Pregnanetriol-3,4,20(α).—A suspension of 300 mg. of platinum oxide in a solution of 100 cc. of ether, 200 cc. of ethanol, and 1.7 g. of 4,20-diacetoxypregnanone-3, m. p. 250°, was shaken with hydrogen under 3 atm. pressure for four hours. The catalyst was filtered off and the filtrate was evaporated to dryness. The residue was crystallized once from dilute methanol to yield 1.4 g. of unsharply melting product. This diacetoxy-pregnanol gave only a slight precipitate when treated with digitonin in 95% ethanol, and when oxidized with excess chromic anhydride in acetic acid gave nearly a quantitative yield of the starting material, 4,20-diacetoxypregnanone-3, m. p. 250°.

A solution of 900 mg. of 4,20-diacetoxypregnanol-3 in 200 cc. of 95% ethanol was refluxed for two hours with a solution of 1.5 g. of potassium hydroxide in 75 cc. of 75% ethanol. The solution was poured into water and the hydrolyzed product was extracted with ether. The ethereal solution of the triol was washed with water and was then evaporated nearly to dryness. Pregnanetriol-3,4,20(α) crystallized from the concentrated solution in white plates of m. p. 182°. This triol gave no precipitate with digitonin. After recrystallization from ether and acetone it melted at 184°.

Anal. Calcd. for $C_{21}H_{36}O_3$: C, 74.9; H, 10.8. Found: C, 74.8; H, 10.8.

The triacetate was prepared by treatment of 100 mg. of triol with 3 cc. of pyridine and 2 cc. of acetic anhydride for two days. The solution was evaporated *in vacuo*, and the residue was dissolved in ether and dilute hydrochloric acid. The ether layer was washed with water and then with dilute potassium carbonate and finally was evaporated to

dryness. The residue, crystallized from methanol, yielded 75 mg. of triacetate of m. p. 181°.

Anal. Calcd. for $C_{27}H_{42}O_6$: C, 70.1; H, 9.2. Found: C, 70.0; H, 9.3.

Reduction of 4,20-Diacetoxypregnanone-3 with Aluminum Isopropylate.—A solution of 700 mg. of this compound, 1.0 g. of aluminum isopropylate and 100 cc. of dry isopropyl alcohol was refluxed in a fractionating column over a period of six hours while acetone was removed slowly. The solution was then poured into a mixture of ether and dilute hydrochloric acid. The ether was washed with water and then was evaporated to dryness. The residue on standing overnight with an alcoholic solution of digitonin gave no precipitate. It was not readily crystallized and was therefore converted to the triacetate by refluxing with 30 cc. of acetic anhydride for an hour. The solution was evaporated to dryness *in vacuo*, and the residue was crystallized from methanol to yield a product of m. p. 181°. The melting point could not be raised by repeated recrystallizations from alcohol.

Anal. Calcd. for $C_{27}H_{42}O_6$: C, 70.1; H, 9.2. Found: C, 70.0; H, 9.4.

This triacetate gave no depression in melting point with the triacetate of the triol obtained by catalytic reduction.

Oxidation of Pregnanetriol-3,4,20(α).—To a solution of pregnanetriol-3,4,20(α) in 50 cc. of acetic acid at 25° was added a solution of 500 mg. of chromic anhydride in 25 cc. of 90% acetic acid. The solution was allowed to stand for one hour. It was then diluted with water and extracted with ether. The ethereal solution was washed with water and then was extracted with dilute potassium carbonate solution. The ethereal layer yielded a yellow oil which could not be crystallized. The potassium carbonate solution on acidification with dilute hydrochloric acid yielded a white solid of m. p. 212°. It was crystallized from dilute ethanol and dilute acetone to yield 75 mg. of acid of m. p. 216°.

Anal. Calcd. for $C_{21}H_{32}O_5$: C, 69.2; H, 8.9. Found: C, 69.1; H, 8.6.

This acid gave a twenty degree depression in melting point with the 2,3-diacid of *allo*-pregnanone-20[9] of m. p. 218°, and melted at 180–220° when mixed with the 2,3-diacid of pregnanone-20 of m. p. 281° obtained by the direct oxidation of pregnanedione.[7]

The dimethyl ester of the 2,3-diacid of pregnanone-20 was prepared by treatment of the acid in ethereal solution with diazomethane. The solution was evaporated to dryness and the residue was crystallized from methanol to yield a substance of m. p. 87°.

Anal. Calcd. for $C_{23}H_{36}O_5$: C, 70.4; H, 9.3. Found: C, 70.1; H, 9.6.

The oxime was prepared by refluxing a mixture of 50 mg. of this acid, m. p. 216°, 100 mg. of hydroxylamine hydrochloride, 150 mg. of sodium acetate and 25 cc. of ethanol for six hours. The solution was diluted with water, the oxime was filtered off and was crystallized from dilute acetone. The substance melted at 238°.

Anal. Calcd. for $C_{21}H_{33}O_5N$: C, 66.4; H, 8.8. Found: C, 66.2; H, 8.7.

(9) Marker, Kamm and Jones, THIS JOURNAL, **59**, 1596 (1937).

3,4-Diacid of Pregnanol-20(α).—A solution of 100 mg. of pregnanetriol-3,4,20(α), and 200 mg. of lead tetraacetate in 25 cc. of acetic acid was allowed to stand for twenty-four hours at room temperature. The solution was poured into water, extracted with ether, and the ethereal solution was evaporated to dryness. The residue was taken up in 15 cc. of acetic acid and was treated with 10 cc. of 30% hydrogen peroxide for five hours on the steam-bath. The solution was poured into water and was extracted with ether. The ethereal solution was washed with water and was extracted with dilute potassium carbonate solution. The basic solution was then acidified and was extracted with ether. The ethereal solution after being washed with water was evaporated to dryness. The residue melted unsharply at 190–205°. After recrystallizations from dilute acetone and methanol, the substance melted at 231°. This acid (m. p. 231°) with the 3,4-diacid of pregnanone-20, m. p. 216°, melted at 185–200°.

Anal. Calcd. for $C_{21}H_{34}O_5$: C, 68.8; H, 9.4. Found: C, 68.8; H, 9.6.

Oxidation of the 3,4-Diacid of Pregnanol-20.—A solution of 200 mg. of this acid, m. p. 228°, in 50 cc. of glacial acetic acid was shaken at room temperature with 300 mg. of chromic anhydride in 25 cc. of 90% acetic acid for one hour. The solution was poured into 500 cc. of water and the product was extracted with ether. The ethereal solution was washed with water and then was evaporated to dryness. The residue was recrystallized twice from dilute acetone to yield 100 mg. of the 3,4-diacid of pregnanone-20 of m. p. 216°. This acid gave no depression in melting point with the acid of m. p. 216°, prepared by direct chromic anhydride oxidation of pregnanetriol-3,4,20(α).

4-Acetoxycoprostanone.—A solution of 20 g. of 4-bromocoprostanone,[10] in 200 cc. of glacial acetic acid containing 30 g. of fused potassium acetate was refluxed for two hours. The acetic acid was removed *in vacuo* and the organic material was extracted with ether. The ethereal solution was washed with sodium bicarbonate solution, and then was evaporated to dryness. The residue was crystallized from alcohol and yielded 4-acetoxycoprostanone, m. p. 149°.

Anal. Calcd. for $C_{29}H_{50}O_3$: C, 78.3; H, 10.9. Found: C, 78.4; H, 10.9.

Coprostanediol-3,4.—A solution of 5 g. of 4-acetoxycoprostanone in 100 cc. of ether and 100 cc. of ethanol was shaken for three hours with 2.0 g. of platinum oxide catalyst under hydrogen at 3 atmospheres. The catalyst was filtered off and the solvent was removed by evaporation. The residue was hydrolyzed by refluxing for one hour with alcoholic potassium hydroxide. The product had a tendency to form a gel when crystallization was attempted. However, after sublimation in a high vacuum at 200° the diol could be crystallized from alcohol and melted at 185–188°. The product may contain some stereoisomer formed in the reduction.

Anal. Calcd. for $C_{27}H_{48}O_2$: C, 80.1; H, 12.0. Found: C, 80.0; H, 12.0.

Coprostane Diacid-3,4.—To a solution of 4 g. of coprostanediol-3,4 in 100 cc. of glacial acetic acid at room temperature was added a solution of 5 g. of chromic oxide in

(10) Butenandt, *Ber.*, **68**, 2094 (1935).

50 cc. of 90% acetic acid. After standing for fifteen minutes, water was added and the organic material was extracted with ether. The ethereal solution was washed well with water and dilute hydrochloric acid and then with dilute potassium hydroxide. The alkaline solution was acidified and extracted with ether. The ether solution was concentrated and pentane was added. This produced 2.4 g. of crystalline acid, m. p. 207–211°. Coprostane-3,4-dicarboxylic acid crystallized from methanol as large transparent rods, m. p. 217°. It gave a 15–20° depression in melting point with dihydro-Diels acid of m. p. 251°, and also with coprostane-2,3-dicarboxylic acid, m. p. 247°.

Anal. Calcd. for $C_{27}H_{46}O_4$: C, 74.6; H, 10.7. Found: C, 74.8; H, 10.7.

The dimethyl ester was prepared with diazomethane in the usual way. It crystallized from methanol as large white flakes, m. p. 74°.

Anal. Calcd. for $C_{29}H_{50}O_4$: C, 75.3; H, 10.7. Found: C, 75.6; H, 11.0.

Summary

Pregnanetriol-3,4,20(α) was oxidized to the 3,4-dicarboxylic acid of pregnanone-20, which was different from the dicarboxylic acid of pregnanone-20 formed by direct oxidation of pregnanedione. The latter acid must therefore be a 2,3-derivative.

Coprostanediol-3,4 was oxidized to a coprostane-dicarboxylic acid. This acid was different from the dicarboxylic acid obtained by direct oxidation of coprostanone.

The greater part of the oxidative fission of 3-substituted derivatives of the coprostane configuration (except those of the bile acid series) takes place at the 2,3-bond rather than at the 3,4-bond as has been generally assumed.

The Preparation of Some Py-Amino Quinolines and Derivatives

BY R. R. RENSHAW[1] AND H. L. FRIEDMAN[2]

This paper describes the preparation of several py-amino quinolines and some of their derivatives. The amines were needed for a study of their coupling reactions with benzene diazonium chloride.[3] The 2-aminoquinoline was readily prepared by the sodamide reaction.[4]

Reduction of 3-nitroquinoline[5] gave the 3-aminoquinoline in small over-all yields. For better yields, Wibaut's[6] method was modified by preparing 3-bromoquinoline from quinoline, bromine and sulfur,[7] followed by conversion to the amine with concentrated ammonia and copper sulfate catalyst.[8]

Since it was found that 3-aminoquinoline forms the 4-azo derivative in the coupling reaction with benzenediazonium chloride,[3] an attempt was made to prepare the unknown 4-nitroquinoline. Anhydrous 3-acetylaminoquinoline was nitrated in concentrated sulfuric acid and the acetyl group removed by hydrolysis. A red nitro-amine was formed. An attempt to remove the amino group by diazotization and boiling in alcohol yielded only a nitro-ethoxy derivative. Attempted reduction to the known 3,4-diaminoquinoline[3] failed; the compound could not be reduced. It is tentatively postulated that 4-nitro-3-aminoquinoline was obtained, although the authors have never seen a quinoline compound with a nitro group in the 4 position recorded in the literature.

The 4-aminoquinoline and the 2,4-diaminoquinoline were prepared from the same material, the 2,4-quinoline-dicarboxylic acid.[9] Decarboxylation of the acid in boiling nitrobenzene gave excellent yields of cinchoninic acid which was converted through the acid chloride,[10] methyl ester,[11] and amide[12] to the amine[13] in an over-all yield of 68%. Similarly, it was found that starting with the 2,4-quinolinedicarboxylic acid, the 2,4-diaminoquinoline could be obtained by the same series of reactions in an over-all yield of 50%. The only method of preparation of the

diamine recorded previously in the literature is the reaction of the 2,4-quinolinedisulfonic acid with concentrated ammonia and zinc chloride.[14]

It was found that the 2-carbethoxy group in the 2,4-diethyl ester could be converted readily into the carboxamide group without the 4-carbethoxy group being appreciably affected. Hofmann degradation of the resulting compound gave the hitherto unknown 2-aminocinchoninic acid.[15] The structure was proved by decarboxylation to 2-aminoquinoline and by diazotization to the known 2-hydroxycinchoninic acid.[16]

Experimental Part[17]

3-Aminoquinoline.—*o*-Aminobenzaldehyde[18] and metazonic acid[19] on standing in a weakly acidic solution gave a 22% yield of 3-nitroquinoline,[20] m. p. 129–130°. Ether extraction of the neutral mother liquor gave an approximately equal weight of the oxime of the aldehyde, m. p. 137–37.5°.[21] Reduction of the nitro compound with stannous chloride in concentrated hydrochloric acid,[5] addition of excess sodium hydroxide, and extraction with ether gave a 97% yield of the 3-amine, m. p. 82–83°; acetyl derivative, m. p. 171–172° (anhydrous), 127–128° (hydrate).

Bromination of quinoline with sulfur and bromine according to Edinger[7] gave 3-bromoquinoline in 50% yield, b. p. (24 mm.) 158–162°. Heating with concentrated ammonium hydroxide and copper sulfate catalyst[8] in a rocking autoclave (twelve hours at 160°) and extraction with ether gave the 3-aminoquinoline in 73% yield.

3-Acetylamino-4(?)-nitroquinoline.—Attempted nitration of the acetylamine in glacial acetic acid precipitated the nitrate of the acetylamine, m. p. 195.5° (with decomp. to gas).

3-Acetylaminoquinoline (2 g.) was dissolved in concentrated sulfuric acid (15 cc.), cooled, fuming nitric acid added (1.5 g.), and the solution allowed to stand for one hour at room temperature. The solution was then poured on cracked ice, made basic, and the precipitate crystallized from much water; small golden yellow needles, m. p. 205–206°.

Anal. Calcd. for $C_{11}H_9N_3O_3$: N, 18.2. Found: N, 18.0.

3-Amino-4(?)-nitroquinoline.—The acetylamino-nitroquinoline was hydrolyzed by boiling in 95% alcohol with potassium hydroxide for fifteen minutes. The red solution was then poured into water, boiled to remove the alcohol, cooled, the precipitate filtered and crystallized from water; small lustrous red needles, m. p. 189–189.5°.

Anal. Calcd. for $C_9H_7N_3O_2$: N, 22.2. Found: N, 21.8.

Attempted reduction in hydrochloric acid with stannous chloride failed. The red color did not disappear after heating for one hour. The solution was made basic and extracted with ether. The ether showed a marked blue fluorescence but no diamine was obtained on evaporation. Reductions were also attempted with stannous chloride and hydrogen chloride in alcohol, with iron powder and acetic acid in water, and with zinc dust in alcoholic sodium hydroxide. No color change was found in any case nor could any product resembling a diamine be obtained.

3-Ethoxy-4(?)-nitroquinoline.—Dry sodium nitrite (90 mg.) was added to the nitroaminoquinoline (200 mg.) in cold concentrated sulfuric acid (5 cc.). The solution was allowed to warm to room temperature and stand for fifteen minutes, then poured into 30 cc. of absolute alcohol and boiled. Most of the alcohol was distilled off and a small amount of water added. On further boiling a solid steam distilled and was crystallized from water, approximately 40 mg. of long, slightly tan crystals, m. p. 113–114°. Evaporation of the alcoholic distillate at room temperature left no residue. Ether extraction of the clear liquid remaining in the distilling flask yielded only a little unreacted nitro-aminoquinoline.

Anal. Calcd. for $C_9H_6N_2O_2$ (nitroquinoline): N, 16.1. For $C_{11}H_{10}N_2O_3$ (nitro-ethoxyquinoline): N, 12.8. Found: N, 12.5.

4-Aminoquinoline.—Finely powdered dry quinoline 2,4-dicarboxylic acid (25 g.) was boiled on a hot-plate with nitrobenzene (100 cc.). Decarboxylation was complete in about ten minutes accompanied by solution. On cooling, the cinchoninic acid crystallized out and was recrystallized from water, yield 90%.

The cinchoninic acid (1 part) was boiled with thionyl chloride[10] (3 parts) for ten minutes and the thionyl chloride removed *in vacuo*. The acid chloride–hydrochloride formed gave with methyl alcohol the methyl ester,[9] b. p. (4 mm.) 136–140°, in 83% yield. The ester (10 g.) with ammoniacal methanol (50 cc. saturated with ammonia at 10°) gave the amide[12] in quantitative amount (twelve hours at 50°), rectangular plates, m. p. 179–181°. Hofmann degradation[13] gave the amine in 90% yield, m. p. 69° (hydrate), 154–156° (anhydr.); acetyl derivative, 177–178°.

2,4-Dicarbomethoxyquinoline and 2,4-Dicarbethoxyquinoline.—Quinoline-2,4-dicarboxylic acid (1 part) was refluxed for eight to ten hours on the water-bath with thionyl chloride (10 parts), at which time complete solution was effected. The thionyl chloride was distilled off *in vacuo* and feathery golden-yellow crystals of the dicarbonyl chloride remained. The chloride may be crystallized from ligroin or petroleum ether but this is not necessary for production of the esters.[22]

The dicarbonyl chloride was dissolved in absolute methanol (or ethanol), boiled with bone-black, filtered, water added to turbidity and the solution cooled. The esters formed white needle crystals; dimethyl ester, m. p. 130–131°; diethyl ester, m. p. 74–75.5°; very insoluble in water, soluble in concentrated sulfuric acid (yellow).

Anal. (Dimethyl ester) Calcd. for $C_{13}H_{11}NO_4$: N, 5.71. Found: N, 5.83, 5.60. (Diethyl ester) Calcd. for $C_{15}H_{15}NO_4$: N, 5.13. Found: N, 5.08, 5.18.

(21) Beilstein, Vol. 14, p. 24.

(22) Compare French Patent 806,640 noted after completion of this work.

Quinoline-2,4-dicarboxanilide.—The dicarbonyl chloride was dissolved in an excess of hot aniline. The dianilide crystallized out on cooling. The compound when recrystallized from aniline or nitrobenzene formed small bluish-white needles; very insoluble in hot water, slightly soluble in hot alcohol, m. p. 285–286°. The crystals turn red in cold concentrated sulfuric acid and go into solution (orange) on warming.

Anal. Calcd. for $C_{23}H_{17}N_3O_2$: N, 11.44. Found: N, 11.42, 11.41.

2,4-Dicarbamylquinoline.—The dimethyl ester (10 g.) was heated with ammoniacal methanol (100 cc.) at 85° for twenty hours. The amide, formed in quantitative yield, crystallized from water or alcohol as small white needles, m. p. 277.5–279.5°; soluble in concentrated sulfuric acid (yellow).

Anal. Calcd. for $C_{11}H_9N_3O_2$: N, 19.53. Found: N, 19.33, 19.02.

2,4-Diaminoquinoline.—Fifteen grams of the diamide was added to 725 cc. of a solution containing 50 g. of potassium hydroxide and 23 g. of bromine. The amide dissolved readily in the cold. The solution was heated on the water-bath for one hour, the small amount of dark brown precipitate filtered off, and the solution bone-blacked, filtered and cooled. The diamine slowly crystallized from the solution. More product was obtained by concentrating the solution. The diamine was recrystallized from water (tendency for supersaturation) as lustrous white needles, m. p. 197–198.5°,[23] yield, 85%. The picrate, crystallized from much hot water, melted at approximately 283° (decomp.).

Anal. Calcd. for $C_9H_9N_3$: N, 26.41. Found: N, 26.51. Calcd. for $C_{15}H_{12}N_6O_7$ (monopicrate): N, 21.64. Found: N, 21.84.

(23) The m. p. in German Patent 615,184 is given as 188–190°; the analysis reported was N, 25.3.

2-Carbamylethyl Cinchoninate.—On heating 2,4-dicarbethoxyquinoline with ammoniacal methanol at 50°, the mono amide was formed in 86% yield; slightly soluble in hot alcohol, very insoluble in water, m. p. 226–227.5° (melts to a tan liquid with a green fluorescence).

Anal. Calcd. for $C_{13}H_{13}N_2O_3$: N, 11.41. Found: N, 11.59, 11.56.

2-Aminocinchoninic Acid.—Five grams of 2-carbamylethyl cinchoninate was heated on the steam-bath for one hour with 250 cc. of water containing 10 g. of potassium hydroxide and 4.75 g. of bromine. Solution (red) was effected on warming. The solution, after being cooled, was diluted to dissolve the potassium salt and made weakly acidic with hydrochloric acid. The yellow precipitate of 2-aminocinchoninic acid was crystallized from much water as lustrous tan crystals, m. p. 362° (dec.); soluble in concentrated sulfuric acid (red), concentrated hydrochloric acid (red), and dilute sodium hydroxide; insoluble in alcohol and benzene.

Anal. Calcd. for $C_{10}H_8N_2O_2$: N, 14.9; neut. equiv., 188. Found: N, 14.3; neut. equiv., 187.

Diazotization in concentrated sulfuric acid with dry sodium nitrite and pouring into water gave the known 2-hydroxycinchoninic acid,[16] m. p. 342°. Fusion with soda-lime gave 2-aminoquinoline, white plates from water, m. p. 125–127°.

Summary

Improved preparations of 3- and 4-aminoquinoline, and a new method of preparation of 2,4-diaminoquinoline and of 2-aminocinchoninic acid are described. The attempted preparation of 4-nitroquinoline from 3-aminoquinoline is discussed.

Coupling Reactions of Aminoquinolines with Benzenediazonium Chloride. A Study of Orientation in the Quinoline Ring

BY R. R. RENSHAW,[1] H. L. FRIEDMAN[2] AND F. J. GAJEWSKI[3]

Knorr[4] and Marckwald[5] pointed out that the chemical properties of naphthalene and quinoline are best explained by accepting the static bond structure proposed by Erlenmeyer, while the chemical properties of benzene are better explained on the basis of Kekulé's concept of shifting double bonds. More recently Pauling[6] has arrived at the same conclusion from quantum mechanical studies, and Le Fèvre and Le Fèvre,[7] from dipole studies of quinoline, favor the Erlenmeyer structure.

There are several good recent surveys of the naphthalene problem,[8] but quinoline has been given only brief discussions.[7,9] Therefore, a comprehensive study of the coupling reactions of the aminoquinolines was undertaken to char-

acterize the orientation and the "fixed bond" structure of quinoline, for Fieser[10] has shown that the coupling reaction is indicative of bond structure.

Table I compares the actual results obtained by coupling the different aminoquinolines with benzenediazonium chloride with those to be expected from Erlenmeyer's static formula.

TABLE I

Position of NH_2	Expected coupling	Obsd. coupling
2	2 (diazoamino)	2 (diazoamino
3	4	4
4	3	Failed
2, 4	3	2(?)
5	8 or 6	8 and 6
6	5	5
7	8	(8)
8	5 or 7	5

These results indicate a good agreement with the Erlenmeyer structure. Since both the methods of preparation and of coupling of the mono-bz- and mono-py-aminoquinolines are very different, they are discussed separately below.

Results of Coupling Bz-Aminoquinolines with Benzenediazonium Chloride.—The bz-aminoquinolines were made by the reduction of the corresponding nitro compounds obtained by the appropriate Skraup reactions. The 7-nitroquinoline was also prepared by the lithium nitrate reaction.[11]

The earlier work on the coupling of mono-bz-aminoquinolines was that of Knuepel[12] and of Jacobs and Heidelberger.[13] The former attempted to prepare the azo derivative of 6-aminoquinoline, but obtained the intermediate diazoamino compound, which did not undergo rearrangement. The latter were successful in coupling diazotized aniline with 5-aminoquinoline in dilute acetic acid–sodium acetate solution. The authors have been successful in applying Jacobs and Heidelberger's conditions to all of the mono-bz-aminoquinolines. They have also effected coupling in dilute hydrochloric acid solutions. The former method yielded the purer product.

The structure of each resulting azo compound was determined by the following procedures. (1) Reduction of the azo compound from 8-aminoquinoline gave a diaminoquinoline which melted at 163°. It did not form a phenanthrenequinone condensation product (test for an ortho diamine[14]).

(2) Reduction of the azo compound formed by coupling 5-aminoquinoline in dilute hydrochloric acid gave two diamines. The main product was a diamine of m. p. 163° which gave no melting point depression with the diamine of (1) and gave no phenanthrene-quinone condensation product. The other diamine present could not be purified sufficiently to show a sharp melting point. It gave a condensation product with phenanthrenequinone, m. p. 294–295°, and must, therefore, have been 5,6-diaminoquinoline. Therefore, 8-aminoquinoline coupled mainly in the 8-position and to a slight extent in the 6-position. It was found that coupling of the 5-amine in dilute acetic acid–sodium acetate solution gave only the 8-phenylazo compound.

(3) Reduction of the azo compound from 6-aminoquinoline gave a diamine which yielded a phenanthrenequinone condensation product of m. p. 294–295°. This azine did not depress the melting point of the azine formed in (2), hence, the 6-aminoquinoline coupled in the 5-position.

(4) Reduction of the azo compound from 7-aminoquinoline gave a new diamine which formed a phenanthroquinone azine, showing it to be an ortho diamine. It was not possible to prove the structure of this diamine. It must be either the 7,8- or 6,7-diaminoquinoline. It is tentatively considered the 7,8-diamine.

The hydrochlorides of the phenylazo-aminoquinolines were prepared for bactericidal tests.

Results of Coupling Py-Aminoquinolines with Benzenediazonium Chloride.—The py-aminoquinolines were prepared by various new or improved methods described in a previous report.[15]

Since negative results were obtained in attempting coupling reactions under the same conditions as for the bz-aminoquinolines, various solvents were tried in order to effect coupling. The results of reactions with benzenediazonium chloride are in Table II.

TABLE II

Solvent	$2NH_2$	$3NH_2$	$4NH_2$	$2,4NH_2$
H_2O, HOAc, NaOAc	No	Diazoamino	No	Diazoamino
H_2O, HCl (dil.)	...	No	No	No
H_2O, HCl (excess)	...	No	...	No
H_2O, MeOH	Diazoamino	Diazoamino	No	Diazoamino
HOAc (glacial)	No	Red tar	No	Diazoamino
EtOH (abs.)	Diazoamino	Azo compound	No	No

The coupling of 2-aminoquinoline with benzenediazonium chloride gave a diazoamino compound, an expected result. No attempt was made to rearrange it, since Chichibabin[16] has shown that the analogous diazoamino compound from 2-aminopyridine does not undergo rearrangement, a result confirmed by the authors.

The 3-aminoquinoline gave in small yield the desired azo compound only by coupling in absolute alcohol. Although the 3-amine is truly aromatic, it gave the diazoamino compound when coupling was effected under the conditions for the bz-aminoquinolines. The 3-diazoaminoquinoline was destroyed readily by boiling in dilute hydrochloric acid. The decomposition is characterized by the appearance of the blue fluorescence of the 3-amine. Reduction of the azo compound 3-aminoquinoline gave a new diamine, m. p. 176–177°,[17] which can be characterized by an intense blue to purple fluorescence in various solvents. This diamine gave a condensation product with phenanthrenequinone, and is, therefore, an ortho diamine. To fix the structure conclusively, 4-aminoquinoline was brominated to yield the 3-bromo derivative[18] and this was converted to the 3,4-diamine with 26% ammonia water.[19] The 3,4-diamine so prepared was identical with that from the reduction of the azo compound. Hence, the 3-aminoquinoline coupling occurred at the 4-position.

The 4-aminoquinoline failed to couple under any conditions tried; the unreacted amine always could be isolated at the end of the reaction. Attempted coupling in absolute alcohol with *p*-nitrobenzenediazonium chloride produced a very interesting phenomenon. A bright red solution was formed which rapidly faded. The fading was accompanied by loss of nitrogen. This effervescence was studied carefully at different temperatures, and was found to occur at as low as −10°. It was not possible to isolate the red compound, since at the temperatures at which it formed, decomposition immediately occurred. Nitrobenzene was isolated from the solution; this is the normal product obtained by the reaction of *p*-nitrobenzenediazonium chloride with hot alcohol.[20] It would appear that an unstable red intermediate was formed and that this immediately decomposed into 4-aminoquinoline, nitrogen, and nitrobenzene. By analogy with 2-aminoquinoline, the formation of a diazoamino compound could be expected. No reason can be given for the instability of the red intermediate without more specific data.

The 2,4-diaminoquinoline was tried in coupling reactions since Morgan and Wootton[21] were able to couple at the position between the two amino groups in substituted meta-phenylenediamines. By analogy it was expected that the 2,4-diamine would couple in the 3-position, no matter which one of the three tautomeric forms might represent the structure. It was found that in glacial acetic acid both benzenediazonium chloride and *p*-nitrobenzenediazonium chloride gave readily yellow-orange compounds which formed yellow hydrochlorides. Without exception it was found that in this series the color of the hydrochlorides of the true azo compounds was red or a deep orange-red, whereas that of the hydrochlorides of the diazoamino compounds was yellow. On this basis it is believed that these compounds are diazoamino. Since 4-aminoquinoline did not undergo coupling reactions under the conditions tried, while 2-aminoquinoline formed a diazoamino compound, it is postulated that 2-diazoamino-4-aminoquinolines are formed.

Experimental Part[22,23]

Bz-Aminoquinolines

6-Amino-5-phenylazoquinoline.—Method I: Benzenediazonium chloride was coupled with 6-aminoquinoline in 0.25 molar hydrochloric acid solution over a period of twelve hours. On salting out the hydrochloride at 60°, it first formed an oil, which on stirring solidified to a light-orange flocculent precipitate. It was purified by dissolving in a minimum amount of water and adding an equal volume of alcohol, whereupon orange needles separated, m. p. 250–255°. These crystals analyzed for the monohydrochloride trihydrate. This product was converted to the monohydrochloride by drying at 120°. The free base was prepared by precipitating it from a solution of the hydrochloride with ammonium hydroxide. It was recrystallized from alcohol, forming light orange needles, m. p. 247–249°.

Method II: Coupling was accomplished in acetic acid–sodium acetate solution in approximately ten minutes. After coupling was complete, the solution was made alkaline with ammonium hydroxide. The precipitated solid was recrystallized from a solution of alcohol and water.

The free base was reduced by means of stannous chloride and concentrated hydrochloric acid. The procedure was the following: after refluxing the reaction mixture for half an hour, it was evaporated to dryness on a water-bath. The residue was dissolved in water and the tin removed by means of hydrogen sulfide. The water solution was evaporated almost to dryness and cooled. The hydrochloride crystallized. It was purified by dissolving in alcohol and

(22) The experimental work on the bz-aminoquinolines was performed by F. J. Gajewski, that on py-aminoquinolines by H. L. Friedman.

(23) All melting points are corrected.

precipitating with ether. The 5,6-diaminoquinoline was obtained by making a solution of the hydrochloride strongly alkaline with potassium hydroxide. A melting point of 135° was found for this product, whereas that reported is 95[24] and 145°.[25] The phenanthroquinoline azine melted at 294–295°; reported[24] 287–288°.

Anal. Calcd. for $C_{15}H_{12}N_4$: N, 22.57. Found: N, 22.58, 22.48. Calcd. for $C_{15}H_{12}N_4 \cdot HCl$: N, 19.67. Found: N, 19.56, 19.60. Calcd. for $C_{15}H_{12}N_4 \cdot HCl \cdot 3H_2O$: N, 16.54. Found: N, 16.66, 16.57.

5-Amino-8-phenylazoquinoline was first prepared by W. A. Jacobs and M. Heidelberger.[13] It was found, however, that the product after several recrystallizations melted at 191–194°, whereas the reported m. p. is 209–211°. This is to be attributed to the fact that a mixture of two coupling products was obtained as shown below. The hydrochloride, m. p. 225–227°, precipitated as a violet powder when dry hydrogen chloride was passed into a chloroform solution of the free base.

The free base was reduced with stannous chloride and concentrated hydrochloric acid. After refluxing the reaction mixture for one-half hour, the solution became decolorized. Solid potassium hydroxide was added under cooling until a 50% solution was obtained. The yellow solid was filtered and dissolved in ether. By slowly evaporating the ether solution, a crust formed on the side of the evaporating dish, which melted over the range 150–155°. There was present in this crust some 5,6-diaminoquinoline, for a phenanthrenequinone ortho condensation product was obtained. The main diaminoquinoline, obtained in long crystals on the bottom of the evaporating dish, was 5,8-diaminoquinoline, m. p. 163°.

Anal. Calcd. for $C_{15}H_{12}N_4 \cdot HCl$: N, 19.67. Found: N, 19.36, 19.32.

8-Amino-5-phenylazoquinoline was prepared by coupling benzenediazonium chloride with 8-aminoquinoline in acetic acid–sodium acetate solution. The product was recrystallized from alcohol, forming lustrous, deep orange plates, m. p. 133°. No trace of any other coupling product was found. The hydrochloride precipitated as a violet powder, m. p. 221–223°, from a chloroform solution of the free base. The hydrochloride was hydrolyzed readily in water.

The free base was reduced by means of stannous chloride and hydrochloric acid to form 5,8-diaminoquinoline, m. p. 163°. No phenanthrenequinone condensation was obtained even after heating for five hours.

Anal. Calcd. for $C_{15}H_{12}N_4$: N, 22.57. Found: N, 22.66, 22.56. Calcd. for $C_{15}H_{12}N_4 \cdot HCl$: N, 19.67. Found: N, 19.49, 19.30.

7-Amino-8-phenylazoquinoline was prepared by coupling benzenediazonium chloride with 7-aminoquinoline in acetic acid–sodium acetate solution. At first a deep orange oil formed which solidified after one week. Recrystallization from alcohol and water gave light orange needles, m. p. 170–173°. The hydrochloride, m. p. 210–211°, was precipitated by dry hydrogen chloride from a solution of the free base in chloroform. It is easily soluble in water.

Reduction of the free base with stannous chloride and hydrochloric acid, by the same method used for 5-amino-8-phenylazoquinoline, gave a new diaminoquinoline, which crystallized from water as a monohydrate in the form of light yellow needles, m. p. 95–97°. It forms an ortho condensation product with phenanthrenequinone after four hours of heating, m. p. 314°. The structure assigned to this new diamine is the 7,8-diaminoquinoline.

Py-Aminoquinolines

General Directions for Coupling Reactions.—Different methods had to be used in effecting coupling of the py-aminoquinolines and benzenediazonium chloride. Directions are given for 1 g. of amine and an equivalent amount of benzene diazonium chloride. (1) Dilute hydrochloric acid—as for the bz-aminoquinolines. (2) Acetic acid–sodium acetate—as for the bz-aminoquinolines. (3) Excess hydrochloric acid—method according to Ostromisslenski[26] and K. H. Meyer.[27] (4) Aqueous alcohol—the aqueous diazonium solution (15 cc.) was added slowly with stirring to an equal volume of a methanol solution of the amine at a temperature below 5°. (5) Glacial acetic acid—the dry diazonium chloride[28] in 5 cc. of solvent was slowly added with stirring to an equal volume of amine solution keeping the temperature below 10°. (6) Absolute alcohol—the dry diazonium chloride in 15 cc. of solvent was slowly added with stirring to a 5 cc. solution of the amine at a temperature below 10°.

Benzenediazonium chloride was used in all cases except where otherwise specified. Coupling reactions which are recorded in Table II as unsuccessful are not described in detail. In all unsuccessful cases aqueous solutions remained overnight below 5° and non-aqueous solutions were allowed to stand for one week below 10°. These reactions were characterized by a lack of color change and non-appearance of precipitate (in a few cases in excess hydrochloric acid solutions, some amine hydrochloride precipitated). The bulk of the amine was always isolated unreacted from the solutions.

2-Benzenediazoaminoquinoline was formed in both aqueous and absolute alcoholic coupling. The yields were small. From 1 g. of the amine 0.375 g. of product was obtained in absolute alcohol. The product on recrystallization from 95% ethanol formed light tan needles, m. p. 165–166.5°, identical in appearance with that of 2-benzenediazoaminopyridine. It is also stable to hot dilute sodium hydroxide and hydrochloric acid.

Anal. Calcd. for $C_{15}H_{12}N_4$: N, 22.57. Found: N, 22.49, 22.70.

3-Benzenediazoaminoquinoline.—The 3-aminoquinoline was dissolved in a dilute hydrochloric acid solution and the diazonium chloride solution was added. Then a saturated solution of sodium acetate was added until turbidity appeared. After standing overnight below 5°, an orange-tan

(25) Rudy, *ibid.*, **71B**, 847–857 (1938).
(26) Ostromisslenski, THIS JOURNAL, **56**, 1714 (1934).
(27) Meyer, *Ber.*, **54**, 2272 (1921).
(28) Hantzsch and Borghaus, *Ber.*, **30**, 90 (1897); Hantzsch and Jochem, *ibid.*, **34**, 3337 (1901).

precipitate of the diazoamino compound formed. The same compound was obtained from aqueous alcoholic coupling. The compound could be recrystallized from water, m. p. 156–157° (with decomposition). Recrystallization from hot 10% sodium hydroxide gave identical crystals but melting at 177–178° (with decomposition). Undoubtedly different degrees of hydration occurred to account for these discrepancies. It was noted that the melting point of a sample would rise after heating at 80° for several hours. The new melting point was always sharp. Boiling dilute hydrochloric acid destroyed the compound readily with the appearance of the blue fluorescence of 3-aminoquinoline.

Reduction of the compound with stannous chloride and hydrochloric acid resulted in the formation of 3-aminoquinoline.

Anal. Calcd. for $C_{15}H_{12}N_4$: N, 22.57. Found: N, 21.95, 21.46.

4-Phenylazo-3-aminoquinoline was obtained by coupling in absolute ethanol. On mixing the diazonium and amine solutions, a bright red color developed immediately. After standing overnight small dark red crystals formed, m. p. 125–135°. Free chloride ion was present. From 0.5 g. of the amine, 0.45 g. of product was obtained. This product was purified by dissolving in 100 cc. of 0.1 *N* hydrochloric acid, then boiling to decompose any diazoamino compound, filtering to remove a small amount of tar, and precipitating the orange-red free base with ammonia, m. p. 198–201°. This purification yielded 70% of product from the crude. On extracting the basic mother liquor with ether, it was found that 0.015 g. of 3-aminoquinoline per 0.1 g. of crude could be isolated. Hence, the original precipitate was a mixture of the azo compound and the diazoamino or of the azo compound and the amine as hydrochlorides. The azo compound was further purified by recrystallization from hot alcohol and water solution. It formed small, lustrous, light red needles, m. p. 203–204°. Evaporation of a hydrochloric acid solution of the free base gave the dark red hydrochloride, m. p. 228–230°.

Anal. Calcd. for $C_{15}H_{12}N_4$: N, 22.57. Found: N, 22.65, 22.37.

3,4-Diaminoquinoline was obtained by the reduction of the azo compound with stannous chloride and hot dilute hydrochloric acid. After the reaction, excess of base was added and the product extracted with ether. The product was further purified by crystallization from toluene, after bone blacking. White crystals were obtained, m. p. 176–177°.

The same product was obtained by bromination of 4-aminoquinoline[18] and conversion of the 3-bromo-4-aminoquinoline to the diamine by heating with concentrated aqueous ammonia and copper sulfate as a catalyst for twelve hours at 155–160°.[19] The diamine was isolated and purified as above. With hot acetic anhydride the acetyl derivative was obtained, which on crystallization from water formed long, white, cottony needles, m. p. 229–229.5°. The diamine also formed in glacial acetic acid with phenanthrenequinone after heating for one hour, an azine, m. p. 280–281°.

Anal. Calcd. for $C_9H_9N_3$: N, 26.41. Found: N, 26.52.

An attempt to couple 4-aminoquinoline with benzenediazonium chloride failed in all cases tried. The coupling in absolute alcohol as pointed out above was of particular interest. As described above, when the solutions were mixed at −5°, a light red color occurred, but rapidly faded with the evolution of nitrogen. The red color would not develop below −10°. Usually about ten minutes were required for a total loss of color. When *p*-nitrobenzenediazonium chloride was used, unreacted amine and *p*-nitrobenzene were isolated from the solution.

2-Benzenediazoamino-4-aminoquinoline was formed in small yields when coupling was effected in dilute hydrochloric acid solution, and in better yields in aqueous alcohol, and in glacial acetic acid. In excess hydrochloric acid and in absolute alcohol the coupling did not proceed. The product after crystallization from an alcohol–water solution is orange-brown in color, and after drying at 110° for eleven hours melted at 247.5–248.5°. The compound is stable in boiling hydrochloric acid solution.

Anal. Calcd. for $C_{15}H_{13}N_5$: N, 26.61. Found: N, 26.88.

2-*p*-Nitrobenzenediazoamino-4-aminoquinoline precipitated in about ten minutes when coupling was effected in glacial acetic acid. In absolute alcohol a dark red solution was first formed. This color disappeared in about fifteen minutes at −5° accompanied by slow evolution of nitrogen. After this time the yellow hydrochloride precipitated, m. p. 323–325°. It was identical with the product from the former coupling. It is only slightly soluble in hot water and on cooling forms gels. Neutralization of the aqueous solution gave a highly water insoluble, orange free base, m. p. 315.5–316.5°.

Anal. Calcd. for $C_{15}H_{12}N_6O_2$: N, 27.27. Found: N, 27.05, 27.78.

Summary

The orientation in the quinoline ring has been determined by a study of the coupling reactions of all the mono-aminoquinolines. Proofs for the structures of the resulting compounds are given. The results are those to be expected from the application of the Erlenmeyer structure for quinoline.

UNIVERSITY HEIGHTS
NEW YORK, N. Y. RECEIVED SEPTEMBER 20, 1939

[CONTRIBUTION FROM THE PATHOLOGICAL DIVISION, BUREAU OF ANIMAL INDUSTRY]

Lupine Studies. XIV.[1] The Isolation of Anagyrine from *Lupinus laxiflorus* var. *silvicola* C. P. Smith

BY JAMES FITTON COUCH

The leguminous plant *Lupinus laxiflorus* var. *silvicola* C. P. Smith ranges from Mariposa County, Calif., northward to southern Oregon. It has long been of interest among the poisonous lupines because of the atypical symptoms which it produces in livestock. Instead of showing the ordinary and characteristic symptoms of lupine poisoning, animals affected by this species exhibit symptoms closely resembling those caused by the larkspurs, notably *Delphinium barbeyi* Huth.[2] This had resulted in some confusion in diagnosing spontaneous range poisoning.

It has now been found that *Lupinus laxiflorus* var. *silvicola* contains anagyrine, not hitherto known to exist in the genus *Lupinus*. The close relationship of anagyrine to the lupine alkaloids has been shown by Ing.[3] Its occurrence in the genus *Lupinus* is further evidence of the close chemical similarity between the papilionaceous genera.

Anagyrine isolated from this lupine is indistinguishable from the alkaloid isolated from *Anagyris foetida*. It constitutes the major portion if not the whole of the alkaloidal material present. The related alkaloids often associated with anagyrine, cytisine, methylcytisine and sparteine, were not found in *L. laxiflorus* var. *silvicola*.

Anagyrine hydrochloride apparently crystallizes with varying quantities of water. Ing[3] prepared it with one molecule, and Hardy and Galois[4] reported a salt with four molecules. In this paper there are reported preparations with one-half and with three molecules of water.

Anagyrine behaves characteristically in the modified Grant's test for sparteine. When a strip of filter paper is moistened with a chloroform solution of anagyrine, dried and exposed to bromine vapor, the usual orange-yellow color develops. If the strip be now suspended in ammonia vapor, instead of bleaching it develops a pale blue color. On heating the strip the color changes to brown instead of scarlet as in the case of sparteine. This behavior appears to be unique with anagyrine.

The alkaloid and its salts have been compared with monolupine previously reported from *Lupinus caudatus*[5] and have been found to be different. Monolupine is not anagyrine. It differs in optical activity, does not form a very insoluble perchlorate, and mixed melting points of similar salts are markedly depressed and indefinite.

Experimental

Material.—Two lots of plant were examined. The first lot was collected by W. W. Eggleston in the Plumas National Forest, California, in July of 1926 and 1927. The second lot was collected by Forest Ranger Ben Beard at the same place in June and July, 1931. The species was identified by Mr. Eggleston.[6] No chemical differences were found between the two lots. They contained 11.94 and 10.62% of moisture, respectively.

Extraction of the Alkaloids.—The coarsely-powdered dried plants were extracted by alcohol and the alkaloids were recovered by the process already described.[7] The first lot, 3.96 kg., yielded 33.6 g. or 0.97% of crude alkaloid; the second, 14.76 kg., yielded 94.5 g. or 0.71% calculated to moisture-free plant.

Anagyrine Hydrochloride.—The crude alkaloid (10 g.) was dissolved in water, filtered and acidified with hydrochloric acid. The solution was concentrated and allowed to crystallize. The crystals were recrystallized from a mixture of hot alcohol and ethyl acetate. White needles, melting at 235–236° (uncor.) after desiccator-drying, were obtained.

Anal. Calcd. for $C_{15}H_{20}ON_2 \cdot HCl \cdot 3H_2O$ (334.7): H_2O, 16.14; Cl, 10.61; N, 8.37. Found: H_2O, 15.62, 15.48; Cl, 10.84; N, 8.34, 8.35.

To 35.5 g. of crude alkaloid in 100 cc. of acetone was added a mixture of 20 cc. of hydrochloric acid and 20 cc. of alcohol and then enough alcohol, 10 cc., to redissolve the oily precipitate. On cooling, anagyrine hydrochloride crystallized out. The salt was recrystallized from a mixture of 2 parts alcohol and 1 part acetone. After several recrystallizations and drying in a desiccator the salt melted at 284.5–285.5°[8] and did not depress the melting point of authentic anagyrine hydrochloride from *Anagyris foetida*.

Anal. Calcd. for $C_{15}H_{20}ON_2 \cdot HCl \cdot 0.5H_2O$ (289.7): H_2O, 3.11; Cl, 12.25. Found: H_2O, 3.31; Cl, 12.43, 12.42. In water $[\alpha]^{25}D$ −124.2°, l = 2, c = 1.7316, a = 4.3°.

(4) Hardy and Galois, *Compt. rend.*, **107**, 247 (1888).
(5) J. F. Couch, THIS JOURNAL, **58**, 686–687 (1936).
(6) This species was described as *Lupinus silvicola* by Heller *Muhlenbergia*, **6**, 81 (1910).
(7) J. F. Couch, THIS JOURNAL, **56**, 2434 (1934).
(8) Melting points are corrected unless otherwise indicated.

The anhydrous hydrochloride melted at 295–297°.

Anagyrine perchlorate was prepared according to Ing as long needles soluble in hot water and crystallizing readily from cold, decomposing without melting at a high temperature.

Anal. Calcd. for $C_{15}H_{20}ON_2 \cdot HClO_4$ (344.7): C, 52.22; H, 6.15; N, 8.12. Found[9]: C, 52.13, 52.30; H, 6.37, 6.31; N, 8.10, 8.13.

Anagyrine Gold Chloride.—An aqueous solution of the hydrochloride was treated with excess of gold chloride and the resulting precipitate was recrystallized from boiling dilute hydrochloric acid after filtering from the gold precipitated by reduction. The double salt crystallized in long golden needles melting at 167–168° (uncor.) after desiccator-drying. Analysis indicated somewhat more than the theoretical gold content, possibly due to reduced gold.

Anal. Calcd. for $C_{15}H_{20}ON_2 \cdot HAuCl_4$ (584.2): Au, 33.75. Found: Au, 34.04, 34.09.

Anagyrine Picrate.—The hydrochloride in water treated with alcoholic picric acid gave a bright yellow crystalline precipitate which was collected and dried. It melted at 169.5° and did not depress the melting point of authentic anagyrine picrate. Attempts to recrystallize these picrates from water resulted only in crystals of picric acid.

Anagyrine Base.—Ten grams of the hydrochloride was alkalized with sodium hydroxide and the free alkaloid shaken out with ether. After removal of the solvent the base was distilled under reduced pressure. At 12 mm. the major portion distilled between 260 and 270°. The distillate was a light yellow oil that solidified to a yellow glass. In water solution it gave a red color with ferric chloride and in acid solution readily reduced potassium permanganate. It was levorotatory in alcohol, $[\alpha]^{25}D$ −168°, l = 1, c = 1.0596, a = 1.78°.

Anagyrine Methiodide.—The base, 2 g., in 15 cc. of acetone and 2 cc. of methyl iodide evolved heat and began to deposit crystals within thirty minutes. The crystals were recrystallized from methanol and dried at 110°. They melted at 262–263°.

Anal. Calcd. for $C_{15}H_{20}ON_2 \cdot CH_3I$: I, 32.86. Found: I, 32.77.

Other Bases.—The mother liquors from the hydrochloride were alkalized with sodium hydroxide in water and the liberated bases were shaken out with chloroform. A portion of the residue was shown to be anagyrine. No other base could be identified in the remainder. Cytisine, methylcytisine and sparteine were proved absent by appropriate tests.

(9) The analyses were made by the Arlington Laboratories, V. A. Conard, Director.

Summary

Dry *Lupinus laxiflorus* var. *silvicola* C. P. Smith contains 0.7 to 1% of alkaloids, principally anagyrine. Cytisine, methylcytisine, and sparteine were not found in the plant. Anagyrine gives a characteristic blue color in the modified Grant test for sparteine.

A Method for the Preparation of α,β-Diglycerides of Fatty Acids

BY B. F. DAUBERT AND C. G. KING

The preparation and identification of α,β-diglycerides of the fatty acids has been difficult, due principally to the migration of acyl groups from the β- to the α′-position, as shown by Fischer.[1] Fairbourne and associates[2,3,4] have shown that the unsymmetrical diglycerides reported by earlier investigators[5,6,7,8,9] were probably the symmetrical isomers or mixtures in every case. The methods reported by Humnicki and Lunkiewicz,[10] Weizman and Haskelberg[11] and Delaby and Dubois[12] also involved reaction conditions that would almost certainly yield products containing little if any of the α,β-diglycerides.

The methods of Abderhalden and Eichwald[13] and Bergmann and associates,[14] using propylamine, and the trityl ether method of Helferich and Sieber,[15] have proved to be satisfactory for the preparation of aromatic α,β-diglycerides, but in no case have α,β-diglycerides of the fatty acids been prepared and characterized as pure compounds. Recently Verkade and associates[16] have outlined a general method for the preparation of α,β-diglycerides that should be satisfactory, involving the catalytic detritylation of α,β-diacyl-α′-trityl glycerol, but their work has not been reported in detail.

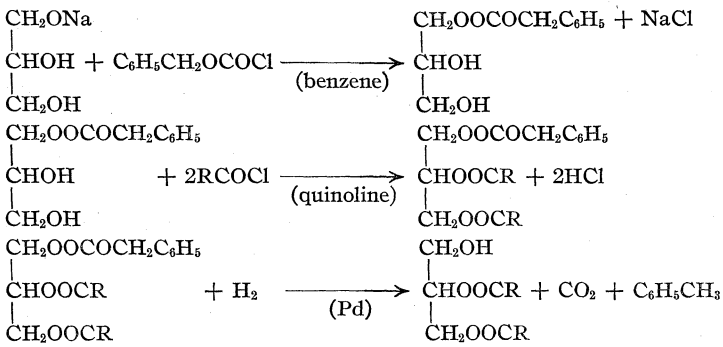
In the present investigation a new method of synthesis has been established, based upon the reaction between α-monosodium glyceroxide and benzyl chloroformate (carbobenzyloxy chloride), followed by esterification and catalytic reduction, as indicated in the following series of reactions



A brief study was also made of the solubilities and relative migration tendencies of aromatic and aliphatic unsymmetrical diglycerides.

Experimental

Preparation of 3-Carbobenzyloxyglycerol.—3-Monosodium glyceroxide was prepared by the method of Fairbourne and Toms.[17] To 5 g. of the oxide dissolved in 75 ml. of dry benzene there was added, in divided portions, 7.5 g. of benzyl chloroformate, previously prepared by the method of Bergmann and Zervas.[18] During the addition of the benzyl chloroformate the reaction mixture became warm. It was then allowed to stand twenty-four hours at room temperature, heated gently, filtered and the precipitate identified as sodium chloride. The filtrate was boneblacked, filtered and evaporated under reduced pressure. The residue consisted of a pale-yellow, oily liquid. Attempts to crystallize it were not successful. The yield was 8.2 g. (83%).

Anal. Calcd. for $C_{11}H_{14}O_5$: C, 58.40; H, 6.24. Found: C, 58.21, 58.16; H, 6.09, 6.16.

Preparation of 3-Carbobenzyloxy-1,2-dipalmitin.—To 5 g. of 3-carbobenzyloxyglycerol dissolved in 20 ml. of benzene and 5 ml. of quinoline there was added slowly a mixture of 5 g. of palmityl chloride and 5 ml. of quinoline. The mixture was shaken continuously for two hours and set aside at room temperature for four days. The product was then taken up in ether and the solution washed successively with cold 0.5 *N* H_2SO_4, saturated sodium bicarbonate, water and finally dried over anhydrous sodium sulfate. After evaporation *in vacuo* to dryness, the residue was redissolved in ether. Small white crystals separated after twenty-four hours at 5°, m. p. after recrystallization, 71°, yield 5 g. (80%).

Anal. Calcd. for $C_{43}H_{74}O_7$: C, 73.46; H, 10.61. Found: C, 73.09, 73.22; H, 10.73, 10.52.

Preparation of 1,2-Dipalmitin.—3-Carbobenzyloxy-1,2-dipalmitin (2 g.) was suspended in 75 ml. of absolute alcohol and transferred to a hydrogenation bottle together with 0.5 g. of palladium black. Reduction was complete after approximately two hours at room temperature and 30 lb. (2 atm.) pressure. The solution was filtered twice to remove the catalyst, then concentrated by evaporation and cooled for twenty-four hours. The 1,2-dipalmitin separated as flaky, white crystals, m. p. 64° after being recrystallized several times from absolute alcohol, yield 1.2 g. (76%).

Anal. Calcd. for $C_{35}H_{68}O_5$: C, 73.80; H, 12.05. Found: C, 73.89, 73.95; H, 11.67, 11.88.

Golendeev[19] reported a m. p. of 70–73° for 1,2-dipalmitin, but his method of esterifying the corresponding allyl halide (heating with the potassium salt of the fatty acid) would almost certainly cause a rearrangement of the structure to produce the 1,3-dipalmitin, m. p. 69.5°.

A second preparation of 1,2-dipalmitin, identical with the above product, was made by the method proposed by Verkade.[16] It was necessary to carry out the reduction at 45 lb. (3 atm.) pressure, 45–50°. For additional identification the triglyceride, 1-*p*-bromobenzoyl-2,3-dipalmitin, m. p. 68.8°, previously made by an independent method[20] was prepared from 1,2-dipalmitin by direct esterification.

Using the same procedure as outlined above for dipalmitin, 1,2-dimyristin was prepared, m. p. 59°, yield 80%.

Anal. Calcd. for $C_{31}H_{60}O_5$: C, 72.59; H, 11.79. Found: C, 72.25, 72.31; H, 11.56, 11.62.

The m. p. of the intermediate carbobenzyloxy-1,2-dimyristin was 67–68°.

Anal. Calcd. for $C_{39}H_{66}O_7$: C, 72.39; H, 10.28. Found: C, 72.11, 72.20; H, 10.06, 10.13.

Preparation of 3-Carbobenzyloxy-1,2-glyceroldibenzoate.—Essentially the same method as outlined above for 3-carbobenzyloxy-1,2-dipalmitin was followed for the preparation of the analogous dibenzoate.

Anal. Calcd. for $C_{25}H_{22}O_7$: C, 69.11; H, 5.10. Found: C, 68.86, 68.92; H, 5.17, 5.21.

Preparation of 1,2-Dibenzoate of Glycerol.—The 1,2-dibenzoate was prepared from the carbonate as described for 1,2-dipalmitin, but considerable difficulty was encountered in crystallizing the sirupy liquid remaining after evaporation of the solvent. Crystallization was accomplished after the product had been held two weeks in a vacuum desiccator, m. p. 58°, yield 70% (Helferich and Sieber[15] 58″–59°).

The 1,2-dibenzoate of glycerol thus obtained was used to prepare 1,2-dibenzoyl-3-trityl glycerol, m. p. 91°.

For further identification, the 1-*p*-bromobenzoyl-2,3-dibenzoate of glycerol, m. p. 107°, was prepared from the above 1,2-dibenzoate and also from 1-*p*-bromobenzoyl glycerol and benzoyl chloride.

Anal. Calcd. for $C_{24}H_{19}O_6Br$: Br, 16.54. Found: Br, 16.38, 16.45.

Migration of Acyl Groups.—When 1,2-dipalmitin was allowed to stand for twenty-four hours in solution in 0.1,

(17) Fairbourne and Toms, *J. Chem. Soc.*, **119**, 1035 (1921).
(18) Bergmann and Zervas, *Ber.*, **65**, 1194 (1932).

(20) Daubert and King, THIS JOURNAL, **60**, 3003 (1938).

0.05 and 0.025 *N* alcoholic hydrochloric acid or ammonia (prepared by passing the gases into alcohol), there was a marked drop in melting point of the recovered product. There was no change in the melting point of 1,2-dibenzoyl glycerol, however, when identical tests were made, giving further evidence of the greater stability of the β-type aromatic esters compared to the β-glycerides of fatty acids.

Solubilities.—In an earlier publication[19] it was noted that the solubility ratios of the α- and β-aromatic and aliphatic monoglycerides in ether were reversed, the aromatic α-esters being more soluble than the β-isomers, but in the aliphatic series, the α-esters were less soluble than the β-isomers. A similar reversal of solubility in alcohol will be noted from the data in Table I.

TABLE I

SOLUBILITIES

Compound	Solvent	Temp., °C. (±0.01°)	Soly. g. per 100 ml.
α-Monopalmitin	Alcohol	25	4.09
β-Monopalmitin	Alcohol	25	4.61
α-*p*-Bromobenzoate	Alcohol	26	16.05[a]
β-*p*-Bromobenzoate	Alcohol	26	4.41[a]
β-*p*-Bromobenzoyl-α,α′-benzylidene glycerol	Alcohol	26	0.50
	Ether	26	1.15
β-Palmityl-α,α′-benzylidene glycerol	Alcohol	26	1.75
	Ether	26	17.40

[a] Repeated from an earlier paper for comparison.[20]

Summary

A new method for the synthesis of α,β- or 1,2-diglycerides has been described, in which sodium glyceroxide and benzyl chloroformate served as intermediates. Good yields were obtained and the reaction conditions made it possible to avoid the common β- to α-shift in structure.

1,2-Dipalmitin, m. p. 64°, 1,2-dimyristin, m. p. 59° and 1,2-dibenzoate of glycerol, m. p. 59°, were prepared and their structures were verified by making derivatives of known constitution.

A solution of 1,2-dipalmitin in 0.1 to 0.025 *N* alcoholic hydrochloric acid and ammonia underwent a rapid change in structure, but the analogous 1,2-dibenzoate was stable under the same conditions of exposure.

On the Effect of Acids in the General Meaning of the Term on the Activity of Invertase

BY WALTER ABBOTT WISANSKY

That the value of the *p*H of a solution in which an enzyme is acting, is a most important factor in controlling the activity of the enzyme, is well known. For example, the enzyme invertase has its maximum power for inverting sucrose in a range of *p*H values surrounding *p*H 4.5. If the *p*H value is raised or lowered sufficiently away from *p*H 4.5, the activity of invertase diminishes.

The explanation of the *p*H effect on enzymatic activity has been sought for a long time. The ionization hypothesis of Michaelis[1] has been a much favored suggestion in spite of certain shortcomings.[2] On the basis of this hypothesis invertase is supposed to be active only in the un-ionized condition.

In considering the effect of *p*H changes, workers have only been concerned with the effect produced on enzymatic activity by changes in the thermodynamic activity of one acid, oxonium ion. Since Brönsted[3] and others have demonstrated the generality of the term "acid," it became of interest to determine whether or not any acid, in the general meaning of the term, could alter the activity of enzymes. It was thought that if neutral acids could exert some effect on the activity of the enzyme invertase under conditions which purported to keep the degree of ionization of the enzyme constant (conditions such as constant ionic strength, and constant *p*H value), then one might impute to oxonium ion a role similar to that played by neutral acids in controlling the enzymatic activity of invertase, beyond oxonium ion's assured role of controlling the degree of ionization of the protein enzyme.

Since in practically all enzyme work, buffers are employed to regulate the *p*H, and since buffer solutions contain acids in the general meaning of the term, here is a very convenient source of acids whose effects on the activity of invertase it is proposed to consider.

The effects of neutral buffer acids on the activity of invertase have been studied.

In brief, the plan pursued in studying the effects of buffer acids on the activity of invertase

(1) L. Michaelis and H. Davidsohn, *Biochem. Z.*, **35**, 386 (1911).

(3) J. N. Brönsted, *ibid.*, **5**, 231 (1928).

was to determine the enzymatic activity in solutions of different buffer concentration, at various *p*H values, keeping the ionic strength of all the buffer solutions constant.

If the total buffer concentration of a solution is varied, the *p*H will remain practically the same and, if the ionic strength is kept constant, the degree of ionization of an enzyme (invertase in this case) in the solution should be unchanged.

Any observed loss in enzymatic activity obtained by increasing the buffer concentration in solution would then be due either to the increase in the concentration of neutral buffer acid or to the greater specific action of the potassium buffer salt as compared to potassium chloride. (The potassium chloride is added to the more dilute buffer solutions to build up the ionic strength to a given value.)

A salt like potassium acetate might well be expected to diminish the activity of invertase after the fashion of potassium chloride.[4] The effect of potassium acetate might be greater or less than that of potassium chloride. It was therefore necessary to determine whether or not any observed change in invertase activity with variations in total buffer concentration is due to buffer salt or buffer acid. One could distinguish between the two possibilities, as will be seen shortly, by studies of the influence of varying buffer concentrations on the activity of invertase at different *p*H values and at constant salt concentration.

As is evident from Fig. 1,[5] *p*H–activity curves for invertase obtained in the presence of different concentrations of acetate ion appear to spread fanlike from an origin near the *p*H optimum, as one passes to more acid *p*H values.

The results of other experiments not reported here indicate a similar effect when one substitutes a formate buffer in place of the acetate buffer Also this effect appears to be independent of the degree of purification of the invertase preparation used, being the same for preparations of very low time value[6] (*i. e.*, pure preparations of time values as low as 0.14 and 0.17 min.) as for a cruder commercial preparation known as Convertite.

In order to find out from Fig. 1 whether it is the difference in concentration of acetate ion or acetic acid which causes the difference between the two *p*H activity curves, consider the following.

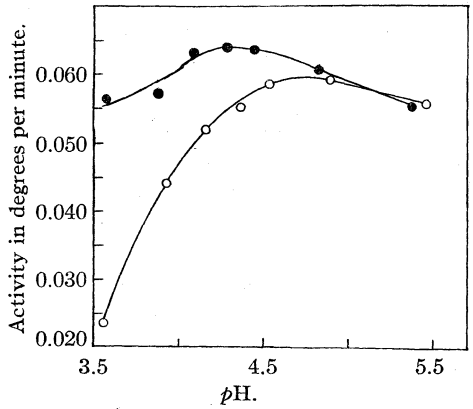

Fig. 1.—*p*H–activity curves based on data obtained in the presence of different concentrations of acetate ion; 10% sucrose; invertase preparation R(0.17); ionic strength, 0.2; ●, 0.02 molar total acetate; ○, 0.2 molar acetate ion.

Suppose the activity of invertase in a solution 0.02 molar in acetate ion is compared with that in a solution 0.05 molar in acetate ion, both solutions at *p*H 4.6. The mole fraction of acetate ion is 0.5. Therefore there is in each solution, respectively, 0.02 and 0.05 molar acetic acid. The activity of invertase is next examined at a more acid *p*H where the mole fraction of acetate ion is now 0.1. There is, in the dilute acetate solution 0.02 molar acetate ion and 0.18 molar acetic acid, and in the more concentrated buffer solution there is 0.05 molar acetate ion and 0.45 molar acetic acid. The difference in concentration of neutral acid has gone up from 0.03 molar at *p*H 4.6 to 0.27 molar at the more acid *p*H.

In Fig. 1, just as in the above example, parallel to the increase in the activity difference between the two *p*H–activity curves, there is a simultaneous increase in the difference of the acetic acid concentration as the *p*H is lowered. This points to the neutral acid as the cause of the loss in activity of invertase, as the buffer concentration is increased.

As further evidence that it is the neutral acid which causes the activity loss rather than the greater inhibitory effect of acetate ion over chloride ion, at *p*H values acid to 4.5, it is seen that on the alkaline side of the *p*H optimum practically no difference in the activity as measured in solutions of different buffer concentrations

(4) M. Washburn, Dissertation, Columbia University (1932).

(5) The numerical data are not given for brevity's sake. An idea of the accuracy of the measurements may be had from Table I in the experimental section. The activities upon which the figures in this paper are based were usually about the order of magnitude of 0.0500 degree per minute, it having been found that such a magnitude is conducive to greatest accuracy.

(6) C. O'Sullivan and F. W. Thompson, *J. Chem. Soc.*, **57**, 834 (1890).

is present. If acetate ion were a more effective retardant of invertase activity than chloride ion, then on the alkaline side of the *p*H optimum this effect should again be in evidence since the enzyme is quite sensitive to salt on the alkaline side as on the acid side of the *p*H optimum. There is, however, little difference between the "potassium acetate" curve (concentrated buffer), and "potassium chloride" curve (dilute buffer) in this region of *p*H.

As a final check, *p*H–activity curves were obtained in the presence of constant concentrations of acetic acid. From Fig. 2 it is evident that, to a first approximation, a given increase in acetic acid concentration causes a certain loss in activity independent of *p*H when this is in the optimum zone.

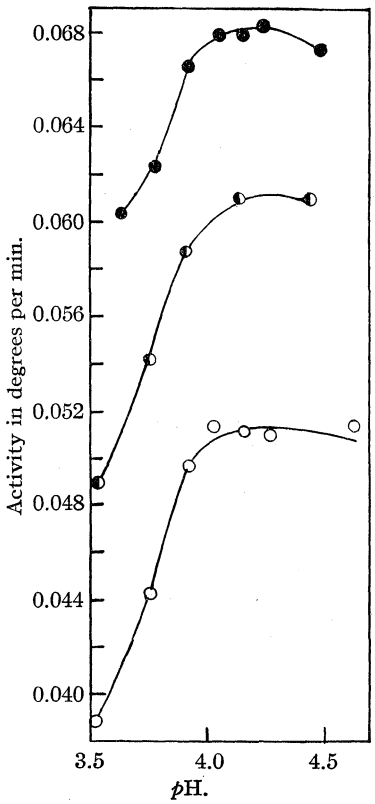

Fig. 2.—*p*H–activity curves based on data obtained in the presence of constant concentrations of acetic acid; 5% sucrose; invertase preparation, commercial Convertite; ionic strength 0.5; ●, 0.01 molar acetic acid; ◐, 0.2 molar acetic acid; ○, 0.5 molar acetic acid.

It is again plain that neutral acetic acid can decrease the activity of invertase.

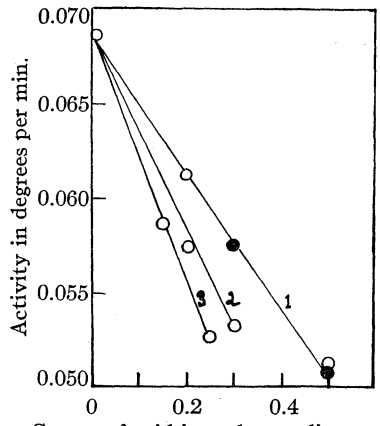

Fig. 3.—Data showing the variation of invertase activity with concentration of acid; 5% sucrose; open points refer to Convertite preparation; closed points refer to preparation R(0.14); curve 1, acetic acid, ionic strength 0.5; curve 2, formic acid, ionic strength 1.7; curve 3, acid phthalate ion, ionic strength 0.5.

In Fig. 3 data are plotted showing the effects of formic acid and acid phthalate ion (a charge type acid) on the activity of invertase as compared to the data on the retardation produced by acetic acid. The activities at zero buffer concentration have been equated. The *p*H values all lie in the optimum zone. The formic acid buffer experiments were performed at an ionic strength of 1.7 since at *p*H values close to the optimum *p*H 4.5 the buffer is practically neutralized and since a fairly large formic acid concentration was required. Because of the larger salt concentration present, a comparison of the effect of formic acid on the activity of invertase with that of acetic acid and acid phthalate ion may not be justified. The effect of these two latter acids on the activity of invertase was studied in 0.5 molar salt solutions.

There is a linear relation between the concentration of acid and the drop in invertase activity. This may be more apparent than real, however, since no correction was applied to correct for the loss in activity that accompanied the displacement of water by acids and salts.[7]

While acetic acid is a stronger acid than acid phthalate ion, as evidenced by their dissociation constants, the latter is the more effective retardant.

(7) It was shown by Nelson and Schubert[8] that decreasing the water concentration even in an essentially aqueous solution produces a loss in the activity of invertase.

(8) J. M. Nelson and M. Schubert, THIS JOURNAL, **50**, 2188 (1928).

Discussion

It is evident from the above that acids in the general meaning of the term can diminish the activity of invertase. It is probable that the effect can be extended to other enzymes. It is therefore suggestive to postulate something as to the meaning of the acid effect.

Mirsky and Pauling[9] hypothesize that proteins are held in their particular configurations through the medium of hydrogen bonds. In the light of this idea, it is suggested that in the case of the retardation of invertase activity by acids, these latter form intermolecular hydrogen bonds with certain electronegative groups in the enzyme protein, which groups are bound by intramolecular hydrogen bonds to other similar groups in the protein. There is a sort of competition in this respect. The result is a breaking of some of the weaker bonds in the protein with the further result that the enzyme passes into some more unspecified form of less enzymatic activity.

Since oxonium ion is an acid, it too might be expected to exert its effect upon the enzyme in a manner similar to that of neutral acids. The first step in the attack of oxonium ion would be the formation of an intermolecular hydrogen bond with the concurrent breaking of an intramolecular hydrogen in the protein enzyme. This would again result in the formation of a more unspecified configuration possessing less activity as an enzyme. The fact that water might subsequently be dissociated from the newly formed hydrogen bond complex, yielding a protein with an extra proton (*i. e.*, a change in the degree of dissociation of the enzyme) may be of secondary importance. In short it is suggested that changes in oxonium ion concentration in altering the activity of invertase do so by bringing about changes in the enzyme protein of a deeper sort than mere ionization changes.

Experimental

(1) The salts and acids used in this investigation were C. P. grade. They were used without further purification. The sucrose used was obtained in a grocery store.

(2) In the experiments on buffer acids it was necessary to know accurately the amount of buffer acid, the concentration of salt (buffer salt and potassium chloride) and that of sucrose in the reaction mixture.

Buffer solutions of known acid and salt concentrations were prepared by standardizing the acid constituent against potassium hydroxide. The alkali was standardized against potassium acid phthalate; 4 molar solutions of the acids were kept in resistance glass bottles; 1 and 2 molar solutions of potassium hydroxide were kept in paraffin lined bottles protected from carbon dioxide. In preparing the buffer a known volume of buffer acid of accurately known concentration was titrated with standard alkali until a given fraction was neutralized. From a knowledge of the total volume of solution, the buffer salt and acid concentration was calculated. A definite volume of the solution so prepared was pipetted into a 250-cc. volumetric flask, keeping in mind the concentration of buffer required to exist in the final reaction mixture. To the volumetric flask was added sucrose and potassium chloride (in sufficient amount to give the required ionic strength in the reaction mixture); 25.00 ± 0.05 cc. of invertase solution was pipetted in six seconds into 200 cc. of solution prepared as above. At recorded time intervals 25.00 cc. of reaction mixture was pipetted into bottles containing sufficient alkali to stop the reaction (*p*H alkaline to phenolphthalein). After allowing five to fifteen minutes for mutarotation, the rotations of the samples were determined. The activity was expressed as the average change in rotation in degrees per min. Usually four constants were used in calculating the average activity.

In calculating the ionic strength, the contribution due to the ionization of the acid constituent of the buffer was neglected, its contribution being too small to affect the activity of invertase when the ionic strength is high (see Table I).

TABLE I

Ionic strength	Enzymatic activity and a. d.	*p*H
0.20	0.380 ± 0.001	3.94
.22	.375 ± .001	3.96
.23	.375 ± .003	3.96

(3) *p*H measurements were made using both the glass and hydrogen electrodes.

(4) **Invertase Preparations.**—The author is grateful to Mr. Stanley Lewis of these laboratories for the preparation of the following highly purified yeast invertase preparations, RaDKDADSDAD[10] time value 0.14 min. known in this paper as R(.14), RaDAceSKSAD time value 0.17 min. known in paper as R(.17). A commercial invertase preparation known as Convertite also was used.

(5) Hydrolyses were conducted at 25.00 ± 0.02°.

Acknowledgment.—The author wishes to express his appreciation to Professor J. M. Nelson for his friendly advice and constructive criticism throughout the course of this investigation.

Summary

1. It has been demonstrated that acids in the general meaning of the term can retard the enzymatic activity of invertase under conditions which purport to hold the degree of ionization of the enzyme constant (*i. e.*, conditions such as constant ionic strength and constant *p*H).

2. It has been suggested that oxonium ion and

(10) For the meaning of the letters which refer to steps in the purification see Lutz and Nelson, *J. Biol. Chem.*, **107**, 169 (1934).

acids in general may alter the activity of an enzyme by causing the rupture of intramolecular hydrogen bonds in the enzyme protein. The results of such bond breaking may be the arising of modified forms of the enzyme with more internal degrees of freedom, possessing less catalytic activity.

Kinetics of Polyesterification: A Study of the Effects of Molecular Weight and Viscosity on Reaction Rate[1]

BY PAUL J. FLORY

Introduction

Investigators in the field of macromolecular chemistry have been prone to attribute the apparent sluggishness of some polymer reactions either to an inherent diminished reactivity of large molecules, or to the high viscosity of the reaction medium. Various arguments have been advanced in an effort to show theoretically that increase in size of the molecule and increase in viscosity should decrease reactivity.[2,3] However, no direct experimental evidence has been advanced to prove even the existence of an effect of either molecular weight or viscosity on reactivity of polymer molecules.

The problem of the effect of viscosity on reaction rate of liquid phase reactions in general has been the subject of frequent discussion,[4] but again conclusive experimental evidence does not seem to be available. Moelwyn-Hughes[5] has concluded that the rate of collision between solute and solvent molecules should increase proportionally with viscosity and, hence, the rate of a reaction between solute and solvent should be proportional to viscosity also. More recently Rabinowitch and Wood[6] have shown with exceptional clarity that one should expect no effect of viscosity on reaction rate, except at very high viscosities (very low rates of diffusion) or when a large fraction of collisions leads to reaction.

The study of the kinetics of a condensation polymerization offers a splendid opportunity to observe the effects of molecular weight and viscosity on reaction rate. Both molecular weight and viscosity increase continuously as such reactions proceed. It should be possible, therefore, to observe the effects of molecular weight and viscosity on reaction rate, if such effects exist.

The present investigation has been primarily concerned with the kinetics of polyesterification reactions between glycols and dibasic acids. The kinetics of several esterifications involving monofunctional reactants have been investigated also, in order that the polyesterification reactions could be compared with similar reactions in which neither molecular weight nor viscosity underwent appreciable change. All of these reactions have been followed by titration of the total free carboxyl in samples removed from the reaction mixture at suitable intervals.

In contrast to monofunctional esterification where there are only two species of reactants, many species of molecules are present during polyesterification. Any one of these species bearing an hydroxyl group may react with any other bearing a carboxyl; the product of this reaction may react with another molecule, etc. Many reactions are occurring simultaneously: *i. e.*, monomers react with monomers, dimers, trimers, etc., dimers react with monomers, dimers, trimers, etc., trimers react with monomers, etc., etc. A complete kinetic analysis, treating each of these reactions individually, is obviously hopeless. All of these reactions, however, are chemically identical, and their rates may differ only in so far as reactivity is affected by molecular weight. Instead of attempting to unravel the maze of individual reactions, one may consider merely the reaction of all functional groups, disregarding the size of the molecule to which each group is attached. If, as usually has been supposed, reac-

tivity decreases with increase in size of the molecule, then the ratio of the rate of polyesterification to the rate of a simple esterification at the same degree of reaction should decrease as the reactions progress. The results presented below show that polyesterification and esterification reactions follow identical courses.

Experimental

Materials.—Diethylene glycol, lauryl alcohol, adipic acid, lauric acid, and caproic acid were obtained from the Eastman Kodak Company. Decamethylene glycol, which had been prepared by hydrogenation of diethyl sebacate, was obtained from the University of Illinois. The diethylene glycol was carefully fractionated through a carborundum packed column. The boiling point was practically constant throughout almost the entire distillation, 129.5 to 130.0° at 10.5 mm. A center cut was retained for use. Decamethylene glycol was treated with boiling 5% aqueous caustic to remove unreduced ester, then recrystallized three times from ethylene dichloride. The final product had a freezing point of 71.9 (±0.1)°. Lauryl alcohol, freezing at 21.9 (±0.1)°, was used without further purification.

Adipic acid was recrystallized from conductivity water; m. p. 151.5°; neutral equivalent 72.9, 73.0; calcd. 73.07. Caproic acid, neutral equivalent 117.6, calcd. 116.2, and lauric acid, neutral equivalent 200.6, 200.9, calcd. 200.3, were used with no further purification.

Apparatus and Procedure.—The apparatus consisted of a Pyrex reaction bulb of about 50 cc. capacity sealed to the bottom of a 15-mm. tube about 25 cm. long. Through a stopper at the top of this tube a pipet was inserted. The pipet was used to remove samples, and also for admitting a slow stream of nitrogen through the reaction mixture in order to facilitate removal of water. The effluent stream of nitrogen and water vapor passed through a 12-mm. tube sealed to the vertical tube just below its upper end. This side tube sloped upward at about 45° from horizontal for about 30 cm., and then led downward to a dry-ice trap. With the apparatus designed in this way loss of glycol was minimized by condensation in the side arm, followed by its return to the reaction mixture. Glycol is lost more readily during the early stages of the reaction; later on nearly all glycol molecules have reacted at one end or the other (or both) and hence are no longer volatile.

The reaction bulb and adjacent tubing were carefully cleaned before each experiment. This is especially important since esterification is an acid catalyzed reaction, and hence is sensitive to traces of acids or bases.

Equivalent quantities of glycol (or alcohol) and acid were placed in the reaction bulb which was then sealed onto the vertical tube. The reaction bulb and several cm. of the vertical tube above were heated with a vapor-bath, which remained within 0.2° of constant temperature throughout any one experiment. Liquids used in the vapor-bath were toluene boiling at 109°, phenetole at 166°, and *m*-cresol, 202°. From time to time samples were removed, weighed and titrated (at 20–25°) with 0.1 *N* alcoholic potassium hydroxide, using phenolphthalein indicator. High molecular weight samples, which tended to dissolve slowly, were dissolved in hot chloroform, cooled and then titrated. The end-point was very sharp.

Reactions catalyzed with *p*-toluenesulfonic acid were carried out in the same manner except that, due to the lower temperature, 109°, it was necessary to reduce the pressure to about 200 mm. in order to ensure rapid removal of water.

Experimental Results

From the neutral equivalent determined by titration one can calculate both the extent of reaction p, *i. e.*, the ratio of the number of ester groups to the number of ester plus free carboxyl groups, and the degree of polymerization DP, which is defined as the average number of glycol and dibasic acid residues per molecule. The number of free carboxyl groups will equal the number of molecules, provided that equivalent amounts of glycol and dibasic acid are used and that the only reaction occurring is intermolecular esterification. When these conditions are fulfilled the neutral equivalent must be equal, therefore, to the average molecular weight, and

$$DP = \frac{\text{neut. equiv.} - 18}{\text{mean segment weight}} = 1/(1 - p) \qquad (1)$$

where the mean segment weight is half the molecular weight of the structural unit —ORO—COR'CO— of the polymer.

As Goldschmidt[7] has shown, esterification reactions are hydrogen ion catalyzed. In the absence of a strong acid catalyst a second molecule of the carboxylic acid undergoing esterification must function as catalyst. Therefore, the reaction rate is proportional to the hydroxyl concentration and to the square of the carboxyl concentration. When hydroxyl and carboxyl groups are present in equal numbers, the process becomes a third order reaction,[8] for which

$$2kt = 1/C^2 - 1/C_0^2 \qquad (2)$$

where k is the velocity constant, C is the concentration of unreacted groups at time t, and C_0 is the initial concentration. If one neglects the effect on concentration of the decrease in volume due to loss of water, this equation may be replaced by

$$2C_0^2kt = 1/(1 - p)^2 - 1 \qquad (3)$$

with which the data presented below will be compared. The error arising from the use of (3) rather than (2) is appreciable only during the

diethylene glycol with adipic acid at 166 and 202°, and of the same glycol with caproic acid at 166°. It has been necessary to use two graphs having different scales in order to show effectively the entire course of the reaction. Dots and circles are used to distinguish data obtained in different experiments. The agreement between two such sets of points indicates the reproducibility. Data from the reactions of decamethylene glycol with adipic acid, lauryl alcohol with adipic acid, and lauryl alcohol with lauric acid are shown in Fig. 3.

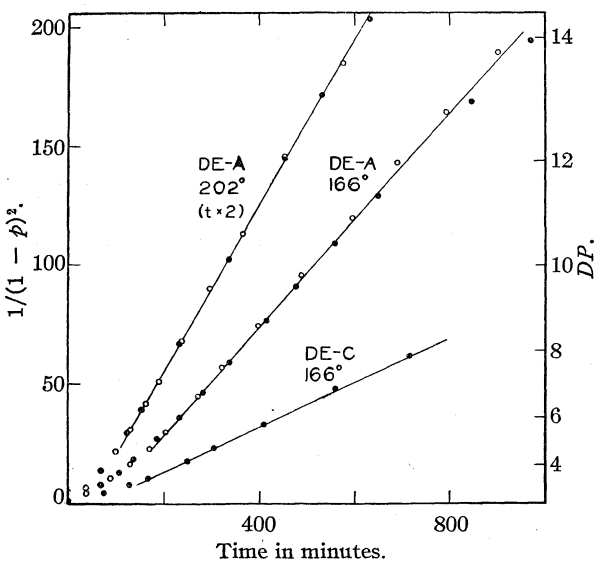

Fig. 2.—Diethylene glycol–adipic acid (DE-A) and diethylene glycol–caproic acid (DE-C) reaction including later stages of the reactions. Time values at 202° have been multiplied by two.

During the portion of the reaction shown in Fig. 1 the relationship between $1/(1-p)^2$ and t is definitely not linear, in disagreement with the

third order equation (3). However, at the larger extents of reaction included in Figs. 2 and 3 the data do approach this linear relationship. Straight lines have been drawn through the points in these two figures in order to show clearly the range over which $1/(1 - p)^2$ is approximately linear with t. Attempts to fit the data to an equation for a reaction of lower order have not been successful; although such equations offer somewhat better agreement within a limited range during the early portion of the reaction, they fail completely at higher extents of reaction.

In the case of the diethylene glycol–caproic acid reaction, reliable data could not be obtained beyond the range given in Fig. 2, due to excessive loss of the comparatively volatile caproic acid. With diethylene glycol and adipic acid at extents of reaction somewhat beyond those covered in Fig. 2 the points fell consistently below the extrapolation of the straight lines shown in the figure. This is attributed to the effect of the inevitable slight loss of the glycol by volatilization. Small losses of one reactant are of no consequence except at large extents of reaction where the concentration of unreacted functional groups is so low that a small deficiency of one functional group produces an appreciable reduction in rate. This deviation sets in at a much later stage in the reaction of decamethylene glycol with adipic acid, since this glycol is less volatile.

Careful examination of the data presented in the figures fails to reveal any significant dissimilarities between polyesterification and esterification. The courses which they follow are so similar that their points may be made to follow approximately the same curve by merely multiplying all time values for one of them by a suitable factor.

Velocity constants for the esterifications and polyesterifications included in this investigation are given in Table III. These have been evaluated, using (3), from the slopes of the straight lines in Figs. 2 and 3.[9] The velocity constants fall into two groups, those for reactions of diethylene glycol and ethylene glycol being lower than those for decamethylene glycol and lauryl alcohol. Between polyesterifications and esterifications within each group there are no important differences in the values of the velocity constants. The lower rates of the esterifications compared with polyesterification (see Fig. 3) are due merely to the diluting effect of the larger proportion of hydrocarbon chain in the esterification reactions which have been studied.

These velocity constants are some ten to twenty times larger than those calculated from Fairclough and Hinshelwood's[10] data for esterification of dilute solutions of various aliphatic acids in ethanol. The energy of activation, 13 kcal., calculated from rates of the diethylene glycol–adipic acid reaction at 166 and at 202°, is slightly less than the value, 15.0 kcal., obtained by these authors for esterifications in ethanol.

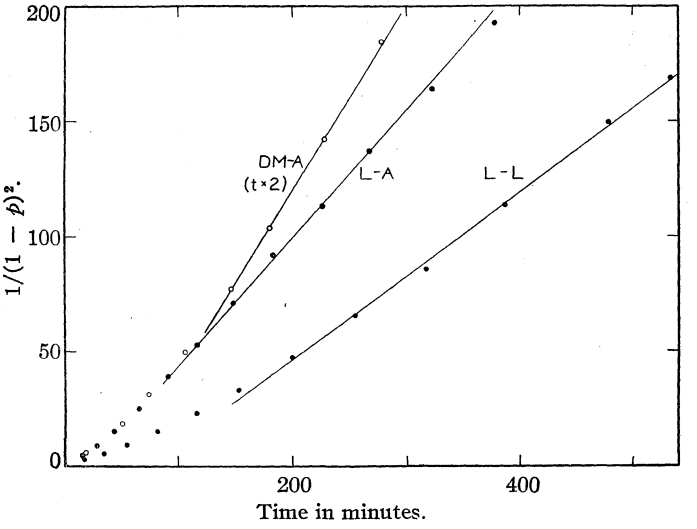

Fig. 3.—Decamethylene glycol–adipic acid (DM-A), lauryl alcohol–adipic acid (L-A), and lauryl alcohol–lauric acid (L-L) reactions at 202°.

TABLE III

VELOCITY CONSTANTS FOR POLYESTERIFICATION AND ESTERIFICATION

Reaction	$k \times 10^{-2}$ at 202° in (equiv./1000 g.)$^{-2}$ min.$^{-1}$
HO—$(CH_2)_2$—O—$(CH_2)_2$—OH + HOOC—$(CH_2)_4$—COOH	0.41
HO—$(CH_2)_2$—O—$(CH_2)_2$—OH + H—$(CH_2)_5$—COOH	0.35
HO—$(CH_2)_2$—OH + HOOC—$(CH_2)_4$—COOH	~0.5
HO—$(CH_2)_{10}$—OH + HOOC—$(CH_2)_4$—COOH	1.63
H—$(CH_2)_{12}$—OH + HOOC—$(CH_2)_4$—COOH	1.57
H—$(CH_2)_{12}$—OH + H—$(CH_2)_{11}$—COOH	2.5

Over the portions of the polyesterifications shown in Figs. 2 and 3 the molecular weight increases about fourteen-fold. In this range the viscosity increased from about 0.015 to 0.30 poise,

(9) The velocity constant for the ethylene glycol–adipic acid reaction could not be determined accurately due to the volatility of this glycol. The experimental data have not been included here.

(10) R. A. Fairclough and C. N. Hinshelwood, *J. Chem. Soc.*, 593 (1939).

in the diethylene glycol–adipic acid reaction. In the esterification reactions the viscosity remains practically constant, at about 0.01 poise, except for a probable slight decrease. The polyesterification reaction is unaffected, therefore, by increase in viscosity, as well as by increase in molecular weight, within the range investigated.

Several experiments on the reaction of diethylene glycol with adipic acid catalyzed by a small amount of *p*-toluenesulfonic acid (0.004 mole per mole of glycol) have been carried out at 109°. These should be second order, according to the results of numerous researches[7] on acid catalyzed esterifications. For a second order reaction, $1/(1 - p)$ increases linearly with time. In striking similarity to the reaction in the absence of added catalyst, the slope of $1/(1 - p)$ plotted against t (see Fig. 4) increases at first, but becomes constant later on. Even as far as DP 90 no tendency of the slope to decrease, as would occur if reactivity decreased as the average molecular weight increases, has been observed. The viscosity increase accompanying this increase in molecular weight is over two thousand-fold.

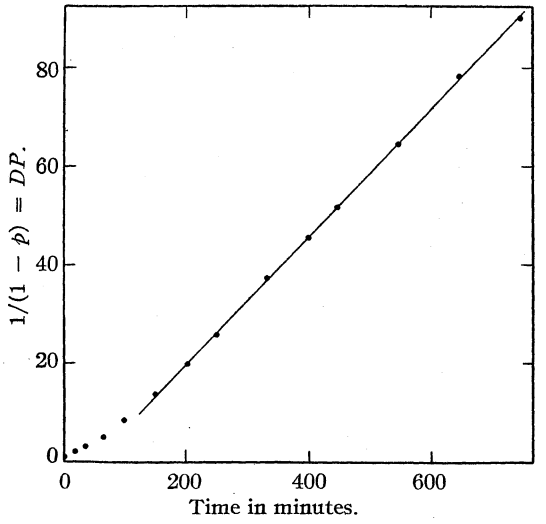

Fig. 4.—Diethylene glycol–adipic acid reaction at 109° catalyzed by 0.4 mole per cent. of *p*-toluenesulfonic acid.

It has been suggested in the past that the rate of polyester formation is governed by the rate at which moisture formed in the reaction escapes from the molten polymer.[11] Recently Schulz[12] has offered a detailed analysis of polyesterification based on the assumption that this is the rate controlling process. In order to test this assumption, diethylene glycol and adipic acid were heated (without catalyst) at 166° under reduced pressure (about 200 mm.), instead of at atmospheric pressure as in other experiments. More efficient removal of moisture resulting from this reduction in pressure should have brought about an increase in the rate of reaction, if the escape of water were the rate determining step. The data obtained in this experiment are given in Table IV.

TABLE IV

REACTION OF DIETHYLENE GLYCOL WITH ADIPIC ACID UNDER REDUCED PRESSURE AT 166°

t in min.	p	t interpolated from expts. at 1 atm.
6.5	0.1535	6
23.5	.3947	23
55	.5927	55
84	.6793	84
135	.7633	137
176	.7983	176

That the reaction velocity is not affected by the reduction in pressure is shown in the table by a comparison of time values with those for the same extent of reaction interpolated from the curve in Fig. 1.[13] The rate must be controlled by factors inherent in the mechanism of the reaction, and not by escape of moisture as Schulz has assumed.

Obviously it is necessary to provide adequate means for escape of water formed in the reaction; otherwise the occurrence of the reverse reaction, hydrolysis, would set up an equilibrium and further polymerization would cease. According to the usual practice, which was followed essentially here, a stream of gas bubbled through the polyester is used to provide for escape of water. Only a very gentle gas stream is required to maintain the normal rate, which cannot be exceeded by increasing the rate of bubbling.

The slow rate of advancement of polyesterification when the average molecular weight becomes large, sometimes attributed in the past to a low reactivity of large molecules or to the difficulty of removing moisture, is a consequence of the kinetic order (third) of the reaction. The rate, being proportional to the third power of the concentration of unreacted functional groups, decreases rapidly as the extent of reaction increases.

(11) See, for example, W. H. Carothers, *Chem. Rev.*, **8**, 367 (1931).
(12) G. V. Schulz, *Z. physik. Chem.*, **A182**, 127 (1938).

(13) The experiment at reduced pressure from which the data in Table IV were taken was not extended to large extents of reaction. The excessive loss of glycol under these conditions might have vitiated results at larger extents of reaction.

Although initially the reaction is rapid, a very long time is required for close approach to complete reaction, which is essential for attainment of high molecular weight.

Discussion

The failure of the reaction to adhere to the third order equation (3) during the first stages of the reaction is difficult to explain. A part of this deviation can be attributed to the decrease in volume due to loss of water (*i. e.*, to the error arising from the use of (3) rather than (2)). This will not account for the entire deviation, however.

Inasmuch as esterification is catalyzed by hydrogen ions (or hydrogen donors, *i. e.*, acids), it probably is sensitive to the nature of the reaction medium. For example, the change in dielectric constant which occurs as hydroxyl and carboxyl groups are converted to ester may influence the reaction rate. In dilute solutions, which have been used almost exclusively in previous work on esterification, the change in properties of the reaction medium as the esterification progresses is inappreciable. If the process is sensitive to changes in the reaction medium, then in the present experiments deviation from third order may be expected, except at large extents of reaction where one is dealing with a dilute solution of functional groups.

The above discussion has been presented merely as a possible explanation for the peculiar course of the reaction. Whatever the cause of this behavior may be, it is typical of both polyesterification and esterification. The fact of primary importance to this investigation is their similarity, in spite of the high molecular weight and viscosity attained in the former.

Bawn[2,14] has attempted to show, on the basis of the transition state method developed by Eyring[15] for the treatment of reaction velocity from a statistical mechanical point of view, that reactivity should decrease continually as size of the molecule increases. According to the transition state method[15]

$$k = K^* (k'T/h) \qquad (4)$$

where k is the velocity constant, k' is Boltzmann's constant, T is the absolute temperature, h is Planck's constant and K^* is the constant for the equilibrium between normal molecules and activated complexes.

$$K^* = (F_{ab}^*/F_aF_b) \exp(-E_0/k'T) \qquad (5)$$

where (F_{ab}^*/F_aF_b) is the ratio of the partition function for the activated complex to the product of the partition functions for the reactants, and E_0 is the activation energy at the absolute zero. Evans and Polanyi[16] have shown that the partition function factor F_{ab}^*/F_aF_b must be smaller for the recombination of radicals (*e. g.*, CH_3) than for the recombination of atoms (*e. g.*, H). Bawn considers that this decrease in "steric factor" will continue indefinitely as the complexity of the molecule increases. Thus, in the vinyl type of polymerizations, in which a polymer molecule bearing a free radical adds on monomers consecutively, he concludes that the rate should decrease with each successive addition of monomer, the rate finally approaching zero when the polymer molecule becomes very large.

