ABSTRACT: A new approach to functionalized fulvenes with an enone or enal moiety has been developed through gold-catalyzed intramolecular cycloisomerization of furan/ynes with a two-carbon tether in between the furan and the triple bond. The reaction proceeds with complete regioselectivity via a 6-endo-cyclization and high stereoselectivity. Moreover, the *E*- or *Z*-stereochemistry of the double bond in fulvene products can be easily controlled by performing the reaction in different solvents.

INTRODUCTION

Fulvenes, which exhibit intriguing cross-conjugated molecular structures, have attracted much attention in theoretical studies, as precursors of cyclopentadienyl ligands for metallocene synthesis, ² and in natural product synthesis.³ They can also undergo a diverse array of cycloaddition reactions such as [4+2], 4a,b [6+2], $^{4c-e}$ and $[6+3]^{4f}$ cyclizations for the construction of fused ring systems. 4 In general, fulvenes are prepared by the condensation reactions of cyclopentadienes with ketones or aldehydes in the presence of an alkali metal base^{5,6} or through pyrrolidinepromoted reactions. However, strongly alkaline conditions limit the substrate scope of these methodologies. Fulvenes could also be prepared by transition-metal-catalyzed reactions, such as Pdcatalyzed cross-coupling reactions of alkynes with vinyl halides,8 Pd-catalyzed cyclotrimerization of alkynes,9 or Ti-catalyzed cyclotrimerization of tert-butylacetylene. 10 However, these reactions were restricted to internal alkynes or special substituted terminal alkynes. Recently, a silver-catalyzed Nazarov-type cyclization of α-hydroxyallenes to benzofulvenes has been reported. 11 Despite progress in this area, the development of synthetic routes that allow the facile assembly of functionalized fulvenes under mild reaction conditions still remains an important objective. Recently, we have developed a new domino approach for the synthesis of substituted benzenes bearing enone or enal functionalities with excellent Z-stereoselectivity through gold(I)catalyzed reactions of (Z)-2-en-4-yn-1-ols with furans (Scheme 1, eq 1).12a The gold catalyst was found to be quite efficient in catalyzing both the Friedel-Crafts and furan/alkyne 12-14 cyclization reactions with a highly regioselective manner of 7-endo-dig cyclization. We envisioned that the readily available enynols of 2-ylidene-buta-3-yn-1-ols 1 might also undergo the Friedel— Crafts reactions with furans to deliver the furanyl group in a close proximity to the alkyne moiety. We hypothesize that a new type of 6-endo-dig cyclization of the thus formed enynyl furans 2 might

take place to generate fulvene derivatives via the π -complex between the gold catalyst and the alkyne (Scheme 1, eq 2). In this paper, we report our success in gold-catalyzed cycloisomerization reactions of enynyl furans 2 to functionalized fulvenes with controllable E- or Z-stereoselectivity. It is noted that there is no report for the ring-opening cyclization of furan/ynes with a two-carbon tether in between the furan and the alkyne moiety. ¹⁵

RESULTS AND DISCUSSION

Initially, we focused on the development of a straightforward synthesis directly from enynols 1 and furan derivatives that combines the Friedel-Crafts and furan/alkyne cyclization reactions in a one-pot procedure. However, although much effort has been made, no satisfactory results were obtained. For example, reactions of enynol 1a $(R^1 = R^2 = R^3 = Ph)$ with 2 equiv of 2-methylfuran in the presence of 5 mol % gold catalysts such as PPh₃AuCl/AgOTf, PPh₃AuCl/AgBF₄, or PPh₃AuNTf₂ in CH₂Cl₂ gave a complicated mixture. We then decided to first synthesize the furanylated substrates 2 by Lewis-acid-catalyzed allylic substitution reactions. Optimization studies indicated that in the presence of 20 mol % of BF₃·Et₂O the Friedel-Crafts reactions could be completed within 3-40 min, and good to high yields were achieved in most cases (Table 1). 2-Methylfuran, 2,3disubstituted furan, 2-phenylfuran, and furan are all suitable for substitution reactions. The (Z)-configuration of the enyne double bond in 2 was determined by the 2D NOESY spectrum of compound 2h. However, when enynol bearing two different substituents (R¹ and R²) at both ends of the allylic moiety was employed, two regioisomers of 21 were formed, which could not be separated by column chromatography (Table 1, entry 12). The failure of the regioselective substitution reactions of

unsymmetrically substituted enynol 1 with furans was the limitations of the substrate synthesis.

