As shown in the previous section, the KdV equation can be linearized into the ordinary linear differential equation (17). In this section we will derive explicit solutions of this equation:

$$\frac{d}{dz}\,g^{(n)}(z,k)+ikg^{(n)}(z,k)=(n-1)S(k)g^{(n)}(z,k). \tag{20}$$

Equation (20) is an ordinary linear first-order differential equation. The general solution of Eq. (20) is given by

$$g^{(n)}(z,k)=C_1e^{M(k,n)z};\quad M(k,n)=(n-1)S(k)-ik. \tag{21}$$

To verify the validity of the ansatz (6), it is convenient to define $S(k)$ in the complex plane. This enables us to solve Eq. (20) using the Green's function technique. If we formulate solutions of Eq. (20) using a Green's function technique, we can find a relationship between the linearization method described in this paper and an inverse scattering method. In order to find a suitable Green's function we first solve the following problem:

$$\frac{d}{d\hat{z}}\,\mathcal{G}(\hat{z},k)+ik\mathcal{G}(\hat{z},k)=\delta(\hat{z}),\quad \hat{z}=z-z', \tag{22}$$

Eq. (22) can be solved easily by applying the following inverse Fourier transform:

$$\tilde{\mathcal{G}}(k',k)=\int_{-\infty}^{\infty}\mathcal{G}(\hat{z},k)e^{-ik'\hat{z}}d\hat{z}. \tag{23}$$

If the Fourier transform (23) is substituted into Eq. (22) we obtain the following result:

$$ik'\tilde{\mathscr{K}}(k',k)+ik.\tilde{\mathscr{K}}(k',k)=1. \tag{24}$$

From Eq. (24), it follows that the solution of $\tilde{\mathscr{K}}(k',k)$ is given by

$$\tilde{\mathscr{K}}(k',k)=\frac{1}{i(k+k')}. \tag{25}$$

By applying the inverse transformation of Eq. (23) we can solve the Green's function $\mathscr{G}(\hat{z},k)$:

$$\mathscr{G}(\hat{z},k)=\lim_{\epsilon\to 0}\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{e^{ik'\hat{z}}}{k+k'+i\epsilon}\,dk'. \tag{26}$$

Once the Green's function is solved, we can formulate the general solution of Eq. (20) in the form of an integral equation:

$$g^{(n)}(z,k)=\lim_{\epsilon\to 0}\frac{(n-1)}{2\pi i}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{e^{ik'[z-z']}}{k+k'+i\epsilon}S(k)g^{(n)}(z',k)dz'dk', \quad n\neq 1. \tag{27}$$

From the function $g^{(n)}(z,k)$ given in Eq. (27), we can solve, using Eq. (16) and the Fourier transformation given in Eq. (8), the function $f^{(n)}(x,t)$:

$$f^{(n)}=(x,t)=\lim_{\epsilon\to 0}\frac{(n-1)}{(2\pi)^2 i}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{\delta(k-k')}{k+k'+i\epsilon}S(k)g^{(n)}(z,k')dkdk', \quad n\neq 1. \tag{28}$$

Before formulating solutions of the KdV equation, we first have to assure that a kernel $G(x-x'|t-t')$ indeed exists. If we compute the left-hand-side of Eq. (6) using the representation presented in Eq. (28) of the solutions $f^{(n)}(x,t)$, we obtain

$$\begin{aligned}6f_x^{(n)}(x,t)f^{(m)}(x,t)=&-\lim_{\epsilon\to 0}\frac{(n-1)(m-1)}{(2\pi)^4}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\\&\times\frac{6ik'S(k)S(k'')}{k+k'+i\epsilon}\frac{\delta(k-k')\delta(k''-k''')}{k''+k'''+i\epsilon}g^{(n)}(z,k')\\&\times g^{(m)}(z,k''')dkdk'dk''dk''', \quad n,m\neq 1.\end{aligned} \tag{29}$$

The kernel $G(x-x'|t-t')$ can be represented in the complex plane according to the following Cauchy formula:

$$G(x-x'|t-t')=\lim_{\epsilon\to 0}\frac{1}{(2\pi)^2 i}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{k'^2e^{ik'[z-z']}}{k+k'+i\epsilon}S(k')dk'dk. \tag{30}$$

In Eq. (30), it is used that $S(k)=k^2\tilde{G}(k)$. The expression obtained in Eq. (29) is, according to Eq. (6), equal to:

$$\begin{aligned}&\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}G(x-x'|t-t')f^{(n+m)}(x',t')dx'dt'\\&=-\lim_{\epsilon\to 0}\frac{[n+m-1]}{(2\pi)^3}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{k'^2S(k')S(k'')}{k+k'+i\epsilon}\frac{\delta(k''-k''')\delta(k'''-k')}{k''+k'''+i\epsilon}\\&\times g^{(n+m)}(z,k''')dkdk'dk''dk'''.\end{aligned} \tag{31}$$

If follows from comparing Eq. (29) to Eq. (31), that the ansatz is satisfied if the following condition is fulfilled:

$$\frac{3i(n-1)(m-1)}{\pi[n+m-1]}\,S(k)\,\delta(k-k')g^{(n)}(z,k')g^{(m)}(z,k''')=k'S(k')\,\delta(k'''-k')g^{(n+m)}(z,k'''). \tag{32}$$

If Eq. (32) is satisfied, we can finally formulate solutions of the KdV equation:

$$u(x,t)=\sum_{n=1}^{\infty} f^{(n)}(x,t)$$

$$=Ae^{ikz}+\lim_{\epsilon\to 0}\sum_{n=2}^{\infty}\frac{(n-1)}{(2\pi)^2 i}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{\delta(k-k')}{k+k'+i\epsilon}\,S(k')g^{(n)}(z,k')dk'dk. \tag{33}$$

We can find explicit solutions of Eq. (33) by using the fact that Eq. (32) defines a recursion relationship for the functions $g^{(n)}(z,k)$. This recursion relation can be made explicit by verifying Eq. (6) if one of the functions $f^{(n)}(x,t)$ is equal to $f^{(1)}(x,t)$. If we choose for $f^{(1)}(x,t)$ the following representation:

$$f^{(1)}(x,t)=\lim_{\epsilon\to 0}\frac{1}{(2\pi)^2 i}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{ik'e^{ik'z}}{k+k'+i\epsilon}\,S(k')dk'dk, \tag{34}$$

the inverse scattering transformation can be retained. From comparing Eq. (28) to Eq. (34), it follows that by giving $f^{(1)}(x,t)$ the form (34), we have implicitly chosen that $\tilde{f}^{(1)}(k')=ik'$. If we compute the left-hand side of Eq. (6), we find that

$$6f_x^{(1)}(x,t)f^{(n-1)}(x,t)=-\lim_{\epsilon\to 0}\frac{(n-2)}{(2\pi)^4}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{6ik'S(k)(k'')}{k+k'+i\epsilon}\,\frac{\delta(k-k')\,\delta(k''-k''')}{k''+k'''+i\epsilon}$$

$$\times g^{(1)}(z,k')g^{(m)}(z,k''')dkdk'dk''dk'''. \tag{35}$$

According to the ansatz, Eq. (6), this has to be equal to

$$\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}G(x-x'|t-t')f^{(n)}(x',t')dx'dt'$$

$$=-\lim_{\epsilon\to 0}\frac{[n-1]}{(2\pi)^3}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{k'^2S(k')S(k'')}{k+k'+i\epsilon}\,\frac{\delta(k''-k''')\,\delta(k'''-k')}{k''+k'''+i\epsilon}$$

$$\times g^{(n)}(z,k''')dkdk'dk''dk'''. \tag{36}$$

By comparing Eq. (35) to Eq. (36) we find that equality is obtained if the following relationship is satisfied:

$$\frac{3i(n-2)}{\pi(n-1)}\,S(k)\,\delta(k-k')g^{(1)}(z,k')g^{(n-1)}(z,k''')=k'S(k')\,\delta(k'''-k')g^{(n)}(z,k'''). \tag{37}$$

Equation (37) is a recursion relation which makes it possible to compute $g^{(n)}(z,k)$ from $g^{(n-1)}(z,k)$. In order to relate $g^{(2)}(z,k)$ to $g^{(1)}(z,k)$, we have to check explicitly the ansatz (6) for the $6f_x^{(1)}(x,t)f^{(1)}(x,t)$ case. This leads to the following result:

$$\frac{3i}{2\pi}\,S(k)\,\delta(k-k')g^{(1)}(z,k')g^{(1)}(z,k''')=k'S(K')\,\delta(k''-k''')g^{(2)}(z,k'''). \tag{38}$$

The result we have obtained indicates that we can solve the KdV equation by using the recursion relationship defined by Eq. (37). If we continue the process of iteration, we obtain the following solutions $f^{(n)}(x,t)$ which determine the solution of the KdV equation:

$$f^{(1)}(x,t)=\lim_{\epsilon\to 0}\frac{1}{(2\pi)^2 i}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{ik'e^{ik'z}}{k+k'+i\epsilon}\hat{S}(k')dk'dk, \tag{39}$$

$$f^{(2)}(x,t)=\lim_{\epsilon\to 0}\frac{1}{2\pi(2\pi i)^2}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{\hat{S}(k')e^{ik'z}}{k+k'+i\epsilon}\frac{\hat{S}(k'')e^{ik''z}}{k'+k''+i\epsilon}i(k'+k'')dk''dk'dk, \tag{40}$$

$$\vdots$$

where we have used that $\hat{S}(k)=2/3iS(k)$. If the infinite series of solutions of which the first two are given by Eq. (39) and Eq. (40) are substituted into Eq. (33), we obtain a solution of the KdV equation of which the first two terms are given by

$$\begin{aligned}u(x,t)=&\lim_{\epsilon\to 0}\frac{1}{(2\pi)^2 i}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{ik'e^{ik'z}}{k+k'+i\epsilon}\hat{S}(k')dk'dk\\&+\lim_{\epsilon\to 0}\frac{1}{2\pi(2\pi i)^2}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{\hat{S}(k')e^{ik'z}}{k+k'+i\epsilon}\frac{\hat{S}(k'')e^{ik''z}}{k'+k''+i\epsilon}i(k'+k'')dk''dk'dk+\cdots .\end{aligned} \tag{41}$$

In the following section it is shown that Eq. (41) describes a generalization of the inverse scattering solution of the KdV equation. From Eq. (41), it is easy to derive the soliton solutions of the KdV equation. This can be done by choosing the following representation of $S(k)$ (see Ref. 8):

$$\hat{S}(k)=\frac{id}{k+2i\beta},\quad \beta>0,\quad d\in\mathbb{R}. \tag{42}$$

We find that the solution (41) reduces to

$$u(x,t)=4d\beta e^{-2(\beta x-4\beta^3 t)}+16d^2 e^{-4(\beta x-4\beta^3 t)}+24\frac{d^3}{\beta}e^{-6(\beta x-4\beta^3 t)}+\cdots . \tag{43}$$

By carrying out the summation in Eq. (43), we can reformulate the solution (43) more compactly:

$$u(x,t)=\frac{8d\beta e^{-2(\beta x-4\beta^3 t)}}{\left(1+\frac{d}{\beta}e^{-2(\beta x-4\beta^3 t)}\right)^2}. \tag{44}$$

Hence, if we set

$$\beta=\frac{1}{2}\sqrt{c},\quad x_0=-\frac{1}{\sqrt{c}}\log\left(-\frac{d}{\beta}\right),\quad d<0, \tag{45}$$

we can simplify Eq. (44) a step further to

$$u(x,t)=-\frac{c}{2}\operatorname{sech}^2\left\{\frac{1}{2}\sqrt{c}(x-ct+x_0)\right\}. \tag{46}$$

Equation (46) describes the well-known KdV soliton.

The results obtained in this section make it clear that the approach suggested in this paper can be used to generate solutions of the KdV equation. For instance, the KdV soliton can be retained as a special case of Eq. (33). In the following section, it is shown that the solutions obtained in this section are, in fact, the inverse scattering solutions. The two-soliton solutions can be obtained by choosing a function $\hat{S}(k)$ which has a double pole. It will be shown in the next section that the

solution (41) is somewhat more general than the inverse scattering solution because the function $S(k)$ is less restricted than the physical scattering data as used in the IST.

IV. RELATION TO THE INVERSE SCATTERING TRANSFORMATION

To show that there is a close relationship between the results obtained by the linearization method and the well-known inverse scattering results, we discuss the latter in this section in more detail. The IST uses the inverse problem of the Schrödinger equation to generate solutions of the KdV equation. The inverse problem of the Schrödinger equation is given by the Marchenko equation:

$$K(x,y,t)+A(x+y,t)+\int_x^\infty K(x,z,t)A(y+z,t)dz=0. \tag{47}$$

The Marchenko equation relates a data function $A(x,t)$ to an integration kernel $K(x,y,t)$. In Eq. (47), the data function $A(x,t)$ is given by

$$A(x,t)=\frac{1}{2\pi}\int_{-\infty}^{\infty} R(k)e^{ik[x+8k^2t]}dt+\sum_{p=1}^{N}\rho_p e^{-k_p[x+4k_p^2t]}. \tag{48}$$

In Eq. (48), the function $R(k)$ describes the physical reflection coefficient. The function $R(k)$ corresponds to the continuous part of the spectrum of the Schrödinger equation. The numbers ρ_p represent the discrete part of the spectrum of the Schrödinger equation corresponding to the discrete eigenvalues k_p. The discrete part of the spectrum of the Schrödinger equation is given by the residues of the transmission coefficient $T(k,t)$ on the positive imaginary axis. The solution $u(x,t)$ of the KdV equation can be solved from the integration kernel $K(x,y,t)$ by using the following relationship:

$$u(x,t)=-2\frac{d}{dx}K(x,x,t). \tag{49}$$

The relation between the linearization method and the IST becomes more transparent if the analysis is performed in the wave number domain. A convenient way to do this is to relate the kernel $K(x,y,t)$ to a function $F(x,k,t)$ by using the following Fourier transform:[9]

$$K(x,y,t)=\frac{1}{2\pi}\int_{-\infty}^{\infty} dk e^{ik(y-x)}(F(x,k,t)-1). \tag{50}$$

It is well known that the function $F(x,k,t)$ is related to the Jost solutions of the Schrödinger equation.[9] If we substitute Eq. (50) into Eq. (47), we obtain the following relationship:

$$F(x,k,t)=1+\int_{-\infty}^{\infty} C(k,k',z)F(x,k',t)dk'. \tag{51}$$

For reasons of simplicity, we do not take the contribution of the transmission coefficient into account in the analysis which follows. It can be shown that the transmission coefficient can be included in the computations in a conceptually similar manner.[9] In the special case of a negligible transmission coefficient, we find that the kernel $C(k,k',t)$ in Eq. (51) is given by

$$C(k,k',z)=\frac{1}{2\pi i}\frac{R(k')e^{2ik'z}}{k+k'+i\epsilon};\quad z=x-8k^2t. \tag{52}$$

If Eq. (52) is substituted into Eq. (51), we find the following relationship:

$$F(x,k,t)-1=+\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{R(k')F(x,k',t)e^{2ikz}}{k+k'+i\epsilon}dk'. \tag{53}$$

To find a relationship between the linearization technique and the IST, we expand Eq. (52) in a series:

$$F(k,x,t)=1+\int_{-\infty}^{\infty}C(k,k',z)dk'+\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}C(k,k',z)C(k',k'',z)dk'dk''+\cdots . \tag{54}$$

If we substitute Eq. (52) into Eq. (54), this result becomes equal to

$$\begin{aligned}F(k,x,t)-1=&\lim_{\epsilon\to 0}\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{R(k')e^{2ik'z}}{k+k'+i\epsilon}dk'\\&+\lim_{\epsilon\to 0}\frac{1}{(2\pi i)^2}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{R(k')e^{2ik'z}}{k+k'+i\epsilon}\frac{R(k'')e^{2ik''z}}{k'+k''+i\epsilon}dk'dk''+\cdots .\end{aligned} \tag{55}$$

By taking the Fourier transform Eq. (50) of both sides of Eq. (55) we can compute the integration kernel $K(x,x,t)$:

$$\begin{aligned}K(x,x,t)=&\lim_{\epsilon\to 0^+}\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{R(k')e^{2ik'z}}{k+k'+i\epsilon}dkdk'\\&+\lim_{\epsilon\to 0^+}\frac{2}{2\pi(2\pi i)^2}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{R(k')e^{2ik'z}}{k+k'+i\epsilon}\frac{R(k'')e^{2ik''z}}{k'+k''+i\epsilon}dkdk'dk''+\cdots .\end{aligned} \tag{56}$$

From this result we obtain by setting $x=y$ and using the relationship (49) that solutions of the KdV equation are given by the following relationship:

$$\begin{aligned}u(x,t)=&\lim_{\epsilon\to 0}\frac{1}{(2\pi)^2 i}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{2ik'e^{2ik'z}}{k+k'+i\epsilon}R(k')dk'dk\\&+\lim_{\epsilon\to 0}\frac{1}{2\pi(2\pi i)^2}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{R(k')e^{2ik'z}}{k+k'+i\epsilon}\frac{R(k'')e^{2ik''z}}{k'+k''+i\epsilon}2i(k'+k'')dk''dk'dk+\cdots .\end{aligned} \tag{57}$$

Modulo some trivial rescaling, the analytical structure of Eq. (58) is equal to the result reflected in Eq. (41). We can therefore conclude that the functions $g^{(n)}(k,z)$ are related to the Jost solution of an inverse scattering problem. This is not a great surprise if we realize that the kernel $K(x,y,t)$ in the Marchenko equation is a Green's function by itself.[9] The linearization method constructs the Green's function directly. However, we have to realize that the results obtained in Sec. III are far more general than the IST. It turns out that Eq. (41) is only a special case on of the linearization method, depending on the initial conditions. Yet, it should be realized that although Eq. (58) and Eq. (41) have a similar structure; Eq. (41) is more general. This is related to the precise definition of the scattering data in Eq. (58). In general, the scattering data given by the reflection coefficient $R(k,t)$ and the transmission coefficient $T(k,t)$ have to satisfy a number of restrictions to assure a unitary S matrix and uniqueness of the corresponding inverse problem. Moreover, additional conditions have to be satisfied so that the Deift–Trubowits condition is not violated (an overview of all the conditions can be found in, for instance, the book by Chadan and Sabatier[9]). These additional constraints do not have to be satisfied by the results obtained by the linearization method. We can therefore consider the results reflected in Eq. (41) to be a generalization of the IST.

V. THE NONLINEAR SCHRÖDINGER EQUATION

In Sec. II it is shown that the KdV equation can be be transformed into a linear partial differential equation. As concluded in Sec. II, this linear differential equation depends on the balances of the dispersion of the nonlinear problem to a function $S(k)$ representing the nonlinear-

ity. We can ask ourselves the question whether there are more NPDEs which can be linearized into an equation having a similar structure as Eq. (20). In this section it is shown that this is indeed the case if we introduce new symmetries in the linearized equation. The most simple one-dimensional generalization of Eq. (20) is given by

$$c_1\left[\frac{d}{dz}\,g_j^{(n)}(z,k)\right]+ikc_2g_j^{(n)}(z,k)=c_3Q(n)S(k)g_j^{(n)}(z,k). \tag{58}$$

In Eq. (58), we have replaced the function $g^{(n)}(z,k)$ of Eq. (20) by an N-dimensional vector function $g_j^{(n)}(z,k)$. Furthermore, in Eq. (58) the $N\times N$ matrices c_i are introduced. The matrices c_i are assumed to have constant entries. Similarly, as in Sec. II, the variable z takes its value in a dispersion relation so that Eq. (58) is invariant under Galileian transformations. As argued in Sec. II, we can expect that Eq. (58) can be transformed into a wide variety of nonlinear equations which all have solitonic solutions. An interesting special case can be considered if we choose $N=2$ and if the matrices c_i take the following representations:

$$c_1=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix},\quad c_2=c_3=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}. \tag{59}$$

We will show in this section that if we choose the dispersion relation to be equal to

$$\omega(k)=\pm k^2, \tag{60}$$

and if the function $Q(n)$ is equal to

$$Q(n)=\tfrac{1}{2}(n-1)(n-2), \tag{61}$$

the linear equation (58) can be transformed into the nonlinear Schrödinger equation. To find a similar cascade of transformations and rescaling which transforms the nonlinear Schrödinger equation into Eq. (58), we take as a starting point the nonlinear Schrödinger equation:

$$iu_t+u_{xx}\pm 2|u|^2u=0. \tag{62}$$

It is useful to transform the nonlinear Schrödinger equation into the following set of coupled differential equations:

$$iu_t+u_{xx}-2u^2v=0,\quad iv_t-v_{xx}+2v^2u=0. \tag{63}$$

The two coupled partial differential equations presented in Eq. (63) are equivalent to the nonlinear Schrödinger equation if we set $v=\mp u^*$. In order to simplify the bookkeeping, we formulate the set of coupled differential equations (63) as the following matrix equation:

$$\mathbf{I}\mathbf{w}_t-i\sigma_3\mathbf{w}_{xx}=-2i\mathbf{A}\mathbf{w}. \tag{64}$$

In Eq. (64), $\mathbf{I}$ represents the unity matrix and the vector $\mathbf{w}$ is given by $\mathbf{w}=(u,v)^T$. Furthermore, the Pauli spin matrices σ_i are introduced:

$$\sigma_1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad \sigma_2=\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix},\quad \sigma_3=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}. \tag{65}$$

Finally, all the nonlinearities are contained in the matrix $\mathbf{A}$ which is defined by the following relationship:

$$\begin{pmatrix}uv & 0\\ 0 & -uv\end{pmatrix}\begin{pmatrix}u\\ v\end{pmatrix}=\mathbf{A}\mathbf{w}. \tag{66}$$

We carry on in a similar manner as in Sec. II by assuming that the functions $u(x,t)$ and $v(x,t)$ can be decomposed in the following infinite perturbation series:

$$\mathbf{w}(x,t)=\sum_{n=1}^{\infty}\mathbf{f}^{(n)}(x,t). \tag{67}$$

Every component $f_i^{(n)}(x,t)$ of $\mathbf{f}^{(n)}(x,t)$ expresses the expansion of the components u and v of $\mathbf{w}(x,t)$. Similarly, as in Sec. II, the nonlinear Schrödinger equation is solved if solutions of all the functions $f_i^{(n)}(x,t)$ are constructed. If Eq. (67) is substituted into Eq. (64), we obtain the following result:

$$\sum_{n=1}^{\infty}(\mathbf{I}\partial_t-i\sigma_3\partial_{xx})\mathbf{f}^{(n)}(x,t)=-2i\sum_{k=1}^{\infty}\sum_{l=1}^{\infty}\sum_{m=1}^{\infty}s^{(klm)}(x,t), \tag{68}$$

where the vector function $\mathbf{s}^{(klm)}(x,t)$ is given by

$$\mathbf{s}^{(klm)}(x,t)=\begin{pmatrix} f^{(k)}(x,t)f_{(l)}(x,t)g^{(m)}(x,t) \\ -g^{(k)}(x,t)g^{(l)}(x,t)f^{(m)}(x,t)\end{pmatrix}. \tag{69}$$

We proceed, as in Sec. II, by collecting all the terms of which the sum of the orders on the left-hand side equals the sum of the orders on the right-hand side. In order to have a better view on the structure of the infinite number of equations which are then obtained, we write out the first four explicitly:

$$\begin{aligned}(\mathbf{I}\partial_t-i\sigma_3\partial_{xx})\mathbf{f}^{(1)}(x,t)&=0,\\ (\mathbf{I}\partial_t-i\sigma_3\partial_{xx})\mathbf{f}^{(2)}(x,t)&=0,\\ (\mathbf{I}\partial_t-i\sigma_3\partial_{xx})\mathbf{f}^{(3)}(x,t)&=\mathbf{s}^{(111)}(x,t),\\ (\mathbf{I}\partial_t-i\sigma_3\partial_{xx})\mathbf{f}^{(4)}(x,t)&=\mathbf{s}^{(211)}(x,t)+\mathbf{s}^{(121)}(x,t)+\mathbf{s}^{(112)}(x,t),\end{aligned} \tag{70}$$

We can linearize the set of equations given in Eq. (70) in the Fourier domain by introducing kernel $G(x',t'|x,t)$:

$$-2i\mathbf{s}^{(klm)}(x,t)=\sigma_3\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}G(x,x'|t,t')\mathbf{f}^{(k+l+m)}(x',t')dx'dt'. \tag{71}$$

If Eq. (71) is substituted into Eq. (70), we can reformulate Eq. (70) in the following way:

$$\begin{aligned}(\mathbf{I}\partial^t-i\sigma_3\partial_{xx})\mathbf{f}^{(1)}(x,t)&=0,\\ (\mathbf{I}\partial_t-i\sigma_3\partial_{xx})\mathbf{f}^{(2)}(x,t)&=0,\\ (\mathbf{I}\partial_t-i\sigma_3\partial_{xx})\mathbf{f}^{(3)}(x,t)&=\sigma_3\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}G(x,x'|t,t')\mathbf{f}^{3}(x',t')dx'dt',\\ (\mathbf{I}\partial_t-i\sigma_3\partial_{xx})\mathbf{f}^{(4)}(x,t)&=3\sigma_3\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}G(x,x'|t,t')\mathbf{f}^{(4)}(x',t')dx'dt',\\ &\vdots\\ (\mathbf{I}\partial_t-i\sigma_3\partial_{xx})\mathbf{f}^{(n)}(x,t)&=\sigma_3Q(n)\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}G(x,x'|t,t')\mathbf{f}^{(n)}(x',t')dx'dt'.\end{aligned} \tag{72}$$

Similar to Sec. II, we proceed, continuing our analysis in the wave number domain, by searching for the following wave-package solutions:

$$\mathbf{f}^{(n)}(x,t)=\frac{1}{2\pi}\int_{-\infty}^{\infty}\tilde{\mathbf{f}}^{(n)}(k)e^{ikz}dk,\quad z=x-\frac{\omega(k)}{k}t. \tag{73}$$

If Eq. (73) is substituted into Eq. (70) and if we solve $\tilde{\mathbf{f}}^{(1)}(k)$, we find that dispersion relation given by Eq. (60) has to be satisfied. If we define, furthermore, the Fourier transform of the kernel $G(x-x'|t-t')$ to be equal to

$$G(x-x'|t-t')=\frac{1}{2\pi}\int_{-\infty}^{\infty}\tilde{G}(k)e^{ik[z-z']}dk, \tag{74}$$

and if we define $S(k)=\tilde{G}(k)/k$, we obtain that the set of equations (72) in the Fourier domain are equal to

$$\begin{aligned}
&\mathbf{I}\frac{d}{dz}\tilde{\mathbf{g}}^{(1)}(z,k)+ik\sigma_3\tilde{\mathbf{g}}^{(1)}(z,k)=0,\\
&\mathbf{I}\frac{d}{dz}\tilde{\mathbf{g}}^{(2)}(z,k)+ik\sigma_3\tilde{\mathbf{g}}^{(2)}(z,k)=0,\\
&\mathbf{I}\frac{d}{dz}\tilde{\mathbf{g}}^{(3)}(z,k)+ik\sigma_3\tilde{\mathbf{g}}^{(3)}(z,k)=\sigma_3S(k)\tilde{\mathbf{g}}^{(3)}(z,k),\\
&\vdots
\end{aligned} \tag{75}$$

In Eq. (75), we have defined

$$\tilde{\mathbf{g}}^{(n)}(z,k)=\tilde{\mathbf{f}}^{(n)}(k)e^{ikz}\quad S(k)=\frac{G(k)}{k}. \tag{76}$$

Resuming, we can conclude that the nonlinear Schrödinger equation can be linearized into

$$\mathbf{I}\frac{d}{dz}\tilde{\mathbf{g}}^{(n)}(z,k)+ik\sigma_3\tilde{\mathbf{g}}^{(n)}(z,k)=Q(n)\sigma_3S(k)\tilde{\mathbf{g}}^{(n)}(z,k). \tag{77}$$

In this section it is shown that the nonlinear Schrödinger equation can be linearized into a generalization of Eq. (20). It can be shown that the ansatz (71) leads to conditions on the solutions of the nonlinear Schrödinger equation.[10] Explicit solutions of the nonlinear Schrödinger equation computed by using the linearization method are given in this reference. It has to be remarked that the linearized equation is invariant under transformations of the SU(2) generators σ_i. This reflects that besides the Galileian invariance (which takes its value as the dispersion relation) another symmetry is present in the linearization of the nonlinear Schrödinger equation.

VI. GENERALIZATION TO HIGHER DIMENSIONS

Inspired by the results obtained in the previous sections, we show that a similar procedure can be applied to find solutions of higher-dimensional NPDEs. We choose as a starting point the most simple three-dimensional generalization of Eq. (20):

$$\sum_{i=1}^{3}\partial_{z_i}g^{(n)}(\mathbf{z},\mathbf{k})+i\sum_{i=1}^{3}k_ig^{(n)}(\mathbf{z},\mathbf{k})=(n-1)S(\mathbf{k})g^{(n)}(\mathbf{z},\mathbf{k}). \tag{78}$$

In Eq. (78), the solution $g^{(n)}(\mathbf{z},\mathbf{k})$ of the linearized problem depends now on a three-dimensional vector $\mathbf{z}$ having components $(z_1,z_2,z_3)^T$ and a three-dimensional wave number $\mathbf{k}$ with elements $(k_1,k_2,k_3)^T$. We derive a three-dimensional generalization of the KdV equation by following the reverse track of Sec. II. We first define a function $\hat{G}(\mathbf{k})$ so that

$$S(\mathbf{k})=\frac{\hat{G}(\mathbf{k})}{\mathbf{k}\cdot\mathbf{k}}. \tag{79}$$

If Eq. (79) is substituted into Eq. (78), we obtain the following result:

$$\mathbf{k}\cdot\mathbf{k}\sum_{i=1}^{3}\{\partial_{z_i}g^{(n)}(\mathbf{z},\mathbf{k})+ik_ig^{(n)}(\mathbf{z},\mathbf{k})\}=(n-1)\hat{G}(\mathbf{k})g^{(n)}(\mathbf{z},\mathbf{k}). \tag{80}$$

We have to take into account that Eq. (80) has to be solved for all n in the range from unity to infinity. Following the recipe derived in Sec. II, we find, if we write out the lowest orders of n in Eq. (80) explicitly, that

$$\begin{aligned}
&\mathbf{k}\cdot\mathbf{k}\sum_{i=1}^{3}\{\partial_{z_i}g^{(1)}(\mathbf{z},\mathbf{k})+ik_ig^{(1)}(\mathbf{z},\mathbf{k})\}=0,\\
&\mathbf{k}\cdot\mathbf{k}\sum_{i=1}^{3}\{\partial_{z_i}g^{(2)}(\mathbf{z},\mathbf{k})+ik_ig^{(2)}(\mathbf{z},\mathbf{k})\}=\hat{G}(\mathbf{k})g^{(2)}(\mathbf{z},\mathbf{k}),\\
&\mathbf{k}\cdot\mathbf{k}\sum_{i=1}^{3}\{\partial_{z_i}g^{(3)}(\mathbf{z},\mathbf{k})+ik_ig^{(3)}(\mathbf{z},\mathbf{k})\}=2\hat{G}(\mathbf{k})g^{(3)}(\mathbf{z},\mathbf{k}),
\end{aligned} \tag{81}$$

We proceed by defining a function $f^{(n)}(\mathbf{x},t)$. The functions $g^{(n)}(\mathbf{z},\mathbf{k})$ in Eq. (81) are defined to be related to functions $f^{(n)}(\mathbf{x},t)$ by the following relationship:

$$f^{(n)}(\mathbf{x},t)=\frac{1}{(2\pi)^3}\int_{-\infty}^{\infty}\tilde{f}^{(n)}(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{z}}d^3k;\quad g^{(n)}(\mathbf{z},\mathbf{k})=\tilde{f}^{(n)}(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{z}};\quad z_i=x_i-\frac{\omega(\mathbf{k})}{k_i}\,t. \tag{82}$$

If we carry out the inverse Fourier transform of Eq. (82), we find that the set of equations given in Eq. (81) is transformed into the following set of equations:

$$\begin{aligned}
&\sum_{i=1}^{3}\partial_{x_i}^3f^{(1)}(\mathbf{x},t)+\partial_tf^{(1)}(\mathbf{x},t)=0,\\
&\sum_{i=1}^{3}\partial_{x_i}^3\,f^{(2)}(\mathbf{x},t)+\partial_tf^{(2)}(\mathbf{x},t)=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}G(\mathbf{x},t|\mathbf{x}',t')f^{(2)}(\mathbf{x}',t')d\mathbf{x}'dt',\\
&\sum_{i=1}^{3}\partial_{x_i}^3\,f^{(3)}(\mathbf{x},t)+\partial_tf^{(3)}(\mathbf{x},t)=2\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}G(\mathbf{x},t|\mathbf{x}',t')f^{(3)}(\mathbf{x}',t')d\mathbf{x}'dt',\\
&\qquad\vdots
\end{aligned} \tag{83}$$

The kernel $G(\mathbf{x},t|\mathbf{x}',t')$ in Eq. (83) is related to the function $\hat{G}(\mathbf{k})$ by means of the following Fourier transform:

$$G(\mathbf{x},t|\mathbf{x}',t)=\frac{1}{(2\pi)^3}\int_{-\infty}^{\infty}\hat{G}(\mathbf{k})e^{i\mathbf{k}\cdot[\mathbf{z}-\mathbf{z}']}d^3k. \tag{84}$$

We continue by defining the three-dimensional generalization of the ansatz (6) which relates the functions $f^{(n)}(\mathbf{x},t)$ to the integration kernel $G(\mathbf{x},t|\mathbf{x}',t')$:

$$6\left[\sum_{i=1}^{3}\partial_{x_i}\,f^{(n)}(\mathbf{x},t)\right]f^{(m)}(\mathbf{x},t)=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}G(\mathbf{x},t'|\mathbf{x}',t')f^{(n+m)}(\mathbf{x}',t')d\mathbf{x}'dt'. \tag{85}$$

If we substitute Eq. (85) into Eq. (83), we obtain that the set of Eqs. (83) can be uniquely decomposed as

$$\sum_{i=1}^{3} \partial_{x_i}^3 f^{(1)}(\mathbf{x},t) + \partial_t f^{(1)}(\mathbf{x},t) = 0,$$

$$\sum_{i=1}^{3} \partial_{x_i}^3 f^{(2)}(\mathbf{x},t) + \partial_t f^{(2)}(\mathbf{x},t) = 6\left[\sum_{i=1}^{3} \partial_{x_i} f^{(1)}(\mathbf{x},t)\right] f^{(1)}(\mathbf{x},t),$$

$$\sum_{i=1}^{3} \partial_{x_i}^3 f^{(3)}(\mathbf{x},t) + \partial_t f^{(3)}(\mathbf{x},t) = 6\sum_{i=1}^{3} \left([\partial_{x_i} f^{(1)}(\mathbf{x},t)] f^{(2)}(\mathbf{x},t) + [\partial_{x_i} f^{(2)}(\mathbf{x},t)] f^{(1)}(\mathbf{xt})\right), \quad (86)$$

$$\sum_{i=1}^{3} \partial_{x_i}^3 f^{(4)}(\mathbf{x},t) + \partial_t f^{(4)}(\mathbf{x},t) = 6\sum_{i=1}^{3} \left([\partial_{x_i} f^{(1)}(\mathbf{x},t)] f^{(3)}(\mathbf{x},t) + [\partial_{x_i} f^{(2)}(x,t)] f^{(2)}(\mathbf{x},t) + [\partial_{x_i} f^{(3)}(\mathbf{x},t)] f^{(1)}(\mathbf{x},t)\right),$$

If we take the sums of both the left-hand sides and the right-hand sides of all the equations (86), we obtain, after some bookkeeping, the following result:

$$\sum_{n=1}^{\infty} \left[\sum_{i=1}^{3} \partial_{x_i}^3 f^{(n)}(\mathbf{x},t)\right] + \sum_{i=1}^{\infty} \partial_t f^{(n)}(\mathbf{x},t) = 6\sum_{n=1}^{\infty}\sum_{m=1}^{\infty} \left[\sum_{i=1}^{3} \partial_{x_i} f^{(n)}(\mathbf{x},t)\right] f^{(m)}(\mathbf{x},t). \quad (87)$$

Finally, if we define, for notational convenience,

$$u(\mathbf{x},t) = \sum_{n=1}^{\infty} f^{(n)}(\mathbf{x},t), \quad (88)$$

we find that Eq. (87) is equivalent with

$$\sum_{i=1}^{3} \partial_{x_i}^3 u(\mathbf{x},t) + \partial_t u(\mathbf{x},t) = 6\left[\sum_{i=1}^{3} \partial_{x_i} u(\mathbf{x},t)\right] u(\mathbf{x},t). \quad (89)$$

Equation (89) is a three-dimensional partial differential equation which can be linearized into Eq. (78) by applying a similar cascade of transformations and rescaling. Equation (89) is the three-dimensional generalization of the KdV equation. We can solve Eq. (89) by solving Eq. (78) and transforming the obtained solutions $g^{(n)}(\mathbf{x},\mathbf{k})$ into the functions $f^{(n)}(\mathbf{x},t)$. Before we can compute the solution, Eq. (78), we first have to find an adequate Green's function to solve the integration kernel $G(\mathbf{x},t|\mathbf{x}',t')$. We therefore first solve

$$\sum_{i=1}^{3} (\partial_{x_i} + ik_i)\mathcal{G}(\hat{\mathbf{z}},\mathbf{k}) = \delta(\hat{\mathbf{z}}), \quad \hat{\mathbf{z}} = \mathbf{z} - \mathbf{z}'. \quad (90)$$

The Fourier transform $\mathcal{H}(\mathbf{k}',\mathbf{k})$ of $\mathcal{G}(\hat{\mathbf{z}},\mathbf{k})$ is given by the following relationship:

$$\mathcal{H}(\mathbf{k}',\mathbf{k}) = \int_{-\infty}^{\infty} \mathcal{G}(\hat{\mathbf{z}},\mathbf{k}) e^{-i\mathbf{k}'\cdot\hat{\mathbf{z}}} d^3\hat{z}. \quad (91)$$

If Eq. (91) is substituted into Eq. (90), we obtain the following solution of $\mathcal{H}(\mathbf{k}',\mathbf{k})$:

$$\mathcal{H}(\mathbf{k}',\mathbf{k}) = \frac{1}{i\Sigma_{j=1}^{3}(p_j + k_j)}. \quad (92)$$

If we apply the inverse transform of Eq. (91) to Eq. (92), we find the following solution of the Green's function $\mathcal{G}(\hat{\mathbf{z}},\mathbf{k})$:

$$\mathcal{G}(\hat{\mathbf{z}},\mathbf{k})=\lim_{\epsilon\to 0}\frac{1}{(2\pi)^3 i}\int_{-\infty}^{\infty}\frac{e^{i\mathbf{k}'\cdot\hat{\mathbf{z}}}}{\Sigma_{j=1}^{3}(k_j+k_j'+i\epsilon)}\,d^3k'. \tag{93}$$

Once the Green's function is known, we can compute the general solution of the linear differential equation, Eq. (78):

$$g^{(n)}(\mathbf{z},\mathbf{k})=\lim_{\epsilon\to 0}\frac{(n-1)}{(2\pi)^3 i}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{e^{i\mathbf{k}'\cdot[\mathbf{z}-\mathbf{z}']}}{\Sigma_{j=1}^{3}(k_j+k_j'+i\epsilon)}\,S(\mathbf{k})g^{(n)}(\mathbf{z}',\mathbf{k})d^3k'd^3z',\quad n\neq 1. \tag{94}$$

If we apply the Fourier transform given in Eqs. (82)–(94), we find that solutions of the functions $f^{(n)}(\mathbf{x},t)$ are given by

$$f^{(n)}(\mathbf{x},t)=\lim_{\epsilon\to 0}\frac{(n-1)}{(2\pi)^6 i}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{\delta(\mathbf{k}-\mathbf{k}')}{\Sigma_{j=1}^{3}(k_j+k_j'+i\epsilon)}\,S(\mathbf{k})g^{(n)}(\mathbf{z},\mathbf{k}')d^3kd^3k',\quad n\neq 1. \tag{95}$$

In a similar manner as pointed out in Sec. III, it can be shown that if the integration kernel $G(\mathbf{x}-\mathbf{x}'|t-t')$ has the following structure:

$$G(\mathbf{x}-\mathbf{x}'|t-t')=\lim_{\epsilon\to 0}\frac{1}{(2\pi)^6 i}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{[\mathbf{k}'\cdot\mathbf{k}']e^{i\mathbf{k}'\cdot[\mathbf{z}-\mathbf{z}']}}{\Sigma_{j=1}^{3}(k_j+k_j'+i\epsilon)}\,S(\mathbf{k}')d^3kd^3k'. \tag{96}$$

A general form of the solutions $u(\mathbf{x},t)$ of the three-dimensional KdV equation is given by the following relationship:

$$u(\mathbf{x},t)=\sum_{n=1}^{\infty}f^{(n)}f^{(n)}(\mathbf{x},t)=Ae^{i\mathbf{k}\cdot\mathbf{x}}+\lim_{\epsilon\to 0}\sum_{n=2}^{\infty}\frac{(n-1)}{(2\pi)^6 i}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{\delta(\mathbf{k}-\mathbf{k}')}{\Sigma_{j=1}^{3}(k_j+k_j'+i\epsilon)}\times S(\mathbf{k}')g^{(n)}(\mathbf{z},\mathbf{k}')d^3kd^3k'. \tag{97}$$

It can be verified by redoing the computations which are carried out in Sec. III, that if the ansatz (85), is satisfied, a recursion relation for the solutions $f^{(n)}(x,t)$ can be obtained. The solutions $f^{(n)}(x,t)$ which lead to a solution of the three-dimensional KdV equation are given by

$$f^{(1)}(\mathbf{x},t)=\lim_{\epsilon\to 0}\frac{1}{(2\pi)^6 i}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{e^{i\mathbf{k}'\cdot\mathbf{z}}}{\Sigma_{j=1}^{3}(k_j+k_j'+i\epsilon)}\,S(\mathbf{k}')\left[\sum_{m=1}^{3}ik_m'\right]d^3kd^3k', \tag{98}$$

$$f^{(2)}(\mathbf{x},t)=\lim_{\epsilon\to 0}\frac{1}{(2\pi)^9 i^2}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{e^{i(\mathbf{k}'+\mathbf{k}'')\cdot\mathbf{z}}S(\mathbf{k}')S(\mathbf{k}'')}{\Sigma_{l,m=1}^{3}(k_l+k_l'+i\epsilon)(k_m'+k_m''+\epsilon)}\times\left[i\sum_{m=1}^{3}(k_m'+k_m'')\right]d^3kd^3k'd^3k', \tag{99}$$

Once the functions $f^{(n)}(\mathbf{x},t)$ are computed, we construct the solution $u(\mathbf{x},t)$ of the three-dimensional KdV equation by summation of the functions $f^{(n)}(\mathbf{x},t)$:

$$u(\mathbf{x},t)=\lim_{\epsilon\to 0}\frac{1}{(2\pi)^6 i}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{e^{i\mathbf{k}'\cdot\mathbf{z}}}{\Sigma_{j=1}^{3}(k_j+k_j'+i\epsilon)}S(\mathbf{k}')\left[\sum_{m=1}^{3}ik_m'\right]d^3kd^3k'$$
$$+\lim_{\epsilon\to 0}\frac{1}{(2\pi)^9 i^2}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{e^{i(\mathbf{k}'+\mathbf{k}'')\cdot\mathbf{z}}S(\mathbf{k}')S(\mathbf{k}'')}{\Sigma_{l,m=1}^{3}(k_l+k_l'+i\epsilon)(k_m'+k_m''+i\epsilon)}$$
$$\times\left[i\sum_{m=1}^{3}(k_m'+k_m'')\right]d^3kd^3k'd^3k''+\cdots . \tag{100}$$

We can conclude that the approach followed in Sec. II for the one-dimensional KdV equation, can also be used to construct special solutions for the three-dimensional KdV equation. By generalizing Eq. (78) and by introducing more symmetry, we can, in principle, find special solutions of other higher-dimensional NPDEs. For proving the integrability, it would be necessary to prove that the set of solutions which are derived is sufficient for solving a reasonable Cauchy problem. It is also still unclear what the relationship between the procedure followed in this paper and the three-dimensional inverse scattering problem exactly is. In one dimension, this issue is clarified in Sec. IV, but in three dimensions the analysis is more complicated. It is not unthinkable that if this relationship is revealed, answers can be given with respect to the integrability of three-dimensional NPDEs.

VII. DISCUSSION

The following novel results are obtained in this paper. First, a new method is presented to obtain solutions of one-dimensional *S*-integrable differential equations. Whereas the IST solves *S*-integrable differential equations by using inversion techniques, the method presented in this paper solves these equations by using a direct method. The *S*-integrable nonlinear partial differential equation is linearized into an ordinary linear differential equation. There are several advantages of using a linearization method. The first advantage is that the method given is fairly general. In principle, the machinery applies to all NPDEs which have a nonlinear part consisting of a power series. Second, the method we have developed does not need Lax pairs for systematically investigating the integrability of NPDEs. The method can be generalized to higher-dimensional NPDEs. This is demonstrated in Sec. VI for the three-dimensional KdV equation. This result demonstrates that at least in one dimension, *S*-integrable NPDEs are also *C*-integrable.

As shown in Sec. II we can conclude that the linearized equation depends on two factors. The first factor is the dispersion relation which defines the space coordinate. The latter is invariant under Galileian transformations. The second factor is a generalization of the scattering data which is related by the ansatz used in this paper to the nonlinearity. By modifying the dispersion relation and the ansatz, Eq. (6), large classes of *S*-integrable NPDEs can be constructed and solved. It is remarked that the Galileian invariance of the space coordinate can be associated with a minimum symmetry property of the linearized differential equation. If the linearized equation, Eq. (17), is generalized, for instance, by making it invariant for other symmetries, more complex NPDEs can be constructed. It is shown in Sec. V that the nonlinear Schrödinger equation follows from a generalization of Eq. (17) which is invariant under the SU(2) generators. The mathematical reason for this invariance is related to the fact that the zero-curvature condition which is responsible for an infinite number of conservation laws, is invariant under gauge transformations, taking their value in a Lie group. As a result of this, the corresponding linearized problem is invariant under similar transformations in the corresponding Lie algebra.

ACKNOWLEDGMENTS

The author would like to thank Professor F. Calogero for raising his interest in the concept of *C*-integrability. Professor P. C. Sabatier has made valuable comments on the manuscript. The numerous discussions about the topic with Hans van den Heuvel were greatly appreciated. I would also like to thank H. M. M. ten Eikelder and Roel Snieder for constructively commenting on the manuscript.

(Received 8 August 1997; accepted for publication 18 March 1998)

A supersymmetric extension for an arbitrary number of odd parameters of the stationary KdV equation is studied; we call this an N-extended super KdV. It is shown that it is related to superelliptic curves, and thereafter the complete ring of superdifferential operators commuting with the associated Schrödinger operator is constructed. © *1998 American Institute of Physics.* [S0022-2488(98)03706-2]

I. INTRODUCTION

The construction of commutative rings of differential operators is a classical problem of differential equations, dating back to the work of Burchnall and Chaundy[1] in the early part of the century. Their results were forgotten for almost 50 years, but rediscovered for the purposes of the theory of finite-zone potentials for the integration of soliton-type equations. These results were beautifully complemented by Krichever's theory,[2] relating the construction of solutions to the Korteweg–de Vries (KdV) hierarchy to the study of line bundles over elliptic curves.

On the other hand, although it is now recognized that supersymmetry may not fulfill all its expected promises,[3] the supersymmetrization of a given construct has nevertheless become a very important theoretical tool, both for physicists and mathematicians. For instance, on the physical side, there is an ongoing active search for supersymmetric extensions of the Toda lattice model,[4] while on the mathematical side, supergeometry is an important special (and tractable) case of noncommutative geometry.[5]

In particular, starting with the works of Manin–Radul,[6] Mulase,[7] and Rabin–Freund[8] among others, there is by now a considerable amount of work devoted to supersymmetric extensions of the KdV equation and associated hierarchy. Usually this proceeds by exploiting, either the property of the KdV of being a completely integrable system, and/or its surprising relation with the geometrical theory of elliptic curves (of course, both sides being united by the theory of Krichever), and making the necessary adaptations to the ''super'' setting. Up to now, however, most of the theory developed concentrates on the cases $N=1$ or $N=2$, obtained by adjoining to the standard theory 1 or 2 odd (fermionic) degrees of freedom.

In this work we adopt mainly the rather algebraic point of view of integrable systems to introduce a new supersymmetric extension to an arbitrary number of odd variables of the stationary KdV equation: such an approach,[9,10] although certainly less intuitive (and probably less appealing) than the geometrical approach, enables us to deal with the case of an arbitrary number of fermionic variables in a rather straightforward manner, and thereby extend to this case some results of Manin–Radul,[6] Rabin,[11] and Melzer.[12] In particular, we are able to construct a complete ring of superdifferential operators commuting with the Schrödinger operator on N odd parameters arising from a superelliptic curve.

The paper is organized as follows: In section II we discuss the algebraic setting of this extension, and obtain the stationary super KdV equation as a necessary condition for commutativity of the even generators of the ring; next, in section III a set of odd generators is obtained by use of the Akhiezer–Baker superfunction. Then, in section IV, we prove that we obtained indeed this way the full ring of commutative superoperators. Finally, there is a short section of the discussion of our results.

II. *N*-EXTENDED SUPER KdV EQUATIONS

First we describe the setting for our constructions and fix some notational conventions. The material in the first part of this section is for the most part well known, and we refer the reader to Mulase[10] for a clear and detailed exposition.

Let $\mathbb{C}[[x]]$ denote the algebra of formal power series in the (complex) variable x, Λ a Grassmann algebra in the generators $\theta_1,\theta_2,\ldots,\theta_N$, and consider the tensor product $\mathscr{A}=\mathbb{C}[[x]]\otimes\Lambda$, whose elements are the superfunctions; hence, we will be working with a formal version of the supermanifold denoted $\mathbb{C}^{1,N}$.

We introduce the following notation: $\partial=\partial_x$, $\partial_\nu=\partial_{\theta_\nu}$, $\partial_{\mu\nu}=\partial_\mu\partial_\nu$, etc. Also if f is a superfunction, we denote $\partial f=f'$; $\partial_\nu f=f_\nu$, and so on.

The ground algebra for us is the algebra $\mathscr{B}$ of superdifferential operators generated by the odd derivatives ∂_ν, with coefficients in $\mathscr{A}$; it is an associative algebra under the composition of operators (denoted by $\circ$), although it is neither commutative nor supercommutative. Its elements will be denoted by the capital letters $U,V,\ldots$, so that a typical element looks like

$$U=u+u^\nu\partial_\nu+u^{\mu\nu}\partial_{\mu\nu}+\ldots\ .$$

(Here and in what follows, to alleviate the notations we will use the summation convention over the Greek indices, running from 1 to N; however, as other types of summations will occur, to avoid confusion we will write these out explicitly).

$\mathscr{B}$ is a differential algebra with the derivation ∂, acting on the coefficients of the elements $U\in\mathscr{B}$; we will write this action as $\partial U=U'$. Observe that $\partial U\neq\partial\circ U$; indeed, $\partial U=\partial\circ U-U\circ\partial=[\partial,U]$. Furthermore, the action of the odd superderivations also extends to $\mathscr{B}$, and we will write it as $\partial_\nu U=U_\nu$, etc. In what follows we restrict our discussion to even operators $U\in\mathscr{B}$, although of course some odd operators, such as U_ν, will also occur.

One readily proves the following commutation formulas:

$$[\partial^k,U]=\sum_{i=1}^{k}\binom{k}{i}U^{(i)}\circ\partial^{(k-i)}, \tag{1}$$

$$[\partial^k,U\circ\partial]=[\partial^k,U]\circ\partial;\quad [U,U\circ\partial]=-U'\circ U;\quad [\partial_\nu,U]=U_\nu. \tag{2}$$

Finally, we extend $\mathscr{B}$ by the formal ''antiderivation'' operator ∂^{-1}, to obtain the algebra $\mathscr{B}((\partial^{-1}))$ of super pseudo-differential operators, whose elements are formal expressions of the form $\Sigma_{i=-\infty}^{k}U_i\circ\partial^i$. The operator ∂^{-1} is a formal inverse of ∂, that commutes with the derivations ∂_ν, and satisfies the following commutation relation with the operator of multiplication by a superfunction f:

$$\partial^{-1}\circ f=\sum_{i=1}^{\infty}(-1)^i f^{(i)}\partial^{-(i+1)}.$$

The action of the superderivations also extends to the algebra of super pseudo-differential operators in the obvious way.

Let us now consider the super Schrödinger operator $L=L_U=\partial^2+U$, as the super Hamiltonian of a system.

If we look for operators that commute with such an operator L, then as in the nonsuper case, the even operators with this property are to be found among the fractional powers of L, $L^{k/2}$, which are in general only pseudo-differential. In particular, for reasons that are quite classic but will also be clarified in section III, we are interested in $L^{3/2}$, which using the above formulas is readily found to be

$$L^{3/2}=\partial^3+\tfrac{3}{2}\,U\circ\partial+\tfrac{3}{4}\,U'+O(\partial^{-1}),$$

where $O(\partial^{-1})$ means terms involving only negative powers of ∂. Still more specifically, we look for conditions on its differential operator part,

$$L_+^{3/2}=\partial^3+\tfrac{3}{2}\,U\circ\partial+\tfrac{3}{4}\,U',$$

that will ensure that it commutes with L. Using again the commutation formulas (1) and (2) one readily finds

$$[L,L_+^{3/2}]=-\tfrac{1}{4}\,U'''-\tfrac{3}{2}\,U\circ U'+\tfrac{3}{4}\,[U,U']=-\tfrac{1}{4}\,U'''-\tfrac{3}{4}\,(U\circ U'+U'\circ U), \tag{3}$$

which is an operator of order 0. Therefore, the condition for commutation becomes

$$U'''+6U\circ U'-3[U,U']=0, \tag{4}$$

which is a supersymmetric analog of the stationary KdV equation with N odd variables.

Remark 1: Although for actual computations formula (3) is more practical, the statement of the super KdV equation in equation (4) bears out an interesting point; namely, that the noncommutativity of the ground ring is reflected in the appearance of the commutator $[U,U']$*, which of course does not appear in the ordinary KdV. This may also be compared to the parallel found between classical electromagnetism and Yang–Mills theories.*

On the other hand, the general form of the super KdV equation we have just written suggests that the relationship with superelliptic curves is preserved in this case, a point that will be developed in the remainder of this paper.

Indeed, in the case $N=2$ one can easily work out the explicit equations arising from equation (4), and we get the following system of equations extending the stationary super KdV equations obtained by Manin–Radul[6] and Rabin:[13]

$$\begin{gathered}u'''+3(uu+u^{\nu}u_{\nu}+u^{12}u_{12})'=0,\\ (u^{12})'''+3(2(uu^{12}-u^1u^2)+u^{\nu}u_{\nu}^{12}+u^{12}(u_{\nu}^{\nu}+u_{12}^{12}))'=0,\end{gathered} \tag{5}$$

$$\begin{gathered}(u^1)'''+3(2uu^1+u^{\nu}u_{\nu}^1-u^{12}(u_2-u_{12}^1))'=0,\\ (u^2)'''+3(2uu^2+u^{\nu}u_{\nu}^2+u^{12}(u_1+u_{12}^2))'=0.\end{gathered} \tag{6}$$

Remark 2: This system is a direct generalization to the case of two odd variables of those of Rabin and Manin–Radul, both of which are obtained from even operators. There are, however, other possible extensions in the literature, and we now discuss the relationship of our equations to one of these.

Two rather general $N=2$ extensions of the KdV may be found in Laberge and Mathieu,[14] who proposed two types of extension, arising from operators of the type

$$\mathscr{L}=\partial^2+2\Phi D_1D_2-(D_2\Phi)D_1+(D_1\Phi)D_2$$

or

$$\mathscr{L}=\partial^2-2\Phi D_1D_2+(D_2\Phi)D_1-(D_1\Phi)D_2+(D_1D_2\Phi)-\Phi^2,$$

where $D_{\nu}=\theta_{\nu}\partial+\partial_{\nu}$; $\nu=1,2$, and Φ is an arbitrary superfunction.

Therefore, in their formulation $\mathscr{L}$ need not be of definite parity, and our system is related to the second type, which allows for an independent term. However, even if one considers only even superfunctions, say $\Phi=v+\theta_1\theta_2w$, our system does not in general coincide with theirs: In fact, in our notation, the operator of Laberge and Mathieu takes the form

$$\mathscr{L}=(1-2\,\theta_1\theta_2w)\,\partial^2-2w(\theta_1\partial_2-\theta_2\partial_1)\circ\partial+U,$$

where U is an operator of the same type as those used in this work. Now, while the first part can be easily transformed into ∂^2 via the change of coordinates $x\mapsto y-g(y)\,\theta_1\theta_2$, with $g=2/3u'$, the second term only changes by the determinant of the transformation of the odd parameters, and thus cannot in general disappear.

Remark 3: On the other hand, our approach could be modified to include even operators of this type by allowing extensions of the form

$$L_{U,V}=\partial^2+U+V\circ\partial.$$

However, the required calculations become much more involved: As an example, the third fractional power becomes in this case

$$(L_{U,V})_+^{3/2}=\partial^3+\tfrac{3}{2}\,U\circ\partial+\tfrac{3}{4}\,U'+(\tfrac{3}{4}\,V'+\tfrac{3}{8}\,V^2)\circ\partial-\tfrac{1}{4}\,(U\circ V+V\circ U)+\tfrac{1}{8}\,(V''+V^2);$$

so we will not pursue this line of study in this note.

We point out that in their work Laberge and Mathieu also considered extensions of the KdV that are bi-Hamiltonian, and their results imply that our equations do not posses this property in general.

Observe that the four equations in (5), (6) share the common property of having a part where no odd derivatives are involved; namely, the first two terms: For instance, for the first of the equations, this part is simply $u'''+3(uu)'=0$, which has exactly the form of the usual KdV (although recall that u is here in general a superfunction); indeed, modulo a change of variables, the reduced part of this equation is just the ordinary KdV.

This remark also gives the clue as to the construction of special solutions, with a nontrivial odd part, to these equations. Indeed, if we let $u=u(x-\theta_\nu\delta^\nu;\tau)$, where τ is an even parameter, and the δ^ν are odd parameters,[15] and set $u^\nu=\delta^\nu\,\dot{u}$, $u^{12}=\delta^1\delta^2\,\ddot{u}$, where a dot means the derivative with respect to the even parameter τ, then if we calculate the Taylor expansion of u we get

$$u(x-\theta_\nu\delta^\nu)=u(x)-\theta_\nu\delta^\nu u'(x)+\theta_1\theta_2\delta^1\delta^2u''(x);$$

then, since $u_\mu=\partial_\mu u=-\delta^\mu u'$, every term involving odd derivatives vanishes. A straightforward computation then shows that every solution of $u'''+3(uu)'=0$ solves the whole set of equations. Since the classical theory of elliptic functions tells us that the solutions to the reduced equation are given in terms of the elliptic function of Weierstrass, $\wp$, it is not surprising that solutions to this system are given by setting $u=-2\wp(x-\theta_\nu\delta^\nu;\tau)$.

For arbitrary N, the equations become rather cumbersome; nevertheless, the core of this argument remains true: for instance for $N=3$, assuming now $u=u(x-\theta_\mu\delta^\mu;\tau)$, and $u^\nu=\delta^\nu\dot{u}$, $u^{\mu\nu}=\delta^\mu\delta^\nu\ddot{u}$, $u^{123}=\delta^1\delta^2\delta^3\dddot{u}$, the super KdV [equation (4)] reduces to

$$u'''+3(uu)'=0;\quad u'''+6(u\dot{u})'=0,$$

$$\ddot{u}'''+6(u\ddot{u}+\dot{u}\dot{u})'=0;\quad \dddot{u}'''+6(u\dddot{u}+3\dot{u}\ddot{u})'=0,$$

and again, the first equation implies the remaining ones. Therefore, a solution is obtained by setting $u=-2\wp(x-\theta_\mu\delta^\mu;\tau)$, as before, and this assertion holds for general N.

III. THE AKHIEZER–BAKER FUNCTION AND SUPERELLIPTIC FUNCTIONS

In the classical case, the systematic construction of commuting operators may be achieved by use of the so-called Akhiezer–Baker functions. This construction also carries over to the super case.

The basic idea is to bring the operator L to a ''standard form'' which, for a second order operator such as Schrödinger's operator L, is ∂^2. This is possible because L is already in normal form (meaning no first order term appears), and is done by conjugating L with a so-called dressing operator Γ, defined by the condition

$$\Gamma\circ\partial\circ\Gamma^{-1}=L^{1/2},$$

from which immediately follows $\Gamma\circ\partial^k\circ\Gamma^{-1}=L^{k/2}$ for all k. It is also not difficult to show that

$$\Gamma=\left(1+\sum_{i\geqslant 1}V_i\circ\partial^{-i}\right).$$

In general, dressing operators are unique modulo monic operators (i.e., with leading coefficient 1) with constant coefficients.

This construction gives isospectral deformations of $L^{k/2}$, meaning that the spectra of the conjugated operators are the same; in particular, the eigenfunctions of each operator are bijectively mapped onto those of the other.

In particular, since the eigenfunctions of ∂ are simply exponentials, this can be explicitly achieved by the Akhiezer–Baker function, defined by a condition of the type $W=\Gamma e^{\xi}$, as follows.

Fix the parameters τ and δ^{ν}, and consider Schrödinger's operator $L=L_U$, as introduced in the previous section; then set $\xi=\kappa x+\theta_{\nu}\delta^{\nu}$, where κ is a complex parameter. Then, the Akhiezer–Baker function defined in the above way does indeed give the eigenfunctions of any of the even operators $L^{k/2}$ commuting with L, because of the relation

$$L^{k/2}W=\Gamma\circ\partial^{k}\circ\Gamma^{-1}\circ\Gamma e^{\xi}=\kappa^{k}\Gamma e^{\xi}=\kappa^{k}W.$$

Furthermore, it is well known in the cases $N=1$ and $N=2$ that Akhiezer–Baker functions are closely related to line bundles over superelliptic Riemann surfaces; this explains the occurrence within the theory of (super)elliptic functions. As we have seen, the condition for commutativity of L and $L_{+}^{3/2}$ shows this is also true in this N-extended case: roughly speaking, the parameters τ and δ^{ν} define a supertorus as a quotient of our base supermanifold, $\mathbb{C}^{1,N}$, by the transformations

$$x\mapsto x+1;\theta_{\nu}\mapsto\theta_{\nu},$$

$$x\mapsto x+\tau+\theta_{\nu}\delta^{\nu};\theta_{\nu}\mapsto\theta_{\nu}+\delta^{\nu};$$

the Akhiezer–Baker function then appears as the transition function of a line bundle from the chart about the point at infinity to the other chart required to cover the underlying elliptic curve (see, e.g., Rabin[13] for a very clear and detailed account of this for the case $N=1$); we now further discuss these facts.

First of all, recall the definition of the super Weierstrass function.[11,12] It is clear that for the case of N odd parameters it should be defined by

$$\mathscr{R}(x,\tau,\theta,\delta)=\wp\left(x,\tau+\frac{1}{2\pi i}(\theta_{\nu}\delta^{\nu})\right), \tag{7}$$

where $\wp$ denotes the classical Weierstrass elliptic function; again by computing its Taylor expansion one readily finds the explicit expression

$$\mathscr{R}=\wp+\frac{1}{2\pi i}\theta_{\nu}\delta^{\nu}\dot{\wp}+\frac{1}{2!}\left(\frac{1}{2\pi i}\theta_{\nu}\delta^{\nu}\right)^{2}\ddot{\wp}+\frac{1}{3!}\left(\frac{1}{2\pi i}\theta_{\nu}\delta^{\nu}\right)^{3}\dddot{\wp}+\frac{1}{4!}\left(\frac{1}{2\pi i}\theta_{\nu}\delta^{\nu}\right)^{4}\ddddot{\wp}\ldots, \tag{8}$$

where again a dot means derivative with respect to the modular parameter τ, and the terms run up to N-th order derivatives.

The superelliptic function $\mathscr{R}$ gives in fact the eigenvalue of L associated to W. To see this, set $W=e^{\xi}(1+\Sigma_{i\geqslant 1}a_i\kappa^{-i})$, and define $h(\kappa)=\mathscr{R}(1/\kappa)$; then one calculates on the one hand that $V_i(e^{\xi})=e^{\xi}a_i$, and $2V_1'+U=0$, and

$$\partial^{2}W=e^{\xi}(\kappa^{2}+a_1\kappa+a_2++2a_1'+O(\kappa^{-1})),$$

where $O(\kappa^{-1})$ means only negative powers of κ appear, and also

$$UW=U(e^{\xi})+O(\kappa^{-1})=-2V_1'(e^{\xi}+O(\kappa^{-1}));$$

and on the other,

$$hW=e^{\xi}(\kappa^{2}+a_1\kappa+a_2+O(\kappa^{-1})),$$

so we get

$$LW = hW + e^{\xi} O(\kappa^{-1}).$$

Hence, because the orders of the zeroes of both sections, LW and hW, are the same, and furthermore, they differ only by terms ''analytic at infinity,'' we can conclude that written in the chart where W describes the transition function of the bundle, h does indeed describe the eigenvalue of W.

(Also observe that $\mathscr{R}$ has a second order pole, and is associated to a second order differential operator; as in the classical theory, since $\partial e^{\xi} = \kappa e^{\xi}$, this fact clearly holds in general: Under the substitution $x \mapsto \kappa = x^{-1}$, a function having a single pole of order k will be associated to an operator also of order k.)

Now, just as in the purely bosonic, nongraded case, besides $\mathscr{R}$, its derivative $\mathscr{R}'$, which has a pole of order 3, is another generator of the even superelliptic functions; and this explains why one is interested in $L_+^{3/2}$. Furthermore, these are all the even generators needed; this is because every superelliptic function should have an elliptic function as its reduction (i.e., its body); since these are generated by $\wp$ and $\wp'$, by a suitable rational transformation, an even superelliptic function with a nontrivial body must differ from either $\mathscr{R}$ or $\mathscr{R}'$ only by higher order nilpotent terms; these can then be modified by coordinate changes to bring the superelliptic function to one of these standard forms.

For our purposes, an important feature of the superelliptic functions is that, as was the case for the coefficients of U;[16] they depend upon the odd parameters only through the combination $(1/2\pi i)(\theta_\nu \delta^\nu)$ [something we already used; cf. equation (7)], and in fact, the factor $1/2\pi i$, which is important for the geometric reasons we have described, may be ignored; roughly speaking, this amounts to work ''upstairs'' on the covering space $\mathbb{C}^{1,N}$. This is in fact essentially what we did in section II, and to simplify the writing, we will also assume this in what follows, and hence that superelliptic functions depend upon θ and δ through the combination $\theta_\nu \delta^\nu$.

Now, besides these even generators, the ring of superfunctions holomorphic off infinity must contain enough odd generators; these may be constructed from the odd superfunctions,

$$\sigma_\nu(x, \tau; \theta_\nu, \delta^\nu) = \delta^\nu (1 + \log \Theta(x, \tau))',$$

where Θ is an ordinary theta function, since the transformation: $\theta_\nu \mapsto \theta_\nu + \sigma_\nu$ is a valid change of the odd generators of the algebra $\mathscr{A}$ [this follows from the fact that $(\log \Theta(x,\tau))'$ only vanishes at the lattice points].

IV. THE FULL RING OF COMMUTATIVE SUPEROPERATORS

Taking all of the above into account, we are now in a position to explicitly construct the ring of differential operators commuting with Schrödinger's operator $L = L_U$. Since we already know the even generators, it remains essentially to determine the odd operators. From our discussion on superelliptic functions, it is clear that we should consider as candidates those associated with the odd superfunctions σ_ν. Let us now carry out the necessary calculations, fixing as above a super Weierstrass function determined by the modular parameters τ and δ, i.e., fixing a supertorus.

First of all, let us verify that indeed $\mathscr{R}'$ is associated to $L_+^{3/2}$. As before, define $g(\kappa) = \mathscr{R}'(\kappa^{-1})$, and let us compute gW and $L_+^{3/2} W$: Then one has

$$gW = e^{\xi}(\kappa^3 + a_1 \kappa^2 + a_2 \kappa + a_3 + O(\kappa^{-1})),$$

and, since one also has the relation $V_1'' + 2V_2' + U \circ V_1 = 0$, and therefore

$$\partial^3 W = e^{\xi}(\kappa^3 + a_1 \kappa^2 + a_2 \kappa + a_3 + 3(a_1' \kappa + a_1'' + a_2') + O(\kappa^{-1})),$$

$$(U \circ \partial) W = U(\partial e^{\xi}) + U(a_1 e^{\xi}) + e^{\xi} O(\kappa^{-1}) = e^{\xi}(-2a_1' \kappa - a_1'' - 2a_2' + O(\kappa^{-1})),$$

$$U' W = e^{\xi}(-2a_1'' + O(\kappa^{-1}));$$

by combining all these equations we get

$$L_+^{3/2} W = gW + O(\kappa^{-1}),$$

as desired.

Next, we define $h_\nu(\kappa)=\sigma_\nu(\kappa^{-1})$, and we need to show that these give the eigenvalues of the first order operators $D_\nu=\partial_\nu+\delta^\nu\partial$. But, since we can write $W=e^\xi g$, we get

$$(\partial_\nu+\delta^\nu\partial)W=\delta^\nu\left(1+\kappa+\frac{g'}{g}\right)W.$$

Now, since $g=1+\Sigma a_i\kappa^{-i}$, g'/g may be written as

$$\frac{g'}{g}=\frac{b_1}{\kappa}+\frac{b_2}{\kappa^2}+\frac{b_3}{\kappa^3}+\ldots,$$

with $b_1=a_1'$, $b_2=a_2-(a_1^2)'$, etc. Since also

$$(\log\Theta)'\left(\frac{1}{\kappa}\right)=\kappa+\frac{r_1}{\kappa}+\frac{r_2}{\kappa^2}+\ldots,$$

we can rewrite

$$1+\kappa+\frac{g'}{g}=1+(\log\Theta)'\left(\frac{1}{\kappa}\right)+O\left(\frac{1}{\kappa}\right),$$

and so

$$(\partial_\nu+\delta^\nu\partial)W=h_\nu W+e^\xi O\left(\frac{1}{\kappa}\right).$$

In this case it is equally easy to directly compute the conditions for D_ν to commute with L, and $L_+^{3/2}$; indeed, they are

$$[L,D_\nu]=[U,D_\nu]=-(U_\nu+\delta^\nu U')$$

and

$$[L_+^{3/2},D_\nu]=-\left(\frac{3}{2}\right)(U_\nu+\delta^\nu U')\circ\partial-\left(\frac{3}{4}\right)(U_\nu+\delta^\nu U')'.$$

Now, for our fixed supertorus, and from the fact that the potential U only depends upon $x-\theta_\nu\delta^\nu$, the vanishing of $U_\nu+\delta^\nu U'$ follows immediately.

To conclude, let us gather our results as a theorem.

Theorem 1: *For each N, a solution to the stationary super KdV equation, equation (4), is given in terms of elliptic functions by setting $U=u+u^\nu\partial_\nu+u^{\mu\nu}\partial_{\mu\nu}+\ldots$, where*

$$u=-2\wp(x-\theta_\mu\delta^\mu;\tau);\quad u^\mu=\delta^\mu u;\quad u^{\mu\nu}=\delta^\mu\delta^\nu\ddot{u},\ \textit{etc.}$$

Furthermore, a complete ring of even and odd superoperators, commuting with the associated Schrödinger operator $L=L_U=\partial^2+U$, is generated by

$$L;\quad L_+^{3/2};\quad D_\nu=\partial_\nu+\delta^\nu\partial,\quad \nu=1,\ldots,N.$$

Via the super Akhiezer–Baker function, $W=e^\xi(1+\Sigma_{i\geqslant 1}a_i\kappa^{-1})$, these are associated to the superelliptic functions $\mathscr{R},\mathscr{R}'$, σ_ν, where

$$\sigma_\nu=\delta^\nu(1+\log\Theta(x,\tau))'.$$

V. DISCUSSION

In this work we introduced, for arbitrary n, an N-extended supersymmetric extension of the theory of Burchnall and Chaundy in the elliptic case, obtaining the full $\mathbb{Z}_2$-graded ring of super-

differential operators commuting with the associated Schrödinger operator. The key step in the explicit construction of the ring is the introduction of a general bosonic Akhiezer–Baker function, which clearly displays the required generators as superelliptic functions; and, in spite of the generality of the setting, it was a pleasant outcome that the resulting equations and operators, and in particular the fermionic generators of the ring of operators, have a particularly simple form. This is witnessed by the example of the conditions for the commutativity of L and $L_+^{3/2}$ obtained for the case $N=2$, extending the original equations of Burchnall and Chaundy[1] ($N=0$), and also those of Manin–Radul,[6] and Mulase[9] and Rabin[11] ($N=1$).

Nevertheless, many aspects of these extensions remain to be studied. For instance, the original problem of Burchnall and Chaundy of writing algebraic expressions for a general pair of commuting operators is still open in the super case.

Another interesting point would be the analysis of the representation given by these operators. Also, it would certainly be interesting to carry out a detailed study of the N-extended superelliptic curves associated to the extension, as is done for the case $N=1$, in Rabin.[13] Furthermore, a Krichever functor[17] should be constructed for this case.

We hope to tackle these geometrical aspects in forthcoming works, but we would like to point out here that, on the other hand, by varying N, we have also embedded the KdV equation in a new ''hierarchy'' of equations, and we think it would be interesting to study the properties of this hierarchy and understand the possible geometrical consequences of this embedding. Furthermore (although this is just speculative) since we have been dealing here with an arbitrary number of odd coordinates, we find it tempting to think that there may be a link between this hierarchy, and the program set forth by Manin,[18] whose purpose is to obtain even geometry as ''a collective effect of odd geometry in an ∞-dimensional odd geometry.''

(Received 27 January 1998; accepted for publication 6 April 1998)

We give a matrix formulation of the Hamiltonian structures of constrained KP hierarchy. First, we derive from the matrix formulation the Hamiltonian structure of the one-constraint KP hierarchy, which was originally obtained by Oevel and Strampp. We then generalize the derivation to the multiconstraint case and show that the resulting bracket is actually the second Gelfand–Dickey bracket associated with the corresponding Lax operator. The matrix formulation of the Hamiltonian structure of the one-constraint KP hierarchy in the form introduced in the study of matrix model is also discussed. © *1998 American Institute of Physics.* [S0022-2488(98)01207-9]

I. INTRODUCTION

The Gelfand–Dickey (GD) hierarchy is defined by[1]

$$l_n=\partial^n+u_{n-1}\partial^{n-1}+\cdots+u_0, \tag{1.1}$$

which satisfies the hierarchy equations

$$\frac{\partial l_n}{\partial t_k}=[(l_n)_+^{k/n},l_n]. \tag{1.2}$$

Here $A_\pm$ denote the differential part and the integral part of the pseudodifferential operator A. The second Hamiltonian structure of (1.1) is described by the GD bracket which in operator form can be written as

$$\begin{aligned}\Theta_2^{\mathrm{GD}}\left(\frac{\delta H}{\delta l_n}\right)&\equiv\{l_n,H\}\equiv\{u_{n-1},H\}\partial^{n-1}+\{u_{n-2},H\}\partial^{n-2}+\cdots+\{u_0,H\}\\&=\left(l_n\frac{\delta H}{\delta l_n}\right)_+l_n-l_n\left(\frac{\delta H}{\delta l_n}l_n\right)_+,\end{aligned} \tag{1.3}$$

where

$$\frac{\delta H}{\delta l_n}\equiv\partial^{-1}\frac{\delta H}{\delta u_0}+\cdots+\partial^{-n}\frac{\delta H}{\delta u_{n-1}}. \tag{1.4}$$

Note that, from (1.2), the equation for u_1 is trivial; thus we can set $u_1=0$. However, imposing such a constraint leads to a modification of the GD bracket (1.3) due to the Dirac reduction. The modified bracket is found to be

[b)]Electronic mail address: shaw@math.nctu.edu.tw
[c)]Electronic mail address: mhtu@phys.nthu.edu.tw

 © 1998 American Institute of Physics

$$\overline{\Theta}_2^{\mathrm{GD}}\left(\frac{\delta H}{\delta l_n}\right)=\left(l_n\frac{\delta H}{\delta l_n}\right)_+ l_n-l_n\left(\frac{\delta H}{\delta l_n}l_n\right)_++\frac{1}{n}\left[l_n,\int^x \mathrm{res}\left[l_n,\frac{\delta H}{\delta l_n}\right]\right] \tag{1.5}$$

where u_1 in l_n and in $\delta H/\delta l_n$ are both set to zero and $\mathrm{res}(\Sigma_i a_i\partial^i)\equiv a_{-1}$.

The above description of the GD hierarchy relied on the use of fractional-power pseudodifferential operators[2] associated with the scalar Lax operator l_n. However, one can put the formalism on a more general setting by considering the GD hierarchy as a reduction of a system of n first-order equations. Following Dickey,[3] one can substitute for the scalar Lax operator l_n a $n\times n$ first-order differential operator,

$$\mathscr{L}=I\partial+U,\quad \partial\equiv\partial/\partial x, \tag{1.6}$$

$$U=\begin{pmatrix} 0 & -1 & 0 & \cdots & \cdots \\ \cdots & \cdots & -1 & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots & 0 \\ \cdots & \cdots & \cdots & 0 & -1 \\ u_0 & u_1 & \cdots & \cdots & u_{n-1} \end{pmatrix}. \tag{1.7}$$

This is the basis of the extension to the more general situation when the matrix U belongs to a semisimple Lie algebra, a task that was accomplished by Drinfeld and Sokolov.[4] Using matrix notation, the hierarchy equations (1.2) can be expressed as

$$\partial_t\mathscr{L}=[Q,\mathscr{L}], \tag{1.8}$$

where Q is another $n\times n$ matrix which cannot be arbitrarily chosen. We have to choose properly the matrix Q such that $[Q,\mathscr{L}]$ is consistent with the form of $\partial_t\mathscr{L}$. In fact, in view of (1.8), if the last column of Q is given then the rest of the elements of Q can be fixed. Following this strategy, it has been shown[3] that the Hamiltonian structure of the GD hierarchy can be extracted from (1.8) and turns out to be the GD bracket (1.3).

Recently, there has been much interest in the so-called constrained KP hierarchy[5–13] which has a pseudodifferential Lax operator of the form

$$L_{(n,m)}=\partial^n+u_{n-1}\partial^{n-1}+\cdots+u_0+\sum_{k=1}^{m}\phi_k\partial^{-1}\psi_k, \tag{1.9}$$

and satisfies the evolution equation

$$\frac{\partial L_{(n,m)}}{\partial t_k}=[(L_{(n,m)})_+^{k/n},L_{(n,m)}]. \tag{1.10}$$

From (1.10), it can be shown that each ϕ_i (each ψ_i) is an eigenfunction (adjoint eigenfunction) of the constrained KP hierarchy, i.e.,

$$\frac{\partial\phi_i}{\partial t_k}=((L_{(n,m)})_+^{k/n}\phi_i),\quad \frac{\partial\psi_i}{\partial t_k}=-((L^*_{(n,m)})_+^{k/n}\psi_i). \tag{1.11}$$

The bi-Hamiltonian structure of (1.10) has been constructed by Oevel and Strampp[8] (see also Ref. 9). The matrix formulation of the cKP hierarchy and its Hamiltonian structure have been discussed in Refs. 13 and 14. In contrast to the affine Lie algebraic approach,[13,14] in this paper we shall follow Dickey's approach[3] to give an elementary derivation of the Hamiltonian structure associated with the Lax operator $L_{(n,m)}$. In our approach, the Hamiltonian structures obtained by Oevel and Strampp[8] come out quite naturally. Since the first Hamiltonian structure can be obtained from the second Hamiltonian structure by replacing the Lax operator $L_{(n,m)}$ by $L_{(n,m)}+\lambda$, where λ is called the spectral parameter, we shall focus only on the second structure.

Our paper is organized as follows: In Sec. II, we follow the approach close to that of Ref. 3 to build up the matrix equation (1.8) associated with the Lax operator $L_{(n,1)}$ and then derive the Hamiltonian structure which was obtained by Oevel and Strampp. In Sec. III, we generalize this formulation to the Lax operator $L_{(n,m)}$ and obtain its Hamiltonian structure. We further show that this Hamiltonian structure is, in fact, the GD bracket (1.3) defined by the Lax operator $L_{(n,m)}$. In Sec. IV, we work out a few simple examples explicitly. Concluding remarks are presented in Sec. V.

II. MATRIX FORMULATION OF THE OEVEL AND STRAMPP HAMILTONIAN STRUCTURE

Now we consider the matrix formulation corresponding to the Lax operator for the one-constraint KP hierarchy,

$$L_{(n,1)}=\partial^n+u_{n-1}\partial^{n-1}+\cdots+u_0+\phi\partial^{-1}\psi. \tag{2.1}$$

A matrix representation can be easily found by expressing the constraint equation $L_{(n,1)}\varphi=0$ in a matrix form as $\mathscr{L}_{(n,1)}\Phi=0$, where $\mathscr{L}_{(n,1)}$ is a square matrix and Φ is a column matrix. An ansatz is given by

$$\mathscr{L}_{(n,1)}=I\partial+U, \quad \partial\equiv\partial/\partial x, \tag{2.2}$$

$$U=\begin{pmatrix} 0 & -\psi & 0 & 0 & \cdots & 0 \\ \cdots & 0 & -1 & 0 & \cdots & \cdots \\ \cdots & \cdots & \cdots & -1 & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & 0 & -1 \\ \phi & u_0 & u_1 & \cdots & \cdots & u_{n-1} \end{pmatrix}, \tag{2.3}$$

where U is an $(n+1)\times(n+1)$ matrix and the numeration of rows and columns will be $i,j=-1,0,1,2,\ldots,n-1$.

We introduce another $(n+1)\times(n+1)$ matrix Q and ask the commutator $[Q,\mathscr{L}_{(n,1)}]\equiv N$ to be consistent with the form of $\partial_t\mathscr{L}_{(n,1)}$. Let us now compute the matrix elements of the commutator: (1) $i=-1$, or $j=-1$,

$$N_{-1,-1}=-Q'_{-1,-1}+\phi Q_{-1,n-1}+\psi Q_{0,-1}, \tag{2.4}$$

$$N_{-1,i}=-Q'_{-1,i}-\epsilon_i Q_{-1,i-1}+\psi Q_{0,i}+u_i Q_{-1,n-1} \quad (\epsilon_0=\psi,\epsilon_1=\cdots=\epsilon_{n-2}=1), \tag{2.5}$$

$$N_{i,-1}=-Q'_{i,-1}+\phi Q_{i,n-1}+Q_{i+1,-1} \quad (i=0,1,2,\ldots,n-2), \tag{2.6}$$

$$N_{n-1,-1}=-Q'_{n-1,-1}+\phi Q_{n-1,n-1}-\phi Q_{-1,-1}-\sum_{j=0}^{n-1} u_j Q_{j,-1}; \tag{2.7}$$

(2) $i\neq-1$ and $j\neq-1$,

$$N_{i,0}=-Q'_{i,0}-\psi Q_{i,-1}+u_0 Q_{i,n-1}+Q_{i+1,0}, \tag{2.8}$$

$$N_{n-1,0}=-Q'_{n-1,0}-\psi Q_{n-1,-1}+u_0 Q_{n-1,n-1}-\phi Q_{-1,0}-\sum_{j=0}^{n-1} u_j Q_{j,0}, \tag{2.9}$$

$$N_{i,j}=-Q'_{i,j}-Q_{i,j-1}+u_j Q_{i,n-1}+Q_{i+1,j}, \tag{2.10}$$

$$N_{n-1,j}=-Q'_{n-1,j}-Q_{n-1,j-1}+u_j Q_{n-1,n-1}-\phi Q_{-1,j}-\sum_{k=0}^{n-1} u_k Q_{k,j}, \tag{2.11}$$

where $i=0,1,...,\ n-2$ and $j=1,2,...,n-2$.

In order to make N of the form $\partial_t \mathscr{L}_{(n,1)}$, we write $N=\delta\mathscr{L}_{(n,1)}$; i.e.,

$$N_{-1,0}=-\delta\psi, \tag{2.12}$$

$$N_{n-1,-1}=\delta\phi, \tag{2.13}$$

$$N_{n-1,j}=\delta u_j \quad (j=0,1,...,n-1), \tag{2.14}$$

and $N_{i,j}=0$ for other (i,j). In the matrix formulation the equation $\delta\mathscr{L}_{(n,1)}=[Q,\mathscr{L}_{(n,1)}]$ would serve as a definition of the Hamiltonian structure. In other words, $\delta\psi$, $\delta\phi$, and δu_j are to be identified as $\{\psi,H\}$, $\{\phi,H\}$, and $\{u_j,H\}$, respectively. Of course, certain matrix elements of Q must be identified as the components of the gradient of H. However, we shall do such an identification later.

We shall see that one can solve $Q_{i,j}$ in terms of $Q_{0,-1}$ and $Q_{i,n-1}$ $(i=-1,0,...,n-1)$. To this end we introduce

$$\hat{Q}_i\equiv\sum_{k=0}^{n-1} Q_{ik}\partial^k, \quad \hat{Q}^j\equiv\sum_{k=0}^{n-1}\partial^{-1-k}Q_{kj}, \tag{2.15}$$

$$\hat{N}_i\equiv\sum_{k=0}^{n-1} N_{ik}\partial^k; \tag{2.16}$$

then (2.8) and (2.10) are equivalent to

$$\hat{N}_i=-\partial\hat{Q}_i-\psi Q_{i,-1}+\hat{Q}_{i+1}+Q_{i,n-1}(L_{(n,1)})_+ \quad (i=0,1,...,n-2), \tag{2.17}$$

while (2.9) and (2.11) give

$$\hat{N}_{n-1}=-\partial\hat{Q}_{n-1}-\psi Q_{n-1,-1}-\phi\hat{Q}_{-1}+Q_{n-1,n-1}(L_{(n,1)})_+-\sum_{k=0}^{n-1} u_k\hat{Q}_k. \tag{2.18}$$

Since $\hat{N}_i=0$ $(i=0,1,...,n-2)$ we deduce a recursion relation for $\hat{Q}_i$ from (2.17),

$$\hat{Q}_{i+1}=\partial\hat{Q}_i-Q_{i,n-1}(L_{(n,1)})_+ +\psi Q_{i,-1} \quad (i=0,1,...,n-2). \tag{2.19}$$

Define

$$\hat{Q}_n\equiv-\sum_{k=0}^{n-1} u_k\hat{Q}_k-\hat{N}_{n-1}-\phi\hat{Q}_{-1}. \tag{2.20}$$

Then (2.19) also holds for $i=n-1$. Using the fact that $\hat{Q}_n$ is a pure differential operator we can solve (2.19) recursively to express $\hat{Q}_i$ in terms of $\hat{Q}^{n-1}$ and $\hat{Q}^{-1}$. The results are (see Appendix A for a proof)

$$\hat{Q}_0=(X(L_{(n,1)})_+)_+=(XL_{(n,1)})_+, \tag{2.21}$$

$$\hat{Q}_i=\partial^i(XL_{(n,1)})_+-(\partial^i X)_+(L_{(n,1)})_+ +(\partial^i\hat{Q}^{-1})_+\psi, \tag{2.22}$$

where we have defined $X\equiv\Sigma_{k=0}^{n-1}\partial^{-1-k}Q_{k,n-1}=\hat{Q}^{n-1}$.

Now from (2.20) we get

$$\hat{N}_{n-1} = -\partial^n (XL_{(n,1)})_+ + (\partial^n X)_+ (L_{(n,1)})_+ - (\partial^n \hat{Q}^{-1})_+ \psi - \phi \hat{Q}_{-1} - \sum_{k=0}^{n-1} u_k [\partial^k (XL_{(n,1)})_+ - (\partial^k X)_+ + (\partial^k \hat{Q}^{-1})_+ \psi]$$

$$= -(L_{(n,1)})_+ (XL_{(n,1)})_+ + (L_{(n,1)}X)_+ (L_{(n,1)})_+ - (L_{(n,1)}\hat{Q}^{-1})_+ \psi - \phi \hat{Q}_{-1}. \quad (2.23)$$

In view of $\delta u_j = N_{n-1,j}$ we have

$$\delta (L_{(n,1)})_+ = (L_{(n,1)}X)_+ (L_{(n,1)})_+ - (L_{(n,1)})_+ (XL_{(n,1)})_+ - (L_{(n,1)}\hat{Q}^{-1})_+ \psi - \phi \hat{Q}_{-1}. \quad (2.24)$$

It remains to characterize $\hat{Q}_{-1}$ and $\hat{Q}^{-1}$. Since $N_{i,-1} = 0$ $(i = -1,0,...,n-2)$, (2.4) and (2.6) give

$$Q_{-1,-1} = \int^x (\phi Q_{-1,n-1} + \psi Q_{0,-1}), \quad (2.25)$$

$$Q_{i+1,-1} = Q'_{i,-1} - \phi Q_{i,n-1} \quad (i = 0,1,...,n-2). \quad (2.26)$$

If we define

$$Q_{n,-1} \equiv -\phi Q_{-1,-1} - \sum_{k=0}^{n-1} u_k Q_{k,-1} - N_{n-1,-1}, \quad (2.27)$$

(2.7) becomes (2.26) with $i = n-1$. Combining (2.26) with (2.5) we find (see Appendix B)

$$\hat{Q}^{-1} = [(Q_{0,-1} - X\phi)\partial^{-1}]_{\geqslant -n}, \quad (2.28)$$

$$\hat{Q}_{-1} = (\hat{Q}_{-1})_+ = (\partial^{-1}\psi (XL_{(n,1)})_+ + \partial^{-1} Q_{-1,n-1} L_{(n,1)})_+. \quad (2.29)$$

Now putting, (2.28) and (2.29) into (2.24), we obtain

$$\delta (L_{(n,1)})_+ = (L_{(n,1)}X)_+ (L_{(n,1)})_+ - (L_{(n,1)})_+ (XL_{(n,1)})_+ - [L_{(n,1)}(Q_{0,-1} - X\phi)\partial^{-1}]_+ \psi - \phi(\partial^{-1}\psi (XL_{(n,1)})_+ + \partial^{-1} Q_{-1,n-1} L_{(n,1)})_+. \quad (2.30)$$

We observe that if we identify

$$X = \frac{\delta H}{\delta (L_{(n,1)})_+} = \partial^{-1} \frac{\delta H}{\delta u_0} + \cdots + \partial^{-n} \frac{\delta H}{\delta u_{n-1}},$$

$$Q_{-1,n-1} = \frac{\delta H}{\delta \phi}, \quad Q_{0,-1} = -\frac{\delta H}{\delta \psi}, \quad (2.31)$$

then (2.30) becomes

$$\delta (L_{(n,1)})_+ = (L_{(n,1)}X)_+ (L_{(n,1)})_+ - (L_{(n,1)})_+ (XL_{(n,1)})_+ + \left[\left((L_{(n,1)}X)_+ \phi + L_{(n,1)} \frac{\delta H}{\delta \psi} \right) \partial^{-1} \psi \right]_+ - \left[\phi \partial^{-1} \psi (XL_{(n,1)})_+ + \phi \partial^{-1} \frac{\delta H}{\delta \phi} L_{(n,1)} \right]_+$$

$$= [(L_{(n,1)}X)_+ L_{(n,1)} - L_{(n,1)}(XL_{(n,1)})_+]_+ + \left[L_{(n,1)} \frac{\delta H}{\delta \psi} \partial^{-1} \psi - \phi \partial^{-1} \frac{\delta H}{\delta \phi} L_{(n,1)} \right]_+, \quad (2.32)$$

which is one of the Hamiltonian flow derived by Oevel and Strampp.[8]

The identification (2.31), which is a generalization of the one used for the GD hierarchy (1.2),[1] is motivated by the following relation:

$$\delta H=\int\left(\frac{\delta H}{\delta u_0}\,\delta u_0+\cdots+\frac{\delta H}{\delta u_{n-1}}\,\delta u_{n-1}+\frac{\delta H}{\delta\phi}\,\delta\phi+\frac{\delta H}{\delta\psi}\,\delta\psi\right)=\mathrm{Tr}(Q\,\delta\mathscr{L}_{(n,1)}),\tag{2.33}$$

where $\mathrm{Tr}(A)=\int\mathrm{tr}(A)$ and $\mathrm{tr}(A)$ denotes the ordinary trace of a square matrix. The relation (2.33) is actually quite common in the matrix formulation of an integrable hierarchy.[4] It is related to the fact that the operation $\mathrm{Tr}(A)$ provides a natural scalar product between the cotangent space (to which Q belongs) and the tangent space (to which $\delta\mathscr{L}_{(n,1)}$ belongs) of the phase space manifold. In the case of GD hierarchy, the identification of this sort can be derived from the associated linear system.[15] However, we have not devised a similar proof for the present case. Here, the validity of (2.31) will be simply justified by the final result.

Now we turn to $\delta\psi$ and $\delta\phi$. First we combine (2.5), (2.25), and (2.31) to get

$$\begin{aligned}\delta\psi&=-N_{-1,0}=Q'_{-1,0}-\psi Q_{0,0}-u_0Q_{-1,n-1}+\psi Q_{-1,-1}\\&=-((L_{(n,1)})^*_+Q_{-1,n-1}+\hat{Q}_0^*\psi)_0+\psi\int^x(\phi Q_{-1,n-1}+\psi Q_{0,-1})\\&=-((L_{(n,1)})^*X^*\psi)_0-\left((L_{(n,1)})^*\,\frac{\delta H}{\delta\phi}\right)_0+\psi\int^x\left(\phi\,\frac{\delta H}{\delta\phi}-\psi\,\frac{\delta H}{\delta\psi}\right).\end{aligned}\tag{2.34}$$

Next, we note that (2.7) and (2.13) together imply

$$\delta\phi=N_{n-1,-1}=-Q'_{n-1,-1}+\phi Q_{n-1,n-1}-\phi Q_{-1,-1}-\sum_{k=0}^{n-1}u_kQ_{k,-1}.\tag{2.35}$$

Using the following identities (which are proved in Appendix C):

$$Q_{j,-1}=[\partial^j(Q_{0,-1}-X\phi)]_0\quad(j=0,1,\ldots,n-1),\tag{2.36}$$

$$Q'_{n-1,-1}=[\partial^n(Q_{0,-1}-X\phi)]_0+\phi Q_{n-1,n-1},\tag{2.37}$$

and the identification (2.31), we rewrite (2.35) as

$$\begin{aligned}\delta\phi&=-[\partial^n(Q_{0,-1}-X\phi)]_0-\sum_{k=0}^{n-1}u_j[\partial^j(Q_{0,-1}-X\phi)]_0-\phi Q_{-1,-1}\\&=\left[(L_{(n,1)})_+\left(X\phi+\frac{\delta H}{\delta\psi}\right)\right]_0-\phi\int^x\left(\phi\,\frac{\delta H}{\delta\phi}-\psi\,\frac{\delta H}{\delta\psi}\right)\\&=(L_{(n,1)}X\phi)_0+\left(L_{(n,1)}\,\frac{\delta H}{\delta\psi}\right)_0-\phi\int^x\left(\phi\,\frac{\delta H}{\delta\phi}-\psi\,\frac{\delta H}{\delta\psi}\right).\end{aligned}\tag{2.38}$$

Once again, (2.34) and (2.38) agree with the Hamiltonian flows reported in Ref. 8.

In conclusion, we have shown that the bracket of Oevel and Strampp[8] comes out naturally from the matrix formulation (which, of course, is basically the AKNS scheme).

III. GENERALIZATIONS

Having derived the Hamiltonian structure of the one-constraint KP hierarchy from a matrix formulation, we now come to the multiconstraint case. The Lax operator for this case is defined by

$$L_{(n,m)}=\partial^n+u_{n-1}\partial^{n-1}+\cdots+u_0+\sum_{j=1}^{m}\phi_j\partial^{-1}\psi_j,\tag{3.1}$$

which has matrix representation of the form

$$\mathscr{L}_{(n,m)}=I\partial+U,\tag{3.2}$$

$$U=\begin{pmatrix} 0 & \cdots & 0 & -\psi_m & \cdots & \cdots & \cdots & 0 \\ & \ddots & \ddots & \vdots & & & & \\ & & 0 & -\psi_1 & & & & \\ & & & 0 & -1 & & & \\ & & & & \ddots & -1 & & \\ & & & & & \ddots & \ddots & \\ & & & & & & 0 & -1 \\ \phi_m & \cdots & \phi_1 & u_0 & u_1 & \cdots & \cdots & u_{n-1} \end{pmatrix}, \tag{3.3}$$

where U is a $(n+m)\times(n+m)$ matrix and the numeration of rows and columns will be $i,j=-m,-m+1,...,n-1$. Our matrix is connected by the Miura transformation, within the generalized Wilson–Drinfeld–Sokolov method, with the matrix used in Ref. 14. We also introduce another $(n+m)\times(n+m)$ matrix Q such that $[Q,\mathscr{L}_{(n,m)}]$ consistent with the form of $\delta\mathscr{L}_{(n,m)}$. We can compute the matrix elements $N_{ij}\equiv[Q,\mathscr{L}_{(n,m)}]_{ij}$ and make it of the form $\delta\mathscr{L}_{(n,m)}$. The result is the following: (1) $i<0$ or $j<0$,

$$\begin{aligned} N_{-\alpha,-\beta}&=-Q'_{-\alpha,-\beta}+\phi_\beta Q_{-\alpha,n-1}+\psi_\alpha Q_{0,-\beta}, \\ N_{-\alpha,0}&=-Q'_{-\alpha,0}+u_0 Q_{-\alpha,n-1}+\psi_\alpha Q_{0,0}-\sum_{k=1}^{m}\psi_k Q_{-\alpha,-k}, \\ N_{-\alpha,i}&=-Q'_{-\alpha,i}-Q_{-\alpha,i-1}+u_i Q_{-\alpha,n-1}+\psi_\alpha Q_{0,i} \quad (i=1,2,...,n-1), \\ N_{i,-\alpha}&=-Q'_{i,-\alpha}+\phi_\alpha Q_{i,n-1}+Q_{i+1,-\alpha} \quad (i=0,1,...,n-2), \\ N_{n-1,-\alpha}&=-Q'_{n-1,-\alpha}+\phi_\alpha Q_{n-1,n-1}-\sum_{k=1}^{m}\phi_k Q_{-k,-\alpha}-\sum_{k=0}^{n-1}u_k Q_{k,-\alpha}, \end{aligned} \tag{3.4}$$

where $\alpha,\beta=1,2,...,m$; (2) $i\geqslant 0$ and $j\geqslant 0$,

$$\begin{aligned} N_{i,0}&=-Q'_{i,0}+u_0 Q_{i,n-1}+Q_{i+1,0}-\sum_{k=1}^{m}\psi_k Q_{i,-k}, \quad (i=0,1,...,n-2), \\ N_{n-1,0}&=-Q'_{n-1,0}+u_0 Q_{n-1,n-1}-\sum_{k=1}^{m}\psi_k Q_{n-1,-k}-\sum_{k=1}^{m}\phi_k Q_{-k,0}-\sum_{k=0}^{n-1}u_k Q_{k,0}, \\ N_{i,j}&=-Q'_{i,j}-Q_{i,j-1}+u_j Q_{i,n-1}+Q_{i+1,j}, \quad -\begin{pmatrix} i=0,1,...,n-2 \\ j=1,2,...,n-1 \end{pmatrix} \\ N_{n-1,j}&=-Q'_{n-1,j}-Q_{n-1,j-1}+u_j Q_{n-1,n-1}-\sum_{k=1}^{m}\phi_k Q_{-k,j}-\sum_{k=0}^{n-1}Q_{k,j} \quad (j=1,2,...,n-1), \end{aligned} \tag{3.5}$$

with

$$\begin{aligned} &N_{-j,0}=-\delta\psi_j, \quad N_{n-1,-j}=\delta\phi_j, \quad j=1,2,...,m, \\ &N_{n-1,j}=\delta u_j, \quad j=0,1,...,n-1, \quad N_{i,j}=0, \quad \text{otherwise}. \end{aligned} \tag{3.6}$$

The definition of $\hat{Q}_i$, $\hat{Q}^i$, and $\hat{N}_i$ are still given by (2.15) and (2.16). Following the steps presented in the previous section and imposing the following identifications:

$$X \equiv \hat{Q}^{n-1} = \frac{\delta H}{\delta (L_{(n,m)})_+}, \quad Q_{-k,n-1} = \frac{\delta H}{\delta \phi_k},$$

$$Q_{0,-k} = -\frac{\delta H}{\delta \psi_k} \quad (k = 1,2,...,m), \tag{3.7}$$

we obtain, after performing a similar derivation the Hamiltonian structure associated with the Lax operator (3.1),

$$\delta (L_{(n,m)})_+ = [(L_{(n,m)} X)_+ L_{(n,m)} - L_{(n,m)} (X L_{(n,m)})_+]_+ + \sum_{k=1}^{m} \left[L_{(n,m)} \frac{\delta H}{\delta \psi_k} \partial^{-1} \psi_k - \phi_k \partial^{-1} \frac{\delta H}{\delta \phi_k} L_{(n,m)} \right]_+,$$

$$\delta \phi_j = (L_{(n,m)} X \phi_j)_0 + \left(L_{(n,m)} \frac{\delta H}{\delta \psi_j} \right)_0 - \sum_{k=1}^{m} \phi_k \int^x \left(\phi_j \frac{\delta H}{\delta \phi_k} - \psi_k \frac{\delta H}{\delta \psi_j} \right), \tag{3.8}$$

$$\delta \psi_j = -((L_{(n,m)})^* X^* \psi_j)_0 - \left((L_{(n,m)})^* \frac{\delta H}{\delta \phi_j} \right)_0 + \sum_{k=1}^{m} \psi_k \int^x \left(\phi_k \frac{\delta H}{\delta \phi_j} - \psi_j \frac{\delta H}{\delta \psi_k} \right).$$

We would like to remark that the Hamiltonian flow equations (3.8) are, in fact, coming from the second GD brackets defined by the Lax operator (3.1). To see this, let us denote $\delta H / \delta L_{(n,m)} = \delta H / \delta (L_{(n,m)})_+ + A$, where A is a differential operator. From the identity

$$\mathrm{tr}\left(\frac{\delta H}{\delta L_{(n,m)}} \delta L_{(n,m)} \right) = \mathrm{tr}\left(\frac{\delta H}{\delta (L_{(n,m)})_+} \delta (L_{(n,m)})_+ \right) + \sum_{j=1}^{m} \int \left(\frac{\delta H}{\delta \phi_j} \delta \phi_j + \frac{\delta H}{\delta \psi_j} \delta \psi_j \right), \tag{3.9}$$

we find that the differential operator A satisfies

$$(A \phi_j)_0 = \frac{\delta H}{\delta \psi_j}, \quad (A^* \psi_j)_0 = \frac{\delta H}{\delta \phi_j}. \tag{3.10}$$

Now, putting $L_{(n,m)}$ and $\delta H / \delta L_{(n,m)} = \delta H / \delta (L_{(n,m)})_+ + A$ into the second GD bracket (1.3) and using the relation (3.10), we obtain the Poisson brackets (3.8).

Note that when we set the next leading coefficient u_{n-1} to vanish we have to impose the constraint $\mathrm{res}[\delta H / \delta L_{(n,m)}, L_{(n,m)}] = 0$. Then the resulting bracket becomes the modified GD bracket (1.5) defined by $L_{(n,m)}$ with $u_{n-1} = 0$. From this modified bracket, it can be shown[16] that the Hamiltonian structures of the coupled AKNS hierarchy ($n = 1$, $m = 2$) and the coupled Yajima–Oikawa hierarchy[17] ($n = 2$, $m = 2$) come out as the special cases.

In the remaining part of this section, we would like to consider another reduction of the KP hierarchy, which has a Lax operator of the form

$$K = \partial^n + u_{n-1} \partial^{n-1} + \cdots + u_0 + a \frac{1}{\partial - s}. \tag{3.11}$$

Such a system was introduced in the study of the matrix model[18] and can be written in the form (2.1) if we equate with each other the integral parts of the two Lax operators:

$$\phi \partial^{-1} \psi = a \frac{1}{\partial - s}. \tag{3.12}$$

Then

$$a = \phi \psi, \quad s = -(\ln \psi)', \tag{3.13}$$

or, equivalently,

$$\phi = a e^{\int^x s}, \quad \psi = e^{-\int^x s}. \tag{3.14}$$

We can also formulate the Hamiltonian structure associated with K in matrix form by introducing

$$\mathscr{K} = \begin{pmatrix} \partial - s & -1 & 0 & 0 & \cdots & 0 \\ \cdots & \partial & -1 & 0 & \cdots & \cdots \\ \cdots & \cdots & \cdots & -1 & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \partial & -1 \\ a & u_0 & u_1 & \cdots & \cdots & \partial + u_{n-1} \end{pmatrix}, \tag{3.15}$$

and choosing an $(n+1)\times(n+1)$ matrix R such that $[R,\mathscr{K}]$ consistent with $\delta\mathscr{K}$.

After equating the matrix elements of $[R,\mathscr{K}]$ with the matrix elements of $\delta\mathscr{K}$:

$$\delta\mathscr{K}_{-1,-1} = -\delta s, \quad \delta\mathscr{K}_{n-1,-1} = \delta a, \tag{3.16}$$

$$\delta\mathscr{K}_{n-1,j} = \delta u_j \quad (j = 0,1,...,n-1), \quad \delta\mathscr{K}_{i,j} = 0, \quad \text{otherwise}, \tag{3.17}$$

we can solve R_{ij} in terms of $R_{-1,-1}$ and $R_{i,n-1}$ from the constraint equation (3.17). Thus, the remaining task is to identify $R_{-1,-1}$ and $R_{i,n-1}$. However, the following naive identifications:

$$R_{-1,-1} = -\frac{\delta H}{\delta s}, \tag{3.18}$$

$$R_{-1,n-1} = \frac{\delta H}{\delta a}, \tag{3.19}$$

$$R_{i,n-1} = \frac{\delta H}{\delta u_i} \quad (i = 0,1,...,n-1), \tag{3.20}$$

do not give us the correct Hamiltonian structure. To get correct identifications we note that Eq. (3.13) can be expressed as a matrix equation:

$$\mathscr{K} = \Psi^{-1}\mathscr{L}_{(n,1)}\Psi, \tag{3.21}$$

where the matrix Ψ is defined by

$$\begin{pmatrix} \psi & \cdots & \cdots & 0 \\ & 1 & & \\ & & \ddots & \\ 0 & \cdots & \cdots & 1 \end{pmatrix}. \tag{3.22}$$

From (3.21) and the Hamiltonian flow equation $\delta\mathscr{L}_{(n,1)} = [Q,\mathscr{L}_{(n,1)}]$, it is easy to show that $\delta\mathscr{K} = [-\Psi^{-1}\delta\Psi + \Psi^{-1}Q\Psi,\mathscr{K}]$. As a consequence, R is related to Q, determined in the previous section by

$$R = -\Psi^{-1}\delta\Psi + \Psi^{-1}Q\Psi. \tag{3.23}$$

From this relation we find that the correct identification of $R_{-1,-1}$ should be

$$R_{-1,-1} = -\frac{\delta H}{\delta s} + \partial_x^{-1}\delta s. \tag{3.24}$$

Substituting (3.19), (3.20), and (3.24) into the ''dynamical'' equations (3.16) involving δa, δs, and δL_+, we obtain the Hamiltonian structure,

$$\delta K_+ = (K_+X)_+K_+ - K_+(XK_+)_+ + \left[K_+\left(Xa + a\,\frac{\delta H}{\delta a} + \left(\frac{\delta H}{\delta s}\right)'\right)(\partial - s)^{-1}\right]_+ - a\left[(\partial - s)^{-1}\left(X + \frac{\delta H}{\delta a}\right)K_+\right]_+,$$

$$\delta a = \left[e^{-\int^x s}K_+\left(Xa + a\,\frac{\delta H}{\delta a} + \left(\frac{\delta H}{\delta s}\right)'\right)e^{\int^x s}\right]_0 - a\left[e^{\int^x s}K_+^*\left(X^* + \frac{\delta H}{\delta a}\right)e^{-\int^x s}\right]_0,$$

$$\delta s = \left(\frac{\delta H}{\delta s}\right)' + \left[e^{\int^x s}K_+^*\left(X^* + \frac{\delta H}{\delta a}\right)e^{-\int^x s}\right]_0', \tag{3.25}$$

where $X \equiv \delta H/\delta K_+$. One can show by explicit calculations that (3.25) is indeed the same as the second GD bracket defined by K.[15]

Rigorously to say, what we obtain here is not really a matrix formulation of the second Hamiltonian structure associated with K. This reason is that the identification of $R_{-1,-1}$, (3.24), contains the term $\partial_x^{-1}\delta s$ which can be determined only after δs is computed. In other words, R is not really the ''dual space'' of the matrix $\mathscr{K}$ (which contains all dynamical variables). The question of whether or not a matrix formulation for the second GD bracket defined by K remains open.

IV. EXAMPLES

In this section, we consider two explicit examples. The first is the cKP hierarchy associated with the Lax operator,

$$L_{(2,1)} = \partial^2 + u + \phi\partial^{-1}\psi. \tag{4.1}$$

It is easy to transform the corresponding eigenvalue equation $L_{(2,1)}\varphi = 0$ into a matrix form by taking

$$\mathscr{L}_{(2,1)} = \begin{pmatrix} \partial & -\psi & 0 \\ 0 & \partial & -1 \\ \phi & u & \partial \end{pmatrix}, \quad \Phi = \begin{pmatrix} \varphi_1 \\ \varphi_2 \\ \varphi_3 \end{pmatrix}. \tag{4.2}$$

Then $\mathscr{L}_{(2,1)}\Phi = 0$ implies

$$\varphi_1' - \psi\varphi_2 = 0, \tag{4.3}$$

$$\varphi_2' - \varphi_3 = 0, \tag{4.4}$$

$$\phi\varphi_1 + u\varphi_2 + \varphi_3' = 0. \tag{4.5}$$

Substitutions of (4.3) and (4.4) into (4.5) gives

$$(\partial^2 + u + \phi\partial^{-1}\psi)\varphi_2 = 0, \tag{4.6}$$

which is precisely $L_{(2,1)}\varphi = 0$ once $\varphi = \varphi_2$ is imposed.

To consider the Hamiltonian structure associated with $\mathscr{L}_{(2,1)}$, let us consider the associated Lax equation,

$$\partial_t\mathscr{L}_{(2,1)} = [\mathscr{M}, \mathscr{L}_{(2,1)}]. \tag{4.7}$$

It is necessary to solve the form of $\mathscr{M}$ to make the above equation consistent.

Writing

$$\mathscr{M}=\begin{pmatrix} a & b & c \\ d & e & f \\ g & h & -a-e \end{pmatrix}, \tag{4.8}$$

we have the following explicit expression for the commutator $[\mathscr{M},\mathscr{L}_{(2,1)}]$:

$$\mathscr{M}\mathscr{L}_{(2,1)}-\mathscr{L}_{(2,1)}\mathscr{M}=-\mathscr{M}' + \begin{pmatrix} c\phi+\psi d & -a\psi+cu+\psi e & -b+\psi f \\ f\phi+g & -d\psi+fu+h & -a-2e \\ -(2a+e)\phi-ud, & -g\psi-(a+2e)u-\phi b, & -h-c\phi-fu \end{pmatrix}. \tag{4.9}$$

Setting the matrix (4.9) equal to

$$\delta\mathscr{L}_{(2,1)}=\begin{pmatrix} 0 & -\delta\psi & 0 \\ 0 & 0 & 0 \\ \delta\phi & \delta u & 0 \end{pmatrix}, \tag{4.10}$$

we obtain five constraint equations,

$$\begin{gathered} -a'+c\phi+\psi d=0, \quad -c'-b+\psi f=0, \quad -d'+f\phi+g=0, \\ -e'-d\psi+fu+h=0, \quad -f'-2e-a=0. \end{gathered} \tag{4.11}$$

It is easy to see that a,b,e,g,h can be solved in terms of c,d,f and u,ϕ,ψ,

$$\begin{gathered} a=\partial^{-1}(c\phi+\psi d), \quad b=-c'+\psi f, \quad g=d'-f\phi, \\ e=-\tfrac{1}{2}(f'+\partial^{-1}(c\phi+\psi d)), \quad h=-\tfrac{1}{2}(f''+c\phi-d\psi)-fu. \end{gathered} \tag{4.12}$$

On the other hand, we have

$$\begin{aligned} \delta u&=-h'-g\psi-(a+2e)u-\phi b, \\ \delta\phi&=-g'-(2a+e)\phi-ud, \\ \delta\psi&=b'+(a-e)\psi-cu. \end{aligned} \tag{4.13}$$

Hence

$$\begin{aligned} \delta u&=(\tfrac{1}{2}\partial^3+\partial u+u\partial)f+\tfrac{1}{2}(\partial\phi+\phi\partial)c-\tfrac{1}{2}(\partial\psi+\psi\partial)d, \\ \delta\phi&=\tfrac{1}{2}(\partial\phi+\phi\partial)f-\tfrac{3}{2}(\phi\partial^{-1}\phi)c-(\partial^2+u+\tfrac{3}{2}\phi\partial^{-1}\psi)d, \\ \delta\psi&=\tfrac{1}{2}(\partial\psi+\psi\partial)f-(\partial^2+u-\tfrac{3}{2}\psi\partial^{-1}\phi)c+\tfrac{3}{2}(\psi\partial^{-1}\psi)d. \end{aligned} \tag{4.14}$$

If we identify

$$f=\frac{\delta H}{\delta u}, \quad c=\frac{\delta H}{\delta\phi}, \quad d=-\frac{\delta H}{\delta\psi}, \tag{4.15}$$

and regard δu, $\delta\phi$, and $\delta\psi$ as Hamiltonian flows, then we can read off the Poisson brackets,

$$\{u(x),u(y)\}=[\tfrac{1}{2}\partial_x^3+\partial_x u(x)+u(x)\partial_x]\delta(x-y),$$

$$\{u(x),\phi(y)\}=[\phi(x)\partial_x+\tfrac{1}{2}\phi'(x)]\delta(x-y),$$

$$\{u(x),\psi(y)\}=[\psi(x)\partial_x+\tfrac{1}{2}\psi'(x)]\delta(x-y),$$

$$\{\phi(x),\phi(y)\}=-\tfrac{3}{2}\phi(x)\epsilon(x-y)\phi(y),$$

$$\{\phi(x),\psi(y)\}=[\partial_x^2+u(x)]\delta(x-y)+\tfrac{3}{2}\phi(x)\epsilon(x-y)\psi(y),$$

$$\{\psi(x),\psi(y)\}=-\tfrac{3}{2}\psi(x)\epsilon(x-y)\psi(y), \tag{4.16}$$

where $\epsilon(x-y)\equiv\partial_x^{-1}\delta(x-y)$ is the antisymmetric step function. These are correct brackets,[8] which can be computed from the modified GD bracket (1.5) associated with $L=\partial^2+u+\phi\partial^{-1}\psi$.

The second example is to consider the Lax operator of the form

$$K=\partial^2+u+a\,\frac{1}{\partial-s}, \tag{4.17}$$

even though we would not get a genuine matrix formulation of the second GD bracket associated with K, as discussed in the previous section. However, we like to check explicitly for this simple case that our identifications (3.19), (3.20), and (3.24) indeed give us a correct Hamiltonian structure.

It is also easy to derive a matrix representation for K,

$$\mathscr{K}=\begin{pmatrix}\partial-s & -1 & 0\\ 0 & \partial & -1\\ a & u & \partial\end{pmatrix},\quad \Phi=\begin{pmatrix}\phi_1\\ \phi_2\\ \phi_3\end{pmatrix}. \tag{4.18}$$

Then, from $\mathscr{K}\Phi=0$ we have

$$(\partial-s)\phi_1-\phi_2=0,\quad \phi_2'-\phi_3=0,\quad a\phi_1+u\phi_2+\phi_3'=0, \tag{4.19}$$

which imply

$$[\partial^2+u\phi_2+a(\partial-s)^{-1}]\phi_2=0, \tag{4.20}$$

as desired. The associated Lax equation is given by

$$\partial_t\mathscr{K}=[\mathscr{N},\mathscr{K}]. \tag{4.21}$$

Writing

$$\mathscr{N}=\begin{pmatrix}n_1 & n_2 & n_3\\ n_4 & n_5 & n_6\\ n_7 & n_8 & n_9\end{pmatrix}, \tag{4.22}$$

then

$$[\mathscr{N},\mathscr{K}]=-\mathscr{N}'+\begin{pmatrix}an_3+n_4 & -n_1+un_3+sn_2+n_5 & -n_2+sn_3+n_6\\ -sn_4+an_6+n_7 & -n_4+un_6+n_8 & -n_5+n_9\\ -sn_7+an_9-an_1-un_4 & -n_7+un_9-an_2-un_5 & -n_8-an_3-un_6\end{pmatrix}, \tag{4.23}$$

which must be equal to

$$\delta\mathcal{K}=\begin{pmatrix} -\delta s & 0 & 0 \\ 0 & 0 & 0 \\ \delta a & \delta u & 0 \end{pmatrix}. \tag{4.24}$$

There are six constraint equations:

$$\begin{gathered} -n_2'-n_1+un_3+sn_2+n_5=0, \quad -n_3'-n_2+sn_3+n_6=0, \\ -n_4'-sn_4+an_6+n_7=0, \quad -n_5'-n_4+un_6+n_8=0, \\ -n_6'-n_5+n_9=0, \quad -n_9'-n_8-an_3-un_6=0, \end{gathered} \tag{4.25}$$

and three dynamical equations:

$$\begin{gathered} \delta s=n_1'-an_3-n_4, \\ \delta a=-n_7'-sn_7+an_9-an_1-un_4, \\ \delta u=-n_8'-n_7+un_9-an_2-un_5. \end{gathered} \tag{4.26}$$

We can solve n_2, n_4, n_5, n_7, n_8, and n_9 from (4.25) in terms of n_1, n_3, and n_6 as follows:

$$\begin{gathered} n_2=-(\partial-s)n_3+n_6, \\ n_4=(2\partial(\partial-s)^2+2\partial u-a)n_3-2\partial n_1-\partial(3\partial-2s)n_6, \\ n_5=-((\partial-s)^2+u)n_3+(\partial-s)n_6+n_1, \\ n_7=(2(\partial+s)\partial(\partial-s)^2+2(\partial+s)\partial u-(\partial+s)a)n_3-2(\partial+s)\partial n_1-((\partial+s)\partial(3\partial-2s)+a)n_6, \\ n_8=(\partial(\partial-s)^2+\partial u-a)n_3-(2\partial^2-\partial s+u)n_6-\partial n_1, \\ n_9=-((\partial-s)^2+u)n_3+(2\partial-s)n_6+n_1. \end{gathered} \tag{4.27}$$

Now, substituting (4.27) into the dynamical equations (4.26) and using the identifications

$$n_1=-\frac{\delta H}{\delta s}+\partial_x^{-1}\delta s, \quad n_3=\frac{\delta H}{\delta a}, \quad n_6=\frac{\delta H}{\delta u}, \tag{4.28}$$

we obtain the expected Poisson brackets,[15]

$$\begin{gathered} \{u(x),u(y)\}=[\tfrac{1}{2}\partial_x^3+2u(x)\partial_x+u'(x)]\delta(x-y), \\ \{u(x),a(y)\}=[3a(x)\partial_x+2a'(x)]\delta(x-y), \\ \{u(x),s(y)\}=[\tfrac{3}{2}\partial_x^2+s(x)\partial_x]\delta(x-y), \\ \{a(x),a(y)\}=[(4a(x)s(x)+2a'(x))\partial_x+a''(x)+2(a(x)s(x))']\delta(x-y), \\ \{a(x),s(y)\}=[(\partial_x+s(x))^2\partial_x+u(x)\partial_x]\delta(x-y), \\ \{s(x),s(y)\}=\tfrac{3}{2}\partial_x\delta(x-y). \end{gathered} \tag{4.29}$$

V. CONCLUDING REMARKS

We have studied the Hamiltonian structure of the cKP hierarchy in the matrix formulation. We showed that the procedure for the GD hierarchy can be gone through without difficulty for the

cKP hierarchy. We have not only reproduced the Oevel and Strampp result for the one-constraint case, but also generalized it to the multiconstraint case. We further showed that this Hamiltonian structure is nothing but the GD bracket. Hence, our result again confirms the fact that the GD bracket can be properly restricted to the Lax operator of the form (3.1). We have also discussed the matrix formulation of the Hamiltonian structure of the one-constraint KP hierarchy in the form given by (3.11). However, we did not obtain a genuine matrix formulation in the usual sense. Nevertheless, we found that one can still compute the Hamiltonian structure from our matrix formulation once a proper modification is made.

Finally, we want to remark that the constrained modified KP hierarchy[8] can be obtained from the Lax operator (2.1) via the gauge transformation

$$K=\phi^{-1}L_{(n,1)}\phi=\partial^n+v_{n-1}+\ldots+v_0+\partial^{-1}v_{-1}, \tag{5.1}$$

which satisfies the hierarchy equation

$$\frac{\partial K}{\partial t_k}=[K^n_{\geqslant 1},K]. \tag{5.2}$$

The bi-Hamiltonian structure associated with (5.2) has been obtained[8] from the lifted bracket of the cKP hierarchy by gauge transformation. It would be interesting to know whether or not a matrix formulation of this bi-Hamiltonian structure exists. Following the spirit of the present work we have worked out this structure in matrix formulation for $n=2$ and 3, but a general construction is yet to be given. We hope to report the results in this direction in the near future.

ACKNOWLEDGMENTS

The authors would like to thank Professor Aratyn for pointing out the gauge equivalence between our matrix representation (3.3) and the one used in Ref. 14. This work is supported by the National Science Council of Taiwan under Grants No. NSC-87-2112-M-018-008 (W.J.H) and No. NSC-87-2811-M-007-0025 (J.C.S and M.H.T). One of us (M.H.T) also wishes to thank the Center for Theoretical Sciences of National Science Council of Taiwan for partial support.

APPENDIX A: PROOFS FOR (2.21) AND (2.22)

From (2.19) we have

$$\hat{Q}_1=\partial\hat{Q}_0-Q_{0,n-1}(L_{(n,1)})_+ +\psi Q_{0,-1},$$

$$\begin{aligned}\hat{Q}_2&=\partial\hat{Q}_1-Q_{1,n-1}(L_{(n,1)})_+ +\psi Q_{1,-1}\\&=\partial^2\hat{Q}_0-\partial Q_{0,n-1}(L_{(n,1)})_+ -Q_{1,n-1}(L_{(n,1)})_+ +\partial\psi Q_{0,-1}+\psi Q_{1,-1},\end{aligned}$$

$$\ldots$$

$$\hat{Q}_i=\partial^i\left(\hat{Q}_0-\sum_{k=0}^{i-1}\partial^{-1-k}Q_{k,n-1}(L_{(n,1)})_+ +\sum_{k=0}^{i-1}\partial^{-1-k}Q_{k,-1}\psi\right) \tag{A1}$$

$$\ldots$$

$$\hat{Q}_n=\partial^n\left(\hat{Q}_0-\sum_{k=0}^{n-1}\partial^{-1-k}Q_{k,n-1}(L_{(n,1)})_+ +\sum_{k=0}^{n-1}\partial^{-1-k}Q_{k,-1}\psi\right). \tag{A2}$$

By the virtue of (2.20), $\hat{Q}_n$ must be a differential operator of order $\leqslant n-1$; it follows that

$$\left(\hat{Q}_0-\sum_{k=0}^{n-1}\partial^{-1-k}Q_{k,n-1}(L_{(n,1)})_+ +\sum_{k=0}^{n-1}\partial^{-1-k}Q_{k,-1}\psi\right)_+$$

$$=\left(\hat{Q}_0-\sum_{k=0}^{n-1}\partial^{-1-k}Q_{k,n-1}(L_{(n,1)})_+\right)_+=0. \tag{A3}$$

Define $X\equiv\Sigma_{k=0}^{n-1}\partial^{-1-k}Q_{k,n-1}=\hat{Q}^{n-1}$ then (A1) and (A3) are just (2.21) and (2.22), respectively.

APPENDIX B: PROOFS FOR (2.28) AND (2.29)

From (2.26) it follows that

$$(\partial^{-n}Q_{n,-1}+\cdots+\partial^{-1}Q_{1,-1})=(\hat{Q}^{-1})'-\hat{Q}^{n-1}\phi. \tag{B1}$$

Using $(\hat{Q}^{-1})'=[\partial,\hat{Q}^{-1}]$, we get

$$Q_{n,-1}=\partial^n(Q_{0,-1}-\hat{Q}^{-1}\partial-X\phi). \tag{B2}$$

Since $Q_{n,-1}$ is a scalar, it follows that

$$[\partial^n(Q_{0,-1}-\hat{Q}^{-1}\partial-X\phi)\partial^{-1}]_+=0. \tag{B3}$$

Moreover, since $\partial^n\hat{Q}^{-1}$ is a pure differential operator, we have

$$\partial^n\hat{Q}^{-1}=[\partial^n(Q_{0,-1}-X\phi)\partial^{-1}]_+, \tag{B4}$$

which leads to (2.28).

Next, from (2.5),

$$Q_{-1,i-1}=-Q'_{-1,i}+\psi Q_{0,i}+u_iQ_{-1,n-1}\quad(i=1,2,\ldots,n-1). \tag{B5}$$

Define $\tilde{Q}_{-1,-1}=-Q'_{-1,0}+\psi Q_{0,0}+u_0Q_{-1,n-1}$; then in view of (B5) we write

$$\tilde{Q}_{-1,-1}+Q_{-1,0}\partial+\cdots+Q_{-1,n-2}\partial^{n-1}+Q_{-1,n-1}\partial^n=-(\hat{Q}_{-1})'+\psi\hat{Q}_0+Q_{-1,n-1}(L_{(n,1)})_+, \tag{B6}$$

which implies

$$\tilde{Q}_{-1,-1}=-\partial\hat{Q}_{-1}+\psi\hat{Q}_0+Q_{-1,n-1}(L_{(n,1)})_+. \tag{B7}$$

Since a scalar is invariant under the adjoint operation; i.e., $f=f^*$, applying the adjoint operation to the both sides of (B7) gives

$$\tilde{Q}_{-1,-1}=(\hat{Q}^*_{-1}\partial+(L_{(n,1)})^*_+Q_{-1,n-1}+\hat{Q}^*_0\psi)_0=((L_{(n,1)})^*_+Q_{-1,n-1}+\hat{Q}^*_0\psi)_0. \tag{B8}$$

Now we treat $\tilde{Q}_{-1,-1}$ a little differently. An equivalent form of (B7) is

$$\partial^{-1}\tilde{Q}_{-1,-1}=-\hat{Q}_{-1}+\partial^{-1}(\psi\hat{Q}_0+Q_{-1,n-1}(L_{(n,1)})_+), \tag{B9}$$

which leads to (2.29), since $\hat{Q}_{-1}$ is a pure differential operator.

APPENDIX C: PROOFS FOR (2.36) AND (2.37)

Note that (2.26) gives

$$Q_{1,-1}=Q'_{0,-1}-\phi Q_{0,n-1},$$

$$Q_{2,-1}=Q''_{0,-1}-\phi Q_{1,n-1}-(\phi Q_{0,n-1})',$$

$$\cdots$$

$$Q_{j,-1}=Q^{(j)}_{0,-1}-\phi Q_{j-1,n-1}-(\phi Q_{j-2,n-1})'\cdots-(\phi Q_{0,n-1})^{(j-1)}, \tag{C1}$$

$$\cdots$$

$$Q_{n-1,-1}=Q^{(n-1)}_{0,-1}-\phi Q_{n-2,n-1}-(\phi Q_{n-3,n-1})'\cdots-(\phi Q_{0,n-1})^{(n-2)}.$$

In particular,

$$Q'_{n-1,-1}=Q^{(n)}_{0,-1}-\phi Q_{n-1,n-1}-(\phi Q_{n-2,n-1})'-\cdots-(\phi Q_{0,n-1})^{(n-1)}+\phi Q_{n-1,n-1}. \tag{C2}$$

The operator forms of (C1) and (C2) are (2.36) and (2.37), respectively.

Second harmonic generation: Hamiltonian structures and particular solutions

K. R. Khusnutdinova
Department of Mathematics, Bashkir State University, Frunze Str. 32, 450074 Ufa, Russia

(Received 3 February 1998; accepted for publication 24 March 1998)

For the equations describing second harmonic generation (SHG), we find a linear system different from one found by Kaup (but connected with it by a gauge transformation), which enables us to consider the SHG equations as related to the first negative flow in the coupled KdV hierarchy and to find therefore the Hamiltonian structures and the recursion operator. With the help of the recursion operator we write down the simplest commuting flows and consider their stationary points in order to find particular solutions of the SHG equations. We also investigate some particular invariant solutions of the SHG equations that can be of physical interest, and find their connections with invariant solutions of the Tzitzéica equation. The latter are either connected with Painlevé III or solvable in elliptic functions. © *1998 American Institute of Physics.* [S0022-2488(98)00507-6]

I. INTRODUCTION

The generation of the second harmonic wave from the red light of a ruby laser in a crystal of quartz in 1961[1] marked the starting point of nonlinear optics. The theory for the one-dimensional stationary process has soon been developed.[2,3] For short pulses, when the group-velocity mismatch between both frequency components becomes important, the process of second harmonic generation (SHG) is described by the equations (see, e.g., Refs. 4 and 5)

$$q_{1\chi}=-2q_2q_1^*, \quad q_{2\tau}=q_1^2, \tag{1}$$

where differentiation with respect to the independent variables χ and τ is indicated by subscripts; the asterisk denotes complex conjugation. Here q_1 and q_2 are slowly varying complex electric field amplitudes of both waves with carrier frequencies ω_1 and $\omega_2=2\omega_1$, respectively. It is assumed that the respective group velocities v_1 and v_2 do not coincide, but that the dispersion within either of the two waves is negligible. The characteristic variables χ and τ are connected with the laboratory space and time coordinates x, t as follows:

$$\chi=\nu\left(-t+\frac{x}{v_2}\right), \quad \tau=\nu\left(t-\frac{x}{v_1}\right),$$

where $\nu=(1/v_2-1/v_1)^{-1}$ is the group-velocity mismatch. (Only characteristic variables will be used below.)

When restricted to real amplitudes q_1, q_2 the SHG equations (1) reduce to the Liouville equation, as was noted in Ref. 6. For that ''C-integrable'' case, particular analytical solutions were studied in Ref. 7, and it was found in Ref. 5 that the *restricted Cauchy problem* (with arbitrary q_1 and $q_2\equiv 0$ given at $x=0$) leads to a Schrödinger or Hill's equation.

The general SHG equations (1) are shown to be ''*S*-integrable'' by Kaup.[8] The application of the inverse scattering method to this problem, however, meets some peculiarities and is not yet fully developed.

[a)]Electronic mail: steudel.photon.fta-berlin.de

 © 1998 American Institute of Physics

The group analysis of the SHG equations was given by Zhiber in Ref. 9, where it was found that the Lie–Bäcklund algebra of these equations consists of two parts: the nonlinear Schrödinger type and the Liouville type. The auto-Bäcklund transformation for the SHG equations was investigated in Ref. 10.

In the present paper we reveal the relationship of the SHG equations to the coupled KdV hierarchy, studied in Refs. 11–16 (see also the references therein) and discuss the Hamiltonian formalism. We also construct some exact solutions of the SHG equations and find connections of the self-similar and the traveling wave solutions with the corresponding solutions of the Tzitzéica equation.[17] The latter are either connected with Painlevé III[18] and studied by the method of isomonodromic deformations[19] or solvable in elliptic functions.[20]

II. LINEAR SYSTEM

Elimination of q_2 from Eqs. (1) implies the equation

$$q_{1\chi\tau}q_1^* - q_{1\tau}^* q_{1\chi} = -2(q_1 q_1^*)^2. \tag{2}$$

From (2) we obtain two scalar equations:

$$(\ln Q)_{\chi\tau} - \phi_\chi \phi_\tau = -Q, \quad (Q\phi_\tau)_\chi = 0, \tag{3}$$

where $q_1 = (\sqrt{Q}/2)\exp[i(\phi/2)]$, and we assume that $Q>0$.

The variable q_2 can be recovered as follows:

$$q_2 = -\tfrac{1}{4}((\ln Q)_\chi + i\phi_\chi)\exp(i\phi).$$

Equations (3) admit the following Lie point symmetries:

$$(1)\ \tilde{\tau} = \tau + a, \quad (2)\ \tilde{\chi} = \chi + a, \quad (3)\ \phi = \phi + a,$$

$$(4)\ \tilde{\tau} = e^a \tau, \quad \tilde{\chi} = e^{-a}\chi, \quad (5)\ \tilde{\tau} = f(\tau), \quad \tilde{Q} = \frac{Q}{f'(\tau)}. \tag{4}$$

Here $a=\text{const}$ (group parameter) and $f(\tau)$ is an arbitrary function ($f' \neq 0$). Applying the standard methods of group analysis of differential equations,[21,22] one can prove that all point symmetries are given by (4).

There exists also an obvious discrete symmetry: $\tau \to -\tau$, $\chi \to -\chi$.

Introducing the variables

$$s = Q^{-1}, \quad u = \phi_\tau, \quad v = (\ln s)_\chi, \quad w = \phi_\chi,$$

we may rewrite system (3) as follows:

$$s_\chi = sv, \quad u_\chi = uv = w_\tau, \quad v_\tau = s^{-1} - uw. \tag{5}$$

Specifying in (5) to $u=0$ one arrives at the Liouville equation $(\ln s)_{\chi\tau} = s^{-1}$,[6] which allowed us recently to investigate the initial value problem for an amplitude-modulated initial pulse.[5]

As a consequence of (5) we get

$$\left(\ln \frac{s}{u}\right)_\chi = 0,$$

so that $s = g(\tau)u$. Since in variables s, u, v, w the last symmetry in (4) takes the form

$$\tilde{\tau} = f(\tau), \quad \tilde{s} = sf'(\tau), \quad \tilde{u} = \frac{u}{f'(\tau)},$$

we can reduce $g(\tau)$ to 1 if $g(\tau)>0$ (i.e., $\phi_\tau > 0$). In this case $s=u$, and Eqs. (5) reduce to

$$u_\chi = uv = w_\tau, \quad v_\tau = u^{-1} - uw. \tag{6}$$

To get the case $s=-u$ [$g(\tau)<0$, i.e., $\phi_\tau<0$] we just have to change in (6), $u\to -u$, $w\to -w$.

Applying the Wahlquist–Estabrook method to system (5), we find out that these equations are the integrability conditions for the following linear system:

$$\Psi_\chi = U\Psi, \quad \Psi_\tau = V\Psi,$$

$$U=\begin{pmatrix} \frac{v}{2} & -\lambda \\ \frac{\alpha}{\lambda}(\alpha - w) & -\frac{v}{2} \end{pmatrix}, \quad V=\begin{pmatrix} 0 & \frac{\lambda}{2\alpha}u \\ \frac{1}{2\lambda}(s^{-1}-\alpha u) & 0 \end{pmatrix}, \tag{7}$$

where α and λ are parameters.

Let us take $\alpha=\lambda$. The linear system (7) transforms to

$$\Psi_\chi = \begin{pmatrix} \frac{v}{2} & -\lambda \\ \lambda - w & -\frac{v}{2} \end{pmatrix}\Psi, \quad \Psi_\tau = \begin{pmatrix} 0 & \frac{u}{2} \\ \frac{1}{2}(\lambda^{-1}s^{-1}-u) & 0 \end{pmatrix}\Psi. \tag{8}$$

It is remarkable that for the first component of the Ψ function we can derive from (8) the following equations:

$$-\Psi^1_{\chi\chi} + \left(\frac{v_\chi}{2} + \frac{v^2}{4} + \lambda w\right)\Psi^1 = \lambda^2\Psi^1, \quad \Psi^1_\tau = -\frac{1}{2\lambda}u\Psi^1_\chi + \frac{1}{4\lambda}uv\Psi^1. \tag{9}$$

The spectral problem (9) in the variables $v^0 = v_\chi/2 + v^2/4$, $v^1 = w$ turns out to be of the type considered in Refs. 11–16. As far as the τ derivative of the Ψ function is proportional to λ^{-1}, our equations (5) [and (6)] correspond to the first negative flow of the coupled KdV hierarchy (in variables v^0, v^1).

Let us note that the linear system (7) is connected with Kaup's linear system,[8]

$$\Psi_\chi = U_0\Psi, \quad \Psi_\tau = V_0\Psi,$$

$$U_0=\begin{pmatrix} i\alpha & 2q_2 \\ 2q_2^* & -i\alpha \end{pmatrix}, \quad V_0=\frac{i}{\alpha}\begin{pmatrix} q_1 q_1^* & q_1^2 \\ -q_1^{*2} & -q_1 q_1^* \end{pmatrix},$$

by the gauge transformation

$$U = C^{-1}(U_0 C - C_\chi), \quad V = C^{-1}(U_0 C - C_\tau),$$

where

$$C=\begin{pmatrix} ie^{i(\phi/2-\pi/4)} & -\frac{\lambda}{\alpha}e^{i(\phi/2-\pi/4)} \\ e^{-i(\phi/2-\pi/4)} & -\frac{i\lambda}{\alpha}e^{-i(\phi/2-\pi/4)} \end{pmatrix}.$$

III. HAMILTONIAN STRUCTURES AND RECURSION OPERATOR

A system of evolution equations admits Hamiltonian structure if it can be written in the form

$$u^i_\tau = \theta^{ij}\frac{\delta H}{\delta u^j},$$

where θ^{ij} is the Hamiltonian operator, i.e., a matrix operator, such that the associated Poisson bracket $\{F,G\}=\int(\delta F/\delta u^i)\,\theta^{ij}(\delta G/\delta u^j)d\chi$ is skew symmetric and satisfies the Jacobi identity. Here δ denotes the variational derivative. The Hamiltonian H is usually a function of the u^i and their χ derivatives, but nonlocal Hamiltonians may also make sense.

In order to discuss the Hamiltonian structures, let us rewrite system (6) in the form

$$p_{\chi\tau}=e^{-p}-e^{p}w, \quad w_\tau=e^{p}p_\chi, \tag{10}$$

where $u=e^p$.

One can easily verify that Eqs. (10) can be written in Hamiltonian form,

$$\begin{pmatrix} p \\ w \end{pmatrix}_\tau = A\begin{pmatrix} \dfrac{\delta H}{\delta p} \\ \dfrac{\delta H}{\delta w} \end{pmatrix}, \quad A=\begin{pmatrix} -\partial^{-1} & 0 \\ 0 & \partial \end{pmatrix}, \tag{11}$$

with the Hamiltonian $H=\int(e^{-p}+e^{p}w)d\chi$. We use the following notation: $\partial=d/d\chi$ is the total derivative and ∂^{-1} is its ''inverse.''

From the results by Antonowicz and Fordy,[14–16] it follows that equations from the coupled KdV hierarchy are tri-Hamiltonian. In the variables v^0,v^1 the Hamiltonian operators have the form

$$B^{(1)}=\begin{pmatrix} -I_1 & \partial \\ \partial & 0 \end{pmatrix}, \quad B^{(2)}=\begin{pmatrix} I_0 & 0 \\ 0 & \partial \end{pmatrix}, \quad B^{(3)}=\begin{pmatrix} 0 & I_0 \\ I_0 & I_1 \end{pmatrix},$$

where $I_0=-1/4\partial^3+1/2(v^0\partial+\partial v^0)$, $I_1=1/2(v^1\partial+\partial v^1)$, and $v^0=p_{\chi\chi}/2+p_\chi^2/4$, $v^1=w$. It was proved that all these Hamiltonian operators are compatible, and the recursion operator R_B (i.e., $B^{(n)}=R_B^{n-1}B^{(1)}$) was found:

$$R_B=\begin{pmatrix} 0 & I_0\partial^{-1} \\ 1 & I_1\partial^{-1} \end{pmatrix}.$$

It turns out that the operator A in (11) corresponds to $B^{(2)}$. Let us denote $A=A^{(2)}$ and $H=H^{(2)}$. Hamiltonian operator $B^{(1)}$ in our variables takes the form

$$A^{(1)}=-2\partial^{-1}\begin{pmatrix} e^{p}w\partial^{-1}e^{-p}+e^{-p}\partial^{-1}e^{p}w & -e^{-p}\partial^{-1}e^{p}\partial^2 \\ -\partial^2 e^{p}\partial^{-1}e^{-p} & 0 \end{pmatrix}\partial^{-1},$$

and is essentially nonlocal, while the third operator $B^{(3)}$ turns out to be of the Dubrovin–Novikov type:[23]

$$A^{(3)}=\frac{1}{2}\begin{pmatrix} 0 & -\partial+p_\chi \\ -\partial-p_\chi & 2w\partial+w_\chi \end{pmatrix}.$$

For all three Hamiltonian operators $A^{(i)}$, $i=1,2,3$, we have an infinite-dimensional analog of the Darboux theorem: there exist coordinates where we obtain a particularly simple expressions for $A^{(i)}$ with constant coefficients. The operator $A^{(3)}$ is of the Dubrovin–Novikov type:[23]

$$\theta^{ij}=g^{ij}\partial-g^{is}\Gamma^j_{sk}u^k_\chi,$$

with the metric

$$g_{ij}=-2\begin{pmatrix} 2w & 1 \\ 1 & 0 \end{pmatrix},$$

and $\Gamma^j_{sk}=-1/2g^{jl}(g_{sl,k}+g_{kl,s}-g_{sk,l})$ being the coefficients of the corresponding Levi–Cività connection. In the flat coordinates of the metric $u^1=e^{-p}+e^p w$, $u^2=e^{-p}-e^p w$, where the metric has the form

$$\tilde{g}_{ij}=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},$$

the operator $A^{(3)}$ takes the form $\tilde{A}^{(3)}=\tilde{g}^{ij}\partial$.

The operator $A^{(2)}$ has the local form

$$\tilde{A}^{(2)}=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}\partial,$$

in variables $u^1=p_\chi$ and $u^2=w$. The essentially nonlocal operator $A^{(1)}$ will take the simple local form

$$\tilde{A}^{(1)}=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\partial$$

in the coordinates $u^1=1/2(p_{\chi\chi}+w)+1/4(p_\chi^2+w^2)$, $u^2=1/2(p_{\chi\chi}-w)+1/4(p_\chi^2+w^2)$.

Let us note that nonlocal Hamiltonian operators arise naturally in applications, and in many cases they have a clear geometrical nature (see, e.g., Ref. 24).

The Hamiltonians corresponding to the operators $A^{(1)}$ and $A^{(3)}$ have the form

$$H^{(1)}=0,\quad H^{(3)}=-\int\left[\frac{1}{2}(e^{-p}+e^p w)[\partial^{-1}(e^{-p}-e^p w)]^2+e^p\right]d\chi.$$

The variational derivatives of the functional $F=\int f(p,w)[\partial^{-1}g(p,w)]^2 d\chi$ are

$$\frac{\delta H}{\delta p}=f_p[\partial^{-1}g]^2-2g_p\partial^{-1}f\partial^{-1}g,\quad \frac{\delta H}{\delta w}=f_w[\partial^{-1}g]^2-2g_w\partial^{-1}f\partial^{-1}g.$$

In variables w^1,w^2 such that $w^1_\chi=u^1=e^{-p}+e^p w$, $w^2_\chi=u^2=e^{-p}-e^p w$, Eqs. (10) take the form

$$\begin{pmatrix}w^1\\ w^2\end{pmatrix}=\begin{pmatrix}-\partial^{-1} & 0\\ 0 & \partial^{-1}\end{pmatrix}\begin{pmatrix}\dfrac{\delta H}{\partial w^1}\\ \dfrac{\delta H}{\delta w^2}\end{pmatrix},$$

with the local Hamiltonian

$$\tilde{H}^{(3)}=-\frac{1}{2}w^1_\chi(w^2)^2-\frac{2}{w^1_\chi+w^2_\chi}.$$

The recursion operator R_A [i.e., $A^{(n)}=R_A^{n-1}A^{(1)}$] takes the form

$$R_A=\frac{1}{2}\begin{pmatrix}0 & -1+p_\chi\partial^{-1}\\ \partial^2+p_\chi\partial & w+\partial w\partial^{-1}\end{pmatrix},$$

and is invertible:

$$R_A^{-1}=2\partial^{-1}\begin{pmatrix}e^p w\partial^{-1}e^{-p}+e^{-p}\partial^{-1}e^p w & e^{-p}\partial^{-1}e^p\\ -\partial^2 e^p\partial^{-1}e^{-p} & 0\end{pmatrix}.$$

The recursion operator generates commuting flows of our system (10). Their Hamiltonians give rise to higher conservation laws (in variables v^0,v^1 they have been discussed in Ref. 15).

The Lie–Bäcklund algebra for the full SHG equations (1) was found in Ref. 9 by Zhiber. It was shown that the algebra consists of two parts, namely the following (with the slight change in notation).

(i) The *nonlinear Schrödinger type*,

$$g_{n+1}=\frac{i}{2}\,\partial g_n-4iq_2\partial^{-1}(q_2g_n^*+q_2^*g_n),\quad f_{n+1}=\frac{(g_{n+1})_\tau}{2q_1}$$

(the functions f and g determine commuting flows as follows: $q_{1T}=f$, $q_{2T}=g$);

(ii) the *Liouville type*,

$$f=\left(q_1\,\frac{\partial}{\partial\tau}+2q_{1_\tau}\right)\Phi,\quad g=2q_1^2\Phi,$$

where $\Phi=\Phi(z,z_\tau,z_{\tau\tau},\ldots)$, $z=q_1^*q_{1_\tau}-q_{1_\tau}^*q_1$.

In our case [the reduction to (6)] the symmetries of the type (i) give rise to the symmetries generated by the recursion operator R_A, while the symmetries of type (ii) degenerate into the trivial symmetry $p_T=P_\tau$, $w_T=w_\tau$.

To the best of our knowledge, the Hamiltonian structures of the SHG equations have not been discussed in the literature so far.

IV. STATIONARY POINTS OF COMMUTING FLOWS

The system (10) possesses the trivial commuting flow (the shift along χ):

$$p_T=p_\chi,\quad w_T=w_\chi. \tag{12}$$

Operating with R_A on this flow we arrive at the new flow,

$$p_T=\tfrac{1}{2}(wp_\chi-w_\chi),\quad w_T=\tfrac{1}{2}(p_{\chi\chi}+\tfrac{1}{2}p_\chi^2+\tfrac{3}{2}w^2)_\chi, \tag{13}$$

commuting with our equations (10) and corresponding in variables v^0,v^1 to the second flow in the coupled KdV hierarchy:

$$v_T^0=-\tfrac{1}{4}v^1_{\chi\chi\chi}+v^0v^1_\chi+\tfrac{1}{2}v^0_\chi v^1,\quad v^1_T=v^0_\chi+\tfrac{3}{2}v^1v^1_\chi.$$

Continuing the procedure, we will obtain the coupled KdV equations and the whole coupled KdV hierarchy, represented in the variables p and w.

Let us consider the stationary points of the simplest commuting flows. For example, let us equate to zero the linear combination of the right-hand sides of (12) and (13), namely

$$\tfrac{1}{2}(wp_\chi-w_\chi)+ap_\chi=0,$$

$$\tfrac{1}{2}(p_{\chi\chi}+\tfrac{1}{2}p_\chi^2+\tfrac{3}{2}w^2)_\chi+aw_\chi=0,$$

which, after integrating, can be rewritten as follows:

$$p_{\chi\chi}+\tfrac{1}{2}p_\chi^2+\tfrac{3}{2}w^2+2aw=b,\quad p=\ln|w+2a|+f(\tau). \tag{14}$$

Here $a,b=\text{const}$, $f(\tau)$ is an arbitrary function, and it is assumed that $w\neq-2a$.

Thus, in order to get particular solutions, we have to consider the overdetermined system formed by initial equations (10) and differential constraints (14):

$$p_{\chi\tau}=e^{-p}-e^pw,\quad w_\tau=e^pp_\chi,$$

$$p_{\chi\chi}+\tfrac{1}{2}p_\chi^2+\tfrac{3}{2}w^2+2aw=b,$$

$$w=\epsilon e^{p-f(\tau)}-2a,\quad \epsilon=\pm1.$$

Eliminating the variable w with the help of the last relation, we arrive at the overdetermined system for the variable p and obtain the following expressions for the first derivatives:

$$p_\chi = \sqrt{A}, \quad p_\tau = \epsilon e^{f(\tau)}\sqrt{A} + f'(\tau),$$

$$A = -e^{2(p-f(\tau))} + 4\epsilon a e^{p-f(\tau)} - 2\epsilon e^{-p-f(\tau)} - 4a^2 + 2b.$$

Since the compatibility condition $p_{\chi\tau} = p_{\tau\chi}$ gives us $f'(\tau) = 0$, we see that $f(\tau) = \text{const}$. Let us denote $c = -\epsilon\epsilon^f$ so that $p_\tau = -cp_\chi$ and $w = -(1/c)e^p - 2a$. Then $p = p(x)$, $x = \chi - c\tau$ and p satisfies the equation

$$\frac{1}{2}p'^2 = -\frac{1}{2c^2}e^{2p} - \frac{2a}{c}e^p + \frac{1}{c}e^{-p} + \tilde{b}, \quad \tilde{b} = b - 2a^2.$$

Since the variable p is connected with the amplitude variable Q by formula $p = -\ln Q$, the latter is determined by the equation

$$Q'^2 = \frac{2}{c}Q^3 + 2\tilde{b}Q^2 - \frac{4a}{c}Q - \frac{1}{c^2},$$

which is solvable in elliptic functions:

$$Q(\chi - c\tau) = 2c\left[\wp(\chi - c\tau + \omega'; g_2, g_3) - \frac{\tilde{b}}{6}\right]. \tag{15}$$

Here $g_2 = \tilde{b}^2/3 + 2a/c^2$, $g_3 = 1/4c^4 - \tilde{b}^3/27 - a\tilde{b}/3c^2$ are the invariants of the Weierstrass $\wp$ function and ω' is a constant. To obtain the real and nonsingular periodic solution we have to impose the condition $\Delta = g_2^3 - 27g_3^2 > 0$ and to take ω' equal to the imaginary half-period of the Weierstrass $\wp$ function.

To obtain the phase of the wave we have to integrate the equations

$$\phi_\chi = w = -\frac{1}{c}Q^{-1} - 2a, \quad \phi_\tau = Q^{-1},$$

from which it follows that

$$\phi = \tilde{\phi}(\chi - c\tau) - 2a\chi, \tag{16}$$

and the function $\tilde{\phi}$ satisfies the equation

$$\tilde{\phi}'(x) = -\frac{1}{2c^2(\wp(x+\omega') - \wp(k))}, \quad \wp(k) = \frac{\tilde{b}}{6} = \text{const}.$$

This quadrature is given by means of the Weierstrass σ and ζ functions (see, e.g., Ref. 25) as follows:

$$\tilde{\phi}(x) = -\frac{1}{2c^2\wp'(k)}\left[\ln\frac{\sigma(x+\omega'-k)}{\sigma(x+\omega'+k)} + 2\zeta(k)x\right] + \phi_0, \quad \phi_0 = \text{const}. \tag{17}$$

The formulas (15)–(17) describe the four-parametric periodic solution of the SHG equations (one-phase solution). Solutions of that type can be reparametrized by means of the spectral parameter of the corresponding linear system and expressed in terms of Jacobi elliptic functions (see, e.g., the review[26]). The stationary points of the higher commuting flows will determine the finite-gap solutions.

If $a = 0$, we get from (15)–(17) the traveling wave solution, which is connected with the traveling wave solution of the Tzitzéica equation by point transformation. There also exists a connection between self-similar solutions, as will be shown below.

V. SIMILARITY REDUCTIONS OF THE SHG EQUATIONS AND PAINLEVÉ III

Similarity reductions of the three-wave interaction system were investigated in Refs. 27–31. In them were found the reductions to Painlevé III, IV, V, and VI. In this section we investigate some particular invariant solutions of the SHG equations (3) that can be of physical interest. (The group of Lie point symmetries is given in Sec. I). We find connection of these solutions with similarity solutions of the Tzitzéica equation.[17] The latter are either connected with solutions of Painlevé III[18,19] or solvable in elliptic functions.[20]

Let us consider first the traveling wave solution of (3). We seek a solution of (3) in the form

$$Q=Q(x), \quad \phi=\phi(x), \quad x=\chi-c\tau,$$

which yields the system

$$(\ln Q)''-(\phi')^2=\frac{Q}{c}, \quad (Q\phi')'=0. \tag{18}$$

Integrating the second equation of (18), we obtain $\phi'=\beta/Q$, $\beta=\text{const}$, and the single equation for the variable Q:

$$(\ln Q)''=\frac{Q}{c}+\frac{\beta^2}{Q^2}. \tag{19}$$

The case $\beta=0$ leads to solutions of the Liouville equation. Therefore we suppose that $\beta\neq 0$. The transformation

$$Q=(\beta^2|c|)^{1/3}\exp(v), \quad x=\left|\frac{c}{\beta}\right|^{1/3} y$$

transforms (19) to the form

$$v_{yy}=\epsilon e^{v}+e^{-2v}, \tag{20}$$

where $\epsilon=\text{sign}\, c$. Equation (20) coincides with the traveling wave reduction of the Tzitzéica equation,

$$v_{\xi\eta}=-\epsilon e^{v}-e^{-2v}, \tag{21}$$

with

$$v=v(y), \quad y=\frac{\xi-c\eta}{\sqrt{c}}, \quad c>0.$$

It turns out that another similarity reduction of the SHG equations, for self-similar solutions, also yields the similarity reduction of the Tzitzéica equation. Indeed, let us consider the solution of (3) invariant with respect to the scaling symmetry,

$$\tilde{\tau}=e^{a}\tau, \quad \tilde{\chi}=e^{na}\chi, \quad \tilde{Q}=e^{-(n+1)a}Q.$$

We may define the similarity variables

$$x=\frac{\chi}{\tau^n}, \quad F(x)=\tau\chi Q, \quad \phi(x), \tag{22}$$

and find the following system of nonlinear ordinary differential equations;

$$x^2(\ln F)''+x(\ln F)'-x^2(\phi')^2=\frac{F}{n}, \quad (F\phi')'=0. \tag{23}$$

The second equation of (23) gives $\phi' = \alpha/F$, $\alpha = \text{const}$. The case $\alpha = 0$ leads to solutions of the Liouville equation. Therefore we suppose that $\alpha \neq 0$. The variable $F(x)$ satisfies the single equation

$$x^2(\ln F)'' + x(\ln F)' = \frac{F}{n} + x^2 \frac{\alpha^2}{F^2}. \tag{24}$$

The change of variables

$$F = \frac{4|n|}{9} y \exp(v), \quad x = \frac{8|n|}{27|\alpha|} y^{3/2}$$

transforms Eq. (24) to the form

$$v_{yy} = -\frac{v_y}{y} + \frac{1}{y}[e^{-2v} + \epsilon e^{v}], \tag{25}$$

with $\epsilon = \text{sign } n$.

If $\epsilon = -1$ then Eq. (25) possesses the trivial solution $v = 0$. The corresponding solution of our equations (3) has the following nontrivial form:

$$Q(\chi, \tau) = -(n\alpha^2)^{1/3} \chi^{-1/3} \tau^{-(1+2n/3)},$$

$$\phi(\chi, \tau) = -3\left(\frac{\alpha}{n}\right)^{1/3} \chi^{1/3} \tau^{-n/3} + \phi_0, \quad \phi_0 = \text{const}.$$

Using the last symmetry in (4) we obtain a solution containing an arbitrary function $T(\tau)$:

$$Q(\chi, \tau) = \frac{1}{3} T(\tau) T'(\tau) \chi^{-1/3}, \quad \phi(\chi, \tau) = T(\tau) \chi^{1/3} + \phi_0.$$

Equation (25) coincides with the scaling reduction of Eq. (21) with $v = v(y)$, $y = -\xi\eta$ and is reducible using the transformation

$$W = \epsilon y^{1/4} e^{v}, \quad z = \frac{4}{3} y^{3/4},$$

to a special case of the Painlevé III equation,[18]

$$W'' = \frac{W'^2}{W} - \frac{W'}{z} + \frac{4}{3}\frac{W^2}{z} + \frac{1}{W}, \tag{26}$$

which was studied in Ref. 19 by the method of isomonodromic deformations.

In Ref. 19 this equation was studied with the help of an auxiliary 3×3 linear system, which can be deduced from the 3×3 linear problem of the Tzitzéica equation.[17]

The similarity reduction from the SHG equations implies the auxiliary 2×2 linear system. Scaling in (8) the independent and dependent variables are as follows:

$$s(\chi, \tau) = -zW^{-1}(z)/2, \quad z = (6\tau\chi)^{1/2},$$

$$u(\chi, \tau) = -3\chi z^{-1} W^{-1}(z), \quad \mu = (3\chi\lambda)^{-1},$$

$$v(\chi, \tau) = \chi^{-1}(1 - zW_z(z)W^{-1}(z))/2,$$

$$w(\chi, \tau) = -\chi z^{-1} W^{-1}(z)/2, \quad \Psi(\chi, \tau; \lambda) = \Phi(z; \mu),$$

we obtain the linear system

$$\Phi_z=\left[\mu\begin{pmatrix}0 & 0\\ -W & 0\end{pmatrix}+\frac{1}{2}\begin{pmatrix}0 & -W^{-1}\\ W^{-1} & 0\end{pmatrix}\right]\Phi,$$

$$\phi_\mu=\left[\begin{pmatrix}0 & 0\\ -\frac{zW}{2} & 0\end{pmatrix}+\frac{1}{4\mu}\begin{pmatrix}1-zW_zW^{-1} & -zW^{-1}\\ -zW^{-1} & 1-zW_zW^{-1}\end{pmatrix}+\frac{1}{3\mu^2}\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}\right]\Phi.$$

These equations are compatible provided that $W(z)$ satisfies (26).

It is interesting that two different reductions of the SHG equations and of the Tzitzéica equation are connected. One may expect that there exists some more general connections between these equations.

VI. CONCLUDING REMARKS

In the present paper we have discussed the relationship of Eqs. (6) to the coupled KdV hierarchy and the Hamiltonian formalism of these equations. Let us note that the full SHG equations (1) can be represented in Lagrangian form,

$$\frac{\delta L}{\delta q_i}=0,\quad \frac{\delta L}{\delta q_i^*}=0,\quad i=1,2,$$

with the Lagrangian

$$L=\int i\left[\frac{1}{2}\,(q_1q_{1\chi}^*-q_1^*q_{1\chi}+q_2q_{2\tau}^*-q_2^*q_{2\tau})-q_1^{*2}q_2+q_1^2q_2^*\right]d\chi,$$

analogously to the finite-dimensional case (see, e.g., Ref. 32), and in Hamiltonian form,

$$\begin{pmatrix}q_1\\ q_2\\ q_1^*\\ q_2^*\end{pmatrix}_T=\begin{pmatrix}0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1\\ -1 & 0 & 0 & 0\\ 0 & -1 & 0 & 0\end{pmatrix}\begin{pmatrix}\frac{\delta H}{\delta q_1}\\ \frac{\delta H}{\delta q_2}\\ \frac{\delta H}{\delta q_1^*}\\ \frac{\delta H}{\delta q_2^*}\end{pmatrix},\tag{27}$$

with the Hamiltonian

$$H=\int i\left[\frac{1}{2}\,(q_1q_{1X}^*-q_1^*q_{1X}-q_2q_{2X}^*+q_2^*q_{2X})-q_1^{*2}q_2+q_1^2q_2^*\right]dX,$$

and $T=\chi+\tau$, $X=\chi-\tau$. The variable T is nothing but the laboratory x coordinate used in the Introduction while X is a mixture of x and t. The other Hamiltonian operators, which can be obtained from (27) using a recursion operator, and their connections with those found in the present paper will be discussed elsewhere.

It is shown that a class of important integrable nonlinear evolution equations in (2+1) dimensions can be associated with the motion of space curves endowed with an extra spatial variable or equivalently, moving surfaces. Geometrical invariants then define topological conserved quantities. Underlying evolution equations are shown to be associated with a triad of linear equations. Our examples include Ishimori equation and Myrzakulov equations which are shown to be geometrically equivalent to Davey-Stewartson and Zakharov-Strachan (2+1) dimensional nonlinear Schrödinger equations, respectively. © *1998 American Institute of Physics.* [S0022-2488(98)02006-4]

The motion of curves in E^3 and the defining equations of surfaces have drawn wide interest in the past, especially since they give nice geometric interpretations of nonlinear evolution equations in (1+1) dimensions.[1–6] There are many physical situations where they play a natural role. Particularly they have important connections with soliton equations solvable by the Ablowitz, Kaup, Newell and Segur (AKNS) formalism.[1–6] For a recent renaissance of interest, see, for example, Ref. 7 and References therein. Other examples include dynamics of interfaces, surfaces and fronts, vortex filaments, supercoiled DNAs, magnetic fluxes, deformation of membranes, dynamics of proteins, propagation of flame fronts and so on.[8,9] Of special interest among these systems is the dynamics of isotropic Heisenberg ferromagnetic spin chains where an interesting equivalence with nonlinear Schrödinger family of equations arise in a natural and physical way.[10]

The question then arises as to whether nonlinear evolution equations in (2+1) dimensions of importance, especially spin equations, can be given a similar geometrical setting associated with motion of curves endowed with an additional coordinate or equivalent motion of surfaces. In this paper, we develop a general theory of obtaining nonlinear evolution equations in (2+1) dimensions as the compatibility requirements of the geometric equations defining the motion of curves and surfaces, incidentally equivalent to a triad of linear equations. Our analysis also brings out certain natural topological integral invariants associated with the resultant systems. We then consider a class of (2+1) dimensional spin systems including (2+1) dimensional generalized Heisenberg ferromagnatic spin systems and deduce their equivalent nonlinear Schrödinger family including Davey-Stewartson, Zakharov-Strachan and other equations. In this context, we also wish to add that in recent times a general approach (mainly due to Konopelchenko) has appeared in the literature[11,12] concerning the interpretation of hierarchies of integrable (2+1) dimensional systems

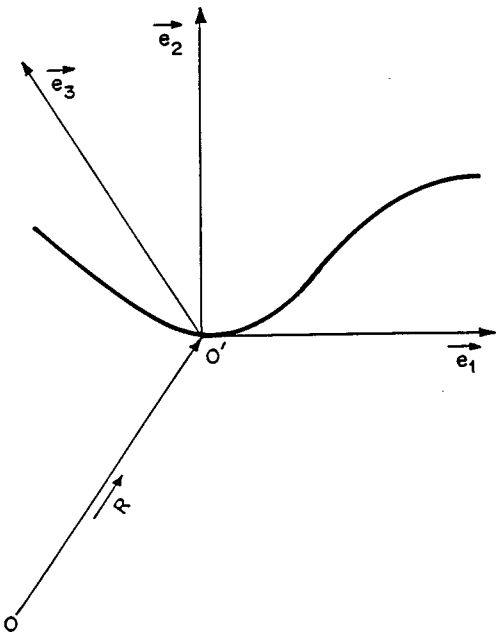

FIG. 1. Motion of a space curve in E^3 with the orthogonal trihedral $\mathbf{e}_1$, $\mathbf{e}_2$ and $\mathbf{e}_3$.

as special motions of surfaces in E^3 by inducing the surfaces in it via the solutions to two dimensional linear problems (2D LPs). But in the present paper, we are interested in extending the theory of moving space curve formalism in (1+1) dimensions to (2+1) dimensions.

We consider the space curve in E^3 as in Fig. 1, defined by the Serret-Frenet equations,[13]

$$\mathbf{e}_{jx}=\mathbf{D}\wedge\mathbf{e}_j, \quad \mathbf{D}=\tau\mathbf{e}_1+\kappa\mathbf{e}_3, \quad j=1,2,3, \tag{1}$$

where $\mathbf{e}_1$, $\mathbf{e}_2$ and $\mathbf{e}_3$ are the unit tangent, normal and binormal vectors, respectively, to the curve. Here x is the arclength parametrizing the curve. The curvature and torsion of the curve are defined, respectively, as

$$\begin{aligned}\kappa&=(\mathbf{e}_{1x}\cdot\mathbf{e}_{1x})^{1/2},\\ \tau&=\kappa^{-2}\mathbf{e}_1\cdot(\mathbf{e}_{1x}\wedge\mathbf{e}_{1xx}).\end{aligned} \tag{2}$$

The unit tangent vector $\mathbf{e}_1$ is given by $\mathbf{e}_1=\partial\mathbf{r}/\partial x=(1/\sqrt{g})(\partial\mathbf{r}/\partial\theta)$ where g is the metric $g=(\partial\mathbf{r}/\partial\theta)(\partial\mathbf{r}/\partial\theta)$ on the curve such that $x(\theta,t)=\int_0^\theta\sqrt{g(\theta',t)}d\theta'$. Here θ defines a smooth curve and $\mathbf{r}(\theta,t)$ is the position vector of a point on the curve at time t. Considering the motion of such a twisted curve, the time evolution of the orthogonal trihedral can be easily seen[3] to be

$$\begin{aligned}\mathbf{e}_{jt}&=\mathbf{\Omega}\wedge\mathbf{e}_j,\\ \mathbf{\Omega}&=\omega_1\mathbf{e}_1+\omega_2\mathbf{e}_2+\omega_3\mathbf{e}_3, \quad j=1,2,3,\end{aligned} \tag{3}$$

where $\omega_i, i=1,2,3$ are some functions of κ and τ and their derivatives. Then the compatibility of Eqs. (1) and (3) gives the evolution equations for κ and τ as[3]

$$\begin{aligned}\kappa_t&=\omega_{3x}+\tau\omega_2,\\ \tau_t&=\omega_{1x}-\kappa\omega_2,\\ \omega_{2x}&=\tau\omega_3-\kappa\omega_1.\end{aligned} \tag{4}$$

Now let us pass on to the subject of this paper, namely, to the theory of curves in (2+1) dimensions by endowing them with an additional spatial variable y. Alternately this could repre-

sent a surface specified by the trihedral $\mathbf{e}_j(x,y,t)$ which is set in motion. A starting point of our approach is the observation that the y-evolution of the trihedral $\mathbf{e}_j$ is determined by the following system of linear equations[14] (see also Refs. 15, 16);

$$\mathbf{e}_{jy}=\mathbf{\Gamma}\wedge\mathbf{e}_j,$$
$$\mathbf{\Gamma}=\gamma_1\mathbf{e}_1+\gamma_2\mathbf{e}_2+\gamma_3\mathbf{e}_3. \tag{5}$$

Here γ_j's are functions to be determined. Using the fact that $\mathbf{e}_i$'s, $i=1,2,3$ form an orthogonal trihedral and using (1) and (5) in the compatibility condition $\mathbf{e}_{jxy}=\mathbf{e}_{jyx}$, we obtain

$$\gamma_1=\partial_x^{-1}(\tau_y+\kappa\gamma_2),\quad \gamma_3=\partial_x^{-1}(\kappa_y-\tau\gamma_2), \tag{6a}$$

and $\gamma_2(x,y,t)$ is a solution of the following equation:

$$-\kappa\gamma_2=\tau_y-\left[\frac{\tau\partial_x^{-1}(\kappa_y-\tau\gamma_2)-\gamma_{2x}}{\kappa}\right]_x, \tag{6b}$$

where $\partial_x^{-1}\equiv\int_{-\infty}^{x}dx$. We also note that Eqs. (1) and (5) may be identified with the Gauss-Weingarten equations of surface theory written in terms of orthogonal coordinates and so Eqs. (6) with the Codazzi-Mainardi equations. On the other hand, the condition $\mathbf{e}_{jty}=\mathbf{e}_{jyt}$ gives rise to the set of equations

$$\gamma_{1t}=\omega_{1y}+\omega_3\gamma_2-\omega_2\gamma_3,$$
$$\gamma_{2t}=\omega_{2y}+\omega_1\gamma_3-\omega_3\gamma_1, \tag{7}$$
$$\gamma_{3t}=\omega_{3y}+\omega_2\gamma_1-\omega_1\gamma_2.$$

Choosing $\gamma_1,\gamma_2,\gamma_3$ consistently so that Eqs. (4) and (7) are compatible, one can obtain (2+1) dimensional evolution equations for κ and τ. Further one can easily show that the defining equations for the motion of the trihedral, namely (1), (3) and (5) are equivalent to a set of three Riccati equations,

$$z_{lx}=-i\tau z_l+\frac{\kappa}{2}[1+z_l^2], \tag{8a}$$

$$z_{ly}=-i\gamma_1 z_l+\tfrac{1}{2}[\gamma_3+i\gamma_2]z_l^2+\tfrac{1}{2}[\gamma_3-i\gamma_2], \tag{8b}$$

and

$$z_{lt}=-i\omega_1 z_l+\tfrac{1}{2}[\omega_3+i\omega_2]z_l^2+\tfrac{1}{2}[\omega_3-i\omega_2], \tag{8c}$$

where z_l, $l=1,2,3$ is a scalar variable obtained through an orthogonal rotation of the trihedral, $z_l=(e_{2l}+ie_{3l})/(1-e_{1l})$, $e_{1l}^2+e_{2l}^2+e_{3l}^2=1$. Introducing the transformation $z_l=v_2/v_1$, we obtain the triad of equivalent linear equations:

$$v_{1x}=\frac{i\tau}{2}v_1-\frac{\kappa}{2}v_2,\quad v_{2x}=\frac{\kappa}{2}v_1-\frac{i\tau}{2}v_2, \tag{9a}$$

$$v_{1y}=\frac{i\gamma_1}{2}v_1-\frac{1}{2}(\gamma_3+i\gamma_2)v_2,\quad v_{2y}=\frac{1}{2}(\gamma_3-i\gamma_2)v_1-\frac{i\gamma_1}{2}v_2, \tag{9b}$$

$$v_{1t}=\frac{i\omega_1}{2}v_1-\frac{1}{2}(\omega_3+i\omega_2)v_2,\quad v_{2t}=\frac{1}{2}(\omega_3-i\omega_2)v_1-\frac{i\omega_1}{2}v_2. \tag{9c}$$

The compatibility of these linear equations again gives rise to Eqs. (4), (6) and (7). Thus any nonlinear evolution equation obtained through the space curve formulation in (2+1) dimensions is equivalent to a triad of linear equations. Specific examples are given below.

The above formulation then leads us in a natural way to certain topological invariants as given in the following theorem.

Theorem: The above constructed evolution equations in (2+1) dimensions possess the following integrals of motion:[14]

$$K_1=\frac{1}{4\pi}\int\int(-\kappa\gamma_2)dxdy,$$
$$K_2=\frac{1}{4\pi}\int\int(-\tau\gamma_2)dxdy. \tag{10a}$$

Proof: The proof is straightforward and follows from the various relations discussed above. For example, from (6a) we get $(-\kappa\gamma_2)_t=(\tau_t)_y-(\gamma_{1t})_x$, or $(-\kappa\gamma_2)_t=(\omega_{1x}-\kappa\omega_2)_y-(\omega_{1y}+\omega_3\gamma_2-\omega_2\gamma_3)_x$. Hence follows the first statement of the theorem. Similarly the second one may also be proved. In terms of the unit vector $\mathbf{e}_1$ these integrals of motion take the form

$$K_1=\frac{1}{4\pi}\int\int\mathbf{e}_1\cdot(\mathbf{e}_{1x}\wedge\mathbf{e}_{1y})dxdy,$$

and

$$K_2=\frac{1}{4\pi}\int\int\frac{[\mathbf{e}_1\cdot(\mathbf{e}_{1x}\wedge\mathbf{e}_{1y})][\mathbf{e}_1\cdot(\mathbf{e}_{1x}\wedge\mathbf{e}_{1xx})]}{(\mathbf{e}_{1x}^2)^{3/2}}dxdy. \tag{10b}$$

So the above quantities K_j are the conserved integrals — invariants of the (2+1) dimensional evolution equations and they play an important role in the theory. In particular, curves can be classified by the value of the topological invariants K_j but we will not pursue this aspect further. We now present a few applications of the above presented formalism in finding the geometrically equivalent counterparts of some known (2+1) dimensional spin systems. To this end, first, following Ref. 10, we identify the tangent vector $\mathbf{e}_1$ with the unit spin vector $\mathbf{e}_1\equiv\mathbf{S}(x,y,t)$. Second, we introduce the following complex transformation which is a generalization of the one given in Ref. 10:

$$q(x,y,t)=a(x,y,t)\exp\, ib(x,y,t), \tag{11}$$

where $a(x,y,t)$ and $b(x,y,t)$ are functions of κ and τ, to be determined, and obtain the equation for the complex function $q(x,y,t)$ which turns out to be an interesting integrable (2+1) dimensional nonlinear evolution equation. We want to demonstrate our approach in the following examples of the (2+1) dimensional spin systems.

A. The Myrzakulov I (M-I) equation. This equation reads as[14,15]

$$\mathbf{e}_{1t}=(\mathbf{e}_1\wedge\mathbf{e}_{1y}+u\mathbf{e}_1)_x,\quad \mathbf{e}_1=\mathbf{S}(x,y,t), \tag{12a}$$

$$u_x=-\mathbf{e}_1\cdot(\mathbf{e}_{1x}\wedge\mathbf{e}_{1y}). \tag{12b}$$

In this case, we obtain

$$\gamma_2=\frac{u_x}{\kappa}, \tag{13a}$$

$$\mathbf{\Omega}=(\omega_1,\omega_2,\omega_3)=\left(\frac{\kappa_{xy}}{\kappa}-\tau\partial_x^{-1}\tau_y,-\kappa_y,-\kappa\partial_x^{-1}\tau_y\right). \tag{13b}$$

For the functions $a(x,y,t)$ and $b(x,y,t)$ in the transformation (11), we take the form

$$a=\frac{\kappa(x,y,t)}{2}, \quad b=-\partial_x^{-1}\tau(x,y,t). \tag{14}$$

Then the function q satisfies the following evolution equation:

$$iq_t(x,y,t)=q_{xy}+Vq, \quad V_x=2(|q|^2)_y, \tag{15}$$

an equation which belongs to the class of equations originally discovered by Calogero[17] and then discussed by Zakharov[18] and recently rederived by Strachan.[19] Many of its properties have received considerable attention recently.[20]

B. The Myrzakulov III (M-III) equation. This equation which is a generalization of Eq. (12) has the form[14]

$$\mathbf{e}_{1t}=(\mathbf{e}_1\wedge\mathbf{e}_{1y}+u\mathbf{e}_1)_x+2f(cf+d)\mathbf{e}_{1y}-4cv\mathbf{e}_{1x}, \tag{16a}$$

$$u_x=-\mathbf{e}_1\cdot(\mathbf{e}_{1x}\wedge\mathbf{e}_{1y}), \quad v_x=\frac{1}{4(2fc+d)^2}(\mathbf{e}_{1x}^2)_y, \tag{16b}$$

where f, c and d are constants. In this case, using the same form for γ_i's and ω_i's as in Eq. (13) and with the following choice for the functions $a(x,y,t)$ and $b(x,y,t)$,

$$a(x,y,t)=\frac{\kappa(x,y,t)}{2(2cf+d)}, \quad b(x,y,t)=2f(cf+d)x-\partial_x^{-1}\tau, \tag{17}$$

we obtain the evolution equation

$$iq_t(x,y,t)=q_{xy}-4ic(Vq)_x+2d^2Vq, \quad V_x=(|q|^2)_y. \tag{18}$$

This equation as well as the M-III equations (16) are integrable, that is, they have the Lax representations[14] and some properties of both equations were investigated in Refs. 14–16, 21, 22. Note that Eqs. (16) and (18) admit integrable reductions: when $c=0$ they pass on to the M-I and Zakharov equations, Eqs. (12) and (15), respectively. If we consider the case $d=0$, then they reduce to the M-II and Strachan equations, respectively.[23]

C. The Ishimori equation. This equation has the form[24]

$$\mathbf{e}_{1t}=\mathbf{e}_1\wedge(\mathbf{e}_{1xx}+\sigma^2\mathbf{e}_{yy})+u_x\mathbf{e}_{1y}+u_y\mathbf{e}_{1x}, \tag{19a}$$

$$u_{xx}-\sigma^2u_{yy}=-2\sigma^2\mathbf{e}_1\cdot(\mathbf{e}_{1x}\wedge\mathbf{e}_{1y}), \tag{19b}$$

where $\sigma^2=\pm1$. For the case $\sigma^2=-1$, we obtain

$$\gamma_2=\frac{u_{xx}+u_{yy}}{-2\kappa},$$

$$\omega_1=\frac{\tau\omega_3-\omega_{2x}}{\kappa}, \tag{20a}$$

$$\omega_2=u_x\gamma_2-\kappa_x+\gamma_{3y}+\gamma_1\gamma_2, \tag{20b}$$

$$\omega_3=-\kappa\tau+\kappa u_y+u_x\gamma_3-\gamma_{2y}+\gamma_1\gamma_3. \tag{20c}$$

If we choose $a(x,y,t)$ and $b(x,y,t)$ in the form

$$a=\tfrac{1}{2}[\kappa^2+\gamma_2^2+\gamma_3^2-2\kappa\gamma_2]^{1/2}, \tag{21a}$$

$$b=\partial_x^{-1}\left(\tau-\frac{u_y}{2}+\frac{\gamma_2\gamma_{3x}-\gamma_3\gamma_{2x}-\kappa\gamma_{3x}}{\kappa^2+\gamma_2^2+\gamma_3^2-2\kappa\gamma_2}\right), \tag{21b}$$

then the function q satisfies the following equation:

$$iq_t(x,y,t)+q_{xx}-q_{yy}-2q\phi=0, \tag{22a}$$

$$\phi_{xx}+\phi_{yy}+(|q|^2)_{xx}-(|q|^2)_{yy}=0, \tag{22b}$$

where ϕ is a function of x, y and t, which is nothing but the Davey-Stewartson equation II.[6] Note that Eqs. (19) and (22) are known to be gauge equivalent to each other.[25] Here their geometrical equivalence has been estabilished. Similarly equivalence can be established for $\sigma^2=1$.

D. The (2+1) dimensional isotropic Heisenberg ferromagnet model. This equation has the form[26]

$$\mathbf{e}_{1t}=\mathbf{e}_1\wedge(\mathbf{e}_{1xx}+\mathbf{e}_{1yy}). \tag{23}$$

In this case, we get

$$\omega_1=\frac{\tau\omega_3-\omega_{2x}}{\kappa},\quad \omega_2=-\kappa_x-\gamma_{3y}-\gamma_1\gamma_2,$$
$$\omega_3=\gamma_{2y}-\kappa\tau-\gamma_1\gamma_3. \tag{24}$$

However one finds that γ_i's can not be uniquely found due to the lack of an equation of the form (12b) or (16b) or (19b). So Eq. (6b) does not appear to be solvable, indicating that no straightforward linearization is available for the (2+1) dimensional isotropic Heisenberg spin equation without introducing constraints.

In conclusion, we have shown that a geometrical formulation can be developed for a class of (2+1) dimensional nonlinear evolution equations through moving space curve formalism. The formulation shows how a class of evolution equations can be associated with a triad of linear equations. Whether such a connection alone is sufficient to prove the integrability of the underlying (2+1) dimensional systems is a further intricate question. Even in (1+1) dimensions, there are some equations which though linearizable are not integrable; for example, the spherically symmetric Heisenberg ferromagnetic spin chain equation is equivalent to a nonlocal nonlinear Schrödinger equation which is of the nonPainlevé type and so is nonintegrable.[27] So also is the (1+1) dimensional isotropic Landau-Lifshitz equation with Gilbert damping[28] and so on. However the three examples considered in this paper are integrable namely, the M-I, M-III and Ishimori equations and their geometrical equivalents namely the Zakharov, Strachan and Davey-Stewartson equations, respectively, are also integrable. Their linearization can be performed through the set of equations (9) and the associated linear eigenvalue problems can be constructed. On the other hand the pure isotropic Heisenberg spin chain equation in (2+1) dimensions (example D above) seems not to be even linearizable by the space curve formalism without constraints, indicating the necessity of additional scalar fields or nonlocal terms for its linearization. It is hoped that other (2+1) dimensional equations of interest like the (2+1) dimensional Korteweg-de Vries, Nizhnik-Novikov-Veselov, breaking soliton, etc. equations and so on may have similar geometrical interpretations in terms of moving space curves or surfaces, for example with restrictions on the value of the curvature κ or torsion τ. These possibilities are being explored at present.

Finally it is of interest to consider the connection between our approach and to that of Konopelchenko who uses the (2+1) dimensional nonlinear PDEs to induce integrable dynamics (deformations) of the induced surfaces.[11] In our approach, we consider the compatibility of three linear problems, namely equations (1), (3) and (5). Two of them [equations (1) and (5)] can be considered as equivalent to general surfaces in orthogonal coordinates. In the approach of Konopelchenko, for a given 2D LP, the variable coordinates X^i $(i=1,2,3)$ of a surface in E^3 are defined as some integrals over certain bilinear combinations of solutions ψ of the 2D LP and solutions ψ^* of the adjoint 2D LP and thus surfaces are induced via the solutions of 2D LPs. Then the compatibilty of 2D LPs with time evolution leads to hierarchies of (2+1) dimensional nonlinear evolution equations both for the coefficients of the 2D LP and for the wave function ψ. This nonlinear evolution equation induces the corresponding evolution of the induced surface. In this sense, we believe that the two approaches differ from each other and give complementary approaches to integrable (2+1) dimensional evolution equations.

The secular solutions of the linearized Korteweg–de Vries equation

H. Leblond
Laboratoire P.O.M.A., E.P.-C.N.R.S. 130, Université d'Angers, 2 Bd Lavoisier, 49045 Angers, Cedex 01, France

(Received 15 December 1997; accepted for publication 20 January 1998)

We study the inhomogeneous linearized Korteweg–de Vries (KdV) equation. It is solved by the inverse scattering transform method. The secular-producing terms on the right-hand side (rhs) are characterized in several ways: first we give a mathematical characterization as resonant terms. Second, the secular-producing terms are interpreted as conserved densities of the KdV equation. Third, it is checked that the removal of all linear terms from the rhs, polynomial in the solution of KdV, ensures the boundness of the solution of the linearized equation. Fourth, considering this solution itself as the rhs, we determine which part of it is secular producing, and which part is not. © *1998 American Institute of Physics.*

I. INTRODUCTION

In multiscale expansions, as in other perturbative methods, conditions are obtained at each step of the calculus, or at each perturbative order, by the requirement that all terms in the expansion are finite. Indeed, the equations derived at each step of the perturbative scheme can present unbounded solutions, called ''secular,'' especially when they grow linearly with time. The elimination of these unphysical solutions give relations to be satisfied by the quantities defined at the previous order.

Let us consider some multiscale expansion, leading to the Korteweg–de Vries (KdV) equation, satisfied by the main term f of the wave under consideration. The KdV equation reads:

$$\partial_t f - 6 f \partial_x f + \partial_x^3 f = 0. \tag{1}$$

Let us consider now some higher order correction g to f. g can be treated either by the renormalization formalism of Kodama and Taniuti,[1] or by the multi-times formalism of Kraenkel *et al.*[2,3] It will obey a KdV equation linearized about f:

$$\partial_t g - 6 \partial_x (f g) + \partial_x^3 g = w. \tag{2}$$

The right-hand side member (rhs) w is some polynomial expression, depending on f and its derivatives, the corrections to f of lower order than g, and on their derivatives.

It is well known that the KdV equation (1) is completely integrable, i.e., that the Cauchy problem for it can be solved by use of the inverse scattering transform (IST) method.[4–6] The IST method also gives explicit formulas for the resolution of the linearized KdV equation (2).[1] We recall this resolution in Sec. II. Unfortunately, the solution computed this way [formulas (15)–(17)] is not always bounded. If not, it is called ''secular.'' This phenomena occurs when a term on the rhs ''resonates,'' that is, from a mathematical point of view, when this term is a solution of the homogeneous equation (5). Physically, the resonance phenomenon occurs when each component of the inverse scattering transform of the source term evolves in time in the same way as the corresponding component in the transform of the main term. This gives rise to some mathematical characterization of the secular-producing terms that we give in Sec. III.

It can be read in the documentation[3,1] that the secular-producing terms are the linear ones. We discuss this assertion in detail in Sec. IV. It is seen that the secular-producing terms coincide with the derivatives of the conserved densities of the KdV equation, and that the removal of the linear terms, using the multiple time formalism of Kraenkel *et al.* and the KdV hierarchy, removes in

 © 1998 American Institute of Physics

fact all the secular-producing terms. Section V is devoted to the question of whether the solutions of the linearized KdV equation (2) are secular producing: indeed, the solution of the equation governing the second order of the perturbative expansion appears on the rhs of the equation that governs the evolution of the term of order three, and so on. It is thus necessary to answer this question, if we intend to prove that a given multiscale expansion, whose first term obeys KdV, can be solved up to any order, with all its terms bounded.

II. RESOLUTION OF THE LINEARIZED KDV EQUATION

The equation is linear, thus one could want to avoid using the heavy machinery of the IST method, and solve it in a simpler way, e.g., by use of a Fourier transform. In fact, here use of the IST method is necessary. Indeed, the solution f of the KdV equation intervenes in the present equation as an essential parameter, and in the general case it can be only expressed in terms of its inverse transform.

Let us recall some features related to the resolution of the KdV equation (1) through the inverse scattering transform (IST) method. Let us call ϕ_k and ψ_k the Jost functions, which are the solutions of the scattering equation:

$$\partial_x^2\psi+(k^2-f\,)\psi=0, \tag{3}$$

which satisfy the conditions

$$\phi_k \underset{x\to+\infty}{\sim} e^{+ikx}, \quad \psi_k \underset{x\to-\infty}{\sim} e^{-ikx}. \tag{4}$$

For each k real, or purely imaginary zero of the scattering coefficient $a(k)$, let us define

$$\Phi_k=\phi_k^2$$

and

$$\Psi_k=\partial_x(\psi_k^2).$$

The functions $\Phi_k e^{-8ik^3t}$ and $\Psi_k e^{-8ik^3t}$ are solutions of the homogeneous linearized KdV equation:

$$\partial_t g-6\partial_x(fg)+\partial_x^3 g=0. \tag{5}$$

Thus, the general solution of this equation is a linear combination (or integral) of these functions. Fortunately, there exists a closure formula for them (it is given, although with some typing mistakes, in Ref. 1, and can be proved in the same way as the closure formula for the Jost functions, which is detailed, e.g., in Ref. 6). It reads:

$$\begin{aligned} &i\int_{-\infty}^{+\infty}\frac{dk}{2\pi}\,\Phi_k(x,t)\,\frac{1}{ka^2(k)}\,\Psi_k(y,t)+\sum_{l=1}^{n}\frac{1}{i\kappa_l\dot a_l^2}\,\partial_k(\Phi_k(x,t)\Psi_k(y,t))|_{k=i\kappa_l}\\ &\quad+\sum_{l=1}^{n}\left(\frac{1}{\kappa_l^2\dot a_l^2}+\frac{i\ddot a_l}{\kappa_l\dot a_l^3}\right)\Phi_l(x,t)\Psi_l(y,t)=\delta(x-y). \end{aligned} \tag{6}$$

We use the notation: $\Phi_l=\Phi_k|_{k=i\kappa_l}$, and the analogous notation for Ψ_l. The scattering data are defined in such a way that (an asterisk denotes complex conjugation):

$$\begin{aligned} &\psi_k=a(k)\phi_k^*+b(k)\phi_k\\ &\dot a_l=\left.\frac{da(k)}{dk}\right|_{k=i\kappa_l}, \quad a(i\kappa_l)=0 \end{aligned} \tag{7}$$

Precisely, we want to solve Eq. (2), in which (1) f is some fixed solution of the KdV equation (1), corresponding to the Jost functions ϕ_k, ψ_k and the scattering data $\{\kappa_l\}_{l=1,\ldots,n}$, $a(k)$, $\dot{a}_l$, $\ddot{a}_l$; (2) w is some given function (real, smooth and vanishing quickly enough at infinity); (3) g is assumed to verify some initial condition, i.e., for $t=0$, g is equal to some given function g_0 (with the same regularity properties as w).

We define the following coefficients:

$$w(k,t)=\lambda(k)(\Phi_k,w)(t), \tag{8}$$

$$w_l^{(1)}(t)=\lambda_l(\Phi_l,w)(t)+\mu_l(\partial_k\Phi_l,w)(t), \tag{9}$$

$$w_l^{(2)}(t)=\mu_l(\Phi_l,w)(t). \tag{10}$$

The scalar product $(\cdot,\cdot)$ is defined by

$$(v_1,v_2)(t)=\int_{-\infty}^{+\infty} v_1(x,t)v_2(x,t)dx$$

and the constants by

$$\lambda(k)=\frac{i}{2\pi}\frac{1}{ka^2(k)}, \tag{11}$$

$$\lambda_l=\frac{1}{\kappa_l^2\dot{a}_l^2}+\frac{i\ddot{a}_l}{\kappa_l\dot{a}_l^3}, \tag{12}$$

$$\mu_l=\frac{1}{i\kappa_l\dot{a}_l^2}. \tag{13}$$

[Notice that the discrete eigenvalues κ_l and the scattering coefficients $a(k)$ do not depend on time.] We use the notation:

$$\partial_k\Phi_l=\partial_k\Phi_k|_{k=i\kappa_l}$$

and its analog for $\partial_k\Psi_l$. Consequently, the rhs w can be expanded in the following way:

$$w(x,t)=\int_{-\infty}^{+\infty} w(k,t)\Psi_k(x,t)dk+\sum_{l=1}^{n}[w_l^{(1)}(t)\Psi_l(x,t)+w_l^{(2)}(t)(\partial_k\Psi_l)(x,t)]. \tag{14}$$

We expand g_0 in the same way as w, with similar notations. Then the solution g of Eq. (2) reads:

$$g=g_1+g_2. \tag{15}$$

g_1 is a solution of the homogeneous equation (5) with the initial data g_0:

$$g_1(x,t)=\int_{-\infty}^{+\infty} g_0(k,t)\Psi_k(x,t)e^{-8ik^3t}dk+\sum_{l=1}^{n}[g_{0_l}^{(1)}(t)\Psi_l(x,t)$$
$$+g_{0_l}^{(2)}(t)[\partial_k\Psi_l(x,t)+24i\kappa_l^2t\Psi_l(x,t)]]e^{-8\kappa_l^3t}. \tag{16}$$

g_2 is a solution of the complete equation (2) with zero initial data:

$$g_2(x,t)=\int_{-\infty}^{+\infty}\Psi_k(x,t)\left[\int_0^t e^{8ik^3t'}w(k,t')dt'\right]e^{-8ik^3t}dk+\sum_{l=1}^{n}\left\{\Psi_l(x,t)\left[\int_0^t e^{8\kappa_l^3t'}w_l^{(1)}(t')dt'\right.\right.$$
$$\left.\left.+24i\kappa_l^2\int_0^t\int_0^{t'}e^{8\kappa_l^3t''}w_l^{(2)}(t'')dt'dt''\right]+\partial_k\Psi_l(x,t)\int_0^t e^{8\kappa_l^3t'}w_l^{(2)}(t')dt'\right\}e^{-8\kappa_l^3t}. \quad (17)$$

The expression of g is thus explicit, but explicit in terms of the squared Jost functions Φ_k, Ψ_k, that depend implicitly on the solution f of KdV.

III. THE SECULAR-PRODUCING TERMS ARE RESONANT

As stated in Sec. I, the solution g of the linearized KdV equation (2) computed previously is not bounded for any rhs w (I mean uniformly bounded in x as $t\to+\infty$). As an example, if the initial data for g is $g_0\equiv 0$, and the rhs $w=\partial_x f$, then

$$g=t\partial_x f. \quad (18)$$

This can be checked by explicit computation, either by transferring the solution (18) to Eq. (2), or by using formulas (8)–(17). This latter computation is lengthy, but it is important to see that it works. A solution like (18) is called *secular*, while it grows linearly with t. The corresponding rhs are called secular producing. They can be characterized as resonant terms, as follows. As written above, the resonance phenomenon occurs when the components of the inverse scattering transform of the source term (the rhs w) evolve in time in the same way as the corresponding components in the transform of the main term, i.e., if they oscillate with the same frequency $(8k^3)$, concerning the radiative part, or decrease with the same rate $(8\kappa_j^3)$, for the discrete spectrum part.

First, we can see that, if some given function w satisfies the condition

$$\partial_t(\Phi_k,w)=-8ik^3(\Phi_k,w) \quad (19)$$

for each k with $\mathrm{Im}\,k\geqslant 0$, then the corresponding solution g of the linearized KdV equation (2), with the rhs w and a zero initial condition is:

$$g=tw. \quad (20)$$

From (19), we see that

$$(\Phi_k w)(t)=(\Phi_k,w)(0)e^{-8ik^3t}, \quad (21)$$

$$(\Phi_j,w)(t)=(\Phi_j,w)(0)e^{-8\kappa_j^3t}, \quad (22)$$

$$(\partial_k\Phi_j,w)(t)=[(\partial_k\Phi_j,w)(0)+24i\kappa_j^2t(\Phi_j,w)(0)]e^{-8\kappa_j^3t}. \quad (23)$$

We compute the solution g of the linearized KdV equation (2) through expressions (15)–(17). We choose a zero initial condition $g_0=0$, thus g_1 is zero. The explicit t-dependency of $w(k,t)$, $w_j^{(1)}(t)$, $w_j^{(2)}(t)$ given by expressions (21)–(23) enables us to compute the integrals in formula (17). After factorization by a t factor, comparison with the expression of w obtained by substituting formulas (21)–(23) into (14) yields Eq. (20). The time evolution law (19) characterizes the secular-producing terms. It is intimately related with the time evolution of the scattering data. Thus we can understand the secular-producing terms as resonant, in the following sense: their components through the inverse scattering transform evolve in time in the same way as does the first-order solution f [see the expression of $\mathscr{A}_1=\frac{1}{2}f$, formula (47) in Sec. IV]. It is not necessary that relation (19) is satisfied for any k with $\mathrm{Im}\,k\geqslant 0$. The following condition is sufficient: (19) is satisfied for any real k and both this relation and its k derivative are satisfied for any $k=i\kappa_j$ of the discrete spectrum. The derivative of relation (19) reads:

$$\partial_t(\partial_k\Phi_j,w)=24i\kappa_j^2t(\Phi_k,w)-8\kappa_j^3(\partial_k\Phi_j,w). \quad (24)$$

An alternative way to describe this feature is the following mathematical property, that also characterizes the secular-producing terms: For a given smooth function w, and for any k with $\mathrm{Im}\, k \geqslant 0$, we define

$$\mathscr{M}_w(k) = \lim_{t \to +\infty} \frac{1}{t} \int_0^t e^{8ik^3 t'} (\Phi_k, w) dt'. \tag{25}$$

Then w is not secular producing if $\mathscr{M}_w(k) = 0$ for each k. Before we give some proof of this feature, we can show that the part of w corresponding to a nonzero $\mathscr{M}_w(k)$ is secular producing. Let us call this part w_m, and define it by

$$w_m(x,t) = \int_{-\infty}^{+\infty} w_m(k,t) \Psi_k(x,t) + \sum_{j=1}^{n} \left(w_{m,j}^{(1)}(t) \Psi_j(x,t) + w_{m,j}^{(2)}(t) \partial_k \Psi_j(x,t) \right) \tag{26}$$

with

$$w_m(k,t) = \lambda(k) \mathscr{M}_w(k) e^{-8ik^3 t}, \quad k \in \mathbb{R}, \tag{27}$$

$$w_{m,j}^{(1)}(t) = \left(\lambda_j \mathscr{M}_w(i\kappa_j) + \mu_j \left[\frac{d\mathscr{M}_w}{dk}(i\kappa_j) + 24 i \kappa_j^2 t \mathscr{M}_w(i\kappa_j) \right] \right) e^{-8\kappa_j^3 t}, \tag{28}$$

$$w_{m,j}^{(2)}(t) = \mu_j \mathscr{M}_w(i\kappa_j) e^{-8\kappa_j^3 t}. \tag{29}$$

If we compare the t dependency of the components of w_m, given by Eqs. (27)–(29), to those of the function w in Eqs. (21)–(23), we see that they evolve in the same way, and conclude that w_m satisfies condition (19), and is thus secular producing. Reciprocally, if w itself satisfies Eq. (19), the t dependency of (Φ_k, w) is known, thus $\mathscr{M}_w(k)$ can be computed explicitly, and it is easily seen that $w = w_m$. Furthermore, we show below that if $\mathscr{M}_w(k) = 0$ for each k (with the necessary assumptions on uniform limits), that is, when w_m is zero, then the solution g of the linearized KdV equation is small with regard to t as t is large, i.e., w is not secular producing. It then appears clearly that the secular-producing part of w is w_m.

Let us now prove that the condition $\mathscr{M}_w(k) = 0$ implies that g is not secular producing. For this, we make different reasonings for the radiation part and for the discrete spectrum part of g. Let us first consider the radiation part. We assume that

$$w(x,t) = \int_{-\infty}^{+\infty} w(k,t) \Psi_k(x,t) dk \tag{30}$$

and we write:

$$m(k,t) = \frac{1}{t} \int_0^t (\Phi_k, w)(t') e^{8ik^3 t'} dt'. \tag{31}$$

Thus

$$\mathscr{M}_w(k) = \lim_{t \to +\infty} m(k,t) \tag{32}$$

and the condition $\mathscr{M}_w(k) = 0$ can be written:

$$m(k,t) \xrightarrow[t \to +\infty]{} 0. \tag{33}$$

Then, using formula (17) to solve Eq. (2), we find that

$$g(x,t) = \int_{-\infty}^{+\infty} \lambda(k) e^{-8ik^3 t} \Psi_k(x,t) t m(k,t) dk. \tag{34}$$

Since k is real, Ψ_k bounded with time, if we assume that the limit (33) is reached uniformly [or at least in $\mathscr{L}_1(k)$] then:

$$g(x,t) \underset{t\to+\infty}{=} o(t). \tag{35}$$

This shows that g is not secular, for the part that comes from the continuous spectrum, if $\mathscr{M}_w(k)=0$ for each real k.

Let us prove the analogous result for the discrete spectrum. Consider first the evolution of the normalization coefficients of the Jost functions φ_j, ψ_j, for the discrete eigenvalues κ_j. We have

$$\int_{-\infty}^{+\infty}[\varphi_j(x,t)]^2dx=\frac{i\dot{a}_j(t)}{c_j(t)}=\frac{i\dot{a}_j(0)}{c_j(0)}\,e^{-8\kappa_j^3t} \tag{36}$$

and

$$\int_{-\infty}^{+\infty}[\psi_j(x,t)]^2dx=i\dot{a}_j(t)c_j(t)=i\dot{a}_j(0)c_j(0)e^{+8\kappa_j^3t}. \tag{37}$$

Thus

$$\Phi_j=\Phi_j^0e^{-8\kappa_j^3t}$$

and

$$\Psi_j=\Psi_j^0e^{+8\kappa_j^3t}, \tag{38}$$

where the functions Φ_j^0 and Ψ_j^0 are bounded with regard to t. The hypothesis reads precisely as follows:

$$\mathscr{M}_w(i\kappa_j)=0$$

and

$$\frac{d\mathscr{M}_w}{dk}(i\kappa_j)=0 \tag{39}$$

for each j with $j=i\kappa_j$ in the discrete spectrum. We define:

$$m_j^{(1)}(t)=\frac{1}{t}\int_0^t[(\partial_k\Phi_j,w)(t')-24i\kappa_j^2t'(\Phi_j,w)(t')]e^{8\kappa_j^3t'}dt', \tag{40}$$

$$m_j^{(2)}(t)=\frac{1}{t}\int_0^t(\Phi_j,w)(t')e^{8\kappa_j^3t'}dt'. \tag{41}$$

Thus condition (39) can be written:

$$m_j^{(1)}(t),m_j^{(2)}(t)\xrightarrow[t\to+\infty]{}0. \tag{42}$$

The nonradiative part g_d of the solution g of Eq. (2) is given by the discrete sum in Eq. (17). The third integral in this sum is straightforward evaluated as $t\mu_lm_l^{(2)}(t)$, while the first one reads:

$$\int_0^te^{8\kappa_l^3t'}w_l^{(1)}(t')dt'=t\mu_lm_l^{(1)}(t)+t\lambda_lm_l^{(2)}(t)+\mu_l\int_0^t24i\kappa_l^2t'(\Phi_l,w)(t')e^{8\kappa_l^3t'}dt'. \tag{43}$$

An integration by part of the latter integral yields a term integrated two times, that cancels the second integral in the expression of g_d. Relation (38) yields the following expression of $\partial_k\Psi_j$:

$$\partial_k \Psi_j = (\partial_k \Psi_j^0 - 24 i \kappa_j 2^t \Psi_j^0) e^{8\kappa_j^3 t}. \tag{44}$$

Making use of (38) and (44) in the expression of g_d yields

$$g_d(x,t) = t \sum_{j=1}^{n} \{\Psi_j^0(x,t)[\mu_j m_j^{(1)}(t) + \lambda_j m_j^{(2)}(t)] + \partial_k \Psi_j^0(x,t) \mu_j m_j^{(2)}(t)\}. \tag{45}$$

Because Ψ_j^0 and $\partial_k \Psi_j^0$ are bounded and $m_j^{(1)}(t)$, $m_j^{(2)}(t)$ tend to zero as $t \to +\infty$, we see that

$$g_d(x,t) \underset{t \to +\infty}{=} o(t). \tag{46}$$

Thus g_d is not secular, that completes the proof.

IV. LINEAR TERMS AND CONSERVED DENSITIES

A. Relation between the conserved densities and the secular-producing terms

A completely integrable equation has the very important property to present an infinite number of conserved densities. These are algebraically independent functionals $\mathscr{A}_j$ of the solution, whose integral over all space is constant in time. In the case of the KdV equation, various representations of these densities are given in many books. Reference 1 gives an explicit expression in the form of an integral and linear combination of the squares of the Jost functions. It reads as follows:

$$\mathscr{A}_j(x,t) = 2(-1)^j \sum_{l=1}^{n} \kappa_l^{2j-1} C_l(t) \psi_l^2(x,t) + \frac{i}{\pi} \int_{-\infty}^{+\infty} k^{2j-1} r(k,t) \psi_k^2(x,t) dk. \tag{47}$$

C_l and $r(kt)$ are, respectively, the normalization coefficient for bounded states and the reflection coefficient, and characterize the scattering data: $r(k,t) = -\overline{b}(k,t)/a(k)$, $C_l(t) = -i/\dot{a}_l c_l(t)$. With the notations of Ref. 6, they are, respectively, $R_-(k,t)$ and $D_{-,j}(t)$. Thus

$$\partial_{x'} \mathscr{A}_j(x,t) = \sum_{l=1}^{n} \lambda_{j,l} e^{-8\kappa_l^3 t} \Psi_l(x,t) + \int_{-\infty}^{+\infty} \lambda_j(k) e^{-8ik^3 t} \Psi_k(x,t) dk \tag{48}$$

with:

$$\lambda_{j,l} = 2(-1)^j \kappa_l^{2j-1} C_l(0), \quad \lambda_j(k) = \frac{i}{\pi} k^{2j-1} r(k,0). \tag{49}$$

We see that $\partial_{x'} \mathscr{A}_j$ is a linear combination and integral of the elementary solutions of the homogeneous linearized KdV equation (5), thus it is itself a solution of this equation. This can also be proved by mathematical induction and direct computation, starting from the recurrence formula for the $\mathscr{A}_j$ (given, e.g., in Ref. 1):

$$\partial_{x'} \mathscr{A}_{j+1} = \frac{-1}{4} (\partial_{x'}^3 \mathscr{A}_j - 4f \partial_{x'} \mathscr{A}_j - 2(\partial_x f) \mathscr{A}_j), \quad \mathscr{A}_0 = 1. \tag{50}$$

Thus, the derivatives of the conserved densities are secular-producing terms.

Reciprocally, a secular-producing term is a solution g of the homogeneous linearized KdV equation (5). Let us prove that $U = \int_{-\infty}^{x} g(x',t) dx'$ is a conserved density. Using (5), we can write:

$$\partial_t \int_{-\infty}^{+\infty} U dx = 6 \int_{-\infty}^{+\infty} f g dx - \int_{-\infty}^{+\infty} \partial_x^2 g dx. \tag{51}$$

Assuming that g vanishes at infinity with its derivatives, the second integral is zero. The first one is a constant. Indeed, using Eqs. (1) and (5):

$$\partial_t(fg)=6\partial_x(f^2g)-\partial_x(f(\partial_x^2g)+(\partial_x^2f\ )g-(\partial_x^2f\ )(\partial_x^2g)). \tag{52}$$

Thus the integral over all space is 0 and

$$\partial_t^2\int_{-\infty}^{+\infty}Udx=0. \tag{53}$$

Thus $\int_{-\infty}^{+\infty}Udx=pt+q$, where p and q are constants. If U is a polynomial in f and its derivatives, U is bounded with time, and hence $p=0$. Finally, $\int_{-\infty}^{+\infty}Udx=q$ is a constant. Together with the above assumption, that U is a polynomial in f, $\partial_x f,\ldots$, this means that U is a conserved density of the KdV equation.

Thus, if we consider only the terms that express explicitly as functions of f and its derivatives, the secular-producing terms are the derivatives of the conserved densities.

B. The KdV hierarchy and the linear terms

Kodama and Taniuti stated that the secular-producing terms are the linear ones.[1] These authors checked this assertion by direct computation of the first few orders, in the particular case of the one soliton solution. But, to my knowledge, no general proof of this feature can be found. Despite this, the multiple time formalism by Kraenkel *et al.* rests on this statement. Let us recall this procedure: Starting from some system of PDE's describing some physical situation, an adequate multiscale expansion leads to the KdV equation (1) at main order $f=f_1$, and to linearized KdV equations (2) for the following orders $g=f_2,f_3,f_4,\ldots$, with rhs. $w=w_2,w_3,w_4,\ldots$, polynomial in f and its derivatives. The rhs w_j also depends on the already computed higher order corrections $f_2,\ldots,f_{j-1}$, and on their derivatives. The secular-producing terms in w_j must be removed, so that the solution g_j is bounded. Therefore, higher-order time variables $t_2,t_3,\ldots$, are introduced, so that, for a given $j\geqslant 2$, the rhs w_j contains a term proportional to $\partial_{t_j}f$. The t_j dependence of f is not yet determined at this order. It is shown that the equation governing this dependence must be the jth equation of the KdV hierarchy, which reads[7]

$$\partial_{\tau_j}f=\partial_x\mathscr{L}^jf. \tag{54}$$

The variable τ_j is proportional to t_j, and the recurrence operator $\mathscr{L}$ is defined by

$$\mathscr{L}=-\frac{1}{4}\partial_x^2+f-\frac{1}{2}\int^x dx(\partial_x f\ ). \tag{55}$$

The only adjustable parameter is the constant α_j such as $\tau_j=\alpha_j t_j$. It is determined by the requirement that the linear term in the equation of the KdV hierarchy (54), $\alpha_j(-1/4)^j\partial_x^{2j+1}f$, cancels the linear term in w_j, that is also proportional to $\partial_x^{2j+1}f$, due to the homogeneity properties of the expansion. If the secular-producing terms are the linear ones, they are removed by this procedure.

But we have shown that the secular-producing terms are the x derivatives of the conserved densities. We prove that the previous procedure not only removes their linear part, but these terms totally. Indeed, integration by parts in expression (50), and immediate mathematical induction show that:

$$\mathscr{A}_j=\tfrac{1}{2}\mathscr{L}^{j-1}f \tag{56}$$

so that the equations of the KdV hierarchy (50) can be written:

$$\partial_{\tau_j}f=2\partial_x\mathscr{A}_{j+1}. \tag{57}$$

Thus the requirement that the linear terms are removed by using the KdV hierarchy, removes all terms of the $\partial_x\mathscr{A}_j$, which are exactly the secular-producing terms. Thus, the removal of the linear terms in the rhs w_j gives a correct result, even if the nonlinear part of the conserved densities is secular-producing.

C. Are the solutions of the linearized KdV equation secular producing?

This question is important because, as soon as we consider the third nonzero term in the perturbative expansion, the rhs w depends on the second term, which is some solution of the linearized KdV equation (2). The secular-producing terms coming from the leading order solution f have been studied in the previous section, the present section is devoted to the study of the effects of the terms of higher order.

Consider the solution $g=g_1+g_2$ for linearized KdV equation (2) described by formulas (15)–(17). The part g_1 of g that comes from the initial data is a solution of the homogeneous linearized KdV equation, and thus is secular producing. We will show that the part g_2 that comes from the rhs is not. To prove this, we shall compute the quantities $\mathscr{M}_{g_2}(k)=\lim_{t\to+\infty} m_{g_2}(k,t)$ and show that they are zero. In order to compute the quantities

$$m_{g_2}(k,t)=\frac{1}{t}\int_0^t e^{8ik^3t'}(\Phi_k,g_2)(t')dt' \tag{58}$$

we need the following formulas, that give the scalar products of the functions Φ_k, Ψ_k:

$$(\Phi_k,\Psi_{k'})=-2i\pi k a^2(k)\delta(k-k') \quad (k,k'\in\mathbb{R}), \tag{59}$$

$$(\Phi_l,\partial_k\Psi_m)=(\partial_k\Phi_l,\Psi_m)=i\kappa_l\dot{a}_l^2\delta_{l,m} \quad (l,m \text{ integer}), \tag{60}$$

$$(\Phi_l,\Psi_m)=(\Phi_k,\Psi_m)=0 \quad (k\in\mathbb{R},l,m \text{ integer}), \tag{61}$$

$$(\partial_k\Phi_l,\partial_k\Psi_m)=(\dot{a}_l^2+i\kappa_l\dot{a}_l\ddot{a}_l)\delta_{l,m} \quad (l,m \text{ integer}). \tag{62}$$

(These formulas are given in Ref. 1.) We find for a real k:

$$m_{g_2}(k,t)=\frac{1}{t}\int_0^t t' m_w(k,t')dt', \tag{63}$$

$m_w(k,t)$ is defined by Eq. (31), as $m_{g_2}(k,t)$, but for the rhs w of Eq. (2) instead of its solution g_2. The hypothesis is that w is not secular producing, thus:

$$m_w(k,t)\xrightarrow[t\to+\infty]{}0.$$

We see that

$$\mathscr{M}_{g_2}(k)=\lim_{t\to+\infty} m_{g_2}(k,t)=0. \tag{64}$$

For the discrete eigenvalues, we find

$$(\Phi_j,g_2)(t)=e^{-8\kappa_j^3 t}i\kappa_j\dot{a}_j^2\int_0^t e^{8\kappa_j^3 t'}w_j^{(2)}(t')dt'. \tag{65}$$

Thus, as previously,

$$m_{g_2}(i\kappa_j,t)=\frac{1}{t}\int_0^t t' m_w(i\kappa_j,t')dt'. \tag{66}$$

Thus $\mathscr{M}_{g_2}(i\kappa_j)=0$. It is also necessary to check that

$$\frac{d\mathscr{M}_{g_2}}{dk}(i\kappa_j)=0.$$

Taking the k derivative of Eq. (58), we obtain

$$\partial_k m_{g_2}(i\kappa_j,t)=\frac{1}{t}\int_0^t[(\partial_k\Phi_j,g_2)(t')-24i\kappa_j^2t'(\Phi_j,g_2)(t')]e^{8\kappa_j^3t'}dt'. \tag{67}$$

We obtain directly

$$(\Phi_j,g_2)(t)=e^{-8\kappa_j^3t}tm_w(i\kappa_j,t) \tag{68}$$

and, after some algebra

$$(\partial_k\Phi_j,g_2)(t)e^{8\kappa_j^3t}=\int_0^t e^{8\kappa_j^3t'}(\partial_k\Phi_j,w)(t')dt'+24i\kappa_j^2\int_0^t dt'\int_0^{t'}dt''e^{8\kappa_j^3t''}(\Phi_j,w)(t''). \tag{69}$$

Equation (67) reduces to

$$\partial_k m_{g_2}(i\kappa_j,t)=\frac{1}{t}\int_0^t dt'\left\{\int_0^{t'}e^{8\kappa_j^3t''}(\partial_k\Phi_j,w)(t'')dt''+24i\kappa_j^2 \times\left[\int_0^{t'}t''m_w(i\kappa_j,t'')dt''-t'^2m_w(i\kappa_j,t')\right]\right\}. \tag{70}$$

Making use of the expression of $\partial_k m_w(i\kappa_j,t)$, analogous to (67), and after an integration by parts, the expression of $\partial_k m_{g_2}(i\kappa_j,t)$, simplifies to

$$\partial_k m_{g_2}(i\kappa_j,t)=\frac{1}{t}\int_0^t t'\partial_k m_w(i\kappa_j,t')dt'. \tag{71}$$

While $\partial_k m_w(i\kappa_j,t)\to_{t\to+\infty}0$, we have

$$\partial_k m_{g_2}(i\kappa_j,t)\xrightarrow[t\to+\infty]{}0. \tag{72}$$

This completes the proof: g_2 is not secular producing.

Thus we have proved that the part of the solution of the linearized KdV equation that comes from the initial data is secular-producing, and the part that comes from the rhs (and would correspond to a zero initial data) is not.

V. CONCLUSION

The higher order terms in the perturbative expansion that describes KdV solitons obey the linearized KdV equation, with some rhs that expresses as a polynomial of the KdV solution. This linearized equation is solved by the inverse scattering transform method, in a quasiexplicit way. Unbounded or secular solutions exist for some values of the rhs. The terms on the rhs that produce these secular solutions have been characterized in several ways: First, a mathematical characterization, that does not take into account the dependency of the rhs on the leading order f, has been given. Second, the secular-producing terms have been interpreted as conserved densities of the KdV equation. Third, it has been checked that the removal of all terms linear in f, in some rhs w polynomial in f, ensures the boundness of the solution g of the linearized equation. Fourth, it has been determined which part of this solution g itself, considered as rhs, is secular producing, and which part is not.

All the conditions derived here are useful in the study of the higher order terms of the KdV-type multiscale expansions. They allow us to show the boundness of all terms in such an expansion. Boundness conditions for the higher order terms also fix the evolution of the main order term. In particular, we have justified an essential point of the multiple time expansions of Kraenkel *et al.*: The procedure that removes the linear terms in the rhs of the linearized KdV equation ensures the boundness of the solution.

ACKNOWLEDGMENTS

I express my gratitude to Dr. Isabelle Gruais (I.R.M.A.R., Université de Rennes, France), for helpful collaboration, and Professor Guy Métivier, for fruitful scientific discussions, and as Director of the P.D.E. lab. of the Institut de Recherche Mathématique de Rennes (I.R.M.A.R.), where I have begun the present study. I am also indebted to my former thesis director Dr. Miguel Manna (Laboratoire de Physique Mathématique, Université de Montpellier II, France), whose works on the KdV hierarchy have considerably influenced the present paper, and who gave me most of the bibliography.

In this paper some results on the local and global stability analysis of magnetic billiard systems, established on two dimensional Riemannian manifolds of constant curvature are presented, with particular emphasis on the hyperbolic plane. For special billiards, possessing a discrete group of (rotational or translational) symmetry, a geometrical theorem, illustrated by numerical simulations, is given on the stability of trajectories with the same symmetry. We also present sufficient criteria for the global hyperbolicity of the dynamics (hard chaos), and give lower estimations for the Lyapunov exponent in terms of the shape of the billiard. © *1998 American Institute of Physics.* [S0022-2488(98)02606-1]

I. INTRODUCTION AND SUMMARY

This paper is devoted to a detailed local and global stability analysis of the classical dynamics of magnetic billiard systems established on two-dimensional Riemannian manifolds of constant curvature. In these systems a pointlike particle moves at unit speed along curves of constant curvature $\beta \in \mathbb{R}$ in a bounded region Q (with a piecewise two times differentiable boundary) of the given two dimensional manifold, and performs elastic reflections at the boundary of the domain Q. This motion can be interpreted as the frictionless motion of a billiard ball of unit charge and mass on the (curved) billiard table Q affected by a homogeneous magnetic field of magnitude β perpendicular to the billiard surface.

Though this model is somewhat artificial, it covers plenty of important and intensively investigated dynamical systems, as limit cases. If the magnetic field and the curvature of the manifold are zero, ordinary billiard systems are obtained, which are fundamental models in ergodic theory[1–4] and have still great importance in studies of quantum chaos.[5] Since the geodesic motion on manifolds of negative curvature is hyperbolic,[6–8] it is also worth investigating billiard systems on curved manifolds in classical[9] or quantum chaos theory.[10,5,11]

The presence of magnetic field changes drastically the dynamics of the billiard system; it breaks time reversal symmetry, diminishes or completely suppresses hyperbolicity in the bounceless segments, and strongly influences the effects of the bounces.[12–14] Previously there has been work done on classical[15–17] and quantum billiards[18] with a magnetic field, even on curved spaces.[19] Recently the study of planar magnetic billiards gains considerable inspiration from mesoscopic physics, since under certain conditions the motion of electrons in two dimensional mesoscopic systems can be approximated with high accuracy by classical or semiclassical methods, and the transport properties of these systems can also be investigated experimentally in the presence of a magnetic field as well.[20]

These are the main motivations of the studies presented in this work. In the rest of this section the main results are summarized along with the organization of the paper.

In the next two sections (in opposition to the main title) manifolds of curvature $+1$ (sphere), 0 (Euclidean plane), and -1 (hyperbolic plane) are treated simultaneously, since parallel results can be obtained by similar arguments in all three cases. In Section II the former results of Ref. 12 concerning the stability of the dynamics in the bounceless segments and at the bounces are briefly reviewed (for the sake of completeness), and they are adapted to our present necessities. Some basic notions and notations are also introduced, which will be used throughout the whole article.

In Section III we deal with the study of the joint stability (Jacobian) matrix of a bounceless flight and the succeeding bounce, which has also been investigated in Refs. 13, 15, 16, 17 in the Euclidean case. In general this linear mapping depends on several parameters (the flying time, the

 © 1998 American Institute of Physics

magnetic field, the angle of incidence, and the curvature of the billiard wall at the bouncing point), nevertheless, a simple geometric rule can be given for determining the stability character of the map in hand. This criterion is derived through a series of lemmas. Some of the subsidiary calculations are put in Appendices A and B.

From the fourth section on, our attention is restricted solely to the hyperbolic plane. In Section IV the result of the preceding section is applied to symmetric periodic orbits in special billiards with discrete symmetry. Numerical investigations are also presented for a regular triangular billiard, showing that the periodic orbit in question loses its stability via period doubling bifurcation, as the magnetic field decreases.

Besides Section III, Section V contains the main results of the paper. In this section we give essentially two types of geometric criteria for global hyperbolicity in weak magnetic fields: one of them applies to Sinai-like[1] (magnetic) billiards, i.e., billiards with a piecewise smooth, everywhere (sufficiently) dispersing boundary and the other concerns Bunimovich-like ones,[2,3,21,22] i.e., billiards with a piecewise smooth boundary containing also (strongly) focusing arcs lying sufficiently far from each other. Our method also enables us to give an efficient lower estimation for the Lyapunov exponent in certain cases; this is demonstrated in Appendix C, for a Bunimovich-like (magnetic) billiard on the hyperbolic plane.

Our main findings are summarized again in the Conclusions.

II. FORMER RESULTS, NOTATIONS

In this section the basic formulas indispensable in stability analysis are shortly reviewed. Further details and the derivation of these relations in a more general context (considering an inhomogeneous magnetic field and nonconstant curvature) can be found in Ref. 12. The notations introduced here will be used throughout the whole paper without explicit reference.

Let $(M,\langle\cdot,\cdot\rangle)$ be a two dimensional Riemannian manifold of constant (Gaussian) curvature $r\in\{-1,0,1\}$ with scalar product $\langle\cdot,\cdot\rangle$, volume form Ω, and Levi-Civita connection ∇. Suppose that the billiard Q is defined on M and let $\gamma_0:\mathbb{R}\to M$ denote a trajectory of unit speed, i.e., a continuous curve parametrized by an arc length which satisfies the equation of motion $\nabla_{\dot\gamma_0}\dot\gamma_0 = \beta\dot\gamma_0$ during the bounceless segments, and obeys the law of elastic reflection at the bounces. The stability of this individual trajectory can be analyzed with the help of *infinitesimal variations* or *Jacobi fields*[23,12] which are piecewise smooth vector fields along γ_0. They are defined as the (partial) derivative of a *variation* $\delta(t,\epsilon)$ of the unvaried trajectory γ_0 with respect to the variational parameter ϵ at $\epsilon=0$, where the *variation* $\delta:\mathbb{R}\times(-\epsilon_0,\epsilon_0)\to M$ is a piecewise smooth (more precisely everywhere C^∞ except at the reflections, where it is C^0) mapping for which $\delta(t,0) = \gamma_0$ holds and the curves $t\mapsto\delta(t,\epsilon)$ are possible trajectories for all $\epsilon\in(-\epsilon_0,\epsilon_0)$.

This latter condition on δ results, that the Jacobi fields (along γ_0) can be equivalently characterized as solutions of a certain second order ordinary linear differential equation during the bounceless segments, which (and the first derivative of which) have certain jumps at the reflection points depending only on geometric data.[12,13] This means that the Jacobi fields are completely determined by four scalar data, their value, and their first derivative at an arbitrary point. (In fact, they constitute a four dimensional vector space.)

Using the orthonormal coordinate frame $\{\dot\gamma_0,\Omega(\dot\gamma_0)\}$ along the trajectory, the Jacobi field $V(t)=a(t)\dot\gamma_0+b(t)\Omega(\dot\gamma_0)$ can be split into a *longitudinal* and a *transverse* component, where a is the *longitudinal*, b is the *transverse coordinate*. Restricting our attention to variations of unit speed (*special variations*) and considering only the transverse part of the infinitesimal variation, the number of relevant dimensions can be reduced from four to two. In terms of the transverse coordinate b and its derivative b' the effect of the reflections and also the evolution during the bounceless segments can be formulated with the help of a linear transformation $\mathbf{L}$, i.e.,

$$\begin{pmatrix} b_+ \\ b'_+ \end{pmatrix} = \begin{pmatrix} L_{11} & L_{12} \\ L_{21} & L_{22} \end{pmatrix} \begin{pmatrix} b_- \\ b'_- \end{pmatrix},$$

where the subscripts ''+'' and ''−'' refer to the values of the coordinates after and before the transformation, respectively. Further we give the concrete form of the transformation $\mathbf{L}$ for different cases.

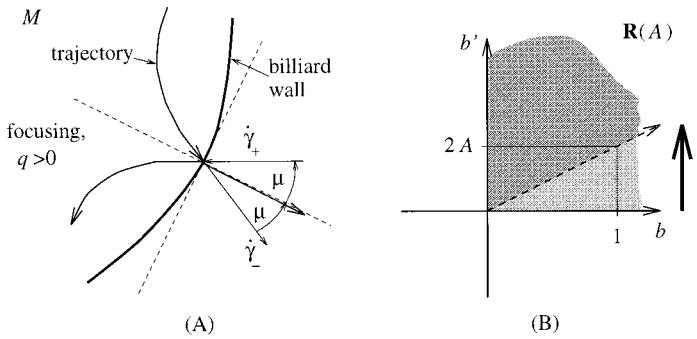

FIG. 1. The effect of the bounce.

A. The bounce

In this case the linear transformation denoted by $-\mathbf{R}(A)$ has the following matrix form:

$$-\mathbf{R}(A) := -\begin{pmatrix} 1 & 0 \\ 2A & 1 \end{pmatrix}, \quad A = -\frac{q+\beta\,\sin(\mu)}{\cos(\mu)}, \tag{1}$$

where q denotes the curvature of the billiard wall at the reflection point, β is the magnetic field, and μ is the angle of incidence. (The minus sign before the matrix, being irrelevant in most of the later calculations, will usually be omitted.) The sign conventions can be seen in figure 1/A; $q>0$ if the wall is focusing, and μ is measured from the incident velocity vector to the outward pointing normal vector. Figure 1/B shows that $\mathbf{R}(A)$ is a shearing in the (b,b') plane along the b' axis with parameter value $2A$.

(It should be noted, that in figure 1/A $\beta>0$, $q>0$ and $0<\mu<\pi/2$, i.e., $A<0$ while in figure 1/B $A>0$, so these figures do not correspond to the same situation.)

It has been derived in Ref. 12 that the transverse coordinate of the (special) Jacobi fields obeys the second order differential equation $b''=-(r+\beta^2)b$ during the bounceless segments, where r is the (constant) curvature of the manifold M and β is the (homogeneous) magnetic field. For describing the bounceless evolution of the Jacobi fields three different cases have to be considered separately according to the sign of $r+\beta^2$.

B. The elliptic case ($r+\beta^2>0$)

If $r=1$ or $r=0$ and $\beta\neq 0$ or $r=-1$ and $|\beta|>1$ then the bounceless segments are arcs of circles of radius R, and

$$\beta = \begin{cases} \cot(R), & \text{if } r=1 \text{ (on the sphere);} \\ 1/R, & \text{if } r=0 \text{ (on the Euclidean plane);} \\ \coth(R), & \text{if } r=-1 \text{ (on the hyperbolic plane).} \end{cases} \tag{2}$$

The evolution of the coordinates b, b' is given by the linear transformation $\mathbf{E}(t)$:

$$\mathbf{E}(t) := \begin{pmatrix} \cos(\chi t) & \dfrac{1}{\chi}\sin(\chi t) \\ -\chi\,\sin(\chi t) & \cos(\chi t) \end{pmatrix}, \quad \chi = \begin{cases} \sqrt{\beta^2+1}, & \text{if } r=1; \\ \beta, & \text{if } r=0; \\ \sqrt{\beta^2-1}, & \text{if } r=-1, \quad |\beta|<1. \end{cases} \tag{3}$$

The quantity χt appearing in the matrix has a geometric meaning; it is the angle at the center belonging to the arc of flight (figure 2/A). The matrix $\mathbf{E}(t)$ performs an (elliptic) rotation in the (b,b') plane (figure 2/B).

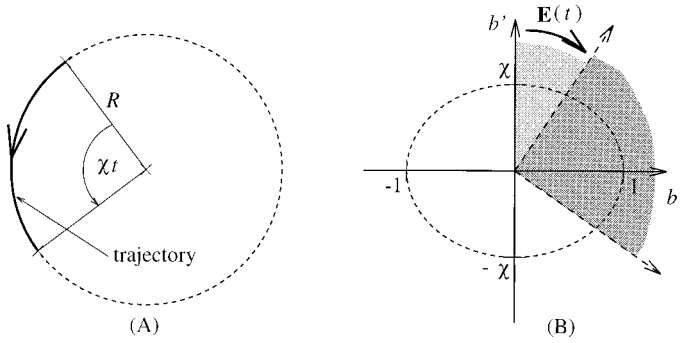

FIG. 2. The elliptic case.

C. The parabolic case ($r+\beta^2=0$)

It arises for $r=0$, $\beta=0$ or for $r=-1$, $|\beta|=1$. In the first case the particle moves along straight line segments on the Euclidean plane, while in the second case it follows segments of paracycles on the hyperbolic plane. In both cases the bounceless evolution of (b,b') is given by the matrix $\mathbf{P}(t)$:

$$\mathbf{P}(t):=\begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix}. \tag{4}$$

This transformation is a shearing in the (b,b') plane along the b axis with parameter value t, as shown in figure 3.

D. The hyperbolic case ($r+\beta^2<0$)

If $r=-1$ and $|\beta|<1$ then the bounceless trajectories are segments of hypercycles of altitude d (or specially geodesics, if $\beta=0$), and

$$\beta=\tanh(d). \tag{5}$$

In this case the evolution of the Jacobi field is described by the transformation $\mathbf{H}(t)$:

$$\mathbf{H}(t):=\begin{pmatrix} \cosh(\chi t) & \dfrac{1}{x}\sinh(\chi t) \\ \chi\sinh(\chi t) & \cosh(\chi t) \end{pmatrix}, \quad \chi=\sqrt{1-\beta^2}. \tag{6}$$

The quantity χt appearing in the matrix has again a geometric meaning; it is the length of the geodesic segment on the base line of the hypercycle which belongs to the arc of the bounceless

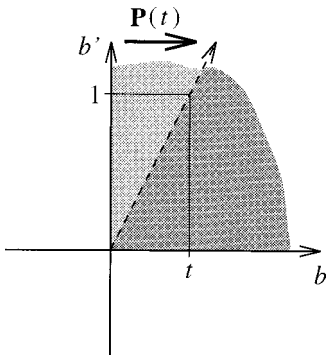

FIG. 3. The parabolic case.

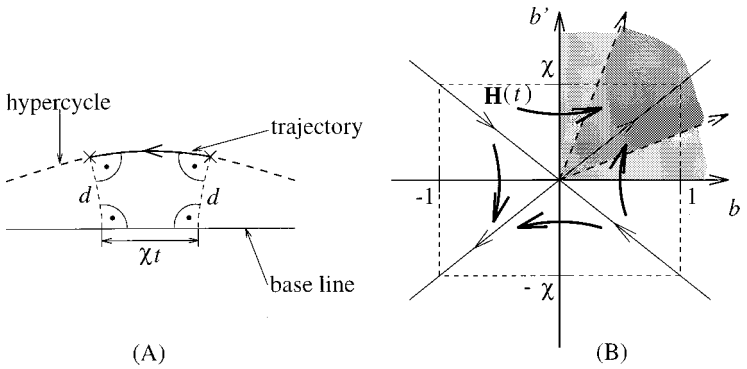

FIG. 4. The hyperbolic case.

flight, as shown in figure 4/A. The effect of the matrix $\mathbf{H}(t)$ is a hyperbolic transformation in the (b,b') plane (figure 4/B).

It is worth noticing that the transformations $\mathbf{R}(A)$, $\mathbf{E}(t)$, $\mathbf{P}(t)$, and $\mathbf{H}(t)$ appearing in the former paragraphs are all one parameter subgroups of the three dimensional Lie group $Sl(2;\mathbb{R})$ consisting of two by two real matrices of unit determinant. (The fact that these transformations are area preserving ones is due to the Hamiltonian nature of the original billiard problem.) The nontrivial elements (unequal to $\pm$identity) of this group can be divided into three disjoint classes; the *elliptic matrices* having trace strictly between -2 and 2 [like $\mathbf{E}(t)$, figure 2/B] perform rotations, and possess a pair of complex conjugate eigenvalues with no real eigenvectors; the *parabolic matrices* having trace ± 2 [like $\mathbf{R}(A)$ or $\mathbf{P}(t)$, figures 1/B, 3] perform shearings, and the 1 is a multiple eigenvalue of them with a single real eigenvector; while the *hyperbolic matrices* having trace strictly greater than 2 or less than -2 [like $\mathbf{H}(t)$, figure 4/B] describe a hyperbolic transformation with two real eigenvectors. Since every power of a matrix remains in the class of the original matrix, this classification carries over to the Lie algebra $sl(2;\mathbb{R})$ (consisting of matrices of zero trace) of the group in question.

The one parameter subgroups mentioned previously are generated by the following Lie algebra elements:

$$\mathbf{r}:=\left.\frac{d}{d(2A)}\right|_0 \mathbf{R}(A)=\begin{pmatrix}0 & 0\\ 1 & 0\end{pmatrix},\quad \mathbf{e}:=\left.\frac{d}{dt}\right|_0 \mathbf{E}(t)=\begin{pmatrix}0 & 1\\ -\chi^2 & 0\end{pmatrix},$$

$$\mathbf{p}:=\left.\frac{d}{dt}\right|_0 \mathbf{P}(t)=\begin{pmatrix}0 & 1\\ 0 & 0\end{pmatrix},\quad \mathbf{h}:=\left.\frac{d}{dt}\right|_0 \mathbf{H}(t)=\begin{pmatrix}0 & 1\\ \chi^2 & 0\end{pmatrix}. \tag{7}$$

Since

$$[\mathbf{r},\mathbf{e}]=[\mathbf{r},\mathbf{p}]=[\mathbf{r},\mathbf{h}]=\begin{pmatrix}-1 & 0\\ 0 & 1\end{pmatrix}, \tag{8}$$

it can be seen, that $\mathbf{r}$ with either $\mathbf{e}$ or $\mathbf{p}$ or $\mathbf{h}$ generates the whole Lie algebra $sl(2;\mathbb{R})$, so in stability analysis for every fixed value of r and β the whole three dimensional Lie group $Sl(2;\mathbb{R})$ must be treated.

III. A GEOMETRICAL THEOREM ON LOCAL STABILITY

For determining the stability of an individual trajectory of the billiard system in the long time limit, an infinite product $\ldots\mathbf{R}_i\mathbf{L}_i\ldots\mathbf{R}_2\mathbf{L}_2\mathbf{R}_1\mathbf{L}_1$ of noncommuting matrices has to be investigated, where the matrices $\mathbf{R}_i$ correspond to the subsequent reflections and the transformations $\mathbf{L}_i$ belong to the bounceless segments. These latter ones equal either the elliptic ($\mathbf{E}(t_i)$), parabolic ($\mathbf{P}(t_i)$), or hyperbolic matrices ($\mathbf{H}(t_i)$) introduced in the previous section, depending on the sign of $r+\beta^2$. All the transformations in this product depend in a very complicated way on the shape of the

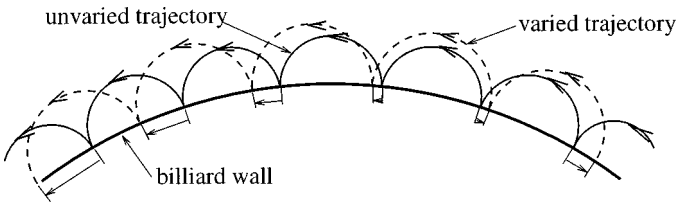

FIG. 5. The skipping orbit along a wall of constant curvature.

billiard domain (through the curvature of the boundary) and the geometry (i.e., flying times, angles of incidence) of the trajectory in question. For this reason the global stability analysis in billiard systems is a rather difficult problem; we turn to this question in Section V.

The stability analysis of individual periodic orbits is much simpler since in this case only a finite product of matrices must be considered. Simplifying the problem further, in this section we deal with a single product of two matrices of the form $\mathbf{R}(A)\mathbf{L}(t)$, which is sometimes called the *tangent map* or the *Jacobian of the bouncing map*.[15–17] It can be considered as the stability matrix of special trajectories having one bounce translational symmetry (examples are given in the next section), or it can also be regarded as the building stone of longer matrix products.

Beyond the non-Euclidean framework the main technical novelty of our approach, in contrast with the above cited works is the use of a coordinate frame fitted to the trajectory itself (and not to the billiard wall), which enables us to split the tangent map in a natural way into two components belonging to the bounceless flight and to the reflection. This decomposition plays a crucial role in the derivations of this section and of Section V.

In the rest of this section through a chain of lemmas and definitions a geometric theorem is derived, which states roughly that the tangent map depends only on the position of the intersection of the arc of the trajectory and the circle of curvature of the billiard wall (at the bounce point). We keep on treating the three cases for the curvature ($r=1,0,-1$) simultaneously.

Lemma 1: The stability of the ''skipping'' motion of the (charged) billiard particle along a billiard wall of constant curvature (on a manifold of constant curvature, in homogeneous magnetic field) is marginal, i.e., the corresponding **RL** matrix is parabolic (figure 5).

Proof: For proving this lemma we have to notice only that due to the (discrete) symmetry of the system, the arcs between the subsequent bounces are congruent, and the bouncing points of both the skipping orbit and its variation follow each other regularly in time and distance along the wall, so the components of the infinitesimal variation tangential to the billiard wall and tangential to the trajectory grow linearly with the number of reflections (i.e., in time). This means that the transverse component of the Jacobi field changes also linearly, so the tangent map **RL** is parabolic. □

The next lemma deals also with parabolic tangent maps, but in the special case of a geodesic billiard wall. For expressing it, the term of *opposite point* is needed. In order to handle extremities in a comprehensive way we equip the Euclidean plane with a single, infinitely far lying ideal point (which is a common intersection of every pair of straight lines), and the hyperbolic plane with an ''ideal line'' consisting of ideal points corresponding to different directions. (Geodesics and hypercycles have two different ideal points belonging to their two ''ends,'' while for paracycles these two points coincide.) In the following it is also advisable to consider a hypercycle as a curve consisting of two branches lying on opposite sides of its base line, and meeting each other in two ideal points.

Let γ be a curve of constant curvature β on a two dimensional manifold of constant curvature $r\in\{1,0,-1\}$, and let S denote an arbitrary point of γ.

Definition 2: The *point S' opposite to S (on γ)* is defined to be the intersection (distinct from S) of the curve γ and the geodesic line perpendicular to γ at S. If specially γ is a geodesic on a manifold of negative curvature (i.e., $\beta=0$, $r=-1$) then let S' be equal to S.

As figure 6 shows, if the curve γ is a circle, then the opposite point S' lies at the other end of the diameter starting at S (for arbitrary r); if γ is a paracycle, then the point S' is at infinity; in the case of hypercycles the opposite point S' lies on the other branch of γ, it is the reflection of the

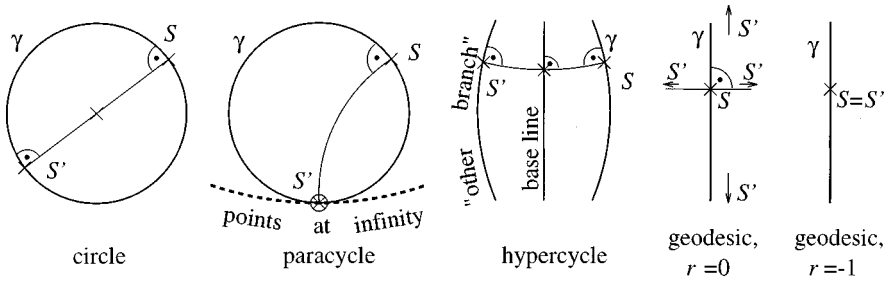

FIG. 6. The position of the point S' opposite to S.

point S in the base line of the hypercycle; while if γ is a geodesic on the Euclidean or hyperbolic plane, then S' is at infinity or coincides with S, respectively.

A better picture can be given for the definition of the opposite point in the case of hypercycles using the Poincaré models (either the P. disk or the P. half-plane model[10]) of the hyperbolic plane. In these models the curves representing the hypercycle γ and the geodesic perpendicular to γ at S do intersect each other in a (real or ideal) point S'' distinct from S, but this point S'' is outside of the disk or half-plane region which represents the points of the hyperbolic plane. Nevertheless, for both models there is a somehow natural involutory geometric transformation (an inversion for the disk model and a reflection for the half-plane model) which sends the points representing the hyperbolic plane out of this domain and vice versa. It can be easily seen that this transformation relates the point S'' to the above defined opposite point S'.

Let the arc SB of the curve γ of constant curvature β be a bounceless trajectory segment with starting point S, which reflects on a geodesic billiard wall η (on a two dimensional manifold of constant curvature $r\in\{1,0,-1\}$) at the bounce point B, and let S' denote the point on γ opposite to S.

Lemma 3: The tangent map belonging to the free flight SB and to the reflection at B is parabolic if and only if the billiard wall η goes through either the starting point S or the opposite point S'.

As figure 7 shows, in most cases this happens for two different positions of the billiard wall. However, if $S'=B$, i.e., the arc SB is a semicircle or if S' is the ideal point of the Euclidean plane, i.e., $r=\beta=0$ then for every possible position of the billiard wall $S'\in\eta$, so the tangent map is parabolic, while if $S=S'$, i.e., $\beta=0$ and $r=-1$ then the tangent map is never parabolic for geodesic billiard walls.

Proof: It follows from lemma 1 that if η goes through S then the tangent map is parabolic. For proving the same for S' different cases must be treated separately.

A. The trajectory γ is a circle

If the particle was started from S' instead of S, then the tangent map belonging to the bounce on the geodesic billiard wall going through S' would be parabolic, according to lemma 1. Since the matrix belonging to the semicircle $S'S$ (which is the difference between the arcs SB and $S'B$) is $-\mathbf{1}$ [equation (3)], the tangent map corresponding to the starting point S and bounce B on the billiard wall BS' is also parabolic.

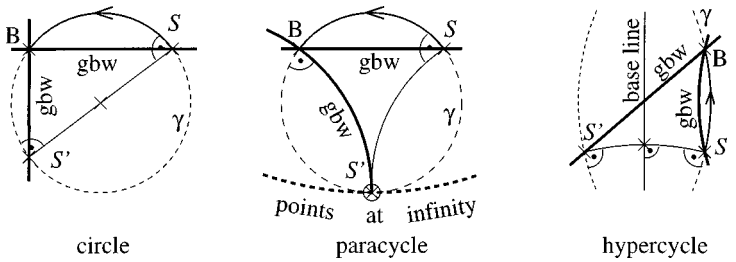

FIG. 7. Marginal cases for the tangent map with a geodesic billiard wall (gbw).

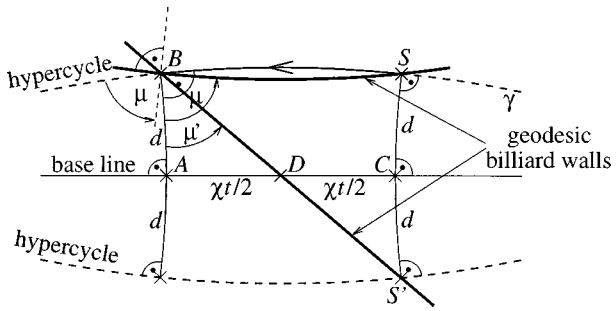

FIG. 8. Marginal positions of geodesic billiard walls in the hyperbolic case.

It can be easily verified by direct calculations [equation (13)], that if $S'=B$, i.e., the arc belonging to the bounceless flight is a semicircle then the tangent map is marginal for every position of the billiard wall.

B. The trajectory γ is a hypercycle

First we calculate the angle of incidence in terms of other geometric data and then compare it with the condition for the marginality of the tangent map. Let μ and μ' denote the angle of incidence belonging to the billiard wall going through S and S', respectively, according to the sign conventions indicated in Figure 1 (Figure 8).

Let d be the altitude of the hypercycle γ, let C and A denote the foot of the perpendicular geodesics dropped from the starting point S of the bounceless segment and from the bounce point B to meet the base line of the hypercycle, respectively, and furthermore let D be the mid-point of the segment AC. (Because of symmetry, D coincides with the mid-point of BS'.) It is also easy to see that $\mu=\angle ABS$ and $\mu'=\angle ABD=\angle CS'D$. According to the elementary connections summarized in Appendix A (A5), it is known that

$$\beta=\tanh(d), \quad \text{so} \quad \sinh(d)=\frac{\beta}{\chi}, \quad \cosh(d)=\frac{1}{\chi},$$

$$|\overline{AC}|=\chi t \quad \text{and} \quad \tan(\mu)=\frac{\cosh(a)}{\sinh(d)\sinh(a)}, \quad \text{where} \quad a=\frac{\chi t}{2}. \tag{9}$$

($|\beta|<1$, $\chi=\sqrt{1-\beta^2}$, t is the flying time on the arc SB, and $a=\chi t/2$ was introduced just to simplify the formulas.) Furthermore, it can be seen from the right triangle $DS'C\Delta$ that

$$\tan(\mu')=\frac{\tanh(a)}{\sinh(d)}=\frac{\sinh(a)}{\sinh(d)\cosh(a)}. \tag{10}$$

The tangent map is parabolic if and only if $\mathrm{Tr}(\mathbf{RH})=\pm 2$ which, having inserted $\mathbf{R}$ and $\mathbf{H}$ from (1) and (6), leads to the condition

$$2\cosh(2a)-\frac{2\beta}{\chi}\tan(\mu^*)\sinh(2a)=\pm 2, \tag{11}$$

where μ^* denotes the angle of incidence corresponding to the parabolic cases. Expressing $\tan(\mu^*)$, one gets

$$\tan(\mu^*)=\begin{cases}\dfrac{\cosh(a)}{\sinh(d)\sinh(a)}=\tan(\mu),\\ \dfrac{\sinh(a)}{\sinh(d)\cosh(a)}=\tan(\mu'),\end{cases} \tag{12}$$

which, comparing to (9) and (10) proves the lemma for the hyperbolic case.

C. The trajectory γ is a paracycle

Instead of getting again entangled in complicated calculations, it is enough to notice that the flying segment SB of a paracycle can be approached either by a series of hypercycle segments or by appropriate circular arcs, and the opposite points S' on the hypercycles or on the circles tend to the (infinitely far lying) opposite point on the paracycle, so by continuity arguments the statement of the lemma becomes evident also for paracycles.

D. The trajectory γ is a geodesic

If the curvature of the manifold r is positive, then the geodesics are at the same time (great) circles and the matrices belonging to the bounceless flights are elliptic; this case has already been treated before. If $r=0,-1$ then the direct calculation of the trace of the tangent map [equations (14), (15)] shows that the bouncing map is always marginal in the case of the Euclidean plane, while it is always hyperbolic for the hyperbolic plane. (Now $q=\beta=0$ so $A=0$.)

Finally, to complete the proof in the opposite direction we must show that in the $\beta\neq 0$ cases there can not be more than two different positions of the (geodesic) billiard wall having a marginal tangent map, since the following traces are strictly monotonic in μ [for geodesic walls $q=0$ so $A=-\beta\tan(\mu)$]:

$$\mathrm{Tr}(\mathbf{R}(A)\mathbf{E}(t))=2\cos(\chi t)+\frac{2A}{\chi}\sin(\chi t), \tag{13}$$

$$\mathrm{Tr}(\mathbf{R}(A)\mathbf{P}(t))=2+2At, \tag{14}$$

$$\mathrm{Tr}(\mathbf{R}(A)\mathbf{H}(t))=2\cosh(\chi t)+\frac{2A}{\chi}\sinh(\chi t). \tag{15}$$

[The quantities A and χ were defined in (1), (3), and (6)]. □

In the next lemma only the transformation **R** belonging to the reflection is investigated in the case of a curved billiard wall. For stating it the following definition is needed in which the concept of ideal point is used in the same sense as in Definition 2.

Let ξ and ξ' be two curves of constant curvature on a (simply connected) manifold of curvature $r\in\{1,0,-1\}$ intersecting each other transversely at the point K.

Definition 4: The *other intersection* (*meeting*) *point* K' *of the curves* ξ, ξ' (*corresponding to* K) is defined to be the common point of the two curves which is distinct from K and lies either on the same branch as K or on the branch opposite to K on both curves ξ and ξ'.

On the sphere and on the Euclidean plane all the curves of constant curvature have only one branch which, in the case of transverse crossing, intersect each other exactly in two points, K and K', so the definition is unambiguous. (The possibility for K' to be an ideal point is allowed.) On the hyperbolic plane, however, the hypercycles have two branches; thus the curves ξ and ξ' can have up to four meeting points; two of them are K and K'. If the branches containing K have two intersections then the one distinct from K is the other intersection point K' and in this case if both ξ and ξ' are hypercycles, their branches opposite to K do not intersect. On the other hand, if the branches containing K have no other intersections then the curves ξ and ξ' are necessarily hypercycles, and their other branches do meet each other in exactly one point which is the other meeting point K'.

Similarly to the definition of opposite point, the motivation for the nonobvious part (concerning the hypercycles) of this definition might also be better understood on special models of the hyperbolic plane. Either on the Poincaré disk or on the Poincaré half-plane model the circles representing the hypercycles ξ and ξ' do cross each other at a (unique) point K'' distinct from K, but this point K'' may well be out of the disk or half-plane region representing the hyperbolic plane. In this case the other meeting point K' can be obtained by affecting K'' by the (natural) involution (inversion or reflection) corresponding to the model; otherwise K' agrees with K''.

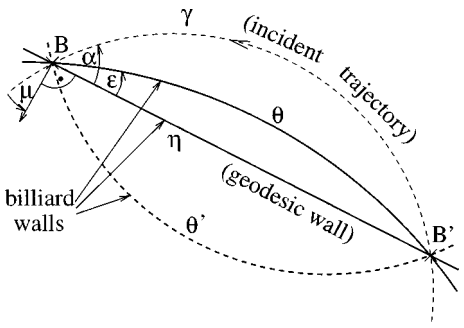

FIG. 9. Bounces having an identical **R** matrix.

Let us consider a particle which moves along the trajectory γ of constant curvature β (on a manifold of constant curvature $r \in \{-1,0,1\}$), and performs a reflection at the point $B \in \gamma$. Let θ, θ' be two possible billiard wall segments of constant curvature q, q', respectively, intersecting γ in B.

Lemma 5: The matrix **R** [equation (1)] belonging to the bounce on θ is equal to the matrix $\mathbf{R}'$ corresponding to the reflection on θ' if and only if the other intersection points of γ and θ as well as γ and θ' coincide (figure 9).

This means that for fixed trajectory γ and bouncing point B, the stability matrix **R** of the reflection depends only on the position of the other meeting point B' of the curves γ and θ.

Proof: The lemma is proven by straightforward calculations, using the polar equations of the curves of constant curvature, which are given in Appendix B. First the general case of $\beta \neq 0$ is considered.

Let η and θ denote the geodesic billiard wall and the billiard wall of constant curvature q, respectively, both of which pass through B and B'. Furthermore, let μ be the angle of incidence of the trajectory γ (of curvature β) in η, and let ϵ denote the angle between η and θ directed as it is shown in figure 9. The angle of incidence of γ in the billiard wall θ is $\mu+\epsilon$. For proving the lemma it is enough to investigate the conditions in which the bouncing effect of the geodesic wall η is identical to that of the curved wall θ. For this reason the coincidence of the only nontrivial element ($R_{2,1}$) of the matrix **R** has to be examined [see equation (1)]:

$$\beta \tan(\mu) = \frac{q+\beta \sin(\mu+\epsilon)}{\cos(\mu+\epsilon)}, \tag{16}$$

which leads to the connection

$$0 = q \cos(\mu) + \beta \sin(\epsilon). \tag{17}$$

Let the angle between the geodesic η and the trajectory γ be denoted by α (figure 9). Since $\alpha = \pi/2 - \mu$, equation (17) can also be written as

$$-\frac{\sin(\alpha)}{\beta} = \frac{\sin(\epsilon)}{q}, \tag{18}$$

which, according to lemma 13 of Appendix B, means that the other intersection points of the trajectory γ with the billiard walls η and θ coincide, which was to be proven. [The minus sign in equation (18) appears because of the sign conventions for the curvatures q and β.]

In the special case of $\beta = 0$ the proof is similar; let θ and θ' be two billiard walls of constant curvature q and q' belonging to the angle of incidence μ and μ', respectively. Requiring the equivalence of the corresponding bouncing maps we get

$$\frac{q}{\sin(\alpha)} = \frac{q'}{\sin(\alpha')}, \tag{19}$$

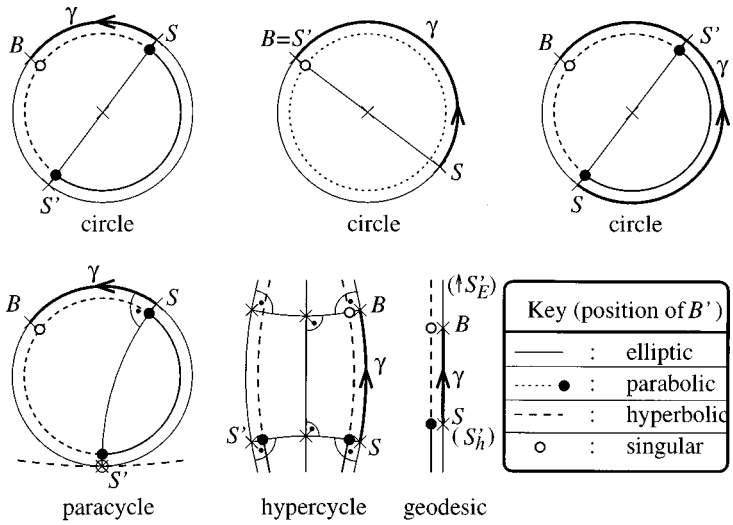

FIG. 10. The stability of the tangent map.

where $\alpha=\pi/2-\mu$ and $\alpha'=\pi/2-\mu'$ are the angles between the billiard walls θ, θ' and the geodesic trajectory γ. This means, using again lemma 13 of Appendix B, that θ and θ' meet each other at a point B' which lies on γ; this completes the proof of the lemma. □

Now, with the help of the previous lemmas we are ready to prove the main geometric theorem on the behavior of the tangent map **RL**.

Let the arc SB of the curve γ of constant curvature β be a bounceless trajectory segment with starting point S, which is reflected on the billiard wall θ of constant curvature q at the bouncing point B (on a two dimensional manifold of constant curvature $r\in\{1,0,-1\}$). (If the curvature of the billiard wall is not constant, then θ should be considered as its circle of curvature at B.) Let S' be the point on γ opposite to the starting point S, and let B' denote the other meeting point (different from B) of the two curves γ and θ.

Theorem 6: (On the stability of the tangent map). For fixed γ, S, and B on it, varying the billiard wall θ, the tangent map **RL** belonging to the bounceless flight SB and to the reflection at B depends only on the position of the other crossing point B'. This map is parabolic, if $B=S'$ (independently of the position of B') or if B' coincides with either S or S'; while **RL** is hyperbolic if ($B\neq S'$ and) B' lies on the same open arc SS' of γ where B is; otherwise the tangent map is elliptic (figure 10).

(Taking into consideration the ideal points, γ is topologically equivalent to a circle, and the points S and S' divide it into two parts.)

Proof: We remark that for geodesic trajectories ($\beta=0$) in the Euclidean case ($r=0$) the opposite point S'_E is the ideal point (so exactly the geodesic billiard walls pass through it), while on the hyperbolic plane $S'_h=S$.

The first statement of the theorem is a trivial consequence of lemma 5, since for fixed γ, S, and B the matrix **L** does not vary either. The positions of B' corresponding to parabolic mappings can also be obtained easily by joining the results of lemma 3 and lemma 5. The rest of the theorem can be proven by calculating Tr(**RL**) for the different cases [equations (13), (14), and (15)], and observing their monotonity properties as μ and q change. □

In the remaining parts of the paper our attention is restricted solely to the hyperbolic plane.

IV. APPLICATION: STABILITY OF TRAJECTORIES WITH DISCRETE SYMMETRY

In this section, applying the results of Theorem 6 of the previous section the stability of a special symmetric orbit, bouncing successively in the adjacent mid-points of the (geodesic) sides of a regular polygonal billiard on the hyperbolic plane is determined (the inset of Figure 11). Let the mid-points of the sides of the regular n-gon $V_1V_2\ldots V_n$ with center O be denoted by $M_1,M_2,\ldots,M_n$; let $R:=|OV_i|$ and $\rho:=|OM_i|$ be the circumradius and the inradius, respectively;

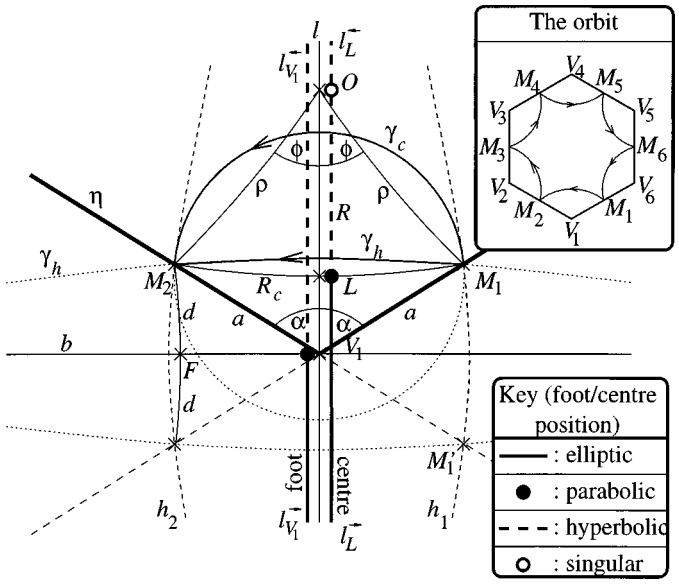

FIG. 11. The stability of the symmetric orbit in the regular polygon billiard.

and finally let $\alpha := \angle OV_iV_{i+1}$ and $a := |V_iM_i|$ denote the half of the interior angle and of the side of the polygon, respectively (Figure 11). These parameters are not independent; they all can be expressed with $\phi := \pi/n$ and R:

$$\sinh(a) = \sin(\phi)\sinh(R), \quad \cot(\alpha) = \tan(\phi)\cosh(R), \tag{20}$$

$$\tanh(\rho) = \cos(\phi)\tanh(R). \tag{21}$$

Figure 11 shows one segment with starting point M_1 and bouncing point M_2 of the investigated orbit in the polygon billiard. Let l be the geodesic line of symmetry passing through O and V_1, and let h_1, h_2 be the two branches of the hypercycle of base line l, going through M_1, M_2, respectively. It is obvious that varying the magnetic field β there is a whole series of trajectory segments γ of constant curvature β joining the points M_1 and M_2. It is also easy to see that if $|\beta| > 1$ (or $|\beta| = 1$) then these curves are circular arcs (or segments of paracycles), whose center lies on l (possibly at the ideal points of l), and the points opposite to the starting point M_1 on γ line up along the hypercycle branch h_2 (at the ideal points for $|\beta| = 1$); while if $|\beta| < 1$ then these curves are arcs of hypercycles, whose base line is perpendicular to l, so the points opposite to M_1 lie on the hypercycle branch h_1. Inversely, given any point L on the symmetry line l, there is exactly one circle/hypercycle segment (or arc of paracycle, if L is an ideal point) going from M_1 to M_2 inside the billiard domain, having a center/foot point L. (The term foot point of the hypercycle is used here to designate the intersection of the base line and l.) The only singular case is the circle of center O (i.e., the inscribed circle) which is tangential to the billiard walls at M_i.

Let L be the mid-point of the geodesic segment M_1M_2 and let us denote the open rays of the (geodesic) symmetry line l with origin L, V_1 directed inwards and outwards the billiard by $l_L^{\leftarrow}, l_{V_1}^{\leftarrow}$ and $l_L^{\rightarrow}, l_{V_1}^{\rightarrow}$, respectively.

Our aim in this section is to determine geometrically the stable, marginal, and unstable positions of the investigated symmetric orbits and the corresponding magnetic field regions. The following theorem answers this question, using the notations of figure 11, introduced before.

Theorem 7: The symmetric orbit bouncing successively in the mid-points M_i of the sides of the regular polygon $V_1V_2 \ldots V_n$ (on the hyperbolic plane) is stable, if the arc M_1M_2 of this orbit is either a circular segment with a center lying on the (open) ray $l_L^{\rightarrow}$ or it is a segment of a hypercycle with a foot point on $l_{V_1}^{\rightarrow}$; the stability of the orbit is marginal if the center of the circular arc is at L or the foot point of the hyperbolic segment is at V_1; while the orbit is unstable, if the center of the circle or the foot point of the hypercycle lies on the opposite rays $l_L^{\leftarrow}, l_{V_1}^{\leftarrow}$, respectively.

The magnetic field region belonging to the stable orbits is $\beta_{\min}<\beta<\beta_{\max}$, where

$$\beta_{\min}=\frac{\sin^2(\phi)\sinh(R)\cosh(R)}{\sqrt{1+\sin^2(\phi)\sinh^2(R)(1+\sin^2(\phi)\cosh^2(R))}}, \tag{22}$$

$$\beta_{\max}=\frac{\sqrt{1+\sin^2(\phi)\sinh^2(R)(1+\cos^2(\phi))}}{\sin(\phi)\cos(\phi)\sinh(R)}. \tag{23}$$

The stability regions for the hypercycles and circles are shown in Figure 11. (The center or foot points can also be ideal points in which case the arcs of the orbit are paracycles.)

Proof: The positions belonging to parabolic tangent maps can easily be found, since in this case, using lemma 3 the points opposite to M_1 are in the intersection of the (geodesic) line V_1M_2 (shortly denoted by η) and the hypercycle h_1, h_2. If the opposite point is $M_2=\eta\cap h_2$ then the corresponding orbit is the circle γ_c of center L, while if the opposite point is $M_1'\coloneqq\eta\cap h_1$ then the marginally stable symmetric trajectory is the hypercycle γ_h of foot point V_1 and base line b (figure 11).

It is quite plausible that the stable and unstable regions are between the two marginal cases. The rigorous proof of the statements of the lemma concerning the elliptic and hyperbolic cases can be accomplished with the use of theorem 6, taking systematically, one by one the different geometric arrangements depending on the position of the center/foot point of γ, the opposite point of M_1, and the other meeting point on η, belonging to M_2. (In theorem 6 the trajectory segment was fixed, and the position of the billiard wall could be varied, while in the present case the billiard wall η is fixed, and the orbit γ changes what makes the proof a bit cumbrous.)

To get the critical magnetic field $\beta_{\max}$ first the radius $R_c\coloneqq|LM_2|$ of the critical trajectory γ_c has to be determined from the right triangle $V_1LM_2\Delta$: $\sinh(R_c)=\sinh(a)\sin(\alpha)$. Having inserted here a and α from (20), and using equation (2) the formula (23) can easily be derived. If $\beta>\beta_{\max}$ then the arc γ between M_1 and M_2 no longer exists. In the $R\to\infty$ limit (23) simplifies to $\lim_{R\to\infty}\beta_{\max}=\sqrt{1+\cos^2(\phi)}/\cos(\phi)$.

For calculating the altitude d of the other critical trajectory γ_h let us consider the right triangle M_2FV_1, where F is the foot of the perpendicular dropped from M_2 to the base line b, which gives $\sinh(d)=\sinh(a)\cos(\alpha)$. The value of $\beta_{\min}$ [equation (22)] can be obtained by substituting here the values of a and α from the formula (20) and using the relationship (5). It is worth noticing that $\lim_{R\to\infty}\beta_{\min}=1$, which is also clear geometrically, since in this limit the vertices V_i tend to infinity, and the arc γ_h becomes a paracycle.

This completes the proof of the theorem. □

In the rest of this section the result of theorem 7 is demonstrated by numerical simulations made for an equilateral triangular billiard $V_1V_2V_3\Delta$ on the hyperbolic plane. The size of the billiard can be characterized by the half of the angle 2ψ subtended by the (whole geodesic) lines of the sides at the center O of the billiard (figure 12/A), which was chosen to be $\psi=75°$ in the investigated case. (For $\psi=60°$ the noncompact billiard with vertices at infinity—one third of which is the fundamental domain of the modular group $Sl(2;\mathbb{Z})$—has already been studied in references 5, 9, 24, 25, 11. Increasing ψ up to 90° the size of the triangle tends to zero.) Knowing this angle ψ the radius ρ of the inscribed circle can be calculated: $\tanh(\rho)=\cos(\psi)=(\sqrt{3}-1)/(2\sqrt{2})=0.2588...$, and using (21) and (22) the circumradius R and the critical magnetic field $\beta_{\min}$ can also be determined: $\tanh(R)=2\cos(\psi)=(\sqrt{3}-1)/\sqrt{2}=0{,}5176...$,

$$\beta_{\min}=\frac{3\cos(\psi)}{\sqrt{16\cos^4(\psi)-11\cos^2(\psi)+4}}=\frac{3(\sqrt{3}-1)\sqrt{22+5\sqrt{3}}}{\sqrt{2}\sqrt{409}}=0{,}4252... . \tag{24}$$

The results of the computer simulation can be seen in Figures 12, 13. The pairs of drawings and plots show the stable periodic orbits and the corresponding Poincaré sections of the phase space of the triangular billiard (i.e., the iterates of the bounce map from a few different initial points), for two magnetic field values $\beta_>=\sin(0{,}44\text{ rad})=0{,}4259...>\beta_{\min}$ (Figures 12(A), 13(A)) and $\beta_<=\sin(0{,}438\text{ rad})=0{,}4241...<\beta_{\min}$ (Figures 12(B), 13(B)) around the critical value $\beta_{\min}$.

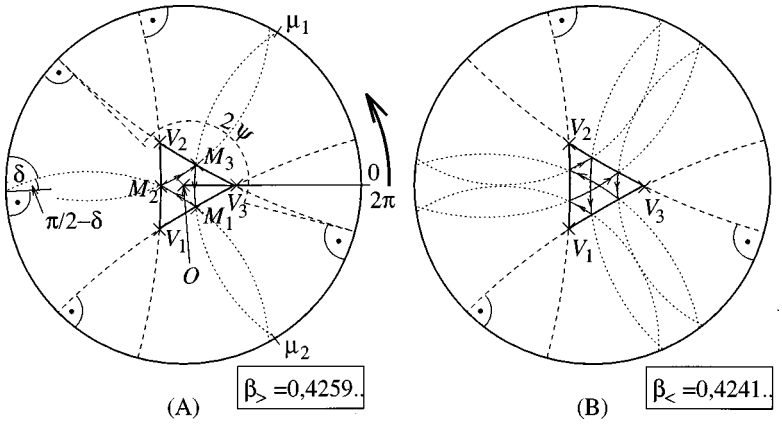

FIG. 12. The stable periodic orbit before (a) and after (b) the bifurcation in the triangular billiard (represented on the Poincaré disk model).

[Taking the $a\to\infty$ limit in the last equation of (A5), the relationship $\beta=\sin(\pi/2-\delta)$ can be obtained for the curvature of the hypercycle β and the angle $\pi/2-\delta$ between the hypercycle and its chord with foot points at infinity (Figure 12(A)). This angle is also meaningful on the Poincaré models of the hyperbolic plane, and it can be used as an alternative to β for characterizing the magnetic field. In our case $\arcsin(\beta_{\min})=0{,}4392...$ rad.]

The dots with coordinates (μ_1,μ_2) in the Poincaré maps (Figure 13) represent the consecutive arcs of the bounceless flights by the angles μ_1, μ_2 of their foot points on the border of the Poincaré disk (Figure 12(A)). (The plottings are enlarged, showing only one of the three ''island'' corresponding to the symmetric orbit of period three.)

It can be clearly seen that the stable periodic orbit belonging to the single ''island'' in figure 13/A loses its stability via period doubling bifurcation.

V. THEOREMS FOR GLOBAL INSTABILITY

The main aim of this section is to provide sufficient criteria for hard chaos in billiards on the hyperbolic plane with weak (i.e., $|\beta|<1$) magnetic field β. The notion *hard chaos* signifies here that there are no stable orbits in the billiard, i.e., every trajectory has a positive Lyapunov exponent. (Or practically, there are no ''islands of stability'' on the Poincaré section.) In most cases the theorems to be introduced also allow us to estimate from below the value of the Lyapunov exponent.

First Sinai-like billiards (i.e., billiards surrounded by dispersing arc segments) will be studied, and then, using the main theorem of Section III (Theorem 6) a more general criterion will be derived concerning Bunimovich-like domains, the boundary of which can contain (strongly) focusing segments, too, which lie sufficiently far from each other.

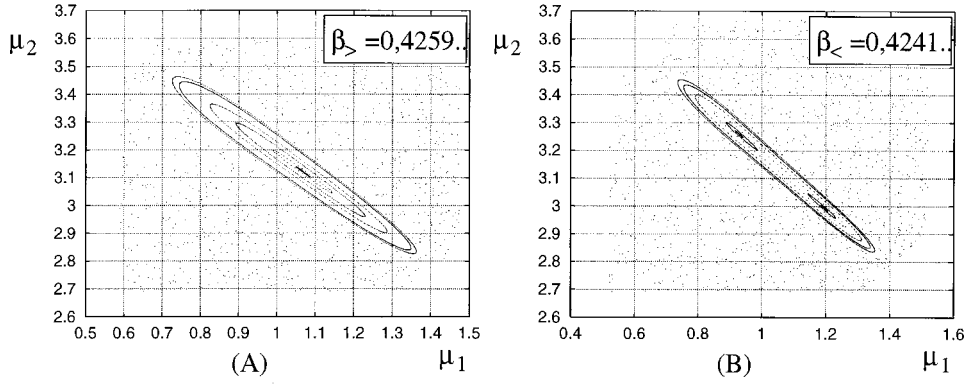

FIG. 13. Poincaré maps slightly above (a) and below (b) the critical field $\beta_{\min}=0,4252...$.

To gain a heuristic insight into the behavior of the product of elements of the $Sl(2;\mathbb{R})$ group (which describes the stability of the trajectories in the billiard system) it is advantageous to use the concept of invariant cone which was introduced and exhaustively studied in Refs. 26, 27.

Let us consider the group $Sl(2;\mathbb{R})$ (of two by two real matrices of unit determinant) with its canonical action on the $\mathbb{R}^2$ plane. For an element $L\in Sl(2;\mathbb{R})$ the (double) *cone* $C\subset\mathbb{R}^2$ (consisting of all the linear combinations of two linearly independent vectors with coefficients having the same sign) is *invariant* if $LC\subset C$. It is a trivial observation that an element of the group $Sl(2;\mathbb{R})$ (unequal to $\pm\mathbf{1}$) is elliptic if and only if it does not possess an invariant cone. (Indeed, if L had an invariant cone, then, by continuity arguments, there would be an invariant straight line, i.e., an eigenvector in this cone. Inversely, for hyperbolic and parabolic matrices an invariant cone can easily be constructed using the eigenvectors; e.g., the coordinate cone $\{(b,b')\in\mathbb{R}^2|bb'\geqslant 0\}$ is invariant in figures 1/B, 3, 4/B.)

The heuristic geometrical picture behind the proofs of the hard chaos theorems is based on the existence of a (fixed) cone in the (b,b') coordinate plane, which is shown to be left invariant by the elements of a suitably chosen partition (consisting of nonelliptic multiplicands) of the matrix product $\ldots\mathbf{R}_i\mathbf{H}_i\ldots\mathbf{R}_2\mathbf{H}_2\mathbf{R}_1\mathbf{H}_1$, which means that the whole product, as it leaves invariant the same cone, too, is also nonelliptic (in fact, it is mostly hyperbolic). (The linear mappings $\mathbf{R}_i$, $\mathbf{H}_i$ correspond to the subsequent reflections and bounceless flying segments, respectively.)

The appearance of a strictly positive Lyapunov exponent in a billiard system can be originated from two types of heuristical reasons; the billiard particle either moves in a domain of negative curvature, in weak magnetic field, so in the first place the bounceless segments are responsible for the strong hyperbolicity, or it performes elastic bounces on dispersing boundary segments sufficiently often, and the common effect of the reflections and the bounceless flights between them result in a net hyperbolic behavior. [As equation (1) shows, the effect of the reflection itself is marginal, but any of the three products $\mathbf{R}(A)\mathbf{H}(t)$, $\mathbf{R}(A)\mathbf{P}(t)$, $\mathbf{R}(A)\mathbf{E}(t)$ can be hyperbolic for sufficiently big parameter values A (i.e., for dispersing walls) and for small values of t in the elliptic case.] The estimations of this section are essentially guided by the first reasoning, since in the case investigated it is technically easier to carry out, and the conditions obtained are simpler and less restrictive on the shape of the billiard. (In Ref. 13 more refined estimations, taking into account also the dispersing effect of the reflections have been worked out and applied for planar magnetic billiards, where the bounceless motion is no more hyperbolic.)

It is easy to see that the previously mentioned $bb'\geqslant 0$ cone of the (b,b') coordinate plane is invariant for the matrices belonging to the bounces with positive parameter values $A>0$ [equation (1), Figure 1(B)] and for the parabolic and hyperbolic matrices corresponding to the bounceless segments with parameter values $t>0$ [equations (4), (6), Figures 3, 4(B)]; this motivates the following statement.

Lemma 8: For the products of the matrices $\mathbf{R}_i:=\mathbf{R}(A_i)$, $\mathbf{P}_i:=\mathbf{P}(t_i)$, and $\mathbf{H}_i:=\mathbf{H}(t_i)$ with positive parameter values $A_i>0$, $t_i>0$ [equations (1), (4), (6)] the following inequalities hold $(n=2,3,\ldots)$:

$$\mathrm{Tr}(\mathbf{R}_n\mathbf{H}_n\ldots\mathbf{R}_2\mathbf{H}_2\mathbf{R}_1\mathbf{H}_1)>\mathrm{Tr}(\mathbf{R}(\hat{A})\mathbf{H}(T))=2\cosh(\chi T)+\frac{2\hat{A}}{\chi}\sinh(\chi t), \tag{25}$$

$$\mathrm{Tr}(\mathbf{R}_n\mathbf{P}_n\ldots\mathbf{R}_2\mathbf{P}_2\mathbf{R}_1\mathbf{P}_1)>\mathrm{Tr}(\mathbf{R}(\hat{A})\mathbf{P}(T))=2+2\hat{A}T, \tag{26}$$

where $T=\Sigma_{i=1}^{n}t_i$, $\hat{A}=\Sigma_{i=1}^{n}A_i$, and χ is the function $\chi=\sqrt{1-\beta^2}$ of the magnetic field β.

Proof: Let us notice that all elements of the matrices $\mathbf{R}_i$, $\mathbf{P}_i$, and $\mathbf{H}_i$ are non-negative, and the matrix belonging to the reflection can be written in the form $\mathbf{R}_i=\mathbf{1}+\mathbf{A}_i$, where $\mathbf{1}$ is the identity matrix and

$$\mathbf{A}_i=\begin{pmatrix}0 & 0\\ A, & 0\end{pmatrix}.$$

Using this,

$$\mathrm{Tr}((\mathbf{1}+\mathbf{A}_n)\mathbf{H}_n\ldots(\mathbf{1}+\mathbf{A}_2)\mathbf{H}_2(\mathbf{1}+\mathbf{A}_1)\mathbf{H}_1)>\mathrm{Tr}(\mathbf{H}(T))+\sum_{i=1}^{n}\mathrm{Tr}(\mathbf{A}_i\mathbf{H}(T))=\mathrm{Tr}(\mathbf{R}(\hat{A})\mathbf{H}(T)), \tag{27}$$

where the trace of the last term equals the right side of the formula (25) of the lemma. [In the derivation (27) first the product of matrices under the trace has been expanded, and the obtained sum (of positive elements) has been reduced by omitting the terms containing more than one of the $\mathbf{A}_i$ factors. Then the result has been simplified using the one parameter subgroup property of the transformations $\mathbf{H}_i$ and the spacial form of the matrices $\mathbf{R}_i$.]

The second inequality (26) of the lemma can be proven along the same lines. □

Using this lemma the criterion for hard chaos in dispersing (magnetic) billiards can be given.

Theorem 9: (Hard chaos in dispersing billiards.) Let Q be a billiard domain in the hyperbolic plane with a piecewise C^2 boundary, the curvature q of which is everywhere $q\leqslant-|\beta|$ (sufficiently dispersing), where the magnetic field β satisfies the condition $|\beta|<1$. Then the magnetic billiard system Q demonstrates hard chaos; every (nonsingular) trajectory of the system has a Lyapunov exponent greater than or equal to $\chi=\sqrt{1-\beta^2}$.

(The attribute ''nonsingular'' means here that the trajectory does not run into a vertex of the billiard in the future.)

Proof: Because of the condition $q\leqslant-|\beta|$ of the theorem the parameters $A=[q+\beta\sin(\mu)]/\cos(\mu)$ are always positive in the matrices corresponding to the reflections [formula (1)], so lemma 8 can be applied for the matrix product describing the stability of the trajectory investigated. Since the ratio of the trace and the greatest eigenvalue of this matrix product tends to unity as $n\to\infty$, the Lyapunov exponent λ can be calculated from the trace of the Jacobian matrix, and it can be estimated from below with the help of the inequality (25):

$$\lambda=\limsup_{n\to\infty}\frac{\ln(\mathrm{Tr}(\mathbf{R}_n\mathbf{H}_n\ldots\mathbf{R}_2\mathbf{H}_2\mathbf{R}_1\mathbf{H}_1))}{T_n}\geqslant\lim_{n\to\infty}\left(\frac{1}{T_n}\ln\left(2\cosh(\chi T_n)+\frac{2\hat{A}_n}{\chi}\sinh(\chi T_n)\right)\right)=\chi, \tag{28}$$

where the matrices $\mathbf{H}_i$ and $\mathbf{R}_i$ correspond to the subsequent bounceless flying segments of time t_i and reflections with parameter A_i, and T_n, $\hat{A}_n$ denote the sums $T_n=\Sigma_{i=1}^{n}t_i$, $\hat{A}_n=\Sigma_{i=1}^{n}A_i$, respectively. (It was supposed, that $\hat{A}_n$ does not grow exponentially with n.) □

It is worth noticing that the result of the estimation obtained above does not contain any information about the reflections, it just tells us that if the dispersive curvature $-q$ of the billiard boundary is greater than the magnetic field β, then the magnetic billiard system is at least as much chaotic as it would be without the bounces. It is quite possible that for $-q-|\beta|>K>0$ (K is constant) stronger—but not so general—results could also be achieved for certain classes of billiards, taking into consideration the dispersive effects of the bounces.

Now let us turn to the investigation of billiards with focusing arcs in their boundary! For curvature values q in the regime $-|\beta|<q<|\beta|$ the sign of the parameter A in the matrices belonging to the bounces [formula (1)] depends on the angle of incidence μ, while for $q>|\beta|$ the shearing $\mathbf{R}(A)$ moves the positive b axis always downwards, in the direction of the $-b'$ axis; thus the cone $bb'\geqslant$ is not left invariant for any values of μ. However, as figure 14/A shows, it is possible that for sufficiently great parameter values τ_A and A, the transformation of the form $\mathbf{H}(\tau_A/2)\mathbf{R}(A)\mathbf{H}(\tau_A/2)$ does leave invariant the double cone mentioned above. (A similar assertion holds for the parabolic case.) This geometric observation is expressed in the following statement.

Lemma 10: If $A=-[q+\beta\sin(\mu)]/\cos(\mu)<-\chi<0$ holds for the shearing parameter A of the stability matrix $\mathbf{R}(A)$, where $\chi=\sqrt{1-\beta^2}$, $q>1$ (i.e., the billiard wall is strongly focusing) and $|\beta|<1$ (i.e., the magnetic field is weak); then there exists a time $\tau_A:=2\chi^{-1}\,\mathrm{artanh}(|\chi/A|)$ in the hyperbolic case, and $\tau_A':=|2/A|$ in the parabolic case, for which

$$\mathbf{H}\left(\frac{\tau_A}{2}\right)\mathbf{R}(A)\mathbf{H}\left(\frac{\tau_A}{2}\right)=-\mathbf{R}(-A), \tag{29}$$

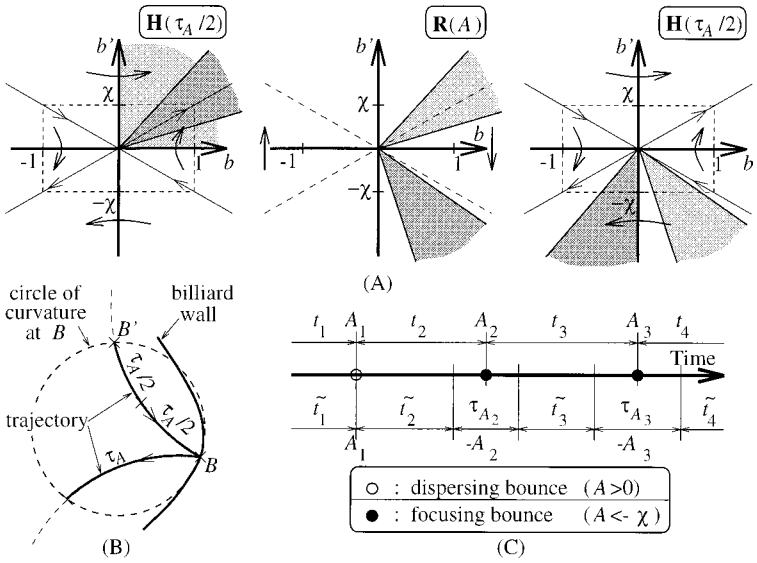

FIG. 14. The effect of the transformation $\mathbf{H}(\tau_A/2)\mathbf{R}(A)\mathbf{H}(\tau_A/2)$ for strongly focusing walls.

$$\mathbf{P}\left(\frac{\tau_A'}{2}\right)\mathbf{R}(A)\mathbf{P}\left(\frac{\tau_A'}{2}\right)=-\mathbf{R}(-A), \tag{30}$$

hold, respectively, and for $t\geqslant\tau_A$ (or for $t\geqslant\tau_A'$) values the double cone $bb'\geqslant 0$ is invariant under the effect of the transformation $\mathbf{H}(t/2)\mathbf{R}(A)\mathbf{H}(t/2)$ [or under that of $\mathbf{P}(t/2)\mathbf{R}(A)\mathbf{P}(t/2)$]. Moreover, the critical time τ_A (or τ_A') is equal to the flying time elapsed between the bouncing point B and the other meeting point B' of the outgoing (or equivalently, the incoming) trajectory segment and the circle of curvature of the billiard boundary.

The geometrical meaning of the critical time τ_A is demonstrated in figure 14/B, and **H**, **P**, and **R** are given by the formulas (1), (4), and (6).

Proof: First we remark, that if $q>1$ then $A+\chi=[-q-\beta\sin(\mu)+\chi\cos(\mu)]/\cos(\mu)=[\cos(\mu+\varphi)-q]/\cos(\mu)<0$, where $\varphi=\arctan(\beta/\chi)$, so the conditions of the lemma are in harmony.

We prove the statement of the lemma only for the hyperbolic case, since the parabolic case can be treated analogously. The validity of the relationship (29) can be shown by direct calculations, using the connection $\tanh(\chi\tau_A/2)=-\chi/A$:

$$\mathbf{H}\left(\frac{\tau_A}{2}\right)\mathbf{R}(A)\mathbf{H}\left(\frac{\tau_A}{2}\right)=\begin{pmatrix} C+\dfrac{AS}{\chi} & \dfrac{A(C-1)}{\chi^2}+\dfrac{S}{\chi} \\ AC+A+\chi S & C+\dfrac{AS}{\chi}\end{pmatrix}=-\begin{pmatrix}1 & 0\\ -2A & 1\end{pmatrix}, \tag{31}$$

where S stands for $S=\sinh(\chi\tau_A)$ and C for $C=\cosh(\chi\tau_A)$.

For $t\geqslant\tau_A$ values the double cone $bb'\geqslant 0$ is left invariant by each matrix in the last form of the product $\mathbf{H}(t/2)\mathbf{R}(A)\mathbf{H}(t/2)=-\mathbf{H}[(t-\tau_A)/2]\mathbf{R}(-A)\mathbf{H}[(t-\tau_A)/2]$.

Since $\mathrm{Tr}(\mathbf{H}(\tau_A/2)\mathbf{R}(A)\mathbf{H}(\tau_A/2))=\mathrm{Tr}(\mathbf{R}(A)\mathbf{H}(\tau_A))=-2$, by theorem 6 the last statement of the lemma is also true. □

This lemma enables us to ''dress up'' the matrices $\mathbf{R}(A)$ corresponding to the strongly focusing bounces ($q>1$) with hyperbolic matrices of the form $\mathbf{H}(\tau_A/2)$ and thus to trace back the stability analysis of certain billiards possessing focusing walls to the case of dispersing billiards. This procedure is shown graphically in figure 14/C. Before expressing the main theorem of this section we introduce a definition.

Let us characterize a trajectory (in a billiard with magnetic field $|\beta|<1$ on the hyperbolic plane) by the times t_i of the subsequent bounceless flying segments and the parameter values A_i [equation (1)] of the succeeding reflections, furthermore, assume, that the bounces take place either on dispersing boundary segments of curvature $q\leqslant-|\beta|$ or on focusing ones having curva-

ture greater than unity [i.e., either $A_i>0$ or $A_i<-\chi=-\sqrt{1-\beta^2}$]. Let τ_A, be zero in the case of $A_i>0$ and let it be $\tau_{A_i}:=2\chi^{-1}\,\mathrm{artanh}(|\chi/A_i|)$ (as in lemma 10), if $A_i<-\chi$.

Definition 11: The *reduced time* $\tilde{t}_i$ is defined to be $\tilde{t}_i:=t_i-(\tau_{A_{i-1}}+\tau_{A_i})/2$ (figure 14/C).

Theorem 12: (hard chaos in nondispersing billiards.) Let Q be a (magnetic) billiard domain (on the hyperbolic plane) with a piecewise C^2 boundary the curvature q of which is either sufficiently dispersing, $q\leqslant-|\beta|$, or strongly focusing, $q>1$, almost everywhere, where the magnetic field β is in the range $|\beta|<1$. Furthermore, suppose, that the focusing segments lie sufficiently far from each other, i.e., the reduced time of each bounceless segment on every trajectory is nonnegative, and along every (nonsingular) trajectory the inequality,

$$\liminf_{n\to\infty}\frac{\tilde{T}_n}{T_n}\geqslant K>0, \tag{32}$$

holds for the sums $\tilde{T}_n:=\Sigma_{i=1}^n\tilde{t}_i$, $T_n:=\Sigma_{i=1}^n t_i$ of the (reduced) flying times, with a positive constant K. In this case the Lyapunov exponent λ of every nonsingular trajectory satisfies the following estimation:

$$\lambda\geqslant K\chi=K\sqrt{1-\beta^2}. \tag{33}$$

Proof: The proof of the theorem is straightforward; first, using lemma 10 the shearings of negative parameters in the infinite matrix product describing the stability of the trajectories have to be ''dressed up'' and converted to shearings with positive parameters, and then theorem 9 should be applied with the estimation (32) to get the desired result:

$$\lambda=\limsup_{n\to\infty}\frac{\ln(\mathrm{Tr}(\mathbf{R}_n\mathbf{H}_n\ldots\mathbf{R}_2\mathbf{H}_2\mathbf{R}_1\mathbf{H}_1))}{T_n}=\limsup_{n\to\infty}\left(\frac{\tilde{T}_n}{T_n}\frac{\ln|\mathrm{Tr}(\tilde{\mathbf{R}}_n\tilde{\mathbf{H}}_n\ldots\tilde{\mathbf{R}}_2\tilde{\mathbf{H}}_2\tilde{\mathbf{R}}_1\tilde{\mathbf{H}}_1)|}{\tilde{T}_n}\right)\geqslant K\chi, \tag{34}$$

where $\mathbf{R}_i=\mathbf{R}(A_i)$, $\mathbf{H}_i=\mathbf{H}(t_i)$, $\tilde{\mathbf{R}}_i=\mathbf{R}(|A_i|)$, and $\tilde{\mathbf{H}}_i=\mathbf{H}(\tilde{t}_i)$. □

It should be noted that since a trajectory can perform more consecutive bounces on the same smooth (or C^2) focusing segment of the boundary, the nonnegativity condition for the reduced times also restricts the shape of the focusing segments, not only the distances between them. It is also clear from lemma 10 and definition 11 that for a circular (focusing) boundary segment the reduced times, corresponding to consecutive bounces on this arc, are zero, but possibly not only segments of constant curvature $q>1$ are allowed.

Wojtkowsky, investigating ordinary planar billiards, was also led to the same problem in a much simpler setup, without a magnetic field, on the Euclidean plane, in which case he could prove that exactly those focusing boundary segments are allowed, which satisfy the so called positive scattering property $R''(s)\leqslant 0$, where $R(s)$ is the radius of curvature of the billiard boundary as the function of arc length on the perimeter.[21] He also proved that this condition is robust under small perturbations of the billiard wall (at least when the inequality is strict). This suggests that the conditions of our theorem 12 are also robust under small perturbations, but we do not turn to the detailed analysis of this question.

In Appendix C an example is given for the application of theorem 12.

It is quite possible that one can go further and using the results of Oseledec[28] and Pesin,[29] suitably generalized for dynamical systems with singularities,[30,31] positive entropy theorems can also be formulated for the investigated billiard types, but these questions are out of the framework of the present study.

VI. CONCLUSIONS

In this work the local and global stability of magnetic billiard systems has been investigated on two dimensional Riemannian manifolds of constant curvature, with a special emphasis on the hyperbolic plane. For tracing the local behavior of the nearby trajectories the technique of Jacobi fields was used. A coordinate frame attached to the investigated trajectory was introduced, which allowed us to decompose the stability matrix into a product of elements of the group $Sl(2;\mathbb{R})$

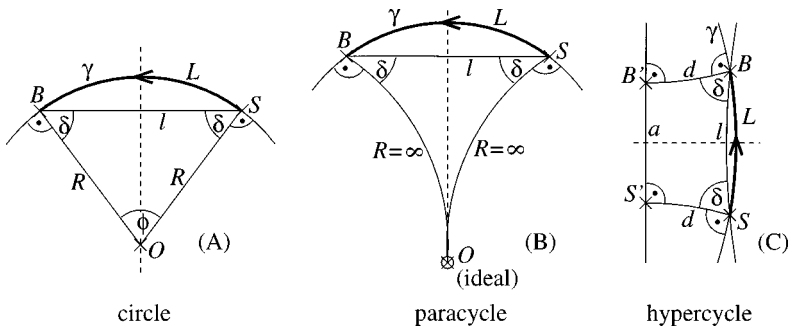

FIG. 15. The arcs, chords in the cycle γ.

related to the reflections and to the bounceless segments. (The foundation of this local analysis in a more general context can be found in Ref. 12, and its adaptation to our present purposes is in Section II of this work.)

Studying the local stability properties of the trajectories, it has been shown via a series of lemmas that on two dimensional manifolds of constant curvature (of arbitrary sign), in a homogeneous magnetic field the Jacobian of the bouncing map depends only on the position of the meeting point (different from the reflection point) of the incoming trajectory and the circle of curvature of the billiard wall at the bouncing point (theorem 6).

Applying this theorem, the stability region for a special symmetric orbit in regular polygon billiards on the hyperbolic plane has been determined, as the magnetic field changes (theorem 7). This result has also been supported by numerical simulations.

Finally, in Section V global criteria for hyperbolicity and lower estimations for the Lyapunov exponent have been given in magnetic billiards with a magnetic field less than unity on the hyperbolic plane. Theorem 9 treats dispersing billiards while theorem 12 deals with Bunimovich-like ones, and expresses a result similar to that of Wojtkowsky,[21] but generalized for magnetic billiards and for spaces of constant negative curvature, and proven with other methods. (See also lemma 10.)

APPENDIX A: BASIC RELATIONSHIPS FOR ARCS AND CHORDS OF CYCLES

In this appendix some useful connections are summarized, concerning the arc and chord lengths (and other specific parameters) of segments of curves of constant curvature on manifolds of curvature $r \in \{1,0,-1\}$. All of these formulas can be derived by straightforward, elementary calculations.

In figure 15 S and B denote the endpoints of the investigated segment of the cycle γ, L is the length of the arc SB while l is the length of the (geodesic) chord SB. From this point different cases are treated separately.

If γ is a *circle* of center O and radius R (i.e., $r+\beta^2>0$), then let ϕ be the central angle of its arc SB, and let δ denote the angle between the chord SB and the radii OS, OB (figure 15/A). Depending on the curvature r of the manifold the following relationships are valid.

On the sphere ($r=1$):

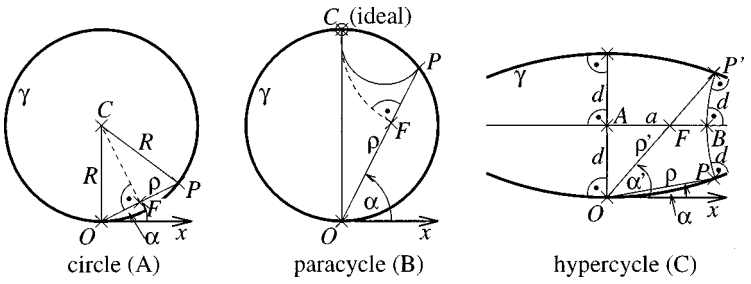

FIG. 16. Polar coordinates for curves of constant curvature.

$$L=\phi\ \sin(R),\quad \cos(l)=\cos^2(R)+\sin^2(R)\cos(\phi),$$

$$\tan(\delta)=\frac{1}{\cos(R)\tan(\phi/2)}=\frac{1+\cos(\phi)}{\sin(\phi)\cos(R)}. \tag{A1}$$

On the Euclidean plane ($r=0$):

$$L=\phi R,\quad l=2R\ \sin(\phi/2),\quad \delta=\frac{\pi-\phi}{2}. \tag{A2}$$

On the hyperbolic plane ($r=-1$, $|\beta|>1$):

$$L=\phi\ \sinh(R),\quad \cosh(l)=\cosh^2(R)-\sinh^2(R)\cos(\phi),$$

$$\tan(\delta)=\frac{1}{\cosh(R)\tan(\phi/2)}=\frac{1+\cos(\phi)}{\sin(\phi)\cosh(R)}. \tag{A3}$$

If γ is a *paracycle* (i.e., $r=-1$, $|\beta|=1$) then O is an ideal point, $R=\infty$, $\phi=0$ (figure 15/B), and the following equations are satisfied:

$$L=\sqrt{2(\cosh(l)-1)},\quad \tan(\delta)=\frac{1}{\sinh(l/2)}. \tag{A4}$$

Finally, if γ is a *hypercycle* (i.e., $r+\beta^2<0$) then the altitude d and the length $a=|S'B'|$ on the base line of the hypercycle are used to describe the geometry of the arc. δ denotes the angle between the (geodesic) chord SB and the altitudes $S'S$, $B'B$ at the endpoints of the chord (figure 15/C). The following connections are fulfilled:

$$L=a\ \cosh(d),\quad \cosh\ l=\cosh^2(d)\cosh(a)-\sinh^2(d),$$

$$\tan(\delta)=\frac{1}{\sinh(d)\tanh(a/2)}=\frac{1+\cosh(a)}{\sinh(d)\sinh(a)}. \tag{A5}$$

APPENDIX B: THE POLAR EQUATIONS OF CURVES OF CONSTANT CURVATURE

Let O be an arbitrary point of the manifold M of curvature $r\in\{1,0,-1\}$, and let x be a (geodesic) ray with origin O. The position of an arbitrary point $P\in M$ is characterized by its polar coordinates $(\rho,\alpha)\in\mathbb{R}_0^+\times[0,2\pi)$, where ρ is the (geodesic) distance from O to P, and α is the angle between the rays x and OP. In this appendix the polar equations of the cycles of M tangential to x at O are summarized (figure 16). (These formulas can be obtained using elementary trigonometric connections and the results of the previous appendix.)