An increase in complexity of one of the reacting molecules modifies both F_{ab}^* and the product F_aF_b. Unless the increase in complexity involves modification at a point in the molecule very close to the functional group, both F_{ab}^* and F_aF_b will be altered by virtually identical factors for the added degrees of freedom. The structure in the immediate vicinity of the functional group of a polymer molecule is independent of its degree of polymerization. Hence, contrary to Bawn's conclusion, no decrease in rate of polymerization due to a decrease in the partition function factor with increasing length of the molecule should be expected.

Rabinowitch and Wood[6] have shown convincingly that the actual collision rate in the liquid phase is not affected appreciably by changes in viscosity, although the rate of diffusion is materially decreased. Even if the frequency of collision is decreased by low mobility of large polymer molecules, the duration of collisions must be proportionately increased. Hence, the concentration of molecules in the collided state cannot be affected by either molecular size or viscosity. Consequently, the rate of reaction should be independent of these factors.

The same conclusion follows directly from the transition state method, since the activated complex is in thermodynamic equilibrium with the reactants; the concentration of activated complexes will not be affected by changes in mobility, unless the mobility is too low to maintain their equilibrium concentration.

(15) H. Eyring, *J. Chem. Phys.*, **3**, 107, 492 (1935).

(16) M. G. Evans and M. Polanyi, *Trans. Faraday Soc.*, **31**, 875 (1935). See also C. E. H. Bawn, *ibid.*, **31**, 1536 (1935).

Rabinowitch and Wood[6,17] have pointed out that at sufficiently high viscosities the rate of diffusion will become too slow to maintain the "equilibrium" number of pairs of reactants adjacent to each other in the liquid (*i. e.*, within colliding distance of each other). Diffusion, rather than the passage of molecules through the activated state, becomes the rate controlling step when such viscosities are reached, and the rate will no longer be independent of molecular size and viscosity. For most reactions (those with very low values of E_0 excepted) extremely high viscosities would be required to effect a perceptible decrease in rate.

Some time ago the author published equations[18] for calculating the numbers of molecules of various sizes in a linear condensation polymer. The validity of these equations rested entirely on the postulate, presented at that time without experimental proof, that the functional groups of all molecules, regardless of size, are equally reactive. Dostal[19] objected to the size distribution equations on the grounds that this postulate could not possibly be valid. The present investigation furnishes proof that this postulate is correct. The quantities of molecules of various sizes in a linear condensation polymer can be determined reliably, therefore, by simple calculation using the distribution equations referred to above.

Summary

1. The kinetics of two polyesterifications, diethylene glycol–adipic acid, and decamethylene glycol–adipic acid, have been compared with several non-polymer forming esterifications, diethylene glycol–caproic acid, lauryl alcohol–adipic acid, and lauryl alcohol–lauric acid. Preliminary experimental data on the reaction of diethylene glycol with adipic acid catalyzed by *p*-toluenesulfonic acid have been presented also.

2. As the reactions proceed (in the absence of catalyst) the course followed corresponds to a continuous increase in kinetic order, becoming approximately third order at large extents of reaction.

3. Polyesterification and esterification follow similar courses, from which it has been concluded that reaction rate is not affected by either increase in molecular weight or the concurrent increase in viscosity.

4. This conclusion has been shown to be in agreement with theory, contrary to previous theoretical deductions.

5. The slow rate of polyesterification when the average molecular weight is large is due to the third order character of esterification.

Acetometallates. II. Acetozincate

BY ALEXANDER LEHRMAN AND PHILIP SKELL

It has been shown[2a] that the solubility of metal hydroxides in aqueous solutions of alkali metal hydroxides can best be explained as the formation of hydroxyl complex ions. $M(OH)_2$, for example, may dissolve to give $M(OH)_4^{=}$. In the case of zinc, Goudriaan[1] isolated as a solid phase the compound $Na_2O{\cdot}ZnO{\cdot}4H_2O$ which was formerly thought to be $Na_2ZnO_2{\cdot}4H_2O$, but which according to the complex ion hypothesis could also be written as $Na_2Zn(OH)_4{\cdot}2H_2O$. More recently, Scholder and co-workers[2] have isolated a monoand a disodium zincate in both the anhydrous and hydrated condition. On the basis of the ease of removal of water from these compounds it was concluded by Scholder that they were $NaZn(OH)_3$ and $Na_2Zn(OH)_4$, respectively, and their hydrates, rather than the various hydrates of $NaHZnO_2$ and Na_2ZnO_2. Subsequently Brintzinger and Wallach[3] showed from the rate of diffusion of zincate ions through a cellophane membrane that their ionic weight is consistent with the formula $Zn_2(OH)_8^{==}$. More light could be thrown on the question if the system $NaOH–Zn(OH)_2$ could be shown to be a simple binary system with com-

pound formation. Such an investigation has not been carried out because zinc hydroxide readily decomposes to the oxide on heating.

For further elucidation it was necessary to resort to the results obtained in analogous systems where the possibility of a phenomenon similar to dehydration is not present. Davidson and co-workers[4] have demonstrated a very close similarity between the water and the acetic acid systems. Davidson and McAllister[4c,d] have carried this analogy into the field of amphoterism. Whereas Goudriaan and Scholder have shown the existence of two solvated compounds of zinc hydroxide and sodium hydroxide in which the ratios of $Zn(OH)_2$ to NaOH were 1:1 and 1:2, Davidson and McAllister were able to obtain from glacial acetic acid solution a solvated compound in which the ratio of zinc acetate to sodium acetate was 1:2, namely, $Na_2Zn(C_2H_3O_2)_4 \cdot 4HC_2H_3O_2$ which has been named sodium acetozincate solvate. Unlike zinc hydroxide the analogous zinc acetate cannot undergo "dehydration" reaction but instead undergoes pyrolytic decompositions on continued heating of the melt. It was thus found feasible to determine the liquidus curve of the unsolvated system zinc acetate–sodium acetate and in this way cast some light on the analogous zinc hydroxide–sodium hydroxide system.

Experimental

Materials.—Zinc acetate and sodium acetate were recrystallized from dilute acetic acid and then dehydrated by the methods of Davidson and McAllister.[4c]

Apparatus.—The temperature measuring device was a single copper–constantan thermocouple and potentiometer. A description of the wire, apparatus, and standardization appear in the literature.[5]

The bath was about 300 ml. of the eutectic mixture of lithium, potassium and calcium nitrates contained in a wide-mouthed Pyrex Erlenmeyer flask.[6]

Method.—The salts were weighed (to the nearest centigram) into 2.5 × 20 cm. Pyrex tubes, the zinc acetate being placed below the sodium acetate. The total weight of each sample was 12 g. The tube was placed in the bath whose temperature was controlled by inserting a thermometer enclosed in a Pyrex shield. The salts were stirred with the thin Pyrex tube containing the thermocouple.

To prevent pyrolytic decomposition of the zinc acetate, five drops of glacial acetic acid were added when the salts were partially melted. All except very small quantities of the acid distilled out of the mixtures since the temperatures of the mixtures were usually raised to about 250°. This small amount of acetic acid enabled us to obtain and maintain a clear melt for a time sufficient to determine the melting point. If this aid is omitted it is almost impossible to get clear melts and maintain them so during the determination of the melting point.

After the mixtures had been melted the temperature of the bath was lowered and the mixtures stirred constantly. Considerable supercooling usually preceded initial crystallization. It was necessary to determine the temperature of disappearance of the last crystal as the mixture was heated. The bath was heated slowly until a large part of the crystals had dissolved and then very slowly to obtain the melting point. The disappearance of the last crystal was observed easily by placing the source of a sharp beam of light behind the bath so that the beam passed through the melt before reaching the eye. The temperature was noted when a clear sharp image of the light source could be seen through the melt. This obviated the possibility of too low a reading because of the presence of very fine crystals. This method was found to be very convenient and to give consistent and reproducible values.

All melting points recorded are the result of at least three determinations coming within a range of one degree.

Results and Discussion

Temperatures of the disappearance of the last crystal are given in the table and plotted in Fig. 1.

0.26 mole fraction zinc acetate to lie between 218 and 220°.

At temperatures below 210° the melts were extremely viscous so that great difficulty was experienced in obtaining crystallization and reproducible melting points. If cooling was rapid stable glasses resulted.

An attempt was made to obtain evidence for the existence of the compound 1 sodium acetate: 1 zinc acetate (0.5 mole fraction of zinc acetate). A number of melting point determinations were made in this region. These freezing points alone, however, did not disprove the existence of this compound, for a slight rise in the curve to a maximum at 50 mole per cent. would not have been detected. However, the point of incipient melting seen on a mixture of 0.49 mole fraction of zinc acetate was 183°. This is wholly inconsistent with the supposition that a maximum in the curve exists at 0.5 mole fraction of zinc acetate. Further, the mixture of mole fraction 0.500 did not behave like a pure compound in that it did not solidify at anything that might reasonably be considered a constant temperature. We found no evidence for the existence of a one to one compound. An attempt was made to check this conclusion by optical and X-ray examination of the mixtures. Neither proved feasible.

The curve definitely points to the existence of the compound $2NaC_2H_3O_2 \cdot ZnC_2H_3O_2$ or $Na_2Zn(C_2H_3O_2)_4$—sodium acetozincate in the unsolvated system. This suggests the existence of the analogous sodium zincate as $Na_2Zn(OH)_4$.

Summary

1. The liquidus curve of the binary system zinc acetate–sodium acetate has been determined.

2. The compound $2NaC_2H_3O_2 \cdot Zn(C_2H_3O_2)_2$ or $Na_2Zn(C_2H_3O_2)_4$ was shown to exist.

3. The analogy between this compound and the hydroxyl zincates was discussed.

Hydrolysis of Stannous Ion in Stannous Perchlorate Solutions

BY MEL GORMAN

The hydrolysis of stannous ion in stannous perchlorate solutions containing free perchloric acid has been investigated by adding sodium hydroxide solution and measuring the *p*H during the titration with a hydrogen electrode.[1] The purpose of the present investigation is to determine the extent of hydrolysis of stannous ion by a method involving the potentiometric measurement of the mean ion activity of total free perchloric acid and an analysis of total stannous ion concentration.

Method and Apparatus

The stannous perchlorate solutions containing free perchloric acid were prepared by the method of Noyes and Toabe,[2] and the concentration of free acid was determined by their method. A fresh stannous perchlorate solution was prepared for each experiment and stored in contact with metallic tin under nitrogen for at least one day before being used. The concentration of total stannous ion was obtained by titration in an atmosphere of nitrogen with 0.1 *N* iodine using starch indicator.

The mean activity of the hydrogen and perchlorate ions in the solutions of stannous perchlorate and perchloric acid was obtained with the aid of a hydrogen electrode and a

(2) Noyes and Toabe, THIS JOURNAL, **39**, 1539 (1917).

normal calomel electrode using cells of the following type

Pt, H_2, $Sn(ClO_4)_2$, $HClO_4$ | saturated NH_4NO_3 | KCl (1 *N*), Hg_2Cl_2, Hg (1)

at 25.0°. The commercial hydrogen used was passed through alkaline pyrogallate solution and then through water at 25° before passing into the stannous perchlorate solution. The partial pressure of the hydrogen was obtained by subtracting the vapor pressure of water from the barometric pressure. The platinum electrodes were strips of approximately one square centimeter. They were cleaned and freshly platinized for each experiment.

The constancy of the reference electrode was checked from time to time during the investigation by connecting it through a bridge of saturated potassium chloride to a solution of 0.05 *M* potassium acid phthalate into which dipped a hydrogen electrode, and noting the electromotive forced developed. The observed and calculated voltages agreed to within 0.5 millivolt.[3]

Experimental Results and Calculations

The calculation of the composition of each solution based on the equation

$$Sn^{++} + H_2O \longrightarrow SnOH^+ + H^+ \qquad (1)$$

was performed as follows. The activity of the total perchloric acid was computed from the voltage of the cell. The activity of the total hydrogen ion was assumed equal to the mean ion activity of the total perchloric acid, and in turn the activity of the total hydrogen ion was assumed equal to its concentration. The concentration of free acid subtracted from the concentration of total hydrogen ion gives the concentration of $SnOH^+$ and of hydrogen ion due to hydrolysis. By subtraction of $SnOH^+$ from total stannous ion the concentration of unhydrolyzed stannous ion can be found. The values of the equilibrium quotient, K_1, were computed from the relation

$$K_1 = c_{SnOH^+} a_{H^+} / c_{Sn^{++}} \qquad (1)$$

in which c is concentration in moles per liter and a is activity. The experimental results and values of K_1 are listed in Table I. μ is the ionic strength.

In Fig. 1, curve I represents log K_1 against $\mu^{1/2}$. The shape of the curve demonstrates that the equilibrium quotient is varying with ionic strength in accord with the theory of Debye and Hückel. However, extrapolation of this curve to zero ionic strength does not give the true equilibrium constant for the reaction because of

(3) When the saturated potassium chloride bridge was replaced by a bridge of saturated ammonium nitrate the electromotive force was five millivolts lower. An attempt to use this difference as a correction factor to the observed voltages of cells of type (1) in calculating the mean ion activity of perchloric acid was unsuccessful.

TABLE I

.3671	.0404	.0346	.0455	.42	.59
.3817	.0227	.0151	.0389	.35	.55
.3914	.0157	.0109	.0184	.24	.56
.3955	.0132	.0104	.00936	.18	.56
.4009	.0108	.00846	.00672	.16	.59
.4078	.00822	.00651	.00396	.12	.62

the uncertainty introduced by the assumption that the activity of total hydrogen ion equals the concentration of total hydrogen ion in making the calculation for $SnOH^+$ by difference between total acid and acid from hydrolysis. Actually this difference term is the subtraction of a concentration from an activity and hence the result is neither of these quantities. In order to obtain the actual concentration of $SnOH^+$ the hydrogen ion concentration must be known. By retaining

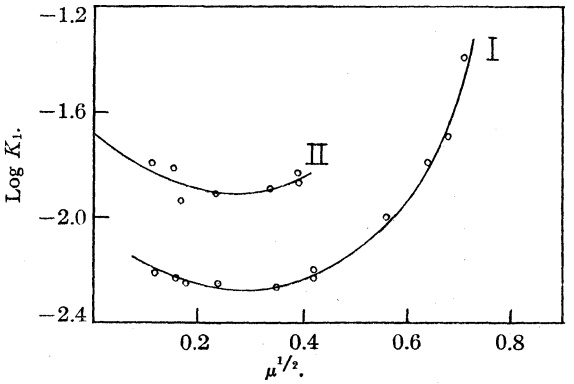

Fig. 1.—Plot of log K_1 against square root of ionic strength.

the assumption that the mean ion activity of the perchloric acid is equal to the activity of the hydrogen ion, the concentration of the latter can be obtained by dividing its activity by its activity coefficient. The activity coefficient of hydrogen ion in a solution of given ionic strength can be calculated from the values of the mean ion activity of perchloric acid and of sodium perchlorate at the stated ionic strength, if in the latter we consider that the activity coefficients of the sodium ion and perchlorate ion are equal.[4]

(4) The activity coefficients of perchloric acid and sodium perchlorate were obtained from Landolt-Börnstein, "Physikalisch-chemische Tabellen," Erg. III, pp. 2144 and 2153 (1936), respectively.

In the range of concentration up to an ionic strength of 0.2 the sodium ion and perchlorate ion activity coefficients are no doubt equal to within two or three per cent. Therefore the activity coefficients of hydrogen ion were computed and used in conjunction with the hydrogen ion activities in solutions of this investigation up to an ionic strength of 0.2 in the calculation of the concentrations of total hydrogen ion. With the aid of these latter values corrected concentrations of $SnOH^+$ and stannous ion were calculated. Using these figures new equilibrium quotients were calculated according to equation 1 and their logarithms plotted against $\mu^{1/2}$ as in Fig. 1, Curve II. The extrapolation to zero ionic strength was accomplished by the method of Randall and Vietti,[5] and the value of the equilibrium constant, K_1^0, is estimated to be 0.02.

According to Prytz[1] the hydrolysis of stannous ion is represented by the equation

$$2Sn^{++} + H_2O = Sn_2O^{++} + 2H^+ \qquad (2a)$$

or

$$2Sn^{++} + 2H_2O = Sn_2O_2H_2^{++} + 2H^+ \qquad (2b)$$

The analytical data of Table I were used to calculate the composition of each stannous perchlorate solution and the equilibrium quotients based on equation 2. The logarithms of these equilibrium quotients when plotted against $\mu^{1/2}$ give a U-shaped curve which does not permit extrapolation to zero ionic strength according to the limiting law of Debye and Hückel. Since Randall and Vietti have shown that in such a plot the curve will resemble one of the family of logarithm of activity coefficient *vs.* $\mu^{1/2}$ for single electrolytes, it is obvious that equation 1, and not equation 2, represents the hydrolysis of stannous ion.

(5) (a) Randall and Vietti, THIS JOURNAL, **50**, 1526 (1928); (b) Randall, *J. Chem. Ed.*, **8**, 1062 (1931); (c) see also Bray and Hershey, THIS JOURNAL, **56**, 1889 (1934).

Summary

Solutions of stannous perchlorate containing free perchloric acid have been analyzed. The variation of the equilibrium quotient, K_1, with ionic strength proves that the hydrolysis follows the equation $Sn^{++} + H_2O = SnOH^+ + H^+$. The value of the equilibrium constant, K_1^0, at 25° is 0.02.

A Study of Diffusion Processes by Electrolysis with Microelectrodes[1]

BY H. A. LAITINEN AND I. M. KOLTHOFF

Introduction

The diffusion of an electro oxidizable or reducible substance in solution can be studied by measuring the current obtained using suitable electrodes in an electrolysis cell if the supply of electro reducible or oxidizable material is determined only by the rate of diffusion of the material to one of the electrodes, and if well-defined boundary conditions of concentration can be maintained at the electrode surface. The latter condition is fulfilled if the concentration of diffusing material is maintained at a value of practically zero at the electrode surface by maintaining a potential at the electrode such that the diffusing material is immediately oxidized or reduced upon reaching the electrode surface.

The theory of the diffusion process in the vicinity of an electrode depends upon the geometric characteristics of the electrode and surrounding solution. Two extreme geometric cases are represented by a flat electrode, to which diffusion can occur from only one direction (linear diffusion), and a spherical electrode, to which diffusion can occur from all directions (spherically symmetrical diffusion). The equations for the current as a function of time, for linear and spherically symmetrical diffusion, are given below, as well as experimental results on the determination of current–time curves with microelectrodes of various types to determine the conditions under which theoretical diffusion conditions in electrolysis can be fulfilled.

The theoretical relation between current and time for linear diffusion has been derived by Cottrell[2] and MacGillavry and Rideal[3] and is

$$i = -A\sqrt{\frac{D}{\pi t}}\,nFC \qquad (1)$$

(1) This paper is based on a thesis to be submitted by H. A. Laitinen to the Graduate Faculty of the University of Minnesota in partial fulfilment of the requirements for the degree of Doctor of Philosophy, June, 1940.

(2) F. G. Cottrell, *Z. physik. Chem.*, **42**, 385 (1902).

where A is the area of the electrode, D and C are the diffusion coefficient and concentration of the diffusing material in the bulk of the solution, respectively, n is the number of electrons involved in the electrode reaction, and F is the faraday.

It is seen that in a given case, $i\sqrt{t}$ is a constant, and that the value of this constant can be calculated if the concentration C, and the diffusion coefficient of the electroactive substance, and the area of the electrode are known.

The corresponding theoretical current–time equation for spherical diffusion is[2]

$$i = -4\pi RnFDC - A\sqrt{\frac{D}{\pi t}}nFC \qquad (2)$$

where R is the radius of the spherical electrode. By comparing equations (1) and (2) it is apparent that for spherical and linear diffusion to electrodes of equal area, the theoretical currents at any time differ by a constant amount, namely, the steady state current with spherical diffusion given by the first term of equation (2).

Experimental

Platinum microelectrodes of various shapes as shown in Fig. 1 were constructed. The various flat electrodes, types A, C, D, F and G, were of very nearly equal area. Electrodes A, C and D permit only linear diffusion in horizontal, upward and downward directions, respectively, while electrodes B, E, F and G approach spherical diffusion to varying degrees of approximation. The linear diffusion electrodes were specially constructed to be as uniform as possible in cross-section by finely grinding the ends of two pieces of glass tubing and cementing a platinum plate between the two pieces of tubing with de Khotinsky cement using a larger piece of glass tubing as a mold. The details of construction are shown in Fig. 1, H. Electrode E most closely approached spherical diffusion, and consisted of a spherical ball of platinum of approximately the same area as the flat electrodes, on the end of a fine platinum wire coated with sealing wax, so that only the spherical surface acted as an electrode. Electrode B consisted of a platinum wire about 4 mm. in length and 0.5 mm. in diameter.

In general, the experiments were run by applying a constant potential to the microelectrode, this potential corresponding to a point near the middle of the diffusion current region of the electrolysis process as determined from a current–voltage curve obtained with the platinum wire microelectrode (type B, Fig. 1). At such a potential, the diffusing material undergoes an immediate electrode reaction upon reaching the electrode, so that its concentration is maintained at a value practically equal to zero at the electrode surface. A large silver–silver chloride electrode in 0.1 N potassium chloride was used as the second electrode. The electrolysis cell was of the type previously described,[4] employing a sintered glass diaphragm to separate the two electrodes. Hereafter, all potentials of the platinum micro-electrodes are referred to the 0.1 N silver–silver chloride electrode.

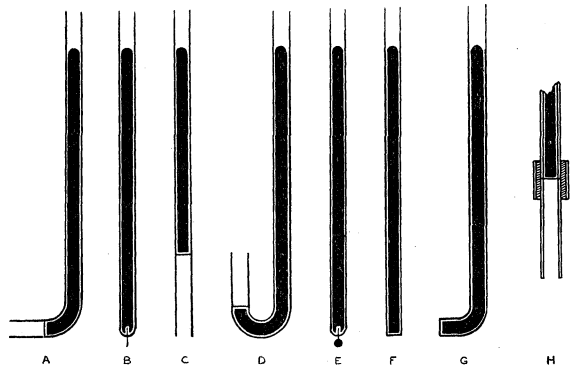

Fig. 1.—Various shapes of platinum electrodes.

The current was measured at various time intervals after beginning electrolysis by noting the deflection of a calibrated wall-type galvanometer in series with the electrolysis cell, and provided with a suitable shunt arrangement to change the galvanometer sensitivity during each run. The electrical circuit was the same as that described by Lingane and Kolthoff[5] except that the standard 10,000-ohm resistance used to calibrate the galvanometer was not left in series with the galvanometer and cell during the experiments, in order that the changing iR drop across this resistance during the experiments would not change the applied e. m. f. across the terminals of the cell. The small change in iR across the galvanometer itself, resulting in a slight shift of the potential of the micro electrode during an experiment, did not affect the current measurement since the same current was obtained over a range of potentials corresponding to the diffusion current region of the electrolysis process.

In the case of electroreductions, dissolved air was removed by bubbling nitrogen through the solution for about thirty minutes. In the case of electro-oxidations, it was found to be unnecessary to remove the dissolved oxygen because no reduction of oxygen occurred at the positive potential used.

The residual current in the absence of electroactive material was determined separately for each value of the time and was subtracted from the measured current. The current thus corrected was used in the calculation of $i\sqrt{t}$.

All measurements were made with the electrolysis cell in a water thermostat regulated to $\pm 0.02°$, with the stirrer mounted on wall brackets so that mechanical vibrations were eliminated.

The Oxidation of Ferrocyanide Ions.—A solution 1.00×10^{-3} M in potassium ferrocyanide and 0.1 N in potassium chloride was electrolyzed at 25°, applying a constant potential of +0.700 volt, and measuring the current at various times after beginning electrolysis. The current–time curves obtained with electrodes A, B, C, E, F and G (Fig. 1) are shown plotted in Fig. 2, together

(4) J. J. Lingane and H. A. Laitinen, *Ind. Eng. Chem., Anal. Ed.*, **11**, 504 (1939).

(5) J. J. Lingane and I. M. Kolthoff, THIS JOURNAL, **61**, 825 (1939).

with the theoretical curves for linear and spherical diffusion calculated from equations (1) and (2). The areas of the various flat electrodes were all equal to 0.0707 sq. cm. The diffusion coefficient D was calculated using the equation given by Lingane and Kolthoff,[5] and found to be equal to 0.74×10^{-5} cm.^{2} sec.$^{-1}$. Introducing the values of D and C in equations (1) and (2) yields the theoretical equations

$$i\sqrt{t} = 10.4 \quad \text{(linear diffusion)} \qquad (3)$$

$$i = 0.674 + 10.4t^{-1/2} \quad \text{(spherical diffusion)} \qquad (4)$$

where the current is expressed in microamperes and the time in seconds.

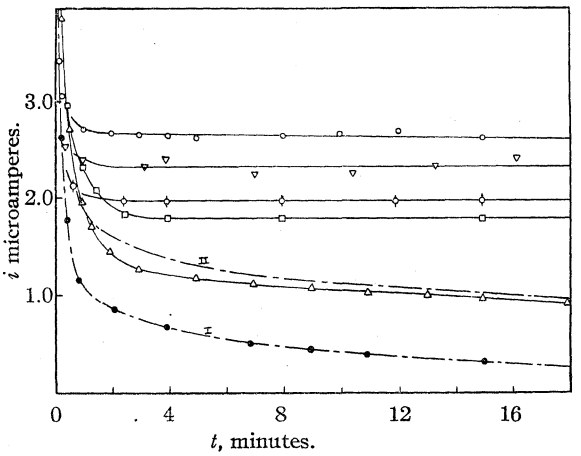

Fig. 2.—Current–time curves for electrolysis of 0.001 M $K_4Fe(CN)_6$ in 0.1 N KCl with various shapes of platinum microelectrodes: ●, electrode C; △, electrode A; □, electrode F; ◌, electrode B; ▽, electrode E; ○, electrode G. Dashed curves: theoretical curves for (I) linear diffusion, (II) spherically symmetrical diffusion.

From Fig. 2 it is evident that the theoretical results are obtained in this case only when the diffusion is linear and in an upward direction. With downward linear diffusion (electrode D) abnormally large currents were obtained which did not give a smooth current–time curve and were therefore not included in Fig. 2. After six to seven minutes, the current was about twice as large as calculated from equation (4), and after this length of time the current fluctuated irregularly, even increasing periodically.

Curve I, Fig. 2, which yielded results in close agreement with theory, was repeated several times using larger concentrations of potassium ferrocyanide so that better accuracy in current readings could be obtained. A typical set of data is given in Table I for the oxidation of 4.88×10^{-3} M potassium ferrocyanide in 0.1 N potassium chloride. The electrode area in this case was 0.1016 sq. cm., and the theoretical equation was $i\sqrt{t} = 73.4$ microamp. sec.$^{1/2}$. The average value of $i\sqrt{t}$ from the 26 points in Table I is 72.3 microamp. sec.$^{1/2}$, in excellent agreement with the theoretical value. Duplicate experiments gave results deviating only ±0.5 to ±1.0% in the value of $i\sqrt{t}$.

The reason for the deviating results obtained if the diffusion did not proceed in an upward direction becomes apparent when the relative densities of 0.001 M potassium ferrocyanide (the diffusing material) and 0.001 M potassium ferricyanide (the oxidation product near the electrode surface) are considered. Although the difference in density is only of the order of one unit in the fifth decimal place, 0.001 M potassium ferricyanide is less dense than 0.001 M potassium ferrocyanide.[6] Unless the direction of diffusion is such that the less dense solution (either the diffusing material or the electrode reaction product) lies above the denser solution, convection currents due to density gradients cause a greater supply of diffusing material to reach the electrode than by diffusion alone, and consequently the measured current is abnormally large.

A simple experimental check of this explanation was made as follows: a solution of 0.001 M potassium ferrocyanide in 0.1 M potassium chloride and 1% in cane sugar was prepared, thus a solution of the same electrolyte concentrations as the original ferrocyanide solution but somewhat more dense due to the presence of the sugar. A thin layer (1 or 2 mm.) of this solution was carefully placed near the platinum surface of elec-

(6) A. Heydweiller, *Z. anorg. allgem. Chem.*, **116**, 42 (1921).

trode D under the original solution by means of a capillary pipet and allowed to diffuse upward for about an hour, so that a sufficient downward density gradient should exist near the electrode surface to overcome any small density gradient in the opposite direction due to the electrode reaction. A current–time curve was then run and found to be identical with the curve obtained previously using electrode C (upward diffusion). This experiment gave conclusive proof that density gradients in the downward direction are necessary to stabilize concentration gradients and lead to theoretical diffusion conditions.

It is therefore to be expected that the theoretical current–time curve for spherical diffusion could never be obtained in aqueous solution, since, in general, spherically symmetrical concentration gradients result in spherically symmetrical density gradients, and convection currents around the electrode inevitably result. From Fig. 2 it is apparent that with various shapes of platinum electrodes approaching spherically symmetrical diffusion conditions, the current tends to approach a "steady state" value, *i. e.*, becomes practically constant after a few minutes. The steady state current, however, is a function not only of the electrode area, but also of the shape of the electrode, and in the case of the flat electrodes depends also on the position of the electrode with regard to the solution. Thus with two flat plates of platinum sealed on the ends of pieces of glass tubing (electrodes G and G), but arranged vertically and horizontally, respectively, a smaller steady state current was obtained with the surface of the electrode horizontal than with a vertical surface, because the horizontal surface acted to stabilize to a certain extent the concentration gradient of ferrocyanide ions.

In general, the steady state current was found to be least subject to irregular periodic fluctuations in the case of the platinum wire electrode (type B) than in any other case investigated including flat surfaces in various orientations and a spherical platinum surface. Apparently the most uniform and reproducible state of convection is obtained with the platinum wire electrode. Since the current reaches a steady value after two to four minutes and remains very nearly constant for relatively long intervals of time, this electrode has been used by us for determining current–voltage curves similar to those obtained with the dropping mercury electrode.

The Diffusion of Ferrocyanide Ions in Gelatin and Agar Gels.—In order to check the theoretical current–time equation for spherically symmetrical diffusion, experiments were performed by allowing the diffusion process to occur in a stiff gel surrounding the electrode, instead of in less viscous aqueous media in which disturbing convection currents occurred.

The absence of convection currents due to density gradients in the vicinity of the electrode was shown by electrolyzing 0.0200 *M* potassium ferrocyanide in 0.5 *N* potassium chloride in a 3% agar gel and in a 4% gelatin gel using electrodes C and D, in which linear diffusion occurred in upward and downward directions, respectively. Identical current–time curves were obtained with the two electrodes, in contrast to the results obtained in aqueous medium.

From the values of $i\sqrt{t}$ thus obtained, which remained constant to $\pm 0.5\%$ for a period of twenty minutes, the diffusion coefficient of the ferrocyanide ion was calculated to be 0.65×10^{-5} cm.^{2} sec.$^{-1}$ for the 3% agar gel and 0.61×10^{-5} cm.^{2} sec.$^{-1}$ for the 4% gelatin gel, as compared with the value 0.74×10^{-5} cm.^{2} sec.$^{-1}$ for an aqueous solution at infinite dilution.

The theoretical current–time curve for spherical diffusion to electrode E for the electrolysis of 0.0200 *M* potassium ferrocyanide in 0.5 *N* potassium chloride in a 3% agar gel becomes

$$i = 15.45 + 322\, t^{-1/2} \text{ microamperes} \qquad (5)$$

when t is expressed in seconds.

Equation (5) and the experimental curve obtained with electrode E in the 3% agar gel are shown plotted in Fig. 3.

It is evident from Fig. 3 that the theoretical and experimental curves are almost identical in shape from a period of five minutes to 110 minutes, although the experimental points in general lie about 5 to 7% below the corresponding theoretical points. The gelatin gel showed a similar behavior, both curves being lower than for the agar gel because of the lower diffusion coefficient in the gelatin gel.

The low observed current and the increasing percentage deviation with time may be explained by the fact that a truly spherical diffusion field does not exist, due to the presence of the coated platinum wire and glass tube above the spherical electrode. The theoretical diffusion layer extends a distance of several millimeters from the electrode surface after a time of two hours, so that a hindering effect becomes quite possible.

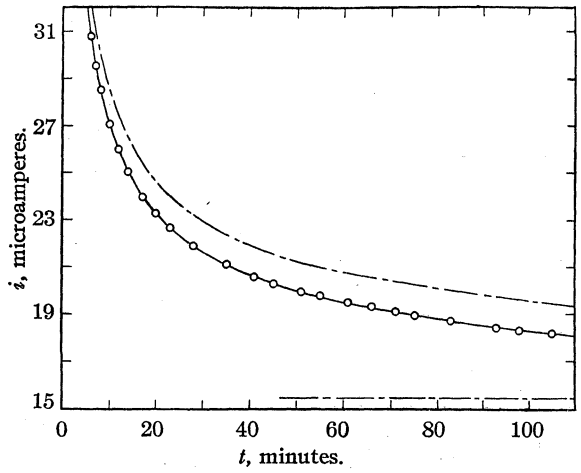

Fig. 3.—Current–time curves for electrolysis of 0.0200 M $K_4Fe(CN)_6$ in 0.5 N KCl in 3% agar gel. Spherical platinum electrode, R = 0.0950 cm. Full curve, experimental; dashed curve, theoretical; lower dashed line, theoretical steady state current.

The Reduction of Ferricyanide Ions.—An air-free solution of 5.01 × 10^{-3} M potassium ferricyanide in 0.1 N potassium chloride was electrolyzed at 25° using electrodes C and D by applying a constant potential of −0.50 volt and determining the current–time curves.

A constant value of $i\sqrt{t}$ was obtained with electrode D (downward diffusion). The experimental value of $i\sqrt{t}$ is compared with the calculated value in Table II.

With electrode C (upward diffusion) abnormally large currents were obtained and irregular fluctuations occurred after about eight minutes of electrolysis.

It is evident that exactly the opposite results (with respect to direction of diffusion) were obtained with the reduction of ferricyanide ions as compared with the oxidation of ferrocyanide ions. Since the electrode reaction is opposite in the two cases, opposite changes in density near the electrode occur, and the results obtained are exactly those predicted on the basis of the direction of the density gradients.

ELECTROLYSIS OF $K_4Fe(CN)_6$, $K_3Fe(CN)_6$ AND $AgNO_3$ IN EXCESS OF INDIFFERENT ELECTROLYTE

Area of electrode 0.1016 cm.², temp. = 25°.

Ion	Concn. mmol./liter	D^0 cm.² sec.$^{-1}$ × 10^{-5}	$i\sqrt{t}$ microamp. sec.$^{1/2}$ Calcd.	Obsd.	Diff., %
$Fe(CN)_6^{----}$	4.88	0.74	73.4	72.3	−1.5
$Fe(CN)_6^{---}$	5.01	.89	82.8	80.4	−2.9
Ag^+	5.00	1.69	113.7	115.4	+1.5

The Deposition of Silver Ions.—Current–time curves were obtained using electrode C in an air-free solution of 5.00 × 10^{-3} M silver nitrate in 0.1 N potassium nitrate at 25°, with an applied potential of −0.10 volt on the microelectrode. The average value of $i\sqrt{t}$ obtained in several such experiments is compared with the calculated value in Table II.

The Temperature Coefficient of the Quantity $i\sqrt{t}$.—For a given linear diffusion electrode and solution, equation (1) may be written in terms of ionic equivalent conductance and temperature[4] to give

$$i\sqrt{t} = k(\lambda^0 T)^{1/2} \qquad (6)$$

where T is the absolute temperature. Differentiating equation (6) with respect to the temperature, we have

$$\frac{d(i\sqrt{t})}{dT} = \frac{k}{2}(\lambda^0 T)^{-1/2}\left(\lambda^0 + T\frac{d\lambda^0}{dT}\right) \qquad (7)$$

Equation (7) may be expressed in terms of the fractional changes of $i\sqrt{t}$ and λ^0 per degree by dividing by the value of $i\sqrt{t}$ at the temperature T, as given by equation (6). The temperature coefficient of $i\sqrt{t}$ becomes

$$\frac{1}{i\sqrt{t}}\frac{d(i\sqrt{t})}{dT} = \frac{1}{2}\left(\frac{1}{T} + \frac{1}{\lambda^0}\frac{d\lambda^0}{dT}\right) \qquad (8)$$

The values of $i\sqrt{t}$ have been measured for temperatures of 25 to 35° for the ferrocyanide, ferricyanide and silver ions. The measured values of the temperature coefficient and the values calculated from equation (8) are given in Table III.

TABLE III

TEMPERATURE COEFFICIENT OF THE QUANTITY $i\sqrt{t}$ IN LINEAR DIFFUSION

Ion	$\frac{1}{\lambda^0}\frac{d\lambda^0}{dT}$ deg.$^{-1}$	$\frac{1}{i\sqrt{t}}\frac{d(i\sqrt{t})}{dT}$ deg.$^{-1}$ Calcd.	Obsd.
$Fe(CN)_6^{----}$	0.0195	0.0114	0.0101
$Fe(CN)_6^{---}$	.0185	.0109	.0118
Ag^+	.0200	.0116	.0116

The calculated and measured values are average temperature coefficients over the temperature range 25 to 35°, expressed in terms of the fraction of the 30° value of $i\sqrt{t}$ and λ^0. For th esilver and ferrocyanide ions, the conductance data of Johnston[7] and Swift[8] were used; for the ferricyanide ion the value of λ^0 of Hartley and Donaldson[9] was used, and the temperature coefficient

(7) J. Johnston, THIS JOURNAL, **31**, 1010 (1909).
(8) E. Swift, Jr., *ibid.*, **60**, 728 (1938).
(9) G. S. Hartley and G. W. Donaldson, *Trans. Faraday Soc.*, **33** 457 (1937).

of λ was calculated from the data of Watkins and Jones[10] on the equivalent conductance of potassium ferricyanide at various temperatures, and the values given by Johnston[7] for the equivalent ionic conductance of the potassium ion at various temperatures.

Discussion

Cottrell[2] has shown in a linear diffusion experiment on zinc sulfate that the quantity $i\sqrt{t}$ remained constant to $\pm 5\%$ for a period of over two days, but made no theoretical calculation of the value of the constant obtained.

It is evident from the data given in Table I that in our experiments the extreme limits of fluctuation in $i\sqrt{t}$ were only $\pm 0.5\%$ from the average value, in 26 readings over a period of twenty minutes. In other experiments a constancy was obtained over a period of several hours, but in general a slight drift toward higher values with very long periods of time was observed, due to unavoidable vibrations.

The data given in Table II show that the observed values for the quantity $i\sqrt{t}$ show a deviation from those calculated from the equivalent ionic conductances at infinite dilution of -1.5, -2.9 and $+1.5\%$ for the ferrocyanide, ferricyanide, and silver ions, respectively. These data are in essential agreement with those of Lingane and Kolthoff[5] on diffusion currents with the dropping mercury electrode.

The observed values of the temperature coefficient of $i\sqrt{t}$ are in good agreement with the calculated values over the same temperature range, as is evident from the data given in Table III. The agreement is probably within the experimental error, since the measurements were made only over a temperature range of ten degrees.

Summary

1. Current–time curves with various shapes of electrodes and diffusion fields in the electro oxidation of ferrocyanide ions were determined, and the condition under which theoretical diffusion conditions can be obtained are discussed. Theoretical conditions were not obtained with spherically symmetrical diffusion in aqueous solution, but were approached in 3% agar and in 4% gelatin gels.

2. With linear diffusion in such a direction as to produce a density gradient in the downward direction, the quantity of $i\sqrt{t}$ was found to be constant to $\pm 0.5\%$ over a period of twenty minutes.

3. The temperature coefficient of the quantity $i\sqrt{t}$ was found to be in agreement with the calculated value.

The Specific Heat of Some Ethylene Halides[1]

BY WILFORD E. RAILING[2]

The problem whether there is free or restricted rotation about the carbon–carbon bond in ethane and its derivatives has led to considerable research upon the 1,2-disubstituted ethanes. Of these, the chloro and bromo derivatives have received the greatest attention. Time–temperature heating curves made by White and Morgan[3] revealed a transition or hump in the specific heat curve in 1,2-dibromoethane at $-23°$. Since the dielectric constant is only minutely affected by the transition, it is likely that the change of state does not affect the polarity of the molecule. Since these transitions are most effectively studied by means of heat capacity measurements, the heat capacities of 1,2-dibromoethane (ethylene bromide), 1,2-dichloroethane (ethylene chloride), and 1,2-bromochloroethane (ethylene chlorobromide) have been determined in the range 90–320°K.

Apparatus and Procedure

The calorimeter employed was the same calibrated conduction calorimeter and the procedure was the same as employed by Stull.[4]

Materials

Benzene.—J. T. Baker C. P. thiophene-free material was distilled through a five-foot (1.5 m.) column packed with glass helices similar to those described by Young and Jasaitis.[5] The middle fraction was then fractionally

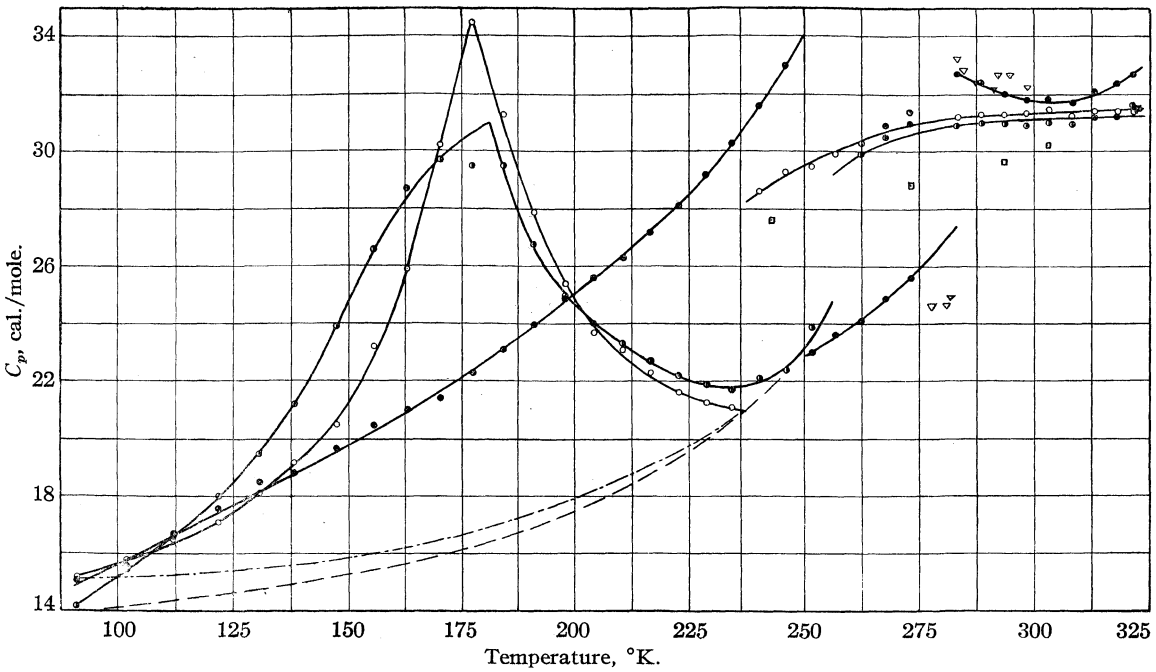

Fig. 1.—Molal heat capacities: ○, 1,2-dichloroethane, mol. wt., 98.97; moles in sample, 0.0358; ●, 1,2-dibromoethane, mol. wt., 187.88; moles in sample, 0.0328; ◐, 1,2-bromochloroethane, mol. wt., 143.42; moles in sample, 0.0343. — - —, extrapolated "Normal" heat capacity for dichloroethane. — —, extrapolated "Normal" heat capacity for bromochloroethane. △, Previously published values for dibromoethane. □, Previously published values for dichloroethane. 0°C. = 273.10°K.; 1 calorie = 4.1850 abs. joules.

crystallized six times, about one-fifth of the material being discarded each time. This was again distilled through the column and a fraction boiling over a 0.02° range was obtained. This material was used in all the calibration runs. The amount of premelting indicated a purity of 99.997 mole per cent.

Ethylene Chloride.—Eastman Kodak Co. material was distilled twice through a five-foot column, a fraction with a boiling range of 0.02° being obtained. This fraction was fractionally crystallized twice and given a final distillation before using; b. p. 83.8°, m. p. −35.5°. The amount of premelting indicated a purity of 99.96 mole per cent.

Ethylene Chlorobromide.—Eastman Kodak Co. material was distilled twice through a 40-cm. Vigreux column, and a 0.2° fraction was obtained. This fraction was recrystallized six times, and given a final distillation before using; m. p. −16.7°. The amount of premelting indicated a purity of 99.8 mole per cent.

Ethylene Bromide.—Eastman Kodak Co. material was given the same treatment that was given the chlorobromide; m. p. 9.93°. The amount of premelting indicated a purity of 99.92 mole per cent.

Experimental Results

The accuracy of averaged determinations obtained with this calorimeter has been placed within 0.75–1.25% of the true values by Stull.[4] It is the author's opinion that a better value for the accuracy would be 1–2%. The heats of fusion are probably accurate to 1% or better, instead of Stull's estimate of 3–4%.

The thermocouples used in this work had been calibrated by Stull,[4] and were used about a year after his research. Comparison of the melting and transition points of several materials with the literature values showed that the calibration had not changed appreciably.

The experimental specific heat values were plotted against the temperature, and a smooth curve drawn through the points. These smooth curves together with the experimental values are sketched in Fig. 1. The values of the experimental points may be read off the figure within the limit of the accuracy (1–2%).

It will be seen that the chlorobromide and chloride exhibit humps of considerable magnitude in the specific heat curve for the solid. To calculate the increase in heat content represented by these humps, the course of the "normal" heat capacity curve was charted as shown by the broken lines in the diagrams. The values of the special increments of heat content estimated in this manner are probably within 10% of the correct values. These values, together with the other transition and heats of fusion data, are presented in Table I,

TABLE I

HEATS OF TRANSITION AND FUSION DATA IN CALORIES PER MOLE AND °C.

	Fusion, This Research	Transition, This Research	Fusion, Demerliac	Fusion, Petersson
1,2-Dichloroethane	2090 at −35.5°	680	....	...
1,2-Dibromochloroethane	2300 at −16.7°	740	....	...
1,2-Dibromoethane	2590 at 9.93°	450 at −22.5°	2540 at 9.55°	2440 at 8.0°

together with the results obtained by other observers. The error in the heat of transition of the bromide is probably less than 2%. The heats of fusion have been corrected for premelting, and represent the heat of fusion for a 100% pure compound. The specific heat values for the solids just below the melting point have also been corrected for premelting.

The previously published data of the specific heats of these compounds[6] disagree somewhat with the values presented here, as can be ascertained from Fig. 1. It should be noted, however, that except for one set (Leblanc and Mobius),[6] the data are from forty to seventy-five years old. The values of Leblanc and Mobius for the bromide agree well with our results in the liquid state, but their values for the solid are about 3% lower than those presented here. No heat capacity data could be found in the literature for ethylene chlorobromide.

The heat of fusion of the bromide is about 2% higher than any previously observed values.[7] This may be due to the fact that a correction for premelting has been included in the data presented here. The melting point of Demerliac's sample (9.55°) is almost 0.4° lower than our value (9.93°). Premelting may have influenced Demerliac's determination. The other reported value,[8] was measured on a sample whose melting point (8°) indicated such an impure material that its heat of fusion is undoubtedly too low. These results will be found in Table I.

Early in this experimental investigation it was found that series of heat capacity determinations made successively on the same sample of ethylene chloride displayed systematic disagreements which could not be attributed to the functioning of the calorimeter. The disagreement was most noticeable in the liquid state. Calibration runs made with benzene checked with their usual accuracy, proving that the fault was not with the calorimeter. It became apparent that the observed heat capacity depended upon the thermal history of the sample. Determinations were then made in the liquid state upon an "annealed" sample, *i. e.*, a sample which had been liquid for a considerable time. Care was taken not to freeze any of this sample when it was cooled down. Determinations carried out upon these annealed samples agreed very well. Determinations made on solid samples that were frozen more slowly than they were melted during the run agreed well; but the measurements upon the liquid made immediately after melting did not agree with those made upon the annealed liquid. The type of results obtained can be seen from Fig. 2, where it can be seen that there are humps in the curves obtained from the recently thawed samples. The magnitude of this hump varied somewhat from run to run. The heat capacity values all approached the values of the annealed liquid at higher temperatures.

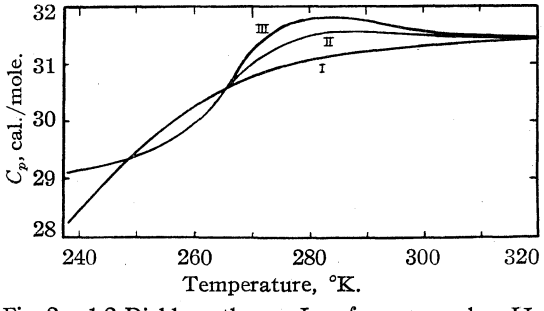

Fig. 2.—1,2-Dichloroethane: I, unfrozen sample; II, rapidly frozen sample; III, slowly frozen sample.

It was also observed that the more rapidly the sample was frozen, the smaller were the specific heat values of the solid in the region of the transition. The greatest variance was about 1 cal./mole/°C.

Effects similar to these were observed in the chlorobromide, though of a lesser magnitude. The heat capacity values in Table I for these two compounds were obtained upon the annealed liquid and the slowly frozen solid. No such effects were noticed in the case of the bromide. However, a slight, constant deviation, not exceeding the limits of experimental error, was noticed in the case of the liquid, depending upon whether the sample had been frozen rapidly or slowly.

Discussion

It is now widely believed that rotation about the carbon–carbon bond in ethane and its derivatives is not free but restricted by an energy barrier of appreciable magnitude. This amounts to more than 5 kg. cal./mole in the case of the halogen derivatives studied here, according to Beach and co-workers.[9] Dielectric constant, dipole moment and Raman spectra measurements indicate that while the solid is almost entirely in the *trans* configuration, considerable rotatory oscillation about the carbon–carbon bond takes place in the liquid state or in solvents. These measurements indicate that the motion is much more pronounced in ethylene chloride and chlorobromide than in the bromide.

Kohlrausch[10] interpreted his Raman spectral studies as indicating the existence of *cis–trans* isomers. Stuart[11] considers that the mutual repulsion of the chlorine atoms would prevent a stable *cis* form. Mizushima and Morino[12] suggest that there may be a potential minimum other than the *trans* configuration. Beach and co-workers,[9] however, interpret their electron diffraction patterns as indicating no other such potential minimum. Their measurements were carried out upon the gaseous phase. In the liquid phase the molecules, due to their greater proximity, may influence each other in such a manner as to render stable such a position of potential minimum.

If it is assumed that a configuration of minimum energy exists other than the *trans* configuration, the data and observations reported above may be explained in the following manner:[13]

1. There exists a dynamic equilibrium between the *cis* and *trans* configurations of the material. In the liquid state, there is a considerable amount of the *cis* form present, while the solid contains very little, if any. This is supported by the Raman spectra measurements of Mizushima and Morino[14] on the solid ethylene halides, in which the line attributed by them to the *cis* form is absent. It is further assumed that it takes an appreciable time for a quantity of one isomer to change into the other.

2. When a sample of an ethylene halide is frozen rapidly, insufficient time is allowed for all of the molecules to assume the *trans* form, and an appreciable amount of the *cis* configuration is frozen in.

White and Morgan[3] suggest that the transition in ethylene bromide might mark the onset of a rotation about the zigzag Br–C–C–Br axis. Probably only the *trans* configuration could undergo this transition, as too much space would be necessary for the *cis* form to rotate. The transitions in ethylene chloride and chlorobromide may be of the same type, in which only the *trans* configuration might be expected to take part.

If an ethylene chloride sample is frozen so rapidly that some of the *cis* form is frozen into the solid, then the heat capacity values in the region of the transition might be smaller than if only *trans* molecules were present, since the *cis* form would not be expected to undergo this zigzag rotation. This was observed experimentally in the case of the chloride and the chlorobromide.

3. A sample that was frozen slowly, upon melting, would consist almost entirely of *trans* molecules, since the normal crystal lattice accommodates only *trans* molecules. But if a rapidly melted sample of the normal solid were heated, *trans* molecules would have to isomerize to the *cis* modification, in order to establish the equilibrium state stable at a temperature just above the melting point. Since the *cis* form would be expected to have a higher energy content than the *trans* form, due to dipole interaction, etc., this isomerization might be expected to absorb heat, thereby increasing the apparent heat capacity of the sample. As the isomerization proceeds and equilibrium is approached, the heat capacities should approach the normal values. As Fig. 2 shows, this is what was observed experimentally. The peak is not so high for a rapidly frozen sample, since some *cis* is already present in the solid state, and therefore less isomerization occurs.

As has already been mentioned, the difference in heat capacity in the liquid state of ethylene bromide between a recently frozen sample and an annealed sample was noticeable, but very slight, being within the limits of experimental error. Mizushima and Morino,[15] as a result of their dipole moment and Raman spectra measurements,

(9) Beach and co-workers, *J. Chem. Phys.*, **6**, 639 (1938); THIS JOURNAL, **61**, 303 (1939).

(10) Kohlrausch, *Z. phys. Chem.*, **B18**, 61 (1932).

(11) Stuart, *Physik. Z.*, **32**, 793 (1931).

(12) Mizushima and Morino, *Sci. Papers Inst. Phys. Chem. Research* (Tokyo), **29**, 188 (1936).

(13) For convenience, the other minimum energy configuration will be called the *cis* configuration to differentiate it from the *trans* form, but this is not intended to imply that this other stable position necessarily involves rotation of 180° from the *trans* form.

(14) Mizushima and Morino, *Sci. Papers Inst. Phys. Chem. Research* (Tokyo), **26**, 1 (1934).

(15) Mizushima and Morino, *ibid.*, **25**, 159 (1934).

concluded that less deviation from the *trans* position occurs in the bromide than in the chloride and chlorobromide. Therefore, to obtain equilibrium in the liquid state of the recently thawed bromide, fewer of the *trans* molecules need isomerize and the effect upon the heat capacity would be considerably less.

The transition in the bromide has been observed by White and Morgan.[3] They explain it as being due to the setting in of rotation about the zigzag Br–C–C–Br axis rather than a rotation about the carbon–carbon bond, since the dielectric constant through the transition was only minutely affected. Raman spectra measurements show that upon solidification, rotation of one halogen with respect to the other is greatly restricted. Since the heat of transition is small, compared to the heat of fusion, this is a plausible explanation of the transition.

However, the transition is of the sharp or fusion type, rather than the gradual or rotational type, and may be just a phase transition. The transitions in the chloride and the chlorobromide are of the hump or rotational type, and may well be attributed to zigzag rotation about the X–C–C–X axis, since the dielectric constant of the chloride was unaffected in the region of the hump. Further information upon these transitions is necessary to establish this point.

While heating through the transition in the bromide, it was noticed that the sample superheated, sometimes as much as 0.35°. The same effect was noticed by White and Morgan.[3]

Acknowledgment.—The author is greatly indebted to Drs. W. T. Ziegler and E. R. Blanchard, whose assistance in carrying out this work and writing this paper was invaluable.

Summary

1. The heat capacities of 1,2-dibromoethane, 1,2-dichloroethane, and 1,2-bromochloroethane have been measured over the range 90–320°K.

2. Heats of fusion and transition have been measured for these compounds.

3. Certain phenomena in connection with the thermal history of these compounds and its effect upon the specific heat have been interpreted in the light of restricted intramolecular rotation in these compounds.

The Viscosity of Solutions of Sulfur Dioxide in Organic Liquids

BY S. B. CUPP AND H. E. ROGERS

This paper is a continuation of the work begun by Lewis[1] and Adams and Rogers[2] on the viscosity of solutions of sulfur dioxide in organic liquids. The present paper includes data concerning the effect of dissolved sulfur dioxide on the viscosity of *n*-propyl bromide, *i*-propyl bromide and *n*-butyl bromide.

Experimental Part

n-Propyl bromide, *i*-propyl bromide and *n*-butyl bromide were each washed four to six times with concentrated sulfuric acid, followed by a solution of sodium carbonate, dried over calcium chloride and distilled.

	B. p., °C.	d^{25}_4	$n^{25}D$
n-Propyl bromide	70.9	1.3430	1.4313
i-Propyl bromide	59.6	1.3060	1.4220
n-Butyl bromide	101.6	1.2689	1.4373

The apparatus and procedure were the same as described in the earlier paper.[2]

(1) J. R. Lewis, THIS JOURNAL, **47**, 626 (1925).
(2) H. E. Adams and H. E. Rogers, *ibid.*, **61**, 112 (1939).

Discussion

Density data for solutions of sulfur dioxide in *n*-propyl bromide, *i*-propyl bromide, and *n*-butyl bromide are found in Table I. Each liquid shows an expansion, in volume, when sulfur dioxide is dissolved in it. In the case of the *n*-propyl bromide solutions, mixtures from 0 to 60% sulfur dioxide have almost the same density as the pure *n*-propyl bromide.

In Fig. 1, the viscosity data in Table II are plotted. The viscosity is plotted against weight % and each curve is concave upward. Similar curves are obtained when the viscosity is plotted against volume %. The viscosity curves in Fig. 1 appear to be typical. The *n*-butyl bromide shows the greatest sag, as is to be expected. The difference between the viscosities of the pure sulfur dioxide and the pure *n*-butyl bromide is greater than it is for the other two liquids; consequently

		100.00	.2472		

the sag is not so great for the *i*-propyl bromide and *n*-propyl bromide curves.

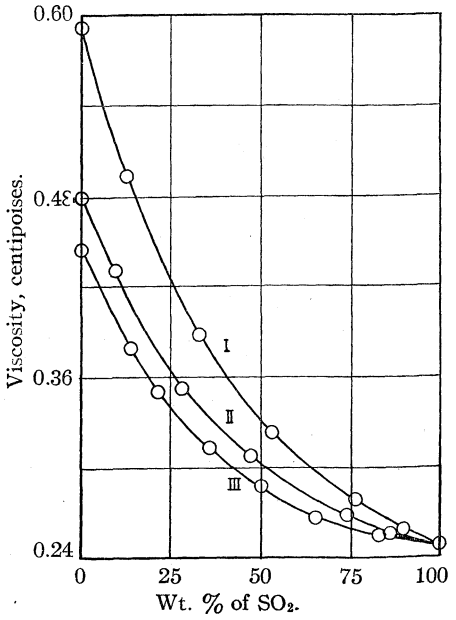

Fig. 1.—I, *n*-Butyl bromide; II, *n*-propyl bromide; III, *i*-propyl bromide.

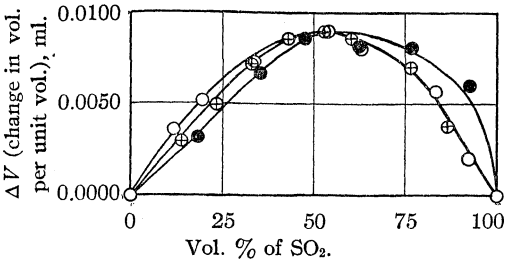

Fig. 2.—⊕, *n*-Butyl bromide; ●, *n*-propyl bromide; ○, *i*-propyl bromide.

Change in volume per unit volume (ΔV) has been plotted against volume per cent. in Fig. 2. ΔV was calculated using the expression in the earlier paper.[2] An expansion, on mixing, was found for each liquid. In the earlier work,[2] it was observed that ΔV was greatest for carbon tetrachloride, chloroform being next and bromoform the least. This was the same order as observed for the density-volume % curves for these three liquids. In this work, the maximum value for ΔV is practically the same for *n*-propyl bromide, *i*-propyl bromide, and *n*-butyl bromide. However, Fig. 1 and Fig. 2 give further evidence for the well-known fact that when liquids show an expansion in volume, on mixing, the fluidity of the mixture is greater than the fluidity calculated from the fluidities of the pure liquids. It is difficult to obtain an exact order for the fluidity and ΔV curves as was done in the earlier paper[2] because the expansion, on mixing, in each case, is almost identical.

Summary

1. The viscosities and densities of many solutions of sulfur dioxide in *n*-propyl bromide, *i*-propyl bromide, and *n*-butyl bromide were measured at 25°.

2. Expansion in volume, on mixing, was found in each case.

3. The results support the well-known fact that when liquids show an expansion, on mixing, the fluidity of the solution is greater than the fluidity calculated from the fluidities of the pure liquids.

Ketene and its Dimer

BY CHARLES D. HURD AND ARTHUR S. ROE

Toward some hydroxyl-containing compounds ketene behaves as an efficient acetylating agent but toward others it is either non-reactive or sluggish. In the latter category are phenols and tertiary alcohols. Van Alphen[1] reported no reaction at room temperature between ketene and phenol, but Rice and co-workers[2] showed that the acetylation proceeded quantitatively at the boiling point. With *t*-butyl alcohol, there was no acetylation at room temperature[3] and the reaction was very slow at its boiling point.[2]

In view of the established catalytic effect[4] of a trace of sulfuric acid or *p*-toluenesulfonic acid on the analogous acetylation of carbohydrates, it was decided to try these catalysts on the reaction between ketene and phenol or tertiary alcohols. The results were striking. With only a trace of either acid it was found possible to effect complete conversion at room temperature of phenol to phenyl acetate, *t*-butyl alcohol to *t*-butyl acetate,[5] and *t*-pentyl alcohol to *t*-pentyl acetate.

Ketene and Aldehydes.—Ketene, in the presence of potassium acetate, is known to react with aldehydes like benzaldehyde[6] and cinnamic aldehyde[3] to yield anhydrides of unsaturated acids. Benzaldehyde yields cinnamic acetic anhydride, as follows

$$C_6H_5CHO + 2CH_2CO \longrightarrow C_6H_5CH{=}CHCOOCOCH_3$$

No such reaction occurs, however, between ketene and butyraldehyde.

Benzaldehyde differs from butyraldehyde in that it has no hydrogen on the α-carbon. Cinnamaldehyde differs in that it is unsaturated on the α-carbon. Acrolein and crotonaldehyde resemble cinnamaldehyde in this respect. Formaldehyde, like benzaldehyde, has no α-hydrogen. If methyl formate may be regarded as an aldehyde because of its CHO group, it also falls in the group of compounds with no α-hydrogen. These four aliphatic compounds—formaldehyde, acrolein, crotonaldehyde and methyl formate—were tested for their reactivity toward ketene. Reaction occurred in all instances, but the substances obtained were unsaturated red oils of high molecular weight (1500–2000).

If the reaction had proceeded like the reaction with benzaldehyde, acrolein would have produced β-vinylacrylic acetic anhydride (I), formaldehyde would have yielded acrylic acetic anhydride (II), and methyl formate would have given rise to methoxyacrylic acetic anhydride (III).

(I) $CH_2{=}CH{-}CH{=}CH{-}CO{-}OCOCH_3$
(II) $CH_2{=}CH{-}CO{-}OCOCH_3$
(III) $CH_3OCH{=}CH{-}CO{-}OCOCH_3$

The course of the reaction was affected little by temperature, for the polymeric products were formed when the reaction was performed at 20° or −80°.

Ketene and Formic Acid.—The general reaction of ketene with acids yielding mixed acetic anhydrides[6,7] was applied to formic acid: $HCOOH + CH_2{=}CO \longrightarrow HCOOCOCH_3$. Formic acetic anhydride, thus produced, was pure by analysis and possessed the boiling point reported by Béhal[8] who prepared it from acetic anhydride and formic acid.

Graves' patent,[9] which appeared since completion of our work, should be mentioned. He states: "Ketene-containing gases from the pyrolysis of acetone were passed into 101.5 grams of 99% formic acid until the gain in weight was 90 grams. The product was acetoformic anhydride." Presumably acetic formic anhydride was in mind rather than "acetoformic anhydride," which would be $(CH_2COCO)_2O$, the anhydride of acetoformic acid. The substance was not purified by distillation nor characterized by reactions and no claim for it was made in the patent. The only claims were for acetic pyruvic anhydride, made from pyruvic acid and ketene.

Formic acetic anhydride proved to be an excellent formylating agent toward aniline

$$C_6H_5NH_2 + HCOOCOCH_3 \longrightarrow C_6H_5NHCHO + CH_3COOH$$

No acetanilide was produced. Since aniline reacts with acetic benzoic anhydride[7] to yield acetanilide and benzoic acid, this places the phenyl,

(9) Graves, U. S. Patent 2,135,709, Nov. 8, 1938.

methyl and hydrogen radicals in this decreasing order of electron attraction: $C_6H_5 > CH_3 > H$. This follows because the splitting of the symmetrical —C(=O)—O—C(=O)— group in the mixed anhydrides must be governed by the terminal groups (R or R′ in R—CO—O—CO—R′).

Non-reaction of Ketene and Tetraethyllead.—Ketene was found to be indifferent toward tetraethyllead. After passing 0.3 mole of ketene into 0.11 mole of tetraethyllead, the latter was poured slowly into concd. hydrochloric acid. The ethane evolved measured 2.38 liters (S. T. P.), compared with the calculated 2.4 liters. This non-reaction with ketene is in contrast to its violent behavior toward diethylmagnesium,[3] and its smooth reaction with diethylzinc.

The Dimer of Ketene

The dimer is known to be either acetylketene (IV) or β-crotonolactone (V) or, more probably, an equilibrium mixture of them, because on ozonolysis[3] it yielded pyruvic aldehyde. Since electron

IV V

readjustment is all that is necessary to maintain the equilibrium between IV and V, they are resonance isomers. This should cause lessened chemical reactivity and it is well known that acetylketene is more sluggish than ketene.

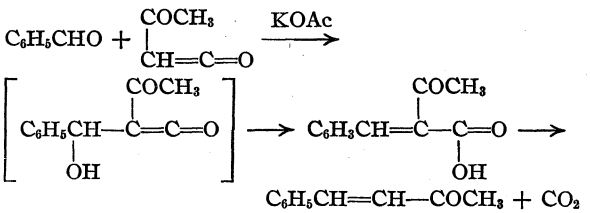
Parachor.—In the earlier work[3] the parachor of acetylketene was reported to be 182. This value was redetermined on material of greater purity and was found to be 188.0. Since that part of the calculated parachor which is contributed by the atoms alone is 127.6, the structural correction factor for the functional group involved (IV ⇄ V) is 60.4.

Enolization.—Acetylketene is a ketone as well as a ketene, so it is capable of enolization. Grignard and Blanchon[10] showed that enolization could be induced by branched-chain Grignard reagents, the amount of enolization being registered by the quantity of hydrocarbon evolved. Kohler and Thompson[11] showed that in some instances one might mistake reduction by the Grignard reagent for enolization, in which case propylene would be formed. The reaction of *i*-propylmagnesium bromide and acetylketene yielded propane, in an amount pointing to 23% enolization. A trace of propylene was present but the gas was chiefly propane.

Pyrolysis.—The pyrolysis of acetylketene at 550° yielded[3] methane, carbon monoxide, carbon, and dehydroacetic acid, but no ketene. It was thought that ketene might be formed at higher temperatures. At 650° over half of the dimer was depolymerized to ketene. As would be expected much gas was formed concurrently.

$$CH_3COCH{=}C{=}O \longrightarrow 2CH_2{=}C{=}O$$

Acetylketene and Benzaldehyde.—By analogy with the synthesis of cinnamic acid from ketene, benzaldehyde and potassium acetate, one would anticipate the synthesis of benzalacetone from acetylketene. This reaction was found to occur.



Carbon dioxide was evolved copiously and a 31% yield of benzalacetone was obtained.

A similar experiment was performed with carbon suboxide, O=C=C=C=O, which is a diketene,[12] but no reaction occurred. This non-reaction with benzaldehyde in the presence of potassium acetate must be associated with the absence of the —CH=C=O group in C_3O_2.

In view of the fact that ketene and diethylzinc react[3] to produce 2-butanone, it was hoped that acetylketene and diethylzinc might react smoothly. An immediate yellow precipitate formed when diethylzinc was added to acetylketene but in a few minutes this material congealed exothermically to a black tar, too stiff to stir. It was possible to keep the yellow precipitate, however, if toluene or benzene were used as diluents; but no products could be obtained from it by hydrolysis with steam, or with sulfuric acid solution, or with benzoyl chloride. Only tars resulted.

Experimental Part

Ketene was prepared in a ketene lamp[3] which delivered 0.1 mole per hour. A liberal supply of acetylketene ("Diketene") was donated by the Carbide and Carbon Chemicals Corporation through the courtesy of Dr. R. W. Mc-

(10) Grignard and Blanchon, *Bull. soc. chim.*, **49**, 27 (1931).

(11) Kohler and Thompson, THIS JOURNAL, **55**, 3822 (1933).

(12) This term is not to be confused with the trivial name "Diketene" which is used sometimes for acetylketene. The latter is a monoketene, not a diketene, and in its resonance modification it is not a ketene at all.

Namee. For it, we are deeply grateful. Part of the acetylketene was stored for a year in a glass-stoppered bottle in a refrigerator. It gradually became quite dark in color, but the greater part of the acetylketene was still present as such at the end of the year. Pure acetylketene will leave a residue of dehydroacetic acid if distilled at atmospheric pressure but no such residue occurs on vacuum distillation. The acetylketene was always distilled prior to use, b. p. 43° (28 mm.).

Ketene and Tertiary Alcohols.—To 0.1 mole of *t*-butyl or *t*-pentyl alcohol was added either 1 drop of concd. sulfuric acid or 0.01 g. of *p*-toluenesulfonic acid. Then the stream of ketene was passed in for seventy minutes. Heat developed at once so the reaction was cooled in an ice-bath. The solutions became slightly yellow in color, less color being apparent in the solution containing the toluenesulfonic acid.

The solutions were treated with 10 cc. of 6 *N* sodium hydroxide and washed with 10 cc. of water. Both of these aqueous solutions were extracted with ether, the ether solution being added to the ester layer. The ether solution was dried with potassium carbonate, the ether carefully removed on a water-bath, and the residue distilled. The *t*-butyl acetate was collected at 94–95° and no liquid came over at 82°, indicating that all the alcohol had been esterified. Similarly, the *t*-pentyl acetate was collected at 123–124°, with no distillate at 100°. The yields of esters in all four experiments were uniformly high at 86–89%.

Ketene and Phenol.—To a solution of 9.4 g. (0.1 mole) of phenol in 40 cc. of dry ether was added a drop of concd. sulfuric acid (A) or 0.01 g. of *p*-toluenesulfonic acid (B). Ketene was bubbled through for an hour and a half. It was necessary to cool the reaction to prevent volatilization of the solvent. The solution was yellow at the end of the reaction, more so with A than with B. It was washed with 20 cc. of 6 *N* sodium hydroxide and then with 20 cc. of water. The aqueous solutions were washed with ether, which was added to the ester layer. The ether solution was dried with potassium carbonate. The ether was removed on a water-bath and the product distilled. In both runs, the yield of phenyl acetate, b. p. 190–191°, was 12.1 g. or 89%.

Ketene and Acrolein.—The acrolein used in these experiments contained the trace of hydroquinone (1:1000) which was added as a preservative. Ten grams (0.18 mole) of it with 1.5 g. of anhydrous potassium acetate were placed in a flask fitted with inlet and exit tubes and a mercury-sealed stirrer. Then 0.2–0.3 mole of ketene was passed into the flask. Heat was evolved so an ice-bath was used after the first hour of reaction. The reaction product was a viscous red oil which decomposed to a black tar on attempted distillation at 19 mm. The red oil was soluble in dioxane and in dilute sodium hydroxide. From the alkaline solution acids precipitated an amorphous brown solid which melted between 75–150°.

The red oil was dried for a week in a vacuum desiccator over sulfuric acid. Pure dioxane, kindly furnished by Dr. R. Umhoefer of this Laboratory, was used as a cryoscopic solvent. The apparent molecular weight of the polymer was 1987, since the freezing point lowering caused by dissolving 0.7014 g. in 18.4906 g. of dioxane was 0.089°.

The course of the reaction with ketene was similar at −80°. The reaction mixture changed slowly to a dark red, viscous liquid, then solidified after two hours. This solid melted at room temperature, then decomposed with evolution of gas, and congealed to a red glass. An intractable oily product was formed by addition of the red solid to a solution of aniline in ether.

In two subsequent experiments of the same size at −80°, the red reaction product was treated in one case with ice water, and in the other with 50 cc. of ethyl alcohol.

From the former, 15.5 g. of brown tar separated and from the latter 11 g. of similar product. The material was soluble in acetone, but could not be crystallized from it. Extraction of the tar with ether yielded 1 cc. of oil on evaporation but it contained no β-vinylacrylic acid for none of the tetrabromide (m. p. 160°) was obtained on treatment with bromine.

Ketone and Monomeric Formaldehyde at −80°.—Liquid formaldehyde was prepared[13] by condensing formaldehyde gas in a trap at −80°. To 4 cc. of this liquid was added 0.05 g. of fused potassium acetate, then ketene was passed into the tube for one hour at −80°. The mixture turned yellow at once and became red before the reaction was over. A small portion of the reaction product was removed and allowed to come to room temperature. It turned a darker red and became viscous after a few minutes. Part of the polymer was dried *in vacuo* over sulfuric acid for a week. The freezing point lowering caused by dissolving 0.6140 g. in 17.1042 g. of dioxane was 0.097°. This indicates a molecular weight of 1740.

The remainder of the mixture was kept at −80° and 30 cc. of a solution of bromine in carbon tetrachloride was added. The solution was left at room temperature overnight. The solvent was removed under diminished pressure, leaving a small amount of a red oil which gave a positive halogen test. Three cc. of water was added to the oil without apparent reaction. The water was removed on the steam-bath and the residue extracted with hot benzene. Any dibromopropionic acid would dissolve in this solvent, but only a trace of red tar remained after evaporation of the benzene. No dibromopropionic acid was isolated, which proved that no acrylic acid, as such, was in the reaction mixture.

Ketene and Methyl Formate.—Ketene was passed for seven hours into a stirred mixture of 28.7 g. of methyl formate and 1.5 g. of fused potassuim acetate, the temperature being maintained at −15° by an ice–salt bath. The color change was from yellow to deep red. The final red sirup weighed 55.2 g. On distillation there was obtained 16.8 g. of a mixture of methyl formate and acetone at 42–45°, and 4.1 g. of acetic anhydride at 39° (30 mm.). The latter, with *p*-toluidine, yielded aceto-*p*-toluidide, m. p. 146–147°. There appeared to be considerable decomposition during the distillation.

To perform the reaction at a lower temperature, 8.4 g. (0.2 mole) of ketene was liquefied and distilled slowly into 12 g. (0.2 mole) of methyl formate and 1 g. of fused potassium acetate at −80°. The yellow color appeared at once but the color did not become red as in the other experiment. When all the ketene was introduced the reaction product was an orange solid. When a little of it was brought to

(13) Spence and Wild, *J. Chem. Soc.*, 338 (1935).

room temperature it melted to a yellow liquid which changed rapidly to the thick red oil mentioned before.

Half of the orange solid was transferred to a flask containing 30 cc. of aniline. The product was a red oil which could not be crystallized or identified.

One-quarter of the orange reaction product from another identical run at −80° was added to water, another quarter to methanol, another to ethanol, and the remainder to 1-butanol. The solutions were kept at 0° for six hours. Orange-brown solids separated in all instances. They were soluble in acetone or dioxane. For purification they were dissolved in acetone and precipitated by petroleum ether. Then the yellow solids were dissolved in dioxane and precipitated by methanol. The melting points of the material from the reactions with water (A), methanol (B), ethanol (C) and butanol (D), respectively, were 71–73°, 67–69°, 66–68°, 64–66°.

Saponification equivalents were determined in the usual manner by heating with standard alcoholic potash. These values were obtained for A–D: 44.5, 48.5, 49.7, 51.5.

Molecular weights were taken cryoscopically in dioxane as before. The values for A, B and C were 1498, 1524, 1533.

Ketene and Crotonaldehyde.—Twenty grams of crotonaldehyde (b. p. 103–104°) and 0.2 g. of potassium acetate were taken. When ketene was introduced heat and a slight coloration developed immediately, so the reaction was cooled in an ice-bath. After three hours the reaction had stopped. The brown reaction mixture was poured into 50 g. of ice. About 22 cc. of a brown liquid separated. It was soluble in acetone or dioxane but was insoluble in benzene, alcohol, ethyl acetate and petroleum ether. The apparent molecular weight of the tar, taken cryoscopically in dioxane as before, was 1761.

Ketene and Formic Acid.—Anhydrous formic acid (13.8 g., 0.3 mole), prepared from the 85% acid by refluxing with phthalic anhydride,[14] was treated with a stream of ketene gas (0.3 mole) freed from acetone vapors. The reaction product was distilled at 19 mm. and 15 cc. of formic acetic anhydride was collected at 33–33.5°: $n^{20}D$ 1.3940; d^{20}_4 1.1458.

Anal. Subs. 0.7216, 0.9094. Cc. of 0.0854 *N* base, 190.31, 240.32. Cc. calcd. for $HCOOCOCH_3$, 192.04, 242.01. Per cent. purity, 99.1, 99.3.

Aniline was added to 8 g. of ice-cold formic acetic anhydride. Distillation of the products at 29 mm. yielded 4 g. of acetic acid up to 50°, 2.5 g. of an intermediate fraction, and 9.2 g. of formanilide at 178–179°. The small amount of residue contained no acetanilide, crystallizable from hot water. The formanilide melted at 46°.

Acetylketene

Surface Tension and Parachor.—The capillary rise method of determining the surface tension was used. The radius of the capillary was found to be 0.0219 cm. by using pure thiophene-free benzene as a standard for calibration. Pure water served as a check on this result. Then pure acetylketene was taken. The latter was freshly distilled (b. p. 43.0–43.1° at 28 mm.). The density of this acetylketene was found to be 1.0817 at 25° since 0.8956 cc. weighed 0.9688 g. The data on surface tension are:

Substance	Water	Acetylketene
Temperature, °C.	25	25
Density	0.9971	1.0817
Av. capillary rise, cm.	6.73	2.92
Surf. tension, dynes/cm., found	71.98	33.89
Value in "Int. Crit. Tables"	71.97	...

From this, the parachor, $M\gamma^{1/4}/D - d$, is calculated to be 188.0 for acetylketene.

Enolization.[15]—*i*-Propylmagnesium bromide was prepared in 75 cc. of dry *n*-butyl ether from 12.3 g. of *i*-propyl bromide and 2.5 g. of magnesium. Then 4.561 g. of pure acetylketene (in 50 cc. butyl ether) was placed in a 250-cc. three-necked flask fitted with a mercury-sealed stirrer. The exit tube led from the flask through a small vertical condenser to an inverted, brine-filled bottle. The apparatus was swept out with nitrogen, placed in an ice-bath, and 36 cc. of Grignard solution was added slowly until no more gas was evolved. An excess of 4 cc. was then added and the reaction was allowed to come to room temperature while it was stirred for three hours.

The volume of the gas evolved at S. T. P., also corrected for the 40 cc. of Grignard solution, was 286.2 cc. This was 0.0128 mole. Since 0.0543 mole of acetylketene was used, there was 23.6% enolization, assuming that only one carbonyl enolized.

Analysis of the gas revealed only propane, propylene and nitrogen (no CO_2, H_2, O_2, CO). The propylene was 1.8% by volume, as determined by absorption in 83% sulfuric acid. The propane was 21.8% by volume. In duplicate analyses, the ratio of contraction (after combustion of the C_nH_{2n+2}) to absorption (of CO_2 after combustion) was 1.03 and 0.97. For propane this ratio should be 1.

Pyrolysis at 650°.—Acetylketene was introduced slowly by mercury displacement into the top of a vertical Pyrex tube maintained at 650° by automatic control. The effective volume of the tube was 156 cc. The exit gas flowed through two ice-cooled traps, vertically through a water-cooled condenser, and then through two aniline traps. The acetylketene taken was 51.4 g. and that recovered in the trap was 12.6 g. (chiefly acetylketene, but it contained a little dehydroacetic acid). The duration of the experiment was seventy-eight minutes, hence, the contact time was about ten seconds.

There was an indication of 19.8 g. of ketene because 63.5 g. of acetanilide, m. p. 114–115°, was obtained.

Reaction with Benzaldehyde.—A 200-cc. three-necked flask was fitted with a dropping funnel, mercury-sealed stirrer and condenser. Into it was placed 19.8 g. (0.18 mole) of freshly distilled benzaldehyde and 2 g. of fused potassium acetate.

During ninety minutes, 15.7 g. (0.187 mole) of acetylketene was added. Heat was applied to start the reaction, after which the heat generated sufficed to sustain it. A light yellow color soon developed which changed to a dark red. Between 1–1.5 liters of carbon dioxide (proved by lime-water test) was evolved.

The reaction mixture was poured into 50 cc. of dilute

(14) Pryanishnikov and Shakhova, *J. Gen. Chem.* (U. S. S. R.), **2**, 84 (1932); *C. A.*, **27**, 2672 (1933).

(15) Preliminary work on this was performed by Jonathan W. Williams.

hydrochloric acid. No visible reaction occurred though a heavy oil separated. The aqueous layer was washed with 25 cc. of benzene, which was added to the oil. The solution was placed on a water-bath to remove the solvent, then distilled at 13 mm.

Fraction	Temp., °C.	Wt., g.	Remark
1	to 60	0.52	.....
2	60–63	8.31	Benzaldehyde
3	63–125	0.84	.....
4	125–128	1.94	Benzalacetone
5	128–130	6.44	Benzalacetone
Residue		7.07	

Fraction 2 was identified as benzaldehyde by preparation of the phenylhydrazone, m. p. 154–155° (literature value 156°). Fractions 4 and 5 were identified as benzalacetone. They solidified in the icebox to crystals which melted at 37–38° (literature, 42°); 0.1 g. gave 0.17 g. of benzalacetone phenylhydrazone, m. p. 154–155° (literature, 156–157°). The total yield of benzalacetone was 8.38 g., or 0.0574 mole. Mixed melting point of phenylhydrazones of fractions 2 and 4 was 125–130°.

Summary

Ketene, in the presence of a trace of sulfuric acid or *p*-toluenesulfonic acid, causes complete acetylation of phenol, *t*-butyl alcohol, or *t*-pentyl alcohol at room temperature.

Ketene, in the presence of potassium acetate, reacts with acrolein, crotonaldehyde, formaldehyde (monomer), or methyl formate to yield in all cases complex reaction products of high molecular weight. These reactions proceeded even at −80°.

Formic acid and ketene give rise to formic acetic anhydride which, in turn, reacts with aniline to yield formanilide, not acetanilide.

Ketene does not react with tetraethyllead.

Pyrolysis of acetylketene at 650° brings about depolymerization to ketene.

Toward *i*-propylmagnesium bromide, acetylketene displays 23% enolization.

The parachor of acetylketene was found to be 188 instead of 182 as previously reported.

Acetylketene, in the presence of potassium acetate, reacts with benzaldehyde with the production of benzalacetone and carbon dioxide. No such reaction occurs between carbon suboxide and benzaldehyde.

The product of reaction of acetylketene and diethylzinc is a yellow solid which yielded nothing but tars on hydrolysis or on reaction with benzoyl chloride.

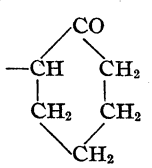
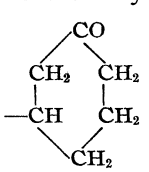
Preparation and Pyrolysis of Cyclohexanone

BY CHARLES D. HURD, HARRY GREENGARD AND ARTHUR S. ROE

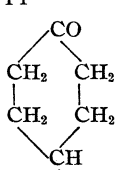
Ordinarily, ketene is prepared by pyrolysis of acetone. A chain mechanism involving radicals has been proposed[1] to explain it. One would predict analogously that cyclohexanone should give rise to ketene because of the three possible radicals (I–III) formed by dehydrogenation of cyclohexanone, ketene and ethylene appear to be



I



II



III

plausible products from each. No ketene was observed, however, when cyclohexanone was pyrolyzed in a tube at 700° or in a ketene lamp.

The observed products were water, cyclohexadiene, ethylene, carbon monoxide, and small amounts of hydrogen and methane.

When cyclohexanone was refluxed for five days, five-sixths of it was still intact but the remainder condensed to cyclohexylidenecyclohexanone.

An interesting development of the present work was the synthesis of cyclohexane in 60% yield by dehydrogenation of cyclohexanol over copper chromite.

Experimental

Cyclohexanone.—A horizontal Pyrex tube (25 × 2 cm.) was filled with pumice coated with the Adkins copper chromite catalyst, prepared as directed by Dunbar and Cooper.[2] It was heated electrically to 290–310°. The vapor of 150 g. of cyclohexanol was forced through the hot tube during eight hours by dropping the liquid slowly into an attached flask at 220°. The reaction products were condensed, dried with potassium carbonate, and distilled. Twelve grams of cyclohexene was collected at 75–85°

(1) Rice and co-workers, THIS JOURNAL, **53**, 1959 (1931); **56**, 1761 (1934).

(2) Dunbar and Cooper, *ibid.*, **58**, 1053 (1936).

There was 8 g. of an intermediate fraction between 85–155°, then 91 g. of cyclohexanone was collected at 155–156.5°. The residue weighed 30 g. The yield was 60% of the theoretical. The cyclohexanone was identified as the semicarbazone, m. p. 165°.

Pyrolysis

By Refluxing.—Twenty-four grams of cyclohexanone was refluxed for one hundred and fifteen hours. The solution became orange-colored. On vacuum distillation, 20 g. of the ketone was recovered at 60–64° (30 mm.), and 2.5 g. of cyclohexylidenecyclohexanone was collected at 158–162° (30 mm.). The oxime of the latter melted at 147–152°.

Through Hot Tube.—During one hour, 24 g. of cyclohexanone was passed through a Pyrex combustion tube heated to 700–725°. The tube was 120 × 2 cm. and was filled with pieces of porcelain. Condensables were removed from the gas stream by a coil condenser, then the gas was passed through aniline. The condensate, on distillation at 85–100°, yielded 1 g. of a mixture of water (droplets visible) and cyclohexadiene. At 150–160° there was collected 2.5 g. of cyclohexanone (oxime, m. p. 87°). The cyclohexadiene was converted into 1,2,3,4-tetrabromocyclohexane, m. p. 140°, on treatment with bromine in carbon tetrachloride.

No acetanilide was found in the aniline trap; hence, no ketene was formed.

With Ketene Lamp.—Ninety grams of cyclohexanone was placed in the ketene lamp[3] and decomposed during one hour. The effluent gas was conducted through aniline. The volume of unabsorbed gas (S. T. P.) was 6.8 liters. No acetanilide was obtained from the aniline trap.

Summary

Cyclohexanone is formed in good yields by dehydrogenation of cyclohexanol. The cyclohexanone yielded no ketene on pyrolysis at 700° but some cyclohexadiene was identified. Prolonged refluxing gave rise to small amounts of cyclohexylidenecyclohexanone.

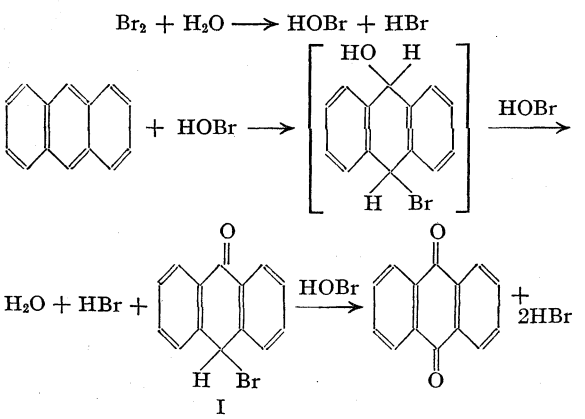
The Reaction of Bromine with Anthracene in Dioxane

BY CHARLES C. PRICE AND CLAY WEAVER

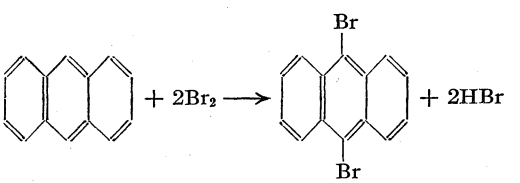
In experiments on the reaction of anthracene with bromine using dioxane as a solvent,[1] it was noted that more hydrogen bromide was evolved than could be accounted for on the basis of bromination of the hydrocarbon, since two-thirds to three-fourths of the bromine consumed appeared as hydrobromic acid after addition of water to the reaction mixture.

As a tentative explanation, it was assumed that the bromination of a mole of anthracene induced the bromination of one or two moles of dioxane by an ionic mechanism. It has been discovered,



I

however, that the anomalous formation of hydrobromic acid in dioxane, even with material which had been distilled from sodium, was due to the presence of traces of water. In the presence of the basic solvent, the water and bromine react with the anthracene as hypobromous acid, leading to the formation of 9-bromoanthrone (I) and anthraquinone, thus accounting for the high percentage of acid formed. When precautions were taken to exclude atmospheric moisture from freshly dried dioxane, the normal reaction took place.



Since this eliminates the evidence for the ionic mechanism suggested by Price and Thorpe[2] for the *cis–trans* isomerization of diethylmaleate in the presence of bromine and anthracene, the alternative atomic-free radical mechanism they suggested is therefore to be preferred, not only from analogy with the photochemical reaction,[3]

(1) Price, THIS JOURNAL, **58**, 1834 (1936).

(2) Price and Thorpe, *ibid.*, **60**, 2839 (1938).

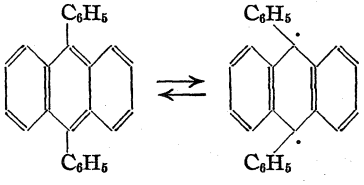
but on the basis of the structure of anthracene (particularly its *meso*-diaryl derivatives). Dufraisse[4] has recently suggested that the reactivity of these compounds, especially their ability to form peroxides on exposure to oxygen, is analogous to the behavior of triarylmethyl radicals, and that these molecules actually exist to some extent as di-radicals.



Experimental

Reagents.—Anthrone, prepared from anthraquinone,[5] was reduced to anthracene according to Martin's directions.[6] The anthracene crystallized as plates which melted at 216–216.5° (corr.) and which showed a deep purple fluorescence. Commercial dioxane was purified according to the directions of Scatchard and Benedict,[7] b. p. 100.5–101° (corr.). Bromine was purified as before.[1] The purified dioxane did not react with this bromine, even up to 75°.

Procedure.—Standard bromine and anthracene solutions (*ca.* 1%) in dry dioxane (protected from atmospheric moisture) were mixed. Canary yellow needles separated in one minute. At the end of fifteen minutes the reaction mixture was poured into water containing potassium iodide. The bromine consumed by one sample was 0.0496 mole and the hydrogen bromide evolved 0.0494 mole, by another 0.0472 and 0.0463 mole, respectively, the required values for the equation of the formation of 9,10-dibromoanthracene. This substance was isolated by filtration after the titrations. It formed canary yellow needles from acetic acid, m. p. 221° (corr.). From a 0.50-g. sample, 0.93 g. (99%) was obtained.

If precautions to exclude atmospheric moisture were not observed, 9-bromoanthrone and anthraquinone were isolated as well. In a particular experiment, 5 cc. of water and 1.2 g. each of bromine and anthracene were added to 95 cc. of dioxane. A sample of this mixture showed a ratio of 0.0566 mole of bromine consumed to 0.0996 mole of hydrogen bromide evolved. After thirty minutes the reaction mixture was poured into 100 cc. of water. The precipitate (0.6 g.) was recrystallized from benzene–petroleum ether to give thick square plates of 9-bromoanthrone (I), m. p. 142–144° (corr.), with decomposition.[8]

Anal. Calcd. for $C_{14}H_9OBr$: Br, 29.30. Found: Br, 29.35.

Extraction of the aqueous filtrate with ether, followed by evaporation of the solvent, yielded 0.6 g. of pale yellow needles of anthraquinone, m. p. 280–282° (corr.).

When a higher percentage of water was added, all the bromine consumed appeared as hydrogen bromide and the sole product was anthraquinone.

Summary

Unless moisture is excluded rigorously, the reaction of bromine with anthracene in dioxane leads to the formation of 9-bromoanthrone and anthraquinone, as well as the normal product, 9,10-dibromoanthracene.

[A COMMUNICATION FROM THE LABORATORY OF ORGANIC CHEMISTRY OF THE UNIVERSITY OF WISCONSIN]

Chlorination of Butyl Trichloroacetates

BY HOWARD M. WADDLE AND HOMER ADKINS

The direct chlorination of *n*-butyl, *i*-butyl and *s*-butyl trichloroacetates seemed to offer a method for the preparation of chlorobutanols and of ascertaining the relative reactivity toward chlorine of hydrogens on primary, secondary and tertiary carbon atoms.[1]

Buffet found that *n*-butyl trichloroacetate could be rather rapidly chlorinated at 110–120° under the light from a 150-watt tungsten electric light bulb. Various monochlorobutyl trichloroacetates were formed which could be methanolyzed to the corresponding chlorobutanols.

