omega_r^{1/2}\mathscr{K} =: D_{T_2}$. (Strictly speaking, the symbol $T_2 \omega_r^{1/2}$ on the right-hand side stands for the continuous extension to $\mathscr{K}$ of the operator considered in the previous Lemma.) Note that T_1 and T_2 still are Γ-invariant. The relevant properties are collected in the following.

Lemma 3.3:

(1) $D_T := \{v \in \mathscr{K} \mid [(1+\Gamma)/2]v \in \omega_r^{1/2}\mathscr{K}\}$ *is a real linear dense subspace of* $\mathscr{K}$.
(2) $T = T_2(1+\Gamma)/2 + T_1(1-\Gamma)/2$ *is well defined on* D_T.
(3) $T: D_T \to \mathscr{K}$ *is a symplectic operator.*
(4) $\mathscr{L} \subset D_T$, *and* $T\mathscr{L}$ *is dense in* $\mathscr{K}$.

Proof: Part 1 is obvious, since $D_0 \subset D_T$; part 2 has been shown in the previous paragraph. For 3, we have to show that $\langle T_1 u_1, T_2 u_2 \rangle = \langle u_1, u_2 \rangle$ remains true for all $u_1 \in D_{T_1}$ and $u_2 \in D_{T_2}$. First, assume $u_1 \in D_0$. Since D_0 is dense in $\mathscr{K}$ and invariant under $\omega_r^{1/2}$, there exists a sequence $u_2^{(n)} \in D_0$, $n \in \mathbf{N}$, such that $\omega_r^{-1/2} u_2 = \lim \omega_r^{-1/2} u_2^{(n)}$, implying $u_2 = \lim u_2^{(n)}$. Using the boundedness of $T_2 \omega_r^{1/2}$, we can compute

$$\langle T_1 u_1, T_2 u_2 \rangle = \langle T_1 u_1, T_2 \omega_r^{1/2} \omega_r^{-1/2} u_2 \rangle = \left\langle T_1 u_1, T_2 \omega_r^{1/2} \lim_{n\to\infty} \omega_r^{-1/2} u_2^{(n)} \right\rangle$$

$$= \lim_{n\to\infty} \langle T_1 u_1, T_2 \omega_r^{1/2} \omega_r^{-1/2} u_2^{(n)} \rangle = \lim_{n\to\infty} \langle u_1, u_2^{(n)} \rangle = \langle u_1, u_2 \rangle.$$

Since T_1 is bounded, the restriction on u_1 can now be dropped by continuity, thus yielding the assertion. Finally, $\mathscr{L} \subset D_T$ is obvious, and the remaining part of 4 is equivalent, in terms of T_1 and T_2, to

$$\frac{1+\Gamma}{2} T\mathscr{L} = T_2 \frac{1+\Gamma}{2}\,\mathscr{L} = T_2 \omega^{-1/2} \widehat{\mathscr{D}_{\mathbf{R}}} \text{ is dense in } \frac{1+\Gamma}{2}\,\mathscr{K},$$

$$\frac{1-\Gamma}{2i} T\mathscr{L} = T_1 \frac{1-\Gamma}{2i}\,\mathscr{L} = T_1 \omega^{1/2} \widehat{\mathscr{D}_{\mathbf{R}}} \text{ is dense in } \frac{1-\Gamma}{2i}\,\mathscr{K}.$$

By $\mathbf{C}$-linearity, this in turn is equivalent to $T_2 \omega^{-1/2} \widehat{\mathscr{D}_{\mathbf{C}}} = T_2 \omega_r^{1/2} \omega_r^{-1/2} \omega^{-1/2} \widehat{\mathscr{D}_{\mathbf{C}}}$ and $T_1 \omega^{1/2} \widehat{\mathscr{D}_{\mathbf{C}}}$ both being dense in $\mathscr{K}$. But this is implied by the fact that, on the one hand, both operators $T_2 \omega_r^{1/2}$ and

T_1 are bounded and have dense images (since they are invertible on the dense, invariant subspace D_0) and that, on the other hand, the subspaces $\omega_r^{-1/2}\omega^{-1/2}\widehat{\mathscr{D}_{\mathbf{C}}}$ and $\omega^{1/2}\widehat{\mathscr{D}_{\mathbf{C}}}$ are dense in $\mathscr{K}$ (by the spectral calculus of ω). ■

With the above preparations, we can define a state $\omega_T : \mathscr{A} \to \mathbf{C}$ and analyze its main properties.

Proposition 3.4: The quasifree state ω_T, defined on $\mathscr{W}(\mathscr{L})$ by

$$\omega_T(W(f)) = e^{-(1/4)\|Tf\|^2}, \quad f \in \mathscr{L},$$

extends to a unique locally normal state ω_T over the quasilocal algebra $\mathscr{A}$. This state is pure and has positive energy.

Proof: The difficult part of this proof is to obtain local normality of ω_T on the net $\mathscr{O} \mapsto \mathscr{W}(\mathscr{L}(\mathscr{O}))$ of Weyl algebras. To this end, recall that T is (on $\mathscr{L}$) the strong limit of symplectic operators T_n such that $T_n - 1$ have finite rank. As a consequence, the associated quasifree states ω_{T_n} are vector states in the vacuum representation and converge weakly to ω_T on $\mathscr{W}(\mathscr{L})$. Now since the Fredenhagen–Hertel compactness condition $C_\sharp$[7,8] is known to be fulfilled in the present model, we can conclude that ω_T is locally normal if the sequence $(\omega_{T_n})_{n \in \mathbf{N}}$ is bounded with respect to some exponential energy norm $\|\cdot\|_\beta$, $\beta > 0$ defined by $\|\omega\|_\beta^2 := \omega(e^{2\beta H})$. But this follows from $\Sigma_i(\epsilon_i/b_i^2)\mathrm{rk}Q_i < \infty$, as F. Hars has shown in Ref. 9, adapting ideas from Ref. 4. (Although our involution Γ differs from that of Refs. 4 and 9, the arguments leading to this conclusion are still valid.) Hence, ω_T is locally normal on $\mathscr{W}(\mathscr{L})$ and thus extends uniquely to a locally normal state on $\mathscr{A}$. Since it is a weak limit of states in the vacuum representation with positive energy, the arguments of Buchholz and Doplicher[10] can be applied to show that ω_T has positive energy, too. Finally, the relation $\overline{T\mathscr{L}} = \mathscr{K}$, established in Lemma 3.3, implies that ω_T is pure, as has been noted at the very beginning of this section. ■

Remark: The inequality $\Sigma_i(\epsilon_i/b_i^2)\mathrm{rk}Q_i < \infty$, which played a crucial role in the previous proof, has a direct physical interpretation. Indeed, performing the limit $\omega_{T_n} \to \omega_T$ corresponds to the excitation of more and more low-energy ''photon'' modes in comparison to the vacuum, namely those singled out by the projections Q_i, $i = 1, \ldots, n$, which appear in T. Since $1/b_i$ measures the amplitude of these modes, each of them carries an energy of about ϵ_i/b_i^2. Hence the modes in the energy interval $[\epsilon_{i+1}, \epsilon_i]$ contribute with (at most) $(\epsilon_i/b_i^2)\mathrm{rk}Q_i$ to the mean energy of the state ω_T, and the above inequality thus means that ω_T describes an infrared cloud with finite total energy. We conjecture that these arguments can be sharpened in order to prove that the transition energy[11] between the sectors π_0 and π_T vanishes. In terms of Ref. 6, the properties of π_T could then be summarized by saying that it is an ''infravacuum representation,'' and we will indeed use this terminology in the sequel.

C. KPR-like quasifree states

We reach our goal of improving the localization of the automorphisms γ by considering a special class of infravacuum representations. The main idea, due to Ref. 4, is to control the angular momentum carried by the low-energy modes. It may be formalized as follows.

Definition: A state ω_T over $\mathscr{A}$ based on the sequences ϵ_i, Q_i, b_i as described above is called a KPR-like state [and π_T (resp. T) a KPR-like representation (resp. symplectic operator)] if the following two additional conditions are fulfilled:

(1) $(\ln(\epsilon_i/\epsilon_{i+1}))_{i \in \mathbf{N}}$ is polynomially bounded, and $\Sigma_i b_i^2 \ln(\epsilon_i/\epsilon_{i+1}) < \infty$.

(2) With respect to the tensor product structure of the subspace $P_i\mathscr{K}$, $P_i\mathscr{K} \cong L^2([\epsilon_{i+1}, \epsilon_i], \omega^2 d\omega) \otimes L^2(S^2)$, the projections Q_i read

$$Q_i = \frac{|\xi_i\rangle\langle\xi_i|}{\langle\xi_i|\xi_i\rangle} \otimes \tilde{Q}_i \quad \text{with} \quad \tilde{Q}_i := \sum_{0 < l \leqslant i} \sum_{m=-l}^{l} |Y_{lm}\rangle\langle Y_{lm}|;$$

here the vector $\xi_i \in L^2([\epsilon_{i+1}, \epsilon_i], \omega^2 d\omega)$ is given by $\xi_i(\omega) = \omega^{-3/2}$ and $Y_{lm} \in L^2(S^2)$ are the spherical harmonics.

This definition has been formulated so as to imply the regularity property of the bounded operator T_1 formulated in the next Lemma. It is only through this result that the two additional

properties of KPR-like infravacua enter the analysis of Sec. IV. It is apparent from the ensuing proof that the above definition may be generalized in several respects. However, we refrain from discussing these possibilities here.

In contrast, we draw the reader's attention to the following crucial difference between our KPR-like states and the ''true'' KPR states as defined in Ref. 4: In our case, the projection $\tilde{Q}_i$ contains no summand $|Y_{00}\rangle\langle Y_{00}|$. In physical terms, this means that the infrared cloud does not contain any spherically symmetric low-energy modes. Such a restriction is necessary, since it is precisely by such modes or, equivalently, by the isotropic long-range behavior of the ''Coulomb potential,'' that the sectors $[\gamma]$ differ from each other. Too strong an $l=0$ contribution to the infrared cloud would therefore render the sectors indistinguishable in front of that background. (Indeed, if one had $0\leqslant l\leqslant i$ in the definition of $\tilde{Q}_i$, one would obtain, instead of Lemma 3.6 below, that $\pi_T\circ\gamma\cong\pi_T$ for all $\gamma\in\mathscr{S}_\Gamma$.) This seemingly artificial restriction on the background states mimics the situation in QED, where the Coulomb field $\vec{\mathscr{E}}(\vec{k})\sim i\vec{k}/\omega^2$ cannot be compensated by transverse photons.

Lemma 3.5: Let the sequences ϵ_i, Q_i, b_i be such that ω_T is a KPR-like state. Let $u\in\mathscr{K}$ have, in a neighborhood of $\vec{k}=0$, the form $u(\vec{k})=\eta(\vec{k}/|\vec{k}|)$ with some $\eta\in C^\infty(S^2)\subset L^2(S^2)$. Then the sequence $(T_1\omega^{-3/2}P_{\epsilon_n}u)_{n\in\mathbf{N}}$ converges iff $\eta\perp Y_{00}$.

Proof: Without any restriction, one may assume $u=c\otimes\eta$ with $c(\omega)=1$ if $\omega<\epsilon_1$. Let $\eta\perp Y_{00}$. For $0<m<n$, one computes

$$T_1\omega^{-3/2}P_{\epsilon_n}u-T_1\omega^{-3/2}P_{\epsilon_m}u=T_1\omega^{-3/2}\sum_{i=m}^{n-1}P_i(c\otimes\eta)=\sum_{i=m}^{n-1}T_1P_i(\xi_i\otimes\eta)$$

$$=\sum_{i=m}^{n-1}((1-Q_i)+b_iQ_i)(\xi_i\otimes\eta)=\sum_{i=m}^{n-1}\xi_i\otimes((1-\tilde{Q}_i)\eta+b_i\tilde{Q}_i\eta).$$

Now $\eta\in C^\infty(S^2)$ entails that $\|(1-\tilde{Q}_i)\eta\|^2=\Sigma_{l>i}\Sigma_m|\langle Y_{lm},\eta\rangle|^2$, $i\in\mathbf{N}$, is a sequence of rapid decrease (since $\eta\in D(\vec{L}^{2N})$ for any N, $\vec{L}$ denoting the angular momentum operator). Thus, using $\|\xi_i\|^2=\int_{\epsilon_{i+1}}^{\epsilon_i}\omega^2d\omega 1/\omega^3=\ln(\epsilon_i/\epsilon_{i+1})$ and $\|b_i\tilde{Q}_i\eta\|^2\leqslant b_i^2\|\eta\|^2$, one obtains

$$\|T_1\omega^{-3/2}P_{\epsilon_n}u-T_1\omega^{-3/2}P_{\epsilon_m}u\|^2\leqslant\sum_{i=m}^{n-1}\|\xi_i\|^2(\|(1-\tilde{Q}_i)\eta\|^2+b_i^2\|\tilde{Q}_i\eta\|^2)\leqslant\sum_{i=m}^{n-1}\ln\frac{\epsilon_i}{\epsilon_{i+1}}\left(\frac{c_N}{i^N}+b_i^2\right).$$

With suitably chosen N, the right-hand side vanishes as $m,n\to\infty$ due to the conditions imposed on ϵ_i and b_i. Hence $(T_1\omega^{-3/2}P_{\epsilon_n}u)_{n\in\mathbf{N}}$ is a Cauchy sequence. Conversely, assume $\langle Y_{00},\eta\rangle\neq0$. With $\eta=\langle Y_{00},\eta\rangle Y_{00}+\eta_1$, $(T_1\omega^{-3/2}P_{\epsilon_n}(c\otimes\eta_1))_{n\in\mathbf{N}}$ is convergent, hence $(T_1\omega^{-3/2}P_{\epsilon_n}u)_{n\in\mathbf{N}}$ is divergent because $(T_1\omega^{-3/2}P_{\epsilon_n}(c\otimes Y_{00}))_{n\in\mathbf{N}}=(\omega^{-3/2}P_{\epsilon_n}(c\otimes Y_{00}))_{n\in\mathbf{N}}$ is. ■

We end this section with a result which shows that the KPR-like infravacua do not affect the superselection structure of the present model. As the previous Lemma, it makes essential use of the fact that $Tf=f$ for all rotation invariant elements $f\in D_T$.

Lemma 3.6: Let π_T be a KPR-like infravacuum representation. Then, for any $\gamma_1,\gamma_2\in\mathscr{S}_\Gamma$, one has

$$\pi_0\circ\gamma_1\cong\pi_0\circ\gamma_2\quad\text{iff}\quad\pi_T\circ\gamma_1\cong\pi_T\circ\gamma_2.$$

Proof: Let $\pi_0\circ\gamma_1\cong\pi_0\circ\gamma_2$. Then $\gamma:=\gamma_1-\gamma_2\in\mathscr{S}_\Gamma$ has charge $q_\gamma=0$, as noted in the Introduction, which does not only yield $\gamma\in\mathscr{K}$, but even $\gamma\in D_T$. Hence, the unitary $W(T\gamma)$ is well-defined and intertwines the representations $\pi_T\circ\gamma_1$ and $\pi_T\circ\gamma_2$. Conversely, assume $\pi_0\circ\gamma_1\ncong\pi_0\circ\gamma_2$, i.e., $q_{\gamma_1}\neq q_{\gamma_2}$. For any *rotation invariant* test function $h\in\mathscr{D}_{\mathbf{R}}(\mathbf{R}^3\backslash\{0\})$, one has $\omega^{-1/2}\hat{h}=:f\in\mathscr{S}(\mathscr{O}')$ for some open neighborhood $\mathscr{O}\subset\mathbf{R}^{1+3}$ of 0. Since $Tf_\lambda=f_\lambda$, Lemma 2.2 implies

$$\pi_T\circ\gamma_j(W(f_\lambda))=\gamma_j(W(f_\lambda))\xrightarrow{\lambda\to\infty}e^{iq_{\gamma_j}\kappa_f}\,e^{-(1/4)\|f\|^2}\mathbf{1}.$$

As it is always possible to obtain $e^{iq_{\gamma_1}\kappa_f} \neq e^{iq_{\gamma_2}\kappa_f}$ by a rescaling of h, it follows that $\pi_T \circ \gamma_1 \not\cong \pi_T \circ \gamma_2$. ■

IV. BETTER LOCALIZATION OF THE SECTORS IN FRONT OF KPR-LIKE INFRAVACUA

The main aim of this section is to prove the following result which establishes some (non-Lorentz invariant) version of BF localization. In the sequel, we will denote by $\mathscr{C} = (\{t\} \times C)''$ an ''upright'' spacelike cone whose basis is the open convex cone $C \subset \mathbf{R}^3$ at time t. Note that the set of upright spacelike cones is translation invariant and that an arbitrary spacelike cone can be obtained from an upright one by a Lorentz transformation.

Proposition 4.1: Let π_T be a KPR-like infravacuum representation, and let $\gamma \in \mathscr{S}_\Gamma$. Then one has for any upright spacelike cone $\mathscr{C}$:

$$\pi_T \circ \gamma|_{\mathscr{A}(\mathscr{C}')} \cong \pi_T|_{\mathscr{A}(\mathscr{C}')}.$$

To prove this assertion, we will first deal with a special case in which the relevant computations can be carried out quite explicitly. Eventually, the formal proof will consist in reducing the general case to the special one.

The case discussed first amounts to the following two assumptions:

(i) $\mathscr{C} = (\{0\} \times C)''$ and the apex of C is the origin $0 \in \mathbf{R}^3$;

(ii) $\gamma \in \mathscr{S}_\Gamma$ has the special form $\gamma = i\omega^{-3/2}\hat{\rho}$, where $\rho \in \mathscr{D}_{\mathbf{R}}(\mathbf{R}^3)$ satisfies $\rho = -\Delta\Phi$ with a rotation invariant function $\Phi \in C^\infty_{\mathbf{R}}(\mathbf{R}^3)$ obeying, for some $0 < r_1 < r_2 < \infty$,

$$\Phi(\vec{x}) = \begin{cases} 0 & \text{if } |\vec{x}| < r_1, \\ \dfrac{q_\gamma}{4\pi|\vec{x}|} & \text{if } |\vec{x}| > r_2. \end{cases}$$

To proceed, we note that the cone $C \subset \mathbf{R}^3$ determines, by projection onto the unit sphere S^2, a subset of S^2 which we denote by C, too. Now we choose a function $\chi^C \in C^\infty_{\mathbf{R}}(S^2)$ with the properties

$$(i)\ \ \chi^C|_{S^2 \setminus C} = 1 \quad \text{and} \quad (ii)\ \ \langle Y_{00}, \chi^C \rangle = 0,$$

and denote by $\Phi^C \in C^\infty_{\mathbf{R}}(\mathbf{R}^3)$ the product

$$\Phi^C(\vec{x}) := (\Phi \cdot \chi^C)(\vec{x}) := \Phi(\vec{x})\chi^C(\vec{x}/|\vec{x}|).$$

This function will now be used to construct a unitary intertwiner from π_T to $\pi_T \circ \gamma$ on the C*-algebra $\mathscr{W}(\mathscr{A}(\mathscr{C}'))$. [Here and in the sequel, we use the notation $\Psi \cdot \eta$ for the pointwise product of a rotation invariant function Ψ and the function $\vec{u} \mapsto \eta(\vec{u}/|\vec{u}|)$, where $\eta \in C^\infty(S^2)$. For definiteness, we let $(\Psi \cdot \eta)(0) := 0$.]

For this purpose, we calculate (using spherical coordinates)

$$-\Delta\Phi^C = \rho \cdot \chi^C + \frac{\Phi}{r^2} \cdot \vec{L}^2 \chi^C.$$

This function is square integrable, hence its Fourier transform $u^C := \widehat{-\Delta\Phi^C}$ lies in $\mathscr{K}$, and

$$v_n^C := i\omega^{-3/2} P_{\epsilon_n} u^C, \quad n \in \mathbf{N},$$

is a well-defined sequence in D_0 which approximates the linear form l_γ on $\mathscr{C}'$ in the following sense:

Lemma 4.2: For any $f \in \mathscr{A}(\mathscr{C}')$, one has $l_\gamma(f) = -\lim_{n\to\infty} \mathrm{Im}\langle v_n^C, f \rangle$.

Proof: Write $f = \omega^{-1/2}\hat{h} + i\omega^{+1/2}\hat{g}$ with $h, g \in \mathscr{D}_{\mathbf{R}}(\mathbf{R}^3 \setminus \overline{C})$ and consider

$$-\mathrm{Im}\langle v_n^C, f\rangle = -\mathrm{Im}\langle i\omega^{-3/2}P_{\epsilon_n}u^C, \omega^{-1/2}\hat{h} + i\omega^{+1/2}\hat{g}\rangle = \int_{|\vec{k}|>\epsilon_n} d^3k\,\omega^{-2}\overline{u^C(\vec{k})}\hat{h}(\vec{k}).$$

Since $u^C \in L^\infty_{\mathrm{loc}}(\mathbf{R}^3)$ (cf. Lemma 4.3), whence $\widehat{\Phi^C} = \omega^{-2}u^C \in L^1_{\mathrm{loc}}(\mathbf{R}^3)$, it follows that this sequence converges for $n\to\infty$ to

$$\int_{\mathbf{R}^3} d^3k\,\overline{\widehat{\Phi^C}(\vec{k})}\hat{h}(\vec{k}) = \Phi^C(h) = \Phi(h) = \int_{\mathbf{R}^3} d^3k\,\overline{\hat{\Phi}(\vec{k})}\hat{h}(\vec{k}).$$

In the previous line, we have viewed Φ^C and Φ as distributions and made use of the fact that they coincide on supp h. The proof is now completed by a straightforward computation showing that the last expression equals $l_\gamma(f)$. ■

Whereas property (*i*) of χ^C was essential for the previous Lemma, the following one will show how property (*ii*) determines the behavior of u^C in a neighborhood of $\vec{k}=0$.

Lemma 4.3: There exists a smooth function $\eta \in C^\infty(S^2)$ *with* $\langle Y_{00}, \eta\rangle = 0$ *and an analytic function* $R:\mathbf{R}^3\to\mathbf{C}$ *with* $R(0)=0$ *such that*

$$u^C(\vec{k}) = \eta(\vec{k}/|\vec{k}|) + R(\vec{k}) \quad for \;\; \vec{k}\neq 0.$$

Proof: Let $\mathscr{S}_{00}$ denote the set of all rotation-invariant test functions. Since $\langle Y_{00}, \vec{L}^2\chi^C\rangle = 0$, there exists a unique distribution F_1 on $\mathbf{R}^3$ which is homogeneous of degree -3 and which coincides on $\mathbf{R}^3\backslash\{0\}$ with $(q_\gamma/4\pi)(1/r^3)\cdot\vec{L}^2\chi^C$. By Theorems 7.1.16 and 18 of Ref. 12 it follows that its Fourier transform $\widehat{F_1}$ is homogeneous of degree 0 and restricts on $\mathbf{R}^3\backslash\{0\}$ to a smooth function, i.e., $\hat{F}_1(\vec{k}) = \eta(\vec{k}/|\vec{k}|)$ for $\vec{k}\neq 0$ with some $\eta\in C^\infty(S^2)$. Moreover, since $F_1|_{\mathscr{S}_{00}} = 0$ and $\mathscr{S}_{00}$ is stable under Fourier transformations, it follows that $\langle Y_{00}, \eta\rangle = 0$. Now consider the distribution $F_2 := -\Delta\Phi^C - F_1$. For $r\neq 0$, it is given by $F_2 = \rho\cdot\chi^C + (\Phi - q_\gamma/4\pi r)1/r^2\cdot\vec{L}^2\chi^C$ and thus has compact support. Hence, its Fourier transform is an analytic function R: $\hat{F}_2(\vec{k}) = R(\vec{k})$, $\vec{k}\in\mathbf{R}^3$. As χ^C was assumed to fulfill $\langle Y_{00}, \chi^C\rangle = 0$, it follows in particular that $R(0) = \int d^3x(\rho\cdot\chi^C)(\vec{x}) = 0$. To sum up, we have $-\Delta\Phi^C = F_1 + F_2$ (in the sense of distributions) and thus $-\widehat{\Delta\Phi^C} = \hat{F}_1 + \hat{F}_2$. Since all three terms of this last equation are smooth on $\mathbf{R}^3\backslash\{0\}$, this implies the identity $u^C(\vec{k}) = -\widehat{\Delta\Phi^C}(\vec{k}) = \eta(\vec{k}/|\vec{k}|) + R(\vec{k})$ for all $\vec{k}\neq 0$. ■

The knowledge of u^C at $\vec{k}=0$ now permits us to establish the connection with the KPR-like infravacuum representations described in Sec. III.

Lemma 4.4: Let T be a KPR-like symplectic operator. Then we have the following.

(1) *The limit* $v_T^C := \lim_{n\to\infty} Tv_n^C$ *exists in* $\mathscr{K}$.
(2) *The unitary* $W(v_T^C)$ *satisfies*

$$\mathrm{Ad}\; W(v_T^C)\circ\pi_T = \pi_T\circ\gamma \;\; on \;\; \mathscr{A}(\mathscr{C}').$$

Proof: Since $\Delta\Phi^C$ is real-valued, one has $\Gamma u^C = u^C$, hence $\Gamma v_n^C = -v_n^C$. Thus, $Tv_n^C = T_1v_n^C = iT_1\omega^{-3/2}P_{\epsilon_n}u^C = iT_1\omega^{-3/2}P_{\epsilon_n}(u_1^C + u_2^C)$ with $u_1^C, u_2^C \in \mathscr{K}$ defined by $u_1^C := (1-P_0)(1\cdot\eta)$ and $u_2^C := u^C - u_1^C = P_0(1\cdot\eta) + R$, where η and R are as in the previous Lemma. In particular, $R(0) = 0$ yields $u_2^C \in D_{\omega^{-3/2}}$ which implies $T_1\omega^{-3/2}P_{\epsilon_n}u_2^C = T_1P_{\epsilon_n}\omega^{-3/2}u_2^C \xrightarrow{n\to\infty} T_1\omega^{-3/2}u_2^C$ by the boundedness of T_1. On the other hand, it follows from $\langle Y_{00}, \eta\rangle = 0$ by Lemma 3.5 that the sequence $(T_1\omega^{-3/2}P_{\epsilon_n}u_1^C)_{n\in\mathbf{N}}$ is convergent, which completes the proof of Part 1. Part 2 is a straightforward computation: Let $f\in\mathscr{S}(\mathscr{C}')$; then, by Lemma 4.2, $\mathrm{Im}\langle v_T^C, Tf\rangle = \lim_{n\to\infty}\mathrm{Im}\langle Tv_n^C, Tf\rangle = \lim_{n\to\infty}\mathrm{Im}\langle v_n^C, f\rangle = -l_\gamma(f)$, which implies

$$\mathrm{Ad}\; W(v_T^C)(\pi_T(W(f))) = W(v_T^C)W(Tf)W(v_T^C)^* = e^{-i\,\mathrm{Im}\langle v_T^C, Tf\rangle}W(Tf)$$
$$= e^{il_\gamma(f)}W(Tf) = \pi_T\circ\gamma(W(f)).$$

This establishes the stated equivalence on $\mathscr{W}(\mathscr{L}(\mathscr{C}'))$ and, hence, by local normality (of both π_T and γ) also on $\mathscr{A}(\mathscr{C}')$. ■

With these preparations, we are ready for the following proof.

Proof of Proposition 4.1: By standard arguments using transportability of the charges, $\gamma_x \cong \gamma$, and translation covariance of the representation π_T, it can always be assumed that the apex of $\mathscr{C}$ is $0 \in \mathbf{R}^{1+3}$. To remove the assumption on the special form of γ as well, we note that, for any $\gamma \in \mathscr{S}_\Gamma$, there exists some equivalent $\gamma_0 \in \mathscr{S}_\Gamma$ with the special form considered. Such a γ_0 automatically satisfies $\gamma_0 - \gamma \in D_T$ and thus provides a unitary $W(T(\gamma_0 - \gamma))$ performing the equivalence $\pi_T \circ \gamma \cong \pi_T \circ \gamma_0$ on all of $\mathscr{A}$. Taking into account all the above, this proves Proposition 4.1. ■

V. CONCLUSIONS

The present work has shown in a concrete example that choosing a background different from the vacuum can improve the localizability properties of superselection sectors in theories with massless particles. Typically, such backgrounds correspond to clouds of infrared radiation which exist in great variety in any such theory, but it appears that *suitable* background states have to be chosen carefully in order to match with the sectors under consideration. To illustrate this point, we recall that this led us, in particular, to choose complex conjugation in *position* space as the involution Γ. If we had, on the other hand, chosen complex conjugation $\hat{\Gamma}$ in *momentum* space instead of Γ, our sectors would only have been localizable in *upright spacelike double cones*, i.e., in regions of the form $\mathscr{C} \cup (a - \mathscr{C})$, where $\mathscr{C}$ is an upright spacelike cone and $a \in \mathbf{R}^{1+3}$, but not in spacelike cones any more. (The former statement can be verified with the method of Sec. IV, the latter can be reduced to an application of Lemma 2.2.)

Finally, we remark that we were unable, with our methods, to establish the *full* BF localization criterion for the sectors $[\gamma]$, i.e., $\pi_T \circ \gamma|_{\mathscr{A}(\mathscr{C}')} \cong \pi_T|_{\mathscr{A}(\mathscr{C}')}$ even for spacelike cones $\mathscr{C}$ which do not contain an upright one. Apart from the obvious fact that the KPR-like states break Lorentz covariance explicitly, there seem to be other indications that such a result might indeed not be true. However, we do not pursue this point further, since the localization properties obtained here should be sufficient for carrying through a DHR-like analysis (along the lines of Ref. 2) in front of the infravacuum background. If this is indeed possible, it has to be studied in a subsequent step under which conditions (to be imposed on the infravacuum) the superselection structure thus obtained will be independent from the particular background.

ACKNOWLEDGMENTS

I would like to thank Professor D. Buchholz for numerous helpful discussions and stimulating interest in this work. Partial financial support from the Deutsche Forschungsgemeinschaft (''Graduiertenkolleg Theoretische Elementarteilchenphysik'' at Hamburg University) is also gratefully acknowledged.

We characterize functionally coexistent observables in terms of biobservables and joint observables. Coexistent sets of effects are characterized in terms of projective systems of simple observables. © *1998 American Institute of Physics.* [S0022-2488(98)00712-9]

I. INTRODUCTION

In an operational formulation of quantum mechanics the notions of *states* (equivalence classes of preparation procedures) and *observables* (equivalence classes of measurements or registration procedures) occur in a statistical duality: each pair (s,o) of a state s and an observable o determines a probability distribution $p(s,o)$ of the possible measurement outcomes in the given experiment.[1,2] This leads one to express the notion of an observable as an assignment $s\mapsto p(s,o)$. Should it be possible to mix preparation procedures into new preparation procedures, the set of states acquires the structure of a convex set. In such a case it is natural to require that the assignment $s\mapsto p(s,o)$ preserves this convex structure.

Given two observables $s\mapsto p(s,o_1)$ and $s\mapsto p(s,o_2)$, the question arises under which conditions it is possible to collect the relevant experimental data under a single observable $s\mapsto p(s,o)$. This leads to the notion of the *coexistence* of observables, and it is an important question in quantum mechanics to characterize such (pairs of or collections of) observables. In Sec. I of this paper we shall define the notion of an observable as an affine function from an abstract convex set to the set of probability measures on a measurable space, and we introduce the notion of the coexistence of such observables. Theorem 2.1.5 then characterizes an important class of functionally coexistent observables in terms of so-called biobservables and joint observables. In the remaining part of Sec. I we illustrate this result in the framework of a total effect algebra (Sec. II B) as well as in the Hilbert space formulation of quantum mechanics (Sec. II C).

In Sec. III we regard an *effect* as a $[0,1]$-valued affine function on an abstract convex set of states. Adopting the usual notion of the coexistence of effects in this setting, we then characterize coexistent sets of effects in terms of projective systems of simple observables.

II. COEXISTENT OBSERVABLES

A. Observables as affine functions

Let S be a convex set, that is, a nonempty set with a convex structure:[3]

(CS1) for any finite set of positive numbers $w_1,\ldots,w_n$ satisfying $\Sigma w_i=1$ and any $s_1,\ldots,s_n\in S$ there is a unique element $\langle w_1,\ldots,w_n;s_1,\ldots,s_n\rangle\in S$;
(CS2) $\langle w_1,\ldots,w_n;s,\ldots,s\rangle=s$.

We assume that the set of (normalized) states of a physical system forms a convex set and we interpret $\langle w_1,\ldots,w_n;s_1,\ldots,s_n\rangle$ as a mixture of the states $s_1,\ldots,s_n$ with the weights $w_1,\ldots,w_n$, respectively.

Let $(\Omega,\mathcal{B})$ be a measurable space, where $\mathcal{B}$ is a σ-algebra of subsets of a nonempty set Ω, and let $M_1^+(\Omega,\mathcal{B})$ denote the convex set of probability measures on $(\Omega,\mathcal{B})$. Let $E:S\to M_1^+(\Omega,\mathcal{B})$ be an affine function, that is, a function $s\mapsto E(s)$ which has the property

$$E(\langle w,1-w;s_1,s_2\rangle)=wE(s_1)+(1-w)E(s_2),$$

for all $s_1,s_2\in S$, and for any $0\leqslant w\leqslant 1$. Let $A_1^+(S)$ denote the set of affine functions $f:S\to[0,1]$. Then we get a map $\tilde{E}:\mathcal{B}\to A_1^+(S)$ by defining

$$\tilde{E}(X)(s):=E(s)(X),$$

for all $s\in S,X\in\mathcal{B}$. Equipping $A_1^+(S)$ with the topology τ of pointwise convergence, the induced product topology of $A_1^+(S)\subset[0,1]^S$, we get

$$\tilde{E}\ \text{ is } \sigma\text{-additive with respect to } \tau,$$

$$\tilde{E}(\Omega)=1_S,$$

where 1_S is the constant one function.

Theorem 2.1.1: The map $E\mapsto\tilde{E}$ is an affine bijection from the convex set of affine functions $E:S\to M_1^+(\Omega,\mathcal{B})$ onto the convex set of σ-additive functions $F:\mathcal{B}\to A_1^+(S)$ (with respect to τ) satisfying $F(\Omega)=1_S$.

Proof: The injectivity is obvious. Let now $F:\mathcal{B}\to A_1^+(S)$ be σ-additive with respect to τ and satisfy $F(\Omega)=1_S$. Define $E(s)(X):=F(X)(s)$ for all $s\in S,X\in\mathcal{B}$. Then $S\ni s\mapsto E(s)\in M_1^+(\Omega,\mathcal{B})$ is affine, and $F=\tilde{E}$.

Definition 2.1.2: (*a*) An affine map $E:S\to M_1^+(\Omega,\mathcal{B})$ is called an *observable*. (*b*) Two observables $E_i:S\to M_1^+(\Omega_i,\mathcal{B}_i)$, $i=1,2$, are called *coexistent*, if there is a measurable space $(\Omega,\mathcal{B})$ with an observable $E:S\to M_1^+(\Omega,\mathcal{B})$ such that

$$\tilde{E}_1(\mathcal{B}_1)\cup\tilde{E}_2(\mathcal{B}_2)\subseteq\tilde{E}(\mathcal{B}).$$

(*c*) Two observables $E_i:S\to M_1^+(\Omega_i,\mathcal{B}_i)$, $i=1,2$, are *functionally coexistent* if there is a measurable space $(\Omega,\mathcal{B})$ with an observable $E:S\to M_1^+(\Omega,\mathcal{B})$ such that for some measurable functions $f_i:\Omega\to\Omega_i$,

$$E_i(s)(X)=E(s)(f_i^{-1}(X)),$$

for all $s\in S,X\in\mathcal{B}_i$, $i=1,2$.

We observe that the condition $E_i(s)(X)=E(s)(f_i^{-1}(X))$, $s\in S,X\in\mathcal{B}_i$, is equivalent to the condition $\tilde{E}_i(X)=\tilde{E}(f_i^{-1}(X))$, $X\in\mathcal{B}_i$. Obviously, functionally coexistent observables are coexistent.

For any two measurable spaces $(\Omega_i,\mathcal{B}_i)$, $i=1,2$, we let $BM_1^+(\Omega_1\times\Omega_2,\mathcal{B}_1\times\mathcal{B}_2)$ denote the set of probability bimeasures on $(\Omega_1\times\Omega_2,\mathcal{B}_1\times\mathcal{B}_2)$, where $\mathcal{B}_1\times\mathcal{B}_2=\{(X,Y)|X\in\mathcal{B}_1,Y\in\mathcal{B}_2\}$. By definition, if $\Phi\in BM_1^+(\Omega_1\times\Omega_2,\mathcal{B}_1\times\mathcal{B}_2)$, then $\Phi(\Omega_1\times\Omega_2)=1$, and for each $X\in\mathcal{B}_1$ the partial function $Y\mapsto\Phi(X,Y)$ is a $[0,1]$-valued measure on $(\Omega_2,\mathcal{B}_2)$ and for each $Y\in\mathcal{B}_2$ the function $X\mapsto\Phi(X,Y)$ is a $[0,1]$-valued measure on $(\Omega_1,\mathcal{B}_1)$. Let $B:S\to BM_1^+(\Omega_1\times\Omega_2,\mathcal{B}_1\times\mathcal{B}_2)$ be an affine function, and define $\tilde{B}:\mathcal{B}_1\times\mathcal{B}_2\to A_1^+(S)$ by putting

$$\tilde{B}(X,Y)(s):=B(s)(X,Y),$$

for all $s\in S,X\in\mathcal{B}_1,Y\in\mathcal{B}_2$. Analogously with Theorem 2.1.1 we get the following.

Theorem 2.1.3: The map $B \mapsto \tilde{B}$ is an affine bijection from the convex set of affine functions $B:S \to BM_1^+(\Omega_1 \times \Omega_2, \mathcal{B}_1 \times \mathcal{B}_2)$ onto the convex set of separately σ-additive (with respect to τ) functions $C:\mathcal{B}_1 \times \mathcal{B}_2 \to A_1^+(S)$ satisfying $C(\Omega_1, \Omega_2) = 1_S$.

Definition 2.1.4: An affine map $B:S \to BM_1^+(\Omega_1 \times \Omega_2, \mathcal{B}_1 \times \mathcal{B}_2)$ is called a *biobservable*.

The question arises under which conditions a biobservable determines an observable.

Assume now that Ω is a Hausdorff space, and let $\mathcal{B}(\Omega)$ be its Borel σ-algebra, that is, the σ-algebra generated by the open subsets of Ω. We call $(\Omega, \mathcal{B}(\Omega))$ a Hausdorff Borel space. Following Ref. 4 we call a probability measure $\mu:\mathcal{B}(\Omega) \to [0,1]$ a *Radon probability measure* if it satisfies the regularity condition:

$$\mu(X) = \sup\{\mu(C) \mid C \subseteq X, C \text{ compact}\}$$

for each $X \in \mathcal{B}(\Omega)$. We let $RM_1^+(\mathcal{B}(\Omega))$ denote the set of Radon probability measures on $(\Omega, \mathcal{B}(\Omega))$, and we call an affine map $E:S \to RM_1^+(\mathcal{B}(\Omega))$ a *Radon observable*. Similarly, if $(\Omega_1, \mathcal{B}(\Omega_1))$ and $(\Omega_2, \mathcal{B}(\Omega_2))$ are two Hausdorff Borel spaces, we say that a probability bimeasure $\Phi:\mathcal{B}(\Omega_1) \times \mathcal{B}(\Omega_2) \to [0,1]$ is a Radon probability bimeasure if

$$\Phi(X,Y) = \sup\{\Phi(C,D) \mid C \subseteq X, D \subseteq Y, C, D \text{ compact}\}$$

for all Borel sets $X \in \mathcal{B}(\Omega_1)$ and $Y \in \mathcal{B}(\Omega_2)$. We let $RBM_1^+(\mathcal{B}(\Omega_1) \times \mathcal{B}(\Omega_2))$ denote the set of Radon probability bimeasures on $(\Omega_1 \times \Omega_2, \mathcal{B}(\Omega_1) \times \mathcal{B}(\Omega_2))$, and we call an affine map $B:S \to RBM_1^+(\mathcal{B}(\Omega_1) \times \mathcal{B}(\Omega_2))$ a *Radon biobservable*.

Let $(\Omega_1, \mathcal{B}(\Omega_1))$ and $(\Omega_2, \mathcal{B}(\Omega_2))$ be two Hausdorff Borel spaces, and let $\mathcal{B}(\Omega_1 \times \Omega_2)$ denote the Borel σ-algebra of $\Omega_1 \times \Omega_2$. Let $E_1:S \to RM_1^+(\mathcal{B}(\Omega_1))$ and $E_2:S \to RM_1^+(\mathcal{B}(\Omega_2))$ be two Radon observables. We say that E_1 and E_2 have a *Radon joint observable* if there is a Radon observable $E:S \to RM_1^+(\mathcal{B}(\Omega_1 \times \Omega_2))$ such that $E_1(s)(X) = E(s)(X \times \Omega_2)$ and $E_2(s)(Y) = E(s)(\Omega_1 \times Y)$ for all $X \in \mathcal{B}(\Omega_1), Y \in \mathcal{B}(\Omega_2)$, and for all $s \in S$. Similarly, we say that E_1 and E_2 have a Radon biobservable if there is a Radon biobservable $B:S \to RBM_1^+(\mathcal{B}(\Omega_1) \times \mathcal{B}(\Omega_2))$ such that $\tilde{E}_1(X) = \tilde{B}(X, \Omega_2)$ and $\tilde{E}_2(Y) = \tilde{B}(\Omega_1, Y)$ for all $X \in \mathcal{B}(\Omega_1), Y \in \mathcal{B}(\Omega_2)$. Similarly, we may specify, for instance, the notion of functional coexistence of Definition 2.1.2 to the notion of *functional R-coexistence* assuming that all the observables involved are Radon observables.

Theorem 2.1.5: Let $(\Omega_1, \mathcal{B}(\Omega_1))$ and $(\Omega_2, \mathcal{B}(\Omega_2))$ be two Hausdorff Borel spaces. For any two Radon observables $E_1:S \to RM_1^+(\mathcal{B}(\Omega_1))$ and $E_2:S \to RM_1^+(\mathcal{B}(\Omega_2))$ the following three statements are equivalent:

(a) E_1 and E_2 have a Radon biobservable;
(b) E_1 and E_2 have a Radon joint observable;
(c) E_1 and E_2 are functionally R-coexistent.

Proof: $(a) \Rightarrow (b)$ Let B be a Radon biobservable associated with E_1 and E_2. Then, for any $s \in S$, the Radon probability bimeasure $B(s)$ determines a unique Radon probability measure $\mu(B,s)$ on $(\Omega_1 \times \Omega_2, \mathcal{B}(\Omega_1 \times \Omega_2))$ such that for all $X \in \mathcal{B}(\Omega_1)$, $Y \in \mathcal{B}(\Omega_2)$,

$$\mu(B,s)(X \times Y) = B(s)(X,Y)$$

(see Theorem 1.10, p. 24, of Ref. 4). Putting $E(s)(Z) = \mu(B,s)(Z)$ for all $s \in S, Z \in \mathcal{B}(\Omega_1 \times \Omega_2)$, one defines a Radon observable $E:S \to RM_1^+(\mathcal{B}(\Omega_1 \times \Omega_2))$ with the property

$$\tilde{E}(X \times \Omega_2) = \tilde{B}(X, \Omega_2) = \tilde{E}_1(X),$$

$$\tilde{E}(\Omega_1 \times Y) = \tilde{B}(\Omega_1, Y) = \tilde{E}_2(Y),$$

for all $X \in \mathcal{B}_1, Y \in \mathcal{B}_2$.

$(b) \Rightarrow (c)$ Let now F be a Radon joint observable of E_1 and E_2, and let π_1 and π_2 be the coordinate projections $\Omega_1 \times \Omega_2 \to \Omega_1$, $\Omega_1 \times \Omega_2 \to \Omega_2$, respectively. Then $\tilde{E}_1(X) = \tilde{F}(\pi_1^{-1}(X))$ and $\tilde{E}_2(Y) = \tilde{F}(\pi_2^{-1}(Y))$, showing that E_1 and E_2 are functionally R-coexistent.

$(c)\Rightarrow(a)$ If $\tilde{E}_1(X)=\tilde{E}(f_1^{-1}(X))$ and $\tilde{E}_2(Y)=\tilde{E}(f_2^{-1}(Y))$, for some Radon observable $E:S\to M_1^+(\mathcal{B}(\Omega))$ and some Borel functions $f_i:\Omega\to\Omega_i$, $i=1,2$, then $\tilde{B}(X,Y)(s):=\tilde{E}(f_1^{-1}(X)\cap f_2^{-1}(Y))(s)$, $X\in\mathcal{B}(\Omega_1), Y\in\mathcal{B}(\Omega_2), s\in S$, defines a biobservable B with the desired properties.

Remark 2.1.6: In physical applications, the underlying spaces Ω,Ω_1,Ω_2, of observables $E:S\to M_1^+(\Omega,\mathcal{B})$ and biobservables $B:S\to BM_1^+(\Omega_1\times\Omega_2,\mathcal{B}_1\times\mathcal{B}_2)$ are often equipped with locally compact metrizable and separable topologies. The measures on the Borel σ-algebras of such spaces are necessarily Radon measures.[5] In such cases one may, therefore, just refer to observables, joint observables, and biobservables without any further qualification of their being Radon, e.g., in Theorem 2.1.5. In particular, this is the case for Ω being the real Borel space $(\mathbf{R},\mathcal{B}(\mathbf{R}))$, or its n-fold Cartesian product.

Remark 2.1.7: The framework of Theorem 2.1.5 is very general. In interesting cases this framework is further specified not only with respect to the measurable spaces $(\Omega,\mathcal{B})$ involved, cf. above, but also giving some further structure on the set of states, like σ-additivity (with respect to an appropriate topology). In such cases it is natural to restrict also the notion of observable further to those affine functions $E:S\to M_1^+(\Omega,\mathcal{B})$ which preserve this additional structure. In the next section we shall come to this question.

B. Observables on effect algebras

Definition 2.2.1: An *effect algebra* is a set L with two distinguished elements 0_L and 1_L, and with a partially defined binary operation $L\times L\ni(a,b)\mapsto a\oplus b\in L$ such that for any $a,b,c\in L$ the following conditions are satisfied, see, e.g., Ref. 6:

(EA1) $a\oplus b$ is defined, if and only if $b\oplus a$ is defined, and then $a\oplus b=b\oplus a$ (commutativity);
(EA2) $b\oplus c$, $a\oplus(b\oplus c)$ are defined, if and only if $a\oplus b$, $(a\oplus b)\oplus c$ are defined, and then $a\oplus(b\oplus c)=(a\oplus b)\oplus c$ (associativity);
(EA3) for every $a\in L$, there is a unique $b\in L$ such that $a\oplus b=1_L$ (orthocomplementation);
(EA4) $1_L\oplus a$ is defined, if and only if $a=0_L$ (zero-one law).

If the assumptions of (EA2) are satisfied, we write $a\oplus b\oplus c$ for the element $a\oplus(b\oplus c)=(a\oplus b)\oplus c$. We say that $a,b\in L$ are $\oplus$-*orthogonal* if $a\oplus b$ is defined. Occasionally we then write $a\perp b$. The element b in (EA3) for which $a\oplus b=1$ is called the *orthocomplement* of a, and we write $b=a'$.

A partial order $\leqslant$ can be defined on L as follows: $a\leqslant b$, if there is a $c\in L$ such that $c\perp a$ and $a\oplus c=b$. The element c is uniquely defined, since (EA3) enables one to prove the cancellation law: if $a\oplus c=b\oplus c$, then $a=b$. In this ordering, 0_L is the smallest and 1_L is the greatest element in L.

We say that a finite sequence $a_1,a_2,\ldots,a_n$ of elements of L is $\oplus$-*orthogonal*, if the element $a_1\oplus a_2\oplus\ldots\oplus a_n$ exists in L, where the latter element is defined recursively using (EA1) and (EA2). An arbitrary system $G=\{a_i\}_{i\in I}$ of (not necessarily different) elements of L is $\oplus$-orthogonal if every finite subsystem $\{a_i\}_{i\in F}$, $F\subset I$, of G is $\oplus$-orthogonal. A $\oplus$-orthogonal system G has $\oplus$-sum, if the least upper bound $\oplus G:=\vee_F(\oplus_{i\in F}a_i)$ over all finite $\oplus$-sums exists. An effect algebra L is called *σ-complete (complete)*, if $\oplus$-sums exist for any countable (arbitrary) system $\{a_i\}_{i\in I}$ of $\oplus$-orthogonal elements of L.

Example 2.2.2: Let $[0,1]$ be the unit interval of the real numbers. For any $a,b\in[0,1]$, define $a\oplus b:=a+b$, whenever $a+b\leqslant 1$. Then $([0,1],0,1,\oplus)$ is a complete effect algebra.

Example 2.2.3: Let $\mathcal{B}$ be a σ-algebra of a nonempty set Ω. $(\mathcal{B},\varnothing,\Omega,\oplus)$ is a σ-complete effect algebra, with the $\oplus$-operation defined as the disjoint set theoretical union: $X\oplus Y:=X\cup Y$, whenever $X\cap Y=\varnothing$.

Example 2.2.4: Let $\mathcal{F}$ be a set of functions from a nonempty set S to the unit interval $[0,1]$ such that (F1a) $1_S\in\mathcal{F}$, (F1b) if $f\in\mathcal{F}$, then also $1_S-f\in\mathcal{F}$, and (F2) if $f,g,h\in\mathcal{F}$, $f+g\in\mathcal{F}$, $f+g+h\in\mathcal{F}$, then also $g+h\in\mathcal{F}$. Defining $f\oplus g=f+g$, whenever $f+g\in\mathcal{F}$, one obtains that $(\mathcal{F},0_S,1_S,\oplus)$ is an effect algebra. If, in addition, the following condition is satisfied,

$$\text{(F3)}\quad f,\ g\in\mathcal{F},\quad f+g\leqslant 1_S\Rightarrow f+g\in\mathcal{F}$$

(with $f+g\leqslant 1_S$ referring to the pointwise ordering), then the partial order on $\mathcal{F}$, derived from the operation $\oplus$, agrees with the pointwise ordering of functions.[7] The above condition may also be strengthened to a σ-additive version:

(F3σ) if $(f_i)_{i\geqslant 1}$ is any countable sequence of functions in $\mathcal{F}$ such that $\Sigma_{i\geqslant 1} f_i \leqslant 1_S$, then $\Sigma_{i\geqslant 1} f_i$ belongs to $\mathcal{F}$.

Here, again, the convergence is the pointwise convergence. If this condition is also satisfied, then $(\mathcal{F},0_S,1_S,\oplus)$ is a σ-complete effect algebra.

Definition 2.2.5: (*a*) Let L and K be two effect algebras. A function $\Phi: L\to K$ is an *effect morphism,* if for all $a,b\in L$,

$$a\perp b \Rightarrow \Phi(a)\perp\Phi(b), \text{ and then } \Phi(a\oplus b)=\Phi(a)\oplus\Phi(b).$$

An effect morphism Φ is *unital* if $\Phi(1_L)=1_K$. An effect morphism is *σ-additive (completely additive)* if it preserves all the existing countable (arbitrary) $\oplus$-sums.

(*b*) A unital effect morphism s from an effect algebra L to the effect algebra $[0,1]$ is called a *state* on L. We let $S(L)$ denote the set of all states on L. A state $s\in S(L)$ is σ-additive (completely additive), if $s(\oplus_{i\in I} a_i)=\Sigma_{i\in I} s(a_i)$ whenever $\oplus_{i\in I} a_i$ exists, where I is a countable (arbitrary) index set.

(*c*) A set $S\subseteq S(L)$ of states on an effect algebra L is *separating,* if for any $a,b\in L$, if $a\neq b$, then $s(a)\neq s(b)$ for some $s\in S$. S is *ordering,* if the condition $s(a)\leqslant s(b)$, $s\in S$, implies $a\leqslant b$ for any $a,b\in L$.

Clearly, an ordering set of states is separating. We also note that the set of all states $S(L)$ on L is a convex set (as a subset of $[0,1]^L\subset \mathbf{R}^L$): if $s_1,s_2\in S(L)$ and $0\leqslant\lambda\leqslant 1$, then $\lambda s_1+(1-\lambda)s_2\in S(L)$ [where $\lambda s_1+(1-\lambda)s_2$ is defined pointwise]. Moreover, $S(L)$ is σ-convex with respect to the topology of pointwise convergence.

Let (L,S) be an effect algebra L with a nonempty set S of states on L. For every $a\in L$, define the function $\underline{a}: S\to[0,1]$, $\underline{a}(s):=s(a)$. Then $a\mapsto\underline{a}$ is a unital morphism from L to the effect algebra of functions from S to $[0,1]$ (that can be considered as an effect algebra in the sense of Example 2.2.4). Let $\mathcal{F}_L(S):=\{\underline{a}: a\in L\}$. Then $L\ni a\mapsto\underline{a}\in\mathcal{F}_L(S)$ is a surjective mapping. If the set S of states on L is separating, this mapping is also injective, so that L and $\mathcal{F}_L(S)$ are, in fact, isomorphic sets. In that case we can transfer the effect algebra structure from L to $\mathcal{F}_L(S)$ by defining $\underline{a}\perp\underline{b}$ whenever $a\perp b$, and putting then $\underline{a}\oplus\underline{b}=\underline{a\oplus b}=\underline{a}+\underline{b}$. However, the ordering on $\mathcal{F}_L(S)$ induced by $\oplus$ need not agree with the pointwise ordering of functions. In fact, these two orderings coincide if and only if S is an ordering set of states on L. Indeed, S is ordering if and only if $a\perp b\Leftrightarrow\underline{a}+\underline{b}\leqslant 1_S$. Moreover, the effect algebra L is σ-complete and the states in the ordering set S are σ-additive, if and only if $\mathcal{F}_L(S)$ satisfies (F3σ). We also note that if S is a convex set of states on L, then $\mathcal{F}_L(S)$ is a subset of the set $A_1^+(S)$ of affine functions $S\to[0,1]$.

Let L be a σ-complete effect algebra, and let $(\Omega,\mathcal{B})$ be a measurable space. Let $A:\mathcal{B}\to L$ be a unital σ-additive morphism. If s is a σ-additive state on L, then $s\circ A$ is a probability measure on $(\Omega,\mathcal{B})$. Therefore, if S is a convex set of σ-additive states on L, then $S\ni s\mapsto s\circ A\in M_1^+(\Omega,\mathcal{B})$ is an observable. The question arises under which conditions an observable $E: S\to M_1^+(\Omega,\mathcal{B})$ comes in this way from a σ-additive morphism $\mathcal{B}\to L$. For a given observable E, we let $\mathrm{ran}(\tilde{E}):=\{\tilde{E}(X)\,|\,X\in\mathcal{B}\}$ denote the range of $\tilde{E}$. It is a subset of $A_1^+(S)$.

Definition 2.2.6: Let (L,S) be an effect algebra L with a convex separating set S of σ-additive states.

(a) The pair (L,S) is said to be *total with respect to a measurable space* $(\Omega,\mathcal{B})$ if, for each observable $E: S\to M_1^+(\Omega,\mathcal{B})$, $\mathrm{ran}\tilde{E}\subseteq\mathcal{F}_L(S)$.
(b) The pair (L,S) is said to be *total* if $\mathcal{F}_L(S)=A_1^+(S)$.

Proposition 2.2.7: Let (L,S) be an effect algebra with a convex separating set of σ-additive states.

(i) If (L,S) is total, then S is ordering.
(ii) If (L,S) is total, then it is total with respect to every measurable space $(\Omega,\mathcal{B})$.

Proof: (i): Since S is separating, L is isomorphic to $\mathcal{F}_L(S)$. The totality of (L,S) implies that $\mathcal{F}_L(S)=A_1^+(S)$. But then S is ordering on L. The other statement is immediate.

Let (L,S) be a total effect algebra with a convex separating set of σ-additive states. If $E:S\to M_1^+(\Omega,\mathcal{B})$ is an observable, we get a map $\hat{E}:\mathcal{B}\to L$ by requiring

$$\underline{\hat{E}(X)}=\tilde{E}(X),$$

for all $X\in\mathcal{B}$, that is, by putting

$$s(\hat{E}(X))=\tilde{E}(X)(s)=E(s)(X),$$

for all $s\in S, X\in\mathcal{B}$. Clearly, $\hat{E}$ is a unital σ-additive morphism $\mathcal{B}\to L$. Indeed, $\underline{\hat{E}(\Omega)}=1_S$, so that $\hat{E}(\Omega)=1_L$, and, if $(X_i)_{i\geqslant 1}$ is a disjoint sequence, then, for any $s\in S$, $s(\hat{E}(\cup X_i))=\tilde{E}(\cup X_i)(s)=\Sigma\tilde{E}(X_i)(s)=\Sigma s(\hat{E}(X_i))=s(\oplus\hat{E}(X_i))$, showing that $\hat{E}(\oplus_{i\geqslant 1}X_i)=\oplus_{i\geqslant 1}\hat{E}(X_i)$.

Corollary 2.2.8: Let (L,S) be a total effect algebra with a convex separating set of σ-additive states. For any measurable space $(\Omega,\mathcal{B})$, the map $E\mapsto\hat{E}$ is an affine bijection from the convex set of observables $E:S\to M_1^+(\Omega,\mathcal{B})$ onto the convex set of unital σ-additive morphisms $A:\mathcal{B}\to L$.

For a total effect algebra L with a convex separating set S of σ-additive states the notion of an observable as an affine function $E:S\to M_1^+(\Omega,\mathcal{B})$ has two alternative equivalent formulations, a σ-additive function $F:\mathcal{B}\to A_1^+(S)$, with the property $F(\Omega)=1_S$, and a unital σ-additive morphism $A:\mathcal{B}\to L$, and we have $s(A(X))=F(X)(s)=E(s)(X)$ for all $s\in S, X\in\mathcal{B}$. The notions of coexistence and functional coexistence of any two observables $E_1:S\to M_1^+(\Omega_1,\mathcal{B}_1)$ and $E_2:S\to M_1^+(\Omega_2,\mathcal{B}_2)$ may then also be given in terms of the morphisms $\hat{E}_1:\mathcal{B}_1\to L$ and $\hat{E}_2:\mathcal{B}_2\to L$. In particular, Theorem 2.1.5 may then be read as a characterization of functional coexistence of such morphisms.

C. Observables in the Hilbert space framework

Let $\mathcal{H}$ be a complex separable Hilbert space, and let $\mathcal{T}(\mathcal{H})_1^+$ denote the set of positive trace one operators on $\mathcal{H}$. It is a convex set as a subset of the real vector space $\mathcal{T}_s(\mathcal{H})$ of the self-adjoint trace class operators on $\mathcal{H}$. Let $(\Omega,\mathcal{B})$ be a measurable space, and consider an observable $E:\mathcal{T}(H)_1^+\to M_1^+(\Omega,\mathcal{B})$. Since $\mathcal{T}(\mathcal{H})_1^+$ is a base for the positive cone $\mathcal{T}(\mathcal{H})^+$ of the vector space $\mathcal{T}_s(\mathcal{H})$, any $f\in A_1^+(\mathcal{T}(\mathcal{H})_1^+)$ extends uniquely to a positive linear functional on $\mathcal{T}_s(\mathcal{H})$. Such a functional is known to be trace-norm continuous,[8] so that, by the duality of the trace class operators and the bounded operators on $\mathcal{H}$, for each $f\in A_1^+(\mathcal{T}(\mathcal{H})_1^+)$ there is a unique positive operator $A\geqslant O$, bounded by the unit operator, $A\leqslant I$, such that $f(T)=\mathrm{tr}[TA]$ for all $T\in\mathcal{T}(\mathcal{H})_1^+$. This shows that for each $X\in\mathcal{B}$, there is a unique $O\leqslant A(X)\leqslant I$ such that $E(T)(X)=\tilde{E}(X)(T)=\mathrm{tr}[TA(X)]$ for all $T\in\mathcal{T}(\mathcal{H})_1^+$. Moreover, if $(X_i)\subseteq\mathcal{B}$ is a disjoint sequence, then, for each $T\in\mathcal{T}(\mathcal{H})_1^+$, $\mathrm{tr}[TA(\cup X_i)]=\tilde{E}(\cup X_i)(T)=\Sigma\tilde{E}(X_i)(T)=\Sigma\ \mathrm{tr}[TA(X_i)]$, showing that the operator-valued function $X\mapsto A(X)$ is σ-additive in the weak operator topology of $\mathcal{L}(\mathcal{H})$, the set of bounded operators on $\mathcal{H}$. Therefore, an observable $E:\mathcal{T}(\mathcal{H})_1^+\to M_1^+(\Omega,\mathcal{B})$ determines a unique normalized $(A(\Omega)=I)$ positive operator-valued measure $\mathcal{B}\ni X\mapsto A(X)\in\mathcal{L}(\mathcal{H})$. Clearly, any such measure $X\mapsto A(X)$ determines an observable $T\mapsto E(T)$ via the formula $E(T)(X):=\mathrm{tr}[TA(X)]$.

Let $\mathcal{E}(\mathcal{H}):=\{A\in\mathcal{L}(\mathcal{H})|O\leqslant A\leqslant I\}$. We equip $\mathcal{E}(\mathcal{H})$ with the $\oplus$-operation defined as $A\oplus B=A+B$, whenever $A+B\leqslant I$. Clearly, the order defined by $\oplus$ on $\mathcal{E}(\mathcal{H})$ coincides with the usual ordering of $\mathcal{E}(\mathcal{H})$. Since every upward directed family of self-adjoint operators which is bounded from above by a self-adjoint operator has a supremum, $\mathcal{E}(\mathcal{H})$ is a complete effect algebra. However, it is not a lattice, unless $\mathcal{H}$ is one-dimensional.

The set $\mathcal{E}(\mathcal{H})$ is also a convex set [as a subset of $\mathcal{L}(\mathcal{H})$], and the set of states on $\mathcal{E}(\mathcal{H})$ in the sense of Definition 2.2.5 equals now the set of affine functions on $\mathcal{E}(\mathcal{H})$, that is, $S(\mathcal{E}(\mathcal{H}))=A_1^+(\mathcal{E}(\mathcal{H}))$. As is well known, the subset of σ-additive states on $\mathcal{E}(\mathcal{H})$ is in one-to-one correspondence with the set $\mathcal{T}(\mathcal{H})_1^+$ of positive trace one operators on $\mathcal{H}$. Indeed, if $s:\mathcal{E}(\mathcal{H})\to[0,1]$ is a unital σ-additive morphism, then there is a unique $T\in\mathcal{T}(\mathcal{H})_1^+$ such that for all $A\in\mathcal{E}(\mathcal{H})$, $s(A)=\mathrm{tr}[TA]$, and conversely, any $T\in\mathcal{T}(\mathcal{H})_1^+$ defines, by this formula, a σ-additive state on $\mathcal{E}(\mathcal{H})$, see, e.g., Refs. 1 and 8. The set $\mathcal{T}(\mathcal{H})_1^+$ is an ordering set of states on $\mathcal{E}(\mathcal{H})$. Moreover, the

pair $(\mathcal{E}(\mathcal{H}),\mathcal{T}(\mathcal{H})_1^+)$ is total. Indeed, as already pointed out above, for each $f\in A_1^+(\mathcal{T}(\mathcal{H})_1^+)$ there is a unique $A\in\mathcal{E}(\mathcal{H})$ such that $f(T)=\mathrm{tr}[TA]$ for all $T\in\mathcal{T}(\mathcal{H})_1^+$, showing that $\mathcal{F}_{\mathcal{E}(\mathcal{H})}(\mathcal{T}(\mathcal{H})_1^+)=A_1^+(\mathcal{T}(\mathcal{H})_1^+)$. This means, in particular, that any observable $E:\mathcal{T}(\mathcal{H})_1^+\to M_1^+(\Omega,\mathcal{B})$ corresponds to a unital σ-additive morphism $A:\mathcal{B}\to\mathcal{E}(\mathcal{H})$. Such a morphism is a normalized positive operator-valued measure.

We conclude that Theorem 2.1.5 serves, in this context, to characterize the functional coexistence of observables represented as normalized positive operator-valued measures. Such a characterization was obtained also in Ref. 9 using different methods and results from Ref. 10.

III. COEXISTENT EFFECTS

Consider, again, an abstract convex set S and let $A_1^+(S)$ be the set of affine functions on S. We call these functions *effects*. If $E:S\to M_1^+(\Omega,\mathcal{B})$ is an observable, then the range $\mathrm{ran}(\tilde{E})$ of $\tilde{E}$ is a subset of $A_1^+(S)$.

Definition 3.1: A set of effects $\mathcal{A}\subseteq A_1^+(S)$ is called *coexistent* if there is a measurable space $(\Omega,\mathcal{B})$ with an observable $E:S\to M_1^+(\Omega,\mathcal{B})$ such that $\mathcal{A}\subset\mathrm{ran}(\tilde{E})$.

The next theorem characterizes coexistent sets of effects. For that we need to introduce the following notions.

Definition 3.2: (*a*) Let $(A,\leqslant)$ be a directed set and Ω_α a finite set for each $\alpha\in A$. Whenever $\alpha,\beta\in A$ and $\alpha\leqslant\beta$, let there be given a mapping $g_{\alpha\beta}:\Omega_\beta\to\Omega_\alpha$, and denote $\mathcal{G}=(g_{\alpha,\beta})_{\alpha\leqslant\beta}$. The pair $((\Omega_\alpha)_{\alpha\in A},\mathcal{G})$ is called a *projective system of finite sets* if the following conditions hold:

(*i*) $g_{\alpha\alpha}$ is the identity map on Ω_α for all $\alpha\in A$;
(*ii*) $g_{\alpha\beta}\circ g_{\beta\gamma}=g_{\alpha\gamma}$ whenever $\alpha\leqslant\beta\leqslant\gamma$.

(*b*) We say that $((\Omega_\alpha,P_\alpha)_{\alpha\in A},\mathcal{G})$ is a *projective system of simple probability spaces* if $((\Omega_\alpha)_{\alpha\in A},\mathcal{G})$ is a projective system of finite sets and, for each $\alpha\in A$, $P_\alpha:2^{\Omega_\alpha}\to[0,1]$ is a probability measure such that the following compatibility condition holds:

(*iii*) $P_\alpha(X)=P_\beta(g_{\alpha\beta}^{-1}(X))$, for all $X\subseteq 2^{\Omega_\alpha}$, whenever $\alpha\leqslant\beta$.

(*c*) We say that $((\Omega_\alpha,E_\alpha)_{\alpha\in A},\mathcal{G})$ is a *projective system of simple observables* if $((\Omega_\alpha)_{\alpha\in A},\mathcal{G})$ is a projective system of finite sets and, for each $\alpha\in A$, $E_\alpha:S\to M_1^+(\Omega_\alpha,2^{\Omega_\alpha})$ is an observable such that the following compatibility condition holds:

(*iv*) $E_\alpha(s)(X)=E_\beta(s)(g_{\alpha\beta}^{-1}(X))$, for all $X\subseteq 2^{\Omega_\alpha}$, $s\in S$, whenever $\alpha\leqslant\beta$.

Theorem 3.3: For $\mathcal{A}\subseteq A_1^+(S)$ the following conditions are equivalent:

(*i*) there is a compact Hausdorff space Ω with a Radon observable $E:S\to M_1^+(\mathcal{B}(\Omega))$ such that $\mathcal{A}\subseteq\mathrm{ran}(\tilde{E})$;
(*ii*) there is a measurable space $(\Omega,\mathcal{B})$ with an observable $E:S\to M_1^+(\Omega,\mathcal{B})$ such that $\mathcal{A}\subseteq\mathrm{ran}(\tilde{E})$;
(*iii*) there is a projective system $((\Omega_\alpha,E_\alpha)_{\alpha\in A},\mathcal{G})$ of simple observables such that for each $a\in\mathcal{A}$ there is an $\alpha\in A$ such that $a\in\mathrm{ran}(\tilde{E}_\alpha)$.

Proof: The implication $(i)\Rightarrow(ii)$ is trivial. Assume (*ii*), and let $E:S\to M_1^+(\Omega,\mathcal{B})$ be an observable such that $\mathcal{A}\subset\mathrm{ran}(\tilde{E})$. Let $\mathcal{R}$ be the set of all finite disjoint measurable partitions of Ω. For each $R=\{X_i\}_{i\leqslant n}\in\mathcal{R}$, the function $R\ni X_i\mapsto\tilde{E}(X_i)=:\tilde{E}^R(\{X_i\})$ corresponds uniquely (Theorem 2.1.1) to a simple observable $S\ni s\mapsto E^R(s)\in M_1^+(R,2^R)$, where R is the finite set $\{X_1,\ldots,X_n\}$. Let $R_1,R_2\in\mathcal{R}$, and assume that R_1 is a refinement of R_2, that is, for every $X_i\in R_1$, there is (exactly one) $Y_j\in R_2$, such that $X_i\subseteq Y_j$. We then write $R_2\leqslant R_1$. For $R_2\leqslant R_1$, the function $f_{R_2R_1}:R_1\to R_2, X_i\mapsto Y_j$ (with $X_i\subseteq Y_j$) is then uniquely defined. If $R_2=R_1$, this function is the identity. If $R_2\leqslant R_1$ and $R_3\leqslant R_2$, then also $R_3\leqslant R_1$, and $f_{R_3R_1}=f_{R_3R_2}\circ f_{R_2R_1}$. Finally, for any two partitions $R_1,R_2\in\mathcal{R}$, the partition $R=\{X_i\cap Y_j: X_i\in R_1, X_j\in R_2\}$ belongs to $\mathcal{R}$, and it is a common refinement of R_1 and R_2, that is, $R_1\leqslant R$, $R_2\leqslant R$. Let $\mathcal{G}:=\{f_{RS}|R,S\in\mathcal{R},R\leqslant S\}$. It is now immediate to check that $((R,E^R)_{R\in\mathcal{R}},\mathcal{G})$ is a projective system of simple observables. By con-

struction it also covers $\mathcal{A}$, that is, $\mathcal{A}\subseteq\cup_{R\in\mathcal{R}}\mathrm{ran}(\tilde{E}^R)$. This shows that $(ii)\Rightarrow(iii)$. Finally, assume (iii). Using Proposition 4 in Ref. 11, p. 120, we see that the projective limit $\Omega=\lim_{\leftarrow}(\Omega_\alpha,g_{\alpha\beta})$ is a compact Hausdorff space, and the projective system $((\Omega_\alpha)_{\alpha\in A},\mathcal{G})$ satisfies Bochner's sequential maximality condition. Let $\pi_\alpha:\Omega\to\Omega_\alpha$ be the natural coordinate projection, $\alpha\in A$. Bochner's generalization of the Kolmogorov consistency theorem (see, e.g., Theorem 5 in Ref. 11, p. 121, or Ref. 12, p. 120) yields for each $s\in S$ a Radon probability measure $P(s):\mathcal{B}(\Omega)\to[0,1]$ such that $P(s)(\pi_\alpha^{-1}(X))=E_\alpha(s)(X)$. Since the projective limit is unique and the function $s\mapsto P(s)$ is affine coordinatewise, that is, for each $\alpha\in A$ the map $s\mapsto E_\alpha(s)$ is affine, we conclude that $P:S\to M_1^+(\mathcal{B}(\Omega))$ is an observable satisfying (i). This completes the proof.

Remark 3.4: Let (L,S) be a total effect algebra L with a convex separating set S of σ-additive states. Since now $L\simeq\mathcal{F}_L(S)=A_1^+(S)$, the above theorem allows one to characterize coexistent subsets of L. As another application, taking $S=\mathcal{T}(\mathcal{H})_1^+$, one obtains a characterization of the coexistent subsets of the Hilbert space effect algebra $\mathcal{E}(\mathcal{H})$. In Ref. 9 an alternative characterization was obtained.

ACKNOWLEDGMENT

We are indebted to an anonymous referee of Ref. 9 for valuable comments which, although dealing with a special case, influenced some ingredients in the proofs of Theorems 2.1.5 and 3.3.

Strict quantization of coadjoint orbits

N. P. Landsman[a)]
Korteweg–de Vries Institute for Mathematics, University of Amsterdam, Plantage Muidergracht 24, 1018 TV Amsterdam, The Netherlands

(Received 8 June 1998; accepted for publication 3 August 1998)

A strict quantization of a compact symplectic manifold S on a subset $I\subseteq\mathbb{R}$, containing 0 as an accumulation point, is defined as a continuous field of C^*-algebras $\{\mathfrak{A}_\hbar\}_{\hbar\in I}$, with $\mathfrak{A}_0=C_0(S)$, and a set of continuous cross sections $\{\mathcal{Q}(f)\}_{f\in C^\infty(S)}$ for which $\mathcal{Q}_0(f)=f$. Here $\mathcal{Q}_\hbar(f^*)=\mathcal{Q}_\hbar(f)^*$ for all $\hbar\in I$, whereas for $\hbar\to 0$ one requires that $i[\mathcal{Q}_\hbar(f),\mathcal{Q}_\hbar(g)]/\hbar\to\mathcal{Q}_\hbar(\{f,g\})$ in norm. We discuss general conditions which guarantee that a (deformation) quantization in a more physical sense leads to one in the above sense. Using ideas of Berezin, Lieb, Simon, and others, we construct a strict quantization of an arbitrary integral coadjoint orbit $\mathcal{O}_\lambda$ of a compact connected Lie group G, associated to a highest weight λ. Here $I=0\cup 1/\mathbb{N}$, so that $\hbar=1/k$, $k\in\mathbb{N}$, and $\mathfrak{A}_{1/k}$ is defined as the C^*-algebra of all matrices on the finite-dimensional Hilbert space $\mathcal{V}_{k\lambda}$ carrying the irreducible representation $U_{k\lambda}(G)$ with highest weight $k\lambda$. The quantization maps $\mathcal{Q}_{1/k}(f)$ are constructed from coherent states in $\mathcal{V}_{k\lambda}$, and have the special feature of being positive maps. © *1998 American Institute of Physics.* [S0022-2488(98)00512-X]

I. INTRODUCTION

The aim of this paper is to combine a number of what appear to the author to be good ideas in mathematical physics, whose interplay has so far not sufficiently been studied. First, there now exists a satisfying C^*-algebraic definition of quantization, which enables one to link Poisson and symplectic geometry[1,2] with noncommutative geometry.[3] In particular, the geometric theory of classical mechanics and reduction is thereby related to the C^*-algebraic formulation of quantum mechanics and induction.[4] The main mathematical idea of this definition goes back to Rieffel,[5] who showed how deformation quantization makes sense in an operator-algebraic context. The physical postulates, of course, may be traced back to Dirac. In this definition, like in conventional (''formal'') deformation quantization, it is crucial that one studies the quantum theory for a family of values of Planck's constant $\hbar$.[6]

Second, one has the well-known connection between coadjoint orbits of certain Lie groups, unitary representations, and geometric quantization.[7] This connection works particularly well for either compact or exponential nilpotent Lie groups. Here one keeps $\hbar$ fixed.

Our third source of inspiration is the work of Lieb,[8] Simon,[9] and others on the classical limit of quantum spin systems and their generalizations to arbitrary compact Lie groups. This work is closely related to Perelomov's coherent states,[10,11] as well as to Berezin's approach to quantization and the classical limit.[6]

Historical comments and extensive references concerning these ideas may be found in Ref. 4.

Using the second and third groups of ideas at both a conceptual and a technical level, we will construct a C^*-algebraic quantization of an arbitrary integral coadjoint orbit of a compact connected Lie group. A different approach to this problem has recently been considered in Ref. 12; see also Ref. 13.

Section II contains a general C^*-algebraic definition of quantization. A quantization satisfying this definition is called ''strict.'' We present criteria on a given quantization which guarantee that the postulates in the definition are met. It is on this basis that we will actually construct the quantizations in this paper. Section III describes our approach to coherent states and Berezin quantization, and develops conditions under which the Berezin quantization constructed from a

a)Electronic mail: npl@wins.uva.nl

 © 1998 American Institute of Physics

family of coherent states is strict. This is done in terms of a so-called pure state quantization, which, in a heuristic sense, is dual to a C^*-algebraic quantization. The material in Secs. II and III is model independent, and should be relevant to quantization theory in general.

Section IV is a brief review of Perelomov coherent states, coadjoint orbits of compact Lie groups, the momentum map, and the connection between these concepts. The material in this section is not new, but is worth summarizing in preparation for our main results. Section V contains the two principal theorems of this paper. The first states that Perelomov's coherent states for compact connected Lie groups define pure state quantizations of particular coadjoint orbits. The second states that such pure state quantizations lead to strict quantizations of the coadjoint orbits in question.

II. ON QUANTIZATION

The central notion in C^*-algebraic quantization theory is that of a continuous field of C^*-algebras.[14] For our purposes the following reformulation is useful.[15]

*Definition 1: A continuous field of C^*-algebras $(\mathfrak{C},\{\mathfrak{A}_x,\varphi_x\}_{x\in X})$ over a locally compact Hausdorff space X consists of a C^*-algebra $\mathfrak{C}$, a collection of C^*-algebras $\{\mathfrak{A}_x\}_{x\in X}$, and a set $\{\varphi_x:\mathfrak{C}\to\mathfrak{A}_x\}_{x\in X}$ of surjective *-homomorphisms, such that for all $A\in\mathfrak{C}$:*

(1) *the function $x\to\|\varphi_x(A)\|$ is in $C_0(X)$;*

(2) *one has $\|A\|=\sup_{x\in X}\|\varphi_x(A)\|$;*

(3) *for any $f\in C_0(X)$ there is an element $fA\in\mathfrak{C}$ for which $\varphi_x(fA)=f(x)\varphi_x(A)$ for all $x\in X$.*

Here $C_0(X)$ is the space of continuous functions on X which vanish at infinity. Note that it is sufficient that each φ_x has dense image, since the image of a *-homomorphism between C^*-algebras is automatically closed. The continuous cross sections of the field in the sense of Ref. 14 consist of those elements $\{A_x\}_{x\in X}$ of $\Pi_{x\in X}\mathfrak{A}_x$ for which there is a $A\in\mathfrak{C}$ such that $A_x=\varphi_x(A)$ for all $x\in X$.

The following definition of quantization, which is a slight reformulation of a definition in Ref. 16, seems to combine the best of the previous definitions in this direction in Refs. 5 and 17.

Definition 2: Let $I\subseteq\mathbb{R}$ contain 0 as an accumulation point. A strict quantization of a Poisson manifold P on I consists of

(1) *a continuous field of C^*-algebras $(\mathfrak{C},\{\mathfrak{A}_\hbar,\varphi_\hbar\}_{\hbar\in I})$ over I, with $\mathfrak{A}_0=C_0(P)$;*

(2) *a dense *-subalgebra $\tilde{\mathfrak{A}}_0$ of $C_0(P)$ on which the Poisson bracket is defined, and which is closed under taking Poisson brackets (so that $\tilde{\mathfrak{A}}_0$ is a complex Poisson algebra);*

(3) *a linear map $\mathcal{Q}:\tilde{\mathfrak{A}}_0\to\mathfrak{C}$ which (with $\mathcal{Q}_\hbar(f)\equiv\varphi_\hbar(\mathcal{Q}(f))$) for all $f\in\tilde{\mathfrak{A}}_0$ and $\hbar\in I$ satisfies*

$$\mathcal{Q}_0(f)=f, \tag{1}$$

$$\mathcal{Q}_\hbar(f^*)=\mathcal{Q}_\hbar(f)^*, \tag{2}$$

and for all $f,g\in\tilde{\mathfrak{A}}_0$ satisfies Dirac's condition

$$\lim_{\hbar\to 0}\left\|\frac{i}{\hbar}[\mathcal{Q}_\hbar(f),\mathcal{Q}_\hbar(g)]-\mathcal{Q}_\hbar(\{f,g\})\right\|=0. \tag{3}$$

Elements of I are interpreted as possible values of Planck's constant $\hbar$, and $\mathfrak{A}_\hbar$ is the quantum algebra of observables of the theory at the given value of $\hbar\neq 0$. For real-valued f, the operator $\mathcal{Q}_\hbar(f)$ is the quantum observable associated with the classical observable f. This interpretation is possible because of condition (2) in Definition 2.

In the examples of the present paper, the Poisson manifold P will be a compact symplectic manifold S, and we will choose $\tilde{\mathfrak{A}}_0=C^\infty(S)$. It will be a special feature that $\mathcal{Q}$ is defined on all of $\mathfrak{A}_0$; condition (3) of course makes sense on $\tilde{\mathfrak{A}}_0$ only.

The connection between Definition 2 and the more physically and historically oriented definition of quantization proposed in Refs. 17 and 4 is established in Proposition 1 below. This

requires two lemmas, the first of which, as a bonus, entails the equivalence between the definition of a continuous field given above, and the one given by Dixmier[14] (restricted to the case that the base space is locally compact).

Lemma 1: The C-algebra $\mathfrak{C}$ of (sections of) a continuous field is locally uniformly closed. That is, if $A \in \Pi_x \mathfrak{A}_x$ is such that for every $y \in X$ and every $\epsilon > 0$ there exists a $B^y \in \mathfrak{C}$ and a neighborhood $\mathcal{N}^y$ of y in which $\|A_x - B^y_x\| < \epsilon$ for all $x \in \mathcal{N}^y$, and also $\lim_{x\to\infty}\|A_x\| = 0$, then $A \in \mathfrak{C}$.*

Alternatively, if the function $x \to \|A_x - C_x\|$ lies in $C_0(X)$ for each $C \in \mathfrak{C}$, then $A \in \mathfrak{C}$.

In the situation of the first part, there is a compact set $K \subseteq X$ for which $\|A_x\| < \epsilon$ outside K, as well as a finite subcover $\{\mathcal{N}^{x_1}, \ldots \mathcal{N}^{x_n}\}$ of K. Taking a partition of unity $\{u_i\}$ on K subordinate to this subcover, the operator $B = \Sigma_i u_i B^{x_i}$ lies in $\mathfrak{C}$ because of Definition 1.3, and satisfies $\sup_{x\in X}\|A_x - B_x\| < \epsilon$. Hence $A \in \mathfrak{C}$ by Definition 1.2 and the completeness of $\mathfrak{C}$.

Given any $A \in \Pi_x \mathfrak{A}_x$ and $y \in X$, because φ_y is surjective there is a $B^y \in \mathfrak{C}$ so that $A_y = B^y_y$. The assumption in the second part of the lemma then implies that the conditions in the first part are satisfied, so that $A \in \mathfrak{C}$. ■

The next lemma adapts Propositions 10.2.3 and 10.3.2 in Ref. 14, which relate to Dixmier's own definition of a continuous field, to Definition 1.

Lemma 2: Suppose one has a family $\{\mathfrak{A}_x\}_{x\in X}$ of C-algebras indexed by a locally compact Hausdorff space X, as well as a subset $\tilde{\mathfrak{C}} \subseteq \Pi_x \mathfrak{A}_x$ which satisfies the following conditions:*

(1) *the set $\{A_x \mid A \in \tilde{\mathfrak{C}}\}$ is dense in $\mathfrak{A}_x$ for each $x \in X$;*
(2) *the function $x \to \|A_x\|$ is in $C_0(X)$ for each $A \in \tilde{\mathfrak{C}}$;*
(3) *the set $\tilde{\mathfrak{C}}$ is closed under pointwise scalar multiplication, addition, adjointing, and operator multiplication.*

There exists a unique continuous field of C-algebras $(\mathfrak{C}, \{\mathfrak{A}_x, \varphi_x\}_{x\in X})$ whose collection of continuous cross sections contains $\tilde{\mathfrak{C}}$. First, as a set $\mathfrak{C}$ consists of all $A \in \Pi_x \mathfrak{A}_x$ for which the function $x \to \|A_x - C_x\|$ lies in $C_0(X)$ for each $C \in \tilde{\mathfrak{C}}$. This set is regarded as a C*-algebra under the pointwise operations listed in item (3) above, and the norm defined in Definition 1.2. Second, $\varphi_x(A) = A_x$ is the evaluation map.*

We first show that if $A \in \Pi_x \mathfrak{A}_x$ is such that for every $x_0 \in X$ and every $\epsilon > 0$ there exists a $B \in \mathfrak{C}$ and a neighborhood $\mathcal{N}$ of x_0 such that $\|A_x - B_x\| < \epsilon$ for all $x \in \mathcal{N}$, and also $\lim_{x\to\infty}\|A_x\| = 0$, then $A \in \mathfrak{C}$. Indeed, take $C \in \tilde{\mathfrak{C}}$ arbitrary, and define the functions $f_{AC}: x \to \|A_x - C_x\|$ and $f_{BC}: x \to \|B_x - C_x\|$. Using the inequality

$$|(\|X\| - \|Y\|)| \leqslant \|X - Y\|, \tag{4}$$

one finds $|f_{AC}(x) - f_{BC}(x)| < \epsilon$ for all $x \in \mathcal{N}$. By assumption, f_{BC} is continuous, so that $|f_{BC}(x) - f_{BC}(x_0)| < \epsilon$ for all x in some neighborhood $\mathcal{N}'$ of x_0. Combining the two inequalities yields $|f_{AC}(x) - f_{AC}(x_0)| < 3\epsilon$ for all $x \in \mathcal{N} \cap \mathcal{N}'$. Hence f_{AC} is continuous at x_0, which was arbitrary, so that $A \in \mathfrak{C}$ by definition of $\mathfrak{C}$.

Using this property, it is easily shown that $\mathfrak{C}$ is a C*-algebra, and that condition 3 in Definition 1 is satisfied. It is clear from Definition 1.1 and the definition of $\mathfrak{C}$ that $\mathfrak{C}$ is maximal. On the other hand, according to the second part of Lemma 1, $\mathfrak{C}$ is minimal, so that it is unique.

Adding an assumption satisfied by the examples in this paper, we are now in a position to relate Definitions 1 and 2.

Proposition 1: Suppose one has a Poisson manifold P and a family $\{\mathfrak{A}_\hbar\}_{\hbar\in I}$ of C-algebras, with $\tilde{\mathfrak{A}}_0 \subset \mathfrak{A}_0 = C_0(P)$ as in Definition 2, and a collection of linear maps $\{\mathcal{Q}_\hbar : \tilde{\mathfrak{A}}_0 \to \mathfrak{A}_\hbar\}_{\hbar\in I}$ satisfying (1), (2), (3), as well as*

$$\lim_{\hbar\to 0} \| \tfrac{1}{2}(\mathcal{Q}_\hbar(f)\mathcal{Q}_\hbar(g) + \mathcal{Q}_\hbar(g)\mathcal{Q}_\hbar(f)) - \mathcal{Q}_\hbar(fg)\| = 0; \tag{5}$$

$$\lim_{\hbar\to 0} \|\mathcal{Q}_\hbar(f)\| = \|f\|_\infty \tag{6}$$

for all $f,g\in\tilde{\mathfrak{A}}_0$, *and finally the completeness condition that the collection* $\{\mathcal{Q}_\hbar(f)\mid f\in\tilde{\mathfrak{A}}_0\}$ *be dense in* $\mathfrak{A}_\hbar$ *for each* $\hbar\in I$. *Furthermore, assume that* $\hbar$ *assumes discrete values.*

There exists a unique continuous field of C-algebras* $(\mathfrak{C},\{\mathfrak{A}_\hbar,\varphi_\hbar\}_{\hbar\in I})$ *whose collection of continuous cross sections* $\{\varphi_\hbar(A)\}_{\hbar\in I}$, $A\in\mathfrak{C}$, *contains all maps* $\{\mathcal{Q}_\hbar(f)\}_{\hbar\in I}$, $f\in\tilde{\mathfrak{A}}_0$.

One defines $\tilde{\mathfrak{C}}\subset\Pi_\hbar\mathfrak{A}_\hbar$ as the complex linear span of all expressions of the form $\hbar\to\mathcal{Q}_\hbar(f_1)\ldots\mathcal{Q}_\hbar(f_n)$, where $f_i\in\tilde{\mathfrak{A}}_0$.

Given that I is discrete, the continuity of each function $F_{f_1,\ldots,f_n}:\hbar\to\|\mathcal{Q}_\hbar(f_1)\ldots\mathcal{Q}_\hbar(f_n)\|$ away from 0 is trivial. Now note that (5) and (3) imply that

$$\lim_{\hbar\to0}\|\mathcal{Q}_\hbar(f)\mathcal{Q}_\hbar(g)-\mathcal{Q}_\hbar(fg)\|=0 \tag{7}$$

for all $f,g\in\tilde{\mathfrak{A}}_0$. Hence $\lim_{\hbar\to0}\|\mathcal{Q}_\hbar(f_1)\mathcal{Q}_\hbar(f_2\cdots f_n)-\mathcal{Q}_\hbar(f_1\cdots f_n)\|=0$, and by induction $\lim_{\hbar\to0}\|\mathcal{Q}_\hbar(f_1)\cdots\mathcal{Q}_\hbar(f_n)-\mathcal{Q}_\hbar(f_1\cdots f_n)\|=0$. Equation (4) then yields $\lim_{\hbar\to0}\|\mathcal{Q}_\hbar(f_1)\cdots\mathcal{Q}_\hbar(f_n)\|-\|\mathcal{Q}_\hbar(f_1\cdots f_n)\|=0$, so that finally $\lim_{\hbar\to0}\|\mathcal{Q}_\hbar(f_1)\cdots\mathcal{Q}_\hbar(f_n)\|=\|f_1\cdots f_n\|_\infty$ by (6). Because of (1), this shows that $F_{f_1,\ldots,f_n}$ is continuous at $\hbar=0$.

Hence one is in the situation of Lemma 2, and the claim follows. ■

Although it is irrelevant for the present paper, we note that Proposition 1 holds equally well (with a different proof) if the set I is not discrete, provided that all $\mathfrak{A}_\hbar$ are identical for $\hbar\neq0$, and in addition the function $\hbar\to\mathcal{Q}_\hbar(f)$ is continuous for each $f\in\tilde{\mathfrak{A}}_0$.[4]

III. QUANTIZATION OF PURE STATES AND BEREZIN QUANTIZATION

A Hilbert space $\mathcal{H}$ is a symplectic manifold, with symplectic form $\omega(\Phi,\Omega)=2\,\mathrm{Im}\,(\Phi,\Omega)$ [here the inner product $(\,,\,)$ on $\mathcal{H}$ is linear in the second entry].[1,2] This form is invariant under the standard action $\exp(i\alpha):\Psi\to\exp(i\alpha)\Psi$ of $U(1)$ on $\mathcal{H}$, so that the quotient $\mathcal{H}^*/U(1)$ is a Poisson manifold (here $\mathcal{H}^*=\mathcal{H}\backslash\{0\}$). The symplectic leaves[2] of $\mathcal{H}^*/U(1)$ are the spaces $S_r=\mathcal{H}_r/U(1)$, where $\mathcal{H}_r=\{\Psi\in\mathcal{H}\mid(\Psi,\Psi)=r^2\}$. In particular, the projective space $\mathbb{P}\mathcal{H}$ may be identified with S_1, and is therefore a symplectic manifold, with symplectic form $\omega_{\mathbb{P}\mathcal{H}}$.

In addition, $\mathbb{P}\mathcal{H}$ is equipped with a transition probability $p:\mathbb{P}\mathcal{H}\times\mathbb{P}\mathcal{H}\to[0,1]$, given by $p(\psi,\varphi)=|(\Psi,\Phi)|^2$; here Ψ and Φ are arbitrary lifts of ψ and φ to unit vectors in $\mathcal{H}$. Equipped with these transition probabilities and with the Poisson bracket defined by $\omega_{\mathbb{P}\mathcal{H}}$, the manifold $\mathbb{P}\mathcal{H}$ is the pure state space of a quantum system without superselection rules. See Ref. 4 and references therein.

The pure state space of a classical system is a symplectic manifold (S,ω_S), supporting the Liouville measure μ_L. Such a classical pure state space may be seen as carrying the ''classical'' transition probability p_0, defined by $p_0(\rho,\sigma)=\delta_{\rho\sigma}$.

Definition 3: Let $I\subseteq\mathbb{R}$ *be as in Definition II, and put* $I_0=I\backslash\{0\}$. *A pure state quantization of a symplectic manifold* (S,ω) *consists of a collection of Hilbert spaces* $\{\mathcal{H}_\hbar\}_{\hbar\in I_0}$ *and a collection of smooth injections* $\{q_\hbar:S\to\mathbb{P}\mathcal{H}_\hbar\}_{\hbar\in I_0}$, *for which the following requirements are satisfied.*

(1) *There exists a positive function* $c:I_0\to\mathbb{R}\backslash\{0\}$ *such that for all* $\hbar\in I_0$ *and all* $\psi\in\mathbb{P}\mathcal{H}_\hbar$ *one has*

$$c(\hbar)\int_S d\mu_L(\sigma)\,p(q_\hbar(\sigma),\psi)=1. \tag{8}$$

(2) *For all fixed* $f\in C_c(S)$ *and* $\rho\in S$ *the function*

$$\hbar\to\int_S d\mu_L(\sigma)\,p(q_\hbar(\rho),q_\hbar(\sigma))f(\sigma)$$

is continuous on I_0 *and satisfies*

$$\lim_{\hbar\to0}c(\hbar)\int_S d\mu_L(\sigma)\,p(q_\hbar(\rho),q_\hbar(\sigma))f(\sigma)=f(\rho). \tag{9}$$

(3) *For each* $\hbar \in I_0$, *the map* $q_\hbar$ *is a symplectomorphism, that is,*

$$q_\hbar^* \omega_{\mathbb{P}\mathcal{H}} = \omega_S . \tag{10}$$

Since $f \in C_c(S)$, the continuity requirement on I_0 in this condition is equivalent to the continuity of the function $\hbar \to p(q_\hbar(\rho), q_\hbar(\sigma))$ for fixed ρ and σ. Using Urysohn's lemma, it is not difficult to show[4] that (9) and (8) imply

$$\lim_{\hbar \to 0} p(q_\hbar(\rho), q_\hbar(\sigma)) = \delta_{\rho\sigma} . \tag{11}$$

That is, in quantizing pure states the quantum-mechanical transition probabilities should converge to the classical ones for $\hbar \to 0$.

More generally, one may replace the Liouville measure μ_L in Definition 3 by a family of measures $\mu_\hbar$, and substitute an appropriate limiting condition for (10); see Ref. 4. This generality is not needed for the present paper. The author is indebted to E. Hawkins for this remark.

A pure state quantization naturally leads to the quantization of observables.

Definition 4: Let $\{\mathcal{H}_\hbar, q_\hbar\}_{\hbar \in I_0}$ *be a pure state quantization of a symplectic manifold* S. *The Berezin quantization of a function* $f \in L^\infty(S)$ *is the family of operators* $\{\mathcal{Q}_\hbar^B(f)\}_{\hbar \in I_0}$, *where* $\mathcal{Q}_\hbar^B(f) \in \mathfrak{B}(\mathcal{H}_\hbar)$ *is defined by the weak integral*

$$\mathcal{Q}_\hbar^B(f) = c(\hbar) \int_S d\mu_L(\sigma) f(\sigma) [q_\hbar(\sigma)]. \tag{12}$$

Here $[q_\hbar(\sigma)]$ *is the projection onto the one-dimensional subspace in* $\mathcal{H}_\hbar$ *whose image in* $\mathbb{P}\mathcal{H}_\hbar$ *is* $q_\hbar(\sigma)$. *In case that* $f \in L^1(S) \cap L^\infty(S)$, *the integral is an ordinary Lebesgue integral (with values in a Banach space).*

A number of properties of $\mathcal{Q}_\hbar^B$ are immediately evident (cf. Ref. 9): $\mathcal{Q}_\hbar^B$ is positive (that is, $f \geqslant 0$ almost everywhere on S implies $\mathcal{Q}_\hbar^B(f) \geqslant 0$ in $\mathfrak{B}(\mathcal{H}_\hbar)$), and if f is real-valued then $\mathcal{Q}_\hbar^B(f)$ is self-adjoint. Moreover, $\mathcal{Q}_\hbar^B(f)$ is bounded, with

$$\| \mathcal{Q}_\hbar^B(f) \| \leqslant \| f \|_\infty . \tag{13}$$

To prove the last property, let A be a bounded symmetric operator such that $|(\Psi, A\Psi)| \leqslant c\|\Psi\|^2$ for some $c > 0$, and all Ψ. One then replaces Ψ by $\Psi \pm A\Psi/c$, and subtracts the two inequalities thus obtained. This implies the inequality $\|A\Psi\| \leqslant c\|\Psi\|$, showing that A is bounded with norm $\leqslant c$. This argument with (8) implies (13).

A Berezin quantization is not necessarily strict when restricted to, say, $C_c^\infty(S)$; even (10) does not imply (3). At the present abstract level, all that can be inferred is the following.

Proposition 2: Let $f \in C_0(S)$, *and assume that* I *is discrete. Then*

$$\lim_{\hbar \to 0} \| \mathcal{Q}_\hbar^B(f) \| = \| f \|_\infty . \tag{14}$$

We initially assume that $f \in L^1(S) \cap C_0(S)$, and at the end extend the result to $f \in C_0(S)$ using the continuity of $\mathcal{Q}_\hbar^B$. Equation (13) implies

$$\limsup_{\hbar \to 0} \| \mathcal{Q}_\hbar^B(f) \| \leqslant \| f \|_\infty . \tag{15}$$

On the other hand, for $f \in C_0(S)$ we can find $\rho \in S$ for which $\|f\|_\infty = |f(\rho)|$. Now for any unit vector $\Psi \in \mathcal{H}_\hbar$, Eq. (12) implies that

$$(\Psi, \mathcal{Q}_\hbar^B(f)\Psi) = c(\hbar) \int_S d\mu_L(\sigma)\, p(q_\hbar(\sigma), \psi) f(\sigma), \tag{16}$$

where ψ is the projection of Ψ to $\mathbb{P}\mathcal{H}_\hbar$. We now use the obvious inequality $\| \mathcal{Q}_\hbar^B(f) \| \geqslant |(\Psi, \mathcal{Q}_\hbar^B(f)\Psi)|$, take Ψ to be a lift of $q_\hbar(\rho)$, and use (9) to find

$$\liminf_{\hbar\to 0}\|\mathcal{Q}^B_\hbar(f)\|\geqslant\|f\|_\infty. \tag{17}$$

Combining this with (15), Eq. (14) follows. ■

IV. COADJOINT ORBITS AND PERELOMOV'S COHERENT STATES

Let G be a Lie group, with Lie algebra $\mathfrak{g}$. The dual $\mathfrak{g}^*$ of $\mathfrak{g}$ is a Poisson manifold under the so-called Lie-Poisson bracket[2,4]

$$\{f,g\}(\theta)=-\theta([df_\theta,dg_\theta]); \tag{18}$$

here the differential df_θ of $f\in C^\infty(\mathfrak{g}^*)$ at $\theta\in\mathfrak{g}^*$, which is a linear map from $T_\theta\mathfrak{g}^*\simeq\mathfrak{g}^*$ to $\mathbb{R}$, is identified with an element of $\mathfrak{g}\simeq\mathfrak{g}^{**}$, so that the right-hand side of (18) is the Lie bracket in $\mathfrak{g}$.

The symplectic leaves of $\mathfrak{g}^*$ with respect to the Lie–Poisson structure are the coadjoint orbits of G.[2,4] This endows each coadjoint orbit $\mathcal{O}$ with the so-called Lie–Kirillov symplectic structure. It is clear that $\theta\in\mathfrak{g}^*$ satisfies $\theta([X,Y])=0$ for all $X,Y\in\mathfrak{g}_\theta$, where $\mathfrak{g}_\theta$ is the Lie algebra of the stabilizer G_θ of θ under the coadjoint action. In other words, $\theta:\mathfrak{g}_\theta\to\mathbb{R}$ is a Lie algebra homomorphism.

Definition 5: A coadjoint orbit $\mathcal{O}\in\mathfrak{g}^*$ is called integral if for some (hence all) $\theta\in\mathcal{O}$ the functional $\theta\restriction\mathfrak{g}_\theta$ exponentiates to a character of G_θ.

In other words, θ is integral iff there is a character U_θ of G_θ such that $\theta=idU_\theta$ on $\mathfrak{g}_\theta$. If this holds for one $\theta\in\mathcal{O}$ it holds for all, since one has $U_{\mathrm{Co}(x)\theta}=U_\theta\circ\mathrm{Ad}(x^{-1})$. Here and in what follows, Co and Ad stand for the coadjoint and the adjoint action of G on $\mathfrak{g}^*$ and on $\mathfrak{g}$, respectively.

In the remainder of this paper, G is a compact connected Lie group. We assume familiarity with the standard Cartan–Weyl description of the unitary irreducible representations of G.[18] We fix a maximal torus $T\subset G$. The coadjoint orbits of T in the dual $\mathfrak{t}^*$ of the Lie algebra $\mathfrak{t}$ of T are points. The integral coadjoint orbits of T form the weight lattice $\Lambda\subset\mathfrak{t}^*$. The Weyl group $W=N(T)/T$ [where $N(T)$ is the normalizer of T] acts on T by conjugation. The derivative of this action is a W-action on $\mathfrak{t}$, whose dual action on $\mathfrak{t}^*$ is the projection of the coadjoint action of $N(T)$ to $N(T)/T$. This action maps the weight lattice Λ into itself.

A functional $\lambda\in\mathfrak{t}^*$ is regular when $w\lambda=\lambda$ for $w\in W$ implies $w=e$ (and singular otherwise); this defines the sets $\mathfrak{t}^*_r$ and $\Lambda_r=\mathfrak{t}^*_r\cap\Lambda$ of regular elements and regular weights in $\mathfrak{t}^*$, respectively. A Weyl chamber is a connected component C of $\mathfrak{t}^*_r$, and thereby forms an open convex cone in $\mathfrak{t}^*$. Singular weights clearly lie on the boundary of some Weyl chamber. One singles out an arbitrary Weyl chamber C_d, and declares a weight dominant if it lies in the closure $\overline{C_d}$. The point is now that each W-orbit intersects a given closed Weyl chamber $\overline{C}$ in exactly one point.

Combining the Cartan–Weyl theory with that of Kostant,[7] one obtains a number of parametrizations of the unitary dual of G (i.e., the set of unitary irreducible representations of G modulo unitary equivalence).

Proposition 3: There exist bijective correspondences between the unitary dual $\hat{G}$ of G, the set of W-orbits in Λ, the set $\Lambda_{\mathrm{d}}=\Lambda\cap\overline{C}_{\mathrm{d}}$ of dominant weights, and the set of integral coadjoint orbits in $\mathfrak{g}^*$. The latter set is isomorphic to $\mathfrak{t}^*/W$. In other words, one has

$$\hat{G}\simeq\Lambda/W\simeq\Lambda_d\simeq(\mathfrak{g}^*/W)_{\mathrm{integral}}. \tag{19}$$

Though exceedingly well-known, we recall the explicit form of the bijection $\hat{G}\simeq\Lambda_d$ in Proposition 3, as it will play an important role in the proof of our main result. We use the standard Cartan–Weyl basis $\{H_j\}_{j=1,\ldots,r}\cup\{E_\alpha,E_{-\alpha}\}_{\alpha\in\Delta^+}$ of $\mathfrak{g}_{\mathbb{C}}$, where r is the rank of G, and Δ^+ is the set of positive roots (relative to a choice of C_d). The vectors H_i lie in $\mathfrak{t}$, and the $E_{\pm\alpha}$ are eigenvectors of each H_i under restriction from $\mathfrak{g}$ to $\mathfrak{t}$ of the adjoint representation of $\mathfrak{g}$ on $\mathfrak{g}_{\mathbb{C}}$.

A Hilbert space $\mathcal{V}_\lambda$ carrying an irreducible representation $U_\lambda(G)$ corresponding to a dominant weight $\lambda\in\Lambda_d$ has a highest weight vector Ψ_λ of norm 1, unique up to a phase, such that

$$dU_\lambda(H_j)\Psi_\lambda=-i\lambda(H_j)\Psi_\lambda \tag{20}$$

for $j=1,\ldots,r$, whereas for all $\alpha\in\Delta^+$ one has

$$dU_\lambda(E_\alpha)\Psi_\lambda=0. \tag{21}$$

Since $dU_\lambda(E_\alpha)^*=-dU_\lambda(E_{-\alpha})$, it follows that

$$(\Psi_\lambda,dU_\lambda(E_\alpha)\Psi_\lambda)=0 \tag{22}$$

for all $\alpha\in\Delta$.

The association of a coadjoint orbit in $\mathfrak{g}^*$ with a W-orbit in $\mathfrak{t}^*$ is as follows. We write $\mathfrak{t}_{\mathbb{C}}^{\perp}$ for the span of all $E_{\pm\alpha}$, and $\mathfrak{t}^{\perp}=\mathfrak{t}_{\mathbb{C}}^{\perp}\cap\mathfrak{g}$. Given a weight $\lambda\in\mathfrak{t}^*$, putting $\theta(\lambda)=0$ on $\mathfrak{t}^{\perp}$ and $\theta(\lambda)=\lambda$ on $\mathfrak{t}$, one obtains an extension $\theta(\lambda)\in\mathfrak{g}^*$ of λ. Thus the coadjoint orbit $\mathcal{O}_\lambda=\mathcal{O}_{\theta(\lambda)}$ associated to λ is the coadjoint orbit through $\theta(\lambda)$; it is obvious from the definition of the W-action on $\mathfrak{t}^*$ that all points of W-orbit of λ are mapped into $\mathcal{O}_\lambda$. We will use the label λ to denote a dominant weight in $\Lambda_d\subset\mathfrak{t}^*$, as well as the corresponding element $\theta(\lambda)$ in the coadjoint orbit $\mathcal{O}_\lambda\subset\mathfrak{g}^*$.

The correspondence $\Lambda_d\simeq\mathfrak{g}^*/G$ is most easily described in terms of the momentum map.[1,2] The representation $U_\lambda(G)$ on $\mathcal{V}_\lambda$ quotients to a G-action $\tilde{U}_\lambda$ on the projective space $\mathbb{P}\mathcal{V}_\lambda$. Since U_λ is unitary, this quotient action may be computed from the action of $U_\lambda(G)$ on unit vectors in $\mathcal{V}_\lambda$. As explained at the beginning of Sec. III, $\mathbb{P}\mathcal{V}_\lambda$ is a symplectic manifold. It is clear from the definition of the symplectic structure on $\mathbb{P}\mathcal{V}_\lambda$ and the unitarity of U_λ that the reduced G-action $\tilde{U}_\lambda$ preserves the symplectic form $\omega_{\mathbb{P}\mathcal{V}_\lambda}$. More strongly, this action admits an equivariant momentum map $J:\mathbb{P}\mathcal{V}_\lambda\to\mathfrak{g}^*$, given by

$$J_X(\psi)=i(\Psi,dU_\lambda(X)\Psi). \tag{23}$$

As always, the unit vector $\Psi\in\mathcal{V}_\lambda$ is an arbitrary lift of $\psi\in\mathbb{P}\mathcal{V}_\lambda$.

Proposition 4: The coadjoint orbit $\mathcal{O}_\lambda$ corresponding to an irreducible representation U_λ with highest weight vector Ψ_λ contains $J\psi_\lambda$. In fact, the restriction of J to $\mathbb{P}U_\lambda(G)\Psi_\lambda$ is a symplectomorphism onto $\mathcal{O}_\lambda$.

Here it is understood that $\mathbb{P}U_\lambda(G)\Psi_\lambda$ inherits the usual symplectic structure of $\mathbb{P}\mathcal{V}_\lambda$, and that $\mathcal{O}_\lambda$ is endowed with the Lie–Kirillov symplectic form. For convenience, as well as for later reference, we include a proof of this fundamental result (see also Ref. 1 or 4).

Equations (23), (20), (21), and (22) imply that $\langle J(\psi_\lambda),X\rangle$ equals $\lambda(X)$ for $X\in\mathfrak{t}$ and equals 0 for $X\in\mathfrak{t}^{\perp}$. Hence $J(\psi_\lambda)$ is precisely the element $\theta(\lambda)\in\mathfrak{g}^*$ discussed after (22), proving the first claim.

By (23), the stability group $G_{J(\psi_\lambda)}$ of $J(\psi_\lambda)$ consists of those $x\in G$ for which

$$(U_\lambda(x)\Psi_\lambda,dU_\lambda(Y)U_\lambda(x)\Psi_\lambda)=(\Psi_\lambda,dU_\lambda(Y)\Psi_\lambda) \tag{24}$$

for all $Y\in\mathfrak{g}$. Since U_λ is irreducible this implies that Ψ_λ and $U_\lambda(x)\Psi_\lambda$ define the same element of $\mathbb{P}\mathcal{H}_\lambda$, proving that $G_{J(\psi_\lambda)}\subseteq G_{\psi_\lambda}$. The opposite inclusion is trivial from the equivariance of J. ∎

The unit vectors in $\mathcal{V}_\lambda$ of the form $U_\lambda(x)\Psi_\lambda$, where $x\in G$, are Perelomov's coherent states[10,11], which are parametrized by G. It should be clear by now that we are not interested in these states themselves, but in their projections to $\mathbb{P}\mathcal{V}_\lambda$. It follows from Proposition 3 that the ensuing family is parametrized by the coadjoint orbit $\mathcal{O}_\lambda$. Remarkably, the coadjoint orbits of maximal dimension among all coadjoint orbits $\mathfrak{g}$, which are the ones for which $G_\lambda=T$, are precisely the ones labeled by a regular weight λ. The ones of smaller dimension, for which G_λ properly contains T, are labeled by a singular weight.

V. BEREZIN QUANTIZATION OF COADJOINT ORBITS

Proposition 4 shows how to construct the coadjoint orbit $\mathcal{O}_\lambda$ corresponding to a given unitary irreducible representation U_λ by Proposition 3. The converse passage is accomplished by the Borel–Weil–Bott theory, which may be seen as a special case of geometric quantization.[7] In what follows we assume the correspondence in question to be given, and instead are interested in constructing an entire family of representations of G that are in some sense associated to a given

coadjoint orbit. The fundamental idea of rescaling the label of an irreducible representation by multiplying with $1/\hbar$ (which accordingly has to be quantized in the compact case) is due to Berezin (1975); see also Perelomov (1986). In a more intuitive setting, this rescaling was explicit in the early years of quantum mechanics, and seems to comprise one of the faces of Bohr's correspondence principle. The idea was further developed in the context of the classical limit of quantum mechanics by Lieb[8] and Simon.[9]

Theorem 1: *Let G be a compact connected Lie group, and $\mathcal{O}_\lambda$ an integral coadjoint orbit (cf. 5), corresponding to a highest weight $\lambda \in \Lambda_d$. For $\hbar = 1/k$, $k \in \mathbb{N}$, define $\mathcal{H}_\hbar = \mathcal{V}_{\lambda/\hbar}$, i.e., the carrier space of the irreducible representation $U_{\lambda/\hbar}(G)$ with highest weight $\lambda/\hbar = k\lambda$.*

Let $\tau: \mathcal{H}_\hbar \to \mathbb{P}\mathcal{H}_\hbar$ be the canonical projection. The map $q_\hbar : \mathcal{O}_\lambda \to \mathbb{P}\mathcal{H}_\hbar$, given by

$$q_\hbar(\mathrm{Co}(x)\lambda) = \tau(U_{\lambda/\hbar}(x)\Psi_{\lambda/\hbar}), \tag{25}$$

is well defined and injective, and provides a pure state quantization of $\mathcal{O}_\lambda$ (equipped with minus the Lie–Kirillov symplectic structure) on $I = 1/\mathbb{N} \cup 0$.

One should note here that $k\lambda \in \overline{C_d}$ when $\lambda \in \overline{C_d}$, since Weyl chambers are convex cones. The map $q_\hbar$ is well-defined and injective by the equation $G_{k\lambda} = G_\lambda$ plus the argument on stability groups used in the proof of Proposition 4. In fact, if we define $J_\hbar : \mathbb{P}\mathcal{H}_\hbar \to \mathfrak{g}^*$ by (23) with the right-hand side divided by k, it follows from (4) that $J_\hbar$ takes values in $\mathcal{O}_\lambda$ and is a left-inverse of $q_\hbar$.

We start from the fact that the Haar measure on G (with total mass 1) pushes forward to the Liouville measure derived from the Lie symplectic structure under the canonical projection $G \to \mathcal{O}_\lambda \simeq G/G_\lambda$. Using the invariance of the Haar measure and the unitarity of $U_{k\lambda}$, we then have

$$\int_{\mathcal{O}_\lambda} d\mu_L(\sigma)\, p(q_\hbar(\rho), q_\hbar(\sigma)) f(\sigma) = \int_G dx\, |(\Psi_{k\lambda}, U_{k\lambda}(x)\Psi_{k\lambda})|^2 f_\lambda(yx) \tag{26}$$

for all $f \in C(\mathcal{O}_\lambda)$, where $f_\lambda = \tau^*_{G \to G/G_\lambda} f \in C(G)$ is a right-G_λ-invariant function, and y is such that $\tau_{G \to G/G_\lambda}(y) = \rho \in \mathcal{O}_\lambda$. Choosing $f = 1$, the orthogonality relations for compact groups then imply (8) with

$$c(\hbar) = d_{\lambda/\hbar}, \tag{27}$$

i.e., the dimension of $\mathcal{H}_\hbar = \mathcal{V}_{\lambda/\hbar}$.

Equation (10) follows from Proposition 4. To prove (9) we use a result of Gilmore.[19]

Lemma 3: Let λ_i be dominant weights with highest weight representations and vectors U_{λ_i} and Ψ_{λ_i}, respectively $(i = 1,2)$. Then for each $x \in G$,

$$(\Psi_{\lambda_1}, U_{\lambda_1}(x)\Psi_{\lambda_1}) \cdot (\Psi_{\lambda_2}, U_{\lambda_2}(x)\Psi_{\lambda_2}) = (\Psi_{\lambda_1+\lambda_2}, U_{\lambda_1+\lambda_2}(x)\Psi_{\lambda_1+\lambda_2}). \tag{28}$$

This is immediate from (20), (21), and the connectedness of G. ∎

This lemma implies that

$$(\Psi_{k\lambda}, U_{k\lambda}(x)\Psi_{k\lambda}) = (\Psi_\lambda, U_\lambda(x)\Psi_\lambda)^k. \tag{29}$$

Using (26), we can write the left-hand side of (9) as

$$\lim_{\hbar \to 0} \int_{\mathcal{O}_\lambda} d\mu_L(\sigma)\, p(\rho_\hbar, \sigma_\hbar) f(\sigma) = \lim_{k \to \infty} \int_G d\mu_k(x) f_\lambda(yx),$$

where μ_k is a probability measure on G defined by

$$d\mu_k(x) = d_{k\lambda}\, dx |(\Psi_\lambda, U_\lambda(x)\Psi_\lambda)|^{2k}. \tag{30}$$

It is obvious that each μ_k is right-G_λ-invariant. It follows from (21), (22), and the fact that the exponential map is surjective for compact Lie groups, that $|(\Psi_\lambda, U_\lambda(x)\Psi_\lambda)|$, which is evidently $\leqslant 1$, equals 1 iff $x \in G_\lambda$. Hence for large k the support of μ_k is increasingly concentrated on G_λ. This suggests that

$$\lim_{k\to\infty} \mu_k(f) = \int_{G_\lambda} dh\, f(h) \tag{31}$$

for all $f \in C(G)$, where dh is the normalized Haar measure on G_λ. This is indeed the case, as proved by Duffield[20] (related results may be found in Refs. 8 and 9). For the right-G_λ-invariant function $f_\lambda \in C(G)^{G_\lambda}$ one therefore obtains

$$\lim_{k\to\infty} \mu_k(f_\lambda) = f_\lambda(e).$$

This proves (9), which finishes the proof of Theorem 1. ■

The Berezin quantization $\mathcal{Q}^B_\hbar$ associated with the pure state quantization in Theorem 1 is defined on $\tilde{\mathfrak{A}}_0 = C^\infty(\mathcal{O}_\lambda)$. By (12), one has

$$\mathcal{Q}^B_{1/k}(f) = d_{k\lambda} \int_G dx\, f_\lambda(x)[U_{k\lambda}(x)\Psi_{k\lambda}]; \tag{32}$$

this is an element of $\mathfrak{A}_{1/k} = \mathfrak{M}_{d_{k\lambda}}(\mathbb{C})$ (the C^*-algebra of complex $d_{k\lambda} \times d_{k\lambda}$ matrices). Recall that $[\Phi]$ is the projection onto $\mathbb{C}\Phi$.

The most important property of $\mathcal{Q}^B_\hbar$ is its G-equivariance. For $x \in G$ we write

$$\alpha^{1/k}_x(A) = U_{k\lambda}(x) A U_{k\lambda}(x)^*, \tag{33}$$

where $A \in \mathfrak{A}_{1/k}$, and for $f \in \mathfrak{A}_0 = C(\mathcal{O}_\lambda)$ we put

$$\alpha^0_x(f) = \mathrm{Co}(x^{-1})^* f. \tag{34}$$

Proposition 5: For all $k \in \mathbb{N}$, $x \in G$, and $f \in L^\infty(\mathcal{O}_\lambda)$ one has

$$\mathcal{Q}^B_{1/k}(\alpha^0_x(f)) = \alpha^{1/k}_x(\mathcal{Q}^B_{1/k}(f)). \tag{35}$$

This is immediate from (32), (34), the fact that $(\mathrm{Co}(y)^* f)_\lambda = L^*_y f_\lambda$, the right-invariance of the Haar measure, and (33). ■

We are now ready for the main result of this paper.

Theorem 2: *The Berezin quantization (32), defined on the space $C^\infty(\mathcal{O}_\lambda)$, is strict.*

We show that the assumptions in Proposition 1 are met. Equation (6) follows from Theorem 1 and Proposition 2. The completeness condition is an easy consequence of Schur's lemma and the irreducibility of $U_{k\lambda}$.

We will now prove the remaining conditions (5) and (3), using the notation of the proof of Theorem 1. We pick a unit vector Φ_k in each $\mathcal{V}_{k\lambda}$, and use the invariance of the Haar measure and the orthogonality relations for compact groups to write

$$(\Phi_k, (\mathcal{Q}^B_{1/k}(f)\mathcal{Q}^B_{1/k}(g) - \mathcal{Q}^B_{1/k}(fg))\Phi_k) = d_{k\lambda} \int_G dx\, f_\lambda(x)(\Phi_k, U_{k\lambda}(x)\Psi_{k\lambda}) I_k(x), \tag{36}$$

where

$$I_k(x) = d_{k\lambda} \int_G dy\, (\Psi_{k\lambda}, U_{k\lambda}(y)\Psi_{k\lambda}) F^x_\lambda(y), \tag{37}$$

in which we have abbreviated

$$F^x_\lambda(y)=(U_{k\lambda}(xy)\Psi_{k\lambda},\Phi_k)[g_\lambda(xy)-g_\lambda(x)]. \tag{38}$$

In the notation used after (26), the function F^x_λ on G corresponds to a function F^x on $\mathcal{O}_\lambda$.

Using (29), we can write $(\Psi_{k\lambda},U_{k\lambda}(y)\Psi_{k\lambda})=\exp(-kS_\lambda(y))$, where $S_\lambda(y)=-\log(\Psi_\lambda,U_\lambda(y)\Psi_\lambda)$ (in view of the exponentiation, the choice of the branch cut of the logarithm is irrelevant). The function S_λ is right-G_λ-invariant; we denote the corresponding function on G/G_λ by S. We identify G/G_λ with $\mathcal{O}_\lambda$, so that the coset $[G_\lambda]\in G/G_\lambda$ is identified with $\lambda\in\mathcal{O}_\lambda$.

Putting $S^+_\lambda(y)=-\log|(\Psi_\lambda,U_\lambda(y)\Psi_\lambda)|$, the absolute value of $\exp(-kS)$ is $\exp(-kS^+)$. As in the argument preceding (31) we see that S^+ takes values in $[0,\infty]$ and assumes its unique absolute minimum 0 at λ. Since F^x_λ in (37) is bounded, a standard argument implies that to $O(\exp(-k))$ we may replace the integration over G/G_λ by one over any neighborhood of λ.

We identify $T_\lambda\mathcal{O}_\lambda$ with $\mathfrak{g}/\mathfrak{g}_\lambda$, and use complex coordinates $\{z_\alpha,\overline{z_\alpha}\}_{\alpha\in\Delta^+_\lambda}$, where Δ^+_λ consists of those positive roots for which $(\lambda,\alpha)\neq 0$. By the definition of a highest weight, this implies that $(\lambda,\alpha)>0$ for all $\alpha\in\Delta^+_\lambda$. The coordinates $(z_\alpha,\overline{z_\alpha})$ correspond to the point in $\mathcal{O}_\lambda$ given by

$$\mathrm{Co}\left[\exp\left(i\sum_{\alpha\in\Delta^+_\lambda}(z_\alpha E_\alpha-\overline{z}_\alpha E_{-\alpha})\right)\right]\lambda.$$

A simple computation, using the Cartan–Weyl form of the commutation relations in $\mathfrak{g}$ (Ref. 18) and (20)–(22), leads to

$$S(z_\alpha,\overline{z_\alpha})=\sum_{\alpha\in\Delta^+_\lambda}(\lambda,\alpha)z_\alpha\overline{z_\alpha}+O(|z|^3). \tag{39}$$

Hence to $O(\exp(-k))$ we may approximate $I_k(x)$ by

$$d_{k\lambda}\int_{\mathfrak{g}/\mathfrak{g}_\lambda}\left(\prod_{\alpha\in\Delta^+_\lambda}\frac{dz_\alpha d\overline{z_\alpha}}{2\pi}\right)J(z_\alpha,\overline{z_\alpha})\exp\left(-k\sum_{\alpha\in\Delta^+_\lambda}(\lambda,\alpha)z_\alpha\overline{z_\alpha}\right)F^x(z_\alpha,\overline{z_\alpha}),$$

where J is a Jacobian, and F^x_λ has been extended to $\mathfrak{g}/\mathfrak{g}_\lambda$ by, say, the exponential map. If we omit the factor $[\cdots]$ in (38), the integral (37) can be done, using the orthogonality relations for compact groups. On the other hand, we can compute the above integral to lowest order in the steepest descent approximation; this avoids the need to compute $J(0)$. Comparing the results computes the prefactor in the steepest descent approximation as unity. As a by-product we obtain the asymptotic expression for $k\to\infty$,

$$d_{k\lambda}\sim\frac{\Pi_{\alpha\in\Delta^+_\lambda}(\lambda,\alpha)}{J(0)}k^{1/2\dim(\mathcal{O}_\lambda)}, \tag{40}$$

where $\dim(\mathcal{O}_\lambda)$ is given by

$$\dim(\mathcal{O}_\lambda)=\dim(\mathfrak{g})-\dim(\mathfrak{t})-2\,\mathrm{Card}\{\alpha\in\Delta^+|(\lambda,\alpha)=0\}. \tag{41}$$

Comparison with the Weyl dimension formula[18] then yields $J(0)=\Pi_{\alpha\in\Delta^+}(\alpha,\delta)$, where $\delta=\frac{1}{2}\Sigma_{\alpha\in\Delta^+}\alpha$. Equation (41) follows from the decomposition

$$\mathfrak{g}_\lambda=\mathfrak{t}\bigoplus\oplus_{\alpha\in\Delta^+|(\lambda,\alpha)=0}\mathfrak{g}^{\mathbb{R}}_\alpha, \tag{42}$$

where $\mathfrak{g}^{\mathbb{R}}_\alpha=\mathfrak{g}\cap(\mathbb{C}E_\alpha\oplus\mathbb{C}E_{-\alpha})$. This decomposition is easily derived from the proof of Proposition 4, the Cartan–Weyl commutation relations, and the fact that $\lambda(E_\alpha)=0$ for all $\alpha\in\Delta$.

Thus the steepest descent approximation to the above integral, and therefore to (37), reads

$$I_k(x)=\sum_{l=0}^{N}\frac{1}{l!}D^l(JF^x)(0)+O(k^{-N-1}), \tag{43}$$

where, abbreviating $\partial_\alpha=\partial/\partial z_\alpha$ and $\overline{\partial}_\alpha=\overline{\partial}/\overline{\partial z}_\alpha$, we have put

$$D=\sum_{\alpha\in\Delta_\lambda^+}\frac{1}{(\lambda,\alpha)}\partial_\alpha\overline{\partial}_\alpha. \tag{44}$$

Substituting this expansion in (36) we see that

$$(\Phi_k,(\mathcal{Q}^B_{1/k}(f)\mathcal{Q}^B_{1/k}(g)-\mathcal{Q}^B_{1/k}(fg))\Phi_k)=O(1/k). \tag{45}$$

To analyze the remainder of $O(1/k)$ we note that the l'th term in the expansion leads to an x-integrand in (36) of the form

$$(U_{k\lambda}(x^{-1})\Phi_k,\Psi_{k\lambda})\overline{(U_{k\lambda}(x^{-1})\Phi_k,\Psi^{(l_1)})}f\partial^{l_2}\overline{\partial}^{l_3}g_\lambda(x),$$

where $l_i\leqslant l$ and the $\Psi^{(l_1)}$ are given by the action of products of $dU_{k\lambda}(E_\alpha)$ and $dU_{k\lambda}(E_{-\alpha})$ on $\Psi_{k\lambda}$. The important point is now that the orthogonality relations (applied to the x-integration) then imply that the $O(k^{-N-1})$ term is bounded by $C\|\Phi_k\|^2/k^{N+1}$ for some constant C. Hence (5) follows.

To prove (3) we need the $l=1$ term in (43). We substitute (44), and perform some partial integrations in the remaining x-integral (using the invariance of the Haar measure). We abbreviate $A=(\Phi_k,U_{k\lambda}(x)\Psi_{k\lambda})$; then (21) implies that $\partial_\alpha A$ and $\overline{\partial}_\alpha\overline{A}$ vanish at $z_\alpha=\overline{z}_\alpha=0$. Terms of the form $\partial_\alpha\overline{\partial}_\alpha A$ (or $\overline{A}$) drop out in the commutator, as do contributions from J (whose first derivatives at 0 already vanish identically). What remains is

$$(\Phi_k,ik[\mathcal{Q}^B_{1/k}(f),\mathcal{Q}^B_{1/k}(g)]-\mathcal{Q}^B_{1/k}(\{f,g\})\Phi_k)=O(1/k), \tag{46}$$

where, in the realization of f,g as G_λ-invariant functions f_λ,g_λ on G,

$$\{f_\lambda,g_\lambda\}=-i\sum_{\alpha\in\Delta_\lambda}\frac{1}{(\lambda,\alpha)}\xi^L_\alpha f_\lambda\,\xi^L_{-\alpha}g_\lambda. \tag{47}$$

Here the left-invariant vector fields $\xi^L_{\pm\alpha}$ on G are defined by first expressing $E_{\pm\alpha}\in\mathfrak{g}_{\mathbb{C}}$ in terms of elements of $\mathfrak{g}$, and then using the usual definition $\xi^L_X f(y)=df(y\exp(tX)/dt(t=0)$. Also, $\Delta_\lambda=\Delta_\lambda^+\cup\Delta_\lambda^-$, i.e., the set of all roots α for which $(\lambda,\alpha)\neq 0$.

To finish the proof, we remark that (47) is precisely the Lie–Kirillov Poisson bracket on $\mathcal{O}_\lambda$; this may be verified at the point $\lambda\in\mathcal{O}_\lambda$ (or $e\in G$) by direct computation from (18), from which the general statement follows by the G-invariance of the Poisson structure.

It is manifest that the right-hand side of (47) is left-G-invariant if f_λ and g_λ are. To prove the right-G_λ-invariance of (47), it is sufficient to establish that it is right-invariant under the derived action of the Lie algebra $\mathfrak{g}_\lambda$, for G_λ is connected. Recall that $[E_\alpha,E_\beta]=N_{\alpha,\beta}E_{\alpha+\beta}$, where $\beta\neq-\alpha$. We now need the identity $N_{-\alpha-\beta,\beta}=-N_{\alpha,\beta}$ (where $\beta\neq\pm\alpha$), which follows from the $\mathrm{Ad}(\mathfrak{g})$-invariance of the inner product on $\mathfrak{g}_{\mathbb{C}}$, combined with the normalization of the E_α. The right-invariance of (47) under $\mathfrak{g}_\lambda$ follows by combining this identity with (42) and the Cartan–Weyl commutation relations.

The higher-order terms in (46) are dealt with as in the above proof of (5). This proves (3), finishing the proof of Theorem 2. ∎

Finally, we remark that the results in this section have an obvious yet somewhat cumbersome generalization: If the orbit $\mathcal{O}_\lambda$ is not integral, but such that $\mathcal{O}_{\lambda/c}$ is integral for some $c\in\mathbb{R}\setminus\{0\}$, we can construct a strict quantization for the values $\hbar=c/k$, $k\in\mathbb{N}$.

Deformations of massless Gupta–Bleuler triplets in 3+2 De Sitter space

Marc Lesimple
Dipartimento di Matematica, Università degli Studi di Padova, via Belzoni 7, 35131 Padova, Italy

(Received 27 May 1998; accepted for publication 27 July 1998)

We study deformations of massless indecomposable representations (Gupta–Bleuler triplets) for the De Sitter group SO(3,2), showing that there is no deformation of such representations toward a kind of massive Gupta–Bleuler triplets which would have corresponded to an analog of a Higgs–Kibble mechanism in anti De Sitter space. © *1998 American Institute of Physics.* [S0022-2488(98)03411-2]

I. INTRODUCTION

Passage from massless field theory to interacting massive field theory involves deformations of massless gauge theories, and so brings forth the stability problem (in the sense of deformations) for a given massless gauge theory.

In a $3+2$ De Sitter space massless fields are described by indecomposable representations with invariant scalar product, which reduce (for some minimal gauge fixing) to representations of the form $\rho=(\pi_3,V_3)\to(\pi_2,V_2)\to(\pi_1,V_g)$, with kernel (π_1,V_g) of type $D(s+2,s-1)$ or $D(2-s,s)$, in the discrete series of the De Sitter group [denoting representations of the De Sitter algebra so(3,2) of the De Sitter group, associated with elementary particles—with lower energy E_0 and spin s—by $D(E_0,s)$].

In particular, the occurrence of the identity representation [as a submodule of (π_2,V_2)] in one of the Gupta–Bleuler triplets of electrodynamics presumes the existence of Higgs–Kibble phenomena[1] to describe interacting massive spin 1 fields.

A possible Higgs–Kibble mechanism describing massive fields in $3+2$ De Sitter space would depend on deformations of massless gauge theories; which one aspect is deformations of massless Gupta–Bleuler triplets.

Spontaneously broken symmetries in the Lagrangian of a massless field would give the occurrence of massless Goldstone fields,[2] now belonging to the kernel V_g^λ of a deformed Gupta–Bleuler triplet ρ^λ containing an extension, say $(\pi_2^\lambda,V_2^\lambda)\to(\pi_1^\lambda,V_g^\lambda)$; where submodules $(\pi_1^\lambda,V_g^\lambda)$, $(\pi_2^\lambda,V_2^\lambda)$, describe, respectively, longitudinal and transverse modes of a massive field.

In other words Higgs–Kibble phenomena invoke stability of massless gauge theories under deformations inside massless gauge theories. The existence (or nonexistence) of a kernel in ρ^λ could be compared with the conservation (or nonconservation) of the sources of interacting massive spin 2 fields in Minkowski space.[3]

In Sec. II we recall the structure of massless representations. We give a characterization of the first cohomological spaces corresponding to massless Gupta–Bleuler triplets.

In Sec. III, considering the problem of stability, we study deformations of a massless Gupta–Bleuler triplet ρ. We shall see that no indecomposable representations, nonequivalent to ρ, can be obtained by deformations.

II. MASSLESS GUPTA–BLEULER TRIPLETS

Presentation of the unitary irreducible representations involved.

We consider De Sitter space as a covering of the hyperboloid $(y^0)^2-(y^1)^2-(y^2)^2-(y^3)^2+(y^5)^2=R^{-1}$ in $(\mathbb{R}^5,g)$, R being the curvature and g the metric $g_{\alpha\beta}=(1,-1,-1,-1,1)$.

$\mathbf{G}$ will denote the connected component $\mathrm{SO}_0(3,2,)$, $\tilde{\mathbf{G}}$ its universal covering, $\mathbf{g}$ the complexified of its Lie algebra $\mathbf{g}_0$, and U($\mathbf{g}$) the universal enveloping algebra of $\mathbf{g}$. Let $\{L_{\alpha\beta}\}_{\alpha,\beta=0,1,2,3,5}$ be a basis of $\mathbf{g}_0$,[4] that satisfies $L_{\alpha\beta}=-L_{\beta\alpha}$, $[L_{\alpha\beta},L_{\gamma\delta}]=g_{\alpha\beta}L_{\beta\gamma}+g_{\beta\gamma}L_{\alpha\delta}-g_{\alpha\gamma}L_{\beta\delta}-g_{\beta\delta}L_{\alpha\gamma}$. We keep the notations of Ref. 5.

 © 1998 American Institute of Physics

Let $(H,H',E_{\pm\alpha},E_{\pm\beta},E_{\pm\gamma},E_{\pm\delta})$ be defined by

$$H=L_{21}+L_{50},\quad H'=L_{21}-L_{50},$$

$$E_{\pm\alpha}=L_{25}+L_{10}\pm i(L_{51}+L_{20}),\quad E_{\pm\beta}=L_{25}-L_{10}\pm i(L_{51}-L_{20}),$$

$$E_{\pm\gamma}=L_{35}\pm iL_{30},\quad E_{\pm\delta}=\pm L_{23}+iL_{31}.$$

We consider the four subalgebras of $\mathbf{g}$, of type A_1, $\mathbf{L}$ (respectively, $\mathbf{L}'$) generated by $(E_{\pm\alpha},H)$ [respectively $(E_{\pm\beta},H')$], $\mathbf{L}_1$ (respectively, $\mathbf{L}_2$) by $(H_1,-E_{\pm\delta})$ with $H_1=-i/2(H+H')$ [respectively $(H_2,-E_{\pm\gamma})$] with $H_2=-i/2(H-H')$.

Let us rewrite the commutation relations for $\mathbf{L}\oplus\mathbf{L}'$,

$$[H,E_{\pm\alpha}]=\pm 2iE_{\pm\alpha},\quad [H,E_{\pm\beta}]=0,$$

$$[H',E_{\pm\beta}]=\pm 2iE_{\pm\beta},\quad [H',E_{\pm\alpha}]=0,$$

$$[E_\alpha,E_{-\alpha}]=-4iH,\quad [E_\beta,E_{-\beta}]=-4iH',\quad [H,H']=0.$$

Let $\mathbf{K}=\mathrm{SO}(3)\times\mathrm{SO}(2)$ be the maximal compact subgroup of $\mathbf{G}$, $\tilde{\mathbf{K}}=\mathrm{SU}(2)\times\mathbb{R}$ its universal covering, $\mathbf{k}=\mathrm{so}(2)\oplus\mathrm{so}(3)$ the complexification of its Lie algebra. The center of the enveloping algebra of, respectively, $\mathbf{L},\mathbf{L}',\mathbf{L}_1,\mathbf{L}_2$ is generated by the following elements:

$$Q_L=H^2+H+E_\alpha E_{-\alpha},\quad Q_{L'}=H'^2+H'+E_{-\beta}E_\beta,$$

$$Q_{L_1}=-\frac{1}{4}(H^2+H'^2)-\frac{1}{2}HH'-\frac{i}{2}(H+H')+E_{-\delta}E_\delta,$$

$$Q_{L_2}=-\frac{1}{4}(H^2+H'^2)+\frac{1}{2}HH'-\frac{i}{2}(H-H')+E_{-\gamma}E_\gamma.$$

Given a unitary irreducible representation of $\tilde{\mathbf{G}}$ in a Hilbert space $\mathscr{H}$, $(U,\mathscr{H})$ of type $D(E_0,s)$ with extremal weight (E_0,s).

The space V of $\mathbf{k}$-finite vectors of $\pi=DU$ (the differential of U) decomposes as the vectorial sum of weight subspaces $V_{\sigma\delta}$, of weight (σ,δ), $V=\oplus_{\substack{\sigma=E_0,E_0+1,\dots\\ \delta=-s,\dots,+s}} V_{\sigma\delta}$.[5,6] There exists an orthonormal basis $(v_{\sigma\delta}^{nn'})n,n'\in\mathbb{N}$ of $V_{\sigma\delta}$ for which the action of $\mathbf{g}$ is given by, noting $l=-(\sigma+\delta)/2$ and $l'=-(\sigma-\delta)/2$,

$$\begin{aligned}
&\pi(H)v_{\sigma\delta}^{nn'}=2i(-l+n)v_{\sigma\delta}^{nn'},\\
&\pi(H')v_{\sigma\delta}^{nn'}=-2i(-l+n')v_{\sigma\delta}^{nn'},\\
&\pi(E_\alpha)v_{\sigma\delta}^{nn'}=2i\alpha_{n+1}^{\sigma\delta}v_{\sigma\delta}^{n+1,n'},\\
&\pi(E_{-\alpha})v_{\sigma\delta}^{nn'}=2i\alpha_n^{\sigma\delta}v_{\sigma\delta}^{n-1,n'}\quad\text{where}\quad \alpha_{n+1}^{\sigma\delta}=[\lambda_n^{\sigma\delta}(\lambda_{n+1}^{\sigma\delta})-l(l+1)]^{1/2},\\
&\pi(E_\beta)v_{\sigma\delta}^{nn'}=2i\alpha_{n'}^{\sigma\delta}v_{\sigma\delta}^{n,n'-1},\quad(\text{with}\ \lambda_n^{\sigma\delta}=-l+n);\\
&\pi(E_{-\beta})v_{\sigma\delta}^{nn'}=2i\alpha_{n'+1}^{\sigma\delta}v_{\sigma\delta}^{n,n'+1}\quad\text{where}\quad \alpha_{n'+1}^{\sigma\delta}=[\lambda_{n'}^{\sigma\delta}(\lambda_{n'+1}^{\sigma\delta})-l'(l'+1)]^{1/2}\\
&\qquad(\text{with}\ \lambda_{n'}^{\sigma\delta}=-l'+n').
\end{aligned}\tag{2.1}$$

$$\pi(E_\delta)v^{nn'}_{\sigma\delta} = -i[(\lambda^{\sigma\delta}_n - l)(\lambda^{\sigma\delta}_{n'} + l')]^{1/2} a_{\sigma\delta} v^{n,n'-1}_{\sigma+1,\delta} - i[(\lambda^{\sigma\delta}_n + l + 1)(\lambda^{\sigma\delta}_{n'} - l' - 1)]^{1/2} b_{\sigma\delta} v^{n+1,n'}_{\sigma-1,\delta}$$
$$- i[(\lambda^{\sigma\delta}_n + l + 1)(\lambda^{\sigma\delta}_{n'} + l')]^{1/2} c_{\sigma\delta} v^{n+1,n'-1}_{\sigma,\delta-1}$$
$$- i[(\lambda^{\sigma\delta}_n - l)(\lambda^{\sigma\delta}_{n'} - l' - 1)]^{1/2} d_{\sigma\delta} v^{n,n'}_{\sigma,\delta+1}, \tag{2.2}$$

where $a_{\sigma\delta}, b_{\sigma\delta}, c_{\sigma\delta}, d_{\sigma\delta} \in \mathbb{C}$, given for $a_{\sigma\delta}$ by

$$a_{\sigma\delta} = \left[\frac{(\sigma+s)(\sigma-s-1)(\sigma-E_0+1)(\sigma+E_0-2)}{(\sigma+s)(\sigma+\delta-1)(\sigma-\delta)(\sigma-\delta-1)} \right]^{1/2}.$$

And similar relations for $\pi(E_{-\delta})$, $\pi(E_{\pm\gamma})$ (see Ref. 5).

We shall need to write the decomposition of V corresponding to the restriction $U_{|\tilde{K}}$, $V = \oplus_{(j,\epsilon)} V_{j\epsilon}$, where $V_{j\epsilon}$ is the $2j+1$ dimensional weight space corresponding to the weight (j,ϵ).

We denote by $(\phi^m_{j\epsilon})_{m=-j,\ldots,j}$ an othonormal basis of $V_{j\epsilon}$.[5,6]

Let us recall,

$$\pi(H_1)\phi^m_{j\epsilon} = m\phi^m_{j\epsilon}, \quad \pi(H_2)\phi^m_{j\epsilon} = \epsilon\phi^m_{j\epsilon} \tag{2.3}$$

and $\pi(Q_{L_1})\phi^m_{j\epsilon} = j(j+1)\phi^m_{j\epsilon}$.

Let us now introduce a few notations. A Gupta–Bleuler triplet is given by an indecomposable unitary representation of $\tilde{\mathbf{G}}$ $(U, \mathscr{H}')$ in a Hilbert space $\mathscr{H}'$ defined in the following way.

We note V' the space of $\mathbf{k}$-finite vectors of $\rho = DU$ and V, V_1 the submodules occurring in the decomposition of V', $V_1 \subset V \subset V'$,

$$(\rho, V') = (\pi_3, V_3) \to (\pi_2, V_2) \to (\pi_1, V_1)$$

with $V_2 \simeq V/V_1$ and $V_3 \simeq V'/V$; the $\mathbf{g}$-simple submodules (π_3, V_3) and (π_1, V_1) being conjugated.[7]

Massless Gupta–Bleuler triplets [that is with (π_1, V_1) of type $D(s+2, s-1)$ or $D(2-s, s)$] appear at limit of the discrete series $E_0 = s+1$ ($s \geqslant 1$, integer or half-integer).

$\phi^m_{ij\epsilon}$ [$(\phi^m_{ij\epsilon})$ is the basis of V_i as defined in (2.3)] can be realized as homogeneous and symmetric tensors (s integer) or tensors-spinors (s half-integer) on De Sitter space, solutions of gauge-fixed wave equations.[4] For some minimal gauge fixing the representation ρ reduces to

$$D(s+2, s-1) \to D(s+1, s) \to D(s+2, s-1) \quad \text{or} \tag{2.4}$$

$$D(2-s,s) \nearrow D(s+1,s) \searrow \quad D(2-s,s). \quad D(2-s,s) \searrow D(1-s,s-1) \nearrow \tag{2.5}$$

Given (π_1, V_1) and (π_3, V_3) [respectively, (π_2, V_2)] of type $D(s+2, s-1)$ [respectively, $D(s+1, s)$]. We shall characterize extensions of the form $\rho = \pi_3 \to \pi_2 \to \pi_1$, which remain Harish–Chandra modules; consequently it is enough to restrict to relative cohomology.

Let $Z^1(\mathbf{g}, \mathscr{L}(V_2, V_1))^{\mathbf{h}}$ [respectively, $B^1(\mathbf{g}, \mathscr{L}(V_2, V_1))^{\mathbf{h}}$] be the space of cocycles (respectively, coboundaries) vanishing on $\mathbf{h}$, the Cartan subalgebra of $\mathbf{g}$ [$\mathscr{L}(V_2, V_1)$ is the space of continuous linear mapping from V_2 into V_1].

We note $H^1(\mathbf{g}, \mathscr{L}(V_2, V_1))^{\mathbf{h}}$ the coset $Z^1(\mathbf{g}, \mathscr{L}(V_2, V_1))^{\mathbf{h}} / B^1(\mathbf{g}, \mathscr{L}(V_2, V_1))^{\mathbf{h}}$.[8] Similarly $H^1(\mathbf{g}, \mathscr{L}(V_3, V))^{\mathbf{h}}$ denotes the relative first cohomological space of $\mathbf{g}$-mod. $\mathbf{h}$, with coefficients in $\mathscr{L}(V_3, V)$ with $V = V_1 \oplus V_2$.

Characterization of $H^1(\mathbf{g}, \mathscr{L}(V_2, V_1))^{\mathbf{h}}$ and $H^1(\mathbf{g}, \mathscr{L}(V_3, V))^{\mathbf{h}}$ have been carried on only so far as to establish results relevant for Sec. III. We denote $\{v^{nn'}_{i\sigma\delta}\}$ and $\{\phi^m_{ij\epsilon}\}$ the relative basis of V_i, $i = 1,2,3$ as defined above (2.3). First we show that $H^1(\mathbf{g}, \mathscr{L}(V_2, V_1))^{\mathbf{h}}$ is generated by cocycles ξ satisfying,

$$\xi_{E_\beta} = \xi_{E_{-\alpha}} = \xi_{E_{-\gamma}} = 0 \quad \xi_{|L_1} = 0,$$

$$\xi_{E_{-\beta}} v^{00}_{2s+1,s} = v^{00}_{1s+2,s-1}.$$

We have $\pi_2(H_2)v^{nn'}_{2\sigma\delta}=(\sigma+n+n')v^{nn'}_{2\sigma\delta}$ and $\pi_2(H_1)v^{nn'}_{2\sigma\delta}=(\sigma+n+n')v^{nn'}_{2\sigma\delta}$. From commutations relations for $E_{-\beta}$ and H_1,H_2, one has $[H_1,\xi_{E_{-\beta}}]=-\xi_{E_{-\beta}}$ and $[H_2,\xi_{E_{-\beta}}]=\xi_{E_{-\beta}}$. Therefore one deduces that

$$\pi_1(H_2)\xi_{E_{-\beta}}v^{00}_{2s+1,s}=(s+2)\xi_{E_{-\beta}}v^{00}_{2s+1,s} \quad \text{and} \quad \pi_1(H_1)\xi_{E_{-\beta}}v^{00}_{2s+1,s}=(s-1)\xi_{E_{-\beta}}v^{00}_{2s+1,s}.$$

From commutation relations for $E_{-\beta}$ and H,H', we deduce that

$$\pi_1(H)\xi_{E_{-\beta}}v^{00}_{2s+1,s}=2i\left(\frac{2s+1}{2}\right)\xi_{E_{-\beta}}v^{00}_{2s+1,s} \quad \text{and} \quad \pi_1(H')\xi_{E_{-\beta}}v^{00}_{2s+1,s}=-2i\left(\frac{3}{2}\right)\xi_{E_{-\beta}}v^{00}_{2s+1,s}.$$

Since $((2s+1)/2,\frac{3}{2})$ is a minimal weight for π_1, we have that $\xi_{E_{-\beta}}v^{00}_{2s+1,s}\in V^{00}_{1s+2,s-1}$. Similarly we have $\xi_{E_\delta}V^m_{2j\epsilon}\subset\oplus_{j<\epsilon}V^{m+1}_{1j\epsilon}$ [with eventually $V^{m+1}_{1j\epsilon}=0$ if (j,ϵ) is not a weight of π_1]. Consider $V^{L_1}_{ij\epsilon}=\pi_i(U(\mathbf{L}_1))\phi^m_{ij\epsilon}$ with $\phi^m_{ij\epsilon}\neq 0$, $i=1,2$; then $\xi_{|_{\mathbf{L}_1}}\in Z^1(\mathbf{L}_1,\mathscr{L}(\oplus_{j<\epsilon}V^{L_1}_{2j\epsilon},\oplus_{j<\epsilon}V^{L_1}_{1j\epsilon}))^{\mathbf{h}_1}$ ($\mathbf{h}_1$ being the Cartan subalgebra of $\mathbf{L}_1$). From Whitehead's lemma, there exist $B_1\in\mathscr{L}(V_2,V_1)$ such that $\xi_{|_{\mathbf{L}_1}}=dB_1$ (d is the coboundary operator).

From commutations relations of $E_{-\gamma}$ with H_1 and H_2, one deduces that $\xi_{E_{-\gamma}}V^m_{2j\epsilon}\subset\oplus_{j<\epsilon-1}V^m_{1j\epsilon-1}$, therefore there exist $B_2\in\mathscr{L}(V_2,V_1)$ defined by $B_2\phi^m_{2j\epsilon}=\Sigma_{j'<\epsilon}b_{j'\epsilon}\phi^m_{1j'\epsilon}$, such that $\xi_{E_{-\gamma}}=[E_{-\gamma},B_2]$. dB_2 vanishes on $\mathbf{h}$ and $\mathbf{L}_1$, thus we can restrict ourselves to cocycles vanishing on $\mathbf{L}_1$ and $E_{-\gamma}$.

Now coboundaries vanishing on $\mathbf{h}$, $\mathbf{L}_1$, and $E_{-\gamma}$ are of the form dB with B diagonal in the basis $\{\phi^m_{ij\epsilon}\}_{i=1,2}$, so $dB(E_{-\beta})v^{00}_{2s+1,s}=0$; consequently $\xi_{E_{-\beta}}v^{00}_{2s+1,s}\neq 0$.

Let us now determine the elements of $H^1(\mathbf{g},\mathscr{L}(V_3,V_1\oplus V_2))^{\mathbf{h}}$ corresponding to the extension $\rho=\pi_3\rightarrow(\pi_2\rightarrow\pi_1)$.

ρ can be written in the following form:

$$\rho=\begin{pmatrix}\pi_1 & \xi & \zeta\\ 0 & \pi_2 & \eta\\ 0 & 0 & \pi_3\end{pmatrix} \quad \text{with} \quad \eta\in Z^1(\mathbf{g},\mathscr{L}(V_3,V_2))^{\mathbf{h}}, \quad \zeta\in Z^1(\mathbf{g},\mathscr{L}(V_3,V_1))^{\mathbf{h}}$$

(Ref. 7). First, ζ defines an element of $H^1(\mathbf{g},\mathscr{L}(V_3,V_1))^{\mathbf{h}}$, but (π_3,V_3) and (π_1,V_1) being equivalent, every restriction of ζ to alternatively $\mathbf{L}$, $\mathbf{L}'$, $\mathbf{L}_1$ and $\mathbf{L}_2$ corresponds to an extension of type $D_k^+\rightarrow D_k^+$ (k integer or half integer) which is inessential.[8]

Thus, up to a coboundary, $\zeta=0$. η defines an element of $H^1(\mathbf{g},\mathscr{L}(V_3,V_2))^{\mathbf{h}}$. We have, in an analogous manner as previously, $\eta_{E_\beta}v^{00}_{3s+2,s-1}=v^{00}_{2s+1,s}$ and $\eta_{E_{-\gamma}}=\eta_{E_{-\beta}}=0$ as well as $\eta_{|_{\mathbf{L}_1}}=0$.

We can summarize,

Proposition 1: All nontrivial extensions $\pi_3\rightarrow\pi_2\rightarrow\pi_1$ with (π_1,V_1), of type $D(s+2,s-1)$ and (π_2,V_2) of type $D(s+1,s)$, are equivalent to an extension of the following form:

$$\rho=\begin{pmatrix}\pi_1 & \xi & 0\\ 0 & \pi_2 & \eta\\ 0 & 0 & \pi_3\end{pmatrix} \quad \textit{with} \quad \xi_X\in\mathscr{L}(V_2,V_1), \quad \eta_X\in\mathscr{L}(V_3,V_2) \quad \textit{for every } X \textit{ in } \mathbf{g}.$$

ξ, η satisfying

$$\xi_{E_{-\beta}}v^{00}_{2s+1,s}=v^{00}_{1s+2,s-1}, \quad \xi_{E_\beta}=\xi_{E_{-\alpha}}=\xi_{E_{-\gamma}}=\xi_{|_{\mathbf{L}_1}}=0,$$

and

$$\eta_{E_\beta}v^{00}_{3s+2,s-1}=v^{00}_{2s+1,s}, \quad \eta_{E_{-\beta}}=\eta_{E_{-\gamma}}=\eta_{|_{\mathbf{L}_1}}=0.$$

$v^{00}_{1s+2,s-1}$, $v^{00}_{2s+1,s}$, and $v^{00}_{3s+2,s-1}$ are cyclic vectors for, respectively, π_1, $\pi_2\rightarrow\pi_1$, and ρ.

For instance a realization of the Gupta–Bleuler triplet (2.4) for $s=1$, corresponding to electrodynamics is given in Ref. 9, with $\xi_{E_{-\beta}} v^{00}_{2s+1,s} = v^{00}_{1s+2,s-1}$ and $\eta_{E_\beta} v^{00}_{3s+2,s-1} = v^{00}_{2s+1,s}$, others terms being null.

Remark: We had previously developed with an irreducible representation π_2 [of type $D(s+1,s)$] but similar arguments extend to the case of a quasisimple (Ref. 10, p. 257) representation. In particular that includes the second triplet (2.5).

III. DEFORMATIONS OF MASSLESS GUPTA-BLEULER TRIPLETS

Let (ρ, V') be a massless Gupta–Bleuler triplet, it can be written in the form

$$\rho = \begin{pmatrix} \pi_1 & \xi & 0 \\ 0 & \pi_2 & \eta \\ 0 & 0 & \pi_3 \end{pmatrix}$$

with $\xi_X \in \mathscr{L}(V_2, V_1)$, $\eta_X \in \mathscr{L}(V_3, V_2)$ for every X in $\mathbf{g}$ $(V' = V_1 \oplus V_2 \oplus V_3,\ V = V_1 \oplus V_2)$. (π_1, V_1), (π_3, V_3) being conjugated and (π_2, V_2) quasisimple. $V^\perp$ will designate the orthogonal of V with respect to the $\tilde{\mathbf{G}}$-invariant inner product in V'.

We now turn to deform the representation (ρ, V'). We denote by $Z^1(\mathbf{g}, \mathscr{L}(V'))$ [respectively, $B^1(\mathbf{g}, \mathscr{L}(V'))$] the space of cocycles (respectively, coboundaries), and by $H^1(\mathbf{g}, \mathscr{L}(V'))$ the first-order cohomological space of $\mathbf{g}$, with coefficients in $\mathscr{L}(V')$ [$\mathscr{L}(V')$ is the space of continuous linear mappings]. We restrict to deformations ρ^λ ($\lambda \in \mathbb{C}$) of ρ which remain Gupta–Bleuler triplets (with components in the discrete or supplementary series).

Looking first to the infinitesimal parts, we shall determine corresponding elements of $H^1(\mathbf{g}, \mathscr{L}(V'))$. Next we shall show that massless gauge theories are stable, as far as deformations to gauge theories that are of concern:

Proposition 2: Let us take $\rho = \pi_3 \to \pi_2 \to \pi_1$, with π_1 of type $D(s+2,s-1)$ or $D(2-s,s)$. Given a deformation $(\rho^\lambda, V'^\lambda)$ of (ρ, V'), integrable to a deformation U^λ of U. Suppose that $(\rho^\lambda, V'^\lambda)$ admits a simple $\mathbf{g}$-submodule V_1^λ of V'^λ with $V_1^{\lambda\perp} \neq V_1^\lambda$, such that restriction θ_1^λ of ρ^λ to V_1^λ is a Verma module and there are no $\mathbf{g}$-invariant complement of V_1^λ in V'^λ.

Then the representation ρ^λ is equivalent to the representation ρ.

In other words, there are no deformations of ρ with a kernel.

Proof: We assume that π_2 is irreducible of type $D(s+1,s)$ and ρ defined by proposition 1 but the same arguments could be repeated with a quasisimple representation π_2.

Let V'^λ be the subspace of $\mathbf{k}$-finite vectors of ρ^λ. Up to equivalence we have $V'^\lambda = V'$ for every λ.[11] Since $V_1^{\lambda\perp} \neq V_1^\lambda$, ρ^λ is a Gupta–Bleuler triplet; there is a submodule V^λ of V', $V_1^\lambda \subset V^\lambda \subset V'$ such that V^λ / V_1^λ is a simple Verma module and: the quotient representation $(\rho^\lambda, V'/V^\lambda)$ is conjugated to $(\rho^\lambda, V_1^\lambda)$.[7]

Actually V_1^λ, V^λ / V_1^λ and V'/V^λ are deformations of the irreducible representations (π_1, V_1), (π_2, V_2) and (π_3, V_3), respectively. So let us denote the representations obtained, restricting ρ^λ to successively V_1^λ, V^λ, and V' modulo the corresponding invariant subspaces, by $(\pi_1^\lambda, V_1^\lambda)$, $(\pi_2^\lambda, V_2^\lambda)$, and $(\pi_3^\lambda, V_3^\lambda)$. Thus ρ^λ is of the form

$$\rho^\lambda = \begin{pmatrix} \pi_1^\lambda & u_{12}^\lambda & u_{13}^\lambda \\ 0 & \pi_2^\lambda & u_{23}^\lambda \\ 0 & 0 & \pi_3^\lambda \end{pmatrix} \quad \text{with} \quad V' = V_1^\lambda \oplus V_2^\lambda \oplus V_3^\lambda .$$

Since we restrict ourselves to the ρ^λ which remain Harish–Chandra modules, we have

$$u_{12}^\lambda \in Z^1(\mathbf{g}, \mathscr{L}(V_2^\lambda, V_1^\lambda))^{\mathbf{h}}, \quad u_{13}^\lambda \in Z^1(\mathbf{g}, \mathscr{L}(V_3^\lambda, V_1^\lambda))^{\mathbf{h}},$$

and $u_{23}^\lambda \in Z^1(\mathbf{g}, \mathscr{L}(V_3^\lambda, V_2^\lambda))^{\mathbf{h}}$. As a submodule of (ρ^λ, V'), $(\rho^\lambda{}_{|V^\lambda}, V^\lambda)$ is a deformation of $(\rho_{|V}, V)$; as well $(\rho^\lambda{}_{|V_1^\lambda}, V_1^\lambda)$ is a deformation of $(\rho_{|V_1}, V_1)$.

Therefore up to an isomorphism (which will not be unitary in general) we can suppose that (ρ^λ, V') decomposes as $V'=V\oplus V_3$ with $V=V_1\oplus V_2$ (that is $V_1^\lambda \simeq V_1$, $V_2^\lambda \simeq V_2$ and $V_3^\lambda \simeq V_3$ as subspaces of V'). Let us write $\rho^\lambda(X)$, $X\in\mathbf{g}$ as

$$\rho^\lambda(X)=\rho(X)+\lambda C(X)+\sum_{n\geqslant 2}\lambda^n C_n(X) \quad \text{with } C(X),C_n(X)\in\mathscr{L}(V').$$

ρ^λ is integrable to a deformation U^λ of U as a representation of $\tilde{\mathbf{G}}$ in $\mathscr{H}'$ (Ref. 11, proposition 9).

We shall characterize the elements C in $Z^1(\mathbf{g},\mathscr{L}(V'))$ corresponding to such deformations. First, we show that we can restrict ourselves to cocycles C vanishing on $\mathbf{L}\oplus\mathbf{L}'$ [in other words we show that C vanishes on C_3, the commutant of so(3) in $U(\mathbf{g})$, Ref. 6],

$$\rho^\lambda=\pi_3^\lambda\to\pi_2^\lambda\to\pi_1^\lambda \quad \text{where } \pi_i^\lambda \text{ are of type } D(E_0^\lambda,s^\lambda).$$

Let $\mathbf{G}_{L\oplus L'}$ be a subgroup of $\mathbf{G}$, connected, closed, associated to $\mathbf{L}\oplus\mathbf{L}'$ ($\mathbf{G}_{L\oplus L'}\simeq \mathrm{SO}(2,2)$). $\mathbf{G}_{L\oplus L'}$ has a maximal compact subgroup $\mathbf{K}_{L\oplus L'}$, thus considering the restriction $C_{|_{\mathbf{L}\oplus\mathbf{L}'}}$ of C to $\mathbf{L}\oplus\mathbf{L}'$, $C_{|_{\mathbf{L}\oplus\mathbf{L}'}}$ defines an element of $H^1(\mathbf{L}\oplus\mathbf{L}',\mathscr{L}(V'))$ integrable to an element of $H^1(\mathbf{G}_{L\oplus L'},\mathscr{L}(\mathscr{H}'))$ (Ref. 8, proposition 7.13). But, ρ being integrable to a representation U of $\tilde{\mathbf{G}}$ and $\mathbf{G}$, $H^1(\mathbf{G}_{L\oplus L'},\mathscr{L}(\mathscr{H}'))=H^1(\mathbf{G}_{L\oplus L'},\mathscr{L}(\mathscr{H}'))^{\mathbf{K}_{L\oplus L'}}$. So $C_{|_{\mathbf{L}\oplus\mathbf{L}'}}$ belongs—up to a coboundary—to $Z^1(\mathbf{L}\oplus\mathbf{L}',\mathscr{L}(V'))^{\mathbf{h}}$. Consequently we can restrict to cocycles C vanishing on $\mathbf{h}$.

We have

$$V'=\bigoplus_{\substack{(\sigma,\delta)\\ i=1,2,3}} V_{i\sigma\delta}$$

[$V_{i\sigma\delta}$ being the null space if (σ,δ) is not a weight of π_i] with $V_{i\sigma\delta}=\pi_i(U(\mathbf{L}\oplus\mathbf{L}'))v_{i\sigma\delta}^{00}$. Let us consider the following Verma $\mathbf{L}\oplus\mathbf{L}'$-modules:

$$F_{i\sigma\delta}=\rho(U(\mathbf{L}\oplus\mathbf{L}'))v_{i\sigma\delta}^{00}, \quad i=1,2,3.$$

One has $F_{1\sigma\delta}\subset V_1$, $F_{2\sigma\delta}\subset V_1\oplus V_2$, and $F_{3\sigma\delta}\subset V_1\oplus V_2\oplus V_3$. We can show that $H^1(\mathbf{L}\oplus\mathbf{L}',\mathscr{L}(F_{i\sigma\delta}))^{\mathbf{h}}=\{0\}$, but every extension appearing in $\rho_{|_{\mathbf{L}\oplus\mathbf{L}'}}$ being trivial,[8] to simplify, we can assume that $F_{i\sigma\delta}=V_{i\sigma\delta}$, $i=1,2,3$. (ρ^λ,V') admits a decomposition relative to $\mathbf{L}\oplus\mathbf{L}'$ as

$$V'=\bigoplus_{\substack{i=1,2,3\\ (\sigma(\lambda),\delta(\lambda))}} V_{i\sigma(\lambda)\delta(\lambda)},$$

where $V_{i\sigma(\lambda)\delta(\lambda)}=\rho^\lambda((U(\mathbf{L}\oplus\mathbf{L}'))v_{i\sigma\delta}^{00}$ (denoting $(\sigma(\lambda),\delta(\lambda))$ the weights of $\rho^\lambda{}_{|_{\mathbf{L}\oplus\mathbf{L}'}}$). Considering

$$\left(\rho^\lambda{}_{|_{\mathbf{L}\oplus\mathbf{L}'}}, \bigoplus_{i'=1,\ldots,i} V_{i'\sigma(\lambda)\delta(\lambda)}\right)$$

as a deformation of

$$\left(\rho_{|_{\mathbf{L}\oplus\mathbf{L}'}}, \bigoplus_{i'=1,\ldots,i} V_{i'\sigma\delta}\right),$$

we can suppose—up to an isomorphism—that $V_{i\sigma(\lambda)\delta(\lambda)}=V_{i\sigma\delta}$ $(i=1,2,3)$ for every λ.

Let us note $V'_{\sigma\delta}=\oplus_{i=1,2,3}V_{i\sigma\delta}$. Now $C_{|_{\mathbf{L}\oplus\mathbf{L}'}}$ defines an element of

$$H^1\left(\mathbf{L}\oplus\mathbf{L}',\mathscr{L}\left(\bigoplus_{i'=1,\ldots,i} V_{i'\sigma\delta}\right)\right)^{\mathbf{h}}$$

and every extension of type $D_k^+\to D_{k'}^+$ $(k,k'\geqslant\frac{1}{2})$ for $sl(2)$ are inessential[8] ($\mathbf{L}\oplus\mathbf{L}'$—submodules occurring in $(\rho_{|_{\mathbf{L}\oplus\mathbf{L}'}},V_{i\sigma\delta})$ $i=1,2,3$, are of type $D_{\frac{1}{2}(\sigma+\delta)}\oplus D_{\frac{1}{2}(\sigma-\delta)}$).

One deduces that

$$H^1(\mathbf{L}\oplus\mathbf{L}',\mathscr{L}(V_{i\sigma\delta},V_{i'\sigma\delta}))^{\mathbf{h}}=\{0\},\quad i,i'=1,2,3;$$

thus $H^1(\mathbf{L}\oplus\mathbf{L}',\mathscr{L}(V'_{\sigma\delta}))^{\mathbf{h}}=\{0\}$ for every weight (σ,δ).[12]

V' being the vectorial sum of $\{V'_{\sigma\delta}\}_{(\sigma,\delta)}$, there exist $T\in\mathscr{L}(V')\cap\mathscr{L}(V'_{\sigma\delta})$, for every (σ,δ), such that $C(X)=dT(X)$ for every $X\in\mathbf{L}\oplus\mathbf{L}'$. That is to say, $H^1(\mathbf{L}\oplus\mathbf{L}',\mathscr{L}(V'))^{\mathbf{h}}=\{0\}$. Then we can restrict ourselves to cocycles C vanishing on $\mathbf{L}\oplus\mathbf{L}'$, and

$$\rho^\lambda|_{\mathbf{L}\oplus\mathbf{L}'}=\rho|_{\mathbf{L}\oplus\mathbf{L}'}+\lambda^2C_2|_{\mathbf{L}\oplus\mathbf{L}'}+\cdots,\quad\text{with } C_2|_{\mathbf{L}\oplus\mathbf{L}'}\in Z^1(\mathbf{L}\oplus\mathbf{L}',\mathscr{L}(V'))^{\mathbf{h}}.$$

Thus up to equivalence, we can suppose that $C_2|_{\mathbf{L}\oplus\mathbf{L}'}=0$; repeating for $C_3,\ldots$, one has—up to equivalence—$\rho^\lambda|_{\mathbf{L}\oplus\mathbf{L}'}=\rho|_{\mathbf{L}\oplus\mathbf{L}'}$. Therefore ρ^λ is a massless Gupta–Bleuler triplet. In order to show that ρ^λ is isomorphic to ρ, it is enough to prove that $\rho^\lambda(Q_{L_1})=\rho(Q_{L_1})$.

Let us consider the decomposition of V', relative to $\tilde{\mathbf{K}}$,

$$V'=\bigoplus_{\substack{(j,\epsilon)\\ i=1,\ldots,3}} V_{ij\epsilon},$$

where as previously $V_{ij\epsilon}$ denote the $2j+1$ dimensional weight subspace (with basis $\{\phi^m_{ij\epsilon}\}_m$) associated to the weight (j,ϵ) for π_i. Let us note $V^{L_1}_{ij\epsilon}=\pi_i(U(\mathbf{L}_1))\phi^m_{ij\epsilon}$ with $\phi^m_{ij\epsilon}\neq0$ and

$$V'^{L_1}_{ij\epsilon}=\bigoplus_{i'=1,\ldots,i} V^{L_1}_{i'j\epsilon}.$$

Then $(\pi_i|_{\mathbf{L}_1},V^{L_1}_{ij\epsilon})$ is a $2j+1$ dimensional representation of type $D(j)$ [the spectrum of H_1 is $j-n$, $0\leqslant n\leqslant 2j$ and the Casimir value is $j(j+1)$]. Moreover $C(X)V^{L_1}_{ij\epsilon}\subset\oplus_{j'<\epsilon}V'^{L_1}_{ij'\epsilon}$ $X\in\mathbf{L}_1$, $i=1,2,3$, since $[\rho(H_2),C(X)]=0$ if X belongs to $\mathbf{L}_1$. So $C|_{\mathbf{L}_1}$ is an element of $Z^1(\mathbf{L}_1,\mathscr{L}(\oplus_{\substack{j<\epsilon\\ i=1,2,3}}V^{L_1}_{ij\epsilon}))^{\mathbf{h}_1}$ and a coboundary by Whitehead's lemma; actually

$$C|_{\mathbf{L}_1}\in\bigoplus_{\substack{j<\epsilon\\ j'<\epsilon\\ i\geqslant i'}} B^1(\mathbf{L}_1,\mathscr{L}(V^{L_1}_{ij\epsilon},V^{L_1}_{i'j'\epsilon}))^{\mathbf{h}_1}.$$

Finally, $C|_{\mathbf{L}_1}=dT_1$, with $T_1\in\mathscr{L}(V')\cap\mathscr{L}(V'^{L_1}_{ij\epsilon})$, $i=1,2,3$.

Indeed $\mathbf{L}_1$-submodules $V^{L_1}_{ij\epsilon}$, $V^{L_1}_{ij'\epsilon}$ are nonequivalent irreducible representations if $j\neq j'$ [of type $D(j)$, $D(j')$] thus corresponding components of the coboundary dT_1 vanish on Q_{L_1}.[8] Consequently, $D(j)$, $D(j')$ $j\neq j'$, having different Casimir values,

$$T_1(V'^{L_1}_{ij\epsilon})\subset V'^{L_1}_{ij\epsilon},\quad i=1,2,3.$$

In other terms $dT_1(Q_{L_1})=0$ on V'. Then $\rho^\lambda|_{\mathbf{L}_1}=\rho|_{\mathbf{L}_1}+\lambda dT_1+\lambda^2C_2|_{\mathbf{L}_1}+\cdots$. Up to an equivalence of type $(Id+\lambda T_1)$, we can assume that $\rho^\lambda|_{\mathbf{L}_1}=\rho|_{\mathbf{L}_1}+\lambda^2C_2|_{\mathbf{L}_1}+\cdots$. Therefore $C_2\in Z^1(\mathbf{L}_1,\mathscr{L}(V'))^{\mathbf{h}_1}=B^1(\mathbf{L}_1,\mathscr{L}(V'))^{\mathbf{h}_1}$ by Whitehead's lemma. Up to an equivalence of type $(Id+\lambda^2T_2)$, $T_2\in\mathscr{L}(V')\cap\mathscr{L}(V'^{L_1}_{ij\epsilon})$, we have, $\rho^\lambda|_{\mathbf{L}_1}=\rho|_{\mathbf{L}_1}+\lambda^3C_3|_{\mathbf{L}_1}+\cdots$. Now we can repeat the same arguments for $C_3,\ldots$. In this way we construct a formal equivalence, A^λ, of $\rho^\lambda|_{\mathbf{L}_1}$ with $\rho|_{\mathbf{L}_1}$ (actually the equivalence is not formal[11] but we do not need it here) with $A^\lambda\in GL(V')\cap GL(V'^{L_1}_{ij\epsilon})$. Thus $\rho^\lambda(Q_{L_1})=A^{\lambda^{-1}}\rho(Q_{L_1})A^\lambda$, restricting to $V'^{L_1}_{ij\epsilon}$ we obtain $\rho^\lambda(Q_{L_1})|_{V'^{L_1}_{ij\epsilon}}=j(j+1)Id_{V'^{L_1}_{ij\epsilon}}$, that is to say $\rho^\lambda(Q_{L_1})=\rho(Q_{L_1})$ on V'.

Conclusion, $\rho^\lambda|_{V_1}\simeq\rho|_{V_1}$ of type $D(s+2,s-1)$ with $v^{00}_{1s+2,s-1}$ as cyclic vector; the quotient representations of ρ^λ on alternatively V/V_1, V'/V is of type $D(s+1,s)$ and $D(s+2,s-1)$. So $\rho^\lambda\simeq\rho$ as a representation of $\mathbf{g}$.

Solitary excitations of a two-dimensional electron gas

A. Nerses and E. E. Kunhardt
Department of Physics, Stevens Institute of Technology, Hoboken, New Jersey 07030

(Received 16 March 1998; accepted for publication 12 June 1998)

The nonlinear collective excitations of a two-dimensional electron gas (2DEG) formed at the interface of a heterostructure are presented. A matrix formulation of the coupled particle dynamics–electromagnetic field equations permits the extraction of the equation of evolution for these excitations. The stationary solutions of the equation are presented. A new class of solitary excitations is shown to form part of the nonlinear mode spectrum of excitations of the 2DEG in the low wave-vector plasmon–polariton regime. © *1998 American Institute of Physics.*

I. INTRODUCTION

Interest in the study of the linear plasmon spectrum of low-dimensional electron gas semiconductor systems has grown considerably in the last decade due to technological advances in the fabrication of submicron, quantum structures. This interest has been driven both by the challenge to fabricate and probe devices based on these low-dimensional structures, and by the search for novel behavior and/or modified behavior from bulk semiconductor systems. The dispersion relation for the plasmons,[1–11] as well as the coupling of these modes to phonons and photons,[8,12–20] in these low-dimensional systems has been studied extensively both experimentally and theoretically, using linearized hydrodynamic models,[10,11,20,21] and quantum many-body formulations.[1,3,18] The results from these models yield similar behavior in the low ω, k regime, where $k<k_F$, the Fermi wave vector.[10] Thus far in the literature, there has been no treatment of the nonlinear behavior of these excitations. Furthermore, the nonlinear regime has not been experimentally accessible due to the weak coupling schemes used to excite the plasmons, including prism and grating couplers.

In this paper, we present a theoretical investigation of the nonlinear excitations in a two-dimensional electron gas (2DEG), e.g., formed at the interface of an AlGaAs/GaAs heterostructure. We find a new class of solitary excitations to form part of the nonlinear mode spectrum in the low wave-vector regime, where the plasmon–polaritons have a strong photon content.

Our objective is to obtain an equation of evolution in space for the excitation amplitudes since this description is suitable for the analysis of experiments in which the generation and detection of the excitations occur at two different spatial locations. For this purpose, we present a novel approach which involves: (1) a matrix formulation of coupled particle dynamics–electromagnetic field equations, (2) transformation of the coupled system of equations into the frequency domain in order to isolate the plasmon spectrum, and (3) transformation back into the time domain, thereby obtaining an equation of evolution in space–time for the amplitude of the excitations. This approach permits the analysis of nonlinear excitations containing a wide spectrum of frequencies (such as pulse excitations). This program is carried out in detail in Sec. III, and the resulting equation of evolution presented in Sec. IV. From the equation of evolution, we find a new class of solitary excitations as part of the nonlinear mode spectrum of the 2DEG. The matrix formulation and the properties of the excitations are presented in Sec. II.

II. MODEL FOR DESCRIBING ELECTRON DYNAMICS

The system under consideration is a 2DEG, e.g., which forms at the interface of an AlGaAs/GaAs heterostructure. The interface in which electron motion is free will be considered as the $y-z$ plane, while the x-axis will denote the direction perpendicular to this plane, where electron motion is confined. For simplicity, the finite width of the potential well at the interface is neglected and the wave function for the 2D system of electrons is assumed to be exactly confined in the $y-z$

 © 1998 American Institute of Physics

plane of the interface, with no extension outside of the plane. This model provides a good description for the nonlinear excitations at low temperatures, for which only the lower subband is occupied.

The dynamics of the 2DEG is described via a hydrodynamic model, with the electrons possessing an isotropic mass and the ions are assumed to form a compensating uniform background. The variables that comprise the hydrodynamic model are: the 2D electron density $n(\mathbf{r},t)$ and the current density $\mathbf{J}(\mathbf{r},t)$. The electron density consists of two contributions, the time-independent background n_0 and time-dependent $n_1(\mathbf{r},t)$; that is,

$$n(\mathbf{r},t)=n_0+n_1(\mathbf{r},t), \tag{1}$$

where $n_1(\mathbf{r},t)<n_0$. For charges confined to a single layer, the plane $x=0$, the three-dimensional number density and current density become singular and can be expressed as follows:

$$n(\mathbf{r},t)=n(z,t)\,\delta(x) \tag{2}$$

and

$$\mathbf{J}(\mathbf{r},t)=J_z(z,t)\,\delta(x)\tilde{\mathbf{z}}, \tag{3}$$

where $\mathbf{z}$ is a unit vector in the propagation direction (in the plane of the 2DEG).

These variables satisfy the continuity equation and the Euler equation of motion,[20] namely:

$$\partial_t(-en(\mathbf{r},t))+\boldsymbol{\nabla}\cdot\mathbf{J}(\mathbf{r},t)=0, \tag{4}$$

$$\partial_t\mathbf{J}(\mathbf{r},t)-\frac{1}{en_0}\,\boldsymbol{\nabla}\cdot(\mathbf{J}(\mathbf{r},t)\mathbf{J}(\mathbf{r},t))=\frac{e^2}{m}\,n(\mathbf{r},t)\mathbf{E}(\mathbf{r},t)+e\beta^2\boldsymbol{\nabla}n(\mathbf{r},t)-\frac{1}{\tau}\,\mathbf{J}(\mathbf{r},t), \tag{5}$$

where β is the spatial dispersion parameter with units of speed, and τ is the momentum relaxation time. The terms on the right-hand side of Eq. (5) contribute to the acceleration of the electrons due to density gradients and an applied electric field, and to the decay of the excitations.

The nonlinear effects arise from the $\boldsymbol{\nabla}\cdot(\mathbf{J}(\mathbf{r},\mathbf{t})\mathbf{J}(\mathbf{r},\mathbf{t}))$ and $n(\mathbf{r},t)\mathbf{E}(\mathbf{r},t)$ terms in Eq. (5). The $\boldsymbol{\nabla}\cdot(\mathbf{J}(\mathbf{r},\mathbf{t})\mathbf{J}(\mathbf{r},\mathbf{t}))$ term is due to the tendency of elements of the 2DEG with different average current density to compress or expand, whereas the $n(\mathbf{r},t)\mathbf{E}(\mathbf{r},t)$ term is due to the dependence on the local density of the force driving a change in the average current density. Thus far in the literature where the hydrodynamic model has been applied to one-dimensional (1D) and 2D systems,[2,10,20] Eq. (5) is linearized for the purpose of obtaining the linear plasmon spectrum.

The field variables, $\mathbf{E}(\mathbf{r},t)$ and $\mathbf{B}(\mathbf{r},t)$, obey Maxwell's equations:

$$\begin{aligned}\boldsymbol{\nabla}\times\mathbf{E}(\mathbf{r},t)&=-\partial_t\mathbf{B}(\mathbf{r},t),\\ \boldsymbol{\nabla}\times\mathbf{B}(\mathbf{r},t)&=\epsilon\partial_t\mathbf{E}(\mathbf{r},t)+\mathbf{J}(\mathbf{r},t),\\ \boldsymbol{\nabla}\cdot\epsilon\mathbf{E}(\mathbf{r},t)&=\rho,\qquad \boldsymbol{\nabla}\cdot\mathbf{B}(\mathbf{r},t)=0,\end{aligned} \tag{6}$$

where ρ is the charge density, $\rho=-en_1(\mathbf{r},t)$. For our purposes, Maxwell's equations are expressed through the vector potential $\mathbf{A}(\mathbf{r},t)$ in the gauge where the scalar potential vanishes. In this gauge, the vector potential satisfies the following wave equation:

$$[\boldsymbol{\nabla}^2-\mu_0\epsilon\partial_t^2]\mathbf{A}(\mathbf{r},t)=-\mu_0\mathbf{J}(\mathbf{r},t)\tilde{\mathbf{z}}-\frac{e}{i\omega\epsilon}\,\partial_z n(\mathbf{r},t)\tilde{\mathbf{z}} \tag{7}$$

and is related to the electric and magnetic fields as follows:

$$\mathbf{E}(\mathbf{r},t)=-\partial_t\mathbf{A}(\mathbf{r},t),\qquad \mathbf{B}(\mathbf{r},t)=\boldsymbol{\nabla}\times\mathbf{A}(\mathbf{r},t). \tag{8}$$

To simplify the system of equations, ϵ, the background dielectric constant, will be used to characterize both the AlGaAs and GaAs surrounding the 2DEG.

The system of Eqs. (4)–(8) forms the basis for the investigations of the nonlinear excitations. This coupled system of equations will be further simplified by neglecting variations in the y-direction and assuming that β and τ are velocity independent. For the present, we choose to emphasize the characteristics of the nonlinear excitations by avoiding mathematical complexities due to the inclusion of microscopic phenomena (such as exchange and correlation effects, and wave–particle interactions) that can obscure the nature of these excitations. Furthermore, this simplification of the model contains sufficient information to describe the nonlinear plasmon excitations in the $k<k_F$ regime. For the future, the formulation presented below can be extended to include more complete descriptions of the electron gas.

III. MATRIX FORMULATION OF THE SYSTEM OF EQUATIONS

To obtain the equation of evolution in space for the amplitude of the nonlinear excitations, Eqs. (4), (5), and (7) are cast in a matrix form. To this end, the gradient operator is decomposed as

$$\boldsymbol{\nabla}=\boldsymbol{\nabla}_t+\partial_z\tilde{\mathbf{z}}, \tag{9}$$

where $\boldsymbol{\nabla}_t$ is the transverse part of the gradient operator, with respect to the propagation direction, $\tilde{\mathbf{z}}$, and the equations are transformed into the frequency domain to facilitate the extraction of the plasmon excitations. With these observations, Eqs. (4), (5), and (7) can be expressed as:

$$-i\partial_z^2 J_z(z,\omega)+\omega e\partial_z n_1(z,\omega)=0, \tag{10}$$

$$-\frac{\beta^2}{i\omega}\partial_z^2 J_z(z,\omega)\tilde{\mathbf{z}}+i\omega\left(1+\frac{i}{\omega\tau}\right)J_z(z,\omega)\tilde{\mathbf{z}}+e^2\frac{n_0}{m}i\omega\mathbf{A}(0,z,\omega)=\mathrm{NL}\tilde{\mathbf{z}}, \tag{11}$$

$$(\partial_z^2+\partial_x^2+\omega^2\mu_0\epsilon)A_z(x,z,\omega)\tilde{\mathbf{z}}+\mu_0\delta(x)J_z(z,\omega)\tilde{\mathbf{z}}+\frac{1}{\omega^2\epsilon}\delta(x)\partial_z^2 J_z(z,\omega)\tilde{\mathbf{z}}=0, \tag{12}$$

$$-\partial_z^2\partial_x A_z(x,z,\omega)\tilde{\mathbf{x}}+\omega^2\mu_0\epsilon\partial_z A_x(x,z,\omega)\tilde{\mathbf{x}}+\partial_z^2(\partial_z A_x(x,z,\omega))\tilde{\mathbf{x}}=0, \tag{13}$$

where NL represents the nonlinear term

$$\begin{aligned}\mathrm{NL}=&-\frac{2}{en_0}\int\int d\omega_1 d\omega_2\delta(\omega-\omega_1-\omega_2)J_z(z,\omega_1)\partial_z J_z(z,\omega_2)\\&+\frac{e}{m}\int\int d\omega_1 d\omega_2\delta(\omega-\omega_1-\omega_2)\frac{\omega_1}{\omega_2}A_z(0,z,\omega_1)\partial_z J_z(z,\omega_2)\end{aligned} \tag{14}$$

and ω represents the transformation variable in time; that is, $G(z,\omega)=\int dt e^{i\omega t}G(z,t)$ with $G(z,t)$ corresponding to any of the independent variables in the model. Note that the wave equation (7) has been written in component form to arrive at Eqs. (12) and (13).

Equations (10)–(13) can be recast in matrix form as a nonlinear equation of evolution along the **z**-direction:

$$\Gamma\partial_z^2\psi(\mathbf{r},\omega)+\mathbf{L}(\boldsymbol{\nabla}_t,\omega)\psi(\mathbf{r},\omega)=\mathrm{NL}[\psi(\mathbf{r},\omega)], \tag{15}$$

where

$$\mathbf{L}(\boldsymbol{\nabla}_t,\omega)=\begin{bmatrix}\frac{1}{c}\{(\partial_x^2+\omega^2\mu_0\epsilon)\tilde{\mathbf{z}}\tilde{\mathbf{z}}-\partial_x\tilde{\mathbf{z}}\tilde{\mathbf{x}}\}+\omega^2\mu_0\epsilon\tilde{\mathbf{x}}\tilde{\mathbf{x}} & \omega\mu_0\delta(x)\tilde{\mathbf{z}}\tilde{\mathbf{z}}\\ \omega\mu_0\delta(x)\tilde{\mathbf{z}}\tilde{\mathbf{z}} & \delta(x)\omega^2 c\frac{\mu_0 m}{e^2 n_0}\left[\left(1+\frac{i}{\tau\omega}\right)\tilde{\mathbf{z}}\tilde{\mathbf{z}}-\frac{e^2\beta^2}{\kappa_z^2}\tilde{\mathbf{x}}\tilde{\mathbf{x}}\right]\end{bmatrix}, \tag{16}$$

$$\Gamma=\begin{bmatrix} -(\partial_x\tilde{\mathbf{xz}}-\tilde{\mathbf{xx}}) & 0 \\ 0 & \delta(x)c\,\dfrac{\mu_0 m\beta^2}{e^2 n_0}\left(\tilde{\mathbf{zz}}-\dfrac{e\omega}{\kappa_z^2}\,\tilde{\mathbf{xz}}\right) \end{bmatrix}, \tag{17}$$

$$\psi(\mathbf{r},\omega)=\begin{bmatrix} \omega(A_z(x,z,\omega)\tilde{\mathbf{z}}+\partial_z A_x(x,z,\omega)\tilde{\mathbf{x}}) \\ \dfrac{1}{c}\,(J_z(z,\omega)\tilde{\mathbf{z}}+i\partial_z n(z,\omega)\tilde{\mathbf{x}}) \end{bmatrix}, \tag{18}$$

and

$$\mathrm{NL}=-\frac{i\omega\mu_0 m}{e^2 n_0}\,\delta(x)\tilde{\mathbf{z}}\left[\int\int d\omega_1 d\omega_2\,\delta(\omega-\omega_1-\omega_2)\begin{Bmatrix} 0 \\ \dfrac{2}{en_0}\,J_{z\omega_1}-\dfrac{e}{m}\,\dfrac{\omega_1}{\omega_2}\,A_{z\omega_1} \end{Bmatrix}\partial_z J_{z\omega_2}\right], \tag{19}$$

where **1** is the unit dyad; **L** is a linear operator that depends only on frequency and the component of the gradient operator, $\boldsymbol{\nabla}_t$, transverse to the direction of propagation of the plasmon excitations (i.e., the z-direction).

Operator **L** is decomposed into a lossless, Hermitian operator, $L_0=L_{\tau=\infty}$, and a smaller perturbative term L_{coll}, such that $L=L_0+L_{\mathrm{coll}}$ and $L_0\gg\mathbf{L}_{\mathrm{coll}}$:

$$L_0(\boldsymbol{\nabla}_t,\omega)=\begin{bmatrix} \dfrac{1}{c}\,\{(\partial_x^2+\omega^2\mu_0\epsilon)\tilde{\mathbf{zz}}-\partial_x\tilde{\mathbf{zx}}\}+\omega^2\mu_0\epsilon\tilde{\mathbf{xx}} & \omega\mu_0\delta(x)\tilde{\mathbf{zz}} \\ \omega\mu_0\delta(x)\tilde{\mathbf{zz}} & \delta(x)\omega^2 c\,\dfrac{\mu_0 m}{e^2 n_0}\left[\tilde{\mathbf{zz}}-\dfrac{e^2\beta^2}{\kappa_z^2}\,\tilde{\mathbf{xx}}\right] \end{bmatrix} \tag{20}$$

and L_{coll}:

$$\mathbf{L}_{\mathrm{coll}}=\begin{bmatrix} 0 & 0 \\ 0 & \delta(x)c\,\dfrac{\mu_0 m}{e^2 n_0}\,\dfrac{i\omega}{\tau}\,\tilde{\mathbf{zz}} \end{bmatrix}. \tag{21}$$

Solutions to (15) are sought in the form of an expansion in terms of the eigenfunctions of the linear, lossless operator, $\mathbf{L}_0$. That is, $\Psi(\mathbf{r},\omega)$ lies in the eigenspace of $\mathbf{L}_0$ and thus can be represented as

$$\Psi(\mathbf{r},\omega)=\sum_\alpha\,\Phi_\alpha(\mathbf{x},\omega)a_\alpha(z,\omega), \tag{22}$$

where $\boldsymbol{\Phi}_\alpha(\mathbf{x},\omega)$ are the eigenfunctions of $\mathbf{L}_0$ defined as

$$\mathbf{L}_0(-i\omega,\partial_x)\Phi_\alpha(\mathbf{x},\omega)=\kappa_{z\alpha}^2(\omega)\Gamma\boldsymbol{\Phi}_\alpha(\mathbf{x},\omega). \tag{23}$$

The eigenfunctions $\Phi_\alpha(\mathbf{x},\omega)$ possess the orthonormality property

$$(\Phi_\alpha(\mathbf{x},\omega),\Gamma\Phi_\beta(\mathbf{x},\omega))=2\,\delta_{\alpha\beta} \tag{24}$$

in the plane perpendicular to **z** and have the form

$$\Phi_\alpha(\mathbf{x},\omega)=\begin{bmatrix} \omega(\varphi^{A_z}\tilde{\mathbf{z}}+\varphi^{\partial_z A_x}\tilde{\mathbf{x}})_\alpha \\ \dfrac{1}{c}\,(\varphi^{J_z}\tilde{\mathbf{z}}+i\varphi^{\partial_z n}\tilde{\mathbf{x}})_\alpha \end{bmatrix}, \tag{25}$$

where, e.g., $\varphi^{J_z}(x,\omega)$ denotes the contribution to the eigenfunctions due to the current density within the subband. In general, this formulation permits the extraction of the equation of evolution for any mode of interest.