The case of *circles* (for arbitrary r) and *paracycles* can be treated simultaneously; let γ be a circle (or paracycle) of center C, radius R, curvature q, which is tangential to x at O, and let P be an arbitrary point of its circumference with polar coordinates (ρ,α) (figures 16/A, B). (If γ is a

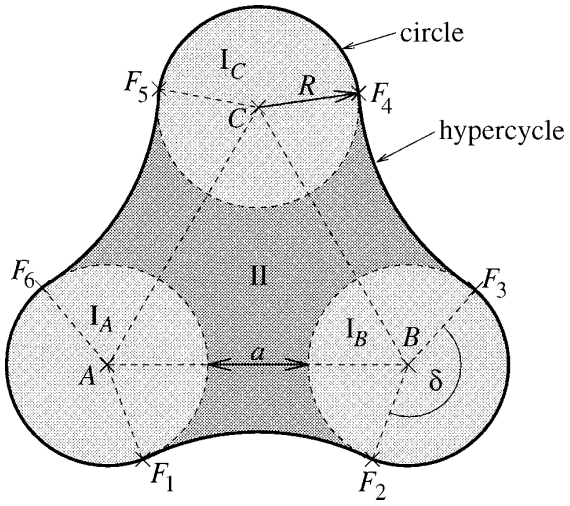

FIG. 17. The triangular billiard with focusing and dispersing boundary segments.

paracycle, then C is an ideal point, $R=\infty$, $q=1$.) Using the relations between the curvature q and the radius R [equation (2), with $\beta=q$], and considering the right triangle $OFC\Delta$ the following equations can be derived:

$$\frac{\sin(\alpha)}{q}=\begin{cases}\tan(\rho/2), & \text{if } r=1 \text{ (on the sphere);}\\ \rho/2, & \text{if } r=0 \text{ (on the Euclidean plane);}\\ \tanh(\rho/2), & \text{if } r=-1, \quad q\geqslant 1 \text{ (on the hyperbolic plane).}\end{cases} \tag{B1}$$

In the case of *hypercycles* the two branches of the curve have to be treated separately. Let γ be a hypercycle of altitude d, curvature $0<q<1$, which is tangential to the ray x at the origin O, and let P, $P'\in\gamma$ be arbitrary, opposite lying points with polar coordinates (ρ,α), (ρ',α'), respectively, on different branches of the hypercycle, as it is indicated in Figure 16(C). (The segment PP' meets the base line at right angle in B.) Using the formulas (A5) (with $l=\rho$, $\delta=\pi/2-\alpha$) and trigonometric relations for the right triangle $OAF\Delta$ (Figure 16(C)) the following equations can be derived:

$$\frac{\sin(\alpha)}{q}=\begin{cases}\tanh(\rho/2), & \text{if } r=-1, \quad |\sin(\alpha)/q|<1 \text{ (for the branch of } O);\\ \coth(\rho/2), & \text{if } r=-1, \quad |\sin(\alpha)/q|>1 \text{ (for the branch avoiding } O).\end{cases} \tag{B2}$$

(The primes on ρ, α have been omitted.)

The previous results can be summarized in the following statement.

Lemma 13: The equation (B1) (for $r+q^2\geqslant 0$) or (B2) (for $r+q^2<0$) holds for the length $\rho=|OO'|$ of the chord OO' of the curve γ of constant curvature q (on a manifold of curvature $r\in\{1,0,-1\}$), where α is the angle between the (geodesic) chord OO' and the curve γ.

APPENDIX C: AN APPLICATION OF THEOREM 12

In this appendix an example of the use of Theorem 12 (in Section V) is given, only for demonstrating purposes. The billiard domain, bounded by three focusing circular arcs and three dispersing segments of hypercycles can be considered as the triangular version of the Bunimovich stadium billiard on the hyperbolic plane (Figure 17). The centers of the circles of radius R lie at the vertices of the equilateral triangle $ABC\Delta$, and the hypercycle segments of curvature q are attached tangentially to the circles at the points $F_1,F_2,\ldots,F_6$ in such a way that the angle δ subtended by the circular boundary arcs at the centers of the circles are less than the straight angle. (Otherwise the particle bouncing back and forth along a diameter could be trapped in one circle for an infinitely long time.)

Let us divide the billiard domain into four regions, three of them being the disks I_A, I_B, I_C belonging to the circles, and the fourth is the rest, denoted by II. Let a be the minimal distance between two disks, and let $L:=\delta\sinh(R)$ be the length of the circular boundary arcs [equation (A3)]. It is evident that for magnetic fields $\beta<q$ the billiard particle (moving at unit speed) spends at most time L (in the limit case sliding along the boundary) inside a disk region of type I, and then passes at least time a (mostly) in region II, bouncing only on dispersive wall segments before entering again one of the disks and preforming a reflection on its focusing boundary. (It is possible that a bounceless trajectory segment intersects one of the disks, though both of its endpoints lie on a hypercycle segment. In this case the particle is not considered to have entered the disk region of type I.) Since the time elapsed outside the disks contributes entirely to the reduced time, theorem 12 can be applied with the constant $K=a/(a+L)$, and the estimation

$$\lambda\geqslant\frac{a}{a+L}\sqrt{1-\beta^2} \tag{C1}$$

can be obtained for the Lyapunov exponent λ, where the magnetic field $\beta<q<1$.

Canonical general relativity: The diffeomorphism constraints and spatial frame transformations

M. A. Clayton[a)]
CERN–Theory Division, CH-1211, Geneva 23, Switzerland

(Received 30 July 1997; accepted for publication 3 April 1998)

Einstein's general relativity with both metric and vielbein treated as independent fields is considered, demonstrating the existence of a consistent variational principle and deriving a Hamiltonian formalism that treats the spatial metric and spatial vielbein as canonical coordinates. This results in a Hamiltonian in standard form that consists of Hamiltonian and momentum constraints as well as constraints that generate spatial frame transformations—all appearing as primary, first class constraints on phase space. The formalism encompasses the standard coordinate frame and vielbein approaches to general relativity, and the constraint algebra derived herein reproduces known results in either limit. © *1998 American Institute of Physics.* [S0022-2488(98)01507-2]

I. INTRODUCTION

A recent review of actions for general relativity (GR)[1] describes formulations in coordinate and (orthogonal) vielbein frames from variations of Einstein-Hilbert and Einstein-Palatini actions. Notably absent is an action that encompasses both of these cases. Such an action possesses the full general linear group invariance, as well as the usual diffeomorphism invariance, allowing the ''limit'' to orthogonal vielbein and coordinate frame approaches as different choices of gauge. This structure is represented on the full arbitrariness of the choice of vielbein (16 functions) as well as those of the spacetime metric (10 functions). That one can construct such an action is perhaps no surprise,[2] however we will also construct a Hamiltonian for the system in which the spatial $\mathrm{GL}(3,\mathbb{R})$ invariance is represented by infinitesimal generators on phase space. The resulting constraint algebra is derived, complete with conditions that determine surface contributions that guarantee that the field equations of GR follow properly from the Hamiltonian.[3]

As is always the case in such constructions, the Hamiltonian is far from unique. We will instead be focusing on the combined algebra of infinitesimal diffeomorphisms and $\mathrm{GL}(3,\mathbb{R})$ transformations which is uniquely determined once the parameterization of phase space and the action of the generations is fixed. In an earlier work[4] this algebra was derived through a generalization of the geometric argument of Teitelboim,[5,6] which led to a ''derivation'' of canonical GR.[7] This generalized algebra has appeared previously in the examination of (orthonormal) tetrad GR[8,9] and here we extend this type of analysis to the more general case, including an arbitrary tetrad as well as metric degrees of freedom.

It is noteworthy that we are not attempting to implement the full set of $\mathrm{GL}(4,\mathbb{R})$ generators,[9,10] nor the full set of spacetime diffeomorphisms,[11,12] instead we view the problem as purely geometrodynamic. Initial data consisting of the components of the spatial metric and vielbein that satisfies the constraints are given on the initial hypersurface, we determine the infinitesimal transformations of this data that lead to an equivalent physical problem (frame rotations and spatial diffeomorphisms), and then determine the conditions on the generator of time evolution that guarantee that the evolution of the system is consistent with spacetime diffeomorphism invariance.

Inevitably we end up with a system with a higher degree of redundancy (30 phase space degrees of freedom and 13 primary, first class constraints) and the possibility of new choices of gauge that are useful for numerical relativity exists; this will not be considered in this work. Ultimately we are interested in exploring the relationship between diffeomorphism invariance, the strong equivalence principle, and the evolution of quantum systems. In particular, whether it is

a)Electronic mail: Michael.A.Clayton@cern.ch

 © 1998 American Institute of Physics

possible to specify some type of quantum evolution that respects diffeomorphism invariance without the need to introduce an (approximate) timelike killing vector as is usually necessary.[13,14] We would also like to quantify the noninvariance of the conventional curved spacetime field theory, towards an understanding of which results may survive in a more fundamental theory based on the strong equivalence principle, and which depend strongly on the choice of frame.

II. THE GENERAL FRAME CONSTRUCTION

The natural setting for this work is the space of moving (vielbein) frames above a manifold **M**, that is, the space of smooth assignments of a frame of reference above each point, equivalent to smooth sections of the general linear frame bundle $GL\mathbf{M}$. Physical fields erected above **M** (the metric, curvature, matter fields, etc., ...) are then associated to this bundle through some representation of $\mathrm{GL}(n,\mathbb{R})$, and components may be defined in terms of said frame. Standard presentations of classical general relativity often adopt coordinate (or holonomic) frames from the outset, introducing moving (or vielbein) frames as a ''generalized'' concept in Riemannian geometry. Even when such frames are given equal footing with holonomic frames, in the variational principle coordinate components are once again given precedence. In order to demonstrate that this is unnecessary, we proceed to review some results from Riemannian geometry in a general linear frame.

A. Moving frames

A moving frame $\{e_A\}$ above a point in **M** will be written in terms of a particular coordinate frame as $e_A := E^\mu{}_A \partial_\mu$ and the coframe that is dual to it as $\theta^A := E^A{}_\mu dx^\mu$, where the duality relation $\theta^A[e_B] = \delta^A_B$ implies that the vielbeins satisfy $E^\mu{}_A E^A{}_\nu = \delta^\mu_\nu$ and $E^\mu{}_B E^A{}_\mu = \delta^A_B$. In this section we consider frames that are chosen to be a smooth section of the general linear frame bundle $GL\mathbf{M}$, however, in Section III we will consider spatial frames defined by $e_a := E^i{}_a \partial_i$, where ∂_i are the partial derivatives with respect to coordinates on a spatial hypersurface.

The volume form in a linear frame is given by[15]

$$\int_{\mathbf{M}} *\mathbf{1} = \int_{\mathbf{M}} \sqrt{|g|}\, \theta^0 \wedge \theta^1 \wedge \theta^2 \wedge \theta^3 = \int_{\mathbf{M}} d^4x \sqrt{|g|} E, \tag{1}$$

the last of which will be used here. Using compatibility and vanishing torsion, Gauss' law takes the form

$$\int_R dx E \sqrt{-g} \nabla_A [V]^A = \int_R dx \partial_\mu [\underline{E}^\mu{}_A \mathbf{V}^A] = \int_{\partial R} dS_\mu \underline{E}^\mu{}_A \mathbf{V}^A = \int_{\partial R} d\underline{S}_A \mathbf{V}^A, \tag{2}$$

where the surface measure is defined in terms of the normal vector n^A to the boundary ∂R of the region $R \subset \mathbf{M}$ by $S_A := *\mathbf{1}[n]_A$. We have also made the definition $\underline{T} := ET$ for tensors weighted by the vielbein density $E := \det[E^A{}_\mu]$, and $\mathbf{T} := \sqrt{|g|} T$ for tensors weighted by the spatial metric density $\sqrt{|g|} := \sqrt{|\det[g_{AB}]|}$.

Under the change of frame determined by $M^A{}_B \in \mathrm{GL}(n,\mathbb{R})$, the frame and coframe transform as $\theta^A \to \theta^B = M^B{}_A \theta^A$, $e_A \to e_B = e_A |M^{-1}|^A{}_B$, where $M^A{}_C |M^{-1}|^C{}_B = |M^{-1}|^A{}_C M^C{}_B = \delta^A_B$, and similarly for the components of tensors. The infinitesimal forms $M^A{}_B = \delta^A_B + \omega^A{}_B$, and $|M^{-1}|^A{}_B = \delta^A_B - \omega^A{}_B$ define the generators $\Delta^A{}_B$ of $\mathfrak{gl}(n,\mathbb{R})$, acting, for example, on vectors, covectors and both types of density as

$$\Delta_{\tilde{\omega}}[T]_A = -\omega^B{}_A T_B, \quad \Delta_{\tilde{\omega}}[T]^A = \omega^A{}_B T^B, \quad \Delta_{\tilde{\omega}}[\gamma] = -\omega^A{}_A \sqrt{\gamma}, \quad \Delta_{\tilde{\omega}}[E] = \omega^A{}_A E, \tag{3}$$

where $\tilde{\omega}$ represents the matrix $\omega^A_B \in \mathrm{GL}(n,\mathbb{R})$. These generators satisfy the Lie algebra of $\mathfrak{gl}(n,\mathbb{R})$, given by the matrix commutator[16]

$$[\Delta_{\tilde{\omega}_1}, \Delta_{\tilde{\omega}_2}] = -\Delta_{[\widetilde{\omega_1,\omega_2}]}, \tag{4}$$

where $[\omega_1,\omega_2]^A{}_B := \omega_1{}^A{}_C \omega_2{}^C{}_B - \omega_1{}^C{}_B \omega_2{}^A{}_C$.

Once one has a definition of parallel transport, the covariant derivative operator is defined. We will assume that it acts on the components of tensors as, for example, $\nabla_A[V]^B = e_A[V^B] + \Gamma^B_{AC} V^C$, and we may then define what it means for the components of the metric g_{AB} to be compatible with this connection:

$$\nabla_A[g]_{BC} = e_A[g_{BC}] - g_{DC}\Gamma^D_{AB} - g_{BD}\Gamma^D_{AC} = 0. \tag{5}$$

From the nonholonomic nature of the frame $\{e_A\}$ we have the structure constants[17]

$$[e_A, e_B] = C_{AB}{}^C e_C, \quad C_{AB}{}^C = E^C{}_\mu (e_A[E^\mu{}_B] - e_B[E^\mu{}_A]), \tag{6}$$

and the vanishing of the torsion tensor $T(X,Y) := \nabla_X[Y] - \nabla_Y[X] - [X,Y]$ ($\nabla_X := X^A \nabla_A$ and $[X,Y] := \mathscr{L}_X[Y]$) results in the relationship between $\Gamma^A_{[BC]}$ and the structure constants (6),

$$T^A_{BC} = 2\Gamma^A_{[BC]} - C_{BC}{}^A = 0. \tag{7}$$

Throughout we denote (anti-)symmetrization by [ ] and ( ), respectively, i.e., $T_{[AB]} := 1/2(T_{AB} - T_{BA})$ and $T_{(AB)} := 1/2(T_{AB} + T_{BA})$. This, combined with (5), allows the explicit solution of Γ^A_{BC} in terms of metric and vielbein components:

$$\Gamma^A_{BC} = \tfrac{1}{2} g^{AD}(e_B[g_{CD}] + e_C[g_{DB}] - e_D[g_{BC}]) + \tfrac{1}{2} g^{AD}(g_{BE} C_{DC}{}^E + g_{CE} C_{DB}{}^E) + \tfrac{1}{2} C_{BC}{}^A, \tag{8}$$

a combination of the standard coordinate frame and orthogonal frame results. We will also require the contraction of the Riemann curvature tensor: $R^A_{BCD} = e_C[\Gamma^A_{DB}] - e_D[\Gamma^A_{CB}] + \Gamma^E_{DB}\Gamma^A_{CE} - \Gamma^E_{CB}\Gamma^A_{DE} - C_{CD}{}^E \Gamma^A_{EB}$ to the Ricci tensor:

$$R_{AB} := e_C[\Gamma^C_{BA}] - e_B[\Gamma^C_{CA}] + \Gamma^D_{BA}\Gamma^C_{CD} - \Gamma^D_{CA}\Gamma^C_{BD} - C_{CB}{}^D \Gamma^C_{DA}. \tag{9}$$

B. The Einstein-Hilbert action in a general linear frame

A direct translation of the action for GR results in (we use $16\pi G = c = 1$ throughout)

$$S_{\mathrm{GR}} = -\int_{\mathbf{M}} d^4x E \sqrt{|g|} g^{AB} R_{AB}, \tag{10}$$

where the spacetime is now described by a section of $Riem_{\mathbf{M}} \times GL\mathbf{M}$, namely, a Riemannian metric and nondegenerate linear frame above $\mathbf{M}$.

In a variation of the connection coefficients in R_{AB} [i.e., not considering the variation of the structure constant in the definition (9)] we find that $\delta_\Gamma R_{AB} = \nabla_C[\delta\Gamma]^C_{BA} - \nabla_B[\delta\Gamma]^C_{CA}$, and therefore treating the components $\Gamma^A_{(BC)}$ as independent leads via a Palatini variation to the compatibility conditions (5),

$$\frac{\delta S_{\mathrm{GR}}}{\delta \Gamma^C_{(AB)}} = -E(\nabla_{e_C}[\mathbf{g}]^{BA} - \nabla_{e_D}[\mathbf{g}]^{(AD}\delta^{B)}_C) = 0. \tag{11}$$

Note that the action is not set up to generate the torsion-free conditions (7); the variations $\delta\Gamma^A_{[BC]}$ must be determined in terms of the vielbein degrees of freedom using (7) and the variation of (6):

$$\delta C_{AB}{}^C = \nabla_A[E^C{}_\mu \delta E^\mu{}_B] - \nabla_B[E^C{}_\mu \delta E^\mu{}_A] + \delta E^\mu{}_A E^D{}_\mu \Gamma^C_{DB} - \delta E^\mu{}_B E^D{}_\mu \Gamma^C_{DA}. \tag{12}$$

To perform the Einstein-Hilbert variation, requires the variation of (8),

$$\delta\Gamma^A_{BC} = \delta E^\mu{}_B E^D{}_\mu \Gamma^A_{DC} + \tfrac{1}{2}\nabla_B[g^{AD}\delta g_{CD} + E^A{}_\mu \delta E^\mu{}_C - g^{AD} g_{CE} E^E{}_\mu \delta E^\mu{}_D]$$
$$+ \tfrac{1}{2}\nabla_C[g^{AD}\delta g_{DB} - E^A{}_\mu \delta E^\mu{}_B - g^{AD} g_{BE} E^E{}_\mu \delta E^\mu{}_D]$$
$$- \tfrac{1}{2} g^{AD}\nabla_D[\delta g_{BC} - g_{BE} E^E{}_\mu \delta E^\mu{}_C - g_{CE} E^E{}_\mu \delta E^\mu{}_B], \tag{13}$$

where we note that the presence of the first term, although implying that $\delta\Gamma^A_{BC}$ is no longer a tensor, is precisely what guarantees that the variation of a covariant derivative will remain covariant.

The variation of (10) will be performed by treating the densitized components of the inverse metric $\mathbf{g}^{AB}$ and the frame degrees of freedom $\underset{\sim}{E}{}^\mu{}_A$ as independent variables, using

$$\delta\underset{\sim}{\mathbf{R}} = \underset{\sim}{R}_{AB}\delta\mathbf{g}^{AB} + \left[2\mathbf{R}^A{}_B E^B{}_\mu - \frac{1}{n-1}\mathbf{R}E^A{}_\mu\right]\delta\underset{\sim}{E}{}^\mu{}_A - E\nabla_A\nabla_B[\delta\mathbf{S}^{AB}], \tag{14}$$

where $\delta\mathbf{S}^{AB} := \delta\mathbf{g}^{AB} + g^{AB}\delta\sqrt{|g|} + 2\mathbf{g}^{AC}E^B{}_\mu\delta E^\mu{}_C - 2\mathbf{g}^{AB}E^C{}_\mu\delta E^\mu{}_C$. In computing this we have left the dimensionality n of spacetime arbitrary and noted that $\delta\sqrt{-g} = g_{AB}\delta\mathbf{g}^{AB}/(n-2)$ and $\delta E = E^A{}_\mu \delta\underset{\sim}{E}{}^\mu{}_A/(n-1)$. Discarding surface terms we find

$$\frac{\delta S_{\mathrm{GR}}}{\delta\mathbf{g}^{AB}} = \underset{\sim}{R}_{AB} = 0, \quad \frac{\delta S_{\mathrm{GR}}}{\delta\underset{\sim}{E}{}^\mu{}_A} = 2\mathbf{R}^A{}_B E^B{}_\mu - \frac{1}{n-1}\mathbf{R}E^A{}_\mu = 0, \tag{15}$$

which are Einstein's equations in empty spacetime. The equivalence of the variational results from the metric and vielbein degrees of freedom is expected algebraically due to an argument by Floreanini and Percacci,[10] and also since we know that Einstein's equations are covariant under frame transformations. This variational principle is actually a specific case of the more general formalism that includes affine frames, nonmetricity and torsion that appears in Ref. 2.

III. HAMILTONIAN FORMALISM

We turn now to the construction of a Hamiltonian formalism for the system, much of which is a straightforward application of the Bergmann-Dirac procedure for constrained systems described in detail in Ref. 18 (which we will follow). In order to consider the initial value problem, we must consider the embedding of a family of nonoverlapping, spacelike hypersurfaces Σ_t that foliate $\mathbf{M}$, labeled by some choice of time parameter. The geometry of this scenario has been considered extensively by Kuchař;[19] here we will give results that will be of some use in this work, ignoring global issues (other than the addition of surface contributions to the Hamiltonian) and assuming in all cases that a global section of the frame bundle $GL\mathbf{M}$ exists.

A. The surface-adapted basis

The spacetime metric (and inverse, respectively) may be put in surface-normal form (note the -2 signature of the spacetime metric),

$$g = \theta^\perp\otimes\theta^\perp - \gamma_{ab}\theta^a\otimes\theta^b, \quad g^{-1} = e_\perp\otimes e_\perp - \gamma^{ab}e_a\otimes e_b, \tag{16}$$

where the frame and its dual coframe are given by

$$e_\perp = \frac{1}{N}\partial_t - \frac{N^a}{N}e_a, \quad e_a = E^i{}_a\partial_i, \quad \theta^\perp = Ndt, \quad \theta^a = N^a dt + E^a{}_i dx^i. \tag{17}$$

The atlas fields N and N^a (the lapse function and shift vector, respectively) play the same geometric role as that assigned to them in coordinate frame work,[18,20] namely, the shift vector is the projection of the spacetime vector field that describes the ''flow of time'' parallel to Σ, and the lapse function the normal projection. (Note that they may either be thought of as a reparameterization of the spacetime metric, or as the $E^A{}_0$ components of the vielbein in a gauge where $E^0{}_i = 0$ in tetrad GR.) The only alteration of this conventional picture is that N^a are the components of the shift vector in the frame $\{e_a\}$ above Σ. It is straightforward to see that $E^{(4)}\sqrt{|g|} = NE\sqrt{\gamma}$

where we distinguish here between the four-dimensional determinant $E^{(4)}$ and from now on write $E \coloneqq \det E^a{}_i$ as representing the determinant of the spatial vielbein. We will also occasionally refer to a spatial vector as, for example $\vec{N} \coloneqq N^a e_a$.

For this surface-adapted frame we find the nonvanishing structure constants from (6),

$$[e_a, e_b] = C_{ab}{}^c e_c, \quad [e_\perp, e_a] = C_{\perp a}{}^\perp e_\perp + C_{\perp a}{}^b e_b, \quad C_{\perp a}{}^\perp = e_a[\ln N], \tag{18a}$$

$$C_{ab}{}^c = E^c{}_i (e_a[E^i{}_b] - e_b[E^i{}_a]), \quad C_{\perp a}{}^b = \frac{e_a[N^b]}{N} + \frac{N^c}{N} C_{ac}{}^b + \frac{1}{N} E^b{}_i \partial_t[E^i{}_a]. \tag{18b}$$

Taking perpendicular and parallel projections of the compatibility conditions (5) results in $\Gamma^\perp_{\perp\perp} = \Gamma^\perp_{a\perp} = 0$, $\Gamma^\perp_{\perp a} \coloneqq a_a$, $\Gamma^a_{\perp\perp} = a^a \coloneqq \gamma^{ab} a_b$, $\Gamma^\perp_{ab} \coloneqq K_{ab}$, $\Gamma^a_{b\perp} = K^a{}_b \coloneqq \gamma^{ac} K_{bc}$ and the surface compatibility conditions $\boldsymbol{\nabla}_a[\gamma]_{bc} = 0$, where $\boldsymbol{\nabla}_a$ is the covariant derivative operator defined on Σ. The remaining compatibility condition gives the relationship between the extrinsic curvature and the time derivatives of the metric and vielbein degrees of freedom,

$$\partial_t[\gamma_{ab}] - 2\gamma_{(ac} E^c{}_i \partial_t[E^i{}_{b)}] - 2NK_{ab} - \mathcal{L}_{\vec{N}}[\gamma]_{ab} = 0. \tag{19}$$

The projections of (7) ($T^\perp_{\perp a}$, $T^\perp_{ab}$, $T^a_{\perp b}$, and T^a_{bc}, respectively) result in $a_a = e_a[\ln N]$, $K_{[ab]} = 0$, $\Gamma^a_{\perp b} = K^a{}_b + C_{\perp b}{}^a$ and $\Gamma^a_{[bc]} = C_{bc}{}^a$, which completes the generalization of the results of Ref. 18.

The projected components of the Ricci tensor (9) that will appear in the surface reduction of (10) are (the operator $d_\perp$ is defined in the following section)

$$R^{(4)}_{\perp\perp} = -d_\perp[K] + \boldsymbol{\nabla}_a[a]^a + a^a a_a - K^a{}_b K^b{}_a, \tag{20a}$$

$$R^{(4)}_{ab} = R_{ab} + d_\perp[K]_{ab} - \boldsymbol{\nabla}_{(b}[a]_{a)} - a_a a_b + KK_{ab} - 2K_{ac} K^c{}_b, \tag{20b}$$

where $K \coloneqq K^a{}_a$ and we have written $R^{(4)}_{ab}$ to indicate the projected spacetime tensor and R_{ab} the intrinsically defined spatial Ricci tensor.

B. Surface-adapted derivatives

In order to consider the representation of diffeomorphisms in frames in which the metric is nondynamical (or prescribed in some manner), we need to consider in some detail the representation of spatial diffeomorphisms. The action of an infinitesimal diffeomorphism of Σ to itself generated by the vector field $\vec{X}$, may be written in an arbitrary frame as

$$\mathcal{L}_{\vec{X}}[T^{ab\cdots}_{mn\cdots}] \coloneqq \boldsymbol{\nabla}_{\vec{X}}[T]^{ab\cdots}_{mn\cdots} - \Delta_{\widetilde{\boldsymbol{\nabla}\vec{X}}}[T]^{ab\cdots}_{mn\cdots}, \tag{21a}$$

which is also applicable to densities: $\mathcal{L}_{\vec{X}}[\sqrt{\gamma}] = \boldsymbol{\nabla}_a[\mathbf{X}]^a$. In this form the outcome of the diffeomorphism is represented on the components of tensors as the sum of a covariant derivative $\boldsymbol{\nabla}_{\vec{X}} \coloneqq X^a \boldsymbol{\nabla}_a$ and a spatial frame rotation $[\widetilde{\boldsymbol{\nabla}\vec{X}}]^a_b \coloneqq \boldsymbol{\nabla}_b[X]^a$. The frame is unaffected: $\mathcal{L}_{\vec{X}}[e_a] = 0$.

This is not necessary though, and while appropriate for considering a fixed frame, is inappropriate for considering diffeomorphisms when constrained to an orthonormal frame since $\mathcal{L}_{\vec{X}}[\gamma]_{ab} = \boldsymbol{\nabla}_{(a}[X]_{b)} \neq 0$. Instead one may define a Lie action that operates on both the frame and tensor components as

$$\mathcal{L}'_{\vec{X}}[e_a] = \Delta_{\widetilde{\boldsymbol{\nabla}\vec{X}}}[e_a] = -\boldsymbol{\nabla}_a[X]^b e_b, \quad \mathcal{L}'_{\vec{X}}[T^{ab\cdots}_{mn\cdots}] = \boldsymbol{\nabla}_X[T]^{ab\cdots}_{mn\cdots}, \tag{21b}$$

so that when the action on a tensor (not just the components) is considered, one finds the same result as (21a). This representation is more appropriate for considering orthonormal frames since the action of $\mathcal{L}'$ on the components of the metric $\mathcal{L}'_{\vec{X}}[\gamma]_{ab} = \nabla_{\vec{X}}[\gamma]_{ab}$ vanishes due to compatibility. This is similar to how parallel transport in a principle bundle is transferred to associated bundles[17] since one could just as easily define the covariant derivative to act as $\boldsymbol{\nabla}_{\vec{X}}[T^{ab\cdots}_{mn\cdots}] = X^a e_a[T^{ab\cdots}_{mn\cdots}]$, and $\boldsymbol{\nabla}_{\vec{X}}[e_a] = X^b \Gamma^c_{ba} e_c$. This we do not pursue since the resulting action is not covariant with respect to general linear frame transformations when acting on frame or tensorial components alone.

Similarly, the definition of the derivative off of Σ that is surface-covariant is defined to act on the components of tensors as[18]

$$d_\perp[T^{ab\cdots}_{mn\cdots}] := e_\perp[T^{ab\cdots}_{mn\cdots}] + \Delta_{\tilde{C}_\perp}[T]^{ab\cdots}_{mn\cdots}, \tag{22}$$

where $\tilde{C}_\perp$ is the matrix with components $C_{\perp a}{}^b$ defined in (18). This operator defines the derivative normal to Σ that ''follows'' the vielbein (since $d_\perp[E^i{}_a]=0$ by definition), and describes the evolution of all quantities in terms of the original frame. (Note that the definition of $C_{\perp a}{}^b$ involves time derivatives of the frame.)

As with the case of the Lie derivative, we may also consider the opposite case, namely where the normal derivative is defined so that the metric does not ''evolve'' and the frame does. Let us introduce an operator that allows a more general evolution of the vielbein,

$$d'_\perp[E^i{}_a] := e_\perp[E^i{}_a] + \Delta_{\tilde{D}_\perp}[E^i{}_a] = e_\perp[E^i{}_a] - D_{\perp a}{}^b E^i{}_b, \tag{23}$$

where $\tilde{D}_\perp$ is determined by requiring that $d'_\perp[T^{ab\cdots}_{mn\cdots} e_a \otimes e_b \cdots \theta^m \otimes \theta^n \cdots] = d_\perp[T^{ab\cdots}_{mn\cdots} e_a \otimes e_b \cdots \theta^m \otimes \theta^n \cdots]$ (so that the operators act on tensors in an identical manner). We find that the action of $d'_\perp$ on the components of a tensor must be given by

$$d'_\perp[T^{ab\cdots}_{mn\cdots}] = e_\perp[T^{ab\cdots}_{mn\cdots}] + \Delta_{\tilde{C}'_\perp}[T^{ab\cdots}_{mn\cdots}], \quad \text{where} \quad C'_{\perp b}{}^a := C_{\perp b}{}^a - D_{\perp b}{}^a + E^a{}_i e_\perp[E^i{}_b]. \tag{24}$$

If we now require that $d'_\perp[\gamma]_{ab}=0$ (so that the normal derivative operator does not affect the components of the metric) then we may choose

$$D_{\perp b}{}^a = -\frac{1}{2N}\,\gamma^{ac}\partial_t[\gamma_{bc}] + \frac{1}{N}\,e_b[N^a] - \frac{1}{N}\,N^c E^a{}_i e_b[E^i{}_c], \tag{25}$$

and therefore $C'_{\perp b}{}^a = -1/2\gamma^{ac} e_\perp[\gamma_{bc}]$. (This is far from unique since any choice of $D_{\perp[ab]}$ will result in $d'_\perp[\gamma]_{ab}=0$, however, we have chosen what we consider to be a ''simplest choice'' which corresponds to the operator considered in Section III C as well as Ref. 4.) In terms of these operators, the compatibility condition (19) takes on either of the two forms

$$d_\perp[\gamma]_{ab} = 2K_{ab} \quad \text{or} \quad E^a{}_i d'_\perp[E^i{}_b] = -K^a{}_b. \tag{26}$$

Note that the total time derivative operators $d_t = N d_\perp + \mathscr{L}_{\vec{N}}$ and $d'_t = N d'_\perp + \mathscr{L}_{\vec{N}}$ correspond to the definition of the total derivative of the tensor, and are not equivalent to the time derivative of the components. For example, $d_t[X^a e_a] = d'_t[X^a e_a] = \partial_t[X^a e_a] \neq \partial_t[X^a] e_a$.

C. The Hamiltonian

From the results of the previous two sections, the GR action (10) is reduced to

$$S_{\mathrm{GR}} = \int dt \int_\Sigma d^3x \underline{\mathbf{N}}(d_\perp[K] + \gamma^{ab} d_\perp[K]_{ab} - 2(\boldsymbol{\nabla}_a[a]^a + a^a a_a) + R + K^2 - K^a{}_b K^b{}_a). \tag{27}$$

Using compatibility we find that $\boldsymbol{\nabla}_a[a]^a + a^a a_a = (\gamma^{ab}\boldsymbol{\nabla}_a\boldsymbol{\nabla}_b[N])/N$ is a surface term in the action which will be dropped, and furthermore that

$$\begin{aligned}\underline{\mathbf{N}}(d_\perp[K] + \gamma^{ab} d_\perp[K]_{ab}) = {} & 2\partial_t[\underline{\mathbf{K}}] - (\underline{K}_{ab} + \gamma_{ab}\underline{K})\partial_t[\boldsymbol{\gamma}^{ab}] - 2\mathbf{K}^a{}_b E^b{}_i \partial_t[\underline{E}^i{}_a] \\ & - 2\underline{\mathbf{N}}^a \boldsymbol{\nabla}_a[K] - 2E\boldsymbol{\nabla}_a[\mathbf{K}^a{}_b N^b] + 2\underline{\mathbf{N}}^a \boldsymbol{\nabla}_b[K]^b{}_a.\end{aligned} \tag{28}$$

Dropping the total time derivative and writing $S_{\mathrm{GR}} = \int dt L_{\mathrm{GR}}$, the Lagrangian is given by

$$\begin{aligned}L_{\mathrm{GR}} = \int_\Sigma d^3x [& -(\underline{K}_{ab} + \gamma_{ab}\underline{K})\partial_t[\boldsymbol{\gamma}^{ab}] - 2\mathbf{K}^a{}_b E^b{}_i \partial_t[\underline{E}^i{}_a] + \underline{\mathbf{N}}(R + K^2 - K^a{}_b K^b{}_a) \\ & + 2\underline{\mathbf{N}}^a(\boldsymbol{\nabla}_b[K]^b{}_a - \boldsymbol{\nabla}_a[K])].\end{aligned} \tag{29}$$

In this form the Lagrangian is most easily treated in Palatini form, that is, by considering the extrinsic curvature K_{ab} as a tensor of Lagrange multipliers that enforce (19). The configuration of the system at any instant in time is described by a section of $Riem_\Sigma \times GL\Sigma$, however, due to the form of (29) it is convenient to choose instead the densitized canonical coordinates $\boldsymbol{\gamma}^{ab}$ and $\underset{\sim}{E}{}^i{}_a$, and so we are considering sections of $\boldsymbol{Riem}_\Sigma \times \underline{GL\Sigma}$. Determining the conjugate momenta via

$$\underset{\sim}{\pi}_{ab} := \frac{\delta L_{\mathrm{GR}}}{\partial_t[\boldsymbol{\gamma}^{ab}]} = -(\underset{\sim}{K}_{ab} + \gamma_{ab}\underset{\sim}{K}), \quad \mathbf{p}^a{}_i := \frac{\delta L_{\mathrm{GR}}}{\partial_t[\underset{\sim}{E}{}^i{}_a]} = -2\mathbf{K}^a{}_b E^b{}_i, \tag{30}$$

the canonical coordinate-momentum pairs are

$$\{(Q^I, P_I)\} := \{(\boldsymbol{\gamma}^{ab}, \underset{\sim}{\pi}_{ab}), (\underset{\sim}{E}{}^i{}_a, \mathbf{p}^a{}_i)\}, \tag{31}$$

corresponding to the phase space $T^*(\boldsymbol{Riem}_\Sigma \times GL\Sigma)$. From the canonical symplectic form on this phase space comes the standard form of the Poisson bracket,

$$\{F, G\} := \int_\Sigma d^3x \sum_I \left(\frac{\delta F}{\delta Q^I(x)} \frac{\delta G}{\delta P_I(x)} - \frac{\delta F}{\delta P_I(x)} \frac{\delta G}{\delta Q^I(x)} \right), \tag{32}$$

where F and G are functions of the phase space variables. (The results herein could be globalized along the lines of Ref. 21, in which case we would introduce the related weak symplectic form on phase space, however, a local treatment is sufficient for this work.) In addition to the phase space coordinates we have the Lagrange multipliers $\{N, N^a, N^a{}_b, K_{ab}, \lambda^{ab}\}$ where the Hamiltonian determined from $H_{\mathrm{GR}} = \int_\Sigma dx \Sigma_I \dot{Q}^I P_I - L_{\mathrm{GR}}$ is written as

$$\begin{aligned} \mathscr{H}_{\mathrm{GR}} = {} & \underset{\sim}{\boldsymbol{\lambda}}^{ab}(K_{ab} - \overline{a}k_{ab} - (1-\overline{a})k'_{ab}) + N^b{}_a \cdot \underset{\sim}{\mathscr{T}}{}^a{}_b + \underset{\sim}{\mathbf{N}}(-R + K^a{}_b K^b{}_a - K^2) \\ & + 2\underset{\sim}{\mathbf{N}}^a \nabla_b[-K^b{}_a + \delta^b_a K], \end{aligned} \tag{33}$$

where we have defined

$$k_{ab} := -(\pi_{ab} - \tfrac{1}{4}\gamma_{ab}\pi), \quad k'_{ab} := -\tfrac{1}{2}\gamma_{(ac}p^c{}_i E^i{}_{b)}. \tag{34}$$

The tensor of constraints enforced by $N^a{}_b$ (defining the scalars $\pi := \gamma^{ab}\pi_{ab}$ and $p := p^a{}_i E^i{}_a$):

$$\cdot\underset{\sim}{\mathscr{T}}{}^a_b := 2\boldsymbol{\gamma}^{ac}\underset{\sim}{\pi}_{bc} - \underset{\sim}{\boldsymbol{\pi}}\delta^a_b - \mathbf{p}^a{}_i \underset{\sim}{E}{}^i{}_b + \underset{\sim}{\mathbf{p}}\delta^a_b, \tag{35}$$

guarantee the consistency of (30), and are uniquely specified by the requirement that they generate infinitesimal $\mathfrak{gl}(3,\mathbb{R})$ frame rotations on phase space, and it is straightforward to show that

$$\{\boldsymbol{\gamma}^{ab}, \cdot\underset{\sim}{\mathscr{T}}{}^c_d[\omega^d_c]\} = \Delta_{\tilde{\omega}}[\boldsymbol{\gamma}]^{ab}, \quad \{\underset{\sim}{\pi}_{ab}, \cdot\underset{\sim}{\mathscr{T}}{}^c_d[\omega^d_c]\} = \Delta_{\tilde{\omega}}[\underset{\sim}{\pi}]_{ab}, \tag{36a}$$

$$\{\underset{\sim}{E}{}^i{}_a, \cdot\underset{\sim}{\mathscr{T}}{}^b_c[\omega^c_b]\} = \Delta_{\tilde{\omega}}[\underset{\sim}{E}{}^i{}_a], \quad \{\mathbf{p}^a{}_i, \cdot\underset{\sim}{\mathscr{T}}{}^b_c[\omega^c_b]\} = \Delta_{\tilde{\omega}}[\mathbf{p}^a{}_i], \tag{36b}$$

where the infinitesimal $\mathrm{GL}(3,\mathbb{R})$ frame rotations $\Delta_{\tilde{\omega}}$ are defined in (3), and we have made use of the notation, for example $\cdot\underset{\sim}{\mathscr{T}}{}^b{}_a[\omega^a{}_b] := \int_\Sigma d^3x \omega^a{}_b \cdot\underset{\sim}{\mathscr{T}}{}^b{}_a$. These generators (the phase space representation of $\Delta^a{}_b$ of Ref. 4) satisfy the $\mathfrak{gl}(3,\mathbb{R})$ Lie algebra,

$$\{\cdot\underset{\sim}{\mathscr{T}}{}^a{}_b, \cdot\underset{\sim}{\mathscr{T}}{}^c{}_d[\omega^d{}_c]\} = \Delta_{\tilde{\omega}}[\cdot\underset{\sim}{\mathscr{T}}]^a{}_b, \tag{37}$$

strongly on phase space. This differs from (4) by a sign due to the fact that the operator Δ acts from the left while $\{\cdot, \mathscr{T}\}$ acts from the right. It is important to note that $\mathscr{T}^{ab}$ is not a symmetric tensor of constraints, in fact, it is precisely the antisymmetric components that generate SO(3) rotations in a local orthonormal frame.

The constraints imposed by λ^{ab} explicitly relate the extrinsic curvature to the conjugate momenta through

$$K_{ab} \approx \overline{a}k_{ab} + (1-\overline{a})k'_{ab}, \tag{38}$$

and in the form given, the variation of (33) with respect to K_{ab} would then determine λ^{ab} in terms of the other Lagrange multipliers as $\lambda_{ab} \approx -2N(K_{ab} - \gamma_{ab}K) - 2(\nabla_{(a}[N]_{b)} - \gamma_{ab}\nabla_c[N]^c$. It is rather inconvenient to carry around the Lagrange multipliers K_{ab} and λ^{ab} solely to deal with the ambiguity in determining K_{ab} from the conjugate momenta. This may be circumvented in a simple manner.

When passing to the Hamiltonian H_{GR}, we may replace each occurrence of the extrinsic curvature in the Hamiltonian with some combination of the canonical momenta consistent with (38) so that the only place K_{ab} will occur is in the constraint enforced by λ^{ab}. The variation of K_{ab} will then enforce $\lambda^{ab} \approx 0$, and neither K_{ab} nor λ^{ab} will play any further role and may therefore be dropped consistently. The Hamiltonian determined in this way is identical to that which would occur if one had replaced the extrinsic curvature by (19) in the Lagrangian (29). In this way we see that the GR Hamiltonian can always be written as

$$H_{\mathrm{GR}} = \int_\Sigma d^3x (N.\underline{\mathscr{H}} + N^a.\underline{\mathscr{H}}_a + N^a{}_b.\underline{\mathscr{T}}^b{}_a) + E_{\mathrm{GR}}, \tag{39a}$$

where

$$.\underline{\mathscr{H}} := -\underline{\mathbf{R}} + \mathbf{E}(K^a{}_b K^b{}_a - K^2), \quad .\underline{\mathscr{H}}_a := -2\mathbf{E}\nabla_b[K^b{}_a - \delta^b_a K], \tag{39b}$$

K_{ab} represents some linear combination of k_{ab} and k'_{ab} consistent with (38).

In order for these field equations to properly follow from the Hamiltonian, it was necessary to add the surface contributions E_{GR} to the Hamiltonian (39a), which are required to satisfy[3]

$$\delta E_{\mathrm{GR}} + S_R + S_k = 0, \tag{40a}$$

in order for the field equations to be properly recovered from the Hamiltonian, where

$$S_R := \int_{\partial\Sigma} d\underline{S}_a (N\boldsymbol{\nabla}_b[\delta \mathbf{S}^{ab}] - \boldsymbol{\nabla}_b[N]\delta \mathbf{S}^{ba}), \tag{40b}$$

comes from the variations of the surface Ricci curvature term, and ($H_{ab} := -2(K_{ab} - \gamma_{ab}K)$, and K_{ab} is again determined in terms of k_{ab} and k'_{ab})

$$\begin{aligned} S_k := & -\frac{1}{2}\int_{\partial\Sigma} d\underline{S}_a N^a \mathbf{H}^{bc}\delta\gamma_{bc} + \int_{\partial\Sigma} d\underline{S}_a N^b \delta \mathbf{H}^a{}_b \\ & + \int_{\partial\Sigma} d\underline{S}_a [N^a \mathbf{H}^c{}_b E^b{}_i \delta E^i{}_c - N^b \mathbf{H}^a{}_b E^c{}_i \delta E^i{}_c + N^b \mathbf{H}^c{}_b E^a{}_i \delta E^i{}_c + N_b \mathbf{H}^{ac} E^b{}_i \delta E^i{}_c], \end{aligned} \tag{40c}$$

comes from variations of the momentum constraint.

D. The constraint algebras

In this section we will consider two choices of the diffeomorphism constraints. First we will choose $.\underline{\mathscr{H}}$ and $.\underline{\mathscr{H}}_a$ to act on phase space as the operators $\mathscr{L}$ and $d_\perp$ from Sec. III B, and refer to the Hamiltonian constructed from these as H_{GR}. This corresponds to $\bar{a} = 1$ in (38), and K_{ab} is replaced everywhere by k_{ab} in (39) and (40). This choice will closely resemble the coordinate approach to canonical GR and has a straightforward coordinate frame gauge reduction. Since these constraints have a nontrivial action on the spatial metric, it is nontrivial to recover the limit where only orthonormal spatial vielbeins are considered. This is instead accomplished by considering a second set of generators $.\underline{\mathscr{H}}'$ and $.\underline{\mathscr{H}}'_a$ which act on phase space as $\mathscr{L}'$ and $d'_\perp$ from Sec. III B, and a second Hamiltonian H'_{GR} is defined by attaching primes to the constraints in (39). In this scheme K_{ab} is replaced everywhere by k'_{ab} (corresponding to $\bar{a} = 0$), and there is also mixing between the

GL(3,$\mathbb{R}$) constraints and the Momentum constraint appearing in (39). This second system will have a straightforward reduction to canonical vierbein GR, however the specialization to spatial coordinate frames is nontrivial.

The Hamiltonian H_{GR} is constructed from (35) and the operators that act on phase space as $d_\perp$ and $\mathscr{L}$, respectively,

$$\mathscr{H}[\underline{\ }] := -\underline{\mathbf{R}} + \mathbf{E}(k^a{}_b k^b{}_a - k^2), \tag{41a}$$

$$\mathscr{H}_a[\underline{\ }] := \mathbf{E}\nabla_b[2\gamma^{bc}\pi_{ac} - \delta^b_a\pi] = -2\mathbf{E}\nabla_b[k^b{}_a - \delta^b_a k]. \tag{41b}$$

From these we compute

$$\{\gamma^{ab}, \mathscr{H}_c[f^c]\} = \mathscr{L}_{\underline{f}}[\boldsymbol{\gamma}]^{ab}, \quad \{\underline{\pi}_{ab}, \mathscr{H}_c[f^c]\} = E\mathscr{L}_{\underline{f}}[\pi]_{ab}, \quad \{\underline{E}^i{}_a, \mathscr{H}_c[f^c]\} = 0, \tag{42a}$$

$$\{\mathbf{p}^a{}_i, \mathscr{H}_c[f^c]\} = -E^b{}_i(f^a\mathscr{H}_b - \tfrac{1}{2}\delta^a_b f^c\mathscr{H}_c) + E^b{}_i\mathscr{L}_{\underline{f}}[2\boldsymbol{\gamma}^{ac}\pi_{bc} - \tfrac{1}{2}\delta^a_b\boldsymbol{\pi}] \approx E^b{}_i\mathscr{L}_{\underline{f}}[\mathbf{p}^a{}_j E^j{}_b], \tag{42b}$$

and (defining $\nabla^2 := \gamma^{ab}\nabla_a\nabla_b$)

$$\{\gamma^{ab}, \mathscr{H}[f]\} = -\mathbf{f}(2k^{ab} - \gamma^{ab}k), \quad \{\underline{E}^i{}_a, \mathscr{H}[f]\} = 0, \tag{43a}$$

$$\{\underline{\pi}_{ab}, \mathscr{H}[f]\} = -E(\nabla_a\nabla_b[f] + \gamma_{ab}\nabla^w[f]) + f\underline{R}_{ab} - \underline{f}(2k_{ac}k^c{}_b + kk_{ab} - \gamma_{ab}k^2) + \underline{f}\gamma_{ab}(k^c{}_d k^d{}_c - k^2), \tag{43b}$$

$$\{\mathbf{p}^a{}_i, \mathscr{H}[f]\} = -2E^b{}_i\boldsymbol{\gamma}^{ac}\nabla_c\nabla_b[f] + fE^b{}_i\boldsymbol{\gamma}^{ac}(2R_{cb} - \tfrac{1}{2}\gamma_{cb}R) + \tfrac{1}{2}E^a{}_i\mathbf{f}(k^c{}_d k^d{}_c - k^2). \tag{43c}$$

It is straightforward to check from these that $\{k_{ab}, \mathscr{H}[N]\} \approx -NR_{ab} + 2Nk_{ac}k^c{}_b - Nkk_{ab} + \nabla_a\nabla_b[N]$, and we therefore reproduce the field equations (20b). We also find [using (43a)] that $\{\gamma_{ab}, \mathscr{H}[N]\} = 2Nk_{ab}$, reproducing the dynamical compatibility condition (19) or, equivalently, (26).

Using the above results we compute the constraint algebra

$$\{\mathscr{H}, \mathscr{T}^a{}_b[\omega^b{}_a]\} = 0, \quad \{\mathscr{H}_a, \mathscr{T}^b{}_c[\omega^c{}_b]\} = \Delta_{\tilde{\omega}}[\mathscr{H}]_a, \tag{44a}$$

$$\{\mathscr{H}[f], \mathscr{H}[g]\} = \int_\Sigma d^3x\,\gamma^{ab}(f\nabla_a[g] - g\nabla_a[f])\mathscr{H}_b, \tag{44b}$$

$$\{\mathscr{H}[f], \mathscr{H}_c[g^c]\} = \int_\Sigma d^3x\,\underline{f}\mathscr{L}_{\tilde{g}}[\mathscr{H}], \tag{44c}$$

$$\{\mathscr{H}_a[f^a], \mathscr{H}_a[g^a]\} = \int_\Sigma d^3x\,\underline{f}^a\mathscr{L}_{\tilde{g}}[\mathscr{H}]_a, \tag{44d}$$

which, in the limit of a spatial coordinate frame ($E^i{}_a = \delta^i_a$), agrees with the Dirac algebra.[5,6,7,21]

The Hamiltonian H'_{GR} is constructed from (35) and the operators that act on phase space as $d'_\perp$ and $\mathscr{L}'$, respectively,

$$\mathscr{H}'[\underline{\ }] = -\underline{\mathbf{R}} + \mathbf{E}(k'^a{}_b k'^b{}_a - k'^2) = \mathscr{H} + k'_{ab}\mathscr{T}^{ab} - \tfrac{1}{4}(\mathscr{T}^{(ab)}\mathscr{T}_{(ab)} - \tfrac{1}{2}\mathscr{T}^a{}_a\mathscr{T}^b{}_b), \tag{45a}$$

$$\mathscr{H}'_a[\underline{\ }] := \mathbf{E}\nabla_b[p^b{}_i E^i{}_a - \delta^b_a p] = -2\mathbf{E}\nabla_b[k'^b{}_a - \delta^b_a k'] + E\gamma_{ab}\nabla_c[\mathscr{T}]^{[bc]} = \mathscr{H}_a - E\nabla_b[\mathscr{T}]^b{}_a, \tag{45b}$$

where we have indicated the relationship between these primed constraints and the unprimed constraints in (41). Note that in (45b) there is a nontrivial mixing of the GL(3,$\mathbb{R}$) constraints and the momentum constraint as it appears in (39b). These act as

$$\{\boldsymbol{\gamma}^{ab}, \mathscr{H}'_c[f^c]\} = 0, \quad \{\underline{E}^i{}_a, \mathscr{H}'_c[f^c]\} = \Delta_{\tilde{\nabla}f}[\underline{E}^i{}_a], \tag{46a}$$

$$\{\underline{\pi}_{ab},\underline{\mathscr{H}}'_c[F^c]\}=E(V_{ab}[f]-\gamma_{ab}V^c{}_c[f])\approx\underline{\mathscr{L}}'_{\vec{f}}[\underline{\pi}]_{ab}, \tag{46b}$$

$$\{\mathbf{p}^a{}_i,\underline{\mathscr{H}}'_c[f^c]\}=\Delta_{\tilde{\nabla}f}[\mathbf{p}^a{}_i]+E^b{}_i\mathbf{U}^a{}_b[\vec{f}]-\tfrac{1}{2}E^a{}_i\mathbf{U}^c{}_c[\vec{f}]\approx\underline{\mathscr{L}}'_{\vec{f}}[\mathbf{p}^a{}_i], \tag{46c}$$

where $(H^a{}_b:=p^a{}_iE^i{}_b-\delta^a_bp)$

$$V_{ab}[f]:=\tfrac{1}{2}\nabla^c[f_aH_{cb}+f_cH_{ab}-f_aH_{bc}], \tag{47a}$$

$$\mathbf{U}^a{}_b[\vec{f}]:=\nabla_b[f]^c\mathbf{H}^a{}_c+\gamma_{bd}\nabla_c[f^c\mathbf{H}^{(ad)}]-\gamma_{bd}\nabla_c[f^a\mathbf{H}^{(cd)}]+\nabla_c[f_b\mathbf{H}^{[ca]}], \tag{47b}$$

and

$$\{\boldsymbol{\gamma}^{ab},\underline{\mathscr{H}}[f]\}=0,\quad\{\underline{E}^i{}_a,\underline{\mathscr{H}}'[f]\}=f\Delta_{\tilde{k}'}[\underline{E}^i{}_a], \tag{48a}$$

$$\{\underline{\pi}_{ab},\underline{\mathscr{H}}'[f]\}=-E(\nabla_a\nabla_b[f]+\gamma_{ab}\nabla^2[f])+f\underline{R}_{ab}+\underline{f}\,\gamma_{ab}(k'^c{}_dk'^d{}_c-k'^2), \tag{48b}$$

$$\{\mathbf{p}^a{}_i,\underline{\mathscr{H}}'[f]\}=-2E^b{}_i\boldsymbol{\gamma}^{ac}\nabla_c\nabla_b[f]+fE^b{}_i\boldsymbol{\gamma}^{ac}(2R_{cb}-\tfrac{1}{2}\gamma_{cb}R)+\mathbf{f}(k'^a{}_b-\delta^a_bk')p^b{}_i+\tfrac{1}{2}\mathbf{f}E^a{}_i(k'^c{}_dk'^d{}_c-k'^2). \tag{48c}$$

Here we find that (46a) reproduces (26) and that (20b) is satisfied when written in terms of the operator $d'_\perp$.

Using these results we compute the primed constraint algebra:

$$\{\underline{\mathscr{H}}',\underline{\mathscr{T}}^a{}_b[\omega^b{}_a]\}=0,\quad\{\underline{\mathscr{H}}'_a,\underline{\mathscr{T}}^b{}_c[\omega^c{}_b]\}=\Delta_{\tilde{\omega}}[\underline{\mathscr{H}}']_a, \tag{49a}$$

$$[\underline{\mathscr{H}}'[f],\underline{\mathscr{H}}'[g]\}=\int_\Sigma d^3x(f\nabla_a[g]-g\nabla_a[f])(\gamma^{ab}\underline{\mathscr{H}}'_b-E\nabla_b[\underline{\mathscr{T}}]^{[ab]}), \tag{49b}$$

$$\{\underline{\mathscr{H}}'[f],\underline{\mathscr{H}}'_c[g^c]\}=\int_\Sigma d^3x(\underline{f}\underline{\mathscr{L}}_{\vec{g}}[\underline{\mathscr{H}}']-fg^a\Delta_{\tilde{k}'}[\underline{\mathscr{H}}']_a+2g^a\nabla_c[fk'_{ab}]\underline{\mathscr{T}}^{[bc]}), \tag{49c}$$

$$\{\underline{\mathscr{H}}'_a[f^a],\underline{\mathscr{H}}'_a[g^a]\}=-\int_\Sigma d^3xf^ag^bR^c{}_{dab}\underline{\mathscr{T}}^d{}_c, \tag{49d}$$

which, when specialized to an orthonormal spatial frame ($\gamma_{ab}=\delta_{ab}$), is equivalent to that in Refs. 8 and 9.

These strong results agree with Ref. 4 up to the overall sign which is due to the fact that we are considering a right (Poisson) action in this work, whereas in Ref. 4 we derived the left action.[7] [Due to an unfortunate typesetting error, the left hand sides of equations (28b-e) of Ref. 4 should read as $[\Delta_{ax},\Delta_y]$, $[\delta_{\mathfrak{n}x},\Delta_y]$, $[\delta_{\mathfrak{n}x},\Delta_{ay}]$, and $[\delta_{ax},\Delta_y]$, respectively. Also note the rather obvious typo in the last line of (10), which should read as $\tilde{\nabla}_b[k]^a_c-g^{ad}\tilde{\nabla}_d[k]_{bc}$.] Either of the algebras (44) or (49) is a local representation of the Lie algebra $L\underline{\mathrm{Diff}}_0\mathbf{M}$ (the connected component since the exponential map is not onto) of the spacetime diffeomorphism group $\underline{\mathrm{Diff}}\mathbf{M}$. Note that although they were derived from a $(3+1)$ action, that algebras are valid in any dimension.

The Hamiltonian H_{GR} generates the weak evolution equations,

$$\partial_t[\boldsymbol{\gamma}^{ab}]=\{\boldsymbol{\gamma}^{ab},H_{\mathrm{GR}}\}\approx\Delta_{\tilde{N}}[\boldsymbol{\gamma}]^{ab}+\mathscr{L}_{\vec{N}}[\boldsymbol{\gamma}]^{ab}-N\Delta_{\tilde{k}}[\boldsymbol{\gamma}]^{ab}, \tag{50a}$$

$$\partial_t[\underline{E}^i{}_a]=\{\underline{E}^i{}_a,H_{\mathrm{GR}}\}\approx\Delta_{\tilde{N}}[\underline{E}^i{}_a], \tag{50b}$$

$$\partial_t[\underline{\pi}_{ab}]=\{\underline{\pi}^{ab},H_{\mathrm{GR}}\}\approx\Delta_{\tilde{N}}[\underline{\pi}]_{ab}+E\mathscr{L}_{\vec{N}}[\pi]_{ab}-E(\boldsymbol{\nabla}_a\boldsymbol{\nabla}_b[N]+\gamma_{ab}\nabla^2[N])+N\underline{R}_{ab}-NE(2k_{ac}k^c_b+kk_{ab})+NE\,\gamma_{ab}k^c_dk^d_c, \tag{50c}$$

$$\partial_t[\mathbf{p}^a{}_i]=\{\mathbf{p}^a{}_i,H_{\mathrm{GR}}\}\approx\Delta_{\tilde{N}}[\mathbf{p}^a{}_i]-2E^b{}_i\mathscr{L}_{\vec{N}}[\mathbf{k}^a_b]-2E^b{}_i\boldsymbol{\gamma}^{ac}\boldsymbol{\nabla}_b\boldsymbol{\nabla}_c[N]+2NE^b{}_i\boldsymbol{\gamma}^{ac}R_{cb}. \tag{50d}$$

Using compatibility (50a) may be written as

$$\Delta_{\tilde{\omega}}[\boldsymbol{\gamma}]^{ab}, \quad \text{where} \quad \omega^a{}_b = N^a{}_b - \boldsymbol{\nabla}_b[N]^a - Nk^a_b, \tag{51}$$

which is consistent with the easily verified result (noting that $\mathscr{T}_{(ab)} \approx 0$ is equivalent to $k_{ab} \approx k'_{ab}$) that the weak evolution equations for the primed system with Hamiltonian written as $H'_{\mathrm{GR}} = \int_\Sigma d^3x (N' \mathscr{H}' + N'^a \mathscr{H}'_a + N'^a{}_b \mathscr{T}'^b{}_a)$ is equivalent to inserting

$$N = N', \quad N^a = N'^a, \quad N^a{}_b = N'^a{}_b + \boldsymbol{\nabla}_b[N]^a + Nk^a_b, \tag{52}$$

in (50). In either of these formulations, the system is parameterized by the 30 fields (31), with 13 primary, first-class constraints ($\mathscr{T}^a_b$ with either $\mathscr{H}$ and $\mathscr{H}_a$, or $\mathscr{H}'$ and $\mathscr{H}'_a$), and the 13 associated Lagrange multipliers (N, N^a and $N^a{}_b$), and we find two configuration space degrees of freedom per spacetime point as expected.[18]

Beginning from the weak evolution equations (50), choosing $N^a{}_b \approx 0$ results in a system in which the spatial vielbeins do not evolve, and solving the GL(3,$\mathbb{R}$) constraints by choosing $p^a{}_i \approx E^b{}_i (2\gamma^{ac}\pi_{bc} - \frac{1}{2}\delta^a_b \pi)$ we can consider the evolution of the $\{\boldsymbol{\gamma}^{ab}, \pi_{ab}\}$ sector exclusively. Instead choosing $N'^a{}_b = 0$, we find a system in which $\boldsymbol{\gamma}^{ab}$ does not evolve and one may play the opposite game, solving the GL(3,$\mathbb{R}$) constraints by $\pi_{ab} \approx 1/2 \gamma_{ac}(p^c{}_i E^i{}_b + p\,\delta^c_b)$ and consider the evolution of $\{\mathbf{p}^a{}_i, E^i{}_a\}$. Note that from (52) one need only require that

$$N^{(ab)} = \gamma^{c(a} \boldsymbol{\nabla}_c [N]^{b)} - N\left(\pi^{ab} - \tfrac{1}{4}\gamma^{ab}\pi\right) = \gamma^{c(a} \boldsymbol{\nabla}_c [N]^{b)} + Nk^{ab}, \tag{53}$$

in order to find a system in which the metric degrees of freedom do not evolve, allowing other gauge choices in this case.

One may treat any choice of initial data in either of these two ways. By transforming the initial data by $\Delta_{\tilde{\omega}}$ defined so that $\Delta_{\tilde{\omega}}[E^i{}_a] = \delta^i_a$ (which is uniquely determined from the inverse as $[\tilde{\omega}]^a{}_i = E^a{}_i$), we transform the initial data to a physically equivalent set for which the frame is holonomic. If instead we make a choice of $\tilde{\omega}$ such that $\Delta_{\tilde{\omega}}[\gamma]^{ab} = \delta^{ab}$ ($\tilde{\omega}$ is defined only up to arbitrary spatial rotations which are generated by $\mathscr{T}^{[ab]}$) we may diagonalize the spatial metric.

IV. CONCLUSIONS

We have shown that by treating the components of the metric and the frame on an equal footing we not only have a consistent variational principle, but the generalized setting encompasses both the coordinate and orthonormal frame approaches via a choice of gauge. From the Einstein-Hilbert action for general relativity we have derived a Hamiltonian in the (extended) standard form $H_{\mathrm{GR}} = \int_\Sigma dx (N \mathscr{H} + N_a \mathscr{H}_a + N^a{}_b \mathscr{T}^b{}_a)$, where $\mathscr{H}$ and $\mathscr{H}_a$ are the generators (of the connected component) of spacetime diffeomorphisms, and $\mathscr{T}^a_b$ are the generators of $\mathfrak{gl}(3,\mathbb{R})$ which generate infinitesimal changes of frame on the spatial hypersurface Σ. The resulting constraint algebra was computed and found to be in agreement with the algebra derived by purely geometric means in Ref. 4. This generalized setting allows a straightforward treatment of fermions in a canonical setting (work in progress), where the primed constraints and algebra naturally appear.

The geodesic equations are integrated for the Lewis metric and the effects of the different parameters appearing in the Weyl class on the motion of test particles are brought out. The appearance of a force parallel to the axial axis is without Newtonian analog and deserves particular attention. © *1998 American Institute of Physics.* [S0022-2488(98)02107-0]

I. INTRODUCTION

The Lewis metric[1] describes the vacuum space–time outside an axially symmetric unbounded, along the axial axis, source, endowed with angular momentum. Usually this metric is presented with four parameters[2] which may be real (Weyl class) or complex (Lewis class). In recent papers,[3–5] the physical and geometrical meanings of these parameters have been discussed for both classes. Thus for the Weyl class, it appears that one of the parameters is proportional to the energy per unit length (at least in the Newtonian limit), a second parameter is the arbitrary constant potential which is always present in the Newtonian solution, and the remaining two parameters are responsible for the nonstaticity of the metric, although they affect staticity in different ways.

It is the purpose of this work to delve more deeply into the physical meaning of the aforesaid parameters. Accordingly, we shall study the motion of test particles in the Lewis space–time.

The possible sources covering the axis of symmetry and matched to the Lewis metrics have been considered by various authors (see Refs. 3, 4), starting with the pioneering work of van Stockum.[6] Recently, the geodesic motion of test particles in van Stockum's source, representing a rigidly rotating dust cylinder with finite thickness, has been studied.[7] Remarkable results emerged from this work and in particular it was found that confinement occurs quite generally in the radial motion of the particles. It was pointed out that this confinement might provide a source for the extragalactic jet formation in active galaxies.[8] Hence it appears auspicious to study the geodesic motion in the exterior Lewis space–time.

As will be seen below, besides the usual dragging effect, to be expected whenever a rotating source is involved, another *mixed*, effect appears, which we call *topological frame dragging*, related simultaneously to the rotation of the source and to the topological defect associated with some metric parameters.

In the next section we shall present the Lewis metric; the geodesic equations are given in Sec. III; and the specific case of circular geodesics is considered in Sec. IV. The two next sections are devoted to the Weyl class. Two specific examples for circular geodesics are studied in Sec. V, exhibiting the difference in the role played by the two parameters responsible for the nonstaticity. Radial geodesics are considered for several different cases in Sec. VI. Furthermore, in this section, the geodesics along the axial axis show the appearance of a force parallel to the axis, without Newtonian analog. This force tends to damp the motion along the z axis, when the particle

[a)]On leave from Departamento de Física, Facultad de Ciencias, Universidad Central de Venezuela, Caracas, Venezuela and Centro de Astrofísica Teórica, Merida, Venezuela.

 © 1998 American Institute of Physics

approaches this axis, whereas this tendency reverses when the particle moves away from it. Finally, conclusions are presented in the last section.

II. LEWIS SPACE–TIME

The general line element for a cylindrically symmetric stationary space–time is given by

$$ds^2=-f\,dt^2+2k\,dt\,d\phi+e^{\mu}(dr^2+dz^2)+l\,d\phi^2, \tag{1}$$

where f, k, μ, and l are functions only of r, and the ranges of the coordinates t, z, and ϕ are

$$-\infty<t<\infty, \quad -\infty<z<\infty, \quad 0\leqslant\phi\leqslant 2\pi, \tag{2}$$

the hypersurfaces $\phi=0$ and $\phi=2\pi$ being identified. The coordinates are numbered

$$x^0=t, \quad x^1=r, \quad x^2=z, \quad x^3=\phi. \tag{3}$$

Einstein's field equations for vacuum are

$$R_{\mu\nu}=0, \tag{4}$$

and with metric (1) the nonidentically null components become in van Stockum's[6] notation,

$$2e^{\mu}DR_0^0=\left(\frac{lf'+kk'}{D}\right)', \tag{5}$$

$$2e^{\mu}DR_0^3=\left(\frac{fk'-kf'}{D}\right)', \tag{6}$$

$$2e^{\mu}DR_3^0=\left(\frac{kl'-lk'}{D}\right)', \tag{7}$$

$$2e^{\mu}DR_3^3=\left(\frac{fl'+kk'}{D}\right)', \tag{8}$$

$$2R_1^1=-\mu''+\mu'\,\frac{D'}{D}-2\,\frac{D''}{D}+\frac{k'^2+f'l'}{D^2}, \tag{9}$$

$$2R_{22}=-\mu''-\mu'\,\frac{D'}{D}, \tag{10}$$

where the primes stand for differentiation with respect to r and

$$D^2=k^2+fl. \tag{11}$$

Equations (5)–(8) are not all independent; any one of them can be expressed in terms of the remaining three. The general solution of (4) for (1) is the stationary Lewis metric[1] given in the notation of[2]

$$f=ar^{-n+1}-\frac{c^2}{n^2a}\,r^{n+1}, \tag{12}$$

$$k=-Af, \tag{13}$$

$$e^{\mu}=r^{(n^2-1)/2}, \tag{14}$$

$$l=\frac{r^2}{f}-A^2f, \tag{15}$$

with

$$A=\frac{cr^{n+1}}{naf}+b. \tag{16}$$

The constants n, a, b, and c can be either real or complex, and the corresponding solutions belong to the Weyl or Lewis classes. For the Lewis class these constants are given by

$$n=im, \tag{17}$$

$$a=\tfrac{1}{2}(a_1^2-b_1^2)+ia_1b_1, \tag{18}$$

$$b=\frac{a_1a_2+b_1b_2}{a_1^2+b_1^2}+\frac{i}{a_1^2+b_1^2}, \tag{19}$$

$$c=\tfrac{1}{2}m(a_1^2+b_1^2), \tag{20}$$

where m, a_1, b_1, a_2, and b_2 are real constants and satisfy

$$a_1b_2-a_2b_1=1. \tag{21}$$

Equations (17)–(21) reveal that if the values of the parameters n and a, or n and b are known, we can obtain the parameter c. However, knowing n and c, we cannot obtain a and b. The metric coefficients (12)–(15) with (17)–(20) become[1]

$$f=(a^2-b_1^2)r\ \cos(m\ \ln r)+2a_1b_1r\ \sin(m\ \ln r), \tag{22}$$

$$k=-(a_1a_2-b_1b_2)r\ \cos(m\ \ln r)-(a_1b_2+a_2b_1)r\ \sin(m\ \ln r), \tag{23}$$

$$e^{\mu}=r^{-(m^2+1)/2}, \tag{24}$$

$$l=-(a_2^2-b_2^2)r\ \cos(m\ \ln r)-2a_2b_2r\ \sin(m\ \ln r). \tag{25}$$

III. GEODESICS

The equations governing geodesics can be derived from the Lagrangian

$$2\mathscr{L}=g_{\mu\nu}\frac{dx^{\mu}}{d\lambda}\frac{dx^{\nu}}{d\lambda}, \tag{26}$$

where λ is an affine parameter along the geodesics. For timelike geodesics λ is the proper time. From the extremal problem emerges the Euler–Lagrange equations

$$\frac{d}{d\lambda}\left(\frac{\partial\mathscr{L}}{\partial\dot{x}^{\alpha}}\right)-\frac{\partial\mathscr{L}}{\partial x^{\alpha}}=0, \tag{27}$$

and from them follow the geodesics given by

$$\ddot{x}^{\alpha}+\Gamma^{\alpha}_{\beta\gamma}\dot{x}^{\beta}\dot{x}^{\gamma}=0, \tag{28}$$

where the overdot stands for differentiation with respect to λ. For space–time (1) the Lagrangian (26) is

$$2\mathscr{L}=-f\dot{t}^2+2k\dot{t}\dot{\phi}+e^{\mu}(\dot{r}^2+\dot{z}^2)+l\dot{\phi}^2, \tag{29}$$

and the geodesic equations (28) are

$$D\ddot{t}+\frac{lf'+kk'}{D}\,\dot{t}\dot{r}+\frac{kl'-lk'}{D}\,\dot{r}\dot{\phi}=0, \tag{30}$$

$$2\ddot{r}+e^{-\mu}(f'\dot{t}^2-2k'\dot{t}\dot{\phi}-l'\dot{\phi}^2)+\mu'(\dot{r}^2-\dot{z}^2)=0, \tag{31}$$

$$\ddot{z}+\mu'\dot{r}\dot{z}=0, \tag{32}$$

$$D\ddot{\phi}+\frac{fk'-kf'}{D}\,\dot{f}\dot{r}+\frac{fl'+kk'}{D}\,\dot{r}\dot{\phi}=0. \tag{33}$$

The corresponding canonical momenta to (29) are

$$p_t=-\frac{\partial\mathscr{L}}{\partial\dot{t}}=f\dot{t}-k\dot{\phi}, \tag{34}$$

$$p_r=\frac{\partial\mathscr{L}}{\partial\dot{r}}=e^{\mu}\dot{r}, \tag{35}$$

$$p_z=\frac{\partial\mathscr{L}}{\partial\dot{z}}=e^{\mu}\dot{z}, \tag{36}$$

$$p_\phi=\frac{\partial\mathscr{L}}{\partial\dot{\phi}}=k\dot{t}+l\dot{\phi}. \tag{37}$$

The integrals of motion follow from the Euler–Lagrange equations (27)

$$\frac{dp_t}{d\lambda}=\frac{\partial\mathscr{L}}{\partial t}=0, \tag{38}$$

$$\frac{dp_z}{d\lambda}=\frac{\partial\mathscr{L}}{\partial z}=0, \tag{39}$$

$$\frac{dp_\phi}{d\lambda}=\frac{\partial\mathscr{L}}{\partial\phi}=0, \tag{40}$$

and the conserved quantities are

$$p_t=E,\quad p_z=P,\quad p_\phi=L, \tag{41}$$

where the constants E, P, and L represent, respectively, the total energy of the test particle, its momentum along the z axis, and its angular momentum about the z axis. From (34), (36), (37), (41) we can have

$$\dot{t}=\frac{1}{D^2}\,(Lk+El), \tag{42}$$

$$\dot{z}=Pe^{-\mu}, \tag{43}$$

$$\dot{\phi}=\frac{1}{D^2}\,(Lf-Ek), \tag{44}$$

and instead of integrating (31) we can use the line element (1) to obtain

$$-\epsilon=-f\dot{t}^2+2k\dot{t}\dot{\phi}+e^{\mu}(\dot{r}^2+\dot{z}^2)+l\dot{\phi}^2, \tag{45}$$

where $\epsilon=0$, 1 or -1 if the geodesics are, respectively, null, timelike, or spacelike.

IV. CIRCULAR GEODESICS

Now we restrict ourselves to the study of circular geodesics assuming

$$\dot{r}=\dot{z}=0, \quad \ddot{t}=0, \quad \ddot{\phi}=0, \tag{46}$$

then (31) becomes

$$f'\dot{t}^2-2k'\dot{t}\dot{\phi}-l'\dot{\phi}^2=0. \tag{47}$$

The angular velocity of the test particle is given by

$$\omega=\frac{\dot{\phi}}{\dot{t}}, \tag{48}$$

which becomes, using (47),

$$\omega=\frac{1}{l'}\left[-k'\pm(k'^2+f'l')^{1/2}\right]. \tag{49}$$

For a stationary space–time the normal velocity W^μ of the particle defined as the change in the displacement normal to $\tau^\mu=(1,0,0,0)$ relative to its displacement parallel to τ^μ, where τ^μ is a timelike Killing vector, is[9]

$$W^\mu=\left[(-g_{00})^{1/2}\left(dx^0+\frac{g_{0a}}{g_{00}}\,dx^a\right)\right]^{-1}V^\mu, \tag{50}$$

where

$$V^\mu=\left(-\frac{g_{0a}}{g_{00}}\,dx^a,dx^1,dx^2,dx^3\right), \tag{51}$$

and Latin indexes range from 1 to 3. Considering the metric (1) and the expression for ω, (48), then (50) becomes

$$W^\mu=\frac{(k\omega,0,0,f\omega)}{f^{1/2}(f-k\omega)}. \tag{52}$$

The modulus of W^μ, defined by $W^2=W^\mu W_\mu$, and using (52) is

$$W=\frac{D\omega}{f-k\omega}. \tag{53}$$

We can write (45) by considering (48)

$$\frac{\epsilon}{\dot{t}^2}=f-2k\omega-l\omega^2. \tag{54}$$

Substituting (53) into (54) we obtain

$$\frac{\epsilon}{\dot{t}^2}=\frac{D^2f}{(D+kW)^2}\,(1-W^2), \tag{55}$$

which shows that circular geodesics are timelike, null, or spacelike for, respectively, $W<1$, $W=1$, or $W>1$.

V. CIRCULAR GEODESICS IN THE WEYL CLASS

In this section we study circular geodesics in the Lewis space–time for the Weyl class, which means that the parameters n, a, b and c appearing in (12)–(15) are real.

The parameter n is associated with the Newtonian mass per unit length σ,

$$\sigma=\tfrac{1}{4}(1-n), \tag{56}$$

of a uniform line mass in the low density regime. The parameter a is connected to the constant arbitrary potential that exists in the corresponding Newtonian solution. The static and locally flat limit produces angular deficit δ, given by

$$\delta=2\pi\left(1-\frac{1}{a^{1/2}}\right). \tag{57}$$

The parameter b is associated, in the locally flat limit, with the angular momentum of a spinning string. Finally, the parameter c is related to the vorticity of the source when it is represented by a stationary completely anisotropic fluid. This parameter, together with the parameter b, is responsible for the nonstaticity of the metric. All these interpretations are restricted to the Weyl class only. For further details see Ref. 3.

We shall now discuss the expression for the angular velocity (49) and the tangential velocity (53). In order to exhibit more clearly the role played by different parameters, we shall consider two different cases, when $b=0$, $c\neq 0$ and $b\neq$, $c=0$.

A. Case $b=0$, $c\neq 0$

For this case substituting metric (12)–(15) into (49) we obtain

$$\omega=\frac{c}{n}\pm\omega_0=\frac{c}{1-4\sigma}\pm\omega_0, \tag{58}$$

where ω_0 is the angular velocity when the space–time is static given by Levi-Civita's metric,

$$\omega_0^2=\frac{1-n}{1+n}\,a^2r^{-2n}=\frac{2\sigma}{1-2\sigma}\,a^2r^{2(4\sigma-1)}, \tag{59}$$

and (56) has been used.

From (59) we can see that when the topological defect a decreases the total angle around the z axis, being $a>1$, it increases the angular velocity. This situation reverses for $a<1$.

The term $c/(1-4\sigma)$ represents an inertial frame dragging correction to the static case, similar to the one appearing in the case of the Kerr metric[10] or in the field of a massive charged magnetic dipole.[11] The presence of c in that term, becomes intelligible when we recall that this parameter measures the vorticity of the source when described by a rigidly rotating anisotropic cylinder.[3] It increases or diminishes the modulus of ω if the vorticity is in the same or opposite direction, respectively, of the rotation of the test particle. Furthermore, the dragging term is increased by the Newtonian mass per unit length σ.

Calculating the tangential velocity of the particle (53) with (12)–(15) and (56) we obtain

$$W=\left(\frac{c}{n}\pm\omega_0\right)\frac{r^n}{a}\left(1\pm\omega_0\,\frac{cr^{2n}}{na^2}\right)^{-1} \tag{60}$$

$$=\left[\frac{cr^{1-4\sigma}}{a(1-4\sigma)}\pm W_0\right]\left[1\pm W_0\,\frac{cr^{1-4\sigma}}{a(1-4\sigma)}\right]^{-1}, \tag{61}$$

where W_0 is the velocity in the static Levi-Civita space–time

$$W_0^2=\frac{1-n}{1+n}=\frac{2\sigma}{1-2\sigma}, \tag{62}$$

which can also be rewritten with (59)

$$W_0=\frac{r^n}{\alpha}\,\omega_0, \tag{63}$$

showing clearly the Newtonian limit $W_0=r\omega_0$. We see that the dragging term $(cr^{1-4\sigma})/[a(1-4\sigma)]$ for low energy densities and $a=1$ is proportional to the vorticity times the radius. However, it is worth noticing that this latter term decreases with a, and furthermore since $W_0<1$, W also decreases with a. Thus we have a dragging effect corrected by a topological defect. In order to understand why W decreases with a, unlike the angular velocity ω, which grows with a, it should be observed that the arc length Λ along a circular path in this case with $n=1$ becomes $d\Lambda=(r/a^{1/2})d\phi$. Therefore, for a given $d\phi$, $d\Lambda$ decreases with a, explaining thereby the decreasing of W. On the other hand, for a given Λ, $d\phi$ increases with a, which explains why the angular velocity also grows with a. This argument is not without its problems. Indeed, if $c=0$ the space–time reduces to the static Levi-Civita space–time, but the tangential velocity W_0 is unaffected by a contrary to the argument above. The same is true for the next case below, with respect to b.

We notice here too, in this case, that c plays no role as a topological defect, i.e., it does not appear in the metric term l, hence it is restricted to its frame dragging effect.

Considering (54) and (12)–(15) we obtain,

$$\frac{\epsilon}{\dot{t}^2}=\frac{r^{n+1}}{a}\left[a^2r^{-2n}-\left(\omega-\frac{c}{n}\right)^2\right], \tag{64}$$

and using (56), (58), (59) it becomes

$$\frac{\epsilon}{\dot{t}^2}=\frac{r^{n+1}}{a}\,(a^2r^{-2n}-\omega_0^2)=\frac{1-4\sigma}{1-2\sigma}\,ar^{4\sigma}. \tag{65}$$

We see from (65) that for circular geodesics the conditions for timelike, null and spacelike orbits, correspondingly $0\leqslant\sigma<1/4$, $\sigma=1/4$ and $1/4<\sigma\leqslant 1/2$ are unaffected by the vorticity of the source c.

B. Case $b\neq 0$, $c=0$

For this case substituting the metric (12)–(15) into (49) we obtain

$$\omega=\frac{\omega_0(b\omega_0\pm 1)}{1-b^2\omega_0^2}. \tag{66}$$

Now we have two different kinds of terms appearing in (66). On one hand, we have the angular velocity corresponding to the Levi-Civita space–time corrected by the factor $1-b^2\omega_0^2$, and on the other, we have the topological frame dragging term associated with b. We call it topological frame dragging since b also produces a topological defect and to distinguish from the frame dragging engendered by c that does not produce a topological defect in the previous case. The increasing of ω with b may be interpreted as follows. In the $n=1$ case the line element (1) takes the form

$$ds^2=-dt^2-2ba^{1/2}\,dt\,d\phi+dr^2+dz^2+\left(\frac{r^2}{a}-b^2a\right)d\phi^2. \tag{67}$$

Therefore, from (67), the arc length Λ along the circular path is given by

$$d\Lambda=\left(\frac{r^2}{a}-b^2a\right)^{1/2}d\phi. \tag{68}$$

Thus, for a given $d\Lambda$, larger b's lead to larger $d\phi$'s and thereby to larger angular velocities.

Considering (54) and (12)–(15) we obtain

$$\frac{\epsilon}{\dot{t}^2}=ar^{-n+1}(1+b\omega)^2-\frac{r^2}{f}\,\omega^2, \tag{69}$$

and using (56), (59), (66) it becomes

$$\frac{\epsilon}{\dot{t}^2}=\frac{1}{(1\mp b\omega_0)^2}\,\frac{r^{n+1}}{a}\,(a^2r^{-2n}-\omega_0^2)=\frac{1}{(1\mp b\omega_0)^2}\,\frac{1-4\sigma}{1-2\sigma}\,ar^{4\sigma}. \tag{70}$$

We see from (70) that for circular geodesics the condition for timelike, null, and spacelike orbits are the same as in cases $b=0$ and $c\neq 0$.

Calculating the tangential velocity of the particle (53) with (12)–(15) we obtain

$$W=\frac{r^n}{a}\,\omega_0=W_0. \tag{71}$$

From (71) we have that the particle velocity is not affected by b, in fact, its velocity is the same as the one in the static Levi-Civita space–time. We emphasize that b does not produce frame dragging upon W but topological frame dragging upon ω. While, in the previous case, we saw that c produces frame dragging upon W without producing topological defect.

In the general case, $b\neq 0$ and $c\neq 0$, both parameters contribute in a cumbersome way to frame dragging and topological effects.

VI. GEODESICS IN THE WEYL CLASS

Substituting (42)–(44) into (45) we have an expression for the radial speed $\dot{r}^2$ of the test particle,

$$\dot{r}^2=e^{-\mu}\left(E^2\,\frac{l}{D^2}+2EL\,\frac{k}{D^2}-\epsilon-L^2\,\frac{f}{D^2}-P^2e^{-\mu}\right). \tag{72}$$

We restrict the study of geodesics to $0<n<1$, which is the condition for circular timelike geodesics as expected in the Newtonian analog.[3]

From (14) and (43) we obtain

$$\dot{z}=Pr^{(1-n^2)/2}, \tag{73}$$

which means that if $P\neq 0$, particles increase their speed along z when distancing radially from the axis, while diminishing their axial speed when moving radially towards the axis. This result indicates that a force parallel to the z axis appears. In the flat case $n=1$ such an effect vanishes, bringing out its non-Newtonian nature.

From (14) and (32) it follows that

$$\ddot{z}=\frac{1-n^2}{2}\,\frac{\dot{r}\dot{z}}{r}, \tag{74}$$

therefore, this force tends to damp any motion along the z axis whenever the particle approaches that axis, and reverses this tendency in the opposite case. A similar result is obtained for the van Stockum space–time,[7] although in that case the effect is related to the vorticity of the source, whereas in our case, neither b nor c appear involved in (73). It is also worth noticing that non-Newtonian forces, parallel to the z axis, also appear in the field of axially symmetric rotating bodies.[12] However, as in the example of Ref. 7, the force parallel to z, in Ref. 12, unlike our case, is directly related to the spin of the source. In a stationary rotating universe a repulsive potential along the axis of rotation has also been observed.[13]

Now we study (72) for the two separate cases considered for circular geodesics and concentrate for null and timelike particles, i.e., $\epsilon=0$ and 1.

A. Case $b=0$, $c\neq 0$

For this case substituting (12)–(15) into (72) we obtain

$$\dot{r}^2 = r^{-(1-n)^2/2}[V_0 - V(r)], \tag{75}$$

where

$$V_0 = \frac{1}{a}\left(E - L\,\frac{c}{n}\right)^2 > 0, \tag{76}$$

$$V(r) = \epsilon r^{1-n} + P^2 r^{(1-n)(3+n)/2} + aL^2 r^{-2n} > 0. \tag{77}$$

The radial acceleration of the particle is from (75)

$$\ddot{r} = \tfrac{1}{4} r^{-1-(1-n)^2/2}[-(1-n)^2 V_0 - (1-n)(1+n)\epsilon r^{1-n} + (1+n)^2 aL^2 r^{-2n} - (1-n)(1+n)P^2 r^{(1-n)(3+n)/2}]. \tag{78}$$

From (77) we find

$$V'(r) = (1-n)\epsilon r^{-n} - 2naL^2 r^{-1-2n} + \tfrac{1}{2}(1-n)(3+n)P^2 r^{-1+(1-n)(3+n)/2}. \tag{79}$$

The equation $V'(r)=0$ has a solution, say $r=r_c$, which satisfies

$$2naL^2 r_c^{-1-2n} = (1-n)\epsilon r_c^{-n} + \tfrac{1}{2}(1-n)(3+n)P^2 r_c^{-1+(1-n)(3+n)/2}. \tag{80}$$

Since

$$V''(r) = \frac{1}{r}\left\{-n(1-n)\epsilon r^{-n} + 2n(2n+1)aL^2 r^{-1-2n} + \frac{1}{2}(1-n)(3+n)\left[\frac{1}{2}(1-n)(3+n) - 1\right]P^2 r^{-1+(1-n)(3+n)/2}\right\}, \tag{81}$$

and with (80) we have

$$V''(r_c) = \frac{1}{r_c}\{(1-n)(1+n)\epsilon r_c^{-n} + \tfrac{1}{2}(1-n)(3+n) \times [2n + \tfrac{1}{2}(1-n)(3+n)]P^2 r_c^{-1+(1-n)(3+n)/2}\}. \tag{82}$$

On the other hand, from (77), if $\epsilon\neq 0$ and/or $P\neq 0$, we have when $r\to 0$ or ∞, $V(r)\to\infty$. Furthermore, from (82) we have $V''(r_c)>0$, hence the equation $V'(r)=0$ has only one solution $r=r_c$ and is a minimum.

We see that in this case the parameter c only affects V_0, (76), by modifying the energy of the test particle, and leaving otherwise the geodesics indistinguishable from the static Levi-Civita space–time.

1. Case $\epsilon=0$, $P=0$

From (77) and (78) we have

$$V(r) = aL^2 r^{-2n}, \tag{83}$$

$$\ddot{r} = \tfrac{1}{4} r^{-1-(1-n)^2/2}[-(1-n)^2 V_0 + (1+n)^2 aL^2 r^{-2n}]. \tag{84}$$

A null particle with large r approaches z with decreasing negative acceleration, $\ddot{r}<0$, and increasing speed $\dot{r}$. Its speed attains a maximum at $\ddot{r}=0$ and then diminishes since the acceleration

becomes positive, $\ddot{r}>0$. The null particle arrives at a minimum distance $r=r_{\min}$ when $\dot{r}=0$ and $V_0=V(r)$. At $r=r_{\min}$, the null particle is reflected to infinity, $r\to\infty$, where $\dot{r}\to 0$.

2. Case $\epsilon\neq 0$, $P=0$

From (77) and (78) we have

$$V(r)=\epsilon r^{1-n}+aL^2r^{-2n}, \tag{85}$$

$$\ddot{r}=\tfrac{1}{4}r^{-1-(1-n)^2/2}[-(1-n)^2V_0-(1-n)(1+n)\epsilon r^{1-n}+(1+n)^2aL^2r^{-2n}]. \tag{86}$$

For this case $V_0=V(r)$ has two real roots, say $r_{\min}$ and $r_{\max}$. The timelike particle approaching z is reflected at $r=r_{\min}$ and moves outwards until it attains $\dot{r}=0$ at $r=r_{\max}$ repeating endlessly this trajectory. This kind of confinement of the test particle has also been found in the van Stockum space–time.[7] In this case if the motion is circular, $\dot{r}=0$, there are stable orbits, since $V(r)$ has a minimum.

3. Case $P\neq 0$

For this case, while the particles move along the z axis as described by (73), there is a confinement similar to the previous case in the $z=$constant plane. The effect of P, if $\epsilon\neq 0$, is to diminish the $r_{\min}$ and $r_{\max}$ attained by the particle. It is interesting to observe that even if $\epsilon=0$ the null particle has a similar trajectory in the $z=$constant plane which is not allowed if $P=0$, as described previously.

B. Case $b\neq 0$, $c=0$

For this case substituting (12)–(15) into (72) we obtain

$$\dot{r}^2=r^{-(1-n)^2/2}[V_0-V(r)], \tag{87}$$

where

$$V_0=\frac{1}{a}E^2>0, \tag{88}$$

$$V(r)=\epsilon r^{1-n}+P^2r^{(1-n)(3+n)/2}+a(L+bE)^2r^{-2n}>0. \tag{89}$$

We see that contrary to c, b affects $V(r)$ and not V_0, by modifying the angular momentum of the test particle. From (89) we see that even if $L=0$ there is an angular momentum term acting on the particle. This difference between the parameters b and c is expected from our analysis for the circular geodesics. For $L\neq 0$ and 0 and $\epsilon=0$, $P=0$; $\epsilon\neq 0$, $P=0$; and $P\neq 0$ the behavior of the geodesics is qualitatively similar to the case $b=0$, $c\neq 0$ with $L\neq 0$.

VII. CONCLUSIONS

As is apparent from the study of circular geodesics, two different types of dragging effects are present in Lewis space–time of the Weyl class. On one hand, there is a *typical* dragging effect, as shown by Eq. (58), related to the parameter c (which in turn is related to the vorticity of the source). On the other hand, there are corrections to the expression of the angular velocity of the test particle [Eq. (66)], as compared to the Levi-Civita case, which are related to the parameter b. Since this last parameter produces a topological defect, we call this effect topological frame dragging. Both effects are in principle observables through the precession of a gyroscope carried along a circular geodesic in Lewis space–time. From the analysis of the geodesic motion along the z axis we have discovered [Eq. (74)] the presence of a force, parallel to this axis and of non-Newtonian nature (it vanishes when $n=1$). Unlike other reported examples of similar forces,[7,12,13] in this case, the force is not related to the spin of the source. Finally, the effect of parameters b and c on the radial motion of a test particle is exhibited in different subcases. The confinement of the particle, appearing in some of these subcases, is also found in the van Stockum space–time[6] and deserves particular attention.

A Poincaré–Birkhoff–Witt theorem for generalized Lie color algebras

César Bautista
Facultad de Ciencias de la Computación, Benemérita Universidad Autónoma de Puebla, Edif. 135, 14 sur y Av. San Claudio, Ciudad Universitaria, Puebla, Pue. C.P. 72570, México

(Received 13 August 1997; accepted for publication 18 February 1998)

A proof of the Poincaré–Birkhoff–Witt theorem is given for a class of generalized Lie algebras closely related to the Gurevich S-Lie algebras. As concrete examples, we construct the positive (negative) parts of the quantized universal enveloping algebras of type A_n and $M_{p,q,\epsilon}(n,\mathbb{K})$, which is a nonstandard quantum deformation of $GL(n)$. In particular, we get, for both algebras, a unified proof of the Poincaré–Birkhoff–Witt theorem, and we show that they are genuine universal enveloping algebras of certain generalized Lie algebras. © *1998 American Institute of Physics.* [S0022-2488(98)00406-X]

I. INTRODUCTION

Yamane[1] presented a proof of the Poincaré–Birkhoff–Witt (PBW) theorem for some class of quantum groups: Drinfeld–Jimbo quantum groups of type A_n. In his proof he did not use explicitly the Lie algebra theory concepts.

In this paper we show that Yamane used in an implicit manner some generalized Lie algebra. Such a generalized Lie algebra will be called *T-Lie algebra*.

The T-Lie algebras satisfy not only generalized antisymmetry and a Jacobi identity, but additional properties like multiplicativity (also generalized, in the same way as the Gurevich S-Lie algebras[2]). Such T-Lie algebras arise in a natural way embedded in the positive and negative parts of the Drinfeld–Jimbo quantum groups $U_q(sl_{n+1})$ of type A_n.

Our T-Lie algebras share some properties with the S-Lie algebras. But they are not equivalent, for example, T-Lie algebras satisfy a weaker multiplicativity condition. In particular, there are some T-Lie algebras that are not S-Lie algebras. However, classical Lie algebras,[3] Lie superalgebras,[4] and Scheunert generalized Lie algebras (Lie color algebras)[5] are all T-Lie algebras.

These T-Lie algebras are related to the problem of finding the appropriate definition of *a quantum Lie algebra*. There are already some generalized Lie algebras proposed to solve this problem: Majid braided Lie algebras,[6] Delius–Gould quantum Lie algebras,[7] new generalized Lie algebras of Gurevich–Rubstov,[8] generalized Lie algebras due to Lyubashenko–Sudbery,[9] among others. But the Delius–Gould definition as well as the Gurevich–Rubstov, depend on the associated universal enveloping algebra. This is not the case for the T-Lie algebras. Our axioms imply the properties of the universal enveloping algebra. In particular, we shall prove the PBW theorem.

The generalized Lie algebras axioms of Lyubashenko–Sudbery are not enough to obtain a PBW theorem (see Example IV.4). The main difference with the braided Lie algebras of Majid is that the symmetry of our T-Lie algebras is not a braid morphism. Only a part of such a symmetry is braided.

In particular, we get a T-Lie algebra $(sl^{\pm}_{n+1})_q$, which is a deformation of the Lie subalgebra of upper (lower) triangular matrices. Such a generalized Lie algebra meets almost all the requirements of a *quantum Lie algebra*, in the sense of Lyubashenko–Sudbery[9] [only it fails point seven; actually the universal enveloping algebra of $(sl^{\pm}_{n+1})_q$ has no Hopf algebra structure, although it seems possible to define a *braided* Hopf algebra on it, but, we do not attempt it in this paper]. Moreover, the universal enveloping of $(sl^{\pm}_{n+1})_q$ coincides $U^{\pm}_q(sl_{n+1})$, which is the positive part of the Drinfeld–Jimbo quantum group of type A_n; therefore the diagram in Fig. 1 commutes. This means that, relative to $U^{\pm}_q(sl_{n+1})$, the T-Lie algebra $(sl^{\pm}_{n+1})_q$ satisfies, in some sense, the quantum Lie algebra condition of Delius.[10]

$$\begin{array}{ccc} sl_{n+1}^{\pm} & \longrightarrow & (sl_{n+1}^{\pm})_q \\ \downarrow & & \downarrow \\ U(sl_{n+1}^{\pm}) & \longrightarrow & U_q^{\pm}(sl_{n+1}) = U(sl_{n+1}^{\pm})_q \end{array}$$

FIG. 1. The classical $sl_{n+1}^{\pm}$ and the quantum $(sl_{n+1}^{\pm})_q$.

Some possible physical applications of the formalism of generalized Lie algebras are in the affine Toda theories,[11] quantum integrable systems,[11] and gauge theory.[9]

The paper is organized as follows. In Sec. II we shall define the T-Lie algebras. In Sec. III a list of classical and new Lie algebras is given. In Sec. IV we shall define the universal enveloping algebra of a T-Lie algebra, and we shall prove that expecting an analog at the PBW theorem for any such universal enveloping algebra constructed by means of commutators is too much, we have to restrict our generalized Lie algebras in an adequate way. However, in Sec. V we pursue the classical challenge: to prove the PBW theorem[3] by constructing a representation of the universal enveloping algebra on the symmetric algebra (with modifications inspired by Ref. 1). In Sec. VI the definition of a representation of T-Lie algebra is given. In Sec. VII we shall prove the PBW theorem for the universal enveloping of an adequate T-Lie algebra. Some remarks about braid morphisms are given in Sec. VIII. Section IX is devoted to explaining why we can apply the T-Lie algebra theory to a nonstandard quantum deformation algebra[12] of $GL(n)$. Similar explanations are given in Sec. X, but instead dealing with $U_q^{\pm}(sl_{n+1})$ the positive (negative) parts of the Drinfeld–Jimbo quantum groups of type A_n. In particular, in Sec. X we shall prove that $U_q^{\pm}(sl_{n+1})$ is a genuine universal enveloping algebra of a certain T-Lie algebra.

II. THE NOTION OF *T*-LIE ALGEBRA

Let k be a commutative unitary ring.

Definition II.1: A k-algebra A is strictly graded if there exist k submodules $(A_\eta)_{\eta\in\mathbb{N}}$ such that

$$A=\oplus_{\eta\in\mathbb{N}}A_\eta \quad and \quad A_{\eta_1}\cdot A_{\eta_2}\subseteq A_{\eta_1+\eta_2-1},$$

for all $\eta_1,\eta_2\in\mathbb{N}$. For $a\in A_\eta$, we shall put $\eta(a)=\eta$.

Remark II.1: For such graded algebras A we can induce a filtration of $A\otimes_k A$, given by

$$(A\otimes_k A)_\eta=\oplus_{\eta_1+\eta_2\leqslant\eta}A_{\eta_1}\otimes A_{\eta_2}.$$

Let L be a free k module with a given basis $\mathscr{B}$ totally ordered.

Definition II.2: Denote by L^n the k submodule of $L^{n\otimes}$ generated by

$$x_{i_1}\otimes\cdots\otimes x_{i_n},\quad x_{i_1}<\cdots<x_{i_n}\quad (x_{i_j}\in\mathscr{B}),$$

and by ${}^nL$ the k submodule generated by

$$x_{i_1}\otimes\cdots\otimes x_{i_n},\quad x_{i_1}>\cdots>x_{i_n}\quad (x_{i_j}\in\mathscr{B}).$$

Definition II.3: The module L with k morphisms,

$$S:L\otimes_k L\to L\otimes_k L\quad (presymmetry), \tag{1}$$

$$T:L\otimes_k L\to L\otimes_k L\quad (symmetry), \tag{2}$$

$$\langle,\rangle:L\otimes_k L\to L\otimes_k L\quad (pseudobracket), \tag{3}$$

$$[,]:L\otimes_k L\to L\quad (bracket), \tag{4}$$

$$\begin{array}{ccc} L_1 \otimes_k L_1 & \xrightarrow{\langle,\rangle_1} & L_1 \otimes_k L_1 \\ {\scriptstyle f\otimes f}\downarrow & & \downarrow{\scriptstyle f\otimes f} \\ L_2 \otimes_k L_2 & \xrightarrow{\langle,\rangle_2} & L_2 \otimes_k L_2 \end{array} \qquad \begin{array}{ccc} L_1 \otimes_k L_1 & \xrightarrow{S_1} & L_1 \otimes_k L_1 \\ {\scriptstyle f\otimes f}\downarrow & & \downarrow{\scriptstyle f\otimes f} \\ L_2 \otimes_k L_2 & \xrightarrow{S_2} & L_2 \otimes_k L_2 \end{array}$$

FIG. 2. A T-Lie algebra morphism.

is called T-Lie algebra with basis $\mathscr{B}$ *(or basic T-Lie algebra) if, for* $S_{12}=S\otimes_k Id_L$, $S_{23}=Id_L\otimes_k S$, *the following axioms are satisfied:*

(1) (a) $S^2=Id$.
  (b) $S(x\otimes y)=q_{x,y}y\otimes x$, *for certain* $q_{x,y}\in k$, $q_{x,x}=1$, $\forall x,y\in\mathscr{B}$.
  (c) *(Multiplicativity)*
    (i) $S(Id\otimes_k[,])|_{L^3}=([,]\otimes_k Id)S_{23}S_{12}|_{L^3}$.
    (ii) $S([,]\otimes_k Id)|_{L^3}=(Id\otimes_k[,])S_{12}S_{23}|_{L^3}$.
(2) *(Stability)*
  (a) *There exists a strict grading,*

$$L=\oplus_\eta L_\eta,$$

  of L relative to [,].
  (b)

$$\langle L_{\eta_1}\otimes L_{\eta_2}\rangle\subseteq(L\otimes_k L)_{\eta_1+\eta_2-1},$$

  for all L_{η_1}, L_{η_2}.
(3) $T=S+\langle,\rangle$.
(4) *(Antisymmetry)*
  (a) $[,]T=-[,]$.
  (b) $\langle,\rangle S=-\langle,\rangle$.
  (c) $[,]\langle,\rangle=0$.
(5) *(Jacobi identity)*

$$[,]((Id\otimes_k[,])S_{12}S_{23}-([,]\otimes_k Id)S_{23}S_{12}+(Id\otimes_k[,])S_{23}S_{12})|_{3_L}=0.$$

Multiplicativity conditions are used to control commutation relations in the universal enveloping algebra, whereas stability conditions are used to obtain a good gradation in the corresponding symmetric algebra.

Definition II.4: Let L_i *be a basic T-Lie algebra with bracket* $[,]_i$, *pseudobracket* $\langle,\rangle_i$ *and presymmetry* S_i, $i=1,2$. *A k morphism* $f:L_1\to L_2$ *is called a T-Lie morphism if f is a morphism of graded algebras relative to* $[,]_i$, $i=1,2$, *and the diagrams in Fig. 2 commute*.

III. EXAMPLES

In order to obtain a graduation in the stability conditions, it suffices to define a map $\eta:\mathscr{B}\to\mathbb{N}$ having properties [(2)(a)] and [(2)(b)] in the stability axiom. This remark will be used in the following examples.

A. Some common Lie algebras

Example III.1: Classical Lie algebras over fields are basic T-Lie algebras:

$$[,]\ \text{classical bracket},\quad \langle,\rangle=0,\quad T=S\ \text{usual switch},\quad \eta=1.$$

Example III.2: Lie superalgebras over fields[4] are basic T-Lie algebras.

Let $L=L_0\oplus L_1$ be a Lie superalgebra with bracket $[,]$ over a field k. Let $\mathscr{B}_\alpha$ be a basis of L_α, $\alpha=0,1$. Define $S:L\otimes_k L\to L\otimes_k L$ on the basis $\mathscr{B}=\mathscr{B}_0\cup\mathscr{B}_1$, by $S(x\otimes y)=(-1)^{\alpha\beta}y\otimes x$ if $x\in L_\alpha$, $y\in L_\beta$. Besides,

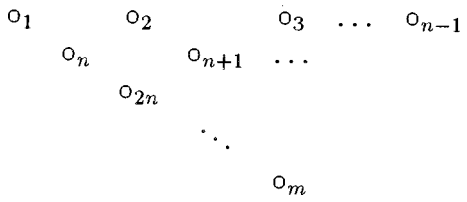

FIG. 3. The basic T-Lie algebra $(sl^+_{n+1})_q$.

$$\langle ,\rangle = 0, \quad T = S, \quad \eta = 1.$$

Example III.3 (Lie color algebras)*:* Let k be a field of characteristic zero. Let

$$L = \oplus_{\gamma\in\Gamma} L_\gamma$$

be a ϵ Lie algebra,[5] where Γ is an Abelian group and ϵ is a commutation factor on Γ. Let $[,]$ be a bracket of L. Put $\mathscr{B}_\gamma$ basis of L_γ for each $\gamma\in\Gamma$.

Define

$$S(x\otimes y) = \epsilon(\alpha,\beta) y\otimes x, \quad \text{if } x\in\mathscr{B}_\alpha, \quad y\in\mathscr{B}_\beta,$$

besides $\langle ,\rangle = 0$ and $\eta = 1$.

Multiplicativity conditions follow easily from the definition of the commutation factor. We conclude that every ϵ Lie algebra is a T-Lie algebra.

B. Linear *T*-Lie algebras

Example III.4: Let e_{ij}, $1\leqslant i, j\leqslant n$ be standard basis of gl_n matrices $n\times n$ over a field $\mathbb{K}$. Let $[,]$ be the usual bracket in gl_n, sl^+_n the Lie subalgebra of upper triangular matrices having trace zero. We put $x_i = e_{i,i+1}$, $i=1,\ldots,n-1$, $x_n=[x_1,x_2]$, $x_{n+1}=[x_2,x_3],\ldots,$ $x_{2n-3}=[x_{n-2},x_{n-1}]$, $x_{2n-2}=[x_1,x_{n+1}]\ldots,$ $x_{3n-6}=[x_{n-3},x_{2n-3}]$, $x_{3n-5}=[x_1,x_{2n-1}]$, $x_{3n-4}=[x_2,x_{2n}],\ldots,$ $x_m = [x_1,x_{m-1}]$, where $m=n(n-1)/2$, besides, we define $h_i=[x_i,x_i^t]$, $i=1,\ldots,m$ diagonal matrices in sl_n. Further, $q=\exp(t)\in\mathbb{K}[[t]]$, the formal series ring with indeterminate t and coefficients in $\mathbb{K}$, $k=\mathbb{K}[q,q^{-1}]$, $c_{i,j}\in\mathbb{Z}$, such that $[h_i,x_j]=c_{i,j}x_j$, $1\leqslant i, j\leqslant m$.

Let $(sl^+_n)_q$ be a free k module with basis $\mathscr{B}=\{x_i | 1\leqslant i\leqslant m\}$. We may define an order in $\mathscr{B}$ according to Fig. 3, from left to right and top to bottom. For example, $x_1<x_n<x_2<x_{2n}$. The first time that a diagram (Auslander–Reiten quiver of type A_{n-1}) of this type appears related to quantum groups, is in Ringel's work about the relationship between Poincaré–Birkhoff–Witt bases, quantum groups, and Hall algebras.[13]

Define

$$[x,y]_q = [x,y], \quad \text{if } x<y\in\mathscr{B},$$

$$\langle e_{ij},e_{uv}\rangle = \begin{cases} (q-q^{-1})e_{iv}\otimes e_{uj}, & \text{if } i<u<j, \quad u<j<v, \\ (q^{-1}-q)e_{uj}\otimes e_{iv}, & \text{if } u<i<v, \quad i<v<j, \\ 0, \text{ otherwise,} \end{cases}$$

$$S(x_i\otimes x_j) = q^{c_{i,j}} x_j\otimes x_i, \quad \text{if } x_i<x_j,$$

$$T = S + \langle ,\rangle.$$

Finally, we define η in such way that every basic element in Fig. 3 is in correspondence with a number belonging to Fig. 4; this yields, $\eta(e_{ij}) = i(j-i)$, $\forall i,j$.

The multiplicativity condition follows from the properties

$$x_i<x_j<x_l \Rightarrow \begin{cases} [x_i,x_j]<x_l, & \text{if } [x_i,x_j]\neq 0, \\ x_i<[x_j,x_l], & \text{if } [x_j,x_l]\neq 0, \end{cases}$$

$$\begin{array}{ccccccc} 1 & & 2 & & 3 & \ldots & n \\ & 2 & & 4 & & \ldots & 2(n-1) \\ & & 3 & & 6 & \ldots & 3(n-2) \\ & & & \ddots & & & \\ & & & & n & & \end{array}$$

FIG. 4. The graduation of $(sl^{+}_{n+1})_q$.

and

$$[h_i,[x_j,x_l]]=(c_{i,j}+c_{i,l})[x_j,x_l].$$

In the cases $n=2,3,4,5$, the Jacobi identity for $[,]_q$ can be verified by straightforward calculations. We get that $(sl^{+}_{n})_q$ with bracket $[,]_q$ is a basic T-Lie algebra, $n=2,3,4,5$.

Similarly, we can define $(sl^{-}_{n})_q$.

Remark III.1: We get

$$(sl^{\pm}_{n})_q|_{t=0}=sl^{\pm}_{n},$$

so in the cases $n=2,3,4,5$, $(sl^{\pm}_{n})_q$ is a deformation of $sl^{\pm}_{n}$ in the category of T-Lie algebras. Later, in Sec. X, such a property will be generalized for every n.

Example III.5: Starting from $(sl^{+}_{4})_q$ we are going to build a new basic T-Lie algebra, denoted $(\widetilde{sl^{+}_{4}})_q$. Its structure is

$$\widetilde{[,]}_q=[,]_q, \quad \widetilde{\langle,\rangle}=0, \quad \tilde{S}=S, \quad \widetilde{T}=S, \quad \tilde{\eta}=\eta.$$

Example III.6 [nonstandard quantum deformations[12] of $GL(n)$]*:* Let p,q be units in a commutative unitary ring k with $pq\neq 1$ and choose $n(n-1)/2$ discrete parameters ϵ_{ij}, $\epsilon_{ij}=\pm 1$, $1\leqslant i<j\leqslant n$, $\epsilon_{ii}=1$, $\epsilon_{ji}=\epsilon_{ij}$.

The k module $L_{p,q,\epsilon}(n,k)$ is then defined to be the free k module with basis

$$\mathscr{B}=\{Z^{j}_{i}|1\leqslant i,j\leqslant n\}.$$

We ordered $\mathscr{B}$ by putting $Z^{j}_{i}>Z^{v}_{u}$ if either $i>u$, or $i=u$ and $j>v$. Define η by $\eta(Z^{i}_{j})=j3^{i-1}$. Besides, we put $[,]=0$, and if $Z^{l}_{i}>Z^{v}_{u}$,

$$\langle Z^{l}_{i},Z^{v}_{u}\rangle=\begin{cases}\epsilon_{vl}(p-q^{-1})Z^{v}_{i}\otimes Z^{l}_{u}, & \text{if } i>u \text{ and } l>v,\\ 0, \text{ otherwise.}\end{cases} \tag{5}$$

$$S(Z^{l}_{i}\otimes Z^{v}_{u})=\begin{cases}\epsilon_{vl}pZ^{v}_{u}\otimes Z^{l}_{i}, & \text{if } i=u,\ l>v\\ \epsilon_{ui}qZ^{v}_{u}\otimes Z^{l}_{i}, & \text{if } l=v,\quad i>u,\\ \epsilon_{iu}\epsilon_{vl}p^{-1}qZ^{v}_{u}\otimes Z^{l}_{i}, & \text{if } i>u,\quad v>l,\\ \epsilon_{vl}\epsilon_{ui}Z^{v}_{u}\otimes Z^{l}_{i}, & \text{if } i>u,\quad l>v.\end{cases}$$

To prove that $L_{p,q,\epsilon}(n,k)$ is a basic T-Lie algebra, since (3.5) it suffices to check the stability condition [(2)(b)] for $Z^{l}_{i}>Z^{v}_{u}$, such that $i>u$ and $l>v$:

$$(i-u)3^{l-1}>(i-u)3^{v-1};$$

then

$$i3^{l-1}+u3^{v-1}>i3^{v-1}+u3^{l-1},$$

but this equation has a left side $\eta(Z^{l}_{i})+\eta(Z^{v}_{u})$, whereas the right side is $\eta(Z^{v}_{i})+\eta(Z^{l}_{u})$. This proves stability conditions.

IV. UNIVERSAL ENVELOPING ALGEBRAS

A. Construction of $U(L)$

Definition IV.1: Let L be a T-Lie algebra with basis $\mathscr{B}$, and $\otimes_k L$ the k-tensor algebra of the module L. The universal enveloping algebra $U(L)$ is the quotient

$$U(L)=\otimes_k L/J,$$

where J is the two-sided ideal generated by

$$x\otimes y-T(x\otimes y)-[x,y], \quad x,y\in\mathscr{B}.$$

Because of the stability axiom [(2)(b)], the algebra $U(L)$ have a similar structure to a *quadratic algebra with an ordering algorithm.*[14]

B. Examples

Example IV.2:

$$U(L_{p,q,\epsilon}(n,k))=M_{p,q,\epsilon}(n,k)$$

is a nonstandard quantum deformation[12] of $GL(n)$.

Example IV.3:

$$U(sl^{\pm}_{n+1})_q=U^{\pm}_q(sl_{n+1}),$$

the positive (negative) part of the Drinfeld–Jimbo quantum group of type A_n, $n=3,4$.

Example IV.4: In $U(\widetilde{sl^{+}_4})_q$, the equation $x_2x_6=0$ holds. Then $U(\widetilde{sl^{+}_4})_q$ is an enveloping algebra where the PBW theorem does not hold. So, if we want a good enveloping algebra, we have to add conditions to the T-Lie algebras.

Besides, if $\beta,\widetilde{S}$ denotes the bracket and the symmetry of $(\widetilde{sl^{+}_4})_q$, respectively, and the characteristic of the field $\mathbb{K}$ is zero, then for $\gamma=Id-\widetilde{S}$, where Id is the identity morphism on $(\widetilde{sl^{+}_4})^{2\otimes}_q$, the condition $\gamma(t)=0$ implies $\beta(t)=0$. Moreover, if $\mathscr{B}$ is the canonical basis of $(\widetilde{sl^{+}_4})_q$, and x,y,z are arbitrary elements in $\mathscr{B}$, straightforward calculations (using MATHEMATICA[15]) gives

$$\beta(\beta(x,y),z)=\beta(x,\beta(y,z))-q_{x,y}\beta(y,\beta(x,z))$$

$$\beta(z,\beta(x,y))=\beta(\beta(z,x),y)-q_{x,y}\beta(\beta(x,y),x)$$

where $\widetilde{S}(x\otimes y)=q_{x,y}y\otimes x$. This means that $(\widetilde{sl^{+}_4})_q$ has a structure of *balanced generalized Lie algebra*[9] and its universal enveloping algebra as such a generalized Lie algebra is the same as the T-Lie algebra. Therefore, the generalized Lie algebra axioms of Lyubashenko–Sudbery are not enough in order to obtain a PBW theorem.

Example IV.5: Let L be a basic T-Lie algebra. We are going to define a new T-Lie algebra L^0: $L^0=L$ in its structure of the k module, $[,]^0=0$, $\langle,\rangle^0=0$, $\eta^0=\eta$, $S^0=S$, and define

$$\mathscr{S}(L)=U(L^0);$$

$\mathscr{S}(L)$ is a free k module with a basis of the monomials formed by finite nondecreasing elements of $\mathscr{B}$. Such an object $\mathscr{S}(L)$ will be called the *q-symmetric algebra of L*.

V. THE RELATIONSHIP BETWEEN UNIVERSAL ENVELOPING ALGEBRAS AND SYMMETRIC ALGEBRAS

Let L be a T-Lie algebra with basis $\mathscr{B}$, $x_\lambda\in\mathscr{B}$, $\Sigma=(x_{\lambda_1},\ldots,x_{\lambda_u})$ finite nondecreasing sequence of elements of $\mathscr{B}$. We write $z_\lambda=x_\lambda\in\mathscr{S}(L)$, $z_\Sigma=z_{\lambda_1}\cdots z_{\lambda_u}\in\mathscr{S}(L)$, $z_\varnothing=1\in\mathscr{S}(L)$, $\eta(\lambda)=\eta(x_\lambda)$, $\eta(\Sigma)=\eta(z_\Sigma)=\eta(x_{\lambda_1})+\cdots+\eta(x_{\lambda_n})$. Besides, we put $x_\lambda\leqslant\Sigma$ if $x_\lambda\leqslant x_{\lambda_1}$.

Lemma V.1 (A–B)*:* Let L be a T-Lie algebra with basis $\mathscr{B}$. $\mathscr{P}=\mathscr{S}(L)$ q-symmetric algebra, $\mathscr{P}_p$ the k submodule generated by z_Σ such that $\eta(\Sigma)\leqslant p$. There is a k morphism,

$$_\cdot_ : L\otimes_k \mathscr{P}\to\mathscr{P}, \tag{6}$$

satisfying
(A) $x_\lambda\cdot z_\Sigma = z_\lambda z_\Sigma$, for $x_\lambda\leqslant\Sigma$;
(B) $x_\lambda\cdot z_\Sigma - z_\lambda z_\Sigma\in\mathscr{P}_{\eta(\lambda)+\eta(\Sigma)-1}$,

Proof: By induction on $\eta(\lambda)+\eta(\Sigma)$. If $\eta(\lambda)+\eta(\Sigma)=1$ then $\eta(\lambda)=1$ and $\Sigma=\varnothing$, it follows that $z_\varnothing=1$. Then define

$$x_\lambda\cdot 1 = z_\lambda,$$

so (A) and (B) holds. Assume the existence of $x_{\lambda'}\cdot z_{\Sigma'}$ for $\eta(\lambda')+\eta(\Sigma')<\eta(\lambda)+\eta(\Sigma)$ satisfying (A) and (B). We have to define $x_\lambda\cdot z_\Sigma$.

There are two cases: $\lambda\leqslant\Sigma$ or $\lambda\not\leqslant\Sigma$.

Case $\lambda\leqslant\Sigma$: Because (A):

$$x_\lambda\cdot z_\Sigma = z_\lambda z_\Sigma.$$

Case $\lambda\not\leqslant\Sigma$: We may write $\Sigma=(x_\mu,N)$ with $x_\mu\leqslant N$ and $x_\lambda>x_\mu$. Since $\eta(N)<\eta(\Sigma)$ and because at the induction hypothesis $x_\lambda\cdot z_N$ is already defined, and

$$w = x_\lambda\cdot z_N - z_\lambda z_N\in\mathscr{P}_{\eta(\lambda)+\eta(N)-1}.$$

Moreover, from $\eta(\mu)+\eta(\lambda)+\eta(N)-1<\eta(\mu)+\eta(\lambda)+\eta(N)=\eta(\lambda)+\eta(\Sigma)$ it follows that $x_\mu\cdot w$ is already defined.

We have

$$T(x_\lambda\otimes x_\mu) = q_{\lambda\mu}x_\mu\otimes x_\lambda + \sum_i \xi_i x_{\mu_i}\otimes x_{\lambda_i}, \tag{7}$$

and because at (B) and the induction hypothesis $x_{\lambda_i}\cdot z_N\in\mathscr{P}_{\eta(\lambda_i)+\eta(N)}$. As a consequence, $x_{\mu_i}\cdot(x_{\lambda_i}\cdot z_N)$ is already defined, because $\eta(\mu_i)+\eta(\lambda_i)+\eta(N)<\eta(\lambda)+\eta(\mu)+\eta(N)$ according to the stability axiom.

We may define

$$x_\lambda\cdot z_\Sigma = q_{\lambda\mu}z_\mu z_\lambda z_N + q_{\lambda\mu}x_\mu\cdot w + \sum_i \xi_i x_{\mu_i}\cdot(x_{\lambda_i}\cdot z_N) + [x_\lambda,x_\mu]\cdot z_N, \tag{8}$$

where $w=x_\lambda\cdot z_N - z_\lambda z_N$; $[x_\lambda,x_\mu]\cdot z_N$ is already defined because $\eta([x_\lambda,x_\mu])+\eta(N)<\eta(\lambda)+\eta(\mu)+\eta(N)=\eta(\lambda)+\eta(\Sigma)$.

Now it only remains to prove (B). From $z_\lambda z_\Sigma = q_{\lambda\mu}z_\lambda z_N$, we obtain

$$x_\lambda\cdot z_\Sigma - z_\lambda z_\Sigma = q_{\lambda\mu}x_\mu\cdot w + \sum_i \xi_i x_{\mu_i}\cdot x_{\lambda_i}\cdot z_N + [x_\lambda,x_\mu]\cdot z_N.$$

Moreover,

$$x_\mu\cdot w\in\mathscr{P}_{\eta(\mu)+\eta(w)}=\mathscr{P}_{\eta(\mu)+\eta(\lambda)+\eta(N)-1}=\mathscr{P}_{\eta(\lambda)+\eta(\Sigma)-1},$$

$$x_{\mu_i}\cdot x_{\lambda_i}\cdot z_N\in\mathscr{P}_{\eta(\mu_i)+\eta(\lambda_i)+\eta(N)}\subseteq\mathscr{P}_{\eta(\mu)+\eta(\lambda)-1+\eta(N)}=\mathscr{P}_{\eta(\lambda)+\eta(\Sigma)-1},$$

$$[x_\lambda,x_\mu]\cdot z_N\in\mathscr{P}_{\eta(\lambda)+\eta(\mu)-1+\eta(N)}=\mathscr{P}_{\eta(\lambda)+\eta(\Sigma)-1},$$

imply

$$x_\lambda\cdot z_\Sigma - z_\lambda z_\Sigma\in\mathscr{P}_{\eta(\lambda)+\eta(\Sigma)-1}.$$

□

Definition V.1: Let L be a T-Lie algebra with basis $\mathscr{B}$. We call L adequate if the morphism from the lemma (A–B) is such that the condition

$$x_{\lambda'}\cdot x_{\mu'}\cdot z_M - T(x_{\lambda'}\otimes x_{\mu'})\cdot z_M = [x_{\lambda'},x_{\mu'}]\cdot z_M, \tag{9}$$

for all $\eta(x_{\lambda'})+\eta(x_{\mu'})+\eta(M)\leqslant r$ *implies*

$$\begin{aligned}
&\langle x_\lambda,x_\mu\rangle\cdot x_\gamma\cdot z_N - q_{\lambda\mu}[x_\mu,[x_\lambda,x_\gamma]]\cdot z_N\\
&\quad = q_{\mu\gamma}q_{\lambda\gamma}\langle x_\gamma[x_\lambda,x_\mu]\rangle\cdot z_N + q_{\mu\gamma}q_{\lambda\gamma}x_\gamma\cdot\langle x_\lambda,x_\mu\rangle\cdot z_N + q_{\mu\gamma}\langle x_\lambda,x_\gamma\rangle\cdot x_\mu\cdot z_N\\
&\quad - q_{\lambda\mu}x_\mu\cdot\langle x_\lambda,x_\gamma\rangle\cdot z_N + q_{\mu\gamma}[x_\lambda,x_\gamma]\cdot x_\mu\cdot z_N - q_{\lambda\mu}x_\mu\cdot[x_\lambda,x_\gamma]\cdot z_N + x_\lambda\cdot\langle x_\mu,x_\gamma\rangle\cdot z_N\\
&\quad - q_{\lambda\mu}q_{\lambda\gamma}\langle x_\mu,x_\gamma\rangle\cdot x_\lambda\cdot z_N - q_{\lambda\gamma}q_{\lambda\mu}\langle[x_\mu,x_\gamma],x_\lambda\rangle\cdot z_N,
\end{aligned} \tag{10}$$

for every $x_\lambda>x_\mu>x_\gamma\in\mathscr{B}$, $x_\gamma\leqslant z_N$, *such that* $\eta(x_\lambda)+\eta(x_\mu)+\eta(x_\gamma)+\eta(N)\leqslant r+1$.

Lemma V.2 (C)*:* Let L be an adequate T-Lie algebra with basis $\mathscr{B}$, and $\mathscr{P}$ the related q-symmetric algebra. Then there exists a k morphism $_\cdot_: L\otimes_k\mathscr{P}\to\mathscr{P}$, such that

$$\text{(C)}\quad x_\lambda\cdot x_\mu\cdot z_N = T(x_\lambda\otimes x_\mu)\cdot z_N + [x_\lambda,x_\mu]\cdot z_N,\quad \forall z_N\in\mathscr{P},\quad \forall x_\lambda,\quad x_\mu\in\mathscr{B}.$$

Proof: Let $_\cdot_$ be the morphism from lemma (A–B). There are two cases:

1. $\mu\leqslant N$ or $\lambda\leqslant N$;
2. $\mu\not\leqslant N$ and $\lambda\not\leqslant N$.

(1) Assume $\mu\leqslant N$ and $\mu<\lambda$. Let $M=(\mu,N)$; then, by definition,

$$\begin{aligned}
x_\lambda\cdot x_\mu\cdot z_N &= x_\lambda z_M,\quad \text{where } \lambda\not\leqslant M,\\
&= z_\lambda\cdot z_M + q_{\lambda\mu}x_\mu\cdot w + \langle x_\lambda,x_\mu\rangle\cdot z_N + [x_\lambda,x_\mu]\cdot z_N.
\end{aligned}$$

On the other hand,

$$\begin{aligned}
T(x_\lambda\otimes x_\mu)\cdot z_N + [x_\lambda,x_\mu]\cdot z_N &= q_{\lambda\mu}x_\mu\cdot x_\lambda\cdot z_N + \langle x_\lambda,x_\mu\rangle\cdot z_N + [x_\lambda,x_\mu]\cdot z_N\\
&= q_{\lambda\mu}x_\mu\cdot(z_\lambda z_N) + q_{\lambda\mu}x_\mu\cdot w + \langle x_\lambda,x_\mu\rangle\cdot z_N + [x_\lambda,x_\mu]\cdot z_N,
\end{aligned}$$

since $\mu<\lambda$ and $\mu\leqslant N$, it holds that $z_\lambda z_N = c z_{N'}$, where $\mu\leqslant N'$ and $c\in k$,

$$x_\mu\cdot(z_\lambda z_N) = c x_\mu\cdot z_{N'} = c z_\mu z_{N'} = z_\mu z_\lambda z_N,$$

so

$$q_{\lambda\mu}x_\mu\cdot(z_\lambda z_N) = q_{\lambda\mu}z_\mu z_\lambda z_N = z_\lambda z_\mu z_N = z_\lambda z_M;$$

therefore

$$T(x_\lambda\otimes x_\mu)\cdot z_N + [x_\lambda,x_\mu]\cdot z_N = z_\lambda z_M + q_{\lambda\mu}x_\mu\cdot w + \langle x_\lambda,x_\mu\rangle\cdot z_N + [x_\lambda,x_\mu]\cdot z_N = x_\lambda\cdot x_\mu\cdot z_N$$

[i.e., (C) holds for $\mu<\lambda$]. It follows, multiplying by $-q_{\mu\lambda}$:

$$-q_{\mu\lambda}x_\lambda\cdot x_\mu\cdot z_N = -x_\mu\otimes x_\lambda\cdot z_N - q_{\mu\lambda}\langle x_\lambda,x_\mu\rangle\cdot z_N - q_{\mu\lambda}[x_\lambda,x_\mu]\cdot z_N. \tag{11}$$

This implies, using antisymmetry,

$$x_\mu\cdot x_\lambda\cdot z_N - T(x_\mu\otimes x_\lambda)\cdot z_N = [x_\mu,x_\lambda]\cdot z_N, \tag{12}$$

and we conclude that (C) also holds for $\lambda<\mu$.

(2) Let $N=(\gamma,Q)$ where $\gamma\leqslant Q$, $\gamma<\lambda$, $\gamma<\mu$. We proceed by induction on $\eta(\lambda)+\eta(\mu)+\eta(N)$. Suppose that for each $\eta(\lambda')+\eta(\mu')+\eta(N')\leqslant r$, (C) holds. Then, for $\eta(\lambda)+\eta(\mu)+\eta(N)\leqslant r+1$, we have

$$x_\mu \cdot z_N = x_\mu \cdot (x_\gamma \cdot z_Q) = T(x_\mu \otimes x_\gamma) \cdot z_Q + [x_\mu, x_\gamma] \cdot z_Q, \tag{13}$$

because $\eta(\mu)+\eta(\gamma)+\eta(Q)=\eta(\mu)+\eta(N)\leqslant r$ and the induction hypothesis.

Now, $x_\mu \cdot z_Q = z_\mu z_Q + w$, where $w \in \mathscr{P}_{\eta(\mu)+\eta(Q)-1}$. We may apply (C) to $x_\lambda \cdot x_\gamma \cdot (z_\mu z_Q)$, since $z_\mu z_Q = c z_{Q'}$, where $c \in k$ and $\gamma \leqslant Q'$ because $\gamma \leqslant Q$, $\gamma < \mu$ and case (A).

Also, (C) applies to $x_\lambda \cdot x_\gamma \cdot w$ since

$$\eta(\lambda)+\eta(\gamma)+\eta(w) \leqslant \eta(\lambda)+\eta(\gamma)+\eta(\mu)+\eta(Q)-1 = \eta(\lambda)+\eta(\gamma)+\eta(N)-1 \leqslant r,$$

and the induction hypothesis.

The preceding remarks show that (C) applies to

$$x_\lambda \cdot x_\gamma \cdot x_\mu \cdot z_Q = x_\lambda \cdot x_\gamma \cdot (z_\mu z_Q) + x_\lambda \cdot x_\gamma \cdot w.$$

Using (13) and multiplying by x_λ,

$$\begin{aligned} x_\lambda \cdot x_\mu \cdot z_N &= x_\lambda \cdot T(x_\mu \otimes x_\gamma) \cdot z_Q + x_\lambda \cdot [x_\mu, x_\gamma] \cdot z_Q \\ &= q_{\mu\gamma} x_\lambda \cdot x_\gamma \cdot x_\mu \cdot z_Q + x_\lambda \cdot \langle x_\mu, x_\gamma \rangle \cdot z_Q + x_\lambda \cdot [x_\mu, x_\gamma] \cdot z_Q \\ &= q_{\mu\gamma} q_{\lambda\gamma} x_\gamma \cdot x_\lambda \cdot x_\mu \cdot z_Q + q_{\mu\gamma} \langle x_\lambda, x_\gamma \rangle \cdot x_\mu \cdot z_Q + q_{\mu\gamma} [x_\lambda, x_\gamma] \cdot x_\mu \cdot z_Q \\ &\quad + x_\lambda \cdot \langle x_\mu, x_\gamma \rangle \cdot z_Q + x_\lambda \cdot [x_\mu, x_\gamma] \cdot z_Q. \end{aligned}$$

Recall that λ, μ are interchangeable:

$$\begin{aligned} x_\mu \cdot x_\lambda \cdot z_N &= q_{\lambda\gamma} q_{\mu\gamma} x_\gamma \cdot x_\mu \cdot x_\lambda \cdot z_Q + q_{\lambda\gamma} \langle x_\mu, x_\gamma \rangle \cdot x_\lambda \cdot z_Q + q_{\lambda\gamma} [x_\mu, x_\gamma] \cdot x_\lambda \cdot z_Q \\ &\quad + x_\mu \cdot \langle x_\lambda, x_\gamma \rangle \cdot z_Q + x_\mu \cdot [x_\lambda, x_\gamma] \cdot z_Q. \end{aligned}$$

Now use $\eta(\lambda)+\eta(\mu)+\eta(Q)=\eta(\lambda)+\eta(N)\leqslant r$ to obtain

$$\begin{aligned} x_\lambda \cdot x_\mu \cdot z_N - q_{\lambda\mu} x_\mu \cdot x_\lambda \cdot z_N &= q_{\mu\gamma} q_{\lambda\gamma} x_\gamma \cdot ([x_\lambda, x_\mu] + \langle x_\lambda, x_\mu \rangle) \cdot z_Q + q_{\mu\gamma} \langle x_\lambda, x_\gamma \rangle \cdot x_\mu \cdot z_Q - q_{\lambda\mu} x_\mu \\ &\quad \cdot \langle x_\lambda, x_\gamma \rangle \cdot z_Q + q_{\mu\gamma} [x_\lambda, x_\gamma] \cdot x_\mu \cdot z_Q - q_{\lambda\mu} x_\mu \cdot [x_\lambda, x_\gamma] \cdot z_Q + x_\lambda \\ &\quad \cdot \langle x_\mu, x_\gamma \rangle \cdot z_Q - q_{\lambda\mu} q_{\lambda\gamma} \langle x_\mu, x_\gamma \rangle \cdot x_\lambda \cdot z_Q + x_\lambda \cdot [x_\mu, x_\gamma] \cdot z_Q \\ &\quad - q_{\lambda\mu} q_{\lambda\gamma} [x_\mu, x_\gamma] \cdot x_\lambda \cdot z_Q. \end{aligned} \tag{14}$$

Furthermore,

$$\begin{aligned} &x_\lambda \cdot [x_\mu, x_\gamma] \cdot z_Q - q_{\lambda\mu} q_{\lambda\gamma} [x_\mu, x_\gamma] \cdot x_\lambda \cdot z_Q \\ &\quad = -q_{\mu\gamma} x_\lambda \cdot [x_\gamma, x_\mu] + q_{\lambda\mu} q_{\lambda\gamma} q_{\mu\gamma} [x_\gamma, x_\mu] \cdot x_\lambda \cdot z_Q \\ &\quad = q_{\mu\gamma} q_{\lambda\gamma} q_{\lambda\mu} ([x_\gamma, x_\mu] \cdot x_\lambda \cdot z_Q - q_{\gamma\lambda} q_{\mu\lambda} x_\lambda \cdot [x_\gamma, x_\mu] \cdot z_Q). \end{aligned} \tag{15}$$

If we suppose that $x_\mu < x_\lambda$, then we can make use of the multiplicativity condition, and since $\eta([x_\gamma, x_\mu])+\eta(\lambda)+\eta(Q) < \eta(\lambda)+\eta(\mu)+\eta(\gamma)+\eta(Q) = \eta(\lambda)+\eta(\mu)+\eta(N)$, we obtain that (15) is equal to

$$\begin{aligned} &= q_{\mu\gamma} q_{\lambda\gamma} q_{\lambda\mu} [[x_\gamma, x_\mu], x_\lambda] \cdot z_Q + q_{\mu\gamma} q_{\lambda\gamma} q_{\lambda\mu} \langle [x_\gamma, x_\mu], x_\lambda \rangle \cdot z_Q \\ &= -q_{\lambda\gamma} q_{\lambda\mu} [[x_\mu, x_\gamma], x_\lambda] \cdot z_Q - q_{\lambda\gamma} q_{\lambda\mu} \langle [x_\mu, x_\gamma], x_\lambda \rangle \cdot z_Q. \end{aligned} \tag{16}$$

Using multiplicativity again and since $\eta(x_\gamma)+\eta([x_\lambda, x_\mu])+\eta(Q) < \eta(x_\lambda)+\eta(\mu)+\eta(\gamma)+\eta(Q) = \eta(x_\lambda)+\eta(x_\mu)+\eta(N)$, we may write

$$x_\gamma \cdot [x_\lambda, x_\mu] \cdot z_Q = q_{\gamma\mu} q_{\gamma\lambda} [x_\lambda, x_\mu] \cdot x_\gamma \cdot z_Q + [x_\gamma, [x_\lambda, x_\mu]] \cdot z_Q + \langle x_\gamma, [x_\lambda, x_\mu] \rangle \cdot z_Q. \tag{17}$$

Substitute (16) and (17) in (14),

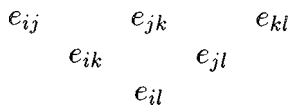

FIG. 5. A basic T-Lie algebra of type $(sl_4^+)_q$.

$$\begin{aligned} x_\lambda \cdot x_\mu \cdot z_N - q_{\mu\lambda} x_\mu \cdot x_\lambda \cdot z_N = {} & [x_\lambda, x_\mu] \cdot x_\gamma \cdot z_Q + q_{\mu\gamma} q_{\lambda\gamma} [x_\gamma, [x_\lambda, x_\mu]] \cdot z_Q + q_{\mu\gamma} q_{\lambda\gamma} \langle x_\gamma, [x_\lambda, x_\mu] \rangle \\ & \cdot z_Q + q_{\mu\gamma} q_{\lambda\gamma} x_\gamma \cdot \langle x_\lambda, x_\mu \rangle \cdot z_Q + q_{\mu\gamma} \langle x_\lambda, x_\gamma \rangle \cdot x_\mu \cdot z_Q - q_{\lambda\mu} x_\mu \langle x_\lambda, x_\gamma \rangle \\ & \cdot z_Q + q_{\mu\gamma} [x_\lambda, x_\gamma] \cdot x_\mu \cdot z_Q - q_{\lambda\mu} x_\mu [x_\lambda, x_\gamma] \cdot z_Q + x_\lambda \cdot \langle x_\mu, x_\gamma \rangle \cdot z_Q \\ & - q_{\lambda\mu} q_{\lambda\gamma} \langle x_\mu, x_\gamma \rangle \cdot x_\lambda \cdot z_Q - q_{\lambda\gamma} q_{\lambda\mu} [[x_\mu, x_\gamma], x_\lambda] \cdot z_Q \\ & - q_{\lambda\gamma} q_{\lambda\mu} \langle [x_\mu, x_\gamma], x_\lambda \rangle \cdot z_Q, \end{aligned}$$

since L is adequate,

$$\begin{aligned} = {} & [x_\lambda, x_\mu] \cdot x_\gamma \cdot z_Q + \langle x_\lambda, x_\mu \rangle \cdot x_\gamma \cdot z_Q + q_{\mu\gamma} q_{\lambda\gamma} [x_\gamma, [x_\lambda, x_\mu]] \cdot z_Q \\ & - q_{\lambda\gamma} q_{\lambda\mu} [[x_\mu, x_\gamma], x_\lambda] \cdot z_Q - q_{\lambda\mu} [x_\mu, [x_\lambda, x_\gamma]] \cdot z_Q. \end{aligned}$$

Thanks to the Jacobi identity and (A), we get

$$x_\lambda \cdot x_\mu \cdot z_N - q_{\lambda\mu} x_\mu \cdot x_\lambda \cdot z_N - \langle x_\lambda, x_\mu \rangle \cdot z_N = [x_\lambda, x_\mu] \cdot z_N, \tag{18}$$

if $x_\mu < x_\lambda$.

Multiplying both sides of (18) by $-q_{\lambda\mu}$ and using antisymmetry, we get

$$x_\mu \cdot x_\lambda \cdot z_N - q_{\lambda\mu} x_\lambda \cdot x_\mu \cdot z_N - \langle x_\mu, x_\lambda \rangle \cdot z_N = [x_\mu, x_\lambda] \cdot z_N,$$

so (18) also holds if $x_\lambda < x_\mu$. □

VI. REPRESENTATIONS

Definition VI.1: Let L be a basic T-Lie algebra and V a k module. A k morphism $_ \cdot _ : L \otimes_k V \to V$ is called a representation of L if it satisfies

$$x \cdot y \cdot v - T(x \otimes y) \cdot v = [x, y] \cdot v, \quad \forall x, y \in L, \quad \forall v \in V,$$

where $(a \otimes b) \cdot v$ means $a \cdot b \cdot v$.

Theorem VI.1: *If L is an adequate basic T-Lie algebra then L has a natural representation on its q-symmetric algebra $\mathcal{S}(L)$.*

Corollary VI.2: If L is an adequate basic T-Lie algebra, then its universal enveloping algebra $U(L)$ has a representation on the q-symmetric algebra $\mathcal{S}(L)$.

Inside $(sl_n^+)_q$, $n \geqslant 4$, the k submodules generated by the basic elements given in Fig. 5 have a structure of basic T-Lie algebra that looks like $(sl_4^+)_q$. But such an algebra has a graduation given by $\eta(e_{ab}) = a(b-a)$; this is not, in general, the graduation of $(sl_4^+)_q$. However, Fig. 5 is still a basic T-Lie algebra.

The basic T-Lie algebras given by Fig. 5 will be called *of type* $(sl_4^+)_q$. In a similar way we may define *basic T-Lie algebras of type* $(sl_n^\pm)_q$.

Example VI.3: Every basic T-Lie algebra of type $(sl_4^\pm)_q$ is adequate.

Proof: Suppose $x_\lambda > x_\mu > x_\gamma \in \mathcal{B}$, $x_\gamma \leqslant z_N$ such that $\eta(x_\lambda) + \eta(x_\mu) + \eta(x_\gamma) + \eta(N) \leqslant r + 1$. We have to prove that (10) holds.

Note that $\langle x_\lambda, x_\mu \rangle = 0$ for any x_λ, $x_\mu \in \mathcal{B}$, except e_{jk}, e_{il}, so each term in Eq. (10) vanishes or e_{jk}, e_{il} appears. This means that Eq. (10) holds trivially, except in the following cases:

$$e_{ij} < e_{jk} < e_{jl}, \quad e_{ij} < e_{ik} < e_{jl}, \quad e_{ik} < e_{jk} < e_{kl}, \quad e_{ik} < e_{jl} < e_{kl}.$$

Case: $e_{ij} < e_{jk} < e_{jl}$: The left side of (10) vanishes whereas the right side is

$$e_{jk}\cdot e_{il}\cdot z_N - q^2 e_{il}\cdot e_{jk}\cdot z_N + q\langle e_{ik},e_{jl}\rangle\cdot z_N = e_{jk}\cdot e_{il}\cdot z_N - q^2 e_{il}\cdot e_{jk}\cdot z_N + (q^2-1)e_{il}\cdot e_{jk}\cdot z_N = 0,$$

because $e_{il}\cdot e_{jk}\cdot z_N = e_{jk}\cdot e_{il}\cdot z_N$, since $\eta(e_{il})+\eta(e_{jk}) < \eta(e_{ij})+\eta(e_{jk})+\eta(e_{jl})$ and supposition (5.9).

Case: $e_{ij} < e_{ik} < e_{jl}$: Let be $d = \eta(e_{ij})+\eta(e_{ik})+\eta(e_{jl})$. The left side of (10) is

$$\begin{aligned}(q^{-1}-q)e_{il}\cdot e_{jk}\cdot e_{ij}\cdot z_N &= (q^{-1}-q)(qe_{il}\cdot e_{ij}\cdot e_{jk}\cdot z_N - qe_{il}\cdot e_{ik}\cdot z_N)\\ &= (q^{-1}-q)(e_{ij}\cdot e_{il}\cdot e_{jk}\cdot z_N) - (q^{-1}-q)qe_{il}\cdot e_{ik}\cdot z_N\end{aligned}$$

$[\eta(e_{il})+\eta(e_{ij})+\eta(e_{jk}) < d$ and (9)$]$

$$= (q^{-1}-q)(e_{ij}\cdot e_{il}\cdot e_{jk}\cdot z_N - e_{il}\cdot e_{ik}\cdot z_N + qe_{ik}\cdot e_{il}\cdot z_N)$$

$[\eta(e_{ik})+\eta(e_{il}) < d]$ and this is the right side of (10).

The remaining cases are similar. □

Example VI.4: Every basic T-Lie algebra of type $(sl_n^{\pm})_q$ is adequate, $n = 5,6$.

Proof: By similar calculations as in the previous example. □

Note that the symbol $\cdot z_N$ is redundant in calculations of Example VI.3. This remark leads to the following lemma.

Let $\otimes_k L$ be the tensorial k algebra and J_r the k submodule generated by

$$x_\alpha\otimes x_\beta\otimes x_\delta - T(x_\alpha\otimes x_\beta)\otimes x_\delta - [x_\alpha,x_\beta]\otimes x_\delta, \tag{19}$$

$$x_\alpha\otimes x_\beta\otimes x_\delta - x_\alpha\otimes T(x_\beta\otimes x_\delta) - x_\alpha\otimes[x_\beta,x_\delta], \tag{20}$$

for $\eta(\alpha)+\eta(\beta)+\eta(\delta)\leqslant r$, $\forall x_\alpha,x_\beta,x_\delta\in\mathscr{B}$.

Lemma VI.2: L is adequate if

$$\begin{aligned}\langle x_\lambda,x_\mu\rangle\otimes x_\gamma - q_{\lambda\mu}[x_\mu,[x_\lambda,x_\gamma]] \equiv{}& q_{\mu\gamma}q_{\lambda\gamma}\langle x_\gamma[x_\lambda,x_\mu]\rangle + q_{\mu\gamma}q_{\lambda\gamma}x_\gamma\otimes\langle x_\lambda,x_\mu\rangle + q_{\mu\gamma}\langle x_\lambda,x_\gamma\rangle\otimes x_\mu\\ &- q_{\lambda\mu}x_\mu\otimes\langle x_\lambda,x_\gamma\rangle + q_{\mu\gamma}[x_\lambda,x_\gamma]\otimes x_\mu - q_{\lambda\mu}x_\mu\otimes[x_\lambda,x_\gamma] + x_\lambda\\ &\otimes\langle x_\mu,x_\gamma\rangle - q_{\lambda\mu}q_{\lambda\gamma}\langle x_\mu,x_\gamma\rangle\otimes x_\lambda\\ &- q_{\lambda\gamma}q_{\lambda\mu}\langle[x_\mu,x_\gamma],x_\lambda\rangle \bmod J_r,\end{aligned} \tag{21}$$

for every $x_\lambda > x_\mu > x_\gamma\in\mathscr{B}$, such that $\eta(\lambda)+\eta(\mu)+\eta(\gamma)\leqslant r+1$.

VII. POINCARÉ–BIRKHOFF–WITT THEOREM

Let us define

$$\mathscr{T}^n = \underbrace{L\otimes_k\ldots\otimes_k L}_{n\text{-times}}.$$

For $u = x_{\lambda_1}\otimes\cdots\otimes x_{\lambda_n}\in\mathscr{T}^n$, define $\delta(u) = \eta(x_{\lambda_1})+\cdots+\eta(x_{\lambda_n})$, $D(u) = \#\{(x_{\lambda_i},x_{\lambda_j})\,|\,x_{\lambda_i} > x_{\lambda_j}$ and $i<j\}$. If $u\in\otimes_k L$ and $u = \Sigma_i\xi_i u_i$ with $u_i\in\mathscr{T}^i$, $\xi_i\in k$, $\forall i$; let us put

$$D(u) = \max\{D(u_i)\,|\,\xi_i\neq 0,i\}, \tag{22}$$

$$\delta(u) = \max\{\delta(u_i)\,|\,\xi_i\neq 0,i\}. \tag{23}$$

The number $D(u)$ is called *the disorder of* u.

Denote by $\mathscr{T}_p$ the k submodule generated by $u\in\otimes_k L$, such that $\delta(u)\leqslant p$.

Theorem VII.1 (Poincaré–Birkhoff–Witt)**:** *Let L be an adequate T-Lie algebra with a basis $\mathscr{B}$. The monomials formed by finite nondecreasing sequences of elements in $\mathscr{B}$ constitute a free k basis of the universal enveloping algebra $U(L)$.*

Proof: Let $P:\otimes_k L\to U(L)$ be the canonical k morphism, $\mathscr{M}$ the k submodule generated by the monomials described in the formulation of the theorem. We have to prove that $U(L)=\mathscr{M}$. Note that

$$U(L)=\sum_{p=1}^{\infty} P(\mathscr{T}_p).$$

If $p=1$, then $\mathscr{T}_p\subseteq L$; it follows that $P(\mathscr{T}_p)\subseteq\mathscr{M}$. Suppose that $P(\mathscr{T}_r)\subseteq\mathscr{M}$. It suffices to show that $P(\mathscr{T}_{r+1})\subseteq\mathscr{M}$.

Define $\mathscr{T}_r^u$ as the k submodule of $\mathscr{T}_r$ generated by elements with disorder $\leqslant u$, and proceed by a second induction on the disorder. We have $P(\mathscr{T}_{r+1}^0)\subset\mathscr{M}$. Suppose that $v=a\otimes x\otimes y\otimes b\in\mathscr{T}_{r+1}^u$, where $x>y\in\mathscr{B}$, and $a\in\mathscr{T}^n$, $b\in\mathscr{T}^m$ monomials formed by basic elements in $\mathscr{B}$. Then

$$P(v)=P(a\otimes q_{xy}y\otimes x\otimes b)+P(a\otimes\langle x,y\rangle\otimes b)+P(a\otimes[x,y]\otimes b)\equiv P(a\otimes q_{xy}y\otimes x\otimes b)\bmod\mathscr{T}_r,$$

but $P(a\otimes q_{xy}y\otimes x\otimes b)\in\mathscr{T}_{r+1}^{u-1}\subseteq\mathscr{M}$; hence $P(v)\in\mathscr{M}$. It follows that $P(\mathscr{T}_{r+1})\subseteq\mathscr{M}$.

It remains to prove linear independence. For a given sequence $\Sigma=(x_{\lambda_1},\ldots,x_{\lambda_n})$ of nondecreasing elements of $\mathscr{B}$; define $x_\Sigma=x_{\lambda_1}\cdots x_{\lambda_n}\in U(L)$. Suppose

$$\sum_i \xi_i x_{\Sigma_i}=0,$$

where each Σ_i is a sequence nondecreasing, and $\xi_i\in k$, $\forall i$. Using the representation of $U(L)$, we get from lemma (C),

$$0=\sum_i \xi_i x_{\Sigma_i}\cdot 1=\sum_i \xi_i z_{\Sigma_i},$$

and because the linear independence of the $z_{\Sigma_i}\in\mathscr{S}(L)$, it follows that $\xi_i=0$, $\forall i$. □

Corollary VII.1: $U(sl_n^{\pm})_q$ has a basis of the Poincaré–Birkhoff–Witt type, $n=2,3,4,5$.

VIII. BRAIDS

Proposition VIII.1: In $L=(sl_n^{\pm})_q$, $n=2,3,4$ the braid equation holds:

$$T_{12}T_{23}T_{12}|_{^3L}=T_{23}T_{12}T_{23}|_{^3L},$$

where $T_{12}=T\otimes_k Id_L$, $T_{23}=Id_L\otimes_k T$.

Proof: By straightforward calculations on the basic elements (using MATHEMATICA[15]). □

Proposition VIII.2: The presymmetry S of a T-Lie algebras holds for the braid equation,

$$S_{12}S_{23}S_{12}=S_{23}S_{12}S_{23}.$$

Proof: Let x,y,z be basic elements. Then

$$S_{12}S_{23}S_{12}(x\otimes y\otimes z)=q_{x,y}q_{x,z}q_{y,z}z\otimes y\otimes x=S_{23}S_{12}S_{23}(x\otimes y\otimes z).$$

□

Remark VIII.1: The symmetry of $\widetilde{(sl_4^+)_q}$ is a braid morphism, however, we have no PBW theorem for $U\widetilde{(sl_4^+)_q}$. As a consequence, the PBW theorem is independent from the braid equation.

IX. NONSTANDARD QUANTUM DEFORMATIONS OF $GL(n)$

Definition IX.1: Let p,q be units in a commutative unitary ring k with $pq\neq 1$ and choose $\alpha(\alpha-1)/2$ discrete parameters ϵ_{ij}, $\epsilon_{ij}=\pm 1$, $1\leqslant i<j\leqslant\alpha$, $\epsilon_{ii}=1$, $\epsilon_{ji}=\epsilon_{ij}$. Let m,n be positive integers such that $m,n\leqslant\alpha$.

The k module $L_{p,q,\epsilon}(n,m,k)$ is then defined to be the free k module with basis

$$\text{(a)}\quad \begin{matrix} Z_1^1 & Z_1^2 & \dots & Z_1^n \\ \vdots & \vdots & & \vdots \\ Z_m^1 & Z_m^2 & \dots & Z_m^n \end{matrix} \qquad \text{(b)}\quad \begin{matrix} \circ_i^j & \circ_i^{j+u} \\ \circ_{i+u}^j & \circ_{i+u}^{j+u} \end{matrix}$$

FIG. 6. (a) The basic T-Lie algebra $L_{p,q,\epsilon'}(\lambda,\mu,k)$. (b) Diagonal relationship.

$$\mathscr{B}=\{Z_i^j \mid 1\leqslant i\leqslant n, 1\leqslant j\leqslant m\}.$$

Now define an order on $\mathscr{B}$ and morphisms S,T, $\langle,\rangle$,[,], copying the structure of $L(n,k)$ in Example III.6.

Proposition IX.2: $L_{p,q,\epsilon}(n,m,k)$ has a structure of a basic T-Lie algebra.

In a similar way to the algebras of type $(sl_n^+)_q$ (see Sec. VI), we can define *algebras of type* $L_{p,q,\epsilon}(n,m,k)$.

Lemma IX.1: Every algebra of type $L_{p,q,\epsilon}(\lambda,\mu,k)$ is an adequate basic T-Lie algebra, where $\lambda,\mu\in\{2,3\}$.

Lemma IX.2: If $Z_u^v>Z_i^j>Z_a^b$, then there exists L being a T-Lie subalgebra of $L_{p,q,\epsilon}(n,m,k)$ and numbers $\lambda,\mu\in\{2,3\}$, such that L is of type $L_{p,q,\epsilon'}(\lambda,\mu,k)$ and $\{Z_u^v,Z_i^j,Z_a^b\}\subset L$.

Proof: Let us put the basic elements in a matrix array [Fig. 6(a)].

Note that for positive integers u,v the elements appearing in the pseudobracket definition are in a diagonal relationship [Fig. 6(b)], and they form a free basis of a T-Lie algebra of type $L_{p,q,\epsilon'}(2,2,k)$, where $\epsilon'=\{1,\epsilon_{i,i+u},\epsilon_{j,j+u}\}$.

For $Z_u^v>Z_i^j>Z_a^b$ there are several cases. The cases given by Figs. 7(a), 7(b), and 7(c), or they form a triangle that can be fitted, with vertices on the border, inside the rectangle of Fig. 7(d).

In the case given by Fig. 7(a) we may complete each triangle to a square and obtain $L_{p,q,\epsilon_0}(2,2,k)$. In the case given by Fig. 7(b), each triangle can be completed to a rectangle in the form of Fig. 7(e), and we get $L_{p,q,\epsilon_1}(3,2,k)$. Similarly, in the case given by Fig. 7(c), we get $L_{p,q,\epsilon_2}(2,3,k)$. Finally, in the case given by Fig. 7(d), we obtain $L_{p,q,\epsilon_3}(3,3,k)$. □

Theorem IX.3: *$L_{p,q,\epsilon}(n,m,k)$ is an adequate basic T-Lie algebra.*

Corollary IX.3: The monomials formed by nondecreasing finite sequences of elements in

$$\mathscr{B}=\{Z_i^j \mid 1\leqslant i\leqslant n, 1\leqslant j\leqslant m\}$$

constitute a free basis of the k module $M_{p,q,\epsilon}(n,m,k)=UL_{p,q,\epsilon}(n,m,k)$.

X. $U(sl_{n+1}^+)_q$. THE GENERAL CASE

Lemma X.1: Let e_{ab},e_{uv},e_{ij} be basic elements in $(sl_{n+1}^+)_q$ and [,] the usual bracket in sl_{n+1}.

(1) $e_{ab}<e_{uv}$ if and only if $a+b<i+j$ or $a+b=i+j$ and $b<j$.

(2) If $S(e_{ab}\otimes e_{uv})=q^{c_{ab,uv}}e_{uv}\otimes e_{ab}$ and $e_{ab}<e_{uv}$, then

$$c_{ab,uv}=-\delta_{v,a}+\delta_{v,b}+\delta_{u,a}-\delta_{u,b}.$$

(3) If $e_{ab}<e_{uv}<e_{ij}$, then

$$q^{c_{uv,ab}}[e_{uv},[e_{ab},e_{ij}]]=[e_{uv},[e_{ab},e_{ij}]]_q.$$

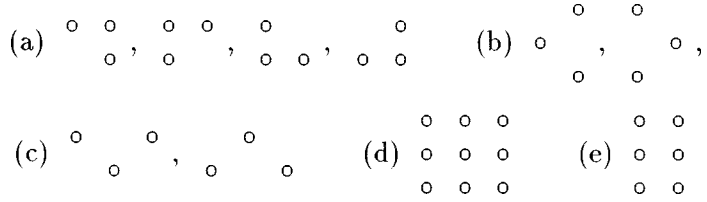

FIG. 7. Some cases in $L_{p,q,\epsilon}(n,m,k)$.

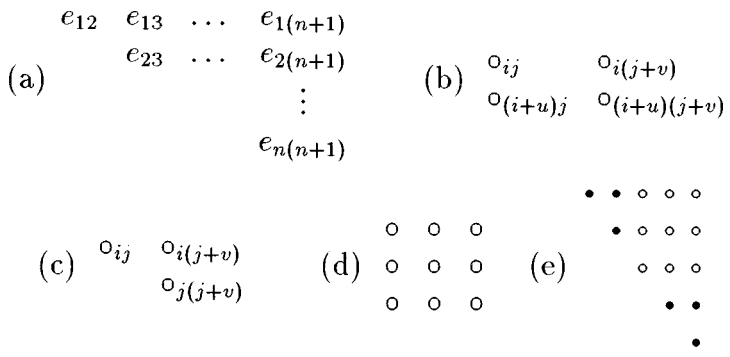

FIG. 8. Some cases in $(sl_{n+1}^{+})_q$.

Proof: (1) By the order definition.

(2) It follows from the formula $[e_{ij},e_{kl}]=\delta_{jk}e_{il}-\delta_{li}e_{kj}$ in the classical Lie algebra sl_n.

(3) Since $e_{ab}<e_{ij}$, we can suppose that $b=i$. We have to prove $q^{c_{uv,ab}}[e_{uv},e_{aj}]=[e_{uv},e_{aj}]_q$. There are two cases: (a) $e_{uv}<e_{aj}$; (b) $e_{uv}>e_{aj}$.

(3a) If $[e_{uv},e_{aj}]\neq 0$ then $v=a$ and $u<v=a<b$, it follows that $e_{uv}<e_{ab}$, since $u+v<a+b$ (a contradiction). Therefore $[e_{uv},e_{aj}]_q=[e_{uv},e_{aj}]=0$.

(3b) We have to prove

$$q_{uv,ab}[e_{aj},e_{uv}]=q_{uv,aj}[e_{aj},e_{uv}].$$

Both sides are zero, because if they are not, then $j=u$ and $i<j=u<v$; these imply $i+j<v+u$, and then $e_{ij}<e_{uv}$. Again, we have a contradiction. □

Theorem X.2: $(sl_{n+1}^{+})_q$ *is an adequate basic T-Lie algebra.*

Proof: Let $\mathscr{B}$ be the canonical basis of sl_{n+1}, and write the basic elements of $\mathscr{B}$ in the form e_{ij}. Now, we put this basic element in an upper triangular array [Fig. 8(a)]. Note that if $\langle e_{ij},e_{(i+u)(j+v)}\rangle\neq 0$, then the elements appearing in the pseudobracket definition are in a diagonal relationship [Fig. 8(b)], and if $[e_{ij},e_{(i+u)(j+v)}]_q\neq 0$ then $j=i+u$, and we get Fig. 8(c).

So, if we suppose that $e_{ij}>e_{uv}>e_{ab}$, then the elements appearing in the formulation of Lemma VI.2 (brackets and pseudobrackets) can be fitted inside a square of the form of Fig. 8(d), and such a square can be extended to an upper triangle [Fig. 8(e)], but this triangle gives a strictly graded algebra of type $(sl_6^{+})_q$. Since these algebras satisfy the condition of Lemma VI.2, in particular, the elements $e_{ij}>e_{uv}>e_{ab}$ satisfy this condition. Besides,

$$[,]_q((Id\otimes[,]_q)S_{12}S_{23}-([,]_q\otimes Id)S_{23}S_{12}+(Id\otimes[,]_q)S_{23}S_{12})(e_{ij}\otimes e_{uv}\otimes e_{ab})$$
$$=q^{c_{uv,ab}+c_{ij,ab}+c_{ij,uv}}([[e_{ab},e_{uv}],e_{ij}]-[e_{ab},[e_{uv},e_{ij}]]+[e_{uv},[e_{ab},e_{ij}]])=0,$$

since Lemma X.1 and the Jacobi identity in sl_n^{+}.

We conclude that $(sl_{n+1}^{+})_q$ is an adequate basic T-Lie algebra. □

Lemma X.3: Suppose that $e_{ij}<e_{ab}\in U_q^{+}(sl_{n+1})$. Then the following equations are satisfied in $U_q^{+}(sl_{n+1})$:

$$[e_{ij},e_{ab}]=\begin{cases} e_{ij}e_{ab}-qe_{ab}e_{ij}, & \text{if } i=a \quad \text{or} \quad j=b,\\ e_{ij}e_{ab}-e_{ab}e_{ij}-\langle e_{ij},e_{ab}\rangle, & \text{if } i\neq a, j\neq b, \quad \text{and} \quad j\neq a,\\ e_{ij}e_{ab}-q^{-1}e_{ab}e_{ij}, & \text{if } j=a. \end{cases} \tag{24}$$

Proof: By induction on n. For the cases $n=1,2,3,4,5$, the Eqs. (24) can be verified by straightforward calculations. So we may suppose $n>5$. Let us consider Fig. 8(a). Such a diagram can be thought of as formed by two overlapping triangles. The first one, a triangle T_1 with vertices $e_{12},e_{1n},e_{(n-1)n}$, and the second one, a triangle T_2 with vertices $e_{23},e_{2(n+1)},e_{n(n+1)}$.

The elements in T_i generate a k subalgebra isomorphic to $U_q^{+}(sl_n)$, $i=1,2$. Then, if e_{ij} and e_{ab} are both in T_1 or T_2, Eqs. (24) hold. As a consequence, we may suppose $i=1$ and $b=n+1$, and put $j\neq n+1$ and $a\neq 1$.

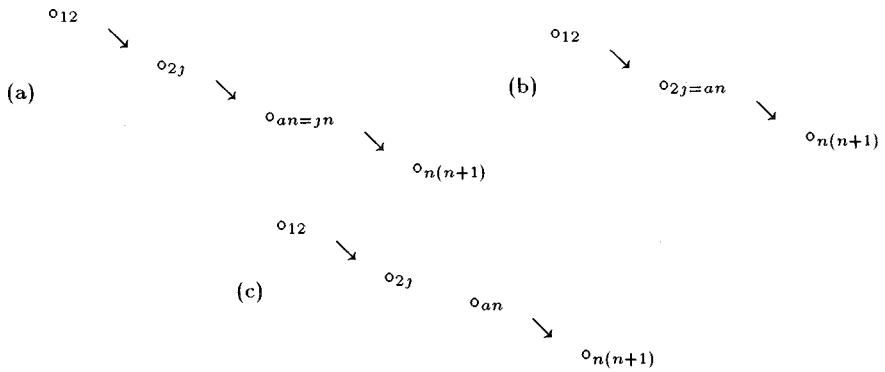

FIG. 9. (a) First case. (b) Second case. (c) Third case.

At Fig. 8(a), join the node rs with the node uv if $[e_{rs},e_{uv}]_q\neq 0$. We have several cases given by Fig. 9 [in the first and third cases, since e_{12},e_{2j},e_{jn} are in T_1 and the induction hypothesis, there is no arrow between 12 and an, whereas there is no arrow between $2j$ and $n(n+1)$ because $e_{2j},e_{an},e_{n(n+1)}$ are in T_2].

At the first case we get a graph of type A_4; then $e_{1j}=[e_{12},e_{2j}]_q$, $e_{a(n+1)}=[e_{an},e_{n(n+1)}]_q$ are in a subalgebra isomorphic to $U_q^+(sl_5)$; it follows that

$$[e_{1j},e_{j(n+1)}]_q=e_{1j}e_{j(n+1)}-q^{-1}e_{j(n+1)}e_{ij}.$$

In the second case we get a graph of type A_3; then $e_{1j}=[e_{12},e_{2n}]_q$, $e_{2(n+1)}=[e_{2n},e_{n(n+1)}]_q$ are in a subalgebra isomorphic to $U_q^+(sl_4)$, besides

$$[e_{1j},e_{a(n+1)}]_q=e_{1n}e_{2(n+1)}-e_{2(n+1)}e_{1n}-(q-q^{-1})e_{1(n+1)}e_{2n}.$$

In the third case we may insert the node ja in order to obtain

$$^\circ 12\longrightarrow{}^\circ 2j\longrightarrow{}^\circ ja\longrightarrow{}^\circ an\longrightarrow{}^\circ n(n+1);$$

this graph is of type A_5; then $e_{1j}=[e_{12},e_{2j}]_q$, $e_{a(n+1)}=[e_{an},e_{n(n+1)}]_q$ are in a subalgebra isomorphic to $U_q(sl_6^+)$ and

$$0=[e_{1j},e_{a(n+1)}]_q=e_{1j}e_{a(n+1)}-e_{a(n+1)}e_{1j}.$$

Now, only the cases $e_{1j}=e_{1(n+1)}$, $e_{a(n+1)}=e_{1(n+1)}$ remain. Suppose that $e_{1j}=e_{1(n+1)}$. Since $e_{12}e_{a(n+1)}=e_{a(n+1)}$, $e_{2(n+1)}e_{a(n+1)}=qe_{a(n+1)}e_{2(n+1)}$, and $e_{1(n+1)}=e_{12}e_{2(n+1)}-q^{-1}e_{2(n+1)}e_{12}$; it follows that

$$e_{1(n+1)}e_{a(n+1)}=qe_{a(n+1)}e_{1(n+1)}.$$

In a similar way, if $e_{a(n+1)}=e_{1(n+1)}$, we get

$$e_{1j}e_{a(n+1)}=qe_{a(n+1)}e_{1j}.$$

□

Theorem X.4: *There exists an isomorphism,*

$$U_q^+(sl_{n+1})\simeq U(sl_{n+1}^+)_q,$$

of k algebras.

Proof: Let us put $c_{ab,cd}=c_{uv}$, where $x_u=e_{ab}$, $x_v=e_{cd}$, and $x_u<x_v$, $1\leqslant a,b,c,d\leqslant n+1$. From

$$[e_{ij},e_{kl}]=\delta_{jk}e_{il}-\delta_{li}e_{kj},$$

it follows, if $e_{ab}<e_{cd}$,

$$c_{ab,cd}=\begin{cases}1, & \text{if } a=c \text{ or } b=d.\\ 0, & \text{if } a\neq c \text{ and } b\neq d\\ -1, & \text{if } b=a.\end{cases}$$

Now use Lemma X.3 in order to obtain the following equations in $U_q^+(sl_{n+1})$:

$$e_{ab}e_{cd}-q^{c_{ab,cd}}e_{cd}e_{ab}=[e_{ab},e_{cd}]_q+\langle e_{ab},e_{cd}\rangle,$$

for all $1\leqslant a,b,c,d\leqslant n+1$.

We conclude that $U_q^+(sl_{n+1})\simeq U(sl_{n+1}^+)_q$. □

Corollary X.1:

(1) *The monomials formed by nondecreasing finite sequences of elements in*

$$\mathscr{B}=\{e_{ij}|1\leqslant i\leqslant j\leqslant m\},$$

constitute a free basis of the k module $U_q^+(sl_{n+1})$, *where* $m=n(n+1)/2$.

(2) *We have*

$$(sl_{n+1}^+)_q|_{t=0}=sl_{n+1}^+,$$

and $(sl_{n+1}^+)_q$ *is a deformation of* sl_{n+1}^+ *in the category of T-Lie algebras.*

Principal vertex operator representations for toroidal Lie algebras

Yuly Billig[a)]
Department of Mathematics and Statistics, University of New Brunswick, Fredericton, New Brunswick E3B 5A3, Canada

(Received 30 June 1997; accepted for publication 30 March 1998)

We introduce the principal vertex operator representations for the toroidal Lie algebras generalizing the construction for the affine Kac–Moody algebras. We also represent the derivations of the toroidal algebras and introduce analogs of the Sugawara operators. © *1998 American Institute of Physics.* [S0022-2488(98)02407-4]

I. INTRODUCTION

Vertex operators discovered by physicists in string theory have turned out to be important objects in mathematics. One can use vertex operators to construct various realizations of the irreducible highest weight representations for affine Kac–Moody algebras. Two of these, the principal and homogeneous realizations, are of particular interest. The principal vertex operator construction for the affine algebra $A_1^{(1)}$ allows one to construct soliton solutions of the Korteweg–de Vries (KdV) hierarchy of partial differential equations. On the other hand, the homogeneous realization is linked to the fundamental nonlinear Schrödinger equation.[1]

Eswara Rao and Moody[2] studied the homogeneous vertex operator construction for toroidal Lie algebras. The present paper is devoted to the principal realization. Here we construct the principal vertex operator representation for the toroidal Lie algebra $\hat{\mathfrak{g}}$ which is a universal central extension of $\tilde{\mathfrak{g}}=\dot{\mathfrak{g}}\otimes\mathbb{C}[t_0^{\pm},\ldots,t_n^{\pm}]$, in which $\dot{\mathfrak{g}}$ is a simply laced simple finite-dimensional Lie algebra over $\mathbb{C}$. This generalizes the principal vertex operator realization of the basic representations of affine Lie algebras.[3,4]

We add the Lie algebra $\mathscr{D}$ of vector fields on a torus to the toroidal Lie algebra $\hat{\mathfrak{g}}$ to form a larger algebra $\mathfrak{g}$. This is necessary in order to have a sufficiently large principal Heisenberg subalgebra. To construct a representation of $\mathfrak{g}$ we consider the standard module F for the principal Heisenberg subalgebra and then extend the action to all of $\mathfrak{g}$ by means of the vertex operators. The module F is irreducible as a module over $\mathfrak{g}$, and it is reducible over $\hat{\mathfrak{g}}$. It will be interesting to see how this representation fits in the framework of the Verma modules over the toroidal Lie algebras.[5]

In a subsequent article[6] we construct an extension of the KdV hierarchy using the representations introduced in the present paper.

The vertex operator representations for the toroidal Lie algebras constructed here may also be useful for quantum field theories in space–time of more than two dimensions.[7,8]

This paper is organized as follows. In Sec. II we recall the construction of the toroidal Lie algebra and in Sec. III we sketch the principal vertex operator realization of the basic representations of affine Lie algebras. In Sec. IV we present the principal Heisenberg subalgebra of $\mathfrak{g}$ and define its standard module. We also introduce there vertex operators that will allow us to extend this representation to $\mathfrak{g}$. At the end of Sec. IV we state the main theorem of the paper. The proof of the main theorem occupies Sec. V. In Sec. VI we construct the analogs of the Sugawara operators.

II. DEFINITIONS AND NOTATIONS

Let $\dot{\mathfrak{g}}$ be a simple finite-dimensional complex Lie algebra of type A_ℓ, D_ℓ, or E_ℓ (i.e., simply laced). The Killing form $(\cdot|\cdot)$ is nondegenerate on the Cartan subalgebra $\dot{\mathfrak{h}}$ of $\dot{\mathfrak{g}}$ and induces the map $\nu:\dot{\mathfrak{h}}\to\dot{\mathfrak{h}}^*$. Let $\dot{\Delta}$ be the root system of $\dot{\mathfrak{g}}$. Since $\dot{\mathfrak{g}}$ is simply laced then $(\alpha|\alpha)=2$ for all nonzero roots $\alpha\in\dot{\Delta}$.

To construct a toroidal algebra let us consider a tensor product of $\dot{\mathfrak{g}}$ with the algebra of Laurent polynomials in $n+1$ variable:

$$\tilde{\mathfrak{g}}=\dot{\mathfrak{g}}\otimes\mathbb{C}[t_0^{\pm},t_1^{\pm},\ldots,t_n^{\pm}].$$

We define the toroidal Lie algebra corresponding to $\dot{\mathfrak{g}}$ as the universal central extension of $\tilde{\mathfrak{g}}$. The explicit construction of this extension[9,10] can be given as follows. Let $\dot{\mathscr{K}}$ be an $(n+1)$-dimensional space with the basis $\{K_0,K_1,\ldots,K_n\}$. Consider a derivation $d_p=t_p(d/dt_p)$ of the algebra $\mathbb{C}[t_0^{\pm},t_1^{\pm},\ldots,t_n^{\pm}]$ which can be naturally extended on the tensor product

$$\widetilde{\mathscr{K}}=\dot{\mathscr{K}}\otimes\mathbb{C}[t_0^{\pm},t_1^{\pm},\ldots,t_n^{\pm}],$$

The space of the universal central extension of $\tilde{\mathfrak{g}}$ is

$$\mathscr{K}=\widetilde{\mathscr{K}}/d\widetilde{\mathscr{K}},$$

where

$$d\widetilde{\mathscr{K}}=\left\{\sum_{p=0}^{n}K_p\otimes d_p(f)\,\middle|\,f\in\mathbb{C}[t_0^{\pm},t_1^{\pm},\ldots,t_n^{\pm}]\right\}\subset\widetilde{\mathscr{K}}.$$

We will denote the image of $K_p\otimes t_0^{r_0}\mathbf{t}^{\mathbf{r}}$ in $\mathscr{K}$ by $t_0^{r_0}\mathbf{t}^{\mathbf{r}}K_p$, where $\mathbf{r}=(r_1,\ldots,r_n)$ and $\mathbf{t}^{r}=t_1^{r_1}\ldots t_n^{r_n}$. Note that $\mathscr{K}$ has the defining relations

$$r_0t_0^{r_0}\mathbf{t}^{\mathbf{r}}K_0+r_1t_0^{r_0}\mathbf{t}^{\mathbf{r}}K_1+\cdots+r_nt_0^{r_0}\mathbf{t}^{\mathbf{r}}K_n=0.$$

The toroidal algebra is the Lie algebra

$$\hat{\mathfrak{g}}=\dot{\mathfrak{g}}\otimes\mathbb{C}[t_0^{\pm},t_1^{\pm},\ldots,t_n^{\pm}]\oplus\mathscr{K}$$

with the bracket

$$[g_1\otimes f_1(t_0\ldots t_n),g_2\otimes f_2(t_0\ldots t_n)]=[g_1,g_2]\otimes(f_1f_2)+(g_1|g_2)\sum_{p=0}^{n}d_p(f_1)f_2K_p \tag{2.1}$$

and

$$[\hat{\mathfrak{g}},\mathscr{K}]=0. \tag{2.2}$$

Finally, we shall add certain derivations to $\hat{\mathfrak{g}}$. Specifically, let $\mathscr{D}$ be the Lie algebra of derivations of $\mathbb{C}[t_0^{\pm},t_1^{\pm},\ldots,t_n^{\pm}]$:

$$\mathscr{D}=\left\{\sum_{p=0}^{n}f_p(t_0,\ldots,t_n)d_p\,\middle|\,f_0,\ldots,f_n\in\mathbb{C}[t_0^{\pm},t_1^{\pm},\ldots,t_n^{\pm}]\right\}.$$

It is a general fact, that a derivation acting on a Lie algebra can be lifted in a unique way to a derivation of the universal central extension of this Lie algebra.[11] Thus the natural action of $\mathscr{D}$ on $\tilde{\mathfrak{g}}$,

$$f_1(t_0,\ldots,t_n)d_p(g\otimes f_2(t_0,\ldots,t_n))=g\otimes f_1d_p(f_2), \tag{2.3}$$

has a unique extension to $\hat{\mathfrak{g}}$. We shall denote the lift of $f(t_0,\ldots,t_n)d_p$ by $f(t_0,\ldots,t_n)D_p$. Its action on the subspace $\tilde{\mathfrak{g}}$ is unchanged, while the action on $\mathscr{K}$ is given by[2]

$$f_1D_a(f_2K_b)=f_1d_a(f_2)K_b+\delta_{ab}\sum_{p=0}^{n}f_2d_p(f_1)K_p. \tag{2.4}$$

Consider a subalgebra $\mathscr{D}_+$ in $\mathscr{D}$:

$$\mathscr{D}_+ = \left\{ \sum_{p=1}^{n} f_p(t_0,\dots,t_n) D_p \,\middle|\, f_1,\dots,f_n \in \mathbb{C}[t_0^{\pm},t_1^{\pm},\dots,t_n^{\pm}] \right\}.$$

We will be working with the algebra $\mathfrak{g}$ which is a deformation of the semidirect product of $\hat{\mathfrak{g}}$ with $\mathscr{D}_+$:

$$\mathfrak{g} = \dot{\mathfrak{g}} \otimes \mathbb{C}[t_0^{\pm},t_1^{\pm},\dots,t_n^{\pm}] \oplus \mathscr{K} \oplus \mathscr{D}_+ .$$

Here multiplication in $\hat{\mathfrak{g}}$ is given by (2.1) and (2.2), the action of $\mathscr{D}_+$ on $\tilde{\mathfrak{g}}$ is given by (2.3) and on $\mathscr{K}$ by (2.4). The Lie bracket in $\mathscr{D}_+$ is the following:

$$[t_0^{r_0}\mathbf{t}^{\mathbf{r}} D_a, t_0^{m_0}\mathbf{t}^{\mathbf{m}} D_b] = m_a t_0^{r_0+m_0}\mathbf{t}^{\mathbf{r}+\mathbf{m}} D_b - r_b t_0^{r_0+m_0}\mathbf{t}^{\mathbf{r}+\mathbf{m}} D_a - m_a r_b \left\{ \sum_{p=0}^{n} r_p t_0^{r_0+m_0}\mathbf{t}^{\mathbf{r}+\mathbf{m}} K_p \right\}.$$

The last term in this formula is a 2-cocycle with values in a nontrivial $\mathscr{D}$-module $\mathscr{K}$. This abelian extension of the Lie algebra of vector fields on a torus is a generalization of the Virasoro algebra and was introduced by Rao and Moody.[2]

III. PRINCIPAL REALIZATION OF THE BASIC REPRESENTATION OF AFFINE LIE ALGEBRA

When $n=0$ the algebra $\mathfrak{g}$ constructed above yields the derived affine Kac–Moody algebra. We set $n=0$ throughout this section. In this case $\mathscr{K}$ is one-dimensional and is spanned by K_0, while $\mathscr{D}_+$ is trivial, so

$$\mathfrak{g} = \dot{\mathfrak{g}} \otimes \mathbb{C}[t_0,t_0^{-1}] \oplus \mathbb{C}K_0 .$$

Lepowsky and Wilson[3] constructed the principal realization of the basic representation of affine Kac–Moody algebra $A_1^{(1)}$, while the construction for a general affine algebra was given by Kac *et al.*[4] Let us recall this construction (see also Ref. 1 for details). Its starting point is the principal Heisenberg subalgebra in $\mathfrak{g}$.

Let $\{\alpha_1,\dots,\alpha_\ell\}$ be simple roots and θ be the highest positive root in $\dot{\Delta}$. We define the height for a root $\beta = \Sigma_{i=1}^{\ell} k_i\alpha_i$ as

$$ht(\beta) = \sum_{i=1}^{\ell} k_i .$$

Note that $ht(\theta) = h-1$, where h is a Coxeter number of $\dot{\mathfrak{g}}$.[12]

Consider the principle gradation of $\tilde{\mathfrak{g}}$ defined by

$$\deg(\dot{\mathfrak{g}}^{\alpha_1}\otimes 1) = \dots = \deg(\dot{\mathfrak{g}}^{\alpha_\ell}\otimes 1) = \deg(\dot{\mathfrak{g}}^{-\theta}\otimes t_0) = 1,$$

$$\deg(\dot{\mathfrak{g}}^{-\alpha_1}\otimes 1) = \dots = \deg(\dot{\mathfrak{g}}^{-\alpha_\ell}\otimes 1) = \deg(\dot{\mathfrak{g}}^{\theta}\otimes t_0^{-1}) = -1.$$

We choose nonzero root vectors $e_0 \in \dot{\mathfrak{g}}^{-\theta}\otimes t_0, e_1 \in \dot{\mathfrak{g}}^{\alpha_1}\otimes 1, \dots, e_\ell \in \dot{\mathfrak{g}}^{\alpha_\ell}$ and form the element $\overline{e} = \Sigma_{i=0}^{\ell} e_i \in \tilde{\mathfrak{g}}$. Since $\overline{e}$ is of degree 1 then its centralizer $\tilde{\mathfrak{s}}$ in $\tilde{g}$ is homogeneous with respect to the gradation.

Next, consider a projection

$$\pi: \quad \dot{\mathfrak{g}}\otimes\mathbb{C}[t_0,t_0^{-1}] \to \dot{\mathfrak{g}} \quad \text{by} \quad t_0 \mapsto 1.$$

Note that $\deg(\dot{\mathfrak{g}}^{-\theta}\otimes t_0) = 1$ and $\deg(\dot{\mathfrak{g}}^{-\theta}\otimes 1) = ht(-\theta) = -h+1$, while $\pi(\dot{\mathfrak{g}}^{-\theta}\otimes t_0) = \pi(\dot{\mathfrak{g}}^{-\theta}\otimes 1)$, and thus the principal $\mathbb{Z}$-gradation of $\tilde{\mathfrak{g}}$ induces the $\mathbb{Z}_h$-gradation of $\dot{\mathfrak{g}}$:

$$\dot{\mathfrak{g}} = \sum_{j\in\mathbb{Z}_h} \dot{\mathfrak{g}}_j .$$

The element $\pi(\overline{e})$ is regular in $\dot{\mathfrak{g}}$, hence its centralizer $\dot{\mathfrak{s}}=\pi(\tilde{\mathfrak{s}})$ in $\dot{\mathfrak{g}}$ is a Cartan subalgebra, which implies that both $\dot{\mathfrak{s}}$ and $\tilde{\mathfrak{s}}$ are abelian.

The preimage $\mathfrak{s}=\tilde{\mathfrak{s}}\oplus\mathbb{C}K_0$ of $\tilde{\mathfrak{s}}$ in $\mathfrak{g}$ is an infinite-dimensional Heisenberg algebra which is called the principal Heisenberg subalgebra of $\mathfrak{g}$. This subalgebra is the cornerstone of the construction of the vertex operator representation of $\mathfrak{g}$. The scheme of this construction is the following: one starts with the standard irreducible representation of $\mathfrak{s}$ and then magically one can lift this representation to the whole of $\mathfrak{g}$. Moreover the action of $\mathfrak{g}$ is prescribed and given by vertex operators. Finally one has only to check in one way or another that this construction works.

The irreducible representation of $\mathfrak{g}$ constructed in this way is of the highest weight Λ_0, where the linear functional Λ_0 is given (we consider the simply laced case) by

$$\Lambda_0(\nu^{-1}(\alpha_i)\otimes t_0^0)=0, \quad \Lambda_0(K_0)=1.$$

This highest weight representation is called the basic representation of $\mathfrak{g}$.

The Cartan subalgebra $\dot{\mathfrak{s}}$ is homogeneous with respect to the principle $\mathbb{Z}_h$-gradation:

$$\dot{\mathfrak{s}}=\sum_{j\in\mathbb{Z}_h}\dot{\mathfrak{s}}_j\,.$$

Since $(\dot{\mathfrak{g}}_i|\dot{\mathfrak{g}}_j)=0$ unless $i+j=0(\mathrm{mod}\ h)$ and $(\cdot|\cdot)$ is nondegenerate on $\dot{\mathfrak{s}}$ then one can choose a basis in $\dot{\mathfrak{s}}$: $\{T_1,T_2,\ldots,T_\ell\}$ such that $T_i\in\dot{\mathfrak{g}}_{m_i}$, where $1\leqslant m_1\leqslant m_2\leqslant\cdots\leqslant m_\ell<h$ and

$$(T_i|T_{\ell+1-j})=h\,\delta_{ij}\,.$$

The numbers $\{m_1,\ldots,m_\ell\}$ are called the exponents of $\dot{\mathfrak{g}}$.[12] Note that $\dot{\mathfrak{s}}\cap\dot{\mathfrak{h}}=(0)$, and therefore zero is not an exponent. Also, $m_{\ell+1-i}=h-m_i$.

It turns out that it is more convenient to work with a slightly different realization of $\mathfrak{g}$ based on the $\mathbb{Z}_h$-gradation of $\dot{\mathfrak{g}}$. Consider

$$\mathfrak{g}_s=\sum_{j\in\mathbb{Z}}\dot{\mathfrak{g}}_j\otimes s^j\oplus\mathbb{C}K_0\,,$$

with the Lie bracket

$$[g_1\otimes s^i,g_2\otimes s^j]=[g_1,g_2]\otimes s^{i+j}+\frac{i}{h}\,(g_1|g_2)\,\delta_{i,-j}K_0\,,$$

$$[K_0,\mathfrak{g}_s]=0.$$

The proof of the following lemma is straightforward, so we omit it.

Lemma 1: The Lie algebras $\mathfrak{g}$ *and* $\mathfrak{g}_s$ *are isomorphic and the isomorphism*

$$\psi:\quad \dot{\mathfrak{g}}\otimes\mathbb{C}[t_0,t_0^{-1}]\oplus\mathbb{C}K_0\to\sum_{j\in\mathbb{Z}}\dot{\mathfrak{g}}_j\otimes s^j\oplus\mathbb{C}K_0$$

is given by

$$\psi(e_\alpha\otimes t^i)=e_\alpha\otimes s^{ht(\alpha)+ih},$$

$$\psi(\nu^{-1}(\alpha)\otimes t^i)=\nu^{-1}(\alpha)\otimes s^{ih}+\delta_{i,0}\,\frac{ht(\alpha)}{h}\,K_0\,,$$

$$\psi(K_0)=K_0.$$

We shall identify $\mathfrak{g}$ and $\mathfrak{g}_s$ using this isomorphism.

In order to describe a basis in the principal Heisenberg subalgebra $\psi(\mathfrak{s})$ we need to introduce the sequence $\{b_i\}_{i\in\mathbb{Z}}$ such that $b_{i+j\ell}=m_i+jh$ for $j\in\mathbb{Z}$, $i=1,...,\ell$. Then $\psi(\mathfrak{s})$ is spanned by $\{T_i\otimes s^{b_i},K_0\}$, $i\in\mathbb{Z}$. Note that $b_{1-i}=-b_i$.

Let $\dot{\Delta}_s$ be the root system of $\dot{\mathfrak{g}}$ with respect to the Cartan subalgebra $\dot{\mathfrak{s}}$. For $\alpha\in\dot{\Delta}_s$ choose a root element

$$A^\alpha=\sum_{j\in\mathbb{Z}_h} A_j^\alpha.$$

Since $\pi(\overline{e})$ is a regular element of the Cartan subalgebra then $[\pi(\overline{e}),A^\alpha]=\lambda^\alpha A^\alpha$ with $\lambda^\alpha\neq 0$. Hence $A_j^\alpha=(ad\,\pi(\overline{e})/\lambda^\alpha)^j A_0^\alpha$ and all the components A_j^α are nonzero. We let the indices i,j in T_i and A_j^α run over $\mathbb{Z}$ by setting $T_{i_1}=T_{i_2}$ if $i_1\equiv i_2(\mathrm{mod}\,\ell)$ and $A_{j_1}^\alpha=A_{j_2}^\alpha$ if $j_1\equiv j_2(\mathrm{mod}\,h)$.

Define constants $\lambda_i^\alpha=\alpha(T_i)$. Then $[T_i,A^\alpha]=\lambda_i^\alpha A^\alpha$ and $[T_i,A_j^\alpha]=\lambda_i^\alpha A_{j+m_i}^\alpha$.

Consider an automorphism σ of $\dot{\mathfrak{g}}$ such that

$$\sigma=\zeta^j\mathrm{Id}\quad\text{on}\quad\dot{\mathfrak{g}}_j,$$

where $\zeta\in\mathbb{C}$ is a primitive h-root of 1. For a root element $A^\alpha=\Sigma_{j=1}^h A_j^\alpha$ we have

$$[T_i,\sigma(A^\alpha)]=\sigma([\sigma^{-1}(T_i),A^\alpha])=\sigma([\zeta^{-m_i}T_i,A^\alpha])=\zeta^{-m_i}\lambda_i^\alpha\sigma(A^\alpha).$$

Thus $\sigma(A^\alpha)=\Sigma_{j=1}^h \zeta^j A_j^\alpha$ is also a root element and σ induces an automorphism of $\dot{\Delta}_s$. Since all A_j^α are nonzero then the length of each orbit of σ in $\dot{\Delta}_s$ is h.

We may choose ℓ roots $\beta_1,\ldots,\beta_\ell\in\dot{\Delta}_s$ such that $A_0^{\beta_1},\ldots,A_0^{\beta_\ell}$ span $\dot{\mathfrak{g}}_0$. Note that if two root elements belong to the same orbit under the action of σ then their zero components are proportional. Therefore every orbit of σ contains exactly one of $\beta_1,\ldots,\beta_\ell$. Consequently, we may choose $\{\sigma^j(A^{\beta_i})\}$, $i=1,...,\ell$, $j=1,...,h$ as our family of the root elements. The set $\{A_j^{\beta_i}\otimes s^j,T_j\otimes s^{b_j},K_0\}$, $i=1,...,\ell,j\in\mathbb{Z}$ forms a basis of $\mathfrak{g}_s$.

Remark: The properties of the automorphism σ were studied by Kostant.[12] He proved, in particular, that σ acts on the root system $\dot{\Delta}_s$ as a Coxeter transformation. Remarkably, the complex coefficients λ_i^α could be interpreted as the orthogonal projections of the roots on a real plane invariant under the Coxeter transformation. These projections were introduced by Coxeter in order to visualize the regular polytopes of higher dimensions. In Chapters 12 and 13 of Ref. 13 and in Section 12.5 of Ref. 14 the case of the root system of type H_4 is treated, which also gives the answer for E_8.

Now we shall construct the standard representation (φ,F) of $\mathfrak{s}$. The space of this representation (called the Fock space) is the polynomial algebra in the infinitely many variables:

$$F=\mathbb{C}[x_1,x_2,x_3,\ldots].$$

For $i\geqslant 1$, $T_{1-i}\otimes s^{-b_i}$ is represented by a multiplication operator:

$$\varphi(T_{1-i}\otimes s^{-b_i})=b_i x_i,$$

$T_i\otimes s^{b_i}$ is represented by a differentiation operator:

$$\varphi(T_i\otimes s^{b_i})=\frac{\partial}{\partial x_i}$$

and $\varphi(K_0)=\mathrm{Id}$.

Indeed, the only relation to be checked is

$$[\varphi(T_i\otimes s^{b_i}),\varphi(T_{1-j}\otimes s^{b_{1-j}})]=\frac{1}{h}(T_i|T_{1-j})b_i\delta_{b_ib_j}\varphi(K_0).$$

But as it can be easily seen, both expressions are equal to $b_i\delta_{ij}$ Id.

One can lift this representation of $\mathfrak{s}$ to the whole $\mathfrak{g}$ using vertex operators. We consider the space $\mathfrak{g}[[z,z^{-1}]]$ of formal Laurent series in a variable z with coefficients in $\mathfrak{g}$ and the space $\mathrm{End}(F)[[z,z^{-1}]]$ of series with coefficients in $\mathrm{End}(F)$ (see Chapter 2 in Ref. 15 for details). The adjoint action of $\mathfrak{g}$ on $\mathfrak{g}[[z,z^{-1}]]$ is well-defined.

Every representation $\varphi:\mathfrak{g}\to\mathrm{End}(F)$ defines a homomorphism $\varphi:\mathfrak{g}[[z,z^{-1}]]\to \mathrm{End}(F)[[z,z^{-1}]]$.

The following theorem shows how to lift the standard representation of the principal Heisenberg subalgebra to $\mathfrak{g}$:

Theorem 2: (Ref. 1) *There exists a representation*

$$\varphi:\mathfrak{g}\to\mathrm{End}(\mathbb{C}[x_1,x_2,\ldots])$$

such that for $i\in\mathbb{N}$

$$\varphi(T_{1-i}\otimes s^{-b_i})=b_ix_i,\quad \varphi(T_i\otimes s^{b_i})=\frac{\partial}{\partial x_i},$$

$$\varphi(K_0)=\mathrm{Id},\quad \sum_{j\in\mathbb{Z}}\varphi(A_j^\alpha\otimes s^j)z^{-j}=A^\alpha(z),$$

where

$$A^\alpha(z)=\Lambda_0(A_0^\alpha\otimes s^0)\exp\left(\sum_{i=1}^{\infty}\lambda_i^\alpha z^{b_i}x_i\right)\exp\left(-\sum_{i=1}^{\infty}\lambda_{1-i}^\alpha\frac{z^{-b_i}}{b_i}\frac{\partial}{\partial x_i}\right).$$

Since $A_j^\alpha\otimes s^j$ together with $T_i\otimes s^{b_i}$ and K_0 span $\mathfrak{g}$ then the above formulas completely determine this representation.

We will use extensively the following Laurent series:

$$\delta(z)=\sum_{j\in\mathbb{Z}}z^j\quad\text{and}\quad D\delta(z)=\sum_{j\in\mathbb{Z}}jz^j.$$

The first of these is the formal analog of the delta function.

For an element $B=\Sigma_{j\in\mathbb{Z}_h}B_j\in\dot{\mathfrak{g}}$ denote by $B(z)$ the formal series $\Sigma_{j\in\mathbb{Z}}\varphi(B_j\otimes s^j)z^{-j}\in\mathrm{End}(F)[[z,z^{-1}]]$.

Corollary 3: Let $A=\Sigma_{j=1}^h A_j$, $B=\Sigma_{j=1}^h B_j\in\dot{\mathfrak{g}}$ *and let* $C^j=[A_j,B]\in\dot{\mathfrak{g}}$. *Then*

$$[A(z_1),B(z_2)]=\sum_{j=1}^{h}\left(C^j(z_2)+\frac{j}{h}(A_j|B_{-j})\right)\left(\frac{z_2}{z_1}\right)^j\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)+\sum_{j=1}^{h}(A_j|B_{-j})\left(\frac{z_2}{z_1}\right)^jD\delta\left(\left(\frac{z_2}{z_1}\right)^h\right).$$

Proof of the Corollary:

$$\begin{aligned}[A(z_1),B(z_2)]&=\sum_{j\in\mathbb{Z}}\sum_{i\in\mathbb{Z}}[\varphi(A_j\otimes s^j),\varphi(B_i\otimes s^i)]z_1^{-j}z_2^{-i}\\&=\sum_{j\in\mathbb{Z}}\sum_{i\in\mathbb{Z}}\left\{\varphi([A_j,B_i]\otimes s^{j+i})+\frac{1}{h}(A_j|B_i)j\,\delta_{j,-i}\varphi(K_0)\right\}z_1^{-j}z_2^{-i}\\&=\sum_{j\in\mathbb{Z}}\sum_{k=i+j\in\mathbb{Z}}\varphi([A_j,B_{k-j}]\otimes s^k)z_1^{-j}z_2^{j-k}+\frac{1}{h}\sum_{j\in\mathbb{Z}}(A_j|B_{-j})j\left(\frac{z_2}{z_1}\right)^j\\&=\sum_{j\in\mathbb{Z}}C^j(z_2)\left(\frac{z_2}{z_1}\right)^j+\frac{1}{h}\sum_{j_1=1}^{h}\sum_{\substack{j_2\in\mathbb{Z}\\ j=j_1+hj_2}}(A_{j_1}|B_{-j_1})(j_1+hj_2)\left(\frac{z_2}{z_1}\right)^{j_1+hj_2}\end{aligned}$$

$$= \sum_{j_1=1}^{h} \left(C^{j_1}(z_2) + \frac{j_1}{h} (A_{j_1}|B_{-j_1}) \right) \left(\frac{z_2}{z_1} \right)^{j_1} \delta\left(\left(\frac{z_2}{z_1} \right)^h \right)$$
$$+ \sum_{j_1=1}^{h} (A_{j_1}|B_{-j_1}) \left(\frac{z_2}{z_1} \right)^{j_1} D\delta\left(\left(\frac{z_2}{z_1} \right)^h \right).$$

IV. CONSTRUCTION OF THE VERTEX OPERATOR REPRESENTATION FOR THE TOROIDAL LIE ALGEBRA

In this section we construct a vertex operator representation for the toroidal Lie algebra that generalizes the principal realization of the basic representation of affine Lie algebra. Again it will be convenient to replace $\mathfrak{g}$ with

$$\mathfrak{g}_s = \sum_{j \in \mathbb{Z}} \dot{\mathfrak{g}}_j \otimes s^j \mathbb{C}[t_1^{\pm}, \ldots, t_n^{\pm}] \oplus \mathscr{K} \oplus \mathscr{D}_+,$$

with the Lie bracket

$$[g_1 \otimes f_1(s,\mathbf{t}), g_2 \otimes f_2(s,\mathbf{t})] = [g_1, g_2] \otimes (f_1 f_2) + (g_1|g_2) \left\{ \frac{1}{h} \left(s \frac{d}{ds} f_1 \right) f_2 K_0 + \sum_{p=1}^{n} d_p(f_1) f_2 K_p \right\},$$

$$[f_1(s,\mathbf{t}) D_p, g \otimes f_2(s,\mathbf{t})] = g \otimes f_1(d_p f_2)$$

while the multiplication in $\mathscr{D}_+$ and its action on $\mathscr{K}$ are the same as in $\mathfrak{g}$. Here and below we make identifications $s^{hr_0}\mathbf{t}^{\mathbf{r}} K_a = t_0^{r_0}\mathbf{t}^{\mathbf{r}} K_a$ and $s^{hr_0}\mathbf{t}^{\mathbf{r}} D_b = t_0^{r_0}\mathbf{t}^{\mathbf{r}} D_b$, $a = 0,1,\ldots,n$, $b = 1,\ldots,n$.

The following lemma is an immediate generalization of Lemma 1:

Lemma 4: The Lie algebras $\mathfrak{g}$ and $\mathfrak{g}_s$ are isomorphic and the isomorphism is given by

$$\psi(e_\alpha \otimes t_0^{r_0}\mathbf{t}^{\mathbf{r}}) = e_\alpha \otimes s^{ht(\alpha)+hr_0}\mathbf{t}^{\mathbf{r}},$$

$$\psi(\nu^{-1}(\alpha) \otimes t_0^{r_0}\mathbf{t}^{\mathbf{r}}) = \nu^{-1}(\alpha) \otimes s^{hr_0}\mathbf{t}^{\mathbf{r}} + \frac{ht(\alpha)}{h} s^{hr_0}\mathbf{t}^{\mathbf{r}} K_0,$$

$$\psi = \mathrm{Id} \quad \text{on} \quad \mathscr{K} \oplus \mathscr{D}_+.$$

We shall identify $\mathfrak{g}$ and $\mathfrak{g}_s$ using this isomorphism.

The subalgebra $\mathfrak{s}$ with the basis $\{T_i \otimes s^{b_i}, s^{ih} D_p, s^{ih} K_p, K_0\}$, $i \in \mathbb{Z}$, $p = 1,\ldots,n$ is the principal (degenerate) Heisenberg subalgebra of $\mathfrak{g}$.

Indeed, K_0 is its central element and the multiplication in $\mathfrak{s}$ is given by

$$[T_i \otimes s^{b_i}, T_{1-j} \otimes s^{-b_j}] = b_i \delta_{ij} K_0,$$

$$[s^{ih} D_a, s^{jh} K_b] = \delta_{ab} i s^{(i+j)h} K_0 = i \delta_{ab} \delta_{i,-j} K_0,$$

$$[s^{jh} D_p, T_i \otimes s^{b_i}] = 0, \quad [s^{ih} D_a, s^{jh} D_b] = 0,$$

$$[T_i \otimes s^{b_i}, s^{jh} K_p] = 0, \quad [s^{ih} K_a, s^{jh} K_b] = 0,$$

where $i,j \in \mathbb{Z}, a,b,p = 1,\ldots,n$. This subalgebra is degenerate as a Heisenberg algebra since $[D_p, K_p] = 0$.

The Heisenberg algebra $\mathfrak{s}$ can be represented on the space

$$F = \mathbb{C}[q_p^{\pm}, x_i, u_{pi}, v_{pi}]_{i \in \mathbb{N}}^{p=1,\ldots,n}$$

by differentiation and multiplication operators:

$$\varphi(T_i\otimes s^{b_i})=\frac{\partial}{\partial x_i},\quad \varphi(T_{1-i}\otimes s^{-b_i})=b_i x_i,$$

$$\varphi(s^{ih}D_p)=\frac{\partial}{\partial u_{pi}},\quad \varphi(s^{-ih}D_p)=iv_{pi},$$

$$\varphi(s^{ih}K_p)=\frac{\partial}{\partial v_{pi}},\quad \varphi(s^{-ih}K_p)=iu_{pi},$$

$$\varphi(D_p)=q_p\frac{\partial}{\partial q_p},\quad \varphi(K_p)=0,\quad \varphi(K_0)=\mathrm{Id},$$

where $i\geqslant 1$ and $p=1,...,n$. Our goal is to extend this representation of $\mathfrak{s}$ to $\mathfrak{g}$. Consider the following elements of $\mathfrak{g}[[z,z^{-1}]]$:

$$\sum_{j\in\mathbb{Z}} s^{jh}\mathbf{t}^{\mathbf{r}}K_0 z^{-jh},\quad \sum_{j\in\mathbb{Z}} A_j^{\alpha}\otimes s^j\mathbf{t}^{\mathbf{r}}z^{-j}.$$

Note that

$$\left[T_i\otimes s^{b_i},\sum_{j\in\mathbb{Z}} s^{jh}\mathbf{t}^{\mathbf{r}}K_0 z^{-jh}\right]=0,\quad \left[s^{ih}K_p,\sum_{j\in\mathbb{Z}} s^{jh}\mathbf{t}^{\mathbf{r}}K_0 z^{-jh}\right]=0,$$

$$\left[s^{ih}D_p,\sum_{j\in\mathbb{Z}} s^{jh}\mathbf{t}^{\mathbf{r}}K_0 z^{-jh}\right]=\sum_{j\in\mathbb{Z}} r_p s^{(i+j)h}\mathbf{t}^{\mathbf{r}}K_0 z^{-jh}=\sum_{k=i+j\in\mathbb{Z}} r_p s^{kh}\mathbf{t}^{\mathbf{r}}K_0 z^{-kh+ih}$$

$$=r_p z^{ih}\sum_{j\in\mathbb{Z}} s^{jh}\mathbf{t}^{\mathbf{r}}K_0 z^{-jh}.$$

The theory of vertex operators suggests (see Lemma 14.5 in Ref. 1) that $\Sigma_{j\in\mathbb{Z}} s^{jh}\mathbf{t}^{\mathbf{r}}K_0 z^{-jh}$ should be represented by

$$K_0(z,\mathbf{r})=\mathbf{q}^{\mathbf{r}}\exp\left(\sum_{p=1}^{n} r_p\sum_{j\geqslant 1} z^{jh}u_{pj}\right)\exp\left(-\sum_{p=1}^{n} r_p\sum_{j\geqslant 1}\frac{z^{-jh}}{j}\frac{\partial}{\partial v_{pj}}\right).$$

Here $\mathbf{q}^{\mathbf{r}}=q_1^{r_1}\cdots q_n^{r_n}$.

In a similar way the commutator relations

$$\left[T_i\otimes s^{b_i},\sum_{j\in\mathbb{Z}} A_j^{\alpha}\otimes s^j\mathbf{t}^{\mathbf{r}}z^{-j}\right]=\sum_{j\in\mathbb{Z}}\lambda_i^{\alpha}A_{j+b_i}^{\alpha}\otimes s^{j+b_i}\mathbf{t}^{\mathbf{r}}z^{-j}=\lambda_i^{\alpha}\sum_{k=j+b_i\in\mathbb{Z}} A_k^{\alpha}\otimes s^k\mathbf{t}^{\mathbf{r}}z^{-k+b_i}$$

$$=\lambda_i^{\alpha}z^{b_i}\sum_{j\in\mathbb{Z}} A_j^{\alpha}\otimes s^j\mathbf{t}^{\mathbf{r}}z^{-j},$$

$$\left[s^{ih}K_p,\sum_{j\in\mathbb{Z}} A_j^{\alpha}\otimes s^j\mathbf{t}^{\mathbf{r}}z^{-j}\right]=0,$$

$$\left[s^{ih}D_p,\sum_{j\in\mathbb{Z}} A_j^{\alpha}\otimes s^j\mathbf{t}^{\mathbf{r}}z^{-j}\right]=\sum_{j\in\mathbb{Z}} r_p A_j^{\alpha}\otimes s^{j+ih}\mathbf{t}^{\mathbf{r}}z^{-j}$$

$$=r_p\sum_{k=j+ih\in\mathbb{Z}} A_j^{\alpha}\otimes s^k\mathbf{t}^{\mathbf{r}}z^{-k+ih}=r_p z^{ih}\sum_{j\in\mathbb{Z}} A_j^{\alpha}\otimes s^j\mathbf{t}^{\mathbf{r}}z^{-j}$$

suggest that $\Sigma_{j\in\mathbb{Z}} A_j^{\alpha}\otimes s^j\mathbf{t}^{\mathbf{r}}z^{-j}$ should be represented by

$$A^{\alpha}(z,\mathbf{r})=\mathbf{q}^{\mathbf{r}}\Lambda_0(A_0^{\alpha}\otimes s^0)\exp\left(\sum_{i=1}^{\infty}\lambda_i^{\alpha}z^{b_i}x_i\right)\exp\left(-\sum_{i=1}^{\infty}\lambda_{1-i}^{\alpha}\frac{z^{-b_i}}{b_i}\frac{\partial}{\partial x_i}\right)\exp\left(\sum_{p=1}^{n}r_p\sum_{j\in\mathbb{Z}}z^{jh}u_{pj}\right)$$
$$\times\exp\left(-\sum_{p=1}^{n}r_p\sum_{j\in\mathbb{Z}}\frac{z^{-jh}}{j}\frac{\partial}{\partial v_{pj}}\right)=A^{\alpha}(z)K_0(z,\mathbf{r}).$$

The last formula hints that for $B\in\dot{\mathfrak{g}}$ we may try to represent $\Sigma_{j\in\mathbb{Z}}B_j\otimes s^j\mathbf{t}^{\mathbf{r}}z^{-j}$ by

$$B(z,\mathbf{r})=B(z)K_0(z,\mathbf{r}).$$

Note that $B(z)$ is known from the affine case (Theorem 2).

In fact, we shall see that the same approach is valid even for $\mathscr{K}$ and $\mathscr{D}_+$, but for these we should first discuss the concept of the normal ordering.

Let $X(z)=\Sigma_{i\in\mathbb{Z}}X_iz^i$, $Y(z)=\Sigma_{j\in\mathbb{Z}}Y_jz^j\in\mathrm{End}(F)[[z,z^{-1}]]$. We say that the product $X(z)Y(z)$ exists if for every $k\in\mathbb{Z}$ and for every $v\in F$ the sum

$$\sum_{i\in\mathbb{Z}}X_iY_{k-i}v$$

has finitely many nonzero terms. If this is the case then

$$X(z)Y(z)=\sum_{k\in\mathbb{Z}}\left(\sum_{i\in\mathbb{Z}}X_iY_{k-i}\right)z^k.$$

It is possible that $X(z)Y(z)$ exists while $Y(z)X(z)$ does not. For example, this happens for

$$X(z)=\sum_{i\geqslant 1}x_iz^i,\quad Y(z)=\sum_{i\geqslant 1}\frac{\partial}{\partial x_i}z^{-i}.$$

To improve the situation we define the normal ordering for the product of operators on F. For a differential operator $P\in\mathrm{End}(F)$ the normal ordering $:x_iP:$ is defined as x_iP, while the normal ordering of the product $:(\partial/\partial x_i)P:$ is defined as $P(\partial/\partial x_i)$. Note that for $X(z)$ and $Y(z)$ from the above example $:X(z)Y(z):=:Y(z)X(z):=X(z)Y(z)$.

From the action of the principle Heisenberg subalgebra on F we see that the series $\Sigma_{j\in\mathbb{Z}}s^{jh}K_pz^{-jh}$ and $\Sigma_{j\in\mathbb{Z}}s^{jh}D_pz^{-jh}$ are represented by

$$K_p(z)=\sum_{i\geqslant 1}iu_{pi}z^{ih}+\sum_{i\geqslant 1}\frac{\partial}{\partial v_{pi}}z^{-ih}$$

and

$$D_p(z)=\sum_{i\geqslant 1}iv_{pi}z^{ih}+q_p\frac{\partial}{\partial q_p}+\sum_{i\geqslant 1}\frac{\partial}{\partial u_{pi}}z^{-ih}.$$

Using the analogy with $A^{\alpha}(z,\mathbf{r})$ we shall represent $\Sigma_{j\in\mathbb{Z}}s^{jh}\mathbf{t}^{\mathbf{r}}K_pz^{-jh}$ by

$$K_p(z,\mathbf{r})=K_p(z)K_0(z,\mathbf{r})$$

and $\Sigma_{j\in\mathbb{Z}}s^{jh}\mathbf{t}^{\mathbf{r}}D_pz^{-jh}$ by

$$D_p(z,\mathbf{r})=:D_p(z)K_0(z,\mathbf{r}):.$$

Note that we use the normal ordering in the case of $D_p(z,\mathbf{r})$ in order for the product to exist.

We summarize this discussion in our main theorem:

Theorem 5: *There exists a representation φ of the toroidal Lie algebra $\mathfrak{g}_s$ on the space*

$$F=\mathbb{C}[q_p^{\pm},x_i,u_{pi},v_{pi}]_{i\in\mathbb{N}}^{p=1,\ldots,n}$$

such that for $i=1,...,\ell$, $p=1,...,n$, $\alpha\in\dot{\Delta}_s$, $\mathbf{r}\in\mathbb{Z}^n$

$$\sum_{j\in\mathbb{Z}}\varphi(s^{jh}\mathbf{t}^{\mathbf{r}}K_0)z^{-jh}=K_0(z,\mathbf{r})=\mathbf{q}^{\mathbf{r}}\exp\left(\sum_{p=1}^{n}r_p\sum_{j\geqslant 1}z^{jh}u_{pj}\right)\exp\left(-\sum_{p=1}^{n}r_p\sum_{j\geqslant 1}\frac{z^{-jh}}{j}\frac{\partial}{\partial v_{pj}}\right), \tag{4.1}$$

$$\sum_{j\in\mathbb{Z}}\varphi(T_i\otimes s^{m_i+jh}\mathbf{t}^{\mathbf{r}})z^{-m_i-jh}=T_i(z,\mathbf{r})=\left\{\sum_{j\geqslant 1}(jh-m_i)z^{jh-m_i}x_{j\ell+1-i}+\sum_{j\geqslant 0}z^{-jh-m_i}\frac{\partial}{\partial x_{j\ell+i}}\right\}K_0(z,\mathbf{r}), \tag{4.2}$$

$$\sum_{j\in\mathbb{Z}}\varphi(A_j^{\alpha}\otimes s^j\mathbf{t}^{\mathbf{r}})z^{-j}=A^{\alpha}(z,\mathbf{r})=\Lambda_0(A_0^{\alpha}\otimes s^0)\exp\left(\sum_{i=1}^{\infty}\lambda_i^{\alpha}z^{b_i}x_i\right)\times\exp\left(-\sum_{i=1}^{\infty}\lambda_{1-i}^{\alpha}\frac{z^{-b_i}}{b_i}\frac{\partial}{\partial x_i}\right)K_0(z,\mathbf{r}), \tag{4.3}$$

$$\sum_{j\in\mathbb{Z}}\varphi(s^{jh}\mathbf{t}^{\mathbf{r}}K_p)z^{-jh}=K_p(z,\mathbf{r})=\left\{\sum_{i\geqslant 1}iu_{pi}z^{ih}+\sum_{i\geqslant 1}\frac{\partial}{\partial v_{pi}}z^{-ih}\right\}K_0(z,\mathbf{r}), \tag{4.4}$$

$$\sum_{j\in\mathbb{Z}}\varphi(s^{jh}\mathbf{t}^{\mathbf{r}}D_p)z^{-jh}=D_p(z,\mathbf{r})=:\left\{\sum_{i\geqslant 1}iv_{pi}z^{ih}+q_p\frac{\partial}{\partial q_p}+\sum_{i\geqslant 1}\frac{\partial}{\partial u_{pi}}z^{-ih}\right\}K_0(z,\mathbf{r}):. \tag{4.5}$$

Remark: By choosing a specialization $q_p\in\mathbb{C}\setminus\{0\}$, $p=1,...,n$, we obtain a representation of the toroidal algebra $\hat{\mathfrak{g}}$ on the Fock space

$$\hat{F}=\mathbb{C}[x_i,u_{pi},v_{pi}]_{i\in\mathbb{N}}^{p=1,...,n}.$$

V. PROOF OF THE MAIN THEOREM

First of all, let us check that formulas (4.1)–(4.5) define a linear map φ: $\mathfrak{g}\to\mathrm{End}(F)$. The linear dependencies between the momenta at the left-hand side are of the form

$$\varphi(A_j^{\sigma^k(\alpha)}\otimes s^j\mathbf{t}^{\mathbf{r}})=\zeta^{kj}\varphi(A_j^{\alpha}\otimes s^j\mathbf{t}^{\mathbf{r}}).$$

and

$$j\varphi(s^{jh}\mathbf{t}^{\mathbf{r}}K_0)+\sum_{p=1}^{n}r_p\varphi(s^{jh}\mathbf{t}^{\mathbf{r}}K_p)=0.$$

These dependencies extend to the following relations for the corresponding series:

$$\sum_{j\in\mathbb{Z}}\varphi(A_j^{\sigma^k(\alpha)}\otimes s^j\mathbf{t}^{\mathbf{r}})z^{-j}=\sum_{j\in\mathbb{Z}}\varphi(A_j^{\alpha}\otimes s^j\mathbf{t}^{\mathbf{r}})(\zeta^{-k}z)^{-j}$$

and

$$-\frac{1}{h}D_z\sum_{j\in\mathbb{Z}}\varphi(s^{jh}\mathbf{t}^{\mathbf{r}}K_0)z^{-jh}+\sum_{p=1}^{n}r_p\sum_{j\in\mathbb{Z}}\varphi(s^{jh}\mathbf{t}^{\mathbf{r}}K_p)z^{-jh}=0,$$

where $D_z=z(\partial/\partial z)$. We have to show that the same relations hold for the right-hand sides of (4.1)–(4.5). Indeed, noting that $\lambda_i^{\sigma^k(\alpha)}=\zeta^{-km_i}\lambda_i^{\alpha}$ we obtain

$$A^{\sigma^k(\alpha)}(z,\mathbf{r})=\Lambda_0(A_0^{\sigma^k(\alpha)}\otimes s^0)\exp\left(\sum_{i=1}^{\infty}\lambda_i^{\alpha}\zeta^{-km_i}z^{b_i}x_i\right)\exp\left(-\sum_{i=1}^{\infty}\lambda_{1-i}^{\alpha}\zeta^{km_i}\frac{z^{-b_i}}{b_i}\frac{\partial}{\partial x_i}\right)K_0(z,\mathbf{r})$$

$$=\Lambda_0(A_0^{\alpha}\otimes s^0)\exp\left(\sum_{i=1}^{\infty}\lambda_i^{\alpha}(\zeta^{-k}z)^{b_i}x_i\right)\exp\left(-\sum_{i=1}^{\infty}\lambda_{1-i}^{\alpha}\frac{(\zeta^{-k}z)^{-b_i}}{b_i}\frac{\partial}{\partial x_i}\right)K_0(\zeta^{-k}z,\mathbf{r})$$

$$=A^{\alpha}(\zeta^{-k}z,\mathbf{r}).$$

The verification of the second relation is also straightforward:

$$D_zK_0(z,\mathbf{r})=D_z\mathbf{q}^{\mathbf{r}}\exp\left(\sum_{p=1}^{n}r_p\sum_{j\geqslant 1}z^{jh}u_{pj}\right)\exp\left(-\sum_{p=1}^{n}r_p\sum_{j\geqslant 1}\frac{z^{-jh}}{j}\frac{\partial}{\partial v_{pj}}\right)$$

$$=\sum_{p=1}^{n}r_p\left\{\sum_{j\geqslant 1}z^{jh}jhu_{pj}+\sum_{j\geqslant 1}z^{-jh}h\frac{\partial}{\partial v_{pj}}\right\}K_0(z,\mathbf{r})=h\sum_{p=1}^{n}r_pK_p(z,\mathbf{r}).$$

Observing that the momenta of the series on the left-hand sides of (4.1)–(4.5) span $\mathfrak{g}$ we conclude that the linear map φ: $\mathfrak{g}\to\mathrm{End}(F)$ is well-defined. We need to show now that φ is a homomorphism of Lie algebras.

The following Lemma and its Corollary which we state without proof are very useful for the computations with formal series.

Lemma 6: (cf. Proposition 2.2.2 in Ref. 15). *Let*

$$\delta(z)=\sum_{k\in\mathbb{Z}}z^k,\quad D\delta(z)=D_z\delta(z)=\sum_{k\in\mathbb{Z}}kz^k.$$

If the products in the left-hand sides exist then the following equalities hold:

$$(i)\quad X(z_1)\delta\left(\frac{z_2}{z_1}\right)=X(z_2)\delta\left(\frac{z_2}{z_1}\right),$$

$$(ii)\quad X(z_1)D\delta\left(\frac{z_2}{z_1}\right)=X(z_2)D\delta\left(\frac{z_2}{z_1}\right)+D_{z_2}(X(z_2))\,\delta\left(\frac{z_2}{z_1}\right).$$

Corollary 7: Let $X(z)=Y(z^h)$. The following equalities hold provided the products in the left-hand sides exist:

$$(i)\quad X(z_1)\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)=X(z_2)\delta\left(\left(\frac{z_2}{z_1}\right)^h\right),$$

$$(ii)\quad X(z_1)D\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)=X(z_2)D\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)+\frac{1}{h}D_{z_2}(X(z_2))\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right).$$

Note that $A^{\alpha}(z,\mathbf{r})=A^{\alpha}(z)K_0(z,\mathbf{r})$ and $T_i(z,\mathbf{r})=T_i(z)K_0(z,\mathbf{r})$, hence for every $B\in\dot{\mathfrak{g}}$ we have $B(z,\mathbf{r})=B(z)K_0(z,\mathbf{r})$.

In order to verify the commutator relations between the elements of $\Sigma_{j\in\mathbb{Z}}\dot{\mathfrak{g}}_j\otimes s^j\times[\mathbb{C}[t_1^{\pm},\ldots,t_n^{\pm}]$ we have to show that for every $A,B\in\dot{\mathfrak{g}}$,

$$\sum_{j,i\in\mathbb{Z}}\varphi([A_j\otimes s^j\mathbf{t}^{\mathbf{r}},B_i\otimes s^i\mathbf{t}^{\mathbf{m}}])z_1^{-j}z_2^{-i}=\sum_{j,i\in\mathbb{Z}}[\varphi(A_j\otimes s^j\mathbf{t}^{\mathbf{r}}),\varphi(B_i\otimes s^i\mathbf{t}^{\mathbf{m}})]z_1^{-j}z_2^{-i}.\qquad(5.1)$$

Indeed, let $C^j=[A_j,B]$. Then

$$\sum_{j,i\in\mathbb{Z}} \varphi([A_j\otimes s^j\mathbf{t}^{\mathbf{r}},B_i\otimes s^i\mathbf{t}^{\mathbf{m}}])z_1^{-j}z_2^{-i}$$

$$=\sum_{j,i\in\mathbb{Z}} \varphi([A_j,B_i]\otimes s^{j+i}\mathbf{t}^{\mathbf{r}+\mathbf{m}})z_1^{-j}z_2^{-i}+\sum_{j,i\in\mathbb{Z}}(A_j|B_i)\varphi\left(s^{j+i}\mathbf{t}^{\mathbf{r}+\mathbf{m}}\left(\frac{j}{h}K_0+\sum_{p=1}^{n} r_pK_p\right)\right)$$

$$=\sum_{j\in\mathbb{Z}}\sum_{k=j+i\in\mathbb{Z}} \varphi([A_j,B_{k-j}]\otimes s^k\mathbf{t}^{\mathbf{r}+\mathbf{m}})z_1^{-j}z_2^{j-k}$$

$$+\sum_{j_1=1}^{h}\sum_{\substack{j_2\in\mathbb{Z}\\ j=j_1+hj_2}}\sum_{\substack{i_2\in\mathbb{Z}\\ i=-j_1+hi_2}}(A_{j_1}|B_{-j_1})\frac{j_1+hj_2}{h}\varphi(s^{h(j_2+i_2)}\mathbf{t}^{\mathbf{r}+\mathbf{m}}K_0)z_1^{-j_1-hj_2}z_2^{j_1-hi_2}$$

$$+\sum_{j_1=1}^{h}\sum_{\substack{j_2\in\mathbb{Z}\\ j=j_1+hj_2}}\sum_{\substack{i_2\in\mathbb{Z}\\ i=-j_1+hi_2}}(A_{j_1}|B_{-j_1})\sum_{p=1}^{n} r_p\varphi(s^{h(j_2+i_2)}\mathbf{t}^{\mathbf{r}+\mathbf{m}}K_p)z_1^{-j_1-hj_2}z_2^{j_1-hi_2}$$

$$=\sum_{j_1=1}^{h}\sum_{j_2\in\mathbb{Z}}\sum_{k\in\mathbb{Z}}\varphi(C_k^{j_1}\otimes s^k\mathbf{t}^{\mathbf{r}+\mathbf{m}})z_2^{-k}\left(\frac{z_2}{z_1}\right)^{j_1}\left(\frac{z_2}{z_1}\right)^{hj_2}$$

$$+\sum_{j_1=1}^{h}\sum_{j_2\in\mathbb{Z}}\sum_{k=j_2+i_2\in\mathbb{Z}}(A_{j_1}|B_{-j_1})\frac{j_1+hj_2}{h}\varphi(s^{hk}\mathbf{t}^{\mathbf{r}+\mathbf{m}}K_0)z_1^{-j_1-hj_2}z_2^{j_1+hj_2-hk}$$

$$+\sum_{j_1=1}^{h}\sum_{j_2\in\mathbb{Z}}\sum_{k=j_2+i_2\in\mathbb{Z}}(A_{j_1}|B_{-j_1})\sum_{p=1}^{n} r_p\varphi(s^{hk}\mathbf{t}^{\mathbf{r}+\mathbf{m}}K_p)z_1^{-j_1-hj_2}z_2^{j_1+hj_2-hk}$$

$$=\sum_{j_1=1}^{h} C^{j_1}(z_2,\mathbf{r}+\mathbf{m})\left(\frac{z_2}{z_1}\right)^{j_1}\delta\left(\left(\frac{z_2}{z_1}\right)^{h}\right)+\frac{1}{h}\sum_{j_1=1}^{h} j_1(A_{j_1}|B_{-j_1})K_0(z_2,\mathbf{r}+\mathbf{m})$$

$$\times\left(\frac{z_2}{z_1}\right)^{j_1}\delta\left(\left(\frac{z_2}{z_1}\right)^{h}\right)+\sum_{p=1}^{n} r_p\sum_{j_1=1}^{h}(A_{j_1}|B_{-j_1})K_p(z_2,\mathbf{r}+\mathbf{m})\left(\frac{z_2}{z_1}\right)^{j_1}\delta\left(\left(\frac{z_2}{z_1}\right)^{h}\right)$$

$$+\sum_{j_1=1}^{h}(A_{j_1}|B_{-j_1})K_0(z_2,\mathbf{r}+\mathbf{m})\left(\frac{z_2}{z_1}\right)^{j_1}D\delta\left(\left(\frac{z_2}{z_1}\right)^{h}\right).$$

For the right-hand side of (5.1) we use Corollary 3, Corollary 7, and the fact that $K_0(z,\mathbf{r})K_0(z,\mathbf{m})=K_0(z,\mathbf{r}+\mathbf{m})$:

$$\sum_{j,i\in\mathbb{Z}}[\varphi(A_j\otimes s^j\mathbf{t}^{\mathbf{r}}),\varphi(B_i\otimes s^i\mathbf{t}^{\mathbf{m}})]z_1^{-j}z_2^{-i}$$

$$=[A(z_1,\mathbf{r}),B(z_2,\mathbf{m})]$$

$$=[A(z_1)K_0(z_1,\mathbf{r}),B(z_2)K_0(z_2,\mathbf{m})]$$

$$=[A(z_1),B(z_2)]K_0(z_1,\mathbf{r})K_0(z_2,\mathbf{m})$$

$$=\sum_{j=1}^{h} C^j(z_2)\left(\frac{z_2}{z_1}\right)^{j}\delta\left(\left(\frac{z_2}{z_1}\right)^{h}\right)K_0(z_1,\mathbf{r})K_0(z_2,\mathbf{m})$$

$$+\frac{1}{h}\sum_{j=1}^{h} j(A_j|B_{-j})\left(\frac{z_2}{z_1}\right)^{j}\delta\left(\left(\frac{z_2}{z_1}\right)^{h}\right)K_0(z_1,\mathbf{r})K_0(z_2,\mathbf{m})$$

$$+\sum_{j=1}^{h}(A_j|B_{-j})\left(\frac{z_2}{z_1}\right)^{j}D\delta\left(\left(\frac{z_2}{z_1}\right)^{h}\right)K_0(z_1,\mathbf{r})K_0(z_2,\mathbf{m})$$

$$
\begin{aligned}
&=\sum_{j=1}^{h} C^j(z_2)\left(\frac{z_2}{z_1}\right)^j \delta\left(\left(\frac{z_2}{z_1}\right)^h\right) K_0(z_2,\mathbf{r})K_0(z_2,\mathbf{m})\\
&\quad+\frac{1}{h}\sum_{j=1}^{h} j(A_j|B_{-j})\left(\frac{z_2}{z_1}\right)^j \delta\left(\left(\frac{z_2}{z_1}\right)^h\right) K_0(z_2,\mathbf{r})K_0(z_2,\mathbf{m})\\
&\quad+\sum_{j=1}^{h} (A_j|B_{-j})\left(\frac{z_2}{z_1}\right)^j D\delta\left(\left(\frac{z_2}{z_1}\right)^h\right) K_0(z_2,\mathbf{r})K_0(z_2,\mathbf{m})\\
&\quad+\sum_{j=1}^{h} (A_j|B_{-j})\left(\frac{z_2}{z_1}\right)^j \delta\left(\left(\frac{z_2}{z_1}\right)^h\right) \frac{1}{h} D_{z_2}(K_0(z_2,\mathbf{r}))K_0(z_2,\mathbf{m})\\
&=\sum_{j=1}^{h} C^j(z_2)\left(\frac{z_2}{z_1}\right)^j \delta\left(\left(\frac{z_2}{z_1}\right)^h\right) K_0(z_2,\mathbf{r}+\mathbf{m})+\frac{1}{h}\sum_{j=1}^{h} j(A_j|B_{-j})\\
&\quad\times\left(\frac{z_2}{z_1}\right)^j \delta\left(\left(\frac{z_2}{z_1}\right)^h\right) K_0(z_2,\mathbf{r}+\mathbf{m})+\sum_{j=1}^{h} (A_j|B_{-j})\left(\frac{z_2}{z_1}\right)^j D\delta\left(\left(\frac{z_2}{z_1}\right)^h\right) K_0(z_2,\mathbf{r}+\mathbf{m})\\
&\quad+\sum_{j=1}^{h} (A_j|B_{-j})\left(\frac{z_2}{z_1}\right)^j \delta\left(\left(\frac{z_2}{z_1}\right)^h\right) \sum_{p=1}^{n} r_p K_p(z_2)K_0(z_2,\mathbf{r})K_0(z_2,\mathbf{m})\\
&=\sum_{j=1}^{h} C^j(z_2)\left(\frac{z_2}{z_1}\right)^j \delta\left(\left(\frac{z_2}{z_1}\right)^h\right) K_0(z_2,\mathbf{r}+\mathbf{m})+\frac{1}{h}\sum_{j=1}^{h} j(A_j|B_{-j})\\
&\quad\times\left(\frac{z_2}{z_1}\right)^j \delta\left(\left(\frac{z_2}{z_1}\right)^h\right) K_0(z_2,\mathbf{r}+\mathbf{m})+\sum_{p=1}^{n} r_p \sum_{j=1}^{h} (A_j|B_{-j})\left(\frac{z_2}{z_1}\right)^j \delta\left(\left(\frac{z_2}{z_1}\right)^h\right)\\
&\quad\times K_p(z_2,\mathbf{r}+\mathbf{m})+\sum_{j=1}^{h} (A_j|B_{-j})\left(\frac{z_2}{z_1}\right)^j D\delta\left(\left(\frac{z_2}{z_1}\right)^h\right) K_0(z_2,\mathbf{r}+\mathbf{m}).
\end{aligned}
$$

Thus (5.1) holds.

It is easy to see that operators $\varphi(s^{jh}t^{\mathbf{r}}K_p)$, $p=0,1,...,n$ commute with $\varphi(\Sigma_{j\in\mathbb{Z}}\dot{\mathfrak{g}}_j\otimes s^j\times\mathbb{C}[t_1^{\pm},...,t_n^{\pm}]\oplus\mathscr{K})$. This follows from the obvious equalities:

$$[K_p(z_1,\mathbf{r}),A^{\alpha}(z_2,\mathbf{m})]=[K_p(z_1,\mathbf{r}),T_i(z_2,\mathbf{m})]=0,$$

$$[K_a(z_1,\mathbf{r}),K_b(z_2,\mathbf{m})]=0,\quad p,a,b=0,1,...,n.$$

In order to check the action of $\mathscr{D}_+$ on $\Sigma_{j\in\mathbb{Z}}\dot{\mathfrak{g}}_j\otimes s^j\mathbb{C}[t_1^{\pm},...,t_n^{\pm}]$ it is sufficient to verify the following equality for the generating series:

$$\sum_{j,i\in\mathbb{Z}}\varphi([s^{jh}\mathbf{t}^{\mathbf{r}}D_p,s^i\mathbf{t}^{\mathbf{m}}A_i^{\alpha}])z_1^{-jh}z_2^{-i}=\sum_{j,i\in\mathbb{Z}}[\varphi(s^{jh}\mathbf{t}^{\mathbf{r}}D_p),\varphi(A_i^{\alpha}\otimes s^i\mathbf{t}^{\mathbf{m}})]z_1^{-jh}z_2^{-i}. \tag{5.2}$$

The corresponding equalities for $T_i\otimes s^{b_i}\mathbf{t}^{\mathbf{m}}$ and $s^{ih}\mathbf{t}^{\mathbf{m}}K_p$ will follow since $s^{jh}\mathbf{t}^{\mathbf{r}}D_p$ acts as a derivation and $s^i\mathbf{t}^{\mathbf{m}}A_i^{\alpha}$ generate $\Sigma_{j\in\mathbb{Z}}\dot{\mathfrak{g}}_j\otimes s^j\mathbb{C}[t_1^{\pm},...,t_n^{\pm}]\oplus\mathscr{K}$.

Let us prove that (5.2) holds.

$$
\begin{aligned}
\sum_{j,i\in\mathbb{Z}}\varphi([s^{jh}\mathbf{t}^{\mathbf{r}}D_p,s^i\mathbf{t}^{\mathbf{m}}A_i^{\alpha}])z_1^{-jh}z_2^{-i}&=\sum_{j,i\in\mathbb{Z}} m_p\varphi(s^{i+jh}\mathbf{t}^{\mathbf{r}+\mathbf{m}}A_i^{\alpha})z_1^{-jh}z_2^{-i}\\
&=\sum_{j\in\mathbb{Z}}\sum_{k=i+jh\in\mathbb{Z}} m_p\varphi(s^k\mathbf{t}^{\mathbf{r}+\mathbf{m}}A_k^{\alpha})z_1^{-jh}z_2^{-k+jh}\\
&=m_pA^{\alpha}(z_2,\mathbf{r}+\mathbf{m})\delta\left(\left(\frac{z_2}{z_1}\right)^h\right).
\end{aligned}
$$

Next, we will show that the right-hand side of (5.2) reduces to the same expression. In the following computations it will be convenient to denote $\varphi(s^{jh}D_p)=\partial/\partial u_{pj}$ by $\gamma_p(j)$, $\varphi(s^{-jh}D_p)=jv_{pj}$ by $\gamma_p(-j)$ and $\varphi(D_p)=q_p(\partial/\partial q_p)$ by $\gamma_p(0)$. Note that $[\gamma_p(j),K_0(z,\mathbf{m})]=m_p z^{jh}K_0(z,\mathbf{m})$ for $j\in\mathbb{Z}$.

$$\sum_{j,i\in\mathbb{Z}}[\varphi(s^{jh}\mathbf{t}^{\mathbf{r}}D_p),\varphi(A_i^{\alpha}\otimes s^i\mathbf{t}^{\mathbf{m}})]z_1^{-jh}z_2^{-i}=[D_p(z_1,\mathbf{r}),A^{\alpha}(z_2,\mathbf{m})]$$

$$=\left[:\left\{\sum_{j\in\mathbb{Z}}\gamma_p(j)z_1^{-jh}\right\}K_0(z_1,\mathbf{r}):\ ,\ A_{\alpha}(z_2)K_0(z_2,\mathbf{m})\right]$$

$$=A_{\alpha}(z_2)\left[:\left\{\sum_{j\in\mathbb{Z}}\gamma_p(j)z_1^{-jh}\right\}K_0(z_1,\mathbf{r}):\ ,\ K_0(z_2,\mathbf{m})\right]$$

$$=A^{\alpha}(z_2)\left[\left\{\sum_{j<0}\gamma_p(j)z_1^{-jh}\right\}K_0(z_1,\mathbf{r}),\ K_0(z_2,\mathbf{m})\right]$$

$$+A^{\alpha}(z_2)\left[K_0(z_1,\mathbf{r})\left\{\sum_{j\geqslant 0}\gamma_p(j)z_1^{-jh}\right\},\ K_0(z_2,\mathbf{m})\right]$$

$$=A^{\alpha}(z_2)\left[\sum_{j<0}\gamma_p(j)z_1^{-jh},\ K_0(z_2,\mathbf{m})\right]K_0(z_1,\mathbf{r})$$

$$+A^{\alpha}(z_2)K_0(z_1,\mathbf{r})\left[\sum_{j\geqslant 0}\gamma_p(j)z_1^{-jh},\ K_0(z_2,\mathbf{m})\right]$$

$$=A^{\alpha}(z_2)\sum_{j<0}z_1^{-jh}z_2^{jh}m_pK_0(z_2,\mathbf{m})K_0(z_1,\mathbf{r})$$

$$+A^{\alpha}(z_2)K_0(z_1,\mathbf{r})\sum_{j\geqslant 0}z_1^{-jh}z_2^{jh}m_pK_0(z_2,\mathbf{m})$$

$$=m_pA^{\alpha}(z_2)K_0(z_1,\mathbf{r})K_0(z_2,\mathbf{m})\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)$$

$$=m_pA^{\alpha}(z_2)K_0(z_2,\mathbf{r})K_0(z_2,\mathbf{m})\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)=m_pA^{\alpha}(z_2,\mathbf{r}+\mathbf{m})\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right).$$

From the above computation we can see that

$$[D_p(z_1,\mathbf{r}),K_0(z_2,\mathbf{m})]=m_pK_0(z_2,\mathbf{r}+\mathbf{m})\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right).$$

To complete the proof of Theorem 5 we need to compute the commutators $[\varphi(s^{jh}\mathbf{t}^{\mathbf{r}}D_a),\varphi(s^{ih}\mathbf{t}^{\mathbf{m}}D_b)]$. We will check the following equality for the generating series:

$$\sum_{j,i\in\mathbb{Z}}\varphi([s^{jh}\mathbf{t}^{\mathbf{r}}D_a,\quad s^{ih}\mathbf{t}^{\mathbf{m}}D_b])z_1^{-jh}z_2^{-ih}=\sum_{j,i\in\mathbb{Z}}[\varphi(s^{jh}\mathbf{t}^{\mathbf{r}}D_a),\quad \varphi(s^{ih}\mathbf{t}^{\mathbf{m}}D_b)]z_1^{-jh}z_2^{-ih}. \quad (5.3)$$

To compute the left-hand side we use multiplication in $\mathfrak{g}$:

$$\sum_{j,i\in\mathbb{Z}}\varphi([s^{jh}\mathbf{t}^{\mathbf{r}}D_a,s^{ih}\mathbf{t}^{\mathbf{m}}D_b])z_1^{-jh}z_2^{-ih}$$

$$=\sum_{j,i\in\mathbb{Z}}\varphi(m_a s^{(j+i)h}\mathbf{t}^{\mathbf{r}+\mathbf{m}}D_b-r_b s^{(j+i)h}\mathbf{t}^{\mathbf{r}+\mathbf{m}}D_a)z_1^{-jh}z_2^{-ih}$$

$$-m_a r_b\varphi\left(s^{(j+i)h}\mathbf{t}^{\mathbf{r}+\mathbf{m}}\left\{jK_0+\sum_{p=1}^{n}r_pK_p\right\}\right)z_1^{-jh}z_2^{-ih}$$

$$=\sum_{j\in\mathbb{Z}}\sum_{k=j+i\in\mathbb{Z}}(m_a\varphi(s^{kh}\mathbf{t}^{\mathbf{r}+\mathbf{m}}D_b)-r_b\varphi(s^{kh}\mathbf{t}^{\mathbf{r}+\mathbf{m}}D_a))z_1^{-jh}z_2^{-kh+jh}$$

$$-\sum_{j\in\mathbb{Z}}\sum_{k=j+i\in\mathbb{Z}}m_a r_b\varphi\left(s^{kh}\mathbf{t}^{\mathbf{r}+\mathbf{m}}\left\{jK_0+\sum_{p=1}^{n}r_pK_p\right\}\right)\Bigg)z_1^{-jh}z_2^{-kh+jh}$$

$$=(m_aD_b(z_2,\mathbf{r}+\mathbf{m})-r_bD_a(z_2,\mathbf{r}+\mathbf{m}))\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)$$

$$-m_a r_b\sum_{p=1}^{n}r_pK_p(z_2,\mathbf{r}+\mathbf{m})\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)-m_a r_bK_0(z_2,\mathbf{r}+\mathbf{m})D\delta\left(\left(\frac{z_2}{z_1}\right)^h\right).$$

Observe that

$$[D_a(z,\mathbf{r}),\gamma_b(i)]=\left[:\left\{\sum_{j\in\mathbb{Z}}\gamma_a(j)z^{-jh}\right\}K_0(z,\mathbf{r}):,\gamma_b(i)\right]$$

$$=\left[\sum_{j<0}\gamma_a(j)z^{-jh}K_0(z,\mathbf{r}),\gamma_b(i)\right]+\left[K_0(z,\mathbf{r})\sum_{j\geqslant 0}\gamma_a(j)z^{-jh},\gamma_b(i)\right]$$

$$=\sum_{j<0}\gamma_a(j)z^{-jh}[K_0(z,\mathbf{r}),\gamma_b(i)]+[K_0(z,\mathbf{r}),\gamma_b(i)]\sum_{j\geqslant 0}\gamma_a(j)z^{-jh}$$

$$=-r_bz^{ih}\sum_{j<0}\gamma_a(j)z^{-jh}K_0(z,\mathbf{r})-r_bz^{ih}K_0(z,\mathbf{r})\sum_{j\geqslant 0}\gamma_a(j)z^{-jh}$$

$$=-r_bz^{ih}D_a(z,\mathbf{r}).$$

We use the last equality to compute the right-hand side of (5.3):

$$\sum_{j,i\in\mathbb{Z}}[\varphi(s^{jh}\mathbf{t}^{\mathbf{r}}D_a),\varphi(s^{ih}\mathbf{t}^{\mathbf{m}}D_b)]z_1^{-jh}z_2^{-ih}$$

$$=[D_a(z_1,\mathbf{r}),D_b(z_2,\mathbf{m})]$$

$$=\left[D_a(z_1,\mathbf{r}),\sum_{i<0}\gamma_b(i)z_2^{-ih}K_0(z_2,\mathbf{m})\right]+\left[D_a(z_1,\mathbf{r}),K_0(z_2,\mathbf{m})\sum_{i\geqslant 0}\gamma_b(i)z_2^{-ih}\right]$$

$$=\sum_{i<0}[D_a(z_1,\mathbf{r}),\gamma_b(i)]z_2^{-ih}K_0(z_2,\mathbf{m})+\sum_{i<0}\gamma_b(i)z_2^{-ih}[D_a(z_1,\mathbf{r}),K_0(z_2,\mathbf{m})]$$

$$+[D_a(z_1,\mathbf{r}),K_0(z_2,\mathbf{m})]\sum_{i\geqslant 0}\gamma_b(i)z_2^{-ih}+K_0(z_2,\mathbf{m})\sum_{i\geqslant 0}[D_a(z_1,\mathbf{r}),\gamma_b(i)]z_2^{-ih}$$

$$=-r_b\sum_{i<0}D_a(z_1,\mathbf{r})z_1^{ih}z_2^{-ih}K_0(z_2,\mathbf{m})+\sum_{i<0}\gamma_b(i)z_2^{-ih}m_aK_0(z_2,\mathbf{r}+\mathbf{m})\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)$$

$$+m_aK_0(z_2,\mathbf{r}+\mathbf{m})\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)\sum_{i\geqslant 0}\gamma_b(i)z_2^{-ih}-r_bK_0(z_2,\mathbf{m})\sum_{i\geqslant 0}D_a(z_1,\mathbf{r})z_1^{ih}z_2^{-ih}$$

$$
\begin{aligned}
&= m_a D_b(z_2,\mathbf{r}+\mathbf{m})\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right) - r_b \sum_{i<0}\left(\frac{z_1}{z_2}\right)^{ih} \sum_{j<0} \gamma_a(j) z_1^{-jh} K_0(z_1,\mathbf{r}) K_0(z_2,\mathbf{m}) \\
&\quad - r_b \sum_{i<0}\left(\frac{z_1}{z_2}\right)^{ih} K_0(z_1,\mathbf{r}) \sum_{j\geqslant 0} \gamma_a(j) z_1^{-jh} K_0(z_2,\mathbf{m}) - r_b K_0(z_2,\mathbf{m}) \sum_{i\geqslant 0} \sum_{j<0} \gamma_a(j) z_1^{-jh} K_0(z_1,\mathbf{r}) \\
&\quad \times \left(\frac{z_1}{z_2}\right)^{ih} - r_b K_0(z_2,\mathbf{m}) \sum_{i\geqslant 0} K_0(z_1,\mathbf{r}) \left(\frac{z_1}{z_2}\right)^{ih} \sum_{j\geqslant 0} \gamma_a(j) z_1^{-jh} \\
&= m_a D_b(z_2,\mathbf{r}+\mathbf{m})\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right) - r_b \sum_{i<0} \sum_{j<0} \left(\frac{z_1}{z_2}\right)^{ih} z_1^{-jh} \gamma_a(j) K_0(z_1,\mathbf{r}) K_0(z_2,\mathbf{m}) \\
&\quad - r_b \sum_{i<0} \sum_{j\geqslant 0} \left(\frac{z_1}{z_2}\right)^{ih} z_1^{-jh} K_0(z_1,\mathbf{r}) [\gamma_a(j), K_0(z_2,\mathbf{m})] \\
&\quad - r_b \sum_{i<0} \sum_{j\geqslant 0} \left(\frac{z_1}{z_2}\right)^{ih} z_1^{-jh} K_0(z_1,\mathbf{r}) K_0(z_2,\mathbf{m}) \gamma_a(j) \\
&\quad - r_b \sum_{i\geqslant 0} \sum_{j<0} z_1^{-jh} \left(\frac{z_1}{z_2}\right)^{ih} [K_0(z_2,\mathbf{m}), \gamma_a(j)] K_0(z_1,\mathbf{r}) \\
&\quad - r_b \sum_{i\geqslant 0} \sum_{j<0} z_1^{-jh} \left(\frac{z_1}{z_2}\right)^{ih} \gamma_a(j) K_0(z_2,\mathbf{m}) K_0(z_1,\mathbf{r}) \\
&\quad - r_b \sum_{i\geqslant 0} \sum_{j\geqslant 0} \left(\frac{z_1}{z_2}\right)^{ih} z_1^{-jh} K_0(z_2,\mathbf{m}) K_0(z_1,\mathbf{r}) \gamma_a(j) \\

&= (m_a D_b(z_2,\mathbf{r}+\mathbf{m}) - r_b D_a(z_2,\mathbf{r}+\mathbf{m}))\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right) \\
&\quad - \frac{1}{h} m_a r_b D_{z_2}(K_0(z_2,\mathbf{r})) K_0(z_2,\mathbf{m})\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right) - m_a r_b K_0(z_2,\mathbf{r}) K_0(z_2,\mathbf{m}) D\delta\left(\left(\frac{z_2}{z_1}\right)^h\right) \\
&= (m_a D_b(z_2,\mathbf{r}+\mathbf{m}) - r_b D_a(z_2,\mathbf{r}+\mathbf{m}))\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right) - m_a r_b \sum_{p=1}^{n} r_p K_p(z_2,\mathbf{r}+\mathbf{m})\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)
\end{aligned}
$$

$$-m_a r_b K_0(z_2,\mathbf{r}+\mathbf{m}) D\delta\left(\left(\frac{z_2}{z_1}\right)^h\right).$$

This establishes (5.3) and completes the proof of Theorem 5.

VI. SUGAWARA OPERATORS

In the representation we constructed the operators from $\mathscr{D}_+$ act as derivations on the algebra $\hat{\mathfrak{g}}=\dot{\mathfrak{g}}\otimes\mathbb{C}[t_0^{\pm},t_1^{\pm},\dots,t_n^{\pm}]\oplus\mathscr{K}$. It is possible to extend this action on $\mathscr{D}$, that is to represent $t_0^j\mathbf{t}^{\mathbf{r}}D_0$ by operators on F. For the affine case these are the Sugawara operators.

We will work with the toroidal algebra realized as $\Sigma_{j\in\mathbb{Z}}\,\dot{\mathfrak{g}}_j\otimes s^j\mathbb{C}[t_1^{\pm},\dots,t_n^{\pm}]\oplus\mathscr{K}$. For this realization

$$\psi(t_0^j\mathbf{t}^{\mathbf{r}}D_0)=\frac{1}{h}\,s^{jh}\mathbf{t}^{\mathbf{r}}D_s-\frac{1}{h}\,\nu^{-1}(\rho)\otimes s^{jh}\mathbf{t}^{\mathbf{r}} \tag{6.1}$$

where $\rho\in\dot{\mathfrak{h}}^*$ with $(\rho|\alpha_i)=1$ for every simple root $\alpha_i\in\dot{\Delta}$ and $D_s=s(d/ds)$.

Since for $\alpha\in\Delta$ the elements $A^{\alpha}\otimes t_0^i\mathbf{t}^{\mathbf{m}}$ generate $\hat{\mathfrak{g}}$ then we have to check that

$$\psi([t_0^j\mathbf{t}^{\mathbf{r}}D_0,A^{\alpha}\otimes t_0^i\mathbf{t}_{\mathbf{m}}])=[\psi(t_0^j\mathbf{t}^{\mathbf{r}}D_0),\psi(A^{\alpha}\otimes t_0^i\mathbf{t}^{\mathbf{m}})].$$

Note that $A^{\alpha}\in\dot{\mathfrak{g}}_{ht(\alpha)}$ and $(\rho|\alpha)=ht(\alpha)$.

We have

$$\psi([t_0^j\mathbf{t}^{\mathbf{r}}D_0,A^{\alpha}\otimes t_0^i\mathbf{t}^{\mathbf{m}}])=i\psi(A^{\alpha}\otimes t_0^{i+j}\mathbf{t}^{\mathbf{r}+\mathbf{m}})=iA^{\alpha}\otimes s^{ht(\alpha)+h(i+j)}\mathbf{t}^{\mathbf{r}+\mathbf{m}},$$

while

$$\begin{aligned}[\psi(t_0^j\mathbf{t}^{\mathbf{r}}D_0),\psi(A^{\alpha}\otimes t_i^0\mathbf{t}^{\mathbf{m}})]&=\left[\frac{1}{h}\,s^{jh}\mathbf{t}^{\mathbf{r}}D_s-\frac{1}{h}\,\nu^{-1}(\rho)\otimes s^{jh}\mathbf{t}^{\mathbf{r}},A_{\alpha}\otimes s^{ht(\alpha)+ih}\mathbf{t}^{\mathbf{m}}\right]\\&=\frac{1}{h}\,(ht(\alpha)+ih-(\rho|\alpha))A^{\alpha}\otimes s^{ht(\alpha)+h(i+j)}\mathbf{t}^{\mathbf{r}+\mathbf{m}}\\&=iA^{\alpha}\otimes s^{ht(\alpha)+h(i+j)}\mathbf{t}^{\mathbf{r}+\mathbf{m}}.\end{aligned}$$

This establishes (6.1). It is then sufficient to construct operators on F corresponding to $s^{jh}\mathbf{t}^{\mathbf{r}}D_s$.

It will be convenient to denote in this section $\varphi(T_i\otimes s^{b_i})$ by $\tau(i)$, $\varphi(s^{jh}D_p)$ by $\gamma_p(j)$, and $\varphi(s^{jh}K_p)$ by $\kappa_p(j)$.

In these notations

$$K_0(z,\mathbf{r})=\mathbf{q}^{\mathbf{r}}\exp\left(\sum_{p=1}^{n}r_p\sum_{j\geqslant 1}\frac{\kappa_p(-j)}{j}\,z^{jh}\right)\exp\left(-\sum_{p=1}^{n}r_p\sum_{j\geqslant 1}\frac{\kappa_p(j)}{j}\,z^{-jh}\right),$$

$$A^{\alpha}(z)=\Lambda_0(A_0^{\alpha}\otimes s^0)\exp\left(\sum_{i\geqslant 1}\lambda_i^{\alpha}\,\frac{\tau(1-i)}{b_i}\,z^{b_i}\right)\exp\left(-\sum_{i\geqslant 1}\lambda_{1-i}^{\alpha}\,\frac{\tau(i)}{b_i}\,z^{-b_i}\right).$$

Nontrivial commutators in the principal Heisenberg subalgebra are

$$[\tau(i),\tau(1-i)]=b_i\quad\text{and}\quad[\gamma_p(j),\kappa_p(-j)]=j.$$

The action of the Heisenberg subalgebra on the vertex operators is determined by

$$[\tau(i),A^{\alpha}(z)]=\lambda_i^{\alpha}z^{b_i}A^{\alpha}(z),$$

$$[\gamma_p(j),K_0(z,\mathbf{r})]=r_pz^{jh}K_0(z,\mathbf{r}).$$

Consider the following operators on the space F:

$$L_\tau(j)=\frac{1}{2}\sum_{i\in\mathbb{Z}}:\tau(1-i)\tau(i+j\not{\ell}):,$$

$$L_{\gamma\kappa}(j)=\sum_{p=1}^{n}\sum_{i\in\mathbb{Z}}:\gamma_p(-i)\kappa_p(i+j):.$$

These are the analogs of the Sugawara operators.

Construct the formal generating series for these:

$$D_s(z)=-\sum_{j\in\mathbb{Z}}(L_\tau(j)+hL_{\gamma\kappa}(j))z^{-jh}.$$

Proposition 8: Formula (4.5) together with

$$\sum_{j\in\mathbb{Z}}\varphi(s^{ih}\mathbf{t}^{\mathbf{r}}D_s)z^{-ih}=D_s(z,\mathbf{r})=:D_s(z)K_0(z,\mathbf{r}):$$

defines the representation of the Lie algebra $\mathscr{D}$ on the space

$$\varphi(\hat{\mathfrak{g}})=\varphi\left(\sum_{j\in\mathbb{Z}}\dot{\mathfrak{g}}_j\otimes s^j\mathbb{C}[t_1^{\pm},\ldots,t_n^{\pm}]\oplus\mathscr{K}\right).$$

Proof: We have an action of $\mathscr{D}$ on $\hat{\mathfrak{g}}$ which is a unique extension of its natural action on $\tilde{\mathfrak{g}}$. Thus we need to prove that $\varphi([D,B])=[\varphi(D),\varphi(B)]$ for every $D\in\mathscr{D}$ and $B\in\hat{\mathfrak{g}}$. For subalgebra $\mathscr{D}_+$ this was proved in the course of Theorem 5, hence we need to consider only $D=s^{ih}\mathbf{t}^{\mathbf{r}}D_s$. Since $s^{ih}\mathbf{t}^{\mathbf{r}}D_s$ act on $\hat{\mathfrak{g}}$ as derivations and $\hat{\mathfrak{g}}$ is generated as an algebra by elements $A_j^\alpha\otimes s^j\mathbf{t}^{\mathbf{m}}$ then it is sufficient to prove that

$$\varphi([s^{ih}\mathbf{t}^{\mathbf{r}}D_s,A_j^\alpha\otimes s^j\mathbf{t}^{\mathbf{m}}])=[\varphi(s^{ih}\mathbf{t}^{\mathbf{r}}D_s),\varphi(A_j^\alpha\otimes s^j\mathbf{t}^{\mathbf{m}})].$$

Again we shall replace this with an equivalent identity for the corresponding series:

$$\varphi\left(\left[\sum_{i\in\mathbb{Z}}s^{ih}\mathbf{t}^{\mathbf{r}}D_sz_1^{-ih},\sum_{j\in\mathbb{Z}}A_j^\alpha\otimes s^j\mathbf{t}^{\mathbf{m}}z_2^{-j}\right]\right)=\left[\sum_{i\in\mathbb{Z}}\varphi(s^{ih}\mathbf{t}^{\mathbf{r}}D_s)z_1^{-ih},\sum_{j\in\mathbb{Z}}\varphi(A_j^\alpha\otimes s^j\mathbf{t}^{\mathbf{m}})z_2^{-j}\right]. \tag{6.2}$$

We have

$$\begin{aligned}
&\varphi\left(\left[\sum_{i\in\mathbb{Z}}s^{ih}\mathbf{t}^{\mathbf{r}}D_sz_1^{-ih},\sum_{j\in\mathbb{Z}}A_j^\alpha\otimes s^j\mathbf{t}^{\mathbf{m}}z_2^{-j}\right]\right)\\
&\quad=\sum_{i\in\mathbb{Z}}\sum_{j\in\mathbb{Z}}j\varphi(A_j^\alpha\otimes s^{j+ih}\mathbf{t}^{\mathbf{r}+\mathbf{m}})z_1^{-ih}z_2^{-j}\\
&\quad=\sum_{i\in\mathbb{Z}}\sum_{k=j+ih\in\mathbb{Z}}(k-ih)\varphi(A_k^\alpha\otimes s^k\mathbf{t}^{\mathbf{r}+\mathbf{m}})z_1^{-ih}z_2^{-k+ih}\\
&\quad=\sum_{k\in\mathbb{Z}}k\varphi(A_k^\alpha\otimes s^k\mathbf{t}^{\mathbf{r}+\mathbf{m}})z_2^{-k}\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)-h\sum_{k\in\mathbb{Z}}\varphi(A_k^\alpha\otimes s^k\mathbf{t}^{\mathbf{r}+\mathbf{m}})z_2^{-k}D\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)\\
&\quad=-(D_{z_2}A^\alpha(z_2,\mathbf{r}+\mathbf{m}))\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)-A^\alpha(z_2,\mathbf{r}+\mathbf{m})\left(D_{z_2}\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)\right)\\
&\quad=-D_{z_2}\left(A^\alpha(z_2,\mathbf{r}+\mathbf{m})\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)\right),
\end{aligned}$$

where $D_{z_2}=z_2(\partial/\partial z_2)$.

In order to compute the right-hand side of (6.2), we will need two lemmas.

Lemma 9:

$$(i) \quad [L_\tau(j), A^\alpha(z)] = z^{jh}(D_z + jh)A^\alpha(z),$$

$$(ii) \quad [L_\tau(z_1), A^\alpha(z_2)] = D_{z_2}\left(A^\alpha(z_2)\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)\right).$$

Proof: We will prove (i) assuming that $j \geqslant 0$. The case $j < 0$ is analogous.

$$\begin{aligned}
[L_\tau(j), A^\alpha(z)] &= \frac{1}{2}\left[\sum_{i\in\mathbb{Z}} :\tau(1-i)\tau(i+j\not{\prime}):, A^\alpha(z)\right] \\
&= \frac{1}{2}\left[\sum_{i>0} \tau(1-i)\tau(i+j\not{\prime}), A^\alpha(z)\right] + \frac{1}{2}\left[\sum_{i\leqslant 0} \tau(i+j\not{\prime})\tau(1-i), A^\alpha(z)\right] \\
&= \frac{1}{2}\sum_{i>0} \tau(1-i)[\tau(i+j\not{\prime}), A^\alpha(z)] + \frac{1}{2}\sum_{i>0} [\tau(1-i), A^\alpha(z)]\tau(i+j\not{\prime}) \\
&\quad + \frac{1}{2}\sum_{i\leqslant 0} \tau(i+j\not{\prime})[\tau(1-i), A^\alpha(z)] + \frac{1}{2}\sum_{i\leqslant 0} [\tau(i+j\not{\prime}), A^\alpha(z)]\tau(1-i) \\
&= \frac{1}{2}\sum_{i>0} \tau(1-i)\lambda^\alpha_i z^{b_i+jh}A^\alpha(z) + \frac{1}{2}\sum_{i>0} \lambda^\alpha_{1-i} z^{-b_i}A^\alpha(z)\tau(i+j\not{\prime}) \\
&\quad + \frac{1}{2}\sum_{i\leqslant 0} \tau(i+j\not{\prime})\lambda^\alpha_{1-i} z^{-b_i}A^\alpha(z) + \frac{1}{2}\sum_{i\leqslant 0} \lambda^\alpha_i z^{b_i+jh}A^\alpha(z)\tau(1-i) \\
&= \frac{1}{2}\sum_{i>0} \tau(1-i)\lambda^\alpha_i z^{b_i+jh}A^\alpha(z) + \frac{1}{2}\sum_{i>0} \lambda^\alpha_{1-i} z^{-b_i}A^\alpha(z)\tau(i+j\not{\prime}) \\
&\quad + \frac{1}{2}\sum_{i\leqslant -j\not{\prime}} \tau(i+j\not{\prime})\lambda^\alpha_{1-i} z^{-b_i}A^\alpha(z) + \frac{1}{2}\sum_{-j\not{\prime}<i\leqslant 0} \lambda^\alpha_{1-i} z^{-b_i}[\tau(i+j\not{\prime}), A^\alpha(z)] \\
&\quad + \frac{1}{2}\sum_{-j\not{\prime}<i\leqslant 0} \lambda^\alpha_{1-i} z^{-b_i}A^\alpha(z)\tau(i+j\not{\prime}) + \frac{1}{2}\sum_{i\leqslant 0} \lambda^\alpha_i z^{b_i+jh}A^\alpha(z)\tau(1-i) \\
&= \frac{1}{2}\sum_{k=i>0} \tau(1-k)\lambda^\alpha_k z^{b_k+jh}A^\alpha(z) + \frac{1}{2}\sum_{k=i+j\not{\prime}>j\not{\prime}} \lambda^\alpha_{1-k} z^{-b_k+jh}A^\alpha(z)\tau(k) \\
&\quad + \frac{1}{2}\sum_{k=1-i-j\not{\prime}>0} \lambda^\alpha_k z^{b_k+jh}\tau(1-k)A^\alpha(z) + \frac{1}{2}\sum_{-j\not{\prime}<i\leqslant 0} \lambda^\alpha_{1-i} z^{-b_i}\lambda^\alpha_i z^{b_i+jh}A^\alpha(z) \\
&\quad + \frac{1}{2}\sum_{0<k=i+j\not{\prime}\leqslant j\not{\prime}} \lambda^\alpha_{1-k} z^{-b_k+jh}A^\alpha(z)\tau(k) + \frac{1}{2}\sum_{k=1-i>0} \lambda^\alpha_{1-k} z^{-b_k+jh}A^\alpha(z)\tau(k) \\
&= z^{jh}D_z A^\alpha(z) + \frac{j}{2}\,z^{jh}\left(\sum_{k=1}^{\not{\prime}} \lambda^\alpha_k\lambda^\alpha_{1-k}\right)A^\alpha(z) = z^{jh}(D_z + hj)A^\alpha(z).
\end{aligned}$$

At the last step we used the equality

$$\frac{1}{2}\sum_{k=1}^{\not{\prime}} \lambda^\alpha_k\lambda^\alpha_{1-k} = \frac{1}{2}\sum_{k=1}^{\not{\prime}} (T_k|\nu^{-1}(\alpha))(T_{1-k}|\nu^{-1}(\alpha)) = \frac{h}{2}\,(\nu^{-1}(\alpha)|\nu^{-1}(\alpha)) = \frac{h}{2}\,(\alpha|\alpha) = h,$$

which follows from the fact that $\{1/h\ T_{1-k}\}$ is the dual basis for $\{T_k\}$.

Part (ii) is an immediate consequence of (i):

$$[L_\tau(z_1),A^\alpha(z_2)]=\sum_{j\in\mathbb{Z}} z_1^{-jh}[L_\tau(j),A^\alpha(z_2)]$$

$$=\sum_{j\in\mathbb{Z}} z_1^{-jh}z_2^{jh}(D_{z_2}+hj)A^\alpha(z_2)$$

$$=(D_{z_2}A^\alpha(z_2))\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)+A^\alpha(z_2)\left(D_{z_2}\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)\right)=D_{z_2}\left(A^\alpha(z_2)\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)\right).$$

Lemma 10:

$$[:L_{\gamma\kappa}(z_1)K_0(z_1,\mathbf{r}):,K_0(z_2,\mathbf{m})]=\frac{1}{h}\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)D_{z_2}(K_0(z_2,\mathbf{m}))K_0(z_1,\mathbf{r}).$$

Proof:

$$[:L_{\gamma\kappa}(z_1)K_0(z_1,\mathbf{r}):,K_0(z_2,\mathbf{m})]$$

$$=\sum_{j\in\mathbb{Z}} z_1^{-jh}\sum_{p=1}^{n}\sum_{i>0}[\gamma_p(-i)\kappa_p(i+j)K_0(z_1,\mathbf{r}),K_0(z_2,\mathbf{m})]$$

$$+\sum_{j\in\mathbb{Z}} z_1^{-jh}\sum_{p=1}^{n}\sum_{i\leqslant 0}[\kappa_p(i+j)K_0(z_1,\mathbf{r})\gamma_p(-i),K_0(z_2,\mathbf{m})]$$

$$=\sum_{j\in\mathbb{Z}} z_1^{-jh}\sum_{p=1}^{n}\sum_{i>0}[\gamma_p(-i),K_0(z_2,\mathbf{m})]\kappa_p(i+j)K_0(z_1,\mathbf{r})$$

$$+\sum_{j\in\mathbb{Z}} z_1^{-jh}\sum_{p=1}^{n}\sum_{i\leqslant 0}\kappa_p(i+j)K_0(z_1,\mathbf{r})[\gamma_p(-i),K_0(z_2,\mathbf{m})]$$

$$=\sum_{j\in\mathbb{Z}} z_1^{-jh}\sum_{p=1}^{n}m_p\sum_{i>0} z_2^{-ih}K_0(z_2,\mathbf{m})\kappa_p(i+j)K_0(z_1,\mathbf{r})$$

$$+\sum_{j\in\mathbb{Z}} z_1^{-jh}\sum_{p=1}^{n}m_p\sum_{i\leqslant 0}\kappa_p(i+j)K_0(z_1,\mathbf{r})z_2^{-ih}K_0(z_2,\mathbf{m})$$

$$=\sum_{j\in\mathbb{Z}}\sum_{k=i+j\in\mathbb{Z}}\sum_{p=1}^{n}m_p z_1^{-jh}z_2^{-kh+jh}\kappa_p(k)K_0(z_2,\mathbf{m})K_0(z_1,\mathbf{r})$$

$$=\frac{1}{h}\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)D_{z_2}(K_0(z_2,\mathbf{m}))K_0(z_1,\mathbf{r}).$$

Using these two lemmas we can handle the right-hand side of (6.2).

$$\left[\sum_{i\in\mathbb{Z}}\varphi(s^{ih}\mathbf{t}^{\mathbf{r}}D_s)z_1^{-ih},\ \sum_{j\in\mathbb{Z}}\varphi(A_j^\alpha\otimes s^j\mathbf{t}^{\mathbf{m}})z_2^{-j}\right]$$

$$=[D_s(z_1,\mathbf{r}),\ A^\alpha(z_2,\mathbf{m})]$$

$$=[:D_s(z_1)K_0(z_1,\mathbf{r}):,A^\alpha(z_2)K_0(z_2,\mathbf{m})]$$

$$=-[L_\tau(z_1)K_0(z_1,\mathbf{r}),A^\alpha(z_2)K_0(z_2,\mathbf{m})]-h[:L_{\gamma\kappa}(z_1)K_0(z_1,\mathbf{r}):,A^\alpha(z_2)K_0(z_2,\mathbf{m})]$$

$$=-[L_\tau(z_1),A^\alpha(z_2)]K_0(z_1,\mathbf{r})K_0(z_2,\mathbf{m})-hA^\alpha(z_2)[:L_{\gamma\kappa}(z_1)K_0(z_1,\mathbf{r}):,K_0(z_2,\mathbf{m})]$$

$$=-D_{z_2}\left(A^\alpha(z_2)\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)\right)K_0(z_2,\mathbf{m})K_0(z_1,\mathbf{r})-A^\alpha(z_2)\,\delta\left(\left(\frac{z_2}{z_1}\right)^h\right)D_{z_2}(K_0(z_2,\mathbf{m}))K_0(z_1,\mathbf{r})$$

$$= -D_{z_2}\left(A^{\alpha}(z_2)\,\delta\left(\left(\frac{z_2}{z_1}\right)^{h}\right) K_0(z_2,\mathbf{m})K_0(z_1,\mathbf{r})\right)$$

$$= -D_{z_2}\left(A^{\alpha}(z_2)\,\delta\left(\left(\frac{z_2}{z_1}\right)^{h}\right) K_0(z_2,\mathbf{m})K_0(z_2,\mathbf{r})\right) = -D_{z_2}\left(A^{\alpha}(z_2,\mathbf{r}+\mathbf{m})\,\delta\left(\left(\frac{z_2}{z_1}\right)^{h}\right)\right).$$

I. INTRODUCTION

In this paper, we study highest-weight-type modules over the $N=2$ superconformal algebra and the affine $sl(2)$ algebra and demonstrate the equivalence of the two representation theories modulo the respective spectral flows. The motivation comes partly from the previous analysis of $\widehat{sl}(2)$ fusion rules,[1] which suggests the occurrence of more general modules than the usual Verma modules.[2] The $N=2$ superconformal algebra,[3] which is essential in a number of conformal field-theoretic/string-theoretic constructions is known to have various relations to $\widehat{sl}(2)$. A prerequisite for constructing complete $N=2$ fusion rules is a better understanding of modules over the $N=2$ algebra, and, in particular, in view of a recent progress in constructing $\widehat{sl}(2)$ conformal blocks,[4–6] of their relation to $\widehat{sl}(2)$ modules.

In what follows, we ''compare'' $\widehat{sl}(2)$ and $N=2$ representation theories and then find certain categories built out of representations of these algebras that are equivalent. In particular, we give a complete proof of the conjecture of Ref. 7 that singular vectors in the ''topological'' (≡ ''chiral'') Verma modules over the $N=2$ algebra are isomorphic to singular vectors in $\widehat{sl}(2)$ Verma modules. We extend this result along two directions. First, the relation between topological $N=2$ Verma modules and the standard $\widehat{sl}(2)$ Verma modules is extended to the equivalence of certain categories of representations of the two algebras, which are essentially the respective *twisted* $\mathcal{O}$ categories (see Ref. 8), in fact, the categories of chains of such modules related by the respective spectral flows. Hence, the importance of twisted (≡ spectral-flow-transformed) modules; on the $N=2$ side, such modules have been around for some time,[9,10] while for the $\widehat{sl}(2)$ algebra they do not seem to have previously been studied in any detail (see, however, Ref. 11). In general, the spectral flow transformations and the canonical involution constitute the automorphism group of $\widehat{sl}(2)$ as well as of the $N=2$ algebra; the action of *automorphisms* on representations can be defined in a natural way, hence the appearance of twisted modules.

Second, we extend the correspondence between $\widehat{sl}(2)$ and $N=2$ Verma modules to representations of a different highest-weight type. For the $N=2$ algebra, one should distinguish between two types of Verma-like objects: the topological Verma modules mentioned above, and the so-called *massive* $N=2$ Verma modules. The latter are often considered[12] as the ''standard $N=2$ Verma modules.'' Their $\widehat{sl}(2)$ counterpart, however, is not so standard: these are the *relaxed Verma modules*, which differ from the usual $\widehat{sl}(2)$ Verma modules by somewhat ''relaxed'' highest-weight conditions, and as a result possess infinitely many highest-weight vectors. On the $\widehat{sl}(2)$ side, the standard $\widehat{sl}(2)$ Verma modules may appear as submodules of the relaxed Verma modules. On the $N=2$ side, the situation is similar: a massive Verma module may contain submodules that are topological Verma modules (in fact, *twisted* topological Verma modules; such are, in particular, the submodules generated from the *charged* $N=2$ singular vectors).

It thus turns out that the modules looking ''standard'' on the $N=2$ side correspond to less

standard $\widehat{sl}(2)$ modules, and vice versa, which is one of the reasons for the appearance of many types of modules that we consider in the following.

A proper identification of relaxed Verma modules may be important for constructing the complete $sl(2|1)_q$-symmetric, fusion rules. The $\widehat{sl}(2)$ modules appearing in the fusion constructions and in the constructions of conformal blocks[1,2,4–6] are related to the relaxed Verma modules introduced in this paper. The relaxed Verma modules can be defined as the induced modules from the representations of the *Lie* algebra $sl(2)$ of neither the highest-weight nor the lowest-weight type. In the modules used previously, however, there occur several ''Wakimoto-type'' effects when some singular vectors vanish and cosingular vectors appear instead.

The main results of this paper are (i) the structural theory of the relaxed $\widehat{sl}(2)$ Verma modules, and (ii) the equivalence of categories. As regards the relaxed Verma modules, we classify possible degenerations, explicitly construct singular vectors in the framework of the ''complex-power'' approach,[13] and describe the nature of the corresponding submodules. The structure of relaxed Verma modules, as regards the appearance of submodules, is identical to that of $N=2$ massive Verma modules; see, however, Ref. 14 for the analysis in intrinsic $N=2$ terms.

As to the equivalence of categories, we establish the pairwise equivalence of the following categories of $\widehat{sl}(2)$ modules on the one hand and $N=2$ modules on the other hand (the respective corners of the squares):

$$\begin{array}{ccc} \mathcal{CHW} & \rightsquigarrow & \mathcal{CRHW} \\ \updownarrow & & \updownarrow \\ \mathcal{CVER} & \rightsquigarrow & \mathcal{CRVER} \\ & \widehat{sl}(2) & \end{array} \quad \text{and} \quad \begin{array}{ccc} \mathcal{CTOP} & \rightsquigarrow & \mathcal{CMHW} \\ \updownarrow & & \updownarrow \\ \mathcal{CTVER} & \rightsquigarrow & \mathcal{CMVER} \\ & N=2 & \end{array} \tag{I.1}$$

In this diagram, ''$\mathcal{C}$'' always stands for *chains*, which we define below, of modules from the corresponding categories, while the categories themselves are as follows.

In the $\widehat{sl}(2)$ square, $\mathcal{VER}$ consists of the usual $\widehat{sl}(2)$ Verma modules together with all their images under the spectral flow (i.e., all the twisted Verma modules, which we also define below). Introducing the spectral-flow-transformed $\widehat{sl}(2)$ modules is essential for establishing the relation with $N=2$ modules, where the role of the spectral flow has been appreciated for some time.[15,16] $\mathcal{RVER}$ consists of (twisted) relaxed Verma modules, which differ from the modules from $\mathcal{VER}$ by one missing annihilation condition satisfied by the highest-weight vector: as a result, relaxed Verma modules acquire infinitely many ''almost-highest-weight'' vectors. Further, in the top line of the $\widehat{sl}(2)$ square we have the respective highest-weight-*type* modules, obtained from the bottom line by taking all possible quotient modules and gluing different modules to each other. These ''$\mathcal{O}$'' categories include twisted modules as well; in what follows, we give an intrinsic definition of these categories using a criterion that is invariant under twisting. (The standard definition of the $\mathcal{O}$ category is less convenient in the case involving twisted modules, because the separation of operators from the algebra into creation and annihilation ones depends on the twist.) We call $\mathcal{HW}$ and $\mathcal{RHW}$ the categories of (twisted) highest-weight- and relaxed-highest-weight-*type* modules. For the category $\mathcal{HW}$, therefore, the ''universal'' role of Verma modules in producing irreducible representations (by taking quotients) is played by the standard $\widehat{sl}(2)$ Verma modules $\mathcal{VER}$. As regards $\mathcal{RHW}$, on the other hand, distinguished in this way are the relaxed Verma modules $\mathcal{RVER}$. As a terminological remark, however, let us note that speaking of *Verma* modules in the $\widehat{sl}(2)$ context, we will always mean only the standard Verma modules $\mathcal{VER}$, as opposed to the *relaxed Verma* modules $\mathcal{RVER}$.

On the $N=2$ side, $\mathcal{TVER}$ are the topological Verma modules and all their spectral flow transforms, while $\mathcal{TOP}$ are the corresponding topological-highest-weight-type modules, constructed from modules from $\mathcal{TVER}$ by taking quotients and gluing. We will also give a spectral-flow-invariant criterion that characterizes modules from $\mathcal{TOP}$, irrespective of their twists. Further, $\mathcal{MVER}$ are the twisted massive Verma modules, those with a zero twist are commonly viewed

as the ''standard'' $N=2$ Verma modules. Finally, $\mathcal{MHW}$ is made up of modules of the same highest-weight type as the twisted massive Verma modules, but contains many more modules, all of which can be constructed out of modules from $\mathcal{MVER}$ by taking quotients and gluing. These, too, will be defined in ''intrinsic'' terms (using the condition of terminating fermionic chains).

The *chains* of the corresponding modules have to be introduced since the mapping that we use to establish equivalence of categories maps a given $\widehat{sl}(2)$ module into a sum involving $N=2$ modules twisted by all integers. Taking chains of modules makes the respective corners of the two squares in (I.1) equivalent. In application to Verma-like modules, a part of this statement amounts to the isomorphism between singular vectors in the respective modules. As another consequence, one can further derive identities between characters of certain $\widehat{sl}(2)$ and $N=2$ modules, as we will do in this paper for the ''Verma'' case, and carry over the fusion rules from $\widehat{sl}(2)$ to $N=2$ theories (which is left for the future).

The tools essential for the analysis of $\widehat{sl}(2)$ and $N=2$ modules include diagrams of *extremal vectors*. The idea to consider extremal vectors was put forward in Ref. 17, where it was observed that a number of representation-theoretic problems can naturally be reformulated, and quite often, solved, in terms of extremal vectors. An independent construction of Ref. 10 (and a similar one[18]) can be considered as a manifestation of this general observation.

As regards singular vectors, we borrow from Ref. 10 the construction of $N=2$ singular vectors in terms of continued fermionic operators. We also develop a parallel construction of singular vectors in the relaxed Verma modules over the affine $sl(2)$. The latter construction is formulated in quite different terms than the former, however, the two constructions turn out to be equivalent and, moreover, allow direct mappings between each other. An important point is that the isomorphism between singular vectors requires that one consider the $N=2$ singular vectors that satisfy *twisted* highest-weight conditions. Allowing the singular vectors to satisfy twisted highest-weight conditions makes it possible to choose those representatives among singular vectors with different twists that generate maximal submodules (see Ref. 14 as to how this ''eliminates'' the superfluous $N=2$ subsingular vectors).

In Sec. II, we introduce the $\widehat{sl}(2)$ and $N=2$ superconformal algebras, review some of their properties (in particular, the corresponding spectral flows), investigate the structure of the corresponding Verma modules, and define different categories of such modules. We also introduce auxiliary free-field systems. In Sec. III, we recall the simplest Kazama–Suzuki (KS) mapping[19,20] and construct another mapping, which is essentially inverse to KS, even though it acts between somewhat different spaces; it will be called the anti-KS mapping. These are used in Sec. IV to prove equivalence between the respective categories of $\widehat{sl}(2)$ and $N=2$ representations.

The paper is rather long, which may be partly excused by a large number of modules that we have to introduce in order to keep balance between the $\widehat{sl}(2)$ and $N=2$ sides. We omit some of the proofs.

II. THE $\widehat{sl}(2)$ AND $N=2$ ALGEBRAS, THEIR AUTOMORPHISMS, AND VERMA MODULES

In this section, we introduce the $\widehat{sl}(2)$ and the $N=2$ superconformal algebras. We recall their properties, define several types of modules, and give theorems describing the structure of singular vectors in these modules. We also introduce free-field theories that will be needed for a constructive realization of the mapping between representations of these two algebras.

A. $\widehat{sl}(2)$

Some of the facts given below about the affine $sl(2)$ algebra are well known, yet we hope to avoid being too boring. However, we try to give more details about twisted and ''relaxed'' modules. In Sec. II A 6, we describe singular vectors in relaxed Verma modules, where the situation is more involved than with the standard Verma modules, and give structural theorems about this class of $\widehat{sl}(2)$ modules.

1. $\widehat{sl}(2)$ Verma modules, spectral flow transform, and extremal diagrams

The level-k algebra is defined as

$$[J^0_m,J^\pm_n]=\pm J^\pm_{m+n},\quad [J^0_m,J^0_n]=\frac{K}{2}\,m\,\delta_{m+n,0},$$

$$[J^+_m,J^-_n]=Km\,\delta_{m+n,0}+2J^0_{m+n} \tag{II.1}$$

(where K is the central element, which we will not distinguish from its value k in representations). Commutation relations (II.1) correspond to the following operator product expansions of currents:

$$J^0(z)J^\pm(w)=\pm\frac{J^\pm}{z-w},\quad J^0(z)J^0(w)=\frac{k/2}{(z-w)^2},$$

$$J^+(z)J^-(w)=\frac{k}{(z-w)^2}+\frac{2J^0}{z-w}. \tag{II.2}$$

In terms of the currents, the Sugawara energy–momentum tensor has the form

$$T^{\mathrm{Sug}}=\frac{1}{k+2}\left(J^0J^0+\frac{1}{2}\,(J^+J^-+J^-J^+)\right). \tag{II.3}$$

Here and in what follows, we assume $k\neq -2$. The usual mode expansion of the energy–momentum tensors is $T^{\mathrm{Sug}}(z)=\Sigma_{n\in\mathbb{Z}}L^{\mathrm{Sug}}_n z^{-n-2}$, and similarly for the other energy–momentum tensors that we work with below.

We now define the Verma module $\mathcal{M}_{j,k}$ with the highest-weight vector $|j,k\rangle_{sl(2)}$ in the standard manner, by imposing the following annihilation conditions on the highest-weight vector:

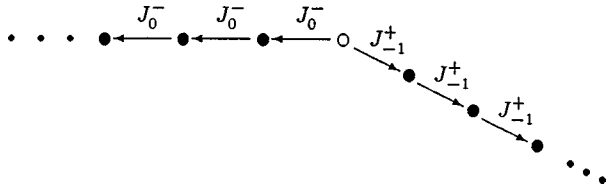
$$\begin{aligned}&J^+_{\geqslant 0}|j,k\rangle_{sl(2)}=J^0_{\geqslant 1}|j,k\rangle_{sl(2)}=J^-_{\geqslant 1}|j,k\rangle_{sl(2)}=0,\\ &J^0_0|j,k\rangle_{sl(2)}=j|j,k\rangle_{sl(2)},\quad K|j,k\rangle_{sl(2)}=k|j,k\rangle_{sl(2)},\end{aligned}\qquad j,k\in\mathbb{C}, \tag{II.4}$$

The module is freely generated from $|j,k\rangle_{sl(2)}$ by the remaining modes of J^+, J^-, and J^0; thus the character of $\mathcal{M}_{j,k}$ is given by

$$\chi^{sl(2)}_{j,k}=(z,q)=\mathrm{Tr}_{\mathcal{M}_{j,k}}(q^{L^{\mathrm{Sug}}_0}z^{J^0_0})=\frac{z^jq^{\Delta_j}}{\Pi^\infty_{i=1}(1-zq^i)\Pi^\infty_{i=0}(1-z^{-1}q^i)\Pi^\infty_{i=1}(1-q^i)}, \tag{II.5}$$

where $\Delta_j=j(j+1)/(k+2)$ is the Sugawara dimension of the highest-weight state.

The $\widehat{sl}(2)$ Verma modules can conveniently be described with the help of the *extremal diagram*,



(II.6)

which expresses the fact that J^+_{-1} and J^-_0 are the highest-level operators that do not yet annihilate the highest-weight state $\circ$. All the other states of the module, according to their (charge, level) bigrading, lie in the interior of the angle in the diagram. In these conventions, e.g., J^0_{-1} is represented by a downward vertical arrow.

We will need automorphisms of the affine $sl(2)$ algebra. These are the canonical involution and the spectral flow transform,[11]

$$\mathcal{U}_\theta:\quad J^+_n\mapsto J^+_{n+\theta},\quad J^-_n\mapsto J^-_{n-\theta},\quad J^0_n\mapsto J^0_n+\frac{k}{2}\,\theta\delta_{n,0},\quad \theta\in\mathbb{Z}. \tag{II.7}$$

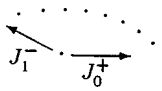
Spectral flow transformations with $\theta \in 2\mathbb{Z}$ are the continuation to the entire algebra of the affine Weyl group action. In general, $\widehat{sl}(2)$ modules are not invariant under the spectral flow and are mapped into ''twisted'' modules. (A notable exception is provided, for $k \in \mathbb{N}$, by the integrable representations. These are invariant under the action of spectral flow transformations with $\theta \in 2\mathbb{Z}$, while the spectral flow transformations with $\theta \in 2\mathbb{Z}+1$ map one integrable representation into another.)

Definition II.1: A twisted Verma module $\mathfrak{M}_{j,k,\theta}$ *is freely generated by* $J^+_{\leqslant \theta-1}$, $J^-_{\leqslant -\theta}$, *and* $J^0_{\leqslant -1}$ *from a twisted highest-weight vector* $|j,k;\theta\rangle_{sl(2)}$ *defined by the conditions*

$$J^+_{\geqslant \theta}|j,k;\theta\rangle_{sl(2)} = J^0_{\geqslant 1}|j,k;\theta\rangle_{sl(2)} = J^-_{\geqslant -\theta+1}|j,k;\theta\rangle_{sl(2)} = 0,$$
$$\left(J^0_0 + \frac{k}{2}\,\theta\right)|j,k;\theta\rangle_{sl(2)} = j|j,k;\theta\rangle_{sl(2)}. \tag{II.8}$$

The respective extremal diagrams are obvious ''rotations'' of (II.6). We identify $|j,k\rangle_{sl(2)} = |j,k;0\rangle_{sl(2)}$.

All possible (integral) twists of Verma modules constitute the category $\mathcal{VER}$. This category is very ''small:'' already in the untwisted case, many (if not all) interesting representations are *not* Verma modules, but rather can be obtained from Verma modules by taking quotients and ''gluing.'' This gives the category $\mathcal{O}$ (see Ref. 8), in which every irreducible representation is a quotient of a Verma module. An important feature, which, in fact, *characterizes* the modules from category $\mathcal{O}$ is that the action of all the annihilation operators on any vector from a given module spans out a finite-dimensional space (and the modules must be finite generated). In terms of extremal diagrams, this means simply that the annihilators act into the interior of the angle,



(II.9)

and therefore continuing to act with the annihilators on a state from a module from $\mathcal{O}$, one inevitably reaches the ''edge,'' at which the annihilators act by zero.

We need an $\mathcal{O}$-type category that would include the twisted modules. A remarkable fact is that it does not have to be defined by ''enumerating'' different twistings of $\mathcal{O}$, as $\cup_{\theta\in\mathbb{Z}}\mathcal{O}_\theta = \cup_{\theta\in\mathbb{Z}}\mathcal{U}_\theta\mathcal{O}$; instead, there exists an intrinsic definition. Consider first the following.

Definition II.2: Let $|X\rangle$ *be an element of a module over the affine* $sl(2)$ *algebra and let us fix an integer* θ. *For* J *being either* J^+ *or* J^-, *we say that the* J_θ *chain terminates on* $|X\rangle$, *and write* $(J_\theta)^{+\infty}|X\rangle = 0$ *if*

$$\exists N \in \mathbb{Z}, \quad n \geqslant N : (J_\theta)^n|X\rangle = 0.$$

Now, the property discussed before Eq. (II.9) is invariant under the twists. This underlies the next definition. Before giving it, let us assume once and for all that all the modules under consideration are finite generated (this requirement is often imposed in the form of the condition that the modules be graded with respect to an appropriate Virasoro generator L_0). Then, we have the following.

Definition II.3: Objects of the category $\mathcal{HW}$ *of* $\widehat{sl}(2)$ *twisted highest-weight-type representations are* $\widehat{sl}(2)$ *modules* $\mathfrak{U}$ *such that the following conditions are satisfied.*

(1) J^0_0 *is a diagonalizable operator, i.e.,* $\mathfrak{U}$ *can be decomposed into a direct sum of* J^0_0 *eigenspaces.*
(2) *The action with all the operators* J^0_p, $p \in \mathbb{N}$, *on any element* $|X\rangle \in \mathfrak{U}$ *spans a finite-dimensional space.*

(3) *For any element* $|X\rangle$ *of* $\mathfrak{U}$,

$$\forall n\in\mathbb{Z},\quad \begin{matrix} \textit{either} & (J_n^+)^{+\infty}|X\rangle=0,\\ \textit{or} & (J_{-n}^-)^{+\infty}|X\rangle=0. \end{matrix} \tag{II.10}$$

Morphisms are standard homomorphisms between $\widehat{sl}(2)$ *modules.*

Thus, conditions (II.10) do not distinguish between different θ twists of category $\mathcal{O}$. Heuristically, these conditions say that each straight line [in the conventions of (II.6)] of $\widehat{sl}(2)$ operators acting in a given module from the category intersects the boundary of the module, or simply that the extremal diagram, even though not of the simple form (II.6), is, nevertheless, angle shaped, the angle being *strictly less* than 180°.

2. Singular vectors in $\widehat{sl}(2)$ Verma modules

A singular vector in a Verma module $\mathcal{M}_{j,k}$ is a vector that is not proportional to the highest-weight vector and nevertheless satisfies the same annihilation conditions (II.4) as the highest-weight vector does.

For $\alpha\in\mathbb{C}$, we introduce the objects $(J_{-1}^+)^\alpha$ and $(J_0^-)^\alpha$ that implement the standard action of generators of the affine Weyl group on the space of highest weights; see Ref. 13 for details. These objects correspond to reflections with respect to two positive simple roots of $\widehat{sl}(2)$. In fact, $(J_{-1}^+)^\alpha$ and $(J_0^-)^\alpha$ define the following Weyl group action on the line $k=\text{const}$ in the kj plane of highest weights:

$$\begin{aligned} &(J_0^-)^{2j+1}{:}\,|j,k\rangle_{sl(2)}\to|-1-j,k\rangle_{sl(2)},\\ &(J_{-1}^+)^{k+1-2j}{:}\,|j,k\rangle_{sl(2)}\to|k+1-j,k\rangle_{sl(2)}. \end{aligned} \tag{II.11}$$

The action of $(J_{-1}^+)^\alpha$ and $(J_0^-)^\alpha$ can be extended from the highest-weight vectors to the Verma modules over these vectors. The extension is given by the following formulas:

$$\begin{aligned} (J_0^-)^\alpha J_m^+ &= -\alpha(\alpha-1)J_m^-(J_0^-)^{\alpha-2}-2\alpha J_m^0(J_0^-)^{\alpha-1}+J_m^+(J_0^-)^\alpha,\\ (J_0^-)^\alpha J_m^0 &= \alpha J_m^-(J_0^-)^{\alpha-1}+J_m^0(J_0^-)^\alpha,\\ (J_{-1}^+)^\alpha J_m^- &= -\alpha(\alpha-1)J_{m-2}^+(J_{-1}^+)^{\alpha-2}-k\alpha\delta_{m-1,0}(J_{-1}^+)^{\alpha-1}+2\alpha J_{m-1}^0(J_{-1}^+)^{\alpha-1}+J_m^-(J_{-1}^+)^\alpha,\\ (J_{-1}^+)^\alpha J_m^0 &= -\alpha J_{m-1}^+(J_{-1}^+)^{\alpha-1}+J_m^0(J_{-1}^+)^\alpha, \end{aligned} \tag{II.12}$$

which can be derived for α being a positive integer and then postulated for an arbitrary complex α. Then, we have the following theorem.

Theorem II.4:

(I) (Ref. 21) *A singular vector exists in the Verma module* $\mathcal{M}_{j,k}$ *over the affine* $sl(2)$ *algebra if and only if* $j=\mathrm{j}^+(r,s,k)$ *or* $j=\mathrm{j}^-(r,s,k)$, *where*

$$\left.\begin{aligned} \mathrm{j}^+(r,s,k)&=\frac{r-1}{2}-(k+2)\,\frac{s-1}{2}\\ \mathrm{j}^{-1}(r,s,k)&=-\frac{r+1}{2}+(k+2)\,\frac{s}{2} \end{aligned}\right\},\quad \begin{matrix} r,s\in\mathbb{N},\\ k\in\mathbb{C}. \end{matrix} \tag{II.13}$$

(II) (Ref. 13) *All singular vectors in the module* $\mathcal{M}_{j^\pm(r,s,k),k}$ *are given by the explicit constructions:*

$$
\begin{aligned}
|\mathrm{MFF}^+(r,s,k)\rangle &= (J_0^-)^{r+(s-1)(k+2)}(J_{-1}^+)^{r+(s-2)(k+2)}(J_0^-)^{r+(s-3)(k+2)}\cdots(J_{-1}^+)^{r-(s-2)(k+2)} \\
&\quad\times(J_0^-)^{r-(s-1)(k+2)}|\mathrm{j}^+(r,s,k),k\rangle_{sl(2)}, \\
|\mathrm{MFF}^-(r,s,k)\rangle &= (J_{-1}^+)^{r+(s-1)(k+2)}(J_0^-)^{r+(s-2)(k+2)}(J_{-1}^+)^{r+(s-3)(k+2)}\cdots(J_0^-)^{r-(s-2)(k+2)} \\
&\quad\times(J_{-1}^+)^{r-(s-1)(k+2)}|\mathrm{j}^-(r,s,k),k\rangle_{sl(2)}.
\end{aligned}
\tag{II.14}
$$

Remark II.5: As is well known,[13] the factors in (II.14) correspond to the affine Weyl group reflections with respect to the simple roots. When there are several singular vectors in a given Verma module, one can have different solutions to Eqs. (II.13) for (r,s), each such pair yielding a singular vector as given by Eqs. (II.14). Whenever we say ''all singular vectors,'' we mean, in accordance with Ref. 22, that the singular vectors are constructed either directly as in (II.14) or—which may be the case for rational k—by composing the factors from two such formulas (the latter being equivalent to truncating a formula from (II.14) as soon as the corresponding Weyl reflections produce a highest weight that differs from the original one by a negative integral multiple of a positive root).

Clearly, singular vectors in the twisted modules $\mathfrak{M}_{j,k;\theta}$ follow from the standard singular vectors (II.14) by applying the spectral flow transform.

3. Relaxed Verma modules

A different class of $\widehat{sl}(2)$ modules can be introduced by relaxing annihilation conditions (II.8).

Definition II.6: For $\theta\in\mathbb{Z}$, the relaxed twisted Verma module $\mathfrak{R}_{j,\Lambda,k;\theta}$ is generated from the state $|j,\Lambda,k;\theta\rangle_{sl(2)}$ that satisfies the annihilation conditions

$$
J^+_{\geqslant\theta+1}|j,\Lambda,k;\theta\rangle_{sl(2)} = J^0_{\geqslant 1}|j,\Lambda,k;\theta\rangle_{sl(2)} = J^-_{\geqslant -\theta+1}|j,\Lambda,k;\theta\rangle_{sl(2)} = 0, \tag{II.15}
$$

by a free action of the operators $J^+_{\leqslant\theta-1}$, $J^-_{\leqslant-\theta-1}$, and $J^0_{\leqslant-1}$ and by the action of operators J^+_θ and $J^-_{-\theta}$ subject to the constraint

$$
J^-_{-\theta}J^+_\theta|j,\Lambda,k;\theta\rangle_{sl(2)} = \Lambda|j,\Lambda,k;\theta\rangle_{sl(2)}. \tag{II.16}
$$

In addition, the highest-weight state $|j,\Lambda,k;\theta\rangle_{sl(2)}$ satisfies

$$
\left(J_0^0+\frac{k}{2}\,\theta\right)|j,\Lambda,k;\theta\rangle_{sl(2)} = j|j,\Lambda,k;\theta\rangle_{sl(2)}. \tag{II.17}
$$

The corresponding extremal diagram opens up to the straight angle; in the case of $\theta=0$ it thus becomes

(II.18)

The state marked with ⋆ is the above $|j,\Lambda,k;\theta\rangle_{sl(2)}$, characterized, besides the level, by two quantum numbers j and Λ. The other states $|j,\Lambda,k;\theta|n\rangle_{sl(2)}$, $n\in\mathbb{Z}$, in the top floor are

$$
|j,\Lambda,k;\theta\rangle_{sl(2)} = \begin{cases} (J^-_{-\theta})^{-n}|j,\Lambda,k;\theta\rangle_{sl(2)}, & n<0, \\ (J^+_\theta)^n|j,\Lambda,k;\theta\rangle_{sl(2)}, & n>0, \end{cases} \tag{II.19}
$$

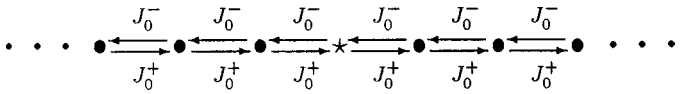
with $|j,\Lambda,k;\theta|0\rangle_{sl(2)} = |j,\Lambda,k;\theta\rangle_{sl(2)}$. We also set $|j,\Lambda,k|n\rangle_{sl(2)} = |j,\Lambda,k;0|n\rangle_{sl(2)}$. The Sugawara dimension of $|j,\Lambda,k;\theta|0\rangle_{sl(2)}$ is

$$
\Delta = \frac{j^2+j+\Lambda}{k+2} - \theta j + \frac{k}{4}\,\theta^2. \tag{II.20}
$$

Remark II.7: As we have already remarked, speaking of *Verma* modules in the $\widehat{sl}(2)$ context, we will always mean only the standard Verma modules, as opposed to the relaxed Verma modules; the same will apply to *Verma* highest-weight conditions, by which we will mean (possibly spectral-flow-transformed) highest-weight conditions in $\mathfrak{M}_{j,k;\theta}$, rather than Eqs. (II.15).

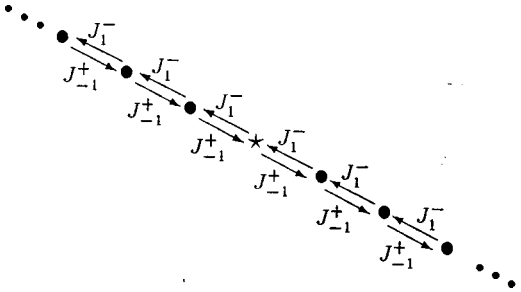
By the *relative charge* of a state $|v\rangle \in \mathcal{R}_{j,\Lambda,k}$ we understand $x=y-j$, where $J_0^0|v\rangle = y|v\rangle$ (and $J_0^0|j,\Lambda,k\rangle = j|j,\Lambda,k\rangle$). Thus, states with a negative (positive) relative charge are on the left (resp., on the right) of $\star = |j,\Lambda,k\rangle$.