(1) Geo. M. Buffet, Ph.D. Thesis, University of Wisconsin, Madison, 1933.

$$CCl_3CO_2C_4H_9 + Cl_2 \longrightarrow CCl_3CO_2C_4H_8Cl + HCl$$
$$CCl_3C_4H_8Cl + CH_3OH \longrightarrow CCl_3CO_2CH_3 + ClC_4H_8OH$$

Later experience showed that it was preferable to separate carefully the chloro-esters by fractional distillation and to saponify the pure esters, rather than to attempt to separate the alcohols obtained by methanolysis or hydrolysis of a mixture of esters.

n-Butyl, *i*-butyl and *s*-butyl trichloroacetates were prepared in 82 to 89% yields by refluxing two moles of trichloroacetic acid and four moles of the alcohol for six to eight hours. The excess alcohol and water were removed by distillation through a Vigreux column, 35 cm. in length. Emulsions are likely to be formed if the alcohol is not rather completely removed before the crude esters are

washed with 10% sodium carbonate solution. The esters were then washed with water, dried over calcium chloride and distilled under reduced pressure at temperatures no higher than 100°. An automatic separator proved useful in the preparation of *s*-butyl trichloroacetate.

The chlorinations were carried out in a liter, round-bottomed, Pyrex flask provided with three side arms. A stirring device, operating through a mercury seal, was placed in the neck of the flask. A thermometer well, an inlet tube for chlorine and a water-cooled reflux condenser were connected through the side arms of the flask. The chlorine passed through a wash bottle[2] containing sulfuric acid into a liter flask and then through a flowmeter and capillary tube into the bottom of the reaction mixture. The exit gases from the reaction mixtures passed up through a coil condenser.

The procedure for chlorination was as follows. Two moles of the ester (440 g.) was placed in the reaction flask and heated to 120° in an electrically heated and controlled oil-bath.[3] A 200-watt clear glass, tungsten light bulb was placed 5 cm. from the surface of the reaction flask which was immersed in the oil-bath to the top of the liquid in the flask. Chlorine was then passed in at the rate of 15 to 20 g. per hour, the reaction mixture being kept at 120 ± 2°. Chlorination was continued (seven to ten hours) until the increase in weight of the reaction flask corresponded to two moles of chlorine (69.9 g.). The product was water white.

The reaction mixtures after chlorination were separated into their components by the use of a packed column of the total reflux–partial take off variety. The packed section of the column was 18 mm. in diameter and 100 cm. in length surrounded by an evacuated jacket. The packing consisted of helices containing 1 to 2 turns, 7 mm. in diameter and made from glass rod 1 mm. in diameter. The air space about the evacuated jacket was electrically heated and maintained at a constant temperature by controlling the current passing through a heating unit of nichrome wire. The pressure within the column during fractionation was held constant by means of a manostat.[4]

The esters were distilled from a flask, immersed in an electrically heated and controlled oil-bath, and connected to the column by a ground glass joint. The procedure used in operating the column is well outlined by Morton.[5] The first distillation of a reaction mixture (510 g.) was carried out rather rapidly during thirty-six hours divided into three intervals. The second fractionation required sixty hours divided into 6 intervals, the reflux ratio being about 20 to 1. Ebullition tubes were not used.

Each of the three butyl trichloroacetates gave four fractions: A, unchanged ester, B and C, two different monochlorobutyl trichloroacetates, and D, a dichlorobutyl trichloroacetate. The weights of the fractions from chlorinated *n*-butyl trichloroacetate (510 g.) were A, 78 g., B, 158 to 175 g., C 93 g. and D, 50 g. From the chlorinated *i*-butyl ester (510 g.) the corresponding weights were A, 81 g., B, 118 to 122 g., C, 139 g. and D, 41 to 56 g., while from the chlorinated *s*-butyl ester (508 g.) the weights were for A, 83 to 84 g., B, 137 to 144 g., C, 122 to 130 g. and D, 21 to 37 g.

The fractions containing the mono- and dichlorobutyl trichloroacetates were washed with 2% sodium carbonate solution and with water, dried over calcium chloride and refractionated. The monochloro esters were rather rapidly distilled, with ebullition tubes, through a Vigreux column 7 cm. in length, while for the dichloro esters a modified Widmer with a spiral 12 cm. in length was used. Data on the physical properties of the various esters are given in Table I.

The ester was saponified at temperatures below 35° during the course of five to seven hours. The ester was rapidly stirred while an equivalent molecular amount of sodium hydroxide in a 10% solution in water was added over a period of several hours. After saponification was complete the solution was extracted continuously with ether for twelve hours. After removal of the ether the chloro-alcohol was distilled under reduced pressure through a modified Widmer column having a spiral 20 cm. in length. A capillary ebullition tube for the inlet of air was used in the distillation.

Chlorobutanols were obtained from five of the nine chloro esters which were isolated. Certain physical properties and the analyses of the alcohols, and the melting point and analyses of their phenyl urethans are given in Table I.

The lower boiling monochloro esters (the fractions labeled B) from the *i*-butyl and *s*-butyl esters reacted with sodium hydroxide much more slowly than in the case of the five esters referred to just above. Approximately one-half of the ester was recovered unchanged after reaction for several hours with a molecular equivalent of sodium hydroxide. *i*-Butyraldehyde was detected among the products from the saponification of the monochloro-*i*-butyl ester. The saponification of this latter ester (32 g.) was then attempted, using two molecular equivalents of sodium hydroxide at 75° for three hours. A stream of nitrogen was passed through the reaction mixture to remove *i*-butyraldehyde as rapidly as it was produced. The aldehyde (5 g.) was condensed in a trap surrounded with solid carbon dioxide. It was identified by boiling point and the formation of a 2,4-dinitrophenylhydrazone, m. p. 185°. There was also obtained 4 g. of a compound, b. p. 69–70° (7 mm.), which was halogen-free and appeared to be a glycol. It was not identified.

The saponification of the lower boiling monochloroester from *s*-butyl trichloroacetate gave no products boiling above 56° and only a small amount of that compound. No other liquid product was obtained by saponification with two moles of sodium hydroxide at 40°. Sufficient quantities of the fractions containing the dichloro esters from *i*-butyl and *s*-butyl trichloroacetates were not available for saponification studies.

The data given above may be summarized as follows. There remains after the reaction of one mole of chlorine with one mole of *n*-, *i*- or *s*-butyl trichloroacetate at 120° approximately 0.2 mole of unchanged ester, a little over 0.5 mole of monochloroesters and a few hundredths of a mole of

[a] Trichloroacetate. [b] Phenyl urethan.

dichloroesters. About 25% of the original ester has not been accounted for except in intermediate fractions and the residue after distillation.

From each of the three butyl trichloroacetates two different monochlorobutyl esters have been produced and separated by fractionation. The structures tentatively assigned to these six alcohols, separated as trichloroacetates, are given below. The figures given after each formula represent the moles of ester isolated from the reaction of one mole of a butyl ester and one mole of chlorine.

I	$CH_3CH_2CHClCH_2OH$	0.33
II	$ClCH_2CH_2CH_2CH_2OH$	.19
III	$(CH_3)_2CClCH_2OH$	.24
IV	$ClCH_2CHCH_2OH$ (with CH_3 branch)	.27
V	$CH_3CHClCHOHCH_3$	.28
VI	$CH_3CH_2CHOHCH_2Cl$ or $ClCH_2CH_2CHOHCH_3$	.25

Four of the alcohols, I, II, IV and VI, have been obtained in a pure state in yields of 83, 86, 76 and 44%, respectively, from the saponification of the esters. The esters of the other two alcohols, III and V, underwent other reactions as well as saponification when attempts were made to prepare the alcohols.

The evidence for the structures suggested for the alcohols is as follows. The chlorobutanol believed to have the structure I was converted into the dichloride through the use of thionyl chloride and pyridine.[6] The dichlorobutane so obtained has a b. p. of 127°, $n^{25}D$ 1.4420, $n^{15}D$ 1.4468, which agrees with the values of b. p. 124° and $n^{15}D$ 1.4474 reported by Navez.[7] The 1,3-dichlorobutane is reported to boil somewhat higher.[8] It is quite possible that both the 2- and 3-chlorobutyl esters were produced by chlorination.

4-Chlorobutanol-1 was prepared from tetrahydrofuran[9] and its phenyl urethan compared with the phenyl urethan of the alcohol, II, believed to have that structure. The boiling points and refractive indices of the two samples of the alcohol and the melting points and mixed melting points of the phenyl urethans, 54–55°, showed them to be identical.

Formulas III and IV represent the only possible chloro-*i*-butanols. An ester of the alcohol IV would boil higher than an ester of the alcohol III, so that formula III is assigned to the alcohol

(6) Clark and Streight, *Proc. Roy. Soc. Canada*, **23**, III, 77 (1929).

(9) Starr and Hixon, THIS JOURNAL, **56**, 1595 (1934).

of the lower boiling ester. The attempted saponification of this lower boiling ester gave *i*-butyraldehyde as the only definitely characterized product. The rearrangement of a chloro alcohol of the type of III to an aldehyde is an orthodox reaction.

All three of the possible chloro-*s*-butyl alcohols have been reported, but solid derivatives have not been prepared nor the physical properties of the alcohols carefully defined. 3-Chlorobutanol-2, b. p. 138–139° (753 mm.), was prepared by the addition of hypochlorous acid to butene-2.[10] 4-Chlorobutanol-2, b. p. 70° (13 mm.), has been prepared from methylmagnesium iodide and β-chloropropionaldehyde.[11] 1-Chlorobutanol-2, b. p. 52° (15 mm.), has been prepared by the reaction of chloroacetaldehyde and ethylmagnesium bromide.[12]

The 3-chloro alcohol would be the lowest boiling of the isomers, and would be the more unstable. It therefore seems probable that the lower boiling of the monochloro esters derived from *s*-butyl ester would be an ester of the 3-chloro isomer. All attempts to saponify this ester gave products such as would correspond to *sym*-dimethylethylene oxide. This is a not unexpected result for the ester of such an alcohol. It should be noted that the ester of similar structure from *i*-butyl trichloroacetate also failed to give a chloro alcohol upon saponification.

There is no adequate basis for deciding whether the chlorobutanol-2 isolated was the 1- or 4-chloro compound. The boiling point is close to that reported for the 1-chloro compound. It would appear that the 4-chloro compound boils somewhat higher.[10] The low yield of alcohol obtained by saponification also suggests the 1-chloro isomer since the 4-chloro alcohol would have a structure similar to 3-chloro-2-methylpropanol-1, which was obtained in excellent yield from its trichloroacetate.

Summary

The *n*-, *i*- and *s*-butyl trichloroacetates have been chlorinated and in each case two monochlorobutyl trichloroacetates have been separated as the major products of chlorination. The corresponding monochlorobutyl alcohols have been obtained in four cases by saponification of the esters while in two cases attempts at saponification failed to yield the alcohols.

MADISON, WISCONSIN RECEIVED SEPTEMBER 28, 1939

[A COMMUNICATION FROM THE LABORATORY OF ORGANIC CHEMISTRY OF THE UNIVERSITY OF WISCONSIN]

Relative Oxidation Potentials of Ketones

BY FRED W. COX[1] AND HOMER ADKINS

Ketones may be arranged in a series according to their strength as oxidizing agents, *i. e.*, of their oxidation potentials. A ketone high in the series will oxidize rather completely the alcohol corresponding to a ketone low in the series. In such a comparison the quinones will be at the top and the dialkyl ketones at the bottom of the series. For example, diphenoquinone is probably one of the most powerful oxidizing agents among the ketones while di-*i*-propyl ketone is one of the weakest. The quinones have been compared with each other by virtue of the fact that the reduction of a quinone to a hydroquinone is a strictly reversible process, and that an aqueous solution containing appreciable quantities of these two substances, and having a fixed hydrogen-ion concentration, establishes a definite and accurately determinable potential on a platinum electrode. A comparison of the oxidation potential may be expressed in volts, as for example 0.95 for diphenoquinone, 0.71 for *p*-benzoquinone, 0.48 for α-naphthoquinone and 0.15 for 9,10-anthraquinone.[2]

The present paper is concerned with the comparison of several ketones which are much weaker as oxidizing agents than the quinones referred to above. It is not possible as yet to express quantitatively their oxidation potentials. It must suffice to state their strength as oxidizing agents in terms of a standard ketone. However, it is hoped that the gap in the series of ketones between the quinones and benzophenone may be bridged by the study of ketones of intermediate oxidation po-

(1) Procter and Gamble Fellow, 1938–1939.
(2) Fieser in Gilman, "Organic Chemistry," John Wiley and Sons, Inc., New York, N. Y., 1938, p. 96.

tentials. It will then be possible to express the oxidation potentials of all members of the series in the same units.

The comparisons here reported are based upon the fact that a ketone and a secondary alcohol may be equilibrated, in the presence of aluminum *t*-butoxide, against the alcohol corresponding to the ketone and the ketone corresponding to the alcohol[3]

$$R_2CO + R'_2CHOH \rightleftharpoons R_2CHOH + R'_2CO$$

The general procedure for equilibration was as follows. Equimolecular amounts (0.01 mole) of a ketone and an alcohol were weighed into a test tube with a constricted neck. Fifteen ml. of toluene containing 2.5 g. of aluminum *t*-butoxide (0.01 mole) was added, the tube sealed off and suspended in a thermostat held at 100°. After a period of twenty to 620 hours a sample from the reaction mixture was analyzed by means of a polarograph.

In order to utilize the polarographic method of analysis at least one of the two ketones in the mixture must be unsaturated since saturated ketones do not show a depolarization potential. In the majority of cases benzophenone was the ketone upon which the analysis was based, while in other instances phenyl ketones carrying an ethyl, *n*-propyl, *i*-propyl, *n*-butyl or *n*-amyl group were used. Equilibrium in the reaction mixtures was always attained from both directions.

In the majority of cases approximately the same concentration of ketones was present after 150 to 200 hours no matter from which direction the reaction was run. For example, in the equilibration of benzophenone against phenyl *i*-propyl ketone, the concentration of benzophenone present after 150 hours was about 47.7 mole per cent. (the maximum deviation from the average being 1.8%) no matter whether the original reaction mixture contained Ph_2CO and *i*-PrCHOHPh or Ph_2CHOH and *i*-PrCOPh. However, in some cases equilibrium was not attained after 150 to 200 hours so that the period of reaction was prolonged to over 600 hours. For example, the concentration of benzophenone present in a reaction mixture varied as much as 7.6% after 200 to 250 hours, depending upon whether the reaction mixture originally contained Ph_2CO and *i*-BuCHOHPh or Ph_2CHOH and *i*-BuCOPh. However, after 600 hours the maximum deviation was 1.4%. After many comparisons had been made, it was found that while the concentration of a ketone was independent, after a suitable interval, of the direction from which the reaction proceeded, it was not independent of the time of reaction. For instance, in the comparison of benzophenone and phenyl *i*-propyl ketone there were variations from a value of 47.6% after 150 to 200 hours, to values of 53.3% after 200 to 250 hours, and 39.3% after 380 to 430 hours. It should be emphasized that each of these values could be duplicated within 1 or 2% from either direction, if the time interval was constant.

It is apparent that a side reaction was occurring which modified the concentration of ketones. This side reaction could not be a condensation for it will be shown in another paper that the ketones under consideration do not undergo such a reaction with aluminum *t*-butoxide. It is probable that the side reaction was of the type

$$3Ph_2CHOH + Al(OC_4H_9)_3 \longrightarrow 3Ph_2CO + 3C_4H_{10} + Al(OH)_3$$

The formation of aluminum hydroxide and butane was indicated by the fact that reaction mixtures in some cases became gelatinous and considerable pressure was developed within the tubes after a few hundred hours.

In order to test the oxidation of alcohols by aluminum *t*-butoxide a few experiments were made in which various phenyl carbinols (0.01 mole) were allowed to react with an equimolecular amount of aluminum *t*-butoxide in 15 ml. of toluene at 100° in a sealed tube for 132 hours. Ketones were produced to the following extent, based upon polarographic analysis, Ph_2CO 4%, EtCOPh 5.5%, *n*-PrCOPh 1%, *i*-PrCOPh 2.4%, *n*-BuCOPh 1.2%, *n*-AmCOPh 4.3%. None of the polarographical non-reducible ketones were studied from this standpoint because of the lack of a convenient method of analysis for the ketones, but it must be assumed that any of the alcohols might undergo oxidation to the extent of a few per cent. within one hundred hours.

In order to minimize the effect of the side reaction upon the concentration of ketones in the reaction mixture, the procedure was modified so that equilibrium would be reached in a shorter time. The reaction mixtures were made up containing *both* ketones and *both* alcohols under comparison, the concentrations in one set of reaction mixtures being somewhat to the "right" of the probable equilibrium concentrations, while the

(3) Adkins and Cox, THIS JOURNAL, **60**, 1151 (1938).

other set was somewhat to the "left." For example, the earlier work suggested that the concentration of benzophenone in equilibrium with diethyl ketone would be about 33 to 34% if it were not modified by a side reaction. Reaction mixtures were therefore made up which contained in one case 0.0025 mole of Ph_2CO, 0.0075 Ph_2CHOH, 0.0075 Et_2CO and 0.0025 of Et_2CHOH, and in the second case 0.0040 Ph_2CO, 0.0060 Ph_2CHOH, 0.0060 Et_2CO and 0.0040 Et_2CHOH, respectively. The first set of mixtures after ninety-six hours gave 32.3, 31.7 and 30.6% benzophenone, while the second set gave values of 30.7 and 32.2.

In only three cases in these later studies did the average of the values from reaction in one direction differ by more than about 1% from the average of the values attained from the other. Thus, equilibrium approximately was attained after a maximum of ninety-six hours and in many cases in much shorter lengths of time. In three mixtures containing di-*i*-propyl or di-*i*-butyl ketones reaction was so slow that even after ninety-six hours the values were from 2.5 to 6% apart. In calculating the relative reactivity of the ketones the average of the values from one direction with that from the other was taken as the true concentration of the ketones at equilibrium.

There is presented in Table I a summary of the experimental data upon which the relative reactivities given in Table II are based. For purposes of comparison the value of 1.00 is assigned to di-*i*-propyl ketone. All the other ketones studied, with possibly one exception, are stronger oxidizing agents than is the standard ketone. That is to say, in an equilibrium mixture there would be a higher concentration of the di-*i*-propyl ketone than of any of the other twelve ketones. Stated in another way, it may be said that di-*i*-propylcarbinol has the greatest tendency to be oxidized as compared with the various carbinols investigated, while cyclohexanol has the least tendency to be oxidized. It may be said that cyclohexanone has the highest oxidation potential, *i. e.*, it is endowed with more power as an oxidation agent than any of the other ketones investigated.

The first four columns of figures in Table II give the relative reactivity values as calculated from the experimental comparisons. The "relative reactivity" values are obtained, for example, by dividing the mole per cent. of benzophenone (24.1%) at equilibrium by the mole per cent. of di-*i*-propyl ketone (75.9%) to give a value of 0.32 for benzophenone.

In the case of the dialkyl ketones, which could not be equilibrated against di-*i*-propyl ketone because of the lack of a convenient and accurate method of analysis, the relative reactivities were calculated indirectly; *i. e.*, for diethyl ketone against benzophenone the ratio of diethyl ketone to benzophenone in the equilibrium mixture is 68.5/31.5, which when multiplied by the ratio of benzophenone to di-*i*-propyl ketone, 24.1/75.9, gives a value of 0.69 for the relative reactivity of diethyl ketone on the basis of di-*i*-propyl ketone being 1.00.

For ten of the ketones experimental comparisons have been made against two different ketones while diethyl ketone was equilibrated against four different ketones. In general it would appear that the oxidizing power of a ketone, relative to the standard ketone, is independent of the particular ketone with which it is compared in experiment. One exception is that the value for diethyl ketone against phenyl *n*-amyl ketone is 0.63, while the other three values for diethyl ketone are 0.69, 0.68 and 0.70. However, if the value for diethyl ketone is calculated through the benzophenone equilibria with diethyl ketone and with phenyl *n*-amyl ketone, then the value is 0.67, which is in excellent agreement with the other values. In a similar manner the value for dibutyl ketone may be raised from 0.92 to 0.96, which is in agreement with that expected for a dialkyl ketone.

The values given in the last column of Table II may thus be taken as fairly accurately depicting the relative tendency of a given ketone to oxidize an alcohol corresponding to one of the other ketones. The values for cyclohexanone and di-*i*-butyl ketone have been enclosed in parentheses to indicate that they are less certain than for the other ketones. The difficulty with di-*i*-butyl ketone is that it is reduced so slowly and di-*i*-butylcarbinol is oxidized so slowly that equilibrium was not obtained within the time limits used in the case of the other ketones and alcohols. The amount of di-*i*-butyl ketone present was 78% when equilibrium was approached from one direction and 72% when approached from the other. The average of these values, 75%, was assumed to be the concentration of the ketone at equilibrium.

The difficulty with cyclohexanone is that it so readily undergoes condensation

$$2C_6H_{10} \rightleftharpoons HOC_6H_{10}C_6H_9O \rightleftharpoons C_6H_9C_6H_9O + H_2O$$

Cyclohexylidene–cyclohexanone, the final condensation product, apparently was not formed, since this compound would show up on a polarographic analysis, but it is possible that the hydroxy ketone first formed would modify the oxidation reduction equilibrium. Possibly the value 0.19 assigned in the table to cyclohexanone is a little too low, but it certainly is not higher than 0.24.

An examination of the data in the last column of Table II reveals several general tendencies rather clearly. The diaryl ketones are better oxidizing agents than the alkyl aryl ketones and they in turn are better oxidizing agents than the majority of the dialkyl ketones. However, there are marked differences among the aliphatic ketones. The *t*-butyl group has an effect markedly similar to an aryl group, for pinacolone and butyrophenone have the same value when they are compared against benzophenone. Diethyl ketone is a stronger oxidizing agent than are dipropyl and dibutyl ketones. The difference between alkyl groups is also shown by the fact that *i*-propyl phenyl ketone has a value of 0.39, while the corresponding *n*-propyl phenyl ketone has a relative reactivity of 0.60 or more.

Most striking of all is the fact that the saturated ketone, cyclohexanone, has an oxidation potential higher than any other ketone, even than the highly unsaturated ketone, benzophenone.

In general there is a parallelism between the depolarization potential or "reduction potential" as measured on a polarograph and the strength of a ketone as an oxidizing agent as determined by equilibration. That is, the aliphatic ketones have a high depolarization potential and a low oxidation potential while the quinones have a very low depolarization potential and a high oxidation potential.[2] However, the depolarization potential cannot be safely used as a guide in predicting the strength of a ketone as an oxidizing agent. For example, the propyl phenyl ketones give practically identical values for depolarization potentials (1.60 to 1.61 volts) while they are quite different as oxidizing agents as noted in a preceding paragraph. An even greater discrepancy is found in the case of cyclohexanone, whose depolarization potential is so high that it cannot be measured, yet it is a stronger oxidizing agent than any of the alkyl aryl ketones, all of which show depolarization potentials.

It must be kept clearly in mind that the oxidation potential of a ketone cannot be considered apart from the reducing power of the alcohol corresponding to it. In this paper for the sake of simplicity reference has been made particularly

to the oxidation potential of a ketone rather than to the reduction potential of the alcohol, but in reality one cannot measure the one tendency without the other. In the systems under investigation the alcohols are present at least in part as aluminum alkoxides and the ketones as addition products with aluminum alkoxides. Tendencies to form these compounds probably vary among the alcohols and ketones under consideration so that the relative reactivities of the ketones as oxidizing agents may be thus modified.

Preparation of Ketones and Alcohols.—The various alkyl phenyl ketones were made by the Friedel and Crafts synthesis, using the proper acid chloride (100 to 150 g.) in excess benzene (130 to 340 ml.) with aluminum chloride (122 to 312 g.). The yields were of the order of 80% of the theoretical amount. Di-*n*-butyl ketone was made as by Breise and McElvain.[4] Benzophenone and pinacolone were made as described in "Organic Syntheses."[5]

All of the six phenyl carbinols as well as methyl-*t*-butylcarbinol, di-*i*-butylcarbinol and di-*n*-butylcarbinol were made by hydrogenation of the corresponding ketones dissolved in ethanol, over Raney nickel or copper chromite. The reaction was stopped after one mole of hydrogen per mole of ketone had been absorbed in the case of the phenyl ketones, otherwise hydrogenolysis of the hydroxy group will occur. The hydrogenations were made under 200 to 300 atm. at temperatures between 95 and 150°. From one-half to three hours were required, using 1 to 2 g. of catalyst per 0.5 mole of ketone. The yield of alcohols averaged 87% of the theoretical amount.

i-Propylphenylcarbinol was also made by reduction of the ketone with aluminum *i*-propoxide, but the yield was only 60%. Both of the propyl phenyl carbinols were also made by the Grignard reaction, the yields being about 88% of the theoretical amount.

The ketones and alcohols not referred to above were obtained from the Eastman Kodak Company.

The reaction mixtures were analyzed as follows. A sample (0.7 ml.) from the reaction mixture was pipetted into a weighed 25-ml. Erlenmeyer flask and weighed. The sample was diluted to approximately 25 ml. with 92.5% isopropyl alcohol and again weighed. The mixture was shaken thoroughly and allowed to stand for several hours during which time it was repeatedly shaken. A sample (1 ml.) of the clear, supernatant liquid was withdrawn and added to a polarographic cell containing 3 ml. of 92.5% isopropyl alcohol and 1 ml. of a 0.84 *N* solution of tetramethylammonium hydroxide.

Three polarographic curves were then made for the solution, and the average wave height computed by the Borcherdt "b" method.[6] Comparing the wave heights so obtained to a graph giving the relationship of wave height to concentration (from Table III) gave the moles, *C*, of the reducible ketone in the polarographic cell. From *C* was calculated the percentage, *K*, of the polarographically reducible ketone in the equilibrium mixture by means of the following relationship

$$K = \frac{C \times 5}{1000} \cdot \frac{V}{d} \cdot \frac{W}{S} \cdot \frac{100}{B}$$

where *V* is the weight of the sample plus the weight of the isopropyl alcohol added; *W* is the total weight of the materials placed in the sealed tube; *S*, the weight of the 0.7-ml. sample; *B*, the moles of the ketone possible of existing in the reaction mixture (0.01 mole in the experiment as carried out above); and *d*, the density of the isopropyl alcohol solution of the sample. The constant "5" represents the volume of liquid in the polarographic cell, "1000," the number of ml. in a liter, and "100" is the factor for converting to percentage. For all practical purposes the value of *d* may be considered to be the same as that for the density of the isopropyl alcohol solution used in the dilution.

In the cases where there were two polarographically reducible ketones in the reaction mixture, the older "ratio of wave heights" method was employed in the analysis,[6] the single ketone method being useful as an alternate method for verifying the value obtained by the ratio method.

The reaction mixtures always contained one of the six phenyl ketones listed in Table III. There are given in Table III the measured wave heights for two or three polarograms for each of three concentrations for each of the six ketones. The data show very clearly the reproducibility of the polarograms and the constancy of the relationship of wave height to concentration of any of the

six ketones. As noted in the earlier paper, acetophenone shows an anomalous behavior.

The relationship of wave height to concentration of ketone was found to be independent of the presence of toluene, *t*-butyl alcohol, aluminum hydroxide, and another ketone, or alcohol such as was known to be present in the reaction mixtures. However, the relationship is not independent of the concentration of water or tetramethylammonium hydroxide in the polarographic cell. The relationship is not independent of the characteristics of the particular capillary electrode.

Summary

Thirteen representative ketones have been compared with each other as oxidizing agents. A numerical statement of the result of the comparison is given in the last column of Table II. The comparisons were made by equilibrating two ketones against each other in the presence of aluminum *t*-butoxide and the alcohols corresponding to the ketones. The concentration of the ketones at equilibrium was determined by means of a polarograph.

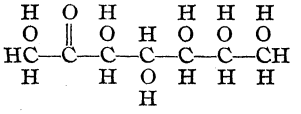
The Reduction Products of *d*-Glucoheptulose[1]

BY FRED L. HUMOLLER, STANLY J. KUMAN AND FRED H. SNYDER

In 1928 Bertrand and Nitzberg[2] prepared *l*-glucoheptulose (designated by them as α-glucoheptulose) by the action of *Bact. xylinium* on α-glucoheptitol. In their studies on the structure of this ketoheptose they subjected it to the action of sodium amalgam. From the reaction products they isolated α-glucoheptitol and a substance which they named α-glucoheptulitol. This new substance melted at 144° and showed a specific rotation of −2.24°.[3] Later Khouvine and Nitzberg[4] repeated the work of Bertrand and Nitzberg and also obtained α-glucoheptulitol as one of the reduction products of *l*-glucoheptulose. They assumed, though not without reservations, that α-glucoheptulitol was either β-*d*-glucoheptitol or β-*l*-glucoheptitol.

In 1930 Austin[5] prepared *d*-glucoheptulose by the rearrangement of α-*d*-glucoheptose in lime water. Because of its method of preparation and because of the identity of its osazone with that obtained from α-*d*-glucoheptose, Austin assigned to *d*-glucoheptulose the formula



From its formula it can be seen that *d*-glucoheptulose should yield upon reduction of its ketone group α-glucoheptitol or β-*d*-glucoheptitol, or both, provided the structure which Austin assigned to this ketose is correct.

However, when Khouvine and Nitzberg[6] reduced *d*-glucoheptulose with sodium amalgam, they obtained α-glucoheptitol and the enantiomorph of α-glucoheptulitol but not β-*d*-glucoheptitol as predicted by Austin's formula. This new substance, which they called α-*d*-glucoheptulitol, melted at 143–143.5° and showed a specific rotation of +2.10°. From their studies on the structure of this substance they came to the conclusion that it was not identical with either β-*d*-glucoheptitol or β-*l*-glucoheptitol, but that it might be a heptitol of unknown structure. They suggested that the glucoheptulitols might be formed by the local concentration of alkali during the reduction with sodium amalgam. This view was strengthened by the fact that when they reduced *d*-glucoheptulose catalytically no α-*d*-glucoheptulitol was obtained but only the two glucoheptitols predicted by Austin's formula.[7]

In view of the findings of the French workers it seemed desirable to us to extend their studies on the structure of the glucoheptulitols. For that purpose *d*-glucoheptulose was prepared by the rearrangement of α-*d*-glucoheptose, using Austin's method[5] with some modifications. These modifications were introduced in the separation of the

(1) These studies, a portion of which was reported on the program of the meeting of the American Chemical Society in Milwaukee, September, 1938, were abstracted in part from a dissertation submitted by Mr. Kuman to the Graduate School of Loyola University in partial fulfilment of the requirements for the degree of Master of Science.

ketoheptose from the unchanged aldoheptose. Whereas Austin had carried out this separation by oxidizing the unchanged aldoheptose with bromine and separating the salt of the aldonic acid from the ketoheptose by alcohol, advantage was taken of the fact that diphenylmethane-dimethyldihydrazine reacts very readily with certain aldoses at room temperature but does not react with ketoses.[8] By means of this reagent it was easily possible to separate the ketose nearly quantitatively from the aldose.

d-Glucoheptulose, prepared in this manner, proved to be identical with a sample left by the late Dr. Austin. The reduction of this ketose was carried out with sodium amalgam at room temperature in a medium kept faintly acid to litmus by frequent additions of sulfuric acid. Several reductions were carried out and in all but one case α-*d*-glucoheptulitol was one of the products of the reaction, the only other crystalline product which could be isolated being β-*d*-glucoheptitol. In one case both α-glucoheptitol and β-*d*-glucoheptitol were obtained along with α-*d*-glucoheptulitol. Both glucoheptitols were identified by comparing their physical constants with those of the respective glucoheptitols prepared by the reduction of the crystalline aldoheptoses and with the constants given in the literature.

The α-*d*-glucoheptulitol obtained, after having been recrystallized three times from absolute ethanol, melted at 141°[9] and showed a specific rotation of +2.04° in water. Further recrystallizations from ethanol failed to change these constants. The molecular weight of α-*d*-glucoheptulitol, as determined by the cryoscopic method, was found to be 192. An elementary analysis of this substance for carbon and hydrogen gave values which differed from those calculated for a heptitol by amounts greater than could be accounted for by experimental errors (Table I). Attempts to determine the number of hydroxyl groups in α-*d*-glucoheptulitol were unsuccessful, for in every attempt to prepare the acetate of glucoheptulitol only the heptaacetate of α-glucoheptitol was obtained. The identity of this heptaacetate was proved by elementary analysis, melting point, absence of optical rotation and melting point when mixed with a sample of pure heptaacetate of α-glucoheptitol. In the same manner every attempt to prepare a trityl derivative of α-*d*-glucoheptulitol yielded as the only crystalline product a substance which was proved to be identical, according to the standards mentioned in the case of the acetate, with the ditrityl derivative of α-glucoheptitol.

(8) Von Braun, *Ber.*, **43**, 1495 (1910); **50**, 42 (1917).

(9) All melting points obtained by the authors were determined in a capillary glass tube suspended in a bath of sulfuric acid and are not corrected for stem exposure. The French workers used the bloc Maquenne for their melting point determinations.

In further studies to elucidate the structure of α-*d*-glucoheptulitol it was subjected to the action of acid and alkali. Boiling α-*d*-glucoheptulitol with 0.1 *N* sulfuric acid for thirty minutes left it totally unchanged. Similarly, boiling it with 10% barium hydroxide for ninety minutes did not produce any change, since the unchanged glucoheptulitol could be isolated from the solution. However, when α-*d*-glucoheptulitol was boiled with 10% sulfuric acid for seventy-five minutes, some reaction did take place, for the only crystalline substance which could be isolated from the solution was α-glucoheptitol besides a small quantity of unchanged glucoheptulitol.

Considering all the properties of glucoheptulitol thus far mentioned, one might be tempted to assume that this substance is an anhydride of α-glucoheptitol, crystallizing as four molecules of anhydride with three molecules of water. It would be necessary to assume three molecules of water of crystallization in order to satisfy the values obtained for carbon and hydrogen in the elementary analysis of α-*d*-glucoheptulitol.[1] It is, however, difficult to visualize a substance containing water of crystallization which can be recrystallized repeatedly from anhydrous solvents and which can be heated in a high vacuum at 100° without any loss of this water of crystallization.

The conclusion, therefore, seems justifiable that α-*d*-glucoheptulitol is not a pure chemical substance but consists of mixed crystals, made up very largely of α-glucoheptitol plus a small amount of an optically active impurity. This latter substance is probably a decomposition product of *d*-glucoheptulose formed during the reduction of the ketose. This conclusion has been reached in

spite of three statements appearing in the literature: (a) The French workers in their several papers on the properties and structure of the glucoheptulitols state that they are pure substance and probably are heptitols of unknown structure; (b) Elsner in Tollens' "Handbook on Carbohydrates"[10] assumes that α-glucoheptulitol is identical with β-*d*-glucoheptitol; (c) and the Armstrongs in their monograph on carbohydrates[11] state that α-glucoheptulitol is a heptitol not identical with the β-glucoheptitols.

Proof of the validity of the conclusion that α-*d*-glucoheptulitol consists of mixed crystals of α-glucoheptitol with a small amount of an optically active impurity is furnished by the solubility studies shown in Table II. As can be seen from this table, when α-glucoheptitol and β-*d*-glucoheptitol or α-*d*-glucoheptulitol and β-*d*-glucoheptitol are dissolved together in methanol their solubilities are additive or nearly so. However, quite different results were obtained when the solubility of α-glucoheptitol and of α-*d*-glucoheptulitol as well as that of a mixture of these two substances was determined. A saturated solution of α-*d*-glucoheptulitol contained 63.5 mg. of substance per 10 ml. and a saturated solution of α-glucoheptitol in the same solvent contained 69.9 mg. of substance. If now a solution of methanol was saturated with respect to both α-glucoheptitol and α-*d*-glucoheptulitol, it contained 71.3 mg. of solids, or the same amount, within limits of experimental error, as a saturated solution of α-glucoheptitol alone in methanol. In other words, a solution saturated with respect to α-glucoheptitol is also saturated with respect to α-*d*-glucoheptulitol.

Experimental

Preparation of *d*-Glucoheptulose.—α-*d*-Glucoheptose was rearranged in lime water according to the method of Austin,[5] and from the rearrangement a mixture of *d*-glucoheptulose and α-*d*-glucoheptose was obtained. An aqueous solution of 278 g. of this material in 1500 ml. of solution was prepared. Iodimetrically it was found that the solution contained 67.5 g. of aldoheptose. To this solution was added 58 g. of diphenylmethane-dimethyldihydrazine dissolved in 1500 ml. of 95% ethanol, and the solution allowed to stand overnight. The precipitate of the dihydrazone of α-*d*-glucoheptose was filtered off and washed with 100-ml. portions of ethanol: yield 52 g.; m. p. 167°.

To the combined filtrate and washings obtained, an excess of formaldehyde was added in order to remove the uncombined diphenylmethane-dimethyldihydrazine. After standing at room temperature overnight, the dihydrazone of formaldehyde was filtered off and discarded. The filtrate was concentrated to a small volume under reduced pressure. It was then rediluted and redistilled several times to remove all traces of formaldehyde. The formaldehyde-free sirup was then taken up in 300 ml. of a 7:3 mixture of methanol and ethanol. Upon seeding and cooling the system soon solidified to a crystalline mass. In this way 212 g. of crude *d*-glucoheptulose, m. p. 163°, was obtained and recrystallized to melt at 169°.

Reduction of *d*-Glucoheptulose.—Twenty grams of *d*-glucoheptulose was reduced with sodium amalgam at room temperature in the usual manner. After removing the sodium sulfate with ethanol, the system was concentrated to a thin sirup which was taken up in 100 ml. of boiling anhydrous ethanol. Upon cooling, a precipitate consisting of fine needles aggregating in rosets began to form. After standing in the refrigerator overnight, the crystals were filtered off, washed with cold ethanol and dried *in vacuo* to give 10 g. of Crop I, melting at 139°. The mother liquors were concentrated to a sirup and taken up in 50 ml. of boiling anhydrous ethanol. Upon standing in the refrigerator overnight the solution yielded 4 g. of crystalline material as Crop II, m. p. 116°, consisting of small rectangles and fine needles.

Crop I was dissolved in 20 ml. of water, filtered through hardened filter paper, concentrated to a thin sirup under reduced pressure and taken up in 100 ml. of boiling absolute ethanol. After chilling the solution for several hours 9 g. of crystalline material was obtained which melted at 141°. Three subsequent recrystallizations from ethanol as well as recrystallizations from anhydrous methanol and from aqueous dioxane failed to alter the melting point of this substance. It was optically active, $[\alpha]^{28}D$ +2.04° (*c*, 0.760; *l*, 2; H_2O). This substance is therefore α-*d*-glucoheptulitol.

Crop II was dissolved in a small quantity of boiling methanol, filtered and allowed to crystallize. Its melting point after this treatment was 119°. Another recrystallization from the same solvent brought the melting point up to 125°, but under the microscope two types of crystals still could be seen. Through fractional crystallization from hot methanol four different crops were obtained: Crop IIa, m. p. 129°, Crop IIb, m. p. 128°, Crop IIc, m. p. 126°, Crop IId, m. p. 126°. Crops IIa and IIb were combined and recrystallized from methanol to yield a product which crystallized in small rectangular plates melting at 129°. Crop IIc was recrystallized twice from methanol to yield a substance melting at 129°. All three crops were combined and recrystallized from methanol to yield 1 g. of small rectangular plates, m. p. 129°. They showed a slight optical activity, $[\alpha]^{25}D$ +0.62° (*c*, 1.004; *l*, 2; H_2O). When mixed with a sample of β-*d*-glucoheptitol, obtained by the reduction of crystalline β-*d*-glucoheptose, it melted at 129°. The substance therefore is β-*d*-glucoheptitol.

Crystals of Crop IId when mixed with crystals of β-*d*-glucoheptitol melted at 115°; when mixed with crystals of α-glucoheptitol (m. p. 129°) they melted at 127°. No op-

(10) Tollens-Elsner, "Kurzes Handbuch der Kohlenhydrate," 4th ed., Verlag Johann Ambrosius Barth, Leipzig, Germany, 1935, p. 407.

(11) E. F. Armstrong and K. F. Armstrong, "The Carbohydrates," 5th ed., Longmans, Green and Co., London, 1934, p. 148.

tical rotation was observed. Presumably Crop IId consisted of impure α-glucoheptitol.

Effect of Acid upon α-*d*-Glucoheptulitol.—Six grams of α-*d*-glucoheptulitol was dissolved in 30 ml. of 10% sulfuric acid and boiled under the reflux for seventy-five minutes. The solution was decolorized with charcoal and its specific rotation was found to be $[\alpha]^{25}D$ −1.83°. The filtrate, obtained after removal of the sulfate ions as barium sulfate, was concentrated to a thin sirup. This sirup was taken up in 85 ml. of hot absolute ethanol. After the solution was cooled, copious crystallization occurred. The crystals were filtered off and after having been dried *in vacuo* at room temperature they weighed 3 g. After three recrystallizations the substance melted at 129° and was found to be optically inactive. A mixture of some of these crystals with pure α-glucoheptitol melted at 129°. Hence this substance is α-glucoheptitol. The mother liquors from the first crystallization of this crop were concentrated to a thin sirup and taken up in absolute ethanol. On cooling a second crop, weighing 0.5 g., was obtained. This crop showed a melting point of 138° and a specific rotation of $[\alpha]^{25}D$ +2.4° (*c*, 0.480; *l*, 1; H_2O), hence it consisted of impure α-*d*-glucoheptulitol. The mother liquors of this crop were strongly levorotatory. They were not investigated any further.

Treatment of α-*d*-glucoheptulitol with 0.1 *N* sulfuric acid at boiling temperature had no effect upon the substance, for it could be recovered unchanged nearly quantitatively.

Effect of Barium Hydroxide upon α-*d*-Glucoheptulitol.—Four grams of α-*d*-glucoheptulitol was dissolved in 30 ml. of 10% barium hydroxide solution and boiled for ninety minutes. After removing the barium as the sulfate the solution was concentrated to a thin sirup under reduced pressure. The sirup was taken up in 50 ml. of boiling ethanol and allowed to crystallize. After drying *in vacuo* at room temperature the crystals weighed 3.1 g. They showed a melting point of 139° and when mixed with a sample of the starting material the melting point remained unchanged.

Reaction of α-*d*-Glucoheptulitol with Acetic Anhydride.—Four grams of α-*d*-glucoheptulitol was heated with acetic anhydride and fused zinc chloride in the usual manner.[12] The product obtained crystallized in rhombic plates, and after one recrystallization from ethanol the crystals melted at 115°. The yield of acetate, starting with 4 g. of α-*d*-glucoheptulitol, was 6 g. The acetate was optically inactive. A mixture of this acetate with the heptaacetate prepared from crystalline α-glucoheptitol did not show any depression of the melting point.

Anal. Calcd. for $C_{21}H_{30}O_{14}$: C, 49.79; H, 5.97. Found: C, 49.65; H, 6.08.

Similar results were obtained when the milder pyridine method of acetylation[13] was used. Again the only crystalline product obtained was found to be identical with α-glucoheptitol heptaacetate.

Reaction of α-*d*-Glucoheptulitol with Trityl Chloride.—The trityl derivative of α-*d*-glucoheptulitol was prepared in the usual manner.[14] When 2 g. of α-*d*-glucoheptulitol was allowed to react with 6 g. of trityl chloride in 25 ml. of anhydrous pyridine according to this procedure, there was isolated a crystalline substance. After three recrystallizations from a 2:1 mixture of methanol and ethanol, it weighed 3.1 g. and showed a melting point of 142–143°. The substance was optically inactive. Mixed with a sample of the dityrityl derivative prepared from α-glucoheptitol (m. p. 142–143°), it showed no depression of the melting point.

Anal. Calcd. for $C_{45}H_{44}O_7$: C, 77.57; H, 6.37. Found: C, 77.82; H, 6.47.

Solubility Studies.—The solubility of α-*d*-glucoheptulitol alone or when mixed with one of the glucoheptitols was determined by suspending an excess of the substances listed in Table II in 30 ml. of anhydrous methanol. The suspensions, contained in tightly stoppered 1 × 8″ (2.5 × 20 cm.) test-tubes, were placed into a shaking machine which operated within an incubator set at 37 ± 1°. The suspensions were shaken for two days and then filtered as quickly as possible. Then 10-ml. portions of the filtrate were pipetted into weighed evaporating dishes and the solvent driven off by heating the dishes on a steam-bath. The dishes were then dried to constant weight in a vacuum desiccator. The results of this study are listed in Table II.

TABLE II

SOLUBILITY STUDIES ON α-*d*-GLUCOHEPTULITOL[a]

Substance	Mg. in 10 ml. of methanol		Av.	Calcd.[b]
β-*d*-Glucoheptitol	47.8	48.0	48.0	
	48.2	48.0		
α-*d*-Glucoheptulitol	63.2	63.5	63.5	
	63.7			
α-Glucoheptitol	69.7	70.0	69.9	
	69.6	70.2		
α-Glucoheptitol + α-*d*-Glucoheptulitol	70.3	71.4	71.3	133.4
	72.0	71.6		
β-*d*-Glucoheptitol + α-*d*-Glucoheptulitol	110.0	109.4	109.8	111.5
	110.2	109.7		
β-*d*-Glucoheptitol + α-Glucoheptitol	112.7	112.3	112.6	117.9
	112.8	112.5		

[a] These studies were carried out in an incubator kept at 37.0 ± 1°. [b] These values were obtained by adding the average solubility of each constituent of the mixture.

Molecular Weight of α-*d*-Glucoheptulitol.—The molecular weight of α-*d*-glucoheptulitol was determined by the cryoscopic method. When 1.0009 g. of the substance was dissolved in 24.95 g. of water, the following lowering of the freezing point of the solution was observed: 0.388°; 0.383°; 0.389°; 0.389°; average, 0.387°. Substituting the average value, 0.387°, in the formula Molecular Weight = kw/dW, where w is the number of grams of solute dissolved in W g. of solvent, thereby causing a lowering of its freezing point of d degrees, and using 1860 as the value for k, the molecular weight of α-*d*-glucoheptulitol was found to be 192.3.

Summary

1. It has been shown that diphenylmethanedimethyldihydrazine is a convenient reagent to

(12) Fischer, *Ann.*, **270**, 64 (1892).
(13) Behrend and Roth, *Ann.*, **331**, 359 (1904).
(14) Helferich, Moog and Juenger, *Ber.*, **58**, 872 (1925).

separate mixtures of *d*-glucoheptulose and α-*d*-glucoheptose.

2. When *d*-glucoheptulose was reduced with sodium amalgam β-*d*-glucoheptitol and a substance which Khouvine and Nitzberg have called α-*d*-glucoheptulitol were obtained.

3. Evidence has been presented to show that the substance called α-*d*-glucoheptulitol is not a pure chemical entity but consists of mixed crystals of α-glucoheptitol plus a small amount of an optically active impurity. This evidence is, briefly:

From the values obtained in elementary analyses and in molecular weight determinations it is not possible to write a formula which is consistent with the chemical behavior of the substance.

The substance when heated in a 10% solution of sulfuric acid goes over into α-glucoheptitol.

The substance when treated with acetic anhydride and a catalyst forms the heptaacetate of α-glucoheptitol.

The substance when treated with trityl chloride in the presence of pyridine forms the ditrityl derivative of α-glucoheptitol.

A saturated solution of α-glucoheptitol in methanol is also saturated with respect to this substance.

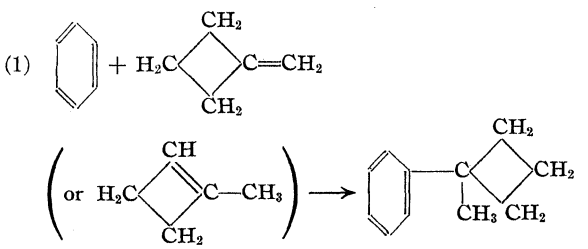
Reaction of Benzene with Methylcyclobutene and Methylenecyclobutane in the Presence of Sulfuric Acid[1]

BY V. N. IPATIEFF AND HERMAN PINES

The reaction between alkenes and aromatic hydrocarbons proceeds readily in the presence of various condensing agents.[2] Of the cycloalkenes only those containing five- and six-membered rings have been studied.

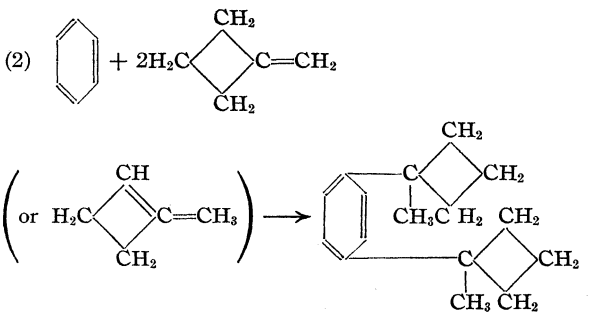
We were interested in studying the reaction of benzene with a cycloalkene containing a four-membered ring, in order to determine whether methylcyclobutylbenzene would be formed and whether a cyclobutyl group attached to a phenyl group is more stable than an unarylated cyclobutane. It was found that a mixture composed of methylcyclobutene and methylenecyclobutane reacts readily with benzene in the presence of 96% sulfuric acid at 0–10° to yield a product consisting of mono-, di- and trimethylcyclobutylbenzenes.

The reaction proceeds according to the equation



(1) Presented before the Division of Organic Chemistry of the American Chemical Society at Boston, Mass., Sept. 11–15, 1939.

(2) Ipatieff, Pines and Schmerling, paper presented before the Organic Division at the American Chemical Society meeting, Milwaukee, Wisconsin, September, 1938.



The monosubstituted benzene, which is probably 1-methyl-1-phenylcyclobutane,[3] contains a cyclobutyl ring which is stable toward nitrating mixture consisting of 1 vol. concentrated nitric and 2 vol. of concentrated sulfuric acid. A nitro compound was obtained from which a solid monoacetamino derivative was prepared. The cyclobutyl ring in methylcyclobutane decomposes when subjected to similar treatment.

The di-substituted benzene consists mainly of *p*-di-(1[1]-methylcyclobutyl)-benzene which melts at 33–34°. The higher-boiling fractions consist of tri-(1[1]-methylcyclobutyl)-benzene.

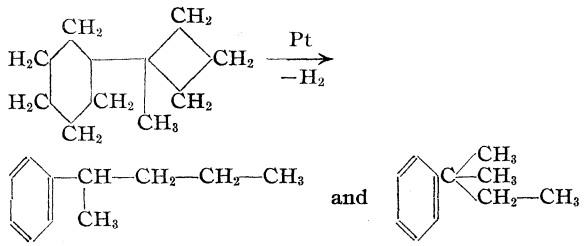
The cyclobutyl ring in the di-substituted benzene is stable toward 2% potassium permanganate at 100° and toward dilute nitric acid at a

(3) The position of the methyl group was not established, but on the basis of reaction of alkenes with benzene[2] one would expect the phenyl group to attach itself to the carbon atom of cyclobutyl containing the methyl group.

temperature of 135°. At 160° oxidation takes place yielding terephthalic acid.

The effect of hydrogen on the cyclobutyl ring was studied with 1-methyl-1-phenylcyclobutane, which undergoes hydrogenation at 65° in the presence of a solvent and a nickel catalyst to yield 1-methyl-1-cyclohexylcyclobutane; if the hydrogenation is carried out at 125° the cyclobutyl ring decomposes and amylcyclohexane is obtained.

The cyclobutyl ring in 1-methyl-1-cyclohexylcyclobutane decomposes when passed over platinized alumina at 250°; a mixture of *t*-amylbenzene and 2-phenylpentane was obtained. This proceeds according to the equation



The percentage of the two amylbenzenes present in the mixture was determined by comparing the melting point of its diacetamino derivative with the melting points of known mixtures of the diacetamino derivatives of *t*-amylbenzene and 2-phenylpentane (Curve 1).

Experimental Part

Preparation of Methylcyclobutane.—This compound was prepared by debrominating[4] pentaerythrityl bromide[5] with zinc dust. A mixture of methylcyclobutene and methylenecyclobutane[6] was obtained having a boiling point of 40–42.5° at 736 mm. The yield was 65%.

Reaction of Methylcyclobutene and Methylenecyclobutane with Benzene.—The apparatus consisted of a 200-cc. three-necked flask, equipped with a mercury-sealed stirrer, a water-jacketed dropping funnel, and a reflux condenser. The flask was immersed in ice water. Thirty grams of 96% sulfuric acid and 35 g. (0.45 mole) of benzene were placed in the flask and cooled to 4°. A mixture consisting of 25 g. (0.37 mole) of methylenecyclobutane and methylcyclobutene and 35 g. (0.45 mole) of benzene was added during one hour. Two layers were formed: acid layer, 31.3 g., and hydrocarbon layer, 93.5 g. The latter was washed and dried. It was stable toward a 2% potassium permanganate solution, which indicates the absence of olefins. The combined product of three experiments was distilled over metallic sodium.

The benzene was distilled at atmospheric pressure and the methylcyclobutylated benzene under 8 mm. pressure. The following fractions were separated: (1) b. p. 69° at 8 mm., 40 wt. %; (2) 125–143° at 8 mm., 49%; (3) 155–182° at 8 mm., 11%.

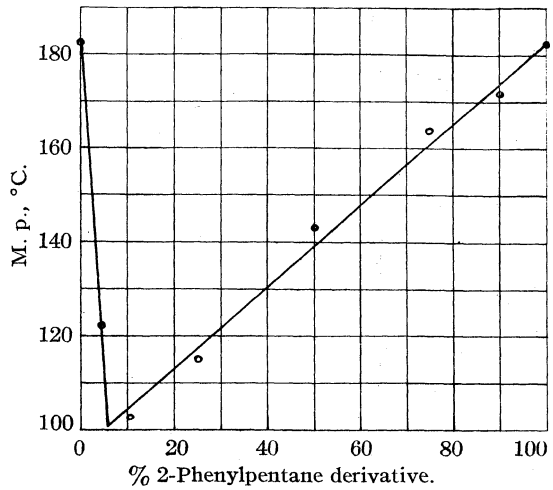


Fig. 1.—Melting point curve for mixtures of the diacetamino derivatives of 2-phenylpentane and *t*-amylbenzene.

On the basis of the distillation it was computed that the reaction mixture consists of

50 Moles mono-methylcyclobutylbenzene
45 Moles di-methylcyclobutylbenzene
5 Moles tri-methylcyclobutylbenzene

The following products were isolated and analyzed.

Fraction 1 consists of 1-methyl-1-phenylcyclobutane, b. p. 69° at 8 mm.; boiling point determined by Cottrell method;[7] 208.6° at 760 mm., dt/dp (760–740 mm.) = 0.05°/mm.; $d^{20}_{vac.}$ 0.9192; $d^{40}_{vac.}$ 0.9044; $-dD/dt$ = 0.00074; $n^{20}D$ 1.5132.

Anal. Calcd. for $C_{11}H_{14}$: C, 90.18; H, 9.82. Found: C, 89.94; H, 9.83.

Monoacetamino derivative[8] (1[1]-methyl-1-cyclobutyl-4-acetaminobenzene), melting point 144°.

Anal. Calcd. for $C_{13}H_{17}O$: C, 76.79; H, 8.43; N, 6.89. Found: C, 76.75; H, 8.32; N, 6.62.

Diacetamino derivative (1[1]-methyl-1-cyclobutyl-2,4-diacetaminobenzene).—Melting point 202°.

Anal. Calcd. for $C_{15}H_{20}O_2N_2$: N, 10.77. Found: N, 10.97.

Fraction 2 was redistilled under 6 mm. pressure. The major part of the product boiled at 124–128° and had $n^{20}D$ 1.5194–1.5245, corresponding to di-(1[1]-methylcyclobutyl)-benzene. Cut b. p. 123–125° at 6 mm., $n^{20}D$ 1.5203, $d^{20}_{vac.}$ 0.9344, $d^{40}_{vac.}$ 0.9198.

Anal. Calcd. for $C_{16}H_{22}$: C, 89.35; H, 10.63. Found: C, 89.48; H, 10.43.

This product crystallizes in ice. A solid was separated which after repeated crystallizations had m. p. 34° and by oxidation was proved to correspond to 1,4-di-(1[1]-methylcyclobutyl)-benzene.

Anal. Calcd. for $C_{16}H_{22}$: C, 89.35; H, 10.65. Found: C, 89.51; H, 10.52.

Oxidation.—Seven-tenths gram of the product of b. p. 124–128° at 6 mm. was heated at 160° for two hours in a 60-cc. sealed tube with 12 cc. of 77% nitric acid and 24 cc. of water, according to the procedure recently described.[9] Terephthalic acid was obtained (40% yield). The dimethyl ester of the acid had a melting point of 140° and showed no depression in melting point when mixed with an authentic sample.

Anal. Calcd. for $C_{10}H_{10}O_4$: C, 61.83; H, 5.19. Found: C, 61.60; H, 5.13.

Fraction 3.—B. p. 155–182° under 8 mm., $n^{20}D$ 1.5342.

Anal. Calcd. for $C_{21}H_{30}$: C, 89.29; H, 10.71. Found: C, 89.31; H, 10.42.

Preparation of 1-Methyl-1-cyclohexylcyclobutane.—Nine grams of 1-methyl-1-phenylcyclobutane was dissolved in 10 cc. of *n*-pentane and hydrogenated in a 125-cc. autoclave in the presence of nickel–kieselguhr catalyst[10] at 65° and under the initial hydrogen pressure of 100 atmospheres. The hydrogenated product did not react with nitrating mixture, which indicates the absence of an aromatic ring. The hydrogenated product distilled at 72–73° at 9 mm., 201.5° at 760 mm. dt/dp (752–739 mm.) = 0.08°/mm.; $n^{20}D$ 1.4662; d^{20}_4 0.8595.

Anal. Calcd. for $C_{11}H_{20}$ (1-methyl-1-cyclohexylcyclobutane): C, 86.75; H, 13.25. Found: C, 86.56; H, 13.45.

Dehydrogenation.—1-Methyl-1-cyclohexylcyclobutane was passed over platinized aluminum oxide at 250°. Details have been given in another paper.[11] Aromatic hydrocarbons were obtained distilling at 187 to 192° at 741 mm. and having $n^{20}D$ 1.4861.

A diacetamino derivative[8] was prepared which melted at 144–145°. It consisted of equimolal proportions of *t*-amylbenzene and 2-phenylpentane. This was proved by preparing a melting point curve of the two amylbenzenes and by taking a mixed melting point of the unknown with a mixture of the authentic diacetamino derivatives of the amylbenzenes.

Acknowledgment.—The authors wish to express their thanks to Mr. M. Savoyias for the assistance which he rendered in the laboratory operations.

Summary

A mixture consisting of methylcyclobutene and methylenecyclobutane reacts with benzene in the presence of sulfuric acid to yield: (a) 1-methyl-1-phenylcyclobutane, characterized by solid mono- and diacetamino derivatives; (b) *p*-di-(1¹-methylcyclobutyl)-benzene, isolated as a crystalline compound; and (c) tri-(1¹-methylcyclobutyl)-benzene.

Hydrogenation of 1-methyl-1-phenylcyclobutane yielded 1-methyl-1-cyclohexylcyclobutane. The latter on dehydrogenation decomposed into *t*-amylbenzene and 2-phenylpentane.

The cyclobutyl ring becomes very stable toward sulfuric acid or nitrating mixture when a phenyl group is attached to it.

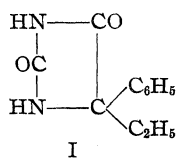
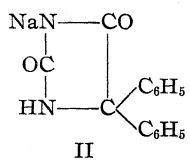
5-[α-(*s*-Butoxy)]-ethyl-5-alkyl Hydantoins

BY ROBERT J. SPEER AND HENRY R. HENZE

During the past few years in this Laboratory considerable attention has been given to the synthesis of hydantoins, a few of which have been shown to possess sufficient physiological activity to warrant continued research in this field. Previous papers of this series have reported extended use of Bucherer's[1] method for the production of substituted hydantoins by interaction of an aqueous alcoholic solution of potassium cyanide and ammonium carbonate with appropriate ketones. The latter have included examples of alkoxymethyl alkyl (or aryl) ketones, phenoxymethyl alkyl (or aryl) ketones, 1,3-dichloroisopropoxyethyl alkyl (or aryl) ketones, dialkylaminoacetones, alkyl nitroaryl ketones, and β-chloroethoxyalkyl alkyl ketones.[2] Although, as yet, but two 5,5-disubstituted hydantoins, namely, Nirvanol (I)[3] and Dilantin (II),[4] have found actual clinical use,



I



II

the hydantoin nucleus offers potentiality as an innocuous heterocycle to which may be attached

groupings appropriate to produce additional derivatives of importance as soporifics or anticonvulsants. Since it is known that the ethyl and *s*-butyl groups are of special physiological potency, it seemed of interest to prepare a series of hydantoins containing these groups connected in an alkoxyalkyl linkage, namely, as the *s*-butoxyethyl grouping. While the preparation of analogous and in a few cases isomeric hydantoins has been accomplished previously, the procedure of Bucherer[1] has not been utilized for the synthesis of 5-(*s*-butoxyethyl)-5-alkyl (or aryl) hydantoins.

Experimental

Preparation of α-(*s*-Butoxy)-ethyl Alkyl Ketones.—The nine ketones used as intermediates in the production of the butoxyethyl hydantoins were prepared by the interaction of the appropriate Grignard reagents and *s*-butyl α-cyanoethyl ether as described previously.[5]

Synthesis of 5-[α-(*s*-Butoxy)]-ethyl-5-Alkyl Hydantoins.—The production of nine members of this series of compounds was accomplished by the interaction of an aqueous alcoholic solution of potassium cyanide and ammonium carbonate with the appropriate butoxyethyl alkyl ketones. One part (0.05 mole) of a ketone was mixed with a suspension of 1.25 parts of potassium cyanide and 3.0 parts of ammonium carbonate in 7–8 volumes of 50% alcohol. Upon warming the mixture to 55–60° for five to six hours, the solids gradually dissolved with evolution of gas, followed in most cases with the separation of the solid reaction product from the warm solution. At the termination of this period of warming the mixture was cooled and the product removed by filtration. Concentration of the filtrate with subsequent acidification yielded additional crystalline material, although in the cases of the *s*-propyl and *s*-butyl derivatives there was considerable tendency toward the formation of oily material. However, in these instances, after solidification of the oil no trouble was experienced in purification by further crystallization.

All of the hydantoins of this series are white crystalline solids soluble in alcohol, acetone, benzene, and chloroform but insoluble in water and petroleum ether. Purification was effected by recrystallization from 50–60% ethyl alcohol or from a benzene–petroleum ether mixture. In some instances treatment with Norite was necessary for complete removal of color. These compounds, in general, possess sharp melting points, fusing to form light straw colored liquids without decomposition. Data for melting points, percentage yields, and the analyses for nitrogen content of these hydantoins are presented in Table I.

Summary

The series of 5,5-disubstituted hydantoins, potentially important as soporifics or anti-convulsants, has been extended to include nine new *s*-butoxyethyl alkyl hydantoins.

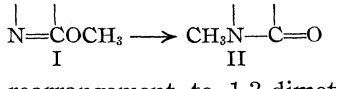
Researches on Pyrimidines. The Molecular Rearrangement of 4-Methyl-5-*n*-propyl-2,6-dimethoxypyrimidine[1]

BY YUOH-FONG CHI, SHAO-SENG WEI AND MEI-SENG LIANG[2]

Previous publications by Hilbert and Johnson from the Yale laboratories,[3] and later by Chi, Wei and Pan[4] have shown that pyrimidine lactim-ethers of configuration I undergo rearrangement to their isomeric and stable lactam forms II. For example, 2,6-dimethoxypyrimidine and 2-oxy-3-methyl-6-methoxypyrimidine on heating both



underwent rearrangement to 1,3-dimethyluracil. Under similar conditions 4-methyl-5-*n*-butyl-2,6-dimethoxypyrimidine and 2-oxy-3,4-dimethyl-5-*n*-butyl-6-methoxypyrimidine are converted to 1,3,4-trimethyl-5-*n*-butyluracil.

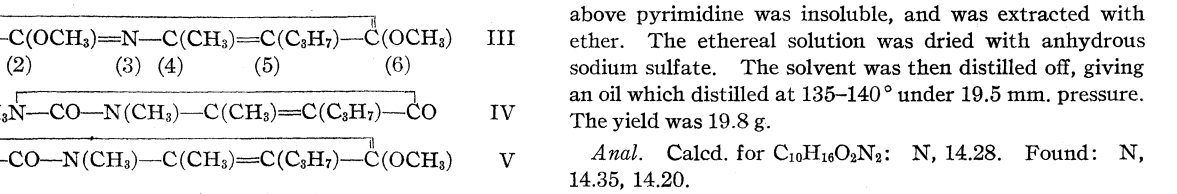
(1) This paper is constructed from a dissertation presented by Shao-Seng Wei and Mei-Seng Liang to the Faculty of Kwangsi University as partial fulfilment of the requirements for the degree of Bachelor of Science in June, 1938.

(2) The authors desire to express their appreciation to Professor Treat B. Johnson of Yale University for his assistance in preparing this paper for publication.

(3) Hilbert and Johnson, THIS JOURNAL, **52**, 2001 (1930).

(4) Chi, Wei and Pan, *ibid.*, **60**, 1719 (1938).

In this paper the authors describe the conditions under which 4-methyl-5-*n*-propyl-2,6-dimethoxy-pyrimidine (III) rearranges into (a) 1,3,4-trimethyl-5-*n*-propyluracil (IV) and (b) 2-oxy-3,4-dimethyl-5-*n*-propyl-6-methoxy-pyrimidine (V).



The authors have made the observation that the pyrimidine (III) is rearranged smoothly to the lactam modification (IV) by heating at 260–280°. On the other hand, when heated at 50–60° under the catalytic influence of methyl iodide, the partially rearranged pyrimidine (V) is formed. This latter pyrimidine is stable only at low temperatures and undergoes rearrangement at 260–280° to the *lactam* form (IV).

Experimental Part

VI, NHCONHC(CH$_3$)=C(C$_3$H$_7$)CO, 4-Methyl-5-*n*-propyl-uracil.—This pyrimidine was prepared by digesting 4-methyl-5-*n*-propyl-2-thiouracil[5] with chloroacetic acid. Thirty grams of the thiouracil was digested with a solution containing 60 g. of ClCH$_2$COOH in 150 cc. of water for two hours, whereupon 26 g. of the desulfurized pyrimidine separated as needles, melting at 247–249°. The same pyrimidine also is formed by digesting 2-ethylmercapto-4-methyl-5-*n*-propyl-uracil[5] with strong hydrochloric acid. Twenty-five grams of this mercaptopyrimidine yielded 20 g. of the uracil compound melting at 246–247°.

4-Methyl-5-*n*-propyl-2,6-dichloropyrimidine, VII.—Sixteen and eight-tenths grams of VI was refluxed with 100 cc. of phosphorus oxychloride in an oil-bath at 120–130° until hydrogen chloride gas ceased to be evolved. This took twelve hours. The excess of phosphorus oxychloride was removed by heating the reaction mixture on a water-bath under a vacuum. There was obtained a brown viscous residue which did not solidify. The residue was treated with cracked ice to decompose phosphorus compounds, and then extracted with ether. The ethereal solution was washed with water, dried with calcium chloride and filtered. After distilling the solvent from the ethereal solution, an oil was obtained which was purified by distillation under a vacuum. The pyrimidine VII boils at 163° under 35 mm. pressure, at 149° under 20.8 mm. pressure or at 145–146° under 19.5 mm. pressure, and melts at 31–33°. The yield is 16.4 g. or 80%.

Anal. Calcd. for C$_8$H$_{10}$N$_2$Cl$_2$: N, 13.66. Found: N, 13.9, 13.86.

4-Methyl-5-*n*-propyl-2,6-dimethoxypyrimidine, III.—Four and six-tenths grams of metallic sodium was dissolved in 50 cc. of absolute methyl alcohol. To the cold methyl alcohol solution of sodium methylate, there was slowly added a solution of 20.5 g. of VII in 50 cc. of absolute methyl alcohol. This gave an immediate precipitation of sodium chloride. After the separation of sodium chloride by filtration, the excess of methyl alcohol was distilled off on a water-bath. There remained an oil, which was shaken with 30 cc. of 30% sodium hydroxide solution in which the above pyrimidine was insoluble, and was extracted with ether. The ethereal solution was dried with anhydrous sodium sulfate. The solvent was then distilled off, giving an oil which distilled at 135–140° under 19.5 mm. pressure. The yield was 19.8 g.

Anal. Calcd. for C$_{10}$H$_{16}$O$_2$N$_2$: N, 14.28. Found: N, 14.35, 14.20.

4-Methyl-5-*n*-propyl-2,6-diethoxy-pyrimidine, VIII.—This pyrimidine was prepared by a procedure similar to that used for synthesizing the corresponding dimethoxy-pyrimidine described above. This distilled as a colorless oil, boiling at 145–148° under 18 mm. pressure. The yield was 8.9 g. from 10.2 g. of the corresponding dichloro-pyrimidine.

Anal. Calcd. for C$_{12}$H$_{20}$O$_2$N$_2$: N, 12.49. Found: N, 12.79, 12.88.

Methylation of VI.—(A) Four and two-tenths grams of VI was dissolved in sodium hydroxide solution, containing 2.2 g. of NaOH in 150 cc. of water. To this ice-cooled solution, 5.5 cc. of dimethyl sulfate was added drop by drop while the solution was shaken vigorously. It was then boiled for ten minutes. On cooling, 1,4-dimethyl-5-*n*-propyl-uracil (IX) separated. After recrystallization from benzene and petroleum ether, it melted at 193.5–194°. The yield was 2 g. On mixing with 3,4-dimethyl-5-*n*-propyl-uracil (X), described below, its melting point was strongly depressed.

Anal. Calcd. for C$_9$H$_{14}$O$_2$N$_2$: N, 15.38. Found: N, 15.76.

(B) Six-tenths gram of sodium was dissolved in 100 cc. of absolute alcohol, and then 2.1 g. of VI was dissolved in the alcoholate solution. To this cold solution, 2.5 cc. of dimethyl sulfate was then added slowly with frequent shaking. The mixture now was heated for two hours. After distilling off the excess alcohol, the residue was treated with water and extracted with benzene. The benzene solution was dried and solvent removed as usual, whereupon a solid residue was obtained. After crystallizing from benzene and petroleum ether, it melted at 193–194°. On mixing with IX described above, there was no lowering of the melting point.

The Molecular Rearrangement of 4-Methyl-5-*n*-propyl-2,6-dimethoxy-pyrimidine (III). (A) Rearrangement of (III) to (IV).—Two grams of III was heated in an oil-bath at 260–280° for three hours. At first, there was vigorous ebullition which gradually subsided and finally ceased as the proportion of the rearranged compound increased. On cooling, the brown colored reaction product completely solidified. It was dissolved in hot benzene, to which petroleum ether was added just to turbidity. On cooling, the rearranged product separated in needles. After recrystallization from a benzene–petroleum ether mixture, it melted at 74–75°. The yield was 1.8 g. or 90%.

Anal. Calcd. for C$_{10}$H$_{16}$O$_2$N$_2$: N, 14.28. Found: N, 14.21, 14.30.

(5) Chi and Chang, THIS JOURNAL, **60**, 1721 (1938).

(B) **Rearrangement of (III) to (V).**—Nine and eight-tenths grams of III was treated with 14.1 g. of freshly distilled methyl iodide. The mixture was then heated in a sealed tube at 50–60° for eight hours. After the tube was opened, the excess of methyl iodide was removed by a blast of air and the residue distilled under a vacuum. Compound V when pure boils at 180–182° under 4.5 mm. pressure and solidifies on slow cooling. The yield was quantitative. For analysis, it was recrystallized from petroleum ether, separating in needles.

Anal. Calcd. for $C_{10}H_{16}O_2N_2$: N, 14.28. Found: N, 14.16.

The structure of the compound was established by its behavior on hydrolysis, giving X.

Formation of X.—Compound V was heated with dilute hydrochloric acid for one hour. The solution was evaporated to dryness on a water-bath and the residue dissolved in hot water, whereupon X crystallized on cooling in colorless needles, melting at 148–150°.

Anal. Calcd. for $C_9H_{14}O_2N_2$: N, 15.38. Found: N, 15.50, 15.47.

(C) **Rearrangement of the Partially Rearranged Pyrimidine (V) into the Completely Rearranged Pyrimidine (IV).**—Five grams of V was heated at 330–350° for six to eight hours. The reaction mixture solidified on cooling. It dissolved in a little hot benzene, to which petroleum ether was added just to turbidity, whereupon (IV) separated in needles, melting at 74–75°. It proved to be identical with 1,3,4-trimethyl-5-*n*-propyluracil (IV) obtained by heating pyrimidine (III).

Anal. Calcd. for $C_{10}H_{16}O_2N_2$: N, 14.28. Found: N, 14.41, 14.55.

Summary

1. The action of phosphorus oxychloride on 4-methyl-5-*n*-propyluracil produces 4-methyl-5-*n*-propyl-2,6-dichloropyrimidine.

2. This 2,6-dichloropyrimidine reacts with sodium methylate and with sodium ethylate in a characteristic manner, giving the corresponding 2,6-dimethoxy-pyrimidine, and 2,6-diethoxy-pyrimidine derivatives, respectively.

3. 4-Methyl-5-*n*-propyl-2,6-dimethoxy-pyrimidine and 2-oxy-3,4-dimethyl-5-*n*-propyl-6-methoxy-pyrimidine can be rearranged to their isomeric and stable *lactam* modification, 1,3,4-trimethyl-5-*n*-propyluracil, on heating at an elevated temperature. On the other hand, 4-methyl-5-*n*-propyl-2,6-dimethoxy-pyrimidine rearranges only partially on heating with methyl iodide at 50–60° to 2-oxy-3,4-dimethyl-5-*n*-propyl-6-methoxy-pyrimidine.

Oxidation of Glycosides by Means of Lead Tetraacetate in Aqueous Solution

BY J. M. GROSHEINTZ

In a previous paper[1] there was described a new technique for the application of lead tetraacetate as an oxidizing agent. It was shown that the cleavage of the carbon chain in compounds containing two and three adjacent hydroxyl groups could be carried out in aqueous solution as well as in non-aqueous solution. Lead tetraacetate therefore can replace periodic acid in most instances in which aqueous solvents are required.

E. L. Jackson and C. S. Hudson,[2] in their determination of ring structure and alpha- and beta-configuration of glycosides, thoroughly investigated the cleavage of the carbon chain of a number of glycosides by oxidation with periodic acid. In the present paper parallel experiments with lead tetraacetate are reported in order to show the similar action of this reagent on glycosides in aqueous solution.[3] Starting with the optical antipodes of two glycosides used by E. L. Jackson and C. S. Hudson[2] the oxidation products and their derivatives were compared with the products already known.

The oxidation of alpha- (I) and beta-methyl-*l*-arabinopyranosides with lead tetraacetate in water was shown to remove carbon atom 3 and form carbonyl groups at carbon atom 2 and 4, producing the two enantiomorphic forms of methoxy-diglycolic aldehyde[4] (II).

Contrary to previous experience,[1] *three* molecules of lead tetraacetate, instead of two, were required to complete this reaction. In seeking for

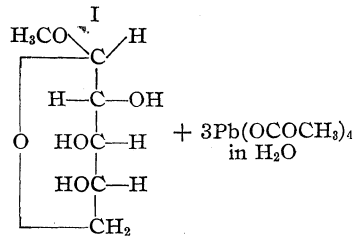
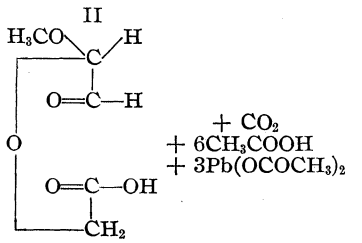
(3) Compare also W. S. McClenahan and R. C. Hockett, *ibid.*, **60**, 2061 (1938).

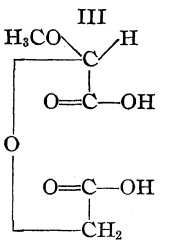
(4) The oxidation products are named in accordance with E. L. Jackson and C. S. Hudson, *ibid.*, **59**, 994 (1937), as derivatives of diglycolic aldehyde. Prefixes D′ and L′ distinguish the configuration of carbon atom 1 in the products from the alpha- and beta-methyl-glycosides, L′ signifying the configuration of carbon atom 1 as in alpha-methyl-*l*-arabinopyranoside.



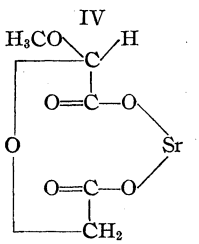
α-Methyl-*l*-arabinopyranoside



L′-Methoxy diglycolic aldehyde



L′-Methoxy-diglycolic acid



Strontium-L′-methoxy-diglycolate

an explanation for this utilization of a third molecule of lead tetraacetate, it was found that one molecule of formic acid in aqueous solution is oxidized by one molecule of lead tetraacetate, yielding one molecule of carbon dioxide.[5] This observation shows that in cases where the velocity of cleavage of the carbon chain between the three adjacent hydroxyl groups is low compared to the rate of oxidation of the formic acid, one must allow for an excess of one mole of lead tetraacetate being used up by the formic acid formed during the reaction.

Further oxidation of the D′- and L′-methoxy-diglycolic aldehydes with bromine water in the presence of strontium carbonate produced the D′- and L′-methoxy-diglycolic acids, the latter being isolated as the crystalline strontium salts. The optical rotations of the starting materials in aqueous solution were $[\alpha]^{20}D$ +17.3° for the alpha-methyl-*l*-arabinopyranoside (m. p. 131°) and $[\alpha]^{21}D$ +246° for the beta-methyl-*l*-arabinopyranoside (m. p. 169–170°). The following rotations for the oxidation products were observed: $[\alpha]^{20}D$ +123.2° and $[\alpha]^{23}D$ −122.5° for the D′- and L′-methoxy-diglycolic aldehydes (II), $[\alpha]^{20}D$ −12.8° and $[\alpha]^{21}D$ +12.7° for the D′- and L′-methoxy-diglycolic acids (III); $[\alpha]^{20}D$ −56.4° and $[\alpha]^{20}D$ +56.4° for the strontium salts of D′- and L′-methoxy-diglycolic acids (IV). The L′-compounds are derived from the alpha-methyl-*l*-arabinopyranoside, the D′-compounds from the beta-methyl-*l*-arabinopyranoside. The optical rotation of each of these compounds checks closely with those obtained by the oxidation of alpha- and beta-methyl-*d*-arabinopyranosides, as recorded by E. L. Jackson and C. S. Hudson.

Experimental

Oxidation of alpha-Methyl-*l*-arabinopyranoside.—A solution of 2.00 g. of alpha-methyl-*l*-arabinoside in 20 cc. of distilled water was poured into 50 cc. of glacial acetic acid[6] containing 13.0 g. of lead tetraacetate, partially undissolved. Within the next six hours 4.0 g. of lead tetraacetate was added in small portions, until the solution turned slightly brown and turbid (=3.2 mole of lead tetraacetate). The solution was then made up to 500.00 cc. with 80 cc. of *N* sulfuric acid and distilled water. The precipitate of lead sulfate was removed by centrifuging and the content of aldehyde determined according to the method of Willstätter and Schudel. The calcd. yield of L′-methoxy-diglycolic aldehyde is 1.61 g.; found, 1.58 g. = 98% yield. The optical rotation of the solution was $\alpha^{23}D$ −0.39, c = 0.316.

The solution was then freed from the slight excess of sulfuric acid with the exact amount of barium acetate and the water and the acetic acid were removed from the dialdehyde by distillation *in vacuo* (bath 35–40°). In order to remove the last traces of acetic acid, the residue was dissolved in 30 cc. of benzene and the solvent evaporated *in vacuo* (bath 35–40°). This operation was repeated twice and the remaining dialdehyde was dried for one hour in high vacuum (40°).

The dialdehyde was then dissolved in 300 cc. of distilled water; 18 g. of strontium carbonate and 8 g. of bromine were added and the mixture was shaken for one hour. After standing at room temperature for an additional sixteen hours, the excess bromine was removed by aeration and the strontium carbonate by filtration. The solution was concentrated and made up to 250.00 cc. The rotation of the strontium L′-methoxy-diglycolate in the solution containing strontium bromide was $[\alpha]^{25}D$ +55.1°.

The bromide ions in the solution were removed by shaking with 25 g. of silver carbonate, and the silver ions precipitated by hydrogen sulfide. The solution was concentrated *in vacuo* (45–50°) to about 100 cc., then filtered

(5) It can be assumed that the formic acid is present in its *ortho* form and that the following steps are involved

This reaction does not take place in dry organic solvents, or in aqueous solution by means of periodic acid.

(6) The amount of water and glacial acetic acid can be chosen freely according to the solubility and amount of substance used. Lead tetraacetate can also be added to the aqueous solution of the glycoside in finely powdered form.

and concentrated again to about 10 cc. This liquid was left to evaporate over phosphorus pentoxide for two days and yielded 2.1 g. of crystalline strontium L'-methoxy-diglycolate. After drying the strontium salt over phosphorus pentoxide for six hours at 100° in high vacuum, it showed the optical rotation $[\alpha]^{20}D$ +56.4°.

Anal. Calcd. for $C_5H_6O_6Sr$: C, 24.03; H, 2.40; Sr, 35.01. Found: C, 23.90; H, 2.53; Sr, 34.98.

Oxidation of beta-Methyl-*l*-arabinopyranoside.—The procedure was the same as reported for alpha-methyl-*l*-arabinopyranoside. The optical rotation of the D'-methoxy-diglycolic aldehyde was $[\alpha]^{20}D$ +123.2° ($\alpha^{20}D$ +1.98°; c = 1.61, H_2O; tube 1 dm.) and the yield determined by titration according to the method of Willstätter and Schudel was 1.53 g. = 95%. The yield of strontium salt was 71%; $[\alpha]^{20}D$ −56.4° ($\alpha^{20}D$ −1.36°; c = 2.41, H_2O; tube 1 dm.) for the anhydrous substance.

Anal. Calcd. for $C_5H_6O_6Sr$: C, 24.03; H, 2.40; Sr, 35.01. Found: C, 23.95; H, 2.55; Sr, 34.96.

Oxidation of Formic Acid.—A roughly 5% aqueous solution of formic acid was prepared and its exact amount of acid determined by titration; 10 cc. of this solution, containing 0.5253 g. of formic acid, was added to 25 cc. of glacial acetic acid and 6 g. of lead tetraacetate in an apparatus suitable for the quantitative determination of carbon dioxide. The mixture was shaken gently and kept at 35°, raising the temperature to 45° within the next half hour, after which time the reaction was completed. In three such experiments 0.4952 g., 0.4843 g., 0.4978 g. of CO_2 were found; yields were 98.8, 96.4 and 99.3%.

Summary

It has been shown that the oxidative cleavage of alpha- and beta-methyl-*l*-arabinopyranosides can be carried out quantitatively in aqueous solution with lead tetraacetate. Three moles of the oxidizing agent, instead of two, are required to complete this reaction. The reason for this excess consumption of reagent is that in aqueous solution the one mole of formic acid formed during the first reaction is oxidized by one mole of lead tetraacetate to one mole of carbon dioxide.[6]

Mechanism of the Reaction between Phthalic Anhydride and an Aminodiol[1]

BY MURRAY M. SPRUNG

Much attention has been devoted recently to the mechanism of polycondensation reactions.[2] Aside from the interesting theoretical deductions to which this work has led, the important practical result is that it is now usually possible to predict whether a condensation reaction will lead to the formation of low molecular weight substances, linear polymers or cross-linked types of resins. The last named are formed, in general, when the initial reactants have higher combined functionalities than 2:2.[2b]

Esterification and amidation reactions conform to these general schemes. Bi-bi-functional esterifications lead to cyclic monomers when rings of five or six members can result; otherwise linear polymers usually are formed. Bi-tri-functional esterifications practically always lead to net-like, cross-linked polymers. As for amidations, Carothers and Berchet[3] found that five and six ring monomers are formed exclusively, that a seven ring monomer and the corresponding linear polymer appeared simultaneously, and that reactions which might lead to cyclic monomers having eight or more ring atoms led, instead, exclusively to polymers.

Hydroxy amines would be expected to react with dibasic acids in accord with these now well-established principles. An amino-alcohol should give a linear polymeric ester-amide; whereas an aminodiol should give a product having a three dimensional, network structure analogous to that of glyceryl phthalate. This product, furthermore, should show the property of passing suddenly through the sol–gel transformation at a definite, critical stage in the polycondensation reaction.

Preliminary Results.—The reactions of 2-amino-2-methyl-1-propanol with adipic acid, and of 2-amino-2-methyl-1,3-propanediol with succinic, maleic, adipic and sebacic acids gave the results anticipated on the basis of these considerations. In the first case, the product was a thermoplastic resin and apparently a linear polymer. In the latter cases, cross-linked resins were formed which were converted to insoluble, infusible materials when the combined esterification and amidation

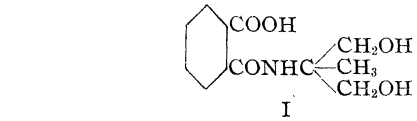
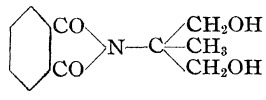
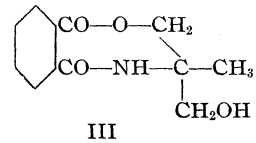
reactions had proceeded to the extent of about 65–75% of that theoretically possible. However, when the aminodiol was caused to react with phthalic acid (or its anhydride), it was found possible to carry the reaction to completion (*i. e.*, to collect 100% of the theoretically available water of reaction) without observing the formation of a gel structure. The product obtained under these conditions was a colophony-like, brittle, amorphous solid, which appeared to be a mixture of several ingredients. In order to obtain an explanation of this rather unexpected result, attempts were made to break down the reaction into distinct stages and to isolate the low molecular weight intermediates involved.



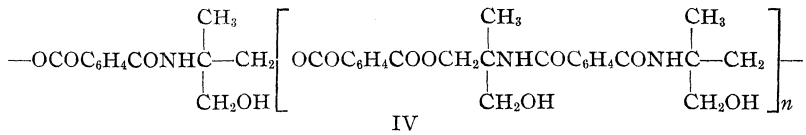
I



II



III



IV

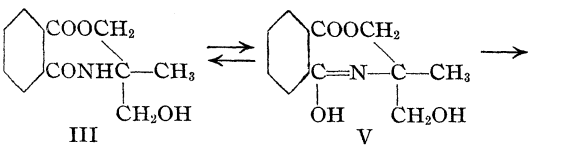
First Stage: Opening of the Anhydride Ring.—Phthalic anhydride and 2-amino-2-methyl-1,3-propanediol, heated to a temperature of 135–145° for two and one-half hours, gave a soft, stringy, sticky, resinous-appearing material which could not be purified by crystallization or solvent extraction (and which naturally could not be distilled without further reaction occurring). However, analysis of the crude reaction product for acidity, saponification equivalent, and hydroxyl indicated that it consisted mainly of the substituted phthalamic acid, namely, N-(1,1-dimethylol)-ethylphthalamic acid (I). The first step in the reaction therefore consists essentially in addition of the *amino group* of the aminodiol to the anhydride linkage of phthalic anhydride.

Second Stage: Ring Closure.—When the reactants were mixed in equimolar proportions and heated at 150–200° for two hours, almost exactly one mole of water was collected. The product was very similar in appearance to that described above, and could not be separated into crystalline fractions by solvent treatment. However, in this case over 50% of the crude reaction product was distillable. The main portion of the distillate consisted of a sluggish, pale yellow liquid boiling at 207–220° at 6 mm., and at 172–177° at about 50 microns. The undistillable portion was a dark colored, hard, brittle, fusible and soluble resin.

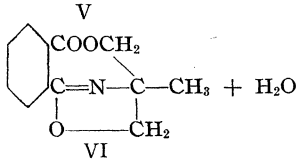
A priori, three substances might be formed under these conditions: the dimethylol phthalimide (II), the cyclic ester-amide (III), or a linear polymeric structure of which (IV) represents one possibility.

Analyses of the main fraction of the distillate gave results reasonably well in accord with those demanded by structures (II) or (III). However, the hydroxyl analyses (using the acetic anhydride–pyridine method) failed to give consistent results, indicating structure (II) in some cases, and something intermediate between (II) and (III) in others. This main fraction, when exhaustively purified by crystallization, gave a well-defined solid, analyzing as expected for $C_{12}H_{13}NO_4$. The formation of a *dibenzoyl derivative* (with benzoyl chloride in pyridine) favors the dimethylol phthalimide structure (II), but leaves unanswered the question as to why the pyridine–acetic anhydride method does not give results consonant with this structure.

Third Stage: Effect of Excess Phthalic Anhydride.—The colophony-like resin obtained when the reactants were used in the ratio 3 phthalic:2 aminodiol, was subjected to vacuum distillation. Over 50% of it distilled over as a thick, viscous, pale reddish liquid. Redistillation under very low pressure yielded two crystalline fractions which, on further purification, gave colorless solids of the composition $C_{12}H_{11}NO_3$ and $C_{19}H_{17}NO_5$, respectively. The latter substance has not been identified as yet. The substance $C_{12}H_{11}NO_3$ is obviously a dehydration product of the substance $C_{12}H_{13}NO_4$. The only reasonable structure which can be assigned to it is one that could result from



III V



VI

the ester amide (III), by enolization to the isoamide (V) and subsequent dehydration to an oxazoline derivative (VI).

On the other hand, it is difficult to see how a substance of the composition $C_{12}H_{11}NO_3$ could be formed from the dimethylol phthalimide structure (II). The structure (VI) represents the very rare case of a five, a six and an eight ring, fused conjointly.[4]

Attempts to reduce the compound $C_{12}H_{11}NO_3$ to a derivative of phthalaldehydic acid ethylene imino acetal failed. Nevertheless, the presence of a basic nitrogen atom was established by the formation of a picrate (m. p. 146–147°). In absolute alcoholic solution an abnormal picrate (m. p. 225–226°, composed of two moles of the "oxazoline" and one of picric acid) was obtained, even in the presence of excess picric acid. This peculiar observation has no obvious explanation.

It is now possible to interpret the observations made during acylation of the compound $C_{12}H_{13}NO_4$. This substance probably has the 8 ring ester-amide structure (III), but is capable of forming a diacyl derivative of the isoamide form (V). Acetic anhydride (in pyridine) does not acylate the "enol" hydroxyl completely, thus giving analytical results between those expected for the normal and iso structures. On the other hand, benzoyl chloride, a more vigorous acylating agent, forces the enol hydroxyl to react completely.

The oxazoline (VI) might be formed from the esteramide (III) during distillation. However, there was no evidence of its presence in the distillate from the 1:1 reaction product. When, however, this product was heated to 200° with an equivalent amount of phthalic anhydride (but without allowing water to distil out), it was possible to isolate the "oxazoline," by means of solvent extraction and fractional crystallization, and without distillation.

Review of Pertinent Literature

The mechanism outlined above is amply supported by existing literature. A substance very closely related to the structure (III) was obtained as early as 1905 by Gabriel[5] by treating N-β-bromoethyl phthalimide with dilute aqueous potassium hydroxide. The corresponding eight-ring thioamide was formed when N-β-thioethyl phthalamic acid was treated with concentrated hydrobromic acid,[6] and a homologous substance was similarly obtained from N-β-methyl-β-carbethoxythiophthalimide by Mylius.[7] Richard Meyer as early as 1903[8] prepared cyclic diamides having 7, 8 and 14 ring atoms by condensing *o*-phenylenediamines with malonic, succinic, isosuccinic, adipic and phthalic acids, their anhydrides or esters. Very little attention seems to have been devoted to these interesting results of Meyer, or to the equally significant observations of Gabriel and co-workers.[5,6,7]

The assumption that the ester-amide reacts in the isoamide form is also in accord with previous observations. Hantzsch has demonstrated,[9] on the basis of spectroscopic measurements, that trichloroacetamide and benzamide exist in solution largely in the isoamide form. Further, it has long been known that N-β-bromoethyl benzamides are converted to 2-aryloxazolines by boiling with hot water or dilute alkali.[10] Closely related to the present case are the formation of 2-phenylbenzoxazoline by heating *o*-benzaminophenol above its melting point[11]; of *o*-benzoylphenylurethan from urethan, benzoyl chloride and sodium[12]; and of phenylalkyloxazolones from benzoylglycine and its homologs.[13] Similarly, intramolecular acylations, leading to the formation of benzoxazones, occur when anthranilic acid or its derivatives are treated with dehydrating agents such as acetic anhydride.[14]

Conclusions

The mechanism of the reaction of 2-amino-2-methyl-1,3-propanediol on phthalic anhydride is accordingly believed to involve the following steps (1) opening of the anhydride ring to give a dimethylol phthalamic acid; (2) intramolecular esterification to give an 8 ring esteramide; (3) dehydration, through the isoamide form of the esteramide, to yield an oxazoline; (4) simultaneous occurrence of intermolecular condensation reac-

(4) The only analogous structure known to the writer is that of an oxy-lactam recently reported as formed from a diketo cholanic acid monoxime by reductive amidation (Barnett and Reichstein, *Helv. Chim. Acta*, **21**, 926 (1938)).