IV. SOLUTION OF EIGENVALUE EQUATION FOR $\mathbf{\Phi}_\alpha(\mathbf{x},\omega)$

Equation (23) is solved by obtaining expressions for $\mathbf{\Phi}_\alpha(\mathbf{x},\omega)$ in the regions $x>0$ and $x<0$, respectively, and satisfying boundary conditions at the interace obeyed by the transverse and longitudinal components of the vector potential. From the continuity of the tangential component of the vector potential at $x=0$:

$$\varphi^{A_z}{}_\alpha(0^+,\omega)=\varphi^{A_z}{}_\alpha(0^-,\omega) \tag{26}$$

and the orthonormality relation, Eq. (24), the eigenfunctions are found to have the form:

$$\Phi_\alpha(\mathbf{x},\omega)=\begin{bmatrix} -\dfrac{\omega}{\sqrt{\omega_p}}\left(1-\dfrac{\beta^2\kappa_{z\alpha}^2}{\omega^2}\right)e^{-|\kappa_{x\alpha}|x}\left(\tilde{\mathbf{z}}\pm\dfrac{\kappa_{z\alpha}^2}{|\kappa_x|}\,\tilde{\mathbf{x}}\right) \\ \dfrac{en_0}{mc\sqrt{\omega_p}}\left(e\tilde{\mathbf{z}}-i\,\dfrac{\kappa_{z\alpha}^2}{\omega}\,\tilde{\mathbf{x}}\right) \end{bmatrix}, \tag{27}$$

where

$$|\kappa_{x\alpha}|^2=\kappa_{z\alpha}^2-\omega^2\mu_0\epsilon, \tag{28}$$

$$\omega_p=\frac{n_0e^2}{2m\epsilon c}. \tag{29}$$

c is the speed of light in the medium and the top (bottom) sign is for solutions $x>0$ ($x<0$).

The boundary condition on the transverse (to z) potential is obtained by integrating the eigenvalue equation, Eq. (23), over the coordinate x, transverse to the direction of propagation. From this boundary condition, the following expression for the transverse wave number is obtained:

$$|\kappa_x|=-\frac{\omega_A}{2\beta}+\frac{\omega_A}{2\beta}\sqrt{1+4\frac{\omega^2}{\omega_A^2}\left(1-\frac{\beta^2}{c^2}\right)}, \tag{30}$$

where

$$\omega_A=\frac{n_0e^2}{2\epsilon m\beta}. \tag{31}$$

For our system, only one subband is occupied and hence there exists only one allowed plasmon–polariton mode of propagation, i.e., α takes on only one value such that $\mathbf{\Phi}_\alpha(x,\omega)\equiv\Phi(x,\omega)$.

From Eqs. (28)–(31), the well-known dispersion relation for linear 2D electron plasmon[21] is obtained, namely,

$$\omega^2=\beta^2\kappa_z^2+\omega_pc\sqrt{\kappa_z^2-\frac{\omega^2}{c^2}}. \tag{32}$$

At very low frequencies, $\omega\ll\omega_p$, the transverse wave number $|\kappa_x|\to0$ and the dispersion relation tends to $\omega\approx c\kappa_z$; hence, the mode structure contained in Eq. (27) becomes electromagneticlike in that the longitudinal component of the wave vector $A_z\to0$. At the other extreme, where $\omega\gg\omega_p/(\beta/c)$, the excitations are nondispersive and characterized by $A_x\to0$, traveling at the thermal speed, that is $\omega\approx\beta\kappa_z$. In the region between these two extremes, the excitations are mixed and dispersive, due to the non-negligible contributions of both the transverse and longitudinal field components to the mode structure.

V. EQUATION OF EVOLUTION FOR THE EXCITATION AMPLITUDE

The equation of evolution for the plasmon excitation amplitude, $a_\alpha(z,\omega)$, may be obtained from Eq. (15) using Eqs. (22), (25), and the orthonormality relation (24). Inserting Eq. (22) into (15) yields:

$$\sum_\alpha (L-L_0)a_\alpha(z,\omega)\Phi_\alpha(x,\omega)+\sum_\alpha L_0 a_\alpha(z,\omega)\mathbf{\Phi}_\alpha(\mathbf{x},\boldsymbol{\omega})+\sum_\alpha \Gamma\partial_z^2 a_\alpha(z,\omega)\mathbf{\Phi}_\alpha(\mathbf{x},\boldsymbol{\omega})=\mathrm{NL}. \tag{33}$$

Again, since only one propagating mode exists, the summation can be dropped and $a_\alpha(\mathbf{z},\boldsymbol{\omega}) \equiv a(z,\omega)$ just as $\mathbf{\Phi}_\alpha(x,\omega)\equiv\Phi(x,\omega)$. Using the eigenfunctions and their orthogonality properties, the equation for $a(z,\omega)$ is obtained as follows. Taking the inner with $\mathbf{\Phi}(x,\omega)$ and using the eigenvalue equation, the above equation becomes

$$\begin{aligned}\{\mathbf{\Phi}(x,\omega),(L-L_0)\mathbf{\Phi}(x,\omega)\}a(z,\boldsymbol{\omega})+\{\mathbf{\Phi}(x,\omega),\Gamma\mathbf{\Phi}(x,\omega)\}\kappa_z^2(\omega)a(z,\boldsymbol{\omega})\\ +\{\mathbf{\Phi}(x,\omega),\Gamma\mathbf{\Phi}(x,\omega)\}\partial_z^2 a(z,\omega)=\{\mathbf{\Phi}(x,\boldsymbol{\omega}),\mathrm{NL}\}.\end{aligned} \tag{34}$$

Applying the orthogonality condition and evaluating the inner products as follows:

$$\{\mathbf{\Phi}(x,\omega),(L-L_0)\mathbf{\Phi}(x,\omega)\}=\frac{2}{c^2\tau}\,i\boldsymbol{\omega} \tag{35}$$

and

$$\{\Phi,\mathrm{NL}\}=\int_{-\infty}^{\infty}[(\varphi^{\partial_z A_x{}^*}\tilde{\mathbf{x}}+\varphi^{A_z{}^*}\tilde{\mathbf{z}})\quad(\varphi^{J_z^*}\tilde{\mathbf{z}}-i\varphi^{\partial_z n^*}\tilde{\mathbf{x}})]\cdot\begin{bmatrix}0\\ I\delta(x)\tilde{\mathbf{z}}\end{bmatrix}dx, \tag{36}$$

where

$$I=-\frac{i\omega\mu_0}{c\sqrt{\omega_p}}\int\int d\omega_1 d\omega_2\,\delta(\omega-\omega_1-\omega_2)\left\{\frac{2}{en_0}J_z(\boldsymbol{\omega}_1)-\frac{e\omega_1}{m\omega_2}A_z(\boldsymbol{\omega}_1)\right\}\partial_z J_z(\boldsymbol{\omega}_2). \tag{37}$$

Equation (34) becomes

$$\begin{aligned}\partial_z^2 a(z,\omega)=-\kappa_z^2(\omega)a(z,\omega)-\frac{i\omega}{\tau c^2}a(z,\boldsymbol{\omega})+\frac{i\omega e^3 n_0\mu_0}{m^2 c\omega_p\sqrt{\omega_p}}\int\int d\omega_1 d\omega_2\,\delta(\omega-\omega_1-\omega_2)\\ \times\left\{2+\frac{\omega_1}{\omega_2}\left(1-\frac{\beta^2\kappa_z^2(\boldsymbol{\omega}_1)}{\boldsymbol{\omega}_1^2}\right)\right\}a(\boldsymbol{\omega}_1)\partial_z a(\boldsymbol{\omega}_2).\end{aligned} \tag{38}$$

VI. EQUATION OF EVOLUTION IN THE REGIME $\omega<\omega_p$

To obtain the nonlinear equation of evolution in space–time, Eq. (38) is inverse transformed to the time domain. In this paper, we shall focus on the nonlinear excitations with frequency bandwidth $\omega<\omega_p$, for which the plasmon–polariton has a strong photon content and the spatial dispersion parameter, β, plays a negligible role. The role of spatial dispersion in the $\omega>\omega_p$ regime will be discussed in a later publication. Thus, in carrying out the inverse transformation, an approximate expansion of $\kappa_z(\boldsymbol{\omega})$ can be used in Eq. (38), valid for $\omega<\omega_p$. In this regime, Eq. (28) becomes

$$|\kappa_x|\approx\frac{\omega^2}{\omega_A\beta}\left(1-\frac{\beta^2}{c^2}\right)=\frac{\omega^2}{\omega_p c}\left(1-\frac{\beta^2}{c^2}\right), \tag{39}$$

such that

$$\kappa_z(\omega_2)\cong\frac{\omega_2}{c}\left(1+\frac{\omega_2^2}{2\omega_p^2}\left(1-\frac{\beta^2}{c^2}\right)^2\right). \tag{40}$$

Using the above approximation, Eq. (38) yields

$$\begin{aligned}\partial_z^2 a(z,\omega)=&\frac{(-i\omega)^2}{c^2}\,a(z,\omega)-\frac{(-i\omega)^4}{\omega_p^2c^2}\,K^2a(z,\omega)+\frac{(-i\boldsymbol{\omega})}{\tau c^2}\,a(\mathbf{z},\boldsymbol{\omega})\\&-\frac{ei\omega}{2mc\sqrt{\omega_p}}\int\int d\omega_1 d\omega_2\,\delta(\omega-\omega_1-\omega_2)\Big\{-2(-i\boldsymbol{\omega}_2)-(-i\boldsymbol{\omega}_1)\mathbf{K}\\&-\frac{\beta^2K^2}{\omega_p^2c^2}(-i\omega_1)^3+\frac{K^2}{f_p^2}(-i\omega_2)^3+\frac{K^2}{2\boldsymbol{\omega}_p^2}(-i\boldsymbol{\omega}_1)(-i\boldsymbol{\omega}_2)^2-\frac{\beta^2K^2}{2\omega_p^2c^2}(-i\omega_1)(-i\omega_2)^2\\&+\frac{\beta^2K^4}{2\omega_p^4c^2}(-i\boldsymbol{\omega}_1)^3(-i\boldsymbol{\omega}_2)^2\Big\}a(\boldsymbol{\omega}_1)a(\boldsymbol{\omega}_2),\end{aligned} \tag{41}$$

where

$$K=\left(1-\frac{\beta^2}{c^2}\right).$$

As a result of the transformation, $-i\omega\rightarrow\partial_t$ (for excitations with spectral distribution $\boldsymbol{\omega}<\boldsymbol{\omega}_p$). After introducing the following change of variables:

$$t\rightarrow f_p t \quad \text{and} \quad z\rightarrow z\,\frac{f_p}{c},$$

$$a(z,t)\rightarrow\frac{1}{a'}\,a(z,t) \quad \text{where}\ \frac{1}{a'}=\frac{e}{mc\sqrt{\boldsymbol{\omega}_p}}, \tag{42}$$

we obtain the nonlinear equation of evolution in space for the amplitude of the excitations:

$$\begin{aligned}\partial_z^2 a(z,t)=&\partial_t^2 a(z,t)-K^2\partial_t^4 a(z,t)+\frac{2}{f_p\tau}\,\partial_t a(z,t)+\frac{1}{2}\,\partial_t\Big\{-(2+K)a(z,t)\partial_t a(z,t)\\&+K^3a(z,t)\partial_t^3a(z,t)+\frac{K^3}{2}\,\partial_t a(z,t)\partial_t^2a(z,t)+\frac{K^4\beta^2}{2c^2}\,\partial_t^2a(z,t)\partial_t^3a(z,t)\Big\}.\end{aligned} \tag{43}$$

Equation (43) is a nonlinear, dispersive equation which is second order in space, implying solutions that propagate in the $+z$ and $-z$ directions.

Using the reductive perturbative method,[22] the evolution equation (43) can be reduced to a more tractable nonlinear equation describing a wave traveling in one direction in the weak amplitude limit. Introducing a small parameter, $\boldsymbol{\epsilon}\ll 1$, and performing the following change of variables:

$$Z=\boldsymbol{\epsilon}^3 z, \qquad T=\boldsymbol{\epsilon}^{1/2}(z-t). \tag{44}$$

The amplitude $a(z,t)$ is expressed in a perturbation series:

$$a=\boldsymbol{\epsilon}a_1+\boldsymbol{\epsilon}^2a_2+\cdots, \tag{45}$$

where $\boldsymbol{\epsilon}^{1/2}$ and $\boldsymbol{\epsilon}^3$ are chosen in order to balance the dispersive and nonlinear terms. Substituting Eqs. (44) and (45) into (43) and integrating once with respect to time, we find to lowest order in $\boldsymbol{\epsilon}$:

$$\partial_Z \hat{a}(Z,T) + K^2 \partial_T^3 \hat{a}(Z,T) - \left(1 + \frac{K}{2}\right) \hat{a}(Z,T) \partial_T \hat{a}(Z,T) \exp\left(-\frac{z}{\omega_p \tau}\right) = 0, \tag{46}$$

where $a_1(z,t) \equiv \hat{a}(z,t)\exp(-z/\omega_p\tau)$. This reduces to the Korteweg de Vries (KdV) equation in the limit $\tau \to \infty$. The KdV equation admits solitary wave solutions, which are localized solutions belonging to the class of traveling waves.[23]

To next higher order in ϵ, Eq. (43) reduces to

$$\partial_Z \hat{z}(Z,T) = K^2 \partial_T^3 \hat{a}(Z,T) - \left\{ \tfrac{1}{2}(2+K) \hat{a}(Z,T) \partial_T \hat{a}(Z,T) + \frac{K^3}{2} \hat{a}(Z,T) \partial_T^3 \hat{a}(Z,T) \right.$$
$$\left. + \frac{K^3}{4} \partial_T \hat{a}(Z,T) \partial_T^2 \hat{a}(Z,T) + \frac{K^4 \beta^2}{4c^2} \partial_T^2 \hat{a}(Z,T) \partial_T^3 \hat{a}(Z,T) \right\} \exp\left(-\frac{z}{\omega_p \tau}\right). \tag{47}$$

We will now consider the damping factor $\exp(-z/\omega_p\tau)$ in the limit $\tau \to \infty$. The effects of damping of the nonlinear terms will be left for a numerical investigation of Eq. (47) to be done at a later date. Equation (47) can be rewritten in the general form shown below:

$$\partial_z \hat{a}(z,t) = v(\hat{a}) \partial_t \hat{a}(z,t) + \chi(\hat{a}) \partial_t^3 \hat{a}(z,t), \tag{48}$$

where

$$\begin{aligned} v(\hat{a}) &= v_0 + \alpha \hat{a}(z,t) + \eta \partial_t^2 \hat{a}(z,t), \\ \chi(\hat{a}) &= \gamma + \delta \hat{a}(z,t) + \xi \partial_t^2 \hat{a}(z,t). \end{aligned} \tag{49}$$

This is a generalized dispersive equation with amplitude dependent coefficients. It contains the Airy equation[23] in the linear regime, where $\hat{a}(z,t) \to 0$ in $v(\hat{a})$ and $\chi(\hat{a})$, and, as shown above, the KdV equation to lowest order in the nonlinear regime.

VII. STATIONARY SOLUTIONS OF THE EQUATION OF EVOLUTION IN THE PLASMON–POLARITON REGIME

The elementary excitations of the system are found by seeking the stationary solutions to Eq. (47) which possess a permanent profile of the form

$$a(Z,T) = f(\theta), \tag{50}$$

where

$$\theta = T - \frac{Z}{v}. \tag{51}$$

θ represents the normalized position in a coordinate system moving at a normalized velocity v for which the wave appears stationary. Substituting this functional relation into Eq. (47) yields the following equation in θ:

$$d_\theta a(\theta) = -u^3 K^2 d_\theta^3 a(\theta) + \tfrac{1}{4} u (2+K) d_\theta a^2(\theta) - \tfrac{1}{2} K^3 u^3 d_\theta \{a(\theta) d_\theta^2 a(\theta)\}$$
$$+ \tfrac{1}{8} K^3 u^3 d_\theta \{d_\theta a(\theta)\}^2 - \frac{\beta^2}{8c^2} u^5 K^4 d_\theta \{d_\theta^2 a(\theta)\}^2, \tag{52}$$

where $d_\theta \equiv d/d\theta$. Integrating once with respect to θ (and setting integration constants to zero since we are looking for localized solutions and derivatives that tend to zero as $\theta \to \pm\infty$):

$$a(\theta) = -u^3 K^2 d_\theta^2 a(\theta) + \tfrac{1}{4} u (2+K) a^2(\theta) - \tfrac{1}{2} u^3 K^3 a(\theta) d_\theta^2 a(\theta)$$
$$+ \tfrac{1}{8} u^3 K^3 \{d_\theta a(\theta)\}^2 - \frac{1}{8} \frac{\beta^2}{c^2} u^5 K^4 \{d_\theta^2 a(\theta)\}^2. \tag{53}$$

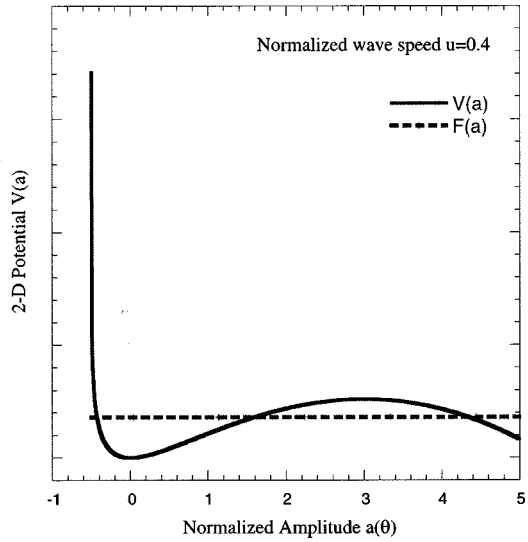

FIG. 1. Potential as a function of normalized amplitude. As the initial amplitude approaches the point of unstable equilibrium, the period of the cnoidal wave$\rightarrow\infty$, corresponding to solitary excitations. The bound, cnoidal excitations exist only for the initial excitation amplitude falling within the range $-0.883<a<3.33$.

Equation (53) can be expressed as:

$$K^2u^3d_\theta^2a(\theta)=-\frac{dV(a)}{da}+\frac{u^3K^3(d_\theta a(\theta))^2-u^5K^4\,\dfrac{\beta^2}{c^2}\,(d_\theta^2a(\theta))^2}{8(1+\frac{1}{2}Ka(\theta))}, \tag{54}$$

where

$$\frac{dV(a)}{da}=\frac{a(\theta)-\frac{1}{4}u(2+K)a^2(\theta)}{1+\frac{1}{2}Ka(\theta)}. \tag{55}$$

We present both a phase plane analysis [i.e., plots of $d_\theta a(\theta)$ vs $a(\theta)$], and a numerical analysis to understand the nature of the solutions of Eq. (54). In general, equations that take the form of a particle in a potential well

$$\frac{1}{2}\,u^3d_\theta^2a(\theta)=-\frac{dV(a)}{da} \tag{56}$$

exhibit solitary behavior near the extrema of $a(\theta)$.[23] At this limit, the second term on the right-hand side of Eq. (54) can be neglected to obtain, approximately, the regions of θ where bound solutions of $a(\theta)$ exist. Neglecting this second term, Eq. (54) takes the form of Eq. (56), with

$$V(a)=\left(\frac{2}{K}\right)^2\left\{\left(1+u\,\frac{2+K}{2K}\right)\left(\frac{K}{2}\,a-\ln\left(1+\frac{1}{2}\,Ka\right)\right)-u\,\frac{K(2+K)}{16}\,a^2\right\}. \tag{57}$$

This potential is plotted as a function of normalized amplitude for a normalized speed of $u=0.6$, in Fig. 1. Integrating Eq. (56) once yields

$$\tfrac{1}{2}u^3(d_\theta a(\theta))^2=V(a_0)-V(a)\equiv F(a), \tag{58}$$

where $V(a_0)$ is a constant of integration and a_0 is the initial excitation amplitude.

Real solutions of Eq. (58) exist for $F(a)>0$ and bound solutions exist for $F(a)$ positive between two of its simple zeros. It has been shown[23] that there exist periodic solutions $F(a)$ if

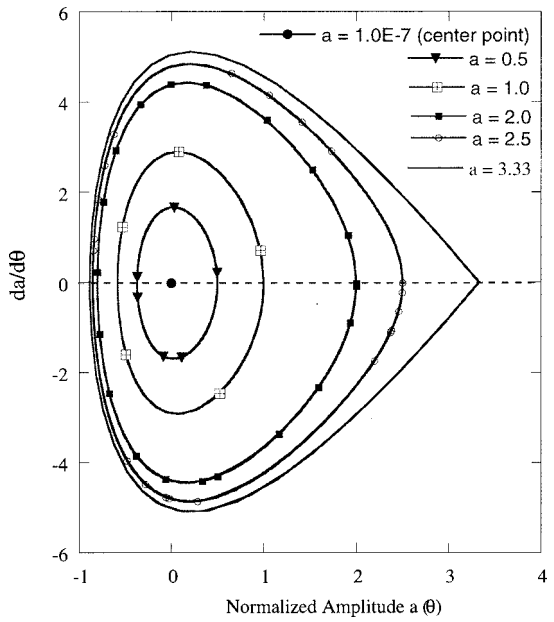

FIG. 2. Phase plane curves $da/d\theta$ vs $a(\theta)$ varying from the linear wave limit (at the center of the curves) to the solitary excitation represented by the largest phase curve, corresponding to an initial excitation amplitude $a_0=3.33$.

$(d_\theta a(\theta))^2$ is positive between two simple zeros of $(d_\theta a(\theta))^2$, and there exist solitary-wave solutions if $(d_\theta a(\theta))^2$ is positive between a simple zero and a double zero [i.e., a zero at a local maximum of minimum of $(d_\theta a(\theta))^2$].

Phase plane curves of Eq. (54) are shown in Fig. 2. From numerical solution of Eq. (54), bound solutions are found for initial amplitudes falling within the range $-0.883 \leqslant a_0 \leqslant 3.33$. The curves in Fig. 2 are plotted with values of the parameter a_0 chosen within this range, and at a fixed value of the normalized speed u. The phase curve for a linear wave reduces to a point at the center of the family of curves. The curves around this point cross normal to the a-axis and correspond to the periodic, nonlinear cnoidal waves. The outermost curve, where parameter $a_0=3.33$, does not exhibit this property and represents a solitary wave. This value of a_0 closely agrees with the initial amplitude corresponding to the maximum bounding potential determined from Fig. 1 [i.e., $F(a)$ is positive between a simple zero and a double zero, which occurs at the point of unstable equilibrium $a \approx 3.33$]. At this limit, the dispersion balances the effects of the nonlinearity, leading to a pulselike wave, a solitary wave, which propagates with constant velocity and profile.

The wave profile of the full equation (55), including all terms, is determined by numerical solution. Figure 3 is a plot of the normalized amplitude versus θ for two different initial excitation amplitudes, a_0. The linear excitations shown in Fig. 3 are obtained for $a_0=1.0E-7$ and, as discussed earlier, are represented by the point in the phase plane curves of Fig. 2. The sinusoidal behavior with θ is characteristic of linear waves. In contrast, the wave profile obtained for $a_0=3.3$ shows the characteristic steepening of nonlinear excitations. These bound, periodic excitations are the cnoidal waves, for which phase plane curves were plotted in Fig. 2. One wavelength (as shown in Fig. 3) corresponds to traveling once around the curve of Fig. 2. The solitary excitations correspond to the limit of infinite period, where $a(\theta)$ tends to a single pulse with $a_0=3.33$. This limit is represented by the outermost phase curve of Fig. 2, where the curve is traveled just once for the entire range $-\infty < \theta < \infty$.

VIII. CONCLUDING REMARKS

In this paper, we have introduced a novel matrix formulation of coupled particle-field equations leading to a nonlinear equation of evolution for the plasmon–polaritons of a 2DEG. The stationary solutions of the evolution equation were shown to yield solitary excitations. The procedure developed here can incorporate more sophisticated effects that may play an important role

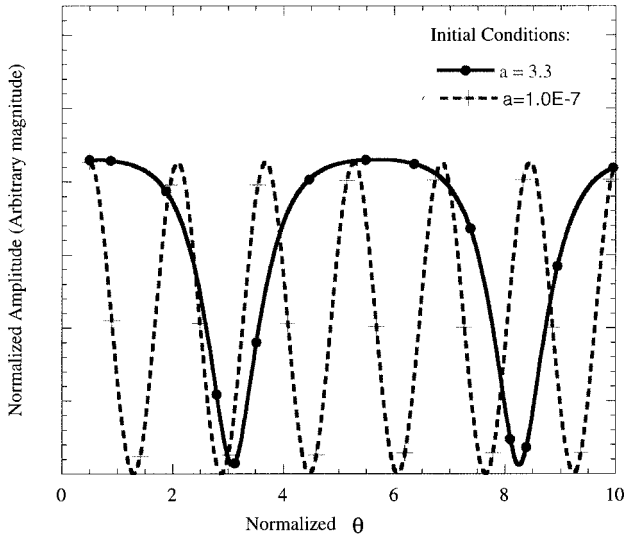

FIG. 3. Normalized amplitude $a(\theta)$ vs θ. The period of oscillation for the normalized amplitude grows as the initial amplitude approaches the point of unstable equilibrium, found from Figs. 1 and 2 to be $a \approx 3.33$.

in the evolution of these solitary excitations. Whether or not these solitary excitations are ''true'' solitons, as well as the stability and general mathematical properties of these excitations, remain to be investigated.

Transition probabilities between quasifree states

H. Scutaru[a)]
Department of Theoretical Physics, Institute of Atomic Physics, Bucharest-Magurele, POB MG-6, Romania

(Received 16 April 1998; accepted for publication 27 August 1998)

We obtain a general formula for the transition probabilities between any state of the C^* algebra of the canonical commutation relations (CCR-algebra) and a squeezed quasifree state (Theorem III.1). Applications of this formula are made for the case of multimode thermal squeezed states of quantum optics using a general canonical decomposition of the correlation matrix valid for any quasifree state. In the particular case of a one-mode CCR-algebra we show that the transition probability between two quasifree squeezed states is a decreasing function of the geodesic distance between the points of the upper half-plane representing these states. In the special case of the purification map it is shown that the transition probability between the state of the enlarged system and the product state of real and fictitious subsystems can be a measure for the entanglement. © *1998 American Institute of Physics.* [S0022-2488(98)02212-9]

I. INTRODUCTION

The notion of the quasifree state has appeared and was developed in the framework of the C^*-algebra approach to the canonical commutation relations (CCR).[1–11] The quasifree states are the natural ground states for the Hamiltonians which are at most quadratic in the bosonic creation and annihilation operators. The essential property of the quasifree states is the fact that all their correlations are expressible in terms of the one- and two-point functions.

The advantage of the C^*-algebra approach to the theory of coherent and squeezed states (thermal or not) follows from the fact that the results are obtained in a representation independent form. This representation independence allows us to elude the hard noncommutative calculation. However, a price must be paid for this. A simple result in usual quantum mechanics is obtained, in this case, with the help of slightly difficult results concerning the transition probabilities between the states of C^*-algebras.[12]

We shall illustrate this assertion by giving a representation-independent formula for the transition probability between a squeezed state and an arbitrary state of the C^*-algebra of CCRs (Theorem III.1).

Many interesting states of the radiation field in quantum optics are quasifree states. The factorization of the correlations in coherent states was discovered by Glauber as the essential property of these states of coherent light. The squeezed states are also quasifree states. The most general case is that of multimodal thermal displaced and squeezed states.

The main result of the paper, given in Sec. III, is the formula for the transition probabilities between any state of the C^*-algebra of the canonical commutation relations and any squeezed quasifree pure state (Theorem III.1). This result is obtained using the fact that any quasifree squeezed pure state can be obtained from a coherent state by a Bogoliubov automorphism and the fact that for any coherent state there is an element of the CCR-algebra which is a minimal orthoprojection.[4] Then a general result of P. M. Alberti and V. Heinemann[12] is applicable.

A new approach to the theory of multimode squeezed thermal states is described in Sec. IV, and is based on the combination of the Williamson theorem,[13] which gives the most general structure of a positive definite matrix with a theorem of Balian, De Dominicis, and Itzykson,[14] which gives the most general structure of a symplectic matrix. In this way a general natural parametrization of the correlation matrix of a quasifree state is obtained. This parametrization

[a)]Electronic mail: scutaru@theor1.ifa.ro

points out the squeezing and the orthogonal symplectic transformations. The orthogonal transformations mix the different modes.

The geometric interpretation, given in Sec. V, is valid only for the one-mode case and shows that the transition probability between two pure squeezed states decreases with the increase of the geodesic distance between the corresponding points of the Poincaré upper half plane.

In Sec. VI the relation between the Wigner function of a quasifree state of a system and that of a subsystem is given in most general form. A first application of this relation is given in Sec. VII where the correlation matrix of a pure quasifree state of an enlarged system (which reduces to the mixed state of the orginal system) is obtained in an elementary way.[4]

In Sec. VIII it is shown that the transition probability between the above pure state obtained for the enlarged system and the mixed state obtained as the direct product of the state of the original subsystem with the state of the fictitious subsystem can be a measure of the entanglement of these two subsystems reflected in the pure state of the total system.

Finally, in Sec. IX, it is shown how the correlations between the original subsystem and the fictitious one are created by the Bogoliubov transformations which map the Fock state into the above pure state obtained by the purification procedure.

II. QUASIFREE STATES

The phase space considered in the present paper is a finite-dimensional symplectic space (E,σ). This is a real vector space endowed with a real, bilinear, antisymmetric form $\sigma(.,.)$ which gives the symplectic structure on E. Then E is of even real dimension $2n$ and there exist in E symplectic bases of vectors $\{e_j,f_j\}_{j=1,\ldots,n}$, i.e., reference systems such that $\sigma(e_j,e_k)=\sigma(f_j,f_k)=0$ and $\sigma(e_j,f_k)=-\sigma(f_k,e_j)=\delta_{jk}$, $j,k=1,\ldots,n$. The coordinates (ξ^j,η^j) of a vector $u\in E$ in a symplectic basis $[u=\Sigma_{j=1}^{n}(\xi^j e_j+\eta^j f_j)]$ are called symplectic coordinates. The measure $dm(u)=\Pi_{j=1}^{n}d\xi^j d\eta^j$ is the same for all symplectic coordinates and is called the Liouville measure on (E,σ).[1] There is a one-to-one correspondence between the symplectic bases and the linear operators J on E defined by $Je_k=-f_k$ and $Jf_k=e_k$, $k=1,\ldots,n$. The essential properties of these operators are $\sigma(Ju,u)\geqslant 0$, $\sigma(Ju,v)+\sigma(u,Jv)=0$ $(u,v\in E$ and $J^2=-I$, I denotes the identity operator on $E)$. Such operators are called complex structures.[1] In the following we shall use the matricial notations with $u\in E$ as column vectors. Then $\sigma(u,v)=u^T Jv$ and the scalar product is given by $\sigma(Ju,v)=u^T v, u,v\in E$. A linear operator S on E is called a symplectic operator if $S^T JS=J$. When S is a symplectic operator, then S^T and S^{-1} are also symplectic operators. The group of all symplectic operators $\mathrm{Sp}(E,\sigma)$ is called the symplectic group of (E,σ). The Lie algebra of $\mathrm{Sp}(E,\sigma)$ is denoted by $\mathrm{sp}(E,\sigma)$ and its elements are operators R on E with the property $(JR)^T=JR$. If J and K are two complex structures, there exists a symplectic transformation S such that $J=S^{-1}KS$.

Definition II.1:[1,3] *The C*-algebra* $\mathbf{A}$ *of the canonical commutation relations (CCR) is obtained by the completion of the *-algebra* $\mathrm{Span}\{\delta_u : u\in E\}$, *the elements of which satisfy the Weyl relations:*

$$\delta_u\delta_v=\exp(-i\sigma(u,v)/2)\,\delta_{u+v},\quad \delta_u^*=\delta_{-u},u,v\in E. \tag{2.1}$$

A state on $\mathbf{A}$ is a positive linear functional ω normalized by $\omega(\delta_0)=1$.[1–11] The complex valued function on the phase space $\omega(\delta_u)$ is called the characteristic or the generating function of the state ω. A continuous complex-valued function f on E, with $f(0)=1$, is the characteristic function of a state on $\mathbf{A}$ if and only if

$$\sum_{j,k=1}^{N}\overline{a}_j a_k\exp(i\sigma(u_j,u_k)/2)f(u_k-u_j)\geqslant 0 \tag{2.2}$$

for all $a_k\in\mathbf{C}$, $u_k\in E$, $k=1,\ldots,N$, and $N\in\mathbf{N}$.

For any $v\in E$ an automorphism τ_v of $\mathbf{A}$ can be defined by

$$\tau_v(x)=\delta_v^* x\,\delta_v. \tag{2.3}$$

A Bogoliubov transformation of $\mathbf{A}$ is a *-automorphism of $\mathbf{A}$ defined for any $S\in\mathrm{Sp}(E,\sigma)$ by

$$\alpha_S(\delta_u)=\delta_{Su},\ u\in E. \tag{2.4}$$

The quasifree automorphisms of **A** are those of the form $\tau_v\circ\alpha_S$ where $v\in E$ and $S\in \mathrm{Sp}(E,\sigma)$.

Let A be a symmetric ($A^T=A$) and positive ($u^TAu\geqslant 0$ for all $u\in E$) matrix.

Definition II.2:[1–11] *A quasifree state* $\omega_{(A,v)}$ *on* **A** *is a state whose characteristic function is given by the formula*

$$\omega_{(A,v)}(\delta_u)=\exp(-u^TAu/4+iu^Tv) \tag{2.5}$$

with the restriction

$$-JAJ\geqslant A^{-1}. \tag{2.6}$$

Evidently, we have

$$\omega_{(A,v)}\circ\alpha_S=\omega_{(S^TAS,S^Tv)} \tag{2.7}$$

and $\omega_{(A,v)}=\omega_{(A,0)}\circ\tau_v$. The state $\omega_{(A,v)}$ is pure iff $\omega_{(A,0)}$ is pure and this is the case iff $-(JA)^2=I$ [this is equivalent with $JA\in \mathrm{Sp}(E,\sigma)$] and, in particular, when $A=I$, i.e., when the state is a coherent state. The pure squeezed states are the quasifree states of the form $\omega_{(I,v)}\circ\alpha_S=\omega_{(S^TS,S^Tv)}$.

III. TRANSITION PROBABILITIES

The transition probability $P(\omega_1;\omega_2)$ between two arbitrary states ω_1 and ω_2 on **A** can be defined in many ways.[15–17,12]

Theorem III.1: *If the state* ω_1 *is a squeezed state, the transition probability to an arbitrary state* ω_2 *can be computed by the following representation-independent formula:*

$$P(\omega_1;\omega_2)=(2\pi)^{-n}\int_E \omega_1(\delta_{-u})\omega_2(\delta_u)\,dm(u), \tag{3.1}$$

where $dm(u)$ *is the Liouville measure defined above.*

A proof of this result can be obtained by combining the construction of a projection as in Lemma 3 from Ref. 4 with the assertion (vi) of Sec. II from Ref. 12.

Lemma III.1: For any coherent state $\omega_{(I,v)}$ *we can define an element* $p_v\in\mathbf{A}$ *such that it is a projector (i.e.,* $p_v^2=p_v$ *and* $p_v^*=p_v$*)* and has the property

$$p_vxp_v=\omega_{(I,v)}(x)p_v \tag{3.2}$$

for any $x\in\mathbf{A}$.

Proof: We take

$$p_v=(2\pi)^{-n}\int_E \omega_{(I,v)}(\delta_{-u})\delta_u\,dm(u). \tag{3.3}$$

The fact that p_v is a self-adjoint element of **A** is evident. The fact that it is an idempotent element of **A** results from

$$p_v^2=(2\pi)^{-2n}\int_E\int_E \omega_{(I,v)}(\delta_{-u})\omega(\delta_{-w})\delta_u\delta_w\,dm(u)\,dm(w)$$

$$=(2\pi)^{-2n}\int_E \omega_{(I,z)}(\delta_{-z})I(z)\,dm(z), \tag{3.4}$$

where $I(z)=\int_E[\omega_{(I,v)}(\delta_{-u})\omega_{(I,v)}(\delta_{-z+u})/\omega_{(I,v)}(\delta_{-z})]\exp(-(i/2)\sigma(u,z))\,dm(u)$. Thus it is sufficient to prove that $I(z)=(2\pi)^n$ and this follows by direct computations. In this way we have associated to any coherent state $\omega_{(I,v)}$ a projector from **A**. In order to prove the last assertion it is sufficient to prove that

$$\int_E \omega_{(I,v)}(\delta_{-w})\omega_{(I,v)}(\delta_{-y+w+u})\exp\left\{-\frac{1}{2}i(\sigma(w,u)+\sigma(w,y))\right\}dm(w)$$

$$=(2\pi)^n\omega_{(I,v)}(\delta_u)\omega_{(I,v)}(\delta_{-y})\exp\frac{1}{2}i\sigma(u,y). \tag{3.5}$$

As it results from Refs. 1–3, the property (3.5) is valid for any $x\in\mathbf{A}$ and (3.2) follows.

Then we can apply the following result of P. M. Alberti and V. Heinemann given in Sec. II of Ref. 12 at the point (vi):

Lemma III.2: Let A a C-algebra and $p\in A$ be a minimal orthoprojection, i.e., $pAp=\mathbf{C}p$. Let $pxp=\nu(x)p$, with $\nu(x)\in\mathbf{C}$. Then the map $\nu:x\to\nu(x)\in\mathbf{C}$ defines a state $\nu\in S(A)$ (the set of states on A) with $\nu(p)=1$ and we have*

$$P(\omega;\nu)=\omega(p) \tag{3.6}$$

for any state $\omega\in S(A)$.

Proof of the Theorem: We must verify the fact that

$$\omega_{(I,v)}(p_v)=1. \tag{3.7}$$

We have

$$\omega_{(I,v)}(p_v)=(2\pi)^{-n}\int_E\exp\left(-\frac{1}{2}w^Tw\right)dm(x)=1. \tag{3.8}$$

Thus we have proved that for any state ω and coherent state $\omega_{(I,v)}$ the transition probability is given by

$$P(\omega;\omega_{(I,v)})=\omega(p_v)=(2\pi)^{-n}\int_E\omega_{(I,v)}(\delta_{-v})\omega(\delta_v)\,dm(v). \tag{3.9}$$

Corrolary III.1: The general formula for the transition probability between any quasifree state and a pure quasifree state is given by

$$P(\omega_{(A,v)},\omega_{(B,w)})=\left(\det\left(\frac{A+B}{2}\right)\right)^{-1/2}\exp(-(w-v)^T(A+B)^{-1}(w-v)). \tag{3.10}$$

Proof: It is well known[15–17,12] that for any automorphism α of **A** we have

$$P(\omega_1\circ\alpha;\omega_2\circ\alpha)=P(\omega_1;\omega_2). \tag{3.11}$$

When the state ω is a quasifree state ω_A we have

$$P(\omega_A;\omega_{(I,v)})=\det\left(\frac{I+A}{2}\right)^{-1/2}\exp(-v^T(I+A)^{-1}v). \tag{3.12}$$

The transition probability between two squeezed states can be also given if we take into account the fact that any squeezed state is obtained by a Bogoliubov automorophism from a coherent state and the invariance of the transition probabilities with respect to automorphisms.

Remark: When both states are squeezed pure states we have

$$P(\omega_{(A,v)};\omega_{(B,w)})=\det\left(\frac{I+S^TS}{2}\right)^{-1/2}\exp(-(w-v)^T(A+B)^{-1}(w-v)), \tag{3.13}$$

where S is the symplectic matrix such that $A=S^TBS$.

IV. APPLICATIONS IN QUANTUM OPTICS

Theorem IV.1: *The most general form of a correlation matrix A is given by*

$$A=O'^T\begin{pmatrix}M & 0\\ 0 & M^{-1}\end{pmatrix}O^T\begin{pmatrix}D & 0\\ 0 & D\end{pmatrix}O\begin{pmatrix}M & 0\\ 0 & M^{-1}\end{pmatrix}O', \tag{4.1}$$

where O and O' are symplectic and orthogonal ($O^TO=I$) operators and M is a diagonal $n\times n$ matrix.

Proof: The proof results by combining two well-known results. Because the correlation matrix A is positive definite it follows[13] that there exists $S\in \mathrm{Sp}(E,\sigma)$ such that

$$A=S^T\begin{pmatrix}D & 0\\ 0 & D\end{pmatrix}S, \tag{4.2}$$

where D is a diagonal $n\times n$ matrix.

The most general real symplectic transformation $S\in \mathrm{Sp}(E,\sigma)$ has[14] the following structure:

$$S=O\begin{pmatrix}M & 0\\ 0 & M^{-1}\end{pmatrix}O', \tag{4.3}$$

where O and O' are symplectic and orthogonal ($O^TO=I$) operators and M is a diagonal $n\times n$ matrix.

Examples: Various particular kinds of such matrices are obtained taking O, O', D, or M to be equal or proportional to the corresponding identity operator. A pure squeezed state is obtained when $D=I$. If this condition is not satisfied, the state is a mixed state called thermal squeezed state.[18] When $M=I$ there is no squeezing and the correspondig states are pure coherent states or thermal coherent states. All these states have correlations between the different modes produced by the orthogonal symplectic operators O and O'. Combining Eqs. (3.2) and (3.12) we obtain that

$$P(\omega_A\circ\alpha_S;\omega_{(I,0)})=P(\omega_A;\omega_{(I,0)}) \tag{4.4}$$

iff $S^TAS=A$ or iff $S^TS=I$, i.e., iff S is orthogonal.

The first situation appears, for example, in the case of a parametric amplifier[19] and this property explains the fact that the nonentanglement of states is preserved by such a transformation. Hence the parametric amplifier is a transition probability preserving device. The second situation appears if there is no squeezing, i.e., $M=I$. As it was shown in Ref. 7 for any quasifree state ω_A we have

$$\omega_A=(\omega_{d_1}\otimes\omega_{d_2}\otimes\ldots\otimes\omega_{d_n})\circ\alpha_S, \tag{4.5}$$

where $d_1,\ldots,d_n$ are the diagonal elements of the matrix D, and where ω_{d_i}, $i=1,\ldots,n$, are the one-mode quasifree states defined on the phase spaces E_i generated by the vectors $\{e_i,f_i\}$ (on which the operator A acts by $Ae_i=d_ie_i$ and $Af_i=d_if_i$) by the formula

$$\omega_{d_i}(\delta_{\xi^ie_i+\eta^if_i})=\exp(-d_i((\xi^i)^2+(\eta^i)^2)/4) \tag{4.6}$$

with $d_i\geqslant 1$ as it follows from Eq. (2.6). It is clear that

$$P(\omega_{d_1}\otimes\omega_{d_2}\otimes\cdots\otimes\omega_{d_n};\omega_{(I,0)})=\prod_{i=1}^{n}P(\omega_{d_i};\omega_{(I,0)}). \tag{4.7}$$

Combining Eqs. (4.5) and (4.7) we obtain that the equality

$$P(\omega_A;\omega_I)=\prod_i^n P(\omega_{d_i};\omega_I) \tag{4.8}$$

is valid only for nonsqueezed states (i.e., when $M=I$).

For pure squeezed states ($D=I$) we still have such a decomposition of the transition probability as a product of transition probabilities for the individual modes. Moreover, there is another class of quasifree states defined by the condition $O=I$ in Eq. (4.3), and for which such a decomposition is valid. The formula which describes these two situations is

$$P(\omega_A;\omega_I)=\prod_i^n \frac{2}{\sqrt{(m_i^2+d_i)(m_i^{-2}+d_i)}}. \tag{4.9}$$

The thermal squeezed states considered in Ref. 18 are obtained when $M=mI$ and $D=dI$. In this case the correlation matrix A takes the following form:

$$A=O'^T\begin{pmatrix} m^2dI & 0 \\ 0 & m^{-2}dI \end{pmatrix}O' \tag{4.10}$$

and

$$P(\omega_A;\omega_I)=\left(\frac{2}{\sqrt{(m^2+d)(m^{-2}+d)}}\right)^n. \tag{4.11}$$

We shall take into account the fact that the most general form of an orthogonal symplectic matrix is[14,13]

$$O'=\begin{pmatrix} X & Y \\ -Y & X \end{pmatrix}, \tag{4.12}$$

where X and Y are $n\times n$ matrices which satisfy the conditions $X^TX+Y^TY=I$ and $X^TY=Y^TX$.

When $Y=0$ the corresponding quasifree state is nonentangled and remains nonentangled in all symplectic frames obtained by such Bogoliubov transformations (i.e., orthogonal with $Y=0$).[18] The ideal (lossless) beam splitter affects a transformation of such kind and the nonentanglement is preserved only when all modes are with the same temperature and equally squeezed.[19] It follows from the above discussion that the ideal beam splitter is a transition probability preserving device.

V. A GEOMETRIC INTERPRETATION

The squeezed states are in a one-to-one correspondence with the elements of $\mathbf{R}=\mathrm{sp}(E,\sigma)\cap\mathrm{Sp}(E,\sigma)$. This correspondence is covariant with respect to the adjoint action of the symplectic group $\mathrm{Sp}(E,\sigma)$ on $\mathbf{R}$ and the action of this group on the squeezed states given by the corresponding Bogoliubov authomorphisms. Because the symplectic group acts transitively on $\mathbf{R}$ it follows that this is a coadjoint orbit of $\mathrm{Sp}(E,\sigma)$. In fact, this is the Hermitian symmetric space $\mathrm{Sp}(E,\sigma)/U(n)$, where $U(n)$ is the subgroup of $\mathrm{Sp}(E,\sigma)$ the elements of which are also orthogonal. Hence the squeezed states are labeled by the elements of this Hermitian symmetric space. In the one-mode case ($n=1$) the Hermitian symmetric space $\mathrm{Sp}(2,R)/U(1)$ is the Poincaré upper half-plane $\mathbf{H}$.[20] The group $\mathrm{Sp}(2,R)$ acts on $\mathbf{H}$ in the usual way:

$$\gamma: z\rightarrow \frac{az+b}{cz+d}, \tag{5.1}$$

where $z=x+\sqrt{-1}y$ and where

$$\gamma=\begin{pmatrix} a & b \\ c & d \end{pmatrix} \tag{5.2}$$

with $\det(\gamma)=ad-bc=1$. The function

$$u(z,z')=\frac{|z-z'|^2}{4yy'} \tag{5.3}$$

is invariant to the action of the group $\mathrm{Sp}(2,R)$:

$$u(\gamma z,\gamma z')=u(z,z'). \tag{5.4}$$

The Poincaré metrics on **H** is also invariant and is given by

$$ds^2=\frac{dx^2+dy^2}{y^2}=\frac{dz\overline{dz}}{y^2}. \tag{5.5}$$

The corresponding distance function $\rho(z,z')$ is equal with the length of the geodesic between z and z'.

Proposition V.1: For any pair of squeezed states ω_z and $\omega_{z'}$,

$$P(\omega_z;\omega_{z'})=\frac{1}{ch(s/2)}, \tag{5.6}$$

where s is the geodesic distance between z and z'.

Proof: For any two points $z,z'\in\mathbf{H}$ there exists $\gamma\in\mathrm{Sp}(2,R)$ such that $\gamma z=\sqrt{-1}$ and $\gamma z'=\sqrt{-1}y_0$ for a real $y_0\geqslant 1$. Evidently $\rho(z,z')=\rho(\sqrt{-1},\sqrt{-1}y_0)$. The geodesic between $\sqrt{-1}$ and $\sqrt{-1}y_0$ is the vertical straight line connecting these two points.[20] Then

$$\rho(\sqrt{-1},\sqrt{-1}y_0)=\int_1^t\frac{dy}{y}=\ln(t)=s \tag{5.7}$$

and $1+u(\sqrt{-1},\sqrt{-1}t)=ch^2(s/2)$. From $\gamma\sqrt{-1}=(a\sqrt{-1}+b)/(c\sqrt{-1}+d)=x+\sqrt{-1}y$ we obtain $x=(bd+ac)/(c^2+d^2)$ and $y=(ad-bc)/(c^2+d^2)$ and

$$1+u(z,\sqrt{-1})=\frac{a^2+b^2+c^2+d^2+2}{4}. \tag{5.8}$$

The correspondence between the points of the Poincaré half-plane **H** and the squeezed states is given by

$$\sqrt{-1}\leftrightarrow J=\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \tag{5.9}$$

and $z\leftrightarrow J\gamma$. Then

$$P(\omega_z,\omega_{\sqrt{-1}})=\det\left(\frac{1+\gamma^T\gamma}{2}\right)^{-1/2}=\frac{1}{ch(s/2)}. \tag{5.10}$$

Evidently, this result is valid for any pair of squeezed states.

VI. THE REDUCTION OF THE WIGNER FUNCTIONS TO THE SUBSYSTEMS

In the following we shall use the fact that the Wigner functions of the states on the algebra of the bosonic commutation relations give a complete description of these states.

Definition IV.1: The Wigner function of the state ω is defined as the Fourier symplectic transform of the corresponding characteristic function $\omega(\delta_u)$:

$$W_\omega(u)=(2\pi)^{-2n}\int_E \exp[i\sigma(u,v)]\omega(\delta_v)\,dm(v). \tag{6.1}$$

Proposition VI.1: The Wigner function of a quasifree state is given by

$$W_\omega(u)=\pi^{-n}(\det G)^{1/2}\exp(-u^TGu), \tag{6.2}$$

where $G=-JA^{-1}J$ *is a* $2n\times 2n$ *real, symmetric and positive definite matrix which satisfies a restriction which is equivalent with the restriction (2.6):*

$$-(JG)^2\leqslant I. \tag{6.3}$$

Remarks: We have also $JG\in \mathrm{sp}(E,\sigma)$. If ω is a pure quasifree state, then $G=A$ and $\det G=\det A=1$ [because G and A belong to $\mathrm{Sp}(E,\sigma)$].

Corrolary VI.1: The most general form of the matrix G which defines the Wigner function of a quasifree state is the following:

$$G=O'^T\begin{pmatrix} M & 0\\ 0 & M^{-1}\end{pmatrix}O^T\begin{pmatrix} D^{-1} & 0\\ 0 & D^{-1}\end{pmatrix}O\begin{pmatrix} M & 0\\ 0 & M^{-1}\end{pmatrix}O', \tag{6.4}$$

where O *and* O' *are symplectic and orthogonal* $(O^TO=I)$ *matrices and* M *is a diagonal* $n\times n$ *matrix.*

Proof: Since $S^TJS=(S^{-1})^TJS^{-1}=SJS^T=J$ for any symplectic matrix S it follows that

$$G=-JA^{-1}J=-JS^{-1}\begin{pmatrix} D & 0\\ 0 & D\end{pmatrix}(S^T)^{-1}J=S^T\begin{pmatrix} D^{-1} & 0\\ 0 & D^{-1}\end{pmatrix}S. \tag{6.5}$$

The most general real symplectic transformation $S\in \mathrm{Sp}(E,\sigma)$ has[17] the following structure

$$S=O\begin{pmatrix} M & 0\\ 0 & M^{-1}\end{pmatrix}O', \tag{6.6}$$

where O and O' are symplectic and orthogonal $(O^TO=I)$ operators and M is a diagonal $n\times n$ matrix.

As a consequence we have that $\det G=(\det D)^{-2}$.

Let us suppose that the state of the quantum system $\mathcal{S}$ is described by the Wigner function $W(u)$ defined on the phase space (E,ω) which can be considered as being composed from two subsystems $\mathcal{S}_1$ and $\mathcal{S}_2$ with the phase spaces (E_1,ω_1) and (E_2,ω_2), respectively, where $E=E_1\oplus E_2$ and ω_1 and ω_2 are the restrictions of the state ω to E_1 and to E_2, respectively. In this case the Wigner function $W_\omega(u)=\pi^{-n}(\det G)^{1/2}\exp(-u^TGu)$ can be written as

$$W(x,y)=\pi^{-n}\left(\det\begin{pmatrix} A & B\\ B^T & C\end{pmatrix}\right)^{1/2}\exp-(x^Ty^T)\begin{pmatrix} A & B\\ B^T & C\end{pmatrix}\begin{pmatrix} x\\ y\end{pmatrix}. \tag{6.7}$$

Theorem VI.1: *If* $\det C\neq 0$, *then the Wigner function of the subsystem* $\mathcal{S}_1$ *is given by*

$$W_1(x)=\pi^{-n/2}(\det(A-BC^{-1}B^T))^{1/2}\exp[-x^T(A-BC^{-1}B^T)x], \tag{6.8}$$

and if $\det A\neq 0$, *the Wigner function of the subsystem* $\mathcal{S}_2$ *is given by*

$$W_2(y)=\pi^{-n/2}(\det(C-B^TA^{-1}B))^{1/2}\exp[-y^T(C-B^TA^{-1}B)y]. \tag{6.9}$$

Proof: The Wigner function $W_1(x)$ of the subsystem $\mathcal{S}_1$ is defined by the integration on the coordinates of the subsystem $\mathcal{S}_2$:

$$W_1(x)=\int_{E_2} W(x,y)\,dm(y). \tag{6.10}$$

If $\det C \neq 0$, then

$$W_1(x) = \pi^{-n/2}(\det(A - BC^{-1}B^T))^{1/2}\exp[-x^T(A - BC^{-1}B^T)x]. \tag{6.11}$$

We have used Schur's formula

$$\det\begin{pmatrix} A & B \\ B^T & C \end{pmatrix} = \det C \det(A - BC^{-1}B^T). \tag{6.12}$$

Analogously, if $\det A \neq 0$, then

$$W_2(y) = \pi^{-n/2}(\det(C - B^TA^{-1}B))^{1/2}\exp[-y^T(C - B^TA^{-1}B)y]. \tag{6.13}$$

Also we have used the fact that

$$\det\begin{pmatrix} A & B \\ B^T & C \end{pmatrix} = \det A \det(C - B^TA^{-1}B). \tag{6.14}$$

VII. THE PURIFICATION OF A MIXED STATE

Theorem VII.1: *For any quasifree mixed state ω_A on the C*-algebra of commutation relations defined on the phase space E there exists a pure quasifree state $\tilde{\omega}_A$ on the C*-algebra of commutation relations defined on the phase space $E \oplus E$ endowed with the symplectic structure $\begin{pmatrix} J & 0 \\ 0 & -J \end{pmatrix}$. This pure quasifree state $\tilde{\omega}_A$ is defined by the correlation matrix $\tilde{A}$ (which is a $4n \times 4n$ real, symmetric and positive definite matrix)*

$$\tilde{A} = \begin{pmatrix} A & A\sqrt{I + (JA)^{-2}} \\ A\sqrt{I + (JA)^{-2}} & A \end{pmatrix}. \tag{7.1}$$

Proof: This pure quasifree state $\tilde{\omega}_A$ is defined by the correlation matrix $\tilde{A}$ (which is a $4n \times 4n$ real, symmetric and positive definite matrix)

$$\tilde{A} = \begin{pmatrix} U & V \\ V & U \end{pmatrix}, \tag{7.2}$$

which satisfies the restriction

$$-\left(\begin{pmatrix} J & 0 \\ 0 & -J \end{pmatrix}\begin{pmatrix} U & V \\ V & U \end{pmatrix}\right)^2 = \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix}, \tag{7.3}$$

i.e.,

$$(JU)^2 - (JV)^2 = -I, JUJV = JVJU. \tag{7.4}$$

The map which associates a pure quasifree state $\tilde{\omega}_A$ to any mixed quasifree state, ω_A is called the purification map. Because $\tilde{\omega}_A$ is a pure quasifree state the corresponding Wigner function is defined by the same matrix:

$$\tilde{G} = \begin{pmatrix} U & V \\ V & U \end{pmatrix}. \tag{7.5}$$

We remark that the original system can be considered as the reduction of the extended one. Then one must have the relation

$$\int_E W_{\tilde{\omega}_A}((u, \tilde{u}))\, dm(\tilde{u}) = W_{\omega_A}(u). \tag{7.6}$$

Hence we can use the result of the preceeding section, i.e., we have

$$G_1 = U - VU^{-1}V = G = -JA^{-1}J. \tag{7.7}$$

From the Schur formula it follows that

$$\det \tilde{G} = \det U \det(U - VU^{-1}V) = \det A \det A^{-1} = 1. \tag{7.8}$$

From the equations (7.3) and (7.6) we have $JGJU = JU - (JV)^2(JU)^{-1}$. Hence $JGJU = (JU)^2 - (JV)^2 = -I$, from which it follows that $U = A$ and $(JV)^2 = I + (JA)^2$. It is easy to prove that $V = A\sqrt{I + (JA)^{-2}}$ is a solution of the last equation.

Remarks: The map defined by (7.6) which acts on the Wigner functions is the inverse map of the purification map. From the formula

$$W_{\tilde{\omega}_A}((u,\tilde{u})) = \pi^{-2n} \exp\{-u^T A u - \tilde{u}^T A \tilde{u} - V^T \tilde{u} - \tilde{u}^T V u)\} \tag{7.9}$$

it follows that the correlations between the variables u of the real system and the variables $\tilde{u}$ of the fictitious one are given by the terms $(A\sqrt{I + (JA)^{-2}}u)^T\tilde{u} + \tilde{u}^T(A\sqrt{I + JA})^{-2}u)$ which appear at the exponent.

In the general case

$$A = S^T \begin{pmatrix} D & 0 \\ 0 & D \end{pmatrix} S \tag{7.10}$$

and $JS^T = S^{-1}J$ and $J\left(\begin{smallmatrix} D & 0 \\ 0 & D \end{smallmatrix}\right) = \left(\begin{smallmatrix} D & 0 \\ 0 & D \end{smallmatrix}\right)J$. From these relations it follows that

$$\begin{aligned} (JA)^{-2} &= A^{-1}JA^{-1}J \\ &= S^{-1}\begin{pmatrix} D^{-1} & 0 \\ 0 & D^{-1} \end{pmatrix}(S^T)^{-1}JS^{-1}\begin{pmatrix} D^{-1} & 0 \\ 0 & D^{-1} \end{pmatrix}(S^T)^{-1}J \\ &= -S^{-1}\begin{pmatrix} D^{-2} & 0 \\ 0 & D^{-2} \end{pmatrix}S. \end{aligned}$$

Hence

$$\begin{aligned} I + (JA)^{-2} &= I - S^{-1}\begin{pmatrix} D^{-2} & 0 \\ 0 & D^{-2} \end{pmatrix}S \\ &= S^{-1}\begin{pmatrix} I - D^{-2} & 0 \\ 0 & I - D^{-2} \end{pmatrix}S \end{aligned}$$

and

$$A\sqrt{I + (JA)^{-2}} = S^T \begin{pmatrix} \sqrt{D^2 - I} & 0 \\ 0 & \sqrt{D^2 - I} \end{pmatrix} S. \tag{7.11}$$

VIII. A MEASURE OF THE ENTANGLEMENT

A characteristic feature of quantum mechanics is the presence of the correlations between the subsystem of a quantum systems described by a pure state. In this situation the states of the subsystems are mixed. Any quantum system can be considered to be a subsystem of a larger quantum system which is in a pure state. The enlarged system can contain real or fictitious additional subsystems. The appearance of the quantum correlations between these auxiliary subsystems and the initial one is the price which must be paid for the purity of the state of the whole system.

For any mixed quasifree state on an *n*-mode bosonic system there exists a standard procedure which defines a compound *2n*-mode bosonic system in a pure quasifree state such that the restriction of this state to the initial subsystem is the initial mixed quasifree state. This procedure is called the purification operation.

The corresponding compound system has two subsystems which are identical with the initial one and which are strongly correlated. These correlations are explicitly defined by the purification operation.

In Sec. III we have obtained the following general formula for the transition probability between any quasifree state and a pure quasifree state:

$$P(\omega_A,\omega_B)=\left(\det\left(\frac{A+B}{2}\right)\right)^{-1/2}. \tag{8.1}$$

Because the state obtained by purification is a pure state we can apply this formula in the case in which the mixed quasifree state is that given by the direct product of the mixed states of the real and fictitious systems. The last one is a mixed quasifree state with the correlation matrix given by

$$\begin{pmatrix} A & 0 \\ 0 & A \end{pmatrix}. \tag{8.2}$$

Hence we must find

$$\det\begin{pmatrix} A & \frac{A}{2}\sqrt{I+(JA)^{-2}} \\ \frac{A}{2}\sqrt{I+(JA)^{-2}} & A \end{pmatrix}. \tag{8.3}$$

One obtains

$$P(\omega_{A\oplus A},\tilde{\omega}_A)=(\det(\tfrac{3}{4}D^2+\tfrac{1}{4}I))^{-1}. \tag{8.4}$$

This transition probability can be considered as a measure of the correlation between the real and fictitious subsystems. One can remark that this transition probability is a decreasing function of the temperature of each mode, i.e., the correlation is increasing with the temperature.

IX. CORRELATIONS THAT ARE GIVEN BY THE BOGOLIUBOV AUTOMORPHISMS

Another useful result of the theory of bosonic commutation relations that can be applied to the pure state which appears from the purification operation is the fact that all quasifree states can be obtained from the Fock state by a Bogoliubov transformation. In other words, the pure quasifree states are squeezed states in a generalized meaning. Hence the strong correlations between the real modes and the fictitious ones are produced by the action of the Bogoliubov automorphisms which are of two kinds: squeezing transformations of each mode and transformations which mix different modes.

In the following we shall disscuss the case of pure quasifree states in detail. If ω_A is a pure quasifree state, then $-(JA)^2=I$. From the Williamson theorem[13] for any positive definite symmetric matrix A there exists an element $S\in \mathrm{Sp}(E,\sigma)$ and a diagonal matrix with positive entries D and with the property $DJ=JD$ and such that $A=S^TDS$. Then from the restriction $-(JA)^2=I$ one obtains $D^2=I$, i.e., $D=I$. Hence for any pure quasifree state ω_A the correlation matrix A is of the form S^TS with $S\in \mathrm{Sp}(E,\sigma)$, i.e., $\omega_A=\omega_I\circ\alpha_S$, where ω_I is called the Fock state. In other words any pure quasifree state can be obtained from the Fock state by a Bogoliubov transformation. Because the Fock state is a state without correlations between different modes it follows that in the state with the correlation matrix ω_A the correlations are produced under the action of the Bogoliubov automorphism α_S, $S\in \mathrm{Sp}(E,\sigma)$. We can apply these considerations to the quasifree pure state $\tilde{\omega}_A$ which arises by purification of the quasifree state ω_A. It follows that $\tilde{\omega}_A$ can be obtained

from the Fock state by the Bogoliubov automorphism α_S. As we have seen in the preceding section, the correlation matrix of the state obtained by purification is given by

$$\begin{pmatrix} S^T & 0 \\ 0 & S^T \end{pmatrix} \begin{pmatrix} \begin{pmatrix} D & 0 \\ 0 & D \end{pmatrix} & \begin{pmatrix} \sqrt{D^2-I} & 0 \\ 0 & \sqrt{D^2-I} \end{pmatrix} \\ \begin{pmatrix} \sqrt{D^2-I} & 0 \\ 0 & \sqrt{D^2-I} \end{pmatrix} & \begin{pmatrix} D & 0 \\ 0 & D \end{pmatrix} \end{pmatrix} \begin{pmatrix} S & 0 \\ 0 & S \end{pmatrix}. \tag{9.1}$$

Hence the most general pure quasifree state is obtained from the mixed quasifree state described by the following correlation matrix:

$$\mathbf{D} = \begin{pmatrix} \begin{pmatrix} D & 0 \\ 0 & D \end{pmatrix} & \begin{pmatrix} \sqrt{D^2-I} & 0 \\ 0 & \sqrt{D^2-I} \end{pmatrix} \\ \begin{pmatrix} \sqrt{D^2-I} & 0 \\ 0 & \sqrt{D^2-I} \end{pmatrix} & \begin{pmatrix} D & 0 \\ 0 & D \end{pmatrix} \end{pmatrix} \tag{9.2}$$

using a specific Bogoliubov transform which does not couple the real and the fictious systems:

$$\begin{pmatrix} S^T & 0 \\ 0 & S^T \end{pmatrix} \begin{pmatrix} J & 0 \\ 0 & -J \end{pmatrix} \begin{pmatrix} S & 0 \\ 0 & S \end{pmatrix} = \begin{pmatrix} J & 0 \\ 0 & -J \end{pmatrix}. \tag{9.3}$$

In the enlarged phase space there exists a Bogoliubov transform $\mathbf{S}$ such that $\mathbf{S}^T\mathbf{S}=\mathbf{D}$. If we denote by $\mathbf{J}=\left(\begin{smallmatrix} J & 0 \\ 0 & J \end{smallmatrix}\right)$, then $\mathbf{S}^T\mathbf{J}\mathbf{S}=\mathbf{J}$. The solution is

$$\mathbf{S} = \begin{pmatrix} \begin{pmatrix} \sqrt{\frac{D+I}{2}} & 0 \\ 0 & \sqrt{\frac{D+I}{2}} \end{pmatrix} & \begin{pmatrix} \sqrt{\frac{D-I}{2}} & 0 \\ 0 & \sqrt{\frac{D-I}{2}} \end{pmatrix} \\ \begin{pmatrix} \sqrt{\frac{D-I}{2}} & 0 \\ 0 & \sqrt{\frac{D-I}{2}} \end{pmatrix} & \begin{pmatrix} \sqrt{\frac{D+I}{2}} & 0 \\ 0 & \sqrt{\frac{D+I}{2}} \end{pmatrix} \end{pmatrix}. \tag{9.4}$$

If we denote by $\mathcal{D}$ the matrix

$$\begin{pmatrix} \begin{pmatrix} D & 0 \\ 0 & D \end{pmatrix} & \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix} \\ \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix} & \begin{pmatrix} D & 0 \\ 0 & D \end{pmatrix} \end{pmatrix}, \tag{9.5}$$

then the transition probability is given by

$$P(\omega_A, \omega_B) = \left(\det\left(\frac{\mathbf{I} + \mathbf{S}\mathcal{D}\mathbf{S}^T}{2} \right) \right)^{-1/2}, \tag{9.6}$$

and we reobtain the result (8.4).

X. CONCLUSIONS

The quasifree states are among the most simple and interesting, from the physical point of view, because they are states on which the quantum correlations (the entanglement) between systems can be relatively easily described. We have applied to the finite-dimensional systems the

ideas and the methods developed for the infinite-dimensional systems by D. Kastler, J. Manuceau, A. Van Daele, A. Verbeure, M. Fannes, and A. S. Holevo. For such systems, which are interesting from the physical point of view, the theory was developed (with rare exceptions) in an (apparently) independent way which is based on noncommutative calculations. In comparison, the methods developed for infinite-dimensional systems are simpler and more adequate in the finite-dimensional case.

The fundamental object which contains all the information about a quasifree state is its correlation matrix. We have shown in the present paper how we can extract this information by elementary means. For this purpose we have used results obtained many years ago. Of great importance is a result of R. Balian, C. De Dominicis, and C. Itzykson concerning the structure of covariance matrices. According to this result all covariance matrices can be obtained from the covariance matrix of a thermal state by orthogonal symplectic transformations and squeezing symplectic transformations. This structure theorem is of fundamental importance and explains all results on the structure of correlations matrices obtained until now. All operations of restriction to subsystems and of extension from a subsystem to the whole system can also be described in terms of correlation matrices. The transition probability from an arbitrary state to a squeezed coherent state can be obtained as the value of the arbitrary state on an element (a projector) of the CCR-algebra which is associated in a natural way to any squeezed coherent state. In the present paper we have shown only that the methods developed for squeezed states can be applied also to the squeezed coherent states. We have constructed explicitly the projector associated to any squeezed coherent state. The transition probability is an immediate result.

The ultimate goal of this research is the desciption of the entanglement in the case of quasifree states. We have shown that the most entangled quasifree states are those obtained by the purification of quasifree states. In the case of pure states all corelations are obtained by Bogoliubov transformations. For the states obtained by purifications we have determined explicitly the Bogoliubov transformation by which these states can be obtained from the Fock state. We have also determined explicitly the transition probability from the state obtained by purification to the state of the system obtained by direct product of the original system to the twin fictitious one. This transition probability is a decreasing function of the temperatures of the original system. This means that a state obtained by the purification is most correlated when the original state is most mixed. Hence we have obtained that the probability transition can be considered as a measure of the entanglement.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 39, NUMBER 12 DECEMBER 1998

Symmetry adapted states for Hubbard clusters

O. Tjernberg
European Synchrotron Radiation Facility, BP 220, 38 043 Grenoble Cedex, France

(Received 27 May 1998; accepted for publication 11 August 1998)

The application of spin, pseudo spin and space group symmetry to find symmetry adapted states for the square planar Hubbard model is discussed. An approach based on pseudo spin configurations and the application of Young tableaux to the permutation group is presented. The method is illustrated for the case of a 4*4 cluster and the complete classification of the states for this cluster is given. It is shown that the linear dimension of the largest matrix block is reduced by three orders of magnitude by application of the above symmetries. © *1998 American Institute of Physics.* [S0022-2488(98)00612-4]

I. INTRODUCTION

In the last decade there has been a strong interest in highly correlated electron systems. This interest was at least partly generated by the discovery of high temperature superconductivity (HTC) in cuprates.[1] In the attempts to unravel the mechanism behind HTC attention has often been focused on the Hubbard model[2] or related models such as the t-J model.[3] These models are considered to be the simplest possible models that might describe physical systems such as the cuprates or other transition metal oxides. Even though the Hubbard model is a very simplified model which only takes intra atomic repulsion into account, it has turned out to be very difficult to treat analytically and an analytical solution has only been obtained in the case of one dimension.[4] In view of these difficulties, numerical calculations on clusters have become an important tool in the study of models for strongly correlated systems.[5] Two approaches to numerical calculations on clusters are in wide use. One is the Quantum Monte Carlo (QMC)[6] technique and the other is the method of exact diagonalization, often implemented by use of a Lanczos algorithm.[7] The (QMC) technique is suitable for larger clusters but the so called sign problem induces large errors at a low temperature. As a result it is difficult to obtain information about ground state properties or low lying excitations from QMC simulations. The exact diagonalization technique is well suited to provide this kind of information and it is also capable of providing dynamical properties. The problem is, of course, that the dimensionality of the Hilbert space involved in the calculations become very large for larger clusters. In the case of a 4*4 cluster at half filling the number of bases states exceeds $6*10^8$ and it becomes necessary to reduce the Hamiltonian matrix to block diagonal form. For larger clusters it is therefore crucial to exploit the available symmetry as much as possible. In previous reports only certain of the available symmetries have been exploited such as the space group symmetry[8] or the spin and translational symmetries.[9] In this paper the application of the spin, pseudo spin and space group symmetries to exact diagonalization studies of clusters is discussed and as an example the classification of all the states of the half filled 4*4 cluster is given.

II. SYMMETRIES

If the Hamiltonian is invariant under spin rotation, i.e., it has a SU(2) symmetry characterized by the usual spin operators,

$$S_z=\frac{1}{2}\sum_i (c^\dagger_{i\uparrow}c_{i\uparrow}-c^\dagger_{i\downarrow}c_{i\downarrow}), \tag{2.1}$$

$$S_+=\sum_i c^\dagger_{i\uparrow}c_{i\downarrow}, \tag{2.2}$$

 © 1998 American Institute of Physics

$$S_- = \sum_i c_{i\downarrow}^\dagger c_{i\uparrow}, \tag{2.3}$$

$$S^2 = \frac{1}{2}(S_+ S_- + S_- S_+) + S_z^2, \tag{2.4}$$

then S^2 and S_z are good quantum numbers which can be used to classify the states of the Hamiltonian. In the standard notation used here, $c_{i\uparrow}^\dagger$ and $c_{i\downarrow}$ represent creation and destruction operators, respectively. The index i represents the lattice site and the arrow indicates the m_z value of the created alt. destroyed electron. In the case of the Hubbard model on a bipartite lattice there is a second SU(2) symmetry available.[10,11] This symmetry, commonly called pseudo spin symmetry, is generated by the following operators:

$$J_z = \frac{1}{2}\sum_i (c_{i\uparrow}^\dagger c_{i\uparrow} + c_{i\downarrow}^\dagger c_{i\downarrow} - 1), \tag{2.5}$$

$$J_+ = \sum_i (-1)^\tau c_{i\uparrow}^\dagger c_{i\downarrow}^\dagger, \tag{2.6}$$

$$J_- = \sum_i (-1)^\tau c_{i\downarrow} c_{i\uparrow}, \tag{2.7}$$

$$J^2 = \frac{1}{2}(J_+ J_- + J_- J_+) + J_z^2. \tag{2.8}$$

In the above equations τ is 1 or 2 depending on which sub-lattice i belongs to. J_z is seen to be the charge operator while J_+ and J_- flip the pseudo spin, i.e., change a positive ion to a negative and vice versa. It can be directly verified that J_z and J^2 commute with the Hubbard Hamiltonian given by[2]

$$H = -t\sum_{i,\delta,\sigma} c_{i,\sigma}^\dagger c_{i+\delta,\sigma} + U\sum_i (c_{i\uparrow}^\dagger c_{i\uparrow} c_{i\downarrow}^\dagger c_{i\downarrow}), \tag{2.9}$$

where t is the hopping energy, U the on site Coulomb repulsion and $\sigma = \uparrow, \downarrow$. The following commutation relations can also be directly verified:

$$[J_z, J_\pm] = J_\pm, \tag{2.10}$$

$$[J_+, J_-] = 2J_z. \tag{2.11}$$

The states of the Hubbard model can therefore be simultaneously characterized by their spin and pseudo spin quantum numbers.

This does, however, not exhaust the available symmetry in most cases since, in general, the cluster under study possesses some space symmetry. In the following, attention will be given to the two dimensional square lattice with periodic boundary conditions but the discussion can equally well be applied to lattices of different shapes and dimensions. The space group of a square planar lattice with periodic boundary conditions has previously been studied in connection to the Hubbard model by Fano *et al.*[8] The derivation of the irreducible representations in the square-planar case is given in Ref. 8 but it should be noted that the irreducible representations of any symmorphic space group can be written down directly with aid of the following theorem.[12]

Let $\vec{k}$ be an allowed $\vec{k}$-vector of the Brillouin zone and $G_0(\vec{k})$ the subgroup of the point group G whose elements conserve $\vec{k}$ to within a reciprocal lattice vector. Let R_i be g/h left coset representatives for the decomposition of G with respect to $G_0(\vec{k})$, where g and h are the order of G and $G_0(\vec{k})$, respectively. Then the elements of the irreducible representations of the space group are given by

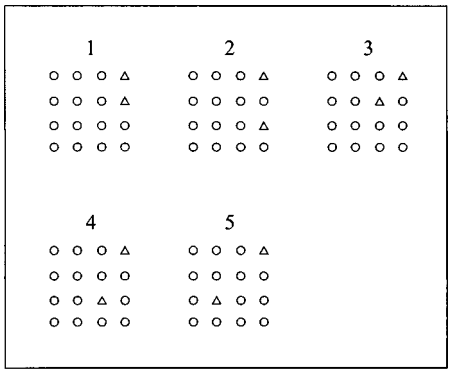

FIG. 1. All possible inequivalent pseudo spin configurations for 2 pseudo spins. ○ represents a spin while △ represents an ion or pseudo spin.

$$\Gamma^{\vec{k}p}(\vec{T},R)_{kt,jr}=\begin{cases} e^{-\{i(R_k\vec{k})\circ\vec{T}\}}\Gamma^{p}_{G_0(\vec{k})}(R_k^{-1}RR_j)_{t,r}, & \text{if } (R_k^{-1}RR_j)\in G_0(\vec{k}), \\ 0, \quad \text{otherwise.} \end{cases} \tag{2.12}$$

In the expression above, R denotes an element of the point group, $\vec{T}$ denotes a translation element of the space group and p denotes an irreducible representation of $G_0(\vec{k})$. The point group in the current case is C_{4v} and the space group of the example of a 4*4 lattice is given in the Appendix in Table II. The above theorem comes from the fact that the space group can be written as the semidirect product of the translation group and the point group. Since the translation group is an Abelian invariant group the method of induced representations, in form of the above theorem, generates the whole set of irreducible representations.

It is worth mentioning that the bipartite requirement for pseudospin symmetry excludes the possibility of including both pseudo spin and translational symmetry for square planar lattices with an odd number of sites, e.g., 3*3.

III. APPLICATION

In order to apply the above discussed symmetries, all possible permutations of spin and pseudo spin are first divided into sets of pseudo spin configurations which do not mix under the operations of the space group. In the example of a 4*4 lattice at half filling, set representatives of all the configurations with 2 pseudo spins are shown in Fig. 1. The representative for a given set of equivalent configurations is picked at random. A circle (○) indicates that the particular site is singly occupied (spin 1/2) and a triangle (△) indicates that the site is unoccupied or doubly occupied (pseudo spin 1/2). By applying all the space group elements to the shown configurations, one can show that none of the configurations mix and that all possible configurations are generated.

The space group symmetry elements which leave each set representative unchanged are listed in Table I, where each operation is written as a product of a translation and an operation of the point group. T_x^i and T_y^i signify an i step translation in the x and y directions, respectively, C_4^n a rotation through $n(\pi/2)$ and σ a reflection in a mirror plane.

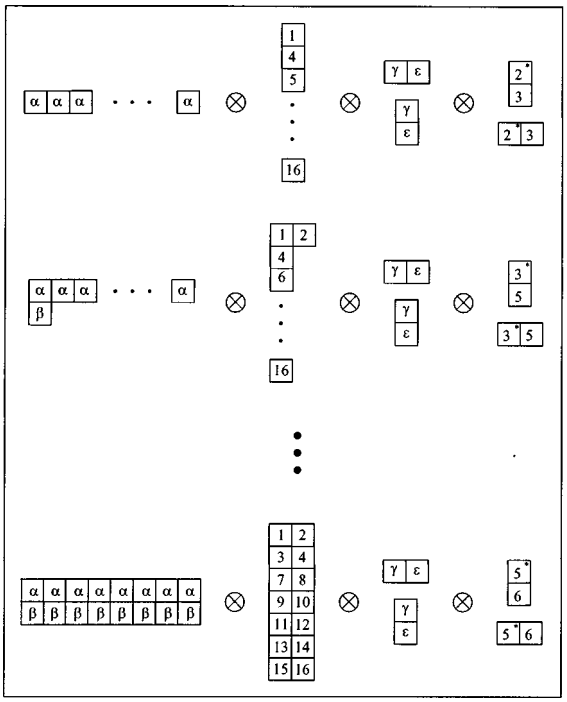

FIG. 2. A few examples of possible states with 2 pseudo spins and 14 spins. α and β denote spin up and spin down while γ and ε denote pseudo spin up and pseudo spin down. For the orbital diagrams the numbers signify that the corresponding orbital is occupied. The two possible pseudo spin configurations have been written out explicitly. In the orbital tableaux for the pseudo spin part, the * signifies double occupancy while no * signifies zero occupancy.

To find the states generated by a given pseudo spin configuration and having definite values of spin and pseudo spin, eigenstates of the spin and pseudo spin operators need first to be constructed. This is accomplished with the aid of the Young tableaux representation of the permutation group.[13,14] In Fig. 2 a few examples of the many possible states for 14 spins and 2 pseudo spins are shown. The highest spin state is given in each case while $J_z=0$ for all states at half filling. Since the total wavefunction must be antisymmetric with respect to any odd permutation only spin and orbital states represented by conjugate Young tableaux are possible as indicated in Fig. 2. In the construction of the states, the usual rules of regular application have been applied.[14] Once states of a given spin and pseudo spin have been obtained, only the orbital parts need to be kept since the Hamiltonian does not depend on spin. In order to proceed and calculate the states also belonging to a specific irreducible representation of the space group, it is necessary to find the characters of the representations generated by the states corresponding to a particular set of orbital Young diagram and pseudo spin configuration. At this point, the fact that the space group is isomorph with a subgroup of the permutation group of all the orbitals is used. By finding the permutation equivalent to the space group element the character generated by the set of pseudo spin configurations with a given spin and pseudo spin can thus be taken from the corresponding permutation group. In the present case this has been done by calculating the character of a given permutation corresponding to an allowed Young diagram or irreducible representation. For small permutation groups, the characters can be taken directly from tables. The characters needed for larger groups can be calculated directly, by e.g., regular applications or directly from the Frobenius formula.[14]

As an example we look at configuration one for two ions in Fig. 1. From Table I, it is seen that the configuration has three symmetry elements, excluding the identity, which belong to $\mathfrak{C}4$, $\mathfrak{C}8$ and $\mathfrak{C}9$ of the space group. Looking at Fig. 1, one finds that the space group operations correspond to the following permutations:

$$T_y^2\sigma_h \rightarrow 2^7 \text{ on spins and 2 on pseudospins,} \tag{3.1}$$

$$^1T_x^3T_y^2C_2 \rightarrow 2^7 \text{ on spins and } 2 \text{ on pseudospins,} \tag{3.2}$$

$$T_x^3\sigma_h' \rightarrow 2^4,1^6 \text{ on spins and } 1^2 \text{ on pseudospins.} \tag{3.3}$$

In the notation above, the permutation x^y denotes y cycles of length x. There are, however, still many spin and pseudo spin states corresponding to configuration two. If spin singlets and pseudo spin singlets, represented by Young diagrams of the type shown in the bottom line of Fig. 2, are chosen as an example then the generated representation has the following characters: 13728 0 0 280 0 0 0 140 104 0 0 0 0 0 0 0 0 0 0 0. The characters are calculated in the following way. The dimension of the representation is given by $g/h*f^{[\lambda]}$ where g is the order of the space group, h is the order of the group which leaves the configuration unchanged and $f^{[\lambda]}$ is the dimension of the irreducible representation corresponding to Young diagram $[\lambda]$ (including both spin and pseudospin). Since the dimension of the irreducible representation corresponding to the single occupation coordinate diagram in the bottom line of Fig. 2 is 429, each equivalent pseudo spin configuration is found to be 429 dimensional due to the isomorphism. As a result, the set of all equivalent pseudo spin configurations of type two generate a $128/4*429=13728$ dimensional representation. For $\mathfrak{C}4$ there are 8 equivalent pseudo spin configurations which remain unaffected by $T_y^2\sigma_h$. All of these equivalent configurations have the same permutational behavior given by expression 3.1. The characters of the irreducible representations in the bottom line of Fig. 2 for the permutation cycles 2^7 and 2 are 35 and 1, respectively. The current representation thus generates $8*35=280$ as a character for $\mathfrak{C}4$. The characters for $\mathfrak{C}8$ and $\mathfrak{C}9$ are found in a similar manner. In some cases the permutations corresponding to a particular space group operation are not the same for all equivalent configurations and care must be taken to calculate the contribution from each configuration separately. With the aid of Table II the found representation can now be decomposed into irreducible representations of the space group.

The same method can be applied to all allowed combinations of configurations, spins and pseudo spins. The result of the complete classification is given in the Appendix in Table IV. As seen from the table, the linear dimension of the largest matrix block which needs to be diagonalized has been reduced by approximately three orders of magnitude from the original 601080390 to 831398. This is one order of magnitude larger reduction than what can be achieved with application of only the space group. Assuming that $U>0$ and $t>0$, it is known[15] that the ground state is a spin and pseudo spin singlet with $k=0$ and the ground state can thus be found by diagonalizing a matrix with a linear dimension no larger than 107 358.

Due to the formidable number of states available it is not feasible to do exact diagonalization on Hubbard clusters much larger than 4*4. It is, however, possible to do an approximate treatment by including only states with a limited number of pseudo spins. This approximation is easily applied in the present context and should be applicable for $U \gg t$.

In order to obtain explicit expressions for the states found during classification, the standard projection operators of the space group are applied to the spin symmetry adapted states represented by the Young tableaux. The projection operators are given by

$$P_{ik}^{\chi_i} = c \sum_R \Gamma_{ik}^{\chi_i}(R)*R, \tag{3.4}$$

where c is a normalization constant, R an operation of the space group and $\Gamma^{\chi_i}(R)$ the matrix representation of operation R in the irreducible representation χ_i as given by (2.12). Applied to an arbitrary Young tableaux representing a given spin, pseudo spin and pseudo spin configuration, this will result in a completely symmetry adapted state. In the application of the projection operators, it is convenient to make use of the fact that the space group operations can be replaced by the equivalent permutation operations. In the case of pseudo spin configurations which possess some symmetry elements, the application of the projection operators can be written as[16]

$$\psi_{ik}^{\chi_i}(S,J) = c \sum_{R_a,Q,t} \Gamma_{ik}^{\chi_i}(R_aQ)*\Gamma_{tt_0}^{[S,J]}(Q^p)R_a\phi^{[S,J]}(t). \tag{3.5}$$

In the above expression, Q are the space group elements which leave the pseudo spin configuration unchanged, R_a are the coset representatives for the division of the space group into left cosets of Q and Q^p is the permutation corresponding to Q. The state $\phi^{[S,J]}(t)$ represents a Young tableaux of spin S and pseudo spin J.

IV. SUMMARY

A technique for finding the spin, pseudo spin and space group symmetry adapted states of Hubbard clusters has been demonstrated. The technique has been applied to classify the states of square planar clusters of size 4*4. The results presented show that the application reduces the dimensions of the involved matrices considerably. In the 4*4 case the reduction is approximately three orders of magnitude. These reductions are of great value especially when the complete or a large part of the energy spectrum is needed, e.g., in calculations of thermodynamic quantities. It should be noted that the method presented in this paper can equally well be applied to any Hamiltonian with all or part of the presented symmetry and with arbitrary filling.

APPENDIX A: TABLES FOR THE 4*4 CLUSTER

TABLE I. All symmetry elements, identity excluded, which leave the different pseudo spin configurations in Fig. 1 unchanged. The labeling of configurations correspond to that of Fig. 1.

Config.	Space group operations

I. INTRODUCTION

In 1994, Parisi published his paper ''*D*-dimensional arrays of Josephson junctions, spin glasses and *q*-deformed harmonic oscillators'' (Ref. 1). It describes a lattice model (to be called the ''Parisi model'' here) that shows a connection with the *q*-harmonic oscillator. We prove some of the claims and conjectures made by Parisi after setting the stage for them in some detail.

We shall work within the framework of noncommutative probability theory or ''quantum probability'' (see, for example, Refs. 2–6), to be described briefly in Sec. II. A fine example of noncommutative probability is free probability theory, as discovered by Voiculescu.

Here we are concerned with an interpolation between the classical Gaussian distribution and the ''free Gaussian'' distribution: Wigner's semicircle law. This is done by *q* deforming the quantum mechanical harmonic oscillator. In Sec. III we show how the *q*-deformed Fock space, as introduced by Bożejko and Speicher in Refs. 7 and 8, can be constructed in an algebraic way, starting from the *q*-deformed commutation relations. It is shown that the moments of the ground state distribution of the *q*-harmonic oscillator can be calculated as a sum over pair partitions interpolating nicely between the well-known moment formulas of the Gauss and Wigner distributions.

In Sec. IV we prepare for the Parisi model by introducing the *d*-dimensional lattice, $\mathcal{T}(N,d)$, and its boundary and coboundary operators. The Parisi model itself is introduced in Sec. V. Section VI shows how we can use pair partitions to describe the walks on $\mathcal{T}(N,d)$ that turn out to be relevant for the Parisi model. Using the possibility of describing walks in terms of partitions, we show in Sec. VII that the position operator of a *q*-harmonic oscillator has the same distribution as the normalized *q*-deformed lattice Laplacian in the Parisi model if we let $d\to\infty$.

In Sec. VIII we show that, in fact, sequences of independent *q*-Gaussians are present in the Parisi model, although on the grounds of Ref. 9 we hesitate to call them ''*q*-independent.''

II. NONCOMMUTATIVE PROBABILITY AND INDEPENDENCE

In this section we shall give a brief outline of noncommutative probability theory and the free probabilistic example.

We shall first describe the transition from classical to noncommutative probability theory.[3,4] This transition follows much the same recipe as the search for ''noncommutative versions'' of mathematical objects as initiated by Connes.[10] A classical probability space will be, following the axiomatic approach outlined by Kolmogorov, a triple $(\Omega,\Sigma,\mathbb{P})$, where Ω is a state space, Σ is a σ-algebra of events, and $\mathbb{P}$ is a probability measure on Σ. The transition of classical probability to noncommutative probability theory is preceded by a replacement of functions by multiplication operators: on $(\Omega,\Sigma,\mathbb{P})$ we can construct a commutative algebra of functions together with a state that contains the same information as $(\Omega,\Sigma,\mathbb{P})$ itself. Problems defined on the space can then be translated to algebraic problems and worked out in the commutative algebra of functions. Then we

[a]Electronic mail: H.van.Leeuwen@abp.nl
[b]Electronic mail: maassen@sci.kun.nl

 © 1998 American Institute of Physics

drop the commutativity requirement on the algebra. The noncommutative algebra can no longer be identified with a space, but it still represents some kind of probability theory.

Definition 1: A general probability space is a unital von Neumann algebra, $\mathcal{A}$, together with a normal state φ.

The events in a general probability space are the projections $p=p^*=p^2$ in $\mathcal{A}$, and the probability that p occurs is $\varphi(p)$. A self-adjoint element $X\in\mathcal{A}$ will be called a random variable and $\varphi(X)$ its expectation. The distribution, μ_X, of a random variable $X\in\mathcal{A}$ will be a linear functional on the ring of complex polynomials in one variable, $\mu_X:\mathbb{C}[x]\to\mathbb{C}$, that satisfies $\mu_X(f)=\varphi(f(X))$ for every $f\in\mathbb{C}[x]$. Such a linear functional uniquely determines a probability measure with compact support on the real line, which is also denoted by μ_X.

As an illustration we shall reconstruct the classical probability space from a commutative general probability space $(\mathcal{A},\varphi)$. First, if $(\Omega,\Sigma,\mathbb{P})$ is a classical probability space, then the associated general probability space $(\mathcal{A},\varphi)$ is $\mathcal{A}:=L^\infty(\Omega,\Sigma,\mathbb{P})$ and $\varphi(f):=\int f d\mathbb{P}$, the expectation of f with respect to $\mathbb{P}$. Now, we can *re*construct the events in Σ by considering all projections $p\in\mathcal{A}$, which are of the form $p=1_S$ for some $S\in\Sigma$. Up to equivalence we can then reconstruct the concrete realization of Ω we had.

In this paper we choose to extend the classical definition of independence in the following way.

Definition 2 (independence): Random variables $X_1,\ldots,X_m$ in a general probability space $(\mathcal{A},\varphi)$ are called independent if for all $n\leqslant m$ and polynomials $f_1,\ldots,f_n$, we have

$$\varphi(f_1(X_{k(1)})\cdots f_n(X_{k(n)}))=\varphi(f_1(X_{k(1)}))\cdots\varphi(f_n(X_{k(n)})), \tag{1}$$

provided $k\in\{1,\ldots,m\}^n$ has all components $k(i)$, $1\leqslant i\leqslant n$, different from each other.

A completely noncommutative notion paralleling the idea of independence is the concept of free independence of random variables.

Definition 3 (free independence): Random variables $X_1,\ldots,X_m$ in a general probability space $(\mathcal{A},\varphi)$ are called freely independent if for all $n\in\mathbb{N}$ and polynomials $f_1,\ldots,f_n$ we have

$$\forall i\leqslant n:\varphi(f_i(X_{k(i)}))=0\Rightarrow\varphi(f_1(X_{k(1)})\cdots f_n(X_{k(n)}))=0,$$

provided $k\in\{1,\ldots,m\}^n$ satisfies $k(1)\neq k(2)\neq k(3)\neq\cdots\neq k(n)$.

Proposition 4: Free independence implies independence.

Proof: Suppose $X_1,\ldots,X_m$ are freely independent. Note that (1) is valid for $n=1$. Suppose that (1) is valid for all polynomials $f_1,\ldots,f_{n-1}$ and different indices $k(1),\ldots,k(n-1)$. Now let $f_1,\ldots,f_n$ be given polynomials and $k(1),\ldots,k(n)$ be different indices. By g_j we denote the difference between f_j and the constant $\varphi(f_j(X_{k(j)}))$ so that $\varphi(g_j(X_{k(j)}))=0$. Then free independence implies

$$\varphi(g_1(X_{k(1)})\cdots g_n(X_{k(n)}))=0.$$

Writing out this product, we find

$$\varphi(f_1(X_{k(1)})\cdots f_n(X_{k(n)}))=-\sum_{\gamma\subsetneq\{1,\ldots,n\}}(-1)^{n-\#\gamma}\left(\prod_{i\notin\gamma}\varphi(f_i(X_{k(i)}))\right)\varphi\left(\prod_{j\in\gamma}f_j(X_{k(j)})\right).$$

Since γ contains less than n elements, the expectation of $\Pi_{j\in\gamma}f_j(X_{k(j)})$ factorizes by the induction hypothesis. So all the terms in the sum are equal apart from their sign. Since the sum of these signs is 1, the result follows. □

III. *q*-HARMONIC OSCILLATORS AND THE *q*-DEFORMED FOCK SPACE

In this section we show how the q-deformed Fock space, as introduced in the papers of Bożejko and Speicher,[7,8] is found naturally, starting from the commutation relation. We show how the moments of the q-harmonic oscillator can be expressed in terms of pair partitions.

We start from the operators $\mathbf{1}$ and $a_1,a_2,\ldots,a_m$, generating a *-algebra $\mathcal{A}_q$ and satisfying

$$a_ia_j^*-qa_j^*a_i=\delta_{i,j}\mathbf{1},\quad q\in(-1,1). \tag{2}$$

On $\mathcal{A}_q$ we introduce a linear functional φ_q that we require to satisfy

$$\varphi_q(\mathbf{1})=1, \quad \varphi_q(a_i^* a_{\mathbf{k}}^{\epsilon})=0, \quad \varphi_q(a_{\mathbf{k}}^{\epsilon} a_i)=0, \tag{3}$$

for $i,j\in\{1,...,m\}$, $\mathbf{k}\in\{1,...,m\}^n$, $n\in\mathbb{N}$, and $\epsilon\in\{1,*\}^n$, i.e., a sequence with length n of 1's and $*$'s. So, by $a_{\mathbf{k}}^{\epsilon}$ we mean the ordered product:

$$a_{\mathbf{k}}^{\epsilon}=\prod_{i=1}^{n} \lambda_i, \quad \text{where } \lambda_i=\begin{cases} a_{\mathbf{k}(i)}, & \text{if } \epsilon(i)=1, \\ a_{\mathbf{k}(i)}^*, & \text{if } \epsilon(i)=*. \end{cases}$$

Next, we show the connection between pair partitions and $\varphi_q(a_{\mathbf{k}}^{\epsilon})$. Let $S=\{1,...,n\}$, for some $n\in\mathbb{N}$. A sequence,

$$\Pi=\{(\alpha_1,\beta_1),(\alpha_2,\beta_2),\ldots,(\alpha_{n/2},\beta_{n/2})\}, \quad \text{for } n \text{ even},$$

such that $\cup_{i=1}^{n/2}\{\alpha_i,\beta_i\}=S$, will be called a *pair partition* of S. A pair partition will be ordered in the sense that $\alpha_i<\beta_i$ for all $i\in\{1,...,n/2\}$ and $\alpha_1<\cdots<\alpha_{n/2}$. The collection of all such pair partitions of the set S will be denoted by $\mathcal{P}_2(S)$ or $\mathcal{P}_2(n)$. For n odd this is just the empty set. A crossing in Π is a subset of Π with two elements, $\{(\alpha_i,\beta_i),(\alpha_j,\beta_j)\}$, which satisfies either $\alpha_i<\alpha_j<\beta_i<\beta_j$ or $\alpha_j<\alpha_i<\beta_j<\beta_i$. The set of all crossings of a partition Π can be conveniently labeled by

$$c(\Pi):=\{(i,j)\,|\,1\leqslant i<j\leqslant n/2,\{(\alpha_i,\beta_i),(\alpha_j,\beta_j)\} \text{ is a crossing}\}.$$

Lemma 5: For all $n\in\mathbb{N}$, $n\geqslant 1$, $\epsilon\in\{1,*\}^n$, and $\mathbf{h}\in\{1,...,m\}^n$, we have

$$\varphi_q(a_{\mathbf{h}}^{\epsilon})=\sum_{\Pi\in\mathcal{P}_2(n)} q^{\#c(\Pi)} \prod_{(i,j)\in\Pi} \varphi_q(a_{\mathbf{h}(i)}^{\epsilon(i)} a_{\mathbf{h}(j)}^{\epsilon(j)}). \tag{4}$$

Note that in this notation (i,j) can stand for an element of Π or for a pair of elements. The context will make clear, which is meant.

A pair partition $\Pi\in\mathcal{P}_2(n)$ is compatible with ϵ, denoted $\Pi\sim\epsilon$, if pairs $(\alpha_i,\beta_i)\in\Pi$ are such that $\epsilon(\alpha_i)=1$ and $\epsilon(\beta_i)=*$ for all $i\in\{1,...,n/2\}$. Compatibility of Π with $\mathbf{h}$ means that for each pair $(\alpha_i,\beta_i)\in\Pi$ we have $\mathbf{h}(\alpha_i)=\mathbf{h}(\beta_i)$. Using this notion of compatibility we can rewrite relation (4) as follows:

$$\varphi_q(a_{\mathbf{h}}^{\epsilon})=\sum_{\substack{\Pi\in\mathcal{P}_2(n)\\ \Pi\sim\epsilon,\mathbf{h}}} q^{\#c(\Pi)}. \tag{5}$$

We shall now prove Lemma 5.

Proof: Suppose that $\epsilon\in\{1,*\}^n$ can be written as $(\sigma,1,*,\varrho)$, where $\sigma\in\{1,*\}^k$ and $\varrho\in\{1,*\}^l$, with $k+l+2=n$. Suppose, furthermore, that $\mathbf{i}\in\{1,...,m\}^k$ and $\mathbf{j}\in\{1,...,m\}^l$ with $(\mathbf{h}(1),\ldots,\mathbf{h}(n))=(\mathbf{i}(1),\ldots,\mathbf{i}(k),\mathbf{h}(k+1),\mathbf{h}(k+2),\mathbf{j}(1),\ldots,\mathbf{j}(l))$. Then the following holds:

$$\varphi_q(a_{\mathbf{h}}^{\epsilon})=\varphi_q(a_{\mathbf{i}}^{\sigma} a_{\mathbf{h}(k+1)} a_{\mathbf{h}(k+2)}^* a_{\mathbf{j}}^{\varrho})=\delta_{\mathbf{h}(k+1),\mathbf{h}(k+2)}\varphi_q(a_{\mathbf{i}}^{\sigma} a_{\mathbf{j}}^{\varrho})+q\varphi_q(a_{\mathbf{j}}^{\sigma} a_{\mathbf{h}(k+2)}^* a_{\mathbf{h}(k+1)} a_{\mathbf{j}}^{\varrho}).$$

This relation, together with (3), determines the left-hand side of (4), and therefore φ_q, completely.

We shall refer to the right-hand side of (5) as $F(a_{\mathbf{h}}^{\epsilon})$ putting $F(\mathbf{1})=1$, and shall show that F satisfies the same recursion relation. Let $\Pi\in\mathcal{P}_2(n)$. Then, for every pair $(i,j)\in\Pi$ we have $\varphi_q(a_{\mathbf{h}(i)}^{\epsilon(i)} a_{\mathbf{h}(j)}^{\epsilon(j)})\neq 0$ if and only if $\epsilon(i)=1$ and $\epsilon(j)=*$ and $\mathbf{h}(i)=\mathbf{h}(j)$. There are now two possibilities: $(k+1,k+2)\in\Pi$ or $(k+1,k+2)\notin\Pi$. In the first case $\Pi':=\Pi\backslash\{(k+1,k+2)\}$ is a partition of $\{1,...,k,k+3,...,n\}$ with $\#c(\Pi)=\#c(\Pi')$. In the second case there must be $i<k+1$ and $j>k+2$ such that $(i,k+2)$ and $(k+1,j)$ are crossing pairs in Π. It is then possible to remove the crossing and construct

$$\Pi''=(\Pi\backslash\{(i,k+2),(k+1,j)\})\cup\{(i,k+1),(k+2,j)\},$$

for which $\#c(\Pi'')=\#c(\Pi)-1$. Now we have $\Pi''\sim(\sigma,*,1,\varrho),\mathbf{h}''$, where $\mathbf{h}''=(\mathbf{i},\mathbf{h}(k+2),\mathbf{h}(k+1),\mathbf{j})$. Note that conversely every pair partition of n, compatible with $\boldsymbol{\epsilon}$ and $\mathbf{h}$ but not containing $(k+1,k+2)$, can be found in $\mathcal{P}_2(n)$ as an element with a crossing between the two pairs that contain $k+1$ and $k+2$. We find

$$
\begin{aligned}
F(a^{\boldsymbol{\epsilon}}_{\mathbf{h}}) &:= \sum_{\substack{\Pi\in\mathcal{P}_2(n)\\ \Pi\sim\boldsymbol{\epsilon},\mathbf{h}}} q^{\#c(\Pi)} \\
&= \sum_{\substack{\Pi\in\mathcal{P}_2(n)\\ \Pi\sim(\sigma,1,*,\varrho)\mathbf{h}\\ (k+1,k+2)\in\Pi}} q^{\#c(\Pi)} + \sum_{\substack{\Pi\in\mathcal{P}_2(n)\\ \Pi\sim(\sigma,1,*,\varrho)h\\ (k+1,k+2)\notin\Pi}} q^{\#c(\Pi)} \\
&= \delta_{\mathbf{h}(k+1),\mathbf{h}(k+2)} \sum_{\substack{\Pi'\in\mathcal{P}_2(n-2)\\ \Pi'\sim(\sigma,\varrho),(\mathbf{i},\mathbf{j})}} q^{\#c(\Pi')} + \sum_{\substack{\Pi''\in\mathcal{P}_2(n)\\ \Pi''\sim(\sigma,*,1,\varrho),\mathbf{h}''}} q^{\#c(\Pi'')+1} \\
&= \delta_{\mathbf{h}(k+1),\mathbf{h}(k+2)} F(a^{\sigma}_{\mathbf{i}}a^{\varrho}_{\mathbf{j}}) + qF(a^{\sigma}_{\mathbf{i}}a^{*}_{\mathbf{h}(k+2)}a_{\mathbf{h}(k+1)}a^{\varrho}_{\mathbf{j}}).
\end{aligned}
$$

Relation (5) now follows because the right-hand side $F(a^{\boldsymbol{\epsilon}}_{\mathbf{h}})$ satisfies the same recursion relation as $\varphi(a^{\boldsymbol{\epsilon}}_{\mathbf{h}})$ with the boundary conditions (3). □

Since the position operator of a harmonic oscillator is usually represented by an operator of the form

$$X_i := a_i + a_i^*,$$

we define X_i to be the position of a q-harmonic oscillator and show that its moments under φ_q can be calculated as a sum over partitions. The operators X_i, $i\in\{1,...,m\}$, generate the *-algebra $\mathfrak{B}_q\subset\mathcal{A}_q$. We shall refer to $\mathfrak{B}_q$ as the q-harmonic oscillator algebra. Let ρ_q denote the restriction of φ_q to $\mathfrak{B}_q$.

Theorem 6: For all $\mathbf{h}\in\{1,...,m\}^n$, $n\in\mathbb{N}$, we have

$$\rho_q(X_{\mathbf{h}}) = \sum_{\Pi\in\mathcal{P}_2(n)} q^{\#c(\Pi)} \prod_{(l,m)\in\Pi} \delta_{\mathbf{h}(l),\mathbf{h}(m)}.$$

Proof: This follows from Lemma 5 by summation over all $\boldsymbol{\epsilon}\in\{1,*\}^n$. □

Corollary 7: The linear functional ρ_q satisfies the following.

(1) For all $j\in\{1,...,m\}$ and $n\in\mathbb{N}$, we have

$$\rho_q(X_j^n) = \sum_{\Pi\in\mathcal{P}_2(n)} q^{\#c(\Pi)}.$$

(2) For $\mathbf{i}\in\{1,...,m\}^n$ and a cyclic permutation $\tau\in S_n$, we have

$$\rho_q(X_{\mathbf{i}(\tau(1))}\cdots X_{\mathbf{i}(\tau(n))}) = \rho_q(X_{\mathbf{i}(1)}\cdots X_{\mathbf{i}(n)}).$$

Proof of 1: Put $\mathbf{h}(1)=\cdots=\mathbf{h}(n)=j$ in Theorem 6. □

Before proving (2) we first give some considerations concerning pair partitions.

The usual way to visualize a partition, $\Pi\in\mathcal{P}_2(S)$, would be to draw the elements of S on a straight line and connect every two points belonging to the same pair in Π with an arc above the

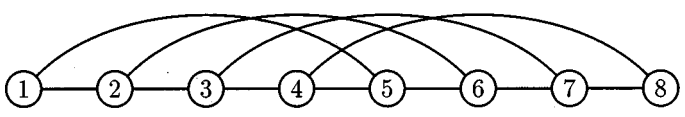

FIG. 1. The line representation of the partition $\Pi=\{(1,5),(2,6),(3,7),(4,8)\}$.

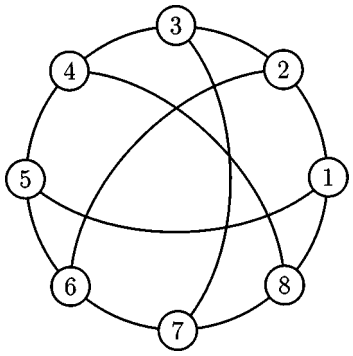

FIG. 2. A circle representation of the partition $\Pi=\{(1,5),(2,6),(3,7),(4,8)\}$.

line in such a way that two different lines cross at most once and no three lines intersect in one point. As an example, in Fig. 1 we draw the partition $\Pi=\{(1,5),(2,6),(3,7),(4,8)\}$. We will refer to this method of visualization as the line representation of a pair partition.

Another way to visualize a pair partition is its circle representation. This consists in drawing the points of S on a circle and connecting them by lines inside the circle, subject to the same restrictions. An example is given in Fig. 2. We note that this can be done in more than one way.

To make the circle representation of pair partitions explicit, we regard the circle as the unit circle in $\mathbb{C}$, and we make the map

$$\mathfrak{T}:S\to\mathbb{C}:s\mapsto e^{2i(s-1)\pi/n}.$$

This map converts every pair $(\alpha,\beta)\in\Pi$ to a pair (f,g) on the unit circle in $\mathbb{C}$.

Definition 8: Two pairs (f,g) and (f',g') of different points on the unit circle in $\mathbb{C}$ are said to be separated if and only if the straight line from f to g crosses the straight line from f' to g' inside the unit circle.

(See Fig. 3.) It is obvious that two pairs (α_i,β_i) and (α_j,β_j) in a partition Π are crossing if and only if the pairs $(\mathfrak{T}(\alpha_i),\mathfrak{T}(\beta_i))$ and $(\mathfrak{T}(\alpha_j),\mathfrak{T}(\beta_j))$ are separated. Let $\tau\in S_n$ be a cyclic permutation and $\Pi\in\mathcal{P}_2(n)$ any pair partition. By $\tau(\Pi)$ we denote the rotated partition:

$$\tau(\Pi):=\{(\tau(\alpha_1),\tau(\beta_1)),\ldots,(\tau(\alpha_{n/2}),\tau(\beta_{n/2}))\}.$$

Since separated pairs on the unit circle remain separated under rotation, we have

$$\#c(\Pi)=\#c(\tau(\Pi)). \tag{6}$$

We now turn to the proof of the second part of Corollary 7.

Proof of (2): The essence of the proof that ρ_q has this cyclic property is the fact that the circle representation of a partition $\Pi\in\mathcal{P}_2(n)$ also has this cyclic property. This is shown in Fig. 4.

More formally, for $\mathbf{i}\in\{1,\ldots,m\}^n$ and $\tau\in S_n$ cyclic, we have the following:

FIG. 3. Two separated and two nonseparated pairs.

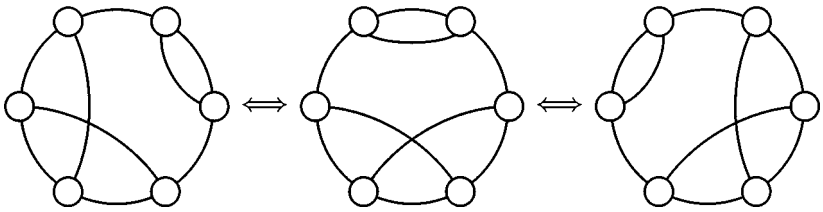

FIG. 4. The linear functional ρ_q satisfies a cyclic property.

$$\rho_q(X_{\mathbf{i}(\tau(1))}\cdots X_{\mathbf{i}(\tau(n))}) = \sum_{\Pi\in\mathcal{P}_2(n)} q^{\#c(\Pi)} \prod_{(l,m)\in\Pi} \delta_{\mathbf{i}(\tau(l)),\mathbf{i}(\tau(m))}$$

$$= \sum_{\Pi\in\mathcal{P}_2(n)} q^{\#c(\Pi)} \prod_{(l,m)\in\tau(\Pi)} \delta_{\mathbf{i}(l),\mathbf{i}(m)}$$

$$= \sum_{\Pi\in\mathcal{P}_2(n)} q^{\#c(\tau^{-1}(\Pi))} \prod_{(l,m)\in\Pi} \delta_{\mathbf{i}(l),\mathbf{i}(m)} = \rho_q(X_{\mathbf{i}(1)}\cdots X_{\mathbf{i}(n)}).$$

We shall represent the pair $(\mathcal{A}_q,\varphi_q)$ on a Hilbert space $\mathcal{K}$ with inner product $\langle\cdot,\cdot\rangle_q$ in which a unit vector Ψ, from now on referred to as vacuum vector, is singled out. To make this representation explicit, let $\mathfrak{h}$ be a Hilbert space with $\dim\mathfrak{h}=m$ and orthonormal basis $\{e_1,\ldots,e_m\}$. Because of (3) we require that for all $i\in\{1,\ldots,m\}$:

$$a_i\Psi = 0.$$

If now we put for all $\mathbf{k}\in\{1,\ldots,m\}^n$:

$$a^*_{\mathbf{k}(1)}a^*_{\mathbf{k}(2)}\cdots a^*_{\mathbf{k}(n)}\Psi =: e_{\mathbf{k}(1)}\otimes\cdots\otimes e_{\mathbf{k}(n)},$$

then we see that for $\mathcal{K}$ we can take the full Fock space over $\mathfrak{h}$, denoted $\mathcal{F}(\mathfrak{h})$:

$$\mathcal{F}(\mathfrak{h}) := \bigoplus_{i=1}^{\infty} \mathfrak{h}^{\otimes i}, \quad \mathfrak{h}^{\otimes 0} := \mathbb{C},$$

with vacuum vector $\Psi = 1\oplus 0\oplus 0\oplus\cdots$. We define a bilinear form $\langle\cdot,\cdot\rangle_q$ on $\mathcal{K}$ as follows:

$$\langle e_{\mathbf{k}(1)}\otimes\cdots\otimes e_{\mathbf{k}(n)}, e_{\mathbf{l}(1)}\otimes\cdots\otimes e_{\mathbf{l}(n')}\rangle_q = \langle a^*_{\mathbf{k}(1)}\cdots a^*_{\mathbf{k}(n)}\Psi, a^*_{\mathbf{l}(1)}\cdots a^*_{\mathbf{l}(n')}\Psi\rangle_q$$

$$:= \varphi_q(a_{\mathbf{k}(n)}\cdots a_{\mathbf{k}(1)}a^*_{\mathbf{l}(1)}\cdots a^*_{\mathbf{l}(n')})$$

$$= \sum_{\Pi\in\mathcal{P}_2(n+n')} q^{\#c(\Pi)} \prod_{(p,q)\in\Pi} \varphi_q(a^{\epsilon(p)}_{\mathbf{h}(p)}a^{\epsilon(q)}_{\mathbf{h}(q)}),$$

for $l\in\{1,\ldots,m\}^{n'}$, $n'\in\mathbb{N}$, $\mathbf{h}=(\mathbf{k}(n),\ldots,\mathbf{k}(1),\mathbf{l}(1),\ldots,l(n))\in\{1,\ldots,m\}^{n+n'}$, and $\epsilon\in\{1,*\}^{n+n'}$, such that $\epsilon(1)=\cdots=\epsilon(n)$ and $\epsilon(n+1)=\cdots=\epsilon(n+n')=*$. Bożejko and Speicher in Ref. 7 show positivity of the bilinear form $\langle\cdot,\cdot\rangle_q$ by proving positive definiteness of the function $S_n\to\mathbb{C}$: $\sigma\mapsto q^{\#i(\sigma)}$. Here the set $i(\sigma)$ is the set of inversions of the permutation $\sigma\in S_n$:

$$i(\sigma) := \{(l,m)\,|\,1\leq l<m\leq n, \sigma(l)>\sigma(m)\}.$$

Because of its positivity, the bilinear form $\langle\cdot,\cdot\rangle_q$ can be regarded as an inner product on $\mathcal{K}$, so we conclude that the linear functional φ_q is, in fact, a state. Therefore the second part of Corollary 7 implies that ρ_q is a trace state.

Since $\varphi_q(a^{\epsilon(p)}_{\mathbf{h}(p)}a^{\epsilon(q)}_{\mathbf{h}(q)})$ only yields something different from 0 for $\epsilon(p)=1$ and $\epsilon(q)=*$, we know that $\langle\cdot,\cdot\rangle_q\neq 0$ only in case $n=n'$, and that the partitions $\Pi\in\mathcal{P}_2(2n)$ contributing to this

inner product have to be compatible with ϵ. This only happens for partitions where, for all $i \in \{1,...,n\}$, we have $1 \leqslant \alpha_i \leqslant n$ and $n+1 \leqslant \beta_i \leqslant 2n$. There are exactly $n!$ of these partitions in $\mathcal{P}_2(2n)$, to be labeled by permutations σ of $\{1,...,n\}$. We find

$$\varphi_q(a_{\mathbf{h}}^{\epsilon}) = \delta_{n,n'} \sum_{\substack{\Pi \in \mathcal{P}_2(2n) \\ \Pi \sim \epsilon}} q^{\#c(\Pi)} \prod_{(p,q)\in\Pi} \delta_{\mathbf{h}(p),\mathbf{h}(q)} = \delta_{n,n'} \sum_{\sigma \in S_n} q^{\#i(\sigma)} \delta_{\mathbf{h}(1),\mathbf{h}(\sigma(1))} \cdots \delta_{\mathbf{h}(n),\mathbf{h}(\sigma(n))}.$$

Repeated use of the commutation relations (2) and the fact that $a_i \Psi = 0$ for all $i \in \{1,...,m\}$ yields, for all $\mathbf{h} \in \{1,...,m\}^n$, the following action of a_i:

$$a_i e_{\mathbf{h}(1)} \otimes \cdots \otimes e_{\mathbf{h}(n)} := \sum_{j=1}^{n} q^{j-1} \delta_{i,\mathbf{h}(j)} e_{\mathbf{h}(1)} \otimes \cdots \check{e}_{\mathbf{h}(j)} \cdots \otimes e_{\mathbf{h}(n)},$$

where by $e_{\mathbf{h}(1)} \otimes \cdots \check{e}_{\mathbf{h}(j)} \cdots \otimes e_{\mathbf{h}(n)}$ we mean the tensor product $e_{\mathbf{h}(1)} \otimes \cdots \otimes e_{\mathbf{h}(j-1)} \otimes e_{\mathbf{h}(j+1)} \otimes \ldots \otimes e_{\mathbf{h}(n)}$.

IV. THE DISCRETE LATTICE $\mathcal{T}(N,d)$

For d, $N \in \mathbb{N}$ we will define the Parisi model on a discrete d-dimensional lattice:

$$\mathcal{T}(N,d) := \{-N,\ldots,0,...,N\}^d.$$

Define the set of h-dimensional, $h \in \mathbb{N}$, elementary facets (i.e., points, edges, planes, etc.) in $\mathcal{T}(N,d)$ as follows:

$$\mathcal{X}_h := \{(v,\gamma) \in \mathcal{T}(N,d) \times \mathcal{P}_h(\{1,...,d\}) | j \in \gamma \Rightarrow v(j) \neq N\},$$

where $\mathcal{P}_h(\{1,...,d\})$ is the collection of all subsets of $\{1,...,d\}$ that contain exactly h elements. In this notation (v,γ) stands for the elementary facet, which has $v \in \mathcal{T}(N,d)$ as its lowest vertex, and whose spatial orientation is defined by the set of spatial directions $\gamma \subset \{1,2,...,d\}$. Then $\mathcal{X}_0$ stands for the set $\mathcal{T}(N,d)$ of vertices itself, $\mathcal{X}_1$ is the set of edges in $\mathcal{T}(N,d)$, and $\mathcal{X}_2$ is the set of two-dimensional planes in $\mathcal{T}(N,d)$, from now on referred to as plaquettes. By $\mathcal{G}_h$ we shall mean the set of all functions from $\mathcal{X}_h$ to $\mathbb{Z}$:

$$\mathcal{G}_h := \mathbb{Z}^{\mathcal{X}_h},$$

and by Ω_h the set of all functions from $\mathcal{X}_h$ to $\mathbb{C}$:

$$\Omega_h := \mathbb{C}^{\mathcal{X}_h}.$$

Then Ω_h is the set of ''forms'' on $\mathcal{X}_h$. They are a discrete analog of the differential forms of Cartan. The set Ω of all differential forms will be denoted by $\Omega := \oplus_{h=0}^{\infty} \Omega_h$. Similarly, we define $\mathcal{G} := \oplus_{h=0}^{\infty} \mathcal{G}_h$. Note that $\#(\mathcal{X}_h) = \dim \mathcal{G}_h = \dim \Omega_h = \binom{d}{h}(2N)^h(2N+1)^{d-h}$. An element of $\mathcal{G}_1$ will be called a curve [on $\mathcal{T}(N,d)$] and an element of $\mathcal{G}_2$ will be called a surface [on $\mathcal{T}(N,d)$]. The mapping,

$$L: \mathcal{G}_1 \to \mathbb{N}: l \mapsto \sum_{j \in \mathcal{X}_1} |l(j)|,$$

associates to a curve its length, and the mapping,

$$A: \mathcal{G}_2 \to \mathbb{N}: k \mapsto \sum_{j \in \mathcal{X}_2} |k(j)|,$$

sends a surface to its area. By a *walk* of length $n \in \mathbb{N}$ on $\mathcal{T}(N,d)$ we shall mean a series of consecutively neighboring points $(\alpha_1,\ldots,\alpha_n)$ in $\mathcal{T}(N,d)$ that trace out a curve $l \in \mathcal{G}_1$. This curve l assigns to every edge $x \in \mathcal{X}_1$, the number of times the walk $(\alpha_1,\ldots,\alpha_n)$ runs through x in positive direction minus the number of times this walk runs through x in the negative direction. So

a curve is thought of as just any configuration of edges equipped with a direction and a multiplicity. A surface is conceived of analogously. A walk will be called *closed* if $\alpha_1=\alpha_n$.

We define the integral of an h-form $\omega\in\Omega_h$ over some element $k\in\mathcal{G}_h$ as follows.

Definition 9:

$$\int_k \omega := \langle k,\omega\rangle = \sum_{x\in\mathcal{X}_h} k(x)\omega(x).$$

We define the boundary and coboundary operators $\partial_h:\mathcal{G}_h\to\mathcal{G}_{h-1}$ and $\delta_h:\Omega_h\to\Omega_{h+1}$ as follows:

$$(\partial_h g)(v,\gamma) := \sum_{j\notin\gamma} \epsilon(j,\gamma)\big(g(v-e_j,\gamma\cup\{j\})-g(v,\gamma\cup\{j\})\big) \quad h\geqslant 1,$$

$$(\delta_h f\ )(v,\gamma) := \sum_{j\in\gamma} \epsilon(j,\gamma\backslash\{j\})\big(f(v+e_j,\gamma\backslash\{j\})-f(v,\gamma\backslash\{j\})\big), \quad h\geqslant 0,$$

where $\epsilon(j,\varrho):=(-1)^{\#\{i\in\varrho|i<j\}}$ and e_j, $j\in\{1,...,d\}$, denotes the unit vector in the jth direction in $\mathcal{T}(N,d)$. We define the operator δ on Ω as δ_h for a differential form in Ω_h, so $\delta_h=\delta|_{\Omega_h}$. The operator δ can be considered the discrete version of the derivative operator on h forms. The operator ∂ on $\mathcal{G}$, defined as $\partial_h=\partial|_{\mathcal{G}_h}$, will be referred to as the boundary operator, since it yields the $(h-1)$-dimensional boundary of an h-dimensional object for $h\geqslant 1$. Stokes' theorem is the statement that δ and ∂ are each other's adjoints.

Theorem 10 (Stokes): For $\omega\in\Omega_h$ and $k\in\mathcal{G}_{h+1}$, we have

$$\int_k \delta\omega = \int_{\partial k}\omega.$$

Proof: By $1_{(v,\gamma)}$ we denote the characteristic function of $(v,\gamma)\in\mathcal{X}_1$. Then to prove this theorem it suffices to show that $\langle\partial 1_{(v,\gamma)},\omega\rangle=\langle 1_{(v,\gamma)},\delta\omega\rangle$ for every $(v,\gamma)\in\mathcal{X}_{h+1}$ and $\omega\in\Omega_h$:

$$\begin{aligned}\langle\partial 1_{(v,\gamma)},\omega\rangle &= \sum_{(w,\varrho)\in\mathcal{X}_h}(\partial 1_{(v,\gamma)})(w,\varrho)\omega(w,\varrho)\\ &= \sum_{(w,\varrho)\in\mathcal{X}_h}\sum_{j\notin\varrho}\epsilon(j,\varrho)\big(1_{(v,\gamma)}(w-e_j,\varrho\cup\{j\})-1_{(v,\gamma)}(w,\varrho\cup\{j\})\big)\omega(w,\varrho)\\ &= \sum_{j\in\gamma}\epsilon(j,\gamma\backslash\{j\})\big(\omega(v+e_j,\gamma\backslash\{j\})-\omega(v,\gamma\backslash\{j\})\big)=(\delta\omega)(v,\gamma)=\langle 1_{(v,\gamma)},\delta\omega\rangle. \quad \square\end{aligned}$$

Theorem 11: $\delta^2=0$.

Proof: For $\omega\in\Omega_h$ and $i<j$ we have, for all $(v,\gamma)\in\mathcal{X}_{h+2}$:

$$(\delta_{h+1}\delta_h\omega)(v,\gamma)=\sum_{i\in\gamma}\epsilon(i,\gamma)\big(\delta_h\omega(v+e_i,\gamma\backslash\{i\})-\delta_h\omega(v,\gamma\backslash\{i\})\big)=\sum_{\substack{i,j\in\gamma\\ i\neq j}}F(i,j)G(i,j),$$

where

$$F(i,j)=\epsilon(i,\gamma)\epsilon(j,\gamma\backslash\{i\})$$

and

$$G(i,j)=\omega(v+e_i+e_j,\gamma\backslash\{i,j\})-\omega(v+e_i,\gamma\backslash\{i,j\})-\omega(v+e_j,\gamma\backslash\{i,j\})+\omega(v,\gamma\backslash\{i,j\}).$$

Note that G is symmetric and F is antisymmetric:

$$F(i,j)F(j,i)=\epsilon(i,\gamma)\epsilon(j,\gamma\backslash\{i\})\epsilon(j,\gamma)\epsilon(i,\gamma\backslash\{j\})$$
$$=(-1)^{\#\{k\in\gamma|k<i\}}(-1)^{\#\{k\in\gamma\backslash\{i\}|k<j\}}(-1)^{\#\{k\in\gamma|k<j\}}(-1)^{\#\{k\in\gamma\backslash\{j\}|k<i\}}=-1.$$

Therefore $\delta_{h+1}\delta_h\omega=\Sigma_{i,j\in\gamma}F(i,j)G(i,j)=0$ for all $\omega\in\Omega_h$. □

Because $\partial=\delta^*$, viewed as $(\#\mathcal{X}_h)\times(\#\mathcal{X}_{h+1})$ matrices, Corollary 12 immediately follows.

Corollary 12: $\partial^2=0$.

Definition 13: An element $p\in\mathcal{G}_h$ is called closed if $\partial_h(p)=0$.

We shall call a closed curve a *loop*. The boundary of a surface k is always a loop since $\partial^2 k=0$. We shall say that $\partial_2 k$ *spans* k. With every loop l we can associate a class of surfaces $\Gamma_l:=\{k\in\mathcal{G}_2|\partial_2 k=l\}$, the class of surfaces spanned by l. A surface $p\in\Gamma_l$ will be called *minimal*, with respect to l, if its area $A(p)$ is minimal in $A(\Gamma_l)$.

Definition 14: By the area $A(l)$ of a loop we shall mean the area of a surface that is minimal with respect to l.

A closed walk traces out a loop. By the area of a closed walk $(\alpha_1,\ldots,\alpha_n=\alpha_1)$ we shall mean the area of the loop traced out by this walk, and denote it by $A((\alpha_1,\ldots,\alpha_n))$.

V. THE PARISI MODEL

In the description of the Parisi model we try to stay as close as possible to the notation used in Ref. 1.

Consider $\mathcal{T}(N,d)$ and put on every plaquette a magnetic field, i.e., we define a 2-form $B\in\Omega_2$ with strength $\mathcal{B}\in[0,\pi]$, the sign of which will be chosen independently for every pair of spatial directions:

$$B(v,\{i,j\})=S_{\{i,j\}}\mathcal{B},$$

where $S_{\{i,j\}}$ is a random variable depending on the pair $\{i,j\}$. The random variable $S_{\{i,j\}}$ is a coin toss, i.e., the value of $S_{\{i,j\}}$ is chosen from $\{-1,1\}$ with distribution $\{1/2,1/2\}$. It is obvious that, for any of the $2^{d(d-1)/2}$ choices for S, the constant field B on $\mathcal{T}(N,d)$ is divergence-free: $\delta B=0$. We put $q:=\cos\mathcal{B}$; then $q\in[-1,1]$.

By $\Phi(k)$ we denote the magnetic flux through some surface $k\in\mathcal{G}_2$. This flux is simply the sum of the fluxes through the plaquettes in k, which, by Definition 9, equals

$$\Phi(k)=\sum_{x\in\mathcal{X}_2}k(x)B(x)=\int_k B.$$

We define the magnetic flux enclosed by a loop $l\in\mathcal{G}_1$ as the flux $\Phi(k)$ for some k spanned by l, and denote it by $\Phi(l)$. Since the field B is divergence-free there must exist some $A\in\Omega_1$ for which $\delta_1 A=B$. Indeed, if, for $k\in\{1,\ldots,d\}$ we choose any $\mathcal{C}_0,\ldots,\mathcal{C}_d\in\mathbb{R}$, and put

$$A(w,\{k\})=\mathcal{C}_0+\sum_{j=1}^{k-1}(\mathcal{C}_j+w(j)S_{\{j,k\}}\mathcal{B});$$

then the requirement $\delta_1 A=B$ is fulfilled, as can be checked easily by calculating $(\delta_1 A)$ at $(v,\{i,j\})$ explicitly. By Stokes' theorem we find, for $\Phi(l)$,

$$\Phi(l)=\int_k\delta A=\int_l A=\sum_{x\in\mathcal{X}_1}l(x)A(x),$$

for all $k\in\Gamma_l$. So $\Phi(l)$ is well defined and does not depend on the choice of k.

Let the magnetic field B on $\mathcal{T}(N,d)$ induce a deformation of the nearest-neighbor $(2N+1)^d\times(2N+1)^d$-interaction matrix or lattice Laplacian, leading to the deformed lattice Laplacian Δ_q. This matrix $(\Delta_q)_{v,w\in\mathbb{N}^d}$ is defined by

$$|(\Delta_q)_{v,w}|=\begin{cases}1, & \text{if } |v-w|=1, \quad \text{for } v,w\in\mathcal{X}_0,\\ 0, & \text{otherwise,}\end{cases}$$

where the phases are determined by the field

$$(\Delta_q)_{v,v+e_k} := e^{iA(v,\{k\})},$$

$$(\Delta_q)_{v+e_k,v} := e^{-iA(v,\{k\})},$$

for all $(v,\{k\}) \in \mathcal{X}_1$. From this definition it is clear that $(\Delta_q)_{v,w} = \overline{(\Delta_q)_{w,v}}$. Now let

$$W(l) := e^{i\Phi(l)} = \prod_{x \in \mathcal{X}_1} e^{il(x)A(x)}$$

be the product of the Δ_q's along a loop l. $W(l)$ is known as the ''Wilson loop,'' although $W(l)$ itself is not a loop but a complex number assigned to the loop l. For a closed walk l' that traces out a loop $l \in \mathcal{G}_1$ we have that the product of the Δ_q's along l' equals the product of the Δ_q's along l, hence $W(l') = W(l)$.

We define an operator $\hat{X}$ as follows:

$$\hat{X} = \frac{1}{\sqrt{2d}} \Delta_q, \tag{7}$$

where the overcaret symbolizes the dependence on N and d. Then $\hat{X}$ is an element in the algebra $\mathcal{A}$ of matrix-valued functions,

$$\{-1,+1\}^{\binom{d}{2}} \to M_{(2N+1)^d}, \tag{8}$$

where $\{-1,+1\}^{\binom{d}{2}}$ is the space of outcomes of the coin tosses and $M_{(2N+1)^d}$ denotes the $(2N+1)^d \times (2N+1)^d$ matrices with complex entries. On $M_{(2N+1)^d}$ we have a normalized trace $\mathrm{tr} = (1/(2N+1)^d)\,\mathrm{Tr}$, where Tr is the standard trace on $M_{(2N+1)^d}$. Since we have here a trace that satisfies $\mathrm{tr}(\mathbf{1}) = 1$, its expectation can serve as a generalized probability measure (a state) $\hat{\varphi}$ on $\mathcal{A}$, and it is therefore possible to calculate generalized expectations of elements of $\mathcal{A}$:

$$\hat{\varphi}(\hat{X}^n) := \hat{\mathbb{E}}(\mathrm{tr}(\hat{X}^n)) = \frac{1}{(2d)^{n/2}(2N+1)^d}\, \hat{\mathbb{E}}(\mathrm{Tr}(\Delta_q^n)), \quad \text{for all } n \in \mathbb{N}.$$

Here $\hat{\mathbb{E}}$ yields the expectation value with respect to the $d(d-1)/2$ coin tosses. The standardization factor $1/\sqrt{2d}$ in (7) ensures that $\hat{X}$ has variance 1 in the limit $N \to \infty$. It remains to show that indeed $\hat{\varphi}(\hat{X}^n)$ can be interpreted as a sum over walks on $\mathcal{T}(N,d)$:

$$\hat{\varphi}(\hat{X}^n) = \frac{1}{(2N+1)^d}\, \hat{\mathbb{E}}(\mathrm{Tr}(\hat{X}^n)) = \frac{1}{(2N+1)^d}\, \hat{\mathbb{E}}\left(\sum_{i_1 \in \mathcal{T}(N,d)} \cdots \sum_{i_n \in \mathcal{T}(N,d)} \hat{X}_{i_1,i_2} \hat{X}_{i_2,i_3} \cdots \hat{X}_{i_n,i_1} \right). \tag{9}$$

The product $\hat{X}_{i_1,i_2} \cdots \hat{X}_{i_n,i_1}$ on the right-hand side of this equation yields something different from 0 if and only if

$$|i_1 - i_2| = |i_2 - i_3| = \cdots = |i_{n-1} - i_n| = |i_n - i_1| = 1;$$

$(i_1,i_2,i_3,\ldots,i_n,i_1)$ is a closed walk on $\mathcal{T}(N,d)$ that starts from i_1 and returns to i_1 and hence describes a loop in $\mathcal{G}_1$. If the walk crosses some point in $\mathcal{T}(N,d)$ more than once, then there is more than one walk yielding the same loop. Therefore the sum over walks in (9) cannot be reduced to a sum over loops easily. However, we shall see that in the limit $d \to \infty$ only a narrow class of walks survive.

VI. PAIR PARTITIONS, WALKS, AND LOOPS

In this section we shall describe the connection between pair partitions, as described in the Introduction, closed walks on $\mathcal{T}(N,d)$, and loops in $\mathcal{G}_1$.

Suppose we have some $\Pi \in P_2(S)$ consisting of n pairs $(\alpha_1,\beta_1),\ldots,(\alpha_n,\beta_n)$ for $S=\{1,\ldots,2n\}$. To every pair (α_1,β_1), $i\in\{1,\ldots,n\}$, we assign the unit vector in the ith direction, e_i. Now for every element $s\in S$, starting with 1, we make a step in the lattice in the direction assigned to the pair in Π to which this number belongs. If s is the first element of such a pair, then the step will be taken in the positive direction. If s is the second element of such a pair, then the step will be taken in the negative direction. If we choose the origin as a starting point for our walks, then we always get a loop on $\{0,1\}^n$, the corners of the unit cube in n dimensions.

For fixed Π, define a mapping $\sigma_\Pi : S\to\{1,\ldots,n\}$ that indicates to what pair $s\in S$ belongs: $\sigma_\Pi(s)=i$ if $s\in(\alpha_i,\beta_i)$. Furthermore, define a mapping $\vartheta_\Pi : S\to\{-1,+1\}$ that indicates whether it is the first or the second element of this pair: $\vartheta_\Pi(s)=1$ if $s=\alpha_i$ and $\vartheta_\Pi(s)=-1$ if $s=\beta_i$. To keep track of our walk we define a mapping $v:S\to\mathcal{X}_0$ as follows:

$$v(s) := \sum_{j=1}^{s} \vartheta_\Pi(j) e_{\sigma_\Pi(j)}, \quad \text{with } v(0) := 0.$$

To fix the starting point and direction of every edge in the walk, we need the following mapping:

$$w: S\to\mathcal{X}_0 : i \mapsto \min(v(i-1),v(i)),$$

where $\min(v(i-1),v(i))$ is the component-wise minimum of $v(i-1)$ and $v(i)$. Now, let $\gamma_1:\mathcal{P}_2(S)\to\mathcal{G}_1$ associate to Π the loop in $\mathcal{G}_1$ traced out by the walk $(0,v(1),v(2),\ldots,v(2n-1),0)$:

$$\gamma_1(\Pi) := \sum_{j=1}^{2n} \vartheta_\Pi(j) 1_{(w(j),\{\sigma_\Pi(j)\})}.$$

Then one easily checks that $\gamma_1(\Pi)$ is indeed a loop, i.e., $\partial_1\gamma_1(\Pi)=0$.

Apart from γ_1 we shall also need an injective mapping $\gamma_2:\mathcal{P}_2(S)\to\mathcal{G}_2$ that maps a partition to a surface spanned by $\gamma_1(\Pi)$. To this end let us regard the pair partition in the circle representation as a planar graph with a closed outer edge. For every planar graph we can construct a dual by regarding every sector inside the outer edge of the graph as a vertex in the dual graph. The vertices in the dual graph are then connected by edges when the corresponding sectors have an edge in common.

Definition 15: The dual graph of a pair partition is the dual of the planar graph generated by its circle representation.

Figure 5 shows the construction of the dual graph of the partition $\Pi=\{(1,5),(2,6),(3,7),(4,8)\}$. To construct γ_2, consider a planar graph, H, given by a circle representation of a pair partition $\Pi\in\mathcal{P}_2(S)$. The disk sectors in this graph represent elements of $\mathcal{X}_0$, as is clear from the construction of the circle representation. Namely, we assign to sectors in

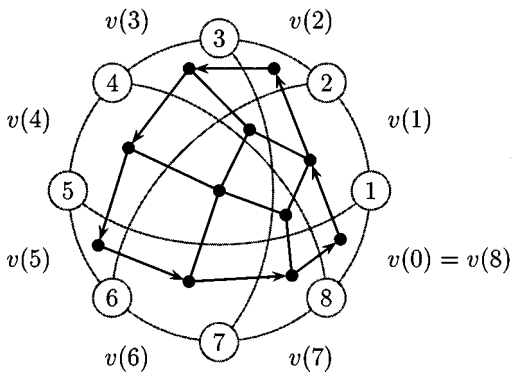

FIG. 5. The dual graph of the pair partition $\Pi=\{(1,5),(2,6),(3,7),(4,8)\}$. The orientation of the walk that traces out $\gamma_1(\Pi)$ is indicated by arrows.

H a vertex in space as follows: denote by A_0 the sector in H that has an edge in common with the circle segment between 1 and $2n$. Then to every sector A in H we associate a vertex $y=(y(1),\ldots,y(n))$ according to the rule.

$$y(i)=\begin{cases}0, & \text{if } A \text{ and } A_0 \text{ lie on the same side of the connecting line with index } i,\\ 1, & \text{otherwise.}\end{cases}$$

As a consequence to A_0 is associated $0\in\{0,1\}^n$. This procedure is illustrated in Fig. 6, which shows a picture of the partition $\Pi=\{(1,5),(2,4),(3,6)\}$ with the corner points in every sector as an element of $\{0,1\}^3$. Since two sectors in the graph that have an edge in common can be associated to points in $\mathcal{X}_0$ that differ only one step in the direction corresponding to the shared edge, we can connect two such points by an edge in the dual graph, H', of Π, corresponding to an edge in $\mathcal{X}_1$. This way the sectors in H' point at plaquettes in $\mathcal{X}_2$, since every crossing of connecting lines in H has four sectors in H that share that point. Since any two lines cross at most once, the number of plaquettes enclosed by H' is equal to $\#c(\Pi)$, the number of crossings of Π. In fact, H' contains a plaquette, based upon the minimum of its four corner points, u_{ij}, for every pair $(i,j)\in c(\Pi)$. We can now define

$$\gamma_2(\Pi):=\sum_{(i,j)\in c(\Pi)} 1_{(u_{ij},\{i,j\})}.$$

Note that every plaquette in $\gamma_2(\Pi)$ receives positive orientation in this definition.

Theorem 16: *For every* $\Pi\in\mathcal{P}_2(2n)$ *we have* $\partial_2\gamma_2(\Pi)=\gamma_1(\Pi)$.

The content of this theorem becomes apparent if one realizes that the outer edge of the dual graph of the pair partition Π represents the walk $(v(0),v(1),\ldots,v(2n))$, as shown in Fig. 5. It is immediately clear that noncrossing partitions $\Pi\in\mathcal{P}_2(2n)$ yield $\gamma_2(\Pi)=0$, so we have $\partial_2\gamma_2(\Pi)=0$. This agrees with $\gamma_1(\Pi)=0$: every step that is taken is retraced later. This, however, will be a special case of the proof we shall give.

Proof: Let H be the planar graph given by the circle representation of Π. Fix an edge $(v,\{i\})$ in the dual graph, H', of Π. This edge crosses a segment, κ, of the ith connecting line in H. There are now three possibilities.

(1) The segment κ is the ith connecting line itself, i.e., the ith connecting line crosses no other connecting lines in H.

(2) The segment κ connects the edge of the circle to a crossing with the jth connecting line in H.

(3) The segment k connects 2 crossings, say with the j_1th and the j_2th connecting line.

In the first case the connecting line in the circle representation corresponding to e_i splits the circle into two separate parts connected by one edge, ζ, in H'. The ith connecting line therefore crosses no other connecting lines. This means that there exist no $k\in\{1,\ldots,n\}$ such that $(i,k)\in c(\Pi)$; therefore $\gamma_2(\Pi)(v,\{i\})=0$. Since the walk that traces out $\gamma_1(\Pi)$ is closed, it has to visit ζ twice; once in the positive direction and once in the negative direction, so $\gamma_1(\Pi)(\zeta)$ also vanishes.

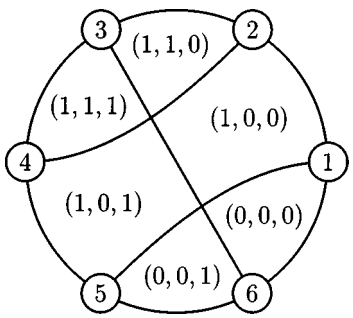

FIG. 6. The corner points of the surface generated by the partition $\Pi=\{(1,5),(2,4),(3,6)\}$.

In the second case the edge $(v,\{i\})$ is in the boundary of the plaquette $(u_{ij},\{i,j\})$, so

$$(\partial_2\gamma_2(\Pi))(v,\{i\})=\epsilon(i,\{j\})(1_{(u_{ij}+e_j,\{i\})}(v,\{i\})-1_{(u_{ij},\{i\})}(v,\{i\})). \tag{10}$$

First suppose $i<j$; then the crossing pairs (α_i,β_i) and (α_j,β_j) in Π satisfy $\alpha_i<\alpha_j<\beta_i<\beta_j$. Now if $v=u_{ij}$, meaning that v and u_{ij} lie on the same side of the ith and jth connecting line as 0, then the walk that traces out $\gamma_1(\Pi)$ reaches v before crossing the jth connecting line. Therefore the step this walk takes from v onward corresponds to α_i, so $\gamma_1(\Pi)(v,\{i\})=1$. From (10) we see that also $(\partial_2\gamma_2(\Pi))(v,\{i\})=1$. If, on the other hand, $v=u_{ij}+e_j$, then v and u_{ij} lie on the same side of the ith connecting line, but not on the same side of the jth connecting line. This means that the walk that traces out $\gamma_1(\Pi)$ has to cross the jth connecting line before it can reach v. But this means that a step in the ith direction has also been taken. Therefore we know that the step in the ith direction corresponds to β_i, so $\gamma_1(\Pi)(v,\{i\})=-1$. From (10) we see that also $(\partial_2\gamma_2(\Pi))(v,\{i\})=-1$. Now suppose $i>j$, then the crossing pairs (α_i,β_i) and (α_j,β_j) in Π satisfy $\alpha_j<\alpha_i<\beta_j<\beta_i$. The same type of argument as used for the case $i<j$ yields

$$v=u_{ij}\Rightarrow(\partial_2\gamma_2(\Pi))(v,\{i\})=\gamma_1(\Pi)(v,\{i\})=-1,$$

$$v=u_{ij}+e_j\Rightarrow(\partial_2\gamma_2(\Pi))(v,\{i\})=\gamma_1(\Pi)(v,\{i\})=1.$$

In the third case $(v,\{i\})$ is in the boundary of two plaquettes; $p_1=1_{(u_{ij_1},\{i,j_1\})}$ and $p_2=1_{(u_{ij_2},\{i,j_2\})}$. Since we are free to choose $j_1<j_2$, we can distinguish three cases:

(a) $i<j_1<j_2$,
(b) $j_1<i_1<j_2$, and
(c) $j_1<j_2<i$.

To prove case (a) we note that in this case we have $u_{ij_2}=u_{ij_1}+e_{j_1}$ and $v=u_{ij_2}$. Now calculate

$$(\partial_2 p_1)(v,\{i\})=\epsilon(j_1,\{i\})(1_{(u_{ij_1}+e_{j_1},\{i\})}(v,\{i\})-1_{(u_{ij_1},\{i\})}(v,\{i\}))=-1,$$

$$(\partial_2 p_2)(v,\{i\})=\epsilon(j_2,\{i\})(1_{(u_{ij_2}+e_{j_2},\{i\})}(v,\{i\})-1_{(u_{ij_2},\{i\})}(v,\{i\}))=1.$$

Therefore we have that $(\partial_2(p_1+p_2))(v,\{i\})=(\partial_2\gamma_2(\Pi))(v,\{i\})=0$. Since $(v,\{i\})$ is not an outer edge of H', we also have that $\gamma_1(\Pi)(v,\{i\})=0$. The reader can now easily verify cases (b) and (c), since the method of proof for these cases is the same as for case (a).

Finally, there are the edges in $\mathcal{X}_1$ that are not part of the dual graph of Π. We have $\gamma_2(\Pi)(u_1)=0$ for every $u_1\in\mathcal{X}_2$ not corresponding to a plaquette in H'. For every such u_1, we have $\partial_2(\gamma_2(\Pi)(u_1))=0$. Furthermore, we have $\gamma_1(\Pi)(u_2)=0$ for every u_2 not in the walk $\{(w(1),\{\sigma_\Pi(1)\}),\ldots,(w(2n),\{\sigma_\Pi(2n)\})\}$, so on the edges that are not in the dual graph of Π we have that $\partial_2\gamma_2(\Pi)=\gamma_1(\Pi)=0$, since every $u_2\in\{(w(1),\{\sigma_\Pi(1)\}),\ldots,(w(2n),\{\sigma_\Pi(2n)\})\}$ is represented in the dual graph of Π. □

Theorem 17: For every $\Pi\in\mathcal{P}_2(2n)$ the surface $\gamma_2(\Pi)$ is minimal in $\Gamma_{\gamma_1(\Pi)}$.

Proof: In case $n=1$ the loop $\gamma_1(\Pi)$ cannot enclose a plaquette. It follows from the definition of $\gamma_2(\Pi)$ that in this case $\gamma_2(\Pi)=0$, so the theorem holds for $n=1$. In the following we assume $n\geqslant 2$ and $i<j$ for $i,j\in\{1,\ldots,n\}$.

On the unit vectors $\{e_1,\ldots,e_n\}$ we introduce the following projection operator:

$$Q_{ij}e_k:=1_{\{i,j\}}(k)e_k.$$

Then the element $\gamma_2(\Pi)$ will be minimal in $\Gamma_{\gamma_1(\Pi)}$ if for every pair $i,j\in\{1,\ldots,n\}$ the projection of the closed walk that traces out $\gamma_1(\Pi)$ is a closed walk around $(0,\{i,j\})\in\mathcal{X}_2$, provided that $(i,j)\in c(\Pi)$. We now introduce

$$\Upsilon_{ij}:=\bigcup_{s=1}^{2n}\{Q_{ij}v(s)\},$$

the set of elements in $\mathcal{X}_0$ the projection to the $\{i,j\}$ plane of the walk that traces out $\gamma_1(\Pi)$ visits, and note that the proof is finished if we show $(i,j)\in c(\Pi)\Rightarrow \#\Upsilon_{ij}=4$.

Suppose $(i,j)\in c(\Pi)$, then (α_i,β_i) and (α_j,β_j) are crossing pairs in Π, so $\alpha_i<\alpha_j<\beta_i<\beta_j$. This means that $\Upsilon_{ij}=\{0,e_i,e_i+e_j,e_j\}$, so $\#\Upsilon_{ij}=4$. □

Corollary 18: For all $\Pi\in\mathcal{P}_2(2n)$ we have that $A(\gamma_2(\Pi))=A(\gamma_1(\Pi))=\#c(\Pi)$.

VII. THE PARISI MODEL AND THE *q*-HARMONIC OSCILLATOR

To show the connection between the *q*-harmonic oscillator and the Parisi model, we prove that, for $d\to\infty$ and $N\to\infty$, the moments of $\hat{X}$ converge to the moments of $X=a+a^*$. In short, $\hat{X}$ converges in distribution to X.

Theorem 19: *Let φ_q be the vacuum state on the q-harmonic oscillator algebra generated by $X=a+a^*$. Then for all $n\in\mathbb{N}$ the following holds:*

$$\varphi_q(X^n)=\lim_{d\to\infty}\lim_{N\to\infty}\hat{\varphi}(\hat{X}^n).$$

Corollary 7 states how the moments of the *q*-harmonic oscillator can be calculated as a sum over pair partitions. Therefore, here it suffices to show that

$$\lim_{d\to\infty}\lim_{N\to\infty}\hat{\varphi}(\hat{X}^n)=\sum_{\Pi\in\mathcal{P}_2(n)}q^{\#c(\Pi)}.$$

Proof: From Eq. (9) we know that $\hat{\varphi}(\hat{X}^n)$ can be interpreted as a sum over closed walks in $\mathcal{T}(N,d)$. The theorem then is trivial for n odd since an odd number has no pair partitions and a closed walk cannot return to its starting point in an odd number of steps. So we may assume $n=2r$, $r\in\mathbb{N}$, in the following.

We define a sublattice $\mathcal{T}'(N,d)$ of $\mathcal{T}(N,d)$ as follows:

$$\mathcal{T}'(N,d):=\{-N+(r+1),\ldots,N-(r+1)\}^d.$$

The set of all walks that start from some $x\in\mathcal{T}'(N,d)$ and have length n will be defined as

$$\mathcal{W}(x,n):=\{(x,j_1,\ldots,j_{n-1},x)|j_1,\ldots,j_{n-1}\in\mathcal{T}(N,d),\quad |x-j_1|=|j_1-j_2|=\cdots=|j_{n-1}-x|=1\}.$$

Note that we have

$$\#\mathcal{W}(x,n)=2^r d(d-1)\cdots(d-r+1).$$

To every walk $w\in\mathcal{W}(x,n)$ we can assign some surface $s\in\Gamma_w$, the set of minimal surfaces s that have the closed walk w as a boundary. We can then choose a set $\mathcal{S}(x,n)$ that contains exactly one surface $s\in\Gamma_w$ for every $w\in\mathcal{W}(x,n)$, i.e., $\#\mathcal{S}(x,n)=\#\mathcal{W}(x,n)$. Every surface $s\in\mathcal{S}(x,n)$ has to be minimal with respect to its corresponding walk $w\in\mathcal{W}(x,n)$ in order for the surface to have the corner points of the plaquettes in this surface in $\mathcal{T}(N,d)$.

With the use of these definitions we can rewrite the sum over i_1 in Eq. (9) as follows:

$$\hat{\varphi}(\hat{X}^n)=\frac{1}{(2N+1)^d}\sum_{i_1\in\mathcal{T}'(N,d)}\hat{\mathbb{E}}\left(\sum_{i_2\in\mathcal{T}(N,d)}\cdots\sum_{i_n\in\mathcal{T}(N,d)}\hat{X}_{i_1,i_2}\hat{X}_{i_2,i_3}\cdots\hat{X}_{i_n,i_1}\right)$$
$$+\frac{1}{(2N+1)^d}\sum_{\substack{i_1\in\mathcal{T}(N,d)\\ i_1\notin\mathcal{T}'(N,d)}}\hat{\mathbb{E}}\left(\sum_{i_2\in\mathcal{T}(N,d)}\cdots\sum_{i_n\in\mathcal{T}(N,d)}\hat{X}_{i_1,i_2}\hat{X}_{i_2,i_3}\cdots\hat{X}_{i_n,i_1}\right),\qquad(11)$$

and calculate

$$\hat{\mathbb{E}}(\hat{X}_{i_1,i_2}\cdots\hat{X}_{i_n,i_1}) = \frac{1}{(2d)^{n/2}} \sum_{w\in\mathcal{W}(x,n)} \hat{\mathbb{E}}(W(w)) = \frac{1}{(2d)^{n/2}} \sum_{w\in\mathcal{W}(x,n)} \hat{\mathbb{E}}(e^{i\Sigma_{p\in\mathcal{X}_1} w(p)A(p)})$$
$$= \frac{1}{(2d)^{n/2}} \sum_{w\in\mathcal{W}(x,n)} \hat{\mathbb{E}}(e^{i\int_w A}) = \frac{1}{(2d)^{n/2}} \sum_{s\in\mathcal{S}(x,n)} \hat{\mathbb{E}}(e^{i\int_s B}),$$

where we used Stokes' theorem. A walk that starts in $\mathcal{T}'(N,d)$ can never reach the boundary of $\mathcal{T}(N,d)$, so we can identify every walk $w\in\mathcal{W}(x,n)$ with a walk $w'\in\mathcal{W}(y,n)$, for $x,y\in\mathcal{T}'(N,d)$, via

$$w=(x,j_2,\ldots,j_n,x)\mapsto(y,j_2-(x-y),\ldots,j_n-(x-y),y)=w'.$$

From the fact that B is constant, it follows that the magnetic flux through $s\in\mathcal{S}(x,n)$, corresponding to w, is equal to the magnetic flux through $s'\in\mathcal{S}(y,n)$, corresponding to w', for $x,y\in\mathcal{T}'(N,d)$. This implies that we have

$$\sum_{s\in\mathcal{S}(x,n)} \hat{\mathbb{E}}(e^{i\int_s B}) = \sum_{s\in\mathcal{S}(y,n)} \hat{\mathbb{E}}(e^{i\int_s B}).$$

We can therefore perform the first sum over i_1 in (11), yielding

$$\frac{(2(N-(r+1))+1)^d}{(2N+1)^d}\,\hat{\mathbb{E}}\left(\sum_{i_2\in\mathcal{T}(N,d)}\cdots\sum_{i_n\in\mathcal{T}(N,d)}\hat{X}_{0,i_2}\hat{X}_{i_2,i_3}\cdots\hat{X}_{i_n,0}\right).$$

Since for every point in $\mathcal{T}(N,d)\backslash\mathcal{T}'(N,d)$ we have, at most, as many loops as for points in $\mathcal{T}'(N,d)$ we can estimate an upper bound for the second sum over i_1 in (11):

$$\frac{(2(N-(r+1))+1)^d-(2N+1)^d}{(2N+1)^d}\,\#\mathcal{W}(0,n).$$

This term tends to 0 for $N\to\infty$, so we find

$$\lim_{N\to\infty}\hat{\varphi}(\hat{X}^n)=\hat{\mathbb{E}}\left(\sum_{i_2\in\mathbb{Z}^d}\cdots\sum_{i_n\in\mathbb{Z}^d}\hat{X}_{0,i_2}\hat{X}_{i_2,i_3}\cdots\hat{X}_{i_n,0}\right).$$

We now turn to the limit $d\to\infty$. There are exactly $\#\mathcal{P}_2(n)\binom{d}{r}2^r$ walks that start in 0, have length n, and go through r different spatial directions. The number of closed walks that go through less than r, say r', spatial directions is less than $(r')^n\binom{d}{r'}$, so the contribution of these walks vanishes in the limit $d\to\infty$ due to the standardization of $\hat{X}$. The closed walks that go through r spatial directions take a step in each direction exactly twice, and therefore correspond to a pair partition $\Pi\in\mathcal{P}_2(2r)$. The expectation value of the magnetic flux through the area of the loop $\gamma_1(\Pi)$ such a walk traces out, is given by

$$\hat{\mathbb{E}}(W(\gamma_2(\Pi)))=\hat{\mathbb{E}}\left(\prod_{x\in\mathcal{X}_2'}e^{i\gamma_2(\Pi)(x)B(x)}\right)=\prod_{x\in\mathcal{X}_2'}\hat{\mathbb{E}}(e^{i\gamma_2(\Pi)(x)B(x)})=(\cos\mathcal{B})^{A(\gamma_2(\Pi))}=q^{A(\gamma_2(\Pi))},$$

where $\mathcal{X}_2':=\{(v,\gamma)\in\mathbb{Z}^d\times\mathfrak{P}_2(\{1,\ldots,d\})\}$ with the same conventions we have for $\mathcal{X}_2$. In the above calculation the expectation of the product over $\mathcal{X}_2$ is interpreted as a product of expectations. To justify this we note that $\gamma_2(\Pi)$ has, at most, one plaquette for every pair of spatial directions and that the sign of the magnetic field B for a pair of spatial directions is independent of that for every other pair of directions. This implies that the fluxes through different plaquettes in $\gamma_2(\Pi)$ are independent. It is now possible to write $\hat{\varphi}(\hat{X}^{2r})$ as a sum over partitions in the limit $d,N\to\infty$:

$$\lim_{d\to\infty}\lim_{N\to\infty}\hat{\varphi}(\hat{X}^{2r})=\lim_{d\to\infty}\frac{1}{(2d)^r}\sum_{i_2\in\mathbb{Z}^d}\cdots\sum_{i_{2r}\in\mathbb{Z}^d}\hat{\mathbb{E}}((\Delta_q)_{0,i_2}\cdots(\Delta_q)_{i_{2r},0})$$

$$=\sum_{\Pi\in\mathcal{P}_2(2r)}q^{A(\gamma_1(\Pi))}=\sum_{\Pi\in\mathcal{P}_2(2r)}q^{\#c(\Pi)},$$

where we used Corollary 18. □

VIII. NONCOMMUTATIVE INDEPENDENCE IN THE PARISI MODEL

Until now we concerned ourselves with only one q-Gaussian random variable. In order to illustrate the concept of q independence in this model, we shall have to define more, say $\mathcal{N}\in\mathbb{N}$, q-Gaussian random variables. The Parisi model allows for such an extension in a straightforward way.

If d is divisible by $\mathcal{N}$, the lattice $\mathcal{T}(N,d)$ can be decomposed as a product of $\mathcal{N}$ sublattices as follows:

$$\mathcal{T}(N,d)=\mathcal{M}_1\times\mathcal{M}_2\times\cdots\times\mathcal{M}_{\mathcal{N}},$$

where $\dim\mathcal{M}_j=d/\mathcal{N}$ for $j\in\{1,...,\mathcal{N}\}$. We can now use the q-deformed lattice Laplacian Δ_q defined in Sec. V to define $\mathcal{N}$ q-Gaussian random variables $\hat{X}_1,\ldots,\hat{X}_{\mathcal{N}}\in\mathcal{A}$ as follows:

$$(\hat{X}_i)_{u,w}=\begin{cases}\sqrt{\dfrac{\mathcal{N}}{2d}}\,(\Delta_q)_{v,w}, & \text{if } v-w\in\mathcal{M}_i,\\ 0, & \text{otherwise.}\end{cases}$$

In this way $\hat{X}_i, i\in\{1,...,\mathcal{N}\}$, is the standardized deformed lattice Laplacian on M_i. From the previous section we can deduce that the operators $\hat{X}_1,\ldots,\hat{X}_{\mathcal{N}}$ defined in this way converge, in distribution, to the q-Gaussian random variables $X_i=a_i+a_i^*$ for $d\to\infty$ and $N\to\infty$. Now fix $\mathcal{N}=2$ and let $\hat{X}=\hat{X}_1$ and $\hat{Y}=\hat{X}_2$.

Theorem 20 (independence): *For $n,m\in\mathbb{N}$ we have that*

$$\lim_{N\to\infty}\hat{\varphi}(\hat{X}^n\hat{Y}^m)=\lim_{N\to\infty}\hat{\varphi}(\hat{Y}^m\hat{X}^n)=\lim_{N\to\infty}\hat{\varphi}(\hat{X}^n)\hat{\varphi}(\hat{Y}^m).$$

Proof: Write out $\hat{\varphi}(\hat{X}^n\hat{Y}^m)$ to find

$$\hat{\varphi}(\hat{X}^n\hat{Y}^m)=\frac{1}{(2N+1)^d}\,\hat{\mathbb{E}}\left(\sum_{\substack{i_1,\ldots,i_n\\ \in\mathcal{T}(N,d)}}\sum_{\substack{j_1,\ldots,j_m\\ \in\mathcal{T}(N,d)}}\hat{X}_{i_1,i_2}\cdots\hat{X}_{i_n,j_1}\hat{Y}_{j_1,j_2}\cdots\hat{Y}_{j_m,i_1}\right).$$

Now, obviously the nonvanishing terms all satisfy

$$(i_1-i_2)+\cdots+(i_n-j_1)+(j_1-j_2)+\cdots+(j_m-i_1)=0.$$

The first n differences all lie in $\mathcal{M}_1$ and the last m differences all lie in $\mathcal{M}_2$ therefore,

$$(i_1-i_2)+\cdots+(i_n-j_1)=(j_1-j_2)+\cdots+(j_m-i_1)=0,$$

and it follows that $i_1=j_1$. With reference to the proof of Theorem 19, we can choose $i_1=j_1=0$, so we find

$$\lim_{N\to\infty}\hat{\varphi}(\hat{X}^n\hat{Y}^m)=\hat{\mathbb{E}}\left(\sum_{\substack{i_2,\ldots,i_n\\ \in\mathbb{Z}^d}}\sum_{\substack{j_2,\ldots,j_m\\ \in\mathbb{Z}^d}}\hat{X}_{0,i_2}\cdots\hat{X}_{i_n,0}\hat{Y}_{0,j_2}\cdots\hat{Y}_{j_m,0}\right)$$

$$=\hat{\mathbb{E}}\left(\sum_{\substack{i_2,\ldots,i_n\\ \in\mathbb{Z}^d}}\hat{X}_{0,i_2}\cdots\hat{X}_{i_n,0}\right)\hat{\mathbb{E}}\left(\sum_{\substack{j_2,\ldots,j_m\\ \in\mathbb{Z}^d}}\hat{Y}_{0,j_2}\cdots\hat{Y}_{j_m,0}\right)=\lim_{N\to\infty}\hat{\varphi}(\hat{X}^n)\hat{\varphi}(\hat{Y}^m).$$

Since $\hat{\varphi}$ is a trace state, we have that $\hat{\varphi}(\hat{X}^n\hat{Y}^m)=\hat{\varphi}(\hat{Y}^m\hat{X}^n)$. □
The same type of proof shows that, for general $\mathcal{N}$, we have

$$\hat{\varphi}(\hat{X}_{k(1)}^{n_1}\cdots\hat{X}_{k(\mathcal{N})}^{n_\mathcal{N}})=\hat{\varphi}(\hat{X}_{k(1)}^{n_1})\cdots\hat{\varphi}(\hat{X}_{k(\mathcal{N})}^{n_\mathcal{N}}),$$

provided the values $k(1),\ldots,k(\mathcal{N})$ are all different.

We conclude that in the sense of Definition 2, the $\hat{X}_i$ tend to independent random variables in the limit $N\to\infty$, and to independent q-Gaussians in the limit $N\to\infty$, $d\to\infty$.

Some kinds of *q*-phase-coherent states of a *q*-harmonic osscillator in a finite-dimensional Hilbert space are constructed. Some properties of these states are discussed. Second-order squeezing properties of these states with respect to the phase quadrature operators are studied. The number-phase squeezing and number-phase uncertainty relations are also studied in detail for a two-state system. Some new number-phase minimum uncertainty states are found. © *1998 American Institute of Physics.* [S0022-2488(98)01412-1]

I. INTRODUCTION

The concept of amplitude and phase of an oscillator plays an important part in mechanics and optics and was introduced into quantum mechanics and electrodynamics at an early stage.[1,2] In quantum theory, the amplitude of the electromagnetic field is proportional to the square root of the photon-number operator, and the phase is described by the exponential phase operators[3–6] which were established by Susskind and Glogower (SG). Unfortunately, the SG phase operators are not unitary, hence the Hermitian phase operators cannot be constructed.

In the late 1980s, Pegg and Barnett (PB)[7–9] suggested a formalism in which all the operators are defined in a finite but arbitrarily large state space. The Hermitian phase operator is then defined as the projection operator on the particular phase state multiplied by the corresponding value of the phase. All the mean values of observables depend parametrically on the dimension of the Hilbert space. When the infinite limit of the dimension is taken, the physical results correspond to the results obtainable in ordinary quantum mechanics. The PB phase-operator formalism has been applied in a variety of problems in quantum mechanics.[10,11] In particular, the coherent states (CSs) of the harmonic osillator (HO) in the finite-dimensional number-state or phase-state space were defined, and their squeezing properties of these CSs were analyzed in detail.[12–14]

In the past few years, *q*-deformed HO[15–17] was introduced in research of the representations of quantum algebra. Futhermore, a polar decomposition phase operator h in context of *q*-deformed oscillator was introduced first by Chaichian and Ellinas,[18] and *q*-deformed SG phase operator and *q*-coherent states were also constructed,[19–21] and the the properties of macro-deformed CSs were discussed.[22,23] But the *q*-deformed SG phase operator is also not unitary, therefore, Nelson and his co-workers have adopted the PB formalism to study the quantum phase problem in the deformed case.[19,22] *q*-Deformed operators in the finite-dimensional Hilbert space were defined,[24,25] and another kind of *q*-coherent states of the *q*-HO was established.[25]

The aim of this paper is to construct *q*-phase-coherent states (*q*-PCSs) based on the *q*-deformed operators of the phase quanta defined in Ref. 25. We shall also pay attention to phase fluctuation and amplitude and phase squeezing properties of *q*-PCSs in a finite-dimensional basis. We will also determine whether *q*-PCSs are minimum uncertainty states (MUSs)[4,5] or intelligent

states[26,27] with respect to the number and phase operators. In Sec. II we present a short review on the q-deformed operators of the phase quanta and discuss their algebraic properties. In Sec. III we define the q-PCSs in the finite-dimensional space and study some properties of these states. In Sec. IV we analyze second-order squeezing properties with respect to the q-PCSs in an arbitrary finite-dimensional phase-state space. Certainly, we also recognize that there are many cases of interest where the state space is genuinely finite. In Sec. V we investigate in detail number-phase squeezing and number-phase uncertainty relations for the simplest in a two-state system.

II. *q*-DEFORMED OPERATORS OF PHASE QUANTA

Let us consider a finite but arbitrarily large state space Ψ of $(s+1)$ dimensions of a q-deformed HO. The number states $|n\rangle \in \Psi$ are orthonormal:

$$\langle n|m\rangle = \delta_{nm}, \quad \sum_{n=0}^{s} |n\rangle\langle n| = 1. \tag{1}$$

The q-annihilation, creation and number operators of q-harmonic oscillator in the finite-dimensional Hilbert space may be defined through the following projection operators:

$$\hat{a}^{+} = \sum_{n=1}^{s} \sqrt{[n]}|n\rangle\langle n-1|, \quad \hat{a} = \sum_{n=1}^{s} \sqrt{[n]}|n-1\rangle\langle n|, \quad \hat{N} = \sum_{n=1}^{s} |n\rangle\langle n|, \tag{2}$$

where $[x]=(q^{x}-q^{-x})/(q-q^{-1})$, and x is a number or an operator. If s goes to infinity, those operators $\hat{a}^{+}$, $\hat{a}$, $\hat{N}$ will be ordinary q-deformed creation, annihilation, and number operator in infinite-dimensional space:

$$[\hat{N},\hat{a}^{+}] = \hat{a}^{+}, \quad [\hat{N},\hat{a}] = -\hat{a}, \quad [\hat{N}] = \hat{a}^{+}\hat{a},$$

$$\hat{a}\hat{a}^{+} - q\hat{a}^{+}\hat{a} = q^{-\hat{N}} - [s+1]|s\rangle\langle s|, \quad \hat{a}\hat{a}^{+} - q^{-1}\hat{a}^{+}\hat{a} = q^{\hat{N}} - [s+1]|s\rangle\langle s|. \tag{3}$$

Let us define a unitary exponential phase operator from the following equation:

$$\hat{a} = e^{i\Phi_\theta} R(\hat{N}). \tag{4}$$

$R(\hat{N})$ represents the amplitude part of $\hat{a}$. Using the similar method in Refs. 18, 24, and 25, we can obtain

$$\hat{a} = e^{i\Phi_\theta}\sqrt{[\hat{N}]}, \quad e^{i\Phi_\theta} = \sum_{n=1}^{s} |n-1\rangle\langle n| + e^{i\psi}|s\rangle\langle 0|. \tag{5}$$

Here ψ is an arbitrary real number. The eigenstate of the unitary exponential phase operator $e^{i\Phi_\theta}$ with eigenvalue $e^{i\theta_m}$ is

$$|\theta_m\rangle = (s+1)^{-1/2} \sum_{n=0}^{s} e^{i\theta_m n}|n\rangle. \tag{6}$$

The phase quanta θ_m is equal to $\theta_0 + (2m\pi)/(s+1)$, and $\theta_0 = \psi/(s+1)$. The phase states $|\theta_m\rangle (m=0,1,...,s)$ are orthonormal

$$\langle \theta_m|\theta_n\rangle = \delta_{m,n}, \quad \sum_{m=0}^{s} |\theta_m\rangle\langle\theta_m| = 1. \tag{7}$$

And the Hermitian phase operator can be expressed as

$$\Phi_\theta=\sum_{m=0}^{s}\theta_m|\theta_m\rangle\langle\theta_m|=\theta_0+\frac{s\pi}{s+1}+\frac{2\pi}{s+1}\sum_{m\neq n}^{s}\frac{\exp(-i(m-n)\theta_0)}{\exp(-i2\pi(m-n)/(s+1))-1}|n\rangle\langle m|, \quad (8)$$

and

$$e^{\pm i\Phi_\theta}=\sum_{m=0}^{s}e^{\pm i\theta_m}|\theta_m\rangle\langle\theta_m|,$$

$$\cos\Phi_\theta=\sum_{m=0}^{s}\cos\theta_m|\theta_m\rangle\langle\theta_m|, \quad \sin\Phi_\theta=\sum_{m=0}^{s}\sin\theta_m|\theta_m\rangle\langle\theta_m|. \quad (9)$$

The q-deformed creation and annihilation operators of phase quanta can be also defined as[25]

$$\hat{\phi}^+=\sqrt{[\Phi_\theta]}e^{(i2\pi\dot{N})/(s+1)}, \quad \hat{\phi}=e^{-(i2\pi\dot{N})/(s+1)}\sqrt{[\Phi_\theta]}. \quad (10)$$

In phase-state space, they can be rewritten as

$$\begin{aligned}\hat{\phi}^+&=\sum_{m=1}^{s}\sqrt{[\theta_m]}|\theta_m\rangle\langle\theta_{m-1}|+\sqrt{[\theta_0]}|\theta_0\rangle\langle\theta_s|,\\ \hat{\phi}&=\sum_{m=1}^{s}\sqrt{[\theta_m]}|\theta_{m-1}\rangle\langle\theta_m|+\sqrt{[\theta_0]}|\theta_s\rangle\langle\theta_0|.\end{aligned} \quad (11)$$

For simplicity, we take $\theta_0=0$ in the following discussion. From the above formulas we obtain

$$\begin{aligned}\hat{\phi}\hat{\phi}^\dagger-q^{2\pi/(s+1)}\hat{\phi}^\dagger\hat{\phi}&=\left[\frac{2\pi}{s+1}\right]q^{-\hat{\Phi}_\theta}-[2\pi]\hat{\mathcal{M}}_{ss},\\ \hat{\phi}\hat{\phi}^\dagger-q^{-2\pi/(s+1)}\hat{\phi}^\dagger\hat{\phi}&=\left[\frac{2\pi}{s+1}\right]q^{\hat{\Phi}_\theta}-[2\pi]\hat{\mathcal{M}}_{ss},\\ [\hat{\Phi}_\theta,\hat{\phi}^{\dagger k}]&=\frac{2\pi}{s+1}k\hat{\phi}^k, \quad 1\leqslant k\leqslant s,\\ [\hat{\Phi}_\theta,\hat{\phi}^k]&=-\frac{2\pi}{s+1}k\hat{\phi}^{\dagger k}, \quad 1\leqslant k\leqslant s,\end{aligned} \quad (12)$$

$$\begin{aligned}[\hat{\phi}^\dagger,\hat{\mathcal{M}}_{ij}]&=\sqrt{[\theta_{i+1}]}\mathcal{H}(s-i)\hat{\mathcal{M}}_{(i+1)j}-\sqrt{[\theta_j]}\hat{\mathcal{M}}_{i(j-1)},\\ [\hat{\phi},\hat{\mathcal{M}}_{ij}]&=\sqrt{[\theta_i]}\hat{\mathcal{M}}_{(i-1)j}-\sqrt{[\theta_{j+1}]}\mathcal{H}(s-j)\hat{\mathcal{M}}_{i(j+1)},\\ [\hat{\Phi}_\theta,\hat{\mathcal{M}}_{ij}]&=(\theta_i-\theta_j)\hat{\mathcal{M}}_{ij}, \quad [\hat{\mathcal{M}}_{ij},\hat{\mathcal{M}}_{kl}]=\delta_{jk}\hat{\mathcal{M}}_{il}-\delta_{il}\hat{\mathcal{M}}_{kj},\end{aligned}$$

where $\hat{\mathcal{M}}_{ij}$ is a projection operator in the phase-state space,[14] $\hat{\mathcal{M}}_{ij}=|\theta_i\rangle\langle\theta_j|$, $(i,j=0,1,...,s)$. The $\mathcal{H}(x)$ is the step function defined as $\mathcal{H}(x)\{^{1\ x>0}_{0\ x\leqslant 0}$. In this section, we can see that, in the phase-state basis, the creation and annihilation operators of the phase quanta are deformed and the number operator is not deformed. When $q\to 1$, these equations can be simplified as the corresponding equations of the normal HO.[14]

III. *q*-PHASE-COHERENT STATES OF *q*-HARMONIC OSCILLATOR

We now give a definition of the q-phase coherent states (q-PCSs) of the finite-dimensional q-HO as follows:

$$|\alpha,s\rangle = C(\alpha,s) e_{q^{2\pi/(s+1)}}^{\alpha \hat{\phi}^\dagger} |0\rangle_p = C(\alpha,s) \sum_{m=0}^{s} \frac{\tilde{\alpha}^m}{\sqrt{[\theta_m]!}} |\theta_m\rangle, \tag{13}$$

where we have used Eq. (11), and introduced the following symbols:

$$[\theta_0]! = 1, \quad [\theta_m]! = \prod_{i=1}^{m} [\theta_i], \quad m = 1,2,...,s,$$

and $e_{q^{2\pi/(s+1)}}^{x}$ is a q-exponential function

$$e_{q^{2\pi/(s+1)}}^{x} = \sum_{m=0}^{\infty} \frac{x^m}{[m]_{q^{2\pi/(s+1)}}!},$$

$$[m]_{q^{2\pi/(s+1)}} = \frac{q^{(2\pi m)/(s+1)} - q^{-(2\pi m)/(s+1)}}{q^{2\pi/(s+1)} - q^{-2\pi/(s+1)}} = \frac{[\theta_m]}{[2\pi/s+1]},$$

and $\tilde{\alpha} = [2\pi/(s+1)]\,\alpha$, α is an arbitrary complex number, and the normalization constant $C(\alpha,s)$ is given by

$$C(\alpha,s) = \left(\sum_{m=0}^{s} \frac{(\tilde{\alpha}\tilde{\alpha}^*)^m}{[\theta_m]!} \right)^{-1/2} = (e_{q,p,s}^{|\tilde{\alpha}|^2})^{-1/2}, \tag{14}$$

where $\tilde{\alpha}^*$ denotes the complex conjugation of $\tilde{\alpha}$ and $e_{q,p,s}^{x}$ is defined as

$$e_{q,p,s}^{x} = \sum_{m=0}^{s} \frac{x^m}{[\theta_m]!}.$$

Obviously, when $s \to \infty$, $e_{q,p,s}^{x} \to e_{q,p}^{x} = \Sigma_{m=0}^{\infty} x^m/[\theta_m]!$, and the q-PCSs become the q-PCSs of the q-HO in an infinite-dimensional Hilbert space.[18,19] When $q \to 1$, $e_{q,p,s}^{x} \to \Sigma_{m=0}^{s}(x^m)/(\theta_m!)$, and the q-PCSs become the PCSs of normal HO in a finite-dimensional Hilbert space.[14]

The q-annihilation operator of the phase quanta $\hat{\phi}$ acts on the q-PCSs $|\alpha,s\rangle$ in the following form:

$$\hat{\phi}|\alpha,s\rangle = \tilde{\alpha}\left\{ |\alpha,s\rangle - (e_{q,p,s}^{|\tilde{\alpha}|^2})^{-1/2} \frac{\tilde{\alpha}^s}{\sqrt{[\theta_s]!}} |\theta_s\rangle \right\}, \tag{15}$$

which means that the q-PCSs are not eigenstates of the q-annihilation operators of the phase quanta for any finite value of s. The second term on the right-hand side of the above formula originates from the finiteness of the dimension. When s goes to infinity, the second term vanishes, and $|\alpha,s\rangle$ is changed to an eigenstate of annihilation operator $\hat{\phi}$.

The q-PCSs are nonorthogonal to each other

$$\langle \alpha,s|\alpha',s\rangle = (e_{q,p,s}^{|\tilde{\alpha}|^2} e_{q,p,s}^{|\tilde{\alpha}'|^2})^{-1/2} e_{q,p,s}^{\tilde{\alpha}^*\tilde{\alpha}'}, \tag{16}$$

but the q-PCSs are complete

$$\int |\alpha,s\rangle\langle\alpha,s| d\mu(\alpha) = \sum_{m=0}^{s} |\theta_m\rangle\langle\theta_m| = 1, \tag{17}$$

where

$$d\mu(\alpha) = \frac{1}{2\pi} e_{q,p}^{-|\tilde{\alpha}|^2} e_{q,p,s}^{|\tilde{\alpha}|^2} d_{q^{2\pi/(s+1)}} |\tilde{\alpha}|^2 d\theta.$$

Note that the integral over θ is a normal integration, but the integral over $|\tilde{\alpha}|^2$ is a q-integration. The q-derivative is defined as

$$\frac{d}{d_{q^{2\pi/(s+1)}}} f(x) = \frac{f(q^{2\pi/(s+1)}x) - f(q^{-2\pi/(s+1)}x)}{(q^{2\pi/(s+1)} - q^{-2\pi/(s+1)})x}.$$

The q-integration can be derived from the definition of the q-derivative.

By the two above properties, the q-PCSs are overcomplete. An arbitrary q-PCS $|\alpha',s\rangle$ can be expressed as

$$|\alpha',s\rangle = \int (e^{|\tilde{\alpha}|^2}_{q,p,s} e^{|\tilde{\alpha}'|^2}_{q,p,s})^{-1/2} e^{\tilde{\alpha}^*\tilde{\alpha}'}_{q,p,s} |\alpha,s\rangle d\mu(\alpha). \tag{18}$$

The phase-state representation of the q-PCSs $|\alpha,s\rangle$, given in Eq. (13), implies that the phase-probability distribution is

$$P(\theta_m,s) = |\langle \theta_m|\alpha,s\rangle|^2 = \frac{|\tilde{\alpha}|^{2m}}{[\theta_m]!} (e^{|\tilde{\alpha}|^2}_{q,p,s})^{-1}, \tag{19}$$

with the normalization condition

$$\sum_{m=0}^{s} P(\theta_m,s) = 1. \tag{20}$$

On account of the completeness relation of the q-PCSs, we can expand the phase states $|\theta_m\rangle$ in terms of the q-PCSs$|\alpha,s\rangle$ as

$$|\theta_m\rangle = \frac{1}{2\pi} \int e^{-|\tilde{\alpha}|^2}_{q,p} (e^{|\tilde{\alpha}|^2}_{q,p,s})^{1/2} \frac{(\tilde{\alpha}^*)^m}{\sqrt{[\theta_m]!}} |\alpha,s\rangle d_{q^{2\pi/(s+1)}} |\tilde{\alpha}|^2 d\theta. \tag{21}$$

After substituting Eq. (6) into Eq. (13), we get

$$|\alpha,s\rangle = (s+1)^{-1/2} (e^{|\tilde{\alpha}|^2}_{q,p,s})^{-1/2} \sum_{n,m=0}^{s} \frac{\tilde{\alpha}^m}{\sqrt{[\theta_m]!}} \exp(in\theta_m)|n\rangle. \tag{22}$$

So the probability distribution of the q-PCSs in the finite-dimensional number-state space is

$$P(n,s) = (s+1)^{-1} (e^{|\tilde{\alpha}|^2}_{q,p,s})^{-1} \left| \sum_{m=0}^{s} \frac{\tilde{\alpha}^m}{\sqrt{[\theta_m]!}} \exp(in\theta_m) \right|^2, \tag{23}$$

with the normalization condition

$$\sum_{n=0}^{s} P(n,s) = 1. \tag{24}$$

Similarly, the number states $|n\rangle$ can also be expanded in terms of the q-PCSs $|\alpha,s\rangle$

$$|n\rangle = \frac{1}{2\pi(s+1)^{1/2}} \sum_{m=0}^{s} \int e^{-|\tilde{\alpha}|^2}_{q,p} (e^{|\tilde{\alpha}|^2}_{q,p,s})^{1/2} \exp(-in\theta_m) \frac{(\tilde{\alpha}^*)^m}{\sqrt{[\theta_m]!}} |\alpha,s\rangle d_{q^{2\pi/(s+1)}} |\tilde{\alpha}|^2 d\theta. \tag{25}$$

IV. SECOND-ORDER SQUEEZING PROPERTIES

In this section, we investigate the second-order squeezing properties of the q-PCSs mentioned in Sec. III. First, we introduce a pair of Hermitian phase quadrature operators $\hat{X}_\phi$ and $\hat{Y}^{12}_\phi$ corresponding to the q-creation and annihilation operators of the phase quanta under consideration as

$$\hat{X}_\phi=\tfrac{1}{2}(\hat{\phi}+\hat{\phi}^\dagger),\quad \hat{Y}_\phi=\frac{1}{2i}(\hat{\phi}-\hat{\phi}^\dagger), \tag{26}$$

which satisfy the following commutation relation:

$$[\hat{X}_\phi,\hat{Y}_\phi]=\frac{i}{2}[\hat{\phi},\hat{\phi}^\dagger], \tag{27}$$

and the uncertainty relation

$$\langle(\Delta\hat{X}_\phi)^2\rangle\cdot\langle(\Delta\hat{Y}_\phi)^2\rangle\geqslant\tfrac{1}{4}|\langle[\hat{X}_\phi,\hat{Y}_\phi]\rangle|^2, \tag{28}$$

where the variances of the operators are defined as $\langle(\Delta\hat{X}_\phi)^2\rangle=\langle\hat{X}_\phi^2\rangle-(\langle\hat{X}_\phi\rangle)^2$, and $\langle(\Delta\hat{Y}_\phi)^2\rangle=\langle\hat{Y}_\phi^2\rangle-(\langle\hat{Y}_\phi\rangle)^2$. We shall say that the variances of the operators $\hat{X}_\phi$ and $\hat{Y}_\phi$ are squeezed if

$$\langle(\Delta\hat{X}_\phi)^2\rangle<\tfrac{1}{2}|\langle[\hat{X}_\phi,\hat{Y}_\phi]\rangle|\ \text{ or }\ \langle(\Delta\hat{Y}_\phi)^2\rangle<\tfrac{1}{2}|\langle[\hat{X}_\phi,\hat{Y}_\phi]\rangle|.$$

To measure the degree of squeezing with respect to the pair of operators, we introduce two parameters S_X and S_Y

$$S_X=\frac{\langle(\Delta\hat{X}_\phi)^2\rangle-\frac{1}{2}|\langle[\hat{X}_\phi,\hat{Y}_\phi]\rangle|}{\frac{1}{2}|\langle[\hat{X}_\phi,\hat{Y}_\phi]\rangle|},\quad S_Y=\frac{\langle(\Delta\hat{Y}_\phi)^2\rangle-\frac{1}{2}|\langle[\hat{X}_\phi,\hat{Y}_\phi]\rangle|}{\frac{1}{2}|\langle[\hat{X}_\phi,\hat{Y}_\phi]\rangle|}. \tag{29}$$

The squeezing condition now takes the simple form

$$S_X<0\ \text{ or }\ S_Y<0. \tag{30}$$

For the q-PCSs defined in Eq. (13), we have some expectation values:

$$\begin{aligned}
&\langle\alpha,s|\hat{\phi}|\alpha,s\rangle=\tilde{\alpha}(e^{|\tilde{\alpha}|^2}_{q,p,s})^{-1}e^{|\tilde{\alpha}|^2}_{q,p,s-1},\quad \langle\alpha,s|\hat{\phi}^\dagger|\alpha,s\rangle=\tilde{\alpha}^*(e^{|\tilde{\alpha}|^2}_{q,p,s})^{-1}e^{|\tilde{\alpha}|^2}_{q,p,s-1},\\
&\langle\alpha,s|\hat{\phi}^2|\alpha,s\rangle=\tilde{\alpha}^2(e^{|\tilde{\alpha}|^2}_{q,p,s})^{-1}e^{|\tilde{\alpha}|^2}_{q,p,s-2},\quad \langle\alpha,s|\hat{\phi}^{\dagger2}|\alpha,s\rangle=\tilde{\alpha}^{*2}(e^{|\tilde{\alpha}|^2}_{q,p,s})^{-1}e^{|\tilde{\alpha}|^2}_{q,p,s-2},\\
&\langle\alpha,s|\hat{\phi}^\dagger\hat{\phi}|\alpha,s\rangle=|\tilde{\alpha}|^2(e^{|\tilde{\alpha}|^2}_{q,p,s})^{-1}e^{|\tilde{\alpha}|^2}_{q,p,s-1},\\
&\langle\alpha,s|\hat{\phi}\hat{\phi}^\dagger|\alpha,s\rangle=(e^{|\tilde{\alpha}|^2}_{q,p,s})^{-1}\left(q^{2\pi/(s+1)}|\tilde{\alpha}|^2e^{|\tilde{\alpha}|^2}_{q,p,s-2}+\left[\frac{2\pi}{s+1}\right]e^{|\tilde{\alpha}|^2q^{-2\pi/(s+1)}}_{q,p,s-1}\right).
\end{aligned} \tag{31}$$

So we obtain the variances of the operators $\hat{X}_\phi$ and $\hat{Y}_\phi$

$$\begin{aligned}
\langle\alpha,s|(\Delta\hat{X}_\phi)^2|\alpha,s\rangle=\frac{1}{4}(e^{|\tilde{\alpha}|^2}_{q,p,s})^{-1}\Bigg\{&(\tilde{\alpha}^2+\tilde{\alpha}^{*2}+q^{2\pi/(s+1)}|\tilde{\alpha}|^2)e^{|\tilde{\alpha}|^2}_{q,p,s-2}+\left[\frac{2\pi}{s+1}\right]e^{|\tilde{\alpha}|^2q^{-2\pi/(s+1)}}_{q,p,s-1}\\
&+|\tilde{\alpha}|^2e^{|\tilde{\alpha}|^2}_{q,p,s-1}\Bigg\}-\{(e^{|\tilde{\alpha}|^2}_{q,p,s})^{-1}e^{|\tilde{\alpha}|^2}_{q,p,s-1}\ \mathrm{Re}(\tilde{\alpha})\}^2,
\end{aligned} \tag{32}$$

$$\begin{aligned}
\langle\alpha,s|(\Delta\hat{Y}_\phi)^2|\alpha,s\rangle=-\frac{1}{4}(e^{|\tilde{\alpha}|^2}_{q,p,s})^{-1}\Bigg\{&(\tilde{\alpha}^2+\tilde{\alpha}^{*2}-q^{2\pi/(s+1)}|\tilde{\alpha}|^2)e^{|\tilde{\alpha}|^2}_{q,p,s-2}-\left[\frac{2\pi}{s+1}\right]e^{|\tilde{\alpha}|^2q^{-2\pi/(s+1)}}_{q,p,s-1}\\
&-|\tilde{\alpha}|^2e^{|\tilde{\alpha}|^2}_{q,p,s-1}\Bigg\}-\{(e^{|\tilde{\alpha}|^2}_{q,p,s})^{-1}e^{|\tilde{\alpha}|^2}_{q,p,s-1}\ \mathrm{Im}(\tilde{\alpha})\}^2,
\end{aligned} \tag{33}$$

and the expectation value of their commutator $[\hat{X}_\phi,\hat{Y}_\phi]$,

$$\langle\alpha,s|[\hat{X}_\phi,\hat{Y}_\phi]|\alpha,s\rangle=\frac{i}{2}\,(e_{q,p,s}^{|\tilde{\alpha}|^2})^{-1}\left\{\left[\frac{2\pi}{s+1}\right]e_{q,p,s-1}^{|\tilde{\alpha}|^2q^{-2\pi/(s+1)}}+q^{2\pi/(s+1)}|\tilde{\alpha}|^2e_{q,p,s-2}^{|\tilde{\alpha}|^2}-|\tilde{\alpha}|^2e_{q,p,s-1}^{|\tilde{\alpha}|^2}\right\}. \tag{34}$$

Eqs. (32)–(34) show that the q-PCSs $|\alpha,s\rangle$ are not the MUSs. However, in the limit $s\to\infty$, we have

$$\langle\alpha,s|(\Delta\hat{X}_\phi)^2|\alpha,s\rangle=\langle\alpha,s|(\Delta\hat{Y}_\phi)^2|\alpha,s\rangle=\tfrac{1}{2}|\langle\alpha,s|[\hat{X}_\phi,\hat{Y}_\phi]|\alpha,s\rangle|=0 \tag{35}$$

and

$$S_X=S_Y=0. \tag{36}$$

The equality in the uncertainty relation (28) holds, i.e., the q-PCSs are the MUSs.

We investigate below the second-order squeezing for α real.