In the generic case, one can travel both ways along the extremal diagram: when $\theta=0$, for example, ''untwisted'' diagram (II.18) acquires a ''fat'' form,



(II.21)

while the one with $\theta=-1$,



(II.22)

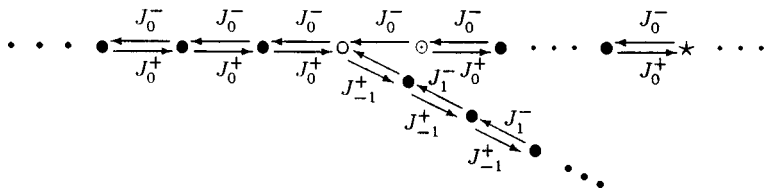
etc. Thus, all the points are equivalent, since the composition of the direct and the inverse arrows does in each case result only in a factor. However, this factor may vanish for some values of the parameters, which gives rise to the ordinary *Verma* modules. Namely, in the untwisted case (II.18), we have

$$\begin{aligned}
n\leqslant 0:\quad & J_0^-|j,\Lambda,k|n\rangle_{sl(2)} &&= |j,\Lambda,k|n-1\rangle_{sl(2)},\\
& J_0^+|j,\Lambda,k|n-1\rangle_{sl(2)} &&= (\Lambda-n(n-1)-2(n-1)j)|j,\Lambda,k|n\rangle_{sl(2)},\\
n\geqslant 0:\quad & J_0^+|j,\Lambda,k|n\rangle_{sl(2)} &&= |j,\Lambda,k|n+1\rangle_{sl(2)},\\
& J_0^-|j,\Lambda,k|n+1\rangle_{sl(2)} &&= (\Lambda-n(n+1)-2nj)|j,\Lambda,k|n\rangle_{sl(2)},
\end{aligned} \tag{II.23}$$

and similarly for nonzero twists $\theta\neq 0$. Whenever the parameters are such that, e.g., $J_0^+\approx 0$ at a certain step, one cannot come back to the $\star$ state by acting with J_0^+:

$$n\leqslant -1:\ \ \Lambda = n(n+1)+2nj \Rightarrow J_0^+|j,\Lambda,k|n\rangle_{sl(2)}=0. \tag{II.24}$$

One keeps on acting with J_{-1}^+ instead (one mode down); and thus the extremal diagram branches



(II.25)

Therefore, any Verma module can be thought of as a *submodule* of a relaxed Verma module. Taking the quotient with respect to this Verma submodule [or, in the notation of (II.25), with

respect to $\circ$], we see that the state $\odot$ would satisfy Verma highest-weight conditions (II.8) with $\theta=1$. Hence, each Verma module is at the same time a *quotient module* of the appropriately twisted relaxed Verma module.

The situation is similar when $J_0^- \approx 0$ at a certain stage in diagram (II.21):

$$n \geqslant 1: \quad \Lambda = n(n-1)+2(n-1)j \Rightarrow J_0^- |j,\Lambda,k|n\rangle_{sl(2)} = 0. \tag{II.26}$$

Then the branching of the extremal diagram is a mirror image of (II.25), and the submodule is given by the spectral flow transform with $\theta=1$ of a standard Verma module. In both cases (II.24) and (II.26), we have

$$J_0^0 |j,\Lambda,k|n\rangle_{sl(2)} = (j+n)|j,\Lambda,k|n\rangle_{sl(2)}, \quad n \in \mathbb{Z}. \tag{II.27}$$

Hence, the Verma-module spin is $j_{\text{Verma}}=j+n$ for $n<0$ (where the Verma submodule in the relaxed module is untwisted), and $j_{\text{Verma}}=j+n+k/2$ for $n>0$ (where the Verma module is twisted by $\theta=1$).

By a straightforward application of the spectral flow, the above considerations translate into those for the *twisted* relaxed Verma modules; diagram (II.25) changes accordingly.

As in the Verma case, we now extend the category $\mathcal{RVER}$ of all twisted relaxed Verma modules to a larger category $\mathcal{RHW}$ of arbitrary (twisted) relaxed-highest-weight-type modules. We use the same method as in the case of the $\mathcal{HW}$ category. Now that the angle in the extremal diagrams has opened up to the straight angle, the extremal diagrams certainly contain straight lines that are infinite on both sides. However, a condition on the class of modules can still be given in the form of the requirement that, starting with any vector from a given module, the action with any of the bent $J^{\pm}$ chains,

terminates.

Definition II.8: The objects of category $\mathcal{RHW}$ are $\widehat{sl}(2)$ modules $\mathcal{U}$ such that the following conditions are satisfied:

(1) *J_0^0 is a diagonalizable operator.*

(2) *The action with all J_p^0, $p \in \mathbb{N}$, on any element $|X\rangle \in \mathfrak{U}$ spans a finite-dimensional space.*

(3) *For any element $|X\rangle$ of $\mathfrak{U}$,*

$$\forall\, \theta \in \mathbb{Z}, \quad \begin{array}{ll} \textit{either} & (J_\theta^+)^{+\infty}|X\rangle = 0, \\ \textit{or} & (J_{-\theta+1}^-)^{+\infty}|X\rangle = 0. \end{array} \tag{II.28}$$

Morphisms are standard homomorphisms between $\widehat{sl}(2)$ modules.

Again, this condition is invariant under the spectral flow, and thus selects all the twisted modules, none of which can be ''over-relaxed'' in the sense of its extremal diagram occupying *more* than half a plane.

4. "Charged" singular vectors

The ''Verma points'' encountered in the top floor of an extremal diagram can, of course, be viewed as singular vectors in the corresponding relaxed Verma module. The construction of these singular vectors is now obvious: we define

$$\Lambda_{\text{ch}}(p,j) = p(p+1)+2pj, \quad p \in \mathbb{Z}; \tag{II.29}$$

then the state

$$|C(p,j,k)\rangle_{sl(2)} = \begin{cases} (J_0^-)^{-p}|j,\Lambda_{\text{ch}}(p,j),k\rangle_{sl(2)}, & p \leqslant -1 \\ (J_0^+)^{p+1}|j,\Lambda_{\text{ch}}(p,j),k\rangle_{sl(2)}, & p \geqslant 0 \end{cases} \tag{II.30}$$

satisfies the Verma highest-weight conditions for $p \leqslant -1$ and the twisted Verma highest-weight conditions with the twist parameter $\theta=1$ for $p \geqslant 1$. We would like to stress that (II.30) follows

immediately from the analysis of extremal diagrams. In fact, these singular vectors may not even deserve a special name, and we mention them specifically in order to make the presentation parallel to the one for the $N=2$ algebra, where ''charged'' singular vectors are traditionally considered as a separate notion[12] [although they are given by an equivalently simple construction;[10] see (II.126)].

5. Relation with the previous constructions of some $\widehat{sl}(2)$ modules

It is of some interest to see how the $\widehat{sl}(2)$ modules constructed using the ''functional realization'' of $sl(2)$, which have appeared in the study of fusion, are related to relaxed Verma modules introduced in this paper. In the untwisted case, consider top-level states (II.18) and assume that Λ is expressed through a superficial variable μ as

$$\Lambda=\mu(\mu-1-2j)$$

(given Λ and j, we would, in general, have two different values of μ, but we do not discuss now how they can be distinguished). Then, *assuming all the relevant factors nonvanishing*, renormalize states (II.19) into

$$|j,\Lambda(\mu,j),k|n\rangle_{sl(2)}=\begin{cases} f_-(n,\mu)|j,\Lambda(\mu,j),k|n\rangle^*, & n\leqslant -1,\\ |j,\Lambda(\mu,j),k|0\rangle^*, & n=0,\\ f_+(n,j,\mu)|j,\Lambda(\mu,j),k|n\rangle^*, & n\geqslant 1,\end{cases} \tag{II.31}$$

where

$$f_-(n,\mu)=(-1)^n\,\frac{\Gamma(1-\mu-n)}{\Gamma(1-\mu)},\quad n\leqslant -1,$$

$$f_+(n,j,\mu)=(-1)^n\,\frac{\Gamma(2j+1-\mu+n)}{\Gamma(2j+1-\mu)},\quad n\geqslant 1. \tag{II.32}$$

Now, we parametrize μ and j as

$$\begin{aligned} j&=\tilde{\mu},\\ \mu&=\tilde{\mu}-s,\end{aligned} \tag{II.33}$$

and introduce a simplified notation,

$$|s,\tilde{\mu},k,n\rangle^{\#}\equiv|\tilde{\mu},(s-\tilde{\mu})(s+\tilde{\mu}+1),k|n\rangle^*. \tag{II.34}$$

Then Eqs. (II.23) are rewritten as

$$\begin{aligned} &J_0^+|s,\tilde{\mu},k,n\rangle^{\#}=-(\tilde{\mu}+n+s+1)|s,\tilde{\mu},k,n+1\rangle^{\#},\\ &J_0^0|s,\tilde{\mu},k,n\rangle^{\#}=(\tilde{\mu}+n)|s,\tilde{\mu},k,n\rangle^{\#},\qquad n\in\mathbb{Z}.\\ &J_0^-|s,\tilde{\mu},k,n\rangle^{\#}=(\tilde{\mu}+n-s-1)|s,\tilde{\mu},k,n-1\rangle^{\#}.\end{aligned} \tag{II.35}$$

We can consider the set of states $|s,\tilde{\mu},k,\cdot\rangle^{\#}$ as representing a state

$$\|s,\tilde{\mu},k\rangle\rangle^{\#}=\{|s,\tilde{\mu},k,\cdot\rangle^{\#}\},$$

which can be written in the ''x representation'' as

$$\langle x\|s,\tilde{\mu},k\rangle\rangle^{\#}=\sum_{n\in\mathbb{Z}}(-1)^n x^{\tilde{\mu}+s+n}|s,\tilde{\mu},k,n\rangle^{\#}, \tag{II.36}$$

so that the action of $J_0^{0,\pm}$ is represented by the right action of the generators,

$$S^+=\frac{\partial}{\partial x},\quad S^0=x\,\frac{\partial}{\partial x}-s,\quad S^-=-x^2\,\frac{\partial}{\partial x}+2sx. \tag{II.37}$$

Denote by $P_{s,\tilde{\mu},k}$ the module freely generated from the states $|s,\tilde{\mu},k,n\rangle^{\#}$, $n\in\mathbb{Z}$, by $J^{\pm,0}_{\leqslant -1}$.

We see from (II.24) and (II.26) that a Verma highest-weight state (a charged singular vector) occurs in the extremal diagram whenever

$$\mu=2j+p,\quad p\in\mathbb{Z},\quad \text{or}\quad \mu=p,\quad p\in\mathbb{Z}. \tag{II.38}$$

Precisely at these values of μ, one of the functions f_+ or f_- either has a pole or is identically zero, which invalidates relations (II.31). Then the charged singular vectors disappear and cosingular vectors appear instead.

6. Singular vectors in relaxed Verma modules

We are going to describe singular vectors in relaxed Verma modules only in the ''untwisted'' case $\theta=0$; similar results for modules with $\theta\neq 0$ can be obtained immediately by applying the spectral flow transform.

Our strategy is to reduce the relaxed case to the case of ordinary Verma modules. Given a relaxed Verma module $\mathcal{R}_{j,\Lambda,k}$, we can arrive at an ordinary Verma module by the following trick. The states $(J_0^-)^{-\mu}|j,\Lambda,k\rangle$ and $(J_0^+)^{\mu+1}|j,\Lambda,k\rangle$ satisfy Verma highest-weight conditions (II.8) with $\theta=0$ or 1, respectively, whenever μ satisfies

$$\mu^2+(2j+1)\mu-\Lambda=0. \tag{II.39}$$

Therefore, the states

$$\begin{aligned}&|j_-,k;0\rangle_{sl(2)}=(J_0^-)^{-\mu}|j,\Lambda,k\rangle,\quad |j'_-,k;0\rangle_{sl(2)}=(J_0^-)^{-\mu'}|j,\Lambda,k\rangle,\quad \mu'=-\mu-2j-1,\\ &|j_+,k;1\rangle_{sl(2)}=(J_0^+)^{\mu+1}|j,\Lambda,k\rangle,\quad |j'_+,k;1\rangle_{sl(2)}=(J_0^+)^{\mu'+1}|j,\Lambda,k\rangle,\quad \mu'=-\mu-2j-1,\end{aligned} \tag{II.40}$$

which, in general, *do not belong to* $\mathcal{R}_{j,\Lambda,k}$, represent Verma highest-weight vectors, with the respective parameters

$$\begin{aligned}&j_-=j+\mu,\quad j'_-=-j-\mu-1,\\ &j_+=j+\mu+1+\frac{k}{2},\quad j'_+=-j-\mu+\frac{k}{2}.\end{aligned} \tag{II.41}$$

We now require that a singular vector exist in one of the ''continued'' modules with the highest-weight states from (II.40). Formulas (II.41) immediately give the following lemma.

Lemma II.9: The following conditions are equivalent:

$$\begin{aligned}&j_-=\mathrm{j}^{\pm}(r,s,k)\Leftrightarrow j'_+=\mathrm{j}^{\mp}(r,s,k)\Leftrightarrow j'_-=\mathrm{j}^{\mp}(r,s\mp 1,k),\\ &j'_-=\mathrm{j}^{\mp}(r,s,k)\Leftrightarrow j_+=\mathrm{j}^{\pm}(r,s,k)\Leftrightarrow j'_+=\mathrm{j}^{\mp}(r,s\pm 1,k).\end{aligned} \tag{II.42}$$

The existence of singular vectors in $\mathcal{R}_{j,\Lambda,k}$ is determined by whether and how many (if any) of the states (II.40) admit a singular vector and/or belong to $\mathcal{R}_{j,\Lambda,k}$. Whenever one of these states belongs to the relaxed Verma module $\mathcal{R}_{j,\Lambda,k}$—or, equivalently, μ or μ' is an integer of the appropriate sign—we arrive at precisely the charged singular vector considered above [observe that (II.29) is nothing but (II.39) with $\mu=p$]. As regards singular vectors that might exist on states (II.40), these must be the MFF vectors, which reduces the problem of explicitly constructing singular vectors in $\mathcal{R}_{j,\Lambda,k}$ to the MFF singular vectors.

We see from (II.41) and (II.39) that the condition for $\mathcal{R}_{j,\Lambda,k}$ to contain a relaxed Verma submodule reads as $\Lambda=\Lambda(r,s,j,k)$, where

$$\Lambda(r,s,j,k)=-(j-\mathrm{j}^-(r,s,k))(j-\mathrm{j}^+(r,s+1,k)). \tag{II.43}$$

Then, the state $(J_0^-)^{-\mu}|j,\Lambda(r,s,j,k),k\rangle_{sl(2)}$, which satisfies the Verma highest-weight conditions, has the spin $\mathrm{j}^-(r,s,k)$. Therefore the singular vector constructed on this state reads as

$$\mathcal{MFF}^-(r,s,k)(J_0^-)^{-\mathrm{j}^-(r,s,k)+j}|j,\Lambda(r,s,j,k),k\rangle_{sl(2)}, \tag{II.44}$$

where $\mathcal{MFF}^-$ is the singular vector *operator* [read off by dropping the highest-weight state in (II.14)]. This Verma-module singular vector has to be mapped back to the original relaxed Verma module $\mathcal{R}_{j,\Lambda(r,s,j,k),k}$, where it will become a relaxed singular vector. In particular, no nonintegral powers of J_0^- should remain, which is achieved by acting on (II.44) with $(J_0^-)^{\mathrm{j}^-(r,s,k)-j+N}$, where N is an integer, and making use of (II.12). However, to be left with only *positive* integral powers after the rearrangements, the integer N has to be $\geqslant r+rs$. We thus define

$$|\Sigma^-(r,s,j,k)\rangle=(J_0^-)^{\mathrm{j}^-(r,s,k)-j+r+rs}\mathcal{MFF}^-(r,s,k)(J_0^-)^{-\mathrm{j}^-(r,s,k)+j}|j,\Lambda(r,s,j,k),k\rangle_{sl(2)}, \tag{II.45}$$

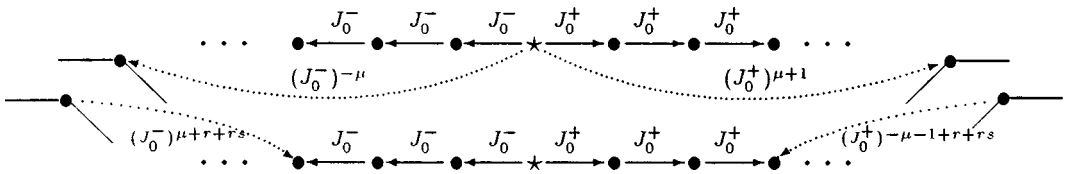
as a ''canonical'' representative of the relaxed singular vector in $\mathcal{R}_{j,\Lambda(r,s,j,k),k}$.

Similarly, the state $(J_0^+)^{\mu+1}|j,\Lambda(r,s,j,k),k\rangle$ with μ as in (II.41), i.e., $(J_0^+)^{1+\mathrm{j}^+(r,s+1,k)-j}\cdot|j,\Lambda(r,s,j,k),k\rangle_{sl(2)}$, is a Verma highest-weight state twisted by the spectral flow transform with $\theta=1$. We then construct the corresponding MFF singular vector and finally map it back to the relaxed Verma module. In this way, the singular vector in the relaxed Verma module becomes

$$|\Sigma^+(r,s,j,k)\rangle=(J_0^+)^{-1-\mathrm{j}^+(r,s+1,k)+j+r+rs}\mathcal{MFF}^{+,1}(r,s,k)(J_0^+)^{1+\mathrm{j}^+(r,s+1,k)-j}|j,\Lambda(r,s,j,k),k\rangle_{sl(2)}, \tag{II.46}$$

where $\mathcal{MFF}^{+,\theta}$ is the spectral flow transform (II.7) of the singular vector operator $\mathcal{MFF}^+$.

The construction can be illustrated in the following extremal diagram:



(II.47)

Every point in the lower floor is annihilated by the operators $J_{\geqslant 1}^{\pm,0}$ and, thus, satisfies the relaxed highest-weight conditions. The Verma module shown on the left contains a submodule. The Verma module and its submodule on the right are ''rotated'' by the spectral flow transform with $\theta=1$. The Verma modules are to be thought of as disconnected from the extremal diagram of the relaxed Verma module $\mathcal{R}_{j,\Lambda(r,s,j,k),k}$, since they do not, in general, belong to $\mathcal{R}_{j,\Lambda(r,s,j,k),k}$ (the mappings shown in dotted lines are given by complex powers of the generators).

Expressions (II.46), (II.45), and (II.30) give explicit constructions for singular vectors that can appear in relaxed Verma modules. In order to describe all degenerate cases with several singular vectors in $\mathcal{R}_{j,\Lambda,k}$ appearing simultaneously, we first classify the different degeneration patterns. Recall that, while the module $\mathcal{R}_{j,\Lambda,k}$ is irreducible for general j, Λ, and k, singular vectors appear in codimension 1, when these parameters are related by one equation. In the general case in codimension 1, j and k are still arbitrary. To describe degeneration patterns in higher codimensions, we divide the space of the highest-weights $O\equiv\{(j,\Lambda,k)\}$ into a union $\cup_i O_i=O$ of such O_i that $O_i\cap O_j=\varnothing$ and all modules $\mathcal{R}_{j,\Lambda,k}$ with $(j,\Lambda,k)\in O_i$ have the same type of degeneration for every i.

For brevity, we will say that a highest-weight state admits a singular vector whenever the Verma module generated from that state contains this singular vector and that a highest-weight state admits no singular vectors if no singular vectors exist in the Verma module. The sets $O_1,O_2,\ldots,O_n$ with the above properties can be singled out by requiring that a certain number of the states from (II.40) belong to the relaxed Verma module or/and admit singular vectors. The list of all possible cases is as follows.

codimension 0:

$O_\varnothing$, none of the states (II.40) belong to the module $\mathcal{R}_{j,\Lambda,k}$ and at least one of the states (II.40) admits no singular vectors.

codimension 1:

O_c, exactly one of the states (II.40) belongs to the module $\mathcal{R}_{j,\Lambda,k}$ and none of the states (II.40) admit a singular vector.

O_r, one of the states (II.40) admits precisely one singular vector; each of the other states (II.40) admits at least one singular vector and none of the states (II.40) belong to the module $\mathcal{R}_{j,\Lambda,k}$.

codimension 2:

O_{rr}, each of the states (II.40) admits at least two singular vectors and none of the states from (II.40) belong to $\mathcal{R}_{j,\Lambda,k}$.

O_{cc}, precisely one of the states from each line in (II.40) belongs to $\mathcal{R}_{j,\Lambda,k}$ and none of these two states admit a singular vector.

O_{rc}, one of the states from (II.40) belongs to $\mathcal{R}_{j,\Lambda,k}$ and admits precisely one singular vector; none of the states (II.40) admit two different singular vectors; no two states from different lines in (II.40) belong to $\mathcal{R}_{j,\Lambda,k}$.

codimension 3:

O_{rrc}, one of the states from (II.40) belongs to $\mathcal{R}_{j,\Lambda,k}$ and admits at least two singular vectors; no two states from different lines in (II.40) belong to $\mathcal{R}_{j,\Lambda,k}$.

O_{rcc}, precisely one of the states from each line in (II.40) belongs to $\mathcal{R}_{j,\Lambda,k}$; each of these two states admits at least one singular vector.

The sets O_i from this list can be singled out by systems of equations. Thus, the O_i of codimension 1 can be thought of as hyperplanes with certain lines eliminated, while the O_i of codimension 2 are lines with some (rational) points eliminated, and the O_i sets of codimension 3 are discrete collections of points.

We will describe degenerate cases in the order given in the above list. To begin with, observe that the completeness of the above list implies that *the relaxed Verma module $\mathcal{R}_{j,\Lambda,k}$ is irreducible if and only if $(j,\Lambda,k)\in O_\varnothing$*. Further, the cases where the relaxed Verma module $\mathcal{R}_{j,\Lambda,k}$ contains precisely one submodule are described in the following theorem. (Whenever we write $k+2=p/q$ or $k=p/q$ with $p\in\mathbb{Z}$, $q\in\mathbb{N}$, we always assume p and q to be coprime.)

Theorem II.10: (I) *The highest-weight (j,Λ,k) of the relaxed Verma module $\mathcal{R}_{j,\Lambda,k}$ belongs to the set O_c if and only if $\Lambda=\Lambda_{\mathrm{ch}}(n,j)$ and*

$$(n,j,k)\in(\mathbb{Z}\times\mathbb{C}\times\mathbb{C})\backslash\{(n,\tfrac{1}{2}(r-2n-1)-\tfrac{1}{2}(k+2)s,k)\,|\,r,s\in\mathbb{Z},r\neq 0,r\cdot s\geqslant 0,n\in\mathbb{Z},k\in\mathbb{C}\}. \tag{II.48}$$

The highest weight of the relaxed Verma module $\mathcal{R}_{j,\Lambda,k}$ belongs to the set O_r if and only if $\Lambda=\Lambda(r,s,j,k)$, with

$$(r,s,j,k)\in(\mathbb{N}\times\mathbb{N}\times\mathbb{C}\times(\mathbb{C}\backslash\mathbb{Q})\cup\mathbb{Y})\backslash\mathbb{X}(\mathbb{C}),$$

where

$$\mathbb{Y}=\left\{\left(r,s,j,-\frac{p}{q}-2\right)\,\middle|\,1\leqslant r\leqslant p,1\leqslant s\leqslant q,p,q\in\mathbb{N},j\in\mathbb{C}\right\}$$
$$\cup\left\{\left(r,1,j,-\frac{p}{q}-2\right)\,\middle|\,p+1\leqslant r\leqslant 2p,p,q\in\mathbb{N},j\in\mathbb{C}\right\}, \tag{II.49}$$

and, for any set $\mathcal{P}\subset\mathbb{C}$, we have defined

$$\mathbb{X}(\mathcal{P})=\{(r,s,\tfrac{1}{2}(\pm r-2n-1)\mp\tfrac{1}{2}(k+2)s,k)\,|\,n\in\mathbb{Z},r,s\in\mathbb{N},k\in\mathcal{P}\}. \tag{II.50}$$

(II) *In the O_c case, the module $\mathcal{R}_{j,\Lambda_{\mathrm{ch}}(n,j),k}$ contains precisely one submodule (which is isomorphic to a Verma module or a twisted Verma module) generated from singular vector (II.30).*

(III) *In the O_r case, the module $\mathcal{R}_{j,\Lambda(r,s,j,k),k}$ contains precisely one submodule (which is isomorphic to a relaxed Verma module). Expressions (II.45) and (II.46) evaluate as elements of the relaxed Verma module $\mathcal{R}_{j,\Lambda(r,s,j,k),k}$ and satisfy the relaxed-highest-weight conditions*

$$J^+_{\geqslant 1}|\Sigma^\pm(r,s,j,k)\rangle=J^0_{\geqslant 1}|\Sigma^\pm(r,s,j,k)\rangle=J^-_{\geqslant 1}|\Sigma^\pm(r,s,j,k)\rangle=0,$$
$$J^-_0J^+_0|\Sigma^\pm(r,s,j,k)\rangle=\Lambda^\pm(r,s,j,k)|\Sigma^\pm(r,s,j,k)\rangle, \tag{II.51}$$
$$J^0_0|\Sigma^\pm(r,s,j,k)\rangle=(j\pm rs)|\Sigma^\pm(r,s,j,k)\rangle,$$

where

$$\Lambda^{\pm}(r,s,j,k)=\tfrac{1}{4}\,(r+(k+2)s-2rs\mp(1+2j))(r+(k+2)s+2rs\pm(1+2j)). \qquad \text{(II.52)}$$

Each of the singular vectors $\Sigma^{\pm}(r,s,j,k)$ generates the entire relaxed Verma submodule; in particular, $J_0^{\pm}$-descendants of (II.45) and (II.46) are on the same extremal subdiagram and coincide up to numerical factors whenever they are in the same grade:

$$\begin{aligned}
&c_+(i,j,k)(J_0^+)^i|\Sigma^-(r,s,j,k)\rangle=c_-(i,j,k)(J_0^-)^{2rs-i}|\Sigma^+(r,s,j,k)\rangle, \quad 0\leqslant i\leqslant 2rs,\\
&c_+(i,j,k)(J_0^+)^i|\Sigma^-(r,s,j,k)\rangle=c_-(i,j,k)(J_0^+)^{i-2rs}|\Sigma^+(r,s,j,k)\rangle, \quad i>2rs, \qquad \text{(II.53)}\\
&c_+(i,j,k)(J_0^-)^{-i}|\Sigma^-(r,s,j,k)\rangle=c_-(i,j,k)(J_0^-)^{-i+2rs}|\Sigma^+(r,s,j,k)\rangle, \quad i<0,
\end{aligned}$$

where the numerical coefficients $c_{\pm}(i,j,k)$ are (r-and s-dependent) polynomials in j and k.

Thus, (II.45) and (II.46) are, in general, different representatives of the same singular vector, since they generate the same submodule. This is not necessarily so in higher codimensions. To see what can happen there, consider again diagram (II.47). There, the Verma modules that contain singular vectors are shown as disconnected pieces, since they are related to the Verma module by mappings with complex powers of $J_0^{\pm}$. However, when one or both of the roots of (II.39) becomes an integer, one or both of these Verma modules are no longer disconnected from the extremal diagram of the relaxed Verma module. Then the Verma highest-weight conditions are encountered in the extremal diagram and restrict the possibilities to travel over the states in the lower floor in (II.47), since some of the states in (II.53) might vanish. For example, it may be impossible to obtain the Σ^+ representative of the singular vector as a J_0^+-descendant of Σ^-, or/and to obtain Σ^- as a J_0^--descendant of Σ^+. These cases in codimension $\geqslant 2$ describe the simultaneous occurrence of several singular vectors, and will be considered in what follows. We now proceed to codimension 2.

Codimension-2 cases: In codimension 2, we have three cases of a simultaneous occurrence of two singular vectors, which are described in the three following theorems. The following lemma governs the appearance of Verma submodules in a relaxed Verma module. If one puts $\Lambda^{\pm}(r,s,j,k)$ in (II.52) equal to $\Lambda_{\rm ch}(N,j\pm rs)$ [see Eq. (II.29)], one discovers that the condition $\Lambda^{\pm}(r,s,j,k)=\Lambda_{\rm ch}(N,j\pm rs)$ implies a similar relation for $\Lambda(r,s,j,k)$, and therefore charged singular vectors in the lower floor occur synchronously with charged singular vectors in the top floor of the extremal diagram. In this way, we arrive at the following.

Lemma II.11: Let $\mathcal{R}$ be the relaxed Verma module $\mathcal{R}\equiv\mathcal{R}_{j,\Lambda,k}$.

(1) *Let $\mathcal{R}\supset\mathcal{R}'$ and $\mathcal{R}\supset\mathcal{C}$, where $\mathcal{R}'$ is a relaxed Verma submodule and $\mathcal{C}$ is a (twisted) Verma module generated from a charged singular vector in $\mathcal{R}$, and let $\mathcal{C}$ be maximal in the sense that $\mathcal{R}\supset\mathcal{C}''\supset\mathcal{C}$, where $\mathcal{C}''$ is any other (twisted) Verma submodule, implies $\mathcal{C}''=\mathcal{C}$, Then $\mathcal{R}'\cap\mathcal{C}=\mathcal{C}'\neq\{0\}$, where $\mathcal{C}'$ is a (twisted) Verma module generated from a charged singular vector in $\mathcal{R}'$.*

(2) *Conversely, if $\mathcal{R}\supset\mathcal{R}'$, where $\mathcal{R}'$ is a relaxed Verma module and $\mathcal{R}'\supset\mathcal{C}'$, where $\mathcal{C}'$ is a submodule generated from a charged singular vector in $\mathcal{R}'$, then $\mathcal{R}\supset\mathcal{C}\supset\mathcal{C}'$, where $\mathcal{C}$ is a submodule generated from a charged singular vector in $\mathcal{R}$, and $\mathcal{R}\supset\mathcal{C}''\supset\mathcal{C}\Rightarrow\mathcal{C}''=\mathcal{C}$.*

(3) *If $\mathcal{R}\supset\mathcal{C}'$, where $\mathcal{C}'$ is a (twisted) Verma module, there exists a (twisted) Verma submodule $\mathcal{C}\subset\mathcal{R}$ such that the embedding is given by a charged singular vector and $\mathcal{R}\supset\mathcal{C}''\supset\mathcal{C}\Rightarrow\mathcal{C}''=\mathcal{C}$.*

This lemma is a necessary tool in the proof of the following three theorems. Consider first the occurrence of two different relaxed singular vectors.

We call a submodule *primitive* if it is not a sum of two other submodules.

Theorem II.12: *The highest weight of the module $\mathcal{R}_{j,\Lambda,k}$ belongs to the set O_{rr} if and only if $\Lambda=\Lambda(r,s,j,k)$, with*

$$(r,s,j,k)\in\mathbb{N}\times\mathbb{N}\times\mathbb{C}\times\mathbb{Q}\backslash(\mathbb{X}(\mathbb{Q})\cup\mathbb{Y}),$$

where $\mathbb{Y}$ and $\mathbb{X}(\mathbb{Q})$ are as in (II.49) and (II.50). Then we have the following.

(1) *Any primitive submodule in $\mathcal{R}_{j,\Lambda(r,s,j,p/q),p/q}$ is a relaxed Verma module. It is generated from $|\Sigma^-(r,s,j,p/q)\rangle$ or, equivalently, from $|\Sigma^+(r,s,j,p/q)\rangle$ with the same r and s.*

(2) *For any primitive submodule* $\mathcal{R}' \subset \mathcal{R}_{j,\Lambda(r,s,j,p/q),p/q}$, *there exists a singular vector* $e \equiv \mathcal{E}\cdot |\mathrm{j}^-(r,s,p/q),p/q\rangle_{sl(2)}$ *in the Verma module* $\mathcal{M}_{\mathrm{j}^-(r,s,p/q),p/q}$, *such that* $\mathcal{R}'$ *is generated from the relaxed singular vector*

$$(J_0^-)^{\mathrm{j}^-(r,s,k)-j+r+rs}\mathcal{E}(J_0^-)^{-\mathrm{j}^-(r,s,k)+j}|j,\Lambda(r,s,j,k),k\rangle_{sl(2)}. \tag{II.54}$$

(3) *Conversely, for any singular vector* e *in* $\mathcal{M}_{\mathrm{j}^-(r,s,p/q),p/q}$, *of the form* $e=|\mathrm{MFF}(r,s,p/q)\rangle^+$, $r\geqslant 1$, $s\geqslant 2$, *or* $e=|\mathrm{MFF}(r,s,p/q)\rangle^-$, $r,s\geqslant 1$, *there exists a relaxed Verma submodule in* $\mathcal{R}_{j,\Lambda(r,s,j,p/q),p/q}$ *generated by the relaxed singular vector (II.54).*

(4) *Two different singular vectors* e_1 *and* e_2 *in* $\mathcal{M}_{\mathrm{j}^-(r,s,p/q),p/q}$ *correspond in this way to the same relaxed Verma submodule in* $\mathcal{R}$ *if and only if one of the* e_i *is the* $\mathrm{MFF}^+(a\geqslant 1,1,p/q)$ *singular vector in the module generated from the other.*

In this case, therefore, the structure of the relaxed Verma module $\mathcal{R}_{j,\Lambda(r,s,j,p/q),p/q}$ is determined by the structure of the Verma module $\mathcal{M}_{\mathrm{j}^-(r,s,p/q),p/q}$.

Now, consider the case where both Verma modules shown in (II.47) actually belong to the relaxed extremal diagram. It is described in the following theorem.

Theorem II.13: *The highest weight of the relaxed Verma module* $\mathcal{R}_{j,\Lambda,k}$ *belongs to the set* O_{cc} *of the list of degeneration patterns if and only if* $j=j_{cc}(n,m)$, $\Lambda=\Lambda_{cc}(n,m)$, *where*

$$j_{cc}(n,m)=-\tfrac{1}{2}(1+m+n), \quad \Lambda_{cc}(n,m)=-mn, \tag{II.55}$$

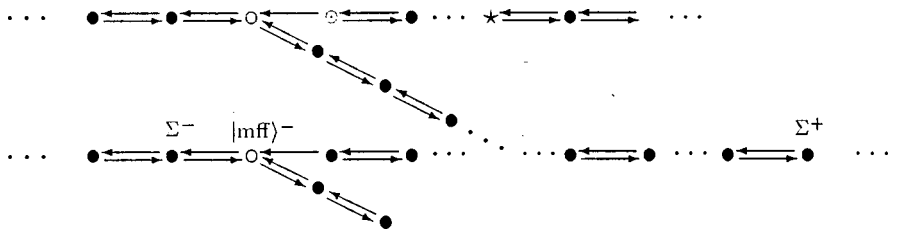
and

$$(n,m,k)\in((-\mathbb{N})\times\mathbb{N}_0\times(\mathbb{C}\backslash\mathbb{Q}))\cup\left\{\left(n,m,-\frac{p}{q}-2\,\middle|\, n\in-\mathbb{N},m\in\mathbb{N}_0,p,q\in\mathbb{N},1\leqslant m-n\leqslant q\right)\right\}. \tag{II.56}$$

Then the relaxed Verma module $\mathcal{R}_{j,\Lambda,k}$ *contains the Verma submodule* $\mathcal{C}_-\approx\mathcal{M}_{(1/2)(n-m-1),k}$ *generated from the charged singular vector* $|C(n,j,k)\rangle$ *and the twisted Verma submodule* $\mathcal{C}_+\approx\mathfrak{M}_{(1/2)(1+m-n+k),k;1}$ *generated from the charged singular vector* $|C(m,j,k)\rangle$. *The maximal submodule is* $\mathcal{C}_+\cup\mathcal{C}_-$, *and* $\mathcal{C}_+\cap\mathcal{C}_-=\varnothing$.

The third possibility in codimension 2, i.e., the case O_{rc} from the list, is when one of the states (II.40) belongs to the module $\mathcal{R}_{j,\Lambda,k}$ (hence this module contains a charged singular vector) and at the same time one of the states (II.40) admits a singular vector. This case is more involved and is analyzed in what follows.

According to Lemma II.11, the Verma submodule growing out of the charged singular vector on the top floor of the extremal diagram necessarily has a submodule generated from a singular vector $\mathrm{MFF}^{\pm}(r,s,k)$, and this submodule coincides with the submodule built on the charged singular vector in the lower floor of the extremal diagram, e.g.,



(II.57)

As we saw in (II.51), the Σ^- representative of the relaxed singular vector is at the distance of rs arrows on the left from the ''center'' (the $\star$), while Σ^+ is at the same distance on the right. It may happen that Σ^- would be inside the Verma submodule. In that case, the entire extremal diagram of the submodule cannot be generated by $J_0^{\pm}$-descendants of Σ^-. Unless we are in codimension 3, however, the entire diagram of the submodule would still be generated from Σ^+. In particular, following the arrows from Σ^+ to Σ^- into the Verma submodule makes the two representatives proportional. This is described more precisely in the following theorem.

Theorem II.14: *The highest weight of the relaxed Verma module $\mathcal{R}_{j,\Lambda,k}$ belongs to the set O_{rc} of the list of degeneration patterns if and only if $j=j^{\sigma}_{rc}(r,s,n,k)$ and $\Lambda=\Lambda^{\sigma}_{rc}(r,s,n,k)$, where $\sigma\in\{+,-\}$,*

$$\begin{aligned} j^{\pm}_{rc}(r,s,n,k)&=-n-\tfrac{1}{2}\pm\tfrac{1}{2}\,(r-(k+2)s),\\ \Lambda^{\pm}_{rc}(r,s,n,k)&=-n^2\pm n(r-(k+2)s), \end{aligned} \tag{II.58}$$

and

$$(\sigma,r,s,n,k)\in(\{\pm\}\times\mathbb{N}\times\mathbb{N}\times\mathbb{Z}\times(\mathbb{C}\backslash\mathbb{Q}))\cup\mathbb{A}(\mathbb{C}\backslash\mathbb{Q})\cup\mathbb{B}, \tag{II.59}$$

where

$$\mathbb{A}(\mathcal{P})=\{(\{+\},r,0,n,k)|r\in\mathbb{N},n\in-\mathbb{N},k\in\mathcal{P}\}\cup\{(\{-\},r,0,n,k)|r\in\mathbb{N},n\in\mathbb{N}_0,k\in\mathcal{P}\},$$

$$\begin{aligned} \mathbb{B}=&\left\{\left(\{+\},r,s,n,-\frac{p}{q}-2\right)\middle|\, n\in-\mathbb{N},\ p,q\in\mathbb{N},\ 1\leqslant r\leqslant p,\ 0\leqslant s\leqslant q-1\right\}\\ &\cup\left\{\left(\{-\},r,s,n,-\frac{p}{q}-2\right)\middle|\, n\in\mathbb{N}_0,\ p,q\in\mathbb{N},\ 1\leqslant r\leqslant p,\ 0\leqslant s\leqslant q-1\right\}. \end{aligned} \tag{II.60}$$

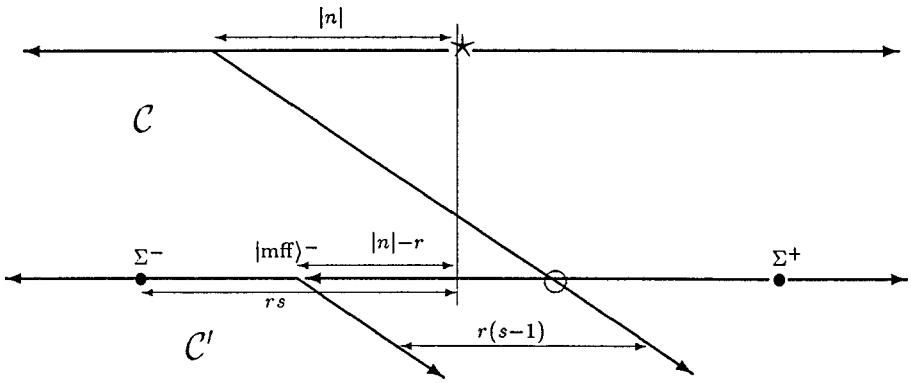
Then, the relaxed Verma module $\mathcal{R}_{j,\Lambda,k}$ contains a relaxed Verma submodule $\mathcal{R}'$ generated from the singular vector $|\Sigma^{+}(r,s,j^{\pm}_{rc}(r,s,n,k),k)\rangle$ (if $n<0$) or from $|\Sigma^{-}(r,s,j^{\pm}_{rc}(r,s,n,k),k)\rangle$ (if $n\geqslant 0$); the module $\mathcal{R}_{j,\Lambda,k}$ contains also a Verma submodule $\mathcal{C}\approx\mathcal{M}_{\mathrm{j}^{\pm}(r,s,k),k}$ (if $n<0$) or a twisted Verma submodule $\mathcal{C}\approx\mathfrak{M}_{\mathrm{j}^{\pm}(r,s,k),k;1}$ (if $n\geqslant 0$) generated from the charged singular vector $|C(n,j,k)\rangle$ in either case. The maximal submodule in $\mathcal{R}_{j,\Lambda,k}$ is $\mathcal{C}\cup\mathcal{R}'$. The intersection $\mathcal{C}'\equiv\mathcal{C}\cap\mathcal{R}'$ is a Verma module (if $n<0$) or a twisted Verma module (if $n\geqslant 0$) generated from a charged singular vector $|c\rangle\in\mathcal{R}'$, which is also a singular vector in $\mathcal{C}$:

$$|c\rangle=\begin{cases} |\mathrm{mff}\rangle^{\pm}=\mathcal{MFF}^{\pm}(r,s+\frac{1}{2}\pm\frac{1}{2},k)|C(n,j^{\pm}_{rc}(r,s,n,k),k)\rangle, & n<0;\\ |\mathrm{mff}\rangle^{\mp,1}=\mathcal{MFF}^{\mp,1}(r,s+\frac{1}{2}\pm\frac{1}{2},k)|C(n,j^{\pm}_{rc}(r,s,n,k),k)\rangle, & n\geqslant 0. \end{cases} \tag{II.61}$$

Remark II.15: When the intersection $\mathcal{C}'=\mathcal{C}\cap\mathcal{R}'$ is generated by the singular vector $\mathcal{MFF}^{-}(r,s,k)|C(n,j^{-}_{rc}(r,s,n,k),k)\rangle$ with $n<0$ and $|n|\leqslant r(s+1)$, the relaxed singular vector $|\Sigma^{-}(r,s,j^{-}_{rc}(r,s,n,k),k)\rangle$ belongs to the Verma submodule $\mathcal{C}'$ and thus cannot generate the entire relaxed submodule $\mathcal{R}$:

$$|\Sigma^{-}(r,s,j^{-}_{rc}(r,s,n,k),k)\rangle=(J^{-}_{0})^{r+rs+n}|c\rangle. \tag{II.62}$$

The relative positions of Σ^{-} and Σ^{+} in the extremal diagram are as follows:[4]



(II.63)

where length $|n|-r$ is shown as if positive. (At the point marked with a circle, two lines do not ''intersect,'' i.e., they lead to different vectors in the same grade. The same applies to the diagrams below, which will not be stated explicitly however.) Under the conditions of the Theorem, Σ^+ still has infinitely many descendants with respect to both J_0^- and J_0^+.

Going ''past the highest-weight'': The above concludes the analysis of codimension 2 cases. In the subsequent analysis of codimension 3, however, it will be very useful to know more subtle properties of the chosen representatives of singular vectors. As we saw in (II.63), descendants of Σ^- may not cover a part of the extremal subdiagram because of the *Verma* highest-weight conditions satisfied at $|\mathrm{mff}\rangle^-$. In applications, however, one needs to know whether or not a given *Verma* submodule in a relaxed Verma module is actually generated from a charged singular vector in some relaxed Verma submodule. (Both cases can occur, and the distinction between the two possibilities is crucial for the correct classification of degenerate cases, and, also, for the construction of embedding diagrams, etc.)

Thus, given a Verma highest-weight state $|X\rangle$, which satisfies $J_0^+|X\rangle=0$, we are interested in whether there exists a state $|Y\rangle$ *in the relaxed Verma module* such that $|X\rangle=J_0^-|Y\rangle$, or, to put it differently, whether $(J_0^-)^{-1}|X\rangle$ can be defined as an element of the relaxed Verma module.

We now answer this question for vectors (II.45) and (II.46). First of all, whenever Σ^- is in the Verma submodule $\mathcal{C}'$ generated by $\mathrm{MFF}^-(r,s,k)$, we consider instead of Σ^- the highest-weight vector of that submodule:

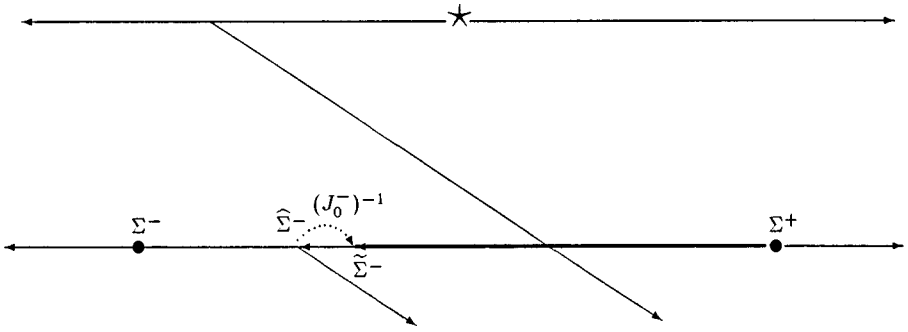
$$|\hat{\Sigma}^-(r,s,j_{rc}^-(r,s,n,k),k)\rangle\equiv|\mathrm{mff}\rangle^-=\mathcal{MFF}^-(r,s,k)|j_{rc}^-(r,s,n,k),\Lambda_{rc}^-(r,s,n,k),k|n\rangle_{sl(2)}, \tag{II.64}$$

of which Σ^- is a J_0^--descendant.

The vector $|\hat{\Sigma}^-(r,s,j_{rc}^-(r,s,n,k),k)\rangle$ is the farthest right one can reach by acting with J_0^+ on the original singular vector $|\Sigma^-(r,s,j_{rc}^-(r,s,n,k),k)\rangle$. To map it farther right, to the outside of the Verma submodule $\mathcal{C}'$, one employs the operator $(J_0^-)^{-1}$, which is understood as one of the ''continued'' operators from (II.11)–(II.12):

$$|\tilde{\Sigma}^-(r,s,j_{rc}^-(r,s,n,k),k)\rangle=(J_0^-)^{-1}|\hat{\Sigma}^-(r,s,j_{rc}^-(r,s,n,k),k)\rangle. \tag{II.65}$$

This can be pictured as



(II.66)

The conditions for $|\tilde{\Sigma}^-(r,s,j_{rc}^-(r,s,n,k),k)\rangle$ to exist are given by the following lemma. Let

$$f(r,s,n,k)=\begin{cases}\displaystyle\prod_{m=0}^{2r-n}(r-m-n-(k+2)s), & 1\leqslant n\leqslant 2r,\\ 1, & n\geqslant 2r+1.\end{cases} \tag{II.67}$$

Lemma II.16: In the relaxed Verma module $\mathcal{R}_{j_{rc}^-(r,s,n,k),\Lambda_{rc}^-(r,s,n,k),k}$ *with* $n<0$ *and* $|n|\leqslant r(s+1)$,

(I) The vector

$$|\tilde{\Sigma}^-(r,s,j_{rc}^-(r,s,n,k),k)\rangle=(J_0^-)^{-1}\mathcal{MFF}^-(r,s,k)|j_{rc}^-(r,s,n,k),\Lambda_{rc}^-(r,s,n,k),k|n\rangle_{sl(2)}, \tag{II.68}$$

exists if and only if $f(r,s,|n|,k)\neq 0$, *in which case it is a relaxed singular vector.*

(II) *Under the conditions of Theorem II.14, a* J_0^+*-descendant of* $|\Sigma^+(r,s,j_{rc}^-(r,s,n,k),k)\rangle$ *is proportional to vector (II.68):*

$$(J_0^-)^{rs-n-r-1}|\Sigma^+(r,s,j_{rc}^-(r,s,n,k),k)\rangle=(-1)^r a(r,s,n,k)|\tilde{\Sigma}^-(r,s,j_{rc}^-(r,s,n,k),k)\rangle, \tag{II.69}$$

where

$$\begin{aligned} a(r,s,n,k)&=\frac{\Pi_{t=0}^{r(s+1)-1}(\Lambda_{rc}^-(r,s,n,k)-i(i+1)-2ij_{rc}^-(r,s,n,k))}{\Pi_{i=0}^{2r-1}(n-i-r(s-1))}\\ &=\prod_{i=0}^{r(s+1)-1}(i-r-n+(k+2)s)\prod_{i=0}^{r(s-1)-1}(n-i). \end{aligned} \tag{II.70}$$

To prove the lemma, we observe that the action of $(J_0^-)^{-1}$ is given by (II.12) and by Eqs. (II.23); this can be rewritten as

$$\begin{aligned} (J_0^-)^{-1}|j,\Lambda,k|m\rangle_{sl(2)}&=|j,\Lambda,k|m+1\rangle_{sl(2)},\quad m\leqslant -1,\\ (J_0^{-1})^{-1}|j,\Lambda,k|m\rangle_{sl(2)}&=\frac{1}{\Lambda-m(m+1)-2mj}\,|j,\Lambda,k|m+1\rangle_{sl(2)},\quad m\geqslant 0. \end{aligned} \tag{II.71}$$

This applies unless the denominator in the last formula vanishes. A simple analysis of the relative charge of $|\hat{\Sigma}^-(r,s,j_{rc}^-(r,s,n,k),k)\rangle$ shows that $f(r,s,-n,k)$ is precisely the function responsible for the existence of $|\tilde{\Sigma}^-(r,s,j_{rc}^-(r,s,n,k),k)\rangle$: to evaluate (II.65), one uses Eqs. (II.12) and then, as negative powers of J_0^- reach the highest-weight state, one applies (II.71) the appropriate number of times; the relevant factors from the denominators are precisely the above $f(r,s,-n,k)$, whence the lemma follows.

Thus, whenever state (II.65) exists, it is proportional to a J_0^--descendant of Σ^+.

Codimension 3: The codimension-3 cases are more involved than the previous ones. Let us begin with the case where a further degeneration occurs in Theorem II.12.

Theorem II.17: *The highest weight of the relaxed Verma module* $\mathcal{R}_{j,\Lambda,k}$ *belongs to the set* O_{rrc} *of the list of degeneration patterns if and only if* $j=j_{rc}^{\sigma}(r,s,n,k)$ *and* $\Lambda=\Lambda_{rc}^{\sigma}(r,s,n,k)$ *as in (II.58), where*

$$(\sigma,r,s,n,k)\in(\{\pm\}\times\mathbb{N}\times\mathbb{N}\times\mathbb{Z}\times\mathbb{Q}\cup\mathbb{A}(\mathbb{Q}))\backslash\mathbb{B}\backslash\mathbb{D}, \tag{II.72}$$

with $\mathbb{A}(\mathcal{P})$ *and* $\mathbb{B}$ *as in (II.60) and*

$$\mathbb{D}=\left\{\left(\sigma,r,s,n,\frac{p}{q}\right)\middle|\, r,s,q\in\mathbb{N},\ \ p,n\in\mathbb{Z},\ \ \left|r-s\left(\frac{p}{q}+2\right)\right|\in\{|n|,|n|+1,|n|+2,\ldots\}\right\}. \tag{II.73}$$

Then we have the following.

(1) $\mathcal{R}_{j,\Lambda,k}$ *contains a submodule* $\mathcal{C}$ *generated from the charged singular vector* $|C(n,j,p/q)\rangle$; *if* $n<0$, *then* $\mathcal{C}\approx\mathcal{M}_{j+n,p/q}$, *where* $\mathcal{M}_{j+n,p/q}$ *is a Verma module with at least two singular vectors; if* $n\geqslant 0$, $\mathcal{C}\approx\mathcal{M}_{j+n+1+p/2q,p/q;1}$.

(2) *Any other primitive submodule in* $\mathcal{R}_{j,\Lambda,k}$ *is isomorphic either to a relaxed Verma module or, depending on whether* $n<0$ *or* $n\geqslant 0$, *to a Verma module or a twisted Verma module with the twist parameter* $\theta=1$, *respectively. Further, we have the following.*

(a) If $n<0$, *each Verma submodule* $\mathcal{C}'\subset\mathcal{R}_{j,\Lambda,k}$ *is a submodule in* $\mathcal{C}$ *and, moreover, there exists a relaxed Verma submodule* $\mathcal{R}'$ *such that* $\mathcal{C}'$ *is generated from a charged singular vector in* $\mathcal{R}'$.

(b) If $n\geqslant 0$, *each twisted Verma submodule* $\mathcal{C}'\subset\mathcal{R}_{j,\Lambda,k}$ *is a submodule in* $\mathcal{C}$ *and, moreover, there exists a relaxed Verma submodule* $\mathcal{R}'$ *such that* $\mathcal{C}'$ *is generated from a charged singular vector in* $\mathcal{R}'$.

(c) For any relaxed Verma submodule $\mathcal{R}'\subset\mathcal{R}_{j,\Lambda,k}$, the intersection $\mathcal{C}'=\mathcal{R}'\cap\mathcal{C}$ is nonempty. If, then, $|v\rangle$ is the highest-weight vector of $\mathcal{C}'$, there exists a vector $\widetilde{|v\rangle}\in\mathcal{R}_{j,\Lambda,k}$, defined as

$$\widetilde{|v\rangle}=\begin{cases}(J_0^+)^{-1}|v\rangle, & n\geqslant 0,\\ (J_0^-)^{-1}|v\rangle, & n<0,\end{cases} \tag{II.74}$$

that satisfies relaxed highest-weight conditions and generates the relaxed Verma submodule $\mathcal{R}'$.

(3) *For any primitive submodule $\mathcal{C}'\subset\mathcal{C}$, there exists a relaxed Verma submodule $\mathcal{R}'$ such that the following occurs.*

(a) $\mathcal{C}'\subset\mathcal{R}'\cap\mathcal{C}$.

(b) $\mathcal{R}'$ is generated from a vector $|\tilde v\rangle$, such that the vector

$$|v\rangle=\begin{cases}J_0^+|\tilde v\rangle, & n\geqslant 0,\\ J_0^-|\tilde v\rangle, & n<0,\end{cases} \tag{II.75}$$

generates a Verma module (if $n<0$) or a twisted Verma module (if $n\geqslant 0$) that either coincides with $\mathcal{C}'$ or contains $\mathcal{C}'$ as a submodule generated from the singular vector $|\mathrm{MFF}^{+}(a,1,k)\rangle$ (if $n<0$) or $|\mathrm{MFF}^{-,1}(a,1,k)\rangle$ (if $n\geqslant 0$), where $a\in\mathbb{N}$.

Whenever $s=0$, we have $\mathcal{R}'=\mathcal{R}_{j,\Lambda,k}$.

Thus, the structure of $\mathcal{R}_{j,\Lambda,k}$ is completely determined by the structure of its Verma submodule $\mathcal{C}=\mathcal{M}_{\mathfrak{j}-(r,s,p/q),p/q}\subset\mathcal{R}_{j,\Lambda,k}$ (if $n<0$) or $\mathcal{C}=\mathfrak{M}_{\mathfrak{j}^+(r,s,p/q),p/q;1}\subset\mathcal{R}_{j,\Lambda,k}$ (if $n\geqslant 0$).

The case O_{rcc} of the list of possible degenerations is the most involved one, and we describe it in the following theorem.

Theorem II.18: *The highest weight of the module $\mathcal{R}_{j,\Lambda,k}$ belongs to the set O_{rcc} of the list of degeneration patterns if and only if*

$$j=j_{cc}(n,m),\quad \Lambda=\Lambda_{cc}(n,m),\quad -n,m+1\in\mathbb{N},\quad k+2=\frac{r\pm(m-n)}{s},\quad r,s\in\mathbb{N}. \tag{II.76}$$

In this case, the module $\mathcal{R}_{j,\Lambda,k}$ contains a Verma submodule $\mathcal{C}_-$ generated from the charged singular vector $|C(n,j_{cc}(n,m),k)\rangle$ and a Verma submodule $\mathcal{C}_+$ (with the twist parameter $\theta=1$) generated from the charged singular vector $|C(m,j_{cc}(n,m),k)\rangle$. Each of the modules $\mathcal{C}_-$ and $\mathcal{C}_+$ admits at least one singular vector. Moreover, a singular vector $|\mathrm{MFF}^{\pm}(a,b,k)\rangle$ exists in the module $\mathcal{C}_-$ if and only if the singular vector $|\mathrm{MFF}^{\mp,1}(a,b,k)\rangle$ with the same $a,b\in\mathbb{N}$ exists in $\mathcal{C}_+$.

Any other primitive submodule $\mathcal{N}\subset\mathcal{R}_{j,\Lambda,k}$ is one of the following: (1) $\mathcal{N}$ is a Verma submodule, such that $\mathcal{N}\subset\mathcal{C}_-$; (2) $\mathcal{N}$ is a twisted Verma submodule with the twist parameter 1, such that $\mathcal{N}\subset\mathcal{C}_+$; (3) $\mathcal{N}$ is a relaxed Verma module, in which case the intersections $\mathcal{N}\cap\mathcal{C}_-=\mathcal{C}'_-$ and $\mathcal{N}\cap\mathcal{C}_+=\mathcal{C}'_+$ are nonempty. Whenever $\mathcal{C}'_+$ is generated from a singular vector $|\mathrm{MFF}^{\pm}(a,b,k)\rangle$, $\mathcal{C}'_-$ is generated from singular vector $|\mathrm{MFF}^{\mp}(a,b,k)\rangle$ with the same $a,b\in\mathbb{N}$ (and the above k).

Next, we give explicit constructions of singular vectors that generate submodules described in Theorem II.18.

Theorem II.19: *Under the conditions of Theorem II.18, we have the following.*

(1) *Whenever $k+2=(m-n+r)/s$, the module $\mathcal{R}_{j,\Lambda,k}$ contains a relaxed Verma submodule $\mathcal{R}'$ such that its intersections with $\mathcal{C}_-$ and $\mathcal{C}_+$ are generated from the following vectors:*

$$\begin{aligned}|\mathrm{mff}\rangle^{+}&=\mathcal{MFF}^{+}(r,s+1,k)(J_0^-)^{-n}|j_{cc}(n,m),\Lambda_{cc}(n,m),k\rangle_{sl(2)},\\ |\mathrm{mff}\rangle^{-,1}&=\mathcal{MFF}^{-,1}(r,s+1,k)(J_0^+)^{m+1}|j_{cc}(n,m),\Lambda_{cc}(n,m),k\rangle_{sl(2)},\end{aligned} \tag{II.77}$$

respectively, and $\mathcal{R}'$ itself is generated from any of the states,

$$(J_0^-)^{-1}|\mathrm{mff}\rangle^{+}\quad or\quad (J_0^+)^{-1}|\mathrm{mff}\rangle^{-,1}. \tag{II.78}$$

The states $|\mathrm{mff}\rangle^{+}$ *and* $|\mathrm{mff}\rangle^{-,1}$ *are charged singular vectors in* $\mathcal{R}'$*; after taking the quotient of* $\mathcal{R}'$ *with respect to* $|\mathrm{mff}\rangle^{+}$ *and* $|\mathrm{mff}\rangle^{-,1}$*, the states remaining on the top level furnish an irreducible representation of the Lie algebra* $sl(2)$ *of dimension* $m-n+2r$.

(2) *Whenever* $k+2=(-m+n+r)/s$ *and* $2r-m+n\leqslant -1$*, the module* $\mathcal{R}_{j,\Lambda,k}$ *contains a relaxed Verma submodule* $\mathcal{R}'$ *such that its intersections with* $\mathcal{C}_-$ *and* $\mathcal{C}_+$ *are generated from the vectors*

$$|\mathrm{mff}\rangle^{-}=\mathcal{MFF}^{-}(r,s,k)(J_0^-)^{-n}|j_{cc}(n,m),\Lambda_{cc}(n,m),k\rangle_{sl(2)},$$
$$|\mathrm{mff}\rangle^{+,1}=\mathcal{MFF}^{+,1}(r,s,k)(J_0^+)^{m+1}|j_{cc}(n,m),\Lambda_{cc}(n,m),k\rangle_{sl(2)}, \tag{II.79}$$

respectively, and $\mathcal{R}'$ *itself is generated from any of the states,*

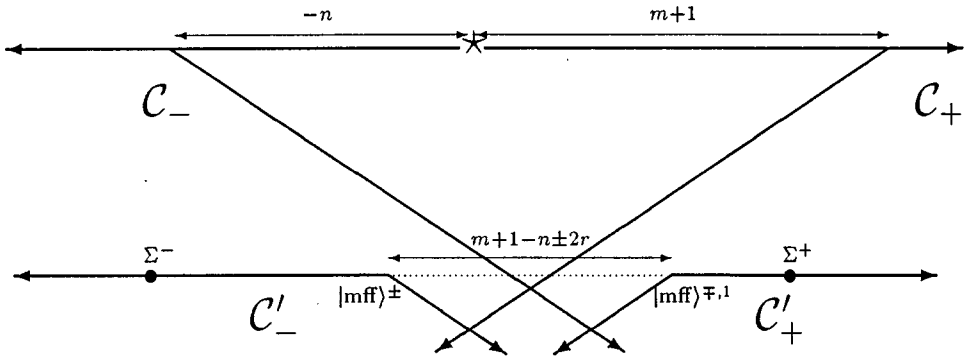
$$(J_0^-)^{-1}|\mathrm{mff}\rangle^{-} \quad \textit{or} \quad (J_0^+)^{-1}|\mathrm{mff}\rangle^{+,1}. \tag{II.80}$$

The vectors $|\mathrm{mff}\rangle^{-}$ *and* $|\mathrm{mff}\rangle^{+,1}$ *are charged singular vectors in* $\mathcal{R}'$*; after taking the quotient with respect to* $|\mathrm{mff}\rangle^{+}$ *and* $|\mathrm{mff}\rangle^{-,1}$*, the states remaining on the top level of* $\mathcal{R}'$ *furnish an irreducible representation of the Lie algebra* $sl(2)$ *of dimension* $m-n-2r$.

(3) *Whenever* $k+2=(-m+n+r)/s$ *and* $2r-m+n\geqslant 0$*, the module* $\mathcal{R}_{j,\Lambda,k}$ *contains submodules* $\mathcal{C}'_-\subset\mathcal{C}_-$ *and* $\mathcal{C}'_+\subset\mathcal{C}_+$ *that are generated from singular vectors (II.79) respectively. There does not exist a relaxed Verma submodule* $\mathcal{R}'\subset\mathcal{R}_{j,\Lambda,k}$ *in which either* $|\mathrm{mff}\rangle^{-}$ *or* $|\mathrm{mff}\rangle^{+,1}$ *would be a charged singular vector.*

Moreover, whenever $2r-m+n\geqslant 1$*, the states* $(J_0^+)^i|\mathrm{mff}\rangle^{+,1}$ *and* $(J_0^-)^{2r-m+n-1-i}|\mathrm{mff}\rangle^{-}$*,* $i=0,\ldots,2r-m+n-1$*, satisfy the relaxed highest-weight conditions, are in the same grade for each* i *and are linearly independent. The module* $\mathcal{C}'_-$ *contains the singular vector* $|\mathrm{MFF}^{+}(2r-m+n,1,(-m+n+r)/s-2)\rangle$*, while the module* $\mathcal{C}'_+$ *contains the singular vector* $|\mathrm{MFF}^{-,1}(2r-m+n,1,(-m+n+r)/s-2)\rangle$*. After taking the quotients with respect to the submodules generated from these two singular vectors, the states remaining in the top level of the submodule* $\mathcal{C}'_-\cup\mathcal{C}'_+$ *arrange into a direct sum of two irreducible representations of the* $sl(2)$ *Lie algebra of the dimension* $2r-m+n$ *each.*

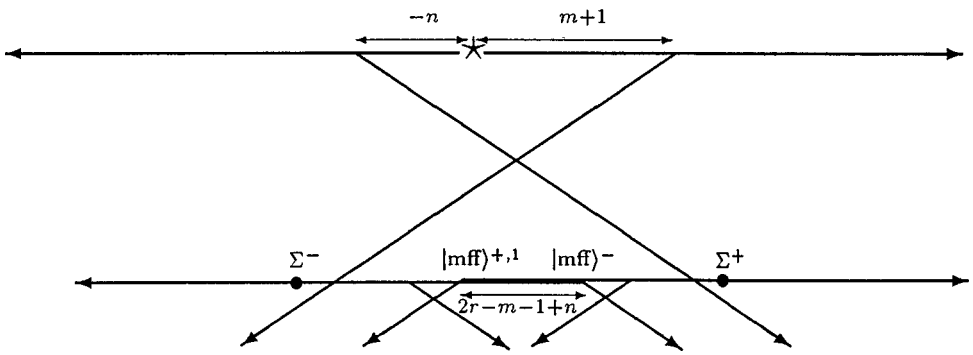
Parts 1 and 2 of Theorem II.19 follow from Lemma II.16. This can be illustrated as



(II.81)

where the upper signs are to be taken in case 1 of the theorem, and the lower signs, in case 2.

In case 3 of the theorem, the appearance of singular vectors $|\mathrm{MFF}^{+}(2r-m+n,1,(n+r-m)/s-2)\rangle$ and $|\mathrm{MFF}^{-,1}(2r-m+n,1,(n+r-m)/s-2)\rangle$ in the modules $\mathcal{C}'_-$ and $\mathcal{C}'_+$, respectively, follows by a direct analysis of the relevant highest weights. This can be illustrated by the extremal diagram,



(II.82)

where $|\mathrm{mff}\rangle^{+,1}$ lies on the upper of the two overlapping lines, and $|\mathrm{mff}\rangle^{-}$, on the lower one.

Remark II.20: As we see from the theorem, whenever two different singular vectors appear in the same grade, these are necessarily descendants of singular vectors in the corresponding (twisted) *Verma* submodules. Thus, understanding by the relaxed singular vector proper the entire floor in the extremal diagram, we can say that two different relaxed singular vectors in the same grade never occur.

This concludes the list of our constructions on the $\widehat{sl}(2)$ side. The above formulation was given in such a way as to facilitate a comparison with the $N=2$ superconformal algebra; as we will see later, all of the above objects and constructions have appropriate $N=2$ analogs.

B. Auxiliaries

We now introduce two free-field systems that will be needed in Sec. III.

1. Fermions (ghosts)

We will need a fermionic system (the so-called ghosts, or a bc system), defined in terms of the operator products as

$$B(z)C(w)=\frac{1}{z-w}, \tag{II.83}$$

with the energy–momentum tensor,

$$T^{\mathrm{GH}}=-B\partial C. \tag{II.84}$$

We use the mode expansions $B(z)=\Sigma_{n\in\mathbb{Z}}B_n z^{-n-1}$ and $C(z)=\Sigma_{n\in\mathbb{Z}}C_n z^{-n}$.

Denote by Ω the module generated from the vacuum $|0\rangle_{\mathrm{GH}}$ defined by the conditions

$$C_{\geqslant 1}|0\rangle_{\mathrm{GH}}=B_{\leqslant 0}|0\rangle_{\mathrm{GH}}=0. \tag{II.85}$$

The thus defined vacuum is an sl_2-invariant state;[23] along with this one, we can choose other highest-weight states, $|\lambda\rangle_{\mathrm{GH}}$, which belong to the same module and are determined by

$$C_{\geqslant 1-\lambda}|\lambda\rangle_{\mathrm{GH}}=B_{\geqslant\lambda}|\lambda\rangle_{\mathrm{GH}}=0. \tag{II.86}$$

Then, as is easy to see,

$$(BC)_0|\lambda\rangle_{\mathrm{GH}}=-\lambda|\lambda\rangle_{\mathrm{GH}},$$

$$L_0^{\mathrm{GH}}|\lambda\rangle_{\mathrm{GH}}=(1/2)\lambda(\lambda-1)|\lambda\rangle_{\mathrm{GH}}. \tag{II.87}$$

The character of Ω is given by

$$\chi^{\mathrm{GH}}(z,q)=\mathrm{Tr}_{\Omega}(q^{L_0^{\mathrm{GH}}}z^{-(BC)_0})=\prod_{i=0}^{\infty}(1+zq^i)\prod_{i=1}^{\infty}(1+z^{-1}q^i). \tag{II.88}$$

We can connect the states $|\lambda\rangle_{\mathrm{GH}}$ with different λ by means of operators $c(\mu,\nu)$ and $b(\mu,\nu)$, which are the products of fermionic modes,

$$c(\mu,\nu)=\prod_{n=1}^{\nu-\mu+1} C_{\mu+n}, \quad b(\mu,\nu)=\prod_{n=1}^{\nu-\mu+1} B_{\nu+n}, \quad \nu-\mu+1\in\mathbb{N}. \tag{II.89}$$

These $c(\mu,\nu)$ and $b(\mu,\nu)$ map a vector $|\lambda\rangle_{\mathrm{GH}}$ as follows:

$$c(-\lambda-l+1,-\lambda):|\lambda\rangle_{\mathrm{GH}}\mapsto|\lambda+l\rangle_{\mathrm{GH}}, \quad b(-\lambda-l,\lambda-1):|\lambda\rangle_{\mathrm{GH}}\mapsto|\lambda-l\rangle_{\mathrm{GH}}, \quad l\in\mathbb{N}. \tag{II.90}$$

All the necessary properties of the objects $c(\mu,\nu)$ and $b(\mu,\nu)$ can be derived when $\nu-\mu+1$ is a positive integer and then generalized to the case of arbitrary μ and ν. For example,

$$c(\mu,\nu-1)c(\nu,\nu_1)=c(\mu,\nu_1), \quad b(\mu,\nu-1)b(\nu,\nu_1)=b(\mu,\nu_1). \tag{II.91}$$

2. The ''Liouville'' scalar

In this section we introduce a ''Liouville'' scalar that will be used to invert the KS mapping. This is just a free scalar, called ''Liouville'' for the signature of its operator product:

$$\phi(z)\phi(w)=-\ln(z-w). \tag{II.92}$$

We define vertex operators $\psi=e^{\phi}$ and $\psi^*=e^{-\phi}$, with the mode expansions

$$\psi(z)=\sum_{n=-\infty}^{\infty}\frac{\psi_n}{z^n}, \quad \psi^*(z)=\sum_{n=-\infty}^{\infty}\frac{\psi_n^*}{z^{n-1}}, \tag{II.93}$$

and

$$\partial\phi(z)=\sum_{n=-\infty}^{\infty}\frac{\phi_n}{z^{n+1}}, \quad \text{with } [\phi_n,\phi_m]=-n\,\delta_{n+m,0}. \tag{II.94}$$

We take the energy–momentum tensor to be

$$T_{\phi}=-\tfrac{1}{2}\,\partial\phi\partial\phi+\tfrac{1}{2}\,\partial^2\phi: \tag{II.95}$$

then ψ and ψ^* have the dimensions 0 and -1, respectively.

The ψ and ψ^* operators are naturally represented as intertwining operators on a direct sum,

$$\Xi=\bigoplus_{n\in\mathbb{Z}}\mathcal{H}_n, \tag{II.96}$$

where $\mathcal{H}_n$ is a Verma module over the Heisenberg algebra (II.94) with the highest-weight vector $|n\rangle_{\phi}$,

$$\begin{aligned}&\phi_m|n\rangle_{\phi}=0, \quad m\geqslant 1, \quad \psi_m|n\rangle_{\phi}=0, \quad m\geqslant n+1,\\ &\psi_m^*|n\rangle_{\phi}=0, \quad m\geqslant -n+2, \quad \phi_0|n\rangle_{\phi}=-n|n\rangle_{\phi}.\end{aligned} \tag{II.97}$$

Note also that the highest-weight vectors $|n\rangle_{\phi}$ can be realized as the operators $|n\rangle_{\phi}\sim e^{n\phi}(0)$.

C. $N=2$

In the description of our second main ingredient, the $N=2$ algebra, we follow Refs. 9 and 10, particularly as regards the singular vectors. Other (nonexhaustive) references on the $N=2$ superconformal algebra are Refs. 3, 12, 15, 16, and 24.

1. The $N=2$ superconformal algebra

The $N=2$ superconformal algebra is spanned by Virasoro generators L_m, two fermionic fields $G_r^{\pm}$, and a $U(1)$ current H_n (and a central element C). The nonvanishing commutation relations are

$$[L_n,L_m]=(n-m)L_{n+m}+\frac{\mathsf{C}}{12}(n^3-n)\delta_{n+m},\quad [H_n,H_m]=\frac{\mathsf{C}}{3}n\delta_{n+m},$$

$$[L_n,H_m]=-mH_{n+m},\quad [L_n,G_r^{\pm}]=(\tfrac{1}{2}n-r)G_{n+r}^{\pm},\quad [H_n,G_r^{\pm}]=\pm G_{n+r}^{\pm}, \tag{II.98}$$

$$\{G_r^{+},G_s^{-}\}=2L_{r+s}+(r-s)H_{r+s}+\frac{\mathsf{C}}{3}(r^2-\tfrac{1}{4})\delta_{r+s},\quad n,m\in\mathbb{Z},\quad r,s\in\mathbb{Z}+\tfrac{1}{2}.$$

We find it more convenient to work with the version of this algebra obtained by redefining the generators as

$$L_n=L_n|_{(\mathrm{II}.98)}+\tfrac{1}{2}(n+1)H_n,\quad G_r=G_{r+1/2}^{+},\quad Q_r=G_{r-1/2}^{-}. \tag{II.99}$$

This redefinition affects two things: the modding of the fermions and the choice of the Virasoro generators. The latter is due to the freedom of adding a derivative of the $U(1)$ current to the energy–momentum tensor, and is nothing but a change of basis in the algebra. As to the different moddings, they label different members of a family of isomorphic algebras related by the spectral flow[15,16] [see Eq. (II.106) below]. Thus, any statement found for one of these algebras does immediately translate to any other one. In order to be specific in our constructions below, we need to choose the concrete representative from that family as well as the modding of the generators. These will be

$$[L_m,L_n]=(m-n)L_{m+n},\quad [H_m,H_n]=\frac{\mathsf{C}}{3}m\delta_{m+n,0},$$

$$[L_m,G_n]=(m-n)G_{m+n},\quad [H_m,G_n]=G_{m+n},$$

$$[L_m,Q_n]=-nQ_{m+n},\quad [H_m,Q_n]=-Q_{m+n},\quad m,n\in\mathbb{Z}. \tag{II.100}$$

$$[L_m,H_n]=-nH_{m+n}+\frac{\mathsf{C}}{6}(m^2+m)\delta_{m+n,0},$$

$$\{G_m,Q_n\}=2L_{m+n}-2nH_{m+n}+\frac{\mathsf{C}}{3}(m^2+m)\delta_{m+n,0},$$

Denote this algebra as $\mathcal{A}$. Its generators L_m, Q_m, H_m, and G_m will be called the Virasoro generators, the ''BRST'' current, the $U(1)$ current, and the spin-2 fermionic current, respectively. [$Q(z)$ *is* the BRST current when the algebra (II.100) is realized on the bosonic string world sheet.[25,26]]

As a Lie superalgebra, $\mathcal{A}$ is generated by the following set of elements:

$$e_1=\tfrac{1}{2}Q_0,\quad e_2=G_1,\quad e_3=H_1,$$

$$h_1=L_0,\quad h_2=L_0+H_0+\frac{C}{3},\quad h_3=\frac{\mathsf{C}}{3}, \tag{II.101}$$

$$f_1=G_0,\quad f_2=\tfrac{1}{2}Q_{-1},\quad f_3=H_{-1}.$$

The elements $h_i, i=1,2,3$ generate the Cartan subalgebra $\mathfrak{h}$.

Now we define the *topological Verma modules* over the $N=2$ algebra [The name is inherited from the noncritical bosonic string, where matter vertices can be dressed into $N=2$ primaries that

satisfy the highest-weight conditions (II.102); in that context, the algebra (II.100) is viewed as a topological algebra.]; the highest-weight vector in any such module satisfies the annihilation and eigenvalue conditions,

$$Q_{\geqslant 0}|h,t\rangle_{\rm top}=G_{\geqslant 0}|h,t\rangle_{\rm top}=L_{\geqslant 1}|h,t\rangle_{\rm top}=H_{\geqslant 1}|h,t\rangle_{\rm top}=0, \tag{II.102}$$

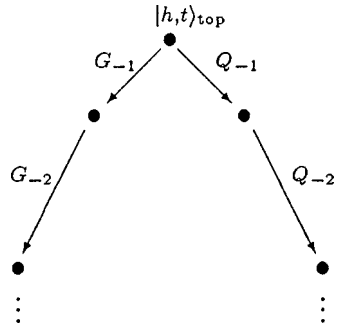
$$H_0|h,t\rangle_{\rm top}=h|h,t\rangle_{\rm top}, \quad L_0|h,t\rangle_{\rm top}=0, \quad \mathsf{C}|h,t\rangle_{\rm top}=\frac{3(t-2)}{t}\,|h,t\rangle_{\rm top} \tag{II.103}$$

(the last equation being simply a parametrization of the central charge in terms of a new parameter, t; later this parameter will be identified with $k+2$, where k is the $\widehat{sl}(2)$ level). Accordingly, the topological Verma module $\mathcal{V}_{h,t}$ is freely generated by

$$L_{-m}, \quad m\in\mathbb{N}, \quad H_{-m}, \quad m\in\mathbb{N}, \quad Q_{-m}, \quad m\in\mathbb{N}, \quad G_{-m}, \quad m\in\mathbb{N}, \tag{II.104}$$

from the *topological highest-weight vector* $|h,t\rangle_{\rm top}$.

The extremal diagram of a topological Verma module is of the form



(II.105)

where the bigrading in the plane of the diagram is by (charge, level).

2. Automorphisms of the N=2 algebra

Spectral flow transform: When applied to the generators of the algebra $\mathcal{A}$, Eqs. (II.100), the spectral flow transformation $\mathcal{U}_\theta$ acts as

$$L_n\mapsto L_n+\theta H_n+\frac{\mathsf{C}}{6}\,(\theta^2+\theta)\,\delta_{n,0}, \quad H_n\mapsto H_n+\frac{\mathsf{C}}{3}\,\theta\delta_{n,0},$$
$$Q_n\mapsto Q_{n-\theta}, \quad G_n\mapsto G_{n+\theta}. \tag{II.106}$$

This gives an isomorphic algebra $\mathcal{A}_\theta$, whose generators L_n^θ, Q_n^θ, H_n^θ, and G_n^θ can be taken as the rhs's of (II.106). For $\theta\in\mathbb{Z}$, the spectral flow is an *auto*morphism of the algebra $\mathcal{A}$. For arbitrary θ, we obtain a family of algebras such that any two of its members, $\mathcal{A}_{\theta_1}$ and $\mathcal{A}_{\theta_2}$, are related by an isomorphism of the type of (II.106) with $\theta=\theta_1-\theta_2$. This family includes the Neveu–Schwarz and Ramond $N=2$ algebras, as well as the algebras in which the fermion modes range over $\pm\theta+\mathbb{Z}$, $\theta\in\mathbb{C}$.

The involutive automorphism: The $N=2$ algebra has the involutive automorphism

$$G_n\to Q_{n+1}, \quad Q_n\to G_{n-1},$$
$$H_n\to -H_n, \quad L_n\to L_n-(n+1)H_n. \tag{II.107}$$

Together with automorphisms (II.106) for $\theta\in\mathbb{Z}$, transformations (II.107) span the group $\mathbb{Z}_2\ltimes\mathbb{Z}$ isomorphic to the group generated by the canonical involution and the spectral flow of the affine $sl(2)$ algebra.

3. Twisted topological Verma modules

We now define *the twisted topological Verma modules* $\mathfrak{V}_{h,t;\theta}$. This will be a module over the algebra $\mathcal{A}_\theta$ [see (II.106)], with the *twisted topological highest-weight vector* $|h,t;\theta\rangle_{\mathrm{top}}$ defined by

$$\begin{array}{llll} L_m|h,t;\theta\rangle_{\mathrm{top}}=0, & m\geqslant 1, & Q_\lambda|h,t;\theta\rangle_{\mathrm{top}}=0, & \lambda\in-\theta+\mathbb{N}_0, \\ H_m|h,l;\theta\rangle_{\mathrm{top}}=0, & m\geqslant 1, & G_\nu|h,t;\theta\rangle_{\mathrm{top}}=0, & \nu\in\theta+\mathbb{N}_0, \end{array} \qquad \theta\in\mathbb{Z}; \tag{II.108}$$

in addition, the ''Cartan'' generators act on the state $|h,t;\theta\rangle_{\mathrm{top}}$ as

$$\left(H_0+\frac{\mathsf{C}}{3}\,\theta\right)|h,t;\theta\rangle_{\mathrm{top}}=h|h,t;\theta\rangle_{\mathrm{top}},$$

$$\left(L_0+\theta H_0+\frac{\mathsf{C}}{6}(\theta^2+\theta)\right)|h,t;\theta\rangle_{\mathrm{top}}=0, \tag{II.109}$$

$$\mathsf{C}|h,t;\theta\rangle_{\mathrm{top}}=\frac{3(t-2)}{t}\,|h,t;\theta\rangle_{\mathrm{top}}.$$

The $\theta=0$ case of (II.108) describes the ''ordinary'' topological Verma modules introduced above.

Next, we need the concept of terminating fermionic chains.

Definition II.21: Let F denote either Q or G (the fermionic $N=2$ generators), and $|X\rangle$ be an element of a module over the $N=2$ algebra. Fix also an integer n. We say that the fermionic F chain terminates on $|X\rangle$, and write ... $F_{n-3}F_{n-2}F_{n-1}F_n|X\rangle=0$ if

$$\exists N\in\mathbb{Z},\quad N\leqslant n:\ F_NF_{N+1}\cdots F_n|X\rangle=0.$$

Now we are in a position to give the following.

Definition II.22: An $N=2$ module $\mathfrak{U}$ is an object of the topological $N=2$ category $\mathcal{TOP}$ whenever the following conditions are satisfied.

(1) *H_0 and L_0 are diagonalizable operators, i.e., $\mathfrak{U}$ can be decomposed into a direct sum of intersections of H_0 and L_0 eigenspaces.*

(2) *The action with all H_p, $p\in\mathbb{N}$, and L_p, $p\in\mathbb{N}$, on any element $|X\rangle\in\mathfrak{U}$ spans a finite-dimensional space.*

(3) *For any element $|X\rangle$ of $\mathfrak{U}$,*

$$\forall n\in\mathbb{Z},\quad \begin{array}{ll} \textit{either} & \ldots Q_{n-3}Q_{n-2}Q_{n-1}Q_n|X\rangle=0, \\ \textit{or} & \ldots G_{-n-4}G_{-n-3}G_{-n-2}G_{-n-1}|X\rangle=0. \end{array} \tag{II.110}$$

Morphisms are standard homomorphisms between $N=2$ modules.

Condition (II.110) will be called the condition of terminating fermionic chains.

Note finally that the characters of twisted topological Verma modules are given by

$$\chi^{N=2}_{h,\theta}(z,q)=\mathrm{Tr}_{\mathfrak{V}_{h,t;\theta}}(q^{L_0}z^{H_0})=q^{-\theta h+\mathsf{C}(\theta^2-\theta)/6}z^{h-\mathsf{C}\theta/3}\,\frac{\prod_{i=-\theta+1}^{\infty}(1+zq^i)\prod_{i=\theta+1}^{\infty}(1+z^{-1}q^i)}{\prod_{i=1}^{\infty}(1-q^i)^2}. \tag{II.111}$$

4. Topological N=2 singular vectors

Here, we describe singular vectors in the topological Verma modules introduced above; later, we will see that these are isomorphic to the $\widehat{sl}(2)$ singular vectors, as suggested in Ref. 7. We introduce two operators $g(\mu,\nu)$ and $q(\mu,\nu)$, with $\mu,\nu\in\mathbb{C}$, that represent the action of two ''$N=2$ Weyl group'' generators r_{α_1} and r_{α_2} when μ and ν are special (see Refs. 9 and 10 for the details): the operators $g(\mu,\nu)$ and $q(\mu,\nu)$ act on the plane $t=\mathrm{const}$ as

$$g(ht+\theta-1,\theta-1):|h,t;\theta\rangle_{\rm top}\mapsto\left|\frac{2}{t}-h,t;ht+\theta-1\right\rangle_{\rm top},$$
$$q(-(h+1)t-\theta+1,-\theta-1):|h,t;\theta\rangle_{\rm top}\mapsto\left|\frac{2}{t}-2-h,t;(h+1)t+\theta-1\right\rangle_{\rm top}. \tag{II.112}$$

The action of operators $g(a,b)$ and $q(a,b)$ on the highest-weight vectors can be extended to the topological Verma module generated from these highest-weight vectors.[10] This allows us to construct singular vectors in topological Verma modules.

Theorem II.23: (I) *A topological singular vector exists in the topological Verma module* $\mathcal{V}_{h,t}$ *if and only if either* $h=\mathsf{h}^+(r,s,t)$ *or* $h=\mathsf{h}^-(r,s,t)$, *where*

$$\begin{aligned}\mathsf{h}^+(r,s,t)&=-\frac{r-1}{t}+s-1,\\ \mathsf{h}^-(r,s,t)&=\frac{r+1}{t}-s,\end{aligned}\qquad r,s\in\mathbb{N}. \tag{II.113}$$

(II) (Ref. 9) *All singular vectors in the topological Verma module* $\mathcal{V}_{\mathsf{h}^\pm(r,s,t),t}$ *are given by the explicit construction:*

$$\begin{aligned}|E(r,s,t)\rangle^+=&\,g(-r,(s-1)t-1)q((1-s)t,r-1-t)\cdots\\ &\times g((s-2)t-r,t-1)q(-t,r-1-(s-1)t)\\ &\times g((s-1)t-r,-1)|\mathsf{h}^+(r,s,t),t\rangle_{\rm top},\end{aligned} \tag{II.114}$$

$$\begin{aligned}|E(r,s,t)\rangle^-=&\,q(-r,(s-1)t-1)g((1-s)t,r-t-1)\cdots\\ &\times q((s-2)t-r,t-1)g(-t,r-1-(s-1)t)\\ &\times q((s-1)t-r,-1)|\mathsf{h}^-(r,s,t),t\rangle_{\rm top},\end{aligned} \tag{II.115}$$

where $r,s\in\mathbb{N}$ *and the factors in the first two lines of each formula are*

$$g(-r-t-mt+st,-1+mt)q(-mt,r-1+mt-st),\quad s-1\geqslant m\geqslant 1 \tag{II.116}$$

and

$$q(-r-t-mt+st,-1+mt)g(-mt,r-1+mt-st),\quad s-1\geqslant m\geqslant 1, \tag{II.117}$$

respectively.

Part (I) can be deduced from Ref. 12. Singular vectors (II.115), (II.114) satisfy highest-weight conditions (II.108) with $\theta=\mp r$, respectively.

5. Massive N=2 Verma modules

We now introduce $N=2$ Verma modules of a different type, in which the highest-weight states satisfy the following annihilation and eigenvalue conditions:

$$Q_{\geqslant 1}|h,l,t\rangle=G_{\geqslant 0}|h,l,t\rangle=L_{\geqslant 1}|h,l,t\rangle=H_{\geqslant 1}|h,l,t\rangle=0, \tag{II.118}$$

$$H_0|h,l,t\rangle=h|h,l,t\rangle,\quad L_0|h,l,t\rangle=l|h,l,t\rangle. \tag{II.119}$$

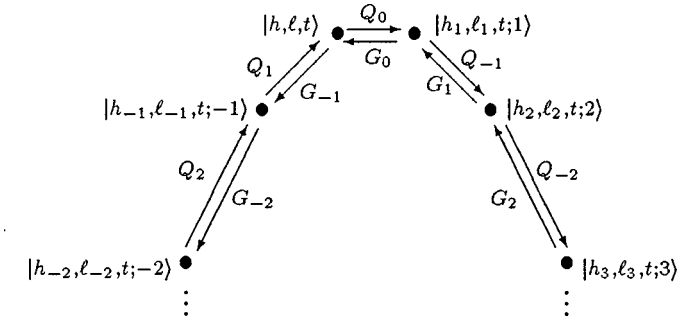
The module freely generated from $|h,l,t\rangle$ by the remaining $N=2$ generators will be denoted as $U_{h,l,t}$. Because of the property to have a dimension l generally different from zero, $|h,l,t\rangle$ are called the massive highest-weight states and $U_{h,l,t}$, accordingly, *the massive* $N=2$ *Verma modules*.

The twists of massive Verma modules are introduced by imposing the highest-weight conditions [as before, $\mathsf{c}=3(t-2)/t$]

$$\begin{aligned}&L_m|h,l,t;\theta\rangle=0,\quad m\geqslant 1,\quad Q_\lambda|h,l,t;\theta\rangle=0,\quad \lambda\in-\theta+\mathbb{N},\\ &H_m|h,l,t;\theta\rangle=0,\quad m\geqslant 1,\quad G_\nu|h,l,t;\theta\rangle=0,\quad \nu\in\theta+\mathbb{N}_0,\end{aligned} \tag{II.120}$$

$$\left(H_0+\frac{c}{3}\,\theta\right)|h,l,t;\theta\rangle=h|h,l,t;\theta\rangle,\quad \left(L_0+\theta H_0+\frac{c}{6}\,(\theta^2+\theta)\right)|h,l,t;\theta\rangle=l|h,l,t;\theta\rangle.$$

Extremal diagrams of massive Verma modules have the following ''fat'' form for $\theta=0$ (see Ref. 10 for the details)



(II.121)

The states in the diagram are freely generated from $|h,l,t\rangle$ by the $G_{-1}G_{-2}\cdots$ and $Q_0Q_{-1}\cdots$ arrows, in accordance with the definition of massive Verma modules. The arrows mapping back toward $|h,l,t\rangle$ are described in the following lemma.

Lemma II.24: The mappings

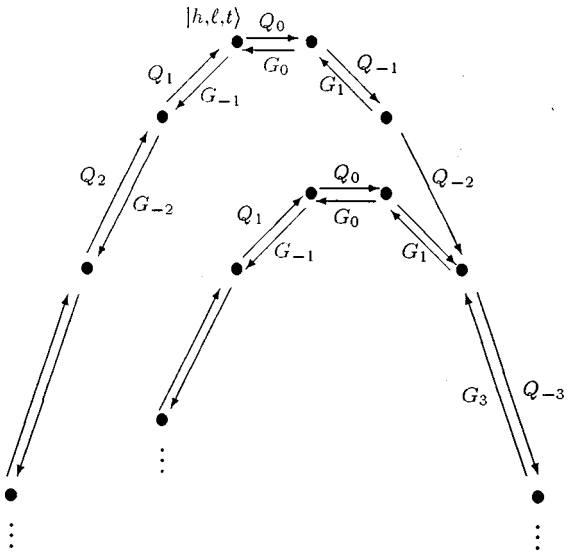
$$\begin{aligned}&|h_\theta,l_\theta,t;\theta\rangle\mapsto|h_{\theta+1},l_{\theta+1},t;\theta+1\rangle,\quad \theta<0,\\ &|h_\theta,l_\theta,t;\theta\rangle\mapsto|h_{\theta-1},l_{\theta-1},t;\theta-1\rangle,\quad \theta>0\end{aligned}\tag{II.122}$$

are implemented by $Q_{-\theta}$ and $G_{\theta-1}$ respectively:

$$\begin{aligned}&Q_{-\theta}|h,l,t;\theta\rangle=2l\left|h-\frac{2}{t},l+h-\frac{2}{t},t;\theta+1\right\rangle,\quad \theta<0,\\ &G_{\theta-1}|h,l,t;\theta\rangle=2(l-h)\left|h+\frac{2}{t},l-h,t;\theta-1\right\rangle,\quad \theta>0.\end{aligned}\tag{II.123}$$

It is worth mentioning that, while $|h,l,t\rangle$ in (II.121) satisfies the untwisted highest-weight conditions [$\theta=0$ in (II.120)], the other states in the diagram satisfy the twisted massive highest-weight conditions (II.120), with θ running over all integers (from $-\infty$ to $+\infty$ as one moves from left to right).

It follows from (II.123) that, as soon as one of the factors on the right-hand sides vanishes, the respective state would satisfy the twisted *topological* highest-weight conditions (II.102). At these ''topological points,'' the extremal diagram branches, e.g.,



(II.124)

The inner diagram in (II.124) corresponds to an $N=2$ *subrepresentation*, which is identified with a singular vector. By iteratively applying formulas (II.123), we arrive at the following theorem.

Theorem II.25: *A massive Verma module $U_{h,l,t}$ contains a twisted topological Verma submodule if and only if $l=\mathsf{l}_{\mathrm{ch}}(r,h,t)$, where*

$$\mathsf{l}_{\mathrm{ch}}(r,h,t)=r\left(h+\frac{r-1}{t}\right),\quad r\in\mathbb{Z}; \tag{II.125}$$

The corresponding singular vector reads as

$$|E(r,h,t)\rangle_{\mathrm{ch}}=\begin{cases} Q_r\cdots Q_0|h,\mathsf{l}_{\mathrm{ch}}(r,h,t),t\rangle, & r\leqslant 0,\\ G_{-r}\cdots G_{-1}|h,\mathsf{l}_{\mathrm{ch}}(r,h,t),t\rangle, & r\geqslant 1.\end{cases} \tag{II.126}$$

It satisfies twisted topological highest-weight conditions (II.102) with $\theta=-r$.
(These are singular vectors of the ''charged'' series from Ref. 12.)

The remaining singular vectors in massive Verma modules can be constructed as follows (we only give the ''untwisted'' case; that of twisted massive modules follows by applying the spectral flow transform). As follows from the analysis of the Kač determinant,[12] the necessary condition for a massive singular vector to exist in the module $\mathcal{U}_{h,l,t}$ is $l=\mathsf{l}(r,s,h,t)$, where

$$\mathsf{l}(r,s,h,t)=\frac{1}{2}\,h-\frac{1}{2}\,rs-\frac{1}{4t}+\frac{r^2}{4t}-\frac{1}{4}\,h^2t+\frac{1}{4}\,s^2t,\quad r,s\in\mathbb{N}. \tag{II.127}$$

The necessary and sufficient condition as well as explicit formulas for the singular vectors are given in the following.

Theorem II.26: (I) (Ref. 14) For $\mathsf{c}\neq 3$, *a massive singular vector in $\mathcal{U}_{h,l,t}$ can be constructed if and only if $l=\mathsf{l}(r,s,h,t)$, where $(r,s,h,t)\in(\mathbb{N}\times\mathbb{N}\times\mathbb{C}\times\mathbb{C})\setminus\mathbb{X}$, with*

$$\mathbb{X}=\{(r,s,h,t)\,|\,st-r=m-n,ht-1=-m-n,r+st=0,n\in\mathbb{N},m\in-\mathbb{N}_0\}. \tag{II.128}$$

(II) (Ref. 10) *The massive singular vectors in $\mathcal{U}_{h,\mathsf{l}(r,s,h,t),t}$ are of the form*

$$
\begin{aligned}
|S(r,s,h,t)\rangle^- &= g(-rs,r+\theta^-(r,s,h,t)-1)\mathcal{E}^{-,\theta^-(r,s,h,t)}(r,s,t)\\
&\quad\cdot g(\theta^-(r,s,h,t),-1)|h,l(r,s,h,t),t\rangle,\\
|S(r,s,h,t)\rangle^+ &= q(1-rs,r-\theta^+(r,s,h,t)-1)\mathcal{E}^{+,\theta^+(r,s,h,t)}(r,s,t)\\
&\quad\cdot q(-\theta^+(r,s,h,t),0)|h,l(r,s,h,t),t\rangle,
\end{aligned}
\tag{II.129}
$$

where

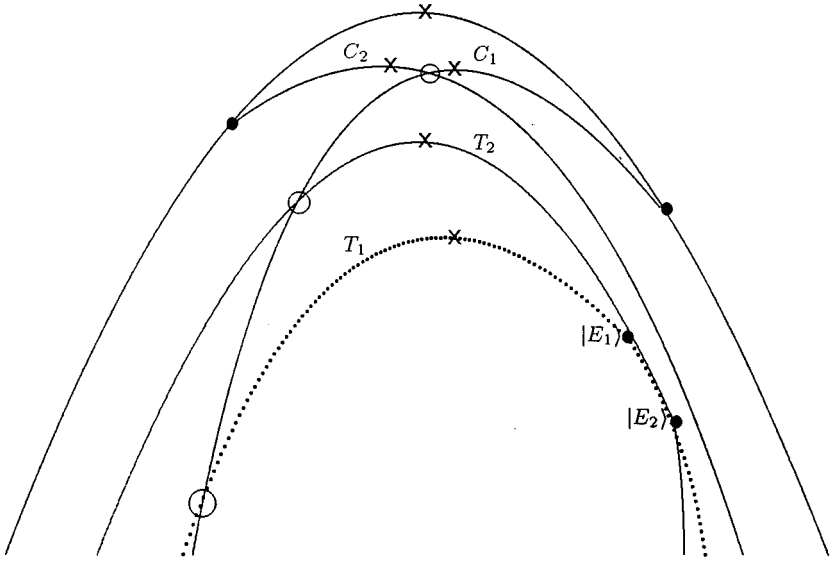
$$
\begin{aligned}
\theta^-(r,s,h,t) &= \frac{t}{2}\,(h-\mathsf{h}^-(r,s,t)),\\
\theta^+(r,s,h,t) &= \frac{t}{2}\,(h-1-\mathsf{h}^+(r,s,t)),
\end{aligned}
\tag{II.130}
$$

and $\mathcal{E}^{\pm,\theta}(r,s,t)$ *denotes the spectral flow transform (II.106) of the topological singular vector operator* $\mathcal{E}^{\pm}(r,s,t)$. *The two expressions (II.129) in the general position belong to the same extremal diagram and generate the same massive submodule.*

This construction translates in the obvious way to the twisted case.

Degenerate cases corresponding to the simultaneous occurrence of several $N=2$ singular vectors can be described similarly to the $\widehat{sl}(2)$ case. An essential point is to consider on equal footing all states from each extremal diagram. Restricting oneself to only top-level representatives of extremal diagrams leads to additional complications in describing the structure of $N=2$ modules. In a number of degenerate cases, the entire $N=2$ submodule is *not* generated by the top-level representative of the extremal diagram of the submodule. This already happens in the case where a charged singular vector $|E(n,h,t)\rangle_{\mathrm{ch}}$ (see Theorem II.25) and a massive singular vector labeled by two integers r and s coexist in a massive $N=2$ module and $r>n$. Describing this case only in terms of top-level representatives of each of the singular vectors would lead one to assume that *sub*singular vectors exist in the module, since the chosen representative of the singular vector does not generate the entire submodule.

Let us describe in more detail the case where two charged singular vectors coexist with a massive singular vector. This is directly analogous to the case considered in part (3) of Theorem II.19:

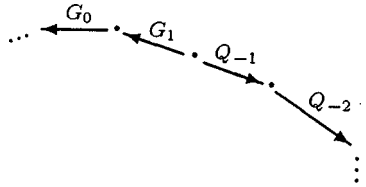


(II.131)

In this extremal diagram, the crosses denote the top-level representatives, the filled dots are twisted topological highest-weight states, and circles indicate that different curves do not intersect, i.e., correspond to linearly independent states at the overlapping points. C_1 and C_2 are extremal

diagrams of submodules built on the charged singular vectors, while T_1 and T_2 are topological submodules in the modules corresponding to C_1 and C_2, respectively. Submodules T_1 and T_2 are generated by topological singular vectors $|E_1\rangle$ and $|E_2\rangle$, respectively. The pairs of states lying on the section of the T_1 and T_2 curves between $|E_1\rangle$ and $|E_2\rangle$ give linearly independent singular vectors in the same grade. For the values of the parameters assumed in the diagram, choosing the top-level representative of T_1 and T_2 would conceal the fact that there exist linearly independent singular vectors in the same grade. By an analysis parallel to the one of Sec. II A 6, two linearly independent singular vectors in the same grade exist whenever $m-n\leqslant 2r$, where $m\geqslant 1$ and $n\leqslant -1$ label the two charged singular vectors and r is the first from the pair of integers (r,s) that label the massive singular vector. The top-level representatives would be inside the overlapping section of the two curves only when both m and $|n|$ are $\leqslant r$; however, these restrictions have nothing to do with the structure of submodules that applies whenever $m+|n|\leqslant 2r$, and is an artifact of the choice of top-level representatives. Let us note also that in the case where two linearly independent singular vectors exist in the same grade, each of these singular vectors belongs to a topological submodule; this is completely similar to the $\widehat{sl}(2)$ case discussed above [see part (3) of Theorem II.19]. For more details and a systematic account of degenerations of $N=2$ Verma modules, we refer the reader to Ref. 14.

The above condition for the fermionic chains to terminate is *not* satisfied for the (twisted) massive Verma modules. Instead, a fermionic chain terminates whenever there are two or more arrows along the same line, e.g.,



(II.132)

which is formalized in the definition of the category of (twisted) massive highest-weight-type modules.

Definition II.27: An $N=2$ module $\mathfrak{M}$ is an object of the category $\mathcal{MHW}$ whenever the following occurs.

(1) *H_0 and L_0 are diagonalizable operators, i.e., $\mathfrak{U}$ can be decomposed into a direct sum of intersections of H_0-L_0 eigenspaces.*
(2) *The action with all H_p, $p\in\mathbb{N}$, and L_p, $p\in\mathbb{N}$, on any element $|X\rangle\in\mathfrak{U}$ spans a finite-dimensional space.*
(3) *For any element $|X\rangle$ of $\mathfrak{U}$,*

$$\forall n\in\mathbb{Z},\quad \begin{matrix} either & \ldots Q_{n-3}Q_{n-2}Q_{n-1}Q_n|X\rangle=0, \\ or & \ldots G_{-n-3}G_{-n-2}G_{-n-1}G_{-n}|X\rangle=0. \end{matrix} \tag{II.133}$$

Morphisms are standard homomorphisms between $N=2$ modules.

III. KAZAMA–SUZUKI AND THE RELATED MAPPINGS

A. The Kazama–Suzuki mapping

We use the simplest KS construction associated with the coset $\widehat{sl}(2)_k\oplus u(1)/u(1)$. The KS ''numerator'' $u(1)$ algebra fermionizes into a couple of spin-1 ghosts, denoted in the following as BC, which allows us to build up the $N=2$ algebra generators in the standard way:[19,20] The odd generators Q and G are given by

$$Q=CJ^+,\quad G=\frac{2}{k+2}BJ^-, \tag{III.1}$$

while the $U(1)$ current and the energy–momentum tensor of the $N=2$ algebra take the form

$$H=\frac{k}{k+2}\,BC-\frac{2}{k+2}\,J^0, \tag{III.2}$$

$$T=\frac{1}{k+2}\,(J^+J^-)-\frac{k}{k+2}\,B\partial C-\frac{2}{k+2}\,BCJ^0. \tag{III.3}$$

Lemma III.1; The modes of currents (III.1), (III.2), and (III.3) satisfy the algebra (II.100). The eigenvalue of the central element in each representation is expressed through the eigenvalue of the $\widehat{sl}(2)$ *central element as*

$$\mathsf{c}=\frac{3k}{k+2}. \tag{III.4}$$

Thus, Eqs. (III.1), (III.2), and (III.3) determine a mapping,

$$F_{\mathrm{KS}}:\mathcal{A}\to\mathcal{U}\widehat{sl}(2)_k\otimes[BC], \tag{III.5}$$

where $\mathcal{A}$ *is the* $N=2$ *algebra (II.100) and* $\mathcal{U}$ *denotes the universal enveloping (and* $[BC]$ *is the free fermion theory).*

The KS mapping also produces a bosonic current,

$$I^+=\sqrt{\frac{2}{k+2}}\,(BC+J^0), \tag{III.6}$$

whose modes commute with the $N=2$ generators (III.1)–(III.3). Expanding as $I^+(z)=\Sigma_{n\in\mathbb{Z}}I^+_n z^{-n-1}$, we get a Heisenberg algebra,

$$[I^+_m,I^+_n]=m\,\delta_{m+n,0}. \tag{III.7}$$

The energy–momentum tensor of this $U(1)$ current is introduced as

$$T^+=\frac{1}{2}\,(I^+)^2-\frac{1}{\sqrt{2(k+2)}}\,\partial I^+. \tag{III.8}$$

We define a module $\mathcal{H}^+_p$ over the Heisenberg algebra by the highest-weight conditions

$$I_{\geqslant 1}|p\rangle^+=0,\quad I_0|p\rangle^+=p|p\rangle^+. \tag{III.9}$$

Its character is

$$\chi^+_{p,k}(z,q)=\mathrm{Tr}_{\mathcal{H}^+_p}(q^{L^+_0}z^{I^+_0})=z^p\,\frac{q^{(1/2)p(p+\sqrt{2/(k+2)})}}{\Pi_{i=1}^{\infty}(1-q^i)}. \tag{III.10}$$

Lemma III.2: Under the KS mapping, we have the identities

$$T_{\mathrm{Sug}}+T_{\mathrm{GH}}=T+T^+ \tag{III.11}$$

[where T is the energy–momentum tensor (III.3)], and

$$J^0-BC=-2H+\frac{k-2}{\sqrt{2(k+2)}}\,I^+.$$

B. The ''anti''-Kazama–Suzuki mapping

A mapping in the inverse direction to the KS mapping can be defined as follows. It is associated with the ''coset'' $\mathcal{A}\oplus u(1)/u(1)$, where the numerator $u(1)$ is represented in terms of the antifermionic system $\psi=e^{\phi}$, $\psi^*=e^{-\phi}$ from Sec. II B 2. Then we can identify the affine $sl(2)$ generators as

$$J^+=Q\psi, \quad J^-=\frac{3}{3-\mathsf{c}}\,G\psi^*,$$
$$J^0=-\frac{3}{3-\mathsf{c}}\,H+\frac{\mathsf{c}}{3-\mathsf{c}}\,\partial\phi. \tag{III.12}$$

Lemma III.3: For $\mathsf{c}\neq 3$, *generators (III.12) close to the algebra (II.2) of the level* $k=2c/(3-\mathsf{c})$, *where* c *is the* $N=2$ *central charge (the eigenvalue of the central element). Thus, Eqs. (III.12) determine a mapping,*

$$F_{\mathrm{KS}}^{-1}:\widehat{sl}(2)\to\mathcal{U}\mathcal{A}\otimes[\psi\psi^*]. \tag{III.13}$$

The Sugawara energy–momentum tensor (II.3) takes for the construction (III.12) the form

$$T^{\mathrm{Sug}}=T+\frac{1}{2}\,\partial H+\frac{k+2}{4}\,HH-\frac{k+2}{2}\,H\partial\phi+\frac{k}{4}\,\partial\phi\partial\phi. \tag{III.14}$$

We also have a free scalar, with signature -1, whose modes commute with the $\widehat{sl}(2)$ generators (III.12):

$$I^-=\sqrt{\frac{k+2}{2}}\,(H-\partial\phi). \tag{III.15}$$

The modes I_n^- introduced as $I^-(z)=\Sigma_{n=-\infty}^{\infty}I_n^-z^{-n-1}$ generate a Heisenberg algebra,

$$[I_n^-,I_m^-]=-n\,\delta_{m+n,0}. \tag{III.16}$$

This current has the energy–momentum tensor,

$$T^-=-\frac{1}{2}\,(I^-)^2-\frac{1}{\sqrt{2(k+2)}}\,\partial I^-. \tag{III.17}$$

The module $\mathcal{H}_q^-$ is defined as a Verma module over the Heisenberg algebra (III.16), with the highest-weight vector defined by

$$I_n^-|q\rangle^-=0, \quad n\geqslant 1, \quad I_0^-|q\rangle^-=q|q\rangle^-. \tag{III.18}$$

Lemma III.4: Under the anti-KS mapping, we have the identities

$$T+T_{\phi}=T^{\mathrm{Sug}}+T^- \tag{III.19}$$

[where T *is the energy–momentum tensor of the* $N=2$ *algebra and* T_{ϕ} *is the energy–momentum tensor of the Liouville system (II.95)], and*

$$-2H+\partial\phi=J^0+\left(\frac{k}{2}-1\right)\sqrt{\frac{k+2}{2}}\,I^-. \tag{III.20}$$

C. Composing the KS and anti-KS mappings

Let us consider compositions of the KS and anti-KS mappings.

Lemma III.5: The composition $F_{KS}^{-1}\circ F_{KS}$ *maps the* $\widehat{sl}(2)$ *algebra into the* $\widehat{sl}(2)$ *algebra in the tensor product* $\mathcal{U}\widehat{sl}(2)\otimes[BC]\otimes[\psi\psi^*]$ *represented by the currents*

$$\overline{J}^+ = J^+ e^{\phi} C, \quad \overline{J}^- = J^- e^{-\phi} B, \quad \overline{J}^0 = J^0 + \frac{k}{2}(\partial\phi - BC). \tag{III.21}$$

For the energy–momentum tensors, we then have

$$\overline{T}^{\mathrm{Sug}} = T^{\mathrm{Sug}} + \frac{k}{4}((\partial\phi)^2 - 2\partial\phi BC + \partial BC - B\partial C) + J^0(\partial\phi - BC). \tag{III.22}$$

A remarkable feature of these formulas is the appearance of a *null current* $BC-\partial\phi$; the fact that it is null is crucial for establishing that the generators on the rhs's close to the $\widehat{sl}(2)$ algebra.

Remark III.6: The formulas of the lemma can be given a coset-like interpretation by noticing that the image of $\widehat{sl}(2)$ under the above embedding is characterized by the fact that it commutes with (the modes of) the currents

$$I^+ = \sqrt{\frac{2}{k+2}}(J^0 + BC), \quad F^- = \sqrt{\frac{2}{k+2}}\left(J^0 - \frac{k}{2}BC + \frac{k+2}{2}\partial\phi\right) \tag{III.23}$$

(these currents do also commute with each other and are matter-like and Liouville-like, respectively).

The same happens with the $N=2$ algebra under the action of $F_{\mathrm{KS}}\circ F_{\mathrm{KS}}^{-1}$:

Lemma III.7: The composition $F_{KS}\circ F_{KS}^{-1}$ *maps the* $N=2$ *algebra into the* $N=2$ *algebra in the tensor product* $\mathcal{UA}\otimes[BC]\otimes[\psi\psi^*]$, *represented by the currents*

$$\overline{Q} = Qe^{\phi}C, \quad \overline{G} = Ge^{-\phi}B,$$

$$\overline{H} = H + \frac{k}{k+2}(BC - \partial\phi), \tag{III.24}$$

$$\overline{T} = T + H(BC - \partial\phi) + \frac{k}{2(k+2)}((\partial\phi)^2 - 2\partial\phi BC + \partial^2\phi - 2B\partial C).$$

Remark III.8: We also find two currents that commute with the ''target'' $N=2$ algebra (III.24):

$$I^- = \sqrt{\frac{k+2}{2}}(H - \partial\phi), \quad F^+ = \sqrt{\frac{k+2}{2}}\left(H - \frac{2}{k+2}BC - \frac{k}{k+2}\partial\phi\right) \tag{III.25}$$

(these currents are Liouville-like and matter-like respectively, and commute with each other).

D. KS and anti-KS mappings at the level of representations

1. The Verma module case

The following theorem is essentially a reformulation of Lemmas III.5 and III.7.

Theorem III.9: (I) *The composition of the KS and anti-KS mappings induces an isomorphism of* $\widehat{sl}(2)$ *representations,*

$$\mathfrak{M}_{j,k;\theta}\otimes\Omega\otimes\Xi \approx \bigoplus_{n,m\in\mathbb{Z}} \mathfrak{M}_{j,k;\theta+n-m}\otimes\mathcal{H}^+_{\sqrt{[2/(k+2)]}(j-(k/2)\theta-m)}\otimes\mathcal{H}^-_{-\sqrt{[2/(k+2)]}(j-(k/2)(\theta-m)-[(k+2)/2]n)}, \tag{III.26}$$

where on the lhs the $\widehat{sl}(2)$ *action is given by the rhs's of (III.21), while on the rhs the* $\widehat{sl}(2)$ *algebra acts naturally on the modules* $\mathfrak{M}_{j,k;\theta}$ *and trivially, on the Heisenberg modules.*

(II) *The composition of the anti-KS mapping and the direct KS mapping induces an isomorphism of* $N=2$ *representations,*

$$\mathfrak{V}_{h,t;\theta}\otimes\Xi\otimes\Omega\approx\bigoplus_{n,m\in\mathbb{Z}}\mathfrak{V}_{h,t;\theta+m-n}\otimes\mathcal{H}^{-}_{\sqrt{t/2}(h-[(t-2)/t]\theta+n)}\otimes\mathcal{H}^{+}_{-\sqrt{t/2}(h-[(t-2)/t](\theta-n)+(2/t)m)}, \tag{III.27}$$

where on the lhs the $N=2$ algebra acts by generators (III.24), while on the rhs we have the natural action of $N=2$ on the modules $\mathfrak{V}_{h,t;\theta}$ and the trivial action on the Heisenberg modules.

Remark III.10: The theorem remains valid when the $\widehat{sl}(2)$ or $N=2$ modules are no longer Verma modules but rather arbitrary modules from the category of highest-weight modules.

In fact, one has a stronger result, which follows from the analysis of each of the mappings F_{KS} and F_{KS}^{-1} separately.

Theorem III.11: (I) *The KS mapping induces an isomorphism of $N=2$ representations,*

$$\mathfrak{M}_{j,k;\theta}\otimes\Omega\approx\bigoplus_{m\in\mathbb{Z}}\mathfrak{V}_{-2j/(k+2),k+2;m-\theta}\otimes\mathcal{H}^{+}_{\sqrt{2/(k+2)}(j-(k/2)\theta-m)} \tag{III.28}$$

where on the lhs the $N=2$ algebra acts by generators (III.1)–(III.3), while on the rhs it acts naturally on the twisted topological Verma modules $\mathfrak{V}_{-2j/(k+2),k+2;m-\theta}$.

(II) *The anti-KS mapping induces an isomorphism of $\widehat{sl}(2)$ representations,*

$$\mathfrak{V}_{h,t;\theta}\otimes\Xi\approx\bigoplus_{n\in\mathbb{Z}}\mathfrak{M}_{-(t/2)h,t-2;n-\theta}\otimes\mathcal{H}^{-}_{\sqrt{t/2}(h-(t-2)/t\theta+n)} \tag{III.29}$$

where on the lhs the $\widehat{sl}(2)$ algebra acts by generators (III.12), while on the rhs it acts naturally on the twisted Verma modules $\mathfrak{M}_{-(t/2)h,t-2;n-\theta}$.

Remark III.12: Observe that for $k\in\mathbb{Z}$, each of the formulas (III.28) and (III.29) translates the periodicity under $\theta\mapsto\theta+2$ on the $\widehat{sl}(2)$ side (which is known to hold for integrable representations) into the periodicity under $\theta\mapsto\theta+k+2$ on the $N=2$ side (which, too, is a well-known property of the corresponding $N=2$ representations and conformal models, where it is observed, for example, in the Landau–Ginzburg formulation).

Proof of the Theorem: It is easy to see that the lhs of (III.26) contains each state $|j,k\rangle_{sl(2)}\otimes|\theta\rangle_{\mathrm{GH}}$ with all $\theta\in\mathbb{Z}$. Further, we see that each state $|j,k\rangle_{sl(2)}\otimes|\theta\rangle_{\mathrm{GH}}$ satisfies the $N=2$ and Heisenberg annihilation conditions, Eqs. (II.102) and (III.9), respectively. Therefore, each state $|j,k\rangle_{sl(2)}\otimes|\theta\rangle_{\mathrm{GH}}$ can be rewritten in the form

$$|j,k\rangle_{sl(2)}\otimes|\theta\rangle_{\mathrm{GH}}=\left|\frac{-2j}{k+2},k+2;\theta\right\rangle_{\mathrm{top}}\otimes\left|\sqrt{\frac{2}{k+2}}\,(j-\theta)\right\rangle^{+},\quad\theta\in\mathbb{Z}. \tag{III.30}$$

Thus, as θ runs over the integers, every $\widehat{sl}(2)$ highest-weight state gives rise to infinitely many states satisfying twisted topological highest-weight conditions (II.108)–(II.109). From any of these states we can generate the twisted topological Verma module $\mathfrak{V}_{-2j/(k+2),k+2;\theta}$. All the states in every such module have a fixed value of the I_0^+ charge [see (III.6)], and this charge is different for modules with different θ. Thus the modules $\mathfrak{V}_{-2j/(k+2),k+2;\theta}$ do not overlap for different $\theta\in\mathbb{Z}$. Therefore, we have the mapping

$$\mathfrak{M}_{j,k;\theta}\otimes\Omega\leftarrow\bigoplus_{m\in\mathbb{Z}}\mathfrak{V}_{-2j/(k+2),k+2;m-\theta}\otimes\mathcal{H}^{+}_{\sqrt{2/(k+2)}(j-(k/2)\theta-m)}, \tag{III.31}$$

whose kernel may be different from zero only as a result of the vanishing of some singular vectors in the modules $\mathfrak{V}_{-2j/(k+2),k+2;m-\theta}$. In a similar way, we arrive at the mapping

$$\mathfrak{V}_{h,t;\theta}\otimes\Xi\leftarrow\bigoplus_{n\in\mathbb{Z}}\mathfrak{M}_{-(t/2)h,t-2;n-\theta}\otimes\mathcal{H}^{-}_{\sqrt{t/2}(h-[(t-2)/t]\theta+n)}. \tag{III.32}$$

Now, we tensor (III.31) with Ξ and make use of (III.32). Note that for the modules under consideration, tensor products preserve exactness. Then the mapping (III.31) gives rise to

$$\mathfrak{M}_{j,k;\theta}\otimes\Omega\otimes\Xi\leftarrow\bigoplus_{m,n\in\mathbb{Z}}\mathfrak{M}_{j,k;\theta+n-m}\otimes\mathcal{H}^{+}_{\sqrt{2/(k+2)}(j-(k/2)\theta-m)}\otimes\mathcal{H}^{-}_{-\sqrt{2/(k+2)}(j-(k/2)(\theta-m)-[(k+2)/2]n)}, \tag{III.33}$$

which is an isomorphism by Theorem III.9; hence both (III.31) and (III.32) are isomorphisms.□

Corollary 1: Singular vectors in the $\widehat{sl}(2)$ Verma modules and in the topological $N=2$ Verma modules occur (or do not occur) simultaneously. Thus, formulas (II.113) for positions of the topological singular vectors are rederived by translating the positions of the $\widehat{sl}(2)$ singular vectors under the KS mapping.

Corollary 2: Let there exist a singular vector with the J_0^0 charge equal to r in the $\widehat{sl}(2)$ Verma module on the lhs of (III.31); then each topological $N=2$ Verma module $\mathfrak{V}_{-2j/(k+2),k+2;m-\theta}$ from the rhs of (III.31) contains a topological singular vector, which satisfies highest-weight conditions (II.108) with $\theta\to m-\theta+r$.

Proof: Let us consider the tensor product $|S(r)\rangle\otimes|\lambda\rangle_{\mathrm{GH}}$, where $|S(r)\rangle$ denotes a singular vector with the charge r in the $\widehat{sl}(2)$ Verma module from the lhs of (III.31), and $|\lambda\rangle_{\mathrm{GH}}$ is the ghost λ-vacuum (II.86). Let us determine which module $\mathfrak{V}_{-2j/(k+2),k+2;m-\theta}$ from the rhs of (III.31) the state $|S(r)\rangle\otimes|\lambda\rangle_{\mathrm{GH}}$ belongs to. To this end, we calculate the eigenvalue of I_0^+ [see (III.6)] on the state $|S(r)\rangle\otimes|\lambda\rangle_{\mathrm{GH}}$:

$$I_0^+|S(r)\rangle\otimes|\lambda\rangle_{\mathrm{GH}}=\sqrt{\frac{2}{k+2}}\left(j+r-\frac{k}{2}-\lambda\right)|S(r)\rangle\otimes|\lambda\rangle_{\mathrm{GH}}.$$

Therefore, the state $|S(r)\rangle\otimes|m+r\rangle_{\mathrm{GH}}$ belongs to $\mathfrak{V}_{-2j/(k+2),k+2;m-\theta}$ and, as follows easily from formulas (II.86) and (III.1), satisfies highest-weight conditions (II.108) with $\theta\to m-\theta+r$. □
A constructive description of the correspondence between singular vectors is considered in Sec. IV A.

Corollary 3: The isomorphism established in the theorem implies an identity for the characters:

$$\begin{aligned}&\mathrm{Tr}_{\mathcal{M}_{j,k}\otimes\Omega}(q^{L_0^{\mathrm{Sug}}+L_0^{\mathrm{GH}}}z^{J_0^0-(BC)_0})\\&\quad=\mathrm{Tr}_{\oplus_{\theta=-\infty}^{\infty}\mathfrak{V}_{-2j/(k+2),k+2;\theta}\otimes\mathcal{H}^{+}_{\sqrt{2/(k+2)}(j-\theta)}}(q^{L_0+L_0^+}z^{-2H_0+(k-2)/\sqrt{2(k+2)}I_0^+}).\end{aligned} \tag{III.34}$$

Inserting the characters, given above, of each of the modules involved, this can be rewritten as the following formal identity:

$$\begin{aligned}\frac{\prod_{i=0}^{\infty}(1+zq^i)\prod_{i=1}^{\infty}(1+z^{-1}q^i)}{\prod_{i=0}^{\infty}(1-z^{-1}q^i)\prod_{i=1}^{\infty}(1-zq^i)}&=\frac{\prod_{i=1}^{\infty}(1+z^2q^i)\prod_{i=1}^{\infty}(1+z^{-2}q^i)}{\prod_{i=1}^{\infty}(1-q^i)^2}\\&\quad\times\left(1+(1+z^2)\sum_{r=1}^{\infty}\left[\frac{z^{-r}}{1+z^2q^r}+\frac{q^rz^{r-2}}{1+z^{-2}q^r}\right]\right).\end{aligned} \tag{III.35}$$

2. The relaxed/massive Verma module case

Now, we give an extension of Theorems III.9–III.11 to the relaxed and massive Verma modules.

Theorem III.13: (I) *The composition of the KS and anti-KS mappings induces an isomorphism of* $\widehat{sl}(2)$ *representations,*

$$\mathfrak{R}_{j,\Lambda,k;\theta}\otimes\Omega\otimes\Xi\approx\bigoplus_{n,m\in\mathbb{Z}}\mathfrak{R}_{j,\Lambda,k;\theta+n-m}\otimes\mathcal{H}^{+}_{\sqrt{2/(k+2)}(j-(k/2)\theta-m)}\otimes\mathcal{H}^{-}_{-\sqrt{2/(k+2)}(j-(k/2)(\theta-m)-[(k+2)/2]n)} \tag{III.36}$$

where on the lhs the $\widehat{sl}(2)$ action is given by the rhs's of (III.21), while on the rhs the $\widehat{sl}(2)$ algebra acts naturally on the modules $\mathfrak{R}_{j,\Lambda,k;\theta}$ and trivially on the Heisenberg modules.

(II) *The composition of the anti-KS mapping and the direct KS mapping induces an isomorphism of $N=2$ representations,*

$$\mathfrak{U}_{h,l,t;\theta}\otimes\Xi\otimes\Omega\approx\bigoplus_{n,m\in\mathbb{Z}}\mathfrak{U}_{h,t,l;\theta+m-n}\otimes\mathcal{H}^{-}_{\sqrt{t/2}(h-[(t-2)/t]\theta+n)}\otimes\mathcal{H}^{+}_{-\sqrt{t/2}(h-[(t-2)/t](\theta-n)+(2/t)m)}, \tag{III.37}$$

where on the lhs the $N=2$ algebra acts by generators (III.24), while on the rhs we have the natural action of $N=2$ on the modules $\mathfrak{M}_{h,l,t;\theta}$ and the trivial action on the Heisenberg modules.

This allows us to obtain, similarly to the above, the following theorem.

Theorem III.14: (I) *The KS mapping induces an isomorphism of $N=2$ representations,*

$$\mathfrak{R}_{j,\Lambda,k;\theta}\otimes\Omega\approx\bigoplus_{\lambda\in\mathbb{Z}}\mathfrak{U}_{-2j/(k+2),\Lambda/(k+2),k+2;\lambda-\theta}\otimes\mathcal{H}^{+}_{\sqrt{2/(k+2)}(j-(k/2)\theta-\lambda)}, \tag{III.38}$$

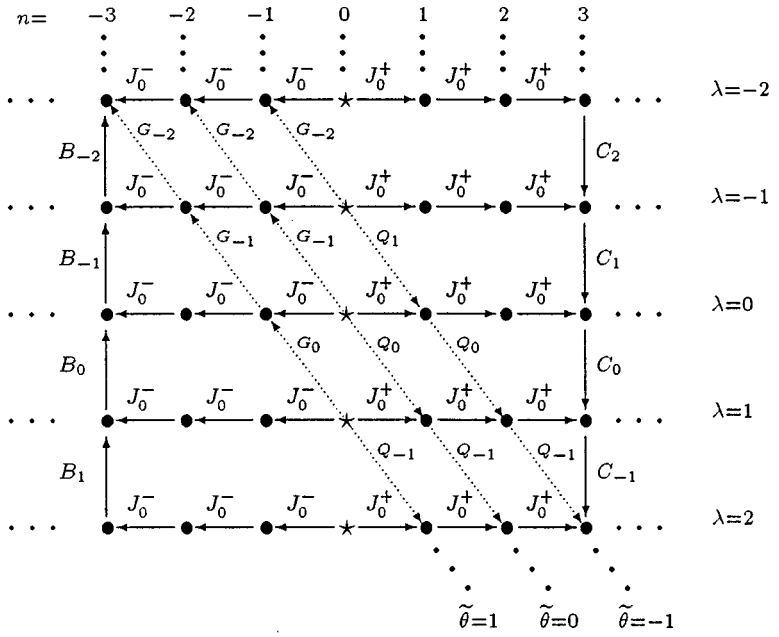
where on the lhs the $N=2$ algebra acts by generators (III.1)–(III.3), while on the rhs it acts naturally on the twisted massive Verma modules $\mathfrak{U}_{-2j/(k+2),l,k+2;\lambda-\theta}$.

(II) *The anti-KS mapping induces an isomorphism of $\widehat{sl}(2)$ representations,*

$$\mathfrak{U}_{h,l,t;\theta}\otimes\Xi\approx\bigoplus_{n\in\mathbb{Z}}\mathfrak{R}_{-(t/2)h,tl,t-2;n-\theta}\otimes\mathcal{H}^{-}_{\sqrt{t/2}(h-[(t-2)/t]\theta+n)}, \tag{III.39}$$

where on the lhs the $\widehat{sl}(2)$ algebra acts by generators (III.12), while on the rhs it acts naturally on the twisted relaxed Verma modules $\mathfrak{R}_{-(t/2)h,tl,t-2;n-\theta}$.

We could word by word repeat the proof of Theorems III.9–III.11 in the case of relaxed Verma modules. Instead, we illustrate the main points by the following diagram:



(III.40)

This describes the case of $\theta=0$ in (III.38) [which is the $\widehat{sl}(2)$ ''spectral'' parameter, not to be confused with the one labeling twisted $N=2$ modules that are also present in the diagram; the $N=2$ spectral parameter is denoted by $\tilde{\theta}$ here]. The diagram represents the tensor product of the relaxed Verma module extremal diagram (II.18) with a ghost extremal diagram. The latter consists of ghost vacua (II.86) taken in different pictures. As we have chosen $\theta=0$, the $\widehat{sl}(2)$ arrows are horizontal, as in (II.18), while the ghost ones are shown vertical. For simplicity, the ghost (B and

C) arrows are shown explicitly only in two columns. Since the different pictures (II.86) in the free-fermion system are all equivalent, all the vertical arrows are invertible, however, we have separated the B and C arrows in the diagram, trying to keep it readable. Thus the • dots denote $|j,\Lambda,k|n\rangle_{sl(2)}\otimes|\lambda\rangle_{\mathrm{GH}}$, the values of n being written in the upper row and those of λ, in the right column. The $\star$'s denote $|j,\Lambda,k\rangle_{sl(2)}\otimes|\lambda\rangle_{\mathrm{GH}}$. Now, the dotted lines are precisely the extremal diagrams (II.121) of massive Verma modules $\mathfrak{U}_{h,l,t;\tilde{\theta}}$ from the rhs of (III.38), viewed from above (the grading with respect to the level is in the direction orthogonal to the page).

Note also that the analogs of Corollaries 1 and 2 from the previous section are straightforward to formulate in the relaxed/massive case.

IV. EQUIVALENCE BETWEEN CATEGORIES

A. Equivalence of Verma chain categories

It follows from the above analysis that an equivalence between some categories of $\widehat{sl}(2)$ and $N=2$ modules can only be established for those categories that effectively allow for a factorization with respect to the spectral flow. These can be defined as follows.

Let us consider the objects that are infinite chains $(\mathfrak{M}_{j,k;\theta})_{\theta\in\mathbb{Z}}$, where $\mathfrak{M}_{j,k;\theta}$ are twisted Verma modules. As a morphism between $(\mathfrak{M}_{j,k;\theta})_{\theta\in\mathbb{Z}}$ and $(\mathfrak{M}_{j',k';\theta})_{\theta\in\mathbb{Z}}$, we take any Verma module morphisms $\mathfrak{M}_{j,k;\theta_1}\to\mathfrak{M}_{j',k';\theta_2}$. Let us call this category the $\widehat{sl}(2)$ Verma chain category $\mathcal{CVER}$.

On the $N=2$ side, the topological Verma chain category $\mathcal{CTVER}$ is defined similarly. Namely, one takes the chains of twisted topological Verma modules, every such chain comprising the modules that are the spectral flow transforms of a topological Verma module with all $\theta\in\mathbb{Z}$. Morphisms of the chains are defined similarly to the $\widehat{sl}(2)$ case. [It is important to note here that any submodule of a (twisted) topological Verma module is a twisted topological Verma module.]

The meaning of the definition of morphisms of chains is that, obviously, given a morphism between any two modules, one spreads it over the entire chains by spectral flow transforms.

To define a functor relating such chains, we first construct correspondences between individual modules in the chains.

Given a topological Verma module $\mathfrak{V}_{h,t;\theta}$, and an arbitrary $\theta'\in\mathbb{Z}$, take the Heisenberg modules $\mathcal{H}^{+}_{-\sqrt{(2/t)}((t/2)j+(t/2)\theta'-\theta)}$ and consider

$$\mathfrak{V}_{h,t;\theta}\otimes\mathcal{H}^{+}_{-\sqrt{(2/t)}((t/2)j+(t/2)\theta'-\theta)}\oplus\bigoplus_{m\in\mathbb{Z},m\neq 0}\mathfrak{V}_{h,t;\theta+m}\otimes\mathcal{H}^{+}_{-\sqrt{2/t}((t/2)j+(t/2)\theta'-\theta+m)}, \tag{IV.1}$$

where $\mathfrak{V}_{h,t;\theta+m}$ are the images of $\mathfrak{V}_{h,t;\theta}$ under the spectral flow. By Theorem III.9, (IV.1) is isomorphic to the tensor product of an $\widehat{sl}(2)$ Verma module $\mathfrak{M}_{-(t/2)h,t-2;\theta'}$ with a ghost module. We define the result of applying $F_{\mathrm{KS}}(\theta,\theta')$ to $\mathfrak{V}_{h,t;\theta}$ to be the module $\mathfrak{M}_{-(t/2)h,t-2;\theta'}$:

$$F_{\mathrm{KS}}(\theta,\theta'):\mathfrak{V}_{h,t;\theta}\rightsquigarrow\mathfrak{M}_{-(t/2)h,t-2;\theta'},\quad \theta,\theta'\in\mathbb{Z}. \tag{IV.2}$$

A similar definition can be given for the correspondence,

$$F^{-1}_{\mathrm{KS}}(\theta,\theta'):\mathfrak{M}_{j,k;\theta}\rightsquigarrow\mathfrak{V}_{-[2/(k+2)]j,k+2;\theta'},\quad \theta,\theta'\in\mathbb{Z}. \tag{IV.3}$$

Given a Verma module $\mathfrak{M}_{j,k;\theta}$ and $\theta'\in\mathbb{Z}$, we construct the sum

$$\mathfrak{M}_{j,k;\theta}\otimes\mathcal{H}^{-}_{-\sqrt{2/(k+2)}(j+\theta'-[(k+2)/2]\theta)}\oplus\bigoplus_{n\in\mathbb{Z},n\neq 0}\mathfrak{M}_{j+(k/2)n,k;\theta+n}\otimes\mathcal{H}^{-}_{-\sqrt{2/(k+2)}(j+\theta'-[(k+2)/2]\theta+n)}, \tag{IV.4}$$

which, by Theorem III.9, is isomorphic to the module $\mathfrak{V}_{-[2/(k+2)]j,k+2;\theta'}$ tensored with a module of antifermions. This twisted topological $N=2$ module is by definition the result of applying $F^{-1}_{\mathrm{KS}}(\theta,\theta')$ to $\mathfrak{M}_{j,k;\theta}$.

While the correspondences from (IV.2) and (IV.3) depend on the chosen θ and θ', the θ dependence disappears when applied to the elements of $\mathcal{CVER}$ and $\mathcal{CTVER}$; therefore $F_{\mathrm{KS}}(\cdot,\cdot)$ and $F^{-1}_{\mathrm{KS}}(\cdot,\cdot)$, which we denote again by F_{KS} and F^{-1}_{KS}, are candidates for the functors

$$F_{\mathrm{KS}} \;:\; \mathcal{CTVER} \;\rightsquigarrow\; \mathcal{CVER}$$
$$F_{\mathrm{KS}}^{-1} \;:\; \mathcal{CVER} \;\rightsquigarrow\; \mathcal{CTVER}$$

Evidently, the composition of F_{KS} and F_{KS}^{-1} maps each chain of twisted Verma modules into an isomorphic chain. Therefore, F_{KS} and F_{KS}^{-1} would be the direct and inverse functors, thus establishing the isomorphism of categories, once we define how F_{KS} and F_{KS}^{-1} act on morphisms.

Recall that in Verma-module categories, morphisms are naturally identified with singular vectors. As we see from the isomorphisms of Sec. III D, an $\widehat{sl}(2)$ singular vector exists in a twisted Verma module $\mathfrak{M}_{j,k;\theta}$ (hence in all those with $\theta \mapsto \theta+n$, $n\in\mathbb{Z}$) if and only if a topological singular vector exists in at least one (hence in each) twisted topological Verma module $\mathfrak{V}_{-2j/(k+2),k+2;m}$, $m\in\mathbb{Z}$, from the rhs of (III.28). The following lemma gives an explicit mapping between the ''building blocks'' of the corresponding singular vectors.

Lemma IV.1: The KS mapping induces a correspondence between the ''continued'' objects, $(J^-_{-\theta})^{\nu-\mu+1}$ and $(J^+_{\theta-1})^{\nu-\mu+1}$ on the one hand, and $g(\mu,\nu)$, $q(\mu,\nu)$ on the other hand, which act on the respective highest weights as shown in (II.11) and (II.112). The correspondence reads as

$$F_{\mathrm{KS}}(\theta',\theta):g(\mu,\nu)\mapsto(J^-_{-\theta})^{\nu-\mu+1}b(\mu,\nu), \qquad F_{\mathrm{KS}}(\theta',\theta):q(\mu,\nu)\mapsto(J^+_{\theta-1})^{\nu-\mu+1}c(\mu,\nu),$$
$$F_{\mathrm{KS}}^{-1}(\theta,\theta'):(J^-_{-\theta})^{\nu-\mu+1}\mapsto g(\mu,\nu)e^{-(\nu-\mu+1)\phi}, \qquad F_{\mathrm{KS}}^{-1}(\theta,\theta'):(J^+_{\theta-1})^{\nu-\mu+1}\mapsto q(\mu,\nu)e^{(\nu-\mu+1)\phi}.$$

This leads us to the following theorem.

Theorem IV.2: *The KS and anti-KS mappings give rise to identifications, which we denote again by $F_{\mathrm{KS}}(\theta,\theta')$ and $F_{\mathrm{KS}}^{-1}(\theta,\theta')$, respectively, between the twisted $\widehat{sl}(2)$ singular vectors (II.14) in the Verma module $\mathfrak{M}_{j,k;\theta}$ and the $N=2$ singular vectors (II.114) and (II.115) $|E(r,s,t)\rangle^{\pm,\theta}$ in the twisted topological Verma modules $\mathfrak{V}_{-[2/(k+2)]j,k+2;\theta}$:*

$$\begin{aligned} F_{\mathrm{KS}}(\theta,\theta'):&|E(r,s,k+2)\rangle^{\pm,\theta}\mapsto|S^{\mathrm{MFF}}_{\pm}(r,s,k)\rangle^{\theta'},\\ F_{\mathrm{KS}}^{-1}(\theta,\theta'):&|S^{\mathrm{MFF}}_{\pm}(r,s,k)\rangle^{\theta}\mapsto|E(r,s,k+2)\rangle^{\pm,\theta'}, \end{aligned} \tag{IV.5}$$

where $|E(r,s,t)\rangle^{\pm,\theta}$ and $|S^{\mathrm{MFF}}_{\pm}(r,s,k)\rangle^{\theta'}$ denote the singular vectors transformed by the corresponding spectral flows.

Evidently, $F_{\mathrm{KS}}(\cdot,\cdot)$ and $F_{\mathrm{KS}}^{-1}(\cdot,\cdot)$ applied to the chains of the respective Verma modules take morphisms (between chains) into morphisms. Thus we have made F_{KS} and F_{KS}^{-1} into functors. The results of this section can be summarized in the following theorem.

Theorem IV.3: *The functors F_{KS} and F_{KS}^{-1} are covariant functors that are inverse to each other and that therefore establish the equivalence between the Verma chain category $\mathcal{CVER}$ on the $\widehat{sl}(2)$ side and the topological Verma chain category $\mathcal{CTVER}$ on the $N=2$ side.*

B. Extending the equivalence to highest-weight-type categories

We have seen in the previous section that the $\widehat{sl}(2)$ Verma, and $N=2$ topological Verma chain categories are equivalent. Now we would like to extend the equivalence to larger categories. Let us define the highest-weight-type chain category.

Definition IV.4: The highest-weight-type chain category $\mathcal{CHW}$ is the category whose objects are chains of modules from the category $\mathcal{HW}$ of $\widehat{sl}(2)$ highest-weight-type representations twisted by the spectral flow with integer parameters. A morphism between two such chains $(\mathcal{N}_\theta)_{\theta\in\mathbb{Z}}$ and $(\mathcal{N}'_\theta)_{\theta\in\mathbb{Z}}$ is any morphism $\mathcal{N}_{\theta_1}\to\mathcal{N}'_{\theta_2}$ (which is understood to be spread over the entire chains by the spectral flow).

Remark IV.5: As an aside, note that the condition for any such chain to admit nontrivial automorphisms singles out the *minimal* $\widehat{sl}(2)$ models, and the same is true for the chains of $N=2$ modules. Then, taking the factors with respect to the respective spectral flows, we would have the same number of fields in the $\widehat{sl}(2)$ and $N=2$ minimal models. Thus, the minimal models of these algebras can be thought of as *periodical chains* of representations; we hope to demonstrate elsewhere the usefulness of such a viewpoint.

On the $N=2$ side, these twisted categories mix into one category because submodules of a (twisted) topological Verma module are the twisted topological Verma modules with different θ.

Definition IV.6: The topological chain category $\mathcal{CTOP}$ is the category whose objects are chains of modules from the topological category $\mathcal{TOP}$ twisted by the spectral flow with integer parameters. A morphism between two such chains $(\mathcal{U}_\theta)_{\theta\in\mathbb{Z}}$ and $(\mathcal{U}'_\theta)_{\theta\in\mathbb{Z}}$ is any morphism $\mathcal{U}_{\theta_1}\to\mathcal{U}'_{\theta_2}$ of $N=2$ modules.

Theorem IV.7: *The functors F_{KS} and F_{KS}^{-1} establish the equivalence between categories $\mathcal{CHW}$ and $\mathcal{CTOP}$.*

C. Equivalence of the relaxed and massive Verma chain categories

We define chains of relaxed Verma modules on the $\widehat{sl}(2)$ side and chains of massive Verma modules on the $N=2$ side, as this was done in Sec. IV A. Then, we formulate the theorem, whose proof is a consequence of Lemma IV.1.

Theorem IV.8: *The KS and anti-KS mappings give rise to identifications, which we denote again by $F_{\mathrm{KS}}(\theta,\theta')$ and $F_{\mathrm{KS}}^{-1}(\theta,\theta')$ respectively, between the following.*

(1) *Singular vectors (II.45) and (II.46) in the relaxed Verma module $\mathfrak{R}_{j,\Lambda,k;\theta}$ and $N=2$ singular vectors (II.129) in the twisted massive Verma modules $\mathfrak{U}_{-[2/(k+2)]j,\Lambda/(k+2),k+2;\theta}$:*

$$\begin{aligned} F_{\mathrm{KS}}(\theta,\theta'):|\Sigma^{\pm}(r,s,j,k)\rangle^{\theta}&\mapsto\left|S\left(r,s,\frac{-2j}{k+2},k+2\right)\right\rangle^{\mp,\theta'},\\ F_{\mathrm{KS}}^{-1}(\theta,\theta'):|S(r,s,h,t)\rangle^{\mp,\theta}&\mapsto\left|\Sigma^{\pm}\left(r,s,-\frac{t}{2}h,t-2\right)\right\rangle^{\theta'}, \end{aligned} \tag{IV.6}$$

and also between the following.

(2) *Charged $\widehat{sl}(2)$ singular vectors (II.30) and charged $N=2$ singular vectors (II.126):*

$$\begin{aligned} F_{\mathrm{KS}}(\theta,\theta'):|C(r,j,k)\rangle^{\theta}&\mapsto|E(r,-2j/(k+2),k+2)\rangle_{\mathrm{ch}}^{\theta'},\\ F_{\mathrm{KS}}^{-1}(\theta,\theta'):|E(r,h,t)\rangle_{\mathrm{ch}}^{\theta}&\mapsto|C(r,-ht/2,t-2)\rangle^{\theta'}, \end{aligned} \tag{IV.7}$$

where $|\Sigma^{\pm}(r,s,j,k)\rangle^{\theta}$, $|S(r,s,h,t)\rangle^{\mp,\theta'}$, etc., denote the respective singular vectors transformed by the corresponding spectral flows.

Again, as in Sec. IV A, we can formulate the following.

Theorem IV.9: *The functors F_{KS} and F_{KS}^{-1} are covariant functors that are inverse to each other and that therefore establish the equivalence of the relaxed Verma chain category $\mathcal{CRVER}$ on the $\widehat{sl}(2)$ side and the massive Verma chain category $\mathcal{CMVER}$ on the $N=2$ side.*

D. Extending the equivalence to the relaxed highest-weight-type categories

We now formulate an extension of the categorial equivalence F_{KS} and F_{KS}^{-1} to the case of the largest categories $\mathcal{CRHW}$ and $\mathcal{CMHW}$ in diagram (I.1). The definitions of the chain categories $\mathcal{CRHW}$ and $\mathcal{CMHW}$ can be obtained by means of a step-by-step repetition of Definitions IV.4 and IV.6 and are omitted. Then the analog of Theorem IV.7 reads as follows.

Theorem IV.10: *The functors F_{KS} and F_{KS}^{-1} establish the equivalence between categories $\mathcal{CRHW}$ and $\mathcal{CMHW}$.*

V. CONCLUDING REMARKS

We believe that the issues addressed in this paper will be essential in a number of problems in the $\widehat{sl}(2)$ and $N=2$ representation theories as well as in conformal field theory.

Comparing the $\widehat{sl}(2)$ and $N=2$ highest-weight representations, it may be observed that the occurrence of infinitely many highest-weight states in $\widehat{sl}(2)$ relaxed Verma modules is intuitively more ''obvious'' than in its $N=2$ counterpart; all of the $\widehat{sl}(2)$ relaxed-highest-weight states are on

the same floor in the extremal diagram, whereas in the $N=2$ case this is not so: extremal diagrams of untwisted massive $N=2$ modules contain only two vectors at the top level, and it may be tempting to assign to these a more fundamental status than to the other vectors from the extremal diagram. Working with the top-level representative of $N=2$ extremal diagrams conceals the ''topological'' (''twisted-chiral'') nature of some of submodules in massive $N=2$ Verma modules (see Ref. 14 for a detailed description of the structure of $N=2$ Verma modules).

As to the structure of relaxed-$\widehat{sl}(2)$ or massive $N=2$ Verma modules, we have seen that a significant difference from the familiar Virasoro or the usual-$\widehat{sl}(2)$ case is that (to use the $N=2$ language) a given massive $N=2$ Verma module may contain submodules of two types: the twisted topological and the massive ones. An important point is that every submodule can be *freely* generated from a twisted (topological) highest-weight vector [singular vectors (II.114) and (II.115) in the topological Verma modules and (II.126) and (II.129) in massive Verma modules]. From these results, it is not too difficult to derive the complete classification of embedding diagrams of the relaxed-$\widehat{sl}(2)$ and massive-$N=2$ Verma modules.[27] These follow (an extension of) the familiar I–II–III pattern; the embedding structure can be described without invoking subsingular vectors,[14] since the above singular vectors generate *maximal* submodules [that subsingular vectors in massive-$N=2$/relaxed-$\widehat{sl}(2)$ modules are superfluous can most clearly be seen in the $\widehat{sl}(2)$ language].

Another problem is the derivation of fusion rules. In order to completely define the fusion rules, one has to fix, among other things, the category of representations. On the $\widehat{sl}(2)$ side, the fusion rules have been obtained in Refs. 1 and 2 (see also Refs. 4 and 5). However, these do not include the twisted (spectral-flow-transformed) $\widehat{sl}(2)$ representations, whose contribution is to be expected on general grounds.[2] This is related to the fact that only the quantum group $osp(1|2)_q$ has so far been observed as a symmetry of $\widehat{sl}(2)$ fusion rules, while a larger quantum group $sl(2|1)_q$ is to be expected. This is an indication that some modules are still missing from the known fusion; we hope that we have described the representation-theoretic part of the desired more general construction. Then the complete $\widehat{sl}(2)$ fusion rules factored with respect to the spectral flow would be isomorphic to complete $N=2$ fusion rules factored over the $N=2$ spectral flow.

I. INTRODUCTION

The purpose of this paper is to provide definitions for, and proofs of, the asymptotic formulas given by Edmonds,[1] which relate the $3j$ and $6j$ symbols to rotation matrices.

The study of the asymptotics of the $6j$ symbol dates back to Racah,[2] who stated an asymptotic formula relating $6j$ symbols and Legendre polynomials. Edmonds[1] later generalized Racah's formula by replacing the Legendre polynomial by a rotation matrix. For $a,b,c \gg f,m,n$, Edmonds stated,

$$\begin{Bmatrix} c & b & a \\ f & a+n & b+m \end{Bmatrix} \approx \frac{(-1)^{a+b+c+f+m}}{\sqrt{(2a+1)(2b+1)}}\, d^{f}_{nm}(\phi), \tag{1}$$

where

$$\cos\,\phi = \frac{a(a+1)-b(b+1)-c(c+1)}{2\sqrt{a(a+1)b(b+1)}}. \tag{2}$$

Edmonds also gave a further result which related the $3j$ symbol to a rotation matrix. For $a,c \gg b$, Edmonds stated,

$$\begin{pmatrix} b & a & c \\ \beta & \alpha & \gamma \end{pmatrix} \approx \frac{(-1)^{b-a-\gamma}}{\sqrt{2c+1}}\, d^{b}_{\delta,-\beta}(\theta), \tag{3}$$

where

$$\cos\,\theta\,\frac{\gamma}{\sqrt{c(c+1)}}. \tag{4}$$

Edmonds did not give a proof of either result, nor did he define how the angular momenta scaled or how the $3j$ and $6j$ symbols approached the rotation matrices.

Edmonds reasoned that, for sufficiently large c, (4) could be replaced by

$$\cos\,\theta = \frac{\gamma}{c}. \tag{5}$$

Brussaard and Tolhoek,[3] following a suggestion of Edmonds, argued heuristically, that if $a,c \gg b$ and θ is defined by (5) then (3) holds. Brussaard and Tolhoek did not define how a and c scaled, nor did they define how the $3j$ symbol approached the rotation matrix.

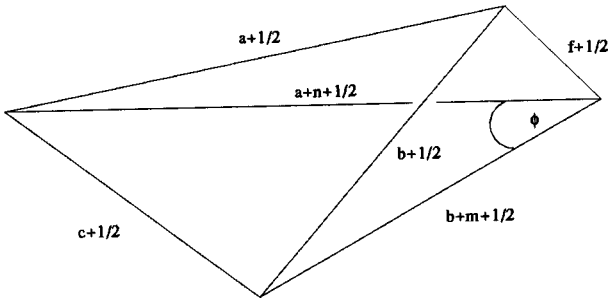

FIG. 1. Associated tetrahedron.

Some years later, Ponzano and Regge[4] discussed the geometry of the asymptotics of the $3j$ and $6j$ symbols. To each asymptotic $6j$ symbol, Ponzano and Regge associated a tetrahedron whose edges had length $j+\frac{1}{2}$, where j is an entry in the $6j$ symbol, and to each asymptotic $3j$ symbol they associated a triangle whose edges were labeled in the same manner. Thus the tetrahedron associated to the above $6j$ symbol is that given in Fig. 1, from which

$$\cos\,\phi=\frac{(a+n+(1/2))^2+(b+m+(1/2))^2-(c+(1/2))^2}{2(a+n+(1/2))(b+m+(1/2))}. \tag{6}$$

The triangle associated to the above $3j$ symbol is given in Fig. 2, from which

$$\cos\,\theta=\frac{\gamma}{c+(1/2)}. \tag{7}$$

Hence there is a discrepancy between the geometrical aspect, given by Ponzano and Regge, and the algebraic aspect, given by Edmonds, Brussaard, and Tolhoek. If we relabel the edges of the associated tetrahedron and triangle by $\sqrt{j(j+1)}$ instead of $j+\frac{1}{2}$ then ϕ and θ are defined by (2) and (4), respectively. In Ref. 4, Ponzano and Regge give an important asymptotic formula for the $6j$ symbol in which the associated tetrahedron is label as above. If we relabel the edges of the associated tetrahedron by $\sqrt{j(j+1)}$ and apply the relevant modifications to Ponzano and Regge's asymptotic formula, then this modified formula provides a worse approximation to the $6j$ symbol than Ponzano and Regge's original formula. This is discussed in the first part of Sec. IV. We define ϕ and θ by (6) and (7), respectively, rather than by (2) and (4) for the following two reasons. The first is that all the formulas are simpler with these definitions and the second is that these definitions are consistent with Ponzano and Regge which is important for the above reasons.

The purpose of this paper is to provide definitions for, and proofs of, the asymptotic formulas which relate the $3j$ symbol and rotation matrix of (3), and the $6j$ symbol and rotation matrix of

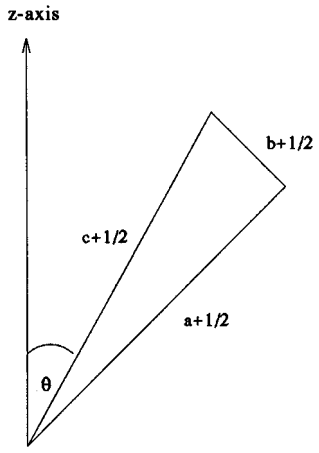

FIG. 2. Associated triangle.

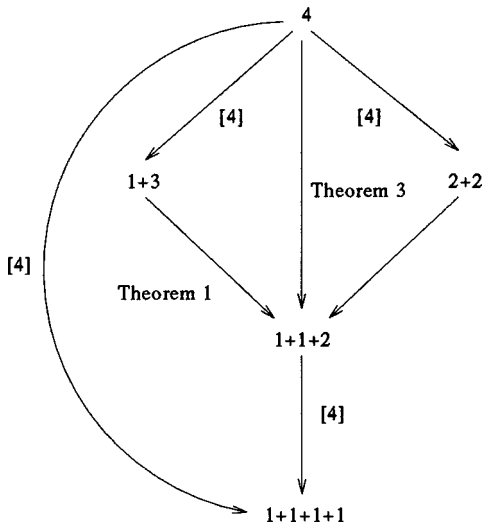

FIG. 3. Asymptotics of the $6j$ symbol.

(1). In both cases, we define how the angular momenta scale, and we also define how these particular $3j$ and $6j$ symbols approach the rotation matrices of (3) and (1), respectively. These definitions make precise $a,c \gg b$ and $a,b,c \gg f,m,n$ and $\approx$. With these definitions, in Sec. II, we prove (3), where θ is defined by (7), and in Sec. III, we prove (1), where ϕ is defined by (6). In the first part of Sec. IV, we discuss why ϕ and θ are defined by (6) and (7) rather than by (2) and (4). In the last part of Sec. IV, we discuss the relationship between the results proved in Secs. II and III. This entails using the result proved in Sec. II to arrive at an expression of a similar type to that proved in Sec. III.

The study of the asymptotics of $3j$ and $6j$ symbols is important in understanding the Ponzano–Regge model of three dimensional Euclidean quantum gravity.[4] In this approach, three dimensional spacetime is approximated by a simplicial manifold formed by gluing together tetrahedra. To each edge of a tetrahedron in this simplicial manifold Ponzano and Regge associate a half integer j, with the length of that edge defined as $j+\frac{1}{2}$, in such a way that the triangle inequality is satisfied on all the faces of that tetrahedron. They then thus associate to each such labeled tetrahedron a $6j$ symbol.

Any potential candidate for the quantum theory of gravity must reduce to general relativity in some suitable limit. By allowing various combinations of the edges in each tetrahedron in the simplicial manifold to become large, the Ponzano–Regge model reduces to three dimensional general relativity without a cosmological constant. Thus to understand the relationship between the Ponzano–Regge model of quantum gravity and general relativity the asymptotics of the $3j$ and $6j$ symbols is important. The reduction of the above asymptotic $6j$ symbol to the rotation matrix $d^{f}_{nm}(\theta)$ plays a crucial role in understanding the relationship between the Ponzano–Regge model of three dimensional quantum gravity and the construction of topological state sums from tensor categories.[5]

Figure 3[6] shows all the possible asymptotic limits of the $6j$ symbol. These limits correspond to moving various combinations of the four vertices of the associated tetrahedron. At the top of Fig. 3 is the unscaled $6j$ symbol in which the four vertices remain fixed. In the $1+3$ case, one vertex is taken to infinity while the remaining three remain fixed. This represents the reduction of a $6j$ symbol to a $3j$ symbol.[4] In the $1+1+2$ case, two of the vertices remain fixed and the remaining two move away from the fixed vertices as well as away from each other. This represents (1).

II. ROTATION MATRICES AND 3*j* SYMBOLS

Following Edmonds,[1] we first define the $3j$ symbol and then the rotation matrix.

Let a, b, and c be non-negative half integers which satisfy the triangle inequality, and let $|\alpha| \leqslant a$, $|\beta| \leqslant b$, and $|\gamma| \leqslant c$ with $\alpha+\beta+\gamma=0$, then the $3j$ symbol is defined by

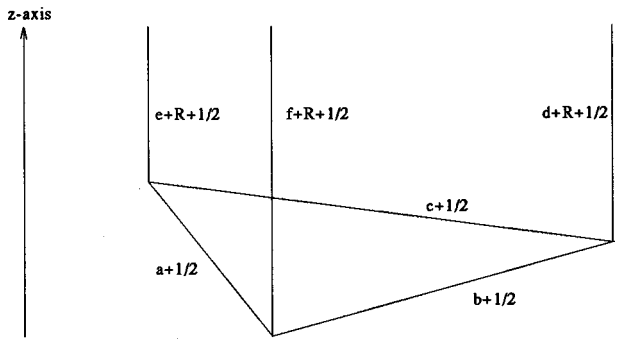

FIG. 4. Associated tetrahedron.

$$\begin{pmatrix} a & b & c \\ \alpha & \beta & \gamma \end{pmatrix} = [\Delta(abc)(a+\alpha)!(a-\alpha)!(b+\beta)!(b-\beta)!(c+\gamma)!(c-\gamma)!]^{1/2} \times \sum_z \frac{(-1)^{z+a-b-\gamma}}{(z!(a+b-c-z)!(c-b+\alpha+z)!(b+\beta-z)!(a-\alpha-z)!(c-a-\beta+z)!)}, \tag{8}$$

where the summation is over all integers z such that the factorial arguments are non-negative and

$$\Delta(abc) = \frac{(a+b-c)!(a-b+c)!(-a+b+c)!}{(a+b+c+1)!}.$$

Let j be a non-negative half integer and let $|m'|$, $|m| \leqslant j$, then the rotation matrices are defined by

$$d^j_{m'm}(\theta) = (-1)^{j-m'}[(j+m')!(j-m')!(j+m)!(j-m)!]^{1/2} \times \sum_k (-1)^k \frac{(\cos\,\theta/2)^{2k+m'+m}(\sin\,\theta/2)^{2j-2k-m'-m}}{k!(j-m'-k)!(j-m-k)!(m'+m+k)!},$$

where the summation is over all integers k such that the factorial arguments are non-negative. The rotation matrices are the matrix elements in the $2j+1$ dimensional representation of rotations about a fixed axis.

We have divided the discussion of the relationship between the $3j$ symbol and the rotation matrix into two cases depending upon γ. We discuss the case where $c-|\gamma| \to \infty$ in theorem 1 and the case where $c = \pm\gamma$ in theorem 2.

Theorem 1: *Fix b and β and let $a, c \to \infty$ in such a way that $c-a=\delta$ is fixed and let $c-|\gamma| \to \infty$, then*

$$\sqrt{a+b+c+1}\begin{pmatrix} b & a & c \\ \beta & \alpha & \gamma \end{pmatrix} - (-1)^{b-a-\gamma} d^b_{\delta,-\beta}(\theta) \to 0,$$

where

$$\cos\,\theta = \frac{\gamma}{c+(1/2)}. \tag{9}$$

The theorem is nontrivial as the right hand side does not converge to zero under this asymptotic limit.

Proof: Eliminating a and α from (8), as $c-a=\delta$ and $\alpha+\beta+\gamma=0$, and then expanding the Δ symbol gives

$$\begin{pmatrix} b & a & c \\ \beta & \alpha & \gamma \end{pmatrix} = (-1)^{b-a-\gamma}\left[\frac{(b+\beta)!(b-\beta)!(b-\delta)!(b+\delta)!}{2c+b-\delta+1}\right]^{1/2} \times \sum_z \frac{(-1)^z[\Omega_1\Omega_2\Omega_3]^{1/2}}{z!(b-\delta-z)!(b-\beta-z)!(\beta+\delta+z)!}, \tag{10}$$

where

$$\Omega_1 = \frac{(2c-\delta-b)!}{(2c-\delta+b)!}, \qquad \Omega_2 = \frac{(c+\gamma-\delta+\beta)!(c+\gamma)!}{[(c+\gamma-b+\beta+z)!]^2},$$

$$\Omega_3 = \frac{(c-\gamma-\delta-\beta)!(c-\gamma)!}{[(c-\gamma-\delta-\beta-z)!]^2}.$$

As a and c tend to infinity in the manner defined above, it is important that the range of summation in (10) remains finite. If this is not the case then the error generated by the approximations used to reduce the $3j$ symbol to a rotation matrix may not converge to zero. Brussaard and Tolhoek[4] did not discuss the effect the asymptotic limit had on the range of summation. The summation variable z is bounded above by

$$\min(c-\delta-\gamma-\beta, b-\delta, b-\beta)$$

and is bounded below by

$$\max(-c+b-\gamma-\beta, 0, -\beta-\delta).$$

By hypothesis, $c-|\gamma|\to\infty$ so that the first term in each of the above is redundant as b, β, and δ are all fixed. Thus the range of summation is fixed eventually.

Stirling's approximation[7] to $n!$ is

$$n! \sim \sqrt{2\pi} n^{n+(1/2)} e^{-n}$$

where $a \sim b$ means $a/b \to 1$ as n tends to infinity. Also,

$$n! \sim \sqrt{2\pi}(n+1)^{n+(1/2)} e^{-(n+1)} \tag{11}$$

and

$$n! \sim \sqrt{2\pi}(n+\tfrac{1}{2})^{n+(1/2)} e^{-(n+(1/2))}. \tag{12}$$

Applying (11) to the first factor in Ω and (12) to the rest gives

$$\Omega \sim \left(\sin\frac{\theta}{2}\right)^{2z+\beta+\delta}\left(\cos\frac{\theta}{2}\right)^{2b-2z-\beta-\delta}, \tag{13}$$

where θ defined by (9) and $\Omega = [\Omega_1\Omega_2\Omega_3]^{1/2}$. The constraint that the factorial arguments in (8) have to be non-negative implies that the above powers are also non-negative as

$$2z+\beta+\delta = z+(z+\beta+\delta),$$

$$2b-2z-\beta-\delta = (b-\beta-z)+(b-\delta-z).$$

The right-hand side of (13) is bounded above by 1 and so

$$\Omega - \left(\sin\frac{\theta}{2}\right)^{2z+\beta+\delta}\left(\cos\frac{\theta}{2}\right)^{2b-2z-\beta-\delta} \to 0.$$

As the range of summation in (10) is eventually fixed, the error generated by applying various approximations to the factorials in Ω_i, $i=1,2,3$, will converge to zero. Thus

$$\sqrt{a+b+c+1}\begin{pmatrix} b & a & c \\ \beta & \alpha & \gamma \end{pmatrix} - (-1)^{b-a-\gamma}(-1)^{\beta-b} d^b_{\beta,\delta}(\pi-\theta) \to 0$$

and as $d^b_{\beta,\delta}(\pi-\theta)=(-1)^{b-\beta} d^b_{\delta,-\beta}(\theta)$ the result follows. □

Theorem 2: *Fix b and β, let $\gamma=\pm c$ and let $a,c\to\infty$ so that $c-a=\delta$ is fixed, then*

$$\sqrt{a+b+c+1}\begin{pmatrix} b & a & c \\ \beta & \alpha & \gamma \end{pmatrix} - (-1)^{\xi}\delta_{\alpha,\mp a} \to 0,$$

where

$$\xi = \begin{cases} -a+b-c & \text{for } \gamma=c \\ 2b+\delta-\beta & \text{for } \gamma=-c. \end{cases}$$

Proof: Similar to that for theorem 1. □

III. ROTATION MATRICES AND 6*j* SYMBOLS

Following Edmonds,[1] we define the $6j$ symbol as follows. Let a, b, c, d, e, and f be non-negative half integers such that each of the triples $\{abc\}$, $\{cde\}$, $\{aef\}$, and $\{bdf\}$ satisfies the triangle inequality and the sum of the entries in each triple is an integer, then the $6j$ symbol is defined by

$$\begin{Bmatrix} a & b & c \\ d & e & f \end{Bmatrix} = [\Delta(abc)\Delta(cde)\Delta(aef)\Delta(bdf)]^{1/2} \times \sum_z \frac{(-1)^z (z+1)!}{\begin{pmatrix} (z-a-b-c)!(z-a-e-f)!(b+c+e+f-z)!(z-d-e-c)! \\ \times (z-b-d-f)!(a+b+d+e-z)!(a+c+f+d-z)! \end{pmatrix}},$$

where the summation is over all integers z such that the factorial arguments are non-negative and

$$\Delta(abc) = \frac{(a+b-c)!(a-b+c)!(-a+b+c)!}{(a+b+c+1)!}.$$

Theorem 3: *Fix f, m, n and let $a=\lambda a_0$, $b=\lambda b_0$ and $c=\lambda c_0$ with $\lambda\to\infty$, then*

$$\sqrt{\omega_a \omega_b}\begin{Bmatrix} c & b & a \\ f & a+n & b+m \end{Bmatrix} - (-1)^{\xi} d^f_{nm}(\phi) \to 0,$$

where

$$\omega_a = 2a+n+f+1, \quad \omega_b = 2b+m+f+1, \quad \xi = a+b+c+f+m$$

and

$$\cos\phi = \frac{(a+n+(1/2))^2+(b+m+(1/2))^2-(c+(1/2))^2}{2(a+n+(1/2))(b+m+(1/2))}.$$

The scaling used in theorem 3 is clearly different from that used in theorem 1. The reason for this is that as λ tends to infinity, ϕ is preserved, whereas, if we had scaled a_0, b_0, and c_0 as we did in theorem 1 then ϕ would not have been preserved. Theorem 3 is nontrivial as $d^f_{nm}(\phi)$ does not converge to zero under this asymptotic limit.

Proof: Changing the summation variable from z to t, where $z=a+b+c+m+n+t$, and then expanding the Δ symbols gives,

$$\sqrt{\omega_a\omega_b}\begin{Bmatrix} c & b & a \\ f & a+n & b+m \end{Bmatrix} = (-1)^{\nu}[(f+m)!(f-m)!(f+n)!(f-n)!]^{1/2} \times \sum_t \frac{(-1)^t[\Pi_{i=1}^6 \Phi_i]^{1/2}}{t!(f-m-t)!(f-n-t)!(m+n+t)1},$$

where $\nu = a+b+c+m+n$ and

$$\Phi_1 = \frac{(2a+n-f)!}{(2a+n+f)!}, \qquad \Phi_2 = \frac{(2b+m-f)!}{(2b+m+f)!},$$

$$\Phi_3 = \frac{(a+b-c)!(a+b-c+m+n)!}{[(a+b-c-t)!]^2},$$

$$\Phi_4 = \frac{(a-b+c)!(a-b+c+n-m)!}{[(a-b+c+n-f+t)!]^2},$$

$$\Phi_5 = \frac{(-a+b+c)!(-a+b+c+m-n)!}{[(-a+b+c+m-f+t)!]^2},$$

$$\Phi_6 = \frac{[(a+b+c+m+n+1+t)!]^2}{(a+b+c+1)!(a+b+c+m+n+1)!}.$$

As in the proof of theorem 1, the constraints on t ensure that as a, b, and c tend to infinity in the manner defined above, the range of summation remains finite so that the error generated by applying various approximations to the factorials in Φ_i, $i=1,2,...,6$, will converge to zero. By applying (11) to Φ_1 and Φ_2 and (12) to the rest and following the arguments used in the proof of theorem 1 the result follows. □

IV. DISCUSSION

In the first part of this section we discuss why ϕ and θ are defined by (6) and (7) rather than by (2) and (4). In the last part of this section we discuss the relationship between theorems 1 and 3 which entails using theorem 1 to arrive at an expression of a similar type to that in theorem 3.

In the Introduction we noted that there was a discrepancy between the geometrical and algebraic parts of the asymptotics of the $6j$ symbol. Edmonds defined ϕ and θ by (2) and (4), respectively, whereas the geometrical interpretation of the asymptotics, given by Ponzano and Regge, leads to ϕ and θ being defined by (6) and (7). Of course, (2) is asymptotic to (6), and (4) is asymptotic to (7), because, if we substitute the binomial expansion of $\sqrt{j(j+1)}$ into each of the terms in (2) and (4) then (2) will converge to (6), and (4) will converge to (7), but, the geometry which leads to ϕ and θ being defined as in (2) and (4), when applied to a certain asymptotic formula, leads to a worse approximation to the $6j$ symbol. In Ref. 4, Ponzano and Regge give an asymptotic formula for the $6j$ symbol in which all the entries all large. They label the edges of the tetrahedron associated to this asymptotic $6j$ symbol by $j+\frac{1}{2}$, where j is an entry in the $6j$ symbol. Suppose we now relabel the edges of the this tetrahedron by $\sqrt{j(j+1)}$ and apply the relevant modifications to the Ponzano–Regge asymptotic formula. Then as can be seen in Table I, this modified asymptotic formula provides a worse approximation to the $6j$ symbol than Ponzano and Regge's original formula. Thus the labeling of the edges of the associated tetrahedron by $j+\frac{1}{2}$ is critical in the Ponzano–Regge asymptotic formula and as (1) and (3) should give rise to an asymptotic formula of the Ponzano–Regge type under some further asymptotic limit, we shall define ϕ and θ as in (6) and (7). Also, by defining ϕ and θ by (6) and (7), all the formulas are simpler, which can be seen in the proofs of theorems 1 and 3.

The column labeled $6j$ contains the exact value of the $6j$ symbol

$$\begin{Bmatrix} a & b & c \\ d & e & f \end{Bmatrix}$$

TABLE I. Exact and approximate values for the $6j$ symbol.

a	b	c	d	e	f	$6j$	$j+\frac{1}{2}$	$\sqrt{j(j+1)}$

13	15	24	$\frac{29}{2}$	$\frac{33}{2}$	$\frac{29}{2}$	−0.005 622 96	−0.005 432 66	−0.004 712 80

as defined in Sec. III. The next column contains the Ponzano–Regge approximation to the $6j$ symbol in which all the entries are large,[4]

$$\begin{Bmatrix} a & b & c \\ d & e & f \end{Bmatrix} \simeq \frac{1}{\sqrt{12\pi V}} \cos\left(\sum_{h<k} j_{hk}\theta_{hk} + \frac{\pi}{4} \right),$$

where

$$j_{12}=a+\tfrac{1}{2}, \quad j_{13}=b+\tfrac{1}{2}, \quad j_{14}=c+\tfrac{1}{2},$$

$$j_{23}=d+\tfrac{1}{2}, \quad j_{24}=e+\tfrac{1}{2}, \quad \text{and } j_{34}=f+\tfrac{1}{2},$$

are the edge lengths of the associated tetrahedron and θ_{hk} is the exterior dihedral angle between the two planes on the associated tetrahedron which meet in the edge j_{hk}, and V is the volume of the associated tetrahedron. The last column contains the modified Ponzano–Regge formula in which $\sqrt{j(j+1)}$ has replaced $j+\frac{1}{2}$ everywhere, including in the calculation of the volume V and the exterior dihedral angles θ_{hk}.

Superficially, theorems 1 and 3 appear to be similar as they both involve the reduction of the primary object to a rotation matrix. It is thus natural to ask if it is possible to arrive at an expression of a similar type to that in theorem 3 by using theorem 1. This is indeed possible, but it is important to point out that the asymptotic limit in this result will be the limit used in theorem 1 which is not the same as the scaling used in theorem 3.

The following arguments are not intended to prove the link between theorems 1 and 3 but are to be regarded as a possible justification for there being a link.

To discuss the existence of such a link we shall use two limits, both of which are of the same type used in theorem 1. The first limit reduces the relevant $6j$ symbol to a $3j$ symbol,[4] and the second limit when applied to this $3j$ symbol reduces it, by theorem 1, to a rotation matrix. The overall result is an expression of the same type as in theorem 3 but with a different scaling of the non-negative half integers.

In Ref. 4, Ponzano and Regge discuss how the $6j$ symbol

$$\begin{Bmatrix} a & b & c \\ d+R & e+R & f+R \end{Bmatrix}$$

reduces to the $3j$ symbol

$$\begin{pmatrix} a & b & c \\ \alpha & \beta & \gamma \end{pmatrix}$$

as $R\to\infty$, where $\alpha=e-f$, $\beta=f-d$, and $\gamma=d-e$. If we expand the particular factorials in the above $6j$ symbol suggested by Ponzano and Regge, using (11) and (12), and then follow the proof of theorem 1, this shows that, as $R\to\infty$,

$$\sqrt{2R+1}\begin{Bmatrix} a & b & c \\ d+R & e+R & f+R \end{Bmatrix} - (-1)^{\chi}\begin{pmatrix} a & b & c \\ \alpha & \beta & \gamma \end{pmatrix} \to 0, \tag{14}$$

where $\chi = a+b+c+2(d+e+f)$. This represents a rigorous statement of Ponzano and Regge's work.

The geometrical interpretation of the above result is discussed by Ponzano and Regge in Ref. 4. As $R \to \infty$ in the above $6j$ symbol, three of the vertices of the associated tetrahedron remain fixed and the remaining one moves further and further away from the others. This causes the edges labeled by d, e, and f to become parallel to each other and it is these edges which define a z axis, with α, β, and γ being the projections of the edges labeled by a, b, and c onto this axis (see Fig. 4). The triangle associated to the above $3j$ symbol is the unscaled triangle in the associated tetrahedron formed by the three fixed vertices.

Now, replace a by b, b by $b+m$, c by f, d by $a+n$, e by a and f by c in (14) and apply the symmetries

$$\begin{Bmatrix} a & b & c \\ d & e & f \end{Bmatrix} = \begin{Bmatrix} f & a & e \\ c & d & b \end{Bmatrix}$$

and

$$\begin{pmatrix} a & b & c \\ \alpha & \beta & \gamma \end{pmatrix} = \begin{pmatrix} c & a & b \\ \gamma & \alpha & \beta \end{pmatrix},$$

which gives

$$\sqrt{\omega_1}\begin{Bmatrix} c+R & b & a+R \\ f & a+n+R & b+m \end{Bmatrix} - (-1)^{\xi}\begin{pmatrix} f & b & b+m \\ n & a-c & c-a-n \end{pmatrix} \to 0, \tag{15}$$

where

$$\omega_1 = 2R+1 \quad \text{and} \quad \xi = 2b+m+f+2n+2(c+R).$$

We now scale b by adding to it a real number R' which is tending to infinity. Thus, by theorem 1,

$$\sqrt{\omega_2}\begin{pmatrix} f & b+R' & b+m+R' \\ n & a-c & c-a-n \end{pmatrix} - (-1)^{\mu} d^{f}_{nm}(\phi) \to 0, \tag{16}$$

where

$$\omega_2 = 2(b+R')+m+f+1 \quad \text{and} \quad \mu = (a+R)-(b+R')-(c+R)+2f$$

and ϕ is the angle between the edges labeled by $a+n+R$ and $b+m+R'$ in the tetrahedron associated to the above $6j$ symbol. Equations (15) and (16) give

$$\sqrt{\omega_1\omega_2}\begin{Bmatrix} c+R & b+R' & a+R \\ f & a+n+R & b+m+R' \end{Bmatrix} - (-1)^{\tau} d^{f}_{nm}(\phi) \to 0,$$

where

$$\tau = (a+R)+(b+R')+(c+R)+f+m$$

and

$$\cos\phi = \frac{(a+n+R+(1/2))^2+(b+m+R'+(1/2))^2-(c+R+(1/2))^2}{2(a+n+R+(1/2))(b+m+R'+(1/2))}.$$

This result is of the same type as theorem 3 but with two scalings.

In the Introduction we had Fig. 3 which represented the different asymptotic limits of the $6j$ symbol in terms of the tetrahedron associated to that $6j$ symbol. The above result is represented by the arrow from 4 to $1+1+2$ via $1+3$. The arrow from 4 to $1+3$ is Ponzano and Regge's reduction of a $6j$ symbol to a $3j$ symbol in which one vertex of the associated tetrahedron is taken to infinity while the remaining three are fixed, and the arrow from $1+3$ to $1+1+2$ is where one of the three previously fixed vertices is taken to infinity. Hence the present paper has completed the triangle with vertices 4, $1+3$ and $1+1+2$.

On a class of Robin boundary value problems in physical geodesy

Stefan Ritter[a)]
Mathematisches Institut II, Universität Karlsruhe, D-76128 Karlsruhe, Germany

(Received 23 October 1997; accepted for publication 2 March 1998)

In physical geodesy one considers several (exterior) Robin boundary value problems for the Laplace equation in three dimensions. The ellipsoidal Stokes problem, which occurs in context of gravimetric determination of the geoid, belongs to this class. Up to now, this and related problems have been treated with high order series expansions of spherical and spheroidal harmonics. In this article we investigate the nullfield method for this class of boundary value problems. An integral equation formulation is achieved, and existence and uniqueness conditions are attained in view of the Fredholm alternative. For the case that the underlying surface is a triaxial ellipsoid or an oblate spheroid, explicit expressions for the eigenvalues and eigenfunctions for the boundary integral operator are provided. © *1998 American Institute of Physics.* [S0022-2488(98)02707-8]

I. INTRODUCTION

The ellipsoidal Stokes problem is an exterior Robin (third) boundary value problem (BVP) for the Laplace equation in three dimensions. It arises in physical geodesy as one possible form of linearized BVP in the context of gravimetric determination of the geoid and is therefore of considerable interest. The ellipsoidal approach to the geoid reflects the real situation much better than the spherical approach.

Let D denote an (open) triaxial ellipsoid with semi-axes $a>b>c$ and boundary ∂D with outer unit normal n (see the Appendix). The Stokes problem is to find a solution u on ∂D of

$$\Delta u = 0, \quad \text{in } \mathbb{R}^3\backslash\overline{D}, \tag{1}$$

$$\frac{\partial u}{\partial n} + \lambda p u = k, \quad \text{on } \partial D, \tag{2}$$

$$u(x) = O\left(\frac{1}{|x|}\right), \quad |x|\to\infty. \tag{3}$$

Here, $\lambda\in\mathbb{R}$, $p(x):=(n(x),x)$, $x\in\partial D$, is the distance of the tangent plane in $x\in\partial D$ from the origin, and $k\in C(\partial D)$. In the mathematical literature the function p is known as the *support function* of D.

The solution u has the physical meaning of the *anomalous potential*, i.e., the difference between the gravity potential of the Earth and a reference gravity potential. By λp we introduce a variety of boundary conditions. In applications, λ will be determined such that λp shall be a fairly good approximation of $-(1/\gamma)(\partial\gamma/\partial n)$, where γ is the *normal gravity*. The right-hand side k is the negative *gravity anomaly*.

There are several papers about this and related problems: in Ref. 1 solutions of the ellipsoidal Stokes problem are considered in terms of an infinite series; and in Refs. 2 and 3, Zagrebin's problem, which differs only slightly (in one term of the boundary condition) from our problem are studied. All of these papers refer to oblate spheroids.

For convenience we introduce the notations

a)Electronic mail: Stefan.Ritter@math.uni-karlsruhe.de

 © 1998 American Institute of Physics

$$u(x)|_{\pm} := \lim_{t\to 0\pm} u(x+t\ n(x)) \quad \text{and} \quad \left.\frac{\partial u(x)}{\partial n(x)}\right|_{\pm} := \lim_{t\to 0\pm} (n(x), \text{grad}\ u(x+t\ n(x))),$$

for $x \in \partial D$.

For $\lambda \leqslant 0$, the first Green theorem for the solution u of the homogeneous problem ($k=0$) yields

$$-\int_{\mathbb{R}^3\setminus\overline{D}} |\text{grad}\ u(y)|^2 dy = \int_{\partial D} u(y)|_{+} \left.\frac{\partial u(y)}{\partial n(y)}\right|_{+} ds(y) = -\lambda \int_{\partial D} p(y)|u(y)|_{+}|^2 ds(y),$$

and hence $u = \text{const}$ in $\mathbb{R}^3\setminus\overline{D}$ and with (3) it follows $u=0$ in $\mathbb{R}^3\setminus\overline{D}$. Unfortunately for $\lambda > 0$, which is the very interesting case in geodesy, uniqueness of u cannot be obtained.

A classical approach is to discuss a single-layer potential ansatz for (1), (2), (3). This leads to an integral equation for an unknown density which is of *mediate* interest, and, the final solution is obtained in an additional step by evaluating the potential on the boundary.

In this paper the nullfield method is applied. By use of suitable representation formulas for harmonic functions, the BVP is transformed to a Fredholm integral equation of the second kind. Since the accompanying integral operators are compact, the Fredholm alternative gives existence and uniqueness conditions for the solution of the integral equation and for the BVP itself. In contrast to the single-layer approach the nullfield method leads directly to an integral equation for the required boundary values.

The plan is as follows: in Sec. II, the nullfield method is introduced and the integral equation formulation for (1)–(3) is derived. In Sec. III, we study the integral equation for the case of the triaxial ellipsoid in detail and work out the consequences of Fredholm's alternative for the case $\lambda > 0$. Then we discuss the important (degenerate) case of ∂D being an oblate spheroid and we provide plots of the eigenvalues of the boundary integral operator. We finish the paper by presenting uniqueness-conditions for u.

II. THE NULLFIELD METHOD

We study the BVP (1)–(3) by an integral equation approach using the so-called *nullfield method* (see Ref. 4): Choose a suitable representation formula for harmonic functions in $\mathbb{R}^3\setminus\overline{D}$ that vanishes for $x \in D$. Then insert the given boundary data into this formula and take it as ansatz for the unknown boundary parameters. Assure for this ansatz the complementary nullfield condition which leads to an integral equation. Then the equivalence of the integral equation and the BVP is to be verified and the integral equation is to be solved.

In the first step we take the representation theorem for a function u which is (i) continuously differentiable in $\mathbb{R}^3\setminus\partial D$, (ii) harmonic in $\mathbb{R}^3 \cup \infty \setminus \partial D$, and (iii) converges uniformly to zero for $|x| \to \infty$ (see Ref. 5, p. 146),

$$u(x) = -\frac{1}{4\pi}\int_{\partial D} \left\{ \left(\left.\frac{\partial u(y)}{\partial n(y)}\right|_{+} - \left.\frac{\partial u(y)}{\partial n(y)}\right|_{-} \right) \frac{1}{|x-y|} - (u(y)|_{+} - u(y)|_{-}) \frac{\partial \frac{1}{|x-y|}}{\partial n(y)} \right\} ds(y),$$
$$x \in \mathbb{R}^3\setminus\partial D. \tag{4}$$

Then the nullfield condition $u=0$ in D yields $u(x)|_{-}=0$ on ∂D and hence $\partial u/\partial n\,|_{-}=0$ on ∂D. The ansatz $\mu := u|_{+}$ and (2) lead to

$$\left.\frac{\partial u(y)}{\partial n(y)}\right|_{+} = k(y) - \lambda p(y)\mu(y), \quad y \in \partial D, \tag{5}$$

and for $u(x)$ in $\mathbb{R}^3\setminus\overline{D}$ we obtain

$$u(x)=-\frac{1}{4\pi}\int_{\partial D}\frac{k(y)-\lambda p(y)\mu(y)}{|x-y|}ds(y)+\frac{1}{4\pi}\int_{\partial D}\mu(y)\frac{\partial\frac{1}{|x-y|}}{\partial n(y)}ds(y). \tag{6}$$

By straightforward use of the continuity of single-layer potentials and the limiting relation for the double-layer potentials (see, e.g., Ref. 4),

$$\lim_{D\ni x\to x_0\in\partial D}\frac{1}{4\pi}\int_{\partial D}\varepsilon(y)\frac{\partial\frac{1}{|x-y|}}{\partial n(y)}ds(y)=\frac{1}{4\pi}\int_{\partial D}\varepsilon(y)\frac{\partial\frac{1}{|x_0-y|}}{\partial n(y)}ds(y)-\frac{1}{2}\varepsilon(x_0), \tag{7}$$

for $\varepsilon\in C(\partial D)$, the nullfield condition $u(x)|_-=0$, $x\in\partial D$, leads to the Fredholm integral equation of the second kind,

$$\mu(x)-\mathbf{A}'\mu(x)=-\mathbf{S}k(x),\quad x\in\partial D, \tag{8}$$

with the integral operator

$$\mathbf{A}'\mu(x):=\frac{1}{2\pi}\int_{\partial D}\mu(y)\frac{\partial\frac{1}{|x-y|}}{\partial n(y)}ds(y)+\lambda\frac{1}{2\pi}\int_{\partial D}\frac{p(y)\mu(y)}{|x-y|}ds(y),\quad x\in\partial D, \tag{9}$$

and the single-layer potential operator,

$$\mathbf{S}k(x):=\frac{1}{2\pi}\int_{\partial D}\frac{k(y)}{|x-y|}ds(y),\quad x\in\partial D, \tag{10}$$

for $\mu,k\in C(\partial D)$. Conversely, by subsequent use of the limiting properties of single-layer and double-layer potentials (see, e.g., Ref. 4) we see that u from (6) with μ from (8) is a solution of the boundary value problem.

The nullfield condition $u=0$ in D, or, equivalently, $u=0$ on ∂D may seem artificial because it prescribes u in D which is the complementary domain of the boundary value problem. But, due to the representation formula, this is not a restriction for u in the domain of our interest. On the other hand this condition yields an integral equation of second kind for $u|_+$ in a direct way.

Integral equation (8) can be solved numerically in various ways, e.g., by boundary element techniques such as Galerkin- and collocation methods. Spectral methods are also appropriate because we obtain a complete system of eigenfunctions of the integral operators $\mathbf{A}'$ and $\mathbf{S}$.

In what follows we investigate the theory of (8), i.e., we study solvability and give uniqueness conditions for its solutions.

First we note that $\mathbf{A}'$ is a linear combination of two classical potential operators, namely the *adjoint electrostatic operator*,

$$\mathbf{K}'\mu(x):=\frac{1}{2\pi}\int_{\partial D}\mu(y)\frac{\partial\frac{1}{|x-y|}}{\partial n(y)}ds(y),\quad x\in\partial D, \tag{11}$$

and the single-layer operator,

$$\mathbf{T}'\mu(x):=\frac{1}{2\pi}\int_{\partial D}\frac{p(y)\mu(y)}{|x-y|}ds(y),\quad x\in\partial D, \tag{12}$$

say

$$\mathbf{A}'\mu=\mathbf{K}'\mu+\lambda\mathbf{T}'\mu. \tag{13}$$

Both $\mathbf{K}'$ and $\mathbf{T}'$ are well known to be compact in the Banach space $C(\partial D)$ of continuous complex valued functions on ∂D equipped with the maximum norm. Hence $\mathbf{A}'$ is compact in $C(\partial D)$. For $k \in C(\partial D)$ we have that $\mathbf{S}k$ is continuous on ∂D and therefore the right-hand side of (8) is continuous.

Let $\langle C(\partial D), C(\partial D)\rangle$ denote the dual system corresponding to the nondegenerate bilinear form

$$\langle u,v\rangle := \int_{\partial D} u(y)\overline{v(y)}ds(y). \tag{14}$$

By interchanging the order of integration, it is readily seen that the adjoint $\mathbf{A}$ of $\mathbf{A}'$ with respect to (14) is given by

$$\mathbf{A}\mu = \mathbf{K}\mu + \lambda \mathbf{T}\mu, \tag{15}$$

where $\mathbf{K}$ is the *electrostatic integral operator* and $\mathbf{T}$ is a single-layer operator, given by

$$\mathbf{K}\mu(x) := \frac{1}{2\pi}\int_{\partial D} \mu(y)\frac{\partial \frac{1}{|x-y|}}{\partial n(x)}ds(y), \quad x \in \partial D, \tag{16}$$

$$\mathbf{T}\mu(x) := \frac{1}{2\pi}p(x)\int_{\partial D}\frac{\mu(y)}{|x-y|}ds(y), \quad x \in \partial D. \tag{17}$$

Hence, $\langle \mathbf{A}\mu,\varepsilon\rangle = \langle \mu, \mathbf{A}'\varepsilon\rangle$, for $\mu,\varepsilon \in C(\partial D)$.

Because of the Fredholm alternative we have to study the homogeneous adjoint equation

$$\mu - \mathbf{A}\mu = 0, \quad \mu \in C(\partial D). \tag{18}$$

If (18) has only the trivial solution $\mu = 0$, then (8) is uniquely solvable for arbitrary $k \in C(\partial D)$. If there exist nontrivial solutions $\mu_1, \mu_2, \ldots, \mu_n$ of (18), integral equation (8) is solvable for k that satisfies

$$\langle -\mathbf{S}k, \mu_j\rangle = 0, \quad j = 1,2,\ldots,n. \tag{19}$$

In this case the solution of (8) is given as sum of a special (inhomogeneous) solution and an arbitrary linear combination of $\mu_1, \mu_2, \ldots, \mu_n$.

III. THE STOKES INTEGRAL OPERATOR FOR THE TRIAXIAL ELLIPSOID

Now we study the homogeneous equation (18) for the case of ∂D being a triaxial ellipsoid with semi-axes $a > b > c$. We derive both eigenvalues and eigenfunctions of $\mathbf{A}$ in terms of Lamé functions and surface ellipsoidal harmonics.

In ellipsoidal coordinates (ρ,μ,ν) (see the Appendix), ∂D is given as parametric surface $\rho = 0$. From Ref. 6, we have the following result.

The functions $p(x)\mathbb{M}_n^m(x)$, $x \in \partial D$, with $p(x) = (n(x),x)$ and $\mathbb{M}_n^m$ from (A9) are eigenfunctions of $\mathbf{K}$ with eigenvalues

$$k_n^m := \frac{2abc}{2n+1}[L_n^m]'(0)K_n^m(0) - 1, \tag{20}$$

say

$$\mathbf{K}(p\mathbb{M}_n^m) = k_n^m\, p\mathbb{M}_n^m, \tag{21}$$

for $n \in \mathbb{N}$, $m = 0,\ldots,2n$. Note that each k_n^m has multiplicity one.

Again, by Ref. 6, it is seen that the eigenvalues and eigenfunctions of $\mathbf{K}'$ are given by

$$\mathbf{K}'(\mathbb{M}_n^m)=k_n^m\ \mathbb{M}_n^m, \tag{22}$$

for $n\in\mathbb{N}$, $m=0,...,2n$, and k_n^m from (20). From the completeness of the $\mathbb{M}_n^m$ in $L^2(\partial D)$, it follows that there are no other eigenfunctions of $\mathbf{K}'$ and $\mathbf{K}$ in $C(\partial D)$.

For $\mathbf{T}$ from (17) we have the following.

Lemma 1: The functions $p\mathbb{M}_n^m$ are eigenfunctions of $\mathbf{T}$,

$$\mathbf{T}(p\mathbb{M}_n^m)=t_n^m p\mathbb{M}_n^m, \tag{23}$$

with eigenvalues

$$t_n^m:=\frac{abc}{2n+1}L_n^m(0)K_n^m(0)\neq 0, \tag{24}$$

for $n\in\mathbb{N}$, $m=0,...,2n$.

Proof: For given n,m consider

$$u(\rho,\mu,\nu):=\begin{cases} u_o(\rho,\mu,\nu)=L_n^m(0)\ \mathbb{K}_n^m(\rho,\mu,\nu), & \rho\leqslant 0,\\ u_i(\rho,\mu,\nu)=K_n^m(0)\ \mathbb{L}_n^m(\rho,\mu,\nu), & \rho>0,\end{cases}$$

with $\mathbb{K}_n^m,\mathbb{L}_n^m$ from (A5), (A7) which is continuous in $\mathbb{R}^3$ and harmonic in $\mathbb{R}^3\backslash\partial D$. Therefore u can be written as a single-layer potential,

$$u(x)=\frac{1}{4\pi}\int_{\partial D}\frac{\sigma(y)}{|x-y|}ds(y),\quad x\in\mathbb{R}^3,$$

with $\sigma\in C(\partial D)$. From the jump relation for the normal derivative of u on ∂D, we obtain by use of (A4)

$$-\sigma(x)=\frac{\partial u_o(x)}{\partial n(x)}-\frac{\partial u_i(x)}{\partial n(x)}=2p(0,\mu,\nu)\mathbb{M}_n^m(\mu,\nu)(L_n^m(0)[K_n^m]'(0)-K_n^m(0)[L_n^m]'(0)),$$

with $x=x(0,\mu,\nu)$. From the Wronskian

$$L_n^m(0)[K_n^m]'(0)-K_n^m(0)[L_n^m]'(0)=-\frac{2n+1}{abc},$$

we conclude

$$\sigma(\mu,\nu)=2(2n+1)\frac{p(0,\mu,\nu)}{abc}\mathbb{M}_n^m(\mu,\nu).$$

Regarding the definition of $\mathbf{T}$ (17), the assertion follows immediately. From (A8) we see that $t_n^m\neq 0$ for all n,m. □

As a consequence of Lemma 1 we observe that the eigenvalues and eigenfunctions of $\mathbf{T}'$ are given by

$$\mathbf{T}'(\mathbb{M}_n^m)=t_n^m\ \mathbb{M}_n^m, \tag{25}$$

for $n\in\mathbb{N}$, $m=0,\ldots,2n$, and t_n^m from (24).

A combination of the above results yields the spectrum of both $\mathbf{A}$ and $\mathbf{A}'$.

Theorem 1: Let $\lambda\in\mathbb{R}$. *The eigenvalues and eigenfunctions of* $\mathbf{A}=\mathbf{K}+\lambda\mathbf{T}$ *and of* $\mathbf{A}'=\mathbf{K}'+\lambda\mathbf{T}'$ *for the triaxial ellipsoid* $\partial D:\rho=0$ *are given by*

$$\mathbf{A}(p\mathbb{M}_n^m)=a_n^m\ p\mathbb{M}_n^m, \tag{26}$$

and

$$\mathbf{A}'(\mathbb{M}_n^m) = a_n^m\ \mathbb{M}_n^m, \tag{27}$$

with

$$a_n^m = k_n^m + \lambda t_n^m = \frac{2abc}{2n+1}[L_n^m]'(0)K_n^m(0) - 1 + \lambda \frac{abc}{2n+1} L_n^m(0)K_n^m(0), \tag{28}$$

for $n \in \mathbb{N}$, $m = 0, \ldots, 2n$.

Now we discuss the consequences of Theorem 1 for the homogeneous adjoint integral equation (18). The eigenvalues and eigenfunctions of $I - \mathbf{A}$ are given by

$$(I - \mathbf{A})(p\mathbb{M}_n^m) = (1 - a_n^m)p\mathbb{M}_n^m, \tag{29}$$

for $n \in \mathbb{N}$, $m = 0, \ldots, 2n$.

In order to guarantee solvability of (8) in view of Fredholm's alternative, λ has **either** to be such that

(i) $a_n^m \neq 1$ for all n, m,

or

(ii) there are some n, m with $a_n^m = 1$. For those n, m, the right-hand side of (8) has to be such that

$$\langle \mathbf{S}k, p\mathbb{M}_n^m \rangle = 0. \tag{30}$$

By use of Fubini's theorem and Lemma 1 [note that $\mathbf{S}k = (1/p)\mathbf{T}k$], this reads as

$$\langle \mathbf{S}k, p\mathbb{M}_n^m \rangle = \int_{\partial D} k(y) \frac{1}{2\pi} \int_{\partial D} \frac{p(x)\mathbb{M}_n^m(x)}{|x-y|} ds(x) ds(y) = t_n^m \int_{\partial D} k(y)\mathbb{M}_n^m(y) ds(y),$$

and because of $t_n^m \neq 0$ this is equivalent to

$$\langle k, \mathbb{M}_n^m \rangle = 0. \tag{31}$$

A very important (degenerate) case of the above analysis is that of D being an oblate spheroid since the Earth's surface can be approximated by a suitable spheroid.

In oblate spheroidal coordinates (ξ, η, ϕ) with parameter $d > 0$ (see the Appendix), ∂D is given as parametric surface $\xi = \xi_0 > 0$.

For the eigenvalues and eigenfunctions of $\mathbf{K}$ and $\mathbf{K}'$ we have

$$\mathbf{K}(p\mathbb{Y}_n^{\pm m}) = k_n^m\ p\mathbb{Y}_n^{\pm m} \quad \text{and} \quad \mathbf{K}'(\mathbb{Y}_n^{\pm m}) = k_n^m\ \mathbb{Y}_n^{\pm m}, \tag{32}$$

with eigenvalues

$$k_n^m := -1 - 2(-1)^m \frac{(n-m)!}{(n+m)!}(\xi_0^2 + 1) Q_n^m(i\xi_0)[P_n^m]'(i\xi_0), \tag{33}$$

for $n \in \mathbb{N}$, $m = 0, \ldots, n$ (see Ahner Refs. 7 and 6). The $\mathbb{Y}_n^m(\eta, \phi)$ are the surface spherical harmonics from (A16) and $p(\xi_0, \eta)$ is given by (A12). Analogously, we obtain

$$\mathbf{T}(p\mathbb{Y}_n^{\pm m}) = t_n^m p\mathbb{Y}_n^{\pm m} \quad \text{and} \quad \mathbf{T}'(\mathbb{Y}_n^{\pm m}) = t_n^m\ \mathbb{Y}_n^{\pm m} \tag{34}$$

with eigenvalues

$$t_n^m := (-1)^m \frac{(n-m)!}{(n+m)!} \frac{id^2}{2} \xi_0(\xi_0^2 + 1)\ Q_n^m(i\xi_0) P_n^m(i\xi_0). \tag{35}$$

Note that k_n^0, t_n^0 have multiplicity one while k_n^m, t_n^m, $m > 0$, have multiplicity two.

Hence

$$\mathbf{A}(p\mathbb{Y}_n^{\pm m}) = a_n^m\ p\mathbb{Y}_n^{\pm m} \quad \text{and} \quad \mathbf{A}'(\mathbb{Y}_n^{\pm m}) = a_n^m\ \mathbb{Y}_n^{\pm m}, \tag{36}$$

with

$$a_n^m = k_n^m + \lambda t_n^m$$
$$= -1 + (-1)^m \frac{(n-m)!}{(n+m)!}(\xi_0^2+1)\ Q_n^m(i\xi_0)\left\{ i\frac{\lambda d^2\xi_0}{2}\ P_n^m(i\xi_0) - 2[P_n^m]'(i\xi_0)\right\}, \qquad (37)$$

for $n \in \mathbb{N}$, $m = 0,...,n$.

The eigenvalues and eigenfunctions of $I - \mathbf{A}$ are given by

$$(I-\mathbf{A})(p\mathbb{Y}_n^{\pm m}) = (1-a_n^m)p\mathbb{Y}_n^{\pm m}, \qquad (38)$$

for $n \in \mathbb{N}$, $m = 0,...,n$.

The condition for λ and k in view of solvability of (8) is the following: λ has **either** to be such that

(i) $a_n^m \neq 1$ for all n,m, i.e.,

$$\lambda \neq -\frac{2i}{d^2\xi_0}\left\{ 2(-1)^m \frac{(n+m)!}{(n-m)!}\frac{1}{(\xi_0^2+1)Q_n^m(i\xi_0)} + 2[P_n^m]'(i\xi_0)\right\}, \qquad (39)$$

or

(ii) there are some n,m with $a_n^m = 1$. For those n,m, the right-hand side $-\mathbf{S}k$ has to be such that

$$\langle \mathbf{S}k, p\mathbb{Y}_n^{\pm m}\rangle = 0. \qquad (40)$$

This reads as

$$\langle \mathbf{S}k, p\mathbb{Y}_n^{\pm m}\rangle = \int_{\partial D} k(y)\frac{1}{2\pi}\int_{\partial D}\frac{p(x)\overline{\mathbb{Y}_n^{\pm m}}(x)}{|x-y|}ds(x)ds(y) = t_n^m \int_{\partial D} k(y)\overline{\mathbb{Y}_n^{\pm m}}(y)ds(y),$$

and because of $t_n^m \neq 0$ it is equivalent to

$$\langle k, \mathbb{Y}_n^{\pm m}\rangle = 0. \qquad (41)$$

IV. APPLICATION

The classical ellipsoidal Stokes problem which occurs in geoid height determination is BVP (1)–(3) for an oblate spheroid with

$$\lambda = \frac{8}{d^2\xi_0^2}. \qquad (42)$$

In the geodetic literature (see, e.g., Ref. 1) the boundary condition (2) is often written in the form

$$\frac{\partial u}{\partial \xi}(x) + \frac{2}{\xi_0}u(x) = -f(x), \quad x \in \partial D, \qquad (43)$$

with

$$f(x) = -\frac{d^2\xi_0}{4}\frac{k(x)}{p(x)}, \quad x \in \partial D. \qquad (44)$$

The eigenvalues of the integral operator $I - \mathbf{A}$ are given by

$$1 - a_n^m = 2 + (-1)^{m+1}\frac{(n-m)!}{(n+m)!}(\xi_0^2+1)\ Q_n^m(i\xi_0)\left\{\frac{4i}{\xi_0}P_n^m(i\xi_0) - 2[P_n^m]'(i\xi_0)\right\}.$$

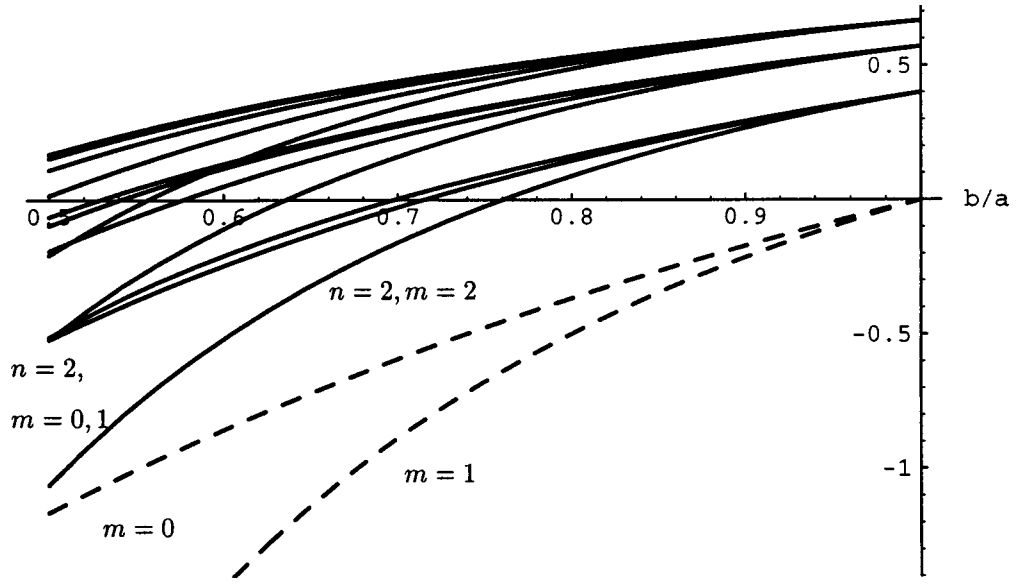

FIG. 1. Eigenvalues of $I-\mathbf{A}$ for $n=1$ (dashed) and $n=2,3,4$.

Figure 1 depicts some eigenvalues $1-a_n^m$. In view of the Stokes problem for a spheroid close to the Earth's surface we are interested in the behavior of the eigenvalues for $4/3<\xi_0<\infty$, i.e., for the axes-ratios $0{,}8<b/a<1$.

For the case $1-a_n^m=0$ for some n,m, the right-hand side f of (43), in view of (35), has to be such that

$$\begin{aligned}\left\langle -\frac{4}{d^2\xi_0}pf,\mathbb{Y}_n^{\pm m}\right\rangle &= -\frac{4}{d^2\xi_0}\int_{\partial D}p(y)f(y)\overline{\mathbb{Y}_n^{\pm m}}(y)ds(y)\\ &= -\frac{d(\xi_0^2+1)}{2}\int_0^{2\pi}\int_{-1}^{1}f(\eta,\phi)\overline{\mathbb{Y}_n^{\pm m}}(\eta,\phi)d\eta\,d\phi\\ &= -\frac{d(\xi_0^2+1)}{2}\langle f,\mathbb{Y}_n^{\pm m}\rangle_{S^2}=0;\end{aligned}$$

hence the solvability condition is

$$\langle f,\mathbb{Y}_n^{\pm m}\rangle_{S^2}=0. \tag{45}$$

Here $\langle\cdot,\cdot\rangle_{S^2}$ denotes the usual inner product in $L^2(S^2)$ for the unit sphere S^2. As indicated in Fig. 1, $1-a_n^m=0$ may be true for spheroids with axes-ratio $b/a<0.8$ for $n\geqslant 2$, and in fact is true for the sphere for $n=1$.

In addition, the condition

$$u(x)=\frac{c}{|x|}+O\left(\frac{1}{|x|^3}\right),\quad |x|\to\infty, \tag{46}$$

with arbitrary $c\in\mathbb{R}$ is imposed. This effect is that f has to satisfy

$$\langle f,\mathbb{Y}_1^j\rangle_{S^2}=0,\quad j=-1,0,1, \tag{47}$$

in order to guarantee solvability of the integral equation for μ.

V. CONCLUSIONS

An integral equation formulation for the ellipsoidal Stokes problem has been achieved by the nullfield method. From explicit expressions for the eigenvalues and eigenfunctions for $(I-\mathbf{A}')$ in the case of the oblate spheroid we have seen that, apart from (47), further assumptions (45) for the inhomogeneity have possibly to be imposed for the case that the axes-ratio is less than 0,8 in order to attain uniqueness of the solution and hence well-posedness of the problem. The results are in agreement with the numerical treatment presented in Ref. 1. Further work to be done is the numerical treatment of integral equation (8) for which the foundation has been presented. This can be done either by boundary element techniques such as Galerkin schemes or collocation methods. An alternative approach are spectral methods which are applicable for this problem since we have a complete set of eigenfunctions for the boundary integral operator.

APPENDIX: ELLIPSOIDAL AND OBLATE SPHEROIDAL COORDINATES

1. Ellipsoidal coordinates and Lamé-functions

The equation of a triaxial ellipsoid D with semi-axes $a>b>c$ is given by

$$D: \frac{x_1^2}{a^2}+\frac{x_2^2}{b^2}+\frac{x_3^2}{c^2}\leqslant 1. \tag{A1}$$

The *ellipsoidal coordinates* of $x(x_1,x_2,x_3)$ are defined as the three roots ρ, μ, ν of the cubic equation in θ,

$$\frac{x_1^2}{a^2+\theta}+\frac{x_2^2}{b^2+\theta}+\frac{x_3^2}{c^2+\theta}=1, \tag{A2}$$

for fixed values of x_1, x_2, x_3, where

$$\rho\in[-c^2,\infty), \quad \mu\in[-b^2,-c^2], \quad \nu\in[-a^2,-b^2]. \tag{A3}$$

The three families of surfaces $\rho=$const (ellipsoids), $\mu=$const (hyperboloids of one sheet) and $\nu=$const (hyperboloids of two sheets) form a triply-orthogonal coordinate system in $\mathbb{R}^3$. ∂D is given by $\rho=0$, points with $\rho<0$ lie in $\underline{D}$, those with $\rho>0$ lie in $\mathbb{R}^3\backslash D$. For a differentiable function u, the normal derivative on ∂D is given by

$$\frac{\partial u(0,\mu,\nu)}{\partial n(\mu,\nu)}=2\,p(0,\mu,\nu)\,\frac{\partial u(\rho,\mu,\nu)}{\partial \rho}\bigg|_{\rho=0}, \quad p(0,\mu,\nu)=\frac{abc}{\sqrt{\mu\nu}}, \tag{A4}$$

with the *support function* $p(x):=(n(x),x)$, $x\in\partial D$ of the ellipsoid.

The *interior ellipsoidal harmonics of order* $n\in\mathbb{N}$ are defined by

$$\mathbb{L}_n^m(\rho,\mu,\nu):=L_n^m(\rho)L_n^m(\mu)L_n^m(\nu), \quad m=0,\ldots,2n, \tag{A5}$$

with the Lamé-functions of the first kind L_n^m. In Cartesian coordinates the $\mathbb{L}_n^m$ turn out as harmonic polynomials of order n.

For $L_n^m(\rho)$, the corresponding function of the *second kind* is given by

$$K_n^m(\rho):=(2n+1)L_n^m(\rho)\int_\rho^\infty \frac{d\rho'}{[L_n^m(\rho')]^2\Delta(\rho')}, \quad \rho>-c^2, \tag{A6}$$

with

$$\Delta(\rho):=\sqrt{(\rho+a^2)(\rho+b^2)(\rho+c^2)}.$$

The second kind Lamé-functions generate the *exterior ellipsoidal harmonics of order* n,

$$\mathbb{K}_n^m(\rho,\mu,\nu) := K_n^m(\rho)L_n^m(\mu)L_n^m(\nu), \quad m=0,\ldots,2n, \tag{A7}$$

which are regular at infinity.

A Theorem due to Stieltjes implies that the zeros of $L_n^m(\lambda)$ are simple and contained in $(-a^2,-c^2)$ (see Ref. 8). Hence we have

$$L_n^m(0)K_n^m(0)\neq 0, \quad n\in\mathbb{N}, \quad m=0,\ldots,2n. \tag{A8}$$

The system of *ellipsoidal surface harmonics of order* $n\in\mathbb{N}$, defined by

$$\mathbb{M}_n^m(\mu,\nu) := L_n^m(\mu)L_n^m(\nu), \quad m=0,\ldots,2n, \tag{A9}$$

forms a complete orthogonal system in $L^2(\partial D)$.

2. Oblate spheroidal coordinates

For the oblate spheroid D with semi-axes $a>b$ we introduce the system of *oblate spheroidal coordinates* (ξ,η,ϕ) by

$$\begin{aligned} x_1 &= \frac{d}{2}[(\xi^2+1)(1-\eta^2)]^{1/2}\cos\phi, \\ x_2 &= \frac{d}{2}[(\xi^2+1)(1-\eta^2)]^{1/2}\sin\phi, \\ x_3 &= \frac{d}{2}\xi\eta, \end{aligned} \tag{A10}$$

with $\xi\in[0,\infty)$, $\eta\in[-1,1]$, $\phi\in[0,2\pi]$ and parameter $d>0$. The surfaces $\xi=\text{constant}>0$ represent oblate spheroids with semi-axes $a=(d/2)(\xi^2+1)^{1/2}$, $b=(d/2)\xi$. The degenerate case $\xi=0$ corresponds to the circular disk of radius $r=d/2$ which lies in the x_1/x_2-plane and is centered at the origin. Hence ∂D is given by

$$\xi=\xi_0=\left(\frac{a^2}{b^2}-1\right)^{-1/2}. \tag{A11}$$

For $p(x)=(n(x),x)$ we have

$$p(\xi,\eta)=\frac{d}{2}\xi\left(\frac{\xi^2+1}{\xi^2+\eta^2}\right)^{1/2}. \tag{A12}$$

The normal derivative of a differentiable function u on $\xi=\text{const}$ is given by

$$\frac{\partial u}{\partial n}=\frac{4}{d^2\xi}\,p(\xi,\eta)\,\frac{\partial u}{\partial \xi}, \tag{A13}$$

and for the surface element on $\xi=\text{const}$ we have

$$ds=\left(\frac{d}{2}\right)^3\xi(\xi^2+1)\frac{1}{p(\xi,\eta)}\,d\eta\,d\phi. \tag{A14}$$

The *interior* and *exterior spheroidal harmonics* are defined by

$$\mathbb{P}_n^m(\xi,\eta,\phi)=P_n^m(i\xi)\,\mathbb{Y}_n^m(\eta,\phi) \quad \text{and} \quad \mathbb{Q}_n^m(\xi,\eta,\phi)=Q_n^m(i\xi)\,\mathbb{Y}_n^m(\eta,\phi), \tag{A15}$$

where

$$\mathbb{Y}_n^m(\eta,\phi)=P_n^{|m|}(\eta)\ e^{im\phi} \tag{A16}$$

denote the *surface spherical harmonics* of order n and degree m,$n\in\mathbb{N}$, $m=-n,\ldots,n$. They form a complete orthogonal system in the Hilbert space $L^2(\partial D)$ with inner product

$$(u,v)=\int_{\partial D}p(y)\ u(y)\overline{v(y)}ds(y). \tag{A17}$$

(Received 27 January 1997; accepted for publication 26 March 1998)

We use the methods of group theory to reduce the equations of motion of two spin systems in $(2+1)$ dimensions to sets of coupled ordinary differential equations. We present solutions of some classes of these sets and discuss their physical significance. © *1998 American Institute of Physics.* [S0022-2488(98)00207-2]

I. INTRODUCTION

In this paper we look for solutions of the equations of the Landau–Lifshitz model (with, perhaps, nonvanishing anisotropy) and of a nonlinear vector diffusion equation. The equations are given, respectively, by

$$\frac{\partial \boldsymbol{\phi}}{\partial t} = \boldsymbol{\phi} \times \mathbf{F} \tag{1.1}$$

and

$$\frac{\partial \boldsymbol{\phi}}{\partial t} = \mathbf{F} - \boldsymbol{\phi}(\boldsymbol{\phi} \cdot \mathbf{F}), \tag{1.2}$$

where $\mathbf{F}$ is given by

$$\mathbf{F} = \Delta \boldsymbol{\phi} + (A\phi_3 + B)\mathbf{e}_3, \tag{1.3}$$

where $\mathbf{e}_3$ is a unit vector in the third direction in the $\boldsymbol{\phi}$ space and $\boldsymbol{\phi}$ satisfies $\boldsymbol{\phi} \cdot \boldsymbol{\phi} = 1$. A and B are possible anisotropy coefficients.

The motivation for this work comes from the original observation made by Landau and Lifshitz[1] in their study of the ferromagnetic continuum. They pointed out that for phenomena for which substantial spatial variations occur only over a large number of lattice spacings, we can use the continuum approximation. They showed that a ferromagnetic medium is characterized by the magnetization vector $\mathbf{M}$ (like the vector $\boldsymbol{\phi}$ above) that precesses around the effective magnetic field and so obeys, what is now called the Landau–Lifshitz equation, namely (1.1). Since the original work of Landau and Lifshitz, many papers have been written on the subject,[2] and the equation has been modified by the inclusion of various additional terms to $\mathbf{F}$. It has been used to describe the dynamics of magnetic bubbles in a ferromagnetic continuum and also of vortices in He II or in a superconductor.[2] Various studies of the dynamics of such topological soliton-like structures have been performed both theoretically and experimentally,[3,4] and they have exhibited many interesting, and perhaps unexpected, phenomena—like the skew deflection of these structures under the influence of a magnetic field gradient that resembles the more familiar Hall motion of electrons in external magnetic and electric fields.[5]

A recent work of Papanicolaou and Tomaras,[2] as well as some earlier work of other people,[6] has shown that many experimentally observed facts can indeed be explained using the Landau–Lifshitz equation. Much of the work involved deriving various conserved quantities describing these structures and then using them to restrict the description of the dynamics. All this work has provided further evidence as to the relevance of the Landau–Lifshitz equation to the description of

 © 1998 American Institute of Physics

physical phenomena. However, as the Landau–Lifshitz equation is quite complicated, only some results were obtained in an analytical form. Most more recent studies[7] involved numerical simulations.

The vector nonlinear diffusion equation (1.2) has less obvious physical applications, but it has been used[8] in the study of phase ordering kinetics, where one investigates the time evolution of a system quenched from the disordered into an ordered phase. This topic has attracted considerable attention in recent years.[9] In fact, it has been shown that many features of phase ordering in systems supporting topologically stable defects [for example, in systems described by the $O(N)$ vector model in d dimensions with $d \leqslant N$[10,11]], or in two- and three-dimensional nematic liquid crystals[12] can be understood theoretically by investigating the dynamics of the numerous topological defects generated during the quench. A special and interesting case is that of the $O(3)$ model system in two spatial dimensions. It supports topologically stable, but nonsingular objects, which, in the condensed matter community language, are called topological textures. Such systems were studied numerically in Ref. 8.

Given the paucity of analytical results for both Eqs. (1.1) and (1.2) (especially involving the dynamics) one of our aims in this paper is to see what time-dependent solutions can be found using the group theoretical method of symmetry reduction.[13–15] This method exploits the symmetry of the original equations to find solutions invariant under some subgroup (the classic example one can give here involves seeking solutions in three dimensions that are rotationally invariant). The method puts all such attempts on a unified footing and it has been applied with success to many equations.[16] The method gives equations whose solutions represent specific solutions of the full equations; the solutions are determined locally and the method does not tell us whether these solutions are stable or not with respect to any perturbations.

In a recent paper,[17] two of us (PW and WJZ), together with Grundland, have applied this technique to looking for solutions of the relativistic CP^1 model.

In this paper we investigate solutions of (1.1) and (1.2). We are particularly interested in time-dependent solutions; all time-independent solutions of (1.1) and (1.2) (when there is no anisotropy) are also the time-independent solutions of the relativistic model and so can be found in Ref. 17.

Like in the relativistic CP^1 model studied before, in order to perform the symmetry reductions, we have to decide what variables to use. To avoid having to use the constrained variables ($\boldsymbol{\phi}$) it is convenient to use the W formulation of the model that involves the stereographic projection of the sphere $\boldsymbol{\phi}\cdot\boldsymbol{\phi}=1$ onto the complex plane. In this formulation instead of using the $\boldsymbol{\phi}$ fields, we express all the dependence on $\boldsymbol{\phi}$ in terms of their stereographic projection onto the complex plane W. The $\boldsymbol{\phi}$ fields are then related to W by

$$\phi_1=\frac{W+W^*}{1+|W|^2}, \quad \phi_2=i\,\frac{W-W^*}{1+|W|^2}, \quad \phi_3=\frac{1-|W|^2}{1+|W|^2}. \tag{1.4}$$

To perform our analysis it is convenient to use the polar version of the W variables; i.e., to put $W=R\,\exp iQ$ and then study the equations for R and Q. The advantage of this approach is that the equations become simple; the disadvantage comes from having to pay attention that R is real and Q should be periodic with a period of 2π. (If the period is not 2π then the solution may become multivalued.) Thus if we find solutions that do not obey these restrictions, then these solutions, however interesting they may be, cannot be treated as solutions of the original model.

In the case of the Landau–Lifshitz equation the equations for R and Q take the form

$$\partial_t R-2\,\frac{(1-R^2)}{(1+R^2)}\,(\partial_x Q\partial_x R+\partial_y Q\partial_y R)-R(\partial_{xx}Q+\partial_{yy}Q)=0 \tag{1.5}$$

and

$$\partial_t Q=B+A\,\frac{1-R^2}{1+R^2}-\frac{\partial_{xx}R+\partial_{yy}R}{R}+\frac{(1-R^2)}{(1+R^2)}\,((\partial_x Q)^2+(\partial_y Q)^2)+\frac{2}{(1+R^2)}\,((\partial_x R)^2+(\partial_y R)^2), \tag{1.6}$$

while for the diffusion case they are, respectively,

$$\partial_t Q - 2\frac{(1-R^2)}{R(1+R^2)}(\partial_x Q\partial_x R+\partial_y Q\partial_y R)-(\partial_{xx}Q+\partial_{yy}Q)=0 \tag{1.7}$$

and

$$\partial_t R+BR+AR\frac{1-R^2}{1+R^2}-\partial_{xx}R-\partial_{yy}R+\frac{(1-R^2)R}{(1+R^2)}((\partial_x Q)^2+(\partial_y Q)^2)$$

$$+\frac{2R}{(1+R^2)}((\partial_x R)^2+(\partial_y R)^2)=0. \tag{1.8}$$

Note, that, in the Landau–Lifshitz case, if we put $R=1$ the equations become $\Delta Q=0$ and $\partial_t Q=B$, which have a very simple solution, and in the diffusion case, we have to set $B=0$ and then we end up with $\partial_t Q-\Delta Q=0$ as the equation for Q. The latter case is the nonrelativistic analog of what was found in the relativistic case where $R=1$ reduced the equation for Q to the linear wave equation for the phase Q.

In the next section we determine the symmetry group of our equations (1.6), (1.5) and of (1.7) and (1.8). In the following sections we solve the derived equations and discuss their solutions.

II. THE SYMMETRY GROUP AND ITS TWO-DIMENSIONAL SUBGROUPS

The symmetry group of our systems of equations, respectively (1.6) and (1.5) and (1.7) and (1.8), can be calculated using the standard methods.[13–16] We actually made use of a MACSYMA package[18] that provides a simplified and partially solved set of determining equations.

Solving the determining equations we find that three different cases must be distinguished.

(1) $A=B=0$, i.e., the anisotropy is absent. The Landau–Lifshitz equation and the diffusion equation have isomorphic symmetry groups, consisting of translations in space and time directions, rotations in the x, y plane, dilations, and a group of $O(3)$ rotations between the components of the field $\boldsymbol{\phi}$. The corresponding Lie algebra L_1 has the structure of a direct sum,

$$L_1=s(2,1)\oplus o(3). \tag{2.1}$$

Bases for these two algebras are given by the following vector fields, acting on space–time and on the fields in the $\{R,Q\}$ realization of Eqs. (1.5)–(1.8):

$$\begin{aligned} s(2,1):\quad & P_0=\partial_t,\quad P_1=\partial_x,\quad P_2=\partial_y,\\ & L=-x\partial_y+y\partial_x,\quad D=2t\partial_t+x\partial_x+y\partial_y. \end{aligned} \tag{2.2}$$

$$\begin{aligned} o(3):\quad & X=\frac{1}{2}\left(\sin Q\left(R-\frac{1}{R}\right)\partial_Q+\cos Q(R^2+1)\partial_R\right),\\ & Y=\frac{1}{2}\left(\cos Q\left(R-\frac{1}{R}\right)\partial_Q-\sin Q(R^2+1)\partial_R\right),\\ & Z=\partial_Q. \end{aligned} \tag{2.3}$$

(2) $A\neq 0$.

The symmetry algebra for both equations is reduced to

$$L_2=\{P_0,P_1,P_2,L\}\oplus\{Z\}, \tag{2.4}$$

i.e., the dilations are absent and the only $\boldsymbol{\phi}$ rotations left are those around the third axis (i.e., around ϕ_3).

(3) $A=0$, $B\neq 0$.

The symmetry algebra for the dissipative equations (1.8) and (1.7) is still L_2, as in (2.4). That of the Landau–Lifshitz equation is

$$L_3=\{P_0,P_1,P_2,L,\tilde{D}\}\oplus\{X,Y,Z\}, \tag{2.5}$$

with

$$\tilde{D}=2t\partial_t+x\partial_x+y\partial_y+2Bt\partial_Q, \tag{2.6}$$

where Q is replaced by $Q-Bt$ in x and y, Eq. (2.3).

In order to perform symmetry reduction we need to classify the subalgebras of the symmetry algebras L_1, L_2, and L_3. We wish to reduce Eqs. (1.5)–(1.8) to ordinary differential equations. To do this, we will require that the solutions are invariant under a two-dimensional subgroup of the symmetry group. In order to do this systematically we need to derive a classification of the two-dimensional subalgebras of the symmetry algebra. Moreover, we can restrict ourselves to subalgebras, all elements of which act nontrivially on space–time, i.e., that do not contain any rotations in $\boldsymbol{\phi}$ space.

The subalgebra classification can be done in an algorithmic way;[14] the results are quite simple and we present them without a proof.

(1) $A=B=0$. Every two-dimensional subalgebra of L_1, each element of which acts nontrivially on space–time, is conjugate under the action of the group of inner automorphisms to one of the following ones:

$$\begin{aligned}
&A_{2,1}=\{P_1+aZ,P_2+bZ\},\\
&A_{2,2}=\{L+aZ,P_0+bZ\},\\
&A_{2,3}=\{P_0+aZ,P_2+bZ\},\\
&A_{2,4}=\{P_0-vP_1+aZ,P_2+bZ\},\quad v\neq 0,\\
&A_{2,5}=\{D+bL+aZ,P_0\},\quad b\neq 0,\\
&A_{2,6}=\{D+aZ,P_0\},\\
&A_{2,7}=\{D+aZ,L+bZ\},\\
&A_{2,8}=\{D+aZ,P_2\}.
\end{aligned} \tag{2.7}$$

The parameters a, b, and v are arbitrary real numbers. In some cases their ranges can be further constrained, but that is not important for our purposes.

(2) $A\neq 0$.
Every two-dimensional subalgebra of the considered type is conjugate to one listed above as $A_{2,1},\ldots,A_{2,4}$.

(3) $A=0$, $B\neq 0$.
For the dissipative equations (1.8) and (1.7) the subalgebra classes are represented by $A_{2,1},\ldots,A_{2,4}$. For the Landau–Lifshitz equations (1.5) and (1.6) they are represented by $A_{2,1},\ldots,A_{2,8}$ with D replaced by $\tilde{D}$ and P_0 replaced by $P_0=P_0+bZ$.

We can now proceed to perform various reductions. We are particularly interested in reductions that do not result in time independence as these were already studied in Ref. 17.

III. SOLUTIONS OF THE LANDAU–LIFSHITZ EQUATION

A. General procedure

Our aim is to solve the Landau–Lifshitz equations (1.5) and (1.6), using the method of symmetry reduction. This involves assuming that a solution is invariant under a subgroup G_0 of the symmetry group G, namely one of the two-dimensional groups corresponding to the algebras $A_{2,1},\ldots,A_{2,8}$ of (2.7). The assumption makes it possible to reduce the partial differential equations (1.5) and (1.6) to a pair of coupled ordinary differential equations. Whenever possible, we decouple them and find explicit solutions for the functions R and Q, hence for W, and finally for the vector $\vec{\phi}$ figuring in (1.1).

For all eight algebras in (2.7) the invariant solution will have the form

$$R(x,y,t)=R(\xi),\quad Q(x,y,t)=\alpha(\xi)+\beta(x,y,t), \tag{3.1}$$

where ξ and β are explicitly given and $R(\xi)$ and $\alpha(\xi)$ satisfied coupled ordinary differential equations obtained by substituting (3.1) into (1.5) and (1.6).

The reduced equation (1.5) is

$$(\nabla\xi)^2\alpha_{\xi\xi}+\left[2\frac{(1-R^2)}{R(1+R^2)}(\nabla\xi)^2R_\xi+\Delta\xi\right]\alpha_\xi=\frac{R_\xi}{R}\xi_t-2\frac{(1-R^2)}{R(1+R^2)}R_\xi(\nabla\xi,\nabla\beta)-\Delta\beta. \tag{3.2}$$

For algebra $A_{2,1}$ we have

$$\nabla\xi^2=\Delta\xi=\Delta\beta=0,\quad \xi_t=1, \tag{3.3}$$

and so (3.2) reduces to $R_\xi=0$.

In all other cases we have $(\nabla\xi)^2\neq 0$. Equation (3.2) is a first-order linear inhomogeneous equation for α_ξ. We can integrate it explicitly and obtain α_ξ in terms of R, whenever the functions ξ and β satisfy

$$\frac{d}{d\xi}\left(\frac{h}{(\nabla\xi)^2}\right)=0,\quad \frac{d}{d\xi}\left[h\frac{(\nabla\xi,\nabla\beta)}{(\nabla\xi)^2}\right]-\frac{h\Delta\beta}{(\nabla\xi)^2}=0, \tag{3.4}$$

where

$$h(\xi)=1,\quad \text{for } \Delta\xi=0,$$

$$\frac{h'(\xi)}{h(\xi)}=\frac{\Delta\xi}{(\nabla\xi)^2},\quad \text{for } \Delta\xi\neq 0. \tag{3.5}$$

Conditions (3.4) are always satisfied for the algebras $A_{2,2}\ldots,A_{2,6}$, not, however, for $A_{2,7}$ and $A_{2,8}$. When conditions (3.4) are satisfied, we can integrate Eq. (3.2) once to obtain

$$\alpha_\xi=\frac{S}{h}\frac{(1+R^2)^2}{R^2}+\mu\frac{1+R^2}{R^2}+\nu, \tag{3.6}$$

where S is an arbitrary real integration constant, and where we have

$$\begin{aligned}
&\mu=-\frac{v}{2}, && \nu=0, && \text{for } A_{2,4},\\
&\mu=0, && \nu=-\frac{a}{b^2+1}, && \text{for } A_{2,5},\\
&\mu=0, && \nu=\frac{a\xi}{1+\xi^2}, && \text{for } A_{2,6},\\
&\mu=0, && \nu=0, && \text{for } A_{2,2},A_{2,3}.
\end{aligned} \tag{3.7}$$

Equation (1.6) for algebras $A_{2,2},\ldots,A_{2,8}$ is reduced to a second-order differential equation for $R(\xi)$ that also involves $\alpha_\xi(\xi)$. For reductions corresponding to Lie algebras $A_{2,2},\ldots,A_{2,6}$, we can substitute α_ξ from (3.6), to obtain an ordinary differential equation for $R(\xi)$ alone. To transform this equation to a standard form we put

$$R(\xi)=\sqrt{-U(\eta)},\quad \eta=\int h^{-1}(\xi)d\xi. \tag{3.8}$$

The equation for $U(\eta)$ is then written as

$$U_{\eta\eta}=\left(\frac{1}{2U}+\frac{1}{U-1}\right)U_\eta^2-\frac{2S^2}{U}(U+1)(U-1)^3+p\frac{U(U+1)}{U-1}+qU+m(U-1)^2. \tag{3.9}$$

Equation (3.9) can be integrated in terms of elliptic functions if p, q, and m are constants. This is always the case for algebras $A_{2,3},\ldots,A_{2,6}$. In the case of algebra $A_{2,2}$ this is true if we set $A=0$, $B=b$.

Equation (3.9) has a first integral that we can write as

$$U_\eta^2=-4S^2U^4+K_1U^3+KU^2+K_2U+K_3, \tag{3.10}$$

where K is an integration constant, and the constants K_1, K_2, and K_3 are related to the coefficients S, p, q, and m in (3.9).

In this article we restrict ourselves to solutions of the Landau–Lifshitz equation that are obtained by solving (3.10).

We shall first discuss solutions of (3.10) in general, then run through algebras $A_{2,2},\ldots,A_{2,6}$ and specify the values of the coefficients in (3.10) in each case, as well as the independent variable η.

Algebra $A_{2,1}$ leading to a first-order equation, will be treated separately.

B. Solutions of the elliptic function equation

We shall call (3.10) the ''elliptic function equation.'' Its solutions are, of course, well known.[19] We shall, however, list those that are relevant in the context of solving (3.9), and more importantly, the Landau–Lifshitz equation.

Several comments are in order here.

(1) The functions $R(\eta)$ must be real (and non-negative); hence $U(\eta)$ must be real and nonpositive.
(2) For $S\neq 0$ the coefficient of the highest power of U in (3.10) is non-negative. This means that all real solutions of (3.10) are nonsingular.
(3) For $S=0$, $K_1\neq 0$ in (3.10) the real solutions of (3.10) can be singular. Since we are really interested in the fields ϕ_i we note that singular solutions of U will give regular functions ϕ_i.
(4) In general, Eq. (3.10) is solved in terms of Jacobi elliptic functions. However, these reduce to elementary functions whenever the polynomial on the right-hand side has multiple roots, or when $S=K_1=0$.

Let us run through individual cases.

I. $S\neq 0$

We rewrite (3.10) as

$$U_\eta^2=-4S^2(U-U_1)(U-U_2)(U-U_3)(U-U_4). \tag{3.11}$$

(1) $U_1\leqslant U\leqslant U_2=U_3=U_4<0$,

$$U(\eta)=U_2-\frac{U_2-U_1}{1+S^2(U_2-U_1)^2(\eta-\eta_0)^2}, \tag{3.12}$$

this is an algebraic solitary wave, equal to U_2 for $\eta\to\pm\infty$, and dipping down to U_1 for $\eta=\eta_0$.

(2) $U_1=U_2=U_3<U\leqslant U_4\leqslant 0$,

$$U(\eta)=U_1+\frac{U_4-U_1}{1+S^2(U_4-U_1)^2(\eta-\eta_0)^2}. \tag{3.13}$$

Also an algebraic solitary wave, rising to $U=U_4$ for $\eta=\eta_0$, equal to U_1 for $\eta\to\pm\infty$.

(3) $U_1\leqslant U<U_2=U_3<U_4$, $U_2\leqslant 0$,

$$U(\eta)=U_2-\frac{(U_4-U_2)(U_2-U_1)}{(U_4-U_1)\cosh^2\,\mu(\eta-\eta_0)-(U_2-U_1)},$$

$$\mu=S\sqrt{(U_4-U_2)(U_2-U_1)}. \tag{3.14}$$

(4) $U_1<U_2=U_3<U\leqslant U_4\leqslant 0$,

$$U(\eta)=U_3+\frac{(U_3-U_1)(U_4-U_3)}{(U_4-U_1)\cosh^2\ \mu(\eta-\eta_0)-(U_4-U_3)}, \tag{3.15}$$

with μ as in (3.14).

The last two solutions are solitons: the first one a well, the second a bump.

(5) $U_1\leqslant U\leqslant U_2<U_3=U_4,\ U_2\leqslant 0$,

$$U(\eta)=U_4-\frac{(U_4-U_2)(U_4-U_1)}{(U_2-U_1)\sin^2\ \mu(\eta-\eta_0)+U_4-U_2},$$

$$\mu=S\sqrt{(U_4-U_2)(U_4-U_1)}. \tag{3.16}$$

(6) $U_1=U_2<U_3\leqslant U\leqslant U_4\leqslant 0$,

$$U(\eta)=U_1+\frac{(U_4-U_1)(U_3-U_1)}{(U_4-U_3)\sin^2\ \mu(\eta-\eta_0)+U_3-U_1},$$

$$\mu=S\sqrt{(U_4-U_1)(U_3-U_1)}. \tag{3.17}$$

(7) $U_1\leqslant U\leqslant U_2<U_3<U_4,\ U_2\leqslant 0$,

$$U(\eta)=U_4-\frac{(U_4-U_2)(U_4-U_1)}{(U_2-U_1)sn^2(\mu(\eta-\eta_0),k)+U_4-U_2},$$

$$\mu=S\sqrt{(U_4-U_2)(U_3-U_1)},\quad k^2=\frac{(U_4-U_3)(U_2-U_1)}{(U_4-U_2)(U_3-U_1)}. \tag{3.18}$$

(8) $U_1<U_2<U_3\leqslant U\leqslant U_4<0$,

$$U(\eta)=U_1+\frac{(U_4-U_1)(U_3-U_1)}{(U_4-U_3)sn^2\ \mu(\eta-\eta_0)+U_3-U_1}, \tag{3.19}$$

with k^2 and μ as in (3.18).

(9) $U_1\leqslant U\leqslant U_2\leqslant 0$, $U_{3,4}=p\pm iq$, $q>0$,

$$U(\eta)=\frac{(MU_1-NU_2)cn(\mu(\eta-\eta_0),k)+MU_1+NU_2}{(M-N)cn(\mu(\eta-\eta_0),k)+M+N},$$

$$M^2=(U_2-p)^2+q^2,\quad N^2=(U_1-p)^2+q^2,$$

$$k^2=\frac{(U_2-U_1)^2-(M-N)^2}{4MN},\quad \mu=2S\sqrt{MN}. \tag{3.20}$$

Solutions (3.16)–(3.20) are periodic. All the elementary solutions can be viewed as limits of solutions (3.18), (3.19), and (3.20).

II. $S=0$, $K_1\neq 0$

Set

$$\mu=\tfrac{1}{2}\sqrt{|K_1|(U_3-U_1)}. \tag{3.21}$$

(1) $K_1<0$, $U_1=U_2<U\leqslant U_3\leqslant 0$,

$$U=U_3-(U_3-U_2)\tanh^2\ \mu(\eta-\eta_0). \tag{3.22}$$

(2) $K_1<0$, $U<U_1=U_2<U_3$, $U_1\leqslant 0$,

$$U=U_3-\frac{(U_3-U_1)}{\tanh^2\ \mu(\eta-\eta_0)}. \tag{3.23}$$

(3) $K_1<0,\ U<U_1=U_2=U_3\leqslant 0,$

$$U=U_1-\sqrt{\frac{2}{-K_1}}\frac{1}{(\eta-\eta_0)^2}. \tag{3.24}$$

(4) $K_1<0,\ U\leqslant U_1<U_2=U_3,\ U_1\leqslant 0,$

$$U=U_3-\frac{U_3-U_1}{\sin^2\ \mu(\eta-\eta_0)}. \tag{3.25}$$

(5) $K_1<0,\ U_1<U_2<U\leqslant U_3\leqslant 0,$

$$U=U_3-(U_3-U_2)sn^2(\mu(\eta-\eta_0),k),\quad k^2=\frac{U_3-U_2}{U_3-U_1}. \tag{3.26}$$

(6) $K_1<0,\ U\leqslant U_1<U_2<U_3,\ U_1\leqslant 0,$

$$U=U_3-\frac{U_3-U_1}{sn^2(\mu(\eta-\eta_0),k)}; \tag{3.27}$$

k as in (3.26)

(7) $K_1>0,\ U_1<U<U_2=U_3=0,$

$$U=U_1\ \frac{1}{\cosh^2\ \mu(\eta-\eta_0)}. \tag{3.28}$$

(8) $K_1>0,\ U_1<U<U_2<0<U_3,$

$$U=(U_2-U_1)sn^2(\mu(\eta-\eta_0),k),\quad k^2=\frac{U_2-U_1}{U_3-U_1}. \tag{3.29}$$

(9) $K_1<0,\ U_1\leqslant 0,\ U_{2,3}=p\pm iq,\ q>0,$

$$U=U_1+A-\frac{2A}{1-cn(\mu(\eta-\eta_0),k)},$$

$$A^2=(p-U_1)^2+q^2,\quad k^2=\frac{A-p+U_1}{2A},\quad \mu=\sqrt{|K_1|A}. \tag{3.30}$$

III. $S=0,\ K_1=0,\ K\neq 0$

(1) $K>0,\ U\leqslant U_1<0<U_2,$

$$U=U_1-(U_2-U_1)\sinh^2\ \frac{\sqrt{K}}{2}\ (\eta-\eta_0). \tag{3.31}$$

(2) $K>0,\ U<U_1=U_2=0,$

$$U=-\exp(-\sqrt{K}(\eta-\eta_0)). \tag{3.32}$$

(3) $K<0,\ U_1<U<U_2\leqslant 0,$

$$U=U_1+(U_2-U_1)\cos^2\ \frac{\sqrt{-K}}{2}\ (\eta-\eta_0). \tag{3.33}$$

IV. $S=K_1=K=0$, $K_2\neq 0$

$$U=-\frac{K_3}{K_2}+\frac{K_2}{4}(\eta-\eta_0)^2, \quad K_2<0, \quad K_3<0. \tag{3.34}$$

V. $S=K_1=K=K_2=0$

$$U=\sqrt{K_3}(\eta-\eta_0), \quad K_3>0. \tag{3.35}$$

C. Individual reductions

1. Algebra $A_{2,1}$

This is an exceptional case when (3.2) implies $R_\xi=0$. We find that the only solution for W of (1.4) is

$$W=R_0e^{iQ}, \quad Q=ax+by+\left(B+\frac{1-R_0^2}{1+R_0^2}(a^2+b^2+A)\right)t+\alpha_0, \tag{3.36}$$

where R_0 and α_0 are integration constants.

2. Algebra $A_{2,2}$

We find

$$W=R(\rho)\exp\, i[\alpha(\rho)+a\phi+bt], \quad \xi=\rho, \tag{3.37}$$

where ρ and ϕ are polar coordinates. The single-valuedness of W requires a to be an integer. The phase $\alpha(\rho)$ and variable η satisfy

$$\alpha_\rho(\rho)=S\frac{(1+R^2)^2}{\rho R^2}, \quad \eta=\ln\,\rho \tag{3.38}$$

[see (3.6)]. For the function $U(\eta)$ of (3.8) we obtain the elliptic function equation if and only if we set

$$A=0, \quad b=B \tag{3.39}$$

[A and B are defined in (1.6)].

We have

$$K_1=K_2=2a^2+4S^2-\frac{K}{2}, \quad K_3=-4S^2, \tag{3.40}$$

in (3.10).

For $S\neq 0$, Eq. (3.40) implies that we can have two negative and two positive roots in Eq. (3.11) or two negative roots and two complex conjugate ones. These cases lead to real solutions, namely (3.16), (3.18), and (3.20). Note that all of them are periodic. In particular, for $a=0$, Eq. (3.11) always has a double root, $U_3=U_4=1$, and reduces to

$$U_\eta^2=-4S^2\left[U^2+\left(1+\frac{K}{8S^2}\right)U+1\right]. \tag{3.41}$$

For $S=0$, $K\neq 4a^2$ we obtain the equation

$$\begin{gathered}U_\eta^2=2\left(a^2-\frac{K}{4}\right)U(U-U_1)(U-U_2),\\ U_1U_2=1, \quad U_1+U_2=\frac{2K}{K-4a^2}.\end{gathered} \tag{3.42}$$

The relevant solutions of (3.42) in this case are the following.
(1) $2a^2 \leqslant K < 4a^2$, $U_1 < U_2 < 0$; solution (3.29) (with $U_3 = 0$). For $K = 2a^2$ we have $U = -1$.
(2) $K > 4a^2$, $U_1 \leqslant U_2 < 0$. Solutions (3.26), (3.27), (3.22), and (3.23) (all with $U_3 = 0$).
(3) $K > 4a^2$, $0 < U_1 < U_2$.
Solutions (3.26) (with $U_3 \to U_2$, $U_2 \to U_1$, $U_1 = 0$).
(4) $K > 4a^2$, $U_{1,2} = p \pm iq$, $q > 0$; solution (3.30).

For $S = 0$, $K = 4a^2$ (3.10) reduces to an elementary one, and its solution is

$$R(\rho) = -R_0^2 \rho^{\pm 2a}, \tag{3.43}$$

where R_0 is an integration constant.

3. Algebra $A_{2,3}$ and $A_{2,4}$

The reduction formulas in both of these cases are

$$W = R(\xi) \exp i[\alpha(\xi) - at - by], \quad \xi = x + vt, \quad \eta = \xi, \tag{3.44}$$

with $v = 0$ and $v \neq 0$ for the algebras $A_{2,3}$ and $A_{2,4}$, respectively. Since the Landau–Lifshitz equation is not Galilei invariant, we cannot change the value of v by a group transformation. The transformation (3.8) leads to (3.10) with

$$K_1 = -\frac{K}{2} + 4S^2 + 2(A + b^2) - \frac{v^2}{2} + 2vS + 2(-B + a),$$

$$K_2 = -\frac{K}{2} + 4S^2 + 2(A + b^2) + \frac{3v^2}{2} - 6vS + 2(B - a), \tag{3.45}$$

$$K_3 = -(2S - v)^2.$$

Equation (3.6) in this case gives

$$\alpha_\xi = S\,\frac{(1 + R^2)^2}{R^2} - \frac{v}{2}\,\frac{1 + R^2}{R^2}. \tag{3.46}$$

For $S \neq 0$ we obtain (3.11) with the constraint

$$U_1 U_2 U_3 U_4 = \left(1 - \frac{v}{2S}\right)^2, \tag{3.47}$$

imposed on these roots. Hence, only an even number of roots can be negative (0, 2, or 4). This, however, means that all solutions (3.12)–(3.20) can occur, though in some cases we must impose $U_4 \leqslant 0$ ($U_4 = 0$ is allowed for $v = 2S$).

For $S = 0$, all solutions (3.22)–(3.30) can occur.

4. Algebra $A_{2,5}$

The reduction formula is

$$W = R(\xi) \exp i\left[\alpha(\xi) + \frac{a}{b}\,\phi + Bt\right], \quad \xi = \ln \rho + \frac{1}{b}\,\phi, \tag{3.48}$$

and we must set $A = 0$ in the Landau–Lifshitz equation. The phase $\alpha(\xi)$ satisfies

$$\alpha_\xi = S\,\frac{(1 + R^2)^2}{R^2} - \frac{a}{b^2 + 1} \tag{3.49}$$

[see (3.6)].

The function $U=-R^2(\xi)$ satisfies (3.10), and for $S\neq 0$ we have

$$K_1=K_2=-\frac{K}{2}+4S^2-\frac{2a^2}{(b^2+1)^2},\quad K_3=-4S^2. \tag{3.50}$$

The solutions that can occur in this case are (3.14)–(3.20). However, there are constraints between various parameters of the solution that follow from the requirement of single-valuedness of W.

For $a=0$, Eq. (3.11) again reduces to (3.41), and we only obtain the elementary periodic solutions (3.16).

For $S=0$, $K_1\neq 0$ we obtain the equation

$$U_\xi^2=K_1U(U-U_1)(U-U_2),$$

$$U_1U_2=1,\quad U_1+U_2=2\left[1+\frac{2a^2}{K_1(b^2+1)}\right]. \tag{3.51}$$

For $-a^2/(b^2+1)<K_1<0$ we have $U_1\leqslant U_2<0$, and solutions (3.22), (3.23), (3.26), and (3.27) are obtained.

For $K_1>0$ we have $0<U_1\leqslant U_2$ but we obtain no real solutions.

For $K_1<-a^2/(b^2+1)$ we obtain solutions (3.30).

Finally, for $S=0$, $K_1=0$ the solution is $U=-R_0^2\exp(\pm\sqrt{K}\xi)$, and hence

$$R=R_0\exp\left[\pm\frac{1}{2}\sqrt{K}\left(\ln\rho+\frac{1}{b}\phi\right)\right]. \tag{3.52}$$

5. Algebra $A_{2,6}$

The reduction formula is

$$W=R(\xi)\exp i[\alpha(\xi)+Bt+a\ln x],\quad \xi=\frac{y}{x},\quad \eta=\arctan\frac{y}{x}=\phi, \tag{3.53}$$

and α satisfies

$$\alpha_\xi=\frac{S}{1+\xi^2}\frac{(1+R^2)^2}{R^2}+\frac{a\xi}{1+\xi^2}, \tag{3.54}$$

and $U(\phi)=-R^2(\xi)$ satisfies (3.11) with $K_1=K_2=-K/2+4S^2+2a^2$, $K_3=-4S^2$. For $a=0$ the equation again reduces to (3.41).

A real solution is obtained only for $K>8S^2$, namely (3.16). It is periodic in ϕ and hence single-valued when μ is an integer.

For $S=0$ we get a real solution for $K_1<0$, namely solution (3.25), which in this case reduces to

$$U(\phi)=-\tan^2\tfrac{1}{2}\sqrt{|K_1|}(\phi-\phi_0). \tag{3.55}$$

This is a single-valued function whenever $\sqrt{|K_1|}$ is an integer.

6. Algebras $A_{2,7}$ and $A_{2,8}$

The corresponding reductions lead to equations that we cannot decouple without introducing higher derivatives, so we will not treat them here.

IV. SOLUTIONS OF THE NONLINEAR DIFFUSION EQUATION

A. General procedure

Let us consider the system (1.7) and (1.8), the NDLE for short. We impose that the solution be invariant under one of the Lie groups generated by the algebra in Eq. (2.7). The functions R and Q will then have the form (3.1) with ξ and β as in Sec. III (different for each subalgebra $A_{2,1},\ldots,A_{2,8}$).

As for the LL equation, algebra $A_{2,1}$ must be treated separately.

For $A_{2,2},\ldots,A_{2,8}$ we always have $(\nabla\xi)^2\neq 0$. Equations (1.7) and (1.8) reduce to

$$\alpha_{\xi\xi}=-2\,\frac{(1-R^2)}{1+R^2}\,\frac{R_\xi}{R}\,\alpha_\xi+\frac{f_\xi}{f}\,\alpha_\xi-2\,fm\,\frac{(1-R^2)}{1+R^2}\,\frac{R_\xi}{R}+hf, \tag{4.1}$$

$$R_{\xi\xi}=\frac{f_\xi}{f}\,R_\xi+\frac{2R}{1+R^2}\,R_\xi^2+\frac{1-R^2}{1+R^2}\,R[\alpha_\xi^2+2mf\alpha_\xi+g^2]+\frac{1}{(\nabla\xi)^2}\left[BR+AR\,\frac{1-R^2}{1+R^2}\right]. \tag{4.2}$$

The functions $f(\xi)$, $m(\xi)$, $h(\xi)$, and $g(\xi)$ are defined by the relations

$$\frac{f_\xi}{f}=\frac{\xi_t-\Delta\xi}{(\nabla\xi)^2},\quad m=\frac{(\nabla\xi,\nabla\beta)}{(\nabla\xi)^2 f},$$

$$h=\frac{\beta_t-\Delta\beta}{(\nabla\xi)^2 f},\quad g^2=\frac{(\nabla\beta)^2}{(\nabla\xi)^2}. \tag{4.3}$$

In order to decouple Eqs. (4.1) and (4.2), we impose a restriction on the functions defined in (4.3), namely

$$m_\xi+h=0. \tag{4.4}$$

Equation (4.1) can then be integrated once to give

$$\alpha_\xi=\left[S\,\frac{(1+R^2)^2}{R^2}-m\right]f(\xi), \tag{4.5}$$

where S is an integration constant. We substitute (4.5) into (4.2) and put

$$R(\xi)=\sqrt{-U(\eta)},\quad \eta=\int f(\xi)d\xi. \tag{4.6}$$

The equations are decoupled and the one for $U(\eta)$ is already in a standard form,[20] namely

$$U_{\eta\eta}=\left(\frac{1}{2U}+\frac{1}{U-1}\right)U_\eta^2+2S^2\,\frac{(1+U)(1-U)^3}{U}+M\,\frac{1+U}{1-U}\,U+NU, \tag{4.7}$$

with

$$M=\frac{2}{f^2}\left(g^2-m^2f^2+\frac{A}{(\nabla\xi)^2}\right),$$

$$N=\frac{2}{f^2}\,\frac{B}{(\nabla\xi)^2}. \tag{4.8}$$

We now make a further restriction, namely, that M and N, defined in (4.8) are constants. Equation (4.7) then has a first integral K and we obtain the elliptic equation (3.10) with

$$K_1=-\frac{K}{2}+4S^2+M+N,$$

$$K_2=-\frac{K}{2}+4S^2+M-N, \tag{4.9}$$

$$K_3=-4S^2.$$

In many cases we have $M=N=0$ and the polynomial on the right-hand side of (3.10) has a double root at $U_3=U_4=1$. The solution we obtain for $S\neq 0$ is (3.16) with $U_4=1$, i.e.,

$$U(\eta)=1-\frac{(1-U_2)(1-U_1)}{(U_2-U_1)\sin^2\ \mu(\eta-\eta_0)+1-U_2},$$
$$\mu=S\sqrt{(1-U_2)(1-U_1)},\quad U_1\leqslant U\leqslant U_2<0. \tag{4.10}$$

For $S=0$, $K>0$ we obtain solution (3.25), i.e.,

$$U=-\tan^2\sqrt{\frac{K}{8}}\,(\eta-\eta_0). \tag{4.11}$$

B. Individual reductions

1. Algebra $A_{2,1}$

We have

$$R=R(t),\quad Q=\alpha_0+ax+by, \tag{4.12}$$

where α_0 is a constant, and R_t satisfies

$$R_t=-\frac{R(1-R^2)}{1+R^2}\,(A+a^2+b^2)-BR. \tag{4.13}$$

Equation (4.13) can easily be integrated [differently depending on whether $(A+B+a^2+b^2)\times(A-B+a^2+b^2)$ vanishes, or not] and we obtain a transcendental equation for $R(t)$.

2. Algebra $A_{2,2}$

The reduction formula is (3.37). We have $m=0$ and (4.4) requires $b=0$, so the solutions are static ones. The variable η and constants involved satisfy

$$\eta=\ln\,\rho,\quad M=2a^2,$$
$$A=B=N=b=0. \tag{4.14}$$

Since we have $b=0$, the solutions are static ones. All solutions (3.12)–(3.30) can occur.

3. Algebra $A_{2,3}$

We have

$$\eta=x,\quad M=2(b^2+A),\quad N=2B,\quad a=0, \tag{4.15}$$

and again, the solutions are static ones, since the reduction formula is (3.44). All solutions of Sec. III B can occur.

4. Algebra $A_{2,4}$

The reduction formula is (3.44), and we have

$$\eta=\frac{1}{v}\,(e^{v(x+vt)}-1),\quad a=0,\quad A=-b^2,\quad B=0,$$

$$M=N=0,\quad v\neq 0. \tag{4.16}$$

The obtained solutions are (4.10) and (4.11) and they are t dependent.

5. Algebra $A_{2,5}$

We have Eq. (3.48) with

$$\eta=\xi=\ln\,\rho+\frac{1}{b}\,\phi,\quad A=B=N=0,$$

$$M=\frac{2a^2b^2}{(b^2+1)^2},\quad b\neq 0. \tag{4.17}$$

Since we have $M\geqslant 0$ we obtain the solutions (3.16), (3.18), (3.20), (3.22), (3.23), (3.26), (3.27), and (3.30). The parameters of these solutions must satisfy, however, certain constraints in order for the solutions to be single-valued. For $K=2M$ we obtain

$$U=-R_0^2\rho^{2|ab|/(b^2+1)}e^{[2|a|/(b^2+1)]\phi}, \tag{4.18}$$

a solution that is not single-valued.

6. Algebra $A_{2,6}$

The reduction formula is (3.54), and we have

$$\eta=\int\frac{d\xi}{1+\xi^2}=\phi,\quad A=B=a=M=N=0, \tag{4.19}$$

so the relevant solutions are (4.10) and (4.11). The solutions are static and they are single-valued for μ or $\sqrt{K/8}$ being integers.

7. Algebra $A_{2,7}$

We put

$$W=R(\xi)\exp\,i\left[\alpha(\xi)+\frac{a}{2}\ln\,t+b\phi\right],$$

$$\xi=\frac{x^2+y^2}{t},\quad \eta=\int\frac{1}{\xi}\,e^{-\xi/4}d\xi=Ei\left(-\frac{1}{4}\,\xi\right), \tag{4.20}$$

where $Ei(x)$ is the exponential integral function. Moreover, we have $b=a=A=B=M=N=0$ and the relevant solutions are (4.10) and (4.11).

8. Algebra $A_{2,8}$

We have

$$W=R(\xi)\exp\,i\left[\alpha(\xi)+\frac{a}{2}\ln\,t\right],\quad \xi=\frac{x}{\sqrt{t}}, \tag{4.21}$$

$$\eta = \int e^{-\xi^2/4} d\xi = \sqrt{\pi}\Phi(\xi),$$

where $\Phi(x)$ is the probability integral. We have $M=N=A=B=a=0$, and so we obtain solutions (4.10) and (4.11)

We see that time-dependent solutions are obtained for the algebras $A_{2,1}$, $A_{2,4}$, $A_{2,7}$, and $A_{2,8}$. For $A_{2,5}$ $A_{2,7}$, and $A_{2,8}$ the solutions are trigonometric ones.

The phases $\alpha(\xi)$ can be calculated by direct integration, since we have

$$\frac{d\alpha}{d\eta} = -S\,\frac{(1-U)^2}{U}, \tag{4.22}$$

and U is already known.

Thus, for U given by (4.10) we get

$$\alpha(\eta) = \sqrt{\frac{(U_1-1)(U_2-1)}{U_1U_2}}\,\arctan\left\{\sqrt{\frac{U_2(U_1-1)}{U_1(U_2-1)}}\,\cot\,\mu(\eta-\eta_0)\right\}$$
$$-\sqrt{(U_1-1)(U_2-1)}\,\arctan\left\{\sqrt{\frac{(U_1-1)}{(U_2-1)}}\,\cot\,\mu(\eta-\eta_0)\right\}+\alpha_0, \tag{4.23}$$

while for U given by (4.11) we have

$$\alpha = 4\sqrt{\frac{2}{K}}\,S\,\cot\{\sqrt{2K}(\eta-\eta_0)\}+\alpha_0. \tag{4.24}$$

V. CONCLUSIONS

The Landau–Lifshitz equation (1.1) has received quite a bit of previous attention, mainly in the context of continuum Heisenberg ferromagnetic spin systems.[21–27] The anisotropy coefficients A and B of Eq. (1.3) were usually set equal to zero. Use was made of the fact that Eq. (1.1) is integrable, at least in the one-dimensional case, or in the two-dimensional, spherically symmetric one.

A one-soliton solution has been obtained;[23,25] a radially symmetric one. In our variables R, Q of Eq. (1.5), (1.6), this solution corresponds to

$$R = \frac{4t+\alpha_1}{4t+\alpha_1+\cosh^2\left[\dfrac{4t+\alpha_1}{(4t+\alpha_1)^2+\alpha_2^2}\,(x^2+y^2)\right]}, \tag{5.1}$$

where α_1 and α_2 are arbitrary real constants. As noted by Lakshamanan and Porsezian[25] the soliton spreads in time.

The solution (5.1) is not among the invariant solutions obtained in this article, nor can it be obtained from such a solution by applying transformations from the symmetry group. As often happens,[28] the method of symmetry reduction that does not rely on integrability, provides different solutions for integrable equations, than the use of Lax pairs or Backlund transformations.

We note that Eq. (1.1) with $A\neq 0$ is not integrable.

In general, we have reduced the LL equation to the ordinary differential equation (3.9). We have integrated Eq. (3.9) in terms of elliptic functions whenever p, q, and m are constants. For the algebras $A_{2,3},\ldots,A_{2,6}$ this was always the case.

For algebra $A_{2,2}$ we obtained Eq. (3.10) only for $A=0$, $B=b$. Let us briefly consider the case when the anisotropy coefficient A does not vanish. We then return to the original variable $\xi=\rho=\sqrt{x^2+y^2}=\exp\,\eta$ and transform Eq. (3.9) into

$$U_{\rho\rho} = \left(\frac{1}{2U}+\frac{1}{U-1}\right)U_\rho^2-\frac{1}{\rho}\,U_\rho+\frac{2S^2}{\rho^2}\,(U-1)^2\left(-U+\frac{1}{U}\right)-\frac{2(a^2+A^2\rho^2)}{\rho^2}+2(B-b). \tag{5.2}$$

For $a=0$, $b=B$ this is the equation for the fifth Painlevé transcendent P_V.[20] However, for $B \neq b$, Eq. (5.2) does not have the Painlevé property. According to the Painlevé conjecture,[29,30] Eq. (1.1) is hence, in general, not integrable.

This has not stopped us from obtaining numerous solutions, both in integrable and nonintegrable cases. The algebra $A_{2,2}$ (cylindrical symmetry) for $A=0$, $B=b$ leads to periodic solutions, as discussed in Sec. III C. The periodicity is in the radial variable ρ. The time dependence is restricted to the phase Q, as is seen in Eq. (3.37). Moreover, the time dependence is entirely due to the presence of the external field B (we have $b=B$) that generates a rotation between the components ϕ_1 and ϕ_2 of the original vector $\boldsymbol{\phi}$.

Some elementary nonperiodic solutions that we can extract from Sec. III are

$$R^2=\frac{U_1-U_2S^2(U_2-U_1)^2(\ln \rho/\rho_0)^2}{1+S^2(U_2-U_1)^2(\ln \rho/\rho_0)^2}, \tag{5.3}$$

$$R^2=\frac{4R_0^2U_4(U_2-U_1)-U_2(U_4-U_1)[2R_0^2+\rho^{2\mu}+R_0^4\rho^{-2\mu}]}{(U_4-U_1)[2R_0^2+\rho^{2\mu}+R_0^4\rho^{-2\mu}]-4(U_2-U_1)R_0^2}, \tag{5.4}$$

with S, R_0, ρ_0, U_i constants and

$$Q=S\int \frac{(1+R^2)^2}{\rho R^2}\,d\rho+a\phi+Bt, \tag{5.5}$$

in both cases.

For $S=0$, we have, for instance,

$$R=\left[-U_1+\sqrt{\frac{2}{-K_1}}\left(\ln\frac{\rho}{\rho_0}\right)^{-2}\right]^{1/2}, \tag{5.6}$$

$$R=\frac{2\sqrt{-U_1}R_0}{\rho^{\mu}+R_0^2\rho^{-\mu}}, \tag{5.7}$$

with

$$Q=a\phi+Bt+Q_0. \tag{5.8}$$

For $A\neq 0$, as mentioned above, solutions are obtained in terms of $P_V(\rho)$. Their time dependence is again given by the term Bt in the phase Q.

For algebras $A_{2,3}$ and $A_{2,4}$ we obtain Eq. (3.10) and a multitude of explicit solutions for all values of a, b, A, and B. Note that for

$$S\neq 0, \quad B=a, \quad A=-b^2, \tag{5.9}$$

in particular, for the one-dimensional ($b=0$), static ($a=0$) with no external fields ($A=B=0$), two of the roots in Eq. (3.11) coincide, and the equation reduces to

$$U_\eta^2=-4S^2(U-1)^2\left[U^2+\left(-\frac{K_1}{4S^2}+2\right)U-\frac{K_3}{4S^2}\right]. \tag{5.10}$$

Equation (5.10) only allows elementary solutions like (3.12)–(3.17), not, however, the elliptic function ones. These occur when the fields A and B are such that (5.9) is not satisfied.

To our knowledge, the NLDE (1.2) has not been investigated from the point of view of its integrability, and we have no solutions to compare ours to.

We have derived many explicit exact solutions of both equations. Looking at them we note that most of them have infinite energy. They can describe coherent phenomena in various solid state and condensed matter applications.

Looking first at the solutions of the LL equation, we note that some of our solutions have finite energy. In particular, this is the case for (3.43). This solution is obtained from the familiar

static solution describing n solitons ''on top of each other.''[31] Its time dependence is given by the factor e^{iBt}, which thus describes a rotation of this static solution in the ϕ_1, ϕ_2 plane with the angular frequency given by the anisotropy B. The other solutions of this class correspond to the static elliptic solutions discussed in Ref. 17 again rotated by e^{iBt}.

The solutions corresponding to algebras $A_{2,1}$, $A_{2,3}$, and $A_{2,4}$ have infinite energies. As such, they describe various waves in the medium (generalizations of plane waves). These can, for instance, be spin waves; the energy per period is finite.

An interesting class of solutions are those corresponding to algebras $A_{2,5}$ and $A_{2,6}$. Given the choice of parameters, these solutions can be of finite energy; however, due to their dependence on the variable $\phi = \arctan(y/x)$, they may become singular when x and y vanish. They can be used to describe media with defects.

Most of the comments made above apply also to the solutions of the NLDE. The static solutions in both cases are, of course, the same. When we consider nonstatic solutions, the most interesting from the physical point of view, are perhaps solutions corresponding to algebras $A_{2,1}$, $A_{2,7}$, and $A_{2,8}$. All of them have infinite energies. The solution corresponding to $A_{2,1}$ describes a structure shrinking toward the origin (or expanding to infinity—depending on the values of the parameters). The other solutions describe field configurations evolving in time. They can be used in the description of some physical phenomena in condensed matter or solid state physics.

Among the questions that we plan to return to, we mention the study of ''partially invariant'' solutions[32–34] of Eqs. (1.1) and (1.2), and also ''conditionally invariant'' ones.[35] A study of solutions involving Painlevé transcendents is also warranted.

ACKNOWLEDGMENTS

Most of the work reported in this paper was performed when one of us (WJZ) visited the CRM, Université de Montréal, Canada. He wishes to thank the Centre de Recherches Mathématiques for its support and hospitality. The research of P.W. was partly supported by research grants from the NSERC of Canada and the FCAR du Québec.

I. INTRODUCTION

Many recent scientific developments in theoretical sciences (mathematics, theoretical physics, signal processing, etc.) are based on *efficient representations* of mathematical objects such as functions, signals, operators. Prototypes of such efficient representations are of course Fourier expansions, or more generally spectral decompositions for self-adjoint operators. However, the word *efficient* may be given several different interpretations. For example, representing efficiently a function may be understood as representing it with a minimal amount of data. Alternatively, an efficient representation may also be a representation from which mathematical or physical properties may be retrieved easily. Another alternative interpretation may be that an efficient representation gives a way to simulate, or generate easily the object under study.

In that respect, wavelet analysis and more generally, time-frequency analysis, may be considered as good candidates for providing efficient representations of functions or operators in a large class of different contexts (ranging from signal compression to mathematical analysis).

Wavelet analysis seems to be a relatively new scientific domain, since it was introduced in its ''modern form'' in the early eighties. However, it is worth pointing out that similar methods have been used for decades in different contexts in mathematics and mathematical physics, as well as signal and image processing. What is really more recent is the fact that since then, strong interactions have been developed between those different areas, which have led to significant advances.

At a very elementary level, wavelet analysis and time-frequency analysis consist in providing alternative representations of functions, from which information regarding time localization as well as frequency localization may be obtained more easily.

This may be done by decomposing those functions into more ''elementary functions,'' generated using simple rules. For example, classical wavelets are translates and dilates of a single function, while the so-called Gabor functions are obtained as translated and modulated copies of a single function. Such a methodology is far from original, and several origins may be quoted. For example, Littlewood–Paley analysis may be considered as one of the ''ancestors'' of wavelet analysis in the field of mathematical analysis (see Ref. 1 for a review), while mathematical physicists have been developing coherent states methods for a long time in the context of coherent optics, or quantization (see, e.g., Ref. 2). In more applied areas, one may mention as well similar developments going back to Gabor[3] in signal processing or Marr[4] in vision.

An alternative approach to time-frequency analysis consists of constructing different types of time-frequency representations for functions, which are merely generalizations of Wigner functions. Needless to say, again, such methods owe a lot to mathematical physics and quantization. Wigner functions have received a renewed interest in recent years, both in engineering (signal processing) and mathematics (for example, the analysis of nonstationary stochastic processes). It is now obvious that time-frequency signal processing and quantization methods have a lot in common, and that enormous progress can be made by developing the connections.

Even though mathematical physics may be considered one of the origins of wavelet and time-frequency analysis, it seems that the recent developments of the latter did not have a significant impact on the former (at least the impact was much less spectacular than the impact on mathematics or more applied sciences). It is one of the goals of this volume to help disseminate

 © 1998 American Institute of Physics

those new techniques in the mathematical physics community. Since there already exist many textbooks (more than 50 in fact) covering various aspects of wavelet theory (see, for example, Refs. 5–7, 1, 8, or 9 for an historical perspective), there is no need for an introductory article on wavelets. All the contributions to this special issue emphasize either specific methodologies that are expected to be useful in mathematical physics, or mathematical physics problems solved with wavelet or time-frequency techniques.

The contributions to this special issue have been organized in four sections: *Coherent states and semiclassical analysis; quantization and signal processing; Littlewood–Paley-type methods; fractals, multifractals and applications;* and *generalized wavelet and time-frequency bases*. Such an organization is only intended to serve as a reader's guide, and not as a clear-cut separation between scientific domains, which would be artificial.

II. COHERENT STATES APPROACHES

The connection of wavelet analysis with coherent states and the theory of square integrable group representations was recognized in a seminal paper by Grossmann, Morlet, and Paul.[10] Based on a famous theorem of Duflo and Moore on square-integrable representations, these authors expressed wavelet transform and Gabor transform as intertwiners between the (left or right) regular representation and a square-integrable representation, in the case of the $ax+b$ group and the Heisenberg group respectively. This work has been the starting point of many further investigations and extensions to more general groups (for example, general semidirect products $H \times \mathbf{R}^n$, with $H \subset GL(n,\mathbf{R})$ in Ref. 11), and representations that are not necessarily square integrable (a review may be found in Ref. 2). Several extensions of this theory are presented in four articles of this volume.

Ali extends the classical Duflo–Moore theorem on square integrable representations of locally compact groups so as to cover the case of vector coherent states. His treatment yields in particular coherent states incorporating spin degrees of freedom.

The case of semidirect products $H \times \mathbf{R}^n$ is considered in the contributions of Aniello *et al.* and Führ. The paper by Aniello *et al.* extends previous results of Bernier and Taylor[11] and Führ, focusing on representations realized as induced representations. They also discuss the existence of discrete frames associated with the continuous transforms.

The paper by Führ focuses on the case where the dilation group H is Abelian. He gives a complete characterization of those groups which yield a resolution of the identity, by establishing a correspondence with commutative associative algebra with unity.

Antoine and Vandergheynst address the problem of the construction of wavelet decompositions on spheres, a problem of great practical importance (for example, in geophysics or in astronomy, for obvious reasons). The main problem is to find an acceptable substitute for dilations on spheres. A natural "$ax+b$" group adapted to the geometry as the sphere is given by $SO(n) \times \mathbf{R}_*^+ \subset SO_o(n,1)$. The corresponding continuous wavelet transform on S^{n-1} is then obtained from a suitable unitary representation of $SO_o(n,1)$ acting in $L^2(S^{n-1}, d\mu)$, which is shown to be square-integrable when restricted to the quotient $SO_o(n,1)/\mathbf{R}^{n-1}$.

The paper by Paul and Uribe is of a different nature, and develops an application of coherent states rather than construction of such states. The main result is a new weighted trace formula for Schrödinger operators with a discrete spectrum. More precisely, the (squared modulus of) coherent states transform of the eigenfunctions of the Hamiltonian H is used to weigh the spectral density smeared out with a test function whose Fourier transform is compactly supported. The leading term in the $\hbar$ expansion of the latter quantity is given an expression which involves the complex trajectories infinitesimally close to closed hyperbolic orbits.

III. QUANTIZATION AND SIGNAL PROCESSING

The so-called time-frequency methods amount to realize functions in a different space, in which both time and frequency variables are present. Besides linear decomposition methods such as wavelet or Gabor transform, bilinear transformations such as (generalized) Wigner transforms have also been quite popular, in particular in the signal processing community. The prototype of such bilinear transforms is the celebrated Wigner function, known as the *Wigner–Ville* distribution in the signal processing community, after the engineer J. Ville who introduced it as a candidate for

local spectrum for nonstationary signals. The Wigner–Ville distribution (defined as a function on the time-frequency plane) has been generalized to yield families of time-frequency distributions, and also families of *time-scale distributions*, transforming functions into functions of one time and one scale variable (the scale being heuristically interpreted as the inverse of a frequency variable). See Ref. 12 for a review.

The article written by Flandrin examines in detail several of the generic properties of bilinear time-frequency distributions. The classical Wigner function is known to be positive and separable in the case of Gaussian functions, which are of minimum spread in the time-frequency plane (minimum uncertainty). The relationship between these properties is examined, as well as their possible generalizations to smoothed Wigner–Ville distributions. Similar questions are answered in the (more complex technically speaking) case of affine distributions.

The interrelations between time-frequency analysis, pseudodifferential calculus and quantization are developed in the papers by Matz and Hlawatsch, and Bertrand and Bertrand. The first article is more ''signal-processing oriented,'' and addresses the problem of time-varying system identification via time-frequency analysis. Time-varying systems (in other words, linear operators relating output data to input data, to be recovered from data) may in some cases be estimated thanks to time-frequency methods. Matz and Hlawatsch describe a class (the underspread systems) for which this may be done, and provide estimates for the accuracy of the method. The connections with the classical pseudodifferential calculus (e.g., associated with the Weyl–Heisenberg group) are also emphasized.

The article of Bertrand and Bertrand develop the symbolic calculus associated with the action of the ''$ax+b$'' group on a (generalized) Hardy space $\mathscr{H}$, and provide the mathematical foundations for a corresponding signal theory. Some of the questions addressed in the previous paper (Wigner functions, star products, etc.) are also studied in this context. The case of larger covariance groups containing the ''$ax+b$'' group is also examined.

IV. LITTLEWOOD–PALEY-TYPE APPROACHES

As mentioned earlier, Littlewood–Paley methods may be considered the ''ancestors'' of wavelet analysis in the harmonic analysis community. Reviews may be found for example in Refs. 1 and 13. Their applications include function space characterization, pseudodifferential calculus, etc.

Frick, Grossmann and Tchamitchian, using similar mathematical tools, address a problem of a different nature, of great practical interest: the analysis of functions which are defined on closed subsets of the real lines (such situations occur, for example, in astronomy, where some observations may be done only during the night). Missing data make spectral analysis quite unprecise, and the authors show how to modify the usual continuous wavelet analysis so as to minimize the effect of these missing data, by perturbing the wavelets near the boundaries of the gaps in order to restore vanishing moments. These techniques have found beautiful applications, for example, for the estimation of cycles in the sunspot data.

Lemarié's contribution is a review paper on recent results that have been obtained on the existence and uniqueness of global solutions for Navier–Stokes equations, which have recently enjoyed a renewed interest, in particular since the work of Cannone.[14] This paper reviews the existence results for global weak and mild solutions, as well as some more recent uniqueness results. It also provides a good sample of the techniques needed for this kind of analysis, in particular the use of Littlewood–Paley decompositions for deriving sharp estimates for the nonlinear terms in the equations.

The paper by Lewalle does not, strictly speaking, rely on Littlewood–Paley methods, but rather on formal analytical methods. He studies the Poisson equation directly in the wavelet domain, with specific choices for the analyzing wavelet (Hermitian wavelets). The motion in the position-scale-number space is actually Hamiltonian, which leads to interesting simplifications.

V. FRACTALS, MULTIFRACTALS AND APPLICATIONS

One of the main contributions of wavelet analysis lies in the development of a rigorous fractal and multifractal analysis for functions and signals. It was first developed in the context of turbulence, as a generalization of the multifractal formalism for measures, and eventually led to a

beautiful connection with microlocal analysis. The very nature of wavelets allow a very precise analysis of local regularity properties of functions, which was used in particular by Jaffard and co-workers (see in particular Refs. 15 and 16) to set up a rigorous multifractal formalism for functions.

Jaffard's paper is an extension of the latter formalism to the case of functions with oscillating singularities (i.e., functions whose local regularity is characterized not only by an usual Hölder exponent, but also by a second exponent which describes the speed at which oscillations accumulate at the singular point). Surprisingly enough, such oscillating singularities have been shown to occur in many apparently simple situations, which made necessary the development of a corresponding version of multifractal formalism.

A numerical version of the multifractal formalism was developed earlier by Arneodo and co-workers, and applied to many practical physical problems (turbulence, DLA aggregates, financial time series, etc.) The contribution of Arneodo, Bacry and Muzy provides statistical justifications for their algorithm, by developing a probabilistic random cascade model based on wavelet bases (also strongly influenced by the cascade models of turbulence). The multifractal formalism previously mentioned thus appears as a method for estimating the parameters of this model, which gives the whole program a beautiful consistency.

Another application of the fractal-based method is presented in the article by Guerin and Holschneider, who consider the problem of wave scattering by fractal measures. They develop the theory of time evolution for Schrödinger operators when the potential is defined as a measure (in the one-dimensional situation). When the potential is fractal, they show how some fractal characteristics of the potential (namely some wavelet-defined fractal dimensions) may be estimated from the reflection coefficient.

VI. GENERALIZED WAVELET AND TIME-FREQUENCY BASES

One of the origins of modern wavelet analysis lies on a famous no-go theorem, known as the Balian–Low theorem (see Ref. 5 for a precise statement and a discussion of consequences), which may be formulated as follows (in a weak form). Let $g \in L^2(\mathbf{R})$ be such that the collection of its time-frequency translates $g_{mn}(t) = \exp\{2i\pi mt\}g(t-n), m,n \in \mathbf{Z}$ form an orthonormal basis of $L^2(\mathbf{R})$. Then the function $g(x)$ cannot be simultaneously smooth and localized, in the following sense: either $\int t^2|g(t)|^2dt = \infty$ or $\int \omega^2|\hat{g}(\omega)|^2d\omega = \infty$. The paper by Zak exploits this result to show that the eigenfunctions of the Schrödinger operator of an electron in the plane, subject to the action of a constant perpendicular magnetic field cannot be localized. A particularly interesting aspect of this paper is that it describes an alternative version of Gabor analysis using magnetic translations.

Classical wavelet bases are associated with periodic tilings of the real axis in the one-dimensional case, and of $\mathbf{R}^n$ in higher dimensions (detailed accounts may be found in many textbooks, see e.g. Ref. 5). Thanks to such a translation invariance, they are particularly well adapted to problems in which translation invariance play a role (for example, they yield simple and efficient representations for large classes of differential and pseudodifferential operators).

There are problems in which such a translation invariance does not exist any more, and is replaced by some more subtle requirements. This is in particular the case for quasicrystals, which are naturally associated with aperiodic tilings of the plane. A natural question was whether it is possible to construct wavelet bases associated with such aperiodic tilings of the plane.

This question receives its first answer in the article by Gazeau, Patera and Pelantova. This paper shows how to construct on such tilings wavelet bases that mimic the celebrated Haar basis (each basis function is the difference of the characteristic functions of two adjacent tiles). In such a case, the dilation has, of course, to be replaced with a more complex operation that preserves the geometry of the tiling.

A complementary answer is also provided by Bernuau's paper. The wavelet bases constructed by Bernuau have a similar algebraic nature, but unlike the Haar-type functions, are smooth, and their smoothness may be controlled (in particular, wavelets with exponential decay are constructed). This article also studies the continuity of the wavelet family with respect to the considered quasicrystal.

The article by Wei and Chen is of a different nature, for it is not, strictly speaking, devoted to time-frequency analysis. The authors develop an elementary theory of square waves, as an alternative for Fourier analysis, useful for practical applications, in electronics for example. This contribution should be useful in particular because of the arguments developed for proving basic results such as orthogonality, completeness, etc.

A general theorem on square-integrability: Vector coherent states

S. Twareque Ali
Department of Mathematics and Statistics, Concordia University, Montréal, Québec, H4B 1R6 Canada

(Received 15 August 1997; accepted for publication 13 March 1998)

We derive a generalization of the well-known theorem for the square integrability of a unitary irreducible representation of a locally compact group. The generalization covers the case of representations admitting vector coherent states. The result is illustrated by an example drawn from the isochronous Galilei group. The construction yields a wide variety of coherent states, labeled by phase space points, which satisfy a resolution of the identity condition, and incorporate spin degrees of freedom. © *1998 American Institute of Physics.* [S0022-2488(98)00108-X]

I. INTRODUCTION

Let G be a locally compact (usually Lie) group and U a continuous, unitary irreducible representation (UIR) of G on some (separable, complex) Hilbert space $\mathfrak{H}$. A nonzero vector $\eta \in \mathfrak{H}$ is said to be *admissible* if

$$I(\eta) \equiv \int_G |\langle U(g)\eta|\eta\rangle|^2 \, d\mu(g) < \infty, \tag{I.1}$$

where μ denotes the left (or right) Haar measure on G. If such a vector exists, the representation U is said to be *square-integrable*. Square-integrable representations have been studied extensively in the literature (see, e.g., Ref. 1 for a general discussion and references) and one of the most important results in this connection is

Theorem I.1: *Let the UIR $g \mapsto U(g)$ of the locally compact group G be square integrable and $\eta \in \mathfrak{H}$ an admissible vector. Then, the mapping*

$$W_\eta : \mathfrak{H} \to L^2(G, d\mu), \quad (W_\eta \phi)(g) = [c(\eta)]^{-1/2} \langle \eta_g | \phi \rangle, \quad \phi \in \mathfrak{H}, \quad g \in G,$$

where

$$c(\eta) = \frac{I(\eta)}{\|\eta\|^2}, \quad \eta_g = U(g)\eta, \tag{I.2}$$

is a linear isometry onto a (closed) subspace $\mathfrak{H}_\eta$ of $L^2(G, d\mu)$. On $\mathfrak{H}$, the resolution of the identity

$$\frac{1}{c(\eta)} \int_G |\eta_g\rangle\langle\eta_g| \, d\mu(g) = I, \tag{I.3}$$

holds. The subspace $\mathfrak{H}_\eta = W_\eta(\mathfrak{H}) \subset L^2(G, d\mu)$ is a reproducing kernel Hilbert space, so that the corresponding projection operator

$$\mathbb{P}_\eta = W_\eta W_\eta^*, \quad \mathbb{P}_\eta L^2(G, d\mu) = \mathfrak{H}_\eta, \tag{I.4}$$

has the reproducing kernel K_η:

$$(\mathbb{P}_\eta \Phi)(g) = \int_G K_\eta(g, g') \Phi(g') d\mu(g'), \quad \Phi \in L^2(G, d\mu),$$

 © 1998 American Institute of Physics

$$K_\eta(g,g')=\frac{1}{c(\eta)}\langle \eta_g|\,\eta_{g'}\rangle, \tag{I.5}$$

as its integral kernel. Furthermore, W_η intertwines U and the left regular representation $U_\swarrow$,

$$W_\eta U(g)=U_\swarrow(g)W_\eta, \quad g\in G. \tag{I.6}$$

The proof of this theorem can, for example, be found in Ref. 2. Note that in the above, the reproducing kernel is a map $K_\eta: G\times G\to\mathbb{C}$, with the properties:

$$K_\eta(g,g')=\overline{K_\eta(g',g)}, \quad g,g'\in G,$$

$$K_\eta(g,g)>0, \quad g\in G, \tag{I.7}$$

$$\int_G K_\eta(g,g'')K_\eta(g'',g')\;\; d\mu(g'')=K_\eta(g,g'),$$

while the left regular representation $U_\swarrow$ acts on $L^2(G,d\mu)$ in the manner

$$(U_\swarrow(g)\Phi)(g')=\Phi(g^{-1}g'), \quad \Phi\in L^2(G,d\mu). \tag{I.8}$$

The vectors η_g, $g\in G$, are called *coherent states* (CS) of the representation U. The class of representations for which the above theorem is applicable is restricted to those of the *discrete series*. For purposes of physical applications, however, the above definitions of square-integrability and coherent states are unduly restrictive. One would like to work with a fairly wide class of UIR's of a locally compact group and still be able to define coherent states and resolutions of the identity—in a sense more general than (I.3). One possibility would be to look for generalizations of Theorem I.1. In the next section we obtain such a generalization in Theorem II.2, which is the main result of this paper. It characterizes square integrability properties of *vector coherent states (VCS)*,[3–5] giving a criterion for obtaining a resolution of the identity for such coherent states. Section III illustrates this generalization with a construction based on a representation of the isochronous Galilei group.

II. A GENERALIZATION TO VECTOR COHERENT STATES

Once again, let G be a locally compact group, H a closed subgroup of G and $X=G/H$ the corresponding left coset space. Assume that X carries the measure ν which is *invariant* under the action of G and for any $g\in G$, denote its coset gH by $[g]$. Let U be a UIR of G and $\mathfrak{K}$ a *finite dimensional* subspace of $\mathfrak{H}$ which is stable under U when the latter is restricted to H:

$$U(h)\,\eta\in\mathfrak{K}, \quad \text{for all} \quad \eta\in\mathfrak{K}, \quad h\in H. \tag{II.1}$$

Let $\mathbb{P}$ be the projection operator for the subspace $\mathfrak{K}$ and write

$$U(h)\mathbb{P}=V(h), \quad h\in H. \tag{II.2}$$

We assume that the representation $h\mapsto V(h)$, of the subgroup H, acts *irreducibly* on $\mathfrak{K}$.

Let $\{\eta^i\}_{i=1}^n$ (n = dimension of $\mathfrak{K}$) be an orthonormal basis for $\mathfrak{K}$ and $\sigma: X\to G$ a (global) Borel section of G. Then for each $[g]\in X$, the set $\{\eta^i_{\sigma([g])}=U(\sigma([g]))\,\eta^i\}_{i=1}^n$ are vector coherent states. Clearly the set of vectors

$$\mathfrak{S}_\sigma=\{\eta^i_{\sigma([g])}|\,i=1,2,\ldots,n, \quad [g]\in X\} \tag{II.3}$$

is total in $\mathfrak{H}$, and we are interested in conditions for their square integrability, i.e., conditions to ensure a resolution of the identity of the type:

$$\sum_{i=1}^n \int_X |\,\eta^i_{\sigma([g])}\rangle\langle\,\eta^i_{\sigma([g])}|\,d\nu([g])=\int_X U(\sigma([g]))\mathbb{P}U(\sigma[g]))^*=\lambda I, \quad \lambda>0. \tag{II.4}$$

When $\mathfrak{K}$ is one dimensional, the set of vectors $\mathfrak{S}_\sigma$ are the well-known *Gilmore–Perelomov coherent states*,[6,7] and a generalization of Theorem I.1 for this case has been worked out in Ref. 8. On the other hand, if H is the trivial subgroup $\{e\}$ consisting of the identity element alone, we are back within the framework of Theorem I.1.

Looking upon G as a principal bundle, fibered over X and with structure group H, we consider the G-homogeneous associated bundle $B=G\times_{V(H)}\mathfrak{K}$. This bundle, also fibered over X, is obtained by identifying elements $(g,\eta),(g',\eta')\in G\times\mathfrak{K}$, whenever $g'=gh$ and $\eta'=V(h)^{-1}\eta$ for some $h\in H$. Elements in B can therefore be put into one to one correspondence with vectors $U(g)\eta \in\mathfrak{H}$, for all $g\in G$ and $\eta\in\mathfrak{K}$. Following the terminology of Ref. 9, these vectors may be called a family of *coherent vectors*. The canonical projection $\pi:B\to X$ is then simply $\pi(U(g)\eta)=[g]$. Sections in the bundle B can be put into one to one correspondence with functions $f:G\to\mathfrak{K}$, which satisfy

$$f(gh)=V(h)^{-1}f(g),\quad h\in H. \tag{II.5}$$

The class of square integrable sections, with respect to the invariant measure ν, is the Hilbert space $L^2_{\mathfrak{K}}(X,d\nu)$ and on it the representation $g\mapsto{}^VU(g),\quad g\in G$,

$$({}^VU(g)f)(g')=f(g^{-1}g'),\quad g'\in G, \tag{II.6}$$

is unitary and is just the standard induced representation[10] of G (induced from the UIR V of the subgroup H).

Consider next the functions $\Phi:G\to\mathfrak{K}$, defined by

$$\Phi(g)=\mathbb{P}U(g)^{-1}\phi,\quad \phi\in\mathfrak{H}. \tag{II.7}$$

Clearly these functions satisfy (II.5) and hence also describe sections of B. We denote this class of sections (for all $\phi\in\mathfrak{H}$) by $\mathfrak{H}_K$, the reason for this subscript will become clear momentarily. A natural question which now arises is under what conditions $\mathfrak{H}_K$ forms a subspace of $L^2_{\mathfrak{K}}(X,d\nu)$. There are two reasons for wanting to know this: First, the linear map $W:\mathfrak{H}\to\mathfrak{H}_K$, such that

$$(W\phi)(g)=\Phi(g)=\mathbb{P}U(g)^{-1}\phi,\quad g\in G,\quad \phi\in\mathfrak{H}, \tag{II.8}$$

it is easily seen to intertwine the representation U (of G on $\mathfrak{H}$) with the induced representation ${}^VU$, and if $\mathfrak{H}_K$ could be identified with a closed subspace of $L^2_{\mathfrak{K}}(X,d\nu)$, then U would be a subrepresentation of an induced representation. Second, square integrability of the sections Φ would imply

$$\int_X\langle\phi|\mathbb{P}([g])\phi\rangle\ \ d\nu([g])<\infty, \tag{II.9}$$

for all $\phi\in\mathfrak{H}$, where we have written, with obvious justification,

$$\mathbb{P}([g])=U(g)\mathbb{P}U(g)^*. \tag{II.10}$$

Thus we would then have

$$\int_X\mathbb{P}([g])\ \ d\nu([g])=A \tag{II.11}$$

for some bounded positive operator A (the above integral converging weakly). On the other hand, from the invariance of the measure ν and (II.10), it would follow that $U(g)AU(g)^*=A$, for all $g\in G$, with the irreducibility of U then requiring that $A=\lambda I$, for some $\lambda>0$. This way we shall have obtained a square integrability condition of the type (II.4).

The set of sections $\mathfrak{H}_K$ has the natural structure of a reproducing kernel Hilbert space,[11,12] with reproducing kernel $K:G\times G\to\mathcal{L}(\mathfrak{K})$ (= bounded operators on $\mathfrak{K}$),

$$K(g,g')=\mathbb{P}U(g)^{-1}U(g')\mathbb{P}. \tag{II.12}$$

Indeed, since $K(g,g')=K(g',g)^*$ and as an operator on $\mathfrak{K}$, $K(g,g)$ is strictly positive, K is a strictly positive definite kernel and therefore the relationship

$$\langle \Phi_g^\eta | \Phi_{g'}^{\eta'} \rangle_K = \langle \eta | K(g,g')\,\eta' \rangle_{\mathfrak{H}} \tag{II.13}$$

can be used to define a scalar product $\langle \cdot | \cdot \rangle_K$ on the linear span of sections of the type Φ_g^η, for all $g \in G$ and $\eta \in \mathfrak{K}$, where

$$\Phi_g^\eta(g') = K(g',g)\,\eta = W(U(g)\,\eta)(g'). \tag{II.14}$$

Using standard analytic techniques,[11] it then follows that $\mathfrak{H}_K$ is complete in this scalar product, hence a Hilbert space, and the map W in (II.8) is unitary. The fact that $\mathfrak{H}_K$ is a reproducing kernel Hilbert space is reflected in the generalized evaluation condition for functions Φ in $\mathfrak{H}_K$ at points $g \in G$:

$$\langle \Phi_g^\eta | \Phi \rangle_K = \langle K(\cdot\ ,\ g)\,\eta | \Phi \rangle_K = \langle \eta | \Phi(g) \rangle_{\mathfrak{H}}, \quad \eta \in \mathfrak{H}, \quad g \in G. \tag{II.15}$$

If now $\mathfrak{H}_K \subset L^2_{\mathfrak{K}}(X, d\nu)$, then for any two sections $\Phi, \Phi' \in \mathfrak{H}_K$,

$$\int_X \langle \Phi(g) | \Phi'(g) \rangle_{\mathfrak{H}}\ \ d\nu([g]) < \infty, \tag{II.16}$$

and taking the particular sections $\Phi_g^\eta, \Phi_{g'}^{\eta'}$ we get,

$$\begin{aligned} \int_X \langle K(g'',g)\,\eta | K(g'',g')\,\eta' \rangle_{\mathfrak{H}}\ \ d\nu([g'']) &= \int_X \langle \eta | U(g^{-1})\mathbb{P}([g''])U(g)\,\eta' \rangle\ \ d\nu([g'']) \\ &= \int_X \langle \eta | \mathbb{P}([g''])\,\eta' \rangle\ \ d\nu([g''], \end{aligned} \tag{II.17}$$

the last equality following from the invariance of the measure ν. Thus square-integrability of the sections Φ implies

$$I(\eta) \equiv \int_X \langle \eta | \mathbb{P}([g])\,\eta \rangle\ \ d\nu([g]) < \infty, \tag{II.18}$$

for all $\eta \in \mathfrak{K}$. In fact, as asserted in Theorem II.2 below, the above condition, which is clearly a generalization of (I.1), is both necessary and sufficient.

Definition II.1: Let U be a UIR of G on the Hilbert space $\mathfrak{H}$ and H a closed subgroup of G. Let V be a finite dimensional UIR of H. A subspace $\mathfrak{K} \subset \mathfrak{H}$ is said to be V-admissible if $U(H)$ restricted to $\mathfrak{K}$ is unitarily equivalent to V and if there exists a nonzero vector $\eta \in \mathfrak{K}$ such that the condition (II.18) is satisfied. If such a subspace $\mathfrak{K}$ exists, the representation U is said to be square integrable mod(H).

With the conditions of the above definition being satisfied, let us set

$$c_V(\eta) = \frac{I(\eta)}{\|\eta\|^2}, \tag{II.19}$$

and denote by $\mathcal{D}$ the dense set in $\mathfrak{H}$ spanned by the vectors $U(g)\,\eta$, $g \in G$. Then, in view of the second equality in (II.17), the map $W_\eta : \mathcal{D} \to L^2_{\mathfrak{K}}(X, d\nu)$,

$$(W_\eta \phi)(g) = [c_V(\eta)]^{-1/2} \mathbb{P} U(g^{-1})\,\phi, \tag{II.20}$$

is well defined. The set $\mathcal{D}$ is stable under U and W_η [being a multiple of the map W in (II.8)]) intertwines U and the induced representation ${}^V U$. Retracing the lines of the proof of Theorem I.1

(as found, for example, in Ref. 2), we can show that W_η is closed. An application of an extended version of Schur's lemma (see Ref. 2) then shows that W_η is an isometry. Thus we have proved the following result:

Theorem II.2: *Let G be a locally compact group, H a closed subgroup of G, U a UIR of G on the Hilbert space $\mathfrak{H}$ and V a finite dimensional UIR of H. Let $\mathfrak{K}$ be a V-admissible subspace of $\mathfrak{H}$. Then, the mapping (II.20) extends to all of $\mathfrak{H}$ as a linear isometry. Its range coincides with the set $\mathfrak{H}_K$, which is thus also closed in the L^2-norm as a subspace of $L^2_{\mathfrak{K}}(X,d\nu)$, and which we then denote by $\mathfrak{H}_\eta$. On $\mathfrak{H}$, the resolution of the identity*

$$\frac{1}{c_V(\eta)}\int_X \mathbb{P}([g])\ \ d\nu([g]) = I \tag{II.21}$$

holds. The subspace $\mathfrak{H}_\eta = W_\eta(\mathfrak{H}) \subset L^2_{\mathfrak{K}}(X,d\nu)$ is a reproducing kernel Hilbert space, so that the corresponding projection operator

$$\mathbb{P}_\eta = W_\eta W_\eta^*, \quad \mathbb{P}_\eta L^2_{\mathfrak{K}}(X,d\nu) = \mathfrak{H}_\eta, \tag{II.22}$$

has the reproducing kernel K_η:

$$(\mathbb{P}_\eta \Phi)(g) = \int_X K_\eta(g,g')f(g')\ \ d\nu([g']), \quad f \in L^2_{\mathfrak{K}}(X,d\nu),$$
$$K_\eta(g,g') = \frac{1}{c(\eta)}\mathbb{P}U(g^{-1})U(g')\mathbb{P}, \tag{II.23}$$

as its integral kernel. Furthermore, W_η intertwines U and the induced representation ${}^V U$,

$$W_\eta U(g) = {}^V U(g) W_\eta, \quad g \in G. \tag{II.24}$$

Note: (i) As a consequence of this theorem, the quantity $c_V(\eta)$ is independent of the particular $\eta \in \mathfrak{K}$ chosen to evaluate it. (ii) The condition (II.23) translates into the property

$$\int_X K_\eta(g,g'')K_\eta(g'',g')\ \ d\nu([g'']) = K_\eta(g,g'). \tag{II.25}$$

(iii) The set of positive, bounded operators

$$a(\Delta) = \int_\Delta \mathbb{P}([g])\ \ d\nu([g]),$$

for arbitrary Borel sets $\Delta \subset X$, form a normalized positive operator-valued measure and $\{U,a\}$ is a system of covariance:[13]

$$U(g)a(\Delta)U(g)^* = a(g\Delta).$$

It is well known (see, for example, Ref. 14) that the existence of such a system of covariance implies that U is a subrepresentation of an induced representation, which in this case is just a restatement of (II.24).