TABLE I

REACTIONS OF 2-AMINO-2-METHYL-1-PROPANOL AND 2-AMINO-2-METHYL-1,3-PROPANEDIOL WITH VARIOUS ACIDS (OR DERIVATIVES)

Reactants		Molar ratio	Time, hr.	Temp., °C.	Water formed, cc.			Nature of product
Amine component	Acid component				Obsd.	Calcd.	% of Calcd.	
Amino alcohol	Diethyl adipate	2/1	7	170–190	111[a]	110	99[b]	Thick sirup
Amino alcohol	Adipic acid	2/2	4	160–190	73	72	(100)	Thick balsam, thermoplastic
Amino diol	Adipic acid	1.1/1.5	2	125–195	42	54	77	Stiff balsam, thermosetting[c]
Amino diol	Adipic acid	1.1/1.5	4	154–195	46	54	85	Gelled resin
Amino diol	Sebacic acid	3.2/4.5	4	142–184	127	162	77	Stiff, hard balsam, thermosetting
Amino diol	Maleic anhyd.	1.1/1.5	1/4	110–160	4.5	27	66.5[d]	Gelled resin
Amino diol	Succinic anhyd.	1.1/1.5	1/4	.....	2.5	27	59.5[d]	Soft balsam, thermosetting[e]
Amino diol	Phthalic anhyd.	2.2/3.0	3	150–220	55	54	(100)[d]	Hard, brittle, amorphous, thermoplastic
1,1,1-Trimethylol propane[f]	Phthalic anhyd.	0.55/0.75	1 1/2	195–250	7.7	13.5	78.5	Gelled resin

[a] Alcohol. [b] On the basis of amine titrations, this reaction is virtually completely amidolysis, with only a small amount of alcoholysis. [c] Acid value, 152. [d] These calculations take into account the opening of the anhydride ring. [e] Acid number, 258. [f] Run for comparison with amino diol, since it has a similar structure.

tions, giving rise to the formation of resinous by-products of the soluble, fusible (non-cross-linked) type.

Experimental

General Procedure for Preparation of Resins.—The aminoalcohol or aminodiol and the appropriate acid or acid derivative were mixed in a three-necked flask fitted with a thermometer, stirrer and short column to which a condenser was attached. The mixture was heated by means of a free flame and maintained at such temperature that even distillation occurred. The course of the reaction was followed roughly by the volume of water (or alcohol) collected; and was checked qualitatively by the rapidity with which the sol–gel transformation was observed to occur when a small sample was spread on a metal surface at 200°. Table I summarizes these experiments.

First Stage of the Reaction between 2-Amino-2-methyl-1,3-propanediol and Phthalic Anhydride.—One mole each of the aminodiol (105 g.) and phthalic anhydride (148 g.) were heated in a 3-necked flask at a temperature of 135–145° for two and one-half hours, with stirring. Practically no water was formed. The acid value decreased from an initial value of 444 to a final value of 223 (calcd. 222), indicating that virtually complete addition to the anhydride linkage had been accomplished. The product was a soft, stringy, reddish resin, which became brittle at about −10°. Numerous attempts to purify this material by crystallization failed, as did attempts to obtain acyl derivatives. Acyl halides reversed the reaction by which it is formed, giving phthalic anhydride and the aminodiol as the sole recognizable products. The crude product, on analysis, gave results reasonably well in accord with those required by the dimethylol phthalamic acid (I).

Calcd. for $C_{12}H_{15}NO_5$: neutral equivalent, 253; saponification value, 0; hydroxyl equivalent, 126.5. Found: neutral equivalent, 251; saponification value, 24[15]; hydroxyl equivalent, 133.

Second Stage of the Reaction between 2-Amino-2-methyl-1,3-propanediol and Phthalic Anhydride.—One mole of phthalic anhydride (148 g.) and 1.1 mole of the aminodiol (115.5 g.) were heated and stirred for two hours at a temperature of 150–200° (thermometer in the liquid). Twenty cubic centimeters of water was collected (calcd., 18 cc.). The product was a sticky, thermoplastic, resinous-appearing substance. A sample was subjected to vacuum distillation. Around 50% of it distilled over as a sluggish, pale reddish liquid (b. p. 207–220° (6 mm.)) which solidified to a stiff balsam-like material.

Anal. Found: sap. equiv., 226, 232; hydroxyl equiv., 234, 218; N (Kjeldahl), 6.15. Calcd.: sapon. equiv., 235; hydroxyl equiv., 235 (structure III), 117.5 (structure II); N, 5.95.

A second sample was distilled under high vacuum. About fifty per cent. of it (boiling point, 172–178° at about 50 microns) was thus obtained as a pale yellow, sluggish liquid which slowly solidified on standing several weeks at room temperature. (A small amount of a higher boiling fraction (b. p. 200–220° at 0.3–0.7 mm.) was also obtained.)

Anal. Found: hydroxyl equiv., 143; N (Kjeldahl), 5.72; mol. wt. (camphor), 247. Calcd.: hydroxyl equiv., 235 or 117.5; N, 5.95, mol. wt., 235.

A sample was further purified by crystallization as follows: from benzene, from ethyl acetate and carbon tetrachloride, from carbon tetrachloride, from ethyl acetate and petroleum ether. Fine, silky, colorless needles were obtained; m. p. 90.5–91.0°.

Anal. Calcd. for $C_{12}H_{13}NO_4$: C, 61.25; H, 5.57; N, 5.95; mol. wt., 235. Found: C, 60.80, 61.50, 61.09, 60.98; H, 5.55, 5.84, 5.72, 5.68; N, 5.93, 6.26; mol. wt., 256, 247.

This compound did not form a picrate nor a nitroso derivative. A benzoyl derivative was formed (in good yield) with benzoyl chloride in pyridine. It melted at 121.5°, after crystallization, once from 95% alcohol and twice from benzene.

Anal. Calcd. for $C_{26}H_{21}O_6N$: C, 70.43; H, 4.74; N, 3.16; mol. wt., 443. Found: C, 70.59, 70.59; H, 4.88, 4.96; N, 3.36, 3.38; mol. wt., 461, 426.

Third Stage of the Reaction between 2-Amino-2-methyl-1,3-propanediol and Phthalic Anhydride.—The reaction

(15) Saponification value, calcd. for the alternate ester structure, i. e., mono-(β-methyl-β-amino-γ-hydroxy)-propyl phthalate, 223.

was carried out as indicated in Table I. A hard, brittle, amber-colored, easily friable, amorphous solid was obtained. The crude product was analyzed. *Anal.* Found: sapon. equiv., 200, 197; N (Kjeldahl), 4.98.

One hundred grams of this crude product, on vacuum distillation in a stream of nitrogen, gave *ca.* 50 g. of a hard, granular, semi-crystalline material, boiling at 195–205° at 2 mm. A portion of it was crystallized from ethyl acetate and then four times from ethylene chloride. A small amount of a colorless, micro-crystalline powder was thus obtained, having a sharp melting point of 165°. A second sample of the crude, colophony-like product was distilled at 2–6 mm. pressure (b. p. 140–219°, mainly 213–219°) and the main fraction redistilled under high vacuum. Three crystalline fractions were thus obtained: (1) b. p. 110–140° (0.07–0.10 mm.); (2) b. p., 145–160° (0.05 mm.); (3) b. p. 165–180° (0.05–0.2 mm.). Fraction (1) was crystallized four times from ethylene chloride. Beautiful, glistening crystals were obtained, melting at 160.5°. A microscopic examination showed large, nearly square, flat plates, some of them elongated to laths.

Anal. Calcd. for $C_{12}H_{11}NO_3$: C, 66.34; H, 5.11; N, 6.45; mol. wt., 217. Found: C, 66.14, 65.78; H, 5.10, 5.14; N, 6.39, 6.42; mol. wt., 235, 227.

The purified material gave a picrate, with 30% excess picric acid in absolute alcohol; melting point, 225–226° (decompn.). Analysis indicated that it contained two moles of the compound $C_{12}H_{11}NO_3$ combined with one of picric acid.

Anal. Calcd. for $2C_{12}H_{11}NO_3 \cdot C_6H_3N_3O_{10}$: N, 10.57. Found: N, 10.48, 10.55. The same substance was formed when picric acid was used in 100% excess. Found: N, 10.57, 10.34.

A little warm water was added to the filtrate from which the 2:1 picrate separated and the solution was again cooled. A second crystalline picrate was thus obtained which melted sharply at 146–147°, and analyzed for the 1:1 compound.

Anal. Calcd. for $C_{12}H_{11}NO_3 \cdot C_6H_3N_3O_{10}$: N, 12.54. Found: N, 12.45, 12.17.

An attempted reduction of the compound $C_{12}H_{11}NO_3$ with zinc and acetic acid failed. Treatment with sodium in absolute alcohol resulted in hydrolysis to 2-amino-2-methyl-1,3-propanediol and sodium phthalate (identified by analysis of the sodium salt, and conversion to phthalic acid, m. p. 187.5°; mixed m. p. 189°; positive fluorescein test).

Anal. Calcd. for $C_8H_4O_4Na_2 \cdot 2H_2O$: Na, 18.9. Found: Na, 19.1, 19.2.

The second fraction obtained on distillation was crystallized as follows: twice from ethyl acetate, once from ethylene chloride and once from benzene and ethyl acetate. Fine, dense, colorless, powdery crystals resulted; m. p. 165–165.2°; mixed m. p. with the compound $C_{12}H_{11}NO_3$, 160–160.5°. Under the microscope it appeared as small clusters of laths, arranged radially, having an extinction coefficient of 38° (sample a). A small amount was purified further by twice crystallizing it from absolute alcohol. The melting point was unchanged (sample b). *Anal.* Calcd. for $C_{19}H_{17}NO_5$: C, 67.32; H, 5.02; N, 4.13; mol. wt., 339. Found: (a) C, 66.90, 66.77; H, 5.33, 5.33; N, 4.20, 4.18; mol. wt., 280, 302. (b) C, 67.15, 67.09; H, 5.33, 5.25; N, 4.22, 4.14; mol. wt., 281, 294.

This substance does not form a picrate. Treatment with sodium and alcohol, followed by acidification, gave some phthalic acid and a small amount of a substance of m. p. 227–228° (decomp.) which has not been identified. Benzoic acid could not be detected, although the analytical composition points to this substance as a possible component of the compound.

Reaction of the Second Stage Product with Excess Phthalic Anhydride.—Forty-five grams of the 1:1 reaction product was heated in a long-necked flask with 50 g. of phthalic anhydride for twenty minutes at 170–200°. The resinous product which resulted was extracted successively with hot ethylene chloride and hot ethyl acetate, and each solution was shaken with sodium carbonate solution to remove phthalic acid and unreacted phthalic anhydride. The ethylene chloride solution was evaporated and treated with warm heptane. Five grams of a colorless powder was obtained which was crystallized several times from a mixture of ethylene chloride and carbon tetrachloride. The small amount of purified material obtained was identified as the oxazoline derivative, $C_{12}H_{11}NO_3$, by melting point and mixed melting point. From the ethyl acetate solution, a substance was obtained (by concentration and precipitation with heptane) which melted unsharply at 155–165° after crystallization from carbon tetrachloride, and which was not identical with any of the substances previously described.

Anal. Found: N, 3.70, 3.71.

This may possibly be a substance derived from two moles of phthalic anhydride and one mole of the aminodiol. Such a compound would have the composition $C_{20}H_{15}NO_6$ (calcd.: N, 3.83).

Summary

1. Succinic, maleic, adipic and sebacic acids react with 2-amino-2-methyl-1,3-propanediol to give "heat convertible" resins.

2. Phthalic anhydride, under the same conditions, gives a mixture of crystalline compounds and, as by-products, resins which are probably linear polymers.

3. This reaction has been shown to involve the following stages: (a) addition to form a dimethylol phthalamic acid (I); (b) intramolecular esterification to an 8-ring ester-amide (III); (c) dehydration, through the isoamide form, to give an oxazoline derivative (VI) which contains a five, a six and an eight ring fused together.

α-Alkylsulfonylamides[1]

BY AUSTIN POMERANTZ[2] AND RALPH CONNOR

In the previous study[3] of α-sulfonylamides the most effective hypnotic was α-*n*-butylsulfonyl-*n*-butyramide. Since this was the only purely aliphatic derivative investigated, the synthesis of a series of α-alkylsulfonylamides was undertaken. From the results described in the preceding paper[4] it seemed advisable to avoid the alkylation reaction previously employed and attention was therefore directed toward the reaction of mercaptides with α-bromoamides, followed by oxidation.

$$RSNa + R'_2CBrCONH_2 \longrightarrow RSCR'_2CONH_2 \xrightarrow{H_2O_2} RSO_2CR'_2CONH_2$$

$$R' = -H \text{ or } -C_nH_{2n+1}$$

Using conditions somewhat similar to those previously described,[3] the reactions of ethyl, *n*-propyl and *n*-butyl mercaptans with chloroacetamide, α-bromopropionamide, α-bromo-*n*-butyramide, α-bromoisobutyramide, α-bromo-*n*-valeramide, α-bromoisovaleramide and α-bromo-*n*-caproamide were carried out and the α-(alkylthio)-amides oxidized to the corresponding α-alkylsulfonylamides.[5] This synthesis proved to be satisfactory; the results are given in the experimental part. The sulfides were readily purified by crystallization but in several cases developed a slight odor of mercaptan on long standing. The oxidations were generally satisfactory but in a few cases the sulfones were rather difficult to purify.

The method of synthesis makes the structures of the products fairly certain. Furthermore, α-*n*-butylsulfonyl-*n*-butyramide and α-*n*-butylsulfonyl-*n*-caproamide were identical with the compounds previously prepared by the alkylation method.[4] The only reactions about which there seemed to be any uncertainty were those of α-bromoisobutyramide. Considering the behavior of the corresponding ester with the sodium derivatives of active methylene compounds,[6] it seemed possible that a mercaptide might cause the elimination of hydrogen bromide from α-bromoisobutyramide with the formation of α-methylacrylamide; addition of mercaptan to the conjugated system would give a β-(alkylthio)-amide isomeric with the desired product. However, β-(*n*-butylthio)-isobutyramide was prepared by the reaction of *n*-butyl mercaptan with α-methylacrylamide.[7]

$$n\text{-}C_4H_9SH + CH_2{=}C(CH_3)CONH_2 \xrightarrow{\text{piperidine}} n\text{-}C_4H_9SCH_2CH(CH_3)CONH_2$$

The product differed from that obtained by metathesis; this establishes the fact that the α-bromoamides react normally with mercaptides to give α-alkylthio derivatives.

Experimental Part

Melting points are uncorrected unless otherwise specified. The acids and mercaptans were products of the Eastman Kodak Company. The ligroin used was the fraction boiling at 70–90°. Pure α-bromopropionamide was obtained in 70% yields from methyl α-bromopropionate[8] but the ethyl ester gave unsatisfactory results. Some of the other α-bromoamides were prepared from the α-bromo acid chlorides by the method of Bischoff.[9] The most satisfactory general method was the bromination of the fatty acids and isolation of the pure α-bromo acids by the method described for α-bromo-*n*-caproic acid.[10] The α-bromo acid chlorides were prepared by the method described for *n*-butyryl chloride[11] and were satisfactory for use without distillation. They were converted to the amides by the use of ammonium hydroxide as described below. All but two of the α-bromoamides had been prepared previously.[9]

α-Bromoamides.—The middle neck of a 1-liter, three-necked, round-bottomed flask was fitted with a mechanical stirrer and gas outlet tube. A gas inlet tube long enough to extend below the surface of the reaction mixture and a dropping funnel were inserted in the other necks. The flask was immersed in an ice–salt-bath, 235 ml. of concentrated ammonium hydroxide added and ammonia gas bubbled into the cold solution over a period of about one hour. The crude acid chloride from one mole of α-bromo acid was then added dropwise over a period of about three hours. During this time the temperature of the ammoniacal solution was maintained at about 0° and ammonia gas passed into the mixture continuously. The in-

[a] Nitrogen analyses were made by the semi-micro Kjeldahl method. The values reported are the average of two determinations which did not differ more than 0.07% from the mean. [b] Sulfur analyses were made by the macro Parr bomb procedure. [c] This compound is included because the melting point had previously been reported[14] as 44°. The values for α-(n-propylthio)-acetamide and α-(n-butylthio)-acetamide agreed with those previously observed.[3,15]

soluble product was separated by filtration, washed with a small amount of cold water, dried and recrystallized from benzene or a mixture of benzene and ligroin. The yield of recrystallized material was 50–70% based on the α-bromo acid.

α-Bromo-n-valeramide.—The purified material melted at 78.5–79° (corr.).

Anal. Calcd. for $C_5H_{10}ONBr$: N, 7.78. Found: N, 7.77, 7.87.

α-Bromo-n-caproamide.—The purified material melted at 58.5–59° (corr.).

Anal. Calcd. for $C_6H_{12}ONBr$: N, 7.22. Found: N, 7.27, 7.28.

α-(Alkylthio)-amides.—To a sodium ethoxide solution prepared by dissolving sodium in absolute alcohol (approximately 50 ml. of alcohol per 0.1 gram atom of sodium) was added an equivalent amount of the mercaptan. The mixture was cooled in an ice–salt-bath[12] to 0° and the α-haloamide added in portions with shaking. The mixture was kept in the ice-bath during the mixing, since the reaction was noticeably exothermic. The mixture was shaken frequently and allowed to come to room temperature as the bath melted. After standing at room temperature for two to five days the reactions were complete, except those involving α-bromoisobutyramide; in these cases the reactions were carried out for two weeks at room temperature. The insolubility of the amide and the decreased reactivity of the tertiary halogen probably combined to retard the reaction of α-bromoisobutyramide.

After the reaction was complete most of the alcohol was removed from the mixture under reduced pressure. In most cases the amides were fairly insoluble in water and were isolated by pouring the distillation residue on chipped ice and collecting the solid product on a filter. The aqueous filtrates contained small amounts of the α-(alkylthio)-amides which were readily removed by ether extraction. The solvent was removed on the steam-bath, the residues dissolved in hot dilute alcohol, decolorized with charcoal and crystallized by the addition of more water. The amount of material so obtained was usually small, especially with the higher homologs.

The α-(alkylthio)-acetamides and α-(ethylthio)-propionamide were too soluble in water to be isolated in good yields by the above method. In these cases the residues remaining after the removal of the solvent were diluted with water (one to two times the original volume of the reaction mixtures) and extracted with four 100-ml. portions of ether. The extracts were dried over sodium sulfate and the ether removed on the steam-bath. The residues were oils but were readily crystallized from ligroin; in a few cases a little benzene was added to increase the solubility. The properties and analyses of the products are given in Table I.

Using 0.15 to 0.30 mole of reactants, the amount of α-(alkylthio)-amides averaged 88%. α-(Ethylthio)-propionamide (64% yield) was the only product obtained in less than 80% yield.

β-(n-Butylthio)-isobutyramide.[13]—A mixture of 14.0 ml. (11.7 g., 0.13 mole) of n-butyl mercaptan, 11.1 g. (0.13 mole) of α-methylacrylamide[7] (m. p. 107.5–110°) and 0.5 ml. of piperidine in 50 ml. of absolute alcohol was

[a] Unless otherwise noted, the sulfones were recrystallized from water. The properties of α-n-butylsulfonylacetamide, α-n-butylsulfonyl-n-butyramide and α-n-butylsulfonyl-n-caproamide agreed with those previously reported.[3,4] [b] See Table I, footnotes [a] and [b]. [c] Recrystallized from alcohol. [d] Recrystallized from benzene–alcohol. [e] Recrystallized from benzene–methanol. [f] Recrystallized from benzene–ligroin. [g] Recrystallized from dilute alcohol. [h] See the remarks about the impure nature of this compound in the discussion of the preparation of α-alkylsulfonylamides.

heated on the steam-bath for six and one-half hours. Most of the alcohol was then removed by distillation and the solution poured on chipped ice. The crude material weighed 12.3 g. (54%), m. p. 52–53°. Recrystallization from ligroin gave a pure product, m. p. 54.5–55° (corr.).

Anal. Calcd. for $C_8H_{17}ONS$: N, 7.99; S, 18.29. Found: N, 8.01, 8.09; S, 18.35.

α-Alkylsulfonylamides.—The sulfide was dissolved in a mixture of equal parts by volume of glacial acetic acid and acetic anhydride, using about 100 ml. of this solvent per 0.1 mole of sulfide. The solution was cooled in an ice–salt-bath and maintained at approximately 0° while 30% hydrogen peroxide was added slowly. Approximately 27 ml. of peroxide (30–35% excess) was used per 0.1 mole of sulfide. The mixture was allowed to come slowly to room temperature as the ice-bath melted and to stand at room temperature for at least three days. A small amount of manganese dioxide was added carefully to decompose the excess peroxide, the solution transferred to a Claisen flask and the solvent entirely removed under a pressure of not more than 30 mm. The solid residue was dissolved in a proper solvent, in most cases water, decolorized with charcoal and allowed to crystallize. In many cases a pure product was obtained from the first crystallization but the caproamides and α-n-ethylsulfonyl-n-valeramide were difficult to purify and required several recrystallizations. The oxidation of α-(n-propylthio)-isobutyramide was quite unsatisfactory (28%) and its abnormality verified by check runs. In this case the product gave a cloudy melt, the analytical data were unsatisfactory and numerous recrystallizations from benzene–ligroin and from acetone (using dry-ice) did not improve the product. The yields of α-alkylsulfonylamides averaged 72%, using 0.1 to 0.2 mole of sulfide. The products are described in Table II.

Summary

The reactions of the sodium mercaptides from ethyl, n-propyl and n-butyl mercaptans with seven α-haloamides have been carried out and the twenty-one α-(alkylthio)-amides oxidized to the corresponding sulfones, which are under examination as hypnotics. The metathesis reaction of the α-bromoamides was shown to be normal by the synthesis of the β-isomer from the reaction of n-butyl mercaptan with α-methylacrylamide. The preparation of α-bromoamides, including two not previously reported, has been described.

The Preparation of Sulfamic Acid by the Hydroxylamine–Sulfur Dioxide Reaction

BY H. H. SISLER AND L. F. AUDRIETH

The reaction of hydroxylamine with sulfur dioxide (or sulfurous acid) is one of the few reactions in which the hydroxylamine molecule plays the role of an augmenting agent,[1] for in this reaction the sulfur dioxide is nitridized to sulfamic acid.

(a) $NH_2OH + SO_2 \longrightarrow NH_2SO_3H$

It is not surprising, however, that hydroxylamine should behave in this manner in certain of its reactions, for it is an aquo ammono analog of hydrogen peroxide,[2] just as the sulfamic acid which is formed is an aquo ammono sulfuric acid.

In addition to its interest from a theoretical point of view, the nitridation of sulfur dioxide by hydroxylamine salts represents one of the best known laboratory methods for the preparation of sulfamic acid.[3] An analogous reaction of acetoxime with aqueous solutions of sulfur dioxide also has been recorded.[4] It is interesting to note

(b) $(CH_3)_2C{=}NOH + H_2O + SO_2 \longrightarrow (CH_3)_2C{=}O + NH_2SO_3H$

that normal sulfites do not react with hydroxylamine derivatives in this way.[5]

Hitherto, these nitridation reactions always have been carried out either by saturating an aqueous solution of the hydroxylamine derivative with sulfur dioxide and allowing it to stand in the cold for an extended period of time, or by bubbling sulfur dioxide through the solution for about forty-eight hours. These procedures have two disadvantages: (1) low yields are obtained, and (2) a relatively long period of time is required to carry out such preparations.

A study of the hydroxylamine–sulfur dioxide reaction was undertaken primarily in an effort to obtain experimental facts which would permit an elucidation of the mechanism of the reaction. The procedure for preparation also was improved and modified by carrying out the reaction under pressure. The experimental portion of this paper deals with the effects of such variables as the concentrations of the hydroxylamine salt, and of hydronium ion, and time upon the yield of sulfamic acid. The reaction between acetoxime, as an example of a hydroxylamine-yielding compound, and sulfur dioxide was also subjected to investigation.

Experimental

Reaction of Hydroxylamine Sulfate with Sulfur Dioxide.—An aqueous solution of hydroxylamine sulfate was cooled to approximately −80° in a dry-ice–acetone mixture. An excess of sulfur dioxide was then condensed in the container. The container was transferred to an autoclave and allowed to warm to room temperature. Under these conditions, the reaction mixture was subject to a pressure of 3.5–4 atmospheres, approximately equal to the vapor pressure of sulfur dioxide at room temperature. After a certain time interval, the pressure was released, and the excess sulfur dioxide allowed to escape. The sulfamic acid which had crystallized was removed by filtration, and the adhering liquid removed as completely as possible by suction on a Buchner funnel. The product was dried by washing with alcohol and ether, and was found to contain only a small trace of sulfate. To recover the sulfamic acid remaining in the solution, the filtrate was treated with concentrated sulfuric acid and cooled in an ice–salt mixture. In typical experiments such as are recorded in Table I, two factors were varied: (1) the reaction time, and (2) the concentration of hydroxylamine sulfate solution.

TABLE I

REACTION OF HYDROXYLAMINE SULFATE WITH SULFUR DIOXIDE UNDER PRESSURE

$(NH_3OH)_2 \cdot H_2SO_4$, g.	H_2O, g.	Concn., equivs. $(NH_2OH)_2 \cdot H_2SO_4$ per 1000 g. H_2O	Time, hr.	Temp., °C.	NH_2SO_3H obtained, g.	Yield, %
1 41	50	10.0	18.3	0	15.5	32
2 16.5	50	4.0	23	25	14	72
3 17	50	4.1	6	25	13	65
4 16.5	20	10.1	15	25	3	15
5 16.5	35	5.7	15	25	11	56
6 16.5	50	4.0	15	25	13	67

Examination of the data listed in Table I shows that the reaction of sulfur dioxide with highly concentrated solutions of hydroxylamine sulfate goes much more slowly than with more dilute solutions. It was thought that this phenomenon might be due to the high concentration of hydronium ions which would be built up under these circumstances as illustrated by the equation

(c) $NH_3OH^+ + SO_2 + 2H_2O \longrightarrow NH_2SO_3^- + 2H_3O^+$

This hypothesis was substantiated by means of the following experiments. A mixture of 16.8 g. of hydroxylamine sulfate, 25 g. of water, and 75 g. of 98% sulfuric acid was sealed in the autoclave with a large excess of sulfur dioxide and allowed to remain at room temperature for sixty-six

hours. No sulfamic acid was obtained. A similar result was obtained when a solution of 16.8 g. of hydroxylamine sulfate in 50 g. of 98% sulfuric acid and 50 ml. of water was treated with sulfur dioxide under pressure for forty-six hours. Sulfamic acid was obtained in both cases by subsequent neutralization and further treatment with sulfur dioxide.

Reaction of Acetoxime with Sulfur Dioxide.—A solution of 11 g. acetoxime in 10 ml. of water and 30 ml. of ethyl alcohol was saturated at 0° with sulfur dioxide gas, and was kept in a stoppered flask at that temperature for a total of three days. The solid sulfamic acid which formed was removed from time to time by filtration and more sulfur dioxide added as needed to keep the solution saturated. The product was washed with alcohol and ether, and dried in air. A total yield of 11.1 g. of sulfamic acid (corresponding to 76% of the theoretical yield) containing neither sulfate nor oxime was obtained.

In carrying out the reactions of acetoxime with sulfur dioxide under pressure at 0°, an aqueous solution of acetoxime in a glass pressure bottle was cooled to approximately −80° in a dry-ice–acetone mixture. An excess of sulfur dioxide was condensed on the frozen mass, and the bottle sealed. The temperature was allowed to come to 0°, and kept at that point by placing the bottle in an ice-bath. After a certain time had elapsed the bottle was again cooled, opened, and the excess sulfur dioxide allowed to escape. The sulfamic acid which had crystallized from the solution was removed by filtration, and dried by washing with alcohol and ether. The results of a number of typical experiments are listed in Table II. A similar series of experiments was carried out at approximately 25° (in an autoclave). The results of these experiments are also listed in Table II.

TABLE II

REACTION OF ACETOXIME WITH SULFUR DIOXIDE UNDER PRESSURE

10	10	25	11.75	12.0	90

Discussion

It is evident from the data in Table I that the yield of sulfamic acid from the reaction of hydroxylamine salts with sulfur dioxide is greatly increased and the time required for the reaction decreased by operating under pressure. This is also true of the acetoxime reaction. The results of these experiments also show that the reaction is inhibited by excessive concentrations of hydronium ions. This fact was demonstrated by the failure of hydroxylamine salts to nitridize sulfur dioxide in the presence of concentrated sulfuric acid, and is further supported by the data from experiments four, five and six in Table I, which show that much lower yields of sulfamic acid are obtained from concentrated solutions of hydroxylamine salts than from more dilute solutions. As may be seen from equation (c), two moles of hydronium ion are released for each mole of hydroxylamine sulfate that reacts. Hence, with concentrated solutions of hydroxylamine sulfate high concentrations of hydronium ions are quickly built up, inhibiting the reaction.

Examination of the data from experiments two, three and six in Table I indicates that the formation of sulfamic acid becomes much slower as the reaction proceeds. Thus, the yield after a six hour reaction time was only 7% less than that after a twenty-three hour period, other conditions being comparable in the two experiments. This effect may be attributed to the formation of hydronium ions as the reaction proceeds, and to the decrease in the amount of hydroxylamine sulfate present.

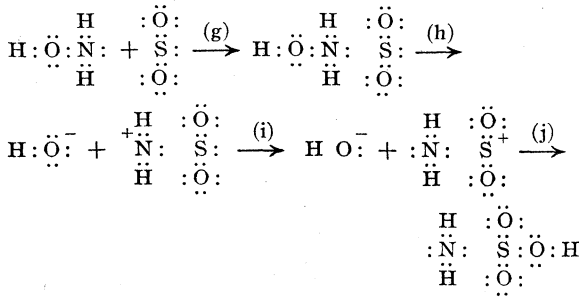
A comparison of the data presented in Table II with those given in Table I shows that much better yields of sulfamic acid are obtained in a shorter length of time by the reaction of sulfur dioxide with acetoxime than by the corresponding reaction with hydroxylamine sulfate. This is not an altogether unexpected result when considered in the light of the effect of high concentrations of hydronium ions on the reaction. As is shown in equation (b), sulfamic acid is the only product contributing hydronium ions in the acetoxime reaction, and the hydronium ion concentration which can be built up from this source is limited by the relatively low solubility of sulfamic acid. This would seem to explain why, under similar conditions, acetoxime gives 90% yields of sulfamic acid after five hours, whereas hydroxylamine sulfate gives only 72% yields after twenty-three hours.

The nitridation of sulfur dioxide to sulfamic acid by hydroxylamine may be explained by the mechanism

(d) $SO_2 + H_2O \underset{}{\overset{+H_2O}{\rightleftharpoons}} H_2SO_3 \overset{+H_2O}{\rightleftharpoons} H_3O^+ + HSO_3^- \overset{+H_2O}{\rightleftharpoons} 2H_3O^+ + SO_3^=$

(e) $:\ddot{O}::\ddot{S}:\ddot{O}: \rightleftharpoons :\ddot{O}:\ddot{S}:\ddot{O}: \rightleftharpoons :\ddot{O}:\ddot{S}::\ddot{O}:$

(f) $H:\ddot{N}:\ddot{O}:H^+ + H_2O \rightleftharpoons H_3O^+ + :\ddot{N}:\ddot{O}:H$ (H on N)



The sulfur dioxide molecule is generally assumed to exist in the resonance forms indicated in (e). The hydroxylammonium ion exists in equilibrium with the hydroxylamine molecule (f). The middle resonance form of the sulfur dioxide molecule, having only six electrons in the outer shell of the sulfur atom, may unite with the hydroxylamine molecule by accepting the free pair of electrons on the nitrogen atom (g). As in Whitmore's electronic mechanism for rearrangements of the Beckmann type,[6] the hydroxyl group may form an ionic bond leaving the nitrogen with a positive charge (h). However, since the nitrogen atom has a much greater affinity for the electron pair than does the sulfur atom, the free pair of electrons on the sulfur atom shifts immediately to the nitrogen atom (i). The negatively charged hydroxyl group can then unite with the positively charged sulfur atom, forming the sulfamic acid molecule (j).

It is probable that steps (h), (i), and (j) take place almost simultaneously. That is certainly the case with steps (h) and (i) due to the greater mobility of the electron pair than of the hydroxyl group. The fact that step (i) can take place probably makes possible step (h). The removal of the electron pair by the oxygen from the nitrogen atom in step (h) does not necessarily mean that the hydroxyl group ever exists as a free ion, but merely that it forms an ionic bond. In fact, it is likely that the hydroxyl group is never out of the sphere of influence of the rest of the molecule during the rearrangement.

This mechanism satisfactorily accounts for the fact that the reaction is inhibited by a large hydronium ion concentration, for the excess of hydronium ions should drive the equilibrium in (f) far to the left so that the free pair of electrons furnished by the nitrogen on the hydroxylamine molecule would be covered up by protons. It also explains why, in the presence of enough alkali to change all the sulfur dioxide, sulfurous acid, and bisulfite to normal sulfite, and to neutralize the acid attached to the hydroxylamine, no reaction takes place, for, as shown in (d), two moles of hydroxide ion would completely convert all the sulfur dioxide to normal sulfite, leaving no free sulfur dioxide to react with the hydroxylamine. Thus, an excess of acid renders the hydroxylamine incapable of coördination, while an excess of alkali makes the existence of sulfur dioxide or of sulfurous acid impossible.

(6) Whitmore, THIS JOURNAL, **54**, 3274 (1932).

Summary

1. The procedure for the preparation of sulfamic acid by the interaction of hydroxylamine salts and hydroxylamine-yielding compounds with sulfur dioxide has been improved by operation under pressure.

2. A mechanism for the reaction has been proposed involving coördination between the hydroxylamine molecule and sulfur dioxide with subsequent rearrangement to sulfamic acid.

The Action of Liquid Ammonia upon Sulfur Trioxide Addition Compounds

BY H. H. SISLER AND L. F. AUDRIETH

Theoretically, interaction of ammonia with sulfur trioxide should lead to ammonium sulfamate; actually, ammonium imidodisulfonate is obtained almost exclusively. However, when aqueous ammonia acts upon various sulfur trioxide–tertiary amine addition compounds[1] appreciable quantities of ammonium sulfamate are formed. In order to gain a clearer insight into the mechanism of these reactions, and also to prevent the simultaneous action of water (present in aqueous ammonia), the behavior of these sulfur trioxide addition compounds in liquid ammonia was investigated. The addition compounds studied were those with pyridine,[2] dimethylaniline,[3] dioxane,[4] hydrogen chloride (chlorosulfonic acid), and sodium chloride (sodium chlorosulfonate). The reaction products were analyzed for sulfamate, imidodisulfonate, and sulfate.

Recorded observations that ammonium imidodisulfonate is the sole product of the reaction of sulfur trioxide with liquid ammonia were verified.

Experimental

Method of Analysis.—The reaction products were analyzed by the following procedure. Sulfate and imidodisulfonate were precipitated as the respective barium salts by the addition of barium chloride to an ammoniacal, aqueous solution of the reaction product. The filtrate was next acidified with dilute hydrochloric acid, then treated with potassium nitrite solution for the purpose of converting the sulfamate ion into sulfate, which was then precipitated as barium sulfate.

$$NH_2SO_3^- + NO_2^- \longrightarrow N_2 + SO_4^= + H_2O$$

The joint precipitate of basic barium imidodisulfonate and barium sulfate was extracted with dilute hydrochloric acid, leaving the barium sulfate in the filtering crucible. The imidodisulfonate was estimated as barium sulfate after treatment of the acidified filtrate with nitrite and barium chloride. This procedure gives results which are fairly reproducible, but is not satisfactory for exact work due to the facts, (1) that the precipitate of basic barium imidodisulfonate is slightly soluble in water, and (2) that complete precipitation of sulfate as barium sulfate is difficult in the presence of large amounts of sulfamate ion.[5]

Experimental Results.—Pyridine–sulfur trioxide and dimethylaniline–sulfur trioxide were added directly to liquid ammonia at −33°. These reactions, while vigorous, could be controlled without difficulty. However, both dioxane–sulfur trioxide and liquid ammonia had to be precooled to the temperature of a solid carbon dioxide–ether bath to moderate the reaction. The chlorosulfonic acid was dissolved in a large excess of chloroform (20 g. in 140 ml. of $CHCl_3$) and then added slowly to liquid ammonia. Even under these conditions the reaction was found to be a very vigorous one, as was the reaction between sodium chlorosulfonate and ammonia. In every case, the excess of ammonia was allowed to evaporate and the residual product, after treatment to remove amine or solvent, was washed with ether and dried to constant weight. Samples were analyzed by the procedure given above.

Quantities of sulfur trioxide addition compounds used varied from 15 to 40 g. Large excesses of liquid ammonia (between 200 and 400 ml.) were used in all experiments. Typical experimental results are reproduced in Table I. The percentage composition of the reaction products, also the ratio of the percentages of ammonium sulfamate to triammonium imidodisulfonate, are given in each case.

	14.5	4.2	39.0	9.3

[a] NH_4Cl and NaCl, respectively, make up the rest of the reaction product.

Discussion

The reactions of ammonia with chlorosulfonic acid and sodium chlorosulfonate obviously are ammonolytic in character, involving replacement of a negative constituent by the amido group and leading to the formation of the sulfamate. The same mechanism also characterizes the reaction of ammonia with sulfur trioxide addition compounds. In fact, the tertiary amine complexes have been shown to be esters of N,N-disubstituted sulfamic acids, existing in the betaine form.[2]

If the three addition compounds of sulfur trioxide with pyridine, dimethylaniline, and dioxane are arranged in the order of the relative predominance of the sulfamate over the imidodisul-

fonate in their respective ammonolytic products, the following series is obtained

$C_5H_5N \cdot SO_3 > C_6H_5N(CH_3)_2 \cdot SO_3 > O(CH_2CH_2)_2O \cdot SO_3$

This is also the order of their decreasing stability toward water.[1,4] In view of the fact that imidodisulfonate only is formed when ammonia and sulfur trioxide react, it is logical to conclude that the presence of this product is due to the ammonation of sulfur trioxide held but loosely by the donor molecule. Consequently, the less stable the sulfur trioxide complex, that is, the weaker the coordinate bond holding the sulfur trioxide molecule, the greater will be the proportion of imidodisulfonate in the ammonolytic product.

Summary

Reactions of liquid ammonia with sulfur trioxide addition compounds result primarily in the formation of ammonium sulfamate. These reactions are considered to be ammonolytic in character.

The Photochemical Decomposition of Solid Hydrogen Compounds at Low Temperatures

BY L. FARKAS, Y. HIRSHBERG AND L. SANDLER

Very little has been known previously of the photochemical decomposition of solids at low temperatures.[1,2] It seemed, therefore, worth while to investigate reactions involving the liberation of hydrogen, since the ortho–para concentration of the hydrogen may reveal interesting features of the decomposition mechanism. It is well known that below 200°K. the ortho–para ratio of equilibrium hydrogen is dependent on the temperature and thus this ratio may indicate at which effective temperature the photochemical formation of the hydrogen has taken place.

In the following some experiments on the photochemical decomposition of hydrogen iodide, formaldehyde and methyl alcohol at temperatures between 65° and 85°K. are reported. All these substances give off hydrogen (besides other reaction products) when decomposed photochemically.[1,3,4]

Experimental

Hydrogen iodide was prepared in the usual way by catalytic combination of hydrogen with iodine and repeated fractional distillation at low temperatures.[5] It was kept in a glass bulb and was perfectly white in the solid state. Apiezon grease was used for the taps, which was only slowly attacked by hydrogen iodide.

The methyl alcohol was the purest obtainable product. As a source of formaldehyde, the vapor of 40% aqueous solution was used.

The experimental arrangement is shown in Fig. 1. The hydrogen iodide, formaldehyde or methyl alcohol was condensed on spot S of tube V, which contained liquid air. The glass tube was specially thin at S, in order to improve the heat exchange between the condensed substance and the liquid air. The amount of substance on S was adjusted by a lock system between the tap T and the storage bulb so as to form a white circle of about 5 mm. diameter and of about 10,000–100,000 molecular layers. A mercury arc served as a light source and the ultraviolet light entered through the quartz window Q opposite the spot S.

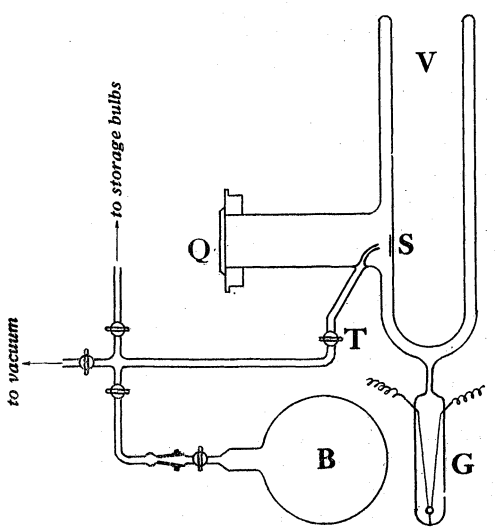

Fig. 1.

Occasionally the temperature of the tube was lowered to 65° K. by pumping off the liquid air. After the substance was condensed into the reaction vessel, the tap T was closed and the evolution of hydrogen during the illumination followed up by the Pirani gage (G). The illumination was continued until 30–40 cu. mm. of gas at S. T. P. was

evolved. The lamp was then switched off and the gas collected in a large bulb (B). The analysis of the ortho–para composition of the hydrogen was carried out by the micro-conductivity method.[6]

Experiments with Hydrogen Iodide.—During the illumination only a small amount of gas was given off by the hydrogen iodide crystals; the greater part of the photochemically formed hydrogen remained trapped in the solid. All the gas was given off immediately when the liquid air level in the tube V was lowered below the spot (S), as then the substance sublimed to the lower part of the tube.

TABLE I

No.	Time of illumination, min.	Temp., °K.	% p-H_2	Equilibration %
1	70	85	34.3	46
2	30	~70	38.6	~44
3	35	65	40.8	45
4	36	85	34.5	47
5	30	85	33.8	44
6	195	85	37.6	63
7	45	85	35.8	54

Experiments 1 and 4 (Table I) show that at 85°K. the evolved hydrogen contained 34% para-hydrogen corresponding to an ortho–para ratio in equilibrium at 115°K.[7]

In order to test the possibility of a secondary ortho–para conversion taking place after the illumination, normal hydrogen was introduced into the reaction vessel. It was found, however, that no conversion to para-hydrogen occurred in the presence of the hydrogen iodide crystals. When the hydrogen trapped inside the crystals was left in them for one hundred and fifty minutes at 85°K. after the illumination had been switched off (expt. 5), no change in the para-hydrogen concentration was observed, showing the absence of any secondary para–ortho conversion within the solid in the "dark." All these experiments show definitely that the formation of the para-hydrogen takes place during the illumination and the para–ortho concentration is in some way determined by the temperature of the solid hydrogen iodide.

By lowering the temperature of the liquid air to 70–65°K. (expt. 2 and expt. 3), para-hydrogen of higher concentration than in expts. 1 and 4 was obtained, the percentage of "equilibration," however, was the same as before. These experiments prove that the para-hydrogen is formed inside the solid during the illumination and not at the time when it is given off by the solid. The temperature at which the sublimation took place was the same in all experiments.

The simplest explanation for the fact that the apparent "equilibration" is not complete is that the actual temperature of the solid during the illumination is higher than that of the liquid air in the tube V. Experiments 6 and 7 show indeed that there is a marked increase in the para-hydrogen concentration of the evolved hydrogen if the amount of heat transferred from the outside or from the source to the illuminated substance is diminished. This was obtained (1) by reducing the light intensity of the mercury lamp through intensive cooling and through increasing the distance between reaction vessel and light source (in expt. 6), (2) by cutting off the infrared radiation by a water filter, (3) by shielding the reaction vessel with tin foil against temperature radiation from outside and (4) by removing continually the gas evolved during the illumination (in expt. 7). These experiments indicate that the para-hydrogen content of the gas formed during the decomposition corresponds nearly or completely to the temperature of the solid hydrogen iodide.

Experiments with Formaldehyde and Methyl Alcohol.—In the photochemical decomposition of formaldehyde hydrogen and carbon monoxide are formed.[3] There is also a possibility of carbon monoxide formation in the photolysis of methyl alcohol by secondary decomposition of the formaldehyde primarily formed.[4] The carbon monoxide was removed from the evolved gas by a cuprous chloride–ammonia solution.[8]

It was found that in all cases normal hydrogen was evolved (see Table II).

TABLE II

No.	Substance	Time of illumination, min.	Temp., °K.	% p-H_2
1	H_2CO	150	85	25
2	CH_3OH	110	85	25
3	CH_3OH	300	85	25
4	CH_3OH	300	75	25

Discussion of the Experiments with Hydrogen Iodide.—The photochemical decomposition of gaseous hydrogen iodide takes place according to the mechanism[1,9]

$$HI + h\nu \longrightarrow H + I \quad (1)$$
$$H + HI \longrightarrow H_2 + I \quad (2)$$
$$I + I \longrightarrow I_2 \quad (3)$$

The same decomposition takes place also in the liquid[10] and the solid state.[1]

The present experiments have shown that the para–ortho ratio of the hydrogen formed corresponds to the temperature of the solid.

There are two different processes which may bring about the equilibration of the photochemically formed hydrogen. One is the catalytic conversion of hydrogen under the influence of the inhomogeneous magnetic field of the iodine atom[11] and the other the reaction (2).

The iodine atom has a paramagnetic ground level $^2P_{3/2}$ and it was shown by Rosenbaum and Hogness[12] that the conversion of para-hydrogen in the reaction $H_2 + I_2 \rightleftarrows 2HI$ is caused by the

paramagnetic action of the iodine atoms present in thermodynamic equilibrium concentration.

A very rough calculation shows that an equilibration by the reaction

$$I + o\text{-}H_2 \rightleftarrows I + p\text{-}H_2 \qquad (4)$$

is only possible if the relevant conditions for the conversion in the solid are very favorable. The lower limit for the theoretical half-life time is given by

$$\tau_{theor.} = 0.69/W_{solid}Z_{solid}[I] \qquad (5)$$

(W_{solid} the transition probability $p \rightleftarrows o$ per collision, Z_{solid} the collision frequency between H_2 and I in the solid, [I] the stationary concentration of the iodine atoms), if for W_s, Z_s, [I] the upper limits are used.[13]

W_{solid} is, as a first approximation, equal to $W_{gas} = 4 \times 10^{-12}$. For the calculation of Z_{solid}, the approximation of Rabinowitch[14] is used according to which $Z_{solid} = Z_{coörd.}\ \nu$, $Z_{coörd.}$ denoting the number of coördinations of the pair $H_2 + I$ per second and ν the number of vibrations during a coördination. In this formula it is assumed that each vibration during the coördination is equivalent to a collision in the gas. The order of magnitude of Z is 3×10^{12} sec.$^{-1}$mole^{-1}l.[15]

The upper limit for [I] will be obtained by considering their production and recombination by diffusion. The time necessary for a particular iodine atom to diffuse the mean distance $\bar{x} = 1/[I]^{1/3}$ between two iodine atoms is given by the expression $t = \bar{x}^2/2D = 1/2D[I]^{2/3}$. Then the iodine atom under consideration will be somewhere on the surface of a sphere with a radius $\bar{x}$. It will collide with another iodine atom with the probability $\sim 4a_I^2/\bar{x}^2$ (coördination number = 8, $\pi a_I^2 = 10^{-15}$ cm.^{2} is the cross section of the iodine atom).

If n iodine atoms are formed per sec., and cm.^{3}, and $[I] = nt_0$, t_0 being the mean life time of an iodine atom, t_0 will be given by the expression

$$(nt_0)^{-2/3} = 8Dt_0a_I^2(nt_0)^{2/3}$$

Using the values $D = 10^{-11}$ cm.^{2} sec.$^{-1}$ and $n = 3 \times 10^{17}$ sec.$^{-1}$ cm.$^{-3}$ (calcd. from the rate of decomposition) one obtains $t_0 = 6$ min. and $[I] = 1.8 \times 10^{18}$ cm.$^{-3}$ $= 3 \times 10^{-3}$ mole/l. On the basis of these figures the half-life time in the solid is $\tau_{theor.} = 20$ min.

Since expts. 1, 3 and 4 have shown that the equilibration of hydrogen is (nearly) completed during the illumination, it is obvious that the half-life time of the conversion must be small compared with the time of illumination. Putting $\tau_{exptl.}$ at least one-sixth of the time of illumination, *i. e.*, 300 min., $\tau_{theor.}$ seems compatible with the experimental result. The margin between these figures, however, is not very large and owing to the nature of simplifications made in the calculation of $\tau_{theor.}$, the value obtained seems far too small. The authors believe that the conversion by the action of iodine atoms is not likely to be the decisive process for the equilibration.

The other possibility for the equilibration is reaction (2). In this reaction about 30,000 cal. are evolved. This circumstance makes it difficult to understand that in this process equilibrium hydrogen of low temperature should be formed, as the heat evolved in the reaction should raise the effective temperature of the particles concerned. Hydrogen corresponding to a low temperature equilibrium could only be formed if the heat of reaction is completely dissipated during the collision $H + HI_{solid}$ and is taken up by the whole hydrogen iodide lattice. Although at present we have no information of the energy exchange in this type of reaction, the present experiments seem to indicate that such dissipation of energy actually occurs.

Discussion of the Experiments with Formaldehyde and Methyl Alcohol.—The photochemical decomposition of formaldehyde takes place according to

$$HCHO + h\nu \longrightarrow CO + H_2 \qquad (6)[3]$$

Two different mechanisms have been suggested for the primary process involved in the photolysis of formaldehyde

$$H_2CO + h\nu \longrightarrow H_2 + CO \qquad (7)[3]$$
$$H_2CO + h\nu \longrightarrow 2H + CO \qquad (8)[16,17]$$

The photolysis of methyl alcohol takes place according to

$$CH_3OH + h\nu \longrightarrow CH_2O + H_2 \qquad (9)$$

and equations analogous to (7) and (8) can be considered as primary processes of this reaction.

If the hydrogen atoms formed in reaction (8) would react with another formaldehyde molecule according to

(13) In the following it is assumed that the hydrogen is dissolved in the solid in molecular form. If microscopic bubbles are formed inside the crystals, the rate of conversion would appear diminished.

(14) Rabinowitch, *Trans. Faraday Soc.*, **33**, 1225 (1937).

(15) According to L. Farkas and U. Garbatski [*Trans. Faraday Soc.*, **35**, 263 (1939)], the rate of conversion of para-hydrogen in presence of nitric oxide in aqueous solution is much slower than the rate corresponding to $Z_{liquid} = Z_{coörd.} \times \nu$.

(16) Norrish, *Nature*, **141**, 1138 (1938).

(17) Bergmann and Samuel, *ibid.*, **141**, 832 (1938).

$$H + H_2CO \longrightarrow H_2 + \dot{H}CO \qquad (10)$$

one might expect the formation of para-hydrogen as found in the decomposition of hydrogen iodide. Thus the absence of para-hydrogen formation can be regarded as excluding the step (10). Consequently the conclusion offers itself that, whichever the actual primary process may be, (7) or (8), the two atoms forming a hydrogen molecule must come from the same parent formaldehyde molecule. The state of affairs in the photolysis of methyl alcohol is exactly analogous.

As no detailed knowledge about the energy exchange during collisions in solids is yet available, one cannot decide between the primary reactions (7) and (8) on the basis of the present experiments. The suggestion that a dissipation of energy takes place at collisions within a solid, as proposed for the reaction $H + HI_{solid}$, would favor mechanism (7) according to which no such dissipation of energy can occur.

Summary

It is found that para-hydrogen is formed when irradiating solid hydrogen iodide at low temperatures. Two explanations are given and discussed: (a) the hydrogen primarily formed can be converted by the paramagnetic action of free iodine atoms; (b) the heat formed in the reaction $H + HI_{solid} = H_2 + I$ is dissipated in the solid. In the photolysis of formaldehyde and methyl alcohol under the same conditions normal hydrogen is formed. This seems to indicate that the two hydrogen atoms forming a molecule are coming from the same formaldehyde or methyl alcohol molecule.

The Catalytic Interaction of Acetylene and Hydrogen on Platinum

BY A. FARKAS AND L. FARKAS

In a series of communications the catalytic hydrogenation of ethylene,[1] benzene[2] and acetone[3] on platinum was investigated. In the first two examples, the hydrogenation consists of the addition of hydrogen to a double bond. In the case of acetone the reduction reaction can be envisaged as a similar type of process. In the present communication the hydrogenation of acetylene was investigated under similar conditions, this reaction being chosen as representative of hydrogen addition to triple bonds.

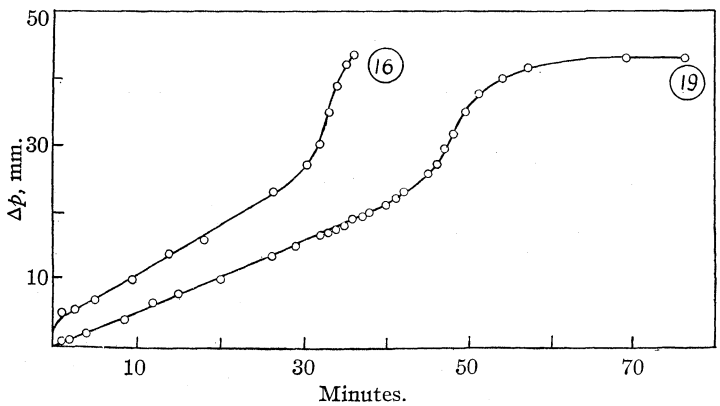

Fig. 1.—Hydrogenation of acetylene: expt. 16, 25 mm. C_2H_2 + 60 mm. H_2 at 101°; expt. 19, 21 mm. C_2H_2 + 49 mm. H_2 at 97°.

Experimental

The general experimental technique was similar to that previously described.[1] A platinized platinum foil (10 × 10 mm.) was used as the catalyst in a reaction vessel of 75 cc. volume. Hydrogen and acetylene were admitted to the reaction vessel through a U-tube kept at −80°. Acetylene was prepared from calcium carbide and purified according to the usual method.[4]

Dependence of the Hydrogenation on Pressure.—In some experiments, first acetylene was admitted to a given pressure and then condensed in a thin side-tube. Subsequently hydrogen was introduced and then acetylene quickly evaporated, the reaction time being calculated from this moment. The progress of the reaction under these conditions is shown in Fig. 1 (expt. 16). The reasons for the sudden drop in the pressure in the first half minute

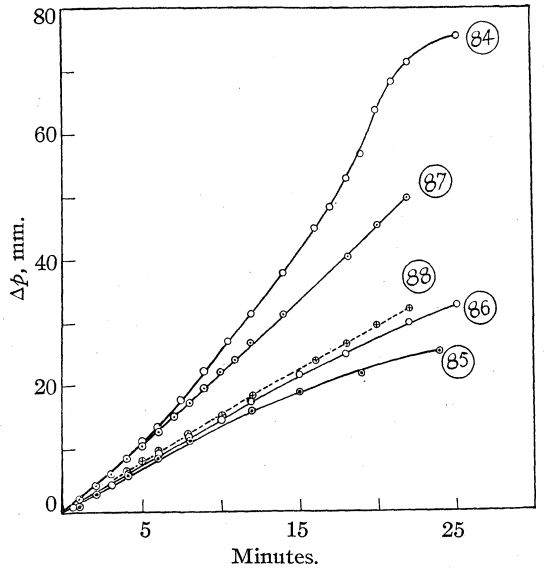

Fig. 2.—Hydrogenation of acetylene at 25°. Dependence on the hydrogen pressure: expt. 84, 40 mm. C_2H_2 + 114 mm. H_2; expt. 87, 39.5 mm. C_2H_2 + 94.5 mm. H_2; expt. 88, 41 mm. C_2H_2 + 92 mm. D_2; expt. 86, 40 mm. C_2H_2 + 70 mm. H_2; expt. 85, 40 mm. C_2H_2 + 51.5 mm. H_2.

were that the pressure of the acetylene was rather low at the beginning of the evaporation, and that the reaction is strongly inhibited by the acetylene. If, however, the hydrogen was added to the acetylene directly without the latter being condensed, as in expt. 19, Fig. 1, the initial pressure drop is absent and the pressure decreases regularly. The sudden pressure drop in the thirtieth and fortieth minutes, respectively, will be referred to below.

The dependence of the hydrogenation on the hydrogen pressure is given in Fig. 2, and that of the acetylene pressure in Fig. 3. These results show that with increasing pressure of acetylene the rate of hydrogenation decreases, while it increases with the hydrogen pressure. The inhibition of the hydrogenation by acetylene is similar to, but more pronounced than, the inhibition of the hydrogenation of ethylene by ethylene.

In the course of the hydrogenation it has been observed repeatedly that at a certain stage the rate of hydrogenation increases rapidly. Examples of this behavior were given in Figs. 1, 2 and 3, expts. 16, 19, 84, 79 and 82. The rate of the hydrogenation in expts. 79 and 84, and in expts. 21 and 22 in which the catalyst was somewhat less active, is shown in dependence of time in Fig. 4. This acceleration is due to two causes: first, the reaction rate increases on account of the acetylene pressure being reduced, and, second, the hydrogenation of the ethylene, which occurs in the second half of the reaction, is much faster than the formation of ethylene. The moment when all acetylene is used up is marked by an arrow in Fig. 4. It will be noted that the sudden increase in the rate of hydrogenation coincides with this moment.

Para-conversion and Hydrogenation.—In order to gain some information on the relative adsorbabilities of hydrogen and acetylene, the rate of hydrogenation and the rate of the para-hydrogen conversion were measured simultaneously. It is interesting to note that from a few experiments with para-hydrogen the same conclusions could be drawn with regard to the composition of the adsorption layer as from the whole series of experiments in which the pressure of the reactants was varied systematically.

The rate of the para-hydrogen conversion in the

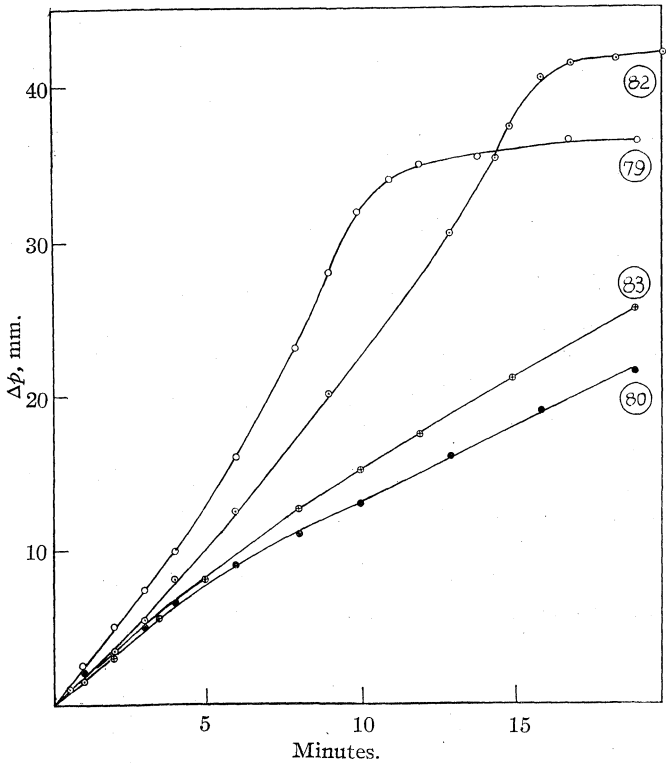

Fig. 3.—Hydrogenation of acetylene at 24°, dependence on the acetylene pressure. Expt. 79, 17.5 mm. C_2H_2 + 72.5 mm. H_2; expt. 82, 23.5 mm. C_2H_2 + 72.5 mm. H_2; expt. 83, 56 mm. C_2H_2 + 72 mm. H_2; expt. 80, 76 mm. C_2H_2 + 71 mm. H_2.

TABLE I

No.	°C.	Reaction mixture	Rate of conversion, mm./min.	Rate of hydrogenation, mm./min.	Ratio $\frac{\text{Conversion}}{\text{Hydrogenation}}$
54	20	74 mm. p-H_2	18.5	..	..
52	20	76 mm. p-H_2 + 19 mm. C_2H_4	6.7	0.83	8.1
53	20	73 mm. p-H_2 + 19 mm. C_2H_2	1.15	.21	5.5
9	22	27 mm. p-H_2 + 36 mm. C_2H_2	0.24	.084	2.8
27	88	27.5 mm. p-H_2 + 16.5 mm. C_2H_2	.089	.0065	7.3
33	20	88 mm. p-H_2 + 17 mm. C_2H_2	1.18	.22	5.4

absence and presenc e of acetylene or ethylene is shown in Fig. 5. As will be recognized from this figure, by the addition of 19 mm. of acetylene to 73 mm. of para-hydrogen, the rate of conversion was reduced by a factor of 15, whereas the same amount of ethylene reduced the rate of para-conversion only by a factor 3. These results show that acetylene replaces the hydrogen to a great extent in the adsorption layer and is much more strongly adsorbed than ethylene.

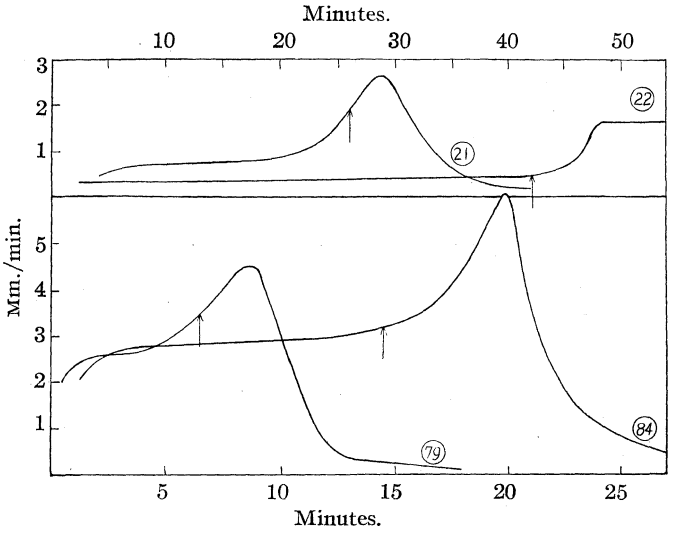

Fig. 4.—Rate of hydrogenation of acetylene—Expt. 21, 18 mm. C_2H_2 + 102 mm. H_2 at 89°; expt. 22, 15 mm. C_2H_2 + 55 mm. H_2 at 92°; expt. 79, 17.5 mm. C_2H_2 + 72.5 mm. H_2 at 24°; expt. 84, 40 mm. C_2H_2 + 114 mm. H_2 at 25°.

The rates of the conversion and hydrogenation reactions and their ratio are given in Table I for catalysts in different states of activity.

The dependence of the hydrogenation on temperature could not be determined with great accuracy on account of a gradual deactivation of the catalyst, especially at higher temperatures. In Table II the first group of figures refers to the catalyst in a more active state, and the second group to a less active catalyst.

TABLE II

No.	°C.	C_2H_2, mm.	H_2, mm.	Rate, mm./min.
55	15	30	72	0.29
58	47	31	78	2.0
57	57	31	76	3.9
64	72	30.5	78.5	0.13
63	98	30.5	78.5	.68
65	147	30.0	79.0	15.0

From these results an energy of activation of 12–17 kcal. can be calculated for the hydrogenation of acetylene. These figures are somewhat higher than the energy of activation for the hydrogenation of ethylene, which was found to be between 7 and 10 kcal. on the same catalyst and in the same temperature range.

Hydrogenation with Deuterium.—In Fig. 2, expts. 87 and 88 show the comparison of two hydrogenation experiments performed by hydrogen and deuterium. It will be recognized that the rate of hydrogenation by deuterium is about 1.5 smaller than that by hydrogen.

In hydrogenation experiments with deuterium the progress of the exchange reaction

$$C_2H_2 + HD \rightleftarrows C_2HD + H_2$$

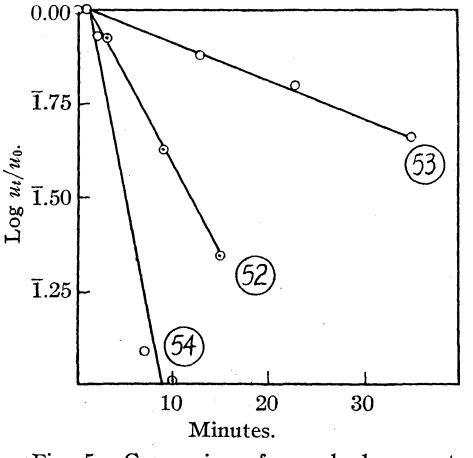

Fig. 5.—Conversion of para-hydrogen at 20°. u_0 and u_t denote the excess concentration of parahydrogen relative to normal hydrogen at the time $t = 0$ and t. Expt. 54, 74 mm. p-H_2; expt. 52, 76 mm. p-H_2 + 19 mm. C_2H_4; expt. 53, 73 mm. p-H_2 + 19 mm. C_2H_2.

also was investigated and compared with the exchange of ethylene. The results indicate that the exchange of acetylene is very much slower than that of ethylene. For example (expts. 24 and 25), at 90° the D-content of 88 mm. of deuterium (initial D-content 99%) in a mixture with 38 mm. of acetylene decreased only by 1%, while all of the acetylene was hydrogenated to ethylene. On the other hand, in a mixture of 47 mm. of ethylene and 62 mm. of deuterium the D-content decreased by 34% when the hydrogenation was completed. Qualitatively the same results were obtained when the exchanges of acetylene and ethylene were compared in the same run. In these experiments a relatively rapid exchange was observed as soon as most of the acetylene was converted into ethylene.

Discussion

The most striking feature of the hydrogenation of acetylene is the fact that the addition of two molecules of hydrogen occurs in two distinct steps. The acetylene is first converted to ethylene and the ethylene is only reduced further to ethane after all (or nearly all) of the hydrogen has been used up. This phenomenon, which is usually referred to as "selective hydrogenation" in organic chemistry, becomes manifest through the sudden change in the rate of hydrogenation as soon as all acetylene is used up.

The explanation for the selective hydrogenation is quite clear and already has been given.[5] It is due to the different absorbabilities of acetylene and of ethylene, but not to different rates of hydrogenation, though in the present case its occurrence can be ascertained kinetically by the sudden change of the reaction rate.

The strong adsorption of acetylene offers a ready explanation for the dependence of the rate of hydrogenation on the acetylene and hydrogen pressures also.

It is suggested that in the catalytic hydrogenation of ethylene the activation consists essentially of the dissociation of hydrogen.[1] This implies that the addition of hydrogen atoms to ethylene occurs with very little energy of activation. The experiments on the hydrogenation of acetylene by deuterium indicate that the same holds true for the hydrogenation of acetylene. The rates of hydrogenation by hydrogen and by deuterium differ by the same factor as was found for ethylene and for the rate of dissociation of hydrogen and deuterium on a similar catalyst.

The relatively higher energy of activation can be accounted for as caused by the extensive displacement of hydrogen by acetylene in consequence of the latter being very strongly adsorbed.

Concerning the mechanism of the catalytic hydrogenation, complete accord has not yet been reached. These authors[6] have the opinion that hydrogenation consists of the simultaneous addition of two hydrogen atoms to unsaturated bonds while Horiuti and Polanyi[7] envisage the hydrogenation as the consecutive and independent addition of hydrogen atoms. Recently Twigg and Rideal[8] came to the same conclusion with regard to hydrogenation as the present authors, while they retain the mechanism suggested by Horiuti and Polanyi for explaining exchange reactions (see below).

If one considers the complete hydrogenation of acetylene under the assumption that one hydrogen atom is added after the other, the following steps are involved

$$C_2H_2 + H \longrightarrow C_2H_3 \quad (1)$$
$$C_2H_3 + H \longrightarrow C_2H_4 \quad (2)$$
$$C_2H_4 + H \longrightarrow C_2H_5 \quad (3)$$
$$C_2H_5 + H \longrightarrow C_2H_6 \quad (4)$$

Steps (1) and (3) represent the addition of hydrogen atoms to adsorbed molecules, while steps (2) and (4) involve the recombination of radicals with hydrogen atoms. This is an essential difference, as one would expect reactions (2) and (4) to proceed with less inertia than reactions (1) and (2), respectively. In other words, the *a priori* probability for a hydrogen atom to be added to the radicals C_2H_3 or C_2H_5 is larger than the probability of being added to the molecules C_2H_2 or C_2H_4, respectively. This means that the addition of the second hydrogen atom to acetylene will follow very quickly the addition of the first, since through the addition of the first atom the inertia inherent in the hydrogenation reaction has been removed. The same holds *mutatis mutandis* for the addition of hydrogen atoms to ethylene also.

Thus it will be recognized that even if in the hydrogenation of acetylene or ethylene the hydrogen atoms are added in consecutive steps, in each case the second atom will be added at a larger speed than the first. Therefore, the addi-

(6) Farkas and Farkas, *ibid.*, **33**, 837 (1937).

(7) Horiuti and Polanyi, *ibid.*, **30**, 1164 (1934).

(8) Twigg and Rideal, *Proc. Roy. Soc.* (London), **171A**, 55 (1939).

tion of the two hydrogen atoms can be regarded for practical purposes as occurring simultaneously.

The second kind of reaction which occurs in the interaction of acetylene and hydrogen is the exchange reaction of the type

$$C_2H_2 + HD \rightleftarrows C_2HD + H_2$$

Though this exchange reaction is not much in evidence in the interaction of hydrogen and acetylene, it will be recognized that its consideration will lead to some important conclusions with regard to the mechanism of the exchange reactions in general.

Two different mechansims for the exchange reaction between unsaturated hydrocarbons and deuterium have been suggested. The so-called "dissociative" mechanism suggested by the present authors[1,2,5,9] consists of the detachment of hydrogen atoms from the hydrocarbon molecules followed by the recombination of the hydrocarbon radicals with deuterium atoms which in turn have been formed by the dissociation of deuterium molecules on the surface of the catalyst. The "associative" mechanism originally suggested by Horiuti and Polanyi[7] is closely connected with the atomic mechanism of hydrogenation and is based on a secondary decomposition of the half hydrogenated form. This mechanism is advocated also by Twigg and Rideal.[8]

As support for the associative mechanism usually the ease is referred to by which the unsaturated hydrocarbons exchange as compared with saturated compounds. This is true in the case of ethylene and ethane but by no means can be generalized. This is best seen in the example of the three compounds, acetylene, ethylene and ethane. In this system a sharp distinction between the rate of exchange of saturated and unsaturated compounds cannot be made since the rate of exchange of ethylene is much larger than either that of ethane or of acetylene.

While the small rate of exchange of ethane compared with that of ethylene is explained readily by the associative mechanism as being due to the saturated character of ethane, the difference in the rate of exchange of acetylene and of ethylene cannot be traced to the same reason as both compounds are unsaturated.

Therefore, in general it cannot be maintained that saturated and unsaturated hydrocarbons undergo exchange reactions with essentially different rates, the more so since ready exchange of saturated compounds also has been observed.[10] Consequently, there is no reason to assume different mechanisms for the exchange reactions of saturated and unsaturated hydrocarbons and it appears that the dissociative mechanism is applicable to both types of exchange reactions.

According to the dissociative mechanism, the rate of exchange depends on the adsorbability of the hydrocarbons, and on the ease with which hydrogen atoms are detached from the hydrocarbon molecule. Thus qualitatively one might suppose that while acetylene is adsorbed strongly when compared with ethane, the hydrogen atoms are detached so much less readily that the effect of the adsorbability is compensated. On the other hand, both adsorbability and dissociation rate are apparently in a favorable relation in the case of ethylene to induce a relatively rapid exchange.

In fact the state of affairs is more complicated, as the rate of exchange depends not only on the absolute concentration of the hydrocarbon, but also on its relation to the concentration of hydrogen on the surface of the catalyst. It seems, however, that a detailed discussion of the kinetics of exchange reactions from this point of view is premature.

Summary

1. The catalytic hydrogenation of acetylene was investigated at pressures of 70–150 mm. and in the temperature range of 20–140° on a platinum catalyst. The rate of hydrogenation increases with increasing hydrogen pressure but is strongly reduced with increased acetylene pressure.

2. If the hydrogenation is carried out by parahydrogen, the ortho–para conversion proceeds very much more slowly than in the absence of acetylene. The ratio of the rate of hydrogenation by hydrogen to that by deuterium is 1.5 at 20°.

3. The hydrogenation of acetylene proceeds in two distinct stages: first, all acetylene is reduced to ethylene and only then is ethylene hydrogenated to ethane. The start of the second step is indicated by a sudden increase in the rate of hydrogenation.

4. The catalytic exchange of hydrogen atoms between acetylene and molecular deuterium is very much slower than that between ethylene and deuterium under similar conditions.

5. The results indicate that acetylene is

strongly adsorbed on the surface of the catalyst and that acetylene can displace both hydrogen and ethylene in the adsorption layer. The mechanisms of hydrogenation and exchange reactions are discussed.

Evidence for Existence of a Selenium Iodide

BY JAMES D. MCCULLOUGH[1]

Various attempts[2] have been made in an effort to detect compound formation between selenium and iodine, but in no case have these led to positive conclusions. During a recent study of the various crystalline forms of elementary selenium made by the author, it was observed that a color change occured when selenium was added to a solution of iodine in carbon tetrachloride. Since selenium is not measurably soluble in carbon tetrachloride in any form, this change seemed significant. Accordingly the following experiments were carried out using carefully purified materials throughout.

Absorption Spectrum Studies.—Light from an incandescent bulb was passed through two similar glass absorption cells placed in series, one of which was filled with a solution containing 0.885 g. of iodine per 1000 g. of carbon bisulfide and the other with a solution containing 0.195 g. of crystalline α-monoclinic selenium per 1000 g. of the solvent. After preparing photographs with this arrangement, the solutions were mixed, the two cells filled with the resulting solution and a second set of absorption spectra prepared.

In Fig. 1, curve A is a reproduction of a microphotometer tracing of the absorption spectrum of the unmixed solutions while curve B is a similar record for the mixed solutions. Since the ordinates represent relative transmission, there is a new region of absorption from 4200 to 4500 Å. on mixing. Because of the care taken in purifying the selenium and iodine used, this must mean that a compound is formed which is responsible for the increased absorption.

The Selenium–Iodine Equilibrium.—Weighed quantities of iodine and carbon tetrachloride were placed in glass-stoppered bottles with an excess of hexagonal selenium and shaken for twenty-four hours or longer in a thermostat at 25°. The solutions were then allowed to settle for at least ten minutes, after which samples of about 200 g. were removed by slowly forcing the solution in a closed system through a sintered glass filter into a weighed, glass-stoppered flask. After weighing

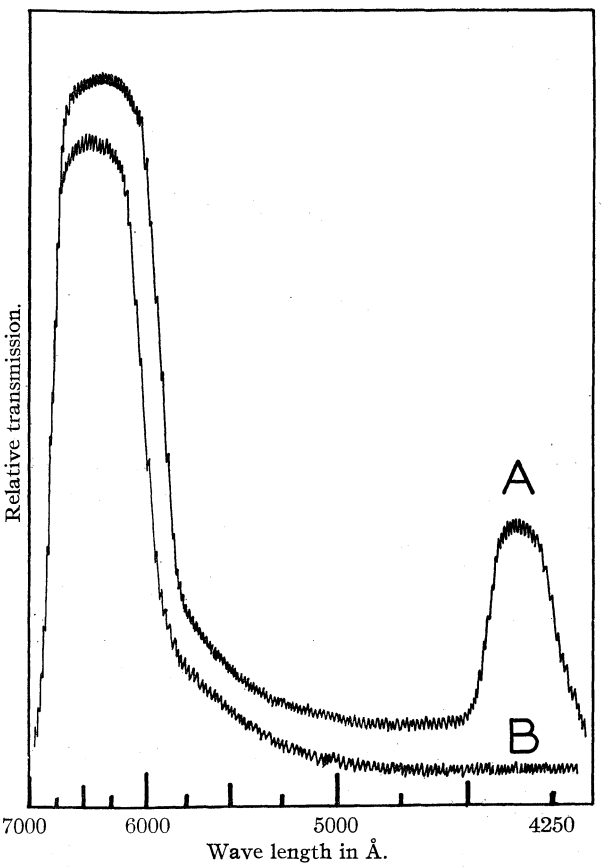

Fig. 1.—Reproduction of microphotometer records of absorption spectra of solutions of selenium and iodine in carbon bisulfide. Curve A is for the superimposed solutions before mixing, while curve B is for the solutions after mixing. Curve A has been displaced upward to reduce overlapping.

the sample, 100 ml. of 3 *N* sodium hydroxide solution was added, the mixture shaken and then transferred to a separatory funnel, where the shaking was continued for several minutes. By this process the selenium and iodine are both quite completely transferred to the aqueous layer, the selenium being oxidized mainly to selenite, with perhaps some selenate. After separating the two layers, the aqueous phase was saturated with sulfur dioxide and an equal volume of concentrated hydrochloric acid was added. More sulfur dioxide was then passed in and the solution was boiled to coagulate the elementary selenium, a process which required several hours. Near the end of the precipitation process a small quantity of hydrazine hydrochloride was added to precipitate any of the element left in the form of selenate. The selenium was collected in a sintered glass crucible, washed with water, then with alcohol, dried for several hours at 105° and then weighed.

The results of these experiments are shown in Table I. It is seen that there is a linear relationship between the quantity of selenium dissolved and the concentration of iodine. This is what would be expected for an equilibrium of the type:

$$n\text{Se(solid)} + I_2 = Se_nI_2$$

This is evidence that the compound has two atoms of iodine per molecule but leaves the number of selenium atoms undetermined.

TABLE I

SELENIUM–IODINE EQUILIBRIUM IN CARBON TETRACHLORIDE

Moles I_2 per 1000 g. solvent	Gram atoms Se per 1000 g. solvent	Moles I_2 / G atoms Se
0.04236	0.00106	40.0
.05622	.00140	40.1
.07620	.00191	39.9

The author wishes to acknowledge his indebtedness to Dr. Arnold O. Beckman, in whose laboratory this work was done, for suggesting the study of selenium and for his interest in the problem.

Summary

1. Absorption spectra give strong evidence in favor of compound formation between selenium and iodine in carbon bisulfide.

2. Quantitative measurements of the equilibrium between selenium and iodine in carbon tetrachloride show the presence of a compound having the formula Se_nI_2 with n undetermined.

Amperometric (Polarometric) Titrations. I. The Amperometric Titration of Lead with Dichromate or Chromate

BY I. M. KOLTHOFF AND YU-DJAI PAN

The classical methods of electrometric titrations are the potentiometric and conductometric titrations. In potentiometric titrations the potential of a suitable indicator electrode is measured during the titration and the end-point is characterized by a more or less pronounced change of the potential upon addition of a small amount of reagent. In conductometric titrations the electrical conductance of the titration mixture is measured during the titration and the end-point is found graphically as the point of intersection of the lines giving the changes of conductance before and after the equivalence point. To these two methods may be added another which we propose to call "*amperometric titrations.*" In amperometric titrations the current which passes between two suitable electrodes at a constant applied e. m. f. is measured. Depending upon the conditions one or both electrodes are placed in the titration medium. Quite generally, the end-point is found as the point of intersection of two lines giving the change of the current before and after the equivalence point.

The principle underlying amperometric titrations was mentioned as early as 1897 by Salomon[1] and later by Nernst and Merriam.[2] It is peculiar that these papers have escaped the attention of analytical chemists. It was shown by the above authors that the so-called "diffusion current"[3] is proportional to the concentration of the electro-reduced substance. In a paper entitled "On a Galvanometric Titration Method"

Salomon[1c] described the amperometric titration of chloride with silver nitrate. He placed two silver electrodes in dilute potassium chloride, applied an e. m. f. of 0.1 v. and titrated with silver nitrate. Until the equivalence point the "residual current" was very small, but after the equivalence point both electrodes became depolarized, resulting in a sudden, large deflection of the galvanometer which was placed in the circuit. Nernst and Merriam[2] placed two palladium electrodes, saturated with hydrogen, in solutions of various acidities and alkalinities and determined the current which passed through upon application of a small e. m. f. Both electrodes adopted the hydrogen potential and the e. m. f. of the cell was zero. The current passing through upon application of a small e. m. f. was determined approximately by Ohm's law ($E = i R$). When the solution contained an excess of acid, the hydrogen ion concentration at the cathode decreased and at the anode increased during the electrolysis. This caused concentration polarization which remained small as long as the current which passed through was small and the excess of acid was great. Similarly, the concentration polarization was found to be small in alkaline medium. However, in neutral medium, when the hydrogen ion concentration is only of the order of 10^{-7}, a slight electrolysis gives rise to a considerable concentration polarization and the setting up of an appreciable back e. m. f. Under ideal conditions the current should quickly drop to zero. Thus, the current passing between two hydrogen electrodes at a small applied e. m. f. during the titration of an acid with a base, or *vice versa*, decreases continuously until the equivalence point is reached and then increases again. Fresenius[4] has investigated the possibility of the determination of small hydrogen ion concentrations by making use of the above principle, but in this particular instance the method is of little importance.

The method proposed by Salomon[1] in 1897 resembles very closely the so-called "dead stop end-point method" of Foulk and Bawden.[5] In their application of this method to various oxidation–reduction titrations, Guzman and Rancano[6] proposed the name "depolarimetry," as the end-point usually is characterized by a sudden depolarization or polarization of one or of both of the electrodes. Heyrovsky and Berezicky[7] used a depolarized anode and the dropping mercury electrode as indicator electrode in the titration of barium with sulfate and suggested the name "polarographic titration." Majer,[8] discussing the titration of lead with sulfate and the fundamentals of the method, coined the term "*polarometric titrations*." As it is the current which is measured during the titration, we prefer to call this type of titration "*amperometric* (or galvanometric, [Salomon]) titration," corresponding to the use of the words potentiometric and conductometric titrations.

So far, no systematic studies have been made of the possibilities and limitations of amperometric titration methods. At present, we are engaged with such studies, using the dropping mercury electrode or a platinum wire microelectrode as the indicator electrode. It is expected that this type of titration will find at least as extensive an application as potentiometric titrations experience now. We find the amperometric method especially useful in the titration of very dilute solutions. For the sake of brevity we will not discuss the general characteristics of amperometric titrations, their possibilities and limitations, but will postpone such a discussion until more experimental data have been made available.

In the present paper the amperometric titration of lead with chromate or dichromate is discussed, using the dropping mercury electrode as indicator electrode.

Experimental

Apparatus.—The set-up used is given in Fig. 1. A is a battery composed of three dry cells with a total voltage of 4.5 v. R is a potential divider composed of two rheostats, one with 1000 and the other with 10 ohms resistance. R_s is a four dial standard resistance box of 9999 ohms, connected in series with the cell. The potential drop across the resistance box is measured with a student's potentiometer P, using a portable galvanometer as a null point instrument. The magnitude of the current which passes through is calculated with the aid of Ohm's law.[9] S. C is a standard cell of known e. m. f. G. S. is a gang switch which makes the various connections with the potentiometer. By the proper adjustment of the potential divider a known e. m. f. E_c is applied between the dropping cathode

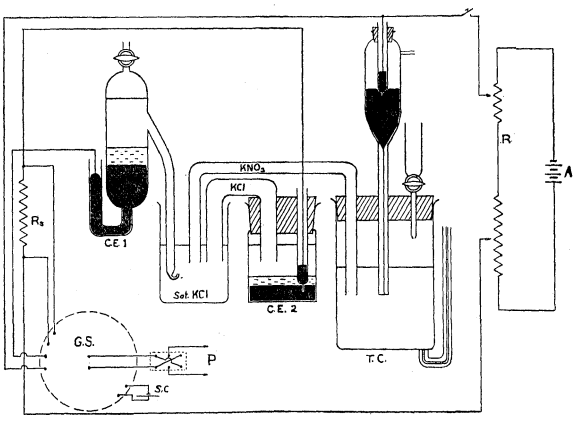

Fig. 1.—Diagram of the set-up.

and a standard saturated calomel electrode (C. E. 1). Another saturated calomel electrode (C. E. 2) was used as a practically depolarizable anode in the electrolysis cell, electrolytic contact with the catholyte in the titration cell being made by two salt bridges. One siphon filled with a 3% agar gel saturated with potassium chloride made electrolytic contact between the anode and a saturated solution of potassium chloride in a beaker, and a second siphon filled with a gel saturated with potassium nitrate made electrolytic contact between the saturated potassium chloride solution and the catholyte in the titration cell. In ordinary work the use of two calomel electrodes is not necessary, as a slight polarization of the anode does not affect the results. In the present work it was preferred to use the C. E. 1 as a reference electrode in order to measure or adjust at any desired time the potential of the dropping electrode against an unpolarized electrode. The use of the outside anode (C. E. 2) can also be dispensed with, as a large layer of pure mercury on the bottom of the titration cell can serve as an internal anode. This involves the practical disadvantage of the use of much mercury, as the cell has to be cleaned after each titration, and a new layer of pure mercury must be added for the next titration. In many titrations a large silver–silver chloride electrode can serve as an internal anode. However, since the use of the external anode does not involve any difficulties and such a saturated calomel electrode can be used for a long period of time, we have not made a special study of the use of suitable unpolarizable internal anodes.

The titration cell T. C. of the model given in Fig. 1 had a capacity of about 100 ml. It was provided with an inlet tube for nitrogen (or hydrogen for the removal of dissolved oxygen before and during the titration. Since oxygen is reducible at the dropping mercury electrode, giving one wave due to reduction to hydrogen peroxide at a relatively small applied e. m. f., and a second drawn out wave due to reduction to hydroxyl ions at higher voltages, the removal of oxygen is recommended, especially in the titration of very dilute solutions. The titration cell was closed with a four-hole rubber stopper; one hole served for the introduction of the salt bridge, the second for the introduction of the buret, the third for the introduction of the mercury capillary and the fourth for the outlet of the gas (not shown in the figure). In most cases the reagent was added from a calibrated semi-microburet of 5 or 10 ml. capacity and with scale divisions of 0.01 ml. The concentration of the reagent was at least 10 times greater than the solution to be titrated. The drop time of the capillary was of the order of three seconds. As in the following work the temperature of the solution remained sensibly constant during the titration, the titration cell was not placed in a thermostat.

Performance of the Titration.—When the characteristics of the substance to be titrated and of the reagent are not known, it is always necessary to determine the current voltage curve of both in the medium in which the titration is being carried out. In order to eliminate the migration current[10] and to reduce the resistance, it is always advisable to have a sufficient excess of indifferent electrolyte present. When the current–voltage curves of the substance to be titrated and of the reagent have been determined, the potential of the dropping electrode is adjusted at the beginning of the titration to such a value that the diffusion current of one or of both of them is obtained. In the case of the titration of dilute lead solutions in the presence of an excess of indifferent electrolyte the diffusion current of lead (after suppression of the maximum with methyl red) was obtained at cathode potentials (against the satd. calomel electrode) between −0.7 and −1.4 v. The shape of the current–voltage curves of potassium chromate and dichromate depend greatly upon the *p*H of the solution When the *p*H of the solution is smaller than 6, the reduction begins immediately upon short circuiting without an applied e. m. f. The reduction proceeds from the hexavalent to the trivalent state. With increasing applied e. m. f., another wave occurs corresponding to the reduction of the trivalent to the divalent chromium and at still greater negative potential a third wave occurs corresponding to the reduction to metallic chromium. The interpretation of the polarograms of chromate is involved and will be discussed in a subsequent paper with Dr. J. J. Lingane. In the present work the cathode potential as a rule was adjusted to a value at which the diffusion currents of lead and of chromate (to Cr^{+++}) were obtained. When at the proper cathode potential, E_c, lead is titrated with chromate or dichromate, the diffusion current of the lead decreases during the titration and becomes equal to the residual current of the medium at the cathode potential at the equivalence point. If the solubility of the precipitate at the equivalence point is negligible and the medium does not contain electroreducible substances at the applied cathode potential, the residual current at the equivalence point is almost equal to zero. Upon addition of an excess of reagent, the diffusion current of chromate is obtained which increases with increasing excess added. When the values of the current (corrected for volume change) are plotted against the amounts of reagent added, two straight lines are obtained which intersect at the end-point (see Fig. 2). In order to obtain straight lines it is necessary to correct for the volume changes during the titration. When the original volume of the solution to be titrated is V ml., the amount of reagent added is X ml. and the current measured is i, then

$$i_{corr.} = \frac{V + X}{V} i$$

(10) *Cf.* J. J. Lingane and I. M. Kolthoff, THIS JOURNAL, **61**, 1045 (1939); see also Ref. 3.

In all of the figures $i_{corr.}$ is plotted against the volume of reagent added. In all of the titrations of lead with chromate or dichromate it was necessary to make only a few (three or four) readings before and after the end-point. However, in order to obtain a greater accuracy a large number of measurements has been made.

The titrations were performed in the following way. A measured volume (usually 50 ml.) of the lead solution was introduced with the aid of a calibrated pipet into the titration cell, and the latter covered with the rubber stopper. Nitrogen (or hydrogen) was passed through for about ten minutes. In the meantime the potentiometer system was adjusted against the Weston standard cell. After passage of the nitrogen the dropping electrode and the reference electrode (Fig. 1) were connected and the desired value of E_c was applied. The dropping electrode was then connected with the saturated calomel electrode which served as anode and by a change of the switch the current measuring device was introduced in the circuit. A measured volume of the reagent was added from the microburet, nitrogen was passed through for one minute to remove any oxygen and to effect a good mixing and the current was measured again. If necessary, the cathode potential was readjusted to its original value. This process was repeated after successive additions of reagent. If necessary, the constancy of the current was checked before a new addition of reagent. If no other reducible substances are present in the solution, the approach of the end-point is indicated by the current, which becomes smaller and smaller. When the solubility of the precipitate is negligibly small it is desirable to make a greater number of measurements in the vicinity of the end-point in order to find the location of the minimum with a greater degree of accuracy. On the other hand, if the solubility is appreciable, there is no practical advantage in making many readings near the end-point. In such a case the minimum current does not necessarily correspond to the location of the equivalence point (*e. g.*, in the titration of lead with dichromate, see Fig. 2). In such cases points are required only at that distance from the end-point where the (corrected) current–reagent line has become straight.

At the end of the titration the values of the current are corrected for the volume effect and plotted against the volume of reagent added. The point of intersection of the two straight lines marks the end-point.

Materials Used.—All chemicals used were of reagent quality. The lead nitrate was recrystallized twice from water and dried at 120°. A standard solution was prepared and the concentration determined by precipitation as chromate and iodometric titration of the precipitate. The potassium dichromate was a standard substance. The C. P. potassium chromate was recrystallized from water and dried at 120°. Its stock solution was standardized iodometrically and compared with a standard dichromate solution.

Experimental Results

In Fig. 2 are represented the results obtained in the titration of 50 ml. of 0.01 *M* lead nitrate which was 0.1 *N* in potassium nitrate with 0.05 *M* potassium dichromate at a cathode potential E_c of

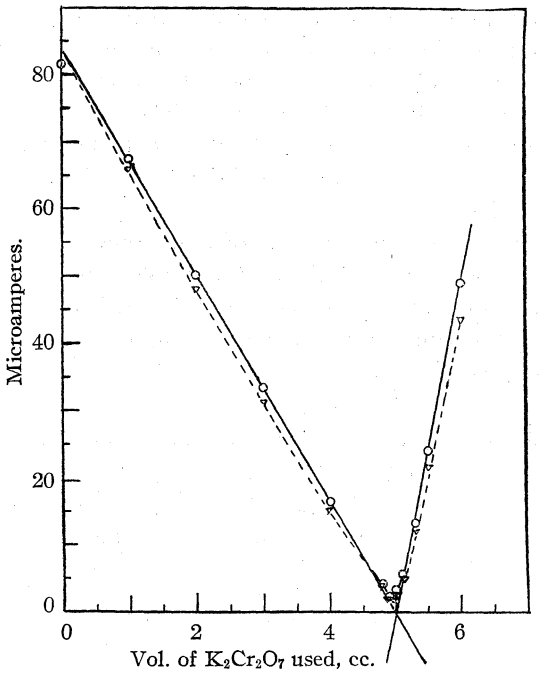

Fig. 2.—Titration of 50 cc. of 0.01 *M* $Pb(NO_3)_2$ in 0.1 *N* KNO_3 with 0.05 *M* $K_2Cr_2O_7$ at $E_c = -1.0$ v.

−1.0 v. *vs.* S. C. E. The dotted lines give the values of the current as actually determined; the drawn lines give the values after volume correction. It is seen that after correction two straight lines were obtained which intersected exactly at the equivalence point. The reproducibility and accuracy were excellent; the end-point was found in four different titrations after addition of 5.00 ± 0.01 ml. of dichromate. From Fig. 2 it is seen that the residual current at the equivalence point was relatively great, and that both the precipitation and the reagent lines were curved in the neighborhood of the end-point. The large residual current at the end-point is to be attributed to dissolved lead chromate while the straight lines intersect at a point where the residual current is smaller than 1 microampere. The relatively large solubility of the lead chromate under the above experimental conditions is due to the free acid which is formed during the titration

$$Cr_2O_7^{=} + 2Pb^{++} + H_2O \longrightarrow 2PbCrO_4 + 2H^+$$

When neutral lead nitrate solutions were titrated with potassium chromate solutions in 0.1 to 1 *N* potassium nitrate the residual current at the point of intersection of the two lines was always found to be less than 1 microampere. However, under the latter conditions the end-point was always found 0.8 to 1% before the equivalence

point, the deviation undoubtedly being due to coprecipitation of basic lead chromate with the neutral lead chromate. For this reason we prefer to carry out the titration with potassium dichromate in neutral or slightly acid medium or with potassium chromate in a buffered or acid solution.

As experimental details of amperometric titrations are not described in the literature, some values of the current measured during a titration and the same data corrected for the volume effect are given in Table I.

TABLE I

TITRATION OF 50 ML. 0.01 *M* $Pb(NO_3)_2$ (IN 0.1 *M* KNO_3) WITH 0.05 *M* $K_2Cr_2O_7$: $E_c = -1.0$ v.

Ml. of $K_2Cr_2O_7$ added	*i* determined, microamp.	$i_{corr.}$ for dilution, microamp.
0	81.56	81.56
1.0	66.22	67.50
2.0	48.34	50.20
3.0	31.66	33.60
4.0	15.25	16.45
4.8	3.79	4.15
4.9	2.09	2.30
5.0	2.9	3.19
5.1	5.1	5.62
5.3	12.03	13.3
5.5	21.86	24.0
6.0	43.86	49.1

As the slope of the reagent line is steeper than that of the lead (precipitation) line, the actual minimum is not found at but before the equivalence point (Fig. 2).