When $[2\pi/(s+1)]e_{q,p,s-1}^{\tilde{\alpha}^2q^{-2\pi/(s+1)}}-\tilde{\alpha}^2\,e_{q,p,s-1}^{\tilde{\alpha}^2}+q^{2\pi/(s+1)}\tilde{\alpha}^2e_{q,p,s-2}^{\tilde{\alpha}^2}>0$, we obtain the two parameters:

$$\begin{aligned}S_X&=\frac{2\tilde{\alpha}^2e_{q,p,s-2}^{\tilde{\alpha}^2}+2\tilde{\alpha}^2e_{q,p,s-1}^{\tilde{\alpha}^2}-4\tilde{\alpha}^2(e_{q,p,s}^{\tilde{\alpha}^2})^{-1}(e_{q,p,s-1}^{\tilde{\alpha}^2})^2}{[2\pi/(s+1)]e_{q,p,s-1}^{\tilde{\alpha}^2q^{-2\pi/(s+1)}}-\tilde{\alpha}^2e_{q,p,s-1}^{\tilde{\alpha}^2}+q^{2\pi/(s+1)}\tilde{\alpha}^2e_{q,p,s-2}^{\tilde{\alpha}^2}},\\ S_Y&=\frac{2\tilde{\alpha}^2e_{q,p,s-1}^{\tilde{\alpha}^2}-2\tilde{\alpha}^2e_{q,p,s-2}^{\tilde{\alpha}^2}}{[2\pi/(s+1)]e_{q,p,s-1}^{\tilde{\alpha}^2q^{-2\pi/(s+1)}}-\tilde{\alpha}^2e_{q,p,s-1}^{\tilde{\alpha}^2}+q^{2\pi/(s+1)}\tilde{\alpha}^2e_{q,p,s-2}^{\tilde{\alpha}^2}}\geqslant 0,\end{aligned} \tag{37}$$

Thus, in this case, there does not exist any squeezing of the $\hat{Y}_\phi$ component for an arbitrary value that s can take. However, it can be deduced from the above formula that squeezing of the $\hat{X}_\phi$ component may be obtained if

$$\begin{aligned}&\left[\frac{2\pi}{s+1}\right]e_{q,p,s-1}^{\tilde{\alpha}^2q^{-2\pi/(s+1)}}-\tilde{\alpha}^2e_{q,p,s-1}^{\tilde{\alpha}^2}+q^{2\pi/(s+1)}\tilde{\alpha}^2e_{q,p,s-2}^{\tilde{\alpha}^2}>0,\\ &2\tilde{\alpha}^2e_{q,p,s-2}^{\tilde{\alpha}^2}+2\tilde{\alpha}^2e_{q,p,s-1}^{\tilde{\alpha}^2}-4\tilde{\alpha}^2(e_{q,p,s}^{\tilde{\alpha}^2})^{-1}(e_{q,p,s-1}^{\tilde{\alpha}^2})^2<0.\end{aligned} \tag{38}$$

When $[2\pi/(s+1)]e_{q,p,s-1}^{\tilde{\alpha}^2q^{-2\pi/(s+1)}}-\tilde{\alpha}^2e_{q,p,s-1}^{\tilde{\alpha}^2}+q^{2\pi/(s+1)}\tilde{\alpha}^2e_{q,p,s-2}^{\tilde{\alpha}^2}<0$, the representations of the two parameters become

$$\begin{aligned}S_X&=\frac{2\tilde{\alpha}^2(1+q^{2\pi/(s+1)})e_{q,p,s-2}^{\tilde{\alpha}^2}+2[2\pi/(s+1)]e_{q,p,s-1}^{\tilde{\alpha}^2q^{-2\pi/(s+1)}}-4\tilde{\alpha}^2(e_{q,p,s}^{\tilde{\alpha}^2})^{-1}(e_{q,p,s-1}^{\tilde{\alpha}^2})^2}{\tilde{\alpha}^2e_{q,p,s-1}^{\tilde{\alpha}^2}-[2\pi/(s+1)]e_{q,p,s-1}^{\tilde{\alpha}^2q^{-2\pi/(s+1)}}-q^{2\pi/(s+1)}\tilde{\alpha}^2e_{q,p,s-2}^{\tilde{\alpha}^2}},\\ S_Y&=\frac{2\tilde{\alpha}^2(q^{2\pi/(s+1)}-1)e_{q,p,s-2}^{\tilde{\alpha}^2}-2[2\pi/(s+1)]e_{q,p,s-1}^{\tilde{\alpha}^2q^{-2\pi/(s+1)}}}{\tilde{\alpha}^2e_{q,p,s-1}^{\tilde{\alpha}^2}-[2\pi/(s+1)]e_{q,p,s-1}^{\tilde{\alpha}^2q^{-2\pi/(s+1)}}-q^{2\pi/(s+1)}\tilde{\alpha}^2e_{q,p,s-2}^{\tilde{\alpha}^2}}.\end{aligned} \tag{39}$$

Obviously, squeezing of the $\hat{X}_\phi$ component is obtained when

$$\begin{aligned}&\left[\frac{2\pi}{s+1}\right]e_{q,p,s-1}^{\tilde{\alpha}^2q^{-2\pi/(s+1)}}-\tilde{\alpha}^2e_{q,p,s-1}^{\tilde{\alpha}^2}+q^{2\pi/(s+1)}\tilde{\alpha}^2e_{q,p,s-2}^{\tilde{\alpha}^2}<0,\\ &2\tilde{\alpha}^2(1+q^{2\pi/(s+1)})e_{q,p,s-2}^{\tilde{\alpha}^2}+2\left[\frac{2\pi}{s+1}\right]e_{q,p,s-1}^{\tilde{\alpha}^2q^{-2\pi/(s+1)}}-4\tilde{\alpha}^2(e_{q,p,s}^{\tilde{\alpha}^2})^{-1}(e_{q,p,s-1}^{\tilde{\alpha}^2})^2<0.\end{aligned} \tag{40}$$

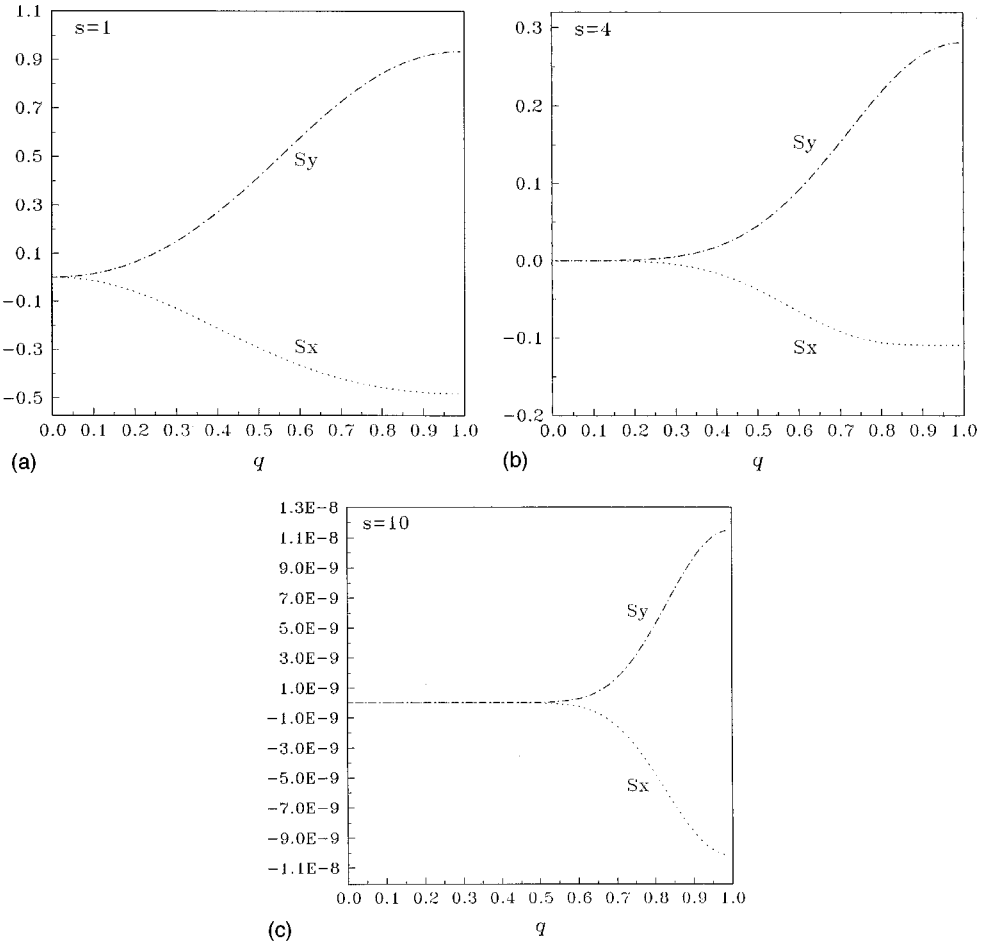

FIG. 1. Parameters S_X and S_Y [see Eqs. (37) and (39)] for the q-PCSs with $\alpha=1$ are plotted as a function of q.

There seems to exist a squeezing of the $\hat{Y}_\phi$ component in some term. However, after quantities of numerical analyses, one can understand that S_Y is always greater than zero, whatever q, s and α are (where $0<q<1$, α is a real number, s is a positive integer), so that there is not any squeezing of the $\hat{Y}_\phi$ component.

In Figs. 1 and 2 we plot the parameters S_X and S_Y for the q-PCSs $|\alpha,s\rangle$ with $\alpha=1,4$ in $(s+1)$-dimensional state space for various values of s as a function of q. From these figures it is clearly seen that S_Y is always greater that zero and in certain cases S_X is less than zero.

From the above analyses, we can conclude that when α is a real number, there does not exist any squeezing of the $\hat{Y}_\phi$ component, but squeezing of the $\hat{X}_\phi$ component can be obtained. A similar discussion shows that when α is a pure imaginary number, no $\hat{X}_\phi$ squeezing appears, while there may exist $\hat{Y}_\phi$ squeezing.

V. NUMBER-PHASE SQUEEZING AND ITS UNCERTAINTY RELATIONS FOR A TWO-STATE SYSTEM

It is instructive to see how the ideas advanced in this paper can be illustrated with the simplest finite-dimensional Hilbert space, namely that of a two-state system (i.e., the $s=1$ case), which is of some importance in quantum optics. We take $\theta_0=0$, then $\theta_1=\pi$. The relations between number-state basis and phase-state basis are

$$|0\rangle=\frac{1}{\sqrt{2}}\,(|0\rangle_p+|\theta_1\rangle),\quad |1\rangle=\frac{1}{\sqrt{2}}\,(|0\rangle_p-|\theta_1\rangle), \tag{41}$$

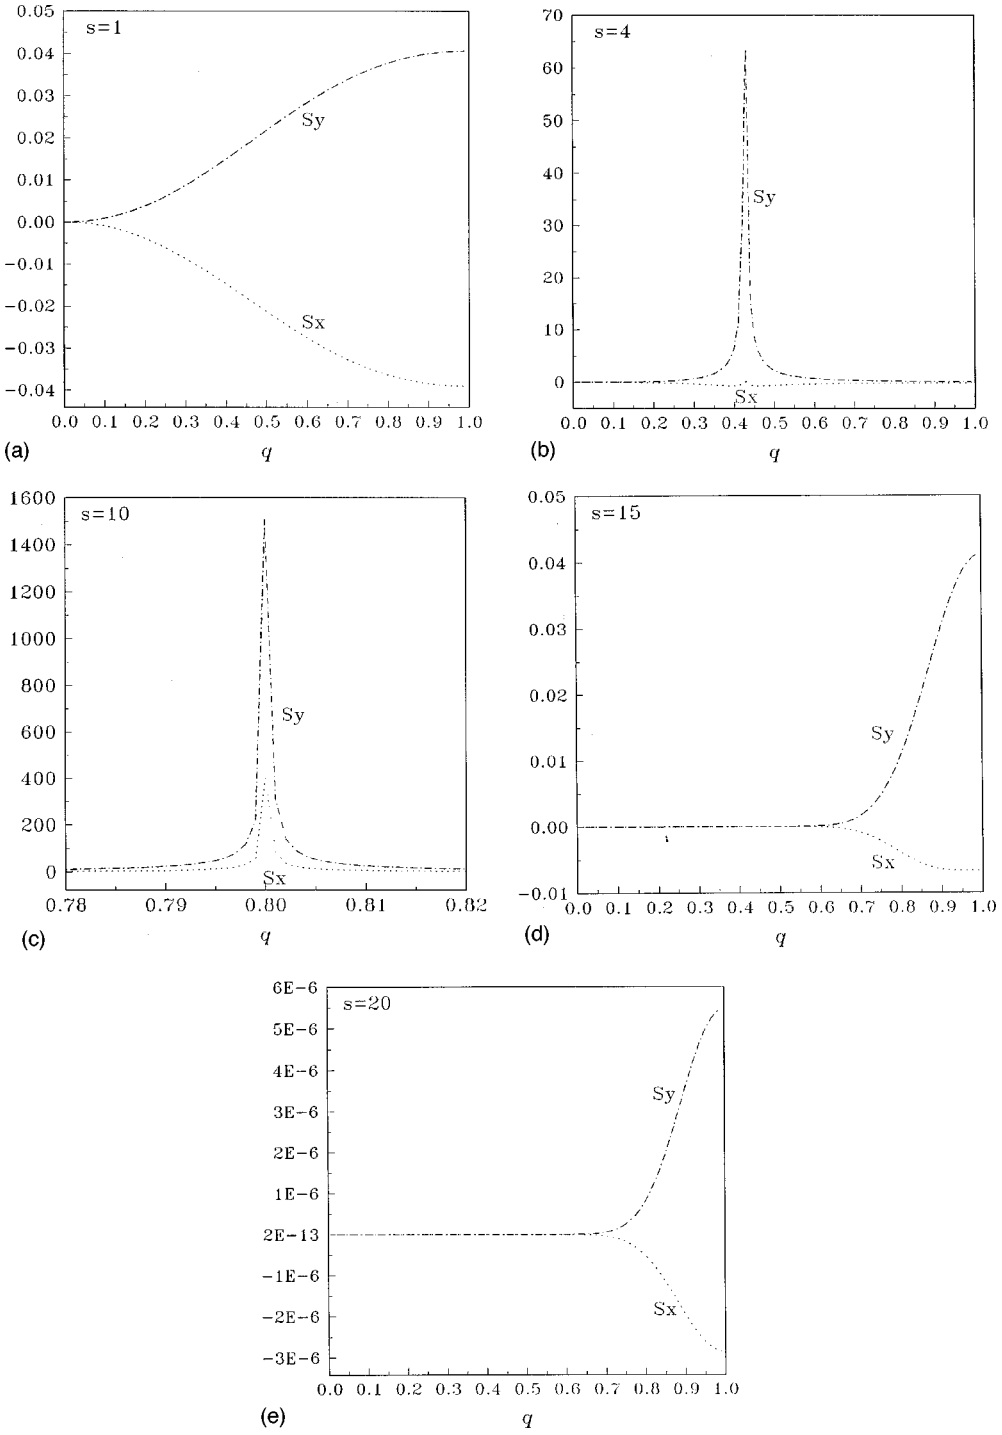

FIG. 2. Parameters S_X and S_Y [see Eqs. (37) and (39)] for the q-PCSs with $\alpha=4$ are plotted as a function of q.

$$|0\rangle_p=\frac{1}{\sqrt{2}}\,(|0\rangle+|1\rangle),\quad |\theta_1\rangle=\frac{1}{\sqrt{2}}\,(|0\rangle-|1\rangle).$$

The number operator and phase operator can be written in the two bases, respectively

$$\hat{N}=|1\rangle\langle 1|=\tfrac{1}{2}(|0\rangle_{pp}\langle 0|+|\theta_1\rangle\langle\theta_1|-|0\rangle_p\langle\theta_1|-|\theta_1\rangle_p\langle 0|),\tag{42}$$

$$\hat{\Phi}_\theta = \pi|\theta_1\rangle\langle\theta_1| = \frac{\pi}{2}(|0\rangle\langle 0| + |1\rangle\langle 1| - |0\rangle\langle 1| - |1\rangle\langle 0|).$$

Using Eq. (9), we get

$$\cos\hat{\Phi}_\theta = |0\rangle_{pp}\langle 0| - |\theta_1\rangle\langle\theta_1|. \tag{43}$$

Then we have the following commutation relations:

$$\begin{aligned}[\hat{N},\hat{\Phi}_\theta] &= \frac{\pi}{2}(|\theta_1\rangle_p\langle 0| - |0\rangle_p\langle\theta_1|),\\ [\hat{N},\cos\hat{\Phi}_\theta] &= |0\rangle_p\langle\theta_1| - |\theta_1\rangle_p\langle 0|.\end{aligned} \tag{44}$$

When $s=1$, the q-PCSs can be expressed as

$$\begin{aligned}|\alpha,1\rangle &= \left(1+\frac{|\tilde{\alpha}|^2}{[\pi]}\right)^{-1/2}\left(|0\rangle_p + \frac{\tilde{\alpha}}{\sqrt{[\pi]}}|\theta_1\rangle\right)\\ &= A|0\rangle_p + \exp(i\phi)B|\theta_1\rangle\\ &= \frac{1}{\sqrt{2}}(A+\exp(i\phi)B)|0\rangle + \frac{1}{\sqrt{2}}(A-\exp(i\phi)B)|1\rangle,\end{aligned} \tag{45}$$

where $\tilde{\alpha}=|\tilde{\alpha}|e^{i\phi}$, $A\equiv(1+|\tilde{\alpha}|^2/[\pi])^{1/2}$, $B\equiv|\tilde{\alpha}|/\sqrt{[\pi]}(1+|\tilde{\alpha}|^2/[\pi])^{-1/2}$, and they satisfy $A^2+B^2=1$.

A. $\hat{\Phi}_\theta - \hat{N}$ squeezing

The variances of the phase and number operator and the expectation value of their commutater in the q-PCSs (45) are

$$\begin{aligned}\langle(\Delta\hat{N})^2\rangle &= \tfrac{1}{4} - A^2B^2\cos^2\phi,\\ \langle(\Delta\hat{\Phi}_\theta)^2\rangle &= \pi^2A^2B^2,\\ \langle[\hat{N},\hat{\Phi}_\theta]\rangle &= -i\pi AB\sin\phi,\end{aligned} \tag{46}$$

so that the corresponding parameters are

$$\begin{aligned}S_\Phi &= \frac{2\pi AB - |\sin\phi|}{|\sin\phi|},\\ S_N &= \frac{1-4A^2B^2\cos^2\phi - 2\pi AB|\sin\phi|}{2\pi AB|\sin\phi|}.\end{aligned} \tag{47}$$

In what follows we will study the q-PCSs (45) in which the operators $\hat{N}$ and $\hat{\Phi}_\theta$ are subfluctuant, that is, in which squeezing of the variances of these operators can be observed.

1. Squeezing in $\hat{\Phi}_\theta$

Let us suppose $\theta_0-\phi=n\pi+\pi/2$ (n is a integer). In this case the q-PCSs (45) take the form

$$|\alpha,1\rangle = A|0\rangle_p \pm iB|\theta_1\rangle. \tag{48}$$

It is easy to check that these are the intelligent states with respect to the operators $\hat{\Phi}_\theta$ and $\hat{N}$ with the Heisenberg relation

$$\langle(\Delta\hat{N})^2\rangle\langle(\Delta\hat{\Phi}_\theta)^2\rangle=\frac{1}{4}\,|\langle[\hat{N},\hat{\Phi}_\theta]\rangle|^2=\frac{\pi^2}{4}\,A^2B^2. \tag{49}$$

The squeezing parameters describing the degree of squeezing of the variances of operators $\hat{\Phi}_\theta$ and $\hat{N}$ in the states (48) are

$$S_\Phi=2\pi AB-1,\quad S_N=\frac{1}{2\pi AB}-1. \tag{50}$$

From above it follows that when $2\pi AB<1$, the phase operator $\hat{\Phi}_\theta$ is subfluctuant (i.e., $S_\Phi<0$) and the number operator $\hat{N}$ is superfluctuant ($S_N>0$) in these states (48). Moreover, when $2\pi AB>1$, $\hat{\Phi}_\theta$ is superfluctuant and $\hat{N}$ is subfluctuant. In particular, if $2\pi AB\to 0$ (i.e., $\alpha\to 0$), $S_\Phi\to -1$ while $S_N\to +\infty$. Simultaneously the Heisenberg relation (49) reaches its minimum, which implies that the q-PCSs under consideration are MUSs. From Eq. (48) we find that the MUSs are

$$\lim_{\alpha\to 0}|\alpha,1\rangle=|0\rangle_p\,. \tag{51}$$

The phase operator $\hat{\Phi}_\theta$ is ultimately subfluctuant (100% squeezed) in these states.

2. Squeezing in $\hat{N}$

If $AB=1$ (i.e., $|\alpha|=1/\sqrt{[}\pi]$), the q-PCSs (45) take the form

$$|\alpha,1\rangle=\frac{1}{\sqrt{2}}\,(|0\rangle_p+\exp(i\phi)|\theta_1\rangle). \tag{52}$$

These are also the intelligent states with respect to the operators $\hat{\Phi}_\theta$ and $\hat{N}$ with the Heisenberg relation

$$\langle(\Delta\hat{N})^2\rangle\langle(\Delta\hat{\Phi}_\theta)^2\rangle=\frac{1}{4}\,|\langle[\hat{N},\hat{\Phi}_\theta]\rangle|^2=\frac{\pi^2}{16}\sin^2\,\phi. \tag{53}$$

In this case, the squeezing parameters take the form

$$S_\Phi=\frac{\pi-|\sin\,\phi|}{|\sin\,\phi|}>0,\quad S_N=\frac{|\sin\,\phi|-\pi}{\pi}<0, \tag{54}$$

which imply that the phase operator is superfluctuant (i.e., $S_\Phi>0$), while the number operator is subfluctuant (i.e., $S_N<0$). In particular, the q-PCSs under consideration become MUSs when $\phi=n\pi$. At this time, $S_N\to -1$, and $S_\Phi\to +\infty$. From Eq. (52) we can obtain the following MUSs:

$$|\alpha,1\rangle=\begin{cases}\dfrac{1}{\sqrt{2}}\,(|0\rangle_p+|\theta_1\rangle), & (\phi=0)\\[2ex] \dfrac{1}{\sqrt{2}}\,(|0\rangle_p-|\theta_1\rangle), & (\phi=\pi)\end{cases}. \tag{55}$$

B. cos $\hat{\Phi}_\theta$–$\hat{N}$ squeezing

The variance of the operator $\cos\hat{\Phi}_\theta$ and the expectation value of the commutator $[\cos\hat{\Phi}_\theta,\hat{N}]$ in the q-PCSs (45) are

$$\langle(\Delta\ \cos\hat{\Phi}_\theta)^2\rangle = 4A^2B^2,$$

$$\langle[\hat{N},\cos\hat{\Phi}_\theta]\rangle = 2iAB\ \sin\ \phi. \tag{56}$$

The corresponding squeezing parameters are

$$S_{\cos\Phi} = \frac{4AB - |\sin\ \phi|}{|\sin\ \phi|}, \quad S_N = \frac{1 - 4A^2B^2\ \cos^2\ \phi - 4AB|\sin\ \phi|}{4AB|\sin\ \phi|}. \tag{57}$$

If $\theta_0 - \phi = n\pi + \pi/2$ (n is a integer), the q-PCSs take the form of Eq. (48), and are also the intelligent states with respect to the operators $\cos\hat{\Phi}_\theta$ and $\hat{N}$ with the Heisenberg relation

$$\langle(\Delta\hat{N})^2\rangle\langle(\Delta\ \cos\hat{\Phi}_\theta)^2\rangle = \tfrac{1}{4}|\langle[\hat{N},\cos\hat{\Phi}_\theta]\rangle|^2 = A^2B^2. \tag{58}$$

In this case, the squeezing parameters become

$$S_{\cos\Phi} = 4AB - 1,$$

$$S_N = \frac{1}{4AB} - 1. \tag{59}$$

From above it can be seen that when $4AB < 1$, $\cos\hat{\Phi}_\theta$ is superfluctuant ($S_\Phi < 0$) while $\hat{N}$ is subfluctuant ($S_N > 0$), and when $4AB > 1$, $\hat{\Phi}_\theta$ is subfluctuant while $\hat{N}$ is superfluctuant. In particular, if $AB \to 0$ (i.e., $\alpha \to 0$), $S_{\cos\Phi} \to -1$ and $S_N \to +\infty$, which means that the operator $\cos\hat{\Phi}_\theta$ is subfluctuant (with 100% degree of squeezing) in these states, and that the q-PCSs under consideration are MUSs as in Eq. (51).

If we take $2AB = 1$, we can get the similar squeezing properties of $\hat{N}$ as in Sec. V A.

VI. CONCLUSIONS

In this paper we have constructed the q-PCSs of the q-HO in the finite-dimensional Hilbert space and discussed some properties of them, for instance, overcompleteness, phase (or number)-distribution, and uncertainty relation. Those results are of interest for working on the q-deformed oscillator problem, and they may be used to investigate the phase properties of a q-deformed single-mode electromagnetic field. We have also studied the second-order squeezing properties of the phase quadrature operators with respect to the q-PCSs. In particular, we have investigated in detail the number-phase squeezing properties and the number-phase uncertainty relations for a two-state system and found some new number-phase MUSs.

(Received 8 May 1998; accepted for publication 11 August 1998)

We obtain the most general time-dependent potential $V(t,x_1,x_2)$ enabling separating of variables in the (1+2)-dimensional Schrödinger equation. With the use of this result the four classes of separable Schrödinger–Maxwell equations are constructed. © *1998 American Institute of Physics.* [S0022-2488(98)01212-2]

I. INTRODUCTION

In the Refs. 1 and 2 we have suggested an efficient direct approach to a problem of variable separation in the (1+2)-dimensional Schrödinger equation (SE) having a time-independent potential

$$i\psi_t+\psi_{x_1x_1}+\psi_{x_2x_2}=V(x_1,x_2)\psi. \tag{1}$$

With the help of this approach we have classified potentials $V(x_1,x_2)$ providing separability of Eq. (1) and, furthermore, obtained the full list of coordinate systems such that the corresponding Schrödinger equations are separable. It occurs that this approach can be extended in order to take into consideration the Schrödinger equation with time-dependent potential, namely

$$i\psi_t+\psi_{x_1x_1}+\psi_{x_2x_2}=V(t,x_1,x_2)\psi. \tag{2}$$

This class of SEs has numerous physical applications, in particular, they can be applied to describe the multiphoton ionization problem in the one electron atom.[3] Furthermore, the Keldysh type models in two space dimensions can be reduced to the particular form (2).[4]

In the present paper we obtain the complete description of potentials $V(t,x_1,x_2)$ such that SE is solvable by the method of separation of variables. Furthermore, we give the forms of the most general coordinate systems providing separability of the corresponding Schrödinger equations. As an application of thus obtained results we consider a problem of solving the Schrödinger–Maxwell equations by the method of separation of variables. This yields four classes of the Schrödinger–Maxwell equations solvable by the method of separation of variables.

II. SEPARATION OF VARIABLES IN EQ. (2)

SE (2) is solvable in the sense of Ref. 2 via the separation Ansatz

$$\psi=Q(t,x_1,x_2)\varphi_0(t)\varphi_1(\omega_1(t,x_1,x_2))\varphi_2(\omega_2(t,x_1,x_2)), \tag{3}$$

if and only if the functions Q,ω_1,ω_2 satisfy the following system of nonlinear partial differential equations:

$$\omega_{1x_1}\omega_{2x_1}+\omega_{1x_2}\omega_{2x_2}=0, \tag{4}$$

$$B_{1a}(\omega_1)(\omega_{1x_1}^2+\omega_{1x_2}^2)+B_{2a}(\omega_2)(\omega_{2x_1}^2+\omega_{2x_2}^2)+R_a(t)=0, \tag{5}$$

$$2(\omega_{ax_1}Q_{x_1}+\omega_{ax_2}Q_{x_2})+Q(i\omega_{at}+\omega_{ax_1x_1}+\omega_{ax_2x_2})=0, \tag{6}$$

[a]Electronic mail: rzhdanov@apmat.freenet.kiev.ua

 © 1998 American Institute of Physics

$$(B_{01}(\omega_1)(\omega_{1x_1}^2+\omega_{1x_2}^2)+B_{02}(\omega_2)(\omega_{2x_1}^2+\omega_{2x_2}^2))Q$$
$$+iQ_t+Q_{x_1x_1}+Q_{x_2x_2}+R_0(t)Q-V(t,x_1,x_2)Q=0, \tag{7}$$

where B_{0a}, B_{1a}, B_{2a}, R_0, R_a are smooth functions of the given arguments and $a=1,2$.

The general solution of the system of Eqs. (4)–(6) has been constructed in Ref. 2. It splits into the four inequivalent classes given below

$$\text{I.}\quad \omega_1=A(t)x_1+W_1(t),\quad \omega_2=B(t)x_2+W_2(t),$$
$$Q(t,x_1,x_2)=\exp\left\{-\frac{i}{4}\left(\frac{A'}{A}x_1^2+\frac{B'}{B}x_2^2\right)-\frac{i}{2}\left(\frac{W_1'}{A}x_1+\frac{W_2'}{B}x_2\right)\right\};$$
$$\text{II.}\quad x_1=W(t)e^{\omega_1}\sin\omega_2+W_1(t),\quad x_2=W(t)e^{\omega_1}\cos\omega_2+W_2(t),$$
$$Q(t,x_1,x_2)=\exp\{iR(t,x_1,x_2)\};$$
$$\text{III.}\quad x_1=\tfrac{1}{2}W(t)(\omega_1^2-\omega_2^2)+W_1(t),\quad x_2=W(t)\omega_1\omega_2+W_2(t), \tag{8}$$
$$Q(t,x_1,x_2)=\exp\{iR(t,x_1,x_2)\};$$
$$\text{IV.}\quad x_1=W(t)\cosh\omega_1\cos\omega_2+W_1(t),\quad x_2=W(t)\sinh\omega_1\sin\omega_2+W_2(t),$$
$$Q(t,x_1,x_2)=\exp\{iR(t,x_1,x_2)\}.$$

Here A, B, W, W_1, W_2 are arbitrary smooth functions and the function $R=R(t,x_1,x_2)$ is given by the formula

$$R(t,x_1,x_2)=\frac{W'}{4W}((x_1-W_1)^2+(x_2-W_2)^2)+\frac{1}{2}(W_1'x_1+W_2'x_2).$$

Inserting the above formulas into Eq. (7) yields the four inequivalent classes of potentials $V(t,x_1,x_2)$ providing separability of SE (2)

$$\text{I.}\quad V(t,x_1,x_2)=F_0(t)+A^2F_1(\omega_1)+B^2F_2(\omega_2)+x_1^2\left[\frac{A''}{4A}-\frac{(A')^2}{2A^2}\right]$$
$$+x_2^2\left[\frac{B''}{4B}-\frac{(B')^2}{2B^2}\right]-x_1\left(\frac{A'W_1'}{A^2}-\frac{W_1''}{2A}\right)-x_2\left(\frac{B'W_2'}{B^2}-\frac{W_2''}{2B}\right), \tag{9}$$
$$\text{II.}\quad V(t,x_1,x_2)=F_0(t)+e^{-2\omega_1}W^{-2}[F_1(\omega_1)+F_2(\omega_2)]$$
$$-\frac{W''}{4W}(x_1^2+x_2^2)+x_1\left(\frac{W_1W''}{2W}-\frac{W_1''}{2}\right)+x_2\left(\frac{W_2W''}{2W}-\frac{W_2''}{2}\right), \tag{10}$$
$$\text{III.}\quad V(t,x_1,x_2)=F_0(t)+(\omega_1^2+\omega_2^2)^{-1}W^{-2}[F_1(\omega_1)+F_2(\omega_2)]$$
$$-\frac{W''}{4W}(x_1^2+x_2^2)+x_1\left(\frac{W_1W''}{2W}-\frac{W_1''}{2}\right)+x_2\left(\frac{W_2W''}{2W}-\frac{W_2''}{2}\right), \tag{11}$$
$$\text{IV.}\quad V(t,x_1,x_2)=F_0(t)+(\sinh^2\omega_1+\sin^2\omega_2)^{-1}W^{-2}[F_1(\omega_1)+F_2(\omega_2)]$$
$$-\frac{W''}{4W}(x_1^2+x_2^2)+x_1\left(\frac{W_1W''}{2W}-\frac{W_1''}{2}\right)+x_2\left(\frac{W_2W''}{2W}-\frac{W_2''}{2}\right), \tag{12}$$

where the functions ω_1,ω_2 are given by the corresponding formulas I–IV from Eq. (8) and F_0, F_1, F_2 are arbitrary functions.

Formulas (9)–(12) give the explicit forms of the most general potentials $V=V(t,x_1,x_2)$ such that the corresponding SE is solvable by the separation of variables. However, the potentials obtained can be substantially simplified if we take into account that the class of partial differential equations (2) is invariant with respect to the following coordinate transformations:

$$1.\ \tilde{t}=t, \quad \tilde{x}_1=x_1+a(t), \quad \tilde{x}_2=x_2+b(t), \tag{13}$$

$$\tilde{\psi}(\tilde{t},\tilde{x}_1,\tilde{x}_2)=\psi(t,x_1,x_2)\exp\left\{\frac{i}{2}\left[a'(t)x_1+b'(t)x_2\right]\right\}; \tag{14}$$

$$2.\ \tilde{t}=T(t), \quad \tilde{x}_1=c(t)x_1, \quad \tilde{x}_2=c(t)x_2, \tag{15}$$

$$\tilde{\psi}(\tilde{t},\tilde{x}_1,\tilde{x}_2)=\psi(t,x_1,x_2)\exp\left\{\frac{ic'(t)}{4c(t)}\left(x_1^2+x_2^2\right)\right\}; \tag{16}$$

$$3.\ \tilde{t}=t, \quad \tilde{x}_1=x_1, \quad \tilde{x}_2=x_2, \quad \tilde{\psi}(\tilde{t},\tilde{x}_1,\tilde{x}_2)=\psi(t,x_1,x_2)\exp\{id(t)\}.$$

Here $a(t)$, $b(t)$, $c(t)$, $d(t)$ are arbitrary smooth functions and the function $T(t)$ is determined by the equation $(dT/dt)=c^2(t)$. Using the above enumerated coordinate transformations we can choose $W_1=0$, $W_2=0$, $B=1$, $W=1$ and get the following expressions for V:

$$1.\ V(t,x_1,x_2)=A^2F_1(\omega_1)+F_2(\omega_2)+x_1^2\left[\frac{A''}{4A}-\frac{(A')^2}{2A^2}\right], \tag{17}$$

$$2.\ V(t,x_1,x_2)=e^{-2\omega_1}[F_1(\omega_1)+F_2(\omega_2)], \tag{18}$$

$$3.\ V(t,x_1,x_2)=(\omega_1^2+\omega_2^2)^{-1}[F_1(\omega_1)+F_2(\omega_2)], \tag{19}$$

$$4.\ V(t,x_1,x_2)=(\sinh^2\omega_1+\sin^2\omega_2)^{-1}[F_1(\omega_1)+F_2(\omega_2)], \tag{20}$$

where the functions F_1,F_2 are arbitrary, the functions ω_1,ω_2 are given by the corresponding relations below

$$1.\ x_1=\frac{1}{A}\omega_1, \quad x_2=\omega_2;$$

$$2.\ x_1=e^{\omega_1}\sin\omega_2, \quad x_2=e^{\omega_1}\cos\omega_2;$$

$$3.\ x_1=\tfrac{1}{2}(\omega_1^2-\omega_2^2), \quad x_2=\omega_1\omega_2;$$

$$4.\ x_1=\cosh\omega_1\cos\omega_2, \quad x_2=\sinh\omega_1\sin\omega_2,$$

and $A=A(t)$ is a solution of the nonlinear ordinary differential equation $(4A)^{-1}A''-(2A)^{-2}(A')^2+C_1A+C_2=0$ with arbitrary constant C_1,C_2.

Note that the Schrödinger equations with potentials (9)–(12) and (17)–(20), being equivalent from the point of view of the standard theory of partial differential equations, are inequivalent within the context of quantum mechanics. The reason for this situation is that the transformations (13) and (15) change the quantity $|\psi(t,x_1,x_2)|$ which is regarded in quantum mechanics as the probability density. This means, in particular, that from the point of view of quantum mechanics time dependence of the potential $V(t,x_1,x_2)$ is essential and cannot be neglected. Nevertheless, in a sequel we restrict our considerations to the simplest case when potentials are of the forms (17)–(20).

III. SEPARATION OF VARIABLES IN THE SCHRÖDINGER–MAXWELL SYSTEM

Now we apply the above results to separate variables in the Schrödinger–Maxwell system

$$(p_0 - eA_0)\psi - (\vec{p} - e\vec{A})^2\psi = 0,$$

$$\Box A_0 - \frac{\partial}{\partial t}(A_{0t} + \operatorname{div}\vec{A}) = 0,$$

$$\Box\vec{A} + \overrightarrow{\operatorname{grad}}(A_{0t} + \operatorname{div}\vec{A}) = \vec{0}.$$

Here $p_0 = i\partial/\partial t$, $p_a = i\partial/\partial x_a$, $a = 1,2,3$, $e = \text{const}$, $\Box = \partial^2/\partial t^2 - \Delta$ is the d'Alembert operator.

To this end we consider the expressions (17)–(20) as the Ansätze for the vector potential of a special form

$$A = (A_0(t,\vec{x}) \equiv e^{-1}V(t,x_1,x_2),\vec{0}). \tag{21}$$

If we insert the above expression into the vacuum Maxwell equations without currents then the three equations for the function V

$$V_{x_1x_1} + V_{x_2x_2} = 0, \quad V_{tx_a} = 0, \quad a = 1,2,$$

are obtained. Hence we get restrictions on the choice of the functions F_1, F_2 in the form of ordinary differential equations. After solving these we arrive at the following expressions for the functions $V(t,x_1,x_2)$:

1. $V = C_1(x_1^2 - x_2^2) + C_2x_1 + C_3x_2$, (22)

2. $V = C_1 \ln(x_1^2 + x_2^2) + (x_1^2 + x_2^2)^{-2}[C_2(x_1^2 - x_2^2) + C_3x_1x_2]$, (23)

3. $V = C_1x_1 + \dfrac{1}{\sqrt{x_1^2 + x_2^2}}\left[C_2\sqrt{\sqrt{x_1^2 + x_2^2} + x_1} + C_3\sqrt{\sqrt{x_1^2 + x_2^2} - x_1}\right]$, (24)

4. $V = \dfrac{f^2}{f^4 + x_2^2}\left[(C_2 + C_1 \operatorname{arcsinh} f)f\sqrt{1 + f^2} + \left(C_3 + C_1 \arcsin\dfrac{x_2}{f}\right)\dfrac{x_2\sqrt{f^2 - x_2^2}}{f^2}\right]$, (25)

where

$$f^2 = \tfrac{1}{2}[x_1^2 + x_2^2 - 1 + \sqrt{(x_1^2 + x_2^2)^2 - 2(x_1^2 - x_2^2) + 1}]$$

and C_1, C_2, C_3 are integration constants.

SE having the potential (22) separates in Cartesian coordinates into two harmonic oscillator one-dimensional stationary Schrödinger equations and, consequently, is exactly solvable. Given the potentials (23) and (25) with $C_1 = 0$, SE (2) separates into the Hill and Mathieu equations. Hence we conclude that its solutions are represented as products of the degenerated hypergeometric and Mathieu functions.[5] At last, SE having the potential (24) separates in parabolic coordinates into two quasi-exactly solvable one-dimensional stationary Schrödinger equations and, consequently, is quasi-exactly solvable. This means that the finite part of the spectrum of the operator $-\Delta + V(x_1,x_2)$ can be computed by purely algebraic methods (for more details about quasi-exactly solvable models of quantum mechanics, see Ref. 6).

IV. CONCLUDING REMARKS

The variable separation technique used in the present paper can be directly applied to the Schrödinger equations with electro-magnetic fields of more general configurations than Eq. (21). Namely it is possible to classify vector potentials of the electro-magnetic field of the form

$$A=(A_0(t,x_1,x_2),\quad A_1(t,x_1,x_2),\quad A_2(t,x_1,x_2),\quad 0).$$

such that the corresponding SEs are solvable by the method of separation of variables. Furthermore, it is also possible to modify this technique in order to take into consideration the Schrödinger equation in $(1+3)$-dimensions. Both problems are under investigation now and will be a topic of our future publications.

(Received 29 May 1998; accepted for publication 8 July 1998)

A wave equation on a one-dimensional interval I has a van der Pol type nonlinear boundary condition at the right end. At the left end, the boundary condition is fixed. At exactly the midpoint of the interval I, energy is injected into the system through a pair of transmission conditions in the feedback form of anti-damping. We wish to study chaotic wave propagation in the system. A cause of chaos by snapback repellers has been identified. These snapback repellers are repelling fixed points possessing homoclinic orbits of the non-invertible map in 2D corresponding to wave reflections and transmissions at, respectively, the boundary and the middle-of-the-span points. Existing literature [F. R. Marotto, J. Math. Anal. Appl. **63**, 199–223 (1978)] on snapback repellers contains an error. We clarify the error and give a refined theorem that snapback repellers imply chaos. Numerical simulations of chaotic vibration are also illustrated. © *1998 American Institute of Physics.* [S0022-2488(98)02012-X]

I. INTRODUCTION

Earlier, in a series of papers (Refs. 1–4), we studied chaotic vibrations of the wave equation due to a nonlinear self-excitation boundary condition of a van der Pol type: For the wave equation

$$w_{tt}(x,t)-w_{xx}(x,t)=0, \quad 0<x<1, \quad t>0, \tag{1}$$

let the right-end boundary condition be self-exciting:

$$w_x(1,t)=\alpha w_t(1,t)-\beta w_t^3(1,t), \quad \alpha,\beta>0, \quad t>0; \tag{2}$$

and let the left-end boundary condition be either fixed or free:

$$w(0,t)=0 \ \ (\text{fixed end}) \quad \text{or} \quad w_x(0,t)=0 \ \ (\text{free end}), \tag{3}$$

then the study in Refs. 2 and 4 shows that for initial conditions of generic type, the gradient (w_x,w_t) and the Riemann invariants (w_x+w_t,w_x-w_t) of (1) will be asymptotically periodic with one (for $0<\alpha\leqslant 1$) or two frequencies (for $\alpha>1$). Thus the wave equation does not have chaotic vibrations. However, instead of (3), if energy is injected into the system at the left end in the form of the boundary condition

$$w_x(0,t) = -\eta w_t(0,t), \quad \eta > 0, \quad \eta \neq 1. \tag{4}$$

Then for a certain parameter range of η, the injected energy will excite (asymptotically) periodic vibrations into chaos (Refs. 3 and 4). The proofs in Refs. 1 and 4 are based upon the reflection relations of the equation (1) at the two endpoints $x=0$ and $x=1$, which is perhaps the most natural Poincaré section of the initial-boundary value problem stated above.

Existing study on chaos in differential equations is concerned mostly with unpredictable behavior originating from nonlinearities appearing either in the governing equations or/and boundary conditions. Very few works have treated chaotic nonlinear systems containing disturbances or excitations from in-span or interior *pointwise sources*. So let us consider the following scenario. Let (1)–(3) stay the same as above and, in addition, assume that energy is injected into the system at an *in-span point*, say $x=a$, where $0<a<1$. This is a *pointwise excitation*. Can this also rouse periodic vibrations to chaos?

A volcanic eruption on earth may be idealized as a pointwise disturbance or excitation to the physical system governing global weather, because the scale of the volcano is negligibly small compared with that of the earth. The eruption injects ashes, chemicals, and energy, among other things, into the atmospheric currents and the stratosphere and can easily throw the global weather patterns off balance and into chaos, provided that the eruption is long and forceful. Our study undertaken here bears the resemblance of the kind of pointwise excitation occurring in Mother Nature and, thus, signifying certain mathematical and physical relevance of both models meriting investigation. However, we must also point out the dissimilarity: the volcanic eruption injects energy into the weather system as *exogenous forcing*, whereas the energy injection at an in-span point considered in this paper is in the *endogenous feedback form of anti-damping.*

We now describe the details of the mathematical model we wish to treat. Consider the wave equation

$$w_{tt}(x,t) - w_{xx}(x,t) = 0, \quad -1<x<0, \quad 0<x<1, \quad t>0. \tag{5}$$

The spatial interval is chosen to be $(-1,1)$ just for convenience. The wave speed plays a very minor role in the subsequent mathematical analysis, so we just set it to be equal to 1 in (5). Again, let the right-end boundary condition be self-exciting:

$$w_x(1,t) = \alpha w_t(1,t) - \beta w_t^3(1,t), \quad 0<\alpha \leqslant 1, \quad \beta>0, \quad t>0. \tag{6}$$

Note here that we require $0<\alpha \leqslant 1$ in order to avoid hysteresis and nonuniqueness of solutions.[2,4] At the left end, assume that the boundary condition be fixed:

$$w(-1,t) = 0, \quad t>0. \tag{7}$$

[If this is replaced by the free end boundary condition $w_x(-1,t)=0, \quad t>0$, then the mathematical analysis remains qualitatively the same.] At *exactly the middle of the span, $x=0$, we consider two types of transmission conditions:*

$$\text{(Type I)} \begin{cases} w_t(0+,t) - w_t(0-,t) = -\eta w_x(0+,t), \\ w_x(0-,t) = w_x(0+,t), \end{cases} \quad t>0, \quad \eta>0, \quad \eta \neq 2, \tag{8}$$

or

$$\text{(Type II)} \begin{cases} w(0-,t) = w(0+,t) \\ w_x(0+,t) - w_x(0-,t) = -\eta w_t(0+,t), \end{cases} \quad t>0, \quad \eta>0, \quad \eta \neq 2. \tag{8'}$$

Also prescribed are two initial conditions

$$w(x,0) = w_0(x), \quad w_t(x,0) = w_1(x), \quad -1<x<1, \tag{9}$$

where the initial state (w_0, w_1) lies in appropriate function spaces. The energy, $E(t)$, of the overall system (5)–(9), at time t, is defined to be

$$E(t)=\frac{1}{2}\int_{-1}^{1}[w_x(x,t)^2+w_t(x,t)^2]\,dx.$$

We now examine the two sets of transmission conditions (8) and (8′). Consider the time rate of change of energy:

$$\begin{aligned}\frac{d}{dt}E(t)&=\int_{-1}^{0}(w_xw_{xt}+w_tw_{tt})\,dx+\int_{0}^{1}(w_xw_{xt}+w_tw_{tt})\,dx\\&=\ldots[\text{integrating by parts and utilizing}(5)\text{–}(8')]\\&=\alpha w_t(1,t)^2-\beta w_t(1,t)^4+\begin{cases}\eta w_x(0+,t)^2 & \text{for (8)},\\ \eta w_t(0+,t)^2 & \text{for (8)}'.\end{cases}\end{aligned}\tag{10}\tag{10′}$$

We see that if $\eta<0$, then the transmission conditions (8) or (8)′ would have contributed *loss* of energy to the system. Indeed, for $\eta<0$, (8) and (8)′ model (the *only*) two primary *feedback damping* designs we know of today in structural dynamics (Ref. 5, pp. 50–51). But here in (8) or (8)′, we require $\eta>0$. Therefore the in-span conditions (8) or (8)′ contribute *energy increase* to the system. Therefore, physically, (8) or (8)′ correspond to *feedback anti-damping* devices which *inject energy* into the system.

Note that the first two terms $\alpha w_t(1,t)^2-\beta w_t(1,t)^4$, in (10) or (10)′, signify as in Refs. 2–4 the *self-regulating* (or self-exciting) effect of the boundary condition (6) because we have

$$\alpha w_t(1,t)^2-\beta w_t(1,t)^4\begin{cases}\geqslant 0 & |w_t(1,t)|\leqslant(\alpha/\beta)^{1/2},\\ \text{if} & \\ <0 & |w_t(1,t)|>(\alpha/\beta)^{1/2},\end{cases}\tag{11}\tag{11′}$$

i.e., it causes energy to *rise* if the velocity magnitude $|w_t(1,t)|$ *is small*, and to *fall* if $|w_t(1,t)|$ *is large*, just like what the damping terms do in the van der Pol ordinary differential equation $m\ddot{x}+(-\alpha\dot{x}+\beta\dot{x}^3)+kx=0$. Incidentally, the transmission conditions (81) can be incorporated into the governing equation (5) by rewriting it as

$$w_{tt}(x,t)-w_{xx}(x,t)-\eta w_t(0+,t)\,\delta(x)=0,\quad t>0,\tag{12}$$

where $\delta(x)$ is the Dirac delta distribution concentrated at $x=0$. Therefore, (8)′ does indeed correspond to a pointwise disturbance or excitation. Even though (8) also corresponds to a pointwise excitation, we do not as yet know of any similar way to incorporate (8) into the governing equation (5) through the adding of some delta functions.

The advantage of choosing the exact middle-of-the-span point $x_0=0\pm$ in (8) or (8)′ is that it makes the *method of characteristics* easily applicable to our model problem for the purpose of mathematical analysis. If, instead, we replace $x_0=0\pm$ by $x_0=a\pm$ therein, for some arbitrary a, $-1<a<1$, then the problem obviously is much more generally posed. Unfortunately, this generality (of x_0) also renders the problem highly intractable in mathematical technicality. As we will see below, the approach of the method of characteristics adopted by us is *not robust* with respect to the choice of energy injection point $x_0=0\pm$ in the sense that a slight perturbation, say, changing $x_0=0\pm$ to $x_0=\varepsilon\pm$ for some small $\varepsilon\neq 0$, would immediately fail all the mathematical analysis based on this approach. So the question is, how good or sound is the main conclusion of the paper that chaotic vibrations exist when $x_0\neq 0\pm$? This may be responded to, in a nonrigorous way, as follows. From the work in Ref. 6, we know that, in the linear case, corresponding to the choice $x_0=\varepsilon\pm$ with ε being irrational, there are many *aperiodic* solutions and, thus, the general system (with $x_0=\varepsilon\pm$) should be ''even more chaotic'' than the special case $x_0=0\pm$ when the nonlinearity (6) is present. However, a rigorous proof of this heuristic claim seems to be far out of reach for the time being; more efforts are required in order to be able to treat the general case.

We are now in a position to apply the method of characteristics to treat (5)–(9) as follows. Define, by folding the interval $(-1,0)$ onto the interval $(0,1)$, the following:

$$\left.\begin{aligned} w^{(1)}(x,t) &= -w(-x,t) \\ w^{(2)}(x,t) &= w(x,t) \end{aligned}\right\} \quad \text{for } x\in[0,1], \quad t\geqslant 0, \tag{13}$$

$$u_i=\tfrac{1}{2}(w_x^{(i)}+w_t^{(i)}), \quad v_i=\tfrac{1}{2}(w_x^{(i)}-w_t^{(i)}), \quad i=1,2. \tag{14}$$

Then the wave equation (5) is converted into a first-order hyperbolic system

$$\frac{\partial}{\partial t}\begin{bmatrix} u_1 \\ u_2 \\ v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \frac{\partial}{\partial x}\begin{bmatrix} u_1 \\ u_2 \\ v_1 \\ v_2 \end{bmatrix}, \quad 0<x<1, \quad t>0. \tag{15}$$

The reflection relation at $x=1$, according to (6), (7), and (14), is

$$\begin{bmatrix} u_1(1,t) \\ u_2(1,t) \end{bmatrix} = \mathcal{R}_{1,\alpha\beta}\left(\begin{bmatrix} v_1(1,t) \\ v_2(1,t) \end{bmatrix}\right) \equiv \begin{bmatrix} v_1(1,t) \\ F_{\alpha,\beta}(v_2(1,t)) \end{bmatrix}, \tag{16}$$

where for each given $v\in\mathbb{R}$ the function $u=F_{\alpha,\beta}(v)$ is well defined through the following implicit cubic equation,[2]

$$\beta(u-v)^3+(1-\alpha)(u-v)+2v=0. \tag{17}$$

Thus (16) constitutes the right-end boundary condition for (15). In what follows, we often write $\mathcal{R}_{1,\alpha\beta}$ simply as $\mathcal{R}_1$, in case no ambiguities should occur.

Remark I.1: In (17), for given fixed α, $0<\alpha\leqslant 1$, there exists a unique $u\in\mathbb{R}$ satisfying (17) for each given $v\in\mathbb{R}$. Contrarily, if $\alpha\notin(0,1]$, i.e., $1-\alpha\notin[0,1)$, for each given $v\in\mathbb{R}$, then there may exist one, two, or three real solution(s) $u\in\mathbb{R}$, and thus $F_{\alpha,\beta}$ is no longer a well-defined function. See more in (31)–(33) below. □

The reflection (i.e., transmission) relation at $x=0$, according to (8), (8′), and (14), is, respectively,

$$\begin{bmatrix} v_1(0,t) \\ v_2(0,t) \end{bmatrix} = \mathcal{R}_{0,\eta}\left(\begin{bmatrix} u_1(0,t) \\ u_2(0,t) \end{bmatrix}\right) \equiv \begin{bmatrix} \dfrac{\eta}{2-\eta} & \dfrac{2}{2-\eta} \\ \dfrac{2}{2-\eta} & \dfrac{\eta}{2-\eta} \end{bmatrix} \begin{bmatrix} u_1(0,t) \\ u_2(0,t) \end{bmatrix} \quad \text{for (8)}; \tag{18}$$

$$\begin{bmatrix} v_1(0,t) \\ v_2(0,t) \end{bmatrix} = -\mathcal{R}_{0,\eta}\left(\begin{bmatrix} u_1(0,t) \\ u_2(0,t) \end{bmatrix}\right), \quad \text{for (8′)}. \tag{18′}$$

The above [(18) or (18′)) constitutes the left-end boundary condition for (15). From now on, we often abbreviate $\mathcal{R}_{0,\eta}$ as $\mathcal{R}_0$. By abuse of notation, we will make no distinction between $\mathcal{R}_{0,\eta}$ and the matrix on the rhs of (18).

The original initial conditions (9) now lead to

$$\begin{bmatrix} u_1(x,0) \\ u_2(x,0) \\ v_1(x,0) \\ v_2(x,0) \end{bmatrix} = \begin{bmatrix} u_{1,0}(x) \\ u_{2,0}(x) \\ v_{1,0}(x) \\ v_{2,0}(x) \end{bmatrix}, \quad 0<x<1, \tag{19}$$

for some functions $u_{i,0}(x), v_{i,0}(x), x\in(0,1), i=1,2$, according to (14). In summary, (15)–(19) constitute the complete set of a well-posed initial-boundary value problem. This system has a unique solution (u_1,u_2,v_1,v_2): for $t=2k+\tau$, $k=0,1,2,\ldots,0\leqslant\tau<2$ and $0\leqslant x\leqslant 1$,

$$\begin{bmatrix} u_1(x,t) \\ u_2(x,t) \end{bmatrix} = \begin{cases} (\mathcal{R}_1 \circ \mathcal{R}_0)^k \left(\begin{bmatrix} u_{1,0}(x+\tau) \\ u_{2,0}(x+\tau) \end{bmatrix} \right), & \tau \leqslant 1-x, \\ \mathcal{R}_0^{-1} \circ (\mathcal{R}_0 \circ \mathcal{R}_1)^{k+1} \left(\begin{bmatrix} v_{1,0}(2-x-\tau) \\ v_{2,0}(2-x-\tau) \end{bmatrix} \right), & 1-x < \tau \leqslant 2-x, \\ (\mathcal{R}_1 \circ \mathcal{R}_0)^{k+1} \left(\begin{bmatrix} u_{1,0}(\tau+x-2) \\ u_{2,0}(\tau+x-2) \end{bmatrix} \right), & 2-x < \tau \leqslant 2; \end{cases}$$

$$\begin{bmatrix} v_1(x,t) \\ v_2(x,t) \end{bmatrix} = \begin{cases} (\mathcal{R}_0 \circ \mathcal{R}_1)^k \left(\begin{bmatrix} v_{1,0}(x-\tau) \\ v_{2,0}(x,\tau) \end{bmatrix} \right), & \tau \leqslant x, \\ \mathcal{R}_0 \circ (\mathcal{R}_0 \circ \mathcal{R}_1)^k \left(\begin{bmatrix} u_{1,0}(\tau-x) \\ u_{2,0}(\tau-x) \end{bmatrix} \right), & x < \tau \leqslant 1+x, \\ (\mathcal{R}_0 \circ \mathcal{R}_1)^{k+1} \left(\begin{bmatrix} v_{1,0}(2+x-\tau) \\ v_{2,0}(2+x-\tau) \end{bmatrix} \right), & 1+x < \tau \leqslant 2, \end{cases} \tag{20}$$

which has the same form as Ref. 2, (13) and (14). In the above, all the $\mathcal{R}_0$'s may be replaced by $-\mathcal{R}_0$'s if (18′) [or, equivalently, (8′))] takes place in lieu of (18).

Naturally, from the explicit representation (20) of the solution, the system (15)–(19) manifests chaotic behavior if and only if (the iterates of) the composite map(s) $\mathcal{R}_0\mathcal{R}_1$ and/or $\mathcal{R}_1\mathcal{R}_0$ is/are chaotic. Actually, $\mathcal{R}_0\mathcal{R}_1$ and $\mathcal{R}_1\mathcal{R}_0$ have identical dynamical behavior. This is seen in the following.

Proposition I.1: For each given α, $0<\alpha\leqslant 1$, $\beta>0$, and $\eta>0$, $\eta\neq 2$, the maps $\mathcal{R}_{0,\eta}\mathcal{R}_{1,\alpha\beta}$ and $\mathcal{R}_{1,\alpha\beta}\mathcal{R}_{0,\eta}$ are topologically conjugate.

Proof: First, we note that $\mathcal{R}_{0,\eta}$ is an invertible 2×2 matrix. The rest is then obvious from the following commutative diagram:

$$\begin{array}{ccc} \mathbb{R}^2 & \xrightarrow{\mathcal{R}_{0,\eta}\mathcal{R}_{1,\alpha\beta}} & \mathbb{R}^2 \\ {\scriptstyle \mathcal{R}_{0,\eta}^{-1}}\downarrow & & \downarrow{\scriptstyle \mathcal{R}_{0,\eta}^{-1}} \\ \mathbb{R}^2 & \xrightarrow{\mathcal{R}_{1,\alpha\beta}\mathcal{R}_{0,\eta}} & \mathbb{R}^2 \end{array}$$

□

Therefore, investigation of the periodic and chaotic behavior of only $\mathcal{R}_0\mathcal{R}_1$ suffices, because it implies that of $\mathcal{R}_1\mathcal{R}_0$, and vice versa.

If the transmission conditions (8′) take effect rather than (8), then we need to use (18′) and, consequently, (20), but with all $\mathcal{R}_0$'s therein substituted by $-\mathcal{R}_0$'s. This means that we must investigate the chaotic behavior of $-\mathcal{R}_0\mathcal{R}_1$ rather than $\mathcal{R}_0\mathcal{R}_1$. From the mathematical analysis point of view, we have found that the treatment of $-\mathcal{R}_0\mathcal{R}_1$ is qualitatively the same as that of $\mathcal{R}_0\mathcal{R}_1$. Henceforth, we will therefore only consider (8), (18), and the ensuing $\mathcal{R}_0\mathcal{R}_1$.

The main objective of this paper is to study the occurrence of chaos for the wave equation system as described. Recall from our earlier studies in Refs. 2–4 that the parameter β plays the *role of scaling*. Therefore, we may just fix β to be a positive constant, say $\beta=1$. By varying α and η increasingly from zero, either separately or jointly, we have observed through computer simulations at least the following three routes/sources of chaos for the map $\mathcal{R}_{0,\eta}R_{1,\alpha\beta}$:

A. Period doubling

For positive α and η close to zero, the map $\mathcal{R}_{0,\eta}\mathcal{R}_{1,\alpha\beta}$ has a stable period-4 orbit in two dimensions (2D). (It does not have any period-2 orbit, according to Proposition III.5 in Sec. III below.) Let us, say, fix $\alpha=1/2$ (and $\beta=1$), for example. By increasing η, at $\eta\approx 0.6725$, we observe that this period-4 orbit loses stability, and a new stable period-8 orbit supersedes it. The ratios of successive differences of parametrical values η where period doublings occur have been verified to tend to Feigenbaum's constant. So the numerical evidence in support of period doubling is strong and beyond doubt. Nevertheless, at this moment, the authors are only partially successful in establishing a period-doubling bifurcation theorem in 2D and in carrying out a computer-aided verification of the theorem. We hope to be able to defer a complete presentation of this to a sequel.

B. Snapback repellers

These are repelling fixed points or periodic points in whose neighborhoods a homoclinic orbit originates. For example (see Example V.1 in Sec. V), the origin in $\mathbb{R}^2$, as a repelling fixed point, is a snapback repeller for a restricted range of α and η values. So far, this is the only case for which we have sufficient understanding; its discussion will be the focus of the study in this paper (see more in Secs. IV and V).

C. Nondiffeomorphic horseshoes

The Smale horseshoe is a powerful technique for proving chaos of multidimensional maps. However, the powerful Smale–Birkhoff homoclinic theorem (Ref. 7, pp. 482–483) requires that the map be a *diffeomorphism*; so it must at least be *invertible*. Ours is not the case here because $\mathcal{R}_{1,\alpha\beta}$ is not invertible for any α, $0<\alpha\leqslant 1$, $\beta>0$; see Remark I.1 and (31)–(33) below. The lack of invertibility of $\mathcal{R}_1$ and, consequently, of $\mathcal{R}_0\mathcal{R}_1$ is related to the prevalent *irreversible* behavior of time-dependent nonlinear PDEs; see Sec. II. Numerical evidence strongly suggests that the map $\mathcal{R}_0\mathcal{R}_1$ has many periodic points of *saddle node* type in whose neighborhoods homoclinic orbits originate and, thus, we speculate that they cause chaos. (For lack of a better term, we call this a ''non-diffeomorphic horseshoe'' for the time being.) See some details in Example V.2. Notwithstanding, we must concede that before a rigorous proof is given, this remains just a speculation. For general non-invertible maps in two- or higher-dimensional spaces, as pointed out by Mira *et al.*[8] there are *not many optional* theoretical methods available to rigorously prove the occurrence of chaos. More dedicated cultivation of this area is very desirable.

The organization of the paper proceeds as follows. In Sec. II, we discuss the time irreversibility of our PDE system. In Sec. III, elementary properties of the map, including fixed points, stability, and invariant domains, are studied. In Sec. IV, we study chaos caused by snapback repellers. We point out an error in an earlier work by Marotto[9] and give a refined proof. In Sec. V, we present examples and illustrations of chaotic vibrations.

II. IRREVERSIBILITY FOR NONLINEAR PARTIAL DIFFERENTIAL EQUATIONS: THE LACK OF DIFFEOMORPHISM TO FORM A SMALE HORSESHOE

Recall from Ref. 2 that for $0<\alpha\leqslant 1$, $\beta>0$, the implicit relation (17) determines a unique function $u=F(v)=F_{\alpha,\beta}(v)$, where

$$u=F(v)=v+\left[-\frac{v}{\beta}+\sqrt{\frac{1}{27}\left(\frac{1-\alpha}{\beta}\right)^3+\frac{v^2}{\beta^2}}\right]^{1/3}+\left[-\frac{v}{\beta}-\sqrt{\frac{1}{27}\left(\frac{1-\alpha}{\beta}\right)^3+\frac{v^2}{\beta^2}}\right]^{1/3}, \tag{21}$$

by Cardan's formula. The function F is odd, with two critical points—one maximum and one minimum—at, respectively $-v_c^*$ and v_c^*, where $v_c^*=[(2-\alpha)/3]\sqrt{(1+\alpha)/3\beta}$. We also know that F satisfies the following properties:

$$\text{(i)}\quad F'(0)=-\frac{1+\alpha}{1-\alpha}, \tag{22}$$

$$\text{(ii)}\quad 0<F'(v)<1 \quad \text{for } |v|>v_c^*; \tag{23}$$

$$\text{(iii)}\quad F \text{ has three intercepts at } v=-v_I,\ 0,\ v_I, \quad \text{where } v_I\equiv\sqrt{\frac{1+\alpha}{\beta}}. \tag{24}$$

Also, recall from Ref. 3 that for η, $0<\eta<1$, the map $u=G\circ F(v)=G_\eta\circ F_{\alpha,\beta}(v)$, where $G_\eta\equiv(1+\eta)/(1-\eta)$, has exactly three fixed points

$$v=G\circ F(v), \quad \text{for } v=-v^*,\ 0,\ v^*; \quad v^*\equiv\frac{1+\eta}{2\eta}\sqrt{\frac{1+\alpha\eta}{\beta\eta}}. \tag{25}$$

Now, let us consider the question whether the system (15)–(19) is *time reversible*. We make a change of variable $t\mapsto -t$ and consider $t\geqslant 0$; we obtain the time-reversed system

$$\frac{\partial}{\partial t}\begin{bmatrix}\tilde{u}_1\\ \tilde{u}_2\\ \tilde{v}_1\\ \tilde{v}_2\end{bmatrix}=\begin{bmatrix}1&0&0&0\\0&1&0&0\\0&0&-1&0\\0&0&0&-1\end{bmatrix}\frac{\partial}{\partial x}\begin{bmatrix}\tilde{u}_1\\ \tilde{u}_2\\ \tilde{v}_1\\ \tilde{v}_2\end{bmatrix},\quad 0<x<1,\quad t>0, \tag{26}$$

with boundary conditions

$$\text{at } x=0\begin{bmatrix}\tilde{v}_1(0,t)\\ \tilde{v}_2(0,t)\end{bmatrix}=\tilde{\mathcal{R}}_0\left(\begin{bmatrix}\tilde{u}_1(0,t)\\ \tilde{u}_2(0,t)\end{bmatrix}\right)=\begin{bmatrix}-\frac{\eta}{2+\eta}&\frac{2}{2+\eta}\\ \frac{2}{2+\eta}&-\frac{\eta}{2+\eta}\end{bmatrix}\begin{bmatrix}\tilde{u}_1(0,t)\\ \tilde{u}_2(0,t)\end{bmatrix},\quad t>0,\quad (\eta>0), \tag{27}$$

$$\text{at } x=1\begin{bmatrix}u_1(1,t)\\ u_2(1,t)\end{bmatrix}=\tilde{\mathcal{R}}_1\left(\begin{bmatrix}\tilde{v}_1(1,t)\\ \tilde{v}_2(1,t)\end{bmatrix}\right)=\begin{bmatrix}\tilde{v}_1(1,t)\\ \tilde{F}_{\alpha,\beta}(\tilde{v}_2(1,t)\end{bmatrix},\quad t>0, \tag{28}$$

and certain initial conditions

$$\tilde{u}_i(x,0)=\tilde{u}_{i,0}(x),\quad \tilde{v}_i(x,0)=\tilde{v}_{i,0}(x),\quad i=1,2,\quad x\in[0,1], \tag{29}$$

where, in (28), the relation $\tilde{u}=\tilde{F}_{\alpha,\beta}(\tilde{v})$ is defined through the following cubic equation:

$$\beta(\tilde{u}-\tilde{v})^3-(1+\alpha)(\tilde{u}-\tilde{v})-2\tilde{v}=0,\quad 0<\alpha\leqslant 1,\quad \beta>0. \tag{30}$$

Note that $\tilde{u}$ and $\tilde{v}$ are restricted to be reals in (30). The relation $\tilde{F}_{\alpha,\beta}$ is *not* a function, as Cardan's formula for cubic algebraic equations gives the solutions of (30) as follows: let

$$D(\tilde{v})\equiv-\frac{1}{27}\frac{(1+\alpha)^3}{\beta^3}+\frac{\tilde{v}^2}{\beta^2}$$

be the discriminant for (30). Then
(i) if $D(\tilde{v})>0$, then $\tilde{u}$ is uniquely determined by $\tilde{v}$:

$$\tilde{u}=\tilde{F}_{\alpha,\beta}(\tilde{v})=\tilde{v}+\left[-\frac{\tilde{v}}{\beta}+\sqrt{D(\tilde{v})}\right]^{1/3}+\left[-\frac{\tilde{v}}{\beta}-\sqrt{D(\tilde{v})}\right]^{1/3}, \tag{31}$$

(ii) If $D(\tilde{v})<0$, then (30) yields three real solutions:

$$\tilde{u}_k=2S\ \cos\frac{\phi+2k\pi}{3};\quad S\equiv\sqrt{\frac{1}{3}\frac{1+\alpha}{\beta}},\quad \phi\equiv\cos^{-1}\left[\frac{3\sqrt{3}\tilde{v}}{(1+\alpha)}\sqrt{\frac{\beta}{1+\alpha}}\right],\quad k=1,2,3. \tag{32}$$

(iii) If $D(\tilde{v})=0$, then (30) yields two distinct real solutions:

$$\tilde{u}_1=2\sqrt[3]{\frac{\tilde{v}}{\beta}},\quad \tilde{u}_2=\sqrt[3]{-\frac{\tilde{v}}{\beta}}\ \text{(with multiplicity 2)}. \tag{33}$$

The multiplicity of solutions given in (32) and (33) spells trouble for the system (26)–(29). We have the following.

Theorem II.1 [Lack of global irreversibility of the system (15)–(19)]: *Let (26)–(29) be the time-reversed system of (15)–(19). Assume that the initial conditions* $\tilde{u}_{i,0}(x),\tilde{v}_{i,0}(x)$, $i=1,2$, *in (29) are continuous functions on [0,1] such that not all of these functions are identically zero. Then there exists an* $\varepsilon>0$ *such that if*

$$0 \leqslant \inf_{x\in[0,1]} |\tilde{u}_{i,0}(x)| < \varepsilon, \quad \text{or} \quad 0 \leqslant \inf_{x\in[0,1]} |\tilde{v}_{i,0}(x)| < \varepsilon, \quad \text{for some } i = 1 \text{ or } 2,$$

then the solution of the system (26)–(29) is not unique for $t>T$, for some $T>0$.

Proof: If $\tilde{v}_{2,0}(x) \not\equiv 0$, and if there exists some $\xi \in (0,1)$ such that

$$|\tilde{v}_{2,0}(\xi)| \leqslant \frac{1+\alpha}{3\sqrt{3}} \sqrt{\frac{1+\alpha}{\beta}}, \tag{34}$$

then $D(\tilde{v}_{2,0}(\xi)) \leqslant 0$. By (32) or (33), after the reflection at $x=1$ takes place at time $t=1-\xi$ through the relation (28), we see that the $\tilde{u}_2$-component lacks uniqueness. Therefore the solution of the system (26)–(29) loses uniqueness after $T=1-\xi$.

If $\tilde{v}_{2,0}(x) \equiv 0$ or if (34) does not hold for any $\xi \in (0,1)$, then there exists some $\xi \in (0,1)$ such that one of the following,

$$0 < |\tilde{u}_{1,0}(\xi)| < \varepsilon, \quad 0 < |\tilde{u}_{2,0}(\xi)| < \varepsilon, \quad 0 < |\tilde{v}_{1,0}(\xi)| < \varepsilon, \tag{35}$$

is true. We note that at $x=0$ the reflection matrix $\tilde{\mathcal{R}}_0$ has two eigenvalues: -1 and $(2-\eta)/(2+\eta)$, both with magnitudes not larger than 1. Thus $\tilde{\mathcal{R}}_0$ is nonexpansive. By choosing ε sufficiently small and tracing reflections along characteristics, by using the nonexpansiveness of $\tilde{\mathcal{R}}_0$ plus some detailed arguments (which are omitted), we obtain from (20) that at some $t_0>0$, we will gain

$$|\tilde{v}_2(\tilde{\xi}, t_0)| \leqslant \frac{1+\alpha}{3\sqrt{3}} \sqrt{\frac{1+\alpha}{\beta}}, \quad \text{for some } \tilde{\xi} \in (0,1).$$

Therefore again (32) or (33) applies, and, by (28), the solution loses uniqueness. □

The above irreversible behavior has all but ruled out the direct applicability of Smale's horseshoe to our problem.

III. ELEMENTARY PROPERTIES OF THE MAP $\mathcal{R}_0\mathcal{R}_1$

In this section, we perform an elementary stability analysis of fixed points of $\mathcal{R}_0\mathcal{R}_1$ and determine some invariant regions.

Proposition III.1: Let $0<\alpha\leqslant 1$, $\beta \geqslant 1$, and $\eta>0, \eta\neq 2$. Then the map $\mathcal{R}_0\mathcal{R}_1$ has exactly three fixed points:

$$(0,0), (v_1^*, v_2^*) \equiv \left(\frac{1}{2\eta} \sqrt{\frac{1+\alpha\eta}{\beta\eta}}, \frac{1+\eta}{2\eta} \sqrt{\frac{1+\alpha\eta}{\beta\eta}} \right), \quad (-v_1^*, -v_2^*). \tag{36}$$

Proof: We determine the fixed points by solving

$$\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \mathcal{R}_0\mathcal{R}_1 \left(\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} \right) = \begin{bmatrix} \dfrac{\eta}{2-\eta} v_1 + \dfrac{2}{2-\eta} F(v_2) \\ \dfrac{2}{2-\eta} v_1 + \dfrac{\eta}{2-\eta} F(v_2) \end{bmatrix}. \tag{37}$$

From the first component equation in (37), we obtain

$$v_1 = \frac{F(v_2)}{1-\eta}, \quad \eta \neq 1, \tag{38a}$$

$$F(v_2) = 0, \quad \eta = 1. \tag{38b}$$

For $\eta \neq 1$, substituting $(38a)_1$ into the second component equation of (37), we obtain

$$v_2=\frac{1+\eta}{1-\eta}F(v_2). \tag{39}$$

However, in the notation of Ref. 3, (2.1), (39) says exactly that $v_2=G\circ F(v_2)$, i.e., v_2 is a fixed point of the 1D map $G\circ F$, which according to (25) and (39) gives three values of v_2:

$$v_2=0,\quad \frac{1+\eta}{2\eta}\sqrt{\frac{1+\alpha\eta}{\beta\eta}},\quad -\frac{1+\eta}{2\eta}\sqrt{\frac{1+\alpha\eta}{\beta\eta}}. \tag{40}$$

Substituting these values first into (39) to obtain $F(v_2)$ and next into (38a), we obtain (36).

For $\eta=1$, (38b) says that v_2 is a v-axis intercept of F. By (24), there are three intercepts:

$$v_2=0,\quad \sqrt{\frac{1+\alpha}{\beta}},\quad -\sqrt{\frac{1+\alpha}{\beta}}. \tag{41}$$

Using these values and (38b) in the second component equation of (37), we obtain $v_1=v_2/2$. Thus we again have (36) with η being set to 1 therein. □

For any differentiable map $\mathcal{F}$: $\mathbb{R}^N\to\mathbb{R}^N$, we let $D\mathcal{F}(x)$ denote the Jacobian matrix of $\mathcal{F}$ at x. For our map $\mathcal{R}_0\mathcal{R}_1$, we have

$$D(\mathcal{R}_0\mathcal{R}_1)(v_1,v_2)=\begin{bmatrix}\frac{\eta}{2-\eta} & \frac{2}{2-\eta}F'(v_2)\\ \frac{2}{2-\eta} & \frac{\eta}{2-\eta}F'(v_2)\end{bmatrix}. \tag{42}$$

The stability analysis of fixed points and periodic points is well known to be important in the understanding of the dynamics of the map $\mathcal{R}_0\mathcal{R}_1$. We perform such an analysis for the three fixed points given in Proposition III.1.

Proposition III.2: Let $0<\alpha\leqslant 1,\beta>0$, and $0<\eta<2$. The fixed point (0,0) is a repelling fixed point of $\mathcal{R}_0\mathcal{R}_1$.

Proof: First, note from Ref. 2, Sec. III, (P. 3), that $F'(0)=-(1+\alpha)/(1-\alpha)$. From (42), we get

$$J\equiv D(\mathcal{R}_0\mathcal{R}_1)(0,0)=\begin{bmatrix}\frac{\eta}{2-\eta} & -\frac{2}{2-\eta}\frac{1+\alpha}{1-\alpha}\\ \frac{2}{2-\eta} & -\frac{\eta}{2-\eta}\frac{1+\alpha}{1-\alpha}\end{bmatrix}. \tag{43}$$

The eigenvalues of J are computed from

$$0=\det(\lambda I_2-J)\quad (\det\equiv\text{determinant})=\lambda^2-\left(1-\frac{1+\alpha}{1-\alpha}\right)\frac{\eta}{2-\eta}\lambda-\frac{1+\alpha}{1-\alpha}\left[\left(\frac{\eta}{2-\eta}\right)^2-\left(\frac{2}{2-\eta}\right)^2\right],$$

which are

$$\lambda_1,\lambda_2=\frac{1}{2}\left[-\frac{2\alpha}{1-\alpha}\frac{\eta}{2-\eta}\pm\sqrt{\left(\frac{2\alpha}{1-\alpha}\frac{\eta}{2-\eta}\right)^2-\frac{4(1+\alpha)}{1-\alpha}\frac{2+\eta}{2-\eta}}\right], \tag{44}$$

$$(\text{``}+\text{''}\quad\text{for}\ \lambda_1,\text{``}-\text{''}\text{for}\lambda_2).$$

If the discriminant Δ is negative,

$$\Delta\equiv\left(\frac{2\alpha}{1-\alpha}\frac{\eta}{2-\eta}\right)^2-\frac{4(1+\alpha)}{1-\alpha}\frac{2+\eta}{2-\eta}<0, \tag{45}$$

which happens if

$$\eta^2-4(1-\alpha^2)<0, \tag{46}$$

then λ_1 and λ_2 are complex conjugates of each other and, for $0<\eta<2$,

$$|\lambda_1|^2=|\lambda_2|^2=\lambda_1\lambda_2=-\frac{1+\alpha}{1-\alpha}\left[\left(\frac{\eta}{2-\eta}\right)^2-\left(\frac{2}{2-\eta}\right)^2\right]=\frac{1+\alpha}{1-\alpha}\frac{2+\eta}{2-\eta}>1.$$

Therefore the origin is a repelling *spiral point*.

On the other hand, if $\Delta\geqslant 0$, then $\lambda_2<\lambda_1<0$. We now show that $\lambda_1<-1$, or, from (44),

$$-\frac{2\alpha}{1-\alpha}\frac{\eta}{2-\eta}+\sqrt{\left(\frac{2\alpha}{1-\alpha}\frac{\eta}{2-\eta}\right)^2-\frac{4(1+\alpha)}{1-\alpha}\frac{2+\eta}{2-\eta}}<-2,$$

or

$$\sqrt{\left(\frac{2\alpha}{1-\alpha}\frac{\eta}{2-\eta}\right)^2-\frac{4(1+\alpha)}{1-\alpha}\frac{2+\eta}{2-\eta}}<-2+\frac{2\alpha}{1-\alpha}\frac{\eta}{2-\eta}. \tag{47}$$

Note that the rhs of the inequality above is non-negative because

$$\Delta\geqslant 0\Rightarrow\alpha^2+\frac{\eta^2}{2^2}\geqslant 1\Rightarrow\alpha+\frac{\eta}{2}\geqslant\left(\alpha^2+\frac{\eta^2}{2^2}\right)^{1/2}\geqslant 1 \quad \text{for } \alpha>0, \quad \eta>0$$

$$\Rightarrow 2\alpha+\eta-2\geqslant 0\Rightarrow -2+\frac{2\alpha}{1-\alpha}\frac{\eta}{2-\eta}\geqslant 0 \quad \text{for } 0<\alpha<1, \quad 0<\eta<2.$$

Squaring both sides of (47), we see that $\lambda_1<-1$ if and only if

$$-\frac{4(1+\alpha)}{1-\alpha}\cdot\frac{2}{2-\eta}<8, \quad \text{for } 0<\alpha<1, \quad 0<\eta<2,$$

which is always valid. Therefore $\lambda_2<\lambda_1<-1$. □

Corollary III.1: Let $0<\alpha\leqslant 1, \beta>0$, *and* $0<\eta<2$. *Then*

(i) if $\eta^2-4(1-\alpha^2)<0$, *then* (0,0) *is a repelling spiral point of* $\mathcal{R}_0\mathcal{R}_1$.

(ii) if $\eta^2-4(1-\alpha^2)\geqslant 0$, *then* (0,0) *is a repelling (star) nodal point of* $\mathcal{R}_0\mathcal{R}_1$. □

Proposition III.3: Let $0<\alpha\leqslant 1, \beta>1$, *and* $0<\eta<2$. *Then the fixed points* (v_1^*, v_2^*) *and* $(-v_1^*, -v_2^*)$ *are unstable saddle nodes of* $\mathcal{R}_0\mathcal{R}_1$.

Proof: We need only consider the stability of (v_1^*, v_2^*); that of $(-v_1^*, -v_2^*)$ follows from a symmetry argument.

The Jacobian matrix at (v_1^*, v_2^*), by (42), is

$$J\equiv\begin{bmatrix}\frac{\eta}{2-\eta} & \frac{2}{2-\eta}F'(v_2^*)\\ \frac{2}{2-\eta} & \frac{\eta}{2-\eta}F'(v_2^*)\end{bmatrix}.$$

The eigenvalues λ_1 and λ_2 of J satisfy

$$\begin{aligned}0&=\det(\lambda I_2-B)=\lambda^2-\frac{\eta}{2-\eta}(1+F'(v_2^*))-\frac{2+\eta}{2-\eta}F'(v_2^*),\\ \lambda_1,\lambda_2&=\frac{1}{2}\left[\frac{\eta}{2-\eta}(1+F'(v_2^*))\pm\sqrt{\left(\frac{\eta}{2-\eta}\right)^2(1+F'(v_2^*))^2+4\cdot\frac{2+\eta}{2-\eta}F'(v_2^*)}\right],\\ &(\text{``}+\text{''} \text{ for } \lambda_1, \quad \text{``}-\text{''} \text{ for } \lambda_2).\end{aligned} \tag{48}$$

From (22), (23), and Ref. 3, Lemma 2.4, we have

$$0<F'(v_2^*)<1, \quad \frac{1+\eta}{1-\eta}F'(v_2^*)>1. \tag{49}$$

Therefore we have $\lambda_1>0$, $\lambda_2>0$. We want to show further that

$$\lambda_1>1, \quad -1<\lambda_2<0. \tag{50}$$

From (48), we see that $\lambda_1>1$ holds if and only if

$$\sqrt{\left(\frac{\eta}{2-\eta}\right)^2(1+F'(v_2^*))^2+4\cdot\frac{2+\eta}{2-\eta}F'(v^*)}>2-\frac{\eta}{2-\eta}(1+F'(v_2^*)). \tag{51}$$

If $2-[\eta/(2-\eta)](1+F'(v_2^*))\leqslant 0$, then (51) automatically holds. So we consider $2-[\eta/(2-\eta)](1+F'(v_2^*))>0$. Squaring both sides of (51) and simplifying yields

$$\lambda_1>0\Leftrightarrow 4\cdot\frac{2+\eta}{2-\eta}F'(v_2^*)>4-\frac{4\eta}{2-\eta}(1+F'(v_2^*)),$$

$$\Leftrightarrow F'(v_2^*)>\frac{1-\eta}{1+\eta},$$

which holds by (49).

Next, we show that $0>\lambda_2>-1$. From (48),

$$\lambda_2>-1\Leftrightarrow 2+\frac{\eta}{2-\eta}(1+F'(v_2^*))>\sqrt{\left(\frac{\eta}{2-\eta}\right)^2(1+F'(v_2^*))^2+4\cdot\frac{2+\eta}{2-\eta}F'(v_2^*)}. \tag{52}$$

Squaring both sides of (52) and simplifying yields

$$\frac{4\eta}{2-\eta}(1+F'(v_2^*))+4>4\cdot\frac{2+\eta}{2-\eta}F'(v_2^*),$$

$$F'(v_2^*)<1.$$

The above again is true by (23). Therefore $\lambda_2>-1$. □

We now determine an elementary invariant rectangle, for positive η which is close to 0.

Proposition III.4: Assume $0<\alpha\leqslant 1,\beta>0$, *and* $0<\eta<1$. *Let* $G=G_\eta, F=F_{\alpha,\beta}$, v^*, v_I *and* v_c^* *be defined as in* (22)–(25). *Assume that* $\eta_{\alpha,\beta}^*$ *satisfies*

$$G_{\eta_{\alpha,\beta}^*}F_{\alpha,\beta}(-v_c^*)\leqslant v^*. \tag{53}$$

Then for η, $0<\eta<\eta_{\alpha,\beta}^*$,

$$D=\{(v_1,v_2)\in\mathbb{R}^2 \,|\, |v_1|\leqslant v_1^*, |v_2|\leqslant v_2^*\} \tag{54}$$

is invariant under $\mathcal{R}_0\mathcal{R}_1$, *i.e.,* $\mathcal{R}_0\mathcal{R}_1(D)\subset D$, *where*

$$v_1^*\equiv\frac{v^*}{1+\eta}, \quad v_2^*\equiv v^*. \tag{55}$$

Proof: Let $(v_1,v_2)\in D$ and

$$\begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \mathcal{R}_0\mathcal{R}_1\left(\begin{bmatrix} v_1 \\ v_2 \end{bmatrix}\right) = \begin{bmatrix} \frac{\eta}{2-\eta}v_1 + \frac{2}{2-\eta}F(v_2) \\ \frac{2}{2-\eta}v_1 + \frac{\eta}{2-\eta}F(v_2) \end{bmatrix}. \tag{56}$$

We want to show that $(u_1,u_2)\in D$.

By (25) and (53), using Ref. 3, Lemma 2.5, we first note that $\mathcal{I}\equiv[-v^*,v^*]$ is an invariant interval of $G\circ F$. So we have

$$-v_2^* \leqslant \frac{1+\eta}{1-\eta}F(v_2) \leqslant v_2^*, \quad \text{for all } v_2, |v_2| \leqslant v_2^* = v^*. \tag{57}$$

Thus, for $v_1, |v_1| \leqslant v_1^*$,

$$u_1 = \frac{\eta}{2-\eta}v_1 + \frac{2}{2-\eta}F(v_2) \leqslant \frac{\eta}{2-\eta}v_1^* + \frac{2}{2-\eta}F(v_2).$$

However,

$$\frac{\eta}{2-\eta}v_1^* + \frac{2}{2-\eta}F(v_2) \leqslant v_1^* \Leftrightarrow \frac{2}{2-\eta}F(v_2) \leqslant \frac{2(1-\eta)}{2-\eta}v_1^* \Leftrightarrow \frac{1+\eta}{1-\eta}F(v_2) \leqslant v_2^*. \tag{58}$$

By (57) we know that the last inequality in (58) holds. Therefore

$$u_2 \leqslant v_1^*. \tag{59}$$

Next,

$$u_1 = \frac{\eta}{2-\eta}v_1 + \frac{2}{2-\eta}F(v_2) \geqslant -\frac{\eta}{2-\eta}v_1^* + \frac{2}{2-\eta}F(v_2).$$

We have

$$\begin{aligned} -\frac{\eta}{2-\eta}v_1^* + \frac{2}{2-\eta}F(v_2) \geqslant -v_1^* &\Leftrightarrow \frac{2}{2-\eta}F(v_2) \\ &\geqslant \frac{(-2)(1-\eta)}{2-\eta}v_1^* \Leftrightarrow \frac{1+\eta}{1-\eta}F(v_2) \\ &\geqslant -(1+\eta)v_1^* \\ &= -v_2^* \Leftrightarrow \frac{1+\eta}{1-\eta}F(v_2) \geqslant -v_2^*. \end{aligned} \tag{60}$$

By (57), we again know that the last inequality in (60) holds. Hence $u_1 \geqslant -v_1^*$, which, incorporated with (59), gives $|u_1| \leqslant v_1^*$.

The proof that u_2 satisfies $|u_2| \leqslant v_2^*$ is similar and therefore omitted. □

Example III.1:

By Ref. 3, (2.20), and (25), we can determine $\eta_{\alpha,\beta}^*$ from the equality

$$G_{\eta_{\alpha,\beta}^*}F_{\alpha,\beta}(-v_c^*) = \frac{1+\eta_{\alpha,\beta}^*}{1-\eta_{\alpha,\beta}^*}\frac{1+\alpha}{3}\sqrt{\frac{1+\alpha}{3\beta}} = v^* = \frac{1+\eta_{\alpha,\beta}^*}{2\eta_{\alpha,\beta}^*}\sqrt{\frac{1+\alpha\eta_{\alpha,\beta}^*}{\beta\eta_{\alpha,\beta}^*}}.$$

Let $\alpha = 1/2$, $\beta = 1$, for example; we have

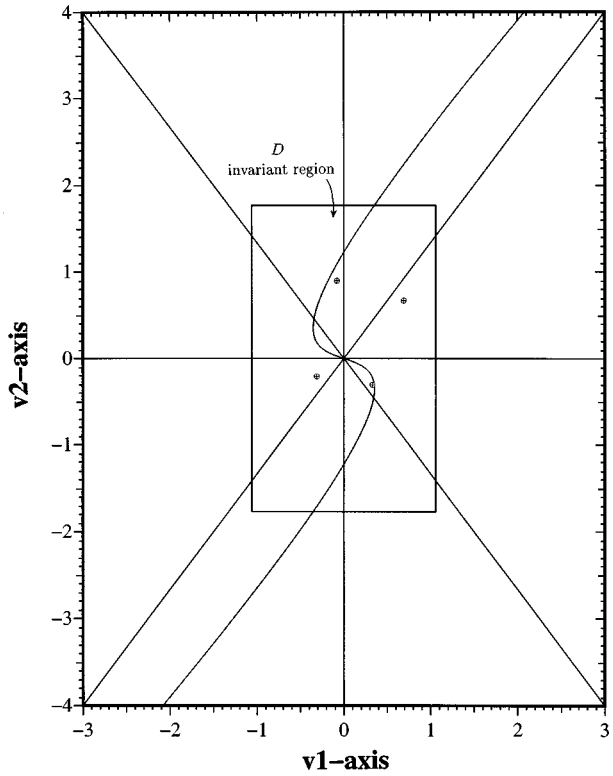

FIG. 1. An attracting period-4 orbit for Example III.1, where $\alpha=1/2$, $\beta=1$, and $\eta=2/3$ are used. The square is an invariant region guaranteed by Proposition III.4.

$$v_c^*\approx 0.3536,\ v^*\approx 1.7678 \quad \text{and} \quad \eta^*_{\alpha,\beta}=2/3\approx 0.6667,$$

$$v_1^*\approx 1.0607, \quad v_2^*=v^*\approx 1.7678.$$

For these values of α, β, and $\eta^*_{\alpha,\beta}$, we use the computer to plot the orbit $(\mathcal{R}_0\mathcal{R}_1)^k P_0$, with $P_0=(0.005,0.005)$ and $10^4\leqslant k\leqslant 10^5$. What we obtain is just an attracting period-4 orbit as shown in Fig. 1. There is another attracting period-4 orbit which is symmetric with respect to the origin of the one shown in Fig. 1 but not plotted there. □

The following can be verified in a straightforward way; its proof is omitted.

Proposition III.5: For given $\alpha, 0<\alpha\leqslant 1$, $\beta>0$, and $\eta>0, \eta\neq 2$, *the map* $\mathcal{R}_0\mathcal{R}_1$ *does not have any prime period-2 points.* □

The following theorem gives two unbounded invariant domains whereupon all trajectories grow unbounded.

Theorem III.1: Let $0<\alpha\leqslant 1$, $\beta>0$, *and* $0<\eta<1$. *Then the following two sets,*

$$U_1=\{(v_1,v_2)\in\mathbb{R}^2 | v_1\geqslant v_1^*, v_2\geqslant v_2^*\},$$

$$U_2=-U_1=\{(v_1,v_2)\in\mathbb{R}^2 | (-v_1,-v_2)\in U_1\},$$

are invariant under $\mathcal{R}_0\mathcal{R}_1$. *Furthermore, for each point* $(v_1,v_2)\in U_1\backslash\{(v_1^*,v_2^*)\}$ *we have*

$$\lim_{n\to\infty}|(\mathcal{R}_0\mathcal{R}_1)^n(v_1,v_2)|_2=\infty, \tag{61}$$

where $||_2$ is the Euclidean norm in $\mathbb{R}^2$. Same for U_2.

Proof: Let $(v_1,v_2)\in U_1$ and $(u_1,u_2)\in\mathcal{R}_0\mathcal{R}_1(v_1,v_2)$. Then

$$
\begin{aligned}
u_1 &= \frac{\eta}{2-\eta} v_1 + \frac{2}{2-\eta} F(v_2) \\
&\geqslant \frac{\eta}{2-\eta} v_1^* + \frac{2}{2-\eta} F(v_2^*) \\
&= \frac{\eta}{2-\eta} v_1^* + \frac{2}{2-\eta} \cdot \frac{1-\eta}{1+\eta} v_2^* \quad \text{[by (25),(55)]} \\
&= \left[\frac{\eta}{2-\eta} + \frac{2}{2-\eta} \cdot \frac{1-\eta}{1+\eta} \cdot (1+\eta) \right] v_1^* = v_1^*, \quad \text{[by (55)];}
\end{aligned}
$$

$$
\begin{aligned}
u_2 &= \frac{2}{2-\eta} v_1 + \frac{\eta}{2-\eta} F(v_2) \\
&\geqslant \frac{2}{2-\eta} v_1^* + \frac{\eta}{2-\eta} F(v_2^*) \\
&= \left[\frac{2}{2-\eta} \cdot \frac{1}{1+\eta} + \frac{\eta}{2-\eta} \frac{1-\eta}{1+\eta} \right] v_2^* = v_2^* \quad \text{[by (25),(55)].}
\end{aligned}
$$

Therefore U_1 is invariant under $\mathcal{R}_0\mathcal{R}_1$. The invariance of U_2 follows immediately from the oddness of the map $\mathcal{R}_0\mathcal{R}_1$.

For any initial state $(v_1^{(0)}, v_2^{(0)}) \in U_1$, let $(v_1^{(n)}, v_2^{(n)}) = (\mathcal{R}_0\mathcal{R}_1)^n (v_1^{(0)}, v_2^{(0)})$ be the nth iterate. Define the following Liapunov function on U_1:

$$
W(v_1, v_2) = \delta v_1 + v_2, \quad \text{for some } \delta > 0.
$$

Then

$$
\begin{aligned}
\Delta_1 W &\equiv W(v_1^{(1)}, v_2^{(1)}) - W(v_1^{(0)}, v_2^{(0)}) \\
&= (\delta v_1^{(1)} + v_2^{(1)}) - (\delta v_1^{(0)} + v_2^{(0)}) \\
&= \delta \left[\frac{\eta}{2-\eta} v_1^{(0)} + \frac{2}{2-\eta} F(v_2^{(0)}) \right] \\
&\quad + \left[\frac{2}{2-\eta} v_1^{(0)} + \frac{\eta}{2-\eta} F(v_2^{(0)}) \right] - (\delta v_1^{(0)} + v_2^{(0)}) \\
&= \left(\frac{\delta\eta + 2}{2-\eta} - \delta \right) v_1 + \left(\frac{2\delta + \eta}{2-\eta} F(v_2) - v_2 \right). \qquad (62)
\end{aligned}
$$

Now choose $\delta = 1/(1-\eta)$. Then $(\delta\eta + 2)/(2-\eta) - \delta = 0$, and

$$
\frac{2\delta + \eta}{2-\eta} = \frac{1+\eta}{1-\eta}.
$$

Continuing from (62), we get

$$
\Delta_1 W = \frac{1+\eta}{1-\eta} F(v_2^{(0)}) - v_2^{(0)} \geqslant 0, \quad \text{for } v_2 \geqslant v_2^*. \qquad (63)
$$

Note that equality in (63) holds when and only when $v_2 = v_2^*$. However, if $v_1^{(0)} > v_1^*$, $v_2^{(0)} = v_2^*$, then

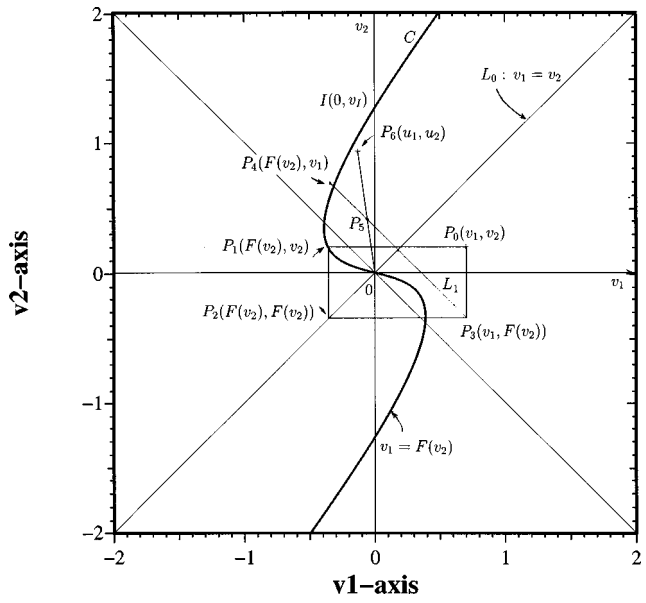

FIG. 2. Graphical construction of $(u_1,u_2)=\mathcal{R}_0\mathcal{R}_1(v_1,v_2)$.

$$v_2^{(1)}=\frac{2}{2-\eta}v_1^{(0)}+\frac{\eta}{2-\eta}F(v_2^*)>\frac{\eta}{2-\eta}v_1^*+\frac{\eta}{2-\eta}\frac{1-\eta}{1+\eta}v_2^*$$
$$=\left(\frac{2}{2-\eta}\frac{1}{1+\eta}+\frac{\eta}{2-\eta}\frac{1-\eta}{1+\eta}\right)v_2^*=v_2^*.$$

Therefore $\Delta_1 W>0$ for $(v_1^{(0)},v_2^{(0)})\in U_1\setminus\{(v_1^*,v_2^*)\}$. A little more elaborate argument further shows that $W(v_1^{(n)},v_2^{(n)})\to\infty$ as $n\to\infty$. Details are omitted. We therefore have (61). □

Remark III.1: By Theorem III.1, clearly chaos will not occur in U_1 and U_2 because trajectories originating or passing therein grow unbounded. This information is rather useful in eliminating nonchaotic cases.

Then, will chaos occur in the bounded invariant rectangle D in (53) for η in the range $0<\eta<\eta^*_{\alpha,\beta}$? Through numerical experiments, we have found that the answer is also negative; the map $\mathcal{R}_0\mathcal{R}_1$ displays only periodic behavior with periods 2^n, i.e., for the parameter range $\eta, 0<\eta<\eta^*_{\alpha,\beta}$, all orbits are asymptotically periodic; see Example III.1. What we have found empirically is that strange attractors (invariant regions) for chaotic $\mathcal{R}_0\mathcal{R}_1$ consist mainly of points in D, plus a small portion of points lying *outside* $D\cup U_1\cup U_2$ (see Figs. 3 and 14, for example).

Also, even though in Proposition III.4 and Theorem III.1 the range of η is restricted to $0<\eta<1$ (rather than $\eta>0$, $\eta\neq 2$), numerical experiments indicate that once η approaches $1-$, then trajectories become unbounded. Thus, it appears that no chaotic cases are lost if we restrict η, $0<\eta<1$.

Graphical methods, such as Lienard's (Ref. 10, pp. 31–33), have been found effective and useful in studying systems of nonlinear differential equations in 2D. To conclude this section, we describe a graphical method for the map $\mathcal{R}_0\mathcal{R}_1$. For any given point (v_1,v_2), we rewrite the relation (56) as

$$\begin{bmatrix}u_1\\u_2\end{bmatrix}=\frac{2+\eta}{2-\eta}\left\{\frac{\eta}{2+\eta}\begin{bmatrix}v_1\\F(v_2)\end{bmatrix}+\frac{2}{2+\eta}\begin{bmatrix}F(v_2)\\v_1\end{bmatrix}\right\}. \tag{64}$$

Note that in (64), the terms inside the curly parentheses are a convex combination of two points $(v_1,F(v_2))$ and $(F(v_2),v_1)$. Thus such a sum of terms corresponds to a point on the line segment with endpoints $(v_1,F(v_2))$ and $(v_2,F(v_1))$. Using (64), we show the graphical construction in Fig. 2 where C is the curve representing the function $v_1=F_{\alpha,\beta}(v_2)$, I is the point $(0,v_I)$, L_0 is the straight line $v_1=v_2$, P_0 is the point (v_1,v_2), P_1 is the point $(F(v_2),v_2)$, P_2 is the point

$(F(v_2),F(v_2))$, P_3 is the point $(v_1,F(v_2))$, P_4 is the point $(F(v_2),v_1)$, L_1 is the line segment joining P_3 with P_4, P_5 is a point on L_1 satisfying $P_5P_3{:}P_5P_4=\eta{:}2$, and P_6 is the image point (u_1,u_2) satisfying $OP_6{:}OP_5=(2+\eta)/(2-\eta)$.

IV. SNAPBACK REPELLERS AS A CAUSE OF CHAOS

Difficulties associated with proving chaos for noninvertible maps in two- or higher-dimensional spaces have been described itemwise in Secs. I A, B and C. As promised, we now focus our study on Sec. I B, the snapback repellers.

Snapback repellers for (noninvertible) one-dimensional maps are repelling fixed points with homoclinic orbits. The proof that they cause chaos may be found in Devaney (Ref. 11, Theorem 1.16.5, p. 124). We have found that that theorem can be properly generalized to N-dimensional noninvertible maps, and that for our 2D model problems under study here, such snapback repellers actually exist and, thus, they cause chaos. However, we are alerted by Ref. 9, p. 63, that a reference citation for snapback repellers by Marotto[9] already exists in the literature. It turns out that, however, by comparing Marotto's proof with ours, we are surprised that there is an error in Ref. 9. The error is not grievous; at his writing Marotto might think that it was just a simple fact (by changing to an equivalent norm to make things work) not worth mentioning at all. We nevertheless feel that the situation is confusing at least, leading us to clarify it below. We will then present a somewhat refined theorem in the spirit of Ref. 11, Theorem 1.16.5, *loc. cit.* (Even though the authors seem to have independently rediscovered such snapback repellers here, the credit of priority clearly goes to Marotto.[9])

First, recall the definition of a snapback repeller based on Marotto (Ref. 9, Def. 2.3, p. 203).

Definition IV.1: Let $\mathcal{F}{:}\mathbb{R}^N\to\mathbb{R}^N$ be C^1. Let Z be a fixed point of $\mathcal{F}$ such that all of the eigenvalues of $D\mathcal{F}(Z)$ have absolute values larger than 1. We say that Z is a snapback repeller if there exists a point X_0 in $W^u_{\rm loc}(Z)$, the local unstable set of Z, and some integer M, such that $\mathcal{F}^M(X_0)=Z$ and $\det D\mathcal{F}^M(X_0)\neq 0$. □

Now, let us restate the main theorem in Ref. 9.

Theorem IV.1: *[Marotto (Ref. 9, Theorem 3.1, pp. 204–205)] Let $\mathcal{F}{:}\mathbb{R}^N\to\mathbb{R}^N$ be C^1. If $\mathcal{F}$ possesses a snapback repeller, then $\mathcal{F}$ is chaotic. That is, there exists*

(i) a positive integer n such that for each integer $p\geqslant n$, $\mathcal{F}$ has a point of period p;

(ii) a ''scrambled set'' of $\mathcal{F}$, i.e., an uncountable set S containing no periodic points of $\mathcal{F}$ such that:

(a) $\mathcal{F}(S)\subset S$,

(b) for every $X,Y\in S$ with $X\neq Y$,

$$\overline{\lim_{k\to\infty}}|\mathcal{F}^k(X)-\mathcal{F}^k(Y)|>0,$$

(c) for every $X\in S$ and any periodic point Y of $\mathcal{F}$,

$$\overline{\lim_{k\to\infty}}|\mathcal{F}^k(X)-\mathcal{F}^k(Y)|>0;$$

(iii) an uncountable subset S_0 of S such that for every $X,Y\in S_0$,

$$\overline{\lim_{k\to\infty}}|\mathcal{F}^k(X)-\mathcal{F}^k(Y)|=0.$$

□

The statements in Theorem IV.1 are all correct without question. However, an error was made in the proof: in Ref. 9, p. 202, line 34, Marotto first states that in $\mathbb{R}^N$ that the usual Euclidean norm is to be used. Let us write it as

$$|x|_2=\left(\sum_{i=1}^N x_i^2\right)^{1/2},\quad \text{for } x=(x_1,\ldots,x_N)\in\mathbb{R}^N,$$

where the subscript 2 denotes the ℓ_2-norm. Then in Ref. 9, p. 203, lines 15–17, he writes:

''If all eigenvalues of $DF(Z)$ are greater than 1 in norm, then F displays the following local behavior at Z. For some $s>1$ and $r>0$:

$$\|F(X)-F(Y)\|>s\|X-Y\| \quad \text{for all } X,Y\in B_r(Z).'' \tag{65}$$

($B_r(Z)$ is the ball with radius r centered at Z.)

There, Marotto obviously was using the following property:

''Let A be an $N\times N$ real constant matrix such that all of its eigenvalues are larger than 1 in absolute value. Then A satisfies

$$|Ax|\geqslant\mu|x|, \quad \text{for some } \mu>1, \quad \text{for all } x\in\mathbb{R}^N.'' \tag{66}$$

Since in (65), the norm of Marotto's choice for the underlying space is the ℓ_2-norm, he must be interpreted to mean that in (66), there is a $\mu>1$ such that

$$|Ax|_2\geqslant\mu|x|_2, \quad \text{for all } x\in\mathbb{R}^N. \tag{67}$$

But it is well known that (67) is false. The following is a simple counterexample.

Example IV.1:Let ε and δ be positive. The matrix

$$A=\begin{bmatrix} 1+\epsilon+\dfrac{\delta}{2} & \dfrac{1}{2\delta} \\ \dfrac{\delta^3}{2} & 1+\epsilon+\dfrac{\delta}{2} \end{bmatrix}$$

has two eigenvalues $1+\epsilon$ and $1+\epsilon+\delta/2$, with respective corresponding eigenvectors

$$\begin{bmatrix} 1 \\ -\delta^2 \end{bmatrix}, \begin{bmatrix} 1 \\ \delta^2 \end{bmatrix}.$$

Choose a unit vector

$$x=\frac{1}{\sqrt{2}}\begin{bmatrix} 1 \\ -1 \end{bmatrix}.$$

Then

$$Ax=\frac{1}{\sqrt{2}}\begin{bmatrix} 1+\epsilon+\dfrac{\delta}{2}-\dfrac{1}{2\delta} \\ \dfrac{\delta^3}{2}-1-\epsilon-\dfrac{\delta}{2} \end{bmatrix}.$$

Take $\delta=1/2$. Then

$$|Ax|_2=\frac{1}{\sqrt{2}}\left[\left(\epsilon+\frac{1}{4}\right)^2+\left(1+\epsilon+\frac{3}{16}\right)^2\right]^{1/2}=\frac{1}{\sqrt{2}}\left[\frac{377}{256}+\epsilon\left(\frac{27}{8}+2\epsilon\right)\right]^{1/2}<0.9<1,$$

if ϵ is small. □

All norms in $\mathbb{R}^N$ or $\mathbb{C}^N$ are equivalent. What we need is a certain norm in $\mathbb{R}^N$ or $\mathbb{C}^N$ making (66) valid. We show, step by step, how to do this in the following.

Lemma IV 1: Let A be an invertible $N\times N$ real (resp. complex) constant matrix and let $|\ |$ be a norm in $\mathbb{R}^N$ (resp. $\mathbb{C}^N$). Then there exists a $\mu>0$ such that $|Ax|\geqslant\mu|x|$ holds for all $x\in\mathbb{R}^N$ (resp. $\mathbb{C}^N$) if and only if $\|A^{-1}\|\leqslant\mu^{-1}$, where $\|A^{-1}\|$ is the operator norm of A^{-1} corresponding to the norm $|\ |$ of the underlying $\mathbb{R}^N$ (resp. $\mathbb{C}^N$).

Proof: For any $x\in\mathbb{R}^N$ or $\mathbb{C}^N$, $x\neq 0$, we have

$$\mu^{-1}=\|A^{-1}\|=\sup_{y\neq 0}\frac{|A^{-1}y|}{|y|}\geqslant\frac{|A^{-1}w|}{|w|}=\frac{|x|}{|Ax|}\quad(x=A^{-1}w).$$

Therefore $|Ax|\geqslant\mu|x|$ for all $x\in\mathbb{R}^N$ or $\mathbb{C}^N$, $x\neq 0$, if and only if $\|A^{-1}\|\leqslant\mu^{-1}$. When $x=0$, the proof is trivial. □

Lemma IV.2: Let $D=\mathrm{diag}(\lambda_1,\ldots,\lambda_N)$ *be an* $N\times N$ *diagonal matrix with diagonal entries* $\lambda_1,\ldots,\lambda_N\in\mathbb{C}^N$. *Let* $\mathbb{C}^N$ *be the N-dimensional complex Euclidean space with* ℓ^2*-norm*

$$|z|_2=\left(\sum_{j=1}^{N}|z_j|^2\right)^{1/2},\quad z=(z_1,\ldots,z_N)\in\mathbb{C}^N.$$

Then $\|D\|_2$, *the operator norm of D corresponding to* $|\ |_2$, *satisfies*

$$\|D\|_2=\max_{1\leqslant j\leqslant N}|\lambda_j|.$$

Proof: Just expand any vector $z\in\mathbb{C}^N$ in terms of the basis eigenvectors $e_1,e_2,\ldots,e_n$, where e_j is the unit vector pointing in the jth axial direction. □

Lemma IV.3: Let J be an $m\times m$ *Jordan matrix with eigenvalue* λ *of Riesz index m:*

$$J=\begin{bmatrix}\lambda & 1 & 0 & \ldots & 0\\ 0 & \lambda & 1 & & \vdots\\ \vdots & & \ddots & \ddots & \\ \vdots & & & \ddots & 1\\ 0 & \ldots & 0 & & \lambda\end{bmatrix}.\tag{68}$$

Then for any given ε, *J has a similarity matrix* $\tilde{J}=D^{-1}JD$, *where D is an invertible diagonal matrix, such that*

$$\tilde{J}=\begin{bmatrix}\lambda & \varepsilon & & & 0\\ & \lambda & \varepsilon & & \\ & & \ddots & \ddots & \\ & & & \ddots & \varepsilon\\ 0 & & & & \lambda.\end{bmatrix}.\tag{69}$$

Proof: This can be found in Devaney (Ref. 11, Proposition 2.1.12, p. 168) or Franklin (Ref. 12, Exercise 13, p. 174). Its proof can be easily illustrated through the following 3×3 similarity matrix:

$$D^{-1}JD=\begin{bmatrix}a^{-1} & 0 & 0\\ 0 & a_2^{-1} & 0\\ 0 & 0 & a_3^{-1}\end{bmatrix}\begin{bmatrix}\lambda & 1 & 0\\ 0 & \lambda & 1\\ 0 & 0 & \lambda\end{bmatrix}\begin{bmatrix}a_1 & 0 & 0\\ 0 & a_2 & 0\\ 0 & 0 & a_3\end{bmatrix}=\begin{bmatrix}\lambda & a_1^{-1}a_2 & 0\\ 0 & \lambda & a_2^{-1}a_3\\ 0 & 0 & \lambda\end{bmatrix}.$$

Therefore, if we choose a_1,a_2, and a_3, the diagonal entries of D, to satisfy $a_1^{-1}a_2=a_2^{-1}a_3=\varepsilon$, we obtain the desired form (69). □

Theorem IV.2: Let A be an $N\times N$ *(real or complex) constant matrix such that all of its eigenvalues have absolute values larger than* μ. *Then there exists a norm* $|\cdot|$ *in* $\mathbb{C}^N$ *such that the associated operator-norm of* A^{-1}, $\|A^{-1}\|$, *satisfies* $\|A^{-1}\|\leqslant\mu^{-1}$. *Consequently, A satisfies* $|Ax|\geqslant\mu|x|$ *for all* $x\in\mathbb{R}^N$ *or* $\mathbb{C}^N$.

Proof: We first perform a similarity transformation to obtain $A^{-1}=PJP^{-1}$, where J is a Jordan canonical form of A^{-1}; J consists of submatrices J_k diagonally, for $k=1,2,\ldots,l$, where each J_k has the form (68). Applying Lemma IV.3, we may now assume that each J_k has the form

(69). Therefore, J is an ε-perturbation of a diagonal matrix; call that diagonal matrix D. The diagonal entries of D consist of λ_j^{-1}, the multiplicative inverses of the eigenvalues λ_j of A. By Lemma IV.2 and the assumption that $|\lambda_j|>\mu$ for all λ_j, we have

$$\|D\|_2=\max_j|\lambda_j^{-1}|<\mu^{-1}.$$

Since J is an ε-perturbation of D, for ε sufficiently small we obtain

$$\|J\|_2\leqslant\|D\|_2+\varepsilon'\leqslant\mu^{-1}, \tag{70}$$

because $\varepsilon'>0$ depends only on ε and can thus be made as small as we wish.

In $\mathbb{C}^N$, we now define a P-norm by

$$|z|_P=|P^{-1}z|_2.$$

Then, for a $z\in\mathbb{C}^N$,

$$|A^{-1}z|_P=|P^{-1}A^{-1}z|_2=|JP^{-1}z|_2\leqslant\|J\|_2|P^{-1}z|_2\leqslant\mu^{-1}|z|_P, \text{ by (70).}$$

Therefore

$$\|A^{-1}\|_P=\sup\frac{|A^{-1}z|_P}{|z|_P}\leqslant\mu^{-1}.$$

By Lemma IV.1, we have

$$|Ax|_P\geqslant\mu|x|_P, \quad \text{for all } x\in\mathbb{R}^N \quad \text{or } \mathbb{C}^N.$$

By incorporating Theorem IV.2 into its proof, Theorem IV.1 is now true. However, in what follows, let us provide a somewhat refined version of Theorem IV.1. Let

$$\mathcal{F}:\mathbb{R}^N\to\mathbb{R}^N, \quad \mathcal{F}(x)=(f_1(x),f_2(x),\ldots,f_N(x)), \quad x\in\mathbb{R}^N,$$

be a C^1 map. Then for $x^{(1)},x^{(2)}\in\mathbb{R}^N$, by applying the mean value theorem to the scalar-valued functions $f_1,\ldots,f_N$, we have

$$\mathcal{F}(x^{(1)})-\mathcal{F}(x^{(2)})=(\nabla f_1(y^1)\cdot(x^{(1)}-x^{(2)}),\nabla f_2(y^2)\cdot(x^{(1)}-x^{(2)}),\ldots,\nabla f_N(y^N)\cdot(x^{(1)}-x^{(2)})), \tag{71}$$

for some $y^1,\ldots,y^N\in\mathbb{R}^N$, where each y^j lies on the open line segment $L=\{y\in\mathbb{R}^N|y=\alpha x^{(1)}+(1-\alpha)x^{(2)},\alpha\in(0,1)\}$. We write (71) as

$$\mathcal{F}(x^{(1)})-\mathcal{F}(x^{(2)})=\mathcal{D}F\cdot[x^{(1)}-x^{(2)}], \tag{72}$$

where $\mathcal{DF}=\mathcal{DF}(Y)$, with $Y=(y^1,\ldots,y^n)\in\mathbb{R}^{N\times N}$, is an $N\times N$ matrix whose ith row vector is $\nabla f_i(y^i)$, where $\nabla f_i(y^i)$ makes (71) satisfied.

Theorem IV.3: Let $\mathcal{F}:\mathbb{R}^N\to\mathbb{R}^N$ be C^1, and p be a snapback repeller of $\mathcal{F}$. Then for each neighborhood U of p, there is an integer $n>0$ such that $\mathcal{F}^n$ has a hyperbolic invariant subset in U on which $\mathcal{F}^n$ is topologically conjugate to the shift map on the binary symbol space Σ_2.

Proof: The argument goes the same way as that in Ref. 11, Theorem 1.16.5, p. 124. Since p is a snapback repeller, all of the eigenvalues of $D\mathcal{F}(p)$ have absolute values larger than 1. By Theorem IV.2, we can define a norm $|\cdot|$ on $\mathbb{R}^N$ such that $\|[D\mathcal{F}(p)]^{-1}\|\leqslant\mu^{-1}$, for some $\mu>1$. By continuity, we can find an open neighborhood W of p in U and some $\tilde{\mu},1<\tilde{\mu}<\mu$, such that

$$\|[\mathcal{DF}(Y)]^{-1}\|\leqslant\tilde{\mu}^{-1}, \quad \text{for all } Y=(y^1,\ldots,y^N)\in W^N. \tag{73}$$

By the assumption of a snapback repeller, we can take a point $q\in W$ such that $\mathcal{F}^n(q)=p$ and $\det(D(\mathcal{F}^n)(q))\neq0$. Since the orbit of q contains only a finite number of points that do not lie in

W, and since $\det(D\mathcal{F}^n(q))\neq 0$, by continuity we can find a neighborhood V of q in W such that $\mathcal{DF}^n(Y)$ is invertible for all $Y=(y^1,\ldots,y^N)\in V^N$. Therefore there exists some $\varepsilon>0$ such that

$$\|[\mathcal{DF}^n(Y)]^{-1}\|<\varepsilon^{-1}, \quad \text{for all } Y=(y^1,\ldots,y^N)\in V^N. \tag{74}$$

From the invertibility of $\mathcal{DF}^n(Y)$, we see that $\mathcal{F}^n$ maps V diffeomorphically onto an open set $\mathcal{F}^n(V)$ containing p in its interior.

We now choose j so that $(\tilde{\mu}^j\varepsilon)^{-1}<1$. We choose V sufficiently small so that $\mathcal{F}^{n+i}(V)\subset W$, but $\mathcal{F}^{n+i}(V)\cap V=\varnothing$, for $i=1,2,\ldots,j$. Since $V\subset W$, from (72), (73), and Lemma IV.1, for $k>j$ and for any two points $x^1,x^2\in V$, we have

$$\begin{aligned}
|\mathcal{F}^{n+k}(x^1)-\mathcal{F}^{n+k}(x^2)| &= |\mathcal{F}^{n+k}(x^1)-\mathcal{F}^{n+k}(x^2)| \\
&= |\mathcal{DF}(Y^1)\cdot(\mathcal{F}^{n+k-1}(x^1)-\mathcal{F}^{n+k-1}(x^2))| \\
&\geqslant \tilde{\mu}|\mathcal{F}^{n+k-1}(x^1)-\mathcal{F}^{n+k-1}(x^2)| \quad (\text{where } Y^1\in W^N) \\
&= \tilde{\mu}|\mathcal{DF}(Y^2)\cdot(\mathcal{F}^{n+k-2}(x^1)-\mathcal{F}^{n+k-2}(x^2))| \quad (\text{where } Y^2\in W^N) \\
&\geqslant \tilde{\mu}^2|\mathcal{F}^{n+k-2}(x^1)-\mathcal{F}^{n+k-2}(x^2)| \\
&\geqslant \cdots \\
&\geqslant \tilde{\mu}^k|\mathcal{F}^n(x^1)-\mathcal{F}^n(x^2)| = \tilde{\mu}^k|\mathcal{DF}^n(Y^k)\cdot(x^1-x^2)| \quad (\text{where } Y^k\in V^N) \\
&\geqslant \tilde{\mu}^k\varepsilon|x^1-x^2| \geqslant \tilde{\mu}^{k-j}|x^1-x^2|.
\end{aligned}$$

Therefore $\mathcal{F}^{n+k}$ expands V and for k sufficiently large, $\mathcal{F}^{n+k}(V)$ covers V. We have a diffeomorphism $\mathcal{F}^{n+k}:V\to\mathcal{F}^{n+k}(V)$ such that $p\in\mathcal{F}^{n+k}(V)$ and $V\subset\mathcal{F}^{n+k}(V)$.

Let us choose a sufficiently small open subset V' containing $(\mathcal{F}^{n+k})^{-1}(V)$. By choosing V sufficiently small and k large, we can make V' satisfy

(i) $V\cap V'=\varnothing$;
(ii) $\mathcal{F}^{n+k}(V)\supset V\cup V'$;
(iii) $\mathcal{F}^{n+k}(V')\supset V$;
(iv) $\mathcal{F}^{n+k}(V')\subset W$;
(v) $\mathcal{F}^{n+k}$ is a strict expansion on V'.

Therefore the map $\mathcal{F}^{n+k}$ has a shift sequence

$$V'\to V\to V'\cup V,$$

where each member (except the leader) of the sequence is covered by the image of the predecessor. Therefore $\mathcal{F}^{n+k}(V'\cup V)\supset V'\cup V$, and $V'\cup V$ has an invariant subset

$$\Lambda\equiv\{x\in V'\cup V|(\mathcal{F}^{n+k})^j(x)\in V'\cup V, j=0,1,2,\ldots\}.$$

For any $x\in\Lambda$ we define its binary (itinerary) symbol as

$$s(x)=(s_0s_1s_2\ldots s_j\ldots), \quad s_j=0 \text{ if } (\mathcal{F}^{n+k})^jx\in V', \quad s_j=1 \text{ if } (\mathcal{F}^{n+k})^jx\in V.$$

Then it is a standard procedure to show that $\mathcal{F}^{n+k}$ is topologically conjugate to the shift automorphism on Σ_2, the space of all binary symbols. The proof is complete. □

Note that all consequences (i), (ii), and (iii) in Marotto's Theorem IV.1 can be deduced from the symbolic dynamics implied by Theorem IV.3.

Remark IV.1: In verifying the snapback repeller assumption in order to be able to apply Theorem IV.3, one needs to check the following conditions according to Definition IV.1:

(i) p is a fixed point of $\mathcal{F}$ such that all eigenvalues of $D\mathcal{F}(p)$ have absolute values larger than 1; (75)
(ii) there exists a $q\in W^u_{\text{loc}}(p)$ such that $\mathcal{F}^M(q)=p$ for some positive integer M; (76)
(iii) $\det D\mathcal{F}^M(q)\neq 0$. (77)

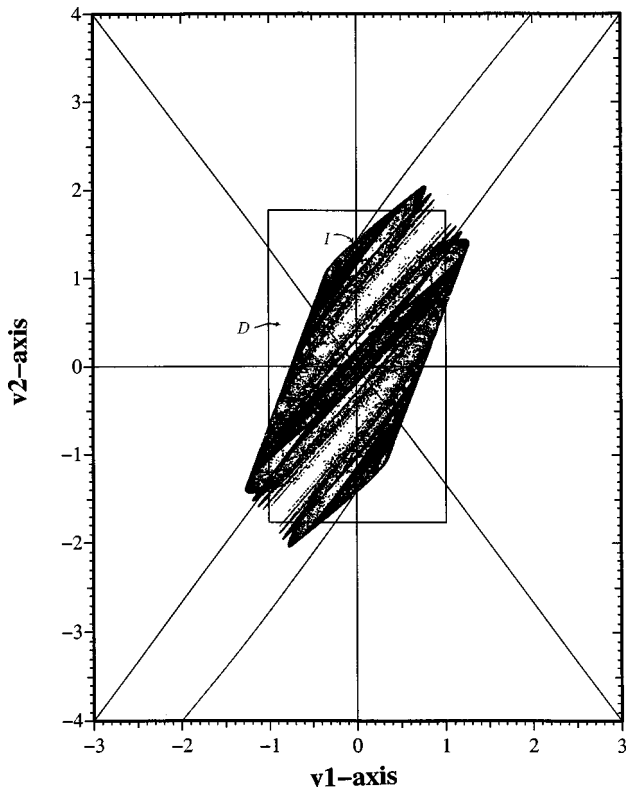

FIG. 3. The strange attractor for Example V.1, where $\alpha=0.9980$, $\beta=1$, and $\eta=0.7570$ are used. D represents the region defined by (54). The origin lies inside the ''cloud'' and, thus, is a snapback repeller.

In most cases, the verification work must be done through the aid of a computer, which automatically involves numerical errors. The verification of (i) is easiest, and the computer result can be trusted with total confidence. To verify (ii), one needs to do computer-aided search of *preimages* of p and then check whether such preimages can wind up in $W^u_{\text{loc}}(p)$. This kind of reverse search can easily accumulate large numerical errors. Therefore, the value of M, even if computable in principle, would *not be entirely trustworthy*. Nevertheless, using the *continuity property of* $\mathcal{F}$, one can still conclude whether such an M (and, consequently, a homoclinic orbit) *exists or not*.

The verification of (iii) is the *most difficult* in general, because as we just pointed out in the above paragraph, it is very difficult to pin down an accurate value of M. Even if M is firmly determined, checking whether $\det D\mathcal{F}^M(q)\neq 0$ is still generally *impossible* because the evaluation of $D\mathcal{F}^M(q)$ usually involves computer roundoff errors. On the one hand, using the holomorphic property of the map $\mathcal{F}$ with respect to the parameter(s), one may claim that there exist at least some parameter values such that (4.13) holds for some snapback homoclinic orbit. On the other hand, we can expect, ''almost beyond reasonable doubt,'' that even if (77) fails, i.e., $\det D\mathcal{F}^M(q)=0$, there should still be chaos. The situation $\det D\mathcal{F}^M(q)=0$ signifies *degeneracy* and leads us to believe that what we have is a *degenerate (snapback) homoclinic orbit*. According to our knowledge of 1D maps, degenerate homoclinic orbits actually causes perhaps the *strongest chaos*.[11] This leads us to pose a conjecture below:

Conjecture: Let $\mathcal{F}:\mathbb{R}^N\to\mathbb{R}^N$ be C^1 satisfying (75) and (76). Then there exists a hyperbolic invariant subset of $W^u_{\text{loc}}(p)$ on which $\mathcal{F}^n$ on Λ is topologically conjugate to the shift map on Σ_2. □

V. NUMERICAL EXAMPLES

We provide two examples in this section. Throughout, we fix $\beta=1$.

Example V.1: The origin as a snapback repeller of $\mathcal{R}_0\mathcal{R}_1$. For α, $0<\alpha\leqslant 1$, we know that the origin (0,0) is a repelling fixed point by Proposition III.2.

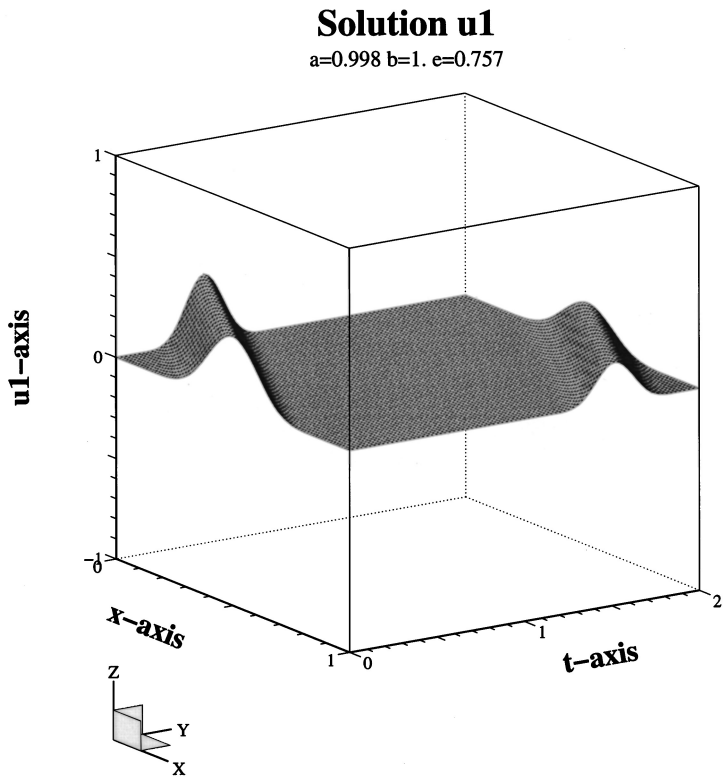

FIG. 4. The spatiotemporal profile of u_1 for initial time duration $[0,\ 2]$.

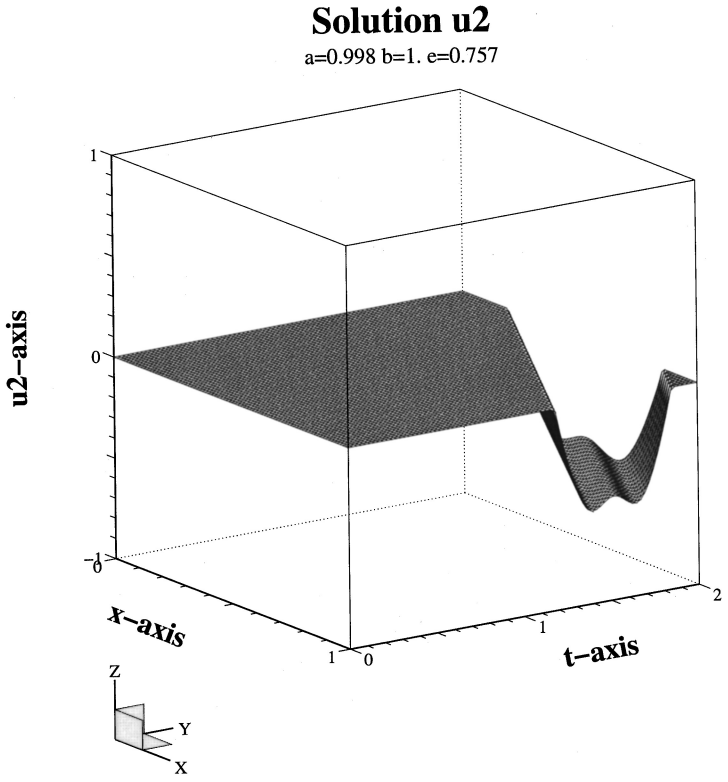

FIG. 5. The spatiotemporal profile of u_2 for initial time duration $[0,\ 2]$.

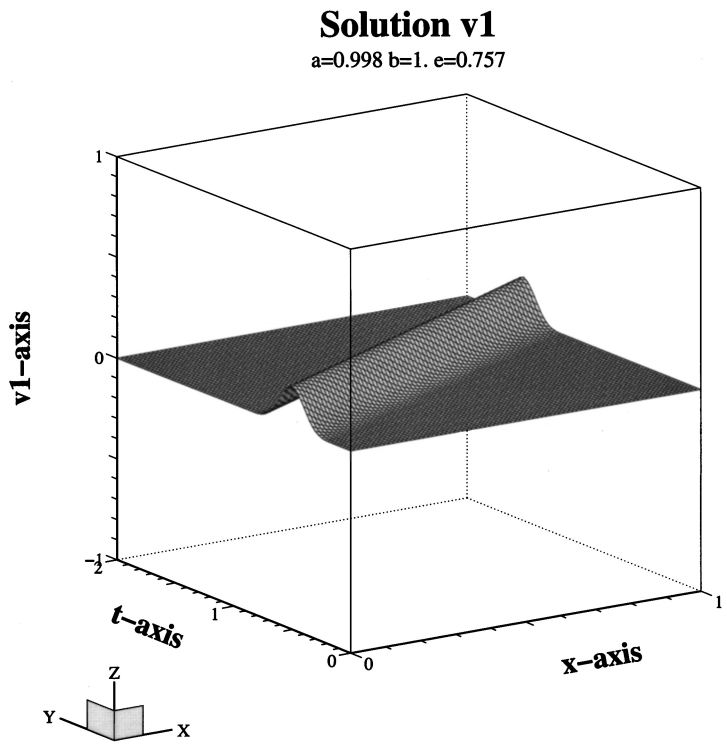

FIG. 6. The spatiotemporal profile of v_1 for initial time duration $[0,\ 2]$.

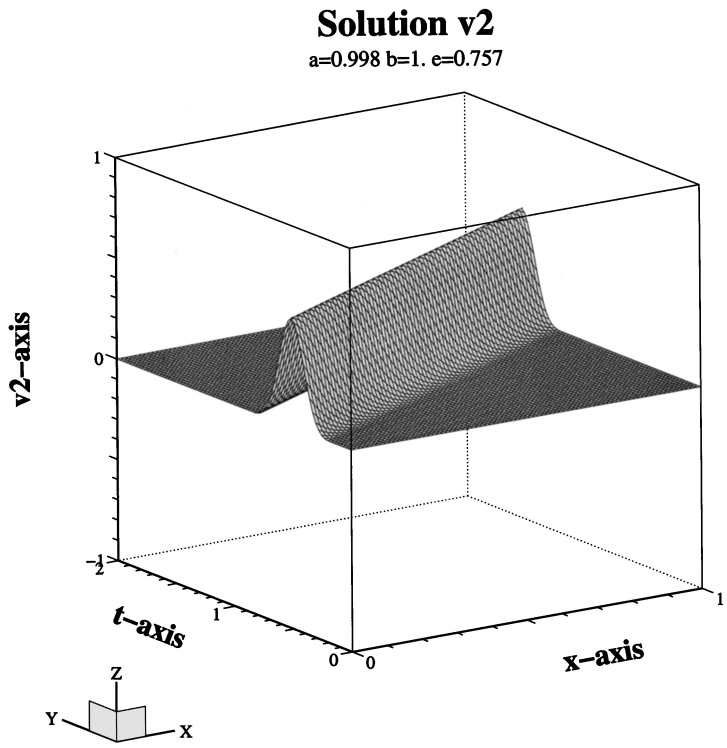

FIG. 7. The spatiotemporal profile of v_2 for initial time duration $[0,\ 2]$.

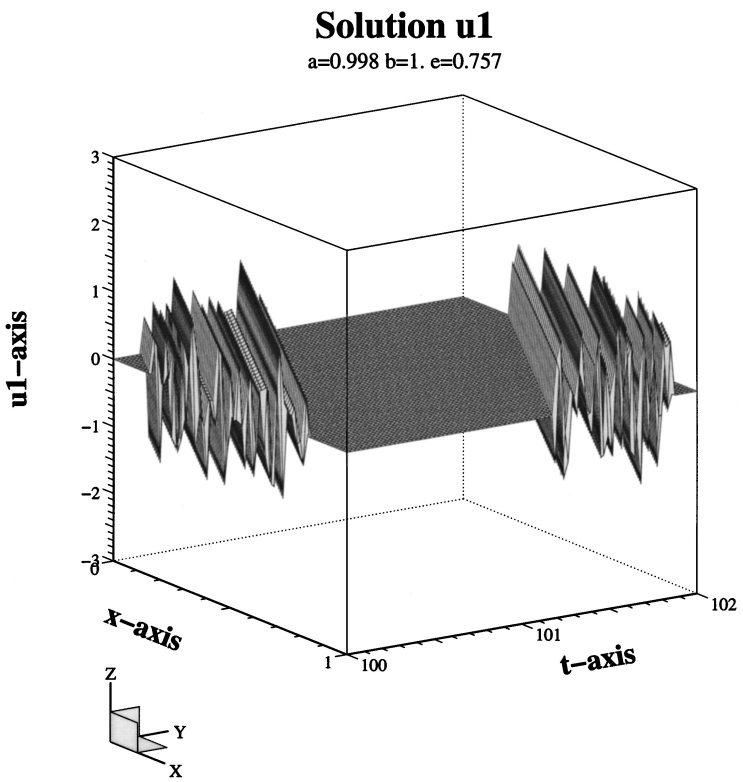

FIG. 8. The spatiotemporal profile of u_1 for time duration [100, 102].

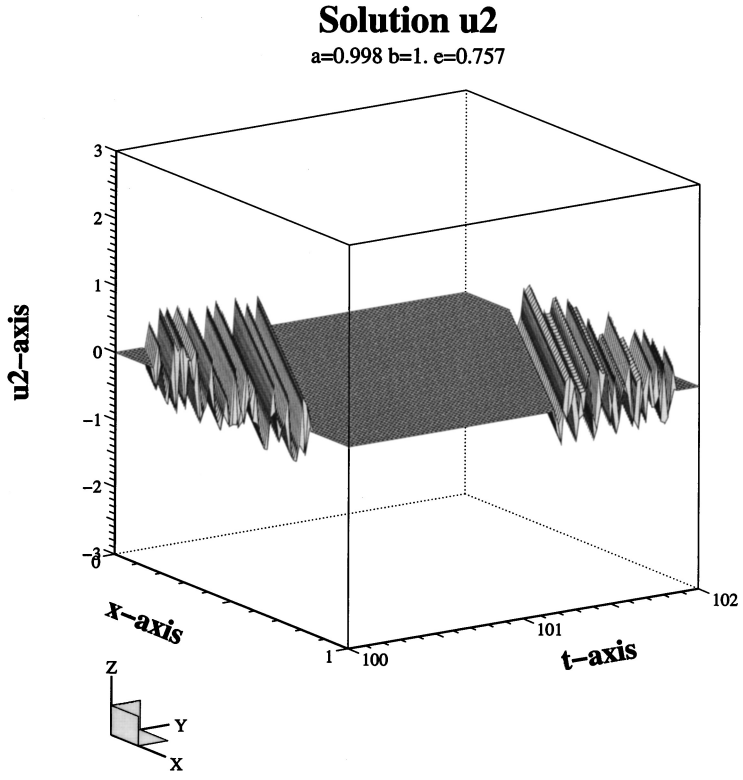

FIG. 9. The spatiotemporal profile of u_2 for time duration [100, 102].

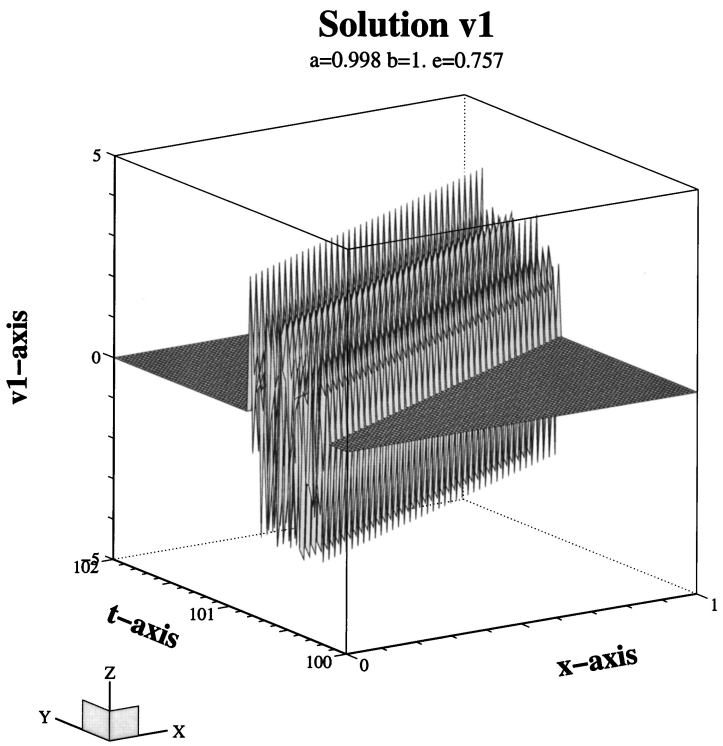

FIG. 10. The spatiotemporal profile of v_1 for time duration [100, 102].

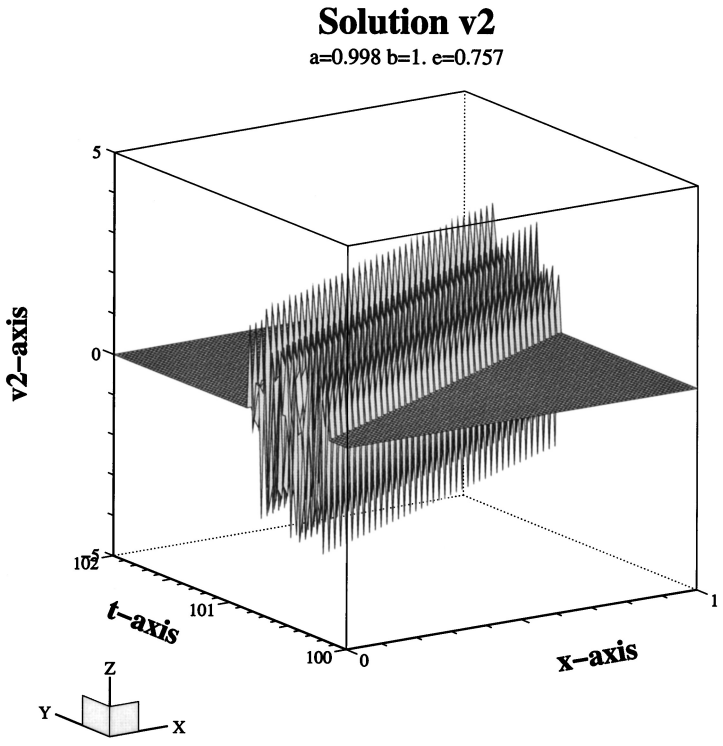

FIG. 11. The spatiotemporal profile of v_2 for time duration [100, 102].

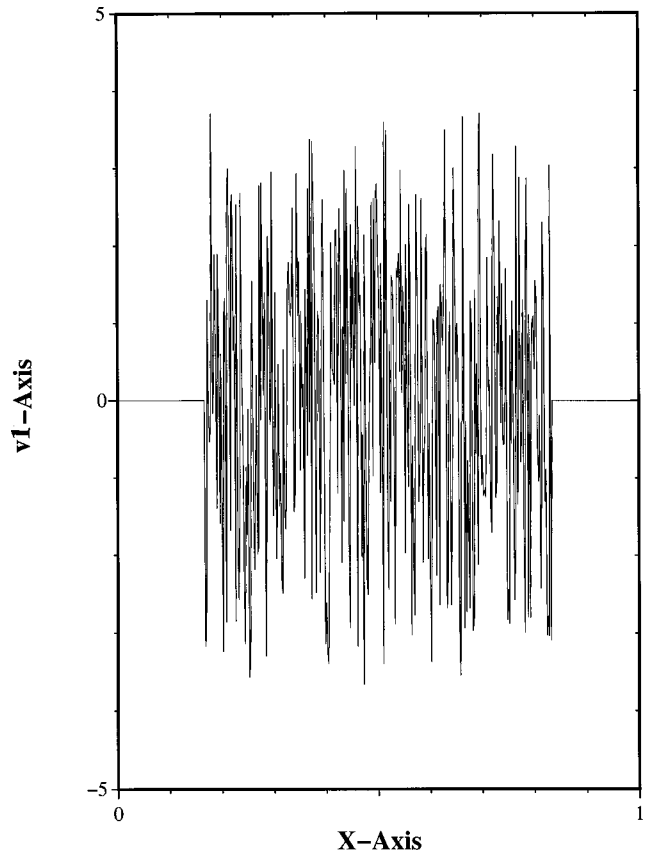

FIG. 12. The snapshot of v_1 at time $t=101$.

Through many numerical experiments, we have found that the origin will not be a snapback repeller unless α is close to 1.

We choose $\alpha=0.9980$, $\beta=1$, and $\eta=0.7570$. To see whether there is a strange attractor, we plot the iterates

$$(\mathcal{R}_0\mathcal{R}_1)^k P_0, \quad P_0=(0.005,0.005), \quad 10^4\leqslant k\leqslant 10^5.$$

What we obtain is a ''cloud,'' the strange attractor, as shown in Fig. 3. Note that the point $I=(0,v_I)$ (cf. Fig. 2) is mapped into the origin:

$$(\mathcal{R}_0\mathcal{R}_1)I=(0,0),$$

and in Fig. 3, I is ''hidden in the cloud.'' Therefore, by Remark IV.1, the continuity of $\mathcal{R}_0\mathcal{R}_1$ implies that the origin is a snapback repeller, i.e., (76) is satisfied. The verification of (77) is difficult, however, as noted in Remark IV.1. We have made no attempts to verify it.

To see chaotic vibration, we consider the system (15)–(18), with the initial data

$$u_{1,0}(x)=\frac{1}{12}\cdot\begin{cases}(x-x_1)^3/h^3, & x_1\leqslant x\leqslant x_2,\\ 1+\dfrac{3(x-x_2)}{h}+\dfrac{3(x-x_2)^2}{h^2}-\dfrac{3(x-x_2)^3}{h^3}, & x_2\leqslant x\leqslant x_3,\\ 1-\dfrac{3(x-x_4)}{h}+\dfrac{3(x-x_4)^2}{h^2}+\dfrac{3(x-x_4)^3}{h^3}, & x_3\leqslant x\leqslant x_4,\\ (x_5-x)^3/h^3, & x_4\leqslant x\leqslant x_5\\ 0, & \text{elsewhere,}\end{cases} \tag{78}$$

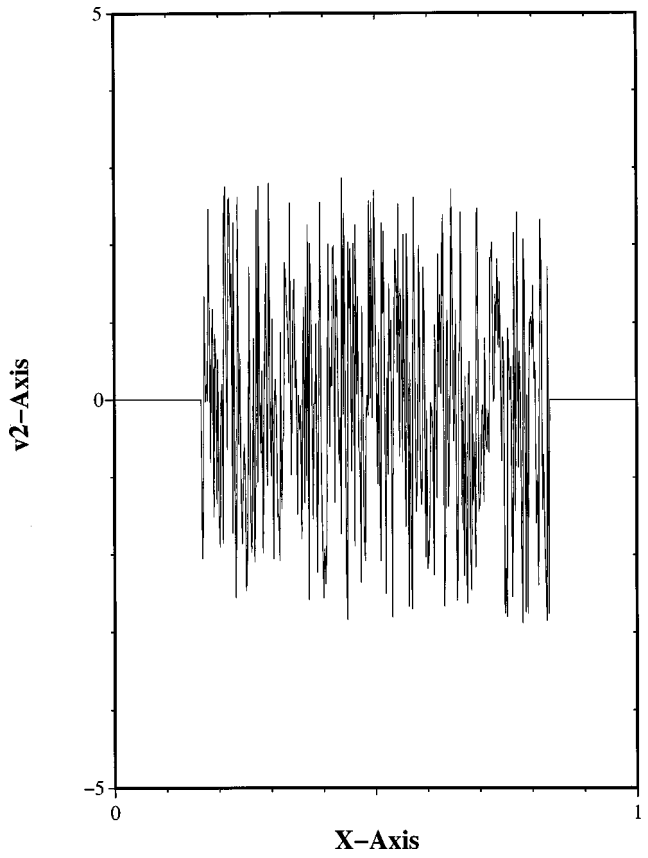

FIG. 13. The snapshot of v_2 at time $t=101$.

$$h=1/6, \quad x_j=j/6, \quad \text{for } j=1,2,3,4,5;$$
$$u_{2,0}(x)=v_{1,0}(x)=v_{2,0}(x)\equiv 0, \quad 0\leqslant x\leqslant 1. \tag{79}$$

Note that the function given in (78) is a C^2-continuous smoothest spline of degree 3. The initial data (78) and (79) satisfy the boundary conditions (16) and (18). It is not difficult to show (by mimicking the proof in Ref. 3, Theorem 6.1 that the system has a unique C^2-solution (u_1,u_2,v_1,v_2) on $(x,t)\in[0,1]\times[0,\infty)$.

The spatiotemporal profiles of u_1,u_2,v_1,v_2 are displayed, respectively, in Figs. 4, 5, 6, and 7 for the first two time units, i.e., $t\in[0,2]$.

For time $t\in[100,102]$, the spatiotemporal profiles of u_1,u_2,v_1,v_2 are displayed, respectively, in Figs. 8, 9, 10, and 11.

The snapshots at $t=101$ of v_1 and v_2 are displayed, respectively, in Figs. 12 and 13. We do not need to display u_1 and u_2 at $t=101$ because u_1 and u_2 are identically zero.

These profiles are computed by using the explicit representation formulas (20). Note that because of the *nondispersive* effects of wave propagation, all components u_1,u_2,v_1, and v_2 of the system can display a ''totally serene'' (i.e., zero or no disturbance) zone right next to the chaotic spatiotemporal region. □

Example V.2: A period-4 point as a snapback repeller of $(\mathcal{R}_0\mathcal{R}_1)^4$. Let us choose $\alpha=0.6$, $\beta=1$, and $\eta=0.8200$.

The map $\mathcal{R}_0\mathcal{R}_1$ has a strange attractor as shown in Fig. 10, suggesting that $\mathcal{R}_0\mathcal{R}_1$ is chaotic. Note in Fig. 14 that neither the point I nor the origin lies inside the strange attractor ''cloud;'' in this case, we can easily rule out the origin as a snapback repeller.

The map $\mathcal{R}_0\mathcal{R}_1$ has many period-4 orbits. So let us compute the fixed points of $(\mathcal{R}_0\mathcal{R}_1)^4$ by Newton's method. We have obtained three sets of such orbits (80), (82), and (84) and other relevant data as given below:

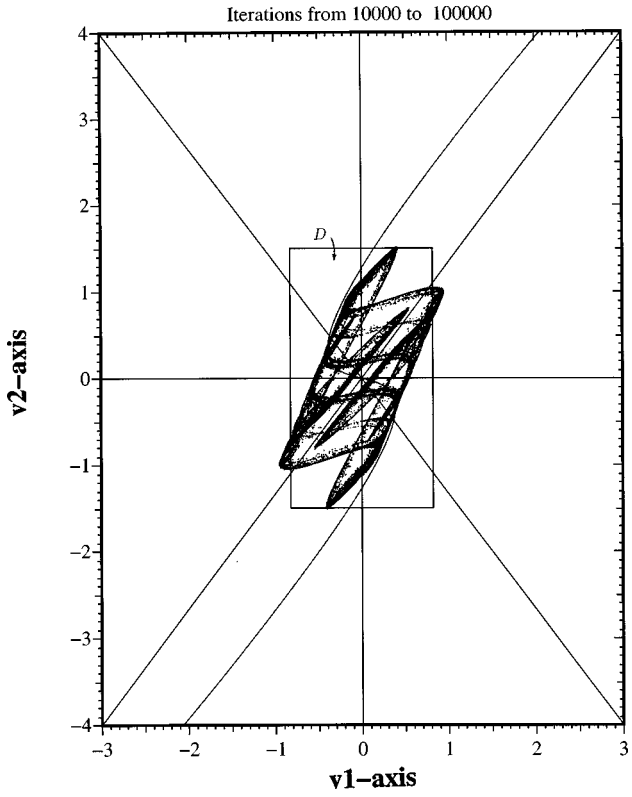

FIG. 14. The strange attractor for Example V.2, where $\alpha=0.6$, $\beta=1$, and $\eta=0.82$ are used. D is the rectangle defined by (54). Note that the origin is not inside the ''cloud'' of the strange attractor.

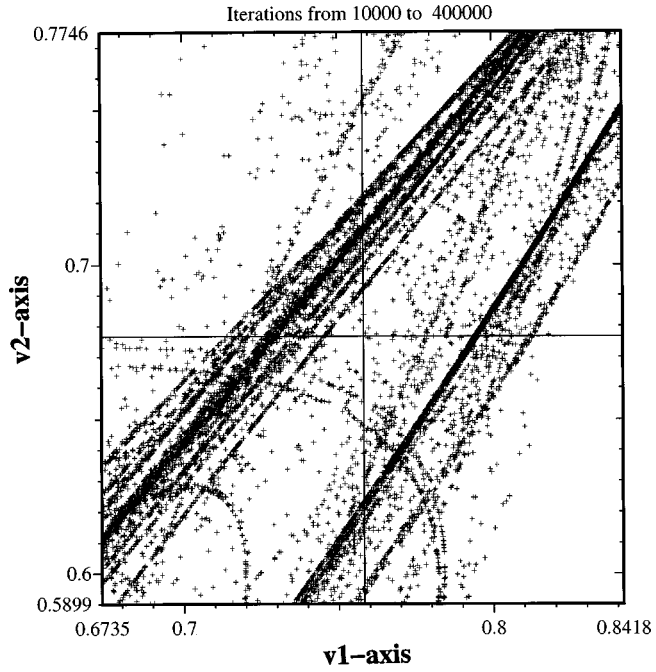

FIG. 15. This is a zoom-in of the vicinity of the period-4 point $P_1^{(1)}=(0.7582,\ 0.6762)$, cf. (80), from Fig. 14. Note that $P_1^{(1)}$is highlighted as the intersection of the horizontal and vertical lines near the center of the figure. Chaos in the immediate vicinity of $P_1^{(1)}$ is not strong.

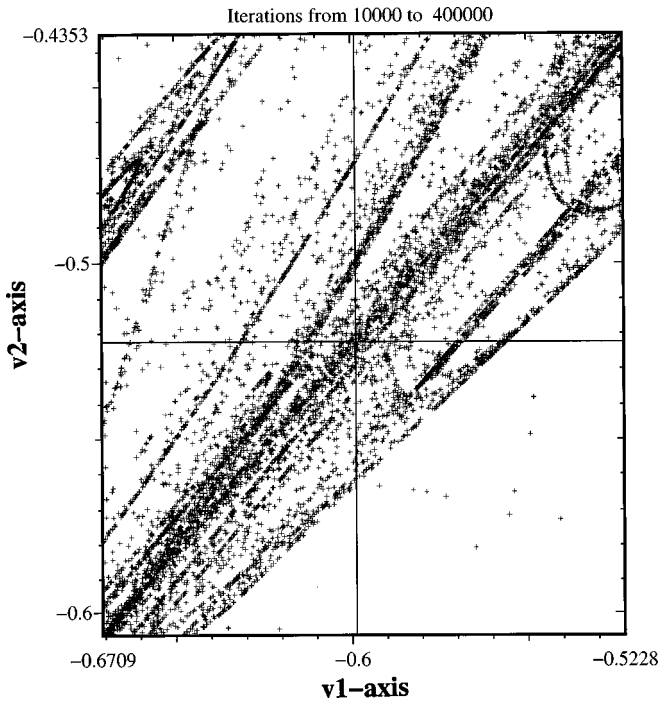

FIG. 16. This is a zoom-in of the vicinity of the period-4 point $P_2^{(1)}=(-0.5988,\ -0.5229)$, cf. (81), from Fig. 14. Note that $P_2^{(1)}$ is highlighted as the intersection of the horizontal and vertical lines near the center of the figure. Chaos is strong in the immediate vicinity of $P_2^{(1)}$.

$$\text{(i)}\quad \begin{cases} P_1^{(1)}=(0.7582,\quad 0.6762), \quad P_1^{(2)}=(2.1507,\quad 1.0699), \\ P_1^{(3)}=(-0.1942,\quad -7.6573), \quad P_1^{(4)}=(0.2591,\quad -0.1675); \end{cases} \tag{80}$$

$$D((\mathcal{R}_0\mathcal{R}_1)^4)(P_1^{(1)})=\begin{bmatrix} -4.4737 & -1.9625 \\ -8.2024 & -5.7953 \end{bmatrix},\ \text{with eigenvalues } -9.2007 \text{ and } -1.0683. \tag{81}$$

$$\text{(ii)}\quad \begin{cases} P_2^{(1)}=(-0.5988,\ -0.5229), \quad P_2^{(2)}=(0.1968,\ -0.7636), \\ P_2^{(3)}=(0.5988,\ 0.5229), \quad P_2^{(4)}=(-0.1968,\ 0.7636); \end{cases} \tag{82}$$

$$D((\mathcal{R}_0\mathcal{R}_1)^4(P_2^{(1)}))=\begin{bmatrix} 3.9208 & 1.2102 \\ 4.4494 & 1.4967 \end{bmatrix},\quad \text{with eigenvalues } 0.0908 \text{ and } 5.3267. \tag{83}$$

$$\text{(iii)}\quad \begin{cases} P_3^{(1)}=(-0.4492,\ -0.0324), \quad P_3^{(2)}=(-0.1076,\ -0.6774), \\ P_3^{(3)}=(0.4492,\ 0.0324), \quad P_3^{(4)}=(0.1076,\ 0.6774). \end{cases} \tag{84}$$

$$D((\mathcal{R}_0\mathcal{R}_1)^4(P_3^{(1)}))=\begin{bmatrix} -6.1730 & 44.6753 \\ -13.7347 & 90.5629 \end{bmatrix},\quad \text{with eigenvalues } 0.6515,\ 83.7384. \tag{85}$$

Note that $P_i^{(j)}$ satisfies

$$(\mathcal{R}_0\mathcal{R}_1)^k(P_i^{(j)})=P_i^{((k+j)\bmod 4)},\quad i=1,2,3.$$

Let us now zoom in on Fig. 10 about these period-4 points $P_1^{(1)}, P_2^{(1)}$, and $P_3^{(1)}$ (see Figs. 15, 16, and 17, respectively.)

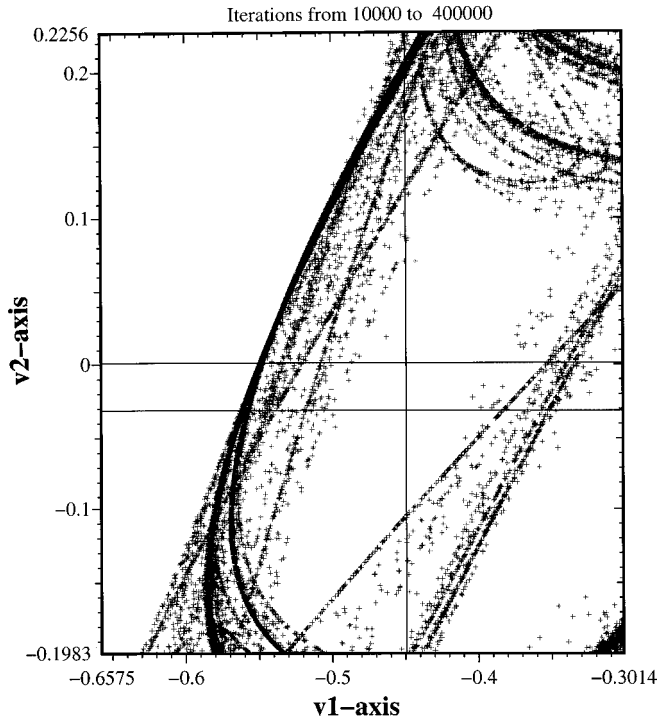

FIG. 17. This is a zoom-in of the vicinity of the period-4 point $P_3^{(1)}=(-0.4492,\ -0.0324)$, cf. (84), from Fig. 14. This point is not inside the ''cloud'' of the strange attractor; it does not have a homoclinic orbit. There is no chaos in the close vicinity of $P_3^{(1)}$.

From (81) and Fig. 15, by the continuity argument as given in Remark IV.1, it is quite clear that with $\mathcal{F}=(\mathcal{R}_0\mathcal{R}_1)^4$, the point $P_1^{(1)}$ satisfies (75) and (76). Thus, $P_1^{(1)}$ ''should be'' a snapback repeller. However, we observe in Fig. 15 that *chaos is not strong in the immediate vicinity of* $P_1^{(1)}$.

From (83) and Fig. 16, we see that $P_2^{(1)}$ is a saddle node fixed point $(\mathcal{R}_0\mathcal{R}_1)^4$ with a homoclinic orbit. *Chaos is very strong in the immediate vicinity of* $P_2^{(1)}$.

From (85), we note that $P_3^{(1)}$ is again a saddle node fixed point of $(\mathcal{R}_0\mathcal{R}_1)^4$. However, $P_3^{(1)}$ is not on the strange attractor, as can be seen from Fig. 17, suggesting that $P_3^{(1)}$ does not have a homoclinic orbit. *There is no chaos at all in the immediate vicinity of* $P_3^{(1)}$.

This example suggests the following:

(1) Snapback repellers imply chaos, but its strength may not be strong when other sources of chaos are present.
(2) A saddle node fixed point having a (forward) homoclinic orbit seems to cause strong chaos, even without the diffeomorphism assumption.

Point (2) above appears particularly important. We hope to be able to report some results in the future. □

(Received 8 April 1998; accepted for publication 17 June 1998)

We discuss the information theoretical foundations of the Kullback information gain, recently generalized within a nonextensive thermostatistical formalism. General properties are studied and, in particular, a consistent test for measuring the degree of correlation between random variables is proposed. In addition, minimum entropy distributions are discussed and the H-theorem is proved within the generalized context. © *1998 American Institute of Physics.* [S0022-2488(98)02712-1]

I. INTRODUCTION

There is a currently growing body of evidence implying that a nonextensive thermostatistical description is needed in order to adequately understand a vast class of physical phenomena, ranging from long-range interactions to self-organized criticality. A generalized thermostatistical formalism recently introduced by one of us[1] may be an interesting candidate for dealing with those kinds of physical scenarios. The generalized formalism has already been applied to astrophysical self-gravitating systems,[2] cosmology,[3] the solar neutrino problem,[4] anomalous diffusion of correlated[5–7] and Lévy[8] types, pure-electron plasma turbulence phenomena,[9] low-[10] and high-dimensional[11] dissipative nonlinear dynamical systems, anomalous Hamiltonian systems,[12] linear response theory,[13] electron–phonon anomalous relaxation,[14] variational and perturbation methods,[15] simulated annealing and other optimization techniques,[16] among many others.[1]

The generalized formalism is based upon the nonlogarithmic entropy[1]

$$S_q = k \sum_j p_j^q \frac{(1-p_j^{1-q})}{1-q}, \tag{1}$$

where q is a real number and the p_j are the usual probabilities of events j; k is a positive constant, from now on taken to be unity without loss of generality. The standard Shannon entropy[17] $S = -\Sigma_j p_j \ln p_j$ is recovered for $q \to 1$,[1] but S_q has some important properties which differ from the Shannon one in the general $q \neq 1$ case. Most noteworthy is the fact that the generalized entropy is *nonextensive*, in the sense that $S_q(A+B) = S_q(A) + S_q(B) + (1-q) S_q(A) S_q(B)$, where A and B are two *independent* systems, i.e., with probabilities satisfying $p_{ij}(A+B) = p_i(A) p_j(B)$. This entropy has been shown to lay the foundation to a generalized statistical mechanics, playing the same role the standard logarithmic entropy does within the standard information theory approach pioneered by Jaynes.[18] General theoretical properties of the nonlogarithmic entropy have been studied in Refs. 19–21. Also, connections have been made with the dynamical thermostatting approach to statistical ensembles.[22]

An important quantity closely related to the standard entropy is the Kullback information gain,[23] which measures the mean change of information associated with two probability distributions p and p'. This measure shows many desirable properties. First, it is *invariant* under arbitrary coordinate transformations, allowing the formulation of physical theories in a covariant fashion. Second, it provides a *minimum* entropy formalism for statistical inference, automatically incorporating a not necessarily uniform prior.[24] Third, the Kullback entropy is of utmost importance in,

 © 1998 American Institute of Physics

for example, correctly formulating the H-theorem for the Fokker–Planck equation based on the relative entropy between *any* two solutions.[25,26] In addition, this entropy also measures the degree of statistical dependence of two random variables.[26]

Recently, one of us proposed a generalization of the Kullback measure[27] within the framework of the generalized thermostatistics. In this paper, we discuss some of the main properties of that measure. In Sec. II we derive the generalized Kullback information gain and in Sec. III we study some general theorems and inequalities. Also, a consistent test for measuring the degree of dependence between random variables (introduced in Ref. 27) is worked out in detail. Section IV presents the minimum Kullback entropy distributions and Sec. V proves the H-theorem for the Fokker–Planck and Liouville equations, based on the generalized Kullback measure. Finally, some conclusions are addressed in Sec. VI.

II. DERIVATION OF THE GENERALIZED KULLBACK INFORMATION GAIN

Let us review the derivation of the Kullback information gain measure in the standard case.[23,26] Assume that a particular set of measurements gives the probabilities p_j of obtaining the outcomes denoted by the index j. Then the Shannon entropy of the system can be written as

$$S=-\sum_j p_j \ln p_j, \tag{2}$$

where we can interpret the quantity $\sigma_j \equiv -\ln p_j$ as the information content of the outcome j. Let us denote the first set of measurements by p'_j and assume that a new set of measurements is made which yields a new set of values p_j for the probabilities of the outcomes j. The change of information $\Delta\sigma_j$ is thus equal to $\Delta\sigma_j=-(\ln p'_j-\ln p_j)$, and the mean change of information is obtained by averaging over the new distribution defined by the p_j to obtain

$$K(p,p')\equiv\sum_j p_j\Delta\sigma_j=\sum_j p_j \ln\frac{p_j}{p'_j}. \tag{3}$$

This is the standard derivation and definition of the Kullback–Leibler information gain (also known as *mutual information, cross entropy*, and *relative entropy*).

We now show that the generalized Kullback–Leibler measure follows naturally from the standard derivation of the Kullback entropy, if only the nonextensive formalism[1] is employed instead of the standard one. Within that setting, the entropy of Eq. (1) is used instead of the Shannon entropy, and all expectation values are replaced with the so-called *q-expectation values* of the form $\langle\omega\rangle_q\equiv\Sigma_j p_j^q\omega_j$, where ω is a state variable of the system.

It follows then that Eq. (1) can be interpreted as the q-average of the generalized information content given by $\sigma_j^q\equiv-(p_j^{1-q}-1)/(1-q)$. We denote the probabilities of the first set of measurements by p'_j and assume that we then obtain a new set of measurements with the probabilities p_j. The change in information is given by $\Delta\sigma_j^q=[1/(1-q)]((1-p_j'^{1-q})-(1-p_j^{1-q}))$. Taking the q-average of $\Delta\sigma_j$ yields

$$K_q(p,p')=\sum_j \frac{p_j^q}{1-q}(p_j^{1-q}-p_j'^{1-q}), \tag{4}$$

which is the generalized Kullback–Leibler information gain. This can alternatively be written as

$$K_q(p,p')=\sum_j p_j \ln_q\frac{p_j}{p'_j}, \tag{5}$$

where we make use of the definition of the q-logarithm function $\ln_q$ (Ref. 28):

$$\ln_q(p)\equiv\frac{p^{1-q}-1}{1-q}. \tag{6}$$

Hence, $\ln_1(p)$ recovers the standard $\ln(p)$. In continuous variables, the measure takes on the form

$$K_q(p,p')=\int dx\,\frac{p(x)^q}{1-q}\,(p(x)^{1-q}-p'(x)^{1-q})=\int dx\;p(x)\ln_q\left(\frac{p(x)}{p'(x)}\right), \tag{7}$$

which coincides exactly with the measure proposed in Eq. (5) of Ref. 27.

III. GENERAL PROPERTIES AND THEOREMS

A. Positivity and concavity properties

As in the standard $q=1$ case, the generalized Kullback information measure has a definite sign (depending on q). Here we provide an alternative proof to the discussion presented in Ref. 27. For $q>0$ we obtain

$$K_q(p,p')=\sum_j\;\frac{p_j}{1-q}\left(1-\left(\frac{p'_j}{p_j}\right)^{1-q}\right) \tag{8}$$

$$\geqslant\frac{1}{1-q}\left(1-\left(\sum_j\;p_j\,\frac{p'_j}{p_j}\right)^{1-q}\right) \tag{9}$$

$$=\frac{1}{1-q}\left(1-\left(\sum_j\;p'_j\right)^{1-q}\right) \tag{10}$$

$$=\frac{1}{1-q}\,(1-1)=0, \tag{11}$$

where we have used Jensens inequality: If $\Sigma_j\alpha_j=1$ and $f''(x)>0$, then

$$\sum_j\;\alpha_j f(x_j)\geqslant f\left(\sum_j\;\alpha_j x_j\right). \tag{12}$$

Here, $f(x)=[1/(1-q)](1-x^{1-q})$ with $x=p'_j/p_j$ and $\alpha_j=p_j$. Conversely, for $q<0$, $f''(x)<0$ and the sign of the inequality reverses. Therefore, we have shown that

$$K_q\geqslant 0,\quad q>0, \tag{13}$$

$$K_q=0,\quad q=0, \tag{14}$$

$$K_q\leqslant 0,\quad q<0. \tag{15}$$

The equalities (for $q\neq 0$) hold if and only if $p_j=p'_j$ for all j. Along the same lines, we obtain for $q>0$

$$\left(\sum_i\;a_i\right)\left\{\frac{[(\Sigma_i a_i)/(\Sigma_j b_j)]^{q-1}-1}{q-1}\right\}\leqslant\sum_i\;a_i\left\{\frac{[a_i/b_i]^{q-1}-1}{q-1}\right\}, \tag{16}$$

where Jensens inequality was employed using

$$f(x)=x\left(\frac{x^{q-1}-1}{q-1}\right), \tag{17}$$

$$\alpha_i=b_i\Big/\left(\sum_j\;b_j\right), \tag{18}$$

$$x_i=a_i/b_i\,. \tag{19}$$

For $q=1$, this expression reduces to the well-known log-sum inequality.[26] A direct consequence of Eq. (16) is that the measure $K_q(p,p')$ is a convex function of its both arguments. This can be seen if we consider the probability distributions p and p' to be equal mixtures of two other distributions, $p=\lambda p_j^1+(1-\lambda)p_j^2$ and $p'=\lambda p_j'^1+(1-\lambda)p_j'^2$. We then apply the log-sum inequality Eq. (16) to each such term, by identifying $a_1=\lambda p_j^1$ and $a_2=(1-\lambda)p_j^2$ and similarly $b_1=\lambda p_j'^1$ and $b_2=(1-\lambda)p_j'^2$. Finally, we obtain after summing over j

$$K_q(\lambda p^1+(1-\lambda)p^2,\lambda p'^1+(1-\lambda)p'^2)\leqslant\lambda K(p^1,p'^1)+(1-\lambda)K(p^2,p'^2) \tag{20}$$

for $q>0$. For $q<0$, $K_q(p,p')$ is instead a concave function of its arguments, and the sign of the inequality reverses.

B. Relative entropy

Let us now inspect the special case when $p=p(x,y)$ and $p'=p(x)p(y)$, corresponding respectively to the *joint* and *marginal* probability distributions of a system consisting of two random variables x and y. In this case, the Kullback information measure is often referred to as the *relative entropy* between x and y, and we shall refer to it as $I(x,y)$. Notice that $I(x,y)$ is a special case of $K(p,p')$ for a particular choice of p and p'. In the $q=1$ case, it is well known that[26]

$$I(x,y)=S(x)+S(y)-S(x,y) \tag{21}$$

$$=S(x)-S(x|y) \tag{22}$$

$$=S(y)-S(y|x), \tag{23}$$

where $S(x)$ and $S(y)$ are the Shannon entropies of the marginal distributions and $S(x,y)$ is the Shannon entropy of the joint probability distribution. $I(x,y)$ vanishes if and only if x and y are independent variables. The conditional entropy of type $S(x|y)$ is however defined as $S(x|y)=-\Sigma_{x,y}p(x,y)\ln p(x|y)=-E_{p(x,y)}[\ln p(x|y)]$, where E_p denotes the expectation value with respect to the distribution p. Notice that all terms in the condition of Eq. (21) can equally be expressed in terms of E_p, namely

$$I(x,y)=-E_{p(x,y)}[\ln p(x)+\ln p(y)-\ln p(x,y)] \tag{24}$$

$$=-E_{p(x,y)}[\ln p(x)-\ln (p(x|y)] \tag{25}$$

$$=-E_{p(x,y)}[\ln p(y)-\ln (p(y|x)], \tag{26}$$

because $p(x,y)=p(y|x)p(x)=p(x|y)p(y)$ and $\Sigma_y p(y|x)=\Sigma_x p(x|y)=1$.

The idea now is to see how these properties generalize in the $q\neq 1$ case. We write

$$I_q(x,y)=-\sum_{x,y}\frac{p(x,y)^q}{1-q}\left((p(x)p(y))^{1-q}-p(x,y)^{1-q}\right) \tag{27}$$

$$=\sum_{x,y}\frac{p(x,y)^q}{1-q}\left((1-(p(x)p(y))^{1-q})-(1-p(x,y)^{1-q})\right). \tag{28}$$

Applying the relation

$$1-ab=(1-a)+(1-b)-(1-a)(1-b) \tag{29}$$

to rewrite the first term in the brackets on the rhs, we immediately obtain

$$I_q(x,y)=\sum_{x,y}\frac{p(x,y)^q}{1-q}\left((1-p(x)^{1-q})+(1-p(y)^{1-q})\right.$$
$$\left.-(1-p(x)^{1-q})(1-p(y)^{1-q})-(1-p(x,y)^{1-q})\right). \tag{30}$$

Using the definition (6) of the $\ln_q$ function, we see that this yields

$$I_q(x,y) = -E^q_{p(x,y)}[\ln_q p(x) + \ln_q p(y) + (1-q)\ln_q p(x)\ln_q p(y) - \ln_q p(x,y)], \tag{31}$$

where we have introduced the notation E^q_p to denote the q-expectation value over the distribution p. One immediately verifies that Eq. (31) is a very natural generalization of the property equation (21) or (24), where the expection values of $\ln p(x)$ over $p(x,y)$ are replaced by the q-expectation values over $p(x,y)$, and the sum of $\ln p(x)$ and $\ln p(y)$ are replaced by the *pseudo-sum* of the nonextensive formalism, namely $\ln_q p(x) + \ln_q p(y) + (1-q)\ln_q p(x) \ln_q p(y)$.

We now return to Eq. (28) and rewrite $p(x,y)$ in the second term within the brackets on the rhs as $p(x,y) = p(x)p(y|x)$. Applying the expansion of Eq. (29) to that term as well, we see that our result of Eq. (31) can equally be written as

$$\begin{aligned} I_q(x,y) = -E^q_{p(x,y)}[&\ln_q p(x) - \ln_q p(x|y) \\ &-(1-q)(\ln_q p(y)\ln_q p(x|y) - \ln_q p(x)\ln_q p(y))] \end{aligned} \tag{32}$$

$$\begin{aligned} = -E^q_{p(x,y)}[&\ln_q p(y) - \ln_q p(y|x) \\ &-(1-q)(\ln_q p(x)\ln_q p(y|x) - \ln_q p(x)\ln_q p(y))]. \end{aligned} \tag{33}$$

These expressions are again very natural generalizations of the properties of Eqs. (25) and (26) for the standard $q=1$ case.

C. Upper and lower bounds

We are now interested in defining bounds on the measure $I_q(x,y)$. If we wish to use it as a criterion to determine the degree of correlation between the two variables x and y, then it is desirable to know its value corresponding to the *minimum* and *maximum* correlation between the variables. Let us first discuss the $q>0$ case. As follows from Eq. (13), we know that $I_q \geqslant 0$, and we see [for example, from Eq. (32)] that $I_q = 0$ occurs when $p(x|y) = p(x)$ which corresponds to the case when x is totally independent of y. Alternatively, we see that if x is maximally correlated with y such that there is a one-to-one mapping between the two variables, then there is no uncertainty of x if one knows y and consequently the conditional entropy

$$S_q(x|y) \equiv \sum_x p^q(x|y)\ln_q p(x|y) \tag{34}$$

must vanish. This case should yield the upper bound on I_q because one expects the mutual information between x and y to be at its height if the two variables are completely correlated. Indeed we see that this is true because the following two terms of I_q of Eq. (32), namely $-E^q_{p(x,y)} \ln_q p(x|y)$ and $-E^q_{p(x,y)} \ln_q p(y) \ln_q p(x|y)$ must vanish in this case, whereas they constitute positive quantities which are subtracted, respectively, from the extensive and nonextensive parts of I_q in all other cases. To see that they do in fact vanish, we consider first the term $E^q_{p(x,y)} \ln_q p(x|y)$ which satisfies

$$0 \leqslant -E^q_{p(x,y)}[\ln_q p(x|y)] = -\sum_{x,y} p^q(y)p^q(x|y)\ln_q p(x|y) \leqslant S_q(x|y) = 0. \tag{35}$$

In a similar way, we see that

$$\begin{aligned} -E^q_{p(x,y)}[\ln_q p(y) \ln_q p(x|y)] &= -\sum_y p(y)^q \ln_q p(y) \sum_x p(x|y)^q \ln_q p(x|y) \\ &= \sum_y p(y)^q \ln_q p(y) S_q(x|y) = 0. \end{aligned} \tag{36}$$

We then see, from Eq (32), that the upper bound $I^{\max}_q$ is given by

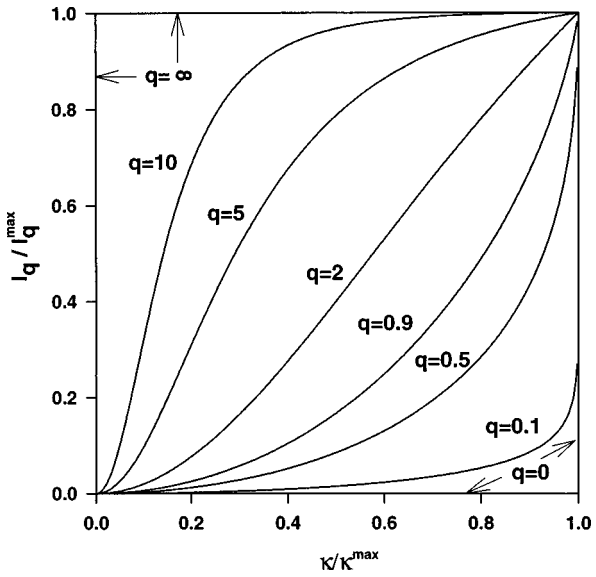

FIG. 1. The normalized index $R \equiv I_q / I_q^{\max}$ is shown as a function of $\kappa/\kappa^{\max}$ for different values of q. The ratio $\kappa/\kappa^{\max}$ is a measure of the degree of correlation of two binary random variables, whose joint probability distribution is given by $p(1,1)=p^2+\kappa$, $p(1,2)=p(2,1)=p(1-p)-\kappa$, and $p(2,2)=(1-p)^2+\kappa$. The curves correspond to typical values of q and $p=\frac{1}{2}$. For this special case one can express R analytically as a function of q (Ref. 40): $R(q)=[(1+4\kappa)^q+(1-4\kappa)^q-2]/[(1-2^{(1-q)})[(1+4\kappa)^q+(1-4\kappa)^q]]$.

$$I_q^{\max}(x,y) = -E^q_{p(x,y)}[\ln_q p(x) + (1-q)\ln_q p(x) \ln_q p(y)]. \tag{37}$$

D. Criterion for statistical testing

Equation (37) together with Eq. (31) enables the definition of the ratio

$$R \equiv I_q / I_q^{\max}, \in [0,1], \tag{38}$$

which can be used as a *criterion for measuring the degree of dependence between random variables* (time series and others). In Fig. 1 we plot the ratio R as a function of the correlation between the variables x and y, for typical values of $q>0$. This ratio varies from 0 (corresponding to zero correlation, i.e., independence between x and y) to 1 (corresponding to maximum correlation, i.e., a one-to-one mapping between x and y). Note that there is an *optimal* q^{opt} (see Fig. 2) for a given degree of correlation, in the sense that the gradient of the index R is most sensitive and therefore most capable of detecting small variations of correlation among the variables. In Fig. 3 we show how the curve R versus q varies for different degrees of correlation.

The criterion R of Eq. (38) can hopefully be quite useful since it is (i) *consistent*, in the sense that it monotonically varies with the degree of dependence of the random variables; (ii) *versatile*, in the sense that it includes a parameter, the entropic index q, which can be tuned, for each given specific problem, to an optimal value q^{opt} for which the sensitivity of the criterion is maximal; (iii) *optimal*, in the sense that its two extreme values precisely correspond to full independence and full dependence.

For $q<0$ all signs reverse but we have the additional problem that the q-generalized entropies diverge whenever the probabilities p_j of any of the microstates j approach 0. Indeed, for negative q, certainty implies that the entropy diverges.[1] Hence, the conditional entropy $S(x|y)\to\infty$ in the case of complete correlation between the variables x and y. Therefore, the difference between the index I_q and $I_q^{\max}$ as defined in Eq. (37) can become arbitrarily large.

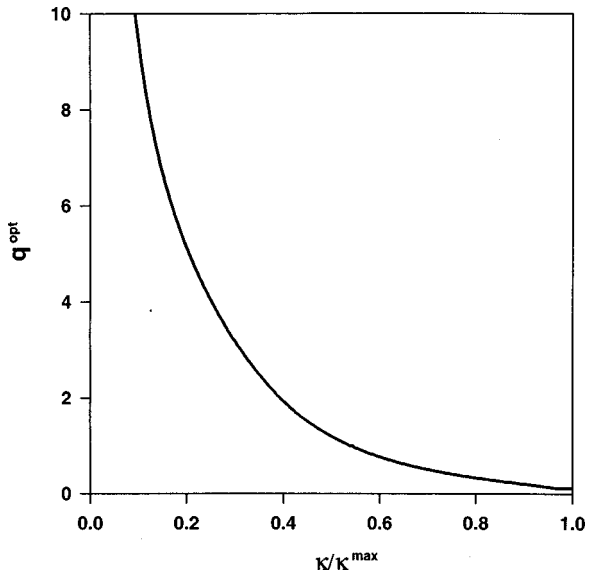

FIG. 2. As can be seen in Fig. 1, for a given value of $\kappa/\kappa^{\max}$, there is an optimal value of q, in the sense that the index R is most sensitive to detect variations on the degree of statistical correlation. Here we plot, for the same example presented in Fig. 1, the optimal value q^{opt} as a function of $\kappa/\kappa^{\max}$.

E. Shift information

Another interesting property of the generalized Kullback information measure is the q-invariance of its relationship to the Fisher information. From now on we treat the measure in its continuous form [Eq. (7)]. As in the $q=1$ case, we consider a monoparametric family of distributions characterized by the parameter θ. One obtains

$$K_q(p(\theta),p(\theta+\Delta))=\frac{1}{q-1}\int dx\; p(x,\theta)\left\{\left(\frac{p(x,\theta)}{p(x,\theta+\Delta)}\right)^{q-1}-1\right\}. \tag{39}$$

A Taylor expansion in the variable Δ yields, up to second order,

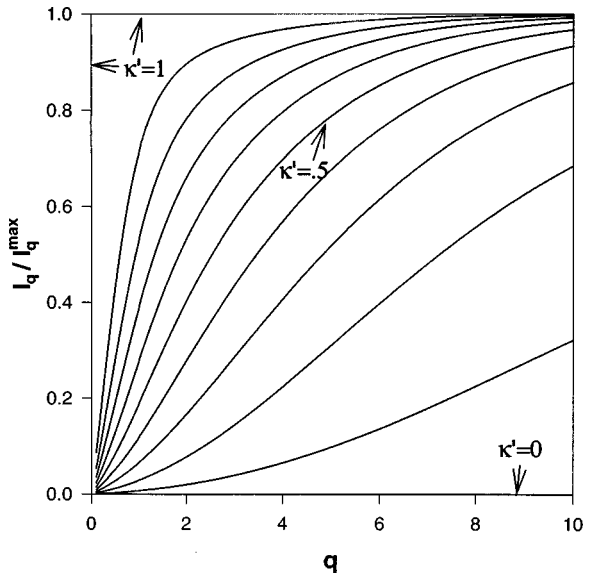

FIG. 3. The index $R=I_q/I_q^{\max}$ as a function of q for different values of $\kappa'=\kappa/\kappa^{\max}$ between 0 and 1, plotted for the same example as in Figs. 1 and 2. The curves for $\kappa'=0$, 0.5 and 1 are indicated, and the intermediate curves correspond to 0.1 increments of κ'.

$$K_q(p(x,\theta),p(x,\theta+\Delta)) \approx \frac{1}{2}\, q\Delta^2 \int \frac{1}{p}\left(\frac{\partial p}{\partial \theta}\right)^2 dx. \tag{40}$$

Up to the factor q, this coincides with the standard result for $q=1$.[29] Note that it is the standard ($q=1$) Fisher information that appears here, and not the q-generalized Fisher information that was introduced in Ref. 30.

IV. MINIMUM RELATIVE INFORMATION DISTRIBUTIONS

Now we will briefly discuss the minimum relative entropy distributions consistent with a set of M given constraints.[24] Let's assume that the only information we know about a probability distribution p_j, $j=1,...,N$, are the q-generalized expectation values of M quantities A_r, $r=1,...M$,

$$\langle A_r \rangle_q = \sum_j A_{rj} p_j^q. \tag{41}$$

Following the q-generalized maximum entropy prescription, one would adopt the probability distribution that *maximizes* the entropy S_q, under the constraints imposed by normalization and the set (41) of mean values. However, such a procedure has a strong, and sometimes undesirable, bias towards the uniform distribution.[23] In many applications, we may prefer a nonuniform prior probability distribution $\tilde{p}_j$ that would be our default choice in the case that no further information was available. A natural way of incorporating an arbitrary prior distribution $\tilde{p}_j$ is to find the probability distribution that *minimizes* the generalized Kullback information measure $K_q(p,\tilde{p})$, under the relevant constraints. Introducing appropriate Lagrange multipliers, the concomitant variational principle reads

$$\delta\left\{ K_q + \alpha \sum_{j=1}^{N} p_j + \sum_{r=1}^{M} \lambda_r \left(\sum_{j=1}^{N} A_{rj} p_j^q \right) \right\} = 0. \tag{42}$$

The Kullback minimum information principle[23] is recovered in the limit $q \to 1$. A straightforward calculation yields

$$p_j = Z_q^{-1} \left[\tilde{p}_j^{1-q} - (1-q) \sum_{r=1}^{M} \lambda_r A_{rj} \right]^{1/(1-q)}, \tag{43}$$

where the partition function Z_q is given by

$$Z_q = \sum_j \left[\tilde{p}_j^{1-q} - (1-q) \sum_{r=1}^{M} \lambda_r A_{rj} \right]^{1/(1-q)}. \tag{44}$$

It is easy to verify that the Lagrange multipliers λ_r, $r=1,...,M$, the corresponding mean values $\langle A_r \rangle_q$, and the relative entropy K_q satisfy

$$K_q = -\lambda_J - \sum_{r=1}^{M} \lambda_r \langle A_r \rangle_q, \tag{45}$$

where the Jaynes parameter λ_J is given by

$$\lambda_J \equiv \frac{Z_q^{1-q} - 1}{1-q} = \ln_q Z_q. \tag{46}$$

After some algebra, it is also possible to obtain Jaynes' well-known thermodynamic relations relating the entropy, the relevant mean values, and the corresponding Lagrange multipliers, i.e.,

$$\frac{\partial \lambda_J}{\partial \lambda_r} = -\langle A_r \rangle_q \quad (r=1,...M) \tag{47}$$

and

$$\frac{\partial K_q}{\partial \langle A_r \rangle_q} = -\lambda_r \quad (r=1,...M). \tag{48}$$

Here, the q-invariance becomes explicit. These thermodynamic relations were recently proved[31,32] to hold true for, essentially, *any* entropic measure. They are a universal feature of the maximum entropy variational procedure. However, the present case of the q-generalized relative information measure K_q shows the interesting property that the partition function Z_q can be explicitly written as a function of the Lagrange multipliers λ_r. This is not a universal characteristic of the maximum entropy prescription. Up to now, there are only a few known entropic functionals that share this property.[33]

V. H-THEOREM

The D-dimensional Fokker–Planck (FP) equation reads[25]

$$\frac{\partial p}{\partial t} = -\sum_i \frac{\partial}{\partial x} (V_i(\mathbf{x})p) + \sum_{i,j} \frac{\partial^2}{\partial x_i \partial x_j} (G_{ij}(\mathbf{x})p), \tag{49}$$

where $p(\mathbf{x},t)$, $\mathbf{x} \in R^D$, is a time-dependent probability distribution; $V_i(\mathbf{x})$, $i=1,...,D$, stand for the components of the drift vector $\mathbf{V}$; and $G_{ij}(\mathbf{x})$, $i,j=1,...,N$, are the components of the diffusion tensor $\mathbf{G}$. We will consider the behavior of the relative information between two arbitrary time-dependent solutions (p_1 and p_2) to the FP equation, i.e.,

$$K_q = \frac{1}{1-q} \int d\mathbf{x}\, p_1(\mathbf{x},t) \left[1 - \left(\frac{p_2(\mathbf{x},t)}{p_1(\mathbf{x},t)} \right)^{1-q} \right]. \tag{50}$$

It is worthwhile to discuss first in some detail the particular, but important, *deterministic* case of a vanishing diffusion tensor.

A. Liouville equation

The D-dimensional Fokker–Planck equation with a vanishing diffusion tensor reduces to the Liouville equation. Although the Liouville equation is usually associated to Hamiltonian systems, it encompasses more general situations as well. The general Liouville equation

$$\frac{\partial p}{\partial t} + \nabla \cdot (\mathbf{V}p) = 0 \tag{51}$$

describes the time evolution of an ensemble of identical dynamical systems (but with different initial conditions), each one of them evolving according to the set of coupled ordinary differential equations:

$$\frac{dx_i}{dt} = V_i(\mathbf{x}) \quad (i=1,...,D). \tag{52}$$

Hamiltonian systems belong to the special family of dynamical systems with divergenceless phase-space flows, i.e.,

$$\nabla \cdot \mathbf{V} = 0. \tag{53}$$

Liouville himself[34] introduced his celebrated equation in the form (51), within the general context of arbitrary dynamical systems.

The behavior of the Shannon entropy $S(p(\mathbf{x},t))$, where $p(\mathbf{x},t)$ stands for a solution to the Liouville equation, has been discussed by many authors.[35–37] Here the time derivative of S is given by the mean value of the divergence of the flow,

$$\frac{dS}{dt}=\langle\nabla\cdot\mathbf{V}\rangle. \tag{54}$$

This implies that the entropy is time-independent for divergenceless flows. However, the entropy increases when the flow in phase space has a positive mean divergence. The above result can be easily generalized for the case of the entropy S_q of Eq. (1). One obtains[5]

$$\frac{dS_q}{dt}=\langle\nabla\cdot\mathbf{V}\rangle_q. \tag{55}$$

It is interesting to realize that the q-generalized mean values allow us to write the well-known equation (54) in a q invariant way.

In spite of its importance within the statistical approach to dynamical systems, Eq. (54) [or its q-generalization (55)] constitutes a somewhat nonoptimal result. It means that the entropy measure associated with the *fine-grained* phase space distribution describing a *deterministic* system may grow with time. Intuitively one expects entropy to increase when there is a loss of information associated with some kind of coarse graining, or with an incomplete knowledge of the equations of motion (such as when stochastic forces are present). A measure that appropriately takes into account these objections is provided by the relative information $K(p_1,p_2)$ [or its q-generalization $K_q(p_1,p_2)$], where $p_1(\mathbf{x},t)$ and $p_2(\mathbf{x},t)$ are two *arbitrary* time-dependent solutions to the Liouville equation. The time derivative of K_q is given by

$$\begin{aligned}\frac{dK_q}{dt}&=\frac{1}{q-1}\int d\mathbf{x}\left\{q\left(\frac{\partial p_1}{\partial t}\right)\left(\frac{p_2}{p_1}\right)^{1-q}+(1-q)\left(\frac{\partial p_2}{\partial t}\right)\left(\frac{p_2}{p_1}\right)^{-q}\right\}\\&=q\int d\mathbf{x}\left[p_2\left(\frac{p_2}{p_1}\right)^{-q-1}-p_1\left(\frac{p_2}{p_1}\right)^{-q}\right]\sum_i V_i\,\frac{\partial}{\partial x_i}\left(\frac{p_2}{p_1}\right)=0.\end{aligned} \tag{56}$$

We can see that $K_q(p_1,p_2)$ is *a constant of motion for the Liouville equation*. Given two arbitrary initial distributions $p_1(\mathbf{x},t_0)$ and $p_2(\mathbf{x},t_0)$, the associated mean change of information $K_q(p_1,p_2)$ is not modified if we let p_1 and p_2 to evolve according to the Liouville equation (i.e., with a *fully deterministic dynamics*).