III. AN EXAMPLE USING THE ISOCHRONOUS GALILEI GROUP

We illustrate Theorem II.2 with an example drawn from the *isochronous Galilei group*. The kinematics of a free nonrelativistic physical particle is governed by its invariance under the action of the Galilei group,[15,16] which is a ten parameter group $\mathcal{G}$ of transformations of Newtonian space-time. An element $g \in \mathcal{G}$ is of the form

$$g = (b,\mathbf{a},\mathbf{v},R), \quad \mathbf{a},\mathbf{v} \in \mathbb{R}^3, \quad R \in \mathrm{SO}(3), \tag{III.1}$$

where b is a time and $\mathbf{a}$ a spatial translation, $\mathbf{v}$ a velocity boost and R a spatial rotation. Actually, we shall work with the *central extension* of $\mathcal{G}$, and also, in order to accommodate particles with half-integral spins, it is necessary to replace the rotation group SO(3) by SU(2). Denoting this extended group by $\tilde{\mathcal{G}}$, its elements will be written as $g=(\theta,b,\mathbf{a},\mathbf{v},\rho)$, $\theta\in\mathbb{R}$, $\rho\in\mathrm{SU}(2)$. The group multiplication in $\tilde{\mathcal{G}}$ is

$$g_1g_2=(\theta_1+\theta_2+\xi(g_1,g_2),b_1+b_2,\mathbf{a}_1+R(\rho_1)\mathbf{a}_2+\mathbf{v}_1b_2,\mathbf{v}_1+R(\rho_1)\mathbf{v}_2,\rho_1\rho_2),$$
$$g_i=(\theta_i,b_i,\mathbf{a}_i,\mathbf{v}_i,\rho_i),\quad i=1,2, \tag{III.2}$$

where $\xi:\mathcal{G}\times\mathcal{G}\to\mathbb{R}$ is a *multiplier*, which up to equivalence (in the sense of cocycles), can be taken to be

$$\xi(g_1,g_2)=\mu[\tfrac{1}{2}\mathbf{v}_1^2b_2+\mathbf{v}_1\cdot R(\rho_1)\mathbf{a}_2],\quad \mu=\mathrm{const}>0. \tag{III.3}$$

A couple of subgroups of $\tilde{\mathcal{G}}$ are of particular interest to us here for the construction of CS. The subgroup $\tilde{\mathcal{G}}'$, having elements $(\theta,0,\mathbf{a},\mathbf{v},\rho)$, i.e., with the time part b set equal to zero, is called the *isochronous extended Galilei group*. Another useful subgroup of $\tilde{\mathcal{G}}$, one which is also a subgroup of $\tilde{\mathcal{G}}'$, consists of elements of the type $g=(\theta,0,\mathbf{a},\mathbf{v},\mathbb{I}_2)$, where $\mathbb{I}_2$) is the 2×2 unit matrix. We denote this group by $\tilde{\mathcal{G}}_{\mathrm{WH}}$ and note that it is isomorphic to the Weyl–Heisenberg group for three degrees of freedom. Finally, the subgroup Θ, with elements $(\theta,0,\mathbf{0},\mathbb{I}_2)$, is called the phase subgroup.

The particular representations of $\tilde{\mathcal{G}}$ which concern us here are the ones which describe free nonrelativistic quantum particles of mass $\mu>0$ and spin $j=0,1/2,1,3/2,\ldots$. These are characterized by μ, j and an additional parameter $E_0\in\mathbb{R}$ which is identified with the internal energy. The *momentum space* realizations of these representations (see, e.g., Ref. 16) are carried by the Hilbert spaces $\mathcal{K}^j\otimes L^2(\hat{\mathbb{R}}^3,d\mathbf{k})$, where $\mathcal{K}^j$ is a $(2j+1)$-dimensional spinor space (which we identify with $\mathbb{C}^{2j+1}$), $\hat{\mathbb{R}}^3$ the dual of $\mathbb{R}^3$ (which we again identify with $\mathbb{R}^3$), and $d\mathbf{k}$ the Lebesgue measure on $\hat{\mathbb{R}}^3$. The spaces $\mathcal{K}^j$ carry the unitary irreducible representations of SU(2), denoted $\mathcal{D}^j(\rho)$, $\rho\in\mathrm{SU}(2)$. The representation of the Galilei group in question, $\tilde{U}^{E_0,j}$, acts on the Hilbert space $\mathcal{K}^j\otimes L^2(\hat{\mathbb{R}}^3,d\mathbf{k})$ in the manner:

$$(\tilde{U}^{E_0,j}(\theta,b,\mathbf{a},\mathbf{v},\rho)\tilde{\boldsymbol{\phi}})(\mathbf{k})=\exp\left[i\left\{\theta+\left(E_0+\frac{\mathbf{k}^2}{2\mu}\right)b-\mathbf{k}\cdot\mathbf{a}\right\}\right]\ \mathcal{D}^j(\rho)\ \ \tilde{\boldsymbol{\phi}}(R(\rho^{-1})(\mathbf{k}-\mu\mathbf{v})), \tag{III.4}$$

for all $\tilde{\boldsymbol{\phi}}\in\mathcal{K}^j\otimes L^2(\hat{\mathbb{R}}^3,d\mathbf{k})$. This is the so-called *momentum space representation* for a nonrelativistic system of mass μ, internal energy E_0 and spin-j. When dealing with a single system, the internal energy may be set equal to zero, simply by adjusting the ground state. We shall do this in what follows and write the representations as $\tilde{U}^j$.

Unitary irreducible representations of the isochronous Galilei group $\tilde{\mathcal{G}}'$ can now be read off from (III.4) after setting $b=0$. These representations are also carried by $\mathcal{K}^j\otimes L^2(\hat{\mathbb{R}}^3,d\mathbf{k})$, and using the same notation as before (also taking $E_0=0$),

$$(\tilde{U}^j(\theta,\mathbf{a},\mathbf{v},\rho)\tilde{\boldsymbol{\phi}})(\mathbf{k})=\exp[i(\theta-\mathbf{k}\cdot\mathbf{a})]\ \mathcal{D}^j(\rho)\ \ \tilde{\boldsymbol{\phi}}(R(\rho^{-1})(\mathbf{k}-\mu\mathbf{v})),\quad (\theta,\mathbf{a},\mathbf{v},\rho)\in\tilde{\mathcal{G}}'. \tag{III.5}$$

We proceed to demonstrate the square integrability mod$(\Theta\otimes\mathrm{SU}(2))$ of these representations in the sense of Theorem II.2.

Let us first decompose the representation space $\mathcal{K}^j\otimes L^2(\hat{\mathbb{R}}^3,d\mathbf{k})$ into rotationally invariant subspaces. For any $\tilde{\boldsymbol{\phi}}\in\mathcal{K}^j\otimes L^2(\hat{\mathbb{R}}^3,d\mathbf{k})$, and $\rho\in\mathrm{SU}(2)$,

$$(\tilde{U}^j(0,\mathbf{0},\mathbf{0},\rho)\tilde{\boldsymbol{\phi}}=\mathcal{D}^j(\rho)\tilde{\boldsymbol{\phi}}(R(\rho^{-1})\mathbf{k}). \tag{III.6}$$

The space $L^2(\hat{\mathbb{R}}^3, d\mathbf{k})$ can be written as the tensor product $L^2(S^2, d\Omega(\mathbf{k})) \otimes L^2(\mathbb{R}^+, r^2 dr)$, where S^2 is the unit sphere, $d\Omega\mathbf{k})$ the angular measure in the angles of $\mathbf{k}$ and $r = \|\mathbf{k}\|$. Let $\{e_n\}_{n=1}^{\infty}$ be an orthonormal basis of $L^2(\mathbb{R}^+, r^2 dr)$:

$$\int_{\mathbb{R}^+} \overline{e_n(r)} e_m(r) r^2 dr = \delta_{nm}. \tag{III.7}$$

For each $\ell = 0,1,2,\ldots$, the spherical harmonics $Y^{\ell m}(\mathbf{k})$ (in the angles of $\mathbf{k}$), $m = -\ell, -\ell + 1, \ldots, \ell - 1, \ell$, span a subspace of $L^2(S^2, d\Omega(\mathbf{k}))$ which is stable under rotations. Furthermore,

$$f_{n\ell m}(R^{-1}\mathbf{k}) = \sum_{m'} \mathcal{D}^{\ell}(R)_{m'm} f_{n\ell m'}(\mathbf{k}), \tag{III.8}$$

where

$$f_{n\ell m}(\mathbf{k}) = Y^{\ell m}(\mathbf{k}) \quad e_n(\|\mathbf{k}\|). \tag{III.9}$$

For fixed ℓ, n, let $\mathfrak{K}^{\ell n}$ be the subspace of $L^2(\hat{\mathbb{R}}^3, d\mathbf{k})$ spanned by the unit vectors $f_{n\ell m}$, $m = -\ell, -\ell + 1, \ldots, \ell - 1, \ell$. Then,

$$L^2(\hat{\mathbb{R}}^3, d\mathbf{k}) = \bigoplus_{n=1}^{\infty} \bigoplus_{\ell=0}^{\infty} \mathfrak{K}^{\ell n}, \tag{III.10}$$

and each subspace $\mathfrak{K}^{\ell n}$ carries a representation of SU(2) unitarily equivalent to the UIR $\mathcal{D}^{\ell}$.

Next, in view of the well-known decomposition (e.g., for angular momenta)

$$\mathcal{D}^j(\rho) \otimes \mathcal{D}^{\ell}(\rho) \simeq \bigoplus_{J=|j-\ell|}^{j+\ell} \mathcal{D}^J(\rho), \tag{III.11}$$

($\simeq$ implying unitary equivalence), the space $\mathfrak{K}^j \otimes L^2(\hat{\mathbb{R}}^3, d\mathbf{k})$ decomposes as

$$\mathfrak{K}^j \otimes L^2(\hat{\mathbb{R}}^3, d\mathbf{k}) = \bigoplus_{n=1}^{\infty} \bigoplus_{\ell=1}^{\infty} \bigoplus_{J=|j-\ell|}^{j+\ell} \mathfrak{K}^{nJ\ell}, \tag{III.12}$$

in which each $\mathfrak{K}^{nJ\ell}$ is a $(2J+1)$-dimensional space, carrying a UIR of SU(2), unitarily equivalent to $\mathcal{D}^J$. The vectors

$$\tilde{\boldsymbol{\eta}}^{nJM\ell}(\mathbf{k}) = \sum_m C(j,m;\ \ell, M-m|JM) \boldsymbol{\chi}^{jm} \quad Y^{\ell,\ M-m}(\mathbf{k}) e_n(\|\mathbf{k}\|), \tag{III.13}$$

where $\boldsymbol{\chi}^{jm}$ is the $2j+1$ component column vector with 1 in the mth position and zeroes elsewhere and the $C(j,m;\ \ell, M-m|JM)$ are SU(2) Clebsch–Gordan coefficients, form an orthonormal basis in $\mathfrak{K}^{nJ\ell}$ and satisfy

$$\tilde{U}^j(0,\mathbf{0},\mathbf{0},\rho)\tilde{\boldsymbol{\eta}}^{nJM\ell} = \mathcal{D}^J(\rho)\tilde{\boldsymbol{\eta}}^{nJM\ell}, \quad M = -J, -J+1, \ldots, J-1, J. \tag{III.14}$$

The sum over m in (III.13) runs through a subset of $-|j-\ell|, -|j-\ell|+1, \ldots, j+\ell$, determined by the constraints $-j \leq m \leq j$ and $-\ell \leq M-m \leq \ell$.

Let V^J denote the UIR of the subgroup $H = \Theta \otimes \mathrm{SU}(2)$ of $\tilde{\mathcal{G}}'$:

$$V^J(\theta,\rho) = e^{i\theta}\mathcal{D}^J(\rho). \tag{III.15}$$

Then (III.14) implies that for any vector $\tilde{\boldsymbol{\eta}} \in \mathfrak{K}^{nJ\ell}$

$$\tilde{U}^j(\theta,\mathbf{0},\mathbf{0},\rho)\tilde{\boldsymbol{\eta}} = V^J(\theta,\rho)\tilde{\boldsymbol{\eta}}. \tag{III.16}$$

This also means that the projection operator,

$$\mathbb{P}^{nJ\ell} = \sum_{M=-J}^{J} |\tilde{\boldsymbol{\eta}}^{nJM\ell}\rangle\langle\tilde{\boldsymbol{\eta}}^{nJM\ell}|, \tag{III.17}$$

for the subspace $\mathfrak{K}^{nJ\ell}$ is a minimal projector satisfying

$$\tilde{U}^j(0,\mathbf{0},\mathbf{0},\rho)\mathbb{P}^{nJ\ell}\tilde{U}^j(0,\mathbf{0},\mathbf{0},\rho)^* = \mathbb{P}^{nJ\ell}, \tag{III.18}$$

for all $\rho \in \mathrm{SU}(2)$ [minimality implying that there is no other projector $\mathbb{P}' \subset \mathbb{P}^{nJ\ell}$ also satisfying (III.18)]. The space $\Gamma = \mathcal{G}'/\Theta \otimes \mathrm{SU}(2)$ has a natural identification with the phase space of a free classical particle of mass μ, and hence is topologically isomorphic to $\mathbb{R}^6$, with global coordinates $(\mathbf{q},\mathbf{p})$, denoting position and momentum, respectively, and such that the measure $d\mathbf{q}d\mathbf{p}$ is $\mathcal{G}'$-invariant. Furthermore, a straightforward computation using properties of spherical harmonics shows that, for any section $\sigma:\Gamma \to \mathcal{G}'$,

$$\begin{aligned} c_{V^J}(\tilde{\boldsymbol{\eta}}^{nJM'\ell}) &= \sum_{M=-J}^{J} \int_{\Gamma} |\langle \tilde{\boldsymbol{\eta}}^{nJM\ell}_{\sigma(\mathbf{q},\mathbf{p})} | \tilde{\boldsymbol{\eta}}^{nJM'\ell}\rangle|^2 \; d\mathbf{q}d\mathbf{p} \\ &= (2\pi)^3 \sum_{M=-J}^{J} \sum_{m} |C(j,m;\ \ell, M-m|JM)|^2 |C(j,m;\ \ell, M'-m|JM')|^2. \end{aligned} \tag{III.19}$$

where of course, $\tilde{\boldsymbol{\eta}}^{nJM\ell}_{\sigma(\mathbf{q},\mathbf{p})} = U(\sigma(\mathbf{q},\mathbf{p}))\tilde{\boldsymbol{\eta}}^{nJM\ell}$. Thus the subspace $\mathfrak{K}^{nJ\ell}$ of $\mathfrak{K}^j \otimes L^2(\hat{\mathbb{R}}^3, d\mathbf{k})$ is V^J-admissible, and the representation $\tilde{U}^j$ is square integrable mod$(\Theta \otimes \mathrm{SU}(2))$, which also implies an interesting relation among Clebsch–Gordan coefficients, namely, that the sum on the right-hand side of (III.19) is independent of M', and indeed $c_{V^J}(\tilde{\boldsymbol{\eta}}^{nJM'\ell}) = c_{V^J}(\tilde{\boldsymbol{\eta}})$ for any vector $\tilde{\boldsymbol{\eta}} \in \mathfrak{K}^{nJ\ell}$.

Consequently, for each $n = 1,2,\ldots,$ and each $J = |j-\ell|, |j-\ell|+1, \ldots, j+\ell$, the map $W_{nJ\ell}: \mathfrak{K}^j \otimes L^2(\hat{\mathbb{R}}^3, d\mathbf{k}) \to \mathfrak{K}^J \otimes L^2(\Gamma, d\mathbf{q}d\mathbf{p})$:

$$(W_{nJ\ell}\tilde{\boldsymbol{\phi}})^M(\mathbf{q},\mathbf{p}) = [c_{V^J}]^{-1/2} \langle \tilde{\boldsymbol{\eta}}^{nJM\ell}_{\sigma(\mathbf{q},\mathbf{p})} | \tilde{\boldsymbol{\phi}}\rangle, \quad M = -J, -J+1, \ldots, J-1, J, \tag{III.20}$$

is an isometry. On $\mathfrak{K}^j \otimes L^2(\hat{\mathbb{R}}^3, d\mathbf{k})$ the resolution of the identity,

$$[c_{V^J}]^{-1} \sum_{M=-J}^{J} \int_{\Gamma} |\tilde{\boldsymbol{\eta}}^{nJM\ell}_{\sigma(\mathbf{q},\mathbf{p})}\rangle\langle \tilde{\boldsymbol{\eta}}^{nJM\ell}_{\sigma(\mathbf{q},\mathbf{p})}| \; d\mathbf{q}d\mathbf{p} = I, \tag{III.21}$$

is valid for the class of *Galilei coherent states*,

$$[c_{V^J}]^{-1/2} \; \tilde{\boldsymbol{\eta}}^{nJM\ell}_{\sigma(\mathbf{q},\mathbf{p})}, \quad (\mathbf{q},\mathbf{p}) \in \mathbb{R}^6, \quad M = -J, -J+1, \ldots, J-1, J. \tag{III.22}$$

Explicitly, using the section $\sigma = \sigma_0$, where

$$\sigma_0(\mathbf{q},\mathbf{p}) = \left(0, \mathbf{q}, \frac{\mathbf{p}}{\mu}, \mathbb{I}_2\right), \tag{III.23}$$

the CS are the functions,

$$\frac{1}{[c_{V^J}]^{1/2}}\ \widetilde{\boldsymbol{\eta}}^{nJM\ell}_{\sigma_0(\mathbf{q},\mathbf{p})}(\mathbf{k})$$

$$=\frac{1}{[c_{V^J}]^{1/2}}\ \left(\widetilde{U}^j\left(0,\mathbf{q},\frac{\mathbf{p}}{\mu},\mathbb{I}_2\right)\widetilde{\boldsymbol{\eta}}^{nJM\ell}\right)(\mathbf{k})$$

$$=\frac{1}{[c_{V^J}]^{1/2}}e^{-i\mathbf{k}\cdot\mathbf{q}}\ \widetilde{\boldsymbol{\eta}}^{nJM\ell}(\mathbf{k}-\mathbf{p})$$

$$=\frac{1}{[c_{V^J}]^{1/2}}e^{-i\mathbf{k}\cdot\mathbf{q}}\sum_m\ C(j,m;\ \ell,M-m|JM)\boldsymbol{\chi}^{jm}Y^{\ell,M-m}(\mathbf{k}-\mathbf{p})e_n(\|\mathbf{k}-\mathbf{p}\|), \tag{III.24}$$

$(M=-J,-J+1,\ldots,J-1,J)$ which in general are vector coherent states.

The image of $\mathfrak{K}^j\otimes L^2(\hat{\mathbb{R}}^3,d\mathbf{k})$ in $\mathfrak{K}^J\otimes L^2(\Gamma,d\mathbf{q}d\mathbf{p})$ under the isometry $W_{nJ\ell}$ is a reproducing kernel Hilbert space $\mathfrak{H}_{nJ\ell}$. Its elements are vector-valued functions $\boldsymbol{\Phi}$ with components,

$$\Phi^M(\mathbf{q},\mathbf{p})=\frac{1}{[c_{V^J}]^{1/2}}\sum_m\ C(j,m;\ \ell,M-m|JM)\int_{\hat{\mathbb{R}}^3}e^{i\mathbf{k}\cdot\mathbf{q}}\ \overline{Y^{\ell,M-m}(\mathbf{k}-\mathbf{p})}\ \overline{e_n(\|\mathbf{k}-\mathbf{p}\|)}\widetilde{\phi}^m(\mathbf{k})\ \ d\mathbf{k},$$

$$M=-J,-J+1,\ldots,J-1,J. \tag{III.25}$$

The reproducing kernel for $\mathfrak{H}_{nJ\ell}$ is matrix-valued with matrix elements

$$[\mathbf{K}_{nJ\ell}(\mathbf{q},\mathbf{p};\ \mathbf{q}'\mathbf{p}')]_{MM'}=\frac{1}{[c_{V^J}]^{1/2}}\sum_m\ \overline{C(j,m;\ \ell,M-m|JM)}C(j,m;\ \ell,M'-m|JM')$$
$$\times\int_{\mathbb{R}^3}\exp[i\mathbf{k}\cdot(\mathbf{q}-\mathbf{q}')]\ \ \overline{Y^{\ell,M-m}(\mathbf{k}-\mathbf{p})}Y^{\ell,M'-m}(\mathbf{k}-\mathbf{p}')$$
$$\times\overline{e_n(\|\mathbf{k}-\mathbf{p}\|)}e_n(\|\mathbf{k}-\mathbf{p}'\|)\ \ d\mathbf{k}, \tag{III.26}$$

$M,M'=-J,-J+1,\ldots,J-1,J$. Finally, the image of $\widetilde{U}^j$ in $\mathfrak{H}_{nJ\ell}\subset\mathfrak{K}^J\otimes L^2(\Gamma,d\mathbf{q}d\mathbf{p})$ under $W_{nJ\ell}$ is

$$\mathbf{U}_{nJ\ell}(g)=W_{nJ\ell}\widetilde{U}^j(g)W^{-1}_{nJ\ell},\ \ g\in\widetilde{\mathcal{G}}',$$

$$(\mathbf{U}_{nJ\ell}(\theta,\mathbf{a},\mathbf{v},\rho)\boldsymbol{\Phi})(\mathbf{q},\mathbf{p})=\exp[i\{\theta+\mu\mathbf{v}\cdot(\mathbf{q}-\mathbf{a})\}]$$
$$\times\mathcal{D}^J(\rho)\boldsymbol{\Phi}(R(\rho^{-1})(\mathbf{q}-\mathbf{a}),\ \ R(\rho^{-1})(\mathbf{p}-\mu\mathbf{v})), \tag{III.27}$$

which again extends to the whole of $\mathfrak{K}^J\otimes L^2(\Gamma,d\mathbf{q}d\mathbf{p})$ as the representation induced from V^J.

IV. DISCUSSION

In conclusion, observe that since the isochronous Galilei group $\widetilde{\mathcal{G}}'$ is essentially the Weyl-Heisenberg group for three degrees of freedom together with rotations, the coherent states (III.22) are also the VCS for this latter group. Also, it should be noted that the coherent states (III.24) are all possible such states arising from the Galilei group, which are labeled by phase space points, which satisfy a resolution of the identity and incorporate spin degrees of freedom. The time evolved versions of these states obey the Schrödinger equation. The vectors $\widetilde{\boldsymbol{\eta}}^{nJM\ell}$, $M=-J,-J-1,\ldots,J$, from which the coherent states (III.22) are built, can be looked upon as quantum mechanical wave functions for a system with spin-j, orbital angular momentum ℓ and total angular momentum J. Thus the associated coherent states (III.22) should be useful in analyzing molecular or atomic systems with such spin and angular momentum content. Actually, the reso-

lution of the identity (III.21) is not so surprising (it is easy to check it by direct computation) and in fact a much more general expression can be obtained as follows: Let $\eta^i, \quad i=1,2,\ldots,n$, be any set of orthonormal vectors in $\mathbb{C}^{2j+1}\otimes L^2(\hat{\mathbb{R}}^3,d\mathbf{k})$, spanning the subspace $\mathfrak{K}$ having projection operator $\mathbb{P}$. Then by direct computation it can be seen that

$$\frac{1}{n(2\pi)^3}\int_\Gamma \mathbb{P}(\mathbf{q},\mathbf{p})\ \ d\mathbf{q}d\mathbf{p}=I, \quad \mathbb{P}(\mathbf{q},\mathbf{p})=\tilde{U}^j(\sigma(\mathbf{q},\mathbf{p}))\mathbb{P}\tilde{U}^j(\sigma(\mathbf{q},\mathbf{p}))^*, \tag{IV.1}$$

for any one of the sections [obtained from the basic section (III.23)]:

$$\sigma(\mathbf{q},\mathbf{p})=\sigma_0(\mathbf{q},\mathbf{p})(\theta(\mathbf{q},\mathbf{p}),\mathbf{0},\mathbf{0},\rho), \tag{IV.2}$$

for fixed $\rho\in \mathrm{SU}(2)$, and where $\theta(\mathbf{q},\mathbf{p})$ is an arbitrary, real valued, measurable function of $(\mathbf{q},\mathbf{p})$. Taking the η^i to be n eigenstates of some observable (e.g., the Hamiltonian of some atomic system in an external potential), one could use the more general coherent states $[n(2\pi)^3]^{-1/2}\eta^i_{\sigma(\mathbf{q},\mathbf{p})}$, $i=1,2,\ldots,n$, $(\mathbf{q},\mathbf{p})\in\Gamma$, in atomic computations involving such n-level systems. Even more generally, if F is any trace-class operator on $\mathbb{C}^{2j+1}\otimes L^2(\hat{\mathbb{R}}^3,d\mathbf{k})$, then with σ as in (IV.2) and $c(F)=(2\pi)^3[\mathrm{Tr}\ \ F]$,

$$\frac{1}{c(F)}\int_\Gamma F(\mathbf{q},\mathbf{p})\ \ d\mathbf{q}d\mathbf{p}=I, \quad F(\mathbf{q},\mathbf{p})=\tilde{U}^j(\sigma(\mathbf{q},\mathbf{p}))F\tilde{U}^j(\sigma(\mathbf{q},\mathbf{p}))^*. \tag{IV.3}$$

From the point of view of quantization theory, Theorem II.2 could be used to extend the method of coherent states quantization (such as in Ref. 17) to include internal degrees of freedom as well. One could also exploit in this way the rich theory of Bergman type kernels associated to holomorphic, Hermitian vector bundles (as worked out, e.g., in Ref. 18). Finally, it would appear that a quantization using the coherent states (III.22) amounts to quantizing a particle with spin using the classical phase space of a spin-0 system. However, there is a great deal of flexibility attained in transferring the spin degrees of freedom to the fibers of a vector bundle rather than working with a classical phase space which artificially incorporates ''classical spin degrees of freedom.''

(Received 11 August 1997; accepted for publication 4 February 1998)

We consider a semidirect product $G=\mathbb{R}^n\times' H$ and its unitary representations U of the form $\mathrm{Ind}_{G_0}^{G}(p_0 m)$ where Ind is the unitary induction, p_0 is in the dual group of $\mathbb{R}^n$, G_0 is the stability group of p_0, and m is a unitary representation of $G_0\cap H$. We give sufficient conditions such that U defines a wavelet transform and a discrete frame. © *1998 American Institute of Physics.* [S0022-2488(98)00208-4]

I. INTRODUCTION

In the framework of *wavelet analysis* it is well known that the groups that are semidirect products with normal Abelian factor play an essential role in the construction of both continuous wavelet transforms and of discrete frames.

The classical example, Ref. 1, is the group $ax+b$ and its quasi-regular representation U acting on $L^2(\mathbb{R})$ as

$$(U_{ab}f\ )(x)=a^{-1/2}f\left(\frac{x-b}{a}\right),\quad x\in\mathbb{R},\ \ f\in L^2(\mathbb{R}),\ \ a\in\mathbb{R}^+,\ \ b\in\mathbb{R}.$$

We refer for this to the treatise of Ref. 2 and to the review paper Ref. 3.

In recent years there has been an interest in extending these kind of results to other groups: on one side, for example, Refs. 4–6, obtaining results valid for a fairly general class of groups; on the other side, discussing specific cases. For example, in Ref. 7, the group $\mathbb{R}^n\times'(\mathbb{R}^+\times\mathrm{SO}(n))$ has been considered in order to define wavelet transforms on $L^2(\mathbb{R}^n)$.

In this paper we consider the case of groups G that are semidirect product of $\mathbb{R}^n$ and a topological group H and their representations U of the form $U=\mathrm{Ind}_{G_0}^{G}(p_0 m)$ where Ind is the unitary induction *à la* Mackey, $p_0\in\mathbb{P}^n$, the dual of $\mathbb{R}^n$, G_0 is the stability group of p_0 with respect to the dual action of G on $\mathbb{P}^n$, and m is a unitary representation of $G_0\cap H$. For such groups we consider two kinds of problems.

First we describe the conditions under which the representations $\mathrm{Ind}_{G_0}^{G}(p_0 m)$ are square-integrable and characterize for them the formal degree operator. Moreover we discuss a concrete example that extends the results of Ref. 7 to vector-valued functions.

Second we consider the problem of the existence of a countable set $(g_i)_{i\in I}$ of G and a vector $\psi\in\mathscr{H}$ such that $(U_{g_i}\psi)_{i\in I}$ is a *frame* in $\mathscr{H}$, denoting by $\mathscr{H}$ the Hilbert space where U acts. In particular we show that, if H is the direct product of $\mathbb{R}^+$ (the multiplicative group of positive numbers) and a semisimple connected Lie group, and m is a cyclic finite-dimensional represen-

tation, then there are discrete frames associated to $\mathrm{Ind}_{G_0}^{G}(p_0 m)$ provided that the stability group $H \cap G_0$ is compact and that the orbit $G[p_0]$ is open. These results extend the ones obtained by Refs. 4 and 6 since we consider wavelet transforms for vector-valued functions and we *do not* assume the existence either of a *fundamental domain*[6] or of a *frame generator*.[4]

II. PRELIMINARIES AND NOTATIONS

Let G be a *locally compact second countable* (lcsc) topological group. We denote by μ_G and Δ_G respectively a left Haar measure on G and its modular function.

We review the basic definition and properties of square integrable representations and of discrete frames. In this paper we will use the word *representation* to mean a continuous unitary representation of G acting in a complex separable Hilbert space $\mathscr{H}$.

A representation U of G in $\mathscr{H}$ is *square integrable* if it is irreducible and there exist two nonzero vectors $\phi, \psi \in \mathscr{H}$ such that the map $c_{\phi,\psi}$ from G to $\mathbb{C}$,

$$c_{\psi,\phi}(g) = \langle U_g \psi, \phi \rangle_{\mathscr{H}},$$

is in $L^2(G, \mu_G)$, where $\langle \cdot, \cdot \rangle$ denotes the scalar product (linear in the second variable). We recall this well-known result of Duflo and Moore (Theorem 3 of Ref. 8).

Theorem 1: (Duflo and Moore) *Let U be a square-integrable representation of G acting in $\mathscr{H}$. There exists a unique positive self-adjoint operator K_U in $\mathscr{H}$ such that*

(1) *if $\phi, \psi \in \mathscr{H}$, $\phi \neq 0$, the map $c_{\psi,\phi}$ is in $L^2(G, \mu_G)$ if and only if $\psi \in \mathrm{Dom}\, K_U^{-1/2}$; and*
(2) *if $\phi, \phi' \in \mathscr{H}$ and if $\psi, \psi' \in \mathrm{Dom}\, K_U^{-1/2}$, then*

$$\langle c_{\psi,\phi}, c_{\psi',\phi'} \rangle_{L^2(G,\mu_G)} = \langle \phi, \phi' \rangle_{\mathscr{H}} \langle K_U^{-1/2} \psi', K_U^{-1/2} \psi \rangle_{\mathscr{H}}.$$

The operator K_U is called the *formal degree* of the representation and the vectors $\psi \in \mathrm{Dom}\, K_U^{-1/2}$ are called *admissible*.

Let $\mathscr{H}$ be a (complex separable) Hilbert space and $\{\psi_i : i \in I\}$ a countable family of nonzero vectors in $\mathscr{H}$. We will say that $\{\psi_i\}_{i \in I}$ is a *frame* in $\mathscr{H}$ if there exist two positive numbers α and β such that the following condition holds:

$$\alpha \|\phi\|^2 \leqslant \sum_{i \in I} |\langle \psi_i, \phi \rangle|^2 \leqslant \beta \|\phi\|^2 \quad \forall \phi \in \mathscr{H}.$$

The numbers α and β are called *frame bounds* of the frame $\{\psi_i\}_{i \in I}$.

If there exists a representation of a group G acting in $\mathscr{H}$, then it is of particular interest to determine frames of the following form:

$$\psi_i = U_{g_i} \psi,$$

where $\{g_i\}_{i \in I}$ is a countable family of elements of G and ψ is a fixed element in $\mathscr{H}$.

From now on let G be the semidirect product $\mathbb{R}^n \times' H$, where H is a lcsc topological group acting continuously on $\mathbb{R}^n$ (G is in a natural way a lcsc topological group). Explicitly, let Ω be the representation of H that defines the action of H on $\mathbb{R}^n$. Denoting $g = (x, h)$ the elements of G, with $x \in \mathbb{R}^n$ and $h \in H$, we have

$$(x,h)(x',h') = (x + \Omega(h)x', hh'),$$

and the inner action of G on $\mathbb{R}^n$ is

$$g[x] := gxg^{-1} = \Omega(h)x, \quad x \in \mathbb{R}^n, \quad g = (y,h) \in G.$$

We denote by $d^n x$ the Lebesgue measure on $\mathbb{R}^n$. Let $\mathbb{P}^n$ be the dual group of $\mathbb{R}^n$, which we identify with $\mathbb{R}^n$ in a natural way, and $d^n p$ be the corresponding Lebesgue measure. By duality, G acts continuously on $\mathbb{P}^n$, explicitly

$$g[p]\cdot x = p\cdot g^{-1}[x], \quad x\in\mathbb{R}^n,\ p\in\mathbb{P}^n,\ g\in G,$$

where $\cdot$ denotes the natural scalar product in $\mathbb{R}^n$. We fix an element p_0 of $\mathbb{P}^n$ and we denote by $\mathcal{O}$ the corresponding orbit

$$\mathcal{O}=\{p\in\mathbb{P}^n : p=g[p_0], g\in G\}$$

and by G_0 the stability subgroup of p_0,

$$G_0=\{g\in G : g[p_0]=p_0\}.$$

Let $H_0=G_0\cap H$, so that $G_0=\mathbb{R}^n\times' H_0$. We choose a representation m of H_0 acting in a complex separable Hilbert space $\mathcal{K}$ and we consider the representation p_0m of G_0 in $\mathcal{K}$:

$$(p_0m)(xh) := e^{ip_0\cdot x}m(h), \quad x\in\mathbb{R}^n, h\in H_0.$$

We denote by $\mathrm{Ind}_{G_0}^{G}(p_0m)$ the representation unitarily induced by p_0m from G_0 to G.[9]

III. SQUARE INTEGRABILITY

The following theorem solves the problem of the square integrability of the induced representations of G.

Theorem 2: *The representation* $\mathrm{Ind}_{G_0}^{G}(p_0m)$ *is square integrable if and only if* $\mathcal{O}$ *has positive Lebesgue measure in* $\mathbb{P}^n$ *and* m *is a square-integrable representation.*

This result was proven by Kleppner and Lipsman (Corollary 11.1 of Ref. 10) as a consequence of the characterization of the Plancherel measure for a locally compact group with a closed normal type I subgroup. In Ref. 11 we give an elementary proof of this theorem, based only on the properties of the commutative Fourier transform.

Let us assume that $\mathrm{Ind}_{G_0}^{G}(p_0m)$ is square integrable. Since the square integrability of a representation depends only on its equivalence class, we can freely choose the explicit form of $\mathrm{Ind}_{G_0}^{G}(p_0m)$. Due to Theorem 2 the measure of $\mathcal{O}$ has to be positive, hence the restriction of the Lebesgue measure d^np to $\mathcal{O}$ is a nonzero σ-finite measure defined on $\mathcal{O}$. In fact it is H-quasi-invariant, due to the following elementary lemma (the proof is given, for example, in Ref. 11). Let $\rho(h)=\Delta_H(h)/\Delta_G(h)$.

Lemma 1: For any $h\in H$ *and* $E\in\mathcal{B}(\mathbb{P}^n)$ *we have*

$$(d^np)(h[E])=\rho(h^{-1})(d^np)(E).$$

With the above notations, a suitable choice is the representation U acting in $L^2(\mathcal{O},\mathcal{K})$ as

$$(U_{xh}\phi)(p)=\rho(h)^{-1/2}e^{ip\cdot x}m(q(p)^{-1}hq(h^{-1}[p]))\phi(h^{-1}[p]), \tag{1}$$

where $p\in\mathcal{O}$, $x\in\mathbb{R}^n$, $h\in H$, $\phi\in L^2(\mathcal{O},\mathcal{K})$, and q is a measurable section for the action of H on $\mathcal{O}$, that is, a measurable map $q:\mathcal{O}\to H$ such that

$$q(p_0)=e \quad \text{where } e \text{ is the identity},$$

$$q(p)[p_0]=p, \quad p\in\mathcal{O}$$

(we recall that the orbit $\mathcal{O}$ is a Borel subset of $\mathbb{R}^n$).

With this choice the condition of admissibility is given by the following corollary (for the proof see Corollary 2 of Ref. 11). Let K_m be the formal degree of m.

Corollary 1: With the above assumptions, $\psi\in L^2(\mathcal{O},\mathcal{K})$ *is an admissible vector for* U *if and only if the following two conditions hold:*

$$\psi(p) \in \mathrm{Dom}\ K_m^{-1/2} \quad \text{for almost all } p \in \mathcal{O},$$

$$\int_{\mathcal{O}} \Delta_G(G(p))^{-1} \|K_m^{-1/2}\psi(p)\|_{\mathcal{K}}^2 \, d^n p < \infty.$$

If H_0 is compact, all its irreducible representations are square integrable, and one can easily show that $\mathrm{Dom}\ K_m^{-1/2} = \mathcal{K}$, K_m is a multiple of the identity, and $\Delta_G(q(p))$ is *independent* of the choice of the section q, precisely

$$\Delta_G(q(p)) = \Delta_G(g_p) \quad \forall g_p \in G \quad \text{such that } g_p[p_0] = p.$$

Going back to the general case, if U is square integrable, we can define a corresponding *wavelet transform*. Let $\psi \in L^2(\mathcal{O}, \mathcal{K})$ be an admissible vector normalized in a such way that

$$\int_{\mathcal{O}} \Delta_G(g(p))^{-1} \|K_m^{-1/2}\psi(p)\|_{\mathcal{K}}^2 \, d^n p = 1.$$

Let $\mathcal{W}_\psi$ be the map from $L^2(\mathcal{O}, \mathcal{K})$ to $L^2(G, \mu_G)$ defined by

$$(\mathcal{W}_\psi \phi)(g) = \langle U_g \psi, \phi \rangle L^2(\mathcal{O}, \mathcal{K}), \quad g \in G, \phi \in L^2(\mathcal{O}, \mathcal{K}).$$

As a consequence of Theorem 1, one can easily prove that $\mathcal{W}_\psi$ is an isometry and the projection on its range is a convolution operator, precisely

$$F \in \mathrm{Ran}\ \mathcal{W}_\psi \Leftrightarrow F * \mathcal{W}_\psi \psi = F,$$

where $*$ denotes the convolution in $L^2(G, \mu_G)$. Moreover, the inverse map of $\mathcal{W}_\psi$ from $\mathrm{Ran}(\mathcal{W}_\psi)$ onto $L^2(\mathcal{O}, \mathcal{K})$ is given by

$$F \mapsto \int_G F(g)(\mathcal{W}_\psi \psi)(g) \, d\mu_G(g),$$

where the integral is in the weak sense.

To present this kind of result, we consider a specific example. Let $G = \mathbb{R}^n \times' (\mathbb{R}^+ \times \mathrm{SO}(n))$, where $\mathrm{SO}(n)$ is the n-dimensional special orthogonal group. The direct product $H = \mathbb{R}^+ \times \mathrm{SO}(n)$ acts on $\mathbb{R}^n$ as

$$(aR)[x] = aRx,$$

where Rx is the usual matrix action and a acts as a scalar. The group H is unimodular and the Haar measure is $a^{-1} da dR$, where dR is the normalized Haar measure on $\mathrm{SO}(n)$. The modular function of G is $\Delta_G(xaR) = a^{-n}$. The dual action is

$$(aR)[p] = a^{-1} Rp.$$

With respect to this action, $\mathbb{P}^n$ is the union of two orbits $\{0\}$ and $\mathcal{O} = \mathbb{P}^n \backslash \{0\}$. The first orbit has zero Lebesgue measure, so that the corresponding representations are not square integrable. We consider the orbit $\mathcal{O}$ and we fix $p_0 = (0,...,0,1) \in \mathcal{O}$. The stability group is $G_0 = \mathbb{R}^n \times' \mathrm{SO}(n-1)$ where $\mathrm{SO}(n-1)$ is regarded as a subgroup of $\mathrm{SO}(n)$ in the following way:

$$\mathrm{SO}(n-1) \ni R \mapsto \begin{pmatrix} R & 0 \\ 0 & 1 \end{pmatrix} \in \mathrm{SO}(n).$$

Since $\mathrm{SO}(n-1)$ is compact, every representation of G induced on the orbit $\mathcal{O}$ is square integrable. The usual way to construct wavelets in $L^2(\mathbb{R}^n)$ is to choose m as the trivial representation. We suggest an alternative way in order to obtain vector-valued wavelets.

Let m be a representation of $\mathrm{SO}(n-1)$. As a consequence of the Frobenius reciprocity theorem and of the fact that $\mathrm{SO}(n)$ is compact, there exists an (in general nonunique) represen-

tation D of SO(n) such that m is a subrepresentation of D, when D is restricted to SO($n-1$). This allows us to use a *covariant realization* of $\mathrm{Ind}_{G_0}^{G}(p_0 m)$, instead of the formula (1). It is defined in the following way. Let D act in W and m act in the subspace $\mathscr{K}$ of W. For all $p \in \mathscr{O}$ let $\mathscr{K}_p = D(R_p)\mathscr{K}$ where $R_p \in \mathrm{SO}(n)$ is such that $R_p p_0 = p/|p|$. Define the Hilbert space $\mathscr{H}$

$$\mathscr{H} = \{\phi \in L^2(\mathbb{P}^n, W) : \phi(p) \in \mathscr{K}_p \quad \text{for almost all } p\}$$

and the representation V acting in $\mathscr{H}$ as

$$(V_{xaR}\phi)(p) = a^{n/2} e^{ip\cdot x} D(R)\phi(aR^{-1}p).$$

It is possible to show[12] that V is equivalent to $\mathrm{Ind}_{G_0}^{G}(p_0 m)$. Moreover, a vector $\psi \in \mathscr{H}$ is admissible if and only if

$$\int |p|^{-n} \|\psi(p)\|_W^2 \, d^n p < \infty.$$

The Fourier–Plancherel transform intertwines V with a *geometric* representation $\hat{V}$ acting on a closed subspace $\hat{\mathscr{H}}$ of $L^2(\mathbb{R}^n, W)$ as

$$(\hat{V}_{xaR} f\,)(y) = a^{-n/2} D(R) f\left(\frac{R^{-1}(y-x)}{a}\right).$$

To give an explicit description of the subspace $\hat{\mathscr{H}}$ let us choose, for example, $n=3$ and D the representation of SO(3),

$$D(R) = R,$$

acting in $W = \mathbb{C}^3$ in a natural way. Let $\mathscr{K} = \{(0,0,c) : c \in \mathbb{C}\}$, hence the restriction m of D to SO(2) leaves invariant $\mathscr{K}$ (m is the trivial representation). An easy calculation shows that

$$\hat{\mathscr{H}} = \{f \in L^2(\mathbb{R}^3, \mathbb{C}^3) : (\nabla \wedge f\,) = 0\},$$

where $\nabla\wedge$ is the curl operator (in the sense of distributions). Moreover, we observe that the orthogonal complement of $\hat{\mathscr{H}}$,

$$(\hat{\mathscr{H}})^{\perp} = \{f \in L^2(\mathbb{R}^3, \mathbb{C}^3) : \nabla \cdot f = 0\},$$

where $\nabla\cdot$ is the divergence operator (in the sense of distributions), is the direct sum of two closed subspaces where $\hat{V}$ acts irreducibly. These subspaces correspond to the choice of the subspaces of W,

$$\mathscr{K}_1 = \{(c, ic, 0) : c \in \mathbb{C}\}, \quad \mathscr{K}_2 = \{(c, -ic, 0) : c \in \mathbb{C}\},$$

and of the representations of SO(2),

$$m_1(\theta) = e^{i\theta}, \quad m_2(\theta) = e^{-i\theta},$$

where $\theta \in [0, 2\pi]$ is the usual parameter of SO(2).

IV. CONSTRUCTION OF DISCRETE FRAMES

In this section we consider the problem of the existence of discrete frames associated to the induced representations of $G = \mathbb{R}^n \times' H$, when $H = \mathbb{R}^+ \times S$ and S is a semisimple connected Lie group.

The action of H on $\mathbb{R}^n$ is

$$h[x]=(as)[x] := a(s[x]),$$

where $x\mapsto s[x]$ is a smooth action of S on $\mathbb{R}^n$. Let $\mathbb{P}^n$ denote the dual group of $\mathbb{R}^n$ and fix $p_0 \in \mathbb{P}^n$. Assume that the orbit $\mathcal{O}=G[p_0]$ for the dual action of G on $\mathbb{P}^n$ is *open* and that the subgroup $H_0=H\cap G_0$ is compact (notice that $\mathbb{R}^+\cap H_0=\varnothing$). In these hypotheses $\mathcal{O}$ is homeomorphic to G/G_0 and to H/H_0.

We will prove the existence of frames associated to the representation $\mathrm{Ind}_{G_0}^{G}(p_0 m)$ where m is any unitary finite dimensional *cyclic* representation of H_0.

We need to establish some preliminary topological results.

Lemma 2: Let Γ be a discrete subgroup of H. Then, for any compact subset C in $\mathcal{O}$, there exists a finite partition $\Gamma_1,\ldots,\Gamma_d$ of Γ such that

$$h',h''\in\Gamma_j \Rightarrow h'[C]\cap h''[C]=\varnothing.$$

Proof: Let $\pi:H\to\mathcal{O}$ be the canonical projection. First of all, we prove that $\pi^{-1}(C)$ is compact. By Theorem 5.11 of Ref. 12, there exists a section $q:\mathcal{O}\to H$ such that the set $q(C)$ is relatively compact in H. Since H_0 is compact also, $\pi^{-1}(C)=q(C)H_0$ is relatively compact. Since $\pi^{-1}(C)$ is closed, it is compact.

By lemma 3.3 of Ref. 5, there exists a finite partition $\Gamma_1,\ldots,\Gamma_d$ of Γ such that

$$h',h''\in\Gamma_j \Rightarrow h'\pi^{-1}(C)\cap h''\pi^{-1}(C)=\varnothing.$$

Hence

$$\pi^{-1}(h'[C]\cap h''[C])=\varnothing$$

and $h'[C]\cap h''[C]=\varnothing$, since π is surjective. □

Lemma 3: There exist a discrete subgroup Γ of H and a compact C in $\mathcal{O}$ such that

$$\mathcal{O}=\cup\{h[C]:h\in\Gamma\}.$$

Proof: Since H is the direct product of $\mathbb{R}^+$ and a semisimple connected Lie group, as a consequence of Theorem C of Ref. 13 H has a discrete subgroup Γ such that H/Γ is compact. Denote by π' the canonical projection of H onto H/Γ. There exists a compact $K'\subset H$ such that $\pi'(K')=H/\Gamma$, hence

$$H=\cup\{hK:h\in\Gamma\},$$

where $K=(K')^{-1}$ is compact in H. Define $C=\pi(K)$. Then C is compact in $\mathcal{O}$ and

$$\cup\{h[C]:h\in\Gamma\}=\cup\{\pi(hK):h\in\Gamma\}=\mathcal{O}.$$

□

Lemma 4: For any nonvoid open set $X\subset\mathcal{O}$ there exists a finite set $\{h_1,\ldots,h_L\}$ in H, such that

$$\cup\{hh_k[X]:h\in\Gamma,\ \ 1\leqslant k\leqslant L\}=\mathcal{O},$$

where Γ is the discrete subgroup of H given by the previous lemma.

Proof: The family of sets $\{h[X]:h\in H\}$ is an open covering of the compact subset C of $\mathcal{O}$ singled out by the previous lemma. Hence there exists a finite subcovering $\{h_k[X]:1\leqslant k\leqslant L\}$ and we have the thesis. □

Having established these results, let m be a unitary cyclic finite dimensional representation of the compact group H_0 acting in the Hilbert space $\mathcal{K}$ of dimension M. Let v be a cyclic vector for m. Then there exist M elements $s_1,\ldots,s_M$ of H_0 such that $\{m(s_i)v:i=1,\ldots,s_M\}$ is an algebraic basis of $\mathcal{K}$. Fix these elements. Let $c:\mathcal{O}\to H$ be a section for the action of H on $\mathcal{O}$. Since H is a Lie group acting smoothly on $\mathcal{O}$ we can assume that c is locally continuous around p_0. For all $h\in H$ and $p\in\mathcal{O}$ define $m(h,p) := m(c(p)^{-1}hc(h^{-1}[p]))$. Then we have the following.

Lemma 5: There exist a closed ball B with center p_0, contained in $\mathcal{O}$, and two positive numbers α, β such that

$$\alpha\|w\|^2_{\mathcal{K}} \leqslant \sum_{i=1}^{M} |\langle m(s_i,p)v,w\rangle_{\mathcal{K}}|^2 \leqslant \beta\|w\|^2_{\mathcal{K}}$$

for all $w \in \mathcal{K}$ and $p \in B$.

Proof: Let $\{e_i\}_{i=1}^{M}$ be an orthonormal basis of $\mathcal{K}$ and, for all $p \in \mathcal{O}$, $A(p)$ be the operator

$$A(p)w = \sum_{i=1}^{M} \langle m(s_i,p)v,w\rangle_{\mathcal{K}}\, e_i, \quad w \in \mathcal{K}.$$

Since the vectors $m(s_i)v = m(s_i,p_0)v$ form a basis of $\mathcal{K}$, $A(p_0)$ is invertible and

$$\|A(p_0)^{-1}\|^{-2}\|w\|^2_{\mathcal{K}} \leqslant \sum_{i=1}^{M} |\langle m(s_i,p)v,w\rangle_{\mathcal{K}}|^2 \leqslant \|A(p_0)\|^2\|w\|^2_{\mathcal{K}}.$$

By the properties of c there exists a neighborhood of p_0 where the function $p \mapsto A(p)$ is continuous. The thesis easily follows. □

We consider the explicit realization of $\mathrm{Ind}_{G_0}^{G}(p_0 m)$ acting in $L^2(\mathcal{O},\mathcal{K})$ as

$$(U_{xh}f\,)(p) = \rho(h)^{-1/2} e^{ix\cdot p} m(h,p) f(h^{-1}[p]).$$

We notice that, since S is semisimple and connected, ρ has the following expression

$$\rho(as) = a^n, \quad a \in \mathbb{R}^+, \quad s \in S.$$

Fix the closed ball B with center p_0 as in Lemma 5 and the discrete subgroup Γ of H as in Lemma 3. Let Y be an open subset of $\mathcal{O}$ such that $p_0 \in Y$ and $s_i[Y] \subset B$ for all $i = 1,...,M$.

The set $X := \cap\{s_i[Y]: 1 \leqslant i \leqslant M\}$ is not empty (since it contains p_0) and open, hence, by Lemma 4, there exists a finite family $\{h_1,\ldots,h_L\} \subset H$ such that

$$\cup\{hh_k[X]: h \in \Gamma, \quad 1 \leqslant k \leqslant L\} = \mathcal{O}.$$

Since the set $\cup\{h_k[B]: 1 \leqslant k \leqslant L\}$ is compact, due to Lemma 2, there exists a finite partition $\Gamma_1,\ldots,\Gamma_d$ of Γ such that

$$h',h'' \in \Gamma_j \Rightarrow h'\left[\bigcup_{k=1}^{L} h_k[B]\right] \cap h''\left[\bigcup_{k=1}^{L} h_k[B]\right] = \varnothing.$$

Let ν be an integer such that $B \subset R$ where

$$R := \{x \in \mathbb{R}^n: -\pi\nu \leqslant x_i \leqslant \pi\nu \;\; 1 \leqslant i \leqslant n\}$$

and, for all $l \in \mathbb{Z}^n$, $x_l = 2\pi l \in \mathbb{R}^n$.

We observe that the countable family of functions

$$\{e_l : l \in \mathbb{Z}^n\}$$

defined as

$$e_l(p) = (2\pi\nu)^{-n/2} e^{ix_l\cdot p}, \quad p \in R,$$

is a Hilbert basis of $L^2(R)$.

Now we are in a position to describe a covariant frame in $L^2(\mathcal{O},\mathcal{K})$. Let $\psi \in L^2(\mathcal{O},\mathcal{K})$ be the vector

$$\psi(p) := \chi_Y(p)v, \quad p \in \mathcal{O},$$

and consider the countable set of vectors

$$\psi_{h,k,i,l} := U_h U_{h_k} U_{s_i} U_{x_l} \psi,$$

where $h \in \Gamma$, $1 \leqslant k \leqslant L$, $1 \leqslant i \leqslant M$ and $l \in \mathbb{Z}^n$ (Γ is countable, since it is discrete). With these notations we have the following result.

Theorem 3: *The set* $\{\psi_{h,k,i,l}\}$ *is a frame in* $L^2(\mathscr{O},\mathscr{K})$.

Proof: Given $f \in L^2(\mathscr{O},\mathscr{K})$, we have

$$\begin{aligned}\langle \psi_{h,k,i,l}, f\rangle_{L^2(\mathscr{O},\mathscr{K})} &= \langle U_{x_l}\psi, U_{(hh_k s_i)^{-1}} f\rangle_{L^2(\mathscr{O},\mathscr{K})} = \int_{\mathscr{O}} e^{-ix_l\cdot p}\langle \psi(p), (U_{(hh_k s_i)^{-1}} f\,)(p)\rangle_{\mathscr{K}}\, d^n p \\ &= (2\pi\nu)^{n/2}\int_R \overline{e_l(p)}\langle \psi(p), (U_{(hh_k s_i)^{-1}} f\,) \\ &\quad \times (p)\rangle_{\mathscr{K}}\, d^n p.\end{aligned}$$

Since ψ is bounded, the function

$$\mathscr{O} \ni p \mapsto \langle \psi(p), (U_{(hh_k s_i)^{-1}} f\,)(p)\rangle_{\mathscr{K}}$$

is in $L^2(R)$, hence

$$\begin{aligned}\sum_{hkil} |\langle \psi_{h,k,i,l}, f\rangle_{L^2(\mathscr{O},\mathscr{K})}|^2 &= (2\pi\nu)^n \sum_{hki} \int_{\mathscr{O}} |\langle \psi(p), (U_{(hh_k s_i)^{-1}} f\,)(p)\rangle_{\mathscr{K}}|^2\, d^n p \\ &= (2\pi\nu)^n \sum_{hki} \int_{\mathscr{O}} |\langle m(s_i, s_i[p])\psi(p), (U_{(hh_k)^{-1}} f\,)(s_i[p])\rangle_{\mathscr{K}}|^2\, d^n p\end{aligned}$$

(changing variable $p \mapsto s_i^{-1}[p]$)

$$\begin{aligned}&= (2\pi\nu)^n \sum_{hki} \int_{\mathscr{O}} |\langle m(s_i, p)\psi(s_i^{-1}[p]), (U_{(hh_k)^{-1}} f\,)(p)\rangle_{\mathscr{K}}|^2\, d^n p \\ &= (2\pi\nu)^n \sum_{hki} \int_{s_i[Y]} |\langle m(s_i, p)v, (U_{(hh_k)^{-1}} f\,)(p)\rangle_{\mathscr{K}}|^2\, d^n p.\end{aligned}$$

Recalling that $X = \cap\{s_i[Y] : 1 \leqslant i \leqslant M\}$, for any positive function ϕ we have

$$\int_X \phi\, d^n p \leqslant \int_{s_i[Y]} \phi\, d^n p \leqslant \int_B \phi\, d^n p$$

for all $1 \leqslant i \leqslant M$. Hence, since the sum on the index i is finite,

$$\begin{aligned}&(2\pi\nu)^n \sum_{hki} \int_{s_i[Y]} |\langle m(s_i, p)v, (U_{(hh_k)^{-1}} f\,)(p)\rangle_{\mathscr{K}}|^2 d^n p \\ &\geqslant (2\pi\nu)^n \sum_{hk} \int_X \sum_i |\langle m(s_i, p)v, (U_{(hh_k)^{-1}} f\,)(p)\rangle_{\mathscr{K}}|^2\, d^n p \\ &\geqslant \alpha(2\pi\nu)^n \sum_{hk} \int_X \|(U_{(hh_k)^{-1}} f\,)(p)\|^2_{\mathscr{K}}\, d^n p \\ &= \alpha(2\pi\nu)^n \sum_{hk} \int_X \rho(hh_k)^{-1} \|f(hh_k[p])\|^2_{\mathscr{K}}\, d^n p\end{aligned}$$

(changing variable $p \mapsto (hh_k)^{-1}[p]$)

$$= \alpha(2\pi\nu)^n \sum_{hk} \int_{hh_k[X]} \|f(p)\|^2_{\mathscr{K}}\, d^n p \geqslant \alpha(2\pi\nu)^n \|f\|^2_{L^2(\mathscr{O},\mathscr{K})},$$

taking into account that

$$\cup\{hh_k[X]: h\in\Gamma,\ \ 1\leqslant k\leqslant L\} = \mathscr{O}.$$

On the other hand

$$(2\pi\nu)^n \sum_{hki} \int_{s_i[Y]} |\langle m(s_i,p)v, (U_{(hh_k)^{-1}} f\ )(p)\rangle_{\mathscr{K}}|^2\, d^n p$$

$$\leqslant (2\pi\nu)^n \sum_{hk} \int_B \sum_i\ |\langle m(s_i,p)v, (U_{(hh_k)^{-1}} f\ )(p)\rangle_{\mathscr{K}}|^2\, d^n p$$

(reasoning in the same way as before)

$$\leqslant \beta(2\pi\nu)^n \sum_{hk} \int_{hh_k[B]} \|f(p)\|^2_{\mathscr{K}}\, d^n p$$

[by property (2)]

$$= \beta(2\pi\nu)^n \sum_{j=1}^{d} \sum_{h\in\Gamma_j} \sum_{k=1}^{L} \int_{hh_k[B]} \|f(p)\|^2_{\mathscr{K}}\, d^n p$$

$$\leqslant d\beta(2\pi\nu)^n \int_{\mathscr{O}} \|f(p)\|^2_{\mathscr{K}}\, d^n p = d\beta(2\pi\nu)^n \|f\|^2_{L^2(\mathscr{O},\mathscr{K})}.$$

Summarizing we have

$$\alpha(2\pi\nu)^n \|f\|^2_{L^2(\mathscr{O},\mathscr{K})} \leqslant \sum_{hkil} |\langle \psi_{h,k,i,l}, f\rangle_{L^2(\mathscr{O},\mathscr{K})}|^2 \leqslant d\beta(2\pi\nu)^n \|f\|^2_{L^2(\mathscr{O},\mathscr{K})}.$$

Continuous wavelet transforms with Abelian dilation groups

Hartmut Führ[a)]

(Received 15 August 1997; accepted for publication 27 March 1998)

This paper is devoted to the construction of wavelet (or coherent state) systems arising from the action of certain semidirect products $G=\mathbb{R}^k \rtimes H$ on $L^2(\mathbb{R}^k)$. For this purpose previous results which guarantee the existence of inversion formulas are applied to the special case where H is Abelian. The questions of systematic construction and conjugacy of such groups are completely resolved by setting up a correspondence to unit groups of commutative associative algebras. As an application the numbers of conjugacy classes of possible Abelian groups are computed for $k=2,3,4$. For $k \geqslant 7$, there are uncountably many conjugacy classes. We then compute the admissibility conditions belonging to Abelian groups. The final section contains a characterization of Abelian matrix groups acting ergodically on some subset of $\mathbb{R}^k$. This result ensures that the approach via associative algebras yields all possible groups. © *1998 American Institute of Physics.*

I. INTRODUCTION

This paper is concerned with the construction of coherent state (or wavelet) systems arising from certain square integrable representations on $L^2(\mathbb{R}^k)$. Recall (e.g., from Ref. 1) that generally a system of coherent states on a Hilbert space $\mathcal{H}$ is given by a triple $(X,(\eta_x)_{x\in X},\mu)$, where X is a topological space, the coherent states $(\eta_x)_{x\in X}$ are a family of vectors in $\mathcal{H}$ (satisfying some continuity condition) and μ is a Borel measure on X yielding a **resolution of the identity**,

$$\mathrm{Id}_{\mathcal{H}}=\int_X |\eta_x\rangle\langle\eta_x| d\mu(x).$$

Here the integral is taken in the weak operator sense and $|\eta_x\rangle\langle\eta_x|$ denotes the rank-one-operator $\phi \mapsto \langle\phi,\eta_x\rangle\eta_x$. The topological assumptions are sometimes weakened to measure theoretic ones. The concept of coherent states arose in quantum optics and has by now spread to a vast range of (quantum) physical applications. The interested reader is referred to the collection Ref. 1, the review paper Ref. 2 and the extensive bibliographies therein.

In this paper we consider the special case where $\mathcal{H}$ is $L^2(\mathbb{R}^k)$ (or a closed subspace), the topological space $X=G=\mathbb{R}^k \rtimes H$ is a group of affine mappings acting on $\mathcal{H}$ via its canonical representation π, the coherent states are given by $\eta_x := \pi(x)\eta$ (η some suitably chosen *fiducial* or *admissible vector*) and finally μ is left Haar measure on G. Coherent states thus obtained from unitary actions have been frequently studied in mathematics and mathematical physics, especially for semidirect products of the type considered here (a small sample of the literature is given in Refs. 3–8). Readers familiar with wavelet theory will recognize the mapping $\phi \mapsto (\langle\phi,\pi(x)\eta\rangle)_{x\in G}$ as a continuous wavelet transform and the resolution of the identity as a reformulation of the wavelet inversion formula. In fact, the well known one-dimensional continuous wavelet transform is a special case of this construction.

The group-theoretic approach leads to the concept of **square integrable group representations**. In this paper we are only concerned with square integrability in the strict sense of Ref. 9: a representation is square integrable iff it is irreducible and has a (nontrivial) square integrable matrix coefficient. This property immediately yields a wavelet inversion formula of the desired

kind; for the one-dimensional wavelet transform this was first observed in Ref. 5. Both requirements have been weakened (irreducibility to cyclicity,[6,7] square integrability to square integrability on quotients[10,11,8]), at the cost of technical difficulties. The strong form of square integrability is better understood, especially for the type of affine groups considered in this paper.[12,13]

Thus, the construction depends on the choice of a matrix group $H<\mathrm{GL}(k,\mathbb{R})$, the so called *dilation group*. The canonical action of the group $\mathbb{R}^k \rtimes H$ on $\mathbb{R}^k$ gives rise to a strongly continuous unitary representation π on $\mathrm{L}^2(\mathbb{R}^k)$, and we call H **admissible** if π has a square integrable subrepresentation.

This paper deals with the case of Abelian dilation groups. We are going to give a full description of the admissible Abelian dilation groups in terms of commutative associative algebras, including the question of conjugacy of the dilation groups. The latter was already raised in Ref. 12, Remark (5), for the special class of groups considered there. It is of interest because replacing one dilation group by a conjugate group results in a simple change of coordinates in the corresponding wavelet transform; we may thus restrict our attention to conjugacy classes. The main tool for the classification may be sketched as follows: We generalize the construction from an algebraic point of view, substituting the affine group $\mathbb{R}\rtimes\mathbb{R}^\times$ underlying the one-dimensional transform by a (somewhat modified) affine group of a k-dimensional associative algebra with unity, $\mathcal{A}\rtimes_{\mathrm{T}}\mathcal{A}^\times$, where $\mathcal{A}$ is viewed as a vector group, $\mathcal{A}^\times$ denotes the group of invertible elements of $\mathcal{A}$ and $\rtimes_{\mathrm{T}}$ denotes a (group-theoretic) semidirect product, in which not the usual action of $\mathcal{A}^\times$ on $\mathcal{A}$ is used but a transposed action. Under the regular representation of the algebra, the action of $\mathcal{A}^\times$ on $\mathcal{A}$ becomes the action of a linear group on $\mathbb{R}^k$. The resulting linear group can then be shown to be admissible. The construction works for general associative algebras with unity. It is the main result of this paper that every admissible **Abelian** group is obtained in this fashion from a commutative associative algebra with unity, and that the question of conjugacy of admissible groups translates on the algebraic level to a question concerning algebra isomorphisms.

It should be noted, however, that while the algebraic viewpoint is extremely useful when it comes to the enumeration and classification of wavelet transforms with Abelian dilation groups, it is not clear how the algebraic structure relates to properties of the wavelet transform (if it does at all). The latter are connected to geometric properties of the action of the dilation group (the ''zooming''-effect, for instance). So far comparatively few groups have been considered, and the relationship between group structure and properties of the wavelet transform has rarely been explicitly investigated. In my opinion this question deserves further attention.

The paper is structured as follows: Section II contains a more detailed review of the group-theoretic approach to the construction of continuous wavelet transforms on $\mathrm{L}^2(\mathbb{R}^k)$. In particular, the admissibility criterion for groups established previously[13] is reviewed, which leads to considering linear groups with open orbits. In addition to these known results, we obtain some further properties of admissible groups.

In Sec. III we deal with Abelian matrix groups with open orbits. We establish a connection with certain maximal Abelian matrix algebras. In particular it is shown that the associative algebra generated by such a group coincides with its Lie algebra, and that the group is an open subgroup of the algebra's unit group. It is thus possible to obtain also the nonconnected Abelian dilation groups from these algebras (Theorem 11).

We then proceed to characterize the algebras in terms of abstract associative algebras (Theorem 13).

In Sec. IV we use the results of Sec. III to show how one can construct a full catalog of (conjugacy classes of) admissible Abelian groups from a (modulo isomorphism) complete system of commutative associative algebras (see Corollary 14). As an application, we compute the numbers of conjugacy classes of Abelian admissible groups in dimensions 2 through 4, and show how the structure theory of associative algebras can be utilized for this task. From dimension 7 on, there are uncountably many conjugacy classes of Abelian admissible groups (Corollary 15). We then turn to the sets of wavelets (or admissible functions) associated to each dilation group. It is shown that only a superficial knowledge of the algebra structure is needed to explicitly compute the admissibility condition.

Section V finally contains a characterization of Abelian matrix groups acting ergodically on some subset $U\subset\mathbb{R}^k$ of positive measure (Theorem 25). This result, together with Proposition 5, ensures that the list of admissible groups obtained via associative algebras is complete.

II. SQUARE INTEGRABLE REPRESENTATIONS OF AFFINE GROUPS

This section contains a review of results on the construction of wavelet transforms on $L^2(\mathbb{R}^k)$ from quasiregular representations of certain groups of affine mappings established previously,[12,13] and some additional results.

As mentioned in the Introduction, the construction depends on the choice of a dilation group H. In Refs. 12, 13, H was assumed to be closed, without any comments concerning the necessity of this assumption, but Proposition 5 below shows that it is, in fact, necessary for the success of the construction. The subgroup of the full affine group of $\mathbb{R}^k$ generated by H and the translations is the semidirect product $G:=\mathbb{R}^k \rtimes H$. Elements of G are denoted by (x,h), with $x \in \mathbb{R}^k$ and $h \in H$, and the group law is given by $(x_1,h_1)(x_2,h_2)=(x_1+h_1x_2,h_1h_2)$. From the canonic action of G on $\mathbb{R}^k$ arises a very natural unitary representation, the *quasiregular representation* π defined by $(\pi(x,h)f)(y):=|\det(h)|^{-1/2}f(h^{-1}(y-x))$, where f denotes an element of $L^2(\mathbb{R}^k)$.

It turns out that the question of admissibility of a matrix group H can be answered by looking at the action of H on the dual group $\widehat{\mathbb{R}^k}$. If we view elements of $\mathbb{R}^k$ as column vectors and elements of $\widehat{\mathbb{R}^k}$ as row vectors, the dual action of H becomes matrix multiplication on the right. There is a one-to-one correspondence between irreducible subrepresentations and subsets $U \subset \widehat{\mathbb{R}^k}$ of positive measure on which H acts ergodically (Ref. 13, Corollary 4). We denote the representation belonging to U by π_U. Now two cases can occur: The action of H on U may be *properly ergodic*, meaning that all H-orbits in U are null sets. To my knowledge, there exists no general criterion for square integrability of π_U in this situation (for partial results see Ref. 13, Remark 12). However, it will turn out that if H is closed and Abelian, then H cannot act ergodically on a subset of $\widehat{\mathbb{R}^k}$ unless this subset is already an open orbit; see Theorem 25 below. Hence, this case never occurs in the context of Abelian dilation groups.

Let us now turn to the second case; without loss of generality we may thus assume U to be an orbit of positive measure. By Ref. 14, Lemma 4, U is, in fact, open. We then have the following characterization of square integrability (see Ref. 13, Theorem 10).

Theorem 1: *π_U is square integrable iff for one (and hence every) $\gamma \in U$ the stabilizer H_γ in H is compact.*

We are now going to give some results on open orbits of matrix groups and their consequences for admissible dilation groups. A simple fact that will be frequently used is that if H is a matrix group such that Hx is open for some $x \in \mathbb{R}^k$, then so is $H'x$ for every matrix group H' containing H. At first we are going to give a simple but very useful characterization for matrix groups with open orbits involving their Lie algebras. We will view these Lie algebras canonically as matrix Lie algebras. In order to simplify the following discussion, we consider the action on column vectors even though we are, in fact, interested in the action on row vectors.

The above cited Lemma 4 of Ref. 14 was obtained by applying Sard's Theorem to the quotient mapping $p_x: H \ni h \mapsto hx$, for $x \in U$. As a further consequence of this we obtain the following characterization:

Lemma 2: Let $H < \mathrm{GL}(k,\mathbb{R})$ be closed, let $\mathfrak{h}$ be its Lie algebra. Then, for $x \in \mathbb{R}^k$ the orbit Hx is open iff the differential of the map $H \ni h \mapsto hx$ has full rank at the neutral element; or more explicitly, iff the condition

$$(\mathcal{O}) \quad \textit{The linear mapping } \mathfrak{h} \ni X \mapsto Xx \in \mathbb{R}^k \textit{ is onto,}$$

is fulfilled.

As a first application we note the following.

Theorem 3: *Let $H < \mathrm{GL}(k,\mathbb{R})$ be closed. Suppose there exists $x \in \mathbb{R}^k$ with Hx open. Then, up to a null set, $\mathbb{R}^k$ is the union of finitely many open H-orbits.*

Proof: The argument uses terminology and results from real algebraic geometry. Let O denote the union of open H-orbits. By condition $(\mathcal{O})$ of Lemma 2, $x \in O$ iff the differential of the quotient map belonging to x has maximal rank, which is the case iff some $k \times k$-subdeterminant of the differential does not vanish. Determinants being polynomial, it follows that O is a nonempty Zariski-open (particularly conull) subset of $\mathbb{R}^k$. By a standard trick, O is homeomorphic to a

Zariski-closed subset in $k+1$ dimensions, hence it has finitely many connected components, as a result of Whitney.[15] But each component is contained in an open orbit. □

Remarks 4: (1) From the requirement that H operate on an open orbit with compact fixed groups one can easily deduce that $k \leqslant \dim H \leqslant 1+k(k-1)/2$. Both bounds are sharp, as examples 15 and 16 of Ref. 13 show.

(2) Since H and the connected component H_0 of the neutral element in H have the same Lie algebra, it follows from Lemma 2 that Hx is open iff H_0x is open. It can be shown that H operates on Hx with compact stabilizers iff H/H_0 is finite and H_0 operates on H_0x with compact stabilizers. Here the sufficiency is clear; the proof for the necessity uses the finiteness of the open H_0-orbits. □

We end this section with the proof that only closed matrix groups are useful for the construction of wavelet transforms. Note that the proposition holds, in particular, for Lie group topologies.

Proposition 5: Let $H<\mathrm{GL}(k,\mathbb{R})$, endowed with a locally compact group topology $\mathcal{T}$. Suppose that the semidirect product $\mathbb{R}^k \rtimes H$ is a topological semidirect product, i.e., $\mathbb{R}^k \rtimes H$ endowed with the product topology ($\mathbb{R}^k$ topologized as usual) is a topological group. If the quasiregular representation of $\mathbb{R}^k \rtimes H$ on $\mathrm{L}^2(\mathbb{R}^k)$ has a square integrable subrepresentation, then H is closed and $\mathcal{T}$ is the relative topology.

Proof: In order that the semidirect product be topological, $\mathcal{T}$ must be finer than the relative topology. Now suppose that π has a square integrable subrepresentation, which is then equivalent to a subrepresentation of the regular representation of $\mathbb{R}^k \rtimes H$, by Ref. 9, Theorem 2. Since the matrix coefficients of the regular representation are C_0-functions,[16] π has a nontrivial C_0 matrix coefficient $V_{f,g}$. We may assume $V_{f,g}(1)=1$. Let $W_{f,g}$ denote the matrix coefficient of the quasiregular representation of $\mathbb{R}^k \rtimes \mathrm{GL}(k,\mathbb{R})$ corresponding to the same pair of functions f,g. Then $V_{f,g}$ is the restriction of $W_{f,g}$ to $\mathbb{R}^k \rtimes H$. Since $W_{f,g}$ is continuous, there exists a compact neighborhood U of 1 in $\mathrm{GL}(k,\mathbb{R})$ with $|W_{f,g}|>1/2$ on U. $U \cap H$ is $\mathcal{T}$-closed in H, since U is closed and $\mathcal{T}$ is finer than the relative topology. Since H is closed in $\mathbb{R}^k \rtimes H$, the restriction of $V_{f,g}$ to H vanishes at infinity. By choice of U, this implies that $U \cap H$ is contained in a $\mathcal{T}$-compact set, hence is $\mathcal{T}$-compact itself. But then $\mathcal{T}$ coincides on $U \cap H$ with the relative topology, and since $U \cap H$ is a neighborhood of 1 for both topologies, it follows that they coincide on H. In particular, the relative topology is locally compact, which means H is closed. □

III. ABELIAN MATRIX GROUPS WITH OPEN ORBITS

In this section we start with the investigation of Abelian matrix groups with open orbits. For this purpose the Lie algebras of these groups will play a crucial role. This may seem surprising, since Abelian Lie algebras have no particular structure. But the algebras we are interested in will turn out to be associative algebras as well and this associative structure is decisive.

The first result of this section is not particularly deep, but will prove to be extremely useful.

Lemma 6: Let $H<\mathrm{GL}(k,\mathbb{R})$ be Abelian and $x \in \mathbb{R}^k$. If Hx is open, then the stabilizer H_x of x is trivial.

Proof: Since the stabilizers H_y of $y \in Hx$ are conjugate in H to H_x and H is Abelian, we have $H_x=H_y$. Being open, Hx spans $\mathbb{R}^k$, whence we obtain that H_x fixes every $y \in \mathbb{R}^k$. But then H_x is trivial. □

The first consequence is that the compactness condition of Theorem 1 is trivially fulfilled when H is Abelian. As a second application we show the following.

Proposition 7: Let *$H<\mathrm{GL}(k,\mathbb{R})$ be Abelian. Suppose there exists $x \in \mathbb{R}^k$ with Hx open. Then H is a closed, k-dimensional subgroup.*

Proof: If Hx is open, then so is $\overline{Hx}$. Since the operation of $\overline{H}$ on the open orbit is free, the quotient mapping $\overline{H} \ni h \mapsto hx \in \overline{Hx}$ is a homeomorphism (in fact, a diffeomorphism), and the image of H under this map is open. Hence, H is open in $\overline{H}$, which entails $H=\overline{H}$. $\dim H=k$ is then clear. □

The next aim is to establish the connection between Abelian matrix groups having an open orbit and maximal Abelian matrix algebras. We start with some definitions.

Definition 8: An Abelian subgroup $H<\mathrm{GL}(k,\mathbb{R})$ is maximal Abelian if H is not properly contained in an Abelian $H'<\mathrm{GL}(k,\mathbb{R})$. It is called maximal connected Abelian if it is connected

and is not properly contained in a connected Abelian subgroup of $\mathrm{GL}(k,\mathbb{R})$. (*Note that being maximal connected Abelian is* not *the same as being maximal Abelian and connected.*)

By $\mathrm{gl}(k,\mathbb{R})$ *we denote the space of* $k\times k$*-matrices, either endowed with its structure as Lie algebra or as associative algebra. A Lie (respectively, associative) subalgebra of* $\mathrm{gl}(k,\mathbb{R})$ *is called maximal Abelian if it is Abelian and not properly contained in another Lie (respectively, associative) subalgebra.*

The following remarks collect the basic properties of maximal Abelian groups and algebras and their relation to Abelian groups with open orbit.

Remarks 9: (1) Clearly, maximal (connected) Abelian subgroups are closed. By Zorn's Lemma, every (connected) Abelian subgroup is contained in a maximal (connected) Abelian subgroup.

(2) Maximal connected Abelian subgroups are in one-to-one correspondence to maximal Abelian Lie-subalgebras of $\mathrm{gl}(k,\mathbb{R})$, via the exponential map. But the latter are in fact maximal Abelian *associative* subalgebras, since every Abelian Lie-subalgebra generates an Abelian associative subalgebra (and since every associative subalgebra is a Lie-subalgebra).

On the other hand, every maximal Abelian associative subalgebra is a maximal Abelian Lie-subalgebra as well.

(3) If H is an Abelian matrix groups having an open orbit, then its connected component H_0 is maximal connected Abelian: Every Abelian connected group H_1 containing H_0 has an open orbit [since H_0 has an open orbit, by (2) of Remark 4]; hence, by Proposition 7 $\dim H_0 = k = \dim H_1$, and thus $H_0 = H_1$.

(4) A trivial but useful observation is that every maximal Abelian subalgebra contains the identity. This fact has consequences for the wavelet transforms constructed from Abelian dilation groups: The group $\mathbb{R}^k \rtimes H$ is never unimodular, since H contains the positive multiples of the identity, and for such an element $a\cdot \mathrm{Id}\in H$ we have $\Delta_G(0,a\cdot \mathrm{Id}) = a^{-k}$. The nonunimodularity then implies that not every vector in $\mathrm{L}^2(\mathbb{R}^k)$ (or a subspace carrying an irreducible subrepresentation) is admissible (see Ref. 9, the remark after Theorem 3). □

Summarizing the results of our discussion so far, we see that we are interested in constructing k-dimensional maximal Abelian (associative or Lie-) subalgebras satisfying condition $(\mathcal{O})$ of Lemma 2. A complete description of these algebras immediately yields a complete description of at least the connected Abelian matrix groups with open orbit. But as we will soon see, it is also possible to obtain the nonconnected Abelian matrix groups with open orbits from these algebras, as open subgroups of their unit groups. Before we prove this result, we need some preliminary results on unit groups of associative subalgebras of $\mathrm{gl}(k,\mathbb{R})$. Generally speaking, for a given associative algebra $\mathcal{A}$ with unity element $1_{\mathcal{A}}$, we let $\mathcal{A}^\times$ denote the *unit group* or group of invertible elements of $\mathcal{A}$.

Proposition 10: Let $\mathcal{A}\subset \mathrm{gl}(k,\mathbb{R})$ *denote a* d*-dimensional associative subalgebra containing the identity. Then* $\mathcal{A}^\times$ *is almost connected and conull with respect to the standard measure on* $\mathcal{A}\cong\mathbb{R}^d$. *If* $H<\mathrm{GL}(k,\mathbb{R})$ *is maximal Abelian, then we have* $H=\mathcal{A}^\times$, *where* $\mathcal{A}=\mathrm{span}(H)$ *denotes the algebra generated by* H. *In particular* H *has only finitely many connected components.*

Proof: We start by observing that $\mathcal{A}^\times = \mathcal{A}\cap \mathrm{GL}(k,\mathbb{R})$: Indeed, if $A\in\mathcal{A}$ is an invertible matrix, then multiplication by A is one-to-one on $\mathcal{A}$, hence onto. This shows ''$\supset$'', and the other direction is trivial. Since det is a polynomial mapping, it follows that $\mathcal{A}^\times$ is a Zariski-open subset of $\mathcal{A}$, hence the same argument as in the proof of Theorem 3 yields that $\mathcal{A}^\times$ has finitely many connected components and is a conull subset. The statements concerning H are obvious. □

Theorem 11: *Let* $H<\mathrm{GL}(k,\mathbb{R})$ *be Abelian with open orbit in* $\mathbb{R}^k$. *Let* $\mathfrak{h}$ *denote its Lie algebra and* $\mathcal{A}:=\mathrm{span}(H)$, *the associative algebra generated by* H. *Then we have* $\mathfrak{h}=\mathcal{A}$, *and* H *is an open subgroup of* $\mathcal{A}^\times$ *with a finite index. There exists exactly one open (and hence conull)* $\mathcal{A}^\times$*-orbit in* $\mathbb{R}^k$.

Proof: We have $H<\mathcal{A}^\times$, hence both have an open orbit, thus both have dimension k by Proposition 7. Thus H is open in $\mathcal{A}^\times$, hence $\mathcal{A}^\times/H$ is finite, by Proposition 10. $\mathcal{A}^\times\subset\mathcal{A}$ is open, hence $\dim\mathcal{A}=k$. $\mathfrak{h}$ being an associative subalgebra containing the identity element, it contains its own image under the exponential mapping, i.e., $\mathfrak{h}\supset H_0$, where H_0 is the connected component of H. But $\mathrm{span}(H_0)$ is at least k-dimensional, hence $\mathfrak{h}=\mathrm{span}(H_0)=\mathcal{A}$.

The single open $\mathcal{A}^\times$-orbit is obtained as follows: Since $\mathfrak{h}=\mathcal{A}$ fulfills condition $(\mathcal{O})$, there exists $x\in\mathbb{R}^k$ such that the mapping $\mathcal{A}\ni X\mapsto Xx\in\mathbb{R}^k$ is a vector space isomorphism. Now

$\mathcal{A}^\times x$ is the image of the open conull subset $\mathcal{A}^\times$ under this isomorphism, so $\mathcal{A}^\times x$ is the desired orbit. □

The following proposition shows a simple method of constructing associative subalgebras satisfying condition $(\mathcal{O})$. It uses the regular representations of associative algebras with unity.

Proposition 12: Let $\mathcal{A}$ be a real k-dimensional associative (not necessarily Abelian) algebra with unity. The (left) regular representation ρ of $\mathcal{A}$ is defined by choosing a vector space isomorphism $\psi:\mathcal{A}\to\mathbb{R}^k$ and defining, for all $A,B\in\mathcal{A}$: $\rho(A)\psi(B):=\psi(AB)$. This defines an algebra-monomorphism of $\mathcal{A}$ into $\mathrm{gl}(k,\mathbb{R})$. *$\rho(\mathcal{A})$ satisfies condition $(\mathcal{O})$ and $\rho(\mathcal{A}^\times)$ operates freely on a single open orbit in $\mathbb{R}^k$. As a consequence, $\rho(\mathcal{A}^\times)^\mathsf{T}$ is an admissible group, in fact the quasiregular representation of $\mathbb{R}^k\rtimes\rho(\mathcal{A}^\times)^\mathsf{T}$ is square integrable.*

Proof: That ρ is an algebra monomorphism is verified easily. $\rho(\mathcal{A})$ satisfies condition $(\mathcal{O})$ because choosing $x:=\psi(1_\mathcal{A})$ we obtain $\rho(A)x=\psi(A)$, for all $A\in\mathcal{A}$. Hence the open orbit $\rho(\mathcal{A}^\times)\psi(1_\mathcal{A})$ is conull. The last statement of the theorem is then clear by Theorem 1. □

We have thus found a simple general procedure to construct admissible matrix groups. Note that nonisomorphic algebras yield nonconjugate groups, since an open subgroup of $\mathcal{A}^\times$ spans $\mathcal{A}$. Hence we see that the conjugacy problem for matrix groups operating freely on an open orbit contains as a subproblem the classification of real finite-dimensional associative algebras; to my knowledge the latter is far from being solved.

Returning to the Abelian case, the strategy from now on will be to show that every maximal Abelian subalgebra satisfying condition $(\mathcal{O})$ is conjugate to its own regular representation. This result answers both questions raised in the beginning of this section at once: Running through all regular representations of all (isomorphism classes of) k-dimensional commutative associative algebras, we obtain all candidates for $\mathfrak{h}$, and from the open subgroups of their unit groups all candidates for H. And: Two Abelian algebras satisfying condition $(\mathcal{O})$ are conjugate iff they are isomorphic as associative algebras.

One should note, however, that only in principle do these results give a full description of the conjugacy classes of Abelian dilation groups. As far as I know, the classification of Abelian algebras has only been achieved for low dimensions.

Now for the theorem. In its present form the proof has been pointed out to me by Professor Stein A. Strømme.

Theorem 13: *An Abelian associative subalgebra $\mathcal{A}\subset\mathrm{gl}(k,\mathbb{R})$ satisfies condition $(\mathcal{O})$ iff it is conjugate to its own regular representation.*

Proof: The ''if'' part is provided by the previous proposition. For the ''only-if'' part, let $x\in\mathbb{R}^k$ be such that the mapping ϕ: $\mathcal{A}\ni X\mapsto Xx$ is a vector space isomorphism. Let ψ: $\mathcal{A}\to\mathbb{R}^k$ denote the vector space isomorphism used to define ρ. Then the relation $\phi\psi^{-1}\rho(A)\psi\phi^{-1}=A$ is easily checked for each $A\in\mathcal{A}$, hence we are done. □

IV. APPLICATIONS AND EXAMPLES

In this section we give some applications of the characterization of admissible Abelian groups. The following corollary gives a summary of how a complete catalog of these groups is obtained from the isomorphism classes of real associative algebras of the same dimension. Given the previous results, the task left is mainly bookkeeping, except for one minor problem: If $H_1,H_2<\mathcal{A}^\times$ are two open subgroups, when are their images under the regular representation conjugate? The answer to this question is fairly obvious, but it somewhat complicates the notation.

Corollary 14: Let $\mathcal{R}_k$ be a system of representatives of the isomorphism classes of real commutative associative algebras with unity of dimension k. For $\mathcal{A}\in\mathcal{R}_k$ let

$$\mathcal{G}_\mathcal{A}\subset\{H<\mathcal{A}^\times : H\subset\mathcal{A}^\times \text{ open}\}$$

be a system of representatives with respect to the equivalence relation ''$\approx$,'' defined by $H_1\approx H_2:\Leftrightarrow$ There exists an algebra automorphism $\eta:\mathcal{A}\to\mathcal{A}$ such that $\eta(H_1)=H_2$.

Since $\mathcal{A}^\times$ has finitely many open subgroups, $\mathcal{G}_\mathcal{A}$ is a finite set. Let $\mathfrak{UD}(k)$ denote the set of conjugacy classes of Abelian groups with open orbits in $\mathbb{R}^k$. Then the following map is a bijection:

$$\dot{\bigcup}_{\mathcal{A}\in\mathcal{R}_k}\mathcal{G}_{\mathcal{A}}\to\mathfrak{UD}(k)$$

$$H\mapsto[\rho(H)].$$

Each algebra contributes exactly one conjugacy class of connected groups and one class of groups having a single open orbit. By transposing each $H\in[H]\in\mathfrak{UD}(k)$ *we obtain the representatives of all admissible Abelian dilation groups.*

Proof: Well-definedness as well as injectivity on each $\mathcal{G}_{\mathcal{A}}$ is proved by the equivalence

$$H_1\approx H_2\Leftrightarrow\rho(H_1)\ \text{ is conjugate to }\rho(H_2).$$

The proof for sufficiency is straightforward. For the necessity, recall that $\rho(H_1)$ and $\rho(H_2)$ both span $\rho(\mathcal{A})$, hence every matrix that conjugates $\rho(H_1)$ into $\rho(H_2)$ conjugates $\rho(\mathcal{A})$ into itself, yielding the desired algebra automorphism. By the same argument it is clear that nonisomorphic algebras yield nonconjugate groups with open orbits; hence, it remains to show that the map is onto. But this is immediate from Theorems 11 and 13 and the assumptions on $\mathcal{G}_{\mathcal{A}}$. The fact that all admissible Abelian groups are covered follows from Proposition 5 and Theorem 25. □

As a further corollary we note the following.

Corollary 15: For $k\geqslant 7$ *there are uncountably many nonconjugate Abelian subgroups of* $\mathrm{GL}(k,\mathbb{R})$ *with open orbits.*

Proof: By Theorem 16 from Ref. 17, Chapter 2, Section 2, there exists an uncountable family $(\mathcal{N}_\alpha)_{\alpha\in\Lambda}$ of nilpotent commutative associative algebras of dimension $k-1$, which are pairwise nonisomorphic. For nilpotent algebras $\mathcal{N}_1$ and $\mathcal{N}_2$, we have $\mathbb{R}\cdot 1+\mathcal{N}_1\cong\mathbb{R}\cdot 1+\mathcal{N}_2$ iff $\mathcal{N}_1\cong\mathcal{N}_2$. The sufficiency is clear, and for the necessity we observe that $\mathcal{N}_i$ is the Jacobson radical in $\mathbb{R}\cdot 1+\mathcal{N}_i$, hence every isomorphism of the bigger algebras maps the smaller algebras onto each other. Thus $(\mathbb{R}\cdot 1+\mathcal{N}_\alpha)_{\alpha\in\Lambda}$ is the desired family of nonisomorphic algebras with unity. □

We are now going to compute the numbers of conjugacy classes of admissible Abelian groups of dimension $\leqslant 4$. The first case is extremely simple.

16 The case $k=2$*:* Clearly, every two-dimensional real algebra is isomorphic to $\mathbb{R}[X]/(X^2+a)$, with $a\in\{-1,0,1\}$, and any two of these algebras are nonisomorphic. For $a=1$ the algebra is isomorphic to $\mathbb{C}$; for $a=-1$ it is isomorphic to the product algebra $\mathbb{R}\times\mathbb{R}$. For $a=1$, we have only one connected component of the unit group. For $a=0$ we observe that $b+cX+(X^2)$ is invertible iff $b\neq 0$, hence the unit group has two connected components, which means that this algebra contributes two conjugacy classes. Finally, $\mathbb{R}\times\mathbb{R}$ has 4 components of the unit groups. The isomorphism $(r,s)\mapsto(s,r)$ maps the open subgroups of index 2 onto each other, hence we obtain 3 conjugacy classes of admissible groups. Summarizing, we have 6 two-dimensional groups, 3 of which are connected. □

For the higher-dimensional cases we need a bit more theory. The following structure theorem is useful in two ways: It reduces the task to classification of nilpotent algebras, and it simplifies the calculation of the unit groups.

In the following, $\mathbb{K}$ denotes $\mathbb{R}$ or $\mathbb{C}$. $\mathbb{C}$-algebras are of course $\mathbb{R}$-algebras as well, and $\mathrm{gl}(m,\mathbb{C})$ is canonically embedded in $\mathrm{gl}(2m,\mathbb{R})$. Recall that an associative algebra $\mathcal{A}$ is called nilpotent if $\mathcal{A}^n=\{0\}$ for some $n\in\mathbb{N}$. The smallest such n is called the nilpotency class of $\mathcal{A}$.

Theorem 17: *Let* $\mathcal{A}$ *be a real finite-dimensional commutative associative algebra with unity. Then there exists a decomposition (unique up to order of summands),*

$$\mathcal{A}=\mathcal{A}_1\oplus\mathcal{A}_2\oplus\cdots\oplus\mathcal{A}_\ell,$$

where each algebra $\mathcal{A}_i$ *is irreducible, i.e. cannot be written as the direct product of proper subalgebras.* $\mathcal{A}$ *is irreducible iff* $\mathcal{A}=1_{\mathcal{A}}\cdot\mathbb{K}+\mathcal{N}$*, with* $\mathcal{N}$ *a nilpotent* $\mathbb{K}$*-algebra.*

Proof: Since I could not find a reference of the theorem in this form, I include a short proof, using results from Ref. 18. The unique decomposition is obtained from the decomposition $1_{\mathcal{A}}=e_1+e_2+\ldots+e_\ell$, where the e_i are the minimal idempotents of $\mathcal{A}$, by letting $\mathcal{A}_i:=e_i\mathcal{A}$ (by Theorem 2.22 of Ref. 18). In particular, $\mathcal{A}$ is irreducible iff $1_{\mathcal{A}}$ is its only idempotent; thus adjoining a unit element to a nilpotent algebra $\mathcal{N}$ yields an irreducible algebra. For the other direction, we conclude from Ref. 18, Theorem 2.14 that the radical $\mathcal{N}$ of an irreducible algebra $\mathcal{A}$

is a maximal ideal (any proper nonnilpotent ideal would contain idempotents), whence $\mathcal{A}/\mathcal{N}$ is a (finite) field extension of $\mathbb{R}$, i.e., either $\mathbb{R}$ or $\mathbb{C}$. Now the Principal Theorem of Wedderburn (Ref. 18, Theorem 3.23) yields the desired structure of $\mathcal{A}$. □

For the calculations carried out below the following definition is useful.

Definition 18: For a finite-dimensional associative algebra $\mathcal{A}$ let

$$\#_{OS}(\mathcal{A}) := |\{H < \mathcal{A}^\times : H \ \ open\}/\approx|,$$

where $|A|$ denotes the cardinality of the set A and $\approx$ is the equivalence relation from Theorem 14.

The fact that an algebra isomorphism maps minimal idempotents onto minimal idempotents accounts for the uniqueness of the decomposition; it also simplifies the computation of $\#_{OS}(\mathcal{A})$, as the following proposition shows.

Proposition 19: Let $\mathcal{A}$ be a real finite-dimensional commutative associative algebra with unity, and let

$$\mathcal{A} = \mathcal{B}_1 \oplus \mathcal{B}_2 \oplus \cdots \oplus \mathcal{B}_m$$

be the (unique) decomposition into algebras $\mathcal{B}_i$, where each $\mathcal{B}_i$ is the direct sum of isomorphic irreducible algebras, and $\mathcal{B}_i$ and $\mathcal{B}_j$ have no isomorphic irreducible subalgebras in common, for $i \neq j$. Such a decomposition is obtained simply by collecting the isomorphic irreducible components. Then we have

$$\#_{OS}(\mathcal{A}) = \#_{OS}(\mathcal{B}_1) \cdot \#_{OS}(\mathcal{B}_2) \cdot \ \cdots \ \cdot \#_{OS}(\mathcal{B}_m).$$

If $\mathcal{B}$ is the direct sum of ℓ pairwise isomorphic irreducible $\mathbb{K}$-algebras, we have

$$\#_{OS}(\mathcal{B}) = \begin{cases} 1 & : \ \mathbb{K} = \mathbb{C}, \\ \ell + 1 & : \ \mathbb{K} = \mathbb{R}. \end{cases}$$

Proof: The first equation is immediate from the fact that an automorphism of $\mathcal{A}$ maps each $\mathcal{B}_i$ into itself, and that every open subgroup of $\mathcal{A}^\times$ is the direct product of open subgroups of the $\mathcal{B}_i^\times$. For the second equation, observe that an element $\alpha 1_{\mathcal{A}_i} + n$ of an irreducible component $\mathcal{A}_i$ ($\alpha \in \mathbb{K}$ and n nilpotent) is invertible iff $\alpha \neq 0$. Hence, the unit group of such an algebra is connected in the complex case and has two connected components in the real case. Since the unit group of the whole algebra is the direct product of the unit groups of the components, we obtain 2^ℓ connected components of the unit group in the real case and 1 in the complex case, whence we obtain $\#_{OS}(\mathcal{A}) = 1$ for the latter. For the former, it is easily seen that two open subgroups having the same number of connected components can be mapped onto each other by an algebra automorphism. □

In the following we will give a complete list of irreducible algebras of real dimension up to 4. k will denote the $\mathbb{K}$-dimension of the algebra and n the nilpotency class of the nilpotent part. Since the algebras of highest and lowest possible nilpotency class are extremely simple to describe, only the case $k=4, n=3$ is not straightforward.

(i) $\mathbb{K}=\mathbb{R}, k=2, n=2$: $\mathcal{A} \cong \mathbb{R}[X]/(X^2)$.
(ii) $\mathbb{K}=\mathbb{R}, k=3, n=2$: $\mathcal{A} \cong \mathbb{R}[X,Y]/(X^2, Y^2, XY)$.
(iii) $\mathbb{K}=\mathbb{R}, k=3, n=3$: $\mathcal{A} \cong \mathbb{R}[X]/(X^3)$.
(iv) $\mathbb{K}=\mathbb{R}, k=4, n=2$: $\mathcal{A} \cong \mathbb{R}[X,Y,Z]/(X^2, Y^2, Z^2, XY, XZ, YZ)$.
(v) $\mathbb{K}=\mathbb{R}, k=4, n=3$: $\mathcal{A} \cong \mathbb{R}[X,Y]/(X^3, Y^2 - aX^2, XY)$, with $a \in \{-1,0,1\}$. For the proof, suppose we are given $\mathcal{A} = \mathbb{R} \cdot 1 + \mathcal{N}$, where $\mathcal{N}$ is a three-dimensional algebra of nilpotency class 3. Pick $X \in \mathcal{N}$ with $X^2 \neq 0$, then X, X^2 and some suitably chosen $Y \in \mathcal{N}$ are a basis of $\mathcal{N}$. From $X^2Y = XY^2 = Y^3 = 0$ we obtain the relations $XY = bX^2$ and $Y^2 = aX^2$ for some $a, b \in \mathbb{R}$. Hence $\mathcal{A} \cong \mathbb{R}[X,Y]/(X^3, Y^2 - aX^2, XY - bX^2)$. Substituting by scalar multiples of X and Y, we may reduce the general case to $(a,b) \in \{-1,0,1\} \times \{0,1\}$. The substitution $Y \mapsto Y - X$ yields an isomorphism $\mathbb{R}[X,Y]/(X^3, Y^2 - X^2, XY - X^2) \to \mathbb{R}[X,Y]/(X^3, Y^2, XY)$ as well as an isomorphism $\mathbb{R}[X,Y]/(X^3, Y^2, XY - X^2) \to \mathbb{R}[X,Y]/(X^3, Y^2 + X^2, XY)$. Moreover, $\mathbb{R}[X,Y]/(X^3, Y^2 + X^2, XY - X^2) \cong \mathbb{R}[X,Y]/(X^3, Y^2, XY - X^2)$, by the substitution $X \mapsto \sqrt{2}X$, $Y \mapsto (\sqrt{2} - 1)X + Y$. In short, we

may assume $b=0$. Among the three remaining cases, $a=0$ yields the only algebra in which the radical has a two-dimensional annihilator (as a short calculation shows). Finally, $a=1$ and $a=-1$ yield nonisomorphic algebras, because in the case $a=1$ every element Z with $Z^2=0$ is a scalar multiple of X^2 (another simple calculation), whereas in the case $a=-1$ we have $(X+Y)^2=0=(X^2)^2$, and $X+Y, X^2$ are linearly independent.

(vi) $\mathbb{K}=\mathbb{R}, k=4, n=4$: $\mathcal{A}\cong\mathbb{R}[X]/(X^4)$.

(vii) $\mathbb{K}=\mathbb{C}, k=2, n=2$: $\mathcal{A}\cong\mathbb{C}[X]/(X^2)$.

Now we can calculate the numbers of conjugacy classes of admissible Abelian groups.

20 The case k=3 Combining the irreducible algebras just given, we obtain the following complete list of algebras and corresponding numbers of conjugacy classes:

$\mathcal{A}=\mathbb{R}\oplus\mathbb{R}\oplus\mathbb{R}$	$\#_{OS}(\mathcal{A})=4$
$\mathcal{A}=\mathbb{R}\oplus\mathbb{C}$	$\#_{OS}(\mathcal{A})=2$
$\mathcal{A}=\mathbb{R}\oplus\mathbb{R}[X]/(X^2)$	$\#_{OS}(\mathcal{A})=4$
$\mathcal{A}=\mathbb{R}[X,Y]/(X^2,Y^2,XY)$	$\#_{OS}(\mathcal{A})=2$
$\mathcal{A}=\mathbb{R}[X]/(X^3)$	$\#_{OS}(\mathcal{A})=2$
5 algebras	14 conjugacy classes

Finally, the four-dimensional groups. □

21 The case k=4: Analogous to the three-dimensional case, we obtain the following.

$\mathcal{A}=\mathbb{R}\oplus\mathbb{R}\oplus\mathbb{R}\oplus\mathbb{R}$	$\#_{OS}(\mathcal{A})=5$
$\mathcal{A}=\mathbb{R}\oplus\mathbb{R}\oplus\mathbb{C}$	$\#_{OS}(\mathcal{A})=3$
$\mathcal{A}=\mathbb{R}\oplus\mathbb{R}\oplus\mathbb{R}[X]/(X^2)$	$\#_{OS}(\mathcal{A})=6$
$\mathcal{A}=\mathbb{R}\oplus\mathbb{R}[X,Y]/(X^2,Y^2,XY)$	$\#_{OS}(\mathcal{A})=4$
$\mathcal{A}=\mathbb{R}\oplus\mathbb{R}[X]/(X^3)$	$\#_{OS}(\mathcal{A})=4$
$\mathcal{A}=\mathbb{C}\oplus\mathbb{R}[X]/(X^2)$	$\#_{OS}(\mathcal{A})=2$
$\mathcal{A}=\mathbb{C}\oplus\mathbb{C}$	$\#_{OS}(\mathcal{A})=1$
$\mathcal{A}=\mathbb{R}[X]/(X^2)\oplus\mathbb{R}[X]/(X^2)$	$\#_{OS}(\mathcal{A})=3$
$\mathcal{A}=\mathbb{C}[X]/(X^2)$	$\#_{OS}(\mathcal{A})=1$
$\mathcal{A}=\mathbb{R}[X,Y]/(X^3,Y^2-aX^2,XY)$ (with $a\in\{-1,0,1\}$)	$\#_{OS}(\mathcal{A})=2$
12 algebras	35 conjugacy classes

It should be noted that the actual construction of the admissible groups from the algebras is straightforward: Direct product decompositions yield block matrix structures, and the relations defining an irreducible algebra allow an almost immediate calculation of the regular representation of that algebra.

We are now going to take a closer look at the admissibility condition that has to be fulfilled by the functions serving as wavelets (or *fiducial vectors* in the terminology of mathematical physics) for the wavelet transform. In Ref. 13, Theorem 13, it was shown how this condition could be obtained from the modular function of $\mathbb{R}^k\rtimes H$. More precisely, $g\in\pi_U$ is admissible iff

$$\int_U |\hat{g}(\omega)|^2\Psi(\omega)d(\omega)<\infty,$$

where the *admissibility function* Ψ is obtained by transporting the modular function of $\mathbb{R}^k\rtimes H$ to the open orbit U, i.e. choosing any $\gamma\in U$, we let $\Psi(\gamma h):=\Delta_G(0,h)=\Delta_H(h)|\det(h)|^{-1}=|\det(h)|^{-1}$. ($H$ is Abelian, hence $\Delta_H\equiv 1$.) We are going to calculate Ψ, restricting our attention

mainly to indecomposable groups. For the general case, observe that if an admissible dilation group H is the direct product of two lower-dimensional admissible dilation groups H_1 and H_2, i.e.,

$$H=\left\{\begin{pmatrix} h_1 & 0 \\ 0 & h_2 \end{pmatrix}: h_i \in H_i, \text{ for } i=1,2\right\},$$

then the open H-orbits are of the form $U=U_1\times U_2$ (U_i an open H_i-orbit), and the admissibility function Ψ is immediately calculated as $\Psi(x_1,x_2)=\Psi_1(x_1)\Psi_2(x_2)$, where Ψ_i is the admissibility function corresponding to the open H_i-orbit U_i. Another rather trivial observation concerns the behavior of admissible vectors when we replace a dilation group by a conjugate group: Clearly, if H is an admissible group and $A\in \mathrm{GL}(k,\mathbb{R})$, then $A^{-1}HA$ is an admissible dilation group and $f\in \mathrm{L}^2(\mathbb{R}^k)$ is admissible for H iff $f\circ A$ is admissible for $A^{-1}HA$.

Hence, we may restrict our attention to particularly simple representatives of conjugacy classes of indecomposable Abelian dilation groups, and for these the admissibility condition has an extremely simple form.

Theorem 22: *Let $H<\mathrm{GL}(k,\mathbb{R})$ be an admissible Abelian matrix group. Suppose that $\mathcal{A}:=\mathrm{span}(H)$ is indecomposable. Without loss of generality we may assume that $H=\mathcal{A}^\times$. Then, after a suitable change of coordinates, the single open orbit in $\widehat{\mathbb{R}^k}$ is*

$$U=\begin{cases} \{(\omega_1,\omega_2,\ \dots\ ,\omega_k): \omega_1^2+\omega_2^2\neq 0\} & : \quad \mathcal{A} \text{ is a } \mathbb{C}\text{-algebra,} \\ \{(\omega_1,\omega_2,\ \dots\ ,\omega_k): \omega_1\neq 0\} & : \quad \text{otherwise.} \end{cases}$$

and the admissibility function Ψ of the square integrable representation $\pi=\pi_U$ is given by

$$\Psi(\omega)=\begin{cases} (\omega_1^2+\omega_2^2)^{-k/2} & : \quad \mathcal{A} \text{ is a } \mathbb{C}-\text{algebra,} \\ |\omega_1|^{-k} & : \quad \text{otherwise.} \end{cases}$$

Proof: We have $\mathcal{A}=\mathbb{K}\cdot 1_k+\mathcal{N}$, with $\mathcal{N}$ nilpotent, and $\mathcal{A}^\mathsf{T}$ satisfies condition $(\mathcal{O})$. Let m denote the $\mathbb{K}$-dimension of $\mathcal{A}$, i.e., $m=k$ when $\mathbb{K}=\mathbb{R}$, $m=k/2$ otherwise. Let $N_2,\ \dots\ ,N_m$ denote a $\mathbb{K}$-basis of $\mathcal{N}$, let $\psi:\mathcal{A}\to\mathbb{K}^m$ be the $\mathbb{K}$-vector space isomorphism with $\psi(1_k)=e_1=(1,0,\ \dots\ ,0)^\mathsf{T}$ and $\psi(N_i)=e_i$ $(2\leqslant i\leqslant m)$, where $e_1,\ \dots\ ,e_m$ denotes the standard basis of $\mathbb{K}^m$. Let ρ denote the corresponding regular representation of $\mathcal{A}$, by Theorem 13 we may consider $\mathcal{B}:=\rho(\mathcal{A})^\mathsf{T}$ instead of $\mathcal{A}$. Now, given $A=a\cdot 1_k+\Sigma_{i=2}{}^m b_i N_i\in\mathcal{A}$, we see that

$$\rho(A)^\mathsf{T}=\begin{pmatrix} a & \mathbf{b} \\ 0_{m,1} & c_{m-1,m-1} \end{pmatrix},$$

where $\mathbf{b}=(b_2,\ \dots\ ,b_m)$ and $c_{m-1,m-1}$ is some element of $\mathrm{gl}(m-1,\mathbb{K})$. Now $\rho(A)$ is invertible iff $a\neq 0$, hence, choosing $\gamma:=(1,0,0,\ \dots\ ,0)\in\widehat{\mathbb{R}^k}$ yields

$$\gamma\mathcal{B}^\times=\begin{cases} \{(\omega_1,\omega_2,\ \dots\ ,\omega_k) & : \ \omega_1^2+\omega_2^2\neq 0\} & \mathbb{K}=\mathbb{C}, \\ \{(\omega_1,\omega_2,\ \dots\ ,\omega_k) & : \ \omega_1\neq 0\} & \mathbb{K}=\mathbb{R}. \end{cases}$$

The absolute value of the *real* determinant of $\rho(a\cdot 1_k+N)=a\cdot 1_k+\rho(N)$ with $a\in\mathbb{K}$ and N nilpotent is easily seen to be $|a|^k$, hence, we obtain for $(\omega_1,\omega_2,\ \dots\ ,\omega_k)\in U$, that

$$\Psi(\omega)=\begin{cases} (\omega_1^2+\omega_2^2)^{k/2} & : \quad \mathbb{K}=\mathbb{C}, \\ |\omega_1|^k & : \quad \mathbb{K}=\mathbb{R}. \end{cases}$$

□

Using this result it is not hard to show that in every dimension there exist (up to a change of coordinates) only finitely many admissibility conditions belonging to Abelian dilation groups. We end this section by noting some representation-theoretic consequences of our results.

Theorem 23: *Let $H<\mathrm{GL}(k,\mathbb{R})$ be closed and Abelian. Then the following are equivalent.*

(a) *The quasiregular representation of $\mathbb{R}^k \rtimes H$ on $\mathrm{L}^2(\mathbb{R}^k)$ contains an irreducible subrepresentation.*

(b) *The quasiregular representation of $\mathbb{R}^k \rtimes H$ on $\mathrm{L}^2(\mathbb{R}^k)$ is a finite direct sum of square integrable representations.*

(c) *There exists an Abelian closed subgroup H' containing H with H'/H finite, such that the quasiregular representation of $\mathbb{R}^k \rtimes H'$ on $\mathrm{L}^2(\mathbb{R}^k)$ is square integrable.*

Any of these conditions implies that the regular representation of $\mathbb{R}^k \rtimes H$ is the direct sum of irreducible subrepresentations.

Proof: $(c)\Rightarrow(b)\Rightarrow(a)$ is obvious. Concerning $(c)\Rightarrow(a)$, it follows from Ref. 13, Corollary 6 and Theorem 25 below, that H has an open orbit in $\hat{\mathbb{R}}^k$, hence, $H<\mathrm{span}(H)^\times$ with finite index, by Theorem 11, and by the same result the larger group is as desired. The statement concerning the regular representation has already been made in Ref. 12, Remark 4 after Theorem 2; for more details see Ref. 19. □

It can even be shown that in the case that the equivalent conditions of the previous theorem are fulfilled the regular representation of $\mathbb{R}^k \rtimes H$ is, in fact, an infinite multiple of π; i.e., π contains *all* square integrable representations of $\mathbb{R}^k \rtimes H$.

V. ERGODICALLY ACTING ABELIAN MATRIX GROUPS

This section is devoted to proving a characterization of Abelian matrix groups acting ergodically on some subset of $\mathbb{R}^k$. For this purpose, a lemma is needed which is intuitively clear and probably well known; however, I could not find a reference for it.

Lemma 24: Let G be group acting on a σ-finite measure space (X,μ), such that the action of G respects measurable sets and μ is quasi-invariant under G. Let H be a subgroup of G acting ergodically on some measurable, H-invariant subset $A\subset X$ of positive measure. Then there exists a measurable G-invariant subset $B\subset X$ on which G acts ergodically.

Proof: We may assume μ to be finite. Then H operates ergodically on some subset of positive measure iff there exists an $\epsilon>0$ such that for each finite union $X=U_1\cup U_2\cup\cdots\cup U_n$ with measurable, H-invariant sets U_i there exists an i with $\lambda(U_i)\geqslant\epsilon$. But clearly this must hold for G also. □

Theorem 25: *Let $H<\mathrm{GL}(k,\mathbb{R})$ be Abelian. H operates ergodically on a subset $U\subset\mathbb{R}^k$ iff $\overline{H}$ has an open orbit in $\mathbb{R}^k$.*

Proof: Let $H<\mathrm{GL}(k,\mathbb{R})$ be an Abelian group acting ergodically on some subset of $\mathbb{R}^k$ of positive measure. Let $H_1\supset H$ be a maximal Abelian subgroup of $\mathrm{GL}(k,\mathbb{R})$; by the previous lemma H_1 acts ergodically on a subset of $\mathbb{R}^k$. H_1 is an algebraic subgroup of $\mathrm{GL}(k,\mathbb{R})$: by Proposition 10 it is the intersection of $\mathrm{GL}(k,\mathbb{R})$ with a subalgebra of $\mathrm{gl}(k,\mathbb{R})$, i.e., with a vector space. Then by Ref. 20, Theorem 3.1.1 the H_1-orbits are locally closed, and Glimm's Theorem (Ref. 20, 2.1.14) finally implies that there exists an H_1-orbit of positive measure. Hence H is contained in an Abelian matrix group with an open orbit.

By Theorem 3, $\mathbb{R}^k$ is (up to a null set) the union of finitely many H_1-orbits, hence, we may assume that H operates ergodically on $U\subset H_1x$ for some $x\in\mathbb{R}^k$ with H_1x open. By Lemma 6, H_1 operates freely on the open orbit, which enables us to move the situation to H_1. Standard Lebesgue measure and the image of Haar measure of H_1 under the projection map $h\mapsto hx$ are equivalent, both being quasi-invariant regular measures. The action of H on H_1x, when moved to H_1, becomes action by translation. Summarizing, we have obtained an action of H by translation on a subset of H_1, which is ergodic with respect to Haar measure. But this is well-known to be the case iff H is dense in an open subgroup of H_1 (see for instance Ref. 20, Lemma 2.2.13). Hence $\overline{H}$ has an open orbit, by (2) of Remark 4.

The other direction uses the result just cited: If H is dense in a group H_1 with open orbit, then H operates ergodically on H_1. Since the operation of H_1 on the open orbit is free, this yields an ergodic operation of H on this open orbit. □

VI. CONCLUDING REMARKS

The object of this paper was the construction and classification of Abelian admissible dilation groups. The restriction to Abelian groups was mainly motivated by their greater accessibility. Even in this setting we obtain a great variety of groups, each of which gives rise to a family of wavelet transforms (indexed by the admissible vectors), and we have found a convenient way of constructing these groups. For the exploitation of the transforms for (more or less) practical purposes, there is still a lot to be done. The construction of the groups ensures the existence of wavelet inversion formulas (i.e., a wavelet synthesis corresponding to the wavelet analysis given by the transform), but the interpretation of the wavelet transform has not been considered. Given the central role that the reconstruction plays in most of the applications of continuous wavelet transforms, it seems plausible that at least some of the various possible groups yield transforms which can be usefully interpreted. So far only comparatively few have been considered.[4,21,22,8] Correspondingly, the physical relevance of a system of coherent states depends not only on the resolution of the identity but also on additional features of the coherent states (as required by the application at hand), which were not under consideration here.

Finally, it should be said that virtually none of the results concerning admissible Abelian groups may be generalized to the non-Abelian case. To begin with, as the example $H=\mathbb{R}^+ \cdot \mathrm{SO}(k)$ studied previously[21,22] shows there exist admissible groups which operate with nontrivial stabilizers on an open orbit in $\widehat{\mathbb{R}^k}$. Even in the case where the dilation group operates freely on an open orbit in $\widehat{\mathbb{R}^k}$, the Lie algebra of the group is no longer an associative algebra (take, for instance, the family of non-Abelian groups constructed in Ref. 12), thus the whole approach fails. The only exception is the construction of admissible groups from the regular representation of an associative algebra given in Proposition 12, and the fact that nonisomorphic algebras yield nonconjugate groups.

The equivalence established in Theorem 23 does not hold in the general case: It is, of course, possible that the quasi-regular representation is irreducible but not square integrable [take $H=\mathrm{GL}(k,\mathbb{R})$, for instance]. But even in the case where π has a square integrable subrepresentation it need not decompose into a direct sum of square integrable subrepresentations. As an example consider the group $H=\mathbb{R}^+ \cdot \mathrm{SO}_0(1,k-1)^4$ (for $k \geqslant 3$). Using Theorem 1, it is easily seen that the quasi-regular representation is the direct sum of two square integrable and one non-square integrable representation.

Wavelets on the *n*-sphere and related manifolds

J.-P. Antoine and P. Vandergheynst
Institut de Physique Théorique, Université Catholique de Louvain,

(Received 15 December 1997; accepted for publication 31 March 1998)

We present a purely group-theoretical derivation of the continuous wavelet transform (CWT) on the $(n-1)$-sphere S^{n-1}, based on the construction of general coherent states associated to square integrable group representations. The parameter space of the CWT, $X \sim \mathrm{SO}(n) \times \mathbb{R}^+_*$, is embedded into the generalized Lorentz group $\mathrm{SO}_0(n,1)$ via the Iwasawa decomposition, so that $X \simeq \mathrm{SO}_0(n,1)/N$, where $N \simeq \mathbb{R}^{n-1}$. Then the CWT on S^{n-1} is derived from a suitable unitary representation of $\mathrm{SO}_0(n,1)$ acting in the space $L^2(S^{n-1}, d\mu)$ of finite energy signals on S^{n-1}, which turns out to be square integrable over X. We find a necessary condition for the admissibility of a wavelet, in the form of a zero mean condition, which entails all the usual filtering properties of the CWT. Next the Euclidean limit of this CWT on S^{n-1} is obtained by redoing the construction on a sphere of radius R and performing a group contraction for $R \to \infty$, from which one recovers the usual CWT on flat Euclidean space. Finally, we discuss the extension of this construction to the two-sheeted hyperboloid $H^{n-1} \sim \mathrm{SO}_0(n-1,1)/\mathrm{SO}(n-1)$ and some other Riemannian symmetric spaces. © *1998 American Institute of Physics.*

I. INTRODUCTION

In most cases of physical interest, experimental data are given on the line (signal processing), on the plane (image analysis), or occasionally in $\mathbb{R}^3$ (e.g., in fluid dynamics). However, there are instances where data are given on a *sphere*. Of course, geophysical data is the prime example (e.g., weather prediction or global circulation models), but others appear, for instance, in statistical problems, computer vision or medical imaging (see Ref. 1 for a list and precise references). In such cases, not only S^2, but also higher dimensional spheres or other manifolds may occur. The standard methods are based on Fourier analysis, but analyzing data with the continuous wavelet transform (CWT) is by now a well-established procedure (see Ref. 2 for a survey of applications in physics). So the question arises, how does one extend the CWT to the sphere or another manifold?

Let us first make that statement precise. We may speak of a genuine spherical CWT if (i) the signals and the wavelets live *on* the sphere; (ii) the transform involves (local) dilations of some kind; and (iii) for small scales, the spherical CWT reduces to the usual CWT on the (tangent) plane (Euclidean limit). The same criteria apply to other manifolds.

The problem has attracted a lot of interest in the last couple of years and many proposals have been made, but, in our opinion, none of them is fully satisfactory according to these criteria. In particular, local dilations are in general missing. For instance:

(i) A number of works extend to S^2 the discrete wavelet scheme based on a multiresolution analysis, using adapted interpolation methods and spline functions.[3–5] This approach is in general motivated by numerical purposes, but leads often to difficulties around the poles. A different technique is to use second generation wavelets.[6,7]

(ii) Others[8–10] exploit the geometry of the sphere, as encoded in the system of spherical harmonics, but as a result their analyzing functions are poorly localized. In fact they do not really resemble wavelets. A comprehensive survey of this approach may be found in the recent monograph of Freeden *et al.*[11]

(iii) One defines a WT on the tangent bundle of the sphere[12] or instead a Gabor transform on the sphere itself[13] (since no dilation is then involved).

 © 1998 American Institute of Physics

(iv) The most satisfactory approach is that of Holschneider,[14] who produces a CWT on S^2 that satisfies the three criteria above. However, the role of dilation is played by an abstract parameter that satisfies a number of *ad hoc* assumptions. The correct Euclidean limit is obtained, but it is essentially put by hand.

As can be seen from this brief description, none of the proposed solutions fully qualifies for a genuine CWT on S^2. In a previous paper,[15] we have presented a new approach to the CWT on the 2-sphere, entirely derived from group theory, following the formalism of general coherent states developed in Ref. 16. In particular, the Euclidean limit has also a precise group-theoretical formulation, in terms of *group contraction*.[17,18]

In the present paper, we shall extend our construction to spheres in higher dimensions (S^{n-1}) and discuss the application to other manifolds, for instance, a two-sheeted hyperboloid or similar Riemannian symmetric spaces. The paper is organized as follows. In Sec. II, we present a rapid survey of the coherent state construction based on square integrable group representations.[16] In Sec. III we describe the affine transformations of S^{n-1}, that is, motions and local dilations, and show that they belong to the conformal group of S^{n-1}, namely the Lorentz group $\mathrm{SO}_0(n,1)$. Then the parameter space of the CWT may be identified as $X \sim \mathrm{SO}(n)\cdot \mathbb{R}^+_* \sim \mathrm{SO}_0(n,1)/\mathbb{R}^{n-1}$, using the Iwasawa decomposition of $\mathrm{SO}_0(n,1)$. Then, in Sec. IV, we select a suitable unitary representation of $\mathrm{SO}_0(n,1)$, acting in the space $L^2(S^{n-1},d\mu)$ of finite energy signals on S^{n-1}, and show that it is square integrable over X. From there, we derive the CWT on S^{n-1}. Section V is devoted to the Euclidean limit, using the theory of contraction of group representations (the main definitions for the latter are collected in the Appendix). Finally, in Sec. VI, we discuss the extension of the construction to other manifolds such as, for instance, the two-sheeted hyperboloid $H^{n-1} \sim \mathrm{SO}_0(n-1,1)/\mathrm{SO}(n-1)$ and some Riemannian symmetric spaces.

As will be seen, the present results are rather similar to those obtained previously in the case of the 2-sphere.[15] As a byproduct, we also obtain a CWT on the circle, for $n=2$. The latter is quite different from that of Holschneider,[19] which is largely based on a periodization procedure applied to wavelets on the interval.

II. GENERAL SETUP: THE CWT ON A MANIFOLD

We begin by a brief sketch of the method of construction of coherent states (CS) associated to a group representation. Further details may be found, for instance, in the review paper, Ref. 16, and the references quoted therein.

Let Y be a manifold. For instance, Y could be space $\mathbb{R}^n$, the 2-sphere S^2, space-time $\mathbb{R}\times\mathbb{R}$ or $\mathbb{R}^2\times\mathbb{R}$, etc. In order to construct coherent states on Y, one typically needs two ingredients:

(1) the class of finite energy signals living on Y, i.e., the space $L^2(Y,d\mu)\equiv\mathcal{H}$.
(2) a (locally compact) group G of transformations acting (transitively) on Y, i.e., $y\mapsto g[y]$, with $g[g'[y]]=gg'[y]$, $e[y]=y$, and for any pair $y,y'\in Y$, there is at least one $g\in G$ such that $g[y]=y'$.

From this one obtains a natural unitary representation of G in the space $L^2(Y,d\mu)$, namely the left quasi-regular representation (for simplicity, we assume that μ is G-invariant, but quasi-invariance suffices):

$$[U(g)f](y)=f(g^{-1}y). \tag{2.1}$$

Then a system of CS on Y associated to G may be defined if U is a *square integrable* representation of G, that is, U is irreducible (cyclicity would be sufficient) and there exists a nonzero vector $\eta\in L^2(Y,d\mu)$, called *admissible*, such that the matrix element $\langle U(g)\,\eta|\,\eta\rangle$ is square integrable as a function on G, with respect to the (left or right) Haar measure on G. When this is the case, the corresponding CS, indexed by G, are obtained as the vectors in the orbit of the admissible vector η under U:

$$\eta_g=U(g)\,\eta, \quad g\in G. \tag{2.2}$$

Quite often, however, the representation U is not square integrable in the strict sense just described [it would be a discrete series representation, and many groups have no discrete series; a case in point is the Lorentz group $SO_0(n,1)$, for $n\neq 2$]. However, it may become square integrable when restricted to a homogeneous space $X=G/H$, for some closed subgroup H. By this we mean the following. Let $\sigma: X\to G$ be a Borel section. Then the nonzero vector $\eta\in L^2(Y,d\mu)$ is said to be *admissible* mod(H,σ), and the representation U *square integrable* mod(H,σ), if the following condition holds:

$$c_X(\eta,\phi)\equiv\int_X d\nu(x)|\langle U(\sigma(x))\,\eta|\phi\rangle|^2<\infty,\quad \forall\,\phi\in\mathcal{H} \tag{2.3}$$

(we assume that ν is a G-invariant measure on X; again this is not a restriction). Then CS indexed by X may be defined as

$$\eta_{\sigma(x)}=U(\sigma(x))\,\eta,\quad x\in X. \tag{2.4}$$

The condition (2.3) may also be rewritten as

$$0<\int_X d\nu(x)|\langle\,\eta_{\sigma(x)}|\phi\rangle|^2=\langle\phi|A_\sigma\phi\rangle<\infty,\quad \forall\,\phi\in\mathcal{H}, \tag{2.5}$$

where A_σ is a positive, bounded, invertible operator.[16] If the operator A_σ^{-1} is also bounded, the family $\mathcal{S}_\sigma=\{\eta_{\sigma(x)},x\in X\}$ is called a *frame*, and a *tight frame* if $A_\sigma=\lambda I$, for some $\lambda>0$. This terminology is familiar in the discrete case, for instance, in wavelet or Gabor analysis.[20,21] From now on, we shall normalize the admissible vector η by $c_X(\eta,\eta)=1$, and we shall assume that it generates a frame $\mathcal{S}_\sigma$ (otherwise domain problems arise).

Under these assumptions, the CS defined in (2.4) have the following properties:

(1) The set $\mathcal{S}_\sigma$ is total in $\mathcal{H}$: $(\mathcal{S}_\sigma)^\perp=\{0\}$.

(2) The range, $\mathcal{H}_\eta$, of the linear map $W_\eta:\mathcal{H}\to L^2(X,d\nu)$, given by

$$(W_\eta\phi)(x)=\langle\,\eta_{\sigma(x)}|\phi\rangle,\quad \phi\in\mathcal{H}, \tag{2.6}$$

is complete with respect to the scalar product $\langle\Phi|\Psi\rangle_\eta\equiv\langle\Phi|W_\eta A_\sigma^{-1}W_\eta^{-1}\Psi\rangle$ and W_η is unitary from $\mathcal{H}$ onto $\mathcal{H}_\eta$.

(3) The orthogonal projection from $L^2(X,d\nu)$ onto $\mathcal{H}_\eta$ is an integral operator K_σ, and $\mathcal{H}_\eta$ is a reproducing kernel Hilbert space of functions:

$$\Phi(x)=\int_X d\nu(y)K_\sigma(x,y)\Phi(y),\quad \forall\Phi\in\mathcal{H}_\eta. \tag{2.7}$$

The kernel is given explicitly by $K_\sigma(x,y)=\langle\,\eta_{\sigma(x)}|A_\sigma^{-1}\eta_{\sigma(y)}\rangle$, that is, K_σ is essentially the autocorrelation function of η.

(4) The map W_η may be inverted on its range by the adjoint operator, $W_\eta^{-1}=W_\eta^*$ on $\mathcal{H}_\eta$, to obtain the reconstruction formula:

$$W_\eta^{-1}\Phi=\int_X d\nu(x)\Phi(x)A_\sigma^{-1}\eta_{\sigma(x)},\quad \Phi\in\mathcal{H}_\eta. \tag{2.8}$$

In more familiar terms, properties (1) and (2) mean that the CS family $\mathcal{S}_\sigma$ yields a new representation of the system under consideration, unitary equivalent to the original one. By property (3), the Hilbert space of this CS representation is a space of (usually nice) functions. Finally, property (4) means that the vector $\phi=W_\eta^{-1}\Phi$ may be expanded in terms of (reconstructed from) CS $\eta_{\sigma(x)}$, in the same sense as an expansion in terms of (possibly generalized) eigenvectors of some self-adjoint operator, exactly as for Fourier series or integrals, or, for that matter, wavelet expansions.

A particular case of this construction is that considered, independently, by Gilmore,[22] and Perelomov,[23] namely the situation where the subgroup H is the subgroup H_η of G that leaves the admissible vector η invariant up to a phase:

$$U(h)\,\eta = e^{i\omega(h)}\,\eta, \quad h \in H_\eta, \tag{2.9}$$

where $\omega(h)$ is a real-valued, measurable function on H_η. Then the admissibility condition (2.3) is independent of the choice of the section σ, and the frame is automatically tight, with $A_\sigma = I$.

In the case where η is invariant under H (thus $H \subset H_\eta$), this construction is standard in noncommutative harmonic analysis (U is then called a representation of the relative discrete series of X). For a review and original references, see Ref. 24 [where the CS map (2.6) is called the Poisson transform].

Let us conclude by giving some familiar examples of this construction.

(1) The ''$ax+b$'' group acting on $\mathbb{R}$ yields the usual one-dimensional (1-D) continuous wavelets.
(2) The Weyl–Heisenberg group, also acting on $\mathbb{R}$, gives the windowed Fourier transform, or Gabor transform. Here all vectors are admissible.
(3) The similitude group of $\mathbb{R}^n$, $\mathrm{SIM}(n) = \mathbb{R}^n \rtimes (\mathbb{R}^+_* \times \mathrm{SO}(n))$, consisting of translations $b \in \mathbb{R}^n$, dilations $a > 0$ and rotations $R \in \mathrm{SO}(n)$, yields the n-dimensional wavelets ($\rtimes$ denotes a semidirect product). For an axisymmetric wavelet η, the isotropy group H is $\mathrm{SO}(n-1)$ and so $X = \mathbb{R}^n \cdot \mathbb{R}^+_* \cdot S^{n-1} \sim \mathbb{R}^{2n}$ (which may be interpreted as phase space), and we are in the Gilmore–Perelomov situation.
(4) Coherent states on the Galilei group or the Poincaré group, both inaccessible to the standard Gilmore–Perelomov method.[16]

III. AFFINE TRANSFORMATIONS ON THE SPHERE S^{n-1}

The usual CWT on the line is derived from a natural unitary representation of the ''$ax+b$'' group, namely the left quasi-regular representation (4.1) in the space of finite energy signals $L^2(\mathbb{R}, dx)$.[25,26] Similarly, in two dimensions, one starts from the quasi-regular representation of the similitude group of the plane in the space $L^2(\mathbb{R}^2, d^2x)$.[27,28] Note that in each case, the group acts transitively on the basis manifold, $\mathbb{R}$ or $\mathbb{R}^2$. The same scheme applies to the CWT on a general manifold, subject to the transitive action of some group of transformations that contains dilations.

Let us apply this method to the sphere S^{n-1} and consider the space of finite energy signals $\mathcal{H} = L^2(S^{n-1}, d\mu)$, where $d\mu(\omega)$ is the usual (rotation invariant) measure on S^{n-1}. The first step for constructing a CWT on S^{n-1} is to identify the appropriate affine transformations. For that purpose, we note first the isomorphism $S^{n-1} \simeq \mathrm{SO}(n)/\mathrm{SO}(n-1)$, from which we deduce immediately that $\mathrm{SO}(n)$ acts transitively on S^{n-1}; these are the so-called motions or displacements on the sphere. Correspondingly, the left quasi-regular representation (4.1), acting in $\mathcal{H} = L^2(S^{n-1}, d\mu)$, is easily computed using the matrix realization of $\mathrm{SO}(n)$ in $\mathbb{R}^n$. It decomposes into the direct sum of all unitary irreducible representations (UIRs) of $\mathrm{SO}(n)$, and this is simply the Fourier series on S^{n-1} (see Sec. IV).

In order to obtain dilations, and also for generalization to other manifolds, let us recall some well-known geometrical facts.[29,30] Let $\mathcal{M}$ be an n dimensional (pseudo-) Riemannian manifold with metric $g_{\mu\nu}$. A *motion* is a transformation $z^\mu = z^\mu(x^1, \ldots, x^n)$, that leaves the metric invariant in the sense that

$$g'_{\mu\nu} \equiv \frac{\partial z^\alpha}{\partial x^\mu} \cdot g_{\alpha\beta} \cdot \frac{\partial z^\beta}{\partial x^\nu} = g_{\mu\nu}. \tag{3.1}$$

For the cases $\mathcal{M} = \mathbb{R}^n, S^n$ and $\mathbb{R}^n_{(p,q)}$ [the pseudo-Euclidean space with metric (p,q)] the motion groups are, respectively, the Euclidean group $E(n) = \mathbb{R}^n \rtimes \mathrm{SO}(n)$, the linear orthogonal group $\mathrm{O}(n+1)$ and the pseudo-orthogonal group $\mathrm{O}(p,q)$ (note that, in the last two cases, reflections are irrelevant for our purposes).

The map $\{x^\mu\} \mapsto \{z^\nu\}$ is a *conformal transformation* if the transformed metric is locally proportional to the initial one:

$$g'_{\mu\nu}(x)=\lambda(x)g_{\mu\nu}(x). \tag{3.2}$$

In the case of the the pseudo-Euclidean space $\mathbb{R}^n_{(p,q)}$, obvious conformal transformations are motions from $O(p,q)$, dilations $x\mapsto a\cdot x,(a>0)$, and inversions. But in fact, there are no other ones, according to the theorem of Liouville: Every differentiable conformal transformation of a domain in the (pseudo-)Euclidean space $\mathbb{R}^n_{(p,q)}, n\geqslant 3$, can be expressed as the composition of a motion, a dilation and an inversion. Note that we consider here *global* conformal transformations. For $n=2$, any analytic function defines a local conformal transformation, but for $n\geqslant 3$, every local conformal transformation is the restriction of a global one, so that no ambiguity arises.

Writing now explicitly the infinitesimal generators of such transformations, as first order differential operators, one obtains the Lie algebra of the conformal group of $\mathbb{R}^n_{(p,q)}$, and it is isomorphic to the Lie algebra $\mathfrak{so}(p+1,q+1)$ of the pseudo-orthogonal group $SO_0(p+1,q+1)$. For the Euclidean case $\mathbb{R}^{n-1}$, the conformal group is the Lorentz group $SO_0(n,1)$. Now the sphere S^{n-1}, with its usual metric, is conformally equivalent to the Euclidean space $\mathbb{R}^{n-1}$. The explicit correspondence may be visualized as the stereographic projection from the South Pole to the tangent hyperplane at the North Pole. Therefore S^{n-1} and $\mathbb{R}^{n-1}$ have the same conformal group, that is, $SO_0(n,1)$. This is the group we are looking for. It remains to compute explicitly the action of $SO_0(n,1)$ on the sphere S^{n-1} in order to identify the dilations, and then to choose an appropriate reprepresentation of $SO_0(n,1)$ in $L^2(S^{n-1},d\mu)$.

First we have to parametrize the sphere S^{n-1}. Let $(x_0,x_1,x_2,\ldots,x_n)$ denote the Cartesian coordinates in Minkowski space $\mathbb{R}^{n+1}_{(1,n)}$ on which $SO_0(n,1)$ acts.[31] We choose the poles of the sphere along the x_n-axis, and introduce spherical coordinates by $\omega=(\theta_1,\theta_2,\ldots,\theta_{n-1})\in S^{n-1}$, in the usual way:

$$\begin{aligned} x_1 &= \sin\theta_{n-1}\cdots\sin\theta_2\sin\theta_1,\\ x_2 &= \sin\theta_{n-1}\cdots\sin\theta_2\cos\theta_1,\\ &\cdots\\ x_n &= \cos\theta_{n-1}, \end{aligned} \tag{3.3}$$

with $0\leqslant\theta_1<2\pi, 0\leqslant\theta_2,\ldots,\theta_{n-1}\leqslant\pi$ (the Euler angles). In these coordinates, the normalized $SO(n)$-invariant measure on S^{n-1} reads

$$d\mu(\omega)=\frac{\Gamma(n/2)}{2\pi^{n/2}}\sin\theta_2\sin^2\theta_3\cdots\sin^{n-2}\theta_{n-1}\,d\theta_1\,d\theta_2\cdots d\theta_{n-1}. \tag{3.4}$$

In order to compute the action of $SO_0(n,1)$ on S^{n-1}, we use the Iwasawa decomposition,[29,32] which gives the unique factorization

$$SO_0(n,1)=KAN, \tag{3.5}$$

where $K\sim SO(n)$ is the maximal compact subgroup, corresponding to rotations in the subspace $(x_1,x_2,\ldots,x_n)$; $A\sim SO_0(1,1)\sim\mathbb{R}^+_*\sim\mathbb{R}$ is the one-dimensional subgroup of Lorentz boosts along the x_n-axis; $N\sim\mathbb{R}^{n-1}$ is $(n-1)$-dimensional and Abelian, and corresponds under stereographic projection to translations in the tangent hyperplane at the North Pole.

In the natural $(n+1)\times(n+1)$ matrix representation, an element of A is given as

$$\hat{a}(t)=\begin{pmatrix}\cosh t & 0^t & \sinh t\\ 0 & \mathbb{I}_{n-1} & 0\\ \sinh t & 0^t & \cosh t\end{pmatrix}, \tag{3.6}$$

whereas elements of the subgroup N are indexed by vectors $\xi\in\mathbb{R}^{n-1}$ and read, with $\Delta=\|\xi\|_2^2$,

$$\hat{n}(\xi)=\begin{pmatrix} 1+\frac{\Delta}{2} & \xi^t & -\frac{\Delta}{2} \\ \xi & \mathbb{I}_{n-1} & -\xi \\ \frac{\Delta}{2} & \xi^t & 1-\frac{\Delta}{2} \end{pmatrix}. \tag{3.7}$$

Thus every $g\in \mathrm{SO}_0(n,1)$ can be written uniquely as $g=\gamma a n(\xi), \gamma\in \mathrm{SO}(n), a\in A, n\in N$.

Let M be the centralizer of A in K, that is, $M=\{\gamma\in K:\ \gamma a=a\gamma,\ \forall a\in A\}$ [since $\mathrm{SO}_0(n,1)$ is connected and has finiter center, we take the simpler definition of M[29,32]]. Then $P=MAN$ is a closed subgroup of G, called the minimal parabolic subgroup. In the present case, we see that $M=\mathrm{SO}(n-1)$, corresponding to rotations around the x_n-axis, so that the stability subgroup of the North Pole is precisely P. This subgroup P is not invariant, but $Y=G/P\simeq K/M$, which gives here $Y=\mathrm{SO}_0(n,1)/\mathrm{SO}(n-1)\cdot A\cdot N\simeq S^{n-1}$. This shows that $\mathrm{SO}_0(n,1)$ acts transitively on S^{n-1}. We have identified above $K=\mathrm{SO}(n)$ with motions on S^{n-1} and A with dilations, which constitute our basic operations. Thus the parameter space of our theory is the homogeneous space $X\equiv \mathrm{SO}_0(n,1)/N\simeq \mathrm{SO}(n)\cdot A$.

In the spherical coordinates (3.3), any $\gamma\in \mathrm{SO}(n)$ admits the following Euler decomposition

$$\gamma=m(\psi)u_{n-1}(\theta_{n-1})\cdots u_1(\theta_1), \tag{3.8}$$

where $m(\psi)\in \mathrm{SO}(n-1), \{\theta_1,\ldots,\theta_{n-1}\}$ are the Euler angles on S^{n-1} and $u_j(\theta_j)$ is a rotation in the 2-plane x_j, x_{j+1} (this expression is unique except when θ_j is equal to 0 or π, $3\leqslant j\leqslant n$). For completeness, we write the integration formula on $\mathrm{SO}_0(n,1)$:

$$\int_{\mathrm{SO}_0(n,1)} dg\ f(g)=\int_{\mathrm{SO}(n)} d\mu_n(\gamma)\int_A\int_N dt\ d^{n-1}\xi\ e^{(n-1)t} f(\gamma a(t)n(\xi)), \tag{3.9}$$

where $d\mu_n(\gamma)$ is the invariant measure on $\mathrm{SO}(n)$. In other words, our parameter space $X=\mathrm{SO}_0(n,1)/N\simeq \mathrm{SO}(n)\cdot A$ admits the $\mathrm{SO}_0(n,1)$-invariant measure

$$d\nu(x)=d\mu_n(\gamma)e^{(n-1)t}dt=\frac{d\mu_n(\gamma)da}{a^n}\ (a=e^{-t}, t\in\mathbb{R}). \tag{3.10}$$

We are now in a position to compute the action of $\mathrm{SO}_0(n,1)$ on S^{n-1}, using the Iwasawa decomposition of the latter. Indeed, for $g_0\in \mathrm{SO}_0(n,1)$, we get in this way

$$g_0 g=\gamma_{g_0} a_{g_0} n_{g_0}. \tag{3.11}$$

This induces a homeomorphism on the quotient, indeed the map $\gamma\mapsto\gamma_{g_0}$ does not depend on γ, but rather on its equivalence class in $K/M\simeq S^{n-1}$. In view of the Cartan decomposition $G=KAK$,[29,32] it is enough to show this for elements $g_0\equiv g_0(a)\in A$, since the action of K is trivial. Let us express $\gamma\in \mathrm{SO}(n)$ by its Euler decomposition (3.8), $\gamma=\gamma(\psi,\theta_1,\ldots,\theta_{n-1})$. By definition of $M\sim \mathrm{SO}(n-1)$, g_0 commutes with $m(\psi)$, so that

$$g_0\gamma=m(\psi)g_0 u_{n-1}(\theta_{n-1})\cdots u_1(\theta_1). \tag{3.12}$$

For a pure dilation, $g_0\equiv g_0(a)\in A$, this reduces to

$$g_0\gamma=m(\psi)u_{n-1}((\theta_{n-1})_{g_0})u_{n-2}(\theta_{n-2})\cdots u_1(\theta_1). \tag{3.13}$$

Indeed an explicit calculation shows that the action of a pure dilation on S^{n-1} is given by $\omega=\{\theta_j\}\mapsto\omega_a=\{(\theta_j)_a\}$, where

$$(\theta_j)_a=\theta_j, j=1,\ldots,n-2,$$
$$\tan\frac{(\theta_{n-1})_a}{2}=a\ \tan\frac{\theta_{n-1}}{2}. \tag{3.14}$$

Thus the transformation corresponding to a pure dilation is exactly the usual Euclidean dilation lifted on S^{n-1} by inverse stereographic projection.

IV. THE CONTINUOUS WAVELET TRANSFORM ON S^{n-1}

A. Principal series representations of the Lorentz group $SO_0(n,1)$

We have seen that the parameter space of the CWT on S^{n-1} is $X\equiv \mathrm{SO}_0(n,1)/N\simeq \mathrm{SO}(n)\cdot A$. According to our program, as outlined in Sec. II, the construction of spherical wavelets, that is, affine coherent states on S^{n-1}, proceeds in two steps. First, to select a realization of X by operators acting in the Hilbert space $L^2(S^{n-1},d\mu)$, that will come, of course, from a unitary irreducible representation U of $\mathrm{SO}_0(n,1)$ on the same space. Then to show that U is square integrable on X, that is, modulo N and a suitable section $\sigma: X\to \mathrm{SO}_0(n,1)$.

Let us look first at rotations only. A natural unitary representation of $\mathrm{SO}(n)$ is the quasi-regular representation,

$$(U_{qr}(\gamma)f)(\omega)=f(\gamma^{-1}\omega),\quad \gamma\in \mathrm{SO}(n),\quad f\in L^2(S^{n-1},d\mu). \tag{4.1}$$

U_{qr} is infinite dimensional and decomposes into the direct sum of all the irreducible unitary representations U_l, $l=0,1,2,...$, which are of finite dimension d_l. A convenient orthonormal basis in the d_l-dimensional representation space of U_l is that of the hyperspherical harmonics Y_l^M, where $M\equiv(m_1,m_2,\cdots,m_{n-2})$ runs over the set I_l^n of all integers m_j such that $l\geqslant m_{n-2}\geqslant\cdots\geqslant m_2\geqslant|m_1|\geqslant 0$. Thus the dimension of U_l is

$$d_l=\#I_l^n=\frac{(2l+n-2)(l+n-3)!}{(n-2)!\,l!}, \tag{4.2}$$

which equals $2l+1$ for $n=3$, $(l+1)^2$ for $n=4$, etc.[33,34] For $n=3$, $Y_l^M(\omega)$ reduces to the usual spherical harmonic $Y_l^{m_1}(\theta_2,\theta_1)$, and for $n\geqslant 4$, $Y_l^M(\theta_1,\ldots,\theta_{n-1})$ is the product of $Y_{m_2}^{m_1}(\theta_2,\theta_1)$ and $(n-3)$ factors $(\sin\theta_j)^{n-j}C_{q_j}^{p_j}(\cos\theta_j)$, for $j=3,\ldots,n-1$, where C_q^p is a Gegenbauer polynomial. In these notations, the expansion of an arbitrary function of $L^2(S^{n-1},d\mu)$ in this hyperspherical basis is just Fourier analysis on S^{n-1}:

$$f(\omega)=\sum_{l=0}^{\infty}\sum_{M\in I_l^n}\hat{f}(l,M)Y_l^M(\omega), \tag{4.3}$$

$$\|f\|^2=\sum_{l=0}^{\infty}\sum_{M\in I_l^n}|\hat{f}(l,M)|^2, \tag{4.4}$$

where $\hat{f}(l,M)=\langle Y_l^M|f\rangle$ denotes the Fourier coefficient of f. We will also make use of the familiar transformation formula for spherical harmonics:

$$[U_{qr}(\gamma)Y_l^M](\omega)=Y_l^M(\gamma^{-1}\omega)=\sum_{M'\in I_l^n}\mathcal{D}^l_{MM'}(\gamma)Y_l^{M'}(\omega),\quad \gamma\in \mathrm{SO}(n), \tag{4.5}$$

where $\mathcal{D}^l_{MM'}$ are Wigner D-functions.

In order to incorporate dilations into this scheme, we have to lift U_{qr} from $\mathrm{SO}(n)$ to $\mathrm{SO}_0(n,1)$. However, the measure $d\mu$ is not dilation invariant, so that a Radon-Nikodym derivative or cocycle $\lambda(g,\omega)$ will necessarily creep in, through the relation

$$d\mu(g^{-1}\omega)=\lambda(g,\omega)d\mu(\omega). \tag{4.6}$$

The function $\lambda(g,\omega)$ must satisfy the cocycle equation

$$\lambda(g_1 g_2,\omega)=\lambda(g_1,\omega)\cdot\lambda(g_2,{g_1}^{-1}\omega). \tag{4.7}$$

A good choice is given by the representations of the continuous principal series of $\mathrm{SO}_0(n,1)$. These representations, originally introduced by Harish-Chandra, are studied in detail the mathematical literature.[24,33,34] Among these are the so-called class I representations, for which there exists a vector in the carrier Hilbert space which is invariant under the action of the maximal compact subgroup $\mathrm{SO}(n)$.[32,33] Class I representations are induced by unitary irreducible representations of the minimal parabolic subgroup $P=MAN$, which are trivial on M. They are given by the operators:

$$[U^s(g)f](\omega)=\lambda(g,\omega)^{s/2}\chi(a)f(g^{-1}\omega),\quad g\in\mathrm{SO}_0(n,1),\quad s\in\mathbb{C},\quad f\in L^2(S^{n-1},d\mu), \tag{4.8}$$

where $g=\gamma a n$, the Iwasawa decomposition, χ is a character of A, and $\lambda(g,\omega)$ is a multiplier, satisfying the cocycle equation (4.7). In the sequel we will choose the trivial character $\chi(a)\equiv 1$. The main properties of these principal series representations are summarized by the following theorem.[33,34]

Theorem 4.1: *The representation*

$$[U^s(g)f](\omega)=\lambda(g,\omega)^{s/2}f(g^{-1}\omega), \tag{4.9}$$

is a strongly continuous representation of $\mathrm{SO}_0(n,1)$ *in* $L^2(S^{n-1},d\mu)$. *It is reducible if* $s=0,-1,-2,\ldots$ *and cyclic otherwise. It is unitary and irreducible if and only if* $\mathrm{Re}\ s=(n-1)/2$.

In the following, we will always set $s=(n-1)/2$ and write simply $U\equiv U^{(n-1)/2}$.

As already mentioned, we are only interested in the action of dilations and motions. We thus restrict ourselves to the corresponding homogeneous space $X\simeq\mathrm{SO}(n)\cdot A\equiv\mathrm{SO}_0(n,1)/N$ using a suitable section σ: $X\to\mathrm{SO}_0(n,1)$ in the principal fiber bundle defined by the Iwasawa decomposition. Thus we will concentrate on the reduced expression

$$[U(\sigma(x))f](\omega)=\lambda(\sigma(x),\omega)^{(n-1)/2}f(\sigma(x)^{-1}\omega). \tag{4.10}$$

We write points of the space X as pairs $x\equiv(\gamma,a)$, with $\gamma\in\mathrm{SO}(n)$ and $a\in A\simeq\mathrm{SO}(1,1)$, and choose the natural (Iwasawa) section

$$\sigma_I(\gamma,a)=\gamma a. \tag{4.11}$$

We have already computed the action of dilations in (3.14) and, by $\mathrm{SO}(n)$ invariance, it is easily seen that, with $\omega=(\theta_1,\theta_2,\ldots,\theta_{n-1})$,[35]

$$\lambda(\sigma_I(\gamma,a),\omega)\equiv\lambda(a,\theta_{n-1})=\frac{4a^2}{[(a^2-1)\cdot\cos\ \theta_{n-1}+(a^2+1)]^2}. \tag{4.12}$$

In addition, the choice of the section (4.11) implies

$$U(\sigma_I(\gamma,a))=U(\gamma a)=U(\gamma)U(a),$$

so that the representation (4.10) factorizes as

$$[U(\sigma_I(\gamma,a))f](\omega)=(U_{qr}(\gamma)\circ D^a f)(\omega), \tag{4.13}$$

where $U_{qr}(\gamma),\gamma\in\mathrm{SO}(n)$ is the quasi-regular representation (4.1) of $\mathrm{SO}(n)$ in $L^2(S^{n-1},d\mu)$, and $D^a,a\in\mathbb{R}^+_*$ is a pure dilation, that is

$$(D^a f)(\omega)=\lambda(a,\theta_{n-1})^{(n-1)/4}f(\omega_{1/a}),$$

where we have used the notation of Eqs. (3.14).

B. Lorentz coherent states as wavelets on the sphere S^{n-1}

We are now ready to build a system of coherent states for the Lorentz group, indexed by points of the homogeneous space $X=\mathrm{SO}_0(n,1)/N$. Since N is not the isotropy subgroup of a particular vector in the representation space $L^2(S^{n-1},d\mu)$, the resulting coherent states are not of the Gilmore–Perelomov type.[24]

Following the general approach outlined in Sec. II, the coherent states associated to the representation U are defined, as in (2.4), by the elements of the orbit of η under $\mathrm{SO}_0(n,1)$:

$$\eta_{\sigma(x)}(\omega)=[U(\sigma(x))\,\eta](\omega), \quad x\in X, \tag{4.14}$$

provided $\eta\in L^2(S^{n-1},d\mu)$ is admissible mod(N,σ).

The result is given by the following theorem.

Theorem 4.2: *The representation U of $\mathrm{SO}_0(n,1)$ is square integrable modulo (N,σ_I), that is, there exists a nonzero admissible vector $\eta\in L^2(S^{n-1},d\mu)$, which means that*

$$\frac{1}{d_l}\sum_{M\in I_l^n}\int\frac{da}{a^n}|\hat{\eta}_a(l,M)|^2<\infty, \quad \textit{uniformly in } l, \tag{4.15}$$

where

$$\eta_a(\omega)\equiv(D^a\eta)(\omega)=\lambda(a,\theta_{n-1})^{(n-1)/4}\eta(\omega_{1/a}). \tag{4.16}$$

Proof: Square integrability means there exists a vector $\eta\in L^2(S^{n-1},d\mu)$ such that

$$I=\int_0^\infty\frac{da}{a^n}\int_{\mathrm{SO}(n)}d\mu_n(\gamma)|\langle U(\sigma(\gamma,a))\,\eta|\phi\rangle|^2<\infty, \forall\,\phi\in L^2(S^{n-1},d\mu). \tag{4.17}$$

Using the factorization (4.13), this reduces to

$$I=\int\frac{da}{a^n}\int d\mu_n(\gamma)|\langle U_{qr}(\gamma)\,\eta_a|\phi\rangle|^2<\infty.$$

Expanding both terms in the scalar product in a Fourier series on the sphere and using orthogonality relations for hyperspherical harmonics, we get

$$\begin{aligned}\langle U_{qr}(\gamma)\,\eta_a|\phi\rangle&=\sum_{l,l'=0}^{\infty}\sum_{M,M'\in I_l^n}\overline{[U_{qr}(\gamma)\,\eta_a](l,M)}\,\hat{\phi}(l',M')\int_{S^{n-1}}d\mu(\omega)\overline{Y_l^M(\omega)}Y_{l'}^{M'}(\omega)\\&=\sum_{l=0}^{\infty}\sum_{M\in I_l^n}\overline{\widehat{[U_{qr}(\gamma)\,\eta_a]}(l,M)}\,\hat{\phi}(l,M).\end{aligned}$$

The addition theorem (4.5) gives

$$\widehat{[U_{qr}(\gamma)\,\eta_a]}(l,M)=\sum_{Q\in I_l^n}\mathcal{D}^l_{MQ}(\gamma)\,\hat{\eta}_a(l,Q),$$

and (4.17) becomes

$$I=\int_0^\infty \frac{da}{a^n}\Bigg\{ \sum_{\text{all indices}} \overline{\widehat{\eta_a}(l,Q)}\widehat{\eta_a}(l',Q')\overline{\hat{\phi}(l,M)\hat{\phi}(l',M')} \times \int_{SO(n)} d\mu_n(\gamma)\overline{\mathcal{D}^l_{MQ}(\gamma)}\mathcal{D}^{l'}_{M'Q'}(\gamma)\Bigg\}.$$

With the orthogonality relations for Wigner functions,

$$\int_{SO(n)} d\mu_n(\gamma)\overline{\mathcal{D}^l_{MQ}(\gamma)}\mathcal{D}^{l'}_{M'Q'}(\gamma)=\frac{1}{d_l}\delta_{ll'}\delta_{MM'}\delta_{QQ'},$$

this expression simplifies into

$$\sum_{l=0}^\infty \sum_{M\in I_l^n} |\hat{\phi}(l,M)|^2 \sum_{M'\in I_l^n}\frac{1}{d_l}\int_0^\infty \frac{da}{a^n}|\widehat{\eta_a}(l,M')|^2.$$

Putting

$$S_l=\sum_{M\in I_l^n}|\hat{\phi}(l,M)|^2,$$

$$G_l=\frac{1}{d_l}\sum_{M'\in I_l^n}\int_0^\infty \frac{da}{a^n}|\widehat{\eta_a}(l,M')|^2,$$

we see that $(S_l)\in l^1$, since $\Sigma_{l=0}^\infty |S_l|=\|\phi\|^2$. Then the admissibility condition (4.17) becomes

$$\sum_{l=0}^\infty S_l G_l<\infty, \quad \forall S_l\in l^1.$$

By Köthe duality,[36] this series converges absolutely if and only if $G_l\in l^\infty$. In conclusion, η is admissible if and only if

$$\frac{1}{d_l}\sum_{M\in I_l^n}\int \frac{da}{a^n}|\widehat{\eta_a}(l,M)|^2<c, \quad \text{uniformly in } l,$$

and there are obviously many functions η (in fact a dense set) that satisfy this condition. ■

Notice that, once η is admissible, (4.15) may be written as

$$I=\int_X d\nu(x)|\langle U(\sigma_I(x))\,\eta|\phi\rangle|^2=\int_X d\nu(x)|\langle \eta_{\sigma_I(x)}|\phi\rangle|^2\leqslant c\|\phi\|^2. \tag{4.18}$$

This means that the family $\{\eta_{\sigma_I(x)}, x\in X\}$ is a continuous family of CS, but not necessarily a frame, in the terminology of Sec. II and Ref. 16. For $n=3$ we have shown in Ref. 15 that the family indeed is a frame. The proof presumably extends to higher dimensions, but this remains to be seen. The next step is whether that frame is tight. For this, we would need an equality in (4.18), with $c=c(\eta)$ the analog of the admissibility constant of the vector η. Equivalently, we would need $G_l=G(\eta)$, independently of l, but we have been unable to prove it, even for $n=3$. In fact, we conjecture this is not true, but becomes so only in the Euclidean limit. In that limit indeed, the family $\{\eta_{\sigma_I(x)}, x\in X\}$ converges to the usual tight frame of the flat two-dimensional (2-D) CWT, as shown in Sec. V below.

Theorem 4.2 yields the basic ingredient for writing the CWT on S^{n-1}. Given an admissible vector (mother wavelet) $\psi\in L^2(S^{n-1},d\mu)$, our wavelets on the sphere are the functions $\psi_{\gamma,a}=U(\sigma_I(\gamma,a))\psi$, and the CWT reads, with $U_S(\gamma,a)\equiv U(\sigma_I(\gamma,a))$:

$$S(\gamma,a)=\langle U(\sigma_I(\gamma,a))\psi|s\rangle=\int_{S^{n-1}}d\mu(\omega)\overline{[U_S(\gamma,a)\psi](\omega)}s(\omega)=\int_{S^{n-1}}d\mu(\omega)\overline{\psi_a(\gamma^{-1}\omega)}s(\omega). \tag{4.19}$$

Now the condition (4.15) is necessary and sufficient for the admissibility of η, but it is somewhat complicated to use in practice, since it requires the evaluation of nontrivial Fourier coefficients. Instead, we have derived in our previous paper a simpler, although only necessary, condition.[15] The same condition is valid in the general case.

Proposition 4.3: An admissible vector $\eta\in L^2(S^{n-1},d\mu)$ *necessarily satisfies the condition*

$$\int_{S^{n-1}}d\mu(\omega)\frac{\eta(\omega)}{(1+\cos\ \theta_{n-1})^{(n-1)/2}}=0,\quad \omega=(\theta_1,\theta_2,\ldots,\theta_{n-1}), \tag{4.20}$$

where $d\mu(\omega)$ *is the invariant measure on* S^{n-1} *given in (3.4).*

Proof: The proof is entirely similar to that given for $n=3$ in Ref. 15, so we give only a brief sketch. In order to compute

$$\int_0^\infty\frac{da}{a^n}|\langle Y_l^M|D^a\eta\rangle|^2, \tag{4.21}$$

we choose for η an axisymmetric function, with support bounded away from the South Pole, that is

$$\eta(\omega)\equiv\eta(\theta_{n-1})\ \text{and}\ \eta(\theta_{n-1})=0\ \text{if}\ \theta_{n-1}>\tilde{\theta},\quad \text{for some}\ \tilde{\theta}<\pi.$$

Hence only the $M=0$ term contributes in $\langle Y_l^M|D^a\eta\rangle$. Then we split the integration range in (4.21) into three parts: $[0,\infty)=[0,\epsilon]\cup[\epsilon,1/\epsilon]\cup[1/\epsilon,\infty)$. In the first term, we make the change of variables $\theta'=(\theta_{n-1})_{1/a}$ and use the relation coming from the cocycle equation (4.7), namely

$$\lambda(a^{-1},\theta')\lambda(a,\theta'_a)=1.$$

Then, for $\epsilon\ll 1$, a is very small, since $0\leqslant a\leqslant\epsilon$, and one has

$$\theta'_a\simeq 0\ \text{and}\ \lambda(a^{-1},\theta')\simeq\frac{4a^2}{(1+\cos\ \theta')^2}.$$

Notice that, for large l, one has $Y_l^0(0)\sim l^{-(n-2)/2}$, which exactly compensates the asymptotic behavior $d_l\sim l^{n-2}$ for $l\gg 1$ in (4.15), so that the only divergence can possibly come from the integral over a. But, counting the powers of a from (4.16), we see that a logarithmic divergence remains in the integral over small scales ($a\leqslant\epsilon$), unless we impose the condition (4.20) (of course, the result must be independent of the support of η, so that we have to integrate over the full sphere S^{n-1}).

The second term poses no problem, since the integrand is bounded and continuous on $[\epsilon,1/\epsilon]$. Finally the last term also converges, since the only large scale divergence will never be reached because of the support property of η.

Now, if we drop the restriction on the support of η, the condition (4.20) is *a fortiori* necessary, which proves the statement. ■

This necessary condition is the exact equivalent of the usual necessary condition for Euclidean wavelets, $\int d^{n-1}x\,\psi(x)=0$. Furthermore, it reduces to the latter in the Euclidean limit, as we shall see in Sec. V. The interesting point is that (4.20) is a zero mean condition, as in the flat case. As such it will play the same role, namely it ensures that the CWT on S^{n-1} given in (4.19) acts as a local filter, a property crucial for applications. Thus our spherical CWT will have a comparable behavior. One should notice also that the poles do not play any particular role in this CWT, since the sphere S^{n-1} is a homogeneous space under SO(n): all the points of S^{n-1} are really equivalent, despite the appearance to the contrary given by (4.20). Practical examples given in Ref. 15 illustrate this statement.

One may also wonder what should be added to condition (4.20) to make it also sufficient. By analogy with the limiting flat case,[21] we expect that a slightly faster vanishing at the South Pole will do, but this remains to be proven.

A nice outcome of Proposition 4.3 is that it yields an easy way of building spherical wavelets. Indeed, given a smooth function $\phi \in L^2(S^{n-1}, d\mu)$, we define

$$\eta_\phi(\omega) = \phi(\omega) - \frac{1}{\alpha}(D^\alpha \phi)(\omega) \quad (\alpha > 1).$$

Then it is easily checked that η_ϕ satisfies the zero mean condition (4.20), that is, it is a spherical wavelet, similar to the ''difference wavelets'' commonly used in vision in the case $n=3$ (the DOG wavelet, for instance).[37] We have shown in Ref. 15 a Gaussian spherical wavelet of that kind, which is the inverse stereographic projection of an ordinary Gaussian in the tangent plane.

V. THE EUCLIDEAN LIMIT

According to Holschneider,[14] a good wavelet transform on the sphere should satisfy a geometrical constraint expressing its asymptotic Euclidean behavior. This means that, the sphere being locally flat, the associated wavelet transform should match the usual CWT in the plane at small scales or, what amounts to the same, for large values of the radius of curvature. In this section, we will give a precise mathematical meaning to this statement using the technique of group contractions. The main definitions concerning the latter are collected in the Appendix.

A. Contracting the Lorentz group and its homogeneous spaces

In the first step, we reformulate the theory described so far on a sphere of radius R and let $R \to \infty$. In this limit, the Lorentz group $\mathrm{SO}_0(n,1)$ is contracted along its minimal parabolic subgroup $P = \mathrm{SO}(n) \cdot \mathbb{R}_*^+ \cdot N$ into a semidirect product:

$$G_1 = \mathrm{SO}_0(n,1) \overset{R\to\infty}{\to} G_2 = \mathbb{R}^{n-1} \rtimes \mathrm{SIM}(n-1),$$

where $\mathrm{SIM}(n-1) = \mathbb{R}^{n-1} \rtimes (\mathbb{R}_*^+ \times \mathrm{SO}(n-1))$ is the similitude group of $\mathbb{R}^{n-1}$, that is, the invariance group of the Euclidean CWT. The detailed calculation runs as follows.

1. At the level of Lie algebras

We start with the Lorentz Lie algebra $\mathfrak{g} = \mathfrak{so}(n,1)$ and write its generators as X_{ij}, $0 \leqslant i < j \leqslant n$, with commutation relations

$$[X_{ij}, X_{mn}] = g_{im}X_{jn} - g_{jm}X_{in} - g_{in}X_{jm} + g_{jn}X_{im}, \tag{5.1}$$

where g_{ij} is the metric tensor $\mathrm{diag}(1,-1,\ldots,-1)$. We also write $X_i = X_{0i} - X_{in}$, $i = 1,\ldots,n-1$.

For this Lie algebra, the Cartan and the Iwasawa decomposition read, respectively (vector space direct sums):

$$\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{l} \tag{5.2}$$

$$= \mathfrak{k} \oplus \mathfrak{a} \oplus \mathfrak{n}, \tag{5.3}$$

where $\mathfrak{k} = \mathfrak{so}(n)$ is the maximal compact subalgebra. Let $\mathfrak{p}$ be the minimal parabolic subalgebra, with the decomposition

$$\mathfrak{p} = \mathfrak{m} \oplus \mathfrak{a} \oplus \mathfrak{n},$$

where $\mathfrak{m} = \mathfrak{so}(n-1)$. In terms of the generators X_{ij} of $\mathfrak{so}(n,1)$, we have the following identifications:

$$\begin{aligned} &\mathfrak{k} = \mathrm{span}\{X_{ij},\ 1 \leqslant i < j \leqslant n\} \sim \mathfrak{so}(n), \qquad &&\mathfrak{l} = \mathrm{span}\{X_{0i}, i = 1,\ldots,n\}, \\ &\mathfrak{n} = \mathrm{span}\{X_i, i = 1,\ldots,n-1\} \sim \mathbb{R}^{n-1}, \quad &&\mathfrak{a} = \mathrm{span}\{X_{0n}\} \sim \mathbb{R}. \end{aligned} \tag{5.4}$$

One can check immediately that $\mathfrak{p}$ is isomorphic to $\mathfrak{sim}(n-1)=\mathfrak{so}(n-1)\oplus\mathbb{R}\oplus\mathbb{R}^{n-1}$, the Lie algebra of the similitude group SIM$(n-1)$.

Then we introduce the following contraction scheme

$$X_{ij}\mapsto R^{-1}X_{ij},\quad 1\leqslant i<j\leqslant n-1,$$

$$\phi_R: X_{in}\mapsto X_{in},\quad i=1,\ldots,n-1,$$

$$X_{0i}\mapsto X_{0i},\quad i=1,\ldots,n.$$

This contraction maps $\mathfrak{k}$ to $\mathfrak{e}(n-1)=\mathbb{R}^{n-1}\oplus\mathfrak{so}(n-1)$, the $(n-1)$-dimensional Euclidean algebra and preserves the parabolic subalgebra $\mathfrak{p}$. The contracted algebra is

$$\mathfrak{g}_2=\mathbb{R}^{n-1}\oplus\mathfrak{so}(n-1)\oplus\mathbb{R}\oplus\mathbb{R}^{n-1}. \tag{5.5}$$

Thus $\mathfrak{g}_2$ contains two subalgebras isomorphic to $\mathfrak{sim}(n-1)$. One is $\mathfrak{p}$, which is the sum of the last three terms in (5.5), and the other one corresponds to the sum of the first three terms. We choose the first possibility. In the notation of the Appendix, this gives $\mathfrak{s}=\mathfrak{p}$, which is preserved under the contraction, and $\mathfrak{v}_c=\text{span}\{X_{in}, i=1,\ldots,n-1\}$. Clearly $\{\mathfrak{s},\mathfrak{v}_c\}$ satisfy the commutation relations (A3).

Of course, the decomposition (A3) is not unique. One could have chosen instead for $\mathfrak{s}'$ the other $\mathfrak{sim}(n-1)$ subalgebra, and for $\mathfrak{v}'_c$ the complement, and obtained an isomorphic structure for $\mathfrak{g}_2$, except that $\mathfrak{s}'$ is no more preserved by contraction.

2. At the level of Lie groups

As a consequence, the group contraction procedure maps $G_1=\text{SO}_0(n,1)$ onto the group G_2 associated with $\mathfrak{g}_2$, namely the semidirect product

$$G_2\equiv V_c\rtimes S\equiv\mathbb{R}^{n-1}\rtimes\text{SIM}(n-1).$$

Hence the quotient G_2/V_c is isomorphic to the similitude group SIM$(n-1)$ of $\mathbb{R}^{n-1}$. The contraction preserves the minimal parabolic subgroup $P=MAN$, which is isomorphic to SIM$(n-1)$.

The contracting map $\Pi_R: G_2\to G_1$ is given in (A4). In order to compute it explicitly, we write $v=\Sigma_{i=1}^{n-1}v_iX_{in}\in\mathfrak{v}_c$ and denote by $s=(m(\psi),t,\xi)$ the elements of P, with $m(\psi)\in\text{SO}(n-1)$, $t\in\mathbb{R}$, $\xi\in N\sim\mathbb{R}^{n-1}$. Finally, we rewrite the Euler decomposition (3.8) as $\gamma=m(\psi)u_{n-1}(\theta_{n-1})u^{(n-2)}(\beta)$, with $\beta=(\theta_1,\cdots,\theta_{n-2})\in S^{n-2}$ and $u^{(n-2)}(\beta)=u_{n-2}(\theta_{n-2})\ldots u_1(\theta_1)$. Introducing polar coordinates (r,α) in $\mathbb{R}^{n-1}$, with $\alpha\in S^{n-2}$, we get $v=re_\alpha=ru^{(n-2)}(\alpha)e_0$, where e_α is the unit vector in $\mathbb{R}^{n-1}$ pointing to $\alpha\in S^{n-2}$, and so e_0 corresponds to the North Pole. Denoting by a hat the $(n+1)\times(n+1)$ matrix representation of the respective elements, as in (3.6) and (3.7), and expanding the matrix elements in powers of R^{-1}, the exponential factor in (A4) becomes

$$(\exp_{G_1}R^{-1}v)\hat{}=\begin{pmatrix}1 & 0^t & 0\\ 0 & \mathbb{I}_{n-1} & \dfrac{v}{R}\\ 0 & -\dfrac{v^t}{R} & 1\end{pmatrix}+\mathcal{O}\left(\frac{1}{R^3}\right).$$

Similarly $s=(m(\psi),t,\xi)\in P=MAN$ reads

$$\hat{s}=\hat{m}(\psi)\cdot\hat{a}(t)\cdot\hat{n}(\xi),\quad\text{with}\quad\hat{m}(\psi)=\begin{pmatrix}1 & 0 & 0\\ 0 & m(\psi) & 0\\ 0 & 0 & 1\end{pmatrix}.$$

Combining the two factors, according to (A4), we obtain, in the limit $r\ll R$:

$$\Pi_R(re_\alpha,(m(\psi),t,\xi))=\hat{m}(\psi)\cdot\hat{u}_{n-1}\left(\frac{r}{R}\right)\cdot\hat{u}^{(n-2)}(\alpha)\cdot\hat{a}(t)\cdot\hat{n}(\xi)\quad(r/R\ll 1). \tag{5.6}$$

This calculation shows that, in geometrical terms, the contraction amounts indeed do let the radius of the sphere go to infinity.

3. At the level of homogeneous spaces

The next step is to transfer the contraction process to the relevant homogeneous spaces. On one hand, the manifolds $S^{n-1}=G_1/MAN$ and $\mathbb{R}^{n-1}=G_2/MAN$, that carry the respective CWT, are related through contraction (notice that we use here the isomorphism between the two forms of the contracted group G_2, as discussed above). On the other hand, since the abelian subgroup N is preserved under the contraction, the parameter space $X=\mathrm{SO}_0(n,1)/N$ of the spherical CWT goes into that of the Euclidean CWT, namely $\mathrm{SIM}(n-1)=G_2/N$. Thus the geometrical picture is coherent.

Next, we have to formulate the contraction directly on the parameter spaces, that is, we have to restrict the contraction map (A4) to the respective homogeneous spaces $\mathrm{SIM}(n-1)$ and X. To achieve this, we introduce a section $\tilde{\sigma}:\mathrm{SIM}(n-1)\to N\rtimes\mathrm{SIM}(n-1)$ by the relation:

$$\tilde{\sigma}:(b,(a,m(\psi)))\mapsto(n(b),(b,(a,m(\psi)))), \tag{5.7}$$

$$b\in\mathbb{R}^{n-1},\quad a\in A,\quad m(\psi)\in\mathrm{SO}(n-1),\quad n(b)\in N\sim\mathbb{R}^{n-1}.$$

Combining this with the canonical projection of the Iwasawa bundle,

$$\Gamma:KAN\to X\simeq KA,$$

we may define the restricted contraction map $\tilde{\Pi}_R:\mathrm{SIM}(n-1)\to X$ by

$$\tilde{\Pi}_R(g)=\Gamma(\Pi_R(\tilde{\sigma}(g))),\quad g\in\mathrm{SIM}(n-1), \tag{5.8}$$

where $\Pi_R:G_2\to G_1$ is the contraction map (A4). Altogether we have the following diagram:

$$\begin{array}{ccc} G_2=\mathbb{R}^{n-1}\rtimes\mathrm{SIM}(n-1) & \overset{\Pi_R}{\to} & G_1=\mathrm{SO}_0(n,1) \\ \uparrow\tilde{\sigma} & & \downarrow\Gamma \\ G_2/N\simeq\mathrm{SIM}(n-1) & \overset{\tilde{\Pi}_R}{\to} & \mathrm{SO}_0(n,1)/N=X. \end{array} \tag{5.9}$$

Notice that the parameter space of the spherical CWT is $X=G_1/N\simeq\mathrm{SO}(n)\cdot A$, which is not a group (and this forced us to use the general formalism of Ref. 16). After contraction, we get $G_2/N\simeq\mathrm{SIM}(n-1)$, so that the missing group structure is restored by the contraction.

B. The Euclidean limit of the spherical CWT

Now we are ready to show that the CWT on the sphere S^{n-1} converges to the usual CWT on $\mathbb{R}^{n-1}$ in the geometrical limit of large radius. For that purpose, we have to prove that the associated series of square integrable representations of $\mathrm{SO}_0(n,1)$ modulo N contracts to the usual wavelet representation of $\mathrm{SIM}(n-1)$,[27,28] and then that the admissibility condition on the sphere carries over to that in the flat case. Here we use the precise definition of contraction introduced by Dooley.[38,39] Essentially the same result was obtained earlier by Mickelsson and Niederle.[40]

Let $\mathcal{H}_R=L^2(S_R^{n-1},d\mu_R)$ be the Hilbert space of square integrable functions on a sphere of radius R, with $d\mu_R(\omega)=R^2\,d\mu(\omega)$ and $\mathcal{H}=L^2(\mathbb{R}^{n-1},d^{n-1}x)$. In view of the geometry of the problem, it is clear that the contracting map $I_R:\mathcal{H}_R\to\mathcal{H}$ amounts essentially to a stereographic projection. As before, we write points on the sphere S^{n-1} as pairs (θ_{n-1},β) and introduce polar coordinates (r,β) in $\mathbb{R}^{n-1}$, with $\beta\in S^{n-2}$. Then, with a suitable convergence factor, we obtain an isometry $I_R:\mathcal{H}_R\to\mathcal{H}$, namely

$$(I_R f)(r,\beta)=\left(\frac{4R^2}{4R^2+r^2}\right)^{(n-1)/2} f\left(2\ \arctan\frac{r}{2R},\beta\right). \tag{5.10}$$

One checks indeed that $\|I_R f\|_{\mathcal{H}}=\|f\|_{\mathcal{H}_R}$, so that injectivity of I_R is ensured. The inverse map reads

$$(I_R^{-1} f)(\theta_{n-1},\beta)=\left(\frac{2}{1+\cos\theta_{n-1}}\right)^{(n-1)/2} f\left(2R\ \tan\frac{\theta_{n-1}}{2},\beta\right), \tag{5.11}$$

and a closer inspection shows that it is also an isometry. Thus I_R is unitary.

For each R, we choose $\mathcal{D}_R=\mathcal{D}=\mathcal{C}_0(\mathbb{R}^{n-1})$, the space of continuous functions of compact support, which is dense in $\mathcal{H}$. Now let U be usual wavelet representation of SIM$(n-1)$ in $\mathcal{H}$ and U_R the representation (4.10) of $\mathrm{SO}_0(n,1)$ realized in $\mathcal{H}_R$.

Theorem 5.4 (Euclidean limit): *The representation U of* SIM$(n-1)$ *is a contraction of the family of representations U_R of* $\mathrm{SO}_0(n,1)$ *as* $R\to\infty$.

Proof: For every $g\in\mathrm{SIM}(n-1)$, we have to verify the strong limit

$$\lim_{R\to\infty}\|I_R U_R(\tilde{\Pi}_R(g))I_R^{-1}\phi-U(g)\phi\|_{\mathcal{H}}=0. \tag{5.12}$$

We look first at pointwise convergence. The subgroups A and $M=\mathrm{SO}(n-1)$ are preserved by contraction, and it is easily seen that the associated operators commute with I_R. Thus it is enough to consider elements $g=(re_\alpha,(t,m(\psi)))\in\mathrm{SIM}(n-1)=\mathbb{R}^{n-1}\rtimes(\mathbb{R}\times\mathrm{SO}(n-1))$ of the form $g=(re_0,(0,\mathbb{I}))$, that is, $\alpha=0,t=0,\psi=0$. Then, according to (5.6) and (5.8), one has

$$\tilde{\Pi}_R(g)=\hat{u}\left(\frac{r}{R}\right),$$

from which one readily checks that, pointwise,

$$\lim_{R\to\infty}|I_R U_R(\tilde{\Pi}_R(g))I_R^{-1}\phi-U(g)\phi|=0.$$

Next, since I_R^{-1} is a unitary operator, we can compute the strong limit in $\mathcal{H}_R$. Define, for $\phi\in\mathcal{D}, C=\max_{x\in\mathbb{R}^{n-1}}\phi(x)$. Then, using the relation (5.11), we obtain the following bound, for all $\phi\in\mathcal{D}$, uniformly in $R\geqslant 1$:

$$\begin{aligned}|U_R(\tilde{\Pi}_R(g))I_R^{-1}\phi-I_R^{-1}U(g)\phi|&<|U_R(\tilde{\Pi}_R(g))I_R^{-1}\phi|+|I_R^{-1}U(g)\phi|\\&<2C\cdot\max\left(1+\tan^2\frac{\theta}{2}\right)^{(n-1)/2},\end{aligned}$$

where the maximum is taken over all θ such that $(2R\ \tan(\theta/2),\beta)\in\mathrm{supp}\ \phi$. Finally Lebesgue's dominated convergence theorem gives the result. ■

This theorem yields the expected result that local wavelet analysis on the sphere, as defined here, is equivalent to local wavelet analysis in flat space. Indeed the whole structure on the sphere S_R^{n-1} goes into the corresponding one in $\mathbb{R}^{n-1}$ as $R\to\infty$. In particular, since $U_R\to U$, the corresponding matrix elements also converge to one another, and therefore the square integrability condition (4.15) converges into the corresponding one for the CWT in $\mathbb{R}^{n-1}$,

$$\int_{\mathbb{R}^{n-1}} d^{n-1}k\frac{|\hat{\psi}(k)|^2}{|k|^{n-1}}<\infty.$$

Admissible wavelets on S^{n-1} converge to admissible wavelets on $\mathbb{R}^{n-1}$. Also, because the renormalizing factor in (5.11) is exactly the one that links the two invariant measures under stereographic projection, it follows that the necessary condition (4.20) also goes into the corresponding necessary condition for wavelets in the plane, $\int d^{n-1}x\,\psi(x)=0$.

VI. EXTENSION TO OTHER MANIFOLDS

Although the spheres S^{n-1}, and in particular S^2, are the manifolds on which a wavelet transform is most desirable for applications, the mathematical analysis made so far invites us to consider other manifolds with similar geometrical properties, and first other Riemannian symmetric spaces of constant curvature. In order to understand better the problems involved in the extension of the preceding construction, we will look first at the case $n=3$.

A. The two-dimensional hyperbolic space

Let us go back to the sphere S^2. In this case, the stereographic projection from the South Pole to the plane tangent at the North Pole is a bijection $\Phi: S^2 \to \mathbb{C} \cup \{\infty\}$, given by

$$\Phi(\omega) \equiv \zeta = 2 \tan \frac{\theta}{2} e^{i\varphi}, \ \omega \equiv (\theta, \varphi); \ 0 \leqslant \theta \leqslant \pi, \ 0 \leqslant \varphi < 2\pi$$

(here S^2 is taken as the Riemann sphere and the tangent plane at the North Pole as the complex plane $\mathbb{C}$; the extra factor 2 is due to our choice of the tangent plane rather than the equatorial one[30]). Then a dilation $\zeta \mapsto a\zeta$ in $\mathbb{C}$ corresponds to the mapping $\theta \mapsto \theta_a$ on S^2, where $\tan(\theta_a/2) = a \tan(\theta/2)$ [compare Eq. (3.14)]. The conformal factor linking the two metrics on S^2 and in the plane is

$$h(r) = \frac{2}{1+(r/2)^2} = 1 + \cos \theta, \quad r = |\zeta|.$$

Now $S^2 = \mathrm{SO}(3)/\mathrm{SO}(2)$ is a compact Riemannian symmetric space of constant curvature $\kappa = 1$, and it has a noncompact dual, $H^2 = \mathrm{SO}_0(2,1)/\mathrm{SO}(2)$, of constant curvature $\kappa = -1$.[29] H^2 is a two-sheeted hyperboloid, of equation $-x_1^2 - x_2^2 + x_3^2 = 1$, symmetric around the x_3-axis. Duality corresponds to the fact that $\mathrm{SO}(3)$ and $\mathrm{SO}_0(2,1)$ are the two real forms of the complex group $\mathrm{SO}(3)^{\mathbb{C}} \sim \mathrm{SL}(2,\mathbb{C})$.

As for the sphere, we can perform the stereographic projection Φ from the South Pole ($x_1 = x_2 = 0, x_3 = -1$) onto the equatorial plane $x_3 = 0$. Then Φ maps the upper sheet H_+^2 onto the interior $\mathcal{D}_+$ of the unit disk, and the lower sheet H_-^2 onto the exterior. The domain $\mathcal{D}_+$ is called the Lobachewskian disk.[41] Introducing hyperbolic coordinates on H_+^2,

$$\begin{aligned} x_1 &= \sinh \chi \cos \varphi, \\ x_2 &= \sinh \chi \sin \varphi \quad (\chi \in \mathbb{R}, 0 \leqslant \varphi < 2\pi), \\ x_3 &= \cosh \chi \end{aligned} \tag{6.1}$$

which give the metric $ds^2 = d\chi^2 + \sinh^2 \chi \, d\varphi^2$, one obtains for a point $\zeta \in \mathcal{D}_+$ (see Fig. 1):

$$\zeta = \tanh \frac{\chi}{2} e^{i\varphi}.$$

The Lobachewskian metric on $\mathcal{D}_+$ is ($\zeta = u + iv$):

$$dl^2 = \frac{4}{[1-(u^2+v^2)]^2}(du^2 + dv^2) = d\chi^2 + \sinh^2 \chi \, d\varphi^2.$$

This shows that $\mathcal{D}_+$ is conformally equivalent to H_+^2, with conformal factor $h(r) = 2/(1-r^2)$, where $r^2 = (u^2+v^2)$. For both manifolds, the isometry group is $\mathrm{SO}_0(2,1)$.

What about dilations? One way to identify them is to consider the Poincaré half-plane realization of the Lobachewski space,[41] $H_+ = \{z \in \mathbb{C}, \mathrm{Im}\, z > 0\}$, which corresponds to $\mathcal{D}_+$ via the Cayley transform, also a conformal map:

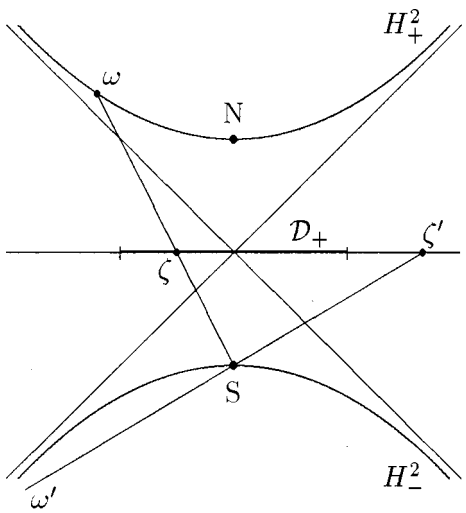

FIG. 1. Stereographic projection from the upper sheet H_+^2 of the hyperboloid onto the interior $\mathcal{D}_+$ of the unit disk.

$$H_+ \ni z \mapsto \zeta = -\frac{z-i}{z+i} \in \mathcal{D}_+ .$$

If one introduces in H_+ geodesic polar coordinates $z=(\chi,\varphi)$, it turns out the curves $\varphi=\text{const}$, which are geodesics, are half-circles centered on the real axis, thus orthogonal to it. In particular, χ is the Poincaré distance between z and i, measured along the geodesic that links the two points. In these coordinates, the Cayley transform reads

$$z=(\chi,\varphi) \mapsto \zeta = \tanh\frac{\chi}{2} e^{i\varphi} \in \mathcal{D}_+ .$$

In particular the point $z=i \in H_+$ goes into $\zeta=0$, and all the geodesics through i go into the diameters of $\mathcal{D}_+$. As for isometries, those of H_+ are matrices from $\mathrm{SL}(2,\mathbb{R})$, acting by homographic transformation, and they correspond to the similar action of SU(1,1) on $\mathcal{D}_+$. In the two cases, there is a simple transitive action of $\mathrm{SL}(2,\mathbb{R})/Z_2$, resp. $\mathrm{SU}(1,1)/Z_2$, both isomorphic to $\mathrm{SO}_0(2,1)$, as expected. In $\mathcal{D}_+$, a dilation should be radial, and leave both $\zeta=0$ and $\zeta=1$ invariant, but there is no such element in SU(1,1). As a way out, we may use as a natural notion of dilation in H_+ the map $\chi \mapsto a\chi, 0<a<\infty$. In $\mathcal{D}_+$, the corresponding map leads to

$$\zeta \mapsto \zeta_a = \tanh\frac{a\chi}{2} e^{i\varphi},$$

which then lifts to H_+^2 by inverse stereographic projection. This map has all the required properties for a dilation, but does not come directly from a linear group action. Thus it can only be used for constructing wavelets on H_+^2 if one puts it by hand, in the same way as Holschneider did for S^2.[14] Of course, it remains to obtain a suitable representation of the resulting set $\mathrm{SO}_0(2,1)\cdot\mathbb{R}_*^+$ in $L^2(H_+^2, d\mu)$, where $d\mu$ is the $\mathrm{SO}_0(2,1)$-invariant measure, and to show that it is square integrable in a suitable sense.

An alternative way of introducing dilations via a group action is based on analytic continuation from the spherical case, that is, using the familiar Weyl trick. We start from the Lie algebra $\mathfrak{so}(3,1)$, with commutation relations (5.1) and Iwasawa decomposition (5.3), for $n=3$. The duality $\mathfrak{so}(3) \mapsto \mathfrak{so}(2,1)$ results from Weyl's unitary trick applied to the compact subalgebra $\mathfrak{k}$:

$$\mathfrak{k} = \mathfrak{m} \oplus \mathfrak{r} \mapsto \mathfrak{k}^* = \mathfrak{m} \oplus i\mathfrak{r},$$

with $\mathfrak{m}=\mathrm{span}\{X_{12}\}$ and $\mathfrak{r}=\mathrm{span}\{X_{13},X_{23}\}$. Define the new generators as $\overline{X_{13}=iX_{13}}$, $\overline{X_{23}=iX_{23}}$. Then do the same for $\mathfrak{n} \mapsto \mathfrak{n}^* = \mathrm{span}\{\overline{X_1,X_2}\}$, $\overline{X_j=iX_j}$. This yields the decomposition

$$\mathfrak{g}^* = \mathfrak{k}^* \oplus \mathfrak{a} \oplus \mathfrak{n}^*, \tag{6.2}$$

and an explicit calculation shows that $\mathfrak{g}^* \sim \mathfrak{so}(1,3)$, that is, the original metric $(+---)$ associated to $\mathfrak{so}(3,1)$ is transformed into $(---+)$. Then $\mathfrak{k}^* = \text{span}\{X_{12}, \overline{X_{13}, X_{23}}\} \sim \mathfrak{so}(1,2)$ and we obtain the pseudo-Iwasawa decomposition

$$G^* = \mathrm{SO}_0(1,3) = \mathrm{SO}_0(1,2) \cdot A \cdot N^*.$$

The Lorentz boosts along H^2_+ are generated by $\overline{X_{13}, X_{23}}$. Hence the subgroup $A \sim \exp tX_{03}$, $t \in \mathbb{R}$, represents dilations, which commute with the subgroup $\mathrm{SO}(2)$ of rotations around the x_3-axis.

The next step is to compute the action of G^* on H^2_+. This may be done, as in the spherical case, using the Euler decomposition (3.8) of $\gamma^* \in \mathrm{SO}_0(1,2)$, corresponding to the hyperbolic coordinates (6.1):

$$\gamma^* = m(\psi) u^*(\chi) u(\varphi), \text{with } m(\psi), u(\varphi) \in \mathrm{SO}(2),\ u^*(\chi) \in \mathrm{SO}_0(1,1).$$

Then, as in Eqs. (3.12) and (3.13), we get:

$$g_0(a)\, \gamma^* = m(\psi) u^*(\chi_a) u(\varphi),$$

where the transformation $\chi \mapsto \chi_a$ may be obtained by a direct calculation.

At this stage, two questions remain to be answered:

(1) Does one have a unitary irreducible representation U of $\mathrm{SO}_0(1,3)$ in $L^2(H^2_+, d\mu)$? As in the spherical case, U should reduce to the quasi-regular representation of $\mathrm{SO}_0(1,2)$ upon restriction to the latter.
(2) Is the representation U, if any, square integrable modulo N^* and a suitable section?

We conjecture that the answer to both questions is positive, which would then yield the CWT on H^2_+. Work in this direction is in progress.

B. Higher dimensional Riemannian symmetric spaces

In higher dimensions, the situation is exactly the same:

$$S^{n-1} = \mathrm{SO}(n)/\mathrm{SO}(n-1) \quad \text{and } H^{n-1} = \mathrm{SO}_0(n-1,1)/\mathrm{SO}(n-1)$$

are dual Riemannian symmetric spaces, with constant curvature $\kappa = \pm 1$, respectively. Again $\mathrm{SO}(n)$ and $\mathrm{SO}_0(n,1)$ are two real forms of the complexified group $\mathrm{SO}(n)^{\mathbb{C}}$.

For the hyperbolic space H^{n-1}, the extension from $n=3$ to arbitrary $n>3$ proceeds exactly as for the spheres, in the way described in the previous section. For instance, stereographic projection $\omega \mapsto \zeta$ from the South Pole maps H^n_+ onto the interior of the unit ball of the equatorial hyperplane, and the two are conformally equivalent when the latter is equipped with the Lobachewskian metric. The reason is that the additional dimensions are compactified, so that nothing essential changes, in particular with respect to square integrability.

The same comment applies to the construction of dilations via the Weyl trick. The metric $(+-\cdots--)$ associated to $\mathfrak{so}(n,1)$ is transformed into $(--\cdots-+)$, and $\mathrm{SO}_0(1,n-1)$ is embedded into $\mathrm{SO}_0(1,n)$. This behavior is illustrated by comparing the present paper with the corresponding one for $n=3$.[15]

In addition, there are now additional noncompact real forms $\mathrm{SO}_0(p,q), p+q=n$, leading to pseudo-Riemannian symmetric spaces $H^{p,q} = \mathrm{SO}_0(p,q)/(\mathrm{SO}(p) \times \mathrm{SO}(q))$. These are homogeneous spaces of higher rank, and few explicit results are available.

How can one extend this machinery to other manifolds? In the case of the sphere S^{n-1}, the conformal group $\mathrm{SO}_0(n,1)$ is larger than the motion group $\mathrm{SO}(n)$, and thus could be used for incorporating dilations. But the sphere is the only compact manifold with that property. In the general case, an alternative way to proceed is to embed the motion group G of the manifold into the complexified group $G^{\mathbb{C}}$ in order to define dilations. This has been done for S^2, in fact, since $\mathrm{SO}(3)^{\mathbb{C}} \sim \mathrm{SL}(2,\mathbb{C})$, that is, the Lorentz group serves both as the conformal group of S^2 and as

complexification of its motion group. This remark may open the way to future extension of wavelets to higher dimensional manifolds. In particular, it could be interesting to consider the case of nontrivial phase spaces. Indeed, the sphere S^2 is the phase space of a rotator, and serves as parameter space for coherent states on SO(3). Other systems exist with ''exotic'' phase spaces, such as a torus $SO(2)\times SO(2)$ and similar manifolds.[42]

Another direction that looks promising is to consider the wavelet problem in the general framework of representation theory of semisimple groups. Let G be a noncompact connected semisimple Lie group, containing subgroups that can be interpreted as motions and dilations of a certain manifold Y. The existence of wavelets associated to G amounts to find an isometry from $L^2(X)$ to $L^2(Y)$, where X is either a subgroup G_0 of G or a quotient $X=G/H$. In the first case, the central tool is a square integrable or discrete series representation of G_0; in the second one, a representation of the relative discrete series of X. At this stage, no general theory is available, but results have been obtained in a number of cases:

(i) Let $G=KAN$ as before, with minimal parabolic subgroup $P=MAN$ and let $\overline{N}=\theta(N)$, where θ is the Cartan involution of G.[29,32] In this case, under specific conditions that involve only $\overline{N}$, a wavelet transform exists for any measurable subset S of MA, with $X=\overline{N}\times S$ and U a principal series representation of G (induced by P), acting in $L^2(\overline{N})$.[43]

(ii) A special case of the previous example is that of $G=SL(n+2,\mathbb{R})$, with $X=\overline{N}\times A_1\simeq H_n\times\mathbb{R}$, where H_n is the Weyl–Heisenberg group and $A_1\subset A$. Here also $Y=\overline{N}\simeq H_n$.[44]

(iii) Other wavelets on H_n have been obtained using closed subgroups of $SU(n+1,1)$, either the affine Weyl–Heisenberg group,[45] or the minimal parabolic subgroup P.[46] More precisely, let $U^{n+1}=\{(z,z_{n+1})\in\mathbb{C}^{n+1}:\text{Im } z_{n+1}>|z|^2\}$ be the Siegel upper half-plane. Then H_n is the boundary of U^{n+1} and P may be considered as the affine automorphism group of U^{n+1}, in the sense that it consists of operations that may be interpreted as translations, dilations and rotations on U^{n+1}. Here again P has a natural unitary representation in $L^2(H_n)$, which decomposes into a direct sum of square integrable representations, each of which thus generates a wavelet transform on H_n (one recovers the case of the affine Weyl–Heisenberg group simply by ignoring the rotations).

(iv) The previous result extends to the group of real symmetric matrices.[47] Let $\mathcal{H}_n=\{z=x+iy\in\mathbb{C}^{n\times n},\ z^t=z,y \text{ real and positive definite}\}$ be the tube domain over the cone of real positive $n\times n$ symmetric matrices, and B its Shilov boundary, that is, the space of $n\times n$ real symmetric matrices. The symplectic group $Sp(n,\mathbb{R})$ acts on $\mathcal{H}_n$, and it contains two automorphism groups of B, called P_0 and P. The elements of P_0 may be identified with translations and dilations, while P contains in addition rotations from $SO(n)$. Both P_0 and P have UIRs on $L^2(B)$, which are square integrable, and B essentially reduces to the nilpotent component in the Iwasawa decomposition of $Sp(n,\mathbb{R})$. Thus we are in a situation very similar to the previous one.

In all those examples, one gets a wavelet transform, either on the Weyl–Heisenberg group H_n, or on the space of real symmetric matrices, starting from various transitive group actions. According to the criteria stated in Sec. I, we ought to ask the question of the Euclidean limit. Formally, in the case where $X=G/K\simeq AN$, one recovers the Euclidean CWT by letting ρ, half the sum of the positive restricted roots of $\mathfrak{g}$, go to 0. However, it remains to be seen whether this limit can be given a rigorous meaning, in particular whether it can be interpreted in terms of group contraction. Should this be true, we would have a whole family of CWTs on nontrivial manifolds.

VII. CONCLUSION

The construction presented here fulfills all the requirements stated in the Introduction for a continuous wavelet transform on the sphere. It is entirely derived from group theory, following the formalism of general coherent states developed in Ref. 16. In addition, the Euclidean limit is valid, with a precise group-theoretical formulation. Thus the formula (4.19) yields a genuine CWT on the sphere, which has none of the defects of the other versions mentioned in the Introduction. Preliminary tests in the case $n=3$ are encouraging, although there remain computational problems, because the formula (4.19) requires a pointwise convolution on the sphere, which is very

time consuming. The construction extends to higher dimensional spheres in a straightforward way, with the same advantages and the same limitations. As for other manifolds, typically Riemannian symmetric spaces of noncompact type, the geometrical picture is similar, but it is not obvious how to define appropriate dilations by a pure group action, through the embedding of the motion group into a larger group, such as the conformal group of the manifold, if it is larger, or the complexified group.

APPENDIX CONTRACTIONS OF LIE GROUPS AND LIE ALGEBRAS

1. Contraction of Lie algebras and Lie groups

We begin by recalling some basic facts concerning the process of contraction, both for Lie algebras and Lie groups. Let $\mathfrak{g}_1=(V,[.,.]_1)$ and $\mathfrak{g}_2=(V,[.,.]_2)$ be two Lie algebras on the same vector space V. We say that $\mathfrak{g}_2$ is a *contraction* of $\mathfrak{g}_1$ if there exists a one parameter family of invertible linear mappings $\phi_R, R\in[1,\infty)$, from V to V such that

$$\lim_{R\to\infty} \phi_R^{-1}[\phi_R X,\phi_R Y]_1=[X,Y]_2, \quad \forall X,Y\in V. \tag{A1}$$

The limit (A1) defines a new Lie algebra structure on V, which is not isomorphic to the original one. In the case of a Inönü–Wigner contraction,[17] a particular subalgebra of $\mathfrak{g}_1$ is conserved throughout the process. More precisely, suppose there exists a subalgebra $\mathfrak{s}$ in $\mathfrak{g}_1$ and a vector subspace $\mathfrak{v}_c$, complement of $\mathfrak{s}$ in $\mathfrak{g}_1$, that is

$$\mathfrak{g}_1=\mathfrak{s}+\mathfrak{v}_c, \tag{A2}$$

such that

$$[\mathfrak{s},\mathfrak{s}]_2\subset\mathfrak{s}, \quad [\mathfrak{v}_c,\mathfrak{v}_c]_2=0, \quad [\mathfrak{s},\mathfrak{v}_c]\subset\mathfrak{v}_c. \tag{A3}$$

Using (A2) we can decompose any $X\in V$ as

$$X=X_{\mathfrak{s}}+X_c, \quad X_{\mathfrak{s}}\in\mathfrak{s}, \quad X_c\in\mathfrak{v}_c,$$

and define the contracting mappings

$$\phi_R(X)=X_{\mathfrak{s}}+\frac{1}{R}X_c.$$

Then applying (A1) does not affect the subalgebra $\mathfrak{s}$. We say in this case that we have a contraction of $\mathfrak{g}_1$ along $\mathfrak{s}$.

The contraction process may be lifted to the corresponding Lie groups.[38,39] Let again $\mathfrak{g}_1$ and $\mathfrak{g}_2$ be two Lie algebras such that $\mathfrak{g}_2$ is a contraction of $\mathfrak{g}_1$. Let G_1 be the simply connected Lie group with Lie algebra $\mathfrak{g}_1$. Let S be the subgroup of G_1 whose Lie algebra is $\mathfrak{s}$ in the decomposition (A2). Defining the semidirect product

$$G_2\equiv V_c\rtimes S, \quad V_c=\exp\,\mathfrak{v}_c\simeq\mathfrak{v}_c,$$

one easily checks that $\mathfrak{g}_2=(V,[.,.]_2)$ is the Lie algebra of G_2. Consider now the family of maps $\Pi_R: G_2\to G_1$ given by

$$\Pi_R:(v,s)\mapsto(\exp_{G_1} R^{-1}v)\cdot s. \tag{A4}$$

They play essentially the same role as the maps ϕ_R of (A1) at the level of the corresponding groups, namely:

$$\lim_{R\to\infty} \Pi_R^{-1}(\Pi_R(g)\overset{1}{\circ}\Pi_R(g'))=g\overset{2}{\circ}g', \forall g,g'\in G_2, \tag{A5}$$

where $\circ_1$, $\circ_2$ denote the product in G_1, G_2, respectively. Indeed one easily checks that $T_e\Pi_R = \phi_R$, where $T_e\Pi_R$ is the derivative of Π_R evaluated at the neutral element of G_1. It is easily seen on (A4) that the subgroup S is preserved during the contraction.

2. Contraction of Lie group representations

Whereas contractions of Lie algebras and Lie groups are relatively ancient and well-known,[17,18] the extension of the procedure to group representations is rather recent.[40] A rigorous version has been given by Dooley,[38,39] which we follow. The additional difficulty here is that the representation space itself varies during the procedure.

Let G_2 be a contraction of G_1, defined by the contraction map $\Pi_R: G_2 \to G_1$ and let U be a representation of G_2 in a Hilbert space $\mathcal{H}$. Suppose that, for each $R \in [1,\infty)$, we have a representation $\{\mathcal{H}_R, U_R\}$ of G_1, a dense subspace $\mathcal{D}_R$ of $\mathcal{H}$ and a linear injective map $I_R: \mathcal{H}_R \to \mathcal{D}_R$. Then one says that the representation U of G_2 is a contraction of the family of representations $\{U_R\}$ of G_1 if there exists a dense subspace $\mathcal{D}$ of $\mathcal{H}$ such that, for all $\phi \in \mathcal{D}$ and $g \in G_2$, one has: (i) for every R large enough, $\phi \in \mathcal{D}_R$ and $U_R(\Pi_R(g)) I_R^{-1}\phi \in I_R^{-1}(\mathcal{D}_R)$, (ii) $\lim_{R\to\infty} \| I_R U_R(\Pi_R g) I_R^{-1}\phi - U(g)\phi\|_{\mathcal{H}} = 0$.

ACKNOWLEDGMENTS

During the preparation of this work, we benefited from illuminating discussions with Bruno Torrésani, Peter Maass, Matthias Holschneider, Jean-Pierre Gazeau and many others. It is a pleasure to thank them all. In addition, we want to thank one of the anonymous referees for his thorough reading and his constructive suggestions. In this paper we consider a weighted trace formula for Schrödinger operators. More precisely, let $\psi_j^\hbar$ and $E_j^\hbar$ denote the eigenfunctions and eigenvalues of a Schrödinger-type operator $H_\hbar$ with a discrete spectrum. Let $\psi_{(x,\xi)}$ be a coherent state centered at a point (x,ξ) of a hyperbolic closed orbit γ. We show that, as $\hbar\to 0$, the leading term of $\Sigma_j \varphi\{[E_j(\hbar)-E]/\hbar\}|(\psi_{(x,\xi)},\psi_j^\hbar)|^2$ can be expressed in terms of the analytic continuation on the upper and lower half-planes of the positive and negative frequencies part of φ. The result is also related to complex trajectories surrounding γ. © *1998 American Institute of Physics.* [S0022-2488(98)01908-2]

I. INTRODUCTION

Consider a Schrödinger operator $H=-\hbar^2\Delta+V(x)$ with V smooth, on $\mathbb{R}^n$ (in which case we assume V tends to infinity at infinity and therefore H has a discrete spectrum) or on a compact Riemannian manifold, M.

The trace (Gutzwiller) formula (Ref. 1) expresses the smeared out spectral density over a Fourier compactly supported test function: let $\{E_j\}$ and $\{\varphi_j\}$ be the eigenvalues and eigenfunctions of H. Then, under certain hypothesis on the classical flow (for example, that the periodic trajectories of energy E are isolated),

$$\sum_j \varphi\left(\frac{E_j-E}{\hbar}\right)\sim\sum_{k=0}^{\infty} c_k(\varphi)\hbar^{-n+1+k}+\sum_{\gamma}\sum_{l=0}^{\infty} d_\gamma^l(\varphi)\hbar^l, \tag{1}$$

where c_k are distributions whose Fourier transform are supported on 0, the second sum is over the periodic trajectories γ of energy E, and d_γ^l have Fourier transforms supported on the set of periods of γ.

We remarked in Ref. 2 that one can isolate the contribution of a given periodic trajectory by ponderating the sum (1) by the so-called Husimi function of φ_j: let $\psi_{(x,\xi)}^a$ be a coherent state at $(x,\xi)\in\mathbb{R}^{2n}$ of ''vacuum'' $a\in\mathcal{S}(\mathbb{R}^n)$:

$$\psi_{(x,\xi)}^a(y)=\rho(y-x)(2\pi\hbar)^{-3n/4}2^{-n/4}e^{-ix\xi/2\hbar}e^{i\xi y/\hbar}a\left(\frac{y-x}{\sqrt{\hbar}}\right) \tag{2}$$

(here ρ is a compactly supported C^∞ function equal to 1 near zero). Let $(x,\xi)\in\gamma$, where γ is a periodic trajectory of the classical underlying flow of energy $E:=\xi^2+V(x)$. We showed that

$$\sum \varphi\left(\frac{E_j-E}{\hbar}\right)|(\psi_{(x,\xi)}^a,\varphi_j)|^2\sim\sum_{k=0}^{\infty}\nu_k(\varphi)\hbar^{-n+1/2+k}, \tag{3}$$

where the ν_k are distributions whose Fourier transforms are supported on the set of periods of (iterates of) γ.

[a)]Electronic mail: paulth@zin.ceremade.dauphine.fr

 © 1998 American Institute of Physics

Let us suppose for simplicity that the dimension $n=2$ (the results being immediately extended to the general case). We remarked in Ref. 2 that if γ is *elliptic*, i.e., if the Poincaré mapping of γ is a rotation of angle θ, the distribution ν_0 could be expressed as a Dirac measure on the energies of the quasimodes associated to γ:

$$\nu_0(\varphi)=\sum_{j,k\in\mathbb{Z}} c_k\varphi\left(\frac{1}{T_\gamma}\left(2\pi j+\left(k+\frac{1}{2}\right)\theta+\frac{S_\gamma}{\hbar}+\sigma_\gamma\right)\right) \tag{4}$$

(here T_γ, S_γ, and σ_γ are the period, action, and Maslov index of γ). On the contrary, if γ is *hyperbolic* the measure ν_0 is Lebesgue continuous.

In this paper we want to give another formulation of ν_0 that involves the complex trajectories of the linearized near γ, i.e., the complex trajectories infinitesimally close to γ (see Theorem 2.1 below). Before we state the results we would like to comment on the role of complex periodic trajectories in the study of the semiclassical spectrum of Schrödinger operators.

Usually the complex trajectories appear to give exponential corrections to the semiclassical expansions. Among the works dedicated to this problem let us mention the work of Balian and Bloch on the trace formula;[3] the resurgence method of Ecalle and Voros;[4–6] and more recently, the work by Fefferman and Secco[7] on the correction term of the number of negative eigenvalues of atomic systems.

More recently, Delande *et al.*[8] and Eckhardt *et al.*,[9] discussed the trace formula for a mapping depending of a parameter near a bifurcation.

A formal computation of the contribution of a given hyperbolic trajectory to the trace formula was given in Ref. 10, where it was remarked, however, that the contribution of different periodic trajectories should interfere destructively. The use of coherent states in the present paper will isolate a given trajectory by microlocalizing near a point in phase space. This makes only one trajectory contributing and the complexified linearized flow near this trajectory present already at the leading order.

The paper is organized as follows: the results are presented in the next section and proven in Sec. III. Section IV contains some concluding remarks.

II. THE RESULTS

Let H be as in the Introduction. Let γ be a hyperbolic closed trajectory of the Hamiltonian $\xi^2+V(x)$. Let μ be the Lyapounov exponent at $(x,\xi)\in\gamma$ [that is, let $e^{\pm\mu}$ be the two eigenvalues of the Poincaré mapping of γ at (x,ξ)] and $\varphi\in\mathscr{S}(\mathbb{R})$ be such that its Fourier transform $\hat{\varphi}$ is compactly supported. We will denote $\varphi^{\pm}$ the Hardy and anti-Hardy part of φ, namely,

$$\varphi^{\pm}(x):=\int_{\mathbb{R}^{\pm}}\hat{\varphi}(\xi)e^{-i\xi x}\,d\xi. \tag{5}$$

We will denote W_a the Wigner function of the symbol a (see the next section) and express W_a on the variables $(x_T,x_\perp,x_s,x_u)$, where x_T is tangent to γ, x_s and x_u are along the stable and unstable manifold of the Poincaré mapping, and $x_\perp$ is a transverse direction to the energy shell.

Then we have the following.

Theorem 2.1: *Let us suppose that*

$$\sum_{k=0}^{\infty}\left(2\frac{1-e^{-\mu}}{1+e^{-\mu}}\right)^k\int|W_a(x_T,x_\perp=0,x_s,x_u)|\frac{|x_sx_u|^k}{k!}dx_T\,dx_s\,dx_u\leqslant\infty. \tag{6}$$

Then as $\hbar\to 0$ along any sequence of the type

$$\hbar=\frac{S_\gamma}{2\pi k+\sigma_\gamma+\alpha},\quad \alpha\in[0,1[,\quad k\to\infty, \tag{7}$$

$$\sum_j\varphi\left(\frac{E_j(\hbar)-E}{\hbar}\right)|(\psi^a_{(x,\xi)},\psi^\hbar_j)|^2=\hbar^{-n+1/2}\sum_{l,m\in\mathbb{Z}}c_{lm}\varphi^{\mathrm{sign}(m)}(z_{lm})+O(\hbar^{-n+3/2}), \tag{8}$$

where $z_{lm} := (2\pi/T_\gamma)\ (l+i(m+\frac{1}{2})\mu+\alpha)$, $l,m\in\mathbb{Z}$. *Moreover, if* $m\geqslant 0$,

$$c_{lm}=\frac{1}{m!}\int x_u^m\ \partial_{x_s}^m W^a(x_T,x_\perp=0,x_s,x_u)e^{ix_sx_u}\,dx_T\,dx_s\,dx_u; \tag{9}$$

if $m<o$,

$$c_{lm}=\frac{1}{m!}\int x_s^m\ \partial_{x_u}^m W^a(x_T,x_\perp=0,x_s,x_u)e^{ix_sx_u}\,dx_T\,dx_s\,dx_u. \tag{10}$$

Remark: The hypothesis (6) is a condition of concentration in phase space of the symbol a near γ along the stable and unstable manifolds. An example of a symbol satisfying (6) is any Gaussian [since in this case the Wigner function is itself a Gaussian and so satisfies (6), as an easy computation shows].

The next result gives a dynamical interpretation of the numbers z_{lm}. In the elliptic case, namely when the linearized flow near γ is stable, one can think, as in Ref. 11 (see also Refs. 12 and 13), at the flow around γ as being integrable, namely, as seating on an (infinitesimal) torus around γ. There are then two ''actions'' arising: the one parametrizing the continuous family of periodic trajectories that γ belongs to (see Ref. 2), and the one coming from the Poincaré mapping. This leads to the following normal form:

$$E(A,B)=E_c(A)+\frac{\theta}{T_\gamma}B,\quad B\ \ small,\quad A\ \ near\ \ S_\gamma, \tag{11}$$

with

$$\frac{\partial E}{\partial A}(S_\gamma,B)=\frac{2\pi}{T_\gamma}. \tag{12}$$

Indeed, $E(A,B)$ induces on the angles φ_A,φ_B, conjugate to A,B a flow at time T_γ given by:

$$\varphi_A(T_\gamma)=\varphi_A(0)+2\pi,$$

$$\varphi_B(T_\gamma)=\varphi_B(0)+\theta.$$

The numbers $(1/T_\gamma)(2\pi j+(k+\frac{1}{2})\theta+(S_\gamma/\hbar)+\sigma_\gamma)$ appearing in (4) are precisely the quantities $[E(A_j,B_k)-E]/\hbar$, where A_j and B_k are the values of the actions quantized by Bohr–Sommerfeld conditions:

$$A_j=S_\gamma+(j+\sigma_\gamma)\hbar\quad\text{and}\quad B_k=(k+\tfrac{1}{2})\hbar. \tag{13}$$

We want to show that this situation is still valid in the hyperbolic case if we consider complex torus and complex actions.

Let P_γ be the Poincaré mapping of γ. Since γ is hyperbolic P_γ can be represented as a matrix of the form

$$P_\gamma=\begin{pmatrix}\cosh\mu & \sinh\mu\\ \sinh\mu & \cosh\mu\end{pmatrix}. \tag{14}$$

We will extend this mapping to the complex in the following way: consider the complex symplectic dilation $D_{\sqrt{i}}$ in $\mathbb{R}^2\otimes\mathbb{C}$:

$$\begin{pmatrix}x\\ \xi\end{pmatrix}\overset{D_{\sqrt{i}}}{\to}\begin{pmatrix}\sqrt{i}x\\ \dfrac{1}{\sqrt{i}}\xi\end{pmatrix}:=\begin{pmatrix}z_1\\ z_2\end{pmatrix}. \tag{15}$$

Under this transformation, the mapping P_γ becomes

$$D_{\sqrt{\hbar}}^{-1} P_\gamma D_{\sqrt{\hbar}} = \begin{pmatrix} \cosh(i\mu) & -i\sinh(i\mu) \\ i\sinh(i\mu) & \cosh(i\mu) \end{pmatrix} = \begin{pmatrix} \cos(i\mu) & -\sin(i\mu) \\ \sin(i\mu) & \cos(i\mu) \end{pmatrix} = R(i\mu), \tag{16}$$

where $R(\theta)$ is the rotation of angle θ.

This means that, thanks to this symplectic complex dilation, we are back to an ''elliptic'' situation *with complex time*. In particular, we find that there exist complex stable tori and a complex normal form $F(A,B)$ satisfying

$$F(A,B) = E_c(A) + i\frac{\mu}{T_\gamma} B, \tag{17}$$

which gives rise to quantized Bohr–Sommerfeld values of the energy $F(A_j, B_k)$ with A_j and B_k given by (13).

We just proved the following.

Proposition 2.2: Let z_{lm} as in Theorem 2.1; then

$$z_{lm} = F(A_l, B_m), \tag{18}$$

with

$$A_j = S_\gamma + (j+\sigma_\gamma)\hbar \quad \textit{and} \quad B_k = (k+\tfrac{1}{2})\hbar. \tag{19}$$

We will come back to the interpretation of this result in the final section of the paper.

III. PROOF OF THE THEOREM

In Ref. 2 we proved that the first coefficient $\nu_0(\varphi)$ in (3) can be written as

$$\nu_0(\varphi) = \sum_n e^{in[(S_\gamma/\hbar)+\sigma_\gamma]} \int_{-\infty}^{\infty} (a, Z(s(\dot{x},\dot{\xi}))U^n a)\, ds\ \hat{\varphi}(nT_\gamma); \tag{20}$$

here $(\dot{x},\dot{\xi})$ is the tangent vector to the flow at (x,ξ); Z is a Weyl operator defined by

$$Z(e,f)a(\eta) = e^{-i(ef/2)} e^{ie\eta} a(\eta - f), \tag{21}$$

and U is the metaplectic operator of the linearized low at time T_γ (see Ref. 2).

We also showed that one can find a symplectic mapping R such that $U = M(S(T_\gamma))$, where M is the metaplectic representation such that

$$R^{-1} S(T_\gamma) R = \begin{pmatrix} 1 & 0 & \alpha & 0 \\ 0 & e^{-\mu} & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & e^{\mu} \end{pmatrix}, \tag{22}$$

where $\alpha \in \mathbb{R}$ and μ is the local Lyapounov exponent of γ at (x,ξ).

Let us denote $a' := M(R)a$. Then one easily checks that, if $\hbar$ satisfies (6),

$$\begin{aligned} \nu_0(\varphi) &= \sum_n e^{in\alpha} \int \overline{a'(\eta)} e^{in(\alpha/2)\partial_{\eta_1}^2} e^{-n(\mu/2)} a'(\eta_1 - s, e^{-n\mu}\eta_2)\, d\eta\, ds \\ &= \sum_n e^{-n(\mu/2)} e^{in\alpha} \int \overline{a'(0,\eta_2)} a'(0, e^{-\mu}\eta_2)\, d\eta_2, \end{aligned} \tag{23}$$

where a' is the Fourier transform of a' with respect to η_1. Let us call $b(x) := a'(0,x)$ and let $W_b(x,\xi)$ be the Wigner function of b, namely,

$$W_b(x,\xi) := \int \overline{b(x-y)}b(x+y)e^{2i\xi y}\, dy. \tag{24}$$

Lemma 3.1: Let us suppose that

$$\sum_{k=0}^{\infty}\left(2\frac{1-e^{-\mu}}{1+e^{-\mu}}\right)^k \int |W_b(x,\xi)|\frac{|x\xi|^k}{k!}dx\ d\xi \leqslant \infty, \tag{25}$$

then

$$e^{-n(\mu/2)}\int \overline{a'(0,\eta_2)}a'(0,e^{-\mu}\eta_2)d\eta_2 = \sum_{k=0}^{\infty}\frac{\overline{b^{(k)}(0)}\hat{b}^{(k)}(0)}{k!}e^{-(k+1/2)\mu}, \tag{26}$$

where $b^{(k)}$ is the kth derivative of b.

Proof: We have, by straightforward computations,

$$\int \overline{a'(0,\eta_2)}a'(0,e^{-\mu}\eta_2)d\eta_2 = \int \overline{b(x)}b(e^{-\mu}x)dx$$

$$= \int W_b\left(\frac{x(1+e^{-\mu})}{2},\xi\right)e^{-i\xi x(1-e^{-\mu})}\, dx\ d\xi \tag{27}$$

$$= \frac{2}{1+e^{-\mu}}\int W_b(x,\xi)e^{-2i\xi x[(1-e^{-\mu}/1+e^{-\mu})]}dx\ d\xi; \tag{28}$$

(25) implies that the RHS of (27) is convergent. Therefore (26) is also convergent. □

Let us show now that the Lemma implies the formula (8). Since $\hat{\varphi}$ is compactly supported we can plug (20) in the expansion (26) and invert the summations. It now suffices to note that $e^{(-\xi)}\chi_{[0,+\infty[}$ is the Fourier transform of $2\pi/(i-x)$ and use the Cauchy and Poisson formulas to get

$$\nu_0(\varphi) = \sum_{l,m\in\mathbb{Z}} c_{lm}\varphi^{\mathrm{sign}(m)}(z_{lm}), \tag{29}$$

with

$$c_{lm} = \frac{\overline{b^{(k)}(0)}\hat{b}^{(k)}(0)}{k!}. \tag{30}$$

We need now to express the hypothesis (25) and the c_{lm} in terms of the Wigner function of a. To do so let us first remark that if S is a symplectic mapping and M the metaplectic representation, we have

$$W_{M(S)a}(x,\xi) = (W_a oS)(x,\xi). \tag{31}$$

Together with the fact that

$$\overline{\hat{a}(0)}\hat{a}(0) = \int W_a(0,\xi)d\xi, \tag{32}$$

we get easily that (25) is equivalent to

$$\sum_{k=0}^{\infty}\left(2\frac{1-e^{-\mu}}{1+e^{-\mu}}\right)^k \int |W_a(x_T, x_\perp = 0, x_s, x_u)|\frac{|x_s x_u|^k}{k!}dx_T\ dx_s\ dx_u \leqslant \infty, \tag{33}$$

and the expression (9) and (10) for the coefficients.

IV. COMMENTS

Link with ''top resonances'': although the operator H is elliptic with discrete spectrum, which implies that there are no ''resonances,'' the formula (8) suggests that the Hardy and anti-Hardy parts of the weighted spectral density $\rho(\lambda):=\Sigma\,\delta(\lambda-[E_j(\hbar)-E]/\hbar)|(\psi^a_{(x,\xi)},\psi^\hbar_j)|^2$ have poles, in the semiclassical limit. These poles are precisely located on the same lattice that in the case of the so-called ''top resonances'' (Refs. 14–16): if the potential V tends to zero at infinity and if there is an unstable fixed point or a manifold of unstable fixed points on the energy surface, then one can prove that H has resonances at a distance $\sim\hbar$ from the real axis. Our result gives a microlocalized version of this phenomenon.

Link with the ''analytic dilation'' method: let us look at the poles z_{l0} and the corresponding coefficient c_0,

$$c_{l0}=\int W^a(x_T,x_\perp=0,x_s,x_u)e^{ix_sx_u}\,dx_T\,dx_s\,dx_u\,. \tag{34}$$

Calling

$$\begin{pmatrix}x\\ \xi\end{pmatrix}:=\begin{pmatrix}\dfrac{x_s+x_u}{\sqrt{2}}\\[2ex] \dfrac{x_s-x_u}{\sqrt{2}}\end{pmatrix}, \tag{35}$$

one gets

$$c_{l0}=\int W^a(x_T,x_\perp=0,x,\xi)e^{i[(\xi^2-x^2)/2]}dx_T\,dx\,d\xi. \tag{36}$$

Using elementary properties of the Wigner function, one gets that

$$c_{l0}=(b,g^+)(g^-,b), \tag{37}$$

where b was defined in Sec. III and $g^\pm(x):=e^{\pm i(x^2/2)}$.

Moreover, the same computation in the case of γ elliptic gives rise to

$$c^{ell}_{l0}=(b,g)(g,b), \tag{38}$$

where $g(x):=e^{-x^2/2}$. Let $|g\rangle\langle g|$ be the orthogonal projector on the vector g in $L^2(\mathbb{R})$. If one calls D_α the operator of dilation by α, one sees that $|g^+\rangle\langle g^-|$ is the analytic continuation of $D_\alpha^{-1}|g\rangle\langle g|D_\alpha$ evaluated at $\alpha=\sqrt{i}$, and so is $c_{l0}:=(b,|g^+\rangle\langle g^-|b)$. This suggest that the poles of the weighted spectral measure can be obtained, as the usual resonances do, by analytic dilation.

Link with ''normal forms'': in Refs. 17 and 18, Guillemin introduced quantized normal forms near a closed trajectory. The result of this paper suggests that the complex dilation of this normal form gives rise to poles of the spectral density suitably microlocalized.

Separability, positivity, and minimum uncertainty in time–frequency energy distributions

Patrick Flandrin[a)]

(Received 24 June 1997; accepted for publication 4 February 1998)

Gaussian signals play a very special role in classical time–frequency analysis because they are solutions of apparently unrelated problems such as minimum uncertainty, and positivity and separability of Wigner–Ville distributions. We investigate here some of the logical connections which exist between these different features, and we discuss some examples and counterexamples of their extension to more general joint distributions within Cohen's class and the affine class. © *1998 American Institute of Physics.* [S0022-2488(98)00508-8]

I. INTRODUCTION

In most cases, physical signals are defined as functions of time. Until the somewhat recent past, signal analysis has been mainly concerned with such a temporal description of signals, or with a dual description in the frequency domain, obtained from a classical Fourier transform. Much information can, of course, be gained from both descriptions, but it is also clear that time-only and frequency-only representations, being in some sense orthogonal to each other, are not best suited for displaying mixed information about time and frequency. In fact, there are many situations in which a Fourier representation, although mathematically correct, is not able to capture in a direct way time-dependent spectral features which may be intuitively expected. This is so, for instance, with music signals, for which our everyday experience suggests that the ''frequency of tones is continuously changing.'' In this case, Fourier analysis is clearly not well adapted and intuition rather calls for a joint time–frequency description, revealing not only the different frequencies occurring in a piece of music, but also their time of occurrence, their duration,..., i.e., the kind of information which is indeed coded on a musical score.

Although interpretation may be different, the search for a joint time–frequency description of signals has much to share with the problem of finding joint distributions of position and momentum in Quantum Mechanics. It is therefore quite natural that most of the tools which have been developed in either domain have indeed found applications in both. This is especially the case for all the Wigner-based distributions which have been proposed and extensively studied since the pioneering works of Wigner in quantum mechanics[1] and Ville in signal theory.[2] One can, however, remark that, in quantum mechanics, joint distributions $P_\psi(q,p)$ are mostly used as a computational tool, allowing us to write

$$(\psi,\mathbf{G}\psi)=\int\int_{-\infty}^{+\infty} g(q,p)P_\psi(q,p)dq\ dp,$$

where **G** stands for the operator associated with a given classical quantity $g(q,p)$ in the sense of some (nonunique) correspondence rule. This nonunicity—which is due to the fact that two dual variables connected by a Fourier transform relationship are associated with elementary operators which do not commute—carries over to the definition of $P_\psi(q,p)$, and the situation is similar for time and frequency. In signal theory, however, a joint distribution is basically considered as a (quasi-) density function of its variables, and the main issue is much more to get a readable time–frequency ''picture'' of a signal, which has therefore to be interpreted *per se* and not only through inner products with test functions.

An extensive body of literature has been devoted to time–frequency analysis with Wigner-type distributions, from the point of view of both theory and interpretation (for a survey, see, e.g., Ref. 3 or 4), and here we would like to focus further on some specific questions related to both aspects. More precisely, if we consider Gaussian signals of the form

$$g(t)=Ce^{-\alpha t^2}, \tag{1}$$

with $C\in\mathbf{C}$ and $\alpha>0$, we know that, besides the fact that their Fourier transform is also Gaussian, namely that

$$G(f)\equiv\int_{-\infty}^{+\infty}g(t)e^{-i2\pi ft}\,dt=C\sqrt{\frac{\pi}{\alpha}}\,e^{-\pi^2f^2/\alpha},$$

such signals happen to play a very special role in classical time–frequency analysis. (Throughout the paper, we will adopt the convention of using a lower case symbol for representing a signal in the time domain, and the corresponding upper case symbol for denoting its Fourier transform, in the frequency domain.) This is in fact so for at least three different reasons.

(1) Minimum uncertainty. Gaussians (1) are the only minimizers for the time–frequency uncertainty relation,[5]

$$\Delta t_x\Delta f_x\geqslant\frac{1}{4\pi}, \tag{2}$$

where

$$\Delta t_x^2=\frac{1}{E_x}\int_{-\infty}^{+\infty}t^2|x(t)|^2\,dt, \tag{3}$$

$$\Delta f_x^2=\frac{1}{E_x}\int_{-\infty}^{+\infty}f^2|X(f)|^2\,df, \tag{4}$$

and

$$E_x=\int_{-\infty}^{+\infty}|x(t)|^2dt.$$

(2) Positivity. Gaussians (1) are—up to linear and quadratic phase terms—the only signals for which the Wigner–Ville distribution

$$W_x(t,f)\equiv\int_{-\infty}^{+\infty}x\left(t+\frac{\tau}{2}\right)\overline{x\left(t-\frac{\tau}{2}\right)}e^{-i2\pi f\tau}\,d\tau=\int_{-\infty}^{+\infty}X\left(f+\frac{\nu}{2}\right)\overline{X\left(f-\frac{\nu}{2}\right)}e^{i2\pi\nu t}\,d\nu, \tag{5}$$

is everywhere non-negative (Hudson's theorem;[6] cf. Proposition 1 below).

(3) Separability. The Wigner–Ville distribution (5) of Gaussians (1) is separable, namely,

$$W_g(t,f)=|C|^2\sqrt{\frac{2\pi}{\alpha}}\,e^{-2\alpha t^2}e^{-(2\pi^2/\alpha)f^2}. \tag{6}$$

These three properties are important ones for attaching to Gaussian signals a specific status and for offering a nice physical interpretation of their time–frequency content by means of the Wigner–Ville distribution.

(1) Minimum uncertainty is often invoked for considering Gaussian signals as time–frequency ''atoms'' and for using them as elementary building blocks (the so-called ''Gabor logons'' [5]) of linear signal decompositions.

(2) Although it is known that no time–frequency distribution—be it positive or not—can be interpreted pointwise,[7] positivity improves the readability of a time–frequency diagram.

(3) Separability provides further insight in the probability picture of time–frequency distributions by corresponding to a notion of ''independence,'' according to which a logon is a state whose time and frequency behaviors are decoupled.[8]

Given these facts, an interesting question is to know whether the three mentioned properties (minimum uncertainty, positivity, and separability) have logical reasons to be related or, on the contrary, if their simultaneous occurrence is only fortuitous. Moreover, since many other joint distributions do exist besides the Wigner–Ville distribution, a further question which is worth investigating is how the results pertaining to the pair ''Gaussian/Wigner–Ville'' can be extended to other situations, especially in the important case of affine (scale-based) distributions.

The paper is devoted to these questions and is organized as follows. In Sec. II, the situation of the Wigner–Ville distribution is considered in some detail by reviewing and/or establishing a number of its specific properties connected in a direct way with the considered problem. In Sec. III we address the question of a possible extension of such results to the more general ''Cohen's class,'' whereas in Sec. IV we are concerned with similar questions within the ''affine class'' framework. Finally, some conclusions are drawn, together with the possibility of getting further extensions in more general situations.

II. WIGNER–VILLE DISTRIBUTION

In this section, we will review and/or establish basic properties—related to positivity, separability, and minimum uncertainty—which hold in the case of the Wigner–Ville distribution. As far as positivity is concerned, it has to be noted that many other important results exist (see, e.g., Refs. 9–12), even with extensions beyond the Wigner–Ville case. The purpose of this paper is not to review all of them, and only those results which are connected in some way with the two other issues of separability and minimum uncertainty will be considered here.

A. Positivity

Proposition 1 (Hudson's theorem[6]): The Wigner–Ville distribution is positive for signals of the type

$$g_{\alpha,\beta,\gamma}(t) \equiv e^{-(\alpha t^2+\beta t+\gamma)}, \tag{7}$$

with $(\alpha,\beta,\gamma)\in \mathbf{C}^3$ *and* $Re\{\alpha\}>0$, *and only for them.*

Proof: The fact that (generalized) Gaussian signals of the form (7) have a positive Wigner–Ville distribution follows from a direct calculation, according to which

$$W_{g_{\alpha,\beta,\gamma}}(t,f) = \sqrt{\frac{2\pi}{\mathrm{Re}\{\alpha\}}}\,\exp\left(-2\,\mathrm{Re}\{\alpha t^2+\beta t+\gamma\}-\frac{2\pi^2}{\mathrm{Re}\{\alpha\}}\,[f-f_i(t)]^2\right),$$

with

$$f_i(t) \equiv \frac{1}{2\pi}\,\mathrm{Im}\{2\alpha t+\beta\}.$$

The original proof of the converse was first stated by Hudson in Ref. 6. It consists of introducing—according to the definition (7)—the test signal $g_{1,z,\gamma}(t)$, for which the corresponding Wigner–Ville distribution is everywhere non-negative. Making use of Moyal's formula,[4] we have

$$\left|\int_{-\infty}^{+\infty} x(t)\overline{g_{1,z,\gamma}(t)}\,dt\right|^2 = \int\int_{-\infty}^{+\infty} W_x(t,f)\,W_{g_{1,z,\gamma}}(t,f)\,dt\,df,$$

and this quantity is guaranteed to be everywhere positive for those signals $x(t)$ whose Wigner–Ville distribution is non-negative. It follows that the function

$$F(z) = e^{\gamma}\int_{-\infty}^{+\infty} x(t)\overline{g_{1,z,\gamma}(t)}\,dt \tag{8}$$

is analytic, has no zeros, and furthermore satisfies

$$|F(z)|^2 \leqslant \sqrt{\frac{\pi}{2}}\, E_x \exp\left(\frac{1}{2}\,(\mathrm{Re}\{z\})^2\right),$$

as can be checked by applying the Cauchy–Schwarz inequality.

As a consequence, $F(z)$ is an entire function of order at most 2, without zeros. Hence, by Hadamard's factorization theorem, $F(z)$ is necessarily the exponential of some quadratic form in z. Letting $z=i2\pi f$ and using the fact that Fourier transforms of Gaussians are still Gaussians, we can deduce from (8) that $x(t)$ is itself the exponential of some quadratic form in t and the proof is complete.

Two remarks.

(1) In order to have finite energy signals—i.e., $x(t)\in L^2(\mathbf{R})$—we have assumed that $\mathrm{Re}\{\alpha\}>0$ and this, in turn, guarantees that the Wigner–Ville distribution is bounded since it is easy to show that $|W_x(t,f)|\leqslant 2E_x$. A degeneracy can, however, be observed whenever $\mathrm{Re}\{\alpha\}=\mathrm{Re}\{\beta\}=0$, a situation for which the Wigner–Ville distribution reads as

$$W_{g_{\alpha,\beta,\gamma}}(t,f) = \exp(-2\,\mathrm{Re}\{\gamma\})\,\delta(f-f_i(t)).$$

(2) Minimum uncertainty implies positivity of the Wigner–Ville distribution, but the class of signals (7) which have a positive Wigner–Ville distribution is larger than the class (1) of signals with minimum uncertainty. In fact, the former can be seen as a modulation of the latter by means of a ''chirp'' wave form whose phase is quadratic in time and, hence, whose instantaneous frequency is linear. Precisely, we get

$$\Delta t_{g_{\alpha,\beta,\gamma}}\Delta f_{g_{\alpha,\beta,\gamma}} = \frac{1}{4\pi}\left(1+\left(\frac{\mathrm{Im}\{\alpha\}}{\mathrm{Re}\{\alpha\}}\right)^2\right)^{1/2} \geqslant \frac{1}{4\pi},$$

with equality if and only if $\mathrm{Im}\{\alpha\}=0$, i.e., if the Gaussian is not modulated in frequency, thus reducing to (1).

B. Separability

Proposition 2: If a Wigner–Ville distribution is separable, it is positive and factorizable as

$$W_x(t,f) = \frac{|x(t)|^2|X(f)|^2}{E_x}. \tag{9}$$

Proof: Starting from the definition (5), it is well known (and easy to check) that a Wigner–Ville distribution always has correct marginals, i.e., that

$$\int_{-\infty}^{+\infty} W_x(t,f)\,dt = |X(f)|^2, \tag{10}$$

$$\int_{-\infty}^{+\infty} W_x(t,f)\,df = |x(t)|^2. \tag{11}$$

Assuming that separability holds, there exist two functions $p(t)$ and $Q(f)$ such that $W_x(t,f)=p(t)Q(f)$. Using (11) and (10), we get $P(0)Q(f)=|X(f)|^2\geqslant 0$ and $p(t)q(0)=|x(t)|^2\geqslant 0$. It follows that $P(0)$ and $Q(f)$ on one hand, and $p(t)$ and $q(0)$ on the other hand, are necessarily of the same sign. One more integration leads to $P(0)q(0)=E_x>0$, and this concludes the proof.

Remark: We know from Moyal's formula that, for any finite energy signal $x(t)$, we have

$$\int\int_{-\infty}^{+\infty} W_x^2(t,f)\,dt\,df = E_x^2.$$

Applying this result to the factorized distribution (9), we are led to the conclusion that signals with a separable Wigner–Ville distribution must necessarily be such that

$$\left(\int_{-\infty}^{+\infty} |x(t)|^4 \, dt \right)^{1/4} \left(\int_{-\infty}^{+\infty} |X(f)|^4 \, df \right)^{1/4} = E_x,$$

a property which holds for Gaussians. Gaussians are therefore solutions for separability. In fact, it can be shown that they are the only solutions, as claimed in the following.

Proposition 3: The Wigner–Ville distribution is separable for Gaussian signals only.

Proof: This result can be viewed as a Corollary to Propositions 2 and 1 (''separability⇒positivity⇒Gaussians''), but it can also be derived in a direct way as follows. Assuming that separability holds for a Wigner–Ville distribution, we can start from the factorization of (9) and, after taking an inverse Fourier transform over frequency, we get

$$\frac{1}{|x(t)|^2} x\left(t+\frac{\tau}{2}\right)\overline{x\left(t-\frac{\tau}{2}\right)} = \gamma_x(\tau), \tag{12}$$

with

$$\gamma_x(\tau) \equiv \frac{1}{E_x} \int_{-\infty}^{+\infty} x\left(t+\frac{\tau}{2}\right)\overline{x\left(t-\frac{\tau}{2}\right)} dt.$$

This defines a functional equation whose first implication is that its left-hand side must be a function of τ only. Writing $x(t)=|x(t)|\exp\{i \arg x(t)\} \equiv \exp\{\varphi(t)+i\psi(t)\}$, we end up with two necessary conditions upon a modulus term and a phase term, respectively. The phase condition (of independence upon the t variable) reads as

$$\frac{\partial}{\partial t}\left[\psi\left(t+\frac{\tau}{2}\right) - \psi\left(t-\frac{\tau}{2}\right) \right] = 0,$$

for any t and τ, with the consequence that the phase must necessarily be of the form $\psi(t)=at+b$, with $(a,b)\in\mathbf{R}^2$. After a change of variables, the companion condition on the modulus leads, for any v and w, to

$$\dot{\varphi}\left(\frac{v+w}{2}\right) = \frac{\dot{\varphi}(v)+\dot{\varphi}(w)}{2},$$

where the overdot indicates the (time) derivative.

We recognize in this relation *Jensen's functional equation*,[13] whose most general (continuous) solution in $\dot{\varphi}(t)$ is given by linear functions of the form $\dot{\varphi}(t)=a't+b'$ with $(a',b')\in\mathbf{R}^2$. It follows that $\varphi(t)=(a'/2)t^2+b't+c'$, with $c'\in\mathbf{R}$ and the requirement that $a'\leqslant 0$ in order to guarantee that $x(t)\in L^2(\mathbf{R})$.

Gaussian signals therefore appear as candidates for defining separable Wigner–Ville distributions. In order to be admissible solutions, we have to further check that the left-hand side of (12) is not only independent of t, but also proportional to the deterministic correlation function $\gamma_x(\tau)$, which an elementary calculation proves to be true.

C. Minimum uncertainty

Proposition 4 (Ref. 14): Given any $T>0$, the Wigner–Ville distribution satisfies the time–frequency uncertainty relation,

$$\Sigma_{tf}^2(W_x) \equiv \frac{1}{E_x} \int \int_{-\infty}^{+\infty} \left(\frac{t^2}{T^2} + T^2 f^2 \right) W_x(t,f)\, dt\, df \geqslant \frac{1}{2\pi}, \tag{13}$$

with equality if and only if $x(t)$ is a Gaussian signal.

Proof: This follows directly from the marginal properties (10)–(11) of the Wigner–Ville distribution and from the definitions (3)–(4), since we can write

$$\Sigma_{tf}^2(W_x)=\frac{1}{E_x}\left[\frac{1}{T^2}\int_{-\infty}^{+\infty}t^2|x(t)|^2dt+T^2\int_{-\infty}^{+\infty}f^2|X(f)|^2df\right]$$

$$=\frac{\Delta t_x^2}{T^2}+T^2\Delta f_x^2=\left(\frac{\Delta t_x}{T}-T\Delta f_x\right)^2+2\Delta t_x\Delta f_x\geqslant 2\Delta t_x\Delta f_x, \tag{14}$$

with equality if the arbitrary duration T is ''matched'' to the signal $x(t)$ according to $T=\sqrt{\Delta t_x/\Delta f_x}$. In this case, we know from (2) that the right-hand side of (14) is lower bounded too, with equality in the only case of Gaussians, whence the result.

Remark: In the above derivation, it has been implicitly assumed that the mean time and the mean frequency of the analyzed signal are both zero, i.e., that

$$\int_{-\infty}^{+\infty}t|x(t)|^2\,dt=\int_{-\infty}^{+\infty}f|X(f)|^2\,df=0.$$

As for the standard Gabor–Heisenberg uncertainty relation (2), this of course does not reduce the generality of the result, since the Wigner–Ville distribution being covariant with respect to shifts in time and frequency, uncertainty relations pertaining to signals with nonzero mean time and/or mean frequency can be established *mutatis mutandis* by introducing suitable shifts.

Because a Wigner–Ville distribution attains generally negative values, the interpretation of (13) as a measure of time–frequency energy spread can be questioned. A companion result can, however, be obtained for *squared* Wigner–Ville distributions, thus reinforcing the prominent role of Gaussians. This is given by the following.

Proposition 5 (Ref. 15): Given any $T>0$, the squared Wigner–Ville distribution satisfies the time–frequency uncertainty relation

$$\Sigma_{tf}^2(W_x^2)=\frac{1}{E_x^2}\int\int_{-\infty}^{+\infty}\left(\frac{t^2}{T^2}+T^2f^2\right)W_x^2(t,f)\,dt\,df\geqslant\frac{1}{4\pi},$$

with equality if and only if $x(t)$ is a Gaussian signal.

Proof: The proof proceeds as previously, except that we have to evaluate second-order moments with respect to $W_x^2(t,f)$. It is easy to show that

$$\int_{-\infty}^{+\infty}W_x^2(t,f)\,df=\int_{-\infty}^{+\infty}\left|x\left(t+\frac{\tau}{2}\right)\right|^2\left|x\left(t-\frac{\tau}{2}\right)\right|^2d\tau,$$

and, therefore,

$$\frac{1}{E_x^2}\int\int_{-\infty}^{+\infty}t^2W_x^2(t,f)\,dt\,df=\frac{1}{E_x^2}\int\int_{-\infty}^{+\infty}\left(\frac{v+w}{2}\right)^2|x(v)|^2|x(w)|^2dv\,dw$$

$$=\frac{1}{4E_x^2}\left[2E_x\int_{-\infty}^{+\infty}v^2|x(v)|^2dv+2\left(\int_{-\infty}^{+\infty}v|x(v)|^2dv\right)^2\right]\geqslant\frac{\Delta t_x^2}{2},$$

with equality for signals whose mean time is zero. It can be proved in a similar way that

$$\frac{1}{E_x^2}\int\int_{-\infty}^{+\infty}f^2W_x^2(t,f)\,dt\,df\geqslant\frac{\Delta f_x^2}{2},$$

with equality for signals whose mean frequency is zero.

Given these two properties, the proof is finished by reorganizing terms exactly as in the nonsquared case.

Remark: The fact that both the Wigner–Ville distribution $W_x(t,f)$ and its square $W_x^2(t,f)$ have a minimum time–frequency spread which is attained for Gaussian signals suggests a natural link between minimum uncertainty and positivity. For simplicity, let us assume that $x(t)$ is of unit energy so that both $W_x(t,f)$ and $W_x^2(t,f)$ integrate to 1 in the time–frequency plane. In fact, as

far as the spread related to $W_x(t,f)$ only is concerned, a decrease in the spread measure could *a priori* be obtained not only by concentrating positive values around the origin, but also by accepting negative values far from the origin. This, however, turns out to be in contradiction with the spread inequality related to $W_x^2(t,f)$ since a distribution with negative values would create ''holes''—in between positive contributions—when squared, thus increasing the spread measure as compared to a positive distribution.

It is possible to find many other ways of formulating uncertainty relations by means of the Wigner–Ville distribution, among which we can cite the following results.

Proposition 6: Any signal $x(t)$ of finite energy E_x satisfies the ''uncertainty relation''

$$\alpha_x \equiv \frac{1}{E_x}\int_{-\infty}^{+\infty} t^2|\dot{x}(t)|^2 dt \geqslant \frac{1}{4},$$

with

$$\lim_{\gamma\to 0_+} \alpha_{x_\gamma} = \tfrac{1}{4},$$

for signals of the form

$$x_\gamma(t) \equiv C\ \exp(-\beta|t|^\gamma), \tag{15}$$

with $C\in\mathbf{C}$ and $(\beta,\gamma)\in\mathbf{R}_+^2$.

Proof: For convenience, let us introduce the quantity

$$J \equiv \int_{-\infty}^{+\infty} t\dot{x}(t)\overline{x(t)}\,dt,$$

whose imaginary part is sometimes referred to as the ''covariance'' of the signal.[3] By applying the Cauchy–Schwarz inequality, we get $|J|^2 \leqslant \alpha_x E_x^2$, whereas an integration by parts shows that $\mathrm{Re}\{J\} = -E_x/2$, and the claimed inequality follows from the fact that we always have $|J|^2 \geqslant (\mathrm{Re}\{J\})^2$.

From the way the lower bound has been derived, it is not clear whether it can be effectively attained. However, it can be shown by a direct calculation that signals of the form (15) are such that $\alpha_{x_\gamma} = (\gamma+1)/4$, with the consequence that $\lim_{\gamma\to 0_+}\alpha_{x_\gamma} = 1/4$, thus completing the proof.

Three remarks.

(1) Although the lower bound $\alpha_x = \frac{1}{4}$ is asymptotically sharp for signals $x_\gamma(t)$ when $\gamma\to 0_+$, it has to be remarked that the bandwidth Δf_{x_γ} and, hence, the usual uncertainty measure remain finite only if $\gamma > \frac{1}{2}$.

(2) The ''alpha moment'' α_x (a quantity which has been introduced and studied by Titlebaum; see Ref. 16) is such that

$$\alpha_x = \frac{1}{E_x}\int_{-\infty}^{+\infty} t^2|\dot{x}(t)|^2 dt = \frac{1}{E_x}\int_{-\infty}^{+\infty} f^2|\dot{X}(f)|^2 df.$$

It follows that any property of α_x which holds for a given signal $x(t)$ also holds for its Fourier transform $X(f)$. In particular, the lower bound for α_x is also attained for signals whose spectrum reads as $X(f) = C\ \exp(-\beta|f|^\gamma)$, in the limit $\gamma\to 0_+$, with the consequence that the corresponding signals have a finite mean-square duration—and, hence, a finite usual uncertainty measure—only if $\gamma > \frac{1}{2}$.

(3) The uncertainty measure given by the ''alpha moment'' α_x is not minimum for Gaussian signals. In fact, expanding $x(t)\in L^2(\mathbf{R})$ as $x(t) = \Sigma_{n=0}^{+\infty} x_n \psi_n(t)$ on the orthonormal basis of Hermite functions $\{\psi_n(t); n\in\mathbf{N}\}$ (defined as in Ref. 17), we get

$$E_x\alpha_x = \sum_{n=0}^{+\infty}\left(\left[\frac{3}{4}+\frac{n(n+1)}{2}\right]|x_n|^2 - \frac{\sqrt{(n+1)(n+2)(n+3)(n+4)}}{2}\,\mathrm{Re}\{x_n x_{n+4}\}\right).$$

This proves that $\alpha_{\psi_n}=3/4+n(n+1)/2$ and thus that the Gaussian (associated to $n=0$) may be considered as a minimizer for α_x, but in the restricted class of Hermite functions.

Proposition 7: For any signal $x(t)$ of finite energy E_x and of mean time and mean frequency identically zero, the Wigner–Ville distribution satisfies the uncertainty relation

$$\sigma_{tf}^2(W_x^2)\equiv\frac{1}{E_x^2}\int\int_{-\infty}^{+\infty}t^2f^2W_x^2(t,f\,)dt\;df\geqslant\frac{1}{32\pi^2}\left(\alpha_x-\frac{1}{2}+4\pi^2\Delta t_x^2\Delta f_x^2\right),$$

with equality for signals whose ''covariance'',

$$\mathrm{cov}_{tf}(x)\equiv\mathrm{Im}\left(\int_{-\infty}^{+\infty}t\dot{x}(t)\overline{x(t)}dt\right),\tag{16}$$

is zero.

Proof: A way of proving this result is to make use of the so-called ''inner interference formula,'' [15] according to which

$$W_x^2(t,f\,)=\int\int_{-\infty}^{+\infty}W_x\left(t+\frac{\tau}{2},\;f+\frac{\nu}{2}\right)W_x\left(t-\frac{\tau}{2},\;f-\frac{\nu}{2}\right)d\tau\;d\nu.$$

By making a change of variable and reorganizing terms, this leads to

$$\sigma_{tf}^2(W_x^2)=\frac{1}{8E_x^2}\int\int\int\int_{-\infty}^{+\infty}K(v,w,\xi,\zeta)W_x(v,\xi)W_x(w,\zeta)dv\;dw\;d\xi\;d\zeta,$$

with

$$K(v,w,\xi,\zeta)=v^2\xi^2+v^2\zeta^2+2v^2\xi\zeta+2vw\xi^2+4vw\xi\zeta.$$

The contribution of the first term of $K(v,w,\xi,\zeta)$ to the integral reduces to

$$\int\int\int\int_{-\infty}^{+\infty}v^2\xi^2W_x(v,\xi)W_x(w,\zeta)dv\;dw\;d\xi\;d\zeta=E_x^2\sigma_{tf}^2(W_x),$$

and it can be shown[4] that

$$\sigma_{tf}^2(W_x)=\frac{1}{4\pi^2}\left(\alpha_x-\frac{1}{2}\right).$$

The second term contributes as

$$\int\int\int\int_{-\infty}^{+\infty}v^2\zeta^2W_x(v,\xi)W_x(w,\zeta)dv\;dw\;d\xi\;d\zeta$$

$$=\int\int_{-\infty}^{+\infty}v^2\zeta^2|x(v)|^2|X(\zeta)|^2dv\;d\zeta=E_x^2\Delta t_x^2\Delta f_x^2,$$

whereas the third and fourth ones provide a null contribution because of the assumptions of mean time and mean frequency equal to zero.

Finally, the fifth term is such that

$$\int\int\int\int_{-\infty}^{+\infty}vw\xi\zeta W_x(v,\xi)W_x(w,\zeta)dv\;dw\;d\xi\;d\zeta=\frac{1}{4\pi^2}\,\mathrm{cov}_{tf}^2(x)\geqslant0,$$

with (following Cohen[3]), the ''covariance'' of $x(t)$ defined by (16).

Remark: If $x(t)$ is chosen to be $x_\gamma(t)$ as defined in (15), we get explicitly

$$\sigma_{tf}^2(W_{x_\gamma}^2)=\frac{1}{128\pi^2}\left[(\gamma-1)+\gamma^2\,\frac{\Gamma(3/\gamma)\Gamma(2-1/\gamma)}{\Gamma^2(1/\gamma)}\right],$$

and a numerical estimate of the γ_0 minimizing the spread measure gives $\gamma_0\approx 1.33$, with $\sigma_{tf}^2(W_{x_{\gamma 0}}^2)\approx 0.77/64\pi^2$. This is less than in the Gaussian case ($\gamma=2$) for which $\sigma_{tf}^2(W_{x_2}^2)=1/64\pi^2$.

III. COHEN'S CLASS

Some results pertaining to Wigner–Ville distributions can be generalized to members of *Cohen's class*, the general class of quadratic time–frequency energy distributions which are covariant to time and frequency shifts. By definition, Cohen's class can be written as[4]

$$C_x(t,f;\varphi)=\int\int_{-\infty}^{+\infty}\varphi(\xi,\tau)A_x(\xi,\tau)e^{-i2\pi(t\xi+f\tau)}d\xi\,d\tau, \tag{17}$$

where $\varphi(\xi,\tau)$ is some arbitrary kernel function and $A_x(\xi,\tau)$ is the so-called ''ambiguity function,'' obtained as a two-dimensional Fourier transform of the Wigner–Ville distribution and defined explicitly by

$$A_x(\xi,\tau)=\int_{-\infty}^{+\infty}x\left(t+\frac{\tau}{2}\right)\overline{x\left(t-\frac{\tau}{2}\right)}e^{i2\pi\xi t}\,dt.$$

Within this more general framework, Gaussian signals still appear to be central with respect to separability properties, as illustrated by the following claims.

Proposition 8: Smoothed pseudo-Wigner–Ville distributions—characterized by a separable kernel—are the only members of Cohen's class which are separable when applied to Gaussian signals.

Proof: Assuming that the analyzed signal $x(t)$ is a Gaussian, we know that its Wigner–Ville distribution $W_x(t,f)$ is separable, a property which carries over to its two-dimensional Fourier transform $A_x(\xi,\tau)$. Using (17), we get

$$\varphi(\xi,\tau)=\frac{1}{A_x(\xi,\tau)}\int\int_{-\infty}^{+\infty}C_x(t,f;\varphi)e^{i2\pi(t\xi+f\tau)}dt\,df,$$

and, if we require $C_x(t,f;\varphi)$ to be separable, it follows that the kernel function $\varphi(\xi,\tau)$ must itself be separable, a situation corresponding to distributions referred to as ''smoothed pseudo-Wigner–Ville distributions.'' [4]

Proposition 9: Smoothed pseudo-Wigner–Ville distributions—characterized by a separable kernel—are separable for Gaussian signals only.

Proof: The proof is very similar to the previous one since, according to (17), we can write

$$W_x(t,f)=\int\int_{-\infty}^{+\infty}\left(\frac{1}{\varphi(\xi,\tau)}\int\int_{-\infty}^{+\infty}C_x(t',f';\varphi)e^{i2\pi(t'\xi+f'\tau)}dt'\,df'\right)e^{-i2\pi(t\xi+f\tau)}d\xi\,d\tau.$$

Assuming therefore that both the kernel function $\varphi(\xi,\tau)$ and the associated smoothed Wigner–Ville distribution $C_x(t,f;\varphi)$ are separable, we get that the Wigner–Ville distribution itself is separable, which in turn implies that $x(t)$ is necessarily a Gaussian.

Proposition 10: When applied to Gaussian signals, spectrograms are separable if and only if their short-time window is Gaussian.

Proof: Assuming that the analyzed signal $x(t)$ is a Gaussian, we know that both its Wigner–Ville distribution $W_x(t,f)$ and its ambiguity function $A_x(\xi,\tau)$ are separable. If we now consider a spectrogram,

$$S_x^{(h)}(t,f)\equiv\left|\int_{-\infty}^{+\infty}x(s)\overline{h(s-t)}e^{-i2\pi fs}\,ds\right|^2=\left|\int_{-\infty}^{+\infty}X(\xi)\overline{H(\xi-f)}e^{i2\pi\xi t}\,d\xi\right|^2$$

having a short-time window $h(t)$ which is Gaussian, we get that the associated kernel function[4] $\varphi(\xi,\tau)=\overline{A_h(\xi,\tau)}$ is separable, and it follows that the spectrogram—as an inverse Fourier transform of $\varphi(\xi,\tau)A_x(\xi,\tau)$—is itself separable.

Conversely, if we suppose that a spectrogram is separable when applied to a Gaussian signal $g(t)$, we get from (17) [with $\varphi(\xi,\tau)=\overline{A_h(\xi,\tau)}$] that

$$\overline{A_h(\xi,\tau)}=\frac{1}{A_g(\xi,\tau)}\int\int_{-\infty}^{+\infty}S_g^{(h)}(t',f')e^{i2\pi(t'\xi+f'\tau)}dt'\,df'$$

is separable, with the consequence that $W_h(t,f)$ itself—as an inverse Fourier transform of $A_x(\xi,\tau)$—is separable and, hence, that the window $h(t)$ must be Gaussian.

More generally, we can remark that imposing the requirement of separability to spectrograms leads to specific constraints which have to be jointly satisfied by the analyzed signal $x(t)$ and the analysis window $h(t)$. Starting from the definition of a spectrogram of window $h(t)$ and assuming that this spectrogram is separable according to $S_x^{(h)}(t,f)=p(t)Q(f)$, we get

$$p(t)q(0)=\int_{-\infty}^{+\infty}S_x^{(h)}(t,f)df=\int_{-\infty}^{+\infty}|x(s)|^2|h(s-t)|^2ds$$

and

$$P(0)Q(f)=\int_{-\infty}^{+\infty}S_x^{(h)}(t,f)dt=\int_{-\infty}^{+\infty}|X(\xi)|^2|H(\xi-f)|^2d\xi.$$

Since $P(0)q(0)=E_xE_h$, separable spectrograms happen to be necessarily of the form

$$S_x^{(h)}(t,f)=\int\int_{-\infty}^{+\infty}\frac{|x(s)|^2|X(\xi)|^2}{E_x}\,\frac{|h(s-t)|^2|H(\xi-f)|^2}{E_h}\,ds\,d\xi,$$

a form which has to be compared to the (always valid) expression

$$S_x^{(h)}(t,f)=\int\int_{-\infty}^{+\infty}W_x(s,\xi)W_h(s-t,\xi-f)ds\,d\xi,$$

or even to

$$S_x^{(h)}(t,f)=\int\int_{-\infty}^{+\infty}C_x(s,\xi;\varphi)\overline{C_h(s-t,\xi-f;\varphi)}ds\,d\xi,$$

with the requirement that the parametrization function $\varphi(\xi,\tau)$ be such that $|\varphi(\xi,\tau)|=1$ (see, e.g., Ref. 4).

Reasoning along the same lines in the more general case of any distribution within Cohen's class, we can end up with the result that a separable distribution is necessarily such that

$$\begin{aligned}C_x(t,f;\varphi)&=\int\int_{-\infty}^{+\infty}W_x(s,\xi)\Pi(s-t,\xi-f)ds\,d\xi\\&=\int\int_{-\infty}^{+\infty}\frac{|x(s)|^2|X(\xi)|^2}{E_x}\,\frac{F(s-t,0)\psi(0,\xi-f)}{\varphi(0,0)}\,ds\,d\xi,\end{aligned}\tag{18}$$

where $\Pi(t,f)$ stands for the two-dimensional Fourier transform of $\varphi(\xi,\tau)$, and $F(t,\tau)$ and $\psi(\xi,\nu)$ for one-dimensional partial Fourier transforms of the same quantity, over frequency and time, respectively. This leads to the following.

Proposition 11: If a Cohen's class distribution has correct marginals and is separable, it is positive and factorizable as

$$C_x(t,f;\varphi)=\frac{|x(t)|^2|X(f)|^2}{E_x}. \tag{19}$$

Proof: This can be proved either directly—as for Proposition 2—or by using (18), since we know[4] that having correct marginals implies that $\varphi(\xi,0)=\varphi(0,\tau)=1$.

Remark: Given *any* signal $x(t)$, one could imagine to formally obtain a distribution factorizable as in (19) by choosing for the parametrization function the (signal-dependent) quantity $\varphi(\xi,\tau)\equiv E_x\gamma_X(\xi)\gamma_x(\tau)/A_x(\xi,\tau)$, with the γ's defined as in Proposition 3. In the general case, this would unfortunately correspond to pathological φ's, with singularities at those points where the ambiguity function vanishes while the individual time and frequency correlation functions do not. Regular solutions can be guaranteed by imposing to the ambiguity function to be everywhere positive but, as mentioned in Ref. 18, imposing positivity of the ambiguity function is equivalent to imposing positivity of the Wigner–Ville distribution, with Gaussians as only solutions.

Proposition 12: The Wigner–Ville distribution is the only member of Cohen's class which both has correct marginals and is separable when applied to Gaussian signals.

Proof: By Fourier transformation, (19) becomes $\varphi(\xi,\tau)A_x(\xi,\tau)=E_x\gamma_X(\xi)\gamma_x(\tau)$. Assuming that $x(t)$ is a Gaussian signal, this simplifies to $\varphi(\xi,\tau)=1$, thus defining the Wigner–Ville distribution as the only solution.

Proposition 13 (Ref. 4): For any signal $x(t)$ whose mean time and mean frequency are zero, and any $T>0$, distributions of Cohen's class satisfy the time–frequency uncertainty relation

$$\Sigma_{tf}^2(C_x)\geqslant\frac{1}{2\pi}-\frac{1}{4\pi^2}\left[\frac{1}{T^2}\frac{\partial^2\varphi}{\partial\xi^2}(0,0)+T^2\frac{\partial^2\varphi}{\partial\tau^2}(0,0)\right],$$

with equality if and only if $x(t)$ is a Gaussian signal.

Proof: The proof is straightforward and follows directly from the fact that $C_x(t,f;\varphi)$ has for Fourier transform $\varphi(\xi,\tau)A_x(\xi,\tau)$. Defining

$$\Sigma_t^2(C_x)\equiv\frac{1}{E_x}\int_{-\infty}^{+\infty}t^2\left(\int_{-\infty}^{+\infty}C_x(t,f;\varphi)df\right)dt,$$

we get

$$\begin{aligned}\Sigma_t^2(C_x)&=\frac{1}{E_x}\int_{-\infty}^{+\infty}|x(s)|^2\left(\int_{-\infty}^{+\infty}t^2F(s-t,0)dt\right)ds\\&=\frac{1}{E_x}\int_{-\infty}^{+\infty}|x(s)|^2\left(\int_{-\infty}^{+\infty}(s^2-2s\theta+\theta^2)F(\theta,0)d\theta\right)ds=\varphi(0,0)\Delta t_x^2-\frac{1}{4\pi^2}\frac{\partial^2\varphi}{\partial\xi^2}(0,0),\end{aligned}$$

and, similarly,

$$\Sigma_f^2(C_x)\equiv\frac{1}{E_x}\int_{-\infty}^{+\infty}f^2\left(\int_{-\infty}^{+\infty}C_x(t,f;\varphi)dt\right)df=\varphi(0,0)\Delta f_x^2-\frac{1}{4\pi^2}\frac{\partial^2\varphi}{\partial\tau^2}(0,0).$$

Assuming that $C_x(t,f;\varphi)$ is a valid energy distribution [i.e., that $\varphi(0,0)=1$], we are led to

$$\Sigma_{tf}^2(C_x)=\frac{\Sigma_t^2(C_x)}{T^2}+T^2\Sigma_f^2(C_x)=\Sigma_{tf}^2(W_x)-\frac{1}{4\pi^2}\left[\frac{1}{T^2}\frac{\partial^2\varphi}{\partial\xi^2}(0,0)+T^2\frac{\partial^2\varphi}{\partial\tau^2}(0,0)\right],$$

and therefore to the claim, from the result established previously for $\Sigma_{tf}^2(W_x)$.

Proposition 14: For any signal $x(t)$ whose mean time and mean frequency are zero, and any $T>0$, spectrograms with a window $h(t)$ satisfy the time–frequency uncertainty relation,

$$\Sigma_{tf}^2(S_x^{(h)})=\Sigma_{tf}^2(W_x)+\Sigma_{tf}^2(W_h)\geqslant\frac{1}{\pi},$$

with equality, if and only if $x(t)$ and $h(t)$ are matched Gaussian signals.

Proof: This can be viewed as a Corollary to the previous Proposition since, in the case of spectrograms, we get

$$-\frac{1}{4\pi^2}\left[\frac{1}{T^2}\frac{\partial^2\varphi}{\partial\xi^2}(0,0)+T^2\frac{\partial^2\varphi}{\partial\tau^2}(0,0)\right]=\frac{1}{T^2}\frac{\partial^2\overline{A_h}}{\partial\xi^2}(0,0)+T^2\frac{\partial^2\overline{A_h}}{\partial\tau^2}(0,0),$$

$$=\Sigma_{tf}^2(W_h)$$

and hence

$$\Sigma_{tf}^2(S_x^{(h)})=\Sigma_{tf}^2(W_x)+\Sigma_{tf}^2(W_h).$$

The total time–frequency spread being the sum of two independent positive quantities, it is minimized when each of these quantities is itself minimized, which is obtained when both $x(t)$ and $h(t)$ are Gaussian signals (see Proposition 4). In order to ensure that the two individual minimizations are compatible, the same arbitrary T has to be chosen for both $\Sigma_{tf}^2(W_x)$ and $\Sigma_{tf}^2(W_h)$. This leads to

$$T=\sqrt{\frac{\Delta t_x}{\Delta f_x}}=\sqrt{\frac{\Delta t_h}{\Delta f_h}},$$

and, hence, to $\Delta t_h=\Delta t_x$ and $\Delta f_h=\Delta f_x$, since $x(t)$ and $h(t)$ being Gaussians, $\Delta t_x\Delta f_x=\Delta t_h\Delta f_h=1/4\pi$.

Remark: Although the derivation is different, this result is equivalent to the one given by Janssen in Ref. 19.

Proposition 15: For any signal $x(t)$ whose mean time and mean frequency are zero, and any $T>0$, spectrograms with a real-valued and even window $h(t)$ are such that

$$\sigma_{tf}^2(S_x^{(h)})=\frac{1}{4\pi^2}[(\alpha_x+\alpha_h-1)+4\pi^2(\Delta t_x^2\Delta f_h^2+\Delta t_h^2\Delta f_x^2)].$$

Proof: Let us introduce the time–frequency spread measure,

$$\sigma_{tf}^2(C_x)\equiv\frac{1}{E_x}\int\int_{-\infty}^{+\infty}t^2f^2C_x(t,f;\varphi)dt\,df, \tag{20}$$

where $C_x(t,f;\varphi)$ stands for any distribution within Cohen's class. This spread measure (20) can be equivalently expressed as

$$\sigma_{tf}^2(C_x)=\frac{1}{16\pi^4E_x}\frac{\partial^4}{\partial\xi^2\partial\tau^2}(\varphi(\xi,\tau)A_x(\xi,\tau))\Big|_{(0,0)},$$

with

$$\frac{\partial^4}{\partial\xi^2\,\partial\tau^2}(\varphi A_x)=\frac{\partial^4\varphi}{\partial\xi^2\,\partial\tau^2}A_x+\frac{\partial^2\varphi}{\partial\tau^2}\frac{\partial^2A_x}{\partial\xi^2}+\frac{\partial^2\varphi}{\partial\xi^2}\frac{\partial^2A_x}{\partial\tau^2}+f\frac{\partial^4A_x}{\partial\xi^2\,\partial\tau^2}$$
$$+2\left(\frac{\partial^3\varphi}{\partial\xi\,\partial\tau^2}\frac{\partial A_x}{\partial\xi}+\frac{\partial^3\varphi}{\partial\xi^2\,\partial\tau}\frac{\partial A_x}{\partial\tau}+\frac{\partial\varphi}{\partial\tau}\frac{\partial^3A_x}{\partial\xi^2\,\partial\tau}+\frac{\partial\varphi}{\partial\xi}\frac{\partial^3A_x}{\partial\tau\,\partial\tau^2}\right).$$

This holds for any distribution within Cohen's class and, in particular, for spectrograms $S_x^{(h)}(t,f)$ with a window $h(t)$. Given such a window, (normalized) spectrograms are known to correspond to the kernel function $\varphi(\xi,\tau)=\overline{A_h(\xi,\tau)}/E_h$. Assuming, furthermore, that the window is real valued and even, we can show that

$$\frac{\partial A_h}{\partial\xi}(0,0)=\frac{\partial A_h}{\partial\tau}(0,0)=0$$

and

$$\frac{\partial^3 A_h}{\partial\xi^2\,\partial\tau}(0,0)=\frac{\partial^3 A_h}{\partial\xi\,\partial\tau^2}(0,0)=0,$$

whereas, for any signal $x(t)$,

$$\frac{\partial^2 A_x}{\partial\xi^2}(0,0)=4\pi^2 E_x\Delta t_x^2,$$

$$\frac{\partial^2 A_x}{\partial\tau^2}(0,0)=4\pi^2 E_x\Delta f_x^2,$$

and

$$\frac{\partial^4 A_x}{\partial\xi^2\,\partial\tau^2}(0,0)=4\pi^2 E_x\left(\alpha_x-\frac{1}{2}\right).$$

It thus follows that, in the case of spectrograms, the overall spread measure (20) reads as announced.

Remark: Positivity of spectrograms guarantees that $\sigma_{tf}^2(S_x^{(h)})\geqslant 0$. In the special case where $h(t)=x(t)$ (matched spectrograms), we get $2\alpha_x-1+4\pi^2(2\Delta t_x^2\Delta f_x^2)\geqslant 0$ and therefore $\alpha_x\geqslant 1/2-4\pi^2\Delta t_x^2\Delta f_x^2\geqslant 1/4$, as already proved in Proposition 6.

IV. AFFINE TIME–FREQUENCY DISTRIBUTIONS

The Wigner–Ville distribution and, more generally, all members of Cohen's class, all belong to a family of time–frequency distributions which are covariant with respect to shifts in time and frequency. Moreover, assuming that an energy distribution depends quadratically on the signal, it can be shown that covariance with respect to shifts in time and frequency is sufficient to reduce the class of admissible solutions to Cohen's class. Following this line, it becomes therefore possible to generate other classes of distributions by modifying in a suitable manner the covariance requirement. Among the various solutions which have been derived this way, a prominent example is given by the class of the so-called *affine* time–frequency distributions, whose construction relies basically on the consideration of dilations in place of frequency shifts.

According to Ref. 20, the general class of affine time–frequency distributions $P_X^{(k)}(t,f)$ which are covariant with respect to each solvable three-parameter extension of the affine group is defined on $\mathbf{R}\times\mathbf{R}_+$ and can be parametrized by

$$P_X^{(k)}(t,f)=f^{2(r+1)-q}\int_{-\infty}^{+\infty}\mu_k(u)X(\lambda_k(u)f)\overline{X(\lambda_k(-u)f)}e^{-i2\pi tf\zeta_k(u)}\,du, \tag{21}$$

with $\zeta_k(u)=\lambda_k(u)-\lambda_k(-u)$, and where r and q are real-valued free parameters. In this expression, $X(f)$ stands as before for the Fourier spectrum of the analyzed signal, but only positive frequencies are considered. The parametrization function $\lambda_k(u)$ is given explicitly by

$$\lambda_k(u)=\left(k\,\frac{e^{-u}-1}{e^{-ku}-1}\right)^{1/(k-1)}, \tag{22}$$

with $k\in\mathbf{R}$, whereas $\mu_k(u)$ is a weight function whose value can be made dependent on $\lambda_k(u)$ so as to guarantee specific requirements for $P_X^{(k)}(t,f)$.[20]

From (21), it is apparent that affine distributions depend naturally on the product variable tf, a quantity which can be interpreted as a Mellin variable. To justify this point, let us recall that a definition of the Mellin transform $\underline{X}(s)$ of $X(f)$ can be given by[21]

$$\underline{X}(s)\equiv\int_0^{+\infty}X(f)f^{i2\pi s+r}\,df,$$

thus corresponding to an expansion of the spectrum $X(f)$ on ''hyperbolic chirps,''

$$C_0(f) \equiv f^r e^{-i2\pi s \log f}, \quad f \geqslant 0,$$

whose group delay is

$$t_{C_0}(f) = -\frac{1}{2\pi}\frac{d}{df}(-2\pi s \log f) = \frac{s}{f}.$$

In this picture, the Mellin variable s appears therefore as a *hyperbolic chirp rate* related to time and frequency by a relation of the type $s = tf$.

A companion interpretation amounts to consider the Mellin variable s as *a scale* variable.[22,3] This comes from the fact that, choosing, e.g., Weyl's correspondence rule, the operator $\mathcal{S}$ associated to $s = tf$ can be written as

$$\mathcal{S} = \frac{\mathcal{T}\mathcal{F} + \mathcal{F}\mathcal{T}}{2},$$

where $\mathcal{T}$ and $\mathcal{F}$ stand for the time and frequency operators, defined, respectively, by $(\mathcal{T}x)(t) = tx(t)$ and $(\mathcal{F}x)(t) = (-i/2\pi)\dot{x}(t)$. It thus follows that, for any $\lambda > 0$,

$$(e^{i2\pi\lambda S}X)(f) = e^{-\lambda/2}X(e^{-\lambda}f),$$

which allows us to interpret $\mathcal{S}$ as the infinitesimal generator of a scaling operator (whose eigenfunctions are precisely hyperbolic chirps).

Whatever the interpretation, and while $P_X^{(k)}(t,f)$ is usually considered as a time–frequency distribution, it can equally well be reparametrized as

$$\tilde{P}_X^{(k)}(s,f) \equiv P_X^{(k)}\left(\frac{s}{f}, f\right), \tag{23}$$

so that it becomes a function of (Mellin) scale and (Fourier) frequency variables.

A. Minimum uncertainty

Because the operators attached to scale and frequency do not commute, namely

$$[\mathcal{S},\mathcal{F}] \equiv \mathcal{S}\mathcal{F} - \mathcal{F}\mathcal{S} = \frac{i}{2\pi}\mathcal{F},$$

the corresponding variables obey a specific form of uncertainty relation. Precisely, let $X(f)$ be an analytic signal such that

$$E_X \equiv \int_0^{+\infty} |X(f)|^2 f^{2r+1} df < +\infty,$$

$$\frac{1}{E_X}\int_{-\infty}^{+\infty} s|\underline{X}(s)|^2 ds = s_0,$$

and

$$\frac{1}{E_X}\int_0^{+\infty} f|X(f)|^2 df = f_0.$$

If we denote by Δs_X and Δf_X its mean-square deviations in scale and frequency, defined, respectively, by

$$\Delta s_X^2 \equiv \frac{1}{E_X} \int_{-\infty}^{+\infty} (s-s_0)^2 |\underline{X}(s)|^2 \, ds \tag{24}$$

and

$$\Delta f_X^2 \equiv \frac{1}{E_X} \int_0^{+\infty} (f-f_0)^2 |X(f)|^2 f^{2r+1} \, df, \tag{25}$$

we can prove the following.[3,21–23]

Proposition 16: Scale and frequency satisfy the uncertainty relation

$$\Delta s_X \Delta f_X \geqslant \frac{f_0}{4\pi}, \tag{26}$$

with equality if and only if $X(f)$ *is a ''Klauder wavelet'' of the form*

$$X(f) = C f^{\alpha} e^{-\beta f} f^{i\gamma} U(f), \tag{27}$$

with $C \in \mathbf{C}$, $(\alpha, \beta, \gamma) \in \mathbf{R}_+ \times \mathbf{R}_+ \times \mathbf{R}$ *and* $U(\cdot)$ *the unit step function.*

Proof: In order to get simplified notations, let us introduce the quantities $\mathcal{S}_0 \equiv \mathcal{S} - s_0 \mathcal{I}$ and $\mathcal{F}_0 \equiv \mathcal{F} - f_0 \mathcal{I}$, with $\mathcal{I}$ the identity operator. It follows from the unitarity of the Mellin transform that

$$\Delta s_X^2 = \int_0^{+\infty} |(S_0 X)(f)|^2 f^{2r+1} \, df,$$

so that we can write, by using the Cauchy–Schwarz inequality,

$$\begin{aligned} E_X^2 \Delta s_X^2 \Delta f_X^2 &= \int_0^{+\infty} |(S_0 X)(f)|^2 f^{2r+1} \, df \int_0^{+\infty} |(\mathcal{F}_0 X)(f)|^2 f^{2r+1} \, df \\ &\geqslant \left| \int_0^{+\infty} \overline{(S_0 X)(f)} (\mathcal{F}_0 X)(f) f^{2r+1} \, df \right|^2 = \left| \int_0^{+\infty} \overline{X(f)} (S_0 \mathcal{F}_0 X)(f) f^{2r+1} \, df \right|^2. \end{aligned}$$

Defining the anticommutator of any two operators $\mathcal{A}$ and $\mathcal{B}$ as $[\mathcal{A}, \mathcal{B}]_+ \equiv \mathcal{A}\mathcal{B} + \mathcal{B}\mathcal{A}$ and remarking that $[\mathcal{S}_0, \mathcal{F}_0] = [\mathcal{S}, \mathcal{F}]$, we get, in the specific case of scale and frequency, that

$$\mathcal{S}_0 \mathcal{F}_0 = \tfrac{1}{2}([\mathcal{S}_0, \mathcal{F}_0] + [\mathcal{S}_0, \mathcal{F}_0]_+) = \tfrac{1}{2}\left(\frac{i}{2\pi} \mathcal{I} + [\mathcal{S}_0, \mathcal{F}_0]_+ \right),$$

and it follows that

$$\Delta s_X^2 \Delta f_X^2 \geqslant \frac{f_0^2}{16\pi^2},$$

with equality if

$$[\mathcal{S}_0, \mathcal{F}_0]_+ = 0, \tag{28}$$

and for those signals $X(f)$ which satisfy, for some $\lambda \in \mathbf{C}$,

$$(\mathcal{S}_0 X)(f) = \lambda (\mathcal{F}_0 X)(f). \tag{29}$$

Plugging (29) into (28) yields that λ is necessarily purely imaginary (namely that $\lambda^2 = -\Delta s_X^2 / \Delta f_X^2$). By developing explicitly Eq. (29) which characterizes the signals with minimum uncertainty in scale and frequency, we end up with the differential equation

$$2 f \dot{X}(f) = [4\pi \, \mathrm{Im}\{\lambda\}(f - f_0) - 1 - i 4\pi s_0] X(f),$$

whose solution is given by

$$X(f)=K\ \exp(2\pi\ \mathrm{Im}\{\lambda\}f-(2\pi\ \mathrm{Im}\{\lambda\}f_0+\tfrac{1}{2}+i2\pi s_0)\log f),$$

with $K\in\mathbf{C}$ and $\mathrm{Im}\{\lambda\}<0$, so that the signal is of finite energy. This solution, which is only defined for positive frequencies, is of the form (27), and this concludes the proof.

In order to get an analog of Proposition 4 in the case of Mellin–Fourier variables, it is natural to consider the *unitary* Bertrand distribution $B_X(t,f)\equiv P_X^{(0)}(t,f)$, which, in many respects, is the counterpart of the Wigner–Ville distribution in the Mellin–Fourier domain. By definition, the unitary Bertrand distribution (also referred to as the *tomographic* distribution[20]) is obtained from (21) by setting $k=0$ in (22), and it reads explicitly as

$$B_X(t,f)=f^{2(r+1)-q}\int_{-\infty}^{+\infty}\left(\frac{u/2}{\sinh(u/2)}\right)^{2(r+1)}X\left(\frac{(u/2)e^{u/2}f}{\sinh(u/2)}\right)\overline{X\left(\frac{(u/2)e^{-u/2}f}{\sinh(u/2)}\right)}e^{i2\pi ftu}\,du. \quad (30)$$

With this definition, we are led to the following.

Proposition 17: Given any $S>0$, the unitary Bertrand distribution satisfies the Mellin-frequency uncertainty relation,

$$\Sigma_{sf}^2(\tilde{B}_X)\equiv\frac{1}{E_X}\int_{-\infty}^{+\infty}\int_0^{+\infty}\left[\left(\frac{s-s_0}{S}\right)^2+S^2\left(\frac{f}{f_0}-1\right)^2\right]\tilde{B}_X(s,f)f^{q-1}ds\ df\geqslant\frac{1}{2\pi},$$

with equality, if and only if $X(f)$ is a Klauder wavelet.

Proof: The proof relies on marginal properties of the unitary Bertrand distribution, according to which

$$\int_{-\infty}^{+\infty}\tilde{B}_X(s,f)ds=f^{2(r+1)-q}|X(f)|^2$$

and

$$\int_0^{+\infty}\tilde{B}_X(s,f)f^{q-1}\,df=|\underline{X}(s)|^2.$$

Using the definitions (24) and (25), it follows directly from these relations that

$$\Sigma_{sf}^2(\tilde{B}_X)=\frac{\Delta s_X^2}{S^2}+S^2\,\frac{\Delta f_X^2}{f_0^2}=\left(\frac{\Delta s_X}{S}-S\,\frac{\Delta f_X}{f_0}\right)^2+2\,\frac{\Delta s_X\Delta f_X}{f_0}\geqslant 2\,\frac{\Delta s_X\Delta f_X}{f_0},$$

with equality if S is ''matched'' to the signal according to $S=\sqrt{f_0\Delta s_X/\Delta f_X}$. In this case, we know from (26) that the product $\Delta s_X\Delta f_X$ is lower bounded too, with equality in the only case of Klauder wavelets, whence the result.

B. Separability

The question we are interested in here can be stated as follows: is it possible to get affine distributions (23) which are separable in their Mellin and Fourier variables for some signal $X(f)$, i.e., such that they can be put in the form

$$\tilde{P}_X^{(k)}(s,f)=p(s)Q(f), \quad (31)$$

where $p(s)$ and $Q(f)$ are functions to be determined?

A first answer to this question can be looked after in the spirit of Proposition 3, which has been established thanks to the correct marginal properties of the Wigner–Ville distribution, in both time and frequency. In the specific case of the unitary Bertrand distribution (30), we have, in fact,[20] the two marginal properties

$$\int_{-\infty}^{+\infty} B_X(t,f)\,dt = f^{2r+1-q}|X(f)|^2 \tag{32}$$

and

$$\int_{-\infty}^{+\infty}\int_{0}^{+\infty} B_X(t,f)\,\delta\left(t-\frac{s}{f}\right) f^{q-1}\,dt\,df = |\underline{X}(s)|^2. \tag{33}$$

Within this new context, and considering first the frequency marginal property (32), it is easy to show that the separability condition (31) leads to

$$\begin{aligned}|X(f)|^2 &= f^{q-2r-1}\int_{-\infty}^{+\infty} B_X(t,f)\,dt \\ &= f^{q-2(r+1)}\int_{-\infty}^{+\infty}\widetilde{B}(s,f)\,\frac{ds}{f} = f^{q-2(r+1)}\int_{-\infty}^{+\infty} p(s)Q(f)\,\frac{ds}{f} = f^{q-2(r+1)}P(0)\,\frac{Q(f)}{f}\geqslant 0,\end{aligned}$$

whereas, by using the Mellin marginal (33), we obtain, in a similar way,

$$\begin{aligned}|\underline{X}(s)|^2 &= \int_{-\infty}^{+\infty}\int_{0}^{+\infty} B_X(t,f)\,\delta\left(t-\frac{s}{f}\right) f^{q-1}dt\,df \\ &= \int_{0}^{+\infty}\widetilde{B}_X(s,f)f^{q-1}\,df = p(s)\int_{0}^{+\infty} Q(f)f^{q-1}\,df \geqslant 0.\end{aligned}$$

Combining these two marginals, we get

$$P(0)\int_{0}^{+\infty} Q(f)f^{q-1}\,df = E_X \geqslant 0,$$

with the consequence that

$$\widetilde{B}_X(s,f) = \frac{|\underline{X}(s)|^2 f^{2(r+1)-q}|X(f)|^2}{E_X} \geqslant 0.$$

We could therefore think of having proved that, as for Wigner–Ville, separability implies positivity. The situation is, however, different since, unfortunately, the assumption of separability can be proved not to be admissible for unitary Bertrand distributions. This is evidenced by the following.

Proposition 18: The only affine distributions which are compatible with separability are characterized by (21) and (22) with $k=-1$, $1/2$, *or* 2.

Proof: Assuming that separability holds, we can take the Fourier transform of (31) with respect to s, and we get

$$\begin{aligned}P(\sigma)Q(f) &= \int_{-\infty}^{+\infty}\widetilde{P}_X^{(k)}(s,f)e^{-i2\pi\sigma s}\,ds \\ &= f^{2(r+1)-q}\int_{-\infty}^{+\infty}\mu_k(u)X(\lambda_k(u)f)\overline{X(\lambda_k(-u)f)}\,\delta(\sigma-\zeta_k(u))du \\ &= f^{2(r+1)-q}\mu_k(\zeta_k^{-1}(\sigma))w(\sigma)X(\lambda_k(\zeta_k^{-1}(\sigma))f)\overline{X(\lambda_k(-\zeta_k^{-1}(\sigma))f)},\end{aligned}$$

with $w(\sigma)=(d/d\sigma)\zeta_k^{-1}(\sigma)$. Setting $\zeta_k^{-1}(\sigma)=u$, we end up with

$$P(\zeta_k(u))Q(f) = f^{2(r+1)-q}\mu_k(u)w(\zeta_k(u))X(\lambda_k(u)f)\overline{X(\lambda_k(-u)f)},$$

a relation which implies that

$$X(\lambda_k(u)f)\overline{X(\lambda_k(-u)f)}=\frac{P(\zeta_k(u))}{\mu_k(u)w(\zeta_k(u))}\,\frac{Q(f)}{f^{2(r+1)-q}}\equiv\tilde{P}(u)\tilde{Q}(f). \tag{34}$$

We know from Ref. 20 that $\lambda_k(0)=1$. Imposing $u=0$ in (34), we get therefore $|X(f)|^2=\tilde{P}(0)\tilde{Q}(f)$ and, hence,

$$\frac{X(\lambda_k(u)f)\overline{X(\lambda_k(-u)f)}}{|X(f)|^2}=\frac{\tilde{P}(u)}{\tilde{P}(0)}. \tag{35}$$

This states that the left-hand side of (35) is necessarily a function of u only. In order to find solutions (and conditions for their existence) to the functional equation (35), we can factor $X(f)$ in a (non-negative) modulus term and a phase term according to $X(f)=|X(f)|\exp\{i\arg X(f)\}\equiv\exp\{\Phi(f)+i\Psi(f)\}$, thus leading to

$$\frac{X(\lambda_k(u)f)\overline{X(\lambda_k(-u)f)}}{|X(f)|^2}=e^{\{\Phi(\lambda_k(u)f)+\Phi(\lambda_k(-u)f)-2\Phi(f)]+i[\Psi(\lambda_k(u)f)-\Psi(\lambda_k(-u)f)\}}.$$

Within this formulation, imposing (35) to hold requires that both the real and imaginary parts of the above exponential do not depend upon f. The condition on the phase $\Psi(f)$ is

$$\frac{\partial}{\partial f}[\Psi(\lambda_k(u)f)-\Psi(\lambda_k(-u)f)]=0,$$

or, equivalently [by letting $\lambda_k(u)f=\xi$ and $\lambda_k(-u)f=\zeta$], $\xi\dot{\Psi}(\xi)=\zeta\dot{\Psi}(\zeta)$ for any $(\xi,\zeta)\in\mathbf{R}_+^2$. This does not impose any restriction on the admissible distributions but constrains the phase to be of the form

$$\Psi(f)=a\,\log f+b, \tag{36}$$

with $(a,b)\in\mathbf{R}^2$. Concerning the modulus, the condition can be written as

$$\frac{\partial}{\partial f}[\Phi(\lambda_k(u)f)+\Phi(\lambda_k(-u)f)-2\Phi(f)]=0,$$

or, equivalently,

$$\dot{\Phi}(f)=\frac{\lambda_k(u)\dot{\Phi}(\lambda_k(u)f)+\lambda_k(-u)\dot{\Phi}(\lambda_k(-u)f)}{2}.$$

This expression can be rewritten by introducing, as before, $\lambda_k(u)f=\xi$ and $\lambda_k(-u)f=\zeta$, thus defining f as the *Stolarsky's generalized mean* of ξ and ζ,[24] whose expression reads explicitly as $f=\Theta(\xi,\zeta)$, with

$$\Theta(\xi,\zeta)=\left(\frac{1}{k}\,\frac{\xi^k-\zeta^k}{\xi-\zeta}\right)^{1/(k-1)}. \tag{37}$$

What we get is $\Theta(\xi,\zeta)\dot{\Phi}(\Theta(\xi,\zeta))=(\xi\dot{\Phi}(\xi)+\zeta\dot{\Phi}(\zeta))/2$, and finally, if we let

$$m(f)\equiv f\dot{\Phi}(f), \tag{38}$$

we end up with $m(\Theta(\xi,\zeta))=(m(\xi)+m(\zeta))/2$ or, equivalently,

$$\Theta(\xi,\zeta)=m^{-1}\left(\frac{m(\xi)+m(\zeta)}{2}\right).$$

We recognize therefore that the Stolarsky's generalized mean (37) must necessarily be of the form of a *quasiarithmetic generalized mean* (in the sense of Kolmogorov and Nagumo), a situation we know to be true only if $k=-1$, 1/2, or 2, as proved in (Ref. 25, Appendix A). This concludes the proof.

It appears therefore that the unitary Bertrand distribution ($k=0$) is excluded from the class of affine distributions which may be separable in their Fourier and Mellin variables. The three cases mentioned in the Proposition can, however, be studied in further detail by specifying the corresponding generalized means and the associated distributions, and by identifying the signals which guarantee separability.

1. Case k=2

The generalized mean (37) reduces in this case to the arithmetic mean[25]

$$\Theta(\xi,\zeta)=\frac{\xi+\zeta}{2}\Leftrightarrow m(f)=af+b,$$

and, according to (38), $\dot{\Phi}(f)=a+b/f$, which leads to $\Phi(f)=af+b\log f+c$. Together with (36), the associated class of signals is therefore of the form

$$X_2(f)=Cf^{\alpha}e^{-\beta f}f^{i\gamma}U(f),$$

with $C\in\mathbf{C}$, $(\alpha,\beta,\gamma)\in\mathbf{R}^3$, and $U(\cdot)$ the unit step function, thus corresponding to the family of the ''Klauder wavelets'' (27) when α and β are both positive.

Assuming that $X(f)$ is analytic, i.e., vanishes for negative frequencies, it is known[20,25] that the case ($k=2$, $q=0$, $r=-1/2$) corresponds to the Wigner–Ville distribution,

$$W_X(t,f)=\int_{-2f}^{+2f}X\left(f+\frac{\nu}{2}\right)\overline{X\left(f-\frac{\nu}{2}\right)}e^{i2\pi\nu t}\,d\nu,$$

for a suitable choice of the weighting function $\mu_2(u)$, namely $\mu_2(u)=\cosh^{-2}(u/2)$. In this case, a direct calculation shows that

$$\widetilde{W}_{X_2}(s,f)=2|C|^2f^{2\alpha+1}e^{-2\beta f}\int_{-1}^{+1}(1-w^2)^{\alpha}\left(\frac{1+w}{1-w}\right)^{i\gamma}e^{i4\pi sw}\,dw\;U(f).$$

One can remark that, in the real case where $\gamma=0$, this result can be given a closed form expression which reads as

$$\widetilde{W}_{X_2}(s,f)=2|C|^2\sqrt{\pi}\Gamma(\alpha+1)f^{2\alpha+1}e^{-2\beta f}\,\frac{J_{\alpha+1/2}(4\pi|s|)}{(2\pi|s|)^{\alpha+1/2}}\,U(f),$$

where $J_{\nu}(\cdot)$ stands for the Bessel function of the first kind.[26]

Remark: Whereas in this special case, $\widetilde{W}_{X_2}(s,f)$ is separable and is of the form $\widetilde{W}_{X_2}(s,f)=k(s)f|X(f)|^2$, it can be checked that $k(s)$ is neither proportional to the Mellin density $|\underline{X}(s)|^2$ nor positive.

2. Case k=−1

The generalized mean (37) reduces in this case to the geometric mean,[25]

$$\Theta(\xi,\zeta)=\sqrt{\xi\zeta}\Leftrightarrow m(f)=a\,\log f+b,$$

and, according to (38), $\dot{\Phi}(f)=a(\log f)/f+b/f$, which leads to $\Phi(f)=(a/2)\log^2 f+b\log f+c$. Together with (36), the associated class of signals reads as

$$X_{-1}(f)=Cf^{\alpha}e^{-\beta\log^2 f}f^{i\gamma}U(f), \tag{39}$$

and it generalizes a family of wave forms defined by Altes[27] (the special case of the above expression with $\alpha=0$ and $\beta>0$).

It is known[20,25] that the case ($k=-1$, $q=0$, $r=-1/2$) corresponds to the so-called *Unterberger distribution*, which, in its ''active form'' [i.e., when setting $\mu(u)=\cosh(u/2)$[20]], reads as

$$\tilde{U}_X(s,f)=f\int_{-\infty}^{+\infty}\left(1+\frac{1}{\gamma^2}\right)X(\gamma f)\overline{X\left(\frac{f}{\gamma}\right)}e^{i2\pi(\gamma-1/\gamma)s}\,d\gamma. \tag{40}$$

A direct calculation shows that

$$\tilde{U}_{X_{-1}}(s,f)=|C|^2f^{2\alpha+1}e^{-2\beta(\log^2 f+\gamma^2/4)}\int_{-\infty}^{+\infty}e^{-2\beta(a\,\sinh w-i(\gamma/2))^2}e^{i4\pi sw}\,dw\;U(f).$$

Remark: The family of wave forms (39) has been introduced by Altes in a context of active sonar, such as encountered in bat echolocation. They are, in fact, solutions to the problem of ''Doppler tolerance,'' which consists in estimating at best (no bias and the highest signal-to-noise ratio) a time delay in the presence of some unknown Doppler shift.

3. Case k=1/2

The generalized mean (37) reduces in this case to the square-root mean[25]

$$\Theta(\xi,\zeta)=\left(\frac{\sqrt{\xi}+\sqrt{\zeta}}{2}\right)^2\Leftrightarrow m(f)=a\sqrt{f}+b,$$

and, according to (38), $\dot{\Phi}(f)=a/\sqrt{f}+b/f$, which leads to $\Phi(f)=2a\sqrt{f}+b\,\log f+c$. Together with (36), the associated class of signals reads as

$$X_{1/2}(f)=Cf^{\alpha}e^{-\beta\sqrt{f}}f^{i\gamma}U(f).$$

It is known[20,25] that the case ($k=1/2$, $q=0$, $r=-1/2$) comprises the so-called ''*D* distribution:''

$$\tilde{D}_X(s,f)=f\int_{-4}^{+4}\left[1-\left(\frac{\gamma}{4}\right)^2\right]X\left(\left(1+\frac{\gamma}{4}\right)^2f\right)\overline{X\left(\left(1-\frac{\gamma}{4}\right)^2f\right)}e^{i2\pi s\gamma}d\gamma,$$

and a direct calculation shows that

$$\tilde{D}_{X_{1/2}}(s,f)=4|C|^2f^{2\alpha+1}e^{-2\beta\sqrt{f}}\int_{-1}^{+1}(1-w^2)^{\alpha}\left(\frac{1+w}{1-w}\right)^{i\gamma}e^{i8\pi sw}\,dw\;U(f).$$

If $\gamma=0$, this result can be simplified to

$$\tilde{D}_{X_{1/2}}(s,f)=4|C|^2\sqrt{\pi}\Gamma(\alpha+1)f^{2\alpha+1}e^{-2\beta\sqrt{f}}\,\frac{J_{\alpha+1/2}(8\pi|s|)}{(4\pi|s|)^{\alpha+1/2}}\,U(f).$$

C. Positivity

It has already been mentioned that Wigner–Ville distributions attain generally negative values, but that they are everywhere positive when applied to a Gaussian signal and, more generally, to the exponential of a quadratic polynomial.[6] It is our purpose in this section to point out related results in the case of affine time–frequency distributions.

1. Unitary Bertrand distributions

We will first show that, in the case of the (unitary) Bertrand distribution (30), ''Klauder wavelets'' play a role which has much to share with the one played by Gaussians in the Wigner–Ville case. To this end, it is convenient to generalize and reparametrize the Klauder wavelet (27) as

$$X_2(f) \equiv C f^{-(r+1)} e^{2\pi\lambda(f_0 \log f - f)} e^{-i2\pi(\beta_0 \log f + \xi f)} U(f), \tag{41}$$

with $C \in \mathbf{C}$, and r, λ, f_0, β_0, and ξ real-valued parameters such that $\lambda \geqslant 0$ and $f_0 > 0$. This reformulation allows a simple physical interpretation of the parameters since the mean frequency f_m and the Q factor defined by $Q \equiv f_m/\Delta f$ are given, respectively, by $f_m = f_0$ and $Q^2 = 4\pi\lambda$. Moreover, the phase term is written so as to correspond to a modulation with a hyperbolic group delay $t_{X_2}(f) = \xi + \beta_0/f$.

Given these notations, we have the following.

Proposition 19: The unitary Bertrand distribution of the Klauder wavelet (41) is everywhere non-negative.

Proof: The proof relies on properties of characteristic functions (which are Fourier transforms of non-negative functions), and it proceeds as follows. We first start from the definition (41) of the Klauder wavelet and we plug it into the definition (30) of the Bertrand distribution. After some manipulations, the result can be expressed as

$$B_{X_2}(t,f) = |C|^2 f^{\alpha-q} \int_{-\infty}^{+\infty} M_{\alpha,\beta}(u) e^{-i2\pi\zeta u}\, du\; U(f), \tag{42}$$

with

$$M_{\alpha,\beta}(u) \equiv \left(\frac{u/2}{\sinh(u/2)} \right)^{\alpha} \exp\{-\beta u \coth(u/2)\} \tag{43}$$

and

$$\alpha \equiv 4\pi\lambda f_0; \quad \beta \equiv 2\pi\lambda f; \quad \zeta \equiv \beta_0 - (t-\xi) f. \tag{44}$$

In order to prove that (42) corresponds to a non-negative quantity, it is then sufficient to show that $M_{\alpha,\beta}(u)$ is—up to a positive constant—a characteristic function, a property which will obviously hold if each of the two factors of (43) is itself proportional to a characteristic function.[28] Using first the fact that[29]

$$\sinh x = x \prod_{k=1}^{\infty} \left(1 + \frac{x^2}{k^2\pi^2} \right),$$

we can write

$$\left(\frac{u/2}{\sinh(u/2)} \right)^{\alpha} = \prod_{k=1}^{\infty} \left(1 + i\, \frac{u}{2k\pi} \right)^{-\alpha} \left(1 - i\, \frac{u}{2k\pi} \right)^{-\alpha}.$$

This is clearly a characteristic function since, α being positive, each of the factors of this infinite product is the characteristic function of a Gamma distribution.[28] Using then the fact that[29]

$$\coth \pi x = \frac{1}{\pi x} + \frac{2x}{\pi} \sum_{k=1}^{\infty} \frac{1}{x^2 + k^2},$$

we can write.

$$\exp\{-\beta u \coth(u/2)\} = e^{-2\beta} \prod_{k=1}^{\infty} \exp\left\{ 4\beta \left(\frac{1}{1 + (u/2k\pi)^2} - 1 \right) \right\}. \tag{45}$$

Since $(1 + (u/2k\pi)^2)^{-1}$ is a characteristic function (namely the characteristic function of a Laplace distribution) and $\beta \geqslant 0$, it suffices to make use of a theorem by Lukacs[28]—stating that, if $g(u)$ is a characteristic function and γ a positive real number, $\exp\{\gamma(g(u)-1)\}$ is itself a characteristic function—for guaranteeing that each of the factors of (45) and, hence, (45) itself is a

characteristic function. The two factors of (43) each being a characteristic function, the Fourier transform of their product is everywhere non-negative and the proof is complete.

Two remarks.

(1) Assuming as we did that $\lambda>0$, we have $X_2(f)\in L^2(\mathbf{R}_+, f^{2r+1}\,df)$ and $B_{X_2}(t,f)$ is a bounded square-integrable function. A degeneracy is, however, observed in the case of the ''hyperbolic chirps'' $C_0(f)$ corresponding to $X_2(f)$ with $\lambda=0$, and for which we know[20] that

$$B_{C_0}(t,f)=|C|^2 f^{-q-1}\delta\left(t-\left(\xi+\frac{\beta_0}{f}\right)\right)U(f),$$

a result which also follows directly from (42), (43), and (44), since we have then $\alpha=\beta=0$, and hence $M_{\alpha,\beta}=1$.