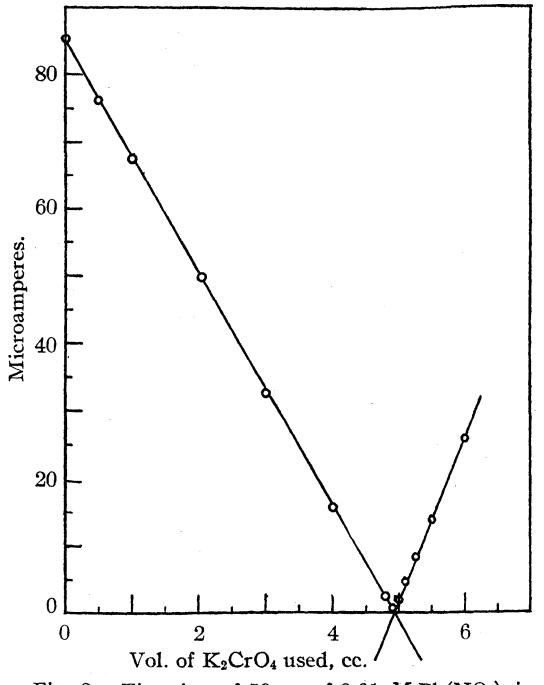

Fig. 3.—Titration of 50 cc. of 0.01 *M* $Pb(NO_3)_2$ in 0.1 *N* KNO_3 with 0.1 *M* K_2CrO_4 at $E_c = -1.2$ v.

The amount of potassium nitrate present in the lead solution was found to be without effect upon the results, if enough was added to eliminate the migration current. Titrations were carried out in 1 *M* potassium nitrate instead of in 0.1 *M* nitrate, the end-point being found again after addition of 5.00 ml. of dichromate.

A straight precipitation line was not obtained in the absence of potassium nitrate. The current at the beginning of the titration is much greater than the diffusion current of lead, as the initial current is the sum of the diffusion current and the migration current. During the titration the amount of dissolved lead decreases, while the concentration of the soluble reaction products potassium nitrate and nitric acid increases. Consequently, the contribution of the migration current becomes less and less the nearer the end-point is approached and during the precipitation of the last 20% of the lead the currents practically correspond to the diffusion current of the dissolved lead. An example of the titration of 0.01 *M* lead nitrate with 0.05 *M* dichromate in the absence of added salt is given in Fig. 4.

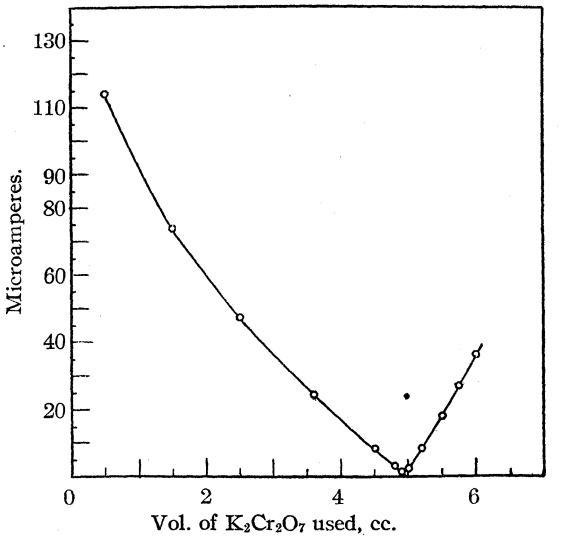

Fig. 4.—Titration of 50 cc. of 0.01 *M* $Pb(NO_3)_2$ with 0.05 *M* $K_2Cr_2O_7$ at $E_c = -1.0$ v.

As the solubility of lead chromate in dilute nitric or perchloric acids is small, titrations of lead could be carried out at relatively high acidities. Three titrations of 50 ml. of 0.01 *M* lead nitrate in 0.01 *N* perchloric acid and 0.1 *N* potassium nitrate and three titrations in 0.1 *N* per-

chloric acid were carried out. Again, the results were perfectly reproducible and accurate within 0.2%. Results obtained in 0.01 and 0.1 *N* acid are given graphically in Fig. 5 in which only the corrected values of the current are plotted. The solubility of the lead chromate and therefore the residual current near and at the equivalence point increase with increasing acidity. In the titration in 0.01 *N* perchloric acid the residual current at the equivalence point was found to be 7.0 microamperes, and in 0.1 *N* perchloric acid 10.1 microamperes. In all these titrations the cathode potential need not be adjusted very accurately; it may vary between −0.8 and −1.2 v., and in neutral solutions it even may be −1.5 v.

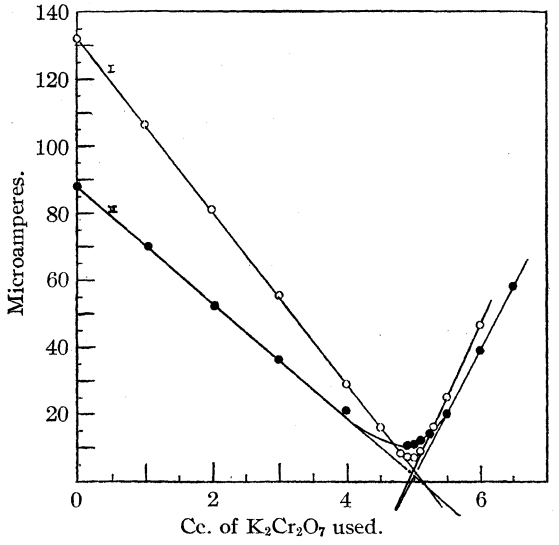

Fig. 5.—Titration of 50 cc. of 0.01 *M* $Pb(NO_3)_2$ in 0.1 *N* KNO_3: (I) in 0.01 *N* $HClO_4$, at E_c = −1.2 v.; (II) in 0.1 *N* $HClO_4$, at E_c = −1.15 v.; with 0.05 *M* $K_2Cr_2O_7$.

Titrations also have been carried out with dichromate and chromate in an acetate buffer with a *p*H of 4.2 at cathode potentials varying between −0.8 and −1.4 v. and accurate results again were obtained. Acetate increases the solubility of the lead chromate and also the residual current at the equivalence point.

The polarogram of 0.001 *M* potassium dichromate in the acetate buffer of *p*H of 4.2 is given in Fig. 6. Evidently the dichromate is already reduced without applying any external e. m. f. The same, of course, is true when the solution is more acidic. Thus, it is possible to carry out the titration without application of an external e. m. f. Under such conditions, which are very

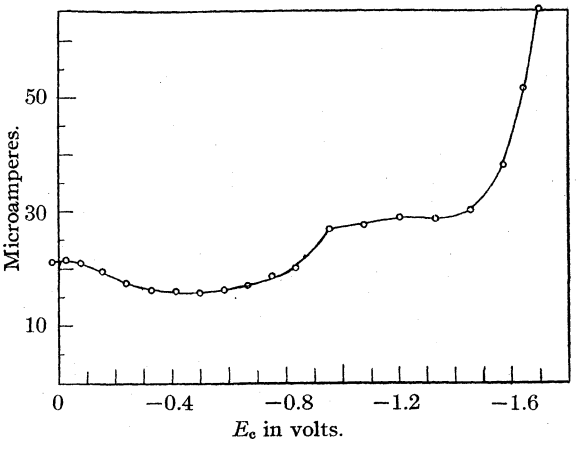

Fig. 6.—Current–voltage curve of 0.001 *M* $K_2Cr_2O_7$ in an acetate buffer of *p*H 4.2.

simple from the practical point of view, the lead is not electro reduced and does not yield a diffusion current. The current remains practically zero until the equivalence point is reached and increases very rapidly (diffusion current of chromate) upon addition of an excess of reagent. An example of such a titration is given in Fig. 7, in which 0.01 *M* lead nitrate in the acetate buffer of *p*H of 4.2 was titrated with 0.05 *M* dichromate without the application of an external e. m. f. Similar results were obtained in more acid media. The performance of the lead titration without application of an external e. m. f. is of particular advantage in cases in which the solution contains constituents which are electro-reduced at potentials at which lead yields a diffusion current. Such a titration can be carried out simply by short circuiting the dropping electrode and the anode and

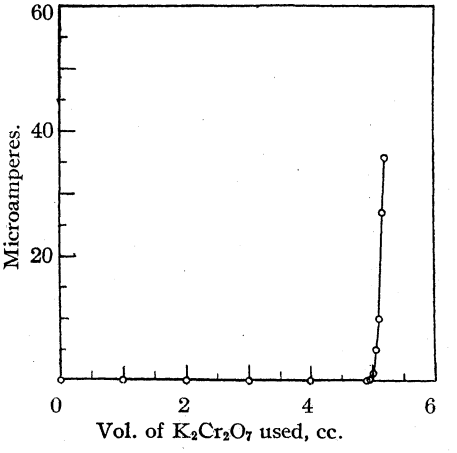

Fig. 7.—Titration of 50 cc. of 0.01 *M* $Pb(NO_3)_2$ in acetate buffer of *p*H 4.2 with 0.05 *M* $K_2Cr_2O_7$ at E_c = 0.

measuring the current in one of the ways described before. It is also possible to use a microammeter for the measurement of the current. We have used a Weston microammeter with 150 scale divisions, each division corresponding to 0.2 microamp. The disadvantage of the instrument is the relatively large fluctuations of the needle during the formation of a drop of mercury, making the determination of the average value of the current relatively difficult.

In the above we have discussed the titration of 0.01 *M* lead solutions under varying conditions. The titration of 0.001 *M* solutions can also be carried out quickly and accurately. In Fig. 8 the data are listed which were obtained in the titration of 50 ml. of 0.001 *M* lead nitrate in 0.01 *M* potassium nitrate with 0.005 *M* dichromate at $E_c = -1.0$ v.

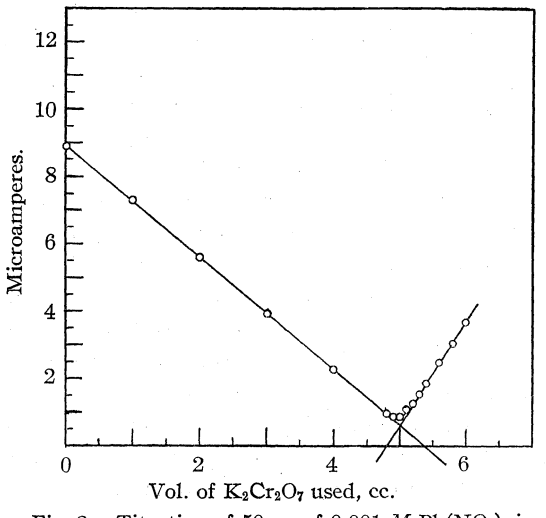

Fig. 8.—Titration of 50 cc. of 0.001 *M* $Pb(NO_3)_2$ in 0.01 *N* KNO_3 with 0.005 *M* $K_2Cr_2O_7$ at $E_c = -1.2$ v.

In three titrations the amount of dichromate used at the point of intersection corresponded within 0.3% with the theoretical amount. When the titration was carried out with potassium chromate instead of dichromate solution the error was even greater than in the titration of more concentrated lead solutions with chromate. The point of intersection with 0.001 *M* lead solutions at E_c values of from -1 to -1.4 v. occurred 3–5% before the equivalence point (coprecipitation of basic salt). The error was eliminated or at least reduced to less than 0.5% by performing the titrations in an acetate buffer with a *p*H of about 4.0.

Titration of Lead in the Presence of Barium.—Although both lead and barium chromate are slightly soluble, the latter differs from the forme in that it is freely soluble in dilute acid. Severa titrations with 0.05 *M* dichromate were carriec out with 50 ml. of a mixture which was 0.01 *M* in lead, 0.01 *M* in barium and 0.01 *M* in perchloric acid. The point of intersection was found 0.1 tc 0.3% before the lead equivalence point. The concentration of the barium even could be increased to 0.1 *M* without affecting the results. In three titrations with a mixture in which the ratio of lead to barium was 1 to 10 and the perchloric acid concentration was 0.01 *N*, the end-point was found within 0.3% of the theoretical value. No irregularities were noticed during the titration (see Fig. 9).

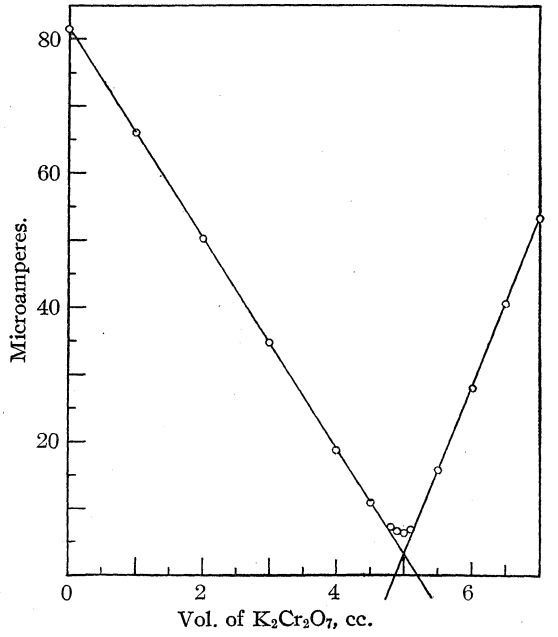

Fig. 9.—Titration of 50 cc. of 0.01 *M* $Pb(NO_3)_2$ in 0.1 *M* $Ba(NO_3)_2$ and 0.01 *N* $HClO_4$ with 0.05 *M* $K_2Cr_2O_7$, at $E_c = -1.0$ v.

In acid medium the lead also can be titrated in the presence of barium without applying an external e. m. f. The titration curves were identical with that given in Fig. 7.

Since the lead chromate is much less soluble than barium chromate an attempt has been made to determine both lead and barium in one titration by fractional precipitation with potassium chromate at cathode potentials (-0.8 to -1.4 v.) at which the lead yields a diffusion current and the barium is not electro-reduced. If all of the lead would precipitate before the precipitation of barium the current would decrease to practically

zero at the point where all of the lead is precipitated, it would then remain very small until all of the barium is precipitated, and it would increase in the usual way with an excess of chromate. It is evident from Fig. 10 that a marked coprecipitation of barium chromate occurs during the precipitation of lead. In the titration of 50 ml. of a mixture which was 0.01 *M* in lead and 0.01 *M* in barium nitrate with 0.2 *M* potassium chromate at $E_c = -1.0$ v., the first end-point (precipitation of lead) was found about 20% after the equivalence point. The second end-point corresponding to quantitative precipitation of lead and barium was found at the correct location. In a subsequent paper the amperometric titration of barium will be discussed more in detail.

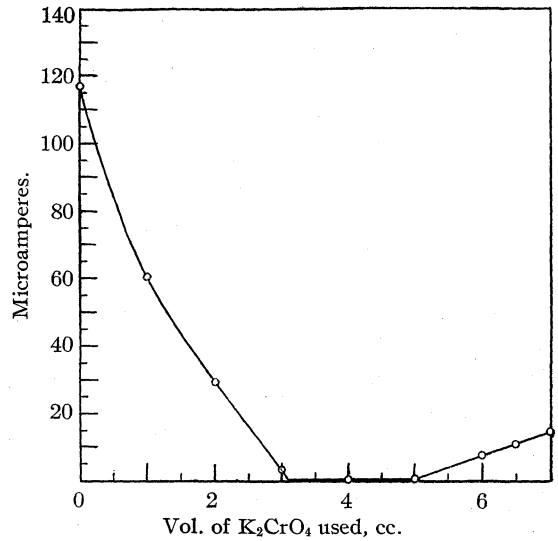

Fig. 10.—Titration of 50 cc. of 0.01 *M* $Pb(NO_3)_2$ in 0.01 *M* $Ba(NO_3)_2$ with 0.2 *M* K_2CrO_4 at $E_c = -1.0$ v.

Summary

1. The word "amperometric titration" is coined and the historical development of this type of titration is discussed.

2. Lead can be titrated accurately, precisely and rapidly by amperometric titration with dichromate or chromate, using the dropping mercury electrode as an indicator electrode. The titration can be carried out without applying an external e. m. f.

3. Even 0.001 *M* lead solutions can be titrated with a high degree of accuracy.

4. Lead can be titrated amperometrically in the presence of large amounts of barium when the solution is slightly acid with perchloric acid. The fractional precipitation of lead and barium in neutral medium with potassium chromate does not yield good results due to coprecipitation of barium chromate with lead chromate.

Studies on Aging and Formation of Precipitates. XXX. The Determination of the Specific Surface of Silver Bromide by the Radioactive and Dye Methods

BY I. M. KOLTHOFF AND A. S. O'BRIEN[1]

In studies on aging of silver bromide it was of interest to determine the specific surface of various products. Dyes, such as orthochrom T,[2] methylene blue,[3] or pinacyanol[4] have been used for this purpose. In this Laboratory wool violet has proved to be of great value in the determination of the specific surface of various precipitates. For this reason, the adsorption of this dye on silver bromide was studied under varying conditions and compared with the adsorption of methylene blue. In order to know the density of occupation of the adsorbed dye on the saturated surface it was necessary to have available the magnitude of the specific surface of the various products used. Particularly when dealing with freshly prepared, heterodisperse precipitates of silver bromide, consisting of extremely fine particles, it was hardly possible to determine the surface microscopically or ultra-microscopically, as the precipitates could not be peptized completely. For this reason, we have made a study of the radioactive method for the determination of the specific surface, the principles of which originated with Paneth[5] and have been successfully applied in this Laboratory. In the present study it was attempted to determine the kinetic equilibrium i

the exchange between a radioactive bromide solution and inactive bromide in the surface of the silver bromide. When equilibrium is established, the following relation holds

$$\frac{Br^*_{surf.}}{Br^*_{sol.}} = \frac{Br_{surf.}}{Br_{sol.}} \quad (1)$$

or

$$Br_{surf.} = \frac{Br^*_{surf.}}{Br^*_{sol.}} Br_{sol.} = R.\ Br_{sol.} \quad (2)$$

in which the asterisk denotes the radioactive bromine. The application of equation (1) or (2) requires the limitation of the exchange to the surface layer only.

Experimental

Preparation of Radioactive Bromide.—Ethyl bromide (C. P.) was dehydrated over anhydrous calcium chloride, filtered and stored in glass-stoppered bottles. One ml. of an approximately 0.08 molar bromine solution in carbon tetrachloride was added to 1 liter of ethyl bromide. After thorough mixing, the flask was suspended at the center of a ten-gallon (40-liter) crock of water. The water was used to reflect the neutrons back into the flask. Soft glass bulbs, about 5 mm. in diameter, containing approximately 100 mg. of beryllium and from 100 to 140 millicuries of radon were secured through the courtesy of Dr. D. Hull of the Division of Physical Chemistry in this University. After radiating from sixteen to twenty hours the bulb was removed and the bromine reduced and extracted by shaking the ethyl bromide in a separatory funnel with 40 ml. of 0.1 molar sodium acid sulfite solution. The ethyl bromide left was dehydrated again and used in subsequent experiments. The aqueous layer containing the radioactive bromide was transferred to a 250-ml. Erlenmeyer flask and the dissolved ethyl bromide boiled off at reduced pressure. The solution was about 0.0013 molar in bromide. Water or solutions of inactive potassium bromide were added to it until the desired volume and bromide concentration were obtained. The four and one-half hour isotope was used in the present experiments, as the thirty-four hour isotope does not have much opportunity to build up and the isotopes of shorter life have almost decayed before the readings are started. In our work no readings were made before three hours had elapsed from the time of the removal of the beryllium–radon bulb.

Measurement of Radioactivity.—A great number of copper dishes of uniform dimensions was prepared and a measured volume of the radioactive solution was evaporated on a steam-bath in a copper dish; if the solution was acid it was neutralized before evaporation. The radioactivity of the residue was measured by placing the dish in the holder under the aluminum window of an ionization chamber. The amplifying circuit, constructed with the valuable aid of Dr. C. S. Copeland, was essentially the one recommended by DuBridge and Brown,[6] details of which are given in the thesis of the junior author.[1]

In all the experiments, the "rate of drift" method was used in measuring the activity of the residue, by determining the rate of the drift of the galvanometer light across an arbitrary number of cm. on a scale.

Materials Used.—Most of the chemicals were of C. P. quality and recrystallized if desirable. A product of wool violet 5BN, purified in the laboratories of the National Aniline Company, was used without further purification. The sample of methylene blue used satisfied the requirements of the "U. S. Pharmacopoeia X."

Analytical.—The dye concentration was determined colorimetrically using a photoelectric colorimeter. Solutions containing small amounts of suspended silver bromide were made entirely clear by addition of sodium thiosulfate. The latter salt did not affect the absorption spectrum of wool violet. In some cases the wool violet concentration was also determined by the chemical method using ceric sulfate or permanganate as oxidizing agents.

The concentration of (inactive) bromide in solution ($Br^-_{sol.}$ in equation 2) was determined by the hypochlorite procedure following the directions of Kolthoff and Yutzy.[7]

Products of Silver Bromide

Well Aged "Product E."—A 200-g. portion of silver bromide was precipitated by adding 0.4 *M* potassium bromide to a slight excess of 0.4 *M* silver nitrate. After washing the precipitate thoroughly with large quantities of water, it was suspended in 0.5 *M* potassium bromide and drastically aged for three days in a stoppered bottle at 95°. The product was then collected on a sintered glass filter, washed thoroughly with water, then with ethanol and finally with ether. It was air-dried until the odor of ether was no longer perceptible. It was then heated at 90° for two hours, ground in an agate mortar and kept in a brown bottle in a desiccator over anhydrous calcium chloride.

Fresh Silver Bromide from 0.1 *M* Solutions (Product B).—Separate samples weighing 0.094 g. were prepared by adding 5 ml. of 0.102 *M* potassium bromide to 5 ml. 0.1 *M* silver nitrate. The samples were not made air-dry, but kept in suspension and investigated immediately after preparation.

Fresh Silver Bromide from 0.43 *M* Solutions (Product A).—Separate samples weighing 2 g. were prepared by adding 25 ml. of 0.423 *M* potassium bromide to 25.5 ml. of 0.423 *M* silver nitrate. Further treatment will be described below.

Determination of Surface by Radioactive Method

Aged Silver Bromide (Product E).—The speed of exchange of radioactive bromide in solution with inactive bromide in the precipitate was determined by shaking at 25° 2-g. samples of product E with a mixture of 4 ml. of 0.001 *N* potassium bromide and 10 ml. of 0.00104 *N* radioactive bromide.

The results are plotted in Fig. 1, in which the amount of exchanged bromide is expressed in equivalents per gram of silver bromide. When the exchange is limited to the surface only this amount of exchanged bromide corresponds to the specific surface ($Br_{surf.}$ in equation 2). From the figure it is seen that the amount of bromide exchanged increases continuously and fairly rapidly with the time of shaking. From the relatively large amount of bromide exchanged it

(6) DuBridge and Brown, *Rev. Sci. Instr.*, **4**, 532 (1933).

(7) Kolthoff and Yutzy, *Ind. Eng. Chem., Anal. Ed.*, **9**, 75 (1937).

is evident that during the shaking much of the radioactive bromide is being incorporated into the solid. This must be due to recrystallization.

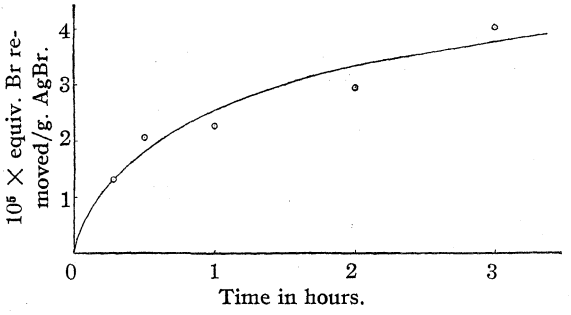

Fig. 1.—Penetration of radioactive bromide ions into aged AgBr.

The speed of recrystallization of this well-aged silver bromide decreases with decreasing temperature. The slope of the exchange curve was found to be much less at 0° than at 25°, but even at this lower temperature most of the radioactive bromide removed from the solution was being incorporated in the precipitate and only a small fraction was present on the surface.

In previous work carried out in this Laboratory and elsewhere[8] it was found that recrystallization and perfection, even of fresh and highly imperfect precipitates, can be prevented by coating the surface of the particles with a layer of a suitable dye. Therefore, experiments were carried out in which the speed of exchange was determined with aged and fresh silver bromide after the particles had been covered with a layer of wool violet or methylene blue or gelatin.

In the following experiments 2 or 4 g. samples of product E were shaken with 4 ml. of a 0.1% solution of wool violet or of methylene blue in 0.001 *M* bromide. After shaking for thirty minutes, 10 ml. of a radioactive solution which was 0.00107 *M* in bromide was added and the mixture shaken for a given period of time, after which the activity of the supernatant liquid was determined. The results are given in Table I and plotted in Fig. 2 (lines 1 and 2).

The results of experiments carried out in the presence of gelatin are given in Table II and also in Fig. 2.

TABLE II

SPEED OF EXCHANGE OF Br* WITH AgBr (E) IN THE PRESENCE OF GELATIN (FIRST SHAKEN 16 HRS. BEFORE ADDN. OF r.a.Br^-)

Time of shaking with Br*, hr.	Presence of gelatin (First shaken 16 hrs. before addn. of r.a.Br^-) With 10 mg. of gelatin R	With 10 mg. of gelatin Br exchanged $\times 10^5$ in eq. p.g. AgBr	With 1 mg. of gelatin R	With 1 mg. of gelatin Br exchanged $\times 10^5$ in eq. p.g. AgBr
1	0.584	0.409		
2	.664	.464	0.516	0.361
3	.736	.515	.549	.384
4	.756	.530	.572	.400

A comparison of the data in Figs. 1 and 2 reveals that adsorbed wool violet, methylene blue and gelatin almost completely prevent the further recrystallization of the aged silver bromide. Extrapolation to a time of shaking of zero should, in the presence of an inhibitor, yield the number of equivalents of bromide in the surface of 1 g. of silver bromide (E). In this way a specific surface of 0.24×10^{-5} equivalent of bromide per gram was found in the presence of wool violet and of 0.21×10^{-5} equivalent per gram in the presence of methylene blue. The values found in the presence of gelatin were somewhat greater, 0.33×10^{-5} in the presence of 1 mg., and 0.37×10^{-5} in the presence of 10 mg. of gelatin. These higher values may be attributed to the fact that the samples had been shaken for sixteen hours with the gelatin solution, and only for half an hour with the dye solutions; more peptization may have occurred after the longer period of shaking with gelatin. It is of interest to note that the slope of the line in the presence of 1 mg. of gelatin is much less than in the presence of 10 mg.

From the agreement of the values of the specific surface found in the presence of the acid dye wool violet and the basic dye methylene blue and from the fact that the specific surface was found to be independent of the amount of silver bromide shaken, it may be concluded that the "dye radioactive method" yields good results in the determination of the specific surface of aged silver bromide.

Fresh Silver Bromide (Product B).—The speed of penetration of radioactive bromide into fresh precipitates of silver bromide is extremely great. Consequently, the radioactive method cannot be used in the determination of the specific surface of fresh silver bromide unless the recrystallization is prevented by the addition of dyestuffs. In the following experiments 2 ml. of a 0.1% solution of wool violet in 0.001 *M* bromide was added to 10 ml. of the freshly prepared suspension of product B which contained 0.094 g. of silver bromide. After shaking for ten to fifteen minutes 10 ml. of about 0.008 *M* radioactive bromide solution was added and the suspensions further shaken for various periods of time, after which the activity was determined in an aliquot part of the supernatant liquid. Similar experiments were performed in which 2 ml. of 0.1% solution of methylene blue in 0.001 *M* bromide was added to the fresh suspension instead of wool violet. In all these experiments the concentration of bromide in the radioactive suspension was 0.004 *M*. In order to increase the percentage of activity removed, the experiments were repeated at a smaller final bromide concentration of 0.00175 *M* (with wool violet) and of 0.00166 *M* (methylene blue). All of the results are reported in Table III and those at the smaller bromide concentration are given graphically in Fig. 3.

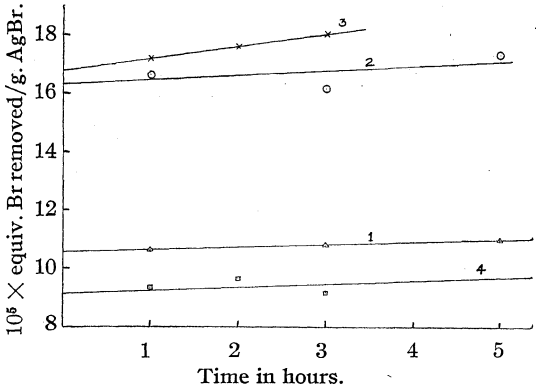

Fig. 3.—Specific surface of fresh silver bromide: ×, AgBr from 0.1 *N* reagents, wool violet–gelatin; △, AgBr from 0.1 *N* reagents, wool violet coating; ⊙, AgBr from 0.1 *N* reagents, methylene blue coating; ⊡, AgBr by method A, wool violet coating.

Experiments were also carried out in the presence of a mixture of gelatin and wool violet. Gelatin alone does not prevent entirely the recrystallization of fresh silver bromide. As wool violet is effective in preventing further recrystallization, the method could be used in the determination of the specific surface of silver bromide aged in the presence of gelatin.

In the experiments reported in Table IV, 2 mg. of wool violet was added to the fresh suspension of product B, and after ten minutes of shaking 10 mg. of gelatin dissolved in 2 ml. of 0.001 *M* bromide. After further shaking for one hour the radioactive bromide solution was added. In other experiments the suspension was first shaken with 10 mg. of gelatin and subsequently for one hour in the presence of wool violet–radioactive bromide solution. The results are given in Table IV and on curve 3 in Fig. 3.

5	M.B.			.445	17.3

TABLE IV

SPEED OF EXCHANGE OF Br* WITH FRESH SILVER BROMIDE (B) IN THE PRESENCE OF 2 MG. OF WOOL VIOLET AND 10 MG. OF GELATIN

Time of shaking with Br*, hr.	First shaken 10 min. with W. V., then gelatin added Br⁻ exchanged × 10^5 in equiv. R	per 1 g. of AgBr	First shaken 1 min. with gelatin, then W. V. added Br⁻ exchanged × 10^5 in equiv. R	per 1 g. of AgBr
1	0.254	17.0	0.260	17.4
2	.306	20.5	.263	17.6
3	(.259)	(17.3)	.286	19.1

In a similar way fresh product A yielded an exchange of 9.0×10^{-5} equivalent of bromide per gram (see line 4 in Fig. 3).

Determination of Specific Surface by the Dye Method.—The adsorption of wool violet on fresh and old products of silver bromide was determined from solutions being either 0.001 *M* in silver or 0.001 *M* in bromide. Independent of the age of the silver bromide, it was found that the amount of dye adsorbed on the saturated surface is twice as great from the silver as from the bromide solutions. Fresh silver bromide coated with dye did not age on further shaking, the amount of dye adsorbed remaining constant with time. In this respect the silver bromide behaves like other fresh precipitates. A summary of the results obtained with the various products is given in Table V. In all of the experiments it was ascertained that the final dye concentration was large enough to have the surface saturated with the dye. In the experiments with methylene blue paraffin lined bottles were used.

Discussion of Results

1. The radioactive method applied in the presence of wool violet or methylene blue yields identical results with well-aged silver bromide. It was found that 0.046 and 0.039%, respectively, of the bromide was present in the surface of silver bromide E. Fresh product B yielded by the "wool violet–r.a." method a specific surface of 10.5×10^{-5} equiv. of bromide per gram, corresponding to the presence of 2.0% of all the bromide in the

[a] After centrifuging, most of the supernatant liquid was decanted and the dye concentration was determined in the mother liquor. The weight of the remaining precipitate and mother liquor was determined and the total amount of dye in this mixture measured after dissolving it in sodium thiosulfate. From the known weight of the precipitate and the dye concentration of the mother liquor and of the total amount of dye in the mixture, the amount of dye adsorbed on the precipitate was calculated.

surface. With the slightly aged product A the values were 9.1×10^{-5} equiv. per g. corresponding to 1.7% surface.

The "methylene blue–r.a." method with the fresh product B yielded a value of the specific surface which was 60% greater than that obtained with the "w.v.–r.a." method, although both methods gave identical results with the aged product E. The difference found with the fresh product undoubtedly is to be attributed to an adsorption of bromide in the form of methylene blue bromide on the active surface of the fresh product. In agreement with this interpretation it is found that the ratio of adsorbed wool violet (from excess of silver) to methylene blue on the saturated surface of aged product E is equal to 0.158/0.073 = 2.16, while this ratio on fresh product B is 12.1/7.6 = 1.6, showing that the adsorption of methylene blue as compared with wool violet is greater on the fresh than on the aged product. The specific surface of product B determined by the "r.a. method" in presence of a mixture of wool violet and gelatin is found equal to that found with the "r.a. methylene blue" method. The radioactive bromide solution used was slightly acid; at the positive side of the isoelectric point, positively charged gelatin particles are adsorbed and also an equivalent amount of bromide, explaining the difference between the "r.a. w.v. gelatin" and the "r.a. w.v." methods on the one hand and the similarity between the former and the "r.a. methylene blue" method on the other.

2. Taking the value of the specific surface determined by the "r.a. w.v." method as a standard, it is possible to calculate the number of bromide ions on the surface per molecule of adsorbed wool violet or methylene blue. A summary of the data is given in Table VI.

TABLE VI

DENSITY OF OCCUPATION OF WOOL VIOLET AND METHYLENE BLUE ON SATURATED SURFACE OF FRESH AND AGED SILVER BROMIDE

Dye	Medium	No. of bromide ions in surface per 1 molecule adsorbed dye: Product E	B	A
W.V.	0.001 *N* Ag	10.9	6.6	6.4
W.V.	.001 *N* Br	20.2	14.8	14.2
M.B.	.001 *N* Br	11.6	5.2	

The density of occupation of adsorbed wool violet on the aged product E, even in the presence of an excess of silver, is very small as compared to that found with other precipitates such as lead sulfate, barium sulfate, and lead chromate. In the latter cases the dye probably is oriented with its polar groups perpendicular to the surface of the polar adsorbents, whereas with the less polar silver bromide the adsorbed dye may be in a more flat position on the surface.[9] The fact that the density of occupation in an excess of silver is twice as great as in an excess of bromide suggests that in the latter case the dye is held in a monomolecular layer and that an extra layer is adsorbed as silver salt when the solution contains an excess of silver. On fresh precipitates the density of occupation of adsorbed wool violet is

(9) Compare Rabinovich and Natanson, *J. Phys. Chem. U. S. S. R.*, **11**, 434 (1930); and espec. Leermakers, Carroll and Staud, *J. Chem. Phys.*, **5**, 873 (1937); Sheppard, Lambert and Walker, *ibid.*, **7**, 265 (1939).

about 1.7 (excess silver) to 1.4 (excess bromide) times as great as on the aged products. It is not possible to say whether this is due to a changed orientation of the adsorbed dye or to other causes.

On the aged product 1 molecule of methylene blue was found to be adsorbed per 11.6 bromide ions on the surface. This value is in fair agreement with that reported by Wulff and Seidl[3] of 7.6 for a well-aged product the surface of which was measured microscopically and found to be about 2.5 times as great as that of our product E. The increased density of occupation of methylene blue on the fresh products has been explained above.

3. From a practical point of view the wool violet method either in an excess of silver or in an excess of bromide seems satisfactory for the determination of the specific surface of silver bromide of varying ages. The values found by the wool violet method are in satisfactory agreement with those found by the "w.v. r.a." method. In Table VII is given the ratio of the specific surfaces of the products determined by different methods.

TABLE VII

COMPARISON OF VARIOUS METHODS FOR DETERMINATION OF SPECIFIC SURFACE

	"r.a. W.V."	W.V. (Ag^+)	W.V. (Br^-)	"r.a. M.B."	M.B.
Surface B/ Surface E	47	77	64	73	104
Surface B/ Surface A	1.16	1.12	1.10		

Summary

1. A rapid incorporation of radioactive bromide into well-aged silver bromide occurs when a solution of the former is shaken with the solid.

2. Adsorbed wool violet and methylene blue limit the exchange between solution and solid to the surface layer only. Use of this is made in the radioactive determination of the specific surface of fresh and aged products of silver bromide. Adsorbed gelatin inhibits the recrystallization of aged silver bromide.

3. Wool violet is found suitable for the determination of the specific surface of silver bromide. From a solution containing an excess of silver the amount of dye adsorbed is twice as great as that from a solution containing an excess of bromide.

4. The saturated surface of an aged product of silver bromide contained per 10.9 bromide ions 1 molecule of wool violet (excess Ag^+) or per 20.2 bromide ions 1 molecule of wool violet (excess Br^-), and per 11.6 bromide ions 1 molecule of methylene blue (excess Br^-). With a fresh product the following figures were found: 6.5, 14.5, and 5.2, respectively.

Studies on Aging and Formation of Precipitates. XXXI. The Aging of Silver Bromide

BY I. M. KOLTHOFF AND A. S. O'BRIEN[1]

In previous studies it has been found that fresh imperfect precipitates perfect themselves as a result of repeated recrystallizations which take place mainly in liquid films around the primary particles. Consequently, lattice material may deposit in interstices of an agglomerate of primary particles, thus cementing the latter together and causing a marked decrease of the specific surface of the precipitate.[2] The speed of this kind of aging was found to be determined by the solubility of the precipitate in the aging medium or more exactly in the liquid film around the particles. Ostwald ripening involving the growth of large particles at the cost of small ones was found to be of secondary significance with regard to the type of aging discussed above.

In the present paper studies on the aging of freshly prepared silver bromide are reported. It was found again that the speed of aging increased with increasing solubility of the precipitate. However, when the solubility had reached a certain minimum value, further decrease of the solubility did not affect the still fairly large speed of aging. Evidence is given in this paper that this relatively rapid aging is due to a thermal aging of silver bromide which also occurs in the dry state even at room temperature.

In general the aging was followed by two methods: (a) by determining the decrease of the

(1) From a doctor's thesis submitted by Albert S. O'Brien to the Graduate School of the University of Minnesota, June, 1938.

specific surface of the precipitate as indicated by the decrease of the amount of wool violet adsorbed on a saturated surface; (b) by determining the speed of exchange between radioactive bromide in solution and inactive bromide in the aging solid. This speed is governed by two factors: the specific surface and the degree of perfection of the precipitate. For this reason more comprehensive conclusions can be arrived at from the dye experiments.

For details regarding the radioactive experiments and the measurement of the wool violet adsorption reference is made to a previous paper.[3]

Experimental

Preparation of Silver Bromide and Study of Aging by the Dye Method.—The specific surface and other characteristics of the precipitate were found to depend upon the method of precipitation. By adopting a definite technique it was possible to obtain reproducible results. To weighed 120-ml. bottles each containing 25 ml. of 0.426 *M* silver nitrate and 0.5 ml. 0.1 *M* silver was added from a pipet in twenty-five seconds 25 ml. of 0.426 *M* potassium bromide. The bottles were swirled in a uniform manner during the precipitation of the 2.0 g. of silver bromide. The bottles were stoppered quickly, shaken vigorously by hand for fifteen seconds and the mother liquor which was 0.001 *N* in silver nitrate was decanted carefully. If the products were to be suspended in dilute silver nitrate solutions for aging, the precipitates were washed three times by decantation with 0.001 *M* silver nitrate. After completion of the washing the bottle was inverted carefully and allowed to drain, after which a convenient volume of aging solution was added. If the aging was to occur in dilute bromide solution, the precipitate was washed three times with water and once with 0.001 *M* bromide, and then it was treated as above. It was impossible to wash the fresh precipitate more than once with 0.001 *M* potassium bromide, as part of it would become peptized. After addition of the aging solution the bottles usually were placed on a mechanical shaker (200 phases per minute). After aging, a sufficient volume of a 0.1% wool violet solution was added to ensure a final dye concentration of 0.01 to 0.02% (saturated surface), and if necessary silver nitrate to give a final silver concentration of 0.001 *M*. The bottles were then replaced on the shaker for about one-half hour, weighed, and centrifuged until the supernatant liquids were perfectly clear. In an aliquot part of the latter, the dye concentration was determined with the aid of a photoelectric colorimeter and the amount of wool violet adsorbed per 1 g. of silver bromide calculated.

General Observations Regarding the Dye Adsorption.—Systematic investigations were carried out to determine the conditions under which the surface became saturated with wool violet. The results are given in a detailed and tabulated form in the thesis of the junior author[1]; they indicate that the surface was saturated when the silver concentration was greater than 0.0005 *M* and the final dye concentration greater than 0.030 g. per liter. The amount of dye adsorbed did not change upon shaking for longer than fifteen to thirty minutes, indicating that adsorption equilibrium was obtained quickly and that no further aging occurred after the precipitate was covered with the dye. In all of the experiments the dye adsorption was determined from a solution which was 0.001 *M* in silver nitrate. Independent of the age of the precipitate it was found that the amount of dye on the saturated surface from a dye solution which contained an excess of bromide was one-half of that from a dye solution containing silver.

Air-dried samples were prepared and kept at room temperature in the dark for a week. Five grams of such a product was exposed for fifteen minutes to direct sunlight, the product being stirred repeatedly during the exposure. The product was dark gray after fifteen minutes, but adsorbed the same amount of wool violet (excess of silver) as the pure yellow unexposed sample. A sample of the gray product was exposed to bromine vapor, the excess of which was removed by a current of air. The product became completely yellow again and adsorbed the same amount of wool violet as before. These experiments show that a photochemical decomposition of the silver bromide does not affect the dye adsorption on the surface.

Aging of Silver Bromide. Wool Violet Method

Aging in Excess of Silver.—Experiments were carried out in which the fresh precipitate after washing was aged by shaking in 0.001 *M* silver nitrate for various periods of time. The results are given in Table I and also on curve 1 in Fig. 1. Even the fresh precipitate settles rapidly in an excess of silver nitrate. Sets of experiments comparable to those in Table I were carried out in which the precipitate was centrifugally packed before the aging, or in which the aging was carried out in 0.01 *M* silver nitrate or in a mixture which was 0.001 *M* in silver and 0.2 *M* in potassium nitrate. The results were the same as given in Table I.

Several experiments were made in which dye was added immediately after precipitation without removing the mother liquor. In this way it was found that the fresh precipitate adsorbed 15.9–16.0 mg. wool violet per gram, corresponding to 13.9–14.0 × 10^{-5} equivalent of bromide in the surface of 1 g. This tremendous surface development corresponds to 2.6% of all the bromide in the surface.

Aging in Excess of Bromide (0.001 *M*).—The results of experiments carried out under different conditions are

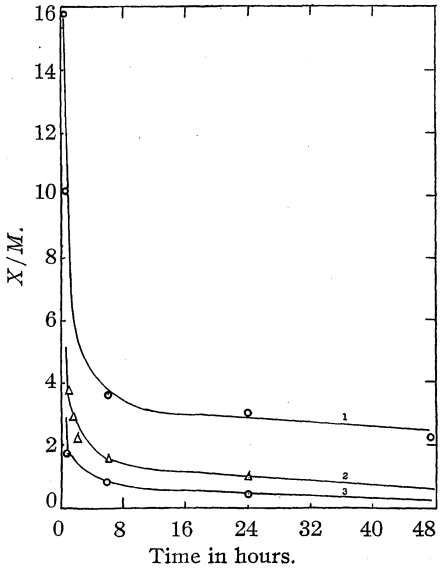

Fig. 1.—The aging of AgBr. Aging media: 1, 0.001 *M* $AgNO_3$; 2, 0.001 *M* KBr; 3, 0.001 *M* KBr, 0.2 *M* in KNO_3.

given in Table II; and some of them in Fig. 1. Comparison of Tables I and II (see also Fig. 1) shows that especially the initial speed of aging is much greater in 0.001 *M* bromide than in 0.001 *M* silver. It was of interest to study the effect of the silver and bromide concentration more systematically. In the first place experiments were carried out in which the fresh precipitate was aged in 0.1 *M* potassium bromide instead of 0.001 *M* solution. The fresh precipitate gave almost complete sol formation; after five minutes of shaking most of the precipitate had flocculated, while after fifteen minutes all of the precipitate settled rapidly. After this period of aging the precipitate was washed rapidly and the dye adsorption was determined in 0.001 *M* silver under standard conditions. The precipitate adsorbed 1.18 to 1.26 mg. of wool violet per gram, while after aging for the same period in 0.001 *M* bromide the dye adsorption amounted to 3.5 to 3.6 mg. per g. If we realize that the fresh precipitate adsorbs 16.0 mg. wool violet per gram the tremendously rapid aging in excess of bromide becomes very striking.

Experiments were performed using 2-g. portions of carefully prepared fifteen-minute old, and six-hour old precipitates of silver bromide prepared from 0.3 *M* solutions which were further aged at varying silver or bromide concentrations. The results are given in Table III.

Finally, a set of experiments was performed in the following manner. Silver bromide was precipitated from 0.426 *M* solutions as described previously. Immediately after precipitation the *p*Ag was adjusted to definite values (silver electrode in suspension) and kept as constant as possible. After aging for fifteen minutes silver nitrate was added to give a *p*Ag of 3 and the adsorption of wool violet determined. The results are given in Table IV.

TABLE IV

AGING OF FRESH PRECIPITATE FOR FIFTEEN MINUTES AT VARYING *p*Ag(*p*Br)

*p*Ag during aging	2	3	4	5	6	7	8	9
Wool violet adsorbed in mg. per g.	11.7	11.7	8.8	5.9	5.0	3.9	3.0–3.1	2.5

At a *p*Ag smaller than 3 the speed of aging did not further decrease, but with increasing *p*Ag the rate of aging increased rapidly. The isoelectric point of fresh silver bromide was found to be located close to a *p*Ag of 5, while the equivalence point is located close to a *p*Ag of 6. At

values of pAg smaller than about 5 the precipitate contains adsorbed bromide.

Aging in Other Media.—In order to investigate the effect of the solubility of silver bromide in the aging medium, studies were made in which the fresh precipitate was kept suspended in various solvents. The results are given in Table V and graphically in Fig. 2. From the curves,

TABLE V

AGING OF SILVER BROMIDE IN VARIOUS MEDIA

Aging medium	Time of aging, hr.	Wool violet removed, %	Wool violet adsorbed in mg. per g.
0.001 M $AgNO_3$ in 1 M NH_3	1	1	<0.1
.001 M $AgNO_3$ in 1 M NH_3	6	0	< .1
.001 M $AgNO_3$ in 99%	1	47	7.0
ethanol	6	27	4.1
Benzene	20	25	2.5

it is seen that the speed of aging is of the same order in 0.001 M silver nitrate in water as in benzene. This made us suspect that under certain conditions the nature of the solvent did not play a part and that we were dealing with a thermal aging of the solid. In order to substantiate this conclusion, fresh samples of the precipitate were washed with water, ethanol and ether, after which air was drawn through until the odor of ether was no longer perceptible. Samples were then allowed to stand in dry bottles in a desiccator protected from light for given periods of time, after which the wool violet adsorption was determined. A comparison of the figures in Tables I and VI (see also curves 1 and 4 in Fig. 2) reveals that the surface decreases at about the same speed when the precipitate is kept in the dry state as when it is suspended in 0.001 M silver nitrate. It is to be expected that the speed of thermal aging will increase greatly with increasing temperature. Experiments were carried out, therefore, in which the precipitate was aged in dry bottles containing a trace of bromine vapor at 100°. The bromine was added to prevent the auto-decomposition of the fresh precipitate at 100°. When the latter was heated to 100°, in the dark a trace of bromine was developed and the surface became dark. When heated in the presence of a trace of bromine vapor the color of the precipitate did not change. After the heating, the samples were cooled and the trace of bromine was removed with a current of air before determining the adsorption of wool violet.

TABLE VI

AGING OF SILVER BROMIDE IN THE DRY STATE

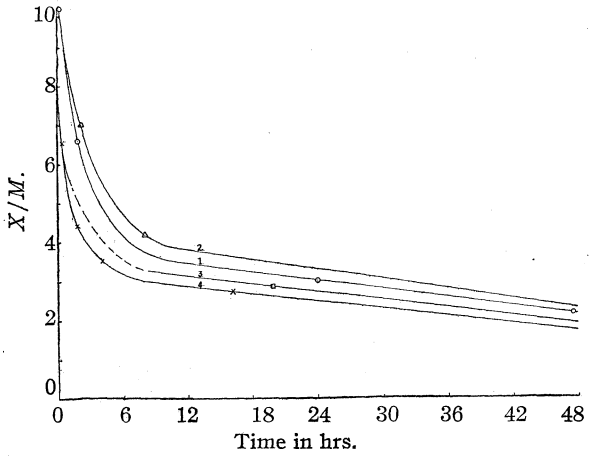

Fig. 2.—Aging of silver bromide. Aging media: 1, 0.001 N $AgNO_3$ water; 2, 0.001 N $AgNO_3$ ethanol; 3, benzene; 4, air dried.

Qualitatively, the coarsening and perfection of the particles when aged in the dry state at room temperature can be shown by a decrease of the peptizability. When a 0.7-g. portion of the fresh air-dried product was shaken with 100 ml. of 0.01 M potassium bromide in a glass-stoppered graduated cylinder, about 80 to 90% of the solid settled out immediately; nevertheless the supernatant liquid consisted of an opaque yellow sol. When the solid was aged for twenty hours at room temperature the supernatant liquid obtained on shaking was only slightly turbid, while after aging for three months in the dry state none of the precipitate could be peptized in 0.01 M bromide.

Aging Studied by the Radioactive Method.—The speed of penetration of radioactive bromide when a solution of the latter was shaken with the solid was determined. Details regarding the experimental technique are given in a previous paper[3] and the thesis of the junior author.[1] Several 0.094-g. samples of silver bromide were prepared by adding 5 ml. of 0.102 M potassium bromide to 5 ml. of 0.1 M silver nitrate. Immediately after precipitation 10 ml. of a radioactive bromide solution of known composition was added and the mixture shaken for a given period of time. From the known activity and the bromide concentration of the mixture (0.0015 M) the number of equivalents of bromide ions exchanged per gram of silver bromide was calculated. The results are given in Table VII and in curve 1 of Fig. 3.

TABLE VII

SPEED OF PENETRATION OF RADIOACTIVE BROMIDE INTO FRESH SILVER BROMIDE

Time of shaking with Br,*[a] hr.	0.094-g. sample in 0.0015 M KBr		0.47 g. sample in 0.1 M KBr

4	93.0	696	63.0	725

[a] The asterisk denotes radioactive bromide.

[b] 1 g. AgBr contains 5.33 milliequivalents of bromide.

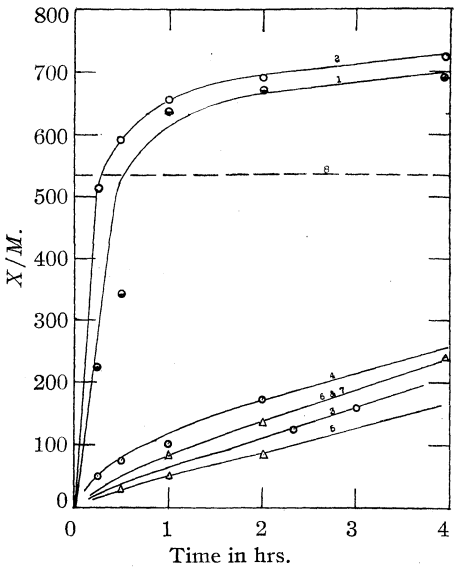

Fig. 3.—The rate of penetration of radioactive bromide ions in various AgBr precipitates: 1 and 2, fresh AgBr; 3, AgBr aged 2 hours in 0.001 *M* $AgNO_3$; 4, AgBr aged 2 hours in 0.001 *M* KBr; 5, AgBr aged 2 hours in 0.001 *M* KBr, 0.2 *M* in KNO_3; 6 and 7, fresh AgBr, with gelatin coating; 8, equilibrium value.

Another set of experiments was carried out with 0.47-g. samples which were washed quickly and shaken with 20 ml. of a radioactive solution which was 0.1 *M* in bromide (curve 2, Fig. 3). One gram of silver bromide contains 533 $\times 10^{-5}$ equivalent of bromide per gram, indicated by the dotted line in Fig. 3. Both fresh precipitates apparently are subject to very rapid recrystallizations. Within an hour of shaking the apparent amount of exchanged bromide is found greater than 100%, indicating the heterogeneous distribution of the active bromide through the precipitate during the early stages of aging. It is to be expected that the curves would show a maximum value after a longer time of shaking and then slowly would approach the point corresponding to homogeneous distribution of the radioactive bromide. The speed of penetration decreases very rapidly upon aging of the precipitate. Curve 3 of Fig. 3 (see also Table VIII) gives the time–penetration curve after aging of the precipitate represented by curve one for two hours in 0.001 *M* silver nitrate. Curve 4 of Fig. 3 refers to a precipitate (prepared as that of curve 1) which had been aged by shaking for two hours in 10 ml. of 0.0C *M* potassium bromide. At the end of this period 0.2 g potassium nitrate and 10 ml. of a radioactive bromid solution were added and the speed of penetration was deter mined.

TABLE VIII

SPEED OF PENETRATION OF RADIOACTIVE BROMIDE INTO SILVER BROMIDE AGED FOR 2 HOURS

Time of shaking with Br,* hr.	Aged in 0.001 *M* $AgNO_3$	Aged in 0.001 *M* KBr	Aged in 0.001 *M* KBr + 0.2 g. of KNO_3
1/4		46	19
1/3	33		
1/2		61	38
1		101	56
2	121 (2 1/3 hrs.)	178	88
3	165		

A similar experiment was carried out in which the agin occurred in 0.001 *M* potassium bromide containing th potassium nitrate (curve 5, Fig. 3). The aging is found t be more pronounced in the presence of potassium nitrate a result in agreement with that obtained from the experi ments with wool violet.

Speed of Penetration in the Presence of Gelatin.—In a previous paper[3] it was shown that adsorbed gelatin pre vented or at least inhibited the penetration of radioactive bromide into aged silver bromide and that, practically speaking, only exchange with bromide ions in the surface layer occurred. The following experiments show that gelatin inhibits but does not prevent the penetration of radioactive bromide into fresh silver bromide when the latter is shaken with a solution of the former. Samples of precipitates (0.094 g.) were prepared from 0.1 *M* solution (excess of Br 0.001 *M*). Immediately after precipitation 10 mg. of gelatin dissolved in 4 ml. 0.001 *M* bromide was added and the bottle shaken for ten minutes. Ten ml. of r. a. bromide solution (0.0039 *M* in bromide) was added and the mixture shaken. Similar experiments were carried out with 1 mg. instead of 10 mg. of gelatin. The number of equivalents of Br exchanged $\times 10^5$ in the presence of 10 mg. of gelatin were 85, 135, and 244 after one, two, and four hours of shaking, and in the presence of 1 mg. of gelatin 98 and 164 after one and three hours of shaking. From these results and the curves 6 and 7 in Fig. 3 it is evident that adsorbed gelatin does not prevent the recrystallization and perfection of fresh silver bromide. It is of interest to mention that the effect of 10 mg. of gelatin was found to be the same as that of 1 mg.

Discussion

1. The speed of aging in 0.001 *M* bromide was found to be much greater than in 0.001 *M* silver nitrate, it increased with increasing bromide concentrations, but increasing concentration of silver was of no further consequence. The great effect of an excess of bromide is attributed to an adsorption of this ion which gives rise to the formation of argento bromide ions in the liquid film around the particles, resulting in an increased solubility and speed of recrystallization of silver bromide in the liquid jackets.[4] The rate of aging in an excess of silver was not found to be affected by the presence of potassium nitrate by shaking and by other factors. On the other hand, shaking and the presence of salt had a distinct effect upon the aging in an excess of bromide (see Table II and Fig. 1). This is attributed by us to a colloidal solution. Upon longer periods of aging, the suspensions which had been shaken had aged

(4) Compare I. M. Kolthoff and H. C. Yutzy, THIS JOURNAL, **59**, 1634 (1937).

more than those which had been allowed to stand. This effect is easily explained by an Ostwald ripening which will be much more rapid in the shaken than in the unshaken suspension. The aging in excess of bromide was strongly promoted by the presence of potassium nitrate in a concentration of 0.2 *M*. The salt flocculates the sol, the number of particles in an agglomerate being dependent upon the concentration and kind of flocculating electrolyte. It seems to us that another factor, namely, the distance of approach of the particles in the agglomerate may be of primary importance in connection with the aging. When the particles are close together less recrystallization is necessary to cause cementing than when the particles are farther apart. We have indication that the distance of approach becomes smaller with increasing concentration of flocculating electrolyte and with increasing flocculating power. In order to test this point, experiments were carried out in which to the fresh suspension of silver bromide in 0.001 *M* potassium bromide, aluminum nitrate was added in a concentration of 0.0004 *M* and 0.001 *M*, respectively. After half an hour of shaking followed by removal of the aluminum the amount of wool violet adsorbed per gram was 1.9 mg. (0.0004 *M* Al) and 1.5 mg. (0.001 *M*), respectively, while in the absence of aluminum this amount was 2.8 to 2.9 mg.

2. An increase of the solubility of the precipitate by the addition of ammonia increases the rate of aging. The most striking result of this study is that, when the solubility has reached a minimum value, the rate of aging no longer depends upon the solubility of the precipitate in the aging medium. Then, it was found that the rate of aging was practically equal in aqueous and ethanolic 0.001 *M* silver nitrate, in pure benzene, and in the air-dried state. Apparently, under the latter conditions the aging cannot occur by recrystallization by way of solution but in the solid itself. Fresh products of silver bromide are extremely imperfect and have a tremendous surface development (2–3% is surface), and, consequently, they have a very large active surface. Silver bromide molecules located on the latter are much richer in energy than those on normal surface which in turn are richer in energy than those within the lattice. The thermal mobility of well-aged silver bromide is very small but that of our fresh products is quite pronounced. This is substantiated by the following experiments.[5] When fresh air-dried silver bromide is shaken with a solution of radioactive bromine in ethyl bromide or with anhydrous vapors of r. a. bromine, a rapid exchange between the radioactive bromine and the inactive bromide in the silver bromide occurs, resulting in a heterogeneous distribution of the active constituent through the solid. The speed of exchange decreased rapidly with increasing age of the precipitate.

Moreover, we found that fresh silver bromide has a relatively large electrical conductivity which, partly at least, is ionic. The properties of fresh bromide seem to be quite abnormal and it is planned to study the physical and also the chemical properties of such products in greater detail in the near future.

Summary

1. The rate of aging of silver bromide is much greater in a medium containing an excess of bromide than of silver, and it increases with the bromide concentration of the solution.

2. The colloidal state of the precipitate in an excess of bromide is of importance with regard to the speed of aging.

3. The effect of shaking upon aging indicates that upon longer periods of aging in a liquid medium of suitable solving power a slight Ostwald ripening occurs.

4. Adsorbed gelatin does not prevent the penetration of radioactive bromide into fresh silver bromide.

5. When the solubility of the silver bromide in the aging medium has reached a minimum value, recrystallization by way of solution becomes of no consequence. It is shown that fresh silver bromide is subject to a rapid thermal aging in the dry state, even at room temperature.

Ionization Constants and Hydrolytic Degradations of Cyameluric and Hydromelonic Acids

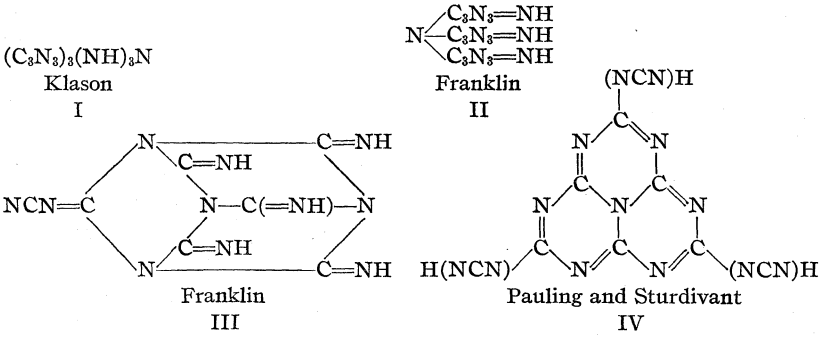
BY C. E. REDEMANN AND H. J. LUCAS

Recently the question of the structure of cyameluric and hydromelonic acids has been reopened by Pauling and Sturdivant.[1] It is rather surprising that cyameluric acid and related compounds, for example melon, melam, melem, and hydromelonic acid, should have received so little attention at the hands of organic chemists. With the exception of a limited amount of work by E. C. Franklin[2] and students, the problems in this field have been neglected for many years. Since most of these compounds are insoluble both in organic solvents and in water, show neither melting nor boiling points, are inert chemically with the exception that they undergo hydrolytic cleavage, and do not yield derivatives which are readily identified, it is probable that the reasons for this neglect bear some relation to their physical and chemical properties.

Tripotassium melonate, the potassium salt of hydromelonic acid, first described by Gmelin[3] as an undesirable by-product when too high a temperature was used in the preparation of potassium thiocyanate by the fusion of sulfur, potassium ferrocyanide and potassium carbonate, was obtained also by Liebig, who dissolved melon in fused potassium thiocyanate.[4,5] Potassium melonate is formed also by heating antimony or bismuth trichloride with potassium thiocyanate. As the result of numerous careful analyses of potassium and silver melonate, Liebig[6] proposed the empirical formula $C_9H_3N_{13}$[7] for hydromelonic[8] acid. Attempts to prepare the pure acid have not been entirely successful due to the great tendency of the acid to polymerize in concentrated aqueous solution.

Cyameluric acid is probably the most important of the compounds discussed in this paper since its nucleus appears to be common to most members of the series. Potassium cyamelurate is formed by the alkaline hydrolysis of melon, or of potassium melonate.[5] When the potassium salt is acidified with a strong acid, sparingly soluble cyameluric acid separates. Henneberg named the acid and assigned to it the formula $H_3C_6O_3N_7$ on the basis of analyses of the salts and of the acid. It seems probable that Liebig[6] was the first to prepare this acid, but he was unable to obtain constant analyses for his product, probably because he recrystallized the acid from a hot hydrochloric acid solution, a procedure now known to cause rapid hydrolysis.

Structures of Hydromelonic Acid.—Only four structures have been proposed



Structure I was proposed by Klason[8] in 1886, and II by Franklin[2a] in 1922. The latter appears to be nothing more than an interpretation of the former. His second structure,[9] III, proposed in 1935, is essentially the structure of hexamethylenetetramine in which three of the six pairs of hydrogen atoms are replaced by the cyanimino group, (=NCN), and the other three by the imino group, (=NH). Structure IV, proposed by Pauling and Sturdivant[1] in 1937, is based upon their belief that hydromelonic acid, $C_6N_7(NCNH)_3$, bears to cyameluric acid, $C_6N_7(OH)_3$, the same relation that

(7) Actually $C_{18}H_3N_{18}$ on the basis of the atomic weights of that time.

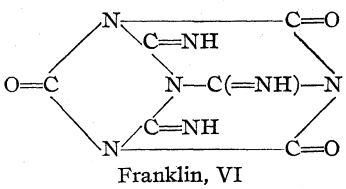
(8) The name was assigned by Gmelin on the basis that the polymer was converted to melon by loss of water when heated, hence the acid was thought to be a hydrate of melon. Klason, *J. prakt. Chem.*, [2] **33**, 289 (1886), called this compound cyamelon, under which name some of the literature appears.

(9) E. C. Franklin, "The Nitrogen System of Compounds," The Reinhold Publishing Corp., New York, 1935, p. 107.

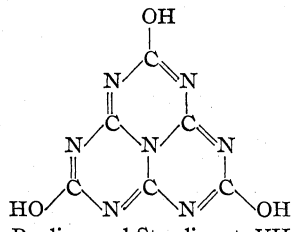
cyanuric tricyanamide, $C_3N_3(NCNH)_3$, bears to cyanuric acid, $C_3N_3(OH)_3$. The planar cyameluric nucleus is shown to have, according to quantum mechanical calculations, a high degree of stability. The stabilization due to resonance is approximately 150 kcal. per mole.

Structures of Cyameluric Acid.—Only three structures have been proposed for cyameluric acid

$(CN)_6O(NH)(OH)_2$
Klason, V



Franklin, VI



Pauling and Sturdivant, VII

Structure V, proposed by Klason,[8] was thought by him to represent the anhydride of an acid having the formula $(HO)_2(CN)_3NH(CN)_3(OH)_2$ (VIII). In structure VI, proposed by Franklin, the central group of atoms has the hexamethylene arrangement as in the hydromelonic acid structure proposed by him, III, and in structure VII, proposed by Pauling and Sturdivant, this group has the planar cyameluric arrangement, as in their structure for hydromelonic acid, IV.

Hydrolytic Degradations

If hydromelonic acid is correctly represented by Structure I or II, then on hydrolysis to cyameluric acid of structure V (the anhydride of VIII), one mole of I or II should yield approximately one mole of cyanuric acid, one mole of cyameluric acid, three moles of ammonia and no carbon dioxide on the assumption that the C_3N_3 groups represent cyanuric acid nuclei and that the cyanuric and cyameluric acids undergo no further hydrolysis. Cyameluric acid of structure V on further hydrolysis should be capable of yielding two moles of cyanuric acid, since in the acid VIII, of which V is the anhydride, there are two C_3N_3 nuclei.

On the other hand, if hydromelonic acid is either III or IV, on hydrolysis to cyameluric acid of structure VI or VII, respectively, one mole should yield not more than one mole of cyameluric acid and at the same time, six equivalents each of ammonia and carbon dioxide. Further hydrolysis of cyameluric acid should yield not more than one mole of cyanuric acid and, at the same time, four equivalents of ammonia and six equivalents of carbon dioxide if converted to cyanuric acid. Actually Liebig[6] isolated from the alkaline hydrolysis of cyameluric acid ammeline, ammelide, and cyanuric acid by progressively increasing the duration of hydrolysis.

Hydromelonic Acid.—When potassium melonate was hydrolyzed in 6 *N* nitric acid, 0.72 mole of cyanuric acid per mole of potassium melonate in the form of the insoluble cupric ammonium salt was obtained. Some hydrolysis of cyanuric acid took place at the same time. When hydrolyzed under alkaline conditions, the ratio of equivalents of carbon dioxide to those of ammonia varied from 1.25 to 1.11 (Table I). Even when hydrolysis was only a fraction of that possible, the $CO_2/2NH_3$ ratio was greater than unity. If hydromelonic acid had structure I or II, this ratio presumably would be below unity at the beginning of the hydrolysis, because carbon dioxide could come only from the breakdown of a C_3N_3 nucleus which is quite stable to further hydrolysis. Since

TABLE I

ALKALINE HYDROLYSIS OF POTASSIUM MELONATE

Sample, g.	KOH, *N*	Time, hrs.	NH_3 equiv.	CO_2 equiv.	Ratio $CO_2/2NH_3$	Extent of hydrolysis,[a] %
0.6531	5.45	1	0.00151	0.00188	1.25	15.7
1.6319	6.0	2	.01796	.02091	1.17	74.7
2.0526	3.5	2	.01464	.01628	1.11	59.3
2.5338	3.7	4	.0328	.0376	1.14	107

[a] Expressed as percentage of theoretical amount of ammonia, on the basis of structure III or IV, if the hydrolysis stopped at cyameluric acid.

potassium cyamelurate, under these conditions, was found to yield carbon dioxide and ammonia in the ratio of 2.24 (equivalents), the deviation from unity in the case of potassium melonate can be ascribed to the partial hydrolysis of the cyamelurate formed. The deviation from the ratio $^6/_4$ in the case of the latter compound probably is due to the formation of ammeline and ammelide, giving theoretical ratios of 3 and 2, respectively. Thus, the data from both acid and alkaline hydrolysis of hydromelonic acid favor structures III and IV over I and II. The hydrolysis is probably best represented by the equation

$$K_3C_9N_{13} + 6KOH + 6H_2O \longrightarrow K_3C_6O_3N_7 + 6NH_3 + 3K_2CO_3$$

Henneberg[5] attempted to write an equation expressing this hydrolysis involving ammelide as one of the products and omitting carbonate.

Cyameluric Acid.—Hydrolysis at 100° in concentrated nitric acid, conditions under which cyanuric acid is attacked but slowly, yielded 0.935 mole of cyanuric acid per mole of cyameluric acid. These results show that cyameluric acid may be represented by either structure VI or structure VII, for only one mole of cyanuric acid would result, but not by structure V, for two moles of cyanuric acid should result if the acid has the last structure.

Ionization Constants of the Acids

On the basis of the Franklin structures III and VI, the two respective acids, hydromelonic and cyameluric, should resemble each other closely as regards their acid strengths, because the atomic groupings responsible for acidity are identical in the two cases, and the groups responsible for the difference in structure, *i. e.*, C=NCN and C=O, respectively, are somewhat remote from the acid groups. Since the inductive effect of each of these two groups, before it can have an influence upon the acidic imino group, must pass through a tertiary nitrogen atom and a double bond, each of which alone has a pronounced damping effect upon induction, the acid strengths of III and VI would be expected to be similar. On the other hand, on the basis of the Pauling and Sturdivant structures, hydromelonic acid IV would be expected to be a much stronger acid than cyameluric acid VII. The hydromelonate ion, $C_9N_{13}^{\equiv}$, should have a much higher stability with respect to hydromelonic acid, $H_3C_9N_{13}$, than cyamelurate ion, $C_6O_3N_7^{\equiv}$, has with respect to cyameluric acid, $H_3C_6O_3N_7$. This is due to the fact that in the former case there are additional structures among which resonance can take place, for in the group of atoms IX, $(CNCN)^-$, the negative charge may be on either of the two nitrogen atoms as shown by X $\left(C—\ddot{\bar{N}}—C\equiv N:\right)$ and XI $\left(C—\ddot{N}=C=\bar{N}:\right)$. Since there are three such groups in the hydromelonate ion, the multiplicity of forms is markedly enhanced in comparison to the forms of the free acid, in which this additional type of resonance is not so important. Thus, from structural considerations, one would expect hydromelonic acid to be much stronger than cyameluric acid on the basis of the Pauling and Sturdivant structures, and to be little if any stronger on the basis of the Franklin structures.

Moreover, as Pauling and Sturdivant have pointed out, hydromelonic acid (IV) would bear the same relationship to cyameluric acid, VII that tricyanomelamine bears to cyanuric acid Tricyanomelamine is such a strong acid that the constant cannot be determined by conductimetric methods,[10] thus approaching the strong mineral acids in strength, whereas cyanuric acid is a weak acid.

The apparent ionization constants of hydromelonic, cyameluric and cyanuric acids were determined by titration of the potassium salts with standard hydrochloric acid, using a glass electrode to measure the *p*H. The solubility of the acids is too low to permit of their use for making titration curves and, in addition, hydromelonic acid polymerizes irreversibly. The cyanuric acid curve was made for the purpose of comparison. From the titration curves, apparent ionization constants were estimated for the acids by taking the *p*H at the "half-neutralization" points. These approximate values for the apparent ionization constants were then adjusted until the calculated titration curves fitted the observed curves very accurately. In this way a value of 1.66×10^{-7} was found for the first ionization constant of cyanuric acid, a value which is in fairly good agreement with that of 1.8×10^{-7} found by Hantzsch[11] but in poor agreement with that of 3.8×10^{-7}, found by Bader.[12]

The curves for the titrations are shown in Fig. 1 and the values for the ionization constants of hydromelonic and cyameluric acids are listed in Table II. Those for the second ionization constant of hydromelonic and the first ionization constant of cyameluric acid are approximations only, because of the separation of a solid phase in the titration shortly before the respective "half-neutralization" points were reached. On this account the assumed values of these two constants, which have been adjusted so as to fit the remainder of the respective curves, are subject to some error.

TABLE II

IONIZATION CONSTANTS

	Hydromelonic acid	Cyameluric acid	Cyanuric acid
K_1	Large	*Ca.* 1.0×10^{-3}	1.66×10^{-7}
K_2	*Ca.* 3.16×10^{-3}	6.30×10^{-7}	
K_3	1.26×10^{-5}	1.12×10^{-9}	

Hydromelonic acid is a much stronger acid than cyameluric, as the curves and table show. These results favor structures IV and VII of Pauling and

(10) Madelung and Kern, *Ann.*, **427**, 26 (1922).
(11) Hantzsch, *Ber.*, **39**, 139 (1906).
(12) Bader, *Z. physik. Chem.*, **6**, 289 (1890).

Sturdivant for these acids. That the cyameluric nucleus is strongly electronegative is shown by the comparison of ionization constants in Table III.

TABLE III

COMPARISON OF IONIZATION CONSTANTS

	K_A		K_A
Hydromelonic acid	Large	Cyameluric acid	1×10^{-3}
Benzoylcyanamide[12]	1.86×10^{-2}	Benzoic acid	6×10^{-5}
Acetylcyanamide[12]	1.54×10^{-4}	Acetic acid	1.6×10^{-5}

In the first column, the common radical is the substituted cyanamino group, H(NCN)[13] and in the second, the OH group.

In a subsequent communication the results of attempts to prepare derivatives of cyameluric acid will be presented. The authors gratefully acknowledge the inspiration of Professor Linus Pauling, who suggested the investigation of cyameluric and hydromelonic acids.

Experimental

Melon.—The following procedure based upon that of Henneberg[5] was most satisfactory. Chlorine gas was passed into a vigorously stirred solution of 1 kg. (12.3 moles) of pure[14] sodium thiocyanate in 2.5 liters of water. The temperature was maintained below 70–80° by external cooling. When the mixture became so thick that stirring was no longer effective, it was cooled to room temperature, the sludge of "pseudothiocyanogen"[15] was filtered off and the filtrate was treated again with additional chlorine. This process was repeated until no further pseudothiocyanogen was formed. The combined precipitate of pseudothiocyanogen was well washed with boiling water to remove all soluble salts, then dried at 120°, giving 512 g. of product.

The 512 g. of pseudothiocyanogen, divided into two batches, was converted into melon by heating in 25-cm. porcelain evaporating dishes with a large brush flame from a Meker type burner until all volatile products were expelled. The light yellow residue of crude melon weighed 240 g.

Other methods of preparing melon were less satisfactory on a laboratory scale. The slow heating of ammonium thiocyanate is reported to give good yields[16] but requires special equipment and much time.

Potassium Melonate.—The following modification of Liebig's[4b] method was most satisfactory. Eighty grams of pure potassium thiocyanate was slowly melted in a 10-cm. porcelain casserole and held at a moderate temperature until all moisture was expelled and a quiet melt was obtained. The temperature was then increased to a dull red heat and 40 g. of melon was added in portions of 5 to 10 g., each portion being allowed to dissolve before another was added. The carbon disulfide which is evolved was allowed to burn. When all the melon had dissolved the mixture was heated more strongly until only very little more carbon disulfide was produced. At this point a few drops of the melt were removed on the end of a Pyrex rod and its solubility[17] in hot water tested. Heating was continued until a 0.1 to 0.2 g. portion of the salt was completely soluble in 5 ml. of hot water. The entire operation required approximately one-half hour. After cooling, the salt was ground into coarse particles, dissolved in hot water, decolorized with carbon, filtered and allowed to cool. The fine felted needles, when air dried, weighed 38.8 g. Repeated crystallization gave a snow-white product.

Liebig's method using potassium thiocyanate and antimony trichloride gave a product which was hard to free from antimony salts.

Sodium Melonate.—Burdick[2b] prepared this salt by heating sodium thiocyanate with antimony trichloride. By dissolving 26 g. of melon in 50 g. of fused sodium thiocyanate, 11 g. of pure white fine needle crystals of sodium melonate was obtained. The sodium salt is very similar in appearance to and less soluble than the potassium salt.

Potassium Cyamelurate.—Two methods, both suggested by Henneberg,[5] were used.

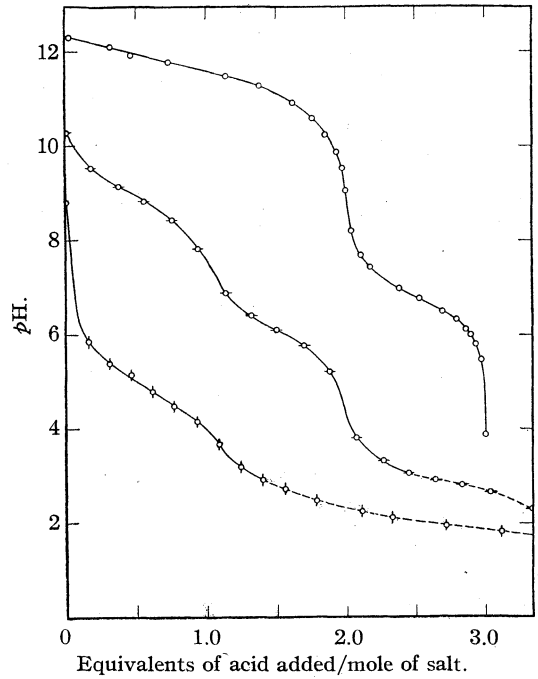


Fig. 1.—○, Cyanuric acid; -○-, cyameluric acid; ◌, hydromelonic acid; – – –, solid separating out.

(13) Madelung and Kern[10] believe that the group present in tricyanomelamine is —NH—C≡N, and not —N=C=NH. However, resonance between these two structures would be expected, and Dr. E. W. Hughes has verified this for the group in the molecule of dicyandiamide (private communication).

(14) A crude grade of sodium thiocyanate prepared by dissolving sulfur in fused sodium cyanide gave only slightly smaller yields.

(15) The name "pseudothiocyanogen" is here applied to the crude mixture composed of isoperthiocyanic acid, kanarin, and various polymers of isoperthiocyanic acid obtained by this procedure instead of to the part insoluble in alkali.

(16) Gludd, Keller and Klempt, *Z. angew. Chem.*, **39**, 1071 (1926).

(17) The test for solubility is very essential, for if heating has been for too short a time or at too low a temperature an insoluble product is formed.

A.—A solution of 20 g. (0.04 mole) of hydrated potassium melonate in 80 ml. of 4 *N* potassium hydroxide solution was boiled under reflux for two hours. A crop of slightly colored crystals of potassium cyamelurate was filtered off after cooling, and a second crop after concentrating the filtrate to one-third its initial volume. The two crops of crystals were washed with alcohol and air-dried; weight 11 g. or 70%. Crystallization from a hot moderately dilute solution with generous use of decolorizing carbon yielded pure white stout needles.

B.—A suspension of 30 g. of crude melon was boiled with 300 ml. of 3 *N* potassium hydroxide for forty-five minutes and the undissolved solid was filtered out. The crystals which separated from the filtrate were filtered off, washed with alcohol and air-dried. Boiling the original undissolved solid with the last filtrate and proceeding as above gave an additional amount. The total weight of potassium cyamelurate was 23 g.

Sodium Cyamelurate.—This salt, which was mentioned casually by Henneberg, is easily prepared in the same manner as the potassium salt by substituting 4 *N* sodium hydroxide for the potassium hydroxide in method (A) above. The yield is 50 to 60% of the theoretical assuming structure (IV) for hydromelonic acid and (VII) for cyameluric acid.

Anal. Calcd. for $Na_3O_3C_6N_7 \cdot 5^1/_2H_2O$: Na, 17.8; H_2O, 25.6. Found: Na, 17.7, 17.8; H_2O, 25.3, 25.4.

Cyameluric Acid.—Acidification of a moderately dilute aqueous solution of the sodium or potassium salt with 6 *N* hydrochloric acid added very slowly from a buret with effective stirring, followed by chilling in an ice-bath, gave a white crystalline powder. This was filtered off, washed well with cold water and air-dried.

Anal. Calcd. for $C_6H_3O_3N_7 \cdot 3H_2O$: C, 26.17; H, 3.27. Found: C, 25.88; H, 3.24.

Precipitation from a hot solution yields an impure product due to the rapid hydrolysis of cyameluric acid to ammelide and ammeline in acid solution. Crystallization from boiling water causes considerable decomposition due to the low *p*H of the solution of this comparatively strong acid.

The acid does not reduce alkaline permanganate either in the cold or upon prolonged boiling; it gives no enol reaction with ferric chloride. Most of its metallic salts are very sparingly soluble.

Acid Hydrolysis of Hydromelonic Acid.—A solution of 2.231 g. of potassium melonate in an excess of 6 *N* nitric acid was gently boiled for one and one-half hours. The solution was made alkaline with a slight excess of 15 *N* ammonium hydroxide, then sufficient cupric ammonium sulfate solution was added to color the solution a dark blue. The amethyst-red precipitate which gradually separated was filtered off, dried and weighed; weight 0.454 g. (72.5% of theoretical, assuming one mole of cyanuric acid per mole of hydromelonic acid).

The Alkaline Hydrolysis of Potassium Melonate.—A series of quantitative determinations of the amount of ammonia and carbon dioxide produced in the hydrolysis of potassium melonate to potassium cyamelurate was made as follows. The ammonia was carried over into standard hydrochloric acid by a current of purified air. The excess acid was then titrated with a standard sodium hydroxide solution using the mixed indicator, *p*-nitrophenol—methyl red. The amount of carbonate formed was determined by the method of Winkler as follows. The alkaline solution in the boiler was diluted to 250 ml., then an aliquot portion was taken. An excess of barium chloride solution was added to the aliquot, then the sodium hydroxide was carefully titrated with a standard hydrochloric acid solution using phenolphthalein as indicator. The data thus obtained are given in Table I.

As a check on the method, potassium melonate was replaced by urea. In this case the ratio of equiv. CO_2/equiv. NH_3 was 1.03. The difference between 1.03 and 1.00 represents about the accuracy to be expected from this method of analysis.

When potassium cyamelurate replaced potassium melonate, 2.24 was the ratio of equiv. CO_2/equiv. NH_3. This would indicate that the cause of a ratio greater than unity in the case of the hydrolysis of potassium melonate is a further hydrolysis of the potassium cyamelurate.

Acid Hydrolysis of Cyameluric Acid.—Two grams of cyameluric acid, purified through the copper ammonium salt, was digested with 10 ml. of concd. nitric acid on a steam-bath for four hours. The solution was diluted to 20 ml., cooled to 0°, saturated with the oxides of nitrogen obtained from the action of concd. nitric acid on metallic copper in order to destroy ammonium ions and make sure that all —NH_2 groups were converted into —OH groups, and evaporated to dryness on a water-bath. The residue was washed onto a weighed Gooch crucible, using 18 ml. of water, dried and weighed; weight 0.975 g. This represents 93.5% of that theoretically obtainable assuming one mole of cyanuric acid per mole of cyameluric acid. The residue gave the characteristic insoluble amethyst-colored copper ammonium salt of cyanuric acid.[18]

Electrometric Titrations of Hydromelonic and Cyameluric Acids.—Potassium melonate, 0.3707 g. (7.45×10^{-4} mole) crystallized four times from water, was dissolved in 50 ml. of water. Potassium cyamelurate, 0.2576 g. (6.62×10^{-4} mole) thrice crystallized from water, was dissolved in 50 ml. of water. In each solution was placed a glass electrode, a standard calomel electrode, and a mechanical stirrer. The former was titrated with 0.2899 *N*, the latter with 0.2493 *N* hydrochloric acid. The e. m. f. measurements were made with a student type potentiometer and a high sensitivity galvanometer in the former case, and with a Beckman *p*H meter in the latter case. Conversion to *p*H values in the former case was made by comparison with standard buffer solutions. The results are shown as the curves in Fig. 1.

Summary

Improved methods have been described for the preparation of melon, potassium and sodium melonate, potassium and sodium cyamelurate, and cyameluric acid. Titration of potassium melonate and cyamelurate, using the glass electrode, shows that hydromelonic acid is much stronger than cyameluric acid.

The titration data and results of hydrolysis

indicate that the molecules of these two acids contain the planar cyameluric nucleus of Pauling and Sturdivant.

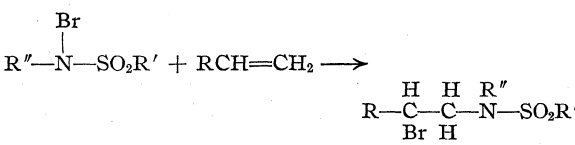
The Addition of N-Haloamides to Olefins

BY M. S. KHARASCH AND HILL M. PRIESTLEY

An unsuccessful attempt to add N-haloamides to olefins is recorded by Seliwanoff.[1] Foldi,[2] however, showed that 1-phenylpropene and N-bromo-N-methylbenzenesulfonamide ($C_6H_5SO_2NBrCH_3$) react to give at least two addition isomers. The reaction was considered by Földi to be of limited applicability, since all the purely aliphatic olefins tried by him yielded the dibromo derivatives when treated with the N-bromo-N-methylbenzenesulfonamide.

We have succeeded in extending this interesting reaction to include aliphatic olefins such as propene, 2-methylpropene, and vinyl chloride, as well as styrene. We have also demonstrated that in the reaction



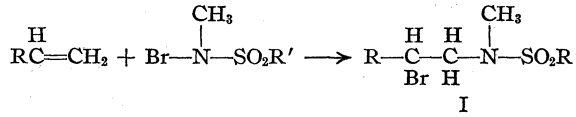
the radicals R, R′ and R″ play only a minor part, since we have employed in these reactions with equal success the phenyl-, *p*-tolyl-, and benzylsulfonyl derivatives of methylamine, benzylamine, phenethylamine, and β-bromo-α-phenylethylamine.

The addition of the bromo derivatives of the sulfonamides to olefins appears to be a unique reaction. We have been unable to obtain addition products of olefins with the following N-bromo-compounds: N-bromobenzamide, N-bromo-N-methylbenzamide, N-bromo-N-methyl-N-carbobenzoxamine, N-bromo-triphenylmethylamine, N-bromosaccharine, N-bromophthalimide, and N-bromosuccinimide.

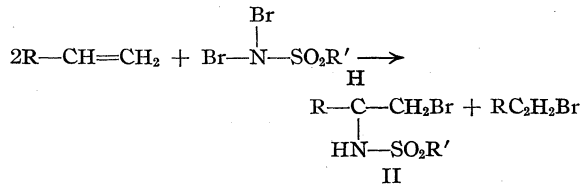
In addition to standardizing the conditions of addition of N-bromosulfonamides to olefins, we have succeeded in effecting the addition of N,N-dibromo derivatives of aromatic sulfonamides, *e. g.*, N,N-dibromo-*p*-toluenesulfonamide, to styrene, anethole, and isosafrole.

(1) Seliwanoff, *Ber.*, **26**, 426 (1893).
(2) Földi, *ibid.*, **63**, 2257 (1930).

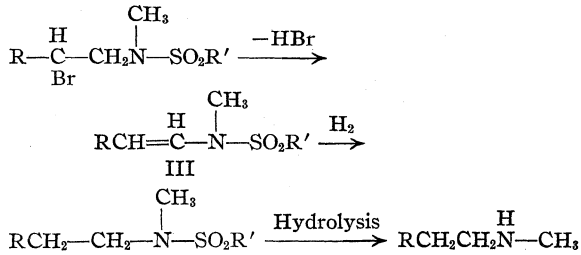
The positions taken by the nitrogen and bromine atoms of the N-bromo- and N,N-dibromosulfonamides is of considerable theoretical interest. The N-bromo-N-methyl aromatic sulfonamides add to propene, 2-methylpropene, vinyl chloride, and styrene to yield products in which the bromine atom takes the same position as the bromine atom in the "normal" addition[3] of hydrogen bromide to these olefins



The N,N-dibromosulfonamides, on the other hand, add to olefins to yield products in which the bromine takes the same position as in the "abnormal" addition of hydrogen bromide. A brominated olefin is formed at the same time.



The structure of the products of reaction I was proved by conversion into known compounds by the following series of reactions. The intermediates cited were all isolated and characterized.



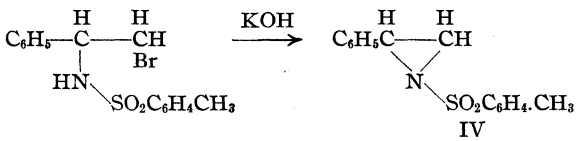
The elimination of hydrogen bromide from I usually was effected by heating the addition product with quinoline or with sodium ethoxide in al-

(3) For definition of "normal" and "abnormal" additions of hydrogen bromide consult the paper by Kharasch, Englemann, and Mayo, *J. Org. Chem.*, **2**, 288 (1937); Kharasch, Kleiger and Mayo, *ibid.*, **4**, 428 (1939).

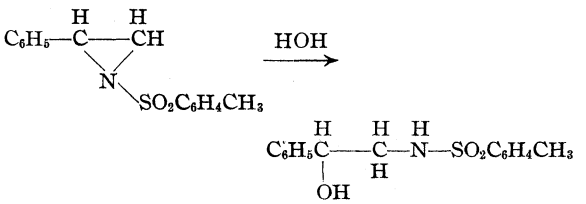
cohol. Palladium, on barium sulfate, usually served as the catalyst in the hydrogenation reactions, and the hydrolysis was effected with the aid of hydrogen chloride at 150°. The same end-product, namely, R–CH_2–CH_2–NH–CH_3, also was obtained in one step if sodium was added to an amyl alcohol solution of the addition product.

In the course of study of the structure of the products formed by the addition of aromatic N,N-dibromosulfonamides to styrene, anethole, and isosafrole, a number of extremely interesting intermediates were isolated.

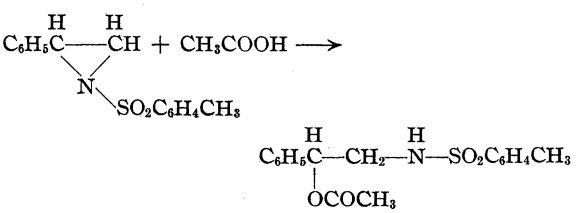
Thus, when the addition product of styrene and N,N-dibromo-*p*-toluenesulfonamide was treated with aqueous or alcoholic alkali, the N-*p*-tolylsulfonyl derivative of phenylethylenimine (styrenimine) was obtained.



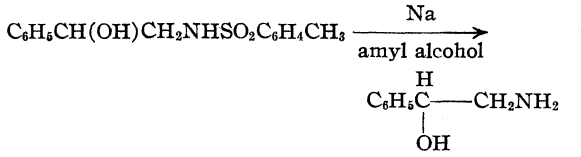
The imine derivative was easily cloven by many reagents. When boiled with water it was easily transformed into the expected *p*-toluenesulfonyl derivative of 2-phenyl-2-hydroxyethylamine.



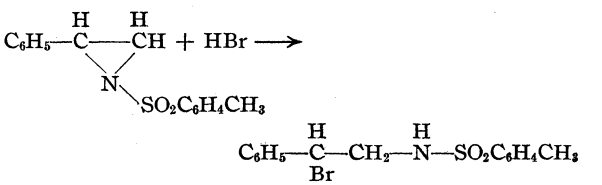
From cold glacial acetic acid the imine derivatives could be recovered unchanged, but heating the mixture for a short time caused the following reaction to take place



The structure of this compound was proved by saponification of the acetate group and treatment of the resulting compound, dissolved in boiling amyl alcohol, with sodium, to yield 2-phenyl-2-hydroxyethylamine.

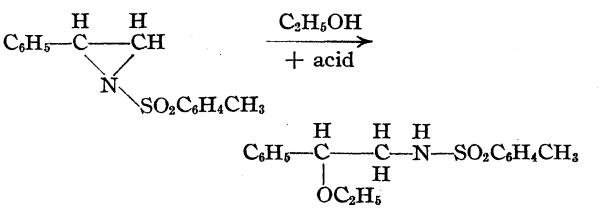


The N-substituted imines combined, at room temperatures, very readily with hydrogen chloride, hydrogen bromide, and hydrogen iodide, but with trichloroacetic and crotonic acids only upon warming. The nature of the products formed is best illustrated by a study of the addition of hydrogen bromide to the substituted imine. When the N-substituted imine, derived from styrene, is treated with hydrogen bromide at room temperatures, a compound of melting point 111° (VI) is obtained.

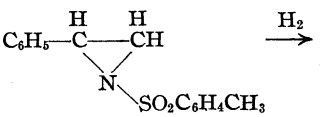


This substance is isomeric with the compound II (m. p. 167°) from which the imine is prepared. Furthermore, treatment of VI with sodium acetate yielded the same product as was obtained by direct action of acetic acid on the substituted imine IV.

Ethyl alcohol, even at the boiling point, does not cause the cleavage of the substituted imine. However, boiling an ethyl alcohol solution of it in the presence of a small amount of trichloroacetic acid, or the addition of a little cold 50% solution of sulfuric acid in alcohol to an alcoholic solution of the imine, causes the following reaction to take place



Catalytic reduction of IV, N-(*p*-toluenesulfonyl)-styreneimine gave N-phenethyl-*p*-toluenesulfonamide, which upon hydrolysis yielded phenethylamine.

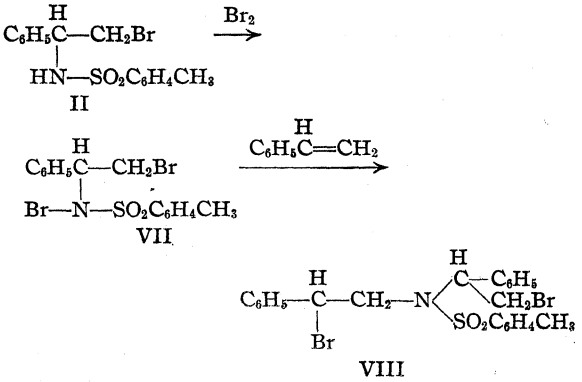


$$C_6H_5CH_2CH_2\overset{H}{N}—SO_2C_6H_4CH_3 \xrightarrow{\text{Hydrolysis}} C_6H_5CH_2CH_2NH_2$$

The same end-product was obtained by treating a solution of IV in amyl alcohol with sodium.