Our results are related to the analysis in Ref. 38 of the behavior of the generalized q-entropy within Liouville dynamics. There, the functional

$$Q=\int d\mathbf{x}\;p(\mathbf{x},t)\left(\frac{p(\mathbf{x},t)}{\gamma(\mathbf{x})}\right)^{q-1} \tag{57}$$

is introduced, where $p(\mathbf{x},t)$ is a solution of the Liouville equation. The function $\gamma(\mathbf{x})$ is interpreted in terms of a volume element $d\Omega=\gamma(\mathbf{x})d\mathbf{x}$. The motivation for introducing the function $\gamma(\mathbf{x})$ and the functional Q is to work within a covariant formalism. The functional Q is interpreted as a covariant form of the entropy S_q. It was shown[38] that the functional Q is time invariant whenever the covariant divergence

$$\tilde{V}(\mathbf{x})=\frac{1}{\gamma}\,\nabla\cdot(\gamma\mathbf{V}) \tag{58}$$

vanishes. However, as already mentioned, the relation $\tilde{V}=0$ implies that $\gamma(\mathbf{x})$ constitutes a stationary solution to the Liouville equation (51). Besides, it is clear that the functional Q, up to unessential multiplicative and additive constants, is just the relative information $K_q(p,\gamma)$. Hence, that result can be reformulated by stating that the relative information between an arbitrary time-dependent solution $p(\mathbf{x},t)$ *and a stationary solution* $\gamma(\mathbf{x})$ of the Liouville equation is constant in

time. In the present work we have proved that the result of Ref. 38 is only a particular case of a more general property: the relative entropy between *two arbitrary solutions* is time independent.

B. Fokker–Planck equation

Now we will consider the case of the full Fokker–Planck equation [Eq. (49)] with a nonvanishing diffusion tensor. It is clear from the last section that the drift term in the Fokker–Planck equation makes no contribution to the time derivative of K_q. After two successive integrations by parts, the time derivative of K_q can be cast as

$$\frac{dK_q}{dt}=q\int d\mathbf{x}\sum_{ij} G_{ij}\left\{p_2\,\frac{\partial}{\partial x_i}\left[\left(\frac{p_2}{p_1}\right)^{-1-q}\frac{\partial}{\partial x_j}\left(\frac{p_2}{p_1}\right)\right]-p_1\,\frac{\partial}{\partial x_i}\left[\left(\frac{p_2}{p_1}\right)^{-q}\frac{\partial}{\partial x_j}\left(\frac{p_2}{p_1}\right)\right]\right\}, \quad (59)$$

which can be simplified to obtain

$$\frac{dK_q}{dt}=-q\int d\mathbf{x}\; p_2\left(\frac{p_2}{p_1}\right)^{-2-q}\sum_{ij} G_{ij}\left[\frac{\partial}{\partial x_i}\left(\frac{p_2}{p_1}\right)\right]\left[\frac{\partial}{\partial x_j}\left(\frac{p_2}{p_1}\right)\right]\leqslant 0, \quad (60)$$

where we have used the fact that G_{ij} is a positive definite tensor. In the $q\to 1$ limit, this expression reduces to the standard H-theorem for the Fokker–Planck equation.[25]

VI. CONCLUSIONS

The q-generalized Kullback information gain has been shown to satisfy suitably generalized versions of some basic theorems and properties fulfilled by the standard $(q=1)$ Kullback one. As already proposed by one of us,[27] the generalized relative entropy can be used as an efficient criterion for statistical independence of, for example, time series data. In the present paper we improved upon that idea by proposing a normalized version of that criterion. Hopefully, it may be quite useful since it is (i) *consistent*, in the sense that it monotonically varies with the degree of dependence of the random variables; (ii) *versatile*, in the sense that it includes a parameter, the entropic index q, which can be tuned, for each given specific problem, to an optimal value q^{opt} for which the sensitivity of the criterion is maximal; (iii) *optimal*, in the sense that its two extreme values precisely correspond to full independence and full dependence.

The q-maximum entropy distributions have already been shown to appropriately describe some experimental situations where the standard theory fails.[9] It is therefore natural to believe that the generalized Kullback minimum entropy solutions, which allow the incorporation of a nonuniform prior, may enlarge the range of successful applications of the q-nonextensive formalism. The H-theorem for a general Fokker–Planck (linear) equation was also reformulated using the generalized information gain. We remark that there is an appreciable advantage to studying the relative change in entropy of two arbitrary solutions. Indeed, in the case of the Liouville equation (purely deterministic dynamics), the cross entropy remains constant in time, whereas for the full Fokker–Planck equation (both deterministic and random components in the dynamics), the cross entropy monotonically decreases with time. Our treatment generalizes and unifies previous results already existing in the literature.[26,35–39] Based on the present considerations, we believe that the generalized Kullback measure may find useful future applications in both statistical physics and information theory.

The phase space Γ of quantum mechanics can be viewed as the complex projective space CP^n endowed with a Kählerian structure given by the Fubini-Study metric and an associated symplectic form. We can then interpret the Schrödinger equation as generating a Hamiltonian dynamics on Γ. Based upon the geometric structure of the quantum phase space we introduce the corresponding natural microcanonical and canonical ensembles. The resulting density matrix for the canonical Γ-ensemble differs from the density matrix of the conventional approach. As an illustration, the results are applied to the case of a spin one-half particle in a heat bath with an applied magnetic field. © *1998 American Institute of Physics.* [S0022-2488(98)00212-6]

I. QUANTUM PHASE SPACE

With a view to certain geometrical generalizations we reformulate the conventional quantum theory in the following manner. Consider a finite dimensional complex Hilbert space $\mathcal{H}_{\mathbf{C}}^{n+1}$ with complex elements Z^α. We identify the state vector Z^α with its multiples λZ^α $(\lambda \in \mathbf{C}-\{0\})$ to obtain the complex projective space CP^n. Here we use Greek indices $(\alpha=0,1,...,n)$ for vectors in $\mathcal{H}_{\mathbf{C}}^{n+1}$, and regard CP^n as the true ''state space'' of quantum mechanics. The complex conjugate of Z^α is written $\overline{Z}_\alpha$, with the Hermitian inner product $Z^\alpha \overline{Z}_\alpha$. We let the state vector Z^α represent homogeneous coordinates for CP^n. Then, the complex conjugate of a point P^α in CP^n corresponds to the hyperplane $\overline{P}_\alpha Z^\alpha = 0$. The points on this plane are the states orthogonal to the original state P^α. Thus, CP^n is equipped with a complex conjugation operation that maps points to hyperplanes of codimension one, and vice versa.

Distinct points X^α and Y^α are joined by a complex projective line $L^{\alpha\beta}=X^{[\alpha}Y^{\beta]}$, representing complex superpositions of the original two states. The quantum mechanical transition probability between two states X^α and Y^α is the cross ratio $\kappa = X^\alpha \overline{Y}_\alpha Y^\beta \overline{X}_\beta / X^\gamma \overline{X}_\gamma Y^\delta \overline{Y}_\delta$. If the system is in the state Y^α and a measurement is made with the projection operator $X^\alpha \overline{X}_\beta / X^\gamma \overline{X}_\gamma$, then κ is the probability that the result is the eigenvalue unity. The angle θ defined by $\kappa = \cos^2(\theta/2)$ can be interpreted as the distance between the states X^α and Y^α. Then if we set $\theta = ds$, $X^\alpha = Z^\alpha$, and $Y^\alpha = Z^\alpha + dZ^\alpha$, retaining terms to second order, we obtain the unitarily invariant Fubini-Study metric[1–3] on the state space, given by

$$ds^2 = 8(Z^\alpha \overline{Z}_\alpha)^{-2} Z^{[\alpha} dZ^{\beta]} \overline{Z}_{[\alpha} d\overline{Z}_{\beta]}. \tag{1}$$

Now suppose we write H^α_β for the Hamiltonian operator, assumed Hermitian. Then, if we set $\hbar = 1$, the Schrödinger equation reads $dZ^\alpha = iH^\alpha_\beta Z^\beta dt$. However, the projective Schrödinger equation

$$Z^{[\alpha} dZ^{\beta]} = iZ^{[\alpha} H^{\beta]}_\gamma Z^\gamma dt, \tag{2}$$

which eliminates the superfluous freedom associated with the scale of Z^α, is defined directly on the state space.

An alternative way of viewing this structure is to regard CP^n as a real manifold Γ of dimension $2n$, equipped with a Riemannian metric g_{ab} and a compatible symplectic structure Ω_{ab}, satisfying $g^{ab}\Omega_{ac}\Omega_{bd}=g_{cd}$ and $\nabla_a\Omega_{bc}=0$, where ∇_a is the metric connection. We use Roman indices ($a=1,2,...,2n$) for tensorial operations in the tangent space of Γ. The Schrödinger equation then takes the form of a Hamiltonian flow $\xi^a=2\Omega^{ab}\nabla_b H$ on Γ. Here the generating function $H(x)$ is given at each point x in Γ by the expectation $H^\alpha_\beta\Pi^\beta_\alpha(x)$ of the Hamiltonian operator, where $\Pi^\beta_\alpha(x)=Z^\beta\overline{Z}_\alpha/Z^\gamma\overline{Z}_\gamma$ is the projection operator for the point $x\in\Gamma$ represented by the state vector $Z^\alpha(x)$. Thus, in quantum mechanics the dynamical trajectories are given by a symplectic flow on the quantum phase space Γ, generated by the Hamiltonian function $H(x)$. The flow is necessarily a Killing field, satisfying

$$\nabla_{(a}\xi_{b)}=0, \tag{3}$$

where $\xi_a=g_{ab}\xi^b$. In other words, the isometries of the Fubini-Study metric on Γ can be lifted to $\mathcal{H}^{n+1}_{\mathbf{C}}$ to yield unitary transformations. Conversely, given the Killing field we recover the observable function $H(x)$ on Γ, up to an additive constant, by use of the relation

$$\Omega^{ab}\nabla_a\xi_b=2(n+1)(H-\overline{H}), \tag{4}$$

where $\overline{H}=H^\alpha_\alpha/(n+1)$ is the average of the eigenvalues of H^α_β.

II. QUANTUM MICROCANONICAL POSTULATES

In this paper we use the metrical symplectic geometry of the quantum phase space as the basis for a re-examination of the traditional hypotheses of quantum statistical mechanics. To this end, we observe that the quantum phase space Γ admits a natural foliation by the $(2n-1)$-dimensional hypersurfaces $\mathcal{E}_E$ determined by level values $H(x)=E$ of the Hamiltonian function. The number of quantum mechanical microscopic configurations (pure states) with expected energy in the small range E to $E+\Delta E$ is then given by $\Omega(E)\Delta E$, where the state density $\Omega(E)$ for energy E is

$$\Omega(E)=\int_{\mathcal{E}_E}\frac{\nabla_a H d\sigma^a}{(\nabla_b H\nabla^b H)}. \tag{5}$$

Here $d\sigma^a=g^{ab}\epsilon_{bc\cdots d}dx^c\cdots dx^d$ is the natural vector-valued $(2n-1)$-form on Γ. In the case of an isolated quantum mechanical system with energy in the given small range, we can adopt the notion of the microcanonical ensemble, and identify the entropy by use of the Boltzmann relation $S(E)=\ln(\Omega(E)\Delta E)$. Here, we implicitly assume what might be called the *quantum microcanonical postulate*, which asserts that for an isolated system in equilibrium all states on a given energy surface in the quantum phase space are equally probable. As a consequence, the temperature of such a system is given by $\beta=dS(E)/dE$, where $\beta=1/kT$. Thus for an isolated quantum system with expected energy E the equilibrium configuration is given by a uniform distribution on the energy surface $\mathcal{E}_E$, with entropy $S(E)$ and temperature $T(E)$ as given above. The corresponding probability density function on Γ, which we call the microcanonical Γ-distribution, is

$$\mu_E(x)=\frac{\delta(H(x)-E)}{\Omega(E)}. \tag{6}$$

It is a straightforward exercise to verify that the state density $\Omega(E)=\int_\Gamma\delta(H(x)-E)dV$, which appears here as a normalization factor, is consistent with expression (5). Here dV is the volume element on Γ.

A general measurable function $F(x)$ on Γ represents a nonlinear observable.[1,5] We interpret $F(x)$ as the conditional expectation $\langle F\rangle_x$ of the observable F in the pure state x. The unconditional expectation of F in the microcanonical Γ-ensemble is then given by $\langle F\rangle_E=\int_\Gamma F(x)\mu_E(x)dV$. In the case of a conventional linear observable we have $F(x)=F^\beta_\alpha\Pi^\alpha_\beta(x)$. Then the unconditional expectation in the state $\mu_E(x)$ is $\langle F\rangle_E=F^\beta_\alpha\mu^\alpha_\beta(E)$, where the quantum microcanonical density matrix $\mu^\alpha_\beta(E)$, parameterized by E, is

$$\mu_\beta^\alpha(E)=\int_\Gamma \Pi_\beta^\alpha(x)\mu_E(x)dV. \tag{7}$$

Providing we only consider linear observables, the state is fully characterized by $\mu_\beta^\alpha(E)$. Now suppose $W(E)$ denotes the total phase space volume for states such that $H(x)\leqslant E$. Then the density matrix $\mu_\beta^\alpha(E)$ can be calculated explicitly by use of the formula

$$\mu_\beta^\alpha(E)=\left(\frac{\partial W(E)}{\partial \overline{H}}\right)^{-1}\frac{\partial W(E)}{\partial H_\alpha^\beta}. \tag{8}$$

III. CANONICAL Γ-ENSEMBLE

Next, we motivate a construction for the corresponding canonical ensemble, representing the situation where a quantum mechanical system is in contact with a heat bath at a fixed temperature. The results we obtain are related to those that follow from the conventional density matrix for the canonical state, though differ in certain essential respects. First we note that the projection operator $\Pi_\beta^\alpha(y)$, for a given state y, can itself be thought of as the density matrix corresponding to a mass distribution $\delta_y(x)$ on Γ, concentrated at the point y. Therefore, we can write $\Pi_\beta^\alpha(y)=\int_\Gamma \Pi_\beta^\alpha(x)\delta_y(x)dV$. Then the conventional density matrix of quantum statistical mechanics, which we denote r_β^α, can be derived from a point mass distribution with density

$$r(x)=Z(\beta)^{-1}\sum_k e^{-\beta E_k}\delta_{y_k}(x) \tag{9}$$

on Γ, concentrated at the energy eigenstates y_k, with E_k being the corresponding eigenvalues and $Z(\beta)=\Sigma_k e^{-\beta E_k}$ the associated partition function. Hence, for the conventional density matrix we have

$$r_\beta^\alpha=Z(\beta)^{-1}\sum_k e^{-\beta E_k}\Pi_\beta^\alpha(y_k). \tag{10}$$

It should be evident that, despite its general usefulness and wide acceptance as a fundamental basis for quantum statistical mechanics, the conventional density matrix r_β^α is in some respects unnatural in the absence of some mechanism forcing the system to energy eigenstates, since its phase space distribution is characterized by $\delta_{y_k}(x)$. Thus we are led to consider an alternative expression, suggested by the geometry of Γ, in which we do not assume a concentration on eigenstates.

Consider two systems I and II and let them make contact to form a combined system I+II. We suppose that the systems only interact weakly, so the support of the resulting state on the quantum phase space Γ_{1+2} of the combined system is concentrated on the product $\Gamma_{1\cdot 2}\subset\Gamma_{1+2}$ of the phase spaces Γ_1 and Γ_2 for the systems I and II. We have in mind the situation where system I represents a heat bath with a given inverse temperature β, while II represents a small system immersed in the bath. We wish to calculate the probability density $p(E_2)$ that system II lies on the energy surface $\mathcal{E}_{E_2}$ in Γ_2, conditional on the total energy of the combined system I+II lying in the small range E to $E+\Delta E$. Now, according to the quantum microcanonical hypothesis, the equilibrium distribution over the energy surface $\mathcal{E}_E$ in $\Gamma_{1\cdot 2}$ is uniform. Therefore, conditional on a given value E for the combined system I+II, the joint probability density function $p_E(E_1,E_2)$ for system I to lie on $\mathcal{E}_{E_1}$ in Γ_1 and for system II to lie on $\mathcal{E}_{E_2}$ in Γ_2 is

$$p_E(E_1,E_2)=\frac{\delta(E-E_1-E_2)\Omega_1(E_1)\Omega_2(E_2)}{\Omega_{1\cdot 2}(E)}. \tag{11}$$

Here, $\Omega_1(E_1)$ and $\Omega_2(E_2)$ are the state densities for the energy surfaces $\mathcal{E}_{E_1}$ in Γ_1 and $\mathcal{E}_{E_2}$ in Γ_2, and the state density $\Omega_{1\cdot 2}(E)$ for the energy surface $\mathcal{E}_E$ in $\Gamma_{1\cdot 2}$ is

$$\Omega_{1\cdot 2}(E)=\int_{-\infty}^{\infty}\Omega_1(E-\epsilon)\Omega_2(\epsilon)d\epsilon. \tag{12}$$

Our goal is to calculate the conditional probability density for system II to have energy E_2. This is given by $p(E_2)=\int_{-\infty}^{\infty}p_E(E_1,E_2)dE_1$, which implies

$$p(E_2)=\frac{\Omega_1(E-E_2)\Omega_2(E_2)}{\Omega_{1\cdot 2}(E)}. \tag{13}$$

Since system I, the heat bath, is in equilibrium, by the microcanonical hypothesis it has entropy $S_1(E_1)=\ln(\Omega_1(E_1)\Delta E)$, and hence temperature $\beta(E_1)=\partial S_1/\partial E_1$. If $E_2\ll E$, then to first order in E_2 we have $\Omega_1(E-E_2)=\Omega_1(E)e^{-\beta E_2}$, where $\beta(E_1)$ is the inverse temperature of the heat bath. As a consequence we deduce that the probability density $p(E_2)$ for system II to lie on the energy surface $\mathcal{E}_{E_2}$ in Γ_2 is given by $p(E_2)=\Omega_2(E_2)e^{-\beta E_2}/\int_{-\infty}^{\infty}\Omega_2(\epsilon)e^{-\beta\epsilon}d\epsilon$. More succinctly, now we drop the subscript 2, and regard the conditioning as implicit in the specification of the parameter β. Then for the probability density of the energy distribution on Γ we have

$$p(\epsilon)=\frac{\Omega(\epsilon)\exp(-\beta\epsilon)}{Z(\beta)}, \tag{14}$$

where $\Omega(\epsilon)$ is the state density on Γ per unit of energy and $Z(\beta)=\int_{-\infty}^{\infty}\Omega(\epsilon)\exp(-\beta\epsilon)d\epsilon$ is the partition function. By the *quantum canonical postulate* we mean the assumption that a small quantum system in equilibrium with a heat bath will be in a state characterized by a distribution over the energy surfaces of Γ with density (14), having a uniform distribution on each such surface. The corresponding probability density function $\rho_\beta(x)$ on Γ is

$$\rho_\beta(x)=\frac{\exp(-\beta H(x))}{Z(\beta)}, \tag{15}$$

which we shall call the *canonical* Γ*-distribution*. Alternatively, we can write $\rho_\beta(x)=\int_\epsilon p(\epsilon)\mu_\epsilon(x)d\epsilon$, expressing $\rho_\beta(x)$ as a weighted average of microcanonical ensembles, where $p(\epsilon)$ is given as in (14). The associated density matrix for the canonical Γ-distribution is therefore

$$\rho_\beta^\alpha(T)=\int_\Gamma \Pi_\beta^\alpha(x)\rho_\beta(x)dV. \tag{16}$$

IV. TWO-STATE SYSTEM

To illustrate how the consequences of the canonical Γ-distribution (15) differ from those of the conventional treatment in terms of the density matrix r_β^α, we study the example of a spin one-half particle in a heat bath. First we review briefly the geometry of the Schrödinger dynamics for a spin one-half particle. The quantum phase space in this case is CP^1, which can be viewed as a sphere S^2. The poles of the sphere correspond to the energy eigenstates, with eigenvalues $E_0=-h$ and $E_1=h$, and the Schrödinger trajectories are generated by a rigid rotation of the sphere about the axis through the poles, the two stationary points. This rotation gives rise to a Killing field on the sphere, where the angular velocity is $2h$, the energy difference between the poles. Thus the Schrödinger evolution generates a latitudinal circle. Now we introduce a complex Hilbert space with coordinates Z^α $(\alpha=0,1)$ which we regard as homogeneous coordinates for CP^1. The complex conjugate of Z^α is the ''plane'' $\overline{Z}_\alpha$ in CP^1, which in this dimension is a point. The point corresponding to $\overline{Z}_\alpha$ is $\overline{Z}^\alpha=\epsilon^{\alpha\beta}\overline{Z}_\beta$, where $\epsilon^{\alpha\beta}$ is the natural symplectic form on the two-dimensional Hilbert space. The formalism in this case is equivalent to the algebra of two-component spinors. By use of the spinor identity $2X^{[\alpha}Y^{\beta]}=\epsilon^{\alpha\beta}X_\gamma Y^\gamma$, where $X^\alpha\epsilon_{\alpha\beta}=X_\beta$, we obtain $ds^2=4Z_\alpha dZ^\alpha Z_\beta d\overline{Z}^\beta/(Z_\gamma\overline{Z}^\gamma)^2$ for the Fubini-Study metric, and $Z_\gamma dZ^\gamma=iH_{\alpha\beta}Z^\alpha Z^\beta dt$ for the projective Schrödinger equation. The Hamiltonian has the representation

$$H_{\alpha\beta}=2h\,\frac{P_{(\alpha}\overline{P}_{\beta)}}{\overline{P}_{\gamma}P^{\gamma}}, \tag{17}$$

where P^{α} and $\overline{P}^{\alpha}$ are the stationary points, satisfying $H^{\alpha}_{\beta}\overline{P}^{\beta}=hP^{\alpha}$ and $H^{\alpha}_{\beta}\overline{P}^{\beta}=-h\overline{P}^{\alpha}$. It follows that the velocity of the trajectory through Γ is

$$\frac{ds}{dt}=2h\,\sin\theta, \tag{18}$$

a special case of the Anandan–Aharonov relation.[4] Here, θ is the distance from Z^{α} to P^{α}, given by the angular coordinate measured down from the north pole. The transition probability from Z^{α} to the north pole P^{α} is $(1+\cos\theta)/2$, and for the evolutionary trajectory we obtain

$$Z^{\alpha}=\cos(\theta/2)e^{i(ht+\phi)}P^{\alpha}+\sin(\theta/2)e^{-i(ht+\phi)}\overline{P}^{\alpha}, \tag{19}$$

where θ and ϕ are the initial coordinates on the sphere for the state at $t=0$. The vector Z^{α} is normalized by setting $P^{\alpha}\overline{P}_{\alpha}=-P_{\alpha}\overline{P}^{\alpha}=1$. The expectation E of the energy for this state is $E=h\,\cos\theta$, and its variance is $h^2\,\sin^2\theta$.

With this in mind we now examine the situation where the spin one-half particle is immersed in a heat bath. The conventional density matrix $r^{\alpha}_{\beta}(T)$ for the system in this case can be expressed as a superposition of projection operators onto energy eigenstates, with Boltzmann weights,

$$r^{\alpha}_{\beta}=\frac{-e^{-\beta E_0}\overline{P}^{\alpha}P_{\beta}+e^{-\beta E_1}P^{\alpha}\overline{P}_{\beta}}{e^{-\beta E_0}+e^{-\beta E_1}}. \tag{20}$$

This can also be written $r^{\alpha}_{\beta}=Z^{-1}\,\exp(-\beta H^{\alpha}_{\beta})$. The fact that r^{α}_{β} has trace unity follows from the normalization condition. For the expected energy $H^{\alpha}_{\beta}r^{\beta}_{\alpha}$ we then obtain $E=-h\,\tanh(\beta h)$.

Next we apply the canonical Γ-distribution to this problem. For this ensemble the probability distribution of the energy in the spin one-half case is

$$p(E)dE=-2\pi Z(\beta)^{-1}\,\sin\theta\,\exp(-\beta h\,\cos\theta)d\theta, \tag{21}$$

where $E=h\,\cos\theta$. The normalization condition on the density function $p(E)$ implies $Z(\beta)=4\pi(\beta h)^{-1}\,\sinh(\beta h)$, from which the expected energy $E=-\partial\,\ln Z/\partial\beta$ can be deduced. The result is $E=kT-\mu B\,\coth(\mu B/kT)$. Here we have reinstated Boltzmann's constant k, the particle's magnetic moment μ, and the external magnetic field strength B, with $h=\mu B$. The behavior of the energy for the cases considered above is sketched in Fig. 1. It is clear that the increase in magnetization, when the temperature decreases, is slower in the case of the canonical Γ-distribution than for the conventional ensemble. This is because the latitudinal circles closer to the equator have larger weights than those closer to the poles. In Fig. 2 we plot the relationship between the specific heat and the temperature.

We note that in the case of the canonical Γ-ensemble the heat capacity for this system is nonvanishing at zero temperature. For many bulk substances, on the other hand, the heat capacity vanishes as zero temperature is approached. Therefore, it would be interesting to enquire if a single electron has a different behavior. To that end, we note that in the case of a general two state system, with energy eigenvalues E_0 and E_1, the density matrix of the canonical Γ-distribution, in the basis of energy eigenstates, is

$$\rho^{\alpha}_{\beta}=-\left[\frac{1}{\beta(E_0-E_1)}+\frac{1}{1-e^{-\beta(E_1-E_0)}}\right]\overline{P}^{\alpha}P_{\beta}+\left[\frac{1}{\beta(E_1-E_0)}+\frac{1}{1-e^{-\beta(E_0-E_1)}}\right]P^{\alpha}\overline{P}_{\beta}. \tag{22}$$

This expression can be contrasted with the conventional result for such a system, given in formula (20). In fact it is not difficult to obtain analogous expressions in higher dimensions, some of which may characterize other systems that can be implemented in experiments to determine whether the Γ-distribution introduced here provides a better account of phenomena in certain situations.

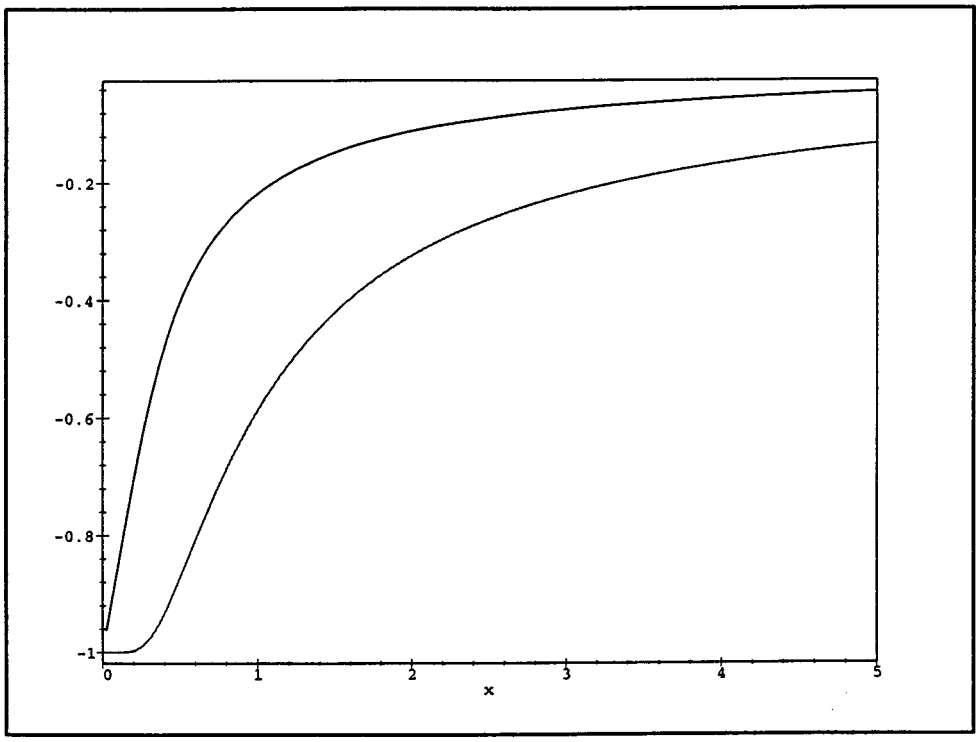

FIG. 1. The energy ratio $E/\mu_e B$ for an electron in a heat bath with temperature T and an applied magnetic field strength B of one Tesla. The x axis is the temperature in degrees Kelvin. Results for the canonical Γ-ensemble (top) and the conventional ensemble (bottom) are shown.

V. DISCUSSION

The foregoing constructions are based on the quantum microcanonical postulate, which for an isolated system in equilibrium implies a uniform distribution over any energy surface of the quantum phase space. We therefore enquire whether this postulate can be derived from the basic principles of quantum mechanics. This would follow, e.g., if quantum dynamics were ergodic on the energy surfaces $\mathcal{E}_E$. In the example of the spin one-half particle, ergodicity is indeed guaranteed by the periodicity of the Schrödinger evolution and the dimensionality of the energy surface.

In higher dimensions, the generic energy surface $\mathcal{E}_E$ is parameterized by $(n-1)$ angular parameters and n phase variables. For each fixed set of angular variables we obtain an n-torus T^n in $\mathcal{E}_E$, and by varying the angular parameters the energy surface is foliated by an $(n-1)$-dimensional family of such tori. If we assume that the Hamiltonian is nondegenerate, and that the ratios E_i/E_j $(i\neq j)$ of the energy eigenvalues are irrational, then the Schrödinger evolution is nonperiodic on each T^n. As a result, ergodicity is guaranteed on the toroidal energy subsurfaces. On the other hand, unitary evolution does not change the angular parameters on $\mathcal{E}_E$. It follows that the energy surfaces are not fully ergodic with respect to the Schrödinger equation, and that we cannot deduce the microcanonical postulate directly from the principles of quantum mechanics. It would be interesting to see if this postulate could be derived as a consequence of a suitable generalization of ordinary quantum mechanics, e.g., nonlinear[1–3,5] or stochastic[6] quantum dynamics.

To summarize, we have formulated quantum mechanical analogs of the microcanonical and canonical ensembles by consideration of the geometry of the quantum phase space. In particular, a key distinction in our proposal is that phase space weightings are fully taken into account in the construction of equilibrium ensembles, whereas in the conventional approach such weights arise only in the event of energy eigenvalue degeneracies. We are thus able to give a coherent meaning to the quantum microcanonical ensemble, and derive an expression for the corresponding density matrix, a construction that is missing in the conventional theory. It may be that for bulk substances there is a further component to the dynamics, perhaps due to internal interactions at low tempera-

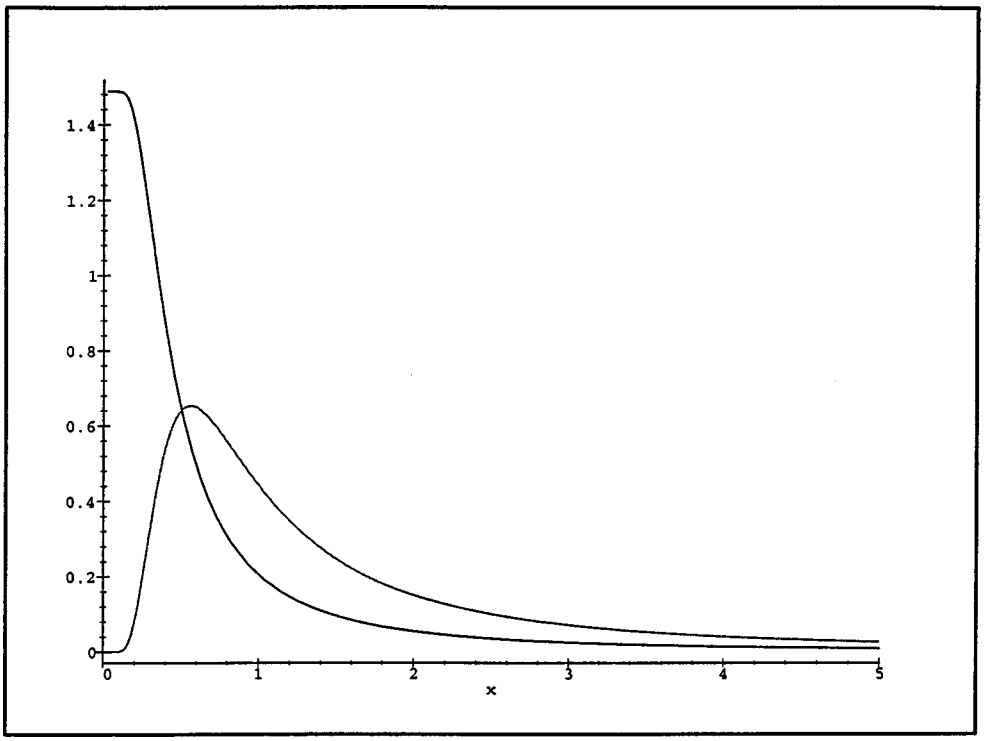

FIG. 2. The heat capacity ratio $C/\mu_e B$ for the system represented in Fig. 1, plotted against the temperature. Results for the canonical Γ-ensemble (top left) and the conventional ensemble (bottom left) are shown.

ture, that forces the quantum phase space to contract down to the lattice of energy eigenstates, with appropriate multiplicities. In that case we recover the conventional theory. It would be interesting to determine, by suitable measurements on quantum mechanical systems, whether the ensembles introduced here are indeed appropriate.

(Received 15 April 1998; accepted for publication 12 June 1998)

We study the Dirichlet forms and the associated Dirichlet operators for Gibbs measures on infinite particle configuration space. The Dirichlet forms are defined to be ''gradient-type'' forms by introducing a measurable field of rigged Hilbert spaces on the configuration space. Under mild conditions on the interaction including singular potentials, we show that the pre-Dirichlet operator is symmetric and that the closure of the pre-Dirichlet form satisfies the Markovian property. When the interaction is three times differentiable and decreasing sub-exponentially, we show that the Dirichlet operator is essentially self-adjoint on a domain consisting of bounded smooth local functions. © *1998 American Institute of Physics.* [S0022-2488(98)02912-0]

I. INTRODUCTION

In this paper we study the Dirichlet forms and the associated Dirichlet operators for Gibbs measures on the configuration space of interacting particles. More precisely, we consider the infinite particle systems on a Euclidean space $\mathbb{R}^d$ interacting via superstable and lower regular two-body interactions in the sense of Ruelle.[1,2] This ensures[2] the existence of a Gibbs measure μ on the locally finite (particle) configuration space Ω. We define a gradient type pre-Dirichlet form on a domain of bounded smooth cylinder functions from $L^2(\Omega,\mu)$. We show that the associated Dirichlet operator is symmetric and the closure of the form satisfies the Markovian property.[3,4] Furthermore, if the interaction is three times differentiable and decreasing faster than any polynomial, we show that the Dirichlet operator is essentially self-adjoint on a space of bounded smooth local functions. See Sec. II for the details.

The study of this paper is closely related to the following first order stochastic differential equations:

$$\begin{cases} dx_k(t) = -\dfrac{1}{2}\beta \sum\limits_{j\neq k} \operatorname{grad}\Phi(x_k - x_j)dt + dW_k(t), \\ x_k(0) = z_k, \quad k \in S, \end{cases} \tag{1.1}$$

where S is a countable set, $\omega := \{x_k(t)\}_{k\in S}$ is a particle configuration and $\{W_k(t)\}_{k\in S}$ is the independent standard Brownian motion on $\mathbb{R}^d$. In a formal level, any stochastic solution to the system (1.1) defines a diffusion process under which any Gibbs measure with interacton Φ at inverse temperature β is stationary. The study of diffusions associated to the system (1.1) has been initiated by Lang[5,6] for smooth compact support potential Φ using a finite dimensional approximation. This approach had been further developed by Fritz,[7] still in the case of smooth compact

support potentials and under the restriction $d \leqslant 4$. On the other hand, Osada and Yoshida, in their papers, Ref. 8 and Ref. 9, respectively, have used a Dirichlet form approach to construct the diffusion process corresponding to (1.1). Under mild conditions on the interaction Φ, including singular potentials such as Lenard-Jones type potentials, they have shown that the corresponding canonical Dirichlet form is quasi-regular in the sense defined in Ref. 4 and the existence of a diffusion process is provided by a general theory.[3,4] In order to set the problem in a systematic way, Albeverio, Kondratiev, and Röckner have extensively developed the analytic and geometric theories for the configuration spaces.[10–13] The main idea is a ''lifting procedure'' from underlying one-particle space to the configuration space. From this approach, one considerably benefits in investigating the Dirichlet form theory. In Refs. 12 and 13, the diffusion process is constructed and also the ergodicity of the process has been established (see also Ref. 14).

In Ref. 7, the essential self-adjointness of the Dirichlet operator associated to the Dirichlet form has been studied. This property is used in the proof of the Gaussian central limit theorem for the measures of the density fluctuation fields in Ref. 15. The essential self-adjointness of the Liouville operator corresponding to an infinite Newtonian system has been solved for one-dimensional hard cores system with singular (and of finite range) two-body interactions in Ref. 16. The essential self-adjointness of the Dirichlet operator is also deeply related to the equivalence of the corresponding strong and weak Sobolev spaces.[13,17] Our purpose in this paper is to reformulate the gradient-type Dirichlet forms in terms of a measurable field of rigged Hilbert spaces and then to show the essential self-adjointness of the Dirichlet operators for Gibbs measures of infinite range interactions.

Let us briefly describe the contents of this paper. Let Ω be the space of locally finite particle configurations on $\mathbb{R}^d$, Φ a two-body interaction, and μ a Gibbs measure for the interaction Φ. We will impose Φ to be superstable and lower regular in the sense of Ruelle so that Gibbs measures do exist.[1,2] The main body of this paper consists of (i) developing a measurable field of rigged Hilbert spaces, a gradient operator for functions on Ω and defining a pre-Dirichlet form on $L^2(\Omega,\mu)$ using those ingredients, (ii) showing that the form is closable, and finally (iii) proving the essential self-adjointness of the corresponding Dirichlet operator on a space of smooth local functions. By using the diffentiability concept of functions on Ω developed in Ref. 6, we will define the ''gradient'' ∇f of a function f. ∇f will be understood as an element of a measurable field of Hilbert spaces, so our Dirichlet form shall be of the form

$$\mathcal{E}(u,v) := \frac{1}{2} \int \langle \nabla u(\omega), \nabla v(\omega) \rangle_{\omega,0} d\mu(\omega), \qquad u,v \in C^2_{b,loc}(\Omega), \tag{1.2}$$

where for each $\omega \in \Omega$, $\langle \cdot,\cdot \rangle_{\omega,0}$ denotes the inner product in a Hilbert space $\mathcal{H}_{\omega,0}$ and we will define further Hilbert spaces $\mathcal{H}_{\omega,+}$ and $\mathcal{H}_{\omega,-}$ so that

$$\mathcal{H}_{\omega,+} \subset \mathcal{H}_{\omega,0} \subset \mathcal{H}_{\omega,-} \tag{1.3}$$

shall be a rigged Hilbert space. $C^2_{b,loc}(\Omega)$ denotes the space of bounded, local, twice-differentiable functions on Ω with bounded derivatives. The form (1.2) is essentially equivalent to that defined in Refs. 9 and 13, respectively. One can see the concept of measurable field of Hilbert spaces, i.e., a ''tangent space'' in Refs. 10–13 and also in Ref. 17. The introduction of the rigged Hilbert space (1.3) is typical in this paper and shall be very much useful in showing the essential self-adjointness of Dirichlet operator. This idea has been used for lattice systems.[18–20] Next, we define the Dirichlet operator H_μ:

$$\begin{aligned} H_\mu v(\omega) &:= -\tfrac{1}{2}\Delta v(\omega) - \tfrac{1}{2}\langle b(\omega), \nabla v(\omega) \rangle_{\omega,0}, \qquad v \in C^2_{b,loc}(\Omega), \\ b(\omega) &= \left(-\beta \sum_{y \in \omega \setminus x} \operatorname{grad} \Phi(x-y) \right)_{x \in \omega}, \end{aligned} \tag{1.4}$$

so that

$$\mathcal{E}(u,v) = (u, H_\mu v)_{L^2(\Omega,\mu)}. \tag{1.5}$$

Being a form defined through a positive symmetric operator, it is closable and it is not hard to show the Markovian property of the form under appropriate conditions on Φ. A similar procedure has been done also in Refs. 8–9 and 13. For the essential self-adjointness of the Dirichlet operator, we will use the general parabolic criterion for the essential self-adjointness developed in Ref. 21 and use uniform estimates on partial dynamics for which we have modified the method developed in Ref. 7 to deal with infinite range interactions.

We organize this paper as follows: In Sec. II, we give necessary definitions, review some properties of Gibbs measures, and give the main results of this paper. In Sec. III, we prove the closability and Markovian property of the forms. Section IV is devoted to showing the essential self-adjointness. In the Appendix, we provide crucial, but technical lemmas used in the contents.

In this paper, we improve some part of the doctoral dissertation of one of the authors (Ref. 22) and the results have been announced at the conference at Rome in February, 1997.

II. NOTATIONS, PRELIMINARIES, AND MAIN RESULTS

In this section, we give basic notations, necessary preliminaries, and main results. Related results can be found also in Refs. 8–9 and 12–13. We begin with a configuration space and definition of Gibbs measures.

A. Configuration space and Gibbs measures

Let $\mathcal{N}$ be the space of non-negative integer-valued Radon measures on $\mathbb{R}^d$ equipped with the vague topology. It is well known[23] that by this topology $\mathcal{N}$ becomes a Polish space, i.e., a complete separable metric space. An element ω of $\mathcal{N}$ is of the form

$$\omega=\sum_{i\geqslant 1}\delta_{x_i},$$

where $(x_i)_{i\geqslant 1}$ is a finite or infinite sequence and δ_x is the Dirac measure at $x\in\mathbb{R}^d$. Let us define by $\mathcal{C}$ the class of all bounded Borel subsets of $\mathbb{R}^d$. For each $\Delta\in\mathcal{C}$, let $\mathcal{N}_\Delta$ be the totality of $\mathbb{Z}_+$-valued Radon measures on Δ, and define a mapping $p_\Delta:\mathcal{N}\to\mathcal{N}_\Delta$ by

$$p_\Delta(\omega)=\sum_{x_i\in\Delta}\delta_{x_i},\quad \text{for } \omega=\sum_{i\geqslant 1}\delta_{x_i}\in\mathcal{N}. \tag{2.1}$$

Frequently we will use the notation ω_Δ for $p_\Delta(\omega)$. We note that for each $\Delta\in\mathcal{C}$, there is a bijection between $\mathcal{N}_\Delta$ and the topological direct sum $\Sigma_{m=0}^{\infty}\Delta^m$ given by

$$\mathcal{N}_\Delta\ni\sum_{i=1}^{m}\delta_{x_i}\leftrightarrow\{x_1,\ldots,x_m\}\in\Delta^m. \tag{2.2}$$

For each $\Delta\in\mathcal{C}$, let $N(\Delta)$ be the counting variable:

$$N(\Delta)(\omega):=\omega(\Delta)=\operatorname{card}(\omega\cap\Delta)\equiv|\omega\cap\Delta|. \tag{2.3}$$

Let $\mathcal{F}_\Delta$ be the σ-algebra on $\mathcal{N}$ generated by $N(\Lambda)$, $\Lambda\subset\Delta$, i.e., $\mathcal{F}_\Delta$ is generated by the sets of the form

$$\{\omega\in\mathcal{N}:N(\Lambda)(\omega)=m\},\qquad \Lambda\subset\Delta,\Lambda\in\mathcal{C}\quad\text{and}\qquad m=0,1,2,\ldots.$$

We notice that the Borel σ-algebra on $\mathcal{N}$ coincides with the σ-algebra generated by $\cup_{\Delta\in\mathcal{C}}\mathcal{F}_\Delta$, which we will donote by $\mathcal{F}$.[2,23]

Let Ω be a subset of $\mathcal{N}$ defined by

$$\Omega:=\{\omega\in\mathcal{N}:\omega(\{x\})=0\quad\text{or}\quad 1,\forall\, x\in\mathbb{R}^d,\quad\text{and}\quad \omega(\Delta)<\infty\,\forall\,\Delta\in\mathcal{C}\}. \tag{2.4}$$

By abuse of words we will regard $\omega \in \Omega$ as a measure and also as a subset of $\mathbb{R}^d$ consisting of the support of ω. We will use also the same notations $\mathcal{F}$ and $\mathcal{F}_\Delta$, $\Delta \in \mathcal{C}$, for the σ-algebras on Ω whose elements are the intersections of those in $\mathcal{F}$ and $\mathcal{F}_\Delta$, $\Delta \in \mathcal{C}$, with Ω. We write Ω_Λ for $p_\Lambda \Omega$, $\Lambda \in \mathcal{C}$.

Let us now introduce the notion of interactions and Gibbs measures. For $x=(x^1,\ldots,x^d) \in \mathbb{R}^d$ and $r=(r^1,\ldots,r^d) \in \mathbb{Z}^d$ we will use the following norms:

$$|x| := ((x^1)^2 + \cdots + (x^d)^2)^{1/2} \qquad \text{and} \qquad |r| := \max_{1 \le k \le d} |r^k|. \tag{2.5}$$

For each $r=(r^1,\ldots,r^d) \in \mathbb{Z}^d$, define a unit cube $Q(r)$ by

$$Q(r) := \{x=(x^1,\ldots,x^d) \in \mathbb{R}^d : r^i - \tfrac{1}{2} \le x^i < r^i + \tfrac{1}{2}, i=1,\ldots,d\}.$$

We say that a Lebesgue measurable function Φ is a pair potential when it satisfies

$$\Phi : \mathbb{R}^d \to \mathbb{R} \cup \{\infty\},$$

$$\Phi(-x) = \Phi(x), \qquad \forall x \in \mathbb{R}^d.$$

We shall assume that the interaction between particles is given by a pair potential, i.e., the energy of m particles $\omega=\{x_1,\ldots,x_m\} \subset \mathbb{R}^d$ is

$$U(\omega) \equiv U(x_1,x_2,\ldots,x_m) = \begin{cases} \dfrac{1}{2} \displaystyle\sum_{i \neq j} \Phi(x_i - x_j), & m=2,3,\ldots, \\ 0, & m=0,1. \end{cases} \tag{2.6}$$

For any $\omega=\{x_1,\ldots,x_m\}$ and $\eta=\{y_1,\ldots,y_n\}$, we write $\omega\eta=\{x_1,\ldots,x_m,y_1,\ldots,y_n\}$ and the interaction energy $W(\omega,\eta)$ between ω and η is defined to satisfy

$$\begin{gathered} U(\omega\eta) = U(\omega) + U(\eta) + W(\omega,\eta), \\ W(\omega,\eta) = \infty, \quad \text{if } U(\omega\eta) = \infty. \end{gathered} \tag{2.7}$$

We will impose the superstability and lower regularity to the pair potential in the sense of Ruelle.[1,2] For $\omega=\{x_i\}_{i \ge 1}$, $n(\omega:r)$ denotes the number of points x_i of ω contained in $Q(r)$, i.e., $n(\omega:r) = \text{card}(\omega \cap Q(r))$. A pair potential Φ is said to be *superstable* if the following holds:

(SS) There exist $A>0$, $B \ge 0$ such that if $\mathcal{R}$ is a finite subset of $\mathbb{Z}^d$ and $\omega=\{x_1,x_2,\ldots,x_m\} \subset \cup_{r \in \mathcal{R}} Q(r)$, then

$$U(\omega) \ge \sum_{r \in \mathcal{R}} [An(\omega:r)^2 - Bn(\omega:r)]. \tag{2.8}$$

A pair potential Φ is said to be *lower regular* if the following holds:

(LR) There exists a decreasing positive function $\Psi : \mathbb{Z}_+ \to \mathbb{R}_+$ such that $\Sigma_{r \in \mathbb{Z}^d} \Psi(|r|) < \infty$ and if $\mathcal{R}$ and $\mathcal{S}$ are finite subsets of $\mathbb{Z}^d$ such that $\omega=\{x_1,x_2,\ldots,x_m\} \subset \cup_{r \in \mathcal{R}} Q(r)$, $\eta=\{y_1,y_2,\ldots,y_n\} \subset \cup_{s \in \mathcal{S}} Q(s)$, then

$$W(\omega,\eta) \ge -\sum_{r \in \mathcal{R}} \sum_{s \in \mathcal{S}} \Psi(|s-r|) \left\{ \frac{1}{2} n(\omega:r)^2 + \frac{1}{2} n(\eta:s)^2 \right\}. \tag{2.9}$$

In order to define Gibbs measures we need a reference measure, which is the Poisson measure on $(\Omega,\mathcal{F})$. Let $z>0$ be an arbitrary but fixed number (the chemical potential) and π the Poisson measure on $(\Omega,\mathcal{F})$ with intensity dx, the Lebesgue measure on $\mathbb{R}^d$, and parameter z. For each $\Lambda \in \mathcal{C}$, let π_Λ be the restriction of π to the sub-σ-algebra $\mathcal{F}_\Lambda$. Obviously, we may regard π_Λ as a measure on Ω_Λ, i.e., for any $\mathcal{F}_\Lambda$-measurable function f on Ω,

$$\int_\Omega f(\omega)\pi(d\omega)\equiv\int_{\Omega_\Lambda} f(\omega_\Lambda)\pi_\Lambda(d\omega_\Lambda)=\sum_{n=0}^{\infty} e^{-z|\Lambda|}\frac{z^n}{n!}\int_{\Lambda^n} f(x_1,\ldots,x_n)dx_1\cdots dx_n, \quad (2.10)$$

where $|\Lambda|$ is the volume of Λ. For $N=1,2,\ldots$, let

$$\mathcal{S}_N=\left\{\omega\in\Omega:\forall l\in\mathbb{N},\sum_{\substack{r\in\mathbb{Z}^d\\ |r|\leqslant l}} n(\omega:r)^2\leqslant N^2(2l+1)^d\right\},$$
$$\mathcal{S}=\cup_{N=0}^{\infty}\mathcal{S}_N. \quad (2.11)$$

The following definitions were given by Ruelle[2].

Definition II.1: *A probability measure μ on Ω is said to be regular if there exist $\overline{\gamma}>0$ and $\overline{\delta}>0$ such that*

$$\mu_\Lambda(d\omega_\Lambda)\leqslant\exp\left\{\sum_{r\in\mathbb{Z}^d}(-\overline{\gamma}n(\omega_\Lambda:r)^2+\overline{\delta}n(\omega_\Lambda:r))\right\}\pi_\Lambda(d\omega_\Lambda),$$

where $\Lambda\in\mathcal{C}$ and μ_Λ is the restriction of μ to $\mathcal{F}_\Lambda$.

Definition II.2: *A probability measure μ on Ω is said to be tempered if $\mu(\mathcal{S})=1$.*

Definition II.3: *A probability measure μ on $(\Omega,\mathcal{F})$ is called a Gibbs measure with potential Φ, activity z, and inverse temperature β if it is tempered and satisfies the following Gibbs condition: for any Borel function $f\in L^1(\Omega,\mu)$ and $\Lambda\in\mathcal{C}$,*

$$\int_\Omega f(\omega)\mu(d\omega)=\int_\Omega\mu(d\eta)\frac{1}{Z_\Lambda(\eta)}\int_{\Omega_\Lambda} f(\omega_\Lambda\cup\eta_{\Lambda^c})\exp\{-\beta[U(\omega_\Lambda)+W(\omega_\Lambda,\eta_{\Lambda^c})]\}\pi_\Lambda(d\omega_\Lambda),$$

where $Z_\Lambda(\eta)=\int_{\Omega_\Lambda}\exp\{-\beta[U(\omega_\Lambda)+W(\omega_\Lambda,\eta_{\Lambda^c})]\}\pi_\Lambda(d\omega_\Lambda)$ is the partition function on Λ with boundary condition $\eta\in\Omega$.

For a superstable and lower regular pair potential Φ the existence of a Gibbs measure was shown by Ruelle.[2]

Theorem II.4: *Suppose that Φ is superstable and lower regular. Then, the set $\mathcal{G}^\Phi(z,\beta)$ of Gibbs measures is nonempty, convex, compact in the topology of local uniform convergence, and Choquet simplex. Furthermore, each $\mu\in\mathcal{G}^\Phi(z,\beta)$ is regular.*

For later use, we introduce the concept of a system of density distributions and a correlation function.[1,2]

Definition II.5: *A family (σ_Δ^m) where $m\in\mathbb{Z}_+$ and Δ runs over the bounded Lebesgue measurable subsets of $\mathbb{R}^d$ is called a system of density distributions if it satisfies the following conditions:*

(a) σ_Δ^m is a positive Lebesgue integrable function on Δ^m and

$$\sigma_\Delta^m(x_{i_1},\ldots,x_{i_m})=\sigma_\Delta^m(x_1,\ldots,x_m),$$

for every permutation $(1,\ldots,m)\to(i_1,\ldots,i_m)$.

(b) (Normalization)

$$\sum_{m=0}^{\infty}\frac{1}{m!}\int\sigma_\Delta^m(x_1,\ldots,x_m)dx_1\cdots dx_m=1.$$

(c) (Compatibility) If $\Delta\subset\Delta'$, then

$$\sigma_\Delta^m(x_1,\ldots,x_m)=\sum_{n=0}^{\infty}\frac{1}{n!}\int_{(\Delta'\setminus\Delta)^n}\sigma_{\Delta'}^{m+n}(x_1,\ldots,x_{m+n})dx_{m+1}\cdots dx_{m+n}.$$

The correlation function is defined by

$$\rho(x_1,\ldots,x_m)=\sum_{n=0}^{\infty}\frac{1}{n!}\int_{\Delta^n}\sigma_\Delta^{m+n}(x_1,\ldots,x_{m+n})dx_{m+1}\cdots dx_{m+n},$$

for $x_1,\ldots,x_m\in\Delta$.

Remark II.6: For any system of density distributions (σ_Δ^m)*, one can associate a probability measure* μ *and conversely, any probability measure* μ *determines* (σ_Δ^m) *completely. They are related as follows: for any* $\mathcal{F}_\Delta$*-measurable function f on* Ω*,*

$$\int_\Omega f(\omega)\mu(d\omega)=\sum_{m=0}^{\infty}\frac{1}{m!}\int_{\Delta^m}f(x_1,\ldots,x_m)\sigma_\Delta^m(x_1,\ldots,x_m)dx_1\cdots dx_m.$$

The following proposition was given by Ruelle (Ref. 2, Propositon 5.2, Corollary 5.3).

Proposition II.7: Let the interaction U be associated with a pair potential Φ *which is superstable, lower regular, and a Borel function. Assume that*

$$\int_{\mathbb{R}^d}|1-e^{-\beta\Phi(x)}|dx<\infty.$$

If a probability measure μ *on* $(\Omega,\mathcal{F})$ *is tempered and satisfies the Gibbs condition, then* μ *is associated with a system of density distributions* (σ_Δ^m) *such that the following inequality holds:*

$$\sigma_\Delta^m(x_1,\ldots,x_m)\leqslant\exp\left\{\sum_{r\in\mathbb{Z}^d}(-\overline{\gamma}n(x_1,\ldots,x_m:r)^2+\overline{\delta}n(x_1,\ldots,x_m:r))\right\},$$

for some $\overline{\gamma}>0$ *and* $\overline{\delta}$ *real and the correlation function defined in Definition II.5 satisfies the Mayer equations,*

$$\rho(\omega\eta)=z^m e^{-\beta[U(\omega)+W(\omega,\eta)]}\sum_{p=0}^{\infty}\frac{1}{p!}\int K(\omega,\zeta)\rho(\eta\zeta)dv_1\cdots dv_p, \tag{2.12}$$

where

$$\omega=(x_1,\ldots,x_m),\qquad \eta=(y_1,\ldots,y_n),\qquad \zeta=(v_1,\ldots,v_p),$$

$$K((x_1,\ldots,x_m),\qquad (v_1,\ldots,v_p))=\prod_{j=1}^{p}K((x_1,\ldots,x_m),v_j),$$

$$K((x_1,\ldots,x_m),v)=\exp\left\{-\beta\sum_{i=1}^{m}\Phi(v-x_i)\right\}-1.$$

Moreover, there exists a constant ξ *such that the correlation function also satisfies*

$$\rho(x_1,\ldots,x_m)\leqslant\xi^m,\qquad x_1,\ldots,x_m\in\mathbb{R}^d,\qquad m\geqslant 0. \tag{2.13}$$

B. Differential operators

In this subsection, we recall the notion of the differentiability introduced by Lang[6] and then define the gradient operator on smooth local functions defined on the configuration space Ω. Our definition of the gradient is essentially same as that introduced in Ref. 12. But there is a minor difference, because we introduce a rigging structure in the field of Hilbert spaces.

Following Lang,[6] let us define

$$\begin{aligned}\Omega^*&=\{(x,\omega)\in\mathbb{R}^d\times\Omega:x\in\omega\},\\ \Omega^{**}&=\{(x,y,\omega)\in\mathbb{R}^d\times\mathbb{R}^d\times\Omega:x\in\omega,y\in\omega\backslash x\}.\end{aligned} \tag{2.14}$$

Ω^* and Ω^{**} are equipped with the topologies induced by those of $\mathbb{R}^d\times\Omega$ and $\mathbb{R}^d\times\mathbb{R}^d\times\Omega$, respectively. For $\omega=\{x_i\}_{i\geqslant 1}$ and $x\in\omega$, $\omega\backslash x$ means the set $\{x_i\in\omega: x_i\neq x\}$ and for $y\in\mathbb{R}^d$ and $\Lambda\in\mathcal{C}$, $\omega\cup y$ means $\omega\cup\{y\}$. For a function $u:\Omega\to\mathbb{R}$ and $(x,\omega)\in\Omega^*$, define a function $u_{\omega\backslash x}$ on $\mathbb{R}^d$ by

$$u_{\omega\backslash x}(p)=u((\omega\backslash x)\cup p),\qquad p\in\mathbb{R}^d. \tag{2.15}$$

Also, for $(x,y,\omega)\in\Omega^{**}$, a function $u_{\omega\backslash x\backslash y}$ on $\mathbb{R}^d\times\mathbb{R}^d$ is defined by

$$u_{\omega\backslash x\backslash y}(p,q)=u((\omega\backslash x\backslash y)\cup p\cup q),\qquad p,q\in\mathbb{R}^d. \tag{2.16}$$

Definition II.8: A function $u:\Omega\to\mathbb{R}$ is said to be continuously differentiable if the following conditions are satisfied:

(a) For each $(x,\omega)\in\Omega^*$, the function $u_{\omega\backslash x}:\mathbb{R}^d\to\mathbb{R}$ is differentiable at x. We write

$$D_x u(\omega):=\left(\frac{\partial u_{\omega\backslash x}}{\partial p^1}(x),\ldots,\frac{\partial u_{\omega\backslash x}}{\partial p^d}(x)\right). \tag{2.17}$$

(b) The mapping $(x,\omega)\mapsto D_x u(\omega)$ is continuous on Ω^*.

Definition II.9: A function $u:\Omega\to\mathbb{R}$ is said to be twice continuously differentiable if the following conditions are satisfied:

(a) For each $(x,\omega)\in\Omega^*$ and $(x,y,\omega)\in\Omega^{**}$, $u_{\omega\backslash x}$ and $u_{\omega\backslash x\backslash y}$ are twice continuously differentiable at x and (x,y)*, respectively. We write*

$$\begin{aligned} D^2_{xx}u(\omega)&:=\left(\frac{\partial^2 u_{\omega\backslash x}}{\partial p^l\,\partial p^m}(x)\right)_{1\leqslant l,m\leqslant d},\\ D^2_{xy}u(\omega)&:=\left(\frac{\partial^2 u_{\omega\backslash x\backslash y}}{\partial p^l\,\partial q^m}(x,y)\right)_{1\leqslant l,m\leqslant d}. \end{aligned} \tag{2.18}$$

(b) The mappings $(x,\omega)\mapsto D^2_{xx}u(\omega)$ and $(x,y,\omega)\mapsto D^2_{xy}u(\omega)$ are continuous on Ω^* and Ω^{**}, respectively.

Let us introduce the spaces of functions on Ω. Put

$$\begin{aligned} \mathcal{F}C^\infty_b(\Omega)=\{u\in L^2(\Omega,\mu):\ &\exists l_1,\ldots,l_n\in C^\infty_0(\mathbb{R}^d)\ \text{ and }\ f\in C^\infty_b(\mathbb{R}^n),\\ &\text{such that }\ u(\omega)=f(\langle l_1,\omega\rangle,\ldots,\langle l_n,\omega\rangle)\ \text{ for }\ \omega\in\Omega, \end{aligned} \tag{2.19}$$

where $C^\infty_0(\mathbb{R}^k)$ and $C^\infty_b(\mathbb{R}^k)$ are the totality of infinitely many continuously differentiable functions on $\mathbb{R}^k$ such that partial derivatives of all order have compact supports and are bounded, respectively, and $\langle\cdot,\cdot\rangle$ is the dualization between $C_0(\mathbb{R}^d)$ and $C_0(\mathbb{R}^d)'$, i.e., $\langle l,\omega\rangle=\Sigma_{i\geqslant 1}l(x_i)$ for $\omega=\Sigma_{i\geqslant 1}\delta_{x_i}$. For $k=1,2$, we define

$$\begin{aligned} C^k(\Omega)&=\{u:\Omega\to\mathbb{R}:\quad u\ \text{ is }\ k\text{-times continuously differentiable}\},\\ C^k_{loc}(\Omega)&=\{u\in C^k(\Omega):\quad u\ \text{ is }\ \mathcal{F}_\Lambda\text{-measurable for some }\ \Lambda\in\mathcal{C}\},\\ C^1_{b,loc}(\Omega)&=\{u\in C^1_{loc}(\Omega):\quad u\ \text{ is bounded and }\ \sup_{(x,\omega)\in\Omega^*}|D_x u(\omega)|<\infty\},\\ C^2_{b,loc}(\Omega)&=\{u\in C^2_{loc}(\Omega):\quad u\ \text{ is bounded, }\ \sup_{(x,\omega)\in\Omega^*}|D_x u(\omega)|<\infty, \end{aligned} \tag{2.20}$$

$$\sup_{(x,\omega)\in\Omega^*} |D^2_{xx}u(\omega)|<\infty \quad \text{and} \quad \sup_{(x,y,\omega)\in\Omega^{**}} |D^2_{xy}u(\omega)|<\infty\}.$$

Analogously, we can define the spaces $C^k(\Omega), C^k_{loc}(\Omega)$, etc., for $k\geqslant 3$.

In order to define Dirichlet forms via the so called square field type operator on $L^2(\Omega,\mu)$, where μ is a Gibbs measure, we introduce some Hilbert space structure, a ''tangent space,'' and the notion of the gradient operator. Let $\nu>d$ be an arbitrary but fixed number. For each $\omega\in\Omega$ and $\varepsilon\in\{-,0,+\}$, we define real Hilbert spaces as follows:

$$\mathcal{H}_{\omega,\varepsilon}=\{h:\omega\to\mathbb{R}^d:|h|_{\omega,\varepsilon}<\infty\}. \tag{2.21}$$

Here, the norms are induced from the following inner products: for $\omega\in\Omega$, $\varepsilon\in\{-,0,+\}$ and $h_1, h_2:\omega\to\mathbb{R}^d$:

$$\langle h_1,h_2\rangle_{\omega,\varepsilon}=\sum_{x\in\omega}(1+|x|)^{\varepsilon\nu}\langle h_1(x),h_2(x)\rangle_{\mathbb{R}^d}. \tag{2.22}$$

Notice that for each $\omega\in\Omega$, the inclusions,

$$\mathcal{H}_{\omega,+}\subset\mathcal{H}_{\omega,0}\subset\mathcal{H}_{\omega,-}, \tag{2.23}$$

hold. The embeddings are everywhere dense and $\mathcal{H}_{\omega,0}$ becomes a rigged Hilbert space by $\mathcal{H}_{\omega,+}$ and $\mathcal{H}_{\omega,-}$. For $\varepsilon=+,0,-$, denote $T_\varepsilon(\Omega)=\cup_{\omega\in\Omega}\mathcal{H}_{\omega,\varepsilon}$ and let $\Gamma(T_\varepsilon(\Omega))$ be the space of functions (sections) $f:\Omega\to T_\varepsilon(\Omega)$ such that $f(\omega)\in\mathcal{H}_{\omega,\varepsilon}$ for each $\omega\in\Omega$ and the mapping $\omega\mapsto|f(\omega)|_{\omega,\varepsilon}$ is measurable. We define the gradient operator ∇ as follows:

$$\begin{gathered} D(\nabla)=C^1_{b,loc}(\Omega),\\ \nabla:D(\nabla)\to\Gamma(T_+(\Omega)),\\ u\mapsto\nabla u,\\ \nabla u(\omega)=(D_x u(\omega))_{x\in\omega}, \quad \text{for } \omega\in\Omega. \end{gathered} \tag{2.24}$$

Since u is $\mathcal{F}_\Lambda$ -measurable for some $\Lambda\in\mathcal{C}$, $\nabla u(\omega)$ has at most finitely many nonzero components for each $\omega\in\Omega$ and so $\nabla u(\omega)$ is well-defined. It may be worthy noting that the gradient operator introduced above is essentially the same as that introduced by Albeverio, Kondratiev, and Röckner.[12]

The Laplace operator Δ is defined as follows:

$$\begin{gathered} D(\Delta)=C^2_{b,loc}(\Omega),\\ \Delta:D(\Delta)\to L^2(\Omega,\mu),\\ u\mapsto\Delta u,\\ (\Delta u)(\omega)=\sum_{x\in\omega}\sum_{k=1}^{d}\frac{\partial^2 u_{\omega\setminus x}}{\partial p^k\partial p^k}(x)\\ \equiv\sum_{x\in\omega}\Delta_x u(\omega). \end{gathered} \tag{2.25}$$

In Sec. III, we will show that for any regular Gibbs measure μ and $u\in C^1_{b,loc}(\Omega)$ [resp., $u\in C^2_{b,loc}(\Omega)$], the function $\omega\mapsto|\nabla u(\omega)|_{\omega,+}$ [resp., $\omega\mapsto\Delta u(\omega)$] is an element of $L^2(\Omega,\mu)$.

C. Main results

We begin with a definition of a pre-Dirichlet form. In the sequel, we assume that the hypotheses of Proposition II.7 are satisfied and fix a Gibbs measure μ. We note that μ is regular in the sence of Definition II.1 and the corresponding system of density functions satisfies the boundedness given in the statement of Proposition II.7. Combining these facts we see that the condition (A.2) of Ref. 8 is satisfied and by the same method given in Lemma 2.4 of Ref. 8 we see that $\mathcal{F}C_b^\infty(\Omega)$ and $C_{b,loc}^2(\Omega)$ are dense in $L^2(\Omega,\mu)$. We define a pre-Dirichlet form as follows:

$$D(\mathcal{E}) := C_{b,loc}^2(\Omega),$$

$$\mathcal{E}(u,v) := \frac{1}{2}\int_\Omega \langle \nabla u(\omega), \quad \nabla v(\omega)\rangle_{\omega,0}\mu(d\omega) \tag{2.26}$$

$$= \frac{1}{2}\int_\Omega \sum_{x\in\omega} \langle D_x u(\omega), \quad D_x v(\omega)\rangle_{\mathbb{R}^d}\mu(d\omega).$$

From the regularity of μ (Definition II.1), it is not hard to see that the form is well-defined. In order to show that the pre-Dirichlet form defined in (2.26) is closable and its closure is a Dirichlet form, we will impose further conditions to the interaction function $\Phi(x)$.

Assumption II.10: The pair potential $\Phi(x)$ satisfies the following conditions:

(a) Φ is superstable and lower regular;

(b) $\int_{\mathbb{R}^d}|1-e^{-\beta\Phi(x)}|dx<\infty$;

(c) $\int_{\mathbb{R}^d}|\text{grad }\Phi(x)|^4 e^{-\beta\Phi(x)}\,dx<\infty$;

(d) there exists $d_1>2, c>0$ such that $|\text{grad }\Phi(x)|\leqslant c(1+|x|)^{-\nu}$ for $|x|>d_1$, where $\nu>d$ is the constant given in the definition of Hilbert spaces $\mathcal{H}_{\omega,\varepsilon}$ in (2.21)–(2.22).

Let us define the pre-Dirichlet operator as follows:

$$D(H_\mu) := C_{b,loc}^2(\Omega),$$

$$(H_\mu v)(\omega) := -\tfrac{1}{2}\Delta v(\omega) - \tfrac{1}{2}\langle b(\omega), \nabla v(\omega)\rangle_{\omega,0}, \quad v\in C_{b,loc}^2(\Omega), \tag{2.27}$$

where

$$b(\omega) = \left(-\beta \sum_{y\in\omega\setminus x} (\text{grad}\,\Phi)(x-y)\right)_{x\in\omega}.$$

The following is one of the main results of this paper.

Theorem II.11: *Suppose that the hypotheses of Assumption II.10 are satisfied. Then the pre-Dirichlet operator H_μ in (2.27) is well defined, symmetric, and the following relation:*

$$\mathcal{E}(u,v) = (u, H_\mu v)_{L^2(\Omega,\mu)}, \qquad u,v\in C_{b,loc}^2(\Omega),$$

holds. Furthermore, the pre-Dirichlet form $(\mathcal{E}, C_{b,loc}^2(\Omega))$ is closable and the closure, which we write as $(\mathcal{E}, D(\mathcal{E}))$ again, is a Dirichlet form.

Remark II.12: Since $\mathcal{F}C_b^\infty(\Omega)\subset C_{b,loc}^2(\Omega)$, the results in Theorem II.11 hold for $\mathcal{F}C_b^\infty(\Omega)$ instead of $C_{b,loc}^2(\Omega)$.

The proof of the above theorem will be given in the next section.

Having established a Dirichlet form one is attempted to study whether there exists a diffusion process which is associated with the Dirichlet form $(\mathcal{E}, D(\mathcal{E}))$. In Ref. 4, it was proved that if a Dirichlet form is quasi-regular, there exists a special standard process which is associated with the given Dirichlet form. See Ref. 4 for details. We do not want to go deep into this direction. Instead, we mention that the Dirichlet forms constructed in this paper and in Refs. 8,9 and also in Ref. 13

are all the same. The quasi-regularity of the Dirichlet form has been proved in Refs. 8,9 and Ref. 13. Here, we just state the result. For a technical reason we will regard the form $(\mathcal{E},D(\mathcal{E}))$ as a form on $L^2(\tilde{\Omega},\mu)$, where $\tilde{\Omega}$ is the closure of Ω. We adjoint an extra point $\square$ (the cemetry) to $\tilde{\Omega}$ and write $\tilde{\Omega}_\square := \tilde{\Omega}\cup\{\square\}$. $\tilde{\Omega}_\square$ has a Borel σ-algebra $\mathcal{F}_\square : \mathcal{F}\cup\{F\cup\{\square\}:F\in\mathcal{F}\}$ and any function $u:\tilde{\Omega}\to\mathbb{R}$ is considered as a function on $\tilde{\Omega}_\square$, putting $u(\square)=0$.

Theorem II.13: *(Ref. 8, Theorem 1, Ref. 9, Theorem 3, Ref. 13, Theorem 5.2) Suppose that the hypotheses in Assumption II.10 are satisfied. Then, the Dirichlet form $(\mathcal{E}, D(\mathcal{E}))$ on $L^2(\tilde{\Omega},\mu)$ constructed through Theorem II.11 is quasi-regular, and hence there exists a Markov process $\mathbb{M}:=(X,\mathcal{A},(X_t)_{t\geqslant 0},(P_z)_{z\in\tilde{\Omega}_\square})$ such that $\mathbb{M}$ is associated with $(\mathcal{E}, D(\mathcal{E}))$, i.e.,*

$$(T^t u)(z)=\int u(X_t)dP_z, \qquad \mu-a.a., \qquad z\in\tilde{\Omega}_\square,$$

where $\{T^t\}_{t\geqslant 0}$ is the strongly continuous semigroup associated with $(\mathcal{E},D(\mathcal{E}))$.

Remark II.14: It is obvious that $(\mathcal{E},D(\mathcal{E}))$ has a local property, i.e., $\mathcal{E}(u,v)=0$ for all $u,v\in D(\mathcal{E})$ with $supp[u]\cap supp[v]=0$. Therefore the Markov process in Theorem II.13 is a diffusion process (Refs. 3–4).

From now on we consider the essential self-adjointness of the Dirichlet operator. We will impose smoothness to the interaction function Φ. We begin with introducing an allowed configuration space.[7]

For $\omega=\{x_i\}\in\Omega, m\in\mathbb{R}^d$, and $l>0$, define

$$H(\omega,m,l):=\sum_{k:|x_k-m|\leqslant l}\left\{1+2B+\sum_{\substack{j\neq k\\ j:|x_j-m|\leqslant l}}\Phi(x_k-x_j)\right\}, \tag{2.28}$$

where $B\geqslant 0$ is the constant given in the superstability assumption (2.8) of Φ. This is a weighted sum of potential energy and particle number in the ball $B_l(m)$ with center m and radius l. We note that it is non-negative.

For $t\in\mathbb{R}$, let

$$g(t)=[1+\log(1+t)]^{1/d} \tag{2.29}$$

and

$$\overline{H}(\omega)=\sup_{m\in\mathbb{Z}^d}\sup_{r\in\mathbb{Z}}\{[rg(|m|)]^{-d}H(\omega,m,rg(|m|))+1\}, \tag{2.30}$$

where $\mathbb{N}$ is the set of positive integers.

The set of allowed configurations is defined to be

$$\overline{\Omega}=\{\omega\in\Omega:\overline{H}(\omega)<\infty\}. \tag{2.31}$$

By a superstable estimate (regularity of Gibbs measures in Definition II.1), it is not hard to show that any Gibbs measure is supported on $\overline{\Omega}$.[7] We now introduce the space of functions defined on $\overline{\Omega}$. For $h>0$, let

$$\overline{\Omega}_h=\{\omega\in\overline{\Omega}:\overline{H}(\omega)\leqslant h\},$$

and for a measurable function $u:\overline{\Omega}\to\mathbb{R}$, let

$$\|u\|_h=\sup\{|u(\omega)|:\omega\in\Omega_h\}.$$

We introduce some useful function spaces.[7]

Definition II.15:

$$C(\overline{\Omega})=\{u:\overline{\Omega}\to\mathbb{R}:\quad \text{the restriction of } u \text{ to each nonempty } \overline{\Omega}_h \text{ is uniformly continuous and bounded}\},$$

$$C_b(\overline{\Omega})=\{u\in C(\overline{\Omega}):\quad u \text{ is bounded }\},$$

$$C_p(\overline{\Omega})=\{u\in C(\overline{\Omega}):\quad \|u\|_h \text{ is bounded by a polynomial of } h\},$$

$$C_1(\overline{\Omega})=\{u\in C(\overline{\Omega}):\quad \|u\|_h\leqslant\exp(c_u h^p) \text{ with } p<1\}.$$

Recall that for $\omega=\{x_i\}_{i\geqslant 1}\in\overline{\Omega}$, $D_{x_i}u$ and $D^2_{x_ix_j}u$ denote the vector in $\mathbb{R}^d$ and $d\times d$ matrix of the first and second partial derivatives of u with respect to the coordinates of x_i and x_j, respectively. For the notational convenience, we write

$$D_i\equiv D_{x_i},$$

$$D_iD_j\equiv D^2_{x_ix_j}, \text{ etc.}$$

Definition II;16: Let $D^q_e(\overline{\Omega})$, $q=1,2,3$, *denote the space of functions* $u\in C_1(\overline{\Omega})$ *possessing derivatives of order less than or equal to* q; *each of these derivatives belongs to* $C_1(\overline{\Omega})$. *Moreover, there exists an* $\varepsilon\equiv\varepsilon_u>0$ *such that for any* $h>0$, *we have*

$$\begin{aligned}
&\||D_ku(\omega)|\exp(\varepsilon|x_k|)\|_h\leqslant c_u(\varepsilon,h), \quad \text{for } q=1,2,3,\\
&\||D_jD_ku(\omega)|\exp(\varepsilon|x_k|+\varepsilon|x_j|)\|_h\leqslant c_u(\varepsilon,h), \quad \text{for } q=2,3,\\
&\||D_iD_jD_ku(\omega)|\exp(\varepsilon|x_k|+\varepsilon|x_j|+\varepsilon|x_i|)\|_h\leqslant c_u(\varepsilon,h), \quad \text{for } q=3.
\end{aligned}\tag{2.32}$$

Also, for $q=1,2,3$, *we define the spaces*

$$D^q_{e1}(\overline{\Omega})=\{u\in D^q_e(\overline{\Omega}):\quad \exists p<1 \text{ such that the first } q \text{ inequalities from (2.32) hold with } c_u(\varepsilon,h)=\exp[c_u(\varepsilon)(1+h)^p]\},$$

$$D^q_0(\overline{\Omega})=\{u\in D^q_{e1}(\overline{\Omega}):\quad u \text{ is } \mathcal{F}_\Lambda\text{-measurable for some } \Lambda\in\mathcal{C}\}.$$

We notice that for $q=1,2,3, C^q_{b,loc}(\overline{\Omega})\subset D^q_0(\overline{\Omega})$.

One of the main purposes of this paper is to show the essential self-adjointness of the Dirichlet operator on a proper domain. For the purpose we need to impose a decreasing rate of the interaction according to the interaction distance. Let $\alpha:\mathbb{R}_+\to\mathbb{R}$ be any monotonic increasing and concave function such that

(i) $\alpha(0)\geqslant 1$ and $\alpha(\lambda)\to\infty$ as $\lambda\to\infty$.

(ii) $\alpha'(\lambda)\leqslant[1/(1+\lambda)]\,\alpha(\lambda)$ for $\lambda\geqslant 0$, and there exists a constant $c>0$ such that $\alpha''(\lambda)\geqslant -c[1/(1+\lambda)]$.

We notice that $\alpha(\lambda)$ might be a very slowly increasing function and there are so many such functions. For example, let $l(\lambda):=\log(1+\lambda)$, $\lambda\geqslant 0$. Then, for any $n\geqslant 1$, the function $\alpha(\lambda):=1+\overbrace{l\circ\cdots\circ l}^{n-\text{times}}(\lambda)$ satisfies the above conditions.

Theorem II.17: *Suppose that a potential* Φ *is superstable and lower regular. Furthermore, we assume that* $\Phi\in C^3_b(\mathbb{R}^d)$ *and there exist a constant* $c_0>0$ *and a function* α *that satisfies the conditions* (i) *and* (ii) *above and for all* $x\in\mathbb{R}^d, i,j,k=1,\ldots,d$,

$$\left|\frac{\partial\Phi}{\partial x^i}(x)\right|+\left|\frac{\partial^2\Phi}{\partial x^j\partial x^i}(x)\right|+\left|\frac{\partial^3\Phi}{\partial x^k\partial x^j\partial x^i}(x)\right|\leqslant\exp[-c_0\log(1+|x|^2)\alpha(1+|x|^2)].$$

Then the pre-Dirichlet operator H_μ defined in (2.27) *is essentially self-adjoint on the domain* $D_0^2(\overline{\Omega})$.

The proof of the above Theorem will be given in Sec. IV. The main idea for the proof is to use a general parabolic criterion of essential self-adjointness[21] and a uniform estimates on partial dynamics.[7]

Before closing this subsection, it may worth giving some comments on Theorem II.17.

Remark II.18: (a) We believe that the result in Theorem II.17 holds under the condition that the derivatives of Φ up to third order are bounded by $(1+|x|)^{-2\nu}$ for $\nu>d$. But the method we used in the proof of Theorem II.17 in this paper may not cover the above case.

(b) Since in the proof of the theorem we have used the method of stochastic differential equations,[7] we were not able to handle singular interactions.

(c) We conjecture that $\mathcal{FC}_b^\infty(\Omega)$ is a core for H_μ. Without the proof, Fritz claimed that for $\Phi\in C_0^3(\mathbb{R}^3)$, H_μ is essentially self-adjoint on $\mathcal{FC}_b^\infty(\Omega)$. See Remark 10 of Ref. 7.

III. DIRICHLET FORMS, DIRICHLET OPERATORS, AND THE ASSOCIATED PROCESSES

In this section, we will give the proof of Theorem II.11. We first collect some estimates, which will be used in the proof. Recall that for any $\omega\in\Omega$ and $r\in\mathbb{Z}^d$, $n(\omega:r)=|\omega\cap Q(r)|$.

Lemma III.1: Let μ be a regular Gibbs measure. Then, for any $p\in\mathbb{N}$ and $r\in\mathbb{Z}^d$,

$$\int_\Omega n(\omega:r)^p\mu(d\omega)\leqslant c(p)<\infty.$$

Proof: Note that $n(\omega:r)$ is $\mathcal{F}_{Q(r)}$-measurable. Hence for $Q(r)\subset\Lambda$,

$$\int_\Omega n(\omega:r)^p\mu(d\omega)=\int_{\Omega_\Lambda} n(\omega_\Lambda:r)^p\mu_\Lambda(d\omega_\Lambda),$$

and so the result follows from the regularity of μ (Definition II.1). ■

Lemma III.2: Let ρ be the correlation function defined in Definition II.5. Then, there exists a constant $b\geqslant 0$ such that for any $\{x_1,\ldots,x_m\}\subset\Delta\in\mathcal{C}$, the bound

$$\rho(x_1,\cdots,x_m)\leqslant z\xi^{m-1}e^{b|\Delta|}\exp\left\{-\beta\sum_{k=2}^m\Phi(x_1-x_k)\right\}$$

holds.

Proof: We prove only for $m=2$. The other cases can be done similarly. By (2.12) of Proposition II.7, we have

$$\begin{aligned}\rho(x_1,x_2)&\equiv\rho((x_1),(x_2))\\&=z\exp\{-\beta\Phi(x_1-x_2)\}\sum_{p=0}^\infty\frac{1}{p!}\int_{\Delta^p}K((x_1),(v_1,\ldots,v_p))\\&\quad\times\rho((x_2)(v_1,\ldots,v_p))\,dv_1\cdots dv_p.\end{aligned}$$

By the lower regularity of Φ, we may assume that $\Phi\geqslant -b_1$ for some $b_1\geqslant 0$. Thus we have

$$|K((x_1),(v_1,\ldots,v_p))|=\left|\prod_{j=1}^p[\exp\{-\beta\Phi(v_j-x_1)\}-1]\right|\leqslant(e^{\beta b_1}+1)^p,\tag{3.1}$$

and by (2.13),

$$\rho((x_2),(v_1,\ldots,v_p))\leqslant \xi^{p+1}. \tag{3.2}$$

Combining (3.1) and (3.2), we obtain the result. ■

Proposition III.3: For any $v\in C^2_{b,loc}(\Omega)$, *there exist constants* K_1 *and* K_2 *such that the bounds*

$$\|\Delta v\|_{L^2(\mu)}\leqslant K_1,$$

$$\int_\Omega |\nabla v(\omega)|^4_{\omega,+}\mu(d\omega)\leqslant K_2,$$

hold.

Proof: For a given $v\in C^2_{b,loc}$, let v be $\mathcal{F}_\Lambda$-measurable for some $\Lambda\in\mathcal{C}$. Then

$$\begin{aligned}\|\Delta v\|^2_{L^2(\mu)}&=\int |\Delta v(\omega)|^2\mu(d\omega)\\ &\leqslant\int\left(\sum_{x\in\omega_\Lambda}\left|\Delta_x v(\omega)\right|\right)^2\mu(d\omega)\\ &\leqslant c(v)\int\left(\sum_{i\in\mathbb{Z}^d\cap\Lambda} n(\omega{:}i)\right)^2\mu(d\omega).\end{aligned}$$

By Lemma III.1, it follows that $\|\Delta v\|_{L^2(\mu)}\leqslant K_1$ for some constant K_1. Since

$$|\nabla v(\omega)|^4_{\omega,+}=\left(\sum_{x\in\omega_\Lambda}(1+|x|)^\nu|D_x v(\omega)|^2\right)^2\leqslant c(\Lambda,v)\left(\sum_{i\in\mathbb{Z}^d\cap\Lambda} n(\omega{:}i)\right)^2,$$

the second bound also follows from Lemma III.1. ■

Now we are in a position to prove Theorem II.11.

Proof of Theorem II.11: First, we will show that the pre-Dirichlet operator H_μ is well-defined as an operator on a dense domain $C^2_{b,loc}(\Omega)$ of $L^2(\Omega,\mu)\equiv L^2(\mu)$. For $v\in C^2_{b,loc}(\Omega)$, by the definition (2.27) of H_μ and Schwarz inequality,

$$\|H_\mu v\|_{L^2(\mu)}\leqslant\frac{1}{2}\|\Delta v\|_{L^2(\mu)}+\frac{1}{2}\left(\int_\Omega|b(\omega)|^4_{\omega,-}\,\mu(d\omega)\right)^{1/4}\left(\int_\Omega|\nabla v(\omega)|^4_{\omega,+}\mu(d\omega)\right)^{1/4}.$$

By Proposition III.3, it is enough to show that

$$\int |b(\omega)|^4_{\omega,-}\mu(d\omega)<\infty.$$

We may assume that $v\in C^2_{b,loc}(\Omega)$ is $\mathcal{F}_\Lambda$-measurable for some $\Lambda\in\mathcal{C}$. A direct computation yields

$$\begin{aligned}\int |b(\omega)|^4_{\omega,-}\mu(d\omega)&\leqslant 8\beta^4\Bigg[\int_\Omega\left\{\sum_{x\in\omega}(1+|x|)^{-\nu}\left(\sum_{\substack{y\in\omega\setminus x\\ |x-y|\geqslant d_1}}|\operatorname{grad}\Phi(x-y)|\right)^2\right\}^2\mu(d\omega)\\ &\quad+\int_\Omega\left\{\sum_{x\in\omega}(1+|x|)^{-\nu}\left(\sum_{\substack{y\in\omega/x\\ |x-y|<d_1}}|\operatorname{grad}\Phi(x-y)|\right)^2\right\}^2\mu(d\omega)\Bigg]\\ &\equiv 8\beta^4[I_1+I_2].\end{aligned}$$

Here, $d_1>0$ is the constant given in Assumption II.10(d). First, we consider the term I_1. By Assumption II.10(d), we have

$$I_1 \leqslant c^4 \int_\Omega \left\{ \sum_{x \in \omega} (1+|x|)^{-\nu} \left(\sum_{\substack{y \in \omega \setminus x \\ |x-y| \geqslant d_1}} (1+|x-y|)^{-\nu} \right)^2 \right\}^2 \mu(d\omega)$$

$$\leqslant c_1 \int_\Omega \left\{ \sum_{i \in \mathbb{Z}^d} (1+|i|)^{-\nu} n(\omega:i) \left(\sum_{\substack{j \in \mathbb{Z}^d \\ |i-j| \geqslant 1}} (1+|i-j|)^{-\nu} n(\omega:j) \right)^2 \right\}^2 \mu(d\omega).$$

Using the Schwarz inequality, the fact $\nu > d$, and Lemma III.1, we obtain $I_1 < \infty$.

Next, let us consider the term I_2,

$$I_2 \leqslant c_2 \int_\Omega \left\{ \sum_{i \in \mathbb{Z}^d} (1+|i|)^{-\nu} \sum_{x \in \omega \cap Q(i)} \left(\sum_{\substack{y \in \omega \setminus x \\ |x-y| < d_1}} |\operatorname{grad} \Phi(x-y)| \right)^2 \right\}^2 \mu(d\omega)$$

$$\leqslant c_3 \int_\Omega \left\{ \sum_{i \in \mathbb{Z}^d} (1+|i|)^{-\nu} \sum_{x \in \omega_{\Delta(i)}} \left(\sum_{\substack{y \in \omega_{\Delta(i)} \\ y \neq x}} |\operatorname{grad} \Phi(x-y)| \right)^2 \right\}^2 \mu(d\omega),$$

where, for each $i \in \mathbb{Z}^d$, $\Delta(i)$ is the finite union of unit cubes such that $\Delta(i) \supset B_{d_1+1}(i)$. We use Schwarz inequality and the translation invariance of interaction and Gibbs measures to see that

$$I_2 \leqslant c_4 \int_\Omega \left\{ \sum_{x \in \omega_\Delta} \left(\sum_{\substack{y \neq \epsilon x_\Delta \\ by \in \omega_\Delta}} |\operatorname{grad} \Phi(x-y)| \right)^2 \right\}^2 \mu(d\omega).$$

Here, Δ is a finite union of unit cubes containing $B_{d_1+1}(0)$. Now, we note that the integrand in the above inequality is an $\mathcal{F}_\Delta$-measurable local function, so we can apply the equality in Remark II.6. Hence,

$$I_2 \leqslant c_4 \sum_{m=2}^{\infty} \frac{1}{m!} \int_{\Delta^m} \left\{ m \left(\sum_{k=2}^{m} |\operatorname{grad} \Phi(x_1 - x_k)| \right)^2 \right\}^2 \sigma_\Delta^m(x_1,\ldots,x_m) dx_1 \cdots dx_m$$

$$\leqslant c_4 \sum_{m=2}^{\infty} \frac{m^2}{m!} (m-1)^3 \int_{\Delta^m} \sum_{k=2}^{m} |\operatorname{grad} \Phi(x_1 - x_k)|^4 \sigma_\Delta^m(x_1,\ldots,x_m) dx_1 \cdots dx_m$$

$$= c_4 \sum_{m=2}^{\infty} \frac{m^2}{m!} (m-1)^4 \int_{\Delta^m} |\operatorname{grad} \Phi(x_1 - x_2)|^4 \sigma_\Delta^m(x_1,\ldots,x_m) dx_1 \cdots dx_m$$

$$= c_4 \sum_{m=2}^{5} \frac{m(m-1)^3}{(m-2)!} \int_{\Delta^m} |\operatorname{grad} \Phi(x_1 - x_2)|^4 \sigma_\Delta^m(x_1,\ldots,x_m)\, dx_1 \cdots dx_m$$

$$+ c_4 \sum_{m=6}^{\infty} \frac{m(m-1)^3}{(m-2)!} \int_{\Delta^m} |\operatorname{grad} \Phi(x_1 - x_2)|^4 \sigma_\Delta^m(x_1,\ldots,x_m) dx_1 \cdots dx_m$$

$$\equiv c_4 (I_{2,1} + I_{2,2}).$$

Consider the first term $I_{2,1}$:

$$I_{2,1}\leqslant c_5\sum_{m=2}^{5}\frac{1}{(m-2)!}\int_{\Delta^m}|\mathrm{grad}\,\Phi(x_1-x_2)|^4 s_\Delta^m(x_1,\ldots,x_m)\,dx_1\cdots dx_m$$

$$\leqslant c_5\int_{\Delta^2}|\mathrm{grad}\,\Phi(x_1-x_2)|^4\left\{\sum_{m=2}^{\infty}\frac{1}{(m-2)!}\int_{\Delta^{m-2}}\sigma_\Delta^m(x_1,\ldots,x_m)\,dx_3\cdots dx_m\right\}dx_1\,dx_2$$

$$= c_5\int_{\Delta^2}|\mathrm{grad}\,\Phi(x_1-x_2)|^4\rho(x_1,x_2)dx_1\,dx_2$$

$$\leqslant c_6\int_{\Delta^2}|\mathrm{grad}\,\Phi(x_1-x_2)|^4 e^{-\beta\Phi(x_1-x_2)}dx_1\,dx_2\leqslant c_6|\Delta|\int_{\mathbb{R}^d}|\mathrm{grad}\,\Phi(x)|^4 e^{-\beta\Phi(x)}\,dx.$$

We have used Lemma III.2 in the third inequality. By Assumption II.10(c), $I_{2,1}$ is finite. To prove the finiteness of $I_{2,2}$, note that $m(m-1)^3/(m-2)!\leqslant c_7[1/(m-6)!]$ for some constant $c_7>0$. So, we have

$$I_{2,2}\leqslant c_7\int_{\Delta^6}|\mathrm{grad}\,\Phi(x_1-x_2)|^4$$
$$\times\left\{\sum_{m=6}^{\infty}\frac{1}{(m-6)!}\int_{\Delta^{m-6}}\sigma_\Delta^m(x_1,\ldots,x_6,x_7,\ldots,x_m)\,dx_7\cdots dx_m\right\}dx_1\cdots dx_6.$$

The finiteness of $I_{2,2}$ comes from Lemma III.2 and Assumption II.10(c). Thus, the proof of the fact that $H_\mu v\in L^2(\mu)$ for $v\in C_{b,loc}^2(\Omega)$ is complete.

Now we prove the relation $\mathcal{E}(u,v)=(u,H_\mu v)_{L^2(\mu)}$ for $u,v\in C_{b,loc}^2(\Omega)$. We may assume that both u and v are $\mathcal{F}_\Lambda$-measurable for some $\Lambda\in\mathcal{C}$. By the definiton of $\mathcal{E}$, the Gibbs condition of μ, and the definition (2.10) of the Poisson measure, we see that

$$\mathcal{E}(u,v)=\frac{1}{2}\int\langle\nabla u(\omega),\nabla v(\omega)\rangle_{\omega,0}\mu(d\omega)$$

$$=\frac{1}{2}\int\mu(d\eta)\frac{1}{Z_\Lambda(\eta)}\int_{\Omega_\Lambda}\sum_{x\in\omega_\Lambda}\langle D_x u(\omega_\Lambda),D_x v(\omega_\Lambda)\rangle_{\mathbb{R}^d}$$
$$\times\exp[-\beta(U(\omega_\Lambda)+W(\omega_\Lambda,\eta_{\Lambda^c}))]\pi_\Lambda(d\omega_\Lambda)$$

$$=\frac{1}{2}\int\mu(d\eta)\frac{1}{Z_\Lambda(\eta)}\sum_{n=0}^{\infty}e^{-z|\Lambda|}\frac{z^n}{n!}$$
$$\times\int_{\Lambda^n}\sum_{i=1}^{n}\langle D_{x_i}u(\{x_1,\ldots,x_n\}),D_{x_i}v(\{x_1,\ldots,x_n\})\rangle_{\mathbb{R}^d}$$
$$\times\exp\{-\beta[U(x_1,\ldots,x_n)+W(\{x_1,\ldots,x_n\},\eta_{\Lambda^c})]\}\,dx_1\cdots dx_n.$$

Applying an integration by parts formula and repeating the above procedure conversely, we obtain the desired equality. By this relation, it follows immediately that H_μ is a positive-definite symmetric operator and so it is closable.

To prove the Markovian property of $\mathcal{E}$, it suffices[4] to consider functions $u\in C_{b,loc}^2(\Omega)$. For each $\varepsilon>0$, choose $\phi_\varepsilon\in C^\infty(\mathbb{R})$ such that $\phi_\varepsilon(t)=t$ for $0\leqslant t\leqslant 1$, $-\varepsilon\leqslant\phi_\varepsilon(t)\leqslant 1+\varepsilon$ for $t\in\mathbb{R}$ and $0\leqslant\phi_\varepsilon(t)-\phi_\varepsilon(s)\leqslant t-s$ for $s<t$. Then for $u\in C_{b,loc}^2(\Omega)$, $\phi_\varepsilon\circ u\in C_{b,loc}^2(\Omega)$ and by a chain rule,

$$\langle\nabla(\phi_\varepsilon\circ u)(\omega),\nabla(\phi_\varepsilon\circ u)(\omega)\rangle_{\omega,0}=(\phi_\varepsilon'(u(\omega)))^2\langle\nabla u(\omega),\nabla u(\omega)\rangle_{\omega,0}\leqslant\langle\nabla u(\omega),\nabla u(\omega)\rangle_{\omega,0}.$$

So, we obtain $\mathcal{E}(\phi_\varepsilon\circ u,\phi_\varepsilon\circ u)\leqslant\mathcal{E}(u,u)$ for $u\in C_{b,loc}^2(\Omega)$. Thus the proof of Theorem II.11 is complete. ■

IV. ESSENTIAL SELF-ADJOINTNESS OF THE DIRICHLET OPERATOR

In this section we show the essential self-adjointness of the Dirichlet operator on a suitable space of local functions, i.e., we prove Theorem II.17. The main ingredient of the proof is the general parabolic criterion developed in Ref. 21. This is an approximate argument. The dynamics of partial systems shall play the role of an approximation.[7] Thus uniform estimates for partial systems are needed. It was extensively investigated by Dobrushin and Fritz.[7,24,25] We will modify it in order to include the case of infinite range interactions. Throughout this section we assume that the interaction Φ satisfies the hypotheses of Theorem II.17. We fix a corresponding Gibbs measure μ, which is a probability measure on unlabeled particle configurations. In order to discuss the dynamics of a given set of particles, it is convenient to label each particle by a given index set. We begin by introducing a partial dynamics.

Let $C(\mathbb{R}_+,\mathbb{R}^d)$ denote the space of continuous functions of $[0,\infty)$ into $\mathbb{R}^d$ with the usual topology corresponding to uniform convergence on compact sets. For a countable index set S, let $\mathcal{W}=[C(\mathbb{R}_+,\mathbb{R}^d)]^S$ with the product topology, $\mathcal{A}$ the associated Borel σ-algebra, and $\mathcal{A}_t$ the smallest σ-algebra for which the projections $w_k(s), k\in S, s\leqslant t$, of $w\in\mathcal{W}$ are measurable. Let $\{W_k\}_{k\in S}$ be a family of independent standard Wiener processes having values in $\mathbb{R}^d$. We assume that we are given a probability measure P on $\mathcal{A}$ such that the Wiener processes $\{W_k\}_{k\in S}$ are realized as the random element $w=\{W_k\}_{k\in S}$ of $\mathcal{W}$. Henceforth, we denote by E^W the expectation with respect to the measure P.

Let us consider the following system of stochastic differential equations: For $\omega=\{x_i\}_{i\geqslant 1}$,

$$\begin{aligned} dx_k(t)&=\tfrac{1}{2}b_k(\omega)\,dt+dW_k(t),\\ \omega(0)&=z=\{z_k\}_{k\in S}\in\overline{\Omega}, \end{aligned} \tag{4.1}$$

where

$$b_k(\omega)=-\beta\sum_{j\neq k}(\operatorname{grad}\Phi)(x_k-x_j).$$

In the case that Φ is compact supported and nonsingular and $d\leqslant 4$, Fritz proved[7] the existence of a unique tempered solution in the sense that the solution $\omega(t,z,W)\equiv\omega(t)$ satisfies $\overline{H}(\omega(t))<\infty$ a.s. for any finite time $t>0$ whenever $\overline{H}(z)<\infty$. Regarding to the essential self-adjointness of the Dirichlet operator H_μ on a dense subset of $L^2(\mu)$, Fritz gave an approximation criterion and claimed that $\mathcal{F}C_b^\infty(\Omega)$ would be a core for H_μ.[7] This approximation uses a uniform *a priori* bound for the partial dynamics crucially. (See also an argument by Spohn.[15]) We will use also an approximation argument (a general parabolic criterion for essential self-adjointness) developed in Ref. 21. We will use the Fritz' method, but to accommodate for infinite range interactions, we need a proper modification. A partial dynamics is defined as follows: For each $\rho\geqslant 1$, define a cut-off function by

$$f_\rho(x)=f_0\left(\frac{|x|}{\rho}\right),\quad \text{for } x\in\mathbb{R}^d, \tag{4.2}$$

where $f_0:\mathbb{R}\to[0,1]$ is a function such that $f_0\in C^3(\mathbb{R})$ and

$$f_0(x)=\begin{cases}1, & \text{for } |x|\leqslant 1,\\ 0, & \text{for } |x|\geqslant 2.\end{cases} \tag{4.3}$$

For $\omega=\{x_i\}_{i\in S}\in\overline{\Omega}$, we define

$$H_k(\omega):=\sum_{j\neq k}\Phi(x_k-x_j), \tag{4.4}$$

$$b_{k,\rho}(\omega):=e^{\beta H_k(\omega)}D_k[f_\rho^2(x_k)e^{-\beta H_k(\omega)}]=f_\rho^2(x_k)b_k(\omega)+2f_\rho(x_k)(\operatorname{grad}f_\rho)(x_k), \tag{4.5}$$

$$\sigma_{k,\rho}(\omega) := f_\rho(x_k). \tag{4.6}$$

Note that $b_{k,\rho}(\omega)=b_k(\omega)$, $\sigma_{k,\rho}(\omega)=1$ for $|x_k|\leqslant\rho$ and $b_{k,\rho}=\sigma_{k,\rho}=0$ for $|x_k|\geqslant 2\rho$. Comparing with the system of (4.1) the partial dynamics is governed by the following stochastic differential equations: Let $\omega=\{x_k\}_{k\in S}$,

$$\begin{gathered} dx_k(t,\rho)=\tfrac{1}{2}b_{k,\rho}(\omega)dt+\sigma_{k,\rho}(\omega)dW_k(t), \qquad k\in S, \\ \omega(0)=z=\{z_k\}_{k\in S}\in\overline{\Omega}. \end{gathered} \tag{4.7}$$

We notice that by the above system (4.7) of stochastic differential equations the particles outside the ball of radius 2ρ centered at 0 are frozen. Note that for each $\omega\in\overline{\Omega}\subset\mathcal{S}$, $b_{k,\rho}(\omega)$ is finite.[2] So, (4.7) is a finite system. Since $\Phi\in C_b^3(\mathbb{R}^d)$, a unique strong solution $\omega=\omega(t,z,\rho)=(x_k(t,z,\rho))_{k\in S}$ of (4.7) exists[5,6,26,27] and $\omega\in\overline{\Omega}_h$ for some $h>0$.[7] If we put $P_\rho^t\phi(z)=E^W[\phi(\omega(t,z,\rho))]$ for a function $\phi\in L^2(\overline{\Omega},\mu)$, then for each $\rho>1$, $\{P_\rho^t\}_{t\geqslant 0}$ is a strongly continuous semigroup of self-adjoint contractions in $L^2(\overline{\Omega},\mu)$. Denote by $H_{\mu,\rho}$ its infinitesimal generator.

For $u\in D_0^2(\overline{\Omega})$, $H_{\mu,\rho}$ has the following explicit form:

$$(H_{\mu,\rho}u)(\omega)=-\tfrac{1}{2}\Delta_\rho u(\omega)-\tfrac{1}{2}\langle b_\rho(\omega), \quad \nabla u(\omega)\rangle_{\omega,0}, \tag{4.8}$$

where

$$\begin{gathered} \Delta_\rho u(\omega)=\sum_{k\in S} f_\rho^2(x_k)\Delta_{x_k}u(\omega), \\ b_\rho(\omega)=(b_{k,\rho}(\omega))_{k\in S}. \end{gathered} \tag{4.9}$$

It is not hard to see that (the closure of) $H_{\mu,\rho}$ is the infinitesimal generator of the following (pre-)Dirichlet form: For each $\rho>1$,

$$\begin{gathered} D(\mathcal{E}_\rho)=D_0^2(\overline{\Omega}), \\ \mathcal{E}_\rho(u,v)=\frac{1}{2}\int_{\overline{\Omega}}\sum_{x\in\omega}\langle D_x u(\omega), \quad D_x v(\omega)\rangle_{\mathbb{R}^d} f_\rho^2(x)\mu(d\omega), \qquad u,v\in D(\mathcal{E}_\rho). \end{gathered} \tag{4.10}$$

We have also the relation

$$\mathcal{E}_\rho(u,v)=(u,H_{\mu,\rho}v)_{L^2(\overline{\Omega},\mu)}, \qquad u,v\in D_0^2(\overline{\Omega}). \tag{4.11}$$

The following is a general parabolic criterion for essential self-adjointness properly expressed for our use (see Ref. 21, Chapter 5, Theorem 1.10).

Proposition IV.1: For $\rho\geqslant 1$, consider the Cauchy problem:

$$\frac{d}{dt}u_\rho(t)+H_{\mu,\rho}u_\rho(t)=0, \qquad t\in[0,1],$$

$$u_\rho(0)=\phi\in D_0^2(\overline{\Omega}),$$

where $H_{\mu,\rho}$ is an infinitesimal generator of the semigroup P_ρ^t induced from the solution of the stochastic differential equation (4.7) and $\phi\in D_0^2(\overline{\Omega})$. Suppose that there exist strong solutions,

$$u_\rho:[0,1]\to L^2(\overline{\Omega},\mu),$$

such that

(a) $t \to u_\rho(t)$ *is differentiable in* $L^2(\bar{\Omega}, \mu)$,

(b) $\forall \rho > 1$ *and* $\forall t \in [0,1]$, $u_\rho(t) \in D_0^2(\bar{\Omega})$,

(c) $\int_0^1 \| (H_\mu - H_{\mu,\rho}) u_\rho(t) \|_{L^2(\bar{\Omega},\mu)} dt \to 0$ *as* $\rho \to \infty$.

Then, H_μ *is essentially self-adjoint on* $D_0^2(\bar{\Omega})$.

In order to apply the above result, we need a uniform bound estimation for finite systems. For this, we use the method developed in Ref. 7. For $\rho \geqslant 1$, let $\omega(t,z,\rho) = (x_k(t,z,\rho))_{k \in S}$ be the strong solution of the stochastic differential equation (4.7). Let $\bar{D}_n^{(r)}$, $n \in S$, $r = 1,2,\ldots,d$, denote the differential operator with respect to $z_n^{(r)}$ ($\equiv r^{\text{th}}$ component of $z_n = (z_n^{(1)}, \ldots, z_n^{(d)})$) and $\bar{D}_n = (\bar{D}_n^{(1)}, \ldots, \bar{D}_n^{(d)})$. Since the system of stochastic differential equations (4.7) is a finite system with smooth coefficients, the following processes:

$$u_k := \bar{D}_n^{(r)} x_k(t,z,\rho), \qquad v_k := \bar{D}_m^{(s)} u_k = \bar{D}_m^{(s)} \bar{D}_n^{(r)} x_k(t,z,\rho), \text{etc.},$$

are well-defined.[28] Therefore for any $\phi \in D_{e1}^1(\bar{\Omega})$ we may have $\bar{D}_n P_\rho^t \phi(z)$, etc., where $P_\rho^t \phi(z) = E^W[\phi(\omega(t,z,\rho))]$. We need a uniform bound on the estimation $\bar{D}_n P_\rho^t \phi(z)$. It will be bounded by an estimation of the following quantities that have been defined in Ref. 7. For $\rho > 1$, define

$$\begin{aligned} Z_p(t,z) &:= t + \int_0^t \bar{H}(\omega(s,z,\rho))^{p/2} ds, \\ V_p(t,z) &:= 1 + Z_p(t,z) + \bar{H}(\omega(t,z,\rho))^{p/2}. \end{aligned} \tag{4.12}$$

For $\omega = (x_i)_{i \geqslant 1}$, we let

$$\begin{aligned} q_k(\omega) &= \bar{H}(\omega)^{1/2} (1 + \log(1 + |x_k|^2))^{1/2}, \\ \dot{Z}_p &= \frac{\partial Z_p}{\partial t}. \end{aligned} \tag{4.13}$$

For the notational brevity, let us write

$$F(t,z;p) := V_p(t,z) + \frac{Z_1(t,z)^2}{h(Z_1(t,z))^{1/2}}, \tag{4.14}$$

where $h(\lambda) := \log(e + \alpha(\lambda))$ and $\alpha(\lambda)$ is the function introduced in Theorem II.17. The bounds in the following proposition corresponds to those in Proposition 4 and Proposition 6 of Ref. 7.

Proposition IV.2: Suppose that the hypotheses of Theorem II.17 are satisfied. Then, we can find a $p \in (1,2)$, $K > 0$, *such that the bounds,*

$$|\bar{D}_n P_\rho^t \phi(z)| \leqslant (1 + |z_n|^2)^{-\nu} \{E^W[\exp[KF(t,z;p)]]\}^{1/2}$$

$$|\bar{D}_m \bar{D}_n P_\rho^t \phi(z)| \leqslant (1 + |z_m|^2)^{-\nu} (1 + |z_n|^2)^{-\nu} \{E^W[\exp[KF(t,z;p)]]\}^{1/2},$$

hold uniformly in $\rho \geqslant 1$.

The proof of the above proposition will be given in the Appendix.

Lemma IV.3: For any $p \in (1,2)$, $K > 0$, *and* $0 \leqslant t \leqslant T$,

$$\int_{\bar{\Omega}} E^W[\exp[KF(t,z;p)]] \mu(dz) \leqslant C_p(T,K) < \infty,$$

where C_p *does not depend on* ρ *and it is a nondecreasing function with respect to its variables* T *and* K.

The proof of this lemma will be given in the Appendix.

We are now ready to give the proof of Theorem II.17.

Proof of Theorem II.17: It is enough to show that all the conditions of Proposition IV.1 are satisfied. So, let $\phi \in D_0^2(\overline{\Omega})$ and $z=\{z_k\}_{k\in S}\in \overline{\Omega}$ be given. Let $\omega(t,z,\rho)=(x_k(t,z,\rho))_{k\in S}$ be the strong solution of the system of stochastic differential equations (4.7). Define $u_\rho(t):=P_\rho^t\phi(z)$ $=E^W[\phi(\omega(t,z,\rho))]$, $t\geqslant 0$. Since the system of stochastic equations (4.7) is a finite system with smooth coefficients, $u_\rho(t)$ solves the Cauchy problem stated in Proposition IV.1. Furthermore, it can be checked that the function $t\mapsto u_\rho(t)$ is differentiable in $L^2(\overline{\Omega},\mu)$.[28] (See also an argument used in Ref. 18, Lemma 5.) In the Appendix, we will show the invariance of $D_0^2(\overline{\Omega})$ under P_ρ^t, i.e., $P_\rho^t D_0^2(\overline{\Omega})\subset D_0^2(\overline{\Omega})$ (Lemma A.4). So, it remains to prove the condition (c) in Proposition IV.1. A direct computation yields

$$\begin{aligned}
&\int_0^1 \|(H_\mu - H_{\mu,\rho})u_\rho(t)\|_{L^2(\overline{\Omega},\mu)}dt \\
&\quad\leqslant \frac{1}{2}\Bigg[\int_0^1 \|\Delta u_\rho(t)-\Delta_\rho u_\rho(t)\|_{L^2(\overline{\Omega},\mu)}dt + \int_0^1\Bigg(\int_{\overline{\Omega}} |b(z)-b_\rho(z)|_{z,-}^4\mu(dz)\Bigg)^{1/4} \\
&\qquad\times\Bigg(\int_{\overline{\Omega}} |\nabla u_\rho(t)(z)|_{z,+}^4\mu(dz)\Bigg)^{1/4}dt\Bigg] \\
&\quad\equiv \frac{1}{2}\Bigg[\int_0^1 I_1(t)dt + \int_0^1 I_{2,1}(t)^{1/4}I_{2,2}(t)^{1/4}dt\Bigg],
\end{aligned} \tag{4.15}$$

where

$$\begin{aligned}
I_1(t)&=\|\Delta u_\rho(t)-\Delta_\rho u_\rho(t)\|_{L^2(\overline{\Omega},\mu)}, \\
I_{2,1}(t)&=\int_{\overline{\Omega}} |b(z)-b_\rho(z)|_{z,-}^4\mu(dz), \\
I_{2,2}(t)&=\int_{\overline{\Omega}} |\nabla u_\rho(t)(z)|_{z,+}^4\mu(dz).
\end{aligned} \tag{4.16}$$

Let us consider the first term $I_1(t)$. Note that $0\leqslant f_\rho\leqslant 1$ and $|\Delta_{z_k}u(z)|\leqslant c|\overline{D}_k\overline{D}_k u(z)|$ for some constant $c>0$. Since $P_\rho^t\phi\in D_0^2(\overline{\Omega})$ and $D_0^2(\overline{\Omega})\subset D_{e1}^2(\overline{\Omega})$, by the second inequality of Proposition IV.2 and Hölder's inequality, we obtain from (4.16) that

$$\begin{aligned}
I_1(t)^2&=\int_{\overline{\Omega}}\Bigg\{\sum_{|z_k|>\rho}|1-f_\rho^2(z_k)||\Delta_{z_k}P_\rho^t\phi(z)|\Bigg\}^2\mu(dz) \\
&\leqslant \int_{\overline{\Omega}}\Bigg\{\sum_{|z_k|>\rho}|\Delta_{z_k}P_\rho^t\phi(z)|\Bigg\}^2\mu(dz) \\
&\leqslant c^2\int_{\overline{\Omega}}\Bigg\{\sum_{|z_k|>\rho}(1+|z_k|^2)^{-2\nu}(E^W[\exp[KF(t,z;p)]])^{1/2}\Bigg\}^2\mu(dz) \\
&\leqslant c^2\Bigg(\int_{\overline{\Omega}}E^W[\exp[2KF(t,z;p)]]\,\mu(dz)\Bigg)^{1/2}\Bigg(\int_{\overline{\Omega}}\Bigg\{\sum_{|z_k|>\rho}(1+|z_k|^2)^{-2\nu}\Bigg\}^4\mu(dz)\Bigg)^{1/2}.
\end{aligned}$$

By Lemma IV.3, the first integration of the last expression is not greater than $C_p(1,2K)<\infty$ for $0\leqslant t\leqslant 1$. We use the regularity of Gibbs measures (Definition II.1) to show the finiteness of the second integral as follows:

$$\int_{\bar{\Omega}}\left\{\sum_{|z_k|>\rho}(1+|z_k|^2)^{-2\nu}\right\}^4\mu(dz)$$

$$\leqslant c_1\int_{\bar{\Omega}}\left\{\sum_{\substack{|i|\geqslant\rho-1\\ i\in\mathbb{Z}^d}}(1+|i|^2)^{-2\nu}n(z{:}i)\right\}^4\mu(dz)$$

$$\leqslant c_1\int_{\bar{\Omega}}\left(\sum_{\substack{|i|\geqslant\rho-1\\ i\in\mathbb{Z}^d}}(1+|i|^2)^{-\frac{4}{3}\nu}\right)^3\left(\sum_{\substack{|i|\geqslant\rho-1\\ ie\mathbb{Z}^d}}(1+|i|^2)^{-4\nu}n(z{:}i)^4\right)\mu(dz)$$

$$\leqslant c_2\sum_{\substack{|i|\geqslant\rho-1\\ i\in\mathbb{Z}^d}}(1+|i|^2)^{-4},$$

where c_1 and c_2 are appropriate constants. Therefore,

$$\int_0^1 I_1(t)dt\leqslant c_3\left(\sum_{\substack{|i|\geqslant\rho-1\\ i\in\mathbb{Z}^d}}(1+|i|^2)^{-4\nu}\right)^{1/4}\to 0,\quad \text{as } \rho\to\infty. \tag{4.17}$$

We next consider $I_{2,1}(t)$. Recall the definitions of $b(z)$ and $b_\rho(z)$ in (2.27) and (4.9), respectively. It follows from (4.16) that

$$I_{2,1}(t)=\int_{\bar{\Omega}}\left\{\sum_{\substack{z_k\in z\\ |z_k|>\rho}}(1+|z_k|)^{-\nu}|b_k(z)-b_{k,\rho}(z)|^2\right\}^2\mu(dz).$$

By the hypotheses of Theorem II.17, we see that

$$I_{2,1}(t)\leqslant c_4\int_{\bar{\Omega}}\left\{\sum_{\substack{z_k\in z\\ |z_k|>\rho}}(1+|z_k|)^{-\nu}|b_k(z)|^2\right\}^2\mu(dz)$$

$$\leqslant c_5\int_{\bar{\Omega}}\left\{\sum_{\substack{z_k\in z\\ |z_k|>\rho}}(1+|z_k|)^{-\nu}\times\left(\sum_{z_j\neq z_k}\exp[-c_0\log(1+|z_k-z_j|^2)\alpha(1+|z_k-z_j|^2)]\right)^2\right\}^2\mu(dz).$$

As in the case of $I_1(t)$, we replace the summations w.r.t. z_k and z_j by summations w.r.t. $k,j\in\mathbb{Z}^d$. Then

$$I_{2,1}(t)\leqslant c_6\int_{\bar{\Omega}}\sum_{\substack{k\in\mathbb{Z}^d\\|k|\geqslant\rho-1}}(1+|k|)^{-\nu}n(z{:}k)^2\mu(dz)$$
$$\times\int_{\bar{\Omega}}\left[\sum_{\substack{k\in\mathbb{Z}^d\\|k|\geqslant\rho-1}}(1+|k|)^{-\nu}\left\{\sum_{j\in\mathbb{Z}^d}\exp\left[-\frac{2}{3}c_0\log(1+|k-j|^2)\mathring{a}(1+|k-j|^2)\right]\right\}\right]^3$$
$$\times\left\{\sum_{j\in\mathbb{Z}^d}n(z{:}j)^4\exp[-2c_0\log(1+|k-j|^2)\alpha(1+|k-j|^2)]\right\}\Bigg]\mu(dz)$$
$$\leqslant c_7\sum_{\substack{k\in\mathbb{Z}^d\\|k|>\rho-1}}(1+|k|)^{-\nu}. \tag{4.18}$$

For $I_{2,2}(t)$, applying the first inequality of Proposition IV.2 and using the Schwarz inequality, we see that

$$I_{2,2}(t)=\int_{\bar{\Omega}}\left\{\sum_{z_k\in z}(1+|z_k|)^{\nu}\left|\overline{D}_kP_\rho^t\phi(z)\right|_{\mathbb{R}^d}^2\right\}^2\mu(dz)$$
$$\leqslant c_8\int_{\bar{\Omega}}\left\{\sum_{z_k\in z}(1+|z_k|)^{\nu}(1+|z_k|^2)^{-2\nu}E^W[\exp[KF(t,z;p)]]\right\}^2\mu(dz)$$
$$\leqslant c_8\left(\int_{\bar{\Omega}}E^W[\exp[4KF(t,z;p)]]\mu(dz)\right)^{1/2}\left(\int_{\bar{\Omega}}\left(\sum_{k\in\mathbb{Z}^d}(1+|k|^2)^{-2\nu+\nu/2}\right)\right.$$
$$\left.\times\left(\sum_{k\in\mathbb{Z}^d}(1+|k|^2)^{-2\nu+\nu/2}n(z{:}k)^4\right)\mu(dz)\right)^{1/2}<\infty. \tag{4.19}$$

By (4.18) and (4.19),

$$\int_0^1 I_{2,1}(t)^{1/4}I_{2,2}(t)^{1/4}\,dt\leqslant c_{10}\left(\sum_{\substack{k\in\mathbb{Z}^d\\|k|>\rho-1}}(1+|k|)^{-\nu}\right)^{1/4}\to 0,\qquad \text{as } \rho\to\infty. \tag{4.20}$$

By (4.15), (4.17), and (4.20) we obtain

$$\int_0^1\|(H_\mu-H_{\mu,\rho})u_\rho(t)\|_{L^2(\bar{\Omega},\mu)}dt\to 0,\qquad \text{as } \rho\to\infty.$$

The proof of Theorem II.17 is complete. ■

APPENDIX: PROOFS OF PROPOSITION IV.2 AND LEMMA IV.3

In this appendix, we provide with the proofs of Proposition IV.2 and Lemma IV.3. The main ideas for the proof of Proposition IV.2 were given in the proof of Proposition 4 and Proposition 6 of Ref. 7. In order to include also the infinite range (sub-exponentially decreasing) interactions, we need proper modifications.

Let $\alpha:\mathbb{R}^+\to\mathbb{R}$ be the function given in Theorem II.17. Define

$$h(\lambda):=\log(e+\alpha(\lambda)),\qquad \lambda\geqslant 0. \tag{A1}$$

Then, h is monotonic increasing and concave. Moreover,

(i) $h(0)\geqslant 1$ and $h(\lambda)\to\infty$ as $\lambda\to\infty$.

(ii) $h'(\lambda)\leqslant 1/(1+\lambda)\leqslant[1/(1+\lambda)]\,h(\lambda),\lambda\geqslant 0$, and there exists a constant $c>0$ such that $h''(\lambda)\geqslant -c[1/(1+\lambda)]$. (A2)

For $x\in\mathbb{R}^d$ and $\lambda\geqslant 0$, define

$$\theta(x,\lambda) := \exp\left[-\frac{\lambda}{h(\lambda)^{1/2}}[1+\lambda^2+\log(1+|x|^2)h(\sqrt{1+|x|^2})]^{1/2}\right](1+|x|^2)^{-\nu}. \tag{A3}$$

The above is a proper modification of the corresponding θ-function in (5.1) of Ref. 7. The followings are crucial lemmas for the estimate of uniform bounds for partial dynamics. Let us denote by $\theta'(x,\lambda)$ the derivative w.r.t. a λ-variable and grad $\theta(x,\lambda), \Delta\theta(x,\lambda)$, the gradient and Laplacian w.r.t. the x-variable, respectively.

Lemma A.1: There exists positive constants c_1, c_2, c_3, and c_4 such that the following holds:

(a) $-\theta'(x,\lambda) \geqslant c_1(1+\log(1+|x|^2))^{1/2}\theta(x,\lambda)$;

(b) $|\text{grad}\,\theta(x,\lambda)| + |\Delta\theta(x,\lambda)| \leqslant c_2\theta(x,\lambda)$;

(c) $\theta(x,\lambda) \leqslant c_3\,\theta(y,\lambda)\exp[c_4\log(1+|x-y|^2)h(1+|x-y|^2)]$.

Proof: (a) Let $G(x,\lambda) := 1+\lambda^2+\log(1+|x|^2)h(\sqrt{1+|x|^2})$. Since $G'(x,\lambda) \geqslant 0$ by (A2) (ii),

$$\begin{aligned} -\theta'(x,\lambda) &\geqslant \left(h(\lambda)^{-1/2} - \tfrac{1}{2}\lambda h(\lambda)^{-3/2}h'(\lambda)\right) G(x,\lambda)^{1/2}\theta(x,\lambda) \\ &\geqslant \tfrac{1}{2}h(\lambda)^{-1/2}G(x,\lambda)^{1/2}\theta(x,\lambda) \\ &\geqslant \tfrac{1}{2}h(G(x,\lambda))^{-1/2}G(x,\lambda)^{1/2}\theta(x,\lambda). \end{aligned}$$

Note that by (A2) (ii), $h(y)^{-1}y$ is nondecreasing and $h(y) \leqslant c(1+\log(1+y))$ for $y \geqslant 0$ and some constant $c>0$. Thus, it is easy to check that

$$h(G(x,\lambda))^{-1}G(x,\lambda) \geqslant h(G(x,0))^{-1}G(x,0) \geqslant c'(1+\log(1+|x|^2)),$$

for some constant $c'>0$. Thus there exists a $c_1>0$ such that

$$-\theta'(x,\lambda) \geqslant c_1(1+\log(1+|x|^2))^{1/2}\theta(x,\lambda).$$

(b) By a direct calculation and the fact that $h(\sqrt{1+|x|^2}) \leqslant c''\log(e+|x|^2)$ for some constant $c''>0$, we obtain the desired result.

(c) Without loss of generality we may assume $|y| \geqslant |x|$. By a fundamental theorem of calculus,

$$\begin{aligned} &\left| \frac{\lambda}{h(\lambda)^{1/2}}G(y,\lambda)^{1/2} - \frac{\lambda}{h(\lambda)^{1/2}}G(x,\lambda)^{1/2}\right| \\ &\quad = \frac{\lambda}{h(\lambda)^{1/2}}\int_{|x|}^{|y|}\frac{d}{du}(1+\lambda^2+\log(1+u^2)h(\sqrt{1+u^2}))^{1/2}du \\ &\quad \leqslant \int_{|x|}^{|y|}\frac{d}{du}(\log(1+u^2)h(\sqrt{1+u^2}))du \\ &\quad = \log(1+|y|^2)h(\sqrt{1+|y|^2}) - \log(1+|x|^2)h(\sqrt{1+|x|^2}). \end{aligned} \tag{A4}$$

Notice that the function $0 \leqslant u \mapsto \log(1+u^2)h(\sqrt{1+u^2})$ is increasing and concave in the region $u \geqslant u_0$ for some constant $u_0>0$. Thus, the last term of (A4) is bounded by

$$\log(1+(u_0+|y|-|x|)^2)h(\sqrt{1+(u_0+|y|-|x|)^2}).$$

Since h and the logarithmic function are concave, we obtain the desired bound. The remaining polynomial part is trivially bounded by the desired term. ■

Lemma A.2: For any $\varepsilon>0$, there exist positive constants c_5 and $c_6(\varepsilon)$ such that the bound

$$e^{-\varepsilon|x|} \leqslant \theta(x,\lambda)\exp\left[c_5\frac{\lambda}{h(\lambda)^{1/2}}(1+\lambda) + c_6(\varepsilon)\right]$$

holds.

Proof: We see that

$$\theta(x,\lambda)^{-1}e^{-\varepsilon|x|}=\exp\left[\frac{\lambda}{h(\lambda)^{1/2}}[1+\lambda^2+\log(1+|x|^2)h(\sqrt{1+|x|^2})]^{1/2}-\varepsilon|x|\right](1+|x|^2)^{\nu}.$$

We devide the x-λ region into two subregions: $\lambda\leqslant|x|^{1/4}$ and $\lambda\geqslant|x|^{1/4}$.

Consider the case $\lambda\leqslant|x|^{1/4}$. Since the function $\lambda\mapsto\lambda/h(\lambda)^{1/2}$ is increasing and $h(\lambda)\geqslant 1$,

$$\begin{aligned}\theta(x,\lambda)^{-1}e^{-\varepsilon|x|}&\leqslant\exp[|x|^{1/4}[1+|x|^{1/2}+\log(1+|x|^2)h(\sqrt{1+|x|^2})]^{1/2}-\varepsilon|x|](1+|x|^2)^{\nu}\\&\leqslant c_6(\varepsilon),\qquad\text{for some } c_6(\varepsilon)>0,\qquad\text{for all } x\in\mathbb{R}^d.\end{aligned}$$

On the other hand, for $\lambda\geqslant|x|^{1/4}$, since $|x|\mapsto\log(1+|x|^2)h(\sqrt{1+|x|^2})$ is increasing,

$$\begin{aligned}\theta(x,\lambda)^{-1}e^{-\varepsilon|x|}&\leqslant\exp\left[\frac{\lambda}{h(\lambda)^{1/2}}[1+\lambda^2+\log(1+\lambda^8)h(\sqrt{1+\lambda^8})]^{1/2}\right](1+\lambda^8)^{\nu}\\&\leqslant\exp\left[c_5\frac{\lambda}{h(\lambda)^{1/2}}(1+\lambda)\right],\end{aligned}$$

for some constant $c_5>0$. ■

Recall the definitions of $b_{k,\rho}(\omega)$ and $\sigma_{k,\rho}(\omega)$ in (4.5) and (4.6). Let $b_{kj}(\omega,\rho)=D_jb_{k,\rho}(\omega)$, $\sigma_{kj}(\omega,\rho)=D_j\sigma_{k,\rho}(\omega)$, $b_{kji}(\omega,\rho)=D_iD_jb_{k,\rho}(\omega)$, and $\sigma_{kji}(\omega,\rho)=D_iD_j\sigma_{k,\rho}(\omega)$. σ_{kji} is a matrix, while b_{kji} is a vector of $d\times d$ matrices, namely $b_{kji}^{(r)}=D_iD_j\langle b_{k,\rho},e_r\rangle$ for $r=1,2,\ldots,d$. Recall the definition of $q_k(\omega)$ in (4.13). We need some estimates.

Lemma A.3: Suppose that the hypotheses of Theorem II.17 are satisfied. Then for any $\gamma>0$ and $i,j,k\in S$, we have a uniform constant $K_1>0$ such that the following bounds hold:

(a) $\Sigma_{j\in S}|b_{kj}(\omega,\rho)|\exp[\gamma\log(1+|x_k-x_j|^2)h(1+|x_k-x_j|^2)]\leqslant K_1q_k(\omega)$;

(b) $\Sigma_{k\in S}|b_{kj}(\omega,\rho)|\exp[\gamma\log(1+|x_k-x_j|^2)h(1+|x_k-x_j|^2)]\leqslant K_1q_j(\omega)$;

(c) $\Sigma_{j,i}|b_{kji}(\omega,\rho)|\exp[\gamma\log(1+|x_k-x_j|^2)h(1+|x_k-x_j|^2)+\gamma\log(1+|x_k-x_i|^2)h(1+|x_k-x_i|^2)]\leqslant K_1q_k(\omega)$;

(d) $\Sigma_k|b_{kji}(\omega,\rho)|\exp[\gamma\log(1+|x_k-x_j|^2)h(1+|x_k-x_j|^2)+\gamma\log(1+|x_k-x_i|^2)\,h(1+|x_k-x_i|^2)]\leqslant K_1q_i(\omega)^{1/2}q_j(\omega)^{1/2}$;

(e) $\Sigma_{j\in S}|\sigma_{kj}(\omega,\rho)|\leqslant K_1$;

(f) $\Sigma_{k\in S}|\sigma_{kj}(\omega,\rho)|\leqslant K_1$;

(g) $\Sigma_{j,i}|\sigma_{kji}(\omega,\rho)|\leqslant K_1$;

(h) $\Sigma_k|\sigma_{kji}(\omega,\rho)|\leqslant K_1$.

Proof: We prove only (a). The bounds (e)–(h) are direct consequences of the definition of $\sigma_k(\omega,\rho)$ in (4.6). The bounds (b)–(d) can be proved by the method used for (a). Recall the definition of $n(\omega:j)$. We have for any $j,k\in\mathbb{Z}^d$,

$$\begin{aligned}n(\omega:j)&=g(|j|)^{-d/2}n(\omega:j)g(|j|)^{d/2}\\&\leqslant[g(|j|)^{-d}n(\omega:j)^2+1]^{1/2}(1+\log(1+|j|))^{1/2}\\&\leqslant c_7\overline{H}(\omega)^{1/2}(1+\log(1+|x_k|))^{1/2}(1+\log(1+|x_k-j|))^{1/2}\\&=c_7q_k(\omega)(1+\log(1+|x_k-j|))^{1/2}.\end{aligned}\tag{A5}$$

From the definition of $b_{k,\rho}(\omega)$, the assumption for Φ in Theorem II.17, and the inequality in (A5), we get

$$\sum_{j\in S}|b_{kj}(\omega,\rho)|\exp[\gamma\log(1+|x_k-x_j|^2)h(1+|x_k-x_j|^2)]$$

$$\leqslant c_8\sum_{j\in S}\exp[\log(1+|x_k-x_j|^2)(-c_0\alpha(1+|x_k-x_j|^2)+\gamma h(1+|x_k-x_j|^2))]$$

$$\leqslant c_9\sum_{j\in\mathbb{Z}^d}n(\omega:j)\exp[\log(1+|x_k-j|^2)(-c_0\alpha(1+|x_k-j|^2)+\gamma h(1+|x_k-j|^2))]$$

$$\leqslant c_{10}q_k(\omega)\sum_{j\in\mathbb{Z}^d}(1+\log(1+|x_k-j|^2))^{1/2}\exp[\log(1+|x_k-j|^2)$$
$$\times(-c_0\alpha(1+|x_k-j|^2)+\gamma h(1+|x_k-j|^2))]\leqslant c_{11}q_k(\omega).$$

The last inequality was obtained by noting $h(\lambda)=\log(e+\alpha(\lambda))$. ■

We are now prepared to prove Proposition IV.2.

Proof of Proposition IV.2: First, let us prove the first bound in the proposition by using the method similar to that employed in the proof of Proposition 4 of Ref. 7. By a chain rule, we have

$$\bar{D}_n^{(r)}\phi(\omega)=\sum_{k\in S}\langle D_k\phi(\omega),u_k\rangle_{\mathbb{R}^d},$$

where $\omega=\omega(t,z,\rho)\equiv(x_k(t,z,\rho))_{k\in S}$ is the solution of (4.7) and $u_k\equiv\bar{D}_n^{(r)}x_k(t,z,\rho)$. Since $D_{e1}^2(\bar{\Omega})\subset D_{e1}^1(\bar{\Omega})$, there exists an $\varepsilon>0$ and $p_0\in(0,1)$ such that

$$|D_k\phi(\omega)|\leqslant e^{-\varepsilon|x_k|}\exp[c_{\phi,\varepsilon}(1+\bar{H}(\omega))^{p_0}].$$

Since $1+\bar{H}(\omega)^{p/2}=\dot{Z}_p$, $p>0$, we thus have a $p_1\in(1,2)$ such that

$$|\bar{D}_n^{(r)}\phi(\omega)|\leqslant\exp[c_{\phi,\varepsilon}\dot{Z}_{p_1}]\sum_{k\in S}e^{-\varepsilon|x_k|}|u_k|\leqslant\exp[c_{\phi,\varepsilon}\dot{Z}_{p_1}]\left(\sum_{k\in S}e^{-\varepsilon|x_k|}\right)^{1/2}\left(\sum_{k\in S}e^{-\varepsilon|x_k|}|u_k|^2\right)^{1/2}. \tag{A6}$$

On the other hand,

$$\sum_{k\in S}e^{-\varepsilon|x_k|}\leqslant\sum_{k\in\mathbb{Z}^d}n(\omega:k)e^{-\varepsilon|k|}\leqslant c_{12}\sum_{k\in\mathbb{Z}^d}\bar{H}(\omega)^{1/2}e^{-\varepsilon|k|}(1+\log(1+|k|))^{1/2}\leqslant c_{13}\dot{Z}_1. \tag{A7}$$

From (A6), (A7), and Lemma A.2, we obtain

$$|\bar{D}_n^{(r)}\phi(\omega)|\leqslant\exp\left[K_2\dot{Z}_{p_1}+K_2\frac{Z_1}{h(KZ_1)^{1/2}}(1+Z_1)+K_2\right]R_1(t,KZ_1)^{1/2}, \tag{A8}$$

where

$$R_1(t,\lambda)=\sum_{k\in S}\theta(x_k(t,z,\rho),\lambda)|u_k(t,z,\rho)|^2. \tag{A9}$$

The constant K_2 depends on ϕ and ε and K is arbitrary. We want to show that

$$E^W[R_1(t,KZ_1(t,z))]\leqslant(1+|z_n|^2)^{-\nu} \tag{A10}$$

with a large $K>0$. Then, (A8), (A10), and the definition of $F(t,z;p)$ in (4.14) imply the first bound in the proposition. We have to calculate the stochastic differential of R_1 when dx_k is given by (4.7) while,

$$du_k=\sum_{j\in S} b_{kj}u_j dt+\sum_{j\in S}\langle\sigma_{kj},u_j\rangle dW_k(t). \tag{A11}$$

As in Ref. 7, if an $\mathcal{A}_t$-adapted process has a stochastic differential $dI=a\,dt+\Sigma b_k\,dW_k$, then $d_dI:=a\,dt$ denotes the deterministic part of dI. For R_1, by Itô's formula, we have

$$d_dR_1(t,KZ_1)=-\dot{Z}_1I_0dt+(I_1+I_2+I_3+I_4)dt, \tag{A12}$$

where

$$I_n=\sum_{k\in S} I_{nk}, \qquad \text{for } n=0,1,2,3,4,$$

$$I_{0k}=-K\theta_k'|u_k|^2,$$

$$I_{1k}=\left(\langle \text{grad}\,\theta_k,b_{k,\rho}\rangle+\tfrac{1}{2}\Delta\theta_k\sigma_{k,\rho}^2\right)|u_k|^2,$$

$$I_{2k}=2\theta_k\sum_{j\in S}\langle u_k,b_{kj}u_j\rangle,$$

$$I_{3k}=d\,\theta_k\left(\sum_{j\in S}\langle\sigma_{kj},u_j\rangle\right)^2,$$

$$I_{4k}=\langle\text{grad}\,\theta_k,u_k\rangle\sigma_{k,\rho}\sum_{j\in S}\langle\sigma_{kj},u_j\rangle.$$

Note that $I_0=-K(\partial R_1/\partial\lambda)$, thus $I_n\leqslant\frac{1}{4}\dot{Z}_1I_0$, $n=1,2,3,4$, implies (A10) as $R_1(0,0)=(1+|z_n|^2)^{-\nu}$. First, by using Lemma A.1 (b) and the assumption in Theorem II.17, we see that

$$|I_1|\leqslant c_{14}\left(\sum_{k\in S}\sum_{j\in S}\exp[-c_0\log(1+|x_k-x_j|^2)\alpha(1+|x_k-x_j|^2)]\theta_k|u_k|^2+\sum_{k\in S}\theta_k|u_k|^2\right).$$

By a similar method as in the proof of Lemma A.3 (a), we have the bound

$$|I_1|\leqslant c_{15}\sum_{k\in S} q_k(\omega)\theta_k|u_k|^2.$$

Consider the term I_2. By Lemma A.1 (c),

$$\begin{aligned}|I_2|&\leqslant\sum_{k\in S}2\theta_k\sum_{j\in S}|u_k||b_{kj}||u_j|\\&\leqslant\sum_{k\in S}\sum_{j\in S}\theta_k|b_{kj}||u_k|^2+\sum_{k\in S}\sum_{j\in S}\theta_k|b_{kj}||u_j|^2\\&\leqslant\sum_{k\in S}\sum_{j\in S}\theta_k|b_{kj}||u_k|^2+c_3\sum_{k\in S}\sum_{j\in S}\theta_j|b_{kj}||u_j|^2\exp[c_4\log(1+|x_k-x_j|^2)h(1+|x_k-x_j|^2)].\end{aligned}$$

By Lemma A.3 (b) and the same technique used for I_1, we have also

$$|I_2|\leqslant c_{16}\sum_{k\in S} q_k(\omega)\theta_k|u_k|^2.$$

Similarly, we obtain the same inequalities for I_3 and I_4. Thus, there exists a constant $K_0>0$ such that

$$|I_1|+|I_2|+|I_3|+|I_4|\leqslant K_0\sum_{k\in S} q_k(\omega)\theta_k|u_k|^2.$$

On the other hand, by Lemma $A.1$ (a),

$$\begin{aligned}\dot{Z}_1 I_0 &= \dot{Z}_1\left(-K\frac{\partial R_1}{\partial\lambda}\right)\\ &= (1+\overline{H}(\omega)^{1/2})(-K)\sum_{k\in S}\theta_k'|u_k|^2\\ &\geqslant Kc_1\overline{H}(\omega)^{1/2}\sum_{k\in S}(1+\log(1+|x_k|^2))^{1/2}\theta_k|u_k|^2 = Kc_1\sum_{k\in S} q_k(\omega)\theta_k|u_k|^2.\end{aligned}$$

So, in order to have the inequality (A10), it suffices to take $Kc_1\geqslant K_0$. This proves the first inequality.

In order to prove the second inequality, one may use the method employed in the proof of Proposition 6 of Ref. 7 together with necessary bounds in Lemma A.6 and the method used in the above. Since the proof is not so hard to carry out, we leave the details to the reader. ■

We now prove Lemma IV.3.

Proof of Lemma IV.3: We have to prove

$$\int_{\Omega} E^W\left[\exp\left[K\left(V_p(t,z)+\frac{Z_1(t,z)^2}{h(Z_1(t,z))^{1/2}}\right)\right]\right]\mu(dz)<\infty,\qquad \forall K>0,\qquad 1<p<2. \tag{A13}$$

By using Schwarz inequality, it suffices to show that

$$\int_{\Omega} E^W[\exp[K'V_p(t,z)]]\mu(dz)<\infty,\qquad \forall K'>0,\qquad p<1 \tag{A14a}$$

and

$$\int_{\Omega} E^W\left[\exp\left[K'\frac{Z_1(t,z)^2}{h(Z_1(t,z))^{1/2}}\right]\right]\mu(dz)<\infty,\qquad \forall K'>0. \tag{A14b}$$

We will prove only the second bound [(A14b)]. The first one can be proved in a similar manner. We notice that the function $0\leqslant\lambda\mapsto\lambda^2/h(\lambda)^{1/2}$ is convex, so by Jensen's inequality and the invariance of μ w.r.t. P_ρ^t, it reduces to show that for any $K'>0$,

$$\int_{\Omega}\exp\left[K'\frac{(1+\overline{H}(z)^{1/2})^2}{h(1+\overline{H}(z)^{1/2})^{1/2}}\right]\mu(dz)<\infty. \tag{A15}$$

Since $h(u)\to\infty$ as $u\to\infty$, it is sufficient to show that

$$\int_{\Omega}\exp(\lambda\overline{H}(\omega))\mu(d\omega)<\infty, \tag{A16}$$

for sufficiently small $\lambda>0$. A direct computation shows that for any $m\in\mathbb{Z}^d$ and $l>0$,

$$H(\omega,m,l)\leqslant c\sum_{i\in B_l(m)\cap\mathbb{Z}^d}(n(\omega{:}i)^2+1),$$

for some constant $c>0$ independent of m and l. Thus, regularity of μ implies that there exists λ_0 such that for $\lambda\leqslant\lambda_0$ the bounds

$$\int_{\bar{\Omega}} \exp(\lambda H(\omega,m,l))\mu(d\omega) \leqslant \exp(Kl^d) \tag{A17}$$

hold for some constant $K>0$ independent of m and l. The bound (A16) follows from the bounds in (A17) and the argument similar to that used in the proof of Lemma 2.1 of Ref. 16. See also the proof of Proposition 1 in Ref. 24. For the detailed derivation of (A16) from (A17), we refer to Ref. 16. ■

Finally, we provide with the proof of condition (b) in Proposition IV.1, that is, we show the invariance of $D_0^2(\bar{\Omega})$ under P_ρ^t.

Lemma A.4: For any $\rho \geqslant 1$, $t \geqslant 0$, $P_\rho^t(D_0^2(\bar{\Omega})) \subset D_0^2(\bar{\Omega})$.

Proof: Recall $u_\rho(t) := P_\rho^t \phi(z) = E^W[\phi(\omega(t,z,\rho))]$ for a given $\phi \in D_0^2(\bar{\Omega})$. For a fixed $T>0$, consider $t \in [0,T]$. By (4.7), it is clear that $u_\rho(t)$ is also a local function. Thus, it remains only to prove the proper bounds of the derivatives of $u_\rho(t)$ in the sense as defined in Definition II.16.

First, we consider the first order derivative of $u_\rho(t)$. Recall the notation $V_p(t,z) = 1 + \bar{H}^{p/2}(\omega(t,z,\rho)) + t + \int_0^t \bar{H}^{p/2}(\omega(s,z,\rho))ds$ in (4.12). We assert that if we can find constants (that may depend on ρ and T) $\sigma>0$, K, and $p \in (1,2)$, such that the bounds

$$|\bar{D}_n P_\rho^t \phi(z)| \leqslant \exp(-\sigma|z_n|) E^W[\exp(KV_p(t,z))], n \in S, \tag{A18}$$

hold (cf. Proposition 4 of Ref. 7), then the lemma is proved. In fact, we observe that the particle numbers inside the ball $B_{2\rho}(0)$ are conserved because the particles outside the ball are frozen in (4.7). By the superstability and decay property of the interaction Φ, one can check that there exists a positive constant $c(\rho)$ such that the bound

$$\bar{H}(\omega(t,z,\rho)) \leqslant c(\rho)\bar{H}(z), \qquad 0 \leqslant t \leqslant T, \tag{A19}$$

holds. Thus, it follows from (4.19) that

$$E^W[\exp(KV_p(t,z))] \leqslant \exp[K'(1+\bar{H}(z)^{p/2})], \tag{A20}$$

for some constant $K'>0$. Inserting this bound into (A18) we have proven our assertion.

Let us now prove (A18). We emphasize that we can not apply Proposition IV.2 directly. First, if $z_n \notin B_{2\rho}(0)$, then $x_n(t,z,\rho) = z_n$. Thus, since $\phi \in D_0^2(\bar{\Omega})$, we can find constants $\varepsilon>0$, $c_\phi(\varepsilon)$, and $p \in (1,2)$ such that the bounds

$$\begin{aligned} |\bar{D}_n P_\rho^t(z)| &= |E^W[\bar{D}_n \phi(\omega(t,z,\rho))]| \\ &\leqslant e^{-\varepsilon|z_n|} E^W[\exp\{c_\phi(\varepsilon)(1+\bar{H}(\omega(t,z,\rho))^{p/2})\}], \quad z_n \notin B_{2\rho}(0) \end{aligned} \tag{A21}$$

hold.

Next, consider the case in which $z_n \in B_{2\rho}(0)$. Since the particles outside the ball are frozen, we have that

$$u_k := \bar{D}_n^{(r)} x_k(t,z,\rho) = 0, \qquad \text{for } z_n \in B_{2\rho}(0) \text{ and } z_k \notin B_{2\rho}(0).$$

Thus, for $z_n \in B_{2\rho}(0)$, $\bar{D}_n P_\rho^t \phi(z) = E^W[\Sigma_{k \in S: \omega_k \in B_{2\rho}(0)} \langle D_k \phi(\omega), u_k \rangle_{\mathbb{R}^d}]$ and the sum in (A11) is actually a finite sum:

$$du_k = \sum_{\substack{j \in S: \\ z_j \in B_{2\rho}(0)}} b_{kj} u_j \, dt + \sum_{\substack{j \in S: \\ z_j \in B_{2\rho}(0)}} \langle \sigma_{kj}, u_j \rangle dW_k(t), \qquad z_k \in B_{2\rho}(0). \tag{A22}$$

Therefore, for a fixed $\rho>0$, we may effectively consider the system as a finite range interaction system with interaction range $2\rho>0$. Now, the exact method used in the proof of Proposition 4 of Ref. 7 gives the bound in (A18).

For the second order derivatives of $u_\rho(t)$, we use a similar argument as above and the method used in the proof of Proposition 6 of Ref. 7. The proof of the lemma is completed. ■

(Received 8 October 1997; accepted for publication 18 August 1998)

We consider the Gyldén problem—a perturbation of the Kepler problem via an explicit function of time. For certain general classes of planar periodic perturbations, after proving a Poincaré–Melnikov-type criterion, we find a manifold of orbits in which the dynamics is given by the shift automorphism on the set of bi-infinite sequences with infinitely many symbols. We achieve the main result by computing the Melnikov integral explicitly. © *1998 American Institute of Physics.* [S0022-2488(98)01912-4]

I. INTRODUCTION

In a note[1] published in 1884, the Swedish astronomer Johan August Hugo Gyldén (the same who in 1889 would compete for King Oscar's Prize—awarded to Poincaré—and then fuel the scandal that followed due to the essential mistake found in the prized paper[2]) proposed a model aimed to describe the secular acceleration of the moon's longitude. He considered a perturbed Kepler problem in which the perturbation μ is an explicit function of time. In its most general form, this problem is given by the Hamiltonian function

$$H(p_1,p_2,q_1,q_2,t)=(p_1^2+p_2^2)/2-(1-\epsilon\mu(t))(q_1^2+q_2^2)^{-1/2}. \tag{1}$$

Later on, Gyldén's model was used to tackle different physical phenomena: a central-force problem with variable mass, the motion of a test particle around a star whose radiation pressure is periodic, a two-body problem in a Dirac-type universe (i.e., one in which the gravitational constant is replaced by a parameter that varies in time), etc. More details on the physical significance of this model can be found in Refs. 3 and 4.

From the mathematical point of view, approximate solutions for slow variations of the perturbation function μ have been obtained by Hadjidemetriou,[5] Verhulst,[6] and Cucu-Dumitrescu and Şelaru.[7] The case of a periodic perturbation function has been tackled by Saslaw (see Ref. 4) and Şelaru, Cucu-Dumitrescu, and Mioc.[8,9] Also, Şelaru and Mioc have applied KAM theory to this problem.[10]

In this paper we consider two classes of planar perturbations: the one for which μ is a periodic even function and the one for which $\mu(t)=A\cos(2\pi t/T)+B\sin(2\pi t/T)$, where A or B is nonzero, and $T>0$ is the period. We show that in both cases the system exhibits chaos in the sense of symbolic dynamics. More precisely, we prove that the dynamics of a manifold of solutions is similar to that of a shift automorphism on the set of bi-infinite sequences with infinitely many symbols. To achieve this goal we first consider the unperturbed problem via McGehee transformations, determine its global flow, and find the Poincaré map near the homoclinic orbit to the degenerate periodic orbit at infinity. Then, using a result of McGehee,[11] we show that this Poincaré map possesses analytic stable and unstable manifolds. Pursuing the Poincaré-Melnikov method, we further prove a Melnikov-type criterion,[12] which tells under what conditions planar periodic perturbations make the stable and unstable manifolds of the periodic orbit at infinity for the Poincaré map split and intersect transversally. Then, using this criterion, we show that the Melnikov integral has zeroes for each of the above-described class of periodic perturbation func-

tions; consequently, the stable and unstable manifolds of the periodic orbit at infinity intersect transversely, giving rise to chaos in the neighborhood of the homoclinic orbit.

The above scenario has been previously used by Moser[13] to prove the existence of chaos in the Sitnikov problem and by Xia[14] to put into evidence the same phenomenon in the elliptic restricted three-body problem. In general, this method is hard to apply due to the difficulty of evaluating the Melnikov integral. However, for the above-described classes of Gyldén systems, we manage to overcome the technical challenge. Moreover, we are able to compute the Melnikov integral explicitly.

II. THE EQUATIONS OF MOTION

Consider a unit point mass moving around a center in a Newtonian gravitational field perturbed by a periodic function of time. The equations of motion are described by the Hamiltonian (1), or in explicit form by the system

$$\begin{aligned} \dot{q}_1 &= p_1, \\ \dot{q}_2 &= p_2, \\ \dot{p}_1 &= -(1-\epsilon\mu(t))q_1(q_1^2+q_2^2)^{-3/2}, \\ \dot{p}_2 &= -1(1-\epsilon\mu(t))q_2(q_1^2+q_2^2)^{-3/2}, \end{aligned} \tag{2}$$

for which (q_1,q_2) and (p_1,p_2) denote the position and the momentum of the moving particle, μ is the periodic perturbation function (of prime period $T>0$), and $\epsilon \geqslant 0$ is a parameter. If $\epsilon=0$, the equations (2) define the *unperturbed system*, whereas if ϵ is positive and small, the equations (2) are called the *perturbed system*. The latter expresses the planar periodic Gyldén problem and the former describes the classical Kepler problem; in both cases the center body and the moving particle have unit mass.

Under the inverse of the transformation

$$(0,\infty)\times S^1\times\mathbb{R}^2\to(\mathbb{R}^2\backslash\{(0,0)\})\times\mathbb{R}^2,$$

$$(r,\theta,p_r,p_\theta)\to(q_1,q_2,p_1,p_2)$$

given by

$$\begin{aligned} q_1 &= r\cos\theta, \\ q_2 &= r\sin\theta, \\ p_1 &= p_r\cos\theta-(p_\theta/r)\sin\theta, \\ p_2 &= p_r\sin\theta+(p_\theta/r)\cos\theta, \end{aligned} \tag{3}$$

which is a real analytic diffeomorphism, the equations (2) become

$$\begin{aligned} \dot{r} &= p_r, \\ \dot{\theta} &= r^{-2}p_\theta, \\ \dot{p}_r &= r^{-3}p_\theta^2-r^{-2}(1-\epsilon\mu(t)), \\ \dot{p}_\theta &= 0. \end{aligned} \tag{4}$$

Notice that the equations (4) have the Hamiltonian

$$\overline{H}(p_r,p_\theta,r,\theta)=p_r^2/2+p_\theta^2/(2r^2)-(1-\epsilon\mu(t))/r. \tag{5}$$

Also, in system (4) the last equation can be dropped.

We will further use *McGehee transformations of the first kind*, given by the inverse of the function

$$(0,\infty)\times S^1\times\mathbb{R}\to(0,\infty)\times S^1\times\mathbb{R},$$

$$(x,\theta,y)\to(r,\theta,p_r),$$

where

$$\begin{aligned} r&=1/x^2,\\ y&=p_r. \end{aligned} \tag{6}$$

(There are two kinds of McGehee transformations: the first ones, which we use here, have been defined in Ref. 11 to address the concept of a ''periodic orbit at infinity;'' the second ones were considered in Ref. 15 to blow up the triple-collision singularity of the rectilinear three-body problem.) The real analytic diffeomorphism (6) transforms the equations (4) into

$$\begin{aligned} \dot{x}&=-x^3y/2,\\ \dot{\theta}&=kx^4,\\ \dot{y}&=-x^4(1-\epsilon\mu(t))+k^2x^6. \end{aligned} \tag{7}$$

Note that the McGehee transformations destroy the Hamiltonian structure of the equations of motion. In exchange they will allow us to understand the dynamics at infinity by bringing infinity to the origin of the system of coordinates. In fact, since the equations (7) make sense for $x=0$, the phase space $(0,\infty)\times S^1\times\mathbb{R}$ can be extended to $[0,\infty)\times S^1\times\mathbb{R}$.

The second equation in (7) can be solved independently on the other two, so from now on we will focus on the nonautonomous system

$$\begin{aligned} \dot{x}&=-x^3y/2,\\ \dot{y}&=-x^4(1-\epsilon\mu(t))+k^2x^6, \end{aligned} \tag{8}$$

in the phase plane $[0,\infty)\times\mathbb{R}$.

III. THE KEPLER PROBLEM IN MCGEHEE COORDINATES

Let us first tackle the particular case of the unperturbed (autonomous) system, i.e., the Kepler problem in McGehee coordinates given by the equations (8) with $\epsilon=0$:

$$\begin{aligned} \dot{x}&=-x^3y/2,\\ \dot{y}&=-x^4+k^2x^6, \end{aligned} \tag{9}$$

with the energy relation

$$y^2/2+k^2x^4/2-x^2=h. \tag{10}$$

The time-rescaling transformation $ds=x^3dt$, which is also a real analytic diffeomorphism, changes system (9) into

$$\begin{aligned} x'&=-y/2,\\ y'&=-x+k^2x^3, \end{aligned} \tag{11}$$

where the prime denotes differentiation with respect to the new time variable s. The equations (11) have two equilibria: $(0,0)$ and $(1/k^2,0)$. For the origin, the eigenvalues of the attached linear

system are $\pm\sqrt{2}/2$, so (0,0) is a saddle; for the other equilibrium, the attached linear system has the eigenvalues $\pm i\sqrt{2}/2$, so no direct conclusion can be drawn about the nonlinear system. However, from the energy relation (10), we can tell that $(1/k^2,0)$ is a center.

For the original system (9), the origin is a degenerate equilibrium, since every solution $(0,y)$ is an equilibrium. Thus in the phase-space picture, the periodic orbits correspond to $h<0$, the heteroclinic ones to $h>0$, and the homoclinic orbit has the energy constant $h=0$. Let us tackle each case.

For $h<0$ and $y\geqslant 0$, the periodic orbits are described by the equation

$$\dot{x}=-(1/2)x^3\sqrt{-k^2x^4+2x^2+2h}, \tag{12}$$

which if integrated yields

$$t=\frac{\sqrt{-k^2x^4+2x^2+2h}}{2hx^2}+\frac{1}{2\sqrt{2}h\sqrt{-h}}\arcsin\frac{x^2+2h}{x^2\sqrt{1+2hk^2}} \tag{13}$$

for the admissible values of x. It looks hopeless to try to express x as an explicit function of t.

For $h=0$ and $y\geqslant 0$ the homoclinic orbit is described by the equation

$$\dot{x}=-(1/2)x^4\sqrt{2-k^2x^2},$$

which if integrated leads to

$$t=(1+k^2x^2)\sqrt{2-k^2x^2}/(3x^3),$$

for $x\in(0,\sqrt{2}/|k|]$. With the substitution $u=x^2$, we obtain the cubic equation

$$u^3+(3/2)k^2u^2-(9t^2+k^6)/2=0,$$

which by Cardano's formula yields

$$u(t)=(1/2)[(3t+\sqrt{9t^2+k^6})^{2/3}+(3t-\sqrt{9t^2+k^6})^{2/3}-k^2].$$

Thus the homoclinic orbit is given by

$$\begin{aligned} x(t)&=\xi(t,k)=\sqrt{2}[(3t+\sqrt{9t^2+k^6})^{2/3}+(3t-\sqrt{9t^2+k^6})^{2/3}-k^2]^{-1,2},\\ y(t)&=\eta(t,k)=\begin{cases}(2x^2(t)-k^2x^4(t))^{1/2}, & t\geqslant 0,\\ -(2x^2(t)-k^2x^4(t))^{1/2}, & t<0,\end{cases}\end{aligned} \tag{14}$$

for $k\neq 0$. The homoclinic orbit intersects the Ox axis at $x=\sqrt{2}/|k|$. Notice that for $k=0$ the motion takes place on a line and that the solution leads to a collision and/or an ejection.

For $h>0$ and $y\geqslant 0$, the heteroclinic orbits are also described by the equation (12). In this case, however, integrating (12) leads to

$$t=\frac{\sqrt{-k^2x^4+2x^2+2h}}{2hx^2}+\frac{1}{2\sqrt{2}h^{3/2}}\log\frac{2\sqrt{2h}\sqrt{-k^2x^4+2x^2+2h}+2x+4h}{x}, \tag{15}$$

for which it also looks hopeless to write x as an explicit function of t.

Up to now we have understood the qualitative behavior of the unperturbed system (the Kepler problem in McGehee coordinates), but have only a very limited understanding of its analytic aspect. Since it looks hopeless to solve the unperturbed system (8) or even to understand its global flow, the natural questions that arise concern the existence of periodic, oscillatory, and dense orbits for the equations (8). A classical expansion theorem in perturbation theory (see, e.g., Ref. 16, Chap. 9) indicates that if periodic orbits of system (8) exist, they can be found only in the region within the homoclinic loop to (0,0), with $O(\epsilon)$ error of the unperturbed orbit. However, this result offers little insight into the problem. Therefore we now proceed with developing a stronger method, along the lines of Poincaré and Melnikov.

IV. THE MELNIKOV FUNCTION

Let us assume from now on that μ has also the property

$$\int_0^T \mu(t)dt = 0.$$

(In fact this condition does not restrain the generality since we can introduce in the Newtonian term of the interaction the temporal average of the perturbation.)

Also notice that since μ is analytic, bounded, and T-periodic, it has the Fourier representation,

$$\mu(t) = \sum_{n=1}^{\infty} [C_n \cos(2\pi nt/T) + S_n \sin(2\pi nt/T)],$$

where the coefficients C_n and S_n are real for all $n \geqslant 1$.

Let us further rewrite the equations (8) as an autonomous system:

$$\frac{dx}{d\tau} = -\frac{x^3 y}{2},$$

$$\frac{dy}{d\tau} = -x^4 + k^2 x^6 + \epsilon x^4 \mu(t), \tag{16}$$

$$\frac{dt}{d\tau} = 1.$$

Consider further a global section $\Sigma^{\tau=\tau_0}$ and denote by $P_{\tau=\tau_0}(x,y)$ the first return of the Poincaré function defined on $\Sigma^{\tau=\tau_0}$. Notice that the origin O is a degenerate fixed point for $P_{\tau=\tau_0}$.

For degenerate situations of this type, McGehee has obtained a result that shows the existence of stable and unstable manifolds for the Poincaré map [see Ref. 11, p. 82, system (7.3) and Proposition (11)]. With the help of this result we can now prove the following:

Lemma 1: The stable and unstable manifold $W^s(\Lambda)$ *and* $W^u(\Lambda)$ *of the periodic orbit* $\Lambda = \{x=0, y=0, \tau \in [0,T)\}$ *are analytic manifolds for* $x>0$ *and for a fixed value of the angular momentum k.*

Proof: McGehee's result cannot be directly applied to system (16), so we will first consider the change of variables

$$\overline{x} = x,$$

$$\overline{t} = t,$$

$$\overline{y} = y + \epsilon x^4 \sum_{n=1}^{\infty} \frac{T}{2\pi n}\left(C_n \sin\frac{2\pi nt}{T} - S_n \cos\frac{2\pi nt}{T}\right),$$

which fulfills the condition $D(x,y,t)/D(\overline{x},\overline{y},\overline{t}) = 1$, and which transforms system (16) into

$$\frac{d\overline{x}}{d\tau} = -\overline{x}^3\left(\frac{\overline{y}}{2} + g_1(\overline{x},\overline{y},\overline{t})\right),$$

$$\frac{d\overline{y}}{d\tau} = -\overline{x}^3(\overline{x} + g_2(\overline{x},\overline{y},\overline{t})),$$

$$\frac{d\overline{t}}{d\tau} = 1,$$

where the functions g_1, g_2 are periodic in $\overline{t}$, C^∞, and such that $|g_i(\overline{x},\overline{y},\overline{t})| \leqslant O(|(x,y)|^2)$, $i=1,2$.

McGehee's result can now be applied to the above equations and Lemma 1 follows. This completes the proof.

Recall that in the unperturbed case the stable and unstable manifolds of Λ are identical and form the homoclinic loop (14). We will see that in the perturbed case the two manifolds split and intersect transversally. The first step in formulating the necessary conditions of transverse intersections is to find suitable estimates of the stable and unstable manifolds of the perturbed system. This is done in the following:

Lemma 2: The solutions $(x^{s,u}(\tau,\tau_0), y^{s,u}(\tau,\tau_0))$ *that remain in the manifolds* $W^s(\Lambda)$ *and* $W^u(\Lambda)$, *and for which* $(x^{s,u}(0,\tau_0), y^{s,u}(0,\tau_0))$ *belong to the Poincaré section at time* $\tau=\tau_0$, *admit, for* ϵ *sufficiently small, the estimates*

$$x^s(\tau,\tau_0)=\xi(\tau-\tau_0,k)+\epsilon x_1^s(\tau,\tau_0)+O(\epsilon^2), \quad \tau\in[\tau_0,\infty),$$

$$y^s(\tau,\tau_0)=\eta(\tau-\tau_0,k)+\epsilon y_1^s(\tau,\tau_0)+O(\epsilon^2), \quad \tau\in[\tau_0,\infty),$$

$$x^u(\tau,\tau_0)=\xi(\tau-\tau_0,k)+\epsilon x_1^u(\tau,\tau_0)+O(\epsilon^2), \quad \tau\in(\infty,\tau_0],$$

$$y^u(\tau,\tau_0)=\eta(\tau-\tau_0,k)+\epsilon y_1^u(\tau,\tau_0)+O(\epsilon^2), \quad \tau\in(\infty,\tau_0],$$

uniformly in the indicated time intervals. The functions $x_1^{s,u}(\tau,\tau_0)$, $y_1^{s,u}(\tau,\tau_0)$ *are determined by the first variational equation of system* (8) *along the unperturbed homoclinic orbit* (14).

The proof of Lemma 2, based on Gronwall's lemma and on the fact that the perturbed and unperturbed manifolds are C^∞-close, can be found in Ref. 17, 18, or 19. The necessary condition for the proposed estimates to be valid is that the period T of the function μ is neither too big nor too small.

The vector

$$\mathbf{d}(\tau_0)=(x^s(\tau_0,\tau_0)-x^u(\tau_0,\tau_0), y^s(\tau_0,\tau_0)-y^u(\tau_0,\tau_0))$$

measures the splitting of the manifolds $W^s(\Lambda)$ and $W^u(\Lambda)$ in the Poincaré section $\Sigma^{\tau=\tau_0}$. Denoting by H_0 the Hamiltonian (1) for $\epsilon=0$, notice that the projection of $\mathbf{d}$ onto the vector

$$\mathbf{H}_{0N}=\left(\frac{\partial H_0}{\partial x}(\xi(0,k),\eta(0,k)), \frac{\partial H_0}{\partial y}(\xi(0,k),\eta(0,k))\right),$$

normal to $H_0(x,y)$ at the point $(\xi(0,k),\eta(0,k))$, approximates the separation of the two manifolds $W^s(\Lambda)$ and $W^u(\Lambda)$ (see Ref. 14). Denoting by $\langle,\rangle$ the scalar product, in the first approximation we have

$$\left\langle \mathbf{d}(\tau_0), \frac{\mathbf{H}_{0N}}{|\mathbf{H}_{0N}|}\right\rangle = \epsilon \frac{\langle \mathbf{H}_{0N}, (x_1^s(\tau_0,\tau_0)-x_1^u(\tau_0,\tau_0), y_1^s(\tau_0,\tau_0)-y_1^u(\tau_0,\tau_0))\rangle}{|\mathbf{H}_{0N}|}+O(\epsilon^2),$$

which, using Lemma 2 (see also Ref. 14), leads to

$$\left\langle \mathbf{d}(\tau_0), \frac{\mathbf{H}_{0N}}{|\mathbf{H}_{0N}|}\right\rangle = \epsilon \frac{H_0(x^s(\tau_0,\tau_0),y^s(\tau_0,\tau_0))-H_0(x^u(\tau_0,\tau_0),y^u(\tau_0,\tau_0))}{|\mathbf{H}_{0N}|}+O(\epsilon^2)$$

$$=\frac{\epsilon}{|\mathbf{H}_{0N}|}\int_{-\infty}^{+\infty}\frac{dH_0}{d\tau}\,d\tau+O(\epsilon^2)=\frac{\epsilon}{|\mathbf{H}_{0N}|}M(\tau_0)+O(\epsilon^2),$$

where $M(\tau_0)$ is the Melnikov function (see Ref. 12, 17, or 19):

$$M(\tau_0)=\frac{1}{\epsilon}\int_{-\infty}^{+\infty}\frac{dH_0(\xi(\tau-\tau_0,k),\eta(\tau-\tau_0,k))}{d\tau}\,d\tau$$

$$=\int_{-\infty}^{+\infty}\xi^4(\tau-\tau_0,k)\,\eta(\tau-\tau_0,k)\,\mu(\tau)d\tau$$

$$=\int_{-\infty}^{+\infty}\xi^4(\tau,k)\,\eta(\tau,k)\,\mu(\tau+\tau_0)d\tau. \tag{17}$$

Substituting the Fourier series representation of μ into the Melnikov function (17), we obtain

$$M(\tau_0)=\sum_{n=1}^{\infty}\left[\left(C_n\cos\frac{2\pi n\tau_0}{T}+S_n\sin\frac{2\pi n\tau_0}{T}\right)\int_{-\infty}^{+\infty}\xi^4(\tau,k)\,\eta(\tau,k)\cos\frac{2\pi n\tau}{T}\,d\tau\right.$$

$$\left.+\left(-C_n\sin\frac{2\pi n\tau_0}{T}+S_n\cos\frac{2\pi n\tau_0}{T}\right)\int_{-\infty}^{+\infty}\xi^4(\tau,k)\,\eta(\tau,k)\sin\frac{2\pi n\tau}{T}\,d\tau\right]$$

$$=\sum_{n=1}^{\infty}\left(-C_n\sin\frac{2\pi n\tau_0}{T}+S_n\cos\frac{2\pi n\tau_0}{T}\right)\int_{-\infty}^{+\infty}\xi^4(\tau,k)\,\eta(\tau,k)\sin\frac{2\pi n\tau}{T}\,d\tau,$$

where the first of the integrals cancels because the function under the integral is odd. We further have

$$M'(\tau_0)=\frac{dM}{d\tau}(\tau_0)=-\sum_{n=1}^{\infty}\frac{2\pi n}{T}\left(C_n\cos\frac{2\pi n\tau_0}{T}+S_n\sin\frac{2\pi n\tau_0}{T}\right)I_n,$$

where $I_n>0$ stands for

$$I_n=\int_{-\infty}^{+\infty}\xi^4(\tau,k)\,\eta(\tau,k)\sin\frac{2\pi n\tau}{T}\,d\tau.$$

The actual form of I_n will not be involved in our future endeavors. However, we compute I_n in the Appendix at the end of our paper to show that $I_n>0$.

Taking now into account the form of the vector $\mathbf{H}_{0N}$ and the equations (14), a straightforward computation leads to

$$|\mathbf{H}_{0N}|=\sqrt{(2k^2\xi^3(0,k)-2\xi(0,k))^2+\eta^2(0,k)}=2\sqrt{2}/|k|,$$

so we have

$$\left\langle\mathbf{d}(\tau_0),\frac{\mathbf{H}_{0N}}{|\mathbf{H}_{0N}|}\right\rangle=\epsilon\frac{|k|M(\tau_0)}{2\sqrt{2}}+O(\epsilon^2).$$

This formula will allow us to reach our conclusions.

V. THE MAIN RESULTS

From the above formula we can see that the necessary conditions for the transverse intersections of $W^s(\Lambda)$ and $W^u(\Lambda)$ are

(i) ϵ is sufficiently small.
(ii) μ is T-periodic, analytic, and bounded.
(iii) There exists $\tau_0\in[0,T)$ such that $M(\tau_0)=0$, the derivative M' is defined and differentiable at τ_0, and $M'(\tau_0)\neq 0$.

We have thus proved the following criterion:

Theorem 3: *For the equations (8), which define the Gyldén problem, for μ T-periodic, analytic, and bounded, for a sufficiently large value of the angular momentum k, and for a sufficiently small $\epsilon>0$, if there exists a $\tau_0\in[0,T)$ such that $M(\tau_0)=0$ and $M'(\tau_0)\neq 0$, then the manifolds $W^s(\Lambda)$ and $W^u(\Lambda)$ of the Poincaré map* (16) *intersect transversally.*

From Theorem 3 we can now draw the following conclusion:

Corollary 4: For the equations (8)*, which define the Gyldén problem, for μ even, T-periodic, analytic, and bounded [i.e., $\mu(t)=\Sigma_{n=1}^{\infty}C_n\cos(2\pi nt/T)$], for a sufficiently large value of the angular momentum k, and for a sufficiently small $\epsilon>0$, the manifolds $W^s(\Lambda)$ and $W^u(\Lambda)$ of the Poincaré map* (16) *intersect transversally. This happens generically, except possibly for functions μ that belong to a certain negligible set included in the set of all functions μ with the above-mentioned properties.*

Proof: Observe that the Melnikov function becomes in this case

$$M(\tau_0)=-\sum_{n=1}^{\infty} C_nI_n \sin\frac{2\pi n\tau_0}{T},$$

and its derivative has the form

$$M'(\tau_0)=-\sum_{n=1}^{\infty} \frac{2\pi nC_nI_n}{T}\cos\frac{2\pi n\tau_0}{T} I_n.$$

Notice that $M(\tau_{0i})=0$, $i=1,2$, at least for the values $\tau_{01}=0$ and $\tau_{02}=T/2$, whereas for the derivative of the Melnikov function at these points we obtain

$$M'(\tau_{01})=-\sum_{n=1}^{\infty} \frac{2\pi nC_n}{T} I_n, \quad M'(\tau_{02})=\sum_{n=1}^{\infty} (-1)^{n+1}\frac{2\pi nC_n}{T} I_n.$$

Clearly, $M'(\tau_{0i})\neq 0$ for most of the coefficients $C_1,C_2,\ldots$. More precisely, $M'(\tau_{0i})\neq 0$ in the space of coefficients, $\{(C_1,C_2,\ldots)|C_i\in\mathbb{R}\}$, except possibly for a negligible subset. This completes the proof.

Another consequence we can draw from Theorem 3 is the following:

Corollary 5: For the equations (8), which define the Gyldén problem, for functions μ that are T-periodic, analytic, bounded and have a single harmonic [i.e., $\mu(t)=A\cos(2\pi t/T)+B\sin(2\pi t/T)$, with $\sqrt{A^2+B^2}\neq 0$], for a sufficiently large value of the angular momentum k, and for a sufficiently small $\epsilon>0$, the manifolds $W^s(\Lambda)$ and $W^u(\Lambda)$ of the Poincaré map (16) *intersect transversally.*

Proof: The Melnikov function becomes in this case

$$M(\tau_0)=\left(-A\sin\frac{2\pi\tau_0}{T}+B\cos\frac{2\pi n\tau_0}{T}\right)I_1,$$

and its derivative takes the form

$$M'(\tau_0)=-\frac{2\pi}{T}\left(A\cos\frac{2\pi\tau_0}{T}+B\sin\frac{2\pi n\tau_0}{T}\right)I_1.$$

We can consider $B(A^2+B^2)^{-1/2}=\sin\alpha$ and $A(A^2+B^2)^{-1/2}=\cos\alpha$, and obtain the expressions

$$M(\tau_0)=I_1\sqrt{A^2+B^2}\sin(\alpha-2\pi\tau_0/T),$$

$$M'(\tau_0)=-I_1\sqrt{A^2+B^2}(2\pi/T)\cos(\alpha-2\pi\tau_0/T)$$

for the Melnikov function and its derivative. The equation $M(\tau_0)=0$ admits the only solutions $\tau_{01}=\alpha T/2\pi$ and $\tau_{02}=(\alpha-\pi)T/2\pi$, for which

$$M'(\tau_{01})=-I_1\sqrt{A^2+B^2}(2\pi/T)\neq 0, \quad M'(\tau_{02})=I_1\sqrt{A^2+B^2}(2\pi/T)\neq 0.$$

By Theorem 3 the conclusion of Corollary 5 follows. This completes the proof.

We will close our endeavors with a symbolic-dynamics description of the above results, which will allow us a better understanding of the dynamics of the Gyldén problem. For this, consider a general Poincaré map P for a transversal homoclinic orbit Λ and let $\mathcal{R}$ be a small rectangle having two of its sides on the stable and unstable manifolds of Λ, respectively, at a point at which the two manifolds intersect transversally. For a point q in $\mathcal{R}$, let n be the smallest positive integer for which $P^n(q)$ belongs to $\mathcal{R}$, and denote by $\mathcal{Q}$ the set of all those q for which such an n (which depends on q) exists. In Ref. 13, Moser shows that $\mathcal{Q}$ is nonempty and proves that a shift automorphism on infinitely many symbols can be embedded in the set $\mathcal{Q}$. The precise formulation of this result is as follows:

Theorem 6: *Let $\mathcal{T}(q)=P^n(q)$, for all $q\in\mathcal{Q}$, and let $\mathcal{B}$ denote the set of bi-infinite sequences on infinitely many symbols. Then there is an invariant set $I\subset\mathcal{Q}$ for the map $\mathcal{T}$, homeomorphic to $\mathcal{B}$, such that the map $\mathcal{T}$ is topologically conjugate to the shift automorphism on $\mathcal{B}$.*

This result has two main consequences. First it proves the existence of periodic orbits of any period, of dense orbits, as well as that of oscillatory ones, or of any other orbits that can be put into correspondence with a symbolic sequence. Second, it shows that real analytic first integrals do not exist. All of these characterize chaotic motion in the Gyldén problem and put into the evidence some of the complicated dynamics in the phase space of the equations (8).

Notice that due to the low dimension of system (8), transition-tori phenomena (like the Arnold diffusion[20–23]) cannot occur. However, such subtle dynamical aspects may very well characterize higher-dimensional systems of the same type, i.e., n-body Gyldén problems with $n\geqslant 3$.

APPENDIX

In this Appendix we compute I_n. For this define

$$J_\omega=\int_{-\infty}^{\infty} x^4 y\,\sin\,\omega\tau\,d\tau$$

along the unperturbed orbit (16). From the equations (11), integrating J_ω by parts, we have

$$J_\omega=-\int_{-\infty}^{\infty}\frac{d}{d\tau}(x^2)\sin\,\omega\tau\,d\tau=\omega\int_{-\infty}^{\infty}\frac{\cos\,\omega\tau}{r}\,d\tau.$$

Using the angular momentum integral and the expression of r as a function of the true anomaly v for unperturbed parabolic motions, given by $r=1/(1+\cos v)$, we obtain

$$J_\omega=\frac{\omega k}{2}\int_{-\pi}^{\pi}(1+\tan^2(v/2))\cos\,\omega\tau\,dv.$$

Denoting $\tan(v/2)=\alpha$ and taking into account the fact that parabolic motion implies that $\tau=(k^3/4)(\alpha+\alpha^3/3)$, we obtain

$$J_\omega=\omega k^3\int_{-\infty}^{\infty}\cos[(\omega k^3/4)(s+s^3/3)]$$

or

$$J_\omega=\frac{2\pi\omega k^3}{3}\left[\tilde{I}\left(-\frac{1}{3},\frac{\omega k^3}{6}\right)-\tilde{I}\left(\frac{1}{3},\frac{\omega k^3}{6}\right)\right],$$

where $\tilde{I}(\nu,z)$ is the modified Bessel function of the first kind.[24] However,

$$\tilde{I}(-\nu,z)-\tilde{I}(\nu,z)=\frac{2\sin\,\pi\nu}{\pi}K_\nu(z),$$

where $K_\nu(z)$ is the modified Bessel function of the second kind (see Ref. 25, p. 78). So

$$J_\omega = \frac{4}{3}\,\omega k^3 \sin\frac{\pi}{3}\,K_{1/3}\left(\frac{\omega k^3}{6}\right). \tag{18}$$

However, $K_\nu(z)$ tends exponentially to 0 when $z\to\infty$ through positive values, and since $I_n = J_{2\pi n/T}$, with $J_{2\pi n/T}$ given by (18), the positivity of I_n follows.

A generalized Hirota equation in 2+1 dimensions

Attilio Maccari
Technical Institute ''G. Cardano,'' Piazza della Resistenza 1, 00015 Monterotondo (Rome), Italy

(Received 2 March 1998; accepted for publication 10 May 1998)

Using an asymptotically exact reduction method based on Fourier expansion and spatiotemporal rescaling, a new integrable and nonlinear partial differential equation (PDE) in $2+1$ dimensions is obtained starting from the Kadomtsev–Petviashvili equation. We apply the reduction technique to the Lax pair of the Kadomtsev–Petviashvili equation and demonstrate the integrability property of the new equation, because we obtain the corresponding Lax pair. The new equation reduces to the Hirota equation in the $1+1$-dimensional limit. © *1998 American Institute of Physics.* [S0022-2488(98)03911-5]

I. INTRODUCTION

It is well known that certain ''universal'' nonlinear evolution PDEs can be obtained, by a limiting procedure involving the wave modulation induced by weak nonlinear effects, from very large classes of nonlinear evolution equations in $1+1$ and $2+1$ dimensions, with a dispersive linear part. The most interesting result is that only a very limited number of model equations are necessary. This reduction technique is the correct one to evince weakly nonlinear effects, and then these model equations are usually of applicative relevance (in plasma physics, nonlinear optics, hydrodynamics). The model equations are integrable, since it is sufficient that the very large class from which they are obtainable contain just one integrable equation, because it is clear from this method that the property of integrability is inherited through this limiting technique.[1–5] The reduction method can be also applied to the weakly nonlinear ordinary differential equations.[6]

The first step of the reduction method (in $2+1$ dimensions) is to use a moving frame of reference via the transformation

$$\xi=\epsilon^{p_1}(x-V_1t), \quad \eta=\epsilon^{p_2}(y-V_2t), \quad \tau=\epsilon^q t, \tag{1.1}$$

where p_1, $p_2>0$, $q>0$, and $V_1=V_1(K_1,K_2)$, $V_2=V_2(K_1,K_2)$ are the components of the group velocity $\mathbf{V}(\mathbf{K})\equiv(V_1(K_1,K_2),V_2(K_1,K_2))$ of the linearized equation, i.e., of the equation obtained after neglecting all the nonlinear terms, and ϵ is the expansion parameter, supposed to be sufficiently small. Fourier modes describe the linear evolution, as they have a constant amplitude and a well-defined group velocity. Nonlinear terms induce a modulation of the amplitude of the Fourier mode. The modulation is best described in terms of the rescaled variables ξ, η, τ, that account for the need to look on larger space and time scales, to obtain a non-negligible contribution from the nonlinear term.

In preceding papers, this method has been applied to certain integrable equations in $1+1$ and $2+1$ dimensions and new integrable nonlinear PDEs have been derived.[7–9] Moreover, the reduction technique is able to derive equations of applicative relevance.[10] In this paper we consider the Kadomtsev–Petviashvili (KP) equation[11] (integrable by means of the spectral transform[12]):

$$U_{xt}(x,y,t)+U_{xxxx}(x,y,t)+sU_{yy}(x,y,t)-3(U^2(x,y,t))_{xx}=0, \tag{1.2}$$

where $U=U(x,y,t)$ is real, $s=\pm1$, and the subscripts denote differentiation. In the following we consider the case $s=1$, because the other possibility has been previously studied.[9] If $p_1\neq p_2$, a new model equation can be derived,

$$i\Psi_\tau+\Psi_{\xi\eta}+i\Psi_{\xi\xi\xi}+\Psi\Phi-i|\Psi|^2\Psi_\xi=0, \tag{1.3a}$$

$$3\Phi_\xi+(|\Psi|^2)_\eta=0, \tag{1.3b}$$

 © 1998 American Institute of Physics

with $\Psi=\Psi(\xi,\eta,\tau)$ complex and $\Phi=\Phi(\xi,\eta,\tau)$ real. If we take $\xi=\eta$, we recover the integrable equation in $1+1$ dimensions obtained by Hirota.[13] The Lax pair relative to Eq. (1.3) will be deduced from the Lax pair of the KP equation.

II. MODEL NONLINEAR PDEs OBTAINED FROM THE KP EQUATION

The linear dispersive part of the KP equation (1.2) is simply described in terms of Fourier modes, with a group velocity $\mathbf{V}(\mathbf{K})=(V_1(K_1,K_2),V_2(K_1,K_2))$,

$$V_1(K_1,K_2)=-3K_1^2-\frac{K_2^2}{K_1^2},\quad V_2(K_1,K_2)=\frac{2K_2}{K_1}. \tag{2.1}$$

We introduce a formal asymptotic Fourier expansion,

$$U(x,y,t)=\sum_{n=-\infty}^{n=+\infty}\epsilon^{\gamma_n}\psi_n(\xi,\eta,\tau;\epsilon)\exp\{in(K_1x+K_2y-\omega t)\}, \tag{2.2}$$

with $\gamma_n=|n|$, for $n\neq 0$, $\gamma_0=r$ a rational number to be determined later on, and $\psi_{-n}(\xi,\eta,\tau;\epsilon)=\psi_n^*(\xi,\eta,\tau;\epsilon)$, because $U(x,y,t)$ is real.

The functions $\psi_n(\xi,\eta,\tau,\epsilon)$'s depend on the parameter ϵ, and we suppose that the limit of the ψ_n's for $\epsilon\to 0$ exists and is finite and, moreover, they can be expanded in power series of ϵ, i.e.,

$$\psi_n(\xi,\eta,\tau;\epsilon)=\sum_{i=0}^{\infty}\epsilon^i\psi_n^{(i)}(\xi,\eta,\tau). \tag{2.3}$$

In the following, for simplicity, we use the abbreviations $\psi_n^{(0)}=\psi_n$ for $n\neq 0,1$ and $\psi_1^{(0)}=\Psi$, $\psi_0^{(0)}=\Psi_0$.

The final goal is to obtain the evolution equation for the modulation amplitude $\Psi=\Psi(\xi,\eta,\tau)$ and to understand how it is modified by choosing different wave numbers. In particular, an interesting result shall be derived, if the special condition $K_2=\sqrt{3}K_1^2$ is verified. We substitute the expansion (2.2) in the KP equation (1.2) and consider the different equations obtained from the coefficients of the Fourier modes. To simplify the treatment, it is more convenient to separate the contributions from the linear and nonlinear parts: $\epsilon^{\gamma_n}[D_n\psi_n]=\epsilon^2F_n$, where D_n is a linear differential operator acting on $\psi_n(\xi,\eta,\tau)$ and F_n is the contribution of the nonlinear part. The operator D_n is

$$\begin{aligned}D_n=&(-in\omega+\epsilon^q\partial_\tau-V_1(K_1,K_2)\epsilon^{p_1}\partial_\xi-V_2(K_1,K_2)\epsilon^{p_2}\partial_\eta)(\epsilon^{p_1}\partial_\xi+inK_1)\\&+(inK_1+\epsilon^{p_1}\partial_\xi)^4+(inK_2+\epsilon^{p_2}\partial_\eta)^2.\end{aligned} \tag{2.4}$$

It is easily seen that the first F_n have the following explicit form:

$$F_0=6(|\Psi|^2)_{\xi\xi}\epsilon^{2p_1}+o(\epsilon^{2p_1+2},\epsilon^{2p_1+2r-2}), \tag{2.5a}$$

$$F_2=-12K_1^2\Psi^2+o(\epsilon^{p_1}), \tag{2.5b}$$

$$F_1=-6K_1^2\Psi_0\Psi\epsilon^r-6K_1^2\psi_2\Psi^*\epsilon+O(\epsilon^{p_1+r-1},\epsilon^{p_1+1}). \tag{2.5c}$$

After taking $q=2$, $p_1=p_2=1$, $r=2$ for the proper balance of terms, we obtain at the lowest order for $n=0$ and $n=2$,

$$V_1\Psi_{0,\xi\xi}+V_2\Psi_{0,\xi\eta}-\Psi_{0,\eta\eta}+6(|\Psi|^2)_{\xi\xi}=0, \tag{2.6a}$$

$$\psi_2^{(0)}=\frac{3K_1^2}{K_2^2-6K_1^4}\Psi^2, \tag{2.6b}$$

and, for $n=1$,

$$iK_1\Psi_\tau-(6K_1^2+V_1)\Psi_{\xi\xi}-V_2\Psi_{\xi\eta}+\Psi_{\eta\eta}+6K_1^2(\Psi_0\Psi+\psi_2\Psi^*)=0. \tag{2.6c}$$

Substituting (2.6b) into (2.6c) and after a trivial rescaling we arrive at the model equation of a nonlinear Schrodinger type:

$$i\Psi_\tau+L_1\Psi+\Psi\Psi_0=0, \tag{2.7a}$$

$$L_2\Psi_0=2L_1(|\Psi|^2), \tag{2.7b}$$

with the linear differential operators L_1 and L_2 given by

$$L_1=\frac{1}{4}(1-\lambda^2)\frac{\partial^2}{\partial\xi^2}+\lambda\frac{\partial}{\partial\xi}\frac{\partial}{\partial\eta}-\frac{\partial^2}{\partial\eta^2}, \tag{2.7c}$$

$$L_2=-\frac{1}{4}(1+\lambda^2)\frac{\partial^2}{\partial\xi^2}+\lambda\frac{\partial}{\partial\xi}\frac{\partial}{\partial\eta}-\frac{\partial^2}{\partial\eta^2}, \tag{2.7d}$$

with $\lambda=K_2/\sqrt{3}K_1^2$. By means of a trivial transformation in the spatial variables, the λ can be eliminated, thereby reducing Eq. (2.7) to the integrable Davey–Stewartson equation.[14,15]

Now, we consider the particular case $K_2=\sqrt{3}K_1^2$ and note that if $p_2>p_1$, a different result is obtained for $n=0$ and $r=2$,

$$\Psi_0=-\frac{1}{K_1^2}|\Psi|^2, \tag{2.8a}$$

and then the second term and the nonlinear term in Eq. (2.6c) vanish. We conclude that in this situation the preceding choice for the coefficients p_1, p_2, q is not able to capture the contribution of nonlinear terms.

We reconsider Eq. (2.6a) and see that if $p_2>p_1$ the most important terms lead to the equation

$$\epsilon^{2p_1+2}V_1\Psi_{0,\xi\xi}+6\epsilon^{2+2p_1}(|\Psi|^2)_{\xi\xi})+\epsilon^{2p_1+3}\Phi_{\xi\xi}+\epsilon^{p_1+p_2+2}V_2\Psi_{0,\xi\eta}=0 \tag{2.8b}$$

where $\Phi=\psi_0^{(1)}$ [see (2.3)]. With the choice $p_2=p_1+1$, we obtain

$$\sqrt{3}K_1^3\Phi_\xi-(|\Psi|^2)_\eta=0, \tag{2.9a}$$

while Ψ_0 is always given by Eq. (2.8a). In a similar way, we obtain, for $n=2$,

$$\psi_2^{(0)}=\frac{1}{K_1^2}\psi^2,\quad \psi_2^{(1)}=-\frac{2i}{K_1^3}\Psi\Psi_\xi,\quad p_1=1,\quad p_2=2. \tag{2.9b}$$

Taking $n=1$ and with the choice $q=3$, a new model nonlinear PDE is obtained:

$$i\Psi_\tau-2\sqrt{3}\Psi_{\xi\eta}+4i\Psi_{\xi\xi\xi}+6K_1\Psi\Phi-\frac{12i}{K_1^2}|\Psi|^2\Psi=0. \tag{2.10}$$

After a trivial rescaling, we arrive at the nonlinear model equation (1.4). It is expected that it is integrable, taking into account that it has been obtained from an equation integrable by the spectral transform.