With furan-ynes 2 in hand, we were interested in exploring the feasibility of 2 in gold-catalyzed cycloisomerization reactions. We first tried the cyclization reaction of 2a with PPh₃AuTf₂ (5 mol %) as the catalyst in CH₂Cl₂. It was found that fulvene 3a with an enone moiety was formed in 52% yield as a single geometric isomer (Table 2, entry 1). Unlike the previously reported benzene formation, ^{12a} in this case, the *E*-isomer of the enone moiety instead of the Z-isomer was obtained. Cyclization of 2a with PPh₃AuOTf as the catalyst in CH₂Cl₂ at 50 °C led to 72% yield of 3a as an E-isomer exclusively within 30 min (entry 3). The reaction could also be performed in DCE or toluene to produce the desired 3a in 58% and 68% yields, respectively (entries 4 and 5). PPh₃AuBF₄ and PPh₃AuSbF₆ could also be used as the catalysts, furnishing 3a in 52-59% yield, whereas gold(III) of NaAuCl₄·2H₂O afforded a low yield of 3a (entries 6-8). Interestingly, switching the solvent to coordinating solvents such as 1,4-dioxane or THF provided the (Z)-isomer 4a in high yields of 89-97% with high stereoselectivity (entries 9 and 10). It is probably due to the coordination of the electrophilic gold cation species by the solvent molecule, which would decrease the Lewis acidity of the gold catalyst to prevent the sequential Z-E isomerization reactions. ¹⁶ The Z/E ratio changed only slightly in THF when elevating the reaction temperature to 50 °C (entry 11). As a control, the reaction was run in the absence of a gold catalyst (entry 12). As expected, AgOTf alone did not promote any transformation. The above results indicated that by choosing the appropriate solvents it is possible to obtain either the *E*- or *Z*-isomer of the desired fulvenes.

After establishing the optimized conditions for both of the double bond isomers 3 and 4 (Table 2, entry 3 for E-isomer 3, entry 10 for Z-isomer 4), we proceeded to examine the scope of this novel approach for the synthesis of fulvene derivatives. The results are shown in Table 3. In all cases, the E/Z isomers 3 and 4 were obtained with high levels of stereoselectivity regardless of the substitution patterns of enynes 2. Generally, Z-isomer 4 was obtained in better yields than that of the E-isomer 3. The structure of 3b was unambiguously determined by X-ray crystallographic analysis.¹⁷ The substituent effects (R⁴, R⁵) on the furan moiety were first investigated. 2-Phenyl and 2,3dimethyl substituents were all compatible under the cyclization conditions, yielding multisubstituted fulvenes in good yields (Table 3, entries 2 and 3). In the reaction of R⁴-phenylsubstituted 2b in THF, Luche reduction was performed to allow for product purification after the cyclization was completed (entry 2, for product 5b). When enyne 2c unsubstituted

both at C-2 and C-3 on the furan ring was subjected to this gold-catalyzed reaction, the expected cyclization occurred smoothly to generate E- or Z-enals 3d and 4d in high yields of 80% and 83%, respectively (entry 4). The substituent effects of the aryl groups on the alkyne terminus (R³) were also examined. It was found that the functionalities of Me, MeO, Cl, and NO2 were well tolerated. The electronic properties of these aryl substituents had an influence on the reaction process for the formation of the E-isomer 3, and enynes with an electron-withdrawing group usually afforded higher yields of fulvenes 3 than that of the substrates with an electron-donating group (entries 5-8). Notably, when terminal alkyne 2i was employed, the desired furans 3i and 4i were still obtained in moderate yield via an endo-cyclization (entry 9). The result is in sharp contrast with the analogous gold-catalyzed cycloisomerization of furan/ynes bearing a terminal alkyne moiety reported previously, which proceeded with exo-type cyclization exclusively. 13a-g Perhaps in our case, less strained intermediates were generated upon endo-cyclization during the reaction. Cyclohexenyl or cyclopropyl tethered alkynes also underwent the cyclization reactions readily in THF to give the corresponding fulvenes 4j and 4k in 62-79% yields (entries 10 and 11). However, when the reactions were performed in CH₂Cl₂, either complicated results or low yield (3k) of the desired product was observed.