Compounds III and IV, obtained by elimination of hydrogen bromide from I and II, respectively, can be differentiated by their reactions with a neutral solution of potassium permanganate. The unsaturated compound III decolorizes the solution instantly, while the substituted imine IV is not affected by it.

It is of interest to note here that compound II, since it is a N-substituted *p*-toluenesulfonamide, reacts with bromine to give the N-bromo derivative of the substituted *p*-toluenesulfonamide VII which reacts smoothly with styrene to give an addition product VIII



Experimental

The sulfonamides and the corresponding N-bromosulfonamides were prepared by well-known methods or suitable modifications thereof.

1-Phenyl-1-bromo-2-(N-methylbenzenesulfonamido)-ethane (IX).—To 10 g. of N-bromo-N-methylbenzenesulfonamide was added 8 cc. of styrene. The mixture was warmed by the hand, until a reaction set in, after which it was cooled immediately in running water. After reaction was complete (disappearance of yellow color), the excess styrene was removed under reduced pressure. The residue was a thick sirup, which on cooling became a hard, glassy mass, but did not crystallize. For analysis, it was purified by dissolving in 25 cc. of warm absolute alcohol, and chilling the solution. A sirup separated. The alcoholic solution was decanted, and the sirup was washed with 10 cc. of cold alcohol. The substance was freed from alcohol by drying *in vacuo* for two hours at 70°, and then overnight in a vacuum desiccator over sodium hydroxide.

1-Phenyl-1-bromo-2-(N-methyl-*p*-toluenesulfonamido)-ethane (X).—To 16 cc. of styrene was added, in 5 g. portions, at first with cooling, a total of 32 g. of N-bromo-N-methyl-*p*-toluenesulfonamide. After the reaction, the warm mixture was dissolved in 60 cc. of absolute alcohol and seeded with a crystal from a previous preparation. The solid mass was collected on a filter, washed with a little alcohol, and finally crystallized from 120 cc. of alcohol. The yield was 32 g.

1-Phenyl-1-acetoxy-2-(N-methyl-*p*-toluenesulfonamido)-ethane (XI).—Ten grams of (X) was refluxed with 100 cc. of glacial acetic acid and 6 g. of sodium acetate for four hours. The cooled solution was decanted from the sodium bromide, concentrated to about one-third volume, and poured into 300 cc. of ice-cold water. On standing the material crystallized. Crystallization may be hastened by rubbing a part of the semi-solid mass with a little alcohol, and introducing the crystals into the main portion. The material was recrystallized from 30 cc. of 95% alcohol, and the crystals were washed with 10 cc. of ice-cold alcohol; yield, 3.5 g. A second crop of 5 g. of less pure material was obtained by working up the mother liquor.

1-Phenyl-1-hydroxy-2-(N-methyl-*p*-toluenesulfonamido)-ethane (XII).—The 3.5 g. of (XI) was dissolved in 25 cc. of absolute alcohol, and was treated with a solution of 0.6 g. of sodium hydroxide in 3 cc. of water. The resulting solution was heated on the water-bath for half an hour under reflux. The alcohol was then removed by evaporation, and to the residue water was added. The resultant oil was dissolved in benzene, washed with a little water, and the benzene solution was concentrated under reduced pressure. A pale-yellowish, thick oil remained. It was dried in the vacuum desiccator over sulfuric acid, but did not crystallize.

Methyl-(2-phenyl-2-hydroxyethyl)-amine.—A solution of 2 g. of (XII) in 60 cc. of amyl alcohol was brought to boiling, and 3.6 g. of sodium was added in small pieces. After the sodium had all dissolved, the amyl alcohol solution was shaken with 25 cc. of water to decompose the sodium amylate. The alcohol solution was separated and extracted several times with 5% hydrochloric acid. The combined hydrochloric acid extracts were evaporated on the water-bath to a small volume, extracted twice with ether to remove amyl alcohol, and made alkaline with solid potassium hydroxide. On cooling of the solution, the base separated in crystalline form. It was extracted with ether, the ether was distilled, and the solid residue was dried *in vacuo* over sulfuric acid. The yield was 0.8 g. (80% of the calculated).

1-Phenyl-2-(N-methyl-*p*-toluenesulfonamido)-ethylene (XIII).—A solution of 2.5 g. of (X) in 2.5 cc. of anhydrous quinoline was boiled for ten seconds. To the cooled solution was added dilute hydrochloric acid, and the crystalline precipitate was thoroughly washed with water. The material was crystallized from 25 cc. of alcohol; yield, 1.4 g., m. p. 106–107°. The alcoholic filtrate was examined for any possible isomers, but was found to contain the same compound in less pure form (m. p. 105°). The same compound was also prepared by treating a solution of 2.5 g. of (X) in 10 cc. of absolute alcohol, and refluxing for ten minutes with 15 cc. of a 3% solution of sodium ethoxide. Eight ml. of water was added to the hot solution; on cooling, 1.5 g. of white plates, m. p. 107°, was obtained.

Catalytic Reduction and Subsequent Hydrolysis to Methylphenethylamine.—A solution of 2.5 g. of (XIII) in 5 cc. of methyl alcohol was hydrogenated, with the aid of 0.8 g. of a 5% palladium–barium sulfate catalyst. In 10

minutes, 98 cc. of hydrogen (1 mole) was taken up, and absorption ceased. The alcohol was allowed to evaporate spontaneously. The residue was a sirup, which could not be brought to crystallization. It was heated with 6 cc. of concentrated hydrochloric acid at 150° for two hours. The contents of the tube were diluted with a little water, 0.5 g. of charcoal was added, and the mixture was filtered. Steam was passed into the filtrate until 50 cc. of distillate (which was discarded) had collected. The solution in the distilling flask was concentrated to a small volume on the water-bath, made alkaline, and steam-distilled until no more amine passed over (litmus). The volume of the distillate was about 50 cc. It was extracted with an equal volume of ether, the ethereal solution was washed with a little water, and dried over solid sodium hydroxide for two days. On passage of dry hydrogen chloride into the clear ethereal solution, the amine hydrochloride separated in the form of white plates. The precipitate was collected by filtration, washed with ether, and dried *in vacuo* over solid sodium hydroxide. The substance melted at 162°. It was not hygroscopic. The melting point of methylphenethylamine hydrochloride is reported by Johnson and Guest[4] as 152–154°, and by Decker and Becker[4] as 156–157°. Methyl-(1-phenylethyl)-amine hydrochloride is reported[5] to melt at 173°. To remove all doubt, the mercuric chloride double salt, the oxalate, and the urea derivative were prepared, the melting points of which were, respectively, 174, 186, and 143°. The corresponding melting points recorded in the literature[6] are 173, 184, and 141°.

Reduction of 1-Phenyl-1-bromo-2-(N-methyl-*p*-toluenesulfonamido)-ethane (X) with Sodium in Amyl Alcohol Solution.—The reduction was carried out in the manner described for the preparation of methyl-2-phenyl-2-hydroxyethylamine, excepting that the acid extract was not concentrated prior to the addition of alkali. Pure methyl-1-phenylethylamine hydrochloride, m. p. 162°, was obtained.

Reduction of 1-Phenyl-1-bromo-2-(N-methylbenzenesulfonamido)-ethane (IX) with Acid and Iron Filings.—In absolute alcoholic hydrogen chloride IX was reduced to the corresponding ethane with iron filings. The gummy product was then hydrolyzed with concentrated hydrochloric acid (two hours, 150°). The resultant methylphenethylamine hydrochloride was purified by solution in alcohol and precipitation with ether; m. p. 152–154°.

1-Phenyl-1-bromo-2-(N-benzylbenzenesulfonamido)-ethane (XIV).—To a solution of 5.0 g. of N-benzylbenzenesulfonamide dissolved in 25 cc. of chloroform, was added 3.4 g. of bromine. Immediately thereafter there was added a solution of 1.2 g. of sodium hydroxide in 15 cc. of water. After decolorization, the chloroform layer was separated and, without drying, was treated with 4 cc. of styrene. The solution was warmed a little on the water-bath, and the chloroform was removed in a stream of air. The residue was dissolved in 15 cc. of hot absolute alcohol. On cooling, an oil separated. The supernatant solution was decanted, the sirup was washed by decantation with a little alcohol, and was dried in the vacuum desiccator over sulfuric acid. Like the corresponding phenylsulfonylmethylamido compound, this substance did not crystallize, even on standing for several months in the ice-chest.

1-Phenyl-1-bromo-2-(N-benzyl-*p*-toluenesulfonamido)-ethane (XV).—This substance was prepared in exactly the same manner as XIV. A sirup was obtained, which, on standing for two days, crystallized; recrystallization from alcohol.

1-Phenyl-2-(N-benzyl-*p*-toluenesulfonamido)-ethylene (XVI).—A solution of 2.5 g. of (XV) in 25 cc. of 2% sodium ethoxide solution was boiled for one hour. Ten milliliters of hot water was added to the hot solution to redissolve the sodium bromide. The crystalline product that separated on cooling was crystallized from alcohol.

1-Phenyl-2-(N-benzyl-*p*-toluenesulfonamido)-ethane (XVII).—A suspension of 1.4 g. of (XVI) was hydrogenated with 1.5 g. of a 5% palladium–barium sulfate catalyst. In twenty minutes, the required 90 cc. of hydrogen was absorbed. Forty milliliters of benzene was added, the solution filtered from the catalyst, evaporated to dryness, and the residue recrystallized from alcohol.

Benzylphenethylamine.—A solution of 1.8 g. of (XVII) in 60 cc. of amyl alcohol was treated with 3 g. of metallic sodium, as described for the preparation of methyl-2-phenyl-2-hydroxyethylamine, with the exception that 10% sulfuric acid was used to extract the amine from the amyl alcohol solution, and the acid solution was made alkaline without preliminary concentration. The crude benzylphenethylamine hydrochloride isolated was purified by dissolving it in a little water and adding concentrated hydrochloric acid. Pure benzylphenethylamine hydrochloride separated.

1,1-Dimethyl-1-bromo-2-(N-methylbenzenesulfonamido)-ethane (XVIII).—A fairly rapid stream of isobutylene (generated from 5 g. of *t*-butyl alcohol and 5 g. of oxalic acid) was passed through a suspension of 5 g. of N-bromo-N-methylbenzenesulfonamide in 10 cc. of chloroform, at 40°, until a colorless solution resulted. This required about fifteen minutes. A special delivery tube with a large surface exposure was used. The chloroform was allowed to evaporate spontaneously, and the solid residue was recrystallized from 15 cc. of absolute alcohol; yield 4.8 g. This substance may also be prepared by treating liquefied isobutylene in a sealed tube, as described for (XIX).

1,1-Dimethyl-1-bromo-2-(N-methyl-*p*-toluenesulfonamido)-ethane (XIX).—Eight grams of liquefied isobutylene was sealed with 10 g. of N-bromo-N-methyl-*p*-toluenesulfonamide, and the contents were allowed to reach room temperature. After all the bromo compound had dissolved, and the solution was colorless, the tube was cooled in a dry ice–acetone mixture and opened. The excess isobutylene was allowed to escape and the solid residue was recrystallized from 30 cc. of absolute alcohol; yield 9.7 g.

1,1-Dimethyl-2-(N-methylbenzenesulfonamido)-ethylene or 1-Methyl-1-methylene-2-(N-methylbenzenesulfonamido)-ethane (XX).—A solution of 8.4 g. of XVIII in 16 cc. of dry quinoline was boiled for one minute. The solution was then cooled, and acidified with dilute hydrochloric acid, and the oil was extracted with ether. The

(5) "Beilstein," 4th ed., Vol. XII, p. 1094.

(6) Johnson and Guest, *Am. Chem. J.*, **42**, 350 (1909).

ethereal solution was dried with calcium chloride and the ether removed by distillation. The residue was distilled *in vacuo*, and practically all of it passed over at 203° at 21 mm. The yield was 3.8 g. of a colorless, viscous oil. The substance reduced permanganate, absorbed bromine, and showed all the reactions of a double bond, including hydrogenation, described below.

Catalytic Reduction of XX, and Hydrolysis to Methylisobutylamine.—A solution of 0.87 g. of (XX) in 6 cc. of alcohol was reduced, with the aid of 0.046 g. of platinum oxide catalyst (Adams). In five minutes, 85 cc., or the theoretical molecular equivalent of hydrogen was absorbed, and further shaking produced no more absorption. The solution was filtered from the catalyst, and the alcohol was distilled. The residue from 2.0 g. of reduced substance was heated with 10 cc. of concentrated hydrochloric acid for two hours at 150°. The amine hydrochloride was isolated as described in the case of the styrene addition product (XI). The substance melted at 178°, which is the melting point recorded in the literature for methylisobutylamine hydrochloride; the melting point of the prepared chloroplatinate (192°) is also in agreement with that recorded. The substance was extremely hygroscopic.

1,1 - Dimethyl - 1 - bromo - 2 - (N-methylbenzylsulfonamido)-ethane (XXI).—Two grams of N-bromo-N-methylbenzylsulfonamide, 6 cc. of chloroform, and 2 cc. of liquid isobutylene were sealed in a Pyrex tube, and the mixture brought to 40°. When the solution had become colorless, the tube was opened, and excess isobutylene allowed to escape. The chloroform was allowed to evaporate spontaneously, and the residue was recrystallized from 40 cc. of absolute alcohol; yield 1.5 g.

1,1-Dimethyl-2-(N-methylbenzylsulfonamido)-ethylene or 1 - Methyl - 1-methylene - 2 - (N - methylbenzylsulfonamido)-ethane (XXII).—On treatment of (XXI) with quinoline, in the usual manner, hydrogen bromide was eliminated, and the unsaturated compound was formed. The substance (XXII) was hydrogenated with platinum oxide (Adams) in alcohol solution, in the usual manner. The resultant N-methyl-N-isobutylbenzylsulfonamide melted at 83°.

1-Bromo-1-chloro-2-(N-methylbenzenesulfonamido)-ethane (XXIII).—Vinyl chloride (15 g.) and 26 g. of N-bromo-N-methylbenzylsulfonamide were sealed up and kept at room temperature until the next day. A colorless solution resulted. Excess vinyl chloride was allowed to escape, and the residue was crystallized from 125 cc. of 95% alcohol; yield 26 g.

1-Bromo-1-chloro-2-(N-methyl-*p*-toluenesulfonamido)-ethane (XXIV).—This substance was prepared in the manner described above.

1 - Chloro - 2 - (N - methyl - *p* - toluenesulfonamido)-ethylene (XXV).—A solution of 1 g. of XXIV in 5 cc. of absolute alcohol was refluxed for fifty minutes with 5 cc. of an alcoholic solution containing 2% of sodium ethoxide. Excess alcohol was removed on the water-bath. To the residue was added water and ether; the ethereal solution was separated and dried with sodium sulfate. The ether was distilled, and the oil was transferred to a desiccator. Several days later it solidified. The material, recrystallized from alcohol, melted at 91°. With the crystalline material at hand, the substance was readily prepared by heating XXIV with sodium ethoxide solution, as described above. After the refluxing was over, water was added to the warm solution to redissolve the inorganic salts, and a crystal was dropped in. On cooling, the substance of m. p. 91° separated.

1 - (N - Methyl - *p* - toluenesulfonamido) - 2 - bromopropane (XXVI).—Ten grams of N-bromo-N-methyl-*p*-toluenesulfonamide was sealed with 10 cc. of liquid propylene and 30 cc. of chloroform. After it had reached room temperature, the bomb tube was heated in a water-bath at 70–80° until the contents became colorless, which required about thirty to forty minutes. Excess propylene was allowed to escape, the chloroform was removed by distillation on the water-bath, and the residue was recrystallized from 40 cc. of absolute alcohol; yield 8.5 g.

Removal of Hydrogen Bromide from XXVI, Catalytic Hydrogenation and Subsequent Hydrolysis to Methylpropylamine.—Eight grams of the addition product XXVI was heated on the water-bath under reflux for two hours with 60 cc. of a 2% sodium ethylate solution in alcohol. The product was then worked up as described in the case of XXV. Evaporation of the ether left a semi-solid mass. The solid could be separated from the oily portion with filter paper. It melted at 54–56.

The oily portion contained 6.12% nitrogen. At 20 mm. the mixture distilled within the range 195–205°. Apparently, we are dealing here with two isomers of the formula $C_{11}H_{15}O_2NS$; $CH_2{=}CHCH_2NCH_3SO_2C_6H_4CH_3$(B) and $CH_3CH{=}CHNCH_3SO_2C_6H_4CH_3$(A). A solution of 1.37 g. of the semi-solid in 8 cc. of methyl alcohol was hydrogenated, with the aid 1.3 g. of 5% palladium–barium sulfate catalyst. After two and one-half hours, 123 cc. of nitrogen was absorbed, or about 90% of the theoretical quantity, for one double bond. After evaporation of the alcohol, the N-methyl-N-*n*-propyl-*p*-toluenesulfonamide was obtained in crystalline form.

One gram of the substance was hydrolyzed, as described previously in the case of the styrene product. The hydrochloride melted at 150°, which is in agreement with the melting point recorded in the literature[7] for methyl-*n*-propylamine hydrochloride. The hydrochloride of methylisopropylamine melts at 77°.

1 - Phenyl - 1 - *p* - toluenesulfonamido - 2 - bromoethane (II).—In an attempted preparation of N-bromo-N-acetyl-*p*-toluenesulfonamide, from N-acetyl-*p*-toluenesulfonamide and sodium hypobromite, N,N-dibromo-*p*-toluenesulfonamide, previously prepared by Chattaway, was obtained. This on interaction with styrene produced simultaneous bromination and addition. The brominated styrene remained in the chloroform solution, and the difficultly soluble addition product separated.

The addition product was conveniently prepared as follows: to 11.5 g. of *p*-toluenesulfonamide was added 6.9 cc. of bromine, the two components being intimately mixed, and then, with cooling and stirring, 27 cc. of 20% sodium hydroxide was added gradually from a separatory funnel. The lower layer containing the reaction product was dissolved in 60 cc. of lukewarm chloroform, and the chloroform layer was separated from the alkaline solution. To the chloroform solution, which was not dried, there was added drop by drop from a buret, at first with cooling and

(7) Chattaway, *J. Chem. Soc.*, **87**, 164 (1905).

stirring, 15 cc. of styrene. Toward the end of the addition, the solution was allowed to warm up, so as to complete the reaction. Usually, a small amount of a yellow substance precipitated from the hot solution toward the end of the styrene addition. This is the sodium salt of the monobromosulfonamide, which is later removed from the addition product by washing with alcohol. On cooling of the chloroform solution with ice water, the addition product separated. It was collected on a filter, washed with 20 cc. of ice-cold chloroform, and then with 30 cc. of cold absolute alcohol, and air-dried. The yield was 14.0 g. of substance, m. p. 163°, which, for the conversion into the imine, is sufficiently pure. Another 4 g. of addition product was obtained by evaporation of the filtrate to dryness, washing of the semi-solid residue with ice-cold alcohol, and recrystallization from alcohol. The bromine in the addition product is held rather firmly; none of it is precipitated by alcoholic silver nitrate solution in the course of twenty-four hours. In the corresponding methylamido addition product (X), the bromine, being attached to a carbon atom holding a phenyl group, is precipitated practically quantitatively during the first five minutes by alcoholic silver nitrate solution. Again, whereas the methylamido compound readily yielded an acetate on heating with sodium acetate and glacial acetic acid for four hours, the amido compound (II), is recovered practically unchanged under the same conditions.

1 - *p* - Anisyl - 1 - *p* - toluenesulfonamido - 2 - bromopropane (XXVII).—To a chloroform solution of the dibromoamide, prepared exactly as described above, was added, with cooling and stirring, 12 cc. of anethole. After the reaction was complete, the solution was cooled in ice water, and the product worked up as in the case of the styrene product.

1 - (3,4 - Methylenedioxyphenyl) - 1 - *p* - toluenesulfonamido - 2 - bromopropane (XXVIII).—The addition product was prepared as described above, from 12 cc. of isosafrole, and the dibromoamide was prepared from 11.5 g. of *p*-toluenesulfonamide. The chloroform solution was set aside in the ice chest for twenty-four hours, since crystallization proceeded very slowly.

1 - Phenyl - 1 - bromo - 2 - [N - (1 - phenyl - 2 - bromoethyl) - *p* - toluenesulfonamido]- ethane (VIII). (Interaction of the Bromo Derivative of 1-Phenyl-1-*p*-toluenesulfonamido-2-bromoethane with Styrene.)—To a solution of 3.5 g. of VI was added 2.5 g. of bromine and then 20% sodium hydroxide solution, drop by drop until almost all the free bromine had disappeared. A trace of free bromine was allowed to remain. At this point, 1.0 g. of unchanged starting material, m. p. 167°, precipitated. It was removed by filtration, and to the chloroform filtrate 1 cc. of styrene was added. The solution was warmed slightly on the water-bath, and the chloroform was removed by a stream of air. The residue still contained "positive" bromine (potassium iodide test). One milliliter of styrene was added, and the mixture was warmed on the water-bath until a test with potassium iodide showed the absence of "positive" halogen. The residue was dissolved in a little chloroform and ligroin was added. The precipitate was recrystallized several times from alcohol.

N-(*p*-Tolylsulfonyl)-styreneimine (IV).—A suspension of 11.5 g. of the styrene addition product (II), m. p. 167°, in 40 cc. of alcohol was brought to boiling on the water-bath. There was then rapidly added, from a pipet, 8 cc. of 20% aqueous sodium hydroxide solution. The addition product dissolved completely. To the hot solution, 8 cc. of warm water was added. On cooling the solution, styreneimine crystallized in glistening plates; yield 8.6 g. An acetone solution of the substance did not decolorize a solution of permanganate in acetone.

1 - Phenyl - 1 - halo - 2 - *p* - toluenesulfonamidoethanes (XXIX–XXXI).—A solution of 1 g. IV in 35 cc. of ether was shaken with 15 cc. of an aqueous hydrobromic acid solution. The ether was allowed to evaporate spontaneously, and the residue was washed with ice-cold alcohol. The addition product (XXIX) crystallized in needles. The corresponding chloro (XXX) and iodo (XXXI) ethanes were also prepared.

Catalytic Hydrogenation of N-(*p*-Tolylsulfonyl)-styreneimine (IV).—A suspension of 2.0 g. of the imine in 6 cc. of methyl alcohol was subjected to hydrogenation, with the aid of 0.5 g. of a 5% palladium–barium sulfate catalyst. In forty-five minutes, the calculated amount of hydrogen (172 cc.) was absorbed, and further treatment caused no more hydrogen to be taken up. The solution was filtered and washed with methyl alcohol, and the filtrate was evaporated to dryness. The N-phenethyl-*p*-toluenesulfonamide (XXXII) was left behind in the form of needles, m. p. 67°. The melting point recorded in the literature is 65–66°.

Hydrolysis of N - Phenethyl - *p* - toluenesulfonamide (XXXII).—On heating 0.7 g. of (XXXII) with 6 cc. of concentrated hydrochloric acid at 150° for two hours, the substance was recovered unchanged. The heating was then repeated for another two hours at 170°, and the hydrochloride of phenethylamine, m. p. 217°, was recovered.

Phenethylamine was obtained in one step by treating IV with an excess of sodium in boiling amyl alcohol solution, in the manner previously described. The same result was obtained by subjecting the styrene addition product (II) to the action of sodium and boiling amyl alcohol.

Treatment of the isosafrole addition product (XXVII), with sodium and amyl alcohol, gave aminoisosafrole; m. p. of hydrochloride 183°.

1-Phenyl-1-bromo-2-(N-phenethyl-*p*-toluenesulfonamido)-ethane (XXXIII).—One gram of XXXII, obtained from the catalytic reduction of IV, was dissolved in 10 cc. of chloroform, and treated successively with 1.2 g. of bromine and 0.6 g. of sodium hydroxide in 10 cc. of water. The chloroform solution was separated and treated with 0.5 cc. of styrene. The chloroform was removed in a stream of air, to the residue was added 0.2 cc. more of styrene, and the mixture was warmed for two to three minutes. It was then dissolved in 4 cc. of absolute alcohol. On cooling, a gum separated. After standing for several days in the ice chest, it solidified. The material was recrystallized several times from alcohol.

N - (2 - Phenyl - 2 - hydroxyethyl) - *p* - toluenesulfonamide (XXXIV).—A suspension of 0.2 g. of IV in 150 cc. of water was boiled under reflux for two hours. On cooling, white needles crystallized.

1 - Phenyl - 1 - trichloroacetoxy - 2 - *p* - toluenesulfonamidoethane (XXXV).—A mixture of 10 g. of IV and 10 g. of trichloroacetic acid was warmed on the water-bath until a homogeneous solution resulted. The gum was poured

in a thin stream into 100 cc. of water contained in a large mortar. The gum was rubbed with a pestle, the supernatant liquor being replaced with fresh water, until crystallization took place. The material, after several recrystallizations from alcohol, melted at 125°. The compound was stable toward boiling water or alcohol but hydrolyzed by alkali to XXXIV.

1 - Phenyl - 1 - ethoxy - 2 - *p* - toluenesulfonamidoethane (XXXVI).—One gram of IV was added to 7 cc. of absolute alcohol which contained 12 drops of concentrated sulfuric acid. The substance immediately dissolved with the evolution of heat. On cooling and scratching of the walls of the container with a glass rod, a precipitate separated. It was collected by filtration and washed with 5 cc. of ice-cold alcohol.

1 - Phenyl - 1 - crotonoxy - 2 - *p* - toluenesulfonamidoethane (XXXVII).—A mixture of 1 g. of IV with 2 g. of crotonic acid was heated at 160° for five minutes. A test

with the cooled material showed it to be completely soluble in alkali. The reaction product was treated with sodium carbonate solution, to remove unchanged crotonic acid, the residue was washed with water, and recrystallized from alcohol. When the crotonate was heated on the water-bath for fifteen minutes with 10% sodium hydroxide, and the solution acidified, XXXIV (m. p. 113°) separated.

1 - Phenyl - 1 - acetoxy - 2 - *p* - toluenesulfonamidoethane (XXXVIII).—A solution of 55 g. of IV in 100 cc. of glacial acetic acid was warmed on the water-bath until a test portion showed it to be completely soluble in alkali. This required thirty minutes. Too much heating renders the isolation of a crystalline acetate a difficult matter. The solution was poured in a fine stream into a liter of ice water. After standing for thirty minutes, the crystals were collected by filtration and air-dried. The yield was 65 g. (97% of the theoretical); m. p. 105°. The same acetate was obtained by refluxing for six hours 1 g. of XXIX (m. p. 111°) with 0.4 g. of anhydrous sodium acetate in 10 cc. of glacial acetic acid.

2-Phenyl-2-hydroxyethylamine.—A solution of 10 g. of XXXIV in 250 cc. of amyl alcohol was brought to boiling, and 18 g. of metallic sodium gradually added. The solution was then worked up in the usual manner. The amine was recovered in the form of a semi-solid mass, which when exposed to carbon dioxide yielded the known carbonate, m. p. 115°. The picrate melted at 158°.

Summary

1. Halosulfonamides of the type $R'SO_2NBrR$ react with a large number of olefins to yield products in which the bromine atom takes the same position as the bromine atom in the "normal" addition of hydrogen bromide to these substances.

2. The N,N-dibromosulfonamides, on the other hand, add to olefins to give products in which the bromine atom takes the same position as the bromine atom in the "abnormal" addition of hydrogen bromide to these compounds.

3. The preparation of N-(*p*-tolylsulfonyl)-styreneimine and its reactions with various reagents are reported.

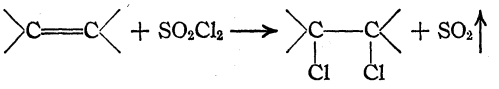
Chlorinations with Sulfuryl Chloride. II. The Peroxide-Catalyzed Reaction of Sulfuryl Chloride with Ethylenic Compounds

BY M. S. KHARASCH AND HERBERT C. BROWN[1]

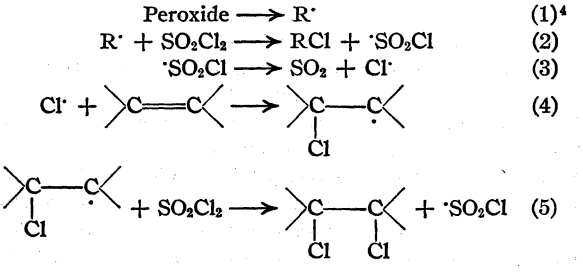
Sulfuryl chloride reacts readily with most ethylenic compounds to yield the saturated dichloro derivatives and sulfur dioxide.



Although this reaction has been used for synthetic purposes,[2] no thorough study has been made of the factors which control these additions.

We have previously shown that the presence of small quantities of organic peroxides brings about a reaction between sulfuryl chloride and saturated aliphatic hydrocarbons.[3] The characteristics of the reaction of sulfuryl chloride with olefins led us to suspect that this reaction is also peroxide-catalyzed. Investigation has confirmed this belief, and the evidence we have obtained indicates that the mechanism of this reaction is similar to that involved in the peroxide-catalyzed reaction of sulfuryl chloride with aliphatic hydrocarbons, a chain reaction involving chlorine atoms.

The following mechanism is in full agreement with the experimental facts and is advanced as representing the most probable course of the reaction in the light of our present-day information.



That the reaction is peroxide-catalyzed is indicated by a number of observations. Thus, an old sample of cyclohexene (which gave a strong test for peroxides) reacted with sulfuryl chloride with explosive violence when the two substances were mixed at room temperature. When the

(1) Eli Lilly Fellow, 1938–1939.

(2) A search of the literature reveals the use of sulfuryl chloride for the chlorination of unsaturated substances in the following instances: (a) chlorination of tetraphenylethylene and its derivatives, Norris, Thomas and Brown, *Ber.*, **43**, 2949 (1910); (b) chlorination of cinnamic acid and cinnamyl aldehyde, Durrans, *J. Chem. Soc.*, **123**, 1424 (1923); (c) chlorination of cyclohexene, Frieze and Djiang, *Ber.*, **71**, 667 (1938); and (d) chlorination of 3-hexene, Spiegler and Tinker, THIS JOURNAL, **61**, 940 (1939).

(3) Kharasch and Brown, *ibid.*, **61**, 2142 (1939).

(4) The dot denotes an unshared electron. The evidence for the assumption that the catalytic effect of peroxides in these chlorinations is due to their decomposition into organic free radicals, is discussed in the first paper of this series: *ibid.*, **61**, 2149 (1939).

cyclohexene was distilled carefully immediately before use (weak peroxide test), a moderate reaction ensued only after an induction period of several minutes. Addition of a drop or two of old cyclohexene, benzaldehyde, or ascaridole to the freshly-distilled cyclohexene catalyzes the reaction and eliminates the initial induction period. Passage of dry air through the relatively inactive cyclohexene also enhances its reactivity. The reactivity of **allyl chloride** is similarly enhanced by peroxidic materials.

Unsaturated compounds which are less sensitive to traces of peroxide can be purified easily to such a degree that no appreciable reaction with sulfuryl chloride occurs in the absence of added peroxide. For example, pure ***sym*-dichloroethylene** can be heated with sulfuryl chloride under reflux for several hours without appreciable reaction. In the presence of a small quantity (0.002 mole) of benzoyl peroxide, however, reaction occurs smoothly to yield *sym*-tetrachloroethane. **Tetrachloroethylene** reacts in a similar manner to form hexachloroethane. This reaction is, however, very slow (15% in five hours) compared to the other olefin chlorinations studied.

Stilbene readily reacts to yield the two isomeric stilbene dichlorides, and **tetraphenylethylene** forms the corresponding dichloride. In previous work on the chlorination of tetraphenylethylene with sulfuryl chloride,[2a] it was reported that different samples of sulfuryl chloride showed different capacities for reacting with tetraphenylethylene. The "inactive" samples could be activated by the addition of small quantities of acetic acid. We have repeated this work and have found that in the dark peroxide-free acetic acid does not catalyze the reaction of sulfuryl chloride, either with this olefin or with any of the others which we have tested (dichloroethylene, tetrachloroethylene, and stilbene). It appears likely that the activation was produced by the presence of peroxidic impurities in the acetic acid.

We have also carried out some preliminary studies of the action of sulfuryl chloride on unsaturated acids and anhydrides, such as crotonic acid, cinnamic acid, and maleic anhydride. However, the reaction which takes place is not the simple peroxide-catalyzed reaction with the double bond mentioned above. Study of this reaction is being continued.

Experimental Part

Chlorination of Cyclohexene.—The chlorination of cyclohexene can be carried out most conveniently by adding the sulfuryl chloride through a condenser to the cyclohexene contained in a flask. It is advisable to use freshly-distilled cyclohexene, adding one or two drops of benzaldehyde or some similar peroxidic material (old cyclohexene, ascaridole) as a catalyst. The reaction is strongly exothermic and the use of a diluent (carbon tetrachloride, methylene chloride, or benzene) to moderate the vigor of the reaction is recommended.

It is also advantageous to use a comparatively volatile solvent and to keep the reaction mixture boiling gently in order to facilitate the escape of the sulfur dioxide from the solution. Otherwise, side reactions of the sulfur dioxide with the olefin decrease the yield.

In a round-bottomed flask fitted with a ground-glass joint were placed 24.6 g. of cyclohexene (0.3 mole) and 30 g. of carbon tetrachloride. The flask was attached to a reflux condenser, and a solution of 27.0 g. of sulfuryl chloride (0.2 mole) in 30 g. of carbon tetrachloride was then added gradually through the condenser in the course of an hour. The heat of the reaction is sufficient to keep the mixture refluxing. After all the sulfuryl chloride had been added, the reaction mixture was heated gently for another hour, and was then fractionated. There was isolated 27.2 g. of dichlorocyclohexane (b. p. 79–80° at 22 mm., $n^{20}D$ 1.4903). This represents a yield of nearly 90% (based on the sulfuryl chloride used).

Chlorination of Allyl Chloride.—The chlorination of allyl chloride is similar to that described above. Yields of 80 to 90% of 1,2,3-trichloropropane are readily obtained.

Chlorination of *sym*-Dichloroethylene.—The chloro derivatives of ethylene are comparatively insensitive to traces of peroxides. For this reason these compounds may be purified easily, and the dependence of the reaction of sulfuryl chloride with the double bond upon peroxide catalysis shown.

Freshly distilled dichloroethylene, b. p. 60–60.5° (19.4 g., 0.2 mole), and sulfuryl chloride (40.5 g., 0.3 mole) were heated under reflux for three hours in the dark. At the end of this time, the reaction mixture was fractionated: no reaction had taken place. The fractions were combined, a small quantity of benzoyl peroxide (0.002 mole) was added, and the refluxing was continued. Slow evolution of sulfur dioxide from the reaction mixture indicated that a reaction was now taking place. At the end of two hours the heating was discontinued, and the mixture was fractionated. There was isolated 29.5 g. of *sym*-tetrachloroethane (b. p. 143–145°, $n^{20}D$ 1.4942). The yield was 85%.

Chlorination of Stilbene.—In the absence of added peroxide, stilbene reacts slowly with sulfuryl chloride. Whether this slow reaction is due to a trace of peroxide, or whether it is a slow thermal bimolecular reaction, could not be determined. The addition of a small quantity of benzaldehyde or ascaridole brings about a rapid, vigorous reaction at room temperature. The yield of crude product (stilbene dichloride) is quantitative. After fractional crystallization of this crude material, first from alcohol to obtain the higher-melting isomer, and then from ligroin to obtain the other isomer, there was obtained a 45% yield of α,α'-stilbene dichloride, m. p. 191–193°, and a 33% yield of the β,β' isomer, m. p. 90–93°.

Chlorination of Tetraphenylethylene.—Tetraphenylethylene, like stilbene, reacts slowly with sulfuryl chloride in the absence of added peroxide. When a trace of a peroxide (benzaldehyde which gives a strong peroxide test, or ascaridole) is added, the reaction is accelerated tremendously. The product formed is the dichloride, m. p. 184–186° (dec.).

Summary

1. Sulfuryl chloride reacts with ethylenic compounds to form the corresponding dichlorides. The following olefins have been chlorinated: cyclohexene, allyl chloride, dichloroethylene, tetrachloroethylene, stilbene, and tetraphenylethylene.

2. The chlorination of these ethylenic compounds by means of sulfuryl chloride is catalyzed by organic peroxides.

3. It is suggested that the reaction proceeds through a chain mechanism involving atoms and free radicals.

The Wound Hormones of Plants. IV. Structure and Synthesis of a Traumatin[1]

BY JAMES ENGLISH, JR.,[1a] JAMES BONNER AND A. J. HAAGEN-SMIT

Many plant tissue extracts are capable of inducing renewed growth activity in mature plant cells. These growth inducing extracts are usually obtained from ground or heated tissues, and they are capable of evoking cell division and cell enlargement in unwounded cells. The active principles have therefore been referred to as "wound hormones."[2] The present paper concerns the structure and synthesis of one highly active "wound hormone," 1-decene-1,10-dicarboxylic acid, whose isolation has already been announced.[3] The authors propose that the name "traumatic acid" be used in referring to this substance.

In earlier papers[4] a quantitative bio-assay (the bean test) for wound hormone activity has been described.

Activity tests of the material described below were always carried out in the presence of a "co-factor"[5] mixture.

One-tenth gamma of the pure substance per applied drop elicits a detectable response in the bean test. The pure product, m. p. 165–166°, is optically inactive and yielded an equivalent weight by titration of 118. A micro-Zerewitinoff determination carried out on the dimethyl ester showed the absence of active hydrogen. Catalytic hydrogenation yielded decane-1,10-dicarboxylic acid, identified by melting point and mixed melting point with an authentic sample prepared from decamethylene glycol.[6]

Since the analysis and the result of the hydrogenation experiment indicated the existence of one double bond, an oxidative degradation was carried out. On oxidation of the methyl ester with permanganate in acetone solution, sebacic acid was formed indicating the presence of a double bond in the α-β position. This conclusion was confirmed by the synthesis of 1-decene-1,10-di-

(5) For a description of the preparation and properties of this co-factor mixture, see note 3. Sucrose and particularly glutamic acid can in part replace the co-factor mixture in augmenting the activity of traumatic acid.

(6) P. Chuit, *Helv. Chim. Acta*, **9**, 264 (1926).

carboxylic acid which proved to be identical with the natural active material. The synthesis was carried out by converting undecylenic acid to the half aldehyde of sebacic acid[7] and condensing this with malonic acid in the presence of pyridine. Carbon dioxide was split off as expected[8] and the unsaturated acid was isolated after hydrolysis of the ester group.

During the course of the investigation a large number of pure organic substances was tested (in the presence of the co-factor mixture noted above) for activity in the bean test. With the exception of certain homologs and analogs of decene-dicarboxylic acid, these materials (indoleacetic acid, vitamins B_1, B_2, B_6, and other known plant growth substances as well as numerous organic acids) were wholly without activity. The hydrogenation product, decane-1,10-dicarboxylic acid, possesses an activity approximately half that of decene-1,10-dicarboxylic acid. The presence of the double bond, therefore, while not essential, nevertheless enhances the activity of this molecule. The saturated dibasic acids possessing 7 or fewer C atoms were without significant activity. Suberic and azelaic acids with 8 and 9 C atoms, respectively, possess slight activity and sebacic acid (10 C atoms) is approximately half as active as decene-1,10-dicarboxylic acid. It is of interest that although succinic acid is completely inactive, maleic acid evokes a small but definite response in the bean test. In this case, as in the case of the C_{12} acids, the presence of one double bond increases wound hormone activity. Lauric acid, with 12 C atoms and but one carboxyl group is completely inactive as are the unsaturated monobasic acids linolic and undecylenic. Two carboxyl groups would therefore appear to be essential for wound hormone activity in the bean test.

The physiological activities of decene-dicarboxylic acid and the related higher dicarboxylic acids are not restricted to the evoking of intumescences in bean pods. Synthetic decene-dicarboxylic acid is capable of evoking intense cell division activity in the "potato test" of Haberlandt.[9] The activity of decene-dicarboxylic acid in this test is further enhanced by the co-factor mixture described above in connection with the bean test. It seems probable therefore that traumatic acid is one of the substances responsible for wound periderm formation in the potato.

Synthetic decene-dicarboxylic acid is also capable of partially inhibiting the germination of seeds, particularly those seeds which are borne in fleshy fruits such as tomato, and it seems possible therefore that traumatic acid is in nature partly responsible for the failure of such seeds to germinate while they remain within the fruit. A fuller account of these physiological investigations will be published elsewhere.

Experimental

Isolation Procedure.—The preparation of the crystalline active material was carried out as described in a previous paper with the added precaution that all solvent evaporations were carried out below 35°. In this way there was obtained, after repeated recrystallization from alcohol, 56.6 mg. of pure material, m. p. 165–166°; 40 mg. dissolved in 2 cc. of absolute alcohol showed no measurable optical rotation in a 10-cm. tube.

Hydrogenation.—Nine milligrams of the product was hydrogenated by shaking with hydrogen at atmospheric pressure in glacial acetic acid in the presence of platinum oxide. On filtering the catalyst and removing the solvent, there was obtained a crystalline product which, after one recrystallization from alcohol, melted at 127° and was pure decene-1,10-dicarboxylic acid. Mixture with an authentic sample showed no m. p. depression.

Five milligrams of the pure reduction product was converted to the anilide by heating with thionyl chloride, removing the excess reagent *in vacuo* and adding aniline. After heating on the steam-bath for fifteen minutes the product was worked up in the usual manner. After recrystallization from alcohol, it gave a melting point of 171° and showed no melting point depression with a sample prepared from synthetic decane-1,10-dicarboxylic acid.

Anal.[10] Calcd. for $C_{24}H_{32}O_2N_2$: N, 7.38. Found: N, 7.38, 7.28.

Oxidation.—Eighteen milligrams of the pure crystalline material was dissolved in ether and an ether solution containing an excess of diazomethane was added. The crude methyl ester[4] obtained on evaporation of the ether was dissolved in acetone and oxidized by adding an acetone solution of potassium permanganate at room temperature until an excess was present. The solution was then refluxed and permanganate added until no more was taken up. The acetone was removed under reduced pressure from the filtered solution and the residue was dissolved in 4 normal sodium hydroxide. This solution was then heated on the steam-bath for two hours, cooled, acidified and extracted with ether. Upon evaporation of the ether there was obtained 14 mg. of crude acid which, after recrystallizing twice from alcohol, melted at 133° and was found to be identical with sebacic acid by mixed melting point. This product yielded an amide, m. p. 200°, identical with sebacic acid di-amide.

(10) Microanalysis by G. A. Swinehart.

Synthesis of 1-Decene-1,10-dicarboxylic Acid.—Undecylenic acid methyl ester (b. p. 119–120°, 10 mm.) prepared from Eastman Kodak Co. undecylenic acid was ozonized according to the procedure of Noller and Adams[7] in acetic acid solution and the half aldehyde of methyl sebacate (b. p. 124–125° (4 mm.)) obtained in 40% yield. Thirteen grams of this product was mixed with 15 g. of malonic acid and 15 g. of dry pyridine and heated under reflux for four hours. A vigorous evolution of carbon dioxide was observed in the early stages of the reaction. The resulting clear solution was acidified, poured into water and extracted with ether. After removal of the pyridine by extraction with dilute hydrochloric acid, the ether was evaporated and the crude product hydrolyzed directly by heating under reflux with 3 normal sodium hydroxide for two hours. Upon acidification the 1-decene-1,10-dicarboxylic acid precipitated and was recrystallized from alcohol or acetone, m. p. 165–166°. This product showed no depression of melting point when mixed with the naturally occurring material and was identical with the latter in crystalline form and physiological activity.

Anal. Calcd. for $C_{12}H_{20}O_4$: C, 63.05; H, 8.80. Found: C, 62.98; H, 8.85.

The S-benzyl thiuronium salt of traumatic acid was prepared according to the method of Donleavy.[11]

Anal. Calcd. for $C_{28}H_{40}O_4N_4S_2$: C, 59.96; H, 7.79; N, 9.99. Found: C, 59.78; H, 7.49; N, 9.90.

(11) J. J. Donleavy, THIS JOURNAL, **58**, 1004 (1936).

An oxidation of the synthetic product with permanganate in hot water solution gave sebacic acid, identified by melting point (133°) and mixed melting point.

Summary

The crystalline substance isolated from string bean pods and capable of inducing renewed cell division and cell extension activity in the parenchymatous cells of the bean pod mesocarp is shown to be 1-decene-1,10-dicarboxylic acid. Synthetic 1-decene-1,10-dicarboxylic acid was prepared and shown to be identical with the natural product both in physical properties and in physiological activity. It is proposed that the name "traumatic acid" be used in referring to this substance.

Traumatic acid is also shown to be capable of inducing wound periderm formation in washed disks of potato tuber and to function thus as a wound hormone of the potato. Traumatic acid is also capable of partially replacing the juice of the tomato fruit in reversibly inhibiting the germination of tomato seeds.

The System *n*-Butylmagnesium Bromide–Magnesium Bromide–Ethyl Ether

BY W. E. DOERING AND C. R. NOLLER

The system magnesium bromide–ethyl ether has been investigated by Menschutkin[1] who found that the solubility of the dietherate varied from 1.08% at −8° to 5.80% at 22°. At 22.8° the dietherate melted under ether to give two liquid phases. The composition of the upper layer changed from 6.8% dietherate at 30° to 10.2% at 90° while that of the lower layer changed from 69.8% at 30° to 68.6% at 90°.

During the course of another investigation[2] it was found that quantities of magnesium bromide greatly in excess of its solubility in ether could be added to Grignard solutions without the separation of two phases and in connection with studies on the composition and constitution of Grignard reagents it became desirable to determine quantitatively the effect of Grignard reagents on the solubility of magnesium halides. Table I and Fig. 1 summarize our results on the system *n*-butylmagnesium bromide–magnesium bromide–ethyl ether. Since the molecules of both the Grignard reagent and the magnesium bromide are present in all probability as the dietherates at ordinary temperatures when an excess of ether is present, the numerical values have been calculated on this basis. It is realized of course that the system is more complicated than indicated because of the equilibrium between *n*-butylmagnesium bromide, di-*n*-butylmagnesium and magnesium bromide. Since it is not possible at the present time to determine accurately the position of this equilibrium,[3] all of the active Grignard reagent has been calculated as being in the form of *n*-butylmagnesium bromide.

It can be seen that the presence of *n*-butylmagnesium bromide greatly modifies the solubility of magnesium bromide dietherate. Whereas magnesium bromide dietherate and ether form homogeneous solutions at 25° only when the con-

[a] Primed and unprimed letters denote compositions in equilibrium with each other. [b] This is an analysis of the liquid magnesium bromide diethereate saturated with ether. A small amount of basic magnesium was present which was calculated as if it were *n*-butylmagnesium bromide but this readily can be ignored.

centration of the diethereate is greater than 73% or less than 5.5%, if the total concentration of *n*-butylmagnesium bromide diethereate is greater than approximately 23% the ratio of the magnesium bromide diethereate to the ether may be any value without the separation into two phases. It is also of interest that when separation into two phases does occur the concentration of the *n*-butylmagnesium bromide diethereate is always greater in the lower layer than in the upper layer. These two results indicate that the mutual solubility of the two diethereates is greater than their solubility in ether.

Experimental

The liquid magnesium bromide diethereate was prepared by the addition of bromine in slight excess over the calculated amount to pure magnesium turnings[4] under absolute ether. The solutions always darkened somewhat as the reaction progressed. The heavy liquid layer was transferred under nitrogen to a graduated reservoir which was fitted so that the liquid could be transferred to the reaction tubes by pressure. A 2 *N* solution of *n*-butylmagnesium bromide was prepared by the usual procedure and stored in the same way as the magnesium bromide solution.

The reaction vessels were cylindrical tubes of approximately 80 cc. capacity and 3 cm. in diameter fitted with

(4) Aluminum Company of America, No. 651 ingot.

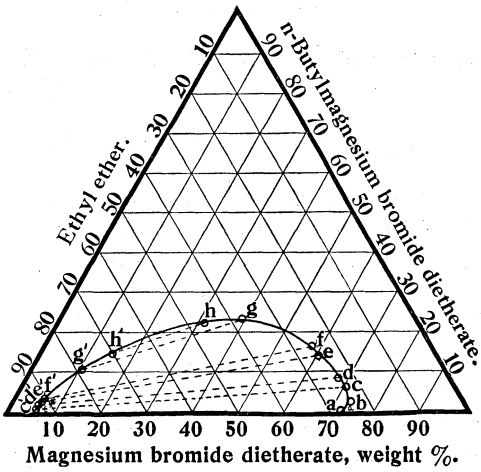

Fig. 1.—System *n*-butylmagnesium bromide–magnesium bromide–ethyl ether.

necks and stoppers made from 10/30 standard taper "No-Lub" ground joints. The stoppers and necks had hooks so that they could be held firmly together by means of rubber bands. The hooks on the necks also permitted the tubes to be suspended above the pan of an analytical balance. Even the "No-Lub" joints permitted the passage of ether by capillarity but this could be prevented by putting a thin line of vaseline around the outermost edge of the stopper. This sealed the air in the ground joint so that the ether did not pass more than a third of the way through the stopper.

Varying amounts of the magnesium bromide diethereate, Grignard solution and absolute ether were added to the flasks under nitrogen and the mixtures shaken for one-half hour at 25 ± 1°. The tubes were then weighed accurately to one centigram and samples of both upper and lower layers rapidly removed by long wash-out pipets, the tubes being reweighed after each withdrawal. The samples were analyzed for Grignard reagent by titration with standard sulfuric acid and for bromine by the Mohr procedure. From these data the weight of *n*-butylmagnesium bromide diethereate and of magnesium bromide diethereate could be calculated and the ether determined by difference. At least duplicate determinations were made of each analysis and the results averaged. The agreement between duplicate determinations was in all cases better than 2%, except in point g′ where the variation was of the order of 5%.

Summary

A study of the system *n*-butylmagnesium bromide–magnesium bromide–ether shows that *n*-butylmagnesium bromide diethereate greatly modifies the solubility of magnesium bromide diethereate in ether and that the mutual solubility of the two diethereates is greater than their solubility in ether.

Ketene in the Friedel–Crafts Reaction. I. Direct Acetylation of Aromatic Hydrocarbons with Ketene[1]

BY JONATHAN W. WILLIAMS[2] AND JAMES M. OSBORN[3]

The use of ketene in the Friedel–Crafts reaction has been the subject of several studies.[4] In each case reported the yield of methyl aryl ketone has been low. In particular, the yield of acetophenone from benzene and ketene has been reported as 20%, or less.

Results of the present investigation show that the yield of acetophenone from ketene and benzene may be increased above previously reported values by the following considerations: (1) use of a considerable excess of ketene; (2) use of ketene which contains minimum amounts of ethylene and carbon monoxide; (3) operation at 0°; (4) addition of aluminum chloride in small portions with rapid stirring; (5) use of at least 1.5 moles of aluminum chloride per mole of hydrocarbon; (6) use of an inert diluent, as carbon disulfide.

The reaction of ketene and naphthalene can be run so that methyl α-naphthyl ketone may be obtained to the practical exclusion of the β-isomer. The use of ketene in the Friedel–Crafts reaction has been extended to the reactions with tetralin and diphenyl.

Experimental Part

Ketene was generated by the pyrolysis of acetone, using a modification[5] of Ott's ketene lamp[4c,6] with an output of 0.45 mole per hour.

Acetophenone.—Ketene was passed into a well-stirred mixture of 100 ml. (1.1 moles) of benzene and 300 ml. of carbon disulfide maintained at 0°. At fifteen-minute intervals approximately 10-g. portions of aluminum chloride were added until 200 g. (1.5 moles) had been used (five hours). Ketene addition and stirring were continued for a total of ten hours (4.5 moles of ketene). The addition complex was decomposed by pouring onto 1 kg. of cracked ice and 30 ml. of concd. hydrochloric acid. After removal of carbon disulfide and benzene from the organic layer, the following fractions were obtained at 22 mm.: (a) 75–105°, 60.1 g.; (b) 105–220°, 30.5 g.: (c) viscous residue, 15 ml. Fraction (a) contained the acetophenone. It was washed with equal volumes of 5% sodium hydroxide solution and water, dried over sodium sulfate, and redistilled. These fractions were obtained at 12 mm.: (a) 75–83°, 1.3 g.; (b) 83–84°, 44.1 g.; (c) residue, 5 ml. Fraction (b) was pure acetophenone; yield, 32.7%.

Methyl α-Naphthyl Ketone.—The procedure was similar to the preparation of acetophenone, using one mole (128 g.) of naphthalene in 600 ml. of carbon disulfide. These fractions were obtained at 7 mm.: (a) 85–90°, 3.0 g.; (b) 145–151°, 70.0 g.; (c) 151–170°, 7.4 g.; (d) viscous residue, 75 ml. Fraction (a) was unchanged naphthalene (2.4%). Fraction (b) was washed with alkali, then with water, dried over sodium sulfate and distilled. A fraction boiling at 150–151° (7 mm.) weighed 59.1 g. This represented a 34.8% yield of methyl α-naphthyl ketone.

The ketone was shown to be the α-isomer by oxidation to α-naphthoic acid[7] and by conversion to the picrate.[4a,8] Fractional crystallization of the picrate showed that the ketone was largely the α-isomer, but that a small amount of the β-isomer was present. For the ketone $n^{27}D$ is 1.6265.

Methyl α-Naphthyl Ketone 2,4-Dinitrophenylhydrazone.—Prepared by the standard procedure and recrystallized from benzene, this substance melted at 259°. *Anal.* Calcd. for $C_{18}H_{14}O_4N_4$: C, 61.71; H, 4.03. Found:[9] C, 61.92, 61.84; H, 4.15, 4.04.

Methyl β-Tetrahydronaphthyl Ketone.—The procedure was similar to that for acetophenone, using one mole (136 ml.) of tetralin in 600 ml. of carbon disulfide. These fractions were obtained at 14 mm.: (a) 85–100°, 25.9 g.; (b) 100–152°, 2.4 g.; (c) 152–172°, 59.5 g.; (d) amorphous residue, 60 ml. Fraction (a) represented 19.6% recovered tetralin. Fraction (c) was redistilled at 14 mm.: (a) 152–159°, 1.7 g.; (b) 159–160°, 42.0 g.: (c) 160–168°, 8.8 g.; (d) viscous residue, 5 ml. Fraction (b) represented a 24.1% yield of methyl β-tetrahydronaphthyl ketone. The ketone was characterized by the preparation of the oxime,[10] m. p. 107°, and tetrahydronaphthalene-β-carboxylic acid,[10] m. p. 150°, obtained by the action of bleaching powder[11] on the ketone. For the ketone $n^{27}D$ is 1.5597.

Methyl β-Tetrahydronaphthyl Ketone 2,4-Dinitrophenylhydrazone.—Recrystallized from benzene, the m. p. was 236°. *Anal.* Calcd. for $C_{18}H_{18}O_4N_4$: N, 15.82. Found:[12] N, 15.97, 16.02.

***p*-Phenylacetophenone.**—Ketene was passed into a solution of one mole (154 g.) of diphenyl in 600 ml. of carbon disulfide at 30° with good stirring for twenty hours (9.0 moles ketene). Two moles (267 g.) of aluminum chloride was added over a ten-hour period. Distillation of the hydrolysis products gave 101.5 g. of material boiling at 140–237° (35 mm.), and which solidified on cooling.

(12) Analysis by L. A. Smith.

It was air-dried and redistilled at 20 mm.: (a) 120–150°, 19.4 g.; (b) 150–195°, 11.9 g.; (c) 195–215°, 51.3 g. Fraction (a) contained 10.7 g. of diphenyl, a 7.0% recovery. Fractions (b) and (c) were recrystallized several times from 95% alcohol and yielded 45.9 g. of *p*-phenylacetophenone, m. p. 121°. This represented a 23.4% yield.

Summary

Factors influencing the yield of acetophenone from benzene and ketene have been studied. Conditions have been determined for the preparation of methyl α-naphthyl ketone to the practical exclusion of the β-isomer. The preparations of methyl β-tetrahydronaphthyl ketone and *p*-phenylacetophenone, using ketene, are reported.

alpha,omega-Amino Alcohols. I. N-Phenyl-N'-(ω-hydroxyalkyl)-piperazines from α,ω-Chlorohydrins. Derivatives of Piperazine. XVII

BY GEORGE W. ANDERSON[1] AND C. B. POLLARD

Pyman and Levene[2] have synthesized α,ω-amino alcohols by the reaction of secondary amines with α,ω-chlorohydrins. We have now employed this reaction for the synthesis of a series of N-phenyl-N'-(ω-hydroxyalkyl)-piperazines.

The general procedure followed was to heat 0.2 mole of the chlorohydrin with 0.4 mole of N-phenylpiperazine for five hours on a water-bath. The white solid product was heated with 40 cc. of 5 *M* potassium carbonate, the resulting orange colored oily layer was separated and after it had cooled and solidified, was washed with water and recrystallized from 250 cc. of 60% ethyl alcohol. The white crystals were dried to constant weight in a vacuum over fused potassium hydroxide. Two recrystallizations from ligroin (70–100°) gave a material of constant melting point. The urethans were prepared in hot ligroin solution and were recrystallized from this solvent.

With one exception, the amino alcohols were obtained in a quantitative crude yield. That of N-phenyl-N'-(4-hydroxybutyl)-piperazine was reduced because of the formation of tetramethylene oxide. Neutral equivalents of the amino alcohols and their phenylurethans and analytical data are recorded in Table I.

N-Phenyl-N'-(8-hydroxyoctyl)-piperazine readily absorbs water from air to form a monohydrate. The other amino alcohols absorb water less rapidly.

The α,ω-chlorohydrins of four and five carbon atoms were obtained in 35% yield by the method of Kirner and Richter.[3] The higher members were prepared in approximately 65% yield by continuous extraction of the reaction mixtures of the corresponding glycols and hydrochloric acid.[4]

Final purification was effected by fractionation at 10 mm. The boiling points of the α,ω-chlorohydrins showed a regular increase with increasing number of carbon atoms.

Phenyl- or α-naphthylurethans were prepared from the chlorohydrins. New urethans prepared were the α-naphthylurethans of hexamethylene-

α,ω-chlorohydrin, m. p. 49–50°, and of decamethylene-α,ω-chlorohydrin, m. p. 63–64°. The melting point of the phenylurethan of nonamethylene-α,ω-chlorohydrin was 70–70.5°, 3° higher than previously reported.[4]

N-Phenyl-N′-(8-hydroxyoctyl)-piperazine Hydrate.—N-phenyl-N′-(8-hydroxyoctyl)-piperazine of m. p. 57–58.5° and neut. equiv. 292.1 (mol. wt. is 290.4) gave a compound of m. p. 80–82° and neut. equiv. 306.5 (theoretical 308.4 for a monohydrate) upon exposure to air.

Summary

A series of seven new amino alcohols, the N-phenyl-N′-(ω-hydroxyalkyl)-piperazines, with the alkyl group having four through ten carbon atoms, has been synthesized from α,ω-chlorohydrins and N-phenylpiperazine. Their phenylurethans are reported. The formation of the monohydrate of N-phenyl-N′-(8-hydroxyoctyl)-piperazine upon exposure to air has been ascertained.

alpha,omega-Chlorohydrins of four through ten carbon atoms have been made by methods reported in the literature. The phenylurethan of nonamethylene chlorohydrin was found to melt 3° higher than previously reported. The α-naphthylurethans of hexamethylene and decamethylene chlorohydrins are reported for the first time.

alpha,omega-Amino Alcohols. II. Morpholino Alcohols. Derivatives of Morpholine. II

BY GEORGE W. ANDERSON[1] AND C. B. POLLARD

Paden and Adkins[2] in their study of the reaction of amines with glycols at 200–250° in the presence of copper–chromium oxide reported one experiment in which equivalent quantities of phenethylamine and tetramethylene glycol in dioxane solution were heated for half an hour with hydrogen at 200–400 atm. with the production of 35% of 4-(N-phenethylamino)-butanol-1, 19% of 1-phenethylpyrrolidine, and 43% of unchanged amine and glycol.

On the basis of this experiment we have investigated the reaction of morpholine with α,ω-glycols of four through ten carbon atoms and, as was to be expected, have obtained only two products, namely, the morpholino alcohol and the dimorpholinoalkane. Data are shown in Tables I, II and III.

Approximately 0.5 mole of each reactant in 300 cc. of dioxane was heated at 235–270° for six hours at a pressure of 100 atm. After cooling, the dioxane was distilled off at atmospheric pressure and the remainder fractionated in an efficient electrically heated air-jacketed column 2 cm. in bore, 70 cm. long, packed with 6 × 6 mm. Raschig rings, and having a total condensation, variable take-off head. In several cases, a similar column, 1.8 cm. in bore and 30 cm. long, packed with 5 × 5 mm. Raschig rings, and having a total condensation, variable take-off head was used.

The morpholino alcohols, with the exception of 7-morpholinoheptanol-1, were also prepared from morpholine and the corresponding chlorohydrins. Almost quantitative yields were obtained by this method. Physical and analytical data for the seven new morpholino alcohols are recorded in Table II.

The aryl urethans of the morpholino alcohols were prepared by mixing hot solutions of the aryl isocyanate and the alcohol and heating the mix-

TABLE I

MORPHOLINO ALCOHOLS BY ALKYLATION[a]

Glycol	Moles used	Moles of morpholine	Yields[b] of pure compd., % Amino alcohol	Diamine	Cu–Cr–O cat. used
Tetramethylene	0.75	0.94	36	22	22
Pentamethylene	.80	1.0	31	28	24
Hexamethylene	.60	0.60	21	18	20
Heptamethylene	.33	.42	19	28	10
Octamethylene	.50	.75	26	41	15
Nonamethylene	.34	.43	38	28	11
Decamethylene	.40	.40	21	13	9

[a] Between 125 and 300 cc. of dioxane was used in each case as solvent. The reaction was carried out under about 100 atm. of hydrogen at 235–270° for six hours. [b] Yields are based on the glycol used. Some of the glycol did not react in each case, but was not recovered pure, so yields were not adjusted for it.

7	Phenyl	71.0–72.0	8.74	8.56
8	α-Naphthyl	73.0–74.0	7.29	6.96
9	α-Naphthyl	54.0–56.0	7.03	6.83
10	α-Naphthyl	66.5–67.5	6.79	6.75

Summary

1. A series of seven morpholino alcohols of the type R-$(CH_2)_n$-OH, where R is the morpholine group and n is 4 through 10, has been synthesized by the catalyzed reaction of α,ω-glycols and morpholine, and also by the reaction of chlorohydrins and morpholine except in the case of 7-morpholinoheptanol-1. Their phenyl- or α-naphthylurethans have been made.

2. A series of seven dimorpholinoalkanes of the type R-$(CH_2)_n$-R, where R is the morpholine group and n is 4 through 10, has been obtained as a by-product in the catalyzed reaction of morpholine and α,ω-glycols. Physical and analytical data are reported.

Analysis of Chaulmoogra Oils. IV. *Hydnocarpus anthelmintica* Oil. V. *Taraktogenos kurzii* (Chaulmoogra) Oil

BY HOWARD IRVING COLE AND HUMBERTO T. CARDOSO

IV. *Hydnocarpus Anthelmintica* Oil

The oil expressed from the seeds of *Hydnocarpus anthelmintica* is extensively used in the treatment of leprosy, ranking next to *H. wightiana* oil in therapeutic importance. *H. anthelmintica* occurs abundantly in Siam, Cambodia, Cochin China, and Laos. It also has been reported from Burma. The tree grows to a height of 20 to 25 meters and is generally found in valleys from sea level to 1300 meters altitude. It has been successfully cultivated in Hawaii and the Belgian Congo. The ripe fruits are more or less globular in shape and vary in size from 8 to 15 centimeters in diameter. The seeds are of approximately the same shape and size as those of *H. wightiana* (1 to 2 centimeters long) but are readily distinguished from the latter because of their smoother and thicker shell. The oil is used by the natives of Siam for cutaneous affections. The seeds form an article of export to China where they are known as Ta-fung-chi or Ta-feng-tzu.

As early as 1905 Power and Barrowcliff[1] attempted to analyze *H. anthelmintica* oil. They reported that the total fatty acids of this oil contained chaulmoogric, hydnocarpic, oleic and palmitic acids. Although several qualitative analyses have been made since, no one has succeeded in making a quantitative analysis due to the difficulty in separating the constituents. We have succeeded in analyzing *H. anthelmintica* oil by the method for chaulmoogra oils given in the first article of this series.[2] The constituents and percentage composition are given in Table I. Besides the acids previously reported as present, our analysis shows that gorlic acid and a small percentage of a lower homolog of hydnocarpic acid are also present.

TABLE I

PERCENTAGE COMPOSITION OF THE FATTY ACIDS OF *H. anthelmintica* AND *T. kurzii* OILS (FROM TABLES II AND III)

Acids	*H. anthelmintica*, %	*T. kurzii*, %
Hydnocarpic	67.8	34.9
Chaulmoogric	8.7	22.5
Gorlic	1.4	22.6
Oleic	12.3	14.6
Palmitic	7.5	4.0
Lower homologs of hydnocarpic acid	0.1	0.4
Loss	2.2	1.0

(1) Power and Barrowcliff, *J. Chem. Soc.*, **87**, 884, 896 (1905).
(2) Cole and Cardoso, THIS JOURNAL, **60**, 614 (1938).

Experimental

The sample of *H. anthelmintica* oil was obtained from a 300-liter drum imported several years ago from Siam by the Departamento de Prophylaxia da Lepra da São Paulo, who generously donated the sample for our analysis. Although the oil was more than five years old, its characteristics indicate that very little decomposition had taken place. The characteristics determined at the time of the analysis were as follows: specific gravity 25/25, 0.952; F. F. A. (as % oleic) 2.9; saponification no., 203.3; iodine no. (Hanus), 89.2; specific optical rotation, $[\alpha]^{25}D$ +49.70; refractive index $[n]^{25}D$ 1.4772; unsaponifiable matter, 0.50%.

Method of Analysis.—Since the medicinal properties of chaulmoogra oils depend upon the percentage of optically active fatty acids, the analysis is reported in per cent. of the various fatty acids present. The sample of oil was saponified and the fatty acids liberated in the usual manner. The solid acids were separated from the liquid acids by crystallization from 80% ethyl alcohol. The two fractions were changed to ethyl esters and then fractionally distilled at 10 mm. in a Podbielniak Model B high temperature fractionating apparatus. The details of the separation and distillation were given in the first article of this series,[2] the only change being that the two final crystallizations for the separation of the liquid acids were made with 80% acetone to prevent the formation of ethyl esters.

Qualitative Analysis

In our analysis of the total fatty acids of *H. anthelmintica* oil we found chaulmoogric, hydnocarpic, gorlic, oleic and palmitic acids besides a very small percentage of a lower homolog of hydnocarpic acid. The acids were identified as follows.

Chaulmoogric Acid.—Pure chaulmoogric acid was obtained readily from the acids from fraction 3, Table III, by crystallization to constant melting point from 80% alcohol. It gave the correct optical rotation, iodine number, neutralization equivalent and melting point for pure chaulmoogric acid.[3]

Hydnocarpic Acid.—This acid was isolated in the pure state from fraction 2, Table III, by repeated crystallization of the acids from 80% alcohol. It gave all the correct constants for pure hydnocarpic acid.[3]

Gorlic Acid.—Ethyl gorlate was isolated by several fractional distillations of those fractions rich in ethyl gorlate such as fraction 3, Table II, by the method previously de-

scribed.[4] The correct constants were obtained for ethyl gorlate and gorlic acid.[4]

Oleic Acid.—Oleic acid was not obtained pure but its presence was indicated in the liquid fraction by the distillation curve of the ethyl esters and by the correct iodine numbers for mixtures containing ethyl oleate in fractions 2, 3, 4 and 5 of Table II. The elaidic acid test cannot be used in the presence of gorlic acid as the latter gives a similar reaction. Hydrogenation tests were also unsatisfactory in the presence of chaulmoogric or hydnocarpic acid.

Palmitic Acid.—This acid was separated by cooling fractions of ethyl esters rich in palmitate, the latter solidifying at a higher temperature than hydnocarpate. The solid ester was separated and crystallized from ethyl alcohol to constant melting point (24°). Upon changing it to the acid and crystallizing from alcohol, the correct melting point and neutralization equivalent for palmitic acid were obtained.

Lower Homologs.—The presence of at least one homolog of hydnocarpic acid was indicated by the optical rotation and boiling point of fraction 1, Table II. The sample was too small to attempt to identify this compound.

Quantitative Analysis

The total fatty acids of *H. anthelmintica* oil when separated into liquid and solid acids by the method described by us consisted of 17.9% liquid acids and 82.1% solid acids. Although the separation is by no means complete, the breaks in the distillation curves of the ethyl esters made from these two fractions are much more distinct than when the whole esters are used. Complete separation is not necessary as the amounts of the various constituents can be computed by taking advantage of the boiling points, optical rotations and iodine numbers or absence of one or both of the two latter constants as described in Part I of

(4) Cole and Cardoso, THIS JOURNAL, **60**, 612 (1938).

this series of articles. The results of these computations are given in Tables II and III and these are summarized in Table I. Fraction 1, Table II was computed on the assumption that it was a mixture of alepric acid[5] and a saturated acid.

V. *Taraktogenos kurzii* (Chaulmoogra) Oil

Chaulmoogra is the native name for *Taraktogenos kurzii* oil which has been used for centuries in Burma and India in the treatment of leprosy. In recent years, however, the word "chaulmoogra" has been used generically to indicate any oil containing chaulmoogric acid which might be used in the treatment of leprosy, such as *H. wightiana* or *C. brasiliensis* oil. *Taraktogenos kurzii* is a tree widely distributed in Burma. It is also found in Siam, Eastern Bengal and Assam. *T. kurzii*, called by the Burmese, kalaw, grows to a height of 15 to 20 meters in dense forests. The fruits are globular, varying in size from 8 to 15 cm. in diameter. The seeds are larger than those from *H. wightiana* with a smoother and thicker shell. Bears are very fond of the white flesh of the fruit (in which the seeds are imbedded) and large numbers of them are said to roam the forests in search of the kalaw fruits. Collecting the seeds is very dangerous on account of tigers, bears and other wild animals. The fruit ripens in June or July, falls in the rainy season and is usually no longer fresh when gathered. For this reason and because of the long time necessary for transportation to a press for expression of the oil the true chaulmoogra oil of commerce is almost always of poor quality with a very high free fatty acid content. It is often adulterated and other hydnocarpus oils are frequently sold as chaulmoogra oil. Because of these disadvantages its use in leprosy treatment has been largely superseded by authentic *H. wightiana* and *H. anthelmintica* oils, which are cheaper and of better quality. Plantations would eliminate these disadvantages. In fact the oil for this analysis was obtained from a plantation at Vicosa, Minas Geraes, where Dr. Rolfs has succeeded in acclimatizing *T. kurzii* to Brazil. It flourishes there, producing heavy crops of fruits.

The first analysis of chaulmoogra oil was made by Power and Gornall[6] in 1904. They reported that the oil contained both chaulmoogric and hydnocarpic as well as a small amount of palmitic and linolic acids. Other investigators have added very little to our knowledge of chaulmoogra oil. No quantitative analysis has ever been made.

(5) Cole and Cardoso, THIS JOURNAL, **61**, 2349 (1939).

(6) Power and Gornall, *J. Chem. Soc.*, **85**, pt. II, 838, 851 (1904).

We have made an analysis of this oil by the method described in the first article of this series.[2] The constituents and percentage composition of chaulmoogra oil are given in Table I. Besides the acids mentioned by Power and Gornall, we have found that the oil also contains gorlic and oleic acids and a small amount of a lower homolog of hydnocarpic acid. No linolic or linolenic acid was found. The high iodine numbers of certain fractions which led previous investigators to suspect the presence of linolic or linolenic acid are due to the presence of gorlic acid, which has two double bonds. If gorlic acid should prove to be of greater value in leprosy treatment than the other optically active fatty acids, then the true chaulmoogra oil would be preferable to the other oils we have analyzed since it contains the highest percentage of this acid (see Table V).

Previous statements that the oil does not keep well are not true. The bad reputation of the oil is due to the fact that the oil is practically never expressed from fresh dried seeds as mentioned above. Oil from old seeds is always irritating. *T. kurzii* oil which we cold-pressed from fresh, dried seeds has changed very little after standing for three years and is still non-irritating upon injection. We have found this generally true of all the chaulmoogra oils we have analyzed.

Experimental

The sample of oil was obtained by cold pressing of fresh, dried seeds kindly donated by the Escola Superior de Agricultura at Vicosa, Minas Geraes. The sample of oil was three years old before it was analyzed but the characteristics of the oil had changed only very slightly in that time. The characteristics of the oil made at the time of analysis were as follows: specific gravity 25/25, 0.952; F.F.A. (as % oleic), 1.3; saponification no., 200.6; iodine no. (Hanus), 101.5; specific optical rotation $[\alpha]^{25}D$ +49.80; refractive index $[n]^{25}D$ 1.4790; unsaponifiable matter 0.29%.

The analysis was made on the total fatty acid content of the oil since the medicinal properties of the oil depend upon the percentage of the optically active acids present and was made in the same manner as that of *H. anthelmintica* oil.

Qualitative Analysis.—The fatty acids of *T. kurzii* oil were found to contain chaulmoogric, hydnocarpic, gorlic, oleic and palmitic acids with a very small percentage of a lower homolog of hydnocarpic acid. The acids were identified in the same manner as those from *H. anthelmintica* oil.

Quantitative Analysis.—The total fatty acids of *T. kurzii* oil when separated into liquid and solid fatty acids by the method described by us consisted of 41.7% liquid acids and 58.3% solid acids. After distillation of the ethyl esters made from these two fractions, the amounts of the various constituents present were computed as previously

TABLE IV

CHARACTERISTICS OF CHAULMOOGRA OILS

	Hydnocarpus wightiana	*Hydnocarpus anthelmintica*	*Taraktogenos kurzii*	*Carpotroche brasiliensis*	*Oncoba echinata*

TABLE V

PERCENTAGE COMPOSITION OF TOTAL FATTY ACIDS OF CHAULMOOGRA OILS

Acids	*H. wightiana*	*H. anthelmintica*	*T. kurzii*	*C. Brasiliensis*	*O. echinata*
Hydnocarpic	48.7	67.8	34.9	45.0	None
Chaulmoogric	27.0	8.7	22.5	24.4	74.9
Gorlic	12.2	1.4	22.6	15.4	14.7
Lower homologs of hydnocarpic	3.4	0.1	0.4	?	?
Oleic	6.5	12.3	14.6	6.3	2.2
Palmitic	1.8	7.5	4.0	6.6	7.8
Loss	0.4	2.2	1.0	2.3	0.4

described. The results of these computations are given in Tables II and III and these are summarized in Table I. Fraction 1, Table II, was computed on the assumption that only alepric and palmitic acids were present as the sample was too small to be separated further.

Summary

The qualitative and quantitative analyses of *Hydnocarpus anthelmintica* and *Taraktogenos kurzii* (chaulmoogra) oils have been made by the methods described in the first article of this series. They are the first quantitative analyses that have been made of these two important medicinal oils.

The percentage compositions of these oils are given in Table I.

A summary of the characteristics and percentage compositions of the five oils of the chaulmoogra group so far analyzed in this series of articles is given in Tables IV and V.

Studies in the omega-Camphor Series. I. On the Synthesis of 2-Keto-apocamphane-1-acetic Acid

BY TORSTEN HASSELSTROM AND BURT L. HAMPTON

Some time ago one of the authors of this paper described the reaction involved in the formation of the Semmler and Bartelt lactone from teresantalic acid and the synthesis of *cis*-2-keto-apocamphane-7-π-carboxylic acid,[1] the corresponding *trans* acid being previously synthesized.[2] In view of the fact that camphor itself does not exert the cardiostimulating action, but certain π-camphor derivatives,[3] derived therefrom, do, it was of interest to synthesize some corresponding ω-2-substituted camphane derivatives.

The present paper deals with the synthesis of the novel 2-keto-apocamphane-1-acetic acid, some derivatives of it and with the reactions involved in its preparation.

As starting material we used the ω-benzoylborneol (II) of Lipp, *et al.*,[4] who obtained this compound from camphene (I) by combining it with benzoyl chloride by means of the Friedel–Crafts synthesis, whereby the asymmetric camphene nucleus is converted into the symmetric camphor skeleton by the Meerwein–Wagner rearrangement.

On subjecting the oxime of ω-benzoylborneol (III) to the Beckmann rearrangement, we obtained a mixture of 2-hydroxy-apocamphane-1-acetanilide (IV) and the anilide of camphenecarboxylic acid (VI) together with some tarry material of unknown composition and small amounts of benzonitrile which was identified as benzoic acid by hydrolysis.

The 2-hydroxy-apocamphane-1-acetanilide was hydrolyzed with alcoholic potassium hydroxide solution. The resulting product was the lactone of 2-hydroxy-apocamphane-1-acetic acid (XIV)

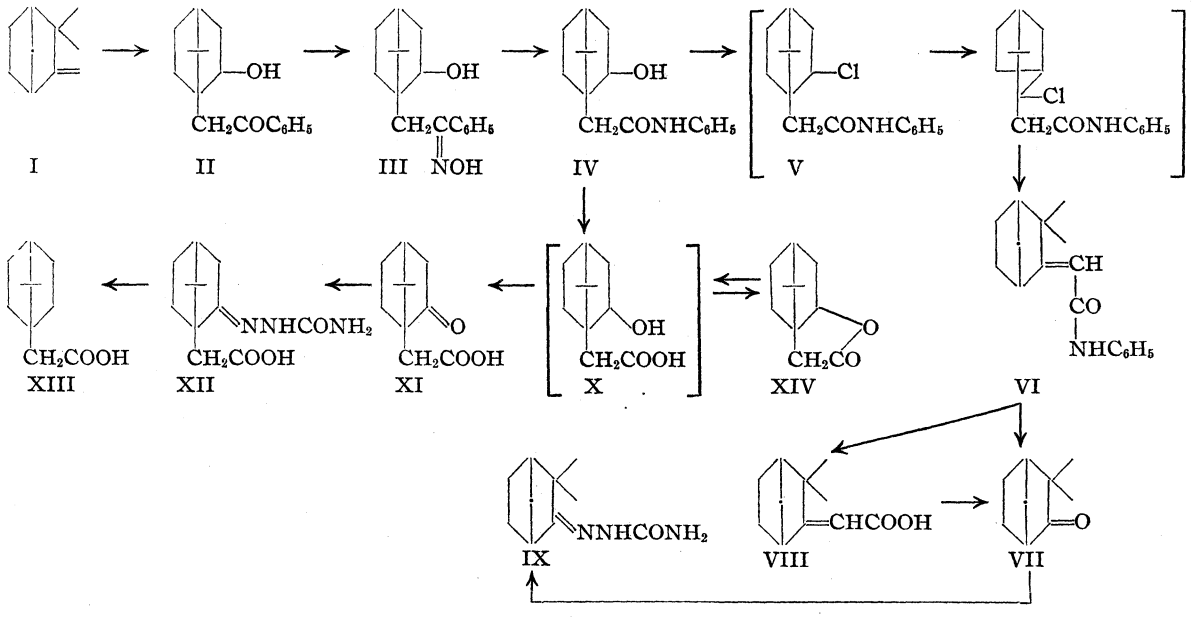
FLOW SHEET



together with aniline which for identification was converted into benzanilide. Attempts to isolate the intermediate hydroxy acid (X) in a pure state failed on account of the ease by which lactone formation takes place. On oxidation with alkaline potassium permanganate solution the potassium salt of 2-hydroxy-apocamphane-1-acetic acid obtained from the lactone by hydrolysis, yielded 2-keto-apocamphene-1-acetic acid (XI). This acid was identified through its semicarbazone (XII), which when subjected to the Wolff–Kishner reaction produced the apocamphane-1-acetic acid (XIII). This series of reactions shows the stability of the hydroxy group of the 2-hydroxy-apocamphane-1-acetanilide in contrast to the corresponding group in ω-benzoylborneol, which on heating is transformed into a furan derivative;[4] this also establishes the evidence that the 2-hydroxy-apocamphane-1-acetanilide and the lactone derived therefrom have the symmetric camphor skeleton.

The camphene-carboxyanilide (VI) obtained as a by-product in the Beckmann rearrangement of the oxime of ω-benzoylborneol is a secondary product apparently formed by way of the Meerwein-Wagner retropinacoline rearrangement from the intermediate 2-chloro-apocamphane-1-acetanilide (V). We observed that on treating 2-hydroxy-apocamphane-1-acetanilide with phosphorus pentachloride in ether solution, the resulting product is camphene-carboxyanilide (VI). On hydrolysis with alcoholic potassium hydroxide solution, this compound yielded camphene-carboxylic acid (VIII) and aniline identified as benzanilide. Since our product showed a higher melting point than the acid recorded by Langlois[5] obtained from ω-bromocamphene by means of the Grignard reaction, for identification it was oxidized with potassium permanganate to camphenilone (VII) whereby oxalic acid was obtained as a by-product. The semicarbazone (IX), prepared subsequently, did not lower the melting point in the mixed melting point test with an authentic sample of camphenilone semicarbazone.

The asymmetric structure of camphene-carboxyanilide was further established by the fact that on direct oxidation with potassium permanganate, it yielded camphenilone which was identified as the semicarbazone, (IX).

Acknowledgment.—Thanks are due to Mr. Ted Calmes of the University of Florida, Gainesville, Florida, for carrying out the Wolff–Kishner reaction.

Experimental

Starting Material.—The camphene was a technical product obtained from E. I. du Pont de Nemours and Company, Wilmington, Del. This material was used in the preparation of ω-benzoylborneol and subsequently for the oxime of this product according to directions by Lipp *et al.*[4]

The Beckmann Rearrangement of the Oxime of ω-Benzoylborneol.—Thirty-five g. (0.12 mole) of the oxime

(5) Langlois, *Ann. chim.*, [IX] **12**, 193, 363 (1919).

(ω-benzoylborneol: m. p. 86–87° (corr.), m. p. 85–86°, Lipp, *et al.;* oxime: m. p. 160–161° (corr.); 159–160° Lipp, *et al.*) was dissolved in 300 cc. of anhydrous ether and 77 g. (0.37 mole) of phosphorus pentachloride was slowly added over a period of one hour to the cooled solution. The temperature of the solution was kept between 20–30° throughout the course of the reaction. After terminating the reaction, the mixture was washed with cold water until the washings were no longer acid to litmus. The ether solution was separated from the water and the ether was removed. The residue was subjected to steam distillation and the distillate extracted with ether. After removal of the ether, 0.5 g. of benzonitrile was isolated and identified by hydrolyzing it to benzoic acid. It was refluxed for three hours with 10 cc. of 20% potassium hydroxide solution. During the reaction some evolution of ammonia took place. After evaporating the alcohol, the solution was acidified with dilute hydrochloric acid and the solid precipitate recrystallized from hexane, m. p. 122.5–123.5° (corr.); it did not lower the melting point when mixed with an authentic sample of benzoic acid.

The residue from the steam distillation was dissolved in a minimum amount of ethanol. After standing in an ice box overnight, a white crystalline precipitate consisting of 2-hydroxy-apocamphane-1-acetanilide was removed by filtration. After two recrystallizations from ethanol, the white rectangular needles melted constantly at 176.5–177.5° (corr.), yield 10 g. (28.2%).

Anal. Calcd. for $C_{17}H_{23}O_2N$: C, 74.9; H, 8.51. Found: C, 74.59; H, 8.72.[6]

The alcoholic mother liquors from the above reaction were evaporated on a steam-bath, leaving 17 g. of an oily residue which was refluxed for three hours with 300 cc. of a 10% alcoholic potassium hydroxide solution. After cooling, the solution was poured into 1200 cc. of ice water and the mixture extracted three times with ether. The ether solution was dried with sodium sulfate and after evaporating the ether, the brownish residue was dissolved in hexane. On standing in the ice box for four hours, a brownish crystalline precipitate was obtained which, after decolorizing with norite, was recrystallized from hexane. After two recrystallizations from hexane and one from dilute ethanol, the solid compound, camphene-carboxyanilide, melted constantly at 154.5–155.5° (corr.); fine white needles; yield 3.3 g. (10.1%).

Anal. Calcd. for $C_{17}H_{21}ON$: C, 80.00; H, 8.28. Found: C, 80.20; H, 8.34.

The hexane filtrates were evaporated, leaving 4.5 g. of a reddish viscous oil which was not identified at this time.

The aqueous alkaline solution was evaporated to a small volume on a hot-plate, carbon dioxide being passed through the solution to prevent oxidation. After filtering, the solution was acidified with dilute hydrochloric acid and extracted with ether. After drying the ether solution with anhydrous sodium sulfate and evaporating the ether, 1.2 g. of a reddish oil was obtained. On standing for about two weeks, it slowly deposited a crystalline solid which after recrystallization from hexane melted constantly at 201.5–202.5° (corr.). It was identified as the lactone of the 2-hydroxy-apocamphane-1-acetic acid since it did not lower the melting point in the mixed melting point test with an authentic sample.

Lactone of 2-Hydroxy-apocamphane-1-acetic Acid.—Four and five-tenths grams of 2-hydroxy-apocamphane-1-acetanilide was refluxed for six hours with 160 cc. of 20% alcoholic potassium hydroxide and, after cooling, poured into 800 cc. of ice water. The solution was then extracted five times with ether. The aqueous layer was evaporated to about 100 cc., carbon dioxide being passed through to prevent oxidation, filtered and, after cooling, acidified with dilute hydrochloric acid. The mixture was now extracted three times with ether and the ether solution dried with anhydrous sodium sulfate. After evaporating the ether, there was obtained a reddish oil which slowly deposited crystals on standing. The semi-solid mass was covered with acetyl chloride and the mixture left standing at room temperature for about fifteen minutes, then the excess of acetyl chloride removed *in vacuo*. The remaining solid was recrystallized from hexane, melting constantly at 201.5–202.5° (corr.); yield, 1.77 g. (60%).

Anal. Calcd. for $C_{11}H_{16}O_2$: C, 72.90; H, 9.45. Found: C, 73.20; H, 9.32.

The ether solution from the extraction of the original alkaline liquors was dried over anhydrous sodium sulfate and distilled, leaving minute quantities of a red oil consisting of aniline since, when treated with benzoyl chloride, it yielded benzanilide melting at 162.5–163.5° (corr.) and did not lower the melting point when mixed with an authentic sample.

2-Keto-apocamphane-1-acetic Acid.—One and seven-tenths grams of the above lactone was dissolved in 34 cc. of a 2% potassium hydroxide solution containing 1.27 g. of potassium permanganate. On refluxing the solution for about fifteen minutes, the permanganate color had disappeared and the mixture was filtered from the precipitated manganese dioxide, evaporated to a small volume on the steam-bath and after cooling to room temperature, acidified with dilute hydrochloric acid and extracted with ether three times. The ether solution was dried with anhydrous sodium sulfate and evaporated, leaving a straw colored oil which was dissolved in a small quantity of water. The precipitated solid melted constantly after three crystallizations from water at 92–93° (corr.), yield 0.6 g. (84.4%).

Anal. Calcd. for $C_{11}H_{16}O_3$: C, 67.33; H, 8.22; neut. equiv., 196.2. Found: C, 67.29; H, 8.20; neut. equiv., 197.1.

Semicarbazone of 2-Keto-apocamphane-1-acetic Acid.—From 0.04 g. of the keto acid, the semicarbazone was prepared in the usual manner, giving an almost quantitative yield. The semicarbazone was recrystallized from ethanol, melting constantly at 199–200° (corr.).

Anal. Calcd. for $C_{12}H_{19}O_4N_3$: C, 56.88; H, 7.56. Found: C, 56.63; H, 7.47.

Apocamphane-1-acetic Acid.—Five-tenths gram of the semicarbazone of 2-keto-apocamphane-1-acetic acid was added to a bomb tube containing sodium ethylate prepared from 0.6 g. of sodium dissolved in 3 cc. of absolute alcohol. After closing the tube, the mixture was heated at 170–180° for fifteen hours. After cooling, the mixture was diluted

(6) All analyses for this paper were done by Mr. S. Gottlieb, Columbia University, New York, N. Y.

with water and the crude acid precipitated with dilute hydrochloric acid; yield 0.3 g. (83.2%). It was dissolved in dilute 20% ethanol, decolorized with norite and recrystallized from the same solvent. After three recrystallizations, it melted constantly at 77–78° (corr.).

Anal. Calcd. for $C_{11}H_{18}O_2$: C, 72.48; H, 9.95; neut. equiv., 182.25. Found: C, 72.53; H, 10.05; neut. equiv., 182.30.

Conversion of 2-Hydroxy-apocamphane-1-acetanilide into Camphene-carboxy-anilide.—Two g. (0.007 mole) of 2-hydroxy-apocamphane-1-acetanilide was suspended in 200 cc. of absolute ether and 1.6 g. (0.007 mole) of phosphorus pentachloride was added slowly, the mixture being cooled during the reaction. The suspended compound gradually went into solution as the reaction progressed and, after completion, the ether solution was washed with cold water until the washings were no longer acid to litmus. The ether solution was dried with anhydrous sodium sulfate and evaporated, leaving a solid which on recrystallization from 85% ethanol melted at 153–154° (corr.); yield 1.2 g. (66%). It did not lower the melting point in the mixed melting point test with an authentic sample of camphene-carboxyanilide.

Camphene-carboxylic Acid.—Eight-tenths gram of camphene-carboxy-anilide was refluxed for thirty-six hours with 100 cc. of 20% alcoholic potassium hydroxide. After cooling, the solution was poured into ice water which was extracted with ether. The aqueous solution was evaporated to about 20 cc. while carbon dioxide was being passed through, filtered and after cooling acidified with dilute hydrochloric acid and extracted with ether. The ether solution was dried with sodium sulfate and evaporated, leaving a brownish solid which was dissolved in hexane, decolorized with norite and recrystallized from the same solvent; melting point 126–127° (corr.); yield, 0.13 g. (23.2%).

Anal. Calcd. for $C_{11}H_{16}O_2$: C, 73.32; H, 8.95; neut. equiv., 180.23. Found: C, 73.41; H, 9.15; neut. equiv., 180.70.

The ether solution obtained by extracting the original alkaline liquors was dried with anhydrous sodium sulfate and evaporated, leaving a residue which partly solidified on cooling. It was washed with a small amount of hexane, leaving a white solid which proved to be identical with the original material; yield 0.282 g. (35%). The hexane washings were evaporated, leaving minute quantities of a residual reddish oil which consisted of aniline since the benzoyl derivative prepared in the usual manner melted at 162.5–163.5° (corr.), and did not lower the melting point when mixed with an authentic sample of benzanilide.

Camphenilone Semicarbazone.—Two and five-tenths grams of camphenecarboxylic acid was dissolved in 75 cc. of water containing 2.61 g. of potassium hydroxide. To this solution was slowly added a solution of 4.38 g. of potassium permanganate solution while steam distilling. A volatile oil of camphoraceous odor was taken up in ether, the solution being dried with anhydrous sodium sulfate. After distilling off the ether, there was obtained 1.5 g. (79%) of camphenilone which was immediately converted into the semicarbazone prepared in the usual manner; yield of semicarbazone 1.8 g. It was recrystallized from dilute ethanol, yielding fine white needles melting at 223–224° (corr.) and did not lower the melting point in the mixed melting point test with an authentic sample.

Anal. Calcd. for $C_{10}H_{17}ON_3$: C, 61.53; H, 8.78 Found: C, 61.34; H, 8.89.

The manganese dioxide was filtered from the aqueous solution, which was evaporated to a small volume, acidified with dilute hydrochloric acid and the precipitate removed by filtration. After recrystallizing from hexane, the acid melted at 126–127° (corr.). The mixed melting point test with the original material showed no lowering; recovery, 0.2 g. A solution of calcium chloride was added to the aqueous solution made alkaline with ammonia after removal of the original acid. The precipitate responded to the usual tests for calcium oxalate.

Three and seven-tenths grams of camphene-carboxyanilide was added to a solution of 6.4 g. of potassium permanganate and 0.8 g. of potassium hydroxide in 230 cc. of water. The mixture was shaken on a machine for fifteen hours and then steam distilled; 200 cc. of distillate was collected to which was added 1 g. of semicarbazide hydrochloride and 1 g. of sodium acetate. On standing *in vacuo* for three days, a crystalline precipitate was separated and recrystallized from ethanol, m. p. 224–225° (corr.). When mixed with an authentic sample of camphenilone semicarbazone, it did not lower the melting point.

Summary

1. When subjected to the Beckmann rearrangement, ω-benzoylborneoloxime yielded 2-hydroxy-apocamphane-1-acetanilide and as secondary product camphene-carboxyanilide, formed apparently by the Meerwein–Wagner rearrangement, and small amounts of benzonitrile, together with some tarry material of unknown composition.

2. The composition of 2-hydroxy-apocamphane-1-acetanilide was established by a series of new ω-homocamphor derivatives: lactone of hydroxy-apocamphane-1-acetic acid, 2-keto-apocamphane-1-acetic acid, semicarbazone of 2-keto-apocamphane-1-acetic acid and apocamphane-1-acetic acid.

3. The Meerwein–Wagner retropinacoline rearrangement on 2-hydroxy-apocamphane-1-acetanilide yielded camphene-carboxyanilide, which was characterized through its oxidation to camphenilone and hydrolysis to camphene-carboxylic acid.

The Density, Thermal Expansion, Vapor Pressure, and Refractive Index of Styrene, and the Density and Thermal Expansion of Polystyrene

BY WINTON PATNODE AND W. J. SCHEIBER

The density of styrene has been reported by a number of investigators,[1] but the values are not in good agreement. We have measured the density of styrene over the range 30–120° with the aid of a dilatometer, and the results of these measurements are plotted in Fig. 1. The points in circles and triangles are our measurements on two samples, and the lettered points indicate the previously published values.[1] The styrene used was obtained from the Dow Chemical Co. and from the Standard Telephones and Cables, Ltd., in England. Each sample was purified by fractional distillation at 80 mm., the middle fractions of constant boiling point and refractive index being taken for measurement of density.