(2) According to the definition (27), the nonzero frequency f_0 can be interpreted as the central frequency of the (envelope of the) Klauder wavelet. Within the narrow band assumption $Q^2=4\pi\lambda\gg 1$, we get the approximation

$$X_2(f)\sim C'\exp\left\{-\frac{\pi}{f_0}(\lambda-i\beta_0)\delta f^2-i2\pi\left(\xi+\frac{\beta_0}{f_0}\right)\delta f\right\},$$

where $\delta f\equiv f-f_0$ and C' is some suitable (complex-valued) constant. This means that narrow band Klauder wavelets reduce to Gaussians, in clear accordance with the fact that the Bertrand distribution reduces to the Wigner–Ville one for narrow band signals,[20] and that Wigner–Ville distributions are non-negative for Gaussians.

2. Unterberger distributions

A result similar to the one of the previous Proposition can be obtained in the case of the active Unterberger distribution (40), but it requires replacing the Klauder wavelet by the signal

$$X_{-1}(f)\equiv Cf^{-(r+1)}e^{-2\pi\lambda(\alpha_0/f+f)}e^{-i2\pi(\xi f-\alpha/f)}U(f),$$

with $\alpha_0>0$. More precisely, we can prove the following.

Proposition 20: The active Unterberger distribution of $X_{-1}(f)$ is everywhere non-negative.

Proof: The proof follows from a direct calculation according to which

$$U_{X_{-1}}(t,f)=2|C|^2 f^{-(2r+1)}\int_{-\infty}^{+\infty}e^{-4\pi\lambda(\alpha_0/f+f)\sqrt{1+(w/2)^2}}e^{i4\pi(tf-\xi f-\alpha/f)w}\,dw\;U(f),$$

a result which can be equivalently expressed as (see, e.g., Ref. 30)

$$U_{X_{-1}}(t,f)=4|C|^2 f^{-(2r+1)}G_\beta\left(4\pi\left(tf-\xi f-\frac{\alpha}{f}\right)\right)U(f),$$

with $\beta\equiv 4\pi\lambda(f+\alpha_0/f)$ and

$$G_\beta(y)\equiv\frac{2\beta}{\sqrt{\beta^2+y^2}}K_1(\beta^2+y^2), \tag{46}$$

$K_1(\cdot)$ being a modified Bessel function of the first kind.[26] Positivity of the distribution is therefore guaranteed by the simple fact that modified Bessel functions $K_\nu(z)$ are known to be positive if $\nu>-1$ and $z>0$.[26]

Unterberger distributions also exist under a ''passive'' form,[20] whose definition reads as

$$V_X(t,f)=f\int_{-\infty}^{+\infty}X(\gamma f)\overline{X\left(\frac{f}{\gamma}\right)}e^{i2\pi(\gamma-1/\gamma)tf}\,\frac{d\gamma}{\gamma}.$$

''Active'' Unterberger distributions are known to be perfectly localized for signals whose group delay is defined by squared hyperbolas of the form $\alpha+\gamma/f^2$, but they are also known not to

be unitary (in fact, it can be shown[20] that unitary Bertrand distributions are the only distributions guaranteeing both localization and unitarity). ''Passive'' Unterberger distributions share a lot of properties with ''active'' ones, at the notable exception of localization. Both forms are, in fact, ''dual'' in the sense that, whereas none has simultaneously properties similar to the unitary Bertrand distribution, they can be combined so as to satisfy the Moyal-type formula

$$\int_{-\infty}^{+\infty}\int_{0}^{+\infty} U_X(t,f)V_Y(t,f)\,dt\,\frac{df}{f}=\left|\int_{0}^{+\infty} X(f)\overline{Y(f)}\,\frac{df}{f}\right|^2.$$

With the above definition for $V_X(t,f)$, the following can be proved.

Proposition 21: The passive Unterberger distribution of $X_{-1}(f)$ is everywhere non-negative.

Proof: This can be checked by a direct calculation, according to which

$$V_X(t,f)=2|C|^2 f^{-(2r+1)}K_0\left(\sqrt{\beta^2+4\pi^2\left(tf-\xi f-\frac{\alpha}{f}\right)^2}\right)U(f),$$

which concludes the proof exactly as in the previous Proposition.

Remark: The closed form expression given above can be found almost exactly in Ref. 31, where the authors introduce a time-scale energy distribution whose definition has essentially the form of a passive Unterberger distribution.

In the case of the Wigner–Ville distribution, Hudson's theorem guarantees that Gaussian signals are the only ones ensuring positivity, whereas the question is left open to prove that Klauder wavelets would be the only signals with a (unitary) Bertrand distribution everywhere positive. In the case of the (active) Unterberger distribution, a class of signals ensuring positivity has been evidenced in Proposition 20, but it can be proved that this solution is not unique. Two counterexamples to unicity for positive Unterberger distributions are provided by the two following claims.

Proposition 22: The active Unterberger distribution of

$$Y_{-1}(f)\equiv Cf^{-(r+1)}e^{-2\pi\lambda f^2}e^{-i2\pi(\xi f-\alpha/f)}U(f),$$

is everywhere non-negative.

Proof: The active Unterberger distribution (40) admits the (time–frequency) equivalent form

$$U_X(t,f)=2f\int_{-\infty}^{+\infty}\cosh u\,X(e^u f)\overline{X(e^{-u}f)}e^{i4\pi tf\sinh u}\,du\,U(f).$$

Plugging the definition of $Y_{-1}(f)$ into this expression yields

$$U_{Y_{-1}}(t,f)=\frac{|C|^2}{\sqrt{2\lambda}}f^{-(2r+1)}e^{-4\pi\lambda f^2}e^{(-2\pi/\lambda)(t-\xi-\alpha/f^2)^2}U(f),$$

whence the result.

Remark: When applied to $Y_{-1}(f)$ with $\alpha=0$ (a constant group delay), the active Unterberger distribution is not only positive, but also separable in time and frequency.

Proposition 23: The active Unterberger distribution of

$$Z_{-1}(f)\equiv Cf^{-(r+1)}e^{-2\pi\lambda f}e^{-i2\pi(\xi f-\alpha/f)}U(f)$$

is everywhere non-negative.

Proof: The proof follows from a direct calculation, according to which

$$U_{Z_{-1}}(t,f)=2|C|^2 f^{-(2r+1)}G_{4\pi\lambda f}\left(4\pi\left(tf-\xi f-\frac{\alpha}{f}\right)\right)U(f), \tag{47}$$

with $G(\cdot)$ defined as in (46), and positivity stemming from the usual assumption $\lambda>0$.

V. CONCLUDING REMARKS

In this paper, a number of results have been given which—although still preliminary in many respects and far from exhausting the subject—are believed to clarify some of the links which exist between positivity, separability, and minimum uncertainty in time–frequency energy distributions. In fact, whereas in the case of the Wigner–Ville distribution, these features may admit order relations of the type ''separability⇒positivity⇒minimum uncertainty,'' it has been shown that the situation of other distributions is more intricate, with possible incompatibilities between the three different properties. Affine distributions (based on frequency and on a Mellin variable, in place of the usual time variable) have especially been considered in some detail, with two main consequences which make them depart from the Wigner–Ville case.

(1) In comparison with the known fact that minimizers of the classical time–frequency uncertainty—Gaussians with a linear phase—have a positive and separable Wigner–Ville distribution, signals with minimum frequency-scale uncertainty—namely, Klauder wavelets—do possess a positive (unitary) Bertrand distribution, but this latter is not separable.
(2) Whereas positivity is an exception in the Wigner–Ville case and can be observed with Gaussian signals only, it turns out that this situation of unicity is no longer true in the affine case, different classes of signals having been evidenced to lead to positive distributions.

As already mentioned, many questions are still left open, such as, e.g., the question of unicity for the positivity of *unitary* Bertrand distributions. From another perspective, it can be finally mentioned that other types of extensions (e.g., to the hyperbolic class[32] and, more generally, to ''warped'' classes[33]) could have been considered, but have not, since the corresponding results can be readily anticipated from those given here. In fact, such extensions being related to usual classes (Cohen of affine) by a warping operation, all the results obtained in one case can be transformed, *mutatis mutandis*, to get the corresponding results in the other case. For instance, the Altes-Marinovic distribution,[34]

$$Q_X(s,f)=f\int_{-\infty}^{+\infty} X(e^{u/2}f)\overline{X(e^{-u/2}f)}e^{i2\pi su}\,du,$$

which is known to belong to (and be a central member of) the hyperbolic class,[32] can be expressed as well in terms of the usual Wigner distribution as

$$Q_X(s,f)=W_{\tilde{X}}\left(\frac{s}{f_0},f_0\log\frac{f}{f_0}\right),$$

with $\tilde{X}(f)=e^{f/2f_0}X(e^{f/f_0})$ and $f_0>0$. It follows that any result pertaining to the Wigner–Ville distribution can be transposed to the Altes–Marinovic distribution, provided that it is applied to signals warped the suitable way. In particular, an analog of Hudson's theorem can be given as (no new proof is really necessary)

Proposition 24: The Altes–Marinovic distribution is positive for ''Altes signals'' of the type (39), and only for them.

Time-frequency transfer function calculus (symbolic calculus) of linear time-varying systems (linear operators) based on a generalized underspread theory[a)]

Gerald Matz and Franz Hlawatsch
Department of Communications and Radio-Frequency Engineering, Vienna University of Technology, Gusshausstrasse 25/389, A-1040 Wien, Austria

(Received 17 December 1997; accepted for publication 31 March 1998)

We introduce a generalized concept of underspread linear time-varying systems (linear operators) which contains a previous definition as a special case. We show that an existing approximate transfer function calculus (symbolic calculus) can be extended to this wider and practically more relevant class of underspread operators. As a mathematical underpinning of this calculus, we establish explicit bounds on various error quantities associated with it. The transfer function calculus provides a theoretical basis for various methods recently proposed for nonstationary signal processing, and it has important implications in the theory of time-varying power spectra. © *1998 American Institute of Physics.* [S0022-2488(98)00708-7]

I. INTRODUCTION

Quantum physics and time-frequency signal theory are strongly interrelated fields. In a formal sense, the phase space of physics (physical quantities position q and momentum p) plays a similar role in quantum mechanics as the time-frequency plane in signal theory (variables time t and frequency f). This formal analogy has led to numerous interactions between the two fields. Important examples are the Wigner distribution,[1–9] the uncertainty principle,[10–15] the connections between coherent states and the short-time Fourier transform or Gabor expansion,[9,12,15–24] and the relation of the Zak (or Weil–Brezin) transform with the polyphase decomposition.[15,20,25–30] However, notwithstanding their similarity on a formal mathematical level, the interpretation and scope of time-frequency signal analysis and semiclassical quantum mechanics are somewhat different.

(i) In the semiclassical approach to quantum mechanics, one desires a ''mock phase space'' [31] that is similar to the phase space of classical mechanics. In contrast, in signal analysis one desires joint time-frequency descriptions (of signals, systems, random processes,...) in order to combine pure time-domain and pure frequency-domain descriptions. More specifically, the phase-space descriptions of quantum observables (corresponding to self-adjoint operators on Hilbert spaces) are intended to preserve as much as possible the structural properties and conceptual power of the phase-space description of classical observables (functions in phase space). An example is the computation of expectations in phase space using quasi-probability densities. On the other hand, in signal analysis there is nothing comparable to classical observables (therefore, taking the classical limit $h \to 0$ does not make sense in signal analysis). Rather, one is interested in extending existing powerful concepts like the transfer function/frequency response of time-invariant linear systems and the power spectral density of stationary random processes to the time-varying and nonstationary cases, respectively. These time-frequency representations should retain as much as possible the conceptual power and intuitive interpretation of the transfer function (power spectral density).

(ii) The difficulties encountered when working with a quantum-mechanical mock phase space arise mainly from the fundamental mathematical difference between functions (classical observables) and operators (quantum-mechanical observables). In contrast, the main complications in the time-frequency description of time-varying systems (nonstationary random

[a)]Dedicated to Professor Wolfgang Mecklenbräuker on the occasion of his sixtieth birthday.

 © 1998 American Institute of Physics

processes) are due to their fundamental difference from time-invariant systems (stationary random processes) for which a pure frequency-domain description is sufficient and satisfactory.

(iii) Another difference between the viewpoints taken in quantum mechanics and in signal analysis concerns the noncommutativity of linear operators. In quantum mechanics, this noncommutativity is a fundamental fact that is part of our mathematical description of the physical world, whereas in signal analysis it can be considered simply as an inconvenience that prevents powerful, simple, and intuitive concepts and methods valid in the time-invariant/stationary case from being extended to the more general time-varying/nonstationary case. In a signal analysis context, therefore, it is reasonable and practically important to ask whether there exists a subclass of operators (time-varying systems) that is approximately commuting (cf. Subsections III C and IV A).

A. Summary of results and outline of paper

In this paper we consider a time-frequency description of linear operators or, equivalently, linear time-varying systems that are related to semiclassical quantum mechanics[2,15,32–36] and to the mathematical theory of pseudo-differential operators.[37–41] This time-frequency description of operators is an attempt to generalize the simple and efficient frequency-domain description of linear time-invariant systems—namely, the transfer function or frequency response—to the time-varying case. The result is a transfer function calculus (known as *symbolic calculus* in a quantum-mechanical context) that extends a previously introduced transfer function calculus[42–44] to a considerably wider and practically more relevant class of linear operators. This extended transfer function calculus provides a theoretical basis for several methods that have recently been proposed for nonstationary signal processing (specifically, to design and implement time-varying filters for signal enhancement, estimation, and detection[45–53]). Furthermore, it has important implications in the theory of time-varying power spectra for nonstationary random processes.[42,53–55]

The transfer function calculus presented is based on the generalized Weyl symbol which is discussed in Subsection I C. This discussion is preceded by a brief review of time-varying, time-invariant, and frequency-invariant linear operators in Subsection I B.

As a basis for our extended transfer function calculus, in Section II we develop a generalized concept of ''underspread'' operators that uses weighted integrals and moments of the operators' spreading function and does not require the spreading function to have compact support. Subsequently, in Section III we employ these integrals/moments to formulate explicit bounds on the errors incurred by the transfer function approximation. These bounds provide a rigorous mathematical underpinning for the extended, approximate transfer function calculus proposed. We note that several of these bounds and their proofs are analogous to similar bounds and proofs presented previously,[42–44] even though our formulation using weighted integrals and moments of the spreading function is new. Finally, in Section IV we show that underspread operators are approximately commuting and normal.

We note that symbolic calculi in a similar spirit have been obtained in the context of semiclassical quantum mechanics[15,33,39,56] and pseudo-differential operators,[15,37,38,40] with particular similarity to classical asymptotics of quantum mechanics[10,15,39,56–58] (like the WBK method[10] or Voros' h-expansions[39,56]). The difference is that these theories define specific symbol classes—whose mathematical sophistication has hitherto prevented their application to signal processing problems—directly in phase space whereas in our approach we formulate growth conditions in the (dual) spreading function domain (cf. Subsection II B). Also, whereas in quantization and pseudo-differential operator theory one studies the operators corresponding to a given symbol, we consider a given linear operator and investigate how close its generalized Weyl symbol comes to the intuitive engineering notion of a time-frequency transfer function.

B. Time-varying, time-invariant, and frequency-invariant linear operators

Linear time-varying systems/operators are useful models in a variety of engineering applications as diverse as speech production and mobile communications. (In what follows, we tacitly assume that all systems/operators are linear.) Except for the limiting cases of time-invariant and

frequency-invariant systems (see below), we will subsequently restrict our attention to Hilbert–Schmidt operators,[59] i.e., operators $\mathbf{H}$ with a finite Hilbert–Schmidt norm,

$$\|\mathbf{H}\|_2 \triangleq \sqrt{\sum_k \|\mathbf{H}u_k\|_2^2} < \infty,$$

where $\{u_k(t)\}$ is an arbitrary orthonormal basis of $L_2(\mathbb{R})$. Although in quantum mechanics many observables correspond to unbounded operators, our restriction to Hilbert–Schmidt operators (which are always bounded) is consistent with most engineering applications. The input-output relation for a Hilbert–Schmidt operator $\mathbf{H}$ can be written as (integrals are from $-\infty$ to ∞)

$$(\mathbf{H}x)(t) = \int_{t'} h(t,t')x(t')dt', \tag{1}$$

where $x(t)$ and $(\mathbf{H}x)(t)$ are the system's input and output signal, respectively, and $h(t,t') \in L_2(\mathbb{R}^2)$ is the kernel (impulse response) of $\mathbf{H}$. We note that $\|\mathbf{H}\|_2^2 = \int_t \int_{t'} |h(t,t')|^2 dt dt'$.

Unfortunately, time-varying systems/operators are much more difficult to analyze and characterize than time-invariant systems, i.e., operators that commute with time shifts and have a convolution-type kernel of the form $h(t,t') = g(t-t')$. For time-invariant systems the *transfer function* (frequency response),

$$G(f) = \int_\tau g(\tau) e^{-i2\pi f\tau} d\tau,$$

is an extremely simple and efficient system description. This is due to the following properties.

(i) The complex sinusoids $\{e^{i2\pi ft}\}$ (parametrized by frequency f) are the generalized[60] eigenfunctions of any time-invariant operator, with $G(f)$ the associated generalized eigenvalues, i.e., $(\mathbf{H}x)(t) = G(f)e^{i2\pi ft}$ for $x(t) = e^{i2\pi ft}$. This is also the reason why all linear time-invariant systems commute with each other.

(ii) As a consequence of the previous property, the Fourier transform of $(\mathbf{H}x)(t)$ equals the Fourier transform of $x(t)$ multiplied by $G(f)$. Hence, in the frequency (Fourier) domain, the input-output relation simplifies to the multiplication of two functions.

(iii) The transfer function of the series connection (product) of two linear time-invariant systems with transfer functions $G_1(f)$ and $G_2(f)$ equals $G_1(f)G_2(f)$.

(iv) The adjoint[59] $\mathbf{H}^+$ of a time-invariant system has impulse response $g^*(-\tau)$, and hence its transfer function is simply the complex conjugate of $G(f)$.

(v) For input signals $x(t) \in L_2(\mathbb{R})$, the maximum system gain is equal to the supremum of $|G(f)|$.

The dual of linear time-invariant systems is given by linear ''frequency-invariant'' systems (i.e., operators commuting with frequency shifts), which correspond to time-domain multiplications and have an impulse response of the form $h(t,t') = m(t)\delta(t-t')$. Here, the factor $m(t)$ plays the role of a ''temporal transfer function'' with properties similar to those of the spectral transfer function $G(f)$ of linear time-invariant systems. We note that the quantum-mechanical counterparts of time-invariant and frequency-invariant systems are observables that depend solely on momentum and solely on position, respectively.

Compared to time-invariant and frequency-invariant systems, general linear operators are much more difficult and less intuitive to work with. In particular, as opposed to time-invariant (frequency-invariant) operators which are always normal (i.e., which satisfy $\mathbf{H}^+\mathbf{H} = \mathbf{H}\mathbf{H}^+$) and which always commute, general operators are potentially non-normal and typically noncommuting. For normal operators, a generalization of the transfer function $G(f)$ or $m(t)$ is provided by the operator's eigenvalues[59] (in the non-normal case one has to recur to singular values[59,61]). For example, the adjoint operator and the operator norm (maximum system gain) correspond to the complex conjugate and supremum, respectively, of the eigenvalues. Unfortunately, for practical engineering applications this concept has certain drawbacks and limitations.

(i) The eigenfunctions of a general linear operator are not known *a priori*, and their computa-

tion is expensive. The lack of a simple structure of the eigenfunctions prevents the application of efficient algorithms like the fast Fourier transform that is useful in the time-invariant case.

(ii) The eigenfunctions and eigenvalues are not related to the frequency or time variable.

(iii) The eigenfunctions of two noncommuting operators are different, and the eigenvalues of the operators' product (series connection of systems) are not equal to the product of the operators' eigenvalues.

C. The generalized Weyl symbol

Since the eigenvalue-based transfer function concept does not yield the desired physical relevance and computational efficiency, an alternative ''transfer function-like'' characterization of linear operators is needed. A ''time-varying transfer function'' of time-varying systems was introduced by Zadeh[62] and later complemented by Bello's frequency-dependent modulation function[63] which is equivalent to the Kohn–Nirenberg symbol[15,37] introduced in the theory of pseudo-differential operators. These two definitions correspond to what is known in the physical literature as standard and anti-standard correspondence rules.[31,34–36] In a signal processing context, the Weyl symbol,[4,15,32,64,65] originally introduced in quantum mechanics,[66] was then recognized as a further definition of a ''transfer function.'' [67]

Finally, Kozek[42,44,68] placed all three definitions within a unifying framework by defining the *generalized Weyl symbol* as

$$L_{\mathbf{H}}^{(\alpha)}(t,f) \triangleq \int_{\tau} h^{(\alpha)}(t,\tau) e^{-i2\pi f\tau} d\tau, \tag{2}$$

with the following coordinate-transformed version of the impulse response $h(t,t')$ in (1),

$$h^{(\alpha)}(t,\tau) \triangleq h(t+(\tfrac{1}{2}-\alpha)\tau, t-(\tfrac{1}{2}+\alpha)\tau). \tag{3}$$

Here, α is a parameter for which an interpretation will be provided in Subsection II A. Although any real-valued number may be taken for α, the case $|\alpha| \leqslant 1/2$ is of particular importance since this condition guarantees that the generalized Weyl symbol satisfies finite support properties.[42] We note that the generalized Weyl symbol is a special case of a more general correspondence rule between classical and quantum observables.[31,34,35,69] It is a function of the physically relevant variables time t and frequency f (in the quantum mechanical context, these correspond to position q and momentum p). For $\alpha = 0$, 1/2, and $-1/2$, it reduces to, respectively, the Weyl symbol, Zadeh's time-varying transfer function, and Bello's frequency-dependent modulation function. For rank-one operators, i.e., operators $\mathbf{H}$ of the type $h(t,t') = s(t)s^*(t')$, it equals the generalized Wigner distribution[70,71] of $s(t)$. For $\alpha = 0$ the generalized Wigner distribution simplifies to the Wigner distribution[1–6,8,9] whereas for $\alpha = 1/2$ the Rihaczek distribution[72] is obtained.

The generalized Weyl symbol satisfies many desirable mathematical properties.[42,68] In particular, it preserves inner products and Hilbert–Schmidt norms of operators, its integral over the entire time-frequency plane yields the operator's trace, and it is ''covariant'' to time-frequency shifts (Galilean invariance) and time-frequency scalings of operators. Furthermore, for time-invariant and frequency-invariant operators it simplifies to the spectral transfer function $G(f)$ and the temporal transfer function $m(t)$, respectively (this is the signal analysis reformulation of the fact that any valid quantum-mechanical correspondence rule yields the position and momentum operators as counterparts of the classical observables position and momentum, respectively).

The Weyl symbol (obtained with $\alpha = 0$) possesses an inherent symmetry which leads to two further important properties.

(i) The Weyl symbol of the adjoint operator $\mathbf{H}^+$ equals the complex conjugate of the Weyl symbol of $\mathbf{H}$, i.e., $L_{\mathbf{H}^+}^{(0)}(t,f) = L_{\mathbf{H}}^{(0)*}(t,f)$. Hence, the Weyl symbol of a self-adjoint (Hermitian) operator, i.e., an operator satisfying $\mathbf{H}^+ = \mathbf{H}$, is real-valued.[15,31,32,36]

(ii) The Weyl symbol is covariant to operator transformations by metaplectic operators $\mathbf{U} \in \mathscr{M}$, i.e., unitary operators that belong to the metaplectic representation $\mathscr{M}$ of the symplectic group $Sp(2,\mathbb{R})$ consisting of measure-preserving, linear time-frequency coordinate

transforms $\binom{t}{f} \to \begin{pmatrix} a & b \\ c & d \end{pmatrix}\binom{t}{f}$ [with $\det\begin{pmatrix} a & b \\ c & d \end{pmatrix} = ad - bc = 1$] such as rotations, shearings, and scalings:[4,15,40,41,64,73–75]

$$L^{(0)}_{\mathbf{UHU}^+}(t,f) = L^{(0)}_{\mathbf{H}}(at+bf, ct+df). \tag{4}$$

Unfortunately, in spite of its attractive mathematical properties the generalized Weyl symbol cannot, in general, be used as a transfer function in a manner similar to the time-invariant or frequency-invariant case. For example, the generalized Weyl symbol of an operator product does not generally equal the product of the individual symbols, and the supremum of the magnitude of the generalized Weyl symbol does not generally reflect the operator norm. Indeed, in a signal analysis context it has often been conjectured that the concept of a time-varying transfer function requires the system to be slowly time-varying.[48,63,76–80] However, it seems that until recently no quantitative formulation of this conjecture has been available.

In his pioneering work,[42–44] Kozek defined a class of ''underspread'' linear operators which even includes operators with fast time variations. He showed that this class allows an approximate transfer function calculus (symbolic calculus) based on the generalized Weyl symbol. Underspread operators were defined by the condition that the operator's spreading function (see Section II) has compact support contained within a rectangle of area $\ll 1$. Unfortunately, in practice this is typically not satisfied exactly but only effectively.

II. EXTENDED CONCEPT OF UNDERSPREAD SYSTEMS

Our extension of the generalized Weyl symbol based transfer function calculus (symbolic calculus) is based on a generalized concept of underspread operators. This concept is related to the time-frequency shifts introduced by linear operators and their characterization by means of the spreading function.

A. The spreading function

Contrary to time-invariant systems (which cause only time shifts) and frequency-invariant systems (which cause only frequency shifts), general linear operators shift the input signal with respect to both time and frequency. This behavior is reflected by the following reformulation of the input-output relation (1) as a weighted superposition of time-frequency-shifted versions of the input signal,[42–44,63,64,68,81]

$$(\mathbf{H}x)(t) = \int_\tau \int_\nu S^{(\alpha)}_{\mathbf{H}}(\tau,\nu) x^{(\alpha)}_{\tau,\nu}(t)\, d\tau\, d\nu. \tag{5}$$

Here, $x^{(\alpha)}_{\tau,\nu}(t) = x(t-\tau)e^{i2\pi\nu t}e^{i2\pi(\alpha-1/2)\tau\nu}$ is the signal $x(t)$ shifted by τ in time and by ν in frequency, with $\alpha \in \mathbb{R}$ expressing the freedom in ordering the time and frequency shifts.[32,42,68] This generalized time-frequency shift is equivalent to the Schrödinger representation of the three-dimensional (3-D) Heisenberg group[15,42,75,82] with parameters $(-\tau, \nu, \alpha\tau\nu)$. Relation (5) is, furthermore, equivalent to Weyl's original idea for establishing a correspondence rule between classical and quantum observables by Fourier-transforming the classical observable and then replacing the position and momentum variables in the exponent by the position and momentum operators.[15,31,32,34,36,83] The ''weighting function'' in (5), $S^{(\alpha)}_{\mathbf{H}}(\tau,\nu)$, is the *(generalized) spreading function* of $\mathbf{H}$ which is defined as[15,42,63,68,81]

$$S^{(\alpha)}_{\mathbf{H}}(\tau,\nu) \triangleq \int_t h^{(\alpha)}(t,\tau) e^{-i2\pi\nu t} dt,$$

with $h^{(\alpha)}(t,\tau)$ as in (3). For $\alpha = \pm 1/2$, the spreading function has first been introduced under the names of the ''delay-Doppler spread function'' and ''Doppler-delay spread function'' by Bello[63] who considered communication channels with multipath propagation and moving scatterers. Here, the received signal $(\mathbf{H}x)(t)$ consists of several delayed and Doppler-shifted versions of the original signal with the spreading function describing the ''reflectivity'' of the individual scatterers.

The spreading function is the 2-D (symplectic) Fourier transform of the generalized Weyl symbol in (2),

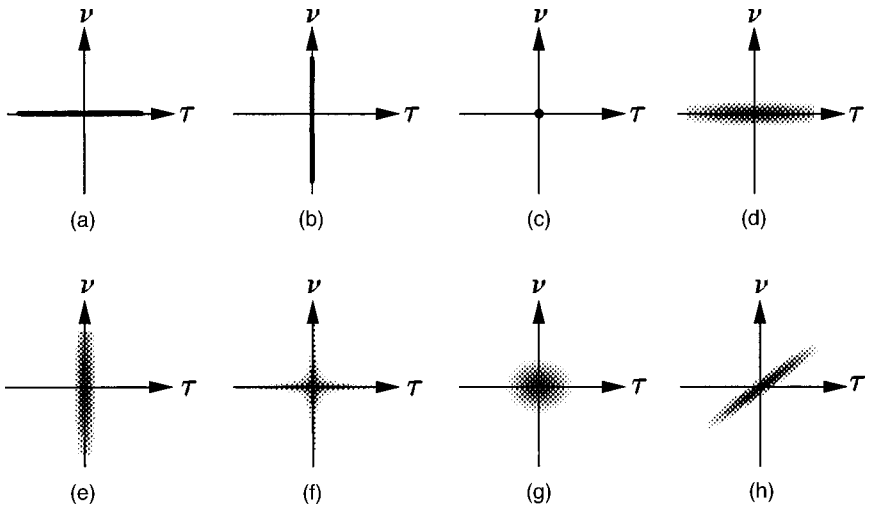

FIG. 1. Examples for the magnitude of the spreading function of some generic types of operators: (a) time-invariant system, (b) frequency-invariant system, (c) identity operator, (d) quasi-time-invariant system, (e) quasi-frequency-invariant system, (f)–(h) three different versions of underspread operators.

$$S_{\mathbf{H}}^{(\alpha)}(\tau,\nu)=\int_t\int_f L_{\mathbf{H}}^{(\alpha)}(t,f\,)e^{-i2\pi(\nu t-\tau f\,)}dtdf. \tag{6}$$

Spreading functions with distinct α differ only by a phase factor,[42]

$$S_{\mathbf{H}}^{(\alpha_2)}(\tau,\nu)=S_{\mathbf{H}}^{(\alpha_1)}(\tau,\nu)e^{i2\pi(\alpha_1-\alpha_2)\tau\nu}, \tag{7}$$

so that $|S_{\mathbf{H}}^{(\alpha_2)}(\tau,\nu)|=|S_{\mathbf{H}}^{(\alpha_1)}(\tau,\nu)|$. Hence, we will write $|S_{\mathbf{H}}(\tau,\nu)|$ instead of $|S_{\mathbf{H}}^{(\alpha)}(\tau,\nu)|$.

Like the generalized Weyl symbol, the spreading function preserves inner products and Hilbert–Schmidt norms of operators. Its value at the origin equals the operator's trace, and its magnitude is covariant to metaplectic transformations $\mathbf{U}\in\mathscr{M}$ (cf. Subsection I C),

$$|S_{\mathbf{UHU}^+}(\tau,\nu)|=|S_{\mathbf{H}}(a\tau+b\nu,c\tau+d\nu)|. \tag{8}$$

For a time-invariant system, we have $S_{\mathbf{H}}^{(\alpha)}(\tau,\nu)=g(\tau)\delta(\nu)$ which is perfectly concentrated along the τ axis. Similarly, for a frequency-invariant system, $S_{\mathbf{H}}^{(\alpha)}(\tau,\nu)=M(\nu)\delta(\tau)$ [with $M(\nu)$ the Fourier transform of $m(t)$] which is perfectly concentrated along the ν axis (cf. Fig. 1). This is in accordance with the fact that time-invariant systems cause only time shifts and frequency-invariant systems cause only frequency shifts.

B. Measures for the spread of the spreading function

The spread, or extension, of the spreading function about the origin of the (τ,ν) plane provides a global characterization of the time-frequency shifts introduced by the operator. [If the spreading function is concentrated about some point $(\tau_0,\nu_0)\neq(0,0)$, this corresponds to an offset time-frequency shift which can be split off from the operator, resulting in an operator whose spreading function is concentrated about the origin.] The extension in the τ direction characterizes the operator's ''length of memory'' whereas the extension in the ν direction determines the fastness of the operator's time-variations or fluctuations. The mathematical formulation of the concept of underspread operators (cf. Subsection II C) requires quantitative measures of the extension of the spreading function about the origin. For operators with a compactly supported spreading function, such a measure is provided by the area of the smallest rectangle containing the support of the spreading function.[42–44] In practice, however, the compact support condition is often not met. To circumvent this problem, we here propose to use the following weighted integrals of the spreading function $S_{\mathbf{H}}^{(\alpha)}(\tau,\nu)$ which are normalized by the L_1 or L_2 norm of $S_{\mathbf{H}}^{(\alpha)}(\tau,\nu)$ [These norms are defined as $\|S_{\mathbf{H}}\|_1=\int_\tau\int_\nu|S_{\mathbf{H}}(\tau,\nu)|d\tau d\nu$ (which is assumed to be finite) and $\|S_{\mathbf{H}}\|_2^2=\int_\tau\int_\nu|S_{\mathbf{H}}(\tau,\nu)|^2d\tau d\nu$. We note that $\|S_{\mathbf{H}}\|_2=\|\mathbf{H}\|_2$]:

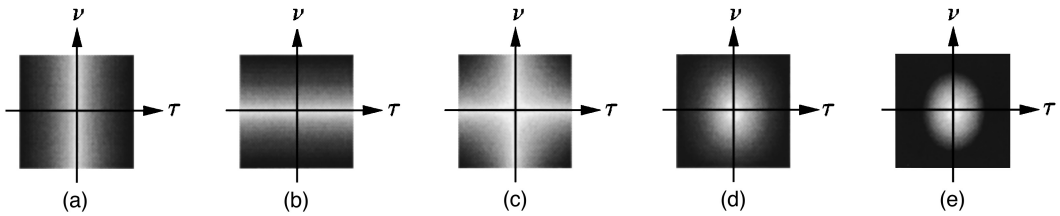

FIG. 2. Gray-scale plots (darker shades correspond to larger values) of some specific weighting functions: (a) $\phi(\tau,\nu)=|\tau|^k$, (b) $\phi(\tau,\nu)=|\nu|^k$, (c) $\phi(\tau,\nu)=|\tau\nu|^k$, (d) $\phi(\tau,\nu)=|1-A_s^{(0)}(\tau,\nu)|$, (e) $\phi(\tau,\nu)=|1-1/A_s^{(0)}(\tau,\nu)|$ with $A_s^{(0)}(\tau,\nu)$ the (symmetric) ambiguity function of a normalized Gaussian function (cf. Subsections III D and III H).

$$m_{\mathbf{H}}^{(\phi)} \triangleq \frac{1}{\|S_{\mathbf{H}}\|_1} \int_\tau \int_\nu \phi(\tau,\nu)|S_{\mathbf{H}}(\tau,\nu)|\,d\tau\,d\nu, \tag{9}$$

$$M_{\mathbf{H}}^{(\phi)} \triangleq \frac{1}{\|\mathbf{H}\|_2} \left[\int_\tau \int_\nu \phi^2(\tau,\nu)|S_{\mathbf{H}}(\tau,\nu)|^2\,d\tau\,d\nu \right]^{1/2}.$$

Here, $\phi(\tau,\nu)$ is a non-negative weighting function which satisfies $\phi(\tau,\nu)\geqslant\phi(0,0)=0$ and thus penalizes contributions of the spreading function lying away from the origin. We note that $m_{\mathbf{H}}^{(\phi)}$ and $M_{\mathbf{H}}^{(\phi)}$ are non-negative and do not depend on the parameter α. Since the spreading function of the adjoint operator $\mathbf{H}^+$ is given by $S_{\mathbf{H}^+}^{(\alpha)}(\tau,\nu)=S_{\mathbf{H}}^{(-\alpha)*}(-\tau,-\nu)$, we have $m_{\mathbf{H}^+}^{(\phi)}=m_{\mathbf{H}}^{(\phi)}$ and $M_{\mathbf{H}^+}^{(\phi)}=M_{\mathbf{H}}^{(\phi)}$ if the weighting function is even-symmetric, i.e., $\phi(-\tau,-\nu)=\phi(\tau,\nu)$. Figure 2 shows some specific weighting functions that will be used in Sections III and IV.

We also introduce the (absolute) moments $m_{\mathbf{H}}^{(k,l)}$ and $M_{\mathbf{H}}^{(k,l)}$ of the spreading function as a special case of the above weighted integrals using weighting functions $\phi(\tau,\nu)=|\tau|^k|\nu|^l$ with $k,l\in\mathbb{N}_0$:

$$m_{\mathbf{H}}^{(k,l)} \triangleq \frac{1}{\|S_{\mathbf{H}}\|_1} \int_\tau \int_\nu |\tau|^k|\nu|^l|S_{\mathbf{H}}(\tau,\nu)|\,d\tau\,d\nu,$$

$$M_{\mathbf{H}}^{(k,l)} \triangleq \frac{1}{\|\mathbf{H}\|_2} \left[\int_\tau \int_\nu \tau^{2k}\nu^{2l}|S_{\mathbf{H}}(\tau,\nu)|^2\,d\tau\,d\nu \right]^{1/2}.$$

We have $m_{\mathbf{H}^+}^{(k,l)}=m_{\mathbf{H}}^{(k,l)}$ and $M_{\mathbf{H}^+}^{(k,l)}=M_{\mathbf{H}}^{(k,l)}$ and, furthermore,

$$0\leqslant m_{\mathbf{H}}^{(k,l)}\leqslant\sqrt{m_{\mathbf{H}}^{(2k,0)}m_{\mathbf{H}}^{(0,2l)}}, \quad 0\leqslant M_{\mathbf{H}}^{(k,l)}\leqslant\sqrt{M_{\mathbf{H}}^{(2k,0)}M_{\mathbf{H}}^{(0,2l)}}. \tag{10}$$

Moments with $k=0$ or $l=0$ penalize mainly contributions of the spreading function that are located away from the τ axis or away from the ν axis, respectively. Thus, operators with a spreading function concentrated along the τ axis [i.e., quasi-time-invariant operators; see Fig. 1(d)] have small $m_{\mathbf{H}}^{(0,l)}$ and small $M_{\mathbf{H}}^{(0,l)}$ [see Fig. 2(b)], whereas operators with a spreading function concentrated along the ν axis [i.e., quasi-frequency-invariant operators; see Fig. 1(e)] have small $m_{\mathbf{H}}^{(k,0)}$ and small $M_{\mathbf{H}}^{(k,0)}$ [see Fig. 2(a)]. Moments with $k=l$ penalize mainly contributions of the spreading function that are located away from the τ *and* ν axes, i.e., that lie in oblique directions in the (τ,ν) plane. This is due to the fact that the corresponding weighting function is constant along the hyperbolas $|\tau\nu|=c$ [cf. Fig. 2(c)]. In particular, a superposition (i.e., parallel connection) of a (quasi-) time-invariant operator and a (quasi-) frequency-invariant operator has a spreading function concentrated along the τ and ν axes and will thus have small $m_{\mathbf{H}}^{(k,k)}$ and $M_{\mathbf{H}}^{(k,k)}$.

C. Underspread operators

Conceptually, a linear operator is called *underspread* if its spreading function is concentrated in a small region about the origin of the (τ,ν) plane, which indicates that the operator introduces only small time-frequency shifts τ,ν or, in other words, that the operator's memory is short and/or its time-variations are slow.

The concept of underspread operators was first used for random linear time-varying systems in the context of fading multipath channels[63,78,81,84,85] where physical considerations (path loss, limited velocities) naturally suggested limitations of delay (τ) and Doppler shifts (ν). Adopting the terminology of the random case, Kozek[42–44] introduced underspread deterministic linear operators by requiring that their spreading function be exactly zero outside a small rectangular support region about the origin. In practice, however, this condition is often not satisfied exactly but only effectively. This raises the question of how to choose the effective support region and how the modeling error resulting from a specific choice of effective support region affects the validity of the results obtained using the compact support model.

These problems and limitations can be circumvented by using the weighted integrals $m_{\mathbf{H}}^{(\phi)}$ and $M_{\mathbf{H}}^{(\phi)}$ and, specifically, the moments $m_{\mathbf{H}}^{(k,l)}$ and $M_{\mathbf{H}}^{(k,l)}$ introduced in Subsection II B. Hence, without being forced to assume that the spreading function has finite support, we can consider an operator $\mathbf{H}$ to be underspread if suitable integrals/moments of the spreading function are ''small.'' We note that this is not a clear-cut definition of underspread operators. Indeed, we will see in Section III that bounds on various error quantities associated with the transfer function approximation are formulated using different integrals/moments of the spreading function. Hence, having these approximation errors small calls for different integrals/moments being small. This is somewhat similar to the many different quantities that can be used to measure the effective bandwidth of a signal. Our concept of underspread operators is thus more complicated and diffuse, but also more flexible and practically relevant, than Kozek's definition which required the spreading function to have (small) compact support. It is precisely this flexibility which, in Section III, will allow us to establish bounds for the transfer function calculus (symbolic calculus) approximation without unnecessarily restrictive assumptions.

If the spreading function is exactly zero outside a finite region $\mathcal{S}$ around the origin, the weighted integrals are bounded as $m_{\mathbf{H}}^{(\phi)} \leqslant \phi_{\max}$ and $M_{\mathbf{H}}^{(\phi)} \leqslant \phi_{\max}$ with $\phi_{\max} = \max_{(\tau,\nu)\in\mathcal{S}}\{\phi(\tau,\nu)\}$. In particular, for rectangular regions $\mathcal{S}=[-\tau_{\max},\tau_{\max}]\times[-\nu_{\max},\nu_{\max}]$, one has $m_{\mathbf{H}}^{(k,l)} \leqslant \tau_{\max}^k \nu_{\max}^l$ and $M_{\mathbf{H}}^{(k,l)} \leqslant \tau_{\max}^k \nu_{\max}^l$. Thus, operators that are underspread in the sense of Kozek,[42–44] i.e., that have compact support contained within a rectangle of area $4\tau_{\max}\nu_{\max} \ll 1$, are a special case of our framework.

It should be noted that the concept of underspread operators is not equivalent to that of slowly time-varying (quasi-time-invariant) operators which requires $|S_{\mathbf{H}}(\tau,\nu)|$ to be narrow with respect to ν [i.e., small moments $m_{\mathbf{H}}^{(0,l)}$ and $M_{\mathbf{H}}^{(0,l)}$; see Fig. 1(d) and Fig. 2(b)]. In particular, a slowly time-varying operator may be overspread (i.e., not underspread) if its memory is very long, and an operator with fast time-variations may be underspread if its memory is short enough.

Due to the 2-D Fourier transform relation (6) between the spreading function and the generalized Weyl symbol, the generalized Weyl symbol of an underspread operator is a smooth (i.e., a 2-D lowpass-type) function. This can also be seen from the following relations between the partial derivatives of the generalized Weyl symbol and the moments of the spreading function:

$$\left|\frac{\partial^{k+l} L_{\mathbf{H}}^{(\alpha)}(t,f)}{\partial t^l \partial f^k}\right| \leqslant (2\pi)^{k+l} \|S_{\mathbf{H}}\|_1 m_{\mathbf{H}}^{(k,l)}, \quad \left\|\frac{\partial^{k+l} L_{\mathbf{H}}^{(\alpha)}}{\partial t^l \partial f^k}\right\|_2 = (2\pi)^{k+l} \|\mathbf{H}\|_2 M_{\mathbf{H}}^{(k,l)}. \tag{11}$$

In particular, $|\partial L_{\mathbf{H}}^{(\alpha)}(t,f)/\partial t|$ will be small—implying smoothness of the generalized Weyl symbol in the time direction—if the moments $m_{\mathbf{H}}^{(0,1)}$ and $M_{\mathbf{H}}^{(0,1)}$ are small. Similarly, the generalized Weyl symbol will be smooth in the frequency direction (i.e., $|\partial L_{\mathbf{H}}^{(\alpha)}(t,f)/\partial f|$ will be small) if $m_{\mathbf{H}}^{(1,0)}$ and $M_{\mathbf{H}}^{(1,0)}$ are small. We note that the first relation (bound) in (11) bears some resemblance to the definition of specific symbol classes[15,37,38,40,41,56] of pseudo-differential operators, with the difference that our bound is uniform over the entire time-frequency plane whereas in pseudo-differential operator theory there is an additional term controlling the growth of the partial derivatives of the symbol.

III. TRANSFER FUNCTION CALCULUS (SYMBOLIC CALCULUS)

In this section, we show that for linear operators that are underspread in the extended sense of Subsection II C, the generalized Weyl symbol $L_{\mathbf{H}}^{(\alpha)}(t,f)$ is an approximate ''time-frequency transfer function'' that generalizes the spectral/temporal transfer function of time-invariant/frequency-

invariant linear systems. As a mathematical underpinning of this approximate time-frequency transfer function calculus (symbolic calculus), we establish explicit upper bounds on the errors associated with it. These bounds are formulated in terms of the integrals and/or moments of the spreading function introduced in Subsection II B; they do not require the spreading function to have compact support. Hence, our subsequent results will show that a transfer function calculus (symbolic calculus) is valid for a significantly wider class of systems than that considered previously.[42–44] This calculus leads to simple and numerically efficient time-frequency methods for specific nonstationary signal processing applications[45–53] and it yields important results on time-varying power spectra of nonstationary random processes.[42,54,55]

A. Approximate uniqueness of the generalized Weyl symbol

The dependence of the generalized Weyl symbol on the parameter α is a difference from the time-invariant and frequency-invariant cases where the transfer function of a given operator is uniquely defined. In a signal processing context, this dependence may be considered an inconvenience since in practice it is often not clear which α value should be selected. In particular, the case $\alpha=0$ features an important symplectic covariance [cf. (4)] whereas the cases $\alpha=\pm 1/2$ lend themselves to simpler discrete-time implementations. Fortunately, the following bounds on the generalized Weyl symbol's α-dependence (which extend existing bounds[42]) show that in the underspread case the choice of α is not critical.

Theorem III.1: *For any operator* $\mathbf{H}$*, the difference* $\Delta_1^{(\alpha_1,\alpha_2)}(t,f)\triangleq L_{\mathbf{H}}^{(\alpha_1)}(t,f)-L_{\mathbf{H}}^{(\alpha_2)}(t,f)$ *between two generalized Weyl symbols with parameters* α_1 *and* α_2 *is bounded as*

$$\frac{|\Delta_1^{(\alpha_1,\alpha_2)}(t,f)|}{\|S_{\mathbf{H}}\|_1}\leq 2\pi|\alpha_1-\alpha_2|m_{\mathbf{H}}^{(1,1)},\quad \frac{\|\Delta_1^{(\alpha_1,\alpha_2)}\|_2}{\|\mathbf{H}\|_2}\leq 2\pi|\alpha_1-\alpha_2|M_{\mathbf{H}}^{(1,1)}. \tag{12}$$

[Here, $\|\Delta_1^{(\alpha_1,\alpha_2)}\|_2$ is the L_2 norm of $\Delta_1^{(\alpha_1,\alpha_2)}(t,f)$ defined as $\|\Delta_1^{(\alpha_1,\alpha_2)}\|_2^2=\int_t\int_f|\Delta_1^{(\alpha_1,\alpha_2)}(t,f)|^2\,dtdf$. We consider bounds on the *normalized* error magnitude and L_2 norm. The magnitude is normalized by $\|S_{\mathbf{H}}\|_1$ since $|L_{\mathbf{H}}^{(\alpha)}(t,f)|\leq\|S_{\mathbf{H}}\|_1$, and the L_2 norm is normalized by $\|\mathbf{H}\|_2$ since $\|L_{\mathbf{H}}^{(\alpha)}\|_2=\|\mathbf{H}\|_2$. Furthermore, in this and subsequent bounds the integrals and moments involved are assumed to exist.]

Proof: With (6) and (7), the 2-D Fourier transform of $\Delta_1^{(\alpha_1,\alpha_2)}(t,f)$ is given by

$$\hat{\Delta}_1^{(\alpha_1,\alpha_2)}(\tau,\nu)=\int_t\int_f\Delta_1^{(\alpha_1,\alpha_2)}(t,f)e^{-i2\pi(\nu t-\tau f)}dtdf=S_{\mathbf{H}}^{(\alpha_1)}(\tau,\nu)[1-e^{i2\pi(\alpha_1-\alpha_2)\tau\nu}].$$

The first bound (L_∞ bound) in (12) is then shown as

$$\begin{aligned}|\Delta_1^{(\alpha_1,\alpha_2)}(t,f)|&=\left|\int_\tau\int_\nu\hat{\Delta}_1^{(\alpha_1,\alpha_2)}(\tau,\nu)e^{i2\pi(t\nu-f\tau)}d\tau d\nu\right|\leq\int_\tau\int_\nu|\hat{\Delta}_1^{(\alpha_1,\alpha_2)}(\tau,\nu)|d\tau d\nu\\&=\int_\tau\int_\nu|S_{\mathbf{H}}(\tau,\nu)||1-e^{i2\pi(\alpha_1-\alpha_2)\tau\nu}|d\tau d\nu\\&=2\int_\tau\int_\nu|S_{\mathbf{H}}(\tau,\nu)||\sin(\pi(\alpha_1-\alpha_2)\tau\nu)|d\tau d\nu\\&\leq 2\pi|\alpha_1-\alpha_2|\int_\tau\int_\nu|S_{\mathbf{H}}(\tau,\nu)||\tau||\nu|d\tau d\nu\\&=2\pi|\alpha_1-\alpha_2|\|S_{\mathbf{H}}\|_1m_{\mathbf{H}}^{(1,1)},\end{aligned}$$

where we used $|\sin x|\leq|x|$. The second bound (L_2 bound) is shown by noting that

$$\|\Delta_1^{(\alpha_1,\alpha_2)}\|_2^2=\|\hat{\Delta}_1^{(\alpha_1,\alpha_2)}\|_2^2=\int_\tau\int_\nu|S_{\mathbf{H}}(\tau,\nu)|^2|1-e^{i2\pi(\alpha_1-\alpha_2)\tau\nu}|^2d\tau d\nu,$$

and proceeding similarly as above, using $\sin^2 x \leq x^2$. □

Note that the bounds in this theorem depend only on the difference $\alpha_1-\alpha_2$ and not on α_1, α_2 individually. For $|\alpha|\leq 1/2$, one obtains the coarser but α-independent bounds $2\pi m_{\mathbf{H}}^{(1,1)}$ and $2\pi M_{\mathbf{H}}^{(1,1)}$. For an *underspread* operator whose moments $m_{\mathbf{H}}^{(1,1)}$ and $M_{\mathbf{H}}^{(1,1)}$ are small, the bounds in (12) show that the generalized Weyl symbol is approximately independent of α, i.e.,

$$L_{\mathbf{H}}^{(\alpha_1)}(t,f)\approx L_{\mathbf{H}}^{(\alpha_2)}(t,f),$$

as long as $|\alpha_1-\alpha_2|$ is not too large. Hence, the time-frequency transfer function of an underspread operator is approximately unique. We note that small $m_{\mathbf{H}}^{(1,1)}$ and $M_{\mathbf{H}}^{(1,1)}$ requires the spreading function to be concentrated along the τ and/or ν axes (i.e., not oriented in oblique directions). Important examples are quasi-time-invariant and quasi-frequency-invariant systems and parallel connections (i.e., sums) thereof. Since small $m_{\mathbf{H}}^{(1,1)}$ and $M_{\mathbf{H}}^{(1,1)}$ do not require the operator's spreading function to be exactly supported within a rectangular region about the origin, the bounds in (12) are more general than previously derived bounds.[42] For example, $m_{\mathbf{H}}^{(1,1)}$ and $M_{\mathbf{H}}^{(1,1)}$ will be small for an operator whose spreading function is concentrated within the region $|\tau\nu|\leq c$ with small c [cf. Fig. 1(f)]. We also note that results in a similar spirit have been derived by Kohn and Nirenberg[37] for the special case $\alpha_1=1/2$ and $\alpha_2=-1/2$ and by Folland[15] for the special case $\alpha_1=0$ and $\alpha_2=1/2$. Finally, we recall from (10) that $m_{\mathbf{H}}^{(1,1)}\leq\sqrt{m_{\mathbf{H}}^{(2,0)}m_{\mathbf{H}}^{(0,2)}}$ and $M_{\mathbf{H}}^{(1,1)}\leq\sqrt{M_{\mathbf{H}}^{(2,0)}M_{\mathbf{H}}^{(0,2)}}$.

B. Adjoint operator

The kernel of the adjoint $\mathbf{H}^+$ of a linear operator $\mathbf{H}$ with kernel $h(t,t')$ is given by $h^*(t',t)$. In the special case of a time-invariant or frequency-invariant operator, the transfer function of the adjoint operator is obtained by complex conjugation of the original transfer function. In contrast, the generalized Weyl symbol of the adjoint of a general linear operator is easily shown to be $L_{\mathbf{H}^+}^{(\alpha)}(t,f)=L_{\mathbf{H}}^{(-\alpha)*}(t,f)$, which does not equal $L_{\mathbf{H}}^{(\alpha)*}(t,f)$ unless $\alpha=0$. However, the following bounds are obtained from Theorem III.1.

Corollary III.2: For any operator $\mathbf{H}$*, the difference* $\Delta_2^{(\alpha)}(t,f)\triangleq L_{\mathbf{H}^+}^{(\alpha)}(t,f)-L_{\mathbf{H}}^{(\alpha)*}(t,f)$ *is bounded as*

$$\frac{|\Delta_2^{(\alpha)}(t,f)|}{\|S_{\mathbf{H}}\|_1}\leq 4\pi|\alpha|m_{\mathbf{H}}^{(1,1)},\quad \frac{\|\Delta_2^{(\alpha)}\|_2}{\|\mathbf{H}\|_2}\leq 4\pi|\alpha|M_{\mathbf{H}}^{(1,1)}. \tag{13}$$

Proof: With $L_{\mathbf{H}^+}^{(\alpha)}(t,f)=L_{\mathbf{H}}^{(-\alpha)*}(t,f)$, we have $\Delta_2^{(\alpha)}(t,f)=L_{\mathbf{H}}^{(-\alpha)*}(t,f)-L_{\mathbf{H}}^{(\alpha)*}(t,f)$. Hence, the above bounds follow straightforwardly by applying (12) with $\alpha_1=-\alpha$, $\alpha_2=\alpha$. □

For $|\alpha|\leq 1/2$ one obtains the α-independent (coarser) bounds $2\pi m_{\mathbf{H}}^{(1,1)}$ and $2\pi M_{\mathbf{H}}^{(1,1)}$. For an underspread operator whose spreading function is concentrated along the τ and ν axes so that $m_{\mathbf{H}}^{(1,1)}$ and $M_{\mathbf{H}}^{(1,1)}$ are small, these bounds show that (for $|\alpha|$ not too large) the generalized Weyl symbol of the adjoint of an operator is approximately equal to the complex conjugate of the operator's generalized Weyl symbol,

$$L_{\mathbf{H}^+}^{(\alpha)}(t,f)\approx L_{\mathbf{H}}^{(\alpha)*}(t,f). \tag{14}$$

Due to the similarity of the bounds in Corollary III.2 and Theorem III.1, the above approximation is valid in the same situations where the generalized Weyl symbol is approximately unique. For the special case $\alpha=-1/2$, a result in a similar spirit has been derived by Kohn and Nirenberg.[37]

An important consequence of Corollary III.2 concerns self-adjoint operators (where $\mathbf{H}^+=\mathbf{H}$). Whereas in the time-invariant or frequency-invariant case the transfer function of a self-adjoint operator is real-valued, the generalized Weyl symbol of a self-adjoint general operator is not real-valued unless $\alpha=0$. However, Corollary III.2 implies that the imaginary part of the generalized Weyl symbol of a self-adjoint operator,

$$\mathcal{I}^{(\alpha)}(t,f)\triangleq\frac{1}{2i}\left[L_{\mathbf{H}}^{(\alpha)}(t,f)-L_{\mathbf{H}}^{(\alpha)*}(t,f)\right]=\frac{1}{2i}\left[L_{\mathbf{H}^+}^{(\alpha)}(t,f)-L_{\mathbf{H}}^{(\alpha)*}(t,f)\right]=\frac{\Delta_2^{(\alpha)}(t,f)}{2i},$$

is bounded as

$$\frac{|\mathscr{T}^{(\alpha)}(t,f)|}{\|S_{\mathbf{H}}\|_1} \leq 2\pi|\alpha| m_{\mathbf{H}}^{(1,1)} \leq \pi m_{\mathbf{H}}^{(1,1)}, \quad \frac{\|\mathscr{T}^{(\alpha)}\|_2}{\|\mathbf{H}\|_2} \leq 2\pi|\alpha| M_{\mathbf{H}}^{(1,1)} \leq \pi M_{\mathbf{H}}^{(1,1)},$$

the coarser bounds being valid for $|\alpha| \leq 1/2$. Hence, the generalized Weyl symbol of an underspread, self-adjoint operator is approximately real-valued even if $\alpha \neq 0$. This result is useful for a discrete-time implementation since here the generalized Weyl symbol with $\alpha = \pm 1/2$ is preferable. Furthermore, the above result shows the approximate real-valuedness of certain time-varying power spectra[86] in the case $\alpha \neq 0$.

C. Operator products

The transfer function of the product (composition, series connection) of two time-invariant linear operators $\mathbf{H}_1$ and $\mathbf{H}_2$ equals the product of the individual transfer functions, $G_1(f)G_2(f)$. Similarly, the temporal transfer function of the product of two frequency-invariant linear operators is given by $m_1(t)m_2(t)$. This composition property of conventional transfer functions is the cornerstone of many techniques for signal detection, estimation, filtering, channel equalization, etc.

Contrary to the time-invariant/frequency-invariant case, the generalized Weyl symbol of the product $\mathbf{H}_2\mathbf{H}_1$ of two general linear operators can not be obtained by multiplying the individual generalized Weyl symbols of $\mathbf{H}_1$ and $\mathbf{H}_2$. In a signal processing context, this is unfortunate since a multiplicative composition property of the generalized Weyl symbol (a multiplicative symbolic calculus) similar to the time-invariant/frequency-invariant case would allow very simple and intuitive formulations of (statistical) signal processing techniques in nonstationary environments.[42,47–54,87] In the context of quantum mechanics, such a symbolic calculus—i.e., the approximation of the star product of symbols by the ordinary product—would establish an asymptotic correspondence (in the classical limit $h \to 0$, where h denotes Planck's constant) between pointwise products and Jordan products as well as between Poisson brackets and commutators[15] (cf. Subsection IV A). Besides the case where $\mathbf{H}_1$ and $\mathbf{H}_2$ are either both time-invariant or both frequency-invariant operators (or, in the case $\alpha = 0$, any metaplectic transformation thereof), for Hilbert–Schmidt operators the relation $L_{\mathbf{H}_2\mathbf{H}_1}^{(\alpha)}(t,f) = L_{\mathbf{H}_1}^{(\alpha)}(t,f) L_{\mathbf{H}_2}^{(\alpha)}(t,f)$ is correct only in the following situations.

(i) For $\alpha = 1/2$, if $\mathbf{H}_1$ is a linear time-invariant operator with spectral transfer function $G_1(f)$ or $\mathbf{H}_2$ is a linear frequency-invariant operator with temporal transfer function $m_2(t)$, it can be shown that

$$L_{\mathbf{H}_2\mathbf{H}_1}^{(1/2)}(t,f) = L_{\mathbf{H}_1}^{(1/2)}(t,f) L_{\mathbf{H}_2}^{(1/2)}(t,f) = \begin{cases} G_1(f) L_{\mathbf{H}_2}^{(1/2)}(t,f), & \text{for } \mathbf{H}_1 \text{ time-invariant,} \\ L_{\mathbf{H}_1}^{(1/2)}(t,f) m_2(t), & \text{for } \mathbf{H}_2 \text{ frequency-invariant.} \end{cases} \tag{15}$$

(ii) In the dual case $\alpha = -1/2$, if $\mathbf{H}_1$ is linear frequency-invariant with temporal transfer function $m_1(t)$ or $\mathbf{H}_2$ is linear time-invariant with spectral transfer function $G_2(f)$, one obtains

$$L_{\mathbf{H}_2\mathbf{H}_1}^{(-1/2)}(t,f) = L_{\mathbf{H}_1}^{(-1/2)}(t,f) L_{\mathbf{H}_2}^{(-1/2)}(t,f) = \begin{cases} m_1(t) L_{\mathbf{H}_2}^{(-1/2)}(t,f), & \text{for } \mathbf{H}_1 \text{ frequency-invariant,} \\ L_{\mathbf{H}_1}^{(-1/2)}(t,f) G_2(f), & \text{for } \mathbf{H}_2 \text{ time-invariant.} \end{cases} \tag{16}$$

In general, however, the generalized Weyl symbol of operator products $\mathbf{H}_2\mathbf{H}_1$ is described by the so-called star (or twisted) product[15,31,33,38,40,41,56,69,88,89] $L_{\mathbf{H}_2}^{(\alpha)} \# L_{\mathbf{H}_1}^{(\alpha)}$, which (when generalized to arbitrary α) can be formulated as

$$(L^{(\alpha)}_{\mathbf{H}_2}\#L^{(\alpha)}_{\mathbf{H}_1})(t,f)\triangleq L^{(\alpha)}_{\mathbf{H}_2\mathbf{H}_1}(t,f)$$

$$=\sum_{k,l=0}^{\infty} c_{kl}\,\frac{\partial^{k+l}L^{(\alpha)}_{\mathbf{H}_2}(t,f)}{\partial t^l\partial f^k}\,\frac{\partial^{k+l}L^{(\alpha)}_{\mathbf{H}_1}(t,f)}{\partial t^k\partial f^l}$$

$$=L^{(\alpha)}_{\mathbf{H}_2}(t,f)L^{(\alpha)}_{\mathbf{H}_1}(t,f)+\sum_{k+l>0} c_{kl}\,\frac{\partial^{k+l}L^{(\alpha)}_{\mathbf{H}_2}(t,f)}{\partial t^l\partial f^k}\,\frac{\partial^{k+l}L^{(\alpha)}_{\mathbf{H}_1}(t,f)}{\partial t^k\partial f^l},$$

with $c_{kl}=(-1)^{k+l}(\alpha+1/2)^k(\alpha-1/2)^l/[(4\pi^2)^{k+l}k!l!]$. It is thus seen that the difference between $L^{(\alpha)}_{\mathbf{H}_2\mathbf{H}_1}(t,f)$ and $L^{(\alpha)}_{\mathbf{H}_2}(t,f)L^{(\alpha)}_{\mathbf{H}_1}(t,f)$ is essentially determined by the higher-order partial derivatives of the symbols. This difference will be small if these derivatives are small, i.e., if the symbols are smooth functions. The following subsections describe quantitative formulations of this qualitative discussion which are simple and relevant to signal processing applications.

1. Approximate multiplicative symbol calculus

A positive statement (in the spirit of earlier results obtained in the context of quantization,[14,15,39,56,88] pseudo-differential operators,[15,37,38,40,41,56] and transfer function calculus[42–44]) on the general validity of an approximate multiplicative transfer function (symbolic) calculus is provided by the following theorem.

Theorem III.3: *For any two operators* $\mathbf{H}_1$ *and* $\mathbf{H}_2$, *the difference* $\Delta^{(\alpha)}_3(t,f)\triangleq L^{(\alpha)}_{\mathbf{H}_2\mathbf{H}_1}(t,f)-L^{(\alpha)}_{\mathbf{H}_1}(t,f)L^{(\alpha)}_{\mathbf{H}_2}(t,f)$ *is bounded as*

$$\frac{|\Delta^{(\alpha)}_3(t,f)|}{\|S_{\mathbf{H}_1}\|_1\|S_{\mathbf{H}_2}\|_1}\leq 2\pi B^{(\alpha)}_{\mathbf{H}_1,\mathbf{H}_2},\quad \textit{with}\quad B^{(\alpha)}_{\mathbf{H}_1,\mathbf{H}_2}\triangleq|\alpha+\tfrac{1}{2}|m^{(0,1)}_{\mathbf{H}_1}m^{(1,0)}_{\mathbf{H}_2}+|\alpha-\tfrac{1}{2}|m^{(1,0)}_{\mathbf{H}_1}m^{(0,1)}_{\mathbf{H}_2}. \quad (17)$$

Proof: The spreading function of the operator product $\mathbf{H}_2\mathbf{H}_1$ is given by the so-called twisted convolution,[15,38,42]

$$S^{(\alpha)}_{\mathbf{H}_2\mathbf{H}_1}(\tau,\nu)=(S^{(\alpha)}_{\mathbf{H}_2}\natural S^{(\alpha)}_{\mathbf{H}_1})(\tau,\nu)\triangleq\int_{\tau'}\int_{\nu'}S^{(\alpha)}_{\mathbf{H}_2}(\tau',\nu')S^{(\alpha)}_{\mathbf{H}_1}(\tau-\tau',\nu-\nu')e^{-i2\pi\phi_\alpha(\tau,\nu,\tau',\nu')}d\tau'd\nu', \quad (18)$$

with $\phi_\alpha(\tau,\nu,\tau',\nu')=(\alpha+1/2)\tau'(\nu-\nu')+(\alpha-1/2)(\tau-\tau')\nu'$ [note that the twisted convolution and the star (twisted) product are 2-D Fourier transform pairs]. Hence, the Fourier transform of $\Delta^{(\alpha)}_3(t,f)$ is obtained as

$$\hat{\Delta}^{(\alpha)}_3(\tau,\nu)=(S^{(\alpha)}_{\mathbf{H}_2}\natural S^{(\alpha)}_{\mathbf{H}_1})(\tau,\nu)-(S^{(\alpha)}_{\mathbf{H}_2}**S^{(\alpha)}_{\mathbf{H}_1})(\tau,\nu)$$

$$=\int_{\tau'}\int_{\nu'}S^{(\alpha)}_{\mathbf{H}_2}(\tau',\nu')S^{(\alpha)}_{\mathbf{H}_1}(\tau-\tau',\nu-\nu')[e^{-i2\pi\phi_\alpha(\tau,\nu,\tau',\nu')}-1]d\tau'd\nu',$$

where $**$ denotes ordinary 2-D convolution. Thus, we obtain

$$|\Delta^{(\alpha)}_3(t,f)|\leq\int_\tau\int_\nu|\hat{\Delta}^{(\alpha)}_3(\tau,\nu)|d\tau d\nu$$

$$\leq 2\int_\tau\int_\nu\int_{\tau'}\int_{\nu'}|S_{\mathbf{H}_2}(\tau',\nu')||S_{\mathbf{H}_1}(\tau-\tau',\nu-\nu')|$$

$$\times|\sin(\pi\phi_\alpha(\tau,\nu,\tau',\nu'))|d\tau d\nu d\tau' d\nu'.$$

Substituting $\tau_1=\tau-\tau'$, $\nu_1=\nu-\nu'$ and using $|\sin x|\leq|x|$ yields the bound (17) after straightforward manipulations. □

By virtue of its symmetry with respect to $\mathbf{H}_1$ and $\mathbf{H}_2$, the bound in (17) also applies to the differences $L^{(\alpha)}_{\mathbf{H}_1\mathbf{H}_2}(t,f)-L^{(\alpha)}_{\mathbf{H}_1}(t,f)L^{(\alpha)}_{\mathbf{H}_2}(t,f)$ and $L^{(\alpha)}_{\mathbf{H}_1\star\mathbf{H}_2}(t,f)-L^{(\alpha)}_{\mathbf{H}_1}(t,f)L^{(\alpha)}_{\mathbf{H}_2}(t,f)$, where $\mathbf{H}_1\star\mathbf{H}_2=(\mathbf{H}_1\mathbf{H}_2+\mathbf{H}_2\mathbf{H}_1)/2$ is the (commutative) Jordan product[15] of $\mathbf{H}_1$ and $\mathbf{H}_2$.

The bound shows that if $\mathbf{H}_1$ and $\mathbf{H}_2$ are ''jointly underspread'' such that $m^{(0,1)}_{\mathbf{H}_1}m^{(1,0)}_{\mathbf{H}_2}$ and $m^{(1,0)}_{\mathbf{H}_1}m^{(0,1)}_{\mathbf{H}_2}$ are both small, then we have an approximate multiplicative composition property,

$$L^{(\alpha)}_{\mathbf{H}_2\mathbf{H}_1}(t,f)\approx L^{(\alpha)}_{\mathbf{H}_1}(t,f)L^{(\alpha)}_{\mathbf{H}_2}(t,f). \tag{19}$$

This approximate relation provides a basis for several signal processing methods for nonstationary environments recently proposed for a variety of problems like equalization of mobile radio channels,[48,49] estimation of nonstationary random signals corrupted by noise,[42,47,50,51,53,87] and detection or classification of nonstationary signals.[52,53,87] Furthermore, the above approximation can be used to show that two important time-varying power spectra of nonstationary random processes—the Wigner–Ville spectrum[86,90] and the (generalized) evolutionary spectrum[54,91]—are basically equivalent for underspread processes.[42,54,55,87]

We note that (19) implies $L^{(\alpha)}_{\mathbf{H}_2\mathbf{H}_1}(t,f)\approx L^{(\alpha)}_{\mathbf{H}_1\mathbf{H}_2}(t,f)$, which suggests that two jointly underspread operators are approximately commuting, i.e., $\mathbf{H}_2\mathbf{H}_1\approx\mathbf{H}_1\mathbf{H}_2$. This issue will be investigated further in Subsection IV A.

In the following, we briefly discuss the approximation (19) for the cases $\alpha=\pm1/2$. The case $\alpha=0$ deserves special attention and will be considered in more detail afterwards.

For $\alpha=1/2$, $B^{(\alpha)}_{\mathbf{H}_1,\mathbf{H}_2}$ simplifies to $B^{(1/2)}_{\mathbf{H}_1,\mathbf{H}_2}=m^{(0,1)}_{\mathbf{H}_1}m^{(1,0)}_{\mathbf{H}_2}$, which will be small if $|S_{\mathbf{H}_1}(\tau,\nu)|$ is concentrated along the τ axis and/or $|S_{\mathbf{H}_2}(\tau,\nu)|$ is concentrated along the ν axis. Thus, for $\alpha=1/2$ the approximation (19) is good when $\mathbf{H}_1$ is a quasi-time-invariant system and/or $\mathbf{H}_2$ is a quasi-frequency-invariant system [note the consistency with the exact multiplicative calculus in (15)].

For $\alpha=-1/2$, we have $B^{(-1/2)}_{\mathbf{H}_1,\mathbf{H}_2}=m^{(1,0)}_{\mathbf{H}_1}m^{(0,1)}_{\mathbf{H}_2}$. This will be small if $|S_{\mathbf{H}_1}(\tau,\nu)|$ is concentrated along the ν axis and/or $|S_{\mathbf{H}_2}(\tau,\nu)|$ is concentrated along the τ axis, i.e., if $\mathbf{H}_1$ is quasi-frequency-invariant and/or $\mathbf{H}_2$ is quasi-time-invariant [note the consistency with (16)].

For both $\alpha=1/2$ and $\alpha=-1/2$, the bound is large, and thus the approximation (19) is poor, if the operators' spreading functions are oriented in oblique directions. For any α with $|\alpha|\leq1/2$, it follows from the definition of $B^{(\alpha)}_{\mathbf{H}_1,\mathbf{H}_2}$ in (17) that $B^{(\alpha)}_{\mathbf{H}_1,\mathbf{H}_2}$ is a convex combination of the two extreme cases $B^{(1/2)}_{\mathbf{H}_1,\mathbf{H}_2}=m^{(0,1)}_{\mathbf{H}_1}m^{(1,0)}_{\mathbf{H}_2}$ and $B^{(-1/2)}_{\mathbf{H}_1,\mathbf{H}_2}=m^{(1,0)}_{\mathbf{H}_1}m^{(0,1)}_{\mathbf{H}_2}$, i.e.,

$$B^{(\alpha)}_{\mathbf{H}_1,\mathbf{H}_2}=\gamma B^{(1/2)}_{\mathbf{H}_1,\mathbf{H}_2}+(1-\gamma)B^{(-1/2)}_{\mathbf{H}_1,\mathbf{H}_2},\quad\text{with}\quad 0\leq\gamma=\alpha+\tfrac{1}{2}\leq1.$$

In particular, this implies

$$\min\{B^{(1/2)}_{\mathbf{H}_1,\mathbf{H}_2},B^{(-1/2)}_{\mathbf{H}_1,\mathbf{H}_2}\}\leq B^{(\alpha)}_{\mathbf{H}_1,\mathbf{H}_2}\leq\max\{B^{(1/2)}_{\mathbf{H}_1,\mathbf{H}_2},B^{(-1/2)}_{\mathbf{H}_1,\mathbf{H}_2}\},\quad|\alpha|\leq\tfrac{1}{2}.$$

2. Case $\alpha=0$

The case $\alpha=0$ is of particular importance. Here, $B^{(\alpha)}_{\mathbf{H}_1,\mathbf{H}_2}$ simplifies to

$$B^{(0)}_{\mathbf{H}_1,\mathbf{H}_2}=\tfrac{1}{2}\,[m^{(0,1)}_{\mathbf{H}_1}m^{(1,0)}_{\mathbf{H}_2}+m^{(1,0)}_{\mathbf{H}_1}m^{(0,1)}_{\mathbf{H}_2}],$$

which is symmetric with respect to $\mathbf{H}_1$ and $\mathbf{H}_2$. Thus, the approximation (19) will be good if both $m^{(0,1)}_{\mathbf{H}_1}m^{(1,0)}_{\mathbf{H}_2}$ and $m^{(1,0)}_{\mathbf{H}_1}m^{(0,1)}_{\mathbf{H}_2}$ are small. This requires that the spreading functions of $\mathbf{H}_1$ and $\mathbf{H}_2$ are both concentrated about the origin of the (τ,ν) plane, with *similar* orientation parallel to the τ or ν axis. However, this requirement is relaxed by a refinement of the bound $2\pi B^{(0)}_{\mathbf{H}_1,\mathbf{H}_2}$ that is stated in the next theorem. This improved bound can be attributed to the covariance of the Weyl symbol $L^{(0)}_{\mathbf{H}}(t,f)$ to metaplectic transformations $\mathbf{U}\in\mathscr{M}$ [cf. (4)].

Theorem III.4: *For any two operators* $\mathbf{H}_1$ *and* $\mathbf{H}_2$, *the difference* $\Delta_3^{(0)}(t,f)=L_{\mathbf{H}_2\mathbf{H}_1}^{(0)}(t,f)-L_{\mathbf{H}_1}^{(0)}(t,f)L_{\mathbf{H}_2}^{(0)}(t,f)$ *obeys the bound [that is generally tighter than (*17*)]*

$$\frac{|\Delta_3^{(0)}(t,f)|}{\|S_{\mathbf{H}_1}\|_1\|S_{\mathbf{H}_2}\|_1}\leqslant 2\pi\min_{\mathbf{U}\in\mathscr{M}} B_{\mathbf{U}\mathbf{H}_1\mathbf{U}^+,\mathbf{U}\mathbf{H}_2\mathbf{U}^+}^{(0)}. \tag{20}$$

Proof: Specializing the proof of Theorem III.3 to $\alpha=0$, it is seen that

$$|\Delta_3^{(0)}(t,f)|\leqslant\pi\int_{\tau_1}\int_{\nu_1}\int_{\tau_2}\int_{\nu_2}|S_{\mathbf{H}_2}(\tau_1,\nu_1)||S_{\mathbf{H}_1}(\tau_2,\nu_2)||\tau_1\nu_2-\tau_2\nu_1|d\tau_1 d\nu_1 d\tau_2 d\nu_2. \tag{21}$$

Performing a symplectic coordinate transform $\binom{\tau_i}{\nu_i}=\mathscr{A}\binom{\tau_i'}{\nu_i'}$, where $\mathscr{A}=\left(\begin{smallmatrix}a & b\\ c & d\end{smallmatrix}\right)$ with $\det\mathscr{A}=ad-bc=1$, and using the invariance of the symplectic form,[15,73,75] $\tau_1\nu_2-\tau_2\nu_1=\tau_1'\nu_2'-\tau_2'\nu_1'$, the right-hand side of (21) becomes

$$\pi\int_{\tau_1'}\int_{\nu_1'}\int_{\tau_2'}\int_{\nu_2'}|S_{\mathbf{H}_2}(a\tau_1'+b\nu_1',c\tau_1'+d\nu_1')||S_{\mathbf{H}_1}(a\tau_2'+b\nu_2',c\tau_2'+d\nu_2')|$$
$$\times|\tau_1'\nu_2'-\tau_2'\nu_1'|d\tau_1' d\nu_1' d\tau_2' d\nu_2'.$$

Let $\tilde{\mathbf{H}}_i=\mathbf{U}\mathbf{H}_i\mathbf{U}^+$ where $\mathbf{U}\in\mathscr{M}$ is the unitary operator corresponding to $\mathscr{A}$ via the metaplectic representation.[15] Using the covariance property (8), the above expression becomes

$$\pi\int_{\tau_1'}\int_{\nu_1'}\int_{\tau_2'}\int_{\nu_2'}|S_{\tilde{\mathbf{H}}_2}(\tau_1',\nu_1')||S_{\tilde{\mathbf{H}}_1}(\tau_2',\nu_2')||\tau_1'\nu_2'-\tau_2'\nu_1'|d\tau_1' d\nu_1' d\tau_2' d\nu_2'.$$

Inserting $|\tau_1'\nu_2'-\tau_2'\nu_1'|\leqslant|\tau_1'\nu_2'|+|\tau_2'\nu_1'|$ and using $\|S_{\tilde{\mathbf{H}}_i}\|_1=\|S_{\mathbf{H}_i}\|_1$ (which holds since the spreading function magnitude of $\tilde{\mathbf{H}}_i$ is obtained from that of $\mathbf{H}_i$ via an area-preserving coordinate transform), we obtain

$$|\Delta_3^{(0)}(t,f)|\leqslant\pi\|S_{\mathbf{H}_1}\|_1\|S_{\mathbf{H}_2}\|_1[m_{\tilde{\mathbf{H}}_1}^{(0,1)}m_{\tilde{\mathbf{H}}_2}^{(1,0)}+m_{\tilde{\mathbf{H}}_1}^{(1,0)}m_{\tilde{\mathbf{H}}_2}^{(0,1)}].$$

As this bound is valid for all $\mathbf{U}\in\mathscr{M}$, we finally obtain the bound (20). □

Since the symplectic group contains time-frequency rotations and time-frequency shearings, this theorem shows that $\Delta_3^{(0)}(t,f)$ may be small even if the spreading functions of $\mathbf{H}_1$ and $\mathbf{H}_2$ are oriented in (similar) *oblique* directions. This is not true for $\alpha\neq0$, which once again shows the exceptional position of the Weyl symbol.

3. Composition of H *with* $\mathbf{H}^+$

In some applications, e.g., for an innovations system representation of random processes[54] or for a quadratic time-frequency analysis of linear operators,[92] the composition of $\mathbf{H}$ with $\mathbf{H}^+$ is of importance (cf. also the proofs of Theorems III.6 and III.12). For time-invariant or frequency-invariant operators, the transfer function of $\mathbf{H}^+\mathbf{H}$ is $|G(f)|^2$ or $|m(t)|^2$, respectively. For general operators, the following result can be obtained from Theorem III.3 and Corollary III.2.

Corollary III.5: For any operator $\mathbf{H}$, *the difference* $\Delta_4^{(\alpha)}(t,f)\triangleq L_{\mathbf{H}^+\mathbf{H}}^{(\alpha)}(t,f)-|L_{\mathbf{H}}^{(\alpha)}(t,f)|^2$ *is bounded as*

$$\frac{|\Delta_4^{(\alpha)}(t,f)|}{\|S_{\mathbf{H}}\|_1^2}\leqslant 2\pi C_{\mathbf{H}}^{(\alpha)},\quad with\quad C_{\mathbf{H}}^{(\alpha)}\triangleq c_\alpha m_{\mathbf{H}}^{(0,1)}m_{\mathbf{H}}^{(1,0)}+2|\alpha|m_{\mathbf{H}}^{(1,1)}, \tag{22}$$

where $c_\alpha=|\alpha+1/2|+|\alpha-1/2|$.

Proof: Subtracting and adding $L_{\mathbf{H}}^{(\alpha)}(t,f)L_{\mathbf{H}^+}^{(\alpha)}(t,f)$ from/to $\Delta_4^{(\alpha)}(t,f)$, we obtain

$$|\Delta_4^{(\alpha)}(t,f)| \leq |L_{\mathbf{H}^+\mathbf{H}}^{(\alpha)}(t,f) - L_{\mathbf{H}}^{(\alpha)}(t,f) L_{\mathbf{H}^+}^{(\alpha)}(t,f)| + |L_{\mathbf{H}^+}^{(\alpha)}(t,f) - L_{\mathbf{H}}^{(\alpha)*}(t,f)||L_{\mathbf{H}}^{(\alpha)}(t,f)|$$
$$\leq 2\pi c_\alpha \|S_{\mathbf{H}}\|_1^2 m_{\mathbf{H}}^{(1,0)} m_{\mathbf{H}}^{(0,1)} + 4\pi|\alpha| m_{\mathbf{H}}^{(1,1)} \|S_{\mathbf{H}}\|_1 |L_{\mathbf{H}}^{(\alpha)}(t,f)|,$$

where we used (17) with $m_{\mathbf{H}^+}^{(k,l)} = m_{\mathbf{H}}^{(k,l)}$ and $\|S_{\mathbf{H}^+}\|_1 = \|S_{\mathbf{H}}\|_1$ as well as (13). From this, (22) follows with $|L_{\mathbf{H}}^{(\alpha)}(t,f)| \leq \|S_{\mathbf{H}}\|_1$. □

Hence, for an underspread operator with small $m_{\mathbf{H}}^{(0,1)} m_{\mathbf{H}}^{(1,0)}$ and small $m_{\mathbf{H}}^{(1,1)}$, we have

$$L_{\mathbf{H}^+\mathbf{H}}^{(\alpha)}(t,f) \approx |L_{\mathbf{H}}^{(\alpha)}(t,f)|^2,$$

i.e., ''squaring'' the operator is approximately equivalent to squaring its generalized Weyl symbol. We note that the bound (22), and thus the above approximation, remain valid if $\mathbf{H}^+\mathbf{H}$ is replaced by $\mathbf{H}\mathbf{H}^+$ or by $\mathbf{H} \star \mathbf{H}^+ = (\mathbf{H}\mathbf{H}^+ + \mathbf{H}^+\mathbf{H})/2$.

For $|\alpha| \leq 1/2$, we have $c_\alpha = 1$ and thus $C_{\mathbf{H}}^{(\alpha)} \leq m_{\mathbf{H}}^{(1,0)} m_{\mathbf{H}}^{(0,1)} + m_{\mathbf{H}}^{(1,1)}$. The bound $C_{\mathbf{H}}^{(\alpha)}$ is tightest for $\alpha = 0$, in which case $C_{\mathbf{H}}^{(0)} = m_{\mathbf{H}}^{(0,1)} m_{\mathbf{H}}^{(1,0)}$. This is due to the fact that the Weyl symbol of the adjoint is exactly obtained by complex conjugation. Furthermore, for $\alpha = 0$ the above result can be refined similarly to Theorem III.4, yielding the tighter bound

$$\frac{|\Delta_4^{(0)}(t,f)|}{\|S_{\mathbf{H}}\|_1^2} \leq 2\pi \min_{\mathbf{U} \in \mathcal{M}} C_{\mathbf{U}\mathbf{H}\mathbf{U}^+}^{(0)} = 2\pi \min_{\mathbf{U} \in \mathcal{M}} m_{\mathbf{U}\mathbf{H}\mathbf{U}^+}^{(0,1)} m_{\mathbf{U}\mathbf{H}\mathbf{U}^+}^{(1,0)}. \tag{23}$$

D. Approximate eigenvalues and eigenfunctions

The response of a time-invariant system to a complex sinusoid $e^{i2\pi f_0 t}$—i.e., a signal with perfect frequency concentration—is $G(f_0)e^{i2\pi f_0 t}$. Thus, the complex sinusoids $e^{i2\pi f_0 t}$ are the generalized[60] eigenfunctions of any time-invariant system, with $G(f_0)$ the associated generalized eigenvalues. Similarly, the response of a frequency-invariant system to a Dirac impulse $\delta(t - t_0)$—i.e., a signal perfectly localized in time—is given by $m(t_0)\delta(t - t_0)$, and hence the Dirac impulses $\delta(t - t_0)$ are the generalized eigenfunctions with $m(t_0)$ the associated generalized eigenvalues. Note that in the time-invariant and frequency-invariant cases the eigenfunctions are highly structured since they are obtained by frequency shifts of the unity function 1 and by time shifts of the Dirac impulse $\delta(t)$, respectively; moreover, the eigenvalues are given by the values of the transfer function.

On the other hand, the eigenfunctions (singular functions) of general linear operators are not localized and structured in any sense, and the eigenvalues (singular values) are not given by the transfer function values. However, we will now show that *underspread* operators have a well-structured set of time-frequency-localized ''approximate eigenfunctions,'' with the associated ''approximate eigenvalues'' given by the values of the generalized Weyl symbol. Note that it is not necessary to consider approximate singular functions since underspread operators are approximately normal—see Subsection IV B.

Let $s(t)$ be a normalized function that is well concentrated about the origin of the time-frequency plane (e.g., a Gaussian function). We consider the family of functions $s_{t_0,f_0}(t) = s(t - t_0)e^{i2\pi f_0 t}$ obtained by time-frequency-shifting $s(t)$ to the time-frequency point (t_0, f_0). By construction, $s_{t_0,f_0}(t)$ is then well time-frequency-concentrated about (t_0, f_0). The practical usefulness of the set $\{s_{t_0,f_0}(t)\}$ stems from the fact that it is highly structured and parameterized by physically meaningful variables. Such time-delayed and frequency-shifted signal sets are particularly appealing in communication applications, for example, in mobile radio and digital broadcasting.[93–96] We shall now state conditions under which the response of a linear operator $\mathbf{H}$ to $s_{t_0,f_0}(t)$ is approximately $L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)s_{t_0,f_0}(t)$, which implies that $s_{t_0,f_0}(t)$ is an ''approximate eigenfunction'' of $\mathbf{H}$ with $L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)$ the associated ''approximate eigenvalue.'' The next theorem is essentially an adaptation and extension of an existing result on approximate eigenpairs.[42,95] (Approximate eigenpairs and approximate operator diagonalization have previously been considered also at a mathematically more sophisticated level.[14,15,17,97–99]) In the following,

$$A_s^{(\alpha)}(\tau,\nu) \triangleq \int_t s(t+(\tfrac{1}{2}-\alpha)\tau)s^*(t-(\tfrac{1}{2}+\alpha)\tau)e^{-i2\pi\nu t}dt$$

denotes the (generalized) ambiguity function[100,101] of the function $s(t)$, which equals the spreading function of the rank-one operator with kernel $s(t)s^*(t')$. We note that $A_s^{(\alpha)}(0,0)=\|s\|_2^2=1$.

Theorem III.6: *For any operator* $\mathbf{H}$*, any time-frequency point* (t_0,f_0)*, and any normalized function* $s(t)$ *(i.e.,* $\|s\|_2=1$*), the difference* $\Delta_5^{(\alpha)}(t) \triangleq (\mathbf{H}s_{t_0,f_0})(t) - L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)s_{t_0,f_0}(t)$ *is bounded as*

$$\frac{\|\Delta_5^{(\alpha)}\|_2}{\|S_{\mathbf{H}}\|_1} \leq D_{\mathbf{H},s}^{(\alpha)}, \quad \text{with} \quad D_{\mathbf{H},s}^{(\alpha)} \triangleq \sqrt{2\pi C_{\mathbf{H}}^{(\alpha)} + m_{\mathbf{H}^+\mathbf{H}}^{(\phi_s)} + 2m_{\mathbf{H}}^{(\phi_s)}}, \tag{24}$$

with the weighting function $\phi_s(\tau,\nu)=|1-A_s^{(\alpha)}(\tau,\nu)|$ *and* $C_{\mathbf{H}}^{(\alpha)}$ *as defined in* (22).

Proof: First, we develop the square of $\|\Delta_5^{(\alpha)}\|_2$ as

$$\begin{aligned}
\|\Delta_5^{(\alpha)}\|_2^2 &= \|\mathbf{H}s_{t_0,f_0}\|_2^2 - 2\,\mathrm{Re}\{L_{\mathbf{H}}^{(\alpha)*}(t_0,f_0)\langle \mathbf{H}s_{t_0,f_0}, s_{t_0,f_0}\rangle\} + |L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)|^2\|s_{t_0,f_0}\|_2^2 \\
&= \|\mathbf{H}s_{t_0,f_0}\|_2^2 - 2\,\mathrm{Re}\{L_{\mathbf{H}}^{(\alpha)*}(t_0,f_0)[\langle \mathbf{H}s_{t_0,f_0}, s_{t_0,f_0}\rangle - L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)]\} - |L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)|^2 \\
&\leq \big|\|\mathbf{H}s_{t_0,f_0}\|_2^2 - |L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)|^2\big| + 2|L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)|\,|\langle \mathbf{H}s_{t_0,f_0}, s_{t_0,f_0}\rangle - L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)|,
\end{aligned} \tag{25}$$

where we used $\|s_{t_0,f_0}\|_2=\|s\|_2=1$. Using

$$\langle \mathbf{G}s_{t_0,f_0}, s_{t_0,f_0}\rangle = \int_\tau\int_\nu S_{\mathbf{G}}^{(\alpha)}(\tau,\nu)A_s^{(\alpha)*}(\tau,\nu)e^{i2\pi(\nu t_0-\tau f_0)}d\tau d\nu, \tag{26}$$

with $\mathbf{G}=\mathbf{H}^+\mathbf{H}$, and recalling the definition of $\Delta_4^{(\alpha)}(t,f)$ in Corollary III.5, the first term in (25) becomes

$$\begin{aligned}
\big|\|\mathbf{H}s_{t_0,f_0}\|_2^2 - |L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)|^2\big| &= |\langle \mathbf{H}^+\mathbf{H}s_{t_0,f_0}, s_{t_0,f_0}\rangle - L_{\mathbf{H}^+\mathbf{H}}^{(\alpha)}(t_0,f_0) + L_{\mathbf{H}^+\mathbf{H}}^{(\alpha)}(t_0,f_0) - |L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)|^2| \\
&= \left|\int_\tau\int_\nu S_{\mathbf{H}^+\mathbf{H}}^{(\alpha)}(\tau,\nu)[A_s^{(\alpha)*}(\tau,\nu)-1]e^{i2\pi(\nu t_0-\tau f_0)}d\tau d\nu + \Delta_4^{(\alpha)}(t_0,f_0)\right| \\
&\leq \int_\tau\int_\nu |S_{\mathbf{H}^+\mathbf{H}}(\tau,\nu)|\,|1-A_s^{(\alpha)}(\tau,\nu)|\,d\tau d\nu + |\Delta_4^{(\alpha)}(t_0,f_0)| \\
&\leq \|S_{\mathbf{H}^+\mathbf{H}}\|_1 m_{\mathbf{H}^+\mathbf{H}}^{(\phi_s)} + \|S_{\mathbf{H}}\|_1^2 2\pi C_{\mathbf{H}}^{(\alpha)} \leq \|S_{\mathbf{H}}\|_1^2[m_{\mathbf{H}^+\mathbf{H}}^{(\phi_s)} + 2\pi C_{\mathbf{H}}^{(\alpha)}],
\end{aligned}$$

where we used (22) and Young's inequality for twisted convolution,[15] $\|S_{\mathbf{H}^+\mathbf{H}}\|_1 \leq \|S_{\mathbf{H}}\|_1^2$. In a similar manner, the factor of the second term in (25) can be developed and bounded as

$$|\langle \mathbf{H}s_{t_0,f_0}, s_{t_0,f_0}\rangle - L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)| \leq \int_\tau\int_\nu |S_{\mathbf{H}}(\tau,\nu)|\,|1-A_s^{(\alpha)}(\tau,\nu)|\,d\tau d\nu = \|S_{\mathbf{H}}\|_1 m_{\mathbf{H}}^{(\phi_s)}.$$

Inserting these two bounds into (25) and using $|L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)| \leq \|S_{\mathbf{H}}\|_1$ yields the bound (24). □

For an underspread operator $\mathbf{H}$ where $D_{\mathbf{H},s}^{(\alpha)} = \sqrt{2\pi C_{\mathbf{H}}^{(\alpha)} + m_{\mathbf{H}^+\mathbf{H}}^{(\phi_s)} + 2m_{\mathbf{H}}^{(\phi_s)}}$ can be made small, we thus have the ''approximate eigenvalue relation,''

$$(\mathbf{H}s_{t_0,f_0})(t) \approx L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)s_{t_0,f_0}(t),$$

which implies that properly time-frequency-localized functions are approximate eigenfunctions and the generalized Weyl symbol $L_{\mathbf{H}}^{(\alpha)}(t,f)$ is an approximate eigenvalue distribution over the time-frequency plane. In particular, small $m_{\mathbf{H}}^{(\phi_s)}$ and $m_{\mathbf{H}^+\mathbf{H}}^{(\phi_s)}$ requires that, on the effective supports of $|S_{\mathbf{H}}(\tau,\nu)|$ and of $|S_{\mathbf{H}^+\mathbf{H}}(\tau,\nu)|$, there is $\phi_s(\tau,\nu)\approx 0$ [recall the definition (9)] and thus

$A_s^{(\alpha)}(\tau,\nu)\approx A_s^{(\alpha)}(0,0)\equiv 1$. The latter condition can be satisfied only if these effective supports are small, i.e., if $\mathbf{H}$ is underspread. [Recall from (18) that $S_{\mathbf{H}^+\mathbf{H}}^{(\alpha)}(\tau,\nu)=(S_{\mathbf{H}^+}^{(\alpha)}\natural S_{\mathbf{H}}^{(\alpha)})(\tau,\nu)$, and note that this twisted convolution enlarges the effective support of $S_{\mathbf{H}}^{(\alpha)}(\tau,\nu)$ maximally by a factor of four.[42,44]] Moreover, $A_s^{(\alpha)}(\tau,\nu)\approx A_s^{(\alpha)}(0,0)$ around the origin implies that the second-order derivatives of $A_s^{(\alpha)}(\tau,\nu)$ with respect to τ and ν are small at the origin. Since these second-order derivatives correspond to the effective duration and bandwidth[102,103] of $s(t)$, it is seen that the function $s(t)$ needs to have good time-frequency concentration.

The bound $D_{\mathbf{H},s}^{(\alpha)}$ is tightest for $\alpha=0$ since here $C_{\mathbf{H}}^{(\alpha)}$ is smallest. Furthermore, $C_{\mathbf{H}}^{(0)}$ can be replaced by $\min_{\mathbf{U}\in\mathscr{U}} C_{\mathbf{UHU}^+}^{(0)}$ which allows oblique orientation of the spreading function of $\mathbf{H}$. We note that $m_{\mathbf{H}}^{(\phi_s)}$ and $m_{\mathbf{H}^+\mathbf{H}}^{(\phi_s)}$ can be adapted to an oblique orientation of the spreading function by a proper choice of the function $s(t)$.

E. Input-output relation for deterministic signals

For time-invariant systems, due to the fact that the complex sinusoids are eigenfunctions, the Fourier transform of the output signal $(\mathbf{H}x)(t)$ is given by $G(f)X(f)$. Similarly, for frequency-invariant systems $(\mathbf{H}x)(t)$ equals $m(t)x(t)$. In the case of general operators, one may desire a similar ''input-output relation'' stating that a suitably defined time-frequency representation of $(\mathbf{H}x)(t)$ equals the time-frequency representation of $x(t)$ multiplied by the time-frequency transfer function $L_{\mathbf{H}}^{(\alpha)}(t,f)$. To derive such an input-output relation, we note that the input signal $x(t)$ can be expanded[15,17,21–23] into the set of time-frequency-shifted versions $s_{t_0,f_0}(t)=s(t-t_0)e^{i2\pi f_0 t}$ of a normalized function $s(t)$,

$$x(t)=\int_{t_0}\int_{f_0}\mathrm{STFT}_x^{(s)}(t_0,f_0)s_{t_0,f_0}(t)\,dt_0\,df_0, \tag{27}$$

where

$$\mathrm{STFT}_x^{(s)}(t,f)=\int_{t'}x(t')s^*(t'-t)e^{-i2\pi f t'}dt'=\langle x,s_{t,f}\rangle \tag{28}$$

is the short-time Fourier transform[9,21,22,24] of the signal $x(t)$ using $s(t)$ as an analysis window. For Gaussian $s(t)$, the short-time Fourier transform is equivalent to the coherent states expansion of quantum physics.[15–18,104] In what follows, we will adopt the short-time Fourier transform as a time-frequency signal representation. Assuming $s(t)$ to have good time-frequency concentration and $\mathbf{H}$ to be underspread, we know from Subsection III D that the $s_{t_0,f_0}(t)$ are approximate eigenfunctions, i.e., $(\mathbf{H}s_{t_0,f_0})(t)\approx L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)s_{t_0,f_0}(t)$. Hence, applying $\mathbf{H}$ to both sides of (27) we obtain

$$\begin{aligned}(\mathbf{H}x)(t)&=\int_{t_0}\int_{f_0}\mathrm{STFT}_x^{(s)}(t_0,f_0)(\mathbf{H}s_{t_0,f_0})(t)\,dt_0\,df_0\\&\approx\int_{t_0}\int_{f_0}\mathrm{STFT}_x^{(s)}(t_0,f_0)L_{\mathbf{H}}^{(\alpha)}(t_0,f_0)s_{t_0,f_0}(t)\,dt_0\,df_0.\end{aligned}$$

Comparing with (27) [with $x(t)$ replaced by $(\mathbf{H}x)(t)$], this suggests that $\mathrm{STFT}_{\mathbf{H}x}^{(s)}(t,f)\approx\mathrm{STFT}_x^{(s)}(t,f)L_{\mathbf{H}}^{(\alpha)}(t,f)$. Hence, the generalized Weyl symbol can be interpreted as a weighting function in the time-frequency (short-time Fourier transform) domain, thus motivating a design and implementation of time-varying filters based on the short-time Fourier transform (see Subsection III F). The next theorem gives a bound on the quality of the above approximation.

Theorem III.7: *For any operator* $\mathbf{H}$, *any signal* $x(t)$, *and any normalized function* $s(t)$, *the difference* $\Delta_6^{(\alpha)}(t,f)\triangleq\mathrm{STFT}_{\mathbf{H}x}^{(s)}(t,f)-L_{\mathbf{H}}^{(\alpha)}(t,f)\mathrm{STFT}_x^{(s)}(t,f)$ *is bounded as*

$$\frac{|\Delta_6^{(\alpha)}(t,f)|}{\|S_{\mathbf{H}}\|_1\|x\|_2}\leq D_{\mathbf{H}^+,s}^{(\alpha)}+4\pi|\alpha|m_{\mathbf{H}}^{(1,1)},\quad \frac{\|\Delta_6^{(\alpha)}\|_2}{\|\mathbf{H}\|_2\|x\|_2}\leq\sqrt{2}M_{\mathbf{H}}^{(\phi_s')}+4\pi|\alpha|M_{\mathbf{H}}^{(1,1)}, \tag{29}$$

with the weighting functions $\phi_s(\tau,\nu)=|1-A_s^{(\alpha)}(\tau,\nu)|$ *[used in* $D^{(\alpha)}_{\mathbf{H}^+,s}$*; see (24)] and* $\phi_s'(\tau,\nu)=\sqrt{1-\mathrm{Re}\{A_s^{(\alpha)}(\tau,\nu)\}}$ *(used in* $M^{(\phi_s')}_{\mathbf{H}}$*).*

Proof: We have

$$\begin{aligned}\Delta_6^{(\alpha)}(t,f)&=\langle \mathbf{H}x,s_{t,f}\rangle-L_{\mathbf{H}}^{(\alpha)}(t,f)\langle x,s_{t,f}\rangle\\&=\langle x,[\mathbf{H}^+-L_{\mathbf{H}}^{(\alpha)*}(t,f)\mathbf{I}]s_{t,f}\rangle\\&=\langle x,[\mathbf{H}^+-L_{\mathbf{H}^+}^{(\alpha)}(t,f)\mathbf{I}+L_{\mathbf{H}^+}^{(\alpha)}(t,f)\mathbf{I}-L_{\mathbf{H}}^{(\alpha)*}(t,f)\mathbf{I}]s_{t,f}\rangle\\&=\Delta_A^{(\alpha)}(t,f)+\Delta_B^{(\alpha)}(t,f),\end{aligned}\tag{30}$$

with

$$\Delta_A^{(\alpha)}(t,f)\triangleq\langle x,[\mathbf{H}^+-L_{\mathbf{H}^+}^{(\alpha)}(t,f)\mathbf{I}]s_{t,f}\rangle,\quad \Delta_B^{(\alpha)}(t,f)\triangleq[L_{\mathbf{H}^+}^{(\alpha)}(t,f)-L_{\mathbf{H}}^{(\alpha)*}(t,f)]^*\langle x,s_{t,f}\rangle.$$

Using Schwarz' inequality, (24), (13), and $\|s_{t,f}\|_2=\|s\|_2=1$, we obtain the bounds

$$|\Delta_A^{(\alpha)}(t,f)|\leqslant\|x\|_2\|\mathbf{H}^+s_{t,f}-L_{\mathbf{H}^+}^{(\alpha)}(t,f)s_{t,f}\|_2\leqslant\|x\|_2\|S_{\mathbf{H}^+}\|_1D^{(\alpha)}_{\mathbf{H}^+,s}=\|x\|_2\|S_{\mathbf{H}}\|_1D^{(\alpha)}_{\mathbf{H}^+,s},\tag{31}$$

$$|\Delta_B^{(\alpha)}(t,f)|\leqslant|L_{\mathbf{H}^+}^{(\alpha)}(t,f)-L_{\mathbf{H}}^{(\alpha)*}(t,f)|\|x\|_2\|s_{t,f}\|_2\leqslant\|x\|_2\|S_{\mathbf{H}}\|_1 4\pi|\alpha|m_{\mathbf{H}}^{(1,1)}.\tag{32}$$

The first (L_∞) bound in (29) then follows upon inserting (31) and (32) into $|\Delta_6^{(\alpha)}(t,f)|\leqslant|\Delta_A^{(\alpha)}(t,f)|+|\Delta_B^{(\alpha)}(t,f)|$ [cf. (30)].

To derive the second (L_2) bound in (29), we note that

$$\begin{aligned}\|\Delta_A^{(\alpha)}\|_2^2&=\int_t\int_f|\langle x,\mathbf{H}^+s_{t,f}-L_{\mathbf{H}^+}^{(\alpha)}(t,f)s_{t,f}\rangle|^2dtdf\\&\leqslant\int_t\int_f\|x\|_2^2\|\mathbf{H}^+s_{t,f}-L_{\mathbf{H}^+}^{(\alpha)}(t,f)s_{t,f}\|_2^2dtdf\\&=\|x\|_2^2\int_t\int_f[\|\mathbf{H}^+s_{t,f}\|_2^2-2\,\mathrm{Re}\{L_{\mathbf{H}^+}^{(\alpha)*}(t,f)\langle\mathbf{H}^+s_{t,f},s_{t,f}\rangle\}+|L_{\mathbf{H}^+}^{(\alpha)}(t,f)|^2\|s_{t,f}\|_2^2]dtdf.\end{aligned}\tag{33}$$

Using (26), it can be shown that

$$\int_t\int_f\|\mathbf{H}^+s_{t,f}\|_2^2dtdf=\int_t\int_f\langle\mathbf{H}\mathbf{H}^+s_{t,f},s_{t,f}\rangle dtdf=S^{(\alpha)}_{\mathbf{H}\mathbf{H}^+}(0,0)=\mathrm{Tr}\{\mathbf{H}\mathbf{H}^+\}=\|S_{\mathbf{H}}\|_2^2$$

and

$$\int_t\int_f L_{\mathbf{H}^+}^{(\alpha)*}(t,f)\langle\mathbf{H}^+s_{t,f},s_{t,f}\rangle dtdf=\int_\tau\int_\nu|S_{\mathbf{H}^+}(\tau,\nu)|^2A_s^{(\alpha)*}(\tau,\nu)d\tau d\nu;$$

furthermore, with $\|s_{t,f}\|_2^2=\|s\|_2^2=1$ we have $\int_t\int_f|L_{\mathbf{H}^+}^{(\alpha)}(t,f)|^2\|s_{t,f}\|_2^2dt\,df=\|L_{\mathbf{H}}^{(\alpha)}\|_2^2=\|S_{\mathbf{H}}\|_2^2$. Inserting these three results into (33) yields

$$\begin{aligned}\|\Delta_A^{(\alpha)}\|_2^2&\leqslant\|x\|_2^2\left[2\int_\tau\int_\nu|S_{\mathbf{H}}(\tau,\nu)|^2d\tau d\nu-2\,\mathrm{Re}\left\{\int_\tau\int_\nu|S_{\mathbf{H}}(\tau,\nu)|^2A_s^{(\alpha)*}(\tau,\nu)d\tau d\nu\right\}\right]\\&=2\|x\|_2^2\int_\tau\int_\nu|S_{\mathbf{H}}(\tau,\nu)|^2[1-\mathrm{Re}\{A_s^{(\alpha)}(\tau,\nu)\}]d\tau d\nu=2\|x\|_2^2\|\mathbf{H}\|_2^2[M^{(\phi_s')}_{\mathbf{H}}]^2.\end{aligned}\tag{34}$$

The L_2 norm of $\Delta_B^{(\alpha)}(t,f)$ can be bounded using (13),

$$\|\Delta_B^{(\alpha)}\|_2^2 \leq \int_t \int_f |L_{\mathbf{H}^+}^{(\alpha)}(t,f) - L_{\mathbf{H}}^{(\alpha)*}(t,f)|^2 \|x\|_2^2 \|s_{t,f}\|_2^2 dt\,df \leq \|x\|_2^2 \|\mathbf{H}\|_2^2 [4\pi|\alpha| M_{\mathbf{H}}^{(1,1)}]^2. \quad (35)$$

The second (L_2) bound in (29) then follows by inserting (34) and (35) into $\|\Delta_6^{(\alpha)}\|_2 \leq \|\Delta_A^{(\alpha)}\|_2 + \|\Delta_B^{(\alpha)}\|_2$ [cf. (30)]. □

Thus, if $D_{\mathbf{H}^+,s}^{(\alpha)}$ (see Subsection III D) and $M_{\mathbf{H}}^{(\phi_s')}$ can be made small by a suitable choice of $s(t)$, and if $m_{\mathbf{H}}^{(1,1)}$ and $M_{\mathbf{H}}^{(1,1)}$ are small, we obtain the approximate input-output relation

$$\mathrm{STFT}_{\mathbf{H}x}^{(s)}(t,f) \approx L_{\mathbf{H}}^{(\alpha)}(t,f)\,\mathrm{STFT}_x^{(s)}(t,f).$$

In particular, small $M_{\mathbf{H}}^{(\phi_s')}$ requires that $\mathrm{Re}\{A_s^{(\alpha)}(\tau,\nu)\} \approx A_s^{(\alpha)}(0,0) \equiv 1$ on the effective support of $|S_{\mathbf{H}}(\tau,\nu)|$, thus implying that this effective support is small, i.e., that $\mathbf{H}$ is underspread. Note that the bounds in (29) simplify, and are tightest, in the case $\alpha = 0$.

F. Performance of the short-time Fourier transform filter

The relation $\mathrm{STFT}_{\mathbf{H}x}^{(s)}(t,f) \approx L_{\mathbf{H}}^{(\alpha)}(t,f)\mathrm{STFT}_x^{(s)}(t,f)$ valid in the underspread case suggests that the output signal $(\mathbf{H}x)(t)$ can approximately be obtained by applying an inverse short-time Fourier transform to $L_{\mathbf{H}}^{(\alpha)}(t,f)\mathrm{STFT}_x^{(s)}(t,f)$. This corresponds to an approximate time-frequency implementation of $\mathbf{H}$ that consists of calculating the short-time Fourier transform of the input signal, $\mathrm{STFT}_x^{(s)}(t,f)$, multiplying by the time-frequency transfer function $L_{\mathbf{H}}^{(\alpha)}(t,f)$, and applying the inverse short-time Fourier transform (27) to $L_{\mathbf{H}}^{(\alpha)}(t,f)\mathrm{STFT}_x^{(s)}(t,f)$. The resulting time-varying system will be called a *short-time Fourier transform filter* and denoted by $\hat{\mathbf{H}}^{(\alpha)}$. Using (27) and (28), the input-output relation of the short-time Fourier transform filter is

$$(\hat{\mathbf{H}}^{(\alpha)}x)(t) = \int_{t'} \int_{f'} \langle x, s_{t',f'}\rangle L_{\mathbf{H}}^{(\alpha)}(t',f') s_{t',f'}(t)\,dt'\,df'.$$

Such short-time Fourier transform filters [possibly with weighting functions other than $L_{\mathbf{H}}^{(\alpha)}(t,f)$] have been considered previously.[17,22–24,42,45,46,105,106] They are an intuitively appealing, practical way of implementing a time-varying filter. In a time-frequency-discretized form, they permit time-varying subband signal processing using the Gabor expansion[12,19,107,108] or, equivalently, DFT filter banks.[23,109–114] Furthermore, in a mathematical context short-time Fourier transform filters are a special case of Toeplitz operators.[42,98,115]

In the following, we first establish a relation and bound for the difference between the generalized Weyl symbol of the original operator $\mathbf{H}$ and that of the short-time Fourier transform filter $\hat{\mathbf{H}}^{(\alpha)}$; subsequently, we will bound the difference between the exact output signal $(\mathbf{H}x)(t)$ and the output signal $(\hat{\mathbf{H}}^{(\alpha)}x)(t)$ of the short-time Fourier transform filter. We note that the L_∞ bound in the next theorem is an extension and adaptation of an existing bound.[42,44]

Theorem III.8: *For any operator* $\mathbf{H}$, *the difference* $\Delta_7^{(\alpha)}(t,f) \triangleq L_{\mathbf{H}}^{(\alpha)}(t,f) - L_{\hat{\mathbf{H}}^{(\alpha)}}^{(\alpha)}(t,f)$ *satisfies*

$$\frac{|\Delta_7^{(\alpha)}(t,f)|}{\|S_{\mathbf{H}}\|_1} \leq m_{\mathbf{H}}^{(\phi_s)}, \quad \frac{\|\Delta_7^{(\alpha)}\|_2}{\|\mathbf{H}\|_2} = M_{\mathbf{H}}^{(\phi_s)},$$

with the weighting function $\phi_s(\tau,\nu) = |1 - A_s^{(\alpha)}(\tau,\nu)|$ *where* $s(t)$ *is the normalized window used in the short-time Fourier transform.*

Proof: The spreading function of $\hat{\mathbf{H}}^{(\alpha)}$ can be written as[15,42,46,64] $S_{\hat{\mathbf{H}}^{(\alpha)}}^{(\alpha)}(\tau,\nu) = S_{\mathbf{H}}^{(\alpha)}(\tau,\nu) \times A_s^{(\alpha)*}(\tau,\nu)$. The first ($L_\infty$) bound is then shown as

$$|\Delta_7^{(\alpha)}(t,f)| = \left| \int_\tau \int_\nu [S_{\mathbf{H}}^{(\alpha)}(\tau,\nu) - S_{\hat{\mathbf{H}}^{(\alpha)}}^{(\alpha)}(\tau,\nu)] e^{i2\pi(\nu t - \tau f)} d\tau\,d\nu \right|$$

$$\leq \int_\tau \int_\nu |S_{\mathbf{H}}(\tau,\nu)||1 - A_s^{(\alpha)*}(\tau,\nu)|\,d\tau\,d\nu = \|S_{\mathbf{H}}\|_1 m_{\mathbf{H}}^{(\phi_s)}.$$

The expression for the L_2 norm of $\Delta_7^{(\alpha)}(t,f)$ is shown by noting that

$$\|\Delta_7^{(\alpha)}\|_2^2=\|S_{\mathbf{H}}^{(\alpha)}-S_{\hat{\mathbf{H}}^{(\alpha)}}^{(\alpha)}\|_2^2=\int_\tau\int_\nu |S_{\mathbf{H}}^{(\alpha)}(\tau,\nu)[1-A_s^{(\alpha)*}(\tau,\nu)]|^2 d\tau d\nu,$$

and proceeding similarly. □

Hence, if $m_{\mathbf{H}}^{(\phi_s)}$ and $M_{\mathbf{H}}^{(\phi_s)}$ can be made small by a suitable choice of $s(t)$, then $L_{\mathbf{H}}^{(\alpha)}(t,f)\approx L_{\hat{\mathbf{H}}^{(\alpha)}}^{(\alpha)}(t,f)$. Furthermore, since $\|\Delta_7^{(\alpha)}\|_2$ equals the Hilbert–Schmidt norm $\|\mathbf{H}-\hat{\mathbf{H}}^{(\alpha)}\|_2$ and since the operator norm[59] $\|\mathbf{H}-\hat{\mathbf{H}}^{(\alpha)}\|$ is bounded from above by the Hilbert–Schmidt norm, we obtain

$$\|\mathbf{H}-\hat{\mathbf{H}}^{(\alpha)}\|\leq\|\mathbf{H}-\hat{\mathbf{H}}^{(\alpha)}\|_2=\|\mathbf{H}\|_2 M_{\mathbf{H}}^{(\phi_s)}. \tag{36}$$

Therefore, if $M_{\mathbf{H}}^{(\phi_s)}$ is small the short-time Fourier transform filter $\hat{\mathbf{H}}^{(\alpha)}$ will be close to $\mathbf{H}$, i.e., $\hat{\mathbf{H}}^{(\alpha)}\approx\mathbf{H}$. This is also shown by the following bounds on the difference of the respective output signals.

Corollary III.9: For any operator $\mathbf{H}$ *and any signal* $x(t)$, *the difference* $\Delta_8^{(\alpha)}(t)\triangleq(\mathbf{H}x)(t)-(\hat{\mathbf{H}}^{(\alpha)}x)(t)$ *is bounded as*

$$\frac{|\Delta_8^{(\alpha)}(t)|}{\|S_{\mathbf{H}}\|_1\|x\|_\infty}\leq m_{\mathbf{H}}^{(\phi_s)},\quad \frac{\|\Delta_8^{(\alpha)}\|_2}{\|\mathbf{H}\|_2\|x\|_2}\leq M_{\mathbf{H}}^{(\phi_s)},$$

with the weighting function $\phi_s(\tau,\nu)$ *as in Theorem III.8. [Here,* $\|x\|_\infty=\sup_t|x(t)|$ *denotes the* L_∞ (sup) *norm of* $x(t)$.*]*

Proof: Using (5), the relation $S_{\hat{\mathbf{H}}^{(\alpha)}}^{(\alpha)}(\tau,\nu)=S_{\mathbf{H}}^{(\alpha)}(\tau,\nu)A_s^{(\alpha)*}(\tau,\nu)$, and $|x_{\tau,\nu}^{(\alpha)}(t)|\leq\|x_{\tau,\nu}^{(\alpha)}\|_\infty=\|x\|_\infty$, the first ($L_\infty$) bound is shown as

$$\begin{aligned}|\Delta_8^{(\alpha)}(t)|&=\left|\int_\tau\int_\nu [S_{\mathbf{H}}^{(\alpha)}(\tau,\nu)-S_{\hat{\mathbf{H}}^{(\alpha)}}^{(\alpha)}(\tau,\nu)]x_{\tau,\nu}^{(\alpha)}(t)\,d\tau d\nu\right|\\&\leq\int_\tau\int_\nu |S_{\mathbf{H}}(\tau,\nu)||1-A_s^{(\alpha)*}(\tau,\nu)||x_{\tau,\nu}^{(\alpha)}(t)|\,d\tau d\nu\leq\|x\|_\infty\|S_{\mathbf{H}}\|_1 m_{\mathbf{H}}^{(\phi_s)}.\end{aligned}$$

The second (L_2) bound is shown by noting that

$$\|\Delta_8^{(\alpha)}\|_2^2=\|(\mathbf{H}-\hat{\mathbf{H}}^{(\alpha)})x\|_2^2\leq\|\mathbf{H}-\hat{\mathbf{H}}^{(\alpha)}\|^2\|x\|_2^2$$

and using (36). □

Thus, for an underspread operator $\mathbf{H}$ for which $m_{\mathbf{H}}^{(\phi_s)}$ and $M_{\mathbf{H}}^{(\phi_s)}$ can be made small by a suitable choice of the short-time Fourier transform window $s(t)$, we have $(\mathbf{H}x)(t)\approx(\hat{\mathbf{H}}^{(\alpha)}x)(t)$, i.e., the output of the short-time Fourier transform filter is a good approximation to the output of the given operator $\mathbf{H}$.

G. Input-output relation for random signals

When a wide-sense stationary random process $x(t)$ with power spectral density[116] $P_x(f)$ is passed through a time-invariant system $\mathbf{H}$ with frequency response $G(f)$, the output $(\mathbf{H}x)(t)$ is again wide-sense stationary with power spectral density $P_{\mathbf{H}x}(f)=|G(f)|^2P_x(f)$. Similarly, the response of a frequency-invariant system with temporal transfer function $m(t)$ to a (generally nonstationary) white process $x(t)$ with mean instantaneous intensity[116] $q_x(t)$ is again white, with mean instantaneous intensity $q_{\mathbf{H}x}(t)=|m(t)|^2q_x(t)$. We shall now investigate whether the simple multiplicative ''input-output relations'' $P_{\mathbf{H}x}(f)=|G(f)|^2P_x(f)$ and $q_{\mathbf{H}x}(t)=|m(t)|^2q_x(t)$, which relate the second-order statistics of $x(t)$ with those of $(\mathbf{H}x)(t)$, can be extended to the general time-varying/nonstationary case.

Let us consider an operator $\mathbf{H}$ whose input $x(t)$ is a general zero-mean, nonstationary random process. The correlation operator of $x(t)$ is defined as $\mathbf{R}_x\triangleq E\{x\otimes x^*\}$, where E denotes the expectation operator and $x\otimes x^*$ is the rank-one operator whose kernel is $x(t)x^*(t')$. Hence, the

kernel of $\mathbf{R}_x$ is the correlation function $r_x(t,t')=E\{x(t)x^*(t')\}$. The system output $(\mathbf{H}x)(t)$ is a zero-mean, nonstationary random process whose correlation operator is given by

$$\mathbf{R}_{\mathbf{H}x}=E\{(\mathbf{H}x)\otimes(\mathbf{H}x)^*\}=\mathbf{H}E\{x\otimes x^*\}\mathbf{H}^+=\mathbf{H}\mathbf{R}_x\mathbf{H}^+.$$

We now look for a time-frequency reformulation of the above input-output relation in terms of the generalized Weyl symbol. Specifically, if $\mathbf{H}$ and $\mathbf{R}_x$ are jointly underspread in the sense of Subsection III C, then (19) and (14) imply (similar results have been obtained previously[42,54])

$$L^{(\alpha)}_{\mathbf{R}_{\mathbf{H}x}}(t,f)=L^{(\alpha)}_{\mathbf{H}\mathbf{R}_x\mathbf{H}^+}(t,f)\approx L^{(\alpha)}_{\mathbf{H}}(t,f)L^{(\alpha)}_{\mathbf{R}_x}(t,f)L^{(\alpha)}_{\mathbf{H}^+}(t,f)\approx|L^{(\alpha)}_{\mathbf{H}}(t,f)|^2L^{(\alpha)}_{\mathbf{R}_x}(t,f),$$

or equivalently,

$$\overline{W}^{(\alpha)}_{\mathbf{H}x}(t,f)\approx|L^{(\alpha)}_{\mathbf{H}}(t,f)|^2\overline{W}^{(\alpha)}_{x}(t,f), \tag{37}$$

where $\overline{W}^{(\alpha)}_x(t,f)$ denotes the generalized Wigner–Ville spectrum[86,90,117] of a nonstationary process $x(t)$. The generalized Wigner–Ville spectrum is defined as the generalized Weyl symbol of the correlation operator,

$$\overline{W}^{(\alpha)}_x(t,f)\triangleq L^{(\alpha)}_{\mathbf{R}_x}(t,f)=\int_\tau r^{(\alpha)}_x(t,\tau)e^{-i2\pi f\tau}d\tau,$$

with $r^{(\alpha)}_x(t,\tau)$ obtained from $r_x(t,t')$ according to (3). It is a second-order time-frequency representation (''time-dependent power spectrum'') of nonstationary random processes. It reduces to the power spectral density $P_x(f)$ in the case of a wide-sense stationary process and to the mean instantaneous intensity $q_x(t)$ in the case of a (nonstationary) white process. The next theorem bounds the error of the approximation (37).

Theorem III.10: *For any operator* $\mathbf{H}$ *and any (generally nonstationary and nonwhite) random process* $\underline{x}(t)$ *with correlation operator* $\mathbf{R}_x$, *the difference* $\Delta^{(\alpha)}_9(t,f)\triangleq\overline{W}^{(\alpha)}_{\mathbf{H}x}(t,f)-|L^{(\alpha)}_{\mathbf{H}}(t,f)|^2\overline{W}^{(\alpha)}_x(t,f)$ *is bounded as*

$$\frac{|\Delta^{(\alpha)}_9(t,f)|}{\|S_{\mathbf{H}}\|_1^2\|S_{\mathbf{R}_x}\|_1}\leq 2\pi c_\alpha[m^{(0,1)}_{\mathbf{H}}m^{(1,0)}_{\mathbf{R}_x}+m^{(1,0)}_{\mathbf{H}}m^{(0,1)}_{\mathbf{R}_x}+m^{(0,1)}_{\mathbf{H}}m^{(1,0)}_{\mathbf{H}}]+4\pi|\alpha|m^{(1,1)}_{\mathbf{H}}, \tag{38}$$

with $c_\alpha=|\alpha+1/2|+|\alpha-1/2|$.

Proof: Subtracting and adding $L^{(\alpha)}_{\mathbf{H}}(t,f)L^{(\alpha)}_{\mathbf{R}_x}(t,f)L^{(\alpha)}_{\mathbf{H}^+}(t,f)$, we have

$$|\Delta^{(\alpha)}_9(t,f)|=|\Delta^{(\alpha)}_A(t,f)+\Delta^{(\alpha)}_B(t,f)|\leq|\Delta^{(\alpha)}_A(t,f)|+|\Delta^{(\alpha)}_B(t,f)|, \tag{39}$$

with

$$\Delta^{(\alpha)}_A(t,f)\triangleq L^{(\alpha)}_{\mathbf{H}\mathbf{R}_x\mathbf{H}^+}(t,f)-L^{(\alpha)}_{\mathbf{H}}(t,f)L^{(\alpha)}_{\mathbf{R}_x}(t,f)L^{(\alpha)}_{\mathbf{H}^+}(t,f), \tag{40}$$

$$\Delta^{(\alpha)}_B(t,f)\triangleq L^{(\alpha)}_{\mathbf{H}}(t,f)L^{(\alpha)}_{\mathbf{R}_x}(t,f)[L^{(\alpha)}_{\mathbf{H}^+}(t,f)-L^{(\alpha)}_{\mathbf{H}}{}^*(t,f)]. \tag{41}$$

Since according to (18) $S^{(\alpha)}_{\mathbf{H}\mathbf{R}_x\mathbf{H}^+}(\tau,\nu)=(S^{(\alpha)}_{\mathbf{H}}\natural S^{(\alpha)}_{\mathbf{R}_x}\natural S^{(\alpha)}_{\mathbf{H}^+})(\tau,\nu)$ and since the 2-D Fourier transform of $L^{(\alpha)}_{\mathbf{H}}(t,f)L^{(\alpha)}_{\mathbf{R}_x}(t,f)L^{(\alpha)}_{\mathbf{H}^+}(t,f)$ is given by $(S^{(\alpha)}_{\mathbf{H}}{**}S^{(\alpha)}_{\mathbf{R}_x}{**}S^{(\alpha)}_{\mathbf{H}^+})(\tau,\nu)$, the 2-D Fourier transform of $\Delta^{(\alpha)}_A(t,f)$ in (40) is obtained as

$$\begin{aligned}\hat{\Delta}^{(\alpha)}_A(\tau,\nu)&=(S^{(\alpha)}_{\mathbf{H}}\natural S^{(\alpha)}_{\mathbf{R}_x}\natural S^{(\alpha)}_{\mathbf{H}^+})(\tau,\nu)-(S^{(\alpha)}_{\mathbf{H}}{**}S^{(\alpha)}_{\mathbf{R}_x}{**}S^{(\alpha)}_{\mathbf{H}^+})(\tau,\nu)\\&=\int_{\tau_1}\int_{\nu_1}\int_{\tau_2}\int_{\nu_2}S^{(\alpha)}_{\mathbf{H}}(\tau_1,\nu_1)S^{(\alpha)}_{\mathbf{R}_x}(\tau_2,\nu_2)S^{(\alpha)}_{\mathbf{H}^+}(\tau-\tau_1-\tau_2,\nu-\nu_1-\nu_2)\\&\quad\cdot[e^{-i2\pi[\phi_\alpha(\tau-\tau_1,\nu-\nu_1,\tau_2,\nu_2)+\phi_\alpha(\tau,\nu,\tau_1,\nu_1)]}-1]d\tau_1d\nu_1d\tau_2d\nu_2.\end{aligned}$$

Using $|\sin x| \leq |x|$ and substituting $\tau_3 = \tau - \tau_1 - \tau_2$, $\nu_3 = \nu - \nu_1 - \nu_2$, the first term in (39) can then be bounded as

$$\begin{aligned}
|\Delta_A^{(\alpha)}(t,f)| &\leq \int_\tau \int_\nu |\hat{\Delta}_A^{(\alpha)}(\tau,\nu)| d\tau d\nu \\
&\leq 2\pi \int_{\tau_1} \int_{\nu_1} \int_{\tau_2} \int_{\nu_2} \int_{\tau_3} \int_{\nu_3} |S_{\mathbf{H}}(\tau_1,\nu_1)||S_{\mathbf{R}_x}(\tau_2,\nu_2)||S_{\mathbf{H}^+}(\tau_3,\nu_3)| \\
&\quad \cdot [|\alpha + \tfrac{1}{2}|[|\tau_1\nu_2| + |\tau_1\nu_3| + |\tau_2\nu_3|] + |\alpha - \tfrac{1}{2}|[|\tau_2\nu_1| + |\tau_3\nu_1| + |\tau_3\nu_2|]] \\
&\quad \cdot d\tau_1 d\nu_1 d\tau_2 d\nu_2 d\tau_3 d\nu_3 \\
&= 2\pi \|S_{\mathbf{H}}\|_1^2 \|S_{\mathbf{R}_x}\|_1 c_\alpha [m_{\mathbf{H}}^{(0,1)} m_{\mathbf{R}_x}^{(1,0)} + m_{\mathbf{H}}^{(1,0)} m_{\mathbf{R}_x}^{(0,1)} + m_{\mathbf{H}}^{(0,1)} m_{\mathbf{H}}^{(1,0)}], \qquad (42)
\end{aligned}$$

where the final expression is obtained by collecting corresponding terms in the integral and using $m_{\mathbf{H}^+}^{(k,l)} = m_{\mathbf{H}}^{(k,l)}$. A bound on the second term in (39) is obtained by using $|L_{\mathbf{H}}^{(\alpha)}(t,f)| \leq \|S_{\mathbf{H}}\|_1$ in (41) and applying (13),

$$|\Delta_B^{(\alpha)}(t,f)| \leq \|S_{\mathbf{H}}\|_1 \|S_{\mathbf{R}_x}\|_1 |L_{\mathbf{H}^+}^{(\alpha)}(t,f) - L_{\mathbf{H}}^{(\alpha)*}(t,f)| \leq \|S_{\mathbf{H}}\|_1^2 \|S_{\mathbf{R}_x}\|_1 4\pi |\alpha| m_{\mathbf{H}}^{(1,1)}. \qquad (43)$$

Inserting (42) and (43) in (39) yields the bound (38). □

The theorem shows that the approximate input-output relation (37) will be valid if $\mathbf{H}$ and $\mathbf{R}_x$ are jointly underspread such that the moments appearing in the bound (38) are small. This requires the spreading functions of $\mathbf{H}$ and $\mathbf{R}_x$ to be similarly concentrated along the τ or ν axis. The bound (38) is tightest for $\alpha = 0$, in which case also a refined bound similar to (20) and (23) can be obtained by using metaplectic transformations of $\mathbf{H}$ and $\mathbf{R}_x$; this allows the spreading functions of $\mathbf{H}$ and $\mathbf{R}_x$ to be oriented in (similar) oblique directions.

H. Infimum and supremum of the Weyl symbol

We have seen in Subsection III D that the generalized Weyl symbol of an underspread operator can be interpreted as an approximate eigenvalue distribution over the time-frequency plane. We now assume $\mathbf{H}$ to be self-adjoint, such that the eigenvalues $\lambda_{\mathbf{H},k}$ of $\mathbf{H}$ are real-valued. Furthermore, we consider the Weyl symbol $L_{\mathbf{H}}^{(0)}(t,f)$ of $\mathbf{H}$ which is real-valued as well. We shall investigate how close $\inf_{t,f} L_{\mathbf{H}}^{(0)}(t,f)$ and $\sup_{t,f} L_{\mathbf{H}}^{(0)}(t,f)$ are to $\lambda_{\mathbf{H}}^{\inf} \triangleq \inf_k \lambda_{\mathbf{H},k}$ and $\lambda_{\mathbf{H}}^{\sup} \triangleq \sup_k \lambda_{\mathbf{H},k}$, respectively. This issue will be seen to be of importance in Subsections III I and IV B. Related issues in the theories of quantization and pseudo-differential operators are the boundedness or positivity of operators corresponding to bounded or positive symbols, the results being theorems of the Calderón-Vaillancourt type[15,40,41,118] and Gårding inequalities,[14,15,40,97] respectively. The next theorem is an extension and adaptation of previous results.[42,44]

Theorem III.11: *For any self-adjoint operator* $\mathbf{H}$*, there is*

$$\frac{|\inf_{t,f} L_{\mathbf{H}}^{(0)}(t,f) - \lambda_{\mathbf{H}}^{\inf}|}{\|S_{\mathbf{H}}\|_1} \leq m_{\mathbf{H}}^{(\phi_s)}, \quad \frac{|\sup_{t,f} L_{\mathbf{H}}^{(0)}(t,f) - \lambda_{\mathbf{H}}^{\sup}|}{\|S_{\mathbf{H}}\|_1} \leq m_{\mathbf{H}}^{(\phi_s)}, \qquad (44)$$

with the weighting function $\phi_s(\tau,\nu) = |1 - 1/A_s^{(0)}(\tau,\nu)|$ *where* $s(t)$ *is an arbitrary normalized function.*

Proof: Let us define[15,42,44] the "lower symbol" $L_{\mathbf{H}}^{L}(t,f) \triangleq \int_\tau \int_\nu S_{\mathbf{H}}^{(0)}(\tau,\nu) \times A_s^{(0)*}(\tau,\nu) e^{i2\pi(t\nu - f\tau)} d\tau d\nu$ and the "upper symbol" $L_{\mathbf{H}}^{U}(t,f) \triangleq \int_\tau \int_\nu [S_{\mathbf{H}}^{(0)}(\tau,\nu)/A_s^{(0)}(\tau,\nu)] \times e^{i2\pi(t\nu - f\tau)} d\tau d\nu$, where $s(t)$ is an arbitrary normalized function. [For Gaussian $s(t)$, the lower and upper symbols can be related to the Wick and anti-Wick symbols of quantum mechanics[15,119] which can be defined using the normal and anti-normal correspondence rules.[34,36,83]] It is known[15,42] that for self-adjoint operators $\mathbf{H}$,

$$\inf_{t,f} L_{\mathbf{H}}^{U}(t,f) \leq \lambda_{\mathbf{H}}^{\inf} \leq \inf_{t,f} L_{\mathbf{H}}^{L}(t,f), \qquad (45)$$

$$\sup_{t,f} L_{\mathbf{H}}^{L}(t,f\,) \leq \lambda_{\mathbf{H}}^{\sup} \leq \sup_{t,f} L_{\mathbf{H}}^{U}(t,f\,). \tag{46}$$

We now have

$$\begin{aligned} |L_{\mathbf{H}}^{(0)}(t,f\,) - L_{\mathbf{H}}^{L}(t,f\,)| &= \left| \int_{\tau}\int_{\nu} S_{\mathbf{H}}^{(0)}(\tau,\nu)[1-A_s^{(0)*}(\tau,\nu)] e^{i2\pi(\tau f-\nu t)} d\tau d\nu \right| \\ &\leq \int_{\tau}\int_{\nu} |S_{\mathbf{H}}(\tau,\nu)||1-A_s^{(0)}(\tau,\nu)| d\tau d\nu = \|S_{\mathbf{H}}\|_1 m_{\mathbf{H}}^{(\tilde{\phi}_s)}, \end{aligned} \tag{47}$$

with $\tilde{\phi}_s(\tau,\nu) = |1-A_s^{(0)}(\tau,\nu)|$. Similarly, we can show

$$|L_{\mathbf{H}}^{(0)}(t,f\,) - L_{\mathbf{H}}^{U}(t,f\,)| \leq \|S_{\mathbf{H}}\|_1 m_{\mathbf{H}}^{(\phi_s)}, \tag{48}$$

with $\phi_s(\tau,\nu) = |1-1/A_s^{(0)}(\tau,\nu)|$. Furthermore, due to $|A_s^{(0)}(\tau,\nu)| \leq \|s\|_2^2 = 1$ there is

$$\begin{aligned} m_{\mathbf{H}}^{(\phi_s)} &= \frac{1}{\|S_{\mathbf{H}}\|_1} \int_{\tau}\int_{\nu} \frac{|1-A_s^{(0)}(\tau,\nu)|}{|A_s^{(0)}(\tau,\nu)|} |S_{\mathbf{H}}(\tau,\nu)| d\tau d\nu \\ &\geqslant \frac{1}{\|S_{\mathbf{H}}\|_1} \int_{\tau}\int_{\nu} |1-A_s^{(0)}(\tau,\nu)||S_{\mathbf{H}}(\tau,\nu)| d\tau d\nu = m_{\mathbf{H}}^{(\tilde{\phi}_s)}. \end{aligned} \tag{49}$$

It can be shown that (47) implies $|\inf_{t,f} L_{\mathbf{H}}^{(0)}(t,f\,) - \inf_{t,f} L_{\mathbf{H}}^{L}(t,f\,)| \leq \|S_{\mathbf{H}}\|_1 m_{\mathbf{H}}^{(\tilde{\phi}_s)}$ and that (48) implies $|\inf_{t,f} L_{\mathbf{H}}^{(0)}(t,f\,) - \inf_{t,f} L_{\mathbf{H}}^{U}(t,f\,)| \leq \|S_{\mathbf{H}}\|_1 m_{\mathbf{H}}^{(\phi_s)}$. Combining these two inequalities with (45) and (49), it can be shown that $|\inf_{t,f} L_{\mathbf{H}}^{(0)}(t,f\,) - \lambda_{\mathbf{H}}^{\inf}| \leq \|S_{\mathbf{H}}\|_1 m_{\mathbf{H}}^{(\phi_s)}$. The bound on $|\sup_{t,f} L_{\mathbf{H}}^{(0)}(t,f\,) - \lambda_{\mathbf{H}}^{\sup}|$ follows similarly using (47), (48), (46), and (49). □

Hence, if $m_{\mathbf{H}}^{(\phi_s)}$ can be made small by a suitable choice of $s(t)$, we have

$$\inf_{t,f} L_{\mathbf{H}}^{(0)}(t,f\,) \approx \lambda_{\mathbf{H}}^{\inf}, \quad \sup_{t,f} L_{\mathbf{H}}^{(0)}(t,f\,) \approx \lambda_{\mathbf{H}}^{\sup}.$$

Small $m_{\mathbf{H}}^{(\phi_s)}$ requires $A_s(\tau,\nu) \approx A_s(0,0) \equiv 1$ on the effective support of $|S_{\mathbf{H}}(\tau,\nu)|$, thus implying that this effective support is small, i.e., that $\mathbf{H}$ is underspread. We note that $m_{\mathbf{H}}^{(\phi_s)}$ can be adapted to oblique orientation of $|S_{\mathbf{H}}(\tau,\nu)|$ by a proper choice of the normalized function $s(t)$.

I. Operator norm (maximum system gain)

We now return to a general (i.e., not necessarily self-adjoint) operator $\mathbf{H}$. The operator norm (maximum system gain) of $\mathbf{H}$ is defined as

$$\|\mathbf{H}\| \triangleq \sup_{\|x\|_2 = 1} \|\mathbf{H}x\|_2.$$

For time-invariant and frequency-invariant operators, $\|\mathbf{H}\|$ equals the supremum of the magnitude of the transfer function. We now ask whether for a general operator $\|\mathbf{H}\|$ is similarly related to the magnitude of $L_{\mathbf{H}}^{(\alpha)}(t,f\,)$.

Theorem III.12: *For any operator* $\mathbf{H}$, *the difference between the supremum of* $|L_{\mathbf{H}}^{(\alpha)}(t,f\,)|^2$ *and the squared operator norm is bounded as*

$$\frac{|\sup_{t,f} |L_{\mathbf{H}}^{(\alpha)}(t,f\,)|^2 - \|\mathbf{H}\|^2|}{\|S_{\mathbf{H}}\|_1^2} \leq 2\pi m_{\mathbf{H}}^{(0,1)} m_{\mathbf{H}}^{(1,0)} + 4\pi|\alpha| m_{\mathbf{H}}^{(1,1)} + m_{\mathbf{H}^+\mathbf{H}}^{(\phi_s)}, \tag{50}$$

with the weighting function $\phi_s(\tau,\nu)$ *as in Theorem* III.11.

Proof: Subtracting and adding $\sup_{t,f} |L_{\mathbf{H}}^{(0)}(t,f\,)|^2$ and $\sup_{t,f} L_{\mathbf{H}^+\mathbf{H}}^{(0)}(t,f\,)$ from/to $\sup_{t,f} |L_{\mathbf{H}}^{(\alpha)}(t,f\,)|^2 - \|\mathbf{H}\|^2$, and using[59] $\|\mathbf{H}\|^2 = \lambda_{\mathbf{H}^+\mathbf{H}}^{\sup}$, we obtain

$$\left|\sup_{t,f}|L_{\mathbf{H}}^{(\alpha)}(t,f)|^2-\|\mathbf{H}\|^2\right| \leq \left|\sup_{t,f}|L_{\mathbf{H}}^{(\alpha)}(t,f)|^2-\sup_{t,f}|L_{\mathbf{H}}^{(0)}(t,f)|^2\right| + \left|\sup_{t,f}|L_{\mathbf{H}}^{(0)}(t,f)|^2-\sup_{t,f}L_{\mathbf{H}^+\mathbf{H}}^{(0)}(t,f)\right| + \left|\sup_{t,f}L_{\mathbf{H}^+\mathbf{H}}^{(0)}(t,f)-\lambda_{\mathbf{H}^+\mathbf{H}}^{\sup}\right|. \tag{51}$$

We next derive a bound on the difference $\Delta_{10}^{(\alpha)}(t,f)\triangleq|L_{\mathbf{H}}^{(\alpha)}(t,f)|^2-|L_{\mathbf{H}}^{(0)}(t,f)|^2$ by noting that the 2-D Fourier transform of $|L_{\mathbf{H}}^{(\alpha)}(t,f)|^2$ is given by $S_{\mathbf{H}}^{(\alpha)}(\tau,\nu)**S_{\mathbf{H}}^{(\alpha)*}(-\tau,-\nu)$ and by using $S_{\mathbf{H}}^{(\alpha)}(\tau,\nu)=S_{\mathbf{H}}^{(0)}(\tau,\nu)e^{-i2\pi\alpha\tau\nu}$,

$$\begin{aligned}
|\Delta_{10}^{(\alpha)}(t,f)| &\leq \int_\tau\int_\nu|\hat{\Delta}_{10}^{(\alpha)}(\tau,\nu)|\,d\tau\,d\nu\\
&= \int_\tau\int_\nu\left|\int_{\tau'}\int_{\nu'}S_{\mathbf{H}}^{(0)}(\tau',\nu')S_{\mathbf{H}}^{(0)*}(\tau'-\tau,\nu'-\nu)\right.\\
&\quad\left.\times[e^{-i2\pi\alpha[\tau'\nu'-(\tau'-\tau)(\nu'-\nu)]}-1]\,d\tau'\,d\nu'\right|d\tau\,d\nu\\
&\leq 2\int_{\tau_1}\int_{\nu_1}\int_{\tau'}\int_{\nu'}|S_{\mathbf{H}}(\tau',\nu')||S_{\mathbf{H}}(\tau_1,\nu_1)||\sin\,\pi\alpha(\tau'\nu'-\tau_1\nu_1)|\,d\tau'\,d\nu'\,d\tau_1\,d\nu_1\\
&\leq 2\pi|\alpha|\int_{\tau_1}\int_{\nu_1}\int_{\tau'}\int_{\nu'}|S_{\mathbf{H}}(\tau',\nu')||S_{\mathbf{H}}(\tau_1,\nu_1)|[|\tau'\nu'|+|\tau_1\nu_1|]\,d\tau'\,d\nu'\,d\tau_1\,d\nu_1\\
&= 4\pi|\alpha|\|S_{\mathbf{H}}\|_1^2m_{\mathbf{H}}^{(1,1)}.
\end{aligned}$$

It can be shown that this bound also implies that the first term in (51) is bounded as $|\sup_{t,f}|L_{\mathbf{H}}^{(\alpha)}(t,f)|^2-\sup_{t,f}|L_{\mathbf{H}}^{(0)}(t,f)|^2|\leq 4\pi|\alpha|\|S_{\mathbf{H}}\|_1^2m_{\mathbf{H}}^{(1,1)}$. Furthermore, it follows from (22) with $\alpha=0$ that the second term in (51) is bounded as $|\sup_{t,f}|L_{\mathbf{H}}^{(0)}(t,f)|^2-\sup_{t,f}L_{\mathbf{H}^+\mathbf{H}}^{(0)}(t,f)|\leq 2\pi\|S_{\mathbf{H}}\|_1^2m_{\mathbf{H}}^{(0,1)}m_{\mathbf{H}}^{(1,0)}$. Finally, since $\mathbf{H}^+\mathbf{H}$ is self-adjoint, the bounds in (44) hold for $\mathbf{H}^+\mathbf{H}$ and we obtain that the third term in (51) is bounded as $|\sup_{t,f}L_{\mathbf{H}^+\mathbf{H}}^{(0)}(t,f)-\lambda_{\mathbf{H}^+\mathbf{H}}^{\sup}|\leq\|S_{\mathbf{H}^+\mathbf{H}}\|_1m_{\mathbf{H}^+\mathbf{H}}^{(\phi_s)}\leq\|S_{\mathbf{H}}\|_1^2m_{\mathbf{H}^+\mathbf{H}}^{(\phi_s)}$. Inserting these three bounds into (51) yields (50). □

Hence, if $m_{\mathbf{H}^+\mathbf{H}}^{(\phi_s)}$ can be made small by a suitable choice of the function $s(t)$, and if $m_{\mathbf{H}}^{(1,1)}$ and $m_{\mathbf{H}}^{(0,1)}m_{\mathbf{H}}^{(1,0)}$ are small too, then

$$\sup_{t,f}|L_{\mathbf{H}}^{(\alpha)}(t,f)|\approx\|\mathbf{H}\|.$$

In particular, small $m_{\mathbf{H}^+\mathbf{H}}^{(\phi_s)}$ requires that $A_s(\tau,\nu)\approx A_s(0,0)\equiv 1$ on the effective support of $|S_{\mathbf{H}^+\mathbf{H}}(\tau,\nu)|$, thus implying that $\mathbf{H}^+\mathbf{H}$ is underspread, which will be true if $\mathbf{H}$ is underspread.

The bound in (50) is tightest for $\alpha=0$ since here the bound's second term vanishes. Moreover, using (23) we obtain the tighter bound,

$$\frac{|\sup_{t,f}|L_{\mathbf{H}}^{(0)}(t,f)|^2-\|\mathbf{H}\|^2|}{\|S_{\mathbf{H}}\|_1^2}\leq 2\pi\min_{\mathbf{U}\in\mathcal{M}}\{m_{\mathbf{UHU}^+}^{(0,1)}+m_{\mathbf{UHU}^+}^{(1,0)}\}+m_{\mathbf{H}^+\mathbf{H}}^{(\phi_s)}. \tag{52}$$

The first term in this refined bound may be small even if the spreading function is oriented in an oblique direction in the (τ,ν) plane. The second term, $m_{\mathbf{H}^+\mathbf{H}}^{(\phi_s)}$, can be adapted to oblique directions by a proper choice of $s(t)$.

IV. PROPERTIES OF UNDERSPREAD OPERATORS

In this section, we show that besides permitting a simple approximate transfer function (symbolic) calculus, underspread operators have other ''desirable'' properties that may simplify their analysis.

A. Approximate commutation

In contrast to the time-invariant or frequency-invariant case, two general linear operators $\mathbf{G}$ and $\mathbf{H}$ typically do not commute, i.e., $\mathbf{GH}\neq\mathbf{HG}$, or equivalently $[\mathbf{G},\mathbf{H}]\triangleq\mathbf{GH}-\mathbf{HG}\neq\mathbf{0}$. The following theorem shows that this situation is somewhat different for jointly underspread operators.

Theorem IV.1: *The operator norm of the commutator of two operators* $\mathbf{G}$ *and* $\mathbf{H}$ *is bounded as*

$$\frac{\|[\mathbf{G},\mathbf{H}]\|^2}{\|S_{\mathbf{G}}\|_1^2\|S_{\mathbf{H}}\|_1^2}\leq 16\pi^2\left[\min_{\mathbf{U}\in\mathcal{M}} B^{(0)}_{\mathbf{UGU}^+,\mathbf{UHU}^+}\right]^2+8\pi\min_{\mathbf{U}\in\mathcal{M}}\{[m^{(0,1)}_{\mathbf{UGU}^+}+m^{(0,1)}_{\mathbf{UHU}^+}][m^{(1,0)}_{\mathbf{UGU}^+}+m^{(1,0)}_{\mathbf{UHU}^+}]\}+4m^{(\phi_s)}_{[\mathbf{G},\mathbf{H}]^+[\mathbf{G},\mathbf{H}]}, \tag{53}$$

with $B^{(0)}_{\mathbf{G},\mathbf{H}}=(1/2)[m^{(0,1)}_{\mathbf{G}}m^{(1,0)}_{\mathbf{H}}+m^{(1,0)}_{\mathbf{G}}m^{(0,1)}_{\mathbf{H}}]$ *and with the weighting function* $\phi_s(\tau,\nu)$ *as in Theorem* III.11.

Proof: Applying (52) to $[\mathbf{G},\mathbf{H}]$ yields

$$\|[\mathbf{G},\mathbf{H}]\|^2\leq\sup_{t,f}|L^{(0)}_{[\mathbf{G},\mathbf{H}]}(t,f)|^2+\|S_{[\mathbf{G},\mathbf{H}]}\|_1^2\left[2\pi\min_{\mathbf{U}\in\mathcal{M}}\{m^{(0,1)}_{\mathbf{U}[\mathbf{G},\mathbf{H}]\mathbf{U}^+}m^{(1,0)}_{\mathbf{U}[\mathbf{G},\mathbf{H}]\mathbf{U}^+}\}+m^{(\phi_s)}_{[\mathbf{G},\mathbf{H}]^+[\mathbf{G},\mathbf{H}]}\right]. \tag{54}$$

In order to bound $\sup_{t,f}|L^{(0)}_{[\mathbf{G},\mathbf{H}]}(t,f)|^2$, we consider $L^{(0)}_{[\mathbf{G},\mathbf{H}]}(t,f)$. Subtracting and adding $L^{(0)}_{\mathbf{G}}(t,f)L^{(0)}_{\mathbf{H}}(t,f)$ and applying (20) twice, we obtain

$$\begin{aligned}|L^{(0)}_{[\mathbf{G},\mathbf{H}]}(t,f)|&=|L^{(0)}_{\mathbf{GH}}(t,f)-L^{(0)}_{\mathbf{HG}}(t,f)|\\&\leq|L^{(0)}_{\mathbf{GH}}(t,f)-L^{(0)}_{\mathbf{G}}(t,f)L^{(0)}_{\mathbf{H}}(t,f)|+|L^{(0)}_{\mathbf{G}}(t,f)L^{(0)}_{\mathbf{H}}(t,f)-L^{(0)}_{\mathbf{HG}}(t,f)|\\&\leq 2\|S_{\mathbf{G}}\|_1\|S_{\mathbf{H}}\|_1 2\pi\min_{\mathbf{U}\in\mathcal{M}} B^{(0)}_{\mathbf{UGU}^+,\mathbf{UHU}^+},\end{aligned}$$

which gives the bound

$$\sup_{t,f}|L^{(0)}_{[\mathbf{G},\mathbf{H}]}(t,f)|^2\leq\|S_{\mathbf{G}}\|_1^2\|S_{\mathbf{H}}\|_1^2 16\pi^2\left[\min_{\mathbf{U}\in\mathcal{M}} B^{(0)}_{\mathbf{UGU}^+,\mathbf{UHU}^+}\right]^2. \tag{55}$$

With regard to the second term in (54), we have

$$\begin{aligned}\|S_{[\mathbf{G},\mathbf{H}]}\|_1 m^{(0,1)}_{\mathbf{U}[\mathbf{G},\mathbf{H}]\mathbf{U}^+}&=\|S_{\mathbf{U}[\mathbf{G},\mathbf{H}]\mathbf{U}^+}\|_1 m^{(0,1)}_{\mathbf{U}[\mathbf{G},\mathbf{H}]\mathbf{U}^+}\\&\leq\int_\tau\int_\nu|\nu|[|S_{\mathbf{UGU}^+\mathbf{UHU}^+}(\tau,\nu)|+|S_{\mathbf{UHU}^+\mathbf{UGU}^+}(\tau,\nu)|]d\tau d\nu\\&\leq\|S_{\mathbf{G}}\|_1\|S_{\mathbf{H}}\|_1 2[m^{(0,1)}_{\mathbf{UGU}^+}+m^{(0,1)}_{\mathbf{UHU}^+}],\end{aligned}$$

where the last step can be shown using the twisted convolution (18). In a similar manner, one can show that $\|S_{[\mathbf{G},\mathbf{H}]}\|_1 m^{(1,0)}_{\mathbf{U}[\mathbf{G},\mathbf{H}]\mathbf{U}^+}\leq\|S_{\mathbf{G}}\|_1\|S_{\mathbf{H}}\|_1 2[m^{(1,0)}_{\mathbf{UGU}^+}+m^{(1,0)}_{\mathbf{UHU}^+}]$. Inserting these bounds into (54) and using $\|S_{[\mathbf{G},\mathbf{H}]}\|_1\leq\|S_{\mathbf{GH}}\|_1+\|S_{\mathbf{HG}}\|_1\leq 2\|S_{\mathbf{G}}\|_1\|S_{\mathbf{H}}\|_1$, the bound (53) follows. □

Hence, the operator norm of the commutator of two jointly underspread operators is small, which shows that two jointly underspread operators approximately commute, i.e., $\mathbf{GH}\approx\mathbf{HG}$. Since two operators commute if and only if they have a common set of eigenfunctions,[15,59] this result is consistent with Theorem III.6. While here we have considered the operator norm $\|[\mathbf{G},\mathbf{H}]\|$, we note that bounds on the Hilbert–Schmidt norm $\|[\mathbf{G},\mathbf{H}]\|_2$ have been formulated previously.[42]

Almost commuting operators may look peculiar to quantum physicists since in the classical limit ($h\to 0$) of the quantum-mechanical symbolic calculus the Weyl symbol of the commutator $[\mathbf{G},\mathbf{H}]$ reduces to the (generally nonzero) Poisson bracket of the symbols which is defined as[15]

$$\{L_{\mathbf{H}}^{(\alpha)},L_{\mathbf{G}}^{(\alpha)}\}\triangleq\frac{\partial L_{\mathbf{H}}^{(\alpha)}(t,f)}{\partial t}\frac{\partial L_{\mathbf{G}}^{(\alpha)}(t,f)}{\partial f}-\frac{\partial L_{\mathbf{G}}^{(\alpha)}(t,f)}{\partial t}\frac{\partial L_{\mathbf{H}}^{(\alpha)}(t,f)}{\partial f}.$$

Specifically, if the Weyl symbol is re-defined[15,34,36,56] to include Planck's constant h, then one can show[15,56] that $L_{[\mathbf{G},\mathbf{H}]}^{(0)}=-i(h/2\pi)\{L_{\mathbf{G}}^{(0)},L_{\mathbf{H}}^{(0)}\}+\mathcal{O}(h^2)$, i.e., the Weyl symbol of $[\mathbf{G},\mathbf{H}]$ is proportional to $\{L_{\mathbf{G}}^{(0)},L_{\mathbf{H}}^{(0)}\}$ up to errors of second order. However, the following bound shows that the Poisson bracket of two jointly underspread operators is close to zero.

Theorem IV.2: *The Poisson bracket of the generalized Weyl symbols of two operators* **G** *and* **H** *is bounded as*

$$\frac{|\{L_{\mathbf{G}}^{(\alpha)},L_{\mathbf{H}}^{(\alpha)}\}|}{\|S_{\mathbf{G}}\|_1\|S_{\mathbf{H}}\|_1}\leq 8\pi^2\min_{\mathbf{U}\in\mathcal{M}}B_{\mathbf{UGU}^+,\mathbf{UHU}^+}^{(0)},\tag{56}$$

with $B_{\mathbf{G},\mathbf{H}}^{(0)}=(1/2)[m_{\mathbf{G}}^{(0,1)}m_{\mathbf{H}}^{(1,0)}+m_{\mathbf{G}}^{(1,0)}m_{\mathbf{H}}^{(0,1)}]$.

Proof: Since differentiations and multiplications in the time-frequency domain correspond to multiplications and convolutions in the (τ,ν) domain, it is easily shown that the 2-D Fourier transform of the Poisson bracket is given by

$$\begin{aligned}\int_t\int_f\{L_{\mathbf{G}}^{(\alpha)},L_{\mathbf{H}}^{(\alpha)}\}e^{-i2\pi(\nu t-\tau f)}dtdf=\int_{\tau'}\int_{\nu'}[&i2\pi\nu' S_{\mathbf{G}}^{(\alpha)}(\tau',\nu')i2\pi(\tau-\tau')S_{\mathbf{H}}^{(\alpha)}(\tau-\tau',\nu-\nu')\\&-i2\pi\tau' S_{\mathbf{G}}^{(\alpha)}(\tau',\nu')i2\pi(\nu-\nu')S_{\mathbf{H}}^{(\alpha)}(\tau-\tau',\nu-\nu')]d\tau' d\nu'.\end{aligned}$$

Furthermore, the magnitude of the Poisson bracket is bounded by the L_1 norm of its Fourier transform, and therefore

$$\begin{aligned}|\{L_{\mathbf{G}}^{(\alpha)},L_{\mathbf{H}}^{(\alpha)}\}|&\leq\int_\tau\int_\nu\left|4\pi^2\int_{\tau'}\int_{\nu'}[\nu'(\tau-\tau')-\tau'(\nu-\nu')]S_{\mathbf{G}}^{(\alpha)}(\tau',\nu')\right.\\&\qquad\left.\times S_{\mathbf{H}}^{(\alpha)}(\tau-\tau',\nu-\nu')d\tau' d\nu'\right|d\tau d\nu\\&\leq 4\pi^2\int_{\tau_1}\int_{\nu_1}\int_{\tau_2}\int_{\nu_2}|\nu_1\tau_2-\tau_1\nu_2||S_{\mathbf{G}}(\tau_1,\nu_1)||S_{\mathbf{H}}(\tau_2,\nu_2)|d\tau_1 d\nu_1 d\tau_2 d\nu_2\\&\leq 4\pi^2\|S_{\mathbf{G}}\|_1\|S_{\mathbf{H}}\|_1[m_{\mathbf{G}}^{(0,1)}m_{\mathbf{H}}^{(1,0)}+m_{\mathbf{G}}^{(1,0)}m_{\mathbf{H}}^{(0,1)}].\end{aligned}\tag{57}$$

Since $\nu_1\tau_2-\tau_1\nu_2$ in (57) is invariant to symplectic coordinate transforms, the above bound remains valid if **G** and **H** are replaced by $\mathbf{UGU}^+$ and $\mathbf{UHU}^+$, respectively, with $\mathbf{U}\in\mathcal{M}$. □

Hence, if **G** and **H** are jointly underspread such that $\min_{\mathbf{U}\in\mathcal{M}}B_{\mathbf{UGU}^+,\mathbf{UHU}^+}^{(0)}$ is small, then the Poisson bracket $\{L_{\mathbf{G}}^{(\alpha)},L_{\mathbf{H}}^{(\alpha)}\}$ is approximately zero, thereby confirming our result that the commutator of jointly underspread operators vanishes approximately. We note that the bound in (56) does not depend on α, and that it equals the bound in (20) up to a factor.

B. Approximate normality

Normal operators have the advantage of allowing an eigenvalue decomposition instead of a (numerically more expensive) singular value decomposition. In contrast to time-invariant or frequency-invariant systems, general operators may be non-normal, i.e., $\mathbf{HH}^+\neq\mathbf{H}^+\mathbf{H}$ or equivalently $[\mathbf{H},\mathbf{H}^+]=\mathbf{HH}^+-\mathbf{H}^+\mathbf{H}\neq\mathbf{0}$. A bound on $\|[\mathbf{H},\mathbf{H}^+]\|$ could be obtained as a special case of (53). However, the following theorem exploits the self-adjointness of $[\mathbf{H},\mathbf{H}^+]$ to yield a tighter and simpler bound.

Theorem IV.3: *The operator norm of the commutator of an operator* $\mathbf{H}$ *and its adjoint* $\mathbf{H}^+$ *is bounded as*

$$\frac{\|[\mathbf{H},\mathbf{H}^+]\|}{\|S_{\mathbf{H}}\|_1^2} \leq 4\pi \min_{\mathbf{U}\in\mathcal{M}} \{m^{(0,1)}_{\mathbf{UHU}^+} m^{(1,0)}_{\mathbf{UHU}^+}\} + m^{(\phi_s)}_{\mathbf{HH}^+} + m^{(\phi_s)}_{\mathbf{H}^+\mathbf{H}}, \tag{58}$$

with the weighting function $\phi_s(\tau,\nu)$ *as in Theorem* III.11.

Proof: It is known[59] that $\|[\mathbf{H},\mathbf{H}^+]\| = \max\{-\lambda^{\inf}_{[\mathbf{H},\mathbf{H}^+]}, \lambda^{\sup}_{[\mathbf{H},\mathbf{H}^+]}\} = \max\{\lambda^{\sup}_{-[\mathbf{H},\mathbf{H}^+]}, \lambda^{\sup}_{[\mathbf{H},\mathbf{H}^+]}\}$. First assume that $\|[\mathbf{H},\mathbf{H}^+]\| = \lambda^{\sup}_{[\mathbf{H},\mathbf{H}^+]}$. In that case, the second bound in (44) yields

$$\begin{aligned}\|[\mathbf{H},\mathbf{H}^+]\| = \lambda^{\sup}_{[\mathbf{H},\mathbf{H}^+]} &\leq \sup_{t,f} L^{(0)}_{[\mathbf{H},\mathbf{H}^+]}(t,f) + \|S_{[\mathbf{H},\mathbf{H}^+]}\|_1 m^{(\phi_s)}_{[\mathbf{H},\mathbf{H}^+]} \\ &\leq \sup_{t,f} |L^{(0)}_{[\mathbf{H},\mathbf{H}^+]}(t,f)| + \|S_{[\mathbf{H},\mathbf{H}^+]}\|_1 m^{(\phi_s)}_{[\mathbf{H},\mathbf{H}^+]}.\end{aligned} \tag{59}$$

Specializing (55), the first term in (59) can be bounded as

$$\sup_{t,f} |L^{(0)}_{[\mathbf{H},\mathbf{H}^+]}(t,f)| \leq \|S_{\mathbf{H}}\|_1^2 4\pi \min_{\mathbf{U}\in\mathcal{M}} m^{(0,1)}_{\mathbf{UHU}^+} m^{(1,0)}_{\mathbf{UHU}^+}, \tag{60}$$

where we used that $B^{(0)}_{\mathbf{H},\mathbf{H}^+} = m^{(0,1)}_{\mathbf{H}} m^{(1,0)}_{\mathbf{H}}$ due to $m^{(k,l)}_{\mathbf{H}^+} = m^{(k,l)}_{\mathbf{H}}$. The second term in (59) can be bounded as

$$\begin{aligned}\|S_{[\mathbf{H},\mathbf{H}^+]}\|_1 m^{(\phi_s)}_{[\mathbf{H},\mathbf{H}^+]} &\leq \int_\tau \int_\nu \phi_s(\tau,\nu)[|S_{\mathbf{HH}^+}(\tau,\nu)| + |S_{\mathbf{H}^+\mathbf{H}}(\tau,\nu)|]\,d\tau\,d\nu \\ &= \|S_{\mathbf{HH}^+}\|_1 m^{(\phi_s)}_{\mathbf{HH}^+} + \|S_{\mathbf{H}^+\mathbf{H}}\|_1 m^{(\phi_s)}_{\mathbf{H}^+\mathbf{H}} \leq \|S_{\mathbf{H}}\|_1^2 [m^{(\phi_s)}_{\mathbf{HH}^+} + m^{(\phi_s)}_{\mathbf{H}^+\mathbf{H}}].\end{aligned} \tag{61}$$

Inserting (60) and (61) into (59), the bound (58) follows. If $\|[\mathbf{H},\mathbf{H}^+]\| = -\lambda^{\inf}_{[\mathbf{H},\mathbf{H}^+]} = \lambda^{\sup}_{-[\mathbf{H},\mathbf{H}^+]}$, the bound is shown similarly by applying the second bound in (44) to $-[\mathbf{H},\mathbf{H}^+]$. □

Hence, an underspread operator $\mathbf{H}$ for which $\min_{\mathbf{U}\in\mathcal{M}}\{m^{(0,1)}_{\mathbf{UHU}^+} m^{(1,0)}_{\mathbf{UHU}^+}\}$ as well as $m^{(\phi_s)}_{\mathbf{HH}^+}$ and $m^{(\phi_s)}_{\mathbf{H}^+\mathbf{H}}$ are small satisfies $\mathbf{HH}^+ \approx \mathbf{H}^+\mathbf{H}$ and is thus approximately normal. We note that bounds on the Hilbert–Schmidt norm $\|[\mathbf{H},\mathbf{H}^+]\|_2$ have been formulated previously.[42]

V. CONCLUSION

We have introduced a new concept of ''underspread'' linear operators (linear time-varying systems) that does not require the support of the spreading function to be compact and thus extends a previous definition of underspread operators. While sufficiently general to be relevant to a broad variety of engineering applications, our underspread concept still is restrictive enough to permit the formulation of a simple and intuitive approximate transfer function calculus (symbolic calculus) that is based on the generalized Weyl symbol. Indeed, in the case of underspread operators the generalized Weyl symbol can be viewed as an approximate ''time-frequency transfer function'' that is similarly simple to use as the conventional transfer function of linear time-invariant systems. The quality and scope of validity of this transfer function approximation was assessed by providing explicit upper bounds on various approximation errors; these bounds are formulated in terms of weighted integrals and moments of the spreading function.

The transfer function calculus provides a foundation and justification of several methods which have been proposed to design and implement time-varying filters for signal enhancement, estimation, and detection.[45–53] Furthermore, the calculus can immediately be applied to the theory of time-varying power spectra of nonstationary random processes. Here, the operators are either correlation operators or innovation systems (cf. Subsection III G). This application leads to the important concept of *underspread random processes* for which several important definitions of time-varying power spectra can be shown to become approximately equivalent.[42,54,55]

(Received 5 August 1997; accepted for publication 9 February 1998)

This study concerns a special symbolic calculus of interest for signal analysis. This calculus associates functions on the time-frequency half-plane $f>0$ with linear operators defined on the positive-frequency signals. Full attention is given to its construction which is entirely based on the study of the affine group in a simple and direct way. The correspondence rule is detailed and the associated Wigner function is given. Formulas expressing the basic operation (star-bracket) of the Lie algebra of symbols, which is isomorphic to that of the operators, are obtained. In addition, it is shown that the resulting calculus is covariant under a three-parameter group which contains the affine group as subgroup. This observation is the starting point of an investigation leading to a whole class of symbolic calculi which can be considered as modifications of the original one. © *1998 American Institute of Physics.* [S0022-2488(98)00408-3]

I. INTRODUCTION

The notion of time-frequency analysis of signals received a theoretical basis when Gabor[1] proposed to interpret signals by operations very similar to those of quantum mechanics. In this approach, the real signals are replaced by their positive-frequency parts (the ''analytic'' signals) and the communication characteristics are introduced as the mean values of Hermitian operators defined on the corresponding Hilbert space. Actually, the analogy with quantum mechanics has rapidly suggested we recognize the time and the frequency as two conjugate variables and has led to the search for a phase space formulation of the theory. Various solutions have then been proposed which were essentially adaptations of solutions developed precedently in the quantum mechanical context.

From a mathematical point of view, the question of the phase space formulation of a quantum theory appears as a problem of symbolic calculus since each operator of the theory has to be replaced by a function (its symbol) of the phase space variables.[2] The construction of such a correspondence rule is determined by the class of operators to symbolize and by subsidiary constraints relative to the physical interpretation of the formalism. In signal theory, this last point concerns simply the formal invariance of the operations in changes of reference clocks. The corresponding constraint will be automatically ensured if the correspondence rule is covariant with respect to relevant representations of the affine group. The object of the following developments is to construct a symbolic calculus on the time-frequency half-plane along these lines.

In Sec. II we describe a study of the affine group and its subgroups, their representations in the Hilbert space $\mathcal{H}$ of signals and their actions in the time-frequency half-plane Γ. Decompositions of $\mathcal{H}$ and Γ into invariant subspaces are carried out in parallel and are shown to be related in a natural way. The correspondence rule is derived in Sec. III by exploiting the completeness of the invariant decompositions just performed. Some properties of this rule are given in Sec. IV and the associated Wigner function is determined. Section V is devoted to the derivation of the star product, which allows to symbolize products of operators and is the core of the symbolic calculus. In Sec. VI, the star bracket is introduced and shown to reduce to an ordinary Poisson bracket in some special cases. As an application of this remark, a Hamiltonian flow is defined in phase space. Finally, it is shown in Sec. VII that the method has possible extensions when working with larger groups containing the affine group.

II. THE AFFINE GROUP IN SIGNAL THEORY

The signals to be considered are real-valued functions of time $s(t)$ which are interpreted independently of the choice of time origin and units. This means that the description of the signal processing operations must not change if time t is replaced by $at+b$ where b is real and a positive. The corresponding change on the signal can be readily written down. Notice that there is the freedom of rescaling the signal when the units are changed. The transformations on the signal that will be considered are written as

$$s(t)\rightarrow a^r s(a^{-1}(t-b)), \tag{II.1}$$

where r is a real exponent.

The set of transformations (II.1) forms the affine group, with parameters (a,b) and composition law expressed by

$$(a,b)(a',b')=(aa',b+ab'). \tag{II.2}$$

The group structure is the mathematical expression of the equivalence of the reference clocks. To stress the fact that only positive dilations are considered, the parameter u such that

$$a=e^u \tag{II.3}$$

will be used instead of a.

A. Representation in the Hilbert space of positive-frequency signals

The Fourier transform of the signal $s(t)$ will be introduced by

$$\hat{s}(f)\equiv\int_{\mathbb{R}} s(t)e^{-2i\pi ft}\,dt. \tag{II.4}$$

Since $s(t)$ is a real-valued function, it is characterized by its positive-frequency part only. In agreement with the usual practice in signal theory, this property will be used to substitute to $s(t)$ the so-called analytic signal whose Fourier transform is given by

$$S(f)=2Y(f)\hat{s}(f), \tag{II.5}$$

where $Y(f)$ is Heaviside's step function.

The counterpart of transformation (II.1) for the analytic signal $S(f)$ is easily obtained. Namely, by action of an element (u,b) of the affine group, signal $S(f)$ goes to a new function $[\mathbf{U}(u,b)S](f)$ defined by

$$\mathbf{U}(u,b)S(f)\equiv e^{(r+1)u}e^{-2i\pi fb}S(e^u f),\quad r\in\mathbb{R}. \tag{II.6}$$

The operators $\mathbf{U}(u,b)$ constitute an irreducible representation of the affine group that is unitary for the scalar product defined by

$$(S,S')\equiv\int_{\mathbb{R}^+} S(f)S'^*(f)f^{2r+1}df. \tag{II.7}$$

The Hilbert space of functions $S(f)$ on the half-line which are square integrable for the measure $f^{2r+1}\,df$ will be denoted by $\mathcal{H}$ (the reference to r being implicit). From a physical point of view, it may be necessary to distinguish between signals transforming according to (II.6) with different values of r. However, the corresponding representations are easily shown to be unitarily equivalent. In fact, it may be shown that the affine group has only two inequivalent unitary representations differing by the sign of the imaginary exponential in (II.6).[3]

The infinitesimal operators of representation (II.6) are introduced by the relations

$$\boldsymbol{\beta}S(f)\equiv-\frac{1}{2i\pi}\frac{d}{du}\mathbf{U}(u,b)S(f)\bigg|_{u=b=0}=-\frac{1}{2i\pi}\left(r+1+f\frac{d}{df}\right)S(f), \tag{II.8}$$

$$\mathbf{f}S(f)\equiv-\frac{1}{2i\pi}\frac{d}{db}\mathbf{U}(u,b)S(f)\Big|_{u=b=0}=fS(f). \tag{II.9}$$

The operators $\boldsymbol{\beta}$ and $\mathbf{f}$ thus obtained verify the commutation relation:

$$[\boldsymbol{\beta},\mathbf{f}]=-\frac{1}{2i\pi}\mathbf{f}. \tag{II.10}$$

The subgroups of the affine group and their representations will now be studied in detail. There are two kinds of subgroups consisting either of pure dilations or of pure translations. The translation subgroup is invariant by conjugation. On the contrary, since a dilation can be performed from an arbitrary time origin ξ, there is a whole family of conjugate dilation subgroups G_ξ which consist of the following set of elements:

$$G_\xi=\{(e^u,\xi(1-e^u))\}. \tag{II.11}$$

The restriction $\mathbf{U}_\xi$ of representation (II.6) to G_ξ is given by

$$\mathbf{U}_\xi(u)S(f)=e^{(r+1)u}e^{-2i\pi f\xi(1-e^u)}S(e^u f), \tag{II.12}$$

and the corresponding generator is

$$\boldsymbol{\beta}_\xi S(f)\equiv-\frac{1}{2i\pi}\frac{d}{du}\mathbf{U}_\xi(u)S(f)\Big|_{u=0}=(\boldsymbol{\beta}-\xi\mathbf{f})S(f), \tag{II.13}$$

where operators $\boldsymbol{\beta}$ and $\boldsymbol{f}$ are given by (II.8) and (II.9), respectively.

The operator of representation (II.12) can be written in terms of generator $\boldsymbol{\beta}_\xi$ as

$$\mathbf{U}_\xi=e^{-2i\pi u\boldsymbol{\beta}_\xi}. \tag{II.14}$$

For a given ξ, the eigenfunctions of the self-adjoint operator $\boldsymbol{\beta}_\xi$ are defined by the equation

$$\boldsymbol{\beta}_\xi\psi_\beta^\xi(f)=\beta\psi_\beta^\xi(f),\quad \beta\in\mathbb{R}, \tag{II.15}$$

whose solution is, up to a multiplicative constant,

$$\psi_\beta^\xi(f)\equiv f^{-2i\pi\beta-r-1}e^{-2i\pi\xi f}. \tag{II.16}$$

By construction, the functions $\psi_\beta^\xi(f)$ are also eigenfunctions of the unitary operator (II.14) and verify

$$\mathbf{U}_\xi(u)\psi_\beta^\xi(f)=e^{-2i\pi\beta u}\psi_\beta^\xi(f). \tag{II.17}$$

For a given ξ, functions (II.16) constitute an improper basis of the Hilbert space $\mathcal{H}$. In fact, one verifies that there is orthogonality of the functions corresponding to different β,

$$(\psi_\beta^\xi(f),\psi_{\beta'}^\xi(f))=\delta(\beta-\beta'), \tag{II.18}$$

where the scalar product has the form (II.7). The completeness of this basis is expressed by

$$\int_{\mathbb{R}}\psi_\beta^\xi(f)\psi_\beta^{\xi*}(f')d\beta=f^{-2r-1}\delta(f-f'). \tag{II.19}$$

For each ξ, the set of all the projectors on the functions $\psi_\beta^\xi(f)$ gives a decomposition of the Hilbert space $\mathcal{H}$. From (II.17) it results that each of these projectors is invariant by the transformations of the subgroup G_ξ.

More generally, the action of the whole affine group on functions $\psi_\beta^\xi(f)$ is given by

$$\mathbf{U}(u,b)\psi_{\beta}^{\xi}(f)=e^{-2i\pi u\beta}\psi_{\beta}^{\xi'}(f), \tag{II.20}$$

with $\xi'=e^{u}\xi+b$. This shows that the set of projectors associated with subgroup G_{ξ} is transformed as a whole into the set of projectors associated with subgroup $G_{e^{u}\xi+b}$. In other words, this means that the set of all decompositions of $\mathcal{H}$ by the various subgroups G_{ξ} is invariant by action of the whole group.

B. Action of the group in the time-frequency half-plane

The physical phase space for signal analysis is the time-frequency half-plane, $\Gamma=\{(t,f)\}$, t real, $f>0$. This space can also be obtained as an orbit of the coadjoint representation of the affine group whose action in variables (t,f) is given by

$$(u,b):(t,f)\rightarrow(e^{u}t+b,e^{-u}f), \tag{II.21}$$

where the pair (u,b) characterizes an element of the group.

This action induces a transformation on functions $\mathcal{A}(t,f)$ defined on Γ. This transformation has the form

$$(u,b):\mathcal{A}(t,f)\rightarrow\mathcal{A}(e^{-u}(t-b),e^{u}f). \tag{II.22}$$

According to definition (II.11), the restriction of representation (II.21) to subgroup G_{ξ} reads as

$$(t,f)\rightarrow(e^{u}t+\xi(1-e^{u}),e^{-u}f), \tag{II.23}$$

and the corresponding transformation of phase space functions is given by

$$\mathcal{A}(t,f)\rightarrow\mathcal{A}(e^{-u}(t-\xi)+\xi,e^{u}f). \tag{II.24}$$

The transformation (II.23) has the following invariant:

$$(t-\xi)f=\tilde{\beta},\quad \tilde{\beta}\in\mathbb{R}, \tag{II.25}$$

where $\tilde{\beta}$ is an arbitrary constant. For each ξ, this relation defines a family of curves in phase space labeled by $\tilde{\beta}$. Actually any point in Γ belongs to one, and only one, of these curves and a partition of phase space has thus been achieved for any value of ξ.

Uniform distributions on curves (II.25) are given by the Dirac distributions:

$$\delta_{\tilde{\beta}}^{\xi}\equiv\delta((t-\xi)f-\tilde{\beta}). \tag{II.26}$$

These distributions are invariant by action of the subgroup G_{ξ} and transform under the full group as follows:

$$(u,b):\delta_{\tilde{\beta}}^{\xi}=\delta((t-\xi)f-\tilde{\beta})\rightarrow\delta((e^{-u}(t-b)-\xi)e^{u}f-\tilde{\beta})=\delta_{\tilde{\beta}}^{\xi e^{u}+b}. \tag{II.27}$$

This result can be compared with (II.20). In fact, the full group connects the various phase space partitions associated with subgroups G_{ξ}.

C. Correspondence between invariant structures

The subgroup G_{ξ}, considered for any given value of ξ, has allowed us to perform decompositions of both $\mathcal{H}$ and Γ where the resulting partitions have been labeled by parameters denoted, respectively, by β and $\tilde{\beta}$. We will now show that a natural connection does exist between these two parameters. To develop this point, it is useful to introduce the notion of localized signals in a consistent way.

A signal $S_{t_0}(f)\in\mathcal{H}$ is said to be localized at time t_0 provided an affine transformation, defined by the element (u,b) of the affine group, sends it into a signal localized at $(e^{u}t_0+b)$. This is expressed by the following equation:

$$\mathbf{U}(u,b)S_{t_0}(f)\equiv e^{(r+1)u}e^{-2i\pi fb}S_{t_0}(e^u f)=S_{e^u t_0+b}(f), \tag{II.28}$$

whose solution is, up to a multiplicative constant,

$$S_{t_0}(f)=f^{-r-1}e^{-2i\pi ft_0}. \tag{II.29}$$

Notice the factor f^{-r-1} which is required by dilation invariance. In this way, the whole set of localized states S_{t_0} is stable by action of the affine group.

In the decomposition of $\mathcal{H}$ relative to the subgroup G_ξ, the β-subspace is generated by $\psi_\beta^\xi(f)$ of the form (II.16). Developing the phase of this function in the vicinity of a frequency f_0 leads to the approximate expression

$$\psi_\beta^\xi(f)\simeq e^{-2i\pi\beta(\ln f_0-1)}f^{-r-1}e^{-2i\pi f(\beta/f_0+\xi)}. \tag{II.30}$$

A comparison with (II.29) shows that, apart from a constant phase, the approximated function can be seen as a state localized at

$$t_0=\beta/f_0+\xi. \tag{II.31}$$

Thus, in a local study of functions (II.16), it is possible to associate with any frequency f a time t given by $t=\beta/f+\xi$. This relation defines precisely an orbit of subgroup G_ξ in phase space Γ [cf. (II.25)]. It leads naturally to identify the parameters of the connected elements by setting

$$\tilde{\beta}=\beta. \tag{II.32}$$

This identification, which is clearly invariant under the group action, will play a central role in the following construction.

III. GEOMETRIC CORRESPONDENCE BETWEEN SYMBOLS AND OPERATORS

The aim now is to set up a correspondence between operators on the Hilbert space $\mathcal{H}$ and functions (their symbols) on the time-frequency half-plane Γ. The approach will be essentially based on the parallel decompositions of $\mathcal{H}$ and Γ introduced in the preceding section. The derived correspondence will be said to be geometric to emphasize the fact that it is essentially founded on a study of the group and of the invariants associated with its subgroups.

A. Characterization of operators by their diagonal elements in the various ξ-bases

Consider an operator $\mathbf{A}$ defined by a kernel according to

$$[\boldsymbol{A}S](f_1)=\int_{\mathbb{R}^+}A(f_1,f_2)S(f_2)f_2^{2r+1}\,df_2. \tag{III.1}$$

Its diagonal matrix elements on the G_ξ-invariant basis defined by (II.16) are given by

$$I_{\mathcal{H}}(\xi,\beta)\equiv(\psi_\beta^\xi,\mathbf{A}\psi_\beta^\xi)=\int_0^\infty\int_0^\infty\psi_\beta^{\xi*}(f_1)A(f_1,f_2)\psi_\beta^\xi(f_2)(f_1f_2)^{2r+1}\,df_1\,df_2. \tag{III.2}$$

Quantities $I_{\mathcal{H}}(\xi,\beta)$ have several properties that will be detailed below. First, for any given value of ξ and β, they are invariant by action of the representation $\boldsymbol{U}_\xi$ on the operator $\mathbf{A}$. Moreover, the operator $\mathbf{A}$ can be recovered from the values of $I_{\mathcal{H}}(\xi,\beta)$ $(-\infty<\xi<\infty,-\infty<\beta<\infty)$, and a simple formula exists for the trace of operators. To be able to discriminate between functions $I_{\mathcal{H}}(\xi,\beta)$ associated with distinct operators, we will also use the notation $I_{\mathcal{H}}(\mathbf{A};\xi,\beta)$ for (III.2).

1. G_ξ-invariance of $I_{\mathcal{H}}(\xi,\beta)$

The matrix elements of the transformed operator $\mathbf{A}'=\mathbf{U}_\xi^{-1}\mathbf{A}\mathbf{U}_\xi$ are given by

$$(\psi_\beta^\xi,\mathbf{U}_\xi^{-1}\mathbf{A}\mathbf{U}_\xi\psi_\beta^\xi)=(\mathbf{U}_\xi\psi_\beta^\xi,\mathbf{A}\mathbf{U}_\xi\psi_\beta^\xi)=(\psi_\beta^\xi,\mathbf{A}\psi_\beta^\xi)$$

the last equality being a consequence of property (II.17).

2. Affine covariance

The action of the full group on $I_{\mathcal{H}}(\xi,\beta)$ is computed in the same way, using property (II.20). One obtains

$$I_{\mathcal{H}}(\mathbf{A}';\xi,\beta)=I_{\mathcal{H}}(\mathbf{A};e^{u}\xi+b,\beta), \tag{III.3}$$

where $\mathbf{A}'=\mathbf{U}^{-1}(u,b)\mathbf{A}\mathbf{U}(u,b)$.

This relation expresses the diagonal elements of $\mathbf{A}'$ in the ξ-basis in terms of the diagonal elements of $\mathbf{A}$ in the basis corresponding to the subgroup $G_{\xi'}$, conjugate of G_{ξ} by the transformation (u,b) of the affine group.

3. Reconstruction of the operator A

Defining the two-dimensional Fourier transform of $I_{\mathcal{H}}(\xi,\beta)$ by

$$\hat{I}_{\mathcal{H}}(u,v)\equiv\int_{\mathbb{R}^2}e^{-2i\pi(u\xi+v\beta)}I_{\mathcal{H}}(\xi,\beta)d\xi\,d\beta, \tag{III.4}$$

we can compute it from (III.2) and find

$$\hat{I}_{\mathcal{H}}(u,v)=A\left(\frac{ue^{(v/2)}}{2\sinh(v/2)},\frac{ue^{(-v/2)}}{2\sinh(v/2)}\right)\left(\frac{u}{2\sinh(v/2)}\right)^{2r}\frac{|u|}{4\sinh^2(v/2)}Y(u/v). \tag{III.5}$$

The inversion of this relation can be done directly by changing the variables.

The kernel of operator $\mathbf{A}$ is thus given by

$$A(f_1,f_2)=\hat{I}_{\mathcal{H}}(f_1-f_2,\ln(f_1/f_2))(f_1f_2)^{-r-1}|f_1-f_2|. \tag{III.6}$$

4. Trace of a product of two operators

The scalar product of two operators can be defined as

$$\mathrm{Tr}(\mathbf{A}\mathbf{B}^{\dagger})=\int_{\mathbb{R}^+\times\mathbb{R}^+}A(f_1,f_2)B^{*}(f_1,f_2)(f_1f_2)^{2r+1}df_1df_2, \tag{III.7}$$

where $\mathbf{B}^{\dagger}$ is the Hermitian conjugate of operator $\mathbf{B}$.

If $\hat{I}_{\mathcal{H}}(\mathbf{A};u,v)$ and $\hat{I}_{\mathcal{H}}(\mathbf{B};u,v)$ are the functions corresponding, respectively, to the operators $\mathbf{A}$ and $\mathbf{B}$, the computation of the trace of $\mathbf{A}\mathbf{B}^{\dagger}$ is performed using (III.6) and the result follows:

$$\mathrm{Tr}(\mathbf{A}\mathbf{B}^{\dagger})=\int_{\mathbb{R}^2}\hat{I}_{\mathcal{H}}(\mathbf{A};u,v)\hat{I}_{\mathcal{H}}(\mathbf{B}^{*};u,v)|u|du\,dv. \tag{III.8}$$

B. Characterization of symbols by their line integrals on ξ-orbits

The description of functions $\mathcal{A}(t,f)$ defined on phase space Γ can be carried out in a way which parallels that followed for the operators. The starting point is the association of a function $I_{\Gamma}(\xi,\beta)$ with each phase space function $\mathcal{A}(t,f)$ by the relation

$$I_{\Gamma}(\xi,\beta)\equiv\int_{\Gamma}\mathcal{A}(t,f)\,\delta((t-\xi)f-\beta)dt\,df. \tag{III.9}$$

For a given ξ, the function defined by (III.9) is interpreted as the integral of $\mathcal{A}(t,f)$ on the various orbits of the subgroup G_{ξ}. The study of the properties of function $I_{\Gamma}(\xi,\beta)$ follows the same steps as in Sec. III A. For practical reasons, the notation $I_{\Gamma}(\mathcal{A};\xi,\beta)$ will also be used for expression (III.9).

1. G_ξ-invariance of $I_\Gamma(\xi,\beta)$

The integral in (III.9) is clearly invariant under the action of G_ξ on $\mathcal{A}(t,f)$ defined by (II.24).

2. Affine covariance

When $\mathcal{A}(t,f)$ is transformed into $\mathcal{A}'(t,f)\equiv\mathcal{A}(e^u t+b,a^{-1}f)$, the function $I_\Gamma(\mathcal{A};\xi,\beta)$ becomes

$$I_\Gamma(\mathcal{A}';\xi,\beta)=I_\Gamma(\mathcal{A};e^u\xi+b,\beta). \tag{III.10}$$

This relation connects the integrals of the function $\mathcal{A}'$ on the G_ξ orbits to the integrals of $\mathcal{A}$ on the orbits of the subgroup $G_{\xi'}$, conjugate of G_ξ by the transformation (u,b) of the affine group.

3. Reconstruction of the function $\mathcal{A}(t,f)$

Relation (III.9) defines, in fact, the Radon transform of $\mathcal{A}(t,f)$ with respect to arrays of hyperbolas parametrized by ξ and β. To invert this transform, we introduce the two-dimensional Fourier transform of $I_\Gamma(\xi,\beta)$ in a manner analogous to (III.4) and compute

$$\hat{I}_\Gamma(u,v)=\int_{\mathbb{R}} e^{-2i\pi ut}\mathcal{A}(t,(u/v))\frac{dt}{|v|}. \tag{III.11}$$

The inversion of this formula gives

$$\mathcal{A}(t,f)=f\int_{\mathbb{R}} e^{2i\pi vft}\hat{I}_\Gamma(fv,v)|v|dv. \tag{III.12}$$

4. Scalar product of two symbols

Consider two functions $\mathcal{A}(t,f)$, $\mathcal{B}(t,f)$ and their corresponding $\hat{I}_\Gamma$ functions. The use of relation (III.12) and Parseval's formula yields

$$\int_\Gamma \mathcal{A}(t,f)\mathcal{B}^*(t,f)dt\,df=\int_{\mathbb{R}^2}\hat{I}_\Gamma(\mathcal{A};u,v)\hat{I}_\Gamma(\mathcal{B}^*;u,v)|u|du\,dv. \tag{III.13}$$

C. The geometric correspondence rule

So far, operators on the Hilbert space $\mathcal{H}$ and functions on the phase space Γ have been characterized, respectively, by functions $I_{\mathcal{H}}(\xi,\beta)$ or $I_\Gamma(\xi,\beta)$. Moreover, for each value of ξ, both functions $I_{\mathcal{H}}(\xi,\beta)$ and $I_\Gamma(\xi,\beta)$ are invariant by action of the subgroup G_ξ. Thus, it is possible to define the correspondence between operators and symbols by requiring that

$$I_{\mathcal{H}}(\xi,\beta)\equiv I_\Gamma(\xi,\beta), \tag{III.14}$$

and to denote the common function by $I(\xi,\beta)$. This relation is stable by the affine group as seen from properties (III.3) and (III.10). Actually, the consistency with the group action implies only the proportionality of the two members of (III.14). The interest of the strict identification which has been adopted is to ensure that the identity operator will be symbolized by the function one.

According to (III.5) and (III.11), the Fourier transform of relation (III.14) leads to

$$\hat{I}(u,v)=A\left(\frac{ue^{(v/2)}}{2\sinh(v/2)},\frac{ue^{(-v/2)}}{2\sinh(v/2)}\right)\left(\frac{u}{2\sinh(v/2)}\right)^{2r}\frac{|u|}{4\sinh^2(v/2)}Y(u/v)$$

$$=\int_{\mathbb{R}} e^{-2i\pi ut}\mathcal{A}(t,(u/v))\frac{dt}{|v|}.$$

The equality of the two right hand sides gives the relation between the kernel $A(f_1,f_2)$ and the symbol $\mathcal{A}(t,f)$. This is the correspondence rule that can be rewritten either as a formula giving the operator kernel in terms of the symbol (Weyl mapping) or as a formula giving the symbol in terms of the kernel (Wigner correspondence). The result is the following

Result 1: The operator **A** *corresponding to the function* $\mathcal{A}(t,f)$*, defined on the time-frequency half-plane* Γ*, is given by its kernel [defined in (III.1)] as*

$$A(f_1,f_2)=(f_1f_2)^{-r-1}\frac{f_1-f_2}{\ln(f_1/f_2)}\int_{\mathbb{R}}e^{-2i\pi(f_1-f_2)t}\mathcal{A}\left(t,\frac{f_1-f_2}{\ln(f_1/f_2)}\right)dt. \tag{III.15}$$

Conversely, the operator **A** *defined by its kernel* $A(f_1,f_2)$*, is represented on phase space by a symbol* $\mathcal{A}(t,f)$ *according to*

$$\mathcal{A}(t,f)=f^{2r+2}\int_{\mathbb{R}}e^{2i\pi vft}A\left(\frac{fve^{v/2}}{2\sinh(v/2)},\frac{fve^{-v/2}}{2\sinh(v/2)}\right)\left(\frac{v}{2\sinh(v/2)}\right)^{2r+2}dv. \tag{III.16}$$

In addition, the following unitarity property holds:

$$\int_{\Gamma}\mathcal{A}(t,f)\mathcal{B}^*(t,f)dt\ df=\mathrm{Tr}(\mathbf{AB}^{\dagger}). \tag{III.17}$$

Among the properties of the correspondence, it can be deduced from (III.16) that the identity operator with kernel

$$I(f_1,f_2)=(f_1f_2)^{-r-1/2}\delta(f_1-f_2), \tag{III.18}$$

has a symbol equal to one, and that operators such that

$$A(f_1,f_2)=A^*(f_2,f_1), \tag{III.19}$$

are in correspondence with real-valued functions $\mathcal{A}(t,f)$.

At this point, it would be desirable to characterize in a precise way classes of operators and functions that are put in correspondence by the above rule. Clearly, because of property (III.17), Hilbert-Schmidt operators can be associated with functions in the space $L^2(\mathbb{R}^+;f^{2r+1}\ df)$. In fact, it is possible to characterize other classes of operators by their symbols,[4,5] as is done in the usual Weyl case with bounded operators.[6,7] But this is outside the scope of the present paper.

Result 1 concerns only functions defined on the positive half-line and their corresponding operators. Some side comments concerning its possible extension are given in the following remark.

Remark 1: A direct extension of Result 1 can be obtained if a function $\mathcal{A}(t,f)$ defined on the whole plane is substituted in (III.15) and if negative values for f_1 and f_2 are allowed. However, the result will be a function $A(f_1,f_2)$ defined only in the first and third quadrant of the (f_1,f_2) plane. The regions where f_1 and f_2 have different signs are definitely forbidden in the above symbolic calculus.

IV. SOME SPECIAL CASES

A. Symbol of the projector on a β-subspace of $\mathcal{H}$

The β-subspace associated with subgroup G_ξ is characterized by the function $\psi^\xi_\beta(f)$ introduced in (II.16). The projector on this subspace is the linear operator defined by

$$S(f)\rightarrow(\psi^\xi_\beta,S)\psi^\xi_\beta(f), \tag{IV.1}$$

where the scalar product has the form (II.7). The corresponding kernel is given by [cf. (III.1)]

$$\Pi^\xi_\beta(f_1,f_2)=\psi^\xi_\beta(f_1)\psi^{\xi*}_\beta(f_2). \tag{IV.2}$$

A direct application of formula (III.16) shows that the symbol associated with (IV.2) is the distribution $\delta((t-\xi)f-\beta)$ with support in Γ localized on the β-orbit of subgroup G_ξ.

B. Affine Wigner function as a particular symbol

Each signal $S(f)$ defines a real linear functional on the set of Hermitian operators by

$$\langle \mathbf{A} \rangle = (\mathbf{A}S, S) = (S, \mathbf{A}S), \tag{IV.3}$$

where the scalar product is given by (II.7).

This functional can also be written as

$$\langle \mathbf{A} \rangle = \mathrm{Tr}(\mathbf{\Pi}_S \mathbf{A}), \tag{IV.4}$$

where the trace operation has been defined by (III.7) and where $\mathbf{\Pi}_S$ is the projector on signal $S(f)$ with kernel given by

$$\Pi_S(f_1, f_2) = S(f_1)S^*(f_2). \tag{IV.5}$$

From the reciprocal correspondence (III.15), (III.16) and its properties, it results that each real linear functional on the set of Hermitian operators can be expressed as a real linear functional of the real-valued functions on the time-frequency half-plane. The Wigner function for the signal $S(f)$ is defined as the function (or distribution) $\mathcal{P}(t,f)$ on the time-frequency half-plane which allows us to rewrite (IV.4) in the form

$$\langle \mathbf{A} \rangle = \int_\Gamma \mathcal{P}(t,f)\mathcal{A}(t,f)\,dt\,df, \tag{IV.6}$$

where $\mathcal{A}(t,f)$ is the symbol of operator $\mathbf{A}$. From this definition, it is clear that the form of the Wigner function is fundamentally dependent of the symbolic calculus which is adopted.

The equality of the right hand sides of (IV.4) and (IV.6) gives a relation of type (III.17) (unitarity property) provided the Wigner function $\mathcal{P}(t,f)$ is identified with the geometric symbol of the projector $\mathbf{\Pi}_S$. This makes it possible to obtain the relevant Wigner function by applying the correspondence rule (III.16) to the kernel (IV.5). The result is the affine Wigner function:[8]

$$\mathcal{P}(t,f) = f^{2r+2}\int_{\mathbb{R}} e^{2i\pi v f t} S\left(\frac{f v e^{v/2}}{2\sinh(v/2)}\right) S^*\left(\frac{f v e^{-v/2}}{2\sinh(v/2)}\right)\left(\frac{v}{2\sinh(v/2)}\right)^{2r+2} dv. \tag{IV.7}$$

This function can be introduced in various ways. In the above development, it arises as a consequence of the general correspondence defined by (III.15), (III.16).

Expression (IV.7) can also be obtained directly by writing the unitarity relation (III.17) with one symbol equal to $\mathcal{P}(t,f)$ and the other one equal to the localized distribution $\delta(t-t_0)\delta(f-f_0)$. This leads to the relation

$$\mathcal{P}(t_0, f_0) = \mathrm{Tr}(\mathbf{\Pi}_S \mathbf{\Delta}_{t_0,f_0}), \tag{IV.8}$$

where $\mathbf{\Delta}_{t_0,f_0}$ is the operator with symbol $\delta(t-t_0)\delta(f-f_0)$. The kernel of this operator is given by (III.15) and reads as

$$\Delta(f_1, f_2) = (f_1 f_2)^{-r-1}\frac{f_1 - f_2}{\ln f_1/f_2} e^{-2i\pi(f_1-f_2)t_0}\delta\left(\frac{f_1-f_2}{\ln f_1/f_2} - f_0\right). \tag{IV.9}$$

Function $\mathcal{P}(t,f)$ can then be obtained by (IV.8). These results are summarized by the following.

Result 2: The Wigner function of signal $S(f)$ associated with the geometric correspondence is given by (IV.7). It can be obtained either as the symbol of the projector $\mathbf{\Pi}_S$ on signal $S(f)$, or as the mean value (IV.8) of the operator $\mathbf{\Delta}_{t_0,f_0}$ whose symbol is $\delta(t-t_0)\delta(f-f_0)$.

The unitarity property (III.17) gives directly the formulas

$$\int_\Gamma \mathcal{P}(t,f)\,dt\,df = \|S\|^2,$$
$$\int_\Gamma \mathcal{P}_1(t,f)\mathcal{P}_2(t,f)\,dt\,df = \mathrm{Tr}(\mathbf{\Pi}_{S_1}\mathbf{\Pi}_{S_2}) = |(S_1,S_2)|^2, \tag{IV.10}$$

where $\mathcal{P}_1$ and $\mathcal{P}_2$ stand for the Wigner functions corresponding to S_1 and S_2, respectively.

Many other properties could be mentioned which are related to the interpretation of the Wigner function as a time-frequency representation.[9,10]

C. Exponentials of generators and Weyl's formulation of the correspondence

We will now show that the symbol of the operator $\mathbf{E}_{u_0v_0} \equiv e^{-2i\pi(u_0\boldsymbol{\beta}+v_0\mathbf{f})}$, where $\boldsymbol{\beta}$ and $\mathbf{f}$ are the generators defined by (II.8) and (II.9), is given by the function $\mathcal{E}_{u_0v_0}(t,f) = e^{-2i\pi(u_0tf+v_0f)}$.

It follows from the developments of Sec. II A that the operator $\mathbf{E}_{u_0v_0}$ satisfies the following eigenvalue equation:

$$e^{-2i\pi(u_0\boldsymbol{\beta}+v_0\mathbf{f})}\psi_\beta^{-v_0/u_0}(f) = e^{-2i\pi\beta u_0}\psi_\beta^{-v_0/u_0}(f). \tag{IV.11}$$

The kernel of $\mathbf{E}_{u_0v_0}$ is obtained directly from the spectral decomposition:

$$E_{u_0v_0}(f_1,f_2) = \int_{\mathbb{R}} e^{-2i\pi\beta u_0}\psi_\beta^{-v_0/u_0}(f_1)\psi_\beta^{*-v_0/u_0}(f_2)\,d\beta, \tag{IV.12}$$

and has the explicit expression

$$E_{u_0v_0}(f_1,f_2) = e^{(r+1)u_0}\exp\{-2i\pi f_1(v_0/u_0)(e^{u_0}-1)\}\,\delta(f_1e^{u_0}-f_2)f_2^{-2r-1}. \tag{IV.13}$$

Substituting this result in (III.16), we can write the symbol of $\mathbf{E}_{u_0v_0}$ as

$$\mathcal{E}_{u_0v_0}(t,f) = \int_{\mathbb{R}} e^{2i\pi vft}e^{(r+1)u_0}\exp\{-2i\pi(f(v_0/u_0)(e^{u_0}-1)\lambda(v))\}$$
$$\times\lambda(-v)e^{(2r+2)(v/2)}\delta(e^{u_0}\lambda(v)-\lambda(-v))\,dv, \tag{IV.14}$$

where, by definition,

$$\lambda(v) = \frac{ve^{v/2}}{2\sinh(v/2)}. \tag{IV.15}$$

Since

$$\delta(e^{u_0}\lambda(v)-\lambda(-v)) = \frac{1}{\lambda(u_0)}\,\delta(v+u_0), \tag{IV.16}$$

the result of integration in (IV.14) is just

$$\mathcal{E}_{u_0v_0}(t,f) = e^{-2i\pi(u_0ft+v_0f)}. \tag{IV.17}$$

Thus, we have established the correspondence

$$\mathcal{E}_{u_0v_0}(t,f) \equiv e^{-2i\pi(u_0ft+v_0f)} \leftrightarrow \mathbf{E}_{u_0v_0} = e^{-2i\pi(u_0\boldsymbol{\beta}+v_0\mathbf{f})}. \tag{IV.18}$$

Remark that the variable $\beta = tf$ rather than t appears naturally. It will sometimes be convenient to use it by performing the change of variables according to

$$\tilde{\mathcal{A}}(\beta,f) = [\mathcal{A}(t,f)]_{t=\beta/f}. \tag{IV.19}$$

The correspondence (IV.18) allows us to write the operator $\mathbf{A}$ in terms of its symbol $\mathcal{A}(t,f)$ by the Weyl formula:

$$\mathbf{A}=\int \hat{\mathcal{A}}(u,v)e^{-2i\pi(u\boldsymbol{\beta}+v\boldsymbol{f})}du\ dv, \tag{IV.20}$$

where $\hat{\mathcal{A}}(u,v)$ is the Fourier transform of $\tilde{\mathcal{A}}(\beta,f)$ given by

$$\hat{\mathcal{A}}(u,v)\equiv\int_{\mathbb{R}\times\mathbb{R}^+} e^{2i\pi(u\beta+vf)}\tilde{\mathcal{A}}(\beta,f)d\beta\ df. \tag{IV.21}$$

The correspondence between functions and operators defined by (IV.20) and (IV.21) has a form analogous to Weyl's original rule. In fact, it is what Cohen calls Weyl's rule for operators $\boldsymbol{\beta}$ and $\boldsymbol{f}$.[11] It can also be obtained as a by-product of Kirillov's analysis[12] as shown by Unterberger[4] (see also Shenoy and Parks[13]).

Remark 2: The symbols of the self-adjoint operators $\boldsymbol{\beta}$ and $\boldsymbol{f}$ are immediately seen to be $\beta=tf$ and f respectively. The time operator, which is especially important in signal analysis, can be defined as the operator with symbol t. A direct computation leads to the result

$$\boldsymbol{t}=(1/2)(\boldsymbol{f}^{-1}\boldsymbol{\beta}+\boldsymbol{\beta}\boldsymbol{f}^{-1}), \tag{IV.22}$$

or

$$\boldsymbol{t}=-\frac{1}{2i\pi}\left(\frac{r+1/2}{f}+\frac{d}{df}\right). \tag{IV.23}$$

Such an operator is not essentially self-adjoint on the Hilbert space $L^2(\mathbb{R}^+;f^{2r+1}df)$ and hence has no conventional spectral decomposition. However, it is known from the deformation quantization theory on phase space[2] that such a difficulty can be easily overcome and does not affect the physical interpretation.

V. STAR PRODUCT ON THE SYMBOLS

Operators on the Hilbert space $\mathcal{H}$ have been mapped to functions on the time-frequency half-plane Γ by the rule (III.16). Since the algebra of operators is non-Abelian, the product of operators is mapped into a composition law of functions that cannot be the ordinary product. This situation is familiar from Weyl's calculus where the composition law of functions is known as Moyal's product and is invariant by Heisenberg's group. Analogous products, invariant by different groups, have been constructed by deformation of the usual product and are generally referred to as star products ($\star$ products).[2] In the present case, the composition law of symbols corresponding to the product of operators leads directly to a star product that is invariant by the affine group.

In the following, it will be convenient to use another notation for the operator $\exp\{-2i\pi(u\boldsymbol{\beta}+v\boldsymbol{f})\}$. In fact, according to (IV.11) and (IV.12), the action of that operator on a signal $S(f)$ can be written as

$$\exp\{-2i\pi(u\boldsymbol{\beta}+v\boldsymbol{f})\}S(f)=e^{(r+1)u}\exp\{-2i\pi f(v/u)(e^u-1)\}S(fe^u). \tag{V.1}$$

Comparing this expression with the definition (II.6) of representation $\mathbf{U}$, we are able to rewrite (V.1) as

$$\exp\{-2i\pi(u\boldsymbol{\beta}+v\boldsymbol{f})\}S(f)=\mathbf{U}\left(u,\frac{v}{u}(e^u-1)\right)S(f). \tag{V.2}$$

This result can also be obtained directly by noticing that, in the description of the affine group by 2×2 matrices, the exponentiation of the Lie algebra element defined by (u,v) is equal to

$$\exp\begin{vmatrix} u & v \\ 0 & 0 \end{vmatrix}=\begin{vmatrix} e^u & (v/u)(e^u-1) \\ 0 & 1 \end{vmatrix}.$$

The use of representation $\mathbf{U}(u,b)$ allows us to take advantage of the group law and to write the composition of operators as

$$\mathbf{U}(u,b)\mathbf{U}(u',b')=\mathbf{U}(u+u',b+e^{u}b'). \tag{V.3}$$

It shows directly that the product of two operators of type (V.1) is an operator of the same type. With notation (V.2), the form (IV.20) of the correspondence rule (III.15) between functions and operators can be written as

$$\mathbf{A}=\int_{\mathbb{R}^2}\hat{\mathcal{A}}(u,v)\mathbf{U}\left(u,v\,\frac{e^{u}-1}{u}\right)du\;dv, \tag{V.4}$$

where $\hat{\mathcal{A}}(u,v)$ is defined in (IV.21).

Let **A** and **B** be operators given in terms of their symbols $\tilde{\mathcal{A}}(\beta,f)$ and $\tilde{\mathcal{B}}(\beta,f)$ by rule (V.4), (IV.21). Their product is equal to

$$\mathbf{AB}=\int_{\mathbb{R}^4}\hat{\mathcal{A}}(u_1,v_1)\hat{\mathcal{B}}(u_2,v_2)\mathbf{U}\left(u_1,v_1\frac{e^{u_1}-1}{u_1}\right)\mathbf{U}\left(u_2,v_2\frac{e^{u_2}-1}{u_2}\right)du_1\;dv_1\;du_2\;dv_2,$$

or, using (V.3),

$$=\int_{\mathbb{R}^4}\hat{\mathcal{A}}(u_1,v_1)\hat{\mathcal{B}}(u_2,v_2)\mathbf{U}\left(u_1+u_2,v_1\frac{e^{u_1}-1}{u_1}+e^{u_1}v_2\frac{e^{u_2}-1}{u_2}\right)du_1\;dv_1\;du_2\;dv_2.$$

This product can be rewritten in the form (V.4) of the correspondence rule if variables (u,v) are introduced such that

$$u=u_1+u_2,\quad v\,\frac{e^{u}-1}{u}=v_1\frac{e^{u_1}-1}{u_1}+e^{u_1}v_2\frac{e^{u_2}-1}{u_2}. \tag{V.5}$$

The result is

$$\mathbf{AB}=\int_{\mathbb{R}^2}\hat{\mathcal{C}}(u,v)\mathbf{U}\left(u,v\,\frac{e^{u}-1}{u}\right)du\;dv, \tag{V.6}$$

with $\hat{\mathcal{C}}(u,v)$ defined by

$$\begin{aligned}\hat{\mathcal{C}}(u,v)=&\int_{\mathbb{R}^2\times\mathbb{R}^2}\hat{\mathcal{A}}(u_1,v_1)\hat{\mathcal{B}}(u_2,v_2)\,\delta(u-u_1-u_2)\\&\times\delta\left(v-\left(v_1\frac{e^{u_1}-1}{u_1}+e^{u_1}v_2\frac{e^{u_2}-1}{u_2}\right)\frac{u_1+u_2}{e^{u_1+u_2}-1}\right)du_1\;dv_1\;du_2\;dv_2.\end{aligned} \tag{V.7}$$

It follows from (V.6) that $\hat{\mathcal{C}}(u,v)$ is the Fourier transform of the symbol of the operator **AB**.

To obtain an explicit expression of the star product $\tilde{\mathcal{A}}(\beta,f)\star\tilde{\mathcal{B}}(\beta,f)$, it suffices now to invert the Fourier transform of $\hat{\mathcal{C}}(u,v)$ and to express the result in terms of $\tilde{\mathcal{A}}(\beta,f)$ and $\tilde{\mathcal{B}}(\beta,f)$. In a first step, we obtain

$$\begin{aligned}\tilde{\mathcal{A}}(\beta,f)\star\tilde{\mathcal{B}}(\beta,f)=&\int\hat{\mathcal{A}}(u_1,v_1)\hat{\mathcal{B}}(u_2,v_2)e^{2i\pi((u_1+u_2)\beta+(v_1+v_2)f)}\\&\times e^{-2i\pi f h(u_1,v_1,u_2,v_2)}du_1\;dv_1\;du_2\;dv_2,\end{aligned} \tag{V.8}$$

where the function h is defined by

$$h(u_1,v_1,u_2,v_2)\equiv(v_1+v_2)-\frac{u_1+u_2}{e^{u_1+u_2}-1}\left(v_1\frac{e^{u_1}-1}{u_1}+e^{u_1}v_2\frac{e^{u_2}-1}{u_2}\right), \tag{V.9}$$

or, after some manipulations,

$$h(u_1,v_1,u_2,v_2)=(v_1u_2-v_2u_1)\frac{u_1e^{u_1}(e^{u_2}-1)-u_2(e^{u_1}-1)}{u_1u_2(e^{u_1+u_2}-1)}. \tag{V.10}$$

The exponential of function $h(u_1,v_1,u_2,v_2)$ in (V.8) is what makes the difference with a classical product. It can be replaced by its series expansion so that the integrals in (V.8) can be performed. In the process, the following replacements take place:

$$v_i\to\frac{1}{2i\pi}\partial_{f_i},\quad u_i\to\frac{1}{2i\pi}\partial_{\beta_i},\quad i=1,2. \tag{V.11}$$

The development of the star product can thus be written as

$$\tilde{\mathcal{A}}(\beta,f)\star\tilde{\mathcal{B}}(\beta,f)=\tilde{\mathcal{A}}(\beta,f)\tilde{\mathcal{B}}(\beta,f)+\sum_{n=1}^{\infty}\frac{1}{n!}\left(\frac{f}{4i\pi}(\partial_{f_2}\partial_{\beta_1}-\partial_{f_1}\partial_{\beta_2})T(\partial_{\beta_1},\partial_{\beta_2})\right)^n\tilde{\mathcal{A}}(\beta_1,f_1)\tilde{\mathcal{B}}(\beta_2,f_2)\Big|_{\substack{f_1=f_2=f\\ \beta_1=\beta_2=\beta}}, \tag{V.12}$$

where the contribution of operator T will be discussed below.

If (V.12) is rewritten in terms of t rather than β, using the definition

$$\beta=tf,\quad \partial_\beta=(1/f)\partial_t; \tag{V.13}$$

the result is reminiscent of the Weyl product. Actually, the difference lies in the presence of the operator $T(\partial_{\beta_1},\partial_{\beta_2})$ which comes from the development in powers of u_1 and u_2 of

$$T(u_1,u_2)=2\frac{u_1e^{u_1}(e^{u_2}-1)-u_2(e^{u_1}-1)}{u_1u_2(e^{u_1+u_2}-1)}. \tag{V.14}$$

Operator T introduces derivatives of all orders with respect to β_1 and β_2. At the lowest orders, one has

$$T(\partial_{\beta_1},\partial_{\beta_2})=1+\frac{i}{12\pi}(\partial_{\beta_2}-\partial_{\beta_1})+\frac{1}{12(2\pi)^2}\partial_{\beta_1}\partial_{\beta_2}+\frac{i}{720(2\pi)^3}(\partial_{\beta_2}-\partial_{\beta_1})(\partial_{\beta_1}^2+\partial_{\beta_2}^2+5\partial_{\beta_1}\partial_{\beta_2})+\cdots. \tag{V.15}$$

As in Weyl's case, the first term in (V.12) is the usual product and the following terms introduce derivatives of the symbols. It can be observed that the star product of two real-valued functions is not real. This is a direct manifestation of the fact that the product of Hermitian operators is not Hermitian.

Remark 3: From Remark 1, it follows that in a product of operators, the positive and negative frequency parts are multiplied separately. Hence, the same property will hold for the star product if its expression is extended to symbols defined on the whole plane.

The star product simplifies when one of the symbols depends only on one variable. This will be illustrated by computing its expression when $\tilde{\mathcal{A}}(\beta,f)$ is equal either to β or to a function of f alone and when $\tilde{\mathcal{B}}(\beta,f)$ is the generic distribution:

$$\Delta_{\beta_0,f_0}(\beta,f)=\delta(\beta-\beta_0)\delta(f-f_0), \tag{V.16}$$

with Fourier transform (IV.21) given by

$$\hat{\Delta}_{\beta_0,f_0}(u,v)=e^{-2i\pi(u\beta_0+vf_0)}. \tag{V.17}$$

(i) Case where $\tilde{\mathcal{A}}(\beta,f)=\beta$. The Fourier transform of β is

$$\hat{\mathcal{A}}(u,v)=-\frac{1}{2i\pi}\delta'(u)\delta(v). \tag{V.18}$$

Computation of the star product from (V.8) and (V.10) gives

$$\beta\star\delta(\beta-\beta_0)\delta(f-f_0)=-\frac{1}{2i\pi}\int \delta'(u_1)e^{-2i\pi[u_2(\beta_0-\beta)+v_2f_0]} \times\exp\left\{2i\pi\left[u_1\beta+fv_2\frac{\lambda(u_1+u_2)}{\lambda(u_2)}\right]\right\}du_1\,du_2\,dv_2, \tag{V.19}$$

where $\lambda(u)$, defined by (IV.15), is such that

$$\lambda(-u)=e^{-u}\lambda(u). \tag{V.20}$$

Performing the u_1-integration, we can write (V.19) as

$$\beta\star\delta(\beta-\beta_0)\delta(f-f_0)=\beta\delta(\beta-\beta_0)\delta(f-f_0) +f\int_{\mathbb{R}^2}e^{2i\pi[u_2(\beta-\beta_0)+v_2(f-f_0)]}\left(\frac{d}{du_2}(\ln(\lambda(u_2)))\right)v_2\,du_2\,dv_2. \tag{V.21}$$

(ii) Case where $\tilde{\mathcal{A}}(\beta,f)$ *depends only on* f. The Fourier transform of $\tilde{\mathcal{A}}(\beta,f)=g(f)$, with $g(f)$ an arbitrary function, is equal to

$$\hat{\mathcal{A}}(u,v)=\delta(u)\int_{\mathbb{R}}g(f)e^{-2i\pi vf}\,df. \tag{V.22}$$

Substitution of the Fourier transforms (V.17) and (V.22) in the expression of the star product (V.8)–(V.10) gives

$$g(f)\star\delta(\beta-\beta_0)\delta(f-f_0)=\int_{\mathbb{R}^2}g(f\lambda(-u))e^{2i\pi[u(\beta-\beta_0)+v(f-f_0)]}\,du\,dv. \tag{V.23}$$

VI. STAR BRACKET OF SYMBOLS AND HAMILTONIAN FLOW

A. Definition of the star bracket

A Lie bracket is now defined on operators by the operation

$$-2\pi i[\mathbf{A},\mathbf{B}]=-2\pi i(\mathbf{AB}-\mathbf{BA}). \tag{VI.1}$$

This bracket defines a composition law on the subspace of Hermitian operators. When transformed by the correspondence rule, using the expression for the star product, this bracket gives rise to an operation on real-valued functions that will be called a star bracket and denoted by $\{,\}_\star$. Thus, the star bracket of symbols $\tilde{\mathcal{A}}(\beta,f)$ and $\tilde{\mathcal{B}}(\beta,f)$ is defined by

$$\{\tilde{\mathcal{A}},\tilde{\mathcal{B}}\}_\star(\beta,f)=-2\pi i(\tilde{\mathcal{A}}(\beta,f)\star\tilde{\mathcal{B}}(\beta,f)-\tilde{\mathcal{B}}(\beta,f)\star\tilde{\mathcal{A}}(\beta,f)). \tag{VI.2}$$

According to (V.12), the bracket can be written as

$$\{\tilde{\mathcal{A}}(\beta,f),\tilde{\mathcal{B}}(\beta,f)\}_\star=\Bigg[f(\partial_{f_1}\partial_{\beta_2}-\partial_{f_2}\partial_{\beta_1})\Bigg(1+\frac{1}{12(2\pi)^2}\partial_{\beta 1}\partial_{\beta_2}+\cdots\Bigg)$$
$$+\sum_{n=2}^{\infty}\frac{2i\pi}{n!}\Bigg(\frac{f}{4i\pi}(\partial_{f_1}\partial_{\beta_2}-\partial_{f_2}\partial_{\beta_1})\Bigg)^{n'}$$
$$\times[T^n(\partial_{\beta_2},\partial_{\beta_1})-(-1)^nT^n(\partial_{\beta_1},\partial_{\beta_2})]\Bigg]\tilde{\mathcal{A}}(\beta_1,f_1)\tilde{\mathcal{B}}(\beta_2,f_2)\Bigg|_{\substack{f_1=f_2=f\\ \beta_1=\beta_2=\beta}}. \tag{VI.3}$$

The first term in f is a Poisson bracket given by

$$\{\tilde{\mathcal{A}}(\beta,f),\tilde{\mathcal{B}}(\beta,f)\}_P=f\Bigg(\frac{\partial\tilde{\mathcal{A}}(\beta,f)}{\partial\beta}\frac{\partial\tilde{\mathcal{B}}(\beta,f)}{\partial f}-\frac{\partial\tilde{\mathcal{A}}(\beta,f)}{\partial f}\frac{\partial\tilde{\mathcal{B}}(\beta,f)}{\partial\beta}\Bigg). \tag{VI.4}$$

In fact, if the variable β is replaced by its definition (V.13), the expression (VI.4) becomes identical with the usual Poisson bracket on Γ. This is the same bracket as obtained by Kirillov's theory[12] when considering phase space as an orbit of the coadjoint representation.

The form (VI.3) of the star bracket is reminiscent of that obtained with the Weyl calculus. However, due to the fact that operator $T(\partial_{\beta_1},\partial_{\beta_2})$ has no symmetry, derivatives of arbitrary order will, in general, appear in the expression of the bracket.

Some symbols are such that their star bracket with any other function has the form of a Poisson bracket. In deformation quantization, such symbols are called *preferred observables*.[2,14,15] A typical example is the harmonic oscillator Hamiltonian on $\mathbb{R}^2$ with Weyl quantization.

In the present case, the preferred observable are represented by the symbols β, f, and $\ln f$. Explicitly, their star brackets with any symbol $\mathcal{X}(\beta,f)$ are given by

$$\{\beta,\mathcal{X}(\beta,f)\}_\star=f\frac{\partial}{\partial f}\mathcal{X}(\beta,f), \tag{VI.5}$$

$$\{f,\mathcal{X}(\beta,f)\}_\star=-f\frac{\partial}{\partial\beta}\mathcal{X}(\beta,f), \tag{VI.6}$$

$$\{\ln f,\mathcal{X}(\beta,f)\}_\star=-\frac{\partial}{\partial\beta}\mathcal{X}(\beta,f). \tag{VI.7}$$

The derivation of these formulas can be based on expressions (V.21), (V.23) and on their counterpart with reverse order in the star products. Final results follow from the relations

$$\lambda(u)-\lambda(-u)=u,\quad \lambda(-u)=e^{-u}\lambda(u), \tag{VI.8}$$

which are verified by the function (IV.15).

B. Extended covariance and Hamiltonian flows

Consider a one-parameter group of transformations on signals $S(f)$ defined by an operator $\mathbf{O}$ such that

$$S(f;\alpha)=e^{-2i\pi\alpha\mathbf{O}}S(f;0), \tag{VI.9}$$

with $S(f;0)=S_0(f)$ given. Signal $S(f;\alpha)$ verifies the equation

$$\frac{\partial S(f;\alpha)}{\partial\alpha}=-2i\pi\alpha\mathbf{O}S(f;\alpha), \tag{VI.10}$$

and the projector $\mathbf{\Pi}$ on $S(f;\alpha)$ verifies

$$\frac{\partial \mathbf{\Pi}}{\partial \alpha} = -2i\pi[\mathbf{O}, \mathbf{\Pi}]. \tag{VI.11}$$

Now, going to phase space, we know that the geometric symbol of $\mathbf{\Pi}$ is the affine Wigner function (IV.7) for signal $S(f;\alpha)$, and that the symbol of the bracket $-2i\pi[,]$ is the star bracket $\{,\}_\star$. Thus equation (VI.11) becomes the following equation in Γ:

$$\frac{\partial \mathcal{P}(t,f;\alpha)}{\partial \alpha} = \{\mathcal{O}(t,f), \mathcal{P}(t,f;\alpha)\}_\star, \tag{VI.12}$$

where $\mathcal{O}(t,f)$ is the symbol of operator $\mathbf{O}$.

Consider now the case where the symbol $\mathcal{O}(t,f)$ has the particular form

$$\mathcal{O}_H(t,f) = \mu t f + \nu f + \sigma \ln f, \tag{VI.13}$$

where μ, ν and σ are real constants. From the values of the star brackets (VI.5), (VI.6) and (VI.7), it follows that the bracket in (VI.12) reduces to Poisson's bracket. As a result, equation (VI.12) takes the form of a Liouville equation with Hamiltonian equal to $\mathcal{O}_H(t,f)$:

$$\frac{\partial \mathcal{P}(t,f;\alpha)}{\partial \alpha} = \{\mu t f + \nu f + \sigma \ln f, \mathcal{P}(t,f;\alpha)\}_P = \mu f \frac{\partial \mathcal{P}(t,f;\alpha)}{\partial f} - (\mu t + \nu + (\sigma/f)) \frac{\partial \mathcal{P}(t,f;\alpha)}{\partial t}. \tag{VI.14}$$

This means that the α-evolution of the Wigner function is identical to that of an incompressible fluid in the time-frequency half-plane. Integration of equation (VI.14) with the initial condition

$$\mathcal{P}(t,f;0) = \mathcal{P}_0(t,f) \tag{VI.15}$$

gives

$$\mathcal{P}(t,f;\alpha) = \mathcal{P}_0((-\nu\mu^{-1} + (t+\nu\mu^{-1})e^{-\mu\alpha} - \sigma f^{-1}\alpha), f e^{\mu\alpha}). \tag{VI.16}$$

The evolution of the Wigner function in terms of parameter α has a counterpart in Hilbert space that can be obtained using the symbolic calculus. The operator $\mathbf{O}_H$ for this evolution is found directly from (IV.20)–(IV.21) and has the expression

$$\mathbf{O}_H = \mu\boldsymbol{\beta} + \nu\mathbf{f} + \sigma \ln \mathbf{f}, \tag{VI.17}$$

where the operators $\boldsymbol{\beta}$ and $\mathbf{f}$ have been introduced in (II.8) and (II.9). The expression (VI.9) written for the operator $\mathbf{O}_H$ then gives the α-evolution in the Hilbert space which corresponds to the phase space evolution (VI.16). In fact, this leads to a special form of a general transformation which can be written as

$$(u,b,c): S(f) \to S'(f) = e^{(r+1)u} e^{-2i\pi b f} f^{-2i\pi c} S(e^u f), \quad u,b,c \in \mathbb{R}. \tag{VI.18}$$

This transformation is a projective unitary representation of a three-parameter group G_0 which has been studied in Ref. 16. It has been proved that transformations (VI.18) correspond to symplectic transformations in the phase space. This extended covariance of the calculus is at the basis of a generalization of the construction process that will now be considered.

VII. OTHER SYMBOLIZATIONS WITH GEOMETRICAL FEATURES

The method presented above to construct a symbolic calculus on the affine group can be embedded in a more general approach based on the systematic consideration of groups containing the affine group and having the time-frequency half-plane as a coadjoint orbit. Such groups belong to the class of simply connected Lie groups having a coadjoint orbit of dimension smaller than or equal to two.[17] In this class, the groups of interest are $SL(2,\mathbb{R})$ and the three-parameter solvable groups with Lie algebras defined by generators X_a, X_b and X_c satisfying[18]

$$[X_a,X_b]=X_b, \quad [X_a,X_c]=kX_c, \quad k\in\mathbb{R}, \tag{VII.1}$$

$$[X_a,X_b]=X_b, \quad [X_a,X_c]=X_c+X_b. \tag{VII.2}$$

Examples of symbolic calculi invariant by $SL(2,\mathbb{R})$ have been thoroughly studied in Refs. 19–20. Here, we will treat the cases of groups G_k with Lie algebras defined by relations (VII.1) for $k\neq 1$, and (VII.2) for $k=1$. They provide a natural generalization of the group G_0 considered so far in this paper and will be associated with new forms of symbolic calculus. All groups G_k have been introduced in Ref. 16 as a tool to find explicit forms of time-frequency pseudo-distributions. We refer to that paper for the details concerning the precise construction of their unitary representations (projective or not) according to the values of k. Here we need only recall the results corresponding to values of k different from 0 and 1.

The groups G_k, $k\neq 0,1$ consist of elements (u,b,c) with the composition law

$$gg'=(u+u',b+e^u b',c+e^{ku}c'). \tag{VII.3}$$

Their unitary representations in the Hilbert space $\mathcal{H}$ defined in Sec. II A are given by

$$\mathbf{U}_k(u,b,c)S(f)=e^{(r+1)u}e^{-2i\pi(bf+cf^k)}S(e^u f). \tag{VII.4}$$

The action of the groups in the time-frequency half-plane Γ is

$$(t,f)\to(e^u t+b+kce^{-(k-1)u}f^{k-1},e^{-u}f). \tag{VII.5}$$

It is clear from (VII.4) and (VII.5) that the cases $k=0$ and $k=1$ are degenerate and deserve a special treatment (see Ref. 16).

Following the same pattern as in Sec. II, we determine the subgroups of G_k that are conjugate to the dilation subgroup. They are labeled by two real parameters ξ,η and consist of

$$G_{\xi\eta}=\{(e^u,\xi(1-e^u),\eta(1-e^{ku})\}. \tag{VII.6}$$

The restriction of representations (VII.4) to subgroups $G_{\xi\eta}$ is

$$\mathbf{U}_{\xi\eta}S(f)=e^{(r+1)u}e^{-2i\pi(\xi(1-e^u)f+\eta(1-e^{ku})f^k)}S(fe^u). \tag{VII.7}$$

The eigenfunctions of $\mathbf{U}_{\xi\eta}$ are

$$\psi_\beta^{\xi\eta}(f)=f^{-2i\pi\beta-r-1}e^{-2i\pi(\xi f+\eta f^k)}. \tag{VII.8}$$

They transform under the full group G_k as

$$\mathbf{U}(u,b,c)\,\psi_\beta^{\xi\eta}(f)=e^{-2i\pi\beta u}\psi_\beta^{\xi e^u+b,\,\eta e^{ku}+c}(f). \tag{VII.9}$$

In phase space Γ, the curves invariant by action (VII.5) restricted to $G_{\xi\eta}$ are given by

$$(t-\xi)f-k\eta f^k=\tilde{\beta}. \tag{VII.10}$$

A local study of $\psi_\beta^{\xi\eta}(f)$ analogous to that performed in Sec. II C leads to the identification

$$\tilde{\beta}=\beta. \tag{VII.11}$$

As in Sec. II, we have achieved a correspondence between invariant structures in $\mathcal{H}$ and Γ. But we now have one extra parameter labeling the vectors $\psi_\beta^{\xi\eta}(f)$ and the curves (VII.10). To proceed with the construction, we must fix one of these parameters in such a way that the affine covariance of the procedure is preserved. Because of the transformation law (VII.9), the only possible choices are either $\eta=0$ or $\beta=\beta_0$ fixed. The case $\eta=0$ yields the calculus just developed in the preceding sections. The only possibility to obtain a new calculus is to fix the value of β and to let η free.

The same geometric construction as in Sec. III will be carried out. Consider an operator **A** on $\mathcal{H}$ and form its diagonal matrix elements on $\psi_{\beta_0}^{\xi\eta}(f)$:

$$I_{\mathcal{H}}^{\beta_0}(\xi,\eta)=(\psi_{\beta_0}^{\xi\eta},\mathbf{A}\psi_{\beta_0}^{\xi\eta}). \tag{VII.12}$$

Consider a function $\mathcal{A}(t,f)$ and form its integral with respect to curves (VII.10):

$$I_{\Gamma}^{\beta_0}(\xi,\eta)=\int_{\Gamma}\mathcal{A}(t,f)\,\delta((t-\xi)f-k\,\eta f^k-\beta_0)dt\;df. \tag{VII.13}$$

The study of the properties of functions $I_{\mathcal{H}}^{\beta_0}(\xi,\eta)$ and $I_{\Gamma}^{\beta_0}(\xi,\eta)$ follow the same steps as in Sec. III.

1. $G_{\xi\eta}$-invariance of $I_{\mathcal{H}}^{\beta_0}(\xi,\eta)$ and $I_{\Gamma}^{\beta_0}(\xi,\eta)$

It can be readily verified, using (VII.6), (VII.9) and the definitions of $I_{\mathcal{H}}^{\beta_0}(\xi,\eta)$ and $I_{\Gamma}^{\beta_0}(\xi,\eta)$.

2. G_k-covariance

If $\mathbf{A}'=\mathbf{U}_k^{-1}(u,b,c)\mathbf{A}\mathbf{U}_k(u,b,c)$ is the operator transformed from **A** by the group representation (VII.4), it follows from (VII.9) that

$$I_{\mathcal{H}}^{\beta_0}(\mathbf{A}';\xi,\eta)=I_{\mathcal{H}}^{\beta_0}(\mathbf{A};e^u\xi+b,e^{ku}\eta+c). \tag{VII.14}$$

On the other hand, if $\mathcal{A}'(t,f)=\mathcal{A}(e^u t+b+kce^{-(k-1)u}f^{k-1},a^{-1}f)$, a direct computation leads to

$$I_{\Gamma}^{\beta_0}(\mathcal{A}';\xi,\eta)=I_{\Gamma}^{\beta_0}(\mathcal{A};e^u\xi+b,e^{ku}\eta+c). \tag{VII.15}$$

3. Possibility of reconstruction of the operator **A** and of the function $\mathcal{A}(t,f)$

In spite of the fact that the functions $\psi_{\beta_0}^{\xi\eta}(f)$ do not form a basis, it can be shown that the operator **A** is completely characterized by its diagonal elements (VII.12).

The reconstruction of the function $\mathcal{A}(t,f)$ could be performed by inverting the Radon transform (VII.13).

These properties allow us to base the correspondence rule on the identification

$$I_{\mathcal{H}}^{\beta_0}(\xi,\eta)=I_{\Gamma}^{\beta_0}(\xi,\eta), \tag{VII.16}$$

which can be seen as an extension of (III.14). The resulting correspondence rule has the form

$$\mathcal{A}(t,f)=f^{2r+2}\int_{\mathbb{R}}e^{2i\pi u\beta_0}e^{2i\pi(tf-\beta_0)(\lambda_k(u)-\lambda_k(-u))}A(f\lambda_k(u),f\lambda_k(-u))(\lambda_k(u)\lambda_k(-u))^{r+1}\,du\,, \tag{VII.17}$$

where the functions $\lambda_k(u)$ are defined by

$$\lambda_k(u)=e^{u/2}\left(k\frac{\sinh(u/2)}{\sinh(ku/2)}\right)^{1/(k-1)}. \tag{VII.18}$$

Conversely, the kernel of the operator **A** can be expressed in terms of the symbol by

$$A(f_1,f_2)=\int e^{-2i\pi(f_1-f_2)(t-(\beta_0/f))}\delta(f_1-f_2-k^{-1}f^{1-k}(f_1^k-f_2^k))\times\left(\frac{f_1}{f_2}\right)^{-2i\pi\beta_0}(f_1f_2)^{-r}f^{-k}|f_2^{k-1}-f_1^{k-1}|\mathcal{A}(t,f)dt\;df\,. \tag{VII.19}$$

The operator **A** corresponding to this kernel can be written in Weyl's form as

$$\mathbf{A}=\int_{\mathbb{R}^2}\hat{\mathcal{A}}(k,\beta_0;u,v)e^{-2i\pi(u\boldsymbol{\beta}+v\boldsymbol{f})}\,du\,dv, \tag{VII.20}$$

where

$$\hat{\mathcal{A}}(k,\beta_0;u,v)=e^u\left|\frac{1-e^{(k-1)u}}{(1-k)u}\right|(\lambda_k(-u))^{k+1}e^{2i\pi\beta_0(u-\lambda_k(u)+\lambda_k(-u))}$$
$$\times\int_\Gamma e^{2i\pi tf(\lambda_k(u)-\lambda_k(-u))}e^{2i\pi f(v/u)\lambda_k(-u)(e^u-1)}\mathcal{A}(t,f)f\,dt\,df. \tag{VII.21}$$

It may be noticed that the limit for $k=0$ of function $\lambda_k(u)$ is identical to $\lambda(u)$ defined in (IV.15). In that case, the relation (VII.21) becomes a Fourier transform with respect to $\beta=tf$ and f and the rule (IV.20)–(IV.21) is recovered. In the general case, the Fourier transform (IV.21) is replaced by the k-dependent transform (VII.21) for which Parseval's formula does not hold. As a consequence, the unitarity property (III.17) cannot be obtained.

However, it is possible to recover an expression for the scalar product of operators in terms of symbols. This is accomplished by associating two symbols with any operator **A**: the symbol $\mathcal{A}(t,f)$ defined by (VII.17) and a dual symbol $\mathcal{A}_d(t,f)$ defined by

$$\mathcal{A}_d(t,f)=f^{2r+2}\int_{\mathbb{R}}e^{2i\pi u\beta_0}e^{2i\pi(tf-\beta_0)(\lambda_k(u)-\lambda_k(-u))}A(f\lambda_k(u),f\lambda_k(-u))\mu_d(u)du, \tag{VII.22}$$

where

$$\mu_d(u)=(\lambda_k(u)\lambda_k(-u))^{r+1}\left|\frac{d}{du}(\lambda_k(u)-\lambda_k(-u))\right|. \tag{VII.23}$$

It can be observed that it is only in the case $k=0$ that

$$\frac{d}{du}(\lambda_k(u)-\lambda_k(-u))=1, \tag{VII.24}$$

leading to

$$\mathcal{A}(t,f)=\mathcal{A}_d(t,f). \tag{VII.25}$$

For an arbitrary value of k, the unitarity formula is replaced by

$$\mathrm{Tr}(\mathbf{A}\mathbf{B}^\dagger)=\int_\Gamma\mathcal{A}(t,f)\mathcal{B}_d^*(t,f)dt\,df, \tag{VII.26}$$

where $\mathcal{A}(t,f)$ is the symbol of **A** and $\mathcal{B}_d(t,f)$ is the dual symbol of **B**.

These different correspondence rules may be of interest for the study of special operators. The case $k=-1$ where

$$\lambda_{-1}(u)=e^{u/2} \tag{VII.27}$$

stands out. The symbolic calculus corresponding to $k=-1$ and $\beta_0=0$ has been introduced directly by Unterberger[21] who applied it in a mathematical context.

A Wigner function $\mathcal{P}_k^{\beta_0}(t,f)$ can be associated with each k-calculus. Because of the form of relation (VII.26), the Wigner function of signal $S(f)$ is defined as the dual symbol of the projector on the signal. We thus associate a time-frequency distribution with each value of (k,β_0). When $\beta_0=0$, these distributions coincide with the generalized passive distributions introduced in Ref. 16. The case $k=1$, which has not been treated explicitly here, can be deduced by continuity.

VIII. CONCLUSION

A correspondence rule between functions on the time-frequency half-plane and operators on the Hilbert space of positive-frequency signals has been obtained. The rule, which is said to be geometric, is entirely based on the study of the affine group and more specially on the representations of its subgroups in the two domains. It is obtained, relatively to each subgroup, by identification of the decomposition in invariant subspaces with the corresponding tomographic decomposition in the time-frequency half-plane. The construction is very natural and the result can be considered as an affine version of the Weyl rule introduced in quantum mechanics.

In the correspondence, a Lie algebra of Hermitian operators is transformed into a Lie algebra of symbols, also called star algebra. The basic operations of this algebra are the star product and the star bracket of symbols. Formulas for these operations have been given. Special attention has been paid to the case where the star bracket reduces to a Poisson bracket.

The obtained symbolic calculus has been integrated into a family of calculi covariant by three-parameter groups G_k, $k \in \mathbb{R}$, containing the affine group. In this family, the geometric rule corresponds to the special value $k=0$ and is the only one to ensure the unitarity property.

(Received 1 January 1998; accepted for publication 9 April 1998)

A recently introduced algorithm [Frick *et al.*, Astrophys. J. **483**, 426 (1997)] of spectral analysis of data with gaps via a modified continuous wavelet transform is developed and studied. This algorithm is based on a family of functions called ″gapped wavelets″ which fulfill the admissibility condition on the gapped support. The wavelet family is characterized by an additional parameter which should be calculated for every scale and position. Three theorems concerning the properties of gapped wavelet transform are formulated and proved. They affirm the global stability of the algorithm as well as its stability in both limits of large and small scales. These results are illustrated by some numerical examples, which show that the algorithm really attenuates the artifacts coming from gaps (and/or boundaries), and is particularly efficient at small and large scales. © *1998 American Institute of Physics.* [S0022-2488(98)01208-0]

I. INTRODUCTION

Finding periodicities in observed quantities has been a most important enterprise for a very long time. There are, however, many fields for which the data come with inevitable gaps due to the existence of time (or space) intervals at which measurements cannot be made. A prominent example is astronomy, where the gaps are caused by seasonal windows of observation, cloudy skies, telescope maintenance, etc. An illustrative example can be seen in Fig. 1.

The causes of the interruptions are in general not related to the quantities under study, and their effects are felt in several ways. The most direct one is, of course, the loss of useful information. A more insidious effect is the possible contamination of data with spurious periodicities arising from the spectral properties of the set of gaps.

A straightforward ''filling of the holes,'' either by interpolation or by arbitrary extension can have quite undesirable properties. A typical result of interpolation will be the smoothing of the signal, leading to the loss of information in high frequencies.

Fourier transform techniques have been adapted to such a situation: Welsh estimators[1] are perhaps the most commonly used. An extension of Fourier transform to an uneven data set is known in astronomy as the Lomb-Scargle periodogram.[2,3] The idea of this technique is to correct the basic functions $\cos(\omega t)$ and $\sin(\omega t)$ by a phase shift and a mean value subtraction to preserve their normalization conditions on a given set of observations.

In some instances, it is desirable to dispose of time-scale transforms. To this end, Foster[4] recently introduced an analogous algorithm for wavelet transform on an irregular data set. He considers the Morlet wavelets and proposes to reorthogonalize the three basic functions (the real and the imaginary parts of Morlet wavelet and a constant) by rotating the matrix of their scalar products.

We study here another technique for analyzing signals with gaps, introduced in Refs. 5,6 in connection with the spectral study of stellar chromospheric activity. Two examples of data records taken from Ref. 7 are given in Fig. 1. They show that the whole time of observations includes only few periods of main oscillation and that the total length of the gaps is comparable with the length of the record. The main idea of the proposed procedure is to consider the wavelet transform not as

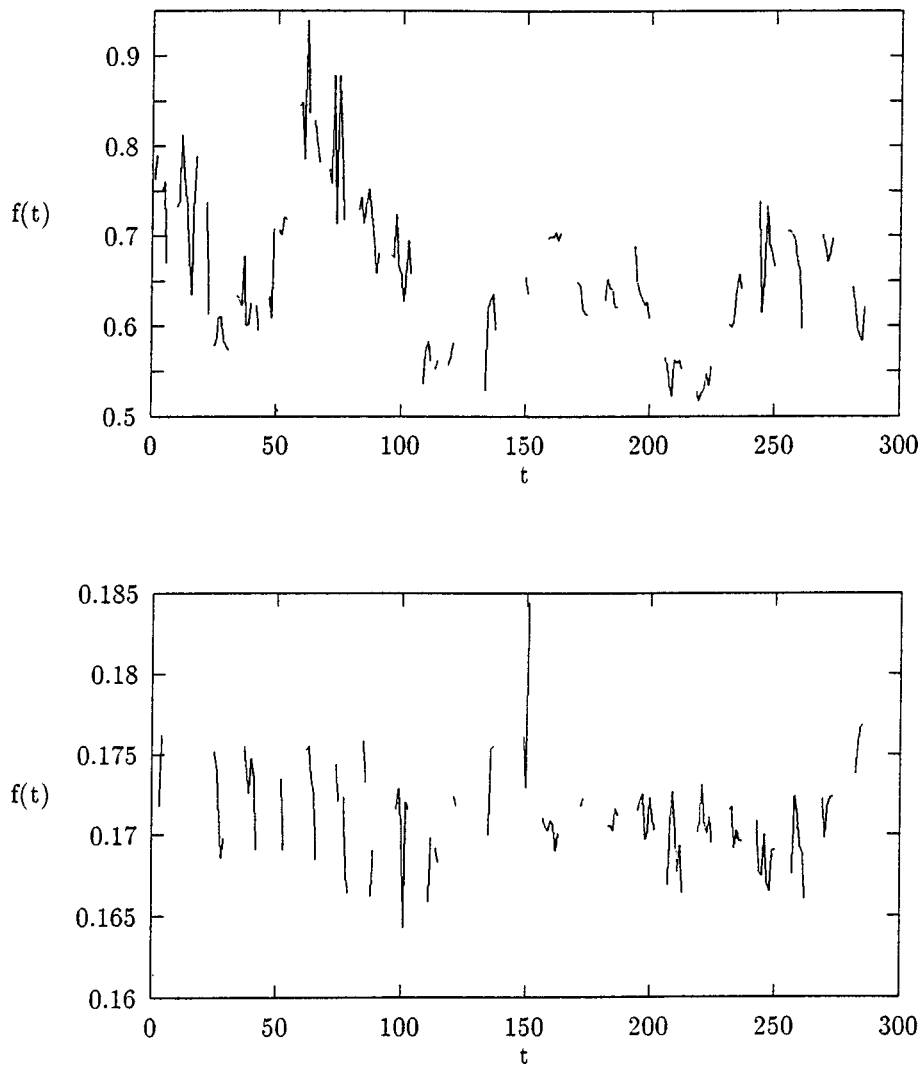

FIG. 1. Two typical examples of data with gaps which concern the stellar chromospheric activity of stars near the lower main sequence at the Mount Wilson Observatory. The figures are taken from Ref. 7.

a convolution of a signal with gaps and a given analyzing wavelet, but as a convolution of a signal and of a wavelet with gaps, thus transferring the gap problem from the unknown signal function to the known wavelet function. Punching holes in a wavelet will of course destroy its useful properties, and one tries to correct the broken wavelet by making it at least admissible.

The algorithm under consideration has been called in Refs. 5 and 6 ''adaptive wavelets'' to emphasize that the analyzing functions are modified by the gaps in the data. This name does not appear to be fortunate because of the extensive use of the word ''adaptive'' in wavelet analysis. This is why we shall write ''the gapped wavelet method'' or ''wavelets with gaps.''

The paper is organized as follows. In Sec. II the definition of wavelets with gaps is given. Some theorems concerning their properties are formulated. The possible developments of the method are also discussed. The properties of wavelet transform with gapped wavelets are illustrated by some examples in Sec. III. The proofs of theorems are given in Sec. IV.

II. DEFINITIONS AND MAIN STATEMENTS

For the sake of simplicity, we limit our study to the one-dimensional setting. The interested reader can verify that all the foregoing statements extend straightforwardly to the n-dimensional case.

Let $\Omega \subset \mathbb{R}$ be an open set. We want to develop a wavelet analysis for functions supported on Ω, which depends as little as possible on Ω. It turns out that the naive approach consisting in performing a standard wavelet analysis of f is not satisfactory. See Sec. III. The reason is the following. Let ψ be the mother wavelet, and denote as usual

$$\psi_{a,b}(x) = \frac{1}{a}\psi\left(\frac{x-b}{a}\right). \tag{1}$$

It is well known that ψ must satisfy the so-called *admissibility condition*, which essentially amounts to demand that the first moment of ψ vanishes. Obviously, when this condition is fulfilled, so it is for all the wavelets $\psi_{a,b}$.

Analyzing a given f supported in Ω means computing the coefficients $\langle f, \psi_{a,b}\rangle$. Hence, even if f is flat on Ω (for example, $f=\chi_\Omega$), this analysis will give significant coefficients for those values of b and a such that $\int_\Omega \psi_{a,b} \neq 0$. This is in contradiction with the very nature of wavelet transform. This is why it is desirable to modify the wavelets so as to enforce an adapted admissibility condition.

A. Gapped wavelets

We start by choosing a mother wavelet ψ satisfying the admissibility condition. We introduce next a non-negative envelope function ϕ such that $|\psi| \leqslant \phi$. Throughout the paper we assume ψ and ϕ to be rapidly decreasing at infinity, as well as their derivative. We define $\phi_{a,b}$ as in (1).

1. The family $\theta_{a,b}$

If $a>0$ and $b \in \mathbb{R}$ we define

$$\theta_{a,b} = \psi_{a,b}\chi_\Omega - C(a,b)\phi_{a,b}\chi_\Omega, \tag{2}$$

where

$$C(a,b) = \begin{cases} \dfrac{\int_\Omega \psi_{a,b}}{\int_\Omega \phi_{a,b}} & \text{if} \quad \displaystyle\int_\Omega \phi_{a,b} \neq 0, \\ 0 \quad \text{otherwise.} \end{cases} \tag{3}$$

This ensures that

$$\int_{\mathbb{R}^n} \theta_{a,b} = 0. \tag{4}$$

Let us note that as $|\psi| \leqslant \phi$, we have

$$|C(a,b)| \leqslant 1 \tag{5}$$

for all a,b. We emphasize that the analyzing function $\theta_{a.b}$ changes for every scale a and every position b if only a gap falls in its vicinity. Thus, strictly speaking, the family $\theta_{a,b}$ is not a family of wavelets because its self-similarity is broken.

2. The family $\theta^{(1)}_{a,b}$

This construction can be generalized by requiring the modified wavelets to have vanishing moments of higher orders. This can be achieved by introducing, for a given integer k, the functions

$$\theta^{(k)}_{a,b}(t) = \psi_{a,b}(t)\chi_\Omega(t) - \left(C_0(a,b) + C_1(a,b)\left(\frac{t-b}{a}\right) + \ldots + C_k(a,b)\left(\frac{t-b}{a}\right)^k\right)\phi_{a,b}(t)\chi_\Omega(t). \tag{6}$$

The constants C_j are readily obtained from the corresponding conditions

$$0 \leqslant j \leqslant k, \quad \int_\Omega \theta_{a,b}^{(k)}(t) \left(\frac{t-b}{a} \right)^j dt = 0. \tag{7}$$

For example, for $k=1$ one finds

$$C_0(a,b) = \frac{\int_\Omega \psi_{a,b} \int_\Omega ((t-b)/a)^2 \phi_{a,b} - \int_\Omega ((t-b)/a) \psi_{a,b} \int_\Omega ((t-b)/a) \phi_{a,b}}{\int_\Omega \phi_{a,b} \int_\Omega ((t-b)/a)^2 \phi_{a,b} - (\int_\Omega ((t-b)/a) \phi_{a,b})^2}, \tag{8}$$

$$C_1(a,b) = \frac{\int_\Omega \phi_{a,b} \int_\Omega ((t-b)/a) \psi_{a,b} - \int_\Omega \psi_{a,b} \int_\Omega ((t-b)/a) \phi_{a,b}}{\int_\Omega \phi_{a,b} \int_\Omega ((t-b)/a)^2 \phi_{a,b} - (\int_\Omega ((t-b)/a) \phi_{a,b})^2}. \tag{9}$$

Let us note that C_0 and C_1 are no longer necessarily bounded by 1. In numerical calculations, described below, we checked the values of these coefficients. They really can become larger than 1, but this only happens for large values of a, such that the (effective) support of the wavelet is at least of the same size as Ω. However, in such a case, the physical meaning of our analysis becomes doubtful.

B. Gapped wavelet transform: Definition and properties

In this subsection, we only consider the case $k=0$.

Definition 1: The gapped wavelet transform is the linear map which associates to any $f \in L^2(\Omega)$ *the set of scalars* $\langle f, \theta_{a,b} \rangle$, $b \in \mathbb{R}$, $a>0$.

As explained before, we may view f as the restriction to Ω of some square-integrable function globally defined on $\mathbb{R}$. Since only the values of f on Ω are relevant, there is no harm in not distinguishing between the various extensions of f in $\mathbb{R}$. For simplicity we will denote all of them by the same letter f. Therefore we have by construction

$$\langle f, \theta_{a,b} \rangle = \langle f \chi_\Omega, \theta_{a,b} \rangle. \tag{10}$$

Our first result states that this map is continuous from $L^2(\Omega)$ to $L^2(\mathbb{R} \times \mathbb{R}^+, (db\ da)/a)$, as for the usual wavelet transform. This is a stability result, in which the most remarkable point is that the stability constant A_0 (see the theorem below) does not depend on Ω. In other words, whatever the shape of Ω, the stability of the gapped wavelet transform is uniformly controlled.

Theorem 2: *There exists a constant* A_0, *independent of* Ω, *such that*

$$\int_0^{+\infty} \int_{\mathbb{R}} |\langle f, \theta_{a,b} \rangle|^2 \frac{da\ db}{a} \leqslant A_0 \int_\Omega |f|^2. \tag{11}$$

When Ω is of finite measure, we may assume that $m_\Omega f$, the mean value of f over Ω, vanishes, since $\int_\Omega \theta_{a,b} = 0$. Therefore, inequality (11) improves in

$$\int_0^{+\infty} \int_{\mathbb{R}} |\langle f, \theta_{a,b} \rangle|^2 \frac{da\ db}{a} \leqslant A_0 \int_\Omega |f - m_\Omega f|^2. \tag{12}$$

We now examine to what extent our gapped wavelet transform carries out some time-scale information. Let $(S_a)_{a>0}$ be a Littlewood–Paley approximation of identity, defined by a function Φ such that $\hat{\Phi}(\omega) = 1$ if $|\omega| \leqslant 1$, $\hat{\Phi}(\omega) = 0$ if $|\omega| \geqslant 2$. Denoting by Φ_a the function $(1/a)\, \Phi(./a)$ we write

$$S_a f = f * \Phi_a. \tag{13}$$

By construction, $S_a f$ is a smoothed version of f, at scale a. Since $\hat{\Phi}_a(\omega) = 1$ when $|\omega| \leqslant (1/a)$ and

$$\widehat{S_a f}(\omega) = \hat{f}(\omega) \hat{\Phi}_a(\omega), \tag{14}$$

the spectral content of f in the interval $|\omega| \leqslant 1/a$ is preserved under the action of S_a. Also, since $\hat{\Phi}_a(\omega)=0$ when $|\omega| \geqslant 2/a$, the spectral content of f in the domain $|\omega| \geqslant 2/a$ is totally erased.

Here of course, the constants 1 and 2 which we use when defining $\hat{\Phi}$ are arbitrary, and may be replaced by any other choice without changing the foregoing statements.

The next theorem describes how the coefficients $\langle f, \theta_{a,b} \rangle$, for fixed $a>0$, attenuate the low-frequency content of f.

Theorem 3: *There exists a constant $A_1>0$, independent of Ω, such that*

$$\int_{\mathbb{R}^n} |\langle S_{a'} f, \theta_{a,b} \rangle|^2 db \leqslant A_1 \left(\frac{a}{a'} \right)^2 \int_{\mathbb{R}} |S_{a'} f|^2, \tag{15}$$

for all $a' \geqslant a > 0$.

This means that $\langle f, \theta_{a,b} \rangle$ filters in f the frequencies lower in modulus than $1/a$. The exponent 2 in the term $(a/a')^2$ is directly linked to the vanishing of the first moment of the gapped wavelets. When using the functions $\theta_{a,b}^{(k)}$ for $k \geqslant 1$, one gets a term $(a/a')^{2k+2}$, provided the constants $C_i(a,b)$, $0 \leqslant i \leqslant k$, in (6) are uniformly controlled. This fact may be proved by a straightforward adaptation of the proof of the theorem (see Sec. IV below).

The situation is more subtle regarding the damping of the high-frequency content of f, because the geometry of Ω must be taken into consideration. This is the reason why we assume a mild regularity property on the boundary $\partial\Omega$ of Ω, quantified by an exponent $\alpha>0$, and defined as follows (for the sake of completeness, the definition is given in arbitrary dimension n).

Definition 4: Ω verifies the property (P_α), where $\alpha \in]0,1]$, when there exists a constant A_Ω, such that for all $b \in \mathbb{R}^n$ and for all $\rho, \varepsilon > 0$, $\varepsilon \leqslant \rho$ one has

$$\min \left\{ \begin{array}{l} |\{y \in B(b,\rho) \cap \Omega ; d(y, \partial\Omega) \leqslant \varepsilon\}| \\ |\{y \in B(b,\rho) \cap \Omega^c ; d(y, \partial\Omega) \leqslant \varepsilon\}| \end{array} \right\} \leqslant A_\Omega \left(\frac{\varepsilon}{\rho} \right)^\alpha |B(b,\rho)|. \tag{16}$$

Here $B(b,\rho)$ is the Euclidean ball of center b and radius ρ, while $|E|$ stands for the Lebesgue measure of E.

Such a property means that, at each scale ρ, the local density in Ω or in Ω^c of the strip around $\partial\Omega$ of width ε is uniformly controlled by $(\varepsilon/\rho)^\alpha$.

For example, if Ω is a finite union of open intervals in dimension 1, or if Ω is a regular domain (at least Lipschitz) in several dimensions, then (P_1) is true. Also, most classical examples of sets with fractal boundary, such as von Koch curve, do fulfill (P_α) for some $\alpha>0$.

Let us go back to our gapped wavelet transform, for an open set Ω fulfilling (P_α). The next theorem states that α describes the damping of the high-frequency content of f in the coefficients $\langle f, \theta_{a,b} \rangle$ for fixed $a>0$.

Theorem 5: *For any $\alpha \in]0,1]$, there exists a constant A_2, independent of Ω, such that if $\partial\Omega$ verifies the property (P_α)*

$$\int_{\mathbb{R}} |\langle f - S_{a'} f, \theta_{a,b} \rangle|^2 \, db \leqslant A_2 (1 + A_\Omega) \left(\frac{a'}{a} \right)^\alpha \int_{\mathbb{R}} |f - S_{a'} f|^2, \tag{17}$$

for all $a \geqslant a' > 0$.

The proof will show that this result does not rely on the cancellation properties of the gapped wavelets and thus is also valid for standard wavelet transforms.

III. ILLUSTRATIONS

The three theorems formulated above show that no dramatical changes (which lead to the growth of the spectral energy) are expected in the spectra of the signal calculated using the gapped wavelets $\theta_{a,b}$ and that the density of spectral energy which reflects the artifacts coming from the boundaries and gaps should be attenuated (at different rates) in both high and low frequencies.

No exact results have been obtained concerning the functions $\theta_{a,b}^{(1)}$, but in numerical simulations we used them as well as the functions $\theta_{a,b}$. We denote by $T0$ the results of the transform using the functions $\theta_{a,b}$, which are only admissible (the zeroth order moment vanishes), and as

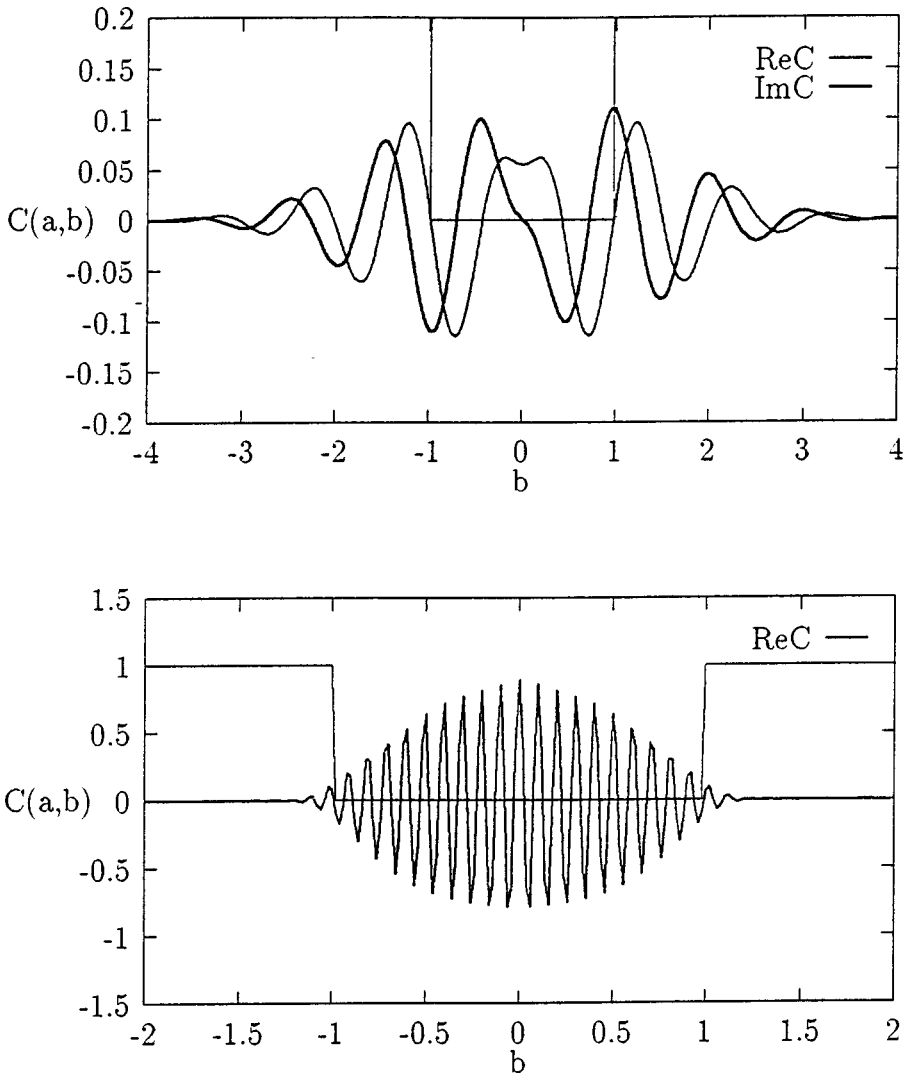

FIG. 2. Variations of parameter $C(a,b)$ in the vicinity of a gap $[-1,1]$ (the characteristic function is shown by the solid line). The real and the imaginary parts of $C(a,b)$ for $a=1$ are shown in the upper panel; the real part of $C(a,b)$ for $a=0.1$ is presented in the lower panel.

$T1$ the results of the transform using the functions $\theta_{a,b}^{(1)}$ for which the first order moment vanishes as well as the zeroth. We compare both with the standard wavelet transform with Morlet wavelet (denoted in the figures as M). Let us emphasize that in the latter case (taken as the reference) we also do not use any interpolation of signals in the gap, and we do not try to eliminate the mean value, the trend, etc.

In the examples to be discussed below, ψ is the Morlet wavelet

$$\psi(t)=e^{i\omega t}e^{-t^2/2} \tag{18}$$

with appropriate ω.

We show in Fig. 2 how the parameter $C(a,b)$ varies when the function $\theta_{a,b}$ passes through an isolated gap $[-1,1]$. In the upper panel of Fig. 2 is presented the graph for $a=1$. Both real and imaginary parts are shown. Notice that the modulus of C does not surpass the value 0.15. In the lower panel of the same figure we present the variations of the real part of $C(a,b)$ for $a=0.1$ (the imaginary one is not shown due to the high density of lines). Now, the maxima of C approach to one in the central part of the gap. Obviously, these large values of $C(a,b)$ correspond to strong

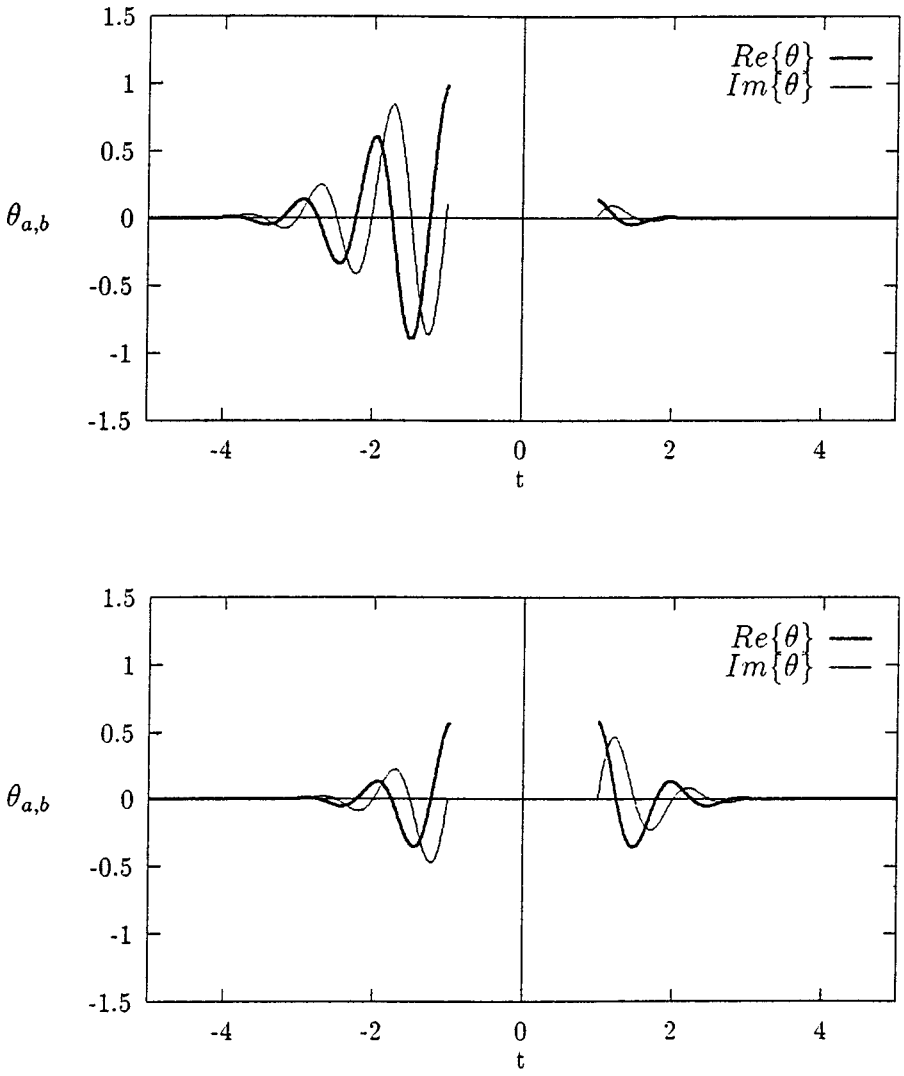

FIG. 3. Gapped wavelet $\theta_{a,b}(t)$ for $a=1$ when going through the gap $[-1,1]$: $b=-1$ (upper panel), $b=0$ (lower panel).

deformations of the analyzing wavelet, provided by the fact that only a far part of exponentially decreasing tail of the wavelet reaches the boundary of the gap. But this also implies that these strongly deformed functions do not give a considerable contribution.

Two examples of gapped wavelets $\theta_{a,b}(t)$ are shown on Fig. 3. We consider the same isolated gap $[-1,1]$ and the scale $a=1$. The functions $\theta_{a,b}(t)$ are plotted for two positions: $b=-1$, where the center of the wavelet is on the boundary of the gaps (upper panel of Fig. 3) and $b=0$, where the wavelet is centered in the gap. One can see that the analyzing wavelet does not undergo drastic changes in the domain lying away from the gap. The discontinuities of the gapped wavelet are on the boundary of the gap and do not introduce additional contributions in the wavelet transform.

We start by analyzing a function with a simple (gaussian) spectrum. The function $f(t)=1+t+\exp(-t^2/2)\cos(2\pi t)$ is a superposition of a Morlet wavelet and a linear trend. The function is given only in a single interval (window) $[-0.6,2.6]$ (Fig. 4.). The true spectrum of this function (the mean value of $|W(a,b)|^2$ for given a) is also shown on the same figure. One can see that the standard algorithm M gives a spectrum that increases with scale a, without any well pronounced peak at $a=1$. The algorithm $T0$ clearly displays the top of the Gaussian bump, but gives the wrong maximum at large scales. Algorithm $T1$ efficiently suppress the wrong power in the large scales, and also slightly improves the small scales part of the spectrum.

In Fig. 5 we show the wavelet spectrum for a harmonic signal superposed with a linear function and known on an interval with regular gaps. The basic spectrum M displays two wrong

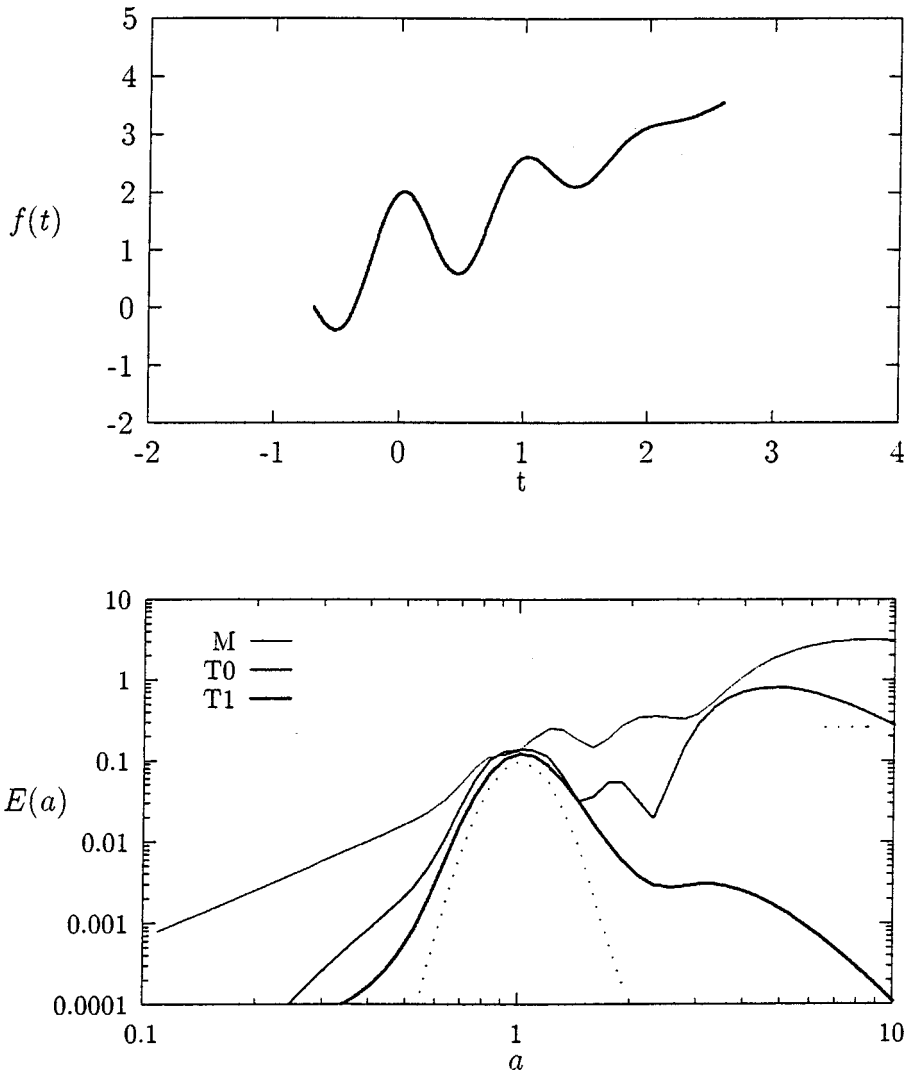

FIG. 4. The function $f(t)=1+t+\exp(-t^2/2)\cos(2\pi t)$ given on the interval $[-0.6,2.6]$ and its wavelet spectra M (line), $T0$(line) and $T1$ (line). The ''ideal'' spectrum is shown by a dotted line.

maxima with orders of magnitude comparable with the main one: in large scales and in a scale smaller than the main one. As indicated by the theorems proved above, the wrong maxima are suppressed in both large and small scales. The transform $T1$ is again essentially more effective in large scales. Let us note that the standard algorithm displays the main maximum at $a=0.74$, $T0$ gives $a=0.76$ and $T1$ shows the maximum at $a=0.79$ (the true value is $a=0.8$ and is marked in the figure by an arrow). This indicates that the gapped wavelet technique not only suppresses the low and high noise frequencies, but is also better at estimating the frequency of the signal.

The next example (Fig. 6) presents a signal with two frequencies in a linear background. In this case the standard technique produces an additional peak in intermediate scales. The gapped algorithm eliminates it. The large scale artifact is again better suppressed by the wavelets $T1$.

The last example (Fig. 7) presents a signal with two harmonic components without any background but with regular gaps. The results show that there is an unavoidable artifact (the left peak, which remains on the same magnitude in all three spectra). At the same time one sees that the standard techniques absolutely lost the high frequency, which is drowned in noise, in spite of being well observed by the naked eye. In the gapped wavelet method spectra this frequency gives a pronounced peak.

Surely, there are a lot of possibilities to improve the results of wavelet transform of signals

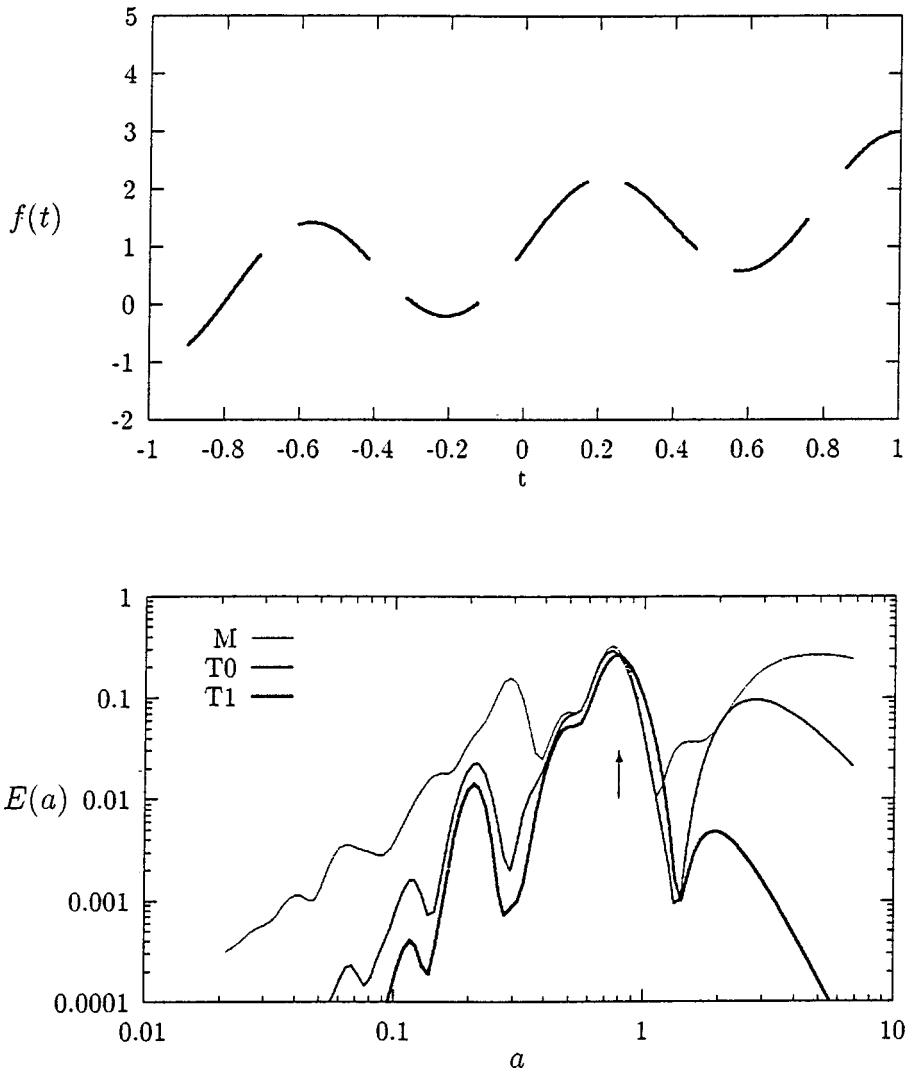

FIG. 5. The analyzed signal $f(t)=1+t+\sin((4\pi/5)\,t)$ with gaps (above) and its spectra (below), obtained by standard Morlet wavelet (M) and gapped wavelets θ ($T0$) and $\theta^{(1)}$ ($T1$). The true frequency is marked by the arrow.

with gaps, especially in a concrete situation when the expected character of the signal is known *a priori*.

Our examples illustrate the proved properties of gapped wavelets $\theta_{a,b}$ and show that the wavelets $\theta^{(1)}_{a,b}$ provide further improvement of spectral resolution of the wavelet transform.

IV. PROOFS

In what follows, the letter A denotes a constant, which may change from line to line.

A. Proof of Theorem 2

This proof is based on classical estimates in the theory of singular integral operators. One can show the following result:

Lemma 6: The matrix $(\langle \theta_{a,b}, \theta_{a',b'} \rangle)$, where $a,a'>0$, $b,b' \in \mathbb{R}$, *defines a continuous operator in* $L^2(\mathbb{R}^2_+, db\ da/a)$.

In this statement, the word ''matrix'' is used by analogy with the standard case where the parameters a,b belong to a discrete, or even finite, set.

Lemma 6 implies Theorem 2. Indeed, if we define an operator T by

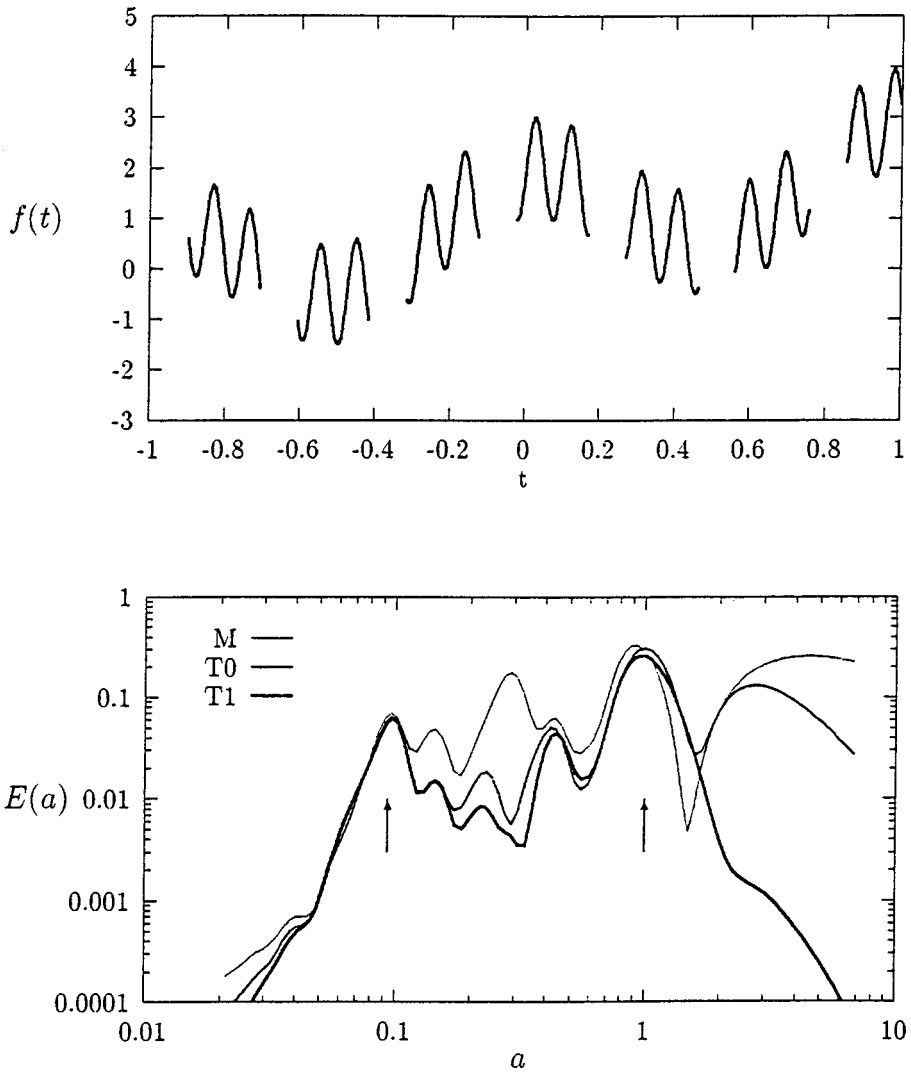

FIG. 6. The analyzed signal $f(t)=t+c+\cos(2\pi t)+\sin(21\pi t)$ with gaps and its spectra. Both frequencies are marked in the scales by arrows.

$$Tf=\int\int \langle f,\theta_{a,b}\rangle \theta_{a,b}\frac{da\ db}{a} \tag{19}$$

then we have

$$\langle Tf,f\rangle=\int\int |\langle f,\theta_{a,b}\rangle|^2\frac{da\ db}{a} \tag{20}$$

and

$$\langle Tf,Tf\rangle=\int\int\int\int \langle f,\theta_{a,b}\rangle\langle \theta_{a,b},\theta_{a',b'}\rangle\langle f,\theta_{a',b'}\rangle\frac{da\ db}{a}\frac{da'db'}{a'}. \tag{21}$$

Applying Lemma 6 to the r.h.s. of (21), we get

$$\langle Tf,Tf\rangle\leqslant A_0\langle Tf,f\rangle \tag{22}$$

which implies continuity of T with $\|T\|\leqslant A_0$. Here A_0 is the norm of the operator defined by $(\langle \theta_{a,b},\theta_{a',b'}\rangle)$. We have to show that it can be bounded uniformly in Ω.

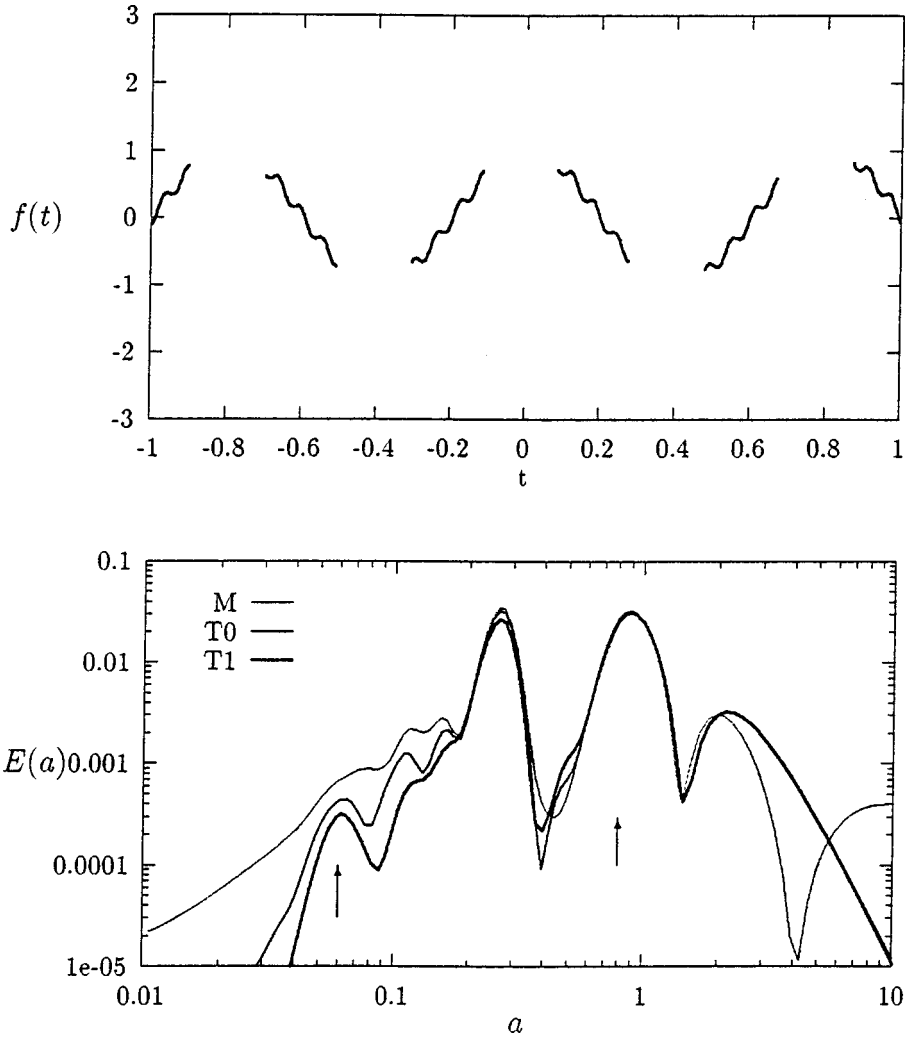

FIG. 7. The analyzed signal $f(t)=\cos(5\pi t/2)+0.1\,\sin(33\pi t)$ with gaps and its spectra.

To do so, we shall show that there exists a constant A, independent on Ω, such that

$$\int\int |\langle \theta_{a,b}, \theta_{a',b'}\rangle| \frac{da'\ db'}{a'} \leqslant A \tag{23}$$

for all $a>0$, $b\in\mathbb{R}$. This inequality implies that the matrix $(\langle \theta_{a,b}, \theta_{a',b'}\rangle)$ defines a continuous operator on $L^{\infty}(\mathbb{R}^2_+, da\ db/a)$. By symmetry one gets the continuity of the same operator on $L^1(\mathbb{R}^2_+, da\ db/a)$ and, by interpolation, on $L^2(\mathbb{R}^2_+, da\ db/a)$. In addition, the corresponding operator norms are controlled by the constant A of (23), which does not depend on Ω.

The proof of (23) depends on the following estimates. By assumption, there exists A such that the wavelet ψ and the function ϕ satisfy the estimates

$$|\psi(x)|+\phi(x)\leqslant A(1+|x|)^{-3}, \tag{24}$$

$$|\psi(x+h)-\psi(x)|+|\phi(x+h)-\phi(x)|\leqslant A|h|(1+|x|)^{-3}, \tag{25}$$

if $x,h\in\mathbb{R}$ and $|h|\leqslant |x|/2$. We set

$$\omega(x)=(1+|x|)^{-3}. \tag{26}$$

Lemma 7: There exists a constant A, independent of Ω, *such that*

$$|\langle \theta_{a,b}, \theta_{a',b'} \rangle| \leqslant A \frac{a'}{a^2} \omega\left(\frac{b'-b}{a} \right) \tag{27}$$

for all $a \geqslant a' > 0$ *and* $b, b' \in \mathbb{R}$.

If $a \geqslant a'$

$$\langle \theta_{a,b}, \theta_{a',b'} \rangle = \int [\psi_{a,b}(x) - C(a,b)\phi_{a,b}(x)] \overline{\theta_{a',b'}(x)} \tag{28}$$

as $G^2 = G$. Since the first moment of $\theta_{a',b'}$ is zero, one can write

$$\langle \theta_{a,b}, \theta_{a',b'} \rangle = \int [\psi_{a,b}(x) - \psi_{a,b}(b')] \overline{\theta_{a',b'}(x)} dx - C(a,b) \int [\phi_{a,b}(x) - \phi_{a,b}(b')] \overline{\theta_{a',b'}(x)} dx. \tag{29}$$

The first term on the r.h.s. is controlled by

$$A \int \frac{|x-b'|}{a^2} \left[\omega\left(\frac{x-b}{a} \right) + \omega\left(\frac{b'-b}{a} \right) \right] \frac{1}{a'} \omega\left(\frac{x-b'}{a'} \right) dx \tag{30}$$

by (5), (24), and (25). This integral can be evaluated as

$$A \frac{a'}{a^2} \omega\left(\frac{b-b'}{a} \right). \tag{31}$$

The second term on the r.h.s. of (29) is controlled in the same way. This completes the proof of Lemma 7.

One then deduces (23) by writing

$$\begin{aligned} &\int \int |\langle \theta_{a,b}, \theta_{a',b'} \rangle| \frac{db'\,da'}{a'} \\ &\leqslant A \int \int_{a' \geqslant a} \frac{a}{a'^2} \omega\left(\frac{b-b'}{a'} \right) \frac{db'\,da'}{a'} + A \int \int_{a' \leqslant a} \frac{a'}{a^2} \omega\left(\frac{b-b'}{a} \right) \frac{db'\ da'}{a'} \\ &\leqslant A \int_a^{+\infty} \frac{a}{a'} \frac{da'}{a'} + A \int_0^a \frac{a'}{a} \frac{da'}{a'} = 2A. \end{aligned} \tag{32}$$

Thus inequality (23) is proved and the proof of theorem 2 is completed.

B. Proof of Theorem 3

Theorem 3 is a consequence of estimates which are close analogs of the preceding ones. Denoting by $\tilde{\Phi}$ the function

$$\tilde{\Phi}(x) = 2\Phi(2x) \tag{33}$$

one has by construction $\tilde{\Phi} * \Phi = \Phi$. From this one gets the identity

$$\tilde{S}_a S_a = S_a, \tag{34}$$

where $\tilde{S}_a$ is the convolution operator with $\tilde{\Phi}_a$. Thus, if $0 < a \leqslant a'$, then

$$\langle S_{a'} f, \theta_{a,b} \rangle = \langle S_{a'} f, \tilde{S}_{a'} \theta_{a,b} \rangle. \tag{35}$$

Inequality (15) is a simple consequence of

Lemma 8: If $0<a\leqslant a'$ *then*

$$|\tilde{S}_{a'}\theta_{a,b}(x)|\leqslant A\frac{a}{a'^2}\omega\left(\frac{x-b}{a'}\right), \tag{36}$$

where A is independent of Ω.

We leave it to the reader to verify that (35) and (36) imply (15) and only explain why (36) is true. We write

$$\tilde{S}_{a'}\theta_{a,b}(x)=\int \tilde{\Phi}_{a'}(x-y)\,\theta_{a,b}(y)dy=\int [\tilde{\Phi}_{a'}(x-y)-\tilde{\Phi}_{a'}(x-b)]\theta_{a,b}(y)dy. \tag{37}$$

Thus one gets as in the proof of (27)

$$|\tilde{S}_{a'}\theta_{a,b}(x)|\leqslant A\int \frac{|y-b|}{a'^2}\left[\omega\left(\frac{x-y}{a'}\right)+\omega\left(\frac{x-b}{a'}\right)\right]\frac{1}{a}\omega\left(\frac{y-b}{a}\right)dy\leqslant A\frac{a}{a'^2}\omega\left(\frac{x-b}{a'}\right). \tag{38}$$

C. Proof of Theorem 5

Let Ψ be an even C^∞ function, such that Supp $\Psi\subset\{\omega\in\mathbb{R};1/4\leqslant|\omega|\leqslant 1\}$, and

$$\int_0^{+\infty}\hat{\Psi}(\tau\omega)\frac{d\tau}{\tau}=1 \tag{39}$$

for all $\omega\neq 0$.

Then, if Δ_τ is the convolution operator by Ψ_τ, where $\Psi_\tau(t)=(1/\tau)\,\Psi(t/\tau)$, the above identity means that for any $f\in L^2(\mathbb{R})$ one has

$$f=\int_0^{+\infty}\Delta_\tau f\frac{d\tau}{\tau}. \tag{40}$$

By construction, one has

$$\Delta_\tau(I-S_{a'})=0 \tag{41}$$

if $\tau\geqslant a'$. It follows that

$$(I-S_{a'})f=\int_0^{a'}\Delta_\tau(I-S_{a'})f\frac{d\tau}{\tau}. \tag{42}$$

This identity enables us to deduce Theorem 5 from the inequality

$$\int_{\mathbb{R}}|\langle\Delta_\tau f,\theta_{a,b}\rangle|^2db\leqslant A(1+A_\Omega)\left(\frac{\tau}{a}\right)^\alpha\int_{\mathbb{R}}|\Delta_\tau f|^2, \tag{43}$$

where $0<\tau\leqslant a$.

Indeed, if $a'\leqslant a$ one applies (42) and then the Minkowski inequality and (43). That gives

$$\left(\int_{\mathbb{R}}|\langle f-S_{a'}f,\theta_{a,b}\rangle|^2db\right)^{1/2}\leqslant A(1+A_\Omega)^{1/2}\int_0^{a'}\left(\frac{\tau}{a}\right)^{\alpha/2}\left(\int_{\mathbb{R}}|\Delta_\tau(I-S_{a'})f|^2\right)^{1/2}\frac{d\tau}{\tau}. \tag{44}$$

Using the Cauchy–Schwarz inequality one gets

$$\int_{\mathbb{R}}|\langle f-S_{a'}f,\theta_{a,b}\rangle|^2db\leqslant A(1+A_\Omega)\left(\int_0^{a'}\left(\frac{\tau}{a}\right)^\alpha\frac{d\tau}{\tau}\right)\left(\int_0^{+\infty}\|\Delta_\tau(I-S_{a'})f\|_2^2\frac{d\tau}{\tau}\right). \tag{45}$$

To deduce inequality (17) one computes

$$\int_0^{+\infty} \|\Delta_\tau (I - S_{a'}) f\|_2^2 \frac{d\tau}{\tau} = A \|(I - S_{a'}) f\|_2^2, \tag{46}$$

and

$$\int_0^{a'} \left(\frac{\tau}{a}\right)^\alpha \frac{d\tau}{\tau} = \frac{1}{\alpha}\left(\frac{a'}{a}\right)^\alpha. \tag{47}$$

It remains to prove (43), by using the geometric hypothesis (P_α). One starts by taking a function $\tilde{\Psi}$, even and C^∞, such that $\hat{\tilde{\Psi}}(\omega) = 1$ if $\omega \in \text{Supp } \hat{\Psi}$, with

$$\text{Supp } \hat{\tilde{\Psi}} \subset \left\{ \omega \in \mathbb{R}^n; \tfrac{1}{8} \leqslant |\omega| \leqslant 2 \right\}. \tag{48}$$

Denoting as usual by $\tilde{\Delta}_\tau$ the convolution operator by $\tilde{\Psi}_\tau$ one gets

$$\tilde{\Delta}_\tau \Delta_\tau = \Delta_\tau, \tag{49}$$

from which one obtains

$$\langle \Delta_\tau f, \theta_{a,b} \rangle = \langle \Delta_\tau f, \tilde{\Delta}_\tau \theta_{a,b} \rangle. \tag{50}$$

Lemma 9: There exists a constant A, independent of Ω, *such that, if* $\tau \leqslant a$, *then for any* $x \in \mathbb{R}$

$$\int_{\mathbb{R}} |\tilde{\Delta}_\tau \theta_{a,b}(x)| db \leqslant A, \tag{51}$$

and for any $b \in \mathbb{R}$

$$\int_{\mathbb{R}} |\tilde{\Delta}_\tau \theta_{a,b}(x)| dx \leqslant A(1 + A_\Omega)\left(\frac{\tau}{a}\right)^\alpha. \tag{52}$$

Inequality (51) means that the operator associating to any function g the function

$$b \mapsto \langle g, \tilde{\Delta}_\tau \theta_{a,b} \rangle \tag{53}$$

(where a and τ are two fixed parameters with $\tau \leqslant a$), is uniformly bounded on $L^1(\mathbb{R})$. Inequality (52) means that the same operator is bounded on $L^\infty(\mathbb{R})$ and that its norm is controlled by

$$A(1 + A_\Omega)\left(\frac{\tau}{a}\right)^\alpha. \tag{54}$$

Inequality (43) follows by interpolation.

Now, let us prove (51). It is enough to write

$$\tilde{\Delta}_\tau \theta_{a,b}(x) = \int_{\mathbb{R}} \tilde{\Psi}_\tau (x - y) \theta_{a,b}(y) dy, \tag{55}$$

and to note that by (5) for any y

$$\int_{\mathbb{R}} |\theta_{a,b}(y)| db \leqslant \|\psi\|_1 + \|\phi\|_1. \tag{56}$$

This yields (51).

The proof of (52) is more elaborate. We write

$$\tilde{\Delta}_\tau \theta_{a,b}(x) = \int_{\mathbb{R}} \tilde{\Psi}_\tau(x-y) G(y) [\psi_{a,b}(y) - C(a,b)\phi_{a,b}(y)] dy. \tag{57}$$

Let us start with

$$\int_{\mathbb{R}} \tilde{\Psi}_\tau(x-y) G(y) \phi_{a,b}(y) dy = \int_{\mathbb{R}} \tilde{\Psi}_\tau(x-y) G(y) [\phi_{a,b}(y) - \phi_{a,b}(x)] dy + \tilde{\Delta}_\tau G(x) \phi_{a,b}(x). \tag{58}$$

The first term on the right is controlled by

$$A \frac{\tau}{a^2} \omega\left(\frac{x-b}{a}\right), \tag{59}$$

as we have seen several times. Its integral with respect to x is dominated by $A\tau/a$.

The hypothesis (P_α) is used for the second term.

Lemma 10: There exists an absolute constant A such that

$$\left| \int_{\mathbb{R}} \tilde{\Delta}_\tau G(x) \phi_{a,b}(x) dx \right| \leqslant A A_\Omega \left(\frac{\tau}{a}\right)^\alpha, \tag{60}$$

for all $\tau \leqslant a$, $b \in \mathbb{R}$.

Admit this result for the moment. Then one has

$$\int_{\mathbb{R}} \left| \int_{\mathbb{R}} \tilde{\Psi}_\tau(x-y) G(y) \phi_{a,b}(y) dy \right| dx \leqslant A(1+A_\Omega) \left(\frac{\tau}{a}\right)^\alpha. \tag{61}$$

By the same argument, one obtains

$$\int_{\mathbb{R}} \left| \int_{\mathbb{R}} \tilde{\Psi}_\tau(x-y) G(y) \psi_{a,b}(y) dy \right| dx \leqslant A(1+A_\Omega) \left(\frac{\tau}{a}\right)^\alpha. \tag{62}$$

Lemma 9 is thus completely proved using (58) and (5) once more.

It remains to prove Lemma 10. There exist two rapidly decreasing sequences of numbers $(c_k)_{k\in\mathbb{Z}}$ and $(d_l)_{l\in\mathbb{Z}}$ and two sequences of functions $(\phi_k)_{k\in\mathbb{Z}}$ and $(\tilde{\Psi}_l)_{l\in\mathbb{Z}}$ satisfying the following properties:

$$\begin{cases} \phi(x) = \sum_{k\in\mathbb{Z}} c_k \phi_k(x), & \tilde{\Psi}(x) = \sum_{l\in\mathbb{Z}} d_l \tilde{\Psi}_l(x), \\ \text{Supp } \phi_k \subset [k-1, k+1], & \text{Supp } \tilde{\Psi}_l \subset [l-1, l+1], \\ \|\phi_k\|_\infty = \|\tilde{\Psi}_l\|_\infty = 1, & \\ \int_{\mathbb{R}} \tilde{\Psi}_l = 0. & \end{cases} \tag{63}$$

One constructs these objects with the help of a partition of the identity which is used to decompose ϕ on one hand, and the primitive of $\tilde{\Psi}$ vanishing at infinity on the other hand. This gives directly the c_k, ϕ_k, and by differentiation the d_l, $\tilde{\Psi}_l$. The sequences (c_k) and (d_l) are rapidly decreasing because so are ϕ and the primitive of $\tilde{\Psi}$, since $\int \tilde{\Psi} = 0$. Verifying the other properties in (63) is straightforward.