III. THE LAX PAIR FOR THE MODEL NONLINEAR PDE

In order to demonstrate the integrability of the new equation (1.3) by the spectral transform, we apply the reduction method to the Lax pair of the KP equation. The Lax operators are

$$L=\frac{1}{\sqrt{3}}\frac{\partial}{\partial y}+\frac{\partial^2}{\partial x^2}-U(x,y,t),\quad L\varphi(x,y,t)=0, \tag{3.1}$$

$$A=4\frac{\partial^3}{\partial y^3}-6U(x,y,t)\frac{\partial}{\partial x}-3U_x(x,y,t)+\sqrt{3}W(x,y,t), \tag{3.2}$$

with $W_x(x,y,t)=U_y(x,y,t)$ and

$$\varphi_t(x,y,t)+A\varphi(x,y,t)=0. \tag{3.3}$$

We introduce an asymptotic Fourier expansion,

$$\varphi(x,y,t)=\sum_{n=-\infty}^{n=+\infty}\epsilon^{\gamma_n}\varphi_n(\xi,\eta,\tau;\epsilon)\exp\left(i\frac{n}{2}z+i(\lambda_1 x+\lambda_2 y+\lambda_3 t)\right), \tag{3.4}$$

where n is odd, $z=K_1x+K_2y-\omega t$, $\gamma_{n+2}=1+\gamma_n$, $\gamma_n=\gamma_{-n}$ for $n>0$, the $\varphi_n(\xi,\eta,\tau;\epsilon)$'s are functions that parametrically depend on ϵ and remain finite if $\epsilon\to 0$ and $\lambda_1,\lambda_2,\lambda_3$ are real constants to be determined later on. Substituting the expression for $\varphi(x,y,t)$ in Eq. (3.1), the coefficients of the Fourier modes generate a series of relations. Obviously, each relation must be valid for a given order of approximation in ϵ. In particular, for the fundamental harmonics $\varphi_{\pm}(x,y,t)=\varphi_{\pm 1}(x,y,t)$, considering terms $O(\epsilon^0)$ in (3.1) and (3.3), the constants $\lambda_1,\lambda_2,\lambda_3$ can be fixed:

$$\lambda_1=-\frac{K_1}{2},\quad \lambda_2=0,\quad \lambda_3=-K_1^3. \tag{3.5}$$

The new spectral problem is obtained by means of the successive order ϵ for the equation (3.1),

$$K_1(i-1)\varphi_{+,\xi}=\Psi\varphi_-, \tag{3.6a}$$

$$K_1(i+1)\varphi_{-,\xi}=-\Psi^*\varphi_+. \tag{3.6b}$$

The spectral problem can be obtained again when we consider the temporal evolution equation (3.3) at the same order ϵ. Only if we take into account the next orders of approximation of (3.3), can the temporal evolution be determined. However, new quantities, the corrections $\tilde{\varphi}_{\pm}(\xi,\eta,\tau)$ of order ϵ to the fundamental harmonics $\varphi_{\pm}(\xi,\eta,\tau)$, appear. These unknown quantities can be eliminated in (3.3), taking advantage of the relation obtained from (3.1), considering terms of order ϵ^2 and ϵ^3. This elimination is possible only because Eqs. (3.1) and (3.3) are identical at the orders ϵ and ϵ^2. The Lax pair of the new integrable equation (1.3) is then

$$L\hat{\varphi}=0,\quad \hat{\varphi}_\tau+A\hat{\varphi}=0, \tag{3.7a}$$

with

$$L=-\frac{1}{2\sqrt{3}}\begin{pmatrix}\partial_\xi & (1+i)\Psi\\ (1-i)\Psi^* & \partial_\xi\end{pmatrix},\quad \hat{\varphi}=\begin{pmatrix}\varphi_+\\ \varphi_-\end{pmatrix} \tag{3.7b}$$

and

$$A=\begin{pmatrix}a_1\Phi+a_2(|\Psi|^2)_\xi+a_3\Psi^*\Psi_\xi & a_4\Psi_{\xi\xi}+a_5|\Psi|^2\Psi+a_6\Psi_\eta\\ a_4^*\Psi^*_{\xi\xi}+a_5^*|\Psi|^2\Psi^*+a_6^*\Psi^*_\eta & a_1^*\Phi+a_2(|\Psi|^2)_\xi+a_3\Psi\Psi^*_\xi\end{pmatrix}, \tag{3.7c}$$

$$a_1=\frac{i}{2},\quad a_2=-\frac{1}{6},\quad a_3=\frac{1}{3},\quad a_4=\frac{i+1}{2\sqrt{3}},\quad a_5=-\frac{i+1}{6\sqrt{3}},\quad a_6=\frac{1-i}{2\sqrt{3}}. \tag{3.7d}$$

IV. CONCLUSION

A new integrable nonlinear evolution PDE in $2+1$ dimensions has been derived from the KP equation, by means of a reduction method based on Fourier decomposition and space–time rescalings. We have applied the reduction method to the Lax pair of the original equation and have

demonstrated the integrability property of the new equation, by exhibiting the corresponding Lax. The reduction method is then able to identify integrable nonlinear evolution PDEs.

Bifurcations of new eigenvalues for the Benjamin–Ono equation

Dmitry E. Pelinovsky and Catherine Sulem
Department of Mathematics, University of Toronto, Toronto, Ontario M5S3G3, Canada

(Received 20 April 1998; accepted for publication 14 August 1998)

A criterion for the emergence of new eigenvalues is found for the linear scattering problem associated with the Benjamin–Ono (BO) equation. This bifurcation occurs due to perturbations of nongeneric potentials which include the soliton solutions of the BO equation. The asymptotic approximation of an exponentially small new eigenvalue is derived. The method is based on the expansion of a localized function through a complete set of unperturbed eigenfunctions. Explicit expressions are obtained for the soliton potentials. © *1998 American Institute of Physics.* [S0022-2488(98)00112-1]

I. INTRODUCTION

This paper studies the problem of soliton generation in the integro-differential Benjamin–Ono (BO) equation,

$$u_t+2uu_x+Hu_{xx}=0, \tag{1.1}$$

where

$$Hu=\frac{1}{\pi}\,\text{p.v.}\int_{-\infty}^{\infty}\frac{u(y)dy}{y-x}$$

and p.v. stands for the principal value of the integral. The evolution equation (1.1) describes the propagation of long internal waves in a deep fluid (see Ref. 1 for review and references). The algebraic and spectral properties of the BO equation were intensely studied in development of the bilinear and inverse scattering transform methods.[2,3] The latter method allows one to relate the number and parameters of solitons generated by a smooth localized initial perturbation $u(x)=u(x,0)$ to the number and location of eigenvalues of the discrete spectrum for the linear spectral problem associated with the potential $u(x)$.

Generations of new solitons (and associated eigenvalues) were studied for several $(1+1)$-dimensional evolution equations in the limit of small and, alternatively, large number of solitons.[4] For instance, the Korteweg–de Vries (KdV) equation associated with the Schrödinger operator possesses *no threshold* for the generation of solitons by a small initial disturbance[4] while the modified KdV (mKdV) equation *does* possess a certain threshold on the area of the potential,

$$\mathcal{M}[u]=\int_{-\infty}^{\infty}u\,dx. \tag{1.2}$$

This threshold is related to spectral properties of the Dirac operator.[5] When the potential has a large amplitude, the problem under consideration has a uniform quasiclassical solution (see Ref. 4 for the KdV equation) which was derived also within the rigorous analysis of the dispersionless limit of the evolution equations.[6]

Surprisely enough, the problem of soliton generation for the BO equation (1.1) has not been finally solved since some independent results have appeared to be contradictory. Suppose that the initial perturbation can be renormalized in dimensionless units, $u=U_0U(x/L_0)$, where U_0 is a characteristic amplitude and L_0 is a characteristic length. Then, the number of solitons essentially

 © 1998 American Institute of Physics

depends on the sole parameter (the so-called Ursell parameter), $\sigma = U_0 L_0$. In the limit $\sigma \gg 1$, the potential generates a large number m of solitons, an approximation for m was found by Matsuno[7] and confirmed by Miloh *et al.*,[8]

$$m = \frac{1}{2\pi} \int_{u(x) \geqslant 0} u(x) dx. \tag{1.3}$$

Some early numerical and analytical data on the generation of solitons by an initial disturbance of an algebraic profile, $u = 2a/(1+x^2)$ were reported in Refs. 9 and 10. An important question, whether a small initial perturbation, i.e., that in the limit $\sigma \ll 1$ ($a \ll 1$), can support propagation of at least a single soliton, remained open however. This problem was first addressed by Pelinovsky and Stepanyants[11] who considered linear approximation in the pulse propagation. The linear part of the BO equation (1.1) has a self-similar solution preserving the area (1.2),

$$u = \frac{1}{t^{1/2}} U\left(\frac{x}{t^{1/2}} \right),$$

i.e., the characteristic amplitude and length of an initial pulse evolves as $U_0 \sim t^{-1/2}$ and $L_0 \sim t^{1/2}$, so that the Ursell parameter σ is effectively constant in time. These arguments imply that an initially small wave disturbance with $\sigma \ll 1$ remains effectively linear for all times t and hence does not support propagation of a soliton since the latter realizes a balance of nonlinear and dispersive effects for the finite value of σ.

Another way to predict the existence of a threshold for the soliton generation (see Ref. 8) is to use the fact that the area (1.2) is invariant for soliton solutions of Eq. (1.1). A single soliton is

$$u = u_s(x - vt) = \frac{2v}{1 + v^2 (x - vt - x_0)^2}, \tag{1.4}$$

where x_0, v are arbitrary parameters with the constraint $v > 0$. Using Eqs. (1.2) and (1.4), one concludes that $\mathcal{M}_s = \mathcal{M}[u_s] = 2\pi$, and thus the area does not depend on the amplitude of the soliton. For the mKdV equation, this property is related to the existence of threshold on the soliton generation, where perturbations with $\mathcal{M}[u] \leqslant \frac{1}{2}\mathcal{M}_s$ do not support a soliton.[5] Direct numerical simulations of the BO equation did not display formation of a soliton for an initial perturbation with $\mathcal{M} < \mathcal{M}_s$ (see Fig. 2 in Ref. 8). However, contrary to these preliminary predictions, we show that a soliton can still be generated in the BO equation (1.1) by a small initial perturbation without a threshold.

The problem at the center of the analysis is the linear spectral problem associated with the potential $u(x)$,

$$i\phi_x^+ + k(\phi^+ - \phi^-) = -u(x)\phi^+, \tag{1.5}$$

where k is a spectral parameter and $\phi^{\pm}(x)$ are the limit values, when x tends to the real axis, of analytical functions in upper/lower half-planes of x. The pioneer analysis of direct and inverse scattering problems for Eq. (1.5) was developed by Fokas and Ablowitz,[12] who showed that the continuous spectrum is located for real positive values of k while the discrete spectrum consists of isolated nondegenerate eigenvalues for real negative values of k. Various aspects of the spectral theory including in particular the complicated asymptotic behavior of the Jost functions (the eigenfunctions associated with the continuous spectrum) were addressed by many authors.[13–18]

Based on the ''improved'' eigenfunctions (i.e., those free of secular divergences at $k \to 0^+$), Coifman and Wickerhauser[15] proved that the scattering problem (1.5) has no bound states in a neighborhood of the origin, if $u(x) \to O(|x|^{-1-\mu})$, $\mu > 0$ (Theorem 7.1 of Ref. 15). Although this result seems to agree with qualitative arguments mentioned above, direct analysis of the problem (1.5) for the algebraic potential $u(x) = 2a/(1+x^2)$ did reveal the existence of a single negative eigenvalue for $0 < a < 1$.[10] The eigenvalue approaches zero very fast as $a \to 0^+$ and this fact makes the detection of the eigenvalue difficult for a small.

The reason for apparent discrepancy between the analytical and numerical results is caused by a very special structure of the Jost functions in the limit $k \to 0^+$. Theorem 7.1 of Ref. 15 is valid for *generic* potentials satisfying $n_0 \neq 0$, where

$$n_0 = \frac{1}{2\pi} \int_{-\infty}^{+\infty} u(x) n(x) dx. \tag{1.6}$$

Here $n(x)$ is the limiting Jost function (see Eq. (2.13) below) which is logarithmically divergent as $k \to 0^+$. However, if the potential is *nongeneric*, i.e., it satisfies $n_0 = 0$, then the limiting Jost function is bounded in the limit $k \to 0^+$ and properties of the scattering problem are modified.[16,17] The zero potential $u(x) = 0$ as well as soliton solutions are particular examples of nongeneric potentials.

Recently, Kaup *et al.*[18] proved the completeness relation for the problem (1.5) and calculated variations of the scattering data under the action of a perturbation of the potential $u(x)$. These variational formulas are derived for generic potentials when the number of bound states is invariant under small perturbations of a potential.

In this paper we study the perturbation of nongeneric potentials where the number of bound states may change depending on the type of the perturbation. More precisely, we consider a potential $u(x)$ in the form $u^\epsilon = u(x) + \epsilon \Delta u(x)$, where $\epsilon \ll 1$ and $u(x)$ satisfies the constraint $n_0 = 0$. In the particular case $u(x) = 0$, this problem reduces to the problem of soliton generation by a small initial perturbation. We derive a criterion for a new eigenvalue to emerge from the edge of the continuous spectrum at $k = 0$. In particular, new eigenvalues may always appear due to perturbations of the zero background and the soliton solutions. We find that the asymptotic behavior of the new eigenvalue is *exponentially small* in terms of the parameter of the perturbation ϵ and obtain the corresponding bound state and the perturbed Jost functions of the continuous spectrum.

This result is to be compared to the classical spectral problem for the Schrödinger operator $-\Delta \psi + \epsilon V(x) \psi = \lambda \psi$, with $\epsilon \ll 1$.[19,20] As above, the problem is to find the condition on the potential so that there exists an eigenvalue λ that bifurcates from the edge of the continuous spectrum, and to compute, as $\epsilon \to 0$, its asymptotic value and the corresponding eigenfunction. In one space dimension, the bifurcation occurs when $\mathcal{M} = \int_{-\infty}^{\infty} V(x) dx < 0$ and one finds the eigenvalue $\lambda \sim -\epsilon^2 \mathcal{M}^2/4$.[19] The situation is more complex in two dimensions even with a radially symmetric potential. The criterion for the bifurcation to occur is $\mathcal{M} = \int_0^{\infty} V(r) r dr < 0$ and the eigenvalue is $\lambda \sim -\lambda_0 \exp(2/\epsilon \mathcal{M})$, where λ_0 can be calculated explicitly in terms of integrals of the potential.[21] Note that the behavior of the new eigenvalue for the BO spectral problem is very similar to the latter case.

For the Schrödinger spectral problem, the analysis of the bifurcation can be performed by various methods such as a direct two-scale asymptotic expansion technique,[19] the analysis based on the positive definiteness of the self-adjoint operators,[20] the analysis involving the Green's function representation,[21] or the study of analytical behavior of transmission coefficients in the scattering problem or, their generalizations given by the Evans' function.[22]

The BO spectral problem has the form of an integro-differential equation which make direct applications of the above methods difficult. In this article, we develop a new approach based on the completeness of Jost functions of the unperturbed problem.

The plan of this article is as follows. In Sec. II we recall the main results on the spectral properties of Eq. (1.5). The regular perturbation theory is described in Sec. III. The bifurcation of a new negative eigenvalue from the origin cannot be obtained through a regular perturbation method and we develop a revised method in Sec. IV to analyze this bifurcation. We derive the leading order terms for the new eigenvalue and for the associated bound state at short and large distances, as well as for the variation of the continuous spectrum data. Explicit expressions are given in Sec. V for the soliton potentials. Section VI is devoted to discussions. Appendix A gives useful relations for eigenfunctions of the BO scattering problem and Appendix B presents new relations for the roots of the Laguerre polynomials which appear in the course of our analysis.

II. SPECTRAL PROPERTIES OF THE BO ASSOCIATED PROBLEM

In this section, we recall some basic results on the direct scattering problem (1.5) that will be used in the analysis. We assume that the potential $u=u(x)$ is real and has a sufficient decay to ensure the convergence of the area integral (1.2), i.e., $u\sim O(|x|^{-2-\mu})$ as $x\to\infty$, $\mu>0$. The details and proofs of these results can be found in Refs. 12 and 17.

A. Spectrum and scattering data

For all $k>0$, there are two solutions N and $\overline{N}$ (the Jost functions) to Eq. (1.5), defined by their boundary conditions as $x\to\infty$,

$$\overline{N}(x,k)\to 1, \quad N(x,k)\to e^{ikx}. \tag{2.1}$$

Using the projection operators

$$P^{\pm}(v)=\pm\frac{1}{2\pi i}\int_{-\infty}^{+\infty}\frac{v(y)dy}{y-(x\pm i0)}=\frac{1}{2}\,(v\mp iHv), \tag{2.2}$$

it is proved that $\overline{N}$ and N satisfy the integro-differential equations

$$i\overline{N}_x+k\overline{N}=-P^{+}(u\overline{N})+k, \tag{2.3a}$$

$$iN_x+kN=-P^{+}(uN). \tag{2.3b}$$

Equation (2.1) has also a discrete number of bound states $\{\Phi_j(x)\}_{j=1}^{m}$, where m is finite, associated to discrete eigenvalues $k_j<0$. They satisfy

$$i\Phi_{jx}+k_j\Phi_j=-P^{+}(u\Phi_j), \tag{2.3c}$$

with the boundary condition

$$\Phi_j(x)\to\frac{1}{x} \text{ as } x\to\infty.$$

We denote ϕ^{+} the set of eigenfunctions $\phi^{+}=\{\overline{N}(x,k);N(x,k);\{\Phi_j(x)\}_{j=1}^{m}\}$. Alternatively, one can consider the set of eigenfunctions $\{M(x,k);\overline{M}(x,k);\{\Phi_j(x)\}_{j=1}^{m}\}$ which satisfy the same equations (2.3) but with the left-side boundary conditions

$$M(x,k)\to 1, \quad \overline{M}(x,k)\to e^{ikx}, \quad \Phi_j(x)\to\frac{1}{x}, \tag{2.4}$$

as $x\to-\infty$. These two sets are related by the scattering equations

$$M(x,k)-\overline{N}(x,k)=\beta(k)N(x,k), \quad \overline{M}(x,k)=\Gamma(k)N(x,k), \quad k>0. \tag{2.5}$$

In the case of a real potential $u(x)$, the scattering coefficients are given by[17]

$$\Gamma(k)=\exp\left[\frac{1}{2\pi i}\int_0^k\frac{|\beta(k')|^2}{k'}\,dk'\right] \tag{2.6a}$$

and

$$\beta(k)=i\int_{-\infty}^{\infty}u(x)N^{*}(x,k)dx. \tag{2.6b}$$

The scattering equation (2.5) relates the functions $M(x,k)$ and $\overline{N}(x,k)$ which are analytic in $\mathrm{Im}(k)>0$ and $\mathrm{Im}(k)<0$, respectively. It has the form of a Riemann–Hilbert problem.[3] In Ref. 12, Fokas and Ablowitz derived a solution of this Riemann–Hilbert problem for the function $\overline{N}(x,k)$ at $\mathrm{Im}(k)\leqslant 0$, in terms of $N(x,k)$ for real k,

$$\overline{N}(x,k)=1-i\sum_{j=1}^{m}\frac{\Phi_j(x)}{k-k_j}+\frac{1}{2\pi i}\int_0^\infty \frac{\beta(k')N(x,k')dk'}{k'-(k-i0)}. \tag{2.7}$$

Here simple poles correspond to the discrete spectrum located at m negative eigenvalues $k_j<0$ while the integral represents the contribution from the continuous spectrum located for $k>0$. The scattering data form a closed system when Eq. (2.7) is coupled with the relation,

$$\frac{\partial N(x,k)}{\partial k}=ixN(x,k)+\frac{\beta^*(k)}{2\pi ik}\overline{N}(x,k) \tag{2.8a}$$

and the limiting behavior of $\overline{N}(x,k)$ as $k\to k_j$ is to be used,

$$\lim_{k\to k_j}\left[\overline{N}(x,k)+\frac{i\Phi_j(x)}{k-k_j}\right]=(x+\gamma_j)\Phi_j(x), \tag{2.8b}$$

where γ_j are the phase constants. The spectral data $\{k_j,\gamma_j\}_{j=1}^m$ can be expressed through the eigenfunctions $\Phi_j(x)$ according to the expressions,

$$k_j=\frac{1}{2\pi i}\int_{-\infty}^{\infty}u(x)\Phi_j(x)dx \tag{2.9a}$$

and

$$\gamma_j=\frac{1}{2\pi k_j}\int_{-\infty}^{\infty}x|\Phi_j(x)|^2dx-\frac{i}{2k_j}. \tag{2.9b}$$

Equation (2.9a) follows from Eq. (2.3c) (see Refs. 12 and 17), while Eq. (2.9b) can be obtained from Eq. (A4a) of Appendix A.

It was recently found for other spectral problems of inverse scattering[23] that the coalescence of two simple poles may occur and, in this case, the proper solution to the Riemann–Hilbert problem must include also multiple poles corresponding to degenerate eigenvalues. However, this coalescence is not possible for the BO spectral problem (1.5) associated with the real potentials. Indeed, suppose that $k_1=k_2+\epsilon$, where $\epsilon\ll 1$ and expand a solution to Eqs. (2.7) and (2.8) into an asymptotic series,[23]

$$\begin{cases}\Phi_1=-\dfrac{1}{\epsilon}\,\Phi^{(-1)}(x)+\Phi_1^{(0)}(x)+O(\epsilon),\\ \Phi_2=\dfrac{1}{\epsilon}\,\Phi^{(-1)}(x)+\Phi_2^{(0)}(x)+O(\epsilon),\end{cases} \tag{2.10a}$$

$$\begin{cases}\gamma_1=\dfrac{i}{\epsilon}+\gamma^{(0)}+O(\epsilon),\\ \gamma^2=-\dfrac{i}{\epsilon}+\gamma^{(0)}+O(\epsilon).\end{cases} \tag{2.10b}$$

This expansion provides a double pole in the limit $\epsilon\to 0$ for the function $\overline{N}(x,k)$ and satisfy the limiting relations (2.8b). However, it contradicts the balance prescribed by Eq. (2.9b), the latter being valid for real potential $u(x)$. Therefore, multiple poles are not present in the representation (2.7) and the eigenvalues $k=k_j$ for $j=\overline{1,m}$ are all simple.

The spectral data $\{\beta(k)\},\{k_j,\gamma_j\}_{j=1}^m$ characterize the BO equation as a completely integrable system[18] and they can be calculated from the Jost functions $N(x,k)$ and the bound states $\Phi_j(x)$ by means of Eqs. (2.6) and (2.9). The functions $N(x,k)$ and $\Phi_j(x)$ satisfy a self-consistent system of integral and algebraic equations[17] which is a crucial step in inverse scattering. The potential $u(x,t)$ can be recovered for $t\geqslant 0$ by means of the formula,

$$u=\frac{1}{2\pi i}\int_0^\infty \beta(k')N(x,k')dk'+i\sum_{j=1}^m \Phi_j(x)+\text{c.c.} \tag{2.11}$$

if the time evolution of the spectral data is taken into account.[12,17] Inverse scattering results will not be used for the problem under consideration. Instead, we mention the well-known fact[12] that the continuous spectrum of the scattering problem (1.5) corresponds to the dispersive wave packets (radiation) induced by the initial potential $u(x)$ while the bound states of the discrete spectrum correspond to solitons (1.4) with the parameters $v=-2k_j$ and $x_0=-\text{Re}(\gamma_j)$. These parameters induced by the initial potential are constant in the time, while the solitons become separated due to different values of their velocities.

B. Asymptotic behavior of the Jost functions

The asymptotic behavior of the Jost functions and of the scattering data as $k\to 0^+$ can be studied by means of their Green's function representation.[16,17] For generic potentials, the Jost functions vanish as $k\to 0^+$ according to the scaling approximation,

$$N(x,k)\to\frac{n(x)}{1+n_0(\gamma+\ln(ik))}+O\left(\frac{k}{\ln k}\right), \tag{2.12}$$

where $\gamma\approx 0.577$ is the Euler's constant, n_0 is defined by Eq. (1.6) and $n(x)$ satisfies

$$in_x=-P^+(un). \tag{2.13a}$$

Equivalently, $n(x)$ is the unique solution to the integral equation

$$n(x)=1-i\int_x^\infty u(y)n(y)dy-\frac{1}{2\pi}\int_{-\infty}^\infty u(y)n(y)\ln(x-y-i0)dy. \tag{2.13b}$$

We notice that the representation (2.12) describes an improved approximation for the asymptotic behavior of the Jost function compared to the conventional expansion,[13]

$$N(x,k)\to\frac{n(x)}{n_0\ln k}+O\left(\frac{1}{(\ln k)^2}\right). \tag{2.14a}$$

Using Eqs. (2.6) and (2.14a) we find the uniform asymptotic representation for the scattering coefficients as $k\to 0^+$,

$$\beta(k)\to\frac{2\pi i}{\ln k}+O\left(\frac{1}{(\ln k)^2}\right),\quad \Gamma(k)=1+\frac{2\pi i}{\ln k}+O\left(\frac{1}{(\ln k)^2}\right). \tag{2.14b}$$

It follows from Eq. (2.13b) that the limiting function $n(x)$ is logarithmically secular and violates the boundary condition (2.1)

$$n(x)\to\begin{cases}1-n_0\ln x & \text{as } x\to\infty\\ 1-n_0\,\text{Ln}\,x & \text{as } x\to\text{-}\infty,\end{cases} \tag{2.15}$$

where Ln x is the principal value of the logarithmic function. Thus, the limiting point $k=0$ does not belong to the continuous spectrum for generic potentials, i.e., $N(x,k)\to 0$ as $k\to 0^+$.

On the contrary, the condition $n_0=0$ defines a class of nongeneric potentials which include the zero background $u(x)=0$ and soliton solutions. In this case, the limiting function $n(x)$ is not secular [see Eq. (2.15)] and the limiting point $k=0$ *does* belong the continuous spectrum, i.e.,

$$N(x,k) \to n(x) + k n_1(x) + O(k^2 \ln k), \tag{2.16a}$$

and

$$\beta(k) \to k\beta_1 + O(k^2 \ln k)$$

$$\Gamma(k) \to 1 + \frac{|\beta_1|^2}{4\pi i} k^2 + O(k^3 \ln k) \tag{2.16b}$$

as $k \to 0^+$. In order to prove validity of the expansions (2.16), we use the relations (2.6b) and (2.8a) in the limit $k \to 0^+$. At leading order, $N(x,k) \sim n(x)$ as $k \to 0^+$.[17] As a result, we find from Eq. (2.8a) the following representation for $n_1(x)$:

$$n_1(x) = i\left(x - \frac{\beta_1^*}{2\pi} \right) n(x), \tag{2.17a}$$

and from Eq. (2.6b) the explicit formula for β_1,

$$\beta_1 = \text{p.v.} \int_{-\infty}^{\infty} x u(x) n^*(x) dx. \tag{2.17b}$$

Any perturbation to the nongeneric potential changes the asymptotic behavior as $k \to 0^+$ and may lead to the occurrence of a new bound state for $k < 0$. This bifurcation is studied in Sec. IV.

C. Number of bound states

For both generic and nongeneric potentials, the total area (1.2) is related to the number of bound states m by

$$\mathcal{M}[u] = 2\pi m - \frac{1}{2\pi} \int_0^{\infty} \frac{|\beta(k)|^2}{k} \, dk. \tag{2.18}$$

To obtain this formula (see Ref. 17), one writes Eq. (2.7) at $k = 0$, multiplies it by u and integrates over $\mathbf{R}$. The integral $\int_{-\infty}^{\infty} u(x) N(x,0) dx = 0$ for both generic and nongeneric potentials. The other terms are evaluated using Eqs. (2.6b) and (2.9a).

Another way to see that

$$\frac{1}{2\pi} \left(\mathcal{M}[u] + \frac{1}{2\pi} \int_0^{\infty} \frac{|\beta(k)|^2}{k} dk \right)$$

is an integer is to take the limit $k \to \infty$, $x \to -\infty$ in the second equation (2.5) and to use Eqs. (2.4), (2.6a) as well as the asymptotic representation of $N(x,k)$ for $k \to \infty$,[17]

$$N(x,k) \sim \exp\left[ikx - i \int_x^{\infty} u(x) dx \right] \quad \text{for real } x. \tag{2.19}$$

In agreement with the distribution (1.3) for large m, the positive regions of the potential $u(x)$ give birth to bound states (solitons) while the negative regions are sources of continuous spectrum (radiation).

III. REGULAR PERTURBATION THEORY

Suppose that the scattering problem (1.5) for $u = u(x)$ has m bound states $\Phi_j(x)$ for $k = k_j < 0$, $j = 1,m$ and let $N(x,k)$ be the Jost functions for $k > 0$. In Ref. 18, Kaup *et al.* proved the orthogonality conditions

$$\int_{-\infty}^{\infty} N^*(x,k') N(x,k) dx = 2\pi \delta(k - k'), \tag{3.1a}$$

$$\int_{-\infty}^{\infty} N^*(x,k)\Phi_j(x)dx=0, \tag{3.1b}$$

$$\int_{-\infty}^{\infty} \Phi_l^*(x)\Phi_j(x)dx=-2\pi k_j\delta_{jl} \tag{3.1c}$$

as well as the completeness relation,

$$\int_0^{\infty} N^*(y,k)N(x,k)dk-\sum_{j=1}^{m} \frac{\Phi_j^*(y)\Phi_j(x)}{k_j}=\frac{-i}{y-(x+i0)}. \tag{3.2}$$

Any function $\Phi^+(x)$ such that $\Phi^+\sim O(|x|^{-1-\mu})$ as $x\to\infty$, $\mu\geqslant 0$, can be expanded over the basis $\{N(x,k);\{\Phi_j(x)\}_{j=1}^m\}$ as follows

$$\Phi^+(x)=\int_0^{\infty} \frac{\alpha(k)N(x,k)}{k-\kappa}\,dk+\sum_{j=1}^{m} \frac{\alpha_j\Phi_j(x)}{k_j-\kappa}, \tag{3.3}$$

where $\alpha(k)$, α_j are coefficients of the expansion and the arbitrary parameter κ is introduced for convenience in the following analysis and will be specified in the next subsection. The coefficients $\alpha(k)$ and α_j can be expressed through the function $\Phi^+(x)$ using the orthogonality relations (3.1).

A classical problem of perturbation theory is to study variations of the spectral data subject to a small variation of the potential. We assume that the perturbed potential is expressed as $u^\epsilon(x)=u(x)+\epsilon\Delta u(x)$, where $\epsilon\ll 1$, and the functions $u(x)$ and $\Delta u(x)$ decay at infinity as $u(x),\Delta u(x)\sim O(|x|^{-2-\mu})$ with $\mu\geqslant 0$. Here and in subsequent sections, we study the variations of the spectral data for perturbed generic and nongeneric potentials.

A. Variations of data of the discrete spectrum

Suppose that $\Phi^+(x)$ solves Eq. (2.3c) with $u^\epsilon=u(x)+\epsilon\Delta u(x)$ and κ is the corresponding eigenvalue. The linear eigenvalue problem (2.3c) can be reduced to a set of integral equations for the coefficients $\alpha(k)$ and α_j in the form

$$\alpha(k)=\frac{\epsilon}{2\pi}\left[\int_0^{\infty} \frac{K(k,k')\alpha(k')}{k'-\kappa}\,dk'+\sum_{j=1}^{m} \frac{K_j(k)\alpha_j}{k_j-\kappa}\right], \tag{3.4a}$$

$$\alpha_j=-\frac{\epsilon}{2\pi k_j}\left[\int_0^{\infty} \frac{K_j^*(k')\alpha(k')}{k'-\kappa}\,dk'+\sum_{l=1}^{m} \frac{K_{jl}\alpha_l}{k_l-\kappa}\right], \tag{3.4b}$$

where

$$K(k,k')=\int_{-\infty}^{\infty}\Delta u(x)N^*(x,k)N(x,k')dx,$$

$$K_j(k)=\int_{-\infty}^{\infty}\Delta u(x)N^*(x,k)\Phi_j(x)dx,$$

$$K_{jl}=\int_{-\infty}^{\infty}\Delta u(x)\Phi_j^*(x)\Phi_l(x)dx.$$

Consider a particular eigenvalue $\kappa=k_j^\epsilon<0$ and the corresponding bound state $\Phi^+=\Phi_j^\epsilon(x)$. The analysis of Eq. (3.4b) shows that the asymptotic balance is satisfied by the following Taylor expansion:

$$k_j^\epsilon=k_j+\epsilon\Delta k_j+\epsilon^2\Delta_2 k_j+O(\epsilon^3) \tag{3.5a}$$

and

$$\alpha_j=(k_j-k_j^\epsilon)(1+\epsilon\alpha_j^{(1)}+O(\epsilon^2)), \tag{3.5b}$$

$$\alpha_l=-\frac{\epsilon K_{lj}}{2\pi k_l}+O(\epsilon^2), \quad l\neq j, \tag{3.5c}$$

$$\alpha(k)=\frac{\epsilon K_j(k)}{2\pi}+O(\epsilon^2). \tag{3.5d}$$

The correction Δk_j is obtained from Eq. (3.4b) as

$$\Delta k_j=\frac{1}{2\pi k_j}K_{jj}. \tag{3.6}$$

We then proceed with the first-order correction term in $\Phi_j^\epsilon(x)$ which is given through Eqs. (3.3) and (3.4) as $\Phi_j^\epsilon=\Phi_j+\epsilon\Delta\Phi_j+O(\epsilon^2)$, where

$$\Delta\Phi_j=\alpha_j^{(1)}\Phi_j+\frac{1}{2\pi}\int_0^\infty\frac{K_j(k)N(x,k)}{k-k_j}\,dk-\sum_{l\neq j}\frac{K_{lj}\Phi_l(x)}{2\pi k_l(k_l-k_j)}. \tag{3.7}$$

The constant $\alpha_j^{(1)}$ can be found from the boundary condition (2.3) by removing the $O(x^{-1})$ term as $x\to\infty$. Using the boundary conditions (A3) of Appendix A this leads to the expression,

$$\alpha_j^{(1)}=\sum_{l\neq j}\frac{K_{lj}}{2\pi k_l(k_l-k_j)}-\frac{K_j(0)}{2\pi i k_j}-\frac{1}{4\pi^2}\int_0^\infty\frac{\beta^*(k)K_j(k)}{k(k-k_j)}\,dk. \tag{3.8a}$$

This formula is equivalent to that given in Ref. 18,

$$\alpha_j^{(1)}=-\frac{1}{2\pi i k_j}\int_{-\infty}^\infty\Delta u(x)(x+\gamma_j)|\Phi_j(x)|^2dx. \tag{3.8b}$$

In order to prove this, we rewrite Eq. (3.8b) as

$$\alpha_j^{(1)}=-\frac{1}{2\pi i k_j}\left(\int_{-\infty}^\infty P^+(\Delta u\Phi_j)dx+\int_{-\infty}^\infty(x+\gamma_j)\Phi_j^*P^+(\Delta u\Phi_j)dx\right). \tag{3.9}$$

Using the completeness formula (3.2) we represent $P^+(\Delta u\Phi_j)$ as

$$P^+(\Delta u\Phi_j)=\frac{1}{2\pi}\int_0^\infty K_j(k)N(x,k)dk-\sum_{l=1}^m\frac{K_{lj}\Phi_l(x)}{2\pi k_l}. \tag{3.10}$$

Substituting Eq. (3.10) into Eq. (3.9) and using Eqs. (A2) and (A4) of Appendix A we recover Eq. (3.8a).

Applying the same method, we expand the relations (2.9) into the asymptotic series for k_j^ϵ [see Eq. (3.5a)] and for γ_j^ϵ, $\gamma_j^\epsilon=\gamma_j+\epsilon\Delta\gamma_j+O(\epsilon^2)$. The first-order perturbation terms are thus expressed as

$$\Delta k_j=\frac{1}{2\pi i}\int_{-\infty}^\infty(\Delta u\Phi_j+u\Delta\Phi_j)dx, \tag{3.11a}$$

$$\Delta\gamma_j=\frac{1}{2\pi k_j}\int_{-\infty}^\infty(x+\gamma_j)(\Phi_j\Delta\Phi_j^*+\Phi_j^*\Delta\Phi_j)dx. \tag{3.11b}$$

Substitution of Eqs. (3.7) and (3.10) into (3.11a) reproduces the result (3.6), while substitution of Eqs. (3.7), (3.8a), and (A4) into Eq. (3.11b) leads to the expression,

$$\Delta\gamma_j = -\frac{1}{2\pi k_j^2}\int_{-\infty}^{\infty}\Delta u(x)(x+\gamma_j)|\Phi_j(x)|^2dx - \frac{i}{2\pi k_j}\sum_{l\neq j}\frac{K_{lj}-K_{jl}}{(k_l-k_j)^2} + \frac{i}{4\pi^2 k_j}\int_0^{\infty}\frac{\beta^*(k)K_j(k)-\beta(k)K_j^*(k)}{(k-k_j)^2}\,dk. \tag{3.12}$$

The formulas (3.6)–(3.8) and (3.12) coincide with the variational derivatives found in Ref. 18 with a different approach. In addition, we find from Eq. (3.4b) the second-order correction to the eigenvalue,

$$\Delta_2 k_j = \frac{1}{2\pi k_j}\left(\int_0^{\infty}\frac{|K_j(k)|^2}{k-k_j}\,dk - \sum_{l\neq j}\frac{|K_{jl}|^2}{2\pi k_l(k_l-k_j)}\right). \tag{3.13}$$

These results are valid both for generic and nongeneric potentials, i.e., those with the asymptotic behavior (2.14) and (2.16), respectively. The variations of data of the discrete spectrum for the BO spectral problem are similar to standard form of perturbation theory in quantum mechanics.[19]

B. Variations of data of the continuous spectrum

The perturbation theory for the Jost function can be constructed with the help of a modified integral representation,

$$N^{\epsilon}(x,\kappa) = N(x,\kappa) + \int_0^{\infty}\frac{\alpha(k,\kappa)N(x,k)}{k-(\kappa-i0)}\,dk + \sum_{j=1}^{m}\frac{\alpha_j(\kappa)\Phi_j(x)}{k_j-\kappa}, \tag{3.14}$$

where $N^{\epsilon}(x,\kappa)$ solves Eq. (2.3b) for $u^{\epsilon}=u(x)+\epsilon\Delta u(x)$ and $k=\kappa$. According to the boundary conditions (2.1), (2.4) and the scattering problem (2.5), Eq. (3.14) reduces in the limit $x\to-\infty$ to the following relation:

$$\frac{1}{\Gamma^{\epsilon}(k)} - \frac{1}{\Gamma(k)} = -\frac{2\pi i\alpha(k,k)}{\Gamma(k)}. \tag{3.15}$$

The coefficients $\alpha(k,\kappa)$ and $\alpha_j(\kappa)$ satisfy a system of integral equations modified compared to Eqs. (3.4),

$$\alpha(k,\kappa) = \frac{\epsilon}{2\pi}\left[K(k,\kappa) + \int_0^{\infty}\frac{K(k,k')\alpha(k',\kappa)}{k'-(\kappa-i0)}\,dk' + \sum_{j=1}^{m}\frac{K_j(k)\alpha_j(\kappa)}{k_j-\kappa}\right], \tag{3.16a}$$

$$\alpha_j(\kappa) = -\frac{\epsilon}{2\pi k_j}\left[K_j^*(\kappa) + \int_0^{\infty}\frac{K_j^*(k')\alpha(k',\kappa)}{k'-(\kappa-i0)}\,dk' + \sum_{l=1}^{m}\frac{K_{jl}\alpha_l(\kappa)}{k_l-\kappa}\right]. \tag{3.16b}$$

As $\epsilon\to 0$, these integral equations can be solved by a Taylor expansion,

$$\alpha(k,\kappa) = \frac{\epsilon}{2\pi}K(k,\kappa) + O(\epsilon^2), \tag{3.17a}$$

$$\alpha_j(\kappa) = -\frac{\epsilon}{2\pi k_j}K_j^*(\kappa) + O(\epsilon^2). \tag{3.17b}$$

Using this explicit asymptotic behavior, the spectral coefficient can also be expanded in the Taylor series, $\Gamma^{\epsilon}(k)=\Gamma(k)+\epsilon\Delta\Gamma(k)+O(\epsilon^2)$, where

$$\frac{\Delta\Gamma(k)}{\Gamma(k)} = iK(k,k). \tag{3.18}$$

Since $\lim_{k\to\infty}K(k,k)=\int_{-\infty}^{\infty}\Delta u(x)dx\equiv\Delta\mathcal{M}$, it follows from Eqs. (2.6a) and (3.18) that

$$\Delta \mathcal{M} = -\frac{1}{2\pi} \Delta \int_0^\infty \frac{|\beta(k)|^2}{k}\, dk. \tag{3.19}$$

This relation is nothing but the variation of Eq. (2.18) which proves that the number m of solitons is invariant under a small change of the potential, i.e., $\Delta m = 0$. However, this result as well as formulas (3.17)–(3.19) of the regular perturbation theory are valid only for generic potentials. When the potential is nongeneric, i.e., it possesses the asymptotic representation (2.16), the regular perturbation theory fails in the limit $k \to 0^+$. Indeed, using Eqs. (2.16) we find that

$$\Delta \Gamma(0) = i \int_{-\infty}^{\infty} \Delta u(x) |n(x)|^2 dx \neq 0. \tag{3.20}$$

This result contradicts the asymptotic behavior (2.14b), which provides $\Delta\Gamma(k) \to 0$ as $k \to 0^+$. For comparison, the relation (3.18) for generic potentials exhibits the limit behavior, $\Delta\Gamma(k) \sim O((\ln k)^{-2})$ as $k \to 0^+$ which is in agreement with Eq. (2.14b). The reason for failure of the regular perturbation theory is related to the fact that the integral in Eq. (3.14) becomes singular as $\kappa \to 0^+$. Thus, the perturbation theory must be revised for perturbations of the nongeneric potentials. This revision is closely related to analysis of bifurcation of a new eigenvalue in a neighborhood of $k = 0$.

IV. REVISED PERTURBATION THEORY

Since multiple degenerate eigenvalues are not permitted in the BO spectral problem, as shown in Sec. II A, the only possible bifurcation may be a formation of a new bound state from the delocalized limiting eigenfunction of the continuous spectrum. In this section we show that this bifurcation can happen due to perturbations of the nongeneric potentials. Using the integral representation (3.3) and (3.4) we find the asymptotic approximations for the new eigenvalue and the corresponding eigenfunction.

A. Asymptotic series for a new eigenvalue

Suppose that $\kappa = k_{m+1} = -p(\epsilon)$, where k_{m+1} is a new eigenvalue detaching from the continuum as $\epsilon \to 0$ and $p(\epsilon) > 0$. The integral in Eq. (3.4a) is singular as $\kappa \to 0^-$ unless $K(k,0) = 0$. The latter condition is always true for the generic potentials since $N(x,k)$ vanishes in the limit $k \to 0^+$. However, for nongeneric potentials, since $N(x,0) \sim n(x)$ [see Eq. (2.16a)], $K(k,0)$ is generally nonzero. Thus, the singularity in Eq. (3.4a) is of resonance pole type and accounts for a nontrivial solution of integral equations which corresponds to a new bound state $\Phi^+ = \Phi_{m+1}(x)$.

In order to construct an asymptotic solution to Eqs. (3.4) at $\kappa = -p(\epsilon)$ we evaluate the singular contribution explicitly,

$$\alpha(k) = -\frac{\epsilon}{2\pi} \ln\left(\frac{p}{1+p}\right) K(k,0)\alpha(0) + \frac{\epsilon}{2\pi}\left[\int_0^1 \frac{K(k,k')\alpha(k') - K(k,0)\alpha(0)}{k'+p}\, dk' + \int_1^\infty \frac{K(k,k')\alpha(k')}{k'+p}\, dk' + \sum_{j=1}^m \frac{K_j(k)\alpha_j}{k_j+p}\right]. \tag{4.1}$$

[The other equation (3.4b) can be transformed in a similar manner.] We notice that the integrals in Eq. (4.1) are now free of singular terms in the limit $p(\epsilon) \to 0^+$. [Still a Taylor expansion with respect to $p(\epsilon)$ would lead to new (weak) singular terms in Eq. (4.1). This modification is required only for calculation of exponentially small corrections of the asymptotic series (4.2) and will be neglected henceforth.] The asymptotic balance of the singular term occurs for $\epsilon \ln p \sim O(1)$ as $\epsilon \to 0$. Thus, the new eigenvalue is exponentially small in terms of ϵ. Under the balance above, the asymptotic series solving Eq. (4.1) can be presented in the form,

$$\ln p = \frac{1}{\epsilon} p_{-1} + \sum_{l=0}^{\infty} \epsilon^l p_l + O(\epsilon^{-1} p(\epsilon)), \tag{4.2a}$$

$$\alpha(k)=\alpha_0(k)+\sum_{l=1}^{\infty}\epsilon^l\alpha_l(k)+O(p(\epsilon)), \tag{4.2b}$$

$$\alpha_j=\alpha_j^{(0)}+\sum_{l=1}^{\infty}\epsilon^l\alpha_j^{(l)}+O(p(\epsilon)). \tag{4.2c}$$

We require $p_{-1}<0$ to ensure the eigenvalue $p=p(\epsilon)$ to be small in the limit $\epsilon\to 0$. All terms of the Taylor series for $\alpha(k)$ and α_j can be found recursively in an explicit form from Eq. (4.1) by neglecting the exponentially small residue terms, i.e., the terms containing the eigenvalue p. We confine our analysis only to the leading-order and first-order approximations in these asymptotic series. The leading order term is

$$\alpha_0(k)=-\frac{p_{-1}}{2\pi}K(k,0)\alpha_0(0). \tag{4.3}$$

The coefficient p_{-1} follows from this equation in the limit $k\to 0$,

$$p_{-1}=-\frac{2\pi}{K(0,0)}. \tag{4.4}$$

Since the restriction $p_{-1}<0$ was assumed in Eq. (4.2a), the following criterion,

$$K(0,0)=\int_{-\infty}^{\infty}\Delta u(x)|n(x)|^2dx>0, \tag{4.5}$$

should be satisfied for the bifurcation of the new eigenvalue $k=k_{m+1}=-p(\epsilon)$ to occur.

In order to find the pre-exponential factor p_0 in the asymptotic expansion for $p=p(\epsilon)$, we derive from Eqs. (3.4b) and (4.1) the following expressions for $\alpha_j^{(0)}$ and $\alpha_1(k)$:

$$\alpha_j^{(0)}=-\frac{K_j^*(0)}{k_jK(0,0)}\alpha_0(0) \tag{4.6a}$$

and

$$\begin{aligned}\alpha_1(k)=&\frac{K(k,0)}{K(0,0)}\alpha_1(0)-\frac{p_0}{2\pi}K(k,0)\alpha_0(0)\\&+\frac{\alpha_0(0)}{2\pi K(0,0)}\left[\int_0^1\frac{K(k,k')K(k',0)-K(k,0)K(0,0)}{k'}dk'\right.\\&\left.+\int_1^{\infty}\frac{K(k,k')K(k',0)}{k'}dk'-\sum_{j=1}^{m}\frac{K_j(k)K_j^*(0)}{k_j^2}\right].\end{aligned} \tag{4.6b}$$

Then, the coefficient p_0 follows from Eq. (4.6b) in the limit $k\to 0$,

$$\begin{aligned}p_0=&\frac{1}{[K(0,0)]^2}\int\int_{-\infty}^{\infty}\Delta u(x)\Delta u(y)n^*(x)n(y)dxdy\left[\int_0^1\frac{N^*(y,k)N(x,k)-n^*(y)n(x)}{k}dk\right.\\&\left.+\int_1^{\infty}\frac{N^*(y,k)N(x,k)}{k}dk-\sum_{j=1}^{n}\frac{\Phi_j^*(y)\Phi_j(x)}{k_j^2}\right].\end{aligned} \tag{4.7}$$

This formula can be simplified if the nongeneric potential reduces to a pure m-soliton solution (see examples in Sec. V). We formulate the main result of our analysis in the following statement.

Proposition 1: Suppose that the potential $u(x)$ satisfies the constraint $n_0=0$ and the perturbation $\Delta u(x)$ satisfies the criterion $K(0,0)>0$. Then, the potential $u^{\epsilon}=u(x)+\epsilon\Delta u(x)$ supports an eigenvalue $k=-p(\epsilon)$ in a neighborhood of $k=0$ for $\epsilon>0$, where

$$p(\epsilon)=c\ \exp(\epsilon^{-1}p_{-1})[1+O(\epsilon)] \tag{4.8}$$

and $c=e^{p_0}$. *The coefficients* p_{-1}, p_0 *are given by Eqs. (4.4) and (4.7). No eigenvalue exists in a neighbourhood of* $k=0$ *for* $\epsilon<0$.

We notice that if $K(0,0)=0$, the asymptotic approximation of $\ln p$ has generally the $O(\epsilon^{-2})$ term and the asymptotic expressions (4.2)–(4.8) must be reconsidered. This special situation occurs if the perturbation $\Delta u(x)$ still conserves the constraint $n_0=0$ for the limiting Jost function $n(x)$ extended to the first-order of the perturbation theory. Alternatively, if $K(0,0)<0$, the bifurcation analyzed above occurs for $\epsilon<0$.

B. The bound state corresponding to the new eigenvalue

Proposition 2: The eigenfunction $\Phi_{m+1}(x)$ *corresponding to the eigenvalue* $k=k_{m+1}=-p(\epsilon)$ *has the asymptotic form*

$$\Phi_{m+1}(x)=\frac{\alpha_0(0)}{K(0,0)}\int_0^\infty \frac{K(k,0)N(x,k)}{k+p(\epsilon)}\,dk+O(\epsilon). \tag{4.9}$$

The spectral data γ_{m+1} *defined in Eq. (2.9b) is given by*

$$\gamma_{m+1}=-\frac{\int_{-\infty}^{\infty}x\Delta u(x)|n(x)|^2dx}{\int_{-\infty}^{\infty}\Delta u(x)|n(x)|^2dx}+\frac{\beta_1+\beta_1^*}{4\pi}(1+\ln p)+\frac{i}{2p}, \tag{4.10}$$

where β_1 *is defined in Eq. (2.17b).*

The eigenfunction $\Phi_{m+1}(x)$ follows from Eqs. (3.3) and (4.2b). At the leading order, this produces the expression (4.9), where the integral has a singular contribution as $\epsilon\to 0$.

The behavior of this eigenfunction is different along different scales of the x variations. In the outer region, i.e., in the limit $x\to\infty$, the function $\Phi_{m+1}(x)$ is localized. Using the boundary conditions (A3) and the asymptotic representation (2.16), we find the limiting behavior,

$$\Phi_{m+1}(x)\big|_{\text{outer}}\to-\frac{\alpha_0(0)}{x}\left[\frac{1}{ip}+\frac{\beta_1^*\ln p}{2\pi}\right]+O(\epsilon), \tag{4.11a}$$

where β_1 is given by Eq. (2.17b). The second term in the brackets is exponentially small compared to the first one, and, therefore, we define $\alpha_0(0)$ as $\alpha_0(0)=-ip$ according to the boundary condition $\Phi_{m+1}(x)\to x^{-1}$ as $x\to\infty$.

In the inner region, where $x\sim O(1)$, the amplitude of the eigenfunction $\Phi_{m+1}(x)$ is exponentially small in terms of ϵ. Using the integral representation (4.9) we find the inner asymptotic expansion for $\Phi_{m+1}(x)$ as follows:

$$\Phi_{m+1}(x)\big|_{\text{inner}}\to ip(\ln p)n(x)+O(p). \tag{4.11b}$$

In order to compute the spectral data γ_{m+1} we use Eqs. (2.9b), (4.9), and (A5) from Appendix A. In addition, we find from Eqs. (2.16a) and (2.17a) that

$$\lim_{k\to 0}\left(\frac{\partial K(k,0)}{\partial k}\right)=-i\int_{-\infty}^{\infty}x\Delta u(x)|n(x)|^2dx-\frac{\beta_1}{2\pi i}K(0,0),$$

where β_1 is given by Eq. (2.17b). The result of these computations is expressed in Eq. (4.10).

C. Revised variations of data of the continuous spectrum

Here we revise the regular perturbation theory for Jost functions. The regular asymptotic expansion is described in Sec. III C, where it was shown that the contradiction (3.20) appears in the limit $k\to 0^+$ for perturbations of nongeneric potentials. In order to calculate this limit correctly, we notice that the integral in Eq. (3.16a) is singular in the limit $\kappa\to 0^+$ if $K(k,0)\neq 0$ and $\alpha(0,\kappa)\neq 0$. Therefore, we cannot use the Taylor expansion (3.17) to solve Eqs. (3.16). Instead, we evaluate the second term of the r.h.s. of Eq. (3.16a) in the form,

$$\int_0^\infty \frac{K(k,k')\alpha(k',\kappa)}{k'-(\kappa-i0)}\,dk' = -\pi i K(k,\kappa)\alpha(\kappa,\kappa) + K(k,\kappa)\alpha(\kappa,\kappa)\ln\left(\frac{1-\kappa}{\kappa}\right) + \text{p.v.}\int_0^1 \frac{K(k,k')\alpha(k',\kappa)-K(k,\kappa)\alpha(\kappa,\kappa)}{k'-\kappa}\,dk' + \int_1^\infty \frac{K(k,k')\alpha(k',\kappa)}{k'-\kappa}\,dk'.$$

Now we impose a scaling transformation,

$$\alpha(k,\kappa) = \frac{1}{\ln\kappa - \ln p + \pi i}\,\beta(k,\kappa), \tag{4.12a}$$

where $\ln p$ is defined by solving Eq. (4.1) and $\beta(k,\kappa)$ satisfies the integral equation,

$$\beta(k,\kappa) = \frac{\epsilon}{2\pi}K(k,\kappa)[-\ln p + (\ln\kappa + \pi i)(1-\beta(\kappa,\kappa))] + \frac{\epsilon}{2\pi}\left[\text{p.v.}\int_0^1 \frac{K(k,k')\beta(k',\kappa)-K(k,\kappa)\beta(\kappa,\kappa)}{k'-\kappa}\,dk' + \int_1^\infty \frac{K(k,k')\beta(k',\kappa)}{k'-\kappa}\,dk' + \sum_{j=1}^m \frac{K_j(k)\beta_j(\kappa)}{k_j-\kappa}\right]. \tag{4.13}$$

Here $\beta_j(\kappa)$ are defined through $\alpha_j(\kappa)$ by the same transformation as Eq. (4.12a). In the asymptotic limit $\kappa \sim p(\epsilon) \ll 1$ we use the approximation $K(k,\kappa) = K(k,0) + O(\kappa)$ and $\beta(\kappa,\kappa) = \beta(0,\kappa) + O(\kappa)$ and compare the integral equation (4.1) with Eq. (4.13). Neglecting the terms of $O(p(\epsilon))$ and $O(\kappa)$ in the integral equations, we derive the following simple result:

$$\beta(k,\kappa) = \frac{\alpha(k)}{\alpha(0)} + O(\kappa, p(\epsilon)), \tag{4.12b}$$

where $\alpha(k)$ is represented by the asymptotic series (4.2b). The remainder term of $O(\kappa)$ follows from the analysis of Eq. (4.13) in the limit $\epsilon \to 0$. Using Eqs. (3.14) and (4.12) we verify that the Jost function $N^\epsilon(x,k)$ has the correct asymptotic behavior as $k \to 0^+$,

$$N^\epsilon(x,k) = \frac{-\epsilon^{-1}p_{-1}}{\ln k - \ln p + \pi i}\,n(x) + O\left(\frac{k}{\ln k}\right). \tag{4.14}$$

This formula agrees with the representation (2.12). Furthermore, comparing the denominators of Eqs. (2.12) and (4.14), we find the relation between the asymptotic expansion of the parameters n_0^ϵ [see Eq. (1.6)] and $p(\epsilon)$ for the new eigenvalue,

$$\frac{1}{n_0^\epsilon} = -\ln p(\epsilon) + \frac{i\pi}{2} - \gamma + O(p(\epsilon)). \tag{4.15}$$

At the leading order, this formula implies that

$$n_0^\epsilon = \frac{\epsilon}{2\pi}K(0,0) + O(\epsilon^2). \tag{4.16}$$

Thus, the criterion for bifurcation of a new eigenvalue ($K(0,0) > 0$) can also be formulated as $n_0^\epsilon > 0$. Furthermore, we use Eqs. (3.15) and (4.12) to find the spectral data $\Gamma^\epsilon(k)$ as $k \sim p(\epsilon) \ll 1$. Since $\Gamma(k) = 1 + O(k^2)$ for nongeneric potentials [see Eq. (2.16b)], we have

Proposition 3: When $k \sim p(\epsilon) \ll 1$, the spectral data $\Gamma^\epsilon(k)$ are given by

$$\Gamma^{\epsilon}(k)=1+\frac{2\pi i}{\ln k-\ln p+\pi i}+O\left(\frac{k}{\ln k},\epsilon\right). \tag{4.17}$$

It is important to notice that the perturbation to the nongeneric potential produces an $O(1)$ effect which occurs however only for $k\sim p(\epsilon)\ll 1$. In the limit $k\ll p(\epsilon)$ the asymptotic solutions (4.14), (4.17) reproduce the behavior of scattering data for the generic potentials [see Eqs. (2.14)]. In the opposite limit $k\gg p(\epsilon)$ the asymptotic solution (4.12) matches with the Taylor expansion (3.17a), while the Jost function (4.14) approaches to the limiting function $n(x)$. Thus, the revised perturbation theory provides a uniform asymptotic solution describing a structural transformation of asymptotic behavior of the Jost function and the scattering coefficients as $k\to 0^+$ induced due to a perturbation of the nongeneric potential.

Finally, we notice that the uniform asymptotic solution (4.12) prescribes a ''hidden'' pole at $k=p(\epsilon)$. This resonant pole occurs due to strong excitation of radiation in the BO equation (1.1) which compensates the unbalance of the area integral (1.2) induced due to formation of a new soliton. Indeed, if the small perturbation to the potential leads to a new soliton (new eigenvalue), then the following relation must be satisfied for Eq. (2.18) at the leading order,

$$\lim_{\epsilon\to 0^+}\frac{1}{2\pi}\int_0^{\infty}\frac{|\beta^{\epsilon}(k)|^2-|\beta(k)|^2}{k}\,dk=2\pi. \tag{4.18}$$

We check this limit by using the asymptotic representation for $\beta^{\epsilon}(k)$ following from Eqs. (2.6b), (2.12), and (4.15),

$$\beta^{\epsilon}(k)=\frac{2\pi i}{\ln k-\ln p-\pi i}+O\left(\frac{k}{\ln k},\epsilon\right). \tag{4.19}$$

The dominant pole-type term is the leading-order term in the difference between $\beta^{\epsilon}(k)$ and $\beta(k)$, so that we find

$$\lim_{\epsilon\to 0^+}\frac{1}{2\pi}\int_0^{\infty}\frac{|\beta^{\epsilon}(k)|^2-|\beta(k)|^2}{k}\,dk=2\pi\int_0^{\infty}\frac{dk}{k((\ln k-\ln p)^2+\pi^2)}=2\pi.$$

V. EXPLICIT EXAMPLES

In this section we apply our general results to the important class of the pure m-soliton potential $u(x)$. In particular, these explicit formulas solve the problem of soliton generation by a small initial disturbance, i.e., when $u(x)=0$. Explicit expressions are also computed for an algebraic potential $u(x)=2a/(1+x^2)$.

A. Asymptotic approximations for *m*-soliton potentials

For m-soliton potentials, the scattering data are $\beta(k)=0$ and $\Gamma(k)=1$ for all k, and the Jost function $N(x,k)$ has the simple explicit form,

$$N(x,k)=n(x)e^{ikx},\quad n(x)=\exp\left[-i\int_x^{\infty}u_0(x)dx\right]. \tag{5.1}$$

Thus, the asymptotic expression (2.19) for large k is valid for any k in the case of m-soliton potentials and provides a function which is analytic in $\mathrm{Im}(x)\geqslant 0$. To prove the latter statement, we rewrite the m-soliton solution through its pole expansions,[2]

$$u(x)=\sum_{j=1}^{m}\left[\frac{i}{x-x_j}-\frac{i}{x-x_j^*}\right], \tag{5.2}$$

where x_j are complex poles of the solutions with $\mathrm{Im}(x_j)<0$. Then, we find the explicit formula for $n(x)$,

$$n(x)=\prod_{j=1}^{m}\frac{x-x_j^*}{x-x_j} \tag{5.3}$$

which is analytical for $\mathrm{Im}(x)\geqslant 0$. It follows from Eqs. (1.6) and (5.1) that the constraint $n_0=0$ is satisfied identically for any m-soliton solution. As a result, we find from Eq. (4.5) that the variation of m-soliton solutions may generate an additional eigenvalue, if

$$\Delta\mathcal{M}=\int_{-\infty}^{\infty}\Delta u(x)dx>0, \tag{5.4}$$

where $\Delta\mathcal{M}$ is the variation of the area integral (1.2). [Note that the area integral for the m-soliton solution is $\mathcal{M}=2\pi m$.] The asymptotic approximation of the eigenvalue $k=-p(\epsilon)$ follows from Eqs. (4.4), (4.7), and (4.8). Using the fact that $|n(x)|^2=1$ [see Eq. (5.1)] and the table integral (see p. 432 in Ref. 24),

$$\int_0^1\frac{e^{ik(x-y)}-1}{k}\,dk+\int_1^{\infty}\frac{e^{ik(x-y)}}{k}\,dk=-\gamma-\ln|x-y|+\frac{i\pi}{2}\,\mathrm{sign}(x-y) \tag{5.5}$$

we find the parameters p_{-1} and p_0 explicitly

$$p_{-1}=-\frac{2\pi}{\Delta\mathcal{M}} \tag{5.6a}$$

and

$$p_0=-\gamma-\frac{\int\int_{-\infty}^{\infty}\Delta u(x)\Delta u(y)\ln|x-y|dxdy}{(\Delta\mathcal{M})^2}-\sum_{j=1}^{m}\frac{\left|\int_{-\infty}^{\infty}\Delta u(x)n^*(x)\Phi_j(x)dx\right|^2}{k_j^2(\Delta\mathcal{M})^2}. \tag{5.6b}$$

The first integral term in Eq. (5.6b) represents the second-order correction to the new eigenvalue from the continuous spectrum while the second integral term is the correction induced due to the presence of other bound states. We notice that the latter contribution is additive which is a consequence of the Darboux transformation of linear eigenvalue problems with bound states.[25] In the particular case $m=0$, when all other bound states are absent, the expression (5.6) give an approximation for a single eigenvalue supported by a small perturbation to the zero background $u(x)=0$ with a positive area integral (1.2).

B. Algebraic potential

The single-humped algebraic potential $u(x)=2a/(1+x^2)$ was considered as an initial condition for numerical simulations of the BO equation.[8,9] In the case $a=1$, this potential is exactly the soliton solution (1.4) for $t=0$, $x_0=0$, and $v=1$ [Due to the scaling invariance of the BO equation the parameter v can be always scaled by unity.] Kodama *et al.*[10] proved that this potential generates an m-soliton solution for $a=a_m=m$ with eigenvalues k_j given by zeros of the Laguerre polynomials $L_m(-2k)$ (see Appendix B). They also proved that, if $a_m<a\leqslant a_{m+1}$, there are $m+1$ bound states. Since the exact solutions of Eq. (1.5) for the algebraic potential are not known, the eigenvalues were calculated numerically. Here we find the explicit analytical approximations of the new small eigenvalue which emerges for $a=a_m+\epsilon$, where $0<\epsilon\ll 1$.

Since the function $n(x)$ is analytical for $\mathrm{Im}(x)\geqslant 0$ we calculate $P^+[un]$ for the algebraic potential $u=2a/(1+x^2)$ as follows:

$$P^+[un]=un+\frac{ian(i)}{x-i}.$$

In addition, we find from Eq. (1.6) that

$$n_0=\frac{1}{2\pi}\int_{-\infty}^{\infty}u(x)n(x)dx=an(i).$$

Then, the limiting function $n(x)$ satisfies a simple differential equation following from Eq. (2.13a),

$$in_x+un=-\frac{in_0}{x-i}.$$

This equation has an explicit solution

$$n(x)=-n_0\left(\frac{x-i}{x+i}\right)^a(I_{a+1}(x)-\alpha), \tag{5.7}$$

where

$$I_{a+1}(x)=\int\frac{(x+i)^a}{(x-i)^{a+1}}\,dx$$

and the constant α is introduced to cancel the nonanalyticity of $n(x)$ at the branching point $x=i$. Using the recurrent relation,

$$I_{a+1}(x)=I_a(x)-\frac{1}{a}\left(\frac{x+i}{x-i}\right)^a \tag{5.8}$$

the function $n(x)$ can be represented for $m\leqslant a<(m+1)$ as

$$n(x)=n_0\left[\sum_{k=0}^{m}\frac{1}{a-k}\left(\frac{x-i}{x+i}\right)^k-\left(\frac{x-i}{x+i}\right)^a(I_{a-m}(x)-I_{a-m}(i))\right]. \tag{5.9}$$

The integral $I_a(x)$ for $0\leqslant a<1$ can be evaluated in two exceptional cases: for $a=1/2$ (see Ref. 16), when $I_{1/2}=\ln(x+\sqrt{1+x^2})$, and for $a=0$, when $I_0=\ln(x+i)$. Using the last formula and comparing the asymptotical behavior of $n(x)$ as $x\to\infty$ given by Eqs. (2.15) and (5.9), we find the asymptotic representation for n_0 as $a=m+\epsilon$,

$$\frac{1}{n_0}=\frac{1}{\epsilon}+\ln 2+\frac{i\pi}{2}+\sum_{k=1}^{m}\frac{1}{k}+O(\epsilon). \tag{5.10}$$

This exact computation of n_0 enables us to find from Eq. (4.15) the asymptotic approximation for a new eigenvalue $k_{m+1}=-p(\epsilon)$ supported by a perturbed algebraic potential,

$$p(\epsilon)=\tfrac{1}{2}\exp(-\epsilon^{-1}-\gamma-q_m+O(\epsilon))\quad q_m=\sum_{k=1}^{m}\frac{1}{k}. \tag{5.11}$$

In Appendix B we derive the formula (5.11) with the help of Eqs. (5.6). This (equivalent) technique leads to a new relation for zeros of Laguerre polynomials.

VI. CONCLUSION

We have shown that small variations of the nongeneric potentials support a new bound state in the BO scattering problem if the generic perturbation leads to a positive value of the governing parameter n_0. For the soliton potentials, the latter condition is equivalent to a positive contribution to the area integral (1.2) induced by the perturbation. The self-consistent asymptotic expansions are constructed and studied not only for the new eigenvalue and an associated bound state but also for the perturbed Jost functions of the BO scattering problem.

Our results on bifurcation of new eigenvalues in the spectral problem (1.5) solve the classical problem of soliton generation by a small initial perturbation within the BO equation. The expo-

nential behavior of the new eigenvalue explains why our results do not fit into the classification of Ref. 11. Although the BO equation (1.1) realizes a marginal case in the criterion on the soliton generation given in Ref. 11, the generation still takes place but is accompanied by a strong radiation. The energy of an initial pulse measured by the integral $P=\int_{-\infty}^{\infty}u^2dx$ all goes to the linear dispersive waves except for an exponentially small addition to the algebraic soliton (1.4). As an indication of this smallness, the new soliton was not identified in the numerical simulations of Ref. 8.

It is interesting to compare the no-threshold soliton generation in the BO equation (1.1) with that in the KdV equation, $u_t+6uu_x+u_{xxx}=0$. In the KdV equation,[4] a small initial pulse with the mass invariant $M=\epsilon\Delta M$, where $\Delta M=\int_{-\infty}^{\infty}u(x,0)dx$, also leads to generation of a single soliton with the mass $M_s=2\epsilon\Delta M$ and emission of linear radiative waves with the mass $M_{\rm rad}=M-M_{\rm sol}=-\epsilon\Delta M$, i.e., all integral quantities remain small in this evolution process. In the BO equation, an initial pulse with the mass $M=\epsilon\Delta M$ generates a soliton with finite mass $M_{\rm sol}=2\pi$ and strong radiation with finite mass $M_{\rm rad}=M-M_{\rm sol}=-2\pi+\epsilon\Delta M$ [see formulas (2.18) and (4.18)].

Similar bifurcations of new eigenvalues (solitons) may also occur when the perturbation of the potential is given not by an initial condition but by a perturbation to the underlying equation itself. The perturbed BO equation was considered recently by Matsuno and Kaup[26,27] who studied variations of the soliton solutions induced by the perturbation. The formation of new solitons has not been discussed yet.

Finally, since the BO equation is believed to be a pivot to multidimensional evolution equations such as the KP1 and DS2 equations (see Ref. 3), another interesting problem is to construct the bifurcation theory for new eigenvalues (solitons) in the multidimensional evolution equation integrable by the inverse scattering method.

APPENDIX A: USEFUL RELATIONS FOR PERTURBATION THEORY

Taking the limits (2.8b) into Eq. (2.7) we derive a system of algebraic equations for $\Phi_j(x)$, $j=\overline{1,m}$,

$$(x+\gamma_j)\Phi_j(x)=1-i\sum_{l\neq j}\frac{\Phi_l(x)}{k_j-k_l}+\frac{1}{2\pi i}\int_0^{\infty}\frac{\beta(k)N(x,k)}{k-k_j}\,dk. \tag{A1}$$

Furthermore, using Eqs. (2.3b), (2.3c), (2.6b), (2.9a) as well as the formula

$$\lim_{x\to+\infty}\ \text{p.v.}\ \frac{e^{\pm ikx}}{k}=\pm i\pi\delta(k),$$

we find the following relations:

$$\int_{-\infty}^{\infty}\Phi_j dx=-\pi i, \tag{A2a}$$

$$\int_{-\infty}^{\infty}N(x,k)dx=2\pi\delta(k)-\frac{i\beta^*(k)}{2k}. \tag{A2b}$$

Equivalently, these formulas also follow from the boundary conditions for $N(x,k)$ and $\Phi_j(x)$ as $x\to\infty$ [cf. Eq. (2.1)],

$$N(x,k) \to e^{ikx} + \frac{\beta^*(k)}{2\pi kx} + O(x^{-2}), \tag{A3a}$$

$$\Phi_j(x) \to \frac{1}{x} + O(x^{-2}). \tag{A3b}$$

We derive from Eqs. (A1), (A2), and orthogonality conditions (3.1) the following important relations:

$$\int_{-\infty}^{\infty} (x+\gamma_j) |\Phi_j(x)|^2 dx = \pi i, \tag{A4a}$$

$$\int_{-\infty}^{\infty} (x+\gamma_j) \Phi_l^*(x) \Phi_j(x) dx = \frac{\pi i (k_j + k_l)}{k_j - k_l}, \quad j \neq l, \tag{A4b}$$

$$\int_{-\infty}^{\infty} (x+\gamma_j) N^*(x,k) \Phi_j(x) dx = 2\pi \delta(k) + \frac{i\beta(k)(k_j+k)}{2k(k_j-k)}. \tag{A4c}$$

In addition, we use Eqs. (2.7), (2.8a), (3.1a), and (A2b) in order to compute an equivalent formula for the Jost functions $N(x,k)$. As a result of straightforward calculations, we derive the relation,

$$\int_{-\infty}^{\infty} x N^*(x,k') N(x,k) dx = -2\pi i \frac{d\delta}{dk}(k-k') + \frac{\beta^*(k)}{2k} \delta(k') + \frac{\beta^*(k')}{2k'} \delta(k) + \frac{i\beta(k')\beta^*(k)(k+k')}{4\pi k k'(k-k')}. \tag{A5}$$

APPENDIX B: DERIVATION OF THE ASYMPTOTIC FORMULA (5.11)

Here we check the asymptotic result (5.11) by virtue of formulas (5.6). First, the potential $u(x) = 2a/(1+x^2)$ can be decomposed for $a = m + \epsilon$ as

$$u(x) = \frac{2m}{1+x^2} \quad \text{and} \quad \Delta u(x) = \frac{2}{1+x^2}. \tag{B1}$$

Then, we find from Eqs. (5.4) and (5.6a) that $\Delta M = 2\pi$ and $p_{-1} = -1$ in agreement with Eq. (5.11). Then, the first integral term in Eq. (5.6b) can be evaluated explicitly[24] as

$$\int \int_{-\infty}^{\infty} \Delta u(x) \Delta u(y) \ln|x-y| dx dy = -8 \int_0^{\pi} t \ln(\sin t) dt = 4\pi^2 \ln 2 \tag{B2}$$

which gives the factor $\frac{1}{2}$ in Eq. (5.11).

Next, in order to evaluate the contribution from the other bound states, we find from Eq. (5.3) the limiting eigenfunction $n(x)$ for the algebraic potential $u(x)$ given by Eq. (B1),

$$n(x) = \frac{(x-i)^m}{(x+i)^m}. \tag{B3}$$

Using Eq. (2.9a), we have

$$k_j = \frac{1}{2\pi i} \int_{-\infty}^{\infty} u(x) \Phi_j(x) dx = -im \Phi_j(i).$$

Similarly to Eq. (5.7), the bound states $\Phi_j(x)$ can also be expressed through an integral representation (see Eq. (7.23) in Ref. 10),

$$\Phi_j(x) = -ik_j\left(\frac{x-i}{x+i}\right)^m e^{ik_j x}\int_{-\infty}^{x}\frac{(y+i)^m}{(y-i)^{m+1}}\,e^{-ik_j y}dy.$$

This integral can be computed through the finite sum,

$$\Phi_j(x) = ik_j\sum_{k=1}^{m}\sum_{l=1}^{k}\frac{(l-1)!m!}{(k!)^2(m-k)!}\,\frac{(2i)^l(2k_j)^{k-l}}{(x+i)^m(x-i)^{l-m}} - ik_j\left(\frac{x-i}{x+i}\right)^m e^{ik_j x}\int_{-\infty}^{x}\frac{e^{ik_j y}}{y-i}\,dy\;L_m(-2k_j), \tag{B4}$$

where $L_m(x)$ is the Laguerre polynomial[24]

$$L_m(x) = \sum_{k=0}^{m}\frac{m!}{(k!)^2(m-k)!}\,(-x)^k. \tag{B5}$$

The eigenvalues k_j satisfy $L_m(-2k_j)=0$. Therefore, the integrals $\int_{-\infty}^{\infty}\Delta u(x)n^*(x)\Phi_j(x)dx$ in Eq. (5.6b) can be evaluated from (B1), (B3), and (B4). As a result, we find from Eqs. (5.6) and (5.11) the following representation for q_m:

$$q_m = \sum_{j=1}^{m}\left(\sum_{k=1}^{m}\sum_{l=1}^{k}\frac{(-1)^l(l-1)!m!}{(k!)^2(m-k)!}\,(2k_j)^{k-l}\right)^2. \tag{B6}$$

According to Eq. (5.11), the sum q_m is equal to $q_m=\Sigma_{k=1}^{m}(1/k)$ which gives a new relation for zeros of the Laguerre polynomials. Indeed, we have checked the first terms following from Eqs. (B5) and (B6): $q_1=1$, $q_2=3/2$, $q_3=11/6$. These results agree with Eq. (5.11).

(Received 9 September 1997; accepted for publication 20 August 1998)

By extending Ashtekar and Romano's definition of spacelike infinity to the timelike direction, a new definition of asymptotic flatness at timelike infinity for an isolated system with a source is proposed. The treatment provides unit spacelike three-hyperboloid timelike infinity and avoids the introduction of the troublesome differentiability conditions which were necessary in the previous works on asymptotically flat space–times at timelike infinity. Asymptotic flatness is characterized by the falloff rate of the energy-momentum tensor at timelike infinity, which makes it easier to understand physically what space–times are investigated. The notion of the order of the asymptotic flatness is naturally introduced from the rate. The definition gives a systematized picture of hierarchy in the asymptotic structure, which was not clear in the previous works. It is found that if the energy-momentum tensor falls off at a rate faster than $\sim t^{-2}$, the space–time is asymptotically flat and asymptotically stationary in the sense that the Lie derivative of the metric with respect to ∂_t falls off at the rate $\sim t^{-2}$. It also admits an asymptotic symmetry group similar to the Poincaré group. If the energy-momentum tensor falls off at a rate faster than $\sim t^{-3}$, the four-momentum of a space–time may be defined. On the other hand, angular momentum is defined only for space–times in which the energy-momentum tensor falls off at a rate faster than $\sim t^{-4}$. © *1998 American Institute of Physics.* [S0022-2488(98)01812-X]

I. INTRODUCTION

If gravitational collapse takes place in an asymptotically flat space–time, we naively expect that the energy of fields and particles in the exterior region would be either radiated away to infinity or fall into the black hole and that the space–time would approach a vacuum space–time. Because the lost energy cannot be restored, the dynamical processes would eventually die away and the space–time would settle down to a stationary state. Thus, we expect that the final state of gravitational collapse be described by a Kerr black hole, since the uniqueness theorem states that the Kerr space–time is the unique asymptotically flat, stationary, vacuum solution.[1] This is the reason why the Kerr solution is used to analyze the black hole candidates observed in the universe. In this paper, to confirm the naive picture above, we shall closely examine the asymptotic structure of the very late time regime of a space–time, i.e., timelike infinity, and see that an ''asymptotic'' vacuum state actually induces an ''asymptotic'' stationary state. This approach may be more reasonable than the assumption of the exact stationarity in the sense that *exact* vacuum or *exact* stationary state would not be achieved in a real gravitational collapse.

A solution of the Einstein equation is normally given in terms of the metric components with respect to some specific coordinates. However, it is not easy from the component expression to grasp what physical system the solution actually represents. One way to overcome the difficulty is to introduce a certain physical index that characterizes the system. For example, if the energy of the system at a given time is defined, we can picture the evolution of the system to some extent from the change in its value. Moreover, if the multipole moments of a space–time are defined, we may obtain a precise Newtonian analog by constructing a Newtonian potential having the same moments. The analog could serve as a powerful guide for the physical interpretation of the solution. Because the gravitational field itself acts as its own source, we expect multipole moments

 © 1998 American Institute of Physics

can be defined only in space–times with gravitational fields satisfying a suitable fall-off condition. It is shown that *stationary* space–times are sufficiently asymptotically flat for the multipole moments to be well defined.[2] However, there are no arguments on more general space–times. In this paper, as a first step towards defining multipole moments of general asymptotically flat space–times, we explore timelike infinity of a space–time to seek what falloff condition the gravitational field must satisfy so that four-momentum or angular-momentum may be defined.

There are some previous works on timelike infinity. A definition of timelike infinity with *everywhere-smooth* unphysical metric is proposed by Cutler in Ref. 3. The high differentiability condition results in demanding that the space–time have vanishing final Bondi mass at timelike infinity. This means the definition applies only for space–times with no bounded sources such as black holes and stars. On the other hand, Porill's definition of the asymptotic flatness at timelike infinity is applicable to space–times with bounded sources.[4] However, as a result of the ''tieing'' of the late time regime with the null regime, the treatment compresses the late time regime, which has a finite volume, down to a point. As a result, we cannot demand smoothness or even differentiability of the unphysical metric at the point. Instead, we need to formulate a notion of direction-dependent ''differentiability'' and demand that the metric possess this awkward property. The treatment makes it difficult to understand what kinds of space–times are investigated.

Recently, Ashtekar and Romano formulated an elegant treatment of spacelike infinity in a coordinate-independent manner.[5] In their work, the corresponding ''awkward'' differentiability at spacelike infinity is avoided by regarding the late time regime of a space–time not as a point but as a three-manifold. This is achieved by abandoning the idea of ''tieing'' the late time regime and the null regime together. As a result, there is no necessity to use a conformally completed unphysical metric for the description of the gravitational field. Instead, a normal vector field and an intrinsic metric on the timelike slices foliating the unphysical space–time are defined, and they provide the three-manifold timelike infinity.

In the present paper, we modify Ashtekar and Romano's treatment of spacelike infinity to the timelike direction and investigate the asymptotic structure of space–times around timelike infinity. Our investigation is more or less a direct application of their work but differs in a number of important points, which enable us to discuss (1) the asymptotic vacuum state and the asymptotic stationary state of a space–time to explore the final product of gravitational collapse, and (2) the order of asymptotic flatness to explore how flat the space–time must be in order to define physical indices. First, we take a different view on how the falloff condition on the energy-momentum tensor should be imposed. We impose conditions on the *physical* components of the physical energy-momentum tensor, while they impose conditions on the *unphysical* components. This change gives a picture of hierarchy in the asymptotic structure at timelike infinity and helps us to understand how the structure is systematized, which is a point that was obscure in the previous treatments. Second, a notion of asymptotic Killing fields is introduced. The formulation of the order of asymptotic symmetries is possible only by the introduction of such a notion. This is also crucial in examining and specifying how fast a space–time becomes stationary. Also, special attention is paid to a bounded source that persists even in the very late time regime of a space–time, in contrast with the spacelike direction.

The rest of the paper is organized as follows. In Sec. II, we construct timelike infinity with certain desirable features for Minkowski space–time. Following the completion of Minkowski space–time, we propose a definition of asymptotic flatness at future timelike infinity for a general space–time with a source in Sec. III. In Sec. IV, we examine the fundamental asymptotic structure of space–times that possess the defined asymptotic flatness. In Sec. V, we propose an asymptotic symmetry group which preserves the studied structure. A notion of asymptotic Killing fields is introduced in Sec. VI, and its relation to the falloff of the energy-momentum tensor is clarified. In Sec. VII, we examine the asymptotic behavior of the gravitational fields. In Sec. VIII, we define conserved quantities associated with the asymptotic symmetry. The Appendix gives some examples of asymptotically flat space–times with timelike infinity defined in this paper and the flat Friedmann space–time which is not asymptotically flat as a counterexample. Throughout the paper, we follow the notation of Wald.[6]

II. COMPLETION OF THE MINKOWSKI SPACE–TIME

In this section, we complete Minkowski space–time $(\hat{\mathcal{M}}, \hat{\eta}_{ab})$ in such a way that future timelike infinity is represented not as a point but as a three-manifold. The construction motivates the general definition of asymptotic flatness in the next section. Hereafter, we only consider *future* timelike infinity and thus omit the word future. All the discussion presented here is also applicable to past timelike infinity with minor changes.

In static spherical coordinates (t,r,θ,ϕ), the metric of Minkowski space–time takes the form

$$\hat{\eta}_{ab} = -(dt)_a(dt)_b + (dr)_a(dr)_b + r^2(d\sigma)_{ab}, \tag{2.1}$$

where $(d\sigma)_{ab} := (d\theta)_a(d\theta)_b + \sin^2\theta(d\phi)_a(d\phi)_b$ is the unit two-sphere metric. Introduce the standard hyperbolic coordinates (ρ,χ,θ,ϕ) in the *interior* of the future light cone at the origin: $t = \rho\cosh\chi$ and $r = \rho\sinh\chi$, where $\chi\in[0,\infty)$ and $\rho\in(0,\infty)$. In this chart, timelike infinity is specified by the limit surface $\rho\to\infty$ and the metric takes the form

$$\hat{\eta}_{ab} = -(d\rho)_a(d\rho)_b + \rho^2 h_{ab}, \tag{2.2}$$

where $h_{ab} := (d\chi)_a(d\chi)_b + \sinh^2\chi(d\sigma)_{ab}$ is the unit spacelike three-hyperboloid metric. If a new coordinate $\Omega := \rho^{-1}$ is introduced and $\hat{\mathcal{M}}$ is extended to include the points on which $\Omega = 0$, timelike infinity is specified by the surface $\Omega = 0$ and the metric is found to be singular there:

$$\hat{\eta}_{ab} = -\Omega^{-4}(d\Omega)_a(d\Omega)_b + \Omega^{-2}h_{ab}. \tag{2.3}$$

To complete the space–time conformally, we take a conformal factor of Ω^4 and obtain a nonsingular unphysical metric:

$$\eta_{ab} := \Omega^4\hat{\eta}_{ab} = -(d\Omega)_a(d\Omega)_b + \Omega^2 h_{ab}. \tag{2.4}$$

With respect to the metric, timelike infinity $\Omega = 0$ is a point with no volume. This is because the components of the metric normal to and those tangent to the Ω-const surfaces are rescaled by the same power of Ω although they diverge with different powers. In other words, if we rescale them according to the power of their divergence, we obtain timelike infinity that is not compressed to a point. Thus, define

$$n^a := \Omega^{-4}\hat{\eta}^{ab}(d\Omega)_b = -(\partial_\Omega)^a \tag{2.5}$$

to the direction normal to the Ω-const surfaces and

$$q_{ab} := \Omega^2(\hat{\eta}_{ab} + \Omega^{-4}F^{-1}(d\Omega)_a(d\Omega)_b) = h_{ab}, \quad \text{where } F := -\pounds_n\Omega = 1 \tag{2.6}$$

to the direction tangent to the Ω-const surfaces. The information on the gravitational fields is completely given by the pair (n^a, q_{ab}), and we do not need the conformally rescaled unphysical metric η_{ab}. With respect to this pair, timelike infinity is a three-surface whose intrinsic metric is h_{ab} and whose normal is ∂_Ω. That is, timelike infinity is a unit spacelike three-hyperboloid.

Note here that the completion presented here does not conserve the causal structure of the physical space–time, in contrast with the conformal completion. Hence, it is inappropriate, for example, to discuss the relation of timelike infinity with null infinity using the method. However, the method provides an adequate basis to investigate asymptotic structure of a spacetime at timelike infinity.

III. DEFINITIONS

In this section, we introduce a definition of asymptotic flatness at timelike infinity to order n and define some tensor fields that are useful for the coming discussion.

We have demonstrated the completion of Minkowski space–time in the previous section. It is important to note that the way which the completion is accomplished crucially depends on the structure of Minkowski space–time at timelike infinity. This motivates us to define an asymptotic flat space–time as a space–time which can be completed ''asymptotically'' in a similar fashion to

Minkowski space–time. More precisely, a space–time is said to be asymptotically flat if the space–time can be extended to enclose the points of infinity and if it is possible to construct the pair (n^a, q_{ab}) that has a smooth limit to the infinity.

Definition: A physical space–time $(\hat{\mathcal{M}}, \hat{g}_{ab})$ is said to possess an *asymptote at future timelike infinity* $\check{\imath}^+$ *to order n* (AFTI-*n*) for a non-negative integer *n*, if there exists a manifold $\mathcal{M}$ with boundary $\mathcal{H}$, a smooth function Ω defined on $\mathcal{M}$, and an imbedding Ψ of an open subset $\hat{\mathcal{F}}$ in $\hat{\mathcal{M}}$ to $\mathcal{M}-\mathcal{H}$ satisfying the following conditions:

(1) $\check{\imath}^+ := \partial\mathcal{F} \cap (\mathcal{M} - \Psi(\hat{\mathcal{M}}))$ is not empty and $\check{\imath}^+ \in I^+(\mathcal{F})$ where $\mathcal{F} := \Psi(\hat{\mathcal{F}})$;
(2) $\Omega \doteq 0$ and $\nabla_a \Omega \neq 0$, where $\doteq$ denotes the equality evaluated on $\check{\imath}^+$;
(3) $n^a := \Omega^{-4} \Psi^* \hat{g}^{ab} \nabla_b \Omega$ and $q_{ab} := \Omega^2 (\Psi^* \hat{g}_{ab} + \Omega^{-4} F^{-1} \nabla_a \Omega \nabla_b \Omega)$ admit smooth limits to $\check{\imath}^+$ with q_{ab} having signature$(+++)$ on $\check{\imath}^+$, where $F := -\pounds_n \Omega$; and
(4) $\lim_{\to \check{\imath}^+} \Omega^{-(2+n)} \hat{T}_{\hat{\mu}\hat{\nu}} = 0$ where $\hat{T}_{\hat{\mu}\hat{\nu}} := \Psi^*[(\hat{e}_\mu)^a (\hat{e}_\nu)^b \hat{T}_{ab}]$ in which $\hat{T}_{ab}$ is the physical energy-momentum tensor and $\{(\hat{e}_\mu)^a\}_{\mu=0,1,2,3}$ is a tetrad of $(\hat{\mathcal{M}}, \hat{g}_{ab})$.

Let us now discuss the meaning of the conditions. First of all, note that the asymptotic flatness is defined for an open *subset* $\hat{\mathcal{F}}$ of the space–time manifold. This is because isolated bodies may be present at the late time regime of a space–time and thus the *whole* space–time is not expected to be asymptotically flat. If there are isolated bodies at the late time regime, the region excluding the bodies should be chosen as $\hat{\mathcal{F}}$. The former part of the first condition ensures that the infinity $\check{\imath}^+$ consists of points that are included by extending the physical manifold. Such $\check{\imath}^+$ resides not in the region $\Psi(\mathcal{M})$, where the physical manifold is mapped, but on the boundary of the region of interest, $\partial\mathcal{F}$. The latter part assures that $\check{\imath}^+$ exists in the *future* of the physical space–time so that $\check{\imath}^+$ represents *future* timelike infinity. The second condition assures that $\check{\imath}^+$ is infinitely far away. The third demands that the asymptotic space–time can be completed asymptotically in a similar fashion to the case of Minkowski space–time and that the infinity $\check{\imath}^+$ is *timelike*. This means that Ω asymptotically plays a role of t^{-1} in Minkowski space–time. The fourth condition specifies how the physical components of the physical energy-momentum tensor should decay. This condition is different from the corresponding one in the definition given by Ashtekar and Romano.[5] If we literally translated their prescription for spacelike infinity to our timelike infinity, we would demand that the energy-momentum tensor fall off faster than Ω^1, $\lim_{\to \check{\imath}^+} \Omega^{-1} \Psi^* \hat{T}_{ab} = 0$, and consider such terms as $q_a^m q_b^n \Omega^{-1} \Psi^* \hat{R}_{mn}$ vanish on $\check{\imath}^+$. Although it is not explicitly stated in Ref. 5, this means that the energy-momentum tensor is evaluated by the components with respect to an *unphysical* coordinate basis, $(e_\mu)^a (e_\nu)^b \Psi^* \hat{T}_{ab}$ where $\{(e_\mu)^a\}_{\mu=0,1,2,3}$ is a tetrad of the unphysical space–time. Here, we take an alternative view. We evaluate the *physical* energy-momentum tensor by its components with respect to a *physical* coordinate basis, $\hat{T}_{\hat{\mu}\hat{\nu}} = \Psi^*[(\hat{e}_\mu)^a (\hat{e}_\nu)^b \hat{T}_{ab}]$. In this view, it is found that the richness of asymptotic structures that a space–time possesses depends on how fast the energy-momentum tensor falls off in the space–time. Thus, we need to specify the rate of the falloff when defining asymptotic flatness. To evaluate $\hat{T}_{\hat{\mu}\hat{\nu}}$ hereafter, we use a tetrad consisting of a unit normal vector to Ω-const surfaces, $\hat{n}^a$, and the triad on Ω-const surfaces, $\{(\hat{e}_I)^a\}_{I=1,2,3}$. They satisfy

$$\hat{g}^{ab} = -\hat{n}^a \hat{n}^b + (\hat{e}_I)^a (\hat{e}_I)^b, \tag{3.1}$$

$$\Psi^* \hat{n}^a = \frac{n^a}{\sqrt{-\Psi^* \hat{g}_{ab} n^a n^b}} = \Omega^2 F^{-1/2} n^a, \tag{3.2}$$

$$\Psi^* (\hat{e}_I)^a = \Omega (e_I)^a, \tag{3.3}$$

where $\{(e_I)^a\}_{I=1,2,3}$ is the smooth triad of q_{ab}. Equation (3.3) will be obtained below. Since all the equations appearing in the following discussion are those on $\mathcal{M}$, unless it may cause ambiguity, we omit hereafter Ψ^* in front of the tensors defined on $\hat{\mathcal{M}}$ for brevity.

It is meaningful to note here that a scalar field ϕ in the Schwarzschild space–time decays asymptotically at the rate $\sim t^{-2}$ or faster, according to the Price's theorem.[7] Thus, the Schwarzschild space–time with such a scalar field is asymptotically flat to order 1.

Now consider the Schwarzschild space–time. We can take the region $r>2m$ for $\mathcal{F}$. Then, all the conditions above are satisfied and $\check{i}^+$ is represented by a unit spacelike three-hyperboloid with a point removed from it. (See the Appendix for the details.) The removed point corresponds to the future of the region $r\leqslant 2m$, or the region excluded from $\hat{\mathcal{M}}$. Recalling that a unit spacelike three-hyperboloid has a topology of $S^2\times\mathbb{R}^+$, we see that the topology of $\check{i}^+$ is now $S^2\times(\mathbb{R}^+ -\{p\})$ where $\mathbb{R}^+$ denotes $[0,\infty)$. This result may be regarded as a common feature of the space–times with sources and motivates the following definition.

Definition: A space–time $(\hat{\mathcal{M}},\hat{g}_{ab})$ is said to be *asymptotically flat at future timelike infinity with a source to order n* (AFFTIS-*n*) if $(\hat{\mathcal{M}},\hat{g}_{ab})$ possesses an asymptote at timelike infinity to order n and $\check{i}^+$ has topology of $S^2\times(\mathbb{R}^+-\{p\})$.

For the convenience of the following discussion, we define some useful tensors and show the relations among them. From the definition, the physical metric $\hat{g}_{ab}$ and its inverse $\hat{g}^{ab}$ are given by

$$\hat{g}_{ab}=-\Omega^{-4}F^{-1}\nabla_a\Omega\nabla_b\Omega+\Omega^{-2}q_{ab}\,, \tag{3.4}$$

$$\hat{g}^{ab}=-\Omega^4F^{-1}n^an^b+\Omega^2q^{ab}, \tag{3.5}$$

respectively, with functions and tensors that are smooth in $\mathcal{F}$ and on $\check{i}^+$. From Eqs. (3.5) and (3.1), we obtain Eq. (3.3). A smooth projection operator on the Ω-const surfaces can be defined from smooth q^{ab} and q_{ab}:

$$q^a{}_b:=q^{ac}q_{cb}=\delta^a{}_b+F^{-1}n^a\nabla_b\Omega. \tag{3.6}$$

The operator is the same as the one defined from $\hat{q}^{ab}$ and $\hat{q}_{ab}$. Thus, derivative operators D_a and $\hat{D}_a$ that are associated with q_{ab} and $\hat{q}_{ab}$, respectively, do not differ. Hence,

$${}^3\hat{R}_{abc}{}^d={}^3R_{abc}{}^d \quad\text{and}\quad {}^3\hat{R}_{ab}={}^3R_{ab}\,, \tag{3.7}$$

where $(\hat{D}_a\hat{D}_b-\hat{D}_b\hat{D}_a)\omega_c=:{}^3\hat{R}_{abc}{}^d\omega_d$, ${}^3\hat{R}_{ab}:={}^3\hat{R}_{abc}{}^c$, $(D_aD_b-D_bD_a)\omega_c=:{}^3R_{abc}{}^d\omega_d$ and ${}^3R_{ab}:={}^3R_{acb}{}^c$. On the other hand, the physical extrinsic curvature of the Ω-const surfaces does not admit a smooth limit to $\check{i}^+$:

$$\hat{K}_{ab}:=\tfrac{1}{2}\,\pounds_{\hat{n}}\hat{q}_{ab}=\Omega^{-1}F^{1/2}q_{ab}+\tfrac{1}{2}\,F^{-1/2}\pounds_nq_{ab}\,. \tag{3.8}$$

Thus, define a smooth tensor

$$K_{ab}:=\Omega\hat{K}_{ab}=F^{1/2}q_{ab}+\tfrac{1}{2}\,\Omega F^{-1/2}\pounds_nq_{ab}\,. \tag{3.9}$$

Hereafter, we raise and lower the indices of tensors without hats on Ω-const surfaces by the smooth metric q_{ab} and the inverse q^{ab}. For example, $K^a_b:=q^{ac}K_{cb}$.

IV. THE ZEROTH-ORDER ASYMPTOTIC STRUCTURE

In this section, we examine the asymptotic structure of an AFTI-0 space–time using the Einstein equation. Consider the momentum constraint equation expressed in terms of smooth tensors and $\hat{T}_{\hat{\mu}\hat{\nu}}$:

$$\Omega^{-2}(\hat{e}_I)^a\hat{n}^b\hat{T}_{ab}=[D_cK^c_a-D_aK](e_I)^a. \tag{4.1}$$

In AFTI-0 space–times, the left-hand side vanishes on $\check{i}^+$ because of the falloff condition on the energy-momentum tensor. Therefore, we get

$$D_cK_a{}^c-D_aK\stackrel{=}{}0. \tag{4.2}$$

Substituting Eq. (3.9) into this equation, we find

$$F\stackrel{=}{}\text{const}. \tag{4.3}$$

By virtue of the conformal freedom of the function F, the above constant can be set to unity without any loss of generality. To see this, complete the space–time with a function $\Omega' := \alpha\Omega$ instead of Ω, where α is a smooth function that is constant on $\check{\imath}^+$. Then, the function $F' := -\pounds_{n'}\Omega'$ in this completion is given by $F' \doteq \alpha^{-2}F$. Thus, there is always a function Ω' that induces $F' \doteq 1$ for any given function Ω. We call a completion with such a function a *unit hyperboloid completion* for the reason that will be clarified below. Because there is no loss of generality, hereafter we consider only unit hyperboloid completions. In the completion,

$$F = 1 + \sum_{l=1}^{\infty} {}^{(l)}F \cdot \Omega^l, \tag{4.4}$$

where ${}^{(n)}F$ are defined by

$${}^{(1)}F := \lim_{\to \check{\imath}^+} \Omega^{-1}(F-1) \quad \text{and} \quad {}^{(n)}F := \lim_{\to \check{\imath}^+} \Omega^{-n}\left(F - 1 - \sum_{l=1}^{n-1} {}^{(l)}F \right) \quad \text{for } n \geqslant 2; \tag{4.5}$$

and

$$K_{ab} = q_{ab} + \tfrac{1}{2}\Omega({}^{(1)}F q_{ab} + \pounds_n q_{ab}) + O(\Omega^2). \tag{4.6}$$

Now consider the space–space components of the Ricci tensor:

$$\Omega^{-2}(\hat{e}_I)^a(\hat{e}_J)^b \hat{R}_{ab} = [{}^3R_{ab} + KK_{ab} - F^{1/2}K_{ab} - 2K_{ac}K^c_b + \Omega F^{-1/2}\pounds_n K_{ab} + F^{-1/2}D_aD_bF^{1/2}] \times (e_I)^a(e_J)^b. \tag{4.7}$$

In AFTI-0 space–times, the left-hand side vanishes on $\check{\imath}^+$ by virtue of the falloff condition on the energy-momentum tensor. Substituting Eqs. (4.4) and (4.6) into Eq. (4.7), we obtain

$${}^3R_{ab} \doteq -2q_{ab}. \tag{4.8}$$

Here, recall that $\check{\imath}^+$ is a submanifold of $\mathcal{M}$ and thus there is an identity imbedding Π of $\check{\imath}^+$ in $\mathcal{M}$. Using the map Π, a tensor field A_{ab} defined on $\mathcal{M}$ induces a tensor field $\mathbf{A}_{ab} := \Pi^+ A_{ab}$ on $\check{\imath}^+$. (Hereafter, we denote the tensor fields on the manifold $\check{\imath}^+$ in boldface.) It is important to note here that if a tensor field is tangential to $\check{\imath}^+$, or $q_a{}^m q_b{}^n A_{mn} \doteq A_{ab}$, the induced tensor field contains the same information as the original. Hence, the investigation of an equation on $\check{\imath}^+$ with tensor fields tangential to $\check{\imath}^+$ can be done by considering the induced equation on $\check{\imath}^+$. Thus, let us consider the following equation induced by Eq. (4.8) on $\check{\imath}^+$:

$${}^3\mathbf{R}_{ab} \doteq -2\mathbf{q}_{ab}. \tag{4.9}$$

The equation tells us that the unphysical three-space–time $(\check{\imath}^+, \mathbf{q}_{ab})$ has negative constant curvature:

$${}^3\mathbf{R}_{abcd} \doteq -2\mathbf{q}_{a[c}\mathbf{q}_{d]b}. \tag{4.10}$$

In other words, timelike infinity $(\check{\imath}^+, \mathbf{q}_{ab})$ is isometric to a unit spacelike hyperboloid in Minkowski space–time and $\mathbf{q}_{ab} \doteq \mathbf{h}_{ab}$. Note here that it is isometric to a *unit* hyperboloid because the *unit* hyperboloid completion induces $F \doteq 1$. This is where the name comes from.

The falloff condition on the time–time component of the energy-momentum tensor gives nothing new.

Now that we have explored everything that can be derived from the falloff condition which AFTI-0 space–times satisfy, the asymptotic structure of AFTI-0 space–time can be summarized as follows.

Definition: The function F which is unity on $\check{\imath}^+$, i.e., $F \doteq 1$ and the manifold $\check{\imath}^+$ with normalized negative-constant curvature, i.e., $\mathbf{q}_{ab} \doteq \mathbf{h}_{ab}$ are called the *zeroth-order asymptotic structure* of an AFTI-0 space–time.

The zeroth-order asymptotic structure corresponds to the universal structure of AM space–times in Ref. 5. However, they differ in that the former does not contain the equivalence class of Ω constructed by regarding two completions Ω and Ω' equivalent if and only if they satisfy

$$\lim_{\to \check{i}^+} \frac{\Omega' - \Omega}{\Omega^2} = 0 \tag{4.11}$$

while the latter does. The reason is that the equivalence class does not arise on its own from the definition of an AFTI-0 space–time. This observation is also supported by the discussion of asymptotic symmetries in Sec. V.

Recalling that the difference between an AFTI-0 space–time and an AFFTIS-0 space–time is the topology of $\check{i}^+$, we define the asymptotic structure of an AFFTIS-0 space–time as follows.

Definition: The function F which is unity on $\check{i}^+$, i.e., $F \stackrel{\check{i}^+}{=} 1$, and the manifold $\check{i}^+$ with normalized negative-constant curvature, i.e., $\mathbf{q}_{ab} \stackrel{\check{i}^+}{=} \mathbf{h}_{ab}$ and topology of $S^2 \times (\mathbb{R}^+ - \{p\})$, are called the *zeroth-order asymptotic structure* of an AFFTIS-0 space–time.

Let us consider the form of the physical metric $\hat{g}_{ab}$ in an AFTI-0 space–time to understand the zeroth-order asymptotic structure more. From the fact that an AFTI-0 space–time possesses the zeroth-order asymptotic structure, we see that the expansions of the function F and the tensor field q_{ab} are given by

$$F = 1 + O(\Omega),$$

$$q_{ab} = h_{ab} + f (d\Omega)_a (d\Omega)_b + f^I (d\Omega)_{(a} (e_I)_{b)} + O(\Omega)$$

in an AFTI-0 space–time where f and f^I are smooth functions. With the expansion above, the definitions of F and q_{ab} give

$$\hat{g}_{ab} = -\Omega^{-4}[1 + O(\Omega)](d\Omega)_a (d\Omega)_b + \Omega^{-2}[h_{ab} + f (d\Omega)_a (d\Omega)_b + f^I (d\Omega)_{(a} (e_I)_{b)} + O(\Omega)]. \tag{4.12}$$

Introducing a conformal time $\eta := \ln \Omega$, we obtain

$$\hat{g}_{ab} = {}^{(0)}\hat{g}_{ab} + \Omega\, {}^{(1)}\hat{g}_{ab} + \cdots, \tag{4.13}$$

where

$${}^{(0)}\hat{g}_{ab} := (e^{-\eta})^2[-(d\eta)_a (d\eta)_b + h_{ab}] \tag{4.14}$$

and $e^{2\eta} \cdot {}^{(0)}\hat{g}_{ab}, e^{2\eta} \cdot {}^{(1)}\hat{g}_{ab}, \ldots$ are tensor fields that do not depend on Ω. If we transform the coordinates, it can be seen that ${}^{(0)}\hat{g}_{ab}$ is a metric of Minkowski space–time. Note that ${}^{(1)}\hat{g}_{ab}$ is arbitrary in an AFTI-0 space–time. That is, Eq. (4.13) tells us that an AFTI-0 space–time is asymptotically Minkowskian but how it approaches an asymptotically Minkowski space–time is not specified in any way.

V. ASYMPTOTIC SYMMETRIES

In this section, we define asymptotic symmetries by considering the transformations that preserve the zeroth-order asymptotic structure of an AFTI-0 and an AFFTIS-0 space–time and analyze their structures. Basically, this section is a review of the corresponding work of Ref. 5 but differs in the following points. First, the definition of the asymptotic symmetries is different due to the difference in the asymptotic structure they are to preserve. Second, one of the subgroups of the asymptotic symmetry group is examined in detail for the explicit evaluation of four-momentum in Sec. VIII. Third, the structure of the asymptotic symmetries differ due to the presence of a bounded source at the late time regime in an AFFTIS space–time.

In Minkowski space–time, the symmetry group, i.e., the Poincaré group, is a group of diffeomorphisms $\{\phi\}$ that preserve the structure of the space–time $\hat{\eta}_{ab}$: $\phi^* \hat{\eta}_{ab} = \hat{\eta}_{ab}$. Because the

structure that is universal to AFTI-0 or AFFTIS-0 space–times is the zeroth-order asymptotic structure, we define the asymptotic symmetries of such space–times to be transformations that preserve the asymptotic structures.

First we examine the infinitesimal asymptotic symmetries. As they are *local* transformations, the structure they preserve is that of an AFTI-0 space–time.

Definition: The infinitesimal Ti symmetry group $\mathcal{L}_{\mathcal{G}}$ is a group of equivalence classes of a C^∞ vector field ξ^a that satisfies the following conditions:

(1) ξ^a induces a smooth function $\boldsymbol{\alpha}$ given by

$$\boldsymbol{\alpha} := \lim_{\to \check{\imath}^+} \frac{\pounds_\xi \Omega}{\Omega^2} \tag{5.1}$$

and

(2) ξ^a induces a Killing vector of $(\check{\imath}^+, \mathbf{h}_{ab})$,

$$\pounds_{\boldsymbol{\xi}} \mathbf{h}_{ab} \doteq 0. \tag{5.2}$$

Two vector fields ξ_1^a and ξ_2^a are regarded as equivalent if and only if $(\boldsymbol{\alpha}_1, \boldsymbol{\xi}_1^a) \doteq (\boldsymbol{\alpha}_2, \boldsymbol{\xi}_2^a)$. [Ti stands for timelike infinity and rhymes with Scri($\mathcal{I}^\pm$) as Ashtekar's Spi(i^0) does.]

The first condition demands that $\Psi_\xi^*(\Omega)$ differs from Ω by terms of $O(\Omega^2)$ so that $\Psi_\xi^*(\Omega)$ also induces a unit hyperboloid completion and thus ξ^a preserves the zeroth-order asymptotic structure $F \doteq 1$, where Ψ denotes an infinitesimal map generated by ξ. The second condition ensures that ξ^a preserves the zeroth-order asymptotic structure $\mathbf{q}_{ab} \doteq \mathbf{h}_{ab}$. The equivalence class is defined because the vector fields that belong to the same class cannot be distinguished as a generator of symmetries.

Let us investigate the structure of the infinitesimal Ti group. Because its element is a C^∞ vector field, $\mathcal{L}_{\mathcal{G}}$ has the structure of a Lie algebra. The Lie bracket on the pairs is given by

$$[(\boldsymbol{\alpha}, \boldsymbol{\xi}^a), (\boldsymbol{\beta}, \boldsymbol{\eta}^a)] \hat{=} (\pounds_{\boldsymbol{\xi}} \boldsymbol{\beta} - \pounds_{\boldsymbol{\eta}} \boldsymbol{\alpha}, [\boldsymbol{\xi}, \boldsymbol{\eta}]^a). \tag{5.3}$$

The introduction of the following subgroup of $\mathcal{L}_{\mathcal{G}}$ helps the investigation of the structure on $\mathcal{L}_{\mathcal{G}}$.

Definition: The *infinitesimal Ti supertranslation group* $\mathcal{L}_{\mathcal{S}}$ is a subgroup of $\mathcal{L}_{\mathcal{G}}$ whose element $(\boldsymbol{\alpha}, \boldsymbol{\xi})$ satisfies

$$\boldsymbol{\xi}^a \doteq 0. \tag{5.4}$$

Because the subgroup contains the following infinitesimal Ti *translation* group, we call it infinitesimal Ti *supertranslation* group.

Definition: The *infinitesimal Ti translation group* $\mathcal{L}_{\mathcal{T}}$ is a subgroup of $\mathcal{L}_{\mathcal{S}}$ whose element $(\boldsymbol{\alpha}, 0)$ satisfies

$$\mathbf{D}_a \mathbf{D}_b \boldsymbol{\alpha} - \boldsymbol{\alpha} \mathbf{h}_{ab} \hat{=} 0, \tag{5.5}$$

where $\mathbf{D}_a$ is the derivative operator associated with the intrinsic metric $\mathbf{h}_{ab}$ on $\check{\imath}^+$. (The group does not depend on the function Ω used in the completion of a space–time because ξ^a vanishes on $\check{\imath}^+$ and thus α does not depend on Ω.)

It is important to note here that there are *four* independent functions that satisfy Eq. (5.5):

$$\boldsymbol{\alpha}_t \hat{=} \cosh \chi, \quad \boldsymbol{\alpha}_x \hat{=} \sinh \chi \sin \theta \cos \phi, \quad \boldsymbol{\alpha}_y \hat{=} \sinh \chi \sin \theta \sin \phi, \quad \text{and} \quad \boldsymbol{\alpha}_z \hat{=} \sinh \chi \cos \theta, \tag{5.6}$$

where (χ, θ, ϕ) is the standard hyperbolic coordinate on $\check{\imath}^+$. It can be shown that if $\check{\imath}^+$ is timelike infinity of n-dimensional space–time and thus $\mathbf{h}_{ab}$ in Eq. (5.5) is the $(n-1)$-hyperboloid metric, there are n independent functions satisfying the equation. The number corresponds to the number of possible ''directions'' of translation in the space–time. When Minkowski space–time is completed, the translational Killing fields correspond to the elements of $\mathcal{L}_{\mathcal{T}}$. It will be shown that the group is closely related with the asymptotic *translation* Killing fields introduced in Sec. VI and the four-momentum of the AFFTIS space–time introduced in Sec. VIII.

The structure of $\mathcal{L}_{\mathcal{G}}$ can be examined by noting that $\mathcal{L}_{\mathcal{S}}$ is a Lie ideal of $\mathcal{L}_{\mathcal{G}}$.[5] Hence, the quotient $\mathcal{L}_{\mathcal{G}}/\mathcal{L}_{\mathcal{S}}$ has the structure of a Lie algebra consisting of cosets $(\{\boldsymbol{\alpha}\},\boldsymbol{\xi}^a)$ where $\{\boldsymbol{\alpha}\}$ is a set of all the functions smooth on $\check{\imath}^+$. Thus, each element of the quotient is characterized by $\boldsymbol{\xi}^a$. In other words, $\mathcal{L}_{\mathcal{G}}/\mathcal{L}_{\mathcal{S}}$ is isomorphic to the group of the Killing fields of $(\check{\imath}^+,\mathbf{h}_{ab})$. Recalling that such Killing fields are in the Lie algebra of the Lorentz group $\mathcal{L}_L$, we obtain

$$\mathcal{L}_{\mathcal{G}}/\mathcal{L}_{\mathcal{S}}\cong\mathcal{L}_L \quad \text{and thus} \quad \mathcal{L}_{\mathcal{G}}\cong\mathcal{L}_{\mathcal{S}}\textcircled{S}\mathcal{L}_L, \tag{5.7}$$

where Ⓢ denotes the semi-direct sum here.

Next, let us consider the asymptotic symmetry group. Following the symmetry group of Minkowski space–time, we define the asymptotic symmetry group as a group of diffeomorphisms. Because AFTI-0 space–times possess only the zeroth-order asymptotic structure in common, the diffeomorphisms can be only defined on $\check{\imath}^+$. However, $\check{\imath}^+$ of an AFTI-0 space–time is not specified enough to consider diffeomorphisms generated on itself. Hence, we consider $\check{\imath}^+$ of an AFFTIS-0 space–time whose topology is restricted and demand that $\check{\imath}^+$ be geodesically complete so that diffeomorphisms could be generated on it.

Definition: The *Ti group* $\mathcal{G}$ is a group of diffeomorphisms generated by elements of $\mathcal{L}_{\mathcal{G}}$ on $\check{\imath}^+$ that is geodesically complete except for the geodesics through a point and that has topology of $S^2\times(\mathbb{R}^+-\{p\})$.

Recall that a three-manifold with negative-constant curvature with topology of $S^2\times(\mathbb{R}^+-\{p\})$ is a spacelike three-hyperboloid with a removed point. Hence, it is only when the removed point is chosen as the origin of the Lorentz transformations that the elements of $\mathcal{L}_L$ do generate diffeomorphisms. Otherwise, the integral curves of the elements of $\mathcal{L}_L$ would be incomplete due to the point. Hence, the Ti group $\mathcal{G}$ is a semi-direct product of the infinite-dimensional additive group of smooth functions on the unit spacelike hyperboloid with the Lorentz group around the removed point, L_{RP}:

$$\mathcal{G}\cong\mathcal{S}\textcircled{S}L_{\mathrm{RP}}. \tag{5.8}$$

The above additive group is *infinite* dimensional in contrast with the *four*-dimensional additive subgroup of the Poincaré groups, the translation group. This is because, as for transformations of the zeroth-order asymptotic structures, translations are the changes of the function Ω used in completions and the changes are possible in ''infinitely different ways.'' It is interesting that this structure is very similar to that of the Bond–Metzner–Sachs (BMS) group defined at null infinity which is a semi-direct product of the infinite-dimensional additive group of *conformally weighted functions on the two-sphere* and the Lorentz group.[8–11]

However, it is important to note here that the additive groups $\mathcal{S}$ in Eq. (5.8) consists of all the possible finite supertranslation. This is against our intuition that there are no spacelike translations when there exists a source, or a removed point on $\check{\imath}^+$, that breaks the symmetries. The reason traces back to the fact that the Ti group is defined only to preserve the structure of $\check{\imath}^+$ but the structure of $\check{\imath}^+$ is preserved as long as the function α is smooth, regardless of the detailed nature of α, which characterizes supertranslations. In the next section, we find that a translation whose associated function is α transforms the points in the vicinity of $\check{\imath}^+$ in $\mathcal{F}$ by the generator $\Omega D_a\alpha$. Hence, to take the actions of the supertranslations into the symmetry group more appropriately, we need to define the group $\mathcal{G}'$ to consist of diffeomorphisms in *the vicinity* of $\check{\imath}^+$. Now, the generators of the group must be vanishing in the vicinity of the removed point on $\check{\imath}^+$, and thus $\mathcal{G}'$ is a semi-direct product of the infinite-dimensional additive group $\mathcal{S}_{\mathrm{RP}}$ of smooth functions whose gradient vanishes in the vicinity of the removed point and the Lorentz group around the removed point:

$$\mathcal{G}'\cong\mathcal{S}_{\mathrm{RP}}\textcircled{S}L_{\mathrm{RP}}. \tag{5.9}$$

This modified Ti group $\mathcal{G}'$ does not contain ''spacelike supertranslation'' because, as we shall see in the next section, the gradients of the functions α associated with spacelike translations do not vanish in the vicinity of the removed point.

VI. ASYMPTOTIC KILLING FIELDS

In this section, we introduce the notion of asymptotic Killing fields. The introduction helps us to understand that the asymptotic symmetries are closely related with the hierarchy found in the asymptotic structure and gives a basis for discussing how fast a space–time becomes stationary.

If a vector field $\hat{\xi}^a$ is a Killing vector field, the Lie derivative of the metric with respect to $\hat{\xi}^a$ vanishes. This fact motivates us to call the vector field $\hat{\xi}^a$ an *asymptotic* Killing field if $\pounds_{\hat{\xi}}\hat{g}_{ab}$ *asymptotically* vanishes to the limit $\Omega\to 0$.

Definition: A space–time $(\hat{\mathcal{M}},\hat{g}_{ab})$ is said to admit an *asymptotic Killing field* $\hat{\xi}^a$ to order n if

$$\lim_{\to \check{\imath}^+} \Omega^{-n}(\pounds_{\hat{\xi}}\hat{g})_{\hat{\mu}\hat{\nu}}=0, \tag{6.1}$$

where $(\pounds_{\hat{\xi}}\hat{g})_{\hat{\mu}\hat{\nu}}:=\Psi^*((\hat{e}_\mu)^a(\hat{e}_\nu)^b\pounds_{\hat{\xi}}\hat{g}_{ab})$.

The local asymptotic symmetries defined above are related to the infinitesimal Ti group defined in the previous section as follows.

Proposition 1: In an AFTI-0 space–time, a vector field $\hat{\xi}^a$ belongs to the infinitesimal Ti group if and only if $\hat{\xi}^a$ is an asymptotic Killing field to order 0.

Proof of If: The components of the Lie derivative of the metric with respect to $\hat{\xi}^a$ are given by

$$\begin{aligned}
\hat{n}^a\hat{n}^b\pounds_{\hat{\xi}}\hat{g}_{ab}&=4\Omega^{-1}\pounds_{\hat{\xi}}\Omega-2F^{-1}\pounds_{[\hat{\xi},n]}\Omega-F^{-1}\pounds_{\hat{\xi}}F,\\
(\hat{e}_I)^a\hat{n}^b\pounds_{\hat{\xi}}\hat{g}_{ab}&=[\Omega^{-1}F^{-1/2}D_m(\pounds_{\hat{\xi}}\Omega)-\Omega q_{ma}F^{-1/2}\pounds_{\hat{\xi}}n^a](e_I)^m,\\
(\hat{e}_I)^a(\hat{e}_J)^b\pounds_{\hat{\xi}}\hat{g}_{ab}&=[-2\Omega^{-1}(\pounds_{\hat{\xi}}\Omega)q_{mn}+q_m{}^aq_n{}^b\pounds_{\hat{\xi}}q_{ab}](e_I)^m(e_J)^n
\end{aligned} \tag{6.2}$$

in terms of smooth functions and tensors. Because $\hat{\xi}^a$ is an asymptotic Killing field to order 0, all the components must be of $O(\Omega^1)$ by the definition. Hence, from the time–time component of $\pounds_{\hat{\xi}}\hat{g}_{ab}$ in the above equation, we find that $\alpha:=\pounds_{\hat{\xi}}\Omega/\Omega^2$ must be a smooth function. Hence, $\boldsymbol{\alpha}:=\lim_{\to \check{\imath}^+}\alpha$ is a smooth function on $\check{\imath}^+$ and the above identities become

$$\begin{aligned}
\hat{n}^a\hat{n}^b\pounds_{\hat{\xi}}\hat{g}_{ab}&=0+\Omega\mathcal{L}^{(1)}_{\hat{\xi}}F+O(\Omega^2),\\
(\hat{e}_I)^a\hat{n}^b\pounds_{\hat{\xi}}\hat{g}_{ab}&=[0+\Omega(D_m\alpha-q_{ma}\mathcal{L}_{\hat{\xi}}n^a)+O(\Omega^2)](e_I)^m,\\
(\hat{e}_I)^a(\hat{e}_J)^b\pounds_{\hat{\xi}}\hat{g}_{ab}&=[q_m{}^aq_n{}^b\mathcal{L}_{\hat{\xi}}q_{ab}-2\Omega\alpha q_{mn}](e_I)^m(e_J)^n
\end{aligned} \tag{6.3}$$

in AFTI-0 space–times where Eq. (4.4) is used in the evaluation. Next, from the space–space component, we find

$$q_m{}^aq_n{}^b\pounds_{\hat{\xi}}q_{ab}\doteq 0, \tag{6.4}$$

must be satisfied so that all the components of $\pounds_{\hat{\xi}}\hat{g}_{ab}$ are of $O(\Omega^1)$. The equation above induces

$$\pounds_{\hat{\boldsymbol{\xi}}}\mathbf{h}_{ab}\doteq 0 \tag{6.5}$$

on $\check{\imath}^+$. The equation tells us that $\hat{\xi}^a$ induces a Killing field of $(\check{\imath}^+,\mathbf{h}_{ab})$.

To summarize, an asymptotic Killing field to order 0 generates a smooth function $\boldsymbol{\alpha}$ on $\check{\imath}^+$ and induces a Killing field of $(\check{\imath}^+,\mathbf{h}_{ab})$. The vector field belongs to the infinitesimal Ti group. □

Proof of Only If: If $\hat{\xi}^a$ belongs to the infinitesimal Ti group, $\alpha:=\pounds_{\hat{\xi}}\Omega/\Omega^2$ is a smooth function from the definition. Thus, in AFTI space–times Eqs. (6.3) are satisfied. Further, $\hat{\xi}^a$ induces a Killing field of $(\check{\imath}^+,\mathbf{h}_{ab})$. Hence, the first term in the space–space component vanishes resulting in $(\pounds_{\hat{\xi}}\hat{g})_{\hat{\mu}\hat{\nu}}=O(\Omega^1)$. That is, $\hat{\xi}^a$ is an asymptotic Killing field to order 0. □

Equations (6.3) show that it was appropriate to define the zeroth-order asymptotic structure such that it does not contain the equivalence class of Ω defined by Eq. (4.11). As we have seen above, if the components of $\pounds_{\hat{\xi}}\hat{g}_{ab}$ are of order $O(\Omega)$, then the vector field ξ^a preserves the zeroth-order asymptotic structure. However, the vector field ξ^a preserves the equivalence class of Ω, only when $D_m\alpha-q_{ma}\pounds_{\hat{\xi}}n^a\doteq 0$ were satisfied in addition, or the time–space components of $\pounds_{\hat{\xi}}\hat{g}_{ab}$ were of $O(\Omega^2)$, as it can be seen from Eqs. (6.3). (For the details on the preservation of the

class, see Ref. 5.) The fact that the time–space components of $\pounds_{\hat{\xi}}\hat{g}_{ab}$ must be $O(\Omega^2)$ instead of $O(\Omega^1)$ to preserve the class indicates that the equivalence class of Ω is of *an order higher* asymptotic structure.

Next, we investigate the asymptotic translational Killing fields. This is to see how fast an AFTI-0 space–time becomes stationary.

Proposition 2: In an AFTI-0 space–time,

$$\begin{aligned}
\hat{\xi}_t{}^a &= \Omega[\sinh\chi (e_1)^a] + \Omega^2 F^{-1/2}\cosh\chi n^a,\\
\hat{\xi}_x{}^a &= \Omega[\cosh\chi \sin\theta\cos\phi (e_1)^a + \cos\theta\cos\phi (e_2)^a - \sin\phi (e_3)^a] + \Omega^2 F^{-1/2}\sinh\chi n^a,\\
\hat{\xi}_y{}^a &= \Omega[\cosh\chi \sin\theta\sin\phi (e_1)^a + \cos\theta\sin\phi (e_2)^a + \cos\phi (e_3)^a] + \Omega^2 F^{-1/2}\sinh\chi n^a,\\
\hat{\xi}_z{}^a &= \Omega[\cosh\chi \cos\theta (e_1)^a - \sin\theta (e_2)^a] + \Omega^2 F^{-1/2}\sinh\chi n^a
\end{aligned} \tag{6.6}$$

are admitted as asymptotic Killing fields to order one, where $e_1=\partial_\chi$, $e_2=(\sinh^{-1}\chi)\partial_\theta$ and $e_3=(\sinh^{-1}\chi\sin^{-1}\theta)\partial_\phi$. $\{\hat{\xi}_{x^\mu}\}_{\mu=0,1,2,3}(\{x^\mu\}=\{t,x,y,z\})$ are four *independent asymptotic translational Killing fields* in the sense that, with respect to the physical metric $\hat{g}_{ab}$, their norms are constant and they are orthogonal to each other:

$$\hat{g}_{ab}(\hat{\xi}_{x^\mu})^a(\hat{\xi}_{x^\nu})^b = \mp\delta_{\mu,\nu},$$

where $-$ is for $\mu=0$ and $+$ is for $\mu=1,2,3$.

Proof: The space components of the above asymptotic translational Killing vector fields are of $O(\Omega)$ and the time components are of $O(\Omega^2)$. Thus, the expansion of the vector field $\hat{\xi}^a$ is given by

$$\hat{\xi}^a = \sum_{l=1}^{\infty}\Omega^{l^{(l)}}\xi^I(e_I)^a + \sum_{l=2}^{\infty}\Omega^{l^{(l)}}\xi^0(\partial_\Omega)^a, \tag{6.7}$$

where $\{{}^{(n)}\xi^\mu\}$ is a set of smooth functions independent of Ω. Hence,

$$\alpha := \pounds_{\hat{\xi}}\Omega/\Omega^2 = \sum_{l=2}^{\infty}{}^{(l)}\xi^0\Omega^{l-2} \tag{6.8}$$

is a smooth function. Thus, the components of $\pounds_{\hat{\xi}}\hat{g}_{ab}$ are given by

$$\begin{aligned}
\hat{n}^a\hat{n}^b\pounds_{\hat{\xi}}\hat{g}_{ab} &= 0 + O(\Omega^2),\\
(\hat{e}_I)^a\hat{n}^b\pounds_{\hat{\xi}}\hat{g}_{ab} &= [\Omega(D_m\alpha - {}^{(1)}\xi^J(e_J)_m) + O(\Omega^2)](e_I)^m,\\
(\hat{e}_I)^a(\hat{e}_J)^b\pounds_{\hat{\xi}}\hat{g}_{ab} &= [\Omega(q_m{}^a q_n{}^b\pounds^{(1)}\xi^J(e_J)q_{ab} - 2\alpha q_{mn}) + O(\Omega^2)](e_I)^m(e_J)^n.
\end{aligned} \tag{6.9}$$

From the equations above, we see that $(\pounds_{\hat{\xi}}\hat{g})_{\hat{\mu}\hat{\nu}} = O(\Omega^2)$ if the space components of the $O(\Omega^1)$ terms of the vector field $\hat{\xi}^a$ satisfy

$$D_m\alpha - {}^{(1)}\xi^J(e_J)_m \doteq 0 \quad \text{and} \quad q_m{}^a q_n{}^b\pounds^{(1)}\xi^J(e_J)q_{ab} - 2\alpha q_{mn} \doteq 0. \tag{6.10}$$

These equations are tangential to $\check{\imath}^+$ and thus induce

$${}^{(1)}\boldsymbol{\xi}^a \doteq \mathbf{D}^a\boldsymbol{\alpha} \quad \text{and} \quad \pounds^{(1)}\boldsymbol{\xi}\mathbf{h}_{ab} - 2\boldsymbol{\alpha}\mathbf{h}_{ab} \doteq 0 \tag{6.11}$$

on $\check{\imath}^+$ without any loss of information where ${}^{(1)}\boldsymbol{\xi}^a$ and $\boldsymbol{\alpha}$ denote the vector field and the function induced by ${}^{(1)}\xi^J(e_J)^a$ and $\lim_{\to\check{\imath}^+}\alpha := {}^{(2)}\xi^0$ on $\check{\imath}^+$, respectively. Thus, the conditions can be restated as

$$\mathbf{D}_a\mathbf{D}_b\boldsymbol{\alpha}-\boldsymbol{\alpha}\mathbf{h}_{ab}\doteq 0, \tag{6.12}$$

$$^{(1)}\boldsymbol{\xi}^a\doteq\mathbf{D}^a\boldsymbol{\alpha}. \tag{6.13}$$

In other words, $(\pounds_{\hat{\xi}}\hat{g})_{\hat{\mu}\hat{\nu}}=O(\Omega^2)$ is satisfied if the leading term of the time component of $\hat{\xi}$, $\boldsymbol{\alpha}=^{(2)}\boldsymbol{\xi}^0$, satisfies Eq. (6.12) and if those of the space components $^{(1)}\boldsymbol{\xi}^a$ are given by Eq. (6.13). Note here that Eq. (6.12) is the same as Eq. (5.5) used in defining the infinitesimal Ti *translation* and that $\{\boldsymbol{\alpha}_{x^\mu}\}$ in Eq. (5.6) are the four independent smooth functions that satisfy the equation. Then, from Eq. (6.13), we see that the corresponding independent space components are

$$\begin{aligned}
^{(1)}\boldsymbol{\xi}_t{}^a&\doteq\sinh\chi(\mathbf{e}_1)^a,\\
^{(1)}\boldsymbol{\xi}_x{}^a&\doteq\cosh\chi\,\sin\theta\,\cos\phi(\mathbf{e}_1)^a+\cos\theta\,\cos\phi(\mathbf{e}_2)^a-\sin\phi(\mathbf{e}_3)^a,\\
^{(1)}\boldsymbol{\xi}_y{}^a&\doteq\cosh\chi\,\sin\theta\,\sin\phi(\mathbf{e}_1)+\cos\theta\,\sin\phi(\mathbf{e}_2)^a+\cos\phi(\mathbf{e}_3)^a\\
^{(1)}\boldsymbol{\xi}_z{}^a&\doteq\cosh\chi\,\cos\theta(\mathbf{e}_1)^a-\sin\theta(\mathbf{e}_2)^a.
\end{aligned} \tag{6.14}$$

The space components of the vector fields in Eqs. (6.6) do take this form and thus are asymptotic Killing fields to order one in Ω. □

As a corollary of Proposition 2, we obtain the relation between the infinitesimal Ti translational group $\mathcal{L}_{\mathcal{T}}$ and the above asymptotic translational Killing fields.

Corollary: The asymptotic translational Killing fields to order one, Eqs. (6.6), belong to the infinitesimal Ti translational group $\mathcal{L}_{\mathcal{T}}$.

Proof: Admitted as asymptotic Killing fields to order one, the asymptotic translational Killing fields belong to the infinitesimal Ti group according to Proposition 1. In addition, the fields vanish on $\check{\imath}^+$ and generate smooth functions satisfying Eq. (5.5). □

Let us consider the finite translations in AFFTIS-0 space–times. From Eqs. (6.7) and (6.13), we see that the generators of translations vanish on $\check{\imath}^+$ but transform the points in vicinity of $\check{\imath}^+$ in the direction of $\Omega D^a\alpha$, or $^{(1)}\xi^a$. Although the generator $^{(1)}\xi_t{}^a$ of a timelike translation vanishes in the vicinity of the removed point $\chi=0$ on $\check{\imath}^+$, the generators $^{(1)}\xi_x{}^a$, $^{(1)}\xi_y{}^a$, and $^{(1)}\xi_z{}^a$ of spacelike translations do not. Hence, there exist only timelike translation symmetry $\hat{\xi}_t$ and no spacelike translation symmetries in AFFTIS-0 space–times. In other words, the existence of source in an AFFTIS-0 space–time breaks the spacelike translation symmetries but leaves the timelike symmetries.

From the above discussion, it can be said that if the energy-momentum tensor of a space–time falls off at a rate faster than Ω^2, the space–time becomes asymptotically stationary at the rate of Ω^2.

We conclude the section with a remark on the relation of the asymptotic symmetries with the hierarchy in asymptotic structure. We have shown that asymptotic translational Killing fields are admitted to order 1 in AFTI-0 space–times. However, we can see that the fields are not admitted to order 2 in general. For the vector fields to be admitted to order 2, the coefficients of the $O(\Omega^2)$ terms in Eqs. (6.9) need to vanish. These terms contain the higher-order asymptotic structure, such as $^{(1)}F$. For example, the $O(\Omega^2)$ term of the time–time component is $\Omega^2[D^{a(1)}FD_a\alpha+^{(1)}F\alpha-2n^a\nabla_a\alpha]$. These higher-order asymptotic quantities are *arbitrary* in AFTI-0 space–times. Hence, in general, the $O(\Omega^2)$ terms in Eqs. (6.9) do not vanish and thus asymptotic translational Killing fields to order two are not admitted in general AFTI-0 space–times. The asymptotic translational Killing fields to order 2 are the asymptotic symmetries that belong to the zeroth-order asymptotic structure.

VII. GRAVITATIONAL FIELDS

In this section, we investigate the gravitational fields and find hierarchy in their asymptotic behaviors.

Because the Ricci tensor of $\hat{g}_{ab}$ is reserved for the definition of AFTI-n space–times, we examine the Weyl tensor $\hat{C}_{abcd}$ to investigate the gravitational fields. For convenience of the discussion, decompose the Weyl tensor into the electric part $\hat{E}_{ab}:=\hat{C}_{ambn}\hat{n}^m\hat{n}^n$ and the magnetic

part $\hat{B}_{ab}:=*\hat{C}_{ambn}\hat{n}^m\hat{n}^n$, where $*\hat{C}_{ambn}$ denotes the dual of the two-form $\hat{C}_{[am]bn}$. In terms of quantities associated with the Ω-const surfaces and the physical components of the energy-momentum tensor, $\hat{E}_{ab}$ and $\hat{B}_{ab}$ are given by

$$\hat{E}_{ab}=\hat{K}_{ar}\hat{K}^r{}_b-\pounds_{\hat{n}}\hat{K}_{ab}+\hat{D}_{(a}\hat{a}_{b)}+\hat{a}_a\hat{a}_b+\tfrac{1}{2}(\hat{q}^r_a\hat{q}^s_b-\hat{q}_{ab}\hat{n}^r\hat{n}^s)\hat{L}_{rs},$$
$$\hat{B}_{ab}=\hat{\epsilon}_{ra}{}^s\hat{D}^r\hat{K}_{bs}+\tfrac{1}{2}\hat{\epsilon}_{ab}{}^r\hat{n}^s\hat{L}_{rs}, \tag{7.1}$$

where $\hat{L}_{ab}:=\hat{R}_{ab}-\frac{1}{6}\hat{R}\hat{g}_{ab}$ and $\hat{a}_a:=\hat{q}_{ar}\hat{n}^s\hat{\nabla}_s\hat{n}^r$.

In AFTI-0 space–times, we find that $\hat{E}_{ab}$ and $\hat{B}_{ab}$ vanish on $\check{\imath}^+$:

$$\hat{E}_{ab}=\sum_{l=1}^{\infty}\Omega^{l(l)}E_{ab} \quad \text{and} \quad \hat{B}_{ab}=\sum_{l=1}^{\infty}\Omega^{l(l)}B_{ab}, \tag{7.2}$$

where ${}^{(n)}E_{ab}$ and ${}^{(n)}B_{ab}$ are defined by

$${}^{(1)}E_{ab}:=\lim_{\to\check{\imath}^+}\Omega^{-1}\hat{E}_{ab}, \quad {}^{(n)}E_{ab}:=\lim_{\to\check{\imath}^+}\Omega^{-n}\left(\hat{E}_{ab}-\sum_{l=1}^{n-1}{}^{(l)}E_{ab}\right) \quad \text{for } n\geqslant 2, \tag{7.3}$$

$${}^{(1)}B_{ab}:=\lim_{\to\check{\imath}^+}\Omega^{-1}\hat{B}_{ab}, \quad {}^{(n)}B_{ab}:=\lim_{\to\check{\imath}+}\Omega^{-n}\left(\hat{B}_{ab}-\sum_{l=1}^{n-1}{}^{(l)}B_{ab}\right) \quad \text{for } n\geqslant 2. \tag{7.4}$$

Note here that, although they depend on the choice of Ω, ${}^{(n)}E_{ab}$ and ${}^{(n)}B_{ab}$ are defined, regardless of whether their lower-order terms vanish. This is in contrast with the treatment of Ref. 5 where the subsequent order terms are defined only when their lower-order terms vanish. Their leading terms are given by

$${}^{(1)}E_{ab}=\tfrac{1}{2}(D_aD_b-h_{ab})^{(1)}F+\tfrac{1}{2}(e_I)_a(e_J)_b({}^{(3)}\hat{L}_{\hat{I}\hat{J}}+\delta_{I,J}{}^{(3)}\hat{L}_{\hat{0}\hat{0}}), \tag{7.5}$$

$${}^{(1)}B_{ab}=\tfrac{1}{2}\epsilon_{ra}{}^sD^{r(1)}K_{bs}+\tfrac{1}{2}\epsilon_{ab}{}^r(e_I)_r{}^{(3)}\hat{L}_{\hat{0}\hat{I}}, \tag{7.6}$$

where ${}^{(1)}K_{ab}:=\lim_{\to\check{\imath}^+}\Omega^{-1}(K_{ab}-h_{ab})$, $\hat{L}_{\hat{0}\hat{0}}:=\Psi*[\hat{L}_{ab}\hat{n}^a\hat{n}^b]$, $\hat{L}_{\hat{0}\hat{I}}:=\Psi*[\hat{L}_{ab}\hat{n}^{(a}(\hat{e}_I)^{b)}]$, $\hat{L}_{\hat{I}\hat{J}}:=\Psi*[\hat{L}_{ab}(\hat{e}_I)^a(\hat{e}_J)^b]$, and ${}^{(n)}\hat{L}_{\hat{\mu}\hat{\nu}}$ denotes the coefficient of the $O(\Omega^n)$ term of $\hat{L}_{\hat{\mu}\hat{\nu}}$. ${}^{(1)}E_{ab}$ and ${}^{(1)}B_{ab}$ depend on ${}^{(3)}\hat{L}_{\hat{\mu}\hat{\nu}}$ that consists of the higher-order asymptotic structure such as ${}^{(1)}F$ and ${}^{(1)}K_{ab}$. Because these quantities are arbitrary in AFTI-0 space–times, we cannot conclude anything more than that $\hat{E}_{ab}$ and $\hat{B}_{ab}$ vanish on $\check{\imath}^+$.

Let us examine the gravitational fields in AFTI-1 space–times. The falloff condition on the energy-momentum tensor demands ${}^{(3)}\hat{L}_{\hat{\mu}\hat{\nu}}$ vanish on $\check{\imath}^+$ and we obtain

$${}^{(1)}E_{ab}\stackrel{\check{}}{=}\tfrac{1}{2}(D_aD_b-h_{ab})^{(1)}F \quad \text{and} \quad {}^{(1)}B_{ab}\stackrel{\check{}}{=}\tfrac{1}{2}\epsilon_{ra}{}^sD^{r(1)}K_{bs}. \tag{7.7}$$

The equation on ${}^{(1)}E_{ab}$ induces

$${}^{(1)}\mathbf{E}_{ab}\stackrel{\check{}}{=}\tfrac{1}{2}(\mathbf{D}_a\mathbf{D}_b-\mathbf{h}_{ab})^{(1)}\mathbf{F} \tag{7.8}$$

on $\check{\imath}^+$. Using Eq. (4.10), it can be shown that ${}^{(1)}\mathbf{E}_{ab}$ obeys the field equation

$$\mathbf{D}_{[a}{}^{(1)}\mathbf{E}_{b]c}\stackrel{\check{}}{=}0. \tag{7.9}$$

Contracting over a and b and recalling that ${}^{(1)}\mathbf{E}_{ab}$ is traceless by definition, we find that ${}^{(1)}\mathbf{E}_{ab}$ is divergence-free:

$$\mathbf{D}_a{}^{(1)}\mathbf{E}^{ab}\stackrel{\check{}}{=}0. \tag{7.10}$$

It can be shown that ${}^{(1)}\mathbf{B}_{ab}$ satisfies the same field equation. Contracting the Bianchi identity $\nabla_{[a}\hat{R}_{bc]}{}^{de}=0$ with $\hat{n}^a\hat{\epsilon}^{bc}{}_m\hat{\epsilon}_{den}$, we obtain

$$\hat{\epsilon}^{ac}{}_{m}\hat{D}_a\hat{B}_{cn}-\hat{n}^a\hat{\nabla}_a\hat{E}_{mn}+\hat{\epsilon}^{ac}{}_{m}\hat{\epsilon}^{de}{}_{n}\hat{K}_{ad}\hat{E}_{ce}-2\hat{\epsilon}^{bc}{}_{(m}\hat{B}_{n)c}\hat{a}_b + \tfrac{1}{2}(\hat{n}^{[a}\hat{q}^{c]e}\hat{q}_{mn}-\hat{n}^{[a}\hat{q}^{c]}_n\hat{q}^e_m)\hat{\nabla}_a\hat{L}_{ce}=0 \tag{7.11}$$

from which we find, in AFTI-n space–times,

$$D_{[a}{}^{(1)}B_{b]c}=O(\Omega)+O(\Omega^n), \tag{7.12}$$

where we have used the equations $n^r\nabla_r(\hat{e}_I)_a=-(e_I)_a+O(\Omega)$, $\Omega\cdot n^r\nabla_r\hat{L}_{\hat{I}\hat{J}}=O(\Omega^{n+3})$, $\hat{L}_{\hat{\mu}\hat{\nu}}=O(\Omega^{n+3})$ and $D_a\hat{L}_{\hat{0}\hat{I}}=O(\Omega^{n+3})$ to evaluate the derivative of $\hat{L}_{ab}$:

$$\begin{aligned}(\hat{n}^{[a}\hat{q}^{c]e}\hat{q}_{mn}-\hat{n}^{[a}\hat{q}^{c]}_n\hat{q}^e_m)\hat{\nabla}_a\hat{L}_{ce}&=\Omega^{-1}[q_{mn}(\Omega n^a\nabla_a\hat{L}_{\hat{I}\hat{J}}-2\hat{L}_{\hat{I}\hat{I}}+2\hat{L}_{\hat{0}\hat{0}}-(e_I)^eD_e\hat{L}_{\hat{0}\hat{I}})\\&\quad+(e_I)_m(e_J)_n(\Omega n^a\nabla_a\hat{L}_{\hat{I}\hat{J}}-\hat{L}_{\hat{I}\hat{J}})+(e_I)_mD_n\hat{L}_{\hat{0}\hat{I}}+O(\Omega^{n+4})]\\&=O(\Omega^{n+2}).\end{aligned}$$

Hence, in AFTI-1 spacetimes, the equation $D_{[a}{}^{(1)}B_{b]c}\stackrel{=}{=}0$ is satisfied and induces

$$\mathbf{D}_{[a}{}^{(1)}\mathbf{B}_{b]c}\stackrel{=}{=}0 \tag{7.13}$$

on $\check{\imath}^+$. Thus ${}^{(1)}\mathbf{B}_{ab}$ is also divergence-free:

$$\mathbf{D}_a{}^{(1)}\mathbf{B}^{ab}\stackrel{=}{=}0. \tag{7.14}$$

Here, it is important to note that the explicit form of the function ${}^{(1)}\mathbf{F}$ can be obtained. Because ${}^{(1)}\mathbf{E}_{ab}$ is traceless by definition, the contraction of Eq. (7.8) gives a differential equation for the function ${}^{(1)}\mathbf{F}$**:**

$$\mathbf{D}^a\mathbf{D}_a{}^{(1)}\mathbf{F}-3{}^{(1)}\mathbf{F}\stackrel{=}{=}0. \tag{7.15}$$

We have obtained the nontrivial equation because the Einstein equation is used in a nontrivial way to obtain Eq. (7.8). That is, the terms that are not traceless, $\frac{1}{2}(e_I)_a(e_J)_b({}^{(3)}\hat{L}_{\hat{I}\hat{J}}+\delta_{I,J}{}^{(3)}\hat{L}_{\hat{0}\hat{0}})$, are discarded to obtain the equation. In contrast, we do not obtain any nontrivial equations from noting that ${}^{(1)}B_{ab}$ is traceless because the discarded terms to obtain the corresponding equation (7.7) are traceless. The general solution of Eq. (7.15) takes the form

$${}^{(1)}\mathbf{F}(\chi,\theta,\phi)=\sum_{\substack{l\geqslant 0\\|m|\leqslant l}}\mathbf{a}_{lm}{}^{(1)}\mathbf{F}_{lm}(\chi,\theta,\phi), \tag{7.16}$$

where

$${}^{(1)}\mathbf{F}_{lm}(\boldsymbol{\chi},\boldsymbol{\theta},\boldsymbol{\phi}):=\frac{1}{\sqrt{\sinh\boldsymbol{\chi}}}\mathbf{P}^{l+1/2}_{3/2}(\cosh\boldsymbol{\chi})\mathbf{Y}_{lm}(\boldsymbol{\theta},\boldsymbol{\phi}). \tag{7.17}$$

Here, $P^\mu_\nu(z)$ denote the associated Legendre functions defined by

$$P^\mu_\nu(z):=\frac{1}{\Gamma(1-\mu)}\left(\frac{z+1}{z-1}\right)^{\mu/2}F\left(-\nu,\nu+1,1-\mu;\frac{1-z}{2}\right)\quad\text{for } z>1, \tag{7.18}$$

where $F(\alpha,\beta,\gamma;z)$ are the hypergeometric functions. Here Y_{lm} stands for the spherical harmonics with their coefficients chosen as

$$\mathbf{Y}_{\diagup m}(\theta,\phi)=\begin{cases}\sqrt{2\pi}\mathbf{P}^m_l(\cos\theta)\cdot\cos m\phi, & m\geqslant 0,\\ \sqrt{2\pi}\mathbf{P}^m_l(\cos\theta)\cdot\sin m\phi, & m<0,\end{cases} \tag{7.19}$$

so that their physical meanings can be conveniently read in the next section. Explicitly, we obtain

$$^{(1)}\mathbf{F}_{00}=2\left(2\sinh\boldsymbol{\chi}+\frac{1}{\sinh\boldsymbol{\chi}}\right), \tag{7.20}$$

$$^{(1)}\mathbf{F}_{11}=2\left(2\cosh\boldsymbol{\chi}-\frac{\cosh\boldsymbol{\chi}}{\sinh^2\boldsymbol{\chi}}\right)\sin\boldsymbol{\theta}\cos\phi. \tag{7.21}$$

When the Schwarzschild spacetimes are completed, the function F indeed consists of the above functions. See the Appendix for the explicit calculations.

To define an angular momentum, it is important to see the conditions for $^{(2)}\mathbf{B}_{ab}$ to be divergence-free. This can be done using the Bianchi identity $\nabla_{[a}\hat{R}_{bc]}{}^{de}=0$ contracted with $\hat{\boldsymbol{\epsilon}}^{abc}\hat{n}_d\hat{q}^s{}_e$,

$$\hat{D}_r\hat{B}^{rs}=\tfrac{1}{2}\hat{\boldsymbol{\epsilon}}_s{}^{rp}\hat{n}^q\nabla_r\hat{L}_{pq}. \tag{7.22}$$

Keeping in mind that $^{(1)}\mathbf{B}_{ab}$ is divergence-free, we find that the above equation induces

$$\mathbf{D}_r{}^{(2)}\mathbf{B}^{rs}\stackrel{\scriptscriptstyle\sim}{=}{}^{(4)}\mathbf{L}_{IJ}\boldsymbol{\epsilon}^{srp}(\mathbf{e}_I)_r(\mathbf{e}_J)_p. \tag{7.23}$$

Hence, $^{(2)}\mathbf{B}_{ab}$ is not divergence-free in general AFTI-1 space–times. However, in AFTI-2 space–times $^{(4)}\mathbf{L}_{IJ}$ vanishes on $\check{\imath}^+$ and $^{(2)}\mathbf{B}_{ab}$ is divergence-free:

$$\mathbf{D}_r{}^{(2)}\mathbf{B}^{rs}\stackrel{\scriptscriptstyle\sim}{=}0. \tag{7.24}$$

Note here that $^{(1)}B_{ab}$ does not need to vanish on $\check{\imath}^+$ for $^{(2)}\mathbf{B}^{ab}$ to be divergence-free. This point is unclear in, Ref. 5.

We conclude the section with a remark on the relation of the asymptotic behavior of gravitational fields with the hierarchy in the asymptotic structure. The gravitational fields of each order, $^{(n)}E_{ab}$ and $^{(n)}B_{ab}$, are constructed from the asymptotic structure of the corresponding order. Hence, if the energy-momentum tensor falls off at a low rate and the space–time lacks the higher-order asymptotic structure, the asymptotic behaviors of the higher-order gravitational fields are arbitrary. In an AFTI-0 space–time, $^{(0)}E_{ab}$ and $^{(0)}B_{ab}$ vanish on $\check{\imath}^+$ and $^{(l)}E_{ab}$ and $^{(l)}B_{ab}$ take arbitrary forms for $l\geqslant 1$. In an AFTI-1 space–time, $^{(1)}E_{ab}$ and $^{(1)}B_{ab}$ induces divergence-free tensor fields on $\check{\imath}^+$ that satisfy the field equations (7.9) and (7.13), respectively, and $^{(1)}E_{ab}$ takes the form given by Eqs. (7.16) and (7.7). $^{(l)}E_{ab}$ and $^{(l)}B_{ab}$ take arbitrary forms for $l\geqslant 2$. In an AFTI-2 space–time, $^{(2)}B_{ab}$ induce a divergence-free tensor field on $\check{\imath}^+$.

VIII. CONSERVED QUANTITIES

In this section, we define two conserved quantities, namely four-momentum of ATI-1 space–times and angular momentum of ATI-2 space–times, which are associated with the asymptotic symmetries that the spacetimes possess.

As Minkowski space–time admits infinitesimal *translation* symmetries, it possesses a conserved four-momentum. The four-momentum is defined as a linear mapping from the four-dimensional vector space of infinitesimal translations to real numbers. Because ATI-n space–times possess infinitesimal Ti translations, we expect that the four-momentum of ATI-n space–times can be also defined as a linear mapping of infinitesimal Ti translations to real numbers.

The four-momentum representing the state of the space–time should be defined with information from the gravitational fields. However, ATI-0 space–times possess no asymptotic gravitational fields, as we have seen in the previous section. This means that the four-momentum cannot be defined in ATI-0 space–times. Now, consider ATI-1 space–times. Here, we have gravitational fields $^{(1)}\mathbf{E}_{ab}$ and $^{(1)}\mathbf{B}_{ab}$. On the other hand, infinitesimal Ti, translations may be represented by $\mathbf{D}^a\boldsymbol{\alpha}_{\mathcal{T}}$, where $\boldsymbol{\alpha}_{\mathcal{T}}$ is a smooth function generated by the elements of $\mathcal{L}_{\mathcal{T}}$. The vector field is a conformal Killing field of $(\check{\imath}^+,\mathbf{h}_{ab})$ by definition:

$$\mathbf{D}_{(a}\mathbf{D}_{b)}\boldsymbol{\alpha}_{\mathcal{T}}\stackrel{\scriptscriptstyle\sim}{=}2\boldsymbol{\alpha}_{\mathcal{T}}\mathbf{h}_{ab}. \tag{8.1}$$

With these $^{(1)}\mathbf{E}_{ab}$ and $\mathbf{D}^a\boldsymbol{\alpha}_{\mathcal{T}}$, the four-momentum of an ATI-1 space–time can be defined as follows.

Definition: Four-momentum $\mathbf{P}$ of an ATI-1 space–time with a region $\mathcal{A}$ on $\check{\imath}^+$ that satisfies

(1) $\mathcal{A}$ is bounded by cross sections $\mathcal{S}_a$ and $\mathcal{S}_b$ that do not intersect with each other, i.e., $\partial\mathcal{A}=\mathcal{S}_a\cap\mathcal{S}_b$ and $\mathcal{S}_a\cap\mathcal{S}_b=\varnothing$,
(2) q_{ab} and n^a have smooth limit to $\mathcal{A}\subset\check{\imath}^+$ and functions $\boldsymbol{\alpha}_{\mathcal{T}}$ generated by elements of $\mathcal{L}_{\mathcal{T}}$ are smooth on $\mathcal{A}$, is a linear mapping of $\boldsymbol{\alpha}_{\mathcal{T}}$ to real numbers defined by

$$\mathbf{P}:\boldsymbol{\alpha}_{\mathcal{T}}\mapsto\mathbb{R} \overset{\text{def}}{\Leftrightarrow} \mathbf{P}(\boldsymbol{\alpha}_{\mathcal{T}}):=-\frac{1}{8\pi}\int_{\mathcal{S}}\boldsymbol{\epsilon}_{ab}{}^{m(1)}\mathbf{E}_{mn}\mathbf{D}^n\boldsymbol{\alpha}_{\mathcal{T}}, \tag{8.2}$$

where $\mathcal{S}$ is a cross section of the region $\mathcal{A}$.

Note that, in general, ATI-1 space–times do not possess a region $\mathcal{A}$ satisfying the above properties; q_{ab} and n^a are demanded to have smooth limits to $\check{\imath}^+\cap\mathcal{F}$ in ATI-1 space–times but the region $\check{\imath}^+\cap\mathcal{F}$ does not need to satisfy the above properties (1) and (2). However, we need such a region on $\check{\imath}^+$ to define a ''conserved quantity'' as we shall see below.

The four-momentum can be considered as a ''conserved quantity'' because it is invariant under a change of the cross section $\mathcal{S}$ chosen for the evaluation. This is because the two-form integrand is closed in $\mathcal{A}$: the three-form $\mathbf{D}_{[c}\boldsymbol{\epsilon}_{ab]}{}^{m(1)}\mathbf{E}_{mn}\mathbf{D}^n\boldsymbol{\alpha}_{\mathcal{T}}$ is proportional to

$$\boldsymbol{\epsilon}^{cab}\mathbf{D}_c(\boldsymbol{\epsilon}_{ab}{}^{m(1)}\mathbf{E}_{mn}\mathbf{D}^n\boldsymbol{\alpha}_{\mathcal{T}})\doteq(\mathbf{D}^{m(1)}\mathbf{E}_{mn})\mathbf{D}^n\boldsymbol{\alpha}_{\mathcal{T}}+{}^{(1)}\mathbf{E}_{mn}(\tfrac{1}{2}\boldsymbol{\alpha}_{\mathcal{T}}\mathbf{h}^{mn})\doteq 0, \tag{8.3}$$

where we used, in the first line, the fact that $\mathbf{D}^a\boldsymbol{\alpha}_{\mathcal{T}}$ is a conformal Killing field and, in the second line, the facts that ${}^{(1)}\mathbf{E}_{ab}$ is divergence-free and traceless. In other words, the four-momentum is ''conserved'' in $\mathcal{A}$ because it consists of a smooth conformal Killing field and a smooth divergence-free, traceless gravitational field.

Recall that there are *four* independent functions of $\boldsymbol{\alpha}_{\mathcal{T}}$ as shown in Eq. (5.6). Thus, there are *four* independent components of *four* momentum $\mathbf{P}$ as we expect.

Now let us evaluate the four-momentum defined above and see where the information is contained. First, we evaluate the $\boldsymbol{\alpha}_t$ component. For simplicity, choose the $\chi=$const surface in $\mathcal{A}$ as $\mathcal{S}$. We obtain

$$\mathbf{P}(\boldsymbol{\alpha}_t)=\frac{1}{16\pi}\int_{\chi=\text{const}}\left(\frac{\partial^2}{\partial\boldsymbol{\chi}^2}{}^{(1)}\mathbf{F}-{}^{(1)}\mathbf{F}\right)\sinh\boldsymbol{\chi}\sqrt{\mathbf{h}}\,d\boldsymbol{\theta}d\boldsymbol{\phi}, \tag{8.4}$$

where $\mathbf{h}:=\det(\mathbf{h}_{ij})=\sinh^2\boldsymbol{\chi}\sin\boldsymbol{\theta}$. Substituting the general solution of ${}^{(1)}\mathbf{F}$, Eq. (7.16), and using the orthogonality of spherical harmonics

$$\int\mathbf{Y}_{lm}\,d(\cos\boldsymbol{\theta})d\boldsymbol{\phi}=4\sqrt{2}\pi^{3/2}\delta_{l,0}\delta_{m,0}, \tag{8.5}$$

we find that all the terms but ${}^{(1)}\mathbf{F}_{00}$ of ${}^{(1)}\mathbf{F}$ vanish and obtain

$$\mathbf{P}(\boldsymbol{\alpha}_t)=\mathbf{a}_{00}. \tag{8.6}$$

The spatial momentum can be evaluated likewise as

$$\mathbf{P}(\boldsymbol{\alpha}_x)=\mathbf{a}_{11},\quad \mathbf{P}(\boldsymbol{\alpha}_y)=\mathbf{a}_{1-1},\quad \mathbf{P}(\boldsymbol{\alpha}_z)=\mathbf{a}_{10}. \tag{8.7}$$

Here, we find that the $l=0$, 1 modes of ${}^{(1)}\mathbf{F}$ contain the information on the four-momentum of an AFTI-0 space–time. Since the function ${}^{(1)}\mathbf{F}$ is of the first-order asymptotic structure, the coefficients of ${}^{(1)}\mathbf{F}$ and thus the four momentum $\mathbf{P}$ is also of the first-order asymptotic structure. If we complete the Kerr space–time and the Schwarzschild space–time, we obtain the expected answers for the four-momentum **P:** $\mathbf{a}_{00}$ equals the mass parameter m. See Eqs. (A3) and (A9) for the explicit calculations. Moreover, $\mathbf{a}_{11}$ equals $-mv$ in the leading order of v for the Schwarzschild space–time boosted by a constant velocity v along the x axis. See Eq. (A11).

Because ${}^{(1)}\mathbf{B}_{ab}$ is also divergence-free and traceless and $\boldsymbol{\xi}\in\mathcal{L}_L$ is a conformal Killing field of $(\check{\imath}^+,\mathbf{h}_{ab})$, we obtain a new ''conserved quantity'' if we replace ${}^{(1)}\mathbf{E}_{mn}\mathbf{D}^n\boldsymbol{\alpha}_{\mathcal{T}}$ in Eq. (8.2) with one

of ${}^{(1)}\mathbf{B}_{mn}\mathbf{D}^n\boldsymbol{\alpha}_{\mathcal{T}}$, ${}^{(1)}\mathbf{E}_{mn}\boldsymbol{\xi}^n$, and ${}^{(1)}\mathbf{B}_{mn}\boldsymbol{\xi}^n$. However, it is found that they all give exact two-form integrands. Hence, the ''conserved quantities'' identically vanish.[5] Because there are no more gravitational fields in an AFFTIS-1 space–time, four-momentum $\mathbf{P}$ can be considered as the sole ''conserved quantity'' of AFFTIS-1 space–times.

Next, consider AFFTIS-2 space–times. There exists a gravitational field ${}^{(2)}\mathbf{B}_{ab}$ that is divergence-free and traceless in such space–times. Hence, we yield another ''conserved quantity'' by replacing ${}^{(1)}\mathbf{E}_{mn}\mathbf{D}^n\boldsymbol{\alpha}_{\mathcal{T}}$ in Eq. (8.2) with ${}^{(2)}\mathbf{B}_{mn}\boldsymbol{\xi}^n$. This quantity can be regarded as angular momentum if a gauge condition ${}^{(1)}\mathbf{B}_{ab}\doteq 0$ is imposed. This is to reduce the Ti group to the Poincaré group so that the angular momentum is defined around an origin in the *four*-dimensional affine space of the infinitesimal Ti translations.[5] Note here that it is clarified that the gauge condition is needed for the quantity to be defined around the four-dimensional origin, not for the quantity to be ''conserved.'' This point was left unclear in Ref. 5.

We conclude the section with a remark on how the conserved quantities are associated with the hierarchy in the asymptotic structure. To define the conserved quantities, we needed vector fields that respect the asymptotic symmetries and gravitational fields that are traceless and divergence-free. However, the asymptotically flat space–times that satisfy only the weakest falloff condition on the energy-momentum tensor do not possess sufficient asymptotic structures that the space–times lack for the conserved quantities to be well defined. As a result, the four-momentum is defined for an AFFTIS-1 space–time and angular momentum is defined for an AFFTIS-2 space–time.

IX. SUMMARY AND DISCUSSIONS

In this paper, we have proposed a new definition of asymptotic flatness at timelike infinity. Instead of rescaling the metric of a space–time conformally as in the previous works,[3,4] we rescaled three-metrics and normal vector fields to the time slices with different powers to provide the information on the gravitational fields. As a result, the causal structure of the physical space–time is not manifest in the unphysical space–time and the timelike infinity arises not as a point but as a *three-manifold*. The three-manifold timelike infinity enables us to characterize the asymptotically flat space–time under investigation with a falloff condition on the physical components of the physical energy-momentum tensor. Hence, it is possible to discuss the properties of such a space–time with *the energy-momentum tensor falling off at a certain rate* where the rate is specified with the function Ω that reads asymptotically the inverse of t, the observer's proper time. This makes a sharp contrast with the treatment using the conformal completion in which the space–time is characterized with the awkward differentiability conditions on the unphysical metric and thus such an argument is not possible. Hereafter in this section, we refer to the physical components of the physical energy-momentum tensor simply by *the energy-momentum tensor* for brevity.

We found the following hierarchy in the asymptotic structure of an asymptotically space–time. If the energy-momentum tensor falls off faster than the rate Ω^2, the space–time possesses an intrinsic structure called the zeroth-order asymptotic structure. The structure consists of a function F that is unity on timelike infinity $\check{\imath}^+$, and the manifold $\check{\imath}^+$ with a unit spacelike three-hyperboloid metric $\mathbf{h}_{ab}$. The presence of the structure means that the space–time is asymptotically Minkowskian. An asymptotic symmetry group, called the Ti group, can be defined to preserve the structure. The group is found to be similar to the Poincaré group but differs in that the four-dimensional translation group is replaced with an infinite-dimensional additive group. Further, by introducing the notion of an asymptotic Killing field, it is found that such a space–time becomes asymptotically stationary at the rate Ω^2 and in general does not become stationary at a faster rate. Although there exists an asymptotically symmetry group, the space–time is just asymptotically Minkowskian and thus does not possess gravitational fields with sufficient properties to have the four-momentum defined. If the energy-momentum tensor falls off faster than the rate Ω^3, there is enough higher-order asymptotic structure for the four-momentum to be defined. The form of one of the asymptotic structure ${}^{(1)}F$ is determined in such space–times. A conserved quantity associated with angular momentum can be defined only for space–times with even more asymptotic structure: the energy-momentum tensor needs to fall off faster than the rate Ω^4. For the quantity to be regarded as angular-momentum in the sense that the angular-momentum should be defined

around the *four*-dimensional origin, the leading order of one of the gravitational fields, ${}^{(1)}B_{ab}$, must vanish.

ACKNOWLEDGMENTS

APPENDIX: SOME AFFTIS SPACE–TIMES AND SOME THAT ARE NOT

We give the explicit construction of the completion of the Schwarzschild space–time and show that it is an AFFTIS space–time. Then, it is shown that the nature of the charge and the angular momentum of the Kerr–Newmann space–time appears in the second-order asymptotic structure. The function $F:=-\pounds_n\Omega$ which contains the information on four-momentum is explicitly calculated for a boosted Schwarzschild space–time. At the end, an example of space–times which do not satisfy the conditions of AFFTIS-n space–times is given.

In static spherical coordinates, the metric of Schwarzschild space–time takes the form

$$\hat{g}_{ab}=-(1-2m/r)(1-2m/r)(dt)_a(dt)_b+(1-2m/r)^{-1}(dr)_a(dr)_b+r^2(d\sigma)_{ab}. \tag{A1}$$

Introducing new coordinates $t=\Omega^{-1}\cosh\chi$ and $r=\Omega^{-1}\sinh\chi$, we obtain smooth n^a, F and q_{ab}:

$$\begin{aligned} n^a&=-\frac{1+4m\Omega\sinh\chi-4m^2\Omega^2}{1-2m\Omega/\sinh\chi}(\partial_\Omega)^a-4m\frac{\cosh\chi-m\Omega/\tanh\chi}{1-2m\Omega/\sinh\chi}(\partial_\chi)^a\\ &=-(\partial_\Omega)^a-\left[\Omega m^{(1)}F_{00}+\Omega^2\frac{4m^2}{\tanh^2\chi}+O(\Omega^3)\right](\partial_\Omega)^a\\ &\quad-\left[4m\cosh\chi+\Omega\frac{4m^2}{\tanh\chi}+O(\Omega^2)\right](\partial_\chi)^a, \end{aligned} \tag{A2}$$

$$F=\frac{1+4m\Omega\sinh\chi-4m^2\Omega^2}{1-2m\Omega/\sinh\chi}=1+\Omega m^{(1)}F_{00}+\Omega^2\frac{4m^2}{\tanh^2\chi}+O(\Omega^3), \tag{A3}$$

and

$$\begin{aligned} q_{ab}&=16m^2\frac{\cosh^2\chi-2m\Omega\cosh\chi/\tanh\chi+m^2\Omega^2/\tanh^2\chi}{1+2m\Omega(2\sinh\chi-1/\sinh\chi)-12m^2\Omega^2+8m^3\Omega^3/\sinh\chi}(d\Omega)_a(d\Omega)_b\\ &\quad-4m\frac{\cosh\chi-m\Omega/\tanh\chi}{1-2m\Omega/\sinh\chi}[(d\Omega)_a(d\chi)_b+(d\chi)_a(d\Omega)_b]\\ &\quad+\frac{1+4m\Omega\sinh\chi-4m^2\Omega^2}{1-2m\Omega/\sinh\chi}(d\chi)_a(d\chi)_b+\sinh^2\chi(d\sigma)_{ab}\\ &=h_{ab}+\left[16m^2\cosh^2\chi-\Omega 64\frac{m^3\cosh\chi\sinh^2\chi}{\tanh\chi}+O(\Omega^2)\right](d\Omega)_a(d\Omega)_b\\ &\quad-\left[4m\cosh\chi+\Omega\frac{4m^2}{\tanh\chi}+O(\Omega^2)\right](d\chi)_{(a}(d\Omega)_{b)}+\left[\Omega 2m^{(1)}F_{00}+\Omega^2\frac{4m^2}{\tanh\chi}+O(\Omega^3)\right]\\ &\quad\times(d\chi)_a(d\chi)_b. \end{aligned} \tag{A4}$$

Together with the fact that it is a vacuum solution of the Einstein equation, the above calculations show that the Schwarzschild space–time is an AFTI-∞ space–time, where we denote a space–time that is an AFTI-n space–time for arbitrary n by an ATI-∞ space–time. Now take the outside of the event horizon $r>2m$ in the original coordinates as $\hat{\mathcal{F}}$. Because the region $r\leqslant 2m$ corresponds to

the point $\chi=0$ on the $\Omega=0$ surface, the choice provides timelike infinity $\check{\imath}^+$ with the point missing. Thus, topology of $\check{\imath}^+$ is $S^2\times(\mathbb{R}-\{p\})$ and the Schwarzschild space–time satisfies the condition of an AFFTIS-n space–time to arbitrary n. It is important to note here that the Oppenheimer–Snyder space–time, which describes dust collapsing to form a Schwarzschild black hole, can be completed to possess $\check{\imath}^+$ with the same structure as the above completed Schwarzschild space–time does. The space–time has the Schwarzschild metric outside the dust and the surface of the dust collapses along $r=(r_{ini}/2)(1+\cos\ \eta)$ where r and r_{ini} are the Schwarzschild radial coordinate and the initial dust radius at time $t=0$, respectively; and η is related to the Schwarzschild time coordinate t by

$$t=2m\ \ln\left|\frac{\sqrt{r_{ini}/2m-1}+\tan\ \eta/2}{\sqrt{r_{ini}/2m-1}-\tan\ \eta/2}\right|+2m\sqrt{r_{ini}/2m-1}\,(\eta+(\eta+\sin\ \eta)r_{ini}/4m). \tag{A5}$$

If we choose the region $r>r_{ini}$ as region $\hat{\mathcal{F}}$, the metric of the region is that of the Schwarzschild space–time and thus $\hat{\mathcal{F}}$ satisfies all the conditions of AFFTIS-n for arbitrary n and can be completed to have exactly the same n^a, F, and q_{ab} in $\mathcal{F}$ as those of the Schwarzschild space–time. Since the region $r\leqslant r_{ini}$ corresponds to the point $\chi=0$ on $\check{\imath}^+$ in this completion also, the global structure of $\check{\imath}^+$ is also the same as that of the above completed Schwarzschild space–time.

In static spherical coordinates, the metric of Kerr–Newmann space–time is given by

$$\begin{aligned}\hat{g}_{ab}=&-\frac{\Delta-a^2\ \sin^2\ \theta}{\Sigma}\,(dt)_a(dt)_b-2\,\frac{a\ \sin^2\ \theta(r^2+a^2-\Delta)}{\Sigma}\,(dt)_{(a}(d\phi)_{b)}+\frac{\Sigma}{\Delta}\,(dr)_a(dr)_b\\&+\Sigma(d\theta)_a(d\theta)_b+\frac{(r^2+a^2)^2-\Delta a^2\ \sin^2\ \theta}{\Sigma}\,\sin^2\ \theta(d\phi)_a(d\phi)_b,\end{aligned} \tag{A6}$$

where $\Sigma=r^2+a^2\ \cos^2\ \theta$ and $\Delta=r^2+a^2+e^2-2mr$. Introducing $\eta:=\ln\Omega$, we clearly see that the nature of the charge and the angular momentum of the space–time appear in the second-order asymptotic structure and do not alter the lower-order asymptotic structure:

$$\begin{aligned}n^a&=e^{-\eta}[{}^{(0)}n^a+\Omega^{(1)}n^a+\Omega^{2\ (2)}n^a+O(\Omega^3)],\\F&={}^{(0)}F+\Omega^{(1)}F+\Omega^{2\ (2)}F+O(\Omega^3),\\q_{ab}&={}^{(0)}q_{ab}+\Omega^{(1)}q_{ab}+\Omega^{2\ (2)}q_{ab}+O(\Omega^3),\end{aligned} \tag{A7}$$

where

$$\begin{aligned}&{}^{(0)}n^a=-(\partial_\eta)^a,\quad {}^{(1)}n^a=m^{(1)}F_{00}(\partial_\eta)^a-4m\ \cosh\ \chi(\partial_\chi)^a,\\&{}^{(2)}n^a=\left(\frac{4m^2-e^2}{\tanh\ \chi}-e^2-a^2\ \sin^2\ \theta\right)(\partial_\eta)^a-\frac{4m^2-2e^2-a^2\ \sin^2\ \theta}{\tanh\ \chi}\,(\partial_\chi)^a+2ma\,\frac{\cosh\ \chi}{\sinh^3\ \chi}\,(\partial_\phi)^a;\end{aligned} \tag{A8}$$

$$\begin{aligned}&{}^{(0)}F=1,\quad {}^{(1)}F=m^{(1)}F_{00},\\&{}^{(2)}F=\frac{4m^2-e^2}{\tanh\ \chi}-e^2-a^2\ \sin^2\ \theta;\end{aligned} \tag{A9}$$

$$\begin{aligned}&{}^{(0)}q_{ab}=h_{ab},\quad {}^{(1)}q_{ab}=-2(4m\ \cosh\ \chi)(d\eta)_{(a}(d\chi)_{b)}+2m^{(1)}F_{00}(d\chi)_a(d\chi)_b,\\&{}^{(2)}q_{ab}=16m^2\ \cosh^2\ \chi(d\eta)_a(d\eta)_b-2\,\frac{4m^2-2e^2-a^2\ \sin\ \theta}{\tanh\ \chi}\,(d\eta)_{(a}(d\chi)_{b)}\\&\quad+4ma\ \sin^2\ \theta\left(\frac{(d\eta)_{(a}(d\phi)_{b)}}{\tanh\ \chi}-(d\chi)_{(a}(d\phi)_{b)}\right)+\left(\frac{4m^2-e^2-a^2\ \sin\ \theta}{\tanh^2\ \chi}-e^2\right)(d\chi)_a(d\chi)_b\\&\quad+a^2\ \cos^2\ \theta(d\theta)_a(d\theta)_b+a^2\ \sin^2\ \theta(d\phi)_a(d\phi)_b.\end{aligned} \tag{A10}$$

In the boosted Schwarzschild space–time with velocity of v along the x axis, or to be precise in the Schwarzschild space–time that is observed by an observer with velocity of v along the x axis,

$$F=1+\Omega\left\{2m\left(2\sinh\chi+\frac{1}{\sinh\chi}\right)-2mv\left(2\cosh\chi-\frac{\cosh\chi}{\sinh^2\chi}\right)\sin\theta\cos\phi\right\}+O(\Omega^2)$$
$$=1+\Omega\{m^{(1)}F_{00}-mv^{(1)}F_{11}+O(v^2)\}+O(\Omega^2). \tag{A11}$$

Let us consider the flat Friedmann–Robertson–Walker space–time, which does not qualify as an AFTI space–time as one expects. The metric of the space–time filled with perfect fluid is

$$\hat{g}_{ab}=-(dt)_a(dt)_b+a^2(t)[(dr)_a(dr)_b+r^2(d\sigma)_{ab}],$$

where $a(t)=a_0(t/t_0)^{2/3(1+w)}$ if the energy density ρ and the pressure p is related by $p=w\rho$. In order to get smooth n^a and q_{ab}, we need to choose the new coordinates (Ω,χ) as

$$t=a_0\frac{1+3w}{1+w}\Omega^{-1}(\cosh\chi)^{(3+3w)/(1+3w)},$$

$$r=t_0^{2/(3+3w)}\Omega^{-(1+3w)/(3+3w)}(\sinh\chi).$$

They give us

$$n^a=\frac{1}{a_0^2}\left(\frac{3+3w}{1+3w}\right)^2(\cosh\chi)^{-4/(1+3w)}(\partial_\Omega)^a, \tag{A12}$$

$$q_{ab}=a_0^2(\cosh\chi)^{4/(1+3w)}[(d\chi)_a(d\chi)_b+\sinh^2\chi(d\sigma)_{ab}]. \tag{A13}$$

However, with this choice of Ω, the time–time component of the energy-momentum tensor decays as Ω^2:

$$\hat{n}^a\hat{n}^b\hat{T}_{ab}=9\rho_0\left(\frac{t}{t_0}\right)^{-2}\cosh^2\chi+O(\Omega)=\Omega^2\rho_0\left(\frac{3t_0(1+w)}{a_0(1+3w)}\right)^2(\cosh\chi)^{-4/(1+3w)}+O(\Omega^3),$$

from which we see that the space–time does not satisfy the third condition of AFTI-n space–times for non-negative n and thus the space–time is not an AFTI-n space–time. Hence, the space–time does not need to possess the properties of an AFTI-n space–time: the function

$$F\doteq\frac{1}{a_0^2}\left(\frac{3+3w}{1+3w}\right)^2(\cosh\chi)^{-4/(1+3w)} \tag{A14}$$

is not unity on $\check{\imath}^+$, and the space–time does not admit an asymptotic stationary Killing field.

Simplicial quantum gravity in the elongated phase

Gabriele Gionti[a)]

(Received 19 November 1997; accepted for publication 8 May 1998)

We discuss the elongated phase of four-dimensional simplicial quantum gravity by exploiting recent analytical results. In particular using Walkup's theorem we prove that the dominating configurations in the elongated phase are treelike structures called ''stacked spheres.'' Such configurations can be mapped into branched polymers and baby universes arguments are used in order to analyze the critical behavior of theory in the weak coupling regime. © *1998 American Institute of Physics.* [S0022-2488(98)03011-4]

I. INTRODUCTION

The key concept of simplicial quantum gravity is to work with a discrete version of space–time. To this purpose it is necessary to consider a simplicial complex Σ by gluing four-dimensional simplexes through their three-dimensional faces in such a way that the link of every p-dimensional simplex σ, $p=0,1,2$, $link(\sigma,\Sigma)$, is homeomorphic to a $(4-p-1)$ sphere. Analytically this last condition implies that the following Dehn–Sommerville constraints should hold:

$$\sum_{i=0}^{4}(-1)^i N_i(T)=\chi(T), \tag{1.1}$$

$$\sum_{i=2k-1}^{4}(-1)^i\frac{(i+1)!}{(i-2k+2)!(2k-1)!}N_i(T)=0 \tag{1.2}$$

with $1\leqslant k\leqslant 2$ and $N_i(T)$ the number of i-dimensional simplexes of the simplicial manifold T and where $\chi(T)$ is the Euler–Poincaré characteristic. Equation (1.1) is just the Euler–Poincaré equation, while (1.2) is a consequence of the fact that the link of every $2k$-simplex is an odd dimensional sphere, and hence has Euler number zero.

Two simplicial manifolds T and T' are said to be Picewise Linear (PL)-equivalent if there exist simplicial subdivisions of them, $\tilde{T}$ and $\tilde{T}'$, such that $\tilde{T}$ and $\tilde{T}'$ are simplicially isomorphic. A simplicial isomorphism[1] is a one to one map ϕ between the vertex of the simplicial manifolds such that $(\phi(v_i),\phi(v_j))$ is an edge of T' if and only if (v_i,v_j) is an edge of T and so on for every simplex of any dimension. A simplicial isomorphism is an equivalence relation among simplicial manifolds. An equivalence class of simplicial manifolds with respect to the isomormorphism above is a Picewise Linear (PL)-manifold.

A dynamical triangulation T_a is a simplicial manifold, that is a representative of a PL manifold, generated by gluing, along their adjacent faces, $N_4(T_a)$ equilateral simplexes, say σ^4, with fixed edge-length a. A dynamical triangulation gives a metric structure on a PL manifold (see, e.g., Ref. 2, p. 20).

The numbers $N_i(T)$ $i=0,...,4$ can be seen as the component of a five-dimensional vector f,

$$f\equiv(N_0(T),N_1(T),N_2(T),N_3(T),N_4(T)) \tag{1.3}$$

called the f-vector of the triangulation T. Dehn–Sommerville equations fix three components of f, leaving two undetermined. In simplicial gravity $N_2(T_a)$ and $N_4(T_a)$ are, usually, the two undetermined components. Their values are subject to some limitations as will be explained below.

Every two-dimensional simplex, in four dimension, is called bone (hinges in Regge calculus). Let us label the bones by an index α and denote by $q(\alpha)$ the number of four simplexes incident on it; the average number of simplexes incident on a bone is

$$b \equiv \frac{1}{N_2} \sum_{\alpha} q(\alpha) = 10 \left(\frac{N_4(T_a)}{N_2(T_a)} \right) \tag{1.4}$$

since each simplex is incident on 10 different bones. b ranges between two kinematical bounds which follows from Dehn–Sommerville and a theorem by Walkup.[3] This latter theorem is also relevant in classifying the ''elongated phase'' of four-dimensional simplicial quantum gravity as we shall see below.

Theorem: *If T is a triangulation of a closed, connected four-dimensional manifold then*

$$N_1(T) \geqslant 5N_0(T) - \tfrac{15}{2}\chi(T). \tag{1.5}$$

Moreover, equality holds if and only if $T \in H^4(1-\frac{1}{2}\chi(T))$, where the class of triangulations $H^4(n)$ is defined inductively according to: (a) The boundary complex of any abstract five-simplex $(Bd\sigma)$ is a member of $H^4(0)$. (b) If K is in $H^4(0)$ and σ is a four-simplex of K, then K' is in $H^4(0)$, where K' is any complex obtained from K by deleting σ and adding the joinder of the boundary complex $Bd\sigma$ and a new vertex distinct from the vertices of K. (c) If K is in $H^d(n)$, then K' is in $H^d(n+1)$ if there exist two four-simplexes σ_1 and σ_2 with no common vertices and a dimension preserving simplicial map ϕ from $K-\sigma_1-\sigma_2$ onto K' which identifies $Bd\sigma_1$ with $Bd\sigma_2$ but otherwise is one to one.

In other words $H^4(0)$ is built up by gluing together five-dimensional simplexes through their four-dimensional faces and considering only the boundary of this resulting complex. $H^4(n)$ differs from $H^4(0)$ by the fact that it has n handles. This way of constructing a triangulation of a four-sphere has a natural connection with the definition of a baby universe. A baby universe[4,5] is associated with a triangulation in which we can distinguish two pieces. A piece that contains the majority of the simplices of the triangulation—called the ''mother''—and a small part called the ''baby.'' In the ''minbus'' (minimum neck baby universes) the two parts are glued together along the boundary of a four-dimensional simplex (in four dimension) that is the ''neck'' of the baby universe. Thus the ''stacked spheres'' can be considered as a network of minbus in which the mother disappears and the baby universes have a minimal volume, that is the boundary of a five simplices minus the simplices of the necks through which they are glued to the others. We will exploit this parallel in Sec. VI to give an estimate of the number of distinct stacked spheres.

As established in Ref. 2, the Walkup theorem fixes a bound on the values of b, in fact formula (1.5) together with the Dehn–Sommerville equations leads to $b \geqslant 4 - 10(\chi/N_2)$.
From the Dehn–Sommerville equations and the fact that $N_0 \geqslant 5$, it follows that $b \leqslant 5 + (10\chi - 50)/N_2$. Thus in the limit of large N, one obtains $4 \leqslant b \leqslant 5$.

As in Regge[6] calculus the curvature of a dynamical triangulation is concentrated on the bones and depends on the number $q(B)$ of incident four-dimensional simplexes. More precisely, the curvature $K(B)$ at a bone B is

$$K(B) = \frac{48\sqrt{15}}{a^2} \left[\frac{2\pi - q(B)\cos^{-1}\frac{1}{4}}{q(B)} \right]. \tag{1.6}$$

The Regge version of Einstein–Hilbert action with cosmological constant for a dynamical triangulation T_a[5] is

$$S(T_a) = k_4 N_4(T_a) - k_2 N_2(T_a), \tag{1.7}$$

where k_4 is a constant depending linearly on the inverse of the gravitational constant and on the cosmological constant, whereas k_2 is proportional to the inverse of the gravitational constant; these constants depend also on the edge-length a; typically to simplify calculations one sets $a = 1$.

The partition function for four-dimensional dynamical triangulations is defined as

$$Z(k_2,k_4)=\sum_{\mathrm{top}(M)}\sum_{N_4(T_a)}\sum_{N_2(T_a)} W_{\mathrm{top}}(N_2,N_4)e^{-k_4N_4+k_2N_2}, \tag{1.8}$$

where $W_{\mathrm{top}}(N_4,N_2)$ is the number of distinct á la Tutte dynamical triangulations with a fixed number of four simplices N_4 and of bones N_2, and a fixed topology. Since in three and in four dimensions there is not yet a mathematical status for the sum over topologies we restrict ourselves to the simply connected topologies:

$$Z_{\mathrm{sc}}(k_2,k_4)=\sum_{N_4(T_a)}\sum_{N_2(T_a)} W_{\mathrm{sc}}(N_2,N_4)e^{-k_4N_4+k_2N_2}. \tag{1.9}$$

Equation (1.9) has the structure of a grand canonical partition function:

$$Z_{\mathrm{GC}}=\sum_N\sum_{\sigma_N} e^{-\beta H(\sigma_N)}z^N \tag{1.10}$$

with the number of simplexes that is playing the role of the number of particles. Following this analogy we refer to $W(N_2,N_4)$ as the microcanonical partition function and to

$$Z(k_2,N_4)=\sum_{N_2} W(N_2,N_4)e^{k_2N_2} \tag{1.11}$$

as the canonical partition function.

II. CANONICAL PARTITION FUNCTION

Recently it has been shown analytically[2] that the dynamical triangulations in four dimensions are characterized by two phases: a strong coupling phase in the region $k_2^{\mathrm{inf}}=\log 9/8<k_2<k_2^{\mathrm{crit}}$ and a weak coupling phase for $k_2>k_2^{\mathrm{crit}}$. k_2^{crit} is the value of k_2 for which in the infinite volume limit the theory has a phase transition from the strong to the weak phase (for a detailed analysis see Ref. 2). The transition between these two phases is characterized by the fact that the subdominant asymptotics of the number of distinct triangulations passes from an exponential to polynomial behavior (cf. Ref. 2, p. 106). Presently the precise value of k_2^{crit} has not been established yet, it is just known that it is close but distinct from $k_2^{\mathrm{max}}=\log 4$, recent numerical simulations suggest that $k_2^{\mathrm{crit}}=1.24$.

In the strong coupling phase the leading term of the asymptotic expansion of the canonical partition function is (cf. Ref. 2)

$$Z(N_4,k_2)=c_4\left(\frac{A(k_2)+2}{3A(k_2)}\right)^{-4}N_4^{-5}\exp[-m(\eta^*)N^{1/n_H}]\exp\left[\left[10\log\frac{A(k_2)+2}{3}\right]N_4\right], \tag{2.1}$$

where for notational convenience we have set

$$A(k_2)\equiv[\tfrac{27}{2}e^{k_2}+1+\sqrt{(\tfrac{27}{2}e^{k_2}+1)^2-1}]^{1/3}+[\tfrac{27}{2}e^{k_2}+1-\sqrt{(\tfrac{27}{2}e^{k_2}+1)^2-1}]^{1/3}-1 \tag{2.2}$$

and

$$\eta^*(k_2)=\frac{1}{3}\left(1-\frac{1}{A(k_2)}\right). \tag{2.3}$$

The explicit form of $m(\eta^*(k_2))$ and n_H, the Hausdorff dimension, are at present unknown.

In the weak phase $k_2>k_2^{\mathrm{crit}}$ the number of distinct dynamical triangulations with equal curvature assignment have a power law behavior in N_4. The phase is characterized by two distinct asymptotic regimes of the leading term of the canonical partition function: the critical coupling regime and the weak coupling regime. In the critical coupling regime $k_2^{\mathrm{crit}}<k_2<k_2^{\mathrm{max}}$ we have

$$Z(N_4,k_2)\asymp c_4\left(\frac{A(k_2)+2}{3A(k_2)}\right)^{-4} N_4^{\tau(\eta^*)-5}\ \exp\left[\left[10\log\frac{A(k_2)+2}{3}\right]N_4\right], \tag{2.4}$$

in which $\tau(\eta^*)$ is not explicitly known.

Instead in the weak coupling regime $k_2>k_2^{\max}$,

$$Z(N,k_2)\asymp \frac{c_4 e}{\sqrt{2\pi}}\frac{\eta_{\max}^{-1/2}(1-2\eta_{\max})^{-4}}{\sqrt{(1-3\eta_{\max})(1-2\eta_{\max})}}(\hat{N}+1)^{\tau-11/2}.\ \frac{e^{(\hat{N}+1)f(\eta_{\max},k_2)}}{k_2^{\sup}-k_2} \tag{2.5}$$

in which $\eta^{\max}=\frac{1}{4}$ for the sphere S^4 and

$$f(\eta,k_2)\equiv-\eta\log\eta+(1-2\eta)\log(1-2\eta)-(1-3\eta)\log(1-3\eta)+k_2\eta. \tag{2.6}$$

From this form of the canonical partition function it follows that in the case of the sphere S^4 and in the infinite volume limit the average value of b, see Eq. (1.4), is a decreasing function of k_2 in the critical coupling regime and it is constantly equal to 4 in the weak coupling regime, that is to say

$$\begin{gathered}\lim_{N_4\mapsto\infty}\langle b\rangle_{N_4}=\frac{1}{\eta(k_2)},\quad k_2^{\mathrm{crit}}\leqslant k_2\leqslant k_2^{\max},\\ \lim_{N_4\to\infty}\langle b\rangle_{N_4}=4,\quad k_2\geqslant k_2^{\max}.\end{gathered} \tag{2.7}$$

If we look at the average curvature we have

$$\lim_{N\to\infty}\frac{1}{N}\left\langle\sum_B K(B)\mathrm{vol}_4(B)\right\rangle=\pi a^2\sqrt{3}\left(10\eta^*(k_2)-\frac{5}{\pi}\cos^{-1}\frac{1}{4}\right),\quad k_2^{\mathrm{crit}}<k_2\leqslant k_2^{\max} \tag{2.8}$$

and

$$\lim_{N\to\infty}\frac{1}{N}\left\langle\sum_B K(B)\mathrm{vol}_4(B)\right\rangle=\pi a^2\sqrt{3}\left(\frac{5}{2}-\frac{5}{\pi}\cos^{-1}\frac{1}{4}\right),\quad k_2>k_2^{\max}, \tag{2.9}$$

in which $\mathrm{vol}_4(B)$ is the volume of the four simplexes incident on the bone B, and it is $a^2(\sqrt{3}/2)q(B)$. As we have already said the value of the average curvature is saturated.

This result was already known in numerical simulations[7] and, as we will see in detail in Sec. III, it is due to the prevalence of stacked spheres in the weak coupling regime.

III. ELONGATED PHASE

We have seen that in the case of triangulations of the sphere S^4 for $k_2\mapsto\log 4$, in the infinite volume limit, $\langle b\rangle_{N_4},\mapsto 4$. Walkup's theorem[3] implies that the minimum value of b is reached on triangulations K of the sphere S^4 that belong to $H^4(0)$ (stacked spheres). Then for $k_2>\log 4$ one has $\langle b\rangle_{N_4}=4$, that means that in this region of k_2 the statistical ensemble of quantum gravity is strongly dominated by stacked spheres.

As explicitly shown in Ref. 3, p. 83, the elements of $H^4(0)$ can be put in correspondence with a tree structure. Let us recall that a d-dimensional simplicial complex T, $d\geqslant 1$, is called a simple d-tree if it is the closure of its d-simplexes $\sigma_1,\ldots,\sigma_t$ and these d-simplexes can be ordered in such a way that

$$\mathrm{Cl}\ \sigma_j\cap\left\{\bigcup_{i=1}^{j-1}\mathrm{Cl}\ \sigma_i\right\}=\mathrm{Cl}\ \tau_j \tag{3.1}$$

for some $(d-1)$-face τ_j of σ_j, $j\geqslant 2$, and where the τ_j are all distinct. This ordering of the simplexes of T induces a natural ordering of its vertices in $v_1,\ldots,v_{t+d}$, where v_{i+d} is the vertex

of σ_i not in Cl τ_i. Note that the interior part of T contains the simplexes σ_i and faces τ_i. The boundary of T, Bd T, consists of the boundary of the σ_i minus the τ_i, and is topologically equivalent to S^{d-1}.

It can be shown,[3] and it is very easy to check, that any element of $K \in H^d(0)$ is the boundary of a simple $(d+1)$-tree T, and that K determines uniquely the simple $(d+1)$-tree T for $d \geqslant 2$.