The apparent ring opening of furans to enone-type products led us to propose the mechanism depicted in Scheme 2. ^{12a,13g} Initial coordination of the gold catalyst to the triple bond affords intermediate 6. This is followed by intramolecular furan/yne cyclization in a highly regioselective 6-endo-dig manner to form a cyclopropyl gold carbenoid 8. ¹⁸ Rearrangement of 8 followed by deprotonation and deauration leads to fulvene 4 with a *Z*-enone moiety. It should be noted that the *endo*-type cyclization in furan/yne cycloisomerization is quite rare. ^{12,13h} The *E*-isomer 3

■ CONCLUSION

In summary, we have developed an efficient gold-catalyzed intramolecular furan/yne cyclization reaction to form functionalized fulvenes with an enone or enal moiety under mild reaction conditions. Notably, the reactions reported here represent the first examples of gold-catalyzed ring-opening cyclizations of furan/ynes with a shortest tether in between furan and the alkyne moiety. The stereochemistry of the enone double bond can be easily controlled by simply changing the solvents. A variety of furan/yne substrates turned out to be applicable to this catalytic system.

■ EXPERIMENTAL SECTION

General Methods. All reactions were carried out under argon. DCE and DCM were distilled from P_2O_5 . THF and Toluene were distilled from sodium and benzophenone. Unless noted, all commercial reagents were used without further purification. Ph_3PAuCl^{19} and $Ph_3PAuNTf_2^{20}$ were

prepared according to the published method. AgOTf was used as a 0.05 M solution in THF.

 ^{1}H NMR spectra were recorded at 300 or 400 MHz, and ^{13}C NMR spectra were recorded at 75.4 or 100.6 MHz, in CDCl₃ (containing 0.03% TMS). ^{1}H NMR spectra were recorded with tetramethylsilane ($\delta=0.00$ ppm) as internal reference; ^{13}C NMR spectra were recorded with CDCl₃ ($\delta=77.00$ ppm) as internal reference.

General Procedure for the Synthesis of Enynols 1. Typical Procedure for the Synthesis of (E)-2-Benzylidene-1,4-diphenylbut-3-yn-1-ol (1a). To a solution of Z-α-bromocinnamaldehyde (2.11 g, 10 mmol) in triethylamine (10 mL) and THF (10 mL) were added phenylacetylene (1.22 g, 1.32 mL, 12 mmol), Pd(PPh₃)₄ (0.12 g, 0.10 mmol), and CuI (0.095 g, 0.50 mmol) at room temperature, and then the mixture was stirred overnight. After the starting material was consumed, the solvent was removed in vacuo, and the residue was purified by chromatography on silica gel (petroleum:ethyl acetate = 20:1 to 10:1) to afford compound (E)-2-benzylidene-4-phenylbut-3-ynal (s-1a) (2.31 g, 99%) as yellow oil. The spectroscopic data are in agreement with that previously reported.

To a solution of bromobenzene (3.96 g, 2.7 mL, 25.2 mmol) in THF (50 mL) was added n-BuLi (10.0 mL, 25.2 mmol, 2.5 M solution in hexanes) at -78 °C. After stirring at the same temperature for 1 h, **s-1a** (4.88 g, 21.0 mmol in 50 mL of THF) was added. The resulting solution was warmed to room temperature and stirred for 8 h. Then the mixture was quenched with saturated ammonium chloride solution. The reaction mixture was extracted with ether and dried over anhydrous Na₂SO₄. The solvent was evaporated, and the residue was purified by chromatography on silica gel (petroleum ether/ethyl acetate = 10:1) to afford compound **1a** (6.49 g, 99%) as brown oil. 1 H NMR (400 MHz, CDCl₃, Me₄Si) δ 3.11 (s, 1H), 5.36 (s, 1H), 6.95 (s, 1H), 7.19 – 7.33 (m, 11H), 7.47 (d, J = 7.2 Hz, 2H), 7.86 (d, J = 7.2 Hz, 2H); 13 C NMR (100 MHz, CDCl₃, Me₄Si) δ 77.6, 87.1, 97.9, 122.9, 124.3, 126.5, 127.6, 128.10, 128.12, 128.2, 128.26, 128.32, 128.8, 131.3, 133.8, 135.8, 141.8. Typical Procedure for Gold(I)-Catalyzed Cyclization of Enynyl Furans 2 to Fulvene Derivatives. *Method A*. To a solution of (*Z*)-2-(2-benzylidene-1,4-diphenylbut-3-ynyl)-5-methylfuran (**2a**) (74.9 mg, 0.2 mmol) in DCM (2 mL) were added PPh₃AuCl (5.0 mg, 0.01 mmol) and AgOTf (0.2 mL, 0.01 mmol, used as a 0.05 M solution in THF). The