One can now write

$$\tilde{\Delta}_\tau G(x)\phi_{a,b}(x)=\sum_k \sum_l c_k d_l \int_{\mathbb{R}} \frac{1}{\tau}\tilde{\Psi}_l\left(\frac{x-y}{\tau}\right) G(y)dy \frac{1}{a}\phi_k\left(\frac{x-b}{a}\right). \tag{64}$$

Let us examine the integral

$$I_{kl}=\int_{\mathbb{R}}\left|\int_{\mathbb{R}}\frac{1}{\tau}\tilde{\Psi}_l\left(\frac{x-y}{\tau}\right)G(y)dy\right|\frac{1}{a}\phi_k\left(\frac{x-b}{a}\right)dx, \tag{65}$$

(we may suppose ϕ_k non-negative.) By support considerations, we may assume that $y\in\Omega$, $(x-y)/\tau\in[k-1,k+1]$ and $(x-b)/a\in[l-1,l+1]$. Moreover, since $\int\tilde{\Psi}_l=0$, the integral w.r.t. y does not vanish only when Supp $\tilde{\Psi}_l((x-)/\tau$ intersects Ω^c, which implies $d(y,\partial\Omega)\leqslant 2\tau$. We notice that

$$\left\{(x,y);\frac{x-b}{a}\in[l-1,l+1],\frac{x-y}{\tau}\in[k-1,k+1],y\in\Omega,d(y,\partial\Omega)\leqslant 2\tau\right\}\subset\mathscr{E}_{kl}, \tag{66}$$

where

$$\mathscr{E}_{kl}=\{(x,y);x\in[y+(k-1)\tau,y+(k+1)\tau],$$
$$y\in\Omega\cap[b-k\tau+a(l-2),b-k\tau+a(l+2)],d(y,\partial\Omega)\leqslant 2\tau\}. \tag{67}$$

We thus have, using (63)

$$I_{kl}\leqslant\frac{1}{\tau a}|\mathscr{E}_{kl}|\leqslant\frac{2}{a}|\mathscr{E}'_{kl}|, \tag{68}$$

where

$$\mathscr{E}'_{kl}=\{y\in\Omega\cap[b-k\tau+a(l-2),b-k\tau+a(l+2)],d(y,\partial\Omega)\leqslant 2\tau\}. \tag{69}$$

Using once more $\int\tilde{\Psi}_l=0$, we replace G by $1-G$ in I_{kl} without changing anything, which amounts to replacing Ω by Ω^c. Hence we also have

$$I_{kl}\leqslant\frac{2}{a}|\mathscr{E}''_{kl}|, \tag{70}$$

where

$$\mathscr{E}''_{kl}=\{y\in\Omega^c\cap[b-k\tau+a(l-2),b-k\tau+a(l+2)],d(y,\partial\Omega)\leqslant 2\tau\}. \tag{71}$$

By (P_α), we have

$$I_{kl}\leqslant 8A_\Omega\left(\frac{\tau}{a}\right)^\alpha. \tag{72}$$

Summing over $k,l\in\mathbb{Z}$ achieves the proof of Lemma 10, and the theorem follows.

V. FURTHER CONSIDERATIONS

The gapped wavelet transform is a simple alternative to the well-known construction of wavelet bases on an interval or a domain (e.g., Ref. 8), which could also be used to define spectral estimators (see Ref. 9).

It should be noted that the computation of the coefficients $\langle f,\theta_{a,b}\rangle$ basically involves standard wavelet and scaling function coefficients of the signal and of the characteristic function of its support. It is therefore possible in principle to use a pyramidal algorithm, following the ideas of Refs. 10,11.

Finally, let us point out that the existence of a reconstruction formula similar to the usual one is an open problem.

ACKNOWLEDGMENTS

Discussions with B. Torrésani have contributed very much to this paper. In particular, the idea of introducing the family $\theta^{(1)}_{a,b}$ is due to him. We study various existence and uniqueness results for solutions of the Navier–Stokes equations in connection with function spaces related to real harmonic analysis. © *1998 American Institute of Physics.* [S0022-2488(98)01708-3]

I. INTRODUCTION

In this paper, we are mainly interested in reviewing recent results concerning weak solutions of the Navier–Stokes equations which belong to $\mathscr{C}([0,+\infty),L^3(\mathbb{R}^3))$. Such solutions were first studied by Kato[1] in 1984. L^3 estimates have been used as well in the study of Leray's weak solutions, leading to the uniqueness theorem of Sohr and Von Wahl.[2]

A new impetus has been given to the study of such solutions by the recent book of Cannone.[3] Following the idea of Federbush[4] that a good time-frequency analysis of the fluctuation term (see below) could give new existence theorems, Cannone uses the Littlewood–Paley decomposition instead of divergence-free wavelet bases (used in Ref. 4) to provide a precise analysis of the fluctuation. In Ref. 5, we show how this *frequential* analysis of the fluctuation, in terms of a *Besov norm*, could solve the uniqueness problem for solutions in $\mathscr{C}([0,+\infty),L^3(\mathbb{R}^3))$. This frequential approach is highlighted by a result of Le Jan and Sznitman,[6] which shows us how to deal with the Fourier transform of the Navier–Stokes equations. A short time after our result, Meyer proposed a new proof using only *spatial* estimates, in terms of a *Lorentz norm*.[7] We find very striking the fact that there is yet no actual *time-frequency* analysis of the Navier–Stokes equations.

We will show as well the relation between our result and the Sohr and Von Wahl theorem. This implies introducing energy estimates for L^3 solutions, a technique which is useful for proving the existence of weak solutions for an initial value with infinite energy.[8]

Besides, we will pay a few words on the self-similar solutions described by Cannone[3] and some related asymptotic results of Planchon.[9]

II. THE NAVIER–STOKES EQUATIONS IN $\mathbb{R}^3$

The classical *Navier–Stokes equations* describe the motion of a Newtonian fluid; we consider only the case when the fluid is viscous, homogeneous, incompressible and fills the entire space and is not submitted to external forces; then, the equations describing the evolution of the motion $\mathbf{u}(t,x)$ of the fluid element at time t and position x are given by

$$\rho\partial_t\mathbf{u}=\mu\Delta\mathbf{u}-\rho(\mathbf{u}\cdot\nabla)\mathbf{u}-\nabla p, \tag{1}$$

$$\nabla\cdot\mathbf{u}=0. \tag{2}$$

ρ is the (constant) *density* of the fluid, and we may assume with no loss of generality that $\rho=1$. μ is the *viscosity* coefficient, and we may assume as well that $\mu=1$. p is the (unknown) *pressure*, whose action is to maintain the divergence of $\mathbf{u}$ to be 0 (this *divergence free* condition expresses the incompressibility of the fluid). p can be expressed as a function of $\mathbf{u}$, provided that $\mathbf{u}$ vanishes at infinity; indeed, taking the divergence of (1), we obtain

$$\Delta p=-\nabla\cdot(\mathbf{u}\cdot\nabla)\mathbf{u}, \tag{3}$$

a)Electronic mail: lemarie@lami.univ-evry.fr

 © 1998 American Institute of Physics

and this formula allows one to eliminate p in many cases: indeed, formula (3) determines p up to a harmonic function and the requirement that $\mathbf{u}$ remains equal to 0 at infinity allows one to get rid of the contribution this harmonic term could have given to $\partial_t \mathbf{u}$.

Since $\nabla \cdot \mathbf{u} = 0$, the equation (1) can be rewritten as well as

$$\partial_t \mathbf{u} = \Delta \mathbf{u} - \nabla \cdot (\mathbf{u} \otimes \mathbf{u}) - \nabla p, \tag{4}$$

and we shall thus study solutions of (4) and (2) which vanish in a suitable sense at $x = \infty$. Moreover, we complement (4) and (2) (and the boundary condition $\mathbf{u} = 0$ at infinity) by an initial value $\mathbf{u} = \mathbf{u}_0$ at $t = 0$, and we study solutions for $t > 0$.

There is a huge amount of literature on the mathematical theory of the Navier–Stokes equations; classical references are the books by Temam,[10] Ladyzhenskaya[11] or Constantin and Foias;[12] a more recent reference is the book by Lions.[13]

A *classical solution* of (2) and (4) is a time-dependent vector field which has one bounded and continuous time derivative and two bounded and continuous space derivatives. The existence of such solutions was obtained first by Oseen in the beginning of the century.[14] Following the Picard iteration scheme, $\mathbf{u}$ is obtained as a fixed point of the associated integral transform: one considers first the linear problems (P1) and (P2):

$$\nabla \cdot \mathbf{u}_1 = 0, \ \partial_t \mathbf{u}_1 = \Delta \mathbf{u}_1 - \nabla p_1, \ \mathbf{u}_1(0,\cdot) = \mathbf{u}_0, \tag{P1}$$

$$\nabla \cdot \mathbf{u}_2 = 0, \ \partial_t \mathbf{u}_2 = \nabla \mathbf{u}_2 + \mathbf{f} - \nabla p_2, \ \mathbf{u}_2(0,\cdot) = 0. \tag{P2}$$

The first one is easily solved by $\mathbf{u}_1 = e^{t\Delta}\mathbf{u}_0 = W_t * \mathbf{u}_0$ where $W_t(x) = (4\pi t)^{-3/2} e^{-|x|^2/4t}$ is the heat kernel on $\mathbb{R}^3$. The second one is solved by the integral formula: $\mathbf{u}_2 = \int_0^t \mathbb{P} e^{(t-s)\Delta} \mathbf{f}(s)\,ds = \int_0^t O_{t-s} * \mathbf{f}(s)\,ds$ where $\mathbb{P}$, the *Leray–Hopf projection operator* on divergence free vector fields, is formally given as the operator matrix $Id_3 - (1/\Delta)\nabla \otimes \nabla$ and where the *Oseen kernel* $O_t(x) = t^{-3/2} O(x/\sqrt{t})$ is a matrix function given by $O_{k,l}{}^{(x)} = (2\pi)^{-3} \int_{\mathbb{R}^3} [(|\xi|^2 \delta_{k,l} - \xi_k \xi_l)/|\xi|^2] \times e^{-|\xi|^2} e^{ix\cdot\xi} d\xi$. The functions $O_{k,l}$ are analytical on $\mathbb{R}^3$ and satisfy for all $\alpha \in \mathbb{N}^3$ the estimate $|(\partial^{|\alpha|}/\partial x^\alpha) O_{k,l}(x)| \leq C_\alpha (1+|x|)^{-(3+|\alpha|)}$. Then, we seek a solution $\mathbf{u}$ of the Navier–Stokes equations as a solution of the integral equation:

$$\mathbf{u} = e^{t\Delta}\mathbf{u}_0 - \int_0^t (\nabla \otimes O_{t-s}) * (\mathbf{u} \otimes \mathbf{u})\,ds, \tag{5}$$

where the j-th component of $(\nabla \otimes O_{t-s}) * (\mathbf{u} \otimes \mathbf{u})$ is given by $\Sigma_k \Sigma_l [1/(t-s)^2] \times \partial_k O_{j,l}(x/\sqrt{t-s}) * (u_k(s,x) u_l(s,x))$. Following Federbush, we call $e^{t\Delta}\mathbf{u}_0$ the tendency and $\int_0^t (\nabla \otimes O_{t-s}) * (\mathbf{u} \otimes \mathbf{u})\,ds$ the *fluctuation*.

The existence of a classical solution, whatever regular the initial value may be, is guaranteed only for a finite interval of time. If we look for *global solutions*, i.e., solutions defined for every $t > 0$, we have to consider *weak solutions*, which were introduced in 1934 by Leray[15] for $\mathbf{u}_0 \in (L^2)^3$, or *mild solutions*, which were introduced by Kato in the early 60's for the equations on a bounded domain and an initial value in a Sobolev space[16] and in 1984[1] for the equations on the whole space and $\mathbf{u}_0 \in (L^3)^3$. Weak solutions satisfy equations (2) and (4) in the sense of distributions and mild solutions satisfy the integral equation (5). As a matter of fact, the notion of mild solutions refers to an abstract approach of evolution equations in a Banach space, but we shall stick to a more simple definition, because in the whole space the Oseen kernel is quite explicit and so the integral equation can be handled in a more direct way.

III. WEAK AND MILD SOLUTIONS

We begin by defining weak and mild solutions of the Navier–Stokes equations on the whole space.

Definition 1 (weak solutions)*:* A *weak solution* of the Navier–Stokes equations on $(0,T) \times \mathbb{R}^3$ is a distribution vector field $\mathbf{u}(t,x)$ in $(\mathscr{D}'((O,T) \times \mathbb{R}^3)^3$ such that:

(a) $\mathbf{u}$ is locally square integrable on $(0,T)\times\mathbb{R}^3$,
(b) $\nabla\cdot\mathbf{u}=0$,
(c) $\exists p\in\mathscr{D}'((0,T)\times\mathbb{R}^3)\ \partial_t\mathbf{u}=\Delta\mathbf{u}-\nabla\cdot(\mathbf{u}\otimes\mathbf{u})-\nabla p$.

For defining mild solutions, we consider only uniformly locally square integrable vector fields.

Definition 2: (uniformly locally integrable functions)*:*

For $1\leqslant p<\infty$, we define F_p of functions which are uniformly locally in L^p by: $f\in F_p$ if and only if $\sup_{x\in\mathbb{R}^3}\int_{|y-x|\leqslant 1}|f(y)|^p dy<+\infty$.

It is normed by

$$\|f\|_{F_p}=\sup_{x\in\mathbb{R}^3}\left(\int_{|y-x|\leqslant 1}|f(y)|^p dy\right)^{1/p}.$$

Moreover we define E_p as the closure in F_p of $\mathscr{D}(\mathbb{R}^3)$; this is the space of the elements in F_p which vanish at infinity and it is characterized by $\lim_{x\to\infty}\int_{|y-x|\leqslant 1}|f(y)|^p dy=0$.

Definition 3 (mild solutions)*:* A *mild solution* of the Navier–Stokes equations on $(0,T^*)\times\mathbb{R}^3$ with initial value $\mathbf{u}_0\in(\mathscr{S}'(\mathbb{R}^3))^3$, $\nabla\cdot\mathbf{u}_0=0$, is a vector field $\mathbf{u}(t,x)$ in $(\mathscr{D}'((0,T^*)\times\mathbb{R}^3)^3$ such that:
(a) $\mathbf{u}\in\cap_{T<T^*}L^2((0,T),(F_2)^3)$,
(b) $\mathbf{u}=e^{t\Delta}\mathbf{u}_0-\int_0^t(\nabla\otimes O_{t-s})*(\mathbf{u}\otimes\mathbf{u})ds$.

The point is that when $v\in F_1$ then $\partial_j v$ belongs to a Banach space Y of tempered distributions whose norm is shift invariant (so that convolution with functions in L^1 operate boundedly on Y) and on which the Riesz transforms $\partial_j/\sqrt{-\Delta}$ operate boundedly (for instance, Y can be defined as the space of distributions which split in a sum of a low-frequency term in $\dot{B}^{-1,\infty}_{\infty}$ and a high-frequency term in $\dot{B}^{-4,\infty}_{\infty}$). Thus, if $\mathbf{u}\in\cap_{T<T^*}L^2((0,T),(F_2)^3)$ we find that $\mathbf{w}=\int_0^t(\nabla\otimes O_{t-s})*(\mathbf{u}\otimes\mathbf{u})ds$ is well defined and belongs to $\cap_{T<T^*}L^\infty((0,T),(Y)^3)$; moreover it satisfies $\partial_t\mathbf{w}=\Delta\mathbf{w}+\mathbb{P}(\nabla\cdot(\mathbf{u}\otimes\mathbf{u}))$ and $\lim_{t\to 0}\|\mathbf{w}\|_Y=0$. See Ref. 5 for further details.

The two notions of weak and mild solutions are equivalent for solutions which vanish at infinity.[5]

Proposition 1: Let $\mathbf{u}\in\cap_{T<T^*}L^2((0,T),(F_2)^3)$. Then the following assertions are equivalent.

(A) $\mathbf{u}$ satisfies the following requirements:
(a) $\nabla\cdot\mathbf{u}=0$,
(b) $\partial_t\mathbf{u}=\Delta\mathbf{u}-\mathbb{P}(\nabla\cdot(\mathbf{u}\otimes\mathbf{u}))$,
where $\mathbb{P}$ is the Leray–Hopf projection operator on divergence free vector fields:

(B) $\mathbf{u}$ is a mild solution of the Navier–Stokes equations: $\exists\mathbf{u}_0\in(\mathscr{S}'(\mathbb{R}^3))^3$ such that
(a) $\nabla\cdot\mathbf{u}_0=0$,
(b) $\mathbf{u}=e^{t\Delta}\mathbf{u}_0-\int_0^t e^{(t-s)\Delta}\mathbb{P}(\nabla\cdot(\mathbf{u}\otimes\mathbf{u}))ds$.

If we assume that $\mathbf{u}$ vanishes at infinity [i.e., we assume more precisely that $\mathbf{u}\in\cap_{T<T^*}L^2((0,T),(E_2)^3)$] then (A) and (B) are equivalent to the following assertion.

(C) $\mathbf{u}$ is a weak solution of the Navier–Stokes equation:
(a) $\nabla\cdot\mathbf{u}=0$,
(b) $\exists p\in\mathscr{D}'((0,T^*)\times\mathbb{R}^3)\ \partial_t\mathbf{u}=\Delta\mathbf{u}-\nabla\cdot(\mathbf{u}\otimes\mathbf{u})-\nabla p$.

Sketch of the proof: Equivalence between (A) and (B) is a simple exercise on distributions [derivatives and integrals are weakly defined: apply equations to a test function in $\mathscr{C}^\infty_{comp}((0,T^*)\times\mathbb{R}^3)$]. For equivalence between (A) and (C), we have to prove that we may apply $\mathbb{P}$ to (C) and that it gives (A); we may apply $\mathbb{P}$ to high frequency components without any problem: let $\varphi\in\mathscr{D}(\mathbb{R}^3)$ be such that $|\xi|\leqslant 1/2\Rightarrow\varphi(\xi)=1$ and $|\xi|\geqslant 1\Rightarrow\varphi(\xi)=0$ and let S_j be defined as the Fourier multiplier $\mathscr{F}(S_j f)=\varphi(\xi/2^j)\mathscr{F}f$; then $\mathbb{P}(Id-S_j)$ operates boundedly on $\mathscr{S}^3$ and $(\mathscr{S}')^3$; thus (C) gives $\partial_t(Id-S_j)\mathbf{u}=\Delta(Id-S_j)\mathbf{u}-(Id-S_j)\mathbb{P}(\nabla\cdot(\mathbf{u}\otimes\mathbf{u}))$ and we may conclude since for $u\in E_2$ we have $S_j u\to 0$ weakly in $\mathscr{S}'$ when $j\to-\infty$ while $\|S_j\mathbb{P}(\nabla\cdot(\mathbf{u}\otimes\mathbf{u}))\|_\infty\leqslant C2^j\|\mathbf{u}\|^2_{F_2}$. ■

Almost all the solutions we shall consider in this paper are weak/mild solutions in the sense of Proposition 1: for instance, the Leray solutions [which are in $L^\infty((L^2)^3)$], the Kato solutions [which are in $L^\infty((L^p)^3)$ for some $p\in[3,\infty)$], the Cannone self-similar solutions [which satisfy for some $p\in(3,\infty)\ t^{1/2-3/2p}\mathbf{u}\in L^\infty((L^p)^3)$], the Meyer solutions in $L^\infty((L^{3,\infty})^3)$ and so on.

Since a mild solution is defined as a fixed point of an integral transform, one may expect some uniqueness results. The following one is quite obvious.

Definition 4 (regular mild solutions): A mild solution $\mathbf{u}$ of the Navier–Stokes equations on $(0,T^*)\times\mathbb{R}^3$ is called *regular* if it satisfies the following requirements:
(a) $\mathbf{u}\in\cap_{T<T^*}L^\infty((0,T),(F_2)^3)$,
(b) $\mathbf{u}\in\cap_{0<\epsilon<T<T^*}L^\infty((\epsilon,T),(L^\infty)^3)$,
(c) $\lim_{t\to 0}\sqrt{t}\|\mathbf{u}(t,\cdot)\|_\infty=0$.

Proposition 2: Let $\mathbf{u}_0\in(F_2)^3$, $\nabla\cdot\mathbf{u}_0=0$. Then there exists at most one regular mild solution with $\mathbf{u}_0$ as an initial value.

Proof: Define $B(\mathbf{f},\mathbf{g})=\int_0^t(\nabla\otimes O_{t-s})*(\mathbf{f}\otimes\mathbf{g})ds$. Let $\mathbf{u}$ and $\mathbf{v}$ be two regular mild solutions: $\mathbf{u}=e^{t\Delta}\mathbf{u}_0-B(\mathbf{u},\mathbf{u})$ and $\mathbf{v}=e^{t\Delta}\mathbf{u}_0-B(\mathbf{v},\mathbf{v})$ so that $\mathbf{w}=\mathbf{u}-\mathbf{v}$ is solution of the equation $\mathbf{w}=-B(\mathbf{w},\mathbf{v})-B(\mathbf{u},\mathbf{w})$. Now, we use the fact that the norm of F_2 is shift invariant and the fact that $\nabla\otimes O_{t-s}$ is a convolution matrix with functions whose L^1 norm is $O(1/\sqrt{t-s})$ to get

$$\|\mathbf{w}(t,\cdot)\|_{F_2}\leqslant C\int_0^t\frac{1}{\sqrt{t-s}}\frac{1}{\sqrt{s}}\,ds\ \sup_{0<s<t}\|\mathbf{w}(s,\cdot)\|_{F_2}\sup_{0<s<t}\sqrt{s}(\|\mathbf{u}(s,\cdot)\|_\infty+\|\mathbf{v}(s,\cdot)\|_\infty).$$

Since $\int_0^t(1/\sqrt{t-s})(1/\sqrt{s})ds=\pi$, we get local uniqueness [as long as $\pi C\sup_{0<s<t}\sqrt{s}(\|\mathbf{u}(s,\cdot)\|_\infty+\|\mathbf{v}(s,\cdot)\|_\infty)<1$]: indeed, we then have $\sup_{0<s<t}\|\mathbf{w}(s,\cdot)\|_{F_2}\leqslant\pi C\ \sup_{0<s<t}\sqrt{s}(\|\mathbf{u}(s,\cdot)\|_\infty+\|\mathbf{v}(s,\cdot)\|_\infty)\sup_{0<s<t}\|\mathbf{w}(s,\cdot)\|_{F_2}$, which gives $\sup_{0<s<t}\|\mathbf{w}(s,\cdot)\|_{F_2}=0$. Then, global uniqueness follows by looking at the largest t such that $\mathbf{u}=\mathbf{v}$ on $[0,t)$ and applying local uniqueness again on $[t,t+\delta t]$: since F_2 is a dual space and since $\mathbf{u}$ and $\mathbf{v}$ are weakly continuous into $(\mathscr{S}'(\mathbb{R}^3))^3$, we find $\mathbf{u}(t,\cdot)=\mathbf{v}(t,\cdot)\in(F_2)^3$ while $\mathbf{u}$ and $\mathbf{v}$ are mild solutions on (t,T^*) with $\mathbf{u}(t,\cdot)$ as the initial value; moreover, since $\mathbf{u}$ and $\mathbf{v}$ are bounded on (t,T) for all $T<T^*$, they are regular mild solutions. ■

IV. EXISTENCE OF REGULAR MILD SOLUTIONS

The existence of regular mild solutions has been proved for an initial value $\mathbf{u}_0$ in many spaces: Sobolev spaces H^s for $s\geqslant 1/2$,[16] Lebesgue spaces L^p for $p\in[3,\infty)$,[1] Besov spaces, Morrey-Campanato spaces and others. We will focus on the Morrey-Campanato space $M_{2,3}$.

Definition 5 (Morrey-Campanato space): For $1\leqslant p\leqslant q\leqslant\infty$, the Morrey-Campanato space $M_{p,q}$ is defined as the spaces of functions f which are locally in L^p and such that

$$\sup_{x\in\mathbb{R}^3,0<r\leqslant 1}\frac{1}{r^{3(1/p-1/q)}}\left(\int_{|x-y|\leqslant r}|f(y)|^p dy\right)^{1/p}<\infty, \tag{6}$$

where the left hand side of inequality (6) is the norm of f in $M_{p,q}$.

The homogeneous Morrey-Campanato space $\dot{M}_{p,q}$ is defined in the same way, by taking the supremum on all $r\in(0,\infty)$ instead of $r\in(0,1]$.

It is easy to check that $M_{p,p}=F_p$, $F_q\subset M_{p,q}$ and $M_{p,\infty}=L^\infty$. The existence of solutions in Morrey-Campanato spaces has been discussed by several authors (see for instance Refs. 3, 4, 5, 17–19). We shall specialize our attention to two subspaces of $M_{2,3}$.

Theorem 1: (mild solutions in $M_{2,3}$) Let $\mathbf{u}_0\in(M_{2,3})^3$, $\nabla\cdot\mathbf{u}_0=0$. Then we have the following.
(a) $\mathbf{U}=e^{t\Delta}\mathbf{u}_0$ satisfies $\sup_{t>0}\|\mathbf{U}\|_{M_{2,3}}+\sup_{0<t\leqslant 1}\sqrt{t}\|\mathbf{U}\|_\infty<C\|\mathbf{u}_0\|_{M_{2,3}}$.
(b) If $\lim_{t\to 0}\sqrt{t}\|e^{t\Delta}\mathbf{u}_0\|_\infty=0$, then there exists $T^*=T^*(\mathbf{u}_0)>0$ and a regular mild solution $\mathbf{u}$ on $(0,T^*)\times\mathbb{R}^3$ with initial value $\mathbf{u}_0$. Moreover, $\mathbf{u}\in\cap_{T<T^*}L^\infty((0,T),(M_{2,3})^3)$.
(c) There exists two constants $\epsilon_0,\epsilon_1>0$ such that if $\mathbf{u}_0\in(\dot{M}_{2,3})^3$ and $\|\mathbf{u}_0\|_{\dot{M}_{2,3}}<\epsilon_0$ then there exists a mild solution $\mathbf{u}$ on $(0,\infty)\times\mathbb{R}^3$ with initial value $\mathbf{u}_0$ such that $\sup_{t>0}\|\mathbf{u}\|_{\dot{M}_{2,3}}<\infty$ and $\sup_{t>0}\sqrt{t}\|\mathbf{u}\|_\infty<\epsilon_1$. Moreover such a solution is unique.
(d) Under the hypotheses of (c), if $\|\mathbf{u}_0\|_{\dot{M}_{2,3}}<\epsilon_0$ and $\mathbf{u}_0$ is homogeneous ($\forall\lambda>0\,\mathbf{u}_0(\lambda x)=1/\lambda\,\mathbf{u}_0(x)$) then $\mathbf{u}$ is self-similar: $\forall\lambda>0\,\mathbf{u}(\lambda^2 t,\lambda x)=(1/\lambda)\mathbf{u}(t,x)$.

Sketch of the proof: The proof is by now quite classical. It is enough to check that the operator B (defined as $B(\mathbf{f},\mathbf{g})=\int_0^t(\nabla\otimes O_{t-s})*(\mathbf{f}\otimes\mathbf{g})ds$) is bilinear continuous on E and on $\dot{E}$ where

$$E=\{\mathbf{f}\in L^\infty((0,T),(M_{2,3})^3/\ \sup_{0<t<T}\sqrt{t}\|\mathbf{f}\|_\infty<\infty,\lim_{t\to 0}\sqrt{t}\|\mathbf{f}\|_\infty=0\},$$

$$\dot{E}=\{\mathbf{f}\in L^\infty((0,\infty),(\dot{M}_{2,3})^3)/\sup_{0<t}\sqrt{t}\|\mathbf{f}\|_\infty<\infty\}.$$

Indeed, we have the inequalities

$$\|(\nabla\otimes O_{t-s})*(\mathbf{f}\otimes\mathbf{g})\|_{M_{2,3}}\leqslant C\ \frac{1}{\sqrt{t-s}}\ \|(\mathbf{f}\otimes\mathbf{g})\|_{M_{2,3}}\leqslant C\ \frac{1}{\sqrt{t-s}}\ \|\mathbf{f}\|_{M_{2,3}}\|\mathbf{g}\|_\infty$$

and

$$\|(\nabla\otimes O_{t-s})*(\mathbf{f}\otimes\mathbf{g})\|_\infty\leqslant C\inf\left(\frac{\|\mathbf{f}\otimes\mathbf{g}\|_\infty}{\sqrt{t-s}},\ \frac{\|\mathbf{f}\otimes\mathbf{g}\|_{M_{2,3}}}{t-s}\right)\leqslant C\inf\left(\frac{\|\mathbf{f}\|_\infty}{\sqrt{t-s}},\ \frac{\|\mathbf{f}\|_{M_{2,3}}}{t-s}\right)\|g\|_\infty,$$

from which we get $\|B(\mathbf{f},\mathbf{g})\|_E\leqslant C_0\|f\|_E\sup_{0<s<T}\sqrt{s}\|g(s,\cdot)\|_\infty$ where C_0 does not depend on T.

Then a contraction argument shows the existence and uniqueness of the solutions. We show how to prove point (b) [point (c) is shown in a very similar way and point (d) is obvious since the norm of $\dot{M}_{2,3}$ is invariant through the transformation $f(x)\to\lambda f(\lambda x)$]. We first notice that we have

$$\|B(\mathbf{f},\mathbf{f})-B(\mathbf{g},\mathbf{g})(t,x)\|_E\leqslant C_0\ \sup_{0<s<t}\ \|(\mathbf{f}-\mathbf{g})(s,x)\|_E\ \sup_{0<s<t}\ (\sqrt{s}\|\mathbf{f}(s,x)\|_\infty+\sqrt{s}\|\mathbf{g}(s,x)\|_\infty).$$

Moreover we have $\|B(\mathbf{f},\mathbf{f})\|_\infty\leqslant C_1\sup_{0<s<t}\|\mathbf{f}\|_{M_{2,3}}^{1/2}\ \sup_{0<s<t}\|\mathbf{f}\|_\infty^{3/2}$. Thus if $R_0=\|\mathbf{u}_0\|_{M_{2,3}}$, if $\epsilon_0>0$ is chosen such that $C_1\sqrt{2R_0\epsilon_0}<1$ and $2C_0\epsilon_0<1$, and if T^* is chosen such that $\sup_{0<s<T^*}\|e^{s\Delta}\mathbf{u}_0\|_\infty<\epsilon_0$, then the map $\mathbf{f}\to e^{t\Delta}\mathbf{u}_0-B(\mathbf{f},\mathbf{f})$ maps the closed subset of E defined by $\{\mathbf{u}/\sup_{0<s<T^*}\|\mathbf{u}\|_{M_{2,3}}<2R_0$ and $\sup_{0<s<T^*}\|\mathbf{u}\|_\infty<\epsilon_0\}$ into itself and is a contraction on it; thus we have a fixed point in this set, which can be obtained by iterating the map. ■

Remark: The smoothness of regular solutions in Morrey-Campanato spaces is discussed in detail by Kato in Ref. 17 and by Taylor in Ref. 19. There is some difficulty in the fact that these spaces are not separable, hence $e^{t\Delta}$ is not a C_0-semigroup on these spaces.

V. THE LITTLEWOOD–PALEY DECOMPOSITION

In the next section, we shall discuss the theory of Cannone about adapted spaces for the Navier–Stokes equations. It relies on the Littlewood–Paley decomposition of tempered distributions. In this section, we recall briefly some points of the Littlewood–Paley theory.

Definition 6 (Littlewood–Paley decomposition): Let $\varphi\in\mathscr{D}(\mathbb{R}^3)$ be such that $|\xi|\leqslant 1/2\Rightarrow\varphi(\xi)=1$ and $|\xi|\geqslant 1\Rightarrow\varphi(\xi)=0$. Let ψ be defined as $\psi(\xi)=\varphi(\xi/2)-\varphi(\xi)$. Let S_j and Δ_j be defined as the Fourier multipliers $\mathscr{F}(S_jf)=\varphi(\xi/2^j).\mathscr{F}f$ and $\mathscr{F}(\Delta_jf)=\psi(\xi/2^j).\mathscr{F}f$. Then for all $N\in\mathbb{Z}$ and all $f\in\mathscr{S}'(\mathbb{R}^3)$ we have $f=S_Nf+\Sigma_{j\geqslant N}\Delta_jf$ in $\mathscr{S}'(\mathbb{R}^3)$. This equality is called the *Littlewood–Paley decomposition* of the distribution f. If moreover $\lim_{N\to-\infty}S_Nf=0$ in $\mathscr{S}'$, then the equality $f=\Sigma_{j\in\mathbb{Z}}\Delta_jf$ is called the homogeneous Littlewood–Paley decomposition of f.

Δ_jf can be viewed as a filtering of f through a bandpass filter which selects the frequencies around $|\xi|\approx 2^j$.

A very basic tool in using the Littlewood–Paley decomposition is the so-called Bernstein inequalities which express how to control the L^p norm of the derivatives of the dyadic blocks:

$$\forall\alpha\in\mathbb{N}^3,\quad\exists C_\alpha,\quad\forall p\in[1,\infty],\quad\forall f\in L^p,\quad\|\partial^\alpha S_jf\|_p\leqslant C_\alpha 2^{j|\alpha|}\|S_jf\|_p,$$

$$\forall\alpha\in\mathbb{N}^3,\quad\exists C_\alpha,\quad\forall p\in[1,\infty],\quad\forall f\in L^p,\quad\|\partial^\alpha\Delta_jf\|_p\leqslant C_\alpha 2^{j|\alpha|}\|\Delta_jf\|_p,$$

$$\forall\alpha\in\mathbb{R},\quad\exists C_\alpha,\quad\forall p\in[1,\infty],\quad\forall f\in L^p,\|(\sqrt{-\Delta})^\alpha\Delta_jf\|_p\leqslant C_\alpha 2^{j|a|}\|\Delta_jf\|_p,$$

whereas we easily control the L^q norm of a dyadic block by its L^p norm if $q>p$:

$$\exists C, \quad \forall p \in [1,\infty], \quad \forall q \in [p,\infty], \quad \forall f \in L^p, \quad \|S_j f\|_q \leqslant C 2^{j(3/p-3/q)} \|S_j f\|_p .$$

Besov space $B_p^{s,q}$ may be easily defined through the Littlewood–Paley decomposition as the space of tempered distributions f such that for all $j \in \mathbb{N}$ we have $S_j f \in L^p$ and such that moreover $2^{js}\|\Delta_j f\|_p \in l^q(\mathbb{N})$. The space $B_\infty^{-1,\infty}$ plays a key role in finding regular mild solutions since $f \in B_\infty^{-1,\infty}$ if and only if $\forall T>0 \sup_{O<t<T} \sqrt{t}\|e^{t\Delta} f\|_\infty < \infty$.

For further information on the Littlewood–Paley decomposition, the reader may consult the classical book by Bergh and Löfström on interpolation spaces,[20] the nice booklet by Frazier, Jawerth and Weiss on Littlewood–Paley decomposition and wavelets,[21] the book by Meyer on Wavelets and Operators (Ref. 22, vol. 3) and the various treatises on paradifferential calculus.

VI. ADAPTED SPACES FOR THE NAVIER–STOKES EQUATIONS

Definition 7 (adapted spaces):[3] A Banach space X is *adapted* to the Navier–Stokes equations if the following assertions are satisfied.
(a) $\mathscr{S}(\mathbb{R}^3) \subset X \subset \mathscr{S}'(\mathbb{R}^3)$ (continuous imbeddings).
(b) The norm of X is shift invariant:

$$\forall f \in X, \quad \forall x_0 \in \mathbb{R}^3 \|f(x)\|_X = \|f(x-x_0)\|_X.$$

(c) The pointwise product between two elements of X is still well defined as a tempered distribution.
(d) There is a sequence of real numbers $\eta_j > 0$, $j \in \mathbb{Z}$, such that

$$\sum_{j \in \mathbb{Z}} 2^{-|j|} \eta_j < \infty,$$

and such that

$$\forall j \in \mathbb{Z}, \quad \forall f \in X, \quad \forall g \in X \|\Delta_j(fg)\|_X \leqslant \eta_j \|f\|_X \|g\|_X .$$

Theorem 2:[3] Let X be a Banach space adapted to the Navier–Stokes equations. Then, for all $\mathbf{u}_0 \in X^3$ such that $\boldsymbol{\nabla} \cdot \mathbf{u}_0 = 0$, there is a $T^* = T^*(\|\mathbf{u}_0\|_X)$ and a unique solution $\mathbf{u}$ of the Navier–Stokes equations on $(0,T^*)$ with initial value $\mathbf{u}_0$ such that $\mathbf{u} - e^{t\Delta}\mathbf{u}_0 \in \mathscr{C}([0,T^*),X^3)$. Moreover we have the inequality

$$\forall t \in (0,T^*) \|\mathbf{u} - e^{t\Delta}\mathbf{u}_0\|_X \leqslant C \left(t \sum_{4^j t \leqslant 1} 2^j \eta_j + \sum_{4^j t > 1} 2^{-j} \eta_j \right) \|\mathbf{u}_0\|_X^2.$$

Sketch of the proof: The proof lies again on the Picard iteration scheme. The main point is to prove that the bilinear transform $\mathbf{u},\mathbf{v} \to \mathbf{w} = \int_0^t e^{(t-s)\Delta}\mathbb{P}(\boldsymbol{\nabla} \cdot (\mathbf{u} \otimes \mathbf{v}))ds$ is continuous on $L^\infty(X^3)$. It is enough to notice the following properties of this operator: (α) $e^{(t-s)\Delta}\mathbb{P}(\boldsymbol{\nabla} \cdot)$ is a matrix of convolution operators; (β) since the norm of X is shift invariant, we have for $f \in X$ and $g \in L^1 \|f * g\|_X \leqslant \|f\|_X \|g\|_1$; γ) for all j we have $\Delta_j = (\Sigma_{k=j-2}^{k=j+2} \Delta_k)\Delta_j$; δ); we thus may conclude that

$$\|e^{(t-s)\Delta}\mathbb{P}(\boldsymbol{\nabla} \cdot \Delta_j(\mathbf{u} \otimes \mathbf{v}))\|_X \leqslant C \min(2^j, 4^{-j}(t-s)^{-3/2}) \|\Delta_j(\mathbf{u} \otimes \mathbf{v}))\|_X .$$

The continuity of the bilinear transform is then easily established, writing

$$\|\mathbf{w}\|_X \leqslant \sum_{j \in \mathbb{Z}} \|\Delta_j \mathbf{w}\|_X \leqslant \int_0^t \sum_{j \in \mathbb{Z}} \|e^{(t-s)\Delta}\mathbb{P}(\boldsymbol{\nabla} \cdot \Delta_j)(\mathbf{u} \otimes \mathbf{v})\|_X ds,$$

and estimating the integral $\int_0^t \Sigma_{j \in \mathbb{Z}} \min(2^j, 4^{-j}(t-s)^{-3/2}) \eta_j ds$. □

If we look precisely at the definition of an adapted space (and at the examples developed by Cannone), we may see that the theorem is not really a result about the *existence* of solutions but a result about *regularity* at $t=0$ of mild solutions. Indeed, let us assume that assertion (c) in the

definition is ensured by the embedding of X in L^2_{loc}, the space of locally square integrable functions, and that X is invariant under dilations as well as translations: $\forall \lambda>0$ $f\to f(\lambda x)$ is a continuous mapping in X. Then we have the following result.

Proposition 3: Let X be an adapted space for the Navier–Stokes equations. If X is continuously embedded in L^2_{loc} and if $\forall \lambda>0$, $f\to f(\lambda x)$ is a continuous mapping in X, then X is continuously embedded in $M_{2,3}$ and for all $f\in X$ we have $\lim_{t\to 0}\ \sqrt{t}\|e^{t\Delta}f\|_\infty=0$.

Proof: Since the norm of X is shift invariant, the embedding $X\subset L^2_{loc}$ is equivalent to $X\subset F_2$. Thus, we may define the following numbers:

$$\alpha(r)=\sup_{\|f\|_X\leqslant 1, x\in\mathbb{R}^3}\int_{|x-y|\leqslant r}|f(y)|^2\,dy.$$

We are going to estimate $\alpha(r)$ for $r\leqslant 1$. We choose a smooth non-negative function θ which is equal to 1 on $|x|\leqslant 1$ and to 0 for $|x|\geqslant 2$, and we write $f^2=S_0(f^2)+(\Sigma_{j\geqslant 0}\Delta_j(f^2))=g+h$. It is easy to see that g is bounded (since $f^2\in F_1$ and that S_0 maps F_1 into L^∞) so that $|\int g(y)\theta((y-x)/r)dy|\leqslant Cr^3\|f\|_X^2$. We may write h as $\Sigma_{1\leqslant j\leqslant 3}\partial_j h_j$ where $h_j\in X$ and $\|h_j\|_X\leqslant C\|f\|_X^2$; we then have $|\int h(y)\theta((y-x)/r)dy|\leqslant\Sigma_{1\leqslant j\leqslant 3}1/r|\int h_j(y)\partial_j\theta((y-x)/r)dy|\leqslant C\sqrt{r}\sqrt{\alpha(2r)}\|f\|_X^2$; since $\alpha(2r)\leqslant C\alpha(r)$ and $\int_{|x-y|\leqslant r}|f(y)|^2\,dy\leqslant\int(g(y)+h(y))\theta((y-x)/r)dy$, we obtain that for $r\leqslant 1$, $\alpha(r)\leqslant C(r^3+\sqrt{\alpha(r)}\sqrt{r})$ which gives $\alpha(r)\leqslant Cr$: thus X is embedded in the Morrey-Campanato space $M_{2,3}$.

This implies that $X\subset B^{-1,\infty}_\infty$ (and in particular that $\sup_{0\leqslant t\leqslant 1}\sqrt{t}\|e^{t\Delta}f\|_\infty\leqslant C\|f\|_X$). We are now going to show that we also have $\lim_{t\to 0}\|e^{t\Delta}f\|_\infty=0$. Indeed let us define

$$C_j=\sup_{\|f\|_X\leqslant 1}\|\Delta_j f\|_\infty.$$

Since X is invariant through dyadic dilations, we see that C_j is slowly varying: $\exists\,\gamma>1$, $\forall j\in\mathbb{Z}(1/\gamma)\leqslant C_j/C_{j+1}\leqslant\gamma$. If f_j satisfies $\|f_j\|_X=1$ and $|\Delta_j f_j(0)|\geqslant 1/2C_j$, then $f_j f_{j+3}=\Sigma_{j+1\leqslant k\leqslant j+5}\Delta_k(f_j f_{j+3})$, hence $1/4C_jC_{j+3}\leqslant(\Sigma_{j+1\leqslant k\leqslant j+5}C_k)(\Sigma_{j\leqslant l\leqslant j+6}\eta_l)$. Thus, we get $\lim_{j\to+\infty}2^{-j}C_j=0$. This is just what we needed to show: indeed, write for $f\in X$ $f=S_N f+\Sigma_{j\geqslant N}\Delta_j f=f_N+g_N$; then for $t\in(0,1]$ and $N\geqslant 1$ we have $\sqrt{t}\|e^{t\Delta}f\|_\infty\leqslant\sqrt{t}\|e^{t\Delta}f_N\|_\infty+\sqrt{t}\|e^{t\Delta}g_N\|_\infty\leqslant\sqrt{t}\|f_N\|_\infty+C\|g_N\|_{B^{-1,\infty}_\infty}\leqslant C(2^N\sqrt{t}+\sup_{j\geqslant N}2^{-j}C_j)\|f\|_X$. ■

Thus, we have shown that the spaces studied by Cannone are subspaces of one space, the space $M_{2,3}$. Moreover, for all the examples quoted in Ref. 3 [Sobolev spaces $H^s_p(p<3,s>3/p-1)$, Morrey-Campanato spaces $M^{2,p}(p>3)$, Lebesgue spaces L^p $(p>3)$], we have the property that $\forall f,g\in X\cap L^\infty\|fg\|_X\leqslant C(\|f\|_X\|g\|_\infty+\|g\|_X\|f\|_\infty)$ so that the regular mild solutions described in Theorem 1 are as well in $\cap_{T<T*}L^\infty((0,T),X^3)$ [and we may notice that conversely a mild solution in $\cap_{T<T*}L^\infty((0,T),X^3)$ where X is one of these spaces and is in fact a regular mild solution]. It means that we do not need a very precise analysis in frequency for proving the existence of a solution. Moreover, the tools used for exhibiting solutions in $M_{2,3}$ can be used as well for obtaining regularity results in the limit cases of Cannone's theorem, when $\eta_j=2^j$ (think of L^3: this is the same recipe that we use in limit cases[5]).

VII. SELF-SIMILAR SOLUTIONS

In view of theorem 1, we see clearly the strategy for exhibiting self-similar solutions to the Navier–Stokes equations. We take a space of tempered distributions X which contains nontrivial homogeneous distributions and try to get a theorem of global existence and uniqueness for solutions of the Navier–Stokes equations. Again, we assume that the norm of X is shift-invariant, and we assume, for the sake of homogeneity, that $\|f(\lambda x)\|_X=(1/\lambda)\|f\|_X$. This implies that $X\subset\dot{B}^{-1,\infty}_\infty$, or equivalently that for all $f\in X$ we have $\sup_{0<t}\sqrt{t}\|e^{t\Delta}f\|_\infty\leqslant C\|f\|_X$.

We write again $B(\mathbf{f},\mathbf{g})=\int_0^t(\nabla\otimes O_{t-s})*(\mathbf{f}\otimes\mathbf{g})ds$ and we have to check on which Banach space based on X and containing the tendencies $e^{t\Delta}\mathbf{u}_0$ for $\mathbf{u}_0\in X^3$ the bilinear transform B is continuous. The first space we can try is $E=L^\infty((0,\infty),X^3)$. Of course, the bilinear product uv should then be defined for elements of X; hence we should assume that X is embedded in L^2_{loc}; we then find that $X\subset\dot{M}_{2,3}$, so that this case has already been discussed. There are many instances of

spaces X which can be treated this way and provide self-similar solutions: homogeneous Besov spaces $\dot{B}^{s,\infty}_p$ where $p<3$ and $s=3/p-1$,[3,5,23] the Lorentz space $L^{3,\infty}$[7] and the space $\dot{B}^{2,\infty}_{PM}=\{f/|\xi|^2.\mathscr{F}f\in L^\infty\}$ used by Le Jan and Sznitman.[6]

We may use the smoothing effect of $e^{t\Delta}$ and try to start from a more singular initial value. Cannone[3] and Planchon[9] have shown that one could take $\mathbf{u}_0\in\dot{B}^{s,\infty}_p$ where $p\in(3,\infty)$ and $s=3/p-1$. Then $E=\{\mathbf{f}/\sup_{0<t}t^{1/2-3/2p}\|\mathbf{f}(t,.)\|_p<\infty\}$ is a good choice.

This latter example can even be generalized by replacing L^p by F_p. We thus may consider a $\mathbf{u}_0\in(\dot{B}^{-1,\infty}_\infty)^3$ such that $\sup_{0<t}t^{1/2-3/2p}\|e^{t\Delta}\mathbf{u}_0\|_{F_p}<\infty$; then if this quantity is small enough, we shall have a mild solution in $X_p=\{\mathbf{f}/\sup_{0<t}t^{1/2-3/2p}\|\mathbf{f}(t,\cdot)\|_{F_p}<\infty\}$. As a matter of fact, the first instance of self-similar solutions was constructed with the help of Morrey-Campanato spaces.[24] X_p is a kind of Besov space above a Morrey-Campanato space, as in Ref. 18.

Self-similar solutions are connected to the asymptotic behavior of solutions as t goes to ∞. Planchon[9] has studied the problem of solutions $\mathbf{u}(t,x)$ such that $\sup_{t>0}t^{1/2-3/2p}\|\mathbf{u}\|_p<\infty$ and $\lim_{t\to\infty}\sqrt{t}\mathbf{u}(t,\sqrt{t}x)$ exists in L^p where p is fixed in $(3,\infty)$. Then the initial value $\mathbf{u}_0$ [well defined since $\mathbf{u}\in\cap_{T>0}L^2((0,T),(F_2)^3)$] belongs to $\dot{B}^{3/p-1,\infty}_p$, the limit $\mathbf{V}=\lim_{t\to\infty}\sqrt{t}\mathbf{u}(t,\sqrt{t}x)$ satisfies that $(1/\sqrt{t})\mathbf{V}(x/\sqrt{t})$ is a self-similar solution of the Navier–Stokes equations and the initial value $\mathbf{v}_0\in\dot{B}^{3/p-1,\infty}_p$ of $(1/\sqrt{t})\mathbf{V}(x/\sqrt{t})$ satisfies $e^\Delta\mathbf{v}_0=\lim_{t\to\infty}\sqrt{t}\{e^{t\Delta}\mathbf{u}_0\}(t,\sqrt{t}x)$ in L^p. Notice that this proves that the asymptotic behavior is governed only by the lowest frequencies of the initial value $\mathbf{u}_0$, since for all $N\in\mathbb{Z}$ we have $\sqrt{t}\|\{e^{t\Delta}(Id-S_N)\mathbf{u}_0\}(t,\sqrt{t}x)\|_p\leqslant C(1/t)\|[(Id-S_N)/\Delta]\mathbf{u}_0\|_{\dot{B}^{3/p-1,\infty}_p}\leqslant C(1/2^Nt)\|(Id-S_N)\mathbf{u}_0\|_{\dot{B}^{3/p-1,\infty}_p}$ and thus $e^\Delta\mathbf{v}_0=\lim_{t\to\infty}\sqrt{t}\{e^{t\Delta}S_N\mathbf{u}_0\}(t,\sqrt{t}x)$.

VIII. UNIQUENESS IN LIMIT SPACES

In this section, we pay a few words to the uniqueness problems for mild solutions in $\mathscr{C}([0,T^*),(L^3)^3)$. As a matter of fact, we may not construct directly a solution in $\mathscr{C}([0,T^*),(L^3)^3)$, given $\mathbf{u}_0\in(L^3)^3$, because L^3 is a limit space and this is not clear whether B is continuous or not on $\mathscr{C}([0,T^*),(L^3)^3)$. The reader may find various constructions in Refs. 1, 3 or 9, and uniqueness was granted only in the subspaces of $\mathscr{C}([0,T^*),(L^3)^3)$ where the iteration algorithm converges (for instance, for regular mild solutions). The constructions aimed to prove that the fluctuation was in $\mathscr{C}([0,T^*),(L^3)^3)$, and even in a smaller subspace [such as $\mathscr{C}([0,T^*),(Y)^3)$ with $Y=\dot{B}^{0,1}_3$ (Refs. 3 and 5) or $Y=\dot{B}^{0,2}_3$ (Ref. 9) or, as one may easily check for a regular mild solution, $Y=L^{3,1}$]. The idea we had in Ref. 5 was that the problem of uniqueness could be treated in a *greater* space, since one did not bother to get an estimate especially in the L^3 norm, the solutions being already given.

The example of Le Jan and Sznitman[6] is particularly interesting. They consider the limit space $X=\dot{B}^{2,\infty}_{PM}$ and show in a very simple way that the operator B is well behaved on this space. As a matter of fact, since the Riesz transforms are obviously bounded on this space, we may just look at the scalar bilinear operator $A(u,v)=\int_0^t e^{(t-s)\Delta}\sqrt{-\Delta}(uv)ds$ operating on $L^\infty(X)$.

Now, they do not try to prove that $\int_0^t\|e^{(t-s)\Delta}\sqrt{-\Delta}(uv)\|_X ds$ can be controlled; this is too gross an estimate. But the estimate they use is even more direct: $(1/\sqrt{-\Delta})(uv)\in X$ since (taking the Fourier transform) it is enough to notice that $1/|\xi|^2*1/|\xi|^2\leqslant C/|\xi|$ (an obvious inequality due to radial invariance and homogeneity), and then one writes

$$|\mathscr{F}\{A(uv)(t,\cdot)\}(\xi)\leqslant\frac{C}{|\xi|^2}\sup_{0<s<t}\|u\|_X\sup_{0<s<t}\|v\|_X\int_0^t e^{-(t-s)|\xi|^2}|\xi|^2ds$$

$$\leqslant\frac{C}{|\xi|^2}\sup_{0<s<t}\|u\|_X\sup_{0<s<t}\|v\|_X\int_0^\infty e^{-\tau}d\tau.$$

These simple estimates suggest that one can deal with certain limit spaces, as far as their norm can be computed *frequency by frequency* or at least by frequency packets. This is the case of the Besov l^∞ spaces: if X is a Banach space of tempered distributions with a shift invariant norm and if $\dot{B}^{s,\infty}_X$ for $s>0$ is the space of distributions $f=\Sigma_{j\in\mathbb{Z}}\Delta_j f$ such that $2^{-js}\|\Delta_j f\|_X\in l^\infty(\mathbb{Z})$, then $\forall s\in(0,2)$, $\forall f\in L^\infty((0,\infty),\dot{B}^{s,\infty}_X)\int_0^\infty\tau\Delta e^{\tau\Delta}f(\tau,\cdot)(d\tau/\tau)\in B^{s,\infty}_X$.

Thus we see for instance that B operates boundedly on $\dot{B}_2^{1/2,\infty}$ and this implies readily the uniqueness of mild solutions in $\mathscr{C}((0,T^*),\dot{H}^{1/2})$. This argument does not work directly for the limit space L^3 since we then should work with the Besov space $\dot{B}_3^{0,\infty}$ which is not embedded in L^2_{loc} so that we would be bound again to use the smoothing effect of the heat kernel.

The next idea is to split the solutions in tendency and fluctuation. We consider two mild solutions $\mathbf{u}=e^{t\Delta}\mathbf{u}_0-B(\mathbf{u},\mathbf{u})=e^{t\Delta}\mathbf{u}_0-\mathbf{w}_1$ and $\mathbf{v}=e^{t\Delta}\mathbf{u}_0-B(\mathbf{v},\mathbf{v})=e^{t\Delta}\mathbf{u}_0-\mathbf{w}_2$ in $\mathscr{C}((0,T^*),(L^3)^3)$ and write $\mathbf{w}=\mathbf{u}-\mathbf{v}=\mathbf{w}_2-\mathbf{w}_1=-B(\mathbf{w},\mathbf{v})-B(\mathbf{u},\mathbf{w})$. Thus we see clearly the role of the fluctuations: they control the behavior of $\mathbf{w}$. Indeed, we now turn to the scalar operator A (since the Riesz transforms operate on all the spaces involved in our computations) and write first

$$A(u,v)=-(-\Delta)^{-1/4}\int_0^t(t-s)\Delta e^{(t-s)\Delta}(-\Delta)^{-1/4}(uv)\,\frac{ds}{t-s},$$

and find that A maps $\mathscr{C}([0,T],L^3)\times\mathscr{C}([0,T],L^3)$ into $L^\infty([0,T],(\dot{B}_2^{1/2,\infty})$ due to Sobolev inequalities. Then we use the continuity of u to split it in u_1+u_2 (and the same for v) where $\forall t<T^*\|u_1(t,\cdot)\|_3<\epsilon$ and $\sup_{0<s<t}\|u_2(s,\cdot)\|_4<\infty$. Now we notice that, due to Sobolev and Hölder inequalities, $\forall f\in L^p(-\Delta)^{-3/2p}M_f$ (where M_f is the operator of pointwise multiplication by f) is continuous on L^q for all $q\in(p/(p-1),\infty)$ and on $\dot{L}^{3/p}_q$ for all $q\in(1,p)$, hence by interpolation on $\dot{B}^{s,\infty}_q$ for all $q\in(p/(p-1),p)$ and all $s\in(0,3/p)$. Taking $p=3{,}4$, $q=2$, $s=1/2$, we easily get that

$$\forall T<T^*,\quad \forall t<T\|A(u,w)(t,\cdot)\|_{\dot{B}_2^{1/2,\infty}}\leqslant C(\epsilon+C(T,u)t^{1/4})\sup_{0<s<t}\|w(s,\cdot)\|_{\dot{B}_2^{1/2,\infty}},$$

which implies $w=0$ as far as $C(\epsilon+C(T,u)t^{1/4})<1$; hence we find that we have local uniqueness and this uniqueness propagates to the whole interval $[0,T^*)$ because of the continuity of $\mathbf{u}$ and $\mathbf{v}$.

Thus, a precise analysis of the frequencies involved in the fluctuation allows one to prove uniqueness in $\mathscr{C}([0,T^*),(L^3)^3)$. This proof works in a more general pattern.

Theorem 3:[5] Let $\dot{m}_{p,3}$ be the closure of the smooth compactly supported functions in $\dot{M}_{p,3}$. If $p>2$ and $\mathbf{u}$ and $\mathbf{v}$ are two weak solutions of the Navier–Stokes equations on $(0,T^*)\times\mathbb{R}^3$ such that $\mathbf{u}$ and $\mathbf{v}$ belong to $\mathscr{C}([0,T^*),(\dot{m}_{p,3})^3)$ and have the same initial value, then $\mathbf{u}=\mathbf{v}$.

Hence we have uniqueness in $\mathscr{C}([0,T^*),(Y)^3)$ for all limit space Y in which the test functions are dense and which is embedded into L^p_{loc} for some $p>2$.

But for L^3, there is now a much simpler way to get uniqueness: the space $\dot{B}_3^{0,\infty}$ was not good for proving uniqueness but it can be replaced by another l^∞ space: $L^{3,\infty}$.[7] Moreover this result is not really *new*: the fact that $f\to\int_0^t(t-s)\Delta e^{(t-s)\Delta}(1/\sqrt{-\Delta})f(s,\cdot)[ds/(t-s)]$ maps $L^\infty((0,T),L^{3/2,\infty})$ into $L^\infty((0,T),L^{3,\infty})$ can be considered as a dual result to the fact that $f\to\int_s^T(t-s)\Delta e^{(t-s)\Delta}(1/\sqrt{-\Delta})f(t,\cdot)[dt/(t-s)]$ maps $L^1((0,T),L^{3/2,1})$ into $L^1((0,T),L^{3,1})$; this latter result is proved in exactly the same way as the fact that $f\to\int_0^t(t-s)\Delta e^{(t-s)\Delta}(1/\sqrt{-\Delta})f(s,\cdot)\times[ds/(t-s)]$ maps $L^1((0,T),L^{3/2,1})$ into $L^1((0,T),L^{3,1})$ or the fact that $f\to\int_0^t e^{(t-s)\Delta}f(s,\cdot)ds$ maps $L^1((0,T),L^{3/2,1})$ into $L^1((0,T),\mathscr{C}_0)$ (remember that $1/\sqrt{-\Delta}$ maps $L^{3,1}$ into $\mathscr{C}_0$), a fact which is used by Lions in Ref. 13 to get the Foias-Guillopé-Temam theorem that the Leray weak solutions belong to $\cap_{T>0}L^1((0,T),\mathscr{C}_0)$!

IX. WEAK SOLUTIONS WITH INFINITE ENERGY

There is still another way to prove uniqueness in L^3. We split $\mathbf{u}_0$ in $\mathbf{v}_0+\mathbf{w}_0$ where $\mathbf{v}_0\in(L^2)^3$ and $\|\mathbf{w}_0\|_3<\epsilon$. Then Kato's theorem allows one to find a regular mild solution $\mathbf{w}$ on $(0,\infty)\times\mathbb{R}^3$ with initial value $\mathbf{w}_0$ and Leray's theory allows one to find a weak solution $\mathbf{v}\in L^\infty((0,\infty),(L^2)^3)\cap L^2((0,\infty),(\dot{H}^1)^3)$ of the problem

$$\mathbf{v}(0,\cdot)=\mathbf{v}_0,\quad \boldsymbol{\nabla}\cdot\mathbf{v}=0,\quad \partial_t\mathbf{v}=\Delta\mathbf{v}-\mathbb{P}(\boldsymbol{\nabla}\cdot[\mathbf{v}\otimes\mathbf{v}+\mathbf{v}\otimes\mathbf{w}+\mathbf{w}\otimes\mathbf{v}]),$$

with an energy estimate:

$$\forall t>0\|\mathbf{v}(t,\cdot)\|_2^2+2\int_0^t\|\boldsymbol{\nabla}\otimes\mathbf{v}(s,\cdot)\|_2^2\,ds\leqslant\|\mathbf{v}_0\|_2^2+2\int_0^t\boldsymbol{\nabla}\otimes\mathbf{v}\cdot\mathbf{v}\otimes\mathbf{w}ds.$$

Now, if $\mathbf{u}$ is a mild solution of Navier–Stokes in $\mathscr{C}([0,T^*),(L^3)^3)$ with initial value $\mathbf{u}_0$, then $\mathbf{z}=\mathbf{u}-\mathbf{w}$ is a solution for the same problem as $\mathbf{v}$ and belongs to $\mathscr{C}([0,T^*),(L^3)^3)$. If we can prove that $\mathbf{z}$ belongs to $\cap_{T<T^*}L^\infty((0,T),(L^2)^3)\cap L^2((0,T),(\dot{H}^1)^3)$, then we may apply the Sohr and Von Wahl uniqueness theorem[2] to get $\mathbf{u}=\mathbf{v}+\mathbf{w}$ on $(0,T^*)$. Since $\mathbf{v}+\mathbf{w}$ does not depend on $\mathbf{u}$, this proves the uniqueness of $\mathbf{u}$! This is exactly what is done in Ref. 8, and moreover this method provides a way to prove the existence of global suitable weak solutions for the Navier–Stokes equations with an initial value with infinite energy.

Definition 8 (suitable weak solutions)*:*[25] A *suitable weak solution* of the Navier–Stokes equations on $(0,T)$ is a distribution vector field $\mathbf{u}(t,x)$ in $(\mathscr{D}'((0,T)\times\mathbb{R}^3)^3$ such that:
(a) $\mathbf{u}$ and $\nabla\otimes\mathbf{u}$ are locally square integrable on $(0,T)\times\mathbb{R}^3$;
(b) $\nabla\cdot\mathbf{u}=0$;
(c) $\exists p\in L^{5/3}_{loc}((0,T)\times\mathbb{R}^3)\ \partial_t\mathbf{u}=\Delta\mathbf{u}-(\mathbf{u}\cdot\nabla)\mathbf{u}-\nabla p$;
(d) for all compact subsets K of $(0,T)\times\mathbb{R}^3$ we have $\sup_{t\in(0,T)}\int_{(t,x)\in K}|\mathbf{u}|^2dx<+\infty$;
(e) $\forall\varphi\in\mathscr{D}((0,T)\times\mathbb{R}^3)$ such that $\varphi\geqslant 0$; we have

$$2\int\int|\nabla\otimes\mathbf{u}|^2\varphi dxdt\leqslant\int\int|\mathbf{u}|^2(\partial_t\varphi+\Delta\varphi)dxdt+\int\int(|\mathbf{u}|^2+2p)(\mathbf{u}\cdot\nabla)\varphi dxdt.$$

We recall that suitable solutions were proved in Ref. 25 to be regular outside from a subset of $(0,T)\times\mathbb{R}^3$ whose one-dimensional Hausdorff measure is equal to 0. The theorem proved in Ref. 8 states the existence of global suitable weak solutions for an initial value $\mathbf{u}_0\in L^q(\mathbb{R}^3)$ where $2\leqslant q<\infty$.

Theorem 4 (suitable weak solutions with unbounded energy)**:** Let $q\in[2,+\infty)$ and let $\mathbf{u}_0\in L^q(\mathbb{R}^3)$ such that $\nabla\cdot\mathbf{u}_0=0$. Then there exists a suitable weak solution $\mathbf{u}$ of the Navier–Stokes equations on $(0,+\infty)$ such that $\mathbf{u}$ belongs to $\cap_{T>0}L^2((0,T),(E_2)^3)\cap L^r((0,T),(L^q)^3)$ (with $1/r=3/2(1/2-1/q)$ if $q\leqslant 6$ and $1/r=1-3/q$ if $q\geqslant 6$) and such that $\mathbf{u}(0,\cdot)=\mathbf{u}_0$.

ACKNOWLEDGMENTS

Formal improvements in the solution of the wavelet-transformed Poisson and diffusion equations

Jacques Lewalle[a)]
Department of Mechanical, Aerospace, and Manufacturing Engineering, Syracuse University, Syracuse, New York 13244-1240

(Received 19 September 1997; accepted for publication 27 March 1998)

Hermitian wavelets' relation to the Laplace operator leads to a natural measure of the scale factor that emphasizes the largest component wave number. For the Poisson equation (e.g. the pressure equation in Navier–Stokes turbulence), the wavelet transform of the solution at a given location and scale depends on the wavelet transform of the source field at the same location and at nearby and larger scales. For the diffusion problem, the Hamiltonian formulation is simplified through a canonical transformation. © *1998 American Institute of Physics.*

I. INTRODUCTION

Navier–Stokes turbulence motivates the present research effort. The improvements in experimental and computational techniques have yielded a wealth of data, and the role of intermittency and near-singularities, among other important physical descriptors, is being actively documented. However, the consistency and importance of the associated scaling relations falls short of a theory, since a link to fundamental principles (mass and momentum conservation) relies on obtaining a solution (experimental or numerical) rather than on symbolic relations.

The closest thing to a theory of turbulence is the renormalization group approach,[1] which is formulated in Fourier space[2,3] and therefore conceals the effects of intermittency as iterative low-pass filtering is applied. Wavelet transforms[4,5] provide a compromise between spectral and spatial information, and could capture scale-dependent intermittency and its dynamics. Recent successes in data analysis[6] and computational simulation[7,8] attest to the relevance of the tool. In this paper, some incremental progress is reported on the analytical treatment of the pressure and viscous terms in Navier–Stokes turbulence. Any wavelet can potentially yield the desired result, but analytical manipulations involving the Laplacian are most effective with the continuous wavelets of the Hermitian family,[9,10] which are used exclusively in this paper. Ostensibly, we will assume an infinite spatial domain, which matches the Fourier version[2] but can be relaxed in simple geometries with the help of Green's functions.[10]

Notations and earlier results[9,10] are summarized below. Hermitian wavelets are the family of continuous wavelets obtained by taking derivatives of the Gaussian bell-shaped curve. In the one-dimensional case, let us define the mother wavelet g_n as

$$g_n(x) = -\frac{d}{dx} g_{n-1}(x),$$

where

$$g_0(x) = e^{-x^2/2}. \tag{1}$$

The family of g_n's obeys the Hermite recursion formula

$$g_n(x) = x g_{n-1}(x) - (n-1) g_{n-2}(x). \tag{2}$$

For $n>0$, the Hermitian wavelet transform at scale κ of a field $p'(x)$ is given by

a)Electronic mail: jlewalle@syr.edu

 © 1998 American Institute of Physics

$$p(\kappa,x)=\kappa^{1/2}\int_{-\infty}^{\infty}p'(y)g_n(\kappa(y-x))dy. \tag{3}$$

The wavelet number κ is a measure of inverse length scale, analogous to the wave number k of Fourier analysis, and equal to the inverse dilation factor a used in much of the wavelet literature. (κ,x) will be refered to as wavelet space, κ (>0) as the wavelet number. In this paper, we will use primed symbols for the spatial representation of fields, hatted symbols for the Fourier representation, and plain symbols for the wavelet representation.

Integration by parts and Eq. (2) yield the compatibility equation

$$\kappa^3\frac{\partial p}{\partial\kappa}+\frac{\partial^2 p}{\partial x^2}+\left(n+\frac{1}{2}\right)\kappa^2 p=0. \tag{4}$$

This condition, which must be satisfied by any Hermitian wavelet transform $p(\kappa,x)$, is the basis of all manipulations of the Laplace operator in the remainder of this paper.

These relations have been generalized[9] to N-dimensions if the transform is carried out in each Cartesian direction independently and if the same wavelet index n applies in each direction. Accordingly, the N-D wavelet transform of the pressure field $p(\mathbf{x})$ is

$$p(\kappa_j,\mathbf{x})=\int\cdots\int_{-\infty}^{\infty}p'(\mathbf{y})\prod_{j=1}^{N}[\kappa_j^{1/2}g_n(\kappa_j(y_j-x_j))dy_j]. \tag{5}$$

It can be noted that $\{\kappa_j\}$ is a set of positive scaling coefficients (wavelet-numbers), and is not a vector. This fact is reflected in the notations, where $\boldsymbol{\kappa}$ will be avoided, and where the summation convention does not apply to κ_j.

In Sec. II, we set out to simplify some results relative to the Poisson equation, with the specific goal of finding workable alternatives to the compact Fourier representation[1–3] of pressure in incompressible turbulence. A change in variables leads to a ''natural'' measure of the scale factor, which favors the largest scale component, in contrast to the Euclidean metric of Fourier space. Then, in Sec. III, we show that this change of variables is part of a canonical transformation that reformulates the Hamiltonian for diffusion[10] in action-angle variables, possibly the simplest expression of conservation in simple transport processes. The Poisson solution is then reformulated in these variables.

II. THE POISSON EQUATION REVISITED

In incompressible flows, pressure obeys the Poisson equation

$$\nabla^2 p'=S'(\mathbf{x}), \tag{6}$$

in which the source terms S' depend on nonlinear interactions. In the spatial representation of the solution

$$p'(\mathbf{x})=\int S'(\mathbf{y})G'(\mathbf{x},\mathbf{y})d\mathbf{y}, \tag{7}$$

the form of Green's function G' depends on the dimension N of the space (and of course on the configuration of the boundaries), but in all cases p' at one point will depend on sources at all other points in the field. This enriches the physics of any flow, and complicates its calculation or modeling.

In the Fourier representation

$$\hat{p}(\mathbf{k})=\int p'(\mathbf{x})e^{-i\mathbf{k}\cdot\mathbf{x}}d\mathbf{x}, \tag{8}$$

the spectral distribution of pressure is given by

$$\hat{p}(\mathbf{k}) = -\frac{\hat{S}(\mathbf{k})}{|\mathbf{k}|^2}. \tag{9}$$

This relation is algebraic, and is local in wave number space. This facilitates enormously the formal manipulations of the Navier–Stokes equations and their coding for spectral calculations; this is also reflected in a rich tradition of modeling[2,3] and in renormalization theory.[1] However, any effect of the localization of the sources, as would occur in an intermittent field, is distributed throughout the Fourier spectrum, and is generally eliminated from modeling considerations. Wavelet transforms are an obvious alternative to address this priority. We will treat successively the one-dimensional case to establish notations and procedures, then generalize the result to *N*-dimensions.

A. The one-dimensional case

Making use of the compatibility condition [Eq. (4)], the 1-D version of Eq. (6) transforms into

$$\kappa^3 \frac{\partial p}{\partial \kappa} + \left(n + \frac{1}{2}\right)\kappa^2 p = -S(\kappa, x). \tag{10}$$

This equation was solved[9] using the method of characteristics, and this section consists of a reformulation of the earlier result. After elimination of the characteristic parameter, the solution is

$$p(\kappa, x) = -\kappa^{-[n+(1/2)]} \int_0^{\kappa} S(\kappa', x)\kappa'^{[n-(5/2)]} d\kappa'. \tag{11}$$

This relation was interpreted as reflecting the asymptotic equilibrium for the corresponding diffusion problem originating in the remote past under the action of fixed sources. An alternative presentation is obtained by defining the relative scale factor

$$\xi = \kappa'/\kappa, \tag{12}$$

i.e., the ratio of the wavelet number for the source to that of the resulting pressure field. Then

$$p(\kappa, x) = -\kappa^{-2} \int_0^1 S(\xi\kappa, x)\xi^{n-\frac{5}{2}} d\xi. \tag{13}$$

It was noted[9] that all spectral contributions to the source terms are evaluated locally at the point x of interest. In order to capture the effect of a remote source, one must look at scales large enough (small κ) for the analyzing wavelet to cover both the source and the point of observation, which will affect the amplitude of the wavelet coefficient. Also noteworthy, the κ^{-2} prefactor is reminiscent of the Fourier solution [Eq. (9)]. Furthermore, it is apparent that only spectral contributions to the source terms for $\kappa' < \kappa$ are reflected in the pressure field. As n increases, we see in Fig. 1 that the weight of spectral contributions shifts closer to $\xi = 1$. The net result of the spatial/spectral compromise is that we retain a strictly local spatial distribution (traceable to the compatibility condition [Eq. (4)]), and a limited spectral localization of the effect of the source. A fuller discussion will benefit from the *N*-dimensional result.

B. The *N*-dimensional case

The properties of the transform used above can be generalized to *N*-dimensions. In particular, the compatibility equation becomes

$$\sum_j \kappa_j^3 \frac{\partial p}{\partial \kappa_j} + \left(n + \frac{1}{2}\right)\sum_j \kappa_j^2 p + \sum_j \frac{\partial^2 p}{\partial x_j^2} = 0. \tag{14}$$

Based on this relation, the transformed Poisson equation and its solution were derived previously.[9] In characteristic form, and with an arbitrary reference characteristic parameter s_0, the solution is

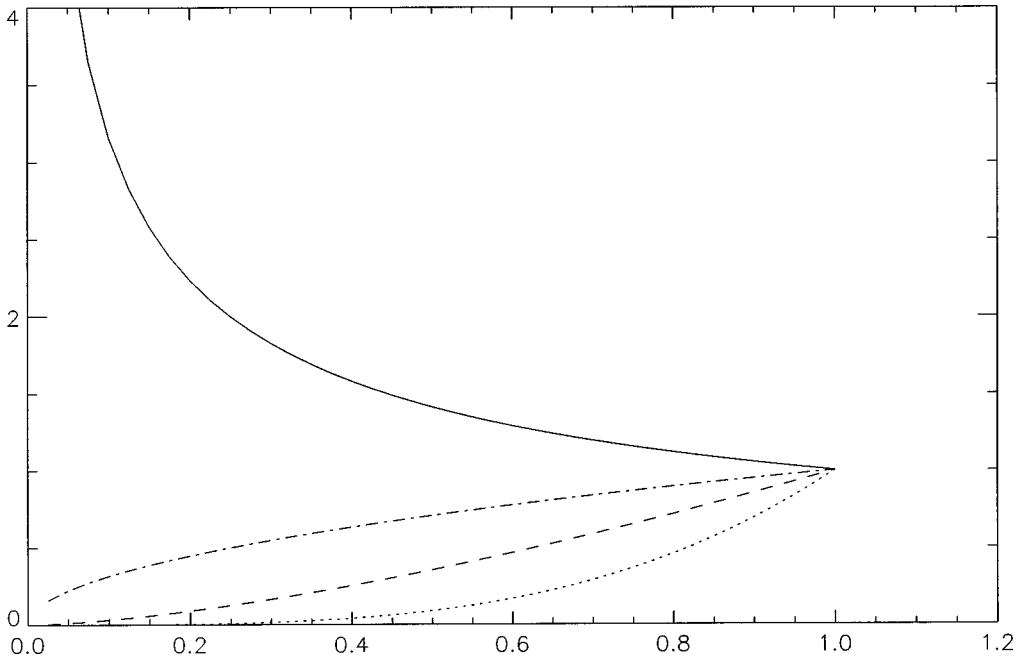

FIG. 1. Relative weight of contributions to the pressure at a given scale κ from sources at relative scale ξ, according to Eq. (13). Solid line: $n=2$; dash-dotted line: $n=3$; dashed line: $n=4$; dotted line: $n=6$.

$$\kappa_j(s)=\frac{\kappa_j(s_0)}{\sqrt{1-2(s-s_0)\kappa_j^2(s-s_0)}} \tag{15}$$

and

$$p(\kappa_j(s),\mathbf{x})=-\int_{-\infty}^{s} S(\kappa_j(\sigma),\mathbf{x})\prod_{i=1}^{N}\left[\frac{\kappa_i(\sigma)}{\kappa_i(s)}\right]^{[n+(1/2)]} d\sigma. \tag{16}$$

In this case, the elimination of the characteristic parameter s is not trivial, and it requires the introduction of a unique scale factor. Let

$$\frac{1}{\kappa^2}=\frac{1}{N}\sum_{i=1}^{N}\frac{1}{\kappa_i^2}. \tag{17}$$

It is easy to show that

$$\frac{d\kappa}{\kappa^3}=ds=\frac{d\kappa_i}{\kappa_i^3}. \tag{18}$$

Simple manipulations yield a new expression for pressure

$$p(\kappa_j,\mathbf{x})=-\kappa^{-2}\int_0^1 S\left(\frac{\xi\kappa_j}{\sqrt{a_j}},\mathbf{x}\right)\xi^{N[n+(1/2)]-3}\prod_{i=1}^{N} a_i^{-(n/2)-(1/4)}d\xi. \tag{19}$$

We recognize, in order, the κ^{-2} prefactor, the wavelet-transformed source field, the relative scale factor as in Eq. (12), and a product of scale-dependent directional factors

$$a_i(\kappa_i,\kappa,\xi)=\xi^2+\frac{\kappa_i^2}{\kappa^2}(1-\xi^2). \tag{20}$$

Dominant and vanishing contributions can be identified from Eqs. (19) and (20). As $\xi\to 0$,

$$a_j(\kappa_j,\kappa,\xi)\to\frac{\kappa_j^2}{\kappa^2}, \tag{21}$$

and the integrand I in Eq. (19) behaves as

$$I\to S(\xi\kappa,\mathbf{x})\xi^{N[n+(1/2)]-3}\prod_{i=1}^{N}\left[\frac{\kappa_i}{\kappa}\right]^{-n-(1/2)}. \tag{22}$$

In this relation, the same scaling parameter $\xi\kappa$ applies in all directions for the source field. The exponent of ξ is increasingly dominant as N increases. This weighting factor is plotted in Fig. 2 for $N=2$ and 3. Next, let us examine the ''diagonal'' terms for which all κ_j's are equal. Then, $\kappa_j=\kappa$ and the integrand reduces to

$$I=S(\xi\kappa_j,\mathbf{x})\xi^{N[n+(1/2)]-3}. \tag{23}$$

Thus, we see that the factor $\xi^{N[n+(1/2))]-3}$ applies for the whole interval $0<\xi<1$ along this line, sharply selecting the contributions from the spectral range $\xi\sim 1$. Directional effects will manifest themselves when the κ_j's are not equal, but the smallest κ_j will always dominate the scalar factor κ, so that κ_j/κ will never be small. Further discussion will be facilitated by the change of variables suggested by Eq. (17).

III. ACTION-ANGLE VARIABLES

A. The diffusion equation

The manipulations from the previous section indicate that a change of variables from κ_j to something proportional to $1/\kappa_j^2$ might simplify all relations derived from the compatibility condition. For the execution of this idea, the broader context of the diffusion equation

$$\frac{\partial u'}{\partial t}=\nu\frac{\partial^2 u'}{\partial x_j^2} \tag{24}$$

is helpful. Following steps similar to those in Sec. II, the compatibility condition was used[9] to obtain the characteristic representation of diffusion. In the one-dimensional case, time t is the characteristic parameter, and we have

$$\frac{d\kappa}{dt}=\nu\kappa^3, \tag{25}$$

and

$$\frac{du}{dt}=-\nu\kappa^2\left(n+\frac{1}{2}\right)u. \tag{26}$$

These characteristic equations can also be derived as the canonical equations corresponding to the Hamiltonian

$$H(K,U,\kappa,u)=\nu\kappa^3K-(n+\tfrac{1}{2})\nu\kappa^2uU. \tag{27}$$

Here, U and K are the configuration variables canonically associated with the momenta u and κ, respectively. This result was extended to N-dimensional diffusion, and explicit solutions for the trajectories were presented. It was shown that trajectories initiating from a given scale escape to infinity in a finite time, with the smallest scales escaping first; in this sense, irreversibility is consistent with the Hamiltonian structure. It was also shown that a Hamiltonian can be written to include nonlinear terms, such as convection, reaction or pressure terms.

For the change in variables, we will consider the general case of fields with M components in an N-dimensional space. Introducing the change of variables

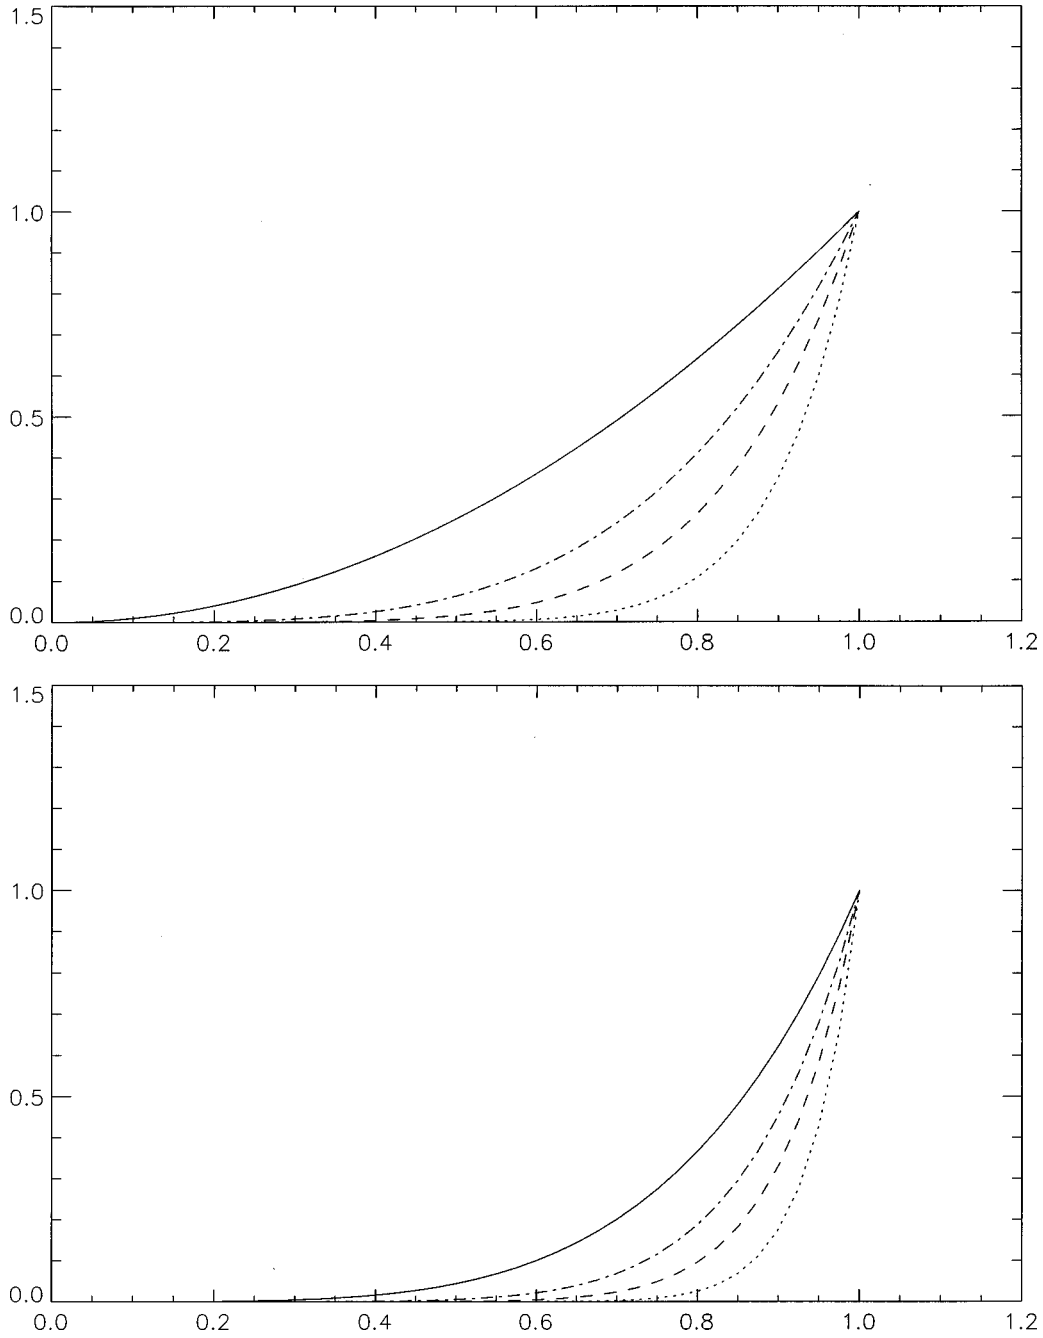

FIG. 2. Two-dimensional and three-dimensional case: relative weight of contributions to pressure at a given scale κ from sources at relative scale ξ, according to Eq. (22). Solid line: $n=2$; dash-dotted line: $n=3$; dashed line: $n=4$; dotted line: $n=6$.

$$\zeta_j = \frac{1}{2\kappa_j^2} \tag{28}$$

in the compatibility relation Eq. (14), elementary substitutions lead us to factor out the asymptotic slope (large κ or small ζ) from the transformed field:

$$u_i(\kappa_j, t; x_m) = f_i(\zeta_j, t; x_m) \prod_j \zeta_j^{(n/2)+(1/4)}. \tag{29}$$

Accordingly, a steep drop-off of f_i towards large scales can be expected. In fact, starting from the smallest scales ($\zeta\sim 0$), the asymptotic slope[11] of the wavelet-transformed field u_i is factored out to give f_i. With these variables, the compatibility equation becomes

$$\sum_{i=1}^{N} \frac{\partial^2 f_m}{\partial x_i^2} = \sum_{j=1}^{N} \frac{\partial f_m}{\partial \zeta_j}. \tag{30}$$

Since the compatibility condition is at the root of the characteristic equations for the diffusion and Poisson equations, considerable simplifications can be expected with these new variables.

The manipulations are best presented in the context of a canonical transformation.[12] We start from the configuration variables K_j and U_i, and their associate momenta κ_j and u_i. Then, let

$$\alpha = \frac{n}{2} + \frac{1}{4} \tag{31}$$

for short. Let us call Z_j and F_i the new configuration variables, and ζ_j and f_i the associated momenta as defined above. This change of variable will be a canonical transformation if there exists a generating function $G(\kappa_j, u_i, Z_j, F_i)$ such that

$$\zeta_j = \frac{\partial G}{\partial Z_j}, \quad f_i = \frac{\partial G}{\partial F_i}, \quad K_j = \frac{\partial G}{\partial \kappa_j}, \quad \text{and } U_i = \frac{\partial G}{\partial u_i}. \tag{32}$$

There is no difficulty in finding

$$G(\kappa_j, u_i, Z_j, F_i) = \sum_j \frac{1}{2\kappa_j^2} Z_j + 2^{\alpha N} \prod_j \kappa_j^{2\alpha} \sum_i u_i F_i. \tag{33}$$

The canonical transformation so defined yields the Hamiltonian

$$H(\zeta_j, f_i, Z_j, F_i) = -\nu \sum_j Z_j. \tag{34}$$

In these coordinates, the only active canonical equations are

$$\frac{d\zeta_j}{dt} = \frac{\partial H}{\partial Z_j} = -\nu, \tag{35}$$

which indicate that

$$\zeta_j(t) = \zeta_j(0) - \nu t. \tag{36}$$

This linear ''motion'' towards negative ζ_j's corresponds to the escape towards large κ_j's discussed elsewhere.[10] The solution for negative ζ_j's has no clear physical meaning and should be discarded.

The other variables remain unchanged under the action of diffusion. First and foremost, for the wavelet transform of the field, we have

$$\frac{df_i}{dt} = \frac{\partial H}{\partial F_i} = 0. \tag{37}$$

From the solution presented earlier,[10] we see that the factoring out of the asymptotic tail of u_i at large κ_j leads to a constant value of f_i in the characteristic representation. When we eliminate t between the two momenta, the initial local spectrum $f_i(\zeta_j, 0; x_m)$ drifts with invariant shape towards small scales (small ζ_j).

The configuration variables Z_j and F_i complete the canonical structure without affecting the diffusion itself. We have:

$$\frac{dF_i}{dt} = -\frac{\partial H}{\partial f_i} = 0 \tag{38}$$

and

$$\frac{dZ_j}{dt} = -\frac{\partial H}{\partial z_j} = 0. \tag{39}$$

The frozen coordinates Z_j, F_i and f_i are similar to those encountered in the ''action-angle'' formulation of some mechanical problems.[12]

B. Reformulation of the pressure solution

The solution of the Poisson equation is also simplified with these variables. Let us call f_p and f_S the action-angle transforms of the pressure field p' and its sources S', respectively. The Poisson equation (6) and the compatibility equation (30) give

$$\sum_i \frac{\partial f_p}{\partial \zeta_i} = f_s(\zeta_j, \mathbf{x}). \tag{40}$$

In characteristic form, this becomes

$$\frac{df_s(\zeta_j(s), \mathbf{x})}{ds} = f_s(\zeta_j, \mathbf{x}), \tag{41}$$

with

$$\frac{d\zeta_i}{ds} = -1. \tag{42}$$

The solution is easily obtained in the form

$$f_p(\zeta_j, \mathbf{x}) = -\int_s^\infty f_s(\zeta_j(\sigma), \mathbf{x}) d\sigma. \tag{43}$$

The elimination of the characteristic parameter is achieved with the introduction of the scalar scale factor

$$\zeta = \frac{1}{N}\sum_i \zeta_i \tag{44}$$

matching Eq. (17), and its relative value

$$X = \frac{\zeta(\sigma)}{\zeta(s)} = \frac{1}{\xi} \tag{45}$$

matching Eq. (12). It is easy to see that $\zeta/\zeta_i \geqslant 1/N$ for any given i. Substitution gives the solution of the Poisson equation in the form

$$f_p(\zeta_j, \mathbf{x}) = \zeta \int_1^\infty f_s\left(\left[1 + \frac{\zeta}{\zeta_j}(X-1)\right]\zeta_j, \mathbf{x}\right) dX. \tag{46}$$

In comparison with Eq. (19), we note the elimination of the scale and directional factors in the integrand. Contribution from the sources at the selected location and nearby scales retains a form comparable to that seen in Sec. II, including directional effects, but all other scale contributions are captured by the prefactor ζ, proportional to κ^{-2}.

The directional effects are also simpler to gage in this representation. With the ζ_j's equal in all directions (''diagonal'' terms), the sources are evaluated as $f_s(X\zeta_j)$, with the same factor in all

directions as in Sec. II B. It was noted in Sec. II A that the wavelet scale must be sufficient to cover both the source (in f_s) and the point of observation (in f_p). If we take this scale as reference, the source could have dominant components both smaller and larger. If smaller, the directional factor ζ/ζ_j is large, and is compounded by the factor $(X-1)$, so that the smallest scales sources are not observable as small scale pressure except in their immediate vicinity. On the other hand, for (directional) scales much larger than the distance to the source, we could have $\zeta/\zeta_j \sim \frac{1}{3}$ and contributions from source terms moderately smaller than the scale of observation. Therefore, the simple one-dimensional result is modified to include a finite vicinity around ζ_j, in addition to all larger values, in the contributions from the source to the integral.

Also, near-singularities of the source field will be somewhat smoothed out in the integration. Here the distinction[13] should be made between mathematical singularities (e.g., the x^{-2} associated with a line vortex, which is not integrable) and the near-singularities associated with arbitrarily large (but finite) Reynolds number. The balance between steepening gradients in near-singularities and the smoothing effects of viscous dissipation, described by the Navier–Stokes dynamics in wavelet space, will be addressed in the future.

IV. DISCUSSION

Wavelet tools show great promise in the understanding and numerical prediction of intermittent and nonhomogeneous phenomena. Particularly with the modern focus on computer simulation and on data storage and transmission, the emphasis in the literature is overwhelmingly on the use of orthonormal wavelets and wavelet packets, and the success of this line of work is undeniable.[6–8] The present work represents one formal step on a longer route toward numerical work, a route in which ''better'' wavelets are intended to facilitate primarily the physical formulation rather than the computer implementation. The underlying rationale is that a better formulation of the intermittent multiscale physics of turbulence might have a natural numerical counterpart.

On the surface, the continuous wavelet transforms are very uneconomical. The doubling of the number of independent variables makes a computational implementation of the equations[9] unrealistic for any problem of technical relevance. On the other hand, the physics of several phenomena intertwined in the theory and modeling of fluid turbulence are captured in promising ways by the Hermitian wavelets. Their unique properties affect directly the spatially localized contribution of source terms to the resulting pressure fluctuations and the spectral content of these contributions. Furthermore, within the Hermitian class, the order n is known to be associated with the cancellation of moments of the mother wavelet up to order $(n-1)$; to correspond to an asymptotic spectral slope $\kappa^{-[n+(1/2)]}$ that can be resolved with the given wavelet;[11] and to be related to the evaluation of structure functions[14,15] and to the resolution of the singularity spectrum of multifractal fields.[16]

This paper represents progress on two counts. First, a better compromise between the remarkable algebraic simplicity of the pressure terms in Fourier space and their nonlocal representation in configuration space is achieved, with the potential to include spatial and spectral intermittency in turbulence models. Second, the Hamiltonian representation is simplified by the same canonical transformation used for the pressure term, so that viscous behavior becomes computationally trivial. At a more general level, something is learned about the measure of scales. The Euclidean metric has been adopted in the spatial and Fourier domain, and is reflected in the Green's function for the former, in shell-related manipulations for the latter. Alternatives to Eq. (17) did not prove successful, and one of the surprises of this research is that the measure embodied in Eq. (17) is the natural one associated with the characteristic formulation. This observation applies to Poisson, Laplace, diffusion and second-order wave problems equally. Unlike the Euclidean metric of Fourier space, the wavelet number norm is dominated by the smallest wavelet number component.

The impact of the change of variables on the nonlinear terms (convective and pressure sources) and of a discrete modeling of the Hermitian wavelet coefficients is currently being studied. Toward this goal, the redundancy built in the continuous wavelet transforms is one untapped asset. Careful consolidation of the wavelet coefficients within a Hamiltonian framework has the potential to help both physical understanding and computational worth.

ACKNOWLEDGMENT

This work initiated from Jean Paul Bonnet's challenge that any alternative to Fourier would be judged by its handling of the pressure term.

We establish a wavelet characterization of the p oscillation, and give two applications: a wavelet formula for the fractal dimension of graphs and a multifractal formalism for ''chirp-type'' Hölder singularities. © *1998 American Institute of Physics.* [S0022-2488(98)01508-4]

I. INTRODUCTION

The global regularity of a function is usually measured either by determining which Sobolev spaces it belongs, or, when more precise information is needed, by determining to which Besov or Triebel–Lisorkin spaces it belongs. Another way to measure global regularity is to estimate the p variation. If one is only interested in determining the range of ps for which the p variation is bounded, both approaches are essentially identical, as shown by Bergh and Peetre (see Ref. 1) who proved the following sharp imbeddings between V_p (the space of functions with bounded p variation) and Besov spaces:

$$\dot{B}_p^{1/p,\inf(1,p)} \hookrightarrow V_p \hookrightarrow \dot{B}_p^{1/p,\infty}. \tag{1}$$

Nonetheless, in several situations one wishes to determine how the p variation increases when one uses finer and finer grids in its definition. This will lead us to new functional spaces that we will study and relate to other new spaces which are defined by a simple condition on the wavelet coefficients. We will consider two situations in which these spaces are needed: the problem of determining the fractal dimension of graphs of functions, and a multifractal formalism for ''chirp-type'' Hölder singularities.

Let λ be a dyadic cube included in $\mathbf{R}^d$; if f is a continuous function defined on $\mathbf{R}^d$; let

$$\operatorname{osc}(f,\lambda) = \sup_{x\in\lambda} f(x) - \inf_{x\in\lambda} f(x) \tag{2}$$

denote the oscillation of f on the cube λ. The p oscillation of f at scale j is defined by

$$\operatorname{Osc}_p(f,j) = \sum_k \left(\operatorname{osc}(f,\lambda_{j,k})\right)^p,$$

where $\lambda_{j,k}$ is the dyadic cube $k2^{-j}+2^{-j}[0,1]^d$. Note that when $p=1$ one uses the term ''oscillation'' instead of ''1-oscillation.'' For analyzing smooth functions, the definition of the p oscillation using (2), which takes into account only first-order differences, has to be modified: one uses instead nth-order differences, which are defined by induction as follows:

$$\Delta_f^1(t,h) = f(t+h) - f(t),$$

$$\Delta_f^n(t,h) = \Delta_f^{n-1}(t+h,h) - \Delta_f^{n-1}(t,h);$$

and, in the definition of the p oscillation, (2) is replaced by

a)Electronic mail: jaffard@cmla.ens-cachan.fr

 © 1998 American Institute of Physics

$$\mathrm{osc}(f,\lambda)=\sup_{[t,t+nh]\subset\lambda}|\Delta_f^n(t,h)|. \tag{3}$$

We will consider two problems where one has to estimate the order of magnitude of the p oscillation when $j\to+\infty$. This can be done by introducing the p-variation spaces $V^{s,p}$ defined by

$$f\in V^{s,p},\quad \text{if } \sup_{j\in\mathbf{Z}}2^{js}\left(\sum_k|\mathrm{osc}(f,\lambda_{j,k})|^p\right)^{1/p}\leqslant C \tag{4}$$

(one chooses here in the definition of the oscillation a fixed n larger than $[s]+1$); the $V^{s,p}$ seminorm is defined by the left-hand side of the inequality (these spaces are defined modulo polynomials of degree n). We can also consider the p-oscillation exponent,

$$\omega_p(f)=\liminf_{j\to\infty}\frac{\log(\mathrm{Osc}_p(f,j))}{\log(2^{-j})}.$$

Of course, $\omega_p(f)=\sup\{s:f\in V^{s/p,p}\}$.

These notions are closely related to the p variation: Recall that a function $f:[0,1]\to\mathbf{R}$ has a bounded p variation (we write $f\in V^p$) if

$$\inf\sum|f(t_{i+1})-f(t_i)|^p\leqslant C, \tag{5}$$

where the infimum is taken on all finite subdivisions of $[0,1]$. Clearly, if f belongs to V_p,

$$A_j=\sum_k\left|\sup_{\lambda_{j,k}}f(x)-\inf_{\lambda_{j,k}}f(x)\right|^p\leqslant C \tag{6}$$

(take for subdivision the points where the supremum and the infimum are attained in each dyadic interval of length 2^{-j}). Thus, if f belongs to V_p, then $f\in V^{0,p}$. Conversely, suppose that there exists a positive ϵ such that $f\in V^{\epsilon,p}$. It follows that for any j, $A_j\leqslant C2^{-\epsilon j}$; let $(t_i)_{i=1,\ldots,n}$ be a finite subdivision; let J be such that each interval of length 2^{-J} contains at most two points of the subdivision. The sum on all indexes i such that t_{i+1} and t_i belong to the same dyadic interval of length 2^{-J} is bounded by A_J. The sum on all indexes i such that t_{i+1} and t_i belong to the same dyadic interval of length 2^{-J-1} but do not belong to the same dyadic interval of length 2^{-J} is bounded by $A_{J-1,\ldots}$; thus, since $A_j\leqslant C2^{-\epsilon j}$, $f\in V_p$. Hence the following imbeddings:

$$\forall\epsilon>0,\quad V^{\epsilon,p}\hookrightarrow V_p\hookrightarrow V^{0,p}. \tag{7}$$

Theorem 1 will give a wavelet characterization of the p-oscillation exponent. We will use a family of 2^d-1 smooth wavelets $\psi^{(i)}$, such that the $\psi^{(i)}$ and their partial derivatives have fast decay. The $2^{dj/2}\psi^{(i)}(2^jx-k)$ $(i=1,\ldots,2^d-1,j\in\mathbf{Z},k\in\mathbf{Z}^d)$ form an orthonormal basis of $L^2(\mathbf{R}^d)$. We will use a L^∞ normalization for wavelets, so that we write

$$f(x)=\sum_{i,j,k}C_{j,k}^{(i)}\psi^{(i)}(2^jx-k), \tag{8}$$

where $C_{j,k}^{(i)}=2^{dj}\int f(t)\psi^{(i)}(2^jt-k)dt$. We will from now on use the following simpler notations; λ and λ' will denote, respectively, the cubes $\lambda_{j,k}=k2^{-j}+[0,2^{-j}]^d$ and $\lambda_{j',k'}=k'2^{-j'}+[0,2^{-j'}]^d$, C_λ will denote the coefficient $C_{j,k}^{(i)}$, and ψ_λ will denote the wavelet $\psi^{(i)}(2^jx-k)$ (note that we ''forget'' to write the index i of the wavelet, which is of no consequence).

The following functional spaces will be closely related to the spaces $V^{s,p}$, and thus will allow us to characterize p-oscillation exponents.

Definition 1: Let $p>0$, and s, $s'\in\mathbf{R}$; a function f belongs to $\mathcal{C}_p^{s,s'}(\mathbf{R}^d)$ if its wavelet coefficients satisfy

$$\sup_{j\in\mathbf{Z}} 2^{sj}\left(\sum_k \sup_{\lambda'\subset\lambda} |C_{\lambda'}2^{s'j'}|^p\right)^{1/p} < \infty. \tag{9}$$

The left-hand side defines the $\mathcal{O}_p^{s,s'}(\mathbf{R}^d)$ *seminorm.*

Proposition 1 will imply that this definition is independent of the wavelet basis chosen.

Theorem 1: *The following imbeddings hold:*

$$\forall \epsilon>0, \quad \forall \eta>0, \quad C^\epsilon \cap V^{s+\eta,p} \hookrightarrow \mathcal{O}_p^{s,0} \hookrightarrow V^{s,p}; \tag{10}$$

thus, if f: $\mathbf{R}^d\to\mathbf{R}$ *belongs to* $C^\epsilon(\mathbf{R}^d)$ *for* $\epsilon>0$, *the p-oscillation exponent of* f is *given by*

$$\omega_p(f) = \sup\{s: f\in \mathcal{O}_p^{s/p,0}\} = \lim_{j\to+\infty} \sup \frac{\log(\Sigma_{\lambda\in\Lambda_j}\sup_{\lambda'\subset\lambda}|C_{\lambda'}|^p)}{j\ \log 2}. \tag{11}$$

The spaces $\mathcal{O}_p^{s,s'}$ are defined by conditions on the wavelet coefficients; therefore the first point to check is that this definition is independent of the wavelet basis chosen. One way to do it, following Ref. 2, is to check that condition (9) is invariant under the action of infinite matrices which belong to the algebras $\mathcal{M}^\gamma$ for γ large enough, which is the purpose of Proposition 1 below; these algebras are defined as follows: an infinite matrix $A(\lambda,\lambda')$ indexed by the dyadic cubes belongs to $\mathcal{M}^\gamma$ if

$$|A(\lambda,\lambda')| \leqslant \frac{C2^{-(d/2+\gamma)(j-j')}}{(1+(j-j')^2)(1+2^{\inf(j,j')}\ \mathrm{dist}(\lambda,\lambda'))^{d+\gamma}}.$$

Matrices of operators which map a wavelet basis onto another belong to these algebras, and more generally matrices (on wavelet bases) of pseudodifferential operators of order 0, such as the Hilbert transform in dimension 1, or the Riesz transforms in higher dimensions; see Ref. 2. We denote by $\mathcal{O}p(\mathcal{M}^\gamma)$ the space of operators whose matrix on a wavelet basis belongs to $\mathcal{M}^\gamma$. The following proposition will be proved in Sec. VI.

Proposition 1: If $\gamma\geqslant\sup(|s|,|s'|)$, *the operators which belong to* $\mathcal{O}p(\mathcal{M}^\gamma)$ *are continuous on* $\mathcal{O}_p^{s,s'}(\mathbf{R}^d)$.

The fractional derivative or order α [which we denote by $(-\Delta)^{\alpha/2}$] can be written as the product of a diagonal operator on a wavelet basis (each ψ_λ is multiplied by $2^{\alpha j}$) and an operator in $\mathcal{O}p(\mathcal{M}^\gamma)$. Therefore, as a consequence of Proposition 1, $\|(-\Delta)^{\alpha/2}f\|_{\mathcal{O}_p^{s,0}}$ and $\|f\|_{\mathcal{O}_p^{s,\alpha}}$ are equivalent norms; it follows that

$$\omega_p((-\Delta)^{\alpha/2}f) = \sup\{s: f\in\mathcal{O}_p^{s/p,\alpha}\}. \tag{12}$$

Before proving Proposition 1 and Theorem 1, we first point out a consequence of Theorem 1 concerning the computation of the fractal dimension of graphs. Let K be a bounded subset of $\mathbf{R}^{d+1}$. Denote by $N(K,j)$ the number of dyadic cubes of size 2^{-j} necessary to cover K. The upper box dimension of K (also called the fractal dimension) is, by definition,

$$\overline{\dim}_b(K) = \lim_{j\to\infty} \sup \frac{\log N(K,j)}{j\ \log 2}.$$

If K is the graph of a compactly supported continuous function, $N(K,j)$ is related to the oscillation of f; indeed, see Ref. 3,

$$N(\mathrm{Graph}(f),j) \sim 2^{dj} + 2^j\ \mathrm{Osc}_1(f,j) \tag{13}$$

[where we use the standard notation $A\sim B$ if $A=\mathcal{O}(B)$ and $B=\mathcal{O}(A)$]. The following corollary is an immediate consequence of (13) and Theorem 1.

Corollary 1: Let f: $\mathbf{R}^d\to\mathbf{R}$ *be a compactly supported function which belongs to* $C^\epsilon(\mathbf{R}^d)$ *for an* $\epsilon>0$;

$$\overline{\dim_b}(\mathrm{Graph}(f))=\sup(d,1-\sup\{s:f\in\mathcal{O}_1^{s,0}\})=\sup\left(d,1+\limsup_{j\to\infty}\frac{\log(\Sigma_\lambda \sup_{\lambda'\subset\lambda}|C_{\lambda'}|)}{j\log 2}\right).$$

Note that Proposition 1 together with Corollary 1 imply that, if $f\in C^\epsilon(\mathbf{R}^d)$ for an $\epsilon>0$, the fractal dimension of the graph of f is left invariant by operators such as the Hilbert and Riesz transforms, or, more generally, by pseudodifferential operators of order 0 with smooth coefficients. This result shows that the fractal dimension of the graph of a function f is in some sense a ''robust'' global regularity criterium for f.

The wavelet characterization given by Corollary 1 should find applications in rugosimetry. Indeed the fractal dimension of a surface has been shown to be a pertinent way to model the notion of *rugosity*; see Ref. 4; note also that in Ref. 5 other generalizations of Sobolev spaces are introduced following a similar motivation. Therefore finding a numerically stable algorithm to measure this fractal dimension became an important issue. Numerical algorithms based on the oscillation are discussed in Ref. 4. Alternative algorithms based on the wavelet characterization of Corollary 1 might prove numerically more stable, since they would not be based directly on the pointwise value of the profile, but on wavelet coefficients, which are averaged quantities, and, as such, are less sensitive to noise.

The idea of relating the fractal dimension of graphs to wavelet coefficients can be traced back to Ref. 6 where Deliu and Jawerth proposed a formula relating the oscillation of f to the Besov spaces $B_1^{s,\infty}$ to which f belongs locally: If $\alpha=\sup\{s:f\in B_1^{s,\infty}\}$, they asserted that $\overline{\dim_b}(\mathrm{Graph}(f))$ is equal to $d+1-\alpha$ [the relationship with wavelet coefficients is a consequence of the wavelet characterization of the $B_1^{s,\infty}(\mathbf{R}^d)$ norm: $\sup_j\Sigma_k 2^{(s-d)j}|C_\lambda|$]. Kamont and Wolnik constructed a counterexample in Ref. 3; the comprehension of this counterexample is actually the starting point which led us to the definition of the spaces $\mathcal{O}_p^{s,s'}$.

In Sec. III, we will propose another use of the spaces $\mathcal{O}_p^{s,s'}$. We will show how a multifractal formalism for chirps can be based of the determination of the spaces $\mathcal{O}_p^{s,s'}$ to which the function f belongs. Theorem 1 will be proved in two steps. In Sec. IV we suppose that the wavelet basis we use is compactly supported, and we obtain an upper and lower bound of the p oscillation. In Sec. V, we prove that, if f satisfies a uniform regularity condition, the upper and lower bounds are of the same order of magnitude, and in Sec. VI we prove that the definition of the spaces $\mathcal{O}_p^{s,s'}$ is independent of the wavelet basis chosen. In Sec. VII we apply these results on the example of lacunary wavelet series already considered in Ref. 7. Indeed, they will supply new counterexamples to the formula proposed in Ref. 6, and the standard multifractal formalism will also be wrong in this case, whereas the use of the spaces $\mathcal{O}_p^{s,s'}$ will allow us to compute easily the fractal dimension of their graphs, and the multifractal formalism for chirps that we construct in Sec. III yield their correct spectrum of chirps, and, as a consequence, their correct spectrum of singularities.

II. IMBEDDINGS WITH BESOV SPACES

Let us now mention a few imbeddings which hold locally. First, clearly, if $s_1\leqslant s_2$ and $s_1'\leqslant s_2'$,

$$\mathcal{O}_p^{s_2,s_2'}\subset\mathcal{O}_p^{s_1,s_1'}.$$

Using the normalization we chose for wavelets, $f\in B_p^{s,q}$ if (see Ref. 2)

$$2^{-nj/p}\left(\sum_k |C_\lambda 2^{js}|^p\right)^{1/p}=\epsilon_j,\quad \text{with}\quad \epsilon_j\in l^q.$$

Since $\sup_{\lambda'\subset\lambda}|C_{\lambda'}2^{j's'}|\geqslant|C_\lambda 2^{js'}|$, it follows that

$$\mathcal{O}_p^{s,s'}\hookrightarrow B_p^{s'+s+n/p,\infty}.$$

If $j'\geqslant j$, for any positive α, $2^{(j'-j)\alpha}\geqslant 1$; therefore

$$\sup_j \sum_k \sup_{\lambda' \subset \lambda} |C_{\lambda'} 2^{j's'} 2^{sj}|^p \leqslant \sup_j \sum_k \sup_{\lambda' \subset \lambda} |C_{\lambda'} 2^{j'(s'+\alpha)} 2^{(s-\alpha)j}|^p;$$

hence the imbeddings,

$$\forall \alpha > 0, \quad \mathcal{O}_p^{s-\alpha, s'+\alpha} \hookrightarrow \mathcal{O}_p^{s,s'} \hookrightarrow \mathcal{O}_p^{s+\alpha, s'-\alpha} \hookrightarrow B_p^{s+s'+n/p,\infty}. \tag{14}$$

Conversely, if $f \in B_p^{s,p}$,

$$\sum_{k'} |C_{\lambda'} 2^{j'(s-n/p)}|^p = \epsilon_{j'}, \quad \text{with} \quad \epsilon_{j'} \in l^1,$$

thus for any j,

$$\sum_{j' \geqslant j} \sum_{k'} |C_{\lambda'} 2^{j'(s-n/p)}|^p \leqslant C.$$

In the sum over k', we group the terms which correspond to a dyadic cube λ' included in a given dyadic cube λ; thus

$$\sum_{\lambda} \sum_{j' \geqslant j} \sum_{\lambda' \subset \lambda} |C_{\lambda'} 2^{j'(s-n/p)}|^p \leqslant C,$$

hence, *a fortiori*,

$$\sum_{\lambda} \sup_{\lambda' \subset \lambda} |C_{\lambda'} 2^{j'(s-n/p)}|^p \leqslant C,$$

and thus $f \in \mathcal{O}_p^{0, s-n/p}$, hence the imbeddings $B_p^{s+n/p,p} \hookrightarrow \mathcal{O}_p^{0,s} \hookrightarrow B_p^{s+n/p,\infty}$. Using (14) we obtain more generally,

$$\forall s > 0, \quad \forall s' \in \mathbf{R}, \quad \forall p > 0, \quad B_p^{s+s'+n/p,p} \hookrightarrow \mathcal{O}_p^{s,s'} \hookrightarrow B_p^{s+s'+n/p,\infty}. \tag{15}$$

Let $H^{s,p}$ denote the space of functions which belong to L^p and whose fractional derivative of order s belongs to L^p. The Besov spaces $B_p^{s,q}$ or the Triebel–Lisorkin spaces $F_p^{s,q}$ can be seen as a slight variation on the definition of Sobolev spaces in the sense that

$$\forall \epsilon > 0, \quad \forall q, \quad H^{s+\epsilon,p} \hookrightarrow B_p^{s,q} \hookrightarrow H^{s-\epsilon,p}$$

and

$$\forall \epsilon > 0, \quad \forall q, \quad H^{s+\epsilon,p} \hookrightarrow F_p^{s,q} \hookrightarrow H^{s-\epsilon,p}.$$

Similarly, (1), together with the above imbeddings, shows that the spaces V_p are also a variation on the definition of Besov or Sobolev spaces, and (15) shows that, for $s \geqslant 0$, it is also the case for oscillation spaces.

On the contrary the spaces $\mathcal{O}_p^{s,s'}$ for $s < 0$ cannot be sharply imbedded between Sobolev spaces, and thus are new spaces of a really different nature. The use of these spaces proposed in the next section is an illustration of this fact: They allow one to capture oscillatory behaviors which are left undetected by Sobolev or Besov spaces.

Another striking difference between the spaces $\mathcal{O}_p^{s,s'}$ and the Besov spaces is shown by the fact that Besov spaces are invariant under a permutation of the wavelet coefficients at the same scale, which is clearly not the case for oscillation spaces. *Such permutations allow us to modify the Hölder singularities, hence the spectrum of singularities of the function, whereas the oscillation spaces take into account the geometric disposition of the wavelet coefficients.*

III. A MULTIFRACTAL FORMALISM FOR CHIRPS

We now consider a situation where the full range of oscillation spaces are needed. Let $f:\mathbf{R}^d \to \mathbf{R}$ be a bounded function and let $x_0 \in \mathbf{R}^d$; f is $C^\alpha(x_0)$ $(\alpha \geqslant 0)$ if there exists a polynomial P of degree at most $[\alpha]$ and a constant C such that, if $|x-x_0| \leqslant 1$, $|f(x)-P(x-x_0)| \leqslant C|x-x_0|^\alpha$. The *Hölder exponent* of f at x_0 [which will be denoted by $h_f(x_0)$] is, by definition, the supremum of all values of α such that f is $C^\alpha(x_0)$. Characterizing the pointwise regularity of a function with the sole Hölder exponent yields a rather poor information since it does not describe the more or less oscillatory behavior of the function near the point x_0. This oscillatory behavior is properly modeled with the help of the following definition, which was introduced by Meyer; see Ref. 8 or 9.

Definition 2: Let f be a function in $L^\infty_{loc}(\mathbf{R}^d)$; f is called a (h,β)-type chirp at x_0 if $\forall n \in \mathbf{N}$, f can be written as a finite sum of partial derivatives of order n of functions which belong to $C^{h+n(1+\beta)}(x_0)$.

The simplest example of a one-dimensional (h,β)-type chirp at x_0 is supplied by the function

$$|x-x_0|^h \sin\left(\frac{1}{|x-x_0|^\beta}\right). \tag{16}$$

The interior of the set of points (h,β) such that a function f is a (h,β)-type chirp at x_0 is always a domain of the form $h<h_f(x_0)$, $\beta<\beta_f(x_0)$; see Ref. 7. The non-negative real number $\beta_f(x_0)$ is called the *chirp exponent at* x_0.

Chirps are known to exist in a variety of signals, ranging from gravitational waves to ultrasounds emitted by bats. Their existence is an open problem in other signals, such as the velocity of a turbulent fluid. One isolated chirp is usually hard to detect, see Refs. 10 and 11, and establishing a multifractal formalism adapted to chirps could be a way to show their presence on a statistical ground, without having to find precisely the location of each of them.

Let us first recall a few basic points concerning multifractal functions and the standard multifractal formalism adapted to the sole Hölder exponents. When considering a multifractal function f, we expect the set of points where f has a given Hölder exponent h to be a fractal set; we have thus to deal with a whole collection of fractal sets indexed by the parameter h. A relevant mathematical notion is the *spectrum of singularities* $d(h)$ of the function f. For each $h \geqslant 0$, $d(h)$ is the Hausdorff dimension of the set of points x_0 where the Hölder exponent of f is h [we take, as usual, $\dim(\varnothing) = -\infty$.) It is clearly impossible to compute numerically the spectrum of a signal following the definition; indeed, it involves the successive determination of several intricate limits which would yield enormous, totally unstable computations. The only method is to derive it using only averaged quantities (which should be numerically stable) extracted from the signal. Therefore Frisch and Parisi, see Ref. 12, introduced a formula which allows us to compute the spectrum of singularities of a signal by a Legendre transform of some numerically easily computable function. An alternative formula based on the local maxima of the wavelet transform was proposed by Arneodo, Bacry, and Muzy; see Ref. 13. The *Structure Function* method of Frisch and Parisi requires first the computation of

$$S_p(l) = \int_{\mathbf{R}^d} |f(x+l)-f(x)|^p dx.$$

Supposing that the scaling $S_p(l) \sim |l|^{\tau(q)}$ holds, the spectrum of singularities is computed using the formula

$$d(h) = \inf_p (ph - \tau(p) + d). \tag{17}$$

Mathematically, this formula, and the wavelet-based formulas, can be shown to yield the same exponent $\tau(p)$ which can also be deduced from the functional, Besov-type spaces to which the function f belongs; see Ref. 14:

$$\tau(p) = \sup\{s : f \in B^{s/p,p}_\infty\}.$$

A careful study of the wavelet formulas shows that this formalism is only adapted to ''cusp-type'' singularities (i.e., singularities with oscillation exponent $\beta=0$); see Ref. 15.

If we want to study chirps located in a signal, we are naturally led to define a *Spectrum of oscillating singularities* as follows.

Definition 3: The Spectrum of oscillating singularities $d(h,\beta)$ of a function f is the Hausdorff dimension of the set of points where f has the chirp exponents (h,β).

We will now establish by thermodynamic arguments (similar to those advocated in Refs. 13 and 12) a multifractal formalism which yields $d(h,\beta)$ from the knowledge of the p-oscillation exponents of f and its partial derivatives, or alternatively from its wavelet coefficients. This formula is thus motivated by two reasons: To obtain a more complete information about the Hölder singularities of the signal; and, by taking into account the ''chirp-type'' behavior explicitly in the construction of the multifractal formalism, to eliminate one cause of failure of the standard multifractal formalism, and therefore to obtain a formula with a wider range of validity.

Let

$$\zeta(p,s')=\liminf_{j\to+\infty}\frac{\log(\Sigma_k \sup_{\lambda'\subset\lambda}|C_{\lambda'}|^p 2^{s'j'})}{\log 2^{-j}}=\sup\{s: f\in \mathcal{C}_p^{s/p,s'/p}\}=\omega_p((-\Delta)^{s'/2p}f\ ).$$

If f has a chirp of exponents (h,β) at x_0, its wavelet coefficients are of the order of magnitude of $|k2^{-j}-x_0|^h$ near the curve $2^{-j}\sim|k2^{-j}-x_0|^{1+\beta}$ and decay fast away from this curve (see Ref. 16 or 8 for a precise mathematical statement). Our purpose is to estimate for each (h,β) the contribution of the chirps of exponents (h,β) to the quantity

$$\sum_{\lambda\in\Lambda_j}\sup_{\lambda'\subset\lambda}|C_{\lambda'}|^p 2^{s'j'}. \tag{18}$$

Consider a cube λ of size 2^{-j} which contains a chirp of exponents (h,β). The wavelet coefficients $C_{\lambda'}$ for $\lambda'\subset\lambda$ are negligible as long as $2^{-j'}\geqslant(2^{-j})^{1+\beta}$, i.e., as long as $j'\leqslant j(1+\beta)$. When $j'\sim j(1+\beta)$, for some values of k',

$$|C_{\lambda'}|\sim(2^{-j})^h\sim 2^{-j'h/(1+\beta)},$$

so that

$$\sup_{\lambda'\subset\lambda}(|C_{\lambda'}|^p 2^{s'j'})\sim 2^{-j'(hp/(1+\beta)-s')}\sim 2^{-j(hp-(1+\beta)s')}$$

[as long as $s'\leqslant ph/(1+\beta)$, otherwise the supremum is infinite]. The contribution of the chirps of exponents (h,β) to (18) is thus

$$2^{d(h,\beta)j}2^{-j(hp-(1+\beta)s')}=2^{-j(hp-(1+\beta)s'-d(h,\beta))}.$$

When $j\to+\infty$, the main contribution is obtained for the couple (h,β), realizing the infimum of $hp-(1+\beta)s'-d(h,\beta)$; hence, the heuristic formula,

$$\zeta(s',p)=\inf_{h,\beta} hp-(1+\beta)s'-d(h,\beta).$$

If $d(h,\beta)$ is a convex function, it follows that

$$d(h,\beta)=\inf_{s',p} hp-(1+\beta)s'-\zeta(s',p). \tag{19}$$

In Sec. VI we will verify that this formula allows us to recover the increasing part of the spectrum in the case of a lacunary wavelet series. Obtaining the decreasing part of the spectrum would correspond to an infimum in (19) obtained for negative values of p, which cannot be expected

from a mathematical approach of this type (in the case of the standard multifractal formalism, this problem already appeared, and was solved numerically by the use of the ''Wavelet Maxima Method;'' see Ref. 13).

If one is interested only in obtaining the spectrum of singularities $d(h)$, it can be recovered from (19): For a fixed h, we expect the value of β which brings the largest contribution to (19) to yield the right dimension $d(h)$; hence we expect the spectrum of singularities to be obtained by the formula

$$d(h)=\sup_{\beta} d(h,\beta)=\sup_{\beta}\inf_{s',p}(1+\beta)s'+hp-\zeta(s',p). \tag{20}$$

Of course, this formula is by no means equivalent to (17), as will be shown in Sec. VI on the example of a lacunary wavelet series.

A mathematical investigation of the range of validity of these formulas, together with numerical algorithms, are now being worked out in collaboration with Arneodo, Bacry, and Muzy, and will be the subject of a forthcoming paper.

IV. UPPER AND LOWER BOUNDS FOR THE *p* OSCILLATION

In the next two sections we compare the spaces $V^{s,p}$ with $\mathcal{O}_p^{s,0}$ when the wavelets are compactly supported. Let D be the smallest integer such that the 2^d-1 functions $\psi^{(i)}$ are all supported in $[0,D]^d$.

For each j, let

$$Q_j(x)=\sum_k C_\lambda \psi(2^j x-k).$$

If $p\leqslant 1$,

$$(\mathrm{osc}(f,\lambda))^p\leqslant\sum_{j'}(\mathrm{osc}(Q_{j'},\lambda))^p,$$

and, if $p>1$, using the Hölder inequality,

$$(\mathrm{osc}(f,\lambda))^p\leqslant\sum_{j'}((1+|j-j'|)\mathrm{osc}(Q_{j'},\lambda))^p.$$

We will now estimate the terms of this sum. We suppose that $p\leqslant 1$. [The case $p>1$ is similar, after adding everywhere the extra factor $(1+|j-j'|)$.]

If $j'<j$, using the mean-value theorem,

$$\mathrm{osc}(Q_{j'},\lambda)=\sup_{\lambda}Q_{j'}(x)-\inf_{\lambda}Q_{j'}(x)\leqslant C2^{-j}\sup_{\lambda}|\nabla Q_{j'}(x)|\leqslant C2^{-j}2^{j'}\sup_{D\lambda'\cap\lambda\neq\varnothing}|C_{\lambda'}|,$$

where $D\lambda'$ is the cube $k'2^{-j'}+2^{-j'}[0,D]^d$ [which contains the support of the wavelet $\psi(2^{j'}x-k')$]. Note that, if we use nth-order differences in the definition of the oscillation, using Taylor's formula, the upper bound becomes

$$\mathrm{osc}(Q_{j'},\lambda)\leqslant C2^{-n(j-j')}\sup_{D\lambda'\cap\lambda\neq\varnothing}|C_{\lambda'}|. \tag{21}$$

If $j'\geqslant j$,

$$\mathrm{osc}(Q_{j'},\lambda)\leqslant C\sup_{D\lambda'\cap\lambda\neq\varnothing}|C_{\lambda'}|.$$

Thus

$$\mathrm{Osc}_p(f,j)\leqslant C\sum_k \sum_{j'<j} 2^{-np(j-j')} \sup_{D\lambda'\cap\lambda\neq\varnothing} |C_{\lambda'}|^p + C\sum_k \sum_{j'\geqslant j} \sup_{D\lambda'\cap\lambda\neq\varnothing} |C_{\lambda'}|^p. \tag{22}$$

We will first bound the second sum; we can suppose that all the suprema in (22) are finite, and, after perhaps changing the constant C, that they are attained. Let λ be fixed and $j'\geqslant j$. Since $\lambda'\subset\lambda$, $D\lambda'\subset D\lambda$; thus, either the supremum is attained for $\lambda'\subset\lambda$, or it is attained in one of the D^d cubes included in $D\lambda$, of size 2^{-j}, so that

$$\sum_k \sum_{j'\geqslant j} \sup_{D\lambda'\cap\lambda\neq\varnothing} |C_{\lambda'}|^p \leqslant CD^d \sum_k \sum_{j'\geqslant j} \sup_{\lambda'\subset\lambda} |C_{\lambda'}|^p.$$

The same argument applied to the first sum of (22) yields the upper bound

$$C'\sum_{j'<j}\sum_k 2^{np(j'-j)}|C_{\lambda'}|^p, \tag{23}$$

where λ' is the dyadic cube of side $2^{-j'}$ which contains λ. Each cube λ' contains $2^{d(j-j')}$ cubes λ, so that (23) is bounded by

$$C\sum_{j'<j}\sum_{k'} 2^{(d-np)(j-j')}|C_{\lambda'}|^p.$$

Thus

$$\mathrm{Osc}_p(f,j)\leqslant C\sum_{j'<j}\sum_{k'} 2^{(d-np)(j-j')}|C_{\lambda'}|^p + C\sum_k \sum_{j'\geqslant j} \sup_{\lambda'\subset\lambda} |C_{\lambda'}|^p. \tag{24}$$

We will now obtain a lower bound for the p oscillation of f; since the wavelets have a vanishing integral,

$$\begin{aligned} |C_{\lambda'}| &= \left| \int f(x) 2^{dj'} \psi(2^{j'}x-k')\,dx \right| \\ &= \left| \int (f(x)-f(k'2^{-j'}))2^{dj'}\psi(2^{j'}x-k')\,dx \right| \\ &\leqslant C\ \mathrm{osc}(f,D\lambda') \end{aligned}$$

(if the oscillation is defined using nth-order differences, the argument is the same, using wavelets with at least n vanishing moments). Let j be fixed and $j'\geqslant j$ and λ' be a dyadic cube. Either there exists λ such that $D\lambda'\subset\lambda$, in which case

$$|C_{\lambda'}|\leqslant C\ \mathrm{osc}(f,\lambda),$$

or $D\lambda'$ intersects, at most, D^d cubes λ and

$$|C_{\lambda'}|\leqslant C\sum \mathrm{osc}(f,\lambda),$$

where the sum is taken on these D^d cubes. Thus,

$$\forall j \sum_k \sup_{\lambda'\subset\lambda} |C_{\lambda'}|^p \leqslant CD^d \sum_k \mathrm{osc}(f,\lambda)^p = CD^d\ \mathrm{Osc}_p(f,j). \tag{25}$$

The second imbedding in (10) follows.

V. COMPARISON OF THE UPPER AND LOWER BOUNDS

The right-hand side of (24) and the left-hand side of (25) need not be of the same order of magnitude. We will nonetheless see that it is the case if $f \in C^{\epsilon}(\mathbf{R}^d)$ for an $\epsilon > 0$. This uniform regularity condition implies that (cf. Ref. 2)

$$\exists C > 0, \quad \forall j', k', \quad |C_{\lambda'}| \leqslant C 2^{-\epsilon j'}. \tag{26}$$

For λ fixed, denote

$$A(\lambda) = \sup_{\lambda' \subset \lambda} |C_{\lambda'}|^p, \tag{27}$$

$$B(\lambda) = \sum_{j' \geqslant j} \sup_{\lambda' \subset \lambda} |C_{\lambda'}|^p. \tag{28}$$

Estimate (25) can be rewritten as

$$\sum_k A(\lambda) \leqslant C \ \mathrm{Osc}_p(f, j), \tag{29}$$

and estimate (24) can be rewritten as

$$\mathrm{Osc}_p(f, j) \leqslant C \sum_{j' < j} \sum_{k'} 2^{(d - np)(j - j')} |C_{\lambda'}|^p + C \sum_k B(\lambda);$$

thus, if ω is such that

$$\forall j \sum_{\lambda \in \Lambda_j} \sup_{\lambda' \subset \lambda} |C_{\lambda'}|^p \leqslant 2^{-\omega j}, \tag{30}$$

$$\mathrm{Osc}_p(f, j) \leqslant C \sum_{j' < j} 2^{(d - np)(j - j')} 2^{-\omega j'} + C \sum_k B(\lambda). \tag{31}$$

Let us now compare $A(\lambda)$ and $B(\lambda)$; of course,

$$A(\lambda) \leqslant B(\lambda). \tag{32}$$

Let $\mu (= \mu(j,k))$ be defined by $A(\lambda) = 2^{-\mu j}$. In (28) we can bound $\sup_{\lambda' \subset \lambda} |C_{\lambda'}|^p$ either by $C 2^{-\epsilon p j'}$, or by $2^{-\mu j}$. Thus

$$B(\lambda) \leqslant \sum_{j' = j}^{[\mu j / \epsilon p]} 2^{-\mu j} + C \sum_{j' = [\mu j / \epsilon p] + 1}^{\infty} 2^{-\epsilon p j'} = \left(\left[\frac{\mu j}{\epsilon p} \right] - j \right) 2^{-\mu j} + C 2^{-\epsilon p [\mu / \epsilon p] j} \leqslant \frac{C \mu j}{\epsilon p} 2^{-\mu j},$$

so that

$$B(\lambda) \leqslant C A(\lambda) |\log A(\lambda)|. \tag{33}$$

We consider now the right-hand side terms of (31).

Let $R > 0$; in the last sum of (31), we separate the terms for which $B(\lambda) \leqslant 2^{-Rj}$ [and the corresponding sum is bounded by $\mathcal{O}(2^{dj} 2^{-Rj})$], and the other terms for which, because of (32) and (33),

$$|\log A(\lambda)| \leqslant 2 |\log B(\lambda)| \leqslant 2 R j \log 2;$$

so that, using (33), we finally get

$$\sum_k B(\lambda) \leqslant CRj \sum_k A(\lambda) + \mathcal{O}(2^{(d-Rp)j}).$$

Thus $\forall \eta > 0$ and $\forall R > 0$, $\mathrm{Osc}_p(f,j)$ is bounded by

$$C \sum_{j'<j} 2^{(d-np)(j-j')} 2^{(-\omega+\eta)j'} + CRj \sum_k A(\lambda) + \mathcal{O}(2^{(d-Rp)j}). \tag{34}$$

The first imbedding in (10) is then a direct consequence of (29), (30), and (34), by taking η arbitrarily small and R large enough; hence Theorem 1 holds for compactly supported wavelets.

VI. INDEPENDENCE OF THE WAVELET BASIS

We now prove Proposition 1. Recall that we write $\lambda = \lambda_{j,k}$, $\lambda' = \lambda_{j',k'}, \ldots$. Let $D_{\lambda'} = \Sigma_{\lambda''} A(\lambda', \lambda'') C_{\lambda''}$ and

$$\omega_{\lambda,\lambda'} = \frac{2^{-(d/2+\gamma)|j-j'|}}{(1+(j-j')^2)(1+2^{\inf(j,j')}\ \mathrm{dist}(\lambda,\lambda'))^{d+\gamma}}.$$

The $D_{\lambda'}$ satisfy $|D_{\lambda'}| \leqslant C \Sigma_{\lambda''} C \omega_{\lambda',\lambda''} |C\lambda''|$; assume that the C_λ satisfy (9); we want to bound

$$\sum_{|\lambda|=2^{-j}} \sup_{\lambda' \subset \lambda} 2^{s'pj'} |D_{\lambda'}|^p \leqslant \sum_{|\lambda|=2^{-j}} \sup_{\lambda' \subset \lambda} 2^{s'pj'} \left(\sum_{\lambda''} \omega_{\lambda',\lambda''} |C_{\lambda''}| \right)^p.$$

We split the sum over λ'' into two terms depending on whether $\lambda'' \subset 3\lambda$ or $\lambda'' \not\subset 3\lambda$.

First case: $\lambda'' \subset 3\lambda$. Then, if $\gamma > |s'|$ (see Ref. 2),

$$\sum_{\lambda'' \subset 3\lambda} \omega_{\lambda',\lambda''} |C_{\lambda''}| \leqslant \Big(\sup_{\lambda'' \subset 3\lambda} 2^{s'j''} |C_{\lambda''}| \Big) \sum_{\lambda''} 2^{-s'j''} \omega_{\lambda',\lambda''} \leqslant C \sup_{\lambda'' \subset 3\lambda} (|C_{\lambda''}| 2^{s'j''}) 2^{-s'j'};$$

therefore

$$\sum_{|\lambda|=2^{-j}} \sup_{\lambda' \subset \lambda} 2^{s'pj'} \left(\sum_{\lambda'' \subset 3\lambda} \omega_{\lambda',\lambda''} |C_{\lambda''}| \right)^p \leqslant C 2^{s'pj''} \sum_{|\lambda|=2^{-j}} \sup_{\lambda'' \subset 3\lambda} |C_{\lambda''}|^p$$

$$\leqslant C 3^d 2^{s'pj''} \sum_{|\lambda|=2^{-j+1}} \sup_{\lambda'' \subset \lambda} |C_{\lambda''}|^p.$$

Second case: $\lambda'' \not\subset 3\lambda$. Then $2^{s'j'} \omega_{\lambda',\lambda''} \leqslant C 2^{s'j''} \tilde{\omega}_{\lambda,\lambda''}$, where $\tilde{\omega}_{\lambda,\lambda''}$ is defined as $\omega_{\lambda,\lambda''}$, except that we pick a $\tilde{\gamma} = \gamma - s'$; so that

$$\sum_{|\lambda|=2^{-j}} \sup_{\lambda' \subset \lambda} 2^{s'pj'} \left(\sum_{\lambda'' \not\subset 3\lambda} \omega_{\lambda',\lambda''} |C_{\lambda''}| \right)^p \leqslant C \sum_{|\lambda|=2^{-j}} \left(\sum_{\lambda''} 2^{s'j''} \omega_{\lambda,\lambda''} |C_{\lambda''}| \right)^p$$

$$\leqslant C \sup_{j'} 2^{s'pj'} \sum_{|\lambda'|=2^{-j'}} |C_{\lambda'}|^p$$

[the last inequality holds by continuity of the operators in $\mathcal{O}p(M^\gamma)$ on the spaces $B_p^{s,\infty}$; see Ref. 2]; hence Proposition 1 follows.

VII. LACUNARY WAVELET SERIES

We first recall the model of the lacunary wavelet series introduced in Ref. 7, and the main properties of the sample paths of these processes. The process $\mathbf{F}_{\alpha,\eta}$ we consider is defined on $[0,1]$ and depends on two parameters: $\eta \in (0,1)$ and $\alpha > 0$. It is defined by its wavelet coefficients as follows. For $j \geqslant 0$ we pick at random and independently $[2^{nj}]$ positions $k \in \{0,\ldots,2^j - 1\}$, and the

corresponding wavelet coefficients will be $C_{j,k}=2^{-\alpha j}$; the other wavelet coefficients are set to 0. The parameter η characterizes the *lacunarity* of the wavelet series, whereas α is related to the uniform regularity; indeed, it follows directly from the uniform regularity criterium of Ref. 2 that, if α is not an integer, $\mathbf{F}_{\alpha,\eta}\in C^{\alpha}(\mathbf{R})$, and this regularity is the best possible uniform regularity. Nonetheless, $\mathbf{F}_{\alpha,\eta}$ has much smoother sample paths at most locations. The Hölder exponent of $\mathbf{F}_{\alpha,\eta}$ is almost surely almost everywhere α/η. The spectrum of chirps of $\mathbf{F}_{\alpha,\eta}$ is supported by the segment $h=\alpha(\beta+1)$, $h\in[\alpha,\alpha/\eta]$ and is equal to $\eta h/\alpha$ on this segment; see Ref. 7.

Let us first compute the fractal dimension of the graph of $\mathbf{F}_{\alpha,\eta}$. Let J be fixed. We will estimate the oscillation of $\mathbf{F}_{\alpha,\eta}$ on each interval λ of length 2^{-J}. Let $\epsilon>0$. If $2^{(\eta-\epsilon)}\geqslant 2^{J}$, at least one wavelet coefficient of generation j is located in each interval with a probability of at least $1-e^{-Cj}$. Therefore

$$\mathrm{Osc}(\mathbf{F}_{\alpha,\eta},J)\geqslant 2^{J}2^{-\alpha J},\quad \text{for } j=\frac{J}{\eta-\epsilon},$$

so that

$$\mathrm{Osc}(\mathbf{F}_{\alpha,\eta},J)\geqslant 2^{J(1-\alpha/(\eta-\epsilon))},\quad \forall\epsilon>0,$$

and $\overline{\dim_b}(\mathrm{Graph}(\mathbf{F}_{\alpha,\eta}))\geqslant 2-\alpha/\eta$.

On the other side, if $j\geqslant J$,

$$\mathrm{osc}(\Delta_j,J)\leqslant 2^{-\alpha j}2^{\eta j},\quad \text{for } j\leqslant\frac{J}{\eta}$$

and

$$\mathrm{osc}(\Delta_j,J)\leqslant 2^{-\alpha j}2^{J},\quad \text{for } j\geqslant\frac{J}{\eta};$$

thus $\mathrm{Osc}(\mathbf{F}_{\alpha,\eta},J)\leqslant C2^{J(1-\alpha/\eta)}$. Hence, the following theorem holds.

Theorem 2: *The fractal dimension of the graph of the lacunary wavelet series* $\mathbf{F}_{\alpha,\eta}$ *is*

$$\overline{\dim_b}(\mathrm{Graph}(\mathbf{F}_{\alpha,\eta}))=\sup\left\{1,2-\frac{\alpha}{\eta}\right\}.$$

We can now check what the formula proposed in Ref. 6 would yield on this example. The norm of $\mathbf{F}_{\alpha,\eta}$ in $B_1^{s,\infty}$ is

$$\sup_j\sum_k 2^{(s-1)j}|C_{j,k}|=\sup_j\sum_k 2^{(s-1)j}2^{-\alpha j}2^{\eta j},$$

which is finite if $s<\alpha-\eta+1$. Thus, the formula of Ref. 6 yields a dimension $2-(\alpha-\eta+1)=1-\alpha+\eta$, which is correct only when $\eta=1$, i.e., when the wavelet series is no longer lacunary. Note that the counterexample proposed by Kamont and Wolnik is very similar: it is a deterministic lacunary series on the Schauder basis.

Let us consider in this example the effect of a fractional integration (or derivation if s is negative) of order s [when $(s+\alpha)/\eta\leqslant 1$] on the fractal dimension of the graph: It amounts to replacing the wavelet coefficients $2^{-\alpha j}$ by $2^{-(\alpha+s)j}$ (and to replace the orthogonal wavelet basis by a biorthogonal one, which is of no consequence here, since the passage matrix belongs to the algebras M^{γ}). Note that, for this example, the imbeddings (14) together with Corollary 1 imply that the dimension of the graph is lessened by s/η and not by s as might be expected. *This happens because the computation of the fractal dimension of a graph takes strongly into account the contribution of the chirps, and their Hölder exponent changes by more than s after a fractional integration or derivation of order s*. Note, for instance, that the fractal dimension of the graph of a Weierstrass function $\Sigma 2^{-\alpha j}\sin(2^{j}x)$ changes by only s after a fractional integration or derivation

of order s, which is consistent with the fact that they have no chirps. It is the same for the Riemann function $\Sigma n^{-2}\sin(n^2x)$; see Ref. 17, which has a too small number of chirps (they are countable; see Ref. 8).

Let us now check formula (19) of the multifractal formalism for chirps in this case. Let J be fixed. For each interval of length 2^{-J} we consider the first nonvanishing wavelet coefficient in the interval. For $2^{\eta J}$ of them, the size of this coefficient will be $2^{-\alpha J}$. For $2^{\eta(J+1)}$ of them, it will be $2^{-\alpha(J+1)},\ldots$, until J', such that $2^{\eta J'}=2^J$ for which the size will be $2^{-\alpha J'}$. After that level, all intervals will contain one coefficient. Thus, with probability arbitrarily close to 1 for J large enough,

$$\sum_k \sup_{\lambda'\subset\lambda}(2^{s'j'}|C_{\lambda'}|^p)=\sum_{j'=J}^{J/\eta}2^{\eta j'}2^{s'j'}2^{-\alpha j'p},\quad \text{if } s'\leqslant\alpha p$$

$$=+\infty,\quad \text{otherwise.}$$

Therefore

$$\text{if } -s'+\alpha p\leqslant 0,\quad \zeta(s',p)=-\infty;$$

$$\text{if } 0\leqslant -s'+\alpha p\leqslant\eta,\quad \zeta(s',p)=(-s'+\alpha p-\eta)/\eta;$$

$$\text{if } -s'+\alpha p\geqslant\eta,\quad \zeta(s',p)=-s'+\alpha p-\eta.$$

A standard computation shows that the Legendre transform (19) of this function is supported by $h=\alpha(\beta+1)$, and is equal to $\eta h/\alpha$ for $h\in[\alpha,\alpha/\eta]$ and to 1 if $h\geqslant\alpha/\eta$. Therefore, the multifractal formalism allows us to recover correctly the increasing part of the spectrum.

The advantage of using the multifractal formalism for chirps is patent on this example: first, it yields more complete information about the Hölder singularities of the function, but, furthermore, the standard multifractal formalism is completely wrong here: The reader can easily check that, for the function $\mathbf{F}_{\alpha,\eta}$, $\tau(p)=1+\alpha p-\eta$ which would yield a spectrum supported only on $h=\alpha$, for which $d(\alpha)=\eta$, whereas the right spectrum is supported by the interval $[\alpha,\alpha/\eta]$ on which $d(h)=h\eta/\alpha$.

(Received 15 January 1998; accepted for publication 31 March 1998)

We introduce a new class of random fractal functions using the orthogonal wavelet transform. These functions are built recursively in the space-scale half-plane of the orthogonal wavelet transform, ''cascading'' from an arbitrary given large scale towards small scales. To each random fractal function corresponds a random cascading process (referred to as a *$\mathscr{W}$-cascade*) on the dyadic tree of its orthogonal wavelet coefficients. We discuss the convergence of these cascades and the regularity of the so-obtained random functions by studying the support of their singularity spectra. Then, we show that very different statistical quantities such as correlation functions on the wavelet coefficients or the wavelet-based multifractal formalism partition functions can be used to characterize very precisely the underlying cascading process. We illustrate all our results on various numerical examples. © *1998 American Institute of Physics.* [S0022-2488(98)01008-1]

I. INTRODUCTION

Fractal and multifractal concepts[1–3] are now widely used to characterize multiscale phenomena that occur in various situations in physics, chemistry, geology and biology.[4–13] The multifractal formalism has been originally established to account for the statistical scaling properties of singular measures.[2,3,14–21] This formalism lies upon the determination of the so-called $f(\alpha)$ singularity spectrum[2] which quantifies the relative contribution of each singularity of the measure: Let S_α be the subset of points x where the measure of an ϵ-box $B_x(\epsilon)$, centered at x, scales like $\mu(B_x(\epsilon))\sim\epsilon^\alpha$ in the limit $\epsilon\to 0^+$, then by definition, $f(\alpha)=\dim_H(S_\alpha)$ is the Hausdorff-dimension of S_α. Actually, there exists a deep analogy that links the multifractal formalism with that of statistical thermodynamics.[22–24] This analogy provides a natural connection between the $f(\alpha)$ spectrum and a directly observable spectrum $\tau(q)$ defined from the power-law behavior, in the limit $\epsilon\to 0^+$, of the partition function[2,25] $Z_q(\epsilon)=\sum_i \mu(B_i(\epsilon))^q\sim\epsilon^{\tau(q)}$, where the sum is taken over a partition of the support of the singular measure into boxes of size ϵ. The variables q and $\tau(q)$ play the same role as the inverse of temperature and the free energy in thermodynamics, while the Legendre transform $f(\alpha)=\min_q(q\alpha-\tau(q))$ indicates that, instead of energy and entropy, we have α and $f(\alpha)$ as the thermodynamical variables conjugate to q and $\tau(q)$, respectively.[2,16–18,26] Let us recall that this thermodynamic multifractal formalism has been worked out in mathematics in the context of dynamical system theory.[22–24] However, rigorous proof of the above connection has been made only on some restricted classes of singular measures, e.g., invariant measures of some expanding Markov maps (''cookie-cutter'' Cantor sets) on an interval or a circle,[17,21] the invariant measure associated to the dynamical systems for period-doubling and for critical circle mappings with golden rotation number.[17] It has been developed into a powerful technique accessible also to experimentalists. Successful applications have been reported for multifractal measures which appear beyond the scope of dynamical systems.[6,10] Although valid for deterministic multifractals only, this description has been mainly applied for characterizing stochastic systems. But there is no reason, *a priori*, that all the realizations of the same stochastic multifractal measure correspond to a unique $f(\alpha)$-curve. Each realization has its own unique distribution of singularities and one crucial issue is to relate these distributions to

some averaged versions computed experimentally. As emphasized in Ref. 27, one can take further advantage of the analogy with the thermodynamic formalism by using methods created specifically to study disorder in spin-glass theory.[28] When carrying out replica averages of the random partition function associated with a stochastic measure, one gets multifractal spectra $\tau(q,n)$ that generally depend on the number of members n in the replica average chosen (let us note that $n=0$ and $n=1$ correspond, respectively, to commonly used quenched and annealed averaging).[27] Then by Legendre transforming $\tau(q,n)$, some type of averaged $f(\alpha)$ spectra are being found.[27] Some care is thus required when interpreting these average spectra in order to avoid some misunderstanding of the underlying physics.

Multiplicative cascade models have enjoyed increasing interest in recent years as the paradigm of multifractal objects.[1–3,27,29] The notion of cascade actually refers to a self-similar process whose properties are defined multiplicatively from coarse to fine scales. In that respect, it occupies a central place in the statistical theory of turbulence.[13,29] Since Richardson's famous poem,[31] the turbulent cascade picture has been often invoked to account for the intermittency phenomenon observed in fully developed turbulent flows:[29,30] Energy is transferred from large eddies down to small scales (where it is dissipated) through a cascade process in which the transfer rate at a given scale is not spatially homogeneous, as supposed in the theory developed by Kolmogorov in 1941,[32] but undergoes local intermittent fluctuations.[13] Over the past 30 years, refined models including the log-normal model of Kolmogorov[33] and Obukhov,[34] multiplicative hierarchical cascade models like the random β-model, the α-model, the p-model (for a review see Ref. 29), the log-stable models[35–37] and more recently the log-infinitely divisible cascade models[38–41] with the rather popular log-Poisson model advocated by She and Leveque,[42] have grown in the literature as reasonable models to mimic the energy cascading process in turbulent flows. On a very general ground, a self-similar cascade is defined by the way the scales are refined and the statistics of the multiplicative factors at each step of the process.[27,29,37] One can thus distinguish discrete cascades that involve discrete scale ratios leading to log-periodic corrections to scaling (discrete scale invariance[43]), from continuous cascades without preferable scale factors (continuous scale invariance). As far as the fragmentation process is concerned, one can specify whether some conservation laws are operating or not;[27] in particular one can discriminate between conservative (the measure is conserved at each cascade step) and nonconservative (only some fraction of the measure is transferred at each step) cascades. More fundamentally, there are two main classes of self-similar cascade processes: deterministic cascades that generally correspond to solvable models and random cascades that are likely to provide more realistic models but for which some theoretical care is required as far as their multifractal limit and some basic multifractal properties (including multifractal phase transitions) are concerned.[27] As a notable member of the later class, the independent random cascades, introduced by Mandelbrot (commonly called $\mathscr{M}$-cascades)[30,44] as a general model of random curdling in fully developed turbulence, have a special status since they are the main cascade model for which deep mathematical results have been obtained.[45,46]

However, in physics as well as in other applied sciences, fractals appear not only as singular measures, but also as singular functions.[1,4–13] In order to stay in the context of fully developed turbulence, directly observable quantities are the velocity field or the temperature field rather than the dissipation field.[13,47] A classical way of analyzing the intermittent character of turbulent velocity signals consists in calculating the moments $S_p(l)=\langle \delta v_l^p \rangle \sim l^{\zeta_p}$ of the probability density function of longitudinal velocity increments $\delta v_l(x)=v(x+l)-v(x)$ over inertial separation l.[13,47,48] As originally prompted by Frisch and Parisi,[49] by Legendre transforming the scaling exponents ζ_p of the structure functions S_p, one expects to get the Hausdorff dimension $D(h)=\min_p(ph-\zeta_p+1)$ of the subset of $\mathbf{R}$ for which the velocity increments behave as $\delta v_l \sim l^h$. In a more general context, $D(h)$ will be defined as the spectrum of Hölder exponents of the signal under study and thus will have a similar status than the $f(\alpha)$-singularity spectrum for singular measures. Unfortunately, as pointed out by Muzy *et al.*,[50] there are some fundamental limitations to the structure function approach which intrinsically fails to fully characterize the $D(h)$ singularity spectrum. In previous work,[51–54] we have shown that there exists a natural way of performing a multifractal analysis of fractal functions which consists of using the continuous wavelet transform.[55–57] By using wavelets instead of boxes, like in the classical multifractal formalism,[2] one can take advantage of the freedom in the choice of these ''generalized oscillating boxes'' to get rid of possible smooth behavior that could mask singularities or perturb the estimation of their

strength h.[52,53] The other fundamental advantage of using wavelets is that the skeleton defined by the wavelet transform modulus maxima (WTMM) provides an adaptative space-scale partitioning from which one can extract the $D(h)$ singularity spectrum via the scaling exponents $\tau(q)$ of some partition functions defined on the skeleton. The so-called WTMM method[50–54] therefore gives access to the entire $D(h)$ spectrum via the usual Legendre transform $D(h)=\min_q(qh-\tau(q))$. We refer the reader to Refs. 52,58 for rigorous mathematical results. Let us mention that for the same reasons previously raised for stochastic multifractal measures, the theoretical treatment of random multifractal functions requires special attention. Let us also note that in a more recent work,[59–61] we have further generalized the WTMM multifractal formalism in order to incorporate in this statistical description (which applies for cusp-like singularities only) the possible existence of oscillating singularities. This new ''grand canonical'' description allows us to get the singularity spectrum $D(h,\beta)$ which accounts for the statistical contribution of singularities of Hölder exponent h and oscillation exponent β (where β characterizes the local power-law divergence of the instantaneous frequency).

Beyond the multifractal description, there is, however, the practical issue of defining in any concrete way how to build a multifractal function. Schertzer and Lovejoy[35] suggested a simple power-law filtering (fractional integration) of singular cascade measure as a mean to stochastically simulate fields reminiscent of passive scalars in turbulence. In the same spirit, the bounded cascade model of Marshak *et al.*[62] consists in acting on the multiplicative weights during the cascade in physical space. In Ref. 63, the midpoint displacement technique for building fractional Brownian motions was generalized to generate deterministic or random multiaffine functions. The same goal was achieved in Refs. 52,53 by combining fractional or ordinary integration with signed measures obtained by recursive cascade like procedures. Several other attempts to simulate ''synthetic turbulence'' that shares the intermittency properties of turbulent velocity data have partially succeeded.[64–66] More recently, the concept of self-similar cascades leading to multifractal measures has been generalized to the construction of scale-invariant signals using orthonormal wavelet basis.[67–70] Instead of redistributing the measure over sub-intervals with multiplicative weights, one allocates the wavelet coefficients in a multiplicative way on the dyadic grid. This method allows us to generate multifractal functions from a given deterministic or probabilistic multiplicative process. The main goal of this paper is to provide some mathematical framework to random $\mathscr{W}$-cascades on wavelet dyadic trees.[67–70]

The paper is organized as follows. In Secs. II and III, we explain how the $\mathscr{W}$-cascades are built using a wavelet orthogonal basis and we characterize the regularity properties of their corresponding random fractal functions by studying the support of their singularity spectrum. This support is linked to the statistical spectrum obtained with the wavelet based multifractal formalism.[50–54] The self-similarity kernel[41,68–72] which, from a statistical point of view, characterizes the self-similarity properties of a cascade process (in a different way from the multifractal formalisms) is introduced in Sec. IV. In Sec. V, we compute explicitly the correlation function of two wavelet coefficients of a $\mathscr{W}$-cascade.[73] It is proved to follow a power-law behavior when varying the spatial distance of the two coefficients. The statistical spectrum, the self-similarity kernel as well as the correlation function are shown to be numerically well estimated directly on the fractal function, using its wavelet decomposition (continuous, orthogonal or its associated extrema representation) with an arbitrary analyzing wavelet. All these results are illustrated on various computer generated numerical signals.

II. INTRODUCING WAVELET RANDOM CASCADES

A. The periodic wavelet orthogonal decomposition

As mentionned in the introduction, a $\mathscr{W}$-cascade[67–70] is built recursively on the dyadic grid of the orthogonal wavelet transform,[55–57] involving only scales that range between a given large scale L and the scale 0 (excluded). Thus the corresponding fractal function $f(x)$ does not involve scales greater than L. We can thus consider, for the sake of simplicity, that $f(x)$ is a periodic function of period L. In the following we will choose $L=1$. The $\mathscr{W}$-cascade will then be defined using a periodic orthonormal wavelet basis[74] of $L^2_{\mathrm{per}}([0,1])$, i.e., the space of 1-periodic functions with finite energy.

Such a basis can be constructed using two functions $\phi(x)$ and $\psi(x)$ of $L^2_{\text{per}}([0,1])$ (ψ is referred to as the *analyzing wavelet*) by means of translations and dilations of $\psi(x)$

$$\psi_{j,k}=2^{j/2}\psi(2^j x-k), \quad j\geqslant 0, \quad 0\leqslant k<2^{j-1}. \tag{1}$$

One can prove[55–57,74] that the so-obtained family of functions $\{\phi(x),\{\psi_{j,k}\}_{j,k}\}$ is an orthonormal basis of $L^2_{\text{per}}([0,1])$ if ϕ and ψ satisfy some conditions. Among these conditions, $\psi(x)$ should be localized around 0 and have N_ψ ($\geqslant 1$) vanishing moments

$$\int_0^1 x^n \psi(x)dx=0, \quad \text{for all } n<N_\psi. \tag{2}$$

The *wavelet coefficients* $\{c_\phi,\{c_{j,k}\}_{j,k}\}$ of a function $f(x)$ are then defined (modulo a normalization factor) as the coefficients of f in the orthonormal wavelet basis

$$\begin{cases} c_\phi=\langle f,\phi\rangle=\displaystyle\int_0^1 f(x)\phi(x)dx, \\ c_{j,k}=2^{j/2}\langle f,\psi_{j,k}\rangle=2^{j/2}\displaystyle\int_0^1 f(x)\psi_{j,k}(x)dx. \end{cases} \tag{3}$$

Remark: Let us note that the usual definition of the wavelet coefficients does not involve any normalization factor.[55–57] However, as we will see in Sec. III, the normalization factor $2^{j/2}$ has been introduced so that the Lipschitz exponent can be directly deduced from the power-law behavior of the coefficients $\{c_{j,k}\}_{j,k}$.

Since $\{\phi(x),\{\psi_{j,k}\}_{j,k}\}$ is an orthonormal basis, one gets the reconstruction formula

$$f(x)=c_\phi\phi(x)+\sum_{j\geqslant 0} 2^{-j/2}\sum_{0\leqslant k<2^j} c_{j,k}\psi_{j,k}(x). \tag{4}$$

On the one hand, let us note that, since all the $\psi_{j,k}$ have at least one vanishing moment, c_ϕ essentially ''captures'' the mean value of f. This explains why it is often referred to as the *approximation coefficient*.[55–57] On the other hand, assuming that the scale 1 ''corresponds'' to $\psi(x)$, one can easily prove that $\psi_{j,k}(x)$ is localized around $x=x_{j,k}$ and corresponds to the scale a_j with

$$x_{j,k}=2^{-j}k \quad \text{and} \quad a_j=2^{-j}. \tag{5}$$

Therefore, $c_{j,k}$ essentially captures the details of $f(x)$ around the point $x_{j,k}$ and at the scale a_j. They will be referred to as the *detail coefficients*.[55–57] As displayed in Fig. 1, these coefficients lie on a *dyadic grid* in the space-scale half-plane.

B. Building a $\mathscr{W}$-cascade

In this section, we build a random function $f(x)$ by specifying its wavelet coefficients $\{c_{j,k}\}_{j,k}$ and c_ϕ. The coefficient c_ϕ is chosen to be an arbitrary random variable and the $\{c_{j,k}\}_{j,k}$ are defined recursively in the following way:[68–70]

$$\begin{cases} c_{0,0}=1, \\ c_{j,2k}=W^{(l)}_{j-1,k}c_{j-1,k}, \\ c_{j,2k+1}=W^{(r)}_{j-1,k}c_{j-1,k}, \end{cases} \tag{6}$$

for all j ($j\geqslant 1$) and k ($0\leqslant k<2^{j-1}$) and where the $W^{(\epsilon)}_{j,k}$ ($\epsilon=l$ or r) are independent identically distributed (i.i.d.) real valued random variables.

Notation 1: Since all the random variables $W^{(\epsilon)}_{j,k}$ are i.i.d., we will often omit the indexes j,k and (ϵ) and we will use W as the generic name for these variables.

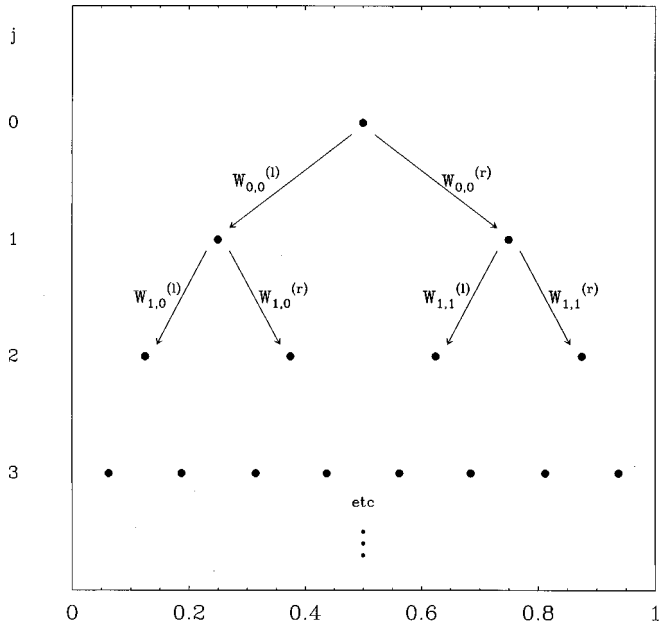

FIG. 1. Sketch of the construction rule of a $\mathscr{W}$-cascade. The wavelet coefficients $\{c_{j,k}\}_{j,k}$ lie on a dyadic grid. At each scale $a_j=2^{-j}$, the grid displays 2^j coefficients with abscissa $x_{j,k}=2^{-j}k$. The value of the wavelet coefficient $c_{j,2k}$ (resp. $c_{j,2k+1}$) is obtained from the value of the wavelet coefficient $c_{j-1,k}$ by multiplying it by $W_{j-1,k}^{(l)}$ (resp. $W_{j-1,k}^{(r)}$) as defined in Eq. (6).

As illustrated in Fig. 1, this recursive rule can be seen as a cascade process going from large scales (starting at scale 1) to smaller scales. It lies on a binary tree whose nodes are the wavelet coefficients and whose branches basically correspond (apart from the sign of the coefficients) to the same action of multiplying by W.

In the following, such a recursive rule will be referred to as a *$\mathscr{W}$-cascade* and $f(x)$ will be referred to as the function *corresponding* to the $\mathscr{W}$-cascade. Let us note that both a $\mathscr{W}$-cascade and its corresponding function are fully defined by the analyzing wavelet ψ, the laws of c_ϕ and W.

Let us note that the so-obtained function $f(x)$ [assuming that the infinite sum in Eq. (4) converges] is *self-similar* in the sense that the law of a wavelet coefficient $|c_{j_1,k}|$ at the scale 2^{-j_1} can be linked to the law of another wavelet coefficient $|c_{j_2,k'}|$ at scale $2^{-j_2}>2^{-j_1}$ using a multiplicative random variable depending only on the ratio of the two scales

$$|c_{j_1,k}| =_l |c_{j_2,k'}| X_{j_1-j_2},$$

where $=_l$ stands for the equality in law and where $X_n=|W_1 \ldots . W_n|$ (the W_i's are i.i.d real valued random variables with the same law as W). Thus, from a statistical point of view, the details of the function f at a scale a_1 are the same as the details at a scale a_2 up to a rescaling factor that depends only on a_1/a_2.

In this section, we just gave a ''theoretical'' description of a $\mathscr{W}$-cascade. Indeed, we have not proved that the sum in Eq. (4) does converge in some sense towards a random function $f(x)$. This will be the purpose of the next section. Actually, we will not only prove that, for almost all realizations of the $\mathscr{W}$-cascade, Eq. (4) does converge in $L^2_{\text{per}}([0,1])$, but we will also be able to characterize some regularity properties of the limit function.

Remark: A $\mathscr{W}$-cascade can be related to the $\mathscr{M}$-cascades previously introduced in Refs. 44–46. An $\mathscr{M}$-cascade is defined using the same recursive rule as a $\mathscr{W}$-cascade [Eq. (6)], but the $c_{j,k}$'s no longer correspond to wavelet detail coefficients: At step j of the recursion, a measure μ_j on $[0,1]$ is defined by $\mu_j[x_{j,k},x_{j,k}+a_j]=c_{j,k}$ $(\forall k, 0\leqslant k<2^{-j})$, where $x_{j,k}$ and a_j are defined as in Eq. (5). In Ref. 45, the authors proved that, under certain conditions (on W), μ_j converges towards a nondegenerated measure μ (when $j\to+\infty$). Thus the main difference between $\mathscr{M}$-cascades and $\mathscr{W}$-cascades is that $\mathscr{M}$-cascades are fractal measure models whereas $\mathscr{W}$-cascades are fractal function models. $\mathscr{M}$-cascades can be used, for instance, for modeling the energy dissipation in a

turbulent flow[29,30,33–42] whereas $\mathscr{W}$-cascades can be used directly for modeling the velocity signal of the same flow.[67–70] Moreover, as we will see in the next section, the underlying wavelet structure of a $\mathscr{W}$-cascade makes the proofs for convergence of the cascade and for the characterization of the corresponding fractal function much easier than for $\mathscr{M}$-cascades.

Remark: Let us note that Eq. (6) can be rewritten as

$$\begin{cases} \ln|c_{0,0}| = 0, \\ \ln|c_{j,2k}| = \ln|c_{j-1,k}| + \ln|W^{(l)}_{j-1,k}|, \\ \ln|c_{j,2k+1}| = \ln|c_{j-1,k}| + \ln|W^{(r)}_{j-1,k}|. \end{cases}$$

If $|W|$ is log-normal, these equations correspond to what one could call a *tree-autoregressive* process. This process is of order 1 in the sense that the regression involves only one term. Actually, we are currently working on higher order models. The notion of autoregressive models lying on a tree (including the orthonormal wavelet dyadic tree) has been introduced by Basseville and collaborators.[75] Let us emphasize that, besides the fact that the processes they study are autoregressive directly on the $c_{j,k}$ and not on their logarithm and that the processes we consider do not really correspond to autoregressive processes in the sense that they are not asymptotically stationnary (i.e., $\{\ln c_{j,k}\}_j$ for a fixed k is not stationary even when $j \to +\infty$), our approach is significantly different from theirs since we concentrate on the analysis of the fractal function $f(x)$ itself and not on the properties of the tree-process.

III. CONVERGENCE AND REGULARITY OF A $\mathscr{W}$-CASCADE

A. Convergence

In order to get the convergence of the sum in Eq. (4) for a given realization of the $\mathscr{W}$-cascade, we need to have upper bounds of the wavelet detail coefficients $\{c_{j,k}\}_{j,k}$. Actually, we are going to study the law of the maximum of the wavelet coefficients $\{c_{j,k}\}_{0 \leqslant k < 2^j}$ at a given scale 2^{-j}. This is the purpose of the following lemma which is proved in Appendix A.

Lemma 1: Let us consider the wavelet coefficients $\{c_\phi, \{c_{j,k}\}_{j,k}\}$ of a given $\mathscr{W}$-cascade associated to the random variable W [Eq. (6)]. Let $m_j = \max_k |c_{j,k}|$ ($m_0 = 1$) and Q_j^α the subset of the probability space Ω

$$Q_j^\alpha = \{\omega \in \Omega, m_j > 2^{-j\alpha}\}.$$

Let us set $q_j^\alpha = \mathrm{Prob}\{Q_j^\alpha\}$ and

$$p_j^\alpha = \mathrm{Prob}\{|W_1 \ldots W_j| > 2^{-j\alpha}\},$$

where the W_i are i.i.d random variables with the same law as W. Then

$$q_j^\alpha \leqslant 2^j p_j^\alpha.$$

Thus in order to get an upper bound to q_j^α, we just need an upper bound of p_j^α. Since p_j^α can be rewritten in the following way: $p_j^\alpha = \mathrm{Prob}\{\Sigma_{i=1}^{\ j} \log_2|W_i| \geqslant -j\alpha\}$, we can easily get an upper bound by using a large deviation property (see Appendix B for the proof of the following Lemma).[76]

Lemma 2: (Same notations as in Lemma 1.) If $\mathscr{E}(\log_2|W|) < +\infty$ then for all $\alpha < -\mathscr{E}(\log_2|W|)$, for all $\epsilon > 0$, there exists $J > 0$ such that for all $j > J$

$$p_j^\alpha < e^{j\epsilon} 2^{j(F(\alpha)-1)},$$

where $F(\alpha)$ is defined as the Legendre transform of the function $\tau(q)$

$$F(\alpha) = \inf_q (q\alpha - \tau(q)), \tag{7}$$

and where $\tau(q)$ is defined as

$$\tau(q) = -\log_2 \mathscr{E}(|W|^q) - 1, \quad \forall q \in \mathbf{R}. \tag{8}$$

Moreover, $F(\alpha)$ is a concave function, such that $F(-\mathcal{E}(\log_2|W|))=1$ and which is increasing on $]-\infty,-\mathcal{E}(\log_2|W|)]$ and decreasing on $[-\mathcal{E}(\log_2|W|),+\infty[$.

We are now ready to state the convergence proposition. For this purpose, we have to make two hypothesis on the law of W. Basically these hypothesis ensure that small values of W are much more probable than large values. This ''asymetry'' of the distribution function of W ensures that, for almost all realizations, the wavelet coefficients will ''fastly'' converge to 0 when the scale goes to 0 and thus that the sum in Eq. (4) will converge.

Proposition 1: (Convergence). *Let us consider a given $\mathcal{W}$-cascade associated with the random variable W [Eq. (6)]. If the law of W is such that*

(H1) $0<-\mathcal{E}(\log_2|W|)$ *and*
(H2) $\exists\,\eta>0,\ F|_{[0,\eta[}<0$ *[where F is defined in Eq. (7)],*
then for almost all realizations of the $\mathcal{W}$-cascade, the sum in Eq. (4) converges in $L^2_{\mathrm{per}}([0,1])$.

Proof: Let $\alpha=\eta/2$. Thus $0<\alpha<-\mathcal{E}(\log_2|W|))$ and $F(\alpha)<0$. By combining Lemma 1 and Lemma 2, one gets that (for ϵ arbitrarily small and j large enough)

$$q_j^\alpha \leqslant 2^j p_j^\alpha < e^{j\epsilon} 2^{jF(\alpha)}$$

and thus

$$\sum_j q_j^\alpha < \infty.$$

This last inequality can be rewritten as $\Sigma_j\ \mathrm{Prob}\{Q_j^\alpha\}<\infty$. By using the Borel-Cantelli lemma, one thus gets

$$\mathrm{Prob}\{Q_j^\alpha \ \text{infinitely often}\}=0,$$

which is equivalent to say that for almost all realizations of the $\mathcal{W}$-cascade, there exists J such that $m_j \leqslant 2^{-j\alpha}$ for $j \geqslant J$. This implies that

$$\sum_{j\geqslant J}\ \sum_{0\leqslant k<2^j} 2^{-j} c_{j,k}^2 \leqslant \sum_{j\geqslant J} m_j^2 \leqslant \sum_{j\geqslant J} 2^{-2\alpha j} < \infty.$$

Thus the sum in Eq. (4) converges in $L^2_{\mathrm{per}}([0,1])$. □

B. Regularity

The global regularity of a function is easily characterized by its orthogonal wavelet coefficients. Indeed, one can prove[77] that $f(x)$ is uniformly Lipschitz α (for $0<\alpha<N_\psi$) if and only if there exists a constant C such that $|c_{j,k}|<C2^{-j\alpha}$ for all j and k.

Let us recall that f is said to be uniformly Lipschitz α with $\alpha\in]0,1]$, if there exists a constant C such that $|f(x)-f(y)|<C|x-y|^\alpha$. Moreover, f is uniformly Lipschitz $\alpha\in]n,n+1]$, if $f^{(n)}$ is uniformly Lipschitz $\alpha-n$ (where $f^{(n)}$ is the nth derivative of f).

Remark: Let us note that the $2^{j/2}$ factor in Eq. (3) has been chosen so that the power-law behavior of $|c_{j,k}|$ when $j\to+\infty$ directly gives the Lipschitz regularity α (instead of $\alpha+1/2$ if there were no factor).

Thus, as for proving the convergence, in order to get the Lipschitz regularity of f, as long as N_ψ is large enough, one just needs to get upper bounds to the wavelet transform coefficients. All the work has already been done in the previous section. The following proposition is a direct application of Lemma 1 and Lemma 2.

Proposition 2: (Maximum global regularity). *Let us consider a given $\mathscr{W}$-cascade associated with the random variable W [Eq. (6)]. Let us suppose that the law of W is such that*

(H1) $0<-\mathscr{E}(\log_2|W|)$ *and*
(H2) $\exists\,\eta>0, F|_{[0,\eta[}<0$ *[where F is defined in Eq. (7)].*

Let us define

$$\alpha_{\min}=\sup\{h<-\mathscr{E}(\log_2|W|),F(h)<0\}. \tag{9}$$

If $\alpha<\alpha_{\min}$ $(0<\alpha<N_\psi)$ *then, for almost all realizations of the $\mathscr{W}$-cascade, $f(x)$ is uniformly Lipschitz α.*

Proof: The proof is very similar to the proof of the convergence proposition (Proposition 1). First, let us note that (according to that proposition) (H1) and (H2) ensure the convergence of the cascade. Let us choose $\alpha<\alpha_{\min}$ and $0<\alpha<N_\psi$. We thus have $0<\alpha<-\mathscr{E}(\log_2|W|)$ and $F(\alpha)<0$. Again, by combining Lemma 1 and Lemma 2 one gets that

$$\sum_j \text{Prob}\{Q_j^\alpha\}<\infty.$$

By using the Borel-Cantelli lemma, one deduces that $\text{Prob}\{Q_j^\alpha \text{ infinitely often}\}=0$. This means that for almost all realizations of the $\mathscr{W}$-cascade, there exists J such that $m_j\leqslant 2^{-j\alpha}$ for $j\geqslant J$, i.e., f is uniformly Lipschitz α. □

Remark: Let us note that, in most common cases, W is such that the left branch F_l of F (i.e., the branch corresponding to $F(\alpha)$ for $\alpha\in]-\infty,-\mathscr{E}(\log_2|W|)]$) is invertible. Thus $\alpha_{\min}$ just corresponds to the value

$$\alpha_{\min}=F_l^{-1}(0). \tag{10}$$

The local *Hölder exponent*[1,53] $h(x_0)$ measures the local regularity of a function f at a given point x_0. It is defined as the greatest exponent h such that there exists a constant C and a polynomial $P(x)$ such that

$$|f(x)-P(x)|<C|x-x_0|^h, \quad \text{for } x \text{ in a neighborhood of } x_0.$$

One can easily prove that $h(x_0)$ is greater than the ''maximum global regularity'' of f (i.e., the maximum α such that f is uniformly Lipschitz α). Thus, Proposition 2 can alternatively be seen as a ''minimum local regularity'' proposition:

Corollary 1: (Minimum local regularity). *Under the hypothesis (H1) and (H2) of Proposition 2, for almost all realizations of the $\mathscr{W}$-cascade, the local Hölder exponent of f at any point x is greater than or equal to $\alpha_{\min}$, i.e.,*

$$\forall x, \quad \alpha_{\min}\leqslant h(x).$$

All the arguments we used in the Lemmas 1 and 2 for deriving upper bounds to the absolute value of the wavelet coefficients can easily be inverted to get lower bounds. These new lemmas will lead to a ''maximum local regularity'' proposition. We are not going to give the full proof of this proposition since it is very close to the proof of the minimum local regularity proposition. We will just give the main steps of the proof.

Proposition 3: (Maximum local regularity). *Let us consider a given $\mathscr{W}$-cascade associated to the random variable W* [*Eq.* (6)]. *Let us suppose that the law of W is such that*

(H1) $0<-\mathscr{E}(\log_2|W|)$ *and*
(H2) $\exists\,\eta>0, F|_{[0,\eta[}<0$ *[where F is defined in Eq. (7)].*
Let us define

$$\alpha_{\max}=\inf\{h>-\mathscr{E}(\log_2|W|),F(h)<0\}. \tag{11}$$

Then, for almost all realizations of the $\mathscr{W}$-cascade, the local Hölder exponent $h(x)$ of $f(x)$ at any point x [as long as $h(x)<N_\psi$] is smaller than or equal to $\alpha_{\max}$, i.e.,

$$\forall x, \quad h(x)<N_\psi \Rightarrow h(x)\leqslant \alpha_{\max}.$$

Proof: We use the same notations as in Sec. III A except that we invert all the inequality signs. We define $\tilde{m}_j=\min_k|c_{j,k}|$, the subset $\tilde{Q}_j^\alpha$ of Ω

$$\tilde{Q}_j^\alpha=\{\omega\in\Omega,\tilde{m}_j<2^{-j\alpha}\},$$

and $\tilde{q}_j^\alpha=\mathrm{Prob}\{\tilde{Q}_j^\alpha\}$ its measure. We also set $\tilde{p}_j^\alpha=\mathrm{Prob}\{|W_1\ldots W_j|<2^{-j\alpha}\}$. Then, using exactly the same proof as for Lemma 1, one can show that

$$\tilde{q}_j^\alpha\leqslant 2^j\tilde{p}_j^\alpha.$$

If $\mathscr{E}(\log_2|W|)<+\infty$ and $\alpha>-\mathscr{E}(\log_2|W|)$ then a large deviation property[76] leads (as for Lemma 2) to

$$\forall\epsilon, \quad \exists J>0, \quad \forall j>J, \quad \tilde{p}_j^\alpha<e^{j\epsilon}2^{j(F(\alpha)-1)}.$$

Then we choose $\alpha>\alpha_{\max}$ with $0<\alpha<N_\psi$. We thus have $\alpha>-\mathscr{E}(\log_2|W|)$ and $F(\alpha)<0$. By using the Borel-Cantelli lemma in the same way as we did in Proposition 2, one gets that for almost all realizations of the $\mathscr{W}$-cascade, one has $\tilde{m}_j>2^{-j\alpha}$.

Moreover, one can prove[78–80] that if $h(x_0)$ $(<N_\psi)$ is the Hölder exponent of a function f at the point x_0, and if h is such that the wavelet coefficients of f verify

$$|c_{j,k}|\leqslant a_j^h+\frac{|x_{j,k}-x_0|^h}{|\ln|x_{j,k}-x_0||}, \tag{12}$$

where $a_j\to 0$ and $x_{j,k}\to x_0$ are defined in Eq. (5), then $h\geqslant h(x_0)$.

Since $c_{j,k}\geqslant\tilde{m}_j>2^{-j\alpha}$, one gets that $\alpha>h(x_0)$. Moreover, α can be chosen arbitrarily close to $\alpha_{\max}$, thus $\alpha_{\max}\geqslant h(x_0)$. □

Remark: In most common cases, W is such that the right branch F_r of F is invertible. In that case, in the same way we had Eq. (10), one gets

$$\alpha_{\max}=F_r^{-1}(0). \tag{13}$$

Generally, a good way to characterize the singular behavior of a function is to compute its *singularity spectrum* $D(h)$.[49–54] It is defined as

$$D(h)=\mathrm{Dim}_H(\{x\in\mathbf{R},h(x)=h\}), \tag{14}$$

where $h(x)$ is the Hölder exponent of the function at the point x and $\mathrm{Dim}_H(\mathscr{P})$ stands for the Hausdorff dimension of a set of points $\mathscr{P}$. Thus one can restate Corollary 1 and Proposition 3 in terms of the support of $D(h)$:

Corollary 2: (Support of the singularity spectrum). *Under the hypothesis (H1) and (H2) of Proposition 2, for almost all realizations of the $\mathscr{W}$-cascade, the support of the singularity spectrum $D(h)$ of f is included in the largest interval on which $F(\alpha)\geqslant 0$, i.e., the interval $[\alpha_{\min},\alpha_{\max}]$ [Eqs. (9) and (11)].*

Remark: Let us note that the Hölder exponents of a given function are fully characterized by its wavelet coefficients $\{c_{j,k}\}_{j,k}$ [through Eq. (12)] as long as these exponents are smaller than N_ψ. Thus the $D(h)$ singularity spectrum of the function $f(x)$ corresponding to a $\mathscr{W}$-cascade does not depend on the analyzing wavelet ψ that is chosen to build the cascade provided N_ψ is large enough. Particularly, as long as ψ satisfies $N_\psi>\alpha_{\max}$ [where $\alpha_{\max}$ defined in Eq. (11) depends only on the law of W], the cascade will correspond to the same singularity spectrum.

Remark: It was proved in Ref. 81 that for any function, the left branch $D_l(h)$ of the singularity spectrum of f is smaller than the left branch $F_l(\alpha)$ of the spectrum obtained with the multifractal formalism. Since the singularity spectrum obtained with the multifractal formalism leads, for almost all realizations of a given $\mathscr{W}$-cascade, to the function $F(\alpha)$ defined by Eq. (7), one can easily prove that for any $\mathscr{W}$-cascade we have

$$D_l(h=\alpha)\leqslant F_l(\alpha).$$

Definition 1: From now on, the function $F(\alpha)$ [Eq. (7)] will be referred to as the statistical spectrum *of the $\mathscr{W}$-cascade.*

Both spectra $D(h)$ and $F(\alpha)$ bring valuable information on the $\mathscr{W}$-cascade. The $D(h)$ spectrum has been initially introduced for characterizing the singular behavior of deterministic fractal signals. It was proved[52,58] that, for a large class of self-similar functions, the $D(h)$ spectrum can be obtained using the wavelet based multifractal formalism. In the case of random $\mathscr{W}$-cascades, we actually get two spectra: the spectrum $D(h)$ for each realization (which *a priori* depends on the realization) and the statistical spectrum $F(\alpha)$ that characterizes the probability that a given singular behavior appears in a realization of the cascade. Thus, for instance, the maximum value of $F(\alpha)$ corresponds to the most probable singular behavior in a realization of a $\mathscr{W}$-cascade. On the other hand, the negative values of $F(\alpha)$ correspond to ''rare'' events that one should not expect to observe in almost all realizations. In the next section, we will show that, in the case of $\mathscr{W}$-cascades, the wavelet based multifractal formalism[50–54] actually leads to a very reliable numerical estimation of the $F(\alpha)$ spectrum. Along with the *kernel* function[41,68–72] that we will introduce in Sec. IV and the correlation functions[73] in Sec. V, these statistical quantities allow a very accurate characterization of the random process.

Before moving on, let us first illustrate our purpose with some numerical simulations of $\mathscr{W}$-cascades corresponding to different laws for W.

C. Numerical simulations of $\mathscr{W}$-cascades

As stated in the Introduction, random cascade models have been introduced in the context of the phenomenological study of fully developed turbulence.[27,29,30,33–42] They were proposed to mimic, in some sense, the kinetic energy transfer from coarser scales to smaller ones. Log-normal statistics have been first guessed, 40 years ago, by Kolmogorov[33] and Obukhov[34] in order to account for the so-called ''intermittency phenomenon'' while the ''log-Poisson'' model[39] has been recently proposed by She and Lévèque[42] as a more accurate description of this phenomenon. Let us illustrate the results discussed above on these two models when extrapolated to multifractal functions.

1. Log-normal $\mathscr{W}$-cascades

Let us first start with W being a log-normal random variable. If μ and σ^2 are, respectively, the mean and the variance of $\ln|W|$ then a straightforward computation leads to

$$\tau(q)=-\frac{\sigma^2}{2\ln 2}q^2-\frac{\mu}{\ln 2}q-1,$$

and

$$F(\alpha)=-\frac{(\alpha+\mu/\ln 2)^2\ \ln 2}{2\sigma^2}+1.$$

Thus a log-normal $\mathscr{W}$-cascade is converging in $L^2_{\mathrm{per}}([0,1])$ if

$$\text{(H1) } \mu<0 \quad \text{and} \quad \text{(H2) } \frac{|\mu|}{\sigma}>\sqrt{2\ln 2}.$$

Moreover, by solving $F(0)=0$, one gets $\alpha_{\min}$ and $\alpha_{\max}$

$$\alpha_{\min}=-\frac{\sqrt{2}\sigma}{\sqrt{\ln 2}}-\frac{\mu}{\ln 2} \quad \text{and} \quad \alpha_{\max}=\frac{\sqrt{2}\sigma}{\sqrt{\ln 2}}-\frac{\mu}{\ln 2}. \tag{15}$$

In Fig. 2, we illustrate one realization of a ''very irregular'' ($\alpha_{\min}=0.13$) log-normal $\mathscr{W}$-cascade as well as one realization of a ''more regular'' one ($\alpha_{\min}=0.3$). The $\tau(q)$ and $F(\alpha)$ spectra corresponding to the irregular $\mathscr{W}$-cascade are displayed on the same figure.

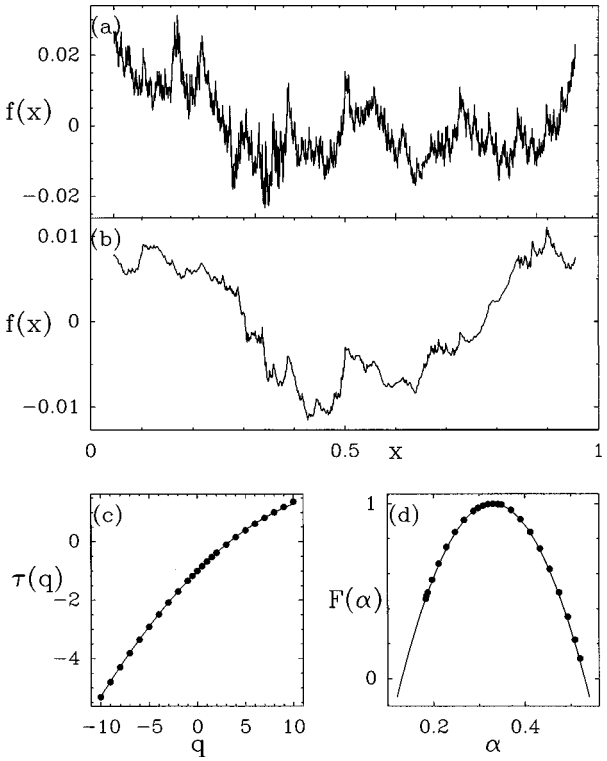

FIG. 2. Log-normal $\mathscr{W}$-cascades. (a) Realization of the random function corresponding to a log-normal $\mathscr{W}$-cascade using the ''Daubechies 5'' compactly supported orthonormal wavelet basis.[56] The law of $\ln|W|$ is Gaussian with mean $\mu=-0.33\ln 2$ and variance $\sigma^2=0.02\ln 2$. From Eq. (15) one gets that $\alpha_{\min}=0.13$ and $\alpha_{\max}=0.53$. (b) Realization of the random function corresponding to a log-normal $\mathscr{W}$-cascade using the ''Daubechies 5'' wavelet with the following parameter values: $\mu=-0.8\ln 2$ and $\sigma^2=0.125\ln 2$. From Eq. (15) one gets that $\alpha_{\min}=0.3$ and $\alpha_{\max}=1.3$. The fact that $\alpha_{\min}$ is greater for the cascade in (b) ($\alpha_{\min}=0.3$) than for the cascade in (a) ($\alpha_{\min}=0.13$) explains why the graph in (a) appears to be much more irregular than the graph in (b). (c) The $\tau(q)$ function [Eq. (8)] for the $\mathscr{W}$-cascade illustrated in (a). The symbols (●) correspond to the data computed using the WTMM method [Eq. (16)] with an order 2 spline wavelet on 1000 realizations of length 65536 of the $\mathscr{W}$-cascade. These numerical data are in remarkable agreement with the theoretical prediction (solid line); this illustrates the fact that the determination of the $\tau(q)$-spectrum can be performed using any analyzing wavelet (i.e., not necessarily the one that was used for building the cascade). (d) The $F(\alpha)$ statistical singularity spectrum [Eq. (7)] for the $\mathscr{W}$-cascade illustrated in (a). The numerical spectrum (●) was obtained by Legendre transforming the $\tau(q)$ data in (c). The theoretical spectrum (solid line) provides a remarkable fit of the data.

2. Log-Poisson $\mathscr{W}$-cascades

Let λ be the mean and the variance of the Poisson variable P. We consider that the law of $\ln|W|$ is the same as $P\ln\delta+\gamma$. A straightforward computation leads to

$$\tau(q)=\frac{\lambda(1-\delta^q)-\gamma q}{\ln 2}-1,$$

and

$$F(\alpha)=\left(\frac{\alpha}{\ln\delta}+\frac{\gamma}{\ln 2\ln\delta}\right)\left(\ln\left(\frac{\alpha\ln 2+\gamma}{-\lambda\ln\delta}\right)-1\right)+1-\frac{\lambda}{\ln 2}.$$

In Fig. 3, one realization of a log-Poisson $\mathscr{W}$-cascade is shown together with the corresponding $\tau(q)$ and $F(\alpha)$ spectra.

D. Computing the $F(\alpha)$ statistical spectrum using the multifractal formalism approach

Let us imagine that we have a large number of numerical signals which correspond to different realizations of the same random function $f(x)$. In order to characterize the self-similar behavior of the underlying cascade process, one could try to compute the $F(\alpha)$ statistical spectrum. In

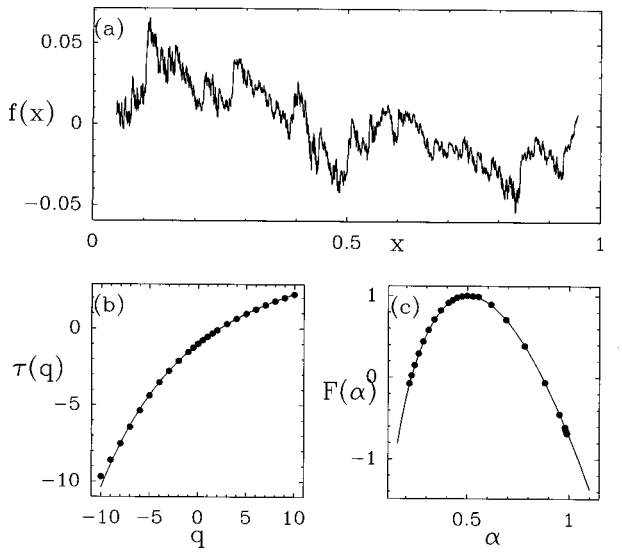

FIG. 3. Log-Poisson $\mathscr{W}$-cascades. (a) Realization of the random function corresponding to a log-Poisson $\mathscr{W}$-cascade using the ''Daubechies 5'' compactly supported orthonormal wavelet basis.[56] The mean of the Poisson variable P is $\lambda=2$ and the law of $\ln|W|$ is the same as $P\ln\delta+\gamma$ with $\delta=0.88$ and $\gamma=-0.11$. (b) The $\tau(q)$ spectrum [Eq. (8)] for the $\mathscr{W}$-cascade illustrated in (a). The data (●) computed using the WTMM method [Eq. (16)] with an order 2 spline analyzing wavelet on 1000 realizations of length 65535 of the $\mathscr{W}$-cascade, are in perfect agreement with the theoretical prediction (solid line). (c) The $F(\alpha)$ statistical singularity spectrum [Eq. (7)] for the $\mathscr{W}$-cascade illustrated in (a). The numerical spectrum (●) obtained by Legendre transforming the $\tau(q)$ data in (b) is compared to the theoretical spectrum (solid line).

order to do so, one can use the *wavelet based multifractal formalism* approach[50–54] which consists of computing a *partition function* $\hat{\mathscr{Z}}_j(q)$ corresponding, at each scale 2^{-j}, to the spatial average of the wavelet coefficients to the power q

$$\hat{\mathscr{Z}}_j(q)=\sum_{\text{realization }(r)}\sum_{0\leqslant k<2^j}|c_{j,k}^{(r)}|^q. \tag{16}$$

If the number of realizations is large enough, one can approximate realization averages by probability averages and get

$$\mathscr{Z}_j(q)=\sum_{0\leqslant k<2^j}\mathscr{E}(|c_{j,k}|^q)=2^j\mathscr{E}(|c_{j,k}|^q). \tag{17}$$

Since the law of $c_{j,k}$ is the same as the law of $W_1\ldots W_j$, one finally gets

$$\mathscr{Z}_j(q)=2^j\mathscr{E}(|W_1\ldots W_j|^q)=2^j\mathscr{E}(|W|^q)^j.$$

The $\tau(q)$ function [and consequently the $F(\alpha)$ spectrum] is obtained by analyzing the power-law scaling of $\mathscr{Z}_j(q)$ along the scales $a_j=2^{-j}$

$$\mathscr{Z}_j(q)=2^j\mathscr{E}(|W|^q)^j=a_j^{-\log_2\mathscr{E}(|W|^q)-1}\sim a_j^{\tau(q)}\quad a_j\to 0, \tag{18}$$

and

$$F(\alpha)=\inf_q(q\alpha-\tau(q)). \tag{19}$$

As long as the number of realizations is large, this approach leads to very precise estimations of $F(\alpha)$. However, from a practical point of view, we have made a major assumption: We have assumed that the realizations of the wavelet coefficients $\{c_{j,k}\}_{j,k}$ were known. This is clearly not the case since the only way to recover them from the realizations of f is to compute the scalar products of these realizations with the $\psi_{j,k}$'s; but we do not know what the analyzing wavelet ψ

is! What happens if we analyze the function f with a different analyzing wavelet ψ^1? Indeed, one can show[55–57] that the new wavelet coefficients $\{c^{(1)}_{j,k}\}$ can be expressed as a linear combination of the old ones

$$c^{(1)}_{j,k}=\sum_{k',j'} K_{\psi,\psi^1}(j-j',k-k')c_{j',k'}, \tag{20}$$

where K_{ψ,ψ^1} is a function that depends on ψ and ψ^1 only. This function basically corresponds to the scalar product of $\psi_{j,k}$ with $\psi^1_{j',k'}$. Let us note that the function K is localized in both variables and, from a numerical point of view, if ψ and ψ^1 are both well localized in Fourier and direct spaces, then the sum in Eq. (20) involves only a few terms. Before showing numerical applications, let us try to understand roughly how this affects the computation of $F(\alpha)$.

Let us note that the $F(\alpha)$ spectrum [and this is true also for any statistical quantity that is based on how the details of $f(x)$ change along scales] is not changed when changing the underlying $\mathscr{W}$-cascade independently on the scale. Indeed, for instance, if one multiplies each wavelet coefficient $c_{j,k}$ [defined recursively in Eq. (6)] by a random variable $X_{j,k}$ whose law does not depend on j or k, then the power-law behavior of $\mathscr{Z}_j(q)$ does not change along the scales

$$\mathscr{Z}_j(q)=2^j\mathscr{E}(|c_{j,k}|^q)=2^j\mathscr{E}(|W|^q)^j\mathscr{E}(|X|^q)\sim a_j^{\tau(q)}, \quad a_j\to 0.$$

Actually, this is exactly what happens if one replaces each coefficient $c_{j,k}$ by a linear combination of itself and its ''sons'' coefficients $c_{j+1,2k}$ and $c_{j+1,2k+1}$

$$c'_{j,k}=\lambda_1 c_{j,k}+\lambda^{(l)}c_{j+1,2k}+\lambda^{(r)}c_{j+1,2k+1}. \tag{21}$$

Indeed, it is easy to prove that the law of $c'_{j,k}$ is the same as the law of $W_1\ldots W_j(\lambda_1+\lambda^{(l)}W^{(l)}+\lambda^{(r)}W^{(r)})$ which can be rewritten as $c_{j,k}X_{j,k}$ with $X_{j,k}=\lambda_1+\lambda^{(l)}W^{(l)}+\lambda^{(r)}W^{(r)}$ (which does not depend on j).

It is somewhat more intricate when one performs a linear combination of the coefficients along the space axis

$$c'_{j,k}=\lambda_1 c_{j,k}+\lambda_2 c_{j,k+1}. \tag{22}$$

One can easily prove that, among the 2^j coefficients at the scale 2^{-j}, 2^l have, with their right neighbor, the first common ancestor at a scale 2^{-l}. Thus one can express the new partition function $\mathscr{Z}'_j(q)$ as

$$\mathscr{Z}'_j(q)=\sum_{l=0}^{j-1} 2^l\mathscr{E}(|W|^q)^l\mathscr{E}(|\lambda_1 W_1^{(1)}\ldots W_{j-l}^{(1)}+\lambda_2 W_1^{(2)}\ldots W_{j-l}^{(2)}|^q), \tag{23}$$

where the $W_i^{(1)}$ and the $W_i^{(2)}$ are i.i.d. random variables with the same law as W. Let T_l be the lth term in the latter sum, i.e.,

$$T_l=2^l\mathscr{E}(|W|^q)^l\mathscr{E}(|\lambda_1 W_1^{(1)}\ldots W_{j-l}^{(1)}+\lambda_2 W_1^{(2)}\ldots W_{j-l}^{(2)}|^q).$$

Let us note that the last term T_{j-1} behaves as $\mathscr{Z}_j(q)$:

$$2^{j-1}\mathscr{E}(|W^q|)^{j-1}\mathscr{E}(|\lambda_1 W_1^{(1)}+\lambda_2 W_1^{(2)}|^q)\sim C(q)2^j\mathscr{E}(|W^q|)^j=C(q)\mathscr{Z}_j(q), \tag{24}$$

where $C(q)$ does not depend on j. Thus one just needs to get an upperbound to all the other terms

$$\sum_{l=0}^{j-2} T_l\leqslant\sum_{l=0}^{j-2} 2^l\mathscr{E}(|W|^q)^l\mathscr{E}((|\lambda_1 W_1^{(1)}\ldots W_{j-l}^{(1)}|+|\lambda_2 W_1^{(2)}\ldots W_{j-l}^{(2)}|)^q),$$

$$\leqslant C_1(q)\sum_{l=0}^{j-2} 2^l\mathscr{E}(|W|^q)^l\mathscr{E}(|\lambda_1 W_1^{(1)}\ldots W_{j-l}^{(1)}|^q+|\lambda_2 W_1^{(2)}\ldots W_{j-l}^{(2)}|^q),$$

$$\leqslant C_2(q)\sum_{l=0}^{j-2} 2^l \mathscr{E}(|W|^q)^l \mathscr{E}(|W|^q)^{j-l},$$

$$\leqslant C_2(q)\sum_{l=0}^{j-2} 2^l \mathscr{E}(|W|^q)^j = C_3(q)2^j \mathscr{E}(|W|^q)^j = C_3(q)\mathscr{Z}_j(q),$$

where $C_1(q)$, $C_2(q)$ and $C_3(q)$ do not depend on j. From this last inequality and from Eq. (24), one deduces that the new partition function $\mathscr{Z}'_j(q)$ [Eq. (23)] behaves as expected

$$\mathscr{Z}'_j(q) \sim \mathscr{Z}_j(q), \quad j \to +\infty.$$

Thus as for Eq. (21), when one performs the linear combination on the wavelet coefficients corresponding to Eq. (22), the partition function displays exactly the same power-law behavior when the scale goes to 0. Actually, one can easily prove that this result still holds when we combine the two linear combinations (21) and (22).

Proposition 4: Let us consider a given $\mathscr{W}$-cascade associated to the random variable W [Eq. (6)]. Let $\mathscr{Z}_j(q)$ be the associated partition function defined by Eq. (17) *and let* λ_1, λ_2, $\lambda^{(l)}$ *and* $\lambda^{(r)}$ *in* **R**. *If we redefine the wavelet cascade coefficients* $c_{j,k}$ *in the following way:*

$$c'_{j,k} = \lambda_1 c_{j,k} + \lambda_2 c_{j,k+1} + \lambda^{(l)} c_{j+1,2k} + \lambda^{(r)} c_{j+1,2k+1},$$

then the newly obtained partition function $\mathscr{Z}'_j(q)$ behaves as the first one

$$\mathscr{Z}'_j(q) \sim \mathscr{Z}_j(q), \quad j \to +\infty.$$

Proof: The proof is straightforward and left to the reader. □

We thus expect the multifractal formalism to lead to a good determination of the $F(\alpha)$ statistical spectrum independently of the considered analyzing wavelet. Actually, it is likely to provide a good estimation of the left branch of $F(\alpha)$ $(q>0)$ but not of the right branch which corresponds to negative values of q. Indeed, the linear combination (20) might lead to null wavelet coefficients that would induce instabilities in the computation of $\hat{\mathscr{Z}}_j(q)$ [Eq. (16)] for $q<0$. In order to circumvent these instabilities, one should use the *Wavelet Transform Modulus Maxima* (WTMM) method introduced in Refs. 50–54. It basically consists in computing the partition function only on the *local modulus maxima* of the wavelet transform. Let us recall that the *modulus maxima* $\{x_i(a)\}_i$ of the continuous wavelet transform are defined at each scale a as the position of the local maxima of the absolute value of the wavelet transform.[80,82] These maxima lie on connected curves called *maxima lines*. The set of all the maxima lines existing at scale a will be denoted $\mathscr{L}(a)$. Then, the WTMM method consists in replacing the partition function $\hat{\mathscr{Z}}_j(q)$ by a new partition function which is stable for all q's in **R**

$$\hat{\mathscr{Z}}_j^{(\max)}(q) = \sum_{l_i \in \mathscr{L}(a)} \Big(\sup_{(x,a') \in l_i} |T_{\psi^1}(x,a')| \Big)^q, \quad \forall q \in \mathbf{R},$$

where $T_{\psi^1}(b,a)$ corresponds to the continuous wavelet transform of $f(x)$ at scale a and position b using the analyzing wavelet ψ^1.

As shown in Figs. 2 and 3, the WTMM method leads to a very good estimation of the $F(\alpha)$ statistical spectrum whatever the law of W and the analyzing wavelet ψ^1 are.

IV. THE SELF-SIMILARITY KERNEL

The function $f(x)$ associated to a $\mathscr{W}$-cascade is self-similar in the sense that the details of f at large scales are ''similar'' to its details at smaller scales up to a normalization factor. Let us look at how this property translates on the laws of the wavelet coefficients. Let P_j be the probability distribution function (p.d.f.) of the coefficients $|c_{j,k}|$ (P_j does not depend on k). Let $P_j^{(\log)}(x)$ be the p.d.f. of $\log|c_j|$

$$P_j^{(\log)}(x)=e^x P_j(e^x).$$

If $j_2>j_1$ then

$$\log|c_{j_2}|=\log|c_{j_1}|+\log|W_{j_1+1}|+\ \ldots\ +\log|W_{j_2}|. \tag{25}$$

This equation can be rewritten as

$$P_{j_2}^{(\log)}(x)=P_{j_1}^{(\log)}*G_{j_1,j_2}(x), \tag{26}$$

where $*$ denotes the convolution product and $G_{j_1,j_2}(x)=G\ *\ \ldots\ *\ G$, where $G(x)$ is the p.d.f. of $\log|W|$.[41,68–72] In the Fourier space, one gets

$$\hat{P}_{j_2}^{(\log)}(p)=\hat{P}_{j_1}^{(\log)}(p)\hat{G}^{s(j_1,j_2)}(p). \tag{27}$$

In the case of the $\mathscr{W}$-cascades, $s(j_1,j_2)=j_2-j_1$ represents the number of steps of the cascade from the scale 2^{-j_1} to the scale 2^{-j_2}. Of course, one cannot pick up any function s. It must satisfy the ''transitivity'' relation

$$s_{j_1,j_3}=s_{j_1,j_2}+s_{j_2,j_3}, \tag{28}$$

and the ''reflexivity'' relation

$$s_{j,j}=0. \tag{29}$$

Using any function s that satisfies both Eqs. (28) and (29), relation (27) can be seen as a *first order self-similarity property* that links the details at a scale 2^{-j_2} to the details at a larger scale 2^{-j_1}. The link is made through the *self-similarity kernel* $G_{j_1,j_2}(x)$ whose Fourier transform is of the form $\hat{G}^{s(j_1,j_2)}$. In the physical space, the kernel relation becomes[41,68–72,83–87]

$$P_{j_2}(e^x)=\int G_{j_1,j_2}(u)e^{-u}P_{j_1}(e^{x-u})du. \tag{30}$$

As we have seen, in the case of $\mathscr{W}$-cascades , the kernel function $G_{j_1,j_2}(x)$ depends only on j_2-j_1, i.e., only on the logarithm of the ratio of the two corresponding scales 2^{-j_1} and 2^{-j_2}. This can be seen as a ''scale-stationarity'' property of the self-similarity kernel.[38] In the following, a function that satisfies Eq. (27) with $s(j_1,j_2)=j_2-j_1$ will be referred to as a *scale-similar* function.

Let us note that, in the case of scale similar functions, the self-similarity kernel is directly linked to the statistical spectrum obtained by the multifractal formalism [Eq. (19)]. Indeed, the partition function [Eq. (17)] can be rewritten as

$$\mathscr{Z}_j(q)=2^j\mathscr{E}(|c_{j,k}|^q)=2^j\int e^{qu}P_j^{(\log)}(u)du=2^j\hat{P}_j^{(\log)}(iq).$$

Using relation (27) in the scale-similar case [i.e., $s(j_1,j_2)=j_2-j_1$] and relation (18), one gets

$$\mathscr{Z}_j(q)=2^j\hat{G}^{-j}(iq)\hat{P}_0^{(\log)}(iq)=2^j\hat{G}^{-j}(iq)\mathscr{Z}_0(q)\sim 2^{-j\tau(q)}.$$

The self-similarity kernel and the $\tau(q)$ spectrum are thus linked by the relation

$$\tau(q)=\log_2\ \hat{G}(iq)-1. \tag{31}$$

Remark: Let us note that if $f(x)$ corresponds to the Brownian motion, the orthogonal wavelet coefficients $\{c_{j,k}\}_{j,k}$ correspond to i.i.d white noises and thus the kernel $G_{j_1,j_2}(u)$ defined by Eq. (30) corresponds to the dirac distribution $\delta(u)$.[68,69]

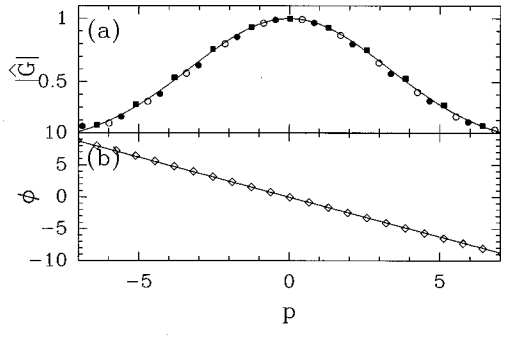

FIG. 4. Numerical computation of the self-similarity kernel of a log-normal $\mathscr{W}$-cascade with parameters $\mu=-0.37\ln 2$ and $\sigma^2=0.026\ln 2$. $\hat{G}_{a,a'}(p)=|\hat{G}_{a,a'}|e^{i\Phi_{a,a'}}$ as computed for $a/a'=5$, when using the Haar wavelet (●), an order 1 spline wavelet (○) and the complex Morlet wavelet (■).[56] (a) $|\hat{G}_{a,a'}|$ vs p; (b) $\Phi_{a,a'}$ vs p. The solid lines correspond to the theoretical predictions given by Eq. (32).

From a numerical point of view, one can compute the kernel of a $\mathscr{W}$-cascade by computing the wavelet coeffcients $\{c_{j,k}\}_{j,k}$ and the p.d.f. $P_j^{(\log)}$ at two different scales j_1 and j_2.[68,69] Then, from Eq. (27), $\hat{G}_{j_1,j_2}(p)=\hat{P}_{j_2}^{(\log)}(p)/\hat{P}_{j_1}^{(\log)}(p)$, i.e., the self-similarity kernel is obtained by performing the deconvolution of $P_{j_2}^{(\log)}$ by $P_{j_1}^{(\log)}$. As pointed out in the remark just below, this deconvolution requires some special care in order to avoid numerical instabilities.[68,69]

Remark: In order to compute $\hat{G}$, one has to perform a deconvolution. The deconvolution is performed in the Fourier space and thus consists basically in dividing $\hat{P}_{j_2}^{(\log)}$ by $\hat{P}_{j_1}^{(\log)}$. This division is unstable in the neighborhood of the (high) frequencies p for which $\hat{P}_{j_1}^{(\log)}(p)\simeq 0$. The smaller the support of $P_{j_1}^{(\log)}$, the slower the decay of $\hat{P}_{j_1}^{(log)}$ and thus the more stable the deconvolution. In order to decrease the support of $P_{j_1}^{(\log)}$, one could compute the p.d.f. $P_j^{(\log),(\max)}$ of the logarithm of the values of the modulus maxima of the continuous wavelet transform instead of computing the p.d.f. $P_j^{(\log)}$ of the logarithm of the orthogonal wavelet coefficients. Since, in the case of deterministic self-similar signals, the self-similarity properties are captured by the modulus maxima,[53,54,88] it is likely that, in the stochastic case, the self-similarity relation (26) still holds if $P_j^{(\log)}$ is replaced $P_j^{(\log),(\max)}$. Actually, from a numerical point of view, one can check[68–70] that it does hold with a very good precision for any scale a and not only for the dyadic scales $a_j=2^{-j}$. Since the support of $P_a^{(\log),(\max)}$ is much smaller than the one of $P_a^{(\log)}$, it gives a much more stable numerical method for performing the deconvolution and thus for computing the kernel $G_{a,a'}$.

Figures 4 and 5 report the results of the numerical computation of the self-similarity kernel of log-normal $\mathscr{W}$-cascades when using different analyzing wavelets ψ.[68–70] For the same reasons as

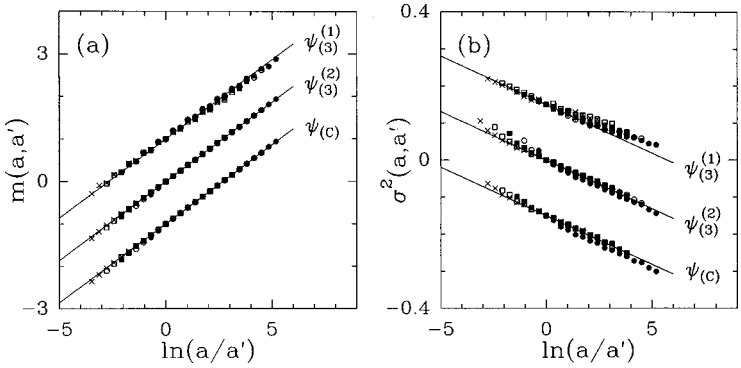

FIG. 5. Numerical computation of the scale dependence of the self-similarity kernel $\hat{G}_{a,a'}(p)$ of the log-normal $\mathscr{W}$-cascade studied in Fig. 4. (a) $m(a,a')=\partial\,\mathrm{Im}(\hat{G}_{a,a'})/\partial p|_{p=0}$ vs $\ln(a/a')$; (b) $\sigma^2(a,a')=-\partial^2(\ln|\hat{G}_{a,a'}|)/\partial p^2|_{p=0}$ vs $\ln(a/a')$. The symbols correspond to the following values of the reference scale $a'=2^5$ (●), 2^6 (○), 2^7 (■), 2^8 (□), 2^9 (×) and 2^{10} (△). The solid lines correspond to the theoretical predictions given by Eq. (33).

the ones we previously mentioned when estimating the $F(\alpha)$ statistical spectrum, since $\hat{G}$ depends only on $\tau(q)$ [Eq. (31)], its estimation should not depend upon the choice of ψ. This is clearly verified in the numerical simulations reported in Figs. 4 and 5. Moreover, the data shown in Fig. 4 are in remarkable agreement with the theoretical shape of a log-normal kernel

$$\hat{G}_{a,a'}(p)=e^{ipm(a,a')-p^2\sigma^2(a,a')/2}, \tag{32}$$

where

$$\begin{cases} m(a,a')=\mu\ \ln(a/a'), \\ \sigma^2(a,a')=-\sigma^2\ \ln(a/a'). \end{cases} \tag{33}$$

For values of $|p|\leqslant 7$, one does not see in the numerical data any significant departure from the Gaussian behavior of the kernel modulus $|G_{a,a'}|$, as well as from the linear behavior of its phase $\Phi_{a,a'}$.

As far as the scale dependence of the self-similarity kernel is concerned, we have plotted in Fig. 5, $m(a,a')=\partial\ \mathrm{Im}(\hat{G}_{a,a'})/\partial p|_{p=0}$ and $\sigma^2(a,a')=-\partial^2(\ln|\hat{G}_{a,a'}|)/\partial p^2|_{p=0}$ as functions of $\ln(a/a')$. One can see that, for different values of the reference scale a', all the points obtained when varying the scale a fall on a unique straight line which matches perfectly the theoretical predictions [Eq. (33)] and confirms the scale-similarity of the log-normal $\mathscr{W}$-cascade under study.

V. CORRELATION FUNCTIONS IN $\mathscr{W}$-CASCADES

The tree structure of a $\mathscr{W}$-cascade induces correlations between different details of the corresponding function $f(x)$.[73,88,89] These correlations can be characterized by computing the correlation between two wavelet coefficients at an arbitrary scale $a=2^{-j}$ and at a distance $\Delta x=2^{-j}\Delta k$. Since the wavelet coefficients $\{c_{j,k}\}_k$ at a given scale 2^{-j} are not stationary in k, we will compute an ''averaged version'' of the correlation function:[73]

Proposition 5: Let us consider a given $\mathscr{W}$-cascade associated with the random variable W [Eq. (6)*]. Let $a_j=2^{-j}$ and $\Delta x_{j,\Delta k}=2^{-j}\Delta k$. If we define $C(\Delta x_{j,\Delta k},a_j)$ as the correlation function*

$$C(\Delta x_{j,\Delta k},a_j)=\frac{1}{2^j}\sum_{k=0}^{k<2^j-\Delta k}\mathrm{Cov}(\log|c_{j,k}|,\log|c_{j,k+\Delta k}|), \tag{34}$$

where Cov *stands for the covariance. Then*

$$C(\Delta x_{j,2^p},a_j)=\sigma^2(j-p-2+2^{p-j+1}),\quad \forall p<j,$$

where σ^2 is the variance of $\log|W|$.

Proof: By definition one has

$$C(\Delta x_{j,2^p},a_j)=\frac{1}{2^j}\sum_{k=0}^{k<2^j-2^p}\mathrm{Cov}(\log|c_{j,k}|,\log|c_{j,k+2^p}|).$$

Let us fix k and set $k_1=k$, $k_2=k+\Delta k$. Let us suppose that the last common ancestor (on the binary tree of the $\mathscr{W}$-cascade) of c_{j,k_1} and c_{j,k_2} is at scale $2^{-d(j,k_1,k_2)}$ [in the following $d(j,k_1,k_2)$ will be referred to as the *$\mathscr{W}$-distance* between the two wavelet coefficients]. Then, one can write

$$|c_{j,k_1}|=|W_1|\ldots|W_{d(j,k_1,k_2)}||W^{(1)}_{d(j,k_1,k_2)+1}|\ldots|W_j|^{(1)},$$

and

$$|c_{j,k_2}|=|W_1|\ldots|W_{d(j,k_1,k_2)}||W^{(2)}_{d(j,k_1,k_2)+1}|\ldots|W_j|^{(2)},$$

where all the W_i, $W_i^{(1)}$ and $W_i^{(2)}$ are i.i.d. random variables with the same law as W. Then their covariance is

$$\mathrm{Cov}(c_{j,k_1},c_{j,k_2})=\sum_{i=1}^{i=d(j,k_1,k_2)}\mathrm{Cov}(\log|W_i|,\log|W_i|)=\sigma^2 d(j,k_1,k_2),$$

where σ^2 is the variance of $\log|W|$. Then

$$C(\Delta x_{j,2^p},a_j)=2^{-j}\sigma^2\sum_{d=0}^{d=j-1}N_{j,2^p}(d)d, \tag{35}$$

where $N_{j,2^p}(d)$ is the number of wavelet coefficients $c_{j,k}$ $(0\leqslant k<2^j-2^p)$ such that $c_{j,k}$ and $c_{j,k+2^p}$ are at a $\mathscr{W}$-distance d. It is clear that $N_{j,2^p}(d)=0$ for $d\geqslant j-p$. Moreover, one can easily show that

$$\forall d<j-p,\quad N_{j,2^p}(d)=2^pN_{j-p,1}(d).$$

Since $N_{j,1}(d)=2^d$, Eq. (35) becomes

$$\begin{aligned}C(\Delta x_{j,2^p},a_j)&=2^{-j}\sigma^2\sum_{d=0}^{d=j-p-1}2^pN_{j-2^p,1}(d)d,\\&=2^{p-j}\sigma^2\sum_{d=0}^{d=j-p-1}2^d d,\\&=2^{p-j}\sigma^2 2((j-p)2^{j-p-1}-2^{j-p}+1),\\&=\sigma^2(j-p-2+2^{p-j+1}).\end{aligned}$$

□

From this Proposition, one easily deduces the asymptotic behavior of the correlation function:[73]

Corollary 3: When Δx is small $(a<\Delta x\ll 1)$, the correlation function $C(\Delta x,a)$ [Eq. (34)] of a $\mathscr{W}$-cascade behaves as a logarithm function

$$C(\Delta x,a)=-\sigma^2\log_2(\Delta x)+o(\Delta x). \tag{36}$$

Thus, asymptotically, the correlation function does not depend on the scale a. From a numerical point of view, the cascade is constructed from the scale 1 $(j=0)$ down to a small scale (corresponding to the sampling rate of the numerical signal) 2^{-J}. If, on the contrary, we consider that the sampling rate is 1, then the signal has a total size $L=2^J$. Increasing J amounts in building a signal longer. The last corollary means that[73]

$$C(\Delta x,a)\sim\sigma^2\log_2(L/\Delta x), \tag{37}$$

when $a<\Delta x\ll L$.

Using the same kind of computations, one gets that the ''two-scale'' correlation function $C(\Delta x,a,a')$ between the coefficients at scale a and the coefficients at scale a' actually follows the same law as $C(\Delta x,a)$ as long as Δx is greater than the supremum of a and a'[73]

$$C(\Delta x,a,a')\sim\sigma^2\log_2(L/\Delta x), \tag{38}$$

when $\sup(a,a')<\Delta x\ll L$.

All these results are illustrated in Fig. 6 in the case of a log-normal $\mathscr{W}$-cascade. As seen in Figs. 6(a) and 6(b), the numerical computation of both the ''one-scale'' $C(\Delta x,a)$ and the ''two-scale'' $C(\Delta x,a,a')$ correlation functions are in very good agreement with the theoretical predictions given by Eqs. (37) and (38).

Remark: By the same kind of arguments as the ones used in Sec. III, one expects Eqs. (37) and (38) to hold even when computing the correlation functions using an analyzing wavelet ψ^1 which is different from the wavelet ψ used to build the $\mathscr{W}$-cascade.

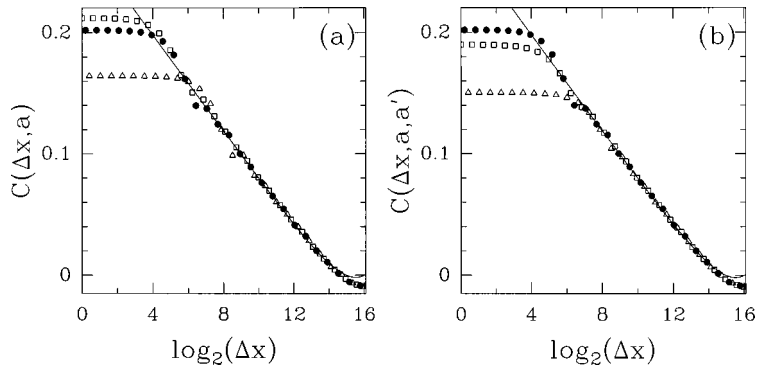

FIG. 6. Numerical computation of the wavelet coefficient correlation functions of a log-normal $\mathscr{W}$-cascade with variance $\sigma^2=0.03$. (a) ''One-scale'' correlation functions $C(\Delta x,a)$ for $a=4$ (□), 16 (●) and 64 (△). (b) ''Two-scale'' correlation functions $C(\Delta x,a,a')$ for $a=a'=16$ (●), $a=4$, $a'=16$ (□) and $a=16$, $a'=64$ (△). The data in (a) and (b) are in perfect agreement with the theoretical logarithm dependence (solid lines) given by Eqs. (37) and (38) ($L=2048$).

VI. CONCLUSION

To summarize, we have presented a first theoretical step towards a rigorous mathematical treatment of random cascading processes on the dyadic tree of their orthogonal wavelet coefficients. We have elaborated on the convergence of these $\mathscr{W}$-cascades and discussed the regularity of the limiting random functions by studying the support of their singularity spectra. We have shown mathematically and checked numerically on various computer synthetized signals, that very different statistical quantities such as the statistical spectrum, the self-similarity kernel and the correlation functions can be extracted directly from the fractal function using its wavelet decomposition (orthogonal, continuous or its associated modulus maxima) with an arbitrary analyzing wavelet. This mathematical study actually provides algorithms that are readily applicable to experimental situations. Recent applications of our methodology in the context of fully-developed turbulence[69,70,73] have revealed the existence of a (nonscale invariant) log-normal cascading process underlying the turbulent velocity fluctuations. More surprising are the results of a similar investigation of financial time series.[90] Underlying the fluctuations of the volatility (standard deviation) of the price variations, there exists a causal information cascade from large to small time scales that can be visualized with the wavelet representation. Let us emphasize that the fact that variations of prices over a one month scale influence in the future the daily price variations, is likely to be extraordinarily rich in consequences and this, not only for the fundamental understanding of the nature of financial markets, but also (and maybe more important) for practical applications. Indeed, the nature of the correlations across scales that are implied by this causal cascade has profound implications on the market risk, a problem of utmost concern for all financial institutions as well as individuals. These preliminary results are very promising as far as further experimental investigations of multiplicative cascade processes are concerned. There is no doubt in our minds that similar wavelet-based statistical analysis will lead to significant progress in fields other than hydrodynamic turbulence and finance.

ACKNOWLEDGMENTS

We are very grateful to S. Manneville and S. G. Roux for interesting discussions and technical assistance.

APPENDIX A: PROOF OF LEMMA 1

We want to prove the following lemma (Sec. III A)

Lemma 1: Let us consider the wavelet coefficients $\{c_\phi,\{c_{j,k}\}_{j,k}\}$ *of a given* $\mathscr{W}$*-cascade associated to the random variable W [Eq. (6)]. Let* $m_j=\max_k|c_{j,k}|$ $(m_0=1)$ *and* Q_j^α *the subset of the probability space* Ω

$$Q_j^\alpha=\{\omega\in\Omega, m_j>2^{-j\alpha}\}.$$

Let us set $q_j^\alpha = \mathrm{Prob}\{Q_j^\alpha\}$ *and*

$$p_j^\alpha = \mathrm{Prob}\{|W_1 \ldots W_j| > 2^{-j\alpha}\},$$

where the W_i *are i.i.d random variables with the same law as* W. *Then*

$$q_j^\alpha \leqslant 2^j p_j^\alpha .$$

Proof: By decomposing the binary tree into two binary subtrees, we obtain

$$\begin{aligned} q_j^\alpha &= \mathrm{Prob}\{m_j > 2^{-j\alpha}\}, \\ &= 1 - \mathrm{Prob}\{m_j \leqslant 2^{-j\alpha}\}, \\ &= 1 - \mathrm{Prob}\{m_{j-1}^{(l)}|W^{(l)}| \leqslant 2^{-j\alpha}, \text{ and } m_{j-1}^{(r)}|W^{(r)}| \leqslant 2^{-j\alpha}\}, \end{aligned}$$

where $W^{(l)}$ and $W^{(r)}$ are i.i.d. random variables with the same law as W and where $m_{j-1}^{(l)}$ and $m_{j-1}^{(r)}$ are i.i.d. random variables (independent from $W^{(l)}$ and $W^{(r)}$) with the same law as m_{j-1}. Since all the involved variables are independent, we get

$$q_j^\alpha = 1 - \mathrm{Prob}\{|W_1| m_{j-1} \leqslant 2^{-j\alpha}\}^2,$$

where W_1 is a random variable (independent from m_{j-1}) with the same law as W. By again decomposing each subtree into two subtrees, we get

$$q_j^\alpha = 1 - \mathrm{Prob}\{|W_1| m_{j-2}^{(l)}|W^{(l)}| \leqslant 2^{-j\alpha} \text{ and } |W_1| m_{j-2}^{(r)}|W^{(r)}| \leqslant 2^{-j\alpha}\}^2,$$

with the same notations as before. This time, since the same variable W_1 appears on both sides of the ''and,'' we cannot just split the two terms on each side of the ''and'' and keep the equality with q_j^α. Actually one can easily prove that for any independent random variables X_0, X_1, and Y, if X_0 and X_1 have the same law then

$$\mathrm{Prob}\{X_0 Y \leqslant a \text{ and } X_1 Y \leqslant a\} \geqslant \mathrm{Prob}\{XY \leqslant a\}^2.$$

By using this result, one easily gets from the last expression of q_j^α

$$q_j^\alpha \leqslant 1 - \mathrm{Prob}\{|W_1||W_2| m_{j-2} \leqslant 2^{-j\alpha}\}^4,$$

where W_2 is a random variable (independent from m_{j-2} and W_1) with the same law as W. By decomposing recursively each subtree into two subtrees and by using the fact that $m_0 = 1$, one finally obtains

$$q_j^\alpha \leqslant 1 - \mathrm{Prob}\{|W_1 W_2 \ldots W_j| \leqslant 2^{-j\alpha}\}^{2^j}.$$

Since $p_j^\alpha = 1 - \mathrm{Prob}\{|W_1 W_2 \ldots W_j| \leqslant 2^{-j\alpha}\}$, one gets

$$q_j^\alpha \leqslant 1 - (1 - p_j^\alpha)^{2^j}.$$

Moreover, since $p_j^\alpha \leqslant 1$ and $j \geqslant 0$, we have $(1 - p_j^\alpha)^{2^j} \geqslant 1 - 2^j p_j^\alpha$ and therefore

$$q_j^\alpha \leqslant 2^j p_j^\alpha . \qquad \square$$

APPENDIX B: PROOF OF LEMMA 2

We want to prove the following lemma (Sec. III A)

Lemma 2: (Same notations as in Lemma 1) If $\mathcal{E}(\log_2|W|) < +\infty$ *then for all* $\alpha < -\mathcal{E}(\log_2|W|)$, *for all* $\epsilon > 0$, *there exists* $J > 0$ *such that for all* $j > J$

$$p_j^\alpha < e^{j\epsilon} 2^{j(F(\alpha)-1)},$$

where $F(\alpha)$ *is defined as the Legendre transform of the function* $\tau(q)$

$$F(\alpha)=\inf_q(q\alpha-\tau(q)),$$

and where $\tau(q)$ *is defined as*

$$\tau(q)=-\log_2 \mathscr{E}(|W|^q)-1.$$

Moreover, $F(\alpha)$ *is a concave function, such that* $F(-\mathscr{E}(\log_2|W|))=1$ *and which is increasing on* $]-\infty,-\mathscr{E}(\log_2|W|)]$ *and decreasing on* $[-\mathscr{E}(\log_2|W|),+\infty[$.

Proof: Since $\alpha<-\mathscr{E}(\log_2|W|)\neq-\infty$, one has the following large deviation property:[76]

$$\limsup_{j\to\infty}\frac{1}{j}\ln p_j^\alpha\leqslant-\Phi(-\alpha), \tag{B1}$$

where Φ is the Cramér transform of $\log_2|W|$, i.e.,

$$\Phi(\alpha)=\sup_q(q\alpha-L(q)),$$

with

$$L(q)=\ln \mathscr{E}(e^{q\log_2 W})=\ln \mathscr{E}(|W|^{q/\ln 2}).$$

Equation (B1) is equivalent to

$$\forall\epsilon>0,\quad \exists J,\quad \forall j>J,\quad \frac{1}{j}\ln p_j^\alpha<-\Phi(-\alpha)+\epsilon,$$

which can be rewritten as

$$p_j^\alpha<e^{j\epsilon}e^{-j\Phi(-\alpha)}. \tag{B2}$$

Since $L(q)=-(\tau(q/\ln 2)+1)\ln 2$, we get

$$\begin{aligned}-\Phi(-\alpha)&=-\sup_q(-q\alpha-L(q)),\\&=-\sup_q(-q\alpha+(\tau(q/\ln 2)+1)\ln 2),\\&=(\inf_q(q\alpha-\tau(q))-1)\ln 2,\\&=(F(\alpha)-1)\ln 2.\end{aligned}$$

By replacing this expression in (B2), we get

$$p_j^\alpha<e^{j\epsilon}2^{j(F(\alpha)-1)}.$$

Moreover, the Cramér transform $\Phi(\alpha)$ is a convex function such that $\Phi(\mathscr{E}(\log_2|W|))=0$ and which is decreasing on $]-\infty,\mathscr{E}(\log_2|W|)]$ and increasing on $[\mathscr{E}(\log_2|W|),+\infty[$. Thus, since $F(\alpha)=1-\Phi(-\alpha)/\ln 2$, $F(\alpha)$ is a concave function such that $F(-\mathscr{E}(\log_2|W|))=1$ and which is increasing on $]-\infty,-\mathscr{E}(\log_2|W|)]$ and decreasing on $[-\mathscr{E}(\log_2|W|),+\infty[$. □

Time-dependent scattering on fractal measures

Charles-Antoine Guerin[a] and Matthias Holschneider[b]
Centre de Physique Théorique,[c] CNRS, Luminy, Case 907, F-13288 Marseille Cedex 9, France

(Received 1 January 1998; accepted for publication 3 April 1998)

In this paper we study the time evolution for the Schrödinger equation and the wave equation on the line when the interaction term is a fractal measure. First, we extend the usual one-dimensional potential scattering formalism to interactions defined as measures. Then we show how to retrieve information on the fractality of the interaction term from time-dependent scattering data. In the case of the Schrödinger equation we shall obtain the wavelet correlation dimension of the scatterer. For the wave equation the whole set of generalized multifractal dimensions can be recovered, provided the scatterer actually is fractal (nonsmooth). In this latter case, we also show how the reflected wave packets can be interpreted in terms of wavelet transform of the interaction. © *1998 American Institute of Physics.* [S0022-2488(98)01108-6]

I. INTRODUCTION AND MAIN RESULTS

In the last two decades, there has been a growing interest in the scattering of waves by fractal objects because of the many important applications in physics and engineering and also because of the mathematical challenge. By now, a huge amount of literature has been devoted to the subject; we refer to, e.g., Refs. 1–8 for some survey articles. The typical result is that the scattered intensity in the stationary regime can be simply related to some fractal dimension of the obstacle. However, the temporal aspect seems to have been neglected in the literature. Other than the paper by Berry and Blackwell,[9] who studied the time-delay of waves encountering multiscales surfaces, we do not know of other theoretical results relating time-dependent data to fractal properties of the scatterer.

The aim of this paper is to study the time evolution generated by Schrödinger operators on the line when the potential term is a fractal measure. We wish to show how the time-space behavior of the wave packets mirrors the ''fractality'' of the scatterer. The problem we want to deal with can be put in the following abstract form. Let $\mathscr{H}$ be some Hilbert space and H a self-adjoint operator on $\mathscr{H}$, with domain $D(H)$. Consider the Cauchy problem of first and second order in time:

$$i\partial_t \Psi_t - H\Psi_t = 0, \quad \Psi_{t=0} = f \in D(H), \tag{1.1}$$

$$\partial_{tt} \Phi_t + H\Phi_t = 0, \quad \Phi_{t=0} = f \in D(H), \quad \partial_t \Phi_{t=0} = g \in D(H). \tag{1.2}$$

The first equation is the Schrödinger equation, which describes the evolution of quantum wave packets under the action of the Hamiltonian H. Its solution is uniquely determined by the initial state:

$$\Psi_t = e^{-itH} f, \quad t \geqslant 0. \tag{1.3}$$

We will refer to the second equation as ''the wave equation.'' It can be solved by reduction to a first-order matricial equation. If H is non-negative, there exists a unique non-negative self-adjoint operator $H^{1/2}$ such that $(H^{1/2})^2 = H$ and $D(H)$ is dense in $D(H^{1/2})$. The unique solution of (1.2) is then given by (see, e.g., Ref. 10)

$$\Phi_t = \cos(H^{1/2}t) f + H^{-1/2} \sin(H^{1/2}t) g, \quad t \geqslant 0, \tag{1.4}$$

where the functions of H are defined by the usual functional calculus. In this paper, we will take $\mathscr{H} = L^2(\mathbb{R})$, the Hilbert space of square integrable functions on $\mathbb{R}$; H will be a generalized Schrödinger operator formally given by $H = -\Delta + V$, where V is a fractal measure on $\mathbb{R}$. We want to analyze the scattering potential V using data that are available away from the scatterer. Instead of reconstructing V completely we are interested only in its fractal features and how they are mirrored in the scattering data. This type of analysis has been proposed in the stationary scattering approach.[11,12] It will turn out that fractal properties described through small scale properties of wavelet transforms play an important role.

A. The results

Let us show briefly the main results, which go in two directions. First, we propose an original approach to study singular Schrödinger operators on the line, by generalizing the tools that are used for smooth interactions (Jost functions, Lippmann–Schwinger solutions, etc.). In particular, we retrieve and strengthen some known results concerning the spectrum of the Hamiltonian and the wave operators and derive an explicit formula for the spectral measure. This makes it possible to study arbitrary evolution operators, in particular those given by (1.3) and (1.4).

The second aspect of this paper concerns the wavelet analysis in connection to the scattering problem. We shall show how to perform ''experimental'' wavelet transforms of the potential by means of time-dependent scattering data. We assume for the moment some familiarity with the usual concepts of wavelet analysis. The complete definitions can be found in Sec. II. A natural quantity to look at is the amount of energy scattered back from the scatterer. For the sake of simplicity suppose that V is compactly supported. We call Ω^- and Ω^+ the regions to the left and to the right of the support of V and $\mathbb{I}_{\Omega^\pm}$ the corresponding characteristic functions, $\mathbb{I}_{\Omega^\pm}(x) = 1$ if $x \in \Omega^\pm$, $\mathbb{I}_{\Omega^\pm}(x) = 0$ else. We use the same notation for the associated multiplication operator, i.e., $(\mathbb{I}_{\Omega^\pm} f)(x) = \mathbb{I}_{\Omega^\pm}(x) f(x)$. First consider the wave equation since here the geometry is simpler and the results are more complete. Let f be compactly supported in Ω^- and consider the solution $\Phi_t = \Phi_t[f]$ of the wave equation corresponding to the initial data $\Phi_0 = f$, $\partial_t \Phi_{t=0} = -\partial_x f$. This corresponds to sending the wave packet of shape f towards the interaction potential. It is natural to look at the part of the wave that will be scattered back into region Ω^-. Therefore for $q \geqslant 1$ we look at the asymptotic amount of q-energy present in region Ω^-.

$$p_q[f] = \lim_{t \to +\infty} \| \mathbb{I}_{\Omega^-} \Phi_t[f] \|_q^q. \tag{1.5}$$

We shall show that the limits actually exist for suitable initial data. As usual we have used the notation $\|s\|_q^q = \int |s|^q$. Now take a function f in $S_0(\mathbb{R})$ the closed subspace of $S(\mathbb{R})$, the class of Schwartz, consisting of those functions for which all moments vanish. Such functions are prototypes of wavelets (see the next section). Let $f_{b,a}$ stand for the scaled and translated version of f,

$$f_{b,a}(x) = \frac{1}{a} f\left(\frac{x-b}{a}\right).$$

We then explore the potential by sending ''test'' functions located at smaller and smaller scales towards the potential. We fix some $b \in \Omega^-$. To make the functions supported by Ω^- we take a compactly supported, smooth function χ which is identically 1 in some neighborhood of b. Let $f_{(b,a)} = \chi f_{b,a}$. We then consider the following integrated reflection probability:

$$\rho(a) = \int_a^1 \frac{d\alpha}{\alpha^{q+1}} p_q[f_{(b,\alpha)}].$$

As we shall show, we have

$$\lim_{a\to 0} \begin{matrix}\sup \\ \inf\end{matrix} \frac{\log \rho(a)}{\log a} = \kappa_q^{\pm}[V],$$

where $\kappa_q^{\pm}[V]$ are the upper and lower generalized wavelet dimensions of the potential, provided this latter is ''sufficiently'' singular (this will be made precise). Thus if the potential is truly fractal, in the sense that it has nontrivial wavelet dimensions, it may be read from the scattering data. The reason for this result is that the backscattered wave is essentially the wavelet transform of the scattering potential with a wavelet given by a primitive of the initial data, provided the latter is supported in Ω^- (Theorem 11.3). We therefore can recover the truly singular parts of the potential.

In the case of the Schrödinger equation the results are limited to the so-called wavelet correlation dimension $\kappa_2^{\pm}$. On the other side, the potential may be a signed measure, since one need not assume H to be positive as for the wave equation. More precisely, for $\Psi_t = e^{-itH} f$ we define

$$p^{\pm}[f] = \lim_{t\to\infty} \|\mathbb{I}_{\Omega^{\pm}} \Psi_t\|_2^2.$$

Again we shall prove that the limit actually exists. This quantity can be interpreted as follows. When f is normalized (i.e., $\|f\|=1$), $p^{\pm}[f]$ is the final probability of finding a particle described by the wave function Ψ_t in the left and right region, respectively. Consider now a function f in $S_+(\mathbb{R})$, the closed subspace of $S(\mathbb{R})$ having a Fourier transform supported by the positive frequencies only. Again we explore V by sending wavelets at smaller and smaller scales towards the scatterer. More precisely, fix again $b \in \Omega^-$ and consider the following integrated reflection probability

$$\rho(a) = \int_a^1 \frac{d\alpha}{\alpha^3} p^-[f_{b,\alpha}].$$

Then we shall show that

$$\lim_{a\to 0} \begin{matrix}\sup \\ \inf\end{matrix} \frac{\log \rho(a)}{\log a} = \min\{\kappa_2^{\pm}[V], 0\},$$

where $\kappa_2^{\pm}[V]$ are the upper and lower wavelet correlation dimensions of the scatterer. Therefore, again for truly fractal potentials, we may characterize their fractality through a scattering experiment.

The rest of the paper is organized as follows. In Sec. II, we recall the definition of fractal wavelet dimensions. In Secs. III–IX we extend the usual one-dimensional scattering formalism (for which we refer to Refs. 13–15) to singular potentials defined as measures. In Sec. X, we study the time evolution and in Sec. XI we show how to retrieve some specific fractal properties from the long time asymptotic. In Sec. XII we give some numerical illustrations of our results.

II. THE GENERALIZED FRACTAL WAVELET DIMENSIONS

As mentioned in the Introduction, we will be concerned in the scattering problem with potentials given by fractal measures on the line. By ''fractal'' we mean, loosely speaking, a measure which has a nontrivial fractal dimension. There are several definitions of the fractal dimension of a measure, such as the box dimension, the information, and the correlation dimension, to cite only a few. Historically, these dimensions have been introduced in the frame of dynamical systems and ergodic theory and characterize essentially probability measures. Recently,[16] a new set of fractal dimensions has been constructed by means of wavelet transform, namely the *fractal wavelet dimensions*. These dimensions are well adapted to characterize fractality of signed or complex measures. One of them, the so-called wavelet correlation dimension, is particularly suited for scattering problems (see Refs. 11 and 12).

A. Wavelet analysis

The wavelet transform can be seen as a generalization of the Fourier transform; while the latter consists in decomposing a function in pure frequencies, the former allows a decomposition on a basis of wavelets, which are basically functions well localized both in position and frequency and which are oscillating. A typical example would be a function g that is in $L^1(\mathbb{R})\cap L^\infty(\mathbb{R})$ and has zero mean, that is $\int g=0$. We will adopt the following notational convention. For all functions g, we write

$$g_a(x)=a^{-1}g(a^{-1}x), \quad g_{b,a}(x)=a^{-1}g(a^{-1}(x-b)), \quad \tilde{g}(x)=\overline{g(-x)}$$

for the dilated, resp. translated and dilated, resp. symmetric version. The wavelet transform of a function or more generally a distribution s with respect to a wavelet g is given by

$$\mathscr{W}_g s(b,a)=\int dt\ a^{-1}\overline{g(a^{-1}(t-b))}s(t)=\int dt\ \overline{g_{b,a}}(t)s(t). \tag{2.1}$$

This expression can also be seen as a convolution,

$$\mathscr{W}_g s(b,a)=(\tilde{g}_a * s)(b), \tag{2.2}$$

or in the Fourier space,

$$\mathscr{W}_g s(b,a)=\int dk\ \overline{\hat{g}(ak)}e^{ibk}\hat{s}(k). \tag{2.3}$$

Intuitively, the wavelet transform acts as a filter, selecting the details present in s at scale a and position b. It is therefore a tool to analyze the local regularity of functions. Convenient classes of wavelets are the following. Let $\mathscr{S}(\mathbb{R})$ be the Schwartz space of smooth functions which, together with their derivatives, decrease faster than any polynomial, that is

$$\max_{q,m\leqslant N}\ \sup_{x\in\mathbb{R}}|x^q\partial^m g(x)|<\infty, \quad N=0,1,2,\ldots .$$

Let $\mathscr{S}_+(\mathbb{R})$ be the closed subspace of Schwartz functions with no negative frequencies [that is $\hat{g}(\xi)=0$ if $\xi\leqslant 0$], $\mathscr{S}_-(\mathbb{R})$ the subspace of Schwartz functions with no positive frequencies, and $\mathscr{S}_0(\mathbb{R})=\mathscr{S}_+(\mathbb{R})\oplus\mathscr{S}_-(\mathbb{R})$. Functions in $\mathscr{S}_+(\mathbb{R})$, $\mathscr{S}_-(\mathbb{R})$, or $\mathscr{S}_0(\mathbb{R})$ have all moments vanishing, that is

$$\int dx\ x^n g(x)=0, \quad n=0,1,2,\ldots,$$

or, what amounts to the same, have a flat Fourier transform near zero,

$$\hat{g}(\xi)=O(\xi^\infty), \quad \xi\to 0,$$

where the convenient notation "$O(\xi^\infty)$" means $O(\xi^n)$ for all n.

B. The generalized wavelet dimension

The generalized wavelet dimensions are now constructed in the following way. Take some wavelet g in $\mathscr{S}_+(\mathbb{R})$ and set for $q\geqslant 1$

$$G_g(a,q)=\|\mathscr{W}_g\mu(\cdot,a)\|_q^q=\int db|\mathscr{W}_g\mu(\cdot,a)|^q$$

and

$$\Gamma_g(a,q)=\min\left\{\int_a^1 \frac{d\alpha}{\alpha}\,G_g(\alpha,q), \int_0^a \frac{d\alpha}{\alpha}\,G_g(\alpha,q)\right\}.$$

Then the (upper and lower) wavelet dimensions $\kappa_q^{\pm}(\mu)$ are defined by

$$\kappa_q^+(\mu)=\limsup_{a\to 0}\frac{\log \Gamma_g(a,q)}{\log a},\quad \kappa_q^-(\mu)=\liminf_{a\to 0}\frac{\log \Gamma_g(a,q)}{\log a},$$

and do not depend on the chosen wavelet g in $\mathscr{S}_+(\mathbb{R})$ provided $g\neq 0$. Clearly analogous definitions hold for wavelets $\mathscr{S}_-(\mathbb{R})$. For real-valued fractals we obtain the same dimensions. However, for complex values they may be different. Note that a wavelet in $\mathscr{S}_\pm(\mathbb{R})$ cannot have compact support (otherwise its Fourier transform would be analytic and hence could not vanish on a semi-axis without vanishing everywhere). However, admitting an arbitrarily small error on the dimensions $\kappa_q^\pm$, one always may suppose that the analyzing wavelet is compactly supported. This is useful in the applications.

Remark: The dimensions κ_q^- can be interpreted in terms of the limiting regularity in some Besov-space sense. Such an interpretation is not possible for the dimensions κ_q^+. Using the partition function G_g, it would be possible to define the analog of the dimensions κ_q^- independently of the wavelet in $\mathscr{S}_+(\mathbb{R})$. However, the analog definition of κ_q^+ may depend on the wavelet due to lacunarity of the scales. This is why the integrated partition function Γ_g has been introduced in Ref. 16.

A particular role is played by the index $q=2$. The so-called *wavelet correlation dimension* $\kappa_2^\pm$ of a signed measure governs the L^2 asymptotic of its Fourier transform, as shows the following:

Theorem 2.1:[16] *If μ is a finite complex measure, then either $\mu\notin L^2(\mathbb{R})$ and*

$$\lim_{p\to\infty}\sup_{\inf}\frac{\log \int_0^p d\xi\ |\hat{\mu}(\xi)|^2}{\log p}=-\kappa_2^\mp[\mu], \tag{2.4}$$

or $\mu\in L^2(\mathbb{R})$ and

$$\lim_{p\to\infty}\sup_{\inf}\frac{\log \int_p^{+\infty} d\xi\ |\hat{\mu}(\xi)|^2}{\log p}=-\kappa_2^\mp[\mu], \tag{2.5}$$

If μ is real, one can take indiscriminately a wavelet g in $\mathscr{S}_0(\mathbb{R})$, $\mathscr{S}_+(\mathbb{R})$, or $\mathscr{S}_-(\mathbb{R})$.

C. The correlation dimension

The wavelet correlation dimension is actually a generalization of the correlation dimension defined for positive measures as follows.[17] Consider the function

$$\Omega_\mu(r)=\int \mu(dx)\ \mu(B(x,r)),$$

where $B(x,r)$ is the ball of radius r around the point x. The quantities

$$D^+[\mu]=\limsup_{r\to 0}\frac{\log \Omega_\mu(r)}{\log r},\quad D^-[\mu]=\liminf_{r\to 0}\frac{\log \Omega_\mu(r)}{\log r},$$

are called respectively upper and lower correlation dimensions of μ. When the upper and lower dimensions coincide, their common value is simply called the correlation dimension. For positive finite measures, the correlation dimension has been related to the mean quadratic Fourier asymptotics:

Theorem 2.2:[18] *For any finite positive measure μ on $\mathbb{R}$,*

$$\lim_{p\to\infty}\sup_{\inf}\frac{\log \int_{|\xi|\leq p} d\xi\ |\hat{\mu}(\xi)|^2}{\log \xi}=1-D^\mp[\mu]. \tag{2.6}$$

Note that the classical correlation dimension and the wavelet correlation are essentially the same in the case of positive measures. Precisely,

$$-\kappa_2^\pm[\mu]=1-D^\pm[\mu]$$

provided $\mu \notin L^2(\mathbb{R})$, which is always the case for nontrivial singular measures.

For signed or complex measures, the correlation dimensions are not sufficient to characterize the Fourier asymptotic. The relevant dimensions in this case are the upper and lower wavelet dimensions. Intuitively, the reason is the following. To compute the ''classical'' fractal dimensions, one sooner or later tests the measures with boxes, whose size becomes smaller and smaller. However, it makes no sense to test signed measures with boxes because cancellations may appear which corrupt the information. The idea of wavelet dimensions is precisely to replace the boxes by functions which oscillate faster and faster.

III. PRELIMINARIES: SOME PROPERTIES OF BOREL MEASURES

We now expose the scattering formalism for singular potentials. (This whole part is taken from the thesis of one of us.[19] We reproduce it here for the convenience of the reader.) Before entering the core of the paper, we list some properties of Borel measures that are necessary for the following. We refer, e.g., to Ref. 20 for all classical results on measure theory and to e.g., Ref. 21 for the functional analysis. We denote by $C_0^k(\mathbb{R})$ the space of complex-valued k times continuously differentiable functions with compact support on $\mathbb{R}$. $\mathscr{D}=C_0^\infty(\mathbb{R})$ is the space of test functions and $\mathscr{D}'$, its dual, is the space of distributions on $\mathbb{R}$. We write (η, f) for the action of a distribution η on a function f. We use the notation $\eta_n \overset{\mathscr{D}'}{\to} \eta$ to say a sequence of distributions (η_n) converges in the weak topology of $\mathscr{D}'$ towards some other distribution η [that is $(\eta_n, s) \xrightarrow[n\to\infty]{} (\eta, s)$ for any test function s]. We denote by $C_b^0(\mathbb{R})$ the Banach space of continuous bounded functions on $\mathbb{R}$, equipped with the supremum norm $\|\cdot\|_\infty$. We call $\mathscr{M}$ the dual of $C_b^0(\mathbb{R})$, that is the space of finite Radon measures on $\mathbb{R}$. The action of a measure μ in $\mathscr{M}$ on a continuous function f in $C_b^0(\mathbb{R})$ is given by

$$(\mu, f) = \int f(x)\ \mu(dx),$$

where the right-hand side is the Lebuesgue integral of f with respect to μ. We use the notation $\mu_n \overset{\mathscr{M}}{\to} \mu$ to say a sequence of measures (μ_n) converges in the weak topology of $\mathscr{M}$ towards some other measure μ [that is $(\mu_n, f) \xrightarrow[n\to\infty]{} (\mu, f)$ for any $f \in C_b^0(\mathbb{R})$]. A strong topology on $\mathscr{M}$ can also be defined via the norm

$$\|\mu\| = \sup_{\substack{f \in C_b^0(\mathbb{R}) \\ \|f\|_\infty = 1}} \left| \int f\mu(dx) \right| = \int |\mu|(dx) = \text{total mass of the measure } \mu.$$

If μ is a Borel measure, we use the canonical notation μ_{ac}, μ_{sc}, and μ_{pp} for its absolutely continuous part, singular continuous part, and discrete part, respectively. In the following, we will always implicitly assume that the measures are σ-finite Borel measures. When $\mu(\mathbb{R}^-) < \infty$, one may define a ''primitive'' of μ by

$$L_\mu(x) = \mu(]-\infty, x[).$$

Here L_μ is a locally bounded measurable function, which is continuous to the left and admits at most a countable set of discontinuities located at the atomic points of μ [i.e., $\mu(\{x\}) \neq 0$]. Moreover, L_μ is almost everywhere (a.e.) differentiable in the classical sense with

$$L'_\mu(x) = f_\mu(x) \quad \text{a.e.},$$

where $f_\mu \in L^1_{\text{loc}}(\mathbb{R})$ is the Radon–Nykodim derivative of μ_{ac}, that is $\mu_{ac}(dx) = f_\mu(x)\ dx$. Unless explicitly stated, the word ''almost everywhere'' will always refer to the Lebesgue measure.

A function f is said to be absolutely continuous on a set K (possibly unbounded) if, for any $\varepsilon > 0$, there is a $\delta > 0$ such that

$$\sum_{i=1}^{n} |b_i - a_i| < \delta \Rightarrow \sum_{i=1}^{n} |f(b_i) - f(a_i)| < \varepsilon$$

for any finite collection of disjoints intervals $[a_1, b_1],\ldots,[a_n, b_n]$ of K. Absolutely continuous functions can be thought of as primitives of absolutely continuous measures: a function is absolutely continuous on K if and only if it is the indefinite integral of some locally integrable function on K. To distinguish between the classical derivatives and the distributional derivatives of a function, say f, we will write $f', f'', \ldots, f^{(n)}$ for the former and $Df, \Delta f, \ldots, D^{(n)}f$ for the latter. This distinction is especially important for functions such as L_μ, for which $L'_\mu = f_\mu$ a.e. but $DL_\mu = \mu$, as can be seen from the following.

Lemma 3.1: If μ is a Borel measure such that $\mu(\mathbb{R}^-) < \infty$ and $s \in C_0^1(\mathbb{R})$, then we have the following ''integration by part'' formula:

$$\int dx\ s'(x) L_\mu(x) = -\int s(x)\mu(dx). \tag{3.1}$$

Hence, μ is the distributional derivative of L_μ in $\mathscr{D}$.

Proof: The proof is a standard exercise of functional analysis and we leave it to the reader.□

The two notions of derivation for L_μ coincide if μ is absolutely continuous. In fact, we have the following simple but convenient criterion for absolute continuity.

Lemma 3.2: Let $\eta \in \mathscr{D}'$. If $D\eta = f$, where $f \in L^1_{\text{loc}}(\mathbb{R})$ (locally integrable functions), then η is absolutely continuous on every compact.

Proof: Obvious. □

The differentiation rule for the product has to be adapted to the functions of type L_μ. If f and g are absolutely continuous functions, it is well known that fg is also absolutely continuous with $(fg)' = f'g + fg'$ a.e. An easy generalization of this is the following.

Lemma 3.3: Let μ be a Borel measure such that $\mu(\mathbb{R}^-) < \infty$ and g be an absolutely continuous function. Then the function $G = gL_\mu$ is a.e. differentiable and

$$G'(x) = g'(x)L_\mu(x) + g(x)f_\mu(x) \text{a.e.}, \tag{3.2}$$

where $\mu_{ac}(dx) = f_\mu(x)dx$.

Proof: Obvious. □

If μ is a Borel measure such that $\mu(\mathbb{R}^+) < \infty$, one can define a primitive by integrating to the right:

$$R_\mu(x) = \mu([x, +\infty[).$$

All the results stated for L_μ can be translated in an obvious way to R_μ. Here and everywhere, we will adopt the notational convention

$$\int_{-\infty}^{x} \mu(dt) := \mu(]-\infty, x[), \quad \int_{x}^{+\infty} \mu(dt) := \mu([x, +\infty[), \quad \int_{a}^{b} \mu(dt) := \mu([a, b[), \quad a < b.$$

Note that this notation preserves the chain rule for integrals.

We end this section with a useful identity. If $h \in L^1(\mathbb{R})$, it is well known that

$$\int_{x}^{+\infty} dx_1\ h(x_1) \int_{x_1}^{+\infty} dx_2 \cdots \int_{x_{p-1}}^{+\infty} dx_p\ h(x_p) = \frac{1}{p!} \left(\int_{x}^{+\infty} dy\ h(y) \right)^p,$$

and if, furthermore, $\int dx |x h(x)| < \infty$, then

$$\int_{x}^{+\infty} (x_1 - x)|h(x_1)|\ dx_1 \int_{x_1}^{+\infty} dx_2 \ldots \int_{x_{p-1}}^{+\infty} (x_p - x_{p-1})\ dx_p |h(x_p)| \leqslant \frac{1}{p!} \left(\int_{x}^{+\infty} dy (y - x)|h(y)| \right)^p.$$

The last inequality can be extended to measures as follows.

Lemma 3.4: If μ is a positive Borel measure such that $\int (1 + |x|)\mu(dx) < \infty$, then

$$\int_x^{+\infty}(x_1-x)\ \mu(dx_1)\cdots\int_{x_{p-1}}^{\infty}(x_p-x)\ \mu(dx_p)\leqslant\frac{1}{p!}\left(\int_x^{+\infty}dy(y-x)\ \mu(dy)\right)^p. \tag{3.3}$$

Proof: First suppose the measure μ is of compact support. Let us introduce the function

$$K(t)=\begin{cases}0 & \text{if } t>0,\\ -t & \text{if } t\leqslant 0.\end{cases}$$

Then

$$G^1_\mu(x)=K*\mu(x)=\int_x^{+\infty}(y-x)\ \mu(dy)$$

is a continuous bounded function. Now take some non-negative function $h\in C_0^\infty(\mathbb{R})$ such that $\int h=1$ and set $h_n(x)=nh(nx)$. Then h_n is an approximate identity. So if we define $\mu_n=\mu*h_n$ and $G^1_{\mu_n}=K*\mu_n=G^1_\mu*h_n$, then $\mu_n\overset{\mathscr{M}}{\to}\mu$ and $G^1_{\mu_n}(x)\to G^1_\mu(x)$ for all x. What is more, we claim that $\mu_nG^1_{\mu_n}\overset{\mathscr{M}}{\to}\mu G^1_\mu$. Indeed, for all $f\in C_b^0(\mathbb{R})$ we have

$$|(\mu_nG^1_{\mu_n},f\ )-(\mu G^1_\mu,f\ )|\leqslant\|\mu_n\|\sup_{x\in\Omega}|f(x)(G^1_{\mu_n}(x)-G^1_\mu(x))|+|(\mu_n-\mu,G^1_\mu s)|,$$

where Ω is some compact including all the supports of μ_n. The second term on the right-hand side converges to zero. On the other hand, the function $G^1_{\mu_n}$ is easily seen to be Lipschitz with a Lipschitz constant $2\|\mu_n\|$. Since the sequence μ_n is strongly bounded for it is weakly convergent, there is a common Lipschitz constant (precisely $\sup_n\|\mu_n\|$) for all the $G^1_{\mu_n}$ and thus this family of functions is equicontinuous. It follows that $G^1_{\mu_n}\to G^1_\mu$ uniformly on every compact and thus the first term converges to zero. Iterating this procedure, one can show that $\mu_nG^p_{\mu_n}\overset{\mathscr{M}}{\to}\mu G^p_\mu$, where G^p_μ and $G^p_{\mu_n}$ are defined recursively by

$$G^p_\mu(x)=K*(\mu G^{p-1}_\mu)(x),\quad G^p_{\mu_n}(x)=K*(\mu_nG^{p-1}_{\mu_n})(x).$$

It follows that

$$\begin{aligned}\int_x^{+\infty}(x_1-x)\ \mu_n(dx_1)\cdots\int_{x_{p-1}}^{\infty}(x_p-x)\ \mu_n(dx_p)&=K*(\mu_nG^p_{\mu_n})(x)\\ &\to K*(\mu G^p_\mu)(x)\\ &=\int_x^{+\infty}(x_1-x)\ \mu(dx_1)\cdots\int_{x_{p-1}}^{\infty}(x_p-x)\ \mu(dx_p)\end{aligned}$$

for all x. Since the formula (3.3) holds for μ_n, this proves the lemma for μ. If μ is not compactly supported, it suffices to take a sequence of truncations $\mu_n(dx)=(1-\theta_n(x))\ \mu(dx)$, where θ_n is the Heaviside function centered at n [$\theta_n(x)=1$ if $x\geqslant n$,0 otherwise] and to repeat the same arguments as previously. □

Remark: Surprisingly, the analog formula

$$\int_x^{+\infty}\mu(dx_1)\cdots\int_{x_{p-1}}^{\infty}\mu(dx_p)=\frac{1}{p!}\left(\int_x^{+\infty}\mu(dy)\right)^p$$

is false, as can be easily seen on the counterexample of the Dirac function. The difference is essentially due to the fact that G_μ is more regular than R_μ.

IV. THE HAMILTONIAN

Now we attack the scattering problem. We equip $L^2(\mathbb{R})$ with the usual scalar product $\langle f,g\rangle = \int fg$ and adopt the notation $\|f\|$ for the induced norm. Let H_0 be the self-adjoint realization of the negative Laplacian $-\Delta$ on $L^2(\mathbb{R})$, with domain $D(H_0)=W^2(\mathbb{R})$, where $W^p(\mathbb{R})$ is the Sobolev space of functions such that

$$\int dk(1+k^{2p})|\hat{f}(k)|<\infty.$$

Let V be a finite real Borel measure on $\mathbb{R}$. The operator sum $H=H_0+V$ is in general not defined on $D(H_0)$, but there exists a unique self-adjoint operator H with domain $D(H)\subset W^1(\mathbb{R})$ corresponding to this formal expression in the sense of quadratic forms (see, e.g., Ref. 22). The action of this operator is given by

$$\langle f,Hg\rangle = \int dx\ \overline{f'(x)}g'(x) + \int \overline{f(x)}g(x)\ V(dx)$$

for all $f\in W^1(\mathbb{R})$ and $g\in D(H)$. The domain $D(H)$ is the set of functions $f\in W^1(\mathbb{R})$ such that the distribution $(-\Delta+V)f\in L^2(\mathbb{R})$. The eigenvectors are those functions $f\in W^1(\mathbb{R})$ for which the distribution $(-\Delta+V-E)f=0$ for some real E.

Throughout this paper, we will assume that V is a real Borel measure satisfying the typical short-range condition

$$\int (1+|x|^2)\ |V|(dx)<\infty. \tag{4.1}$$

For Hamiltonians with such singular interactions, it is known that the spectral and scattering theory do not qualitatively differ from the regular case. The essential spectrum of H and H_0 coincide and there is no singular continuous spectrum (see Ref. 23 for the dimension one and Ref. 24 for the general case); the wave operators exist and are complete.[23,25]

In order to compute the time evolution generated by the Hamiltonian H, we need an explicit formula for the spectral measure and/or an eigenfunction expansion. This can be achieved by means of the so-called generalized eigenfunctions. We begin by introducing the usual definitions for smooth potentials. First suppose $V(x)$ is some continuous real function with compact support and V is the associated multiplication operator. Then the Hamiltonian $H=H_0+V$ is a self-adjoint operator on $D(H)=D(H_0)$. The generalized eigenfunctions associated to this operator are solutions of the stationary Schödinger equation or, what amounts to the same, the Helmholtz equation,

$$(\Delta+z^2)\varphi = V\varphi, \tag{4.2}$$

where $z>0$ and φ satisfies an appropriate asymptotic condition (radiation condition). For the spectral analysis of H, it is useful to let the parameter z run in the complex upper half-plane. We define the family of functions $\varphi_z^{\pm}$, with $\Im z\geqslant 0$, as the unique solutions of the Helmholtz equation (4.2) with asymptotic behavior

$$\varphi_z^{\pm}(x)\to\begin{cases} t_z^{\pm}e^{\pm izx}, & x\to\pm\infty,\\ e^{\pm izx}+r_z^{\pm}e^{\mp izx}, & x\to\mp\infty.\end{cases} \tag{4.3}$$

The coefficients t_z^+ and t_z^- are called transmission coefficients from the left and from the right, respectively, and the coefficients r_z^+ and r_z^- are the reflection coefficients from the left and from the right, respectively. The functions $\varphi_z^{\pm}$ are generalized functions in the sense that $H\varphi_z^{\pm} = z^2\varphi_z^{\pm}$, formally because $\varphi_z^{\pm}\notin L^2(\mathbb{R})$. For $z\neq 0$, the Helmholtz equation (4.2) together with asymptotic condition (4.3) is equivalent to the integral equation

$$\varphi_z^{\pm}(x) = e^{\pm izx} + \frac{1}{2iz}\int dy\ e^{iz|x-y|}V(y)\varphi_z^{\pm}(y). \tag{4.4}$$

Indeed, the above function verifies the Helmholtz equation and has the same asymptotic as $\varphi_z^{\pm}$, so by the uniqueness of the solution it is $\varphi_z^{\pm}$. This integral equation may be used to derive an expression of the transmission and reflection coefficients. Letting $x \to \pm\infty$ in (4.4) and comparing with (4.3) gives

$$t_z^{\pm} = 1 + \frac{1}{2iz} \int dy\ e^{\mp izy} V(y) \varphi_z^{\pm}(y), \tag{4.5}$$

$$r_z^{\pm} = \frac{1}{2iz} \int dy\ e^{\pm izy} V(y) \varphi_z^{\pm}(y). \tag{4.6}$$

When the potential is a measure, we cannot treat the Helmholtz equation as an ordinary differential equation any more. However, the integral equation (4.4) can still make sense if we understand $V(y)$ as a distribution. So, the idea is to seek a solution of (4.4) and verify *a posteriori* that it has the same properties as the usual generalized eigenfunctions for the Hamiltonian defined in the sense of quadratic forms. We define the generalized eigenfunctions of our problem as the continuous bounded solutions of

$$\varphi_z^{\pm}(x) = e^{\pm izx} + \frac{1}{2iz} \int e^{iz|x-y|}\ V(dy) \varphi_z^{\pm}(y), \quad \mathcal{I}z \geqslant 0. \tag{4.7}$$

We will study the existence and analycity properties of these functions, which will then allow us to compute explicitly the spectral measure and the wave operators and to establish an eigenfunction expansion.

V. THE JOST FUNCTIONS

Following the standard method used for regular potentials, we will first study a more convenient family of functions, namely the Jost functions $J_z^{\pm}$, that we define as the solutions of

$$J_z^{+}(x) = e^{izx} + \int_x^{+\infty} \frac{\sin(z(y-x))}{z} J_z^{+}(y)\ V(dy), \tag{5.1}$$

$$J_z^{-}(x) = e^{-izy} + \int_{-\infty}^{x} \frac{\sin(z(x-y))}{z} J_z^{-}(y)\ V(dy). \tag{5.2}$$

To remove the trivial oscillatory part, it is convenient to introduce the functions $j_z^{\pm}(x) = e^{\mp izx} J_z^{\pm}(x)$. These functions satisfy the modified integral equations

$$j_z^{+}(x) = 1 + \int_x^{+\infty} e^{iz(y-x)} \frac{\sin(z(y-x))}{z} j_z^{+}(y)\ V(dy), \tag{5.3}$$

$$j_z^{-}(x) = 1 + \int_{-\infty}^{x} e^{iz(x-y)} \frac{\sin(z(x-y))}{z} j_z^{-}(y)\ V(dy). \tag{5.4}$$

In order to solve these integral equations, we introduce the formal operators

$$G_z^{+} f(x) = \int_x^{+\infty} e^{iz(y-x)} \frac{\sin(z(y-x))}{z} f(y)\ V(dy), \tag{5.5}$$

$$G_z^{-} f(x) = \int_{-\infty}^{x} e^{iz(x-y)} \frac{\sin(z(x-y))}{z} f(y)\ V(dy). \tag{5.6}$$

Note that $G_z^{\pm}$ can also be defined in $z=0$. The properties of these operators are summarized in the following theorem.

Theorem 5.1: *Let V be a real Borel measure satisfying condition (4.1). Then, we have the following.*

(a) *For $\Im z \geqslant 0$, $G_z^{\pm}$ and $(1-G_z^{\pm})^{-1}$ are well-defined operators in $\mathscr{B}(C_b^0(\mathbb{R}))$, the space of bounded operators on $C_b^0(\mathbb{R})$. They are uniformly bounded in the upper half-plane $\Im z \geqslant 0$.*

(b) *The operator-valued functions $z \mapsto G_z^{\pm}$ and $z \mapsto (1-G_z^{\pm})^{-1}$ are analytic in $\Im z > 0$, continuous in $\Im z \geqslant 0$, and continuously differentiable on $\Im z \geqslant 0$, $z \neq 0$. Their derivatives are uniformly bounded in $\Im z \geqslant 0$.*

Proof: (a) Let us introduce the kernels $g_z^{\pm}(x) = \mp \theta_0(\mp x) e^{\mp izx} z^{-1} \sin(zx)$, where as before θ_0 is the Heaviside function centered at 0. For $\Im z \geqslant 0$, these functions satisfy the following estimates, which can be obtained by elementary but tedious computations (here the upper dot indicates the derivative with respect to the variable z):

$$|g_z^{\pm}(x)| \leqslant C\theta_0(\mp x)\frac{|x|}{1+|zx|} \leqslant C\theta_0(\mp x)|x|, \tag{5.7}$$

$$|\dot{g}_z^{\pm}(x)| \leqslant C\theta_0(\mp x)\left(|x| + \frac{|x|^2}{1+|zx|}\right) \leqslant C\theta_0(\mp x)(1+|x|^2), \tag{5.8}$$

$$|\ddot{g}_z^{\pm}(x)| \leqslant C\theta_0(\mp x)\left(|x| + |x|^2 + \frac{|x|^3}{1+|zx|}\right) \leqslant C\theta_0(\mp x)\left(1 + |x|^2 + \frac{|x|^2}{|z|}\right), \tag{5.9}$$

for some constant $C > 0$. Now, $G_z^{\pm} f$ can be rewritten as the convolution of a bounded continuous function with a finite measure, $G_z^{\pm} f = g_z^{\pm} * (Vf)$, and so $G_z^{\pm} f$ is itself continuous and bounded. Let us show that it is in fact uniformly bounded. For, note that

$$\sup_{x \in \mathbb{R}} \int_x^{+\infty} (y-x)\ |V|(dy) < \infty, \quad \sup_{x \in \mathbb{R}} \int_x^{+\infty} (y-x)^2\ |V|(dy) < \infty, \tag{5.10}$$

as soon as condition (4.1) is verified. Using the estimations (5.7) and (5.10) we obtain

$$|G_z^{\pm} f(x)| \leqslant C_1 \|f\|_{\infty} \int \theta_0(\pm(x-y))|x-y|\ |V|(dy) < C_2 \|f\|_{\infty}$$

for some constants C_1, $C_2 > 0$. Thus, $G_z^{\pm}$ is uniformly bounded on $\Im z \geqslant 0$. To prove the existence of $(1-G_z^{\pm})^{-1}$, we will show that its Neumann series is absolutely convergent. We detail the proof for $(1-G_z^{+})^{-1}$, the proof for $(1-G_z^{-})^{-1}$ being similar. Let us form the nth iterate

$$(G_z^{+})^n f(x) = \int_x^{+\infty} g_z^{+}(x_1 - x)\ V(dx_1) \int_{x_1}^{+\infty} \cdots \int_{x_{n-1}}^{+\infty} g_z^{+}(x_n - x_{n-1}) f(x_n)\ V(dx_n).$$

Since $|g_z^{\pm}(x)| \leqslant c|x|$ for some constant $c > 0$, we have

$$|(G_z^{+})^n f(x)| \leqslant c^n \|f\|_{\infty} \int_x^{+\infty} (x_1 - x)\ |V|(dx_1) \int_{x_1}^{+\infty} \cdots \int_{x_{n-1}}^{+\infty} (x_n - x_{n-1})\ |V|(dx_n),$$

and it follows from Lemma 3.4 that

$$|(G_z^{+})^n f(x)| \leqslant \|f\|_{\infty} \frac{c^n}{n!} \left(\int_x^{+\infty} (y-x)\ |V|(dy) \right)^n \leqslant \frac{C^n}{n!}$$

for some constant $C > c > 0$. Thus,

$$\|(G_z^{+})^n\| \leqslant \frac{C^n}{n!}$$

in the operator norm of $\mathscr{B}(C_b^0(\mathbb{R}))$. It follows that the Neumann series $\Sigma(G_z^+)^n$ is uniformly absolutely convergent and so the inverse $(1-G_z^+)^{-1}$ exists and its norm is uniformly bounded.

(b) Let us define the operator $\dot{G}_z^\pm$, $\Im z \geqslant 0$, by

$$\dot{G}_z^\pm f(x) = \int \dot{g}_z^\pm(x-y) f(y)\ V(dy).$$

Using (5.8) and (5.10), one can easily check that $\dot{G}_z^\pm$ is a well-defined operator on $\mathscr{B}(C_b^0(\mathbb{R}))$, uniformly bounded on $\Im z \geqslant 0$. We omit the details. For $\Im z > 0$, one can show by direct computation that $\dot{G}_z^\pm$ is the norm derivative of $G_z^\pm$ and $(1-G_z^\pm)^{-1}\dot{G}_z^\pm(1-G_z^\pm)^{-1}$ is the norm derivative of $(1-G_z^\pm)^{-1}$. So $G_z^\pm$ and $(1-G_z^\pm)^{-1}$ are norm differentiable on $\Im z > 0$, hence analytic there. Moreover, by virtue of (5.7) and (5.10), we have, for any $\varepsilon > 0$,

$$\begin{aligned}
|(G_{k+i\varepsilon}^\pm - G_k^\pm) f(x)| &\leqslant \|f\|_\infty \int |g_{k+i\varepsilon}^\pm(x-y) - g_k^\pm(x-y)|\ |V|(dy) \\
&\leqslant \varepsilon \|f\|_\infty \int \sup_{\Im z \geqslant 0} |\dot{g}_z^\pm(x-y)|\ |V|(dy) \\
&\leqslant \varepsilon C \|f\|_\infty \int \theta_0(\mp(x-y))(1+|x-y|^2)\ |V|(dy) \\
&\leqslant \varepsilon C' \|f\|_\infty
\end{aligned}$$

for some constants C', $C > 0$, and thus $G_z^\pm$ is continuous on $\Im z \geqslant 0$. That $(1-G_z^\pm)^{-1}$ is also continuous on $\Im z \geqslant 0$ follows from the second resolvent formula

$$\begin{aligned}
\|(1-G_{k+i\varepsilon})^{-1} - (1-G_k)^{-1}\| &= \|(1-G_{k+i\varepsilon})^{-1}(G_{k+i\varepsilon} - G_k)(1-G_k)^{-1}\| \\
&\leqslant \|(1-G_{k+i\varepsilon})^{-1}\| \|G_{k+i\varepsilon} - G_k\| \|(1-G_k)^{-1}\|.
\end{aligned}$$

In the same manner, one can prove using (5.9) and (5.10) that $\dot{G}_z^\pm$ is continuous on $\Im z \geqslant 0$, $z \neq 0$, as well as $(1-G_z^\pm)^{-1}\dot{G}_z^\pm(1-G_z^\pm)^{-1}$. This concludes the proof of Theorem 5.1. □

Corollary 5.2: For $\Im z \geqslant 0$, the equations (5.1) and (5.2) admit unique continuous solutions $J_z^\pm$. They are given by

$$J_z^\pm(x) = e^{\pm izx}[(1-G_z^\pm)^{-1} I](x),$$

where $I \equiv 1$ is the constant function one. The functions $J_z^\pm$ are analytic in $\Im z > 0$, continuous in $\Im z \geqslant 0$, and continuously differentiable on $\Im z \geqslant 0$, $z \neq 0$. Moreover, the functions $J_k^\pm(x)$ and $(1+|x|)^{-1}\dot{J}_k^\pm(x)$ are uniformly bounded on the real k axis, and we have the symmetry $\overline{J_k^\pm} = J_{-k}^\pm$.

Proof: The existence, analyticity, and boundedness properties of $J_z^\pm$ follow from Theorem 5.1. Moreover, since V is real we have, for real k, $\overline{G_k^\pm I} = G_{-k}^\pm I$, and also $\overline{(G_k^\pm)^n I} = (G_{-k}^\pm)^n I$ for all n. This property carries on the Neumann series, leading to $\overline{J_k^\pm} = J_{-k}^\pm$. □

Next we study the asymptotic properties of the Jost functions. Letting $x \to \pm\infty$ and using the short-range condition (4.1) together with (5.7), a straightforward computation shows that

$$J_z^\pm(x) = \begin{cases} e^{\pm izx} + O(x^{-2} e^{\mp \Im z x}), & x \to \pm\infty, \\ \alpha_z^\pm e^{\pm izx} + \beta_z^\pm e^{\mp izx} + O(x^{-2} e^{\pm \Im z x}), & x \to \mp\infty, \end{cases} \tag{5.11}$$

where

$$\alpha_z^\pm = 1 - \frac{1}{2iz} \int j_z^\pm(y)\ V(dy), \quad \beta_z^\pm = \int \frac{e^{\pm 2izy}}{2iz}\, j_z^\pm(y)\ V(dy). \tag{5.12}$$

The coefficients $\alpha_z^\pm$ and $\beta_z^\pm$ satisfy the following.

Proposition 5.3: For $\Im z \geqslant 0$, the coefficients $\alpha_z^\pm$ verify

$$\alpha_z^+ = \alpha_z^- =: \alpha_z, \tag{5.13}$$

and for real k we have the additional relations

$$\beta_k^+ = -\overline{\beta_k^-}, \quad |\alpha_k|^2 - |\beta_k^\pm|^2 = 1. \tag{5.14}$$

Proof: The classical method (see, e.g., Ref. 26) to prove (5.14) relies upon the properties of the Wronskian associated to the functions $J_z^\pm$. In our case the manipulations with the Wronskian become touchy because of the poor regularity of the involved functions. Therefore, we have to proceed more carefully. We start with the following.

Lemma 5.4: For $\Im z \geqslant 0$, the functions $J_z^\pm$ are absolutely continuous on every compact.

Proof: The functions $J_z^\pm$ satisfy the following estimates as $x \to \pm\infty$:

$$|J_z^\pm(x) - e^{\pm izx}| \leqslant \mathcal{O}(1/x^2), \quad |J_z^\pm(x)| \leqslant \mathcal{O}(1).$$

So we may define the functions

$$F_z^-(x) = \int_{-\infty}^{x} J_z^-(t)\ V(dt) - z^2 \int_{-\infty}^{x} dt (J_z^-(t) - e^{-izt}) - ize^{-izx},$$

$$F_z^+ = (x) = -\int_{x}^{+\infty} J_z^+(t)\ V(dt) + z^2 \int_{x}^{+\infty} dt (J_z^+(t) - e^{+izt}) + ize^{+izx}.$$

Using Lemma 3.1 we see that $DF_z^\pm = (V - z^2) J_z^\pm = \Delta J_z^\pm$. Hence $DJ_z^\pm = F_z^\pm + C^\pm$ for some constant $C^\pm$. To estimate the constants, take some sequence of test functions $s_n^\pm(x) = s(x \mp n)$, with $s \in C_0^\infty$. Then

$$(DJ_z^\pm, s_n^\pm) = -(J_z^\pm, s_n'^\pm) \xrightarrow{n \to \pm\infty} -(e^{\pm izx}, s_n'^\pm) = \pm iz (e^{\pm izx}, s_n^\pm).$$

On the other hand, $(F_z^\pm, s_n^\pm) \xrightarrow{n \to \pm\infty} \pm iz (e^{\pm izx}, s_n^\pm)$. Hence $C^\pm = 0$ and thus $DJ_z^\pm = F_z^\pm$. Now $F_z^\pm$ is locally bounded and measurable, hence locally integrable. It follows from Lemma 3.2 that $J_z^\pm$ is absolutely continuous. This concludes the proof of Lemma 5.4. □

The functions $F_z^\pm(x)$ are defined for all x and so we may define everywhere the ''Wronskian''

$$\mathcal{W}[J_z^+, J_z^-](x) = J_z^+(x) F_z^-(x) - J_z^-(x) F_z^+(x).$$

A priori, $\mathcal{W}[J_z^+, J_z^-]$ is only measurable with a countable number of discontinuities. However, a cancellation of the singularities makes the Wronskian more regular than expected.

Lemma 5.5: $\mathcal{W}[J_z^+, J_z^-](x)$ is absolutely continuous on every compact.

Proof: We keep the notations of Lemma 5.4. For any x we can rewrite

$$\mathcal{W}[J_z^+, J_z^-](x) = w_1(x) + w_2(x),$$

where

$$w_1(x) = J_z^+(x) \int_{-\infty}^{x} J_z^-(t)\ V(dt) + J_z^-(x) \int_{x}^{+\infty} J_z^+(t)\ V(dt)$$

and w_2 is an absolutely continuous function. So it suffices to prove the absolute continuity of w_1. After some splittings and rearrangements of integrals, we obtain, for any $b > a$,

$$w(b) - w(a) = [J_z^+(b) - J_z^+(a)] \int_{-\infty}^{a} J_z^-(t)\ V(dt) + \int_{a}^{b} [J_z^+(b) J_z^-(t) - J_z^+(t) J_z^-(a)] V(dt)$$

$$+ [J_z^-(b) - J_z^-(a)] \int_{b}^{+\infty} J_z^+(t)\ V(dt) = \mathrm{Term}_1 + \mathrm{Term}_2 + \mathrm{Term}_3.$$

We then estimate each term independently:

$$|\mathrm{Term}_1| \leqslant \|V\| e^{\Im z b} \|j_z^-\|_\infty |J_z^+(b) - J_z^+(a)|,$$

$$|\mathrm{Term}_2| \leqslant \|j_z^+\|_\infty e^{-\Im z a} \int_a^b |J_z^-(t) - J_z^-(a)|\,|V|(dt) + \|j_z^-\|_\infty e^{\Im z b} \int_a^b |J_z^+(t) - J_z^+(b)|\,|V|(dt),$$

$$|\mathrm{Term}_3| \leqslant \|V\| \|j_z^+\|_\infty e^{-\Im z a} |J_z^-(b) - J_z^-(a)|\,.$$

Now the functions $J_z^\pm$ are themselves absolutely continuous on every bounded interval $[a, b]$. So given $\varepsilon > 0$, there exists some $\delta > 0$ such that for any finite collection of disjoint segments $[a_1, b_1], [a_2, b_2], \ldots, [a_n, b_n]$ of $[a, b]$,

$$\sum |b_i - a_i| < \delta \Rightarrow \sum |J_z^\pm(b_i) - J_z^\pm(a_i)| < \varepsilon.$$

For such a_i and b_i we have, in view of the previous estimations,

$$\sum |w(b_i) - w(a_i)| \leqslant 2\|V\| (e^{\Im z b} \|j_z^-\|_\infty + e^{-\Im z a} \|j_z^+\|_\infty) \varepsilon,$$

which proves the absolute continuity of the function w_1 on the interval $[a, b]$. This concludes the proof of Lemma 5.5. □

Corrolary 5.6: The Wronskian is constant.

Proof: $J_z^\pm$ is absolutely continuous and $F_z^\pm$ is the sum of a smooth function and a function of type L_μ, so we may apply the differentiation rule of Lemma 3.3 to the Wronskian:

$$\mathscr{W}[J_z^+, J_z^-]'(x) = J_z^+(x) F_z^{-\prime}(x) + J_z^{+\prime}(x) F_z^-(x) - J_z^-(x) F_z^{+\prime}(x) + J_z^{-\prime}(x) F_z^+(x).$$

Now $F_z^{\pm\prime} = J_z^\pm f_V - z^2 J_z^\pm$ a.e. (where f_V is the density of V_{ac}) and $J_z^{\pm\prime} = F_z^\pm$ a.e. Using these identities, we obtain $\mathscr{W}[J_z^+, J_z^-]'(x) = 0$ a.e. Since $\mathscr{W}[J_z^+, J_z^-](x)$ is absolutely continuous on every compact, it follows that $\mathscr{W}[J_z^+, J_z^-](x)$ is constant. □

The value of the Wronskian can be computed by letting $x \to \pm\infty$. This yields

$$\mathscr{W}[J_z^+, J_z^-](x) = -2iz\alpha_z^+ = -2iz\alpha_z^-, \tag{5.15}$$

proving $\alpha_z^+ = \alpha_z^-$. For real z, one can derive other relations. Since the measure V is real, the functions $J_k^\pm$ and $\overline{J_k^\pm}$ satisfy for real k the same equation (6.4), so we may apply the same method (that is, the Wronskian method) to the pairs of solutions $\mathscr{W}[J_k^\pm, \overline{J_k^\pm}]$ and $\mathscr{W}[J_k^\pm, \overline{J_k^\mp}]$. This yields (5.14) and completes the proof of Proposition 5.3. □

We end the study of the Jost function with the usual characterization of bound states.

Proposition 5.7: α_z has a finite number of zeros in the upper half-plane. They lie on the positive imaginary axis, away from zero. If z_0 is a zero of α_z, then z_0^2 is an eigenvalue of the Hamiltonian H.

Proof: By the mere definition, we see that $\alpha_z = 0$ if and only if $\int j_z^\pm(t)\ V(dt) = 2iz$. Now, $j_z^\pm$ is uniformly bounded in the upper half-plane and thus $|z| = |\int j_z^\pm(t)\ V(dt)|/2 \leqslant M$ for some constant $M > 0$. It follows that the zeros of α_z lie within some semicircle $|z| \leqslant M$, $\Im z \geqslant 0$. Moreover, the condition $|\alpha_k|^2 - |\beta_k^\pm|^2 = 1$ when $k \in \mathbb{R}$ forces $|\alpha_k| \geqslant 1$. Since α_z is continuous on $\Im z \geqslant 0$, this means that the possible zeros are relegated to some compact region $|z| \leqslant M$, $\Im z \geqslant \varepsilon > 0$, in which α_z is analytic. Hence, there is only a finite number of zeros in the upper half-plane. Now suppose z_0 is a zero of α_z. Then $J_{z_0}^\pm$ is in $L^2(\mathbb{R})$. Since $J_z^\pm$ is also a solution of the weak Helmholtz equation (6.4), this implies that z_0^2 is an eigenvalue of H and $J_{z_0}^\pm$ is an associated eigenvector. Since H is self-adjoint, this implies $z_0^2 \in \mathbb{R}$. This concludes the proof of Proposition 5.7 and Theorem 6.1. □

VI. THE GENERALIZED EIGENFUNCTIONS

Let us now return to the generalized eigenfunctions $\varphi_z^\pm$. Set $\varphi_z^\pm = J_z^\pm / \alpha_z$ whenever $\alpha_z \neq 0$. Then

$$\alpha_z = 1 - \frac{1}{2iz}\int j_z^{\pm}(y)\ V(dy) = \left(1 + \frac{1}{2iz}\int e^{\mp izy}\varphi_z^{\pm}(y)\ V(dy)\right)^{-1} =: t_z^{-1}$$

and, using the integral equations (5.1)/(5.2), $\varphi_z^{\pm}$ is easily seen to satisfy (4.7). Conversely, if $\varphi_z^{\pm}$ is a continuous solution of (4.7), then the same computation shows that $t_z^{-1}\varphi_z^{\pm}$ verifies the integral equation (5.1)/(5.2) and thus coincides with $J_z^{\pm}$ by the uniqueness of the solution. Thus, the integral equation (4.7) admits a unique continuous solution $\varphi_z^{\pm}$ as soon as $\alpha_z \neq 0$. Summing up all the results we have obtained for $J_z^{\pm}$ and translating them to $\varphi_z^{\pm}$ we can state the following.

Theorem 6.1: *For $\Im z \geqslant 0$ and $\alpha_z \neq 0$, the functions $\varphi_z^{\pm}(x)$ have the following asymptotics,*

$$\varphi_z^{\pm}(x) \to \begin{cases} t_z e^{\pm izx}, & x \to \pm\infty, \\ e^{\pm izx} + r_z^{\pm} e^{\mp izx}, & x \to \mp\infty, \end{cases} \tag{6.1}$$

for complex numbers $t_z = \alpha_z^{-1}$ and $r_z^{\pm} = \beta_z^{\pm}/\alpha_z$ that we refer to as the transmission and reflection coefficients, respectively. If the potential V has compact support, this asymptotic becomes exact outside the support. For fixed x, the functions $\varphi_z^{\pm}(x)$ are meromorph in $\Im z > 0$ with a finite number of poles located on the imaginary axis, corresponding to the zeros of α_z. Moreover, the functions $\varphi_z^{\pm}(x)$ are continuous on the closed upper half-plane $\Im z \geqslant 0$ and continuously differentiable on $\Im z \geqslant 0$, $z \neq 0$. The same result holds for the transmission and reflection coefficients. On the real k axis, the functions $\varphi_k^{\pm}(x)$ and $(1+|x|)^{-1}\dot{\varphi}_k^{\pm}(x)$ are uniformly bounded and we have the additional properties

$$\overline{\varphi_k^{\pm}} = \varphi_{-k}^{\pm}, \quad \overline{t_k} = t_{-k}, \quad \overline{r_k^{\pm}} = r_{-k}^{\pm}, \tag{6.2}$$

and

$$r_k^{+}\overline{t_k} + t_k\overline{r_k^{-}} = 0, \quad |t_k|^2 + |r_k^{\pm}|^2 = 1. \tag{6.3}$$

Remark: As in the regular case, the relations (6.3) express the unitarity of the *scattering matrix*

$$S = \begin{pmatrix} t_k & r_k^{-} \\ r_k^{+} & t_k \end{pmatrix}.$$

The terminology ''generalized eigenfunctions'' for $\varphi_z^{\pm}$ is justified by the following fact.

Proposition 6.2: For $\Im z \geqslant 0$ and $\alpha_z \neq 0$, the functions $\varphi_z^{\pm}$ satisfy the weak Helmholtz equation

$$(\Delta + z^2)\varphi_z^{\pm} = V\varphi_z^{\pm} \quad in \quad \mathscr{D}'. \tag{6.4}$$

Proof: Let us define the kernel $K_z(x) = (2iz)^{-1}e^{iz|x|}$. When $\alpha_z \neq 0$, the integral equation (4.7) satisfied by $\varphi_z^{\pm}$ can be rewritten as $\varphi_z^{\pm}(x) = e^{\pm izx} + K_z * (V\varphi_z^{\pm})(x)$, where the convolution is well defined since

$$|K_z * (V\varphi_z^{\pm})(x)| = \left|\frac{1}{2iz\alpha_z}\int e^{iz|x-y|}e^{\pm iz(y-x)}j_z^{\pm}(y)\ V(dy)\right| \leqslant \frac{1}{2|z\alpha_z|}\,\|V\|\|j_z^{\pm}\|_{\infty}.$$

The function K_z is well known to be a fundamental solution in $\mathscr{D}'$ of $(\Delta + z^2)K_z = \delta_0$. Now take some test function $s \in \mathscr{D}$. Then

$$((\Delta + z^2)\varphi_z^{\pm}, s) = ((\Delta + z^2)(K_z * (V\varphi_z^{\pm})), s) = (K_z * (V\varphi_z^{\pm}), s'' + z^2 s).$$

The formula $(f * g, h) = (g, h * \tilde{f}\,)$, where $\tilde{f}(x) = f(-x)$, holds as soon as both sides are defined. Since $\tilde{K}_z = K_z$, it follows that

$$((\Delta + z^2)\varphi_z^{\pm}, s) = (V\varphi_z^{\pm}, K_z * (s'' + z^2 s)) = (V\varphi_z^{\pm}, s).$$

This proves the proposition. □

On the real z axis, one can state a uniqueness theorem for the Helmholtz equation.

Proposition 6.3: Let $f \in C_b^0(\mathbb{R})$ be a weak solution of

$$(\Delta + k^2) f = Vf, \quad k \in \mathbb{R}.$$

If $\lim_{|x|\to+\infty} |\varphi_k^+(x) - f(x)| = 0$, then $f = \varphi_k^+$. The analogous result holds for φ_k^- and any linear combination of φ_k^+ and φ_k^-.

Proof: The function $K_k * (Vf)$ is well defined in $C_b^0(\mathbb{R})$ because it is the convolution of a continuous bounded function K_k with a finite measure Vf. Now $(\Delta + k^2)(f - K_k * (Vf)) = 0$, and thus the general form of f is $f(x) = K_k * (Vf)(x) + ae^{ikx} + be^{-ikx}$. Hence, $\varphi_k^+(x) - f(x) = K_k * V(\varphi_k^+ - f) + (1-a)e^{ikx} - be^{-ikx}$. The condition on the asymptotic behavior imposes $a = 1$ and $b = 0$. Thus, $f(x) = K_k * (Vf)(x) + e^{+ikx}$. Since the solution of the above equation is unique [in $C_b^0(\mathbb{R})$], we have in fact, $f = \varphi_k^+$. This concludes the proof. □

We end the study of the generalized eigenfunctions with a useful approximation for the following. For real k, it follows from Eqs. (5.3)/(5.4) that $j_k^{\pm} = 1 + O(1/k)$, $k \to +\infty$, and consequently

$$r_k^{\pm} = \beta_k^{\pm} = -i\sqrt{\frac{\pi}{2}} \frac{\hat{V}(\mp 2ik)}{k} + O(1/k^2), \quad k \to \infty, \tag{6.5}$$

where $\hat{V}$ is the Fourier transform of V:

$$\hat{V}(\xi) = \frac{1}{\sqrt{2\pi}} \int e^{-i\xi x} \, V(dx).$$

The first term on the rhs of (6.5) is known as the *Born approximation* for the reflection coefficient.

VII. THE SPECTRUM

In this section, we will retrieve and strengthen some known results concerning the spectrum (see Refs. 23 and 24) and compute the spectral measure. Let $R(\zeta) = (H - \zeta)^{-1}$ be the resolvent of H. Let us look for a kernel of $R(\zeta)$, that is a function $\mathcal{G}(x, y, \zeta)$ such that $\mathcal{G}(x, \cdot, \zeta) \in L^2(\mathbb{R})$ and for all $f \in L^2(\mathbb{R})$,

$$R(\zeta) f = \int dy \; \mathcal{G}(\cdot, y, \zeta) f(y). \tag{7.1}$$

For continuous potentials V, the Green's function $\mathcal{G}(x, y, \zeta)$ may be easily computed by the standard method,

$$\mathcal{G}(x, y, \zeta) = \frac{J_z^+(\max(x,y)) J_z^-(\min(x,y))}{\mathcal{W}(J_z^+, J_z^-)}, \tag{7.2}$$

where z is the complex square root of ζ in the upper half-plane $z^2 = \zeta$, $\Im z > 0$. In fact, this expression of the kernel remains valid if V is a finite measure, as will be shown.

Theorem 7.1: *Let V be a finite real Borel measure satisfying (4.1) and $H = -\Delta + V$ be defined in the sense of quadratic forms. Then the resolvent $R(\zeta) = (H - \zeta)^{-1}$ is given by (7.1) and (7.2).*

We begin with the following.

Lemma 7.2: For all $y \in \mathbb{R}$, we have the distributional equality

$$(-\Delta + V - \zeta) \mathcal{G}(\cdot, y, \zeta) = \delta_y, \tag{7.3}$$

where δ_y is the Dirac distribution centered at y.

Proof: The function $\mathcal{G}(x, y, \zeta)$ can be rewritten as

$$\mathcal{G}(x,y,\zeta)=\frac{J_z^+(y)J_z^-(x)}{\mathcal{W}(J_z^+,J_z^-)}+\theta_y(x)\tilde{\mathcal{G}}_y(x),\quad\text{with}\quad\tilde{\mathcal{G}}_y(x)=\frac{J_z^+(y)J_z^-(x)-J_z^+(x)J_z^-(y)}{\mathcal{W}(J_z^+,J_z^-)},$$

and, as usual, θ_y is the Heaviside function centered at y. Since $J_z^\pm$ satisfy the weak Helmholtz equation (6.4) we have $(-\Delta+V-\zeta)\mathcal{G}(\cdot,y,\zeta)=(-\Delta+V-\zeta)\theta_y\tilde{\mathcal{G}}_y$. Let us first compute the term $\Delta(\theta_y\tilde{\mathcal{G}}_y)$. Take some positive function $h\in C_0^\infty$ such that $\int dx\ h(x)=1$ and set $h_n(x)=nh(nx)$ and $\theta_{y,n}(x)=\theta_y*h_n(x)$. The sequence h_n is an approximate identity and so $\theta_{y,n}\overset{\mathcal{D}'}{\to}\theta_y$. The same holds for the derivatives, that is, $D^{(k)}\theta_{y,n}\overset{\mathcal{D}'}{\to}D^{(k)}\theta_y$. Now the function $\theta_{y,n}$ is C^∞ and so we may apply the usual differentiation rule (see, e.g., Ref. 27) for the distribution $\theta_{y,n}\tilde{\mathcal{G}}_y$, that is

$$\begin{aligned}\Delta(\theta_{y,n}\tilde{\mathcal{G}}_y)&=D(\theta'_{y,n}\tilde{\mathcal{G}}_y+\theta_{y,n}D\tilde{\mathcal{G}}_y)=D(\theta'_{y,n}\tilde{\mathcal{G}}_y)+\theta'_{y,n}D\tilde{\mathcal{G}}_y+\theta_{y,n}\Delta\tilde{\mathcal{G}}_y\\&=D(\theta'_{y,n}\tilde{\mathcal{G}}_y)+\theta'_{y,n}D\tilde{\mathcal{G}}_y-\theta_{y,n}(V-\zeta)\tilde{\mathcal{G}}_y.\end{aligned}$$

On the other hand we have $\Delta(\theta_{y,n}\tilde{\mathcal{G}}_y)\overset{\mathcal{D}'}{\to}\Delta(\theta_y\tilde{\mathcal{G}}_y)$, $\theta'_{y,n}\tilde{\mathcal{G}}_y\overset{\mathcal{D}'}{\to}\delta_y\tilde{\mathcal{G}}_y(y)=0$ and $\theta_{y,n}(V-\zeta)\tilde{\mathcal{G}}_y\overset{\mathcal{D}'}{\to}\theta_y(V-\zeta)\tilde{\mathcal{G}}_y$. It remains the term $\theta'_{y,n}D\tilde{\mathcal{G}}_y$ which must be manipulated more carefully. Keeping the notations of Lemma 5.4, we have the distributional equality

$$D\tilde{\mathcal{G}}_y(x)=\frac{J_z^+(y)F_z^-(x)-F_z^+(x)J_z^-(y)}{\mathcal{W}(J_z^+,J_z^-)}.$$

The rhs is defined everywhere and can easily be shown to be continuous at y (although the functions $F_z^\pm$ are themselves not necessary continuous). Hence, $D\tilde{\mathcal{G}}_y$ coincides with a function which is continuous at y, and takes the value 1 there. It follows that $\theta'_{y,n}D\tilde{\mathcal{G}}_y\overset{\mathcal{D}'}{\to}\delta_y$. Putting all this together, we obtain (7.3). □

Proof of Theorem 7.1: Now call $R^\sharp(\zeta)f$ the rhs of (7.1). For $\zeta=z^2$, $\Im z>0$, $R^\sharp(\zeta)$ is a bounded operator (in fact Hilbert–Schmidt) on $L^2(\mathbb{R})$. Moreover, $R^\sharp(\zeta)f$ is easily seen to be a continuous bounded function for all $f\in\mathcal{D}$, so we may consider the distribution $(-\Delta+V-\zeta)R^\sharp(\zeta)f$. Now, for all $s\in\mathcal{D}$ we have

$$((-\Delta+V-\zeta)R^\sharp(\zeta)f,s)=\int dy\ f(y)\left[\int dx(-s''(x)-\zeta s(x))\mathcal{G}(x,y,\zeta)+\int V(dx)\ \mathcal{G}(x,y,\zeta)\right]$$

by Fubini's theorem. On the other hand,

$$\int dx(-s''(x)-\zeta s(x))\mathcal{G}(x,y,\zeta)+\int V(dx)\ \mathcal{G}(x,y,\zeta)=((-\Delta+V-\zeta)\mathcal{G}(\cdot,y,\zeta),s)=s(y).$$

Therefore, we have the distributional equality $(-\Delta+V-\zeta)R^\sharp(\zeta)f=f$. It follows that $R^\sharp(\zeta)f\in D(H)$ and $(H-\zeta)R^\sharp(\zeta)f=f$. Thus $R^\sharp(\zeta)f=R(\zeta)f$ holds on the dense set $\mathcal{D}$, hence on $L^2(\mathbb{R})$ and so $R^\sharp(\zeta)=R(\zeta)$. This completes the proof of Theorem 7.1. □

We now turn to the study of the spectrum. Let $\sigma_d(H)$, $\sigma_{sc}(H)$, and $\sigma_{ac}(H)$ stand for the discrete, singular continuous, and absolutely continuous spectrum of H, respectively, and let $\sigma_c(H)=\sigma_{ac}(H)+\sigma_{sc}(H)$ be the continuous spectrum of H. The spectrum has the same characteristics as for regular potentials, as will be shown.