In Fig. 2 is plotted log vapor pressure *versus* $1/(t + 230)$ of data taken from the literature[2] (lettered points), and of our samples which boiled at 76.2–76.7° at 80 mm. A good straight line can be drawn through these points, and it indicates a boiling point of 145.1° at 760 mm. This is in good agreement with an experimentally determined boiling point on very pure styrene of 145.0–145.4°.[1x]

In Fig. 3 is a plot of refractive index *versus* temperature, the lettered points again referring to the literature.[3] Our measurements, made with the aid of an Abbé refractometer, appear to be somewhat higher than many of the others, which, however, is to be expected if the earlier samples contained saturated impurities such as ethylbenzene. Phenylacetylene, however, would have the opposite effect, but our samples were found to contain less than 0.25% (limit of sensitivity of our test) of this impurity, if any at all.

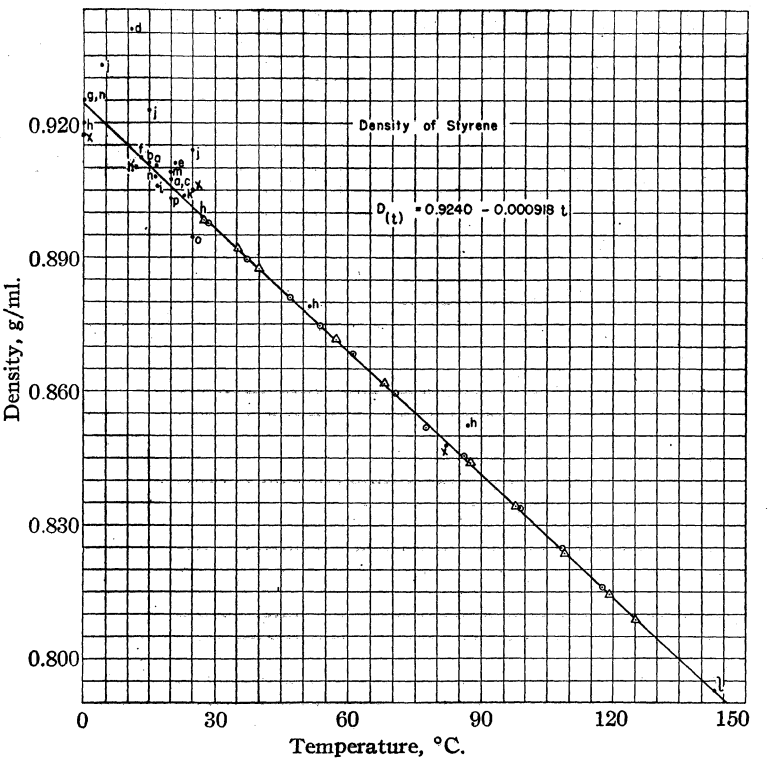

Fig. 1.—Density of styrene.

The density of resinous polystyrene was measured with the aid of a dilatometer for solids, the immersion liquid being mercury. Figure 4 is a plot of density *versus* temperature for two samples. Note that the curves consist of two straight lines that intersect at a point. At the temperature corresponding to this point there is apparently a fundamental change in the structure of the polymer. Sample I was prepared by heating pure, degassed styrene in a sealed tube under pressure

of mercury for several weeks at 100° and then for three additional weeks at 125°. Sample II was prepared by heating for four weeks in a sealed tube at 150°, a piece of polystyrene that had spontaneously polymerized in a bottle at room temperature over a period of about six months. Although the purity of this sample was unknown, it is believed to have been over 98% styrene. As a measure of the relative average molecular weights of the samples measured, their specific viscosities, $\eta_{sp.} = \eta_r - 1$, of 1 g. of polymer in 40 g. of benzene were measured at 26°, and found to be 2.04 for Sample I and 1.42 for Sample II. These values are in contradiction to the general rule that the lower the temperature of polymerization, the higher the molecular weight of the polymer, and

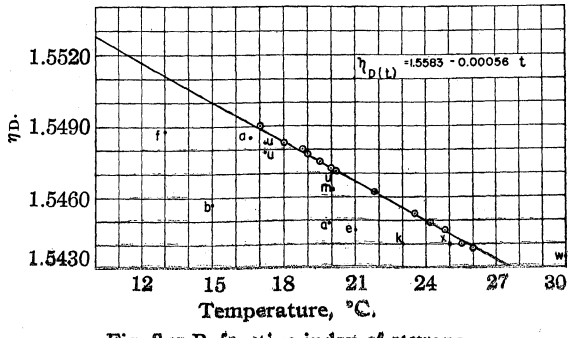

Fig. 3.—Refractive index of styrene.

may be attributed to the fact that Sample II was subsequently heated at 150°, which brings up the interesting question of change in average molecular weight with temperature, and the possibility of equilibria. An attempt to measure the density of the piece of polystyrene that had been formed at room temperature, and had never been heated, was successful at low temperatures only; at 70° and above the volume decreased continuously with time, probably owing to continued polymerization.

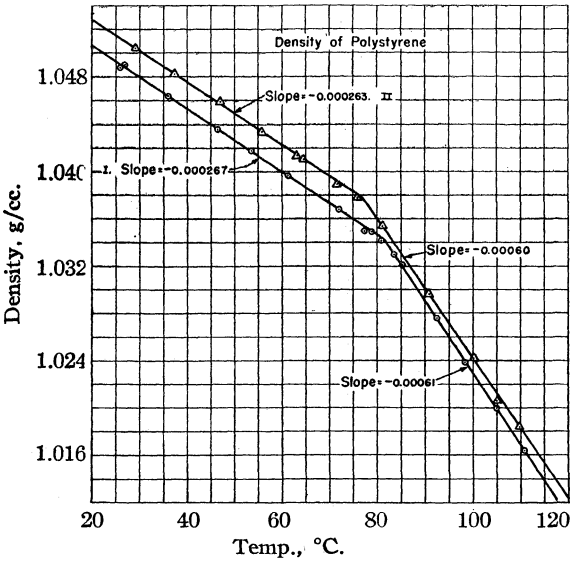

Fig. 4.—Density of polystyrene.

The data plotted in Fig. 4 were readily reproducible, even though the samples were repeatedly heated and cooled. It was necessary, however, to wait for considerable time, sometimes hours, for the volume to become constant at constant temperature, apparently long after temperature equilibrium had been established. This slow, persistent change in volume is a common property of glasses. The relative densities of the two samples are real, although the absolute density of each was found to be about 0.1% higher when measured by weighing in air and in water. The transition temperatures of the two samples are 81.5 and 77.5°. Measurement of the "high elasticity temperatures" of the same two samples by J. J. Russell in this Laboratory gave the values of 86 and 81°. Although these values are not identical with those for the transition temperature, they are in the same relative order. This lends further evidence to the assumption that polystyrene undergoes a fundamental change in struc-

ture at a definite temperature, depending upon the sample, which in some respects resembles the melting of crystals. It is also interesting to observe that although the densities and transition temperatures of these two samples are different, the slopes of the curves are identical.

Recently Jenckel and Ueberreiter[4] published a long paper describing the change in specific volume of polystyrene with temperature which confirms the general phenomena described above, and in addition they conclude that the transition temperature is depressed not only by a low average molecular weight of the polymer, but also by the presence of impurities in the resin such as monomeric styrene, paraffin, or polystyrene of very low molecular weight. Their data indicate an upper limit for transition temperature of slightly above 100° regardless of molecular weight, although their data for transition temperature and molecular weight do not fall upon a smooth curve. Neither do their values for density bear any regular relationship to average molecular weight or to transition temperature, although some such relationship might be expected. And, finally, their values for coefficient of expansion, as indicated by the slopes of the specific volume–temperature curves, show no regular relationship to molecular weight. This lack of regularity may indicate either that their measurements are in error by quantities greater than the differences found, or that the measured properties are influenced greatly by factors which have but little influence upon the viscosities of solutions of the polymers.

This bi-linear thermal expansion of polystyrene, the sharp transition temperature, and the closely accompanying sharp "high elasticity temperature" all point to the conclusion that polystyrene is a body of fairly definite composition and structure. It would be interesting to examine other linear polymers in the light of these observations, and to investigate the effect of cross-linking on the transition temperature.

Summary

This paper includes the density, thermal expansion, vapor pressure, and refractive index of styrene, and the density and thermal expansion of polystyrene. A discussion of these latter properties is given in relation to other properties of the polymer.

The Radioactive Determination of Protactinium in Siliceous Terrestrial and Meteoritic Material

BY WALTER C. SCHUMB,* ROBLEY D. EVANS† AND JANE L. HASTINGS*

In order to test more completely the validity of the general rule that the abundance ratio of the isotopes of any element is a constant, independent of the source or of the mode of combination of the element, it is of interest and importance to determine such abundance ratios in meteorites, which represent the only available specimens of extra-terrestrial matter. Atomic weight or isotopic abundance ratios have been determined for carbon, oxygen, silicon, chlorine, iron, cobalt and nickel, by various workers[1]; and in the case of all the elements studied the isotopic abundance ratios are not measurably different in meteoritic and in terrestrial matter.

In the case of radioactive elements, such as uranium, these abundance ratios assume additional interest, in that by means of them a knowledge may be obtained of the difference in age between these atoms in the meteorite specimen and in terrestrial substances containing the same element. This subject was discussed in some detail by Evans,[2] who on the working assumption that the "isotopic ratio of any element is a constant of nature, and is independent of its place of origin in the galactic system," derived the following expression for the differential age in years of

uranium atoms in a meteorite and in the earth:[3]

$$t_m - t_e = 2.8 \times 10^9 \log (R_e/R_m) \qquad (1)$$

where t_m and t_e are the respective ages in the meteorite and in the earth, R_e is the $_{92}U^{235}:{}_{92}U^{238}$ activity ratio observed in the earth today, and R_m is the same ratio measured in the meteorite.

The present paper reports the results obtained in a portion of a program for the determination of isotopic abundance ratios in meteorites being carried on jointly in these laboratories, in particular, the determination of the isotopic ratio of $_{92}U^{235}$ (or AcU) to $_{92}U^{238}$ (or UI) in a specimen of the Pultusk[4] meteorite, which, because of its reported[2] high heliocentric velocity (56 km. per sec.) has been considered as representing not only extra-terrestrial but possibly extra-solar material.[5] The sample used in this work was very kindly furnished to Professor Evans by Dr. C. C. Gregg and Mr. H. W. Nichols of the Field Museum of Natural History, Chicago. Nier[6] has recently checked the constancy of the isotopic abundance ratio of U^{235}/U^{238} in terrestrial material by means of mass spectroscopic determinations on Pb^{207} and Pb^{206} for twenty-one uranium minerals and on U^{238} and U^{235} for three minerals.

In all but very young rocks radioactive equilibrium has been established in the three radioactive series, that is, the rate of disintegration is equal to the rate of formation of all members of each series derived from the three parent elements, $_{92}U^{238}$, $_{92}U^{235}$ and $_{90}Th^{232}$. Therefore, by determining the amount of any one member of a series present, the quantity of any other may be calculated. Thus the determination of the protactinium content of a specimen permits the calculation of the amount of the parent element AcU, and the determination of the radon content of the sample makes possible the calculation of the amount of the parent element UI present, and from these two values the abundance ratio U^{235}/U^{238} may be obtained.

(3) The numerical factor 2.8 has been changed from 1.46, given in the reference cited, to 2.8 as the result of more recent work on the actinium series branching ratio by A. O. Nier, *Phys. Rev.*, **55**, 150 (1939).

(4) A shower of fragments of a stony meteorite fell in Pultusk, Poland, on Jan. 30, 1868.

(5) Professor C. C. Wylie of the State University of Iowa has kindly communicated to us the results of his recent recalculation of the Pultusk trajectory observations, originally reported by Galle in 1868, following interviews with those who observed the meteorite fall. Professor Wylie's extensive experience in such interviews leads him to reduce the reported height of appearance of the meteorite. This has the effect of reducing the computed velocity so that the Pultusk meteorite would be of solar-system origin rather than extra-solar. Professor Wylie has just summarized his work in *Science*, **9**, 264 (1939).

(6) Nier, *Phys. Rev.*, **55**, 150, 153 (1939).

A method has been worked out by v. Grosse[7] and others for the isolation of protactinium from other radioactive elements. The present method is a modification of that of v. Grosse in that provision had to be made for the elimination of large amounts of silica and some 5% of free metal along with metal sulfides. The chemical analysis of two specimens of the Pultusk meteorite, as given in Farrington's[8] compilation, are presented in Table I.

TABLE I

Experimental

Preliminary Work.—The preliminary work for testing the method was carried out on granite of known radium content. All solid reagents to be used were tested separately and a record made of their alpha activity. The efficiency of the method for the removal of radioelements other than protactinium and their isotopes was checked by adding known amounts of solutions of the salts of uranium, thorium, and polonium, respectively, and repeating all operations. These experiments proved that three separations (as described in Table II and the section on analytical procedure) removed 94% of the added uranium, 100% of the thorium and 95% of the polonium. Finally, a small sample of pure protactinium, deposited in zirconium pyrophosphate, and kindly furnished us for the purpose by Dr. v. Grosse, was converted into a highly dilute solution. The alpha activity of a portion of this solution was measured, and a known amount of it was carried through the chemical procedure. The activity of the recovered protactinium was determined, whereby it was demonstrated that 90 ± 6% of the protactinium could be recovered. In view of the many steps required in the analytical procedure employed, this recovery is considered to be satisfactory.

Sampling.—Due to the probability of surface leaching and contamination, only the inner portions of specimens of granite were used. These were ground, first in a steel mortar and finally in agate, both mortars being "rinsed" by grinding inactive sodium carbonate in them before use. After thorough mixing, a third of the finely ground material was reserved in a stoppered bottle for the radon de-

terminations and the remainder used for the separation of protactinium. In the case of the Pultusk meteorite sample, all of the outer black layer, or "skin," was carefully removed and samples of the inner portions were prepared as in the case of the granite.

Analytical Procedure.—A 50-g. sample of the siliceous material was treated with 100 cc. of aqua regia and heated on the steam-bath for a half hour. After cooling, the diluted acid solution was filtered and the residue dried and ignited in platinum. The filtrate was evaporated and the residue dehydrated. The residue was taken up with concd. hydrochloric acid, followed by water, and the silica filtered and combined with the original residue. The dehydration process was then repeated. The combined residues were treated several times with 47% hydrofluoric acid to which a few drops of concd. sulfuric acid had been added, and evaporated to fumes after each treatment. Three times the calculated amount of hydrofluoric acid was used to ensure complete removal of silica, assuming the latter to be 50% of the original sample. The residue then was heated to dull red heat and after cooling was treated with hot, concd. hydrochloric acid followed by hot water. There remained very little residue and this was filtered off and washed with hot water, dried, ignited and reserved for future work, if necessary.

The filtrate was combined with that from the final dehydration and the solution was evaporated to 200 cc. To the cooled solution zirconyl chloride solution was added equivalent to 100 mg. of ZrO_2. An excess of 6 *N* phosphoric acid was added and the solution stirred for several minutes. The precipitate of zirconium phosphate was allowed to stand for at least two hours before filtering. The precipitate was washed with 5% hydrochloric acid, dried, ignited, and weighed. The filtrate was reserved.

To the zirconium pyrophosphate, which contained the protactinium, 20 cc. of 2% hydrofluoric acid was added and the vessel heated until solution was complete. After cooling, solutions of the nitrates of barium, lead, lanthanum, and bismuth, equivalent to 4 mg. of each element, were added. The insoluble sulfates and fluorides of these elements co-precipitate those of radioactive elements other than protactinium, as indicated in Table II.

TABLE II

RADIOACTIVE SEPARATIONS FROM SOLN. OF ZrP_2O_7 + Pa IN 2% HF

Reagent	Radioactive elements and isotopes removed
$Ba(NO_3)_2$	Ra, $MsTh_1$, AcX, ThX
$Pb(NO_3)_2$	RaB, ThB, AcB, RaD, ThD, AcD, RaG
$Bi(NO_3)_3$	Po, RaC, ThC, AcC, RaE
$La(NO_3)_3$	Ac, $MsTh_2$

After standing for one hour, the precipitates were filtered, using hard rubber funnels. The residues were discarded. This operation was carried out three times to assure satisfactory elimination of radioactive contaminants, because blanks on which only two separations had been made occasionally showed residual counts. The third filtrate was evaporated to dryness, the residue ignited at red heat for ten minutes, and after cooling each residue so obtained was placed in a separate desiccator to avoid possible contamination.

A portion of the residue was transferred to an agate mortar and finely ground under alcohol. A suspension of the ground material was made in ethyl alcohol and poured upon a weighed silver disk, which had been sealed to a brass evaporating cylinder by means of rubber cement. The alcohol was evaporated in a heated cabinet in an atmosphere of well-aged and hence radioactively inert nitrogen. When the sample was dry, the cylinder and rubber cement were quantitatively removed from the disk and the disk plus the sample was weighed.

Measurement of Activity.—The weighed disk, containing the protactinium with zirconium pyrophosphate deposit, was placed in the recording alpha counter. An ionization chamber of the parallel plate condenser type was used, the design and operation of which has been discussed fully by Finney and Evans.[9] The ions formed by the alpha rays are collected, the current amplified, and the resulting galvanometer deflections recorded photographically upon sensitized bromide paper contained in a Telechron-driven drum camera which makes one revolution every two hours. Twenty consecutive hours of observation were generally employed in order to minimize the probable error. These could be recorded on a single sheet of 5 × 37.5 in. paper, by using a laterally moving light source.

The inner parts of the ionization chamber are made of spun copper and are easily removable for cleaning. Some contamination is, of course, inevitable, due to radioactive material in the walls of the ionization chamber, so that even without a radioactive sample in the chamber the record obtained will show some countable α-rays. Careful cleaning and the use of inactive silver for the metal disks minimizes this "background."

A blank on all reagents was carried along in parallel with the samples, and this served as a check on the completeness of removal of radioactive contaminants and on the overall manipulative procedures.

Calculated Results and Conclusions.—A sample of granite from Ontario, designated as "K. D. Fine," known to be low in radioactive material, was selected for a representative terrestrial material. The protactinium content was calculated from the observed alpha count per sq. cm. of source by means of the following two equations, discussed in the paper of Finney and Evans.[9]

$$n_a' = \frac{N\mu\tau}{4}\left[\frac{2(R-\rho)-\tau}{(R-\rho)}\right] \qquad (2)$$

in which

n_a' = alpha counts observed per cm.^{2} of source
N = alpha rays per cm.^{3} emitted in the source
R = 3.61 air-cm. = mean range in air at 15° and 760 mm. for alpha particles from Pa
ρ = 0.5 air-cm. (assumed maximum range of short range α-rays not detected)
μ = $15.6 \times 10^{-4}/d$ = ratio of range of α rays in the solid to the range in air
$\mu\tau$ = thickness of source in cm.
τ = mass/(area × density × μ) = source thickness in air-cm.

$$N = \frac{6.02 \times 10^{23} Q.\lambda.d}{W} \qquad (3)$$

			34.2	2.7 ± 0.8	.....	8.7 ± 2.6	.049 ± .013
					Mean	6.0 ± 1.7	0.035 ± 0.011

where

W = 231 = at. wt. of Pa
λ = 2.5×10^{-9} hr.$^{-1}$ = decay constant of Pa
Q = concentration of Pa in g. per g. of source
d = density of ZrP_2O_7.

The probable error for each background run and determination of alpha rays due to protactinium was calculated in the usual way:

$$\text{P. E.} = 0.67\left[\frac{\Sigma(x - \bar{x})^2}{n(n-1)}\right]^{1/2}$$

where $\bar{x}$ is the average of n individual observations of x.

Table III summarizes the results obtained with the granite and Pultusk meteorite.

In equation (1) above the quotient of the activity ratios R_e/R_m is equal to the quotient of the mass ratios, since the radioactive decay constants and the atomic weights involved cancel out in the quotient.

The mean values of the radium content of these two specimens, as determined by Mr. Clark Goodman of the Physics Department, are 0.28 ± 0.02 $\times 10^{-12}$ g. Ra per g. for the granite and 0.023 ± 0.005 $\times 10^{-12}$ for the Pultusk meteorite. The corresponding observed weight ratios, Pa/Ra for the granite, and similarly for the meteorite, become 1.64 ± 0.5 and 1.52 ± 0.5, respectively. From these results the conclusion may be drawn that, if the probable errors are considered, there is no appreciable difference in the age of terrestrial uranium atoms and those in this specimen of the Pultusk meteorite.

The observed Pa/Ra ratio, and consequently the U^{235}/U^{238} ratio, is about twice the value observed by Nier[6] in terrestrial uranium minerals. Our probable error is based on the observed fluctuations in the α-ray counting rates, and does not include the contributions of any unknown systematic errors. Our observed Pa/Ra ratio, 1.64 ± 0.5, is higher than Nier's value by 1.5 times our probable error. According to the theory of errors, there is a 30% chance that the true value differs from the observed by more than 1.5 times the probable error. Therefore, the two values are compatible with each other. The differential age estimated from these observations depends (Equation 1) only on the logarithm of the *ratio* of the observations on meteoritic and terrestrial material, and is therefore much more accurate than the observations themselves.

From the chemical standpoint a more definite conclusion may be arrived at: the method employed for the separation and estimation of protactinium has proved satisfactory for as little as 10^{-13} g. of protactinium per g. of siliceous material, and with larger samples this limit probably could be set much lower.

This investigation was materially assisted by a grant from the Cyrus M. Warren Fund of the American Academy of Arts and Sciences, which is hereby gratefully acknowledged.

Summary

The protactinium contents of a granite and of a specimen of a meteorite (Pultusk), both high in silica, have been determined by the co-precipitation of the protactinium with zirconium phosphate, followed by purification of the ignited pyrophosphate, employing a modification of the method of v. Grosse. The alpha activity of the protactinium thus isolated was measured on a re-

cording alpha-counter and the concentration of protactinium in the two specimens of terrestrial and of meteoritic material calculated.

From these data and the corresponding radium concentrations of the same specimens determined independently, the weight ratios Pa/Ra have been derived for the two materials. From these results the conclusion has been reached that within the limits of error the age of the uranium atoms in this specimen of the Pultusk meteorite is the same as for terrestrial uranium.

The method is capable of estimating as little as 10^{-13} g. of Pa per g. of siliceous material, and the limit may probably be lower than this if larger samples are taken.

Rates of the Thermal Reduction of Dichromic Acid by Quinine, Hydroquinine, and Cinchonine in Dilute Sulfuric Acid at 0 to 60°

BY LAWRENCE J. HEIDT

Quinine and ten similar alkaloids reduce dichromic acid when ultraviolet light is absorbed by the alkaloid.[1] This reaction was studied in dilute sulfuric acid at 0 to 30°. The variations in the photochemical efficiencies with structural changes in the alkaloids suggested that the hexavalent chromium was reduced mostly by the secondary hydroxyl group.[1d] The kinetics of the photochemical reaction were also studied and interpreted.[1c] This paper presents a study of the kinetics of the thermal reaction in the same environment.

Materials.—The source and purification of the reagents were the same as in the photochemical work. Acid solutions were standardized by comparison with sample 84 of U. S. Bureau of Standards potassium acid phthalate.

Stock solutions of ferrous ammonium sulfate were made from clear green crystals of Analytical Reagent material and were stored in the dark. They were standardized against dichromate solutions each week they were used and the proper factors at other times interpolated.

Apparatus and Procedure.—One of the two reaction cells is sketched[2] in Fig. 1a. The stirrer was the Pyrex plunger, D. In the cell not sketched, the part of D containing the disks was replaced with a Pyrex ribbon twisted like a screw. The fall of each plunger was cushioned by a Pyrex button fused onto the end that struck the bottom of the cell. An iron nail, B, was sealed into the top of each plunger whereby it was lifted at intervals by an electromagnet and fell when a "flasher" interrupted the current in the magnet. The cell outlet, C, used in the preliminary work, was replaced by a glass joint whose cap contained the male part made of solid glass. An umbrella fused to this cap fit loosely around the joint and extended as far down as the female part illustrated in the sketch. The volume of each cell was 100 cc. Their other characteristics have been published,[3] although these cells and the accompanying apparatus were used first in this research.

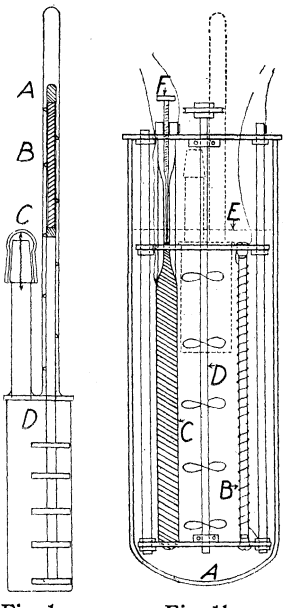

Fig. 1a.

Fig. 1b.

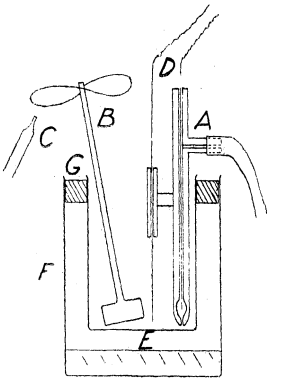

Fig. 1c.

The arrangement of the apparatus in the thermostat is sketched in Fig. 1b. The thermoregulator was a relay operated by a vacuum tube whose grid was in series with the contact, F, made in the glass capillary. This capillary was sealed to a welded steel tube filled with mercury. The quick response of the mercury in the steel tube to changes in the temperature of the bath enabled all adjustments for a new temperature setting to be completed within an hour. The bath then remained within 0.01° for ten hours and within 0.03° for several days. The container was the silvered dewar flask, A. The level of the thermo-

stating oil was kept at E. In later work above 60° it became necessary to place the glass capillary outside of A, and connection with the steel tube was made through a piece of steel capillary. The contact with the grid was then made at room temperature—held within 2° to maintain the bath within the ranges of temperature given above.

At 0°, the reaction vessels were placed in a mush of crushed ice and distilled water in a commercial one-gallon (5-liter) vacuum jug fitted with a light-proof cover but without any other apparatus to control the temperature. Nevertheless, T remained at 0.00° in the center of the bath around the reaction cell. Only clear pieces of ice were used and they were washed with distilled water. Stirring of the reacting mixtures was restricted to shaking the cell and contents just before removing a sample, and weighing it out directly for analysis.

Reference (3) describes the way in which temperatures were measured and solutions brought quickly to the temperature of the thermostat. Tared samples of dry alkaloid and stock solutions of sulfuric acid and potassium dichromate were used to make up the reaction mixtures. When less than 10 mg. of alkaloid was required, the appropriate volume of a more concentrated, *freshly prepared* solution was used. This procedure helped avoid any peroxide which might have formed if stock solutions of these alkaloids had been kept in contact with air for long periods.

Reactions were followed by measuring the change in concentration of the substances that oxidized, in acid solution at room temperature, solutions of ferrous ammonium sulfate. Presumably these oxidizing substances were mainly hexavalent chromium, so the measured rate has been taken as $-\Delta(K_2Cr_2O_7)/\Delta t$.

The apparatus sketched in Fig. 1c was used to titrate the weighed samples of the reaction mixtures. These were placed in the inner beaker, E, and thermostated with a water-bath in the outer beaker, F, centered with the cork ring, G. The end-point was taken as the maximum potential difference, p. d., produced between the platinum wires, D, by a drop of titer. This maximum usually occurred within five drops (0.1 ml.) after the bulb (volume about 0.02 ml.) surrounding one of the electrodes had been flushed by blowing repeatedly through A until no p. d. between the electrodes dipping in the solution was measurable. The galvanometer which detected the p. d. had a sensitivity of 45 meg., and a CDRX of 18,000 ohms. Analyses were reproduced to 0.03 g. of 0.001 *M* Mohr salt. Solutions were weighed to 1 mg., and were transferred with clean, dry pipets.

Samples for analyses were taken from tubes at 0° or directly from the reaction cell if at 0°. The tubes were sealed with glass caps ground to fit tightly without grease. Often, two sets of analyses were made upon the samples in the tubes; the first set, within an hour after the sample had been transferred from the reaction cell, and the second set, after the sample had stood overnight at 0°. The difference between the two sets was usually small, so that a linear extrapolation was made to the time when the sample was taken from the reaction cell. When the correction thereby applied to the first set of analyses was less than 0.2%, the second set was omitted for the remaining samples.

The photochemical reaction was made negligible by keeping the reacting solutions in the dark except during sampling and when made up and analyzed in dim, diffuse light.

Results

The initial concentration of the sulfuric acid was fixed at 1.55 *M*, so that only a small fraction of the hydrogen ions was consumed. The *p*H, therefore, remained almost unchanged throughout the reaction. The thermal as well as the photochemical reactions were paralyzed even at 60° in the absence of added acid, and a precipitate appeared when the alkaloid and dichromate concentrations were much greater than 0.0003 *M*.

The increase in the initial rate of the reaction with the concentrations of dichromate and alkaloid are plotted on a logarithmic scale in Figs. 2A and 2B. The abscissa has been adjusted to make the points at 0, 30 and 60° coincide at 0.000167 *M* dichromate and 0.01 *M* alkaloid. The reaction rates were the same in either cell, and each point on the plot represents the average of many experiments, which agreed within 5% in the stirred solutions and within 10% in solutions not stirred. The rates for quinine, hydroquinine, and cinchonine were the same within the limits of error.

The straight lines through the points in Figs. 2A and 2B are given by equation (1) $-\Delta(K_2Cr_2O_7)/\Delta t = k(K_2Cr_2O_7)(\text{alkaloid})^{1/2}$. The average k in kilograms$^{1/2}$ moles$^{-1/2}$ and minutes^{-1} was 0.00055 at 0°, 0.0026 at 30°, and 0.011 at 60°.

The straight line through the points on the plot, in Fig. 2C, of $\log_{10} k$ against $1/T$, is given by equation (2) $\log_{10} k = 4.05 - 2000/T$. $T = 273.2° +$ °C. The energy of activation is 9 kilocalories.

In quinine, the methoxyl group in position six of the quinoline nucleus, and the vinyl group, do not enter the reaction; otherwise, equation (1) would not be expected to hold for all three alkaloids unless the rates of oxidation of these groups were also given by (1). The small activation energy suggests that a large number of degrees of freedom contribute energy to the activation process in accord with the large conjugated system of single and double bonds which transmit energy readily throughout the quinoline part of the alkaloid. It may also mean that the potential of the oxidation–reduction system and the steric factor largely determine these rates. The small value of the frequency factor implies a large steric effect often associated with reactions between complex molecules.[4]

(4) See, for example, H. W. Melville, *Chem. Soc., Annual Reports*, **35**, 69 (1939).

As the thermal reaction proceeded, its rate at first increased slightly as shown, for example, at 30° in Table I, before it began to decrease very slowly as the hexavalent chromium continued to disappear.

TABLE I

Temp., 30.0°; quinine, 0.01 *M*; $K_2Cr_2O_7$, 0.00017 *M*; H_2SO_4, 1.55 *M*.

% Dichromate reduced	$-\Delta(K_2Cr_2O_7)/\Delta t$ (moles/kg./min.) $\times 10^3$	$k \times 10^3$ calculated from equation (1)
1 to 5	4.5	2.7
5 to 48	5.5	4.4
48 to 53	4.0	4.7
53 to 84	3.5	6.5
84 to 89	1.8	8.2

In all cases, the observed rate in the latter stages of the reaction was several times greater than the rate calculated by equation (1) for the initial reaction. The reaction, therefore, was autocatalyzed as are a large number of oxidations involving organic molecules and oxygen, probably due to the formation of peroxides[5] and easily oxidized products such as the ketone.[1d]

In the photochemical reaction, autocatalysis also occurred.[1b,c] The equation for the initial reaction, however, may be written as

$$(1)^* \quad -\Delta(K_2Cr_2O_7)/\Delta t = k^*(K_2Cr_2O_7)^{1/2}\,(\text{alkaloid})^\circ$$

k^* not only varied with the temperature, but also with structural differences in the alkaloids and the wave length and intensity of monochromatic light absorbed by the alkaloids. Light absorbed by the other reactants did not affect the reaction measured. The independence of the photochemical rate upon the concentration of the alkaloid (indicated in (1)* by (alkaloid)°) therefore suggested[1c] that one molecule of alkaloid entered the photochemical reaction. $\text{Log}_{10}\ k^*$ was a linear function of $1/T$ but the slopes of the plots were nearly horizontal, *e. g.*, for quinine at λ 366 mμ, $\log_{10} k^* = a - 370/T$, when other variables were fixed.

A comparison of equations (1)* and (1) shows that the light effective in the photochemical reaction initiates a different reaction (as measured by the disappearance of dichromate) than takes place upon the absorption of thermal energy alone.

Summary

The thermal rates of oxidations of quinine, hydroquinine and cinchonine by dichromic acid in 1.55 *M* sulfuric acid are the same within 5%. The reactions are autocatalytic.

The initial rates are given by the equations

$$-\Delta(K_2Cr_2O_7)/\Delta t = k(K_2Cr_2O_7)\,(\text{alkaloid})^{1/2} \quad (1)$$

and

$$\log_{10} k = 4.05 - 2000/T \quad (2)$$

The Unesterified Primary Hydroxyls in Acetone Soluble Cellulose Acetate[1]

BY F. B. CRAMER AND C. B. PURVES

It is well known that cellulose triacetate, subjected to a mild hydrolysis, loses some of its original solubilities in organic solvents and acquires new ones, among which a capacity to dissolve in acetone is of great technical importance.[2] Although there have been various opinions as to the cause of this change,[3] it now seems certain that an alteration in the average chain length of the cellulose macromolecule is not necessarily involved.[4] On the other hand, only those acetates which average 2.1 to 2.6 acetyl groups per anhydroglucose unit are soluble in acetone and they must be prepared by the partial hydrolysis of the triacetate rather than by the partial esterification of cellulose.[3,5] These observations suggest that true acetone solubility depends not only upon the numerical ratio of acetyl to hydroxyl groups[6] but also on their relative distribution. Whatever this may be, unesterified hydroxyl is confined to the second, third and sixth positions of the glucose residues and is accordingly of a secondary or a primary alcoholic nature. We have found only one attempt to discriminate chemically between the two possible types of hydroxyl, and this was by determining the molar amount of triphenylmethyl chloride which would condense with commercial acetone-soluble acetate dissolved in pyridine.[7] By assuming that only unesterified primary as opposed to secondary hydroxyls would react under these conditions, approximately one-third of the free hydroxyls were assigned to the primary or sixth position of the glucose units. This assumption was subsequently shown to be unfounded in the case of simple glycosides[8] and the result required confirmation by an independent method.

In the present work, two commercial acetone-soluble cellulose acetates averaging 0.56 and 0.67 mole of free hyroxyl per glucose unit were condensed, in dilute pyridine solution at 20°, with a large excess of *p*-toluenesulfonyl chloride (tosyl chloride). Samples were isolated at intervals and their sulfur content plotted against time (Fig. 1). About one-third of the hydroxyls were rapidly esterified in the first three hours, then the rate decreased markedly and the tosylation reached a maximum between the third and tenth days, when the reaction was about three-quarters complete. An extremely slow replacement of tosyl groups by chlorine progressed during the subsequent months. The tosylation removed no acetyl groups because the products analyzed for acetyl retained the original quota. It was also improbable that acetyl had wandered from one hydroxyl to another during the reaction, the reagents used not having caused this even with partly acetylated glucoses where such wandering was known to occur readily.[9] The tosyl groups were therefore considered to be faithful reproductions of the positions of the hydroxyls in the original cellulose acetate. In order to determine these positions, it was hoped that the tosylated acetate could be degraded to partly tosylated glucoses, the examination of which would give the desired information. Attempts to accomplish this degradation with hydrogen bromide in glacial acetic acid,[10] with cold

(10) Hess, Littmann and Pfleger, *ibid.*, **507**, 55 (1933), obtained 2,3,6-tritosylacetobromoglucose in 70% yield from tritosyl starch by using this reagent.

72% sulfuric acid,[11] or with cold 43% hydrochloric acid[12] produced dark decomposition products. The use of alcoholic hydrogen chloride in a sealed tube[13] removed the tosyl residues. In these circumstances recourse was had to less drastic methods.

When *p*-toluenesulfonyl esters of glucose were heated with an excess of sodium iodide in acetone, the residues in the primary or sixth position were exclusively and quantitatively replaced by iodine.[14] This method of estimating primary in the presence of secondary hydroxyl proceeded very smoothly in the present case and showed that 0.197 tosyl group was in the sixth position of the anhydroglucose units. Of the available 0.56 hydroxyls in the original acetone soluble acetate, 0.197 or 35% was accordingly of a primary nature. The acetyl and sulfur analyses of the fully tosylated material failed to account for 0.13 mole of original hydroxyl. Failure to reacetylate this completely, together with the presence of traces of chlorine and nitrogen, suggested that the discrepancy was partly due to the accumulation of small analytical errors. The above estimate of 35% primary hydroxyl was therefore a minimum value and the true figure may have been close to 50%.

Pyridinium hydrochloride, in pyridine solution at 100°, rapidly replaced a tosyl group on the primary hydroxyl of methyl glucoside by chlorine.[15] When the fully tosylated cellulose acetate was submitted to this reaction, 0.24 mole of chlorine was introduced and 0.24 or 43% of the original hydroxyls were by inference primary. Thus both estimations went to show that one-third to one-half of the exposed hydroxyls in acetone-soluble acetate were in the sixth position of the anhydroglucose units. It followed that the partial deacetylation of cellulose triacetate to the acetone soluble condition involved the removal of acetyl from primary and secondary positions at approximately the same rate.

The amount of primary hydroxyl corresponded quite closely with the number of tosyl groups entering the cellulose acetate molecule in the initial, rapid reaction. This fact, in conjunction with the occasional preferential reaction of the same group

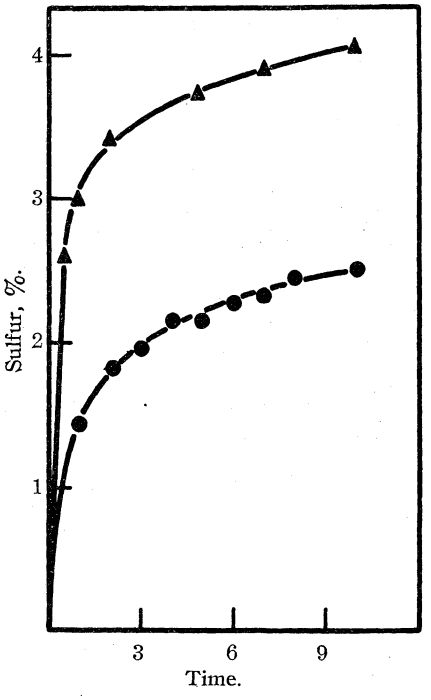

Fig. 1.—Tosylation rate curve of acetone soluble cellulose acetate I. Initial portion, ●; time in hours. Later portion of same curve ▲; time in days.

in methylglycosides,[16] suggested that the product be isolated and examined at the break in the tosylation–rate curve (Fig. 1). Specimens from two different cellulose acetates both contained 0.19 tosyl group per glucose unit, of which no less than 84 and 90% was in the primary position and replaceable by iodine. The form of the tosylation rate curve was thus definitely shown to be determined by the eleven- or twelvefold superiority in reaction velocity of the primary in contrast to the combined rates of the two secondary hydroxyls. There is no reason to believe that this superiority is displayed only toward *p*-toluenesulfonyl chloride. It is therefore probable that other acid chlorides in pyridine solution will acylate up to 0.2 mole of primary hydroxyl in acetone soluble cellulose acetates with rapidity and without causing acetyl wandering. Mixed acylated celluloses of approximately known constitution probably can be prepared in this way.

It is interesting to note that the tosylation rate curve (Fig. 1) is similar in shape to that observed in the heterogeneous acetylation of fibrous cellulose.[17] The break in the latter was considered to

mark the end of a rapid, superficial, intramicellar reaction, involving one-third to one-half of the hydroxyls, and the beginning of a slower reaction governed by the rate of diffusion into the interior of the micelles. As these were undoubtedly penetrated, it is possible that the entire reaction was permutoid in character and conditioned by the greater esterification rate of that third of the hydroxyls which were primary. Such a directly acetylated product might have the same acetyl content and the same average molecular weight as an acetone soluble acetate produced by the partial saponification of the triacetate. The distribution of acetyl and hydroxyl would nonetheless be sharply different, as primary hydroxyl would be present in the latter case and none in the former.[18] Free primary hydroxyl may prove to be necessary for true solubility in acetone.[19]

Attempts were made to confirm the presence of iodine in the primary position of the iodo-cellulose acetate by degrading it to 6-iodoglucose. The iodine atom was as unstable toward the usual reagents as the tosyl group was found to be in the earlier experiments. A highly degraded desoxycellulose acetate was finally prepared in almost quantitative yield by reducing the iodo acetate with a zinc–copper couple. The fact that glucomethylose (isorhamnose) units were present in the desoxy acetate was supported by the formation of methyl furfural on distillation with aqueous acid, and also by the isolation of isorhamnose as the crystalline, well-defined tetraacetate after the degradation had been completed by standard methods. With the exception of these degradations, all the reactions described proceeded practically quantitatively and without significant alteration in the average chain length as measured by Staudinger's viscosity method.[20] The derivatives had a wide range of complete solubility in organic solvents and, chlorinated and degraded products excepted, were fibrous.

Experimental

The Roman numerals refer to the table of viscosities at the end of the article.

Materials.—Two commercial acetone soluble acetates were studied, sample I being an Eastman Kodak Co. and sample II a du Pont Co. product.[21] The acetyl analyses were 39.7 and 38.6%, respectively, corresponding to averages of 2.44 and 2.33 moles per glucose unit. The ash was 0.063 and 0.044%, the sulfur contents were negligible and both specimens dissolved completely in acetone to almost colorless solutions free of opalescence. They were dried over phosphorus pentoxide *in vacuo* at 55–65°.

High grade pyridine was redistilled from barium oxide shortly before use and the *p*-toluenesulfonyl chloride was recrystallized from ether.

Rate of Tosylation.—Twenty grams (1 mole hydroxyl) and 106 g. of pure tosyl chloride (18.3 moles) were separately dissolved in 115 and 240 cc., respectively, of pyridine. The solutions were separately brought to 20°, quickly mixed by shaking and the mixture kept at 20°. At intervals, 30-cc. samples were withdrawn, quickly cooled to 0° and mixed with equal volumes of ice-cold acetone containing more than sufficient water to decompose the excess tosyl chloride. After five minutes of shaking in a bath at 0°, the mixture was stirred into 600 cc. of distilled water and twenty minutes later the precipitate was filtered, washed well with water and dried over anhydrous calcium chloride. Solution in 40 cc. of acetone, filtration to remove impurities, reprecipitation from water, washing and drying followed. The above procedure diminished local heating of the viscid samples during isolation and thus avoided a replacement of tosyl by chlorine. A white, fibrous, acid-free product was obtained in nearly quantitative yield. After a final drying over phosphorus pentoxide *in vacuo*, analyses for sulfur were made by Waters' method,[22] since Carius estimations were erratic and frequently low. The data were plotted in Fig. 1.

The cellulose acetate II gave very similar results, with a sulfur maximum of 4.43% (fourth and eleventh days). This corresponded to a substitution of 2.33 acetyl and 0.46 mole tosyl per glucose unit, *i. e.*, to a substitution of 73% of the original 0.67 mole of hydroxyl. The very slow and partial replacement of primary tosyl by chlorine at 20° was followed on this sample for another four months.

Anal. Calcd. for 2.33 acetyl, 0.39 tosyl and 0.22 chlorine: S, 3.80; Cl, 2.41. Found (III): S, 3.81, 3.79; Cl, 2.40, 2.37.

Maximum Degree of Tosylation.—A 20-g. batch of the acetate, sample I, was withdrawn from the above reaction mixture after ten days, or when the sulfur content was near the maximum. The white, fibrous material was completely soluble in acetone, glacial acetic acid, dioxane, pyridine and chloroform to clear, nearly colorless, viscid solutions. It was insoluble in alcohols, ether and hydrocarbons.

Anal. Calcd. for 2.44 acetyl and 0.43 tosyl groups: acetyl, 31.7; S, 4.16. Found (IV): acetyl, 31.3, 31.5; S, 4.04, 4.08. Nitrogen and chlorine were present in traces.

(18) Spurlin, THIS JOURNAL, **61**, 2222 (1939), dealt mathematically with the arrangement of substituents in cellulose derivatives and reviewed the literature.

(19) The acetone soluble acetate loses this property when heated with glacial acetic acid (U. S. Patent 1,668,946), which probably re-esterifies the primary hydroxyls preferentially. A direct acetylation of cellulose with acid catalysts in presence of sufficient aldehyde may produce acetone soluble products of technical value (U. S. Patent 1,930,145). Here some primary hydroxyls may be protected from acetylation by a prior and selective reaction with the aldehyde.

(21) We wish to thank Drs. J. W. Hill and F. Schulze of the du Pont Co., for the gift of this acetate. It was part of an individually manufactured lot representing the most uniform type of high grade commercial product. The acetyl quoted was 39.3% and a 24% solution in anhydrous acetone had a viscosity of 375 poises.

(22) Waters, *Ind. Eng. Chem.*, **12**, 482 (1920).

A second preparation (acetyl, 31.4; S, 3.9%) was reacetylated with pyridine and acetic anhydride. *Anal.* Calcd. for complete substitution with 2.57 moles acetyl and 0.43 moles tosyl: acetyl, 33.0. Found (V): acetyl, 31.6, 31.9.

A 6-Chloro-tosyl Cellulose Acetate.—The dry, tosylated acetate (IV), 2 g., dissolved in 20 cc. of pyridine, was added to the suspension made by passing 1.5 g. of dry hydrogen chloride into 30 g. of pyridine. The pyridine hydrochloride dissolved while the mixture was kept at 80–85° in a glass-stoppered flask. After four hours the dark solution was cooled and stirred into 600 cc. of water and the white precipitate, which filtered normally, was well washed and dried. Solution of this precipitate in acetone, filtration and addition of water to the filtrate gave a colloidal suspension which was separated with difficulty. The material dried to a horny mass which behaved in the same way when reprecipitated from acetone by water. Among the cellulose derivatives studied, the 6-chloro-tosyl acetate was the only one with a marked tendency to disperse in this fashion.

Anal. Calcd. for 2.44 acetyl, 0.19 tosyl and 0.24 moles chlorine: S, 2.04; Cl, 2.86. Found (VI): S, 1.89, 1.92; Cl, 2.80.

A 6-Iodo-tosyl Cellulose Acetate.—Ten grams of the tosylated acetate (IV) and 20 g. of sodium iodide were dissolved in 150 cc. of pure dry acetone. The glass-stoppered bottle containing the solution was kept at 100° for two hours in an autoclave containing additional acetone to compensate the pressure within and without the bottle. After cooling and diluting with acetone, the viscid solution was filtered from the insoluble sodium *p*-toluenesulfonate. The acetone filtrate was poured into much distilled water and the precipitate purified by reprecipitation in the usual way. Tests with silver nitrate and starch solutions showed that iodine, either free or combined, was absent from the final supernatant liquors. The iodo-tosyl acetate was fibrous, had a slight yellow tinge and the same solubilities as the parent tosyl derivative.

Anal. Calcd. for 2.44 acetyl, 0.233 tosyl and 0.197 moles iodine: S, 2.31; I, 7.77. Found (VII): S, 2.33, 2.36; I, 7.94, 7.88.

A duplicate iodination on a smaller scale was heated for sixteen hours at 100° without increasing the iodine content of the product, which was therefore the maximum obtainable. Found: I, 7.7.

Partial Tosylation of Cellulose Acetate I.—The mixture already described was used and the tosylation was interrupted after three hours at 20°. The initial, rapid reaction was then almost over (Fig. 1).

Anal. Calcd. for 2.44 acetyl and 0.19 tosyl groups: acetyl, 35.7; S, 2.07. Found (VIII): acetyl, 35.0; S, 2.00.

A 6-Iodo-cellulose Acetate.—The above partially tosylated derivative (VIII) was heated in 10% acetone solution with twice its weight of sodium iodide at 100° for two hours before isolation of the product.

Anal. Calcd. for 2.44 acetyl, 0.031 tosyl and 0.159 iodine: S, 0.35; I, 7.04. Found (IX): S, 0.32; I, 6.55, 6.51.

Of the original tosyl groups, 0.159 or 84% had been replaced by iodine.

A Desoxy-cellulose Acetate.—The partial tosylation of the acetone soluble acetate (II), 162 g., was carried out as before save that only one-tenth of the previous amount of tosyl chloride was used. This economy was compensated by a reaction time of twenty-four hours instead of three. The mixture was then diluted with 1500 cc. of acetone containing 30 cc. of water and after ten minutes was worked up in the ordinary way; yield, 175 g. or 97%.

Anal. Calcd. for 2.33 acetyl and 0.19 tosyl: S, 2.10. Found (X): S, 2.10.

The iodination of 170 g. of this derivative was with 1400 cc. of acetone and 170 g. of sodium iodide: yield of 6-iodo-cellulose acetate, 165 g. or quantitative. *Anal.* Calcd. for 2.33 acetyl, 0.02 tosyl and 0.17 iodine: S, 0.23; I, 7.67. Found (XI): S, 0.17; I, 7.56, 7.53. Here 89.5% of the original tosyl groups had been replaced by iodine.

The iodo acetate, 20-g. lots, dissolved in 300 cc. of glacial acetic acid on the steam-bath, was stirred vigorously while 100 g. of a zinc–copper couple was added during forty-five minutes. Heating and stirring were continued for a total of five hours. The pasty mass, containing zinc acetate, was then poured into 3000 cc. of water and the precipitate was filtered, washed, dried and extracted with acetone. This extract was centrifuged to remove small particles of zinc and the desoxy acetate precipitated by pouring the concentrated solution into cold, dilute hydrochloric acid. As soon as traces of gray, colloidal zinc had dissolved and the powdery product was perfectly white, it was recovered by filtration, washed well with water and dried. An almost quantitative yield (149 g. from 160 g. of the iodo acetate) of iodine free material was obtained.

Anal. Calcd. for 2.33 acetyl, 0.02 tosyl: acetyl 38.6; S, 0.25. Found (XII): acetyl, 38.6; S, 0.14, 0.25. The reduction had not altered the number of acetyl or tosyl groups.[23]

Examination of the Desoxy Cellulose Acetate.—(a) The customary procedure for furfural analysis[24] gave 0.0338 g. of phloroglucide from 0.7377 g. of material. This phloroglucide resembled that of methylfurfural in being completely soluble in alcohol and in having a red-brown color. In the same circumstances pure α-methylisorhamnoside, 0.0496 g., gave 0.0274 g. of a similar phloroglucide. Calculation from this preliminary calibration experiment showed the presence of 8.3% of methylisorhamnoside residues in the desoxy cellulose acetate. Calcd. from the 6-iodo acetate, 11.6%.

(b) The degradation of 100 g. of the desoxy acetate was accomplished by alternately heating under reflux with 2% methyl alcoholic hydrogen chloride and reacetylating the undissolved residue. When all had been dissolved, the combined, neutralized, alcoholic solutions were concentrated and about 50 g. of crystalline methylglucosides were removed. The residual sirup was hydrolyzed to constant rotation with 5% sulfuric acid on the steam-bath (225 min.), the solution was neutralized, fermented to remove glucose and evaporated to dryness. Acetylation of the residue with acetic anhydride and anhydrous sodium

(23) Our thanks are due to Dr. G. E. Murray for these analyses.

acetate gave 2.7 g. of pure glucomethylose (isorhamnose) tetraacetate with a specific dextrorotation of 21.6° in chloroform (sodium light) and m. p. 145–146° (corr.), not depressed by admixture with an authentic specimen. *Anal.* Calcd. for $C_6H_8O_5(COCH_3)_4$: acetyl, 51.8. Found: acetyl, 52.3, 52.5.

This authentic specimen was prepared from α-methylglucomethyloside by hydrolysis and acetylation exactly similar to that employed above. As the yield was only 52%, 100 g. of the desoxy cellulose acetate contained the equivalent of 2.7 × 100/52 or 5.4 g. of the glucomethylose tetraacetate, *i. e.*, about 25% of the calculated amount.

Viscosities of the above Derivatives.—Staudinger's methods[20] were followed, the solvent being glacial acetic acid at 25 ± 0.1° in every case. An Ostwald type viscometer was used and η_{sp}/c became approximately constant in the range c 0.006 to 0.001 molar glucose residues per liter. The Roman numerals in Table I refer to derivatives and analyses already recorded.

TABLE I

VISCOSITIES OF ACETONE SOLUBLE CELLULOSE ACETATES AND VARIOUS DERIVATIVES

	Calcd. mol. wt.	η_{sp}/c
Derivatives of Acetate I		
Acetate I	264	44.1
Fully tosylated IV	331	39.4
IV, reacetylated V	337	42.9
6-Chlorotosyl VI	298	41.2
6-Iodotosyl VII	322	39.6
Partly tosylated VIII	294	49.1
6-Iodo acetate IX	292	46.6
Derivatives of Acetate II		
Acetate II	260	52.5
6-Chlorotosyl III	324	53.3
Partly tosylated X	289	54.3
6-Iodo acetate XI	282	50.5
6-Desoxy acetate XII	260	6.8[a]

[a] c was 0.03 to 0.01 mole per liter.

Summary

1. *p*-Toluenesulfonyl chloride in pyridine at 20° rapidly esterified about one-third of the free hydroxyl groups in commercial, acetone soluble cellulose acetates. The remainder reacted much more slowly. No removal, and probably no wandering, of acetyl groups occurred.

2. Sodium iodide in acetone at 100°, or hydrogen chloride in pyridine at 85°, smoothly substituted iodine or chlorine atoms for *p*-toluenesulfonyl residues derived from primary, as opposed to secondary, hydroxyls. Analyses of the halogenated mixed cellulose esters indicated that at least one-third of the free hydroxyls in acetone soluble cellulose acetate were in the primary (sixth) positions of the anhydroglucose units.

3. The esterification (1) was interrupted at the end of the initial, rapid reaction and the groups introduced were replaceable to the extent of 85 to 90% by iodine. *p*-Toluenesulfonyl chloride had therefore reacted ten or twelve times as rapidly with the free primary as with the free secondary hydroxyl groups (second and third positions).

4. All the above reactions proceeded almost quantitatively and without appreciable degradation of the cellulose as measured by viscosity methods.

5. The position of iodine in a 6-iodocellulose acetate was confirmed by reduction to a degraded iodine-free desoxy acetate. This gave methylfurfural on distillation with mineral acid and glucomethylose (isorhamnose) after complete hydrolysis. Glucomethylose was identified as the crystalline tetraacetate, m. p. 145–146°, with a specific dextrorotation of 21.6° in chloroform.

The Unesterified Secondary Hydroxyls in Acetone Soluble Cellulose Acetate[1]

BY F. B. CRAMER, R. C. HOCKETT AND C. B. PURVES

The examination of a commercial acetone soluble cellulose acetate,[2] containing on the average 2.33 moles of acetyl and 0.67 mole of hydroxyl per glucose unit, led to the conclusion that at least 0.22 mole of the hydroxyl occupied the primary or sixth position in the anhydro-glucose residues.[3] This left not more than 0.45 mole distributed between the second and third positions in an unknown manner. If this distribution was a random one, some of the glucose units along the partly acetylated cellulose macromolecule should be devoid of acetyl in both the second and third positions. In other words, they should contain the —CHOH—CHOH— or glycol grouping. Extensive work[4] has shown that many glycols are oxidized quantitatively to two aldehyde groups by one mole of lead tetraacetate, that secondary reactions are very slow and that semi or complete acetylation thoroughly protects the glycol from the reagent. It was possible, therefore, to investigate the occurrence of 2,3 deacetylation in suitable solutions of cellulose acetates by noting their consumption of lead tetraacetate. This was followed easily by the potassium iodide–sodium thiosulfate method.[5] Both the commercial cellulose acetate and the triacetate prepared from it remained dissolved in a 50% chloroform–acetic acid mixture. The triacetate solution utilized no lead tetraacetate over a period of several days and acetylation thus protected the glycol groups of the anhydroglucose units from oxidation in a satisfactory manner. As expected, the normality of the lead tetraacetate in the acetone soluble acetate solution diminished with time but unfortunately the instability of the solvent[6] interfered with a prolonged examination. This was possible when pure glacial acetic acid was used (Fig. 1). By analogy with the similar behavior of many simple glycosides,[7] the break in the curve (Fig. 1, eighty hours) was taken to mark the end of the true glycol oxidation, and the subsequent much slower change was regarded as an oxidation of another type. With this assumption, inspection of the curve showed that each glucose residue in the acetone soluble cellulose acetate averaged $7 - 10 \times 10^{-3}$ mole of glycol grouping, or one such group was present in every 100–150 glucose residues.

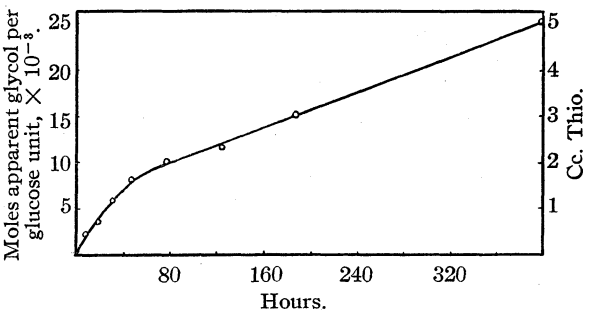

Fig. 1.—Oxidation of acetone soluble cellulose acetate with lead tetraacetate in glacial acetic acid at 25°.

If a partly acetylated cellulose averaged H moles of hydroxyl, randomly distributed along the macromolecule as x moles in the second and $H - x$ moles in the third position, the probability of the glycol grouping is $x(H - x)$ per glucose unit. This probability attains its maximum value of $H^2/4$ when $x = H/2$ or when hydroxyls in the two positions are numerically equal. In the present case, $H = 0.45$ or, at the very least, 0.35 and the probabilities of the glycol group are 0.0506 and 0.0306, respectively, or one occurs in every 20 to 32 glucose residues. The disagreement between this calculated value and the experimental one of one in 100 to 150 shows that the distribution of hydroxyl was by no means a matter of chance.

Although speculation concerning the method of distribution is premature, it seems evident that the assumption of a micellar structure for cellulose acetate in which acetyl had been lost preferentially from the surface of the micelles would lead to calculated ratios lying between 1:2 and 1:32. On the other hand, if the second positions averaged about ten times the number of unesterified hydroxyls as the third, or *vice versa*, calculation would agree approximately with experiment.

(1) Delivered at the Boston meeting of the American Chemical Society, September, 1939.

(2) Kindly given by the du Pont Company. The acetyl content was 38.6%, sulfur 0.007, ash 0.004, and the viscosity in 24% anhydrous acetone solution was 375 poises. It was a high grade sample of the most uniform commercial type.

(3) Cramer and Purves, THIS JOURNAL, **61**, 3458 (1939).

(4) Criegee, *Ber.*, **64**, 260 (1931).

(5) Dimroth and Schweitzer, *ibid.*, **56**, 1375 (1923).

(6) Eventually the thiosulfate blank titration increased and crystalline lead chloride separated owing to slight decomposition of the carefully purified chloroform.

(7) Hockett and McClenahan, THIS JOURNAL, **61**, 1667 (1939).

This would also be true if, in the partial hydrolysis from cellulose triacetate, the loss of acetyl from either one of the two positions tended to stabilize the adjacent group in the same anhydroglucose residue.

Experimental

Materials.—The acetone soluble cellulose acetate was from the batch previously studied[3] and the triacetate was made from it by careful acetylation with pyridine and acetic anhydride. Both were dried over phosphorus pentoxide in a vacuum at 55°.

The chloroform was washed with water and distilled from phosphorus pentoxide while the glacial acetic acid was distilled from chromic anhydride to free it from any aldehyde.

Oxidation with Lead Tetraacetate.—The cellulose acetate, 2.6 g. or 0.01 mole, was dissolved completely in 25 cc. of glacial acetic acid contained in a 100-cc., glass-stoppered volumetric flask. An approximately decinormal solution of lead tetraacetate in the same solvent, 25 cc., was then added at 25° and the volume made up to the mark. The viscid solution required prompt and thorough mixing, after which it was kept at 25 ± 0.5° in the dark. Samples were withdrawn at intervals in a 10-cc. pipet and discharged into 20 cc. of an aqueous solution containing 20 g. of potassium iodide and 250 g. of sodium acetate per liter. The pipet was rinsed well with 5 cc. of the acetic acid and after the addition of the rinsings the liberated iodine was titrated with $N/100$ sodium thiosulfate.[5] Vigorous shaking of the heterogeneous mixtures was necessary during the titrations, which took about five minutes each to complete. The blank on the reagents remained constant at 37.5 cc. of thiosulfate throughout the experiment. Differences from the blank are plotted as the right-hand ordinate in Fig. 1 and at the break in the curve (eighty hours) the 1 millimole sample of cellulose acetate utilized about 2 cc. of $N/100$ sodium thiosulfate. This corresponded to 10^{-5} mole of lead tetraacetate or of glycol. The results of precisely similar experiments, carried out in chloroform–acetic acid solution, are mentioned in the Introduction.

Summary

A commercial acetone soluble cellulose acetate had an average of 0.35 to 0.45 mole of unesterified hydroxyl distributed between the second and third positions of the anhydroglucose units. The unsubstituted —CHOH—CHOH— or glycol groupings it contained were estimated, by means of lead tetraacetate, to occur not more frequently than once in a hundred glucose residues. A significantly greater frequency of once in twenty to thirty was calculated by assuming a purely random distribution of hydroxyl between the two positions.

Ricinus communis. I. Oxidation of Ricinoleic Acid

BY ST. ELMO BRADY

The oxidation of ricinoleic acid, its ethyl ester and its isomer, ricinelaidic acid, as well as some of their oxidation products, the trihydroxystearic acids and the *n*-aldehydo-octanoic acid has been studied and the experimental results obtained in these studies are presented in this communication.

Experimental Part

(a) Preparation and Purification of Ricinoleic Acid and Derivatives.—The castor oil was saponified with alcoholic potassium hydroxide, the excess alcohol removed, the potassium salt dissolved in water and the solution exhausted with ether to remove the unsaponifiable materials. These will be the subject of a future investigation. The free fatty acids were liberated with dilute hydrochloric acid, collected and allowed to stand for two days during which time the insoluble acids separated and were removed. The free fatty acids were mixed with an equal volume of alcohol and cooled below zero for several days, when another small portion of insoluble acids separated. The free fatty acids were again converted into the sodium salts using approximately the calculated weight of pure sodium hydroxide dissolved in alcohol. After the removal of the solvent and dilution with water a practically clear solution remained. The barium salt was precipitated from this solution, filtered, dried and refluxed with ether to remove any soluble barium salt present. Several recrystallizations of the barium ricinoleate from alcohol finally gave a white crystalline product that analyzed pure.

The dry salt was suspended in ether and carefully decomposed with dilute hydrochloric acid. After washing thoroughly and drying the ethereal solution over anhydrous sodium sulfate, the solvent was removed in a vacuum desiccator by the aid of the pump. Especial care was exercised not to heat the acid since it polymerizes very easily even at a temperature of 40°. The acid so prepared was of a very slight yellowish tinge, somewhat viscous and perfectly clear. It solidified in the refrigerator at 3–4° to a white waxy solid which melted approximately at 5°.

Anal. Calcd. for $C_{18}H_{34}O_3$: iodine no., 85.1. Found: iodine no., 85.0, 85.1.

Preparation of the Ethyl Ester of Ricinoleic Acid.—The pure ricinoleic acid was dissolved in twice the volume

of absolute alcohol and the temperature reduced to near 0° in a freezing mixture. A stream of dry hydrogen chloride was introduced slowly until the solution was saturated. The solution was then allowed to stand overnight at room temperature. The alcohol was washed out of the solution and the residue taken up with ether. The ethereal solution was shaken several times with a dilute solution of potassium hydroxide, washed with water and dried over anhydrous sodium sulfate. After the removal of the solvent, the ethyl ricinoleate was distilled under reduced pressure and collected at 193–194° (1–2 mm.) or 206° (3–4 mm.). The ester so prepared is water clear.

Anal. Calcd. for $C_{20}H_{38}O_3$: iodine no., 77.91. Found: iodine no. (Hanus), 77.92, 77.93. Refractive index, $n^{25}D$ 1.4595, $n^{26}D$ 1.4590. Specific gravity 20°/20°, 0.9182.

Preparation of the Ethyl Acetylricinoleate.—The ethyl ricinoleate (50 g.) as described above was dissolved in 70 cc. of chloroform, 30 cc. of pyridine added and the solution cooled to 0° in a salt–ice-bath. A slight excess of acetyl chloride was introduced carefully and the solution allowed to remain at the temperature of the bath for two hours and then overnight at room temperature. The excess acid chloride and pyridine were washed out with water, the residue taken up in ether, dried over anhydrous sodium sulfate and the solvent removed. The acetyl derivative was distilled under reduced pressure and collected at 196° (2–3 mm.); refractive index, $n^{27}D$ 1.452; iodine no., 69.1; theoretical, 69.02.

(b) Oxidations. (1) Ethyl Ricinoleate: with Neutral Potassium Permanganate.—Fifty grams of the ester was dissolved in 350 cc. of dry acetone and 200 g. of finely powdered potassium permanganate added during the course of an hour, the solution being refluxed gently during the addition and finally for fifteen hours.

The solvent was then removed, the residue mixed with water and the precipitated oxides of manganese brought into solution by the action of sulfuric acid and sodium bisulfite. After cooling, the acid solution was exhaustively extracted with ether.

The ethereal extract was washed, then repeatedly extracted with sodium carbonate solution (20%) and the combined alkaline extracts shaken with ether to remove any suspended neutral products.

The ethereal solution from the alkaline extract was washed with water, dried, the solvent removed and the resulting oil cooled. The neutral substances amounted to 7.1 g. The odor was somewhat aromatic and pleasant.

Separation of the Acid Products.—The sodium carbonate extract was treated with solid sodium hydroxide dissolved in a little water and heated under the reflux for an hour. This ensured the conversion of any esters into the sodium salts. The cooled solution was acidified and extracted with ether several times. After the removal of the solvent, the residue partially solidified on cooling and amounted to 40.7 g.

The mixture of solid acids was refluxed with five successive portions of petroleum ether (b. p. 40–60°), employing 150 cc. of solvent each time, for one-half hour. The undissolved acids were of a light yellow color and amounted to 22.0 g. About 0.4 g. of solid acid was deposited from the light petroleum which was filtered before the removal of the solvent.

There were 17.1 g. of liquid acids remaining after the evaporation of the petroleum ether. This material was fractionated under reduced pressure several times and the following fractions finally obtained. Fraction 1, b. p. 84–85° (3 mm.), was a colorless, limpid liquid. Calcd. for $C_6H_{11}O_2Ag$: Ag, 48.40; mol. wt., 116. Found: Ag, 48.23; neut. equiv., 128: caproic acid. Fraction 2, b. p. 90–95° (3 mm.), was a colorless liquid, slightly viscous. Calcd. for $C_7H_{13}O_2Ag$: Ag, 45.54; mol. wt., 130. Found: Ag, 45.37; neut. equiv., 128: heptylic acid. Fraction 3, b. p. 95–100° (3 mm.), colorless liquid. Calcd. for $C_8H_{15}O_2Ag$: Ag, 43.00; mol. wt., 147. Found: Ag, 42.87; neut. equiv., 146.8, 146: caprylic acid. Fraction 4, b. p. 159–160 (3 mm.), was a colorless liquid which solidified to a white solid at room temperature. It was recrystallized from petroleum ether and separated in large glistening plates, m. p. 49–50°. Calcd. for $C_9H_{18}O_3$: C, 62.06; H, 10.34; mol. wt., 174. Found: C, 62.15; H, 10.40; mol. wt. (Rast), 176: β-hydroxypelargonic acid.

Purification of the Insoluble Acids.—The crude product insoluble in petroleum ether was dissolved in hot water, filtered from a small quantity of impurities and then heated with decolorizing charcoal. The final filtrate was water-clear and deposited, on cooling, fine needles of m. p. 95°. The crystals had the odor of one of the liquid acids which seemed to persist after several recrystallizations, even though the melting point increased to 104°. To remove this persistent odor, the crystals were refluxed with petroleum ether and filtered hot. The large glistening crystals now had no odor and melted at 106–107°. Further recrystallization did not raise the melting point.

Anal. Calcd. for $C_9H_{14}O_4Ag_2$: Ag, 53.70; mol. wt., 188. Found: Ag, 53.82; neut. equiv., 94; mol. wt. (Rast), 190: azelaic acid.

The dianilide of azelaic acid was prepared and melted at 186.5–187°.

The aqueous filtrate from the above crystallization was evaporated to a small bulk and cooled. A white amorphous solid separated which was removed and dried. This was recrystallized from hot water when small granular crystals separated, m. p. 125–126°. These crystals were thought to contain possibly a small amount of stearic acid and were therefore refluxed with benzene, in which the latter is soluble. On filtering and drying the crystals no increase was noted in the melting point. Because of the variation in the analytical data, the product was recrystallized several times from hot water without any change in the melting point. The crystals were then dissolved in a sufficient volume of ether for the solution and cooled in the refrigerator at 3–4° when a separation of crystals took place. These were filtered off and the solution again cooled for twelve hours when a second crop of crystals was obtained. The solution was then concentrated on the bath and allowed to cool and a third crop of crystals was obtained. The three fractions showed the same melting point, 141°.

Anal. Calcd. for $C_8H_{12}O_4Ag_2$: Ag, 55.64; mol. wt., 174. Found: Ag, 55.52; neut. equiv., 86.4; mol. wt. (Rast), 175: suberic acid.

The ethereal solution from the suberic acid failed to produce additional crystals after standing in the refrigerator for forty-eight hours. The solution was concentrated to a

small bulk and crystals separated which were filtered and dried. These amounted to almost the same weight of the suberic acid and of m. p. 96°. These crystals were not further examined at this time but will be the subject of future investigation as will be true of the neutral products obtained in the oxidation.

(2) **Ricinoleic Acid: with Alkaline Potassium Permanganate.**—Five grams of ricinoleic acid was dissolved in an alkaline solution containing 1.6 g. of potassium hydroxide and made up to 2500 cc. of solution. Ice was then added until the temperature was around 0°. A solution of potassium permanganate (5.3 g. in 250 cc. water) was added hurriedly and the solution stirred for ten minutes, after which time a solution of bisulfite (30 g. in 150 cc. of water) was added and then 70 cc. of 5 *N* hydrochloric acid. During this time ice remained and the stirring was continued until it had melted. The solution amounted to approximately 3000 cc., and was allowed to stand overnight, when a white flocculent precipitate settled. This was collected and dried. The yield of the crude product was practically quantitative.

The crude product was refluxed with petroleum ether (b. p. 40–60°) and the insoluble portion removed. The latter was refluxed with chloroform and the insoluble portion filtered. On cooling the chloroform solution deposited crystals which were filtered and recrystallized from alcohol. On standing, white needle-like crystals separated, m. p. 110°.

Anal. Calcd. for trihydroxystearic acid, $C_{18}H_{36}O_5$: C, 65.06; H, 10.84. Found: C, 65.12; H, 10.90.

The solid insoluble in chloroform was recrystallized from alcohol and white crystals were obtained, m. p. 141°. Recrystallization did not alter the melting point.

Anal. Calcd. for trihydroxystearic acid: mol. wt., 332. Found: neut. equiv., 337, 334; mol. wt. (Rast), 335.

Five grams of ricinoleic acid gave under the conditions of the experiment: 1.80 g. of acid, m. p. 141°; 1.70 g. of acid, m. p. 110°; 1.50 g. of oily product of pleasant odor.

(3) **Ricinelaidic Acid: with Alkaline Potassium Permanganate.**—The ricinelaidic acid was prepared by the action of nitric acid and potassium nitrite on ricinoleic acid. Crystallization from petroleum ether gave a white product, m. p. 51°. The same procedure was used in the oxidation of this acid as with the ricinoleic acid. The product, however, was the acid of m. p. 110° with a very small amount of the acid with m. p. 141°.

(4) **Trihydroxystearic Acid: with Periodic Acid.**—Potassium periodate (6 g.) was dissolved in 200 cc. of *N* sulfuric acid at 20° and was added rapidly to a solution of trihydroxystearic acid, 6 g. in 400 cc. of alcohol at 40°. After ten minutes the clear solution was cooled to 15°, diluted with water to dissolve any potassium sulfate precipitating, and extracted with ether. The ethereal solution, on the removal of the solvent, gave an oily product which was submitted to steam distillation. The aqueous distillate was extracted with ether, the ethereal solution dried over anhydrous sodium sulfate, and the solvent removed. The β-hydroxypelargonic aldehyde gave a semicarbazone, crystallized from alcohol, m. p. 151°. The bisulfite compound crystallized in thin plates, from which the aldehyde was regenerated easily.

The acetyl derivative is a colorless oil, b. p. 61–62°, while the semicarbazone of the β-acetylpelargonic aldehyde forms shining plates from water, m. p. 171°.

Attempted purification of the aldehyde by distillation under reduced pressure resulted in the elimination of water and the formation of an unsaturated aldehyde. This decomposition took place around 100° (3 mm.).

The aqueous solution of the non-volatile product, after the steam distillation, was filtered from a small amount of material and reduced to a small volume. On cooling, an oily product separated which finally solidified on cooling. This was extracted with ether, the ethereal solution dried and the solvent removed. The product was a light yellow solid. The impure *n*-aldehydo-octanoic acid was extracted with boiling petroleum ether (b. p. 40–60°) in which most of the product dissolved. Cooling of the petroleum ether solution in the refrigerator over a long period of time gave small plates which were recrystallized from water and separated in glistening plates, m. p. 40°. The 2,4-dinitrophenylhydrazone crystallized from methyl alcohol in orange prisms, m. p. 121° (King[1] gave 122.5°). The semicarbazone separated immediately in the cold, was recrystallized from alcohol in small, colorless crystals, m. p. 166°, insoluble in light petroleum (Harries and Thieme,[2] gave 166°; King[1] 166.5°).

The oxidation of the trihydroxystearic acid, m. p. 110°, with periodic acid gave the same products and yields equally as good as those obtained from the acid, m. p. 141°.

(5) ***n*-Aldehydo-octanoic Acid: with Acid Permanganate.**—A solution of potassium permanganate containing 2 g. in 100 cc. of water at 50°, was added slowly to a solution of the semialdehyde in 100 cc. of water acidified with sulfuric acid (3.5 g.), until the color of the permanganate persists for several minutes. After decolorizing with a solution of sodium bisulfite, the clear solution was cooled. The deposit of azelaic acid was recrystallized from hot water and gave the characteristic rectangular plates, m. p. 107°, which was unchanged when mixed with an authentic specimen.

Summary

1. Ricinoleic acid and its ethyl ester with theoretical iodine numbers have been prepared.

2. The oxidation of ethyl ricinoleate in dry acetone yields the liquid acids, caproic, heptylic and caprylic; and the solid acids, β-hydroxypelargonic acid, azelaic, suberic, and an acid of m. p. 96°.

3. The oxidation of ricinoleic acid in alkaline permanganate solution at 0° gave two trihydroxystearic acids already known, m. p. 110° and 141°, respectively, in approximately equal amounts. The oxidation of ricinelaidic acid, on the other hand, gave a large percentage of the acid, m. p. 110°, and a small amount of the acid, m. p. 141°.

4. The oxidation of both the trihydroxystearic acids obtained from ricinoleic and ricine-

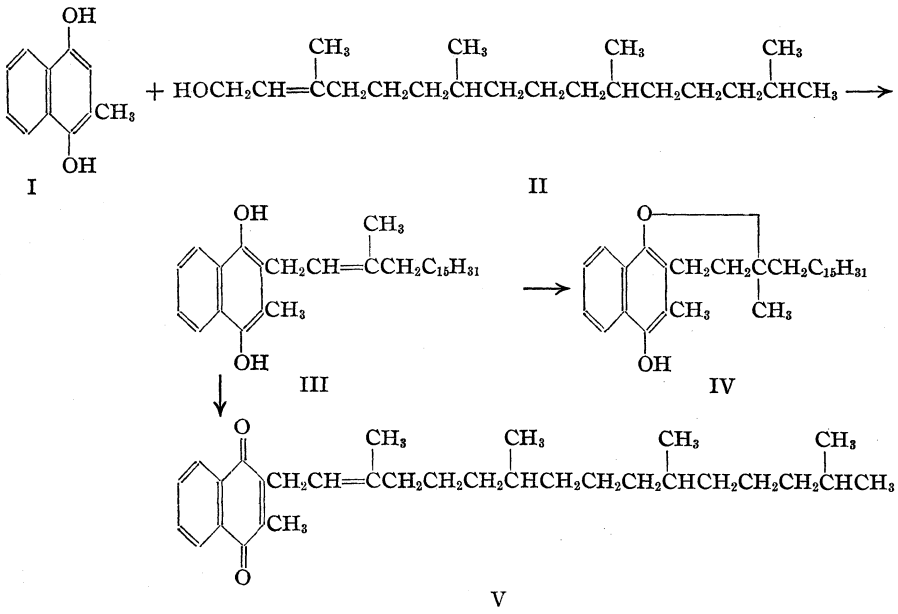
Synthesis of Vitamin K_1[1]

BY LOUIS F. FIESER

In seeking to apply to the synthesis of vitamin K_1 the method of condensation employed successfully[2] for the synthesis of simple quinones of the structural type postulated[3] for the natural substance, trial was first made[2] of the condensation of 2-methyl-1,4-naphthohydroquinone with an equivalent amount of phytol in molten oxalic acid dihydrate at 140°. A smooth reaction ensued but the product had the properties of the naphthotocopherol IV, rather than of the desired substituted hydroquinone III. The result was much the same on conducting the reaction in the presence of anhydrous oxalic acid in dioxane solution at the reflux temperature.[2] On attempting to avoid the cyclization step by further moderating the conditions, it was found that reaction occurs at a reasonable rate at 75° and there were indications of the formation of 2-methyl-3-phytyl-1,4-naphthohydroquinone (III). A further improvement consisted in using a large excess of methylnaphthohydroquinone (up to 5.7 equivalents) in order to accelerate the bimolecular condensation reaction and thus give it precedence over the monomolecular cyclization. The tabulation of results given in the Experimental Part shows that this definitely increases the yield based upon phytol. The best results were obtained with a reaction time of thirty-six hours; the yield falls off on more prolonged heating, evidently because of cyclization to the naphthotocopherol. The proportion of oxalic acid can be varied considerably without change in the results and this reagent can be replaced by trichloroacetic acid.



The problem of separating the primary product III from the reaction mixture was solved very simply by working with the material in the reduced condition. The unchanged methylnaphthohydroquinone can be separated completely and recovered in a usable condition by extraction of an ethereal solution of the mixture with 1–2% alkali containing sodium hydrosulfite to prevent oxidation, the yellow vat color providing a convenient index of the course of the extraction. The more highly substituted naphthohydroquinone is not extracted from ether even with 25% aqueous alkali, and the separation of the two dihydroxy compounds is therefore very sharp. The impurities retained in the ether, including the naphthotocopherol, phytol, and possibly phytadiene, are all very soluble in petroleum ether whereas methylphytylnaphthohy-

droquinone is sparingly soluble in this solvent and separates as a waxy white solid. By repeated centrifugation and digestion with fresh solvent, the substance can be freed completely from contaminants, and no difficulty was experienced in isolating the material from an oil containing as little as 6% of product. Although the substance can be oxidized to the quinone by deliberately shaking an ethereal solution with air, as observed for vitamin K_1 hydroquinone by Doisy, *et al.*,[4,5] no difficulty was experienced in manipulating and evaporating ethereal solutions without protection from the air. When covered with petroleum ether the white solid shows little tendency to undergo air oxidation.

Conversion to the quinone was accomplished by shaking an ethereal solution of the well washed hydroquinone with silver oxide and magnesium sulfate. Evaporation of the filtered yellow solution left a light yellow oil consisting of 2-methyl-3-phytyl-1,4-naphthohydroquinone in a directly pure condition. The substance gives an intense Dam–Karrer color test with alcoholic alkali and the spectrum[1] corresponds closely to the pattern of simple 2,3-dialkyl-1,4-naphthoquinones.[2,3,6,7] That the structure is correctly represented by formula V was inferred from considerations already outlined.[1] The synthesis can be completed in a very short working period and provides a practical method for the preparation of the quinone in quantity. The yield amounts to 44% of the weight of phytol used, or 29% of the theoretical amount.

The synthetic quinone corresponded closely in properties with vitamin K_1 from alfalfa as described by Doisy, *et al.*,[8] and by the Dam–Karrer group.[9] In addition to the properties noted, the substance was found to have high antihemorrhagic activity[1] and to yield a crystalline hydroquinone diacetate. The fully purified derivative melted at 60–61.5° and remelted at 60–60.5°, whereas Doisy's dihydro vitamin K_1 diacetate was reported[4] to melt at 59° (purified sample,[5] m. p. 62–63°). At the time the synthetic diacetate was first isolated in a crystalline condition (Aug. 10) it was known from Doisy's degradative work[10] that the vitamin very probably is either 2-methyl or 2-ethyl-3-phytyl-1,4-naphthoquinone. While Doisy had tentatively favored the latter structure, the close correspondence to the synthetic methyl compound strongly suggested that we had the vitamin in hand. This view was strengthened by the consideration that in this series ethyl compounds melt considerably lower than the methyl homologs, as shown in the following comparison of data previously published.[2] Difference in m. p. between 2-methyl and 2-ethyl compounds:

2-Alkyl-1,4-naphthohydroquinone diacetates	+ 8°
2-Alkyl-1,4-naphthohydroquinone dibenzoates	+16°
2-Alkyl-3-cinnamyl-1,4-naphthohydroquinone diacetates	+44°
2-Alkyl-3-cinnamyl-1,4-naphthoquinones	+ 9°

A direct comparison was of course essential, and it seemed possible that the isolation of the natural vitamin might be accomplished far more easily than heretofore by applying the information and experience gained in the synthesis. While previously reported methods of isolation involve processing the material in the quinone form, it was found that considerable advantage can be taken of the distinctive chemical and physical properties of the vitamin hydroquinone. The starting material was very kindly supplied by Dr. Byron Riegel and consisted of a purified alfalfa concentrate containing 3–5% of vitamin prepared as described by Riegel, Schweitzer and Smith.[11] The vitamin present was reduced by shaking an alcoholic suspension of the concentrate with aqueous sodium hydrosulfite and the material was then extracted with petroleum ether. Unlike the experience of the synthesis, the vitamin hydroquinone did not separate at this point but remained in solution, apparently because of the high proportion and nature of the companion substances. Another method of separation was sought and in trials with pure synthetic 2-methyl-3-phytyl-1,4-naphthohydroquinone it was soon found that this very weakly acidic substance can

(7) In this connection belated reference may be made to the extensive study of the spectra of naphthoquinones by Macbeth, Price and Winzor, *J. Chem. Soc.*, 325 (1935). This paper was of considerable value to us in arriving at the conception of vitamins K_1 and K_2 as α-naphthoquinones; the marked similarity of the spectra of the vitamins to that reported by the British investigators for 2,3-diacetoxy-1,4-naphthoquinone was noted by Dr. R. N. Jones on May 19.

be extracted from petroleum ether with Claisen's alkali (aqueous potassium hydroxide–methanol). When hydrosulfite is added to keep the material in the reduced condition the alkaline liquor acquires a bright yellow vat color which clearly indicates the course of the extraction. The yellow alkaline layer is then separated and merely diluted with water in the presence of ether, when the hydroquinone is liberated from its salt and passes into the ether layer. On processing the reduced concentrate in this way the vitamin hydroquinone was extracted easily and completely, and on evaporation of the ether layer and treatment of the residue with petroleum ether it separated as a white solid. The well washed hydroquinone was then oxidized and afforded a light yellow oil having the characteristics of very pure vitamin K_1. The entire process appears very simple and efficient and avoids difficulties arising from the sensitivity of the vitamin in its oxidized form to heat, light, alkali, and adsorbents.

The sample of natural vitamin K_1 was found by Dr. W. L. Sampson to have the same degree of antihemorrhagic activity as synthetic 2-methyl-3-phytyl-1,4-naphthoquinone. Assayed with chicks by the eighteen-hour procedure,[1] the minimum dose for both substances was approximately 2 γ.[12] The absorption curve determined by D. M. Bowen for the synthetic quinone has already been reported,[1,13] and this corresponds well in form and in the position of the maxima with the curve for vitamin K_1 published by Dam, Karrer, *et al.*[9] A direct comparison of the present samples was kindly made by Dr. T. J. Webb. For the synthetic quinone he found the following maxima (mμ) and log ϵ values (in alcohol): 241(4.18), 248(4.24), 263(4.22), 271(4.23), 330(3.45); the only significant difference between this and Bowen's determination is in placing one of the subsidiary maxima in the region of intense absorption at 263 instead of 260.5 mμ. The maxima for the natural sample occurred at the same wave lengths as above but were slightly lower, the log ϵ values at the several maxima differing by the constant amount of 0.04 unit. This indicates that the natural sample at the time of examination was not quite as pure as the synthetic.

The natural vitamin K_1 gave a crystalline diacetate corresponding in melting point with the synthetic sample and giving no depression when mixed with this substance. While it is perhaps questionable if, among closely related compounds of this series, the absence of a depression in the mixed melting point determination constitutes a rigid proof of identity, it seems significant that the mixture was observed to exhibit the behavior characteristic of both individual samples of solidifying in a few hours and remelting at a sharper and slightly lower temperature. That the synthetic and natural quinone samples give diacetates which thus appear to be identical does not exclude the possibility of the presence in the samples of a certain amount of the geometrical isomer differing from that affording the crystalline diacetate, for the yields of crystalline product in the few reductive acetylations conducted were not quantitative. Although this point merits further investigation, the present indication from the behavior and assay of various samples is that stereoisomerism probably plays a minor role.

Before drawing a final conclusion concerning the identity of the vitamin it seemed desirable to investigate the alternate possibility, and 2-ethyl-naphthohydroquinone was consequently condensed as above with phytol. The reaction proceeded less readily than in the methyl series and the phytyl-substituted hydroquinone proved to be much more soluble in petroleum ether and failed to separate. The method of extraction with Claisen's alkali was successfully applied, but even after removal of all but traces of impurities in this way the substance, in sharp contrast to the behavior noted with both the synthetic methyl compound and the vitamin hydroquinone, did not solidify on treatment with petroleum ether. Oxidation of the unpurified material gave a sample of 2-ethyl-3-phytyl-1,4-naphthoquinone having the characteristic vitamin K type of spectrum but a lower extinction coefficient and estimated from the value found and from the extinction coefficient of the pure synthetic methyl compound to be 95 ± 3% pure (T. J. Webb). Dr. Sampson found this material inactive at a dosage of 160 γ. The lack of activity and the marked contrast in the solubility relationships of the hydroquinone eliminate any possibility of identity with vitamin K_1.

The evidence is therefore conclusive that vitamin K_1 is identical with synthetic 2-methyl-3-phytyl-1,4-naphthoquinone. The conclusion based upon the present synthesis, which was completed before the structure of the vitamin had

(12) A full account of the assays mentioned in this series of papers will be reported elsewhere by Dr. Sampson.

(13) The log ϵ value for the broad band at 328 mμ was inadvertently printed as 2.42 in place of 3.42.

been established by other evidence, agrees with that reached by Doisy, *et al.*, from degradative experiments[14] and from a further synthesis.[14,15]

In confirmation of a prediction[16] based on the behavior of simpler synthetic models, it has been established that vitamin K_1 (synthetic) yields phthiocol as one product of the Dam–Karrer color reaction with alcoholic alkali.

2,6 - Dimethyl- 3- phytyl - 1,4 - naphthoquinone was synthesized by M. D. Gates, Jr., by the procedure given above and found to be devoid of antihemorrhagic activity at a dosage of 50 γ (W. L. Sampson). D. M. Bowen observed the following absorption maxima (mμ) and log ϵ values in alcohol): 247(4.24), 256.5(4.33), 264.5(4.22), 271-(4.22), 331(3.47). A comparison with Bowen's results[1] for the 2-methyl compound shows that the nuclear methyl group at the 6-position displaces the absorption bands 4.4 mμ (av.) in the direction of longer wave lengths while the logarithm of the extinction coefficient is 0.05 unit higher. A similar shift attending substitution in the benzenoid ring has been observed with simpler models.[16] 2-Methyl-1,4-naphthohydroquinone was condensed under comparable conditions with geraniol and with the diene myrcene, which presumably bears the relationship to geraniol which phytadiene bears to phytol. The reaction proceeded considerably better with the alcohol than with the diene. In each case the substituted hydroquinone separated from petroleum ether in such a gelatinous condition that full purification was not achieved. The quinone obtained from geraniol is referred to as 2-methyl-3-geranyl-1,4-naphthoquinone and assigned the structure VI; it is not yet known whether the product from myrcene is identical with this substance. 2-Methyl-3-geranyl-1,4-naphthoquinone is active at a dosage of 25 γ but not at 5 γ (W. L. Sampson).

(15) MacCorquodale, McKee, Binkley, Cheney, Holcomb, Thayer and Doisy, *J. Biol. Chem.*, **130**, 433 (1939).

(16) Fieser, Campbell and Fry, THIS JOURNAL, **61**, 2206 (1939). Essentially the same interpretation of the initial phase of the color reaction has been advanced more recently by Karrer, *Helv. Chim. Acta*, **22**, 1146 (1939).

The assay results now available for the series of 2,3-dialkyl-1,4-naphthoquinones for the most part point to a certain specificity in the structures associated with significant antihemorrhagic activity, while the 2,3-dimethyl compound constitutes a rather anomalous example which seems to indicate a lack of such specificity. Since the natural vitamins may be described as 2,3-dialkyl derivatives having at least one long side chain, it is odd that activity[16] should be encountered in the 2,3-dimethyl compound and not in substances more closely related to the vitamins in structure such as the 2,3-diallyl, 2-methyl-3-trimethylallyl, and 2-methyl-3-benzyl compounds. Excepting this anomalous case the results form a consistent picture. Activity begins to appear as the alkyl groups are increased in size beyond the limits just noted (total of 6–8 carbons) and is encountered in the 2-methyl-3-cinnamyl (10 carbons) and 2-methyl-3-geranyl (11 carbons) compounds. Activity reaches a high point in vitamins K_1 and K_2 with a total of 21 and 30 carbon atoms, respectively, in the side chains. The structure 2-methyl-3-phytyl-1,4-naphthoquinone seems highly specific, for the activity is lost on introducing a methyl group into the benzenoid nucleus or enlarging the 2-methyl to an ethyl group.

In view of these indications of specificity it seems very remarkable that the simple and rather remotely related 2-methyl-1,4-naphthoquinone should exhibit striking potency, as first reported by Ansbacher and Fernholz.[17] It is to be noted that early assays in three different laboratories[18,19,20] indicated the compound to be but very weakly active and that the more recent results, while all pointing to a high order of potency, still differ in the exact relative activity assigned to the compound with respect to vitamin K_1. Two groups of investigators[20,21] find the 2-methyl compound about four times as potent as the vitamin, another regards the two compounds as equally active,[22] while according to a third group methylnaphthoquinone "is by no means as active as vitamin K."[23] A possible explanation both for

the high potency shown in certain of the chick-assays and for the evident variability of the results is suggested by the present observation that methylnaphthoquinone in the reduced form is a component in a simple synthesis of vitamin K_1 which can be conducted in the laboratory at a moderate temperature and with a mildly active catalyst. It is conceivable that the material administered orally in the assays merely provides one component for a similar synthesis in the organism. The substance in the reduced form may combine with phytol or similar component, available to a greater or less extent according to the nature of the diet and the technique of the assay, giving vitamin K_1 or a related compound. A given amount of the simple quinone could then give rise to as much as 2.6 times its weight of active vitamin, which might account for an apparently greater activity on the weight basis.

The author is indebted to various workers in the Merck Laboratories for their coöperation in conducting the bio-assays and for spectrographic determinations and analyses kindly carried out after the summer closing of the Harvard Laboratory.

Experimental Part[24]

Synthesis of 2-Methyl-3-phytyl-1,4-naphthoquinone.—The procedure found most satisfactory is illustrated by the following experiment. A mixture of 5 g. of 2-methylnaphthohydroquinone, 1 g. of powdered anhydrous oxalic acid, 1.48 g. of phytol, and 15 cc. of dioxane (purified with sodium) was warmed to 75° and shaken to bring the solid into solution. The flask was closed with a stopper carrying a thermometer and heated on a hot-plate for thirty-six hours at 75° (±3–4°). During this time the initially light orange or orange-red solution becomes deep red. The solution was cooled, washed into a separatory with ether, diluted with water, and the mixture extracted with ether. The red ethereal solution was separated, washed with a fresh portion of water, and then extracted with successive 50-cc. portions of 2% potassium hydroxide in which sodium hydrosulfite was dissolved just before use (1–2 g. per 100 cc.). Shaking with the first portion of alkali-hydrosulfite should result in the discharge of the red color and the appearance of a bright yellow alkaline layer; more hydrosulfite is added if the red color persists, while more alkali is used in case the yellow color does not appear. The mixture often forms a rather persistent emulsion and in this case the funnel is kept stoppered until the layers separate in order to avoid oxidation by the air. In the present experiment the unchanged methylnaphthohydroquinone responsible for the yellow vat was nearly all removed in three extractions, and two more were made to eliminate traces of the substance, the fourth being weakly yellow and the fifth colorless. The alkaline extracts were run into a large separatory funnel containing about 50 cc. of ether to protect the solution from oxidation, and after collecting the total yellow liquor in this way it was shaken with the ether and the yellow layer run into another separatory funnel containing 75–100 cc. of ether. Sufficient acetic acid was then added to discharge the yellow color and the liberated methylnaphthohydroquinone was extracted into the ether. The aqueous layer was extracted with a fresh portion of ether and the total extract was dried with magnesium sulfate and evaporated nearly to dryness. The residual cake of hydroquinone was covered with petroleum ether, broken up, collected, and washed with petroleum ether. The recovered material was obtained as a colorless or slightly gray crystalline powder suitable for further use and weighing 3.55 g.