flask was sealed and immersed in an oil bath at 50 °C and stirred at this temperature until the reaction was complete as monitored by thin-layer chromatography. The solvent was evaporated under the reduced pressure, and the residue was purified by chromatography on silica gel (petroleum ether/ethyl acetate = 10:1) to afford (*E*)-4-((*E*)-3-benzylidene-2,5-diphenylcyclopenta-1,4-dienyl)but-3-en-2-one 3a (53.8 mg, 72%) as a brown oil. $^1{\rm H}$ NMR (400 MHz, CDCl₃, Me₄Si) δ 2.07 (s, 3H), 5.89 (d, *J* = 16.0 Hz, 1H), 6.82 (s, 1H), 7.11 (s, 1H), 7.35-7.51 (m, 14H), 7.57-7.59 (m, 2H); $^{13}{\rm C}$ NMR (100.6 MHz, CDCl₃, Me₄Si) δ 27.5, 120.6, 127.85, 127.88, 128.2, 128.3, 128.4, 128.8, 129.6, 129.7, 130.8, 131.0, 134.0, 135.0, 136.3, 136.5, 136.6, 140.6, 143.8, 144.9, 148.0, 198.5. Synthesis of (Z)-3-((E)-3-Benzylidene-2,5-diphenylcyclopenta-1,4dienyl)-1-phenylprop-2-en-1-ol (**5b**). To a solution of (Z)-2-(2-benzylidene-1,4-diphenylbut-3-ynyl)-5-phenylfuran (2b) (87.3 mg, 0.2 mmol) in THF (2 mL) were added PPh₃AuCl (5.0 mg, 0.01 mmol) and AgOTf (0.2 mL, 0.01 mmol, used as a 0.05 M solution in THF) at 50 °C. After stirring for 10 min, the reaction was quenched by 2 drops of Et₃N. The solvent was evaporated under the reduced pressure, and the residue was dissolved in methanol (2 mL). To the above mixture were added CeCl₃·7H₂O (149.0 mg, 0.4 mmol) and NaBH₄ (14.9 mg, 0.4 mmol) at 0 °C. The resulting solution was kept at 0 °C and stirred for 2 h. Then the mixture was quenched with water, extracted with ether, and dried over anhydrous Na₂SO₄. The solvent was evaporated under the reduced pressure, and the residue was purified by chromatography on silica gel (petroleum ether/ethyl acetate = 20:1) to afford 5b (50.6 mg, 58%) as a brown oil. ¹H NMR (400 MHz, CDCl₃, Me₄Si) δ 0.54 (d, J = 2.0 Hz, 1H), 5.09 (d, J = 9.6 Hz, 1H), 5.60 (td, J = 10.0, 0.8 Hz, 1H), 6.33 (d, J = 10.08.4 Hz, 1H), 6.95 (s, 1H), 7.12-7.24 (m, 6H), 7.31-7.47 (m, 11H), 7.58 (dd, J = 18.4, 8.0 Hz, 4H); ¹³C NMR (75.5 MHz, CDCl₃, Me₄Si) δ 70.9, 118.1, 124.4, 125.4, 127.0, 127.2, 127.8, 128.0, 128.2, 128.4, 128.7, 129.1, 130.6, 131.0, 135.2, 135.5, 136.2, 138.8, 137.0, 137.1, 138.4, 142.3, 143.8, 148.6. HRMS (EI) calcd for C₃₃H₂₆O: 438.1984, found 438.1992.