Note that any stacked sphere $K \in H^4(0)$ can be mapped into a tree graph (see also Ref. 8). This mapping is defined in the following way: Let us consider the (unique) simple five-simple tree T associated with K, every five-simplex is mapped to a vertex and every four-dimensional face in common with two five simplexes is mapped to an edge which has end points at the two vertices which represent the two five simplexes. Since the map between K and T is one to one, we have a map from a stacked-sphere into a tree-graph whose number of links at every vertex can be at most 6 (since a five simplex has *six* faces). This map, from the stacked spheres $H^4(0)$ to the simple tree-graphs, is not one to one. The mathematical reason is that the previous construction maps every T to a tree-graph by an application that is the dual map restricted to the five- and four-dimensional simplexes of T in its domain and whose image is the tree graphs that are the one-dimensional skeleton of the dual complex. It is well known that the dual map is a one to one correspondence only if we take into account the simplexes of T of any dimension. It follows that our map is such that a simple tree-graph may correspond to many stacked spheres. To illustrate better this point we shall use a picture closer to the physical intuition. Let us consider a stacked sphere K and its simple tree T. Consider on T one of its ordered simplexes σ_j and let τ_j be the face that it shares with one of the simplexes $\sigma_1,\ldots,\sigma_t$ introduced previously. Repeating the same arguments used in the calculations of the inequivalent triangulations for baby universes,[4] we can cut T in τ_j into two parts, such that each part has two copies of τ_j as a part of its boundary. Since τ_j is a four-dimensional simplex it is easy to admit that we can glue these two different copies in $5 \cdot 4 \cdot 3$ ways to rebuild again a simple five tree T'. In general all the possible gluings will generate distinct triangulations and consequently distinct stacked spheres (if the two parts are highly symmetric triangulations some of the 60 ways of joining will not be distinct but, since for large N_4 asymmetrical triangulations will dominate, the number of cases in which this will happen will be trascurable). The corresponding tree graph associated with these configurations T' will always be the same since this operation has not modified the one skeleton of the tree T.

In statistical mechanics simple-tree structures correspond to ''branched-polymers.'' So we have that for $k_2 \geqslant k_2^{\max}$ the dominant configurations for the triangulations of S^4 are branched polymers. This fact was already observed in numerical simulations in four dimensions. In Ref. 9 a network of baby universes of minimum neck (minbu) and of minimum size (blips) without a mother universe was obtained. These have been interpreted as branched polymerlike structures.

IV. STACKED SPHERES AND BRANCHED POLYMERS

In this section we will establish a parallel between the standard mean field theory of branched polymers and the stacked spheres, in the sense that we will use the counting techniques of branched polymers to give an upper and lower estimation of the number of inequivalent stacked spheres. As we have stressed in Sec. III there exists a map between the stacked spheres and tree graphs and this map is *not* one to one in the sense that there are more stacked spheres than tree graphs. This means that the number of inequivalent stacked spheres with a fixed number N_5 of five-simplexes is bounded below by the corresponding number of tree graphs. Now we will study the statistical behavior of the tree graphs using the measure of simplicial quantum gravity and restricting it to the stacked spheres. In this analysis we will follow[10] in a way adapted to our case. The reader may refer to it for the details. A more mathematical analysis on the enumeration of inequivalent tree graphs is contained in Ref. 11.

First of all we notice that the boundary of a five-simplex has six four-simplexes and every edge of a tree graph corresponds to a cancellation of two four-simplexes in the corresponding boundary of the stacked sphere. Since in a tree graph with N_5 vertices there are N_5-1 edges, we have that the boundary of a stacked sphere, whose corresponding tree graph has N_5 points, is made by a number N_4 of four-simplexes,

$$N_4 = 4N_5 + 2. \tag{4.1}$$

From the condition for stacked spheres (1.5), we have that the Einstein–Hilbert action, for dynamical triangulations, restricted to the stacked spheres is

$$S=N_4(k_4-\tfrac{5}{2}k_2)-5k_2. \tag{4.2}$$

It follows that the Gibbs factor for the ensemble of tree graphs (branched polymers) corresponding to stacked spheres is

$$\exp(-(4N_5+2)(k_4-\tfrac{5}{2}k_2)+5k_2). \tag{4.3}$$

Following the same notation of Ref. 10, let $r^6(N_5)$ be the number of inequivalent rooted tree graphs with N_5 vertices and with at most six incident edges on each vertex, with one rooted vertex with one incident edge. $\xi^6(N_5)$ is the number of inequivalent tree graphs with N_5 vertices. By simple geometrical considerations, or from the asymptotic formula[10,11] for $r^6(N_5)$ and $\xi^6(N_5)$, we get the asymptotic formula

$$\xi^6(N_5)=\frac{1}{N_5}\,r^6(N_5+1). \tag{4.4}$$

Now let $R^6(k_4,k_2)$ be the partition function for rooted tree graphs with statistical weight (4.3), and $Z^6(k_4,k_2)$ be the partition function for unrooted tree graphs. We have

$$R^6(k_4,k_2)\equiv\sum_{N_5=2}^{\infty} e^{-(4(N_5-1)+2)(k_4-\frac{5}{2}k_2)+5k_2}r^6(N_5), \tag{4.5}$$

$$Z^6(k_4,k_2)\equiv\sum_{N_5=1}^{\infty} e^{-(4N_5+2)(k_4-\frac{5}{2}k_2)+5k_2}\xi^6(N_5). \tag{4.6}$$

Let us define

$$R^{*6}(\Delta k_4)\equiv(e^{-2(k_4-5)}R^6(k_4,k_2))=\sum_{N_5=2}^{\infty} e^{-4(N_5-1)\Delta k_4}r^6(N_5), \tag{4.7}$$

$$Z^{*6}(\Delta k_4)\equiv(e^{-2(k_4-5)}Z^6(k_4,k_2))=\sum_{N_5=1}^{\infty} e^{-4N_5\Delta k_4}\xi^6(N_5), \tag{4.8}$$

where $\Delta k_4\equiv k_4-\frac{5}{2}k_2$. It is easy to see, from (4.4), that

$$R^{*6}(\Delta k_4)=-\frac{1}{4}\,\frac{d}{d\Delta k_4}\,Z^{*6}(\Delta k_4). \tag{4.9}$$

From simplicial quantum gravity it is well known that the susceptibility $\chi(k_4,k_2)$ is given by

$$\chi(k_4,k_2)\asymp\frac{\partial^2}{\partial k_4^2}\,Z(k_4,k_2). \tag{4.10}$$

By analogous consideration on the graph it follows that

$$\chi(\Delta k_4)\asymp\frac{d^2}{d(\Delta k_4)^2}\asymp\frac{d}{d(\Delta k_4)}\,R^{*6}(\Delta k_4). \tag{4.11}$$

Now we will study the critical behavior of this system in order to obtain some information about the critical behavior of stacked spheres.

As easily verified the following identity, which is true for rooted tree graphs

$$r^6(N_5)=\sum_{\gamma=0}^{5}\ \frac{1}{\gamma!}\sum_{n_1,\ldots,n_\gamma;\Sigma_{i=1}^{\gamma}n_i=n-\gamma-2}\ \prod_{i=1}^{\gamma} r^6(n_i), \tag{4.12}$$

implies

$$R^{*6}(\Delta k_4)=e^{-4\Delta k_4}\left(\sum_{\gamma=0}^{5}\ \frac{1}{\gamma!}\,R^{*6}(\Delta k_4)\right). \tag{4.13}$$

Differentiating the previous equation we get a differential equation for $R^{*6}(\Delta k_4)$,

$$\frac{d}{d\Delta k_4}\,R^{*6}(\Delta k_4)=-\frac{1}{4}\,R^{*6}(\Delta k_4)\left[1+\frac{e^{-4\Delta k_4}}{5!}\,(R^{*6}(\Delta k_4))^5-R^{*6}(\Delta k_4)\right]^{-1}. \tag{4.14}$$

So $R^{*6}(\Delta k_4)$ shows a singularity when

$$R^{*6}((\Delta k_4)^c)=1+\frac{e^{-4\Delta k_4}}{5!}\,(R^{*6}((\Delta k_4))^c)^5. \tag{4.15}$$

This equation has only one real solution and since $(d/d\Delta k_4)R^{*6}|_{(\Delta k_4)^c}$ diverges, the inverse function is zero

$$\left.\frac{d(\Delta k_4)(R^{*6})}{dR^{*6}}\right|_{(\Delta k_4)^c}=0. \tag{4.16}$$

By the implicit function theorem $(\Delta k_4)(R^{*6})$ is analytic function at $R^{*6}((\Delta k_4)^c)$, which implies

$$\Delta k_4(R^{*6})-\Delta k_4^c=\frac{1}{2}\left.\frac{d^2(\Delta k_4)(R^{*6})}{d(R^{*6})^2}\right|_{R^{*6}((\Delta k_4)^c)}(R^{*6}(\Delta k_4)-R^{*6}(\Delta k_4{}^c))^2$$
$$+o((R^{*6}(\Delta k_4)-R^{*6}(\Delta k_4^c))^2). \tag{4.17}$$

So near $(\Delta k_4)^c$ we can write

$$R^{*6}(\Delta k_4)\asymp R^{*6}((\Delta k_4)^c)+C((\Delta k_4)-(\Delta k_4)^c)^{1/2}. \tag{4.18}$$

From (4.11) we get

$$\chi^6(\Delta k_4)\asymp((\Delta k_4)-(\Delta k_4)^c)^{-1/2}. \tag{4.19}$$

This means that the critical exponent of the susceptibility for the system of these tree graphs is $\gamma=\frac{1}{2}$.

The partition function that has been studied is a lower estimate of the partition function of the stacked spheres. Consider, now, a stacked sphere K and a face τ_j through which two five-simplexes are glued together (a link on the corresponding tree graph). We can glue a two four face of a stacked sphere in $5\cdot4\cdot3$ different ways, for large number of simplexes this will generate distinct configurations of stacked spheres whose associated tree-graph is always the same. Repeating the same argument for every j, $j=1,\ldots,N_5-1$ (that is to say for every link of the dual tree graph) we obtain a factor, $(5\cdot4\cdot3)^{N_5-1}$, that multiplied by $r^6(N_5)$ and $\xi^6(N_5)$, gives an upper bound on the number of, respectively, rooted and unrooted inequivalent stacked spheres. In other words

$$Z_{\text{tree}}(k_4,k_2)\leqslant Z_{\text{ss}}(k_4,k_2)\leqslant\tilde{Z}_{\text{tree}}(k_4,k_2) \tag{4.20}$$

where $Z_{\text{tree}}(k_4,k_2)$ is the partition function for tree graphs studied above, $Z_{\text{ss}}(k_4,k_2)$ is the partition function for stacked spheres, and $\tilde{Z}_{\text{tree}}(k_4,k_2)$ is the partition function for tree graphs with the additional weight defined above.

A similar analysis as for $Z_{\text{tree}}(k_4,k_2)$ shows that the critical line of $\tilde{Z}_{\text{tree}}(k_4,k_2)$ is, of course, a straight line parallel and above with respect to the k_4 axis to $Z_{\text{tree}}(k_4,k_2)$ one, and the susceptibility exponent is again $\gamma=\frac{1}{2}$.

Obviously the estimates (4.20) are true for the canonical partition functions too,

$$Z_{\text{tree}}(N_4,k_2)\leqslant Z_{\text{ss}}(N_4,k_2)\leqslant \tilde{Z}_{\text{tree}}(N_4,k_2), \tag{4.21}$$

and the previous calculations show that

$$Z_{\text{tree}}(N_4,k_2)\asymp N_4^{-5/2}e^{N_4(k_4-(5/2)k_2-t_4)} \tag{4.22}$$

and

$$\tilde{Z}_{\text{tree}}(N_4,k_2)\asymp N_4^{-5/2}e^{-N_4(k_4-(5/2)k_2+t_4-(1/4)\ \log 60)}, \tag{4.23}$$

where t_4 is a constant that may be calculated by Eq. (4.15). More easily from the table in Ref. 11 we get that $t_4\approx\frac{1}{4}\log 0.34$.

The circumstance that in the weak coupling region the partition function of quantum gravity, as found in an analytically way in Ref. 2, is strongly dominated by stacked spheres, allows us to write

$$Z_{\text{ss}}\asymp N_4^{\gamma_s-3}e^{k_4^c(k_2)}, \tag{4.24}$$

where γ_s is the susceptibility exponent.[12]

Thus the critical line of the stacked spheres is a straight line parallel and between the critical lines of the systems of the two branched polymers. This implies

$$k_4-\tfrac{5}{2}k_2+t_4\leqslant k_4^c(k_2)\leqslant k_4-\tfrac{5}{2}k_2+t_4-\tfrac{1}{4}\log 60. \tag{4.25}$$

Moreover from Eqs. (4.22) and (4.23) the one loop green functions[5] of the two model of branched polymers have, respectively, near their critical lines, the asymptotic behavior

$$G_{\text{tree}}(\Delta k_4)\asymp \text{cost}_1+(\Delta k_4-\Delta k_4^c)^{1/2},\quad \tilde{G}_{\text{tree}}(\Delta\tilde{k}_4)\asymp \text{cost}_2+(\Delta\tilde{k}_4-\Delta\tilde{k}_4^c)^{1/2}. \tag{4.26}$$

Equation (4.21) together with Eqs. (4.21) and (4.24) prove that the one loop function of the stacked spheres $G_{\text{ss}}(k_4,k_2)$ near the critical line has the asymptotic behavior

$$G_{\text{ss}}(k_4,k_2)\asymp \text{cost}_3+(k_4-k_4^c(k_2))^{1-\gamma_s}, \tag{4.27}$$

with $\gamma_s<1$ [the value $\gamma_s=1$ is not allowed because in this case the one loop green function of stacked spheres at the critical line will have a behavior like $\Sigma_{N_4=5}^{\infty}\,1/N$ that is divergent and then incompatible with the upper bound given by the second equation of (4.26)].

Motivated by physical considerations, we can use a well-known argument[5,13] in favor of the fact that the susceptibility exponent of the stacked spheres is $\gamma_s=\frac{1}{2}$. More precisely we will show that a model of proliferating baby universes, with the measure of quantum gravity restricted to stacked spheres, can be put in correspondence with the statistical system of stacked spheres.

Let us consider four-dimensional triangulations that are (boundary of the) stacked spheres in which there can be loops made by two three-dimensional simplexes. This is possible whenever the stacked spheres are pinched on a three simplex creating a bottle neck loop of two three-simplexes. These loops could be either the loops of a Green function or the minimum bottle neck of a baby universes. This class of triangulations, following the notation in literature, is called $\mathbf{T}_2$. The other class of triangulations is the stacked spheres in which the minimum loop length can be made by the boundary of a four-simplex that are five three-simplexes. We call this last class $\mathbf{T}_5$. In the two-dimensional theory, the introduction in $\mathbf{T}_2$ of two link loops (the two-dimensional analog of two three-simplex loop) corresponds in the matrix model ϕ^3 to consider Feynman diagrams with self-energy (cf. Refs. 5, 13). Since the minima loops of $\mathbf{T}_2$ and $\mathbf{T}_5$, for which they differ, are of

the order of lattice spacing we will expect that the two classes of triangulations, as a statistical mechanics system, coincide in the scaling limit, that is to say they belong to the same universality class.

Let us consider the minimum neck one loop function $G(\Delta k_4)$ in $\mathbf{T}_2$. In every triangulation of $\mathbf{T}_2$ we can cut out the maximal size baby universe of minimum neck and close the two three-simplex loop. We will obtain again a triangulation that belongs to $\mathbf{T}_2$. In this way we will obtain all the triangulations of $\mathbf{T}_2$ from the triangulations of the stacked spheres $\mathbf{T}_5$ considering that for each three-simplex either leave them in their actual form or we can open the triangulation to create a two three-simplex loop and gluing on it a whole one loop universe $G(\Delta k_4)$. We note that in the triangulations of $\mathbf{T}_5$ $\bar{N}_3=5/2\bar{N}_4$ (Dehn–Sommerville). Calling the one loop function of $\mathbf{T}_5$ $\bar{G}(\overline{\Delta k_4})$, the above considerations lead to the identity

$$G(\Delta k_4)=\sum_{\mathbf{T}\in\mathbf{T}_5} e^{-\bar{N}_4\Delta k_4}(1+G(\Delta k_4))^{\bar{N}_3}=\sum_{\mathbf{T}\in\mathbf{T}_5} e^{-\bar{N}_4\overline{\Delta k_4}}=\bar{G}(\overline{\Delta k_4}), \tag{4.28}$$

in which $\Delta k_4=k_4-5/2k_2$ comes out from restricting the action of quantum gravity to stacked spheres (4.2) and where we have defined

$$\overline{\Delta k_4}=\Delta k_4-\tfrac{5}{2}\log(1+G(\Delta k_4)). \tag{4.29}$$

By (4.28) we can also write Eq. (4.29) as

$$\Delta k_4=\overline{\Delta k_4}+\tfrac{5}{2}\log(1+\bar{G}(\overline{\Delta k_4})). \tag{4.30}$$

By universality and the estimates (4.21) it follows that near the critical point we have $G(\Delta k_4)\asymp \mathrm{cost}+(\Delta k_4-\Delta k_4^c)^{1-\gamma_s}$ with $\gamma_s<1$.

The susceptibility functions of $\mathbf{T}_2$ and $\mathbf{T}_5$ by (4.28) are

$$\chi(\Delta k_4)\asymp -\frac{d}{d\Delta k_4}G(\Delta k_4),\quad \bar{\chi}(\overline{\Delta k_4})\asymp -\frac{d}{d\overline{\Delta k_4}}\bar{G}(\overline{\Delta k_4}). \tag{4.31}$$

From (4.30) we have

$$\frac{d(\Delta k_4)}{d(\overline{\Delta k_4})}=1-\frac{5}{2}\frac{\bar{\chi}(\overline{\Delta k_4})}{(1+\bar{G}(\overline{\Delta k_4})}. \tag{4.32}$$

If we calculate di derivative with respect to Δk_4 of the one loop function $G(\Delta k_4)$ and use the previous equation we get

$$\chi(\Delta k_4)=\frac{\bar{\chi}(\overline{\Delta k_4})}{1-\frac{5}{2}\frac{\bar{\chi}(\overline{\Delta k_4})}{(1+\bar{G}(\overline{\Delta k_4})}}. \tag{4.33}$$

Now it is clear that $\chi(\Delta k_4)\mapsto+\infty$ for $\Delta k_4\mapsto(\Delta k_4)^c$ and with the same critical exponent $\bar{\chi}(\overline{\Delta k_4})\mapsto+\infty$ for $\overline{\Delta k_4}\mapsto(\overline{\Delta k_4})^c$. From Eq. (4.33) when $\chi(\Delta k_4)\mapsto+\infty$ we have that $\bar{\chi}(\overline{\Delta k_4})\mapsto\frac{2}{5}(1+\bar{G}(\overline{\Delta k_4}(\Delta k_4^c)))<+\infty$, then the system $\mathbf{T}_5$ is above his critical line, i.e., $\overline{\Delta k_4}(\Delta k_4^c)>\overline{\Delta k_4}^c$. These facts imply that at $\overline{\Delta k_4}(\Delta k_4^c)d(\Delta k_4)/d(\overline{\Delta k_4})=0$ and around it $\bar{\chi}(\overline{\Delta k_4})/(1+G(\overline{\Delta k_4}))$ is a decreasing monotonic function of Eq. (4.32) because $\chi(\Delta k_4)\mapsto+\infty$, we can expand Eqs. (4.30) and (4.33) around $\overline{\Delta k_4}(\Delta k_4^c)$

$$\Delta k_4-\Delta k_4^c=\mathrm{cost}(\overline{\Delta k_4}-\overline{\Delta k_4}(\Delta k_4^c))^2. \tag{4.34}$$

$$\chi(\Delta k_4)\asymp\frac{1}{\overline{\Delta k_4}-\overline{\Delta k_4}(\Delta k_4^c)}\asymp\frac{1}{\sqrt{\Delta k_4-\Delta k_4^c}}. \tag{4.35}$$

The second asymptotic equality of the last equation implies

$$\gamma_s = \tfrac{1}{2}. \tag{4.36}$$

The dominance of stacked spheres in the weak phase allows us to fix the parameter τ in the partition function of quantum gravity in the weak coupling regime:

$$\tau - \tfrac{11}{2} = -\tfrac{5}{2} \Rightarrow \tau = 3. \tag{4.37}$$

Is there a general area theorem for black holes?

Domenico Giulini[a)]
Institut für theoretische Physik, Universität Zürich,
Winterthurerstrasse 190, CH-8057 Zürich, Switzerland

(Received 15 July 1998; accepted for publication 3 August 1998)

The general validity of the area law for black holes is still an open problem. We first show in detail how to complete the usually incompletely stated textbook proofs under the assumption of piecewise C^2-smoothness for the surface of the black hole. Then we prove that a black hole surface necessarily contains points where it is not C^1 (called ''cusps'') at any time before caustics of the horizon generators show up, like, e.g., in merging processes. This implies that caustics never disappear in the past and that black holes without initial cusps will never develop such. Hence black holes which will undergo any nontrivial processes anywhere in the future will always show cusps. Although this does not yet imply a strict incompatibility with piecewise C^2 structures, it indicates that the latter are likely to be physically unnatural. We conclude by calling for a purely measure theoretic proof of the area theorem. © *1998 American Institute of Physics.* [S0022-2488(98)01612-0]

I. INTRODUCTION

It seems to be widely accepted as fact that the surface area of a black hole cannot decrease with time. However, the proofs offered in standard textbooks, like Refs. 1–3, are basically content with the remark that this law follows from the nonconvergence of the generators of the future event horizon. It would indeed follow from this remark and some elementary differential geometric considerations if the horizon were a sufficiently smooth submanifold. Mathematically there is absolutely no reason why this should be true in general,[4] which means that extra assumptions must be invoked (implicitly) in the textbooks arguments. However, not much precise information seems to exist in the literature concerning these extra assumptions. Perhaps the clearest statement is given in Ref. 4, where the authors mention that in the textbook proofs of the area theorem ''something close to C^2 differentiability 'almost everywhere' of the event horizon seems to have been assumed.'' The textbooks themselves do not mention any such condition. Below we show explicitly how to complete the textbook argumentation under the assumption of piecewise C^2-smoothness. But this clearly does not imply its necessity.

General considerations only prove the horizon to be locally Lipschitz continuous (denoted by C^{1-}).[1] Mathematically this implies (pointwise) differentiability almost everywhere (with respect to the Lebesgue measures defined by the charts, see Ref. 5 Theorem 3.1.6), but it still allows the points of nondifferentiability to be densely distributed.[4] Hence horizons exist which are nowhere C^1. Given these mathematical facts, it is of interest to learn what *physical* conditions imply a breakdown of C^1 differentiability. We prove that a black hole whose surface is C^1 at one time can never merge with other black holes and, more generally, never encounter new null generators for its future event horizon. In other words, an initial C^1-condition basically rules out any interesting physical process to happen in the future. Hence the only dynamically interesting holes for which the area law is actually proven are those whose surfaces are piecewise C^2 but not C^1. Presumably this class does not contain many, if any, physically realistic members. Cusps on the surface of colliding black holes can be clearly seen in numerical studies,[6] but no analytic proof of their general existence seems to have been given so far.

Given the widely believed connection of the area law with thermodynamic properties of black holes on one side, and the widely expressed hope that this connection may be of heuristic value in understanding certain aspects of quantum gravity on the other, it seems important to know the most general conditions under which the area law is valid.

II. NOTATION, FACTS, AND ASSUMPTIONS

We assume space–time (M,g) to be strongly asymptotically predictable (in the sense of Ref. 3) and globally hyperbolic. (It would be sufficient to restrict to a globally hyperbolic portion, as in Thm. 12.2.6 of Ref. 3.) $\mathcal{I}^+$ (scri-plus) denotes future null infinity, $J^-(\mathcal{I}^+)$ its causal past and $B:=M-J^-(\mathcal{I}^+)$ the black hole region. Its boundary, $\partial B=:H$, is the future event horizon. H is a closed, imbedded, achronal three-dimensional C^{1-}-submanifold of M (Proposition 6.3.1 in Ref. 1). H is generated by null geodesics without future endpoints. Past endpoints occur only where null geodesics—necessarily coming from $J^-(\mathcal{I}^+)$—join onto H. Such points are called ''caustics.'' Only at a caustic can a point of the horizon be intersected by more than one generator, and *all* generators that intersect a caustic enter the horizon at this point. Once a null geodesic has joined onto H it will never encounter a caustic again (i.e., not intersect another generator) and never leave H. See Box 34.1 in Ref. 2 for a lucid discussion and partial proofs of these statements. Hence there are two different processes through which the area of a black hole may increase: First, new generators can join the horizon and, second, the already existing generators can mutually diverge.

Caustic points where n (possibly infinite) new generators join in are said to be of multiplicity n. In Ref. 7 it is proven that H is not differentiable at p iff p is a caustic of multiplicity $n\geqslant 2$, and that caustics of multiplicity 1 are contained in the closure of those of higher multiplicity. In particular, H cannot be of class C^1 at any caustic point. Points where H is not C^1 will be called ''cusps.'' By definition, being C^1 at p implies that H is differentiable in a whole neighborhood U of p. Conversely, it was shown that differentiability in some open neighborhood U of p implies that H is C^1 in U (Ref. 7, Prop. 3.3), so that the set of points where H is C^1 is open. It follows that being C^1 at p is in fact equivalent to being differentiable in some neighborhood of p. Hence the set of cusps is the closure of the set of points where H is nondifferentiable (caustics of multiplicity $\geqslant 2$) and hence also the closure of the set of all caustics.

Let Σ be a suitably smooth (usually C^2) Cauchy surface, then $\mathcal{B}:=B\cap\Sigma$ is called the black-hole region at time Σ and $\mathcal{H}:=H\cap\Sigma=\partial\mathcal{B}$ the (future-event-) horizon at time Σ. A connected component $\mathcal{B}_i$ of $\mathcal{B}$ is called a black hole at time Σ. Its surface is $\mathcal{H}_i=\partial B_i$, which is a two-dimensional, imbedded C^{1-}-submanifold of Σ. We have seen that in general $\mathcal{H}$ may contain all kinds of singularities which would render standard differential geometric methods inapplicable. Adding the hypothesis of piecewise C^2-smoothness circumvents this problem.

By $\exp{:}TM\to M$ we denote the exponential map. Recall that $\exp_p(v):=\gamma(1)$, where γ is the unique geodesic with initial conditions $\gamma(0)=p\in M$ and $\dot{\gamma}(0)=v\in T_p(M)$. For each p it is well defined for v in some open neighborhood of $0\in T_p(M)$. One has $\gamma(t)=\exp_p(tv)$. We shall assume the Lorentzian metric g of M to be C^2, hence the connection (i.e., the Christoffel symbols) is C^1 and, therefore, the map exp is also C^1. The last assertion is e.g., proven in Ref. 8.

III. LOCAL FORMULATION OF THE AREA LAW

We consider two C^2 Cauchy surfaces with Σ' to the future of Σ. The corresponding blackhole regions and surfaces are denoted as above, with a prime distinguishing those on Σ'. We make the *assumption* that $\mathcal{H}$ is piecewise C^2, i.e., each connected component $\mathcal{H}_i$ of $\mathcal{H}$ is the union of open subsets $\mathcal{H}_i^k$ which are C^2 submanifolds of M and whose two-dimensional measure exhaust that of $\mathcal{H}_i$: $\mu(\mathcal{H}_i-\cup_k\mathcal{H}_i^k)=0$, where μ is the measure on $\mathcal{H}$ induced from the metric g.

For each point $p\in\mathcal{H}_i^k$ there is a unique future- and outward-pointing null direction perpendicular to $\mathcal{H}_i^k$, which we generate by some future directed $l(p)\in T_p(M)$. We can choose a C^1-field $p\mapsto l(p)$ of such vectors over $\mathcal{H}_i^k$. The geodesics $\gamma_p: t\mapsto\gamma_p(t):=\exp_p(tl(p))$ are generators of H without future endpoint. Therefore, each γ_p cuts Σ' in a unique point $p'\in\mathcal{H}'$ at a unique parameter value $t=\tau(p)$. By appropriately choosing the affine parametrizations of γ_p as p varies over $\mathcal{H}_i^k$ we can arrange the map τ to be also C^1. Hence $p\mapsto m(p):=\tau(p)l(p)$ is a null vector field of class C^1 over $\mathcal{H}_i^k$. We can now define the map

$$\Phi_i^k:\mathcal{H}_i^k\to\mathcal{H}',\quad p\mapsto\Phi_i^k(p):=\exp_p(m(p)),\tag{1}$$

which satisfies the following.

Lemma 1: Φ_i^k is (i) C^1, (ii) injective, (iii) not measure-decreasing.

(i) follows from the fact that the functions m and exp are C^1. Injectivity must hold, since otherwise some of the generators of H through $\mathcal{H}_i^k$ would cross in the future. By being not measure-decreasing we mean the following: Let μ and μ' be the measures on $\mathcal{H}$ and $\mathcal{H}'$ induced by the space–time metric g. Then $\mu[U] \leqslant \mu'[\Phi_i^k(U)]$ for *each* measurable $U \subset \mathcal{H}_i^k$. Assuming the weak energy condition, this is a consequence of the *nowhere* negative divergence for the future geodesic congruence $p \mapsto \gamma_p$ (Lemma 9.2.2 in Ref. 1), as we will now show.

Proof of (iii): Set $H_i^k := \cup_{p,t} \exp_p(tl(p))$, $\forall p \in \mathcal{H}_i^k$ and $\forall t \in R_+$, which is a C^1-submanifold of M (the future of $\mathcal{H}_i^k$ in H). Let l be the unique (up to a constant scale) future directed null geodesic (i.e., $\boldsymbol{\nabla}_l l = 0$) vector field on H_i^k parallel to the generators. Then $0 \leqslant \nabla_\mu l^\mu = \pi_\nu^\mu \nabla_\mu l^\nu$, where π denotes the map given by the g-orthogonal projection $T(M)|_{H_i^k} \to T(H_i^k)$, followed by the quotient map $T(H_i^k) \to T(H_i^k)/\mathrm{span}\{l\}$. Note that tangent spaces of C^1-cross sections of H_i^k at the point p are naturally identified with $T_p(H_i^k)/\mathrm{span}\{l(p)\}$. Since $\pi_\nu^\mu l^\nu = 0$, we also have $\pi_\nu^\mu \nabla_\mu k^\nu \geqslant 0$ for $k = \lambda l$ and any C^1-function λ: $H_i^k \to \mathbf{R}_+$. Hence this inequality is valid for any future pointing C^1-vector-field k on H_i^k parallel to the generators. Given that, let $t \mapsto \phi_t$ be the flow of k and $A(t) := \mu_t[\phi_t(U)] := \int_{\phi_t(U)} d\mu_t$, then $\dot{A}(t) = \int_{\phi_t(U)} \pi_\nu^\mu(t) \nabla_\mu k^\nu(t) d\mu_t \geqslant 0$, where $\pi(t)$ projects onto $T(\phi_t(\mathcal{H}_i^k))$, $k(t) = d/(dt')|_{t'=t} \phi_{t'}$ and $\mu_t =$ measure on $\phi_t(\mathcal{H}_i^k)$. Now choose k such that $\phi_{t=1} = \Phi_i^k$, then $\mu'[\Phi_i^k(U)] - \mu[U] = \int_0^1 dt \dot{A}(t) \geqslant 0$. □

Part (iii) of Lemma 1 is the local version of the area law. By turning it into a global statement about areas one usually abandons some of its information. The most trivial global implication is that the total sum of areas cannot decrease. A more refined version is as follows: Recall that black holes cannot bifurcate in the future (Proposition 9.2.5 of Ref. 1). Hence all surface elements $\mathcal{H}_i^k$ of the ith black hole at time Σ are mapped via Φ_i^k into the surface $\mathcal{H}'_i$ of a *single* black hole at time Σ'. We call $\mathcal{H}'_i$ (i.e., the connected component of $\Sigma' \cap H$ into which $\mathcal{H}_i$ is mapped) the development of $\mathcal{H}_i$ at time Σ'. Lemma 1 now implies that its area cannot be less than that of $\mathcal{H}_i$. The nonbifurcation result implies that if the number N' of black holes at time Σ' is bigger than the number N at time Σ, then there is an intermediate formation of $K \geqslant N' - N$ new black holes. That these black holes are ''new,'' i.e., not present at time Σ, means that all generators of H which intersect $\mathcal{H}'_1 \cup \cdots \cup \mathcal{H}'_K$ must have past endpoints somewhere between Σ and Σ'. A black hole at time Σ' which is smaller than any black hole at time Σ must also be new in this sense. Hence one way to express an area law would be as follows:

Assertion (Area Law): Consider two Cauchy surfaces, Σ and Σ', with Σ' to the future of Σ. Then the area of the development $\mathcal{H}'_i$ of any $\mathcal{H}_i$ cannot be less than that of $\mathcal{H}_i$. In particular, black holes at time Σ' whose area is smaller than that of any black at time Σ must have been formed in the meantime.

Presently we do not have a proof that this statement is true in general. But since it is a statement about measures, we suggest that it should be possible to give a proof without invoking fiducial (and probably irrelevant) differentiability assumptions.

IV. CONSEQUENCES

The previous discussion allows one to show that black holes whose surface is C^1 at one instant cannot undergo any nontrivial change in the future, like merging processes or any other process involving the incorporation of new generators. This we shall now explain in more detail. Let $\mathcal{H}_1$ be the surface a black hole at time Σ. We assume $\mathcal{H}_1$ to be a compact, two-dimensional C^1-submanifold. As before, Σ' is to the future of Σ and $\mathcal{H}' = H \cap \Sigma'$. We can construct a map $\Phi_1 : \mathcal{H}_1 \to \mathcal{H}'$, just analogous to the construction of Φ_i^k above, but now defined on *all* of $\mathcal{H}_1$. The C^1-condition on $\mathcal{H}_1$ now implies that Φ_1 is C^0. Φ_1 is also injective for the same reason as given for Φ_i^k. Since $\mathcal{H}_1$ is connected, its image under Φ_1 is also connected. Let $\mathcal{H}'_1 \subset \mathcal{H}'$ be the connected part containing the image of Φ_1. We show

Lemma 2: $\Phi_1 : \mathcal{H}_1 \to \mathcal{H}'_1$ is a homeomorphism.

Proof: Φ_1 is a closed map, because if $U \subset \mathcal{H}_1$ is closed $\Rightarrow U$ is compact (since $\mathcal{H}_1$ is compact) $\Rightarrow U' := \Phi_1(U)$ is compact (since Φ_1 is continuous) $\Rightarrow U'$ is closed (since $\mathcal{H}'_1$ is Hausdorff). From this it follows that Φ_1 is a homeomorphism onto its image. But Φ_1 is also open; this follows directly from Brouwer's theorem on the invariance-of-domain, which states that any continuous injective map from an open $X \subset R^n$ into R^n is open (Proposition 7.4 in Ref. 9). This clearly

generalizes to manifolds. Hence the image $\Phi_1(\mathcal{H}_1)\subset\mathcal{H}_1'$ is open, closed and connected, and hence all of $\mathcal{H}_1'$. □

Surjectivity of Φ_1 implies that all generators of H which intersect $\mathcal{H}_1'$ also intersect $\mathcal{H}_1$. Hence nowhere in its future will $\mathcal{H}_1$ be joined by new generators. Similar to the definition of H_i^k above, let $H_1\subset H$ denote the future of $\mathcal{H}_1$ in H; then it follows that H_1 is free of caustics and therefore C^1. Hence we have

Proposition 1: Let the surface of a black hole at time Σ be without cusps. Then this black hole will never encounter cusps to the future of Σ, in particular, it will not merge with other black holes.

Another equivalent formulation, emphasizing that cusps will not die out in the past, is as follows:

Proposition 2: At no time to the past of a cusp on H will the surface of a black hole be without cusps.

It is sometimes suggested that caustics just exist for some finite time interval during which the actual processes take place, like collision and coalescence of black holes or the infall of matter through the horizon (see e.g., Ref. 2, 34.5). Proposition 2 shows that this is not quite the right picture.

Time-independent bounds on solutions with shocks to the relativistic Euler equations on conformally flat space–times with curvature singularities

Jeffrey M. Groah
Department of Mathematics and Computing, La Sierra University, Riverside, California 92515

(Received 15 October 1997; accepted for publication 7 November 1997)

We consider the initial value problem of the relativistic Euler equations when the underlying space–time is not flat but conformally flat, and demonstrate existence of solutions with shocks, with time-independent bounds, in some cases from big bang till big crunch. Our theorem requires that the space–time metric satisfy certain bounds, but these do not constrain the curvature of space–time, and hence our theorem may guarantee uniform bounds on solutions until the formation of curvature singularities. © *1998 American Institute of Physics.*
[S0022-2488(98)04003-1]

I. INTRODUCTION

We study the global evolution of shock dynamics on space–times given a fixed conformally flat metric. We analyze the fluid motion using Glimm's method with operator splitting, a numerical method that accounts for the effects of the fluid in the first step, using Glimm's method, and the effects of the geometric sources in the second iteration of the method. Glimm's method with operator splitting is the only method of analysis that has been successfully shown to yield global estimates for the shock dynamics when sources are present.[1] In Ref. 2, we considered conformally flat space–times with trace-free energy-momentum tensor, and found a special compatibility between the gravitational sources and the fluid which allowed us to obtain solutions with uniform total variation bounds independent of the strength of the gravitational potential, and hence from big bang till big crunch. Here, we do not assume that the energy-momentum tensor is trace-free, and we find it necessary to assume certain bounds on the gravitational sources in order to obtain uniform bounds on the fluid solutions. Since these restrictions do not constrain the space–time curvature, they allow us to establish existence of uniformly bounded solutions on space–times having both a big bang and a big crunch singularity.

We study here the initial value problem for solutions with shocks to the relativistic Euler equation on a 4-dimensional space–time on which we assume a fixed background metric which is conformally flat, $g=e^{2\varphi}\eta$, where η is the Minkowski metric diag$(-1,1,1,1)$, where fluid motion occurs in one spatial coordinate direction and along the time coordinate, and with the equation of state for isothermal flow, or the extreme relativistic limit of free particles, $p=\sigma^2\rho$. Here, ρ is the fluid pressure, σ is the constant sound speed, and ρ is the mass-energy density of the fluid as measured in units of mass in a reference frame moving with the fluid particles. Let the space–time manifold M be given coordinates (x^0,x^1,x^2,x^3) and assume, without loss of generality, that $x^0=ct$ is the time coordinate, and $x^1=x$ is the spatial coordinate along which fluid moves.

We will show that, under these conditions, the relativistic Euler equations can be written in the form

$$\frac{1}{c}\frac{\partial}{\partial t}\left\{\overline{\rho}\left((\sigma^2+c^2)\,\frac{c^2}{c^2-v^2}-\sigma^2\right)\right\}+\frac{\partial}{\partial x}\left\{\overline{\rho}(\sigma^2+c^2)\,\frac{cv}{c^2-v^2}\right\} \tag{1}$$

$$=-\overline{\rho}\,\frac{1}{c}\,\frac{\partial\varphi}{\partial t}\,\{\sigma^2(n-1)-c^2\}, \tag{2}$$

 © 1998 American Institute of Physics

$$\frac{1}{c}\frac{\partial}{\partial t}\left\{\overline{\rho}(\sigma^2+c^2)\,\frac{cv}{c^2-v^2}\right\}+\frac{\partial}{\partial x}\left\{\overline{\rho}\left((\sigma^2+c^2)\,\frac{v^2}{c^2-v^2}+\sigma^2\right)\right\} \tag{3}$$

$$=\overline{\rho}\,\frac{\partial\varphi}{\partial x}\{\sigma^2(n-1)-c^2\}, \tag{4}$$

where $\overline{\rho}=\rho e_{n\varphi}$, c is the speed of light, and v is the particle velocity. Our main theorem establishes the existence of uniformly bounded weak solutions to (4) on conformally flat space–times when the gravitational potential φ satisfies certain bounds.

Theorem I.1: *Suppose a 4-dimensional space–time manifold is given a coordinate system* (x^0,x^1,x^2,x^3), *a conformally flat metric* $g=e^{2\varphi}\eta$ *of signature* $(-1,1,1,1)$ *where* φ *is a function of the space–time coordinates* x^0 *and* x^1, *and arbitrary initial data* $\rho_0(x^1)$, $v_0(x^1)$ *satisfying*

$$\mathrm{TV}(\ln(\rho_0))<\infty \tag{5}$$

and

$$\mathrm{TV}\left\{\ln\left(\frac{v_0(\cdot)+c}{v_0(\cdot)-c}\right)\right\}<\infty, \tag{6}$$

where $\mathrm{TV}(f)$ *denotes the total variation of the function* f. *Suppose that* $|\varphi_{,0}|+|\varphi_{,1}|\in L^1(R\times R^+)$, *and*

$$\int_0^\infty \mathrm{TV}_x(|\varphi_{,0}|+\varphi_{,1}|)dt\leqslant\infty. \tag{7}$$

Then there exists a bounded weak solution $\rho(x,t),v(x,t)$ *of system (4) satisfying:*

$$\mathrm{TV}\ \ln(\rho)\leqslant\mathrm{TV}\ \ln(\rho_0)+C \tag{8}$$

and

$$\mathrm{TV}\left\{\ln\left(\frac{v(\cdot,t)+c}{v(\cdot,t)-c}\right)\right\}\leqslant\mathrm{TV}\left\{\ln\left(\frac{v_0(\cdot)+c}{v_0(\cdot)-c}\right)\right\}+C, \tag{9}$$

where C *is a constant depending only on the metric* g. *Moreover, the solution is a limit of approximate solutions* $(\rho_{\Delta x},v_{\Delta x})$ *generated by a Glimm type operator splitting scheme, and converges a.e., and in* L^1_{loc} *at each time, uniformly on bounded subsets of* (x,t)*-space.*

Theorem I.1 generalizes the results in Ref. 2 to space–times without trace-free energy-momentum tensors, but on this more general class of spaces, the metric must satisfy the bound (7). The approximation scheme used here is necessarily different due to the different form of the lower order gravitational source terms, and is similar to an operator splitting scheme used by Luskin and Temple in Ref. 3 (see also Ref. 4). The operator splitting scheme consists of two parts which we call the Conservation Law Step and the ODE Step. Our proof of the Conservation Law Step bounds in Lemma IV.9 follows the flat Minkowski space case proved by Smoller and Temple in Ref. 5, and is based on the geometry of the shock-curves is the plane of Riemann invariants, first used by Nishida[6] in his solution of the classical case. Our assumption of the bounds (7) is necessary for our proof of the ODE Step bounds, and amounts to assuming that the gravitational source term adds a finite amount of wave strength. Assuming the spatial total variation of the source is bounded implies the source adds a finite amount of wave strength in each time interval, while assuming that the spatial total variation of the source is integrable implies that the total contribution to wave strength over all time will be integrable. The assumption that the gravitational source term is $L^1(R\times R^+)$ assures that the source diminishes in space and time, and is used in our proof of convergence.

The bounds on $\varphi_{,0}$ and $\varphi_{,1}$ are not restrictions on space–time curvature since curvature depends not only on these quantities but also on the second derivatives of the metric. Instead, the bounds (7) are restrictions on the divergence of the coordinate vector fields $\partial/\partial x^0$ and $\partial/\partial x^1$.

When the Einstein equation $G=\kappa T$ holds for a perfect fluid with the equation of state $p=\sigma^2\rho$, curvature is singular if and only if the mass-energy-momentum tensor is singular. Here, however, we do not require that the Einstein equation be satisfied, and as long as the integrability conditions (7) hold, solutions with uniform bounds to (4) may be found, even in the presence of curvature singularities such as occur in a big bang or a black hole. This theorem applies in the presence of these singularities but only when the integrability conditions (7) are satisfied.

For classical fluids, the equation of state $p=\sigma^2\rho$ is considered theoretically as the limiting case of a polytropic gas, $p=\sigma^2\rho^\gamma$, as $\gamma\to 1^+$. In relativistic physics, the case $p=\sigma^2\rho$ is the equation of state for a gas in which radiation energy dominates, or the extreme relativistic limit of free particles (see Ref. 7 p. 12 or Ref. 8 p. 51). It arises in connection with the big bang, massless neutrinos, ultrarelativistic electron-positron pairs, Neutron stars and the early stages of stellar formation. See also Ref. 5.

The organization of this paper is as follows. In Sec. II, the equations we study are derived. The necessity of coordinate vector fields in the construction of a grid and the Courant–Friedrichs–Lewy condition is described in Sec. III, and then the approximate solutions are defined in Sec. III A, and the operator splitting scheme described in detail. Wave strengths and the potential are then defined. In Sec. IV, the geometry of the shock curves is discussed, followed by the solution of the Riemann problem, and then bounds are demonstrated to exist on the growth of the total wave strength on the conservation law step of the operator splitting scheme. In Sec. V, bounds are demonstrated to exist on the growth of the total wave strength on the ODE step of the operator splitting scheme. Finally, in Sec. VI, we show that a subsequence of the approximate solutions converges to a solution.

II. DERIVATION OF THE EQUATIONS

In this section the equations are put into the form needed for the operator splitting scheme. Then we discuss a restriction on the metric which arises in connection with construction of a grid on which to carry out a Glimm-type approximation scheme. The approximate solutions are next defined and the operator splitting scheme described in detail. Wave strengths and the potential are then defined.

One spatial dimensional fluid motion requires that the initial data be constructed appropriately, and that the space–time manifold have sufficient symmetry so that the curvature of space–time will not cause fluid to flow in directions other than those permitted. The assumption that fluid moves along the x^0 and x^1 coordinates directly affects our choice of metric. The symmetry of fluid motion requires that the space–time manifold have sufficient symmetry; otherwise, gravitation will cause fluid motion in the x^2 and x^3 coordinate directions. The following lemma gives sufficient conditions on the metric so that fluid will move only in the x^0 and x^1 coordinate directions.

Lemma II.1: Suppose the space–time metric has the block structure,

$$\begin{pmatrix} \tilde{g} & 0 \\ 0 & \tilde{g} \end{pmatrix}, \tag{10}$$

where $\hat{g}$ is a 2×2 block. Given the equation of state $p(\rho)$, when $g_{ij}, i,j\leqslant 1$ and ρ are functions of x^0 and x^1 alone, and $u^2\equiv u^3\equiv 0$, then the Eqs. (4) $j\geqslant 2$ are identically satisfied, and hence the Eqs. (4) $j\leqslant 1$ may be solved independently. Moreover, the components of acceleration in the x^2 and x^3 coordinates directions, as well as the pressure gradient in these directions, is zero.

Proof: That the Eqs. (4) $j\leqslant 1$ may be solved independently of the Eqs. (4) $j\geqslant 2$ may be readily checked. The particle acceleration is given by $\nabla_U U$. That this acceleration should vanish in the coordinate directions $\partial/\partial x^k$, $k=2,3$ is expressed by $0=g(\nabla_U U,\partial/\partial x^k)$, $k=2,3$ or in coordinates by

$$u^i u^j_{,i} g_{jk} + u^i u^j \Gamma^l_{ij} g_{lk} = 0. \tag{11}$$

To analyze the second term, let i, $j\leqslant 1$, $k\geqslant 2$. Since the metric is block diagonal,

$$\Gamma^l_{ij} g_{lk} = \frac{g^{lm}}{2}(-g_{ij,m}+g_{mi,j}+g_{jm,i})g_{lk} = \frac{-1}{2} g_{ij,k}. \tag{12}$$

Since the metric components $g_{ij}, i,j \leqslant 1$ are functions of x^0 and x^1 alone,

$$\Gamma^l_{ij} g_{lk} = 0. \tag{13}$$

This implies that if the solution satisfies the equation

$$u^i u^j_{,i} g_{jk} = 0, \tag{14}$$

then the fluid is not accelerated in the x^2 and x^3 coordinate directions. Since $k \geqslant 2$, and $u^k \equiv 0$, $k \geqslant 2$, (14) is satisfied. Thus the acceleration in the x^2 and x^3 coordinate directions is zero.

We now analyze the pressure gradient. To this end, consider the relativistic Euler equations, which can be written in the form

$$0 = \mathrm{div}(T) = U(p+\rho c^2)U + (p+\rho c^2)\nabla_U U + (p+\rho c^2)\mathrm{div}(U)U + \mathrm{grad}(p).$$

Since U is a unit vector (and since the metric is parallel), $0 = U(g(U,U)) = 2g(\nabla_U U, U)$, so $\nabla_U U \perp U$. From this we deduce the two equations

(1) $c^2 U(\rho) = -(p+\rho c^2)\mathrm{div}(U)$ (energy equation);

(2) $(p+\rho c^2)\nabla_U U = -\mathrm{grad}_\perp p$ (force equation),

where $\mathrm{grad}_\perp(p)$ is the component of $\mathrm{grad}(p)$ orthogonal to U, and is known as the *spatial pressure gradient* (see Ref. 9 p. 339.) If $g(\nabla_U U, \partial/\partial x^k) = 0$ for $k = 2,3$, the force equation implies $0 = g(\mathrm{grad}_\perp p, \partial/\partial x^k)$, $k \geqslant 2$. Now, $\mathrm{grad}(p) = -U(p)U + \mathrm{grad}_\perp p$, so it must be that $0 = p_{,k}$, $k \geqslant 2$. Given the equation of state $p(\rho)$, we deduce that since $\rho_{,k} = 0$ when $k \geqslant 2$, $0 = g(\mathrm{grad}_\perp p, \partial/\partial x^k)$, for $k \geqslant 2$. □

For conformally flat space–times, the condition that the functions $g_{ij}, i,j \leqslant 1$ are functions of x^0 and x^1 alone implies φ is a function of x^0 and x^1 alone.

Let T be the energy-momentum tensor for a fluid defined on M. Conservation of mass-energy and momentum is expressed by the equation

$$\mathrm{div}\ T = 0. \tag{15}$$

We will use the following proposition in the first step in rewriting the Euler equations.

Proposition II.0.1: Suppose T is a symmetric (2,0) tensor, $\overline{T} = e^{(n+2)\varphi} T$ *where n is the dimension of the manifold, and we have two metrics g and* $\overline{g}$*, which are conformally related,* $\overline{g} = e^{2\varphi} g$*. Then*

$$e^{(n+2)\varphi}\ \mathrm{div}_{\overline{g}} T = \mathrm{div}_g \overline{T} - e^{(n+2)\varphi}\ \mathrm{grad}_g\ \varphi \mathrm{tr}_g(T), \tag{16}$$

and therefore $\mathrm{div}_{\overline{g}} T = 0$ *if and only if*

$$\mathrm{div}_g\ \overline{T} = e^{(n+2)\varphi}\ \mathrm{grad}_g(\varphi)\mathrm{tr}_g(T). \tag{17}$$

Moreover, T is a weak solution of $\mathrm{div}_{\overline{g}} T = 0$ *if and only if it is a weak solution to (17).*

Proof: When $\overline{g} = e^{2\varphi} g$, the connection $\overline{\nabla}$ with respect to the metric $\overline{g}$ is related to the connection ∇ with respect to the metric g by the equation

$$\overline{\nabla}_X Y = \nabla_X Y + X(\varphi)Y + Y(\varphi)X - g(X,Y)\mathrm{grad}_g(\varphi), \tag{18}$$

(see Ref. 10). Therefore,

$$\overline{\Gamma}^j_{ik} = \Gamma^j_{ik} + \varphi_{,k}\delta^j_i + \varphi_{,i}\delta^j_k - \varphi_{,l} g_{ik} g^{jl}. \tag{19}$$

In addition, we use the following identity:

$$\overline{\Gamma}^i_{ik} = \tfrac{1}{2}\ln(-\overline{g})_{,k}, \tag{20}$$

(see Refs. 11, 12) whereby

$$\overline{\Gamma}^i_{ik} = \tfrac{1}{2}\ln(-e^{2n\varphi}g)_{,k} = \tfrac{1}{2}\{\ln(-g)+2n\varphi\}_{,k} = \Gamma^i_{ik} + n\varphi_{,k}. \tag{21}$$

Using (19) and (20) to compute the covariant divergence of T with respect to the metric $\overline{g}$ we obtain

$$\begin{aligned}\operatorname{div}_{\overline{g}} T^j &= T^{ij}{}_{,i} + \overline{\Gamma}^i_{ik}T^{kj} + \widetilde{\Gamma}^j_{ik}T^{ik}\\ &= T^{ij}{}_{,i} + (\Gamma^i_{ik} + n\varphi_{,k})T^{kj} + (\Gamma^j_{ik} + \varphi_{,k}\delta^j_i + \varphi_{,i}\delta^j_k - \varphi_{,l}g^{lj}g_{ik})T^{ik}\\ &= \operatorname{div}_g T^j + (n+2)\varphi_{,k}T^{kj} - \varphi_{,k}g^{kj}\ \operatorname{tr}_g(T),\end{aligned}$$

where by $\operatorname{div}_{\overline{g}}T^j$ we mean the jth component of $\operatorname{div}_{\overline{g}}T$. Setting $\overline{T} = e^{(n+2)\varphi}T$ and using the last equation we find

$$\begin{aligned}\operatorname{div}_g \overline{T}^j = \overline{T}^{ij}{}_{,i} &= (n+2)\varphi_{,i}e^{(n+2)\varphi}T^{ij} + e^{(n+2)\varphi}T^{ij}{}_{;i}\\ &= e^{(n+2)\varphi}\{(n+2)\varphi_{,i}T^{ij} + \operatorname{div}_g T^j\}\\ &= e^{(n+2)\varphi}\{g^{ij}\varphi_{,i}\ \operatorname{tr}_g(T) + \operatorname{div}_{\overline{g}}T^j\}.\end{aligned}$$

The same equation written invariantly is

$$\operatorname{div}_g \overline{T} = e^{(n+2)\varphi}\{\operatorname{grad}_g(\varphi)\operatorname{tr}_g(T) + \operatorname{div}_{\overline{g}}T\}, \tag{22}$$

verifying (16). From (22) it follows directly that

$$\operatorname{div}_g \overline{T} = e^{(n+2)\varphi}\ \operatorname{grad}(\varphi)\operatorname{tr}(T) \tag{23}$$

if and only if $\operatorname{div}_{\overline{g}}T = 0$.

By equation (22),

$$\operatorname{div}_g T = e^{-(n+2)\varphi}\{\operatorname{div}_g \overline{T} - e^{(n+2)\varphi}\ \operatorname{grad}_g\ \varphi\ \operatorname{tr}_g(T)\}. \tag{24}$$

Therefore, weak solutions to $0 = \operatorname{div}_{\overline{g}}T$ are weak solutions to

$$0 = e^{-(n+2)\varphi}\{\operatorname{div}_g \overline{T} - e^{(n+2)\varphi}\ \operatorname{grad}_g\ \varphi\ \operatorname{tr}_g(T)\}. \tag{25}$$

Equation (25) differs from (17) by a factor of $e^{-(n+2)\varphi}$. Weak solutions must satisfy

$$0 = \int_{\infty}^{\infty}\int_{t_0}^{T} e^{-(n+2)\varphi}\{\operatorname{div}_g \overline{T} - e^{(n+2)\varphi}\ \operatorname{grad}_g\ \varphi\ \operatorname{tr}_g(T)\}\phi\, dx^0\, dx^1, \tag{26}$$

but the factor $e^{-(n+2)\varphi}$ may be combined with the function ϕ in Eq. (26) because $e^{-(n+2)\varphi}$ is nonzero and smooth, yielding

$$0 = \int_{\infty}^{\infty}\int_{t_0}^{T} \{\operatorname{div}_g \overline{T} - e^{(n+2)\varphi}\ \operatorname{grad}_g\ \varphi\ \operatorname{tr}_g(T)\}\psi\, dx^0\, dx^1, \tag{27}$$

where $\psi = e^{-(n+2)\varphi}\phi$. Therefore, T is a weak solution of $\operatorname{div}_{\overline{g}}T = 0$ if and only if it is a weak solution to (17). □

There are several alternate forms of Eq. (17). From the following facts:

(1) $\operatorname{tr}_{\overline{g}}(\underline{T}) = \overline{g}_{ik}T^{ik} = e^{2\varphi}g_{ik}T^{ik} = e^{2\varphi}\operatorname{tr}_g(T)$,

(2) $\operatorname{tr}_g(T) = \operatorname{tr}_g(e^{(n+2)\varphi}T) = e^{(n+2)\varphi}\operatorname{tr}_g(T)$.

The following are equivalent to $\operatorname{div}_g T = 0$:

$$\operatorname{div}_g(\overline{T}) = e^{(n+2)\varphi}\ \operatorname{grad}_g(\varphi)\operatorname{tr}_g(T) = e^{n\varphi}\ \operatorname{grad}_g(\varphi)\operatorname{tr}_{\overline{g}}(T) = \operatorname{grad}_g(\varphi)\operatorname{tr}_g(\overline{T}) = e^{-2\varphi}\ \operatorname{grad}_g(\varphi)\operatorname{tr}_{\overline{g}}(\overline{T}).$$

For the Minkowski metric case presented in Ref. 5, the Christoffel symbols are zero. In addition, $\varphi \equiv 0$, so the source term is zero, leaving a pure conservation law. Note that from Eq.

(17) we see that it is not necessary to assume that $\varphi \equiv 0$ in order to obtain a pure conservation law. The assumption that $\text{grad}(\varphi)\text{tr}(T)=0$ will accomplish the same result. This assumption implies either $\text{grad}(\varphi)=0$ on an open set, in which case the metric in question is the Minkowski metric, or $\text{tr}(T)=0$, the case investigated in Ref. 2.

The energy-momentum tensor for a perfect fluid is given by

$$T^{ij}=(p+\rho c^2)u^i u^j+pg^{ij}, \tag{28}$$

where ρ is the mass-energy density, p is the fluid pressure, u^i, $i=0,1,2,3$ are the components of the 4-velocity vector field U of fluid particles, and g is the space–time metric. If T is the energy-momentum tensor for a perfect fluid, then (15) is called the *relativistic Euler equation.*

Perfect fluids with trace free energy-momentum tensors are precisely those with the equation of state

$$p=\frac{c^2}{(n-1)}\,\rho, \tag{29}$$

since

$$0=\text{tr}(T)=g_{ik}T^{ik}=g_{ik}\{(p+\rho c^2)u^i u^k+pg^{ik}\}=-(p+\rho c^2)+np=(n-1)p-\rho c^2.$$

Here we assume only that $p=\sigma^2\rho$, where σ is the constant sound speed, $0<\sigma<c$.

With the metric $g=e^{2\varphi}\eta$, (17) takes the form

$$\text{div}_\eta\,\overline{T}=e^{n\varphi}\,\text{grad}_\eta(\varphi)\text{tr}_g(T). \tag{30}$$

Substituting the energy-momentum tensor for a perfect fluid we obtain,

$$\begin{aligned}\{e^{(n+2)\varphi}((p+\rho c^2)u^i u^j+pe^{-2\varphi}\eta^{ij})\}_{,i}&=e^{n\varphi}\varphi_{,i}\eta^{ij}g_{lk}\{(p+\rho c^2)u^l u^k+pg^{lk})\}\\&=e^{n\varphi}\varphi_{,i}\eta^{ij}\{-(p+\rho c^2)+pn\}\\&=e^{n\varphi}\varphi_{,i}\eta^{ij}\{p(n-1)-\rho c^2\}.\end{aligned}$$

With the equation of state $p=\sigma^2\rho$, we obtain the system of equations

$$\begin{aligned}&\{e^{n\varphi}\rho((\sigma^2+c^2)(u^0)^2-\sigma^2e^{-2\varphi})\}_{,0}+\{e^{n\varphi}(\rho(\sigma^2+c^2)u^0u^1\}_{,1}\\&\quad=-e^{n\varphi}\rho\varphi_{,0}\{\sigma^2(n-1)-c^2\}\{e^{n\varphi}\rho((\sigma^2+c^2)u^0u^1)\}_{,0}\\&\qquad+\{e^{n\varphi}\rho((\sigma^2+c^2)(u^1)^2+\sigma^2e^{-2\varphi})\}_{,1}\\&\quad=e^{n\varphi}\rho\varphi_{,1}\{\sigma^2(n-1)-c^2\}.\end{aligned} \tag{31}$$

Since $-1=g(U,U)$ and $u^1=\dfrac{v}{c}\,u^0$, it follows that

$$u^1=\frac{v^2e^{-2\varphi}}{c^2-v^2}. \tag{32}$$

Substituting (32) into the system (31), and setting $\overline{\rho}=\rho e^{n\varphi}$, we have

$$\left\{\overline{\rho}\left((\sigma^2+c^2)\,\frac{c^2}{c^2-v^2}-\sigma^2\right)\right\}_{,0}+\left\{\overline{\rho}(\sigma^2+c^2)\,\frac{cv}{c^2-v^2}\right\}_{,1}=-\overline{\rho}\varphi_{,0}\{\sigma^2(n-1)-c^2\}, \tag{33}$$

$$\left\{\overline{\rho}(\sigma^2+c^2)\,\frac{cv}{c^2-v^2}\right\}_{,0}+\left\{\overline{\rho}\left((\sigma^2+c^2)\,\frac{v^2}{c^2-v^2}+\sigma^2\right)\right\}_{,1}=\overline{\rho}\varphi_{,1}\{\sigma^2(n-1)-c^2\}, \tag{34}$$

from which we obtain (4).

In the classical theory of shock waves, a conservation law is a PDE of the form

$$U_t + F(U)_x = 0, \tag{35}$$

where $U \in R^n$, $n \in N$ and $(x,t) \in R \times R^+$ (Ref. 1, p. 239). However, due to the existence of a gravitational source term, it will be seen that the relativistic Euler equations for one-dimensional fluid flow with conformally flat metrics can be written as a system of two equations of the form

$$U_t + F(U)_x = G(x,t,U). \tag{36}$$

This type of equation is known as a system of conservation laws with a lower order source term.

Set

$$U^0 \overset{\text{def}}{=} \left\{ \overline{\rho}(\sigma^2 + c^2) \, \frac{c^2}{c^2 - v^2} - \sigma^2 \right\},$$

$$U^1 \overset{\text{def}}{=} \left\{ \overline{\rho}(\sigma^2 + c^2) \, \frac{cv}{c^2 - v^2} \right\},$$

$$U^2 \overset{\text{def}}{=} \left\{ \overline{\rho}(\sigma^2 + c^2) \, \frac{v^2}{c^2 - v^2} + \sigma^2 \right\},$$

as well as $U \overset{\text{def}}{=} (U^0, U^1)^T$, $F(U) \overset{\text{def}}{=} (U^1, U^2)^T$, and

$$G(x^0, x^1, U) \overset{\text{def}}{=} - \begin{pmatrix} -e^{(n+2)\varphi} \overline{\rho} \varphi_{,0} \{\sigma^2 (n-1) - c^2\} \\ e^{(n+2)\varphi} \overline{\rho} \varphi_{,1} \{\sigma^2 (n-1) - c^2\} \end{pmatrix}. \tag{37}$$

The system (31) can be put into the form (36), if we can show that U^2 is a function of U^0 and U^1, and if we can show that G is a function of U and the coordinates x^0 and x^1 alone.

First, define $\Phi(\rho, v) = (U^0, U^1)$, where for simplicity, we write ρ instead of $\overline{\rho}$. If Φ is one-to-one, then we may set $\Phi^{-1}(U^0, U^1) = (\rho, v)$, where we can write $\Phi_1^{-1}(U) = \rho$ and $\Phi_2^{-1}(U) = v$, and

$$f(U) \overset{\text{def}}{=} U^2(\Phi_1^{-1}(U), \Phi_2^{-1}(U)) = U^2(\rho, v). \tag{38}$$

From this we may set $(U^1, U^2)^T = (U^1, f(U))^T$ which shows that F is indeed a function of U. We must still show that Φ is invertible, which is accomplished via the following lemma.

Let J be the subset of the (ρ, v) plane corresponding to positive densities $\rho > 0$ and timelike velocities $|v| < c$.

Lemma II.2: The function $\Phi(\rho, v) = (U^0, U^1)$ *satisfies the following on the region* J:

(1) *the Jacobian determinant of* Φ *is continuous,*

(2) *the Jacobian determinant of* Φ *does not vanish,*

(3) Φ *is one-to-one.*

Proof: The Jacobian determinant of Φ is

$$|J\Phi| = \frac{c(p + \rho c^2)}{-e^{4\varphi}(c^2 - v^2)^2} \{c^4 - \sigma^2 v^2\} \tag{39}$$

which is continuous on J.

If $|J\Phi| = 0$, then $c^4 = \sigma^2 v^2 < c^2 v^2$ which in turn implies that $c < |v|$. Thus, v is outside of the assumed range and $|J\Phi| \neq 0$ in the region of interest.

To show that Φ is one-to-one, let $(\rho_1,v_1)\neq(\rho_2,v_2)$ be two points such that $\Phi(\rho_1,v_1)=\Phi(\rho_2,v_2)$. First, note that if $\rho_1=\rho_2$, then since $U^0(\rho_1,v_1)=U^0(\rho_2,v_2)$ we have that $c^2-v_1^2=c^2-v_2^2$. Substituting this into the equation $U^1(\rho_1,v_1)=U^1(\rho_2,v_2)$ we find that $v_1=v_2$. Similarly, if $v_1=v_2$, then $\rho_1=\rho_2$.

Since $\Phi(\rho_1,v_1)=\Phi(\rho_2,v_2)$,

$$\rho_1\left(\frac{(c^2+\sigma^2)cv_1e^{-2\varphi}}{c^2-v_1^2}\right)=\rho_2\left(\frac{(c^2+\sigma^2)cv_2e^{-2\varphi}}{c^2-v_2^2}\right), \tag{40}$$

$$\rho_1e^{-2\varphi}\left(\frac{(c^2+\sigma^2)c^2}{c^2-v_1^2}-\sigma^2\right)=\rho_2e^{-2\varphi}\left(\frac{(c^2+\sigma^2)c^2}{c^2-v_2^2}-\sigma^2\right). \tag{41}$$

Dividing (41) by (40), we have

$$\frac{c}{v_1}-\frac{\sigma^2(c^2-v_1^2)}{(c^2+\sigma^2)cv_1}=\frac{c}{v_2}-\frac{\sigma^2(c^2-v_2^2)}{(c^2+\sigma^2)cv_2}. \tag{42}$$

After some simplification, (42) becomes

$$c^2(c^2+\sigma^2)(v_2-v_1)=\sigma^2(v_2-v_1)\{c^2-v_1v_2\}. \tag{43}$$

Assuming that $v_1\neq v_2$, we may simplify (43) further as

$$\frac{c^4}{\sigma^2}=-v_1v_2. \tag{44}$$

Taking the absolute value of both sides of (44), we have

$$|v_1v_2|\geqslant c^2, \tag{45}$$

which is not possible for timelike particles. Thus $v_1=v_2$, which implies that $\rho_1=\rho_2$ as we have seen. We conclude that Φ is one-to-one. □

III. THE APPROXIMATE SOLUTIONS

In order to implement a Glimm-type scheme it is necessary to construct a grid, for which, in order to be well-defined, it is necessary that the grid lines be constructed from coordinate lines. To see this, suppose that two arbitrary linearly independent vector fields X and Y are chosen, in place of $\partial/\partial x^0$ and $\partial/\partial x^1$, with which we are to construct a grid. Following the vector field X a distance Δx from some point (x_0,y_0), and then following the vector field Y a distance Δy, we end up at some point (x_1,y_1). Conversely, if we follow the vector field Y a distance Δy from the point (x_0,y_0), and then following the vector field X a distance Δx we end up at some point (x_2,y_2). In general $(x_1,y_1)\neq(x_2,y_2)$ making it impossible to form a closed grid, unless X and Y are *coordinate* vector fields (see Ref. 13 pp. 218, 219).

The establishment of a Courant–Friedrichs–Lewy (CFL) condition is complicated by the fact that in some coordinate systems on space–time manifolds, the speed of light is not bounded. For lightlike particles,

$$\frac{dx^1}{dx^0}=\left(\frac{-g_{01}\pm\sqrt{-\hat{g}}}{g_{11}}\right), \tag{46}$$

where $g_{11}\neq 0$. If the supremum in absolute value of (46) exists,

$$C=\sup_{p\in M}\left|\frac{-g_{01}(p)\pm\sqrt{-\hat{g}(p)}}{g_{11}(p)}\right|, \tag{47}$$

then we can set $\Delta x^1/\Delta x^0>2C$. In the present case, $dx^1/dx^0=\pm 1$.

As examples of the CFL condition, we consider conformally flat spaces, the Schwarzschild metric, and a Robertson–Walker space. For a conformally flat space, $C=1$ so a single grid can be used clear till the space crashes to a point (or from a point). For the Robertson–Walker metric

$$ds^2=-(dx^0)^2+f^2(x^0)((dx^1)^2+(dx^2)^2+(dx^3)^2), \tag{48}$$

we have

$$C=\sup_{p\in M} 1/f \tag{49}$$

so, as long as f is bounded away from zero, one grid can be used for as long as time makes sense. This means that big bangs and big crunches must be avoided in order for the existence theorem to go through, though this is only partly true. In the limit, existence is guaranteed from big bang to big crunch though uniform bounds are not guaranteed by this method. This should not be surprising since density is expected to become unbounded in these extreme situations anyway. Note however, that uniform bounds have been demonstrated to exist from big bang to big crunch on conformally flat space–times with trace-free energy-momentum tensors in Ref. 2.

For the Schwarzschild metric,

$$ds^2=-\left(1-\frac{2M}{r}\right)dt^2+\left(1-\frac{2M}{r}\right)^{-1}dr^2+r^2\,d\Omega^2, \tag{50}$$

where $d\Omega^2=d\theta^2+\sin^2\theta\,d\varphi^2$, we have

$$C=\sup_{p\in M}|1-2M/r|. \tag{51}$$

In the region $r\geqslant\delta>0$, the sup exists and a CFL condition can be imposed on a grid.

A. The approximate solutions

An operator splitting technique is used to construct the approximate solutions for the initial value problem

$$U_t+F(U)_x=G(x,t,U), \tag{52}$$

$$U(x,0)=U_0(x). \tag{53}$$

The approximates are constructed in two steps which will be called the *Conservation law step*, and the *ODE step*. On the conservation law step the solution at time t_i is discretized (made piecewise constant) by Glimm's method (see, e.g., Refs. 14, 1), and the resulting Riemann problems are solved with respect to the equations

$$U_t+F(U)_x=0 \tag{54}$$

on the discretized data, and for a time step. Then, on the ODE step, the ODE's $U_t=G(x,t,U)$ are solved with initial values being the solutions to the Riemann problems. The approximates at time $t\in[t_i,t_{i+1}]$ are defined to be the value of the solution to the ODE after $t-i\Delta t$ units of time. More precisely, let Δx and Δt be chosen so as to satisfy the CFL condition, and set $x_i=i\Delta x$ and $t_i=t_0+i\Delta t$. We may, without loss of generality, set $t_0=0$. Select a sequence of random points $\theta=(\theta_1,\theta_2,\cdots),\theta_i\in(0,1)$, and denote the solution to the conservation law step on the ith time step by ${}^R_iU$ and the solution to the ODE step on the ith time step by ${}^{\mathrm{ODE}}_iU$. Then ${}^R_iU$ solves the homogeneous equation (54) on $R\times[t_i,t_{i+1}]$ with initial data being ${}^{\mathrm{ODE}}_{i-1}U(x,t_i)$. Let ${}^{\mathrm{Temp}}U(t,U_0)$ solve the ODE

$$U_t=G(x,t,U),$$

$$U(0)=U_0.$$

Then ${}^{\mathrm{ODE}}_{i}U$ is defined by ${}^{\mathrm{ODE}}_{i}U(x,t)={}^{\mathrm{Temp}}U(t-t_i,{}^{R}_{i}U(x,t)),\ t\in[t_i,t_{i+1}]$.

B. The potential

We next define I-curves, and a potential on the I-curves. As in Ref. 3, we define *vertex points* as

$$(x_i,t_j+\tfrac{1}{2}\Delta t),$$

$$(x_i+\theta_i\Delta x_i,t_j),$$

where $j\geqslant 0$ and $i\in Z$. An I-curve is a piecewise linear curve in xt-space which connects a vertex point on t_j to a vertex point on $t_j\pm\frac{1}{2}\Delta t$ with line segments, and where I-curves are functions of x. I-curves are given a partial ordering by defining that larger curves lie toward larger time. We call I_2 an *immediate successor* to I_1 if these two I-curves connect the same vertices except one, and if $I_2>I_1$.

Let γ be a wave. We define its strength by $|\gamma|=|\ln(\rho_r)-\ln(\rho_l)|$. Given this definition of wave strength we define the potential for the conservation law step to be

$$L(I)=\sum_{\gamma\ \mathrm{crosses}\ I}|\gamma|. \tag{55}$$

IV. CONSERVATION LAW STEP BOUNDS

In this section we consider the solutions on the conservation law step, and bound the potential. We first find the eigenvalues and Riemann invariants, and we determine when the conservation laws are strictly hyperbolic and genuinely nonlinear. Next we prove that the Lax entropy inequalities hold, and parameterize the shock curves. The geometry of the shock curves is then described. Finally, the Riemann problems are solved and it is shown that the potential is nonincreasing on the conservation law step.

By demonstrating that the entropy inequalities hold, we show that the approximate solutions we construct are physically relevant, and any shock waves in our approximate solutions are not entropy violating rarefaction shocks. The geometry of the shock curves as described in Lemma IV.6 is necessary, first to demonstrate existence of solutions to Riemann problems, and then to show that interacting waves produce waves of equal or lesser total variation. In this way, the approximate solutions on the conservation law step will be total variation diminishing. Note, however, that the gravitational source term can increase the total variation of the approximate solutions.

On the conservation law step, we set the source term to zero and solve Riemann problems on the source-free equations, isolating the analysis of the sources in the next section. Therefore, our analysis in this section will closely follow the Minkowski metric case, which can be found in Ref. 5. We note that our proof that the Lax entropy inequalities hold is ours.

A. Eigenvalues and Riemann invariants

For the conservation law step we set the source term to zero and consider only the equations

$$U_{,0}+F(U)_{,1}=0. \tag{56}$$

For what follows, set $A=U^0$, $B=U^1$, and $C=U^2$. We also write, for simplicity, ρ in place of $\overline{\rho}$.

The wave speeds are the eigenvalues λ_i of the Jacobian matrix $dF=\partial F/\partial U$. Let R_i denote the ith eigenvector of dF. We will calculate the wave speeds and the Riemann invariants using the following well-known theorem due to Lax.[15]

Theorem IV.1 (Lax): *Assume that the system (56) is strictly hyperbolic, and for some fixed state U_l, the solutions U and s of the Rankine–Hugoniot relation $s(U-U_l)=F(U)-F(U_l)$ can be described (in a neighborhood of U_l) by two families of smooth curves $U=\mathbf{S}_i(\epsilon)$, $\mathbf{S}_i(0)=U_l$, with corresponding speeds $s_i(\epsilon), i\in\{1,2\}$. Moreover, as $\epsilon\to 0$, we have $s_i(\epsilon)\to\lambda_i(U_l)$ and $U_i'(\epsilon)\to R_i$. Here, the parameter ϵ can be taken to be (Euclidean) arc length along the shock curve $\mathbf{S}_i$ in U-space.*

First, we use this theorem to calculate the eigenvalues and eigenvectors for the equation of state $p(\rho)$. The Rankine–Hugoniot jump conditions imply that if the state (ρ_r, v_r) lies on a shock curve starting at (ρ_l, v_l), then

$$[B]^2=[A][C]. \tag{57}$$

Since (57) defines v implicitly as a function of ρ, we may differentiate (57) with respect to ρ and divide by $[B]$ to obtain

$$2B'=\frac{[A]}{[B]}C'+\frac{[C]}{[B]}A', \tag{58}$$

where the prime denotes differentiation with respect to ρ. Using L'Hospital's rule,

$$\lim_{\rho\to\rho_l}\frac{[A]}{[B]}=\left.\frac{A'}{B'}\right|_{\rho=\rho_l}. \tag{59}$$

Thus, at $\rho=\rho_l$, (57) can be written as

$$(B')^2=A'C'. \tag{60}$$

We solve (60) for v' obtaining

$$\frac{v'}{c^2-v^2}=\pm\frac{\sqrt{p'}}{p+\rho c^2}. \tag{61}$$

We use (61) to find the Riemann invariants. As defined in Ref. 1 p. 321, a k-Riemann invariant is a smooth function w such that $\langle R_k, \nabla w\rangle=0$, where $\langle\cdot,\cdot\rangle$ denotes the Euclidean inner product on R^n. We note that Riemann invariants are constant along integral curves of eigenvector fields of dF. By Theorem IV.1, we ultimately obtain the Riemann invariants

$$r=\frac{1}{2}\ln\left|\frac{c+v}{c-v}\right| c\int_1^\rho\frac{\sqrt{p'(\epsilon)}}{p(\epsilon)+\epsilon c^2}\,d\epsilon, \tag{62}$$

$$s=\frac{1}{2}\ln\left|\frac{c+v}{c-v}\right|+c\int_1^\rho\frac{\sqrt{p'(\epsilon)}}{p(\epsilon)+\epsilon c^2}\,d\epsilon. \tag{63}$$

We now calculate the eigenvalues. Again using Theorem IV.1 and L'Hospital's rule we have

$$\lambda_i=\lim_{\rho\to\rho_l}\frac{[B]}{[A]}=\left.\frac{B'}{A'}\right|_{\rho=\rho_l}. \tag{64}$$

B'/A' is a quantity involving $\rho, v, p'=dp/d\rho$, and $v'=dv/d\rho$. Substituting (61) into (64) and simplifying we obtain

$$\lambda_1=\frac{cv-\sqrt{p'}c}{c^2-\sqrt{p'}v}, \tag{65}$$

$$\lambda_2=\frac{cv+\sqrt{p'}c}{c^2+\sqrt{p'}v}. \tag{66}$$

We are now in a position to prove strict hyperbolicity and genuine nonlinearity.

Theorem IV.2: *System (56) is strictly hyperbolic at* (ρ,v) *if and only if*

$$\sqrt{p'(\rho)}<c. \tag{67}$$

Moreover, assuming (67), system (4) is genuinely nonlinear at each (ρ,v) *if and only if*

$$p''(\rho)\neq -2\frac{(c^2-p')p'}{(p+\rho c^2)}. \tag{68}$$

Proof: We first show that $\lambda_1<\lambda_2$ if and only if $\sqrt{p'(\rho)}<c$ and hence (56) is strictly hyperbolic. To this end, a calculation can show that

$$\lambda_1-\lambda_2=-\frac{2c\sqrt{p'}(c^2-v^2)}{c^4-p'v^2}. \tag{69}$$

The right-hand side of Eq. (69) is negative for all $|v|<c$ if and only if p' is bounded by the square of the speed of light, c^2. We have shown that $\lambda_1<\lambda_2$, which demonstrates strict hyperbolicity, if and only if $\sqrt{p'(\rho)}<c$.

We are now in a position to verify that r (respectively, s) is indeed a 1- (respectively, 2-) Riemann invariant. To determine under what conditions the system (4) will be genuinely nonlinear, we must calculate the right eigenvectors of dF. We do this using the Riemann invariants and then check that $\langle \text{grad}\,\lambda_i,R_i\rangle\neq 0$. The eigenvectors may be found using the equations

$$R_1=\left(-\frac{\partial r}{\partial v},-\frac{\partial r}{\partial \rho}\right)^T,$$

$$R_2=\left(-\frac{\partial s}{\partial v},-\frac{\partial s}{\partial \rho}\right)^T=\left(\frac{\partial r}{\partial v},-\frac{\partial r}{\partial \rho}\right)^T,$$

from which we obtain

$$R_1=\left(\frac{-c}{(c^2-v^2)},\frac{\sqrt{p'}}{p+\rho c^2}\right)^T,$$

$$R_2=\left(\frac{c}{(c^2-v^2)},\frac{\sqrt{p'}}{p+\rho c^2}\right)^T.$$

A straightforward computation shows that

$$\text{grad}\,\lambda_i=\frac{1}{\{c^2\mp\sqrt{p'}v\}^2}\left(\pm\frac{p''c(c^2-v^2)}{2\sqrt{p'}},c(p'-c^2)\right)^T.$$

The gradient here is with respect to the Euclidean inner product on R^2. It can now be shown that

$$\langle \text{grad}\,\lambda_i,R_i\rangle=\frac{c^2}{\{c^2\mp\sqrt{p'}v^2\}^2}\left(\frac{p''}{2\sqrt{p'}}+\frac{\sqrt{p'}(c^2-p')}{(p+\rho c^2)}\right). \tag{70}$$

From this it follows that the system (4) is genuinely nonlinear if and only if (68) holds. □

B. The shock curves and the entropy inequalities

Simplifying the Eq. (57) we obtain

$$\frac{(p_r-p_l)(\rho_r-\rho_l)}{(p_r+\rho_r c^2)(p_l+\rho_l c^2)}=\frac{(v_r-v_l)^2}{(c^2-v_r^2)(c^2-v_l^2)}. \tag{71}$$

With the equation of state $p=\sigma^2\rho$, (71) becomes

$$\frac{(\rho_r-\rho_l)^2}{\rho_r\rho_l}=\frac{(\sigma^2+c^2)^2(v_r-v_l)^2}{\sigma^2(c^2-v_r^2)(c^2-v_l^2)}. \tag{72}$$

The right-hand side of (72) we define to be

$$2\beta \overset{\text{def}}{=} \frac{(\sigma^2+c^2)^2(v_r-v_l)^2}{\sigma^2(c^2-v_r^2)(c^2-v_l^2)}. \tag{73}$$

Setting

$$z \overset{\text{def}}{=} \frac{\rho_r}{\rho_l}, \tag{74}$$

and solving for z in (72) yields

$$z = 1+\beta\left\{1 \pm \sqrt{1+\frac{2}{\beta}}\right\} \overset{\text{def}}{=} f_{\pm}(\beta). \tag{75}$$

For simplicity of the equations that follow, set

$$K \overset{\text{def}}{=} \frac{2\sigma^2c^2}{(\sigma^2+c^2)^2}. \tag{76}$$

We now address the Lax entropy inequalities, which are shown to hold all along the shock curves. The following lemma appears in Ref. 5 p. 81 in their treatment of the 2-dimensional space–time Minkowski metric case, though the proof given here is different.

Lemma IV.3: The shock speed s_i is monotone all alone the shock curve $\mathbf{S}_i$ of system (4), $i=1,2$, and moreover, the following inequalities (Lax shock conditions) hold at each state $U_r \neq U_l$ on the shock curve $\mathbf{S}_i$:

$$\lambda_i(\rho_r,v_r) < s_i < \lambda_i(\rho_l,v_l). \tag{77}$$

Proof: Recall that (57) defines v as a function of ρ. Therefore, the equation $s=[B]/[A]$ defines the shock speeds s as a function of ρ. We show that $ds/d\rho \neq 0$. To this end, note that since

$$s^2 = \frac{[C]}{[A]}, \tag{78}$$

we have

$$2s\,\frac{ds}{d\rho} = \frac{1}{[A]}\{C'-s^2A'\}. \tag{79}$$

Note that $ds/d\rho$ equals zero if and only if

$$s^2 = \frac{C'}{A'} = \lim_{\rho_l \to \rho_r} \frac{[C]}{[A]}. \tag{80}$$

Since

$$\lambda_i(\rho_r,v_r) = \frac{B'}{A'}, \tag{81}$$

Eqs. (80) and (81) together imply that the only way that $s'=0$ is if $s=\lambda_i(\rho_r,v_r)$. We solve

$$\lambda_i = s_j = \frac{[B]}{[A]} \tag{82}$$

for v_r, where the numerator and denominator of the right-hand side of (82) is divided through by ρ_l and ρ_r/ρ_l is replaced by $1+\beta\{1\mp\sqrt{1+(2/\beta)}\}$. β is then replaced by

$$\frac{(\sigma^2+c^2)^2(v_r-v_l)^2}{2\sigma^2(c^2-v_r^2)(c^2-v_l^2)}. \tag{83}$$

After this tedious computation, the only solutions are $v_r=v_l$, in which case there is no shock, and

$$v_r=\frac{c^4}{\sigma^2 v_l}. \tag{84}$$

Since $\sigma<c$ and $|v_l|<c$, we have $|v_r|>c$. Note that this contradiction implies that either $\lambda_i(\rho_{r,l},v_{r,l})<s_j$ or $\lambda_i(\rho_{r,l},v_{r,l})>s_j$. We have shown that the shock speed s_i is monotone all along the shock curves $\mathbf{S}_i$, since $s'\neq 0$ on these curves. There is now a simple procedure to verify that the shock inequalities hold. Since we have shown that $s_i\neq\lambda_j$, we need only test one point in each of the six relevant intervals. This was done and it was found that

$$\begin{gathered}\lambda_1(r)<s_1<\lambda_1(l)\lambda_2(r)<s_2<\lambda_2(l),\\ s_1<\lambda_2(r),\quad \lambda_1(l)<s_2.\end{gathered} \tag{85}$$

□

C. Geometry of the shock curves

The goal of this section is to prove that the i-shock curves at different points are translates of each other in Riemann invariant coordinates on state space, and that 1-shock and 2-shock curves are reflections of each other about a particular line in the state space under Riemann invariant coordinates.

All of the lemma's in this section are the same as in Ref. 5 pp. 84–87,90. (Note that some of the pages were printed out of order.) All of the proofs are essentially identical. However, these lemma's are important to the existence theorem so, they will be included here.

Lemma IV.4: Let $r\equiv r(\rho,v)$, $s\equiv s(\rho,v)$, $\Delta r\equiv r(\rho,v)-r(\rho_l,v_l)$ *and* $\Delta s\equiv s(\rho,v)-s(\rho_l,v_l)$, *where we let* $(\rho,v)\equiv(\rho_l,v_l)$. *Then the 1-shock curve* $\mathbf{S}_1$ *for system (4) based at* (r_l,s_l) *is given by the following parametrization with respect to* $\beta,0\leqslant\beta<\infty$:

$$\Delta r=-\frac{1}{2}\ln\{f_+(2K\beta)\}-\sqrt{\frac{K}{2}}\ln\{f_+(\beta)\}, \tag{86}$$

$$\Delta s=-\frac{1}{2}\ln\{f_+(2K\beta)\}+\sqrt{\frac{K}{2}}\ln\{f_+(\beta)\}; \tag{87}$$

and the 2-shock curve $\mathbf{S}_2$ *based at* (r_l,s_l) *is given for* $0\leqslant\beta<\infty$, *by*

$$\Delta r=-\frac{1}{2}\ln\{f_+(2K\beta)\}-\sqrt{\frac{K}{2}}\ln\{f_-(\beta)\}, \tag{88}$$

$$\Delta s=-\frac{1}{2}\ln\{f_+(2K\beta)\}+\sqrt{\frac{K}{2}}\ln\{f_-(\beta)\}. \tag{89}$$

Lemma IV.5: The 2-shock curve based at an arbitrary point (r_l,s_l) *is the reflection in the* rs*-plane of the 1-shock curve based at the same point, where the axis of reflection is the line passing through* (r_l,s_l), *parallel to the liner* $r=s$.

Lemma IV.6: The shock curves $\mathbf{S}_i$ *define convex curves in the* rs*-plane and moreover,*

$$0\leqslant\frac{ds}{dr}<\frac{\sqrt{2K}-1}{-\sqrt{2K}-1}<1 \tag{90}$$

all along the 1-shock curve $\mathbf{S}_1$, *and*

$$0 \leqslant \frac{dr}{ds} < \frac{\sqrt{2K}-1}{-\sqrt{2K}-1} < 1 \tag{91}$$

all along the 2-shock curve $\mathbf{S}_2$.

D. The Riemann problem

The Riemann problem solutions we generate are not Riemann problem solutions to the full relativistic Euler equations. Instead, they are Riemann problem solutions to the Euler equations with the source set to zero. The geometry of the shock curves in the plane of Riemann invariants as described in Lemma's IV.5, and IV.6 is special to the equation of state $p=\sigma^2\rho$. Given a different equation of state, the geometry of the shock curves could be much more complex. This remarkable geometry was first noticed by Nishida in Ref. 6 in his treatment of the classical case. It was also used by Smoller and Temple in Ref. 5 in their treatment of the special relativistic case. We take advantage of the special geometry in this case to demonstrate the existence of solutions to each Riemann problem, and to obtain an inequality which will be important in proving the bounds (8), (9) in Theorem I.1.

Theorem IV.7: *There exists a solution of the Riemann problem for system (4) in the case of an equation of state of the form* $p=\sigma^2\rho$, $\sigma^2<c^2$, *so long as density is positive and velocities are for timelike particles. Moreover, the solution is given by a 1-wave followed by a 2-wave, also has positive density, and particle velocities are for timelike particles. The solution is unique in the class of rarefaction waves and admissible shock waves.*

Briefly, the proof of Theorem IV.7 is as follows. Lemmas IV.5 and IV.6 show that the wave curves at a point (r_l,s_l) form a coordinate system. Thus for each point (r_r,s_r) there is a unique 1-wave curve and a unique 2-wave curve such that we may pass from (r_l,s_l) to (r_r,s_r) along the path consisting of the 1-wave curve followed by the 2-wave curve. The solution to the Riemann problem (U_l,U_r) will be these two waves.

The wave interaction estimates for solutions to the Riemann problems on the conservation law step can be obtained exactly as in Ref. 5 pp. 92–93 by which we have the following lemma.

Lemma IV.8: Let U_l, U_m, *and* U_r *denote three arbitrary states with positive density and timelike velocities. Let* $\alpha_1,\alpha_2,\beta_1,\beta_2$, and γ_1,γ_2 *denote the waves that solve the Riemann problems*

$$[U_l,U_m],[U_m,U_r],[U_l,U_r], \tag{92}$$

respectively. Then

$$|\gamma_1|+|\gamma_2| \leqslant |\alpha_1|+|\alpha_2|+|\beta_1|+|\beta_2|. \tag{93}$$

The idea of the proof is quite simple. The strengths of the waves going in for all possible cases of wave interactions are compared to the strengths of the waves going out using the geometry of the wave curves in the plane of Riemann invariants. The inequalities (90) and (91) are particularly helpful in demonstrating the inequality (93) when shock waves are involved in the interaction. Note that since rarefaction waves are straight lines in the plane of Riemann invariants, equality holds in (93) when only rarefaction waves are involved.

Lemma IV.8 establishes the following.

Lemma IV.9: Recall that $L(j)$ *is the total strength of the waves in the approximate solution at time step* j, *and let* $\hat{L}(j)$ *denote the total strength of the waves in the approximate solutions after the conservation law step (but before the ODE step) at time step* j. *Then* $\hat{L}(j+1) \leqslant L(j)$.

V. ODE STEP BOUNDS

In the construction of the approximate solutions we first solve conservation laws with the source term set to zero. We then modify these solutions by a system of ODE's which adds the effects of the source term. The potential function may increase through this process, so bounds on the potential function must be demonstrated to exist. In this section we find bounds on the

solutions needed in order to maintain bounds on the potential. It will not be possible to demonstrate the existence of these bounds for all metrics. In general, black holes and big bangs can cause the potential to become unbounded in finite time.

The wave strengths are measured in terms of variations in $\log \rho$, and therefore, the total wave strength is the total variation in $\log \rho$. The source term may add to the total variation in $\log \rho$ by increasing wave strengths and adding new waves. For our proof of convergence to go through, we must show that the total variation in $\log \rho$ will remain bounded. The following theorem shows that if the total variation of the gravitational source term is of bounded variation for each time t, then it cannot increase the total wave strength by more than a finite amount on each time step. Furthermore, if the total variation of the gravitational source term is an integrable function of time, then total wave strength contributed by the gravitational source term is integrable, and hence the total variation in $\log \rho$ will remain uniformly bounded. If, however, the gravitational source term does not depend on time, then the sources will continue to feed wave strength into the solution, and hence we can at best guarantee a linear growth bound on the total variation of the solution.

Theorem V.1: *If*

$$\int_0^\infty \mathrm{TV}_x(\varphi,i)(t)dt<\infty \tag{94}$$

for $i\in\{0,1\}$, *then* $L(j)\leqslant L(0)+K$, *where* K *is a constant depending only on the metric. If* $\varphi_{,i}$, $i\in\{0,1\}$ *is a function of bounded variation in* x *alone, then* $L(j)\leqslant L(0)+Kt$.

Proof: Let ${}^R\rho^j$ denote the solution of the Conservation Law Step on the time interval $[t_j,t_{j+1}]$ at time t_{j+1}^-, since this will be the data for the ODE's at time t_j. Denote by ρ^j the solution of the ODE's on $[t_j,t_{j+1}]$, i.e., after the ODE's have operated on the solutions for time $t-t_j$. We will write the ODE's in the form $\rho_t/\rho=\sigma$, where σ is the source term. In this case, for a fixed x,

$$\ln(\rho^j)=\ln({}^R\rho^j)+\int_{t_j}^t \sigma\, dt. \tag{95}$$

Therefore,

$$\mathrm{TV}_x(\ln(\rho^j))\leqslant \mathrm{TV}_x(\ln({}^R\rho^j))+\mathrm{TV}_x\left(\int_{t_j}^t \sigma\, dt\right) \tag{96}$$

$$\leqslant \mathrm{TV}_x(\ln({}^R\rho^j))+\int_{t_j}^t \mathrm{TV}_x(\sigma)(t)dt. \tag{97}$$

By the Mean Value Theorem for Integrals, (97) leads to

$$\mathrm{TV}_x(\ln(\rho^j))\leqslant \mathrm{TV}_x(\ln({}^R\rho^j))+\mathrm{TV}_x(\sigma)(\xi_j)\Delta t, \tag{98}$$

where $\xi_j\in[t_j,t]$. By induction, (98) implies

$$\mathrm{TV}_x(\ln(\rho^{j+1}))\leqslant \mathrm{TV}_x(\ln({}^R\rho^0))+\sum_{k=0}^{j} \mathrm{TV}_x(\sigma)(\xi_k)\Delta t, \tag{99}$$

and therefore

$$\mathrm{TV}_x(\ln(\rho^j))\leqslant \mathrm{TV}_x(\ln({}^R\rho^0))+K\int_0^{t_{j+1}} \mathrm{TV}_x(\sigma)(t)dt. \tag{100}$$

Equation (100) shows that if

$$\int_0^\infty \mathrm{TV}_x(\sigma)(t)dt \tag{101}$$

converges, then the total variation of $\log(\rho)$ is uniformly bounded. But, if the source σ is a function of x alone, then the total variation will grow at most linearly.

We must now examine the source term of the relativistic Euler equations. On the ODE step we solve the ODE's

$$U_t = G(x,t,U). \tag{102}$$

Now, $U_t = U_\rho \rho_t + U_v v_t$, which may be solved for ρ_t and v_t, where we are using the convention that ρ here means $\rho e^{n\varphi}$ for simplicity. We may write the ODE's for the Euler equations in the form

$$U^0_{,\rho}\rho_{,0} + U^0_{,v} v_{,0} = G^0, \tag{103}$$

$$U^1_{,\rho}\rho_{,0} + U^1_{,v} v_{,0} = G^1. \tag{104}$$

Set

$$D = \begin{vmatrix} U^0_{,\rho} & U^0_{,v} \\ U^1_{,\rho} & U^1_{,v} \end{vmatrix}, \tag{105}$$

$$D_\rho = \begin{vmatrix} G^0_{,\rho} & U^0_{,v} \\ G^1_{,\rho} & U^1_{,v} \end{vmatrix}, \tag{106}$$

$$D_v = \begin{vmatrix} U^0_{,\rho} & G^0_{,v} \\ U^1_{,\rho} & G^1_{,v} \end{vmatrix}.$$

Then by Cramer's rule, $\rho_{,0} = D_\rho / D$ and $v_{,0} = D_v / D$. Using the form for U^0, U^1, G^0, and G^1 in (4), we obtain

$$\frac{\rho_{,0}}{\rho} = -\frac{(\sigma^2(n-1)-c^2)[(c^2+v^2)\varphi_{,0} + 2cv\varphi_{,1}]}{c^4 - \sigma^2 v^2}, \tag{107}$$

$$v_{,0} = \frac{(\sigma^2(n-1)-c^2)(c^2-v^2)}{c(\sigma^2+c^2)(c^4-\sigma^2 v^2)}\,((c^4+\sigma^2 v^2)\varphi_{,1} + (\sigma^2+c^2)cv\varphi_{,0}). \tag{108}$$

Set

$$\sigma_0(v,\varphi) = \frac{(\sigma^2(n-1)-c^2)[(c^2+v^2)\varphi_{,0} + 2cv\varphi_{,1}]}{c^4 - \sigma^2 v^2}, \tag{109}$$

and

$$\sigma_1(v,\varphi) = \frac{(\sigma^2(n-1)-c^2)(c^2-v^2)}{c(\sigma^2+c^2)(c^4-\sigma^2 v^2)}\,((c^4+\sigma^2 v^2)\varphi_{,1} + (\sigma^2+c^2)cv\varphi_{,0}), \tag{110}$$

and let $S(t)$ be the set of points at which the approximate solution is discontinuous at time t. Note that σ_0 is in the form $\alpha(v)\varphi_{,0} + \beta(v)\varphi_{,1}$. Then,

$$\mathrm{TV}_x(\sigma_0(v,\varphi)) = \int_{R-S(t)} \left(\alpha'(v) v_x \varphi_{,0} + \beta'(v) v_x \varphi_{,1} + \alpha(v)\,\frac{\partial \varphi_{,0}}{\partial x} + \beta(v)\,\frac{\partial \varphi_{,1}}{\partial x} \right) dx$$

$$+ \sum_{S(t)} |[\sigma(v,\varphi)]|. \tag{111}$$

Noting that $\alpha(v)$, $\alpha'(v)$, $\beta(v)$, and $\beta'(v)$ are bounded, and since $\mathrm{TV}_x(\varphi,_i)$, $i \in \{0,1\}$ is bounded, $\varphi_{,i}$, $i \in \{0,1\}$ is bounded as well, we deduce that

$$\mathrm{TV}_x(\sigma_0(v,\varphi)) \leqslant C_1 \mathrm{TV}_x(v) + C_2 \mathrm{TV}_x(\varphi_{,0}) + C_3 \mathrm{TV}_x(\varphi_{,1}). \tag{112}$$

Therefore, substituting (112) into (94) implies

$$\mathrm{TV}_x(\log(\rho^j)) \leqslant \mathrm{TV}_x(\log({}^R\rho^j)) \tag{113}$$

$$+ \int_{t_j}^{t} (C_1 \mathrm{TV}_x(v) + C_2 \mathrm{TV}_x(\varphi_{,0}) + C_3 \mathrm{TV}_x(\varphi_{,1}))dt. \tag{114}$$

Similarly,

$$\mathrm{TV}_x\left(\log\left(\frac{c+v}{c-v}\right)\right)^j \leqslant \mathrm{TV}_x^R\left(\log\left(\frac{c+v}{c-v}\right)\right)^j \tag{115}$$

$$+ C_4 \int_0^{\infty} (\mathrm{TV}_x(\varphi_{,0}) + \mathrm{TV}_x(\varphi_{,1}))dt. \tag{116}$$

It follows that if the bounds (94) hold, then the total variation on $\log((c+v)/(c-v))$ is uniformly bounded. In addition, since

$$\frac{\partial}{\partial x}\left(\log\left(\frac{c+v}{c-v}\right)\right) = \frac{v_x}{c^2-v^2}, \tag{117}$$

it follows that

$$\mathrm{TV}_x\left(\log\left(\frac{c+{}^Rv^j}{c-{}^Rv^j}\right)\right) = C\ \mathrm{TV}_x({}^Rv^j) \tag{118}$$

since (116) implies that velocity must be bounded away from the speed of light. Substituting (118) into (114), shows that as long as (94) holds, then we can achieve the bounds (7) sought in Theorem I.1. □

Note that a uniform total variation bound on $\log \rho$ was sufficient to demonstrate a uniform total variation bound on the solution U in the Minkowski metric case in Ref. 5 since the v and ρ are related through the geometry of the wave curves in the plane of Riemann invariants. Here, however, we must bound both the variations of $\log \rho$ and $\log((c+v)/(c-v))$ since on the ODE step the geometry of the wave curves is changed by the action of the ODE. Placing bounds on the variations of $\log \rho$ and $\log((c+v)/(c-v))$ is equivalent to bounding the arc length of the wave curves.

Also, we have loosely used the phrase ''bound the gravitational source term'' since more than gravitation is involved. In particular, $\varphi_{,0}$ is proportional to the divergence of the time vector field, and $\varphi_{,1}$ is proportional to the divergence of the coordinate vector field in the direction of fluid motion. To see this,

$$\mathrm{div}\left(\frac{\partial}{\partial x^0}\right) = \Gamma^i_{i0} \tag{119}$$

$$= \tfrac{1}{2}\log(-g)_{,0} \tag{120}$$

$$= n\varphi_{,0},$$

where n is the dimension of the space–time manifold. Similarly, $\mathrm{div}(\partial/\partial x^0) = n\varphi_{,1}$. These divergences depend on the gravitational field, but they also depend on the coordinate system we choose. Recall that we must choose coordinate vector fields in order to construct a grid on which to implement this scheme. With spherically symmetric coordinates on Minkowski space–time, the divergence of the radial vector field becomes unbounded at the origin. In this case, the ''source term'' becomes unbounded, even though there is *no* gravitation in Minkowski space. In this way it can be seen that coordinates can contribute equally to increases in total variation with gravitation.

VI. CONVERGENCE

In this section we show that a subsequence of approximate solutions, as described in Sec. III A, converges to a solution of the relativistic Euler equations. The analysis is similar to that in Ref. 3 with some modifications.

A function U is a weak solution to (36) if for each $\phi \in C_0^\infty(R\times R^+)$

$$0=\int_{-\infty}^{\infty}\int_0^{\infty}\{U\phi_t+F(U)\phi_x+G(x,t,U)\phi\}dt\ dx+\int_{-\infty}^{\infty}U(x,0^+)\phi(x,0)dx. \tag{121}$$

Define the error function for the approximate solutions as

$$\epsilon(\theta,\Delta x,\phi)\overset{\text{def}}{=}\int_{-\infty}^{\infty}\int_0^{\infty}\{U_{\Delta x}\phi_t+F(U_{\Delta z})\phi_x+G(x,t,U_{\Delta x})\phi\}dt\ dx + \int_{-\infty}^{\infty}U_{\Delta x}(x,0^+)\phi(x,0)dx.$$

It will be shown that there exists a sequence $\{\Delta x_n\}$ such that $\Delta x_n\to 0$ and $\epsilon(\theta,\Delta x_n,\phi)\to 0$ as $n\to\infty$ for all $\phi\in C_0^\infty(R\times(0,\infty))$.

It follows from the definition of the approximate solutions that

$$U_{\Delta x}(x,t)={}^RU_{\Delta x}(x,t)+\int_{t_j}^{t}G(x,\xi,\ {}^{\text{Temp}}U_{\Delta x}(\xi-t_j,\ {}^RU_{\Delta x}(x,t)))d\xi. \tag{122}$$

Multiplying (122) by ϕ_t and integrating gives

$$\int_{-\infty}^{\infty}\int_{t_j}^{t_{j+1}}U_{\Delta x}\phi_t\ dt\ dx=\int_{-\infty}^{\infty}\int_{t_j}^{t_{j+1}}{}^RU_{\Delta x}\phi_t\ dt\ dx + \int_{-\infty}^{\infty}\int_{t_j}^{t_{j+1}}\int_{t_j}^{t}G(x,\xi,\ {}^{\text{Temp}}U_{\Delta x}(\xi-t_j,\ {}^RU_{\Delta x}))d\xi\ \phi_t\ dt\ dx. \tag{123}$$

Since ${}^RU_{\Delta x}$ solves the Riemann problems for the homogeneous equation (54), we have

$$0=\int_{-\infty}^{\infty}\int_{t_j}^{t_{j+1}}{}^RU_{\Delta x}\phi_t\ dt\ dx+\int_{-\infty}^{\infty}\int_{t_j}^{t_{j+1}}F({}^RU_{\Delta x})\phi_x\ dt\ dx + \int_{-\infty}^{\infty}\{{}^RU_{\Delta x}(x,t_j^+)\phi(x,t_j)-{}^RU_{\Delta x}(x,t_{j+1}^-)\phi(x,t_{j+1})\}dx. \tag{124}$$

Using integration by parts, substituting (122), and using the fact that

$$\frac{d}{dt}\int_a^t f(\xi,t)d\xi=f(t,t)+\int_a^t\frac{\partial}{\partial t}f(\xi,t)d\xi, \tag{125}$$

we have

$$\int_{-\infty}^{\infty}\int_{t_j}^{t_{j+1}}\left\{\int_{t_j}^{t}G(x,\xi,\ {}^{\text{Temp}}U_{\Delta x}(\xi-t_j,\ {}^RU_{\Delta x}(x,t)))d\xi\right\}\phi_t\ dt\ dx$$
$$=\int_{-\infty}^{\infty}\left\{\int_{t_j}^{t_{j+1}}G(x,\xi,\ {}^{\text{Temp}}U_{\Delta x}(\xi-t_j,\ {}^RU_{\Delta x}((x,t_{j+1}^-)))d\xi\right\}\phi(x,t_{j+1})dx$$
$$-\int_{-\infty}^{\infty}\int_{t_j}^{t_{j+1}}\left\{\frac{\partial}{\partial t}\int_{t_j}^{t}G(x,\xi,\ {}^{\text{Temp}}U_{\Delta x}(\xi-t_j,\ {}^RU_{\Delta x}(x,t)))d\xi\right\}\phi\ dt\ dx$$

$$= \int_{-\infty}^{\infty} \{U_{\Delta x}(x,t_{j+1}^-) - {}^R U_{\Delta x}(x,t_{j+1}^-)\}\phi(x,t_{j+1})dx$$

$$- \int_{-\infty}^{\infty}\int_{t_j}^{t_{j+1}} G(x,t,U_{\Delta x}(x,t))\phi \; dt \; dx$$

$$- \int_{-\infty}^{\infty}\int_{t_j}^{t_{j+1}} \left\{ \int_{t_j}^{t} \frac{\partial}{\partial t} G(x,\xi, {}^{\text{Temp}}U_{\Delta x}(\xi - t_j, {}^R U_{\Delta x}(x,t)))d\xi \right\} \phi(x,t) dt \; dx. \quad (126)$$

Substituting (124) and (126) into (123) we have

$$\int_{-\infty}^{\infty}\int_{t_j}^{t_{j+1}} U_{\Delta x}\phi_t \; dt \; dx = -\int_{-\infty}^{\infty}\int_{t_j}^{t_{j+1}} \{F({}^R U_{\Delta x})\phi_x + G(x,t,U_{\Delta x})\phi\} dt \; dx$$

$$+ \int_{-\infty}^{\infty} \{U_{\Delta x}(x,t_{j+1}^-)\phi(x,t_{j+1}) - U_{\Delta x}(x,t_j^+)\phi(x,t_j)\}dx$$

$$- \int_{-\infty}^{\infty}\int_{t_j}^{t_{j+1}}\int_{t_j}^{t} \frac{\partial}{\partial t} G(x,\xi, {}^{\text{Temp}}U_{\Delta x}(\xi - t_j, {}^R U_{\Delta x}(x,t)))d\xi \phi(x,t) dt \; dx.$$

Thus after summing over j we obtain

$$\epsilon(\theta,\Delta x,\phi) = \sum_{j=0}^{\infty} \epsilon_j(\theta,\Delta x,\phi) + \sum_{j=1}^{\infty} E_j(\theta,\Delta x,\phi), \quad (127)$$

where we define

$$\epsilon_j(\theta,\Delta x,\phi) \overset{\text{def}}{=} \int_{-\infty}^{\infty} \{U_{\Delta x}(x,t_j^-) - U_{\Delta x}(x,t_j^+)\}\phi(x,t_j)dx \quad (128)$$

and

$$E_{j+1}(\theta,\Delta x,\phi) \overset{\text{def}}{=} \int_{-\infty}^{\infty}\int_{t_j}^{t_{j+1}} \{F(U_{\Delta x}) - F({}^R U_{\Delta x})\}\phi \; dt \; dx$$

$$- \int_{-\infty}^{\infty}\int_{t_j}^{t_{j+1}}\int_{t_j}^{t} \frac{\partial}{\partial t} G(x,\xi, {}^{\text{Temp}}U(\xi - t_j, {}^R U_{\Delta x}(x,t)))d\xi \; \phi \; dt \; dx,$$

where $U_{\Delta x}(x,t_0^-) \overset{\text{def}}{=} 0$. We may write

$$\epsilon_j(\theta,\Delta x,\phi) = \sum_i \int_{x_{i-1}}^{x_i} \{U_{\Delta x}(x,t_j^-) - U_{\Delta x}(x_i + \theta_j \Delta x, t_j^-)\}\phi(x,t_j)dx, \quad (129)$$

which shows that coordinatewise we have

$$|\epsilon_j(\theta,\Delta x,\phi)| \leq C\left(\sum_{i,l} |\gamma_{i,j}^l|\right)\Delta x |\phi|_\infty \leq C \; \text{TV} \; \Delta x |\phi|_\infty, \quad (130)$$

so

$$\left|\sum_{j=1}^{\infty} \epsilon_j(\theta,\Delta x,\phi)\right| \leq C \; \text{TV} T \frac{\Delta x}{\Delta t} |\phi|_\infty = C|\phi|_\infty, \quad (131)$$

where the support of ϕ is in $R \times [0,T)$. We also have that

$$\left| \int_0^1 \epsilon_j(\theta,\Delta x,\phi)\,d\theta_j \right| \leqslant C\left(\sum_{i,l} |\gamma_{i,l}^j| \right) \Delta x^2 |\phi_x|_\infty \leqslant C\ \mathrm{TV}\Delta x^2 |\phi_x|_\infty = C\Delta x^2 |\phi_x|_\infty .$$

Therefore, for $0<j_1<j_2$,

$$\left| \int \epsilon_{j_1}(\theta,\Delta x,\phi)\epsilon_{j_2}(\theta,\Delta x,\phi)\,d\theta \right| = \left| \int \left\{ \int_0^1 \epsilon_{j_2}(\theta,\Delta x,\phi)\,d\theta_{j_2} \right\} \epsilon_{j_1}(\theta,\Delta x,\phi)\,d\hat{\theta}_{j_2} \right|$$
$$\leqslant C\Delta x^3 |\phi|_\infty |\phi_x|_\infty ,$$

where $\hat{\theta}_{j_2}$ denotes the sequence obtained from θ by deleting the j_2th element. By (130) we see that

$$\int \epsilon_j(\theta,\Delta x,\phi)^2\,d\theta \leqslant C\Delta x^2 |\phi|_\infty^2. \tag{132}$$

Thus

$$\int \left(\sum \epsilon_j(\theta,\Delta x,\phi) \right)^2 d\theta = 2\sum_{j_1<j_2} \int \epsilon_{j_1}\epsilon_{j_2}\,d\theta + \sum_j \int \epsilon_j^2\,d\theta$$
$$\leqslant \frac{T^2}{\Delta t}\, C\ \mathrm{TV}_0^2 \Delta x^3 |\phi|_\infty |\phi_x|_\infty$$
$$+ \frac{T^2}{\Delta t}\, C\ \mathrm{TV}_0^2 \Delta x^2 |\phi|_\infty^2 = C\Delta x(|\phi|_\infty^2 + |\phi_x|_\infty^2).$$

We deduce that for each $\phi \in C_0^\infty(R\times(0,\infty))$ there exists a sequence $\Delta x_m \to 0$ and a set $A \subset \Pi_{i=1}^\infty [0,1]$ with measure one such that if $\theta \in A$, then

$$\sum_j \epsilon_j(\theta,\Delta x_m,\phi) \to 0, \tag{133}$$

as $\Delta x_m \to 0$. Now, let $\{\phi_n\}_{n\in N}$ be a countable dense set in $C_0^\infty(R\times(0,\infty))$ with respect to the norm $|\cdot|_\infty$. After refining Δx_m by a diagonal argument and after taking the appropriate countable intersection of sets A_n of measure one, we can conclude that there exists a sequence $\Delta x_m \to 0$ and a set $A \subset \Pi_{i=1}^\infty [0,1]$ with measure one such that if $\theta \in A$ and $n \in N$, then

$$\sum_j \epsilon_j(\theta,\Delta x_m,\phi_n) \to 0, \tag{134}$$

as $m \to \infty$. It follows from (131) that if $\theta \in A$ and $\phi \in C_0^\infty(R\times(0,\infty))$, then

$$\sum_j \epsilon_j(\theta,\Delta x_m,\phi) \to 0. \tag{135}$$

It remains to show that the second term on the right-hand side of Eq. (127) goes to zero as $\Delta x \to 0$. Note that by (122), the Mean Value Theorem for Integrals,

$$|U_{\Delta x} - {}^R U_{\Delta x}| = \left| \int_{t_j}^t G \right| = G(x,\xi_j)\Delta t. \tag{136}$$

Therefore,

$$\int_{-\infty}^\infty \int_{t_j}^{t_{j+1}} |U_{\Delta x} - {}^R U_{\Delta x}|\,|\phi| = \Delta t^2 |\phi|_\infty \int_{-\infty}^\infty G(x,\xi_j)\,dx. \tag{137}$$

Since the source term is assumed to be $L^1(R\times R^+)$,

$$\int_{-\infty}^{\infty}\int_{0}^{\infty}|U_{\Delta x}-{}^{R}U_{\Delta x}||\phi|_{\infty}\leqslant\Delta t^{2}|\phi|_{\infty}\sum_{j=0}^{\infty}\int_{-\infty}^{\infty}G(x,\xi_{j})dx \tag{138}$$

$$\leqslant C\Delta t^{2}|\phi|_{\infty}. \tag{139}$$

These estimates may be interpreted coordinatewise. We want the same bounds on

$$|F(U_{\Delta x})-F({}^{R}U_{\Delta x})|. \tag{140}$$

Since $F(U)=(U^{1},U^{2})$, we have the estimate (139) on the first coordinate of $F(U)$. The Jacobian $dF(U)$ is

$$\frac{-c^{2}(\sigma^{2}-v^{2})}{(c^{4}-\sigma^{2}v^{2})}, \tag{141}$$

which is bounded. We make this calculation by setting $F(U)=\Psi(\Phi^{-1}(U))$, where $\Phi(U)$ is defined in Lemma II.2, and $\Psi(\rho,v)$ is defined by $F(U)=\Psi(\Phi^{-1}(U))$. By the Mean Value Theorem,

$$|F(U_{\Delta x})-F({}^{R}U_{\Delta x})|\leqslant C|U_{\Delta x}-{}^{R}U_{\Delta x}|, \tag{142}$$

from which we conclude

$$\left|\int_{-\infty}^{\infty}\int_{t_{j}}^{t_{j+1}}\{F(U_{\Delta x})-F({}^{R}U_{\Delta x})\}\phi\ dt\ dx\right|\leqslant C\Delta t^{2}|\phi|_{\infty}. \tag{143}$$

In addition, for $x\in[x_{i-1},x_{i}]$,

$$\left|\int_{t_{j}}^{t_{j+1}}\int_{t_{j}}^{t}\frac{\partial}{\partial t}\,G(x,\xi,U(\xi-t_{j},\,{}^{R}U_{\Delta x}(x,t)))d\xi\ \phi\ dt\right| \tag{144}$$

$$=\left|\int_{t_{j}}^{t_{j+1}}\int_{t_{j}}^{t}G_{U}U_{\mathrm{Temp}_{U}}{}^{R}U_{\Delta x,t}\phi\ d\xi\ dt\right| \tag{145}$$

$$\leqslant C\Delta t|\phi|_{\infty}\int_{t_{j}}^{t_{j+1}}|{}^{R}U_{\Delta x,t}|dt$$

$$\leqslant C\Delta t|\phi|_{\infty}(|\gamma_{i-1,j}^{2}|+|\gamma_{i,j}^{1}|). \tag{146}$$

Hence,

$$\left|\int_{-\infty}^{\infty}\int_{t_{j}}^{t_{j+1}}\int_{t_{j}}^{t}\frac{\partial}{\partial t}\,G(x,t,{}^{\mathrm{Temp}}U(\xi-t_{j},{}^{R}U_{\Delta x}(x,t)))\phi\ d\xi\ dx\ dt\right|$$

$$\leqslant C\Delta t\Delta x|\phi|_{\infty}\left(\sum_{i,l}\ |\gamma_{i,j}^{l}|\right)$$

$$\leqslant C(\mathrm{TV})\Delta t\Delta x|\phi|_{\infty}$$

$$\leqslant C\Delta t\Delta x|\phi|_{\infty}. \tag{147}$$

It follows from (143) and (147) that

$$\left|\sum_{j=1}^{\infty}E_{j}(\theta,\Delta x,\phi)\right|\leqslant C\cdot T\Delta t|\phi|_{\infty}+C\cdot T\Delta x|\phi|_{\infty}. \tag{148}$$

Thus, from (135) and (148) we can conclude that if $\theta\in A$ and $\phi\in C_{0}^{\infty}(R\times R^{+})$, then

$$\epsilon(\theta,\Delta x_m,\phi)\to 0 \tag{149}$$

as $m\to\infty$.

Now, choose $T>0$ and let $\{t_i\}_{i\in N}\subset(0,T)$ be countable and dense and let $\theta\in A$ be fixed. Since

$$\mathrm{TV}_{x\in R}U_{\Delta x}(\cdot,t)\leqslant C \tag{150}$$

for $t\in(0,\infty)$, Helly's theorem (Ref. 16 p. 372) implies that there exists a function $U(\cdot,t)$: $\{t_i\}\to L^1(R)$ such that (after further refining $\{\Delta x_m\}$) for $i\in N$, $U_{\Delta x_m}(\cdot,t_i)\to U(\cdot,t_i)$, in $L^1(R)$ as $m\to\infty$.

To proceed, we must prove that the approximates are L_1 Lipschitz in time.

Lemma VI.1: There exists a constant C, such that

$$\int_{-\infty}^{\infty}|U_{\Delta x}(x,t_2)-U_{\Delta x}(x,t_1)|dx\leqslant C\{|t_2-t_1|+\Delta t\}. \tag{151}$$

Proof: Suppose that

$$0\leqslant t_{m-1}\leqslant t_1<\cdots<t_M<t_2\leqslant t_{M+1}. \tag{152}$$

Then

$$\begin{aligned}\int_{-\infty}^{\infty}|U_{\Delta x}(x,t_2)-U_{\Delta x}(x,t_1)|dx\leqslant{}&\int_{-\infty}^{\infty}|U_{\Delta x}(x,t_m^-)-U_{\Delta x}(x,t_1)|dx+\sum_{j=m}^{M-1}\int_{-\infty}^{\infty}|U_{\Delta x}(x,t_{j+1}^-)\\&-U_{\Delta x}(x,t_j^+)|dx+\int_{-\infty}^{\infty}|U_{\Delta x}(x,t_2)-U_{\Delta x}(x,t_M^+)|dx\\&+\sum_{j=m}^{M}\int_{-\infty}^{\infty}|U_{\Delta x}(x,t_j^+)-U_{\Delta x}(x,t_j^-)|dx.\end{aligned} \tag{153}$$

For $s,\ t\in[t_j,t_{j+1}]$ we have that

$$\begin{aligned}\int_{-\infty}^{\infty}|U_{\Delta x}(x,s)-U_{\Delta x}(x,t)|dx\leqslant{}&\int_{-\infty}^{\infty}|U_{\Delta x}(x,s)-{}^RU_{\Delta x}(x,s)|dx+\int_{-\infty}^{\infty}|{}^RU_{\Delta x}(x,s)-{}^RU_{\Delta x}(x,t)|dx\\&+\int_{-\infty}^{\infty}|{}^RU_{\Delta x}(x,t)-U_{\Delta x}(x,t)|dx.\end{aligned} \tag{154}$$

But

$$\int_{x_{i-1}}^{x_i}|{}^RU_{\Delta x}(x,s)-{}^RU_{\Delta x}(x,t)|dx\leqslant C\Delta x(|\gamma_{i-1,j}^2|+|\gamma_{i-1,j}^1|). \tag{155}$$

Thus

$$\int_{-\infty}^{\infty}|{}^RU_{\Delta x}(x,s)-{}^RU_{\Delta x}(x,t)|dx\leqslant C\Delta x\hat{L}(j). \tag{156}$$

Moreover, by (122) it follows that

$$\max_x|U_{\Delta x}(x,s)-{}^RU_{\Delta x}(x,s)|\leqslant C|s-t_j|, \tag{157}$$

for $s\in[t_j,t_{j+1}]$, so by (154)

$$\int_{-\infty}^{\infty}|U_{\Delta x}(x,s)-U_{\Delta x}(x,t)|dx\leqslant C\Delta xL(j)+C\Delta t. \tag{158}$$

In addition, by (157)

$$\int_{x_{i-1}}^{x_i} |U_{\Delta x}(x,t_j^+) - U_{\Delta x}(x,t_j^-)|dx = \int_{x_{i-1}}^{x_i} |U_{\Delta x}(x+\theta_j \Delta x, t_j^-) - U_{\Delta x}(x,t_j^-)|dx$$

$$\leqslant C\Delta x(|\gamma^2_{i-1,j-1}| + |\gamma^1_{i,j-1}|) + C\Delta x \Delta t,$$

so

$$\int_{-\infty}^{\infty} |U_{\Delta x}(x,t_j^+) - U_{\Delta x}(x,t_j^-)|dx \leqslant C\Delta x Ł(j-1) + C\Delta t. \tag{159}$$

Now, putting (158) and (159) into (153) and summing yields

$$\int_{-\infty}^{\infty} |U_{\Delta x}(x,t_2) - U_{\Delta x}(x,t_1)|dx \leqslant C\Delta x(M-m+1)\mathrm{TV}_0 + C\Delta t(M-m+1) \leqslant C\{|t_2-t_1| + \Delta t\}.$$

Now, it follows from Lemma VI.1 that $U_{\Delta x_m}(\cdot,t)$ converges to $U(\cdot,t)$ in $L^1(R)$ for each $t \in (0,T)$ and

$$\|U(\cdot,t_2) - U(\cdot,t_1)\|_{L^1(R)} \leqslant C|t_2-t_1|, \tag{160}$$

for $t_1,\ t_2 \in (0,T)$. Hence,

$$\int_{-\infty}^{\infty}\int_0^{\infty} \{U_{\Delta x_m}\phi_t + F(U_{\Delta x_m})\phi_x + G(x,t,U_{\Delta x_m})\phi\}dt\ dx$$

$$\to \int_{-\infty}^{\infty}\int_0^{\infty} \{U\phi_t + F(U)\phi_x + G(x,t,U)\phi\}dx\ dt$$

as $m \to \infty$.

Since $\epsilon(\theta, \Delta x_m, \phi) \to 0$, U is a weak solution to (36). Furthermore, since $U_{\Delta x}(0) \to U_0$ in $L^1(R)$, (160) implies that $\lim_{t\to 0} U(\cdot,t) = U_0$.

Rest frame system for asymptotically flat space–times

Osvaldo M. Moreschi[a] and Sergio Dain[b]
FaMAF, Ciudad Universitaria, Universidad Nacional de Córdoba, (5000) Córdoba, Argentina

(Received 7 July 1997; accepted for publication 8 July 1998)

The notion of center of mass for an isolated system has been previously encoded in the definition of the so-called nice sections. In this article we present a generalization of the proof of existence of solutions to the linearized equation for nice sections, and formalize a local existence proof of nice sections relaxing the radiation condition. We report on the differentiable and non-self-crossing properties of this family of solutions. We also give a proof of the global existence of nice sections. © *1998 American Institute of Physics.* [S0022-2488(98)00912-8]

I. INTRODUCTION

There is an increasing interest in obtaining results from general relativity that could be applied to real systems. In particular, the possibility of detecting gravitational waves in the near future motivates the research for the description of systems containing very compact objects. In modeling these systems as isolated ones, it is possible to distinguish at least two very different approaches for tackling this problem. In one of them the description is attempted by introducing data, with some criteria, for the numeric solution of the field equation. In the other the description is attempted by trying to reduce the infinite degrees of freedom of the fields to some finite set, analogous to what is done in the particlelike description in Newtonian or in post-Newtonian dynamics. If this second approach has any chance of success, it will be because it is possible to ascribe, in a geometric invariant way, the finite degrees of freedom to the physical system one wants to describe.

It is important to emphasize that the present indication of the existence of gravitational radiation comes from the usage of the balance equation in the description of the binary pulsar PSR 1913+16. The applicability of the present derivations of the balance equation to the binary pulsar system is still a matter of discussion. However, even in the case of having a formally complete derivation of this equation valid at an instant of time, one is still faced with the issue of its validity for long periods of time, or for systems involving strong gravitational fields and possible high velocities. The nature of the problem can be seen by noting that the balance equation relates time derivatives of the energy of the systems with time derivatives of the quadrupole moments of the system. Although the total energy of the system could be related with the unambiguously defined Bondi momentum; the notion of quadrupole moment has meaning only after one has settled down the issue of supertranslation freedom. Our construction of the center of mass sections at future null infinity through the definition of nice sections provides a procedure to give a precise meaning to concepts such as angular momentum and multipole moments.

Therefore, from the study of gravitating isolated systems in the vicinity of the asymptotic region, i.e., future null infinity, one concludes that it is essential[1] to introduce a family of sections of scri, embodying the notion of generalized center of mass. This is the analog of having a frame of reference with respect to which one can study the asymptotic fields. With this aim in Ref. 2 the ''supercenter of mass'' at future null infinity was introduced; which was defined in terms of the so-called *nice sections*. It was indicated in this reference that the notion of center of mass can be attained by requiring an asymptotic nice section for the retarded time $u \to -\infty$ to satisfy that the angular momentum coincides with the intrinsic angular momentum. Then, if the subsequent nice sections are constructed by infinitesimal time translations which are parallel to the Bondi momen-

tum, one obtains a one parameter family of nice sections at future null infinity embodying the notion of center of mass.

In this work we study some mathematical properties of nice sections. In Sec. II we review the nice section equation and some of its basic properties. We present a more general proof of the existence of solutions to the linearized equation for nice sections, and formalize a local existence proof of nice sections in Sec. III. The differentiable properties of nice sections are studied in Sec. IV. We report on the desired non-self-crossing property of this family of solutions in Sec. V. In Sec. VI we present a proof of global existence of nice sections. Finally, several complementary results are presented in three Appendices.

II. THE NICE SECTION EQUATION

We will start by recalling the nice section equation. Given a section S of future null infinity, one can always find a Bondi coordinate (see, e.g., Ref. 3) system $(u,\zeta,\bar{\zeta})$ such that S is given by the equation $u=0$. The supermomentum at S is defined[2] by

$$P_{lm}(S)\equiv -\frac{1}{\sqrt{4\pi}}\int_S Y_{lm}(\zeta,\bar{\zeta})\Psi dS^2, \tag{1}$$

where

$$\Psi\equiv\Psi_2+\sigma\dot{\bar{\sigma}}+\eth^2\bar{\sigma}, \tag{2}$$

with Ψ_2 and σ being the leading order asymptotic behavior of the second Weyl tensor component and the Bondi shear, respectively, and where we are using the Geroch–Held-Penrose (GHP) notation[4] for the edth operator of the unit sphere. It is probably worth noting that in a Bondi system[3] the quantity Ψ is a real function on future null infinity (see, e.g., Eqs. (3.35) and (5.20) in Ref. 5).

Given another section $\tilde{S}$ of scri, one can find another Bondi system $(\tilde{u},\tilde{\zeta},\bar{\tilde{\zeta}})$ such that $\tilde{S}$ is given by $\tilde{u}=0$. One can further demand for that Bondi system to be aligned with the total (Bondi) momentum at $\tilde{S}$, i.e., that the $l=1$ components of the momentum are zero:

$$\tilde{P}_{l=1,m}(\tilde{S})=0.$$

The relation between the new and the original Bondi system is given by the Bondi–Metzner–Sach (BMS) transformation

$$\tilde{u}=K(\zeta,\bar{\zeta})(u-\gamma(\zeta,\bar{\zeta})), \tag{3}$$

$$\bar{\zeta}=\frac{a\zeta+b}{c\bar{\zeta}+d} \tag{4}$$

with

$$ad-bc=1,\quad K=\frac{(1+\zeta\bar{\zeta})}{(a\zeta+b)(\bar{a}\bar{\zeta}+\bar{b})+(c\zeta+d)(\bar{c}\bar{\zeta}+\bar{d})},$$

where a, b, c and d are complex constants. Note that $\tilde{S}$ can also be determined by $u=\gamma(\zeta,\bar{\zeta})$.

The section $\tilde{S}$ is said to be of the nice[2] type if

$$\tilde{P}_{lm}(\tilde{S})=0\quad\text{for}\quad l\neq 0; \tag{5}$$

that is all the ''spacelike'' components of the supermomentum, when calculated with respect to the adapted Bondi system, are zero; and the only nonvanishing one, namely $\tilde{P}_{00}(\tilde{S})$, coincide with the total Bondi mass at $\tilde{S}$.

This is the original version of the nice section equation; however its information is hidden in the simplicity of its form. Since the nice section can be determined by the supertranslation $\gamma(\zeta,\bar{\zeta})$, mentioned above, it is more useful to restate the nice section equation in terms of an equation for $\gamma(\zeta,\bar{\zeta})$.

The supermomentum at $\tilde{S}$ can also be expressed in terms of the original Bondi coordinate system:[2]

$$\tilde{P}_{lm}(\tilde{S}) \equiv -\frac{1}{\sqrt{4\pi}} \int_{\tilde{S}} Y_{lm}(\tilde{\zeta},\bar{\tilde{\zeta}})\tilde{\Psi}\, d\tilde{S}^2$$

$$= -\frac{1}{\sqrt{4\pi}} K_{lm}^{l'm'} \int_{\tilde{S}=(u=\gamma)} Y_{l'm'}(\zeta,\bar{\zeta})[\Psi(u=\gamma) - \eth^2\bar{\eth}^2\gamma] dS^2, \tag{6}$$

where the matrix $K_{lm}^{l'm'}$ is the transformation matrix of the generators of supertranslations, that is:

$$\tilde{p}_{lm} = K_{lm}^{l'm'} p_{l'm'}, \tag{7a}$$

with

$$p_{lm} = Y_{lm}(\zeta,\bar{\zeta})\frac{\partial}{\partial u}. \tag{7b}$$

The fourth-order edth operator appearing in Eq. (6) comes from the transformation properties of the quantities entering into the definition of Ψ; in particular, the term $\eth^2\bar{\sigma}$ transforms under the law:

$$\tilde{\eth}^2\tilde{\bar{\sigma}} = \frac{1}{K^3}(\eth^2\bar{\sigma} - \eth^2\eth^2\gamma), \tag{8}$$

and similarly, after a straightforward but long calculation, one can prove that Ψ transforms as

$$\tilde{\Psi} = \frac{1}{K^3}(\Psi - \eth^2\bar{\eth}^2\gamma), \tag{9}$$

where the transformation of Bondi systems under BMS transformations, appearing in the appendix of Ref. 3, have been used in deriving the last two relations. The nice section equation can be understood as a condition for $\gamma(\zeta,\bar{\zeta})$ and K.

It is important to note that there exists different choices for Ψ in the literature; because by adding any function with $l \geqslant 2$ (e.g., $\eth^2\bar{\sigma}$) one obtains the same expression for the Bondi momentum. But the supermomentum (2) is the only one that has the simple transformation (9). We mention also (but we do not make use of this) that the time derivative of (2) have also a very simple form:

$$\dot{\Psi} = \dot{\sigma}\dot{\bar{\sigma}},$$

the other definitions of supermomentum have a flux that is not positive definite.

Although in Eq. (6) one has an expression that involves the original Bondi coordinate system $(u,\zeta,\bar{\zeta})$, the difficulty with it is the appearance of the infinite transformation matrix $K_{lm}^{l'm'}$; therefore it is convenient to seek a simpler expression. It was indicated in Ref. 2 that Eq. (5) can be expressed by

$$\eth^2\bar{\eth}^2\gamma = \Psi(u=\gamma,\zeta,\bar{\zeta}) + K(\gamma;\zeta,\bar{\zeta})^3 M(\gamma), \tag{10}$$

where the function on the sphere K is the conformal factor of the BMS transformation that aligns the $\tilde{p}_{00}$ with the Bondi momentum at $u=\gamma(\zeta,\bar{\zeta})$; which justifies the notation indicating the γ dependence on it; and finally the total mass M is also calculated at $\tilde{S}$. Equation (10) is our main

equation that is studied throughout the rest of this article. The validity of Eq. (10) can be deduced either from the discussion in Ref. 2, using the properties of the matrix $K_{lm}^{l'm'}$; or it can be deduced from Eqs. (5) and (9); since the nice section equation (5) can be understood as requiring that $\tilde{\Psi}$ be a constant when evaluated at the section $u=\gamma(\zeta,\bar{\zeta})$; and this constant is precisely the negative of the Bondi mass M evaluated on this section.

Clearly $K(\gamma;\zeta,\bar{\zeta})$ and $M(\gamma)$ are determined by the value of the total momentum at $\tilde{S}$, which can explicitly be given by

$$P^{\underline{a}}(\tilde{S})=-\frac{1}{4\pi}\int l^{\underline{a}}(\zeta,\bar{\zeta})\Psi(u=\gamma,\zeta,\bar{\zeta})dS^2, \tag{11}$$

where $\underline{a}=0,1,2,3$, and the vector $l^{\underline{a}}$ is given in terms of the first spherical harmonics by

$$l^{\underline{a}}=\sqrt{4\pi}\left(Y_{00},-\frac{1}{\sqrt{6}}(Y_{11}-Y_{1-1}),\frac{i}{\sqrt{6}}(Y_{11}+Y_{1-1}),\frac{1}{\sqrt{3}}Y_{10}\right). \tag{12}$$

Note that one can also express the total momentum at $\tilde{S}$ by

$$\begin{aligned}P^{\underline{a}}(\tilde{S})&=-\frac{1}{4\pi}\int l^{\underline{a}}(\zeta,\bar{\zeta})\left(\int_0^{\gamma}\dot{\Psi}(u',\zeta,\bar{\zeta})du'+\Psi(u=0,\zeta,\bar{\zeta})\right)dS^2\\&=-\frac{1}{4\pi}\int l^{\underline{a}}(\zeta,\bar{\zeta})\int_0^{\gamma}\dot{\Psi}(u',\zeta,\bar{\zeta})du'\;dS^2+P^{\underline{a}}(S),\end{aligned} \tag{13}$$

where a dot means u derivative; this shows a more explicit dependence of $P^{\underline{a}}(\tilde{S})$ on $\gamma(\zeta,\bar{\zeta})$ and the momentum flux. Then, the conformal factor K can be given by

$$K(\gamma;\zeta,\bar{\zeta})=\frac{M(\gamma)}{P^{\underline{a}}(\tilde{S})l^{\underline{b}}(\zeta,\bar{\zeta})\eta_{\underline{a}\underline{b}}}, \tag{14}$$

where the Lorentzian metric $\eta_{\underline{a}\underline{b}}$ was defined in Ref. 3 and

$$M(\gamma)=\sqrt{P^{\underline{a}}(\tilde{S})P^{\underline{b}}(\tilde{S})\eta_{\underline{a}\underline{b}}}. \tag{15}$$

Then, it is observed that Eq. (10) is an elliptic, nonlinear, integro-differential equation for $\gamma(\zeta,\bar{\zeta})$. Let us mention some properties of this equation. Calling D the differential operator appearing on the left-hand side of Eq. (10), we have that:

$$D\equiv\eth^2\bar{\eth}^2=\tfrac{1}{4}\Delta^2-\tfrac{1}{2}\Delta, \tag{16}$$

where Δ is the Laplacian of the unit sphere. Note that when the operator D is applied to the spherical harmonics it gives[3]

$$DY_{lm}=\frac{(l-1)l(l+1)(l+2)}{4}Y_{lm}. \tag{17}$$

This means that the left-hand side of (10) has an expansion in spherical harmonics with $l\geqslant 2$; and in order to be a consistent equation the right-hand side must also have this property for an arbitrary Ψ (see Appendix 1 for a proof of this property).

In the stationary case, $\Psi=\Psi(\zeta,\bar{\zeta})$, the equation becomes linear and always has solutions.[2] Let γ_0 be the *a* solution of the stationary case, then if $x(\zeta,\bar{\zeta})$ is such that $Dx=0$ we have that γ_0+x is also a solution. Then, in the stationary case there exists a four-parameter family of solution (the real solutions of $Dx=0$ are linear combinations of the spherical harmonics with $l\leqslant 1$, i.e., they are determined by four real numbers). To illustrate this situation let us consider for example the Schwarzschild space–time. In the usual coordinates and null tetrad the equation

simplifies considerably since $\Psi=-M$ and $K=1$; where M is the Schwarzschild mass. Therefore, in this case, the right-hand side of Eq. (10) vanishes, and so $\gamma_0=0$ is a nice section. This means that the usual coordinate system is a ''global rest frame'' system; and one still has the freedom of the translation x's. If instead we had begun with an arbitrary system in the Schwarzschild space–time, then we would have $\Psi\neq -M$ and we would need a nontrivial γ_0 to solve the nice section equation (10). This γ_0 is the supertranslation we have to make in order to come back to ''global rest frame.'' In order to gain the notion of center of mass from this family of solutions, one impose on the ''first'' section at $u=-\infty$ the condition that the angular momentum coincide with the intrinsic angular momentum; this eliminates a three-dimensional freedom in the choice of the translation x's. Then, if from the first nice section we only allow for infinitesimal translations that are parallel to the total momentum, we generate from $u=-\infty$ the ''center of mass system'' with the solutions of the nice section equation.

What happens in general, with a radiative asymptotically flat space–time? Let us first put a conjecture:

Conjecture: Under mild hypothesis for Ψ, there exists solutions γ of (10) of the form $\gamma=x+y$ for each choice of translation x ($Dx=0$), and with y a supertranslation (i.e., with spherical harmonics $l\geqslant 2$ expansion). The solution is C^2 in the sphere and if x_1 and x_2 are time constant translations, with x_1 in the future of x_2; that is,

$$x_1\geqslant x_2$$

then:

$$\gamma_1\geqslant\gamma_2 (*)$$

where γ_1 is the solution corresponding to x_1 and γ_2 that corresponding to x_2.

If this conjecture were true, and by using the selection of the ''initial'' nice section as it was explained for the Schwarzschild case, we would have that for any asymptotically flat space–time there exists one globally defined ''rest frame'' at null infinity, that have the appropriate properties to be interpreted as the ''center of mass'' system of the space–time. We note that the last property (*) requires that the sections defining the center of mass system must be a one-parameter family, without self-crossing behavior. We also remark that the differentiability property means that they are smooth sections of scri.

Of course this conjecture is very difficult to prove, because Eq. (10) is a complicated nonlinear equation, but here we can give an argument[2] (not a proof) that can help one to understand why one might think the conjecture is true.

The idea is to construct a perturbation series beginning with an arbitrary translation x. Let,

$$\gamma_0=x,\quad \gamma_n=x+\sum_{k=1}^{n} y_k,$$

where y_n is the solution of the linear equation:

$$\eth^2\bar{\eth}^2 y_n=\Psi(u=\gamma_{n-1},\zeta,\overline{\zeta})+K(\gamma_{n-1};\zeta,\overline{\zeta})^3 M(\gamma_{n-1}).$$

If the series converges we have for each translation x a solution γ.

In the following part of this paper we prove the following results that indicate to the validity of the conjecture.

(1) ''Local'' version of the conjecture: Given a space–time which satisfies, using geometric units, $|\partial\Psi/\partial u|\leqslant\sqrt{27/4}$(**) and assuming there exists a solution γ_0, then there exists locally for each infinitesimal translation a solution γ, which is C^2 and satisfies (*).

This is done in Secs. III, IV, and V. Let us note that the condition (**) means that the space–time does not admit arbitrary amount of radiation; however, for realistic astrophysical systems it turns out that (**) is always true (see Ref. 2).

(2) If Ψ is near the stationary case, then the there exist a global four-parameter family of solution.

This result is proved in Sec. VI.

III. LOCAL EXISTENCE OF SOLUTIONS

The result of the local existence of solutions will be constructed around the implicit function theorem; therefore appropriate Banach spaces must be introduced. We begin by introducing some notation.

For any pair of regular functions on the spheres a and b let the inner product $\langle a|b\rangle$ be defined by

$$\langle a|b\rangle = \int \overline{a}b \; dS^2, \tag{18}$$

and associated to this let the norm of a function a be given by

$$\|a\|^2 = \langle a|a\rangle, \tag{19}$$

that is, $\|\ \|$ is the standard L^2 norm on the unit sphere S^2.

We will next introduce three sets of real regular functions on the sphere. Let us start with the set:

$$X = \{x(\zeta,\overline{\zeta}) \in L^2(S^2)/Dx = 0\}, \tag{20}$$

note that the real functions $x(\zeta,\overline{\zeta})$ are determined by four real numbers.

Let Z be the set of real functions on the sphere with finite norm and residing in the orthogonal complement of X; equivalently,

$$Z = X^{\perp} = \{z(\zeta,\overline{\zeta}) \in L^2(S^2)/\langle x|z\rangle = 0 \,\forall x \in X\}. \tag{21}$$

Note that if γ is in L^2, then it can be decomposed as a sum of two terms; one in X and the other in Z; that is $\gamma = x + z$, $x \in X$, $z \in Z$. Furthermore, it is convenient to define the projector operator T, such that $T(\gamma) = T(x+z) = x$; that is T projects to the subspace X and therefore satisfies $T^2 = T$.

It is clear from the definitions that X and Z are Hilbert spaces.

Let us now define the following inner product. For any four time differentiable functions y_1 and y_2, in Z, let $\langle|\rangle_D$ be defined by

$$\langle y_1|y_2\rangle_D \equiv \int D\overline{y_1} \; Dy_2 \; dS^2, \tag{22}$$

the fact that this is really an inner product in Z follows from the existence of an inverse of the operator D; as it is deduced from Eq. (17). It is natural to define the norm

$$\|y\|_D^2 \equiv \langle y|y\rangle_D . \tag{23}$$

As it was stated in Ref. 2 it is not difficult to see that

$$\|y\| \leqslant \|y\|_D . \tag{24}$$

Let us define now the space of real functions on the sphere Y by

$$Y = \{y(\zeta,\overline{\zeta}) \in Z/\|y\|_D < \infty \text{ completed with respect to this norm}\}. \tag{25}$$

If one expresses the functions x and y in terms of spherical harmonics one has

$$x = \sum_{\substack{l=0 \\ |m|\leqslant l}}^{1} x^{lm} Y_{lm}(\zeta,\overline{\zeta}) \tag{26}$$

and

$$y=\sum_{\substack{l=2\\|m|\leqslant l}}^{\infty} y^{lm}Y_{lm}(\zeta,\zeta), \tag{27}$$

for some constant coefficients x^{lm} and y^{lm}.

Note that the space Y is also a Hilbert space.

Given regular radiation data at future null infinity, let the real function $f(x,y)$ on the sphere be defined in terms of functions $x\in X$ and $y\in Y$ by the expression:

$$f(x,y)=Dy-(\Psi(u=x+y,\zeta,\bar{\zeta})+K(x+y;\zeta,\bar{\zeta})^3M(x+y)); \tag{28}$$

where the radiation data enter into the determination of Ψ, K and M at $u=\gamma=x+y$; and it is easily seen that the condition $f(x,y)=0$ coincides with the nice section equation. It is also a property of any $f(x,y)$, so constructed, that it lives in the orthogonal complement space of X; in other words, for any f and any x' in X one has $\langle f,x'\rangle=0$; see Appendix A for a proof of this assertion. This means that f is expressible in terms of spherical harmonics Y_{lm} with $l\geqslant 2$; that is,

$$f=\sum_{\substack{l=2\\|m|\leqslant l}}^{\infty} f^{lm}Y_{lm}(\zeta,\zeta). \tag{29}$$

It is worth mentioning that the decomposition of the supertranslation γ as the sum $\gamma=x+y$ is a natural one due to the fact that $Dx=0$ for any x in X.

Since Ψ, K and M are completely determined by the free data at future null infinity, one can see that for smooth data, any f will have finite norm and so any f, so defined, belongs to Z.

Let us now consider the difference

$$\begin{aligned} &f(x,y+\delta y)-f(x,y)\\ &\quad=D\,\delta y-\left(\int_{x+y}^{x+y+\delta y}\dot{\Psi}(u',\zeta,\bar{\zeta})du'+K(x+y+\delta y;\zeta,\bar{\zeta})^3M(x+y+\delta y)\right.\\ &\qquad\left.-K(x+y;\zeta,\bar{\zeta})^3M(x+y)\right). \end{aligned}$$

From the definition (28) one can prove that

$$f(x,y+\delta y)-f(x,y)=f_y(x,y)\,\delta y+O(\delta y^2) \tag{30}$$

with

$$f_y(x,y)\,\delta y=D\,\delta y-\left[\dot{\Psi}(u=x+y,\zeta,\bar{\zeta})\,\delta y+K^3\left(\frac{4P_{\underline{a}}}{M}-3Kl_{\underline{a}}(\zeta,\bar{\zeta})\right)\delta P^{\underline{a}}\right], \tag{31}$$

where $P_{\underline{a}}$, M, and K are evaluated at $u=x+y$, and $\delta P^{\underline{a}}$ is given by

$$\delta P^{\underline{a}}=-\frac{1}{4\pi}\int l^{\underline{a}}(\zeta,\bar{\zeta})\dot{\Psi}(u=x+y,\zeta,\bar{\zeta})\,\delta y\;dS^2, \tag{32}$$

therefore by definition, $f_y(x,y)$ is the Fréchet derivative[6] of the map f in terms of the argument y.

Let us observe that for smooth data $f_y(x,y)$ is continuous in x, and

$$\delta z=f_y(x,y)\,\delta y \tag{33}$$

is a linear continuous map from Y onto Z. The *onto* property is deduced from the fact that the first term in Eq. (31) is an operator providing an onto map.

Let us assume that

$$f(x_0,y_0)=0; \tag{34}$$

that is, the pair (x_0,y_0) defines a nice section through the relation $\gamma_0=x_0+y_0$, then

$$P^{\underline{a}}(x_0,y_0)=M(x_0,y_0)\,\delta^{\underline{a}}_0, \tag{35}$$

which implies that

$$K(x_0,y_0)=1. \tag{36}$$

So the last term in Eq. (31) is given by

$$K^3\left(\frac{4P_{\underline{a}}}{M}-3Kl_{\underline{a}}(\zeta,\overline{\zeta})\right)\delta P^{\underline{a}}=(4\delta^0_{\underline{a}}-3l_{\underline{a}}(\zeta,\overline{\zeta}))\,\delta P^{\underline{a}}, \tag{37}$$

which is clearly an expression involving only spherical harmonics Y_{lm} with $l\leqslant 1$.

Therefore one has that (see also Appendix A)

$$f_y(x_0,y_0)\,\delta y=D\,\delta y-[F\,\delta y-T(F\,\delta y)], \tag{38}$$

with $F=F(\zeta,\overline{\zeta})\equiv\dot{\Psi}(u=x_0+y_0,\zeta,\overline{\zeta})$. As it was done in Ref. 2, we will assume that the modulus of the flux is bounded by the quantity λ, i.e.,

$$|\dot{\Psi}(u,\zeta,\overline{\zeta})|\leqslant\lambda; \tag{39}$$

and therefore $|F|\leqslant\lambda$.

Then the following result holds:

Lemma 3.1: If $(\lambda^2\frac{4}{27})<1$ then the map $\delta z=f_y(x_0,y_0)\,\delta y$ from Y onto Z is invertible.

Proof: We start with the expression

$$D\,\delta y-[F\,\delta y-T(F\,\delta y)]=\delta z. \tag{40}$$

Note that from Eq. (17) one can see that there exists an operator D^{-1}, acting on elements of Z, such that on spherical harmonicas, with $l\geqslant 2$, it gives

$$D^{-1}Y_{lm}=\frac{4}{(l-1)l(l+1)(l+2)}\,Y_{lm}, \tag{41}$$

then one deduces that $z\in Z\Rightarrow D^{-1}z\in Z$. Let us now define the operator $A:Y\to Y$, such that $\forall\,\delta z\in Z$,

$$A\,\delta y\equiv D^{-1}(\delta z+F\,\delta y-T(F\,\delta y)). \tag{42}$$

Then Eq. (40) is equivalent to the equation:

$$A\,\delta y=\delta y. \tag{43}$$

We will next show that if $(\lambda^2\frac{4}{27})<1$ then A is a contracting map,[6] and therefore Eq. (43) has a unique solution.

It is shown in Appendix B that for any function $\Gamma(\zeta,\overline{\zeta})\in Y$ one has the following inequality:

$$\|\Gamma\|^2\leqslant\tfrac{4}{27}\|\Gamma\|^2_D. \tag{44}$$

This clearly improves the inequality (24). It then follows that

$$\begin{aligned}\|A\,\delta y-A\,\delta y'\|^2_D&=\|D^{-1}F(\delta y-\delta y')-D^{-1}T(F(\delta y-\delta y'))\|^2_D\\&=\|F(\delta y-\delta y')-T(F(\delta y-\delta y'))\|^2\\&\leqslant\|F(\delta y-\delta y')\|^2\leqslant\lambda^2\|(\delta y-\delta y')\|^2\leqslant\lambda^2\tfrac{4}{27}\|(\delta y-\delta y')\|^2_D,\end{aligned} \tag{45}$$

where we have used the fact that for any $\gamma \in L^2(S^2)$ one has $\|\gamma - T\gamma\| \leqslant \|\gamma\|$. Consequently A defines a contracting map, which implies that (43) has a unique solution. Then $f_y(x_0, y_0)$ provides with a one-to-one map and onto from Z to Y. ■

Therefore $f_y(x_0, y_0)$ is an homeomorphism of Y onto Z.

This result along with the implicit function theorem[6] allows us to prove the following:

Theorem 3.1: Let $\gamma_0 = x_0 + y_0$ be a nice section, i.e., $f(x_0, y_0) = 0$, and the smooth data $\dot{\Psi}$ satisfying $|\dot{\Psi}(u, \zeta, \bar{\zeta})| \leqslant \lambda$, with $\lambda < \sqrt{\frac{27}{4}}$, then there exist a local four-parameter family of nice sections near γ_0.

Proof: Lemma 3.1 allows us to use the implicit function theorem[6] for the Banach spaces X, Y and Z, and the map $z = f(x, y)$; which tell us that there is a unique continuous mapping $g: U \to Y$ defined in a neighborhood U of x_0 such that $y_0 = g(x_0)$ and

$$Dg(x) = \Psi(u = x + g(x), \zeta, \bar{\zeta}) + K(x + g(x); \zeta, \bar{\zeta})^3 M(x + g(x)). \tag{46}$$

Since there is a four-parameter family of solutions to the equation $D\,x = 0$; one deduces that given a nice section and data satisfying $\lambda < \sqrt{\frac{27}{4}}$, there exists a four-parameter family of them in a neighborhood of the original one. ■

This result generalizes the calculations of Ref. 2 in several ways; notably by pushing the permissible upper value of λ from 1 to $\sqrt{\frac{27}{4}}$, and also by allowing a general translation x.

IV. DIFFERENTIABLE PROPERTIES OF THE LOCAL SOLUTIONS

In order to study the differentiable properties of nice sections we need to introduce further notation. Let us express the Sobolev norm H_4 by[7]

$$\|y\|_{H_4} = \sum_{i=0}^{4} \|\nabla^{(i)} y\|, \tag{47}$$

where the multi-index i is used as

$$|\nabla^{(i)} y|^2 = \nabla^{a_i} \nabla^{a_2} \cdots \nabla^{a_i} y \nabla_{a_1} \nabla_{a_2} \cdots \nabla_{a_i} y. \tag{48}$$

Since the operator D is strongly elliptic[8] of fourth degree on the compact manifold S^2, then the following inequalities hold:[9,10]

$$\|Dy\| \leqslant c_1 \|y\|_{H^4}, \tag{49}$$

$$\|y\|_{H^4} \leqslant c_2 (\|Dy\| + \|y\|), \tag{50}$$

for some positive constants c_1 and c_2.

We will use these relations to prove the next result.

Lemma 4.1: There exist constants C and C', independent of y such that $\forall y \in Y$ one has that:

$$C\|y\|_{H^4} \leqslant \|y\|_D \leqslant C' \|y\|_{H^4}. \tag{51}$$

That is the norms are equivalent.

Proof: The second inequality is just relation (49). The first inequality follows from (50) and the fact that for $y \in Y$ one has:

$$\|y\|_{H^4} \leqslant c(\|Dy\| + \|y\|) = c(\|y\|_D + \|y\|) \leqslant c\left(d\|y\|_D + \sqrt{\frac{4}{27}}\, \|y\|_D \right) = c\left(1 + \sqrt{\frac{4}{27}} \right) \|y\|_D .$$

■

It then follows:

Theorem 4.1: The local four-parameter family of nice sections is two times differentiable functions on the sphere.

Proof: Using the last Lemma and the Sobolev imbedding theorem for compact manifolds (see, e.g., Ref. 7) one deduces that the solutions $g(x)$, mentioned in the proof of the theorem of the last section, are in $C^2(S^2)$. ■

V. NON SELF-CROSSING PROPERTY OF THE LOCAL SOLUTIONS

Let $\gamma(\tau)$ be a one-parameter family of nice sections for $\tau\in[0,t]$. Then since $\gamma(x,y)$ is linearly expressed in terms of x and y by $\gamma(\tau)=x(\tau)+y(x(\tau))$, it is clear that the Fréchet derivative of $f(\gamma(x,y))$, with respect to γ, $f_\gamma(\gamma(x,y))$, is given by the analog expression (31) when one substitutes δy by $\delta\gamma$, that is,

$$f_\gamma(\gamma(x,y))\,\delta\gamma=D\,\delta\gamma-\left[\dot{\Psi}(u=\gamma,\zeta,\bar{\zeta})\,\delta\gamma+K^3\left(\frac{4P_{\underline{a}}}{M}-3Kl_{\underline{a}}(\zeta,\bar{\zeta})\right)\delta P^{\underline{a}}(\delta\gamma)\right], \tag{52}$$

where $P_{\underline{a}}$, M, and K are evaluated at $u=\gamma$, and $\delta P^{\underline{a}}(\delta\gamma)$ is given by

$$\delta P^{\underline{a}}(\delta\gamma)=-\frac{1}{4\pi}\int l^{\underline{a}}(\zeta,\bar{\zeta})\dot{\Psi}(u=\gamma,\zeta,\bar{\zeta})\,\delta\gamma\,dS^2. \tag{53}$$

Recalling that the nice section equation is equivalent to $f(x,y)=0$, it is deduced from the properties of the equation that its Fréchet derivative with respect to γ must also vanish. But it is observed that the equation $f_\gamma(\gamma)\,\delta\gamma=0$ coincides with the linearization of the nice section equation; therefore, if one takes $\delta\gamma=(d\gamma/d\tau)d\tau$ and wants to study the properties of $d\gamma/d\tau$, one needs to analyze the linearized nice section equation.

So, let us consider now the solutions of the linear nice section equation of the form

$$\delta\gamma=\delta x+\Gamma, \tag{54}$$

with $\delta x\in X$ and $\Gamma\in Y$. From the arguments of Ref. 2, and their extension to general translations, presented above, it is deduced that a solution can be constructed by the sequence $\delta\gamma_n=\delta x+\Gamma_n$ defined in the following form:

$$\delta\gamma_0=\delta x, \tag{55}$$

$$\delta\Gamma_1=A_0\,\delta\gamma_0, \tag{56}$$

and in general, for $n>1$,

$$\delta\Gamma_n=A_0(\delta x+\delta\Gamma_{n-1}) \tag{57}$$

or

$$\delta\gamma_n=\delta x+A_0\,\delta\gamma_{n-1}, \tag{58}$$

where A_0 is the trivial extension of the operator defined in (42) to act on $X\oplus Y$, with $\delta z=0$. Let us note that if $\delta x=0$, then $\delta\gamma_1=0$ which implies that $\delta\gamma_n=0\,\forall n$, or equivalently $\Gamma=0$.

It is interesting to observe that this solution for the homogeneous linear equation can also be expressed by

$$\delta\gamma=\sum_{i=0}^{\infty}A_0^i\,\delta x; \tag{59}$$

in particular, one can see that

$$\Gamma_n=\sum_{i=1}^{n}A_0^i\,\delta x. \tag{60}$$

The proof that (59) gives the solution of the homogeneous linear equation can be given in the following way. First let us check that if the series (59) converges then it is a solution, since

$$A_0\delta\gamma = A_0\left(\sum_{i=0}^{\infty} A_0^i \delta x\right) = \sum_{i=1}^{\infty} A_0^i \delta x = \Gamma, \tag{61}$$

which is the representation of the homogeneous linear equation in terms of the operator A_0. Now let us prove that the series (59) converges. Note that

$$\|\delta\gamma_n - \delta\gamma_{n-1}\|_D = \|\Gamma_n - \Gamma_{n-1}\|_D = \|A_0^n \delta x\|_D; \tag{62}$$

then, since for $n \geqslant 1$, $A_0^n \delta x \in Y$, one has from (45) that

$$\|A_0 y\|_D \leqslant \lambda \sqrt{\tfrac{4}{27}} \|y\|_D; \tag{63}$$

therefore

$$\|\delta\gamma_n - \delta\gamma_{n-1}\|_D \leqslant (\lambda \sqrt{\tfrac{4}{27}})^{n-1} \|A_0 \delta x\|_D, \tag{64}$$

which implies that the sequence converges if $(\lambda \sqrt{\frac{4}{27}}) < 1$.

Using the notation of the last section, and denoting $\dot{\Psi}_0 = \dot{\Psi}(u = x_0 + g(x_0), \zeta, \overline{\zeta})$, one can prove the following result:

Theorem 5.1: Let $\gamma_0 = x_0 + g(x_0)$ be a nice section and let δx_0 be a positive constant such that $x = x_0 + \delta x_0 \in U$. There exist $\lambda_* \in (0, \sqrt{\frac{27}{4}})$ such that for data satisfying $|\dot{\Psi}_0| < \lambda_*$ the solution $\delta\gamma(\delta x_0)$ of the linear nice section equation is also positive.

This implies, as is mentioned below, that the solutions of the nice section equation generated by an aligned time translation do not cross among them.

Proof: Using the fact that for any $\gamma \in L^2(S^2)$, $\|\gamma - T\gamma\| \leqslant \|\gamma\|$, one deduces that if $\delta\gamma = \delta x + \Gamma$ is a solution of the linear nice section equation, then

$$\|\Gamma\|_D^2 \leqslant \|\dot{\Psi}_0(\delta x + \Gamma)\|^2 \leqslant \lambda^2 \|\delta x + \Gamma\|^2 \leqslant \lambda^2 \|\Gamma\|^2 + \lambda^2 \|\delta x\|^2 \leqslant \lambda^2 (\tfrac{4}{27} \|\Gamma\|_D^2 + \|\delta x\|^2), \tag{65}$$

therefore

$$\|\Gamma\|_D^2 \leqslant \frac{\lambda^2}{1 - \frac{4}{27}\lambda^2} \|\delta x\|^2. \tag{66}$$

From Appendix B, one has

$$|\Gamma(\zeta, \overline{\zeta})|^2 \leqslant \frac{1}{4\pi} \frac{4}{27} \|\Gamma\|_D^2; \tag{67}$$

therefore, it is deduced that

$$\sup|\Gamma|^2 < \frac{4}{27} \frac{\lambda^2}{1 - \frac{4}{27}\lambda^2} (\delta x_0)^2. \tag{68}$$

Then, the inequality

$$\sup|\Gamma|^2 < (\delta x_0)^2, \tag{69}$$

will be satisfied if

$$\lambda < \lambda_* = \frac{1}{\sqrt{2}} \sqrt{\frac{27}{4}} \cong 1.8371 \qquad \blacksquare \tag{70}$$

The constant λ_* appearing in the result depends on the technique one uses for the proof. In order to illustrate this, in Appendix C we present three other alternative proofs, using different techniques, which impose three different bounds on the data, which do not improve the last one.

It is not yet clear to us whether the above value of λ_* is the best possible one.

Theorem 5.1 proves that $\delta\gamma>0$ for an aligned future time translation $d\tau$, which implies that $d\gamma/d\tau>0$, and therefore that the nice section family does not show self-crossing since $\gamma(\tau+d\tau)$ is to the future of $\gamma(\tau)$.

VI. GLOBAL EXISTENCE OF NICE SECTIONS NEAR THE STATIONARY CASE

The results appearing in the previous sections deal only with local properties of nice sections; in this section the issue of global existence will be tackled. In Ref. 2 it was proved that there exists a four-parameter family of nice sections in a stationary space–time. This suggests that when radiation is ''small'' one could probably find an analogous result. In what follows we will apply once more the implicit function theorem to prove this assertion.

Let $\mathcal{C}^0(\mathcal{I}^+)$ represent the vector space of all bounded continuous functions on scri plus, with the norm $\|F\|_{\mathcal{C}^0(\mathcal{I}^+)}=\sup|F(u,\zeta,\bar{\zeta})|$. The vector space $\mathcal{C}^0(\mathcal{I}^+)$ defines a Banach space.

Let us denote with $\mathcal{C}^0_{-\infty}(\mathcal{I}^+)$ the set of functions $F(u,\zeta,\bar{\zeta})$ at scri plus, which belong to the set $\mathcal{C}^0(\mathcal{I}^+)$ and such that

$$\int_{-\infty}^{u} F(u',\zeta,\bar{\zeta})du' \in C^0(I^+), \tag{71}$$

where $C^0(\mathcal{I}^+)$ represents the set of bounded continuous functions on scri plus. The set $\mathcal{C}^0_{-\infty}(\mathcal{I}^+)$ is a vector subspace of $\mathcal{C}^0(\mathcal{I}^+)$, and therefore is a Banach space.

Let X, Y and Z represent the spaces defined in Sec. III, and let us denote with Ξ the space whose elements are of the form $\xi=(x,F)$, with $x\in X$, $F\in\mathcal{C}^0_{-\infty}(\mathcal{I}^+)$ and with norm $\|\xi\|=\|x\|_x+\|F\|_{\mathcal{C}^0(\mathcal{I}^+)}$. The space Ξ is a Banach space. Consider now the map from (Ξ,Y) into Z defined by

$$\Phi(\xi,y)=Dy-\left(\int_{-\infty}^{x+y}F(u',\zeta,\bar{\zeta})du'+K(x+y,F;\zeta,\bar{\zeta})^3M(x+y,F)\right), \tag{72}$$

which coincide with the map $f(x,y)$ defined in Sec. III, but where now it is taken into account explicitly the dependence on the flux F. The Fréchet derivative of this map with respect to the variable y is

$$\Phi_y(\xi,y)\,\delta y=D\,\delta y-\left[F(u=\gamma=x+y,\zeta,\bar{\zeta})\,\delta y+K^3\left(\frac{4P_{\underline{a}}}{M}-3Kl_{\underline{a}}(\zeta,\bar{\zeta})\right)\delta P^{\underline{a}}\right], \tag{73}$$

where $P_{\underline{a}}$, M, and K are evaluated at $u=\gamma=x+y$; in particular one has

$$P^{\underline{a}}(\gamma)=-\frac{1}{4\pi}\int l^{\underline{a}}(\zeta,\bar{\zeta})\int_{-\infty}^{\gamma}F(u',\zeta,\bar{\zeta})du'\;dS^2+P^{\underline{a}}(u=-\infty) \tag{74}$$

and $\delta P^{\underline{a}}$ is given by

$$\delta P^{\underline{a}}=-\frac{1}{4\pi}\int l^{\underline{a}}(\zeta,\bar{\zeta})F(u=\gamma=x+y,\zeta,\bar{\zeta})\,\delta y\;dS^2. \tag{75}$$

Let us denote with ξ_0 the nonradiation case, that is, $\xi_0=(x_0,F=0)$; we have shown in Ref. 2 that there exists a relation $y_0(x_0)$ such that $\Phi(\xi_0,y_0)=0$, for any translation x_0; in other words, in the absence of radiation $(F=0)$, the map $\gamma_0(x_0)=x_0+y_0(x_0)$ defines a four-parameter family of nice sections globally on scri. It is observed that $\delta P^{\underline{a}}(F=0)=0$; therefore

$$\Phi_y(\xi(x,F=0),y)\,\delta y=D\,\delta y, \tag{76}$$

and it is clear that the map $\delta z=\Phi_y(\xi(x,F=0),y)\,\delta y$ from Y onto Z is invertible; that is, it is an homeomorphism of Y onto Z.

The implicit function theorem implies that there exists a unique continuous mapping G defined in a neighborhood $U_0\subset\mathcal{C}^0_{-\infty}(\mathcal{I}^+)$ of $F=0$, $G:U_0\to Y$, parametrized by x_0, such that $G(\xi(x_0,F=0))=y_0$ and $\Phi(\xi(x_0,F),y)=0$ for $F\in U_0$.

Let us call *small radiation data* the one that satisfies $F\in U_0$ in the last result. Then, the continuity properties contained in the implicit function theorem and the fact that x lives in a four-dimensional vector space, imply the following result:

Theorem 6.1: For *small radiation data* there exists a global four-parameter family of nice sections at scri.

VII. FINAL COMMENTS

Summarizing, in this article several results concerning local and global properties of the center of mass of isolated systems in general relativity have been presented; in terms of the so-called nice sections. In Sec. VI the global existence of nice sections has been established for *small radiation data*. In Sec. III there appears a formal proof of existence of nice sections with less restrictive assumptions on the strength of the radiation data that had appeared in the literature before.[2]

Although the global result of Sec. VI is very important from a formal perspective of the whole picture based on nice sections, the local result of Sec. III might be more important from the operational point of view, since if one wants to make a concrete calculation based on this construction it is natural to start by taking an initial nice section and then calculating the dynamics of the system on a local family around the initial one. The relaxation of the strength of the radiation warrants a wider set of applicability of this formalism.

Differentiable properties of nice sections have been established in Sec. IV. And in Sec. V the desired non-self-crossing property of nice sections was proved.

It is important to emphasize that this last property is what one expects from making the analogy with the case of a set of particles in linearized gravity; since in this case any sensible notion of center of mass, defined in the interior of the space–time, would follow a timelike curve whose future null cones would define the corresponding one-parameter family of center of mass at future null infinity. This latter family clearly could not show self-crossing since this would imply a faster than light velocity for the trajectory of the center of mass in the interior of the spacetime.

We conclude then that the present approach for the notion of center of mass of isolated gravitating systems, based on the definition of nice sections, not only has the necessary mathematical properties, but it also has the appropriate physical properties that make possible its interpretation.

ACKNOWLEDGMENTS

Most of this work was developed while one of the authors (O.M.) was visiting the Albert-Einstein-Institut, Max-Planck-Institut für Gravitationsphysik, Potsdam, Germany. This author is very grateful to all the people at the Institute and in particular Dr. Helmut Friedrich, for their kind hospitality. It is a pleasure to thank Dr. H. Friedrich, Dr. O. Reula, Dr. B. Schmidt, and Dr. E. T. Newman for illuminating discussions on our work. APPENDIX A

For any regular real function on the sphere f let us define

$$f^{\underline{a}}=\frac{1}{4\pi}\int l^{\underline{a}}(\zeta,\bar{\zeta})f(\zeta,\bar{\zeta})dS^2,$$

and let us also define

$$\hat{f}\equiv f^{\underline{a}}l_{\underline{a}}=f^0-\hat{f}^{(3)},$$

with $\hat{f}^{(3)} \equiv (f^1 l^1 + f^2 l^2 + f^3 l^3)$. Then it is easy to prove by direct calculation

Lemma A1.1:

$$T(f\ ) = f^0 - 3\hat{f}^{(3)}.$$

The following result is also useful.

Lemma A1.2: For any timelike vector U^a one has

$$\frac{1}{4\pi} \int \frac{l^{\underline{a}}}{(U^{\underline{b}} l_{\underline{b}})^3}\, dS^2 = \frac{U^{\underline{a}}}{(U^{\underline{b}} U_{\underline{b}})^2}.$$

Proof: First let us prove that the left-hand side transforms as a four-vector under Lorentz transformations. This can easily be seen from the fact that under Lorentz transformations:

$$l^{\underline{a}} \to K l^{\underline{a}}, \quad dS^2 \to K^2\, dS^2.$$

Therefore

$$\frac{1}{4\pi} \int \frac{l^{\underline{a}}}{(U^{\underline{b}} l_{\underline{b}})^3}\, dS^2 = \frac{V^{\underline{a}}}{(U^{\underline{b}} U_{\underline{b}})^2}$$

for some four-vector $V^{\underline{a}}$

Since U^a is a timelike vector, one can choose a frame for which

$$U^{\underline{a}} = (U^0, 0, 0, 0),$$

from which it is immediately deduced that

$$V^{\underline{a}} = (U^0, 0, 0, 0) = U^{\underline{a}}.$$

■

Then it follows:

Corollary A1.3: Let U^a be a timelike vector, then:

$$T\left(\frac{1}{(U^{\underline{a}} l_{\underline{a}})^3}\right) = \frac{1}{(U^{\underline{a}} U_{\underline{a}})^2}\,(u^0 - 3\hat{u}^{(3)}),$$

where

$$U^{\underline{a}} l_{\underline{a}} = u^0 - \hat{u}^{(3)}.$$

Proof: From Lemma A1.1, one has:

$$T\left(\frac{1}{(U^{\underline{a}} l_{\underline{a}})^3}\right) = \frac{1}{4\pi} \int \frac{1}{(U^{\underline{a}} l_{\underline{a}})^3}\,(l^0 l_0 - 3 l^i(\zeta', \overline{\zeta'}) l^i(\zeta, \overline{\zeta}))\, dS'^2 = \frac{1}{(U^{\underline{a}} U_{\underline{a}})^2}\,(u^0 - 3\hat{u}^{(3)}),$$

where $i = 1,2,3$. ■

Then it follows that

$$T(\Psi) = -T(K^3 M).$$

APPENDIX B

Let us note that for any function $\Gamma(\zeta, \overline{\zeta}) \in Y$ one has

$$|\Gamma(\zeta,\bar{\zeta})|^2=\left|\sum_{l=2}^{\infty}\sum_{m=-l}^{l}\Gamma^{lm}Y_{lm}(\zeta,\bar{\zeta})\right|^2$$
$$=\left|\sum_{l=2}^{\infty}\sum_{m=-l}^{l}\Gamma^{lm}\frac{(l-1)l(l+1)(l+2)}{4}\frac{4}{(l-1)l(l+1)(l+2)}Y_{lm}(\zeta,\bar{\zeta})\right|^2$$
$$\leqslant\left[\sum_{l=2}^{\infty}\sum_{m=-l}^{l}|\Gamma^{lm}|^2\left[\frac{(l-1)l(l+1)(l+2)}{4}\right]^2\right]$$
$$\times\left[\sum_{l=2}^{\infty}\sum_{m=-l}^{l}\left[\frac{4}{(l-1)l(l+1)(l+2)}\right]^2|Y_{lm}(\zeta,\bar{\zeta})|^2\right].$$

Now, using the addition theorem for the spherical harmonics, one can prove that

$$\sum_{m=-l}^{l}|Y_{lm}(\zeta,\bar{\zeta})|^2\leqslant\frac{2l+1}{4\pi}.$$

Also one can see[3] that

$$\|\Gamma\|_D^2=\left[\sum_{l=2}^{\infty}\sum_{m=-l}^{l}|\Gamma^{lm}|^2\left[\frac{(l-1)l(l+1)(l+2)}{4}\right]^2\right]$$

from which it is deduced that

$$|\Gamma|^2\leqslant\frac{1}{4\pi}\|\Gamma\|_D^2\left\{\sum_{l=2}^{\infty}\left[\frac{4}{(l-1)l(l+1)(l+2)}\right]^2(2l+1)\right\}=\frac{1}{4\pi}\frac{4}{27}\|\Gamma\|_D^2.$$

Since the modulus $\|\Gamma\|$ is bounded by its maximum value, namely

$$\|\Gamma\|^2\leqslant 4\pi\ \sup\|\Gamma(\zeta,\bar{\zeta})|^2;$$

it is deduced the inequality:

$$\|\Gamma\|^2\leqslant\tfrac{4}{27}\|\Gamma\|_D^2. \tag{B1}$$

APPENDIX C

Since the peculiar value of λ_* depends on the technique of the proof of Theorem 5.1, we present here three other proofs of this result.

Proof 1: Let us observe that

$$\langle\Gamma|\eth^2\bar{\eth}^2\Gamma\rangle=\langle\bar{\eth}^2\Gamma|\bar{\eth}^2\Gamma\rangle=\langle\eth^2\Gamma|\eth^2\Gamma\rangle;$$

the question arises then whether there is an extension of the Sobolev inequality that will relate $|\Gamma(\zeta,\bar{\zeta})|$ with the previous expression. We will now prove that there is such a relation.

Let the regular function Γ be given by

$$\Gamma=\sum_{l=2}^{\infty}\sum_{m=-l}^{l}\Gamma^{lm}Y_{lm}(\zeta,\bar{\zeta}),$$

then one has

$$
\begin{aligned}
|\Gamma(\zeta,\bar{\zeta})|^2 &= \left| \sum_{l=2}^{\infty} \sum_{m=-l}^{l} \Gamma^{lm} Y_{lm}(\zeta,\bar{\zeta}) \right|^2 \\
&= \left| \sum_{l=2}^{\infty} \sum_{m=-l}^{l} \Gamma^{lm} \sqrt{\frac{(l-1)l(l+1)(l+2)}{4}} \sqrt{\frac{4}{(l-1)l(l+1)(l+2)}}\, Y_{lm}(\zeta,\bar{\zeta}) \right|^2 \\
&\leqslant \left[\sum_{l=2}^{\infty} \sum_{m=-l}^{l} |\Gamma^{lm}|^2 \left[\frac{(l-1)l(l+1)(l+2)}{4} \right] \right] \\
&\quad \times \left[\sum_{l=2}^{\infty} \sum_{m=-l}^{l} \left[\frac{4}{(l-1)l(l+1)(l+2)} \right] |Y_{lm}(\zeta,\bar{\zeta})|^2 \right].
\end{aligned}
$$

Now, using the inequality implied by the addition theorem for the spherical harmonics, and that[3]

$$
\langle \Gamma | \eth^2 \bar{\eth}^2 \Gamma \rangle = \left[\sum_{l=2}^{\infty} \sum_{m=-l}^{l} |\Gamma^{lm}|^2 \left[\frac{(l-1)l(l+1)(l+2)}{4} \right] \right],
$$

one deduces

$$
|\Gamma|^2 \leqslant \frac{1}{4\pi} \langle \Gamma | \eth^2 \bar{\eth}^2 \Gamma \rangle \left[\sum_{l=2}^{\infty} \frac{4(2l+1)}{(l-1)l(l+1)(l+2)} \right] = \frac{1}{4\pi} \frac{4}{3} \langle \Gamma | \eth^2 \bar{\eth}^2 \Gamma \rangle.
$$

One also has that

$$
\langle \Gamma | \eth^2 \bar{\eth}^2 \Gamma \rangle = \langle \Gamma | \dot{\Psi}_0 \delta x \rangle + \langle \Gamma^2 | \dot{\Psi}_0 \rangle,
$$

where we have used that Γ is orthogonal to the last term appearing in the linear nice section equation.

Let us note that from the Schwarz inequality one obtains

$$
|\langle \Gamma | \dot{\Psi}_0 \delta x \rangle| \leqslant \|\Gamma\| \lambda \| \delta x \|;
$$

and similarly

$$
\langle \Gamma^2 | \dot{\Psi}_0 \rangle \leqslant \lambda \|\Gamma\|^2,
$$

from which it is deduced

$$
\sup |\Gamma|^2 \leqslant \frac{1}{4\pi} \frac{4}{3} (\lambda \|\Gamma\|^2 + \|\Gamma\| \lambda \| \delta x \|).
$$

It follows from the techniques used in Ref. 2 and in Sec. V that Γ is expressible as a series of the form:

$$
\Gamma = \Gamma_1 \lambda + \Gamma_2 \lambda^2 + \cdots,
$$

which satisfies

$$
\|\Gamma_n \lambda^n\| \leqslant \left(\lambda \sqrt{\frac{4}{27}} \right)^{n-1} \|\Gamma_1 \lambda\|
$$

with

$$
\|\Gamma_1 \lambda\| \leqslant \sqrt{\frac{4}{27}} \|\eth^2 \bar{\eth}^2 \Gamma_1 \lambda\| = \sqrt{\frac{4}{27}} \|\dot{\Psi}_0 \delta x + \Psi_0 + K_1^3 M_1\| \leqslant \sqrt{\frac{4}{27}} \|\dot{\Psi}_0 \delta x\| \leqslant \lambda \sqrt{\frac{4}{27}} \|\delta x\|.
$$

Then the modulus of Γ is bounded by

$$\|\Gamma\| \leqslant \sum_{n=1}^{\infty} \|\Gamma_n \lambda^n\| \leqslant \sum_{n=1}^{\infty} \left(\lambda \sqrt{\frac{4}{27}}\right)^{n-1} \|\Gamma_1 \lambda\| \leqslant \sum_{n=1}^{\infty} \left(\lambda \sqrt{\frac{4}{27}}\right)^{n} \|\delta x\| = \frac{\lambda \sqrt{\frac{4}{27}}}{1-\lambda \sqrt{\frac{4}{27}}} \|\delta x\|,$$

for $\lambda < \sqrt{\frac{27}{4}} \cong 2.598$.

Using this in our main inequality one obtains

$$\sup|\Gamma|^2 \leqslant \frac{1}{4\pi} \frac{4}{3} \sqrt{\frac{27}{4}} \left(\frac{\lambda}{\sqrt{\frac{27}{4}}-\lambda}\right)^2 \|\delta x\|^2 = \frac{1}{\pi} \sqrt{\frac{3}{4}} \left(\frac{\lambda}{\sqrt{\frac{27}{4}}-\lambda}\right)^2 \|\delta x\|^2.$$

Taking $\delta x = \delta x_0 > 0$ where δx_0 is constant, then one has that

$$\|\delta x\|^2 = 4\pi (\delta x_0)^2$$

and so:

$$\sup|\Gamma|^2 \leqslant 2\sqrt{3} \left(\frac{\lambda}{\sqrt{\frac{27}{4}}-\lambda}\right)^2 (\delta x_0)^2.$$

One can see that $\delta g(\delta x_0)$ will be positive if

$$\sup|\Gamma|^2 < (\delta x_0)^2,$$

which is equivalent to

$$2\sqrt{3} \left(\frac{\lambda}{\sqrt{\frac{27}{4}}-\lambda}\right)^2 < 1.$$

This inequality is satisfied for $\lambda \in (0, \lambda_*)$ with

$$\lambda_* = \sqrt{\frac{27}{4}} \frac{1}{1+\sqrt{2}\sqrt{3}} = 0.9080.$$

Proof 2: From the Sobolev inequality one obtains

$$\sup|\Gamma|^2 \leqslant \frac{1}{4\pi} \frac{1}{4} \|\Delta \Gamma\|^2,$$

as can be deduced from the following argument.

Let the regular function Γ be given by

$$\Gamma = \sum_{l=2}^{\infty} \sum_{m=-l}^{l} \Gamma^{lm} Y_{lm}(\zeta, \overline{\zeta}),$$

then one has

$$|\Gamma(\zeta,\bar{\zeta})|^2=\left|\sum_{l=2}^{\infty}\sum_{m=-l}^{l}\Gamma^{lm}Y_{lm}(\zeta,\bar{\zeta})\right|^2=\left|\sum_{l=2}^{\infty}\sum_{m=-l}^{l}\Gamma^{lm}l(l+1)\,\frac{1}{l(l+1)}\,Y_{lm}(\zeta,\bar{\zeta})\right|^2$$
$$\leqslant\left[\sum_{l=2}^{\infty}\sum_{m=-l}^{l}|\Gamma^{lm}|^2[l(l+1)]^2\right]\left[\sum_{l=2}^{\infty}\sum_{m=-l}^{l}\left[\frac{1}{l(l+1)}\right]^2|Y_{lm}(\zeta,\bar{\zeta})|^2\right].$$

Using the inequality deduced from the addition theorem for spherical harmonics and that

$$\|\Delta\Gamma\|^2=\left[\sum_{l=2}^{\infty}\sum_{m=-l}^{l}|\Gamma^{lm}|^2[l(l+1)]^2\right],$$

one deduces

$$|\Gamma|^2\leqslant\frac{1}{4\pi}\|\Delta\Gamma\|^2\left[\sum_{l=2}^{\infty}\frac{(2l+1)}{(l(l+1))^2}\right]=\frac{1}{4\pi}\frac{1}{4}\|\Delta\Gamma\|^2.$$

Then from the linear nice section equation, one obtains

$$\langle\Gamma|\eth^2\bar{\eth}^2\Gamma\rangle=\frac{1}{4}\|\Delta\Gamma\|^2+\frac{1}{2}\int\nabla_a\Gamma\nabla^a\Gamma\;dS^2=\langle\Gamma|\dot{\Psi}_0\delta x\rangle+\langle\Gamma^2|\dot{\Psi}_0\rangle,$$

where we have used that Γ is orthogonal to the last term appearing in the linear nice section equation.

Using the inequalities mentioned in Proof 1 and

$$\|\Gamma\|^2\leqslant(2\pi)^2\int\nabla_a\Gamma\nabla^a\Gamma\;dS^2,$$

coming from the Poincaré lemma, one can deduce

$$4\pi\,\sup|\Gamma|^2+\frac{1}{2(2\pi)^2}\|\Gamma\|^2\leqslant\lambda\|\Gamma\|^2+\|\Gamma\|\lambda\|\delta x\|;$$

or equivalently

$$\sup|\Gamma|^2\leqslant\frac{1}{4\pi}\left\{\|\Gamma\|^2\left(\lambda-\frac{1}{8\pi^2}\right)+\|\Gamma\|\lambda\|\delta x\|\right\}.$$

Substituting the bound for $\|\Gamma\|$ found above, one obtains

$$\sup|\Gamma|^2\leqslant\frac{1}{4\pi}\left\{\left(\frac{\lambda}{\sqrt{\frac{27}{4}}-\lambda}\|\delta x\|\right)^2\left(\lambda-\frac{1}{8\pi^2}\right)+\left(\frac{\lambda}{\sqrt{\frac{27}{4}}-\lambda}\|\delta x\|\right)\lambda\|\delta x\|\right\},$$

from which it is deduced

$$\sup|\Gamma|^2\leqslant\frac{1}{4\pi}\left(\frac{\lambda}{\sqrt{\frac{27}{4}}-\lambda}\right)^2\left(\sqrt{\frac{27}{4}}-\frac{1}{8\pi^2}\right)\|\delta x\|^2.$$

Taking $\delta x=\delta x_0>0$ where δx_0 is constant, one has

$$\sup|\Gamma|^2\leqslant\left(\frac{\lambda}{\sqrt{\frac{27}{4}}-\lambda}\right)^2\left(\sqrt{\frac{27}{4}}-\frac{1}{8\pi^2}\right)(\delta x_0)^2.$$

Then in order for $\delta g(\delta x_0)$ to be positive, one needs

$$\sup|\Gamma|^2<(\delta x_0)^2,$$

or equivalently

$$\left(\frac{\lambda}{\sqrt{\frac{27}{4}}-\lambda}\right)^2\left(\sqrt{\frac{27}{4}}-\frac{1}{8\pi^2}\right)<1.$$

This inequality is satisfied for $\lambda\in(0,\lambda_*)$ with

$$\lambda_*=\sqrt{\frac{27}{4}}\left(\frac{1}{1+\sqrt{\sqrt{\frac{27}{4}}-\frac{1}{8\pi^2}}}\right)\cong 0.9962.$$

Proof 3: Let the regular function Γ be given by

$$\Gamma=\sum_{l=2}^{\infty}\sum_{m=-l}^{l}\Gamma^{lm}Y_{lm}(\zeta,\overline{\zeta}).$$

It was proved in Appendix B that

$$|\Gamma(\zeta,\overline{\zeta})|^2\leqslant\frac{1}{4\pi}\frac{4}{27}\langle D\Gamma|D\Gamma\rangle=\frac{1}{4\pi}\frac{4}{27}\|\Gamma\|_D^2.$$

If Γ is a solution of the linear nice section equation then

$$\|\Gamma\|_D^2\leqslant\|\dot{\Psi}_0(\delta x+\Gamma)\|^2\leqslant\lambda^2\|\delta x+\Gamma\|^2\leqslant\lambda^2\|\Gamma\|^2+\lambda^2\|\delta x\|^2;$$

as was explained above. Then using the bound

$$\|\Gamma\|\leqslant\frac{\lambda}{\sqrt{\frac{27}{4}}-\lambda}\|\delta x\|,$$

for $(\lambda\sqrt{\frac{4}{27}})<1$; one obtains

$$\sup|\Gamma|^2\leqslant\frac{1}{4\pi}\frac{4}{27}\left\{\lambda^2\left(\frac{\lambda}{\sqrt{\frac{27}{4}}-\lambda}\right)^2\|\delta x\|^2+\lambda^2\|\delta x\|^2\right\}.$$

Taking $\delta x=\delta x_0>0$ where δx_0 is constant, then one has that

$$\|\delta x\|^2=4\pi(\delta x_0)^2$$

and so:

$$\sup|\Gamma|^2\leqslant\frac{4}{27}\lambda^2\left\{\left(\frac{\lambda}{\sqrt{\frac{27}{4}}-\lambda}\right)^2+1\right\}(\delta x_0)^2.$$

One can see that $\delta g(\delta x_0)$ will be positive if

$$\sup|\Gamma|^2<(\delta x_0)^2,$$

which is equivalent to

$$\frac{4}{27}\lambda^2\left\{\left(\frac{\lambda}{\sqrt{\frac{27}{4}}-\lambda}\right)^2+1\right\}<1.$$

This inequality is satisfied for $\lambda\in(0,\lambda_*)$ with $\lambda_*\cong 1.5134$.

(Received 25 June 1997; accepted for publication 24 June 1998)

The circularity property of stationary-axisymmetric asymptotically flat solutions of the coupled Einstein conformally invariant scalar field equations is investigated. It is proven that as a result of the coupling of the scalar field to the background scalar curvature, in general such solutions fail to be circular. Consequently, it is argued that the space of stationary, black hole equilibrium states may contain states which are not circular. However, the circular stationary-axisymmetric sector is nonempty and in fact it is proven that: All circular, stationary-axisymmetric asymptotically flat black hole solutions are those and only those black holes states described by the two parameter family of Kerr black holes. © *1998 American Institute of Physics.* [S0022-2488(98)02910-7]

I. INTRODUCTION

The purpose of the present paper is to discuss stationary, asymptotically flat, black hole solutions admitted by the coupled Einstein conformally invariant massless scalar field equations. In a previous paper,[1] considerations were restricted to the static black hole sector of the theory. It was proven that the above system, admits no other static, asymptotically flat, black holes apart from the Schwarzschild class. Furthermore, the peculiar structure of the conformal stress tensor and its impact on the spectrum of possible static black hole states of the system was briefly discussed.[2]

Presently we shall extend the inquires of Ref. 1 to the nonstatic case. Even though the present work is a natural extension of the work presented in Ref. 1, the transition to the study of the nonstatic black hole sector involves rather slippery steps. At first recall that the coupled Einstein conformally invariant scalar field system is described by

$$(1-\alpha\Phi^2)R_{mn}=\alpha[4\nabla_m\Phi\nabla_n\Phi-2\Phi\nabla_m\nabla_n\Phi-g_{mn}\nabla^l\Phi\nabla_l\Phi], \tag{1a}$$

$$\nabla^m\nabla_m\Phi=0, \tag{1b}$$

where all indices are four-dimensional $\alpha=k/6$ with k signifying the gravitational coupling constant. Due to the fact that the right-hand side of (1a) contains second derivatives of the scalar field, as well as the presence of the factor $1-\alpha\Phi^2$, the conformal stress tensor fails to satisfy the familiar energy conditions. In particular the dominant energy condition as well as the null convergence conditions fail. Recall that validity of the null convergence conditions implies $R_{ab}l^al^b \geqslant 0$ for every null vector l. From (1a) one can easily deduce that $R_{ab}l^al^b$ has indefinite sign, signaling failure of the null convergence condition. The above mentioned failures are not without consequences. Let us first recall a few fundamental facts and some recent developments concerning black hole equilibrium states.

Hawking's original proof of the rigidity theorem[3] (see also Ref. 4) intended to guarantee three important attributes of any asymptotically flat black hole solution (possessing no ergoregion disconnected from the horizon) within Einstein (or Einstein Brans–Dicke[5]) gravity

(a) The Killing property of the event horizon,
(b) the axisymmetry property of the domain of outer communication, and

(c) the topologically spherical like cross sections of the horizon.

In the original proof of the rigidity theorem, Hawking assumed validity of Einstein's field equations under the condition that the energy momentum of the matter-fields satisfies the dominant energy condition. Furthermore it was assumed by Hawking, that suitable hyperbolic equations govern the evolution of matter fields, and analyticity for geometry matter fields holds from infinity up to and including the horizon. One of the key steps in Hawking's proof of the rigidity theorem, involved the extension of the horizon isometries as a local space–time isometry group valid in the near vicinity of the horizon. Although such local extension does not lead into problems, its subsequent extension via analytical continuation as an isometry over all the domain of outer communication was problematic. This last step appeared as not well justified and concerns expressed in Ref. 6. Very recently, work by Chruściel[7,8] has offered a refinement in the proof of the rigidity theorem. The new approach aims at arriving at conclusions (a) and (b) but at the same time it avoids some of the weak points of the initial proof.[9] The key ingredient in this new formulation is a theorem established by Chruściel (abbreviated here after as CT) which, leaving aside precise mathematical definitions, states the following:[7,8]

Suppose a space–time satisfies the following conditions:

(1) It is analytic and asymptotically flat;
(2) possesses a nonempty globally hyperbolic and simply connected domain of outer communication $\langle\langle M\rangle\rangle$;
(3) admits a Killing vector field X with complete orbits;
(4) its ADM four momentum is timelike;
(5) in addition to the original Killing field X, there exist another distinct, (i.e., not constant multiple of X) Killing field Y, defined only in some neighborhood of $\langle\langle M\rangle\rangle$.