Theorem 7.3: *The positive spectrum is purely absolutely continuous and the negative spectrum is composed of a finite number of negative eigenvalues,*

$$\sigma_{ac}(H)=[0,+\infty[,\quad \sigma_{sc}(H)=\varnothing,\quad \sigma_d(H)=\{-\lambda_1^2,\ldots,-\lambda_N^2\},\tag{7.4}$$

where $i\lambda_1,\ldots,i\lambda_N$ are the zeros of α_z in the upper half-plane. Let (E_λ) be the spectral family associated to H, i.e., formally $H=\int \lambda\, dE_\lambda$. For any states $f,g\in\mathscr{D}$, the associated spectral measure $\mu_{f,g}$, defined by $d\mu_{f,g}(\lambda)=(f,dE_\lambda g)$, is absolutely continuous on the positive axis with density:

$$\frac{d\mu_{f,g}(\lambda)}{d\lambda}=m_{f,g}(\lambda)=\int dx\, dy\, \overline{f(y)}g(x)p(x,y,\lambda), \tag{7.5}$$

where the kernel $p(x,y,\lambda)$ is given by

$$p(x,y,\lambda)=\frac{1}{2\pi}\,\Re\left\{\frac{\varphi_k^+(y)\varphi_k^-(x)}{kt_k}\right\}=\frac{1}{2\pi}\,\Re\left\{\frac{\varphi_k^+(x)\varphi_k^-(y)}{kt_k}\right\},\quad k^2=\lambda,k>0. \tag{7.6}$$

Proof: In view of Proposition 6.1, the kernel of the resolvent $\mathscr{G}(x,y,\zeta)$ is analytic on the negative real axis with only poles produced by the zeros of the Wronskian, which are also the zeros of α_k, that is, bound states (see Proposition 5.7). Hence, there is no continuous spectrum on the negative axis. Let us show that there are no imbedded eigenvalues in the positive spectrum. Suppose $E=k^2$, $k\geqslant 0$, is an eigenvalue. Then there exists some nonzero $f\in D(H)\subset C_b^0(\mathbb{R})\cap L^2(\mathbb{R})$ such that $(\Delta+k^2)f=Vf$. Now, as was explained in Proposition 6.3, any continuous bounded solution of the above equation can be written as $f(x)=K_k*(Vf)+ae^{ikx}+be^{-ikx}$ for some constants a and b. The supplementary condition $f\in L^2(\mathbb{R})$ forces $f(x)\to 0$ as $|x|\to+\infty$. The inspection of the asymptotic behavior of f then imposes $a=b=0$ and $f=0$. Hence E cannot be an eigenvalue. So far, we have proven $\sigma(H)\cap\,]-\infty,\,0[=\sigma_d(H)$, where $\sigma_d(H)$ as in (7.4). Let us use Stone's formula to derive the spectral projectors on the positive spectrum. If $E[\alpha,\,\beta]$ is the spectral projector on the interval $[\alpha,\beta]\subset\mathbb{R}^+$, then

$$E(\alpha,\beta)=\text{s.}\lim_{\varepsilon\to 0}\frac{1}{2i\pi}\int_\alpha^\beta d\zeta\; R(\zeta+i\varepsilon)-R(\zeta-i\varepsilon),\quad 0<\alpha<\beta.$$

The above operator is a projector with kernel

$$e_{\alpha,\beta}(x,y)=\frac{1}{2i\pi}\int_\alpha^\beta d\zeta\;\mathscr{G}(x,y,\zeta+io)-\mathscr{G}(x,y,\zeta-io). \tag{7.7}$$

The integrand can be computed more precisely since for $\zeta=k^2$ $(k>0)$ we have

$$\frac{1}{2i\pi}\{\mathscr{G}(x,y,\zeta+io)-\mathscr{G}(x,y,\zeta-io)\}=p(x,y,\zeta),$$

with

$$p(x,y,\zeta)=\frac{1}{2\pi}\,\Re\left\{\frac{J_k^+(y)J_k^-(x)}{k\alpha_k}\right\}=\frac{1}{2\pi}\,\Re\left\{\frac{\varphi_k^+(y)\varphi_k^-(x)}{kt_k}\right\},\quad x<y,$$

and $p(x,y,\zeta)=p(y,x,\zeta)$, $x>y$. The distinction $x<y$ and $x>y$ is actually unnecessary, as is shown in the following.

Lemma 7.4: For all $x,y,k\in\mathbb{R}$ we have

$$2\Re\left\{\frac{\varphi_k^+(y)\varphi_k^-(x)}{t_k}\right\}=\Re\{\overline{\varphi_k^+(x)}\varphi_k^+(y)\}+\Re\{\overline{\varphi_k^-(x)}\varphi_k^-(y)\}. \tag{7.8}$$

This implies in particular

$$\Re\left\{\frac{\varphi_k^+(y)\varphi_k^-(x)}{t_k}\right\}=\Re\left\{\frac{\varphi_k^+(x)\varphi_k^-(y)}{t_k}\right\}. \tag{7.9}$$

Proof: We may expand $\varphi^\pm(x,k)$ on the basis $\{\varphi^\mp(x,k),\overline{\varphi^\pm(x,k)}\}$:

$$\varphi_k^+(x)=\frac{1}{\overline{r_k^+}}\,\overline{\varphi_k^+(x)}+\frac{t_k}{r_k^-}\,\varphi_k^-(x), \tag{7.10}$$

$$\varphi_k^-(x)=\frac{1}{\overline{r_k^-}}\,\overline{\varphi_k^-(x)}+\frac{t_k}{r_k^+}\,\varphi_k^+(x). \tag{7.11}$$

Indeed, the functions on the left- and right-hand sides both verify the weak Helmholtz equation and satisfy the same asymptotic condition. They must therefore coincide, by Proposition 6.3. Now using the relations (6.3) between the coefficients, (7.8) is easily verified □

After the change of variables $\zeta=k^2$, we obtain

$$E[\alpha,\ \beta]f(x)=\int dy\ e_{\alpha,\beta}(x,y)f(y), \tag{7.12}$$

with

$$e_{\alpha,\beta}(x,y)=e_{\alpha,\beta}(y,x)=\frac{1}{\pi}\int_{\sqrt{\alpha}}^{\sqrt{\beta}}dk\ \Re\left\{\frac{\varphi_k^+(y)\varphi_k^-(x)}{t_k}\right\}. \tag{7.13}$$

This shows in particular that $\sigma_c=[0,+\infty[$. It remains to prove the absence of singular continuous spectrum. To this end, it suffices to show that the spectral measure $\mu_{f,g}$ is absolutely continuous on $(0,+\infty)$ for all $f,g\in\mathscr{D}$. Now, for all $\alpha>0$, a straightforward computation using (7.12) and the continuity properties of $\varphi_z^\pm$ stated in Theorem 6.1 shows that

$$\lim_{h\to 0}\frac{u_{f,g}([\alpha,\alpha+h])}{h}=\int dx\ dy\ \overline{f}(y)g(x)p(x,y,\alpha)=:m_{f,g}(\alpha).$$

Since $m_{f,g}(\alpha)$ is continuous, it follows that $\mu_{f,g}$ is absolutely continuous on $\mathbb{R}^+$ with Radon–Nikodym derivative $m_{f,g}$, and since this holds on a dense set of functions f,g, it implies $\sigma_{ac}=[0,+\infty[$. This completes the proof of Theorem 7.3. □

VIII. THE GENERALIZED FOURIER TRANSFORMS

Let $\mathscr{F}_0$ be the unitary Fourier transform on $L^2(\mathbb{R})$ with adjoint $\mathscr{F}_0^*$

$$\mathscr{F}_0 f(k)=\text{l.i.m.}\ \frac{1}{\sqrt{2\pi}}\int dx\ e^{-ikx}f(x), \tag{8.1}$$

$$\mathscr{F}_0^* g(x)=\text{l.i.m.}\ \frac{1}{\sqrt{2\pi}}\int dk\ e^{+ikx}g(k), \tag{8.2}$$

where l.i.m. $\int$ stands for the limit in the $L^2(\mathbb{R})$ norm of $\int_{-R}^{+R}$ as $R\to\infty$. To simplify the notation, we will sometimes set $\hat{f}(k)=\mathscr{F}_0 f(k)$. Let us now introduce a family of solutions of physical importance for the scattering problem. For $k\in\mathbb{R}$, we define the functions $\psi_k^\pm$ by

$$\psi_k^+=\begin{cases}\varphi_k^+ & \text{if } k\geqslant 0,\\ \overline{\varphi_k^-} & \text{if } k<0,\end{cases}\qquad \psi_k^-=\begin{cases}\varphi_k^- & \text{if } k\geqslant 0,\\ \overline{\varphi_k^+} & \text{if } k<0.\end{cases}$$

They are solutions of the integral equation

$$\psi_k^\pm(x)=e^{\pm ikx}+\int\frac{e^{i|k||x-y|}}{2i|k|}\,V(dy)\ \psi_k^\pm(y). \tag{8.3}$$

These functions write as the superposition of an ingoing free wave and an outgoing perturbed wave. For regular potentials, (8.3) is the well-known Lippmann–Schwinger equation. We define the linear maps $\mathscr{T}_\pm : L^1 \to L^\infty$ and $\mathscr{T}_\pm^* : L^1 \to L^\infty$ by

$$\mathscr{T}_+ f(k) = \frac{1}{\sqrt{2\pi}} \int dx\ \overline{\psi_k^+(x)} f(x) \quad \text{and} \quad \mathscr{T}_+^* g(x) = \frac{1}{\sqrt{2\pi}} \int dk\ \psi_k^+(x) g(k),$$

$$\mathscr{T}_- f(k) = \frac{1}{\sqrt{2\pi}} \int dx\ \psi_k^-(x) f(x) \quad \text{and} \quad \mathscr{T}_-^* g(x) = \frac{1}{\sqrt{2\pi}} \int dk\ \overline{\psi_k^-(x)} g(k).$$

Then we have the following proposition.

Proposition 8.1: $\mathscr{T}_\pm$ and $\mathscr{T}_\pm^*$ can be extended to continuous maps from $L^2(\mathbb{R})$ to $L^2(\mathbb{R})$. $\mathscr{T}_\pm^*$ is the adjoint of $\mathscr{T}_\pm$.

Proof: The proof is a straightforward consequence of the asymptotics of the functions $\psi_k^\pm$, which behave like planes waves $e^{\pm ikx}$ for large arguments. We omit the details. □

The operators $\mathscr{T}_+$ and $\mathscr{T}_-$ are usually called *generalized Fourier transform*. They satisfy the so-called *intertwining property*, which we state in the following form:

Proposition 8.2 (intertwining property): For all bounded measurable function η we have

$$\eta(H).\mathscr{T}_\pm^*.\mathscr{T}_0 = \mathscr{T}_\pm^*.\mathscr{T}_0\, \eta(H_0), \tag{8.4}$$

where $\eta(H)$ and $\eta(H_0)$ are defined according to the spectral theorem.

Proof: We will first show that $H.\mathscr{T}_+^*.\mathscr{T}_0 f = \mathscr{T}_+^*.\mathscr{T}_0 H_0 f$ holds on $D(H_0)$. For any x,y we have

$$\begin{aligned} |\psi_k^+(x) - \psi_k^+(y)| &\leqslant \left| \int \frac{e^{i|k||x-t|} - e^{i|k||y-t|}}{2i|k|}\ \psi_k^+(t)\ V(dt) \right| + |e^{ikx} - e^{iky}| \\ &\leqslant \|V\| \sup_{k\in\mathbb{R}} \|\psi_k^+\|_\infty |x-y| + |k||x-y|\,. \end{aligned}$$

It follows that $\mathscr{T}_+^*.\mathscr{T}_0 f$ is Lipschitz and *a fortiori* continuous for all $f \in D(H_0)$. So, we may consider the distribution $(-\Delta + V).\mathscr{T}_+^*.\mathscr{T}_0 f$ in $\mathscr{D}'$. Now for any $s \in \mathscr{D}$ we have

$$\begin{aligned} ((-\Delta+V).\mathscr{T}_+^*.\mathscr{T}_0 f, s) &= -(\mathscr{T}_+^*.\mathscr{T}_0 f, s'') + (V, \mathscr{T}_+^*.\mathscr{T}_0 f s) \\ &= -\int dx\ s''(x) \int dk\ \psi_k^+(x) \hat{f}(k) + \int V(dx)\ s(x) \int dk\ \psi_k^+(x) \hat{f}(k) \\ &= \int dk\ \hat{f}(k) \left[-\int dx s''(x) \psi_k^+(x) + \int V(dx)\ s(x) \psi_k^+(x) \right], \end{aligned}$$

where we have used Fubini's theorem to interchange the integrals. Now,

$$-\int dx\ s''(x) \psi_k^+(x) + \int V(dx)\ s(x) \psi_k^+(x) = k^2 \int dx\, s(x) \psi_k^+(x),$$

owing to the weak Helmholtz equation $(-\Delta + V)\psi_k^+ = k^2 \psi_k^+$. Hence, using again Fubini's theorem,

$$((-\Delta+V).\mathscr{T}_+^*.\mathscr{T}_0 f, s) = \int dx\ s(x) \int dk\ k^2 \hat{f}(k) \psi_k^+(x) = (\mathscr{T}_+^*.\mathscr{T}_0 H_0 f, s).$$

Now $\mathscr{T}_+^*.\mathscr{T}_0 H_0 f$ is in $L^2(\mathbb{R})$. So, the distribution $(-\Delta + V).\mathscr{T}_+^* f$ is in $L^2(\mathbb{R})$, which means that $\mathscr{T}_+^* f$ is in $D(H)$ and $H.\mathscr{T}_+^*.\mathscr{T}_0 f = \mathscr{T}_+^*.\mathscr{T}_0 H_0 f$. Also we have

$$(H-\zeta).\mathscr{T}_+^*.\mathscr{T}_0 f = \mathscr{T}_+^*.\mathscr{T}_0 (H_0 - \zeta) f$$

for any $\zeta \in \mathbb{C}\backslash\mathbb{R}$ and for all $f \in D(H_0)$. If we introduce the free resolvent $R_0(\zeta)=(H_0-\zeta)^{-1}$, it follows that $R(\zeta).\mathscr{F}_+^*.\mathscr{F}_0 g=.\mathscr{F}_+^*.\mathscr{F}_0 R_0(\zeta)g$ for all $g \in \mathrm{Ran}\,(H_0-\zeta)$ (Ran=range). H_0 being self-adjoint, we have $\mathrm{Ran}\,(H_0-\zeta)=L^2(\mathbb{R})$ and thus $R(\zeta).\mathscr{F}_+^*.\mathscr{F}_0=.\mathscr{F}_+^*.\mathscr{F}_0 R_0(\zeta)$ for all $\zeta \notin \mathbb{R}$. This implies $E(\Lambda).\mathscr{F}_+^*.\mathscr{F}_0=.\mathscr{F}_+^*.\mathscr{F}_0 E_0(\Lambda)$ for all Borel sets Λ, where $E_0(\cdot)$ is the spectral family associated to H_0 (the last identity can be obtained by means of Stone's formula). The relation (8.4) then follows from the spectral theorem. □

Corrolary 8.3: Let $\mathscr{H}_{ac}$ be the absolutely continuous subspace of $\mathscr{H}$,

$$\mathscr{H}_{ac}=\{f \in \mathscr{H} \mid \textit{the spectral measure associated to } f \textit{ is absolutely continuous}\},$$

and P_{ac} is the orthogonal projector on $\mathscr{H}_{ac}$. Then

$$\mathscr{F}_\pm P_{ac}=\mathscr{F}_\pm . \tag{8.5}$$

Proof: Let $\mathscr{H}_{pp}$ be the purely punctual subspace, that is the set of bound states. Then $\mathscr{H}_{pp} \oplus .\mathscr{H}_{ac}=\mathscr{H}$, so it suffices to prove that $\mathscr{F}_\pm$ vanishes on $\mathscr{H}_{pp}$. If $-\lambda^2 \in \sigma_d(H)$ is an eigenvalue and f an associated eigenfunction, then $Hf=-\lambda^2 f$. Now by taking the adjoint in Eq. (8.4), with $\eta(x)=(x-i)^{-1}$, we have $\mathscr{F}_\pm(H+i)^{-1}f=.\mathscr{F}_0(H_0+i)^{-1}.\mathscr{F}_0^*.\mathscr{F}f$, and thus $(-\lambda^2+i).\mathscr{F}_\pm f(k)=(k^2+i)^{-1}.\mathscr{F}_\pm f(k)$ for all k, which forces $\mathscr{F}_\pm f(k)=0$ for all k. □

IX. THE WAVE OPERATORS

We are now able to derive explicit formulas for the wave operators.

Theorem 9.1: *The (strong) wave operators $W_\pm$ exist and are complete. They are given by*

$$W_\pm = \mathrm{s.}\lim_{t\to\pm\infty} e^{itH}e^{-itH_0}=.\mathscr{F}_\mp^*.\mathscr{F}_0 . \tag{9.1}$$

Proof: The existence and completeness of the wave operators have already been proved in a more general setting.[25] Once the intertwining property and minimal regularity properties for $\varphi_k^\pm(x)$ [precisely, for fixed x, $\varphi_k^\pm(x)$ should be continuously differentiable on $\mathbb{R}\backslash 0$ with respect to k] have been established (Theorem 6.1 and Proposition 8.2), the proof of formula (9.1) is the same as for regular potentials (see, e.g., Ref. 28), so we omit it. The main ingredient is a stationary phase argument. □

The following is a straightforward consequence of the last theorem.

Corrolary 9.2: The generalized functions $\psi_k^\pm$ form a complete orthonormal set of $\mathscr{H}_{ac}$,

$$\mathscr{F}_\pm.\mathscr{F}_\pm^*=1, \quad \mathscr{F}_\pm^*.\mathscr{F}_\pm=\mathscr{P}_{ac} . \tag{9.2}$$

Proof: The wave operators are isometric, as a strong limit of unitary operators. So $W_\pm^* W_\pm = .\mathscr{F}_\pm.\mathscr{F}_\pm^*=1$, where $*$ stands for the Hermitian conjugation. This expresses the ''orthogonality'' of the generalized functions $\psi_k^\pm$, for it corresponds formally to $\langle \psi_k^\pm, \psi_{k'}^\pm \rangle = \delta(k-k')$. Furthermore, $W_\pm W_\pm^* = (W_\pm W_\pm^*)(W_\pm W_\pm^*)$ is a projector onto $\mathscr{H}_{ac}$, hence $W_\pm W_\pm^* = .\mathscr{F}_\pm^*.\mathscr{F}_\pm = P_{ac}$, which proves the completeness of the functions $\psi_k^\pm$. □

The wave operators provide a simple approximation of the evolution operator $e^{\pm itH}$ at large time:

$$\mathrm{s.}\lim_{t\to+\infty}(e^{\pm itH}-W_\pm e^{\pm itH_0})\mathscr{P}_{ac}=0. \tag{9.3}$$

In particular, for all initial states $f \in .\mathscr{H}_{ac}$ we have

$$\mathrm{s.}\lim_{t\to+\infty} \Psi_t-\tilde{\Psi}_t=0, \tag{9.4}$$

where $\Psi_t=e^{-itH}f$ and $\tilde{\Psi}_t=W_- e^{-itH_0}f$ is explicit,

$$\tilde{\Psi}_t(x)=\frac{1}{\sqrt{2\pi}}\left(\int_{-\infty}^0 dk\; e^{-itk^2}\overline{\varphi_k^-}(x)\hat{f}(k)+\int_0^{+\infty} dk\; e^{-itk^2}\varphi_k^+(x)\hat{f}(k)\right). \tag{9.5}$$

X. THE TIME EVOLUTION

We now wish to look at the time-space behavior of the wave packets Ψ_t and Φ_t defined in the Introduction. For sake of simplicity, we will now suppose V is a finite measure of compact support. In fact, the more general condition (4.1) also works, but brings in technical complications and carries no new essential idea. We call Ω^- and Ω^+ the regions to the left and to the right of the support of V and $\mathbb{I}_{\Omega^\pm}$ the corresponding characteristic functions, $\mathbb{I}_{\Omega^\pm}(x)=1$ if $x\in\Omega^\pm$, $\mathbb{I}_{\Omega^\pm}(x)=0$ else. We use the same notation for the associated multiplication operator, i.e., $(\mathbb{I}_{\Omega^\pm} f\,)(x)=\mathbb{I}_{\Omega^\pm}(x)f(x)$. Let us now define

$$p^\pm[f]=\lim_{t\to+\infty}\|\mathbb{I}_{\Omega^\pm}\Psi_t\|_2^2,\quad \Psi_t=e^{-iHt}f, \tag{10.1}$$

assuming for the moment that the limits exist. When f is normalized (i.e., $\|f\|=1$), these quantities can be interpreted as the final probability of finding a particle described by the wave function Ψ_t in the left, respectively right, region. Analogously, we define

$$p_q^\pm[f]=\lim_{t\to+\infty}\|\mathbb{I}_{\Omega^\pm}\Phi_t\|_q^q \tag{10.2}$$

with Φ_t the solution of the wave equation with initial data $(f,-f')$. It will be clear from the context which definition we use.

The probability of presence $p^\pm[f]$ can be related to the transmission and reflection coefficients as follows.

Theorem 10.1: (Schrödinger equation) *For any initial state $f\in\mathscr{H}_{ac}$ we have*

$$p^-[f]=\int_{-\infty}^0 dk\ |\overline{r_k^+}\hat f(-k)+\overline{t_k}\hat f(k)|^2,\quad p^+[f]=\int_0^{+\infty}dk\ |r_k^-\hat f(-k)+t_k\hat f(k)|^2. \tag{10.3}$$

This result is perfectly intelligible. Indeed, it merely states that the energy that can be found on the left of the potential are the positive frequencies traveling to the right that have been reflected by V and the negative frequencies traveling to the left that have been transmitted through the potential.

Proof: For the sake of simplicity we will only consider the quantity p^-. The case of p^+ is analogous. As before, define $\tilde\Psi_t=W_-e^{-itH_0}f$. In view of (9.4), we have $p^\pm[f]=\lim_{t\to+\infty}\|\mathbb{I}_{\Omega^\pm}\tilde\Psi_t\|^2$. Now, since outside of the potential support the functions $\varphi_k^\pm$ are given by their asymptotic expressions (6.1), the function $\tilde\Psi_t$ takes a simple form there and we have

$$\mathbb{I}_{\Omega^-}\tilde\Psi_t(x)=(\sqrt{2\pi})^{-1}\mathbb{I}_{\Omega^-}(x)\Bigg(\int_{-\infty}^0 dk\ e^{-itk^2}e^{ikx}\overline{t_k}\hat f(k)+\int_0^{+\infty}dk[e^{-itk^2}e^{ikx}\hat f(k)$$
$$+e^{-itk^2}e^{-ikx}r_k^+\hat f(k)]\Bigg), \tag{10.4}$$

At this point, let us introduce the following operators defined through Fourier multipliers:

$$T:\hat s(k)\mapsto\overline{t_k}\hat s(k),\quad R_\pm:\hat s(k)\mapsto r_k^\pm\hat s(k).$$

In addition we need the parity operator $\Pi:s(x)\mapsto s(-x)$ and the positive/negative frequencies projectors $P^\pm$:

$$\widehat{P^\pm f}(k)=\begin{cases}\hat f(k) & \text{if sign }(k)=\pm1,\\ 0 & \text{otherwise.}\end{cases}$$

Then the previous equations may be rewritten more intuitively as follows:

$$\mathbb{I}_{\Omega^-}\tilde\Psi_t=\mathbb{I}_{\Omega^-}e^{-itH_0}[P^+ +\Pi R_+P^+ +TP^-]f. \tag{10.5}$$

Note that the positive frequencies of f are reflected ($\Pi R_+ P^+ f$) while the negative frequencies are transmitted through the potential ($TP^- f$). Eventually only the waves with negatives frequencies—$(\Pi R_+ P^+ + TP^-)f$—will contribute to the wave function in Ω^-. Indeed, we have the following.

Lemma 10.2: For all $f \in L^2(\mathbb{R})$ we have

$$\lim_{t\to+\infty} \|\mathbb{I}_{\Omega^-} e^{-itH_0} f\|^2 = \int_{-\infty}^{0} dk |\hat{f}(k)|^2, \quad \lim_{t\to+\infty} \|\mathbb{I}_{\Omega^+} e^{-itH_0} f\|^2 = \int_{0}^{+\infty} dk |\hat{f}(k)|^2.$$

Proof: The proof follows from the well-known (see, e.g., Ref. 29, p. 60) asymptotics s. $\lim_{t\to+\infty} e^{-itH_0} - V_t = 0$, where $V_t f(x) = (\sqrt{2it})^{-1} e^{ix^2/4t} \hat{f}(x/2t)$. □

A direct application of the last lemma yields the formula (10.3). Thanks to the relations (5.3), it can be easily verified that $p^+[f] + p^-[f] = 1$; that is, no energy remains trapped in the region of interaction. □

Remark: Theorem 10.1 can be seen as the one-dimensional version of the famous Dollard's ''scattering into cones theorem'' (see Ref. 30 for a complete discussion) which asserts that the probability $P_C[f]$ for the wave function $e^{-iHt} f$ to emerge in a cone C in $\mathbb{R}^3$ with apex at the origin is given by

$$P_C[f] = \lim_{t\to+\infty} \|\mathbb{I}_C e^{-iHt} f\|^2 = \int_C dk |\widehat{\mathscr{S} f}(k)|^2,$$

where $\mathscr{S} = W_+^\star W_-$ is the scattering operator. In the one-dimensional case, there are only two possible directions (left and right), and the ''cones'' reduce to the left and right half-axes.

We now turn to the study of the wave equation. We will assume that the initial wave packet Φ_0 is prepared by sending an incident wave train from the remote left on the scatterer. Thus, for $t<0$, the wave function is simply a (free) solution of the wave equation propagating to the right, that is, of the form $\Phi_t(x) = s(x-t)$. Therefore, it is natural to impose the initial conditions

$$g = \partial_t \Phi_0 = -\partial_x \Phi_0 = -f'. \tag{10.6}$$

The temporal properties of the wave equation can now be summarized in the following theorem. We make the statements for initial states located in Ω^- and propagating to the right; they can be adapted in an obvious way to states with support in Ω^+ and propagating to the left.

Theorem 10.3: (wave equation) *Suppose V is compactly supported and such that $-\Delta + V$ is a positive operator. Let $f \in W^1(\mathbb{R})$ be a function with compact support in Ω^- and consider the solution of the wave equation with initial conditions (10.6), that is,*

$$\Phi_t = \cos(H^{1/2}t) f - H^{-1/2} \sin(H^{1/2}t) f'.$$

Then

$$\mathbb{I}_{\Omega^-} \Phi_t(x) = \mathbb{I}_{\Omega^-}(x)[f(x-t) + (\Pi R^+ f)(x+t)], \tag{10.7}$$

$$\mathbb{I}_{\Omega^+} \Phi_t(x) = \mathbb{I}_{\Omega^+}(x)(Tf)(x-t). \tag{10.8}$$

We will use the spectral density $m_{f,g}(\lambda)$ introduced in Sec. VI to compute the exact time-dependent solution of the wave equation. We begin with the following.

Lemma 10.4: For all bounded measurable function η and all $f \in \mathscr{H}_{ac}$ with support in Ω^- we have

$$\eta(H) f(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} dk \ \eta(k^2) \varphi_k^+(x) \hat{f}(k), \tag{10.9}$$

the equality holding in $L^2(\mathbb{R})$. If $f \in D(H)$, then both left- and right-hand sides are continuous functions and thus the equality holds pointwise.

Proof: For any $u \in \mathscr{D}$, we have

$$\langle u,\eta(H)f\rangle=\int_0^\infty d\lambda\ \eta(\lambda)m_{u,f}(\lambda)=\frac{1}{2\pi}\int_0^\infty d\lambda\ \eta(\lambda)\int dx\ dy\ \overline{u}(y)f(x)\Re\left\{\frac{\varphi^+_{\sqrt{\lambda}}(y)\varphi^-_{\sqrt{\lambda}}(x)}{\sqrt{\lambda}t_{\sqrt{\lambda}}}\right\}.$$

Interchanging the order of integration, which is justified since the inner integrals are absolutely convergent, we obtain

$$\langle u,\eta(H)f\rangle=\langle u,Af\rangle,$$

with

$$Af(y)=\frac{1}{2\pi}\int dx\ f(x)\int_0^\infty d\lambda\ \eta(\lambda)\Re\left\{\frac{\varphi^+_{\sqrt{\lambda}}(y)\varphi^-_{\sqrt{\lambda}}(x)}{\sqrt{\lambda}t_{\sqrt{\lambda}}}\right\}.$$

Making the change of variables $\lambda=k^2$, using the symmetry properties of $\varphi_k^\pm$, and interchanging again the integrals yields finally

$$Af(y)=\frac{1}{2\pi}\int_{-\infty}^{+\infty}dk\ \eta(k^2)\varphi_k^+(y)\int dx\ f(x)t_k^{-1}\varphi_k^-(x).$$

Since f is supported on Ω^-, we have $f(x)t_k^{-1}\varphi_k^-(x)=f(x)e^{-ikx}$ and

$$Af(y)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{+\infty}dk\ \eta(k^2)\varphi_k^+(y)\hat{f}(k). \tag{10.10}$$

Now A can be extended to a bounded operator in $L^2(\mathbb{R})$. Hence, by density, $\eta(H)f=Af$ holds on $L^2(\mathbb{R})$. Note that Af is a continuous function [since φ_k^+ is continuous and the integral in (10.10) is uniformly convergent in y]. If $f\in D(H)$, then $\eta(H)f\in D(H)\subset W^1(\mathbb{R})$ is also continuous and thus the equality $\eta(H)f=Af$ holds pointwise. This concludes the proof. □

Proof of Theorem 10.3: It follows from the last lemma that

$$\Phi_t(x)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{+\infty}dk\ e^{-ikt}\varphi_k^+(x)\hat{f}(k).$$

Using the asymptotic expression (6.1) of φ_k^+ yields (10.7) and (10.8) and the theorem is proved. □

In order to gain a deeper understanding, we now present an alternative proof. Consider the following function,

$$\Phi_t(x)=\frac{1}{\sqrt{2\pi}}\int dk\ \hat{f}(k)\varphi_k^+(x)e^{-ikt}, \tag{10.11}$$

where $\varphi_k^+(x)$ are the generalized eigenfunctions. Clearly this presents a solution of the wave equation in the sense of distributions. Moreover, upon using the asymptotic expressions valid in $\Omega^\pm$, we recover the equations of the theorem. We only have to check that Φ_t corresponds to the initial data requested. For $t=0$ we have

$$\Phi_0(x)=\frac{1}{\sqrt{2\pi}}\int dk\ \hat{f}(k)e^{ikx}\varphi_k^+(x)e^{-ikx}. \tag{10.12}$$

Now for each x, $\varphi_k^+(x)e^{-ikx}$ is analytic and bounded in the upper complex k half-plane (see Theorem 6.1). Therefore, by the Paley–Wiener theorem, it follows that Φ_0 is supported by inside Ω^-. Now for $x\in\Omega^-$ we may use the asymptotic expressions for φ_k^+ and we have

$$\Phi_0(x)=\frac{1}{\sqrt{2\pi}}\int dk\ \hat{f}(k)(e^{ikx}+r_k^+e^{-ikx}). \tag{10.13}$$

Now again thanks to Paley–Wiener, the second part is a function supported outside Ω^-. Therefore by inverse Fourier transform, we have $\Phi_0 = f$. On the other hand, upon derivating under the integral sign, we have $\partial_t \Phi_0 = -f'$ and the theorem is proved. □

Remark: Lemma 10.4 can also be used to compute the exact time evolution in the Schrödinger case for initial states supported in $\Omega^\pm$ and thus provides an alternative proof of Theorem 10.1 without using the wave operators. However, the advantage of the first method is that the initial state need not be with support inside $\Omega^\pm$.

XI. RECOVERING THE FRACTAL DIMENSIONS

We shall now propose a method to retrieve wavelet dimensions of the potential from the asymptotic probabilities of presence $p^\pm[f]$ and $p_q[f]$ by choosing an appropriate family of initial states. As usual, we begin with the quantum evolution. Suppose we can prepare some initial state f in $\mathscr{S}_+(\mathbb{R})$. Then we have the following.

Theorem 11.1: (Schrödinger equation) *Let $f \in \mathscr{S}_+(\mathbb{R})$. For all $b \in \mathbb{R}$, we have*

$$p^-[f_{b,a}] = a^2 \| \mathscr{W}_g V(\cdot, a/2) \|^2 + O(a^2), \quad a \to 0, \tag{11.1}$$

where the wavelet $g \in \mathscr{S}_+(\mathbb{R})$ is essentially a primitive of f: $\hat{g}(k) = \sqrt{\pi/8}\hat{f}(k)/k$.

Corrolary 11.2: For all $b \notin \mathrm{supp}(V)$, we have

$$\lim_{a \to 0} \begin{matrix} \sup \\ \inf \end{matrix} \frac{\log \rho(b,a)}{\log a} = \min\{\kappa_2^\pm[V], 0\}, \quad \textit{where} \quad \rho(b,a) = \int_a^1 \frac{d\alpha}{\alpha^3} p^-[f_{b,\alpha}].$$

Proof of Theorem 11.1: First suppose $f \in \mathscr{H}_{ac}$. Then a straightforward computation using the Born approximation (6.5) and Eq. (10.3) yields

$$p^-[f_{b,a}] = a^2 \int_0^{+\infty} dk |\hat{V}(k)|^2 |\hat{g}(ak)|^2 + O(a^2) = a^2 \| \mathscr{W}_g V(\cdot, a) \|^2 + O(a^2),$$

which is the desired result. If $f \notin \mathscr{H}_{ac}$, then we may still apply formula (10.3) to its projection $P_{ac} f$ on $\mathscr{H}_{ac}$, that is,

$$p^-[P_{ac} f_{b,a}] = \int_{-\infty}^0 dk \, |\overline{r_k^+}(P_{ac} f_{b,a})\hat{}(-k) + \overline{t_k}(P_{ac} f_{b,a})\hat{}(k)|^2. \tag{11.2}$$

Now, take an orthonormal basis $(\eta_1, \ldots, \eta_n)$ of the space of bound states and call P_{bs} the orthogonal projector on this basis. The states $f_{b,a}$ can be decomposed as

$$f_{b,a} = P_{ac} f_{b,a} + P_{bs} f_{b,a} = P_{ac} f_{b,a} + \sum_{j=1}^n \langle f_{b,a}, \eta_j \rangle \eta_j .$$

The scalar products $\langle f_{b,a}, \eta_j \rangle$ are nothing but wavelet transforms of the eigenvectors η_j,

$$\langle f_{b,a}, \eta_j \rangle = \mathscr{W}_f \eta_j(b,a).$$

Now, outside of the support of V, the η_j are smooth and rapidly decreasing because they are merely exponential functions (as solutions of $\Delta \eta_j = \lambda_j^2 \eta_j$). Hence the wavelet coefficients in this region are rapidly decreasing at small scales (see, e.g., Ref. 31), that is, for fixed b,

$$|\langle f_{b,a}, \eta_j \rangle| \leqslant O(a^\infty). \tag{11.3}$$

Using (11.2) and (11.3), we obtain after some elementary estimates,

$$p^-[f_{b,a}] = p^-[P_{ac} f_{b,a}] + O(a^\infty) = \int_0^{+\infty} dk \, |r_k^+|^2 |\widehat{f_{b,a}}(k)|^2 + O(a^\infty),$$

and (11.1) follows again from the Born approximation. □

Thus, the behavior of $p^-[f]$ as one varies the characteristic scale of the initial state f is governed by the wavelet correlation dimension of the potential, provided the latter is sufficiently singular (at least nonsquare integrable). Analogous results can be stated for $p^+[f]$ in place of $p^-[f]$. It suffices to take a wavelet in $\mathscr{S}_-(\mathbb{R})$ (no positive frequencies) instead of $\mathscr{S}_+(\mathbb{R})$.

Remark: The assumption that the initial states belong to $\mathscr{S}_\pm(\mathbb{R})$ is somewhat unrealistic. Indeed, such states cannot have compact support and thus have to be prepared and controlled not only far from the target, but also in the region of interaction, which is practically impossible. However, as was explained previously, admitting an arbitrarily small error on the dimensions $\kappa_2^\pm$ we may compute the latter with wavelets having a finite number of moments vanishing. So, in fact, we may assume that the initial state has compact support outside the potential range.

For the wave equation we can say a little more. However, the initial data has to be chosen with some more care. Let us describe briefly the ''experiment'' we want to set. We want to prepare an initial state located at position b_{in}, then send the wave packet toward the target and observe the reflected part at position b_{out} in order to analyze the scatterer at position b. We proceed as follows. The time needed by the wave packet to travel from b_{in} to b and then back to b_{out} is $t=2(b-b_{\text{in}})+(b_{\text{in}}-b_{\text{out}})=2b-b_{\text{in}}-b_{\text{out}}$. By looking at the wave function at time t and position b_{out} we expect to recover the local structure of the potential at position b. Now fix some $f\in S_0(\mathbb{R})$, and some cutoff function χ in $C_0^\infty(\Omega^-)$ such that $\chi=1$ in a neighborhood of b_{in}. We make a smooth truncation of the initial state $f_{b,a}$ by considering the family of pseudo-wavelets $f_{(b_{\text{in}},a)}=\chi f_{b_{\text{in}},a}$, which have now compact support inside Ω^-. With this kind of initial data, the intuitive result is actually verified as shows the following.

Theorem 11.3: *Let $\Phi_{t,b,a}$ be the solution of the wave equation with initial data $(f_{(b,a)},f'_{(b,a)})$. Choose b_{in}, b, and b_{out} and set $t=2b-b_{\text{in}}-b_{\text{out}}$. We then have for b_{out} large enough*

$$\Phi_{t,b_{\text{in}},a}(b_{\text{out}})=a\mathscr{W}_h V(b,a/2)+O(a), \tag{11.4}$$

where h is essentially a primitive of f: $\hat{h}(k)=i\sqrt{\pi/8}\,\overline{\hat{f}(-k)}/k$.

Proof: A direct application of Theorem 10.3 allows us to conclude. We obtain, for all for t large enough [see Eq. (10.8)],

$$\begin{aligned}
\Phi_{t,b,a}(b_{\text{out}}) &= \int dk\ \widehat{f_{(b_{\text{in}},a)}}(k)\,r_k^+\,e^{-ik(2b-b_{\text{in}})}\\
&= f_{(b_{\text{in}},a)}*(\mathscr{T}_0^{-1}r_k^+)(2b-b_{\text{in}})\\
&= f_{b_{\text{in}},a}*(\mathscr{T}_0^{-1}r_k^+)(2b-b_{\text{in}})+O(a^\infty)\\
&= -i\sqrt{\pi}/2\int dk\ \hat{f}(ak)\,\frac{\hat{V}(-2k)}{k}\,e^{-2ikb}+O(a)\\
&= a\mathscr{W}_h V(b,a/2)+O(a).
\end{aligned}$$

Here we have used the Born approximation (6.5) and the fact that the wavelet transform with respect to f may be approximated by the $f_{(b,a)}$ in such that

$$|\mathscr{W}_f s(b,a)-(f_{(b,a)},s)|\leqslant O(a^\infty),\quad a\to 0.$$

□

Upon varying the observation point, we may compute the q-energy:

$$
\begin{aligned}
p_q^-[f_{(b_{\mathrm{in}},a)}] &= \lim_{t\to+\infty} \int_{\Omega^-} db_{\mathrm{out}} |\Phi_{t,b_{\mathrm{in}},a}(b_{\mathrm{out}})|^q \\
&= \lim_{b\to+\infty} \int_{\Omega^-} db_{\mathrm{out}} |\Phi_{2b-b_{\mathrm{in}},b_{\mathrm{in}},a}(b_{\mathrm{out}})|^q \\
&= \lim_{b\to+\infty} \int_{\Omega^-} db_{\mathrm{out}} |a\dot{\mathscr{W}}_h V(b+b_{\mathrm{out}}/2,a/2)+a\varepsilon(b+b_{\mathrm{out}}/2,a)|^q \\
&= 2\int db_{\mathrm{out}} |a\dot{\mathscr{W}}_h V(b_{\mathrm{out}},a/2)+a\varepsilon(b_{\mathrm{out}},a)|^q,
\end{aligned}
$$

where $|\varepsilon(b,a)|\leqslant O(1)$ is the Born error term. Thus if the ''wavelet term'' is preponderant with respect to the ''error term,'' one may compute the wavelet dimensions, as it is shown next.

Proposition 11.4: Suppose V is sufficiently singular in the sense that

$$\lim_{a\to 0} \|\dot{\mathscr{W}}_h V(\cdot,a)\|_q^q = \infty$$

for some (and hence all) $h\in\mathscr{S}_0(\mathbb{R})$. Then for the integrated q-energy of the wave packets

$$\rho_q(a) = \int_a^1 \frac{d\alpha}{\alpha^{q+1}}\, p_q^-[f_{(b_{\mathrm{in}},\alpha)}]$$

we have

$$\lim_{a\to 0} \sup_{\inf} \frac{\log \rho_q(a)}{\log a} = \kappa_q^{\pm}[V]. \tag{11.5}$$

Proof: In view of the inequalities

$$|\|f\|_q - \|g\|_q|^q \leqslant \|f+g\|_q^q \leqslant C(\|f\|_q+\|g\|_q)^q$$

we have

$$a^q|\|\dot{\mathscr{W}}_h V(\cdot,a/2)\|_q - \|\varepsilon(\cdot,a)\|_q|^q \leqslant p_q^-[f_{(b_{\mathrm{in}},a)}] \leqslant Ca^q(\|\dot{\mathscr{W}}_h V(\cdot,a/2)\|_q^q + \|\varepsilon(\cdot,a)\|_q^q).$$

Now the norm $\|\varepsilon(\cdot,a)\|_q$ remains bounded as $a\to 0$. This implies that $p_q^-[f_{(b_{\mathrm{in},a})}]$ and $a^q\|\dot{\mathscr{W}}_h V(\cdot,a)\|_q^q$ are equivalent at small scales and the conclusion follows. □

The scattering process performs a wavelet analysis of the potential. Therefore, in particular for singular potentials, its singularities may be analyzed with the help of remote wavelet techniques.

XII. NUMERICAL RESULTS

We wish to end this paper with a numerical illustration of the ''wavelet transform'' $\Phi_{t,b,a}$. Once the reflection coefficient r_k^+ is known for all k, Lemma 10.4 yields an exact expression of the evolution operators (hence the wave packets Φ_t) in the left region Ω^-, provided the initial state has its support in Ω^-. So we need only sample r_k^+ at different frequencies and estimate the integral (10.9) by a discrete sum. This shall be done on self-similar potentials.

A self-similar measure on $\mathbb{R}$ was defined by Hutchinson[32] to be a probability measure V satisfying

$$V = \sum_{i=1}^N p_i V\circ S_i^{-1},$$

where the p_i are a set of weights ($0<p_i<1$, $\Sigma_{i=1}^N p_i = 1$) and the S_i a set of similarities $S_i(x) = l_i x + b_i$, with $0<l_i<1$. The support of V is the unique nonempty compact K globally invariant

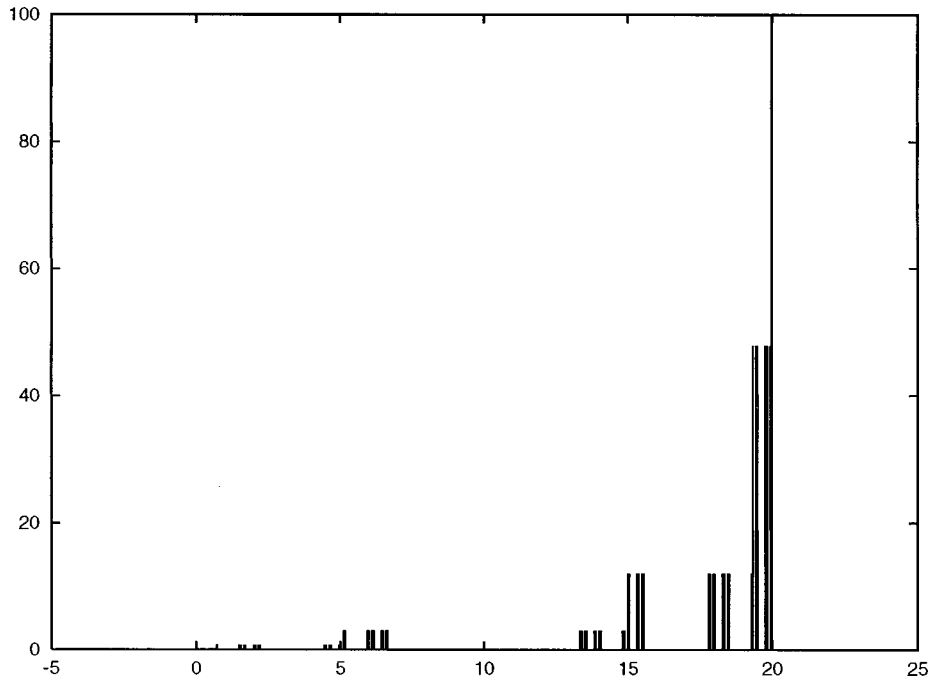

FIG. 1. Approximation of order 6 of the triadic Cantor measure on [0, 20] with weights $p_1=0.2$ and $p_2=0.8$.

under these contractions, i.e., $K=\cup_{i=1}^{N} S_i(K)$. This support may be of zero Lebesgue measure. This occurs when the so-called *strong open set condition*[33] is satisfied; that is, there exist a closed bounded set U such that $S_i(U)\cap S_j(U)=\varnothing$ for $i\neq j$. It can be shown that the set U at least contains K. When there are only two similitudes satisfying the strong open set condition with same contraction ratio $l_1=l_2=1/3$ and same weights $p_1=p_2=1/2$, V is the well-known triadic

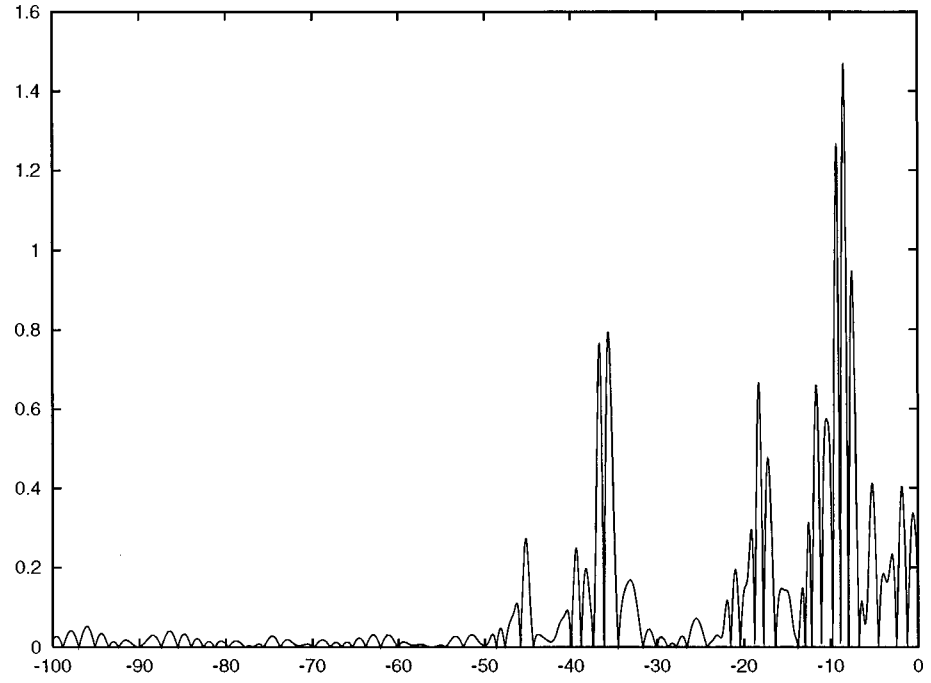

FIG. 2. Modulus of the wave function $\Phi_{t,b,a}(x)$ against x for $b=-30$, $a=0.1$, and $t=80$ and as initial state f a second derivative of the Gaussian. The potential lies to the right (between 0 and 20). Here only the reflected part of the wave is visible.

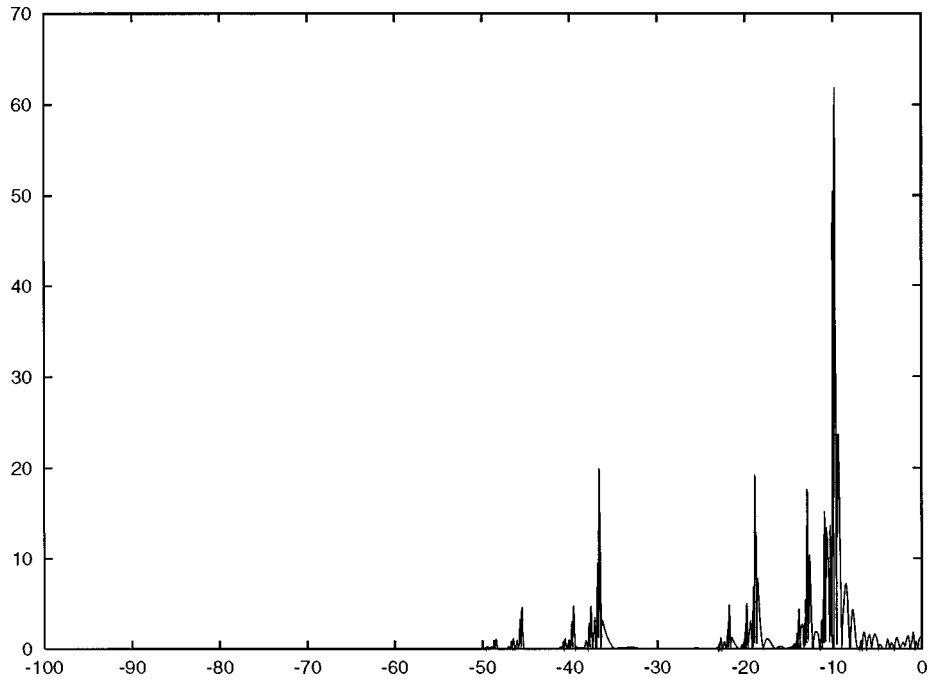

FIG. 3. Same as Fig. 2 with $a=0.05$ and $t=80$.

Cantor measure. Self-similar measures can be constructed by an iterative procedure. Starting from the characteristic function $\mathbb{I}_{[a,b]}$ of some interval $[a, b]$, the sequence $V_n=U^n\mathbb{I}_{[a,b]}$, where $Uf=\Sigma_{i=1}^{N}p_i f\circ S_i^{-1}$, is shown to converge toward V in the sense of distributions (see, e.g., Ref. 31). Thus, a self-similar measure can be approximated arbitrarily well by a finite sum of characteristic functions. Now for these approximations, the corresponding reflection coefficient $r_{k,n}^{+}$ can be computed by the transfer matrix method (see Ref. 11 for a description of the algorithm). Moreover, we have uniform convergence $r_{k,n}^{+}\rightarrow r_k^{+}$ on any finite range of frequencies.

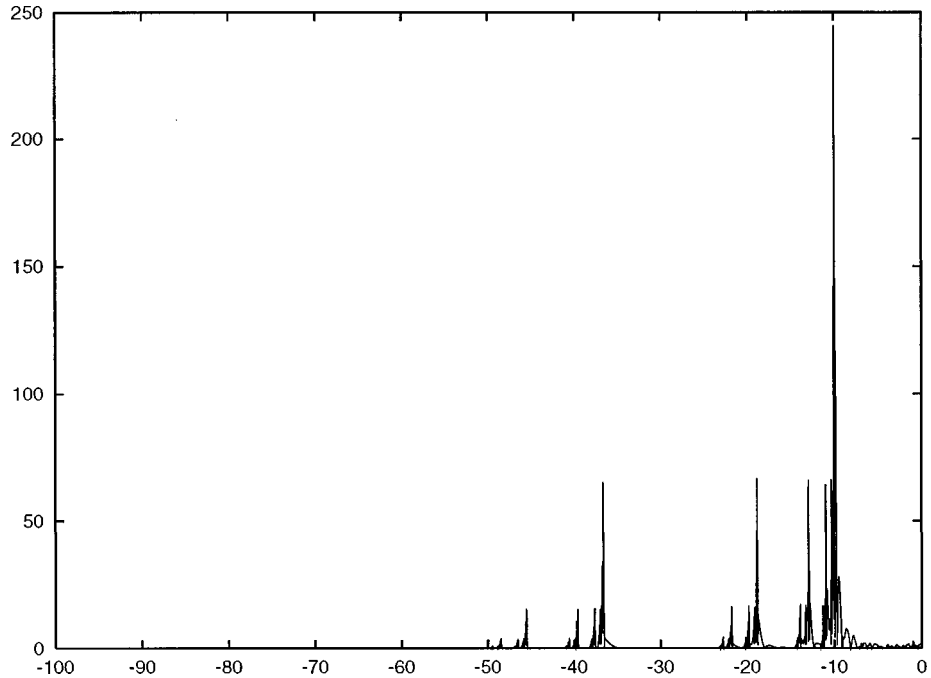

FIG. 4. Same as Fig. 2 with $a=0.01$ and $t=80$. The structure of the potential is recovered, but dilated by two.

We have computed the wave functions $\Phi_{t,b,a}$ when V is an approximation $(n=6)$ of the triadic Cantor measure on the interval $[0, 20]$ with $p_1=0.2$, $p_2=0.8$ (Fig. 1). We have taken a family of initial states $f_{b,a}$, where f is the second derivative (in order to have two vanishing moments) of a Gaussian, located to the left of the potential:

$$f(x)=\partial_{xx}\left(\frac{1}{\sqrt{2\pi}}\,e^{-|x|^2/2}\right). \tag{12.1}$$

Note that the effective support of this function is finite in the numerical application. In Figs. 2–4, we have plotted the modulus of the wave function $\Phi_{t,b,a}$ in the left region after a sufficiently long time (so that the incident part wave has completely traveled to the right and only the reflected part of the wave function is visible) for different dilation parameters. As the scale parameter a becomes smaller, the pattern of the wave function converges to the wavelet transform of the potential, but dilated by two (this is due to the fact that the interrogating wave, which is sent in and then reflected, interacts with the scatterer during a time which is twice the length of the support.)

Orthonormal sets of localized functions for a Landau level

J. Zak
Department of Physics, Technion—Israel Institute of Technology, Haifa, Israel 32000

(Received 15 January 1998; accepted for publication 27 March 1998)

Maximal sets of commuting magnetic translations are used for constructing a set of eigenfunctions for a Landau level on a von Neumann–Gabor lattice. Localization and orthogonality turn out to be two conflicting features of this set. It is shown how to construct complete orthonormal sets of optimally localized eigenfunctions on a von Neumann–Gabor lattice for each Landau level. By using the Balian–Low theorem it is pointed out that the uncertainties of the orbit center coordinates cannot both be made finite. © *1998 American Institute of Physics.*
[S0022-2488(98)00908-6]

Among the most elementary problems in early Quantum Mechanics is the motion of an electron in a magnetic field.[1] In a 2-dimensional case the energy spectrum of this problem consists of Landau levels which have been attracting much attention over the years. Each such Landau level is infinitely degenerate, which is a consequence of the magnetic translational symmetry,[2] the latter being a subgroup of the Weyl–Heisenberg group.[3] Maximal sets of commuting magnetic translations are closely linked to von Neumann lattices.[4,5] The latter is a rectangular lattice in the phase plane with a unit cell of area h. Such a lattice was first introduced by von Neumann[5] in the xp (coordinate-momentum)-plane and independently by Gabor[6] in the $t\nu$ (time-frequency)-plane.

The Balian[7]–Low[8] theorem relates to a set of states on a von Neumann lattice, and can be formulated in the following way. Given a square integrable function $\psi(x)$, one builds out of it by translations in the phase plane a von Neumann set $\psi_{mn}(x)$, where the indices m,n label the number of the unit cell on the von Neumann lattice in the phase plane $[\psi_{00}(x)\equiv\psi(x)]$. m and n assume all integer values $0,\pm1,\ldots$. In the theorem it is then claimed that if $\psi_{mn}(x)$ are orthogonal to $\psi_{m'n'}(x)$ for all $m,n\neq m',n'$ it follows that at least one of the two quantities $\langle x^2\rangle$ or $\langle p^2\rangle$ in the state $\psi(x)$ diverges (the triangular brackets denote the expectation value). Although discovered by physicists, the Balian–Low theorem has become of widespread interest in the Engineering literature of signal processing.[9]

In physics the von Neumann lattice has been known to appear in a natural way in the motion of an electron in a constant magnetic field $\boldsymbol{B}$ because of the magnetic translational symmetry of the problem.[2,10] In particular, this has to do with the construction of magnetic Wannier functions.[4,11] There is an interesting connection between the Balian–Low theorem and the properties of magnetic Wannier functions in the xy-plane for the case when $\boldsymbol{B}$ is parallel to the z-axis, despite the fact that the latter problem has two degrees of freedom. This can be seen in the following way. Instead of the pairs of the conjugate coordinates xp_x and yp_y one can choose two other pairs: the x- and y-components of the velocity v_x,v_y (which will later be connected to the operators P_W and W, respectively) and the components X,Y of the magnetic orbit center. The Hamiltonian does not depend on the XY-degree of freedom. They are constants of motion and they determine the infinitesimal magnetic translations.[2] Correspondingly, the commuting finite translations for X and Y create a von Neumann lattice in the phase plane of the orbit center.[10] These same translations when considered in the xy-plane are nothing else but the commuting magnetic translations (translations accompanied by gauge shifts),[2] which are used in the construction of magnetic Wannier functions.[12–14] As was already mentioned, when only a magnetic field is present and there is no periodic potential, the Hamiltonian does not depend on the coordinates X and Y of the orbit center.[15] Each Landau level is then infinitely degenerate with respect to the location of this center and one can therefore apply the Balian–Low theorem to it.

This paper is an extension of a publication by the author in Ref. 16, and it shows now that the Balian[7]–Low[8] theorem can be directly applied in the construction of orthonormalized sets of localized eigenfunctions for a single Landau level. When the motion is restricted to the xy-plane

 © 1998 American Institute of Physics

perpendicular to the magnetic field $\boldsymbol{B}$ the energy spectrum consists of discrete levels which carry the name of Landau.[1] The wave function for each Landau level l can be written either as $\psi_l(x,y)$ or $\phi_l(W,X)$, where W and X are defined in the following way ($[W,\ P_W]=[X,\ P_X]=i\hbar$):

$$W\equiv\frac{m\lambda^2}{\hbar}v_y=\frac{\lambda^2}{\hbar}\left(p_y+\frac{\lambda^2}{\hbar}x\right),\quad P_W\equiv mv_x=p_x, \tag{1}$$

$$X=\frac{\lambda^2}{\hbar}\left(p_x+\frac{\hbar}{\lambda^2}y\right),\quad P_X=p_y=\frac{\hbar}{\lambda^2}Y. \tag{2}$$

Here λ^2 is the square of the cyclotron radius, WP_W denotes the velocity degree of freedom and XP_X—the orbit center degree of freedom (as was already mentioned above). The relation between the wave function $\psi(x,y)$ in the xy-representation and the wave function $\phi(WX)$ in the WX-representation is[17]

$$\psi(x,y)=\frac{1}{2\pi\lambda^2}\int\int\exp\left[-\frac{i}{\lambda^2}(xy+WX-xX-yW)\right]\phi(W,X)dWdX. \tag{3}$$

Since the Hamiltonian for an electron in a magnetic field does not depend on the orbit center degree of freedom,[15] the wave function $\phi(WX)$ separates into a product function with one factor $\gamma_l(W)$ depending on W and the other one $\delta(X)$ on X only. The factor $\delta(X)$ in the wave function can be chosen completely arbitrarily and one can then apply to the XY-degree of freedom the Balian–Low theorem. This is done by applying to $\delta(X)$ the complete commuting set of translations in the XY-plane, which are also the commuting magnetic translations. They create the von Neumann set, and an explicit condition is given on $\delta(X)$ for the set to be orthogonal.[7] For this purpose the kq-representation[14] turns out to be convenient. Having carried everything out in the WX-coordinates one can then transform the results into the xy-plane [Eq. (3)]. An analysis of the Balian–Low theorem for an arbitrary Landau level is presented. It should be stressed that the magnetic field problem considered here contains two degrees of freedom, XP_X and WP_W. However, only the latter enters into the Hamiltonian [see Eq. (15)]. The von Neumann lattice is built in the phase plane of XP_X, which correspondingly leads to a lattice in the xy-plane.

We start by formulating the Balian–Low theorem in the XY-plane of the orbit center, or in the X and P_X couple of conjugate coordinates in Eq. (2). The shift operator $D(\alpha)$ is used,[18]

$$D(\alpha)=\exp(\alpha a^+-\alpha^* a), \tag{4}$$

where a is the annihilation operator,

$$a=\frac{1}{\lambda\sqrt{2}}\left(X+\frac{i}{\hbar}\lambda^2P_X\right), \tag{5}$$

and α is a number,

$$\alpha=\frac{1}{\lambda\sqrt{2}}\left(\overline{X}+\frac{i}{\hbar}\lambda^2\overline{P}_X\right). \tag{6}$$

Here $\overline{X}$ and $\overline{P}_X$ are expectation values of the operators X and P_X in the eigenstate of a. a^+ is the Hermitian conjugate of a and α' is the complex conjugate of α. A von Neumann set in the XP_X phase plane is[5]

$$\delta_{mn}(X)=D(\alpha_{mn})\,\delta(X), \tag{7}$$

where α_{mn} is obtained from α in Eq. (6) by setting $\overline{X}=md$, $\overline{P}_X=n\hbar\,(2\pi/d)$ with d a constant. $\delta(X)$ in Eq. (7) is an arbitrary square integrable function. The properties of the von Neumann set in Eq. (7) are determined by the initial function $\delta(X)$. The Balian–Low theorem states that if the

functions in Eq. (7) are orthogonal for $mn \neq m'm'$, then at least one of the uncertainties ΔX or ΔP_X in the $\delta(X)$-state diverges. An example of a normalized δ-function, that leads to an orthogonal von Neumann set in Eq. (7), is

$$\delta(X) = \begin{cases} \dfrac{1}{\sqrt{d}}, & |X| < d/2, \\ 0, & |X| > d/2. \end{cases} \tag{8}$$

For the δ in Eq. (8), $\Delta X = d/\sqrt{12}$ and $\Delta P_X = \infty$, in agreement with the Balian–Low theorem.

The condition on δ for an orthogonal von Neumann set in Eq. (7) was first formulated in the kq-representation[14,19] (see also Ref. 7). This condition is that the absolute value of the kq-function, $C(k,q)$, for δ is constant,[16]

$$|C(k,q)| = \text{const}, \tag{9}$$

where (a is an arbitrary constant) $C^{(a)}(k,q)$ and $\delta(X)$ are related in the following way:[12]

$$C^{(a)}(k,q) = \left(\frac{a}{2\pi}\right)^{1/2} \sum_n e^{ikan} \delta(q - na). \tag{10}$$

It is easy to check that the function $\delta(X)$ in Eq. (8) leads to $|C^{(d)}(k,q)| = \text{const}$ [$C^{(d)}(k,q)$ is the kq-function in Eq. (10) with a replaced by d]. A normalized kq-function that satisfies Eq. (9) is necessarily a pure phase factor,

$$C(k,q) = \frac{1}{\sqrt{2\pi}} \exp[i\varphi(k,q)], \tag{11}$$

where $\varphi(k,q)$ is real. It is to be pointed out that the kq-functions $C(k,q)$ satisfy the following Bloch-like boundary conditions:[14]

$$C^{(a)}(k,q) = C^{(a)}\left(k + \frac{2\pi}{a}, q\right) = \exp(-ika) C^{(a)}(k, q+a). \tag{12}$$

It is easy to check that a kq-function, $C(k,q)$, that satisfies Eqs. (12) and the condition in Eq. (9) [or Eq. (11)] is necessarily discontinuous in either k or q (or both). The Balian-Low theorem is a consequence of this discontinuity.[7]

In the X-representation the condition given by Eq. (9) [or Eq. (11)] assumes the following form [Eq. (10) is used]:

$$a \sum_n \delta^*(X - na)\, \delta(X - na - la) = \delta_{l0}. \tag{13}$$

Again it is easy to check that the function in Eq. (8) with $d = a$ satisfies Eq. (13).

Now let us connect the Balian–Low theorem with the dynamics of an electron in a magnetic field B. When the motion is in the xy-plane with the magnetic field $\boldsymbol{B}$ in the z-direction, Schrödinger's equation assumes the form [the Landau gauge $\boldsymbol{A} = (0, Bx)$ is chosen]

$$\left[\frac{p_x^2}{2m} + \frac{(p_y + (\hbar/\lambda^2)x)^2}{2m}\right] \psi(x,y) = E\psi(x,y), \quad \lambda^2 = \frac{\hbar c}{eB}. \tag{14}$$

Eq. (14) is written in the xy-representation. For the magnetic field problem it is convenient to work in the WX-representation according to the transformation given in Eqs. (1)–(3). In the WX-representation, Schrödinger's equation [Eq. (14)] assumes the form

$$\left[\frac{P_W^2}{2m} + \frac{mw^2W^2}{2}\right] \phi(W,X) = E\phi(W,X). \tag{15}$$

Since the Hamiltonian does not depend on the orbit center degree of freedom XP_X, the wave function $\phi(W,X)$ can therefore be chosen as a product function,

$$\phi_l(W,X)=\gamma_l(W)\,\delta(X), \tag{16}$$

where l labels the Landau levels. On the other hand, the magnetic translations depend on the orbit center operators X and P_X only.[2,14] In particular, the commuting finite magnetic translations in x- and y-directions can be written in the following way:[10]

$$\begin{aligned}\tau_x(d)&=\exp\left[\frac{i}{\hbar}\left(p_x+\frac{\hbar}{\lambda^2}y\right)Nd\right]\equiv\exp\left(iX\frac{2\pi}{d}\right),\\ \tau_y(Nd)&=\exp\left(\frac{i}{\hbar}p_y d\right)\equiv\exp\left(\frac{i}{\hbar}P_X d\right),\end{aligned} \tag{17}$$

where N is an integer which is defined by the following rationality condition:[2]

$$N=\frac{hc/e}{Bd^2}=\frac{2\pi\lambda^2}{d^2}. \tag{18}$$

This relation has a simple meaning of the ratio of the elementary fluxon hc/e to the flux of the magnetic field B through a unit cell of area d^2 [d is an arbitrary constant;[20] see α_{mn} in Eq. (7)]. As is seen from Eq. (17), the magnetic translations depend only on the XP_X degree of freedom of the orbit center. We can therefore use directly the results in Eqs. (4)–(7) for constructing a von Neumann set for a Landau level, by replacing $\delta(X)$ in Eq. (16) by $\delta_{mn}(X)$ in Eq. (7). We get

$$\phi_{lmn}(W,X)=\gamma_l(W)\,\delta_{mn}(X). \tag{19}$$

Now, when $\delta(X)$ satisfies the condition given by Eq. (9) or (11), the set of functions in Eq. (19) for each Landau level l is orthogonal. By using the transformation in Eq. (3) we get the orthonormal von Neumann set $\psi_{lmn}(x,y)$ in the xy-representation [the operators in Eqs. (1) and (2) are used],

$$\psi_{lmn}(x,y)=(-1)^{mn}\exp\left(\frac{i}{\lambda^2}yNdn\right)\psi_l(x+Ndn,y+dm). \tag{20}$$

The function $\psi_l(x,y)$ in Eq. (20) is found according to Eqs. (3) and (16), and can be given by the two alternative forms,

$$\begin{aligned}\psi_l(x,y)&=\frac{1}{\sqrt{2\pi}}\int\exp(iyk)\,\gamma_l(k\lambda^2+x)F_\delta(k)\,dk\\ &=\frac{\exp(-ixy/\lambda^2)}{(1/\sqrt{2\pi})\,\lambda^2}\int\exp\left(\frac{i}{\lambda^2}xz\right)F_\gamma\left(\frac{z-y}{\lambda^2}\right)\delta(z)\,dz,\end{aligned} \tag{21}$$

where F_δ and F_γ are the Fourier transforms of δ and γ, respectively [γ and δ are the functions in Eq. (16)]. It should be pointed out that the condition given by Eq. (9) [or Eq. (11)] is necessary and sufficient for the von Neumann set [Eqs. (19) or (20)] for each Laudau level l to be orthogonal.

By using the results for the single degree of freedom XP_X [$P_X=(\hbar/\lambda^2)\,Y$], the Balian–Low theorem implies that the coordinates X and Y of the orbit center in the state ψ_l [Eq. (21)] for a magnetic field cannot both be well localized, or in a more precise language, at least one of the two uncertainties ΔX or ΔY in the ψ_l-state [Eq. (21)] diverges. It is interesting to point that for obtaining the result there is no need to go to the configuration plane xy [see Eq. (3)]. However, since the coordinates x and y of the electron in a magnetic field are related to the operators WP_W and XP_X [$P_X=(\hbar/\lambda^2)\,Y$] in Eqs. (1) and (2), one has

$$x=W-Y, \quad y=X-\frac{\lambda^2}{\hbar}P_W. \tag{22}$$

Bearing in mind that the uncertainties ΔW and ΔP_W are finite in the state given by Eq. (16) [or alternatively, by Eq. (21)], we come to the conclusion [by using Eq. (22)] that at least one of the uncertainties Δx or Δy diverges in the state $\psi_l(x,y)$ of Eq. (21). This also means that the electron in a magnetic field cannot be well localized in both the x- and y- directions.

It is of interest to compare the consequences of the Balian–Low theorem with the known results for the Wannier function in a magnetic field.[11,21] In Ref. 11 it was shown that Wannier functions for a Bloch electron in the xy-plane, with the magnetic field B perpendicular to the plane, cannot fall off at infinity faster than r^{-2} ($r^2=x^2+y^2$). In Ref. 21 Wannier functions with a r^{-2} fall off were actually constructed for such a two-dimensional problem where only a magnetic field is present. One can see that the Balian-Low theorem for Landau levels is in good agreement with the results of Refs. 11 and 21. In order to see it, we notice that as a consequence of the Balian–Low theorem the quantity $\langle x^2+y^2\rangle=\langle r^2\rangle$ diverges (the triangular brackets denote the expectation value) because either $\langle x^2\rangle$ or $\langle y^2\rangle$ has to diverge. This divergence of $\langle r^2\rangle$ also follows when the function falls off as r^{-2} at infinity, like in Ref. 21.

It should be pointed out that the Balian–Low theorem is completely general in nature. For example, when $\delta(X)$ is given by Eq. (8), then $\psi_0(x,y)$ in Eq. (21) assumes the form (for the lowest Landau level, $l=0$)

$$\psi_0(x,y)=\left(\frac{1}{4\pi^3 d^2\lambda^6}\right)^{1/4}\exp\left(-\frac{ixy}{\lambda^2}\right)\int_{-d/2}^{d/2}\exp\left[\frac{i}{\lambda^2}xz-\frac{(y-z)^2}{2\lambda^2}\right]dz. \tag{23}$$

In deriving Eq. (23), use was made of the second line in Eq. (21). For large y, Eq. (23) becomes

$$\psi_0(x,y)\sim\left(\frac{d^2}{4\pi^3\lambda^6}\right)^{1/4}\exp\left(-\frac{ixy}{\lambda^2}-\frac{y^2}{2\lambda^2}\right)\sin\left(\frac{xd}{2\lambda^2}\right)\Big/\left(\frac{xd}{2\lambda^2}\right). \tag{24}$$

This function has a $1/x$ fall-off in the x-direction and is Gaussian in the y-direction.

Finally, it can be directly checked that the von Neumann set in Eq. (20) is orthonormal, when $\psi_l(x,y)$ is given by Eq. (21). In the particular case of the localized function in Eq. (23), the explicit orthonormal von Neumann set is [see Eq. (20)]

$$\psi_{0mn}(x,y)=\frac{(-1)^{mn}}{(4\pi^3 d^2\lambda^6)^{1/4}}\exp\left(-\frac{i}{\lambda^2}xy-\frac{i}{\lambda^2}xmd\right)$$
$$\times\int_{-d/2}^{d/2}\exp\left[\frac{i}{\lambda^2}(x+nNd)z-\frac{(y+md-z)^2}{2\lambda^2}\right]dz. \tag{25}$$

In conclusion, the Balian–Low theorem was applied to the motion of an electron in the xy-plane, with a magnetic field perpendicular to this plane. By using this theorem it was shown that orthonormality on a von Neumann lattice and localizability are incompatible features. In particular, it is shown that even for the best localized eigenfunctions for the Landau levels the uncertainties Δx and Δy can never both be made finite. On a qualitative level, incompatibility of orthonormality and localizability is not an unexpected feature for wave functions in quantum mechanics.[22] In this paper we derive complete orthonormal sets of localized functions for Landau level wave functions. Although the derivation was carried out in the Landau gauge, the result that Δx and Δy can never both be finite in a Landau level state $\psi_l(x,y)$ [see Eq. (20)], for any l, is gauge independent. This is seen from the expression of the wave function in the WX-representation [Eq. (19)]. The part of the wave function $\delta_{mn}(X)$ in Eq. (19) that leads to the von Neumann set does not depend on the gauge because the X-coordinate does not appear in the Hamiltonian of the problem [Eq. (14)].

As is well known, in the symmetric gauge the wave function for any Landau level can be chosen well localized in both x- and y-directions.[15] However, for such a well localized wave

function, the von Neumann set in Eq. (20) will *not be orthogonal*. As was shown in this paper the uncertainties Δx and Δy for the functions in the orthonormal set [Eq. (20)] cannot both be finite. This, however, does not limit the applicability of these functions in perturbation theory for well localized potentials. We should also point out that the idea of constructing orthonormalized sets of localized functions for the lowest Landau level was recently utilized in the framework of wavelets.[23] The orthonormal sets in Eq. (20) are built on a von Neumann lattice which is related to the Weyl–Heisenberg group. The orthonormal set in Ref. 23 is related to the group $ax+b$.

First an iterative process is described for subdivision and for scaling-up of the Penrose–Robinson tiles. Then we build the τ-wavelets of Haar (i.e., suitably normalized characteristic functions) on the tiles so that the orthogonality and multiresolution conditions are satisfied. Here $\tau=\frac{1}{2}(1+\sqrt{5})$. © *1998 American Institute of Physics.* [S0022-2488(98)01608-9]

I. INTRODUCTION

This paper should be seen as a continuation (and also an improvement) of our recent construction of discrete wavelets based on an algebraic scaling factor.[1,2] We call these functions tau-wavelets of Haar. The mathematical idea backing our approach originated in the identity

$$\tau^j=\tau^{j-1}+\tau^{j-2}, \tag{1.1}$$

valid for any $j\in\mathbb{Z}$ and obeyed by the (ubiquitous) golden mean

$$\tau=\frac{1}{2}\,(1+\sqrt{5})=2\cos\frac{\pi}{5}=1.618\ldots\,. \tag{1.2}$$

Indeed, comparing (1.1), with the dyadic splitting,

$$2^j=2^{j-1}+2^{j-1}, \tag{1.3}$$

which underlies most of the wavelet constructions along multiresolution guidelines, it was natural to explore the ''τ-adic'' multiresolution analysis. With regard to their algebraic properties exemplified by (1.1) and (1.3), we can view 2 and τ as similar at a certain extent. This fact has deep repercussions on the relationship between the two kinds of wavelets. Whereas the dyadic wavelets (Ref. 3 and references therein) are the functions $\psi(x)\in L^2(\mathbb{R})$ such that the family of functions,

$$\psi_{j,k}:=2^{j/2}\psi(2^jx-k),\quad j,k\in\mathbb{Z}, \tag{1.4}$$

form an orthonormal basis in $L^2(\mathbb{R})$[6], the same holds (or can be defined so) for τ-adic wavelets.

By a τ-adic wavelet[1,2] we mean a vector $\psi\in L^2(\mathbb{R})$ such that the family

$$\tau^{j/2}\psi(\tau^jx-b),\quad j\in\mathbb{Z},$$

is an orthonormal basis in $L^2(\mathbb{R})$ when b assumes its values in an appropriate subset Λ of the set $\mathbb{Z}_\tau$ of τ-integers. The set $\mathbb{Z}_\tau$ is discrete and can be defined as the set of real numbers which have a zero fractional part in the numeration system[4] based on τ,

$$\mathbb{Z}_\tau = -\mathbb{Z}_\tau. \tag{1.5}$$

It tiles the real line aperiodically with two tiles of length 1 and $1/\tau$. The subset Λ is given by

$$\Lambda = \tau\mathbb{Z}_\tau^+ \cup (-1-\tau\mathbb{Z}_\tau^+) \subset \mathbb{Z}_\tau,$$

where $\mathbb{Z}_\tau^+$ stands for the set of non-negative elements of $\mathbb{Z}_\tau$. Equivalently, one can define $\mathbb{Z}_\tau^+$ as the non-negative part of the 1-dimensional quasicrystal with acceptance window the open interval $(-1,\tau)$; see (2.11) and (2.12) below.

The extension of τ-wavelets of Haar to smooth, compactly supported, τ-wavelets is conceivable in spite of the current lack of algorithms like Daubechies construction.[3] Indeed, standard multiresolution involves integers for scaling parameters 2^j as well as for the translation parameter k in (1.4). The underlying additive group structure of the integers greatly facilitates any harmonic approach which makes Fourier series enter into the game. With the τ-integers we lose the ring structure. The next best property is the Meyer's,[5] $\mathbb{Z}_\tau + \mathbb{Z}_\tau \subset \mathbb{Z}_\tau + F$ and also[6] $\mathbb{Z}_\tau \times \mathbb{Z}_\tau \subset \mathbb{Z}_\tau + G$, where F and G are finite sets. These properties appear to pave the road to analysis of τ-wavelets based on almost periodic functions.[5,7,8] Another indication in favor of this direction are the summation formulas for Fourier exponentials in Refs. 2, 9.

It is natural to ask the question about the reason for extending the τ-wavelets to two dimensions. Our motivation stems mainly from quasicrystalline studies.[10–13] Quasicrystals are alloys like $Al_{0.86}Mn_{0.14}$ or $Al_xPd_yMn_z$, discovered in 1984.[14] Their x-ray diffraction patterns show local n-fold point symmetry, with $n=5,8,10,12$. Similar features are unveiled in quasicrystalline surfaces by scanning microscopy. Such symmetries are crystallographically ''forbidden'' for being incompatible with translational invariance. An observed diffraction pattern is a constellation of bright Bragg spots of unequal intensity displaying self-similarity with irrational scaling factors. Similar self-similarity is encountered in other types of quasicrystal experiments. The scaling parameters involve the following (algebraic) integers:

$$\begin{aligned} &\tfrac{1}{2}(1+\sqrt{5}), \quad \text{for } n=5,10; \\ &1+\sqrt{2}, \quad \text{for } n=8; \\ &2+\sqrt{3}, \quad \text{for } n=12. \end{aligned} \tag{1.6}$$

Only in the first case an exhaustive description of self-similarities in a large class of n-dimensional quasicrystals can be found in literature.[15]

In the study of quasicrystals, there appears to be at least three types of problems amenable to wavelet analysis. The first one concerns the diffraction patterns (see, for example, the papers of Hof, and Gähler, Klitzing in Ref. 13) where, at a given resolution, it is necessary to classify and label the Bragg spots according to their position and intensity. Concepts like the Meyer sets Λ and their star map, yielding the dual Λ^*, are crucial in this content.[16–18]

The second application of wavelet analysis is the treatment of patterns obtained by the tunnelling or atomic force microscopy of quasicrystals surfaces. The images faithfully reflect electronic densities of atomic sites. Two-dimensional wavelets based on irrationalities (1.6) appear to be particularly appropriate for the scanning analysis, especially where it is a matter of discerning defects, shearing or other breaking of scaling invariance or local symmetries.

The third application, possibly the most promising one, concerns the determination of electronic transport properties in quasicrystals. Interesting results already exist for 1-dimensional models of aperiodic Hamiltonians (see Ref. 19 for a recent review) but the situation for real quasicrystals is far from being clarified. The lack of periodicity hampers the efficiency of making use of Fourier analysis and related theorems (Floquet, Bloch,...) for determining transport wave functions and spectral characteristics (gap positions, integrated density of states,...). However, it seems natural to expand the wave function of an electron, submitted to a quasiperiodic potential whose minima are distributed according to the nodes of a quasicrystal Λ, in terms of a wavelet family corresponding to Λ such as the one constructed in this paper.

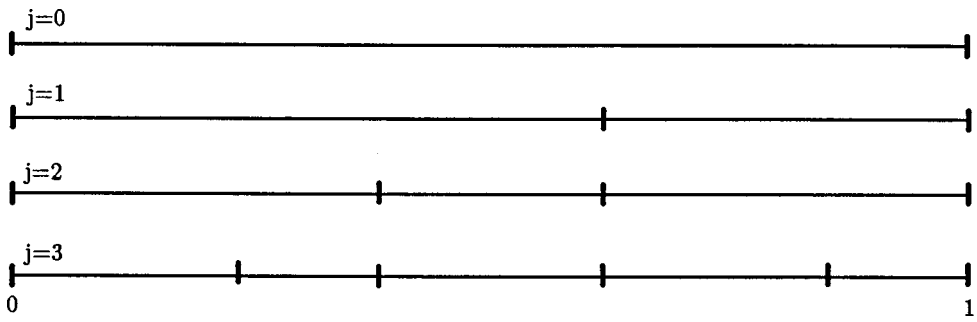

FIG. 1. The beginning of the iterative sequence of subdivisions of the unit interval.

There have been several attempts to involve wavelet analysis in the field of spectral problems (diffraction or Schödinger) related aperiodic (mostly self-similar) structures.[3,20] However, none makes use of the concept of algebraic discrete wavelet as the one presented in Ref. 2 and in this paper.

In the next section we recall the one-dimensional case in order to present in a simpler manner the algebraic τ-integers and the analytic τ-wavelet material. The two-dimensional case is considered in Section III. There we describe a nonunique process for subdividing the two types of Penrose–Robinson triangles. Section IV is devoted to the construction of τ-wavelets in the plane. Finally, Section V contains a definition of multiresolution analysis adapted to our present approach.

II. TAU-WAVELETS OF HAAR ON THE LINE

In this section we first recall the procedure followed in Ref. 2 during the construction of the Haar set based on scaling by the irrational factor $\tau=\frac{1}{2}(1+\sqrt{5})$. Later in the section we point out on this transparent one-dimensional case the strategy we use in two dimensions.

The algebraic nature of τ (it is a solution of the equation $x^2=x+1$) allows for the τ-adic property,

$$\frac{1}{\tau^j}=\frac{1}{\tau^{j+1}}+\frac{1}{\tau^{j+2}}, \quad j\in\mathbb{Z}.$$

This equality provides a subdivision of the unit interval into two parts:

$$A=[0,1]=[0,1/\tau]\cup[1/\tau,1]. \tag{2.1}$$

Equation (2.1) is the starting point of an iterative sequence of subdivisions of A into intervals (Fig. 1). At each step only the large intervals get divided. Thus at each stage we have two lengths of intervals:

$$A_{j,b}=\left[\frac{b}{\tau^j},\frac{b+1}{\tau^j}\right], \quad j\in\mathbb{N}, \quad A_{0,0}=A; \tag{2.2}$$

$$A_{j,b}=A_{j+1,\tau b}\cup A_{j+2,\tau^2 b+\tau}, \tag{2.3}$$

where b is what we called a τ-integer.[2] It is submitted to a certain boundedness condition.

Let us first explain the concept of the τ-integer.[21,1,2] It is derived from the system of numeration based on τ.[4] Each non-negative real number x can be expanded in powers of τ with coefficients of the expansion taking only two values: 0 or 1. More precisely,

$$x=\sum_{l=-\infty}^{j}\xi_l\tau^l=\xi_j\tau^j+\xi_{j-1}\tau^{j-1}+\ldots, \tag{2.4}$$

with

$$\xi_l \in \{0,1\}, \quad \xi_l \xi_{l-1} = 0. \tag{2.5}$$

The second condition in (2.5) means that no partial sum like $\tau^k + \tau^{k-1}$ occurs in (2.4), owing to the fact that it is equal to τ^{k+1}.

Coefficients ξ_k in (2.4) are computed using the so called Rényi algorithm: First, j in (2.4) is the integer satisfying

$$\tau^j \leqslant x < \tau^{j+1}, \quad \text{i.e.,} \quad 1 \leqslant \frac{x}{\tau^j} < \tau, \tag{2.6}$$

and so

$$\xi_j = \left[\frac{x}{\tau^j}\right] := \text{integer part of } \frac{x}{\tau^j} = 1.$$

Then we put

$$r_j = \left\{\frac{x}{\tau^j}\right\} := \text{fractional part of } \frac{x}{\tau^j},$$

and the other coefficients ξ_k, $k<j$ are determined recursively from (ξ_j, r_j):

$$\xi_k = [\tau r_{k+1}], \quad r_k = \{\tau r_{k+1}\}. \tag{2.7}$$

Equivalently we have

$$\xi_{j-k} = [\tau T_\tau^k (x/\tau^{j+1})], \tag{2.8}$$

where

$$T_\tau y := (\tau y) \pmod 1, \quad \text{for any } y \in [0,1].$$

In this system of numeration based on τ, the set of non-negative τ-integers is the strictly increasing sequence of real numbers having only non-negative powers of τ in their τ-expansion,

$$\mathbb{Z}_\tau^+ = \{0,1,\tau,\tau^2,\tau^2+1,\tau^3,\tau^3+1,\tau^3+\tau,\tau^4,\ldots\}. \tag{2.9}$$

The set $\mathbb{Z}_\tau$ of τ-integers is then defined by

$$\mathbb{Z}_\tau = \mathbb{Z}_\tau^+ \cup (-\mathbb{Z}_\tau^+). \tag{2.10}$$

It was pointed out in Ref. 22 that the numbers in $\mathbb{Z}_\tau^+$ can be introduced as the subset of all the non-negative points $a+b\tau$ of the 1-dimensional cut and project quasicrystal,

$$\Sigma((-1,\tau)) = \{a+b\tau \,|\, a,b \in \mathbb{Z}, a+b\tau' \in (-1,\tau)\}, \tag{2.11}$$

whose acceptance window is the open interval $(-1,\tau)$. Here τ and τ' are the two solutions of the quadratic equation $x^2 = x+1$. Note that $\Sigma((-1,\tau))$ has the reflection symmetry in the point $-\tau/2$. In order to have the desired reflection symmetry (1.5) in the origin, we use (2.10) together with

$$\mathbb{Z}_\tau^+ = \Sigma((-1,\tau))^+ = \{a+b\tau \geqslant 0 \,|\, a,b \in \mathbb{Z}, a+b\tau' \in (-1,\tau)\}. \tag{2.12}$$

Furthermore, from Ref. 22 we know all the inflation (or scaling) centers of the point set $\Sigma((-1,\tau))$. We say that x is an s-inflation center of $\Sigma((-1,\tau))$ provided

$$s(y-x)+x \in \Sigma((-1,\tau)), \quad \text{for all } y \in \Sigma((-1,\tau)). \tag{2.13}$$

That includes the centers which belong to $\Sigma((-1,\tau))$ as well as all those which lie outside of it. Consequently, we also know the scaling properties of the set $\mathbb{Z}_\tau^+$. In particular, we know not only that every point $x \in \mathbb{Z}_\tau^+$ is an inflation center of $\mathbb{Z}_\tau^+$, but also all its scaling factors s. It was shown

in Ref. 22 that the scaling factors s, appropriate for all points $x \in \Sigma((-1,\tau))$, form the one-dimensional quasicrystal $\Sigma([0,1])$ contained in $\Sigma((-1,\tau))$. For just one point $x \in \Sigma((-1,\tau))$, the admissible scaling factors form in general a larger x-dependent quasicrystal denoted by $\Sigma([-\mu(x),1])$ in Ref. 22. In all cases one has

$$\Sigma([0,1]) \subseteq \Sigma([-\mu(x),1]) \subset \Sigma((-1,\tau)).$$

We now come to the explicit construction of the τ-Haar basis in $L^2[0,1]$. For that we need a ''mother'' wavelet called here the τ-Haar wavelet.

Definition 2.1: The τ-Haar wavelet is the function defined on the real line $\mathbb{R}$ as

$$h^\tau(x) = \begin{cases} \tau^{-1/2}, & \text{for } x \in \left[0, \dfrac{1}{\tau}\right], \\ -\tau^{1/2}, & \text{for } x \in \left]\dfrac{1}{\tau}, 1\right], \\ 0, & \text{otherwise.} \end{cases} \tag{2.14}$$

One can verify directly that

$$\int_0^1 (h^\tau(x))^2 dx = \frac{1}{\tau^2} + \tau\left(1 - \frac{1}{\tau}\right) = 1, \tag{2.15}$$

$$\int_0^1 h^\tau(x)\,dx = \tau^{-1/2} \cdot \frac{1}{\tau} - \tau^{1/2} \cdot \frac{1}{\tau^2} = 0. \tag{2.16}$$

Thus $h^\tau(x)$ is orthogonal to $\chi_{[0,1]} \equiv \chi_A$, the characteristic function of the unit interval.

The following summarizes the construction.

Theorem 2.2: The system

$$\{\tau^{j/2} h^\tau(\tau^j x - b) \equiv h^\tau_{j,b}(x), \tau^{j/2} h^\tau(\tau^j x + b + 1)\}, \quad j \in \mathbb{Z}, \ b \in \tau\mathbb{Z}_\tau, \tag{2.17}$$

is an orthonormal basis in $L^2(\mathbb{R})$. It is called the τ-Haar basis of $L^2(\mathbb{R})$.

The following expansion formula is crucial for the proof of the theorem

$$\tau^{-1/2} \sum_{j<0} \tau^{j/2} h^\tau_{j,0}(x) = \chi_A(x). \tag{2.18}$$

Our task in this paper is to construct the τ-wavelets in the plane. The analogy with the one-dimensional Haar wavelets can be made very close. For that, however, we have to reformulate the one-dimensional problem in an equivalent way.

All Haar wavelets with support $[0,1]$ have the form

$$f_{j,k}(x) = 2^{j/2} f(2^j x - k), \quad j = 0,1,...; \quad k = 0,1,...,2^j - 1.$$

These functions can be generated from the step function f by means of the scale-up function $\varphi(x) = 2x$ and the displacement function $\alpha(x) = x - 1$. Let us describe the first steps of the generation process:

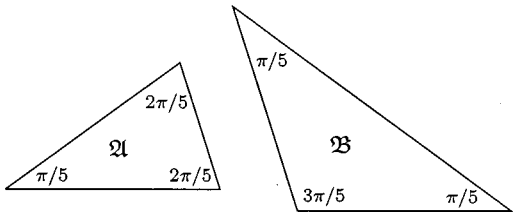

FIG. 2. The Penrose–Robinson triangles $\mathfrak{A}$ and $\mathfrak{B}$.

$$
\begin{aligned}
j=1:\quad & f_{1,0}=2^{1/2}f(2x)=2^{1/2}f(\varphi(x)),\\
& f_{1,1}=2^{1/2}f(2x-1)=2^{1/2}f(\alpha\varphi(x));\\
\\
j=2:\quad & f_{2,0}=2\,f(4x)=2\,f(\varphi\varphi(x)),\\
& f_{2,1}=2\,f(4x-1)=2\,f(\alpha\varphi\varphi(x)),\\
& f_{2,2}=2\,f(4x-2)=2\,f(\varphi\alpha\varphi(x)),\\
& f_{2,3}=2\,f(4x-3)=2\,f(\alpha\varphi\alpha\varphi(x));\\
& \vdots
\end{aligned}
$$

Thus by composing the mother function with ''admissible'' words formed from the letters α and φ, we are able to generate all functions. Here a word w is admissible provided it ends by φ and it does not contain adjacent α's; an empty word is also admissible. Let us denote by ''Admis'' the set of admissible words, and by $l(w)$ the multiplicity of occurrence of the letter φ in the word w. Then all the Haar wavelets with support $[0,1]$ are described as follows:

$$\{2^{l(w)/2}f(w(x))\,|\,w\in\text{Admis}\}.$$

The same discussion is also valid for τ-Haar wavelets.

III. SUBDIVISION OF PENROSE–ROBINSON TRIANGLES

Our construction of τ-wavelets in the plane will start out from successive subdivisions of the Penrose–Robinson triangles. The latter will play the role of the interval $[0,1]$ in the previous section. More precisely, there will be two of them to play this role, namely the triangles $\mathfrak{A}$ and $\mathfrak{B}$ shown on Figure 2.

Let us denote by ΔABC a triangle with vertices labeled by A,B,C counterclock-wise in $\mathbb{C}$. The length of the side with vertices A,B is denoted by $\overline{AB}$.

Let us define on the set of all triangles in $\mathbb{C}$, congruent to either $\mathfrak{A}$ or $\mathfrak{B}$, a splitting operator Ψ,

$$\Psi(\Delta ABC)=(\Psi_{\mathfrak{A}}(\Delta ABC),\Psi_{\mathfrak{B}}(\Delta ABC)),$$

in the following way.

(a) Let ΔABC be similar to $\mathfrak{A}$, where A is the vertex at the angle $\pi/5$. Denote by D the point on the side AC such that $\overline{AD}:\overline{DC}=\tau$ (Fig. 3). Then we define the two components of the splitting to

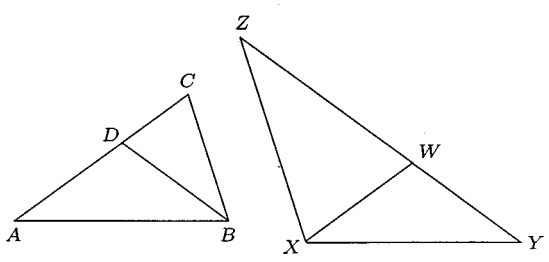

FIG. 3. The first subdivision of the triangles $\mathfrak{A}$ and $\mathfrak{B}$.

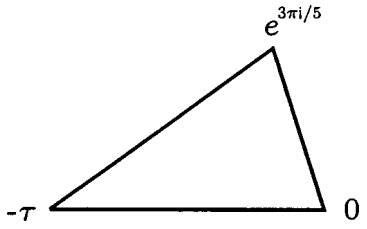

FIG. 4. The basic triangle T and the coordinates of its vertices in the complex plane.

be the following:

$$\Psi_{\mathfrak{U}}(\Delta ABC) := \Delta BCD, \quad \Psi_{\mathfrak{B}}(\Delta ABC) := \Delta ABD.$$

(b) Let ΔXYZ be similar to $\mathfrak{B}$, where X is the vertex at the angle $3\pi/5$. Denote by W the point on the side YZ such that $\overline{YW}:\overline{WZ} = 1/\tau$ (Fig. 3). Then we define the two components of the splitting to be the following:

$$\Psi_{\mathfrak{U}}(\Delta XYZ) := \Delta YWX, \quad \Psi_{\mathfrak{B}}(\Delta XYZ) := \Delta WZX.$$

It follows immediately that

• $\Delta = \Psi_{\mathfrak{U}}(\Delta) \cup \Psi_{\mathfrak{B}}(\Delta)$, where $\Psi_{\mathfrak{U}}(\Delta)$ is always similar to $\mathfrak{U}$ and $\Psi_{\mathfrak{B}}(\Delta)$ is always similar to $\mathfrak{B}$.

• If Δ is similar to $\mathfrak{U}$, then

$$\text{vol } \Psi_{\mathfrak{U}}(\Delta) : \text{vol } \Psi_{\mathfrak{B}}(\Delta) = 1/\tau.$$

• If Δ is similar to $\mathfrak{B}$, then

$$\text{vol } \Psi_{\mathfrak{U}}(\Delta) : \text{vol } \Psi_{\mathfrak{B}}(\Delta) = \tau.$$

Now we can start the wavelet construction. The basic area will be the triangle T given by its vertices $-\tau, 0, e^{3\pi i/5}$ in $\mathbb{C}$ (Fig. 4). Its area is given by vol $T = \frac{1}{2}\tau^2 \sin \pi/5$.

The idea of the subdivision is to proceed as follows. The triangle T is divided in the first step to $\Psi_{\mathfrak{U}}(T)$ and $\Psi_{\mathfrak{B}}(T)$. Subsequently at each step we have triangles of only two sizes. The division is accomplished by applying the operator Ψ to the triangles of larger volume (Fig. 5).

Let us now describe the subdivision in detail. Denote $\mathfrak{U}_n$ and $\mathfrak{B}_n$ the set of all triangles similar, respectively, to $\mathfrak{U}$ and $\mathfrak{B}$ which are obtained in the n-th step of the division process.

The sequences of division sets $(\mathfrak{U}_n)_0^\infty$ and $(\mathfrak{B}_n)_0^\infty$ can be described recursively as follows:

$$\begin{aligned}
&\mathfrak{U}_0 = \{T\}, && \mathfrak{B}_0 = \varnothing,\\
&\mathfrak{U}_1 = \{\Psi_{\mathfrak{U}}(T)\}, && \mathfrak{B}_1 = \{\Psi_{\mathfrak{B}}(T)\},\\
&\mathfrak{U}_2 = \{\Psi_{\mathfrak{U}}(T), \Psi_{\mathfrak{U}}\Psi_{\mathfrak{B}}(T)\}, && \mathfrak{B}_2 = \{\Psi_{\mathfrak{B}}\Psi_{\mathfrak{B}}(T)\},\\
&\vdots && \vdots\\
&\mathfrak{U}_{2n} = \mathfrak{U}_{2n-1} \cup \Psi_{\mathfrak{U}}(\mathfrak{B}_{2n-1}), && \mathfrak{B}_{2n} = \Psi_{\mathfrak{B}}(\mathfrak{B}_{2n-1}),\\
&\mathfrak{U}_{2n+1} = \Psi_{\mathfrak{U}}(\mathfrak{U}_{2n}), && \mathfrak{B}_{2n+1} = \mathfrak{B}_{2n} \cup \Psi_{\mathfrak{B}}(\mathfrak{U}_{2n}).
\end{aligned}$$

The number of similar triangles at each step can be readily determined using the following rule: Let n be even. Then the number of triangles similar to $\mathfrak{U}$ is equal to the term F_{n+1} of the

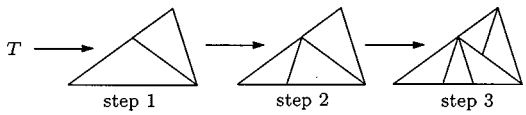

FIG. 5. The first three steps of the subdivision process.

Fibonacci series (which starts at $F_0=0$ and $F_1=1$) and the number of triangles similar to $\mathfrak{B}$ is equal to F_n. For n odd the numbers are interchanged for the triangles $\mathfrak{U}$ and $\mathfrak{B}$.

Note that all the triangles in $\mathfrak{U}_{2n}\cup\mathfrak{U}_{2n-1}$ have the volume vol T/τ^{2n} while all the triangles in $\mathfrak{B}_{2n}\cup\mathfrak{B}_{2n+1}$ have the volume vol T/τ^{2n+1}.

IV. TAU-WAVELETS IN THE PLANE

So far we have been subdividing the triangles. Now we define the system of orthonormal step functions on them.

For every triangle Δ which is being divided at the step n, we define the function $f_{\Delta,n}$ as follows.

(a) If $n=2k$, then for each $\Delta\in\mathfrak{U}_{2k}$ put

$$f_{\Delta,2k}(z)=\begin{cases}\tau^{k+1/2}(\mathrm{vol}T)^{-1/2}, & \text{for } z\in\Psi_{\mathfrak{U}}(\Delta),\\ -\tau^{k-1/2}(\mathrm{vol}T)^{-1/2}, & \text{for } z\in\Psi_{\mathfrak{B}}(\Delta),\\ 0, & \text{otherwise.}\end{cases}$$

(b) If $n=2k-1$, then for each $\Delta\in\mathfrak{B}_{2k-1}$ put

$$f_{\Delta,2k-1}(z)=\begin{cases}-\tau^{k-1}(\mathrm{vol}T)^{-1/2}, & \text{for } z\in\Psi_{\mathfrak{U}}(\Delta),\\ \tau^{k}(\mathrm{vol}T)^{-1/2}, & \text{for } z\in\Psi_{\mathfrak{B}}(\Delta),\\ 0, & \text{otherwise.}\end{cases}$$

Consider the example of $f_{T,0}$ and $f_{\Psi_{\mathfrak{B}}(T),1}$. These two functions will play the role of two ''mother'' wavelets:

$$f_{\mathfrak{U}}\equiv f_{T,0}(z)=\begin{cases}\tau^{1/2}(\mathrm{vol}T)^{-1/2}, & \text{for } z\in\Psi_{\mathfrak{U}}(T),\\ -\tau^{-1/2}(\mathrm{vol}T)^{-1/2}, & \text{for } z\in\Psi_{\mathfrak{B}}(T),\\ 0, & \text{otherwise;}\end{cases}$$

$$f_{\mathfrak{B}}\equiv f_{\Psi_{\mathfrak{B}}(T),1}(z)=\begin{cases}-(\mathrm{vol}T)^{-1/2}, & \text{for } z\in\Psi_{\mathfrak{U}}\Psi_{\mathfrak{B}}(T),\\ \tau(\mathrm{vol}T)^{-1/2}, & \text{for } z\in\Psi_{\mathfrak{B}}\Psi_{\mathfrak{B}}(T),\\ 0, & \text{otherwise.}\end{cases}$$

Let us point out that supp $f_{\Delta,n}=\Delta$, the powers of τ and the signs are chosen so that

$$\int_T f_{\Delta,n}^2(z)\,dz=1,$$

$$\int_T f_{\Delta,n}(z)\,dz=\int_\Delta f_{\Delta,n}(z)\,dz=0.$$

Note that the integral over Δ implies that $f_{\Delta,n}$ is orthogonal to the characteristic function of its support.

We obtained an orthonormal system of functions on T because for any $m\leqslant n$ and for any function $f_{\Delta',m}$ one has

(a) either the supp $f_{\Delta',m}=\Delta'$ and supp $f_{\Delta,n}=\Delta$ are disjoint;

(b) or $f_{\Delta',m}$ is constant on Δ.

We have attached to the triangles in $(\cup_{n=0}^{\infty}\mathfrak{U}_n)\cup(\cup_{n=0}^{\infty}\mathfrak{B}_n)$ step functions. The set of all these functions is denoted by B.

So far we have a system of orthogonal functions on the triangle T but not yet wavelets. For our system we need to find two mother wavelets because the supports are found on tiles of two shapes. We are now ready to show that we are able to generate the whole wavelet system starting from the two mother wavelets $f_{\mathfrak{U}}$ and $f_{\mathfrak{B}}$ by the scale-up function Φ, and two planar displacement-isometries α and β.

The functions Φ, α and β are defined by

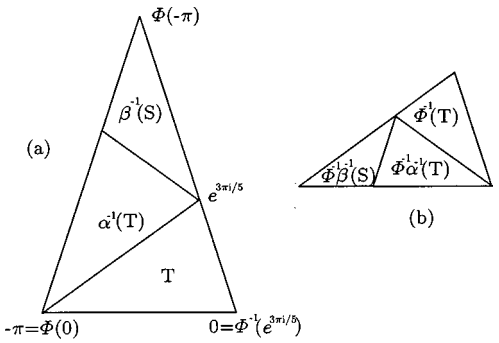

FIG. 6. The action of scaling-up Φ and of displacement isometries α and β. For simplicity of notation we set $S=\Psi_{\mathfrak{B}}(T)$.

$$\Phi(z)=\tau e^{-3\pi i/5}z-\tau, \tag{4.1}$$

$$\alpha(z)=e^{-\pi i/5}(z+\tau)-\tau, \tag{4.2}$$

$$\beta(z)=e^{-3\pi i/5}z-1-\tau. \tag{4.3}$$

For simplicity of notation we introduce $S=\Psi_{\mathfrak{B}}(T)$. That action of the functions α, β and Φ is illustrated in Fig. 6(a). For the scaled-up triangles T and S, we have

$$\begin{aligned}\Phi(T)&=T\cup\alpha^{-1}(T)\cup\beta^{-1}(S),\\ \Phi(S)&=\alpha^{-1}(T)\cup\beta^{-1}(S).\end{aligned} \tag{4.4}$$

Applying Φ^{-1} to (4.4), we get

$$\begin{aligned}T&=\Phi^{-1}T\cup\Phi^{-1}\alpha^{-1}(T)\cup\Phi^{-1}\beta^{-1}(S),\\ S&=\Phi^{-1}\alpha^{-1}(T)\cup\Phi^{-1}\beta^{-1}(S).\end{aligned} \tag{4.5}$$

The transformations are shown in Fig. 6(b).

In order to determine the requirements imposed on the words in α, β and Φ, we perform one more step of the iteration. Substitution of (4.5) into the right side of (4.4) followed by inversion yields

$$\begin{aligned}T=&\Phi^{-1}\Phi^{-1}(T)\cup\Phi^{-1}\Phi^{-1}\alpha^{-1}(T)\cup\Phi^{-1}\Phi^{-1}\beta^{-1}(S)\cup\Phi^{-1}\alpha^{-1}\Phi^{-1}(T)\\ &\cup\Phi^{-1}\alpha^{-1}\Phi^{-1}\alpha^{-1}(T)\cup\Phi^{-1}\alpha^{-1}\Phi^{-1}\beta^{-1}(S)\cup\Phi^{-1}\beta^{-1}\Phi^{-1}\alpha^{-1}(T)\\ &\cup\Phi^{-1}\beta^{-1}\Phi^{-1}\beta^{-1}(S).\end{aligned}$$

The admissibility rules which one sees so far are (i) $\alpha^{-1}\alpha^{-1},\alpha^{-1}\beta^{-1},\beta^{-1}\beta^{-1},\beta^{-1}\alpha^{-1}$ are not admissible, i.e., α^{-1},β^{-1} are always separated by Φ^{-1}; (ii) a word acting on S ends always by β^{-1}; (iii) the combination $\beta^{-1}\Phi^{-1}\Phi^{-1}$ is forbidden because by β^{-1} we map only $T-\Phi^{-1}\Phi^{-1}(T)=S$ and not the whole T.

Application of all the admissible words to T and S generates the system of triangles $\mathfrak{U}_n$ and $\mathfrak{B}_n$, respectively. We have now the rules for constructing the supports of all the step functions starting from the triangles T and S. Therefore we can describe the set of all orthonormal step functions by the two mother wavelets $f_{\mathfrak{U}}$ and $f_{\mathfrak{B}}$,

$$B=\{\tau^{l(w)}f_{\mathfrak{U}}(w(x))\,|\,w\in\mathrm{Admis}_{\mathfrak{U}}\}\cup\{\tau^{l(w)}f_{\mathfrak{B}}(w(x))\,|\,w\in\mathrm{Admis}_{\mathfrak{B}}\},$$

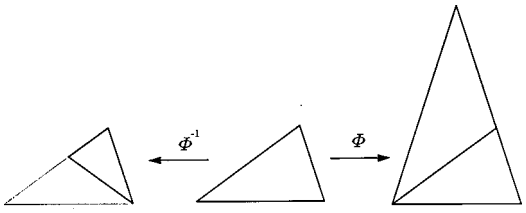

FIG. 7. The action of Φ and Φ^{-1} on the basic triangle T.

where $l(w)$ is the multiplicity of Φ in the word w. The sets $\mathrm{Admis}_{\mathfrak{U}}$, $\mathrm{Admis}_{\mathfrak{B}}$ consist of all words in α, β, and Φ which end by Φ and do not contain the strings $\alpha\alpha$, $\alpha\beta$, $\beta\beta$, $\beta\alpha$ and $\Phi\Phi\beta$. Furthermore the words in $\mathrm{Admis}_{\mathfrak{U}}$ never begin with β, and the words in $\mathrm{Admis}_{\mathfrak{B}}$ always begin with β.

Our next task is to scale-up the orthonormal system on the whole plane $\mathbb{C}$. For that we define

$$W_n=\{f_{\Delta,2n}|\Delta\in\mathfrak{U}_{2n}\}\cup\{f_{\Delta,2n+1}|\Delta\in\mathfrak{B}_{2n+1}\},\quad \text{for } n=0,1,2,\ldots .$$

The idea of the process is to proceed step-by-step each time enlarging a triangle of type $\mathfrak{U}$ to the next larger triangle of type $\mathfrak{U}$ by adjoining to it an appropriate triangle of type $\mathfrak{B}$. We want to exploit the property of Φ,

$$\forall z\in\mathbb{C},\quad \exists k\in\mathbb{N},\quad z\in\Phi^k(T),$$

which implies that

$$\mathbb{C}=\bigcup_{k\in N}\Phi^k(T)$$

On Fig. 7 we illustrate the action of Φ and Φ^{-1} on the triangle T. The self-similarity of the triangles (and functions as well) is guaranteed by the property $\Phi^{-1}(T)=\Psi_{\mathfrak{U}}(T)$. Indeed, we have

$$\Phi^{-1}(\mathfrak{U}_n)=\{\Delta\in\mathfrak{U}_{n+2}|\Delta\in\Psi_{\mathfrak{U}}(T)\},$$

$$\Phi^{-1}(\mathfrak{B}_n)=\{\Delta\in\mathfrak{B}_{n+2}|\Delta\in\Psi_{\mathfrak{U}}(T)\}.$$

For all $n\in\mathbb{N}$ and for all functions $f\in W_{n-1}$ one has

$$f(z)\in W_{n-1}\Rightarrow\tau f(\Phi(z))\in W_n . \tag{4.6}$$

In order to illustrate the scale-up process of the functions, let us first carry out the enlargement by one step: from T to $\Phi(T)$.

Putting

$$W_n^{(-1)}=\left\{\frac{1}{\tau}\,f_{\Delta,n}(\Phi^{-1}(z))\,\middle|\, f_{\Delta,n}\in W_n\right\},$$

we have taken an orthonormal system W_n of functions and by a linear mapping Φ we have stretched it. The scale factor of Φ is τ, therefore we had to multiply the result by $1/\tau$ in order to preserve the normalization. The old function set is contained in the new one, $W_n\subset W_{n+1}^{(-1)}$, as follows from (4.6). The system $W_n^{(-1)}$, $0\leqslant n<\infty$, is orthonormal on $\Phi(T)$. The orthonormal system in the plane $\mathbb{C}$ is defined by

$$\widetilde{W}_n=\bigcup_{k=0}^{\infty}W_{n+k}^{(-k)},\quad n\in\{0,1,\ldots\}, \tag{4.7}$$

where

$$W_n^{(-k)}=\left\{\frac{1}{\tau^k}\,f_{\Delta,n}(\Phi^{-k}(z))\,\middle|\,f_{\Delta,n}\in W_n\right\}.$$

The inversion of the implication in (4.6) was not possible until now because the support of a function in W_n could have been mapped out of T. It now becomes possible because we have the supports in the whole plane.

Our system (4.7) now has the multiresolution property

$$f(z)\in\tilde{W}_n\Leftrightarrow\tau f(\Phi(z))\in\tilde{W}_{n+1},\quad\text{for all } n=0,1,\ldots. \tag{4.8}$$

The relation (4.8) can be used now to define $\tilde{W}_n$ for negative values of the index n. Then (4.8) applies to all $n\in\mathbb{Z}$.

In this paper we have disregarded the standard matching rules of the tiling based on the algebraic coloring of the vertices. Their observation would lead to some technical complications but would not prevent the construction.

V. MULTIRESOLUTION ANALYSIS

Recall that the multiresolution analysis in $\mathbb{R}^2$ based on wavelets[23] is a decomposition of $L^2(\mathbb{R}^2)$ into a chain of subspaces,

$$\cdots\subset V_2\subset V_1\subset V_0\subset V_{-1}\subset V_{-2}\subset\cdots,\quad \cap_{j\in\mathbb{Z}}V_j=\{0\}, \tag{5.1}$$

such that $\cup_{j\in\mathbb{Z}}V_j$ is dense in $L^2(\mathbb{R}^2)$. In addition for each $f\in L^2(\mathbb{R}^2)$ one has

$$f(x)\in V_j\Leftrightarrow f(2x)\in V_{j+1}. \tag{5.2}$$

Furthermore there exists a mother function $f_0\in V_0$ such that the functions $2^j f_0(2^j x-k)$ form an orthonormal basis of V_0. It means that one can generate an orthonormal basis of V_0 by a scale-up function $\Phi(x_1,x_2)=(2x_1,2x_2)$ and by two displacement functions $\alpha(x_1,x_2)=(x_1-1,x_2)$ and $\beta(x_1,x_2)=(x_1,x_2-1)$.

Let us compare that with the properties of our system. Let us introduce the notation V_j for the linear span

$$V_j:=\left\{\bigcup_{k=j}^{\infty}\tilde{W}_k\right\}_{\text{linear span}},\quad \forall j\in\mathbb{Z}.$$

Our V_j's satisfy (5.1). The property (5.2) can be rewritten for our subspaces in the form

$$f(x)\in V_j\Leftrightarrow f(\Phi(x))\in V_{j+1},$$

where $\Phi(x)$ is defined in (4.1). We have found two mother functions $f_{\mathfrak{U}}$ and $f_{\mathfrak{B}}$ in V_0 such that we can generate orthonormal basis of V_0 by Φ, α and β from (4.1).

It remains to show that our system is dense in $L^2(\mathbb{R}^2)$. For that we define the linear span of the characteristic functions of all supports in our system,

$$S=\left\{\chi\Delta\,\middle|\,\exists f\in\bigcup_{n\in\mathbb{Z}}V_n,\quad\text{such that }\Delta=\sup f\right\}_{\text{linear span}}.$$

As in the one-dimensional case like (2.18) an expansion formula allows one to express the characteristic function of T in terms of the affine transforms of the mother wavelets $f_{\mathfrak{U}}$ and $f_{\mathfrak{B}}$. Then according to the Stone–Weierstrass theorem, every continuous function in $L^2(\mathbb{R}^2)$ can be approximated with any precision by a linear combination of functions from our system. Since continuous functions are dense in $L^2(\mathbb{R}^2)$, it follows that the closure of the linear span of our system equals $L^2(\mathbb{R}^2)$.

Wavelets bases adapted to a self-similar quasicrystal

Guillaume Bernuau[a)]
Ceremade, Université Paris IX Dauphine, Paris, France

(Received 15 January 1998; accepted for publication 3 April 1998)

Given any self-similar quasicrystal Λ in $\mathbb{R}^n$ with inflation $\theta>1$, we construct bases of $\mathbb{L}^2(\mathbb{R}^n)$ having the following structure: $\theta^{nj/2}\psi_\lambda(\theta^j x-\lambda)$, $\lambda\in\Lambda\backslash\theta\Lambda$, $j\in\mathbb{Z}$, where the mother wavelets ψ_λ, $\lambda\in\Lambda\backslash\theta\Lambda$, are smooth and with exponential decay or compact support. We also show that wavelets ψ_λ constitute a relatively compact set in some Sobolev space and that they depend continuously on λ when Λ is equipped with an appropriate topology. © *1998 American Institute of Physics.* [S0022-2488(98)01808-8]

I. INTRODUCTION

A. Physical motivations

Wavelets theory finds interesting applications in problems involving some self-similarity or fractal properties. Thus it may appear very useful in the study of those new physical structures named quasicrystals, which were first discovered in 1982.[1] Indeed quasicrystals are long range ordered physical structures exhibiting symmetries which are incompatible with translational invariance and their existence proves that order is not synonymous with periodicity. In particular, many observed quasicrystals revealed a scale invariance involving an irrational scaling factor. Precisely, in quasicrystal studies, adapted wavelets could be valuable in the analysis of the diffraction pattern of self-similar quasicrystals, in the analysis of quasicrystals surfaces by tunneling or atomic face microscopy, and in the study of the Schrödinger equation with quasiperiodic potential, appearing in the field of electronic transport in quasicrystals.

B. Mathematical motivations

Mathematical quasicrystals are discrete aperiodic point sets which enlarge lattices from the harmonic analysis point of view (see Refs. 2–5 for an overview). Self-similarity may exist for those sets and usually the involved scaling factor is an irrational number $\theta>1$.[2] Thus a self-similar mathematical quasicrystal Λ gives rise to an increasing sequence of discrete aperiodic grids $\Lambda_j=\theta^{-j}\Lambda$, $j\in\mathbb{Z}$, which approximate the whole space $\mathbb{R}^n$,

$$\cdots\subset\Lambda\subset\theta^{-1}\Lambda\subset\cdots\subset\theta^{-j}\Lambda\subset\cdots\subset\mathbb{R}^n.$$

Wavelets construction usually relies on the approximation of the whole space $\mathbb{R}^n$ by an increasing sequence of discrete grids $(\Gamma_j)_{j\in\mathbb{Z}}$. The main idea consists in introducing a sequence of embedded subspaces V_j of $\mathbb{L}^2(\mathbb{R}^n)$ which mimics the approximation $\Gamma_j\approx\mathbb{R}^n$. Usually one has no reason to get rid of translation invariance and hence chooses dyadic grids $\Gamma_j=2^{-j}\mathbb{Z}^n$. Meanwhile many problems, especially in the study of quasicrystalline structures, involve aperiodicity and irrational self-similarity. Therefore it is natural to try to construct wavelet bases where the grids $\Lambda_j=\theta^{-j}\Lambda$ play a key role and replace the usual dyadic grids $2^{-j}\mathbb{Z}^n$.

Another important (and purely mathematical) reason motivating our work is the construction of wavelets bases of $\mathbb{L}^2(\mathbb{R}^n)$ having the following structure:

$$\theta^{nj/2}\psi_\gamma(\theta^j x-\gamma),\quad j\in\mathbb{Z},\quad \gamma\in\Gamma, \tag{1}$$

where $\theta>1$ is some irrational factor, Γ is a denumerable subset of $\mathbb{R}^n$, and the set of mother wavelets $\{\psi_\gamma,\gamma\in\Gamma\}$ should have the lowest cardinality possible.

C. Related papers and objectives

The construction of wavelets associated with aperiodic grids or enjoying nonintegral scaling factor has been widely studied (see Refs. 6–9) but in these constructions either the involved self-similarity is a rational number (Refs. 9 and 7) or there is simply no self-similarity (Refs. 6 and 8). The first example, to our knowledge, of wavelets bases having the structure given in (1), with an irrational scaling factor θ, was obtained by Gazeau and Patera.[10] They prove the existence of an orthonormal Haar basis of $\mathbb{L}^2(\mathbb{R})$ having the following structure:

$$\tau^{j/2}h(\tau^j x-\lambda),\quad j\in\mathbb{Z},\quad \lambda\in\Lambda_\tau,$$

where h is compactly supported and piecewise constant, τ is the golden number $(1+\sqrt{5})/2$, and Λ_τ is a mathematical quasicrystal in $\mathbb{R}$. Then Gazeau and Spiridonov[11] gave two other explicit examples of a Haar basis of $\mathbb{L}^2(\mathbb{R})$ where the value of the scaling factor is $1+\sqrt{2}$ or $2+\sqrt{3}$. Recently, Gazeau, Patera, and Pelantova[12] have constructed a Haar basis of $\mathbb{L}^2(\mathbb{R}^2)$ adapted to Penrose–Robinson tiling and with scaling factor $(1+\sqrt{5})/2$.

In this paper, we present two constructions of wavelets bases of $\mathbb{L}^2(\mathbb{R}^n)$ adapted to any prescribed self-similar mathematical quasicrystal Λ in $\mathbb{R}^n$ with inflation $\theta>1$. By adapted wavelets bases, we mean Riesz bases of $\mathbb{L}^2(\mathbb{R}^n)$ having the following structure:

$$\theta^{nj/2}\psi_\lambda(\theta^j x-\lambda),\quad \lambda\in\Lambda\backslash\theta\Lambda,\quad j\in\mathbb{Z},$$

where the set of mother wavelets $\mathcal{M}=\{\psi_\lambda,\lambda\in\Lambda\backslash\theta\Lambda\}$ consists of arbitrarily regular functions with exponential decay in the multidimensional case and with compact support in the one-dimensional case. These constructions are based on the results of Lemarié-Rieusset[7] for the multidimensional case and may be connected, in the one-dimensional case, with the results of Michelli and Buhmann.[8]

We also focus on the study of the set $\mathcal{M}$. If Λ is a lattice, $\mathcal{M}$ is made of one single wavelet. If Λ is no longer a lattice, we show that $\mathcal{M}$ becomes a relatively compact set in some Sobolev space. Indeed we show that Λ can be equipped with a topology which makes it precompact and which makes the mapping $\lambda\in\Lambda\backslash\theta\Lambda\to\psi_\lambda\in H$ continuous (H is some Sobolev space). In one dimension we describe a construction of compactly supported wavelets bases and obtain a finite set $\mathcal{M}$ of compactly supported mother wavelets.

In Sec. II, we recall some definitions about Delaunay sets, quasicrystals, and algebraic numbers. In Sec. III, the multiresolution scheme into which wavelets will be derived is introduced and studied. In Sec. IV, wavelets with exponential decay are constructed. In Sec. V, the set $\mathcal{M}$ is studied. In Sec. VI, we restrict our attention to the one-dimensional case and construct compactly supported wavelets.

This work is part of a Ph.D. thesis[5] where we also construct orthonormal Haar bases adapted to any self-similar tiling of $\mathbb{R}^n$ and frames adapted to quasicrystals.

II. DELAUNAY SETS, QUASICRYSTALS, AND ALGEBRAIC NUMBERS

Let us recall some definitions and properties about self-similar aperiodic sets. A Delaunay set is a subset Λ of $\mathbb{R}^n$ such that there exist $0<R_1<R_2$ satisfying the following conditions:

(i) Λ is uniformly discrete: any ball of radius R_1 contains at most one point of Λ.
(ii) Λ is relatively dense: any ball of radius R_2 contains at least one point of Λ.

Λ is said to be self-similar if there exists $\theta>1$ such that $\theta\Lambda\subset\Lambda$. We are interested here in the study of very special Delaunay sets: quasicrystals. These special sets may be considered as mathematical models for physical quasicrystals (see Refs. 1, 4, 2, 5, 3). Here is their definition:

Definition 2.1: A Delaunay set Λ is a quasicrystal (in the mathematical sense) if there exists a finite set $F\subset\mathbb{R}^n$ such that $\Lambda-\Lambda\subset\Lambda+F$.

The terminology concerning mathematical quasicrystals is not unified yet. One can find a quasilattice, Meyer set, model, or simply a quasicrystal. In the following, ''quasicrystal'' will always denote the mathematical concept defined above. There are many equivalent definitions of

a quasicrystal including the famous cut and project method construction (see Ref. 5 for an overview). In this article, only two fundamental properties of quasicrystals will be needed. The first one deals with the local configurations of a quasicrystal:

Property 2.1: Let Λ *be a quasicrystal in* $\mathbb{R}^n$. *For any* $R>0$ *the local configuration of size R, around* $\lambda \in \Lambda$, *defined by*

$$C_{\lambda,R}=(\Lambda-\lambda)\cap B_{0,R}$$

describes a finite set as λ *goes through* Λ.

Here $B_{0,R}$ denotes the ball centered at 0 with radius *R*.

Proof: $C_{\lambda,R}\subset B_{0,R}\cap(\Lambda-\Lambda)\subset B_{0,R}\cap(\Lambda+F)$. Since F is a finite set and since Λ is a Delaunay set, $B_{0,R}\cap(\Lambda+F)$ is finite. □

The second property deals with self-similarity. We first have to recall the definitions of two classes of algebraic integers (see Ref. 13 for further details):

Definition 2.2: A Pisot number is an algebraic integer $\theta>1$ *whose algebraic conjugates lie in the complex open disk of radius* 1.

Definition 2.3: A Salem number is an algebraic integer $\theta>1$ *whose algebraic conjugates lie in the complex closed disk of radius* 1 *with at least one of them having modulus equal to* 1.

The fundamental result concerning quasicrystals' self-similarity is

Theorem 2.1 (Meyer): *Let* Λ *be a self-similar quasicrystal with inflation* $\theta>1$. *Then* θ *is either a Pisot number or a Salem number.*

One can refer to Ref. 2 for a proof.

Let us give some examples of self-similar quasicrystals:

Example 2.1: Let $\tau=(1+\sqrt{5})/2$ *be the golden number. Then the set*

$$\Lambda=\{p+q\tau,(p,q)\in\mathbb{Z}^2,|p-q/\tau|\leqslant 1\}$$

is a self-similar quasicrystal in $\mathbb{R}$ *with inflation* τ.

Proof:

(i) τ is a Pisot number since
$$X^2-X-1=(X-\tau)(X+\tau^{-1}).$$

(ii) One way to check that Λ is a quasicrystal is to use Lagarias's characterization.[14] A Delaunay set Λ is a quasicrystal if and only if $\Lambda-\Lambda$ is uniformly discrete. In our example, $\Lambda\cap\mathbb{R}_+$ is relatively dense in $\mathbb{R}_+$ because, if $\lambda\in\Lambda$, either $\lambda+1$ or $\lambda+\tau$ is also in Λ. Consequently Λ is relatively dense in $\mathbb{R}$ because it is symmetric about 0. Λ is uniformly discrete because the following conditions:
$$\begin{cases}|p+q\tau|\leqslant 1,\\ |p-q/\tau|\leqslant 2,\end{cases}$$
determine a finite set of integral solutions (p,q). Hence 0 is isolated in $\Lambda-\Lambda$. The same argument holds for $\Lambda-\Lambda$ replacing 2 by 4 in the second condition. Finally Λ and $\Lambda-\Lambda$ are both Delaunay sets: Λ is a quasicrystal.

(iii) $\tau\Lambda$ is a subset of Λ because if $\tau(p+q\theta)=p'+q'\tau$ then
$$|p'-q'\tau^{-1}|=|-\tau^{-1}(p-q\tau^{-1})|\leqslant 1.$$ □

Example 2.2: Let $\theta=(1+\sqrt{2}+\sqrt{2\sqrt{2}-1})/2$ *and* $\alpha=\arccos((1-\sqrt{2})/2)$. *Denote by* σ *and* σ' *the linear mappings defined by*

$$\sigma(p+q\theta+r\theta^2+s\theta^3)=p+q\theta^{-1}+r\theta^{-2}+s\theta^{-3},$$

$$\sigma'(p+q\theta+r\theta^2+s\theta^3)=p+qe^{i\alpha}+re^{2i\alpha}+se^{3i\alpha},$$

where $(p,q,r,s)\in\mathbb{Z}^4$. *Then the set*

$$\Lambda=\{(a,b)\in\mathbb{Z}[\theta]^2,|\sigma(a)|+|\sigma(b)|+|\sigma'(a)|+|\sigma'(b)|\leqslant 1\}$$

is a self-similar quasicrystal in $\mathbb{R}^2$ *with inflation* θ.

Proof:

(i) θ is a Salem number since

$$X^4-2X^3+X^2-2X+1=(X-\theta)(X-\theta^{-1})(X-e^{i\alpha})(X-e^{-i\alpha}).$$

(ii) One can show, using similar arguments as in the first example, that Λ and $\Lambda-\Lambda$ are both Delaunay sets in $\mathbb{R}^2$. Hence Λ is a quasicrystal in $\mathbb{R}^2$.

(iii) Let $\lambda=(a,b)$ in Λ. Then $\theta\lambda=(a',b')$ is in $\mathbb{Z}[\theta]^2$ and $\sigma(a')=\theta^{-1}\sigma(a)$, $\sigma'(a')=e^{i\alpha}\sigma'(a)$. The same relations hold between b and b'. Hence $|\sigma(a')|+|\sigma(b')|+|\sigma'(a')|+|\sigma'(b')|\leqslant 1$. Consequently $\theta\Lambda\subset\Lambda$. □

III. MULTIRESOLUTION ANALYSIS ADAPTED TO A SELF-SIMILAR QUASICRYSTAL

To achieve the construction of wavelets bases, one needs to introduce a multiresolution analysis (Ref. 15). In its most general form, it consists of an increasing sequence $(V_j)_{j\in\mathbb{Z}}$ of closed subspaces whose union is dense in $\mathbb{L}^2(\mathbb{R}^n)$ and whose intersection reduces to $\{0\}$. Moreover if, for some absolute constant $\theta>1$, V_j is linked to V_0 by a change of scale equal to θ^j, i.e.,

$$f(x)\in V_j \Leftrightarrow f(\theta^{-j})\in V_0,$$

then wavelets bases derived from the sequence $(V_j)_{j\in\mathbb{Z}}$ will have the desired following structure:

$$\theta^{nj/2}\psi_\gamma(\theta^j x-\gamma),\quad j\in\mathbb{Z},\quad \gamma\in\Gamma.$$

Therefore, given any self-similar quasicrystal Λ in $\mathbb{R}^n$ with inflation $\theta>1$, we wish to construct a multiresolution analysis where the inflation θ and the translations lying in Λ will play a key role. A possible answer to our requirement is implicitly given in Ref. 7 and we shall present it now.

Let s be an integer strictly greater than $n/2$. $H^s(\mathbb{R}^n)$ will be the Sobolev space of functions f in $\mathbb{L}^2(\mathbb{R}^n)$ such that each distribution $\partial^\alpha f$, with $|\alpha|\leqslant s$, is an element of $\mathbb{L}^2(\mathbb{R}^n)$. Let us denote by $\mathcal{V}_0^{(s)}(\Lambda)$ (or more simply $\mathcal{V}_0^{(s)}$) the subspace of $\mathbb{L}^2(\mathbb{R}^n)$ defined by

$$\mathcal{V}_0^{(s)}(\Lambda)=\left\{ f\in\mathbb{L}^2(\mathbb{R}^n),\quad \exists(a_\lambda)_{\lambda\in\Lambda},\quad \Delta^s f=\sum_{\lambda\in\Lambda} a_\lambda\delta_\lambda\right\}.$$

$\mathcal{V}_0^{(s)}$ is the space of splines of order s with knots in Λ. Then one makes a change of scale to define the subspace $\mathcal{V}_j^{(s)}$, $j\in\mathbb{Z}$:

$$\mathcal{V}_j^{(s)}=\left\{ f\in\mathbb{L}^2(\mathbb{R}^n),\quad \exists(a_\lambda)_{\lambda\in\Lambda},\quad \Delta^s f=\sum_{\lambda\in\Lambda} a_\lambda\delta_{\theta^{-j}\lambda}\right\}.$$

We are ready to introduce a multiresolution analysis adapted to Λ:

Property 3.1: The sequence of subspaces $(\mathcal{V}_j^{(s)})_{j\in\mathbb{Z}}$ is a multiresolution analysis of $\mathbb{L}^2(\mathbb{R}^n)$ i.e.,

(*i*) *for any $j\in\mathbb{Z}$, $\mathcal{V}_j^{(s)}$ is a closed subspace of $\mathbb{L}^2(\mathbb{R}^n)$,*
(*ii*) *for any $j\in\mathbb{Z}$, $\mathcal{V}_j^{(s)}\subset\mathcal{V}_{j+1}^{(s)}$,*
(*iii*) *the union of $\mathcal{V}_j^{(s)}$, $j\in\mathbb{Z}$, is dense in $\mathbb{L}^2(\mathbb{R}^n)$,*
(*iv*) *the intersection of $\mathcal{V}_j^{(s)}$, $j\in\mathbb{Z}$, reduces to $\{0\}$,*
(*v*) *$f\in\mathcal{V}_j^{(s)}$ if and only if $f(\theta^{-j}x)\in\mathcal{V}_0^{(s)}$.*

Proof:

(*i*) Let $(f_j)_{j\in\mathbb{Z}}$ be a convergent sequence in $\mathbb{L}^2(\mathbb{R}^n)$ with values in $\mathcal{V}_0^{(s)}$. Let f denote its limit. Then $\Delta^s f_j$ converges to $\Delta^s f$ in $\mathcal{D}(\mathbb{R}^n)$ the space of distributions on $\mathbb{R}^n$. Write $\Delta^s f_j=\Sigma_{\lambda\in\Lambda} a_\lambda^j\delta_\lambda$. Choosing $\varphi\in C_0^\infty(\mathbb{R}^n)$, $\varphi(0)=1$, with support sufficiently small around 0, we get $\lim_{j\to\infty} a_\lambda^j=\langle\Delta^s f,\varphi(x-\lambda)\rangle=a_\lambda$. Finally for any $\varphi\in C_0^\infty(\mathbb{R}^n)$, one has $\langle\Delta^s f,\varphi\rangle=\Sigma_{\lambda\in\Lambda} a_\lambda\varphi(\lambda)$.

(*ii*) Clear since $\theta\Lambda\subset\Lambda$.

(*iii*) We use the fundamental property 4.1 mentioned below: if $f \in (\cup_{j\in\mathbb{Z}} \mathcal{V}_j^{(s)})^{\perp} = \cap_{j\in\mathbb{Z}} \mathcal{V}_j^{(s)^{\perp}}$ then $f = \Delta^s h$ where $h \in H^{2s}(\mathbb{R}^n)$ vanishes on $\cup_j \theta^{-j}\Lambda$ which is dense in $\mathbb{R}^n$. Hence h, which is continuous, vanishes on the whole space and so does f.

(*iv*) If $f \in \cap_j \mathcal{V}_j^{(s)}$ then $\Delta^s f$ is a sum of Dirac masses located on $\cap_j \theta^{-j}\Lambda = \{0\}$. Then $\Delta^s f = \alpha\delta_0$ and, since $f \in \mathbb{L}^2(\mathbb{R}^n)$, $f = 0$.

(*v*) Straightforward using Fourier transform. □

The sequence $(\mathcal{V}_j^{(s)})_{j\in\mathbb{Z}}$ is said to be adapted to Λ. We now study the subspace $\mathcal{V}_0^{(s)}$.

A. Variational study of $\mathcal{V}_0^{(s)}$

All the results of this subsection can be found in Ref. 7. Some technical proofs will not be detailed and the reader may refer to the original work of Lemarié-Rieusset.

We are concerned with the problem of constructing a Riesz basis of $\mathcal{V}_0^{(s)}$, i.e., a family of vectors of $\mathcal{V}_0^{(s)}$, $\{g_\lambda, \lambda \in \Lambda\}$, whose linear combinations are dense in $\mathcal{V}_0^{(s)}$ and for which there exist $0 < c_1 < c_2$ such that for any real sequence $(a_\lambda)_{\lambda\in\Lambda}$ with finite support:

$$c_1 \sum_{\lambda\in\Lambda} |a_\lambda|^2 \leqslant \left\| \sum_{\lambda\in\Lambda} a_\lambda g_\lambda(x) \right\|_{\mathbb{L}^2}^2 \leqslant c_2 \sum_{\lambda\in\Lambda} |a_\lambda|^2.$$

In order to solve this problem one considers the following minimization problem:

> Given $F \in H^s(\mathbb{R}^n)$, find, among functions of $H^s(\mathbb{R}^n)$ equal to F on Λ, a function f which minimizes the functional:

$$J(f) = \int_{\mathbb{R}^n} |\Delta^{s/2} f|^2 dx.$$

f is a solution of this problem if and only if f minimizes, among the same set of functions, the following functional:

$$\tilde{J}(f) = J(f) + \sum_{\lambda\in\Lambda} |f(\lambda)|^2.$$

This functional is coercive on $H^s(\mathbb{R}^n)$ since we have

Property 3.2: Let n be a positive integer and $s > n/2$ a real number. Then, on Sobolev space $H^s(\mathbb{R}^n)$, $\|f\|_{H^s}$ and $|||f|||_s = (\Sigma_{\lambda\in\Lambda} |f(\lambda)|^2)^{1/2} + \|\Delta^{s/2} f\|_{\mathbb{L}^2}$ are equivalent norms.

One can refer to Ref. 7 for a proof of this property.

Consequently the initial minimization problem has a unique solution f. Then for any $h \in C_0^\infty(\mathbb{R}^n)$, vanishing on Λ, for any $\alpha \in \mathbb{R}$, one has

$$J(f) \leqslant J(f + \alpha h),$$

which leads to

$$\int_{\mathbb{R}^n} \Delta^{s/2} f \Delta^{s/2} h \, dx = 0 \tag{2}$$

and hence

$$\Delta^s f = \sum_{\lambda\in\Lambda} a_\lambda \delta_\lambda$$

for a sequence $(a_\lambda)_{\lambda\in\Lambda}$. Therefore f is in $\mathcal{V}_0^{(s)}$.

Conversely if $f \in \mathcal{V}_0^{(s)}$, f is the unique solution of the minimization problem associated with $F = f$. Hence $\mathcal{V}_0^{(s)}$ is exactly the set of all solutions obtained as F goes through $H^s(\mathbb{R}^n)$.

B. Lagrangian Riesz basis of $\mathcal{V}_0^{(s)}$

On the subspace $\mathcal{V}_0^{(s)}$, one has

$$\|f\|_{H^s} \sim \left(\sum_{\lambda \in \Lambda} |f(\lambda)|^2 \right)^{1/2}.$$

Indeed using property 3.2 we find

$$\|f\|_{H^s} \leqslant C \left(\left(\sum_{\lambda \in \Lambda} |f(\lambda)|^2 \right)^{1/2} + \|\Delta^{s/2} f\|_{\mathbb{L}^2} \right),$$

$$\left(\sum_{\lambda \in \Lambda} |f(\lambda)|^2 \right)^{1/2} \leqslant C' \|f\|_{H^s}.$$

Conversely let $K_s = \{h \in H^s(\mathbb{R}^n), \forall \lambda \in \Lambda, h(\lambda) = 0\}$. Using (2), $\Delta^{s/2} f$ is orthogonal to $\Delta^{s/2} K_s$. In particular, $\Delta^{s/2} f$ is orthogonal to $\Delta^{s/2}(F - f)$ for any function F in $H^s(\mathbb{R}^n)$ equal to f on Λ. Therefore the orthogonal projection of $\Delta^{s/2} F$ on $\Delta^{s/2} K_s$ is $\Delta^{s/2}(F - f)$ and one has $\|\Delta^{s/2} f\|_{\mathbb{L}^2} \leqslant \|\Delta^{s/2} F\|_{\mathbb{L}^2}$. One can choose $F(x) = \Sigma_{\lambda \in \Lambda} f(\lambda) \varphi(x - \lambda)$ where all $\varphi(x - \lambda)$, $\lambda \in \Lambda$, have disjoined supports. Hence

$$\|\Delta^{s/2} f\|_{\mathbb{L}^2} \leqslant C \left(\sum_{\lambda \in \Lambda} |f(\lambda)|^2 \right)^{1/2}.$$

We are now ready for the following result:

Theorem 3.1: *For any integer s greater than n/2, each element $f \in \mathcal{V}_0^{(s)}$ can be written, in $H^s(\mathbb{R}^n)$:*

$$f(x) = \sum_{\lambda \in \Lambda} f(\lambda) \mathcal{L}_\lambda^{(s)}(x),$$

where $\mathcal{L}_\lambda^{(s)}$ is the unique element of $\mathcal{V}_0^{(s)}$ equal to 1 at $\lambda \in \Lambda$ and vanishing on $\Lambda \backslash \{\lambda\}$. Moreover $\{\mathcal{L}_\lambda^{(s)}, \lambda \in \Lambda\}$ is a Riesz basis of $\mathcal{V}_0^{(s)}$.

This basis is called a Lagrangian interpolation basis and $\mathcal{L}_\lambda^{(s)}$ is called Lagrangian spline of order s associated with λ.

C. Regularity of functions in $\mathcal{V}_0^{(s)}$

Let f be in $\mathcal{V}_0^{(s)}$. f is in $\mathbb{L}^2(\mathbb{R}^n)$ and hence $\Delta^s f$ is in $H^{-2s}(\mathbb{R}^n)$. We also know that $\Delta^s f = \Sigma_{\lambda \in \Lambda} a_\lambda \delta_\lambda$ for some sequence $(a_\lambda)_{\lambda \in \Lambda}$. Hence, for any φ in $C_0^\infty(\mathbb{R}^n)$

$$\left| \sum_{\lambda \in \Lambda} a_\lambda \varphi(\lambda) \right| \leqslant \|\Delta^s f\|_{H^{-2s}} \|\varphi\|_{H^{2s}}.$$

Let $\Lambda_R = \Lambda \cap B_{0,R}$. Choosing $\varphi_R = \Sigma_{\lambda \in \Lambda_R} a_\lambda \theta(x - \lambda)$ where all $\theta(x - \lambda)$, $\lambda \in \Lambda$, have disjoined supports and where $\theta(0) = 1$, we get

$$\sum_{\lambda \in \Lambda_R} |a_\lambda|^2 \leqslant \|\Delta^s f\|_{H^{-2s}} C_s \left(\sum_{\lambda \in \Lambda_R} |a_\lambda|^2 \right)^{1/2}.$$

Hence $(a_\lambda)_{\lambda \in \Lambda}$ is in $\ell^2(\Lambda)$. But then, for any $\sigma > n/2$,

$$|\langle \Delta^s f, \varphi \rangle| = \left| \sum_{\lambda \in \Lambda} a_\lambda \varphi(\lambda) \right| \leqslant \left(\sum_{\lambda \in \Lambda} |a_\lambda|^2 \right)^{1/2} \left(\sum_{\lambda \in \Lambda} |\varphi(\lambda)|^2 \right)^{1/2} \leqslant \left(\sum_{\lambda \in \Lambda} |a_\lambda|^2 \right)^{1/2} C_\sigma \|\varphi\|_{H^\sigma}.$$

Therefore $\mathcal{V}_0^{(s)}$ is included in $H^{2s-\sigma}(\mathbb{R}^n)$ for any $\sigma > n/2$ which shows that elements of $\mathcal{V}_0^{(s)}$ are regular functions. Let us end this section with a fundamental result of Lemarié-Rieusset concerning the decay of Lagrangian splines $\mathcal{L}_\lambda^{(s)}$:

Theorem 3.2 (Lemarié-Rieusset): *Let Λ be a Delaunay set in $\mathbb{R}^n$. Then for any integer s greater than $n/2$, there exist two constants $A=A(\Lambda,s)>0$ and $\beta=\beta(\Lambda,s)>0$ such that for any $\lambda\in\Lambda$:*

$$|\mathcal{L}_\lambda^{(s)}(x)|\leqslant Ae^{-\beta|x-\lambda|}.$$

One can refer to Ref. 7 for this technical result.

Thus a basis of $\mathcal{V}_0^{(s)}$ has been constructed and it consists of regular and well located functions. We are now ready to construct wavelets bases.

IV. CONSTRUCTION OF WAVELETS BASES

A nontrivial element of $\mathcal{V}_0^{(s)}$ is a wavelet if it is orthogonal to $\mathcal{V}_{-1}^{(s)}$. Let $\mathcal{W}_{-1}^{(s)}$ be the orthogonal of $\mathcal{V}_{-1}^{(s)}$ in $\mathcal{V}_0^{(s)}$. We wish to construct a Riesz basis of $\mathcal{W}_{-1}^{(s)}$. The fundamental property which makes things possible is

Property 4.1: Let $s>n/2$ be an integer. Then the orthogonal subspace, in $\mathbb{L}^2(\mathbb{R}^n)$, of $\mathcal{V}_0^{(s)}$ is $\Delta^s K_{2s}=\{\Delta^s h, h\in H^{2s}(\mathbb{R}^n), \forall\lambda\in\Lambda, h(\lambda)=0\}$.

Proof: If $f\in\mathcal{V}_0^{(s)}$ and if $h=\Delta^s h_1$ with $h_1\in K_{2s}$ then $\int_{\mathbb{R}^n} fh=\langle\Delta^s f,h_1\rangle=0$. Hence $\mathcal{V}_0^{(s)}$ is included in the orthogonal of $\Delta^s K_{2s}$.

Conversely let $f\in\mathbb{L}^2(\mathbb{R}^n)$ be orthogonal to $\Delta^s K_{2s}$. We call φ a C^∞ function, equal to 1 at 0, and with support sufficiently small so that all $\lambda+\text{supp }\varphi$ are disjoined. Then for any $g\in C_0^\infty$, $g(x)-\Sigma_{\lambda\in\Lambda} g(\lambda)\varphi(x-\lambda)$ is in K_{2s}. Hence

$$\int_{\mathbb{R}^n} f(x)\Delta^s\left(g(x)-\sum_{\lambda\in\Lambda} g(\lambda)\varphi(x-\lambda)\right)dx=0$$

and

$$\langle\Delta^s f,g\rangle=\sum_{\lambda\in\Lambda}\langle f,\Delta^s\varphi(x-\lambda)\rangle g(\lambda)$$

which means that $f\in\mathcal{V}_0^{(s)}$. □

The construction of a basis of $\mathcal{W}_{-1}^{(s)}$ is straightforward:

Property 4.2: The wavelets family:

$$\{\Psi_\lambda^{(s)}(x)=\Delta^s\mathcal{L}_\lambda^{(2s)}(x),\ \lambda\in\Lambda\backslash\theta\Lambda\}$$

is a Riesz basis of $\mathcal{W}_{-1}^{(s)}$.

Proof: Consider $f\in\mathbb{L}^2(\mathbb{R}^n)$ orthogonal to $\mathcal{V}_{-1}^{(s)}$. Then there exists $h\in H^{2s}(\mathbb{R}^n)$ vanishing on $\theta\Lambda$ such that $f=\Delta^s h$. Moreover if $f\in\mathcal{V}_0^{(s)}$ then $h\in\mathcal{V}_0^{(2s)}$. We deduce that h can be written in $H^{2s}(\mathbb{R}^n)$:

$$h(x)=\sum_{\lambda\in\Lambda} h(\lambda)\mathcal{L}_\lambda^{(2s)}(x).$$

Since h vanishes on $\theta\Lambda$, we have:

$$h(x)=\sum_{\lambda\in\Lambda\backslash\theta\Lambda} h(\lambda)\mathcal{L}_\lambda^{(2s)}(x).$$

Hence f can be written in $\mathbb{L}^2(\mathbb{R}^n)$:

$$f(x)=\sum_{\lambda\in\Lambda\backslash\theta\Lambda} h(\lambda)\Delta^s\mathcal{L}_\lambda^{(2s)}(x).$$

Once again h vanishes on $\theta\Lambda$, hence, by property 3.2, its H^{2s} norm is equivalent to $\|\Delta^s h\|_{\mathbb{L}^2} = \|f\|_{\mathbb{L}^2}$. h is in $\mathcal{V}_0^{(2s)}$ hence $\|h\|_{H^{2s}}$ is equivalent to $(\Sigma_{\lambda\in\Lambda}|h(\lambda)|^2)^{1/2}$. Finally the $\mathbb{L}^2$ norm of $\Sigma_{\lambda\in\Lambda\setminus\theta\Lambda}\ a_\lambda \Delta^s \mathcal{L}_\lambda^{(2s)}(x)$ is equivalent to the l^2 norm $(\Sigma_{\lambda\in\Lambda\setminus\theta\Lambda}\ |a_\lambda|^2)^{1/2}$. □

As a corollary of the preceeding results, we obtain a Riesz basis of $\mathbb{L}^2(\mathbb{R}^n)$ composed with regular wavelets:

Theorem 4.1: *Let Λ be a self-similar quasicrystal in $\mathbb{R}^n$ with inflation $\theta>1$. Then for any integer $s>n/2$, there exists a Riesz basis of $\mathbb{L}^2(\mathbb{R}^n)$ having the following structure:*

$$\theta^{nj/2}\psi_\lambda^{(s)}(\theta^j x-\lambda),\quad \lambda\in\Lambda\setminus\theta\Lambda,\quad j\in\mathbb{Z}.$$

The wavelets $\psi_\lambda^{(s)}$ belong to $H^{2s-\sigma}(\mathbb{R}^n)$ for any $\sigma>n/2$. Moreover any $f\in\mathbb{L}^2(\mathbb{R}^n)$ can be expanded into a unique orthogonal series:

$$f=\sum_{j\in\mathbb{Z}} f_j,$$

where for each integer j:

$$f_j(x)=\sum_{\lambda\in\Lambda\setminus\theta\Lambda} a_{j,\lambda}\theta^{nj/2}\psi_\lambda^{(s)}(\theta^j x-\lambda).$$

Proof: Let $\psi_\lambda^{(s)}(x-\lambda)=\Psi_\lambda^{(s)}(x)=\Delta^s\mathcal{L}_\lambda^{(2s)}(x)$. We use the following results:
(*i*) $\mathbb{L}^2(\mathbb{R}^n)=\oplus_{j\in\mathbb{Z}}\mathcal{W}_j^{(s)}$ where the sum is orthogonal.
(*ii*) The collection of functions $\theta^{nj/2}\Psi_\lambda^{(s)}(\theta^j x)$, $\lambda\in\Lambda\setminus\theta\Lambda$, is a Riesz basis of $\mathcal{W}_j^{(s)}$. □

V. STUDY OF THE MOTHER WAVELETS

In this section, we shall study the set of mother wavelets $\mathcal{M}_s=\{\psi_\lambda^{(s)},\lambda\in\Lambda\setminus\theta\Lambda\}$. First, we will show that wavelets $\psi_\lambda^{(s)}$ have exponential decay in a strong sense. Second, we will evaluate how different wavelets $\psi_\lambda^{(s)}$ are one from the other. Indeed if Λ is a lattice, $\mathcal{M}_s$ consists of one single function thanks to translation invariance. If Λ is aperiodic, $\mathcal{M}_s$ will lose its finiteness and will become a relatively compact set in some Sobolev space.

Wavelets $\psi_\lambda^{(s)}$ are very well localized functions as stated in the following result:

Theorem 5.1: *Let $s>n/2$ be an integer and let Λ be a self-similar quasicrystal in $\mathbb{R}^n$ with inflation $\theta>1$. Then there exist two constants $A=A(\Lambda,s)>0$ and $\beta=\beta(\Lambda,s)>0$ such that, for any $\lambda\in\Lambda\setminus\theta\Lambda$ and for any multi-index α whose length is strictly less than $2s-n$, the following estimate holds:*

$$|\partial^\alpha\psi_\lambda^{(s)}(x)|\leqslant Ae^{-\beta|x|}.$$

The proof relies on a fundamental property which can be seen as a local Bernstein inequality:

Property 5.1: Let $s>n/2$ be an integer. Consider a Delaunay set Λ in $\mathbb{R}^n$ and a radius $r>0$ such that each open ball $B_{x,2r}$ contains at most one point of Λ. Then there exists $C=C(\Lambda,s,r)$ such that, for any f in $\mathcal{V}_0^{(s)}(\Lambda)$, for any $\sigma\in]0,2s-n/2[$ and for any open ball $B_{x,r}$ centered on a point of Λ or whose distance to Λ exceeds 0, the following estimate holds:

$$\|f\|_{H^\sigma(B_{x,r/2})}\leqslant C\|f\|_{\mathbb{L}^2(B_{x,r})}. \tag{3}$$

Here the norm $\|f\|_{H^\sigma(B)}$ is the ''restriction'' Sobolev norm defined by $\inf\|F\|_{H^\sigma(\mathbb{R}^n)}$ where $F\in H^\sigma(\mathbb{R}^n)$ and where $F=f$ on B.

Proof: Let f be in $\mathcal{V}_0^{(s)}$ and $\lambda\in\Lambda$. On $B_{\lambda,r}$, f satisfies $\Delta^s f=\gamma\delta_\lambda$ for some $\gamma\in\mathbb{R}$. Translating f if necessary, we can restrict our attention to the case where $\lambda=0$ and for the sake of simplicity we will assume $r=1$. Let $B=B_{0,1}$ and let us show the following preliminary inequality:

$$\|f\|_{H^\sigma(B/2)}\leqslant C|\gamma|+C'\|f\|_{\mathbb{L}^2(B)},\quad \sigma\in]0,2s-n/2[,$$

where C and C' depend only on s and $|B|$.

First case: $\gamma=0$

Define $\tilde{f}\in\mathbb{L}^2(\mathbb{R}^n)$ to coincide with f on B and to vanish outside B. Then $S=\Delta^s\tilde{f}$ is a distribution belonging to $H^{-2s}(\mathbb{R}^n)$ and whose support is included in $|t|=1$. Let E be the fundamental solution of Δ^s given by

$$E(t)=c(s,n)|t|^{2s-n}(\log|t|)^{\epsilon},$$

where $\epsilon=0$ if n is odd and $\epsilon=1$ if n is even (see, e.g., Ref. 16). Then

$$\Delta^s(\tilde{f}\star E)=\tilde{f}$$

and

$$\tilde{f}=S\star E.$$

If $|t|<1/2$, $y\to E(t-y)$ coincides, in a neighborhood of supp S, with a C^∞ function $y\to E'(t,y)$ vanishing outside $|y|\leqslant 2$ and the following uniform estimate holds

$$\sup_{|t|<1/2}\|E'(t,\cdot)\|_{H^{2s}(\mathbb{R}^n)}<C_s.$$

Thus, for $|\alpha|\leqslant 2s-[n/2]=q$, ($[x]$ denotes the integral part of x):

$$|\partial^\alpha f(t)|\leqslant C_s\|S\|_{H^{-2s}}\leqslant C_s\|f\|_{\mathbb{L}^2(B)}.$$

Integrating on $B/2$ gives

$$\|f\|_{H^q(B/2)}\leqslant C_s\|f\|_{\mathbb{L}^2(B)}.$$

Hence, by interpolation, the same inequality holds when replacing q by $\sigma\in]0,2s-n/2[$.

Second case: $\gamma=1$

f can be written $f=g+E$ where E is defined above and where g satisfies $\Delta^s g=0$. E is in $\mathbb{L}^2(B)$ and hence so is g. The preceeding estimate then holds for g,

$$\|g\|_{H^\sigma(B/2)}\leqslant C_s\|g\|_{\mathbb{L}^2(B)},\quad \sigma\in]0,2s-n/2[.$$

Then observe that $E\in H^\sigma(B)$, $\sigma\in]0,2s-n/2[$, since $E=f-g$. Therefore

$$\|f\|_{H^\sigma(B/2)}\leqslant C_s\|g\|_{\mathbb{L}^2(B)}+\|E\|_{H^\sigma(B/2)}\leqslant C_s\|f\|_{\mathbb{L}^2(B)}+(1+C_s)\|E\|_{H^\sigma(B/2)}\leqslant C_s\|f\|_{\mathbb{L}^2(B)}+C_s'.$$

One can deduce the general case $\gamma\in\mathbb{R}$ using a homogeneity argument. Let $\varphi\in C_0^\infty$ be a function with value 1 at 0 and vanishing for $|x|\geqslant r$. One has

$$\gamma=\langle\gamma\delta_0,\varphi\rangle=\langle\Delta^s f,\varphi\rangle=\langle f,\Delta^s\varphi\rangle$$

hence $|\gamma|\leqslant C\|f\|_{\mathbb{L}^2(B)}$ and 5.1 holds true when $B_{x,r}$ is centered on a point $\lambda\in\Lambda$. If the distance from $B_{x,r}$ to Λ exceeds 0 then things work just as in the preceeding case where $\gamma=0$. □

Proof of theorem 5.1: Write $\mathcal{L}_\lambda^{(s)}(x)=L_\lambda^{(s)}(x-\lambda)$. Let α be a multi-index with $|\alpha|<2s-n$. Choose $\sigma>n/2$ such $|\alpha|+\sigma<2s-n/2$. Then using Sobolev injections

$$|\partial^\alpha L_\lambda^{(s)}(x)|\leqslant C_{\sigma,r}\|\partial^\alpha L_\lambda^{(s)}\|_{H^\sigma(B_{x,r/2})}\leqslant C_{\sigma,r,\alpha}\|L_\lambda^{(s)}\|_{H^{\sigma+|\alpha|}(B_{x,r/2})}$$

since $\sigma+|\alpha|<2s-n/2$, property 5.1 applies and we obtain

$$|\partial^\alpha L_\lambda^{(s)}(x)|\leqslant C'_{\sigma,r,\alpha}\|L_\lambda^{(s)}\|_{\mathbb{L}^2(B_{x,r})}.$$

Finally using the exponential decay of $L_\lambda^{(s)}$ given in theorem 3.2, we get

$$|\partial^\alpha L_\lambda^{(s)}(x)|\leqslant C''_{\sigma,r,\alpha}e^{-\beta|x|}.$$

Consequently the same estimates hold true for $\psi_\lambda^{(s)}$ since $\psi_\lambda^{(s)}=\Delta^s L_\lambda^{(2s)}$. □

We, now, wish to study the deformation $\lambda \to \psi_\lambda^{(s)}$ in order to measure how different wavelets $\psi_\lambda^{(s)}$ are one point to another. To achieve this goal, we introduce a topology on Λ that will make it precompact.

Property 5.2: Let Λ be an aperiodic Delaunay set in $\mathbb{R}^n$. Define a mapping d on Λ^2 by the rule $d(\lambda,\lambda')=R^{-1}$ if R is the supremum of all $r>0$ such that $\Lambda-\lambda$ and $\Lambda-\lambda'$ coincide on $B_{0,r}$. Then d is a distance on Λ called local configurations distance. Moreover, if Λ is an aperiodic quasicrystal, (Λ,d) is precompact.

Proof: If $d(\lambda,\lambda')=0$ then $\Lambda-\lambda$ and $\Lambda-\lambda'$ coincide on the whole space. Hence $\lambda-\lambda'+\Lambda=\Lambda$ which forces $\lambda=\lambda'$ since Λ is aperiodic. Let λ, λ', and λ'' be three points in Λ. Put $d(\lambda,\lambda'')=a^{-1}$, $d(\lambda,\lambda')=b^{-1}$, $d(\lambda'',\lambda')=c^{-1}$ and $\rho\in]0,1[$. $\Lambda-\lambda$ and $\Lambda-\lambda'$ coincide on $B_{0,\rho b}$ whereas $\Lambda-\lambda''$ and $\Lambda-\lambda'$ coincide on $B_{0,\rho c}$. Therefore $\Lambda-\lambda$ and $\Lambda-\lambda''$ coincide on $B_{0,\rho\ \min(b,c)}$. Hence $a\geqslant\rho\ \min(b,c)$ and $a^{-1}\leqslant b^{-1}+c^{-1}$. Suppose Λ is an aperiodic quasicrystal and let $\epsilon>0$. Using property 2.1, we know that $(\Lambda-\lambda)\cap B_{0,\epsilon^{-1}}$ describes a finite set as λ goes through Λ. Hence Λ can be covered with a finite number of d-balls with radius ϵ. □

We are ready to state the second result concerning the set $\mathcal{M}_s$:

Theorem 5.2: *Let $s>n/2$ be an integer and let Λ be a self-similar quasicrystal in $\mathbb{R}^n$ with inflation $\theta>1$. Then the mapping*

$$\lambda\in\Lambda\backslash\theta\Lambda\to\psi_\lambda^{(s)}\in H^{2s-[n/2]-1}(\mathbb{R}^n)$$

is continuous when Λ is equipped with the local configurations distance.

Proof: Let $\epsilon>0$ and $\lambda\in\Lambda\backslash\theta\Lambda$. We use a technical result of Lemarié-Rieusset[7] ensuring that there exists a family of functions $g_{\lambda,j}$, $\lambda\in\Lambda$, $j\in\mathbb{N}$, such that

$$\lim_{j\to\infty}\ \sup_{\lambda\in\Lambda}\|L_\lambda^{(2s)}-g_{\lambda,j}\|_{H^{2s}}=0$$

and such that $g_{\lambda,j}$ depends only on the set $(\Lambda-\lambda)\cap B_{0,R_j}$ where $(R_j)_j$ is an unbounded increasing sequence. Therefore choose j such that $\sup_{\lambda\in\Lambda}\|L_\lambda^{(2s)}-g_{\lambda,j}\|_{H^{2s}}\leqslant\epsilon$ and λ' such that $d(\lambda,\lambda')\leqslant R_j^{-1}$. Then

$$\|L_\lambda^{(2s)}-L_{\lambda'}^{(2s)}\|_{H^{2s}}\leqslant\|L_\lambda^{(2s)}-g_{\lambda,j}\|_{H^{2s}}+\|g_{\lambda,j}-g_{\lambda',j}\|_{H^{2s}}+\|g_{\lambda',j}-L_{\lambda'}^{(2s)}\|_{H^{2s}}\leqslant 2\epsilon.$$

Since Λ is a quasicrystal, $\Lambda-\Lambda$ is a Delaunay set and each $L_\lambda^{(2s)}$ belongs to $\mathcal{V}_0^{(2s)}(\Lambda-\Lambda)$. We then apply property 5.1 to the Delaunay set $\Lambda-\Lambda$ and observe that inequalities (3) can be turned into global estimates which show that $\|f\|_{H^{2s}}$ and $\|f\|_{H^{4s-[n/2]-1}}$ are equivalent norms on $\mathcal{V}_0^{(2s)}(\Lambda-\Lambda)$. Hence

$$\|L_\lambda^{(2s)}-L_{\lambda'}^{(2s)}\|_{H^{4s-[n/2]-1}}\leqslant 2C\epsilon$$

and since $\psi_\lambda^{(s)}=\Delta^s L_\lambda^{(2s)}$:

$$\|\psi_\lambda^{(s)}-\psi_{\lambda'}^{(s)}\|_{H^{2s-[n/2]-1}}\leqslant 2C\epsilon.$$ □

Consequence 5.1: The set $\mathcal{M}_s$ is relatively compact in $H^{2s-[n/2]-1}(\mathbb{R}^n)$.

Proof: This follows from the precompacity of (Λ,d) and the continuity of $\Lambda\to\psi_\lambda^{(s)}$. □

VI. COMPACTLY SUPPORTED WAVELETS ADAPTED TO A SELF-SIMILAR QUASICRYSTAL IN $\mathbb{R}$

We now restrict our attention to the one-dimensional case and the quasicrystal Λ can be considered as a strictly increasing sequence $(\lambda_k)_{k\in\mathbb{Z}}$. We wish to construct a Riesz basis of $\mathbb{L}^2(\mathbb{R})$ composed with compactly supported wavelets adapted to Λ and to its self-similarity. This means that the basis should have the following structure:

$$\theta^{j/2}\psi_\lambda(\theta^j x-\lambda),\quad j\in\mathbb{Z},\quad \lambda\in\Lambda.$$

Once again we will introduce a multiresolution analysis $(V_j^{(s)})_{j\in\mathbb{Z}}$ and then obtain the wavelet basis.

Let s be an integer greater than 1. We call $V_0^{(s)}$ the closed subspace of $\mathbb{L}^2(\mathbb{R})$ of all functions whose derivative of order s (in the sense of distributions) is a sum of Dirac masses located on Λ,

$$\frac{d^s}{dx^s} f = \sum_{\lambda\in\Lambda} a_\lambda \delta_\lambda .$$

With the notations of Sec. III, $V_0^{(2s)} = \mathcal{V}_0^{(s)}$.

It is equivalent to defining $V_0^{(s)}$ as the subspace of functions in C^{s-2}, in $\mathbb{L}^2(\mathbb{R})$ and whose restriction to each $[\lambda_k,\lambda_{k+1}]$ is a polynomial of degree $s-1$. These spline spaces have been widely studied. Nevertheless the context of a self-similar quasicrystal is interesting because it involves irrational inflations (Pisot or Salem numbers) which is quite unusual in the field of wavelets.

A. Riesz basis of $V_0^{(s)}$ composed with translates of a finite number of compactly supported functions

One can find many references about one-dimensional splines with knots located on a Delaunay set (see e.g., Ref. 17 or 18) so only classical results will be recalled. The first one deals with a Riesz basis of $V_0^{(s)}$:

Theorem 6.1: *Let Λ be a Delaunay set in $\mathbb{R}$. For any integer $s\geqslant 2$, there exists a Riesz basis of $V_0^{(s)}$, $\{B_\lambda^{(s)}(x),\lambda\in\Lambda\}$, defined as follows:*
$B_\lambda^{(s)}$ is the unique function in $V_0^{(s)}$ satisfying
(i) supp $B_\lambda^{(s)} = [\lambda,\lambda']$ *where* $\lambda'\in\Lambda$.
(ii) $]\lambda,\lambda'[$ *contains exactly* $s-1$ *points of* Λ.
(iii) $\int_{\mathbb{R}} B_\lambda^{(s)}(x)dx = (\lambda'-\lambda)/s$.
One can refer to Ref. 17 for a proof.
Now if Λ is a quasicrystal, the B-spline basis has a very simple structure:

Corollary 6.1: If Λ is a quasicrystal in $\mathbb{R}$, the B-spline basis of $V_0^{(s)}$ can be written

$$\{\varphi_\lambda(x-\lambda),\ \ \lambda\in\Lambda\},$$

where the set $\{\varphi_\lambda(x),\lambda\in\Lambda\}$ is a finite set of compactly supported functions:

Proof: It is straightforward since the B-spline $B_{\lambda_k}^{(s)}$ depends only on the local structure $\Lambda\cap[\lambda_k,\lambda_{k+s}]$ and since the quasicrystal Λ has only a finite number of local configurations $[\lambda_k,\lambda_{k+s}]-\lambda_k$ when k goes through $\mathbb{Z}$. □

B. Compactly supported wavelets

As in the n-dimensional case, we define a multiresolution analysis involving Λ's scaling property:

$$f\in V_j^{(s)} \Leftrightarrow f(\theta^{-j}x)\in V_0^{(s)} .$$

Then once again the sequence $(V_j)_j$ is a multiresolution analysis and the problem is to construct a Riesz basis of $W_{-1}^{(s)}$, the orthogonal subspace of $V_{-1}^{(s)}$ in $V_0^{(s)}$:

$$V_0^{(s)} = V_{-1}^{(s)} \oplus^{\perp} W_{-1}^{(s)} .$$

Let us prove the following result:

Theorem 6.2: *Let Λ be a self-similar quasicrystal with inflation $\theta>1$. Then for each $s>1$, there exists a Riesz basis of $W_{-1}^{(s)}$ having the following structure:*

$$\psi_\lambda^{(s)}(x-\lambda),\ \ \lambda\in\Lambda\backslash\theta\Lambda,$$

where $\{\psi_\lambda^{(s)},\lambda\in\Lambda\backslash\theta\Lambda\}$ is a finite set of compactly supported wavelets.

This result should be connected with a method developed by Buhmann and Micchelli[8] to construct spline wavelets. Let us first recall the setting of the problem in Ref. 8:

Given two embedded Delaunay sets $\Lambda_{-1}\subset\Lambda_0$, does there exist a Riesz basis of the orthogonal supplement of $V_0^{(s)}(\Lambda_{-1})$ in $V_0^{(s)}(\Lambda_0)$ composed with compactly supported functions?

Our problem is a similar one since $\theta\Lambda$ is a Delaunay set included in Λ and since $V_{-1}^{(s)} = V_0^{(s)}(\theta\Lambda)$. But its originality comes from the finite number of mother wavelets and also from the fact that our wavelets satisfy some scaling equations involving an irrational scale.

Proof of theorem 6.2: We first observe that $W_{-1}^{(s)}$ has an explicit characterization just as it works in property 4.1: for any integer $s\geqslant 2$, $W_{-1}^{(s)}$ is the set of $f\in\mathbb{L}^2(\mathbb{R})$ which can be written

$$f=\frac{d^s}{dx^s}\,g,$$

where $g\in V_0^{(2s)}$ and where g vanishes on $\theta\Lambda$.

Therefore the idea is to study the subspace $\widetilde{W}_0^{(s)}$ of $V_0^{(s)}$ of functions which vanish on $\theta\Lambda$. We are going to construct a Riesz basis of $\widetilde{W}_0^{(2s)}$ composed with compactly supported functions. Then by differentiation, wavelets of $W_{-1}^{(s)}$ will be obtained. To achieve this goal, the main idea is to look for functions in $\widetilde{W}_0^{(s)}$ with minimal support. Precisely we denote by E the set of integers k such that $\lambda_{k+1}\notin\theta\Lambda$, and for each $k\in E$, define $\Psi_k^{(s)}$ as the unique element in $\widetilde{W}_0^{(s)}$ satisfying the following conditions:

(i) the support of $\Psi_k^{(s)}$ is compact and included in $[\lambda_k,+\infty)$,
(ii) $\Psi_k^{(s)}(\lambda_{k+1})=1$,
(iii) any function in $\widetilde{W}_0^{(s)}$ whose support is included in the support of $\Psi_k^{(s)}$ is proportional to $\Psi_k^{(s)}$.

Then we can state:

Theorem 6.3: *The collection $\{\Psi_k^{(s)},k\in E\}$ is a Riesz basis of $\widetilde{W}_0^{(s)}$.*

Sketch of the proof: This result can be found in detail in Ref. 5. We will only recall the main steps to the proof:

Proposition 6.1: For any $k\in E$, the support of $\Psi_k^{(s)}$ writes $[\lambda_k,\lambda_{k+N_k}]$ where N_k is the smallest integer greater than s such that:

$$N_k=s+\mathrm{card}(]\lambda_k,\lambda_{k+N_k}[\cap\theta\Lambda).$$

Proposition 6.2: There exists a finite set $\mathcal{G}_s$ of compactly supported functions such that for each $k\in E$, $\Psi_k^{(s)}(x+\lambda_k)\in\mathcal{G}_s$.

Proposition 6.3: Any function in $\widetilde{W}_0^{(s)}$ with compact support is a linear combination of $\Psi_k^{(s)},k\in E$.

Proposition 6.4: The set of all functions in $\widetilde{W}_0^{(s)}$ with compact support is dense in $\widetilde{W}_0^{(s)}$.

Proposition 6.5: There exist $0<c_1\leqslant c_2$ depending only on s and Λ such that for any real sequence $(\alpha_k)_{k\in E}$ with finite support

$$c_1\sum_{k\in E}|\alpha_k|^2\leqslant\left\|\sum_{k\in E}\alpha_k\Psi_k^{(s)}\right\|_{\mathbb{L}^2}^2\leqslant c_2\sum_{k\in E}|\alpha_k|^2.$$

Theorem 6.3 is straightforward using these technical properties. Therefore one can deduce theorem 6.2: using property 3.2, $\|g\|_{\mathbb{L}^2}$ and $\|(d^s/dx^s)g\|_{\mathbb{L}^2}$ are equivalent norms on $\widetilde{W}_0^{(2s)}$. Then $\{(d^s/dx^s)\Psi_k^{(2s)},k\in E\}$ is a Riesz basis of $W_{-1}^{(s)}$ with the desired structure. □

As a corollary of theorem 6.2 we can state:

Corollary 6.2: Let Λ be a self-similar quasicrystal in $\mathbb{R}$ with inflation $\theta>1$. Then, for any integer $s>1$, there exists a Riesz basis of $\mathbb{L}^2(\mathbb{R})$ having the following structure:

$$\theta^{j/2}\psi_\lambda^{(s)}(\theta^j x-\lambda),\quad \lambda\in\Lambda\setminus\theta\Lambda,\quad j\in\mathbb{Z},$$

where $\{\psi_\lambda^{(s)},\lambda\in\Lambda\setminus\theta\Lambda\}$ is a finite set of C^{s-1} compactly supported functions.

This paper concerns square wave analysis, which is in no small part a generalization of the Fourier analysis based on sine and cosine functions. Following sine and cosine functions square waves become another frequently used and easily generated waveform in electronics, so it is an urgent practical problem to study the basic properties of square waves and the fundamental theory of square wave analysis. Like the sine-cosine function system, the square wave system, i.e., the function system of square waves with different frequencies (or periods), is linearly independent and complete in the real Hilbert spaces $L^2(-\pi,\pi)$, so square waves can approximate an arbitrary quadratically integrable function with a vanishing mean-square error. Since the square wave system is nonorthogonal, its biorthogonal functions are presented so that a function with a certain condition can be expanded as a square wave series easily. Meanwhile the orthogonalization of the square wave system is discussed so that a quadratically integrable function can be approximated best by a superposition of finite square waves. These results form the theory basis of the square wave analysis technique in modern electronics. © *1998 American Institute of Physics.* [S0022-2488(98)00808-1]

I. INTRODUCTION

About two hundred years ago, the French mathematician J. B. J. Fourier asserted that any function with period 2π can be expressed as a trigonometric series. This great idea has had an important influence upon many sciences including mathematics and physics. In electronics, Fourier analysis has been playing an important role, and a signal is often considered as a superposition of many sine and cosine waves with different frequencies. However, with the development of switching circuits and pulse technique, it becomes very easy to generate and process square waves. For example, it is quite convenient to obtain a system of square waves with different frequencies from a common high-frequency oscillation by means of counting circuits, whereas it is complicated to do the same thing with sine and cosine functions. Again, multipliers and summers for square waves are very simple. The following basic questions arise naturally:

(1) Can a signal be considered as a superposition of square waves with different frequencies (or periods)?
(2) How to decompose a signal into a square wave series?
(3) How to approximate a signal best by a superposition of finite square waves?

This problem is called square wave analysis, which is a natural generalization of Fourier's idea.

The aim of this paper is to answer these practical questions mathematically and lay a theory foundation for the square wave analysis technique in electronics. In terms of mathematics, we shall consider the following items one after another in $L^2(-\pi,\pi)$:

(1) Square wave system and its basic properties,

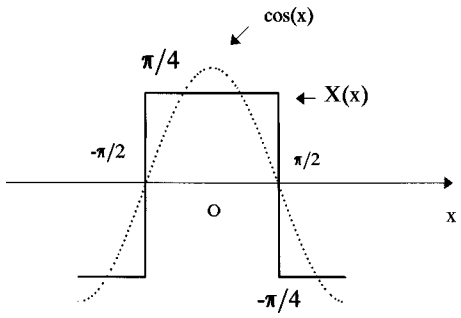

FIG. 1. The even square wave $X(x)$.

(2) biorthogonal functions and square wave series,
(3) orthogonalization and the best approximation.

In this paper $L^2(-\pi,\pi)$ denotes the Hilbert space of real quadratically integrable functions defined on $(-\pi,\pi)$, and $\langle,\rangle$ denotes the inner product in the space.

The results show that square wave analysis has a close relation with the Möbius function in the number theory unexpectedly.

II. SQUARE WAVE SYSTEM AND ITS BASIC PROPERTIES

Definition: The functions $X(x)$ and $Y(x)$ are called an even and odd square wave, respectively, which are defined on $(-\infty,+\infty)$ by

$$X(x)=\frac{\pi}{4}\operatorname{sgn}(\cos x), \tag{1}$$

and

$$Y(x)=\frac{\pi}{4}\operatorname{sgn}(\sin x). \tag{2}$$

Here sgn is the sign function:

$$\operatorname{sgn}(x)=\begin{cases} 1, & x>0 \\ 0, & x=0 \\ -1, & x<0. \end{cases} \tag{3}$$

For convenience let the amplitude of the square waves be $\pi/4$. See Figs. 1 and 2.

The Fourier series of the square waves are

$$X(x)=\cos x-\tfrac{1}{3}\cos(3x)+\tfrac{1}{5}\cos(5x)-\tfrac{1}{7}\cos(7x)+\ldots \tag{4}$$

$$=\sum_{n=1}^{\infty} A(n)\cos(nx), \tag{5}$$

and

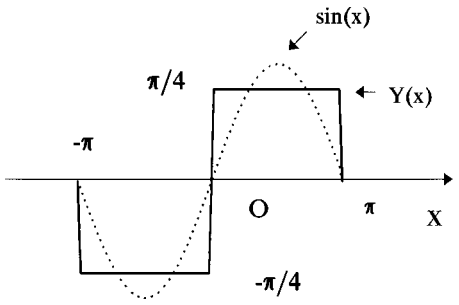

FIG. 2. The odd square wave $Y(x)$.

$$Y(x)=\sin x+\tfrac{1}{3}\sin(3x)+\tfrac{1}{5}\sin(5x)+\tfrac{1}{7}\sin(7x)+\cdots \tag{6}$$

$$=\sum_{n=1}^{\infty} B(n)\sin(nx). \tag{7}$$

Notice that the Fourier coefficients

$$A(n)=\begin{cases}(-1)^{(n-1)/2}\dfrac{1}{n}, & n=1,3,5,\ldots\\ 0, & n=2,4,6,\ldots\end{cases} \tag{8}$$

and

$$B(n)=\begin{cases}\dfrac{1}{n}, & n=1,3,5,\ldots\\ 0, & n=2,4,6,\ldots\end{cases} \tag{9}$$

have the property that

$$A(n)A(m)=A(mn) \tag{10}$$

and

$$B(n)B(m)=B(mn), \tag{11}$$

for any two positive integers m and n. We shall use this property many times.

Definition: We call the function system of square waves

$$1,X(x),Y(x),X(2x),Y(2x),\ldots,X(nx),Y(nx),\ldots \tag{12}$$

the square wave system.

By the way, please note that the square wave system defined here is quite different from the Walsh function system, which consists of very complicated rectangular waves (Ref. 1, Chap. 1). The Redemacher function system can be considered as a proper subset of the square wave system in essence, which is a well-known incomplete system (Ref. 1, Chap. 1).

In what follows we shall show that the square wave system is linearly independent, nonorthogonal and complete in $L^2(-\pi,\pi)$.

(1) Linear independence

Proposition 1: The function system of odd square waves

$$Y(x),Y(2x),Y(3x),\ldots,Y(nx),\ldots \tag{13}$$

is linearly independent, i.e., any finite subsystem of the function system is linearly independent.

Proof: We will prove that $\{Y(nx)\}_{n=1}^{N}$ is linearly independent for $N=2,3,4,\ldots$ by mathematical induction.

1^0. $Y(x)$ and $Y(2x)$ are linearly independent.

Notice that

$$c_1Y(x)+c_2Y(2x)=\begin{cases}\dfrac{\pi}{4}(c_1+c_2) & x\in\left(0,\dfrac{\pi}{2}\right)\\ \dfrac{\pi}{4}(c_1-c_2) & x\in\left(\dfrac{\pi}{2},\pi\right).\end{cases} \tag{14}$$

Therefore

$$\begin{aligned}&c_1Y(x)+c_2Y(2x)=0\\ \Rightarrow&\begin{cases}(c_1+c_2)=0\\(c_1-c_2)=0\end{cases}\\ \Rightarrow&c_1=c_2=0.\end{aligned}$$

2^0. If $\{Y(nx)\}_{n=1}^{k}$ is linearly independent, then so is $\{Y(nx)\}_{n=1}^{k+1}$.

Notice that

$$\begin{aligned}&c_1Y(x)+c_2Y(2x)+\ldots+c_kY(kx)+c_{k+1}Y((k+1)x)\\ =&\begin{cases}\dfrac{\pi}{4}(c_1+c_2+\ldots+c_k+c_{k+1}), & x\in\left(0,\dfrac{\pi}{k+1}\right)\\ \dfrac{\pi}{4}(c_1+c_2+\ldots+c_k-c_{k+1}), & x\in\left(\dfrac{\pi}{k+1},\dfrac{\pi}{k}\right).\end{cases}\end{aligned} \tag{15}$$

Therefore,

$$\begin{aligned}&c_1Y(x)+c_2Y(2x)+\ldots+c_kY(kx)+c_{k+1}Y((k+1)x)=0\\ \Rightarrow&\begin{cases}c_1+c_2+\ldots+c_k+c_{k+1}=0\\c_1+c_2+\ldots+c_k-c_{k+1}=0\end{cases}\\ \Rightarrow&c_{k+1}=0\\ \Rightarrow&c_1Y(x)+c_2Y(2x)+\ldots+c_kY(kx)=0\\ \Rightarrow&c_1=c_2=\ldots=c_k=0\\ \Rightarrow&c_1=c_2=\ldots=c_k=c_{k+1}=0.\end{aligned}$$

From 1^0 and 2^0, it follows that the function system of odd square waves $\{Y(nx)\}_{n=1}^{\infty}$ is linearly independent. □

It can be proved in the same way that the function system of even square waves

$$1,X(x),X(2x),\ldots,X(nx),\ldots \tag{16}$$

is linearly independent as well. Considering the orthogonality of even functions and odd functions, we have

Proposition 2: The square wave system is linearly independent.

(2) Nonorthogonality

Though odd square waves and even square waves are orthogonal, the square wave system is not an orthogonal system. In fact, we have the following inner product formulas.

Formula: For any two positive integers m and n, we have

$$\langle X(mx),X(nx)\rangle=\frac{\pi^3}{8}A\left(\frac{mn}{(m,n)^2}\right), \tag{17}$$

$$\langle Y(mx),Y(nx)\rangle=\frac{\pi^3}{8}B\left(\frac{mn}{(m,n)^2}\right), \tag{18}$$

where (m,n) denotes the greatest common divisor of m and n.

Proof:

$$\begin{aligned}\langle Y(mx),Y(nx)\rangle&=\left\langle\sum_{l=1}^{\infty}B(l)\sin(mlx),\sum_{k=1}^{\infty}B(k)\sin(nkx)\right\rangle\\&=\pi\sum_{ml=nk}B(l)B(k)\\&=\pi\sum_{r=1}^{\infty}B\left(\frac{r[m,n]}{m}\right)B\left(\frac{r[m,n]}{n}\right)\\&=\pi B\left(\frac{[m,n]^2}{mn}\right)\sum_{r=1}^{\infty}B(r^2)\\&=\frac{\pi^3}{8}B\left(\frac{mn}{(m,n)^2}\right).\end{aligned}$$

Here $[m,n]$ denotes the least common multiple of m and n, and we have

$$mn=(m,n)[m,n]. \tag{19}$$

The other equality can be deduced similarly. □

(3) Completeness

We have two basic series

$$\sin x=\sum_{n=1}^{\infty}\mu(n)B(n)Y(nx) \tag{20}$$

and

$$\cos x=\sum_{n=1}^{\infty}\mu(n)A(n)X(nx) \tag{21}$$

in $L^2(-\pi,\pi)$.

Here, $\mu(n)$ denotes the Möbius function (Ref. 2, Chap. 6), which is defined by

$$\mu(n)=\begin{cases}1, & \text{if } n=1\\(-1)^r, & \text{if } n \text{ is the product of } r \text{ distinct primes}\\0, & \text{if } n \text{ is divisible by a prime square.}\end{cases} \tag{22}$$

Notice that $\mu(n)$ takes three values $1,-1$, and 0 only. The first ten values are $\mu(1)=1$, $\mu(2)=-1$, $\mu(3)=-1$, $\mu(4)=0$, $\mu(5)=-1$, $\mu(6)=1$, $\mu(7)=-1$, $\mu(8)=0$, $\mu(9)=0$, $\mu(10)=1$.

The Möbius function has a simple property that

$$\sum_{d|n}\mu(d)=\begin{cases}1 & n=1\\0 & n=2,3,4,\ldots,\end{cases} \tag{23}$$

where the summation goes over the positive factors of n including 1 and n, and $d|n$ denotes that d is a factor of n. For example, for $n=6$, we have

$$\sum_{d|6} \mu(d)=\mu(1)+\mu(2)+\mu(3)+\mu(6)=0.$$

Proof of the series (20) and (21).

$$\sum_{n=1}^{\infty} \mu(n)B(n)Y(nx) \tag{24}$$

$$=\sum_{n=1}^{\infty} \mu(n)B(n)\sum_{m=1}^{\infty} B(m)\sin(mnx) \tag{25}$$

$$=\sum_{k=1}^{\infty}\left(\sum_{d|k} \mu(d)\right)B(k)\sin kx \tag{26}$$

$$=\sin x. \tag{27}$$

From (25) to (26) the summation order was changed, but this does not matter for the series encountered here are unconditionally convergent in $L^2(-\pi,\pi)$. The reason for unconditional convergence is that the series

$$\sum_{k=1}^{\infty}\left(\sum_{d|k} |\mu(d)|\right)|B(k)|\ \sin kx \tag{28}$$

is convergent, the norm square of which is

$$\pi\sum_{k=1}^{\infty}\left(\sum_{d|k} |\mu(d)|\right)^2 B^2(k)\leqslant \pi\sum_{k=1}^{\infty} d^2(k)B^2(k)$$

$$=\pi\left[\frac{1}{1^2}+\frac{d^2(3)}{3^2}+\frac{d^2(5)}{5^2}+\ldots\right]$$

$$=\frac{3}{128}\pi^5. \quad \text{(Reference 2, Sec. 6.14.)}$$

Here $d(k)$ denotes the number of positive factors of the positive integer k (Ref. 2, Chap. 6), and we have

$$\sum_{d|k} |\mu(d)|\leqslant d(k). \tag{29}$$

The series about cos$x$ can be discussed similarly. □

The convergence process of the series (20) is shown in Fig. 3. The first few square wave components contained in sin$x$ are shown in Fig. 4.

Proposition 3: The square wave system is complete in $L^2(-\pi,\pi)$.

Proof: Since the sine and cosine function system is complete in $L^2(-\pi,\pi)$, and sine and cosine functions can be expressed as a square wave series, the square wave system is complete in the Hilbert space $L^2(-\pi,\pi)$. In other words, superpositons of square waves can approximate an arbitrary quadratically integrable function with a vanishing mean-square error. □

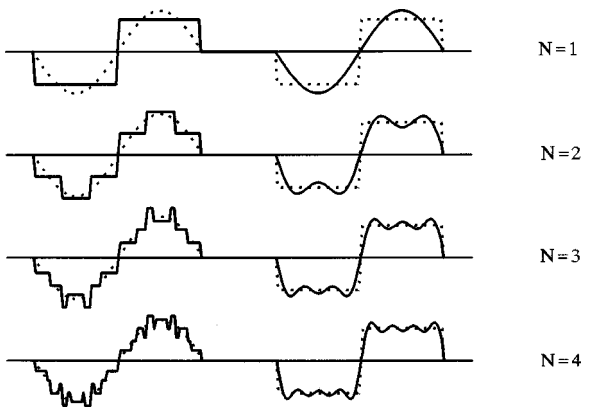

FIG. 3. The trigonometric polynomials $\Sigma_{k=1}^{N}(1/(2k-1))\sin((2k-1)x)$ approximate $Y(x)$, and the square wave polynomials $\Sigma_{k=1}^{N}[\mu(2k-1)/2k-1]\,Y((2k-1)x)$ approximate $\sin x$ as their term number N increase.

Remark: Since the square wave system is linearly independent and complete, one can synthesize any signal with many square waves with different frequencies by a summation circuit. See Fig. 5. However, due to its nonorthogonality, one needs a special method when decomposing a signal into square waves.

III. BIORTHOGONAL FUNCTIONS AND SQUARE WAVE SERIES

Proposition 4: If $f(x)\in L^2(-\pi,\pi)$ has a square wave series:

$$f(x)=C_0+\sum_{n=1}^{\infty}(C(n)X(nx)+D(n)Y(nx)), \tag{30}$$

then all the coefficients $C_0, C(n), D(n)$ are unique.

Proof: Suppose $f(x)$ has another square wave series:

$$f(x)=C_0'+\sum_{n=1}^{\infty}(C'(n)X(nx)+D'(n)Y(nx)). \tag{31}$$

So,

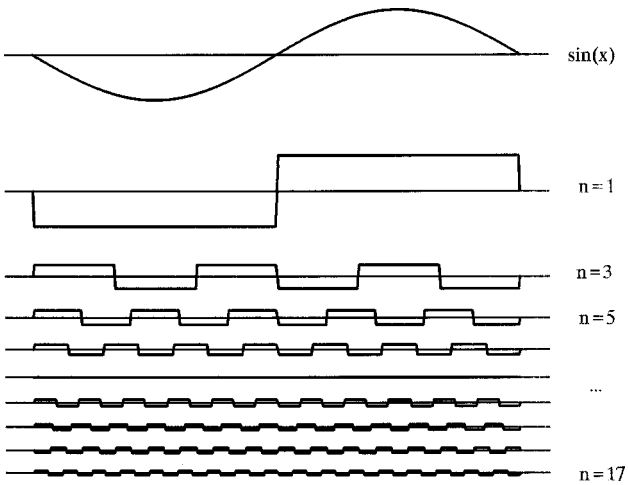

FIG. 4. The first few square wave components $\mu(n)B(n)Y(nx)$ contained in $\sin x$. ($n=1,3,5,7,9,11,13,15,17$.)

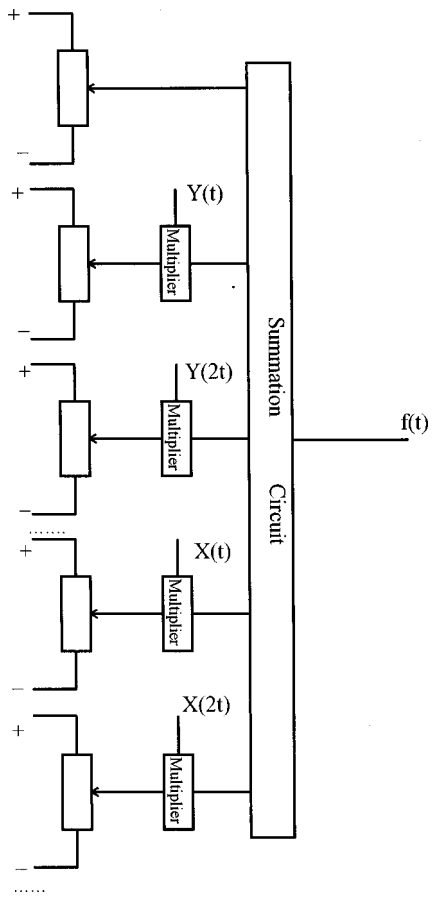

FIG. 5. Schematic diagram of synthesizing a time signal $f(t)$ by means of a series of square waves with different frequencies.

$$(C_0-C_0')+\sum_{n=1}^{\infty}((C(n)-C'(n))X(nx)+(D(n)-D'(n))Y(nx))=0.$$

Substituting their Fourier series for square waves $X(nx)$ and $Y(nx)$, one obtains that

$$a_0+\sum_{n=1}^{\infty}(a(n)\cos nx+b(n)\sin nx)=0, \tag{32}$$

where

$$a_0=C_0-C_0'=0,$$

$$a(n)=\sum_{d|n}A\left(\frac{n}{d}\right)(C(d)-C'(d))=0,$$

$$b(n)=\sum_{d|n}B\left(\frac{n}{d}\right)(D(d)-D'(d))=0.$$

Therefore (see Ref. 3, Chap, 2)

$$C_0-C_0'=0,$$

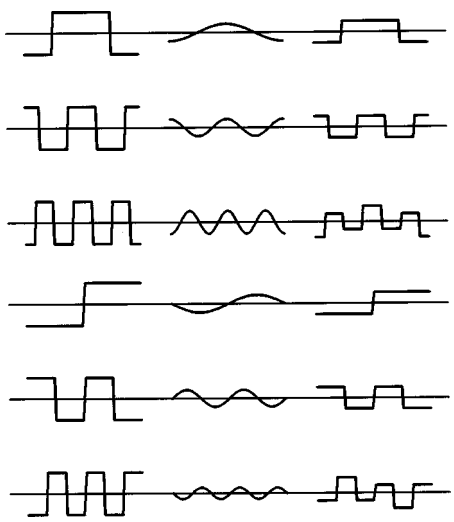

FIG. 6. Square waves, biorthogonal functions and orthonormalized functions.

$$C(n)-C'(n)=\sum_{d|n} 0\mu\left(\frac{n}{d}\right)A\left(\frac{n}{d}\right)=0,$$

$$D(n)-D'(n)=\sum_{d|n} 0\mu\left(\frac{n}{d}\right)B\left(\frac{n}{d}\right)=0.$$

In other words, $C_0, C(n), D(n)$ are unique. □

Definition: For $n=1,2,3,\ldots$, the functions $h_n(x)$ and $g_n(x)$ are defined by

$$h_n(x)=\frac{1}{\pi}\sum_{d|n} \mu\left(\frac{n}{d}\right)A\left(\frac{n}{d}\right)\cos dx, \tag{33}$$

and

$$g_n(x)=\frac{1}{\pi}\sum_{d|n} \mu\left(\frac{n}{d}\right)B\left(\frac{n}{d}\right)\sin dx, \tag{34}$$

respectively.

Example: When $n=1,2,3$, we have

$$h_1(x)=\frac{1}{\pi}\cos x, \quad h_2(x)=\frac{1}{\pi}\cos 2x, \quad h_3(x)=\frac{1}{\pi}\left(\cos 3x+\frac{1}{3}\cos x\right),$$

and

$$g_1(x)=\frac{1}{\pi}\sin x, \quad g_2(x)=\frac{1}{\pi}\sin 2x, \quad g_3(x)=\frac{1}{\pi}\left(\sin 3x-\frac{1}{3}\sin x\right),$$

as shown in Fig. 6. In Fig. 6, the graphs of 18 functions are arranged in the following order:

$$\begin{pmatrix} X(x) & h_1(x) & E_1(x) \\ X(2x) & h_2(x) & E_2(x) \\ X(3x) & h_3(x) & E_3(x) \\ Y(x) & g_1(x) & e_1(x) \\ Y(2x) & g_2(x) & e_2(x) \\ Y(3x) & g_3(x) & e_3(x) \end{pmatrix}$$

Proposition 5: For any two positive integers m and n, we have

$$\langle X(mx), h_n(x)\rangle = \delta_{mn}, \tag{35}$$

$$\langle Y(mx), g_n(x)\rangle = \delta_{mn}, \tag{36}$$

where δ_{mn} is the Kronecher's delta symbol.

Proof:

$$\begin{aligned}
\langle Y(mx), g_n(x)\rangle &= \left\langle \sum_{k=1}^{\infty} B(k)\sin(mkx), \frac{1}{\pi}\sum_{d|n} B\left(\frac{n}{d}\right)\mu\left(\frac{n}{d}\right)\sin dx \right\rangle \\
&= \sum_{m|d,d|n} B\left(\frac{n}{d}\right)\mu\left(\frac{n}{d}\right)B\left(\frac{d}{m}\right) \\
&= \begin{cases} 0, & m \nmid n \\ B\left(\dfrac{n}{m}\right)\displaystyle\sum_{m|d,d|n}\mu\left(\frac{n}{d}\right) = \begin{cases} 0, & \dfrac{n}{m} = 2,3,\ldots \\ 1, & \dfrac{n}{m} = 1 \end{cases} \end{cases} \\
&= \begin{cases} 0, & m \neq n \\ 1, & m = n \end{cases} \\
&= \delta_{mn}.
\end{aligned}$$

Here $m \nmid n$ denotes that m is not a factor of n.

The other relation in this proposition can be proved similarly. □

Proposition 6: The square wave system

$$1, X(x), Y(x), X(2x), Y(2x), \ldots, X(nx), Y(nx), \ldots \tag{37}$$

and the function system

$$\frac{1}{2\pi}, h_1(x), g_1(x), h_2(x), g_2(x), \ldots, h_n(x), g_n(x), \ldots \tag{38}$$

are biorthogonal.

Proof: Due to Proposition 5 and the orthogonality of even functions and odd functions, this proposition is plain. □

Proposition 7: If a function $f(x) \in L^2(-\pi, \pi)$ has a square wave series:

$$f(x) = C_0 + \sum_{n=1}^{\infty} (C(n)X(nx) + D(n)Y(nx)), \tag{39}$$

then the coefficients in the square wave series can be determined by

$$C_0=\frac{1}{2\pi}\int_{-\pi}^{+\pi} f(x)dx, \tag{40}$$

$$C(n)=\int_{-\pi}^{+\pi} f(x)h_n(x)dx, \tag{41}$$

$$D(n)=\int_{-\pi}^{+\pi} f(x)g_n(x)dx. \tag{42}$$

Proof: By Proposition 6, this proposition is plain. □

Consequence of Proposition 7: If a function $f(x)\in L^2(-\pi,\pi)$ has a square wave series:

$$f(x)=C_0+\sum_{n=1}^{\infty}\,(C(n)X(nx)+D(n)Y(nx)), \tag{43}$$

and its Fourier series is written as

$$f(x)=a_0+\sum_{n=1}^{\infty}\,(a(n)\cos nx+b(n)\sin nx), \tag{44}$$

then we have

$$C_0=a_0,\quad C(n)=\sum_{d|n}\,\mu\left(\frac{n}{d}\right)A\left(\frac{n}{d}\right)a(d),\quad D(n)=\sum_{d|n}\,\mu\left(\frac{n}{d}\right)B\left(\frac{n}{d}\right)b(d), \tag{45}$$

or inversely (Ref. 3, Chap. 2),

$$a_0=C_0,\quad a(n)=\sum_{d|n}\,A\left(\frac{n}{d}\right)C(d),\quad b(n)=\sum_{d|n}\,B\left(\frac{n}{d}\right)D(d). \tag{46}$$

Now a natural question is satisfying what conditions a function can be expanded as a square wave series. The following is a sufficient condition.

Proposition 8: Let the Fourier series of $f(x)\in L^2(-\pi,\pi)$ be

$$f(x)=a_0+\sum_{n=1}^{\infty}\,(a(n)\cos nx+b(n)\sin nx). \tag{47}$$

If the Fourier coefficients satisfy the condition

$$\sum_{n=1}^{\infty}\,a^2(n)d(n)<\infty, \tag{48}$$

$$\sum_{n=1}^{\infty}\,b^2(n)d(n)<\infty, \tag{49}$$

then we have

$$f(x)=C_0+\sum_{n=1}^{\infty}\,(C(n)X(nx)+D(n)Y(nx)), \tag{50}$$

where

$$C_0=a_0,\quad C(n)=\sum_{d|n}\,\mu\left(\frac{n}{d}\right)A\left(\frac{n}{d}\right)a(d),\quad D(n)=\sum_{d|n}\,\mu\left(\frac{n}{d}\right)B\left(\frac{n}{d}\right)b(d). \tag{51}$$

Proof:

$$f(x)=a_0+\sum_{n=1}^{\infty}(a(n)\cos nx+b(n)\sin nx) \tag{52}$$

$$=a_0+\sum_{n=1}^{\infty}a(n)\sum_{l=1}^{\infty}A(l)\mu(l)X(nlx)+\sum_{n=1}^{\infty}b(n)\sum_{l=1}^{\infty}B(l)\mu(l)Y(nlx) \tag{53}$$

$$=a_0+\sum_{n=1}^{\infty}\left(\sum_{d|n}a(d)\mu\left(\frac{n}{d}\right)A\left(\frac{n}{d}\right)\right)X(nx)+\sum_{n=1}^{\infty}\left(\sum_{d|n}b(d)\mu\left(\frac{n}{d}\right)B\left(\frac{n}{d}\right)\right)Y(nx) \tag{54}$$

$$=C_0+\sum_{n=1}^{\infty}(C(n)X(nx)+D(n)Y(nx)). \tag{55}$$

From (53) to (54), the summation orders were changed. But this does not matter because all the following series

$$\sum_{n=1}^{\infty}a(n)\sum_{l=1}^{\infty}A(l)\mu(l)X(nlx) \tag{56}$$

$$=\sum_{n=1}^{\infty}a(n)\sum_{l=1}^{\infty}A(l)\mu(l)\sum_{m=1}^{\infty}A(m)\cos(nlmx) \tag{57}$$

$$=\sum_{k=1}^{\infty}\left(\sum_{nlm=k}a(n)A(l)\mu(l)A(m)\right)\cos(kx) \tag{58}$$

and

$$\sum_{n=1}^{\infty}b(n)\sum_{l=1}^{\infty}B(l)\mu(l)Y(nlx) \tag{59}$$

$$=\sum_{n=1}^{\infty}b(n)\sum_{l=1}^{\infty}B(l)\mu(l)\sum_{m=1}^{\infty}B(m)\sin(nlmx) \tag{60}$$

$$=\sum_{k=1}^{\infty}\left(\sum_{nlm=k}b(n)B(l)\mu(l)B(m)\right)\sin(kx) \tag{61}$$

are unconditionally convergent in $L^2(-\pi,\pi)$, or one can say, they have sums independent of orders. The reason for the unconditional convergence is that the series

$$\sum_{k=1}^{\infty}\left(\sum_{nlm=k}|a(n)A(l)\mu(l)A(m)|\right)\cos(kx) \tag{62}$$

and

$$\sum_{k=1}^{\infty}\left(\sum_{nlm=k}|b(n)B(l)\mu(l)B(m)|\right)\sin(kx) \tag{63}$$

are convergent in $L^2(-\pi,\pi)$. As an example, the norm square of the series (62) is

$$\pi\sum_{k=1}^{\infty}\left(\sum_{nlm=k}|a(n)A(l)\mu(l)A(m)|\right)^2 \tag{64}$$

$$= \pi \sum_{k=1}^{\infty} \left(\sum_{nj=k} |a(n)||A(j)| \sum_{lm=j} |\mu(l)| \right)^2 \tag{65}$$

$$= \pi \sum_{k=1}^{\infty} \left(\sum_{nj=k} |a(n)|A'(j) \right)^2 \tag{66}$$

$$\leqslant \pi \sum_{k=1}^{\infty} d(k) \sum_{nj=k} a^2(n) A'^2(j) \tag{67}$$

$$\leqslant \pi \sum_{k=1}^{\infty} \sum_{nj=k} a^2(n) d(n) A'^2(j) d(j) \tag{68}$$

$$= \pi \sum_{n=1}^{\infty} a^2(n) d(n) \sum_{j=1}^{\infty} A'^2(j) d(j) \tag{69}$$

$$< \infty, \tag{70}$$

where

$$A'(j) = |A(j)| \sum_{l|j} |\mu(l)|. \tag{71}$$

From (67) to (68) we used (Ref. 2, Sec. 6.5)

$$d(nj) \leqslant d(n) d(j), \tag{72}$$

and from (69) to (70) we used

$$\sum_{j=1}^{\infty} A'^2(j) d(j) = \sum_{j=1}^{\infty} A^2(j) d(j) \left(\sum_{d|j} |\mu(d)| \right)^2$$

$$\leqslant \sum_{j=1}^{\infty} A^2(j) d^3(j) < \infty. \quad \text{(Ref. 2, Section 6.5)}$$

□

Definition: A subset K of $L^2(-\pi, \pi)$ is defined by

$$K = \left\{ f(x) \in L^2(-\pi, \pi) : f(x) = a_0 + \sum_{n=1}^{\infty} (a(n) \cos nx + b(n) \sin nx), \right.$$

$$\left. \text{where } \sum_{n=1}^{\infty} a^2(n) d(n) < \infty \text{ and } \sum_{n=1}^{\infty} b^2(n) d(n) < \infty \right\}.$$

Proposition 9: K is a linear subspace of $L^2(-\pi, \pi)$.
Proof: One can prove the following two items easily.
1^0. If $f(x) \in K$, then $cf(x) \in K$, where c is any real number.
2^0. If $f_1(x), f_2(x) \in K$, then $f_1(x) + f_2(x) \in K$. □
Proposition 10: The square wave system is a basis of the subspace K .
Proof: First of all, the square wave system is in K.
As an example, let us consider

$$Y(mx) = \sum_{l=1}^{\infty} B(l) \sin(lmx) = \sum_{n=1}^{\infty} b(n) \sin(nx). \tag{73}$$

It follows that

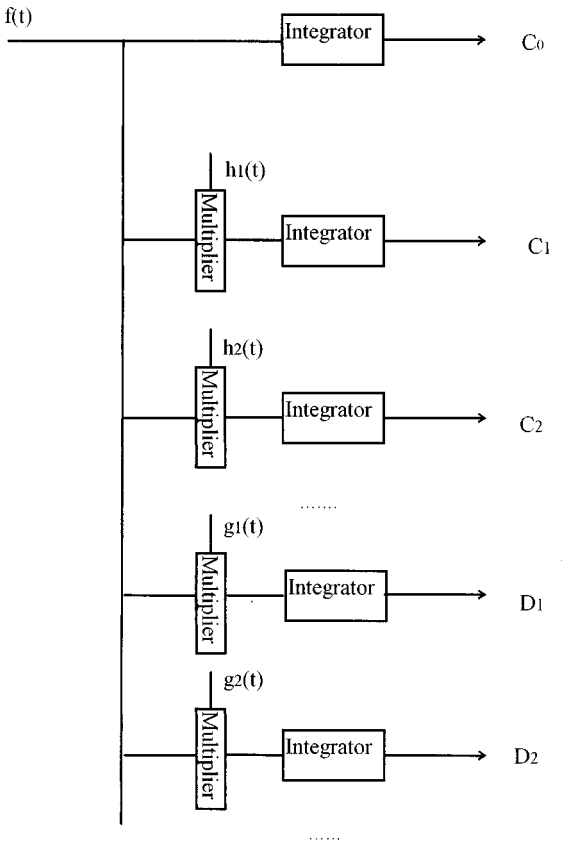

FIG. 7. Schematic diagram of decomposing a time signal into a series of square waves with different frequencies.

$$\sum_{n=1}^{\infty} b^2(n)d(n)=\sum_{l=1}^{\infty} B^2(l)d(ml)$$
$$\leqslant d(m)\sum_{l=1}^{\infty} B^2(l)d(l)$$
$$<\infty.$$

Second, by Proposition 4 and Proposition 8, the square wave system is a basis of the subspace K. □

Whether the square wave system is a basis of $L^2(-\pi,\pi)$ is still unknown.

Remark: A true signal always has little components with very high frequencies, so one can decompose any signal into the square wave series with the help of the biorthogonal functions, either by a computer program or by a specially designed device (see Fig. 7).

IV. ORTHOGONALIZATION AND THE BEST APPROXIMATION

Now that the square wave system is linearly independent, nonorthogonal and complete, one can get an orthonormal basis of $L^2(-\pi,\pi)$ by the Gram-Schmidt orthogonalization process.

Definition: The function $\beta(n)$ is defined on positive integers by

$$\beta(n)=\sum_{d|n} \mu(d)A^2(d)=\sum_{d|n} \mu(d)B^2(d). \tag{74}$$

For example, $\beta(1)=1$, $\beta(2)=1$, $\beta(3)=1-(\frac{1}{3})^2=\frac{8}{9}$.

Proposition 11: For $n=1,2,3,\ldots$, we have

$$\sum_{d|n} \beta(d)A^2\left(\frac{n}{d}\right)=\sum_{d|n} \beta(d)B^2\left(\frac{n}{d}\right)=1. \tag{75}$$

Proof:

$$\begin{aligned}\sum_{d|n} \beta(d)A^2\left(\frac{n}{d}\right)&=\sum_{d|n} A^2\left(\frac{n}{d}\right)\sum_{d'|d} \mu(d')A^2(d')\\&=\sum_{d|n}\sum_{d'|d} \mu(d')A^2\left(\frac{n}{d/d'}\right)\\&=\sum_{r|n} A^2\left(\frac{n}{r}\right)\sum_{d'|\frac{n}{r}} \mu(d')\\&=\sum_{r|n} A^2\left(\frac{n}{r}\right)\delta_{\frac{n}{r},1}\\&=A^2(1)=1.\end{aligned}$$

□

Definition: For $n=1,2,3,\ldots$, the functions $E_n(x)$ and $e_n(x)$ are defined by

$$E_n(x)=\frac{1}{\sqrt{\pi^3/8}}\frac{1}{\sqrt{\beta(n)}}\sum_{d|n} \mu\left(\frac{n}{d}\right)A\left(\frac{n}{d}\right)X(dx), \tag{76}$$

and

$$e_n(x)=\frac{1}{\sqrt{\pi^3/8}}\frac{1}{\sqrt{\beta(n)}}\sum_{d|n} \mu\left(\frac{n}{d}\right)B\left(\frac{n}{d}\right)Y(dx), \tag{77}$$

respectively.

Example: For $n=1,2,3$, we have

$$E_1(x)=\frac{1}{\sqrt{\pi^3/8}}X(x)\quad E_2(x)=\frac{1}{\sqrt{\pi^3/8}}X(2x)\quad E_3(x)=\frac{1}{\sqrt{\pi^3/9}}\left(X(3x)+\frac{1}{3}X(x)\right),$$

and

$$e_1(x)=\frac{1}{\sqrt{\pi^3/8}}Y(x)\quad e_2(x)=\frac{1}{\sqrt{\pi^3/8}}Y(2x)\quad e_3(x)=\frac{1}{\sqrt{\pi^3/9}}\left(Y(3x)-\frac{1}{3}Y(x)\right),$$

as shown in Fig. 6.

Proposition 12: Both $\{E_n(x)\}_{n=1}^{\infty}$ and $\{e_n(x)\}_{n=1}^{\infty}$ are orthonormal systems (ONS).

Proof:

$$\begin{aligned}&\langle E_m(x),E_n(x)\rangle\\&=\frac{1}{\pi^3/8}\frac{1}{\sqrt{\beta(m)}}\frac{1}{\sqrt{\beta(n)}}\sum_{d|m} A\left(\frac{m}{d}\right)\mu\left(\frac{m}{d}\right)\sum_{d'|n} A\left(\frac{n}{d'}\right)\mu\left(\frac{n}{d'}\right)\langle X(dx),X(d'x)\rangle\\&=\frac{1}{\sqrt{\beta(m)}}\frac{1}{\sqrt{\beta(n)}}\sum_{d|m} A\left(\frac{m}{d}\right)\mu\left(\frac{m}{d}\right)\sum_{d'|n} A\left(\frac{n}{d'}\right)\mu\left(\frac{n}{d'}\right)A\left(\frac{dd'}{(d,d')^2}\right)\end{aligned}$$

$$
\begin{aligned}
&= \frac{1}{\sqrt{\beta(m)}} \frac{1}{\sqrt{\beta(n)}} \sum_{d|m} A\left(\frac{m}{d}\right) \mu\left(\frac{m}{d}\right) \sum_{d'|n} A\left(\frac{n}{d'}\right) \mu\left(\frac{n}{d'}\right) A\left(\frac{dd'}{(d,d')^2}\right) \sum_{l|(d,d')} \beta(l) A^2\left(\frac{(d,d')}{l}\right) \\
&= \frac{1}{\sqrt{\beta(m)}} \frac{1}{\sqrt{\beta(n)}} \sum_{d|m} A\left(\frac{m}{d}\right) \mu\left(\frac{m}{d}\right) \sum_{d'|n} A\left(\frac{n}{d'}\right) \mu\left(\frac{n}{d'}\right) \sum_{l|(d,d')} \beta(l) A\left(\frac{d}{l}\right) A\left(\frac{d'}{l}\right) \\
&= \frac{1}{\sqrt{\beta(m)}} \frac{1}{\sqrt{\beta(n)}} \sum_{d|m} A\left(\frac{m}{d}\right) \mu\left(\frac{m}{d}\right) \sum_{l|d} \beta(l) A\left(\frac{d}{l}\right) \sum_{l|d',d'|n} A\left(\frac{n}{d'}\right) A\left(\frac{d'}{l}\right) \mu\left(\frac{n}{d'}\right) \\
&= \frac{1}{\sqrt{\beta(m)}} \frac{1}{\sqrt{\beta(n)}} \sum_{d|m} A\left(\frac{m}{d}\right) \mu\left(\frac{m}{d}\right) \sum_{l|d} \beta(l) A\left(\frac{d}{l}\right) \delta_{nl} \\
&= \frac{1}{\sqrt{\beta(m)}} \frac{1}{\sqrt{\beta(n)}} \sum_{n|d,d|m} A\left(\frac{m}{d}\right) \mu\left(\frac{m}{d}\right) A\left(\frac{d}{n}\right) \beta(n) \\
&= \delta_{mn}.
\end{aligned}
$$

Similarly, one has

$$\langle e_m(x), e_n(x) \rangle = \delta_{mn}. \qquad \square$$

Proposition 13: The function system

$$\frac{1}{\sqrt{2\pi}}, E_1(x), e_1(x), E_2(x), e_2(x), \ldots, E_n(x), e_n(x), \ldots \tag{78}$$

is an orthonormal basis of $L^2(-\pi, \pi)$.

Proof: The square wave system is linearly independent and complete, so its orthonormalized function system is an orthonormal basis of $L^2(-\pi, \pi)$. $\square$

Consequence of Proposition 13: Any function $f(x) \in L^2(-\pi, \pi)$ can be written as the following series:

$$f(x) = r_0 + \sum_{n=1}^{\infty} (r(n) E_n(x) + q(n) e_n(x)), \tag{79}$$

where

$$r_0 = \frac{1}{2\pi} \int_{-\pi}^{+\pi} f(x)\, dx, \tag{80}$$

$$r(n) = \int_{-\pi}^{+\pi} f(x) E_n(x)\, dx, \tag{81}$$

$$q(n) = \int_{-\pi}^{+\pi} f(x) e_n(x)\, dx. \tag{82}$$

Example:

$$\sin x = \frac{\pi}{\sqrt{\pi^3/8}} \sum_{n=1}^{\infty} \frac{1}{\sqrt{\beta(n)}} \mu(n) B(n) e_n(x), \tag{83}$$

$$\cos x=\frac{\pi}{\sqrt{\pi^3/8}}\sum_{n=1}^{\infty}\frac{1}{\sqrt{\beta(n)}}\mu(n)A(n)E_n(x). \tag{84}$$

Proof of example:

It is because

$$\langle \sin x,e_n(x)\rangle=\frac{1}{\sqrt{\pi^3/8}}\frac{1}{\sqrt{\beta(n)}}\sum_{d|n}\mu\left(\frac{n}{d}\right)B\left(\frac{n}{d}\right)\langle \sin x,Y(dx)\rangle$$

$$=\frac{\pi}{\sqrt{\pi^3/8}}\frac{1}{\sqrt{\beta(n)}}\mu(n)B(n)$$

and

$$\langle \cos x,E_n(x)\rangle=\frac{\pi}{\sqrt{\pi^3/8}}\frac{1}{\sqrt{\beta(n)}}\mu(n)A(n). \qquad \square$$

Next let us consider how to approximate a given function $f(x)\in L^2(-\pi,\pi)$ by a superposition of finite square waves.

Definition: Let N be a given positive integer. For $n=1,2,3,\ldots,N$, one defines

$$h_n^{(N)}(x)=\frac{1}{\pi^3/8}\sum_{m=1}^{N}\left(\sum_{m|k,n|k}^{1\leqslant k\leqslant N}\frac{1}{\beta(k)}A\left(\frac{k}{m}\right)A\left(\frac{k}{n}\right)\mu\left(\frac{k}{m}\right)\mu\left(\frac{k}{n}\right)\right)X(mx) \tag{85}$$

$$g_n^{(N)}(x)=\frac{1}{\pi^3/8}\sum_{m=1}^{N}\left(\sum_{m|k,n|k}^{1\leqslant k\leqslant N}\frac{1}{\beta(k)}B\left(\frac{k}{m}\right)B\left(\frac{k}{n}\right)\mu\left(\frac{k}{m}\right)\mu\left(\frac{k}{n}\right)\right)Y(mx). \tag{86}$$

Proposition 14: The best approximation of a function $f(x)\in L^2(-\pi,\pi)$ by a superposition of the finite square waves

$$1,X(x),Y(x),X(2x),Y(2x),\ldots,X(Nx),\quad \text{and } Y(Nx) \tag{87}$$

is

$$f^{(N)}(x)=C_0+\sum_{n=1}^{N}(C^{(N)}(n)X(nx)+D^{(N)}(n)Y(nx)), \tag{88}$$

where

$$C_0=\frac{1}{2\pi}\int_{-\pi}^{+\pi}f(x)dx, \tag{89}$$

$$C^{(N)}(n)=\int_{-\pi}^{+\pi}f(x)h_n^{(N)}(x)dx, \tag{90}$$

$$D^{(N)}(n)=\int_{-\pi}^{+\pi}f(x)g_n^{(N)}(x)dx. \tag{91}$$

Proof: $f(x)\in L^2(-\pi,\pi)$ can be written as

$$f(x)=r_0+\sum_{n=1}^{\infty}(r(n)E_n(x)+q(n)e_n(x)), \tag{92}$$

where

$$r_0=\frac{1}{2\pi}\int_{-\pi}^{+\pi}f(x)dx,$$

$$r(n)=\int_{-\pi}^{+\pi}f(x)E_n(x)dx, \tag{93}$$

$$q(n)=\int_{-\pi}^{+\pi}f(x)e_n(x)dx.$$

The best approximation to $f(x)$ out of the subspace spanned by

$$1,X(x),Y(x),X(2x),Y(2x),\ldots,X(Nx), \quad \text{and } Y(Nx)$$

is

$$\begin{aligned}
f^{(N)}(x)&=r_0+\sum_{n=1}^{N}(r(n)E_n(x)+q(n)e_n(x))\\
&=r_0+\sum_{n=1}^{N}\left[r(n)\frac{1}{\sqrt{\pi^3/8}}\frac{1}{\sqrt{\beta(n)}}\sum_{d|n}\mu\left(\frac{n}{d}\right)A\left(\frac{n}{d}\right)X(dx)\right.\\
&\quad\left.+q(n)\frac{1}{\sqrt{\pi^3/8}}\frac{1}{\sqrt{\beta(n)}}\sum_{d|n}\mu\left(\frac{n}{d}\right)B\left(\frac{n}{d}\right)Y(dx)\right]\\
&=C_0+\sum_{n=1}^{N}(C^{(N)}(n)X(nx)+D^{(N)}(n)Y(nx)),
\end{aligned}$$

where

$$\begin{aligned}
C^{(N)}(n)&=\frac{1}{\sqrt{\pi^3/8}}\sum_{s=1}^{sn\leqslant N}\mu(s)A(s)r(sn)\frac{1}{\sqrt{\beta(sn)}}\\
&=\frac{1}{\sqrt{\pi^3/8}}\sum_{s=1}^{sn\leqslant N}\mu(s)A(s)\frac{1}{\sqrt{\beta(sn)}}\int_{-\pi}^{+\pi}f(x)E_{sn}(x)dx\\
&=\int_{-\pi}^{+\pi}f(x)\ \frac{1}{\sqrt{\pi^3/8}}\sum_{s=1}^{sn\leqslant N}\mu(s)A(s)\frac{1}{\sqrt{\beta(sn)}}E_{sn}(x)dx\\
&=\int_{-\pi}^{+\pi}f(x)\frac{1}{\pi^3/8}\sum_{s=1}^{sn\leqslant N}\mu(s)A(s)\frac{1}{\beta(sn)}\sum_{d|sn}\mu\left(\frac{sn}{d}\right)A\left(\frac{sn}{d}\right)X(dx)dx\\
&=\int_{-\pi}^{+\pi}f(x)\frac{1}{\pi^3/8}\sum_{m=1}^{N}\left(\sum_{m|k,n|k}^{1\leqslant k\leqslant N}\frac{1}{\beta(k)}A\left(\frac{k}{m}\right)A\left(\frac{k}{n}\right)\mu\left(\frac{k}{m}\right)\mu\left(\frac{k}{n}\right)\right)X(mx)dx\\
&=\int_{-\pi}^{+\pi}f(x)h_n^{(N)}(x)dx,
\end{aligned}$$

and similarly

$$D^{(N)}(n)=\int_{-\pi}^{+\pi}f(x)g_n^{(N)}(x)dx. \qquad \square$$

In fact, $\{h_n^{(N)}(x)\}_{n=1}^N$ are the biorthogonal functions of $\{X(nx)\}_{n=1}^N$ in the subspace spanned by $\{X(nx)\}_{n=1}^N$, and $\{g_n^{(N)}(x)\}_{n=1}^N$ are the biorthogonal functions of $\{Y(nx)\}_{n=1}^N$ in the subspace spanned by $\{Y(nx)\}_{n=1}^N$.

Example: When $N=3$, we have

$$h_1^{(3)}(x)=\frac{1}{\pi^3}(9X(x)+3X(3x)),\quad h_2^{(3)}(x)=\frac{1}{\pi^3}8X(2x),$$

$$h_3^{(3)}(x)=\frac{1}{\pi^3}(3X(x)+9X(3x)),\quad g_1^{(3)}(x)=\frac{1}{\pi^3}(9Y(x)-3Y(3x)),$$

$$g_2^{(3)}(x)=\frac{1}{\pi^3}8Y(2x),\quad g_3^{(3)}(x)=\frac{1}{\pi^3}(-3Y(x)+9Y(3x)).$$

The best approximations of sin$x$ and cos$x$ are

$$\begin{aligned}\sin^{(3)}x&=\frac{\pi}{\sqrt{\pi^3/8}}\sum_{n=1}^{3}\frac{1}{\sqrt{\beta(n)}}\mu(n)B(n)e_n(x)\\&=\frac{1}{\pi^2}(9Y(x)-3Y(3x)),\end{aligned}$$

$$\begin{aligned}\cos^{(3)}x&=\frac{\pi}{\sqrt{\pi^3/8}}\sum_{n=1}^{3}\frac{1}{\sqrt{\beta(n)}}\mu(n)A(n)E_n(x)\\&=\frac{1}{\pi^2}(9X(x)+3X(3x)).\end{aligned}$$

If square waves are generated from a common high-frequency pulse signal by frequency-division technique, we need consider a function $f(x)$'s best approximation by a superposition of the finite square waves 1, $\{X(dx)\}_{d|N_1}$and $\{X(d'x)\}_{d'|N_2}$, where N_1 and N_2 are two positive integers.

Proposition 15: Let N_1 and N_2 be two positive integers and $f(x)\in L^2(-\pi,\pi)$. Then $f(x)$'s best approximation by a linear combination of 1, $\{X(dx)\}_{d|N_1}$ and $\{X(d'x)\}_{d'|N_2}$, is

$$f^{[N_1,N_2]}(x)=C_0+\sum_{d|N_1}C^{[N_1]}(d)X(dx)+\sum_{d'|N_2}D^{[N_2]}(d')Y(d'x).\tag{94}$$

The coefficients in (94) are determined by

$$C_0=\frac{1}{2\pi}\int_{-\pi}^{+\pi}f(x)dx,\tag{95}$$

$$C^{[N_1]}(d)=\int_{-\pi}^{+\pi}f(x)h_d^{[N_1]}(x)dx,\tag{96}$$

$$D^{[N_2]}(d')=\int_{-\pi}^{+\pi}f(x)g_{d'}^{[N_2]}(x)dx,\tag{97}$$

where

$$h_d^{[N_1]}(x)=\frac{1}{\pi^3/8}\sum_{m|N_1}\left(\sum_{m|k,d|k}^{k|N_1}\frac{1}{\beta(k)}A\left(\frac{k}{m}\right)A\left(\frac{k}{d}\right)\mu\left(\frac{k}{m}\right)\mu\left(\frac{k}{d}\right)\right)X(mx),\tag{98}$$

$$g_{d'}^{[N_2]}(x)=\frac{1}{\pi^3/8}\sum_{m'|N_2}\left(\sum_{m'|k,d'|k}^{k|N_2}\frac{1}{\beta(k)}B\left(\frac{k}{m'}\right)B\left(\frac{k}{d'}\right)\mu\left(\frac{k}{m'}\right)\mu\left(\frac{k}{d'}\right)\right)Y(m'x). \tag{99}$$

Proof: It is plain that $f(x)$'s best approximation in this case is

$$f^{[N_1,N_2]}(x)=r_0+\sum_{d|N_1}r(d)E_d(x)+\sum_{d'|N_2}q(d')e_{d'}(x). \tag{100}$$

The rest of the proof is similar to that of proposition 14. □

Example: $N_1=N_2=6$.

The best approximations of sin$x$,cos$x$ by a superposition of the square waves 1, $Y(x),Y(2x),Y(3x),Y(6x)$ and $X(x),X(2x),X(3x),X(6x)$ are

$$\begin{aligned}\sin^{[6,6]}x&=\frac{\pi}{\sqrt{\pi^3/8}}\sum_{d|6}\frac{1}{\sqrt{\beta(d)}}\mu(d)B(d)e_d(x)\\&=\frac{1}{\pi^2}(9Y(x)-3Y(3x)),\end{aligned}$$

$$\begin{aligned}\cos^{[6,6]}x&=\frac{\pi}{\sqrt{\pi^3/8}}\sum_{d'|6}\frac{1}{\sqrt{\beta(d')}}\mu(d')A(d')E_{d'}(x)\\&=\frac{1}{\pi^2}(9X(x)+3X(3x)).\end{aligned}$$

Remark: Since the orthogonalized square waves are none other than combinations of several square waves, one can generate them easily as well, so they can be regarded as a new basic waveform in electronics (see Fig. 6). In applications we have to express a signal as a superposition of finite square waves rather than infinite square waves, since the number of square waves is finite after all, and therefore the best approximation is an important practical problem.

V. CONCLUSION

Since the square wave system is linearly independent and complete, one can synthesize any signal by a summation circuit of square waves with different frequencies (see Fig. 5). By means of biorthogonal functions one can decompose any signal into a square wave series with a computer or a specially designed device (see Fig. 7). With the orthogonalized square waves, a signal can be easily represented as a superposition of finite square waves with the least mean-square error. These results form the theory basis for the square wave analysis technique in modern electronics.

We will discuss other common waveforms later (Ref. 4).

The number of bound states of the one-dimensional Schrödinger equation is analyzed in terms of the number of bound states corresponding to ''fragments'' of the potential. When the potential is integrable and has a finite first moment, the sharp inequalities $1-p+\Sigma_{j=1}^{p} N_j \leqslant N \leqslant \Sigma_{j=1}^{p} N_j$ are proved, where p is the number of fragments, N is the total number of bound states, and N_j is the number of bound states for the jth fragment. When $p=2$ the question of whether $N=N_1+N_2$ or $N=N_1+N_2-1$ is investigated in detail. An illustrative example is also provided. © *1998 American Institute of Physics.* [S0022-2488(98)03109-0]

I. INTRODUCTION

Consider the one-dimensional Schrödinger equation

$$\psi''(k,x)+k^2\psi(k,x)=V(x)\psi(k,x), \tag{1.1}$$

where the potential V is real valued and belongs to $L_1^1(\mathbf{R})$, the class of measurable functions for which $\int_{-\infty}^{\infty} dx(1+|x|)|V(x)|$ is finite. The prime denotes the derivative with respect to the spatial coordinate x. Let us partition the real axis as $\mathbf{R}=\cup_{j=1}^{p}(x_{j-1},x_j)$, with $x_{j-1}<x_j$ for $j=1,...,p$. Here we use the convention $x_0=-\infty$ and $x_p=+\infty$. We obtain a fragmentation of the potential by setting $V(x)=\Sigma_{j=1}^{p} V_j(x)$, where

$$V_j(x)=\begin{cases} V(x), & x\in(x_{j-1},x_j) \\ 0, & \text{elsewhere.} \end{cases} \tag{1.2}$$

In this paper we analyze the relationship between the number of bound states of V and the number of bound states of its fragments. In Sec. II we prove a pair of sharp inequalities relating these numbers (Theorem 2.1); we also study the case $p=2$ in more detail, and in Theorems 2.2 and 2.3 we present criteria that tell us when $N=N_1+N_2$ or $N=N_1+N_2-1$. In Sec. III we give another proof of Theorem 2.1 by using a factorization formula for the scattering matrix and exploiting its small-k asymptotics. We also briefly discuss what happens if we increase the separation distance between two fragments (Theorem 3.1). In Sec. IV we give an example which illustrates various aspects of our results.

The inequality (2.5) in Theorem 2.1 has been proved before by different methods and under stronger assumptions on the potential. In Ref. 1, (2.5) was proved when $p=2$ and the fragments have compact support. In Refs. 2 and 3, some special cases of (2.5) were proved for parity invariant, compactly supported fragments, but, as already mentioned in those references, the parity invariance is not an essential restriction. The method used in Ref. 1 was based on the nodal properties of the zero-energy solutions of the Schrödinger equation but was fairly contrived, while

the method used in Refs. 2 and 3 relied on a factorization formula[4] for the scattering matrix and the small-k behavior of the scattering coefficients. In the proofs of Theorems 2.1 and 2.2 we use certain properties of the Jost solutions, especially the interlacing property of zeros, in a very straightforward way. As a result, we are able to establish the connection with the factorization method used in Sec. III. Furthermore, no additional technical restrictions are imposed on the potential besides $V \in L_1^1(\mathbf{R})$.

At various places in this paper we need to distinguish between ''generic'' and ''exceptional'' potentials. Recall that a potential is called generic if the corresponding transmission coefficient T vanishes at $k=0$, and that a potential is called exceptional if $T(0)\neq 0$. Equivalently, a potential is generic (exceptional) if for $k=0$ the two Jost solutions are linearly independent (dependent)[5–7].

II. INEQUALITY FOR THE NUMBER OF BOUND STATES

In preparation of this section we first establish some notation and collect some results about the Jost solutions and their nodal properties. Let $f_{l;j}(k,x)$ and $f_{r;j}(k,x)$ denote the Jost solutions from the left and right, respectively, for the fragment V_j. Recall that $f_{l;j}(k,x)=e^{ikx}[1+o(1)]$ as $x\to+\infty$ and $f_{r;j}(k,x)=e^{-ikx}[1+o(1)]$ as $x\to-\infty$. Furthermore, let n_j denote the number of zeros of $f_{r;j}(0,x)$ lying in $(-\infty,x_j)$, m_j the number of zeros of $f_{l;j}(0,x)$ lying in $(x_{j-1},+\infty)$, and N_j the number of bound states of the fragment V_j. Since N_j is equal[8,9] to the number of zeros of either $f_{l;j}(0,x)$ or $f_{r;j}(0,x)$, we conclude that

$$N_j=\begin{cases} n_j, & \text{if } f_{r;j}(0,x_j)f'_{r;j}(0,x_j)\geqslant 0 \quad \text{and} \quad f_{r;j}(0,x_j)\neq 0 \\ n_j+1, & \text{if } f_{r;j}(0,x_j)f'_{r;j}(0,x_j)\leqslant 0 \quad \text{and} \quad f'_{r;j}(0,x_j)\neq 0, \end{cases} \tag{2.1}$$

$$N_j=\begin{cases} m_j, & \text{if } f_{l;j}(0,x_{j-1})f'_{l;j}(0,x_{j-1})\leqslant 0 \quad \text{and} \quad f_{l;j}(0,x_{j-1})\neq 0 \\ m_j+1, & \text{if } f_{l;j}(0,x_{j-1})f'_{l;j}(0,x_{j-1})\geqslant 0 \quad \text{and} \quad f'_{l;j}(0,x_{j-1})\neq 0. \end{cases} \tag{2.2}$$

Note that on $(x_j,+\infty)$ the function $f_{r;j}(0,x)$ is equal to $f'_{r;j}(0,x_j)(x-x_j)+f_{r;j}(0,x_j)$ and that this linear function has the root $x=x_j-f_{r;j}(0,x_j)/f'_{r;j}(0,x_j)$ which lies in $[x_j,+\infty)$ precisely if $f_{r;j}(0,x_j)=0$ or $f_{r;j}(0,x_j)f'_{r;j}(0,x_j)<0$; in this case we have $N_j=n_j+1$. On the other hand, if $f'_{r;j}(0,x_j)=0$ or $f_{r;j}(0,x_j)f'_{r;j}(0,x_j)>0$, then $f_{r;j}(0,x)$ has no zeros in $[x_j,+\infty)$, i.e., all its zeros are in $(-\infty,x_j)$; thus $N_j=n_j$. This proves (2.1). We obtain (2.2) by applying a similar argument to $f_{l;j}(0,x)$. We will also need the Jost solutions for the potential V, which we denote by $f_l(k,x)$ and $f_r(k,x)$, respectively. In the generic case when $k=0$ the following asymptotic relations hold[10] as $x\to+\infty$:

$$f_l(0,x)=1+o(1), \quad f'_l(0,x)=o(1/x), \tag{2.3}$$

$$f_r(0,x)=c_r x+o(x), \quad f'_r(0,x)=c_r+o(1), \tag{2.4}$$

with some constant $c_r\neq 0$.

Theorem 2.1: Suppose that $V\in L_1^1(\mathbf{R})$. Let N denote the number of bound states of V. Then

$$1-p+\sum_{j=1}^{p} N_j \leqslant N \leqslant \sum_{j=1}^{p} N_j, \quad p=1,2,..., \tag{2.5}$$

where both inequalities are sharp.

Proof: It suffices to prove (2.5) for $p=2$ because the general case follows by induction. Let $u(x)$ denote the solution of (1.1) for $k=0$ satisfying the initial conditions $u(x_1)=1$ and $u'(x_1)=0$. Then $u(x)=f_{r;2}(0,x)$ on $x\geqslant x_1$ and $u(x)=f_{l;1}(0,x)$ on $x\leqslant x_1$. Hence $u(x)$ has N_1 zeros on $(-\infty,x_1)$ and N_2 zeros on $(x_1,+\infty)$, i.e., N_1+N_2 zeros in all. Hence, by the interlacing property of zeros, $f_l(0,x)$ has either N_1+N_2 or N_1+N_2-1 zeros. This proves (2.5). To see that the inequalities are sharp, note that a square-well potential of depth $-H^2$ and width w has exactly N bound states, where N is the positive integer satisfying $(N-1)\pi<wH\leqslant N\pi$. Choosing V to be a square-well potential of depth $-\pi^2$ with support $(0,1)$, we obtain $N=1$. Let us partition the interval $(0,1)$ into p nonempty subintervals and hence obtain a fragmentation of V; each fragment still contains exactly one bound state and hence the lower bound in (2.5) becomes equal to N. On

the other hand, consider the square-well potential of depth $-\pi^2$ with support $(0,p)$, and partition $(0,p)$ into the p subintervals $(j-1,j)$ for $j=1,...,p$. Then $N_j=1$, $N=p$, and hence the upper bound in (2.5) becomes equal to N. ■

We remark that the short proof of (2.5) given here was suggested by the referee. Inequality (2.5) also follows from the next theorem that gives us, in case of two fragments, the precise information on whether $N=N_1+N_2$ or $N=N_1+N_2-1$. Let

$$Z(x_1)=\frac{f_{l;2}(0,x_1)}{f'_{l;2}(0,x_1)}-\frac{f_{r;1}(0,x_1)}{f'_{r;1}(0,x_1)}. \tag{2.6}$$

Theorem 2.2: Assume that V is partitioned into two fragments. Then:
(a) If $f'_{r;1}(0,x_1)\neq 0$, $f'_{l;2}(0,x_1)\neq 0$, and $Z(x_1)\geqslant 0$, then $N=N_1+N_2-1$; if $Z(x_1)<0$, then $N=N_1+N_2$.
(b) If $f'_{r;1}(0,x_1)=0$ or $f'_{l;2}(0,x_1)=0$, then $N=N_1+N_2$.

Proof: (a) In order to determine N we will count the zeros of $f_r(0,x)$ that lie in $[x_1,+\infty)$. We do this by using the interlacing property of the zeros of $f_r(0,x)$ and $f_l(0,x)$, noting that $f_l(0,x)=f_{l;2}(0,x)$ on $[x_1,+\infty)$ and $f_r(0,x)=f_{r;1}(0,x)$ on $(-\infty,x_1]$. We already know that n_1 zeros of $f_r(0,x)$ lie in $(-\infty,x_1)$, where n_1 is related to N_1 by (2.1). Upon multiplying $f_{l;2}(0,x)$ and $f_{r;1}(0,x)$ by suitable constants α and β, we can achieve that $\varphi_{l;2}(0,x)=\alpha f_{l;2}(0,x)$ and $\varphi_{r;1}(0,x)=\beta f_{r;1}(0,x)$ satisfy $\varphi'_{l;2}(0,x_1)=\varphi'_{r;1}(0,x_1)=1>0$. Then $Z(x_1)$ in (2.6) becomes

$$Z(x_1)=\varphi_{l;2}(0,x_1)-\varphi_{r;1}(0,x_1).$$

First suppose that $Z(x_1)>0$, which is equivalent to assuming $W[\varphi_l,\varphi_r](x_1)>0$, where $W[g,h](x)=g(x)h'(x)-g'(x)h(x)$ denotes the Wronskian. We first consider the case when $\varphi_{l;2}(0,x)$ has at least one zero on $(x_1,+\infty)$. Suppose that $\varphi_{l;2}(0,x)$ has its zeros at z_j for $j=1,...,m_2$, where $x_1<z_1<z_2<\cdots<z_{m_2}$. If $\varphi_{l;2}(0,x_1)>\varphi_{r;1}(0,x_1)>0$, then $\varphi_{l;2}(0,x)$ has m_2 zeros in $(x_1,+\infty)$ because, by a Wronskian argument, there are no zeros in (x_1,z_1) and there is exactly one zero in each of the intervals (z_1,z_2), (z_2,z_3),...,$(z_{m_2},+\infty)$. To see that there is a zero in $(z_{m_2},+\infty)$, note that by (2.3) and (2.4), $W[\varphi_l,\varphi_r](x)=\alpha\beta c_r>0$. Hence α and βc_r have the same sign. Moreover, if $\alpha>0$, then $\varphi'_{l;2}(0,z_{m_2})>0$ and hence $\varphi_r(0,z_{m_2})<0$. Similarly, if $\alpha<0$, then $\varphi'_{l;2}(0,z_{m_2})<0$ and hence $\varphi_r(0,z_{m_2})>0$. Because $\varphi_r(0,x)=\beta c_r x+o(x)$ as $x\to+\infty$, it follows that $\varphi_r(0,x)$ must have a zero in $(x_1,+\infty)$ and, by the interlacing property, this is the only zero on this interval. Hence, using (2.1) and (2.2), we have $n_1=N_1$, $m_2=N_2-1$, and $N=n_1+m_2=N_1+N_2-1$. The same result holds when $\varphi_{l;2}(0,x)$ has no zeros on $(x_1,+\infty)$. Then $\varphi_r(0,x)$ has no zeros on $(x_1,+\infty)$ either and we have $m_2=0$. If $\varphi_{l;2}(0,x_1)>\varphi_{r;1}(0,x_1)=0$, then the previous argument goes through with only a minor change in counting the zeros because now $\varphi_r(0,x)$ also has a zero at $x=x_1$. We have $n_1=N_1-1$, $m_2=N_2-1$, and $N=n_1+m_2+1=N_1+N_2-1$. If $\varphi_{l;2}(0,x_1)\geqslant 0>\varphi_{r;1}(0,x_1)$, then $\varphi_r(0,x)$ has m_2+1 zeros on $(x_1,+\infty)$ because now there is also a zero in (x_1,z_1). Thus $n_1=N_1-1$, $m_2=N_2-1$, and $N=n_1+m_2+1=N_1+N_2-1$. If $0>\varphi_{l;2}(0,x_1)>\varphi_{r;1}(0,x_1)$, then $n_1=N_1-1$, $m_2=N_2$, and $N=N_1+N_2-1$ because $\varphi_r(0,x)$ has no zeros in (x_1,z_1). All the possibilities with $Z(x_1)>0$ have now been exhausted. If $Z(x_1)<0$, we can apply similar arguments and find that $N=N_1+N_2$. Finally, if $Z(x_1)=0$ because $\varphi_{l;2}(0,x_1)=\varphi_{r;1}(0,x_1)>0$, then $n_1=N_1$, $m_2=N_2-1$, and $N=n_1+m_2=N_1+N_2-1$. If $Z(x_1)=0$ because $\varphi_{l;2}(0,x_1)=\varphi_{r;1}(0,x_1)=0$, then $n_1=N_1-1$, $m_2=N_2-1$, and $N=n_1+m_2+1=N_1+N_2-1$. If $Z(x_1)=0$ because $\varphi_{l;2}(0,x_1)=\varphi_{r;1}(0,x_1)<0$, then $n_1=N_1-1$, $m_2=N_2$, and $N=n_1+m_2=N_1+N_2-1$. This concludes the proof of part (a). The proof of (b) is similar, using (2.1), (2.2), and the Wronskian. The details are omitted. ■

Theorem 2.3: Assume that V is partitioned into two fragments, and let $W(x_1)$ denote the Wronskian $W[f_{l;2}(0,\cdot);f_{r;1}(0,\cdot)](x_1)$. Then:
(i) Suppose N_1 and N_2 are either both even or both odd. If $W(x_1)>0$ $(W(x_1)<0)$, then $N=N_1+N_2$ $(N=N_1+N_2-1)$.
(ii) Suppose N_1 is even and N_2 is odd or vice versa. If $W(x_1)>0$ $(W(x_1)<0)$, then $N=N_1+N_2-1$ $(N=N_1+N_2)$.

Proof: The proof is a consequence of the following observation. If $W(x_1)>0$, then the constant c_r in (2.4) is positive and so N is even, while if $W(x_1)<0$, then c_r is negative and N is odd. ■

If $W(x_1)=0$, then Theorem 2.3 gives no information as to which possibility is realized. However, Theorem 2.2 (a) says that if $W(x_1)=0$ because $Z(x_1)=0$, then $N=N_1+N_2-1$. The only other possibility is that $W(x_1)=0$ because $f'_{r;1}(0,x_1)=f_{l;2}(0,x_1)=0$, in which case $N=N_1+N_2$ by Theorem 2.2 (b).

III. FURTHER OBSERVATIONS

In this section we analyze the result of Theorem 2.1 in conjunction with the scattering matrices corresponding to the fragments of this potential. For simplicity let us consider the fragmentation of V as $V=V_1+V_2$, where V_1 has support in $(-\infty,x_1]$ and V_2 has support in $[x_1,+\infty)$. The analysis for three or more fragments can be carried out by using induction. Let $\mathbf{S}_1$, $\mathbf{S}_2$, and $\mathbf{S}$ be the scattering matrices corresponding to the potentials V_1, V_2, and V, respectively. The scattering coefficients appear in the scattering matrix as follows:

$$\mathbf{S}(k)=\begin{bmatrix} T(k) & R(k) \\ L(k) & T(k) \end{bmatrix}, \tag{3.1}$$

where T is the transmission coefficient, and L and R are the reflection coefficients from the left and from the right, respectively. Similarly, T_j, R_j, and L_j denote the corresponding entries of $\mathbf{S}_j$ for $j=1,2$. Let us define the so-called transition matrix associated with $\mathbf{S}$ as follows:

$$\Lambda(k)=\begin{bmatrix} \dfrac{1}{T(k)} & -\dfrac{R(k)}{T(k)} \\ \dfrac{L(k)}{T(k)} & \dfrac{1}{T(k)^*} \end{bmatrix}=\begin{bmatrix} \dfrac{1}{T(k)} & \dfrac{L(k)^*}{T(k)^*} \\ \dfrac{L(k)}{T(k)} & \dfrac{1}{T(k)^*} \end{bmatrix}, \tag{3.2}$$

where the asterisk denotes complex conjugation. Similarly, let Λ_1 and Λ_2 be the transition matrices corresponding to $\mathbf{S}_1$ and $\mathbf{S}_2$, respectively. It is known[4] that

$$\Lambda(k)=\Lambda_1(k)\Lambda_2(k). \tag{3.3}$$

From the (1,1) entry of the matrix product in (3.3) we get

$$\frac{1}{T(k)}=\frac{1-R_1(k)L_2(k)}{T_1(k)T_2(k)}. \tag{3.4}$$

Let $\mathbf{R}^+=(0,+\infty)$. For $k\in\mathbf{R}^+$, let us define the phases $\phi(k)$, $\phi_1(k)$, and $\phi_2(k)$ of the transmission coefficients as follows:

$$T(k)=|T(k)|e^{i\phi(k)}, \quad T_1(k)=|T_1(k)|e^{i\phi_1(k)}, \quad T_2(k)=|T_2(k)|e^{i\phi_2(k)}, \tag{3.5}$$

where it is understood that ϕ, ϕ_1, and ϕ_2 are continuous in $k\in\mathbf{R}^+$ and normalized such that

$$\phi(+\infty)=\phi_1(+\infty)=\phi_2(+\infty)=0. \tag{3.6}$$

Similarly, let

$$1-R_1(k)L_2(k)=|1-R_1(k)L_2(k)|e^{i\omega(k)}, \tag{3.7}$$

where ω is assumed continuous in $k\in\mathbf{R}^+$ and to satisfy $\omega(+\infty)=0$. From (3.4) we obtain

$$\phi(k)=\phi_1(k)+\phi_2(k)-\omega(k), \quad k\in\mathbf{R}^+. \tag{3.8}$$

From Levinson's theorem[11] we have

$$\phi(0+)=\left[N-\frac{d}{2}\right]\pi, \quad \phi_1(0+)=\left[N_1-\frac{d_1}{2}\right]\pi, \quad \phi_2(0+)=\left[N_2-\frac{d_2}{2}\right]\pi, \tag{3.9}$$

where N, N_1, and N_2 denote the number of bound states corresponding to the potentials V, V_1, and V_2, respectively; $d=1$ if V is a generic potential and $d=0$ if V is exceptional; in a similar manner, d_1 and d_2 take values 1 or 0 depending on whether V_1 and V_2 are generic or exceptional. Using (3.9) in (3.8) we obtain

$$N=N_1+N_2+\frac{1}{2}\,[d-d_1-d_2]-\frac{1}{\pi}\,\omega(0+). \tag{3.10}$$

Now let us analyze ω further. Note that R_1 and L_2 are continuous and nonzero and strictly less than one in absolute value for $k\in\mathbf{R}^+$ and that, as $k\to+\infty$, both R_1 and L_2 vanish.

In the following we need to distinguish between the generic case and the exceptional case. When V_1 and V_2 are both generic we have

$$R_1(k)=-1-2ika_{r;1}+\mathrm{o}(k),\quad L_2(k)=-1-2ika_{l;2}+\mathrm{o}(k),\quad k\to 0, \tag{3.11}$$

where

$$a_{r;1}=\left(1-\int_{-\infty}^{x_1}dx\;xV_1(x)f_{r;1}(0,x)\right)\Big/\int_{-\infty}^{x_1}dx\;V_1(x)f_{r;1}(0,x), \tag{3.12}$$

$$a_{l;2}=\left(1+\int_{x_1}^{\infty}dx\;xV_2(x)f_{l;2}(0,x)\right)\Big/\int_{x_1}^{\infty}dx\;V_2(x)f_{l;2}(0,x). \tag{3.13}$$

In the exceptional case we define

$$\gamma_1=\frac{f_{l;1}(0,x)}{f_{r;1}(0,x)}=\frac{1}{f_{r;1}(0,x_1)},\quad \gamma_2=\frac{f_{l;2}(0,x)}{f_{r;2}(0,x)}=f_{l;2}(0,x_1), \tag{3.14}$$

and note that, if V_1, resp. V_2, is exceptional, then

$$R_1(k)=-b_1+\mathrm{o}(1),\quad \text{resp.}\quad L_2(k)=b_2+\mathrm{o}(1),\quad k\to 0, \tag{3.15}$$

where

$$b_j=\frac{\gamma_j^2-1}{\gamma_j^2+1},\quad j=1,2. \tag{3.16}$$

The relations (3.11)–(3.13) follow from p. 146 of Ref. 6; (3.15) was proved in Ref. 12. We remark that the validity of (3.11) depends on the property that V_1 and V_2 are each supported on a semi-infinite interval; this guarantees the convergence of the integrals in the numerators in (3.12) and (3.13). In general, for potentials in $L_1^1(\mathbf{R})$ one can only conclude[12] that the reflection coefficients behave like $-1+\mathrm{o}(1)$ as $k\to 0$ in the generic case.

When both V_1 and V_2 are generic we have

$$1-R_1(k)L_2(k)=-2ik[a_{r;1}+a_{l;2}]+\mathrm{o}(k),\quad k\to 0. \tag{3.17}$$

When both V_1 and V_2 are exceptional we get

$$1-R_1(k)L_2(k)=1+b_1b_2+\mathrm{o}(1),\quad k\to 0. \tag{3.18}$$

When V_1 is generic and V_2 is exceptional we have

$$1-R_1(k)L_2(k)=1+b_2+\mathrm{o}(1),\quad k\to 0, \tag{3.19}$$

and finally, when V_1 is exceptional and V_2 is generic, we have

$$1-R_1(k)L_2(k)=1-b_1+\mathrm{o}(1),\quad k\to 0. \tag{3.20}$$

From (3.15) and (3.18)–(3.20) we see that if at least one of V_1 and V_2 is exceptional, then the quantity $[1-R_1(0)L_2(0)]$ is strictly positive, and hence $\omega(0+)=0$.

If both V_1 and V_2 are generic, the analysis is slightly more complicated: If $a_{r;1}<-a_{l;2}$, then $\omega(0+)=\pi/2$; if $a_{r;1}>-a_{l;2}$, then $\omega(0+)=-\pi/2$. If $a_{r;1}=-a_{l;2}$, then, as $k\to 0$, we get $1-R_1(k)L_2(k)=o(k)$, where we have used (3.17). As a result, (3.4) implies that $k/T(k)=o(1)$ as $k\to 0$, and this, in turn, implies that V is exceptional. Therefore the left-hand side of (3.4) has a limit as $k\to 0$, which means that in fact $1-R_1(k)L_2(k)=O(k^2)$, from which we obtain $\omega(0+)=0$.

It is known[13] that when V_1 and V_2 are both exceptional, then V is exceptional. If exactly one of V_1 and V_2 is exceptional, then V is generic. If both V_1 and V_2 are generic, then V can be exceptional or generic. By using these facts along with the value of $\omega(0+)$ and (3.10), we arrive at the following conclusions:

(i) If both V_1 and V_2 are exceptional, then $N=N_1+N_2$.
(ii) If exactly one of V_1 and V_2 is exceptional and the other is generic, then $N=N_1+N_2$.
(iii) If both V_1 and V_2 are generic and V is also generic, then $\omega(0+)=\pm\pi/2$. In this case, we have $N=N_1+N_2-1$ if $\omega(0+)=\pi/2$, and this happens if $a_{r;1}<-a_{l;2}$ in (3.17); or we have $N=N_1+N_2$ if $\omega(0+)=-\pi/2$, and this happens if $a_{r;1}>-a_{l;2}$.
(iv) If both V_1 and V_2 are generic and V is exceptional, then we must have $\omega(0+)=0$ and $N=N_1+N_2-1$. This happens if $a_{r;1}=-a_{l;2}$ in (3.17).

Summarizing, if $a_{r;1}\leqslant -a_{l;2}$ in (3.17) and both $a_{r;1}$ and $a_{l;2}$ are finite, then we have $N=N_1+N_2-1$; if at least one of $a_{r;1}$ and $a_{l;2}$ is infinite or if $a_{r;1}>-a_{l;2}$, then we have $N=N_1+N_2$.

There is a direct connection between cases (i)–(iv) above and cases (a) and (b) of Theorem 2.2 because the coefficients $a_{r;1}$ and $a_{l;2}$ are related to the quantity $Z(x_1)$ defined in (2.6). To see this recall that $f_{r;1}(0,x)$ and $f_{l;2}(0,x)$ obey the integral equations

$$f_{r;1}(0,x)=1+\int_{-\infty}^{x}dy(x-y)V_1(y)f_{r;1}(0,y), \tag{3.21}$$

$$f_{l;2}(0,x)=1+\int_{x}^{\infty}dy(y-x)V_2(y)f_{l;2}(0,y). \tag{3.22}$$

Hence from (3.21) and (3.22) we obtain

$$f_{r;1}(0,x)=c_{r;1}x+d_{r;1},\quad x>x_1,$$

$$f_{l;2}(0,x)=-c_{l;2}x+d_{l;2},\quad x<x_1,$$

with

$$c_{r;1}=\int_{-\infty}^{x_1}dy\ V_1(y)f_{r;1}(0,y),\quad d_{r;1}=1-\int_{-\infty}^{x_1}dy\ yV_1(y)f_{r;1}(0,y), \tag{3.23}$$

$$c_{l;2}=\int_{x_1}^{\infty}dy\ V_2(y)f_{l;2}(0,y),\quad d_{l;2}=1+\int_{x_1}^{\infty}dy\ yV_2(y)f_{l;2}(0,y). \tag{3.24}$$

Thus from (3.12), (3.13), (3.23), and (3.24) we conclude that

$$a_{r;1}=\frac{d_{r;1}}{c_{r;1}},\quad a_{l;2}=\frac{d_{l;2}}{c_{l;2}}. \tag{3.25}$$

Moreover,

$$\frac{f_{r;1}(0,x_1)}{f'_{r;1}(0,x_1)}=x_1+a_{r;1},\quad \frac{f_{l;2}(0,x_1)}{f'_{l;2}(0,x_1)}=x_1-a_{l;2},$$

and hence

$$Z(x_1) = -a_{r,1} - a_{l;2}.$$

Thus (i) and (ii) above correspond to the possibilities of Theorem 2.2 (b); (i) is the case when $f'_{r;1}(0,x_1) = f'_{l;2}(0,x_1) = 0$, and (ii) is the case when exactly one of $f'_{r;1}(0,x_1)$ and $f'_{l;2}(0,x_1)$ is zero. Case (iii) corresponds to (a) of Theorem 2.2 with $Z(x_1) \neq 0$ and case (iv) corresponds to (a) with $Z(x_1) = 0$.

We conclude this section with a brief look at families of potentials of the form

$$V_\xi(x) = V_1(x) + V_2(x-\xi), \tag{3.26}$$

where ξ is a non-negative parameter and V_1 and V_2 are the two fragments of V. In other words, the parameter ξ controls the separation distance between the two fragments. The next result shows that the number of bound states can only increase if ξ is increased. By virtue of (2.5) it can only increase by one. Since the proof is short we present two versions, one using the method of Sec. II and the other using the method of this section. In the case of compactly supported fragments the result is already known from Refs. 1 and 3.

Theorem 3.1: Let N_ξ denote the number of bound states of V_ξ given in (3.26). Then either $N_\xi = N_1 + N_2$ for all $\xi \geqslant 0$ or there is a unique $\xi_0 \geqslant 0$ such that $N_\xi = N_1 + N_2 - 1$ for $0 \leqslant \xi \leqslant \xi_0$ and $N_\xi = N_1 + N_2$ for $\xi > \xi_0$.

Proof: (a) First, if one of the fragments is exceptional, then we have $N_\xi = N_1 + N_2$ for all $\xi \geqslant 0$. If both fragments are generic, then we let $f_{l;2;\xi}(k,x)$ denote the Jost solution from the left for the potential $V_2(x-\xi)$. Then $f_{l;2;\xi}(0,x) = -c_{l;2}(x-\xi) + d_{l;2}$ for $x < x_1 + \xi$, and thus, by using (2.6) and (3.26), we obtain $Z_\xi(x_1) = -\xi - a_{l;2} - a_{r;1}$. Thus if $Z_0(x_1) < 0$, then, for all $\xi \geqslant 0$, $Z_\xi(x_1) < 0$ and hence $N_\xi = N_1 + N_2$. If $Z_0(x_1) \geqslant 0$, then $Z_{\xi_0}(x_1) = 0$ when $\xi_0 = Z_0(x_1) = -a_{l;2} - a_{r;1}$ and the assertion follows.

(b) Replacing $L_2(k)$ by $e^{2ik\xi}L_2(k)$ in (3.18) we obtain

$$1 - R_1(k)L_{2;\xi}(k) = -2ik[a_{r;1} + a_{l;2} + \xi] + o(k), \quad k \to 0.$$

Now the conclusion follows using (iii) and (iv) above. ■

IV. AN EXAMPLE

The following example illustrates Theorems 2.1 and 3.1. Let

$$V(x) = \begin{cases} A^2, & x \in (0,1) \\ -B^2, & x \in (1,2) \\ 0, & \text{elsewhere,} \end{cases} \tag{4.1}$$

where A and B are some positive constants. We can fragment V as $V = V_1 + V_2$, where V_1 is a square potential barrier of height A^2 with support (0,1) and V_2 is a square well of depth $-B^2$ with support (1,2). Then, a straightforward computation using (3.23)–(3.25) yields $c_{r;1} = A \sinh A$, $d_{r;1} = \cosh A - A \sinh A$, $c_{l;2} = -B \sin B$, $d_{l;2} = \cos B - B \sin B$, and thus

$$a_{r;1} = \frac{1}{A}\coth A - 1, \quad a_{l;2} = -\frac{1}{B}\cot B + 1.$$

Let us demonstrate that by choosing A and B suitably, we can have $N_1 = 0$, $N_2 = 1$, $N = 0$. In other words, the positive fragment V_1 may cancel the bound state caused by the negative fragment V_2, resulting in no bound states for V. Unless B is a multiple of π, both V_1 and V_2 are generic. If we let, for example, $B = \pi/4$, then from (2.6) we get $Z(x_1) = -a_{r;1} - a_{l;2} \geqslant 0$ whenever $A \geqslant A_0$, where A_0 satisfies $A_0 \tanh A_0 = \pi/4$, i.e., $A_0 = 1.0201\ldots$. For $A = A_0$ the potential V is exceptional with no bound state and for $A > A_0$ it is generic with no bound state. Now let us consider the family V_ξ defined in (3.26). If $A < A_0$ and $B = \pi/4$, then $Z_0(x_1) < 0$ and we have $N_\xi = N_1 + N_2 = 1$ for all ξ. If $A = A_0$, then we have $N_0 = 0$ but $N_\xi = 1$ for $\xi > 0$, i.e., $\xi_0 = 0$. If $A > A_0$, then ξ_0 is given by

$$\xi_0 = \frac{1}{B \tan B} - \frac{1}{A \tanh A},$$

and we have $N_\xi = 0$ for $\xi \leqslant \xi_0$ and $N_\xi = 1$ for $\xi > \xi_0$.

Symplectic structure for Gaussian diffusions

Augusto Brandão[a)]
Av Prof. Gama Pinto 2, 1669 Lisboa Cedex, Portugal

(Received 24 April 1997; accepted for publication 13 January 1998)

Using information exclusively about classical Hamiltonian boundary value problems (with quadratic time-dependent potentials) we construct probability measures providing a symplectic structure associated with some inhomogeneous Gaussian diffusion processes introduced earlier [T. Kolsrod and J. C. Zambrini, J. Math. Phys. **33**, 1301 (1992)]. © *1998 American Institute of Physics.*

I. INTRODUCTION

At the end of the 1940s, Feynman introduced a new interpretation of nonrelativistic quantum mechanics.[1] Let us briefly discuss it, in order to introduce some notations, by considering a one-particle system in $\mathbb{R}^3$ (of unit mass) described by the quantum Hamiltonian

$$H=-\frac{\hbar^2}{2}\Delta+V, \tag{1}$$

where $\hbar$ is the Planck constant and V is a regular, bounded below, scalar potential. Quantum dynamics is given (in any time interval, e.g., $[0, T]$) by the solution of the Cauchy problem in $L^2(\mathbb{R}^3)$, for χ in the domain of H, by

$$i\hbar\,\partial_t\psi=H\psi, \quad \psi(0,x)=\chi(x). \tag{2}$$

According to Born's interpretation of $\psi(t,x)$, the probability of finding the particle on a certain region B (B being a Borelian in $\mathbb{R}^3$) at time t is given by

$$\int_B \psi(x,t)\,\overline{\psi}(x,t)\;dx,$$

where $\overline{\psi}$ is the complex conjugate of ψ. Introducing the integral kernel or ''propagator,'' written symbolically as

$$K(x_1,t_1,x_2,t_2)=\int_{\Omega_{x_1}^{x_2}} e^{(i/\hbar)S(\omega)}\mathscr{D}\omega, \quad t_1<t_2,$$

where S is the action of the underlying classical system, i.e., here,

$$S(\omega)=\int_{x_1}^{x_2}\left(\frac{1}{2}\,\dot{\omega}(s)^2-V(\omega(s),s)\right)\,ds,$$

$\omega\in\Omega_{x_1}^{x_2}$ is a continuous path joining x_1 and x_2, and $D\omega$ represents a formal ''measure'' $D\omega=\Pi_{t_1<s<t_2}\,d\omega(s)$ on $\Omega_{x_1}^{x_2}$, the solution to the Schrödinger initial value problem (2) can be represented by

$$\psi(t,y)=\int_{\mathbb{R}^3} K(0,x,t,y)\chi(x)\;dx.$$

a)Electronic mail: abrandao@cc.fc.ul.pt

 © 1998 American Institute of Physics

So the probability that at time t the particle is in B should be

$$\begin{aligned} P(t) &= \int_B \psi(t,y)\overline{\psi}(t,y)\ dy \\ &= \int_B \int_{\mathbb{R}^3} K(0,x,t,y)\chi(x)\overline{\psi}(t,y)\ dx\ dy \\ &= \int_B \int_{\mathbb{R}^3} \chi(x)\overline{\chi}(x)K(0,x,t,y)\ \frac{\overline{\psi}(t,y)}{\overline{\chi}(x)}\ dx\ dy \\ &= \int_B \int_{\mathbb{R}^3} \chi(x)\overline{\chi}(x)\mathbf{K}(0,x,t,y)\ dx\ dy, \end{aligned} \tag{3}$$

where if $\overline{\chi}(x_1)\neq 0$,

$$\mathbf{K}(t_1,x_1,t_2,x_2) = K(t_1,x_1,t_2,x_2)\ \frac{\overline{\psi}(t_2,x_2)}{\overline{\chi}(x_1)}.$$

This suggests that $\mathbf{K}$ is formally the density of a transition probability wrt dx_2, in the sense of the classical theory of Markov processes.[2,3] Also observe that Feynman's path integral formula provides an informal way to describe quantum mechanics exclusively in terms of classical data, the action functional of the system.

Unfortunately, as it is well known today,

(i) $\mathscr{D}_\omega$ does not exist as a measure on $\Omega_{x_1}^{x_2}$.

(ii) $\mathbf{K}$ is complex valued, so it cannot be the transition probability of a real-valued stochastic process. There is no probability space where one can find such a stochastic process compatible with the Born interpretation and the predictions of regular quantum mechanics.

On the other hand, Schrödinger[4] has considered the following associated problem of classical statistical mechanics (Refs. 4–8), when the scalar potential V is zero:

Suppose that the position of a classical Brownian particle in a domain $X\in\mathbb{R}^3$ is observed at times t_1 and t_2 $(t_1<t_2)$ and found to have strictly positive probability densities with respect to Lebesgue measure:

$$\rho_{t_1}(x)\ dx, \quad \rho_{t_2}(z)\ dz.$$

What then, is the most probable evolution of a probability density compatible with those two arbitrary measurements?

Schrödinger shows that the probability density should be of the form

$$\rho(y,t) = \eta(t,y)\,\hat{\eta}(t,y), \quad t_1\leqslant t\leqslant t_2,$$

where the pair $\{\eta,\hat{\eta}\}$ are regular positive solutions of the two adjoint heat equations:

$$\partial_t \eta(t,y) = \tfrac{1}{2}\Delta\,\eta(t,y), \quad t\geqslant t_1, \quad y\in B, \tag{4}$$

$$-\partial_t \hat{\eta}(t,y) = \tfrac{1}{2}\Delta\,\hat{\eta}(t,y), \quad t\leqslant t_2, \quad y\in B, \tag{5}$$

So the problem amounts to proving the existence and uniqueness of positive solutions of the following nonlinear system of equations for $\eta(x,t_1)=\chi(x)$ and $\hat{\eta}(z,t_2)=\hat{\chi}(z)$,

$$\eta_{t_1}(x)\int_{\mathbb{R}^3} h(x,t_1,z,t_2)\,\hat{\eta}_{t_2}(z)\ dz = \rho_{t_1}(x), \tag{6}$$

$$\hat{\eta}_{t_2}(z)\int_{\mathbb{R}^3} \eta_{t_1}(x)h(x,t_1,z,t_2)\ dx = \rho_{t_2}(z), \tag{7}$$

where h denotes the (positive) integral kernel associated with the heat equations (4) and (5).

This problem was not solved by Schrödinger but by Beurling, almost 30 years later, in a much more general setting.[5,9]

In particular, Beurling's result provides us with the existence and uniqueness of the pair $\{\eta, \hat{\eta}\}$ of solutions of the adjoint heat equations for any potential V in the Kato class.[7] Using this, Zambrini[6] established the existence of a class of $\mathbb{R}^3$ Markovian (''Bernstein'') diffusion processes Z_t, for any V in the Kato class, such that

$$P(Z_t \in B) = \int_B \eta(t,y)\, \hat{\eta}(t,y)\, dy, \tag{8}$$

$$\frac{d^2 E(Z_t)}{dt^2} = E[\nabla V(Z_t, t)], \tag{9}$$

where E denotes the (absolute) expectation of the process. Notice the Euclidean change of sign of (9). For such processes Z_t we can define two transition probabilities:

$$P_f(s,x,t,B) = P(Z_t \in B \,|\, Z_s = x) \to Z_{s,x},$$

$$P_b(t,B,u,z) = P(Z_t \in B \,|\, Z_u = z) \to Z^{u,z},$$

where $t \in I = [s, u]$, a fixed time interval, and $Z_{s,x}$, $Z^{u,z}$ denote the associated conditioned processes. The Euclidean analog of Feynman's formula ''transition amplitude''[1,10] can be expressed as

$$P(Z_t \in B) = \int_B \int_{\mathbb{R}^3} \eta(s,x)\, \hat{\eta}(s,x) \rho_{s,x}(t,y)\, dx\, dy, \tag{10}$$

but also as

$$P(Z_t \in B) = \int_B \int_{\mathbb{R}^3} \eta(u,z)\, \hat{\eta}(u,z) \rho^{u,z}(t,y)\, dz\, dy, \tag{11}$$

where $\rho_{s,x}$, $\rho^{u,z}$ are respectively the probability densities of the conditioned processes $Z_{s,x}$, $Z^{u,z}$.

The essential element of Feynman's path integral representation is its relation with classical Lagrangian mechanics, and, in this respect, the quadratic Lagrangians play a very special role. In this case, Feynman shows that the sum over the paths of his formal stochastic process is entirely characterized by classical mechanics. This aspect has also been essential in his use of path integrals in quantum electrodynamics. The main objective of the present paper is to prove an analogous result in the Euclidean counterpart suggested by Schrödinger, i.e., given two Gaussian densities at time s and u, $\rho_s\, dx$, $\rho_u\, dx$, and a time-dependent quadratic potential V, construct (using only classical information) a diffusion process Z_t compatible with the above data and verify

$$\frac{d^2}{dt^2} E(Z_t) = \nabla V(E(Z_t t)).$$

In other words, we want to construct the relevant Gaussian probability measures from purely classical information.

Although we only treat quadratic potentials in this paper, recent developments show that the same treatment holds for some nonlinear equation of motion.[11]

In Sec. II we will describe the underlying classical model. Here the (real time) quantum Hamiltonian given by (1) will be replaced by the Euclidean one:

$$H = \frac{p^2}{2} - V(q,t).$$

The boundary conditions we will impose on the system will take the form of a pair of Lagrangian manifolds at the end points of the time interval. Then, we will show that the resulting classical dynamics can be completely described in terms of the flow of the pair of Lagrangian manifolds (in both senses of time), in particular the solution of the resulting boundary value problem is obtained by the intersection at each time of a pair of Lagrangian manifolds which are the time evolution of the original ones. In Sec. III, using the above-mentioned natural symplectic structure of phase space, we construct the probability measures which are completely characterized at each time by the pair of Lagrangian manifolds at the same instant. The resulting Gaussian density on the time interval will satisfy by construction the required boundary conditions of the quantum problem.

The general framework underlying our study is the one of ''Euclidean Quantum Mechanics.''[10,12] Its relations with regular quantum theory are deeper than the ones of the traditional Euclidian counterpart inspired by the Feynman–Kak formula.[13] For example, it has been proved recently that this framework provides better information about the quantum system than the familiar theorems of quantum mechanics.[14]

II. THE CLASSICAL MODEL

In this paper, our basic dynamical equation will be the classical n-dimensional (Euclidean) Newtonian equation,

$$\ddot{q}(t)=K(t)q(t), \tag{12}$$

on a time interval $I\equiv[s,u]$, where $K(t)$ is a symmetric $n\times n$ matrix on I with a continuous dependence in t. Moreover, we will assume that (12) is disconjugate[15,16] on the time interval I, i.e., Eq. (12) has no trivial solution $q(t)$ such that $q(t_1)=q(t_2)=0$, where t_1 and t_2 are distinct points of I. Equation (12) can be regarded as the classical Jacobi equation for the Euler–Lagrange equations with (Euclidean) Lagrangian of the form

$$L(q,\dot{q},t)=\tfrac{1}{2}|\dot{q}|^2+V(q,t), \tag{13}$$

where $|.|$ denotes the Euclidean norm. Then

$$K(t)=\left(\left.\frac{\partial^2 V}{\partial_{q_i}\,\partial_{q_j}}\right|_{\overline{q}(t)}\right), \quad i,j=1,2,3,...,n,$$

for $\overline{q}(t)$ an extremal of the action functional with Lagrangian L. This is the point of view of the semiclassical [or Wentzel–Kramers–Brillouin (WKB)] approximation in Feynman's approach to quantum mechanics.[1] Equation (12) can be transformed into an Hamiltonian form on $\mathbb{R}^{2n}$ for the Hamiltonian function given by

$$H(q,p,t)=\tfrac{1}{2}|p|^2-\tfrac{1}{2}\langle K(t)q,q\rangle. \tag{14}$$

The correspondent Hamilton's equation of motion will be given by the system:

$$\dot{q}_i=p_i, \quad \dot{p}_i=\sum_{1\leqslant j\leqslant n} K_{ij}(t)q_j, \quad i=1,...,n. \tag{15}$$

We also consider the matrix form of (15), i.e.,

$$\dot{C}_{ij}=D_{ij}, \quad \dot{D}_{ij}=\sum_{1\leqslant l\leqslant n} K_{il}(t)C_{lj}, \tag{16}$$

with the correspondent matrix second-order differential system:

$$\ddot{C}_{ij}(t)=\sum_{1\leqslant l\leqslant n} K_{il}(t)C_{lj}(t). \tag{17}$$

We will denote by $\mathbf{C}_t$ the matrix solution $(C_t,D_t)=(C_t,\dot{C}_t)$ of (16). The disconjugacy assumption for (12) on the time interval I implies that for any solution (C_t,D_t) of (16), C_t can only be noninvertible at one point of I. In particular, for $t_0\in I$, if one defines $E_{t_0}(t)$ as the solution on I of (17) that satisfies the Cauchy data,

$$E_{t_0}(t_0)=0, \quad \dot{E}_{t_0}(t_0)=I_{n\times n}, \tag{18}$$

then $E_{t_0}(t)$ is a nonsingular matrix for $t\neq t_0$.

The linearity of the Hamiltonian system ensures that the phase space has a natural vector space structure that we can identify with $\mathbb{R}^{2n}$. Hence the canonical symplectic structure provided by the two-form[17]

$$\omega=dq\wedge dp=\sum_{i=1}^{n} dq_i\wedge dp_i$$

can be used to define an antisymmetric inner product between elements of the phase space. Given two phase space vectors $X_1\equiv(q_1^1,\ldots,q_n^1,p_1^1,\ldots p_n^1)$ and $X_2\equiv(q_1^2,\ldots,q_n^2,p_1^2,\ldots p_n^2)$, their *symplectic inner product* is defined as

$$\omega(X_1,X_2)=\sum_{i=1}^{2n} q_i^1p_i^2-q_i^2p_i^1. \tag{19}$$

It is easy to prove that if $(X_1(t),X_2(t))$ are solutions of (15) on a time interval I, then $\omega(X_1(t),X_2(t))$ is constant.

We will need a generalization of the symplectic inner product to matrix functions. In order to simplify the notation if $A=(A_{\alpha\beta})$ and $B=(B_{\alpha\beta})$ are $n\times r$ matrices, then the $2n\times r$ matrix $C=(C_{\alpha,\beta})(\alpha=1,2,...,n;\beta=1,2,...,r)$ with $C_{\alpha\beta}=A_{\alpha\beta}$, $C_{n+\alpha,\beta}=B_{\alpha\beta}$ will be denoted as $(A;B)$. Hence if $C=(C_1;C_2)$ and $D=(D_1;D_2)$ are $2n\times n$ matrices and ^{T} denotes the transpose, we will call the matrix function

$$\omega(C,D)=C_1^TD_2-C_2^TD_1 \tag{20}$$

the symplectic inner product of C and D. If $X\in\mathbb{R}^{2n}$ and $C=(C_1;C_2)$, then $\omega(X,C)$ or $\omega(C,X)$ can be defined as $\omega(I_X,C)$ or $\omega(C,I_X)$ where I_X is the diagonal matrix with $(I_X)_{ii}=X_i$ for $i=1,...,2n$.

Although it is true that if $\mathbf{C}_1$ and $\mathbf{C}_2$ are two solutions of (16) on a time interval I, then $\omega(\mathbf{C}_t^1,\mathbf{C}_t^2)$ is a constant matrix on I, but, in contrast with (20), ω is not antisymmetric, hence in general we do not have $\omega(\mathbf{C},\mathbf{C})=0$. The solutions $\mathbf{C}_t$ of (16) [or the solutions C_t of (17)] such that $\omega(\mathbf{C},\mathbf{C})=0$ are sometime called *isotropic* solutions of (17) on I.

Definition 1: A Lagrangian manifold M is defined as an n manifold in a $2n$-dimensional phase space such that for all points (x,p) on M and for all vectors X,Y tangent to M at (x,p) we have

$$\omega(X,Y)=0. \tag{21}$$

Some obvious consequences of this definition are the following:

(1) In $\mathbb{R}^2$ it is clear that a Lagrangian manifold must be a one-dimensional surface, i.e., a curve.

(2) Any manifold of the form $q=\text{const}$ or $p=\text{const}$ on a phase space is a Lagrangian manifold. We will call a *singular Lagrangian manifold associated with a configuration* $x\in\mathbb{R}^n$ a Lagrangian manifold of the form

$$M^x=\{(q,p)|q=x\}. \tag{22}$$

(3) Any graph of a curl-free momentum field $p=p(q)$ is a Lagrangian manifold. If the Lagrangian manifold M is of the form

$$M=\left\{(q,p)\in\mathbb{R}^{2n}\middle| p=\frac{\partial S(q)}{\partial q}\right\} \tag{23}$$

for some regular function $S(q)$, this function is called the *generating function* of the Lagrangian manifold. Given an arbitrary Lagrangian manifold, its generating function may not be defined. A typical example of this is the singular Lagrangian manifold associated with a configuration $x \in \mathbb{R}^n$.

In this paper we only consider linear Lagrangian manifolds, i.e., n-planes on $\mathbb{R}^{2n}$.

A. Evolution of Lagrangian manifolds

Consider the Lagrangian manifolds M_s and M_s^x defined by

$$M_s=\{(q,p)\in\mathbb{R}^{2n}|p=\alpha q-\beta\}, \tag{24}$$

$$M_s^x=\{(q,p)\in\mathbb{R}^{2n}|q=x\}, \tag{25}$$

where α is a non-negative definite invertible $n\times n$ matrix and $\beta,x\in\mathbb{R}^n$.

Our first aim is to explicitly compute the images under the Hamiltonian flow associated with (14) of these two Lagrangian manifolds in a time interval $I=[s,\ u]$.

Definition 2: Given an initial Lagrangian manifold, we define its associated (matrix) function F_t on an interval $I=[s,\ u]$ as an isotropic matrix solution of (17) such that the following hold.

(1) If the Lagrangian manifold is defined by (24), F_t is a nonsingular matrix for $t\in I$ such that

$$\dot{F}_sF_s^{-1}=\alpha. \tag{26}$$

(2) If the Lagrangian manifold is singular [i.e., defined by (25)], then F_t is a nonsingular matrix for $t\in(s,u]$ and satisfies $F(s)=0$. An example of such a function is $E_s(t)$, the solution of (17) on I that satisfies the Cauchy data $E_s(s)=0$, $\dot{E}_s(s)=I_{n\times n}$.

Lemma 1: If F_t and H_t are two associated functions to a Lagrangian manifold M_s or M_s^x on the time interval I, then $\omega(\mathbf{F}_t,\mathbf{H}_t)=0$.

Proof: If the Lagrangian manifold is defined by (24), then both F_t and H_t satisfy (26). Hence,

$$0=\dot{F}_sF_s^{-1}-\dot{H}_sH_s^{-1}=F_s^{-T}(\dot{F}_s^TH_s-F_s^T\dot{H}_s)H_s^{-1}=-F_s^{-T}\omega(\mathbf{F}_t,\mathbf{H}_t)H_s^{-1},$$

which implies that

$$\omega(\mathbf{F}_t,\mathbf{H}_t)=0. \tag{27}$$

If the Lagrangian manifold is defined by (25), then F_t and H_t satisfy $F(s)=H(s)=0$. Since both matrix functions are solutions of (16), their symplectic product is time independent which implies that

$$\omega(\mathbf{F}_t,\mathbf{H}_t)=F_s^T\dot{H}_s-\dot{F}_sH_s=0.$$

□

Proposition 1: The image of the Lagrangian manifolds defined by (24) or (25) under the Hamiltonian flow defined by (14), for $t\in I$, is given by

$$M_t=\{(q,p)|\dot{F}^T(t)q-F^Tp=\delta\}, \tag{28}$$

where $F(t)$ is the associated function to M_s (resp. M_s^x) and $\delta=F_s^T\beta$ (resp. $\delta=x$). Moreover, the expression (28) is independent of the choice of the associated function to M_s, i.e., if H_t is another associated function to M_s on I, then

$$\{(q,p)|\dot{F}^T(t)q-F^Tp=\delta\}=\{(q,p)|\dot{H}^T(t)q-H^Tp=\delta^H\},$$

where $\delta^H=H_s^T\beta$.

For the proof we will need the following Lemma:

Lemma 2: On the time interval $I=[s,u]$ *and for any two configurations* $x,y\in\mathbb{R}^n$, *consider Hamilton's principal function* $R(s,x,t,y)$ *defined*[17] *as the line integral*

$$R(s,x,t,y)=\int_\gamma L\ dt, \tag{29}$$

where L *denotes the Lagrangian defined by (13) along the solution of (12),* $\gamma_\tau=(q(\tau),\dot{q}(\tau))$ *connecting the points (s,x) and (t,y). We have*

$$R(s,x,t,y)=\tfrac{1}{2}\langle\dot{E}_sE_s^{-1}(t)y,y\rangle-\tfrac{1}{2}\langle\dot{E}_t(s)E_t^{-1}(s)x,x\rangle-\langle E_s^{-1}(t)y,x\rangle, \tag{30}$$

where $E_t(\tau)$ *and* $E_s(\tau)$ *are solutions of (16) on the interval I satisfying the Cauchy data*

$$E_t(t)=0,\quad \dot{E}_t(t)=I_{n\times n}; \tag{31}$$

$$E_s(s)=0,\quad \dot{E}_s(s)=I_{n\times n}. \tag{32}$$

Proof: By (29),

$$R(s,x,t,y)=\int_s^t\left[\frac{|\dot{q}_\lambda|^2}{2}+\frac{1}{2}\langle K(\lambda)q_\lambda,q_\lambda\rangle\right]d\lambda,$$

where q_λ is the solution of (12) satisfying $q(s)=x$ and $q(t)=y$ (we will assume for the moment that this solution is well defined on I and is unique). Hence

$$\begin{aligned}R(s,x,t,y)&=\int_s^t\left[\frac{|q_\lambda|^2}{2}+\frac{1}{2}\langle K(\lambda)q_\lambda,q_\lambda\rangle\right]d\lambda\\&=\int_s^t\frac{|\dot{q}_\lambda|^2}{2}\,d\lambda+\frac{1}{2}\int_s^t\langle\ddot{q}_\lambda,q_\lambda\rangle\,d\lambda=\frac{1}{2}\langle\dot{q}_t,y\rangle-\frac{1}{2}\langle\dot{q}_s,x\rangle.\end{aligned} \tag{33}$$

Using the ansatz

$$q_\tau=E_s(\tau)\lambda_1+E_t(\tau)\lambda_2,$$

where $\lambda_i\in\mathbb{R}^n$, $i=1,2$, and taking into account the boundary conditions $[q(s)=x,q(t)=y]$ we will obtain

$$q_\tau=E_s(\tau)E_s^{-1}(t)y+E_t(\tau)E_t^{-1}(s)x. \tag{34}$$

Substituting in (33),

$$R(s,x,t,y)=\tfrac{1}{2}\langle\dot{E}_sE_s^{-1}(t)y,y\rangle-\tfrac{1}{2}\langle\dot{E}_t(s)E_t^{-1}(s)x,x\rangle+\tfrac{1}{2}\langle E_s^{-1}(t)y,x\rangle-\tfrac{1}{2}\langle E_s^{-1}(t)x,y\rangle. \tag{35}$$

As $E_s(\tau)$ and $E_t(\tau)$ are both solutions of (16), the symplectic inner product $\omega(\mathbf{E}_s,\mathbf{E}_t)$ will be constant on the interval I. Hence, using (31) and (32),

$$\omega(\mathbf{E}_s(s),\mathbf{E}_t(s))=\omega(\mathbf{E}_s(t),\mathbf{E}_t(t)),$$

$$E_s^T(s)\dot{E}_t(s)-\dot{E}_s^T(s)E_t(s)=E_s^T(t)\dot{E}_t(t)-\dot{E}_s^T(t)E_t(t),$$

$$-E_t(s)=E_s(t).$$

Using this equality in (35), we obtain the desired result. Observe also that as we are assuming the disconjugacy of (15), $E_s(\tau)$ and $E_t(\tau)$ will be invertible respectively on the time interval $(s,u]$ and $[s,t)$; in particular $E_s(t)$ is invertible, which proves that (34) is the unique solution of (12) that satisfies the required boundary conditions. □

Proof of Proposition 1: Let us assume that the initial Lagrangian manifold is given by (24), i.e.,

$$M_s=\{(q,p)=\alpha q-\beta\},$$

and let us take the associated function to the Lagrangian manifold, F_t, which, by definition, satisfies the following relation at time s:

$$F_sF_s^{-1}=\alpha.$$

Then we can write the generating function for the initial Lagrangian manifold as

$$S(x)=\tfrac{1}{2}\langle F_sF_s^{-1}x,x\rangle-\beta y+\gamma, \tag{36}$$

where γ is an arbitrary real constant.

The idea of the proof is to explicitly compute $\nabla_y S(t,y)$, where $S(t,y)$ will be the generating function for the Lagrangian manifold M_t, since, then we will have[18]

$$M_t=\left\{(q,p)|p=\frac{\partial S}{\partial q}\,(t,q)\right\}, \tag{37}$$

for $S(t,y)$ the solution of the Hamilton–Jacobi equation on I,

$$\frac{\partial S}{\partial y}+H\left(t,y,\frac{\partial S}{\partial y}\right)=0, \tag{38}$$

subject to the Cauchy data

$$S(s.x)=S(x). \tag{39}$$

The solution of the initial value problem defined by (38) and (39) is given by (cf. Ref. 18)

$$S(t,y)=S_s(x)+R(s,x,t,y), \tag{40}$$

where $R(s,x,t,y)$ denotes Hamilton's principal function defined as the line integral of Poincaré–Cartan form $pdq-Hdt$ evaluated along the solution of Hamilton's equation that connects x at time s to y at time t. The starting configuration x may itself be regarded as a function of y and t, i.e., as the starting point of a trajectory that at time t is in the configuration y. A simple computation will give us (cf. Ref. 19) the following expression for x:

$$x=F^{-1}(t)y+F^{-1}(t)E_s(t)\beta, \tag{41}$$

where $F(t)$ is an associated function to M_s. Observing that (40) implies (cf. Ref. 18)

$$\nabla_y S(t,y)=\nabla_y R(s,x,t,y), \tag{42}$$

we obtain, using Lemma 2,

$$\nabla_y R=\tfrac{1}{2}(\dot{E}_sE_s^{-1}(t)+E_s^{-T}\dot{E}_s^T(t))y-[E_s^{-1}(t)]^Tx. \tag{43}$$

As $E_s(t)$ is an isotropic solution of (17), $\dot{E}_s(t)E_s^{-1}(t)$, in particular, is symmetric on the interval $(s,u]$. Hence,

$$\nabla_y R=\dot{E}_sE_s^{-1}(t)y-[E_s^{-1}(t)]^Tx.$$

Using (41) we obtain,

$$\nabla_y S(t,y)=f(t)y-\beta(t), \tag{44}$$

where $f(t)$ and $\beta(t)$ are defined by

$$f(t)=\dot{E}_s(t)E_s^{-1}(t)-[E_s^{-1}(t)]^T F(s)F^{-1}(t),$$

$$\beta(t)=[E_s^{-1}(t)]^T F^{-1}(t)E_s(t)\beta.$$

As $-F(s)=\omega(\mathbf{E}_s(\tau),\mathbf{F}(\tau))$, we can simplify the expression for $f(t)$:

$$\begin{aligned} f(t)&=\dot{E}_s(t)E_s^{-1}(t)-[E_s^{-1}(t)]^T F(s)F^{-1}(t)=[E_s^{-1}(t)]^T[\dot{E}_s^T(t)-F(s)F^{-1}(t)]\\ &=[E_s^{-1}(t)]^T[\dot{E}_s^T(t)F(t)-F(s)]F^{-1}(t)=[E_s^{-1}(t)]^T E_s^T(t)\dot{F}(t)F^{-1}(t)=\dot{F}F^{-1}(t). \end{aligned}$$

As F_t is the associated function for M_s on I, F_t is an isotropic solution of (17) which implies that $\dot{F}F^{-1}(t)$ is a symmetric matrix in I. Using this property we can simplify as well the expression for $\beta(t)$:

$$\begin{aligned} \beta(t)&=[E_s^{-1}(t)]^T F(s)F^{-1}(t)E_s(t)\beta=[\dot{E}_s(t)-f(t)E_s(t)]\beta=[\dot{E}_s(t)-\dot{F}(t)F^{-1}(t)E_s(t)]\beta\\ &=[\dot{E}_s(t)-[F^{-1}(t)]^T\dot{F}^T(t)E_s(t)]\beta=[F^{-1}(t)]^T[F^T\dot{E}_s(t)-\dot{F}^T(t)E_s(t)]\beta\\ &=[F^{-1}(t)]^T\omega(F,E_s)\beta=[F^{-1}(t)]^T F^T(s)\beta=[F^{-1}(t)]^T\delta. \end{aligned}$$

Hence, using (37) and (44) we obtain

$$M_t=\{(q,p)|p=\dot{F}_t F_t^{-1}(t)q-[F^{-1}(t)]^T\delta\}. \tag{45}$$

Using again the fact that F_t is an associated function for M_s on I, we will obtain for $(q,p)\in M_t$

$$F_t^T p-\dot{F}_t^T q=-\delta. \tag{46}$$

If the initial manifold is a singular one associated with a configuration $x\in\mathbb{R}^n$, i.e.,

$$M_s=\{(q,p)|q=x\},$$

then we do not have a generating function for this manifold. However, for $t>s$ the corresponding momentum field is given by

$$M_t=\{(q,p)|p=\nabla R(s,x,t,q)\}.$$

Using Lemma 2 directly we have, for $t>s$,

$$\nabla R(s,x,t,y)=\dot{E}_s(t)E_s^{-1}(t)q-E_s^{-T}(t)x.$$

Hence, as E_s is invertible and isotropic on the interval $(s,u]$, we obtain (28) for the singular Lagrangian manifold case with $\delta=x$:

$$M_t=\{(q,p)|E_s^T(t)p-\dot{E}_s^T(t)q=-x\}.$$

Suppose now that we choose another associated function H_t to M_s on I. In particular H_t will be another solution of (17) on I, hence we will have the following relation between F_t and H_t:

$$H_t=F_t[F_s^{-1}H_s+G(t)\omega(\mathbf{F}_t,\mathbf{H}_t)], \tag{47}$$

where

$$G(t)=\int_s^l F_\tau^{-1}F_\tau^{-T}\,d\tau.$$

Applying Lemma 2, $\omega(\mathbf{F}_t,H_t)=0$ which implies

$$H_t = F_t F_s^{-1} H_s . \tag{48}$$

Consequently, for $(q,p) \in M_t$

$$\dot{H}_t^T p - H_t^T q = [F_s^{-1} H_s]^T [\dot{F}_t^T p - F_t^T q] = [F_s^{-1} H_s]^T F_s^T \beta = H_s^T \beta,$$

which proves that $M_t \subset M_t^H$, where

$$M_t^H = \{(q,p) | \omega(\mathbf{H}_t, \mathbf{I}_{q,p}) = -H_s^T \beta\}.$$

In a similar way we could prove the reverse statement. Hence

$$M_t = M_t^H .$$

□

Now instead of giving an initial Lagrangian manifold or an initial momenta field we are given a final one. Consider the following Lagrangian manifolds,

$$R_u = \{(q,p) | -p = \hat{\alpha} q - \hat{\beta} x\}, \tag{49}$$

$$R_u^z = \{(q,p) | q = z\}, \tag{50}$$

where $\hat{\alpha}$ is a symmetric invertible $n \times n$ matrix and $\hat{\beta}, z \in \mathbb{R}^n$. The trajectories consistent with these final manifolds will be solutions $\gamma(t) = (q(t), p(t))$ of Hamilton's equation of motion on I such that $\gamma(u) \in R_u$ [or $q(u) = z$]. We want to compute for $t \in I$ the time-reversed image R_t of these manifolds.

Definition 3: Given a final Lagrangian manifold we define its *associated function* on an interval $I = [s, u]$, $\hat{F}_t$, as an isotropic matrix solution of (17) such that we have the following.

(1) If the Lagrangian manifold is defined by (49), $\hat{F}_t$ is a nonsingular matrix for $t \in I$ such that

$$-\dot{\hat{F}}_u \hat{F}_u^{-1} = \hat{\alpha}. \tag{51}$$

(2) If the Lagrangian manifold is a singular, i.e., defined by (50), then $\hat{F}_t$ is a nonsingular matrix for $t \in [s,u)$ and satisfies $F(u) = 0$.

As in Lemma 1, we have the following.

Lemma 3: If $\hat{F}_t$ and $\hat{H}_t$ are two associated functions on the time interval I to a Lagrangian manifold R_u, then $\omega(\hat{\mathbf{F}}_t, \hat{\mathbf{H}}_t) = 0$.

Proposition 2: The image of the Lagrangian manifolds defined by (49) [or (50)] under the time reversed Hamiltonian flow defined by (14) is, for $t \in I$, given by

$$R_t = \{(q,p) | \dot{\hat{F}}^T(t) q - \hat{F}^T p = \hat{\delta}\}, \tag{52}$$

where $\hat{F}(t)$ is the associated function to R_u (or R_z^u) and $\hat{\delta} = \hat{F}_u^T \hat{\beta}$ (or $\hat{\delta} = z$). Moreover, the expression (52) is independent of the choice of the associated function to M_s, i.e., if $\hat{H}_t$ is another associated function to R_u on I, then

$$\{(q,p) | \dot{\hat{F}}^T(t) q - \hat{F}^T p = \hat{\delta}\} = \{(q,p) | \dot{\hat{H}}(t) q - \hat{H}^T p = \hat{\delta}^H\},$$

where $\hat{\delta}^H = H_u^T \hat{\beta}$.

Proof: The proof follows the same lines as the proof of the last proposition, i.e., R_t will now be given by

$$R_t = \left\{ (q,p) | -p = \frac{\partial \hat{S}(t,y)}{\partial y} \right\},$$

where $\hat{S}(t,y)$ is the solution for the time-reversed Hamilton–Jacobi equation

$$-\frac{\partial \hat{S}(t,y)}{\partial t}+H\left(t,y,-\frac{\partial \hat{S}(t,y)}{\partial y}\right)=0, \quad y\in\mathbb{R}^n, \quad t\in I, \tag{53}$$

satisfying

$$\hat{S}(u,z)=\hat{S}(z) \tag{54}$$

with $\hat{S}(z)$ denoting the generating function of $\hat{R}_u=\mathscr{T}(R_u)$, where $\mathscr{T}:\mathbb{R}^{2n}\to\mathbb{R}^{2n}$ is defined as $\mathscr{T}(q,p)=(q,-p)$. □

Remark 1: It follows from Propositions 1 and 2 that the images of the Lagrangian manifolds M_s and R_u can be written in terms of the symplectic product, i.e.,

$$M_t=\{(q,p)\,|\,\omega(\mathbf{F}_t,\mathbf{I}_{q,p})=F_s^T\beta\}, \tag{55}$$

$$R_t=\{(q,p)\,|\,\omega(\hat{\mathbf{F}}_t,\mathbf{I}_{q,p})=\hat{\beta}\}, \tag{56}$$

where $\mathbf{I}_{q,p}=(\delta_{ij}q_i;\delta_{ij}p_i)_{t\leqslant i,j\leqslant n}$, $\mathbf{F}_t=(F_t,\dot{F}_t)$, and $\hat{\mathbf{F}}_t=(\hat{F}_t,\dot{\hat{F}}_t)$, with F_t and $\hat{F}_t$ denoting the solutions associated with M_s and R_u.

Remark 2: From the proof of Proposition 1 we can obtain explicit expressions for the solution of the Hamilton–Jacobi equation initial value problem given by (38) and (39). Using (45) we obtain

$$S(t,y)=\langle \dot{F}_t F_t^{-1},y\rangle - F_t^{-T}\beta y+\gamma_t. \tag{57}$$

As the above expression is a solution of the boundary value problem (38) and (39) we can easily show that γ_t is a solution on I of the first-order differential equation:

$$\dot{\gamma}_t+|F_t^{-T}\beta|^2=0, \quad \gamma(s)=\gamma_s. \tag{58}$$

Using Proposition 2 we obtain in the same way a solution of the boundary value problem (53) and (54):

$$\hat{S}(t,y)=-\langle \dot{\hat{F}}_t\hat{F}_t^{-1},y\rangle - \hat{F}_t^{-T}\hat{\beta}y+\hat{\gamma}_t. \tag{59}$$

In this case, $\hat{\gamma}_t$ solves the time-reversed equation on the time interval I, (58), i.e.,

$$\dot{\hat{\gamma}}_t+|\hat{F}_t^{-T}\hat{\beta}|^2=0, \quad \hat{\gamma}(u)=\hat{\gamma}_u. \tag{60}$$

B. Consistent solutions

Consider the pair of Lagrangian manifolds M_s and R_u defined by the associated functions F_t and $\hat{F}_t$ on the interval $I=[s,\ u]$ and the two $\mathbb{R}^n$ vectors $\delta,\hat{\delta}$.

