

## A CALCULATION OF THE NUMBER OF POSITIONAL ISOMERS IN SOME AROMATIC SYSTEMS

RUSSELL F. EVANS AND WALTER J. LE QUESNE

*Received February 11, 1949*

Hill (1, 2, 3) and Polya (4, 5, 6) have given detailed mathematical treatments of position isomerism in simple ring compounds. With the exception of a short table (5), the present authors do not believe that the results for aromatic systems have been published. Part II of this paper is devoted to tables of isomers for all possible modes of substitution in the benzene, naphthalene, anthracene, and phenanthrene systems, together with a table showing only the number of isomers, with all the substituents identical, in a number of more complicated aromatic hydrocarbons. Since the calculations were made before the attention of the authors was drawn to the work of Hill and Polya, a résumé of our treatment of this particular problem is given below.

*Method of calculation:* The substituents in the aromatic systems to be considered may be either single atoms or univalent groupings, though for ease of explanation, the word "grouping" is used below. Any question, therefore, of isomerism in the side chain is excluded from this discussion. Optical isomers due to restricted rotation are also not counted.

It will be obvious that the number of dimethylnaphthalenes will be the same as that of the hexamethyl compounds: both of these are referred to as the  $A_6B_2$  naphthalenes. The lettering in the final table is arranged so that in the expression  $A_aB_bC_c \dots$ ,  $a \geq b \geq c$ , etc. The sum of  $a, b, c$ , etc. is equal to  $n$ , the number of replaceable hydrogen atoms in the original hydrocarbon.

In every case, the parent hydrocarbon is planar and the symmetry elements within the plane are considered. A symmetry factor  $S$  is defined as follows:—

- (a) If the hydrocarbon molecule has one or more axes of two-fold symmetry,  $S$  is equal to twice the number of such axes.
- (b) If the hydrocarbon molecule has a center of two-fold symmetry but no axis,  $S = 2$  (for one of three-fold symmetry,  $S = 3$ ).
- (c) If the hydrocarbon molecule has neither a center nor an axis of symmetry,  $S = 1$ .

Thus, for example:—

	TWO-FOLD AXES	TWO-FOLD CENTRE	S
Benzene	6	(1)	12
Coronene	6	(1)	12
Triphenylene	3	—	6
Naphthalene	2	(1)	4
Anthracene	2	(1)	4
Phenanthrene	1	—	2
Chrysene (1:2-Benzphenanthrene)	—	1	2
1:2-Benzanthracene	—	—	1

Now the number of ways in which  $b$  groupings of type  $B$  can be arranged in  $n$  positions, while  $a$  groupings of type  $A$  fill the remaining  $(n - b)$  positions, is

$$C = \frac{n!}{a! b!}$$

This would be the number of  $A_a B_b$  isomers if the parent hydrocarbon had no elements of symmetry.

For the  $A_a B_b C_c D_d \cdots$  isomers, this formula becomes

$$C = \frac{n!}{a! b! c! d! \cdots}$$

If the symmetry factor of the parent hydrocarbon is  $S$ , and none of the  $A_a B_b C_c D_d \cdots$  isomers derived from it has an element of symmetry, the number of such isomers is given by

$$C = \frac{1}{S} \times \frac{n!}{a! b! c! d! \cdots}$$

In cases where none of the axes of symmetry of the original hydrocarbon passes through a substitutable CH group, the above condition is satisfied if any of the numbers  $a, b, c, d$ , etc. is odd. In cases such as benzene or anthracene, where an axis of symmetry can pass through a pair of CH positions, more than two of these numbers must be odd. Another exception must be made in cases such as triphenylene and coronene, where three-fold symmetry is possible if the number of groups of each substituent is a multiple of three.

If all of the  $A_a B_b C_c D_d \cdots$  isomers had the same symmetry factor  $S'$  (defined in the same way as  $S$  for the parent hydrocarbon) then equation [1] would be

$$C = \frac{S'}{S} \times \frac{n!}{a! b! c! d! \cdots}$$

$$\text{i.e.,} \quad \frac{S}{S'} C = \frac{n!}{a! b! c! d! \cdots} \dots\dots\dots [2]$$

Unless  $S' = 1$ , the isomers will not, in fact, all have the same symmetry factor  $S'$ . There will be  $C_1$  isomers of symmetry factor  $S'_1$ ,  $C_2$  isomers of symmetry factor  $S'_2$ , and so on. Hence the left hand side of equation [2] is actually the sum of terms of the type  $\frac{S}{S'_1} C_1$ . In other words

$$\sum \frac{S'_1}{S} C_1 = \frac{n!}{a! b! c! d! \cdots} \dots\dots\dots [3]$$

The numbers of symmetrical  $A_a B_b C_c D_d \cdots$  isomers were found by drawing or inspection, and application of equation [3] gave the number of asymmetrical

compounds. Thus where two of the numbers  $a, b, c \dots$  etc. in the  $A_aB_bC_c \dots$  substituted anthracenes are odd,  $S' = 2$  for the symmetrical cases and application of equation [3] shows that the number of  $A_aB_bC_c \dots$  compounds exceeds that given by equation [1] by half the number of symmetrical isomers.

Another equation of some value is the following: if the number of  $A_a B_b C_c \cdots$  isomers is  $N$  that of  $A_{a-1} B_b C_c X \cdots$  is  $N_1$  and that of  $A_{a-2} B_b C_c X_2 \cdots$  is  $N_2$

then  $N_2 = \left(\frac{a}{2} - 1\right) N_1 + \frac{aN}{2}$  .....[4]

This relation, however, only holds for cases where the quantity  $N_1$  can be obtained from equation [1]. In addition, it is inapplicable to benzene, triphenylene or coronene derivatives, since in these compounds certain arrangements become identical on rotation through  $60^\circ$  or  $120^\circ$  about the centre of symmetry.

However, the phenanthrene system may be quoted as one where equation [4] has been useful. Thus, for example,

$$\text{Number of } A_8B_2 = 4 \times (\text{Number of } A_9B) + 5 \times (\text{Number of } A_{10})$$

Number of  $A_6B_2C_2 = 3 \times (\text{Number of } A_7B_2C) + 4 \times (\text{Number of } A_8B_2)$   
 and Number of  $A_6B_2C_2 = (\text{Number of } A_6B_3C) + 2 \times (\text{Number of } A_6B_4)$  the  
 third equation being used to obtain the value for  $A_6B_4$ .