Then: The isometry group of $\langle\langle M\rangle\rangle$ must contains an $RxU(1)$.

Based on this theorem, the validity of which is independent of any field equations and energy conditions, it was shown in Ref. 7 that any stationary electrovacuum black hole space–time necessary satisfies properties (a) and (b). [Due to the fact that the Ricci tensor for electrovacuum satisfies the null convergence condition then property (c) above follows and the simply connectedness property of the domain of outer communication can be removed from condition (2) of CT (see comments in Ref. 9).] We may add parenthetically that as a bonus of the new reformulation, uniqueness of the Pappapetrou–Majumbar class of extreme black holes has eventually proven true.[11]

However, attempts to use the abovementioned work to prove a rigidity theorem for the black holes solution of (1a) and (1b) run into obstacles. We shall now indicate that the peculiarities of systems (1a) and (1b) coupled with the failure of the dominant and null convergence condition, makes us unable to use CT as a mean of proving a rigidity theorem for (1a) and (1b).

Right at the start, one is confronted with the issue of the Arnowitt, Deser, Misner (ADM) four momentum, namely, whether all asymptotically flat solutions of (1a) and (1b) possess timelike four momenta. As is well known, every nonsingular asymptotically flat solution of Einstein nonvacuum equations possesses positive ADM mass and timelike ADM four momentum, provided the stress tensor satisfies the dominant energy condition. However, even though for (1a) and (1b), the dominant energy condition fails one should not rush to conclude that all asymptotically flat solutions of (1a) and (1b) possess nonpositive ADM mass. In fact as we shall indicate in Sec. III below, (1a) and (1b) admit initial data, ''close enough'' to Minkowski data, which possess timelike ADM four momenta. Of course there is no contradiction with the powerful conclusion of the positivity of gravitation mass theorem. Validity of the dominant energy condition serves only as sufficient condition for the positivity of the ADM mass (-momentum). This point as has been recently discussed in Ref. 12 and in fact, in the same reference it was pointed out that the positivity of ADM mass and timelike nature of the ADM momenta may follow without even imposing the full strength of the dominant energy condition. In view of this discussion, it is fair to state that at this point we do not know the character of the ADM four momentum for every asymptotically flat solution of (1a) and (1b). Beyond the issue of ADM momenta, a stronger reason that unable us to prove a rigidity type theorem for (1a) and (1b), is centered around the analyticity property of arbitrary asymptotically flat solutions of (1a) and (1b). We have no evi-

dence of analyticity. Although every static or stationary solution of the Einstein vacuum,[13] or for instance, of the Einstein minimally coupled massless scalar field equations[14] are analytic on an appropriately constructed coordinate atlas, this is not the case for systems (1a) and (1b). We may recall that analyticity of every static solution for the two former systems, follows as a consequence of the elliptical nature of the dynamical equations clearly exhibited in the specially constructed coordinate atlas. Attempts to prove the elliptic character of the dynamical equations (1a) and (1b) do not yield the desired conclusion and work under progress indicates that analyticity for arbitrary static solutions of (1a) and (1b) may be lost.[14] We shall also, further below, provide additional evidence supporting loss of analyticity. On the other hand, analyticity is a crucial condition for the validity of CT. In particular the extension of the locally defined Killing field Y into a global one over the entire $\langle\langle M\rangle\rangle$, is a sole consequence of the analyticity. [In this regard, the reader is urged to examine the content of theorem (2.1) quoted in Ref. 8.] But the strongest reason for the nonapplicability of CT for our purpose, is centered in the failure of the null convergence condition. As we have already discussed in Ref. 9, satisfaction of the null convergence condition, asymptotic flatness at null infinity J, combined with some additional form of weak regularity near J (see Refs. 7 and 8 for the precise definitions of the term weak regularity), guarantees the simply connectedness property of the domain of outer communication and the S^2xR topological nature of every connected component of the event horizon. In turn, in order to establish the rigidity theorem at least for the electrovacuum cases, the S^2xR character of the horizon appears mandatory (see details in Ref. 8). It is not clear at all whether one can even contemplate a rigidity theorem, if the horizon is allowed to possess arbitrary topologies, for instance, to be toroidal or possess more exotic topologies of higher than genus two.

Due to the above (actually interrelated) reasons and irrespective of the status of other conditions in CT, the relationships between the event horizon and the Killing horizon, the axisymmetry of $\langle\langle M\rangle\rangle$ and the allowed horizon topologies for the possible black hole solutions of systems (1a) and (1b) are presently unknown. Because of the luck of that vital information, the present paper intends to analyze only a special class of black hole solutions of (1a) and (1b). More precisely we shall probe the sector of black hole solutions of (1a) and (1b) covered by Carter's work.[15,16] Carter's work on black hole equilibrium states, begins with the reasonable assumption that $\langle\langle M\rangle\rangle$ does not admit compact causal curves[15] an assumption referred to as the causality axiom.[15] [In this section we shall employ closely the terminology used in Ref. 15. In particular (pseudo) stationary action refers to the action where the infinitesimal Killing generator is restricted to be timelike only in the asymptotic region.] For a weakly asymptotically simple, (pseudo)-stationary space–time M, the domain of outer communication $\langle\langle M\rangle\rangle$ is defined by Carter, as the set of points from which there exist both future and past directed timelike curves extending to arbitrarily large asymptotic distances. It is then proven[15,16] that $\langle\langle M\rangle\rangle$ is a maximal asymptotically flat domain having the property that for every point x in $\langle\langle M\rangle\rangle$, the trajectory or orbit of the (pseudo) stationary action will if extended far enough, enter and remains in the chronological future of x. Equivalently, $\langle\langle M\rangle\rangle$ possess the structure of a fiber bundle with a three-dimensional base manifold and fibers the trajectories of the (pseudo) stationary group action.[17] Although the construction of $\langle\langle M\rangle\rangle$ involves only the use of the (pseudo) stationary group action, asymptotic flatness and validity of the causality axiom, the identification of the event horizon, for the class of nonstatic black holes needs additional inputs. Partially motivated by astrophysical considerations, Carter restricted attention only to axisymmetric black holes. More precisely, in Refs. 15 and 16 attention was restricted to black holes stationary states where the domain of outer communication $\langle\langle M\rangle\rangle$ admits two commuting actions, one (pseudo) stationary and the other axisymmetric,[18,19] the horizon admits spherical-like cross sections and additionally the Ricci tensor obeys the circularity condition.[20] Under those assumptions, the event horizon of any black hole which is either static, or stationary-axisymmetric must coincide with the ''staticity limit'' or ''circularity limit,'' respectively. The staticity limit is defined as the boundary of the region where the hypersurface orthogonal Killing field is timelike while the circularity limit is defined to be the boundary where a particular combination of the timelike at infinity and the axial Killing fields is timelike. Thus Carter's work, even though broad enough, does not employ any particular set of field equations and makes no specific reference to energy conditions, it does cover, as far as the stationary class is concerned, only the class of stationary-axisymmetric and circular ones.

The above brief description of the space–times associated with stationary black holes indi-

cates that even though the benefits of a rigidity theorem for (1a) and (1b) would be very welcomed, axisymmetry follows rather than being imposed in advance, at this stage and for the reason discussed above we are unable to prove such a theorem. For the purpose of the present paper we shall employ Carter's work, with all the limitations that entails.

II. THE CIRCULARITY ISSUE

According to the above discussion, in order to get the benefits of Carter's work, we must first examine whether the Ricci tensor of (1a) is circular. Although vacuum or electrovacuo stationary-axisymmetric asymptotically flat solutions of Einstein's equations are necessary circular[15,16,20] nothing is known about the circularity properties of stationary-axisymmetric solutions of (1a) and (1b). The results of the present section are of interest in their own right and are actually independent of the other sections[21] of the paper.

Accordingly, let us consider an arbitrary stationary-axisymmetric solution of (1a) and (1b). Denote by ξ, ψ the two commuting Killing fields generators of the (pseudo) stationary and axisymmetric actions, respectively, with the former being timelike at infinity and the later spacelike possessing closed orbits. Asymptotic flatness implies the existence of an axis where ψ is vanishing, a property that we shall often use later on. In the terminology of Carter[15,16,20] circularity or orthogonal transitivity of the action generated by the two commuting Killing fields, guarantees that the distribution of the two-dimensional subspaces of the tangent spaces of the manifold, orthogonal to the planes spanned by the commuting Killing fields is integrable. Such integrability property implies that one may choose coordinates such that the metric takes the Lewis–Pappapetrou form,[22] a form that simplifies enormously the field equations. Referring the reader to the original work of Carter[15,16,20] or to Sec. 7.1 and Appendix B.3 of Walds book,[22] if by $\omega_{(\xi)a}=\epsilon_{abcd}\xi^b\nabla^c\xi^d$, $\omega_{(\psi)a}=\epsilon_{abcd}\psi^b\nabla^c\psi^d$ we denote the twists of the two Killing fields, then circularity in a domain containing the axis is ensured provided: $\omega_{(\xi)a}\psi^a=\omega_{(\psi)a}\xi^a=0$. A computation, based on the properties of the Killing equation alone, shows[22]

$$\nabla_m(\omega_{(\xi)a}\psi^a)=-2\epsilon_{mbcd}\psi^b\xi^c R^d_e\xi^e, \tag{2}$$

with a similar expression for $\nabla_m(\omega_{(\psi)a}\xi^a)$. Using (1a) in (2) one gets

$$\begin{aligned}(1-\alpha\Phi^2)\nabla_m(\omega_{(\xi)a}\psi^a)&=-2\alpha\epsilon_{mbcd}\psi^b\xi^c[(4\nabla^d\Phi\nabla_e\Phi-2\Phi\nabla^d\nabla_e\Phi-\delta^d_e\nabla^l\Phi\nabla_l\Phi)]\xi^e\\&=-4a\Phi\epsilon_{mbcd}\psi^b\xi^c(\nabla^d\xi^e)\nabla_e\Phi.\end{aligned} \tag{3}$$

The last part in Eq. (3) is obtained by explicitly taking into account that the Lie derivative of Φ along the two Killing fields is vanishing, the term proportional to the magnitude of the gradient of Φ gives zero contribution after antisymmetrization, and a differentiation by parts has been performed in the term containing the second derivatives of Φ. The right-hand side of Eq. (3) can be simplified further by virtue of the symmetries of Φ and the Killing equation. It is convenient at this point, to introduce a set of local (t,ϕ,x,y) coordinates adapted to the Killing fields i.e., $\xi=\partial/\partial t$, $\psi=\partial/\partial\phi$ and x,y for the moment arbitrary spacelike ones. In such coordinates, the scalar field as well as $\omega_{(\xi)a}\psi^a$ have nonvanishing gradient only along the two nonignorable coordinates i.e.,

$$\nabla_e\Phi=(\nabla_x\Phi)\,\delta^x_e+(\nabla_y\Phi)\,\delta^y_e,$$

$$\nabla_m(\omega_{(\xi)a}\psi^a)=\nabla_x(\omega_{(\xi)a}\psi^a)\,\delta^x_m+\nabla_y(\omega_{(\xi)a}\psi^a)\,\delta^y_m.$$

Therefore, one may easily see that $\nabla_m(\omega_{(\xi)a}\psi^a)$ is proportional to $\nabla_m\Phi$ and in fact Eq. (3) can be rewritten as

$$\begin{aligned}(1-a\Phi^2)\nabla_m(\omega_{(\xi)a}\psi^a)&=-4a\Phi\epsilon_{abcd}\psi^b\xi^c(\nabla^d\xi^a)\nabla_m\Phi\\&=4a\Phi(\omega_{(\xi)a}\psi^a)\nabla_m\Phi=2a(\omega_{(\xi)a}\psi^a)\nabla_m\Phi^2=-2(\omega_{(\xi)a}\psi^a)\nabla_m(1-a\Phi^2).\end{aligned} \tag{4}$$

The additional minus sign appearing in passing from the second to the third equality results from transposing the indices a to the last slot of the the antisymmetric tensor so that the twist of ξ is compatible with the one employed in the derivation of Eq. (2).

From Eq. (4) one infers that as long as $(1-a\Phi^2)$ is nonzero then.

$$\omega_{(\xi)a}\psi^a = C(1-a\Phi^2)^{-2}, \tag{4a}$$

with C an arbitrary space–time integration constant. Similar considerations apply for the term $\omega_{(\psi)a}\xi^a$ as well, and an equation analogous to (5) is also easily obtained. Because of the presence of the axis, one could have concluded from (4a) that it is necessary for $C=0$ everywhere. This implies that in a region containing the axis an arbitrary stationary-axisymmetric solution of Eqs. (1a) and (1b) is locally circular. However, to conclude that circularity holds globally is a more delicate matter. Implicit in the derivation of Eq. (4a) lies the assumption that in the region under consideration the factor $(1-a\Phi^2)$ is no where vanishing. However, extending this property globally is a strong assumption. There is no *a priori* reason that an arbitrary solution of the field Eqs. (1a) and (1b) will necessarily obey such a property. Therefore, we shall examine the analog of

$$(1-a\Phi^2)\nabla_m(\omega_{(\xi)a}\psi^a) = -2(\omega_{(\xi)a}\psi^a)\nabla_m(1-a\Phi^2), \tag{4b}$$

in a region of space–time where $(1-a\Phi^2)=0$. If we could prove that indeed in such regions circularity is preserved, then we can safely conclude that all stationary-axisymmetric solutions of Eqs. (1a) and (1b) are indeed globally circular. In turn to settle this question one first needs to address the following one: Suppose that (g,Φ) is a nonsingular solution of the field equations (1a) and (1b). What is the value of the Ricci tensor at points where $1-a\Phi^2=0$? This question is addressed in details in Appendix A. There it is shown that at a point (or points) where $(1-a\Phi^2)=0$, but the gradient of Φ is not identically zero,[23] the Einstein field equations (1a) imply the following expression for the Ricci tensor:

$$\Phi R_{mn} = \nabla_m\nabla_n\Phi - \frac{\nabla^k\Phi}{\nabla^l\Phi\nabla_l\Phi}\left[2\nabla_k\nabla_m\Phi\nabla_n\Phi + 2\nabla_k\nabla_n\Phi\nabla_m\Phi - \Phi\nabla_k\nabla_n\nabla_m\Phi - g_{mn}\nabla_k\nabla^a\Phi\nabla_a\Phi\right]. \tag{5}$$

The above form of the Ricci tensor is more complex that the one shown in Eq. (1a) and consequently it is expected that the final form of Eq. (2) to be significantly different than the form shown in Eq. (4b). Forming now $R_{mn}\xi^n$ by utilizing (5), one notices that the first term in the square bracket of the right-hand side of (5) gives zero contribution. The second term after a trivial rearrangement, due to the Killing equation satisfied by ξ, also contributes zero. Finally, the last term results to a contribution proportional to ξ_m, and since $R_{mn}\xi^n$ is antisymmetrized with another copy of ξ it eventually contributes to zero. Therefore, one now gets

$$\nabla_m(\omega_{(\xi)a}\psi^a) = -2\epsilon_{mbcd}\psi^b\xi^c\left[\frac{1}{\Phi}\,\xi^n\nabla^d\nabla_n\Phi + \frac{1}{\nabla^l\Phi\nabla_l\Phi}\,\xi^n\nabla^k\Phi\nabla_k\nabla^d\nabla_n\Phi\right]. \tag{5a}$$

Even as it stands, by comparison to the steps that lead to the derivation of Eq. (4b) from Eq. (3) one realizes that the last term in (5a) contributes additional terms resulting into a considerable modification of the gradient of $\omega_{(\xi)a}\psi^a$. In Appendix B a rearrangement of this last term is presented that makes its contribution more transparent. Eventually from (5a), we are lead to the following equation satisfied by $\omega_{(\xi)a}\psi^a$:

$$\nabla_m(\omega_{(\xi)a}\psi^a) = -2\epsilon_{mbcd}\psi^b\xi^c\Bigg[-\frac{1}{\Phi}\,(\nabla^d\xi^n)\nabla_n\Phi + \frac{1}{\nabla^l\Phi\nabla_l\Phi}\,(-\nabla^k\Phi(\nabla^d\xi^n)\nabla_k\nabla_n\Phi$$
$$-\nabla^k\Phi(\nabla_k\xi_n)\nabla^d\nabla^n\Phi - R_k{}^d{}_{rn}\nabla^k\Phi\nabla^r\Phi\xi^n)\Bigg]. \tag{5b}$$

Repeating the arguments that lead to the derivation of Eq. (4b) from Eq. (3), one now gets

$$\nabla_m(\omega_{(\xi)a}\psi^a)=2(\omega_{(\xi)a}\psi^a)\,\frac{\nabla_m\Phi}{\Phi}+\frac{1}{\nabla^l\Phi\nabla_l\Phi}\,(\omega_{(\xi)a}\psi^a)\nabla^k\Phi\nabla_k\nabla_m\Phi$$

$$+2\epsilon_{mbcd}\psi^b\xi^c\,\frac{1}{\nabla^l\Phi\nabla_l\Phi}\,[\nabla^k\Phi(\nabla_k\xi_n)\nabla^d\nabla^n\Phi+R_k{}^d{}_{rn}\nabla^k\Phi\nabla^r\Phi\xi^n]. \qquad (5c)$$

This is the differential equation satisfied by $\omega_{(\xi)a}\psi^a$ whenever locally $1-a\Phi^2=0$ but its gradient is not vanishing.[24] Similarly the scalar $\omega_{(\psi)a}\xi^a$, satisfies an equation analogous to Eq. (5c) with the sole exception the axial Killing is switched with the timelike one and vice versa.

Comparing Eq. (5c) to Eq. (4b) one immediately notices an important difference: Whereas Eq. (4b) implies for instance that along the integral curves of any nonsingular vector field, $\omega_{(\psi)a}\xi^a$ satisfies a linear homogeneous equation, that is no longer the case for (5c). Of course some care must be exercized in interpreting the content of (5c). From its derivation it is clear that if indeed we were dealing with a theory where the Ricci tensor was given globally by Eq. (5), then one would easily have concluded from (5c) that for such theory circularity was broken. Within the present content, Eq. (5c) provides information regarding the gradient of $\omega_{(\psi)a}\xi^a$ at point (or points) of the space–time where $1-a\Phi^2=0$. Nevertheless we shall prove below that the information is sufficient, under certain conditions, in proving that circularity is broken for the theory (1a), (1b). To do so it is helpful first to advance an equivalent representation for each of the scalars $\omega_{(\xi)a}\psi^a=\epsilon_{abcd}\psi^a\xi^b\nabla^c\xi^d$, $\omega_{(\psi)a}\xi^a=\epsilon_{abcd}\xi^a\psi^b\nabla^c\psi^d$ that will be proven to be very helpful for the calculations that follow. We shall present the detailed calculations leading to the new representation only for the first one, because identical derivation holds for the second one. Obviously we have

$$\omega_{(\xi)a}\psi^a=\epsilon_{abcd}\psi^a\xi^b\nabla^c\xi^d=\epsilon_{abcd}\psi^a\xi^b\nabla^{(c}\xi^{d)}+\epsilon_{abcd}\psi^a\xi^b\nabla^{[c}\xi^{d]}=\epsilon_{abcd}\psi^a\xi^b\nabla^{[c}\xi^{d]}, \qquad (6)$$

where in arriving at the final equality, we have used the Killing equation satisfied by ξ. In above and in the following equations indices enclosed within square brackets ought to be antisymmetrized. Furthermore, since our analysis is purely local, it is convenient to work within the (t,ϕ,x,y) coordinate patch introduced earlier on and presently denote by (ξ,ψ,X,Y) the associated coordinate basis vector fields, respectively. In terms of this coordinate basis we may expand the antisymmetric part of $\nabla^{[a}\xi^{b]}$ in the following manner:

$$\nabla^{[a}\xi^{b]}=a_1\xi^{[a}\psi^{b]}+a_2\xi^{[a}X^{b]}+a_3\xi^{[a}Y^{b]}+a_4\psi^{[a}X^{b]}+a_5\psi^{[a}Y^{b]}+a_6X^{[a}Y^{b]}, \qquad (6a)$$

where the expansion coefficients a_i, $i=(1,...,6)$, are local bounded functions carrying all the informations regarding $\nabla^{[a}\xi^{b]}$. Although we can compute them explicitly, for the purpose of the following considerations their form is not required. Substituting Eq. (6a) into Eq. (6) we obtain

$$\psi_{(\xi)a}\psi^a=\tfrac{1}{2}a_6\epsilon_{abcd}\psi^a\xi^bX^cY^d. \qquad (6b)$$

This representation of $\omega_{(\xi)a}\psi^a$ is rather insightful, in the sense that all information regarding the circularity–noncircularity aspect of the action generated by the the Killing fields (ξ,ψ), is encoded in the coefficient a_6. For our purpose Eq. (6b) combined with (6a) will shorten considerably an otherwise messy and lengthy set of calculations.

Keeping in mind (6a) and (6b), we shall show in details that Eq. (5c) implies loss of circularity. At this point we have to make some assumptions concerning the distribution of zeros of the $1-a\Phi^2$ factor. As we have already argued earlier on, there is no fundamental reason to expect that for all stationary-axisymmetric solutions of (1a) and (1b) the factor $1-a\Phi^2$ is no where vanishing. If on the other hand we assume that $1-a\Phi^2$ admits zeros, it is expected that this set in the (x,y)-''plane,'' to be made either by isolated points, one-dimensional segments, or closed loops (and perhaps their unions). Our task now is to investigate the consequences of such configurations upon the circularity property of the underlying solution.

For that we shall first assume that on the (x,y)-plane the set of points where $1-a\Phi^2=0$ forms a nonintersecting smooth S^1-loop (smooth in the sense that the loop is minimally everywhere C^1, although the considerations that follow will remain intact if the loop is piecewise C^1). Let us here after denote the above loop by Γ. Due to stationary and axisymmetry of the background, such a set

of zeros for the $1-a\Phi^2$ factor, generate on each three $t=\text{const}$ spacelike section a two-dimensional torus, while in the space–time generate the product of a two torus with the real line. We may without loss of generality take the two coordinate basis vector fields X,Y defined earlier on, so that the first one is tangential to Γ while the other one is normal to the loop pointing ''inwards.'' [Such arrangement may require a change of coordinates on the (x,y)-plane, but basically it can be arranged.] Utilizing Γ we may locally foliate its vicinity by a family of loops. The construction of this local foliation is essentially equivalent to the construction of the two-dimensional Gaussian coordinates based on Γ. Each point of Γ is pushed to a fixed infinitesimal parameter distance along the geodesic integral curves originating at the point under consideration and having initial tangent the (two-dimensional) normal vector field of Γ. Relative to this foliation or coordinates, one then has the following behavior of Φ on Γ: $X^a\nabla_a\Phi=0$ and $Y^a\nabla_a\Phi\neq 0$. The idea now is to use Eq. (5c) to compute the gradients of $\omega_{(\xi)a}\psi^a$, $\omega_{(\psi)a}\xi^a$ along the tangential and normal directions of Γ. Again, we shall restrict considerations only to $\omega_{(\xi)a}\psi^a$, with the understanding that identical considerations hold for the other scalars as well.

Let us first compute the gradient of $\omega_{(\xi)a}\psi^a$ along the tangential direction X of Γ, i.e., form $X^m\nabla_m(\omega_{(\xi)a}\psi^a)$. This is given by contracting both sides of (5c) with X. One immediately notices that the contribution of first term in the right-hand side of (5c) is vanishing. Let us now shift attention to the terms within the square bracket of (5c) by first examining the term involving the Riemann tensor. Ignoring for the moment the innocuous and by assumption nonvanishing $\nabla^l\Phi\nabla_l\Phi$ term, we are interest to compute on Γ the following term:

$$I_1=\epsilon_{mbcd}X^m\psi^b\xi^c R_l{}^d{}_{rn}\nabla^r\Phi\nabla^l\Phi\xi^n. \tag{7}$$

Due to the symmetries of the Riemann tensor, the assumption that the gradient of Φ lies on the normal direction and the fact that the only nonvanishing component of $\epsilon_{mbcd}X^m\psi^b\xi^c$ must be taken along the Y direction, one concludes that $I_1=0$. Let us now consider the other term within the square bracket of Eq. (5c), i.e.,

$$I_2=\epsilon_{mbc}{}^d X^m\psi^b\xi^c\nabla_l\Phi(\nabla^l\xi^n)\nabla_d\nabla_n\Phi. \tag{7a}$$

We shall now rearrange I_2 so its content will be more clear. This, however, is not a straightforward task. A brute force computation of the the right-hand side of (7a) is a tedious and very lengthy. However, the identities (6a) and (6b) provide a shortcut. To make use of them, at first we substitute $\nabla^l\xi^n$ in (7a) above, by its antisymmetric part given by (6b). Because one of the indices of $\nabla^l\xi^n$ is contracted with the gradient of Φ, only the terms proportional to the terms a_6, a_5, a_3 in the expansion (6a) will survive i.e., we have

$$I_2=-\tfrac{1}{2}\epsilon_{mbc}{}^d X^m\psi^b\xi^c[a_6X^n+a_5\psi^n+a_3\xi^n]\nabla_d\nabla_n\Phi(Y^l\nabla_l\Phi). \tag{7b}$$

Now we need to compute the contraction of $\nabla_d\nabla_n\Phi$ with the three basis vectors in the square bracket of (7b). For that we should keep in mind that $\epsilon_{mbc}{}^d X^m\psi^b\xi^c$ will yield a nonzero contribution only when $\nabla_d\nabla_n\Phi=cY_dA_n$ with c in general nonvanishing and bounded and A_n a linear combination of the basis vectors. Furthermore notice we can write

$$X^n\nabla_d\nabla_n\Phi=\nabla_d(X^n\nabla_n\Phi)-(\nabla_dX^n)\nabla_n\Phi. \tag{7c}$$

Identical expressions to (7c) valid also for the case where X is replaced the Killing fields ξ, ψ, respectively. However, for the latter case the net contribution to I_2 is vanishing. This can be easily deduced since obviously for the case of ξ we have: $(\nabla^d\xi^n)\nabla_n\Phi=(\nabla^{[d}\xi^{n]})\nabla_n\Phi$. Substituting the antisymmetric part of the covariant derivative of ξ with its equivalent expression (6a), one eventually concludes that the net contributions of the a_5, a_3 terms to I_2 is vanishing. However, as can be easily seen the contribution arising from the term proportional to a_6 is not vanishing and in general it can be written in the following form:

$$I_2=-\tfrac{1}{2}a_6f\epsilon_{mbcd}X^m\psi^b\xi^cY^d(Y^l\nabla_l\Phi)=\omega_{(\xi)a}\psi^aF, \tag{7d}$$

where in passing to the last equality use of the representation (6b) has been made and the multiplicative factor F stands for all additional contributions arising from the gradient of Φ. Finally,

notice that the second term in the right-hand side of (5c) contributes a term proportional to $\omega_{(\xi)a}\psi^a$ in $X^m\nabla_m(\omega_{(\xi)a}\psi^a)$. It is not necessary to work out its exact form but it is suffice to comment that the proportionality function is necessarily a well behaved one. In view of the considerations so far and with reference to Eq. (5c), we conclude that $\omega_{(\xi)a}\psi^a$ satisfies a linear a equation along the tangential direction of the loop Γ. We may symbolically write it as $X^m\nabla_m(\omega_{(\xi)a}\psi^a)=G(\omega_{(\xi)a}\psi^a)$ with G a bounded function on Γ.

So far we have said nothing about the location of Γ relative the origin of the (x,y)-plane i.e., relative to the intersection of of the axis with the (x,y)-plane. Let us first assume, that this origin lies outside the the loop Γ. Then as we have shown earlier $\omega_{(\xi)a}\psi^a=0$, along the integral curves of any smooth vector field passing through the origin of (x,y)-plane and reaching the loop without intersecting regions or points where the factor $1-a\Phi^2$ is vanishing. By assumption the geometry of the space–time is nonsingular on and in the vicinity of the loop. This nonsingularity property of the geometry necessary dictates that $\omega_{(\xi)a}\psi^a$ must be minimally continuous on and also across the loop. If for instance, one assumes that at a point $\omega_{(\xi)a}\psi^a$ fails to be continuous, then necessarily the first derivatives of the metric must be discontinuous. In turn that implies that the curvature must exhibit singularities. As a consequence of the continuity requirement of $\omega_{(\xi)a}\psi^a$ along and across Γ coupled with the fact that outside of the loop $\omega_{(\xi)a}\psi^a=0$ one concludes from $X^m\nabla_m(\omega_{(\xi)a}\psi^a)=G(\omega_{(\xi)a}\psi^a)$ that $\omega_{(\xi)a}\psi^a$ is identically vanishing along the entire loop Γ. Similar conclusions apply also for the case where the loop Γ encloses the origin or even passes through the origin. In that case, the continuity requirement of $\omega_{(\xi)a}\psi^a$ implies that $\omega_{(\xi)a}\psi^a=0$ at the interior and on the loop.

Let us now consider the behavior of $\omega_{(\xi)a}\psi^a$ along the normal directions. We shall follow similar procedure as we did in computing the gradient of $\omega_{(\xi)a}\psi^a$ along the tangential direction. Accordingly, using (5c) we are first computing $Y^m\nabla_m(\omega_{(\xi)a}\psi^a)$ on Γ. For the present case, the analog I_1 of Eq. (7) reads

$$I_1=\epsilon_{mbcd}Y^m\psi^b\xi^c R_l{}^d{}_{rn}\nabla^r\Phi\nabla^l\Phi\xi^n, \tag{8}$$

thus the sole difference to the right-hand side of (7) is the exchange of the basis vector X for Y. However that difference carries enormous consequences. Since now the totally antisymmetric tensor is contracted with (Y,ξ,ψ), the only available contraction with the Riemann tensor is via the X direction. Consequently, and even though the other two indices of the Riemann tensor are contracted with the gradient of Φ the net effect is that in general

$$I_1=\epsilon_{mbcx}Y^m\psi^b\xi^c R_l{}^x{}_{rn}\nabla^r\Phi\nabla^l\Phi\xi^n\neq 0. \tag{8a}$$

Similarly the analog of (7b) presently takes the form

$$I_2=-\tfrac{1}{2}\epsilon_{mbc}{}^dY^m\psi^b\xi^c[a_6X^n+a_5\psi^n+a_3\xi^n]\nabla_d\nabla_n\Phi(Y^l\nabla_l\Phi). \tag{8b}$$

However, now again for the same reasons leading to the nonvanishing of (7d), one concludes that I_2 is nonvanishing and the terms proportional to a_6, a_5, a_3 contribute a term proportional to $\omega_{(\xi)a}\psi^a$ in $Y^m\nabla_m(\omega_{(\xi)a}\psi^a)$. We may eventually write the gradient of $\omega_{(\xi)a}\psi^a$ along the normal direction of the loop Γ in the following form:

$$Y^m\nabla_m(\omega_{(\xi)a}\psi^a)=2\epsilon_{mbcd}Y^m\psi^b\xi^c\,\frac{1}{\nabla^l\Phi\nabla_l\Phi}\,[R_k{}^d{}_{\rho n}\nabla^\rho\Phi\nabla^k\Phi\xi^n]=\frac{A}{\nabla^l\Phi\nabla_l\Phi}, \tag{9}$$

where A stands symbolically for the contribution of the Riemann tensor and in (9) we have ignored the terms proportional to $(\omega_{(\xi)a}\psi^a)$ since, as we have already discussed earlier on, $\omega_{(\xi)a}\psi^a=0$ along Γ. It is worth noticing that for a general stationary axisymmetric solution of (1a) and (1b), in general the contribution of $R_y{}^x{}_{yt}$ that appears in Eq. (9) will be different than zero. This term would be zero provided the geometry is invariant under $t\to -t$ i.e., the timelike Killing field ξ is hypersurface orthogonal. Thus under the mere assumption of stationarity and axisymmetry, the right-hand side of (9) would be different than zero. Before we continue it is worth reminding the reader that even though we have concentrated on the behavior of $\omega_{(\xi)a}\psi^a$, similar equations valid for the other scalar $\omega_{(\psi)a}\xi^a$. The detailed derivations are essentially identical and are omitted.

Let us now consider the implications of (9) upon circularity. We shall consider first the case where the loop Γ does not enclose the origin of the (x,y)-plane and for simplicity the factor $1-a\Phi^2$ is no where vanishing within Γ. As we have already discussed above continuity arguments imply that outside and on the loop $\omega_{(\xi)a}\psi^a=0$. But let us now shift attention to the value of $\omega_{(\xi)a}\psi^a$ at points interior to the loop. Accordingly in the interior of the loop $\omega_{(\xi)a}\psi^a$ satisfies Eq. (4b) and for every two points (1,2) belonging to the interior of Γ one has

$$\omega_{(\xi)a}\psi^a(1-a\Phi^2)^2|_1=\omega_{(\xi)a}\psi^a(1-a\Phi^2)^2|_2. \tag{9a}$$

Those are the only information, under the present conditions, that Eq. (4b) can provide. Let us, however, take an arbitrary point M on the loop Γ and consider for simplicity the geodesic emanating from the point M with initial tangent equal to the (inward pointing) normal at the M. Furthermore, we affinely parameterize the geodesic with the proper distance s, normalized so that $s=0$ at M. According to Eq. (9) the normal derivative of $\omega_{(\xi)a}\psi^a$ at M is different than zero, and that implies for points near by M and along this geodesic we may write

$$\omega_{(\xi)a}\psi^a|_s=\left[\frac{A}{\nabla^l\Phi\nabla_l\Phi}\,s+O(s^2)\right]. \tag{9b}$$

In other words the nonvanishing normal gradient of $\omega_{(\xi)a}\psi^a$ on Γ implies that in the interior of the loop necessary $\omega_{(\xi)a}\psi^a$ is not identically zero. That is sufficient to infer that circularity is indeed lost.

Similar conclusion regarding the value of $\omega_{(\xi)a}\psi^a$ valid also for the case where the loop Γ encloses or passes through the origin of the (x,y)-plane. The sole difference with the above case, lies in the fact that now $\omega_{(\xi)a}\psi^a$ is identically zero in the interior of the loop, but different than zero in the exterior region.

Notice furthermore, even though according to (9), $\omega_{(\xi)a}\psi^a$ is continuous on and across the loop, it fails to be differentiable in the normal direction. As a consequence the second normal derivatives of the metric must exhibit discontinuities. The situation here is similar to the constant density spherical star solution of Einstein equations (see, for example, Ref. 22). In that solution, whenever the surface of the star is matched to a vacuum solution, the curvature (for instance scalar curvature) exhibits discontinuities. The normal second derivatives of the metric are discontinuous across the surface. The same situation is encountered here as well. In conclusion, at points where $1-a\Phi^2$ passes through zeros, the geometry is characterized by a low differentiability class. It is that evidence that lets us conclude that analyticity of static solutions of (1a) and (1b) is likely absent, with the implications that we have already discussed in Sec. I. We shall say more about that elsewhere.

In summary we have shown that as a consequence of Eq. (5c) and in the case where the topology of zeros of the factor $1-a\Phi^2$ forms a smooth closed loop then circularity is necessarily broken. In principle one may apply similar considerations to the case where the factor $1-a\Phi^2$ is zero, for instance, along a linear segment. With the help of (5c) one can still prove that the tangential derivative $\omega_{(\xi)a}\psi^a$ is zero while the norm is nonvanishing. However, the conclusion may be different than the loop case. Let us suppose that the line segment along which $1-a\Phi^2$ is vanishing, is surrounded by a region where $\omega_{(\xi)a}\psi^a=0$. In that case we lead to the conclusion that the geometry is singular on the segment. However, if the region around the segment is characterized by the vanishing $\omega_{(\xi)a}\psi^a$ (such a situation can arise for instance whenever the segment is embedded within a loop) the geometry can be perfectly regular on the segment. Similar conclusions are valid for the case where $1-a\Phi^2$ is zero at an isolated point. In short, the issue of the zeros of $1-a\Phi^2$ needs additional attention. We may only add here that the fact that an arbitrary asymptotically flat solution of (1a) and (1b) may allow regions where $1-a\Phi^2=0$ it lead us to the conclusion that not all stationary asymptotically flat solutions of the theory are circular. There may exist torilike regions around the symmetry axis where circularity fails. It is of interest to note here that the underlying reason for the failure of circularity, is not really the mere presence of the second derivatives of the scalar field Φ in the right hand side of Eq. (1a) but rather is due to in the uncontrollable sign of the $1-\alpha\Phi^2$ factor combined with the existence of second derivatives.[25]

The above considerations remain valid whenever one considers asymptotically flat, stationary axisymmetric black hole solutions of the theory. One has no *a priori* reason to expect that 1

$-\alpha\Phi^2$ remains nonvanishing over the entire domain of the black hole exterior. Consequently at this stage we are lead to the conclusion that systems (1a) and (1b) may admit noncircular stationary axisymmetric black hole states. The nature of those black holes (if indeed they exist), in view of the discussions of the previous section, is unknown. We cannot any longer appeal to Carter's theorem, to conclude that their event horizon is a Killing horizon nor that they are uniformly rotating.

III. STATIONARY AXISYMMETRIC CIRCULAR STATES

Let us, in this section, concentrate on the sector of circular black hole states i.e., on the space of stationary-axisymmetric black holes where the Ricci tensor is circular at least in the domain of outer communication. We already know that the space of such black hole solutions of (1a) and (1b) is nonempty. The Kerr black hole is a ''trivial'' solution of Eqs. (1a) and (1b) with the field Φ zero everywhere. But do there exist other stationary-axisymmetric circular black hole states admitting a nontrivial conformal field? If so, what is the corresponding space–time geometries? The present section is intended to settle these questions. We shall show that actually all such black hole states must necessarily belong to the Kerr family, and thus the conformal field outside the horizon must be trivial.

One way of proving the statement is to make use of the fact that Eqs. (1a) and 1(b), via the action of a suitable conformal transformation, can be recast into an equivalent Einstein minimally coupled massless scalar field equation. In fact the conformal transformation accomplishing that is given by $\bar{g}_{mn}=(1-\alpha\Phi^2)g_{mn}$.[26] With further analysis, one can show that the above conformal transformations maps black hole solutions of the conformal system to that of the minimal one and vice versa. However, in the present paper we shall not follow this route. Instead, we shall work with the original systems (1a) and (1b). As it will become clear further below, the method of establishing the claim, utilizes only the wave equation obeyed by the scalar field, the Killing property of the horizon and asymptotic flatness and thus is actually independent upon the precise form of the field equations.

Let us begin by assuming that (1a) and (1b) admit a stationary, axisymmetric, circular asymptotically flat black hole away from the Kerr family. According to Carter's theorem, the location of the event horizon is marked by the vanishing of the norm of Killing field $X_1=\xi+\Omega\psi$, with the nonzero constant Ω defining the angular velocity of the event horizon. From Eq. (1b) after multiplication by Φ one easily obtains

$$\nabla_a(\Phi\nabla^a\Phi)-\nabla^a\Phi\nabla_a\Phi=0. \tag{10}$$

We shall integrate the above equation over a suitable space–time region Ω. This region Ω is chosen as follows: First we consider an arbitrary spacelike hypersurface labeled as t_1, intersecting only the future event horizon H^+ and being deformed so that it becomes asymptotically null.[27] We translate t_1 along the orbits of the Killing field ξ by a specified amount of parameter distance and label the resulting hypersurface as t_2. (In the conformal completion of the space–time, such hypersurfaces intersect the future null infinity J^+ across regular two spheres.) The region Ω, is the region enclosed between the two hypersurfaces, the future event horizon H^+, and future null infinity J^+. By integrating Eq. (10) over Ω and with the help of Stoke's theorem one easily obtains

$$\int \nabla_a\Phi\nabla^a\Phi d\Omega|_\Omega=\int \Phi\nabla^a\Phi d\Sigma_a|_{t_1}+\int \Phi\nabla^a\Phi d\Sigma_a|_{t_2}+\oint \Phi\nabla^a\Phi d\Sigma_a|_H+\oint \Phi\nabla^a\Phi d\Sigma_a|_\infty. \tag{10a}$$

However, because of translational invariance the volume integral over the two hypersurfaces (t_1,t_2) cancel out. The only potentially nonvanishing contributions to the right-hand side of above, come from the integral along H^+ and J^+, respectively.[28] Let us first deal with the surface integral across the horizon. We shall employ as the measure $d\Sigma_A$ the standard one (see, for instance, Ref. 15) i.e.,

$$d\Sigma_a=dS_{ab}l^b=(-l_an_b+l_bn_a)l^bdSdu, \tag{10b}$$

where l is the tangent field to the null generator field of H^+ while n is the other null future directed field normalized according to $l^a n_a = -1$.

One then finds

$$\oint \Phi \nabla^a \Phi d\Sigma_a|_H = \oint \Phi \nabla^a \Phi(-l_a n_b + l_b n_a) l^b dS du = \oint \Phi[(-n_a l^a) L_l \Phi + (l^a l_a) L_n \Phi] dS du, \tag{11}$$

with L_x signifying Lie differentiation along x. On the horizon, by assumption the Killing field X_1 coincides with l. Consequently one may conclude that the first term in the integrand of (11) always vanishes, provided Φ is bounded on the horizon. We shall impose this requirement, but we may stress that by allowing an unbounded Φ on the horizon requires a separate treatment. Under this assumption, it would be sufficient to show that the Lie derivative of Φ along the other null vector field n orthogonal to l, computed on the horizon is vanishing or more precisely $l^a l_a L_n \Phi|_{H^+} = 0$. On physical grounds one expects that to be the case, since otherwise there would be fluxes of scalar radiation across the horizon, a situation that is not expected to occur for a stationary state. Indeed we shall explicitly verify that expectation, by introducing a set of local regular across the horizon coordinates, and then studying the behavior of Φ near the vicinity of the horizon. In Ref. 1 we have explicitly constructed such a coordinate system, which, however, made use of Einstein field equations via the employment of Israel's formalism[29,30] as well as the hypersurface orthogonality of the timelike at infinity Killing vector field. For the present case, such construction it is not easily adaptable. However, in Ref. 1 we have also pointed out that one could have employed one of the regular on the horizon coordinate systems discussed in the work of Racz and Wald[31] (see also the account of Carter in Ref. 15). The Racz–Wald coordinate systems are rather advantageous, since their construction is solely based on the geometrical structure of the horizon and are being entirely independent upon the underlying field equations. For the present purpose we shall only make use of their generalized advanced Eddington–Filkenstein type coordinate system and for completeness purposes a brief outline of the basic steps involved in the construction of these coordinates will be presented.

Since by assumption the horizon admits topological spherical cross sections one can always consider a small open neighborhood A lying on an arbitrary but fixed here after section of the horizon. Introduce an arbitrary local coordinate patch x^i, $i=1, 2$ covering A and denote by A the portion of the horizon lying on the null geodesics intersecting A. Lie-drag x^i along the null generators piercing A and introduce further the Killing parameter u so that on the horizon $l = \partial/\partial u$ with $-\infty < u < \infty$ and $u=0$ on A. For any point p in A consider the other null vector n defined by $n^a l_a = -1$ and being orthogonal to other two coordinate basis vectors attached to x^i. By construction u, x^i is a local coordinate covering of A. Next, consider the null geodesics emanating from the horizon, with initial tangent n and introduce an affine parameter r along them so that $r=0$ on A. Lie-drag u, x^i along those geodesics thus locally extending u, x^i of A. By construction (u, r, x^i) is a local coordinate system covering a small space–time neighborhood of the horizon. This coordinate system for the obvious reasons is termed in Ref. 31 as a (local) Eddington–Filkenstein coordinate system. After glopalizing the construction over the entire cross section of the horizon the space–time metric in this neighborhood reads, $V^2 = -X_1 \cdot X_1$[31]

$$ds^2 = -V^2 du^2 + 2 du dr + 2 g_{ui} du dx^i + g_{ij} dx^i dx^j. \tag{12}$$

Relative to such system, near the horizon the timelike Killing field X_1 admits the following representation: $X_1 = \partial/\partial u$. It is worth pointing out that the so far the construction is valid irrespective of whether the orbits of l are incomplete or complete null geodesics and consequently this local Eddington–Filkenstein coordinate system is valid for any horizon. (Consequences of this observation will be discussed further below.) Note also that the field $n = -\partial/\partial r$ satisfies $n^a n_a = 0$ and on the horizon $l^a n_a = -1$.

Consider now the following null vector field:

$$\underline{l} = \frac{\partial}{\partial u} + \frac{1}{2} V^2 \frac{\partial}{\partial r}. \tag{13}$$

It is well defined near the horizon and smoothly reduces to the Killing field l on the horizon. Because Φ remains invariant along the orbits of the Killing field $X_1=\partial/\partial u$ one deduces that on and of the horizon

$$\overline{l}(\Phi)=\frac{1}{2}\,V^2\,\frac{\partial\Phi}{\partial r}. \tag{14}$$

As however the horizon is approached the left-hand side of the above equation is by itself vanishing, implying that on the horizon

$$V^2\,\frac{\partial\Phi}{\partial r}=-V^2n^a\,\frac{\partial\Phi}{\partial x^a}=-V^2L_n\Phi=0. \tag{15}$$

In view of those considerations we conclude that

$$\oint \Phi\nabla^a\Phi\, d\Sigma_a|_H=0. \tag{16}$$

Let us now shift considerations to the other boundary integral, i.e.,

$$I=\oint \Phi\nabla^a\Phi\, d\Sigma_a|_\infty\,. \tag{17}$$

We shall prove that its contribution is vanishing as well. To do so, we shall exploit the fact that any asymptotically flat black hole solution by definition is asymptotically flat at future null infinity J^+.[32] Using the existence of J^+, in principle we could have treated the above integral exactly in the same manner as its counterpart along H^+. In fact in the unphysical manifold i.e., the conformal completion of the physical space–time, (17) is an integral along J^+ taking between two specified smooth cross sections of J^+. The appropriate measure along J^+ is identical to that (10b) with suitable reinterpretation of the null fields l and n, respectively. One simply has to transform the integrand over the unphysical space–time and proceed with its computation. Equally well, however, we could compute I directly over the physical space–time. We shall pursue the second approach. To do so, we shall introduce first, Bondi coordinates,[33] (u,r,x^i) covering the asymptotic region between and around the two asymptotically null hypersurfaces (t_1,t_2). Bondi coordinates in the present discussion will play the analogous role that the generalized advanced Eddington–Filkenstein coordinate system played earlier on. By definition, $u=con$ is a family of null hypersurfaces ''intersecting'' J^+, r is an affine parameter along the null geodesics of the u spaces, and x^i parametrize the null geodesics, respectively. For an asymptotic at null infinity flat space–time and relative to those coordinates, the nonvanishing components of the physical metric are exhibiting the following asymptotic fall of rates[33]

$$g^{rr}=O(r),\quad g^{ri}=O(1),\quad g^{ij}=O(r^{-2}), \tag{18}$$

and by construction over the entire domain of validity of the Bondi chart, $g^{ur}=1$. On the other hand if by $l^m=g^{mn}(\partial u/\partial x^n)$ denote the future point tangent to outgoing null geodesics, then asymptotic flatness at J^+[34] demands

$$R_{mn}l^ml^n=O(r^{-4}). \tag{19}$$

From Eq. (1a) and after ignoring for the moment the irrelevant $1-\alpha\Phi^2$ factor, the above condition implies that asymptotically

$$L(\Phi)=4\left(l^m\,\frac{\partial\Phi}{\partial x^m}\right)^2-2\Phi l^ml^n\,\frac{\partial^2\Phi}{\partial x^m\partial x^n}=O(r^{-4}). \tag{20}$$

In deriving this expression, we are taking into account that the covariant components of the asymptotic metric in Bondi coordinates have the same form as in Eq. (12), and consequently

$l^m l^n \Gamma^a_{mn}(\partial\Phi/\partial x^a)=0$. Therefore, any solution of the wave Equation (1a) compatible with asymptotic flatness at null infinity must exhibit the following asymptotic behavior:[35]

$$\Phi = O(r^{-1}), \quad l^m \frac{\partial \Phi}{\partial x^m} = O(r^{-2}), \quad l^m l^n \frac{\partial^2 \Phi}{\partial x^m \partial x^n} = O(r^{-3}). \tag{21}$$

Relative to those asymptotic coordinates the integral (17) can be written as

$$I = \oint \Phi \nabla^a \Phi d\Sigma_a|_\infty = \lim \oint \Phi \nabla^a \Phi d\Sigma_a = \lim \oint \Phi g^{ab} \frac{\partial \Phi}{\partial x^a} n_b dV, \tag{22}$$

where the limit is understood as the affine parameter r tends to infinity. The integral is computed along an $r=$const timelike three surface with a spacelike outgoing pointing unit normal $n_a = \delta^r_a/(g^{rr})^{1/2}$ and $dV=\frac{1}{6}(-g)^{1/2}e_{abc}dx^a dx^b dx^c$ with $(-g)$ the determinant of the induced three metric on the $r=con$ hypersurface. Taking into account the quoted fall of rates in (18), and the fact $(-g)^{1/2}=O(r^2)$, when the the integral in (22) is computed and one passes to the limit of infinity affine distance, gets $I=0$.

From the discussion so far and with reference to integrals (10a), (16), and (17) one concludes that the field Φ is trivial outside the horizon. In turn this implies that all stationary-axisymmetric black hole solutions of theories (1a) and (1b) are Ricci flat. Appealing to well-known uniqueness theorems[36] for the Einstein vacuo equations we conclude that the space of stationary-axisymmetric black hole solutions of systems (1a) and (1b) is described by the familiar Kerr family.

Notice that as a byproduct of the fact that the generalized Eddington–Filkenstein coordinates are entirely independent of the value of the surface gravity of the horizon, the above discussion shows that the conformal system (modulo the boundenes property) does not admit static black holes possessing degenerate horizons,[37] a conclusion that was not covered in the approach of Ref. 1. The stationary sector contains extremal states, namely the maximally rotating Kerr states.

IV. DISCUSSION

It is clear from the above sections that the conformal system brings out challenges requiring additional work. Primarily the present work does not exclude the existence of stationary but not necessarily axisymmetric black hole states. As we have emphasized the employment and conclusions of Carter's work preassumes that one is working with the stationary-axisymmetric circular sector of the theory. It may be that the stationary, nonaxisymmetric sector is empty particularly in view of CT discussed in the Introduction. The new approach initiated by Chruściel[7,8] is inspiring and highly motivating. Are the actions predicted by CT necessarily circular? Can the CT theorem be adopted to the peculiarities of the conformal systems (1a) and (1b)? What are the consequences of the failure of the null convergence condition for the topological and metrical properties of black hole space–times? It may be that some of the questions raised are trivial but for the moment the answers are not known. Closely related to those issues is a quest for a better understanding of the nature of the domain of outer communication of black hole solutions of (1a) and (1b). In many of the so far established uniqueness theorems[36] considerations are restricted to black hole states where the stationary, timelike at infinity Killing field, remains timelike at the entire domain of outer communication and only becomes null at the boundary i.e., on the event horizon. This assumption also employed in the construction of the original uniqueness theorems for the Einstein–Maxwell case, although convenient, leaves open the possibility that there may exist black hole characterized by a nontrivial ergoregion entirely disconnected from the event horizon. For the case of the Einstein–Maxwell system, only very recently the work of Sudarsky and Wald[38] settled the issue. For the Einstein conformally invariant system or other systems that issue remains open.

Beyond the above considerations, one would also have had to consider the challenge posed by the Bekenstein solution.[2] Recall that this solution is an exact static, spherically symmetric, asymptotically flat solution of the Einstein conformally invariant system characterized by the property that the scalar field becomes unbounded on a regular horizon. Ignoring the fact that it is unstable, the solution was interpreted as a black hole. Recently, however, a critical examination of the unboundedness property of the scalar field has been carried out in Ref. 39. It was proven in Ref.

39 that the unboundedness property carries severe consequences. The Einstein field equations fail to be satisfied on the horizon and consequently the solution does not represent a genuine black hole. For the stationary case, proving in the last section that all stationary-axisymmetric circular states belong to the Kerr family, we have made use of the boundedness assumption of the scalar field on the horizon. Preliminary work indicates that unbounded fields on the rotating horizon leads to the same type of problems as for the nonrotating case. Those issues, however, will be discussed elsewhere.

In conclusion we may add that with the removal of the Bekenstein solution as a possible black hole, the present work on the conformal system combined with the work of other researchers on the Einstein scalar field system characterized by a variance of couplings (for minimal coupling see Refs. 40 and 41, for conformal,[1] arbitrary coupled[42,43] and for particular kind of self interaction[44–47]), strongly suggest that the following conjecture put forward in Ref. 39 appears to be correct: Spherical black holes cannot be endowed by (classical) scalar hair alone.

It has been completed, via the support of a Catedral Patrimonial administered by Conacyt-Mexico, and by a grant from Coordination-Cientifica of UMSNH. The author is thankful to the above institutions. Thanks are also due to Daniel Sudarsky for many discussions related to the content of Ref. 38.

APPENDIX A: ZEROS OF $1-a\Phi^2$ AND THE VALUES OF RICCI

In this Appendix we shall examine the following question. Suppose in an open neighborhood of a space–time point P, (g,Φ) is a singularity free solution of the Eqs. (1a) and (1b). Further suppose at P or more generally in a vicinity of P, the scalar field Φ satisfies: $1-a\Phi^2=0$. What then would Eqs. (1a) and (1b) tell us about the components of the Ricci tensor at P?

To address this question, let us first denote by S_{mn} the right-hand side of (1a) i.e., define S_{mn} by

$$S_{mn}=\alpha[4\nabla_m\Phi\nabla_n\Phi-2\Phi\nabla_m\nabla_n\Phi-g_{mn}\nabla^l\Phi\nabla_l\Phi]. \tag{A1}$$

The singularity free character of the geometry would then demand that the tensor S_{mn} must be vanishing at the point P. Accordingly the true value of $R_{mn}(P)$ would be determined via a limiting procedure. Such procedure would be sufficient for the determination of $R_{mn}(P)$, since by assumption the geometry is regular at P and consequently the components of the Ricci are minimally continuous at P provided they are expressed in a regular set of coordinates covering the vicinity of P. Relative to such setting, the components of the Ricci are obtained by first performing a covariant type Taylor series expansion of the tensor field S_{mn} and the scalar $1-a\Phi^2$. If for instance, the coordinates of P and a nearby point Q collectively are denoted by (x,y), respectively, and consider the geodesic joining the two (assuming it exists and is unique), then one may compute S_{mn} and $1-a\Phi^2$ at Q, take their ratio, and then the limit of the ratio, as Q is sliding along the geodesic towards P. In that manner

$$R_{mn}(P)=\lim\frac{S_{m'n'}(Q)}{1-a\Phi(Q)^2}, \tag{A2}$$

where the prime over the tensor indices signifies a tensor indices at the point Q. Formally one would then develops a power series for $S_{m'n'}(Q)$ and $1-a\Phi(Q)^2$, i.e., write

$$\delta^{m'}_m\delta^{n'}_n S_{m'n'}(Q)=A_{mn}+A_{mnl}\sigma^l+O(\sigma^l)^3, \tag{A3}$$

with a similar expression for the $1-a\Phi(Q)^2$. In above, $\sigma^m=\nabla^m\sigma(P,Q)$ where $\sigma(P,Q)$ is half of the square of the geodesic distance between Q,P and $\delta^{n'}_m$ is the bitensor of parallel transport.[48] The expansion coefficients can then computed by differentiating the series and take the coincidence limits.[48] The above procedure yields the value of Ricci, but it preassumes analyticity for both the space–time geometry and the scalar field Φ. Such assumption is unjustified. Even though

vacuum static or stationary solution of Einstein equation respect analyticity,[13] at least in the domain where the Killing field is timelike, it is not known whether the same property holds true for the nonvacuum case as for the present situation. Currently we have the question of analyticity of solutions of (1a) and (1b) under scrutiny and hope to come back.[14] We shall avoid the assumption of analyticity by resorting to a different method.

Writing the field Eq. (1a) in the form

$$(1-a\Phi^2)R_{mn}=S_{mn}, \tag{A4}$$

and covariantly differentiating both sides we obtain

$$-2a\Phi\nabla_k\Phi R_{mn}+(1-a\Phi^2)\nabla_k R_{mn}=\nabla_k S_{mn}. \tag{A5}$$

Evaluating the above equation at the points where $1-a\Phi^2=0$ one gets

$$-2a\Phi\nabla_k\Phi R_{mn}=\nabla_k S_{mn}. \tag{A6}$$

Assuming that the gradients of Φ are nonvanishing and contracting the above equation with $\nabla^k\Phi$ one gets after a trivial rearengement

$$\Phi R_{mn}=\nabla_m\nabla_n\Phi-\frac{\nabla^k\Phi}{\nabla^l\Phi\nabla_l\Phi}[2\nabla_k\nabla_m\Phi\nabla_n\Phi+2\nabla_k\nabla_n\Phi\nabla_m\Phi-\Phi\nabla_k\nabla_n\nabla_m\Phi-g_{mn}\nabla_k\nabla^a\Phi\nabla_a\Phi], \tag{A7}$$

which is the representation for the Ricci tensor given in the text.

APPENDIX B: DERIVATIVES OF Φ AND THE RIEMANN TENSOR

In this Appendix we shall manipulate further the third derivatives of the field Φ appearing in the right-hand side of Eq. (7) and shall give all the intermediate calculations leading to the derivation of Eq. (8). Let us begin with the term $\nabla_k\nabla_d\nabla_n\Phi$ and contract it with the ξ^n. Commuting the two covariant derivatives using the well-known identity: $\nabla_a\nabla_b A_c-\nabla_b\nabla_a A_c=R_{abc}{}^d A_d$ we obtain the following series of operations:

$$\begin{aligned}
\xi^n\nabla_k\nabla_d\nabla_n\Phi&=\xi^n\nabla_d\nabla_k\nabla_n\Phi-\xi^n R_{kd\rho n}\nabla^\rho\Phi\\
&=\nabla_d(\xi^n\nabla_k\nabla_n\Phi)-(\nabla_d\xi^n)\nabla_k\nabla_n\Phi-\xi^n R_{kd\rho n}\nabla^\rho\Phi\\
&=\nabla_d[\nabla_k(\xi^n\nabla_n\Phi)]-\nabla_d[(\nabla_k\xi_n)\nabla^n\Phi]-(\nabla_d\xi^n)\nabla_k\nabla_n\Phi-R_{kd\rho n}\nabla^\rho\Phi\xi^n\\
&=-\nabla_d[(\nabla_k\xi_n)\nabla^n\Phi]-(\nabla_d\xi_n)\nabla_k\nabla^n\Phi-R_{kd\rho n}\nabla^\rho\Phi\xi^n\\
&=-(\nabla_d\nabla_k\xi_n)\nabla^n\phi-(\nabla_k\xi_n)\nabla_d\nabla^n\Phi-(\nabla_d\xi_n)\nabla_k\nabla^n\Phi-\xi^n R_{kd\rho n}\nabla^\rho\Phi.
\end{aligned}$$

Using further the well-known identity valid for any Killing vector field

$$\nabla_d\nabla_k\xi_n=R_{ldkn}\xi^l,$$

we can eliminate the second derivatives of ξ at the expense of introducing the Riemann tensor. We then obtain

$$\xi^n\nabla_k\nabla_d\nabla_n\Phi=-R_{ldkn}\xi^l\nabla^n\Phi-(\nabla_k\xi_n)\nabla_d\nabla^n\Phi-(\nabla_d\xi_n)\nabla_k\nabla^n\Phi-\xi^n R_{kd\rho n}\nabla^\rho\Phi.$$

The contribution of the first Riemann tensor to Eq. (7) is vanishing since it is additionally contracted with $\nabla^k\Phi$. Therefore

$$\xi^n\nabla^k\Phi\nabla_k\nabla_d\nabla_n\Phi=-\nabla^k\Phi[(\nabla_k\xi_n)\nabla_d\nabla^n\Phi+(\nabla_d\xi_n)\nabla_k\nabla^n\Phi]-R_{kd\rho n}\nabla^\rho\Phi\nabla^k\Phi\xi^n,$$

which is the expression used in the text.

[9] Condition (c), i.e., the spherical like cross sections of the horizon, actually follows from other considerations of the CT. In particularly the CT assumes that the domain of outer communication is simply connected. Such property is guaranteed as long as the Ricci tensor satisfies the null convergence condition, and additionally the null infinity satisfies some additional conditions referred as regularity conditions (or some equivalent version as those for example spell out in the Ref. 10 below.) As a byproduct of the satisfaction of the null convergence condition and regularity of the null infinity it then follows that the event horizon necessarily possess spherical like cross sections. For a proof see P. T. Chruściel and R. M. Wald in Ref. 6 above as well as the following Ref. 10.

[16] B. Carter, in *Gravitation in Astrophysics*, edited by B. Carter and J. B. Hartle (Kluwer, Gargese, 1986).
[17] The construction of $\langle\langle M\rangle\rangle$ used in Carter's work is to be contrasted with the corresponding definitions in Refs. 7 and 8. Chruściel makes heavy use of the concept of completeness of trajectories of the asymptotically timelike Killing vector field.
[18] There is no loss of generality in imposing the commuting property of the two actions. The justification for this can be found in B. Carter, Commun. Math. Phys. **17**, 233 (1970), In fact a slightly more general conclusion can be drawn whenever axisymmetry action is replaced by the closely related but not identical concept of cyclic symmetry. See, for instance, discussion in the following Ref. 19.
[19] L. B. Szabados, J. Math. Phys. **28**, 2688 (1987).
[20] B. Carter, J. Math. Phys. **10**, 70 (1969).
[21] Even though considerations in the present section are restricted to the conformal coupling, i.e., for $\alpha=k/6$, the same calculations of the present section can be repeated for the case whenever an arbitrary coupling of the scalar field Φ to the background scalar curvature is considered. For such arbitrary coupling one finds $\alpha=\xi k$ with ξ a real parameter and the structure of the field Eqs. (1a) and (1b) remain the same although numerical coefficients will be altered. The inclusion of an arbitrary potential $V(\Phi)$ adds a term $g_{mn}V(\Phi)$ to the right-hand side of (1a).
[22] R. M. Wald, *General Relativity* (Chicago University Press, Chicago, 1984).
[23] In the case where the gradient of Φ is also identically vanishing one can still apply the method of the Appendix A to compute the Ricci tensor. In such event Eq. (A4) of Appendix A is differentiated twice, and one follows the same steps leading to (A7). Note in that event, the resulting Ricci contains fourth-order derivatives of the field Φ.
[24] In the case of vanishing gradients, even though the resulting form of Eq. (9) is more complex it nevertheless maintains similar structure. An inhomogeneous term is also appearing.
[25] In this regard it is of interest to repeat the calculations for arbitrary coupling of the scalar field Φ to scalar curvature. In this case one expects, if ξ is chosen to be negative circularity ought to hold although this has to be verified by detailed computations.
[26] A more extensive discussion about this transformation can be found in J. D. Bekenstein in Ref. 2; B. C. Xanthopoulos and A. Dialynas in Ref. 2; T. Zannias in Ref. 1. We may parenthetically add here that because of this property of the Einstein conformal system, asymptotically flat nonsingular initial should exist, possessing positive ADM mass and timelike four momenta.
[27] We could have assumed that those hypersurfaces merely intersect null infinity. Their asymptotic identification to some retarded time coordinates simply makes the evaluation of integral of Eq. (17) cited below an easier task.
[28] Although we are working in the physical space–time occasionally we shall use terminology associated with the conformal completion of the physical space–time.
[29] W. Israel, Phys. Rev. **164**, 1776 (1967).
[30] W. Israel, Commun. Math. Phys. **8**, 245 (1968).
[31] I. Racz and R. M. Wald, Class. Quantum Grav. **9**, 2643 (1992).
[32] Although there exist diverse definitions of asymptotic flatness at null infinity (see for instance discussion in Chap. 11 of Walds book, Ref. 12) nevertheless all proposed definitions agree on the existence of a smooth null hypersurface J^+ constituting part of the space–time ''boundary.'' In the present context asymptotic flatness implies the existence of J^+. In turn for nonvacuum spaces that requires, besides the peeling property of the Weyl tensor, certain asymptotic fall of rates for the Ricci and scalar curvature. For a relevant discussion consult Refs. 33 and 34 below.
[33] See, for instance, E. Newman and R. Penrose, J. Math. Phys. **5**, 566 (1962).
[34] For a discussion concerning the asymptotic decay of the curvature for a vacuo, asymptotically flat at null infinity space

see Ref. 33, while for electrovac, or general arbitrary nonvacuo space–times consult the following Ref., respectively; A. R. Exton, E. Newman, and R. Penrose, J. Math. Phys. **10**, 1566 (1969); G. Ludwig, Gen. Relativ. Gravit. **7**, 293 (1976).

[35] One source of concern is the possible existence of solutions f of the wave equation satisfying additionally $L(f)=0$ and exhibiting fall of rates of the form $f=O(r^a)$ with a in general nonvanishing positive or negative exponent. If such solutions exist, then due to the nonlinear structure of the operator L there may exists combinations of the form $\Phi=f+\phi$ with ϕ fulfilling the asymptotic conditions (21), so that that $L(f+\phi)=O(r^{-4})$. In such an event the integral (17) may not be vanishing. However, such possibility cannot occur. One can easily show that all f satisfying $L(f)=0$ have the form: $f=1/[K_0(x^i)-K_1(x^i)r]$ with $K_a(x^i)$ $a=0,1$ arbitrary integration ''functions.'' A superposition then of the form $\Phi=f+\phi$ satisfies (21). The trivial combination $\Phi=1/K_0(x^i)+\phi$ is not compatible with (19) unless $1/K_0(x^i)=0$.

Integrable discretizations of the Euler top

A. I. Bobenko,[a] B. Lorbeer,[b] and Yu. B. Suris[c]
Fachbereich Mathematik, Technische Universität Berlin,
Str. 17 Juni 135, 10623 Berlin, Germany

(Received 15 June 1998; accepted for publication 17 July 1998)

Discretizations of the Euler top sharing the integrals of motion with the continuous time system are studied. Those of them which are also Poisson with respect to the invariant Poisson bracket of the Euler top are characterized. For all these Poisson discretizations a solution in terms of elliptic functions is found, allowing a direct comparison with the continuous time case. We demonstrate that the Veselov–Moser discretization also belongs to our family, and apply our methods to this particular example. © *1998 American Institute of Physics.*

I. INTRODUCTION

The subject of integrable discretizations of integrable dynamical systems is slightly more than twenty years old. During the first decade of its existence several different approaches were proposed for discretizing soliton equations,[1–5] but neither of them dealt with integrable systems of the classical mechanics. The first examples in this important subarea seem to appear about ten years ago.[6,7] Veselov's paper contained discrete time versions of such classical integrable systems as the Euler case of the rigid body motion and the Neumann system. The algebraic construction behind these examples was later elaborated in more detail in Ref. 8. However, the nature of these exceptionally beautiful examples remains somewhat mysterious. They still resist being included in any of the existing general frameworks for integrable discretizations (cf. Ref. 9). The origin of the Veselov–Moser discretizations, their place in the corresponding continuous time hierarchies, their relations to other existing examples, and several further points remain to be clarified. The problem of comparing the explicit solutions found in Refs. 6–8 with the classical continuous time counterparts was also left open (despite the fact that on the level of equations of motion the continuous limit is easy to perform).

The present work may be considered as a sort of extensive comment on Refs. 6 and 8 in the part concerned with the Euler top. We do not close all the open problems mentioned above, but we do hope to bring some light into some of them. In particular, we find formulas for the solution of the discrete time Euler top in the form which makes the comparison with the continuous time case immediate. Moreover, the Veselov–Moser system turns out to be by no means the only reasonable discretization of the Euler top. We introduce a whole family of discretizations sharing integrals of motion with the continuous time system, and characterize those of them which share also the underlying invariant Poisson structure. In this context the Veselov–Moser system becomes just one particular case, and not the most simple one.

It has to be mentioned that, unlike Refs. 6 and 8, our procedure for obtaining explicit solutions is rather pedestrian; it does not use such advanced tools as spectral theory of difference operators[6] or Baker–Akhiezer functions.[8] Actually, our construction is based on the addition formulas for elliptic functions, and could have been invented by Jacobi. However, as a heuristic tool for finding it we used the Lax representation of the Euler top in su(2) with a spectral parameter on an elliptic curve, which was certainly unknown in the times of Euler and Jacobi.

II. THE EULER TOP

The famous Euler's equations describing the motion of a rigid body with the fixed center of mass (Euler top) read[10]

$$\begin{aligned}\dot{M}_1&=\left(\frac{1}{B}-\frac{1}{C}\right)M_2M_3,\\ \dot{M}_2&=\left(\frac{1}{C}-\frac{1}{A}\right)M_3M_1,\\ \dot{M}_3&=\left(\frac{1}{A}-\frac{1}{B}\right)M_1M_2.\end{aligned}\tag{1}$$

Here $\mathbf{M}=(M_1,M_2,M_3)^T$ is the kinetic momentum vector in the coordinate system attached firmly to the body; the axes of this system coincide with the principal axes of inertia, and the numbers $A,B,C>0$ are the corresponding moments of inertia.

The vector form of the equations (1) is

$$\dot{\mathbf{M}}=\mathbf{M}\times\boldsymbol{\Omega}(\mathbf{M}),\tag{2}$$

where the vector of the angular velocity is introduced:

$$\boldsymbol{\Omega}(\mathbf{M})=\left(\frac{M_1}{A},\frac{M_2}{B},\frac{M_3}{C}\right)^T.\tag{3}$$

The equations (1) are Hamiltonian with respect to the following Poisson bracket on $\mathbb{R}^3(\mathbf{M})$:

$$\{M_1,M_2\}=M_3,\quad \{M_2,M_3\}=M_1,\quad \{M_3,M_1\}=M_2,\tag{4}$$

with the Hamilton function $H(\mathbf{M})=E(\mathbf{M})/2$, where

$$E(\mathbf{M})=\frac{M_1^2}{A}+\frac{M_2^2}{B}+\frac{M_3^2}{C}.\tag{5}$$

The bracket (4) is degenerate and has one Casimir function,

$$M^2(\mathbf{M})=M_1^2+M_2^2+M_3^2.\tag{6}$$

Generic symplectic leaves of the bracket (4) are two-dimensional spheres $M^2(\mathbf{M})=\text{const}$, hence each system Hamiltonian with respect to this bracket is integrable in the Liouville–Arnold sense; in particular, the Euler top is integrable.

An explicit solution to the equations (1) can be given in terms of the Jacobi elliptic functions.[10] Suppose for the sake of definiteness that

$$A>B>C>0,\tag{7}$$

then

$$\frac{1}{A}\leqslant\frac{E}{M^2}\leqslant\frac{1}{C}.$$

The formulas for the solution look different depending on whether this quantity is greater or smaller than $1/B$:

$$M_1(t)=a\begin{Bmatrix}\operatorname{cn}\nu(t-t_0)\\ \operatorname{dn}\nu(t-t_0)\end{Bmatrix},\quad M_2(t)=b\operatorname{sn}\nu(t-t_0),\quad M_3(t)=c\begin{Bmatrix}\operatorname{dn}\nu(t-t_0)\\ \operatorname{cn}\nu(t-t_0)\end{Bmatrix}.\tag{8}$$

Here and below in similar situations the upper expressions in curly brackets refer to the case $1/B<E/M^2\leqslant 1/C$, while the lower ones refer to the case $1/A\leqslant E/M^2<1/B$. The module k of the elliptic functions in (8) is given by

$$k^2=\left\{\begin{array}{l}\dfrac{(A-B)(M^2-CE)}{(B-C)(AE-M^2)}\\[2ex]\dfrac{(B-C)(AE-M^2)}{(A-B)(M^2-CE)}\end{array}\right\},\tag{9}$$

so that we always have $0<k^2<1$. The coefficients a,b,c are defined by

$$a^2=A\frac{M^2-CE}{A-C},\quad b^2=\left\{\begin{array}{l}B\dfrac{M^2-CE}{B-C}\\[2ex]B\dfrac{AE-M^2}{A-B}\end{array}\right\},\quad c^2=C\frac{AE-M^2}{A-C}.\tag{10}$$

Finally, the frequency ν is given by

$$\nu^2=\left\{\begin{array}{l}\dfrac{(B-C)(AE-M^2)}{ABC}\\[2ex]\dfrac{(A-B)(M^2-CE)}{ABC}\end{array}\right\}.\tag{11}$$

In the case $E/M^2=1/B$ the elliptic functions degenerate to the hyperbolic ones, and we have

$$M_1(t)=\frac{a}{\cosh\nu(t-t_0)},\quad M_2(t)=b\tanh\nu(t-t_0),\quad M_3(t)=\frac{c}{\cosh\nu(t-t_0)},$$

where

$$a^2=\frac{A(B-C)}{B(A-C)}M^2,\quad b^2=M^2,\quad c^2=\frac{C(A-B)}{B(A-C)}M^2,$$

and

$$\nu^2=\frac{(A-B)(B-C)}{AB^2C}M^2.$$

In all three cases the numbers a,b,c,ν satisfy the condition $abc\nu>0$. In what follows, we shall denote by $\nu(M^2,E)$ the positive square root of the function given in (11), and hence we must have $abc>0$.

III. DISCRETIZATIONS

Our aim here is to find *integrable discretizations* of the Euler top.

Definition 1: An integrable discretization of the Euler top (2) is a one-parameter family of diffeomorphisms $F\colon \mathbb{R}^3\times[0,\epsilon)\mapsto\mathbb{R}^3$,

$$\hat{\mathbf{M}}=F(\mathbf{M},h),\tag{12}$$

such that each one of them $F(\cdot,h)\colon \mathbb{R}^3\mapsto\mathbb{R}^3$ *is Poisson with respect to the bracket* (4), *has two integrals of motion* M^2 *and* E, *i.e.,*

$$M^2(F(\mathbf{M},h))=M^2(\mathbf{M}),\quad E(F(\mathbf{M},h))=E(\mathbf{M}),\tag{13}$$

and the following asymptotics hold:

$$F(\mathbf{M},h)=\mathbf{M}+h\mathbf{M}\times\boldsymbol{\Omega}(\mathbf{M})+o(h),\quad h\to 0. \tag{14}$$

Actually, our maps always will be defined by *implicit* equations of motion:

$$\hat{\mathbf{M}}-\mathbf{M}=hf(\mathbf{M},\hat{\mathbf{M}},h). \tag{15}$$

Proposition 1: Let $f\colon \mathbb{R}^3\times\mathbb{R}^3\times[0,\epsilon)\mapsto\mathbb{R}^3$ *be a* C^1*-function in each argument such that*

$$f(\mathbf{M},\mathbf{M},0)=\mathbf{M}\times\boldsymbol{\Omega}(\mathbf{M}).$$

Then for h small enough the equation (15) defines a local diffeomorphism (12) satisfying (14).

Proof: This follows immediately from the implicit function theorem for all h satisfying $\det(I-h\partial f/\partial\hat{\mathbf{M}})\neq 0$, i.e., for all h small enough. ■

When speaking about discretizations, it is natural to think about $\mathbf{M}$ in (12) as about sequences $\mathbf{M}_m\colon\mathbb{Z}\mapsto\mathbb{R}^3$ approximating solutions $\mathbf{M}(t)\colon\mathbb{R}\mapsto\mathbb{R}^3$ of the Euler top (2) in the sense that $\mathbf{M}_m\approx\mathbf{M}(mh)$. In this context the formula (12) takes the form of the difference equation,

$$\mathbf{M}_{m+1}=F(\mathbf{M}_m,h),$$

and, similarly, the formula (15) has to be thought of as

$$\mathbf{M}_{m+1}-\mathbf{M}_m=hf(\mathbf{M}_m,\mathbf{M}_{m+1},h).$$

The approximation property $\mathbf{M}_m=\mathbf{M}(mh)+O(h)$ holds on finite time intervals and is assured by (14) (this is a standard fact from the numerical analysis).

IV. ELLIPTIC COORDINATES AND POISSON DISCRETIZATIONS

Now we would like to find a manageable criterium for a map (12) to be Poisson with respect to the bracket (4). The corresponding statement becomes rather transparent in a new coordinate system in $\mathbb{R}^3(\mathbf{M})$. The corresponding change of variables,

$$\Phi\colon(M^2,E,\varphi)\mapsto(M_1,M_2,M_3),$$

is suggested by the formulas (8) for a solution of the Euler top. In the above formula $(M_1,M_2,M_3)\in\mathbb{R}^3$, and $(M^2,E,\varphi)\in\mathbb{R}_+\times\mathbb{R}_+\times\mathbb{T}$, where $\mathbb{T}=\mathbb{R}/(4K\mathbb{Z})$, and $K=K(k^2)$ is the full elliptic integral of the first kind corresponding to the value of k^2 given in (9). The formulas for Φ are different in two regions of $\mathbb{R}^3$ separated by the two planes:

$$\frac{E(\mathbf{M})}{M^2(\mathbf{M})}=\frac{1}{B}\quad\Leftrightarrow\quad\left(\frac{1}{B}-\frac{1}{A}\right)M_1^2=\left(\frac{1}{C}-\frac{1}{B}\right)M_3^2. \tag{16}$$

Each one of the sets $\{E(\mathbf{M})/M^2(\mathbf{M})>1/B\}$ and $\{E(\mathbf{M})/M^2(\mathbf{M})<1/B\}$ consists of two sectors, and each one of these sectors is bounded by two half-planes.

The *elliptic coordinates* in $\mathbb{R}^3(\mathbf{M})$ are introduced by

$$M_1=a\begin{Bmatrix}\operatorname{cn}\varphi\\ \operatorname{dn}\varphi\end{Bmatrix},\quad M_2=b\operatorname{sn}\varphi,\quad M_3=c\begin{Bmatrix}\operatorname{dn}\varphi\\ \operatorname{cn}\varphi\end{Bmatrix}, \tag{17}$$

with a,b,c given by (10), and the modulus k^2 of the elliptic functions given by (9). On the subset $\{E/M^2>1/B\}$ the sign of c coincides with the sign of M_3 (which is constant in each one of two sectors), and the signs of a,b satisfy the condition $\operatorname{sign}(ab)=\operatorname{sign}(c)$. Similarly, on the subset $\{E(\mathbf{M})/M^2(\mathbf{M})<1/B\}$ the sign of a coincides with the sign of M_1, while the signs of b,c satisfy $\operatorname{sign}(bc)=\operatorname{sign}(a)$. Finally, on the four half-planes described by (16) the elliptic coordinates are defined by continuity according to

FIG. 1. Different energy levels for constant M^2.

$$M_1=\frac{a}{\cosh\varphi},\quad M_2=b\tanh\varphi,\quad M_3=\frac{c}{\cosh\varphi},$$

the signs of a,c being the same as the signs of M_1,M_3, respectively, and $\operatorname{sign}(b)=\operatorname{sign}(ac)$.

Proposition 2: The formulas (17) define a valid change of variables (a local diffeomorphism) near each point of $\mathbb{R}^3$ *(see Fig. 1).*

Proof: It can be verified by a direct calculation that in the region $\{E(\mathbf{M})/M^2(\mathbf{M})\neq 1/B\}$ we have

$$\frac{\partial(M_1,M_2,M_3)}{\partial(M^2,E,\varphi)}=-\frac{1}{4\nu(M^2,E)}\operatorname{dn}^2\varphi\neq 0,$$

and that the partial derivatives of which this Jacobian is composed allow a continuation to the boundary $\{E(\mathbf{M})/M^2(\mathbf{M})=1/B\}$. ■

Now it is obvious that an arbitrary map (12) having two integrals of motion $M^2(\mathbf{M})$ and $E(\mathbf{M})$, can be cast, in the elliptic coordinates (M^2,E,φ), in the form

$$\hat{M}^2=M^2,\quad \hat{E}=E,\quad \hat{\varphi}=\hat{\varphi}(M^2,E,\varphi). \tag{18}$$

Proposition 3: The map (12) having two integrals of motion $M^2(\mathbf{M})$ *and* $E(\mathbf{M})$ *is Poisson with respect to the bracket (4) if in the elliptic coordinates* (M^2,E,φ) *it takes the form*

$$\hat{M}^2=M^2,\quad \hat{E}=E,\quad \hat{\varphi}=\varphi+g(M^2,E), \tag{19}$$

with the function g not depending on φ.

Proof: To prove this statement, we have to calculate the Poisson bracket (4) in the coordinates (M^2,E,φ). The corresponding formulas read:

$$\{M^2,E\}=\{M^2,\varphi\}=0,\quad \{E,\varphi\}=-2\nu(M^2,E). \tag{20}$$

Indeed, the function M^2 is a Casimir function, hence it Poisson commutes with both E and φ. To calculate the bracket $\{E,\varphi\}$, we substitute (away from the boundary $E/M^2=1/B$) the expressions (17) into an arbitrary one of the formulas (4), and after straightforward calculations arrive at the expression given above.

Actually, the concrete expression for $\{E,\varphi\}$ is not essential for the proof of our proposition. The only important thing is that this Poisson bracket does not depend on φ. Indeed, we have

$$\{\hat{E},\hat{\varphi}\}=\frac{\partial\hat{\varphi}}{\partial\varphi}\{E,\varphi\}.$$

Since the Poisson bracket $\{E,\varphi\}$ depends only on M^2,E which are integrals of motion, we see that the necessary and sufficient condition for our map to be Poisson reads as $\partial\hat{\varphi}/\partial\varphi=1$, which is equivalent to the last equation in (19). ■

V. SPECIAL DISCRETIZATIONS

We derive now a family of discretizations of the Euler top. Our derivation is based on a Lax representation with a spectral parameter for the Euler top. We prefer to work with a su(2) Lax representation, since our experience in discretizing various geometric structures (see, for example, Ref. 11) convinced us that this procedure may be performed most straightforwardly when applied to su(2) Lax formulations.

To find a suitable Lax representation for the Euler top, we use a stationary version of the Lax representation of the chiral field model due to Cherednik.[12] Set

$$M(u)=\frac{1}{2i}\sum_{k=1}^{3} M_k w_k(u)\sigma_k, \tag{21}$$

where $\sigma_k\,(k=1,2,3)$ are the Pauli matrices, and $w_k(u)$ are the following elliptic functions:

$$w_1(u)=\rho\frac{1}{\mathrm{sn}(u,\kappa)},\quad w_2(u)=\rho\frac{\mathrm{dn}(u,\kappa)}{\mathrm{sn}(u,\kappa)},\quad w_3(u)=\rho\frac{\mathrm{cn}(u,\kappa)}{\mathrm{sn}(u,\kappa)}. \tag{22}$$

Here the parameter ρ and the module κ of the elliptic functions are defined by

$$\rho^2=\frac{A-C}{AC},\quad \kappa^2=\frac{C(A-B)}{B(A-C)}. \tag{23}$$

Further, for a vector $\mathbf{V}=(V_1,V_2,V_3)^{\mathrm{T}}\in\mathbb{R}^3$ set

$$V(u)=\frac{1}{2i}\sum_{k=1}^{3} V_k w_k(u-u_0)\sigma_k, \tag{24}$$

where the point u_0 is chosen so that

$$w_1(u_0)=A^{-1/2},\quad w_2(u_0)=B^{-1/2},\quad w_3(u_0)=C^{-1/2}. \tag{25}$$

Consider now the Lax equation,

$$\dot{M}(u)=[M(u),V(u)]. \tag{26}$$

With the help of identities

$$w_j(u)w_k(u-u_0)=w_j(u_0)w_l(u-u_0)-w_k(u_0)w_l(u), \tag{27}$$

where (j,k,l) is a permutation of (1,2,3), one sees that the matrix equation (26) is equivalent to the set of the following two equations:

$$\dot{\mathbf{M}}=\mathbf{M}\times\boldsymbol{\Omega}^{1/2}(\mathbf{V}), \tag{28}$$

$$0=\mathbf{V}\times\boldsymbol{\Omega}^{1/2}(\mathbf{M}). \tag{29}$$

Here the second equation is equivalent to $\mathbf{V}=\gamma\,\boldsymbol{\Omega}^{1/2}(\mathbf{M})$ with some $\gamma\in\mathbb{R}$, which, being substituted in the first equation, results in

$$\dot{\mathbf{M}}=\gamma\,\mathbf{M}\times\boldsymbol{\Omega}(\mathbf{M}). \tag{30}$$

Obviously, for a nonvanishing function $\gamma=\gamma(t)$ the latter equation is nothing but a time reparametrization of the Euler top (2). In this sense (26) is a Lax representation of the Euler top.

Discretizing the above construction in time, we introduce the matrix

$$\mathcal{V}(u)=I+\frac{h}{2i}\sum_{k=1}^{3} V_k w_k(u-u_0)\sigma_k, \tag{31}$$

and consider instead of (26) the discrete time Lax equation

$$\hat{M}(u)=\mathcal{V}^{-1}(u)M(u)\mathcal{V}(u). \tag{32}$$

(this equation may be interpreted as a stationary version of the lattice chiral field model by Ref. 13). Representing the latter equation as $\mathcal{V}(u)\hat{M}(u)=M(u)\mathcal{V}(u)$ and using the identities (27), we find that our matrix equation is equivalent to the set of the following three equations:

$$\hat{\mathbf{M}}-\mathbf{M}=\frac{h}{2}(\mathbf{M}+\hat{\mathbf{M}})\times\boldsymbol{\Omega}^{1/2}(\mathbf{V}), \tag{33}$$

$$0=\mathbf{V}\times\boldsymbol{\Omega}^{1/2}(\mathbf{M}+\hat{\mathbf{M}}), \tag{34}$$

and

$$\sum_{k=1}^{3}(\hat{M}_k-M_k)V_k w_k(u)w_k(u-u_0)=0. \tag{35}$$

Now (34) is equivalent to

$$\mathbf{V}=\tfrac{1}{2}\gamma\,\boldsymbol{\Omega}^{1/2}(\mathbf{M}+\hat{\mathbf{M}}), \tag{36}$$

with some $\gamma\in\mathbb{R}$, which, being substituted in (33), results in

$$\hat{\mathbf{M}}-\mathbf{M}=\tfrac{1}{4}h\gamma\,(\mathbf{M}+\hat{\mathbf{M}})\times\boldsymbol{\Omega}(\mathbf{M}+\hat{\mathbf{M}}). \tag{37}$$

It remains to notice that, plugging (36), (37) into (35), we bring the latter equation to the form

$$\sum_{k=1}^{3}w_k(u)w_k(u-u_0)w_k(u_0)(w_l^2(u_0)-w_j^2(u_0))=0,$$

which is automatically satisfied due to the identity

$$w_l(u)w_l(u-u_0)w_j(u_0)-w_j(u)w_j(u-u_0)w_l(u_0)=w_k(u_0)(w_l(u_0)-w_j(u_0)). \tag{38}$$

So, the matrix equation (32) is equivalent to (37) with some $\gamma\in\mathbb{R}$, the vector $\mathbf{V}$ being given by (36).

However, the equation (37) does not completely define the discretization due to arbitrariness of γ. In what follows we shall consider this equation with γ being a certain fixed function on $\mathbf{M}$, $\hat{\mathbf{M}}$. In other words, the subject of our further investigations will consist of discretizations governed by implicit equations of motion of the following special form:

$$\hat{\mathbf{M}}-\mathbf{M}=\tfrac{1}{4}h\gamma(\mathbf{M},\hat{\mathbf{M}},h)\,(\mathbf{M}+\hat{\mathbf{M}})\times\boldsymbol{\Omega}(\mathbf{M}+\hat{\mathbf{M}}). \tag{39}$$

We call them *special discretizations*. It is obvious that if

$$\gamma\colon \mathbb{R}^3\times\mathbb{R}^3\times[0,\epsilon)\mapsto\mathbb{R}_+$$

is a C^1–function of each argument satisfying

$$\gamma(\mathbf{M},\mathbf{M},0)=1, \tag{40}$$

then the equation (39) fulfills the conditions of Proposition 1, and therefore defines a map (12).

In components, special discretizations may be presented as

$$\hat{M}_1-M_1=\frac{1}{4}h\gamma(\mathbf{M},\hat{\mathbf{M}},h)\left(\frac{1}{B}-\frac{1}{C}\right)(M_2+\hat{M}_2)(M_3+\hat{M}_3), \tag{41}$$

$$\hat{M}_2 - M_2 = \frac{1}{4} h \gamma(\mathbf{M}, \hat{\mathbf{M}}, h) \left(\frac{1}{C} - \frac{1}{A} \right) (M_3 + \hat{M}_3)(M_1 + \hat{M}_1), \tag{42}$$

$$\hat{M}_3 - M_3 = \frac{1}{4} h \gamma(\mathbf{M}, \hat{\mathbf{M}}, h) \left(\frac{1}{A} - \frac{1}{B} \right) (M_1 + \hat{M}_1)(M_2 + \hat{M}_2). \tag{43}$$

VI. POISSON PROPERTY OF SPECIAL DISCRETIZATIONS [ ]

We investigate now the integrability properties of special discretizations (which are naturally expected due to the existence of a Lax representation with a spectral parameter).

Proposition 4: Maps defined by equations of motion (39) possess $M^2(\mathbf{M})$ *and* $E(\mathbf{M})$ *as integrals of motion.*

Proof: It follows from (39) that

$$\langle \hat{\mathbf{M}} - \mathbf{M}, \mathbf{M} + \hat{\mathbf{M}} \rangle = 0 \quad \text{and} \quad \langle \hat{\mathbf{M}} - \mathbf{M}, \mathbf{\Omega}(\mathbf{M} + \hat{\mathbf{M}}) \rangle = 0, \tag{44}$$

or, equivalently,

$$\langle \hat{\mathbf{M}}, \hat{\mathbf{M}} \rangle = \langle \mathbf{M}, \mathbf{M} \rangle \quad \text{and} \quad \langle \hat{\mathbf{M}}, \mathbf{\Omega}(\hat{\mathbf{M}}) \rangle = \langle \mathbf{M}, \mathbf{\Omega}(\mathbf{M}) \rangle. \tag{45}$$

This proves our statement. ■

Actually, this statement can be almost inverted. Namely, consider an arbitrary discretization having $M^2(\mathbf{M})$ and $E(\mathbf{M})$ as integrals of motion. Then the pairs $(\mathbf{M}, \hat{\mathbf{M}})$ satisfy (45), which is equivalent to (44). If, in addition, $(\mathbf{M} + \hat{\mathbf{M}}) \times \mathbf{\Omega}(\mathbf{M} + \hat{\mathbf{M}}) \neq 0$, then there exists a real number $\gamma = \gamma(\mathbf{M}, \hat{\mathbf{M}})$ such that (39) holds.

In what follows we shall also need the following technical and obvious statement.

Lemma 1: The set of fixed points of the maps (12) defined by (39) coincides with the set of the points $\mathbf{M}$ *for which* $(\mathbf{M} + \hat{\mathbf{M}}) \times \mathbf{\Omega}(\mathbf{M} + \hat{\mathbf{M}}) = 0$*, and this coincides with the union of the coordinate axes,*

$$\{M_1 = M_2 = 0\} \cup \{M_2 = M_3 = 0\} \cup \{M_3 = M_1 = 0\}.$$

For all other points $\mathbf{M}$*, at least two of the three expressions* $M_1 + \hat{M}_1$*,* $M_2 + \hat{M}_2$*,* $M_3 + \hat{M}_3$ *do not vanish.*

Now we find conditions for a map defined by (39) to be Poisson. To this end notice that the pairs $(\mathbf{M}, \hat{\mathbf{M}}) = (\mathbf{M}, F(\mathbf{M}, h))$ belong to the subset of $\mathbb{R}^3(\mathbf{M}) \times \mathbb{R}^3(\hat{\mathbf{M}})$ singled out by the conditions $M^2(\mathbf{M}) = M^2(\hat{\mathbf{M}})$ and $E(\mathbf{M}) = E(\hat{\mathbf{M}})$. The elements of this subset may be parametrized by the quadruples $(M^2, E, \varphi, \hat{\varphi})$ according to

$$\mathbf{M} = \left(a \begin{Bmatrix} \operatorname{cn} \varphi \\ \operatorname{dn} \varphi \end{Bmatrix}, \; b \operatorname{sn} \varphi, \; c \begin{Bmatrix} \operatorname{dn} \varphi \\ \operatorname{cn} \varphi \end{Bmatrix} \right), \tag{46}$$

$$\hat{\mathbf{M}} = \left(a \begin{Bmatrix} \operatorname{cn} \hat{\varphi} \\ \operatorname{dn} \hat{\varphi} \end{Bmatrix}, \; b \operatorname{sn} \hat{\varphi}, \; c \begin{Bmatrix} \operatorname{dn} \hat{\varphi} \\ \operatorname{cn} \hat{\varphi} \end{Bmatrix} \right). \tag{47}$$

Equivalently, we can use the following coordinates: $(M^2, E, \overline{\varphi}, \Delta\varphi)$, where

$$\overline{\varphi} = \frac{\varphi + \hat{\varphi}}{2}, \quad \Delta\varphi = \frac{\hat{\varphi} - \varphi}{2}. \tag{48}$$

Let us denote from the above mentioned subset that

$$\gamma(\mathbf{M}, \hat{\mathbf{M}}, h) = \Gamma(M^2, E, \overline{\varphi}, \Delta\varphi, h). \tag{49}$$

Theorem 1: *The equations of motion of the special discretization (39) in the elliptic coordinates* (M^2,E,φ) *have the form (18), where the function* $\hat{\varphi}(M^2,E,\varphi,h)$ *is implicitly defined by the equation*

$$\frac{\Gamma(M^2,E,\overline{\varphi},\Delta\varphi,h)}{1-k^2\mathrm{sn}^2(\overline{\varphi})\mathrm{sn}^2(\Delta\varphi)}=\frac{2}{h\,\nu(M^2,E)}\frac{\mathrm{sn}(\Delta\varphi)}{\mathrm{cn}(\Delta\varphi)\mathrm{dn}(\Delta\varphi)}. \tag{50}$$

The map defined by (39) is Poisson, iff the equation (50) may be solved for $\Delta\varphi$ *as*

$$\Delta\varphi=\delta(M^2,E,h)=\frac{h\,\nu(M^2,E)}{2}(1+O(h)), \tag{51}$$

with the function δ *not depending on* $\overline{\varphi}$.

Proof: Denoting

$$D=D(M^2,E,\overline{\varphi},\Delta\varphi)=1-k^2\mathrm{sn}^2(\overline{\varphi})\mathrm{sn}^2(\Delta\varphi), \tag{52}$$

we find from (46), (47) with the help of addition formulas for elliptic functions:

$$\hat{M}_1-M_1=-\frac{2a}{D}\begin{Bmatrix}\mathrm{sn}(\overline{\varphi})\mathrm{dn}(\overline{\varphi})\mathrm{sn}(\Delta\varphi)\mathrm{dn}(\Delta\varphi)\\ k^2\mathrm{sn}(\overline{\varphi})\mathrm{cn}(\overline{\varphi})\mathrm{sn}(\Delta\varphi)\mathrm{cn}(\Delta\varphi)\end{Bmatrix},\quad \hat{M}_1+M_1=\frac{2a}{D}\begin{Bmatrix}\mathrm{cn}(\overline{\varphi})\mathrm{cn}(\Delta\varphi)\\ \mathrm{dn}(\overline{\varphi})\mathrm{dn}(\Delta\varphi)\end{Bmatrix}, \tag{53}$$

$$\hat{M}_2-M_2=\frac{2b}{D}\mathrm{cn}(\overline{\varphi})\mathrm{dn}(\overline{\varphi})\mathrm{sn}(\Delta\varphi),\quad \hat{M}_2+M_2=\frac{2b}{D}\mathrm{sn}(\overline{\varphi})\mathrm{cn}(\Delta\varphi)\mathrm{dn}(\Delta\varphi), \tag{54}$$

$$\hat{M}_3-M_3=-\frac{2c}{D}\begin{Bmatrix}k^2\mathrm{sn}(\overline{\varphi})\mathrm{cn}(\overline{\varphi})\mathrm{sn}(\Delta\varphi)\mathrm{cn}(\Delta\varphi)\\ \mathrm{sn}(\overline{\varphi})\mathrm{dn}(\overline{\varphi})\mathrm{sn}(\Delta\varphi)\mathrm{dn}(\Delta\varphi)\end{Bmatrix},\quad \hat{M}_3+M_3=\frac{2c}{D}\begin{Bmatrix}\mathrm{dn}(\overline{\varphi})\mathrm{dn}(\Delta\varphi)\\ \mathrm{cn}(\overline{\varphi})\mathrm{cn}(\Delta\varphi)\end{Bmatrix}. \tag{55}$$

Plugging this into an arbitrary one of the equations of motion (41)–(43), we arrive after some cancellations at the equation (50). Notice that Lemma 1 assures that, away from the fixed points, these cancellations are legitimate in at least one of the equations of motion.

So, we have arrived at the equation (50) of the form

$$\Psi(M^2,E,\overline{\varphi},\Delta\varphi,h)=0, \tag{56}$$

which serves for determining the function $\hat{\varphi}(M^2,E,\varphi,h)$ for our map. The equation (56) may be rewritten as

$$\Psi\left(M^2,E,\frac{\varphi+\hat{\varphi}}{2},\frac{\hat{\varphi}-\varphi}{2},h\right)\overset{\text{def}}{=}\tilde{\Psi}(M^2,E,\varphi,\hat{\varphi},h)=0. \tag{57}$$

Proposition 3 gives a necessary and sufficient condition $\partial\hat{\varphi}/\partial\varphi=1$ for our map to be Poisson, and this is equivalent to the following condition:

$$\frac{\partial\tilde{\Psi}}{\partial\hat{\varphi}}+\frac{\partial\tilde{\Psi}}{\partial\varphi}=0\quad \text{on the solutions of (57).} \tag{58}$$

Since, obviously,

$$\frac{\partial\tilde{\Psi}}{\partial\hat{\varphi}}=\frac{1}{2}\left(\frac{\partial\Psi}{\partial\overline{\varphi}}+\frac{\partial\Psi}{\partial(\Delta\varphi)}\right),\qquad \frac{\partial\tilde{\Psi}}{\partial\varphi}=\frac{1}{2}\left(\frac{\partial\Psi}{\partial\overline{\varphi}}-\frac{\partial\Psi}{\partial(\Delta\varphi)}\right),$$

we find that the Poisson property is equivalent to the following condition:

$$\frac{\partial \Psi}{\partial \overline{\varphi}} = 0 \quad \text{on the solutions of (56).} \tag{59}$$

In turn, (59) assures that the solutions of (56) for $\Delta\varphi$ do not depend on $\overline{\varphi}$. ■

Corollary: In the conditions of the above theorem, solutions $\mathbf{M}_m = (M_{1,m}, M_{2,m}, M_{3,m})^{\mathrm{T}}$ to the difference equation,

$$\mathbf{M}_{m+1} - \mathbf{M}_m = \tfrac{1}{4} h\, \gamma(\mathbf{M}_m, \mathbf{M}_{m+1}, h)\, (\mathbf{M}_m + \mathbf{M}_{m+1}) \times \mathbf{\Omega}(\mathbf{M}_m + \mathbf{M}_{m+1}), \tag{60}$$

in the integrable (≡ Poisson) case are given by

$$M_{1,m} = a \begin{Bmatrix} \mathrm{cn}(2m\delta + \varphi_0) \\ \mathrm{dn}(2m\delta + \varphi_0) \end{Bmatrix}, \quad M_{2,m} = b\, \mathrm{sn}(2m\delta + \varphi_0), \quad M_{3,m} = c \begin{Bmatrix} \mathrm{dn}(2m\delta + \varphi_0) \\ \mathrm{cn}(2m\delta + \varphi_0) \end{Bmatrix}. \tag{61}$$

VII. FIRST EXAMPLES OF INTEGRABLE DISCRETIZATIONS

We use Theorem 1 to investigate the Poisson property of several discretizations. We start with the following negative result.

Proposition 5: The function $\gamma_0(\mathbf{M}, \hat{\mathbf{M}}, h) \equiv 1$ *defines a non-Poisson map.*

The simplest way to find Poisson (and therefore integrable) discretizations is to assure that the left-hand side of the equation (50) does not depend on $\overline{\varphi}$.

Proposition 6: The functions

$$\gamma_1(\mathbf{M}, \hat{\mathbf{M}}, h) = \frac{4M^2}{\langle \mathbf{M} + \hat{\mathbf{M}}, \mathbf{M} + \hat{\mathbf{M}} \rangle} \tag{62}$$

and

$$\gamma_2(\mathbf{M}, \hat{\mathbf{M}}, h) = \frac{4E}{\langle \mathbf{M} + \hat{\mathbf{M}}, \mathbf{\Omega}(\mathbf{M} + \hat{\mathbf{M}}) \rangle} \tag{63}$$

define Poisson maps.

Proof: Using the second expressions in (53)–(55), it is not difficult to derive the following formulas:

$$\frac{1}{4}\langle \mathbf{M} + \hat{\mathbf{M}}, \mathbf{M} + \hat{\mathbf{M}} \rangle = \frac{a^2 + c^2 - b^2 \mathrm{sn}^2(\Delta\varphi)}{1 - k^2 \mathrm{sn}^2(\overline{\varphi}) \mathrm{sn}^2(\Delta\varphi)},$$

$$\frac{1}{4}\langle \mathbf{M} + \hat{\mathbf{M}}, \mathbf{\Omega}(\mathbf{M} + \hat{\mathbf{M}}) \rangle = \frac{\dfrac{a^2}{A} + \dfrac{c^2}{C} - \dfrac{b^2}{B} \mathrm{sn}^2(\Delta\varphi)}{1 - k^2 \mathrm{sn}^2(\overline{\varphi}) \mathrm{sn}^2(\Delta\varphi)}.$$

Hence, the left-hand side of the equation (50) for $\gamma = \gamma_{1,2}$ does not depend on $\overline{\varphi}$. Taking into account that, according to (10),

$$a^2 + c^2 = M^2, \qquad \frac{a^2}{A} + \frac{c^2}{C} = E,$$

we find the following expressions for this left-hand side:

$$1 - \alpha_{1,2}\, \mathrm{sn}^2(\Delta\varphi),$$

where

$$\alpha_1(M^2,E)=\frac{b^2}{M^2},\quad \alpha_2(M^2,E)=\frac{b^2}{BE} \tag{64}$$

[see (10) for the expression of b^2 through M^2 and E]. Therefore, the equation (50) in these two cases is equivalent to

$$\frac{\mathrm{sn}(\Delta\varphi)}{\mathrm{cn}(\Delta\varphi)\mathrm{dn}(\Delta\varphi)}=\frac{h\nu}{2}\frac{1}{1-\alpha_{1,2}\,\mathrm{sn}^2(\Delta\varphi)}. \tag{65}$$

Obviously, its solutions satisfy

$$\Delta\varphi=\delta_{1,2}(M^2,E,h)=\frac{h\nu(M^2,E)}{2}(1+O(h)).$$

VIII. VESELOV–MOSER DISCRETIZATION

In order to introduce the Veselov–Moser discretization, we need, first of all, the matrix notation for the Euler top equation (2). Using the well-known isomorphism between the Lie algebra $(\mathbb{R}^3,\times)$ with the Lie algebra $(\mathrm{so}(3),[\cdot,\cdot])$ of 3×3 skew-symmetric matrices with the usual commutator, we can rewrite the equations of motion (2) also in the matrix form

$$\dot{M}=[M,\Omega(M)], \tag{66}$$

where

$$M=\begin{pmatrix} 0 & M_3 & -M_2 \\ -M_3 & 0 & M_1 \\ M_2 & -M_1 & 0 \end{pmatrix} \tag{67}$$

and

$$\Omega(M)=\begin{pmatrix} 0 & M_3/C & -M_2/B \\ -M_3/C & 0 & M_1/A \\ M_2/B & -M_1/A & 0 \end{pmatrix}. \tag{68}$$

The relation between the matrices M and $\Omega=\Omega(M)$ may be expressed as follows:

$$M=J\Omega+\Omega J, \tag{69}$$

where the entries of the diagonal matrix,

$$J=\mathrm{diag}(J_1,J_2,J_3), \tag{70}$$

are defined by the relations

$$A=J_2+J_3,\quad B=J_3+J_1,\quad C=J_1+J_2. \tag{71}$$

A spectral parameter dependent Lax representation for (66) is

$$(M+\lambda J^2)^{\cdot}=[M+\lambda J^2,\Omega(M)+\lambda J]. \tag{72}$$

Now we can describe the Veselov–Moser construction. The differential equation (66) is replaced by the difference one,

$$\hat{M}=\omega^T M\omega, \tag{73}$$

where $\omega \in \mathrm{SO}(3)$ is an orthogonal matrix related to M by means of the following relation, coming to replace, or to approximate, (69):

$$hM = \omega J - J\omega^T. \tag{74}$$

It is easy to see that the previous two relations imply also

$$h\hat{M} = J\omega - \omega^T J. \tag{75}$$

Moser and Veselov demonstrated that, in general, the equation (74) does not determine the matrix $\omega \in \mathrm{SO}(3)$ uniquely. This nonuniqueness may be described as follows. Notice that (74), (75) are equivalent to the following factorizations of matrix polynomials:

$$I - h\lambda M - \lambda^2 J^2 = (\omega + \lambda J)(\omega^T - \lambda J)$$

and

$$I - h\lambda \hat{M} - \lambda^2 J^2 = (\omega^T - \lambda J)(\omega + \lambda J),$$

respectively. Denote by S the set of six roots of the equation $\det(I - h\lambda M - \lambda^2 J^2) = 0$. Then to each decomposition $S = S_+ \cap S_-$ into two disjoint sets of three roots satisfying $S_+ = \overline{S_+} = -S_-$ there corresponds a unique solution $\omega \in \mathrm{SO}(3)$ of (74) such that S_+ is the set of the roots of $\det(\omega + \lambda J) = 0$, while S_- is the set of the roots of $\det(\omega^T - \lambda J) = 0$.

However, in the continuous limit, when h is supposed to be small, there exists a *unique* decomposition, for which the roots from S_- are positive real numbers $O(h)$–close to J_1^{-1}, J_2^{-1}, J_3^{-1}. This is the only decomposition for which the corresponding ω has the following asymptotics:

$$\omega = I + h\Omega(M) + O(h^2). \tag{76}$$

Supposing h small enough, we consider from now on only this choice of ω, and demonstrate that the discretization of Veselov and Moser also belongs to the class of special discretizations described by the equation (39).

Theorem 2: *The Veselov–Moser discretization for h small enough may be represented in the form (39) with*

$$\gamma_{\mathrm{VM}}(\mathbf{M}, \hat{\mathbf{M}}, h) = \frac{2}{1 + \sqrt{1 - \frac{1}{4}h^2 ||\mathbf{\Omega}(\mathbf{M} + \hat{\mathbf{M}})||^2}}. \tag{77}$$

Proof: We shall need the following lemma, proof of which is put in the Appendix.

Lemma 2: For a matrix $\omega \in \mathrm{SO}(3)$, $O(h)$—close to I, there exists a unique matrix $W \in \mathrm{so}(3)$ such that $W = O(h)$, and

$$\omega = I + W + \frac{\gamma}{2} W^2,$$

where

$$\gamma = \frac{2}{1 + \sqrt{1 - |W|^2}}.$$

Here

$$|\mathrm{W}|^2 = W_1^2 + W_2^2 + W_3^2, \quad \text{for} \quad W = \begin{pmatrix} 0 & W_3 & -W_2 \\ -W_3 & 0 & W_1 \\ W_2 & -W_1 & 0 \end{pmatrix} \in \mathrm{so}(3).$$

With the help of this lemma we derive the following two equations:

$$\omega-\omega^T=2W, \quad \omega+\omega^T=2I+\gamma W^2. \tag{78}$$

Now from (74), (75), and the first equation in (78) we find

$$h(M+\hat{M})=(\omega-\omega^T)J+J(\omega-\omega^T)=2(WJ+JW); \tag{79}$$

hence

$$W=\tfrac{1}{2}h\Omega(M+\hat{M}). \tag{80}$$

Further, from (74), (75), and the second equation in (78) we find

$$h(\hat{M}-M)=J(\omega+\omega^T)-(\omega+\omega^T)J=\gamma[J,W^2]=\gamma[WJ+JW,W]=\tfrac{1}{4}\gamma h^2[M+\hat{M},\Omega(M+\hat{M})], \tag{81}$$

where

$$\gamma=\frac{2}{1+\sqrt{1-\dfrac{1}{4}h^2|\Omega(M+\hat{M})|^2}}.$$

Using the above-mentioned isomorphism between $(\mathbb{R}^3,\times)$ and (so(3),$[\cdot,\cdot]$), we see that the theorem is proved. ■

It remains to reproduce from our point of view the result of Moser and Veselov concerning the Poisson property of their discretization. To this end, we demonstrate that the equation (50) with Γ_{VM} corresponding to γ_{VM} allows a $\overline{\varphi}$–independent solution for $\Delta\varphi$.

Theorem 3: *For the Veselov–Moser discretization the equation (50) is equivalent to*

$$\mathrm{sn}(\Delta\varphi)\mathrm{cn}(\Delta\varphi)\mathrm{dn}(\Delta\varphi)=\frac{h\nu}{2}(1+\alpha\,\mathrm{sn}^2(\Delta\varphi)-\beta\,\mathrm{sn}^4(\Delta\varphi)), \tag{82}$$

where

$$\alpha=\left\{\begin{array}{l}\dfrac{2ACE-(A+C-B)M^2}{(B-C)(AE-M^2)}\\[2ex] \dfrac{2ACE-(A+C-B)M^2}{(A-B)(M^2-CE)}\end{array}\right\}, \quad \beta=\left\{\begin{array}{l}\dfrac{AC \quad M^2-CE}{(B-C)^2AE-M^2}\\[2ex] \dfrac{AC \quad AE-M^2}{(A-B)^2M^2-CE}\end{array}\right\}. \tag{83}$$

The solution of (82) satisfies

$$\Delta\varphi=\delta_{\mathrm{VM}}(M^2,E,h)=\frac{h\nu(M^2,E)}{2}(1+O(h)). \tag{84}$$

Proof: For the Veselov–Moser discretization the left-hand side of the equation (50) can be calculated with the help of (77) and the second expressions in (53)–(55):

$$\frac{\Gamma(M^2,E,\overline{\varphi},\Delta\varphi,h)}{1-k^2\,\mathrm{sn}^2(\overline{\varphi})\mathrm{sn}^2(\Delta\varphi)}=\frac{2}{1-k^2\,\mathrm{sn}^2(\overline{\varphi})\mathrm{sn}^2(\Delta\varphi)+\sqrt{(1-k^2\,\mathrm{sn}^2(\overline{\varphi})\mathrm{sn}^2(\Delta\varphi))^2-h^2G}}, \tag{85}$$

where

$$G=\frac{a^2}{A^2}\begin{Bmatrix}\mathrm{cn}^2(\overline{\varphi})\mathrm{cn}^2(\Delta\varphi)\\ \mathrm{dn}^2(\overline{\varphi})\mathrm{dn}^2(\Delta\varphi)\end{Bmatrix}+\frac{b^2}{B^2}\mathrm{sn}^2(\overline{\varphi})\mathrm{cn}^2(\Delta\varphi)\mathrm{dn}^2(\Delta\varphi)+\frac{c^2}{C^2}\begin{Bmatrix}\mathrm{dn}^2(\overline{\varphi})\mathrm{dn}^2(\Delta\varphi)\\ \mathrm{cn}^2(\overline{\varphi})\mathrm{cn}^2(\Delta\varphi)\end{Bmatrix}. \quad (86)$$

Hence the equation (50) in the present case is equivalent to

$$1-k^2\,\mathrm{sn}^2(\overline{\varphi})\mathrm{sn}^2(\Delta\varphi)+\sqrt{(1-k^2\,\mathrm{sn}^2(\overline{\varphi})\mathrm{sn}^2(\Delta\varphi))^2-h^2G}=h\nu\frac{\mathrm{cn}(\Delta\varphi)\mathrm{dn}(\Delta\varphi)}{\mathrm{sn}(\Delta\varphi)}.$$

We leave the radical alone on the left-hand side and square the resulting equation to derive

$$-h^2G=h^2\nu^2\frac{\mathrm{cn}^2(\Delta\varphi)\mathrm{dn}^2(\Delta\varphi)}{\mathrm{sn}^2(\Delta\varphi)}-2h\nu\frac{\mathrm{cn}(\Delta\varphi)\mathrm{dn}(\Delta\varphi)}{\mathrm{sn}(\Delta\varphi)}(1-k^2\,\mathrm{sn}^2(\overline{\varphi})\mathrm{sn}^2(\Delta\varphi)). \quad (87)$$

Obviously, we have

$$G=G_0(M^2,E,\Delta\varphi)-G_1(M^2,E,\Delta\varphi)\,\mathrm{sn}^2(\overline{\varphi}), \quad (88)$$

where

$$G_0=\frac{a^2}{A^2}\begin{Bmatrix}\mathrm{cn}^2(\Delta\varphi)\\ \mathrm{dn}^2(\Delta\varphi)\end{Bmatrix}+\frac{c^2}{C^2}\begin{Bmatrix}\mathrm{dn}^2(\Delta\varphi)\\ \mathrm{cn}^2(\Delta\varphi)\end{Bmatrix}, \quad (89)$$

$$G_1=\frac{a^2}{A^2}\begin{Bmatrix}\mathrm{cn}^2(\Delta\varphi)\\ k^2\,\mathrm{dn}^2(\Delta\varphi)\end{Bmatrix}+\frac{c^2}{C^2}\begin{Bmatrix}k^2\,\mathrm{dn}^2(\Delta\varphi)\\ \mathrm{cn}^2(\Delta\varphi)\end{Bmatrix}-\frac{b^2}{B^2}\mathrm{cn}^2(\Delta\varphi)\mathrm{dn}^2(\Delta\varphi). \quad (90)$$

We shall prove that

$$G_1-k^2\,\mathrm{sn}^2(\Delta\varphi)G_0=k^2\nu^2\,\mathrm{cn}^2(\Delta\varphi)\mathrm{dn}^2(\Delta\varphi). \quad (91)$$

This formula allows one to derive from (88),

$$G=\frac{G_1}{k^2\,\mathrm{sn}^2(\Delta\varphi)}(1-k^2\,\mathrm{sn}^2(\overline{\varphi})\mathrm{sn}^2(\Delta\varphi))-\nu^2\frac{\mathrm{cn}^2(\Delta\varphi)\mathrm{dn}^2(\Delta\varphi)}{\mathrm{sn}^2(\Delta\varphi)}, \quad (92)$$

so that (87) is equivalent to

$$\frac{h^2G_1}{k^2\,\mathrm{sn}^2(\Delta\varphi)}=2h\nu\frac{\mathrm{cn}(\Delta\varphi)\mathrm{dn}(\Delta\varphi)}{\mathrm{sn}(\Delta\varphi)},$$

or

$$\mathrm{sn}(\Delta\varphi)\mathrm{cn}(\Delta\varphi)\mathrm{dn}(\Delta\varphi)=\frac{h}{2\nu k^2}G_1.$$

This is equivalent to (82), as one easily calculates from the definition (90) that

$$G_1=k^2\nu^2(1+\alpha\,\mathrm{sn}^2(\Delta\varphi)-\beta\,\mathrm{sn}^4(\Delta\varphi))$$

with α and β as in (83). It remains to prove the relation (91). But it follows from the definitions (89), (90):

$$G_1 - k^2 \operatorname{sn}^2(\Delta\varphi) G_0 = \left\{ \begin{array}{l} \dfrac{a^2}{A^2} + \dfrac{k^2 c^2}{C^2} - \dfrac{b^2}{B^2} \\ \\ \dfrac{k^2 a^2}{A^2} + \dfrac{c^2}{C^2} - \dfrac{b^2}{B^2} \end{array} \right\} \operatorname{cn}^2(\Delta\varphi)\operatorname{dn}^2(\Delta\varphi),$$

and the expressions in the curly brackets here in both cases are equal to $k^2\nu^2$, due to (10), (9), (11). ■

IX. CONCLUSIONS

In the present work we have introduced a large family of discretizations of the Euler top sharing the integrals of motion with the continuous time system. We characterized those of them which are also Poisson with respect to the invariant Poisson bracket of the Euler top. For all these Poisson discretizations we found a solution in terms of elliptic functions which allows a direct comparison with the continuous time case. We demonstrated that the Veselov–Moser discretization also belongs to our family, and applied our methods to this particular example.

Let us mention some of the possible directions for further progress. First of all, our construction works on the level of reduced equations of motion of the rigid body [in the Lie algebra $\mathbb{R}^3 \approx \mathrm{so}(3) \approx \mathrm{su}(2)$]. It would be important to lift it to the level of the corresponding Lie group SO(3) [or SU(2)]. In a more mechanical language, we want to discretize the equations of motion in the rest frame, and not only in the frame attached firmly to the body. Notice that the Veselov–Moser construction has a variational (Lagrangian) origin, which makes it valid in the group. Another example of such a discretization admitting a variational formulation in the corresponding group is the recently found discrete time Lagrange top.[14]

As a second problem, our construction has to be generalized to higher dimensions (for the general Euler-Manakov case of the multidimensional rigid body). Notice that the Veselov–Moser construction goes through in higher dimensions.

Further, it would be important to include our construction into the general r-matrix framework, connected to factorizations in the loop groups; cf. Ref. 15.

APPENDIX: PROOF OF LEMMA 2

Let $\omega \in \mathrm{SO}(3)$, $\omega = \mathrm{I} + O(h)$. Set $V = (\omega - \mathrm{I})/(\omega + \mathrm{I})$, then $V \in \mathrm{so}(3)$, $V = O(h)$, and

$$\omega = \frac{I+V}{I-V} = \frac{2}{I-V} - I.$$

But for $V \in \mathrm{so}(3)$ we have: $V^3 = -|V|^2 V$, and by induction,

$$V^{2k+1} = (-1)^k |V|^{2k} V, \quad V^{2k+2} = (-1)^k |V|^{2k} V^2, \quad k \geqslant 1,$$

so that

$$\frac{I}{I-V} = I + \frac{1}{1+|V|^2} V + \frac{1}{1+|V|^2} V^2,$$

hence

$$\omega = I + \frac{2}{1+|V|^2} V + \frac{2}{1+|V|^2} V^2.$$

Now setting

$$W = \frac{2}{1+|V|^2} V,$$

so that $W \in \mathrm{so}(3)$, $W = O(h)$, we find

$$\omega = I + W + \frac{\gamma}{2} W^2, \quad \text{where} \quad \gamma = 1 + |V|^2.$$

We have, obviously,

$$|W|^2 = \frac{4}{(1+|V|^2)^2} |V|^2 \ \Rightarrow |V|^2 = \frac{2 - |W|^2 - 2\sqrt{1-|W|^2}}{|W|^2},$$

and

$$\gamma = 1 + |V|^2 = \frac{2 - 2\sqrt{1-|W|^2}}{|W|^2} = \frac{2}{1+\sqrt{1-|W|^2}}.$$

This proves the lemma. ■

On harmonic maps into gauge groups

Qing Ding[a)]
Institute of Mathematics and Laboratory of Mathematics for Nonlinear Sciences, Fudan University, Shanghai 200433, People's Republic of China

(Received 2 December 1997; accepted for publication 26 June 1998)

We continue the work of the paper [J. Math. Phys. **37**, 4076 (1996)] on the existence of globally defined harmonic maps from the Minkowski plane $R^{1,1}$ into an infinite-dimensional Hilbert Lie group. We prove that the Cauchy problem for harmonic maps from $R^{1,1}$ into Hilbert loop groups $H_s(LG)$ can be solved globally for all remaining cases $\frac{1}{2}<s\leqslant\frac{3}{4}$ and we obtain similar results for harmonic maps from $R^{1,1}$ into certain Hilbert Lie gauge groups $H_s(S^n,G)$ $(n\geqslant 2)$. These answer the two questions remaining from the above paper. © *1998 American Institute of Physics.* [S0022-2488(98)02612-7]

I. INTRODUCTION

An infinite-dimensional Hilbert Lie group $\tilde{G}$ is a smooth group which is at the same time an infinite-dimensional smooth Riemann–Hilbert manifold. The tangent space to $\tilde{G}$ at the identity element is its Lie algebra. The theory of finite-dimensional Lie groups is a classical subject and has been well developed since the fundamental works by Killing (Ref. 1) and Cartan (Ref. 2) at the end of the last century. However, infinite-dimensional Lie groups are much more complicated and the theory is still under development. Until now only some particular infinite-dimensional Lie groups have been studied. A good and classical example is mapping space $\mathrm{Map}(M,G)$, i.e., the maps from a compact Riemannian manifold M into a compact semi-simple Lie group G. Such infinite dimensional groups are called sometimes—and we will follow this custom—gauge groups. The name comes from the fact that such gauge groups arise in the representation theory of gauge quantum fields, in which case M has the interpretation of physical space. G has the interpretation of the structure Lie group for the principal fiber bundle whose connections define the classical gauge fields. It should be mentioned that the gauge groups were also introduced by Gelfand and his collaborators (Ref. 3) into the mathematical literature from the point of view of noncommutative distributions. The study of such groups and the associated (infinite-dimensional) Lie algebras is a topic of great interest in itself and because of its numerous and fruitful connections with many domains of mathematics and its applications in theoretical physics.

The theory of gauge groups and loop groups has been actively developed recently (Refs. 4–6). Let $H_s(M,G)=\{\gamma:M\to G|\,\gamma \text{ is } H_s \text{ integrable}\}$ $(s>\frac{1}{2}\dim M)$ be a real Hilbert Lie gauge group. It is well known that $H_s(M,G)$ admits a Riemannian Hilbert metric structure (see, for example, Ref. 7). In particular, the groups $H_s(S^1,G)$ [we will denote them by $H_s(LG)$ following the notation used in Ref. 8] are loop groups, which becomes a very important tool in solving problems both in mathematics and physics. Following this point of view, among all the gauge groups the most interesting and important class is the class of gauge groups $H_s(S^n,G)$ from an n-dimensional Euclidean sphere. On the other hand, roughly speaking, the study of the gauge groups $\mathrm{Map}(M,G)$ mainly involves analysis on the source M. The best candidate of a higher-dimensional compact Riemannian manifold with well known harmonic theory is undoubtedly a Euclidean sphere S^n $(n\geqslant 2)$.

In this paper, we continue the work of Ref. 8 in studying harmonic maps globally defined on the Minkowski plane $R^{1,1}$ (i.e., the two-dimensional space–time) to the Hilbert Lie gauge (loop) groups $H_s(S^n,G)$. In this direction of study, Gu (Ref. 9) in 1980, Ginibre and Velo (Ref. 10) in 1982 proved that the solution of the Cauchy problem for harmonic maps from the two-dimensional space–time (i.e., the Minkowski plane) into a complete Riemannian manifold (or a symmetric space such as complex projective space or Grassmann manifold) exist globally, which implies that if a (two-dimensional) σ-model is regular at a certain time, then it is regular in the past and future.

Their works stimute the deeper study of the Cauchy problem for the higher-dimensional σ-model or two-dimensional σ-model defined on the curved Lorentzian manifolds (Refs. 11–14). Recently, the author and Lu (Ref. 8) gave a geometric description of certain Hilbert loop groups and showed that there is a wealth of globally defined harmonic maps from $R^{1,1}$ into the Hilbert loop groups $H_s(LG)$ $(s>\frac{3}{4})$. However, two natural questions are left in Ref. 8. One is the following: do there exist globally defined harmonic maps from $R^{1,1}$ into the Hilbert loop groups $H_s(LG)$ when $\frac{1}{2}<s\leqslant\frac{3}{4}$ too? On the other hand, the geometric characterization of the loop groups explored in Ref. 8 cannot be generally guaranteed on a Riemannian–Hilbert manifold (see Remark 2 in Ref. 8). So another question is the following: does the analogous result still hold for the Hilbert Lie gauge groups $H_s(M,G)$ with $\dim M\geqslant 2$? Our purpose in this paper is to give an affirmative answer to the first question and a positive answer to the second question in the most important case of $M=S^n(n\geqslant 2)$. Our discussions will strongly depend on the important relations [see (6) and (7) below] of the structure constants of the gauge algebras $H_s(S^n,g)$ displayed in Sec. II and certain geometric characterizations (see Lemmas 1–2 below) of the Hilbert Lie gauge groups $H_s(S^n,G)$ revealed in Sec. III.

This paper is organized as follows. In Sec. II we present some basic materials about the Hilbert Lie gauge groups $H_s(M,G)$ and some well known facts concerning the harmonic theory on the Euclidean sphere S^n. Then we calculate the structure constants of the infinite-dimensional Lie algebra of the smooth gauge group $\mathrm{Map}(S^n,G)$. In Sec. III we prove that the geometric characterizations of the uniform positive and homogeneity for the loop groups (see Lemma 1 in Ref. 8) still hold for a certain Hilbert–Sobolev metric on $H_s(S^n,G)$. These can be regarded as natural generalizations of the geometric properties of loop groups. In Sec. IV we present the main results of this paper, i.e., the global existence of the solutions of the Cauchy problem for harmonic maps from $R^{1,1}$ into the Hilbert loop groups $H_s(LG)$ $(s>1/2)$ and the Hilbert Lie gauge groups $H_s(S^n,G)$ $(n\geqslant 2, s>(n+1)/2)$. In Sec. V we give some remarks and problems.

II. LIE GAUGE ALGEBRAS AND GROUPS

Although our main objects are gauge groups $\mathrm{Map}(S^n,G)$, where G is a semi-simple compact Lie group, we would like to give a brief summary of some relevant results of general gauge groups $\mathrm{Map}(M,G)$ (the details may be find, for example, in Ref. 7). Gauge groups $\mathrm{Map}(M,G)$ enjoy a richer structure—they can be endowed with a class of Sobolev–Hilbert metrics. The local model for $\mathrm{Map}(M,G)$ is a completion of the Lie algebra of smooth maps $\mathrm{Map}(M,g)$, where g is the (finite-dimensional) Lie algebra of G. Let $(\cdot,\cdot)_g$ be an inner product on g given by minus the Killing form. Then for any real number s, the Sobolev–Hilbert H_s metric on $\mathrm{Map}(M,g)$ is defined by

$$(X,Y)_s=\int_M((1+\Delta)^sX(\theta),Y(\theta))_g dx,\quad X,Y\in Lg, \tag{1}$$

where dx is the volume form on M and Δ is the Laplacian operator on M. The Hilbert completion of smooth maps in this inner product is denoted by $H_s(M,g)$. The elements in $H_s(M,g)$ are continuous for $s>\frac{1}{2}\dim M$. In this range there are corresponding Hilbert Lie groups $H_s(M,G)$ modeled on $H_s(M,g)$. Of course, throughout this paper, we regard $H_s(M,G)$ as the connected component part containing the identity element. The exponential map $\exp: g\to G$ induces a map $\mathrm{Exp}: H_s(M,g)\to H_s(M,G)$, which gives a local chart near the identity element in $H_s(M,G)$. Left translations by smooth $f\in H_s(M,G)$ provide a system of coordinate charts covering the entire manifold. The above coordinate charts, according to Ref. 8, are also called the exponential coordinate charts in this paper.

Next we turn to the theory of spherical harmonics (the details are referred to Refs. 15–16). Let P_k be the space of homogeneous polynomials of degree k on the $n+1$-dimensional Euclidean space R^{n+1}, and let H_k be the subspace of harmonic polynomials in P_k. The restrictions of the element of H_k to the unit sphere S^n in R^{n+1} are called spherical harmonics of degree k. The space of spherical harmonics of degree k will be denoted by $\tilde{H}_k$, which are the eigenfunctions of the Laplace Δ on S^n with eigenvalue $\lambda_k=k(n+k-1)$. It is well known that $P_k=H_k\oplus r^2H_{k-2}\oplus r^4H_{k-4}\oplus\cdots$, where $r=|x|=\sqrt{x_1^2+\cdots+x_{n+1}^2}$ and hence the restriction to the unit sphere S^n of

any element of P_k is a sum of spherical harmonics of degree at most k. Furthermore, $L^2(S^n)=\oplus_0^\infty \tilde{H}_k$ and $\dim \tilde{H}_k=\dim P_k-\dim P_{k-2}:=d_k=(2k+n-1)(n+k-2)!/(n+1-k)!k!$ when $k\geqslant 1$ and $\dim \tilde{H}_0=1$.

There is an inner product in $\tilde{H}_k$ given by

$$\langle f,g\rangle=\int_{S^n} fg\,d\sigma,\quad \forall f,g\in\tilde{H}_k,$$

where $d\sigma$ is proportional to the volume form of the standard volume form dx on S^n and normalized in such a way that $\int_{S^n} d\sigma=\dim \tilde{H}_k$. Let $\{f_1(x),\ldots,f_{d_k}(x)\}$ be an orthonormal basis of $\tilde{H}_k$ $(k\geqslant 0)$. Then we have (Ref. 16)

$$\sum_{i=1}^{d_k} f_i^2=1,\quad \text{for all}\quad x\in S^n. \tag{2}$$

From now on, we fixed a system of the eigenfunctions $\{\phi_{k,\tau}\}$ $(k\in Z_+=\{0,1,2,\ldots\},1\leqslant\tau\leqslant d_k)$ of the Laplace operator Δ on S^n as above, i.e., for any $k\geqslant 0$,

$$\phi_{k,\tau}=f_\tau,\quad \tau=1,\ldots,d_k, \tag{3}$$

where f_τ are the spherical harmonics that appeared in (2). Note that $\phi_{0,1}=1$ is the first eigenfunction of Δ with eigenvalue $\lambda=0$ and $\int_{S^n}\phi_{k,\tau}\phi_{l,\sigma}=\delta_{kl}\delta_{\tau\sigma}\,\mathrm{vol}(S^n)/d_k$.

Throughout the paper, we always let G be a semi-simple Lie matrix group, especially the unitary groups $U(N)$, with the Lie algebra g on which there is minus the Killing metric $(\cdot,\cdot)_g$. From the fundamental results of finite-dimensional Lie theory, one may see that the above restriction of G is not serious but it simplifies our calculations and statements. It is well known that the gauge algebra $\mathrm{Map}(S^n,g)$ of the gauge group $\mathrm{Map}(S^n,G)$ can be identified with $\{\xi: S^n\to g\}$ which takes the form

$$\xi(x)=\sum_{k\geqslant 0,1\leqslant\tau\leqslant d_k}\xi_{k,\tau}\phi_{k,\tau}, \tag{4}$$

where $\phi_{k\tau}$ are the eigenfunctions that appeared in (3) and $\xi_{k,\tau}$ are g-valued constant coefficients. When $G=U(N)$, the coefficients $\xi_{k,\tau}$ are skew-Hermitian complex $N\times N$ matrices.

Let $T^1,\ldots,T^N$ be a basis of g with structure constants C_{ab}^c, $1\leqslant a,b,c\leqslant N$. Then, obviously, $\{T^a\phi_{k,\tau}: 1\leqslant a\leqslant N, k\in Z_+,\ 1\leqslant\tau\leqslant d_k\}$ spans the whole space $\mathrm{Map}(S^n,g)$. Set $T^a_{k,\tau}=T^a\phi_{k,\tau}$, thus $\{T^a_{k,\tau}: 1\leqslant a\leqslant N, k\in Z_+, 1\leqslant\tau\leqslant d_k\}$ is a basis of $\mathrm{Map}(S^n,g)$. Now we come to calculate the structure constants $\{C^{(ak\tau)}_{(bl\sigma)(cm\mu)}\}$ $(1\leqslant a,b,c\leqslant N, k,l,m\in Z_+, 1\leqslant\tau\leqslant d_k, 1\leqslant\sigma\leqslant d_l, 1\leqslant\mu\leqslant d_m)$ of the Lie algebra $\mathrm{Map}(S^n,g)$ with respect to the basis $\{T^a_{k,\tau}\}_{1\leqslant a\leqslant N; k\in Z_+, 1\leqslant\tau\leqslant d_k}$.

In order to do this, we first expand

$$\phi_{k,\tau}\phi_{l,\sigma}=\sum_{m\geqslant 0,1\leqslant\mu\leqslant d_m} A^{m,\mu}_{k,\tau;l,\sigma}\phi_{m,\mu},$$

where

$$A^{m,\mu}_{k,\tau;l,\sigma}=\begin{cases}\displaystyle\int_{S^n}\phi_{k,\tau}\phi_{l,\sigma}\phi_{m,\mu}dx, & m\leqslant k+l;\\ 0, & \text{else,}\end{cases}$$

since $\phi_{k,\tau}\phi_{l,\sigma}\in P_{k+l}$. Next we have

$$\begin{aligned}[T^a_{k,\tau},T^b_{l,\sigma}]=[T^a\phi_{k,\tau},T^b\phi_{l,\sigma}]&=\sum_{1\leqslant c\leqslant N,0\leqslant m\leqslant k+l,1\leqslant\mu\leqslant d_m} C^c_{ab}T^cA^{m,\mu}_{k,\tau;l,\sigma}\phi_{m,\mu}\\ &=\sum_{1\leqslant c\leqslant N,0\leqslant m\leqslant k+l,1\leqslant\mu\leqslant d_m} C^c_{ab}A^{m,\mu}_{k,\tau;l,\sigma}T^c_{m,\mu}.\end{aligned} \tag{5}$$

Hence

$$C^{(cm\mu)}_{(ak\tau)(bl\sigma)}=\begin{cases} C^c_{ab}A^{m,\mu}_{k,\tau;l,\sigma}, & \text{if } m\leqslant k+l, k\leqslant l+m, m\leqslant m+k;\\ 0, & \text{else,}\end{cases} \tag{6}$$

since $A^{m,\mu}_{k,\tau;l,\sigma}$ satisfying $A^{m,\mu}_{k,\tau;l,\sigma}=A^{k,\tau}_{l,\sigma;m,\mu}=A^{l,\sigma}_{m,\mu;k,\tau}$. Note that, for any fixed k,l,m, we have

$$\sum_{\tau,\sigma,\mu}|A^{m,\mu}_{k,\tau;l,\sigma}|^2\leqslant\sum_{\tau,\sigma,\mu}\int_{S^n}\phi^2_{m,\mu}\int_{S^n}\phi^2_{k,\tau}\phi^2_{l,\sigma}=\mathrm{vol}^2(S^n),$$

from (2) and (3) and hence

$$\sum_{a,b,c,\tau,\sigma,\mu}|C^{(cm\mu)}_{(ak\tau)(bl\sigma)}|^2\leqslant\sum_{a,b,c}|C^c_{ab}|^2\sum_{\tau,\sigma,\mu}|A^{m,\mu}_{k,\tau;l,\sigma}|^2\leqslant\sum_{a,b,c}|C^c_{ab}|^2\,\mathrm{vol}^2(S^n):=C_0. \tag{7}$$

Finally, we would like to point out that Lie algebras $H_s(S^n,g)$ also have $\{T^a_{k,\tau}\}$ as their basis and have the same structure constants expressed in (6). The relations (6) and (7) are very important for us to explore some geometric properties of the Hilbert gauge groups $H_s(S^n,G)$ in the next section.

III. LOCAL GEOMETRY OF HILBERT LIE GAUGE GROUPS

For simplicity, we denote by $\tilde{G}$ a Hilbert Lie gauge group $H_s(S^n,G)$ $(s>n/2)$. We have already seen that Exp:$\tilde{g}\to\tilde{G}$ gives a local chart near the identity element of $\tilde{G}$. As doing in the finite-dimensional case, we can also use the left translations $DL_w:T_e\tilde{G}\to T_w\tilde{G}$ (here $L_wx=w\cdot x$ is a left translation of $\tilde{G}$) to obtain a left-invariant Riemannian Hilbert metric on $\tilde{G}$ from any given inner product $\langle\cdot,\cdot\rangle$ on $T_e\tilde{G}$.

The Sobolev–Hilbert metric defined by (1) on $H_s(S^n,g)$ may be expressed equivalently as follows:

$$\left\langle\sum_{k,\tau}\xi_{k,\tau}\phi_{k,\tau},\sum_{l,\sigma}\eta_{l,\sigma}\phi_{l,\sigma}\right\rangle=\sum_{k,\tau}[(1+\lambda_k)^s/d_k]\langle\xi_{k,\tau},\eta_{k,\tau}\rangle_g,$$

where $\xi=\Sigma_{k,\tau}\xi_{k,\tau}\phi_{k,\tau}$, $\eta=\Sigma_{k,\tau}\eta_{k,\tau}\phi_{k,\tau}\in H_s(S^n,g)$, $\langle\cdot,\cdot\rangle_g$ on the right hand side is a bi-invariant metric (e.g., minus the Killing metric) on g and $\lambda_k=k(k+n-1)$ the eigenvalues of Δ on S^n.

For a finite-dimensional Riemannian manifold, the Levi-Civita theorem states that there is a unique torsion-free connection compatible with a given Riemannian metric. This theorem persists for infinite-dimensional Riemannian Hilbert manifolds on which the tangent space is complete with respect to the given Riemannian Hilbert metric. Associated with a given complete Riemannian Hilbert manifold $\tilde{G}$, let $(x_1,\ldots,x_k,\ldots)$ be its countable coordinates in a chart U_p of a point p with p as the origin. Then

$$h_{ij}(x)=h_x\left(\frac{\partial}{\partial x_i},\frac{\partial}{\partial x_j}\right)$$

is the metric tensor over the chart which is a linear inversible continuous (=bounded) transformation from $T_x\tilde{G}\to T_x\tilde{G}$. The inverse of the metric tensor $(h_{ij}(x))$ is denoted by $(h^{ij}(x))$.

Let ∇ be the torsion-free connection compatible with the Riemannian Hilbert metric h and we define Γ^k_{ij}, the coefficients of the Riemannian Hilbert connection or Christoffel symbols, by the following formula

$$\nabla_{\partial/\partial x_i}\frac{\partial}{\partial x_j}=\sum_{k=1}^{\infty}\Gamma^k_{ij}\frac{\partial}{\partial x_k}.$$

Then

$$\Gamma_{ij}^{k}=\frac{1}{2}h^{kl}\left(\frac{\partial h_{il}}{\partial x_j}+\frac{\partial h_{lj}}{\partial x_i}-\frac{\partial h_{ij}}{\partial x_l}\right) \tag{8}$$

if the right hand side of (8) makes sense (i.e., the series are convergent).

Now we return to the Hilbert Lie gauge groups $H_s(S^n,G)$. Let $\{T^1,\ldots,T^N\}$ be an orthonormal basis of g. The vectors $T_{k,\tau}^a=T^a\phi_{k,\tau}$ $(1\leqslant a\leqslant N;k\in Z_+,1\leqslant\tau\leqslant d_k)$ form a basis of the gauge algebra $\tilde{g}$ with the orthogonality relation $\langle T_{k,\tau}^a,T_{l,\sigma}^b\rangle=(1+\lambda_k)^s/d_k\delta^{ab}\delta_{kl}\delta_{\tau\sigma}$. On a local exponential coordinate chart U_e of the identity of $H_s(S^n,G)$, without loss of generality assuming $B_e(1)\subset U_e$, we introduce the exponential real coordinates $\{x_{k,\tau}^a\}$ $(1\leqslant a\leqslant N;0\leqslant k\leqslant\infty,1\leqslant\tau\leqslant d_k)$ as follows:

$$\{x_{k,\tau}^a\}\in H_s(S^n,g)\to\mathrm{Exp}\left(\sum_{a,k,\tau}x_{k,\tau}^aT_{k,\tau}^a\right)\in U_e.$$

With the above exponential real coordinates, let us denote by $(h_{(ak\tau)(bl\sigma)}(x))$ the Riemannian–Hilbert H_s-metric tensor on the chart.

The following lemmas give a geometric characterization of the Hilbert Lie gauge groups $H_s(S^n,G)$ $(s>(n+1)/2)$ as well as that of the Hilbert loop groups $H_s(LG)(s>3/4)$ (Ref. 8), which reflect some essential geometric features of these infinite-dimensional gauge groups and will play a very important role in establishing the global existence results of harmonic maps from $R^{1,1}$ into them.

Lemma 1: Let $\tilde{G}=H_s(S^n,G)$ $(s>(n+1)/2)$. Then

(a) there are positive numbers A and α such that

$$\sum_{a,b;k,l,\tau,\sigma}h_{(ak\tau)(bl\sigma)}(x)\xi_{k,\tau}^a\xi_{l,\sigma}^b\geqslant A\sum_{a,k,\tau}[(1+\lambda_k)^s/d_k](\xi_{k,\tau}^a)^2, \tag{9}$$

for all $x\in B_e(\alpha)\subset U_e$, and $(\xi_{k,\tau}^a)\in\tilde{g}=H_s(S^n,g)$, *the Lie algebra of* $\tilde{G}$.

(b) For any given point $w\in\tilde{G}$, *in the neighborhood* $B_w(\alpha)=w\cdot B_e(\alpha)$ *of* w, (9) *is still valid.*

Proof: We only prove that (a) is true. (b) comes directly from (a) and the isometricity of left translations $L_w:B_e(\alpha)\to B_w(\alpha)$ given by $x\to w\cdot x$ on $\tilde{G}$.

In order to give an explicit expression of the metric tensor $(h_{(ak\tau)(bl\sigma)}(x))$ over U_e, we come to calculate the left-invariant vector fields $X_{k,\tau}^a=dL_x\,\mathrm{Re}\,T_{k,\tau}^a$ $(1\leqslant a\leqslant N;k\in Z_+,1\leqslant\tau\leqslant d_k)$ in the chart. Let $\{f_{k,\tau}^a(x,y)\}$ be the exponential coordinates of the point $\mathrm{Exp}(\Sigma x_{k,\tau}^aT_{k,\tau}^a)\cdot\mathrm{Exp}(\Sigma y_{k,\tau}^aT_{k\tau}^a)$ in U_e, where two points $\{x_{k,\tau}^a\},\{y_{k,\tau}^a\}\in B_e(1)\subset U_e$. Since the exponential map $\mathrm{Exp}:\tilde{g}\to\tilde{G}$ of the gauge group $\tilde{G}$ is induced from the exponential map $\exp:g\to G$ of the finite-dimensional compact group G, we set $Z=\Sigma(x_{k,\tau}^aT_{k,\tau}^a),W=\Sigma(y_{k,\tau}^aT_{k,\tau}^a)$ which are regarded as elements in g. Applying the Campbell–Baker–Hausdorff formula

$$\begin{aligned}&\mathrm{Exp}\left(\sum x_{k,\tau}^aT_{k,\tau}^a\right)\cdot\mathrm{Exp}\left(\sum y_{k,\tau}^aT_{k,\tau}^a\right)\\&\quad=\exp Z\cdot\exp W\\&\quad=\exp\left(Z+\int_0^1\psi((\exp\mathrm{ad}\,Z)(\exp t\,\mathrm{ad}\,W))(W)dt\right),\end{aligned}$$

where

$$\psi(z)=1+\sum_{k=1}^{\infty}\frac{(-1)^{k-1}(z-1)^k}{k(k+1)};$$

we have

$$f^a_{k,\tau}(x,y)=(Z+W)^a_{k,\tau}+\tfrac{1}{2}(\mathrm{ad}\,Z(W))^a_{k,\tau}+\tfrac{1}{12}((\mathrm{ad}\,Z)^2(W)+(\mathrm{ad}\,W)^2(Z))^a_{k,\tau}+\cdots$$
$$=x^a_{k,\tau}+y^a_{k,\tau}+\tfrac{1}{2}x^c_{m,\mu}w^b_{l,\sigma}C^{(ak\tau)}_{(cm\mu)(bl\sigma)}+\tfrac{1}{12}(x^e_{q,\iota}x^c_{m,\mu}y^b_{l,\sigma}+y^e_{q,\iota}y^c_{m,\mu}x^b_{l,\sigma})$$
$$\times C^{(dp\kappa)}_{(cm\mu)(bl\sigma)}C^{(ak\tau)}_{(dp\kappa)(eq\iota)}+\cdots, \tag{10}$$

where $C^{(cm\mu)}_{(ak\tau)(bl\sigma)}$ are the structure constants that appeared in (6).

Notice that $|\psi(\exp z)|\leqslant 1+\Sigma_{k=1}^{\infty}e^k|z|^k$, $|z|\leqslant 1$ and

$$\max_{a,b,c;k,l,m,\tau,\sigma,\mu}\{(C^{(ak\tau)}_{(bl\sigma)(cm\mu)})^2\}\leqslant C_0:=C_1^2,$$

where C_0 is the constant that appeared in (7); we have

$$|f^a_{k,\tau}|\leqslant\|x^a_{k,\tau}+y^a_{k,\tau}\|+eC_1(\|x\|+\|y\|)^2+\cdots+(eC_1)^k(\|x\|+\|y\|)^{k+1}+\cdots, \tag{11}$$

where $\|\cdot\|$ denote the norm of the H_s-metric ($s>n/2$), which implies that $f^a_{k,\tau}$ are actually uniformal convergence series in a neighborhood $B_e(\beta)$ for some fixed number $\beta<\frac{1}{2}\min\{1,1/eC_1\}$. We shall reformulate (10) with aid of the convenient Laudau symbol $O(x^k)$:

$$f^a_{k,\tau}(x,y)=x^a_{k,\tau}+y^a_{k,\tau}+\tfrac{1}{2}x^c_{m,\mu}y^b_{l,\sigma}C^{(ak\tau)}_{(cm\mu)(bl\sigma)}$$
$$+\tfrac{1}{12}x^e_{q,\iota}x^c_{m,\mu}y^b_{l,\sigma}C^{(dq\kappa)}_{(cm\mu)(bl\sigma)}C^{(ak\tau)}_{(dp\kappa)(eq\iota)}+O(x^3y), \tag{12}$$

where $O(x^k)$ means any continuous map in a neighborhood of the identity satisfying $|O(x^k)/||x||^k|\leqslant C<\infty$ as $x\to 0$.

Hence we can calculate left-invariant vectors from (12) as follows:

$$X^a_{k,\tau}(x)=\sum_{b;l,\sigma}\frac{\partial f^b_{l,\sigma}(x,y)}{\partial y^a_{k,\tau}}\bigg|_{y=0}\frac{\partial}{\partial x^b_{l,\sigma}}=\sum_{b;l,\sigma}A_{(ak\tau)(bl\sigma)}(x)\frac{\partial}{\partial x^b_{l,\sigma}},$$

where $A_{(ak\tau)(bl\sigma)}(x)=\delta^{ab}\delta_{kl}\delta_{\tau\sigma}+\frac{1}{2}C^{(bl\sigma)}_{(cm\mu)(ak\tau)}x^c_{m,\mu}+O(x^2)$. From the definition of the (left-invariant) H_s-metric on $H_s(S^n,G)$, we have

$$[(1+\lambda_k)^s/d_k]\delta^{ab}\delta_{kl}\delta_{\tau\sigma}=\langle X^a_{k,\tau}(0),X^b_{l,\sigma}(0)\rangle$$
$$=\langle X^a_{k,\tau}(x),X^b_{l,sigma}(x)\rangle$$
$$=A_{(ak\tau)(dp\kappa)}(x)A_{(bl\sigma)(eq\iota)}(x)h_{(dp\kappa)(eq\iota)}(x),$$

where $h_{(dp\kappa)(eq\iota)}(x)=h(\partial/\partial x^d_{p,\kappa},\partial/\partial x^e_{q,\iota})$. Since $\{X^a_{k,\tau}\}$ and $\{\partial/\partial x^a_{k,\tau}$ are two independent vector fields spanning $H_s(S^n,g)$, we find $(A_{(ak\tau)(bl\sigma)}(x))\in GL(H_s(S^n,g))$ for $x\in B_e(\beta)$. Let $(A^{(ak\tau)(bl\sigma)}(x))$ be the inverse of $(A_{(ak\tau)(bl\sigma)}(x))$. Obviously, $A^{(ak\tau)(bl\sigma)}(x)=\delta_{ab}\delta^{kl}\delta^{\tau\sigma}-\frac{1}{2}C^{(bl\sigma)}_{(cm\mu)(ak\tau)}x^c_{m\mu}+O(x^2)$ which is also analytic and uniform convergence in $B_e(\beta)$. From this we have

$$h_{(dp\kappa)(eq\iota)}(x)=A^{(dp\kappa)(ak\tau)}A^{(eq\iota)(bl\sigma)}[(1+\lambda_k)^s/d_k]\delta^{ab}\delta_{kl}\delta_{\tau\sigma}$$
$$=[(1+\lambda_p)^s/d_p]\delta^{de}\delta_{pq}\delta_{\kappa\iota}-\tfrac{1}{2}([(1+\lambda_p)^s/d_p]C^{(dp\kappa)}_{(cm\mu)(eq\iota)} \tag{13}$$
$$+[(1+\lambda_q)^s/d_q]C^{(eq\iota)}_{(cm\mu)(dp\kappa)})x^c_{m,\mu}(1+O(x)).$$

Thus $h_{(ak\tau)(bl\sigma)}(x)$ are also analytic and uniformly convergent in $B_e(\beta)$.

Now for any $\{\xi^a_{k,\tau}\}\in H_s(S^n,g)$,

$$\left|\sum_{a,b;k,l,\tau\sigma}h_{(ak\tau)(bl\sigma)}(x)\xi^a_{k,\tau}\xi^b_{l,\sigma}-\sum_{a;k,\tau}[(1+\lambda_k)^s/d_k](\xi^a_{k,\tau})^2\right|$$

$$= \left| \sum_{a,b;k,l,\tau,\sigma} (h_{(ak\tau)(bl\sigma)}(x) - h_{(ak\tau)(bl\sigma)}(0)) \xi^a_{k,\tau} \xi^b_{l\sigma} \right|$$

$$= \frac{1}{2} \Bigg| \sum \left(\frac{(1+\lambda_k)^s}{d_k} C^{(ak\tau)}_{(cm\mu)(bl\sigma)} + \frac{(1+\lambda_l)^s}{d_l} C^{(bl\sigma)}_{(cm\mu)(ak\tau)} \right) x^c_{m,\mu} (1 + O(x)) \xi^a_{k,\tau} \xi^b_{l,\sigma} \Bigg|. \tag{14}$$

The crucial point is to give an estimate of the term

$$Q := \left| \sum \frac{1}{2} ([(1+\lambda_k)^s/d_k] C^{(ak\tau)}_{(cm\mu)(bl\sigma)} + [(1+\lambda_l)^s/d_l] C^{(bl\sigma)}_{(cm\mu)(ak\tau)}) x^c_{m,\mu} \xi^a_{k,\tau} \xi^b_{l,\sigma} \right|$$

in case of $s > (n+1)/2$. In fact, we see that

$$Q \leqslant \sum_{a,b,c;k,l,m,\tau,\sigma,\mu} [(1+\lambda_k)^s/d_k] |C^{(ak\tau)}_{(cm\mu)(bl\sigma)} x^c_{m,\mu} \xi^a_{k,\tau} \xi^b_{l,\sigma}|$$

$$\leqslant C_2 \sum_{a,b,c;k,l,m,\tau,\sigma,\mu} (1+k)^{2s-n+1} |C^{(ak\tau)}_{(cm\mu)(bl\sigma)} x^c_{m,\mu} \xi^a_{k,\tau} \xi^b_{l,\sigma}|,$$

for some absolute constant C_2 since $\lambda_k = k(k+n-1) \sim k^2$ and $d_k \sim k^{n-1}$ as $k \to \infty$. Put $\alpha = (2s - n + 1)/2$; then

$$\sum_{a,b,c;k,l,m,\tau,\sigma,\mu} (1+k)^{2\alpha} |C^{(ak\tau)}_{(cm\mu)(bl\sigma)} x^c_{m,\mu} \xi^a_{k,\tau} \xi^b_{l,\sigma}|$$

$$\leqslant \sqrt{\sum_{a;k,\tau} \left[\sum_{b,c;l,m,\sigma,\mu} \frac{(1+k)^{2\alpha}}{(1+l)^{2\alpha}(1+m)^{2\alpha}} \left| C^{(ak\tau)}_{(cm\mu)(bl\sigma)} \right|^2 \right] (1+k)^{2\alpha} |\xi^a_{k,\tau}|^2}$$

$$\cdot \sqrt{\sum_{b;l,\sigma} (1+l)^{2\alpha} |\xi^b_{l,\sigma}|^2} \cdot \sqrt{\sum_{c;m,\mu} (1+m)^{2\alpha} |x^c_{m,\mu}|^2}.$$

Now we must have to indicate that $\Sigma_{b,c;l,m,\sigma,\mu} [(1+k)^{2\alpha}/(1+l)^{2\alpha}(1+m)^{2\alpha}] |C^{(ak\tau)}_{(cm\mu)(bl\sigma)}|^2$ are uniformly bounded for arbitrary k under the restriction $s > (n+1)/2$. Indeed, we have $\forall k$:

$$\sum_{b,c;l,m,\sigma,\mu} \frac{(1+k)^{2\alpha}}{(1+l)^{2\alpha}(1+m)^{2\alpha}} |C^{(ak\tau)}_{(cm\mu)(bl\sigma)}|^2$$

$$\leqslant \sum_{l+m \geqslant k, k+l \geqslant m, m+k \geqslant l} C_0 \frac{(1+k)^{2\alpha}}{(1+l)^{2\alpha}(1+m)^{2\alpha}} \quad [\text{using} \quad (6),\ (7)]$$

$$\leqslant C_0 \sum_{m \geqslant k/2; k \leqslant l+m, l \leqslant k+m, m \leqslant k+l} \frac{(1+k)^{2\alpha}}{(1+l)^{2\alpha}(1+m)^{2\alpha}}$$

$$+ C_0 \sum_{l \geqslant k/2; k \leqslant l+m, m \leqslant k+l, l \leqslant k+m} \frac{(1+k)^{2\alpha}}{(1+l)^{2\alpha}(1+m)^{2\alpha}}$$

$$\leqslant 2C_0 (1+k)^{2\alpha} \sum_{m=0}^{\infty} \frac{1}{(1+m)^{2\alpha}} \frac{2m}{(1+k/2)^{2\alpha}}$$

$$\leqslant C_3 \quad [\text{when} \quad s > (n+1)/2], \tag{15}$$

where C_3 is some absolute constant. Furthermore, note that there exists an absolute constant $C_4 > 1$ such that

$$C_4^{-1}\sqrt{\sum_{a;k,\tau}(1+k)^{2\alpha}|\xi^a_{k,\tau}|^2}\leqslant\|\xi\|:=\sqrt{\sum_{a;k,\tau}[(1+\lambda_k)^s/d_k]|\xi^a_{k,\tau}|^2}$$
$$\leqslant C_4\sqrt{\sum_{a;k,\tau}(1+k)^{2\alpha}|\xi^a_{k,\tau}|^2};$$

we arrive the estimate

$$Q\leqslant C_5\|x\|\|\xi\|^2,$$

for some absolute constant C_5 from the above estimates when $s>(n+1)/2$. This gives

$$\left|\sum_{a,b;k,l,\tau,\sigma}h_{(al\tau)(bl\sigma)}(x)\xi^a_{k,\tau}\xi^b_{l,\sigma}-\sum_{a;k,\tau}[(1+\lambda_k)^s/d_k](\xi^a_{k,\tau})^2\right|\leqslant(C_6+O(\|x\|))\|x\|\|\xi\|^2,$$

for some absolute constant C_6 from (14).

Hence there exist suitably small positive constants A,α $(0<\alpha\leqslant\beta)$ such that

$$\sum_{a,b;k,l,\tau,\sigma}h_{(ak\tau)(bl\sigma)}(x)\xi^a_{k,\tau}\xi^b_{l,\sigma}\geqslant A\|\xi\|^2,\quad\forall x\in B_e(\alpha).$$

The proof of Lemma 1 is completed.

Remark 1: The property of Lemma 1 (a) is called the uniform positive of the metric and the property of Lemma 1 (b) the homogeneity of the metric. As showing in Remark 2 in Ref. 8, the uniform positive and homogeneity of the metric can not be guaranteed on a Riemann–Hilbert manifold in general. This is one of the reasons why we restrict our attention to gauge groups.

Substituting (13) into (8) and by a direct calculation, we have

$$\Gamma^{(cm\mu)}_{(ak\tau)(bl\sigma)}(x)=\frac{d_m}{2|1+\lambda_m|^s}\left(\frac{1}{2}B^{(ak\tau)}_{(bl\sigma)(cm\mu)}+\frac{1}{2}B^{(cm\mu)}_{(ak\tau)(bl\sigma)}-\frac{1}{2}B^{(bl\sigma)}_{(cm\mu)(ak\tau)}\right)(1+O(x)),\quad(16)$$

where $B^{(cm\mu)}_{(ak\tau)(bl\sigma)}=-[(1+\lambda_m)^s/d_m]C^{(cm\mu)}_{(ak\tau)(bl\sigma)}-[(1+\lambda_l)^s/d_l]C^{(bl\sigma)}_{(ak\tau)(cm\mu)}$. Using the same method used in proving Lemma 1 above, from the expression (16), we may have the following (the details are omitted)

Lemma 2: Under the same assumptions as in Lemma 1, we have

(i)

$$\|\Gamma^{(cm\mu)}_{(ak\tau)(bl\sigma)}(x)\xi^a_{k\tau}\eta^b_{l,\sigma}\|^2:=\sum_{c;m,\mu}[(1+\lambda_m)^s/d_m]\left(\sum_{a,b;k,l,\tau,\sigma}\Gamma^{(cm\mu)}_{(ak\tau)(bl\sigma)}(x)\xi^a_{k,\tau}\eta^b_{l,\sigma}\right)^2$$
$$\leqslant C_7\|\xi\|^2\|\eta\|^2,\qquad x\in B_e(\alpha),$$

for some constant $C_7>0$;

(ii)

$$\|(\Gamma^{(cm\mu)}_{(ak\tau)(bl\sigma)}(x)-\Gamma^{(cm\mu)}_{(ak\tau)(bl\sigma)}(y))\xi^a_{k,\tau}\eta^b_{l,\sigma}\|^2\leqslant C_8\|x-y\|^2\|\xi\|^2\|\eta\|^2,\qquad x,y\in B_e(\alpha),$$

for some positive constant C_8.

It seems that gauge groups $\mathrm{Map}(M,G)$ for higher-dimensional M can not be rewritten by a complexification with some reality condition in general. However, loop groups $\mathrm{Map}(S^1,G)$ does (see Refs. 5,8) and it is very convenient for calculations and statements. With the help of its complexification (with a reality condition), we can prove that Lemmas 1 and 2 are still valid for all the Hilbert loop groups $H_s(LG)$ $(s>1/2)$. Following the same notations in Ref. 8 (note that the symbol n denotes a index this time), we have Lemma $1'$.

Lemma $1'$: Let $\tilde{G}=H_s(LG)$ $(s>1/2)$. Then

(a) there are positive numbers A and α such that

$$\sum_{a,b,n,m} h_{(na)(mb)}(x)\lambda_n^a\lambda_m^b \geqslant A\sum_{a,n} (|n|^s\lambda_n^a)^2,$$

for all $x\in B_e(\alpha)\subset U_e$, and $(\lambda_n^a)\in\tilde{g}=H_s(Lg)$, the Lie algebra of $\tilde{G}$.

(b) For any given point $w\in\tilde{G}$, in the neighborhood $B_w(\alpha)=w\cdot B_e(\alpha)$ of w, the estimate in (a) above is still valid.

Proof: With the same methods used in the proof of Lemma 1 in Ref. 8, the key step is to prove that the estimate (11) in Ref. 8 is still valid for all the fixed $s>1/2$. We can arrive this estimate by the following two observations:

(α) An inequality $|l+n|\leqslant 2|l||n|$ for all nonzero integers l,m and hence

$$|l+n|^s\leqslant 2^s|l|^s|n|^s, \quad l,n\neq 0.$$

(β)

$$\begin{aligned}
I &\leqslant \sum_{a,b,c,n,m,l} |m|^{2s}|\alpha_{(lc)(na)}^{(mb)}x_l^c\lambda_n^a\lambda_m^b| \\
&\leqslant 3C_0\sum_{a,b,c,l,n} |l+n|^{2s}|x_l^c\lambda_n^a\lambda_{l+n}^b| \quad [\text{using} \quad (3),(4) \quad \text{in} \quad \text{Ref. 8}] \\
&\leqslant 3C_0 2^s\sum |l+n|^s|l|^s|n|^s|x_l^c\lambda_n^a\lambda_{l+n}^b| \\
&\leqslant 3\cdot 2^sC_0\sqrt{\sum_{a,n}|n|^{2s}|\lambda_n^a|^2}\sqrt{\sum_{c,l}|l|^{2s}|x_l^c|^2}\sqrt{\sum_{b,l,n}|l+n|^{2s}|\lambda_{l+n}^b|^2} \\
&\leqslant C_2\|x\|\|\lambda\|^2,
\end{aligned}$$

for some constant C_2 [this estimate holds similarly if we instead have $|\cdot|^{2s}$ by $(1+|\cdot|^2)^s$]. This establishes (11) for all $s>1/2$. The proof of Lemma $1'$ is completed.

Using the same argument (β) above with the aid of the inequality (α), we can also have Lemma $2'$.

Lemma $2'$: Under the same assumptions as in Lemma $1'$, we have

(i)

$$\|\Gamma_{(nk)(bm)}^{(cl)}(x)\lambda_n^a\mu_m^b\|^2\leqslant C_7\|\xi\|^2\|\eta\|^2, \qquad x\in B_e(\alpha),$$

for some constant $C_7>0$;

(ii)

$$\|(\Gamma_{(an)(bm)}^{(cl)}(x)-\Gamma_{(an)(bm)}^{(cl)}(y))\lambda_n^a\mu_m^b\|^2\leqslant C_8\|x-y\|^2\|\xi\|^2\|\eta\|^2, \qquad x,y\in B_e(\alpha),$$

for some positive constant C_8.

IV. HARMONIC MAPS FROM $R^{1,1}$ INTO GAUGE GROUPS

Let $R^{1,1}=\{(t,x):ds^2=dt^2-dx^2\}$ be the Minkowski plane (throughout this section x denotes the second coordinate of $R^{1,1}$). We represent a smooth map $u:R^{1,1}\to\tilde{G}=H_s(S^n,G)$ in an exponential coordinate chart as $u=\{u_{k,\tau}^a\}$ $(1\leqslant a\leqslant N;k\in Z_+,1\leqslant\tau\leqslant d_k)$. u is called a harmonic map if and only if u satisfies the following (hyperbolic) harmonic systems:

$$\frac{\partial^2u_{m,\mu}^c}{\partial t^2}-\frac{\partial^2u_{n,\mu}^c}{\partial x^2}+\sum \Gamma_{(ak\tau)(bl\sigma)}^{(cm\mu)}(u)\left(\frac{\partial u_{k,\tau}^a}{\partial t}\frac{\partial u_{l,\sigma}^b}{dt}-\frac{\partial u_{k,\tau}^a}{\partial x}\frac{\partial u_{l,\sigma}^b}{\partial x}\right)=0,\forall c;m,\mu. \tag{17}$$

In fact, (17) is the Lagrange–Euler equations of the (formal) energy $E(u)$,

$$E(u)=\int_{R^{1,1}} e(u)dt\,dx,$$

where $e(u)$ is the energy density:

$$e(u)=\left(\frac{\partial u^a_{k,\tau}}{\partial t}\frac{\partial u^b_{l,\sigma}}{dt}-\frac{\partial u^a_{k,\tau}}{\partial x}\frac{\partial u^b_{l,\sigma}}{\partial x}\right)h_{(ak\tau)(bl\sigma)}.$$

If $\tilde{G}$ is a finite-dimensional Lie group, then (18) is nothing but the equations of a two-dimensional σ-model or chiral. Since (18) is hyperbolic, we also propose an initial condition (Ref. 8) by

$$u^c_{m,\mu}(0,x)=(\phi_0)^c_{m,\mu}(x),\quad \frac{\partial u^c_{m,\mu}}{\partial t}(0,x)=(\phi_1)^c_{m,\mu}(x), \tag{18}$$

where $\phi_0=\{(\phi_0)^c_{m,\mu}(x)\}:R\to\tilde{G}$ is a smooth curve on $\tilde{G}$ and $\phi_1=\{(\phi_1)^c_{m,\mu}(x)\}$ is a smooth vector field along the curve ϕ_0 (i.e., $\|\phi_1(x)\|<\infty$).

Without a loss of generality, we assume that $\phi_0(0)=id\in\tilde{G}$, and introduce the characteristic coordinates (ξ,η) of $R^{1,1}$ (throughout this section ξ,η always denote the characteristic coordinates of $R^{1,1}$):

$$\xi=\frac{t+x}{2},\quad \eta=\frac{t-x}{2}.$$

Hence harmonic systems (18) become

$$\frac{\partial^2 u^c_{m,\mu}}{\partial\xi\partial\eta}+\Gamma^{(cm\mu)}_{(ak\tau)(bl\sigma)}(u)\frac{\partial u^a_{k,\tau}}{\partial\xi}\frac{\partial u^b_{l,\sigma}}{\partial\eta}=0,\quad \forall c;m,\mu. \tag{19}$$

Now can completely follow the program displayed in Ref. 8 IV to establish the global existence of harmonic map systems (17) with the initial condition (18). Here we give a sketch as follows

First of all we come to state a local existence result for hyperbolic harmonic maps from $R^{1,1}$ into $\tilde{G}=H_s(S^n,G)[n\geqslant 2,s>(n+1)/2$ or $n=1,s>1/2]$. For a given large positive number $L>0$, let M be a number defined by

$$\sup_{|x|\leqslant L}\left\{\left[h_{(ak\tau)(bl\sigma)}(\phi_0)\frac{\partial u^a_{k,\tau}}{\partial\xi}\bigg|_{t=0}\frac{\partial u^b_{l,\sigma}}{\partial\xi}\bigg|_{t=0}\right]^{1/2},\left[h_{(ak\tau)(bl\sigma)}(\phi_0)\frac{\partial u^a_{k,\tau}}{\partial\eta}\bigg|_{t=0}\frac{\partial u^b_{l,\sigma}}{\partial\eta}\bigg|_{t=0}\right]^{1/2}\right\}$$

from (18). Let Λ_ν be a characteristic triangle in $R^{1,1}$ such that $\frac{1}{2}\nu\geqslant\xi\geqslant-\eta\geqslant-\frac{1}{2}\nu$, where

$$\nu=\min\left\{L,\alpha\sqrt{\frac{A}{M}}\right\},$$

and α,A are the positive constants that appeared in Lemma 1.

Lemma 3: For s with the restriction as in Lemma 1 (or the restriction in Lemma 1′), there exists a unique solution of (17) or (19) on Λ_ν satisfying the initial condition (18).

Outline of Proof: We consider, in a similar way as done in Ref. 8, the first order infinite systems as follows:

$$\begin{gathered}\frac{\partial y^c_{m,\mu}}{\partial\eta}+\Gamma^{(cm\mu)}_{(ak\tau)(bl\sigma)}(v)y^a_{k,\tau}z^b_{l,\sigma}=0,\quad \frac{\partial z^c_{m,\mu}}{\partial\xi}+\Gamma^{(cm\mu)}_{(ak\tau)(bl\sigma)}(u)z^a_{k,\tau}y^b_{l,\sigma}=0,\\ \frac{\partial u^c_{m,\mu}}{\partial\xi}=y^c_{m,\mu},\qquad \frac{\partial v^c_{m,\mu}}{\partial\eta}=z^c_{m,\mu},\end{gathered} \tag{20}$$

with the corresponding initial conditions:

$$u^c_{m,\mu}(0,x)=v^c_{m,\mu}(0,x)=(\phi_0)^c_{m,\mu}(x),\quad y^c_{m,\mu}(0,x)=\frac{\partial(\phi_0)^c_{m,\mu}(x)}{\partial x}+(\phi_1)^c_{m,\mu}(x),\tag{21}$$

$$z^c_{m,\mu}(0,x)=-\frac{\partial(\phi_0)^c_{m,\mu}(x)}{\partial x}+(\phi_1)^c_{m,\mu}(x).$$

It is easy to see that if we can construct a unique solution of (20), (21) satisfying $u^c_{m,\mu}(t,x)=v^c_{m,\mu}(t,x)$, $\forall c,m,\mu$, then $u=\{u^c_{m,\mu}\}$ is the unique solution of (17), (18) over Λ_ν.

Thus, our aim is to construct a solution of (20), (21) on Λ_ν and to prove that such a solution must satisfy $u^c_{m,\mu}=v^c_{m,\mu},\forall c;m,\mu$. In fact, by using the same methods used in proving Lemma 2 in Ref. 8 with the aid of Corollary 1 (i.e., a local existence result for a linear partial differential system in Hilbert space) stated in Sec. IV (A) in Ref. 8, an elementary result in Riemann–Hilbert geometry which says that the length of a parallel vector field is still preserved invariant and the completeness of Hilbert Lie groups, we may be able to arrive at this conclusion. It should be pointed out that Lemma 1 and Lemma 2 (or Lemma 1′ and Lemma 2′) have played an essential role in this proof.

Next we come to state our main existence results of globally defined harmonic maps from the Minkowski plane into Hilbert Lie loop groups $H_s(LG)(s>1/2)$ or Hilbert Lie gauge groups $H_s(S^n,G)$ $(n\geqslant 2;s>(n+1)/2)$. These answer the two questions remaining from Ref. 8.

Theorem 1: There exists a unique globally defined harmonic map $u:R^{1,1}\to H_s(LG)$ $(s>1/2)$ satisfying a given initial conditions (18).

Theorem 2: There exists a unique globally defined harmonic map $u:R^{1,1}\to H_s(S^n,G)$ $(n\geqslant 2;s>(n+1)/2)$ satisfying a given initial conditions (18).

Since the proofs of Theorem 1 or 2 mainly depend on Lemma 3, we can give a unified proof of Theorem 1 and 2 as follows:

Proof: It is sufficient to prove the existence of a solution for the Cauchy problem (17), (18) in a given characteristic triangle $\Lambda_L=\{-\frac{1}{2}L\leqslant-\eta\leqslant\xi\leqslant\frac{1}{2}L\}$, where L is an arbitrary fixed positive number.

We write the initial conditions in the form

$$u\Big|_{t=0}=\phi_0(x),\quad \frac{\partial u}{\partial t}\Big|_{t=0}=\phi_1(x),$$

where $\phi_0=\phi_0(x)$ is a curve γ in $\tilde{G}=H_s(S^n,G)(n\geqslant 2,s>(n+1)/2$ or $n=1,s>1/2)$ and $\phi_1=\phi_1(x)$ is a tangent vector field along γ. Let

$$M=\max\left\{\sup_{-L\leqslant x\leqslant L}\left\|\frac{\partial u}{\partial\xi}\right\|_{t=0},\ \sup_{-L\leqslant x\leqslant L}\left\|\frac{\partial u}{\partial\eta}\right\|_{t=0}\right\},$$

where $\|\cdot\|$ denotes the length of a vector field on $\tilde{G}$ with respect to the H_s-metric. Put $\rho=\min\{L,\alpha\sqrt{A/M}\}$ where α,A are the constants that appeared in Lemma 1 (or Lemma 1′).

From Lemma 3 we see that the Cauchy problem (17), (18) on each characteristic triangle whose base side is not larger than 2ρ and lies in the interval $-L\leqslant x\leqslant L$ admits a solution. By uniqueness, on any overlapping region of two such characteristic triangles the two solutions coincide. Hence the Cauchy problem is solvable up to $t=\rho$ and the solution $u=p(t,x)$ is smooth.

Next we consider the Cauchy problem for (17) or (19) with the initial conditions

$$u|_{t=\varsigma\rho}=p(\varsigma\rho,x),\quad \frac{\partial u}{\partial t}\Big|_{t=\varsigma\rho}=\frac{\partial p}{\partial t}(\varsigma\rho,x),\qquad -L+\varsigma\rho\leqslant x\leqslant L-\varsigma\rho,\tag{22}$$

where $\varsigma>0$ is a fixed positive integer, provided the problem is solved up to $t=\varsigma\rho$. Evidently, on the line segment $-L+\varsigma\rho\leqslant x\leqslant L-\varsigma\rho$, we have

$$\left\|\frac{\partial p}{\partial \xi}\right\|_{t=s\rho}=\left\|\frac{\partial p}{\partial \xi}\right\|_{t=0}\leqslant M,\quad \left\|\frac{\partial p}{\partial \xi}\right\|_{t=s\rho}=\left\|\frac{\partial p}{\partial \xi}\right\|_{t=0}\leqslant M,$$

by the conservational law of harmonic map systems on $R^{1,1}$ [refer to (24) in Ref. 8 for details]. Therefore, by using Lemma 1 (b) [or Lemma 1′ (b)], we may also choose the same $\rho=\min\{L,\alpha\sqrt{A/M}\}$ for obtaining the local existence result of the Cauchy problem (17), (22). With the same arguments above, we see that the Cauchy problem for (17), (22) is solvable up to $t=(s+1)\rho$. Using this procedure successively we conclude the existence of a global solution on Λ_L. The uniqueness of solutions is obvious. This completes the proofs of Theorems 1–2.

V. CONCLUSION AND REMARKS

In the present paper, we have proved the global existence of the Cauchy problem of harmonic maps from $R^{1,1}$ into Hilbert loop groups $H_s(LG)$ $(s>1/2)$ or into Hilbert Lie gauge groups $H_s(S^n,G)$ $(n\geqslant 2; s>(n+1)/2)$. The proof strongly depends on certain geometric properties of these infinite-dimensional groups (Lemmas 1–2). It is natural to ask the following question: do there exist globally defined harmonic maps from $R^{1,1}$ into $H_s(S^n,G)$ when $n\geqslant 2$ and $n/2<s\leqslant(n+1)/2$ too?

The analogous results to the Hilbert Lie gauge groups $H_s(M,G)$ for M to be a real projective space RP^n or complex projective space CP^n may be established in the same way, since one has also known the detailed information about the spectrum of the Laplace operator on RP^n or CP^n. However, the same geometric properties (Lemmas 1–2) of the Hilbert Lie gauge groups $H_s(M,G)$ $(\dim M\geqslant 2)$ for a general Riemannian manifold M are still to be characterized, since one has not had a full understanding of the harmonic theory on an arbitrary Riemannian manifold M yet.

Finally we would like to mention a related interesting conjecture proposed by Atiyah (Ref. 17) states that any harmonic map from S^2 to the based loop group $\Omega(SU(2))$ (with the $H_{1/2}$-metric) is either a holomorphic or anti-holomorphic map. Combining it with an excellent work by Sibner, Sibner, and Uhlenbeck (Ref. 18), we wonder if it is possible to construct a counterexample to Atiyah's conjecture. Similar to a story, which says that the study of Yang–Mills systems over the 4-dimensional Minkowski space $R^{3,1}$ can be transformed to the study of Yang–Mills systems over the 4-dimensional Euclidean space R^4 by the path integral approach, the study of globally defined harmonic maps from $R^{1,1}$ into loop groups treated in this paper perhaps relates to constructions of nontrivial harmonic maps from R^2 or S^2 (for $S^2=R^2\cup\{\infty\}$) into the loop group $\Omega(G)$.

(Received 8 July 1998; accepted for publication 4 August 1998)

The space–time disclination is studied by making use of the decomposition theory of gauge potential in terms of the antisymmetric tensor field and ϕ-mapping method. It is shown that the self-dual and anti-self-dual parts of the curvature compose the space–time disclinations which are classified in terms of topological invariants—winding number. The projection of space–time disclination density along an antisymmetric tensor field is quantized topologically and characterized by Brouwer degree and Hopf index. © *1998 American Institute of Physics.* [S0022-2488(98)03412-4]

I. INTRODUCTION

The topological space–time defects, if they exist, may help to explain some of the largest-scale structures seen in the universe today. They may have been found at phase transitions in the early history of the universe, analogous to those found in some condensed matter systems—the vortex line in liquid helium, flux tubes in type-II superconductors, or disclination lines in liquid crystals.

As a kind of space–time defect, torsion plays an important role in modern physics. Recently, a lot of works on the spin and torsion have been done by many physicists.[1–11] Many of them[8–11] are focused on the so-called space–time dislocation by considering the effect of topology of torsion in the Riemann–Cartan manifold. The consideration partially comes from the gauge field theory of dislocation and disclination continuum about deformable material media.[12–16] These works are trying to clarify the quantization of the gravitation (i.e., to quantize the Riemann–Cartan space-time itself). Moreover, they hope to find that the dynamical relation between the stress-energy-momentum tensor and curvature is expressed in general relativity by Einstein equations.

On the other hand, there exists another kind of space–time defect called space–time disclination. This kind of defect has the same important meaning as that of the torsion. Space-time disclination reflects the intrinsic property of the curved space–time. It is caused by inserting solid angles into the flat space–time. In Riemann–Cartan geometry, this effect is shown by the integral of the affine curvature along a closed surface. Duan, Duan and Zhang[12] had discussed the disclinations in deformable material media by applying the gauge field theory and decomposition theory of gauge potential. In their works, the projection of disclination density along the gauge parallel vector was found to correspond to a set of isolated disclinations in the three-dimensional sense and to be topologically quantized. The decomposition theory of gauge potential and ϕ-mapping method that they used are good tools to study the problems of gauge field.

In this paper, we discuss the space–time disclinations in a similar way to that used in Duan *et al.*'s works on the condensed matter disclination.[12] The decomposition formulas of SO(4) and SU(2) gauge potentials are given in terms of the antisymmetric tensor field and unit vector field, respectively. Using this decomposition theory the space–time disclinations are classified into two classes which are marked by the self-dual and anti-self-dual parts of the curvature. The projection of space–time disclination density along the gauge parallel tensor can be written in terms of winding numbers. Moreover we show that the projection of space–time disclination density,

a)Electronic mail: ysduan@lzu.edu.cn
b)Author to whom all correspondence should be addressed; electronic mail: lisheng@itp.ac.cn

 © 1998 American Institute of Physics

which is quantized topologically, corresponds to two groups of isolated disclinations. The positions of the disclination vertices are determined by the zeroes of the self-dual or anti-self-dual part of an antisymmetric tensor. And the Hopf index and Brouwer degree classify the disclinations and characterize the local nature of the space–time disclinations. For this quantization of the space-time, disclinations are directly related to the space–time curvature. As will be shown in this paper, it perhaps relates to the quantization of space–time.

This paper is arranged as follows: In Sec. II, we discuss the representation of the space–time disclination. In Sec. III, the decomposition of the SO(4) gauge potential is given by considering the relationship between SO(4) gauge theory and SU(2) gauge theory. Finally, we discuss the topological quantization and the local topological property of the space–time disclination in Sec. IV.

II. THE REPRESENTATION OF SPACE-TIME DISCLINATION

Let $\mathbf{M}$ be a compact, oriented four-dimensional Riemannian–Cartan manifold and $P(\mathbf{M},G,\pi)$ be a principal bundle with structure group $G=\mathrm{SO}(4)$. As was shown in Ref. 12, the dislocation and disclination continuum can be described by the reference, deformed and natural states. For the natural state there is only an anholonomic rectangular coordinate Z^a $(a=1,2,3,4)$ and

$$\delta Z^a = e^a_\mu \, dx^\mu, \tag{1}$$

where e^a_μ is vielbein. The metric tensor of the Riemann–Cartan manifold of natural state is defined by

$$g_{\mu\nu} = e^a_\mu e^a_\nu. \tag{2}$$

We have known that the metric tensor $g_{\mu\nu}$ is invariant under the local SO(4) transformation of vielbein. The corresponding gauge covariant derivative one-form of an antisymmetric tensor field $\phi^{ab}=-\phi^{ba}$ on $\mathbf{M}$ is given as

$$D\phi^{ab} = d\phi^{ab} - \omega^{ac}\phi^{cb} - \omega^{bc}\phi^{ac}, \tag{3}$$

where ω^{ab} is the SO(4) spin connection one-form

$$\omega^{ab} = -\omega^{ba}, \quad \omega^{ab} = \omega^{ab}_\mu \, dx^\mu. \tag{4}$$

The affine connection of the Riemann–Cartan space is determined by

$$\Gamma^\lambda_{\mu\nu} = e^{\lambda a} D_\mu e^a_\nu. \tag{5}$$

The torsion tensor is the antisymmetric part of $\Gamma_{\mu\nu}$ and is expressed as

$$T^\lambda_{\mu\nu} = e^{\lambda a} T^a_{\mu\nu}, \tag{6}$$

where

$$T^a_{\mu\nu} = \tfrac{1}{2}(D_\mu e^a_\nu - D_\nu e^a_\mu). \tag{7}$$

The Riemannian curvature tensor is equivalent to the SO(4) gauge field strength tensor two-form F^{ab}, which is given by

$$F^{ab} = d\omega^{ab} - \omega^{ac}\wedge\omega^{cb}, \quad F^{ab} = \tfrac{1}{2}F^{ab}_{\mu\nu} \, dx^\mu \wedge dx^\nu \tag{8}$$

and relates to the Riemann curvature tensor by

$$F^{ab}_{\mu\nu} = -R^\lambda_{\mu\nu\sigma} e^a_\lambda e^{\sigma b}. \tag{9}$$

The dislocation density is defined by

$$\alpha^a = T^a, \quad T^a = \tfrac{1}{2}T^a_{\mu\nu} \, dx^\mu \wedge dx^\nu. \tag{10}$$

Analogous to the definition of the three-dimensional disclination density in the gauge field theory of condensed matter, we define the space–time disclination density as

$$\theta^{ab}=\tfrac{1}{2}R^{\lambda}_{\mu\nu\sigma}e^{a}_{\lambda}e^{\sigma b}\ dx^{\mu}\wedge dx^{\nu}=-F^{ab}. \tag{11}$$

The size of the space–time disclination can be represented by means of the surface integral of the projection of the space–time disclination density along an antisymmetric tensor field n^{ab},

$$\Omega=\oint_{\Sigma}\theta^{ab}n^{ab}=-\oint_{\Sigma}F^{ab}n^{ab}, \tag{12}$$

where Σ is a closed surface including the disclinations. The new quantity Ω defined by (12) is dimensionless. Using the so-called ϕ-mapping method and the decomposition of gauge potential Duan *et al*. have proved that the dislocation flux is quantized in units of the Planck length.[11] In this paper we will show the size of the space–time disclination (12) is topologically quantized and is the sum of two groups of solid angles representing the size of disclinations.

III. DECOMPOSITION THEORY OF SO(4) SPIN CONNECTION

In this section we will give the decomposition theory of the SO(4) gauge potential in terms of an antisymmetric tensor field on a compact and oriented four-dimensional manifold, which is the foundation of topological gauge field theory. It will be seen in the following discussion that this decomposition of the SO(4) gauge potential is expressed by the combination of the SU(2) gauge potential. Hence we must first study the decomposition of the SU(2) gauge potential in terms of the sphere bundle on a compact and oriented four-dimensional manifold.

Let n be a unit SU(2) Lie algebraic vector

$$n=n^{A}I_{A},\quad A=1,2,3, \tag{13}$$

and

$$n^{A}n^{A}=1, \tag{14}$$

in which I_A is the generator of the group SU(2), which satisfies the commutation relation

$$[I_A,I_B]=-\epsilon^{ABC}I_C. \tag{15}$$

The covariant derivative one-form of n is given by

$$D_{\mathrm{SU}(2)}n=dn-[\omega_{\mathrm{SU}(2)},n], \tag{16}$$

where $\omega_{\mathrm{SU}(2)}$ is the SU(2) gauge potential one-form:

$$\omega_{\mathrm{SU}(2)}=\omega^{A}_{\mathrm{SU}(2)}I_A, \tag{17}$$

and

$$\omega^{A}_{\mathrm{SU}(2)}=\omega^{A}_{\mathrm{SU}(2)\mu}\ dx^{\mu},\quad \mu=0,1,2,3. \tag{18}$$

The curvature two-form is

$$F_{\mathrm{SU}(2)}=F^{A}_{\mathrm{SU}(2)}I_A=d\omega_{\mathrm{SU}(2)}-\omega_{\mathrm{SU}(2)}\wedge\omega_{\mathrm{SU}(2)}, \tag{19}$$

and

$$F^{A}_{\mathrm{SU}(2)}=\tfrac{1}{2}F^{A}_{\mathrm{SU}(2)\mu\nu}\ dx^{\mu}\wedge dx^{\nu}=d\omega^{A}_{\mathrm{SU}(2)}+\tfrac{1}{2}\epsilon^{ABC}\omega^{B}_{\mathrm{SU}(2)}\wedge\omega^{C}_{\mathrm{SU}(2)}. \tag{20}$$

Let $m=m^{A}I_A$, $l=l^{A}I_A$ be another two unit SU(2) algebraic vector orthornormal to n and to each other, satisfying

$$n^A = \epsilon^{ABC} m^B l^C. \tag{21}$$

It can be proved that the SU(2) gauge potential can be decomposed by n, m, l as

$$\omega^A_{\mathrm{SU}(2)} = \epsilon^{ABC}(dn^B\, n^C - D_{\mathrm{SU}(2)} n^B n^C) - n^A A, \tag{22}$$

where

$$A = dm^A\, l^A - D_{\mathrm{SU}(2)} m^A l^A \tag{23}$$

is a U(1)-like gauge potential.

If n is taken as a gauge parallel vector, i.e.,

$$D_{\mathrm{SU}(2)} n = 0, \tag{24}$$

the SU(2) gauge potential becomes

$$\omega^A_{\mathrm{SU}(2)} = \epsilon^{ABC}\, dn^B\, n^C - n^A A. \tag{25}$$

Then we can easily get the curvature two-form $F^A_{\mathrm{SU}(2)}$ as

$$F^A_{\mathrm{SU}(2)} = n^A\, dA - \tfrac{1}{2}\epsilon^{ABC}\, dn^B \wedge dn^C. \tag{26}$$

Now let us consider the SO(4) gauge theory. Let the four-dimensional Dirac matrix γ_a ($a = 1,2,3,4$) be the basis of the Clifford algebra which satisfies

$$\gamma_a \gamma_b + \gamma_b \gamma_a = 2\delta_{ab}. \tag{27}$$

The antisymmetric tensor field ϕ^{ab} on $\mathbf{M}$ can be expressed in the following matrix form:

$$\phi = \tfrac{1}{2}\phi^{ab} I_{ab}, \tag{28}$$

in which I_{ab} is the generator of the group SO(4),

$$I_{ab} = \tfrac{1}{4}[\gamma_a, \gamma_b]. \tag{29}$$

Similarly, the spin connection one-form and curvature two-form can be expressed as

$$\omega = \tfrac{1}{2}\omega^{ab} I_{ab}, \quad F = \tfrac{1}{2} F^{ab} I_{ab}. \tag{30}$$

It is well known that the spin representation of the SO(4) group is hormorphic to the direct product of the representations of two SU(2) groups,[17]

$$\mathrm{so}(4) \cong \mathrm{su}(2) \otimes \mathrm{su}(2). \tag{31}$$

The generators of the SO(4) group can be divided into two terms. Each term is a generator of some SU(2) group. Define

$$I^1_{\pm} = \tfrac{1}{2} I_{23}(1 \mp \gamma_5) = \tfrac{1}{4}(\gamma_2 \gamma_3 \pm \gamma_1 \gamma_4), \tag{32}$$

$$I^2_{\pm} = \tfrac{1}{2} I_{31}(1 \mp \gamma_5) = \tfrac{1}{4}(\gamma_3 \gamma_1 \pm \gamma_2 \gamma_4), \tag{33}$$

$$I^3_{\pm} = \tfrac{1}{2} I_{12}(1 \mp \gamma_5) = \tfrac{1}{4}(\gamma_1 \gamma_2 \pm \gamma_3 \gamma_4), \tag{34}$$

in which $\gamma_5 = \gamma_1 \gamma_2 \gamma_3 \gamma_4$. It can be proved $I^A_{\pm} (A = 1,2,3)$ satisfy the commutation relation of group $\mathrm{SU}(2)_{\pm}$,

$$I^A_{\pm} = -\epsilon^{ABC}[I^B_{\pm}, I^C_{\pm}], \tag{35}$$

and

$$[I_{\pm}^{A}, I_{\mp}^{B}] = 0. \tag{36}$$

Therefore $I_{\pm}^{A}$ are the generators of two different groups $\mathrm{SU}(2)_{\pm}$, and they are the basis of $\mathrm{SU}(2)_{\pm}$ Lie algebraic spaces.