Consider the problem of finding regular trajectories $\mathbf{m}_t\equiv(m(t),\dot{m}(t))\in\mathbb{R}^{2n}$ such that $\mathbf{m}(t)$ is a solution of Hamilton's equations of motion (15) on I satisfying the following boundary conditions:

$$\mathbf{m}(s)\in M_s, \tag{61}$$

$$\mathbf{m}(u)\in R_u. \tag{62}$$

It turns out that this boundary value problem is equivalent to finding, for each $t\in I$, the intersection $L_t\cap R_t$:

Proposition 3: Consider a pair of Lagrangian manifolds M_s and R_u, defined by the associated functions $F_t,\hat{F}_t$ on the time interval I, satisfying $\omega(\mathbf{F}_t,\hat{\mathbf{F}}_t)\neq 0$. Then, for each $t\in I$, the set $M_t\cap R_t$ is a single-element set given by

$$L_t\cap R_t=\{(\mathbf{m}_t)\} \tag{63}$$

with $\mathbf{m}_t=(m_t,\dot{m}_t)$, *where* $\mathbf{m}_t$ *is the solution of Hamilton's equations of motion (15) on I satisfying the boundary conditions given by (61) and (62). Moreover, we can write* $\mathbf{m}_t$ *as*

$$\mathbf{m}_t=\mathbf{F}_t[\omega(\hat{\mathbf{F}},\mathbf{F})]^{-1}\hat{\delta}+\hat{\mathbf{F}}_t[[\omega(\hat{\mathbf{F}},\mathbf{F})]^T]^{-1}\delta, \tag{64}$$

where $\hat{\mathbf{F}}\equiv(\hat{F}_t,\dot{\hat{F}}_t)$ *and* $\mathbf{F}_t\equiv(F_t,\dot{F}_t)$. *This solution* $\mathbf{m}_t$ *will be referred to as the "*M_sR_u *consistent solution."*

Proof: Consider (q,p) in the intersection set. Then, by Propositions 1 and 2,

$$\omega(\mathbf{F}_t,\mathbf{I}_{q,p})=-\delta,\quad \omega(\hat{\mathbf{F}}_t,\mathbf{I}_{q,p})=-\hat{\delta}.$$

Hence using the fact that $\omega(\mathbf{F}_t,\hat{\mathbf{F}}_t)\neq 0$ and solving the system we will obtain the unique solution

$$\mathbf{m}_t=\mathbf{F}_t[\omega(\hat{\mathbf{F}},\mathbf{F})]^{-1}\hat{\delta}+\hat{\mathbf{F}}_t[[\omega(\hat{\mathbf{F}}_t,\mathbf{F}_t)]^T]^{-1}\delta,$$

which is obviously a solution of the Hamilton equations of motion that satisfies the required boundary conditions. □

Remark 3: In the conditions of the above proposition we can also consider for any $t\in I$ and $y\in\mathbb{R}^n$ the pairs of Lagrangian manifolds M_s,R_t^y and M_t^y,R_u, where the Lagrangian manifolds R_t^y and M_t^y both denote the singular Lagrangian manifold at time t associated with the configuration y (we adopt different notation since R_t^y is viewed as a final condition with respect to the Lagrangian manifold M_s on the time interval $[s,\ t]$ whereas M_t^y is an initial manifold with respect with the manifold R_u on the time interval $[t,\ u]$). We can take $E_t(\tau)$ as the associated function to R_t^y on the interval $[s,\ u]$ and $E_t(\tau)$ as the associated function to the manifold M_t^y. Denoting by $\gamma_{M_s}^{R_t^y}(\tau)$ and $\gamma_{M_t^y}^{R_y^l}(\tau)$ the consistent solutions to the pairs of Lagrangian manifolds M_t^y,R_u and M_s,R_t^y, respectively, we will have, applying Proposition 3. the following expressions:

$$\gamma_{M_s,R_t^y}(\tau)=\mathbf{F}_\tau[\omega(\hat{\mathbf{E}}_t(\tau),\mathbf{F})]^{-1}y+\hat{\mathbf{E}}_t(\tau)[[\omega(\hat{\mathbf{E}}_t(\tau),F)]^T]^{-1}\delta,$$

$$\gamma^{M_t^y,R_u}(\tau)=\mathbf{E}_t(\tau)[\omega(\hat{\mathbf{F}}(\tau),\mathbf{E}_t)]^{-1}\hat{\delta}+\hat{\mathbf{F}}(\tau)[[\omega(\hat{\mathbf{F}}(\tau),\mathbf{E}_t)]^T]^{-1}y,$$

but as

$$\omega(\hat{\mathbf{E}}_t(\tau),\mathbf{F}(\tau))=\hat{E}_t(t)^T\dot{F}(t)-\dot{\hat{E}}_t(t)^TF(t)=F(t),$$

$$\omega(\hat{\mathbf{F}}(\tau),\mathbf{E_t})=\hat{F}(t)^T\dot{E}_t(t)-\dot{\hat{F}}(t)^TE_t(t)=\hat{F}(t)^T,$$

we obtain

$$\gamma_{M_s,R_t^y}(\tau)=\mathbf{F}_\tau F(t)^{-1}y+\hat{\mathbf{E}}_t(\tau)[F(t)^T]^{-1}\delta, \tag{65}$$

$$\gamma^{M_t^y,R_u}(\tau)=\mathbf{E}_t(\tau)[\hat{F}^T(t)]^{-1}\hat{\delta}+\hat{\mathbf{F}}(\tau)[\hat{F}(t)]^{-1}y. \tag{66}$$

III. EUCLIDEAN (OR PROBABILISTIC) QUANTIZATION

We will show that there is a natural way to associate to a pair of Lagrangian manifolds a Gaussian probability density function defining a $\mathbb{R}^n$-valued diffusion process.

A. Associating a Gaussian probability density to a pair of Lagrangian manifolds

Proposition 3 allows us to consider a regular solution $m(t)$ of $\ddot{q}(t)=K(t)q(t)$ on $I=[s,\ u]$ with boundary values given by the pair of Lagrangians manifolds L_s and R_u. Any configuration $y\neq m(t)$ will determine two points, respectively, $(y,p_1)\in M_t$ and $(y,p_2)\in R_t$, to which a pair of

trajectories $\gamma_{M_s}^{R_t^y}(\tau)=(q^{t,y}(\tau),\dot{q}^{t,y}(\tau))$ and $\gamma_{M_t^y}^{R_u}(\tau)=(q_{t,y}(\tau),\dot{q}_{t,y}(\tau))$ can be associated where $q^{t,y}(\tau)$ and $q_{t,y}(\tau)\tau\in[s,\ u]=I$ denote, respectively, solutions of Hamilton's equation of motion satisfying the relations

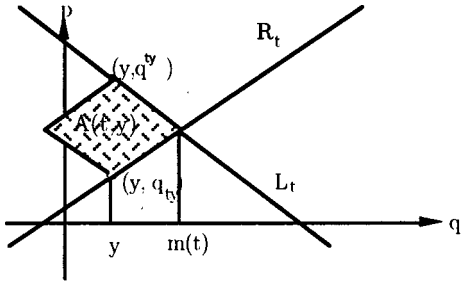
$$\gamma_{M_s}^{R_t^y}(s)\in M_s,\quad \gamma_{M_t^y}^{R_u}(u)\in R_u,\quad \gamma_{M_s}^{R_t^y}(t)=(y,p_1),\quad \gamma_{M_t^y}^{R_u}(t)=(y,p_2).$$

Definition 4: Given a pair of Lagrangian manifolds M_s, R_u with associated functions defined on a time interval $I=[s,\ u]$, we will call the area associated to the pair of manifolds the symplectic inner product defined by

$$A_{M_s}^{R_u}(t,y)=\omega(\mathbf{X}_{t,y}(\tau),\mathbf{Y}^{t,y}(\tau)), \tag{67}$$

where $\mathbf{X}_{t,y}(\tau)$ and $\mathbf{Y}^{t,y}(\tau)$ are respectively the solutions of Hamilton's equations (15). defined by

$$\mathbf{X}_{t,y}(\tau)\equiv\gamma_{M_s}^{R_t^y}(\tau)-\mathbf{m}(\tau),\quad \mathbf{Y}^{t,y}(\tau)\equiv\gamma_{M_t^y}^{R_u}(\tau)-\mathbf{m}(\tau).$$



Lemma 4: Consider a pair of Lagrangian manifolds M_s, R_u defined by its associated functions F, $\hat{F}$ on $I=[s,\ u]$ and by the two vectors $\delta,\hat{\delta}\in\mathbb{R}^n$. Then we can write the associated area $A_{M_s}^{R_u}(t,y)$ as

$$A_{M_s}^{R_u}(t,y)=(y-m(t))^TC^{-1}(t)(y-m(t)), \tag{68}$$

where $m(t)$ and $C(t)$ are respectively the projection onto the configuration space of $\mathbf{m}_t$ and the consistent trajectory to the pair of Lagrangian manifold, a symmetric matrix defined by

$$m_t=F_t[\omega(\hat{\mathbf{F}},\mathbf{F})]^{-1}\hat{\delta}+\hat{F}_t[[\omega(\hat{\mathbf{F}},\mathbf{F})]^T]^{-1}\delta, \tag{69}$$

$$C(t)=F(t)[\omega(\hat{\mathbf{F}},\mathbf{F})]^{-1}\hat{F}^T(t). \tag{70}$$

Moreover, $C(t)$ is independent of the choice of the associated functions $F_t,\hat{F}_t$ to the Lagrangian manifolds M_s,R_u.

Proof: As associated functions to the pair of Lagrangian manifolds on the time interval I, they are isotropic, which implies that $\dot{F}_tF_t^{-1}$ and $\dot{\hat{F}}_t\hat{F}_t^{-1}$ are symmetric matrices on the interval I. Hence $\dot{F}_tF_t^{-1}-\dot{\hat{F}}_t\hat{F}_t^{-1}$ is also a symmetric matrix on I. However,

$$\dot{F}_tF_t^{-1}-\dot{\hat{F}}_t\hat{F}_t^{-1}=\hat{F}_t^{-T}\hat{F}_t^T\dot{F}_tF_t^{-1}-\hat{F}_t^{-T}\dot{\hat{F}}_t^TF_tF_t^{-1}=\hat{F}_t^{-T}[\hat{F}_t^T\dot{F}_t-\dot{\hat{F}}_t^TF_t]F_t^{-1}=C^{-1}(t),$$

which proves that, for all $t\in I$, $C(t)$ is a symmetric matrix.

Now we prove (68). By (67) we can write

$$A_{M_s}^{R_u}(t,y)=\omega(\gamma_{M_s}^{R_t^y}(\tau),\gamma_{M_t^y}^{R_u}(\tau))-\omega(\gamma_{M_s}^{R_t^y}(\tau),\mathbf{m}(\tau))-\omega(\mathbf{m}(\tau),\gamma_{M_t^y}^{R_u}(\tau)). \tag{71}$$

Using (65) and (66), we compute the first term of (71):

$$\omega(\gamma_{M_s}^{R_t^y}(\tau),\gamma_{M_t^y}^{R_u}(\tau))=y^T\hat{F}^{-T}\hat{\delta}+y^TF^{-T}\omega(\mathbf{F},\hat{\mathbf{F}})\hat{F}^{-1}y+\delta^TF^{-1}y, \tag{72}$$

but

$$\begin{aligned} y^T\hat{F}^{-T}\hat{\delta}&=y^T\hat{F}^{-T}[F\omega^{-1}(\hat{\mathbf{F}},\mathbf{F})]^{-1}[F\omega^{-1}(\hat{\mathbf{F}},\mathbf{F})]\hat{\delta}\\ &=y^T\hat{F}^{-T}\omega(\hat{\mathbf{F}},\mathbf{F})F^{-1}[F\omega^{-1}(\hat{\mathbf{F}},\mathbf{F})]\hat{\delta}=y^Tc^{-1}(t)F\omega^{-1}(\hat{\mathbf{F}},\mathbf{F})\hat{\delta} \end{aligned} \tag{73}$$

and

$$\delta^TF^{-T}y=\delta^TF^{-T}[\omega^T(\hat{\mathbf{F}},\mathbf{F})\hat{F}^{-1}][\omega^T(\hat{\mathbf{F}},\mathbf{F})\hat{F}^{-1}]^{-1}y=\delta^Tc^{-T}\hat{F}\omega^{-T}(\hat{\mathbf{F}},\mathbf{F})y=y^Tc^{-1}\hat{F}\omega^{-T}(\hat{\mathbf{F}},\mathbf{F})\delta. \tag{74}$$

Hence

$$\begin{aligned} \omega(\gamma_{M_s}^{R_t^y}(\tau),\gamma_{M_t^y}^{R_u}(\tau))&=y^Tc^{-1}[F\omega^{-1}(\hat{\mathbf{F}},\mathbf{F})\hat{\delta}+\hat{F}\omega^{-T}(\hat{\mathbf{F}},\mathbf{F})\delta]+y^TF^{-T}\omega(\mathbf{F},\hat{\mathbf{F}})\hat{F}^{-1}y\\ &=y^Tc^{-1}m(t)+y^Tc^{-1}(t)y=y^Tc^{-1}(t)(m(t)-y). \end{aligned} \tag{75}$$

By similar computations, we also verify that

$$\omega(\gamma_{M_s}^{R_t^y}(\tau),\mathbf{m}(\tau))=\delta^TF^{-1}(m(t)-y), \tag{76}$$

$$\omega(\gamma_{M_t^y}^{R_u}(\tau),\mathbf{m}(\tau))=(y-m(t))^T\hat{F}^{-T}\hat{\delta}. \tag{77}$$

Using (71), (75), (76), and (77) we will obtain

$$\begin{aligned} A_{M_s}^{R_u}(t,y)&=\omega(\gamma_{M_s}^{R_t^y}(\tau),\gamma_{M_t^y}^{R_u}(\tau))-\omega(\gamma_{M_s}^{R_t^y}(\tau),\mathbf{m}(t))-\omega(\mathbf{m}(t),\gamma_{M_t^y}^{R_u}(\tau))\\ &=y^Tc^{-1}(t)(m(t)-y)-\delta^TF^{-1}(m(t)-y)-(y-m(t))^T\hat{F}^{-T}\hat{\delta}\\ &=(y-m_t)C^{-1}(t)(y-m_t). \end{aligned}$$

Now we prove that $C(t)$ is independent of the choice of the associated functions to the Lagrangian manifolds. Let us denote by H_t another function associated to the Lagrangian manifold L_s. Using the argument of the proof of Proposition 2, we have the following relationship between F_t and H_t for $t\in I$:

$$H_t=F_tF_s^{-1}H_s.$$

Therefore,

$$\begin{aligned} H_t[\omega(\hat{\mathbf{F}}_t,\mathbf{H}_t)]^{-1}\hat{F}_t^T&=F_tF_s^{-1}H_s[\omega(\hat{\mathbf{F}}_t,\mathbf{F}_tF_s^{-1}H_s)]^{-1}\hat{F}_t^T\\ &=F_tF_s^{-1}H_s[\omega(\hat{\mathbf{F}}_t,\mathbf{F}_t)F_s^{-1}H_s]^{-1}\hat{F}_t^T\\ &=F_t[\omega(\hat{\mathbf{F}}_t,\mathbf{F}_t)]^{-1}\hat{F}_t^T=C(t). \end{aligned}$$

A similar argument is valid if one replaces $\hat{F}_t$ by another associated function to the Lagrangian manifold R_u. □

Definition 5: A pair of Lagrangian manifolds M_s, R_u is called a compatible pair on the time interval $I=[s,u]$ if

(i) their associated functions $F_t,\hat{F}_t$ are defined on I, and

(ii) $C(t)$, defined by (70), is positive definite on the interior of I and non-negative definite for $t=s$ and $t=u$.

Proposition 4: Given an arbitrary final (resp. initial) Lagrangian manifold with an associated function $\hat{F}_t$ (resp. F_t) defined on the interval $I=[s,u]$, there exists a family of compatible initial (resp. final) Lagrangian manifolds.

Proof: Consider a final Lagrangian manifold R_u and $\hat{F}_t$, its associated function defined on the interval I. For any $n\times n$ nonsingular matrix σ, let us denote by P the positive definite matrix

$$P\equiv\sigma\sigma^T. \tag{78}$$

We now define a family F_t^P of solutions of the matrix differential equation on I,

$$\ddot{F}_t=K(t)F_t$$

[where, as usual, $K(t)$ denotes a symmetric nonsingular matrix on I], by

$$F_t^P=\hat{F}_tP+\hat{F}_t\int_s^t\hat{F}_\lambda^{-1}F_\lambda^{-T}\,d\lambda, \tag{79}$$

which, in turn, will allow us to define a family of initial Lagrangian manifolds, $M_s^{P,\delta}$:

$$M_s^{P,\delta}=\{(q,p):p=\dot{F}_s^P[F_s^P]^{-1}q-[F_s^P]^{-T}\delta\},$$

compatible with R_u. Observe that for any P fulfilling (78) we have

$$\omega(\hat{F}_t,F_t^P)=I_{n\times n}. \tag{80}$$

An analogous argument is valid if one starts from a fixed initial Lagrangian manifold M_s. □

Remark 4: In fact we can always choose, for two compatible Lagrangian manifolds on I, associated functions such that (80) holds.

Indeed consider F_t and $\hat{F}_t$ any associated functions for the pair of Lagrangian manifolds on the time interval I. If (80) is not verified, we can replace $\hat{F}_t$ by $H\equiv\hat{F}_t\omega(\hat{\mathbf{F}}_t,\mathbf{F}_t)^{-T}$ (which is also a function on I associated to the Lagrangian manifold R_u). Then

$$\begin{aligned}\omega(\mathbf{H}_t,\mathbf{F}_t)&=\omega(\omega(\hat{\mathbf{F}}_t,\mathbf{F}_t)^{-T}\hat{\mathbf{F}},\mathbf{F}_t)\\&=(\hat{F}_t\omega(\hat{\mathbf{F}}_t,\mathbf{F}_t)^{-T})^T\dot{F}_t-(\dot{\hat{F}}\omega(\hat{\mathbf{F}}_t,\mathbf{F}_t)^{-T})^TF_t\\&=\omega(\hat{\mathbf{F}}_t,\mathbf{F}_t)^{-1}\omega(\hat{\mathbf{F}}_t,\mathbf{F}_t)=I_{n\times n}.\end{aligned}$$

Proposition 5: If R_u (resp. M_s) is a final (resp. initial) Lagrangian manifold with associated function $\hat{F}_t$ (resp. F_t) on I, then the pair $M_{t_0}^y,R_u$ (resp. $M_s,R_{t_0}^y$) is compatible in the interval $[t_0,\,u]$ (resp. $[s,\,t_0]$) and for all configurations $y\in\mathbb{R}^n$.

Proof: A solution associated to the singular manifold $M_{t_0}^x$ on the time interval $[t_0,\,u]$ is given by $E_{t_0}(t)$ [i.e., the solution of the matrix equation (17) satisfying the Cauchy data $E_{t_0}(t_0)=0$, $\dot{E}_t0(t_0)=I_{n\times n}$]. The corresponding matrix (70) relative to this case is

$$C(t)=E_{t_0}(t)[\omega(\hat{\mathbf{F}}_t,E_{t_0}(t))]^{-1}\hat{F}(t).$$

To prove that the pair of Lagrangian manifolds are compatible we need to prove that the above expression is non-negative definite. For this we write $E_{t_0}(t)$ on $[t_0,\,u]$ as

$$E_{t_0}(t)=\hat{F}(t)\left[\int_{t_0}^t\hat{F}^{-1}(\lambda)\hat{F}^{-T}(\lambda)\,d\lambda\right]F^T(t_0).$$

Then we obtain for $C(t)$

$$E_{t_0}(t)[\omega(\hat{\mathbf{F}}_t,E_{t_0}(t))]^{-1}\hat{F}^T(t)=E_{t_0}(t)[\hat{F}^T(t_0)]^{-1}\hat{F}^T(t)$$
$$=\hat{F}(t)\left[\int_{t_0}^{t}\hat{F}^{-1}(\lambda)\hat{F}^{-T}(\lambda)\,d\lambda\right]F^T(t_0)[\hat{F}^T(t_0)]^{-1}\hat{F}^T(t)$$
$$=\hat{F}(t)\left[\int_{t_0}^{t}\hat{F}^{-1}(\lambda)\hat{F}^{-T}(\lambda)\,d\lambda\right]\hat{F}^T(t),$$

which is clearly a non-negative definite matrix. In the same way we can prove that, given an initial Lagrangian manifold L_s such that the associated solution $F(t)$ is invertible on the time interval $[s,\,u]$, then, for all configurations $z\in\mathbb{R}^n$ and all $t_0\in I-\{s\}$, the pair of Lagrangian manifolds M_s, $R^z_{t_0}$ are compatible.

Finally, for $s\leqslant t_1<t_2\leqslant u$ and for all configurations $x,\,z\in\mathbb{R}^n$, the pairs of singular Lagrangian manifolds $M^x_{t_1}$, $R^z_{t_2}$ are compatible. In this case the associated functions are $E_{t_1}(t)$ and $\hat{E}_{t_2}(t)\equiv -E_{t_2}(t)$, hence the corresponding $C(t)$ is given by

$$E_{t_1}(t)[\omega(\hat{\mathbf{E}}_{t_2}(t),\mathbf{E}_{t_1}(t))]^{-1}\hat{E}_{t_2}(t),$$

which is clearly a positive definite matrix. □

In a two-dimensional phase space there is no restriction on the pairs of boundary Lagrangian manifolds, i.e., all pairs of Lagrangian manifolds with associated functions on an interval I are compatible.

Let us consider the following pairs of Lagrangian manifolds in $\mathbb{R}^2$:

$$M_s=\{(q,p)\in\mathbb{R}^2|p=\alpha q-\beta\},$$

$$R_u=\{(q,p)\in\mathbb{R}^2|-p=\hat{\alpha}q-\hat{\beta}\},$$

where $\alpha,\,\hat{\alpha},\,\beta,\,\hat{\beta}\in\mathbb{R}$. Consider associated functions F_t, $\hat{F}_t$ on the time interval I. By definition of associated function, both functions have a definite sign on the interior of the interval I. Without loss of generality we can assume also that $\omega(\hat{\mathbf{F}}_t,\mathbf{F}_t)=1$. Hence two cases are possible:

(1) $F_t\hat{F}_t>0$,

(2) $F_t\hat{F}_t<0$.

In the first case, we have $C(t)>0$ on I so the Lagrangian manifolds are compatible. For the second case, we consider the following two Lagrangians manifolds:

$$M'_s=R_u\,, \tag{81}$$

$$R'_u=M_u\,. \tag{82}$$

As it can easily be verified, the correspondent functions for the pair M'_s, R'_u will be given by H_t, $\hat{H}_t$ defined as

$$H_t=\hat{F}_t\,, \tag{83}$$

$$\hat{H}_t=F_t\,. \tag{84}$$

Therefore we will have $H_t\hat{H}_t<0$ and

$$\omega(\hat{\mathbf{H}}_t,\mathbf{H}_t)=\omega(\mathbf{F}_t;\hat{\mathbf{F}}_t)=-1,$$

which implies that $C(t)>0$.

Returning to the general case, we state the main result of this section, i.e., we can associate to any compatible pair of Lagrangian manifolds a Gaussian probability density:

Theorem 1: *A pair of compatible Lagrangian manifolds M_s, R_u define on the time interval I a Gaussian probability density $\rho(t,y)$ whose mean is the consistent trajectory associated with M_s, R_u and variance $C(t)$ given by*

$$C(t)=F_t[\omega[\hat{\mathbf{F}}_t,\mathbf{F}_t)]^{-1}\hat{F}_t^T, \tag{85}$$

where F_t and $\hat{F}_t$ are the functions associated with the Lagrangian manifolds M_s and R_u.

Proof: By Lemma 4, a pair of Lagrangian manifolds defines a symplectic area $A(t,y)$ defined by

$$A(t,y)=(y-m(t))^T C^{-1}(t)(y-m(t)).$$

As we are assuming that the pair of Lagrangian manifolds are compatible, $C(t)$ in the above expression is a non-negative definite symmetric matrix which implies that

$$\rho(y,t)\ dy=\frac{1}{\sqrt{2\pi c(t)}}\exp\ (-A(t,y))\ dy$$

is a Gaussian density function having as mean the consistent trajectories and variance (85). □

B. The associated probability density and a system of adjoint heat equations

Given a pair of compatible Lagrangian manifolds L_s, R_u we know, using the results of the last section, that we have a Gaussian probability density function associated to the manifolds. We now show that this density can be expressed as a product of positive solutions of the adjoint heat equations:

$$\frac{\partial\eta}{\partial t}=H\eta, \tag{86}$$

$$-\frac{\partial\hat{\eta}}{\partial t}=H\hat{\eta}, \tag{87}$$

where $y\in\mathbb{R}^n$ and $t\in I$ and

$$H=-\tfrac{1}{2}\Delta+\langle K(t)y,y\rangle$$

with $K(t)$ denoting a symmetric $n\times n$ positive matrix with a continuous dependence in t.

Proposition 6: Consider a pair of compatible Lagrangian manifolds M_s, R_u on a time interval I. Then (up to a normalizing factor) we can write the associated density as a product of two positive solutions $\eta(t,y)$, $\hat{\eta}(t,y)$ of the adjoint heat equations (86) and (87), satisfying boundary conditions on the interval $I=[s,u]$ which are specified by the pair of Lagrangian manifolds.

Proof: Let us first consider the compatible Lagrangian manifolds on a time interval $I\equiv[s,\ u]$:

$$M_s=\{(q,p)|p=\alpha q-\beta\}, \tag{88}$$

$$R_u=\{(q,p)|-p=\hat{\alpha}q-\hat{\beta}\}, \tag{89}$$

where, as usual, α, $\hat{\alpha}$ are invertible symmetric matrix and β, $\hat{\beta}\in\mathbb{R}^n$. This pair will determine a pair of generating functions (up to additive constants γ_s and γ_u) $S(s,x)$ and $-\hat{S}(u,z)$, namely,

$$S(s,x)=\tfrac{1}{2}\langle\alpha x,x\rangle-\beta x+\gamma_s,\quad -\hat{S}(u,z)=-\tfrac{1}{2}\langle\hat{\alpha}z,z\rangle+\hat{\beta}z+\hat{\gamma}_u.$$

For any $t\in I$, the solutions $S(t,y)$ and $\hat{S}(t,y)$ of the Hamilton Jacobi equations (38) and (53) with boundary conditions given, respectively, by $S(s,x)$ and $S(u,z)$ are given, according to Propositions 1 and 2, by

$$S(t,y)=\tfrac{1}{2}\langle \dot{F}_t F_t^{-1} y,y\rangle - F_t^{-T}\beta y+\gamma_t, \tag{57$'$}$$

$$\hat{S}(t,y)=\tfrac{1}{2}\langle \dot{\hat{F}}_t \hat{F}_t^{-1} y,y\rangle - \hat{F}_t^{-T}\hat{\beta} y+\hat{\gamma}_t, \tag{59$'$}$$

where γ_t and $\hat{\gamma}_t$ are, respectively, solutions on I of the first-order differential equations (58) and (60). Adding (57) with (59) we will obtain

$$S(t,y)+\hat{S}(t,y)=\frac{A(t,y)}{2}+g, \tag{90}$$

where $A(t,y)$ is the symplectic area associated to the pair of manifolds and g denotes a reminder, to be determined. Let us take m_t, the consistent solution to the manifolds M_s, R_u. Obviously $A(t,m_t)=0$, which implies

$$g=S(t,m_t)+\hat{S}(t,m_t).$$

Using (40),

$$g=S_s(m_s)+R(s,m_s,t,m_t)+R(t,m_t,u,m_u)+\hat{S}(u,m_u)=S_s(m_s)+R(s,m_s,u,m_u)+\hat{S}(u,m_u).$$

Hence g does not depend on the variables (t,y), $t\in I$. Using Theorem 1, we can express the associated probability density, $\rho(y,t)$, as

$$\begin{aligned}\rho(t,y)&=\frac{1}{\sqrt{(2\pi)^n \det C(t)}}\exp\left(-\frac{A(t,y)}{2}\right)=\frac{1}{\sqrt{(2\pi)^n \det C(t)}}\exp(-S(t,y)-\hat{S}(t,y)+g)\\&=\frac{1}{\sqrt{(2\pi)^n \det[F_t\omega(\hat{\mathbf{F}},\mathbf{F})\hat{F}_t]}}\exp(-S(t,y)-\hat{S}(t,y)+g)\\&=\frac{\exp(-S(t,y))}{\sqrt{(2\pi)^n|\det[F_t]|}}\frac{\exp(-\hat{S}(t,y))}{\sqrt{(2\pi)^n|\det[\hat{F}_t]|}}\sqrt{\frac{(2\pi)^n}{|\omega(\hat{\mathbf{F}},\mathbf{F})|}}\exp(g),\end{aligned} \tag{91}$$

which implies that this density can be written as

$$\rho(y,t)dy=\mathbf{N}^{-1}\eta(t,y)\,\hat{\eta}(t,y)dy, \tag{92}$$

where $\mathbf{N}$ is a normalizing constant defined by

$$\mathbf{N}=\sqrt{\frac{(2\pi)^n}{|\omega(\hat{\mathbf{F}},\mathbf{F})|}}\exp(g), \tag{93}$$

and $\eta(t,y)$ and $\hat{\eta}(t,y)$ are defined by

$$\eta(t,y)=\frac{\exp(-S(t,y))}{\sqrt{(2\pi)^n|\det[F_t]|}},$$

$$\hat{\eta}(t,y)=\frac{\exp(-\hat{S}(t,y))}{\sqrt{(2\pi)^n|\det[\hat{F}_t]|}},$$

which, as we can easily verify, are positive solutions of the adjoint heat equations (86) and (87). Also, the boundary conditions satisfied by η and $\hat{\eta}$ depend on the pair of Lagrangian manifolds M_s, R_u.

Although (92) was obtained assuming that both Lagrangian manifolds were nonsingular, a similar expression follows in the case where one or both of them are singular. If one considers the

pair M_s^x, R_u (where, as before, M_s^x denotes the singular Lagrangian manifold associated with an initial configuration $x \in \mathbb{R}^n$), then, using (30) and changing $S(t,y)$ for Hamilton's principal function $R(s,x,t,y)$, we obtain

$$R(s,x,t,y)+\hat{S}(t,y)=\tfrac{1}{2}A_{s,x}(t,y)+g_1, \tag{94}$$

where $A_{s,x}(t,y)$ is the symplectic area defined by (67) and associated with the pair of Lagrangian manifolds M_s^x, R_u. Substituting, in (94), y by $m_{s,x}(t)$ (the solution consistent to the Lagrangian manifolds $M_{s,x}$ and R_u), we find that

$$g_1=R(s,x,u,m_{s,x}(u))+\hat{S}(u,m_u)=\hat{S}(s,x).$$

Adapting to this case the calculations used in (91),

$$\begin{aligned}\rho_{s,x}(t,y)&=\frac{\exp(-R_{s,x}(t,y))}{\sqrt{(2\pi)^n \det[E_s(t)]}}\frac{\exp(-\hat{S}(t,y))}{\sqrt{(2\pi)^n|\det[\hat{F}_t]|}}\sqrt{\frac{(2\pi)^n}{|\det[\omega(\hat{\mathbf{F}},\mathbf{E}_s(t))]|}}\exp(g_1)\\&=h(s,x,t,y)\,\hat{\eta}(t,y)\sqrt{\frac{(2\pi)^n}{|\det[\hat{F}(s)]|}}\exp(\hat{S}(s,x))\\&=\frac{h(s,x,t,y)\,\hat{\eta}(t,y)}{\exp\sqrt{(2\pi)^n/|\det[\hat{F}(s)]|}(-\hat{S}(s,x))}\\&=\frac{h(s,x,t,y)\,\hat{\eta}(t,y)}{\hat{\eta}(s,x)}.\end{aligned} \tag{95}$$

Here $h(s,x,t,y)$, $s \leqslant t$, is the fundamental solution of (59) which as can be easily verified, can also be written as

$$\frac{\exp(-R_{s,x}(t,y))}{\sqrt{(2\pi)^n \det[E_s(t)]}}.$$

The cases where one considers the pair of Lagrangian manifolds M_s, R_u^z or M_s^x, R_u^z are treated similarly. We would obtain, respectively,

$$\rho^{u,z}(t,y)=\frac{\eta(t,y)h(t,y,u,z)}{\eta(u,z)}, \tag{96}$$

$$\rho_{s,x}^{u,z}(t,y)=h(s,x,t,y)h(t,y,u,z). \tag{97}$$

□

C. Diffusion processes

In Sec. III A we saw how a pair of compatible Lagrangian manifolds determines a probability density and how this density is written in terms of a pair of solutions of adjoint heat equations with boundary values specified by the pair of Lagrangian manifolds. In this section, we will show that a pair of compatible Lagrangian manifolds determines a Gaussian diffusion process. Our setting will be given by the pair of compatible manifolds M_s, R_u. We will begin by the definition of an $\mathbb{R}^n$-valued diffusion process Z_t on the time interval $[s, u]$ by means of the value of the density associated with the pair M_s, R_u at time s, $\rho(s,x)$ and a transition function. This process will verify $E[Z_t]=m_t$, where E denotes the mathematical expectation and m_t denotes the consistent solution associated with the pair of Lagrangian manifolds. In this sense, we call Z_t the Euclidean quantization of m_t. It is crucial to stress that, as suggested by Feynman's path integral approach,[1] the probabilistic framework is extracted exclusively from the classical model.

Let us first define a transition probability function: Given any configuration $x \in \mathbb{R}^n$ and a Borelian $B \in \mathscr{B}$ we define for t_1, t such that $s \leqslant t_1 < t \leqslant u$ the function:

$$Q^{R_u}_{L^x_{t_1}}(t,B)=\int_B \rho^{R_u}_{L^x_{t_1}}(t,y)\ dy, \tag{98}$$

where $\rho^{R_u}_{L^x_{t_1}}(t,y)$ is the density associated to the pair of Lagrangian manifolds $L^x_{t_1}$, R_u which was given (cf. Theorem 6) by

$$\rho^{R_u}_{L^x_{t_1}}(t,y)=\frac{h(t_1,x,t,y)\,\hat{\eta}(t,y)}{\hat{\eta}(t_1,x)}.$$

We can easily verify that $Q^{R_u}_{L^x_{t_1}}(t,y)$ is a transition probability using the semigroup properties of the solution of the heat equation or using the additivity of the solutions of the Hamilton–Jacobi equation. Together with the initial probability density provided by the density associated with the pair of manifolds M_s, R_u at time $t=s$, i.e., $\rho^{R_u}_{M_s}(s,x)$ and the transition probability defined by (98), we satisfy the conditions of existence of a Gaussian diffusion process Z_t (cf. Ref. 2) called the Euclidean quantization of the classical solution consistent with M_s, R_u. This process will verify, by construction,

$$P(Z_t\in B)=\int_B \rho(t,y)\ dy. \tag{99}$$

However, we could as well start from the ''final'' information, i.e., the value of the probability density associated with the pair of Lagrangian manifolds M_s, R_u at time u, $\rho(u,z)$ and use a time-reversed version of the probability function $\dot{Q}^{R_u}_{L^x_{t_1}}(t,y)$ constructed as follows:

Consider for $t<t_2\leqslant u$ and $y_1\in\mathbb{R}^n$ the density $\rho^{R^z_{t_2}}_{M_s}(t,y)$ associated with the pair $M_sR^z_{t_2}$,

$$\rho^{R^z_{t_2}}_{M_s}(t,y)=\frac{\eta(t,y)h(t,y,t_2,z)}{\eta(t_2,z)},$$

and define for $x\in\mathbb{R}^n$. $B\in\mathscr{B}$, and t_1,t_2 such that $s\leqslant t_1<t_2\leqslant u$ the function

$$Q^{R^z_{t_2}}_{M_s}(t_1,B)=\int_B \rho^{R^z_{t_2}}_{M_s}(t_1,y)\ dy, \tag{100}$$

which is, as is easily verified, a (backward) transition probability function. This will enable us to construct an $\mathbb{R}^n$-valued Gaussian diffusion process Y_t with a backward transition function given by (100) and final probability given by the probability density associated with the pair of manifolds M_s, R_u at time $t=u$, $\rho^{R_u}_{M_s}(u,z)$. This process satisfies (cf. Ref. 20) as well

$$P(Y_t\in B)=\int_B \rho(t,y)\ dy, \tag{101}$$

Y_t and Z_t, as diffusion processes having the same probability density for all t in $[s,\ u]$. We will call this process the Euclidean quantization of the M_sR_u consistent trajectory. Summarizing, we have the following.

Theorem 2: *Given any pair of compatible manifolds on an interval $I=[s,u]$, there exists a Gaussian diffusion process Z_t such that* (i) $E[Z_t]=m_t$, *where m_t is the solution consistent with the pair of Lagrangian manifolds. Hence in particular we have*

$$\frac{d^2}{dt^2}E[Z_t]=K(t)E[Z_t],$$

where $K(t)$ is a symmetric $n\times n$ matrix nonsingular on I. (ii) *The variance of this process is completely described by the functions F_t and $\hat{F}_t$ associated to both Lagrangian manifolds, i.e.,*

$$C(t)=F_t[\omega(\hat{F}_t,F_t)]^{-1}\hat{F}_t^T.$$

D. Uniqueness

One can see that the Euclidean quantization Z_t associated with a pair of compatible Lagrangian manifolds M_s and R_u on a time interval I solves the following Itô standard differential equations (sde's):

$$dZ_t=(A(t)Z_t+a(t))\,dt+dW_t, \tag{102}$$

$$d_*Z_t=(A^*(t)Z_t-a^*(t))\,dt+d_*W_{*t}, \tag{103}$$

with respect to the past and future filtration $(\mathscr{P}_t)$ and $(\mathscr{F}_t)$, respectively. Here d and d_* denote forward and backward differentials and W and W_* are $\mathbb{R}^n$-valued Wiener processes wrt the filtration.[20] The drift terms are given in terms of the associated functions of the Lagrangians manifolds i.e.,

$$f(t)=\dot{\hat{F}}_t\hat{F}_t^{-1},\quad a(t)=\hat{F}_t^{-T}\hat{F}_u^T\hat{\beta},$$

$$f^*(t)=\dot{F}_tF_t^{-1},\quad a^*(t)=F_t^{-T}F_s^T\beta.$$

Now we will prove the reverse statement. Consider an $\mathbb{R}^n$-valued Gaussian diffusion process Z_t with a fixed identity diffusion matrix and satisfying the following hypothesis:

(H1) The expectation of the process $m_t=E(Z_t)$ is a solution of the ordinary differential equation on *I:*

$$\ddot{m}_t=K(t)m_t. \tag{104}$$

This assumption establishes the link between the diffusion process Z_t and the classical Hamiltonian system.

(H2) The variance $C(t)$ of the process is nonzero on the interior of the time interval. Also, let us denote by C_s and C_u the non-negative values of the variance at the endpoints of the interval I, i.e., $C_s=C(s)$ and $C_u=C(u)$.

(H3) Z_t satisfies in I the following forward and backward Itô sde's:

$$dZ_t=(f(t)Z_t+\beta(t))dt+dW_t. \tag{105}$$

$$d_*Z_t=(f^*(t)Z_t-\beta(t)^*)dt+d_*W_{*t}, \tag{106}$$

where $f(t)$, $f^*(t)$ are two nonsingular symmetric matrices on the time interval I.

Lemma 5: Consider a $\mathbb{R}^n$-valued Gaussian diffusion process Z_t defined on the interval I. satisfying the assumptions (H2) and (H3). Then its variance is given by

$$C(t)=M_t^*\omega^{-1}(\mathbf{M}_t,\mathbf{M}_t^*)M_t^T, \tag{107}$$

where M_t and M_t^* satisfy the (deterministic) matrix equations on I.

$$\dot{M}_t=f(t)M_t,\quad M_s=I_{n\times n}, \tag{108}$$

$$\dot{M}_t^*=f^*(t)M_t^*,\quad M_u^*=I_{n\times n}. \tag{109}$$

Moreover, if assumption (H1) is satisfied, then the expectation m_t of the process can be written as

$$m_t=M_t^*\omega^{-1}(\mathbf{M}_t,\mathbf{M}_t^*)\,\delta+M_t\omega^{-T}(\mathbf{M}_t,\mathbf{M}_t^*)\,\delta^*. \tag{110}$$

Proof: The general solutions of (105) and (106) are given respectively by

$$Z_t = M_t\left(Z_s + \int_s^t M_\lambda^{-1} f(\lambda)\, d\lambda + \int_s^t M_\lambda^{-1}\, dW_\lambda \right), \tag{111}$$

$$Z_t = M_t^*\left(Z_u + \int_t^u [M_\lambda^*]^{-1}\beta^*(\lambda)\, d\lambda + \int_t^u [M_\lambda^*]^{-1} dW_{*,\lambda} \right), \tag{112}$$

where M_t and M_t^* satisfy (108) and the last integrals are Itô's forward and backward integrals.[16] Using (111), we can conclude (cf. Ref. 3) that the variance $C(t)$ of the process is the only positive definite matrix solution of the following ordinary differential equation:

$$\dot{C}(t) = f(t)C(t) + C(t)f(t)^T + I, \quad C(s) = C_s.$$

However, $C(t)$ is also the variance of the backward process. Hence the solution of the above ordinary differential equation must also be the solution of

$$\dot{C}(t) = f^*(t)C(t) + C(t)f^*(t)^T - I, \quad C(u) = C_u.$$

As f and f^* are both symmetric matrices, we conclude that $C(t)$ verifies

$$2f(t)C(t) + I = 2f^*(t)C(t) - I.$$

Hence

$$C(t) = (f^*(t) - f(t))^{-1}. \tag{113}$$

Using (108) and (109) we obtain

$$C(t) = (\dot{M}_t^*[M_t^*]^{-1} - \dot{M}_t M_t)^{-1} = (M^{-T}\omega(\mathbf{M}_t, \mathbf{M}_t^*)M^*)^{-1} = M_t^*\omega^{-1}(\mathbf{M}_t, \mathbf{M}_t^*)M_t^T.$$

Taking expectations on both sides of (111) and (112) and differentiating with respect to t we will obtain

$$\dot{m}_t = f(t)m_t + \beta(t), \tag{114}$$

$$\dot{m}_t = f^*(t)m_t - \beta^*(t), \tag{115}$$

obtaining

$$f(t)m_t + \beta(t) = f^*(t)m_t - \beta^*(t),$$

which implies that

$$m_t = (f^*(t) - f(t))^{-1}.$$

By (113) we obtain

$$m_t = C(t)[\beta(t) + \beta^*(t)]. \tag{116}$$

Since m_t is, by assumption, a solution of Hamilton's version of equations of motion (12), we obtain that $\beta(t)$, $\beta^*(t)$ are solutions of the differential equations

$$\dot{\beta}(t) + f(t)\beta(t) = 0,$$

$$\dot{\beta}^*(t) - f^*(t)\beta^*(t) = 0.$$

Using (108) and (109) the solutions are

$$\beta(t)=M_t^{-T}\delta, \tag{117}$$

$$\beta^*(t)=[M_t^*]^{-T}\delta^*, \tag{118}$$

where δ and δ^* are two arbitrary vectors of $\mathbb{R}^n$. Substituting in (116), the following formula holds for the expectation:

$$\begin{aligned} m_t=C(t)[\beta(t)+\beta^*(t)]&=M_t^*\omega^{-1}(\mathbf{M}_t,\mathbf{M}_t^*)M_t^T[M_t^{-T}\delta+[M_t^*]^{-T}\delta^*\\ &=M_t^*\omega^{-1}(\mathbf{M}_t,\mathbf{M}_t^*)\,\delta+M_t\omega^{-T}(\mathbf{M}_t,\mathbf{M}_t^*)\,\delta^*. \end{aligned}$$

□

Theorem 3: *Consider an $\mathbb{R}^n$-valued Gaussian diffusion Z_t on an interval I, satisfying the assumptions (H1), (H2), and (H3). Then Z_t is the Euclidean quantization of the pair of Lagrangian manifolds M_s, R_u given by*

$$M_s=\{(q,p)|p=f_s^*q-\beta^*(s)\}, \tag{119}$$

$$R_u=\{(q,p)|-p=f_uq+\beta_u\}. \tag{120}$$

Proof: Consider F_t, $\hat{F}_t$ defined as

$$F_t=M_t^*, \tag{121}$$

$$\hat{F}_t=M_t, \tag{122}$$

where M_t, M_t^* are defined by (108) and (109). As $f(t)$ and $f^*(t)$ are nonsingular symmetric matrices on the interval I, F_t and $\hat{F}_t$ are disconjugate solutions of (104). Using these functions together with δ and $\hat{\delta}$ defined by (117) and (118) we can introduce a pair of Lagrangian manifolds:

$$M_s=\{(q,p)|p=\dot{F}_sF_s^{-1}q-F_s^{-T}\delta\}, \tag{123}$$

$$R_u=\{(q,p)|-p=\dot{\hat{F}}_u\hat{F}_u^{-1}q-\hat{F}_u^{-T}\hat{\delta}\}. \tag{124}$$

They define a Gaussian process whose mean is given by

$$m_t=F_t[\omega(\hat{\mathbf{F}},\mathbf{F})]^{-1}\delta+\hat{F}_t[[\omega(\hat{\mathbf{F}},\mathbf{F})]^T]^{-1}\delta^* \tag{125}$$

$$=M_t^*[\omega(\mathbf{M}_t,\mathbf{M}_t^*)]^{-1}\delta+M_t[[\omega(\mathbf{M}_t,\mathbf{M}_t^*)]^T]^{-1}\delta^*. \tag{126}$$

and whose variance is given by

$$C(t)=M_t^*\omega^{-1}(\mathbf{M}_t,\mathbf{M}_t^*)M_t^T.$$

□

Remark 5: In Ref. 21 the authors consider diffusions satisfying the sde's (102) and (103) as ''Gaussian Bernstein processes'' associated with the quantum Hamiltonian

$$H=-\tfrac{1}{2}\Delta+\tfrac{1}{2}\langle K(t)x,x\rangle$$

in the following way: The forward and backward drifts are related to a pair of positive solutions η, η^* of the adjoint heat equations (86) and (87):

$$\frac{\nabla\eta_t}{\eta_t}=f(t)x+\beta(t), \quad -\frac{\nabla\eta_t^*}{\eta_t^*}=f^*(t)x-\beta_t^*.$$

From these two relations we can easily obtain (104). In the present paper, however, we insist on starting exclusively from the classical Hamiltonian system. Now we see that these Bernstein

processes are, in fact, associated to a pair of Lagrangian manifolds. It should be noted that in Ref. 21 the necessary assumption of symmetry on the matrices f, f^* is missing.

IV. EXAMPLES

A. The Bernstein bridge

Let H be the time-dependent quadratic Hamiltonian on $\mathbb{R}^{2n}$,

$$H=\tfrac{1}{2}|p|^2-\langle K(t)q,q\rangle,$$

where $K(t)$ denotes a symmetric nonsingular matrix on the interval $[s,\ u]$. The Bernstein bridge associated with H is characterized as a Bernstein diffusion Z_t with boundary data given by $Z_s=x$, $Z_u=z$, where x and z are two configurations in $\mathbb{R}^n$. This implies that the variance of Z_t satisfies $C(s)=C(u)=0$. By Lemma 5, using in particular (108) and (109), the matrices M_t and M_t^* are determined by the boundary conditions

$$M_s=I_{n\times n},\quad M_s^*=0,$$

$$M_u=0,\quad M_u^*=I_{n\times n},$$

which implies that

$$M_t=E_u(t)E_u^{-1}(s),\quad M_t^*=E_s(t)E_s^{-1}(u).$$

Using (109) we can write the variance of the process as

$$C(t)=E_s(t)\omega^{-1}(\hat{\mathbf{E}}_u,\mathbf{E}_s)\hat{E}_u^T(t),\quad t\in[s,u],$$

where $\hat{E}_u(t)=-E_u(t)$. Using now (109), the mean of the process is

$$m_t=E_s(t)\omega^{-1}(\hat{\mathbf{E}}_u,\mathbf{E}_s)z+\hat{E}_u(t)\omega^{-T}(\hat{\mathbf{E}}_u,\mathbf{E}_s)x.$$

The formulas for the mean and variance suggest that we can rescale (M_t and M_t^*) so that

$$M_t=\hat{E}_u(t),\quad M_t^*=E_s(t).$$

This shows that the Bernstein bridge is the Euclidean quantization associated with the pair of Lagrangian manifolds:

$$M_s^x=\{(q,p)|q=x\},\tag{127}$$

$$R_u^z=\{(q,p)|q=z\}.\tag{128}$$

The stochastic differential equations satisfied by the process Z_t are, respectively,

$$dZ_t=\left[\frac{\dot{\hat{E}}_u(t)}{\hat{E}_u(t)}\,Z_t+\frac{z}{\hat{E}_u^{-1}(t)}\right]dt+dW_t,\tag{129}$$

$$dZ_t=\left[\frac{\dot{E}_s(t)}{E_s(t)}\,Z_t-\frac{x}{E_u^{-1}(t)}\right]dt+dW_t,\tag{130}$$

with respect to the past and future filtrations.

When $K=0$ this is the rigorous version of Feynman's example (cf. pp. 179–180 of Ref. 1).

B. Brownian motion starting at $x_0\in\mathbb{R}$

The Brownian motion can be characterized as a Bernstein process associated with the free Hamiltonian

$$H=\frac{p^2}{2}$$

on $I=[0, T]$ that satisfies the forward sde

$$dZ_t=dW_t, \quad Z_0=x.$$

As the forward drift is zero, we must have $\dot{M}_t\equiv 0$ on the time interval and, as $M_T=1\forall t \in I$, we get $M_t\equiv 1$ and $\delta=0$. Using the same reasoning as in the previous example [since $Z_0=x$ we must have $C(0)=0$] we obtain $M_t^*=E_0(t)=t$. With these values, the expectation will be

$$m_t=\frac{\delta^* M_t+\delta M_t^*\delta}{\omega(\mathbf{M}_t,\mathbf{M}_t^*)}=\delta^*,$$

but as $m_0=x$ this will imply that $\delta^*=x$ and $m_t\equiv x\forall t\in I$.

As for the variance of Z_t,

$$C(t)=\frac{M_t M_t^*}{\omega(\mathbf{M}_t,\mathbf{M}_t^*)}=t.$$

Hence the associated Lagrangian manifolds will be, in this case

$$L_0=\{(q,p)|q=x\}, \tag{131}$$

$$R_T=\{(q,p)|p=0\}. \tag{132}$$

The backward stochastic differential equation satisfied by this process is

$$d^*Z_t=\left[\frac{1}{t}Z_t-\frac{x}{T-t}\right]dt+d_*W_t.$$

C. The Ornstein–Uhlenbeck process on the time interval [0,1]

The process is defined as a solution of

$$dZ_t=-\lambda Z_t+dW_t, \quad \lambda>0, \tag{133}$$

$$Z_0=x. \tag{134}$$

Equation (133) shows that we should choose $f(t)\equiv\lambda$ and $\beta(t)\equiv 0$ on the whole interval. This is equivalent to choosing a final Lagrangian manifold (i.e., at time $t=1$) of the form

$$R_1=\{(q,p)|p=\lambda q\}.$$

The missing Lagrangian manifold will be determined by the initial condition (134). Hence we should choose

$$L_0=\{(q,p)|q=x\}.$$

This will correspond to choosing $M^*(t)=e_0(t)$ and $\delta^*=x$, where $e_0(t)$ is the solution of

$$\ddot{q}(t)=\lambda^2 q(t), \quad q(0)=0, \quad \dot{q}(0)=1,$$

i.e.,

$$e_0(t)=\frac{1}{a}\sinh(at), \quad a=\text{sqrt }\lambda.$$

Hence we can conclude that this Ornstein–Uhlenbeck on the interval $[0, 1]$ can be considered as the EQ under the Hamiltonian

$$H=\frac{1}{2}\,p^2-\lambda^2\,\frac{q^2}{2}$$

of the pair of Lagrangians manifolds L_0, R_1. Moreover, the expectation of the process will be

$$m(t)=\frac{\delta M_t^*+\delta^* M_t}{\omega(M_t,M_t^*)}=\frac{xe^{-\lambda t}}{M(0)}=xe^{-\lambda t}$$

and its variance

$$c(t)=\frac{M_t M_t^*}{\omega(M_t,M_t^*)}=\frac{1}{2a}\,(1-e^{-2at}).$$

The backward differential equation will be

$$d_*Z_t=\left[\lambda\,\coth\,(at)Z_t-\frac{x}{\sinh(\lambda t)}\right]dt+dW_t.$$

If Z_0 is $N(x,c_0)$, then one can easily find that

$$M_t=\frac{1}{\lambda}\,\sinh(\lambda t)+c_0e^{-at}$$

and

$$\delta^*=\frac{x}{c_0},$$

which will give us mean and variance

$$m_t=\left[\frac{x}{c_0}\,\frac{1}{\lambda}\,\sinh(\lambda t)+c_0e^{-at}\right], \tag{135}$$

$$c_t=\frac{1}{\lambda}\,e^{-\lambda t}\,\sinh(\lambda t)+c_0e^{-2\lambda t}. \tag{136}$$

The backward differential equation will be

$$d_*Z_t=\left[\lambda\,\frac{1-2\lambda c_0+e^{2\lambda t}}{-1+2\lambda c_0+e^{2\lambda t}}\,Z_t-\frac{2\lambda e^{\lambda t}x}{c_0(-1+\lambda c_0+e^{2\lambda t})}\right]dt+dW_t.$$

The effect of configuration mixing on the first-order moments of polarized hydrogen lines

Roberto Casini
High Altitude Observatory, National Center for Atmospheric Research,[a] P.O. Box 3000, Boulder, Colorado 80307-3000

(Received 30 March 1998; accepted for publication 1 May 1998)

We extend previous work on the algebraic first-order moments of polarization profiles of hydrogen lines in the presence of external fields, to include the effect of configuration mixing induced by the applied fields. An algebraic formula for hydrogen line shifts due to the quadratic Stark effect is derived, under the assumption that the applied electric field is weak enough that line quenching induced by field ionization can be neglected. The derivation of such a formula is made possible by an aimed use of standard techniques of projection-operator algebra and of the fundamental implications of the spectral theorem. The results of this paper should help in decreasing the amount of numerical work needed in the calculation of line shifts of hydrogen lines induced by the presence of electric fields, as the preliminary numerical calculation of the Hamiltonian eigenvalues and eigenvectors is avoided, thus making calculations tractable for lines of higher hydrogen series than considered so far, e.g., in applications of pressure-broadening theory. © *1998 American Institute of Physics.* [S0022-2488(98)02609-7]

I. INTRODUCTION

In previous work[1,2] we gave the definition of the Nth-order moments of the Stokes profiles of hydrogen lines, and explicitly worked out the algebraic calculation of the first- and second-order moments as functions of the external fields and of the principal quantum numbers of the transition levels. Those calculations required two fundamental assumptions. The first assumption was that atomic polarization, i.e., the presence of anisotropy in the magnetic level populations and of quantum coherences among state vectors representing those levels, were negligible. The second assumption was that the intensity of the external fields were such that configuration mixing, i.e., the interaction of Hamiltonian eigenstates from different atomic configurations, which in the absence of external fields would be distinguished by different principal quantum numbers, could also be neglected. This last assumption, in particular, implied an upper bound to the intensity of the external fields that were tractable, depending on the principal quantum numbers involved (see Ref. 3, Fig. 1).

In the present work we relax this last constraint, thus allowing for the interaction of distinct atomic configurations. In particular, we will determine how centers of gravity of polarized hydrogen lines are affected by configuration mixing induced by the presence of electric fields (quadratic Stark effect), a phenomenon of relevant importance, for instance, in applications of the theory of pressure broadening of hydrogen lines (see, e.g., Ref. 4).

A limiting assumption that we will consider is that the applied electric fields must be weak enough that line quenching due to field ionization of the atom (see, e.g., Refs. 5–7) can be neglected. Using simple classical arguments, it is possible to provide, for any transition, a qualitative (yet safe) estimate of the maximum electric-field strength allowed by the above assumption as a function of the principal quantum number of the upper level of the transition, n. Following Ref. 6, such an estimate gives

$$E_{\max}(n) \approx 3.2 \times 10^{8} n^{-4} \text{ V cm}^{-1}. \tag{1}$$

[a]The National Center for Atmospheric Research is sponsored by the National Science Foundation.

 © 1998 American Institute of Physics

In spite of the above constraint, the applied electric field can still be strong enough to produce observable shifts of the line center. For instance, Ref. 5 reports a 5% relative shift of the outermost intense components of $H\gamma\,(n=5)$ for a field of 4×10^5 V cm^{-1}, whereas the critical value of the field for line quenching of the same line is estimated around 7×10^5 V cm^{-1}. Equation (1) gives in this case $E_{\max}(5)\approx5.1\times10^5$ V cm^{-1}, showing that a classical treatment of field ionization leads to a rather pessimistic estimate of the critical field strength for line quenching.

II. PERTURBATION EXPANSION OF THE *N*TH-ORDER MOMENTS OF POLARIZED HYDROGEN LINES

In this section we will derive a rigorous formulation of the *N*th-order moments of polarized hydrogen lines in terms of suitable operators, $\mathscr{O}_{\prime}^{(k)}$, $0\leqslant k\leqslant N$, which are known functions of the eigenvalues and eigenvectors of the Hamiltonian $\mathscr{H}$ for the hydrogen atom in the presence of external fields [cf. Eq. (6) below]. We will then consider a truncated second-order perturbation expansion of the Hamiltonian eigenvalues and eigenvectors, which will enable us to derive an approximate (to second order of perturbation) yet workable expression of the operators $\mathscr{O}_{\prime}^{(k)}$. The approximations involved by this second-order perturbation approach will be extensively discussed later in this section.

We start from the definition of the *N*th-order moments of Stokes profiles for the transition between two hydrogen levels of principal quantum numbers n and m $(n>m)$, assuming for the moment that no line broadening mechanism is present [cf. Ref. 2, Eq. (3)],

$$\langle\omega_{\mathbf{k}}^N(i)\rangle=\frac{\Sigma_{\nu\mu}s_{\nu\mu}(i,\mathbf{k})(\omega_{\nu\mu}-\overline{\omega})^N}{\Sigma_{\nu\mu}s_{\nu\mu}(0,\mathbf{k})},\quad i=0,1,2,3. \tag{2}$$

In the above equation, $s_{\nu\mu}(i,\mathbf{k})$ are the strengths of the polarized components of the line at the frequencies $\omega_{\nu\mu}$, where ν and μ, respectively, span the dimensions of the subspaces $\mathscr{E}_n$ and $\mathscr{E}_m$ of the levels n and m. (In the following, a latin index will always represent a principal quantum number of the discrete spectrum, or the energy parameter for the continuum, whereas a greek index will stand for a corresponding degeneracy parameter or set of parameters.) The index i enumerates the four Stokes parameters (I,Q,U,V), and $\mathbf{k}$ is the propagation vector [specifying, in particular, the direction of the line of sight (LOS)]. For the frequency $\overline{\omega}$, about which the moments are calculated, we choose the center of gravity of the line *in the absence of external fields*. With this choice, the first-order moments, as given by Eq. (2), are vanishing when no external fields are present.[1] The normalization of the *N*th-order moments to the integrated intensity, $\Sigma_{\nu\mu}\,s_{\nu\mu}(0,\mathbf{k})$, is chosen because, in the absence of atomic polarization and neglecting configuration mixing, the integrated polarization profiles, $\Sigma_{\nu\mu}\,s_{\nu\mu}(i,\mathbf{k})$, are vanishing for $i=1,2,3$ (see Ref. 1, Appendix A). In this paper, in fact, we will show that electric-field induced configuration mixing is responsible for a nonvanishing (second-order) contribution to such integrated profiles. On the other hand, we will see that such contribution can be safely neglected in our derivation of the algebraic first-order moments.

The strengths $s_{\nu\mu}(i,\mathbf{k})$ are quadratic expressions of the matrix elements of the radial vector operator, $\mathbf{r}$, between Hamiltonian states of the two levels of the transition $n-m$. These expressions assume a particularly convenient form when use is made of the (complex) spherical-vector basis

$$\begin{cases}\mathbf{e}_{\pm1}=\mp\dfrac{1}{\sqrt{2}}\,(\mathbf{e}_{x_1}\pm i\mathbf{e}_{x_2}),\\ \mathbf{e}_0=e_{x_3},\quad x_3\equiv\text{quantization axis},\end{cases}$$

in terms of which a vector operator, $\mathbf{v}$, has expansion $\mathbf{v}=\Sigma_q(-1)^q v_q\mathbf{e}_{-q}$, $q=0,\pm1$. We then have [see, e.g., Ref. 1, Eq. (4)],

$$s_{\nu\mu}(i,\mathbf{k})=\sum_{qq'}(-1)^{q+q'}\mathscr{T}_{-q-q'}(i,\mathbf{k})(r_q)_{n\nu,m\mu}(r_{q'})^*_{n\nu,m\mu},\quad q,q'=0,\pm1, \tag{3}$$

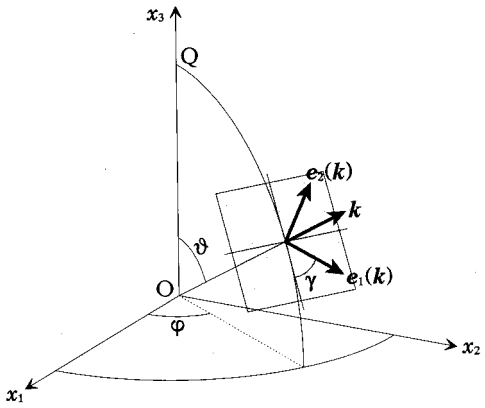

FIG. 1. Frame of reference of the quantization axis (x_3 axis). The plane of polarization, generated by the basis vectors for linear polarization, $\mathbf{e}_1(\mathbf{k})$ and $\mathbf{e}_2(\mathbf{k})$, is normal to the propagation vector, $\mathbf{k}$. The position angle γ fixes the reference direction for linear polarization, $\mathbf{e}_1(\mathbf{k})$, along which the observable $\frac{1}{2}(I+Q)$ is measured (adapted from Ref. 1).

where the (reducible) spherical tensor $\mathscr{T}_{qq'}(i,\mathbf{k})$ depends only on the geometry of the observer (i.e., LOS and position angle of the reference axis for Q-polarization measurement; see Fig. 1) relative to the frame of reference of the quantization axis. The definition and explicit expressions of the components $\mathscr{T}_{qq'}(i,\mathbf{k})$ are also given in Ref. 1 [cf. Eqs. (2) and (3) in that paper]; however, as we will not need them for the following development, they are not reported here.

If we expand the binomial power in Eq. (2) and recall Eq. (3), we see that we ultimately have to evaluate quantities of the form

$$\sigma^{(j)}_{nm}(i,\mathbf{k}) \equiv \sum_{\nu\mu} s_{\nu\mu}(i,\mathbf{k})\omega^j_{\nu\mu} = \sum_{qq'} (-1)^{q+q'} \mathscr{T}_{-q-q'}(i,\mathbf{k}) S^{(j)}_{nm}(q,q'), \quad 0 \leqslant j \leqslant N, \tag{4}$$

where, assuming for convenience of notation $\hbar = 1$ (so that frequencies have the dimensions of energy), and indicating with $\omega_{\ell\lambda}$ and $|\psi_{\ell\lambda}\rangle$ the eigenvalues and *orthonormal* eigenvectors of $\mathscr{H}$ for the generic energy level of principal quantum number ℓ,

$$\begin{aligned} S^{(j)}_{nm}(q,q') &\equiv \sum_{\nu\mu} (r_q)_{n\nu,m\mu} (r_{q'})^*_{n\nu,m\mu} \omega^j_{\nu\mu} \\ &= \sum_{k=0}^{j} (-1)^k \binom{j}{k} \sum_{\nu\mu} \omega^{j-k}_{n\nu} \omega^k_{m\mu} \langle \psi_{n\nu}|r_q|\psi_{m\mu}\rangle \langle \psi_{m\mu}|r^\dagger_{q'}|\psi_{n\nu}\rangle, \end{aligned} \tag{5}$$

having introduced in the last equivalence the bra-ket notation for the matrix elements of the operator r_q, and also considered that $\omega_{\nu\mu} = \omega_{n\nu} - \omega_{m\mu}$.

It is convenient at this point to introduce a suitable orthonormal basis on the Hilbert space of the Hamiltonian of the hydrogen atom. Consistent with Ref. 1, we choose to adopt a basis of degenerate eigenvectors of the Schrödinger Hamiltonian,

$$\mathscr{H}_0 = \frac{p^2}{2m_e} - \frac{e_0^2}{r}$$

(m_e and e_0 are, respectively, the mass and the charge of the electron). According to our notation, such a basis can be chosen in the form $\{|a\,\alpha\rangle\}$, where a is the energy parameter (which reduces to the principal quantum number for a state of the discrete spectrum) and $\alpha \equiv \{(ls)(ji)fm_f\}$. The quantum numbers l, $s=1/2$, j, $i=1/2$, f, and m_f, which account for the high degeneracy of the energy states of the Schrödinger Hamiltonian (for the discrete state of principal quantum number ℓ, the order of degeneracy is $4\ell^2$), are associated, respectively, to the commuting (with $\mathscr{H}_0$ and among themselves) operators L^2, $S^2=3/4$, J^2, $I^2=3/4$, F^2, and F_z, where $\mathbf{L}$ is the electron orbital angular momentum (a.m.), $\mathbf{S}$ is the electron spin a.m., $\mathbf{J}=\mathbf{L}+\mathbf{S}$ is the electron total a.m., $\mathbf{I}$ is the nuclear (proton) spin a.m., $\mathbf{F}=\mathbf{J}+\mathbf{I}$ is the total (electron+proton) a.m., and F_z is the projection of $\mathbf{F}$ on the quantization axis.

Because of the form of Eq. (5), it proves useful to introduce the operator

$$\mathscr{O}_{\ell}^{(k)} \equiv \sum_{\lambda} \omega_{\ell\lambda}^{k} |\psi_{\ell\lambda}\rangle\langle\psi_{\ell\lambda}|, \tag{6}$$

and consider the resolution of the identity, $\mathbf{S}_{a\alpha}|a\alpha\rangle\langle a\alpha| = 1$ (where $\mathbf{S}$ is the symbol of generalized summation over the states of the discrete and continuous spectra of the Schrödinger Hamiltonian). Equation (5) then becomes

$$\begin{aligned}
S_{nm}^{(j)}(q,q') &= \sum_{k=0}^{j} (-1)^k \binom{j}{k} \sum_{\mu} \omega_{m\mu}^{k} \langle\psi_{m\mu}| r_{q'}^{\dagger} \mathscr{O}_{n}^{(j-k)} r_q |\psi_{m\mu}\rangle \\
&= \sum_{k=0}^{j} (-1)^k \binom{j}{k} \mathbf{S}_{a\alpha,a'\alpha'} \langle a\alpha|\mathscr{O}_{n}^{(j-k)}|a'\alpha'\rangle \sum_{\mu} \omega_{m\mu}^{k} \langle a'\alpha'|r_q|\psi_{m\mu}\rangle\langle\psi_{m\mu}|r_{q'}^{\dagger}|a\alpha\rangle \\
&= \sum_{k=0}^{j} (-1)^k \binom{j}{k} \mathbf{S}_{a\alpha,a'\alpha'} \langle a\alpha|\mathscr{O}_{n}^{(j-k)}|a'\alpha'\rangle\langle a'\alpha'|r_q \mathscr{O}_{m}^{(k)} r_{q'}^{\dagger}|a\alpha\rangle \\
&= \sum_{k=0}^{j} (-1)^k \binom{j}{k} \mathbf{S}_{\substack{a\alpha,a'\alpha' \\ b\beta,b'\beta'}} \langle a\alpha|\mathscr{O}_{n}^{(j-k)}|a'\alpha'\rangle\langle a'\alpha'|r_q|b\beta\rangle\langle b\beta|\mathscr{O}_{m}^{(k)}|b'\beta'\rangle \\
&\quad \times \langle b'\beta'|r_{q'}^{\dagger}|a\alpha\rangle.
\end{aligned} \tag{7}$$

If configuration mixing is at all negligible, the operator $\mathscr{O}_{\ell}^{(k)}$ projects onto the subspace $\mathscr{E}_{\ell}$ of the level ℓ, since $|\psi_{\ell\lambda}\rangle \in \mathscr{E}_{\ell}$ in that case. In particular, since the eigenvectors $|\psi_{\ell\lambda}\rangle$ are normalized to unity, for $k=0$ we have $\mathscr{O}_{\ell}^{(0)} = \mathscr{P}_{\ell}$, while for $k \neq 0$ we have $\mathscr{O}_{\ell}^{(k)} = (\mathscr{P}_{\ell}\mathscr{H}\mathscr{P}_{\ell})^k$, $\mathscr{P}_{\ell}$ being the projection operator onto $\mathscr{E}_{\ell}$ (i.e., $\mathscr{P}_{\ell} = \Sigma_{\lambda}|\psi_{\ell\lambda}\rangle\langle\psi_{\ell\lambda}|$, or $\mathscr{P}_{\ell} = \Sigma_{\lambda}|\ell\lambda\rangle\langle\ell\lambda|$ using the representation basis $\{|a\alpha\rangle\}$). This also means that, in the absence of configuration mixing, n and m are ''good'' quantum numbers.

If instead configuration mixing cannot be neglected, then $\mathscr{O}_{\ell}^{(k)}$ operates into the whole Hilbert space of the Hamiltonian $\mathscr{H}$, since the eigenvectors $|\psi_{\ell\lambda}\rangle$ in general have components in other subspaces besides $\mathscr{E}_{\ell}$. This is easily understood if we consider orders of approximation of $|\psi_{\ell\lambda}\rangle$ higher than zeroth, within the framework of the Rayleigh–Schrödinger theory of stationary perturbations for the degenerate case (see, e.g., Ref. 8). Assuming that the eigenvectors in the absence of configuration mixing, $|\psi_{\ell\lambda}^{(0)}\rangle$, are orthogonal and normalized to unity, while choosing for the perturbed eigenvectors the normalization $\langle\psi_{\ell\lambda'}^{(0)}|\psi_{\ell\lambda}\rangle = \delta_{\lambda\lambda'}$, we have, to second order of perturbation,

$$|\psi_{\ell\lambda}\rangle = |\psi_{\ell\lambda}^{(0)}\rangle + \epsilon|\psi_{\ell\lambda}^{(1)}\rangle + \epsilon^2|\psi_{\ell\lambda}^{(2)}\rangle \tag{8a}$$

(as is customary, the dimensionless parameter ϵ is introduced only for convenience, in order to keep track of the perturbation order, and must be put equal to unity at the end of the calculations), where $|\psi_{\ell\lambda}^{(0)}\rangle \in \mathscr{E}_{\ell}$, and

$$|\psi_{\ell\lambda}^{(1)}\rangle = \mathbf{S}'_{s\sigma} \frac{|s\sigma\rangle\langle s\sigma|W|\psi_{\ell\lambda}^{(0)}\rangle}{\omega_{\ell}^{(0)} - \omega_{s}^{(0)}}, \tag{8b}$$

$$|\psi_{\ell\lambda}^{(2)}\rangle = \mathbf{S}'_{s\sigma,t\tau} \frac{|s\sigma\rangle\langle s\sigma|W|t\tau\rangle\langle t\tau|W|\psi_{\ell\lambda}^{(0)}\rangle}{(\omega_{\ell}^{(0)} - \omega_{s}^{(0)})(\omega_{\ell}^{(0)} - \omega_{t}^{(0)})} - \omega_{\ell\lambda}^{(1)} \mathbf{S}'_{s\sigma} \frac{|s\sigma\rangle\langle s\sigma|W|\psi_{\ell\lambda}^{(0)}\rangle}{(\omega_{\ell}^{(0)} - \omega_{s}^{(0)})^2}. \tag{8c}$$

In general, the operator W in the above equations represents the whole perturbation Hamiltonian, $\mathscr{H}_1 \equiv \mathscr{H} - \mathscr{H}_0$. However, in this formulation, we explicitly distinguish between the operators $\mathscr{H}_1$ and W, assuming the latter to be the entire contribution in $\mathscr{H}_1$ that is responsible for configuration mixing [i.e., that has nonvanishing matrix elements in Eqs. (8b) and (8c)]. The prime on the summations in Eqs. (8b) and (8c) means that the subspace $\mathscr{E}_{\ell}$ must be excluded from the sum-

mation range. In fact, as a consequence of our choice for the normalization of the perturbed eigenvectors, $|\psi_{\ell\lambda}\rangle$, the corrections $|\psi^{(k)}_{\ell\lambda}\rangle$ are all orthogonal to $\mathscr{E}_\ell$, for $k>0$. In Eq. (8c), $\omega^{(1)}_{\ell\lambda}$ is the first-order correction to the energy of the unperturbed level, $\omega^{(0)}_\ell$ [see Eq. (9a) below].

The reason for maintaining the notation $|\psi_{\ell\lambda}\rangle$ even when the eigenvectors have components outside $\mathscr{E}_\ell$ is that the corrections $|\psi^{(k)}_{\ell\lambda}\rangle$ are supposed to affect ''continuously'' the eigenvectors in the zeroth-order approximation, $|\psi^{(0)}_\ell\rangle$, so that $|\psi_{\ell\lambda}\rangle$ tends continuously to $|\psi^{(0)}_{\ell\lambda}\rangle$ (and its norm to unity) if the perturbation to $\mathscr{H}_0$ becomes negligible (i.e., for $\epsilon\to 0$). This assumption, however, becomes problematic when the perturbation radically modifies the character of the energy spectrum, as in the presence of a perturbing electric field, which introduces a completely continuous spectrum in contrast with the discrete+continuous spectrum of $\mathscr{H}_0$. In fact, the so-called bound states of the Stark effect actually are ''resonances'' in a continuous spectrum with a typical lifetime that decreases rapidly as the electric-field strength and/or the principal quantum numbers of the levels involved increase, because of the increased probability of tunneling through the ionization potential barrier (see Refs. 5–7). Therefore, in our treatment we will limit ourselves to considering electric-field intensities below the critical value given by Eq. (1), so that the resonant states of the Stark effect can be safely considered as bound states of the Hamiltonian $\mathscr{H}$.

Analogous to Eqs. (8), for the eigenvalue $\omega_{\ell\lambda}$ we can write

$$\omega_{\ell\lambda}=\omega^{(0)}_\ell+\epsilon\omega^{(1)}_{\ell\lambda}+\epsilon^2\omega^{(2)}_{\ell\lambda}, \tag{9a}$$

$$\omega^{(2)}_{\ell\lambda}=\sum_{s\sigma}{}' \frac{\langle\omega^{(0)}_{\ell\lambda}|W|s\sigma\rangle\langle s\sigma|W|\psi^{(0)}_{\ell\lambda}\rangle}{\omega^{(0)}_\ell-\omega^{(0)}_s}. \tag{9b}$$

As is well known, the solution of the perturbation problem to first order yields the eigenvalues $\omega^{(0)}_\ell+\epsilon\omega^{(1)}_{\ell\lambda}$ by diagonalization of the operator $\mathscr{P}_\ell\mathscr{H}\mathscr{P}_\ell$ (with $\mathscr{H}=\mathscr{H}_0+\epsilon\mathscr{H}_1$), along with the zeroth-order eigenvectors, $|\psi^{(0)}_{\ell\lambda}\rangle$. Analogously, the perturbation solution of our problem to second order would yield second-order eigenvalues, along with first-order eigenvectors. The second-order correction to the eigenvectors, Eq. (8c), is also needed if we want to account for configuration mixing in a consistent way, since we must keep at least every second-order contribution to the operators $\mathscr{O}^{(k)}_\ell$.

On the other hand, a rather important consistency problem is originated by our choice for the normalization of the perturbed eigenvectors, $|\psi_{\ell\lambda}\rangle$. In fact, whereas the eigenvectors in the expression of $S^{(j)}_{nm}(q,q')$, Eq. (5), or in the expression of the operator $\mathscr{O}^{(k)}_\ell$, Eq. (6), are supposed to be normalized to unity, the norm of the perturbed eigenvectors of Eqs. (8) is instead, to second order,

$$\langle\psi_{\ell\lambda}|\psi_{\ell\lambda}\rangle=\langle\psi^{(0)}_{\ell\lambda}|\psi^{(0)}_{\ell\lambda}\rangle+\epsilon^2\langle\psi^{(1)}_{\ell\lambda}|\psi^{(1)}_{\ell\lambda}\rangle=1+\epsilon^2\sum_{s\sigma}{}' \frac{\langle\psi^{(0)}_{\ell\lambda}|W|s\sigma\rangle\langle s\sigma|W|\psi^{(0)}_{\ell\lambda}\rangle}{(\omega^{(0)}_\ell-\omega^{(0)}_s)^2}.$$

If we then use the perturbed eigenvectors in Eq. (5) [or Eq. (6)] without correcting for their nonunitary norm, we introduce an error in the expressions of $S^{(j)}_{nm}(q,q')$ that is at least of the same order of perturbation as the corrections that we need to consider for a consistent treatment of configuration mixing. Further in this paper we will be able to show that the second-order corrections introduced by the nonunitary norm of the perturbed eigenvectors either are compensated by the normalization of Eq. (1) or can otherwise be safely neglected in our approximation. For this reason, in the following we will simply ignore these corrections.

III. CALCULATION OF THE FIRST-ORDER MOMENTS IN THE PRESENCE OF CONFIGURATION MIXING

In Sec. II we considered a second-order approximation of the eigenvalues $\omega_{\ell\lambda}$ and eigenvectors $|\psi_{\ell\lambda}\rangle$ that enter the expression of the operators $\mathscr{O}^{(k)}_\ell$ defined in Eq. (6). Through Eqs. (4) and (7), we are then in a position to determine a second-order approximation of the Nth-order moments of polarized hydrogen lines, where configuration mixing is accounted for in a natural way (at least to the lowest order of approximation). We should also note that, because of Eqs. (8) and

(9), the only unknowns in this second-order approximation of the Nth-order moments of hydrogen lines are $\omega^{(1)}_{\ell\lambda}$ and $|\psi^{(0)}_{\ell\lambda}\rangle$. The key point in our algebraic derivation of the first-order moments of hydrogen lines in the presence of configuration mixing is therefore the elimination from the expression of $S^{(1)}_{nm}(q,q')$ [cf. Eq. (7)] of any reference to $\omega^{(1)}_{\ell\lambda}$ and $|\psi^{(0)}_{\ell\lambda}\rangle$ (which otherwise had to be calculated numerically via diagonalization of the perturbation Hamiltonian, $\mathscr{H}_1$), making use of standard techniques of projection-operator algebra and of the fundamental results of the spectral theorem.

A. Calculation of the operators $\mathscr{O}^{(k)}_{\ell}$ for $k=0,1$

For the evaluation of $S^{(1)}_{nm}(q,q')$ we only need to consider the operators $\mathscr{O}^{(k)}_{\ell}$ for $k=0,1$. In the following we will simply write ω_a instead of $\omega^{(0)}_a$ for the degenerate, zeroth-order eigenvalues (the absence of the degeneracy parameter, α, indicating that ω_a is necessarily degenerate).

From Eqs. (6) and (8a), we then have, for $k=0$,

$$\mathscr{O}^{(0)}_{\ell}=\sum_{\lambda}|\psi^{(0)}_{\ell\lambda}\rangle\langle\psi^{(0)}_{\ell\lambda}|+\epsilon\sum_{\lambda}\left(|\psi^{(0)}_{\ell\lambda}\rangle\langle\psi^{(1)}_{\ell\lambda}|+|\psi^{(1)}_{\ell\lambda}\rangle\langle\psi^{(0)}_{\ell\lambda}|\right)$$

$$+\epsilon^2\sum_{\lambda}\left(|\psi^{(1)}_{\ell\lambda}\rangle\langle\psi^{(1)}_{\ell\lambda}|+|\psi^{(0)}_{\ell\lambda}\rangle\langle\psi^{(2)}_{\ell\lambda}|+|\psi^{(2)}_{\ell\lambda}\rangle\langle\psi^{(0)}_{\ell\lambda}|\right),$$

where explicitly

$$|\psi^{(0)}_{\ell\lambda}\rangle\langle\psi^{(1)}_{\ell\lambda}|=\sum_{s\sigma}{}'\,\frac{|\psi^{(0)}_{\ell\lambda}\rangle\langle\psi^{(0)}_{\ell\lambda}|W|s\sigma\rangle\langle s\sigma|}{\omega_\ell-\omega_s}=\left(|\psi^{(1)}_{\ell\lambda}\rangle\langle\psi^{(0)}_{\ell\lambda}|\right)^{\dagger},$$

$$|\psi^{(1)}_{\ell\lambda}\rangle\langle\psi^{(1)}_{\ell\lambda}|=\sum_{s\sigma,t\tau}{}'\,\frac{|s\sigma\rangle\langle s\sigma|W|\psi^{(0)}_{\ell\lambda}\rangle\langle\psi^{(0)}_{\ell\lambda}|W|t\tau\rangle\langle t\tau|}{(\omega_\ell-\omega_s)(\omega_\ell-\omega_t)},$$

$$|\psi^{(0)}_{\ell\lambda}\rangle\langle\psi^{(2)}_{\ell\lambda}|=\sum_{s\sigma,t\tau}{}'\,\frac{|\psi^{(0)}_{\ell\lambda}\rangle\langle\psi^{(0)}_{\ell\lambda}|W|t\tau\rangle\langle t\tau|W|s\sigma\rangle\langle s\sigma|}{(\omega_\ell-\omega_s)(\omega_\ell-\omega_t)}$$

$$-\omega^{(1)}_{\ell\lambda}\sum_{s\sigma}{}'\,\frac{|\psi^{(0)}_{\ell\lambda}\rangle\langle\psi^{(0)}_{\ell\lambda}|W|s\sigma\rangle\langle s\sigma|}{(\omega_\ell-\omega_s)^2}=\left(|\psi^{(2)}_{\ell\lambda}\rangle\langle\psi^{(0)}_{\ell\lambda}|\right)^{\dagger}.$$

Therefore

$$\mathscr{O}^{(0)}_{\ell}=\mathscr{P}_\ell+\epsilon\sum_{s\sigma}{}'\,\frac{\mathscr{P}_\ell W|s\sigma\rangle\langle s\sigma|+|s\sigma\rangle\langle s\sigma|W\mathscr{P}_\ell}{\omega_\ell-\omega_s}$$

$$+\epsilon^2\Bigg[\sum_{s\sigma,t\tau}{}'\,\frac{|s\sigma\rangle\langle s\sigma|W\mathscr{P}_\ell W|t\tau\rangle\langle t\tau|}{(\omega_\ell-\omega_s)(\omega_\ell-\omega_t)}$$

$$+\sum_{s\sigma,t\tau}{}'\,\frac{\mathscr{P}_\ell W|t\tau\rangle\langle t\tau|W|s\sigma\rangle\langle s\sigma|+|s\sigma\rangle\langle s\sigma|W|t\tau\rangle\langle t\tau|W\mathscr{P}_\ell}{(\omega_\ell-\omega_s)(\omega_\ell-\omega_t)}$$

$$-\sum_{s\sigma}{}'\,\frac{\mathscr{P}_\ell\mathscr{H}_1\mathscr{P}_\ell W|s\sigma\rangle\langle s\sigma|+|s\sigma\rangle\langle s\sigma|W\mathscr{P}_\ell\mathscr{H}_1\mathscr{P}_\ell}{(\omega_\ell-\omega_s)^2}\Bigg],\tag{10}$$

where for the last term we considered that, to first order of perturbation,

$$\sum_{\lambda}\omega^{(1)}_{\ell\lambda}|\psi^{(0)}_{\ell\lambda}\rangle\langle\psi^{(0)}_{\ell\lambda}|=\mathscr{P}_\ell\mathscr{H}_1\mathscr{P}_\ell.\tag{11}$$

Analogously, to second order,

$$\begin{aligned}\mathscr{O}_\ell^{(1)} &= \omega_\ell \sum_\lambda |\psi_{\ell\lambda}^{(0)}\rangle\langle\psi_{\ell\lambda}^{(0)}| + \epsilon \sum_\lambda [\omega_{\ell\lambda}^{(1)} |\psi_{\ell\lambda}^{(0)}\rangle\langle\psi_{\ell\lambda}^{(0)}| + \omega_\ell (|\psi_{\ell\lambda}^{(0)}\rangle\langle\psi_{\ell\lambda}^{(1)}| + |\psi_{\ell\lambda}^{(1)}\rangle\langle\psi_{\ell\lambda}^{(0)}|)] \\ &\quad + \epsilon^2 \sum_\lambda [\omega_{\ell\lambda}^{(2)} |\psi_{\ell\lambda}^{(0)}\rangle\langle\psi_{\ell\lambda}^{(0)}| + \omega_{\ell\lambda}^{(1)} (|\psi_{\ell\lambda}^{(0)}\rangle\langle\psi_{\ell\lambda}^{(1)}| + |\psi_{\ell\lambda}^{(1)}\rangle\langle\psi_{\ell\lambda}^{(0)}|) \\ &\quad + \omega_\ell (|\psi_{\ell\lambda}^{(1)}\rangle\langle\psi_{\ell\lambda}^{(1)}| + |\psi_{\ell\lambda}^{(0)}\rangle\langle\psi_{\ell\lambda}^{(2)}| + |\psi_{\ell\lambda}^{(2)}\rangle\langle\psi_{\ell\lambda}^{(0)}|)] \\ &\equiv \omega_\ell \mathscr{O}_\ell^{(0)} + \epsilon \sum_\lambda (\omega_{\ell\lambda}^{(1)} + \epsilon\omega_{\ell\lambda}^{(2)}) |\psi_{\ell\lambda}^{(0)}\rangle\langle\psi_{\ell\lambda}^{(0)}| + \epsilon^2 \sum_\lambda \omega_{\ell\lambda}^{(1)} (|\psi_{\ell\lambda}^{(0)}\rangle\langle\psi_{\ell\lambda}^{(1)}| + |\psi_{\ell\lambda}^{(1)}\rangle\langle\psi_{\ell\lambda}^{(0)}|).\end{aligned} \tag{12}$$

The second addendum in the last equivalence can be expressed through the projection operator $\mathscr{P}_\ell$, in a fashion similar to Eq. (11), since it represents the spectral resolution of a suitable operator on the subspace $\mathscr{E}_\ell$. In fact, it can be proved (see, e.g., Ref. 9) that the zeroth-order eigenvectors, $|\psi_{\ell\lambda}^{(0)}\rangle$, and the energy corrections to any order r of perturbation, $\Delta_{\ell\lambda}^{(r)}(\epsilon) \equiv \sum_{k=1}^r \epsilon^k \omega_{\ell\lambda}^{(k)}$, are the solution of the eigenvalue problem for some suitable operator on the subspace $\mathscr{E}_\ell$ including terms of order $k=1,\ldots,r$ in the perturbation Hamiltonian, $\mathscr{H}_1$. Equation (11) illustrates this property in the particular case $r=1$. To second order we find instead (considering that, by definition, only W contributes to configuration mixing)

$$\sum_\lambda (\omega_{\ell\lambda}^{(1)} + \epsilon\omega_{\ell\lambda}^{(2)}) |\psi_{\ell\lambda}^{(0)}\rangle\langle\psi_{\ell\lambda}^{(0)}| = \mathscr{P}_\ell \mathscr{H}_1 \mathscr{P}_\ell + \epsilon {\sum_{s\sigma}}' \frac{\mathscr{P}_\ell W |s\sigma\rangle\langle s\sigma| W \mathscr{P}_\ell}{\omega_\ell - \omega_s}. \tag{11'}$$

Of course, the expressions of the zeroth-order eigenvectors which are obtained by solving the eigenvalue problem for the operators of Eqs. (11) and (11′) differ for quantities of the second order in the perturbation W. However, for our purposes, these differences are unessential, as they are only responsible for corrections to the operators $\mathscr{O}_\ell^{(0)}$ and $\mathscr{O}_\ell^{(1)}$ of order higher than second. Equation (12) then becomes, to second order,

$$\begin{aligned}\mathscr{O}_\ell^{(1)} &= \omega_\ell \mathscr{O}_\ell^{(0)} + \epsilon \mathscr{P}_\ell \mathscr{H}_1 \mathscr{P}_\ell + \epsilon^2 \Bigg\{ {\sum_{s\sigma}}' \frac{\mathscr{P}_\ell W |s\sigma\rangle\langle s\sigma| W \mathscr{P}_\ell}{\omega_\ell - \omega_s} \\ &\quad + {\sum_{s\sigma}}' \frac{\mathscr{P}_\ell \mathscr{H}_1 \mathscr{P}_\ell W |s\sigma\rangle\langle s\sigma| + |s\sigma\rangle\langle s\sigma| W \mathscr{P}_\ell \mathscr{H}_1 \mathscr{P}_\ell}{\omega_\ell - \omega_s} \Bigg\},\end{aligned} \tag{12'}$$

where we used both Eqs. (11) and (11′).

We must notice how any explicit reference to the unknown quantities $\omega_{\ell\lambda}^{(1)}$ and $|\psi_{\ell\lambda}^{(0)}\rangle$ has been removed from Eqs. (10) and (12′).

B. Calculation of the contribution of the quadratic Stark effect to $\sigma_{nm}^{(1)}(i,\mathbf{k})$

As we stated in the beginning of Sec. III, for the algebraic calculation of the first-order moments of polarized hydrogen lines we need to evaluate the quantity $S_{nm}^{(1)}(q,q')$, which is expressed through the operators $\mathscr{O}_\ell^{(0)}$ and $\mathscr{O}_\ell^{(1)}$ [cf. Eq. (7)]. However, it proves useful to rather consider the operator $\tilde{\mathscr{O}}_\ell^{(1)} \equiv \mathscr{O}_\ell^{(1)} - \omega_\ell \mathscr{O}_\ell^{(0)}$, and correspondingly introduce the new quantity

$$\begin{aligned}\tilde{S}_{nm}^{(1)}(q,q') &= {\sum_{\substack{a\alpha,a'\alpha' \\ b\beta,b'\beta'}}}' \langle a\alpha|\tilde{\mathscr{O}}_n^{(1)}|a'\alpha'\rangle\langle b\beta|\mathscr{O}_m^{(0)}|b'\beta'\rangle\langle a'\alpha'|r_q|b\beta\rangle\langle a\alpha|r_{q'}|b'\beta'\rangle \\ &\quad - {\sum_{\substack{a\alpha,a'\alpha' \\ b\beta,b'\beta'}}}' \langle a\alpha|\mathscr{O}_n^{(0)}|a'\alpha'\rangle\langle b\beta|\tilde{\mathscr{O}}_m^{(1)}|b'\beta'\rangle\langle a'\alpha'|r_q|b\beta\rangle\langle a\alpha|r_{q'}|b'\beta'\rangle,\end{aligned} \tag{13}$$

where we took into account that $\langle a\alpha|r_q|b\beta\rangle=\langle b\beta|r_q^\dagger|a\alpha\rangle$, since $\langle a\alpha|r_q|b\beta\rangle$ is a real quantity because of our choice of the representation basis [cf. Ref. 10, Eq. (23)]. The quantity $\tilde{S}^{(1)}_{nm}(q,q')$ is then related, through Eq. (4), to the quantity

$$\tilde{\sigma}^{(1)}_{nm}(i,\mathbf{k})\equiv\sum_{\nu\mu} s_{\nu\mu}(i,\mathbf{k})(\omega_{\nu\mu}-\omega_{nm}), \tag{14}$$

where $\omega_{nm}\equiv\omega_n-\omega_m$. Further in this section we will find it particularly convenient to express the first-order moments, $\langle\omega_{\mathbf{k}}(i)\rangle$, in terms of $\tilde{\sigma}^{(1)}_{nm}(i,\mathbf{k})$ rather than $\sigma^{(1)}_{nm}(i,\mathbf{k})$.

We then have, considering Eq. (10) and letting $\epsilon\to 1$,

$$\begin{aligned}\langle k\kappa|\mathscr{O}^{(0)}_{\ell}|k'\kappa'\rangle=&\,\delta_{k\ell}\delta_{k'\ell}\delta_{\kappa\kappa'}+\delta_{k\ell}(1-\delta_{k'\ell})\frac{\langle\ell\kappa|W|k'\kappa'\rangle}{\omega_\ell-\omega_{k'}}+\delta_{k'\ell}(1-\delta_{k\ell})\frac{\langle k\kappa|W|\ell\kappa'\rangle}{\omega_\ell-\omega_k}\\&+(1-\delta_{k\ell})(1-\delta_{k'\ell})\sum_\lambda\frac{\langle k\kappa|W|\ell\lambda\rangle\langle\ell\lambda|W|k'\kappa'\rangle}{(\omega_\ell-\omega_k)(\omega_\ell-\omega_{k'})}\\&+\delta_{k\ell}(1-\delta_{k'\ell})\sum_{t\tau}{}'\frac{\langle\ell\kappa|W|t\tau\rangle\langle t\tau|W|k'\kappa'\rangle}{(\omega_\ell-\omega_{k'})(\omega_\ell-\omega_t)}\\&+\delta_{k'\ell}(1-\delta_{k\ell})\sum_{t\tau}{}'\frac{\langle k\kappa|W|t\tau\rangle\langle t\tau|W|\ell\kappa'\rangle}{(\omega_\ell-\omega_k)(\omega_\ell-\omega_t)}\\&-\delta_{k\ell}(1-\delta_{k'\ell})\sum_\lambda\frac{\langle\ell\kappa|\mathscr{H}_1|\ell\lambda\rangle\langle\ell\lambda|W|k'\kappa'\rangle}{(\omega_\ell-\omega_{k'})^2}\\&-\delta_{k'\ell}(1-\delta_{k\ell})\sum_\lambda\frac{\langle k\kappa|W|\ell\lambda\rangle\langle\ell\lambda|\mathscr{H}_1|\ell\kappa'\rangle}{(\omega_\ell-\omega_k)^2}.\end{aligned} \tag{15}$$

Analogously, considering Eq. (12′) and letting $\epsilon\to 1$,

$$\begin{aligned}\langle k\kappa|\tilde{\mathscr{O}}^{(1)}_{\ell}|k'\kappa'\rangle=&\,\delta_{k\ell}\delta_{k'\ell}\langle\ell\kappa|\mathscr{H}_1|\ell\kappa'\rangle+\delta_{k\ell}\delta_{k'\ell}\sum_{s\sigma}{}'\frac{\langle\ell\kappa|W|s\sigma\rangle\langle s\sigma|W|\ell\kappa'\rangle}{\omega_\ell-\omega_s}\\&+\delta_{k\ell}(1-\delta_{k'\ell})\sum_\lambda\frac{\langle\ell\kappa|\mathscr{H}_1|\ell\lambda\rangle\langle\ell\lambda|W|k'\kappa'\rangle}{\omega_\ell-\omega_{k'}}\\&+\delta_{k'\ell}(1-\delta_{k\ell})\sum_\lambda\frac{\langle k\kappa|W|\ell\lambda\rangle\langle\ell\lambda|\mathscr{H}_1|\ell\kappa'\rangle}{\omega_\ell-\omega_k}.\end{aligned} \tag{16}$$

As we anticipated in the previous section, the operator W in general coincides with the perturbation Hamiltonian, $\mathscr{H}_1$. From now on, we will consider the following explicit form of $\mathscr{H}_1$ [cf. Ref. 10, Eq. (2′)]:

$$\mathscr{H}_1=\mathscr{H}_{\rm fs}+\mathscr{H}_{\rm hfs}+\mathscr{H}_E+\mathscr{H}_B^{(1)}+\mathscr{H}_B^{(2)},$$

where $\mathscr{H}_{\rm fs}$ is the fine-structure Hamiltonian [comprehensive of the relevant radiative corrections; see Ref. 10, Eq. (6)], $\mathscr{H}_{\rm hfs}$ is the hyperfine-structure Hamiltonian, $\mathscr{H}_E$ is the electric Hamiltonian (associated with the external, uniform electric field), and $\mathscr{H}_B$ is the magnetic Hamiltonian, responsible for both the linear Zeeman effect (electronic and nuclear; $\mathscr{H}^{(1)}_B$) and the quadratic Zeeman effect (diamagnetic term; $\mathscr{H}^{(2)}_B$). The expressions for all these operators have been given in Ref. 10; however, we will not need them explicitly in the present paper.

If the external magnetic field is not too strong, relative to the principal quantum numbers involved ($B\ll 10^{10}n^{-4}$ G), so that $\|\mathscr{H}^{(2)}_B\|\ll\|\mathscr{H}^{(1)}_B\|$, only the electric Hamiltonian, $\mathscr{H}_E$, contributes sensibly to configuration mixing. In fact, the configuration mixing due to the fine structure terms, $\mathscr{H}_{\rm fs}$

and $\mathscr{H}_{\rm hfs}$, is always negligible, whereas $\mathscr{H}_B^{(1)}$ does not mix different configurations (as can easily be proved through the Wigner–Eckart theorem). So we can just replace W with $\mathscr{H}_E$ in Eqs. (15) and (16). This will enable us to account for the quadratic Stark effect in the algebraic formalism of the first-order moments of polarized hydrogen lines.

To first order of perturbation, the only contribution to $\tilde{S}^{(1)}_{nm}(q,q')$ comes from the matrix element $\langle \ell\kappa|\mathscr{H}_1|\ell\kappa'\rangle$ in Eq. (16). To second order, instead, the only nonvanishing contributions to $\tilde{S}^{(1)}_{nm}(q,q')$ come from products of matrix elements of $\mathscr{H}_E$ only. In fact, all terms in $\mathscr{H}_1$ other than $\mathscr{H}_E$ determine the selection rules $|\Delta l|=0$ and/or $|\Delta l|=2$ for the azimuthal quantum number, l, whereas $\mathscr{H}_E$ yields $|\Delta l|=1$. Then we notice the presence into Eq. (13) of $3j$-symbol products of the form

$$\begin{pmatrix} l & 1 & l' \\ 0 & 0 & 0 \end{pmatrix}\begin{pmatrix} l' & 1 & l'' \\ 0 & 0 & 0 \end{pmatrix}\begin{pmatrix} l'' & 1 & l''' \\ 0 & 0 & 0 \end{pmatrix}\begin{pmatrix} l''' & C & l \\ 0 & 0 & 0 \end{pmatrix},$$

which are nonvanishing only for odd values of $C=|\Delta l|$ because of the electric–dipole selection rule (Laporte's rule), $|\Delta l|=1$.

After substitution of Eqs. (15) and (16) into Eq. (13), $\tilde{S}^{(1)}_{nm}(q,q')$ can be written as a finite sum of contributions originated by all possible products between the terms in Eqs. (15) and (16). Formally, there are 32 such contributions for each of the two summations in Eq. (13), many of which correspond to corrections of order higher than second and so are negligible in our approximation. Only six non-negligible terms remain for each of the summations in Eq. (13), so we can write

$$\tilde{S}^{(1)}_{nm}(q,q')=\sum_{r=1}^{6}(K_r^+-K_r^-). \tag{17}$$

The coefficients $K_1^{\pm}$ of first order in the perturbation Hamiltonian, $\mathscr{H}_1$, are easily found to be

$$K_1^+=\sum_{\alpha\alpha'\beta}\langle n\alpha|.\mathscr{H}_1|n\alpha'\rangle\langle n\alpha'|r_q|m\beta\rangle\langle n\alpha|r'_q|m\beta\rangle,$$

$$K_1^-=\sum_{\alpha\beta\beta'}\langle m\beta|.\mathscr{H}_1|m\beta'\rangle\langle n\alpha|r_q|m\beta\rangle\langle n\alpha|r'_q|m\beta'\rangle.$$

If we compare them with Eq. (9) in Ref. 1, we see that the contribution $K_1^+-K_1^-$ in $\tilde{S}^{(1)}_{nm}(q,q')$ corresponds to the contribution of the perturbation $\mathscr{H}_1$ to the first-order moments of polarized hydrogen lines in the absence of configuration mixing. The remaining five terms of the form $(K_r^+-K_r^-)$ in Eq. (17) then yield second-order corrections, due to electric-field induced configuration mixing, to those first-order moments. The corresponding coefficients $K_r^{\pm}$ are the following:

$$K_2^+=\sum_{b'}{}'(\omega_m-\omega_{b'})^{-1}\sum_{\alpha\alpha'\beta\beta'}\langle n\alpha|.\mathscr{H}_E|n\alpha'\rangle\langle m\beta|.\mathscr{H}_E|b'\beta'\rangle\langle n\alpha'|r_q|m\beta\rangle\langle n\alpha|r_{q'}|b'\beta'\rangle, \tag{18a}$$

$$K_2^-=\sum_{a'}{}'(\omega_n-\omega_{a'})^{-1}\sum_{\alpha\alpha'\beta\beta'}\langle n\alpha|.\mathscr{H}_E|a'\alpha'\rangle\langle m\beta|.\mathscr{H}_E|m\beta'\rangle\langle a'\alpha'|r_q|m\beta\rangle\langle n\alpha|r_{q'}|m\beta'\rangle, \tag{19a}$$

$$K_3^+=\sum_{b}{}'(\omega_m-\omega_b)^{-1}\sum_{\alpha\alpha'\beta\beta'}\langle n\alpha|.\mathscr{H}_E|n\alpha'\rangle\langle b\beta|.\mathscr{H}_E|m\beta'\rangle\langle n\alpha'|r_q|b\beta\rangle\langle n\alpha|r_{q'}|m\beta'\rangle, \tag{18b}$$

$$K_3^- = \sum_a{}' (\omega_n - \omega_a)^{-1} \sum_{\alpha\alpha'\beta\beta'} \langle a\alpha|\mathscr{H}_E|n\alpha'\rangle\langle m\beta|\mathscr{H}_E|m\beta'\rangle\langle n\alpha'|r_q|m\beta\rangle\langle a\alpha|r_{q'}|m\beta'\rangle, \tag{19b}$$

$$K_4^+ = \sum_s{}' (\omega_n - \omega_s)^{-1} \sum_{\alpha\alpha'\sigma\beta} \langle n\alpha|\mathscr{H}_E|s\sigma\rangle\langle s\sigma|\mathscr{H}_E|n\alpha'\rangle\langle n\alpha'|r_q|m\beta\rangle\langle n\alpha|r_{q'}|m\beta\rangle, \tag{18c}$$

$$K_4^- = \sum_s{}' (\omega_m - \omega_s)^{-1} \sum_{\alpha\sigma\beta\beta'} \langle m\beta|\mathscr{H}_E|s\sigma\rangle\langle s\sigma|\mathscr{H}_E|m\beta'\rangle\langle n\alpha|r_q|m\beta\rangle\langle n\alpha|r_{q'}|m\beta'\rangle, \tag{19c}$$

$$K_5^+ = \sum_{a'}{}' (\omega_n - \omega_{a'})^{-1} \sum_{\alpha\alpha'\beta\lambda} \langle n\alpha|\mathscr{H}_E|n\lambda\rangle\langle n\lambda|\mathscr{H}_E|a'\alpha'\rangle\langle a'\alpha'|r_q|m\beta\rangle\langle n\alpha|r_{q'}|m\beta\rangle, \tag{18d}$$

$$K_5^- = \sum_{b'}{}' (\omega_m - \omega_{b'})^{-1} \sum_{\alpha\beta\beta'\lambda} \langle m\beta|\mathscr{H}_E|m\lambda\rangle\langle m\lambda|\mathscr{H}_E|b'\beta'\rangle\langle n\alpha|r_q|m\beta\rangle\langle n\alpha|r_{q'}|b'\beta'\rangle, \tag{19d}$$

$$K_6^+ = \sum_a{}' (\omega_n - \omega_a)^{-1} \sum_{\alpha\alpha'\beta\lambda} \langle a\alpha|\mathscr{H}_E|n\lambda\rangle\langle n\lambda|\mathscr{H}_E|n\alpha'\rangle\langle n\alpha'|r_q|m\beta\rangle\langle a\alpha|r_{q'}|m\beta\rangle, \tag{18e}$$

$$K_6^- = \sum_b{}' (\omega_m - \omega_b)^{-1} \sum_{\alpha\beta\beta'\lambda} \langle b\beta|\mathscr{H}_E|m\lambda\rangle\langle m\lambda|\mathscr{H}_E|m\beta'\rangle\langle n\alpha|r_q|b\beta\rangle\langle n\alpha|r_{q'}|m\beta'\rangle. \tag{19e}$$

It is worth noting that all of the summations of matrix element products in Eqs. (18) and (19) have already been evaluated in Ref. 2. In fact, if we compare Eqs. (6) and (14) in Ref. 2 [see also Eq. (13) in that paper], we realize that sums of the form

$$\begin{aligned} S^{(1)} &= \sum_{\alpha\alpha'\alpha''\alpha'''} \langle a\alpha|\mathscr{H}_E|a'\alpha'\rangle\langle a'\alpha'|\mathscr{H}_E|a''\alpha''\rangle\langle a''\alpha''|r_q|a'''\alpha'''\rangle\langle a\alpha|r_{q'}|a'''\alpha'''\rangle \\ &\equiv \sum_{\alpha\alpha'\alpha''\alpha'''} \langle a\alpha|\mathscr{H}_E|a'\alpha'\rangle\langle a'\alpha'|\mathscr{H}_E|a''\alpha''\rangle\langle a''\alpha''|r_q|a'''\alpha'''\rangle\langle a'''\alpha'''|r_{q'}^\dagger|a\alpha\rangle, \end{aligned}$$

or

$$\hat{S}^{(1)} = S^{(1)}\{r_q \leftrightarrow r_{q'}^\dagger\},$$

yield the following ''electric'' contribution to the quantity $\tilde{\sigma}_{nm}^{(1)}(i,\mathbf{k})$,

$$[\tilde{\sigma}_{nm}^{(1)}(i,\mathbf{k})]_E^{(1)} = 4e_0^2 a_0^2 E^2 \sum_{K=0,2} T_K(i) A_K^{(1)} \tag{20a}$$

(a_0 is the Bohr radius), where, using the shorthand notation $\Pi_{\alpha\beta\ldots} = [(2\alpha+1)(2\beta+1)\cdots]^{1/2}$, we have [cf. Ref. 2, Eq. (14)]

$$\begin{aligned} A_K^{(1)} = a_0^{-2} \sum_{ll'l''l'''} \Pi^2_{ll'l''l'''} &\langle al|r|a'l'\rangle\langle a'l'|r|a''l''\rangle\langle a''l''|r|a'''l'''\rangle\langle a'''l'''|r|al\rangle \begin{pmatrix} l & 1 & l' \\ 0 & 0 & 0 \end{pmatrix} \\ &\times \begin{pmatrix} l' & 1 & l'' \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} l'' & 1 & l''' \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} l''' & 1 & l \\ 0 & 0 & 0 \end{pmatrix} \begin{Bmatrix} l & l'' & K \\ 1 & 1 & l' \end{Bmatrix} \begin{Bmatrix} l & l'' & K \\ 1 & 1 & l''' \end{Bmatrix}. \end{aligned} \tag{20b}$$

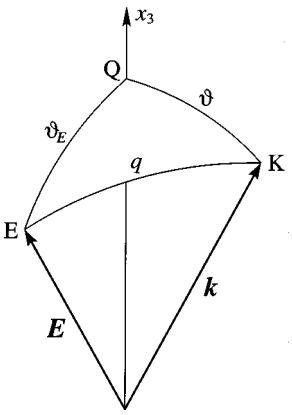

FIG. 2. Geometry of the electric field and the LOS relative to the quantization axis. The angle $\hat{Q}$ in the spherical triangle $\Delta(EQK)$ is equivalent to $(\varphi-\varphi_E)$, where φ and φ_E are respectively the azimuthal angles of the propagation vector, **k**, and of the electric field, **E**, in the frame of reference of the quantization axis.

Analogously, sums of the form

$$S^{(2)}=\sum_{\alpha\alpha'\alpha''\alpha'''}\langle a\alpha|\mathscr{H}_E|a'\alpha'\rangle\langle a''\alpha''|\mathscr{H}_E|a'''\alpha'''\rangle\langle a'\alpha'|r_q|a''\alpha''\rangle\langle a\alpha|r_{q'}|a'''\alpha'''\rangle$$

$$\equiv\sum_{\alpha\alpha'\alpha''\alpha'''}\langle a\alpha|\mathscr{H}_E|a'\alpha'\rangle\langle a'\alpha'|r_q|a''\alpha''\rangle\langle a''\alpha''|\mathscr{H}_E|a'''\alpha'''\rangle\langle a'''\alpha'''|r^{\dagger}_{q'}|a\alpha\rangle,$$

or

$$\hat{S}^{(2)}=S^{(2)}\{r_q\leftrightarrow r^{\dagger}_{q'}\},$$

yield

$$[\tilde{\sigma}^{(1)}_{nm}(i,\mathbf{k})]^{(2)}_E=4e_0^2a_0^2E^2\sum_{K=0,2}T_K(i)A^{(2)}_K, \tag{21a}$$

where [cf. Ref. 2, Eq. (14)]

$$A^{(2)}_K=a_0^{-2}\sum_{ll'l''l'''}\Pi^2_{ll'l''l'''}\langle al|r|a'l'\rangle\langle a'l'|r|a''l''\rangle\langle a''l''|r|a'''l'''\rangle\langle a'''l'''|r|al\rangle\begin{pmatrix}l & 1 & l'\\ 0 & 0 & 0\end{pmatrix}$$

$$\times\begin{pmatrix}l' & 1 & l''\\ 0 & 0 & 0\end{pmatrix}\begin{pmatrix}l'' & 1 & l'''\\ 0 & 0 & 0\end{pmatrix}\begin{pmatrix}l''' & 1 & l\\ 0 & 0 & 0\end{pmatrix}\begin{Bmatrix}1 & 1 & K\\ l' & l & 1\\ l'' & l''' & 1\end{Bmatrix}. \tag{21b}$$

The quantities $T_K(i)$ in Eqs. (20a) and (21a), which depend on the field geometry, for $K=0,2$ are given by

$$T_0(i)=\tfrac{1}{3}\delta_{i0}, \tag{22}$$

and

$$T_2(0)=\tfrac{1}{6}(1-3\cos^2 q), \tag{23a}$$

$$T_2(1)=\tfrac{1}{2}\{\sin^2\vartheta_E[\cos 2(\varphi-\varphi_E)-1]-\sin^2 q\}\cos 2\gamma+\sin\vartheta_E\sin(\varphi-\varphi_E)\sin q\cos\hat{K}\sin 2\gamma, \tag{23b}$$

$$T_2(2)=T_2(1)\begin{Bmatrix}\cos 2\gamma\rightarrow-\sin 2\gamma\\ \sin 2\gamma\rightarrow\cos 2\gamma\end{Bmatrix}, \tag{23c}$$

$$T_2(3)=0, \tag{23d}$$

where, for the fundamental formulas of spherical triangles (see Fig. 2),

$$\begin{cases} \cos q = \cos\vartheta\,\cos\vartheta_E + \sin\vartheta\,\sin\vartheta_E\,\cos(\varphi-\varphi_E), \\ \sin q\,\cos\hat{K} = \sin\vartheta\,\cos\vartheta_E - \cos\vartheta\,\sin\vartheta_E\,\cos(\varphi-\varphi_E). \end{cases}$$

In the particular case in which the LOS coincides with the quantization axis, so that $\vartheta=\varphi=0$ and $q=\vartheta_E$, Eqs. (23) reduces to Eqs. (18) in Ref. 2.

To recover Eqs. (20) and (21) from comparison of Eqs. (6) and (14) in Ref. 2, we also had to consider the following result, valid in the absence of configuration mixing [see Ref. 1, Eq. (A3)],

$$\sum_{\nu\mu} s_{\nu\mu}(i,\mathbf{k}) = \delta_{i0}\,\frac{4}{3}\sum_{ll'}\Pi^2_{ll'}\langle nl|r|ml'\rangle^2\begin{pmatrix} l & 1 & l' \\ 0 & 0 & 0\end{pmatrix}^2 \equiv \delta_{i0}\mathscr{N}_{nm}. \tag{24}$$

[The factor 4 in Eqs. (20a), (21a), and (24) is related to the electronic- and nuclear-spin quantum numbers, $s=i=1/2$, and comes from $\Pi^2_{si}=(2s+1)(2i+1)=4$.]

C. Estimate of the contribution of the quadratic Stark effect to $\sigma^{(0)}_{nm}(i,\mathbf{k})$

To completely define the first-order moments of polarized hydrogen lines, according to Eq. (2) we still have to evaluate the integrated profiles, $\Sigma_{\nu\mu}\, s_{\nu\mu}(i,\mathbf{k})$, in the presence of configuration mixing, which in general will differ from the result stated by Eq. (24).

According to Eq. (7), we must evaluate the quantity

$$S^{(0)}_{nm}(q,q') = \sum_{\substack{a\alpha,a'\alpha' \\ b\beta,b'\beta'}} \langle a\alpha|\mathscr{O}^{(0)}_n|a'\alpha'\rangle\langle b\beta|\mathscr{O}^{(0)}_m|b'\beta'\rangle\langle a'\alpha'|r_q|b\beta\rangle\langle a\alpha|r_{q'}|b'\beta'\rangle.$$

From Eq. (15), and applying the same arguments as in the previous calculation of $\tilde{S}^{(1)}_{nm}(q,q')$, we see that there are 15 nonvanishing contributions to $S^{(0)}_{nm}(q,q')$, originating from products between terms of Eq. (15), so we can write

$$S^{(0)}_{nm}(q,q') = \sum_{r=0}^{14} L_r.$$

For $r=0$ we have trivially [cf. Ref. 1, Appendix A, and Eq. (24) above]

$$L_0 = \sum_{\alpha\beta}\langle n\alpha|r_q|m\beta\rangle\langle n\alpha|r_{q'}|m\beta\rangle \equiv \delta_{qq'}\,\frac{4}{3}\sum_{ll'}\Pi^2_{ll'}\langle nl|r|ml'\rangle^2\begin{pmatrix} l & 1 & l' \\ 0 & 0 & 0\end{pmatrix}^2 \equiv \delta_{qq'}\mathscr{N}_{nm},$$

which is the zeroth-order term that would give Eq. (24) if configuration mixing were absent. The remaining 14 coefficients L_r are all of second order in $W\equiv\mathscr{H}_E$, and they also can be expressed through the set of coefficients $A^{(i)}_K(n,m)$ $(i=1,2;\ K=0,2)$ given in Eqs. (20b) and (21b).

We then see that, because of configuration mixing, to second order of perturbation we no longer have $\Sigma_{\nu\mu}\, s_{\nu\mu}(i,\mathbf{k})=0$ for $i\neq 0$. This is a fact that needs to be taken into account in the evaluation of the numerator of Eq. (2). The denominator of Eq. (2), on the contrary, can be safely approximated by $\mathscr{N}_{nm}$ [cf. Eq. (24)], just like in the absence of configuration mixing. To see this in the case of the first-order moments we rewrite

$$\langle\omega_{\mathbf{k}}(i)\rangle = \frac{\Sigma_{\nu\mu}s_{\nu\mu}(i,\mathbf{k})(\omega_{\nu\mu}-\omega_{nm})}{\Sigma_{\nu\mu}s_{\nu\mu}(0,\mathbf{k})} + (\omega_{nm}-\overline{\omega})\,\frac{\Sigma_{\nu\mu}s_{\nu\mu}(i,\mathbf{k})}{\Sigma_{\nu\mu}s_{\nu\mu}(0,\mathbf{k})}.$$

The first term on the right-hand side (rhs) is a quantity of first order in the perturbation $\mathscr{H}_1$ (plus second-order corrections due to configuration mixing), so the second-order corrections in $\Sigma_{\nu\mu}\, s_{\nu\mu}(0,\mathbf{k})$ can be neglected, as they would yield at least third (or higher) order corrections to $\langle\omega_{\mathbf{k}}(i)\rangle$. On the other hand, the second term on the rhs is exactly equal to $(\omega_{nm}-\overline{\omega})$ if $i=0$, whereas it is a quantity of second order in the perturbation $W\equiv\mathscr{H}_E$ if $i\neq 0$, so the second-order corrections to the denominator can be ignored in both cases. Finally, we observe that the difference $(\omega_{nm}-\overline{\omega})$ is essentially determined by the fine structure of the hydrogen atom, so it represents a quantity of the first order in the perturbation $\mathscr{H}_{\rm fs}$. Therefore, the second term on the rhs of

the above equation, for $i\neq 0$, represents a correction to $\langle\omega_{\mathbf{k}}(i)\rangle$ that actually is comparable with terms of order higher than second in the perturbation $\mathscr{H}_1$. For all these reasons, to second order we can safely approximate [cf. Eq. (14)]

$$\langle\omega_{\mathbf{k}}(i)\rangle\approx\mathscr{N}_{nm}^{-1}\sum_{\nu\mu}s_{\nu\mu}(i,\mathbf{k})(\omega_{\nu\mu}-\omega_{nm})+\delta_{i0}(\omega_{nm}-\overline{\omega})=\mathscr{N}_{nm}^{-1}\tilde{\sigma}_{nm}^{(1)}(i,\mathbf{k})+\delta_{i0}(\omega_{nm}-\overline{\omega}), \tag{25}$$

which manifestly supports our earlier choice of evaluating $\tilde{\sigma}_{nm}^{(1)}(i,\mathbf{k})$ rather than $\sigma_{nm}^{(1)}(i,\mathbf{k})$.

We note that the above arguments also justify our decision of neglecting the second-order corrections to the first-order moments due to the nonunitary norm of the perturbed eigenvectors (see Sec. II), as these corrections are unessential, to our order of approximation, in the evaluation of the summation in Eq. (25).

D. Algebraic formulation of the first-order moments

Because of the approximation of the denominator $\Sigma_{\nu\mu}\,s_{\nu\mu}(0,\mathbf{k})$ by Eq. (24), the corrections to the first-order moments due to electric-field induced configuration mixing are simply added to the expressions of the first-order moments in the absence of configuration mixing, so we can rewrite Eq. (25) in the form

$$\begin{aligned}\langle\omega_{\mathbf{k}}(i)\rangle&\approx\{\delta_{i0}(\omega_{nm}-\overline{\omega})+\mathscr{N}_{nm}^{-1}[\tilde{\sigma}_{nm}^{(1)}(i,\mathbf{k})]_{\text{no cm}}\}+\mathscr{N}_{nm}^{-1}[\tilde{\sigma}_{nm}^{(1)}(i,\mathbf{k})]_{\text{cm}}\\&\equiv\langle\omega_{\mathbf{k}}(i)\rangle_{\text{no cm}}+\langle\omega_{\mathbf{k}}(i)\rangle_{E},\end{aligned} \tag{25$'$}$$

where $\langle\omega_{\mathbf{k}}(i)\rangle_{\text{no cm}}$ represents the first-order moments in the absence of configuration mixing [inclusive of the first-order term $\delta_{i0}(\omega_{nm}-\overline{\omega})$], which were evaluated in Ref. 1, whereas $\langle\omega_{\mathbf{k}}(i)\rangle_E$ represents the correction to those first-order moments due to the configuration mixing induced by the presence of the electric field. This correction, as suggested by Eqs. (20a) and (21a), can be written

$$\langle\omega_{\mathbf{k}}(i)\rangle_E=4e_0^2a_0^2E^2\sum_{K=0,2}T_K(i)\tilde{A}_K(n,m), \tag{26}$$

with a suitable choice of the coefficients $\tilde{A}_K(n,m)$.

To provide a compact formulation of these coefficients, it is useful to introduce the following symbols,

$$\begin{aligned}R(al,a'l',a''l'',a'''l''')\equiv a_0^{-2}\Pi_{ll'l''l'''}^2\langle al|r|a'l'\rangle\langle a'l'|r|a''l''\rangle\langle a''l''|r|a'''l'''\rangle\langle a'''l'''|r|al\rangle\\\times\begin{pmatrix}l&1&l'\\0&0&0\end{pmatrix}\begin{pmatrix}l'&1&l''\\0&0&0\end{pmatrix}\begin{pmatrix}l''&1&l'''\\0&0&0\end{pmatrix}\begin{pmatrix}l'''&1&l\\0&0&0\end{pmatrix},\end{aligned} \tag{27}$$

$$f_K^{(1)}(ll'l''l''')\equiv\begin{Bmatrix}l&l''&K\\1&1&l'\end{Bmatrix}\begin{Bmatrix}l&l''&K\\1&1&l'''\end{Bmatrix},\quad f_K^{(2)}(ll'l''l''')\equiv\begin{Bmatrix}1&1&K\\l'&l&1\\l''&l'''&1\end{Bmatrix}, \tag{28}$$

and the ''contracted'' coefficients

$$\mathscr{R}_K^{(i)}(aa'a''a''')\equiv\sum_{ll'l''l'''}R(al,a'l',a''l'',a'''l''')f_K^{(i)}(ll'l''l'''),\quad i=1,2,\quad K=0,2. \tag{29}$$

If we consider the symmetry properties of the $6j$ and $9j$ symbols (see, e.g., Ref. 11) we can easily demonstrate the following symmetries of the coefficients $\mathscr{R}_K^{(i)}$ for even values of K,

$$\mathscr{R}_K^{(1)}(aa'a''a''')=\mathscr{R}_K^{(1)}(aa'''a''a')=\mathscr{R}_K^{(1)}(a''a'aa''')=\mathscr{R}_K^{(1)}(a''a'''aa'),$$

$$\mathscr{R}_K^{(2)}(aa'a''a''')=\mathscr{R}_K^{(2)}(a'aa'''a'')=\mathscr{R}_K^{(2)}(a''a'''aa')=\mathscr{R}_K^{(2)}(a'''a''a'a).$$

The coefficients $\tilde{A}_K(n,m)$ of Eq. (26) then assume a particularly symmetric form. In fact, from Eqs. (18) and (19), after some renaming of summation indexes and collecting of similar terms, we find

$$\mathscr{N}_{nm}\tilde{A}_K(n,m)=\sum_a{}'(\omega_m-\omega_a)^{-1}[2.\mathscr{R}_K^{(2)}(nnma)-2.\mathscr{R}_K^{(1)}(anmm)-\mathscr{R}_K^{(1)}(mnma)]$$

$$-\sum_a{}'(\omega_n-\omega_a)^{-1}[2.\mathscr{R}_K^{(2)}(mmna)-2.\mathscr{R}_K^{(1)}(amnn)-\mathscr{R}_k^{(1)}(nmna)]. \quad (30)$$

Equations (26) and (30) finally give an algebraic expression for the quadratic Stark effect on the centers of gravity of polarized hydrogen lines.

Whereas the numerical calculation of the discrete part of Eq. (30) [or of Eqs. (18) and (19)] is straightforward and does not present any conceptual difficulty, things are much more complicated when integration over the continuum must be considered. A prescription given by Ruffa,[12] on the use of the integral representation of the hydrogenic wave functions for the continuum (see, e.g., Ref. 13), which reduces the calculation of summations of matrix elements over the continuum to integrations in the complex domain, might probably be the best approach to this problem. However, we will not investigate the continuum problem any further in this paper.

E. Generalization of the first-order moments in the presence of line broadening

A final remark must be made about the generalization of the result expressed by Eq. (30) when typical line-broadening mechanisms (e.g., pressure broadening, thermal-Doppler broadening) are also present. In the beginning of Sec. II, in fact, we explicitly noted that Eq. (2) holds in the absence of any broadening mechanism of the line profile other than the external fields.

This problem has already been dealt with in Ref. 2 (see Sec. 5 in that paper). However those previous results must be somewhat modified to account for the no-longer vanishing (because of configuration mixing) integrated polarization profiles, $\Sigma_{\nu\mu}\, s_{\nu\mu}(i,\mathbf{k})$, for $i\neq 0$. Following the notation of Ref. 2, where ϕ_a and ϕ_b are, respectively, the unbroadened Stokes profile and the line profile resulting from the intervening broadening mechanisms, we indicate with $\mathscr{I}_a$ and $\mathscr{I}_b$ the corresponding integrated profiles, and with $\mathscr{N}_a$ and $\mathscr{N}_b$ the corresponding normalization constants. Operating as in Ref. 2 we then easily find for the first-order moment of the broadened Stokes profile (obtained as the convolution product of ϕ_a and ϕ_b),

$$\langle\omega\rangle=\frac{\mathscr{I}_b}{\mathscr{N}_b}\langle\omega_a\rangle+\frac{\mathscr{I}_a}{\mathscr{N}_a}\langle\omega_b\rangle+\frac{\mathscr{I}_a\mathscr{I}_b}{\mathscr{N}_a\mathscr{N}_b}\,\overline{\omega}. \quad (31)$$

As is customary, the line-broadening profile is normalized to unit integrated area, so that $\mathscr{I}_b=\mathscr{N}_b=1$. For the Stokes profile, instead, we must distinguish between the intensity profile ($i=0$) and the other polarization profiles ($i\neq 0$). For the intensity profile we can choose the standard normalization, $\mathscr{I}_a=\mathscr{N}_a=1$, so we recover Eq. (25a) in Ref. 2. For the linear- and circular-polarization profiles, instead, Eq. (31) becomes, recalling Eq. (24),

$$\langle\omega(i)\rangle=\langle\omega_a(i)\rangle+[\langle\omega_b\rangle+\overline{\omega}]\mathscr{N}_{nm}^{-1}\sum_{\nu\mu}\, s_{\nu\mu}(i,\mathbf{k}), \quad i=1,2,3. \quad (32)$$

The second term then determines a second-order correction to the first-order moments of broadened, polarized hydrogen lines, which is induced by configuration mixing. [Compare the above equation with Eq. (25a′) in Ref. 2, where configuration mixing was neglected.] However, if the line-broadening profile, ϕ_b, is *symmetric*, as is almost always the case, we easily see that $\langle\omega_b\rangle+\overline{\omega}=0$, so Eq. (31) reduces to $\langle\omega\rangle=\langle\omega_a\rangle$ for *all* four Stokes profiles. In this case, Eq. (25′) gives directly the algebraic first-order moments of polarized hydrogen lines also in the presence of broadening mechanisms other than the external fields.

IV. CONCLUSIONS

Equation (26), along with Eqs. (30) and (24), provides an algebraic expression for the quadratic Stark effect on the centers of gravity of polarized hydrogen lines.

We remark that the success of the algebraic approach followed in this paper essentially relies on the possibility of expressing the operators $\mathscr{O}_\ell^{(0)}$ and $\mathscr{O}_\ell^{(1)}$, given, respectively, by Eqs. (10) and (12′), in terms of the projection operator $\mathscr{P}_\ell$, so that it becomes possible, making use of standard techniques of projection-operator algebra and of the fundamental results of the spectral theorem, to remove from $\mathscr{O}_\ell^{(0)}$ and $\mathscr{O}_\ell^{(1)}$ any explicit reference to the unknown first-order eigenvalues, $\omega_{\ell\lambda}^{(1)}$, and zeroth-order eigenvectors, $|\psi_{\ell\lambda}^{(0)}\rangle$, which otherwise had to be determined numerically via diagonalization of the perturbation Hamiltonian, $\mathscr{H}_1$.

We think that the availability of an algebraic formula for the centers of gravity of hydrogen lines, accounting for the quadratic Stark effect, might be useful for future estimates of hydrogen line shifts—for instance, in applications of pressure-broadening theory to solar and fusion plasma research—as it opens to the investigation of (relatively) high hydrogen series at the cost of a comparatively modest computational effort, at least for the contribution from the discrete spectrum.

ACKNOWLEDGMENT

A direct link between a one-loop N-point Feynman diagram and a geometrical representation based on the N-dimensional simplex is established by relating the Feynman parametric representations to the integrals over contents of $(N-1)$-dimensional simplices in non-Euclidean geometry of constant curvature. In particular, the four-point function in four dimensions is proportional to the volume of a three-dimensional spherical (or hyperbolic) tetrahedron which can be calculated by splitting into birectangular ones. It is also shown that the known formula of reduction of the N-point function in $(N-1)$ dimensions corresponds to splitting the related N-dimensional simplex into N rectangular ones. © *1998 American Institute of Physics.* [S0022-2488(98)00709-9]

I. INTRODUCTION

The development of techniques for an efficient calculation of one-loop N-point Feynman diagrams is very important for studying the leading and next-to-leading corrections to elementary particle processes within and beyond the Standard Model. Since any one-loop diagram can be reduced to a combination of scalar integrals,[1] in what follows we shall mainly deal with scalar Feynman integrals.

It is well known (see e.g., in Ref. 2) that results for the three- and four-point functions in four dimensions can be expressed in terms of dilogarithms (or related functions). The first explicit calculation of the general one-loop four-point function was given in Ref. 3 and later on, more compact results were presented in Refs. 2 and 4 (see also in Refs. 5 and 6). Moreover, it is known that (in four dimensions) the five-point function, the ''pentagon,'' can be reduced to a linear combination of four-point functions[7–9] (see also in Refs. 10–13). Using linear dependence of the external momenta, a similar reduction procedure can be applied to the N-point functions with $N \geqslant 6$ (see in Refs. 14 and 8).

As a rule, explicit results for diagrams with several external legs possess a rather complicated analytical structure. For example, separate terms in a sum of dilogarithms may have singularities (cuts) which cancel in the whole sum. As the result, there are certain difficulties in describing analytic continuation to all regions (in external momenta and masses) of interest.

Another approach to the evaluation of one-loop integrals[15] makes it possible to represent them in terms of multiple hypergeometric functions. In Ref. 16, such results for the integrals with an arbitrary number of external legs were presented. As a rule, the corresponding hypergeometric series have a rather restricted region of convergence. In general, the problem of analytic continuation of occurring functions to all other regions of interest is very complicated.

The analytical structure of the results can be better understood if one employs a geometrical interpretation of kinematic invariants and other quantities. For example, the singularities of the general three-point function can be described pictorially through a tetrahedron constructed out of the external and internal momenta. This method can be used to derive Landau equations defining the positions of possible singularities[17] (see also in Refs. 18–20) and a similar approach can be applied to the four-point function[21,3] too.

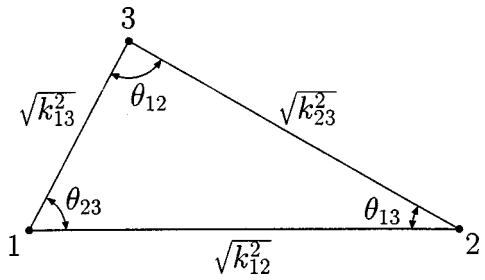

FIG. 1. The triangle associated with the massless three-point function.

Another well-known example of using geometrical ideas is the massless three-point function with arbitrary (off-shell) external momenta. Let us denote them as k_{12}, k_{23}, and k_{31}, so that $k_{12}+k_{23}+k_{31}=0$, and assume that all these momenta are time-like ($k_{jl}^2>0$). Using the standard notation for the ''triangle'' Källen function,

$$\lambda(x,y,z)=x^2+y^2+z^2-2xy-2yz-2zx, \tag{1.1}$$

and assuming that we are in the region $\lambda(k_{12}^2,k_{23}^2,k_{31}^2)\leqslant 0$, the result for the corresponding one-loop scalar Feynman integral (in four dimensions) can be neatly expressed as

$$\frac{2i\pi^2}{\sqrt{-\lambda(k_{12}^2,k_{23}^2,k_{31}^2)}}\{\mathrm{Cl}_2(2\theta_{12})+\mathrm{Cl}_2(2\theta_{23})+\mathrm{Cl}_2(2\theta_{31})\}, \tag{1.2}$$

where the angles θ_{12}, θ_{23}, and θ_{31} are nothing but those of the triangle with sides $\sqrt{k_{12}^2}$, $\sqrt{k_{23}^2}$, and $\sqrt{k_{31}^2}$, as shown in Fig. 1. Moreover, the denominator $\sqrt{-\lambda}$ is nothing but four times the area of this triangle. [Here we use the same normalization as in (2.1). The results for the massless three-point functions can be found, e.g., in Refs. 22, 2, 23. They are closely connected with the results for two-loop massive vacuum diagrams.[24–26] The functions related to the dilogarithm (including the Clausen function $\mathrm{Cl}_2(\theta)$) are defined in Appendix A (see also Ref. 27).]

In this paper, we discuss the geometrical interpretation of the kinematic variables related to the one-loop N-point functions. The generalization of the tetrahedron representation (which was used in the three-point case) is an N-dimensional simplex. Furthermore, we show that there is a direct transition from the Feynman parametric representation to the geometrical description connected with an N-dimensional simplex. We thereby arrive at a ''geometrical'' way of evaluating Feynman integrals.

The paper is organized as follows. In Sec. II we describe the connection of the N-point variables and the corresponding N-dimensional simplex. In Sec. III we show how one can ''geometrize'' the ordinary Feynman parametric representation. In Secs. IV, V, and VI we consider application of these geometrical ideas to the two-, three- and four-point functions, respectively. In Sec. VII we discuss how to use geometrical ideas for the reduction of N-point integrals in $(N-1)$ dimensions, and also for the calculation of the integrals with higher powers of denominators. Finally, in Sec. VIII, we summarize the main ideas and results.

II. BASIC SIMPLICES IN *N* DIMENSIONS

A. *N*-point function and the related simplex

Consider a one-loop scalar N-point ''sun-type'' diagram presented in Fig. 2. The corresponding Feynman integral is

$$J^{(N)}(n;\nu_1,\ldots,\nu_N)\equiv\int\frac{d^nq}{\Pi_{i=1}^N[(p_i+q)^2-m_i^2]^{\nu_i}}, \tag{2.1}$$

where n is the space–time dimension and ν_i are the powers of the propagators. (Here and below, the usual causal prescription for the propagators is understood, i.e., $1/[q^2-m^2]^\nu\leftrightarrow 1/[q^2-m^2+i0]^\nu$.) In general, it depends on $\frac{1}{2}N(N-1)$ momenta invariants k_{jl}^2 ($j<l$), where

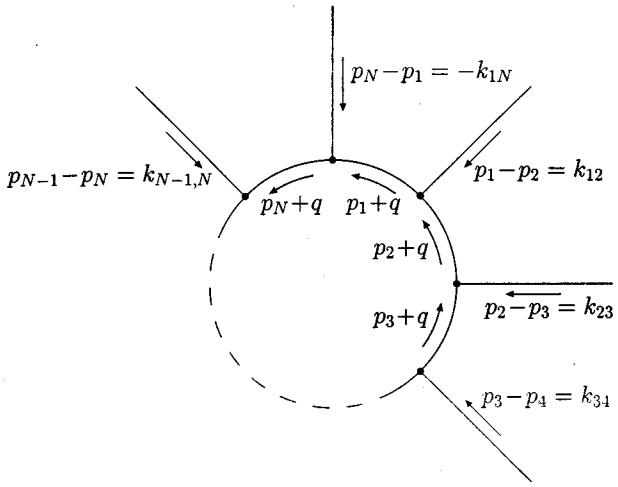

FIG. 2. The one-loop N-point diagram.

$$k_{jl}\equiv p_j-p_l\,, \tag{2.2}$$

and N masses m_i corresponding to the internal propagators. The momenta p_i are auxiliary in the sense that they all can be shifted by a constant vector without changing the momenta k_{jl} (2.2). We shall discuss this freedom below [see Eqs. (2.49)–(2.53)].

It is well known that, using the condition $\Sigma\alpha_i=1$, the standard quadratic form occurring in the denominator of the integrand of the Feynman parametric representation for these integrals [cf. Eqs. (3.1)–(3.2) below] can be rewritten in a homogeneous form,

$$\left[\sum_{j<l}\sum\ \alpha_j\alpha_l k_{jl}^2-\sum\ \alpha_i m_i^2\right]\Rightarrow-\left[\sum\ \alpha_i^2 m_i^2+2\sum_{j<l}\sum\ \alpha_j\alpha_l m_j m_l c_{jl}\right], \tag{2.3}$$

where (in some papers, the notation y_{jl} is used for $\pm c_{jl}$)

$$c_{jl}\equiv\frac{m_j^2+m_l^2-k_{jl}^2}{2m_j m_l}. \tag{2.4}$$

In the region between the corresponding two-particle pseudo-threshold, $k_{jl}^2=(m_j-m_l)^2$, and the threshold, $k_{jl}^2=(m_j+m_l)^2$, we have $|c_{jl}|<1$, and therefore in this region they can be understood as cosines of some angles τ_{jl},

$$c_{jl}=\cos\ \tau_{jl}=\begin{cases}1, & k_{jl}^2=(m_j-m_l)^2\\ -1, & k_{jl}^2=(m_j+m_l)^2.\end{cases} \tag{2.5}$$

The corresponding angles τ_{jl} are

$$\tau_{jl}=\arccos(c_{jl})=\arccos\left(\frac{m_j^2+m_l^2-k_{jl}^2}{2m_j m_l}\right)=\begin{cases}0, & k_{jl}^2=(m_j-m_l)^2\\ \pi, & k_{jl}^2=(m_j+m_l)^2.\end{cases} \tag{2.6}$$

The expressions in other regions should be understood in the sense of analytic continuation, using (when necessary) the causal prescription for the propagators. For example, when $k_{jl}^2<(m_j-m_l)^2(c_{jl}>1)$, i.e., below the pseudothreshold, we should interpret

$$\tau_{jl}=-i\ \mathrm{Arch}(c_{jl})=-\frac{i}{2}\ln\left(\frac{m_j^2+m_l^2-k_{jl}^2+\sqrt{\lambda(m_j^2,m_l^2,k_{jl}^2)}}{m_j^2+m_l^2-k_{jl}^2-\sqrt{\lambda(m_j^2,m_l^2,k_{jl}^2)}}\right), \tag{2.7}$$

where $\lambda(x,y,z)$ is the Källen function defined by Eq. (1.1). When $k_{jl}^2>(m_j+m_l)^2(c_{jl}<-1)$, i.e., above the threshold, we get

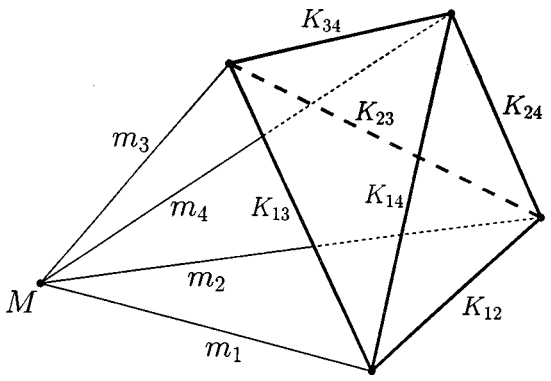

FIG. 3. The basic simplex for $N=4$.

$$\tau_{jl}=\pi+i\ \mathrm{Arch}(-c_{jl})=\pi+\frac{i}{2}\ \ln\left(\frac{k_{jl}^2-m_j^2-m_l^2+\sqrt{\lambda(m_j^2,m_l^2,k_{jl}^2)}}{k_{jl}^2-m_j^2-m_l^2-\sqrt{\lambda(m_j^2,m_l^2,k_{jl}^2)}}\right). \tag{2.8}$$

Note that $\lambda(m_j^2,m_l^2,k_{jl}^2)$ is positive when $k_{jl}^2<(m_j-m_l)^2$ or $k_{jl}^2>(m_j+m_l)^2$.

When the angles τ_{jl} [defined by Eq. (2.6)] are real, the quadratic form on the right-hand side in Eq. (2.3) has a rather simple geometrical interpretation. Let us consider a set of Euclidean ''mass'' vectors whose lengths are m_i. Let them be directed so that the angle between the jth and the lth vectors is τ_{jl}. If we denote the corresponding unit vectors as a_i (so that the ''mass'' vectors are $m_i a_i$), we get

$$(a_j\cdot a_l)=\cos\ \tau_{jl}=c_{jl}. \tag{2.9}$$

This is also valid for the case $j=l$, since $\tau_{jj}=0$ and $c_{jj}=1$, cf. Eqs. (2.5)–(2.6). Now, we can represent Eq. (2.3) as

$$\sum\ \alpha_i^2 m_i^2+2\sum_{j<l}\sum\ \alpha_j\alpha_l m_j m_l c_{jl}=\left(\sum\ \alpha_i m_i a_i\right)^2. \tag{2.10}$$

In N dimensions, if we put all ''mass'' vectors together as emanating from a common origin, they, together with the sides connecting their ends, will define a *simplex* (or hypertetrahedron) which is the *basic* one for a given Feynman diagram. An example of such a simplex for $N=4$ is illustrated by Fig. 3. [Since the four-dimensional Euclidean space is understood, one should consider Fig. 3 just as an illustration (rather than precise picture).] It is easy to see that the length of the side connecting the ends of the jth and the lth mass vectors is $(m_j^2+m_l^2-2m_j m_l c_{jl})^{1/2}=(k_{jl}^2)^{1/2}$, so we shall call it a ''momentum'' side. In total, the *basic* N-dimensional simplex has $\frac{1}{2}N(N+1)$ sides, among them N mass sides (corresponding to the masses $m_1,\ldots,m_N$) and $\frac{1}{2}N(N-1)$ momentum sides (corresponding to the momenta k_{jl}, $j<l$), which meet at $(N+1)$ vertices. Each vertex is a ''meeting point'' for N sides. There is one vertex where all mass sides meet, which we shall call the *mass meeting point*, M. All other vertices are meeting points for $(N-1)$ momentum sides and one mass side. Furthermore, the number of $(N-1)$-dimensional hyperfaces is $(N+1)$. N of them (the *reduced* hyperfaces) can be obtained by excluding one mass side in turn, together with the corresponding vertex and the momentum sides meeting at that vertex. The reduced hyperface without the jth mass side is nothing but the $(N-1)$-dimensional simplex corresponding to an $(N-1)$-point function obtained from the N-point function by shrinking the jth propagator; this is equivalent to the power of propagator vanishing, $\nu_j=0$. The last hyperface, namely the *momentum* hyperface involves all momentum sides but does not include any mass sides. It is associated with the massless N-point function possessing the same external momenta as the basic one.

In general, in the N-point function only $(N-1)$ external momenta are independent, because they are related via the conservation law. We can choose, for example, the vectors $k_{1N},k_{2N},\ldots,k_{N-1,N}$. Considering all scalar products of these momenta, including their squares,

we get $\frac{1}{2}N(N-1)$ invariants, as stated above. However, when n is integer and less than $(N-1)$, only n of the $(N-1)$ momenta are independent, e.g., $k_{1N},k_{2N},\ldots,k_{nN}$. Each of the remaining $(N-n-1)$ vectors k_{jN} $(j=n+1,\ldots,N-1)$ can be fixed by n scalar products $(k_{jN}\cdot k_{lN})$ $(l=1,\ldots,N-1)$. Hence the total number of independent momentum invariants for integer $n\leqslant N-1$ is

$$\tfrac{1}{2}n(n+1)+n(N-n-1)=\tfrac{1}{2}n(2N-n-1). \tag{2.11}$$

while for $n\geqslant N-1$ it remains equal to $\frac{1}{2}N(N-1)$; both expressions coincide for $n=N-1$. The linear dependence between the external momenta reveals itself in the degeneracy of the results associated with the vanishing of certain hypervolumes (see below).

We note that there is a difference between the ''real'' momenta of the N-point diagram, k_{jl}, and the vectors

$$K_{jl}\equiv m_j a_j - m_l a_l, \tag{2.12}$$

corresponding to the momentum sides of the simplex (the same applies to the momenta p_i and P_i discussed in Sec. II D). The momenta k_{jl} are defined in *pseudo-Euclidean* (Minkowski) space, and they are time-like $(k_{jl}^2>0)$ in the region between the threshold and pseudo-threshold. The momentum sides of the simplex, K_{jl}, are vectors in *Euclidean* space, the (Euclidean) squares of their lengths (K_{jl}^2) being equal to k_{jl}^2. In what follows, we shall consider the K_{jl} as Euclidean analogs of the k_{jl} and, *vice versa*, the k_{jl} are pseudo-Euclidean analogs of the K_{jl}. Since the k_{jl}^2 $(j<l)$ form the complete basis of external invariants, all invariant scalars in Minkowski and Euclidean spaces are the same.

The matrix with the components (2.4),

$$\|c\|\equiv\|c_{jl}\|\equiv\begin{pmatrix} 1 & c_{12} & c_{13} & \ldots & c_{1N} \\ c_{12} & 1 & c_{23} & \ldots & c_{2N} \\ c_{13} & c_{23} & 1 & \ldots & c_{3N} \\ \multicolumn{5}{c}{\ldots\ldots\ldots\ldots\ldots\ldots} \\ c_{1N} & c_{2N} & c_{3N} & \ldots & 1 \end{pmatrix}, \tag{2.13}$$

is associated with many geometrical properties of the basic simplex. [The matrix (2.13) is nothing but the Gram matrix of the vectors $a_1,\ldots,a_N$.] In particular, we shall need its determinant,

$$D^{(N)}\equiv\det\|c_{jl}\|, \tag{2.14}$$

and the minors

$$D_{jl}^{(N-1)}\equiv\{\text{minor of (2.13) obtained by eliminating the } j\text{th row and the } l\text{th column}\}. \tag{2.15}$$

In particular, when $j=l$ the minor $D_{jj}^{(N-1)}$ is a *principal* one for the matrix (2.13).

The formulas for the *content* or hypervolume of the basic N-dimensional simplex and its hyperfaces, in terms of the determinant (2.14) and the minors (2.15), are well known in the N-dimensional Euclidean geometry (see for instance Refs. 28 and 29). Thus the content of the N-dimensional simplex is given by

$$V^{(N)}=\frac{1}{N!}\left(\prod_{i=1}^{N} m_i\right)\sqrt{D^{(N)}}. \tag{2.16}$$

The content of the jth $(N-1)$-dimensional reduced hyperface (which does not contain the jth mass side) is

$$\overline{V}_j^{(N-1)}=\frac{1}{(N-1)!}\left(\prod_{i\neq j} m_i\right)\sqrt{D_{jj}^{(N-1)}}, \tag{2.17}$$

whereas the content of the $(N-1)$-dimensional momentum hyperface is

$$\overline{V}_0^{(N-1)}=\frac{1}{(N-1)!}\sqrt{\Lambda^{(N)}}, \tag{2.18}$$

where $\Lambda^{(N)}$ is symmetric combination of the momenta defined in the same way as in Ref. 11,

$$\Lambda^{(N)}\equiv\det\|(k_{jN}\cdot k_{lN})\|. \tag{2.19}$$

Note that the content of the basic simplex can also be presented as

$$V^{(N)}=\frac{1}{N}\,\overline{V}_0^{(N-1)}m_0, \tag{2.20}$$

where m_0 is the distance between the mass meeting point and the momentum hyperface, i.e., the length of the vector of the height of the simplex, H_0. Therefore,

$$m_0\equiv|H_0|=N\,\frac{V^{(N)}}{\overline{V}_0^{(N-1)}}=\left(\prod_{i=1}^{N}m_i\right)\sqrt{\frac{D^{(N)}}{\Lambda^{(N)}}}. \tag{2.21}$$

B. Normals, dihedral angles, and the dual matrix

The dihedral angles between the hyperfaces can be defined via the angles between their normals. Thus, we get $\frac{1}{2}N(N-1)$ dihedral angles between pairs of the reduced hyperfaces and N angles between the momentum hyperface and the reduced ones.

Again, let a_i be unit vectors directed along the mass sides of the basic N-dimensional simplex. The normals to the $(N-1)$-dimensional reduced hyperfaces can be defined as

$$n_{j\lambda}=\frac{\partial}{\partial a_j^{\lambda}}\,(\epsilon_{\nu_1\ldots\nu_N}a_1^{\nu_1}\ldots a_N^{\nu_N}), \tag{2.22}$$

where $\epsilon_{\nu_1\ldots\nu_N}$ is the completely antisymmetric tensor in N dimensions.

Using the well-known expression for the contraction of the product of two ϵ tensors in terms of the determinant with Kronecker δ symbols, it is easy to show that

$$(n_j\cdot n_l)=(-1)^{j+l}D_{jl}^{(N-1)}, \tag{2.23}$$

where $D_{jl}^{(N-1)}$ is defined in (2.15). In particular, n_j^2 is nothing but the principal minor $D_{jj}^{(N-1)}$ related to the $(N-1)$-point function associated with the corresponding reduced hyperface. The cosine of the angle $\tilde{\tau}_{jl}$ between the normals to the jth and the lth reduced hyperfaces is

$$\tilde{c}_{jl}\equiv\cos\,\tilde{\tau}_{jl}=\frac{(n_j\cdot n_l)}{\sqrt{n_j^2n_l^2}}=\frac{(-1)^{j+l}D_{jl}^{(N-1)}}{\sqrt{D_{jj}^{(N-1)}D_{ll}^{(N-1)}}}. \tag{2.24}$$

In particular, this means that the matrix with the elements $\sqrt{D_{jj}^{(N-1)}D_{ll}^{(N-1)}}\tilde{c}_{jl}/D^{(N)}$ is the inverse of the matrix (2.13). Namely,

$$\|c_{jl}\|^{-1}=\frac{1}{D^{(N)}}\,\mathrm{diag}(\sqrt{D_{11}^{(N-1)}},\ldots,\sqrt{D_{NN}^{(N-1)}})\|\tilde{c}_{jl}\|\mathrm{diag}(\sqrt{D_{11}^{(N-1)}},\ldots,\sqrt{D_{NN}^{(N-1)}}), \tag{2.25}$$

where $D^{(N)}$ is defined in (2.14). We shall call the matrix $\|\tilde{c}_{jl}\|$ the *dual* matrix (with respect to $\|c_{jl}\|$). [The matrix $\|\tilde{c}_{jl}\|$ is nothing but the Gram matrix of unit vectors directed along the normals n_i $(i=1,\ldots,N)$.] A trivial corollary of (2.25) is that

$$\tilde{D}^{(N)}\equiv\det\|\tilde{c}_{jl}\|=\frac{(D^{(N)})^{N-1}}{\Pi_{i=1}^{N}D_{ii}^{(N-1)}}. \tag{2.26}$$

Note that the dihedral angles ψ_{jl} are related to the angles $\tilde{\tau}_{jl}$ as

$$\psi_{jl}=\pi-\tilde{\tau}_{jl},\ \ \cos\,\psi_{jl}=-\cos\,\tilde{\tau}_{jl}. \tag{2.27}$$

The normal to the momentum hyperface can be defined as

$$n_{0\lambda}=-\epsilon_{\mu_1\ldots\mu_{N-1}\lambda}(K_{1N})^{\mu_1}\ldots(K_{N-1,N})^{\mu_{N-1}}. \tag{2.28}$$

If we represent $K_{jN}=(m_j a_j-m_N a_N)$ and use the fact that all terms involving two or more $m_N a_N$ disappear in (2.28) (due to the antisymmetry of the ϵ tensor), we get the following representation

$$n_{0\lambda}=-\left(\prod_{i=1}^{N} m_i\right)\sum_{j=1}^{N}\frac{n_{j\lambda}}{m_j}. \tag{2.29}$$

On one hand, the original definition (2.28) leads to

$$n_0^2=\det\|(k_{jN}\cdot k_{lN})\|\equiv\Lambda^{(N)}, \tag{2.30}$$

where $\Lambda^{(N)}$ is defined in (2.19). On the other hand, using (2.29) we obtain

$$n_0^2=\left(\prod_{i=1}^{N} m_i^2\right)\sum_{l=1}^{N}\frac{1}{m_l^2}F_l^{(N)}, \tag{2.31}$$

where [cf. Eq. (4) of Ref. 11]

$$F_l^{(N)}=\sum_{j=0}^{N}(-1)^{j+l}D_{jl}^{(N-1)}\frac{m_l}{m_j}=\frac{\partial}{\partial m_l^2}\,(m_l^2 D^{(N)}), \tag{2.32}$$

i.e., $F_l^{(N)}$ is the determinant obtained from $\det\|c_{jl}\|$ by substituting, instead of the lth column, the mass ratios m_l/m_j (where j is the line number). When taking the partial derivative in (2.32), it is implied that the set of independent variables involves m_i^2 and k_{jl}^2, rather than c_{jl}. In particular, the representation of $F_l^{(N)}$ in terms of determinants (2.32) (see also in Ref. 11) shows that they obey the following set of linear equations:

$$\sum_{l=1}^{N} c_{jl}F_l^{(N)}\frac{1}{m_l}=D^{(N)}\frac{1}{m_j}. \tag{2.33}$$

Another useful representation of n_0 is

$$n_0=-\frac{\Pi m_l}{\sqrt{D^{(N)}}}\sum_{i=1}^{N}\frac{1}{m_i}F_i^{(N)}a_i. \tag{2.34}$$

where, as usually, a_i are the unit vectors directed along the mass sides of the basic simplex. Using Eq. (2.33) (and remembering that $(a_j\cdot a_l)=c_{jl}$), one can easily see that the representation (2.34) is equivalent to Eqs. (2.28) and (2.29). Namely, n_0 (defined by (2.34)) is orthogonal to all $K_{jl}=m_j a_j-m_l a_l$ and n_0^2 is the same as in Eq. (2.31).

C. Splitting the basic simplex

The geometrical meaning of $F_l^{(N)}$ can be understood as follows. Using Eqs. (2.29) and (2.23), we get

$$(n_0\cdot n_l)=-\left(\prod_{i\neq l} m_i\right)F_l^{(N)}. \tag{2.35}$$

Therefore, the cosine of the angle $\tilde{\tau}_{0l}$ between the normals to the momentum hyperface and the lth reduced hyperface is

$$\tilde{c}_{0l} \equiv \cos\ \tilde{\tau}_{0l} = \frac{(n_0 \cdot n_l)}{\sqrt{n_0^2 n_l^2}} = -\frac{(\Pi_{i \neq l} m_i) F_l^{(N)}}{\sqrt{\Lambda^{(N)} D_{ll}^{(N-1)}}}, \tag{2.36}$$

whereas the dihedral angle between these hyperfaces is given by

$$\psi_{0l} = \pi - \tilde{\tau}_{0l}, \quad \cos\ \psi_{0l} = -\cos\ \tilde{\tau}_{0l}. \tag{2.37}$$

The orthogonal projection of the ith reduced hyperface onto the momentum hyperface is

$$\overline{V}_i^{(N-1)} \cos\ \psi_{0i}. \tag{2.38}$$

The sum of all such projections should cover the whole momentum hyperface,

$$\sum_{i=1}^{N} \overline{V}_i^{(N-1)} \cos\ \psi_{0i} = \overline{V}_0^{(N-1)}. \tag{2.39}$$

Using Eqs. (2.36), (2.17), and (2.18), we see that condition (2.39) is equivalent to

$$\left(\prod_{j=1}^{N} m_j^2 \right) \sum_{l=1}^{N} \frac{F_l^{(N)}}{m_l^2} = \Lambda^{(N)}, \tag{2.40}$$

which is the case, cf. Eqs. (2.30) and (2.31). The condition (2.40) is equivalent to Eq. (38) of Ref. 11 (see also in Ref. 3). Equation (2.39) illustrates the geometrical meaning of (2.40). Moreover, we can see that, if we use the ''height'' H_0 for splitting the basic N-dimensional simplex into N rectangular ones whose ''bases'' correspond to the projections (2.38), the content of the ith rectangular simplex $V_i^{(N)}$ is proportional to $F_i^{(N)}$, namely,

$$V_i^{(N)} = \frac{1}{N} \overline{V}_i^{(N-1)} m_0 \cos\ \psi_{0i} = \frac{V^{(N)}}{\Lambda^{(N)}} \left(\prod_{l \neq i} m_l^2 \right) F_i^{(N)}. \tag{2.41}$$

In the same manner we can consider a projection onto one of the reduced hyperfaces. This gives

$$\sum_{l \neq i} \overline{V}_l^{(N-1)} \cos\ \psi_{il} + \overline{V}_0^{(N-1)} \cos\ \psi_{0i} = \overline{V}_i^{(N-1)} \tag{2.42}$$

or

$$\sum_{l=1}^{N} \overline{V}_l^{(N-1)} \tilde{c}_{il} + \overline{V}_0^{(N-1)} \tilde{c}_{0i} = 0. \tag{2.43}$$

In terms of $F_l^{(N)}$, Eq. (2.43) corresponds to definition (2.32).

The cosine of the angle τ_{0j} between the jth mass side and the height H_0 is

$$c_{0j} \equiv \cos\ \tau_{0j} = \frac{m_0}{m_j}. \tag{2.44}$$

Consider the matrix of cosines (similar to (2.13)) associated with the ith rectangular simplex. Its elements are

$$\begin{cases} c_{jl}, & \text{if } j \neq i \text{ and } l \neq i \\ c_{0l}, & \text{if } j = i \text{ and } l \neq i \\ c_{0j}, & \text{if } l = i \text{ and } j \neq i \\ 1, & \text{if } j = l = i. \end{cases} \tag{2.45}$$

Denoting

$$D_i^{(N)} \equiv \{\text{determinant of the matrix } (2.45)\}, \tag{2.46}$$

and using Eqs. (2.16) and (2.21), we get

$$V_i^{(N)} = \left(\prod_{l \neq i} m_l \right) \sqrt{\frac{D_i^{(N)}}{\Lambda^{(N)}}}. \tag{2.47}$$

Comparing Eqs. (2.41) and (2.47), we obtain the following result for the determinant (2.46):

$$D_i^{(N)} = \left(\prod_{l \neq i} m_l \right) \frac{(F_i^{(N)})^2}{\Lambda^{(N)}}. \tag{2.48}$$

D. Choice of the momenta p_i

Let us discuss possibilities for a choice of the momenta p_i in Eq. (2.1) and their Euclidean analogs P_i, such that $K_{jl} = P_j - P_l$. Due to Eq. (2.2), the p_i vectors emanating from an origin, together with the vectors k_{jl}, form an N-dimensional simplex in pseudo-Euclidean space. (For integer $n < N$, this simplex is degenerate, since one cannot use more than n dimensions for external vectors.) Analogously, in Euclidean space the vectors P_i together with the K_{jl} momentum hyperface (taken as a base), form an N-dimensional Euclidean simplex similar to the basic one. Using translational invariance of p_i, we can shift their origin as we like. In particular, we can make one of the p_i vectors zero, whereupon the origin of P_i coincides with one of the vertices belonging to the momentum hyperface. However, this way would break the symmetry of the problem. There are at least two reasonable, *symmetric* ways to fix the origin of p_i (and P_i):

(1) Choose the mass meeting point as the origin of P_i vectors, so that $P_i^2 = p_i^2 = m_i^2$ and the P_i vectors coincide with the mass sides, $P_i = m_i a_i$. In this case, the basic simplex becomes even ''more basic,'' and the integral (2.1) can be expressed as

$$J^{(N)}(n; \nu_1, \ldots, \nu_N) = \int \frac{d^n q}{\prod_{i=1}^N [q^2 + 2(p_i \cdot q)]^{\nu_i}} \Bigg|_{(p_j \cdot p_l) = m_j m_l c_{jl}}. \tag{2.49}$$

Such a choice of p_i simplifies study of singularities via Landau equations.[17,20](In this case, the main Landau singularity is associated with $q \to 0$.) Note that, according to Eq. (2.34), in this case the vector of the height H_0 can be represented as

$$H_0 = \frac{\Pi m_l^2}{\Lambda^{(N)}} \sum_{i=1}^N \frac{1}{m_i^2} F_i^{(N)} P_i. \tag{2.50}$$

However, this choice of p_i cannot be used for integer $n < N$.

(2) Pick, as the origin of P_i vectors, the point of intercept of the height H_0 and the momentum hyperface. This is nothing but a projection of the previous option onto the momentum hyperface. In this case (cf. Eq. (2.44)),

$$p_i^2 = P_i^2 = m_i^2 - m_0^2 = m_i^2 (1 - c_{0i}^2), \tag{2.51}$$

$$(p_j \cdot p_l) = (P_j \cdot P_l) = m_j m_l c_{jl} - m_0^2 = m_j m_l (c_{jl} - c_{0j} c_{0l}), \tag{2.52}$$

and the denominators in the integral (2.1) become

$$[(p_i + q)^2 - m_i^2] \Rightarrow [q^2 + 2(p_i \cdot q) - m_0^2]. \tag{2.53}$$

The projection of Eq. (2.34) onto the momentum hyperface shows that there exists the following relation which is valid for *this* choice of P_i,

$$\sum_{i=1}^N \frac{1}{m_i^2} F_i^{(N)} P_i = 0. \tag{2.54}$$

III. FROM FEYNMAN PARAMETERS TO NON-EUCLIDEAN GEOMETRY

A. Moving from linear to quadratic hypersurface

The standard Feynman parametric representation of a one-loop N-point integral in n dimensions (2.1), corresponding to the diagram presented in Fig. 2, reads

$$J^{(N)}(n;\nu_1,\ldots,\nu_N)=i^{1-n}\pi^{n/2}\,\frac{\Gamma\left(\Sigma\nu_i-\frac{n}{2}\right)}{\Pi\Gamma(\nu_i)}\int_0^1\cdots\int_0^1\frac{\Pi\alpha_i^{\nu_i-1}d\alpha_i\,\delta(\Sigma\alpha_i-1)}{[\Sigma\sum\limits_{j<l}\alpha_j\alpha_l k_{jl}^2-\Sigma\alpha_i m_i^2]^{\Sigma\nu_i-n/2}}. \tag{3.1}$$

As we have already mentioned (2.3), the integrand can be written in a homogeneous form,

$$J^{(N)}(n;\nu_1,\ldots,\nu_N)=i^{1-2\Sigma\nu_i}\pi^{n/2}\,\frac{\Gamma\left(\Sigma\nu_i-\frac{n}{2}\right)}{\Pi\Gamma(\nu_i)}\int_0^1\cdots\int_0^1\frac{\Pi\alpha_i^{\nu_i-1}d\alpha_i\,\delta(\Sigma\alpha_i-1)}{[\Sigma\alpha_i^2m_i^2+2\Sigma\sum\limits_{j<l}\alpha_j\alpha_l m_j m_l c_{jl}]^{\Sigma\nu_i-n/2}}, \tag{3.2}$$

where the ''cosines'' c_{jl} are defined in (2.4). Note that the limits of integration in Eqs. (3.1)–(3.2) can be extended from (0,1) to $(0,\infty)$, since the actual region of integration is defined by the δ function. It corresponds to a part of an $(N-1)$-dimensional hyperplane $\Sigma\alpha_i=1$ which is cut out by the conditions $\alpha_i\geqslant 0$ $(i=1,\ldots,N)$.

Now, let us consider the integral (3.2), and let us use a rescaling which is similar to one used in Refs. 21, 2, 4 (see also in Ref. 25, where the transformations of a general form have been discussed). Let us rescale $\alpha_i=m_i^{-1}\alpha_i'$, so that the δ function becomes

$$\delta\left(\sum\ \frac{\alpha_i'}{m_i}-1\right). \tag{3.3}$$

To restore the argument of the δ function in its original form, let us substitute

$$\alpha_i'=\mathscr{F}(\alpha_1'',\ldots,\alpha_N'')\,\alpha_i'',\ \text{ with }\ \mathscr{F}(\alpha_1,\ldots,\alpha_N)=\frac{\Sigma\alpha_i}{\Sigma\,\dfrac{\alpha_i}{m_i}}. \tag{3.4}$$

Note that the Jacobian of this substitution is $\mathscr{F}^N$ (cf. Appendix B).

Suppressing the primes, we arrive at the following representation:

$$J^{(N)}(n;\nu_1,\ldots,\nu_N)=i^{1-2\Sigma\nu_i}\pi^{n/2}\,\frac{\Gamma\left(\Sigma\nu_i-\frac{n}{2}\right)}{\Pi\Gamma(\nu_i)}\,\frac{1}{\Pi m_i^{\nu_i}}\int_0^1\cdots\int_0^1\frac{\Pi\alpha_i^{\nu_i-1}d\alpha_i\,\delta(\Sigma\alpha_i-1)}{\left(\Sigma\,\dfrac{\alpha_i}{m_i}\right)^{n-\Sigma\nu_i}(\alpha^T\|c\|\alpha)^{\Sigma\nu_i-n/2}}, \tag{3.5}$$

where we use matrix notation (2.13),

$$\alpha^T\|c\|\alpha\equiv\sum_{j=1}^N\sum_{l=1}^N c_{jl}\alpha_j\alpha_l=\sum\ \alpha_i^2+2\sum_{j<l}\sum\ \alpha_j\alpha_l c_{jl}. \tag{3.6}$$

Next, let us change the variables from α to α' via

$$\alpha_i=\mathscr{G}(\alpha_1',\ldots,\alpha_N')\,\alpha_i',\ \text{ with }\ \mathscr{G}(\alpha_1',\ldots,\alpha_N')=\frac{\Sigma(\alpha_i')^2+2\Sigma\sum\limits_{j<l}\alpha_j'\alpha_l'c_{jl}}{\Sigma\alpha_i'}. \tag{3.7}$$

Here, the Jacobian of the substitution is $2\mathscr{F}^N$ (see Appendix B). Effectively, we put the quadratic form into the argument of the δ function. However, the linear denominator (coming from the $\mathscr{F}$ function) survives and we arrive at

$$J^{(N)}(n;\nu_1,\ldots,\nu_N)=2i^{1-2\Sigma\nu_i}\pi^{n/2}\,\frac{\Gamma\left(\Sigma\nu_i-\frac{n}{2}\right)}{\Pi\Gamma(\nu_i)}\,\frac{1}{\Pi m_i^{\nu_i}}\int_0^\infty\cdots\int_0^\infty\frac{\Pi\alpha_i^{\nu_i-1}d\alpha_i}{\left(\Sigma\,\frac{\alpha_i}{m_i}\right)^{n-\Sigma\nu_i}}\,\delta(\alpha^T\|c\|\alpha-1), \tag{3.8}$$

where we continue to use the matrix notation (3.6).

B. The case $\Sigma\nu_i=n$

In the particular case $\Sigma\nu_i=n$ the linear denominator disappears and Eq. (3.5) gives

$$J^{(N)}(n;\nu_1,\ldots,\nu_N)\big|_{\Sigma\nu_i=n}=i^{1-2\Sigma\nu_i}\pi^{n/2}\,\frac{\Gamma\left(\frac{n}{2}\right)}{\Pi\Gamma(\nu_i)}\,\frac{1}{\Pi m_i^{\nu_i}}\int_0^1\cdots\int_0^1\frac{\Pi\alpha_i^{\nu_i-1}d\alpha_i\,\delta(\Sigma\alpha_i-1)}{(\alpha^T\|c\|\alpha)^{\Sigma\nu_i-n/2}}. \tag{3.9}$$

Here all dependence on the external momenta and masses in the integral is through c_{jl}, Eq. (2.4).

Since the final integral (3.9) is the same as in the equal-mass case, we can formulate the following statement: Let $\Sigma\nu_i=n$, and let the result for the Feynman integral (3.1) with equal masses ($m_i=m$, $i=1,\ldots,N$) be represented by a dimensionless function Ψ depending on the quantities $\bar{\bar{c}}_{jl}\equiv 1-k_{jl}^2/(2m^2)$ (corresponding to Eq. (2.4) in the equal-mass case) as

$$J^{(n)}(n;\nu_1,\ldots,\nu_N)\big|_{\Sigma\nu_i=n,\quad m_i=m}=\frac{1}{m^{\Sigma\nu_i}}\,\Psi(\{\bar{\bar{c}}_{jl}\}). \tag{3.10}$$

Then the result for the corresponding integral with different masses m_i can be expressed in terms of *the same* function Ψ as

$$J^{(N)}(n;\nu_1,\ldots,\nu_N)\big|_{\Sigma\nu_i=n}=\frac{1}{\Pi m_i^{\nu_i}}\,\Psi(\{c_{jl}\}), \tag{3.11}$$

where c_{jl} are defined in Eq. (2.4).

Simplification of the integrals $J^{(N)}(n;\nu_1,\ldots,\nu_N)$ when $\Sigma\nu_i=n$ is not surprising; to some extent, this may be considered a generalization of the so-called ''uniqueness'' formula for massless triangle diagrams[30] to the case of massive N-point integrals.

Whenever $\Sigma\nu_i=n$ the denominator of the integrand of (3.8) disappears, and the result is

$$J^{(N)}(n;\nu_1,\ldots,\nu_N)\big|_{\Sigma\nu_i=n}=2i^{1-2\Sigma\nu_i}\pi^{n/2}\,\frac{\Gamma\left(\frac{n}{2}\right)}{\Pi\Gamma(\nu_i)}\,\frac{1}{\Pi m_i^{\nu_i}}\int_0^\infty\cdots\int_0^\infty\prod\,\alpha_i^{\nu_i-1}d\alpha_i\,\delta(\alpha^T\|c\|\alpha-1). \tag{3.12}$$

In particular, when all $\nu_i=1$ ($n=N$), our integrand is just a δ function,

$$J^{(N)}(N;1,\ldots,1)=2i^{1-2N}\pi^{N/2}\,\frac{\Gamma\left(\frac{N}{2}\right)}{\Pi m_i}\int_0^\infty\cdots\int_0^\infty\prod\,d\alpha_i\,\delta(\alpha^T\|c\|\alpha-1). \tag{3.13}$$

Consider also a very special situation, when all nondiagonal c_{jl} vanish (i.e., $c_{jl}=\delta_{jl}$). Physically, this corresponds to the case where all external momenta squared take the mean values

between the threshold and the pseudo-threshold, $k_{jl}^2=m_j^2+m_l^2$ (for $j<l$). In this case, all the angles τ_{jl} ($j\neq l$) are equal to $\frac{1}{2}\pi$. Employing the representation (3.12) we arrive at a very simple result for this special case,

$$J^{(N)}(n;\nu_1,\ldots,\nu_N)\Big|_{\substack{\Sigma\nu_i=n\\ c_{jl}=\delta_{jl}}}=i^{1-2\Sigma\nu_i}\pi^{n/2}\,\frac{\Pi\Gamma\left(\frac{1}{2}\,\nu_i\right)}{2^{N-1}\Pi\Gamma(\nu_i)}\,\frac{1}{\Pi m_i^{\nu_i}}. \tag{3.14}$$

Imagine the N-dimensional Euclidean space of the parameters α_i. The quadratic argument of the δ function in (3.13) defines a $(N-1)$-dimensional hypersurface. Provided that all eigenvalues of this quadratic form are positive, this is an N-dimensional ellipsoid. Otherwise, this is an N-dimensional hyperboloid. So, the integral (3.13) is nothing but the measure (i.e., the content) of the part of this hypersurface which belongs to the region where all α's are non-negative. This region is a 2^Nth part of the whole N-dimensional space.

To calculate the content of this part of the hypersurface, it is reasonable to diagonalize the quadratic form. Suppose there is an N-dimensional rotation transforming the old coordinates α_i into the new ones, β_i, so that

$$\alpha^T\|c\|\alpha=\sum\ \alpha_i^2+2\sum_{j<l}\sum\ \alpha_j\alpha_l c_{jl}\Rightarrow\sum\ \lambda_i\beta_i^2. \tag{3.15}$$

Obviously, the product of λ's must be equal to the determinant $D^{(N)}$ of the matrix (2.13) corresponding to the quadratic form (3.6),

$$\lambda_1\ldots\lambda_N=D^{(N)}. \tag{3.16}$$

Note that this determinant $D^{(N)}$ is related to the content $V^{(N)}$ of the basic N-dimensional simplex via Eq. (2.16).

Now, let us assume that all eigenvalues λ_i are real and positive, i.e., the hypersurface defined by the quadratic form is an N-dimensional ellipsoid. After rotation from α's to β's, we get into the coordinate system corresponding to the principal axes of the ellipsoid. Then, we can rescale

$$\beta_i=\frac{\gamma_i}{\sqrt{\lambda_i}}, \tag{3.17}$$

the Jacobian of this transformation being $(\lambda_1\ldots\lambda_N)^{-1/2}=(D^{(N)})^{-1/2}$, according to (3.16). In this way, our N-dimensional ellipsoid is transformed into a hypersphere. Now all we need to calculate is the content of a part of this hypersphere which is cut out (in the space of γ_i) by the images of the hyperfaces restricting the region where all α_i are positive (in the space of α_i). This content, which we shall denote by $\Omega^{(N)}$, can be understood as the N-dimensional solid angle subtended by the above-mentioned hyperfaces. In terms of $\Omega^{(N)}$, the relevant integral (3.13) can be written as

$$J^{(N)}(N;1,\ldots,1)=i^{1-2N}\pi^{N/2}\,\frac{\Gamma\left(\frac{N}{2}\right)}{\Pi m_i}\,\frac{\Omega^{(N)}}{\sqrt{D^{(N)}}}. \tag{3.18}$$

An interesting fact is that $\Omega^{(N)}$ is also related to the basic simplex. To see this, let us note that effectively (in terms of α's), the transformation $\alpha_i\to\beta_i\to\gamma_i$ is equivalent to using the matrix $\|c\|$ as a new metric. Say, for a vector α the *new* length squared is

$$|\alpha|_c^2\equiv\alpha^T\|c\|\alpha. \tag{3.19}$$

For unit vectors $e_i^{(\alpha)}$, the *new* scalar product is

$$(e_j^{(\alpha)}\cdot e_l^{(\alpha)})_c=c_{jl}\equiv\cos\ \tau_{jl}\,. \tag{3.20}$$

Taking into account that $|e_i^{(\alpha)}|_c^2=1$, we see that in the space with the c-metric (i.e., in the space of γ_i) the angle between $e_j^{(\alpha)}$ and $e_l^{(\alpha)}$ is τ_{jl}. Therefore, we get nothing but the N-dimensional solid angle at the mass meeting point of the basic simplex. It defines the region of integration on the hypersurface of the unit hypersphere in the γ_i coordinate system. We also note that the cosines c_{jl} are invariant under simple rescaling of α's.

It is easy to see that the image of $e_i^{(\alpha)}$ in the γ_i-space is directed along the vector a_i. Moreover, according to Eq. (2.34), the image of the vector with the components $F_i^{(N)}/m_i$ is directed along the height H_0.

To summarize, the following statement is valid: The content of the N-dimensional solid angle $\Omega^{(N)}$ in the space of γ_i is equal to that at the vertex of the basic N-dimensional simplex where all mass sides meet. Moreover, the angles between the corresponding hyperfaces in the space of γ_i and those in the basic simplex are the same. Therefore, the result for the integral (3.13) can be expressed in terms of the content of the basic simplex and the content of its N-dimensional solid angle at the vertex which is common for all mass sides as

$$J^{(N)}(N;1,...,1)=i^{1-2N}\pi^{N/2}\,\frac{\Gamma\left(\frac{N}{2}\right)}{N!}\,\frac{\Omega^{(N)}}{V^{(N)}}. \tag{3.21}$$

Looking at Eq. (3.21), we see that $\Omega^{(N)}$ is indeed the only thing which is to be calculated, since $V^{(N)}$ is known through Eq. (2.16). In the following sections, we shall consider the lowest examples to understand how to calculate $\Omega^{(N)}$.

Nevertheless, the above discussion leads us to the following significant statement: The content $\Omega^{(N)}$ is nothing but the content of a *non-Euclidean* $(N-1)$-dimensional simplex calculated in the spherical (or hyperbolic, depending on the signature of the eigenvalues λ_i) space of constant curvature. The sides of this non-Euclidean simplex are equal to the angles τ_{jl}. Therefore, the problem of calculating Feynman integrals is intimately connected with the problem of calculating the content of a simplex in non-Euclidean geometry.

C. The general case

To understand how to deal with the general case, when $\Sigma\nu_i\neq n$, we need some modification of the above transformations. First of all, we note that Eqs. (2.33) can be rephrased as

$$\sum_{l=1}^{N}\,(\sqrt{F_j^{(N)}}c_{jl}\sqrt{F_l^{(N)}})\,\frac{\sqrt{F_l^{(N)}}}{m_l}=D^{(N)}\,\frac{\sqrt{F_j^{(N)}}}{m_j}. \tag{3.22}$$

In other words, the vector with components

$$f_i=\frac{\sqrt{F_i^{(N)}}}{m_i} \tag{3.23}$$

is an eigenvector of the matrix $\|C\|\equiv\|C_{jl}\|$ with the elements

$$C_{jl}=(\sqrt{F_j^{(N)}}c_{jl}\sqrt{F_l^{(N)}}), \tag{3.24}$$

and the corresponding eigenvalue is equal to $D^{(N)}$. Note that

$$f^2\equiv(f\cdot f\,)=\sum_{i=1}^{N}\,\frac{F_i^{(N)}}{m_i^2}=\frac{\Lambda^{(N)}}{\Pi_{i=1}^{N}m_i^2}, \tag{3.25}$$

$$\det\|C\|=D^{(N)}\prod_{j=1}^{N}\,F_j^{(N)}. \tag{3.26}$$

The idea is that it may be more convenient to use the quadratic form defined by the matrix $\|C_{jl}\|$, rather than $\|c_{jl}\|$, since we know one of its eigenvectors with the corresponding eigenvalue.

After using the masses m_i to rescale the Feynman parameters α_i and ''hiding'' the quadratic form into the argument of the delta function, we obtained the representation (3.8). Analogously, we can use $1/f_i = m_i/\sqrt{F_i^{(N)}}$, rather than m_i, to rescale the original α's. The result is

$$J^{(N)}(n;\nu_1,\ldots,\nu_N) = 2i^{1-2\Sigma\nu_i}\pi^{n/2}\,\frac{\Gamma\left(\Sigma\nu_i - \frac{n}{2}\right)}{\Pi\Gamma(\nu_i)}\left(\prod f_i^{\nu_i}\right)\int_0^\infty\cdots\int_0^\infty \frac{\Pi\alpha_i^{\nu_i-1}d\alpha_i}{(\Sigma\alpha_i f_i)^{n-\Sigma\nu_i}}\,\delta(\alpha^T\|C\|\alpha-1), \tag{3.27}$$

where notation (3.6) has been used again. A nice feature of this representation is that in the denominator we have the contraction (scalar product) of α and the known eigenvector of the matrix $\|C\|$ defining the quadratic form (see Eqs. (3.22)–(3.24)).

If $\nu_1 = \cdots = \nu_N = 1$, we get

$$J^{(N)}(n;1,\ldots,1) = 2i^{1-2N}\pi^{n/2}\Gamma\left(N-\frac{n}{2}\right)\left(\prod f_i\right)\int_0^\infty\cdots\int_0^\infty \frac{\Pi d\alpha_i}{(\Sigma\alpha_i f_i)^{n-N}}\,\delta(\alpha^T\|C\|\alpha-1). \tag{3.28}$$

Now, let us use the same transformations of variables as earlier. Namely, let us first rotate from α_i to the variables β_i such that the quadratic form becomes diagonal,

$$\alpha^T\|C\|\alpha = \sum_{i=1}^N \lambda_i\beta_i^2. \tag{3.29}$$

One of these β's, say β_N, is directed along the eigenvector f. Therefore, $\lambda_N = D^{(N)}$ and $\Pi_{i=1}^{N-1}\lambda_i = \Pi_{j=1}^N F_j^{(N)}$. Moreover, the denominator is also proportional to β_N. Finally, we rescale $\beta_i = \gamma_i/\sqrt{\lambda_i}$, and the denominator becomes

$$\left(\sum \alpha_i f_i\right) \Rightarrow \frac{1}{\Pi m_i}\,\sqrt{\frac{\Lambda^{(N)}}{D^{(N)}}}\,\gamma_N = \frac{1}{m_0}\,\gamma_N, \tag{3.30}$$

where m_0, defined in Eq. (2.21), is the distance between the mass meeting point and the momentum hyperface (i.e., the length of the height H_0).

Now, the transformation $\alpha_i \to \beta_i \to \gamma_i$ is equivalent to using the matrix $\|C\|$ as a new metric. For a vector α the *new* length squared is

$$|\alpha|_C^2 \equiv \alpha^T\|C\|\alpha. \tag{3.31}$$

For unit vectors $e_i^{(\alpha)}$, the *new* scalar product is

$$(e_j^{(\alpha)}\cdot e_l^{(\alpha)})_C = C_{jl}, \tag{3.32}$$

and the corresponding cosine of the angle is

$$\frac{(e_j^{(\alpha)}\cdot e_l^{(\alpha)})_C}{|e_j^{(\alpha)}|_C|e_l^{(\alpha)}|_C} = \frac{C_{jl}}{\sqrt{C_{jj}C_{ll}}} = c_{jl} \equiv \cos\,\tau_{jl}. \tag{3.33}$$

[Note that in the γ_i-space with the C-metric the $e_i^{(\alpha)}$ vectors are not unit, $|e_i^{(\alpha)}|_C^2 = C_{ii} = F_i^{(N)}$.] Again, as in the case of the c-metric, we get the same N-dimensional solid angle as that occurring at the mass meeting point of the basic simplex.

But we can go further. In particular, we can comprehend what the image of the vector f is. Consider the scalar products

$$(e_i^{(\alpha)}\cdot f)_C = (e_i^{(\alpha)}\cdot\|C\|f) = D^{(N)}(e_i^{(\alpha)}\cdot f) = D^{(N)}f_i, \tag{3.34}$$

$$(f\cdot f\ )_C=(f\cdot\|C\|f\ )=D^{(N)}(f\cdot f\ )=\frac{D^{(N)}\Lambda^{(N)}}{\Pi_{j=1}^{N}m_j^2}. \tag{3.35}$$

Hence, the cosine of the angle between the images of f and $e_i^{(\alpha)}$ is [cf. Eq. (2.44)]

$$\frac{(e_i^{(\alpha)}\cdot f\ )_C}{\sqrt{(e_i^{(\alpha)}\cdot e_i^{(\alpha)})_C(f\cdot f\ )_C}}=\sqrt{\frac{D^{(N)}}{\Lambda^{(N)}}}\prod_{j\neq i}\ m_j=\frac{m_0}{m_i}=\cos\ \tau_{0i}\equiv c_{0i}\,. \tag{3.36}$$

Therefore, in the basic simplex, with the mass sides m_i, etc., the image of the vector f is directed along the height H_0!

In terms of γ's, the integral becomes

$$J^{(N)}(n;1,...,1)=2i^{1-2N}\pi^{n/2}\Gamma\left(N-\frac{n}{2}\right)\ \frac{m_0^{n-N-1}}{\sqrt{\Lambda^{(N)}}}\int_{\Omega^{(N)}}\cdots\int\ \frac{\Pi d\gamma_i}{\gamma_N^{n-N}}\ \delta\left(\sum\ \gamma_i^2-1\right), \tag{3.37}$$

where the integration goes over the interior of the N-dimensional solid angle $\Omega^{(N)}$ of the basic simplex. If we define the angle between the ''running'' unit vector and the Nth axis as θ, the above formula means that we should integrate over the hypersurface of the unit hypersphere with the ''weight'' $(\cos\theta)^{N-n}$, within the limits set by $\Omega^{(N)}$,

$$J^{(N)}(n;1,...,1)=i^{1-2N}\pi^{n/2}\Gamma\left(N-\frac{n}{2}\right)\ \frac{m_0^{n-N}}{\sqrt{D^{(N)}}\Pi m_i}\ \Omega^{(N;n)}, \tag{3.38}$$

with

$$\Omega^{(N;n)}\equiv\int_{\Omega^{(N)}}\cdots\int\ \frac{d\Omega_N}{\cos^{n-N}\ \theta}. \tag{3.39}$$

Obviously, $\Omega^{(N;N)}=\Omega^{(N)}$. Using Eq. (2.16), the formula (3.38) can be exhibited in the following form:

$$J^{(N)}(n;1,...,1)=i^{1-2N}\pi^{n/2}\Gamma\left(N-\frac{n}{2}\right)\ \frac{m_0^{n-N}\Omega^{(N;n)}}{N!\,V^{(N)}}. \tag{3.40}$$

D. Splitting the *N*-dimensional solid angle

Now, let us again use the height H_0 to split the basic N-dimensional simplex into N rectangular ones, each time replacing one of the mass sides, m_i, by $m_0=|H_0|$. The content of the ith rectangular simplex $V_i^{(N)}$ is given by Eq. (2.41). Let us denote the corresponding N-dimensional solid angle as $\Omega_i^{(N)}$, so that

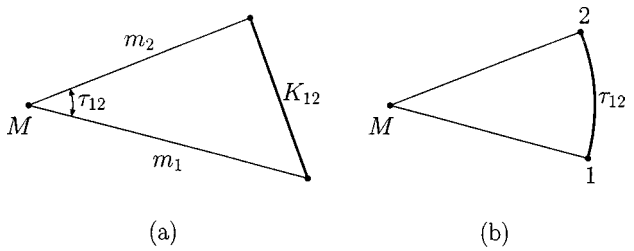
$$\Omega_i^{(N;n)}=\int_{\Omega_i^{(N)}}\cdots\int\ \frac{d\Omega_N}{\cos^{n-N}\ \theta},\quad \Omega^{(N;n)}=\sum_{i=1}^{N}\ \Omega_i^{(N;n)}\,. \tag{3.41}$$

Substituting (3.41) into Eq. (3.40), we get

$$J^{(N)}(n;1,...,1)=\sum_{i=1}^{N}\ \frac{V_i^{(N)}}{V^{(N)}}\,J_i^{(N)}(n;1,...,1), \tag{3.42}$$

where $J_i^{(N)}$ are the integrals corresponding to the rectangular simplices. Specifically, in the integral $J_i^{(N)}$ the internal masses are

$$m_1,\ldots,m_{i-1},m_0,m_{i+1},\ldots,m_N, \tag{3.43}$$



(a) (b)

FIG. 4. Two-point case: (a) the basic triangle and (b) the arc τ_{12}.

while the momenta invariants are

$$\begin{cases} k_{jl}^2, & \text{if } j\neq i \text{ and } l\neq i \\ m_l^2-m_0^2, & \text{if } j=i \\ m_j^2-m_0^2, & \text{if } l=i \end{cases} . \tag{3.44}$$

Using (2.41), we arrive at

$$J^{(N)}(n;1,...,1)=\frac{1}{\Lambda^{(N)}}\left(\prod\ m_i^2\right)\sum_{i=1}^{N}\ \frac{1}{m_i^2}\,F_i^{(N)}J_i^{(N)}(n;1,...,1). \tag{3.45}$$

We are now ready to tackle some specific examples using the geometrical approach.

IV. TWO-POINT FUNCTION

Here, the two-dimensional basic simplex is a triangle and the angle τ_{12} lies between the two mass sides (see Fig. 4). We obtain

$$D^{(2)}=1-c_{12}^2=\sin^2\ \tau_{12},\ \ V^{(2)}=\tfrac{1}{2}m_1m_2\ \sin\ \tau_{12},\ \ \Omega^{(2)}=\tau_{12}, \tag{4.1}$$

$$m_0=m_1m_2\sqrt{\frac{D^{(2)}}{\Lambda^{(2)}}},\ \ \cos\ \tau_{0i}=\frac{m_0}{m_i},\ \ \tau_{01}+\tau_{02}=\tau_{12},\ \ \Lambda^{(2)}=k_{12}^2. \tag{4.2}$$

In two dimensions, from (3.21) we obtain the well-known result

$$J^{(2)}(2;1,1)=\frac{i\pi}{m_1m_2}\,\frac{\tau_{12}}{\sin\ \tau_{12}}, \tag{4.3}$$

while in three dimensions, Eqs. (3.40)–(3.41) yield

$$J^{(2)}(3;1,1)=i\pi^2\,\frac{1}{\sqrt{\Lambda^{(2)}}}\,\{\Omega_1^{(2;3)}+\Omega_2^{(2;3)}\}, \tag{4.4}$$

with

$$\Omega_i^{(2;3)}=\int_0^{\tau_{0i}}\frac{d\theta}{\cos\ \theta}=\ln\left(\frac{1+\sin\ \tau_{0i}}{1-\sin\ \tau_{0i}}\right). \tag{4.5}$$

Combining the logarithms, we get

$$J^{(2)}(3;1,1)=\frac{i\pi^2}{\sqrt{k_{12}^2}}\ln\left(\frac{m_1+m_2+\sqrt{k_{12}^2}}{m_1+m_2-\sqrt{k_{12}^2}}\right). \tag{4.6}$$

In the Euclidean region ($k_{12}^2<0$) the logarithm gives $\arctan(\sqrt{-k_{12}^2}/(m_1+m_2))$, and the result coincides with those presented in Refs. 11 and 31.

In four dimensions, the Γ function in front of the integral (3.38) becomes singular. Introducing dimensional regularization[32] to circumvent that difficulty, we get

$$J^{(2)}(4-2\varepsilon;1,1)=i\pi^{2-\varepsilon}\Gamma(\varepsilon)\,\frac{m_0^{1-2\varepsilon}}{\sqrt{\Lambda^{(2)}}}\,\{\Omega_1^{(2;4-2\varepsilon)}+\Omega_2^{(2;4-2\varepsilon)}\}, \tag{4.7}$$

with

$$\Omega_i^{(2;4-2\varepsilon)}=\int_0^{\tau_{0i}}\frac{d\theta}{\cos^{2-2\varepsilon}\,\theta}. \tag{4.8}$$

Expanding the integrand in ε and taking into account that

$$\int_0^{\tau}\frac{d\theta}{\cos^2\,\theta}\ln(\cos\,\theta)=\tan\,\tau\,\ln(\cos\,\tau)+\tan\,\tau-\tau, \tag{4.9}$$

we reach the well-known result (cf., e.g., in Refs. 2 and 33),

$$J^{(2)}(4-2\varepsilon;1,1)=i\pi^{2-\varepsilon}\Gamma(1+\varepsilon)\times\left\{\frac{1}{\varepsilon}+2-\ln\,m_1-\ln\,m_2+\frac{m_1^2-m_2^2}{k_{12}^2}\ln\frac{m_2}{m_1}-\frac{2m_1m_2}{k_{12}^2}\,\tau_{12}\sin\,\tau_{12}\right\}+\mathcal{O}(\varepsilon). \tag{4.10}$$

Furthermore, the representations (4.7)–(4.8) make it possible to construct next terms of the expansion in ε. For example, the ε term requires just

$$\int_0^{\tau}\frac{d\theta}{\cos^2\,\theta}\ln^2(\cos\,\theta)=\tan\,\tau(\ln^2(\cos\,\tau)+2\ln(\cos\,\tau)+2)-2\tau(1-\ln 2)-\mathrm{Cl}_2(\pi-2\tau) \tag{4.11}$$

(the corresponding result was obtained in Ref. 34; the Clausen function $\mathrm{Cl}_2(\theta)$ is defined in Appendix A). Moreover, the result for an arbitrary space–time dimension or ε can be obtained in terms of the Gauss hypergeometric function (cf. in Refs. 35 and 33), using

$$\Omega_i^{(2;4-2\varepsilon)}=\int_0^{\tau_{0i}}\frac{d\theta}{\cos^{2-2\varepsilon}\,\theta}=2\tan\,\tau_{0i}\;{}_2F_1\left(\left.\begin{matrix}1/2,\varepsilon\\3/2\end{matrix}\right|-\tan^2\,\tau_{0i}\right). \tag{4.12}$$

Using formulas of analytic continuation of the ${}_2F_1$ function, one can establish a connection with the result presented in Eq. (A7) of Ref. 33.

V. THREE-POINT FUNCTION

A. Geometrical picture and the three-dimensional case

Here the three-dimensional basic simplex is a tetrahedron with three mass sides (the angles between these mass sides are τ_{12}, τ_{13}, and τ_{23}) and three momentum sides. It is shown in Fig. 5(a). The volume of this tetrahedron is defined as

$$V^{(3)}=\tfrac{1}{6}m_1m_2m_3\sqrt{D^{(3)}}, \tag{5.1}$$

where (cf. Eqs. (2.13)–(2.14))

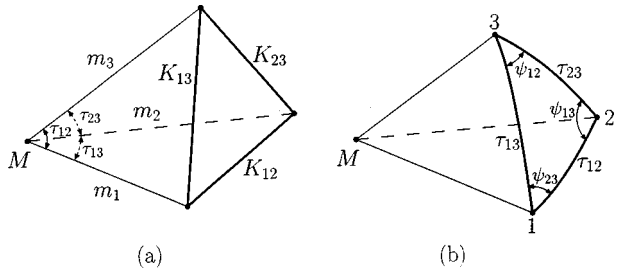


FIG. 5. Three-point case: (a) the basic tetrahedron and (b) the solid angle.

$$D^{(3)} \equiv \begin{vmatrix} 1 & c_{12} & c_{13} \\ c_{12} & 1 & c_{23} \\ c_{13} & c_{23} & 1 \end{vmatrix} = 1 - c_{12}^2 - c_{13}^2 - c_{23}^2 + 2c_{12}c_{13}c_{23}. \tag{5.2}$$

Furthermore, $\Omega^{(3)}$ is the usual solid angle at the vertex derived by the mass sides [cf. Fig. 5(b)]. Its value can be defined as the area of a part of the unit sphere cut out by the three planar faces adjacent to the vertex; in other words, this is the area of a spherical triangle corresponding to this section. The sides of this spherical triangle are obviously equal to the angles τ_{12}, τ_{13}, and τ_{23} while its angles, ψ_{12}, ψ_{13}, and ψ_{23}, are equal to those between the plane faces (we define ψ_{12} as the angle between the sides τ_{13} and τ_{23}, etc.). This definition is in agreement with Eq. (2.27). Using Eq. (2.24) or the well-known formulas of the spherical trigonometry, it is easy to show that

$$\cos\,\psi_{12} = \frac{\cos\,\tau_{12} - \cos\,\tau_{13}\cos\,\tau_{23}}{\sin\,\tau_{13}\sin\,\tau_{23}}, \quad \sin\,\psi_{12} = \frac{\sqrt{D^{(3)}}}{\sin\,\tau_{13}\sin\,\tau_{23}}, \tag{5.3}$$

and analogous expressions for ψ_{13} and ψ_{23}. The solid angle corresponding to spherical triangle can be obtained via

$$\Omega^{(3)} = \psi_{12} + \psi_{13} + \psi_{23} - \pi. \tag{5.4}$$

Using Eqs. (5.3) and (5.4), it is straightforward to show that

$$\begin{aligned} \Omega^{(3)} &= 2\,\arccos\left(\frac{1 + c_{12} + c_{13} + c_{23}}{\sqrt{2(1+c_{12})(1+c_{13})(1+c_{23})}} \right) \\ &= 2\,\arcsin\left(\sqrt{\frac{D^{(3)}}{2(1+c_{12})(1+c_{13})(1+c_{23})}} \right) \\ &= 2\,\arctan\left(\frac{\sqrt{D^{(3)}}}{1 + c_{12} + c_{13} + c_{23}} \right). \end{aligned} \tag{5.5}$$

Finally, the result

$$J^{(3)}(3;1,1,1) = -\frac{i\pi^2}{2m_1m_2m_3} \frac{\Omega^{(3)}}{\sqrt{D^{(3)}}}, \tag{5.6}$$

with $\Omega^{(3)}$ defined by (5.5), corresponds to one obtained in Ref. 11 in a different way. Note that here we have derived it purely geometrically.

However, Eq. (5.4) cannot be easily generalized to the four-dimensional case. This is why it is instructive to reproduce the three-dimensional result (5.5) in a different manner, splitting the basic tetrahedron into rectangular ones (cf. Eq. (3.42)).

Consider a spherical triangle 123 on the unit sphere, cut out by the solid angle of the basic tetrahedron in the γ space, as illustrated in Fig. 6. The points 1,2,3 correspond to the intersections of the mass sides of the basic tetrahedron and the unit sphere. The sides of the triangle are equal

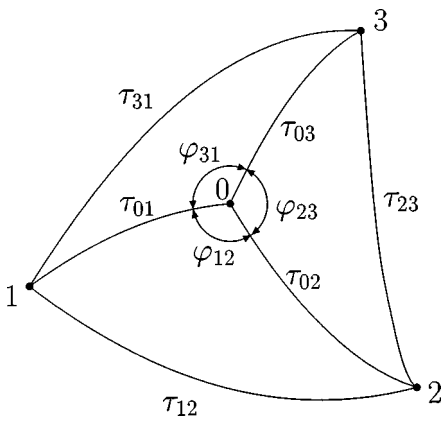

FIG. 6. The spherical triangle 123.

to the angles τ_{12}, τ_{23}, and τ_{31}. There is another point 0, also on the unit sphere, corresponding to the intersection of the height H_0 of the tetrahedron and the unit sphere. The point 0 is connected with each of the points 1,2,3. The corresponding sides 01, 02, and 03 are equal to τ_{01}, τ_{02}, and τ_{03}, respectively, so that

$$\cos\,\tau_{0i}=\frac{m_0}{m_i},\quad m_0=m_1m_2m_3\sqrt{\frac{D^{(3)}}{\Lambda^{(3)}}}, \tag{5.7}$$

with (cf. Eq. (2.19))

$$\Lambda^{(3)}=-\tfrac{1}{4}[(k_{12}^2)^2+(k_{13}^2)^2+(k_{23}^2)^2-2k_{12}^2k_{13}^2-2k_{12}^2k_{23}^2-2k_{13}^2k_{23}^2]=-\tfrac{1}{4}\lambda(k_{12}^2,k_{13}^2,k_{23}^2), \tag{5.8}$$

where $\lambda(x,y,z)$ is defined in Eq. (1.1) (cf. Fig. 1). The triangle 123 is thereby split into three triangles 012, 023, and 031. The angle between 01 and 02 is denoted as φ_{12}, etc. Obviously,

$$\varphi_{12}+\varphi_{23}+\varphi_{31}=2\pi. \tag{5.9}$$

For the calculation of three-dimensional triangle integral, it does not really matter where the point 0 lies, though this becomes essential for the four-dimensional case. As we know, the $N=n$ integrals can be reduced to the integrals with equal masses. So, let us start with the equal mass case. In Fig. 6, this means that $\tau_{01}=\tau_{02}=\tau_{03}\equiv\tau_0$. Therefore, the spherical triangles 012, 023, and 031 are isosceles. Consider one of these triangles, say 012, as illustrated in Fig. 7. The sides 01 and 02 are equal to τ_0. The third side, 12, is equal to τ_{12}. The length of the perpendicular dropped from the point 0 to the side 12 is denoted as η_{12}. This perpendicular intersects the side 12 in a point T_{12} which in the equal-mass case divides the side 12 into two equal parts (each of them equals $\tau_{12}/2$). It also divides the angle φ_{12} into two equal parts. The angles at the vertices 1 and 2 (which are also equal in the equal-mass case) are denoted as κ_{12}. The lengths of two of the sides of a smaller isosceles triangle $01_\xi2_\xi$, 01_ξ and 02_ξ, are $\tau_0\xi$ $(0\leqslant\xi\leqslant1)$. The third side, $1_\xi2_\xi$, is parallel (in the spherical sense) to the side 12 and its length is denoted as $\tau(\xi)$; obviously, $\tau(0)=0$ and $\tau(1)=\tau_{12}$. The perpendicular $0T_{12}$ also splits it into two equal parts of the length $\tau(\xi)/2$. The length of the part of the perpendicular within the triangle $01_\xi2_\xi$ is denoted as $\eta(\xi)$, whereas the angles at the vertices 1_ξ and 2_ξ are $\kappa(\xi)$; obviously, $\eta(0)=0$, $\eta(1)=\eta_{12}$, $\kappa(0)=(\pi-\varphi_{12})/2$, $\kappa(1)=\kappa_{12}$.

The main idea of introducing an auxiliary variable ξ is to simplify the limits of integration. We define the usual spherical integration angle θ in a way that it is the angle between the direction of H_0 and the ''running'' point. For the triangle 012 presented in Fig. 7, let us define that $\varphi=0$ corresponds to the direction of the perpendicular $0T_{12}$. In this way, the limits of the φ integration are $\pm\varphi_{12}/2$. The lower limit of the θ integration is zero, whereas the upper limit depends on φ and varies from τ_0 (at $\varphi=\pm\varphi_{12}/2$) to η_{12} (at $\varphi=0$). If we use, instead of θ, the variable ξ, its limits will be $0\leqslant\xi\leqslant1$, independently of φ. The result of an infinitesimal variation of ξ will be a thin strip based on the side $1_\xi2_\xi$ (cf. Fig. 7). Moreover, all such strips from the triangles 012, 023 and

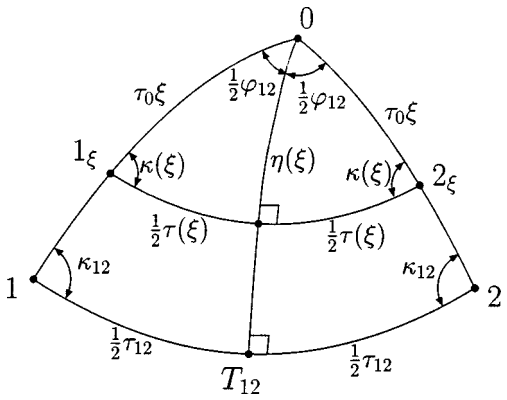

FIG. 7. The isosceles spherical triangle 012.

031 (cf. Fig. 6) can be ''glued'' together. So, the whole result of a variation in ξ is a thin closed spherical triangle. Alternatively, one can perform the azimuthal φ-integration first, and then evaluate the remaining ξ integral. As we shall see, both ways work in the three-point case.

Using formulas of spherical trigonometry (cf. Fig. 7), we get the following relations:

$$\sin(\tfrac{1}{2}\tau(\xi)) = \sin(\tfrac{1}{2}\varphi_{12})\sin(\tau_0\xi),$$

$$\sin\ \eta(\xi) = \sin\ \kappa(\xi)\sin(\tau_0\xi),$$

$$\cos\ \kappa(\xi) = \sin(\tfrac{1}{2}\varphi_{12})\cos\ \eta(\xi),$$

$$\tan\ \kappa(\xi) = (\cos(\tau_0\xi)\tan(\tfrac{1}{2}\varphi_{12}))^{-1},$$

$$\tan\ \eta(\xi) = \cos(\tfrac{1}{2}\varphi_{12})\tan(\tau_0\xi).$$

The situation for arbitrary φ is drawn in Fig. 8. This is a rectangular spherical triangle with an upper vertex 0 and one of the outgoing sides being the perpendicular of the length $\eta(\xi)$, as in Fig. 7. This side corresponds to $\varphi = 0$. The angle at the vertex 0 is equal to φ and a running value of φ is understood. The side opposite to 0 is perpendicular to the one mentioned before, $\eta(\xi)$. This is a part of the corresponding side directed to the point 1_ξ in Fig. 7, i.e. the line of constant ξ. Its length is denoted as $\rho(\xi,\varphi)$. The third side or ''hypotenuse'' has length $\theta(\xi,\varphi)$. The vertex opposite to the $\eta(\xi)$ side is the running point with the coordinates θ, φ. The angle at this vertex is denoted as $\kappa(\xi,\varphi)$.

We want to express θ in terms of ξ and φ. Using the formulas of spherical trigonometry for the triangle in Fig. 8, analogous to ones written above, it is straightforward to show that

$$\tan\ \theta(\xi,\varphi) = \frac{\tan\ \eta(\xi)}{\cos\ \varphi} = \frac{\cos(\tfrac{1}{2}\varphi_{12})}{\cos\ \varphi}\tan(\tau_0\xi). \tag{5.10}$$

The area is obtained by integrating

$$\sin\ \theta\ \ d\theta\ \ d\varphi = -d(\cos\ \theta)d\varphi \Rightarrow -\frac{\partial(\cos\ \theta(\xi,\varphi))}{\partial\xi}\,d\xi\ \ d\varphi, \tag{5.11}$$

where, according to Eq. (5.10),

$$\cos\ \theta(\xi,\varphi) = \left(1 + \frac{\cos^2(\tfrac{1}{2}\varphi_{12})}{\cos^2\ \varphi}\tan^2(\tau_0\xi)\right)^{-1/2}. \tag{5.12}$$

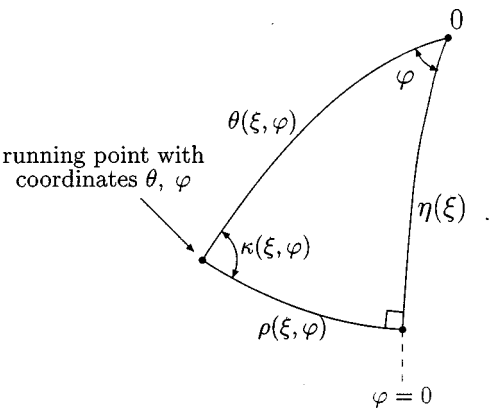

FIG. 8. Integration variables on the sphere.

If we first perform the φ-integral, this effectively corresponds to the area of the infinitesimal strip between two sides of constant ξ,

$$-2d\{\arctan(\cos(\tau_0\xi)\tan(\tfrac{1}{2}\varphi_{12}))\}. \tag{5.13}$$

Then, the remaining ξ integral gives just this arctan. Collecting the results for all triangles (cf. Fig. 6), we get the same as in Eq. (5.5). This can be seen if we observe that the expression (5.13) is nothing but $2d\kappa(\xi)$ and the spherical excess for the triangle $01_\xi 2_\xi$ is $(\varphi_{12}+2\kappa(\xi)-\pi)$. A nice thing about Eq. (5.13) is that in the ξ-integral we can glue all arctan functions into a symmetric answer at the *infinitesimal* level. The same final result can also be obtained when we first integrate over ξ, it being trivial since the integrand is a derivative with respect to ξ.

B. The four-dimensional case

If we consider the four-dimensional three-point function, the only (but very essential!) difference is that we should divide the integrand by $\cos\theta(\xi,\varphi)$, cf. Eq. (3.37). Therefore, the function in the integrand can be written as

$$-\frac{\partial}{\partial\xi}\ln(\cos\,\theta(\xi,\varphi)). \tag{5.14}$$

As in the previous case, one can integrate first over either φ or ξ; both ways lead to equivalent results. Let us integrate first over ξ, this gives

$$\ln\left(\frac{\cos\,\theta(0,\varphi)}{\cos\,\theta(1,\varphi)}\right)=\tfrac{1}{2}\ln\left(1+\frac{\tan^2\,\eta_{12}}{\cos^2\,\varphi}\right). \tag{5.15}$$

In the equal-mass case, the remaining φ-integral becomes

$$\int_0^{\varphi_{12}/2}d\varphi\,\ln\left(1+\frac{\tan^2\,\eta_{12}}{\cos^2\,\varphi}\right)=\frac{1}{2}\int_0^{\varphi_{12}}d\varphi'\left\{\ln(1+2\tan^2\,\eta_{12})+\ln\left(1+\frac{\cos\,\varphi'}{1+2\tan^2\,\eta_{12}}\right)\right.$$
$$\left.-\ln(1+\cos\,\varphi')\right\}, \tag{5.16}$$

where $\varphi'=2\varphi$. Using a result from Ref. 27 (p. 308, Eq. (38)), this integral can be expressed in terms of the Clausen function (see in Appendix A) as

$$\tfrac{1}{2}\tau_{12}\ln\left(\frac{\sin(\frac{1}{2}(\varphi_{12}+\tau_{12}))}{\sin(\frac{1}{2}(\varphi_{12}-\tau_{12}))}\right)+\tfrac{1}{2}\mathrm{Cl}_2(\varphi_{12}+\tau_{12})+\tfrac{1}{2}\mathrm{Cl}_2(\varphi_{12}-\tau_{12})-\mathrm{Cl}_2(\varphi_{12}). \tag{5.17}$$

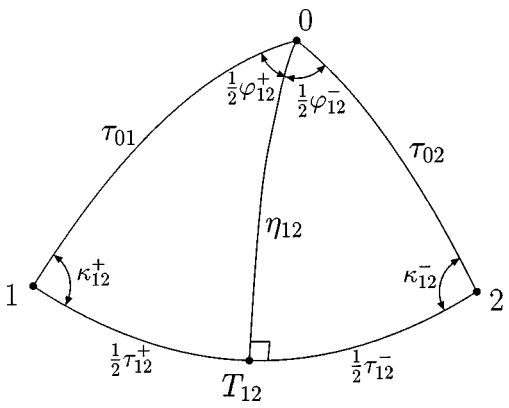

FIG. 9. An asymmetric spherical triangle 012.

The arguments of the Clausen functions have a very transparent geometric interpretation. We note that the logarithmic term can also be presented as

$$\tfrac{1}{2}\tau_{12}\,\ln\!\left(\frac{1+\sin\,\eta_{12}}{1-\sin\,\eta_{12}}\right). \tag{5.18}$$

The function (5.17) can also be expressed in terms of the generalized inverse tangent integral (A8) as

$$\mathrm{Ti}_2(\tan(\tfrac{1}{2}\tau_{12}),\tan(\tfrac{1}{2}\varphi_{12}))-\mathrm{Ti}_2(\tan(\tfrac{1}{2}\tau_{12}),-\tan(\tfrac{1}{2}\varphi_{12})). \tag{5.19}$$

The generalization to the case of unequal masses is easy. To understand why, let us consider Fig. 9. This is again a close-up of the triangle 012 from Fig. 6, but now it is asymmetric, because τ_{01} and τ_{02} are different. We denote the quantities in one of the triangles as $\varphi_{12}^{+}/2$, $\tau_{12}^{+}/2$, $\kappa_{12}^{+}/2$, and in another triangle as $\varphi_{12}^{-}/2$, $\tau_{12}^{-}/2$, $\kappa_{12}^{-}/2$. The height η_{12} is the same for both triangles. Obviously,

$$\tfrac{1}{2}(\varphi_{12}^{+}+\varphi_{12}^{-})=\varphi_{12}\ \text{ and }\ \tfrac{1}{2}(\tau_{12}^{+}+\tau_{12}^{-})=\tau_{12}\,. \tag{5.20}$$

One can immediately see that the result for the integral over this asymmetric triangle is nothing but a half of the sum of the functions (5.17) labeled with plus and with minus. Namely,

$$\begin{aligned}\tfrac{1}{2}\tau_{12}\,\ln\!\left(\frac{1+\sin\,\eta_{12}}{1-\sin\,\eta_{12}}\right)&+\tfrac{1}{4}\mathrm{Cl}_2(\varphi_{12}^{+}+\tau_{12}^{+})+\tfrac{1}{4}\mathrm{Cl}_2(\varphi_{12}^{+}-\tau_{12}^{+})-\tfrac{1}{2}\mathrm{Cl}_2(\varphi_{12}^{+})\\&+\tfrac{1}{4}\mathrm{Cl}_2(\varphi_{12}^{-}+\tau_{12}^{-})+\tfrac{1}{4}\mathrm{Cl}_2(\varphi_{12}^{-}-\tau_{12}^{-})-\tfrac{1}{2}\mathrm{Cl}_2(\varphi_{12}^{-}).\end{aligned} \tag{5.21}$$

Again, the geometric interpretation of the arguments of the Clausen functions is very transparent, thanks to Fig. 9.

Some useful relations are

$$\cos(\tfrac{1}{2}\tau_{12}^{+})=\frac{\cos\,\tau_{01}}{\cos\,\eta_{12}},\ \ \cos(\tfrac{1}{2}\tau_{12}^{-})=\frac{\cos\,\tau_{02}}{\cos\,\eta_{12}},$$

$$\sin(\tfrac{1}{2}\tau_{12}^{+})=\sin\,\tau_{01}\,\sin(\tfrac{1}{2}\varphi_{12}^{+}),\ \ \sin(\tfrac{1}{2}\tau_{12}^{-})=\sin\,\tau_{02}\,\sin(\tfrac{1}{2}\varphi_{12}^{-}),$$

$$\tan(\tfrac{1}{2}\tau_{12}^{+})=\sin\,\eta_{12}\,\tan(\tfrac{1}{2}\varphi_{12}^{+}),\ \ \tan(\tfrac{1}{2}\tau_{12}^{-})=\sin\,\eta_{12}\,\tan(\tfrac{1}{2}\varphi_{12}^{-}).$$

Worth noting is

$$\cos\ \eta_{12}=\frac{m_0\sqrt{k_{12}^2}}{m_1 m_2\ \sin\ \tau_{12}}. \tag{5.22}$$

To get the complete result for the three-point integral in four dimensions, we should sum up the functions (5.21) for all three triangles 012, 023, and 031, and multiply by the overall factor (see Eq. (3.37)) which is

$$-i\pi^2\ \frac{1}{\sqrt{\Lambda^{(3)}}}. \tag{5.23}$$

Note that in this case we get $\sqrt{\Lambda^{(3)}}$ rather than $\sqrt{D^{(3)}}$ in the denominator.

VI. FOUR-POINT FUNCTION

A. The general case

In this case, the four-dimensional simplex has four mass sides and six momentum sides (see Fig. 3). It has five vertices and five three-dimensional hyperfaces. Four of these hyperfaces are the *reduced* ones, corresponding to three-point functions, whereas the fifth one is the momentum hyperface. In fact, this four-dimensional simplex is completely defined by its mass sides m_1, m_2, m_3, m_4 and six ''planar'' angles between them, τ_{12}, τ_{13}, τ_{14}, τ_{23}, τ_{24}, and τ_{34}. According to Eq. (2.16), the content (hypervolume) of this simplex equals

$$V^{(4)}=\frac{1}{24}\ m_1 m_2 m_3 m_4\sqrt{D^{(4)}}, \tag{6.1}$$

with $D^{(4)}$ given by (2.13)–(2.14) at $N=4$,

$$D^{(4)}=\det\|c_{jl}\|,\ \ \|c_{jl}\|=\begin{pmatrix} 1 & c_{12} & c_{13} & c_{14}\\ c_{12} & 1 & c_{23} & c_{24}\\ c_{13} & c_{23} & 1 & c_{34}\\ c_{14} & c_{24} & c_{34} & 1 \end{pmatrix}. \tag{6.2}$$

The four-dimensional four-point function can be exhibited as [cf. Eqs. (3.18) and (3.21)]

$$J^{(4)}(4;1,1,1,1)=\frac{1}{12}\ i\pi^2\ \frac{\Omega^{(4)}}{V^{(4)}}=\frac{2i\pi^2}{m_1 m_2 m_3 m_4}\ \frac{\Omega^{(4)}}{\sqrt{D^{(4)}}}. \tag{6.3}$$

So, the main problem is how to calculate $\Omega^{(4)}$.

In four dimensions, $\Omega^{(4)}$ is the value of the four-dimensional generalization of the solid angle at the vertex of the simplex where all four mass sides meet. In the spherical case, it can be defined as the volume of a part of the unit hypersphere which is cut out from it by the four three-dimensional reduced hyperfaces, each hyperface involving three mass sides of the simplex. This hypersection is a three-dimensional spherical tetrahedron whose six sides (edges) are equal to the angles τ_{jl}. [In the hyperbolic case, this is a hyperbolic tetrahedron whose volume can be obtained by analytic continuation (see below).]

It is illustrated in Fig. 10 where the ith vertex ($i=1,2,3,4$) corresponds to the intersection of the ith mass side of the basic simplex and the unit hypersphere. [It should be stressed that Fig. 10 is just an illustration (rather than a precise picture) since a realistic non-Euclidean tetrahedron should be understood as embedded into four-dimensional Euclidean space.] Furthermore, the dihedral angles of this *three*-dimensional spherical tetrahedron coincide with those of the *four*-dimensional basic simplex, ψ_{jl} (cf. Eqs. (2.24), (2.27)). The dual matrix $\|\tilde{c}_{jl}\|$ as well as its determinant $\tilde{D}^{(4)}$, cf. Eq. (2.26),

$$\|\tilde{c}_{jl}\| = \begin{pmatrix} 1 & \tilde{c}_{12} & \tilde{c}_{13} & \tilde{c}_{14} \\ \tilde{c}_{12} & 1 & \tilde{c}_{23} & \tilde{c}_{24} \\ \tilde{c}_{13} & \tilde{c}_{23} & 1 & \tilde{c}_{34} \\ \tilde{c}_{14} & \tilde{c}_{24} & \tilde{c}_{34} & 1 \end{pmatrix}, \quad \tilde{c}_{jl} = -\cos\,\psi_{jl}, \quad \tilde{D}^{(4)} = \det\|\tilde{c}_{jl}\|, \tag{6.4}$$

are usually referred to as the Gram matrix and determinant of the spherical or hyperbolic tetrahedron. For example, the dihedral angle at the edge 12 of the spherical tetrahedron in Fig. 10 is ψ_{34}, etc. (The digits labeling the edge and the dihedral angle at this edge should cover the whole set 1234.) We note that the dihedral angle is well defined in spherical and hyperbolic spaces, i.e. it remains unchanged along the given edge.

Unfortunately, there are no *simple* relations like (5.4) which might make it possible to express the volume of a spherical (or hyperbolic) tetrahedron in terms of its sides or dihedral angles. In fact, calculation of this volume in an elliptic or hyperbolic space is a well-known problem of non-Euclidean geometry (see e.g. Refs. 36–38). A standard way to solve this problem, say in spherical space, is to split an arbitrary tetrahedron into a set of birectangular ones. For example, the tetrahedron 1234 (shown in Fig. 10) is called *birectangular* (or *double-rectangular*) if (i) the edge 12 is perpendicular to the face 234 and (ii) the opposite edge, 34, is perpendicular to the face 123. It is easy to check that in this case three dihedral angles, ψ_{13}, ψ_{14}, and ψ_{24}, are right angles. The other three are usually denoted[39,40] as

$$\psi_{12} = \alpha, \quad \psi_{23} = \beta, \quad \psi_{34} = \gamma. \tag{6.5}$$

The volume of a birectangular tetrahedron is known (see below) and can be expressed in terms of Lobachevsky or Schläfli functions which can be related to dilogarithms (see Refs. 39 and 40).

The volume of the general tetrahedron must be a symmetrical function of the six edges τ_{jl}, or equivalently of the six dihedral angles ψ_{jl}. When we break it up into a sum of birectangular tetrahedra, this explicit symmetry may be lost, although of course it must be hidden in the properties of the sums of dilogarithmic functions.

The general way to split an arbitrary tetrahedron into a sum of birectangular ones is to fix a point 0, say inside the tetrahedron. [If this point (or the feet of some of the perpendiculars) happen to be outside the tetrahedron, this would mean that some of the volumes of the resulting birectangular tetrahedra should be taken with an opposite sign.] Then, connecting this point 0 with each of the vertices of the tetrahedron 1234, we split it into four smaller tetrahedra: 0123, 0124, 0134, and 0234. Consider one of these tetrahedra, say 0123. Dropping the perpendicular from 0 onto the face 123 and connecting the foot of this perpendicular F_{123} with the vertices 1, 2, and 3, we split 0123 into three *rectangular* tetrahedra, $012F_{123}$, $013F_{123}$, and $023F_{123}$. Then, each of these

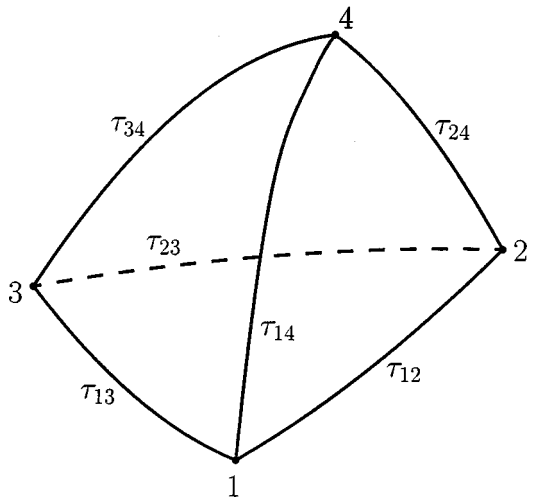

FIG. 10. The spherical tetrahedron 1234.

rectangular tetrahedra (say, $012F_{123}$) can be split into a sum of two *birectangular* tetrahedra by dropping a perpendicular from F_{123} onto the only side belonging to the original tetrahedron 1234 (the edge 12). In this way, we get $4\times3\times2=24$ birectangular tetrahedra.

Since we are free to choose the position of the point 0, there are (at least) two ways to reduce the number of terms involved in this volume splitting in the general case:

(i) The point 0 may coincide with one of the vertices of the original tetrahedron, say with the vertex 4 [cf. Fig. 11(a)]. In this case, we do not need to split into four smaller tetrahedra and can start just by dropping a perpendicular from the point 4 onto the face 123. In this way, we reduce the number of birectangular tetrahedra involved to six. However, the price we pay for this is the loss of explicit symmetry.

(ii) A symmetric choice of the point 0 can be related to the structure of the basic four-dimensional Euclidean simplex. In particular, we can take as the point 0 the intersection of the height H_0 and the unit hypersphere. Moreover, since the general four-point function can be reduced to the equal-mass case (see Eqs. (3.10)–(3.11)), it is enough to consider the case when the point 0 is equidistant from the vertices 1, 2, 3, and 4. In this case, at the first stage of splitting we get four ''*isosceles*'' tetrahedra, signifying for each of them the three sides meeting at the point 0 are equal. Continuing the splitting, we see that due to ''isoscelesness'' the pairs of the tetrahedra produced at the last stage have equal values. Effectively, we get the sum of $4\times3=12$ volumes of birectangular tetrahedra. Although this is twice as much as in the case (i), the advantage is that we are able to preserve the explicit symmetry at all stages.

We note that the possibility to rescale the Feynman parameters in the case $n=N$ is closely connected with the freedom to choose the point 0 as we like. [See Eqs. (3.27)–(3.28). For $n=N$, the denominator disappears. In general, the f_i can take arbitrary positive values.] As we have seen, this rescaling preserves the angles τ_{jl} between the mass vectors, whereas the direction of the height H_0 varies. In particular, we can make it coincide with one of the mass vectors, which corresponds to the splitting (i) considered above. From this point of view, we lose the explicit symmetry since the corresponding rescaling is not symmetric.

Another possibility to reduce the number of birectangular volumes involved is to try to choose the point 0 in such a way that the volumes of the four tetrahedra (produced at the first stage of splitting) are equal (or proportional) to each other. In this case, the further splitting would give just $3\times2=6$ birectangular terms, i.e., the same number as in the case (i); but here we may preserve the explicit symmetry. However, it seems to be difficult (if possible at all) to define the position of the point 0 in this case, because one needs to solve a set of transcendental equations.

In some special examples described below we show that an additional symmetry of the diagram can also be employed.

B. Volume of birectangular tetrahedra in curved space

As we have seen (cf. Eq. (6.5)), the birectangular tetrahedron may be specified by three dihedral angles $\psi_{12}=\alpha$, $\psi_{23}=\beta$, $\psi_{34}=\gamma$, so that the corresponding Gram matrix $\|\tilde{c}_{jl}\|$ and its determinant (cf. Eq. (20) of Ref. 40) are

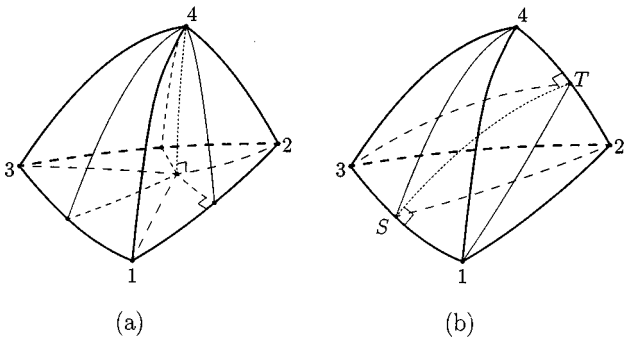

FIG. 11. Different ways of splitting the non-Euclidean tetrahedron.

$$\|\tilde{c}_{jl}\|=\begin{pmatrix} 1 & -\cos\alpha & 0 & 0 \\ -\cos\alpha & 1 & -\cos\beta & 0 \\ 0 & -\cos\beta & 1 & -\cos\gamma \\ 0 & 0 & -\cos\gamma & 1 \end{pmatrix}, \quad \tilde{D}^{(4)}=\sin^2\alpha\,\sin^2\gamma-\cos^2\beta. \tag{6.6}$$

The volume of this birectangular tetrahedron (i.e., its contribution to $\Omega^{(4)}$) can be presented as

$$\Omega^{(4)}=V(\alpha,\beta,\gamma)=\tfrac{1}{4}S(\pi/2-\alpha,\beta,\pi/2-\gamma). \tag{6.7}$$

The notation $S(\alpha,\beta,\gamma)$ corresponds to the Schläfli function as defined in Ref. 39, whereas the notation $V(\alpha,\beta,\gamma)$ was used in Ref. 40 and is proportional to the function originally used by Schläfli.[37] Note that function (6.7) is symmetric with respect to α and γ.

If we define (cf. Eq. (3.21) of Ref. 39)

$$X\equiv\frac{\cos\alpha\,\cos\gamma-\sqrt{\tilde{D}^{(4)}}}{\cos\alpha\,\cos\gamma+\sqrt{\tilde{D}^{(4)}}}, \tag{6.8}$$

the result for the volume can be expressed in terms of dilogarithms,[39]

$$\begin{aligned} 4V(\alpha,\beta,\gamma)=&\tfrac{1}{2}[\mathrm{Li}_2(Xe^{2i\alpha})+\mathrm{Li}_2(Xe^{-2i\alpha})]+\tfrac{1}{2}[\mathrm{Li}_2(Xe^{2i\gamma})+\mathrm{Li}_2(Xe^{-2i\gamma})] \\ &-\tfrac{1}{2}[\mathrm{Li}_2(-Xe^{2i\beta})+\mathrm{Li}_2(-Xe^{-2i\beta})]-\mathrm{Li}_2(-X)-\left(\frac{\pi}{2}-\alpha\right)^2-\left(\frac{\pi}{2}-\gamma\right)^2+\beta^2. \end{aligned} \tag{6.9}$$

When the condition $\tilde{D}^{(4)}\geqslant 0$ ($\sin\alpha\sin\gamma\leqslant\cos\beta$) is obeyed, the tetrahedron exists in the usual geometrical sense, and its volume is real. In this case, one can express $V(\alpha,\beta,\gamma)$ in terms of the real function $\mathrm{Li}_2(r,\theta)\equiv\mathrm{Re}[\mathrm{Li}_2(re^{i\theta})]$ (see Appendix A). However, one should distinguish between the cases $X\geqslant 0$ (or $\cos^2\alpha+\cos^2\beta+\cos^2\gamma\geqslant 1$) and $X\leqslant 0$ (or $\cos^2\alpha+\cos^2\beta+\cos^2\gamma\leqslant 1$). The corresponding expressions are

$$\begin{aligned} 4V(\alpha,\beta,\gamma)\big|_{X\geqslant 0}=&\,\mathrm{Li}_2(X,2\alpha)+\mathrm{Li}_2(X,2\gamma)-\mathrm{Li}_2(X,\pi-2\beta)-\mathrm{Li}_2(-X) \\ &-\left(\frac{\pi}{2}-\alpha\right)^2-\left(\frac{\pi}{2}-\gamma\right)^2+\beta^2, \end{aligned} \tag{6.10}$$

$$\begin{aligned} 4V(\alpha,\beta,\gamma)\big|_{X\leqslant 0}=&\,\mathrm{Li}_2(-X,\pi-2\alpha)+\mathrm{Li}_2(-X,\pi-2\gamma)-\mathrm{Li}_2(-X,2\beta)-\mathrm{Li}_2(-X) \\ &-\left(\frac{\pi}{2}-\alpha\right)^2-\left(\frac{\pi}{2}-\gamma\right)^2+\beta^2. \end{aligned} \tag{6.11}$$

In particular, when $X=-1$ we take into account that $\mathrm{Li}_2(1,\theta)=\frac{1}{4}(\pi-\theta)^2-\frac{1}{12}\pi^2$ and get

$$V(\alpha,\beta,\gamma)\big|_{X=-1}=\tfrac{1}{4}\pi(\alpha+\beta+\gamma-\pi). \tag{6.12}$$

When $\alpha=\beta=\gamma=\frac{1}{2}\pi$, this gives $\frac{1}{8}\pi^2$, which agrees with Eq. (3.14) (at $N=4$, $\nu_i=1$).

When $\tilde{D}^{(4)}<0$ ($\sin\alpha\sin\gamma<\cos\beta$), the tetrahedron does not exist in the usual geometrical sense (in the spherical case), but its volume (more precisely, the analytic continuation of the function corresponding to the volume) can be obtained from Eq. (6.9), and it is imaginary. In this case we define (according to Refs. 39, 40)

$$X=e^{-2i\delta},\ \text{so that}\ \tan\delta=\frac{\sqrt{-\tilde{D}^{(4)}}}{\cos\alpha\,\cos\gamma}, \tag{6.13}$$

and we get

$$V(\alpha,\beta,\gamma)=(1/(8i))[\mathrm{Cl}_2(2\alpha+2\delta)-\mathrm{Cl}_2(2\alpha-2\delta)+\mathrm{Cl}_2(2\gamma+2\delta)$$
$$-\mathrm{Cl}_2(2\gamma-2\delta)-\mathrm{Cl}_2(\pi-2\beta+2\delta)+\mathrm{Cl}_2(\pi-2\beta-2\delta)+2\mathrm{Cl}_2(\pi-2\delta)]. \quad (6.14)$$

Using the connection between the Clausen function and the Lobachevsky function $L(\theta)$ (cf. Eq. (A10) in Appendix A), Eq. (6.14) can be rewritten in terms of the Lobachevsky function. [The function used in Ref. 40 which was denoted by a Cyrillic ''L'' can be expressed in terms of the Clausen function as $\frac{1}{2}\mathrm{Cl}_2(2\theta)$.] The same expression (6.14) gives the volume of a birectangular tetrahedron in the hyperbolic space (see Refs. 39 and 40).

C. Some cases with an additional symmetry

There are a few cases of particular practical interest because of their inherent higher symmetries. In particular, there is the most symmetrical case where all $c_{ij}=c$. Thus all dihedral angles of the full (regular) tetrahedron are equal, to ψ say. In that case the six birectangular tetrahedra corresponding to splitting (i) are all of equal size and $\Omega^{(4)}$ reduces to

$$\Omega^{(4)}=6V(\pi/3,\psi/2,\psi)=\tfrac{3}{2}S(\pi/6,\psi/2,\pi/2-\psi). \quad (6.15)$$

Coxeter gives the identities (Eqs. (4.31)–(4.32) of Ref. 39)

$$S(\pi/6,\psi/2,\pi/2-\psi)=4S(\pi/6,\pi/3,(\pi-\psi)/2)=\tfrac{2}{3}S((\pi-\psi)/2,\psi,(\pi-\psi)/2), \quad (6.16)$$

which he derived algebraically, and which can be used to convert $\Omega^{(4)}$ given by Eq. (6.7) into other forms. We will presently explain the geometrical meaning of these identities.

Another case of interest corresponds to equal mass scattering with equal internal masses; this means $c_{12}=c_{23}=c_{34}=c_{14}$ and in general are not equal to c_{13},c_{24}, which are associated with energy and scattering angle variables. This case has four of the tetrahedral sides equal and different from the other two (which are opposite to one another). Thus there are three distinct c's. We shall see that it is possible here to break up full tetrahedron into four birectangular ones by joining the midpoints of the unequal sides to render the problem more tractable and make the maximum use of what symmetry exists.

We shall carry out our analysis by relaxing the symmetry relations. First we consider the case where all six c_{ij} are equal to c and treat this in three different ways. Then we let $c_{13}\equiv c_s$ and $c_{24}\equiv c_t$ be unequal.

1. Completely symmetrical box diagram

Here all c_{jl} are equal and we are dealing with a completely regular tetrahedron. For example, in the equal-mass case this would mean that all k_{jl}^2 are equal (of course this represents an unphysical point in the Mandelstam diagram), to k^2 say, and all $c=1-k^2/(2m^2)$. We have

$$\|c_{jl}\|=\begin{pmatrix}1&c&c&c\\c&1&c&c\\c&c&1&c\\c&c&c&1\end{pmatrix},\quad \|\tilde{c}_{jl}\|=\begin{pmatrix}1&\tilde{c}&\tilde{c}&\tilde{c}\\\tilde{c}&1&\tilde{c}&\tilde{c}\\\tilde{c}&\tilde{c}&1&\tilde{c}\\\tilde{c}&\tilde{c}&\tilde{c}&1\end{pmatrix},\quad \tilde{c}=-\frac{c}{1+2c}. \quad (6.17)$$

This means that the dihedral angle ψ between each and every pair of hyperplanes equals $\arccos[c/(1+2c)]$. {The generalization of this totally symmetric case to an N-point function is quite easy and leads to $\cos\psi=c/[1+(N-2)c]$.}

We can evaluate the hypervolume in at least three ways (the first two correspond to the ways (i) and (ii) considered in the general case):

(i) By dropping a perpendicular from one corner onto the opposite hyperplane and another perpendicular onto one of the opposite sides, we subdivide the full tetrahedron into six equal birectangular tetrahedra [see Fig. 11(a)]. By inspection, each birectangular tetrahe-

dron has dihedral angles ψ, $\psi/2$, and $\pi/3$. Therefore the total hypervolume equals

$$\Omega^{(4)}=6V(\psi,\psi/2,\pi/3)=\tfrac{3}{2}S(\pi/6,\psi/2,\pi/2-\psi). \tag{6.18}$$

(ii) We can alternatively consider the total volume as four times the volume contained in the tetrahedron generated by one base triangle and the ''center of mass'' point 0: $P_0=\frac{1}{4}(P_1+P_2+P_3+P_4)$ (here, we use the notation $P_i=m_ia_i$, cf. Eq. (2.49)). In this case the matrix associated with the tetrahedron 0123 is found to be

$$\|c_{jl}\|=\begin{pmatrix} 1 & c' & c' & c' \\ c' & 1 & c & c \\ c' & c & 1 & c \\ c' & c & c & 1 \end{pmatrix},\quad c'=\frac{\sqrt{1+3c}}{2}. \tag{6.19}$$

leading to

$$\|\tilde{c}_{jl}\|=\begin{pmatrix} 1 & \tilde{c}' & \tilde{c}' & \tilde{c}' \\ \tilde{c}' & 1 & 1/2 & 1/2 \\ \tilde{c}' & 1/2 & 1 & 1/2 \\ \tilde{c}' & 1/2 & 1/2 & 1 \end{pmatrix},\quad \tilde{c}'=-\sqrt{\frac{1+3c}{2(1+2c)}}. \tag{6.20}$$

This implies that there are two distinct dihedral angles,

$$\tfrac{2}{3}\pi \ \text{ and } \ \arccos\sqrt{\frac{1+3c}{2(1+2c)}}=\tfrac{1}{2}\arccos\left(\frac{c}{1+2c}\right)=\frac{\psi}{2} \tag{6.21}$$

in fact. Actually the result is hardly surprising since it can be deduced by simple inspection of the geometrical figure. Anyhow if we now divide 0123 into six identical birectangular tetrahedra by dropping a perpendicular from 0 onto the center of the triangle 123, these smaller tetrahedra possess dihedral angles $\psi/2$, $\pi/3$, $\pi/3$. Consequently we have an alternative geometrical expression for the full volume,

$$\Omega^{(4)}=24V(\pi/3,\pi/3,\psi/2)=6S(\pi/6,\pi/3,(\pi-\psi)/2). \tag{6.22}$$

Comparing this with the previous answer we have a geometrical explanation of one of the Coxeter identities (6.16). Furthermore, because (see Ref. 39, p. 18) there exists the differential relation

$$dS(\pi/6,\pi/3,\gamma)=-2\arccos\left(\frac{\cos\gamma}{\sqrt{4\cos^2\gamma-1}}\right)d\gamma, \tag{6.23}$$

we get the following integral representation of the four-dimensional solid angle (6.22):

$$\Omega^{(4)}=\pi^2-12\int_0^{(\pi-\psi)/2}d\gamma\,\arccos\left(\frac{\cos\gamma}{\sqrt{4\cos^2\gamma-1}}\right). \tag{6.24}$$

(iii) We take the two midpoints S and T of the opposite sides: $P_S=(P_1+P_3)/2$, $P_T=(P_2+P_4)/2$ [see Fig. 11(b)]. The full volume is then just four times that of the tetrahedron $12ST$, which is already birectangular as can be seen by inspection. In this case the matrix $\|c_{jl}\|$ associated with the tetrahedron $12ST$ has the following nondiagonal elements:

$$c_{12}=c,\quad c_{13}=c_{24}=\sqrt{\frac{1+c}{2}},\quad c_{14}=c_{23}=c\sqrt{\frac{2}{1+c}},\quad c_{34}=\frac{2c}{1+c}. \tag{6.25}$$

The corresponding Gram matrix of the tetrahedron $12ST$ is

$$\|\tilde{c}_{jl}\|=\begin{pmatrix} 1 & 0 & \tilde{c}' & 0 \\ 0 & 1 & 0 & \tilde{c}' \\ \tilde{c}' & 0 & 1 & \tilde{c} \\ 0 & \tilde{c}' & \tilde{c} & 1 \end{pmatrix}, \tag{6.26}$$

with $\tilde{c}$ and $\tilde{c}'$ defined in Eqs. (6.17) and (6.20), respectively. From this we extract the three dihedral angles.

$$\alpha=\gamma=\tfrac{1}{2}\psi \quad \text{and} \quad \beta=\psi, \tag{6.27}$$

where ψ is nothing but the dihedral angle at the side 12, i.e., one of the dihedral angles of the full tetrahedron. This accords completely with the shape of $12ST$. Hence the total volume of the complete tetrahedron 1234 is given by

$$\Omega^{(4)}=4V(\psi/2,\psi,\psi/2)=S((\pi-\psi)/2,\psi,(\pi-\psi)/2). \tag{6.28}$$

Comparing with the earlier expression, this provides a geometric meaning of the second Coxeter identity (6.16).

2. Partially symmetric box diagram

In this case we shall take four sides of the tetrahedron to be equal and two opposite sides to be unequal to them. In the equal-mass case, this would correspond to setting $k_{12}^2=k_{23}^2=k_{34}^2=k_{14}^2=k^2$, $k_{13}^2=s$, $k_{24}^2=t$, and we would get three different c's: $c=1-k^2/2m^2$, $c_s=1-s/2m^2$, $c_t=1-t/2m^2$ (s and t are just the Mandelstam variables). In this case much the simplest way of evaluating the volume of the tetrahedron is to break it up into four equal birectangular tetrahedra by taking the midpoints of the sides 13 and 24, as before; $P_S=(P_1+P_3)/2$, $P_T=(P_2+P_4)/2$. There is enough symmetry in the problem that the full tetrahedron is four times the birectangular tetrahedron $12ST$. The latter is described by the matrix $\|c_{jl}\|$ with the nondiagonal elements,

$$c_{12}=c, \quad c_{13}=\sqrt{\frac{1+c_s}{2}}, \quad c_{24}=\sqrt{\frac{1+c_t}{2}},$$

$$c_{23}=c\sqrt{\frac{2}{1+c_s}}, \quad c_{14}=c\sqrt{\frac{2}{1+c_t}}, \quad c_{34}=\frac{2c}{\sqrt{(1+c_s)(1+c_t)}}. \tag{6.29}$$

The nondiagonal elements of the ''dual'' matrix $\|\tilde{c}_{jl}\|$ are

$$\tilde{c}_{13}=-\sqrt{\frac{(1+c_s)(1+c_t)-4c^2}{2(1+c_t-2c^2)}}, \quad \tilde{c}_{24}=-\sqrt{\frac{(1+c_s)(1+c_t)-4c^2}{2(1+c_s-2c^2)}},$$

$$\tilde{c}_{34}=-c\sqrt{\frac{(1-c_s)(1-c_t)}{(1+c_s-2c^2)(1+c_t-2c^2)}}, \quad \tilde{c}_{12}=\tilde{c}_{14}=\tilde{c}_{23}=0. \tag{6.30}$$

We can now read off the three nontrivial dihedral angles,

$$\alpha=\arccos\left(\sqrt{\frac{(1+c_s)(1+c_t)-4c^2}{2(1+c_t-2c^2)}}\right), \quad \gamma=\arccos\left(\sqrt{\frac{(1+c_s)(1+c_t)-4c^2}{2(1+c_s-2c^2)}}\right),$$

$$\beta=\arccos\left(c\sqrt{\frac{(1-c_s)(1-c_t)}{(1+c_s-2c^2)(1+c_t-2c^2)}}\right). \tag{6.31}$$

Finally then the required volume of the full tetrahedron 1234 is obtained from

$$\Omega^{(4)}=4V(\alpha,\beta,\gamma)=S(\pi/2-\alpha,\beta,\pi/2-\gamma). \tag{6.32}$$

A well-known physical example of partially symmetric box diagram is related to the photon–photon scattering.[41] In this case, $k^2=0$, $c=1$, $\cos\beta=1$, $\beta=0$. Furthermore, $\widetilde{D}^{(4)}=\sin^2\alpha\sin^2\gamma-1$ and we should use formula (6.14) for $V(\alpha,0,\gamma)$.

D. The massless limit

In the case when all masses m_i vanish, the quantities c_{jl} become infinite (cf. Eq. (2.4)) and should be be considered as hyperbolic cosines. The determinant $D^{(4)}$, Eq. (6.2), has the following limit:

$$\begin{aligned}(m_1^2m_2^2m_3^2m_4^2D^{(4)})|_{m_i\to0}\Rightarrow{}&\tfrac{1}{16}[(k_{12}^2k_{34}^2)^2+(k_{13}^2k_{24}^2)^2+(k_{14}^2k_{23}^2)^2\\&-2k_{12}^2k_{34}^2k_{13}^2k_{24}^2-2k_{12}^2k_{34}^2k_{14}^2k_{23}^2-2k_{13}^2k_{24}^2k_{14}^2k_{23}^2]\\&=\tfrac{1}{16}\lambda(k_{12}^2k_{34}^2,k_{13}^2k_{24}^2,k_{14}^2k_{23}^2)\end{aligned} \tag{6.33}$$

with $\lambda(x,y,z)$ defined by Eq. (1.1).

The elements of the dual matrix $\|\widetilde{c}_{jl}\|$ still can be interpreted as cosines of the dihedral angles, namely,

$$\widetilde{c}_{12}=\widetilde{c}_{34}=-\cos\psi_{34}=-\cos\psi_{12}=\frac{k_{13}^2k_{24}^2+k_{14}^2k_{23}^2-k_{12}^2k_{34}^2}{\sqrt{k_{13}^2k_{24}^2k_{14}^2k_{23}^2}}, \tag{6.34}$$

$$\widetilde{c}_{13}=\widetilde{c}_{24}=-\cos\psi_{24}=-\cos\psi_{13}=\frac{k_{14}^2k_{23}^2+k_{12}^2k_{34}^2-k_{13}^2k_{24}^2}{\sqrt{k_{14}^2k_{23}^2k_{12}^2k_{34}^2}}, \tag{6.35}$$

$$\widetilde{c}_{14}=\widetilde{c}_{23}=-\cos\psi_{23}=-\cos\psi_{14}=\frac{k_{12}^2k_{34}^2+k_{13}^2k_{24}^2-k_{14}^2k_{23}^2}{\sqrt{k_{12}^2k_{34}^2k_{13}^2k_{24}^2}}. \tag{6.36}$$

Therefore, in this situation we get nothing but an *ideal* hyperbolic tetrahedron (see pp. 39–40 of Ref. 40), i.e., the tetrahedron whose vertices are all at infinity. The pairs of opposite dihedral angles of the ideal tetrahedron are equal, $\psi_{12}=\psi_{34}$, $\psi_{13}=\psi_{24}$, $\psi_{14}=\psi_{23}$, whereas its volume is given by

$$\Omega^{(4)}=\frac{1}{2i}\,[\mathrm{Cl}_2(2\psi_{12})+\mathrm{Cl}_2(2\psi_{13})+\mathrm{Cl}_2(2\psi_{23})],\quad \psi_{12}+\psi_{13}+\psi_{23}=\pi, \tag{6.37}$$

according to Eq. (41) of Ref. 40 (see also Ref. 42).

First of all we see that Eqs. (6.33)–(6.36) depend only on the products $k_{12}^2k_{34}^2$, $k_{13}^2k_{24}^2$, and $k_{14}^2k_{23}^2$. This corresponds to the ''glueing'' of arguments in the massless case observed in Ref. 43. Moreover, the result (6.37) is of the same form as the massless three-point function in four dimensions (1.2). This accords completely with the reduction of the massless four-point function to the three-point function which has been proven in Ref. 43.

VII. REDUCTION OF INTEGRALS WITH $N>n$ AND RELATED PROBLEMS

A. Integrals with $N>n$

Consider Eq. (3.45) in the case when $n=N-1$,

$$J^{(N)}(N-1;1,\ldots,1)=\frac{1}{\Lambda^{(N)}}\left(\prod\ m_i^2\right)\sum_{i=1}^{N}\ \frac{1}{m_i^2}\,F_i^{(N)}J_i^{(N)}(N-1;1,\ldots,1). \tag{7.1}$$

The integrals on the right-hand side, $J_i^{(N)}(N-1;1,...,1)$, correspond to splitting the basic N-dimensional simplex into N rectangular ones. The ith rectangular simplex is obtained via substituting the ith mass side of the basic simplex by its height H_0 whose length is m_0. Therefore, the corresponding elements of the $\|c\|$ matrix (2.13) should be replaced by (cf. Eqs. (3.43)–(3.44))

$$c_{ji}\to\cos\ \tau_{0j}=\frac{m_0}{m_j},\quad c_{il}\to\cos\ \tau_{0l}=\frac{m_0}{m_l}. \tag{7.2}$$

At this point let us consider what the representation (3.8) gives for $J_i^{(N)}$. The α-integrand becomes

$$\left(\sum_{l\neq i}\ \frac{\alpha_l}{m_l}+\frac{\alpha_i}{m_0}\right)\delta\left((\alpha^T\|c\|\alpha)\Big|_{\alpha_i=0}+2m_0\alpha_i\sum_{l\neq i}\ \frac{\alpha_l}{m_l}+\alpha_i^2-1\right). \tag{7.3}$$

One can see that the first factor in (7.3) is proportional to the derivative of the argument of the δ function with respect to α_i. Therefore, Eq. (7.3) can be expressed as

$$\frac{1}{2m_0}\frac{\partial}{\partial\alpha_i}\ \theta\left((\alpha^T\|c\|\alpha)\Big|_{\alpha_i=0}+2m_0\alpha_i\sum_{l\neq i}\ \frac{\alpha_l}{m_l}+\alpha_i^2-1\right). \tag{7.4}$$

Integrating over α_i, we get

$$J_i^{(N)}(N-1;1,...,1)=\frac{i^{1-2N}\pi^{(N-1)/2}}{m_0^2\Pi_{l\neq i}m_l}\ \Gamma\left(\frac{N+1}{2}\right)\int_0^\infty\cdots\int_0^\infty\prod_{l\neq i}\ d\alpha_l\theta(1-(\alpha^T\|c\|\alpha)|_{\alpha_i=0}). \tag{7.5}$$

Inserting

$$\frac{1}{N-1}\sum_{l\neq i}\ \frac{\partial\alpha_l}{\partial\alpha_l}=1 \tag{7.6}$$

and integrating by parts, the integrand of (7.5) can be transformed as

$$\begin{aligned}\theta(1-(\alpha^T\|c\|\alpha)|_{\alpha_i=0})&\Rightarrow-\frac{1}{N-1}\left(\sum_{l\neq i}\ \alpha_l\frac{\partial}{\partial\alpha_l}\right)\theta(1-(\alpha^T\|c\|\alpha)|_{\alpha_i=0})\\&\Rightarrow\frac{1}{N-1}\ \delta(1-(\alpha^T\|c\|\alpha)|_{\alpha_i=0})\sum_{l\neq i}\ \alpha_l\frac{\partial}{\partial\alpha_l}(\alpha^T\|c\|\alpha)|_{\alpha_i=0}\\&\Rightarrow\frac{2}{N-1}\ \delta((\alpha^T\|c\|\alpha)|_{\alpha_i=0}-1).\end{aligned} \tag{7.7}$$

Using Eq. (3.8), we arrive at

$$J_i^{(N)}(N-1;1,...,1)=-\frac{1}{2m_0^2}\ J^{(N-1)}(N-1;1,...,1)|_{\text{without }i}. \tag{7.8}$$

Therefore, we get

$$J^{(N)}(N-1;1,...,1)=-\frac{1}{2D^{(N)}}\sum_{i=1}^{N}\ \frac{1}{m_i^2}\ F_i^{(N)}J^{(N-1)}(N-1;1,...,1)|_{\text{without }i}. \tag{7.9}$$

This corresponds to Eq. (47) of Ref. 11, when the number of external legs N is equal to the space–time dimension plus one. For $N=3,4,5$, Eq. (7.9) reproduces Eqs. (10), (8), (13) from Ref. 11, respectively. (For $N=3$, the explicit result was presented in Ref. 10.)

Similar reduction formulas have also been considered in Refs. 8–13. In Ref. 14 it was shown how the linear dependence of external momenta in the case $N\geqslant 6$ and for $n=4$ may be employed

to reduce the N-point function to a set of $(N-1)$-point ones. A method for expressing the five-point function in four dimensions in terms of a sum of four-point functions was first shown in Ref. 7, whereas the reduction of the three-point function in two dimensions was studied in Ref. 10 (see also Ref. 18). These results were generalized in Refs. 8 and 9. For example, in Ref. 8 (see also Ref. 10) the representation for the coefficients corresponding to $F_l^{(N)}$ (Eq. (7) of Ref. 8) is given in terms of the propagators whose momenta are solutions to a certain set of equations corresponding to the other propagators. Moreover, it is possible to make a direct as opposed to step-by-step reduction to n-point functions for any $N>n$. More recently, some other approaches to this problem were suggested in Refs. 12 and 13.

It is also instructive to consider another derivation of Eq. (7.9). The representation (3.8) yields

$$J^{(N)}(N-1;1,...,1)=\frac{2i^{1-2N}\pi^{(N-1)/2}}{\Pi m_l}\,\Gamma\left(\frac{N+1}{2}\right)\int_0^\infty\cdots\int_0^\infty\prod\,d\alpha_l\left(\sum_{i=1}^N\,\frac{\alpha_i}{m_i}\right)\delta(\alpha^T\|c\|\alpha-1). \tag{7.10}$$

Using Eq. (2.33) we get

$$\sum_{i=1}^N\,\frac{\alpha_i}{m_i}=\frac{1}{D^{(N)}}\sum_{i=1}^N\,\alpha_i\sum_{l=1}^N\,\frac{c_{il}}{m_l}\,F_l^{(N)}=\frac{1}{D^{(N)}}\sum_{i=1}^N\,\frac{F_i^{(N)}}{m_i}\sum_{l=1}^N\,c_{il}\alpha_l\,. \tag{7.11}$$

Repeating steps (7.3)–(7.7) for the resulting α-integrals, we arrive at the following result:

$$\frac{2i^{1-2N}\pi^{(N-1)/2}}{\Pi m_l}\,\Gamma\left(\frac{N+1}{2}\right)\int_0^\infty\cdots\int_0^\infty\prod\,d\alpha_l\left(\sum_{l=1}^N\,c_{il}\alpha_l\right)\delta(\alpha^T\|c\|\alpha-1)$$

$$=-\frac{1}{2m_i}\,J^{(N-1)}(N-1;1,...,1)\big|_{\text{without }i}\,. \tag{7.12}$$

Substituting (7.11) and (7.12) into (7.10), we obtain once again Eq. (7.9).

A similar approach can also be used to obtain formulas connecting the integrals with different values of the space–time dimension.[13,44,45]

B. Integrals with higher powers of propagators

Equations like (7.12) can also be used for calculating integrals with higher powers of propagators. Such integrals can be associated with derivatives with respect to m_i^2, provided that m_i and k_{jl}^2 are considered as the set of independent variables. Specifically, consider the sum

$$c_{1i}m_1J^{(N)}(N+1;2,1,1,...,1)+c_{2i}m_2J^{(N)}(N+1;1,2,1,...,1)$$

$$+\cdots+c_{iN}m_NJ^{(N)}(N+1;1,...,1,2)\equiv\sum_{l=1}^N\,c_{il}m_lJ^{(N)}(N+1;\{1+\delta_{lj}\}). \tag{7.13}$$

(The notation for the set of arguments $\{\nu_j\}=\{1+\delta_{lj}\}$ means that all powers of denominators are equal to one, except for the ν_l which is equal to two. As usually, it is implied that $c_{ji}=c_{ij}$ and $c_{ii}=1$.) Employing the representation (3.8) for all integrals in (7.13), we obtain the same integral as in Eq. (7.12), multiplied by $(-\pi)$. Therefore, we get a system of equations which can be displayed in the matrix form,

$$\|c_{jl}\|\begin{pmatrix} m_1J^{(N)}(N+1;2,1,1,...,1)\\ m_2J^{(N)}(N+1;1,2,1,...,1)\\ \cdots\\ m_NJ^{(N)}(N+1;1,1,...,1,2)\end{pmatrix}=\frac{\pi}{2}\begin{pmatrix} m_1^{-1}J^{(N-1)}(N-1;1,...,1)\big|_{\text{without }1}\\ m_2^{-1}J^{(N-1)}(N-1;1,...,1)\big|_{\text{without }2}\\ \cdots\\ m_N^{-1}J^{(N\text{-}1)}(N-1;1,...,1)\big|_{\text{without }N}\end{pmatrix}. \tag{7.14}$$

The matrix inverse to $\|c_{jl}\|$ is given by Eq. (2.25). Applying $\|c_{jl}\|^{-1}$ to both sides, we get

$$\begin{pmatrix} (m_1/\sqrt{D_{11}^{(N-1)}})J^{(N)}(N+1;2,1,1,...,1) \\ (m_2/\sqrt{D_{22}^{(N-1)}})J^{(N)}(N+1;1,2,1,...,1) \\ \cdots \\ (m_N/\sqrt{D_{NN}^{(N-1)}})J^{(N)}(N+1;1,1,...,1,2) \end{pmatrix}$$

$$= \frac{\pi}{2D^{(N)}} \|\widetilde{c}_{jl}\| \begin{pmatrix} m_1^{-1}\sqrt{D_{11}^{(N-1)}}J^{(N-1)}(N-1;1,...,1)|_{\text{without } 1} \\ m_2^{-1}\sqrt{D_{22}^{(N-1)}}J^{(N-1)}(N-1;1,...,1)|_{\text{without } 2} \\ \cdots \\ m_N^{-1}\sqrt{D_{NN}^{(N-1)}}J^{(N-1)}(N-1;1,...,1)|_{\text{without } N} \end{pmatrix}. \tag{7.15}$$

(Similar results can also be obtained using the integration-by-parts approach.[46,23])

Using the expression (2.24) for $\widetilde{c}_{jN}$, we arrive at

$$J^{(N)}(N+1;\{1+\delta_{il}\}) = \frac{\pi}{2m_l D^{(N)}} \sum_{j=1}^{N} \frac{(-1)^{j+l}}{m_j} D_{jl}^{(N-1)} J^{(N-1)}(N-1;1,...,1)|_{\text{without } j}. \tag{7.16}$$

In particular, in the three-point four-dimensional case we end up with

$$J^{(3)}(4;1,1,2) = \frac{i\pi^2 \sin \tau_{12}}{2m_1 m_2 m_3^2 D^{(3)}} [\tau_{23} \cos \psi_{13} + \tau_{13} \cos \psi_{23} + \tau_{12}]. \tag{7.17}$$

The results for $J^{(3)}(4;1,2,1)$ and $J^{(3)}(4;2,1,1)$ can be obtained by permutation of indices. The sum of these three integrals is in agreement with the result obtained in Ref. 18.

It is easy to check the consistency of the results (7.16) and (7.9). Using the standard Feynman parametric representation (or the representation (3.8) involving the δ function of the quadratic form) it is straightforward to show that

$$\sum_{j=1}^{N} J^{(N)}(N+1;\{1+\delta_{ij}\}) = -\pi J^{(N)}(N-1;1,...,1). \tag{7.18}$$

[The generalization of this formula to the case of arbitrary n and the powers of the propagators ν_i can be found, e.g., in Ref. 47, Eq. (6).] Considering the sum of the integrals (7.16) and employing the relation (7.18), we arrive at Eq. (7.9).

VIII. CONCLUSION

Let us briefly summarize the main results of the present paper. We have proven that there is a direct link between Feynman parametric representation of a one-loop N-point function and the basic simplex in N-dimensional Euclidean space. To show this, we have changed the surface of integration in the Feynman parametric representation, from a linear one ($\Sigma \alpha_i = 1$) to a quadratic one ($\alpha^T \|c\| \alpha = 1$). The integral representation involving the δ function of this quadratic form is given by Eq. (3.8).

In the case $N = n$, the result for the Feynman integral turns out to be proportional to the ratio of an N-dimensional solid angle at the meeting point of the mass sides to the content of the N-dimensional basic simplex. (Moreover, in the case $N = n$ the result for the diagram with unequal masses can be expressed in terms of the function corresponding to the equal-mass case.) For example, to reproduce the result for the three-dimensional three-point function[11] we just require the expression for the area of a spherical triangle which can easily be calculated as the sum of the angles minus π (in general, an analytic continuation of the area function should be taken).

For the four-dimensional four-point function, the representation (3.8) provides a very interesting connection with the volume of the non-Euclidean (spherical or hyperbolic) tetrahedron. By splitting the non-Euclidean tetrahedron into birectangular ones, the latter can be expressed in terms of dilogarithms or related functions. (A compact integral representation for this volume can be found in Ref. 48.) Different ways of splitting correspond to different representations of the result for the four-point function. This ''freedom'' can be used to construct more compact representations (cf. Refs. 3, 2, 4).

In other cases, such as, for example, the four-dimensional three-point function, we get an extra factor in the integrand corresponding to a power of the cosine of the angle between the height of the basic simplex and the vector of integration. In general, the height of the basic simplex, H_0, plays an essential role in calculation of the integrals with $N \neq n$. It is used to split the basic Euclidean simplex into N rectangular simplices. When $N=n+1$, each integral corresponding to one of the resulting rectangular tetrahedra can be reduced to an $(N-1)$-point function. When $N<n$, this splitting also simplifies the calculation of separate integrals.

The derivations in this paper have been based on a purely geometrical approach to evaluation of N-point Feynman diagrams. In the resulting expressions, all arguments of functions arising possess a straightforward geometrical meaning in terms of the dihedral angles, etc. In particular, this is quite useful for choosing the most convenient kinematic variables to describe the N-point diagrams. We suggest that this approach can serve as a powerful tool for understanding the geometrical structure of loop integrals with several external legs, as well as the structure of the corresponding phase-space integrals (see, e.g., Ref. 49). More optimistically, it may shed light on analytical results for higher loops.

Note added in proof: After our manuscript was accepted for publication Ref. 50 appeared, which deals with nonrelativistic Feynman integrals. It cited Ref. 51 where the relativistic one-loop Feynman amplitudes (in Euclidean quantum field theory) were studied and expressed in terms of definite integrals over simplices. We also note that some representations for the Schläfli function (similar to those discussed in Sec. VI B) can be found in Ref. 52.

A.I.D.'s research was partly supported by Grant Nos. INTAS–93-0744 and RFBR–96-01-00654.

APPENDIX A: DILOGARITHM AND RELATED FUNCTIONS

Here we present definitions and some representations of the dilogarithm and related functions. More detailed information can be found in Ref. 27.

The Euler's dilogarithm is defined by

$$\mathrm{Li}_2(z) \equiv -z \int_0^1 d\xi \, \frac{\ln \xi}{1-\xi z}. \tag{A1}$$

The Clausen function is related to the imaginary part of the dilogarithm,

$$\mathrm{Cl}_2(\theta) = \mathrm{Im}[\mathrm{Li}_2(e^{i\theta})] = -\int_0^\theta d\theta' \, \ln\left|2\sin\left(\tfrac{1}{2}\theta'\right)\right|, \tag{A2}$$

and it can also be represented as

$$\mathrm{Cl}_2(\theta) = -\sin\theta \int_0^1 \frac{d\xi \, \ln \xi}{1-2\xi\cos\theta+\xi^2}. \tag{A3}$$

Note that $\mathrm{Cl}_2(2\pi-\theta) = -\mathrm{Cl}_2(\theta)$.

If we consider dilogarithm of a general complex argument, $\mathrm{Li}_2(re^{i\theta})$, we get

$$\mathrm{Re}[\mathrm{Li}_2(re^{i\theta})] \equiv \mathrm{Li}_2(r,\theta), \tag{A4}$$

$$\mathrm{Im}[\mathrm{Li}_2(re^{i\theta})] = \omega \ln r + \tfrac{1}{2}[\mathrm{Cl}_2(2\theta)+\mathrm{Cl}_2(2\omega)+\mathrm{Cl}_2(2\chi)], \tag{A5}$$

with $\tan\omega = r\sin\theta/(1-r\cos\theta)$ and $\chi \equiv \pi-\theta-\omega$. We note that

$$\tfrac{1}{2}[\mathrm{Cl}_2(2\theta)+\mathrm{Cl}_2(2\omega)+\mathrm{Cl}_2(2\chi)] = -\sin\theta \int_0^r \frac{d\eta \, \ln \eta}{1-2\eta\cos\theta+\eta^2}. \tag{A6}$$

The imaginary part can also be rewritten as

$$\mathrm{Im}[\mathrm{Li}_2(re^{i\theta})]=\mathrm{Ti}_2(\tan\,\omega)-\mathrm{Ti}_2(\tan\,\omega,\tan\,\theta)=-r\,\sin\,\theta\int_0^1\frac{d\xi\,\ln\,\xi}{1-2r\xi\,\cos\,\theta+r^2\xi^2},\quad\text{(A7)}$$

where $\mathrm{Ti}_2(z)$ and $\mathrm{Ti}_2(z,a)$ are the ordinary and the generalized inverse tangent integrals, respectively,

$$\mathrm{Ti}_2(z)=\int_0^z\frac{dz'}{z'}\arctan\,z',\quad \mathrm{Ti}_2(z,a)=\int_0^z\frac{dz'}{z'+a}\arctan\,z'.\quad\text{(A8)}$$

In particular, $\mathrm{Ti}_2(z)=\mathrm{Ti}_2(z,0)$.

Finally the Lobachevsky function $L(\theta)$ is defined by

$$L(\theta)\equiv-\int_0^\theta d\theta'\,\ln(\cos\,\theta'),\quad(-\tfrac{1}{2}\pi\leqslant\theta\leqslant\tfrac{1}{2}\pi).\quad\text{(A9)}$$

It is related to Clausen's function by

$$\mathrm{Cl}_2(\theta)=-2L\left(\frac{\pi-\theta}{2}\right)+(\pi-\theta)\,\ln 2,\quad L(\theta)=-\tfrac{1}{2}\mathrm{Cl}_2(\pi-2\theta)+\theta\,\ln 2.\quad\text{(A10)}$$

APPENDIX B: ON THE RESCALING OF α'S

Consider the transformation

$$\alpha_i=\mathscr{G}(\alpha'_1,\ldots,\alpha'_N)\alpha'_i,\quad i=1,\ldots,N,\quad\text{(B1)}$$

where the ''scaling'' function $\mathscr{G}$ is the same for all α's. The Jacobian of the transformation is

$$\text{Jacobian}=\left(\prod_{j=1}^N\alpha'_j\,\frac{\partial\mathscr{G}}{\partial\alpha'_j}\right)\begin{vmatrix}1+d_1 & 1 & \cdots & 1\\ 1 & 1+d_2 & \cdots & 1\\ \cdots & \cdots & \cdots & \cdots\\ 1 & 1 & \cdots & 1+d_N\end{vmatrix},\quad d_i\equiv\mathscr{G}\left(\alpha'_i\,\frac{\partial\mathscr{G}}{\partial\alpha'_i}\right)^{-1}.\quad\text{(B2)}$$

Since the determinant in (B2) is equal to

$$\left(\prod_{i=1}^N d_i\right)\left[1+\frac{1}{d_1}+\frac{1}{d_2}+\cdots+\frac{1}{d_N}\right],\quad\text{(B3)}$$

the expression for the Jacobian reduces to

$$\text{Jacobian}=\mathscr{G}^N\left(1+\frac{1}{\mathscr{G}}\sum_{j=1}^N\alpha'_j\,\frac{\partial\mathscr{G}}{\partial\alpha'_j}\right)=\mathscr{G}^N\left(1+\sum_{j=1}^N\alpha'_j\,\frac{\partial(\ln\,\mathscr{G})}{\partial\alpha'_j}\right).\quad\text{(B4)}$$

If $\mathscr{G}$ is a homogeneous function of α's of the order R, i.e.,

$$\mathscr{G}(Z\alpha'_1,\ldots,Z\alpha'_N)=Z^R\mathscr{G}(\alpha'_1,\ldots,\alpha'_N),\quad\text{(B5)}$$

then

$$\sum_{j=1}^N\alpha'_j\,\frac{\partial\mathscr{G}}{\partial\alpha'_j}=R\mathscr{G}\ \text{ and }\ \text{Jacobian}=[1+R]\mathscr{G}^N.\quad\text{(B6)}$$

In particular, if $\mathscr{G}=Q_r/Q'_{r'}$, where Q_r is a polynomial of degree r and $Q'_{r'}$ is a polynomial of degree r' in α', Jacobian$\to[1+(r-r')]\mathscr{G}^N$, i.e., $R=r-r'$. In the text we have encountered the situations when $r=r'=1$ $(R=0)$ and $r=2$, $r'=1$ $(R=1)$.

I. INTRODUCTION

This work is a contribution to the investigations of some quantum systems under general time-dependent Hamiltonians; physical problems with nonperiodic characters have been discussed mainly in the context of discrete Schrödinger operators,[1–4] models in statistical mechanics and dynamical systems.[5–7] Besides the intrinsic physical interest, two other points justify these choices: the discovery of quasicrystals[8,9] and the rather well-developed techniques to treat such problems (mainly in one dimension).

The investigations become even more exciting as soon as one realizes that there are many different kinds of nonperiodicity, ranging from quasiperiodic to random. An effective way to materialize nonperiodicities is by considering sequences of substitution. The autocorrelation of each sequence probes its randomness; there are examples of (nonperiodic) substitution sequences with pure point, pure singular continuous, and even pure absolutely continuous autocorrelation measures.[10,11] Inserting in some way these sequences in physical models and understanding their influences is a problem of major interest currently.

Another attractive area for the investigation of the influence of nonperiodicity is the dynamical behavior of systems with time-dependent Hamiltonians. In this context there is a lack of tools to investigate the asymptotic behavior of such systems as time goes to infinity, at least when compared with statistical mechanics, dynamical systems and the analysis of tight-binding models. Although there is a generalization of the Floquet operator for the case of quasiperiodic forces (finite number of fundamental frequencies),[12] no such generalization seems evident for general time dependence (see, e.g., Ref. 13). An important point here is the quantum autocorrelation measure, a notion that is expected to replace the concept of spectral measures[14] (recall that we have a family of possible different Hamiltonians), but even in the case of periodic Hamiltonians it may be very difficult to compute the autocorrelation functions and the corresponding measures. See Ref. 15 for some rare explicit computations in the case of kicked Hamiltonians driven by the Thue–Morse sequence and Refs. 16–18 for related numerical tricks and comments.

In Ref. 19 (see also Refs. 20 and 21 and references therein for other investigations on nonautonomous quantum systems) another quantity has been proposed to study the dynamical behavior of quantum systems driven by the Fibonacci substitution sequence. It is strongly based on the notion of Fourier transform and on a conjecture of Bombieri and Taylor[22,23] about diffraction by nonperiodic structures, and we shall denote this quantity by $\mathscr{B}$ (see Sec. II for precise statements). It is expected that in some cases $\mathscr{B}$ should be easier to compute than autocorrelation functions and that it gives information about the point part of the autocorrelation measures. Nevertheless, no relation between $\mathscr{B}$ and autocorrelation measures has been explicitly considered yet. Therefore we have a ''dynamical conjecture,'' i.e., it is necessary to clarify the relations between $\mathscr{B}$ and the autocorrelation measures of general time-dependent quantum systems. We refer to this problem as ''the dynamical version of the Bombieri–Taylor conjecture.'' The main

goals of this work are to formulate precisely this problem and present a proof (not its applications).

This work is organized as follows. In Sec. II we briefly recall the original Bombieri–Taylor conjecture and set up a rigorous formulation of its dynamical version. In Sec. III a proof of this ''dynamical conjecture'' is given. In Sec. IV we discuss some particular cases.

II. THE PROBLEM

A. The Bombieri–Taylor prescription

In this subsection we recall the Bombieri–Taylor argument. The general question raised by Bombieri and Taylor[22,23] is ''what nonperiodic distribution of matter would show spots in a diffraction experiment.'' In a diffraction experiment one measures the intensity of the scattered radiation (x-rays, for example) from a material, and this intensity tells us about the microscopic structure of the material. A regularity in the bright spots pattern indicates an organization of the structure and was usually related only to crystals until the experimental discovery of the so-called quasicrystals.[8] See Ref. 24 for a discussion about the definitions of crystals and quasicrystals and Steffen Weber's home page[9] for an updated introduction to the subject.

Let $X=\{x_j\}_{j=0}^{\infty}$ be a countable set in $\mathbb{R}$ with no accumulation point (here it is enough to consider dimension one), which represents the positions of the atoms in a sample of matter. The diffraction pattern is related to the Fourier transform of the density distribution of atoms; in this case the density is represented by the measure

$$\rho(x)=\sum_{x_j\in X}\delta(x-x_j),$$

where δ denotes the Dirac measure. According to Bombieri–Taylor, the set X looks ordered in a diffraction experiment if the Fourier transform of ρ, i.e., $\hat{\rho}$, has the form

$$\hat{\rho}(\xi)=\sum_{\lambda\in Y}a_\lambda\delta(\xi-\lambda)+g(\xi)$$

with Y being a subset of $\mathbb{R}$. The presence of an atomic part (i.e., δ terms) in $\hat{\rho}$ is the indication of long-range correlations in the atomic positions and is an effect of constructive interference. The function g would describe a diffusive background. The Bombieri–Taylor question has been discussed and accurately modified by Hof.[25]

In order to decide if $\hat{\rho}$ has an atomic part at $\xi\in\mathbb{R}$, Bombieri–Taylor argued that this will occur if and only if

$$F_N(\xi)=\sum_{j=0}^{N}\exp(2\pi i\xi x_j)$$

is such that the ratio $F_N(\xi)/(N+1)$ has a nonzero limit as N goes to infinity. Since they did not present a justification of this statement, one calls it a conjecture. Certainly it has its roots in the Wiener–Khinchin theorem.[26] We refer to Refs. 25 and 27 for a discussion about this conjecture, including references of applications to physical models.

B. The dynamical version

In this subsection we discuss the dynamical version of the Bombieri–Taylor conjecture. The physical framework here is composed by quantum systems subjected to kicks at each positive integer instant of time. Let $\{V_j\}$ be a sequence of potentials; the Hamiltonian we consider is

$$H=H_0+\sum_{j=1}^{\infty}V_j\delta(t-j).$$

Notice that a kick does not occur at instant n if V_n is the null function.

We have not specified the Hilbert space $\mathscr{H}$ in which the operators act since, for our results, it is relevant only for the existence of dynamics. In this respect we suppose the operators involved are self-adjoint and, by using a standard construction, we suppose the propagator between $t=(j-1+0)$ and $t=(j+0)$ has been found and is given by a unitary operator U_j acting on $\mathscr{H}$. We shall denote the evolution operator from the initial instant $t=0$ until $t=n+0$ by $\Lambda(n)$, so that

$$\Lambda(n)=U_nU_{n-1}\cdots U_1.$$

The general question to be addressed is about the asymptotic behavior of $\Lambda(n)$ for n large. This kind of question is commonly referred to as the quantum stability problem and for autonomous systems a major role is played by the Hamiltonian spectrum. Continuous spectrum and point spectrum entail different dynamical behaviors. For general nonautonomous systems we do not have a spectral theory at our disposal, so that one has to use other tools to classify the dynamical behavior of these systems. On the basis of the Bombieri–Taylor conjecture and the idea that point spectrum is also a kind of constructive interference, in Ref. 19 a dynamical version of the Bombieri–Taylor conjecture was proposed and applied to two-level systems subjected to kicks modulated along the Fibonacci substitution sequence.

The authors of Ref. 19 argued that a pointlike (''quasiperiodic'') dynamical behavior is present if for some $\omega\in\mathbb{R}$ the quantity

$$G_N(\omega)=\sum_{j=0}^{N} e^{ij\omega}\Lambda(j)$$

is such that $G_N/(N+1)$ has a nonzero limit for $N\to\infty$. The application of this conjecture was also the focus of Refs. 20 and 21.

The admitted generalization of spectrum for nonautonomous systems is given by the support of autocorrelation measures. The autocorrelation function for $\psi\in\mathscr{H}$ (assume $\|\psi\|=1$) is

$$C_\psi(k)=\lim_{N\to\infty}\frac{1}{N+1}\sum_{j=0}^{N}\langle\Lambda(j+k)\psi|\Lambda(j)\psi\rangle$$

for integers numbers $k\geqslant 0$, and we define $C_\psi(-k)=\overline{C_\psi(k)}$ (the limits are supposed to exist). This function is of positive type and so is the Fourier transform of a unique positive measure σ_ψ, the so-called autocorrelation measure associated with ψ. The key observation is that for autonomous systems the autocorrelation measure σ_ψ is the spectral measure μ_ψ of the Hamiltonian operator[14] [this can be easily seen by direct substitution of $\Lambda(n)=\exp(-inH)$ into the limit that defines $C_\psi(k)$].

In analogy with the case of diffraction, the general question now can be put in the following form: which kind of kick mimics a pointlike component in the system time evolution? In other words, which kind of kick generates deltas (atoms) in the autocorrelation measures? Therefore, the dynamical version of the Bombieri–Taylor conjecture is to relate the limit of $G_N/(N+1)$ with the point part of autocorrelation measures.

C. Main results

In this subsection we give a precise formulation of the dynamical version of the conjecture and state the main results of this work. Let $\{U_j\}_{j=1}^{\infty}$ be a sequence of unitary operators acting on the Hilbert space $\mathscr{H}$ and set $\Lambda(n)=U_nU_{n-1}\ldots U_1$, $\Lambda(0)=\mathrm{Id}$ (the identity operator). Suppose that for any $\psi\in\mathscr{H}$ the autocorrelation function exists and denote by σ_ψ the corresponding autocorrelation measure. In general, the proof of the existence of the autocorrelation function is far from trivial and should be analyzed separately in each case.

For $\omega\in[0,2\pi]$ (it is enough to consider ω values in this interval) set

$$\phi_N(\omega)=\frac{1}{N+1}\sum_{j=0}^{N}\exp(ij\omega)\Lambda(j)$$

and

$$\mathscr{B}_\psi(\omega)=\limsup_{N\to\infty}\|\phi_N(\omega)\psi\|^2.$$

Theorem 1: *Suppose the autocorrelation functions of* Λ *exist. Then, for any* $\omega\in[0,2\pi]$, $\psi\in\mathscr{H}$, *we have* $0\leqslant\mathscr{B}_\psi(\omega)\leqslant 2\sigma_\psi(\{\omega\})$.

Corollary 1: If σ_ψ *is a continuous measure, then* $\mathscr{B}_\psi(\omega)=0$ *for any* ω.

Corollary 2: If for some ω *we have* $\mathscr{B}_\psi(\omega)>0$, *then* σ_ψ *has an atom at* ω.

The above Theorem and Corollaries constitute the rigorous formulation of the dynamical version of the Bombieri–Taylor conjecture; see Sec. IV for a nonperiodic example such that $\mathscr{B}_\psi(\omega)<\sigma_\psi(\{\omega\})$. We suspect the factor ''2'' in Theorem 1 is an artifact of our nonoptimal estimates and should be replaced by ''1.'' Another useful concept borrowed from material science is the structure factor.[5,7]

Definition 1: For each ω *set*

$$\Xi_N(\omega)=\frac{1}{N+1}\left[\sum_{j=0}^{N}e^{-ij\omega}\Lambda^*(j)\right]\left[\sum_{j=0}^{N}e^{ij\omega}\Lambda(j)\right].$$

Any weak limit point of the sequence of absolutely continuous measures*

$$d\nu_N(\omega)=\langle\Xi_N(\omega)\psi|\psi\rangle d\omega$$

will be called a structure factor *for* Λ *(associated with* ψ*).*

Theorem 2: *Suppose the autocorrelation functions of* Λ *exist. Then, for each* ψ, Λ *has a unique structure factor and it coincides with the autocorrelation measure* σ_ψ.

In other words, Theorem 2 says that the sequence of measures $d\nu_N(\omega)$ converges in the weak* topology to the autocorrelation measure of ψ (in case this autocorrelation exists). This could be of practical relevance since one can approximate autocorrelation measures by absolutely continuous measures (with respect to Lebesgue measure).

III. PROOFS

We begin with some notation. For any Borelian measure μ on the unit circle S we shall denote its Fourier transform by $\hat{\mu}(k)=\int_0^{2\pi}e^{-ikx}\mu(dx)$, $k\in\mathbb{Z}$, and for any integrable function f we shall also denote $\mu(f)=\int f d\mu$. In many opportunities we shall drop the index ψ.

Proof of Theorem 1: Direct substitution gives

$$\|\phi_N(\omega)\psi\|^2=\frac{1}{(N+1)^2}\sum_{n,j=0}^{N}\exp(i(n-j)\omega)\langle\Lambda(n)\psi|\Lambda(j)\psi\rangle=\frac{1}{N+1}\sum_{k=-N}^{N}\exp(ik\omega)C_N(k),$$

where $C_N(k)$ depends on ψ and, for $-N\leqslant k\leqslant N$, it is given by

$$C_N(k)=\frac{1}{N+1}\sum_{j=0}^{N-k}\langle\Lambda(j+k)\psi|\Lambda(j)\psi\rangle,\quad k\geqslant 0,$$

and $C_N(-k)=\overline{C_N(k)}$. We extend C_N for $|k|>N$ by defining

$$C_N(k)=\frac{1}{N+1}\sum_{j=0}^{N}\langle\Lambda(j+k)\psi|\Lambda(j)\psi\rangle,\quad k>N,$$

and $C_N(-k)=\overline{C_N(k)}$. Therefore, for each N there is a measure σ^N such that $C_N(k)=\hat{\sigma}^N(k)$ for any $k\in\mathbb{Z}$. Notice that, for normalized vectors, σ^N are probability measures.

Since it is supposed that the autocorrelation functions exist, it is readily checked that, for each $k\in\mathbb{Z}$, $C_N(k)\to C_\psi(k)$ for $N\to\infty$; therefore, $\hat{\sigma}^N(k)\to\hat{\sigma}_\psi(k)$ for each integer k and $\sigma^N\to\sigma_\psi$ in the weak* topology.

Now we rewrite

$$\|\phi_N(\omega)\psi\|^2=\frac{1}{N+1}\sum_{k=-N}^{N}\exp(ik\omega)\int_0^{2\pi}\exp(-ikx)\sigma^N(dx)=\sigma^N(f_N),$$

where $f_N(x)=(1/(N+1))\Sigma_{k=-N}^{N}\exp(ik(\omega-x))$ is a continuous function for each N. Notice that $|f_N|\leqslant 2$ and that $f_N\to 2\chi_{\{\omega\}}$ (the characteristic function of the set $\{\omega\}$) for $N\to\infty$.

Let $0<\epsilon<1$ and set $A_\epsilon(\omega)=[\omega-\epsilon,\omega+\epsilon]\cap[0,2\pi]$. For N large we have

$$0\leqslant\sigma^N(f_N)=\sigma^N(\chi_{A_\epsilon}f_N)+\sigma^N((1-\chi_{A_\epsilon})f_N)\leqslant\sigma^N(\chi_{A_\epsilon}|f_N|)+\sigma^N((1-\chi_{A_\epsilon})|f_N|)$$

$$\leqslant 2\sigma^N(\chi_{A_\epsilon})+\sigma^N((1-\chi_{A_\epsilon})|f_N|).$$

Since $\epsilon>0$, it follows that $(1-\chi_{A_\epsilon})|f_N|\to 0$ uniformly and $\sigma^N((1-\chi_{A_\epsilon})|f_N|)\leqslant c\epsilon/N$ for some positive constant c. Therefore,

$$0\leqslant\sigma^N(f_N)\leqslant 2\sigma^N(\chi_{A_\epsilon})+c\epsilon/N.$$

Since A_ϵ is a closed set, it follows that $\limsup_{N\to\infty}\sigma^N(\chi_{A_\epsilon})\leqslant\sigma_\psi(\chi_{A_\epsilon})$.[28] Therefore, taking the lim sup for $N\to\infty$ in the above expression we obtain

$$0\leqslant\mathscr{B}_\psi(\omega)\leqslant 2\sigma_\psi(\chi_{A_\epsilon}).$$

Now consider a sequence $\epsilon_n\downarrow 0$ so that $\cap_{n=1}^{\infty}A_{\epsilon n}=\{\omega\}$; σ_ψ being a finite measure, the theorem follows.

Remark: If $C_N(k)$ converges uniformly to $C_\psi(k)$, then it is possible to show that $\mathscr{B}_\psi(\omega)=\sigma_\psi(\{\omega\})=0$ for all ω.

Proof of Theorem 2: We have $\Xi_N(\omega)=1/(N+1)\Sigma_{j=0}^{N}\Sigma_{k=-j}^{N-j}e^{ik\omega}\Lambda^*(j)\Lambda(j+k)$, so that

$$d\nu_N(\omega)=\left[\frac{1}{N+1}\sum_{j=0}^{N}\sum_{k=-j}^{N-j}e^{ik\omega}\langle\Lambda(j+k)\psi|\Lambda(j)\psi\rangle\right]d\omega;$$

its Fourier transform is given by ($r\in\mathbb{Z}$ and $N>|r|$)

$$\hat{\nu}_N(r)=\frac{1}{N+1}\sum_{j=0}^{N}\sum_{k=-j}^{N-j}\delta_{k,r}\langle\Lambda(j+k)\psi|\Lambda(j)\psi\rangle=\frac{1}{N+1}\sum_{j=0}^{N}\langle\Lambda(j+r)\psi|\Lambda(j)\psi\rangle.$$

Therefore, $\hat{\nu}_N(r)\to\hat{\sigma}_\psi(r)$ for any r and ν_N weak* converges to σ_ψ.

IV. PARTICULAR CASES

A. Example

Here we present an example of a nonperiodic sequence $\{U_j\}$ for which $\mathscr{B}_\psi(\omega)=0$ for any ω but $\sigma_\psi(\{0\})=1$. This shows that the ''if and only if'' part of the dynamical version of the Bombieri–Taylor conjecture cannot hold without further restrictions. This example is a very simple adaptation of an analysis of Allouche and Mendès France[29] and was also used in Ref. 27.

Take $\Lambda(n)=\exp(2\pi in^{1/3})Id$ for each $n\in\mathbb{Z}$ acting on a Hilbert space $\mathscr{H}$. Thus

$$\phi_N(\omega=0)=\frac{1}{N+1}\sum_{j=0}^{N}\exp(2\pi ij^{1/3})\mathrm{Id}.$$

By the Fejer theorem[30] the sequence $\{j^{1/3}\bmod(1)\}_{j=0}^{\infty}$ is uniformly distributed in $[0,1]$. Therefore

$$\phi_N(0)\psi=\frac{1}{N+1}\sum_{j=0}^{N}\exp(2\pi ij^{1/3})\psi\to 0$$

for $N\to\infty$ and $\mathscr{B}_\psi(0)=0$ for any normalized $\psi\in\mathscr{H}$.

On the other hand,

$$d\nu_N(\omega)=\left[\frac{1}{N+1}\sum_{j,n=0}^{N}\exp(i(j-n)\omega)\exp(-i2\pi(j^{1/3}-n^{1/3}))\right]\|\psi\|^2 d\omega$$

so that

$$\hat{\nu}_N(k)=\frac{1}{N+1}\sum_{j=0}^{N}\exp(-i2\pi(j^{1/3}-(j+k)^{1/3})).$$

Since $(j^{1/3}-(j+k)^{1/3})\to 0$ for $j\to\infty$, it follows that $\hat{\nu}_N(k)\to 1$ for any $k\in\mathbb{Z}$, so that ν_N weak* converges to the Dirac measure δ_0. By Theorem 2 we get $\sigma_\psi=\delta_0$; then $\sigma_\psi(\{0\})=1$ for any normalized vector ψ, while $\mathscr{B}_\psi(0)=0$.

This example shows that $\mathscr{B}_\psi$ is too sensitive to phase variations, which sometimes is not so important in quantum mechanics, as its autocorrelation measures attest.

B. Periodic case

Here we discuss the case $\Lambda(n)=U_{n-1}U_{n-1}\cdots U_1U_0$ with $\{U_j\}$ being a periodic sequence (of period T) of unitary operators. We have introduced U_0 just for notational convenience.

Let $U_F=\Lambda(T)$ (the Floquet operator) and $L(\omega)=\Sigma_{j=0}^{T-1}\exp(ij\omega)\Lambda(j)$; for each ω, $L(\omega)$ is a bounded operator on the (in this subsection we suppose separable) Hilbert space $\mathscr{H}$ [$\|L(\omega)\|\leqslant T$ for any ω]. Let $\{\psi_k\}$ be an orthonormal basis (of eigenvectors of U_F, $U_F\psi_k=e^{-iT\alpha_k}\psi_k$, with $0\leqslant T\alpha_k<2\pi$) of the point subspace $\mathscr{H}_p$ of U_F; denote the continuous subspace of U_F by $\mathscr{H}_c$ and define $\mathscr{H}_p^1=\{\psi\in\mathscr{H}_p:\psi=\Sigma_k a_k\psi_k$ with $\Sigma_k|a_k|<\infty\}$. $\mathscr{H}_p^1$ is a dense subspace of $\mathscr{H}_p$.

Theorem 3: *(i) If zero is not an eigenvalue of $L(\omega)$ for all ω (i.e., L is invertible) and $\psi\in\mathscr{H}_p^1$, then $\mathscr{B}_\psi(\omega)>0$ if and only if $\mu_\psi(\{\omega\})>0$, where μ_ψ is the spectral measure of U_F associated with ψ.*

(ii) For $\psi\in\mathscr{H}_c$ we have $\mathscr{B}_\psi(\omega)=0$ for all ω.

Corollary 3: If zero is not an eigenvalue of $L(\omega)$ for all ω, then $\mathscr{B}_\psi(\omega)=0$ for all vectors $\psi\in\mathscr{H}_p^1\oplus\mathscr{H}_c$ if and only if $\omega\neq\alpha_k$ for all k.

Proof: Each N can be written in the form $N=nT+s$, with $0\leqslant s<T$ and n is an integer number. Then

$$\phi_N(\omega)=\frac{1}{N+1}\sum_{j=0}^{N}\exp(ij\omega)\Lambda(j)=\frac{1}{N+1}\left[\sum_{j=0}^{nT}+\sum_{j=nT+1}^{nT+s}\right]\exp(ij\omega)\Lambda(j)$$

$$=L(\omega)\frac{1}{N+1}\sum_{j=0}^{n-1}\exp(ijT\omega)U_F^j+\frac{1}{N+1}\sum_{j=nT+1}^{nT+s}\exp(ij\omega)\Lambda(j).$$

By the inequality $\|[1/(N+1)]\Sigma_{j=nT+1}^{nT+s}\exp(ij\omega)\Lambda(j)\|\leqslant T/(N+1)$ we are justified in discarding the last term in the above expression; it does not contribute to $\mathscr{B}_\psi$. From now on we simply ignore it.

(i) For an eigenvector of U_F, say ψ_k, we have $\phi_N(\omega)\psi_k\approx(1/T)L(\omega)\times(1/n)\Sigma_{j=0}^{n-1}e^{iTj(\omega-\alpha_k)}\psi_k$; for $N\to\infty$ we have $n\to\infty$ and we get $\mathscr{B}_{\psi_k}(\omega)=(1/T^2)\delta_{\omega,\alpha_k}\|L(\omega)\psi_k\|^2$. Since $\|L(\omega)\psi_k\|\neq 0$ we conclude $\mathscr{B}_{\psi_k}(\omega)\neq 0$ if and only if $\omega=\alpha_k(\omega\in[0,2\pi])$.

Now let $\psi=\Sigma_k a_k\psi_k$ with $\Sigma_k|a_k|<\infty$. Then it is possible to justify an interchange of limits and we obtain

$$\mathscr{B}_\psi(\omega)=\frac{1}{T^2}\left\|L(\omega)\sum_k\delta_{\omega,\alpha_k}a_k\psi_k\right\|^2.$$

By the hypothesis that $L(\omega)$ is invertible it follows that $\mathscr{B}_\psi(\omega)\neq 0$ if and only if the vector $\Sigma_k\delta_{\omega,\alpha_k}a_k\psi_k\neq 0$, and this happens if and only if $\omega=\alpha_k$ for some k and $a_k\neq 0$. This proves the first part of Theorem 3.

(ii) Let $\psi\in\mathscr{H}_c$. Taking into account that $(1/T)\|L(\omega)\|\leqslant 1$. We obtain

$$\|\phi_N(\omega)\| \leqslant \left\| \frac{1}{n} \sum_{j=0}^{n-1} \exp(ijT\omega) U_F^j \psi \right\|.$$

(Recall we have discarded a small term.) From this it follows that

$$\|\phi_N(\omega)\|^2 \leqslant \frac{1}{n^2} \sum_{j,k=0}^{n-1} |\langle \psi | U_F^{k-j} \psi \rangle|;$$

the right-hand side of this expression vanishes for $N \to \infty$, as it is shown in Ref. 31, p. 165. This proves the second part of Theorem 3.

Remark: The spectral measures of U_F are closely related to the autocorrelation measures of Λ.[14]

Remark: By using Theorem 3 it is easy to construct examples with $\mathscr{B}_\psi < \sigma_\psi$; choose the periodic sequence $\{U_j\}$ such that $L(\omega) = 0$. For instance, take $U_0 = \mathrm{Id}$. $U_1 = -\mathrm{Id}$, and repeat these values periodically (period 2). In this case $L(0) = 0$ while $\sigma_\psi = \delta_0$ for all normalized vector ψ. Therefore $0 = \mathscr{B}_\psi(0) < \sigma_\psi(\{0\}) = 1$. The example in the previous subsection shows that this can also happen in the nonperiodic case.

C. Period one

Here $T = 1$ and the situation is simpler than the general periodic case. We have a constant sequence of unitary operators, i.e., there is a unitary operator U_F such that $U_j = U_F$ for all $j > 0$ and $\Lambda(n) = U_F^n$ ($U_0 = \mathrm{Id}$). In this case it is readily seen that the autocorrelation measures of Λ are exactly the spectral measures of U_F.

By following the arguments of the previous subsection, with $L(\omega) = \mathrm{Id}$, for $\psi \in \mathscr{H}_p$ ($= \mathscr{H}_p(U_F)$), $\psi = \Sigma_k a_k \psi_k$, one obtains (no additional condition on ψ is needed)

$$\|\phi_N(\omega)\psi\|^2 = \sum_k |a_k|^2 \left| \frac{1}{N+1} \sum_{j=0}^{N} \exp(i(\omega - \alpha_k)) \right|^2.$$

Therefore, for $N \to \infty$ we find $\mathscr{B}_\psi(\omega) = \Sigma_k \delta_{\omega,\alpha_k} |a_k|^2 = \mu_\psi(\{\omega\})$, where μ_ψ is the spectral measure of U_F associated to ψ.

For $\psi \in \mathscr{H}_c$ one also gets $\mathscr{B}_\psi(\omega) = 0$ for all ω, as a consequence of the RAGE theorem[31] (similar to what we argued in the previous section). Summing up,

Theorem 4: *Let U_F be a unitary operator on the separable Hilbert space $\mathscr{H}$ and $\{\mu_\psi\}$ its spectral measures. If $\Lambda(n) = U_F^n$, then $\mathscr{B}_\psi(\omega) = \mu_\psi(\{\omega\}) = \sigma_\psi(\{\omega\})$ for any $\psi \in \mathscr{H}$.*

Remark: Suppose $\{U_j\}$ is a periodic sequence of period T. Defining

$$\tilde{\mathscr{B}}_\psi(\omega) = \limsup_{N \to \infty} \left\| \frac{1}{N+1} \sum_{j=0}^{N} \exp(ijT\omega) U_F^j \psi \right\|^2,$$

one obtains results analogous to Theorem 4 (but now for periodic systems) with $\tilde{\mathscr{B}}_\psi$ instead of $\mathscr{B}_\psi$. What is crucial here is that L becomes the identity operator. This idea of using ''symmetries'' to redefine $\mathscr{B}_\psi$ may also be fruitful in other cases.

(Received 7 October 1997; accepted for publication 14 May 1998)

By means of the geometric algebra the general decomposition of SU(2) gauge potential on the sphere bundle of a compact and oriented four-dimensional manifold is given. Using this decomposition theory the SU(2) Chern density has been studied in detail. It shows that the SU(2) Chern density can be expressed in terms of the δ-function $\delta(\phi)$. One can also find that the zero points of the vector fields ϕ are essential to the topological properties of a manifold. It is shown that there exists the crucial case of branch process at the zero points. Based on the implicit function theorem and the Taylor expansion, the bifurcation of the Chern density is detailed in the neighborhoods of the bifurcation points of ϕ. It is pointed out that, since the Chern density is a topological invariant, the sum topological chargers of the branches will remain constant during the bifurcation process. © *1998 American Institute of Physics.* [S0022-2488(98)02809-6]

I. INTRODUCTION

The topological properties of physics systems play important roles in studying some physical problems. It is well known that the gauge potential (connection) and gauge field (curvature) are essential to establish a direct relationship between differential geometry and topological invariants. The decomposition theory of gauge potential provides a powerful method in researching some topological properties. It has been effectively used to study the topological gauge theory of dislocation and disclinations in condensed matter physics,[1] the geometrization of the Planck constant in terms of the space–time defect in general relativity,[2,3] the space–time dislocations in the early universe,[4] and the Gauss–Bonnet–Chern theorem.[3,5] The essential feature of the decomposition shows that the gauge potential has inner structure.[6,1] Generally, the topological characteristics of a manifold are represented by the properties of a smooth vector field on it, or, in other words, the smooth vector fields carry the topological information of a manifold, which inspires us to study the decomposition theory of the gauge potential in terms of the unit vector field on the manifold.

It is well known that the SU(2) gauge theory and the second Chern class has been widely used in discussing many physical problems such as the magnetic monopole,[6–9] and the anomaly in nonlinear σ-models,[10] and especially the problems on the four-manifold,[11,12] the instantons,[13–15] the merons,[16,17] the Donsdson theory,[18] and so on. It urges us to study the decomposition theory of the SU(2) gauge potential and the topological properties on the four-manifold.

In this paper, we will establish a general decomposition theory of the SU(2) gauge potential in terms of the unit vector **n** on the compact and oriented four-dimensional manifold. Also, by means of geometric algebra, we can describe the unit vector **n** as an element of Spin(3).[19] One can show that the general decomposition formula of SU(2) gauge potential has a global property. The Chern density of the principal $P(\pi, M, \mathrm{SU}(2))$ will be studied by using the decomposition formula. One shows that the SU(2) Chern density takes the form of the δ-function $\delta(\boldsymbol{\phi})$. The topological structure of the SU(2) Chern density can be labeled by the Brouwer degrees and the Hopf index. Further research shows that there exist the crucial cases of branch process in the topological

density, when the Jacobian $D(\phi/x)=0$. We calculate out the different branches of the Chern density by using the implicit function theorem. It is pointed out that the topological charges will be split at the critical points.

This paper is arranged in five sections. In Sec. II we will study a general decomposition theory of SU(2) gauge potential on a sphere bundle. In Sec. III we will study the topological structure of the SU(2) Chern density by using the decomposition expression given in Sec. II. The bifurcation of the Chern density will be studied in Sec. IV. Last, we present our conclusion.

II. THE DECOMPOSITION THEORY OF SU(2) GAUGE POTENTIAL

In this section we will give the decomposition theory of SU(2) gauge potential in terms of the sphere bundle on a compact and oriented four-dimensional manifold. First we have to give the basic notions which are necessary for our discussions.

Let V be a unit SU(2) Clifford vector

$$V=V^a\sigma_a, \quad a=1,2,3, \tag{1}$$

and

$$V^aV^a=1 \tag{2}$$

in which σ_a are Pauli matrixes and the base of SU(2) Clifford algebra.[20]

The covariant derivative one-form of V is given by

$$DV=dV-[A,V], \tag{3}$$

where A is the SU(2) gauge potential one-form:

$$A=i/2A^a\sigma_a \tag{4}$$

and

$$A^a=A^a_\mu dx^\mu, \quad \mu=0,1,2,3. \tag{5}$$

In gauge theory, the potential one-form undergoes the gauge transformation:

$$A'=SAS^{-1}+dSS^{-1}. \tag{6}$$

In our viewpoint,[6] the gauge potential one-form A can be decomposed and has inner structure. The main feature of the decomposition theory of the gauge potential is that the gauge potential A can be generally decomposed as

$$A=a+b, \tag{7}$$

where a and b are required to satisfy the gauge transformation and vector covariant transformation rules, i.e.,[19]

$$a'=SaS^{-1}+dSS^{-1} \tag{8}$$

and

$$b=SbS^{-1}. \tag{9}$$

From (8) and (9), one can show that the gauge potential A rigorously satisfies the gauge transformation

$$A'=a'+b'=S(a+b)S^{-1}+dSS^{-1}.$$

Let $V_{(i)}$ $(i=1,2,3)$ be an orthonormal basis of SU(2) Clifford vector with the orthogonal relations