An arbitrary antisymmetric tensor field ϕ^{ab} can be decomposed as

$$\phi^{ab} = \phi_{+}^{ab} + \phi_{-}^{ab}, \tag{37}$$

where

$$\phi_{+}^{ab} = \tfrac{1}{2}(\phi^{ab} + \tfrac{1}{2}\epsilon^{abcd}\phi^{cd}), \quad \phi_{-}^{ab} = \tfrac{1}{2}(\phi^{ab} - \tfrac{1}{2}\epsilon^{abcd}\phi^{cd}) \tag{38}$$

are the self-dual and anti-self-dual parts of ϕ^{ab}. Define

$$\phi_{\pm}^{1} = \phi^{23} \pm \phi^{14}, \quad \phi_{\pm}^{2} = \phi^{31} \pm \phi^{24}, \quad \phi_{\pm}^{3} = \phi^{12} \pm \phi^{34}. \tag{39}$$

We can rewrite ϕ as

$$\phi = \tfrac{1}{2}\phi^{ab} I_{ab} = \phi_{+} + \phi_{-}, \tag{40}$$

and

$$\|\phi_{\pm}\|^{2} = \phi_{\pm}^{A}\phi_{\pm}^{A} = \phi_{\pm}^{ab}\phi_{\pm}^{ab}, \tag{41}$$

in which

$$\phi_{\pm} = \tfrac{1}{2}\phi(1 \mp \gamma_5) = \phi_{\pm}^{A} I_{\pm}^{A}. \tag{42}$$

From the above discussion, we see that $\phi_{\pm}$ are the $\mathrm{SU}(2)_{\pm}$ algebraic vectors. With a similar decomposition as above it can be verified that

$$D\phi_{+} + D\phi_{-} = d\phi_{+} - [\omega_{+}, \phi_{+}] + d\phi_{-} - [\omega_{-}, \phi_{-}]. \tag{43}$$

For the independent of I_{+} and I_{-} we have

$$D\phi_{\pm} = d\phi_{\pm} - [\omega_{\pm}, \phi_{\pm}] \quad or \quad D\phi_{\pm}^{A} = d\phi_{\pm}^{A} - \epsilon^{ABC}\omega_{\pm}^{C}\phi_{\pm}^{B}, \tag{44}$$

in which

$$\omega_{\pm} = \omega_{\pm}^{A} I_{\pm}^{A} \tag{45}$$

is the gauge potential of the $\mathrm{SU}(2)_{\pm}$ gauge field. Similarly curvature two-form can be decomposed as

$$F = F_{+} + F_{-}, \tag{46}$$

and

$$F_{\pm} = d\omega_{\pm} - \omega_{\pm} \wedge \omega_{\pm}. \tag{47}$$

$F_{\pm} = F_{\pm}^{A} I_{\pm}^{A}$ are the curvature two-forms of the $\mathrm{SU}(2)_{\pm}$ gauge field.

Now define an antisymmetric tensor

$$n^{ab} = \frac{\phi_{+}^{ab}}{\|\phi_{+}\|} + \frac{\phi_{-}^{ab}}{\|\phi_{-}\|}, \tag{48}$$

i.e.,

$$n_{+}^{ab} = \frac{\phi_{+}^{ab}}{\|\phi_{+}\|}, \quad n_{-}^{ab} = \frac{\phi_{-}^{ab}}{\|\phi_{-}\|}. \tag{49}$$

Then

$$n=\tfrac{1}{2}n^{ab}I_{ab}=n_{+}+n_{-} \tag{50}$$

and

$$n_{\pm}=\frac{1}{2\|\phi_{\pm}\|}\phi(1\mp\gamma_5)=n_{\pm}^{A}I_{\pm}^{A}\,. \tag{51}$$

It naturally guarantees the constraint

$$n_{\pm}^{A}n_{\pm}^{A}=1, \tag{52}$$

i.e., $n_{\pm}^{A}$ are the $\mathrm{SU}(2)_{\pm}$ lie algebraic unit vectors. If n is taken as a gauge parallel tensor field

$$Dn=0, \tag{53}$$

we have

$$Dn_{\pm}=dn_{\pm}-[\omega_{\pm},n_{\pm}]=0. \tag{54}$$

From the decomposition formula of the SU(2) gauge potential (26) we get

$$F_{\pm}^{A}=n_{\pm}^{A}\ dA_{\pm}-\tfrac{1}{2}\epsilon^{ABC}\ dn_{\pm}^{B}\wedge dn_{\pm}^{C}\,. \tag{55}$$

This formula is very useful in the following discussion of space–time disclinations.

IV. THE TOPOLOGICAL QUANTIZATION AND THE LOCAL TOPOLOGICAL STRUCTURE OF THE SPACE–TIME DISCLINATION

It is easy to see that

$$F^{ab}n^{ab}=F_{+}^{ab}n_{+}^{ab}+F_{-}^{ab}n_{-}^{ab} \tag{56}$$

and

$$F_{\pm}^{A}n_{\pm}^{A}=F_{\pm}^{ab}n_{\pm}^{ab}\,. \tag{57}$$

By considering (55) we have

$$F_{\pm}^{A}n_{\pm}^{A}=dA_{\pm}-\tfrac{1}{2}\epsilon^{ABC}n_{\pm}^{A}\ dn_{\pm}^{B}\wedge dn_{\pm}^{C}\,. \tag{58}$$

Define

$$\Omega_{\pm}=\oint_{\Sigma}\left(\frac{1}{2}\epsilon^{ABC}n_{\pm}^{A}\ dn_{\pm}^{B}\wedge dn_{\pm}^{C}-dA_{\pm}\right). \tag{59}$$

$\Omega_{\pm}$ represent the components of space–time disclination corresponding to a different gauge group $\mathrm{SU}(2)_{\pm}$. The space–time disclination can be expressed as

$$\Omega=\Omega_{+}+\Omega_{-}\,. \tag{60}$$

If the surface Σ is closed, the second term on the right-hand side of (59) contributes nothing to $\Omega_{\pm}$, i.e.,

$$\Omega_{\pm}=\oint_{\Sigma}\frac{1}{2}\epsilon^{ABC}n_{\pm}^{A}\ dn_{\pm}^{B}\wedge dn_{\pm}^{C}\,. \tag{61}$$

To study the relationship between the solid angle $\Omega_{\pm}$ and the local properties of the disclinations inside the closed surface Σ, using the Stokes formula, $\Omega_{\pm}$ can be expressed as

$$\Omega_{\pm}=\int_V \frac{1}{2}\epsilon^{ABC}\, dn_{\pm}^A\wedge dn_{\pm}^B\wedge dn_{\pm}^C, \tag{62}$$

in which $\partial V=\Sigma$. Let us choose coordinates $y=(u^1,u^2,u^3,v)$ on M such that $u=(u^1,u^2,u^3)$ are intrinsic coordinate on V. For the coordinate component, v does not belong to V. Then

$$\Omega_{\pm}=\int_V \frac{1}{2}\epsilon^{ABC}\partial_i n_{\pm}^A\partial_j n_{\pm}^B\partial_k n_{\pm}^C\, du^i\wedge du^j\wedge du^k=\int_V \frac{1}{2}\epsilon^{ijk}\epsilon^{ABC}\partial_i n_{\pm}^A\partial_j n_{\pm}^B\partial_k n_{\pm}^C d^3u, \tag{63}$$

where $i,j,k=1,2,3$ and $\partial_i=\partial/\partial u^i$. Define solid angle densities as

$$\rho_{\pm}=\tfrac{1}{2}\epsilon^{ijk}\epsilon^{ABC}\partial_i n_{\pm}^A\partial_j n_{\pm}^B\partial_k n_{\pm}^C. \tag{64}$$

Then we get

$$\Omega_{\pm}=\int_V \rho_{\pm}d^3u. \tag{65}$$

For Eq. (51), the unit vectors $n_{\pm}^A(x)$ can expressed as follows:

$$n_{\pm}^A=\frac{\phi_{\pm}^A}{\|\phi_{\pm}\|}. \tag{66}$$

Hence

$$dn_{\pm}^A=\frac{1}{\|\phi_{\pm}\|}d\phi_{\pm}^A+\phi_{\pm}^A d\left(\frac{1}{\|\phi_{\pm}\|}\right), \tag{67}$$

and

$$\frac{\partial}{\partial\phi_{\pm}^A}\left(\frac{1}{\|\phi_{\pm}\|}\right)=-\frac{\phi_{\pm}^A}{\|\phi_{\pm}\|^3}. \tag{68}$$

Substituting the above equations into the solid angle density (64) we obtain

$$\begin{aligned}\rho&=\frac{1}{2}\epsilon^{ABC}\epsilon^{ijk}\partial_i(n_{\pm}^A\partial_j n_{\pm}^B\partial_k n_{\pm}^C)\\&=\frac{1}{2}\epsilon^{ABC}\epsilon^{ijk}\partial_i\frac{\phi_{\pm}^A}{\|\phi_{\pm}\|^3}\partial_j\phi_{\pm}^B\partial_k\phi_{\pm}^C\\&=-\frac{1}{2}\epsilon^{ABC}\epsilon^{ijk}\frac{\partial}{\partial\phi_{\pm}^D}\frac{\partial}{\partial\phi_{\pm}^A}\left(\frac{1}{\|\phi_{\pm}\|}\right)\partial_i\phi_{\pm}^D\partial_j\phi_{\pm}^B\partial_k\phi_{\pm}^C.\end{aligned} \tag{69}$$

Define the Jacobian $J(\phi_{\pm}/u)$ as

$$\epsilon^{ABC}J\left(\frac{\phi_{\pm}}{u}\right)=\epsilon^{ijk}\partial_i\phi_{\pm}^A\partial_j\phi_{\pm}^B\partial_k\phi_{\pm}^C. \tag{70}$$

By making use of the Laplacian relation in ϕ-space,

$$\partial_A\partial_A\frac{1}{\|\phi_{\pm}\|}=-4\pi\delta^3(\phi_{\pm}),\quad \partial_A=\frac{\partial}{\partial\phi_{\pm}^A}, \tag{71}$$

we can write the density of the solid angle as the δ-like expression

$$\rho_{\pm}=4\pi\delta^3(\phi_{\pm})J\left(\frac{\phi_{\pm}}{u}\right) \tag{72}$$

and

$$\Omega_{\pm}=\int_V 4\pi\delta^3(\phi_{\pm})J\left(\frac{\phi_{\pm}}{u}\right)d^3u. \tag{73}$$

It is obvious that $\rho_{\pm}$ are nonzero only when $\phi_{\pm}=0$.

Suppose that $\phi_{\pm}^A(x)$ $(A=1,2,3)$ possess $K_{\pm}$ isolated zeros, according to the deduction of Ref. 18 and the implicit function theorem,[19] the solutions of $\phi_{\pm}(u^1,u^2,u^3,v)=0$ can be expressed in terms of $u=(u^1,u^2,u^3)$ as

$$u^i=z_{\pm}^i(v), \quad i=1,2,3 \tag{74}$$

and

$$\phi_{\pm}^A(z_l^1(v),z_l^2(v),z_l^3(v),v)\equiv 0, \tag{75}$$

where the subscript $l=1,2,\ldots,K_{\pm}$ represents the lth zero of $\phi_{\pm}^A$, i.e.,

$$\phi_{\pm}^A(z_{\pm l}^i)=0, \quad l=1,2,\ldots,K_{\pm}, \quad A=1,2,3. \tag{76}$$

It is easy to get the following formula from the ordinary theory of δ-function that

$$\delta^3(\phi_{\pm})J\left(\frac{\phi_{\pm}}{u}\right)=\sum_{i=1}^{K_{\pm}}\beta_{\pm l}\eta_{\pm l}\delta^3(u-z_{\pm l}) \tag{77}$$

in which

$$\eta_{\pm l}=\text{sign } J\left(\frac{\phi_{\pm}}{u}\right)\Bigg|_{x=z_{\pm l}}=\pm 1 \tag{78}$$

is the Brouwer degree of ϕ-mapping and $\beta_{\pm l}$ are positive integers called the Hopf index of map $\phi_{\pm}$. This means that while the point x covers the region neighboring the zero $x=z_{\pm l}$ once, $\phi_{\pm}$ covers the corresponding region $\beta_{\pm l}$ times. Therefore the solid angle density becomes

$$\rho_{\pm}=4\pi\sum_{l=1}^{K_{\pm}}\beta_{\pm l}\eta_{\pm l}\delta^3(u-z_{\pm l}) \tag{79}$$

and

$$\Omega_{\pm}=4\pi\sum_{l=1}^{K_{\pm}}\beta_{\pm l}\eta_{\pm l}\int_V\delta^3(u-z_{\pm l})d^3u=4\pi\sum_{l=1}^{K_{\pm}}\beta_{\pm l}\eta_{\pm l}. \tag{80}$$

Therefore the space–time disclination is

$$\Omega=4\pi\sum_{l=1}^{K_+}\beta_{+l}\eta_{+l}+4\pi\sum_{l=1}^{K_-}\beta_{-l}\eta_{-l}. \tag{81}$$

We find that (79) is the exact density of a system of K_+ and K_- classical pointlike objects with ''charge'' $\beta_{+l}\eta_{+l}$ and $\beta_{-l}\eta_{-l}$ in space–time, i.e., the topological structure of disclinations formally corresponds to a pointlike system. These point objects may be called disclination points as in nematic crystals.[20] In Ref. 21, it was shown that the existence of disclination points is related to a kind of broken symmetry. The dislocations and disclinations appear as singularities of dis-

tortions of an order parameter.[22] In our paper, the disclination points are identified with the isolated zero points of vector field $\phi_{\pm}^{A}(x)$. From (72) we know that these singularities are those of the disclination density as well.

On another hand, the winding number $W_{\pm}$ of the surface Σ and of the mapping $\phi_{\pm}$ is defined as[23]

$$W_{\pm}=\oint_{\Sigma}\frac{1}{8\pi}\epsilon^{ABC}\frac{\phi_{\pm}^{A}}{\|\phi_{\pm}\|^{3}}d\phi_{\pm}^{B}\wedge d\phi_{\pm}^{C}, \tag{82}$$

which is equal to the number of times Σ encloses (or, wraps around) the point $\phi_{\pm}=0$. Hence, the space–time disclinations is quantized by the winding numbers

$$\Omega_{\pm}=4\pi W_{\pm}. \tag{83}$$

The winding number $W_{\pm}$ of the surface Σ can be interpreted or, indeed, defined as the degree of the mappings $\phi_{\pm}$ onto Σ. By (62) and (72) we have

$$\Omega_{\pm}=4\pi\int_{V}\delta(\phi_{\pm})J_{\pm}\left(\frac{\phi_{\pm}}{u}\right)d^{3}u=4\pi\ \deg\ \phi_{\pm}\int_{\phi_{\pm}(V)}\delta(\phi_{\pm})d^{3}\phi_{\pm}=4\pi\ \deg\ \phi_{\pm}, \tag{84}$$

where deg $\phi_{\pm}$ are the degrees of map $\phi_{\pm}:V\to\phi_{\pm}(V)$. Comparing Eq. (84) with (83), it shows the degrees of map $\phi_{\pm}:V\to\phi_{\pm}(V)$ is just the winding number $W_{\pm}$ of surface Σ and map $\phi_{\pm}$, i.e.,

$$\deg\ \phi_{\pm}=W_{\pm}(\Sigma,\phi_{\pm}). \tag{85}$$

Then the space–time disclination is

$$\Omega=4\pi(\deg\ \phi_{+}+\deg\ \phi_{-})=4\pi(W_{+}+W_{-}). \tag{86}$$

Divide V by

$$V=\sum_{l=1}^{K_{\pm}}V_{\pm l} \tag{87}$$

and $V_{\pm l}$ includes only one zero $z_{\pm l}$ of $\phi_{\pm}$, i.e., $z_{\pm l}\in V_{\pm l}$. The winding number $W_{\pm}$ of the surface $\Sigma_{\pm l}=\partial V_{\pm l}$ and the mapping $\phi_{\pm}$ is defined as

$$W_{\pm l}=\oint_{\Sigma_{\pm l}}\frac{1}{8\pi}\epsilon^{ABC}\frac{\phi_{\pm}^{A}}{\|\phi_{\pm}\|^{3}}d\phi_{\pm}^{B}\wedge d\phi_{\pm}^{C}, \tag{88}$$

which is equal to the number of times $\Sigma_{\pm l}$ encloses (or, wraps around) the point $\phi_{\pm}=0$. It is easy to see that

$$W_{\pm}=\sum_{l=1}^{K_{\pm}}W_{\pm l} \tag{89}$$

and

$$|W_{\pm l}|=\beta_{\pm l}. \tag{90}$$

Then

$$\Omega=4\pi\sum_{l=1}^{K_{+}}W_{+l}+4\pi\sum_{l=1}^{K_{-}}W_{-l}. \tag{91}$$

Assuming that is proved in Ref. 24, the increment

$$\frac{1}{2}\epsilon^{ABC}\frac{\phi_{\pm}^{A}}{\|\phi_{\pm}\|^{3}}\, d\phi_{\pm}^{B}\wedge d\phi_{\pm}^{C}=\epsilon^{ABC}\epsilon_{ijk}\frac{\phi_{\pm}^{A}}{\|\phi_{\pm}\|^{3}}\partial_i\phi_{\pm}^{B}\partial_j\phi_{\pm}^{C}dS^{k} \tag{92}$$

may be regarded as the solid angle on $\phi_{\pm}(\Sigma_{\pm l})$ subtended by the surface element dS on $\Sigma_{\pm l}$. Now it is easy to see why the space–time disclination is caused by inserting solid angles into the flat space–time.

Also we can write

$$\Omega=4\pi(N_{+}^{+}+N_{-}^{+})-4\pi(N_{+}^{-}+N_{-}^{-}) \tag{93}$$

in which $N_{+}^{\pm}$ are the sums of the Hopf indexes with respect to $\eta_{+}=\pm 1$ and $N_{-}^{\pm}$ are the sums of the Hopf indexes with respect to $\eta_{-}=\pm 1$. We see that while x covers V once, ϕ_{+}^{A} must cover $\phi_{+}(V)$ N_{+}^{+} times with $\eta=1$ or N_{+}^{-} times with $\eta=-1$ while ϕ_{-}^{A} must cover $\phi_{-}(V)$ N_{-}^{+} times with $\eta=1$ or N_{-}^{-} times with $\eta=-1$. Therefore the topological disclinations are distinguished by the sign of the Jacobian $J(\phi_{\pm}/u)$ at the zero point $x^{\mu}=z_{\pm l}^{\mu}$. Consequently, the global topological property of disclinations is characterized by the Brouwer degrees and Hopf indices of each disclination point, which label the local structure of disclinations.

In this paper, we have studied the topological structure, global and local properties of space–time disclinations. The disclinations we discussed are the general four-dimensional case, which is characterized by the so-called topological points. The decomposition of gauge potential, introduction of the gauge parallel tensor field $n^{ab}(x)$ $(a,b=1,2,3,4)$ and the ϕ-mapping method play important roles in establishing our theory. The disclination points are the zeros of the self-dual or anti-self-dual parts of the tensor field $\phi^{ab}(x)$ and the topological characteristics of the space–time disclinations are determined by the winding numbers which can be represented by the Brouwer degrees and Hopf indices at the disclination points. From the definition of the space–time disclination (11), we know that the space–time disclination is expressed exactly by the curvature of space–time. Therefore the quantization of the space–time disclination has a close relationship with the quantization of space–time.

(Received 5 May 1998; accepted for publication 16 June 1998)

The generalized moment problem in the framework of the maximum entropy approach is considered. A proof for the existence conditions of the solution is provided. © *1998 American Institute of Physics.* [S0022-2488(98)01012-3]

I. INTRODUCTION

The problem of estimating an unknown probability density function on the basis of some generalized known moments is an underdetermined inverse problem which occurs frequently in the physical and economic sciences. In the probabilistic framework, for instance, most often all that we are able to obtain from the governing stochastic equations are the moments of the solution, or the equations for moments.

One widely used technique of solving such an underdetermined problem is that of maximum entropy (M.E.) to determine the approximate probability density. The idea of M.E. is simply to choose an approximant function which maximizes some measure of entropy, subject to given moment constraints.

Much attention is paid to reconstruct a probability density on a finite measurable space (Refs. 1–2), while scarce attention has been devoted to probability densities on an infinite measurable space.

In this paper we wish to show how the idea of maximum entropy can be used in the approximate characterization of a probability density function, defined on the interval $[0,+\infty)$, whose first generalized moments are assigned. Necessary and sufficient conditions guaranteeing existence of the solution will be provided.

Let $M+1$ generalized moments $g_0=1$ and g_k, $k=1,2,\ldots,M$ of the probability density $f(t)$ be known,

$$g_k=\int_0^\infty g_k(t)f(t)dt, \quad k=0,\ldots,M \tag{1}$$

[as we are interested in probability measures then $g_0(t)=1$ is assumed].

Define the entropy $H[f]$ of a positive function $f(t)$,

$$H[f]=-\int_0^\infty f(t)\log(f(t))dt, \tag{2}$$

one looks for a solution of the problem

$$\max_f\left\{H[f]-(\lambda_0-1)\left(\int_0^\infty g_0(t)f(t)dt-g_0\right)-\sum_{k=1}^M \lambda_k\left(\int_0^\infty g_k(t)f(t)dt-g_k\right)\right\}, \tag{3}$$

with the constraints

$$\int_0^\infty g_k(t)f(t)dt=g_k, \quad k=0,1,\ldots,M. \tag{4}$$

It is easy to verify that (Ref. 3) $f(t)$, if it exists, will assume the following expression:

$$f(t)=f_M(t)=\exp\left(-\lambda_0-\sum_{j=1}^M \lambda_j g_j(t)\right), \tag{5}$$

 © 1998 American Institute of Physics

constrained by

$$\int_0^\infty g_k(t) f_M(t)\,dt = g_k, \quad k=0,\ldots,M. \tag{6}$$

The unicity of the M.E. solution, if it exists, is guaranteed by convexity of the functional $\Gamma(\lambda_1,\ldots,\lambda_M)$ defined by (Ref. 3)

$$\Gamma(\lambda_1,\ldots,\lambda_M) = \sum_{k=1}^{M} \lambda_k g_k + \ln\left(\int_0^\infty \exp\left(-\sum_{k=1}^{M} \lambda_k g_k(t) \right) dt \right). \tag{7}$$

The existence proof of the M.E. solution will be carried out in two parts: in Sec. III we will show that the lower bound of the generalized moment g_j is analogous to those furnished by the general moment problem; in Sec. IV we will provide, when they exist, the upper bound for the moment g_j.

The proof is an extension of a technique previously introduced (Refs. 4 and 5) that allows us to furnish the lower and upper bounds (when these exist) of the moment g_j, after having transformed the problems (5), (6) in an equivalent system of differential equations.

II. BACKGROUND

Our technique to find the admissible values of the moments g_j, $j=1,...,M$ consists in transforming (6) in a system of differential equations as follows. Let us maintain the moments g_j, $j=1,...,M-1$ constant and let us vary g_M in continuity. Then $\lambda_0,\ldots,\lambda_M$ are functions of g_M. By differentiating both sides of (6) with respect to g_M we have the system of differential equations,

$$G_M \cdot \begin{bmatrix} d\lambda_0/dg_M \\ \vdots \\ \vdots \\ d\lambda_M/dg_M \end{bmatrix} = -\begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}, \tag{8}$$

where

$$G_M = \begin{bmatrix} g_0 & g_1 & \cdots & g_M \\ g_1 & g_{11} & \cdots & g_{1M} \\ \vdots & \vdots & \vdots & \vdots \\ g_M & g_{M1} & \cdots & g_{MM} \end{bmatrix}, \tag{9}$$

with $g_{ij} = \int_0^\infty g_i(t) g_j(t) f_M(t)\,dt$, $i,j=1,\ldots,M$, is the bordered cross-product matrix, in general positive definite being strictly related to the variance–covariance matrix.

A. The functions $g_j(t)$

The functions $g_j(t)$, $j=1,\ldots,M$, defined on the interval $[0,+\infty)$, are linearly independent continuous functions of a proper Hilbert space. In various concrete questions it is necessary to deal with systems of functions $g_j(t)$, $j=0,\ldots,M$ satisfying the following properties:

(1) $g_j(t)>0$ $(0\leqslant t<\infty)$;

(2) $\lim_{t\to\infty}[g_j(t)/g_M(t)]=0$, $j=0,\ldots,M-1$.

From the adopted conditions on $g_j(t)$, $j=1,\ldots,M$ then (5) satisfies the following constraint:

$$\lambda_M \geqslant 0, \tag{10}$$

and $\lambda_{M-1}>0$ whenever $\lambda_M=0$.

Let us consider $f_M(t)$ where the multipliers λ_j, $j=0,\ldots,M$ assume finite values and the measure $d\psi(t)=f_M(t)dt$. By taking into account (9) the further hypothesis is assumed $g_j(t) \in L^2_{d\psi}([0,\infty))$, where, as usual,

$$L^2_{d\psi}([0,\infty))=\left\{ g_j(t): \int_0^\infty g_j^2(t)d\psi(t)dt=\int_0^\infty g_j^2(t)f_M(t)dt<+\infty \right\}, \quad j=1,\ldots,M, M\geqslant 1$$

(thus $|G_M|$ represents the Gramian).

B. The moment space

$\{g_1(t),\ldots,g_M(t)\}$ being linearly independent on $[0,\infty)$ then the following:
(1) The Gramian is not singular (Ref. 6).
(2) The space V_M of moments, given by the convex hull generated by the points $\{g_1(t),\ldots,g_M(t)\}$, $t\in[0,\infty)$, has a nonempty interior (Ref. 7).
(3) If the sequence of prescribed moments $\{g_j\}$, $j=1,\ldots,M$ is an inner point of V_M then there are uncountably many probability measures $d\sigma(t)$ having such prescribed moments (Ref. 7).

Elsewhere if $\{g_1(t),\ldots,g_M(t)\}$ are linearly dependent then the following:
(1) The Gramian is singular.[6]
(2) The points $\{g_1(t),\ldots,g_M(t)\}$, $t\in[0,\infty)$ belong to the boundary of V_M (Ref. 7).
(3) If the sequence of prescribed moments $\{g_j\}$, $j=1,\ldots,M$ is a boundary point of V_M then there is a unique probability measure $d\sigma(t)$ having such prescribed moments. Such a measure is a step-function with a finite number of jumps (Ref. 7).

Remark 1: In the adopted procedure to obtain (8), as g_M varies continuously, both the measure $d\psi(t)=f_M(t)dt$ and the Hilbert space $L^2_{d\psi}([0,\infty))$ vary.

C. Domain $D^{(M)}_{g_j}$

Let us indicate with $D^{(M)}_{g_j}$ the domain of the acceptable values of g_j moment, when the first M moments are assigned. Considering $f_{M+1}(t)$ and assuming the value $\lambda_{M+1}=0$ then we came back to $f_M(t)$ where g_j, $j=1,\ldots,M$ are assigned. The following relation is therefore valid:

$$D^{(M)}_{g_j}\subseteq D^{(M+1)}_{g_j}, \quad j=1,\ldots,M. \tag{11}$$

D. An auxiliary result

Let $f_M(t)=\exp(-\Sigma_{j=0}^M\lambda_j g_j(t))$ given, to which correspond the moments $\{g_0,g_1,\ldots,g_M\}$, we will prove inductively the existence of the function

$$f^{(M)}(t)=\exp\left(-\sum_{j=0}^{M}\tilde{\lambda}_j g_j(t)-\sum_{j=M+1}^{M^*}\lambda_j^* g_j \right),$$

where $M\geqslant 1$, $M^*\geqslant M+1$ and λ_j^*, $j=M+1,\ldots,M^*$ are arbitrarily fixed and $\lambda^*_{M^*}>0$.

First of all we show that for $M=1$ there exists $f_1(t)$ and then $f^{(1)}(t)$.

(a) Existence of $f_1(t)$. $g_1>g_1^-$ assigned. To determine the admissible values, g_1 is varied continuously. Thus it results that $\lambda_j=\lambda_j(g_1)$, $j=0,1$. By differentiating both sides of (6) with respect to g_1, the following system of differential equations is obtained:

$$G_1\cdot\begin{bmatrix} d\lambda_0/dg_1 \\ d\lambda_1/dg_1 \end{bmatrix}=-\begin{bmatrix} 0 \\ 1 \end{bmatrix}. \tag{12}$$

Equation (12) is solved starting from the following initial condition. Let us assign to λ_1 an arbitrary positive value then from the first equation of (6) we obtain $\tilde{\lambda}_0$ and from the second equation $\tilde{g}_1$. From (12) λ_1 is a monotonic decreasing function. The solution $\lambda_1=0$ is not allowed. Integrating (12) starting from the initial condition $\tilde{\lambda}_0$, λ_1 and $\tilde{g}_1$, previously found, we can reach the given g_1 value.

(b) Existence of $f^{(1)}(t)$. In a similar way, by considering (6) with $f_1(t)$ replaced by $f^{(1)}(t)$, differentiating with respect to g_1 we obtain again system (12) which we can integrate starting from a different initial condition $\hat{\lambda}_0$, λ_1 and $\hat{g}_1$ obtained analogously as done for $f_1(t)$.

To complete the induction we prove that if exists the function $f^{(M-1)}(t)$ with the moments $\{g_0,g_1,\ldots,g_{M-1}\}$ of $f_{M-1}(t)$ then exists the function $f^{(M)}(t)$ with the moments $\{g_0,g_1,\ldots,g_M\}$ of $f_M(t)$. From the existence of the function $f^{(M-1)}(t)$ we can obtain

$$\tilde{g}_M=\int_0^\infty g_M(t)f^{(M-1)}(t)dt.$$

Then exists $\tilde{f}^{(M)}(t)$ with $\tilde{\lambda}_0,\ldots,\tilde{\lambda}_{M-1},\tilde{\lambda}_M\equiv 0$, and λ_j^* fixed, which moments are $\{g_0,g_1,\ldots,g_{M-1},\tilde{g}_M\}$. Such a particular solution represents an initial condition to solve the system of differential equations obtained as follows. Let $\{g_0,g_1,\ldots,g_{M-1}\}$ be fixed and g_M vary continuously. By differentiating both sides of (6) with respect to g_M, where $f_M(t)$ is replaced by $f^{(M)}(t)$, then (8) is obtained. Such a system of differential equations is solved, starting from the initial condition $\tilde{f}^{(M)}(t)$ previously found, until the assigned value of g_M is reached. Thus $f^{(M)}(t)$ exists with the same moments $\{g_0,g_1,\ldots,g_{M-1},g_M\}$ of $f_M(t)$.

III. LOWER BOUND

Once assigned $\{g_1,\ldots,g_{M-1}\}$ we call g_M^- the lower bound of g_M in the moment space. We calculate g_M^- inductively. Let us suppose assigned $\{g_1,\ldots,g_{M-1}\}$ to which the function $f_{M-1}(t)$ corresponds. From $f_{M-1}(t)$ we calculate

$$\tilde{g}_M=\int_0^\infty g_M(t)f_{M-1}(t)dt,$$

where $\tilde{g}_M>g_M^-$. Next we solve (8), starting from the initial condition given by $\{g_1,\ldots,g_{M-1},\tilde{g}_M\}$. Then

$$\frac{d\lambda_M}{dg_M}=-\frac{|G_{M-1}|}{|G_M|}, \tag{13}$$

so that λ_M is a monotonic decreasing function.

Equation (8) is solved until $\lambda_M\to+\infty$. In such a case $|G_M|\to 0$, $|G_{M-1}|$ being bounded for each $g_M\leqslant\tilde{g}_M$ value. Then g_M assumes values greater than $\tilde{g}_M^-$, where $\tilde{g}_M^-$ is an opportune value, satisfying, in general, the relationship $\tilde{g}_M^->g_M^-$. When $g_M=\tilde{g}_M^-$, $|G_M|=0$, as the set of functions $\{g_1(t),\ldots,g_M(t)\}$ is linearly independent, consequently the point $\{g_1,\ldots,g_{M-1},\tilde{g}_M^-\}$ belongs to a boundary of the moment space [$d\psi(t)=f_M(t)dt$, is degenerated in a measure with a finite number of increasing points]. Thus we have

$$\tilde{g}_M^-=g_M^-, \tag{14}$$

where g_M^- depends on the assigned sequence $\{g_1,\ldots,g_{M-1}\}$.

Thus $g_M>g_M^-$, $M=1,2,\ldots$, is a necessary condition for the existence of M.E. distribution. It remains to prove $g_M>g_M^-$ is an even sufficient condition.

IV. UPPER BOUNDS

The following notation will be used:
$g_j^+=$upper bound of the moment g_j, $j=1,\ldots,M$.

A. $M=1$

In Sec. II D we proved that $f_1(t)$ exists $\forall g_1>g_1^-$. Then g_1 does not admit an upper bound. The admissible values of g_1 is then represented by $g_1>g_1^-$.

Given g_1, from (5) and (6) the following value $\tilde{g}_2$ is obtained:

$$\tilde{g}_2=\int_0^\infty g_2(t)f_1(t)dt, \tag{15}$$

and used in the next.

B. $M=2$

Let $g_1(>g_1^-)$ be fixed. We vary g_2 continuously to determine its admissible values. Thus it results that $\lambda_j=\lambda_j(g_2)$, $j=0,1,2$. By differentiating both sides of (6) with respect to g_2, the following system of differential equations is obtained:

$$G_2\cdot\begin{bmatrix} d\lambda_0/dg_2 \\ d\lambda_1/dg_2 \\ d\lambda_2/dg_2 \end{bmatrix}=-\begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}. \tag{16}$$

Thus λ_2 is a decreasing monotonic function that must be non-negative for the existence of the integrals (6). So, as $\lambda_2=0$ is an admissible solution which leads to $f_1(t)$, one deduces that an M.E. solution exists if $g_2\leqslant\tilde{g}_2=g_2^+$. Therefore (5),(6) admit a solution $f_2(t)$ if and only if g_2 satisfies the inequality

$$g_2^-<g_2\leqslant g_2^+. \tag{17}$$

By obtaining $f_2(t)$, the following value $\tilde{g}_3$ is obtained:

$$\tilde{g}_3=\int_0^\infty g_3(t)f_2(t)dt. \tag{18}$$

Before discussing the case $M=3$ we show a preliminary result.

For every $\lambda_k\geqslant 0$ we can construct the following auxiliary function:

$$f^{(1)}(t)=\exp(-\lambda_0-\lambda_1 g_1(t)-\lambda_k g_k(t)),\quad k>2, \tag{19}$$

with the following constraints:

$$\int_0^\infty g_j(t)f^{(1)}(t)dt=g_j,\quad j=0,1,2, \tag{20}$$

in which the moments g_j, $j=0,1$ are assigned and g_2 depends on λ_k [being $k>2$, (19) is not an M.E. solution].

Equation (20) admits the particular solution $f_1(t)$, which is of the form (19) with $\lambda_k=0$ (and such that g_0,g_1 are given and $g_2=\tilde{g}_2$).

Varying g_2 continuously, in its admissible range $g_2^-<g_2\leqslant g_2^+$, we obtain $\lambda_j=\lambda_j(g_2)$, $j=0,1,k$. Differentiating both sides of (20) we have

$$\begin{bmatrix} g_0 & g_1 & g_k \\ g_1 & g_{11} & g_{1k} \\ g_2 & g_{21} & g_{2k} \end{bmatrix}\cdot\begin{bmatrix} d\lambda_0/dg_2 \\ d\lambda_1/dg_2 \\ d\lambda_k/dg_2 \end{bmatrix}=-\begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}. \tag{21}$$

Thus taking into account (9) λ_k is a monotonic decreasing function as (20) admits the particular solution $f_1(t)$ with $\lambda_k=0$, $\lambda_1>0$, $g_2=g_2^+$ and as $g_2\to g_2^-$ then $\lambda_k\to+\infty$, from which we have the following relationship:

$$\begin{vmatrix} g_0 & g_1 & g_k \\ g_1 & g_{11} & g_{1k} \\ g_2 & g_{21} & g_{2k} \end{vmatrix}>0,\quad \forall k>2. \tag{22}$$

C. $M=3$

We would calculate the admissible domain of the moments g_2,g_3.

(a) Domain of g_2. Let us consider (19), with $k=3$. Let g_2^* be an assigned value of g_2 that satisfies (17) to which correspond three values $\lambda_0^*,\lambda_1^*,\lambda_3^*$ of $\lambda_0,\lambda_1,\lambda_3$, respectively.

For every $\lambda_3^*\geqslant 0$ we can construct the following auxiliary function:

$$f^{(2)}(t)=\exp(-\lambda_0-\lambda_1 g_1(t)-\lambda_2 g_2(t)-\lambda_3^* g_3(t)) \tag{23}$$

(where λ_3^* represents the previously fixed value), of which the moments g_j, $j=0,1,2$ are assigned. Thus (23) is not an M.E. function. Varying g_2 continuously, then $\lambda_j=\lambda_j(g_2)$, $j=0,1,2$ and differentiating both sides of (6) with $f_M(t)$ replaced by $f^{(2)}(t)$, (16) is still obtained. λ_2 is a monotonic decreasing function of g_2. By choosing as an initial condition for the integration of (16) the solution $\lambda_0^*,\lambda_1^*,\lambda_2^*=0,\lambda_3^*$, $g_2=g_2^*$ there exists, because of monotonicity of λ_2, values of $g_2>g_2^*$ in correspondence of which $\lambda_2<0$ holds. Therefore we have shown that, fixed $g_1(>g_1^-)$ and g_2 [verifying (17)], there exist functions of the form (23) with $\lambda_2<0$ having such moments.

Let us consider the auxiliary function,

$$f^{(3)}(t)=\exp(-\lambda_0-\lambda_1 g_1(t)-\lambda_2^* g_2(t)-\lambda_3 g_3(t)) \tag{24}$$

(with $\lambda_2=\lambda_2^*<0$ fixed) of which the moments g_j, $j=0,1$ are assigned [for each arbitrary value $\lambda_3=\lambda_3^*>0$ then $f^{(3)}(t)$ exists from the results of Sec. II D) (24) is not an M.E. function. Let us vary g_2 continuously; then the multipliers $\lambda_0,\lambda_1,\lambda_3$ will be functions of g_2. Differentiating both sides of (6) with respect to g_2, with $f_M(t)$ replaced by $f^{(3)}(t)$, (21) is obtained, with $k=3$. λ_3 results therefore, as λ_k in (21), a strictly positive monotonic decreasing function of g_2, being $\lambda_2=\lambda_2^*<0$. Therefore g_2 does not admit an upper bound and the domain of the admissible values of g_2 is

$$g_2>g_2^- . \tag{25}$$

(b) Domain of g_3. Let us consider (5) and let $g_2>g_2^-$, while g_3 varies continuously; then $\lambda_j=\lambda_j(g_3)$, $j=0,1,2,3$. Differentiating both sides of (6) with respect to g_3 we have the system

$$G_3\cdot\begin{bmatrix} d\lambda_0/dg_3 \\ \vdots \\ \vdots \\ d\lambda_3/dg_3 \end{bmatrix}=-\begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}. \tag{26}$$

Thus from (13) λ_3 is a monotonic decreasing function. To determine the possible upper bound of g_3 it is necessary to distinguish two subcases.

(i) $g_2\leqslant g_2^+$. In such a case (6) admits a solution of the form (5) with $\lambda_3=0$, a solution of the problem with $M=2$. Therefore for each $g_2\leqslant g_2^+$, g_3 admits an upper bound $g_3^+=g_3^*$, where g_3^* is provided by (18).

(ii) $g_2>g_2^+$. In such a case (6) does not admit the solution $\lambda_3=0$. In fact, in correspondence of that solution would bring us back to the case $M=2$, but with a value $g_2>g_2^+$, contradicting the existence of an upper bound when $M=2$. Excluding the hypothesis $\lambda_3=0$, λ_3 being monotonic decreasing, it follows that g_3 does not admit an upper bound.

Figure 1 illustrates in a qualitative manner the admissible values of the moments g_2,g_3.

Before discussing the case $M=4$ we show a preliminary result.

The auxiliary function is considered,

$$f^{(4)}(t)=\exp(-\lambda_0-\lambda_1 g_1(t)-\lambda_2 g_2(t)-\lambda_k g_k(t)),\quad k>3, \tag{27}$$

of which the moments g_j, $j=0,1,2$ are assigned [for each arbitrary value $\lambda_k=\lambda_k^*>0$ then $f^{(4)}(t)$ exists from the results of Sec. II D] [(27) is not of M.E., being $k>3$]. Let g_0,g_1,g_2 be fixed, while g_3 varies continuously. The multipliers in (27) are functions of g_3. Differentiating both sides of (6), with $f_M(t)$ replaced by $f^{(4)}(t)$, the system is obtained:

$$\begin{bmatrix} g_0 & g_1 & g_2 & g_k \\ g_1 & g_{11} & g_{12} & g_{1k} \\ g_2 & g_{21} & g_{22} & g_{2k} \\ g_3 & g_{31} & g_{32} & g_{3k} \end{bmatrix}\cdot\begin{bmatrix} d\lambda_0/dg_3 \\ d\lambda_1/dg_3 \\ d\lambda_2/dg_3 \\ d\lambda_k/dg_3 \end{bmatrix}=-\begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix}. \tag{28}$$

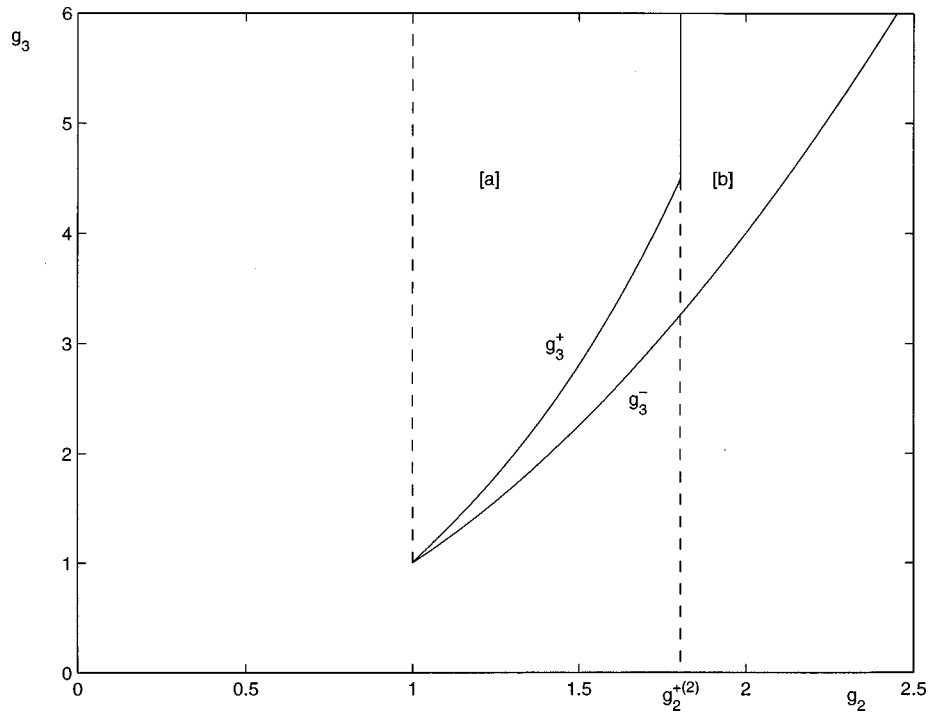

FIG. 1. $M=3$, admissible values of the moments g_2, g_3.

Thus λ_k is a monotonic function. The character of monotonicity of λ_k does not vary by varying g_2 as λ_k represents a family of disjointed curves. We suppose then $g_2 \leqslant g_2^+$, in such a case (6) admits the solution $\lambda_k=0$. Therefore λ_k is a monotonic decreasing for each value of g_2, from which the relationship,

$$\begin{vmatrix} g_0 & g_1 & g_2 & g_k \\ g_1 & g_{11} & g_{12} & g_{1k} \\ g_2 & g_{21} & g_{22} & g_{2k} \\ g_3 & g_{31} & g_{32} & g_{3k} \end{vmatrix} > 0, \quad k>3. \tag{29}$$

D. $M=4$

We wish to solve the domain of the admissible values of the moments g_3, g_4.

(a) *Domain of* g_3. Fixed $g_2>g_2^-$, $\lambda_3=\lambda_3^*<0$, varied g_3 continuously $\lambda_0,\lambda_1,\lambda_2,\lambda_4,g_4$ are functions of g_3. Differentiating both sides of (6) we have the system

$$\begin{bmatrix} g_0 & g_1 & g_2 & g_4 & 0 \\ g_1 & g_{11} & g_{12} & g_{14} & 0 \\ g_2 & g_{21} & g_{22} & g_{24} & 0 \\ g_3 & g_{31} & g_{32} & g_{34} & 0 \\ g_4 & g_{41} & g_{42} & g_{44} & 1 \end{bmatrix} \cdot \begin{bmatrix} d\lambda_0/dg_3 \\ d\lambda_1/dg_3 \\ d\lambda_2/dg_3 \\ d\lambda_4/dg_3 \\ dg_4/dg_3 \end{bmatrix} = - \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \\ 0 \end{bmatrix}. \tag{30}$$

Thus λ_4 results monotonic decreasing with $\lambda_4>0$, the particular solution $\lambda_4=0$ being not admissible because of the condition $\lambda_3=\lambda_3^*<0$. Therefore, due to the arbitrarity of g_2 for each $g_2>g_2^-$, g_3 does not admit an upper bound.

(b) *Domain of* g_4. To underline possible upper bounds of g_4 it is necessary to show preliminarly that, having fixed an arbitrary couple (g_2,g_3), infinite solutions of the form (5) exist, characterized by large arbitrary values of λ_3.

(i1) Let $(g_2,g_3)\in[\mathrm{a}]$ (Fig. 1) a fixed couple and λ_3 vary continuously. $\lambda_0,\lambda_1,\lambda_2,\lambda_4,g_4$ are functions of λ_3. Differentiating (6) with respect to λ_3 we have the system

$$\begin{bmatrix} g_0 & g_1 & g_2 & g_4 & 0 \\ g_1 & g_{11} & g_{12} & g_{14} & 0 \\ g_2 & g_{21} & g_{22} & g_{24} & 0 \\ g_3 & g_{31} & g_{32} & g_{34} & 0 \\ g_4 & g_{41} & g_{42} & g_{44} & 1 \end{bmatrix} \cdot \begin{bmatrix} d\lambda_0/d\lambda_3 \\ d\lambda_1/d\lambda_3 \\ d\lambda_2/d\lambda_3 \\ d\lambda_4/d\lambda_3 \\ dg_4/d\lambda_3 \end{bmatrix} = - \begin{bmatrix} g_3 \\ g_{31} \\ g_{32} \\ g_{33} \\ g_{34} \end{bmatrix}. \tag{31}$$

Taking into account (29) λ_4 results in monotonic decreasing, while g_4 results in monotonic increasing. Nevertheless the solution $\lambda_4=0$ is not allowed as it would lead back to the case $M=3$, but in the presence of a couple (g_2,g_3) not belonging to the domain of the admissible values. Therefore between the infinite solutions obtained by varying λ_3 and corresponding to the same couple $(g_2,g_3)\in[\mathrm{a}]$, there exist some with large arbitrary values of λ_3.

(i2) Let $\lambda_k^{(M=3)}$, $k=0,1,2,3$ be the coefficients of the M.E. solution $f_3(t)$, in the case $M=3$, with $(g_2^{(b)},g_3^{(b)})\in[\mathrm{b}]$.

Let be $M=4$. $(g_2^{(a)},g_3^{(a)})\in[\mathrm{a}]$ a couple, with $g_3^{(a)}=g_3^{(b)}$. To the couple $(g_2^{(a)},g_3^{(a)})\in[\mathrm{a}]$, as previously shown, there are corresponding infinite solutions obtained by varying λ_3. We choose one of them characterized by

$$\lambda_3=\lambda_3^*>\lambda_3^{(M=3)}. \tag{32}$$

Let $g_3=g_3^{(a)}(=g_3^{(b)})$, $\lambda_3=\lambda_3^*>\lambda_3^{(M=3)}$ be fixed, while g_2 varies continuously in the interval $[g_2^{(a)},g_2^{(b)}]$. Then $\lambda_0,\lambda_1,\lambda_2,\lambda_4,g_4$ are functions of g_2. Differentiating both sides of (6) we have the following system:

$$\begin{bmatrix} g_0 & g_1 & g_2 & g_4 & 0 \\ g_1 & g_{11} & g_{12} & g_{14} & 0 \\ g_2 & g_{21} & g_{22} & g_{24} & 0 \\ g_3 & g_{31} & g_{32} & g_{34} & 0 \\ g_4 & g_{41} & g_{42} & g_{44} & 1 \end{bmatrix} \cdot \begin{bmatrix} d\lambda_0/dg_2 \\ d\lambda_1/dg_2 \\ d\lambda_2/dg_2 \\ d\lambda_4/dg_2 \\ dg_4/dg_2 \end{bmatrix} = - \begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \end{bmatrix}. \tag{33}$$

By taking into account (22), (29) λ_4 is monotonic increasing. Besides, by increasing g_2, the couple $(g_2,g_3^{(a)})$, that initially belongs to the region [a], will belong subsequently to the region [b]. Therefore to each couple $(g_2,g_3^{(b)})\in[\mathrm{b}]$ corresponds to a solution with λ_3 given by (32). The achieved result is interpreted in the following way. When $M=4$ is also in the region [b], as in the [a], to each couple $(g_2,g_3^{(b)})\in[\mathrm{b}]$ correspond infinite solutions obtained by varying λ_3. A direct way of proof, analogous to that of the region $[a]$, is not immediate as in the region $[b]$, fixed a couple (g_2^*,g_3^*), varied λ_3 continuously, λ_4 is monotonic decreasing, but with solution $\lambda_4=0$ admissible, as to the solution it corresponds the value $\lambda_3^{(M=3)}$ of λ_3, not making evident the existence of solutions $\lambda_3>\lambda_3^{(M=3)}$.

Let $g_2=g_2^*$, $g_3=g_3^*$ be fixed within the the range of its admissible values. Let us vary g_4 continuously: then $\lambda_k=\lambda_k(g_4)$, $k=0,\ldots,4$. Differentiating both sides of (6) we have the system

$$G_4\cdot\begin{bmatrix} d\lambda_0/dg_4 \\ \vdots \\ \vdots \\ d\lambda_4/dg_4 \end{bmatrix} = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}. \tag{34}$$

λ_4 is monotonic decreasing. To underline that there does not exist an upper bound of g_4 it is necessary to distinguish the two following cases concerning the domain of affiliation of the couple (g_2^*,g_3^*).

(i) $(g_2^*, g_3^*) \in [a]$. The solution $\lambda_4 = 0$ is not allowed as it would lead back to the case $M = 3$, but with a couple (g_2^*, g_3^*) not belonging to the domain of the admissible values of (g_2, g_3). Therefore, λ_4 being a monotonic decreasing and must be strictly positive, g_4 does not admit an upper bound.

(ii) $(g_2^*, g_3^*) \in [b]$. In such a case the solution $\lambda_4 = 0$ could be admissible, bringing us again to the case $M = 3$ and originating an upper bound of g_4. We wish, instead, to show the relationship $\lambda_4 > 0$. By choosing an initial condition for the solution of (34) verifying (32), the solution $\lambda_4 = 0$ is not allowed. In fact, if $\lambda_4 = 0$ we are led back to the case $M = 3$ but with a value $\lambda_3 > \lambda_3^{(M=3)}$, contradicting the hypothesis of unicity of the solution. From (31) g_4 being monotonic increasing function of λ_3, the moment g_4 does not admit an upper bound.

The relative analysis of the case $M = 4$ allows us to conclude that the moments g_3, g_4 does not admit an upper bound.

E. $M > 4$

The lack of upper bounds for the moments g_3, g_4 allows us to solve the general case $M > 4$, using for each M the results achieved in the case $M - 1$.

Let g_k, $k = 1, \ldots, M > 4$ be assigned.

(i) *Domain of* $g_1, \ldots, g_{M-1}$. By choosing $\lambda_M = 0$ one is led back to the case $M - 1$, where upper bounds of the moments $g_1, \ldots, g_{M-1}$ do not exist.

(ii) *Domain of* g_M. Let g_k, $k = 1, \ldots, M-1$ be assigned, $f_{M-1}(t)$ the corresponding density with multipliers that we will point out with $\lambda_k^{(M-1)}$, $k = 0, \ldots, M-1$.

By varying g_M, the family of functions $f_M(t)$ is considered. There exist between the infinite solutions that meet the moments g_k, $k = 1, \ldots, M-1$, also those characterized by large arbitrary values of λ_{M-1} [generalizing (31)]. We choose the one with $\lambda_{M-1} > \lambda_{M-1}^{(M-1)}$. Fixed g_k, $k = 0, \ldots, M-1$, g_M varied continuously then λ_k, $k = 0, \ldots, M$ are functions of g_M. Particularly, from the achieved system of differential equations (8), λ_M is monotonic decreasing, while λ_{M-1} is monotonic increasing. To solve such a system of differential equations one considers an initial condition characterized by $\lambda_{M-1} > \lambda_{M-1}^{(M-1)}$. An upper bound g_M does not exist as, in correspondence of such a bound, the solution $\lambda_M = 0$ holds. In such a case one is led back to the case $M - 1$, but with a value $\lambda_{M-1} > \lambda_{M-1}^{(M-1)}$, contradicting the unicity of the solution. Therefore g_M does not admit an upper bound.

V. CONCLUSIONS

Existence conditions of the generalized moment problem have been considered. From the achieved results it is deduced that, except the cases in which 2 or 3 moments are assigned, where unexpected upper bounds of the moments raise, in the remaining cases the necessary and sufficient conditions of existence of the M.E. solution are identical to ones of the moment problem.

We present a new integral theorem based on the well-known Gauss and Stokes theorems which provides a straightforward physical interpretation of the quantum mechanical energy balance equation governing the steady-state propagation of charge carriers through closed electric circuits. © *1998 American Institute of Physics.* [S0022-2488(98)03312-X]

I. INTRODUCTION

Recent developments in the field of mesoscopic physics and technology have lead to the fabrication of novel semiconductor structures and devices (quantum dots, quantum wires, quantum point contacts, single electron transistors) the working principles of which are directly based on generic quantum mechanical rules. Although thorough theoretical investigations of these new devices are being conducted on a world-wide scale, several fundamental features of quantum transport—such as the phenomenon of nonlocal resistance—are still not fully understood, especially when regarded from the side of nonequilibrium statistical mechanics. Contrary to the case of ''classical'' devices, the so-called active areas of quantum devices typically have sizes on the nanometer scale nanostructures, thereby allowing in principle for phase-coherent transport. This observation directly affects the strategy to be adopted when dynamical observables such as the electric current as a response to the external electric field are to be calculated: We believe that a reliable quantum mechanical calculation should encompass the entire, closed electric circuit without making any subdivision into spatial regions some of which could be taken into consideration for a semiclassical treatment. Our viewpoint is therefore completely opposed to the reservoir concept which considers the leads connecting the current source to the nanostructure[1,2] massive reservoirs where charge carriers have reached some local equilibrium and the presence of the current source is merely emulated by a chemical potential difference. On the other hand, within our approach a set of balance equations, based on the Heisenberg equations of motion obeyed by the charge field operators can be obtained to yield a dynamical characterization of a closed circuit containing one (or more) nanostructures or nanodevices.[3,4] One particular term arising in the energy balance equation and describing the electric power acquired by the charge carriers from the external field, can be given a straightforward interpretation for steady-state conditions (dc) with the help of a new integral theorem.

Section II illustrates the physical background which has led to the need of formulating a new integral theorem. The latter is proven in Sec. III and some concluding remarks are given in Sec. IV.

II. INTERPRETATION OF THE ENERGY BALANCE EQUATION

Representing a closed electric circuit by a toruslike region Ω confining the charge carriers but allowing exchange of energy with the environment, we have derived quantum mechanical momentum and energy balance equations describing the transport properties of the carrier gas residing in the interior of Ω. Taking the form of a rate equation, the energy balance equation reads:[3]

$$\frac{d\langle H_c\rangle_t}{dt} = \int_\Omega d\tau \langle \vec{J}(\vec{r})\rangle_t \cdot \vec{E}(\vec{r}) - \frac{i}{\hbar}\langle [H_c, H']\rangle_t, \tag{1}$$

 © 1998 American Institute of Physics

where H_c is the gauge invariant Hamiltonian of the carrier gas and H' represents the interaction of the carrier gas with all relevant scattering mechanisms (phonons, impurities, ...). $\vec{J}(\vec{r})$ denotes the electric current density operator whereas $\vec{E}(\vec{r})$ is the local, static electric field caused by an externally applied voltage in order to maintain a dc current through the circuit. The time dependence referred to by the subscript t in the statistical averages $\langle\ \rangle_t$ can in principle be obtained by combining the solution to the Heisenberg equations for all operators and the density matrix ρ_0 describing the circuit at the time the field was turned on, i.e.,

$$\langle X\rangle_t=\langle X(t)\rangle_0\equiv \mathrm{Tr}[\rho_0 X(t)] \quad \text{for } X=H_c,H',\vec{J}(\vec{r}). \tag{2}$$

Having attained a steady state for $t\to\infty$ the carrier gas may be characterized by a dc current and a stationary average energy. Hence the left-hand side of (1) vanishes and the energy balance equation reduces to

$$\int_\Omega d\tau\ \vec{j}(\vec{r})\cdot\vec{E}(\vec{r})=\frac{i}{\hbar}\lim_{t\to\infty}\langle[H_c,H']\rangle_t, \tag{3}$$

where $\vec{j}(\vec{r})\equiv\lim_{t\to\infty}\langle\vec{J}(\vec{r})\rangle_t$ denotes the current density vector.

Clearly, the left-hand side can be interpreted without further effort as the average power the carrier gas is extracting from the electric field in its steady state. However, the ultimate goal of circuit simulation programs is not to calculate the spatial distribution of the current *density* $\vec{j}(\vec{r})$ but rather to express the total current I as a function of measurable quantities such as the external voltage applied to the circuit. As is well-known from elementary electromagnetic theory,[5] the latter can be easily represented by the so-called electromotive force $\mathcal{E}$ which is nothing but the circulation of the electric field along a closed curve Γ lying in the circuit region:

$$\mathcal{E}=\oint_\Gamma \vec{E}\cdot d\vec{r}. \tag{4}$$

In general the circulation of a vector field depends on the curve Γ. In our case however, since no magnetic fields are involved, the third Maxwell equation leads to an irrotational electric field. At first sight, this conclusion seems to contradict the necessity of having a nonconservative field. However, an irrotational vector field needs not be conservative unless it is defined on a simply connected region, whereas the toruslike topology of an electric circuit implies only connectivity and the presence of at least one ''hole.'' Therefore, application of Stokes theorem to the circuit region Ω shows that the circulation of an irrotational vector field is merely independent of the choice of the circulation curve without having to be zero in the first place, thereby corroborating the intuitive result that an electromotive force may be considered a unique quantity for characterizing the strength of a nonconservative static electric field. The next step is to investigate how a stationary current I—unavoidably carried by a divergence-free current density vector—can go along with the concept of electromotive force and relate to power dissipation. More concretely, we would need a theorem from which it follows that the product $\mathcal{E}I$ equals the volume integral of $\vec{j}\cdot\vec{E}$ for any torus-shaped circuit. Such a theorem is provided by an integral theorem based on the familiar Gauss and Stokes theorems known from ordinary vector calculus.

III. INTEGRAL THEOREM

Proposition: Let Ω be a closed, multiply connected subset of $\mathbf{R}^3$ having one hole and being bounded by a surface $\partial\Omega$. If $\vec{J}$ and $\vec{E}$ are two differentiable vector fields defined on Ω, circulating around the hole and satisfying the conditions

$$\vec{\nabla}\cdot\vec{J}=0,$$

$$\vec{\nabla}\times\vec{E}=\vec{0}, \tag{5}$$

$$\vec{J}\parallel\partial\Omega \ \text{ or } \ \vec{J}=\vec{0} \ \textit{in each point of } \partial\Omega,$$

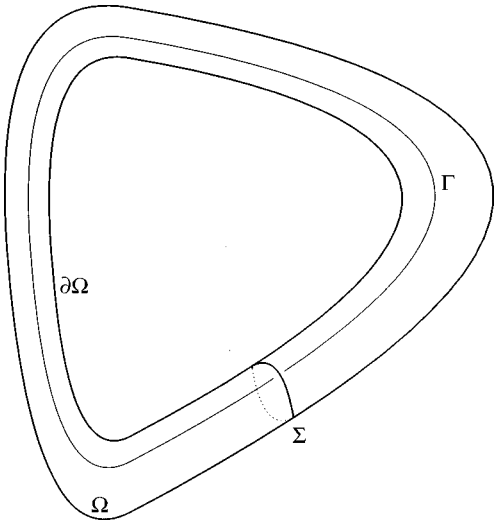

FIG. 1. Topology of the connected region Ω.

then

$$\int_{\Omega} \vec{J}\cdot\vec{E}\, d\tau = \left[\int_{\Sigma} \vec{J}\cdot d\vec{S}\right]\left[\oint_{\Gamma} \vec{E}\cdot d\vec{r}\right], \tag{6}$$

where Σ *is an arbitrary cross section, intersecting* Ω *only once and* Γ *is a simple closed curve, encircling the hole and lying within* Ω *but not intersecting* $\partial\Omega$ (see Fig. 1). The orientation of Σ is uniquely determined by the orientation of Γ.

Proof: Define curvilinear coordinates (u^1,u^2,u^3) and a corresponding basis $(\vec{a}_1,\vec{a}_2,\vec{a}_3)$ such that the coordinate curves $du^1=0$, $du^2=0$ coincide with the closed field lines of $\vec{J}$. Then, by definition, the field vector $\vec{J}$ has only a component along the third basis vector $\vec{a}_3$:

$$\vec{J}=J^k\vec{a}_k=J^3\vec{a}_3. \tag{7}$$

According to the last condition of (5), the field lines of $\vec{J}$ are nowhere intersecting the boundary surface $\partial\Omega$. Consequently, the particular choice of the curvilinear coordinates leads to the following observation:

(1) The outer surface $\partial\Omega$ is spanned by a subset of the curves $du^1=0$, $du^2=0$ and therefore, it must correspond to either $du^1=0$ or $du^2=0$.
(2) All internal points of Ω are addressed when u^1, u^2, and u^3 are bound to vary within three independent intervals A_1, A_2, and A_3.

Then, denoting the Jacobian determinant by $g(u^1,u^2,u^3)$ and using (7), the volume integral may be written

$$\int_{\Omega} \vec{J}\cdot\vec{E}\, d\tau = \int_{A_1} du^1 \int_{A_2} du^2 \int_{A_3} du^3\, g(u^1,u^2,u^3)\, J^3(u^1,u^2,u^3)\, E_3(u^1,u^2,u^3). \tag{8}$$

On the other hand, the divergence of $\vec{J}$ generally reads

$$\vec{\nabla}\cdot\vec{J}=\frac{1}{g}\frac{\partial}{\partial u^k}(gJ^k) \tag{9}$$

which, due to (7), reduces to

$$\vec{\nabla}\cdot\vec{J}=\frac{1}{g}\frac{\partial}{\partial u^3}(gJ^3). \tag{10}$$

In other words, the proposition $\vec{\nabla}\cdot\vec{J}=0$ implies that $K\equiv gJ^3$ is independent on u^3. Consequently,

$$\int_\Omega \vec{J}\cdot\vec{E}\; d\tau=\int_{A_1} du^1\int_{A_2} du^2 K(u^1,u^2)\int_{A_3} du^3 E_3(u^1,u^2,u^3). \tag{11}$$

For each fixed pair $(u^1,u^2)\in(A_1,A_2)$ we may define a coordinate curve $\Gamma(u^1,u^2)$, lying within Ω and being parametrized by u^3. The tangent vector along $\Gamma(u^1,u^2)$ is then given by

$$d\vec{r}=du^3\;\vec{a}_3, \tag{12}$$

whence

$$\int_{A_3} du^3\; E_3(u^1,u^2,u^3)=\oint_{\Gamma(u^1,u^2)}\vec{E}\cdot d\vec{r}. \tag{13}$$

Since $\vec{E}$ is irrotational, according to Stokes' theorem its circulation does not depend on the particular choice of the circulation curve as was already discussed in more detail in Sec. II. Consequently, $\Gamma(u^1,u^2)$ may be replaced by any other closed curve Γ encircling the hole region and sharing the traversal sense with $\Gamma(u^1,u^2)$:

$$\int_\Omega \vec{J}\cdot\vec{E}\; d\tau=\left[\oint_\Gamma \vec{E}\cdot d\vec{r}\right]\left[\int_{A_1} du^1\int_{A_2} du^2\; K(u^1,u^2)\right]. \tag{14}$$

Now, let u_0^3 be any number in the interval A_3 and let Σ be the piece of the surface $u^3=u_0^3$, cut off by the boundary surface $\partial\Omega$. Then we may define a vector surface element $d\vec{S}$ on Σ as follows:

$$d\vec{S}=\pm\vec{a}_1\times\vec{a}_2 du^1 du^2 \quad \text{for } (u^1,u^2)\in(A_1,A_2) \text{ and } u^3=u_0^3. \tag{15}$$

The plus sign corresponds with the correct orientation. Indeed, remembering that $d\vec{r}=du^3\;\vec{a}_3$ defines a traversal sense for the curve $\Gamma(u^1,u^2)$ intersecting Σ in the point (u^1,u^2,u_0^3) and that

$$g=(\vec{a}_1\times\vec{a}_2)\cdot\vec{a}_3 \quad \text{for } (u^1,u^2)\in(A_1,A_2) \text{ and } u^3=u_0^3. \tag{16}$$

We see that

$$d\vec{S}\cdot d\vec{r}=g du^1\; du^2\; du^3=d\tau \tag{17}$$

or that—for a positive volume element $d\tau$—$d\vec{S}$ and $d\vec{r}$ are pointing to the same side of Σ. Moreover, from (14) and (15) it becomes clear that

$$\int_{A_1} du^1\int_{A_2} du^2\; K(u^1,u^2)=\int_\Sigma \vec{J}\cdot d\vec{S}. \tag{18}$$

Finally, it should be noticed that the surface integral of $\vec{J}$ remains unchanged when Σ is replaced by another cross section Σ_1 which does not correspond to $du^3=0$. In such a case, one may always construct a Gaussian pill box from Σ, Σ_1 and the enclosed part of the boundary surface $\partial\Omega$. Applying Gauss' theorem to the pill box and bearing in mind that $\vec{\nabla}\cdot\vec{J}=0$, we conclude that the integral of $\vec{J}$ over the surface of the pill box vanishes, and since $\vec{J}$ itself is tangential along the surface $\partial\Omega$, it does not contibute to the surface integral so that

$$\int_\Sigma \vec{J}\cdot d\vec{S}=\int_{\Sigma_1}\vec{J}\cdot d\vec{S}_1 \tag{19}$$

for equal orientations of $d\vec{S}$ and $d\vec{S}_1$.
This completes the proof.

IV. DISCUSSION

Apart from the possibility of having other proofs and perhaps even more general formulations of the presented theorem, it should be noted that the present proof requires the field lines of $\vec{J}$ to be closed. Indeed, the theorem first envisages the circulation of $\vec{E}$ around a *coordinate curve* $\Gamma(u^1,u^2)$ before addressing the generalization to more general curves Γ, where $\Gamma(u^1,u^2)$ is by definition an arbitrary field line of $\vec{J}$. Strictly speaking from the point of view of mathematical rigor, the condition $\nabla\cdot\vec{J}=0$ does not generally lead to closed field lines for $\vec{J}$, and therefore the addition of the latter as a supplementary proposition may be required. On the other hand, we believe that in most of the physical applications for which the theorem has been formulated, the solenoidal character of the vector field $\vec{J}$ together with the condition that $\vec{J}$ ''follows'' the geometry of the finite and bounded region Ω inevitably leaves us with a pattern of closed field lines, at least if pathological field distributions are to be avoided.

V. CONCLUSION

The above discussed integral theorem provides a transparent physical interpretation of the quantum mechanical transport equation balancing power supply and power dissipation in a closed electric circuit. Although the evaluation of the scattering term may be quite elaborate, depending on the approximation scheme adopted, the theorem at least facilitates the expression of the transport equations in terms of macroscopic observables:

$$I\mathcal{E}=\frac{i}{\hbar}\lim_{t\leftrightarrow\infty}\langle[H_c,H']\rangle_t. \tag{20}$$

Furthermore, it indirectly supports the thesis that the electromotive force is the relevant parameter characterizing the strength of the applied electric field rather than the electrostatic or chemical potential differences existing between contact reservoirs.

We consider the problem of extending the solution of a particular two-dimensional Poisson equation to a larger domain. This problem is related to the problem of putting a non-neutral plasma into equilibrium by applying a suitable wall potential, and to similar problems in two-dimensional fluid dynamics. While one cannot always find an exact solution, one can always find an approximate solution if the plasma has no holes. © *1998 American Institute of Physics.* [S0022-2488(98)02312-3]

I. INTRODUCTION

We consider the Poisson equation

$$\nabla^2\Phi(z)=\begin{cases}-4\pi: z\in G,\\ 0: z\in D\backslash G,\end{cases}$$
$$\Phi|_{\partial G}=0, \tag{1}$$

where G is a planar domain, and D is a disk containing G. The unusual feature of Eq. (1) is that, while Φ is a function on D and its Laplacian there is given, the ''boundary condition'' is given on the interior curve ∂G, the boundary of G. It is routine to solve Eq. (1) in G, so one can view the problem as asking when a solution can be found that extends harmonically to the larger set D.

Indeed, the function

$$v(z)=-2\int_G \log|z-\zeta|\,dA(\zeta) \tag{2}$$

satisfies

$$\nabla^2 v(z)=\begin{cases}-4\pi: z\in G,\\ 0: z\in D\backslash G.\end{cases}$$

(Throughout the paper we shall use complex notation; $z=x+iy$ and $\zeta=\eta+i\xi$ will represent points in the plane, thought of as complex numbers. We write area integrals as $\int dA(\zeta)$ rather than $\int\int d\eta\, d\xi$.)

So the question becomes whether one can find a function u that is harmonic in all of D, and satisfies the ''interior condition'' $u=-v$ on ∂G, as then $\Phi=u+v$ will solve Eq. (1).

This problem originates in the study of equilibria of non-neutral plasmas.[1–3] Consider a flat-top (constant density) charged plasma that forms a (not necessarily symmetric) infinite cylinder. The plasma is enclosed by a circular wall, on which we can place an arbitrary potential, and is permeated by a uniform axial magnetic field **B**. Because the plasma and boundary are assumed to form infinite cylinders, this is really a two-dimensional system[4] in which the planar cross section of the plasma is G and the wall is ∂D. The charged plasma particles follow $\mathbf{E}\times\mathbf{B}$ orbits, where **E** is the sum of the field induced by the plasma itself and the field coming from the wall.

If we assume unity charge density, the plasma potential is given by Eq. (2). The wall potential will be some harmonic function u in D. Then the total electric field **E** will be the gradient of

 © 1998 American Institute of Physics

$u+v$. As the plasma particles travel perpendicularly to **E** and to **B**, they stay in the plane. The direction perpendicular to **E** defines the equipotentials of $u+v$; consequently the particles travel along these equipotentials. The plasma will be in equilibrium when the plasma boundary ∂G is an equipotential. Hence we are led to Eq. (1).

It was shown in Refs. 2 and 3 that most non-neutral plasmas without holes can be put into equilibrium, at least approximately, by the application of a suitable wall potential. This paper explores the mathematics behind solving this problem. Two-dimensional fluid systems share similar considerations; we hope that our results may have applications to other areas of physics.

In Sec. II, we discuss the exact solution for a class of shapes G, namely, polynomial images of the disk. We solve this problem completely, and show that the plasma can be put into an exact equilibrium if and only if the wall lies inside certain critical points. In Sec. III we show that for almost any plasma without holes, we can find an approximate equilibrium, in the sense that for an appropriate potential on the wall, the sum of this potential and the potential of the plasma itself has an equipotential that surrounds the plasma and is arbitrarily close to it.

We do not discuss the issue of stability of these plasma equilibria. Stability is considered in Refs. 2 and 5.

II. EXACT RESULTS

A. Mathematical setup

Let G be the planar cross section of the plasma, and let D be a disk containing G. We wish to place a potential on ∂D (the boundary of D) such that the sum of this potential and the potential from G itself is constant on ∂G. For simplicity, we shall assume that the charge density on G is 1.

The potential induced by the plasma itself is the function v from Eq. (2). The potential placed on ∂D will extend to a bounded harmonic function u on D. So we wish to find a function u, harmonic on D, that agrees with $-v$ on ∂G. [Note that the potential from the image charge, normally incorporated into v by replacing the integrand in Eq. (2) by the Green's function that vanishes on ∂D, has been incorporated into u instead.]

Thus we wish to solve the problem

$$\begin{aligned} \nabla^2 u &= 0 \quad \text{on } G, \\ u+v &= 0 \quad \text{on } \partial G. \end{aligned} \tag{3}$$

We know u on ∂G; it is uniquely determined inside G as the solution of the Dirichlet problem with those boundary values. Let $\phi: G \to \mathbf{D}$ be a Riemann map, that is, an analytic univalent function that maps G onto the unit disk **D** (such a map always exists for a simply connected domain G—see Ref. 6). Consider the function

$$\omega(\zeta,z) = \log \left| \frac{(z-\zeta)(1-\overline{\phi(\zeta)}\phi(z))}{\phi(z)-\phi(\zeta)} \right|. \tag{4}$$

The logarithm of the modulus of a nonvanishing analytic function is harmonic, so the function $\omega(\zeta,\cdot)$ is harmonic on G for any fixed ζ in G. Moreover, if ζ is in G and z is in ∂G, then $\omega(\zeta,z) = \log|z-\zeta|$ because $|\phi(z)| = 1$. So, inside G the function u is given by

$$u(z) = 2\int_G \log \left| \frac{(z-\zeta)(1-\overline{\phi(\zeta)}\phi(z))}{\phi(z)-\phi(\zeta)} \right| dA(\zeta). \tag{5}$$

[This function is harmonic, by differentiating under the integral sign, and has the right boundary values, by comparison with Eq. (2).]

There are two problems with extending the formula in Eq. (5) to values of z outside of G. The first is extending the function ϕ. The second is that, as soon as the point z is outside G, the function $\log|1-\overline{\phi(\zeta)}\phi(z)|$ will have a singularity for some ζ in G, and so Eq. (5) may no longer represent a harmonic function.

If the boundary of G is an analytic curve, then ϕ will extend to an analytic function on a neighborhood of ∂G. Moreover, the integral in Eq. (5) can be replaced by an integral (or distribution) over a compact subset of G, so that the new formula replacing Eq. (5) will represent a function that equals u on G, and is harmonic on a larger set containing G. Rather than explaining how to do this in general, using the theory of quadrature domains in the wide sense discussed in Ref. 7, it is sufficient for our purposes to discuss only the case where ϕ is the inverse of a polynomial mapping.

B. Polynomial images of disks

Let p be a polynomial of degree N that is univalent (one-to-one) on $\mathbf{D}$, and let G be the image of $\mathbf{D}$ under p. Assume $p(0)=0$. Then G is a *quadrature domain*, which means there are constants $a_0,a_1,\ldots,a_{N-1}$ and $b_1,\ldots,b_{N-1}$ such that, for any function h that is harmonic and integrable on G, the following quadrature formula holds:

$$\int_G h(z)\ dA(z)=a_0h(0)+\sum_{n=1}^{N-1} a_n\left(\frac{\partial^n h}{\partial x^n}\right)_{z=0}+b_n\left(\frac{\partial^n h}{\partial x^{n-1}\partial y}\right)_{z=0}. \tag{6}$$

If p is of degree 1, then G is a disk and Eq. (6) is the familiar mean-value property for harmonic functions. For how to calculate the coefficients a_n and b_n, see Appendix A.

The integrand in Eq. (5) is $\omega(\zeta,z)$, and we are integrating with respect to ζ. But for every fixed z in G, the function $\omega(\zeta,z)$ is harmonic in ζ for ζ in G, because Eq. (4) can be written as

$$\omega(\zeta,z)=\log\left|\frac{(z-\zeta)(1-\phi(\zeta)\overline{\phi(z)})}{\phi(z)-\phi(\zeta)}\right|,$$

i.e., as the logarithm of the modulus of a nonvanishing function that is analytic in ζ. Therefore, by combining Eqs. (5) and (6), we get that, for z in G,

$$u(z)=2\left[a_0\omega(0,z)+\sum_{n=1}^{N-1} a_n\left(\frac{\partial^n\omega(\zeta,z)}{\partial\eta^n}\right)_{\zeta=0}+b_n\left(\frac{\partial^n\omega(\zeta,z)}{\partial\eta^{n-1}\partial\xi}\right)_{\zeta=0}\right]. \tag{7}$$

The beauty of Eq. (7) is that, for any z *outside* G, as long as $\phi(z)$ is analytic and nonzero, the right-hand side of Eq. (7) is a harmonic function. As it agrees with u on G, this must give the harmonic extension of u to a domain containing G.

Now in our current case, ϕ is the inverse of the polynomial p, and maps G to D. Then ϕ will have branch points at the (at most) $N-1$ points outside G that it maps to a critical point of p (a point where p' vanishes). Choose nonintersecting branch cuts connecting the branch points of ϕ to ∞, and let Ω denote the plane minus these branch cuts. Then ϕ is a single-valued analytic function on Ω, and ϕ takes the value 0 only at 0. With this choice of ϕ, Eq. (7) gives the unique extension of u to Ω (unique because two harmonic functions on a connected set cannot agree on an open subset without agreeing everywhere).

A different choice of branch cuts could give rise to a different domain, Ω' say, and a different harmonic function u' on Ω'. But u and u' would have to agree on the connected component of $\Omega\cap\Omega'$ containing G.

It was shown by Ebenfelt[8,9] that one cannot continue u harmonically across the branch points. This can be seen by considering the behavior of ∇u near a branch point. By differentiating Eq. (7) one gets various terms in powers of $\phi(z)$, which remain bounded, and also terms in negative powers of z, which are also bounded (as we are only concerned with branch points outside G, and 0 is in G), and a term $-a_0\phi'(z)/\phi(z)$ which results from taking the $\partial/\partial z$ derivative of $2a_0\log|1/\phi(z)|$. As a_0 is never zero [indeed, it follows from Eq. (6) that a_0 is the area of G] and $\phi'(z)$ tends to ∞ at a branch point [because $p(\phi(z))=z$, so by the chain rule $\phi'(z)=1/p'(\phi(z))$, and $p'(\phi(z))$ tends to zero], it follows that ∇u tends to infinity as one tends to a branch point, so every branch point is a singularity of u.

We conclude the following: *It is impossible to extend u to be harmonic on any domain containing a branch point of ϕ, but this is the only obstruction. Therefore one can find a potential on a wall surrounding G that puts the plasma into equilibrium if and only if no branch points of ϕ lie within the wall.*

C. An example: Cardioids

The simplest example is when p is a second degree polynomial. Let β be a real number greater than or equal to 1, and let $p(z)=z^2+2\beta z$. The corresponding shapes are shown in Fig. 1 for different values of β.

One can calculate directly that $\phi(z)=-\beta+\sqrt{\beta^2+z}$. From Appendix A it follows that Eq. (6) becomes

$$\int_G h(z)\ dA(z)=2\pi(1+2\beta^2)h(0)+4\pi\beta^2\ \frac{\partial h}{\partial x}\ (0). \tag{8}$$

Therefore Eq. (7) becomes

$$u(z)=4\pi(1+2\beta^2)\ \log\left|\frac{z}{\phi(z)}\right|+4\pi\beta\ \mathrm{Re}\left[-\frac{2\beta}{z}+\frac{1}{\phi(z)}-\phi(z)\right]. \tag{9}$$

The function ϕ has a branch point at $-\beta^2$. Choose a branch of ϕ—the most obvious is to cut the plane along the negative real axis from $-\infty$ to $-\beta^2$. Then Eq. (9) defines a harmonic function on $\mathbf{C}\backslash(-\infty,-\beta^2]$ that agrees with $-v$ on the boundary of the plasma; but the function cannot be extended to be harmonic in any neighborhood of the point $-\beta^2$.

We conclude, therefore, that if the disk D does not contain $-\beta^2$ in its interior, then we can place a potential on ∂D that puts G into equilibrium. But if D does contain $-\beta^2$ in its interior, then it is impossible to put the plasma G into equilibrium by just putting a potential on ∂D.

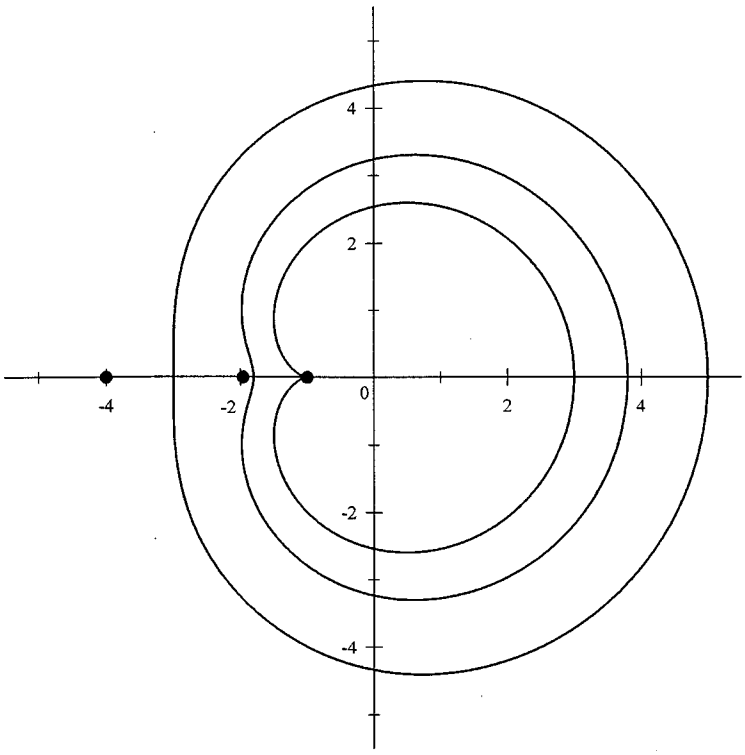

FIG. 1. Cardioids with β=2, 1.4, and 1. The corresponding critical points, indicated by the dots, are at -4, -1.96, and -1.

As β tends to 1, it becomes more and more difficult to put the plasma into equilibrium, because the branch point $-\beta^2$ gets closer and closer to the plasma (see Fig. 1). In particular, if $\beta<\sqrt{2}$, the branch point lies inside the convex hull of the plasma, so no disk D that surrounds the plasma can have the branch point outside it. (If one allowed a noncircular wall, it could surround the plasma but not the branch point, except in the limiting case $\beta=1$ when the branch point is on the boundary of the plasma.)

III. APPROXIMATE RESULTS

A. General theory

Despite the conclusion in Sec. II B above, it is nonetheless possible to put any simply connected plasma that does not have a pathological boundary into an *approximate* equilibrium, in the sense that one can distort the plasma by an arbitrarily small amount and then find a wall potential so that the sum of the wall potential and the potential from the plasma has an equipotential that is very close to the boundary of the plasma. (By very close we mean in the strong sense that the Hausdorff distance between the new plasma and the old plasma is very small, i.e., every point in one set is very close to some point in the other set.)

The technical condition we must impose on G is that its boundary be *locally connected*, which means the boundary is the continuous image of a circle. This implies that the inverse of the Riemann map, the analytic, univalent function p that maps $\mathbf{D}$ to G, extends to be continuous on the closure of $\mathbf{D}$.[10] It can therefore be uniformly approximated by polynomials, and the image of $\mathbf{D}$ under one of these approximating polynomials will be very close to G. Thus, by distorting the plasma by an arbitrarily small amount, we can assume that the map p is a polynomial, and that we are in the situation discussed in Sec. II B. Moreover, by another arbitrarily small perturbation if necessary, we can assume that the derivative of p does not vanish on ∂D, so ϕ has no branch points on ∂G.

We know that the exact solution is the function u from Eq. (7), but that this has singularities at the branch points of ϕ. Define G_ε to be the set of points that are within ε of G, and choose ε to be positive but small enough so that $G_{3\varepsilon}$ contains no branch points of ϕ, and so that the only point in $G_{3\varepsilon}$ where ϕ attains the value 0 is 0. The function u is harmonic on $G_{3\varepsilon}$ and gives the exact solution there.

Suppose one could find a function ψ, analytic on D and continuous on the closure of D, and very close to ϕ on $G_{2\varepsilon}$. Moreover, suppose $\psi(0)=\phi(0)$, $\psi'(0)=\phi'(0),\ldots,\psi^{(N-1)}(0)=\phi^{(N-1)}(0)$, and that ψ only takes the value 0 at 0. Then substitute ψ for ϕ in Eq. (4), and plug this into Eq. (7) to get a function $w(z)$ that is harmonic on D and very close to u on G_ε.

Now consider the set $H=\{z:v(z)+w(z)=0\}$. This will be a small distortion of the set $\{z:v(z)+u(z)=0\}$. The only way H could fail to contain a closed curve that is close to ∂G would be if the set $\{z:v(z)+u(z)=0\}$ contained, in addition to ∂G, a path connecting ∂G to ∂D [for then a small perturbation of the zero set of $u+v$ might no longer enclose (a small perturbation of) G]. But this cannot happen, as is shown in Appendix B. Therefore w restricted to the boundary of D will give a wall potential that produces an approximate solution.

How does one find ψ? Consider the function $\log(\phi(z)/z)$. This is analytic on $G_{3\varepsilon}$, so it can be uniformly approximated on $G_{2\varepsilon}$ by a polynomial q (by Runge's theorem[6]). Moreover, one can modify q slightly, if necessary, to ensure that the values of $q(0),\ldots,q^{(N-1)}(0)$ match those of $\log(\phi(z)/z)$ exactly. Then $\psi(z)=z\exp(q(z))$ will be analytic on all of $\mathbf{C}$, take the value 0 only at 0, be uniformly close to ϕ on $G_{2\varepsilon}$, and the first $N-1$ derivatives of ψ at 0 will match those of ϕ.

B. An example: Cardioids

Consider first the cardioid in Fig. 1, with $\beta=2$. As the branch point of ϕ lies outside the convex hull of G, we can approximate ϕ by a power series, centered at 1, say. Suppose we calculate the seventh-order Taylor polynomial for $\log(\phi(z)/z)$ about 1.

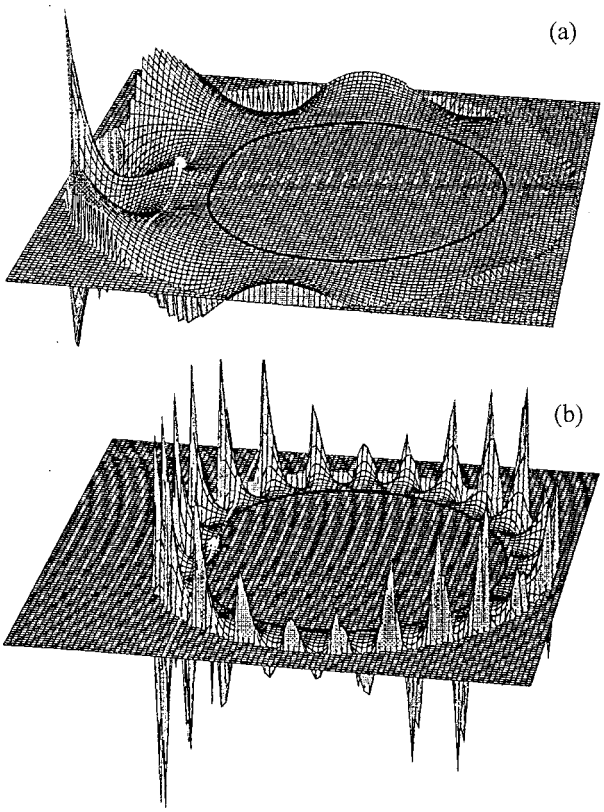

FIG. 2. (a) The difference between the exact solution $u(z;\beta=2)$ [Eq. (9)] and the approximate solution $w(z)$ [Eq. (10)], plotted out to a radius of 6.5. (b) The same difference for the $\beta=1.4$ cardioid, plotted out to a radius one unit larger than the radius of the cardioid. The outline of the appropriate cardioid is indicated by the black line. The corresponding critical points are indicated by the white dots; no exact solution valid in the cardioid interior can be analytic to the left of the white lines. Note that $u(z)$ and $w(z)$ agree closely inside the cardioids. There are more spikes in (b) that in (a) because of the increased number of terms used in (b).

We obtain

$$q_7(z) = -1.4436354 - 0.052786404(z-1) + 4.0325224\ 10^{-3}(z-1)^2 - 4.5228033\ 10^{-4}(z-1)^3 + 5.9701757\ 10^{-5}(z-1)^4 - 8.6302161\ 10^{-6}(z-1)^5 + 1.3221683\ 10^{-6}(z-1)^6 - 2.1090911\ 10^{-7}(z-1)^7.$$

Let

$$\psi(z) = z e^{q_7(z)}.$$

Then we obtain

$$\sup_{z \in G} |\psi(z) - \phi(z)| \leqslant 0.008.$$

So, if on any wall surrounding G we put the potential

$$w(z) = 36\pi \log \left| \frac{z}{\psi(z)} \right| + 8\pi \operatorname{Re} \left[-\frac{4}{z} + \frac{1}{\psi(z)} - \psi(z) \right], \tag{10}$$

then the equipotential $\{v + w = 0\}$ will be very close to the boundary of G. The difference between this approximate solution w and the exact, but divergent, solution u is plotted in Fig. 2(a). We can

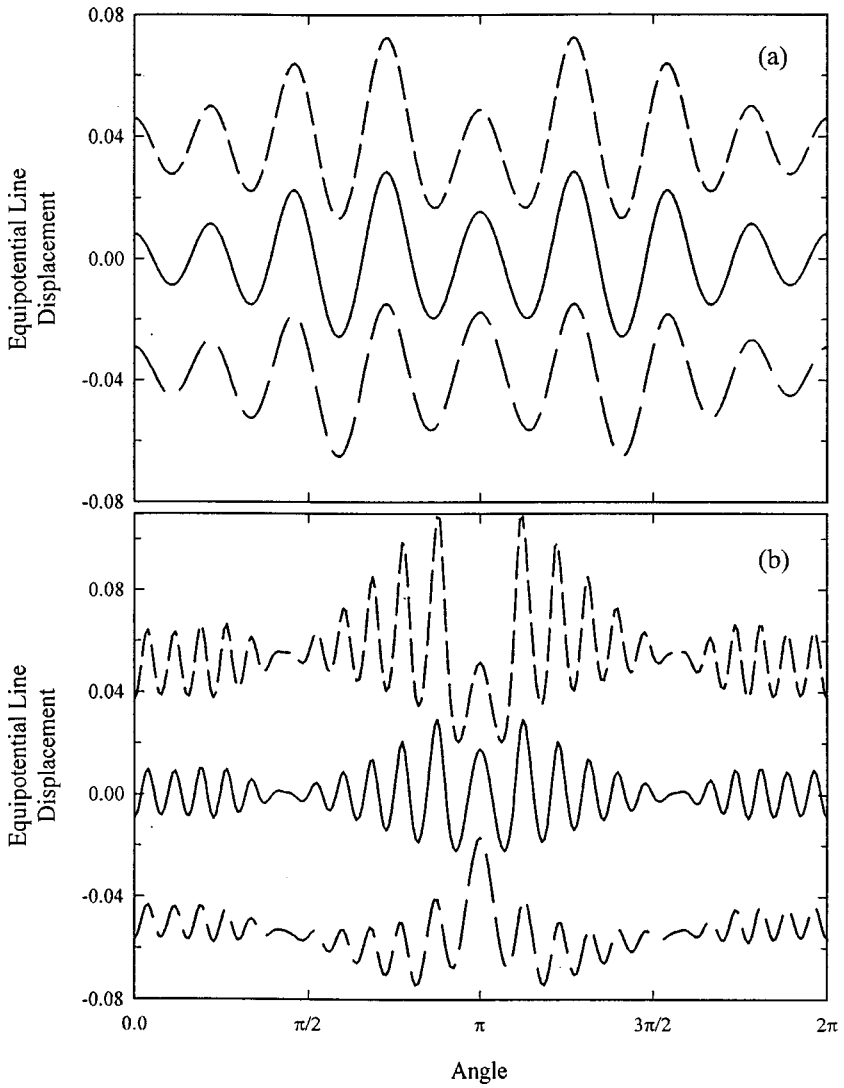

FIG. 3. (a) The distance of the $+1$ (the long dashed curve), the 0 (the solid curve), and the -1 (the short dashed curve) equipotentials of $v+w$ from the $\beta=2$ cardioid boundary, plotted as a function of angle around the cardioid. (b) The equivalent curves for the $\beta=1.4$ cardioid.

calculate that on ∂G, the function $v+w$ takes values between -0.66 and $+0.66$ (for reference, $v+w$ equals 53.4 at $r=0$). Figure 3(a) shows that the equipotential $v+w=0$ is very close to ∂G, and that the equipotentials $+1$ and -1 surround ∂G.

Note 1: The function w does not depend on the size of the disk D surrounding G. The size of the applied potential w on the wall of D does go up somewhat as D grows—in this case, if D is the disk centered at 1 of radius 6, then w ranges between -2224 and 679; if D is the disk of radius 12, then w ranges between -5893 and 3330.

Note 2: To increase accuracy, one need only include more terms in the Taylor expansion. This method will work whenever the branch points of ϕ lie outside some disk containing G, as the Taylor series for ϕ will converge on this disk.

Now consider the $\beta=1.4$ cardioid in Fig. 1. While we can still approximate $\log(\phi(z)/z)$ by polynomials on G, we can no longer do it by Taylor polynomials, and the construction of the polynomials is therefore much harder. One way to do it is to follow the usual construction in the proof of Runge's theorem, wherein path integrals are approximated by rational functions, and the poles of these functions are moved away to infinity.[6] This method is cumbersome, and will result in polynomials of very high degree.

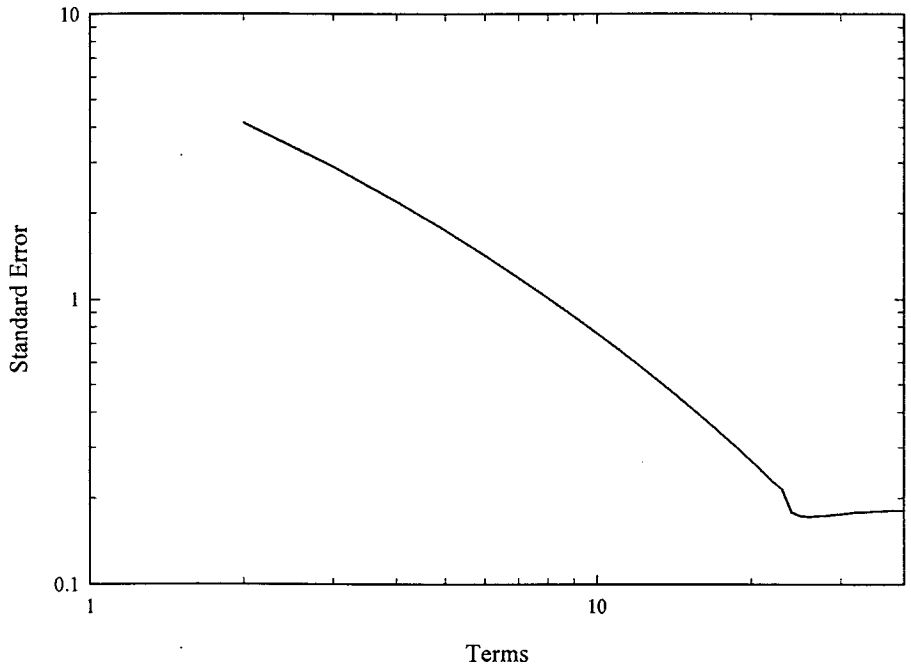

FIG. 4. The standard error (the standard deviation of $v+w$ evaluated on the cardiod boundary) of the $\beta=1.4$ expansion as a function of the number of terms in the expansion.

A better way is to pull the functions back to the disk. Consider not $f(z)=\log(\phi(z)/z)$ but the function $f(p(\zeta))=\log(\zeta/p(\zeta))$. Approximate this on the unit disk by polynomials in $p(\zeta)$. Do this by using Gramm–Schmidt to make an orthonormal basis from the functions $(p(\zeta))^n$, $n=0,1,2,...N$, and then finding the best L^2 approximant of $f(p(\zeta))$ with respect to this basis. If $\Sigma_{n=0}^{N} a_n(p(\zeta))^n$ approximates $f(p(\zeta))$, then $\Sigma_{n=0}^{N} a_n z^n$ will approximate $f(z)$ on G. Notice that following this procedure, if one increases N to improve the accuracy, all the coefficients a_n will change; one does not just add higher-order terms.

We used the above procedure to develop expansions for the $\beta=1.4$ cardioid shown in Fig. 1. The standard error of the expansion on the cardioid boundary ∂G is graphed in Fig. 4 as a function of the number of terms in the expansion. The error drops steadily with the number of terms until approximately 25 terms, at which point numeric errors limit the expansion accuracy. As for the $\beta=2$ cardioid, the difference between the approximate solution w and the exact, but divergent solution u is plotted in Fig. 2(b) for a 32-term expansion. On ∂G, the function $v+w$ takes values between -0.51 and $+0.52$ (for reference, $v+w$ equals 27.7 at $p=0$). Figure 3(b) shows that the equipotential $v+w=0$ is very close to ∂G, and that the equipotentials $+1$ and -1 surround ∂G.

APPENDIX A: QUADRATURE DOMAINS

Let r be a rational function that is univalent on $\mathbf{D}$, and let $G=r(\mathbf{D})$. Such a G is the most general sort of simply connected quadrature domain. Let $\phi: G\to\mathbf{D}$ be the inverse (the Riemann map). Define the *Schwarz function* of G by

$$S(z)=\overline{r\left(\frac{1}{\phi(z)}\right)}.$$

Let $z_1,\ldots,z_K$ be the poles of S inside G. Then if f is any analytic function that is integrable on G, the following formula holds (Ref. 7, p. 19):

$$\int_G f(z)\ dA(z)=\pi\sum_{n=1}^{K}\ \mathrm{Res}\ (fS;z_n). \tag{A1}$$

Now, if r is actually a polynomial of degree N, and $r(0)=0$, then the Schwarz function of G will have a single pole of order N at 0. If the principal part of S at 0 is

$$\frac{\Sigma_{k=0}^{N-1}\ c_k z^k}{z^N},$$

then we obtain from Eq. (A1) that

$$\int_G \sum\ \alpha_k z^k\ dA(z)=\pi[\,\alpha_0 c_{N-1}+\alpha_1 c_{N-2}+\cdots+\alpha_{N-1}c_0].$$

Now suppose h is a real-valued harmonic function on G. Let $h=\mathrm{Re}\,(f)$ for some analytic function f (you can always do this when G is simply connected). With

$$\alpha_k=\frac{1}{k!}\frac{d^k f}{dz^k}\bigg|_{z=0}$$

we obtain that

$$\int_G h(z)\ dA(z)=\pi\ \mathrm{Re}[\,\alpha_0 c_{N-1}+\alpha_1 c_{N-2}+\cdots+\alpha_{N-1}c_0]. \tag{A2}$$

By the Cauchy–Riemann equations,

$$\frac{d^k f}{dz^k}=\frac{\partial^k h}{\partial x^k}-i\ \frac{\partial^k h}{\partial x^{k-1}\partial y}.$$

Substituting into Eq. (A2), we obtain

$$\int_G h(z)dA(z)=\pi\ \mathrm{Re}\left[\sum_{k=0}^{N-1}\ \frac{c^{N-k}}{k!}\left(\frac{\partial^k h}{\partial x^k}-i\ \frac{\partial^k h}{\partial x^{k-1}\partial y}\right)\right]. \tag{A3}$$

This is how one finds formula (6). One can calculate for the cardioids that the Schwarz function is

$$S(z)=\frac{2\beta^2+z+2\beta^2 z+2\beta(1+z)\sqrt{\beta^2+z}}{z^2},$$

and this has principal part

$$\frac{4\beta^2+(4\beta^2+2)z}{z^2}.$$

Combining this with Eq. (A3), one obtains Eq. (8).

APPENDIX B: EQUIPOTENTIALS AROUND *G* FORM SIMPLE CLOSED CURVES

We wish to show that ∂G is an isolated component of the set $\{z:u(z)+v(z)=0\}$, when G is a quadrature domain as in Sec. II B, and the boundary of G is smooth (as it is an algebraic curve,

we only need to avoid cusps like the point -1 in the $\beta=1$ cardioid in Fig. 1). This will mean that if one perturbs u slightly to get a function w, the zero set of $w+v$ will contain a closed curve close to the boundary of G.

As the equipotentials of $u+v$ are perpendicular to $\nabla(u+v)$, we will avoid degeneracy if we can show that $\nabla(u+v)$ is never 0 on ∂G. Let $\tilde{v}(\zeta)$ be the function we get by substituting $h(z) = -2\log|z-\zeta|$ into Eq. (6). Then $\tilde{v}$ has a singularity at 0, is harmonic everywhere else, and agrees with v outside of G. As both $u+v$ and $u+\overline{v}$ are superharmonic on G (because their Laplacian is nonpositive on G) and vanish on ∂G, they must be strictly positive on G. Therefore the zero set of $u+v$ is contained in $D\backslash G$, and equals the zero set of $u+\tilde{v}$. (For a discussion of superharmonic functions, see Ref. 11).

Let z_0 be a point in ∂G. Near z_0 the function $u+\overline{v}$ is harmonic, so it can be written as Re (f) for some analytic function f.[6] Without loss of generality, we can assume $f(z_0)=0$; if $f'(z_0)$ were zero, then $f(z)$ would behave like $(z-z_0)^n$ for some $n\geqslant 2$. But then f could not map a one-sided neighborhood of z_0 in G into the right half-plane (recall that ∂G has no cusp at z_0).

So we conclude that $f'(z_0)$ cannot be zero, and therefore

$$\nabla(u+\overline{v})\big|_{z_0}=\nabla(u+v)\big|_{z_0}=(\mathrm{Re}\,[f'(z_0)],\mathrm{Im}\,[f'(z_0)])\neq 0.$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 39, NUMBER 12 DECEMBER 1998

On the triple sum formula for Wigner 9*j*-symbols

Hjalmar Rosengren[a)]
Department of Mathematics, Lund University, Box 118, S-221 00, Lund, Sweden

(Received 23 June 1998; accepted for publication 24 June 1998)

We give a new proof of the triple sum formula for Wigner 9*j*-symbols due to Ališauskas and Jucys. The proof uses explicit expressions for the coupling kernels recently introduced by the author. Parts of our results generalize to general recoupling coefficients. © *1998 American Institute of Physics.*

I. INTRODUCTION

The Wigner 9*j*-symbols arise in quantum mechanics as recoupling coefficients of four angular momenta. They were first introduced by Eugene Wigner in 1940. For the general theory of Wigner symbols and related objects we refer to the two-volume treatise of Biedenharn and Louck.[1,2]

There are many known expressions for 9*j*-symbols as multiple hypergeometric sums. Generally speaking, the larger the number of summation variables, the more symmetries these sums exhibit. The most compact known expression is the triple sum formula of Ališauskas and Jucys,[3] which does not exhibit any of the 72 symmetries of the 9*j*-symbol. Because of the low number of summation variables, this formula is useful in numerical computations,[4] and it has also been used to study the zeroes of 9*j*-symbols.[5,6] On the other hand, since the 72 symmetries are not exhibited in the triple sum formula, they give rise to nontrivial symmetries of this type of sums. This has been used to find several new hypergeometric summation and transformation formulas.[7–9]

The original proof in Ref. 3 uses a more complicated interpretation of 9*j*-symbols than the standard one, involving an embedding $\mathrm{SU}(2)\times\mathrm{SU}(2)\subseteq\mathrm{SO}(5)$. An elementary proof was given in Ref. 10. There the starting point is a formula expressing the 9*j*-symbol as a double sum, each term being the product of three 3*j*-symbols (Clebsch–Gordan coefficients). The triple sum formula is then derived using only elementary series manipulations. The proof is however quite tricky, and it seems very hard to find without knowledge of the end result.

In a previous paper,[11] we introduced some polynomials in $2n$ variables which were called coupling kernels. They are the reproducing kernels of certain spaces of coupling coefficients for n angular momenta, and may be expressed as n-variable hypergeometric sums. Using this explicit formula (for $n=4$) we will derive an expression for Wigner 9*j*-symbols as a double sum, each term being the product of only two 3*j*-symbols. After inserting appropriate single sum expressions for the 3*j*-symbols it is possible to perform the summation in one variable and arrive at a triple sum, which is equivalent to the one given in Ref. 3. Thus, in this case, there are no series manipulations involved and one can easily derive the formula without knowing it in advance.

We will follow the approach to coupling and recoupling coefficients of Refs. 11, 12. In particular, we will work with the Lie algebra $\mathfrak{su}(1,1)$ rather than with $\mathfrak{su}(2)$, which is more common in the literature. It is well-known that the Wigner symbols of $\mathfrak{su}(2)$ may be obtained from those of $\mathfrak{su}(1,1)$ by continuation. One may also generalize the relevant results of Refs. 11, 12 to $\mathfrak{su}(2)$, and then give a direct proof, analogous to the one below, of the triple sum formula in this case.

In Sec. II we survey parts of Refs. 11, 12. Most of this is reformulation of well-known facts in slightly different terms. The only new result that we need is the explicit expression for coupling kernels from Ref. 11 [equation (16) below]. In Sec. III we prove an expansion formula, given in Theorem 3.1, of which our double sum mentioned above is a special case. In Sec. IV we derive the Ališauskas–Jucys triple sum formula. Finally, in Sec. V we generalize Theorem 3.1 to arbitrary recoupling coefficients. We hope that this result, Theorem 5.5, may be useful also in the study of Wigner 3*nj*-symbols with $n>3$.

II. PRELIMINARIES

We will work with the holomorphic realization of highest weight representations of $\mathfrak{su}(1,1)$. Thus we let $\mathcal{A}^\nu$ ($\nu>0$) be the Hilbert space of analytic functions in the complex unit disc with reproducing kernel $(1-z\overline{w})^{-\nu}$. The norm of a function,

$$f(z)=\sum_{k=0}^{\infty} a_k z^k,$$

is then given by

$$\|f\|^2=\sum_{k=0}^{\infty} \frac{k!}{(\nu)_k}|a_k|^2,$$

where

$$(\nu)_k=\nu(\nu+1)\cdots(\nu+k-1), \quad (\nu)_0=1$$

is the Pochhammer symbol. This norm is invariant under the transformations,

$$f\mapsto f(\phi(z))\phi'(z)^{\nu/2},$$

where ϕ is an analytic automorphism of the disc. The derived representation is a unitary representation of $\mathfrak{su}(1,1)$ on $\mathcal{A}^\nu$ with the highest weight vector 1 of weight $-\nu$. Passing to the complexified Lie algebra $\mathfrak{sl}(2,\mathbb{C})$ yields the densely defined operators

$$E=-\frac{d}{dz}, \quad F=z^2\frac{d}{dz}+\nu z, \quad H=-\left(2z\frac{d}{dz}+\nu\right),$$

which satisfy the structure equations

$$[EF]=H, \quad [HE]=2E, \quad [HF]=-2F,$$

and the $\mathfrak{su}(1,1)$-reality conditions

$$E^*=-F, \quad F^*=-E, \quad H^*=H.$$

Consider a Hilbert tensor product $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$ of such spaces. We will use $\|\ \|$ and $\langle\ ,\ \rangle$ to denote its norm and scalar product. It decomposes under the Lie algebra action as

$$\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}\simeq\bigoplus_{s=0}^{\infty}\binom{n+s-2}{n-2}\mathcal{A}^{|\nu|+2s}, \tag{1}$$

(where $|\nu|=\Sigma\nu_i$), that is, the space $\mathcal{A}^{|\nu|+2s}$ occurs with multiplicity $\binom{n+s-2}{n-2}$. A highest weight vector Q in $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$ of weight $-(|\nu|+2s)$ is the image of the function 1 under an intertwining embedding,

$$\mathcal{A}^{|\nu|+2s}\to\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}.$$

In our realization, this means that Q is a homogeneous polynomial of degree s, which can be expressed in terms of the differences z_i-z_j of the coordinates. Equivalently, Q satisfies the identity

$$Q(az_1+b,\ldots,az_n+b)=a^sQ(z_1,\ldots,z_n), \quad a,b\in\mathbb{C}. \tag{2}$$

In agreement with (1), the space of such polynomials has dimension $\binom{n+s-2}{n-2}$.

Let $\mathcal{K}_Q$ be the embedding defined by $\mathcal{K}_Q(1)=Q$. In Ref. 12 it was proved that if

$$Q(z)=\sum_{|t|=s} c_t z_1^{t_1}\cdots z_n^{t_n}, \tag{3}$$

then the adjoint map $\mathcal{K}_Q^*$ is the differential operator given by

$$\mathcal{K}_Q^*(f_1\otimes\ldots\otimes f_n)(z)=\sum_{|t|=s}\overline{c_t}\frac{f_1^{(t_1)}(z)\cdots f_n^{(t_n)}(z)}{(\nu_1)_{t_1}\cdots(\nu_n)_{t_n}}. \tag{4}$$

In particular, writing $e_m(z)=z^m$,

$$\mathcal{K}_Q^*(e_{m_1}\otimes\ldots\otimes e_{m_n})=\sum_{|t|=s}\overline{c_t}\frac{(-m_1)_{t_1}\cdots(-m_n)_{t_n}}{(\nu_1)_{t_1}\cdots(\nu_n)_{t_n}}(-1)^s e_{|m|-s}=\overline{TQ(m_1,\ldots,m_n)}e_{|m|-s},$$

where TQ is the polynomial of degree s given by

$$TQ(m)=(-1)^s\sum_{|t|=s} c_t\frac{(-m_1)_{t_1}\cdots(-m_n)_{t_n}}{(\nu_1)_{t_1}\cdots(\nu_n)_{t_n}}.$$

This exhibits TQ as a coupling coefficient of our representation. If Q and Q' are two highest weight vectors, the corresponding coupling coefficients satisfy

$$\sum_{|m|=k+s}\frac{(\nu_1)_{m_1}\cdots(\nu_n)_{m_n}}{m_1!\cdots m_n!}TQ(m)\,\overline{TQ'(m)}=\frac{(|\nu|+2s)_k}{k!}\langle Q,Q'\rangle, \tag{5}$$

for $k=0,1,2,\ldots$. Here s is the degree of Q or Q'; if their degrees are different both sides vanish.

For $n=2$, the space of highest weight vectors of degree s is one-dimensional, and spanned by $(z_1-z_2)^s$. The norm of this vector is given by

$$\|(z_1-z_2)^s\|^2=\frac{s!(\nu_1+\nu_2+s-1)_s}{(\nu_1)_s(\nu_2)_s}. \tag{6}$$

It will be convenient to write

$$\begin{aligned}P_s^{(\nu_1,\nu_2)}(m_1,m_2)&=(\nu_1)_s(\nu_2)_s(T(z_1-z_2)^s)(m_1,m_2)\\&=\sum_{k=\max(0,\,s-m_2)}^{\min(s,\,m_1)}\binom{s}{k}(-1)^k\frac{(\nu_1)_s(\nu_2)_s}{(\nu_1)_k(\nu_2)_{s-k}}(-m_1)_k(-m_2)_{s-k}.\end{aligned} \tag{7}$$

These polynomials are essentially Clebsch–Gordan coefficients, or Wigner $3j$-symbols, of our representation. As is well-known, they can be expressed in terms of Hahn polynomials; in standard notation,[13]

$$P_s^{(\nu_1,\nu_2)}(m_1,m_2)=(\nu_1)_s(-m_1-m_2)_s\,Q_s(m_1;\nu_1-1,\nu_2-1,m_1+m_2).$$

We will use some well-known properties of Clebsch–Gordan coefficients. First, it is clear from (7) that

$$P_s^{(\nu_1,\nu_2)}(m_1,m_2)=\begin{cases}(-1)^{m_2}s!\dfrac{(\nu_1)_s(\nu_2)_s}{(\nu_1)_{m_1}(\nu_2)_{m_2}}, & m_1+m_2=s,\\ 0, & m_1+m_2<s.\end{cases} \tag{8}$$

From (5) and (6) one obtains the orthogonality relations,

$$\sum_{m_1+m_2=s+k}\frac{(\nu_1)_{m_1}(\nu_2)_{m_2}}{m_1!\,m_2!}P_s^{(\nu_1,\nu_2)}(m_1,m_2)P_t^{(\nu_1,\nu_2)}(m_1,m_2)=\frac{(\nu_1+\nu_2+2s)_k}{k!}C_s^{\nu_1\nu_2}\delta_{st},\quad(9)$$

where

$$C_s^{\nu_1\nu_2}=s!(\nu_1)_s(\nu_2)_s(\nu_1+\nu_2+s-1)_s.\quad(10)$$

The expression (7) may be rewritten in terms of a terminating ${}_3F_2(1)$-series,

$${}_3F_2\left(\left.\begin{matrix}-n,a,b\\c,d\end{matrix}\right|1\right)=\sum_{k=0}^{n}\frac{(-n)_k(a)_k(b)_k}{(c)_k(d)_k k!}.$$

Because of the known symmetries of such series, cf. Ref. 14, p. 59, there is a large number of similar expressions, such as

$$P_s^{(\nu_1,\nu_2)}(m_1,m_2)=\sum_{k=0}^{s}\binom{s}{k}(-1)^{s-k}\frac{(\nu_1)_s(\nu_2)_s}{(\nu_1)_k(\nu_2)_{s-k}}(\nu_1+m_1)_k(\nu_2+m_2)_{s-k},\quad(11)$$

$$=(-1)^s\frac{m_2!}{(m_1+m_2-s)!}(\nu_1)_s(\nu_2+m_2)_{m_1}\,{}_3F_2\left(\left.\begin{matrix}-m_1,\nu_1+s,1-\nu_2-s\\\nu_1,1-\nu_2-m_1-m_2\end{matrix}\right|1\right),\quad(12)$$

$$=(\nu_1)_s(-m_1-m_2)_s\,{}_3F_2\left(\left.\begin{matrix}-m_1,-s,\nu_1+\nu_2+s-1\\\nu_1,-m_1-m_2\end{matrix}\right|1\right).\quad(13)$$

From the transformation formulas used to derive (12) it follows that

$${}_3F_2\left(\left.\begin{matrix}-m_1,\nu_1+s,1-\nu_2-s\\\nu_1,1-\nu_2-m_1-m_2\end{matrix}\right|1\right)=0,\quad(14)$$

if m_1, m_2, and s are integers with

$$m_1,s\geqslant 0,\quad m_1+m_2\geqslant s,\quad m_2<0.$$

This is a special case of Karlsson's summation formula.[15]

We will now discuss the coupling kernels introduced in Ref. 11. Let us consider the Hilbert subspace of highest weight vectors of degree s in $\mathcal{A}^{\nu_1}\otimes\ldots\otimes\mathcal{A}^{\nu_n}$. It has a reproducing kernel,

$$K_s(z,\overline{w})=\sum_{|t|=|u|=s}c_{t,u}z_1^{t_1}\cdots z_n^{t_n}\overline{w}_1^{u_1}\cdots\overline{w}_n^{u_n}.$$

The coupling kernels are obtained by applying the transform T in each of the two variables z and w; thus we define

$$\mathbf{P}_s(i,j)=\sum_{|t|=|u|=s}c_{t,u}\frac{(-i)_t(-j)_u}{(\nu)_t(\nu)_u},$$

where we use multi-index notation such as

$$(-i)_t=(-i_1)_{t_1}\cdots(-i_n)_{t_n}.$$

This is a reproducing kernel for the space of coupling coefficients of degree s; in fact,

$$\frac{(|\nu|+2s)_k}{k!}TQ(l)=\sum_{|m|=k+s}\frac{(\nu_1)_{m_1}\cdots(\nu_n)_{m_n}}{m_1!\cdots m_n!}TQ(m)\mathbf{P}_s(l,m),$$

for each $k=0,1,2,\ldots$, and each highest weight vector Q of degree s. If (Q_k) and $(\tilde{Q}_l)$ are any two orthogonal bases of this space, then

$$\mathbf{P}_s(i,j)=\sum_{k,\,l}\frac{\langle Q_k,\tilde{Q}_l\rangle}{\|Q_k\|^2\|\tilde{Q}_l\|^2}\overline{TQ_k(i)}\,T\tilde{Q}_l(j). \tag{15}$$

In Ref. 11 an explicit expression for the coupling kernels was found, namely,

$$\mathbf{P}_s(i,j)=\frac{(-1)^s(-|i|)_s(-|j|)_s}{(|\nu|+s-1)_s s!}\sum_{m_1,\ldots,m_n=0}^{\infty}\frac{(|\nu|+s-1)_{|m|}(-s)_{|m|}(-i)_m(-j)_m}{(-|i|)_{|m|}(-|j|)_{|m|}m!(\nu)_m} \tag{16}$$

(with the convention $0/0=0$, so that the sum is actually finite). Our proof of the triple sum formula will use this expression, though in fact we only need the case $|i|=|j|=s$, which is slightly easier to prove.

Let us now see how to introduce recoupling coefficients, and in particular Wigner $9j$-symbols, in the present approach. First we define the binary coupling of two highest weight vectors. Suppose that we decompose the tensor product as

$$\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}\simeq(\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_k})\otimes(\mathcal{A}^{\nu_{k+1}}\otimes\cdots\otimes\mathcal{A}^{\nu_n}),$$

where $1\leqslant k\leqslant n-1$. Let Q_1 be a highest weight vector in $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_k}$ of weight $-\mu_1$ and Q_2 one in $\mathcal{A}^{\nu_{k+1}}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$ of weight $-\mu_2$. Thus

$$\mu_1=\nu_1+\ldots+\nu_k+2t_1,\quad \mu_2=\nu_{k+1}+\ldots+\nu_n+2t_2,$$

where t_1 and t_2 are the degrees of Q_1 and Q_2. For s a non-negative integer we define

$$(Q_1,Q_2)_s=(\mu_1)_s(\mu_2)_s(\mathcal{K}_{Q_1}\otimes\mathcal{K}_{Q_2})(z_1-z_2)^s,$$

which is a highest weight vector in $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$ of weight $-(\mu_1+\mu_2+2s)$ and degree t_1+t_2+s. Equivalently, $(Q_1,Q_2)_s$ is determined by

$$\mathcal{K}^*_{(Q_1,Q_2)_s}(f_1\otimes\ldots\otimes f_n)=(\mu_1)_s(\mu_2)_s\mathcal{K}^*_{(z_1-z_2)^s}(\mathcal{K}^*_{Q_1}(f_1\otimes\ldots\otimes f_k)\otimes\mathcal{K}^*_{Q_2}(f_{k+1}\otimes\ldots\otimes f_n)).$$

Choosing $f_i(z)=z^{m_i}$ gives the important formula

$$T(Q_1,Q_2)_s(m)=TQ_1(m')\,TQ_2(m'')\,P_s^{(\mu_1,\mu_2)}(|m'|-t_1,|m''|-t_2), \tag{17}$$

where

$$m'=(m_1,\ldots,m_k),\quad m''=(m_{k+1},\ldots,m_n).$$

Moreover,

$$\|(Q_1,Q_2)_s\|^2=C_s^{\mu_1\mu_2}\|Q_1\|^2\|Q_2\|^2,$$

with the constant as in (10).

We also need a more general type of binary coupling, corresponding to a decomposition,

$$\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}\simeq(\mathcal{A}^{\nu_{\sigma_1}}\otimes\cdots\otimes\mathcal{A}^{\nu_{\sigma_k}})\otimes(\mathcal{A}^{\nu_{\sigma_{k+1}}}\otimes\cdots\otimes\mathcal{A}^{\nu_{\sigma_n}}),$$

where σ is a permutation of $(1,2,\ldots,n)$. If Q_1 and Q_2 are highest weight vectors in $\mathcal{A}^{\nu_{\sigma_1}}\otimes\cdots\otimes\mathcal{A}^{\nu_{\sigma_k}}$ and $\mathcal{A}^{\nu_{\sigma_{k+1}}}\otimes\cdots\otimes\mathcal{A}^{\nu_{\sigma_n}}$ respectively, we define

$$(Q_1,Q_2)_s^{\sigma}(z_1,\ldots,z_n)=(Q_1,Q_2)_s(z_{\sigma_1},\ldots,z_{\sigma_n}).$$

Then $(Q_1,Q_2)_s^{\sigma}$ is a highest weight vector in $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$.

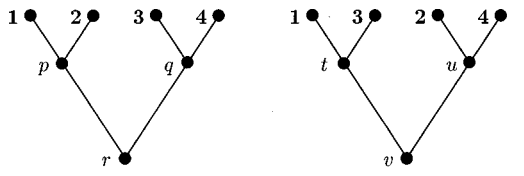

FIG. 1.

Now let $n=4$ and $\sigma=(1,3,2,4)$. We consider the two orthogonal systems of highest weight vectors in $\mathcal{A}^{\nu_1}\otimes\mathcal{A}^{\nu_2}\otimes\mathcal{A}^{\nu_3}\otimes\mathcal{A}^{\nu_4}$ defined by

$$\begin{aligned} Q_{pqr}&=((1,1)_p,(1,1)_q)_r,\\ \tilde{Q}_{tuv}&=((1,1)_t,(1,1)_u)_v^{\sigma}. \end{aligned} \tag{18}$$

Graphically, these iterated couplings may be represented as in Figure 1.

Let

$$W_{pqr}^{tuv}=\langle Q_{pqr},\tilde{Q}_{tuv}\rangle,$$

where the parameters ν_i are suppressed from the notation. These are essentially the Wigner $9j$-coefficients of our representation. Since W_{pqr}^{tuv} vanishes if $p+q+r\neq t+u+v$, we may assume that

$$p+q+r=t+u+v=s.$$

In more standard notation for $9j$-symbols, we have

$$\begin{Bmatrix} j_1 & j_2 & j_{12}\\ j_3 & j_4 & j_{34}\\ j_{13} & j_{24} & j \end{Bmatrix}=\frac{1}{\|Q_{pqr}\|\|\tilde{Q}_{tuv}\|}W_{pqr}^{tuv},$$

where the ''angular momenta'' are given by

$$j_1=-\tfrac{1}{2}\nu_1,\quad j_2=-\tfrac{1}{2}\nu_2,\quad j_3=-\tfrac{1}{2}\nu_3,\quad j_4=-\tfrac{1}{2}\nu_4,$$

$$j_{12}=-\tfrac{1}{2}(\nu_1+\nu_2+2p),\quad j_{34}=-\tfrac{1}{2}(\nu_3+\nu_4+2q),$$

$$j_{13}=-\tfrac{1}{2}(\nu_1+\nu_3+2t),\quad j_{24}=-\tfrac{1}{2}(\nu_2+\nu_4+2u),$$

$$j=-\tfrac{1}{2}(\nu_1+\nu_2+\nu_3+\nu_4+2s),$$

and the normalizing factor by

$$\|Q_{pqr}\|\|\tilde{Q}_{tuv}\|=(C_p^{\nu_1\nu_2}C_q^{\nu_3\nu_4}C_r^{\nu_1+\nu_2+2p,\ \nu_3+\nu_4+2q}C_t^{\nu_1\nu_3}C_u^{\nu_2\nu_4}C_v^{\nu_1+\nu_3+2t,\ \nu_2+\nu_4+2u})^{1/2}.$$

We conclude this section with a remark on transvectants and Wigner symbols. Let us consider the case $n=2$ of (4). It will be convenient to write

$$\begin{aligned} \mathcal{J}_s^{\nu_1\nu_2}(f_1,f_2)(z)&=(\nu_1)_s(\nu_2)_s\,\mathcal{K}^{*}_{(z_1-z_2)^s}(f_1\otimes f_2)(z)\\ &=\sum_{k=0}^{s}\binom{s}{k}(-1)^{s-k}\frac{(\nu_1)_s(\nu_2)_s}{(\nu_1)_k(\nu_2)_{s-k}}f_1^{(k)}(z)f_2^{(s-k)}(z), \end{aligned}$$

so that, again with $e_m(z)=z^m$,

$$\mathcal{J}_s^{\nu_1\nu_2}(e_{m_1},e_{m_2})=P_s^{(\nu_1,\nu_2)}(m_1,m_2)\,e_{m_1+m_2-s}.$$

This operator occurs in classical invariant theory and is known as the transvectant. It has also been called Cohen's operator and the Rankin–Cohen bracket.[16] It is clear from the above that the Wigner $9j$-symbols occur in the expansion

$$\mathcal{J}_r^{\nu_1+\nu_2+2p,\,\nu_3+\nu_4+2q}(\mathcal{J}_p^{\nu_1\nu_2}(f_1,f_2),\mathcal{J}_q^{\nu_3\nu_4}(f_3,f_4))$$
$$=\sum_{t+u+v=p+q+r}\frac{W_{pqr}^{tuv}}{\|\tilde{Q}_{tuv}\|^2}\,\mathcal{J}_v^{\nu_1+\nu_3+2t,\,\nu_2+\nu_4+2u}(\mathcal{J}_t^{\nu_1\nu_3}(f_1,f_3),\mathcal{J}_u^{\nu_2\nu_4}(f_2,f_4)).$$

It is interesting that in a recent paper[17] the coefficients occurring in

$$\mathcal{J}_r^{\nu_1+\nu_2+2q,\,\nu_3}(\mathcal{J}_q^{\nu_1\nu_2}(f_1,f_2),f_3)=\sum_{t+u=q+r}R_{qr}^{tu}\,\mathcal{J}_u^{\nu_1,\,\nu_2+\nu_3+2t}(f_1,\mathcal{J}_t^{\nu_2\nu_3}(f_2,f_3))$$

arise in a seemingly very different context. These are, up to a normalizing factor, the Racah coefficients, or Wigner $6j$-symbols, of our representation.

III. AN EXPANSION FORMULA

In this section we will derive a formula expressing the product of one $9j$- and two $3j$-symbols as a quadruple sum, each term being a product of four $3j$-symbols. As a special case we get an expression for the $9j$-symbols as a double sum of products of two $3j$-symbols, of which the triple sum formula is a rather easy consequence.

Let us choose Q and $\tilde{Q}$ in (15) as the bases given by (18). This gives

$$\mathbf{P}_s(i,j)=\sum_{\substack{p+q+r=s\\t+u+v=s}}\frac{W_{pqr}^{tuv}}{\|Q_{pqr}\|^2\|\tilde{Q}_{tuv}\|^2}\,\overline{TQ_{pqr}(i)}\,T\tilde{Q}_{tuv}(j). \tag{19}$$

Moreover, by (17),

$$TQ_{pqr}(i)=P_p^{(\nu_1,\nu_2)}(i_1,i_2)\,P_q^{(\nu_3,\nu_4)}(i_3,i_4)\,P_r^{(\nu_1+\nu_2+2p,\nu_3+\nu_4+2q)}(i_1+i_2-p,i_3+i_4-q),$$

$$T\tilde{Q}_{tuv}(j)=P_t^{(\nu_1,\nu_3)}(j_1,j_3)\,P_u^{(\nu_2,\nu_4)}(j_2,j_4)\,P_v^{(\nu_1+\nu_3+2t,\nu_2+\nu_4+2u)}(j_1+j_3-t,j_2+j_4-u).$$

Since these are real polynomials, we may ignore the conjugate bar in (19). Let us temporarily write $P_p=P_p^{(\nu_1,\nu_2)}$ and so on. We fix eight non-negative integers,

$$k_{12},k_{34},k_{13},k_{24},p',q',t',u',$$

and apply, to both sides of (19), the summation operator,

$$\sum_{\substack{i_1+i_2=p'+k_{12}\\i_3+i_4=q'+k_{34}}}\frac{(\nu)_i}{i!}P_{p'}(i_1,i_2)P_{q'}(i_3,i_4)\sum_{\substack{j_1+j_3=t'+k_{13}\\j_2+j_4=u'+k_{24}}}\frac{(\nu)_j}{j!}P_{t'}(j_1,j_3)P_{u'}(j_2,j_4).$$

By the orthogonality of Clebsch–Gordan coefficients (9), the right hand side vanishes unless

$$(p',q',t',u')=(p,q,t,u),$$

and we obtain

$$\sum_{\substack{i_1+i_2=p+k_{12}\\ i_3+i_4=q+k_{34}}}\sum_{\substack{j_1+j_3=t+k_{13}\\ j_2+j_4=u+k_{24}}}\frac{(\nu)_i(\nu)_j}{i!\,j!}\mathbf{P}_s(i,j)P_p(i_1,i_2)P_q(i_3,i_4)P_t(j_1,j_3)P_u(j_2,j_4)$$

$$=\frac{(\nu_1+\nu_2+2p)_{k_{12}}(\nu_3+\nu_4+2q)_{k_{34}}(\nu_1+\nu_3+2t)_{k_{13}}(\nu_2+\nu_4+2u)_{k_{24}}}{k_{12}!\,k_{34}!\,k_{13}!\,k_{24}!\,C_r^{\nu_1+\nu_2+2p,\,\nu_3+\nu_4+2q}C_v^{\nu_1+\nu_3+2t,\,\nu_2+\nu_4+2u}}$$

$$\times W_{pqr}^{tuv}P_r(k_{12},k_{34})P_v(k_{13},k_{24}). \tag{20}$$

Now we expand $\mathbf{P}_s$ according to (16). Then the left hand side of (20) takes the form

$$(-1)^s\frac{(-p-q-k_{12}-k_{34})_s(-t-u-k_{13}-k_{24})_s}{(|\nu|+s-1)_s s!}$$

$$\times\sum_{m_1,m_2,m_3,m_4=0}^{\infty}\frac{(|\nu|+s-1)_{|m|}(-s)_{|m|}}{(-p-q-k_{12}-k_{34})_{|m|}(-t-u-k_{13}-k_{24})_{|m|}m!(\nu)_m}$$

$$\times\sum_{i_1+i_2=p+k_{12}}\frac{(\nu_1)_{i_1}(\nu_2)_{i_2}}{i_1!\,i_2!}(-i_1)_{m_1}(-i_2)_{m_2}P_p(i_1,i_2)$$

$$\times\sum_{i_3+i_4=q+k_{34}}\frac{(\nu_3)_{i_3}(\nu_4)_{i_4}}{i_3!\,i_4!}(-i_3)_{m_3}(-i_4)_{m_4}P_q(i_3,i_4)$$

$$\times\sum_{j_1+j_3=t+k_{13}}\frac{(\nu_1)_{j_1}(\nu_3)_{j_3}}{j_1!\,j_3!}(-j_1)_{m_1}(-j_3)_{m_3}P_t(j_1,j_3)$$

$$\times\sum_{j_2+j_4=u+k_{24}}\frac{(\nu_2)_{j_2}(\nu_4)_{j_4}}{j_2!\,j_4!}(-j_2)_{m_2}(-j_4)_{m_4}P_u(j_2,j_4). \tag{21}$$

The four inner sums may be computed using the probably well-known formula

$$\sum_{i_1+i_2=s+k}\frac{(\nu_1)_{i_1}(\nu_2)_{i_2}}{i_1!\,i_2!}(-i_1)_{m_1}(-i_2)_{m_2}P_s^{(\nu_1,\nu_2)}(i_1,i_2)$$

$$=(-1)^{m_1+m_2}\frac{(\nu_1+\nu_2+s+m_1+m_2)_{k+s-m_1-m_2}}{(k+s-m_1-m_2)!}(\nu_1)_{m_1}(\nu_2)_{m_2}P_s^{(\nu_1,\nu_2)}(m_1,m_2). \tag{22}$$

Note that, by (8), the left hand side vanishes unless $m_1+m_2\leqslant s+k$, and the right hand side unless $m_1+m_2\geqslant s$. One may prove (22) by inserting expression (11) for the Clebsch–Gordan coefficients (see the proof of Lemma 5.4 below).

It follows that the expression (21) equals

$$
\begin{aligned}
&(-1)^s \frac{(-p-q-k_{12}-k_{34})_s(-t-u-k_{13}-k_{24})_s}{(|\nu|+s-1)_s s!} \\
&\times \sum_{m_1,m_2,m_3,m_4=0}^{\infty} \frac{(|\nu|+s-1)_{|m|}(-s)_{|m|}(\nu)_m}{(-p-q-k_{12}-k_{34})_{|m|}(-t-u-k_{13}-k_{24})_{|m|} m!} \\
&\times \frac{(\nu_1+\nu_2+p+m_1+m_2)_{k_{12}+p-m_1-m_2}(\nu_3+\nu_4+q+m_3+m_4)_{k_{34}+q-m_3-m_4}}{(k_{12}+p-m_1-m_2)!(k_{34}+q-m_3-m_4)!} \\
&\times \frac{(\nu_1+\nu_3+t+m_1+m_3)_{k_{13}+t-m_1-m_3}(\nu_2+\nu_4+u+m_2+m_4)_{k_{24}+u-m_2-m_4}}{(k_{13}+t-m_1-m_3)!(k_{24}+u-m_2-m_4)!} \\
&\times P_p(m_1,m_2)P_q(m_3,m_4)P_t(m_1,m_3)P_u(m_2,m_4).
\end{aligned}
$$

On the other hand, this is equal to the right hand side of (20). After some cancellations, this gives the following formula.

Theorem 3.1: *Let* k_{12}, k_{34}, k_{13}, k_{24}, p, q, r, t, u, and v be non-negative integers with

$$p+q+r=t+u+v=s.$$

Then, in the notation above, the equality

$$
\begin{aligned}
&\frac{1}{k_{12}!\,k_{34}!\,k_{13}!\,k_{24}!\,C_r^{\nu_1+\nu_2+2p,\,\nu_3+\nu_4+2q} C_v^{\nu_1+\nu_3+2t,\,\nu_2+\nu_4+2u}} \\
&\quad \times W_{pqr}^{tuv} P_r^{(\nu_1+\nu_2+2p,\nu_3+\nu_4+2q)}(k_{12},k_{34}) P_v^{(\nu_1+\nu_3+2t,\nu_2+\nu_4+2u)}(k_{13},k_{24}) \\
&= (-1)^s \frac{(-p-q-k_{12}-k_{34})_s(-t-u-k_{13}-k_{24})_s}{(|\nu|+s-1)_s s!} \\
&\quad \times \sum_{m_1,m_2,m_3,m_4} \frac{(|\nu|+s-1)_{|m|}(-s)_{|m|}(\nu)_m}{(-p-q-k_{12}-k_{34})_{|m|}(-t-u-k_{13}-k_{24})_{|m|} m!} \\
&\quad \times \frac{1}{(k_{12}+p-m_1-m_2)!(k_{34}+q-m_3-m_4)!(k_{13}+t-m_1-m_3)!(k_{24}+u-m_2-m_4)!} \\
&\quad \times \frac{1}{(\nu_1+\nu_2+2p)_{m_1+m_2-p}(\nu_3+\nu_4+2q)_{m_3+m_4-q}(\nu_1+\nu_3+2t)_{m_1+m_3-t}(\nu_2+\nu_4+2u)_{m_2+m_4-u}} \\
&\quad \times P_p^{(\nu_1,\nu_2)}(m_1,m_2) P_q^{(\nu_3,\nu_4)}(m_3,m_4) P_t^{(\nu_1,\nu_3)}(m_1,m_3) P_u^{(\nu_2,\nu_4)}(m_2,m_4),
\end{aligned}
$$

holds, where the sum is over all non-negative integers such that

$$
\begin{aligned}
&p \leqslant m_1+m_2 \leqslant p+k_{12}, \\
&q \leqslant m_3+m_4 \leqslant q+k_{34}, \\
&t \leqslant m_1+m_3 \leqslant t+k_{13}, \\
&u \leqslant m_2+m_4 \leqslant u+k_{24}, \\
&m_1+m_2+m_3+m_4 \leqslant s.
\end{aligned}
$$

To prove the triple sum formula we only need the case

$$k_{12}=k_{13}=0, \quad k_{34}=r, \quad k_{24}=v.$$

Then the two conditions,

$$m_1+m_2=p, \quad m_1+m_3=t,$$

hold, so that the sum in the theorem reduces to a double sum. Moreover, the factors P_r, P_v, P_p, and P_t become trivial by (8), so we obtain a formula expressing the Wigner $9j$-symbol as a double sum of products of two Clebsch–Gordan coefficients. After further simplifications, such as writing

$$k_{34}+q-m_3-m_4=s-|m|,$$

we obtain the following formula.

Corollary 3.2: For p, q, r, t, u, and v non-negative integers with

$$p+q+r=t+u+v=s,$$

the equality

$$\begin{aligned}W_{pqr}^{tuv}=&(-1)^{r+v+s}\frac{p!\,r!\,t!\,v!(\nu_1)_p(\nu_2)_p(\nu_1)_t(\nu_3)_t}{(|\nu|+s-1)_s}\\&\times(|\nu|+2p+2q+r-1)_r(|\nu|+2t+2u+v-1)_v\\&\times\sum_{m_1,m_2,m_3,m_4}\frac{(|\nu|+s-1)_{|m|}(\nu_4)_{m_4}}{m!(s-|m|)!(\nu_1)_{m_1}}(-1)^{m_1+m_4}P_q^{(\nu_3,\nu_4)}(m_3,m_4)P_u^{(\nu_2,\nu_4)}(m_2,m_4)\\&\times(\nu_2+\nu_4+u+m_2+m_4)_{s-|m|}(\nu_3+\nu_4+q+m_3+m_4)_{s-|m|},\end{aligned}$$

holds, where the sum is over all non-negative integers such that

$$\begin{aligned}&m_1+m_2=p,\\&q\leqslant m_3+m_4\leqslant q+r,\\&m_1+m_3=t,\\&u\leqslant m_2+m_4\leqslant u+v.\end{aligned}$$

IV. THE TRIPLE SUM FORMULA

We will now prove the triple sum formula. Let us rewrite the sum in Corollary 3.2 using $j=s-|m|$ and m_1 as summation variables, thus replacing m_2, m_3, and m_4 by

$$p-m_1,\quad t-m_1,\quad s+m_1-p-t-j,$$

respectively. Using the identities

$$(a)_{s-k}=(-1)^k\frac{(a)_s}{(1-a-s)_k},$$

$$(a)_k=(-1)^k(1-a-k)_k,$$

we obtain

$$\begin{aligned}W_{pqr}^{tuv}=&(-1)^{q+u}(|\nu|+2p+2q+r-1)_r(|\nu|+2t+2u+v-1)_v\\&\times r!\,v!(\nu_1)_p(\nu_2)_p(\nu_1)_t(\nu_3)_t\sum_{j,m_1}\frac{(1-\nu_2-\nu_4-2u-v)_j(1-\nu_3-\nu_4-2q-r)_j}{j!(2-|\nu|-2s)_j}\\&\times\frac{(-p)_{m_1}(-t)_{m_1}}{m_1!(\nu_1)_{m_1}}\frac{(\nu_4)_{s+m_1-p-t-j}}{(s+m_1-p-t-j)!}\\&\times P_q^{(\nu_3,\nu_4)}(t-m_1,s+m_1-p-t-j)\,P_u^{(\nu_2,\nu_4)}(p-m_1,s+m_1-p-t-j),\end{aligned}$$

where the sum is over j and m_1 such that

$$0\leqslant m_1\leqslant \min(p,t),$$
$$0\leqslant j\leqslant \min(r,v),$$
$$p+t+j\leqslant s+m_1.$$

Now let us expand P_q and P_u using formulas (12) and (13), respectively. Thus we write

$$P_q=(-1)^q\frac{(s+m_1-p-t-j)!}{(r-j)!}(\nu_3)_q(\nu_4+s+m_1-p-t-j)_{t-m_1}$$
$$\times\sum_{i=0}^{t-m_1}\frac{(m_1-t)_i(\nu_3+q)_i(1-\nu_4-q)_i}{i!(\nu_3)_i(1-\nu_4-q-r+j)_i},$$

$$P_u=(\nu_2)_u(j-u-v)_u\sum_{k=0}^{\min(u,\,p-m_1)}\frac{(-u)_k(m_1-p)_k(\nu_2+\nu_4+u-1)_k}{k!(j-u-v)_k(\nu_2)_k}.$$

We then change the order of summation, pulling m_1 inside. We also manipulate the Pochhammer symbols to make i,j,k appear only as subscripts. This gives

$$W^{tuv}_{pqr}=(u+v)!(\nu_1)_p(\nu_1)_t(\nu_2)_p(\nu_2)_u(\nu_3)_q(\nu_3)_t(\nu_4)_{q+r}$$
$$\times(|\nu|+2p+2q+r-1)_r(|\nu|+2t+2u+v-1)_v$$
$$\times\sum_{i=0}^{t}\sum_{j=0}^{\min(r,\,v)}\sum_{k=0}^{\min(p,\,u)}\frac{1}{i!\,j!\,k!}\frac{1}{(1-\nu_4-q-r)_{i+j}(-u-v)_{j+k}}$$
$$\times\frac{(-r)_j(-v)_j(1-\nu_3-\nu_4-2q-r)_j(1-\nu_2-\nu_4-2u-v)_j}{(2-|\nu|-2s)_j}$$
$$\times\frac{(-t)_i(\nu_3+q)_i(1-\nu_4-q)_i}{(\nu_3)_i}\frac{(-p)_k(-u)_k(\nu_2+\nu_4+u-1)_k}{(\nu_2)_k}$$
$$\times\sum_{m_1=\max(0,\,p+t+j-s)}^{\min(t-i,\,p-k)}\frac{(i-t)_{m_1}(k-p)_{m_1}}{m_1!(\nu_1)_{m_1}}.$$

However, it follows from (14), that if we instead first sum over i, then the sums for which $m_1\leqslant p+t+j-s$ (if there are any such) vanish. Thus we can replace the lower limit in the inner sum by 0, and then compute it using the Chu–Vandermonde formula:

$$\sum_{m_1}\frac{(i-t)_{m_1}(k-p)_{m_1}}{m_1!(\nu_1)_{m_1}}=\frac{(\nu_1)_{p+t-i-k}}{(\nu_1)_{t-i}(\nu_1)_{p-k}}=\frac{(\nu_1)_{p+t}}{(\nu_1)_p(\nu_1)_t}\frac{(1-\nu_1-t)_i(1-\nu_1-p)_k}{(1-\nu_1-p-t)_{i+k}}.$$

This gives the following result, which is equivalent to the Ališauskas–Jucys triple sum formula. As remarked in Ref. 18, the sum may be expressed in terms of generalized hypergeometric functions introduced by Srivastava.[19]

Theorem 4.3: *The Wigner* $9j$*-symbols for* $\mathfrak{su}(1,1)$ *are given by*

$$
\begin{aligned}
W_{pqr}^{tuv}=&(u+v)!(\nu_1)_{p+t}(\nu_2)_p(\nu_2)_u(\nu_3)_q(\nu_3)_t(\nu_4)_{q+r}\\
&\times(|\nu|+2p+2q+r-1)_r(|\nu|+2t+2u+v-1)_v\\
&\times\sum_{i=0}^{t}\sum_{j=0}^{\min(r,\,v)}\sum_{k=0}^{\min(p,\,u)}\frac{1}{i!\,j!\,k!}\,\frac{1}{(1-\nu_4-q-r)_{i+j}(1-\nu_1-p-t)_{i+k}(-u-v)_{j+k}}\\
&\times\frac{(-t)_i(1-\nu_1-t)_i(\nu_3+q)_i(1-\nu_4-q)_i}{(\nu_3)_i}\\
&\times\frac{(-r)_j(-v)_j(1-\nu_3-\nu_4-2q-r)_j(1-\nu_2-\nu_4-2u-v)_j}{(2-|\nu|-2s)_j}\\
&\times\frac{(-p)_k(-u)_k(1-\nu_1-p)_k(\nu_2+\nu_4+u-1)_k}{(\nu_2)_k},
\end{aligned}
$$

where $p+q+r=t+u+v=s$.

This formula might look awkward, but we stress that it is the most compact known expression for Wigner $9j$-symbols. Note that the parameter occurring in the Pochhammer symbol $(\,)_{i+j}$ may be written in two ways:

$$1-\nu_4-q-r=(1-\nu_4-q)+(-r)=(\nu_3+q)+(1-\nu_3-\nu_4-2q-r),$$

as a sum of those occurring in $(\,)_i$ and $(\,)_j$ in the numerator. This is also true for $(\,)_{i+k}$ and $(\,)_{j+k}$, and each of the twelve numerator parameters occur once in the corresponding six sums.

V. GENERAL RECOUPLING COEFFICIENTS

In this section we will extend Theorem 3.1 to arbitrary recoupling coefficients. Thus we consider two decompositions:

$$
\begin{aligned}
\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}&\simeq(\mathcal{A}^{\nu_{\sigma_1}}\otimes\cdots\otimes\mathcal{A}^{\nu_{\sigma_l}})\otimes(\mathcal{A}^{\nu_{\sigma_{l+1}}}\otimes\cdots\otimes\mathcal{A}^{\nu_{\sigma_n}})=B_1\otimes B_2\\
&\simeq(\mathcal{A}^{\nu_{\tau_1}}\otimes\cdots\otimes\mathcal{A}^{\nu_{\tau_{l'}}})\otimes(\mathcal{A}^{\nu_{\tau_{l'+1}}}\otimes\cdots\otimes\mathcal{A}^{\nu_{\tau_n}})=B_1'\otimes B_2',
\end{aligned}
$$

where σ and τ are permutations and $1\leqslant l, l'\leqslant n-1$. We choose arbitrary highest weight vectors,

$$Q_1\in B_1,\quad Q_2\in B_2,\quad Q_1'\in B_1',\quad Q_2'\in B_2',$$

of respective degree,

$$s_1,\quad s_2,\quad s_1',\quad s_2',$$

and weight,

$$-\mu_1,\quad -\mu_2,\quad -\mu_1',\quad -\mu_2'.$$

For a multi-index $(i_1,\ldots,i_n)$ we write

$$i_1^\sigma=(i_{\sigma_1},\ldots,i_{\sigma_l}),\quad i_2^\sigma=(i_{\sigma_{l+1}},\ldots,i_{\sigma_n}),$$

$$i_1^\tau=(i_{\tau_1},\ldots,i_{\tau_{l'}}),\quad i_2^\tau=(i_{\tau_{l'+1}},\ldots,i_{\tau_n}),$$

so that

$$\mu_1=|\nu_1^\sigma|+2s_1,\quad \mu_2=|\nu_2^\sigma|+2s_2,$$

$$\mu_1'=|\nu_1^\tau|+2s_1',\quad \mu_2'=|\nu_2^\tau|+2s_2'.$$

We will study the recoupling coefficient,

$$\langle (Q_1,Q_2)^{\sigma}_{s_3},(Q_1',Q_2')^{\tau}_{s_3'}\rangle,$$

where we may assume that

$$s_1+s_2+s_3=s_1'+s_2'+s_3'=s.$$

In (19) we replace Q_{pqr} and $\tilde{Q}_{tuv}$ by suitable orthogonal systems of highest weight vectors containing $(Q_1,Q_2)^{\sigma}_{s_3}$ and $(Q_1',Q_2')^{\tau}_{s_3'}$. Using (5) instead of (9) we obtain

$$\sum_{\substack{|i_1^{\sigma}|=s_1+k_1,\ |i_2^{\sigma}|=s_2+k_2,\\ |j_1^{\tau}|=s_1'+k_1',\ |j_2^{\tau}|=s_2'+k_2'}} \frac{(\nu)_i(\nu)_j}{i!\,j!}\mathbf{P}_s(i,j)\,TQ_1(i_1^{\sigma})\,TQ_2(i_2^{\sigma})\,\overline{TQ_1'(j_1^{\tau})\,TQ_2'(j_2^{\tau})}$$

$$=\frac{(\mu_1)_{k_1}(\mu_2)_{k_2}(\mu_1')_{k_1'}(\mu_2')_{k_2'}}{k_1!\,k_2!\,k_1'!\,k_2'!\,C_{s_3}^{\mu_1\mu_2}C_{s_3'}^{\mu_1'\mu_2'}}\langle (Q_1,Q_2)^{\sigma}_{s_3},(Q_1',Q_2')^{\tau}_{s_3'}\rangle$$

$$\times P_{s_3}^{(\mu_1,\mu_2)}(k_1,k_2)P_{s_3'}^{(\mu_1',\mu_2')}(k_1',k_2'),$$

where k_1,k_2,k_1',k_2' are arbitrary non-negative integers. By (16), the left hand side equals

$$(-1)^s\frac{(-s_1-s_2-k_1-k_2)_s(-s_1'-s_2'-k_1'-k_2')_s}{(|\nu|+s-1)_s s!}$$

$$\times\sum_m \frac{(|\nu|+s-1)_{|m|}(-s)_{|m|}}{(-s_1-s_2-k_1-k_2)_{|m|}(-s_1'-s_2'-k_1'-k_2')_{|m|}m!(\nu)_m}$$

$$\times\sum_{|i_1^{\sigma}|=s_1+k_1}\frac{(\nu_1^{\sigma})_{i_1^{\sigma}}}{i_1^{\sigma}!}(-i_1^{\sigma})_{m_1^{\sigma}}TQ_1(i_1^{\sigma})\sum_{|i_2^{\sigma}|=s_2+k_2}\frac{(\nu_2^{\sigma})_{i_2^{\sigma}}}{i_2^{\sigma}!}(-i_2^{\sigma})_{m_2^{\sigma}}TQ_2(i_2^{\sigma})$$

$$\times\sum_{|j_1^{\tau}|=s_1'+k_1'}\frac{(\nu_1^{\tau})_{j_1^{\tau}}}{j_1^{\tau}!}(-j_1^{\tau})_{m_1^{\tau}}\overline{TQ_1'(j_1^{\tau})}\sum_{|j_2^{\tau}|=s_2'+k_2'}\frac{(\nu_2^{\tau})_{j_2^{\tau}}}{j_2^{\tau}!}(-j_2^{\tau})_{m_2^{\tau}}\overline{TQ_2'(j_2^{\tau})}.$$

To compute the inner sums we need instead of (22) the following lemma.

Lemma 5.4: If Q is a highest weight vector of degree s in $\mathcal{A}^{\nu_1}\otimes\ldots\otimes\mathcal{A}^{\nu_n}$, then

$$\sum_{|i|=s+k}\frac{(\nu)_i}{i!}(-i)_m\,TQ(i)=(-1)^{|m|}\frac{(|\nu|+s+|m|)_{k+s-|m|}}{(k+s-|m|)!}(\nu)_m\,TQ(m).$$

In Ref. 11 this is derived as a limit case of a more general formula. We will give an independent proof here.

Proof: Let Q be given by (3). Then, by (2),

$$\sum_{|t|=s}c_t z^t=\sum_{|t|=s}c_t(1+z_1)^{t_1}\cdots(1+z_n)^{t_n}$$

$$=\sum_{|t|=s}c_t\sum_{k_1,\ldots,k_n\geqslant 0}\frac{(-t)_k}{k!}(-1)^{|k|}z^k.$$

Applying T on both sides gives

$$TQ(m)=\sum_{|t|=s}c_t\sum_{k_1,\ldots,k_n\geqslant 0}\frac{(-t)_k(-m)_k}{k!(\nu)_k}=\sum_{|t|=s}c_t\frac{(\nu+m)_t}{(\nu)_t}, \tag{23}$$

by the Chu–Vandermonde formula; that is $TQ(m)=(-1)^sTQ(-\nu-m)$. This generalizes expression (11). Thus we have

$$\sum_{|i|=s+k}\frac{(\nu)_i}{i!}(-i)_m\,TQ(i)=\sum_{|i|=s+k}\frac{(\nu)_i}{i!}(-i)_m\sum_{|t|=s}c_t\frac{(\nu+i)_t}{(\nu)_t}$$

$$=\sum_{|t|=s}c_t\sum_{|i|=s+k}\frac{(\nu+t)_i}{i!}(-i)_m.$$

Replacing i by $i+m$ in the inner sum gives

$$\sum_{|i|=s+k}\frac{(\nu+t)_i}{i!}(-i)_m=\sum_{|i|=s+k-|m|}\frac{(\nu+t)_{i+m}}{(i+m)!}(-i-m)_m$$

$$=(-1)^{|m|}(\nu+t)_m\sum_{|i|=s+k-|m|}\frac{(\nu+t+m)_i}{i!}$$

$$=(-1)^{|m|}(\nu+t)_m\frac{(|\nu|+|t|+|m|)_{s+k-|m|}}{(s+k-|m|)!},$$

where the last step is the multivariable Chu–Vandermonde formula. This gives

$$\sum_{|i|=s+k}\frac{(\nu)_i}{i!}(-i)_m\,TQ(i)=(-1)^{|m|}(\nu)_m\frac{(|\nu|+s+|m|)_{s+k-|m|}}{(s+k-|m|)!}\sum_{|t|=s}c_t\frac{(\nu+m)_t}{(\nu)_t},$$

which, again by (23), proves the lemma. □

Applying this lemma gives the following generalization of Theorem 3.1.

Theorem 5.5: *In the notation above, the equality*

$$\frac{1}{k_1!\,k_2!\,k_1'!\,k_2'!\,C_{s_3}^{\mu_1\mu_2}C_{s_3'}^{\mu_1'\mu_2'}}\langle(Q_1,Q_2)_{s_3}^{\sigma},(Q_1',Q_2')_{s_3'}^{\tau}\rangle\,P_{s_3}^{(\mu_1,\mu_2)}(k_1,k_2)P_{s_3'}^{(\mu_1',\mu_2')}(k_1',k_2')$$

$$=(-1)^s\frac{(-s_1-s_2-k_1-k_2)_s(-s_1'-s_2'-k_1'-k_2')_s}{(|\nu|+s-1)_s s!}$$

$$\times\sum_{m_1,\dots,m_n}\frac{(|\nu|+s-1)_{|m|}(-s)_{|m|}(\nu)_m}{(-s_1-s_2-k_1-k_2)_{|m|}(-s_1'-s_2'-k_1'-k_2')_{|m|}m!}$$

$$\times\frac{1}{(k_1+s_1-|m_1^{\sigma}|)!(k_2+s_2-|m_2^{\sigma}|)!(k_1'+s_1'-|m_1^{\tau}|)!(k_2'+s_2'-|m_2^{\tau}|)!}$$

$$\times\frac{1}{(\mu_1)_{|m_1^{\sigma}|-s_1}(\mu_2)_{|m_2^{\sigma}|-s_2}(\mu_1')_{|m_1^{\tau}|-s_1'}(\mu_2')_{|m_2^{\tau}|-s_2'}}$$

$$\times TQ_1(m_1^{\sigma})\,TQ_2(m_2^{\sigma})\,\overline{TQ_1'(m_1^{\tau})\,TQ_2'(m_2^{\tau})},$$

holds, where the sum is over all non-negative integers such that

$$s_1\leqslant|m_1^{\sigma}|\leqslant s_1+k_1,$$
$$s_2\leqslant|m_2^{\sigma}|\leqslant s_2+k_2,$$
$$s_1'\leqslant|m_1^{\tau}|\leqslant s_1'+k_1',$$
$$s_2'\leqslant|m_2^{\tau}|\leqslant s_2'+k_2'.$$

We remark that for Wigner $6j$-symbols, that is for the recoupling coefficient,

$$\langle((1,1)_q,1)_r,(1,(1,1)_t)_u\rangle,$$

then in certain cases such as

$$k_1 = k_2' = 0, \quad k_2 = r, \quad k_1' = u,$$

the sum in the theorem reduces to a single hypergeometric sum, which is in fact a terminating balanced ${}_4F_3(1)$-series. This gives a new proof of Racah's single sum formula for $6j$-symbols.

Lie symmetry and integrability of ordinary differential equations

R. Z. Zhdanov[a)]
Institute of Mathematics, 3 Tereshchenkivska Street, 252004 Kyiv, Ukraine

(Received 21 January 1998; accepted for publication 8 July 1998)

Combining a Lie algebraic approach that is due to Wei and Norman [J. Math. Phys. **4**, 475 (1963)] and the ideas suggested by Drach [Compt. Rend. **168**, 337 (1919)], we have constructed several classes of systems of linear ordinary differential equations that are integrable by quadratures. Their integrability is ensured by integrability of the corresponding stationary cubic Schrödinger, KdV, and Harry–Dym equations. Next, we obtain a hierarchy of integrable reductions of the Dirac equation of an electron moving in the external field. Their integrability is shown to be in correspondence with integrability of the stationary mKdV hierarchy. © *1998 American Institute of Physics.* [S0022-2488(98)04311-4]

I. INTRODUCTION

The object of the study in the present paper is the system of first-order ordinary differential equations (ODEs) of the following structure:

$$\frac{d\psi}{dx}+L(x)\psi=0. \tag{1}$$

Here $\psi(x)$ is an n-component real-valued function column and $L(x)$ is an $n\times n$ matrix function taking values in some real r-dimensional matrix Lie algebra g, namely,

$$L(x)=\sum_{k=1}^{r} f_k(x)Q_k, \tag{2}$$

where Q_k are constant $n\times n$ matrices fulfilling the commutation relations,

$$[Q_i,Q_j]=\sum_{k=1}^{r} C_{ij}^k Q_k. \tag{3}$$

The general Lie algebraic approach to integrating systems of ordinary differential equations having the structure (1) has been developed by Wei and Norman.[1,2] The principal idea of their approach is a proper utilization of the Baker–Campbell–Hausdorff formula in order to represent the general solution of (1) in the form

$$\psi(x)=\exp\left\{\sum_{i=1}^{r} l_i(x)Q_i\right\}\chi, \tag{4}$$

where χ is an arbitrary constant n-component column.

However, with all its elegance and simplicity the approach is still too general and gives a kind of an existence theorem of a special representation of the general solution. The principal problem is that after representing the general solution of (1) in the form (4), we have to integrate a system of *nonlinear* ODEs for unknown functions $l_1(x),\ldots,l_r(x)$. On the other hand, there is the well-known inverse scattering method which reduces a problem of finding special solutions of nonlinear partial differential equations to an auxiliary linear problem (see, e.g., Refs. 3–5). So it is only

a)Electronic mail: rzhdanov@apmat.freenet.kiev.ua

 © 1998 American Institute of Physics

natural to make an attempt of combining both approaches in order to develop a routine for choosing special subclasses of ODEs (1) that can be reduced to solving some nonlinear (stationary) solitonic equations. Namely, we pick out specific subclasses of equations of the form (1) such that their integrability by quadratures is ensured by integrability of the corresponding stationary solitonic equations. To this end we consider systems of ODEs of the following special form:

$$\mathcal{L}\psi \equiv \left(\frac{d}{dx} + \lambda F(x) + G(x) \right) \psi = 0, \tag{5}$$

where $F(x)$, $G(x)$ are matrix functions taking values in a real r-dimensional matrix Lie algebra g. The parameter λ may be thought of as an auxiliary independent variable, i.e., $\psi = \psi(x,\lambda)$. Note that the functions $F(x)$, $G(x)$ are independent of λ.

Systems of ODEs (1) are of the utmost importance for the separation of variables in systems of partial differential equations (say, in the Dirac equation of an electron). This is due to the fact that after separating variables in a given system of partial differential equations, we have to integrate separated equations that are exactly of the form (1).

Since we deal with more specific models as compared with ones considered by Wei and Norman, it is possible to input more information into the ansatz (4). To this end we make use of its ''infinitesimal analog'' in the form of the Lie symmetry of the system of ODEs (5), whose coefficients are required to be polynomials in λ. The last restriction is crucial and provides a link of the system of ODEs (5) to stationary solitonic equations whose integrability is ensured by the inverse scattering method. As we learned recently, a similar idea was used about 80 years ago by Drach[6] in order to integrate by quadratures the one-dimensional stationary Schrödinger equation,

$$\psi'' - (\lambda + V(x))\psi = 0.$$

He had made an ansatz for a solution of the above equation by a proper fixing of its dependence on λ. As a result, he discovered a remarkable class of integrable stationary Schrödinger equations. Namely, it had been proved that, provided $V(x)$ is a solution of the nonlinear ODE called now the equation of the stationary KdV hierarchy, the stationary Schrödinger equation is integrable by quadratures. Moreover, Drach, in fact, suggested the method for integrating the stationary KdV hierarchy and discovered in this way the basics of the theory of the finite-gap solutions of the KdV equation. As shown in Ref. 7 the results of Ref. 6 can be obtained with the use of Lie symmetry of the stationary Schrödinger equation. One of the aims of the present paper is developing a technique that is a proper synthesis of the methods by Drach and Wei and Norman in order to reduce the problem of integrability by quadratures of systems of ODEs (5) to integrable solitonic hierarchies. A principal tool to be used in this respect is the Lie symmetry of (5).

The paper is organized as follows. The second section is devoted to a description of our approach to integrating systems of ODEs of the form (5). The approach is based on the utilization of symmetry properties of these systems within the class of Lie symmetries that are spanned by the basis elements of the Lie algebra g, with coefficients being polynomials in parameter λ. The problem of constructing such Lie symmetries is shown to be reduced to integrating some systems of nonlinear ODEs. Remarkably, for many interesting cases these ODEs are nothing more than equations of the stationary solitonic hierarchies (which is not unexpected in view of what was said above). Utilizing this approach we give in Sec. III, a systematic treatment of the case when the Lie algebra g is three dimensional. In this way, we find a number of linear systems of ODEs integrable in quadratures due to integrability of the stationary cubic Schrödinger, KdV, and Harry–Dym equations. Section IV is devoted to an analysis of a reduction of the Dirac equation for a particle moving in a specific electric field that is integrable with the help of the suggested procedure. It occurs that the reduced system of ODEs is integrable provided the nonzero component of the electromagnetic field satisfy one of the equations of the stationary mKdV hierarchy. The last section contains a brief discussion of the results of the paper.

II. THE GENERAL SCHEME

We are reminded that a Lie vector field,

$$X=\xi(x,\lambda)\,\frac{d}{dx}+\eta(x,\lambda),$$

where ξ is a smooth scalar function and η is an $n\times n$ matrix whose entries are smooth functions of x, is called the (Lie) symmetry of system (5) if X transforms the set of its solutions into itself, i.e.,

$$\mathcal{L}\psi=0\Rightarrow\mathcal{L}X\psi=0.$$

The above relation can be represented in the form[8]

$$[\mathcal{L},X]=R(x,\lambda)\mathcal{L}, \tag{6}$$

where R is some $n\times n$ matrix function. This operator equality is to be understood in the following way: the operators on the left- and right-hand sides should give the same result when acting on any continuously differentiable function.

Making use of the formula (6) it is easy to become convinced of the fact that if X is a symmetry of the system of ODEs (5), then $X+\Xi(x,\lambda)\mathcal{L}$ with an arbitrary smooth function Ξ is a symmetry as well. Consequently, without a loss of generality we can restrict our considerations to symmetries of the form

$$X=\eta(x,\lambda). \tag{7}$$

Importantly, operator (7) is the symmetry of the system (5) if and only if in (6) $R=0$, i.e.,

$$[\mathcal{L},X]=0 \tag{8}$$

(this is proved by direct computation).

The key idea of our approach is to fix *a priori* dependence of a symmetry on the parameter λ and to consider the case when η is a polynomial in λ of the order N with matrix coefficients.

So a Lie symmetry of system (5) is looked for as a polynomial in λ which coefficients are linear combinations of the basis elements $Q_1,\ldots,Q_r$ of the Lie algebra g,

$$X=\sum_{l=1}^{N}\sum_{k=1}^{r}s_{kl}(x)Q_k\lambda^l, \tag{9}$$

where $s_{kl}(x)$ are sufficiently smooth functions. From the invariance criterion (8) we get the following relation:

$$\sum_{l=1}^{N}\sum_{k=1}^{r}s'_{kl}Q_k\lambda^l+\sum_{l=1}^{N}\left\{\sum_{i,j,k=1}^{r}(f_is_{jl}C_{ij}^kQ_k+\lambda g_is_{jl}C_{ij}^kQ_k)\right\}\lambda^l=0.$$

Splitting it with respect to the powers of λ yields

$$\lambda^{N+1}:\quad\sum_{i,j=1}^{r}g_is_{jN}C_{ij}^k=0, \tag{10}$$

$$\lambda^{l}:\quad s'_{kl}+\sum_{i,j=1}^{r}(f_is_{jl}+g_is_{jl-1})C_{ij}^k=0, \tag{11}$$

$$\lambda^{0}:\quad s'_{k0}+\sum_{i,j=1}^{r}f_is_{j0}C_{ij}^k=0, \tag{12}$$

where $k=1,...,r,\ l=1,...,N$.

Equations (10) are purely algebraic. Solving these, we obtain recursively from Eqs. (11) the remaining coefficients of the symmetry operator X. Inserting the obtained results into (12), we get a system of relations for functions f_i, g_i that form a system of nonlinear ODEs. The structure of this system is determined both by the form of the initial system of ODEs and by the form of the commutation relations of the Lie algebra g.

The next step depends on the kind of the problem we are dealing with. If the problem is to check whether a given system of ODEs is integrable within the framework of our approach, then the only thing to be done is to verify whether the obtained system of ODEs is identically satisfied by the coefficients of system (5). If, on the contrary, we have to solve a classification problem, i.e., the one of describing functions f_i, g_i such that system (5) is integrable, then we have to find a (general or particular) solution of the mentioned system of nonlinear ODEs. What makes the whole procedure efficient is the fact that the nonlinear ODEs obtained are often the well-studied stationary solitonic equations.

Now with a Lie symmetry of system of ODEs (5) in hand, we can integrate it with the use of the following procedure. We diagonalize the operator X with the help of a properly chosen linear transformation of the dependent variables. The initial system of ODEs (5) being transformed in this way simplifies substantially and can be integrated by quadratures (at least for the low-dimensional Lie algebras).

The above procedure proves to be efficient, not only for integrating specific ODEs, but also for classification of systems of ODEs integrable by quadratures.

III. INTEGRABLE ODEs

We apply the above described method to classify integrable systems of ODEs of the form

$$\mathcal{L}\psi \equiv \left(\frac{d}{dx} + \sum_{a=1}^{3} (f_a(x) + \lambda g_a(x)) Q_a \right) \psi = 0, \tag{13}$$

where Q_1, Q_2, Q_3 are basis elements of a real three-dimensional Lie algebra g. It is not difficult to show that if a three-dimensional Lie algebra g is a direct sum of the lower-dimensional Lie algebras, then the corresponding system of ODEs (13) is integrated by quadratures. According to Ref. 9, the list of real inequivalent Lie algebras of the dimension three that are not direct sums of lower-dimensional Lie algebras is exhausted by the following algebras:

$$A_1: [Q_2, Q_3] = 0,$$

$$A_2: [Q_1, Q_3] = Q_1, \quad [Q_2, Q_3] = Q_1 + Q_2,$$

$$A_3: [Q_1, Q_3] = Q_1, \quad [Q_2, Q_3] = Q_2,$$

$$A_4: [Q_1, Q_3] = Q_1, \quad [Q_2, Q_3] = -Q_2,$$

$$A_5: [Q_1, Q_3] = Q_1, \quad [Q_2, Q_3] = aQ_2 \quad (0 < |a| < 1),$$

$$A_6: [Q_1, Q_3] = -Q_2, \quad [Q_2, Q_3] = Q_1,$$

$$A_7: [Q_1, Q_3] = aQ_1 - Q_2, \quad [Q_2, Q_3] = Q_1 + aQ_2 \quad (a > 0),$$

$$A_8: [Q_1, Q_2] = -Q_3, \quad [Q_1, Q_3] = -Q_2, \quad [Q_2, Q_3] = Q_1,$$

$$A_9: [Q_1, Q_2] = Q_3, \quad [Q_2, Q_3] = Q_1, \quad [Q_3, Q_1] = Q_2,$$

the remaining commutation relations being zero.

For the algebras $A_1 - A_7$ system of ODEs (13) is integrated by quadratures with arbitrary f_a, g_a. This is due to the fact that making a transformation,

$$\psi \to \tilde{\psi} = \exp\{F(x)Q_1 + G(x)Q_2\},$$

with properly chosen functions F,G, we can always reduce (13) to the system of ODEs of the form

$$\frac{d\tilde{\psi}}{dx}+f(x,\lambda)Q_3\tilde{\psi}=0,$$

whose general solution is given by the quadrature

$$\tilde{\psi}=\exp\left\{-Q_3\int f(x,\lambda)dx\right\}\chi,$$

where χ is an arbitrary constant column.

To complete the classification of systems of ODEs (13) integrable by quadratures within the framework of the above suggested approach, we have to consider the two remaining algebras $A_8=so(2,1)$ and $A_9=so(3)$. Both algebras lead to nontrivial results, even if we restrict our considerations to Lie symmetries that are second-order polynomials in λ.

We consider first the case when coefficients of system (13) take values in the $so(2,1)$ algebra. Using a sequence of transformations,

$$\psi\to\tilde{\psi}=\exp\{\alpha(x)Q\}, \tag{14}$$

where Q is one of the operators Q_1,Q_2,Q_3, together with a transformation of the independent variable,

$$x\to\tilde{x}=f(x),$$

we can reduce (13) to the form $\tilde{\mathcal{L}}\tilde{\psi}=0$ with

$$\tilde{\mathcal{L}}=\begin{cases}\dfrac{d}{dx}+V_2(x)Q_2+V_3(x)Q_3+\lambda Q_1, & \text{if } \Delta>0,\\ \dfrac{d}{dx}+V_1(x)Q_1+V_2(x)Q_2+\lambda Q_3, & \text{if } \Delta<0,\\ \dfrac{d}{dx}+V_1(x)Q_1+V_2(x)(Q_2+Q_3)+\lambda(Q_2-Q_3), & \text{if } \Delta=0.\end{cases}$$

Here Δ stands for $V_1^2+V_2^2-V_3^2$.

We restrict our analysis of symmetries of the above enumerated systems to the class of the second-order polynomials in λ. This means that symmetries of the systems of ODEs in question are looked for in the form (9) under $N=2$. Omitting the details of calculations we present below the explicit forms of symmetries and corresponding nonlinear ODEs for the ''potentials'' $V_1(x)$, $V_2(x)$.

Case 1. $\tilde{\mathcal{L}}=d/dx+V_2(x)Q_2+V_3(x)Q_3+\lambda Q_1$.

In this case the symmetry X reads as

$$X=\lambda^2C_1Q_3+\lambda C_2Q_1+\lambda C_1(V_2(x)Q_2+V_3(x)Q_3)+(\tfrac{1}{2}C_1(V_2^2-V_3^2)+C_3)Q_1$$
$$+(C_1V_3'+C_2V_2)Q_2+(C_1V_2'+C_2V_3)Q_3,$$

and what is more, the functions V_2, V_3 satisfy the hyperbolic stationary cubic Schrödinger equation,

$$C_1V_2''+C_2V_3'+(\tfrac{1}{2}C_1(V_2^2-V_3^2)+C_3)V_2=0,$$

$$C_1V_3''+C_2V_2'+(\tfrac{1}{2}C_1(V_2^2-V_3^2)+C_3)V_3=0.$$

As usual, when talking about stationary solitonic equations, we mean the ODEs obtained from standard $(1+1)$-dimensional solitonic equations via the ansatz $u(t,x)=u(x+Ct)$, $C=\text{const}$.

Case 2. $\tilde{\mathcal{L}}=d/dx+V_1(x)Q_1+V_2(x)Q_2+\lambda Q_3$.

In this case the operator X has the form

$$X=\lambda^2 C_1 Q_1+\lambda C_1 V_1 Q_1+\lambda C_1 V_2(x) Q_2+\lambda C_2 Q_3+(-C_1 V_2'+C_2 V_1) Q_1$$
$$+(C_1 V_1'+C_2 V_2) Q_2+(\tfrac{1}{2} C_1(V_1^2+V_2^2)+C_3) Q_3,$$

and what is more, the functions V_1, V_2 satisfy the stationary cubic Schrödinger equation,

$$C_1 V_1''+C_2 V_2'-(\tfrac{1}{2} C_1(V_1^2+V_2^2)+C_3) V_1=0,$$

$$C_1 V_2''-C_2 V_1'-(\tfrac{1}{2} C_1(V_1^2+V_2^2)+C_3) V_2=0.$$

Case 3. $\widetilde{\mathcal{L}}=d/dx+V_1(x) Q_1+V_2(x)(Q_2+Q_3)+\lambda(Q_2-Q_3)$.

Provided $V_2=0$, the corresponding system of ODEs is integrable by quadratures with an arbitrary V_1. If $V_2\neq 0$, then we can transform the operator $\widetilde{\mathcal{L}}$ to obtain

$$\frac{d}{dx}+V_1(x)(Q_2+Q_3)+V_2(x)(Q_2-Q_3)+\lambda(Q_2-Q_3).$$

We have not succeeded in constructing the general form of V_1, V_2 and therefore restrict our considerations to the particular cases (i) $V_1=\text{const}$, (ii) $V_2=0$.

Subcase 3.1. $V_1(x)=\alpha\equiv\text{const}$.

The Lie symmetry for this case reads as

$$X=\lambda^2(Q_2-Q_3) C_1+\lambda(\alpha C_1+C_2+\tfrac{1}{2} C_1 V_2) Q_2+\lambda(\alpha C_1-C_2-\tfrac{1}{2} C_1 V_2) Q_3$$
$$+\frac{1}{2} C_1 V_2' Q_1+\left(\alpha C_2+\left(C_2-\frac{1}{2}\alpha C_1\right) V_2-\frac{1}{2} C_1 V_2^2+\frac{1}{2\alpha} C_1 V_2''\right) Q_2$$
$$+\left(\alpha C_2-\left(C_2+\frac{1}{2}\alpha C_1\right) V_2+\frac{1}{2} C_1 V_2^2+\frac{1}{2\alpha} C_1 V_2''\right) Q_3,$$

the function $V_1(x)$ being a solution of the stationary KdV equation,

$$\frac{1}{2\alpha} C_1 V_2'''-3 C_1 V_2' V_2+2 C_2 V_2'=0.$$

Subcase 3.2. $V_2(x)=0$.

The Lie symmetry for this case is of the form

$$X=\lambda^2 C_1 V_1^{-1/2}(Q_2-Q_3)+\tfrac{1}{2}\lambda C_1 V_1' V_1^{-3/2} Q_1+\lambda(C_2 x+C_3+C_1 V_1^{1/2}) Q_2$$
$$-\lambda(C_2 x+C_3-C_1 V_1^{1/2}) Q_3+C_2 Q_1+\{(C_2 x+C_3) V_1+\tfrac{1}{8} C_1(2 V_1'' V_1^{-3/2}-3(V_1')^2 V_1^{-5/2})\} Q_2$$
$$+\{(C_2 x+C_3) V_1+\tfrac{1}{8} C_1(2 V_1'' V_1^{-3/2}-3(V_1')^2 V_1^{-5/2})\} Q_3,$$

the function $V_1(x)$ satisfying the nonlinear ODE,

$$\tfrac{1}{2} C_1 V_1''' V_1^{-3/2}-\tfrac{9}{4} C_1 V_1'' V_1' V_1^{-5/2}+\tfrac{15}{8} C_1(V_1')^3 V_1^{-7/2}+2(C_2 x+C_3) V_1'+4 C_2 V_1=0.$$

With $C_2=0$, the above equation is nothing other than the stationary Harry Dym equation,

$$-C_1(V_1^{-1/2})'''+2 C_3 V_1'=0,$$

which is known to be integrable by quadratures and, furthermore, under $C_3=0$ possesses solutions in terms of elementary functions,

$$V_1(x)=(\alpha_1 x^2+\alpha_2 x+\alpha_3)^{-2},$$

where α_1, α_2, α_3 are arbitrary real constants.

Now we turn to the case of the algebra $A_9=so(3)$ and consider a system of ODEs (13), where Q_1, Q_2, Q_3 are constant matrices satisfying the commutation relations

$$[Q_a,Q_b]=Q_c, \quad (a,b,c)=\text{cycle}(1,2,3).$$

Using a sequence of transformations (14), where Q is one of the operators Q_1, Q_2, Q_3, we can substantially simplify system (13) and reduce it to the following equivalent form:

$$\mathcal{L}\psi\equiv\left(\frac{d}{dx}+V_1(x)Q_1+V_2(x)Q_2+\lambda Q_3\right)\psi=0. \tag{15}$$

As above, a Lie symmetry X of system (15) is looked for as a second-order polynomial in λ with matrix coefficients. Inserting X into the invariance criterion $[\mathcal{L},X]=0$ yields a system of determining equations for its coefficients. Having solved these, we obtain the explicit form of the Lie symmetry admitted by a system of ODEs (15),

$$X=\lambda^2C_1Q_3+\lambda C_1(V_1Q_1+V_2Q_2)+\lambda C_2Q_3+(-C_1V_2'+C_2V_1)Q_1$$
$$+(C_1V_1'+C_2V_2)Q_2+\left(\frac{1}{2}(V_1^2+V_2^2)+C_3\right)Q_3,$$

where $V_1(x)$, $V_2(x)$ are solutions of the stationary cubic Schrödinger equation,

$$C_1V_1''-C_2V_2'-\left(\frac{1}{2}C_1(V_1^2+V_2^2)+C_3\right)V_1=0,$$

$$C_1V_2''+C_2V_1'-\left(\frac{1}{2}C_1(V_1^2+V_2^2)+C_3\right)V_2=0,$$

and C_1, C_2, C_3 are arbitrary constants.

In what follows, we will briefly discuss a method for integrating systems of ODEs (13), (15) based on their symmetry properties. Generally speaking, information about a Lie symmetry admitted by a system of ODEs is not sufficient to provide its integrability by quadratures within the Lie group approach (for more details see, e.g., Refs. 10–13). However, due to the remarkable algebraic structure of the ODEs under study, knowledge of a Lie symmetry makes it possible to construct their general solutions by quadratures. Namely, the following assertions hold true.

Lemma 1: Let the system of ODEs,

$$\mathcal{L}\psi\equiv\left(\frac{d}{dx}+f_a(x)Q_a\right)\psi=0, \tag{16}$$

where Q_1, Q_2, Q_3 are constant matrices forming a basis of the Lie algebra so(2,1), admit a Lie symmetry,

$$X=\sum_{a=1}^{3}g_a(x)Q_a. \tag{17}$$

Then it is integrable by quadratures.

Lemma 2: Let the system of ODEs (16), where Q_1, Q_2, Q_3 are constant matrices forming a basis of the Lie algebra so(3), admit a Lie symmetry (17) Then it is integrable by quadratures.

We adduce the proof of Lemma 2 (the first lemma is proved in a similar way). Making a change of dependent variables,

$$\psi\to\tilde{\psi}=\mathcal{V}(x)\psi, \quad \mathcal{V}(x)=\exp\left\{\sum_{a=1}^{3}h_a(x)Q_a\right\},$$

we can always transform the operator X to become

$$\tilde{X}=\mathcal{V}^{-1}X\mathcal{V}=g(x)Q_1, \quad g(x)\neq 0,$$

and what is more, this transformation preserves the structure of system (16). The invariance criterion $[\tilde{\mathcal{L}},\tilde{X}]=0$, where

$$\tilde{\mathcal{L}}=\mathcal{V}^{-1}\mathcal{L}\mathcal{V}=\frac{d}{dx}+\sum_{a=1}^{3}\tilde{f}_a(x)Q_a,$$

implies that

$$g(\tilde{f}_2Q_3-\tilde{f}_3Q_2)-g'Q_1=0.$$

As the matrices Q_1, Q_2, Q_3 are linearly independent, hence it follows that

$$\tilde{f}_2=0, \quad \tilde{f}_3=0, \quad g=\text{const}.$$

Consequently, the transformed system of ODEs necessarily takes the form

$$\left(\frac{d}{dx}+\tilde{f}_1Q_1\right)\psi=0,$$

and is evidently integrable by quadratures. Lemma 2 is proved.

Consequently, all the systems of linear ODEs considered in Sec. III possessing nontrivial symmetries of the form (9) can be integrated by quadratures with the use of the algebraic procedure described above. This is due to the well-known fact that the stationary solitonic equations arising as the invariance conditions are integrable by quadratures (see, e.g., Refs. 14, 15).

IV. THE HIERARCHY OF INTEGRABLE REDUCTIONS OF THE DIRAC EQUATION

The technique developed above applies straightforwardly to systems of ODEs having complex-valued coefficients. In this section we use this technique for obtaining integrable reductions of the Dirac equation of an electron,

$$i\sum_{\mu=0}^{3}\gamma_\mu\psi_{x_\mu}-\left(e\sum_{\mu=0}^{3}\gamma_\mu A^\mu+m\right)\psi=0, \tag{18}$$

moving in the electric field,

$$A_0=A_0(x_3), \quad A_1=A_2=A_3=0.$$

In the formulas (18) γ_μ are 4×4 Dirac matrices, $\psi=\psi(x_0,x_1,x_2,x_3)$ is a four-component complex-valued function, and e, m are constants.

The form of the vector-potential A_μ imply the following ansatz for the spinor field $\psi(x)$:

$$\psi(x)=\varphi(x_3).$$

Inserting this expression into the Dirac equation (18) yields a system of ordinary differential equations for the four-component function $\varphi(x_3)$,

$$\varphi'-(ie\gamma_3\gamma_0A_0-im\gamma_3)\varphi=0. \tag{19}$$

Denoting

$$x=2x_3, \quad V(x)=eA_0(x_3),$$

$$J_1=\frac{1}{2}\gamma_0 \quad J_2=\frac{i}{2}\gamma_3, \quad J_3=\frac{i}{2}\gamma_3\gamma_0,$$

we rewrite (19) in the following form:

$$\mathcal{L}\varphi\equiv(D_x-V(x)J_3-mJ_2)\varphi=0,\quad D_x=\frac{d}{dx}. \tag{20}$$

Note that the 4×4 matrices J_1, J_2, J_3 satisfy the commutation relations of the Lie algebra $so(3)$. Consequently, we can apply the routine developed in Sec. I in order to construct a Lie symmetry admitted by (20).

First we consider the case when coefficients of a Lie symmetry Q are third-order polynomials in m, and choose

$$X=\sum_{k=1}^{3}(a_k(x)+b_k(x)m+c_k(x)m^2+d_k(x)m^3)J_k, \tag{21}$$

where a_k, b_k, c_k, d_k are some smooth complex-valued functions.

Inserting the expression for X into the invariance criterion $[\mathcal{L},X]=0$ and splitting with respect to the powers of m and then with respect to linearly independent matrices J_1, J_2, J_3, we get the system of determining equations for the functions a_k, b_k, c_k, d_k,

$$d_1=0,\quad d_3=0,$$

$$d_2'-Vd_1=0,\quad d_1'+Vd_2-c_3=0,\quad d_3'-c_1=0,$$

$$c_2'-Vc_1=0,\quad c_1'+Vc_2-b_3=0,\quad d_3'-b_1=0,$$

$$b_2'-Vb_1=0,\quad b_1'+Vb_2-a_3=0,\quad c_3'-a_1=0,$$

$$a_2'-Va_1=0,\quad a_1'+Va_2=0,\quad a_3'=0.$$

Integrating the above system of ODEs yields

$$d_1=0,\quad d_2=C_1,\quad d_3=0,$$

$$c_1=0,\quad c_2=C_2,\quad c_3=C_1V,$$

$$b_1=C_1V',\quad b_2=\frac{1}{2}C_1V^2+C_3,\quad b_3=C_2V,$$

$$a_1=C_2V',\quad a_2=\frac{1}{2}C_2V^2+C_4,\quad a_3=C_1\left(V''+\frac{1}{2}V^3\right)+C_3V,$$

where C_1, C_2, C_3, C_4 are arbitrary constants and, furthermore, the potential $V(x)$ has to satisfy the following nonlinear ODEs:

$$C_1(V'''+\tfrac{3}{2}V^2V')+C_3V'=0,\quad C_2(V''+\tfrac{1}{2}V^3)+C_4V=0.$$

Thus, we have established that if the function $V(x)$ is a solution of the stationary mKdV equation,

$$C_1(V'''+\tfrac{3}{2}V^2V')+C_3V'=0, \tag{22}$$

then the initial system of ODEs (20) admits the Lie symmetry,

$$Q=C_1J_2m^3+C_1VJ_3m^2+C_1V'J_1m+(\tfrac{1}{2}C_1V^2+C_3)J_2m+(C_1(V''+\tfrac{1}{2}V^3)+C_3V)J_3.$$

This symmetry solves the problem of the integrability of the system of ODEs (20) by quadratures due to Lemma 2. Hence, we conclude that provided $V(x)$ is a solution of the stationary mKdV equation (22), then the system of ODEs (20) is integrable by quadratures.

Now we turn to the case when a Lie symmetry is looked for as a polynomial in m of an arbitrary order n,

$$X=\sum_{k=0}^{n}\sum_{a=1}^{3} f_a^k(x)J_a m^{n-k}.$$

The invariance criterion $[\mathcal{L},X]=0$ yields the following system of determining equations for the coefficients of the operator Q:

$$f_1^0=0, \quad f_3^0=0,$$

$$(f_3^k)'-f_1^{k+1}=0, \quad (f_1^k)'-Vf_2^k=0,$$

$$(f_2^k)'+Vf_1^k-f_3^{k+1}=0, \quad k=0,...,n-1,$$

$$(f_3^n)'=0, \quad (f_1^n)'-Vf_2^n=0, \quad (f_2^n)'+Vf_1^n=0.$$

We have obtained the two classes of solutions of the above system of ODEs that are given below

(1) $n=2N+1, \quad N\in\mathbf{N}$,

$$f_1^0=0, \quad f_2^0=1, \quad f_3^0=0,$$

$$f_1^{2k+1}=f_2^{2k+1}=0, \quad f_3^{2k+1}=R_k, \quad k=1,...,N,$$

$$f_1^{2k+2}=D_xR_k, \quad f_1^{2k+2}=(V-D_x^{-1}V')R_k,$$

$$f_3^{2k+2}=0, \quad k=0,...,N-1,$$

and the equation

$$D_xR_N=0, \tag{23}$$

holds.

(2) $n=2N+2, \quad N\in\mathbf{N}$

$$f_1^0=0, \quad f_2^0=1, \quad f_3^0=0,$$

$$f_1^{2k+1}=f_2^{2k+1}=0, \quad f_3^{2k+1}=R_k, \quad k=1,...,N,$$

$$f_1^{2k+2}=D_xR_k, \quad f_2^{2k+2}=(V-D_x^{-1}V')R_k,$$

$$f_3^{2k+2}=0, \quad k=0,...,N,$$

and the equation

$$R_{N+1}=0,$$

holds.

In the above formulas we make use of the following notations:

$$R_k=\sum_{j=0}^{k} C_j(D_x^2+V^2-VD_x^{-1}V')^jV, \quad k=0,...,N+1,$$

where $C_0,\ldots,C_{N+1}$ are arbitrary real constants and D_x^{-1} is the inverse of D_x.

A reader familiar with the soliton theory will immediately recognize the operator $\mathcal{X}=D_x^2+V^2-VD_x^{-1}V_x$ as the recursion operator for the mKdV equation,[5,11]

$$V_t+V_{xxx}+\frac{3}{2}V^2V_x=0.$$

Acting repeatedly with the operator $\mathcal{X}$ on the trivial conserved density $I_0=V$, we get the whole set of conserved densities of the mKdV equation. Next, the operator,

$$\mathcal{Y}=D_x\mathcal{X}D_x^{-1}\equiv D_x^2+V^2+V_xD_x^{-1}V$$

is the second recursion operator for the mKdV equation. Its repeated action on the trivial Lie symmetry $S_0=V_x$ yields the whole hierarchy of the higher symmetries of the mKdV equation. Hence, it follows, in particular, that condition (23) is rewritten in the form

$$\sum_{k=0}^{N}C_kS_k=0,\quad S_k=\mathcal{Y}^kV'. \tag{24}$$

The above equation is nothing other than the higher stationary mKdV equation. Provided $N=1$, it reduces to the standard stationary mKdV equation (22).

Hence, due to Lemma 2, the validity of the following assertion follows.

Theorem 1: *Let the function $V(x)$ satisfy the higher stationary mKdV equation (24) with some fixed N and $C_0,\ldots,C_N$. Then, the system of ODEs (20) is integrable by quadratures.*

It is common knowledge that the stationary mKdV hierarchy is reduced to the stationary KdV hierarchy with the help of the Miura transformation (see, e.g., Refs. 4, 5). Furthermore, the latter are integrated in terms of θ functions.[6,15] Consequently, the system of ODEs (19) is also integrable by quadratures, thus giving rise to exact solutions of the initial Dirac equation (18).

V. CONCLUSIONS

Here we have demonstrated how one can make use of powerful ideas and methods developed in the theory of solitons in order to integrate systems of ODEs of the form (5). Here we have to give its due to the paper by Drach,[6] where almost all the principal ideas necessary for consistent implementation of the technique described in Sec. II can be found (though Drach did not use Lie symmetries explicitly).

One more important remark is that the Lie symmetries of the reduced Dirac equation (19) constructed in Sec. IV have nothing to do with the maximal symmetry group $C(1,3)\otimes U(1)$ admitted by the initial Dirac equation. This means that they cannot be obtained by an appropriate reduction of the group $C(1,3)\otimes U(1)$. These symmetries correspond to conditional symmetry of the Dirac equation (for more details about conditional symmetries of linear and nonlinear Dirac equations, see Ref. 16). We believe that there exist numerous reductions of the Dirac equations that could be integrated in the way described in Sec. IV, thus giving principally new exact solutions to (18) with specific electromagnetic fields. A further possible application of the results of the paper is integrating systems of ODEs obtained after separating variables in the Dirac equation (18).

The next remark is concerned with the restriction of our considerations to the case of three-dimensional Lie algebras. This restriction is not at all essential, and it is quite clear how to include into consideration the higher-dimensional Lie algebras. The peculiarity of the three-dimensional case is that all the systems of ODEs of the form (13) possessing a Lie symmetry (7) are integrable by quadratures. For the case of a higher-dimensional Lie algebra, this might not be the case.

ACKNOWLEDGMENTS

It is a pleasure for the author to thank R. Conte, who has drawn the author's attention to the paper by Jules Drach.[6] Special thanks are addressed to A. Nikitin for stimulating discussions of the results presented in the paper. The author is supported by the Ukrainian DFFD Foundation (Project No. 1.4/356).