The weakly yellow ethereal solution remaining after extraction with alkali was washed with water and with a small volume of saturated sodium chloride solution, dried with magnesium sulfate and the solvent evaporated, eventually in vacuum, leaving 2.00 g. of a light orange-brown oil. When cooled and rubbed, this had the consistency of a soft wax, and on stirring with 30–50 cc. of petroleum ether (b. p. 20–40°) a fine white solid separated. Lumps of brown wax were disintegrated by rubbing and by digesting the mixture at the boiling point, and the pasty, white suspension was then transferred to centrifuge tubes and cooled in ice. On centrifugation the 2-methyl-3-phytyl-1,4-naphthohydroquinone separated as a white, somewhat waxy, and fairly voluminous sludge. The brownish supernatant liquor was decanted and the solid stirred with a rather liberal quantity of fresh solvent, cooled, and centrifuged, when the liquor was definitely but faintly colored. Evaporation of the combined petroleum ether liquors and washings gave 1.29 g. of residual, dark brown oil.

When the petroleum ether paste of the hydroquinone is covered with a little fresh solvent it may be manipulated or kept for several hours without protection from the air. Two digestions as above seem to give a very pure product, but the substance is so sparingly soluble in cold petroleum ether that the process can be repeated with little loss. The hydroquinone can be dissolved in hot ligroin but separates on cooling as a fine powder which is not easily retained on a filter paper.

For conversion to the quinone the petroleum ether sludge was dissolved in a little dry ether (very soluble) and the colorless solution shaken for twenty minutes with excess silver oxide (1 g.) and magnesium sulfate. The clear yellow solution was evaporated on the hot-plate and the last traces of ether removed in vacuum. (A brownish color observed during the filtration or on evaporation is due to the presence of quinhydrone and indicates incomplete oxidation.) 2-Methyl-3-phytyl-1,4-naphthoquinone was left as a residue in the form of a pure yellow, heavy, but rather mobile oil; yield 0.65 g. (29%, based on phytol). The sample for analysis was dried at 78° and 2 mm. pressure.

[a] With the addition of 4 g. of anhydrous magnesium sulfate. [b] Exposed to bright sunlight in the daylight hours.

At 50° there was no evidence of reaction and the mobile oil left on extraction with alkali seemed to be unchanged phytol. In the experiment conducted at the reflux temperature the product was a viscous brown oil which gave only a trace of solid when cooled in petroleum ether solution and which evidently consisted very largely of the naphthotocopherol. At the intermediate temperature of 75° the reaction proceeds satisfactorily and the optimum time seems to be about thirty-six hours. The results show that a too prolonged reaction period results in a marked drop in the yield (formation of the naphthotocopherol) and that a large excess of methylnaphthohydroquinone is definitely advantageous. The addition of a drying agent or a threefold increase in the amount of condensing agent does not materially influence the results, and trichloroacetic acid seems to be about as effective as anhydrous oxalic acid. No differences were observed on conducting the condensation on a four- or five-fold scale, or on exposing the solution to bright August sunlight in a Pyrex Erlenmeyer flask. In the latter experiment the solution was flushed with nitrogen at 75° before stoppering the flask.

Properties of the Quinone.—Synthetic 2-methyl-3-phytyl-1,4-naphthoquinone is very soluble in petroleum ether, moderately soluble in acetone, and sparingly soluble in methyl or ethyl alcohol; the solutions are pure yellow. The substance can be caused to separate from acetone in fluffy yellow crystals by cooling in a bath of solid carbon dioxide and rubbing. There was no evidence of decomposition on evaporation of ethereal solutions of the quinone to dryness on the hot-plate, even at atmospheric pressure, or in manipulating the substance in the diffused light of the laboratory, although undue exposure to light was always avoided. On overnight distillation of a 0.7-g. sample with a mercury vapor pump at 150–180° some decomposition occurred, for the distillate was dark reddish-yellow. As initially prepared the quinone has a pure, light yellow color, and a useful test of purity consists in shaking a yellow ethereal solution of the substance with aqueous sodium hydrosulfite. With vigorous shaking the yellow color is slowly discharged and both layers become colorless.

On shaking the quinone with equal volumes of petroleum ether and 90% aqueous methanol, the yellow color seemed to be retained completely in the hydrocarbon layer. Such a distribution was tried as a possible method of isolating the substance from the reaction mixture in the above synthesis. After removal of phenolic starting material the solution was shaken with silver oxide and the total oil (1.91 g.) taken into petroleum ether (40 cc.) and extracted with eight 40-cc. portions of 90% methanol. The extracts were all weakly yellow and when tested by warming with an equal volume of 10% potassium hydroxide the first and second were negative, the third intermediate, and the remainder gave an identical positive response consisting in the appearance of a clear light purple color persisting for one or two minutes. The yellow petroleum ether layer retained 1.41 g. of material which gave a strong but rather dull color test; when shaken with ether–hydrosulfite the color faded slightly to a straw-yellow, and on separation of the hydroquinone from petroleum ether and oxidation there was obtained 0.16 g. of the pure quinone (under the conditions used the total yield should be 0.65 g.). The material collected from the fourth to eighth methanol extracts by back extraction with petroleum ether was a light yellow oil (0.19 g.), but it gave only a weak and dull color with alcoholic alkali and the yellow color was not completely discharged on shaking with ether–hydrosulfite. It therefore appears that while a certain amount of contaminant (phytol?) is removed in one or two distributions between petroleum ether and 90% methanol, the latter solvent then extracts some other (yellow) impurity (naphthotocopherol?) along with small amounts of the quinone.

Dam–Karrer Color Reaction.—The following tests were made with a 10% solution of potassium hydroxide in 95% ethanol. A solution of 1–2 mg. of the quinone in 1 cc. of this solvent when treated with 1–2 drops of the alkali in the cold slowly developed a light purple color (three minutes) which became stronger on warming and then faded in one or two minutes to dull red. On treating a similar solution of the quinone with an equal volume of the alcoholic alkali, a clear intense indigo-blue color appeared

almost at once in the cold. This changed to purple in about one minute and in about three minutes more the dull red end stage had been reached.

In a typical exploratory cleavage experiment 0.62 g. of the quinone was dissolved in 30 cc. of alcohol by warming to about 40° and the solution was treated with 12 cc. of alcoholic potassium hydroxide solution. The solution became indigo blue at once, cloudy (one minute), dull purple (two to three minutes), and then dull red (five minutes). It was diluted, giving a cloudy precipitate, extracted with ether, and the orange-red aqueous layer separated from the brown ethereal solution and acidified. The brown-yellow solution was extracted with ether and the latter shaken with soda solution; the light red extract was acidified and the liberated material taken into ether. Evaporation gave 30–40 mg. of an orange-yellow solid, which was extracted with successive portions of boiling ligroin (b. p. 60–90°). On clarifying and concentrating the solution there was obtained a small amount (2–3 mg.) of a yellow crystallizate melting at 166–168°. The results were not as good when less alkali was used. On conducting the reaction at 0° the indigo-purple phase persisted for about ten minutes. When the alkali was added to the quinone solution at the boiling point the color changes were soon over; the yield of yellow pigment was lower and the bulk of the quinone seemed to be converted into a neutral, bright red oil (isomerization product?).

The combined crude cleavage product from several experiments was further purified by solution in soda and precipitation from the clarified deep cherry-red solution. The crystalline product was then sublimed at 90–105° (2 mm.) and obtained as pure yellow microcrystals, m. p. 170–171°. A mixture of this with a sample of phthiocol, m. p. 171–172°, from the collection of Samuel C. Hooker[25] melted at 171.5–172.5°.

Anal.[26] Calcd. for $C_{11}H_8O_3$: C, 70.21; H, 4.26. Found: C, 70.33; H, 4.29.

2-Methyl-3-phytyl-1,4-naphthohydroquinone Diacetate.—For reductive acetylation 0.50 g. of the synthetic quinone was suspended in 5 cc. of acetic anhydride and treated with 0.5 g. of zinc dust and then, while cooling in ice, with 5 drops of pyridine. A part of the quinone was reduced at once but some adhered to the walls and formed a mat with the zinc. On working this with a spatula under ice cooling the oil soon dissolved to an almost colorless solution leaving the zinc as a clean powder. After ten minutes in the ice-bath and one-half hour at room temperature, acetic acid was added and the mixture boiled and filtered and the residue extracted with acetic acid and with water. After further dilution with water the filtrate was warmed for ten minutes, cooled, and the oily product extracted with ether. After washing with acid, alkali, and water, the solution was dried and evaporated and gave 0.55 g. of the diacetate as a very faintly yellow, viscous oil. An earlier sample prepared in this way and dried at 80° and 2 mm. was analyzed with the following results.

Anal. Calcd. for $C_{35}H_{52}O_4$: C, 78.31; H, 9.77. Found: C, 78.43; H, 10.01.

Even when in a good and analytically pure condition the diacetate often is slow to crystallize. The most successful expedient found was to dissolve the oil in a rather liberal quantity of methanol, cause some of the material to separate as an oil by cooling (well below 0° if necessary), and rub this thoroughly with a stirring rod. Once the oil is obtained in a somewhat waxy condition, solidification usually occurs after standing for a time at room temperature and is further promoted by rubbing and cooling. The first crystallizate was obtained on exposure of an alcoholic solution containing suspended oil to bright sunlight for a few hours in a Pyrex flask, but it now seems likely that the prior rubbing was of more significance than the irradiation. The sample in question melted at 57–59° and the m. p. was the same on forced crystallization from methanol (Found: C, 78.34; H, 9.87). In the experiment referred to above the material crystallized within a few minutes without irradiation and on merely rubbing with methanol and cooling under the tap. The first crop (0.23 g.) softened at 56° and melted at 59.5° to a clear liquid, the behavior resembling that of camphor. Recrystallization from methanol was not very satisfactory, giving a white powder, m. p. 59–60°, and 95% ethanol was used in the further purification with better success. On seeding a not too concentrated alcoholic solution at room temperature and allowing the solution to stand without external cooling, the diacetate slowly formed cottony clusters of fine needles, m. p. (camphor-like) 60.5–63°. The melt solidified within a few hours and remelted sharply at 60–60.5°. After a further crystallization the material had the same appearance and m. p. characteristics. When heated extremely slowly, the sample melted at 60–61.5°; it remelted at 60–60.5°. While the temperature of first remelting seems significant, the m. p. becomes slightly lower on repeating the process, and if the sample is heated to 160° it fails to solidify in the tube.

In duplicate determinations with the best sample of the diacetate, Dr. R. N. Jones found for the extinction coefficient at 230 mμ (absolute ethanol, per cent. by volume) the values $E^{1\%}_{1\,cm.}$ = 1770, 1780. Doisy reports a much lower coefficient (1250,[4] 1300, or 1600[5]). It may be noted that the extinction coefficient for the quinone found both in this Laboratory[1] and by Dr. Webb ($E^{1\%}_{1\,cm.,\ 248\ m\mu}$ = 386) agrees with Doisy's first value (385[8]) but not with that more recently reported (540[4]).

The **dibenzoate** was prepared by adding pyridine to a petroleum ether sludge of the hydroquinone, removing the hydrocarbon solvent in vacuum, and adding benzoyl chloride. After standing overnight water was added and the product extracted with ether. The solution was washed well with dilute acid, 10% alkali and water and afforded a rather yellow, oily product on evaporation. After various trials the dibenzoate was obtained crystalline from alcohol, exposing the solution to direct sunlight, and melted at 85–86°. Recrystallization from methanol gave slightly waxy white nodules of the same m. p. and the small sample was not purified further.

2,6-Dimethyl-3-phytyl-1,4-naphthoquinone (M. D. Gates, Jr.).—The 2,6-dimethyl-1,4-naphthohydroquinone required as starting material was prepared by reduction of the quinone (11.5 g.) in suspension in alcohol (110 cc.)

(25) S. C. Hooker, THIS JOURNAL, **58**, 1174 (1936).

(26) Microanalysis conducted at the Merck Research Laboratory.

with stannous chloride (45 g.)–hydrochloric acid (50 cc.); water (100 cc.) was added, the solution was boiled with Norite, filtered (with the addition of 50 cc. of alcohol), and diluted with 100 cc. of water. The product separated as fine, slightly pink needles; yield 9.9 g. (85%). A solution of 4 g. of this material, 1.48 g. of phytol, and 1 g. of anhydrous oxalic acid in 15 cc. of dioxane was heated at 70–80° for twenty-four hours. The reaction mixture was worked up exactly as described in the above example, the recovered hydroquinone amounting to 2.37 g. and the yield of quinone being 0.54 g. In another experiment using 5 g. of starting material the yield was 0.59 g. The quinone was obtained as a viscous yellow oil having a slight reddish tinge. The Dam–Karrer color test is the same as with the lower homolog.

Anal. Calcd. for $C_{32}H_{48}O_2$: C, 82.70; H, 10.41. Found: C, 82.53; H, 10.44.

The **hydroquinone diacetate,** prepared as above, was obtained as a solid without difficulty from methanol, but the substance did not form good crystals from either methanol or ethanol. It separated as gelatinous masses which shrank to hard, solid granules on drying. When heated at the ordinary rate the substance melted at 55–56.5°.

Anal. Calcd. for $C_{36}H_{54}O_4$: C, 78.50; H, 9.88. Found: C, 78.84; H, 9.88.

2-Methyl-3-geranyl-1,4-naphthoquinone.—On heating 2 g. of methylnaphthohydroquinone, 1.13 g. of geraniol, 1 g. of anhydrous oxalic acid, and 10 cc. of dioxane at approximately 84° for twenty-four and one-half hours and working up the mixture by the above procedure, 1.0 g. of starting material was recovered and on adding petroleum ether to the alkali-insoluble oil the substituted hydroquinone separated as a voluminous white gel. The precipitated material was so gelatinous that removal of the impurities in the mother liquor was difficult. The substance was stirred and centrifuged with three additional portions of petroleum ether, but probably still retained impurities, as seen from the analysis below. Oxidation with silver oxide gave 0.26 g. of the quinone as a viscous yellow oil tinged slightly with red. A solution of the quinone in alcohol when treated with an equal volume of 10% alcoholic potassium hydroxide gave an intense indigo-blue solution changing to purple and then dull red. Yellow crystals resulted on cooling a methanol solution to −70°.

Anal. Calcd. for $C_{21}H_{24}O_2$: C, 81.78; H, 7.85. Found: C, 81.22; H, 8.01.

A parallel experiment was carried out with the quantities given above but replacing the geraniol by an equivalent quantity of myrcene (1.00 g.). The mixture was kept at 90–95° for twenty-four hours. Extraction with dilute alkali gave 1.31 g. of recovered starting material and left 1.0 g. of dark oil. The latter afforded a very small quantity of substituted hydroquinone as a petroleum ether sludge and on oxidation this afforded 79 mg. of the quinone as a yellow (slightly dark) oil (Found: C, 81.16, 81.24; H, 7.88, 7.99).

2-Ethyl-3-phytyl-1,4-naphthoquinone.—A mixture of 4.8 g. of 2-ethyl-1,4-naphthohydroquinone, 1.48 g. of phytol, 1 g. of anhydrous oxalic acid, and 15 cc. of dioxane was heated at 75° for twenty-four hours, diluted with water, extracted with ether, and the unchanged hydroquinone removed as usual. A brown oil (1.85 g.) of the usual appearance was obtained from the alkali-insoluble fraction, but this dissolved readily in petroleum ether and the substituted hydroquinone failed to separate even on cooling well below 0°. A partial purification was accomplished by shaking this in ether with silver oxide and magnesium sulfate and extracting a petroleum ether solution of the oxidized product with two portions of 90% methanol. Evaporation of the petroleum ether layer gave 1.37 g. of a rather reddish oil giving with alcoholic alkali a strong greenish-blue color changing to purple and then dull red. A fairly sharp separation finally was made by the extraction procedure described in detail below as applied to the isolation of vitamin K_1. Following the same procedure, 1.21 g. of the reddish oil was reduced in alcoholic suspension and a petroleum ether solution of the reduced material extracted with Claisen's alkali and hydrosulfite. On dilution of the yellow liquor with water, extraction with ether, and evaporation there was obtained 0.28 g. of crude substituted hydroquinone as a brownish oil which still failed to yield a solid from petroleum ether and which consequently was oxidized with silver oxide to the quinone (0.27 g.). This was obtained as a yellow (slightly dark) oil giving, when warmed with 5% alcoholic potassium hydroxide, an intense indigo-blue changing to purple and then dull red. On reductive acetylation it gave a clear, nearly colorless oil which failed to crystallize from methanol.

Isolation of Natural Vitamin K_1.—The starting material supplied by Dr. Riegel was described by him as an alfalfa concentrate containing 3–5% vitamin. In the Dam–Karrer test it gave a pale but distinct transient purple in dilute solution and a quite strong purple at higher concentrations. A 5.32 g. portion of the viscous yellow oil was suspended in 90 cc. of alcohol at room temperature, a fresh solution of 4.5 g. of sodium hydrosulfite in 30 cc. of water was added, the flask was stoppered, and the mixture containing oil droplets and precipitated salts was shaken vigorously for ten minutes. After adding 50 cc. of water to dissolve the salts the mixture was shaken again for ten minutes.[27] The suspension of light yellow oil was diluted further and extracted with about 100 cc. of petroleum ether and the weakly yellow solution was shaken thoroughly with 5% potassium hydroxide containing 1–2% of hydrosulfite, the colorless aqueous layer being separated and discarded (no precipitate with acetic acid). The petroleum ether solution was then extracted with 50 cc. of Claisen's alkali[28] to which 3 cc. of saturated aqueous hydrosulfite had been added, the alkaline liquor acquiring a bright yellow color characteristic of the salt of the vitamin hydroquinone. The solution is cloudy and apparently contains suspended salt, but a fairly clean separation is possible. The yellow alkaline layer was drawn off into a separatory funnel containing 50 cc. of ether, and two further extractions were made, the last being only pale yellow. The unextracted material recovered from the petroleum ether was a yellow oil weighing 4.61 g. The total alkaline liquor was shaken with the covering layer of

(27) When the pure synthetic vitamin is reduced by the above procedure the hydroquinone separates at this point as a white solid.

(28) Prepared from 35 g. of potassium hydroxide in 25 cc. of water, diluted to 100 cc. with methanol; Claisen, *Ann.*, **418**, 96 (1919).

ether, adding a little petroleum ether to facilitate the settling of the (colorless) ether layer. (If darkening occurs at any time in the ether layer due to oxidation, more hydrosulfite is added.) The washed yellow liquor was then run into another separatory funnel containing 50 cc. of ether and diluted with 2–3 volumes of 2–4% aqueous hydrosulfite solution (the hydroquinone is particularly sensitive to oxidation when in contact with aqueous alcohol). The dilution results in liberation of the free hydroquinone with disappearance of the yellow color, and on shaking the mixture the substance passes into the ether layer to give a pale yellowish solution. This was separated, washed with aqueous hydrosulfite solution and with water, dried and evaporated. The residual pale reddish-brown oil (0.17 g.) became waxy on cooling, and on adding 10 cc. of petroleum ether the vitamin hydroquinone separated at once as a fine white solid. The suspension was iced and centrifuged and the white sludge stirred with fresh solvent and the process repeated. The purified material was taken up in dry ether and shaken for one-half hour with silver oxide and magnesium sulfate. The filtered yellow solution on evaporation, eventually under vacuum, left a residue of 60 mg. of vitamin K_1 in the form of a pure yellow, rather mobile oil.

Anal.[26] Calcd. for $C_{31}H_{46}O_2$: C, 82.61; H, 10.29. Found: C, 82.64; H, 10.20.

The behavior in the Dam–Karrer test was exactly as described for the synthetic material.

Vitamin K_1 hydroquinone diacetate was obtained by reductive acetylation of 35 mg. of the quinone by the pyridine procedure and obtained initially as a colorless oil (40 mg.). After suitable rubbing in methanol (one hour) this formed waxy, semi-solid masses, and on standing overnight at room temperature with exposure to the morning sun solid particles appeared. On rubbing, the wax all went to a good white powder which was collected after cooling and afforded 6 mg. of material melting at 57–59.5° (camphor-like) and remelting at 57–58.5°. Recrystallized from 95% ethanol the substance formed compact clusters of microneedles, m. p. 58.5–60°.

Anal.[26] Calcd. for $C_{35}H_{52}O_4$: C, 78.31; H, 9.77. Found: C, 78.13; H, 10.11.

A mixture of this substance with the best sample of synthetic 2-methyl-3-phytyl-1,4-naphthohydroquinone diacetate melted at 59.5–61.5°. The melt solidified in about one hour and remelted sharply at 59.5–60°. Dr. E. A. Doisy kindly compared the synthetic diacetate with a sample of the natural vitamin K_1 hydroquinone diacetate prepared in his laboratory (m. p. 61.5–63°) and found that a mixture of equal parts melted at 59.5–61.5°.

Summary

2-Methyl-3-phytyl-1,4-naphthoquinone has been synthesized and found identical with natural vitamin K_1 from alfalfa by a direct comparison of samples with regard to analysis, spectrum, antihemorrhagic activity, color reaction, and the melting point and mixed melting point of a crystalline derivative.

The synthesis is an essentially one-step process utilizing 2-methyl-1,4-naphthohydroquinone and phytol and provides a practical method of preparing the vitamin in quantity. By separating and purifying the product in the reduced form prior to oxidation, the quinone is obtained in a pure condition without recourse to distillation or adsorption. Natural vitamin K_1 can be isolated very easily from alfalfa concentrates by a similar procedure.

Vitamin K_1 yields phthiocol on cleavage with alcoholic alkali.

The 2-ethyl-3-phytyl and 2,6-dimethyl-3-phytyl derivatives of 1,4-naphthoquinone were synthesized and found inactive in the chick-assay, while 2-methyl-3-geranyl-1,4-naphthoquinone shows moderate potency. Indications of a certain structural specificity are discussed and a tentative hypothesis is suggested concerning the action of 2-methyl-1,4-naphthoquinone.

Sterols. LXXVIII. Sterols from Sow Pregnancy Urine

BY RUSSELL E. MARKER AND EWALD ROHRMANN

The fact that mares pregnancy urine has been shown recently to exhibit some interesting differences[1] from the other pregnancy urines which have been studied indicates the desirability of further investigations of pregnancy urines of other animals.

The present preliminary investigation of sow pregnancy urine indicates that this urine is strikingly different from the other urines studied. Sow pregnancy urine differs from other urines mainly in the absence of the three common pregnanediols which have been found in all of the other pregnancy urines heretofore investigated. However, both pregnanol-3(α)-one-20 and *allo*-pregnanol-3(β)-one-20 were isolated from the ketonic sterol fraction. The presence of these two products and the absence of pregnanediols suggests that the sow in the course of the *in vivo* reduction of progesterone[2] is unable to effect the reduction of a C-20 carbonyl group to a C-20 carbinol. This also receives support from the fact that progesterone has been isolated from sow ovaries.[3]

The *epi*-ketone fraction remaining after the removal of pregnanol-3(α)-one-20 when treated with hydroxylamine acetate yielded an oxime which appears to be identical with androsterone oxime, thus indicating the presence of androsterone. This lends further support to the theory that these products are derived from the adrenal compounds. Callow[4] has recently suggested that *trans*-dehydroandrosterone is probably derived from the adrenal cortical secretions and not from testosterone. It should be pointed out that from the generalizations previously made in regard to the origin of these substances,[2,5] both androsterone and *trans*-dehydroandrosterone may be derived from the adrenal cortical secretions and it is not necessary to assume that they are reduction products of $\Delta^{4,5}$-androstenedione-3,17.

Both cholesterol and the characteristic urinary hydrocarbon[1,6,7] of the composition $C_{28}H_{58}$ were isolated from the sow urine. β-Equistanol[8,9,10] was not encountered.

There appear to be other C-3 beta sterols present in the sow pregnancy urine but these could not be isolated from the quantity of urine studied. No apparent differences were observed in urine collected during the second month of pregnancy and during the last month of pregnancy.

This investigation was supported by a grant from the Committee for Research in Problems of Sex, National Research Council.

Experimental Part

To 30 gallons (110 liters) of sow pregnancy urine, collected from Chester sows during the last month of pregnancy was added enough concentrated hydrochloric acid to bring it to a *p*H of 1. The urine was then heated at 100° for three hours, thoroughly extracted with butanol, and the solvent removed *in vacuo*. The residue, consisting of a black tar, was steam distilled for two hours from aqueous sodium hydroxide. The neutral products were extracted with ether and the solvent removed.

The total neutral fraction (14 g.) was dissolved in pyridine (20 cc.) and 10 g. of succinic anhydride was added. The mixture was heated for ninety minutes on the steam-bath, after which ether and water were added and the pyridine removed by dilute hydrochloric acid. The succinates were removed from the ether by potassium carbonate solution, and hydrolyzed by boiling with alcoholic potassium hydroxide.

Hydrocarbon Fraction.—The non-carbinol fraction was treated with Girard's reagent in alcohol, but only a negligible amount of ketones was obtained. The non-ketonic fraction was then sublimed in high vacuum at 80–100° and the sublimate crystallized from acetone to give white plates, m. p. 60–63°. It gave no depression in melting point when mixed with the urinary hydrocarbon obtained from mares pregnancy and human pregnancy urine, m. p. 61–63°.

Anal. Calcd. for $C_{28}H_{58}$: C, 85.3; H, 14.8. Found: C, 85.1; H, 14.8.

The carbinol fraction was dissolved in a small amount of alcohol and treated with 10 g. of digitonin dissolved in 500 cc. of hot 90% ethanol. The digitonide was allowed to stand overnight, filtered, washed and dried; yield, 8.6 g. The digitonide was heated on the steam-bath for one hour with 25 cc. of dry pyridine and the solution poured into ether and filtered. The pyridine was removed from the filtrate by dilute hydrochloric acid and the ether was evaporated to 1.9 g. of oily residue.

The ketones were spearated from the beta-sterols by means of Girard's reagent in the usual manner. These were sublimed in high vacuum and the fraction distilling from 100–200° was collected. The sublimate was crystallized from ether–pentane to give white crystals, m. p. 191–193°. This gave no depression in melting point when mixed with *allo*-pregnanol-3(β)-20-one, m. p. 193–194°.

Anal. Calcd. for $C_{21}H_{34}O_2$: C, 79.2; H, 9.9. Found: C, 79.0; H, 9.6.

No other crystalline products could be obtained from the mother liquors.

beta-Non-ketonic Sterols.—The fraction of non-ketonic, digitonin precipitable sterols was sublimed in high vacuum, the fraction subliming at 100–200° being collected. This was crystallized from ether–pentane and then from ethanol, to give white crystals, m. p. 146–147°. This gave no depression in melting point when mixed with an authentic sample of cholesterol, m. p. 147–148.5°.

Anal. Calcd. for $C_{27}H_{46}O$: C, 83.9; H, 12.0. Found: C, 83.8; H, 11.9.

No additional crystalline products were obtained from the mother liquors. The solvent was evaporated and the residual tar oxidized by chromic anhydride in acetic acid at 25°. The small ketone fraction obtained was treated with semicarbazide acetate. None of the extremely insoluble disemicarbazone of *allo*-pregnanedione could be isolated, indicating the absence of *allo*-pregnanediol-3(β), 20(α).

Epimeric Ketones.—The fraction of sterols not precipitated by digitonin was treated with Girard's reagent in alcohol in the usual manner. The hydroxy ketones were sublimed *in vacuo*, the fraction subliming at 100–200° being collected. The sublimate was crystallized repeatedly from ether–pentane to give white crystals, m. p. 139–142°. This gave no depression in melting point when mixed with epipregnanolone, m. p. 144°.

Anal. Calcd. for $C_{21}H_{34}O_2$: C, 79.2; H, 9.9. Found: C, 79.1; H, 9.7.

The filtrate was evaporated and the residue dissolved in 5 cc. of ethanol. To this was added 600 mg. of sodium acetate and 500 mg. of hydroxylamine hydrochloride and the solution heated four hours at 90°. Water was added and the gum which deposited was crystallized from 60% ethanol and then from 80% acetone to give white crystals, m. p. 210–212°. This gave no depression in melting point when mixed with the oxime of androsterone, m. p. 212–214°.

Anal. Calcd. for $C_{19}H_{31}O_2N$: C, 74.7; H, 10.2. Found: C, 74.2; H, 10.1.

The epimeric non-ketonic sterol fraction was sublimed in high vacuum. The sublimate could not be obtained crystalline. The total sublimate was oxidized by chromic anhydride in acetic acid at 25° and the ketonic fraction isolated from the mixture by means of Girard's reagent. Only a small amount of ketones was obtained which resisted crystallization after sublimation. These were treated with semicarbazide hydrochloride and sodium acetate in alcohol. The semicarbazones which were formed were extremely soluble in cold ethanol. Since *allo*-pregnanedione forms a very insoluble semicarbazone, even in boiling alcohol, the absence of this product is indicated.

Fifteen gallons (55 liters) of urine collected during the second month of pregnancy of the hogs gave the same results as those reported above.

Summary

Sow pregnancy urine differs from other pregnancy urines studied in that the pregnanediols appear to be absent.

Pregnanol-3(α)-one-20, *allo*-pregnanol-3(β)-one-20, cholesterol and the urinary hydrocarbon were isolated.

Evidence of the presence of androsterone was obtained.

STATE COLLEGE, PENNA. RECEIVED OCTOBER 23, 1939

Sterols. LXXIX. Oxidation Products of Dihydrosarsasapogenin

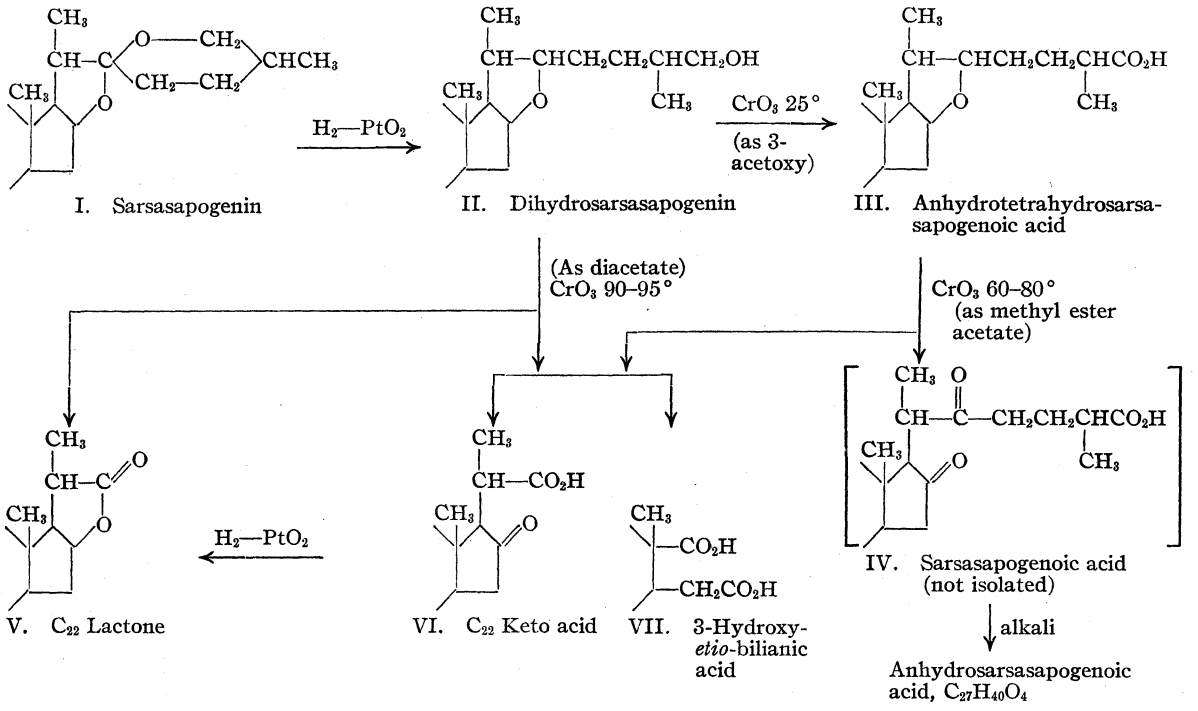
BY RUSSELL E. MARKER AND EWALD ROHRMANN

In order to obtain further evidence concerning the structure of the side chain of sarsasapogenin (I),[1] we have oxidized with chromic anhydride the methyl ester acetate of anhydrotetrahydrosarsasapogenoic acid (III) (obtained both from sarsasapogenoic acid by catalytic hydrogenation and from 3-acetoxydihydrosarsasapogenin by mild oxidation) and by treatment of the neutral fraction from the oxidation with aqueous ethanolic alkali have obtained a good yield of an acid identical with anhydrosarsasapogenoic acid. This indicates that the methyl ester acetate of sarsasapogenoic acid was formed in the oxidation and was in turn converted to the anhydro acid by the alkali treatment. In this reaction sarsasapogenoic acid could only have arisen from the oxidative opening of an oxide ring to yield a diketo compound, thus supporting IV which we recently proposed[2] for sarsasapogenoic acid.

Further support of the structure assigned to di-

(1) Marker and Rohrmann, THIS JOURNAL, **61**, 846 (1939).

(2) Marker and Rohrmann, THIS JOURNAL, **61**, 2072 (1939).



hydrosarsasapogenin[1] (II) has been obtained from a study of its oxidation products. The oxidation of the diacetate with chromic anhydride at 90–95° yielded a neutral fraction from which the C_{22} lactone[3] was isolated. The acidic fraction (extractable with 3% sodium hydroxide) yielded the C_{22} keto acid[4] (IV) and the C_{19} dibasic acid[5] (VII).

We wish to thank Parke, Davis and Company for the generous help and assistance rendered during the course of this work.

Experimental Part[6]

Oxidation of the Diacetate of Dihydrosarsasapogenin.—A mixture of 20 g. of dihydrosarsasapogenin, m. p. 165–166°, and 200 cc. of acetic anhydride was refluxed for thirty minutes. The acetic anhydride was evaporated *in vacuo* and the residual sirup dissolved in 400 cc. of acetic acid. The well stirred solution was heated at 90–95° on a steam-bath while 44 g. of chromic anhydride in 250 cc. of 80% acetic acid was added over a period of two hours, after which the mixture was heated for an additional two hours. The mixture was concentrated *in vacuo* to a volume of about 100 cc. The residual material was diluted with water and the precipitated solids taken up in ether. The ethereal solution, after thorough washing with water, was washed twice with 3% sodium hydroxide solution to remove the acidic fraction.

The ether solution containing the neutral material was evaporated to a sirup which was hydrolyzed by refluxing with an excess of ethanolic potassium hydroxide. The resulting solution was diluted with water and the precipitated solid taken up in ether. The alkaline water layer was washed several times with ether. Evaporation of the combined ether extracts gave approximately 2 g. of a neutral sirup which was not investigated further. The alkaline water layer was acidified with hydrochloric acid and the mixture extracted with ether. Evaporation of the ether gave almost 600 mg. of crude lactonic material (noncrystalline). This was sublimed in high vacuum and the material distilling at 140–160° was crystallized from ether–pentane to give fine white needles, m. p. 200–201.5°. This gave no depression with the hydroxy lactone of sarsasapogenin, m. p. 200–201.5°.

Anal. Calcd. for $C_{22}H_{34}O_3$: C, 76.25; H, 9.9. Found: C, 76.1; H, 9.9.

The sodium hydroxide washings containing the acidic material from the oxidation was heated on the steam-bath for twenty minutes to complete the hydrolysis. The cooled mixture was acidified with hydrochloric acid and the precipitated acids taken up in ether. Upon standing the ethereal solution deposited 600 mg. of small compact white crystals which were recrystallized once from methanol to give a product, m. p. 285–288° dec. This gave no depression with a sample of the C_{22} keto acid previously reported,[4] m. p. 285–287° dec.

Anal. Calcd. for $C_{22}H_{34}O_4$: C, 72.9; H, 9.5. Found: C, 72.5; H, 9.3.

The filtrate remaining after removal of the C_{22} keto acid was evaporated and the residual sirup crystallized from chloroform to give 1.9 g. of white crystals, m. p. 219–222°. This gave no depression with a sample of the C_{19} dibasic acid,[5] m. p. 220–222°.

Anal. Calcd. for $C_{19}H_{30}O_5$: C, 67.4; H, 8.9. Found: C, 67.2; H, 9.0.

When refluxed for thirty minutes with acetic anhydride

(3) Farmer and Kon, *J. Chem. Soc.*, 414 (1937).

the acid formed the **acetate anhydride,** m. p. 202–203.5°. This gave no depression with a previously reported sample,[5] m. p. 203–204°.

Anal. Calcd. for $C_{21}H_{30}O_5$: C, 69.6; H, 8.3. Found: C, 69.7; H, 8.3.

Conversion of Anhydrotetrahydrosarsasapogenoic Acid to Anhydrosarsasapogenoic Acid.—The methyl ester of anhydrotetrahydrosarsasapogenoic acid was prepared by refluxing the acid (prepared from 3-acetoxydihydrosarsasapogenin) in methanol solution acidified with sulfuric acid. The ester, m. p. 124–126°, was identical with that obtained by the action of diazomethane on the acid.

A mixture of 7 g. of the methyl ester and 60 cc. of acetic anhydride was refluxed for thirty minutes. The acetic anhydride was evaporated *in vacuo* and the residual sirup dissolved in 200 cc. of acetic acid. To this well-stirred solution heated at 55–60° was added 10 g. of chromic anhydride in 80 cc. of 80% acetic acid over a period of two hours. The mixture was heated for an additional two hours at 55–60° and then for one hour at 80°. The excess chromic anhydride was destroyed with 5 cc. of ethanol and the mixture was evaporated *in vacuo* to a volume of approximately 75 cc. The mixture was diluted with water and the solid extracted with ether. The ethereal extract was washed with water and then twice with 3% sodium hydroxide solution.

The ethereal solution containing the neutral material was evaporated to give approximately 2 g. of sirup. This was dissolved in 30 cc. of 95% ethanol and to this solution was added 3 g. of potassium hydroxide and 15 cc. of water. The solution, after refluxing for two hours, was diluted with water and the resulting clear solution acidified with hydrochloric acid. The precipitated acid was taken up in ether. The ethereal solution was evaporated to a volume of about 30 cc. when 575 mg. of compact white crystals separated. These were recrystallized once from methanol–ether to give a product with m. p. 243–245° dec. This gave no depression with a sample of anhydrosarsasapogenoic acid prepared from sarsasapogenoic acid, m. p. 242–244°.

Anal. Calcd. for $C_{27}H_{40}O_4$: C, 75.7; H, 9.4. Found: C, 75.6; H, 9.4.

The acidic fraction from the oxidation yielded the C_{22} keto acid, m. p. 283–285°.

A similar oxidation of the methyl ester acetate of anhydrotetrahydrosarsasapogenoic acid (1.45 g.) prepared from sarsasapogenoic acid by catalytic hydrogenation yielded the C_{22} keto acid, m. p. 284–286° dec.

Anal. Calcd. for $C_{22}H_{34}O_4$: C, 72.9; H, 9.5. Found: C, 72.6; H, 9.4.

The acidic filtrate from this yielded 3-hydroxy-*etio*-bilianic acid, m. p. 219–221°.

Anal. Calcd. for $C_{19}H_{30}O_5$: C, 67.4; H, 8.9. Found: C, 67.2; H, 9.0.

The neutral fraction from the oxidation upon treatment with aqueous ethanolic potassium hydroxide as described previously yielded anhydrosarsasapogenoic acid, m. p. 243–245° dec.

Anal. Calcd. for $C_{27}H_{40}O_4$: C, 75.7; H, 9.4. Found: C, 75.9; H, 9.4.

Summary

The chromic anhydride oxidation products of dihydrosarsasapogenin have been studied.

Sterols. LXXX. Reactions of Chlorogenin

BY RUSSELL E. MARKER AND EWALD ROHRMANN

In a previous paper[1] we presented evidence indicating that the nuclear hydroxyl groups of the steroid sapogenin, chlorogenin,[2] were located at C-3 and C-6 and that the hydroxyl group at C-3 was of the β-configuration. Noller[3] had previously postulated that the hydroxyl groups were at C-3 and C-12 and that the group at C-3 was of the α-configuration. We also presented evidence indicating that chlorogenin belongs to the *allo* series in its configuration at C-5. Further evidence concerning the nuclear structure is afforded by the fact that tigogenone and chlorogenone upon Clemmensen reduction yield the same desoxy compound.[4] The catalytic hydrogenation of the desoxy compounds in an acidic medium likewise gives the same dihydrodesoxy compound. This indicates that chlorogenin differs from tigogenin only in the presence of an additional hydroxyl group.

In a previous paper[4] we alluded to the highly interesting studies of Tsukamoto, Ueno and Ota[5] on diosgenin (I), an unsaturated steroid sapogenin which yields tigogenin upon reduction. Of especial interest are the experiments of Tsukamoto, Ueno, Ota and Tschesche[6] on the oxidation of dios-

genin with hydrogen peroxide. The product of this reaction is a triol (II) which upon oxidation with chromic anhydride and subsequent dehydration yielded an enedione (III). Reduction of this product with zinc and acetic acid yielded a diketone (V), $C_{27}H_{40}O_4$, m. p. 234°. This diketone yielded a crystalline pyridazine derivative, $C_{27}H_{40}O_2N_2$, dec. 308°.

Professor T. Tsukamoto has kindly compared a sample of chlorogenone, m. p. 234°, with the saturated diketone (V) obtained from diosgenin. The substances appeared to be identical in properties and the mixed melting point showed no depression.

It now appears that the only objection which can be advanced against the formulation of chlorogenin as a 3,6-dihydroxy compound is the fact that on mild oxidation with chromic anhydride, Noller[3] obtained a keto dibasic acid which he stated to be different from digitogenic acid, the chromic anhydride oxidation product of digitogenin. However, no direct comparison of the acids was reported. We have pointed out previously[7] that the chemistry of the oxidation of digitogenin is in a rather confused state. In nearly all of the work on digitogenic acid and its alkali isomerization product, digitoic acid, there appears to be a lack of adequate data on the purity of the acids.

The relationships existing between diosgenin, tigogenin and chlorogenin raise many interesting questions in regard to the biogenesis of the steroidal saponins.

In the present work chlorogenin has been subjected to the reactions characteristic of sarsasapogenin.[8] As would be expected, chlorogenin resembles tigogenin more closely than it does sarsasapogenin in its various reactions involving the side chain. It shows little tendency to undergo isomerization with hydrochloric acid in ethanol solution. Attempts to reduce the substance by the Clemmensen method were unsuccessful.

(8) Marker and Rohrmann, *ibid.*, **61**, 746 (1939).

Chlorogenin upon catalytic hydrogenation in acetic acid yielded dihydrochlorogenin (VIII), a substance analogous to dihydrosarsasapogenin. Dihydrochlorogenin formed a tris-3,5-dinitrobenzoate, indicating the presence of a third hydroxyl group. Mild oxidation of dihydrochlorogenin with chromic anhydride readily yielded an acid, $C_{27}H_{40}O_5$, which formed a disemicarbazone and a methyl ester. This acid (IX) has been designated tentatively as 3,6-dehydroanhydrotetrahydrochlorogenoic acid[9] because of its analogy to 3-dehydroanhydrotetrahydrosarsasapogenoic acid.[9]

Chlorogenin diacetate reacted readily with one mole of bromine in acetic acid to yield bromochlorogenin diacetate. Reduction of the bromo compound with sodium and ethanol yielded chlorogenin.[8,10]

McMillan and Noller,[11] in their studies on the oxidation of chlorogenin diacetate with chromic anhydride under relatively mild conditions, obtained the chlorogenin lactone diacetate as one of the products. Both their lactone diacetate and the hydroxy lactone were crystallized from methanol and their analyses indicated the presence of methanol of crystallization. We have oxidized chlorogenin diacetate with chromic anhydride under somewhat more vigorous conditions to obtain the lactone diacetate in yields comparable to the lactone yields obtained in an analogous oxidation of sarsasapogenin acetate. Analyses of our lactone diacetate, dihydroxy lactone, lactone dibenzoate and diketo lactone, none of which were crystallized from methanol, indicated the absence of any solvent of crystallization. From the acidic products of the oxidation there was obtained a small amount of an acid which analyses indicated as analogous to the C_{22} keto acid obtained by a similar oxidation of sarsasapogenin acetate.[12] Unfortunately, the yield of this acid was too low to permit further characterization.

We wish to thank Parke, Davis and Company for their generous help and assistance in the various phases of this work. We are especially grateful to Professor T. Tsukamoto of Kanazawa University, Kanazawa, Japan, for comparing a sample of chlorogenone with the saturated diketone derived from diosgenin. We also wish to thank Mr. Paul H. Williams, and Drs. Elmer J. Lawson and H. C. Benedict for their assistance in obtaining the bulbs of *Chlorogalum pomeridianum*.

Experimental Part

The chlorogenin was isolated from *Chlorogalum pomeridianum* by the procedure described by Liang and Noller.[2] The material was crystallized from methanol as white needles, m. p. 265–268°.

A sample of chlorogenin (1 g.), m. p. 265–268°, was refluxed for fifty hours with 150 cc. of 95% ethanol and 30 cc. of concentrated hydrochloric acid. The product (800 mg.) recovered from the reaction melted at 258–265°. A mixture with chlorogenin melted at 260–267°.

Chlorogenin was recovered essentially unchanged after treatment with amalgamated zinc in ethanol–hydrochloric acid solution. When heated at 80° with an acetic acid solution of selenium dioxide a red precipitate formed almost at once. No product was isolated.

Dihydrochlorogenin.—A mixture of 7 g. of chlorogenin, 1 g. of Adams catalyst and 160 cc. of glacial acetic acid was shaken with hydrogen at 70° and 3 atmospheres for sixteen hours. The mixture was filtered and the filtrate evaporated *in vacuo*. The residual sirup, which would not crystallize, was refluxed on the steam-bath for thirty minutes with an excess of alcoholic potassium hydroxide. The resulting solution was diluted with water. The precipitate was collected, washed with water and dried. The white residue was crystallized from 95% ethanol to give 5 g. of white needles, m. p. 233–235°, sparingly soluble in ether.

Anal. Calcd. for $C_{27}H_{46}O_4$: C, 74.6; H, 10.7. Found: C, 74.8; H, 10.6.

It gave a precipitate with a 2% ethanolic solution of digitonin but did not react with bromine or selenium dioxide.

Tris-3,5-dinitrobenzoate of Dihydrochlorogenin.—To a solution of 400 mg. of dihydrochlorogenin in 15 cc. of dry pyridine was added 800 mg. of 3,5-dinitrobenzoyl chloride. The resulting solution was allowed to stand at room temperature for eight hours. It was then heated at 60° for three hours and the material poured into an excess of dilute hydrochloric acid. The resulting precipitated mixture, after standing overnight, was collected, washed with water, dried, and crystallized from acetone to give white crystals, m. p. 210–212°.

Anal. Calcd. for $C_{41}H_{50}O_{14}N_4$: C, 68.1; H, 7.0. Calcd. for $C_{48}H_{52}O_{19}N_6$: C, 56.7; H, 5.2. Found: C, 57.1; H, 5.1.

Oxidation of Dihydrochlorogenin.—To a solution of 1.5 g. of dihydrochlorogenin in 60 cc. of glacial acetic acid was added a solution of 1.5 g. of chromic anhydride in 30 cc. of 80% acetic acid. After standing at room temperature for two hours the solution was diluted with water and the mixture extracted with ether. The ethereal extract was washed first with water and then with dilute sodium carbonate solution. The sodium carbonate washings were acidified with hydrochloric acid and the white precipitate which separated was collected and washed with water. The dried material was crystallized from acetone as white plates, m. p. 202–204°.

Anal. Calcd. for $C_{27}H_{40}O_5$: C, 72.9; H, 9.1; neut. equiv., 454. Found: C, 73.1; H, 9.1; neut. equiv., 460.

The acid reacted with an ethanolic solution of semicarbazide acetate under the usual conditions to yield a **disemicarbazone** which was crystallized from ethanol to give a product, with m. p. 240° dec.

Anal. Calcd. for $C_{29}H_{46}O_5N_6$: C, 62.3; H, 8.3. Found: C, 62.5; H, 8.4.

With diazomethane the acid yielded a **methyl ester** which was crystallized from ether–pentane as white needles, m. p. 156.5–158°.

Anal. Calcd. for $C_{28}H_{42}O_5$: C, 73.3; H, 9.2. Found: C, 73.5; H, 9.4.

Bromochlorogenin Diacetate.—To a solution of 500 mg. of chlorogenin diacetate in 40 cc. of glacial acetic acid containing two drops of 48% hydrobromic acid was added 1.1 cc. of 1.05 *M* bromine in glacial acetic acid as rapidly as the bromine was absorbed. Hydrogen bromide was liberated. The solution was poured into water and the precipitate collected and washed with water. The dried white residue was crystallized from methanol to give white crystals, m. p. 200° with slight decomposition.

Anal. Calcd. for $C_{31}H_{47}O_6Br$: C, 62.5; H, 7.9. Found: C, 62.5; H, 7.8.

Dihydrodesoxychlorogenin (Dihydrodesoxytigogenin).—A mixture of 100 mg. of desoxychlorogenin, m. p. 173–175°, prepared by Clemmensen reduction of chlorogenone with amalgamated zinc, 120 cc. of acetic acid and 500 mg. of Adams catalyst was shaken with hydrogen at 3 atmospheres pressure for sixteen hours at 25°. The product was worked up as described for dihydrochlorogenin. Crystallization from ether–pentane gave white needles, m. p. 92.5–93.5°. This gave no depression with a sample of dihydrodesoxytigogenin,[4] m. p. 92.5°.

Anal. Calcd. for $C_{27}H_{46}O_2$: C, 80.5; H, 11.5. Found: C, 80.4, 80.5; H, 11.6, 11.6.

Oxidation of Chlorogenin Diacetate.—To a solution of 4 g. of chlorogenin diacetate in 175 cc. of glacial acetic acid heated on the steam-bath at 90–95° was added 5.5 g. of chromic anhydride in 50 cc. of 80% acetic acid over a period of one hour. The mixture was heated for an additional ninety minutes. After evaporating to a volume of approximately 50 cc. *in vacuo* the mixture was diluted with water and the precipitated solids taken up in ether. The ethereal extract was washed with water and then with 3% sodium hydroxide solution to remove acidic products.

The sodium hydroxide solution was heated for fifteen minutes on the steam-bath, cooled and acidified with hydrochloric acid. The precipitated acids were taken up in ether and crystallized from acetone to give a small amount of white crystals, m. p. 224–226°.

Anal. Calcd. for $C_{22}H_{34}O_5$: C, 69.8; H, 9.0. Found: C, 69.6, 69.4; H, 9.1, 9.0.

The ethereal solution containing the neutral fraction was evaporated and the residue crystallized from ether–pentane–acetone to give white needles, m. p. 247–250°, of the **lactone diacetate.**

Anal. Calcd. for $C_{26}H_{38}O_6$: C, 69.9; H, 8.6. Found: C, 69.9; H, 8.6.

Hydrolysis of the lactone diacetate with ethanolic potassium hydroxide gave **chlorogenin lactone** which crystallized from ether–acetone as white needles, m. p. 250–251.5°.

Anal. Calcd. for $C_{22}H_{34}O_4$: C, 72.9; H, 9.5. Found: C, 72.6; H, 9.7.

Oxidation of chlorogenin lactone with chromic anhydride in acetic acid at 25° for one hour gave the **diketo lactone** which crystallized from ether–pentane as compact white crystals, m. p. 243–245°.

Anal. Calcd. for $C_{22}H_{30}O_4$: C, 73.7; H, 8.4. Found: C, 73.6; H, 8.2.

Treatment of chlorogenin lactone with benzoyl chloride in pyridine at 25° for twenty hours gave the **lactone dibenzoate** which crystallized from aqueous acetone as white needles, m. p. 278–280°.

Anal. Calcd. for $C_{36}H_{42}O_6$: C, 75.75; H, 7.4. Found: C, 75.4; H, 7.4.

Summary

Chlorogenone prepared by the oxidation of chlorogenin appears to be identical with the 3,6-diketone of diosgenin.

Chlorogenin was reduced catalytically to give dihydrochlorogenin, mild oxidation of which gave an acid, $C_{27}H_{40}O_5$, which formed a disemicarbazone and a methyl ester.

Chlorogenin formed a monobromo derivative with bromine in acetic acid. Reduction of this gave back chlorogenin.

The lactone diacetate, dihydroxy lactone, lactone dibenzoate and diketo lactone were prepared from chlorogenin.

Molecular Rearrangements in the Sterols. IV. The Structure of *i*-Cholestanone[1]

BY KURT LADENBURG,[2] PURNENDU NATH CHAKRAVORTY[3] AND EVERETT S. WALLIS

In parts I, II and III[4,5,6] of this series, experiments on the preparation and on the determination of the structure of a new isomer of cholesterol, designated by us as *i*-cholesterol, and shown to be the parent alcohol of the isomeric dextrorotatory cholesteryl ethers, have been described. Although our experimental results were confirmed at once by other investigators,[7] our interpretation and proposed formulation of the structure of this new isomer was sharply questioned.

In this paper we wish to report the results of certain experiments which establish more rigidly the original formulation proposed in this Laboratory of the structure of these highly interesting compounds. Before the existence of *i*-cholesterol was suspected, Windaus and Dalmer[8] had treated α-3-chlorocholestanone-6 with alcoholic potassium hydroxide, and had obtained a halogen-free ketone which they believed to contain a true double bond, and which they named "heterocholestenone." That this "heterocholestenone" was in reality *i*-cholestanone was first pointed out by Heilbron and co-workers,[9] who prepared *i*-cholestanone not only by the method of Wallis, *et al.*,[4] by oxidation of *i*-cholesterol, but also obtained it from *i*-cholesteryl acetate and from *i*-cholesterol methyl ether. We are now able to report that we have prepared the isomer of *i*-cholestanone containing a true double bond by refluxing α-3-bromocholestanone-6 with quinoline. The double bond so produced by the removal of hydrogen bromide shifts from the C_3:C_4 position to the position conjugated to the ketone group as is indicated by its absorption spectra; the compound shows absorption in the ultraviolet, maximum at 2450 Å., the wave length characteristic for conjugation across two rings. Therefore, we have assigned to it the structural formula III. This new ketone melts at 105°; its oxime melts at 185°. The same compound is also obtained in somewhat smaller yields from α-3-chlorocholestanone-6 by treatment with quinoline. It is, thus, the "true heterocholestenone."

In Part III of this series it was shown that the cyclopropane ring of *i*-cholestanone can be opened without difficulty. Thus when treated with dry hydrogen chloride α-3-chloro-cholestanone-6 is formed. We have found that a similar reaction takes place when aqueous hydrogen bromide is added to an acetic acid solution of *i*-cholestanone; α-3-bromo-cholestanone-6 (m. p. 123°) crystallizes out quantitatively. Another interesting observation is the fact that when an acetic acid solution of *i*-cholestanone is refluxed with dilute sulfuric acid, it is converted into β-3-hydroxy-cholestanone-6 (m. p. 142–143°) identical with the compound prepared by the method of Windaus.[10]

To establish further proof of the structure of *i*-cholestanone (II), a study of degradative oxidations of this ketone has been made. The following experiments show that there is no double bond in the molecule. Hydrogen peroxide, when heated with an acetic acid solution of the ketone, has no effect. Neither is the compound oxidized by neutral or alkaline potassium permanganate, reagents which attack violently compounds containing a double bond. However, when a pyridine solution of *i*-cholestanone is shaken for twenty-four hours with an aqueous solution of potassium hypobromite, an acid (IV) is obtained. This acid melts at 233°. It is dibasic and does not decolorize bromine solution nor does it give an active Liebermann reaction. Unlike the ketone, it does not add water or halogen acid; its analysis agrees with the assigned formula IV.

The facts mentioned above show the marked difference in the stability of the cyclopropane ring in the series: *i*-cholesterol, *i*-cholestanone, *i*-cholestane diacid. *i*-Cholesterol has been prepared from cholesterol by molecular rearrangement, and can be converted back into cholesterol under certain conditions; *i. e.*, the cyclopropane linkage can shift to a double bond and *vice versa*. *i*-Cho-

lestanone does not undergo isomerization. The cyclopropane linkage, however, can be opened without difficulty. In the dicarboxylic acid the cyclopropane linkage exhibits the greatest stability and resists strongly efforts to rupture it. Thus, it can be concluded that the stability of the cyclopropane ring depends on the nature of the state of oxidation of the C_6 carbon atom. Exactly the same relationship has been observed with sabina ketone and its derivatives.[11]

In an attempt to relate the above diacid (IV) to a known compound, β-3-chloro-cholestane-diacid-6,7 (VI) was prepared from β-3-chlorocholestanone-6 (V) according to the method of Windaus and Stein.[12] When this compound is treated with alcoholic potassium hydroxide, hydrogen chloride is not removed. Treatment with sodium ethylate, however, at higher temperature results in a halogen-free dicarboxylic acid (VII), m. p. 231°. This compound gives no reaction characteristic of the ethylenic double bond but exhibits all those properties associated with the presence of a cyclopropane ring. Experiments show that it is not identical with the acid obtained from *i*-cholestanone. Thus this second acid is an isomer of *i*-cholestane-diacid (IV).

This isomerism can be explained as being due to the relative positions of the groups at C_3, since the two acids were obtained from the α- and β-chloro ketones, respectively. However, the isomerism may be due to the relative positions of the groups at C_5.

The following experiments show that the stereochemical positions of both asymmetric centers, C_3 and C_5, are involved.

In order to establish the isomeric relationship of the above dicarboxylic acids, α-3-chlorocholestane-diacid-6,7 (VIII) was prepared from α-3-chlorocholestanone-6 according to Windaus and Staden.[13] This diacid loses hydrogen chloride with greater difficulty than the other halogen compounds studied in this series. But it can be removed when the acid is treated with sodium ethylate at 150°. When this procedure is followed, a halogen-free diabasic acid (IX), melting at 265°, is obtained. This third acid also gives no reactions of the double bond and is an isomer of the other two. Since, like the diacid (IV), it also has been derived from α-3-chlorocholestanone-6, the steric position of the hydrogen at C_3 with respect to the methyl group at C_{10} should be the same in these two diacids (IV and IX), and the latter will be designated as α_2-*i*-cholestane-diacid-6,7. We believe that its non-identity with the α_1-*i*-cholestane-diacid-6,7 (IV) is due to a difference in the steric position of the carboxyl group at C_5, the inversion being caused by the influence of the alkaline reagent on α-3-chlorocholestane-diacid-6,7 (VIII). The mechanism of such an inversion may be explained by the formation of an enol. Thus, the carboxyl group at C_5 in the diacid (IX) is believed to have a *trans* orientation with respect to the methyl group at C_{10}. In the diacid (IV), however, the carboxyl group at C_5 should be in *cis* position to the methyl group at C_{10} since in the oxidation of the ketone (II) to the acid (IV) inversion cannot take place, there being no available hydrogen at C_5.

Theoretically there should exist a fourth isomeric acid of the structure (XI) which should be obtained by the oxidation of the isomer of *i*-cholestanone (X). As yet this acid has not been prepared. This diacid (XI) should have the same stereochemical configuration at C_3 as the diacid (VII) but would differ from the latter in the steric position of the carboxyl group at C_5. In accordance with the naming of the α-diacids, the diacid (VII) will be designated as β_2-*i*-cholestane-diacid-6,7. The method of preparation of the β_1-*i*-cholestane-diacid-6,7 is being studied at the present time.

The chart contains in outline the reactions discussed.

While the nature of the isomeric relationship between these acids is clear, the assignment of the steric position of the hydrogen at C_3 and of the carboxyl at C_5 is difficult. It is possible, however, to make certain deductions based on some observations of other investigators[14] in closely allied fields. If one considers for example the α- and β-cholestanols, one sees that these two compounds each yield different chlorides depending on whether they are treated with phosphorus pentachloride or with thionyl chloride. With cholesterol, however, the same product in each case results. Ruzicka assumes that the β-cholestyl chloride (m. p. 105°) is the *trans* form and the α-isomeride (m. p. 116°) is the *cis* form, basing his assumption on the fact that in the cholestanols

the α-form (*cis* or *epi*) has a higher melting point than the β-form (*trans* or normal). It must be remembered that *cis* and *trans* here refer to the position of the functional group at C_3 with respect to the hydrogen at C_5. Therefore, if this be true, it follows that a Walden inversion takes place in the chlorination of cholesterol with either phosphorus pentachloride or thionyl chloride, whereas with the cholestanols only chlorination with thionyl chloride causes an inversion.

If we apply these relationships to the reactions described in this paper and assume inversion to take place in the chlorination of cholesterol but not with cholestanol, a *cis*- or *epi* configuration should be assigned to the α-chlorocholestanone-6 (m. p. 129°) and a *trans*- or normal configuration to the β-chloro ketone (m. p. 181°). It should be pointed out that this leads to confusion, when considered in the light of Ruzicka's rule, which assumes that of the two isomers the one of higher melting point has the *epi*- or *cis* configuration. It is interesting to note, however, that the two chloro diacids obtained from the α- and β-ketones, respectively, are in accordance with Ruzicka's assumption, the α-chloro diacid melting at 263° and the β-form melting at 243°.

We also can state that the stereochemical configurations so assigned to the α- and β-3-chlorocholestanone-6 are supported by certain experimental observations. Windaus[8] has observed that hydrogen chloride may be removed from the α-chloro ketone without difficulty by simply warming with alcoholic potassium hydroxide, whereas a similar or even more drastic treatment leaves the β-chloro ketone unchanged. Since it is now believed that the removal of the hydrogen chloride with an alkaline reagent involves the hydrogen atom at C_5 and not, as Windaus assumed, at C_4, the difference of the α- and β-chloro ketones in this particular reaction may well be attributed to the *cis* orientation of the chlorine atom to the hydrogen at C_5 in the α-compound and to the *trans* orientation in the β-isomer. It is also possible to follow this argument through to the 3-chloro diacids. If we consider that sodium ethylate first produces an inversion of the carboxyl group at C_5 before removal of hydrogen chloride from the chloro acids is attained, then the reaction would be expected to proceed more easily in the case of the β-form than in the case of the α-isomeride. This expectation is substantiated by the experiments.

Experimental Part

Preparation of *i*-Cholestanone (II) from *i*-Cholestanone-oxime.—*i*-Cholestanone-oxime (m. p. 143–144°) prepared by the method of Wallis, Fernholz, and Gephart was hydrolyzed with dilute sulfuric acid in alcohol solution. The solution was boiled for three hours, diluted with water, and extracted several times with ether. Evaporation of the ether and recrystallization of the residue gave a crystalline ketone which melted at 96°.[15] When mixed with an authentic specimen of the halogen-free ketone of m. p. 96° (oxime 143°) prepared from α-3-chlorocholestanone-6 by the Windaus and Dalmer method, no depression of the melting point was observed.

Preparation of β-3-Hydroxycholestanone-6 from *i*-Cholestanone.—One gram of *i*-cholestanone was dissolved in 200 cc. of acetic acid and 50 cc. of 5 *N* sulfuric acid. The solution was refluxed for two hours, diluted with water, and extracted with ether. After removing the solvent, the residue was taken up in alcoholic sodium hydroxide and refluxed for one hour to hydrolyze any acetate formed in the reaction. The hydroxy ketone was precipitated with water, filtered, and recrystallized from alcohol; yield 0.95 g. (91%), m. p. 142–143°. The acetate was prepared by refluxing 0.1 g. of the material with acetic anhydride for one hour. On making up the product in the usual manner, crystals were obtained from alcohol which melted at 127–128°. No depression of the melting point of the free hydroxy ketone as well as of its acetate could be observed when these compounds were mixed with specimens prepared according to Windaus.[10]

Preparation of the Oxime of β-3-Acetoxycholestanone-6.—The oxime was prepared in the usual manner. It melted at 194–195°.

Anal. Calcd. for $C_{29}H_{49}O_3N$: C, 75.77; H, 10.74; N, 3.04. Found: C, 75.96; H, 10.49; N, 3.08.

Preparation of α-3-Bromocholestanone-6.—To a solution of 0.25 g. of *i*-cholestanone in acetic acid, 2.5 cc. of a 34% aqueous hydrobromic acid solution was added. After standing overnight at room temperature, a crystalline product separated which was filtered and recrystallized from dilute acetic acid and alcohol. It melted at 123°, yield quantitative.

Anal. Calcd. for $C_{27}H_{45}OBr$: C, 69.65; H, 9.74; Br, 17.17. Found: C, 69.76; H, 9.84; Br, 17.47.

Preparation of Δ^4-Cholestanone-6 (III).—Four grams of α-3-bromocholestanone-6 (m. p. 123°) was dissolved in 60 cc. of freshly distilled quinoline and the solution refluxed for one hour in an atmosphere of nitrogen. The product was precipitated with water and extracted with ether. The quinoline was removed with dilute sulfuric acid. The solvent was evaporated, and the residue was crystallized from alcohol. Crystals were obtained which melted at 104–105°, yield 2.6 g. (79%).

Anal. Calcd. for $C_{27}H_{44}O$: C, 84.31; H, 11.53. Found: C, 84.24; H, 11.31.

The oxime of Δ^4-cholestenone-6 was prepared in the usual way, giving crystals from alcohol which melted at 184–185°.

Anal. Calcd. for $C_{27}H_{45}ON$: C, 81.14; H, 11.35; N, 3.51. Found: C, 80.98; H, 11.16; N, 3.72.

Preparation of α_1-*i*-Cholestane-diacid-6,7 (IV).—To a solution of 100 cc. of 10% potassium hydroxide and 2.5 cc. of bromine, 2.5 g. of *i*-cholestanone-6 (II) was added; the temperature was raised to about 50° so that all of the solid material became properly suspended. After cooling to room temperature, 250 cc. of pyridine was added and the solution was shaken vigorously for twenty-four hours; the solution was clear and almost colorless. After cooling to 0° sulfuric acid was added until the smell of pyridine was no longer noticeable, and the precipitate was taken up in ether. The ether was extracted with dilute alkali and the acidic product was precipitated with sulfuric acid. The precipitate was filtered and the product was recrystallized from dilute alcohol. Crystals were obtained which melted at 232–233°, yield quantitative, 18.1 mg. in 2 cc. of absolute acetone, α_D +0.16, $[\alpha]^{25}_D$ +18° in absolute acetone.

Anal. Calcd. for $C_{27}H_{44}O_4$: C, 74.95; H, 10.25; neut. equiv., 216. Found: C, 74.72; H, 10.13; neut. equiv., 216.

Preparation of β-*i*-Cholestane-diacid-6,7 (VII).—Two grams of metallic sodium was dissolved in 25 cc. of absolute alcohol in a bomb tube. To the clear solution 1 g. of β-3-chlorocholestane-diacid-6,7 (m. p. 243°), prepared according to Windaus and Stein, was added. The tube was sealed and heated in a furnace at 120° for one hour. A

(15) In the original recording of the melting point of this compound an error was made. We believe, however, that we are correct in our statement that the oxime melts at 143–144° and not at 122–123° as later reported by Heilbron, Hodges and Spring.[9] We have prepared this oxime many times by both methods, and never have we been able to obtain the melting point recorded by them.

successful reaction was indicated by the precipitation of sodium chloride. Water was added and the acidic reaction product was precipitated with sulfuric acid, filtered and recrystallized from dilute alcohol and dilute acetic acid. The crystals melted at 230–231°, 17.4 mg. in 2 cc. absolute acetone, α_D + 0.48, $[\alpha]^{24}D$ +55°. Experiment showed that this halogen-free dicarboxylic acid crystallizes with one molecule of water, which is still retained after drying in vacuum at 110°.

Anal. Calcd. for $C_{27}H_{44}O_4 \cdot H_2O$: C, 71.97; H, 10.29; neut. equiv., 226. Found: C, 72.16; H, 10.28; neut. equiv., 230.

Preparation of α_2-*i*-Cholestane-diacid-6,7 (IX).—This acid was prepared from α-3-chlorocholestane-diacid-6,7 (m. p. 263°) in a manner similar to the one described above. In this case, however, the reaction had to be carried out at 150°, and the time had to be increased to eight hours. The halogen-free dicarboxylic acid melts at 265°, 18.8 mg. in absolute dioxane, α_D +0.43, $[\alpha]^{25}D$ +46° in dioxane.

Anal. Calcd. for $C_{27}H_{44}O$: C, 74.95; H, 10.25; neut. equiv., 216. Found: C, 75.03; H, 10.46; neut. equiv., 217.

We wish to take this opportunity to express our thanks to Merck and Company, Inc., of Rahway, New Jersey, for the analyses published in this paper, for the determination of the absorption of Δ^4-cholestenone and for the cholesterol used as the starting material.

Summary

Further evidence has been given to show that Windaus' method of removing hydrogen chloride from α-3-chlorocholestanone-6 gives *i*-cholestanone and not the unsaturated ketone heterocholestenone.

The true heterocholestenone, Δ^4-cholestenone-6, has been obtained and characterized.

A new dicarboxylic acid, m. p. 233°, has been prepared from *i*-cholestanone. This acid has been shown to be an isomer of another new acid, m. p. 231°, obtained from β-3-chlorocholestanone-6. A third isomeric acid, m. p. 265°, has been prepared from α-3-chlorocholestanone-6.

A detailed discussion of the stereochemical relationships of these compounds has been given.

The Oxidation of Certain Heteronuclear-Substituted Polybromodiphenyls

BY FRANCIS H. CASE

In the course of various investigations in this Laboratory dealing with the structures of certain heteronuclear polybromodiphenyls, it seemed desirable to obtain more information as to the behavior of these compounds on oxidation. Although it is known, in general, that in the case of those diphenyls substituted by bromine in one ring only, the unsubstituted ring is destroyed by oxidation, there appears to be no information concerning the oxidation of those compounds in which bromine is a substituent in both rings. The method of oxidation employed utilizes chromic anhydride in approximately 75% acetic acid solution.[1] In each case a considerable amount of the total molecule was destroyed.

The oxidation of 3,4′-[2] and of 2,3′-dibromodiphenyls yielded *p*- and *m*-bromobenzoic acids, respectively, as the sole resulting products. The tribromodiphenyls investigated may (with the exception of 2,4,6-tribromodiphenyl) be divided into two groups in each of which the dibromo substituted nucleus remains the same, while the position of the monobromo substituent in the other nucleus is varied. Group A consists of 2,3′,5′-(I),[3] 3,3′,5′-(II), and 3′,4,5′-(III) tribromodiphenyls. Group B contains 2,2′,5′-(IV), 2′,3,5′-(V) and 2′,4,5′-(VI) tribromodiphenyls. The results of the oxidation of these six isomers are as follows: I and II yield only 3,5-dibromobenzoic acid; III, only *p*-bromobenzoic acid; IV, only 2,5-dibromobenzoic acid; V, both *m*-bromobenzoic and 2,5-dibromobenzoic acid; VI, both *p*-bromobenzoic and 2,5-dibromobenzoic acid.

The oxidation of 2,4,4′,6-tetrabromodiphenyl was found to yield only *p*-bromobenzoic acid, while 2,4,6-tribromodiphenyl, subjected to the same treatment, also yielded a certain amount of *p*-bromobenzoic acid. This surprising result was at first attributed to the presence of a small amount of 2,4,4′,6-tetrabromo-3-aminodiphenyl in the 2,4,6-tribromo-3-aminodiphenyl from which the 2,4,6-tribromodiphenyl was obtained by deamination. However, this explanation had to be

(1) L. F. Fieser, "Experiments in Organic Chemistry," D. C. Heath and Co., Inc., Boston, Mass., 1935, p. 230.

(3) Case, THIS JOURNAL, **61**, 767 (1939).

discarded when it was found that 2,4,6-tribromodiphenyl prepared by Ullmann's reaction from 2,4,6-tribromoiodobenzene and iodobenzene yielded the same product on oxidation. It is possible that bromine liberated during the oxidation of the tribromo compound attacks the unsubstituted nucleus of some of the still unoxidized material, thus producing momentarily the tetrabromo derivative.

The synthesis of 2,4,6-tribromodiphenyl by Ullmann's reaction and the establishment of its identity with that produced by the method of Blakey and Scarborough[4] leave no further doubt as to the structure of the latter. The structure of 2,4,4',6-tetrabromodiphenyl, obtained by bromination of 4-bromo-3'-aminodiphenyl,[4] followed by deamination, is based on analogy with that of 2,4,6-tribromodiphenyl obtained similarly from 3-aminodiphenyl.

As a result of these studies of the oxidation of various polybromo substituted diphenyls, it is possible to arrange the various bromo-substituted phenyl radicals in the order of decreasing stability toward oxidation as follows: 4-bromo-, 3,5-dibromo-, (2,5-dibromo- and 3-bromo-), 2-bromo-, and 2,4,6-tribromo- phenyl.

The 2,3'-dibromodiphenyl used in this work was prepared by the deamination of 2,3'-dibromo-4'-aminodiphenyl.[3]

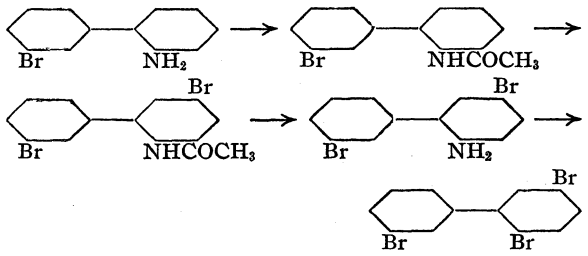
3,3',5'-Tribromodiphenyl was obtained by the following series of reactions: 2-amino-3'-bromodiphenyl[8] ⟶ 2-amino-3,3',5-tribromodiphenyl ⟶ 3,3',5'-tribromodiphenyl. Since on oxidation 3,3',5'-tribromodiphenyl yields 3,5-dibromobenzoic acid, the positions taken by the two entering bromine atoms in the dibromination of 2-amino-3'-bromodiphenyl are proved.

3',4,5'-Tribromodiphenyl was prepared by deamination of 3',4,5'-tribromo-4'-aminodiphenyl.[5] It evidently is identical with the tribromodiphenyl synthesized by Bellavita[6] from 2-amino-3,5-dibromo-4'-nitrodiphenyl.

2',4,5'-Tribromodiphenyl was synthesized by the following series of reactions: 4-bromo-3'-acetaminodiphenyl[4] ⟶ 2',4-dibromo-5'-acetaminodiphenyl ⟶ 2',4-dibromo-5'-aminodiphenyl ⟶ 2',4,5'-tribromodiphenyl.

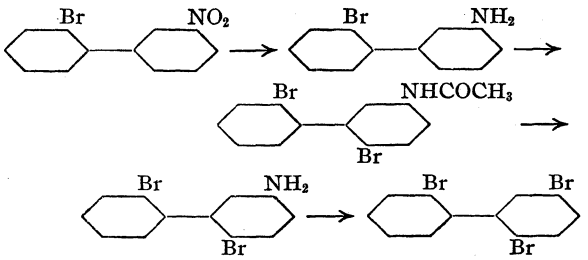
The structure of the dibromo base was proved by its conversion to 2,4'-dibromodiphenyl on deamination. The final product is evidently identical with the tribromodiphenyl prepared by Bellavita[7] from *o*, *p*'-bianiline.

2',3,5'-Tribromodiphenyl was prepared in the manner indicated[8]



The structure of the dibromo base was proved by its conversion to 3,3'-dibromodiphenyl on deamination.

The synthesis of 2,2',5'-tribromodiphenyl was effected by the following procedure[2]



The structure of the dibromo base was proved by its conversion to 2,2'-dibromodiphenyl on deamination.

Attempts to prepare 3,3',5'-tribromodiphenyl from 3-nitrobenzidine[9] by monobromination of the corresponding diurethan, removal of the urethano groups, reduction of the resulting 3-bromo-3'-nitrodiphenyl, followed by acetylation, monobromination, hydrolysis, and replacement of amino by bromine were unsuccessful, as it was found that 3-nitrobenzidine formed only a monourethan under the experimental conditions. This product upon monobromination, hydrolysis and deamination yielded 3-bromo-5-nitrodiphenyl, whose structure is proved by the fact that on reduction, replacement of amino by bromine and oxidation, 3,5-dibromobenzoic acid was formed. This bromonitrodiphenyl is evidently identical with that obtained by Scarborough and Waters[10] by deamination of 5-bromo-3-nitro-4-aminodiphenyl.

Experimental Part

The compounds described in Table I, grouped according to their generic relationships, were

[a] Blakey and Scarborough[4] record m. p. 104° for this compound. [b] Free base not isolated.

prepared by the following general methods according to the scheme already indicated: (1) reduction of nitro compounds was effected by stannous chloride in ethanol; (2) acetylation of amines by means of an acetic acid–acetic anhydride mixture in the presence of a small amount of sulfuric acid; (3) bromination of acetamino derivatives by the use of one mole of bromine in acetic acid solution containing sodium acetate; (4) deamination of amines by means of saturated sodium nitrite solution in a boiling alcoholic solution of the amine containing dilute sulfuric acid; (5) hydrolysis of acetamino compounds by alcoholic hydrobromic acid.

2,4,6-Tribromodiphenyl.—To 45 g. of iodobenzene heated to 180°, was added gradually a mixture of 44 g. of 2,4,6-tribromoiodobenzene and 40 g. of copper powder. The mixture was heated for two hours at 200° with stirring. After cooling, the mass was extracted with ether and the ether residue distilled. From it was obtained, after two distillations, 17.5 g. of a fraction, b. p. 190–198° (4 mm.), which after crystallization from petroleum ether yielded a pure tribromodiphenyl, m. p. 65–66°.

Anal. Calcd. for $C_{12}H_7Br_3$: Br, 61.34. Found: Br, 61.45.

This product melted unchanged when mixed with 2,4,6-tribromodiphenyl prepared by the method of Blakey and Scarborough.[4] The tribromodiphenyl prepared by either method yields on oxidation only *p*-bromobenzoic acid.

3-Nitrobenzidine.—The following method was found superior to that of Le Fèvre and Turner.[9] Twenty grams of 3,4′-dinitro-4-aminodiphenyl,[9] dissolved in 200 cc. of dioxane, was treated with 4 g. of sulfur and 24 g. of hydrated sodium sulfide and the mixture heated on the steam-bath for ten hours. After removal of the dioxane on the steam-bath by means of an aspirator, the residue was purified by washing with hot water, followed by extraction with hot 1–1 acetic acid. The base was precipitated by ammonia from the acetic acid solution, and not further purified; yield of crude base, 17 g.

Monourethan of 3-Nitrobenzidine.—A boiling solution of 121 g. of crude 3-nitrobenzidine and 169 g. of diethylaniline in 1250 cc. of ethanol was treated gradually with 146 g. of ethyl chlorocarbonate. The mixture was boiled for ten minutes after the reaction had subsided, and then poured into a large volume of water. The resulting precipitate was crystallized from benzene: yield, 88 g. of a product melting at 163–164°. The pure monourethan melts at 167–168°.

Anal. Calcd. for $C_{15}H_{15}N_3O_4$: C, 59.77; H, 5.02. Found: C, 59.58; H, 4.81.

Monourethan of 3-Nitro-5-bromobenzidine.—This was prepared by the bromination of the monourethan of 3-nitrobenzidine in glacial acetic acid containing anhydrous sodium acetate. It was crystallized from benzene, m. p. 167–168°.

Anal. Calcd. for $C_{15}H_{14}O_4N_3Br$: Br, 21.03. Found: Br, 21.24.

3-Nitro-5-bromobenzidine.—The crude base was prepared from the urethan by hydrolysis with hot 60% sulfuric acid.

3-Nitro-5-bromodiphenyl.[10]—Eighty grams of crude 3-nitro-5-bromobenzidine was dissolved in 326 cc. of concd. sulfuric acid, and the mixture diluted with 300 cc. of water. Diazotization was then effected by the slow addition of 80 g. of sodium nitrite, keeping the temperature below 10°. Following this, the mixture was treated with 300 cc. of 20% oleum at a temperature below 30°, and poured into 2 liters of boiling alcohol. After refluxing for two hours, the alcohol was removed and water added. The desired product was extracted with ether, and, after removal of ether, distilled *in vacuo*, yielding 31 g., b. p. 200–242°

(5 mm.). The crude distillate was recrystallized from methanol: yield, 10.5 g.; m. p. 71–72°.

Anal. Calcd. for $C_{12}H_8NO_2Br$: Br, 28.75. Found: Br, 29.12.

Summary

1. A study has been made of the oxidation products of the following polybromodiphenyls: 2,3′- and 3,4′-dibromodiphenyl, 2,3′,5′-, 3,3′,5′-, 3′,4,5′-, 2,2′,5′-, 2′,3,5′-, 2′,4,5′- and 2,4,6-tribromodiphenyls, and 2,4,4′,6-tetrabromodiphenyl.

2. The preparation of those polybromodiphenyls not previously recorded is described.

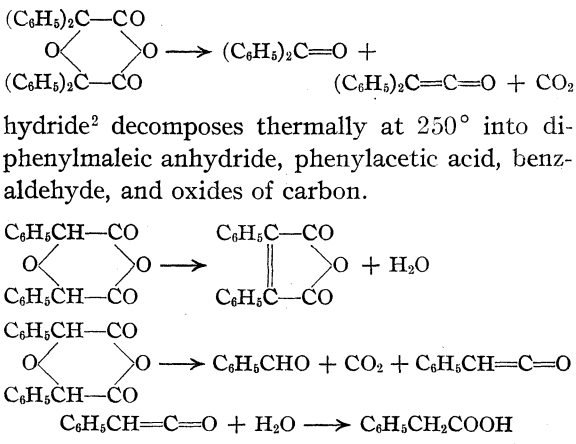
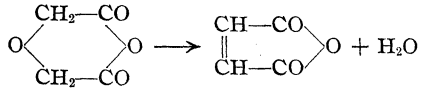
The Pyrolysis of Diglycolic Anhydride

BY CHARLES D. HURD AND HOWARD G. GLASS

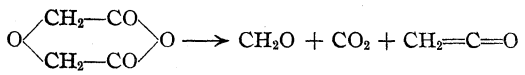
On pyrolysis, dibenzilic anhydride[1] yields benzophenone and diphenylketene. Dimandelic anhydride[2] decomposes thermally at 250° into diphenylmaleic anhydride, phenylacetic acid, benzaldehyde, and oxides of carbon.



The present work deals with diglycolic anhydride. From the above one would predict for it a bidirectional breakdown on heating. One reaction should give rise to maleic anhydride



whereas the other should yield ketene



A good yield of maleic anhydride was obtained at 450–500°. Some ketene was observed too, but since water was formed in this reaction it must have changed much of the ketene into acetic acid.

The production of maleic anhydride from diglycolic anhydride involves lengthening of the carbon chain. This is an interesting, unusual method of bringing about such an effect.

(1) Staudinger, *Ber.*, **44**, 543 (1911).

(2) Hurd and Raterink, THIS JOURNAL, **55**, 1541 (1933).

Experimental

Diglycolic Anhydride.—To 35 g. of diglycolic acid was added 65 g. of acetic anhydride and the mixture was refluxed four hours. Then 35 g. of acetic acid was distilled off, 30 g. more of acetic anhydride added and the mixture was refluxed for two hours longer. On distillation 5 g. more of acetic acid was collected and 61 g. of acetic anhydride was recovered. The residue was vacuum distilled. There was collected 32 g. (94% yield) of diglycolic anhydride at 130° and 20 mm. It solidified on cooling; m. p. 94–95°. The derivative with aniline, diglycolic phenylimide, was prepared. Its melting point of 109–110° confirmed Anschütz' value[3] of 111°.

Analysis of Mixtures of Maleic and Diglycolic Anhydrides.—The separation of these two anhydrides was accomplished satisfactorily by the selective solvent action of benzene. Both anhydrides were soluble in hot benzene whereas diglycolic anhydride separated on cooling the solution to 6°. After concentrating the filtrate and cooling till crystals of this compound no longer appeared, furan was added to the solution. After a time, crystals of the addition product of furan and maleic anhydride separated.[4] This material melted at 122–124° and at 125° after recrystallization (literature, 125°).

In various mixtures, recovery of the diglycolic anhydride was almost quantitative and recovery of the maleic anhydride derivative was 89–95%. The results are presented in Table I.

TABLE I

SEPARATION OF MALEIC AND DIGLYCOLIC ANHYDRIDES

Mixture, g.		Diglycolic anhydride found		Maleic anhydride found	
Maleic anhydride	Diglycolic anhydride	G.	%	Furan deriv. G.	%
3.0	12.0	11.6	97	4.75	94
1.0	1.0	1.0	100	1.6	95
0.8	1.0	0.97	97	1.25	93
.6	1.0	.95	95	0.90	89
.4	1.0	.96	96	.60	89
.2	1.0	.97	97	.30	89

Pyrolysis of Diglycolic Anhydride.—The sample of diglycolic anhydride was placed in a test-tube with a side

(3) Anschütz, *Ann.*, **273**, 66 (1892).

(4) Diels and Alder, *Ber.*, **62**, 554 (1929).

arm capillary. An oil-bath at 100° kept the anhydride melted and mercury, which was dropped in through a capillary jet, forced the anhydride at a uniform rate into the top of the vertical hot reaction tube. The reaction products were condensed in a side-arm flask, attached to the bottom of the tube. The flask was cooled in ice and connected to a gas collecting bottle. The tube was flushed out with nitrogen before each run.

The effective hot volume of the reaction tube was 87 cc. This volume makes allowance for the volume of the thermocouple well. The tube was electrically heated in a furnace whose temperature was recorded and controlled by a Leeds and Northrup potentiometer-type recorder-controller.

In the first run at 450°, 20 g. of diglycolic anhydride was passed through the tube during eighty minutes (contact time, about forty seconds). From the reaction products was obtained 15.5 g. of diglycolic anhydride and 1.2 g. of diglycolic acid. Hence, 3.3 g. of the anhydride was the amount pyrolyzed. The furan derivative weighed 3.2 g. From Table I it may be assumed that this represents 95% of the maleic anhydride present. Hence, the corrected yield of maleic anhydride, based on the diglycolic anhydride not recovered, was 71%.

The second run was performed also with 20 g. of diglycolic anhydride during eighty-seven minutes (contact time, forty-two seconds). There was recovered 10.2 g. of the anhydride and 1.5 g. of diglycolic acid; therefore, 8.3 g. of the anhydride was pyrolyzed. The furan derivative weighed 4.9 g. With the 95% correction factor, this represents a 44% yield of maleic anhydride.

The gas evolved in runs 1 and 2, respectively, measured 600 and 2500 cc. The gas was analyzed for CO_2, unsaturates, H_2 and CO. These relative amounts were formed in run 1 (% by volume): 16.6, 4.7, 20.7, 58.0. In run 2: 13.1, 21.6, 20.7, 44.6.

Ketene in the Products.—An 8-g. sample of diglycolic anhydride was pyrolyzed in the same apparatus at 500°. The gases which were evolved were passed through a low-pitched coil condenser cooled to −15° by ice and salt, and the uncondensed gas was conducted through standard alkali. The ketene in the gas stream neutralized 0.56 cc. of 2.218 *N* sodium hydroxide. This represents 0.00124 mole of ketene or 0.052 g. This is a 4% yield, calculated on the basis of 3.3 g. of unrecovered diglycolic anhydride.

Summary

Diglycolic anhydride undergoes pyrolysis at 450–500° into maleic anhydride. This reaction involves lengthening of the carbon chain. Concurrently, a small yield of ketene is obtained. A method for the separation of mixtures of diglycolic anhydride and maleic anhydride is included.

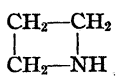
Azetidine Derivatives. I. 2,4-Diketo-3-hydroxy-3-arylazetidines

BY J. L. RIEBSOMER, HOWARD BURKETT, THOMAS HODGSON AND FRED SENOUR

The five- and six-membered heterocyclic compounds are well known since they are found in such important substances as pyrrole and pyridine. Interest in the structure and synthesis of such compounds has been fostered by the study of natural products in which these basic structures are often found.

On the other hand, four-membered heterocyclic compounds containing nitrogen in the ring have been found difficult to prepare and since no relationship between their structure and important natural products has been observed, this field of chemistry has been almost neglected.

Azetidine, or trimethyleneimine, has been known since about 1890[1] when it was prepared by the distillation of trimethylenediamine hydrochloride and by heating γ-bromopropylamine with alkali.[2]



A few syntheses of substituted azetidines have been reported such as the synthesis of 3,3-dimethylazetidine,[3] N-phenyl-3,3-diphenyl-2,4-diketo-azetidine,[4] O-methylol-O-benzyleneimine,[5] 3-hydroxy-3-2,4,6-trimethoxyphenyl-2,4-diketo-azetidine,[6] and others.[7,8,9,10]

The purpose of this paper is to present a new method for the synthesis of substituted diketo-azetidines and to report certain pharmacological studies of these new compounds.

In an attempt to condense phenylhydroxymalonic esters[11] with urea in the presence of sodium ethylate to produce the corresponding barbituric acid derivatives, there were produced instead imides or azetidine derivatives such as

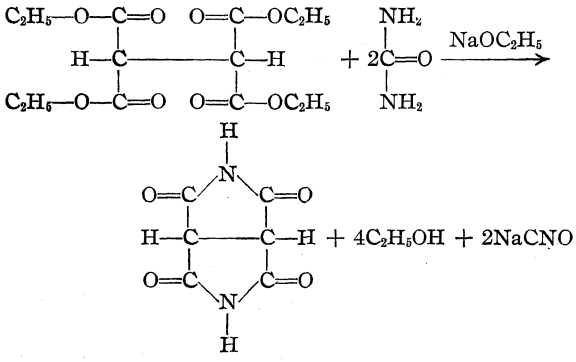
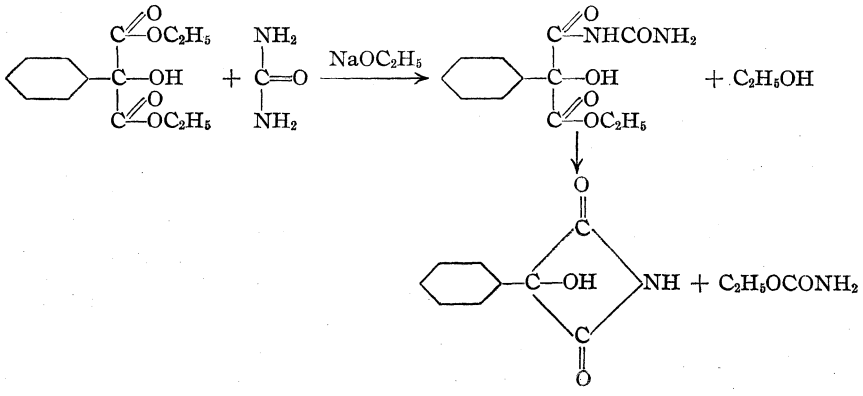
Further investigation proved that gaseous ammonia passed into the mixture of substituted malonic ester, and sodium ethylate dissolved in alcohol, produced the same substituted azetidines as when urea was added, though in lower yields.

This formation of azetidine derivatives is not so unusual as might be expected when one considers that urea has been used under similar conditions to synthesize five-membered heterocyclic nitrogen compounds.

Roeder[12] treated diethyl succinate with urea in the presence of sodium ethylate and produced succinimide. In the same publication Roeder reported a reaction very similar to the one by which we have prepared substituted azetidines and wrote the equation

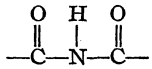


On the basis of such experience it would seem reasonable to represent the reactions by which we have prepared azetidine derivatives thus



Or since ammonia may be substituted for urea to produce the same azetidine derivatives one might reasonably postulate that urea is first decomposed by the sodium ethylate to produce ammonia which would then react to give the imide and ethyl alcohol.

Since these azetidine derivatives contain the grouping



which is associated with many compounds possessing hypnotic activity,[13] it seemed justifiable to expect some hypnotic activity when these compounds were administered to animals. All the compounds prepared in this series, however, proved to be inactive as hypnotics when given to rabbits. Not only are they inactive as hypnotics but they are toxic to rabbits in relatively small doses.

Experimental

General Method of Preparation.—Since these compounds were all prepared by essentially the same procedure, it is necessary to describe in detail the preparation of only one. For the preparation of 2,4-diketo-3-phenyl-3-hydroxy-azetidine, 25 g. of phenylhydroxymalonic ester was added to a sodium ethylate solution prepared from 80 g. of absolute alcohol and 7.5 g. of sodium. The mixture was placed in a 3-necked flask equipped with a stirrer, condenser and addition tube and was heated to 115–120° with an oil-bath and 10 g. of urea was added. After stirring at 115–120° for five hours 10 g. more urea was added and the stirring and heating continued for about eleven hours.

When the reaction was finished, the excess alcohol was evaporated to complete dryness. The dried product was dissolved in 100 cc. of water. To this solution was added 50 g. of ice and 10% hydrochloric acid was introduced slowly with stirring until the solution was acid to litmus. A large excess of acid should be avoided. The acidified solution was extracted with three 50-cc. portions of ether, and the ether solution dried over anhydrous sodium sulfate and filtered. The ether solution then was evaporated and the oily residue crystallized from a benzene–petroleum ether mixture. The yield of 2,4-diketo-3-hydroxy-3-phenylazetidine was 4.3 g., or 17% of the theoretical based on the quantity of ester used. In some cases the final purification was rather difficult and involved several crystallizations.

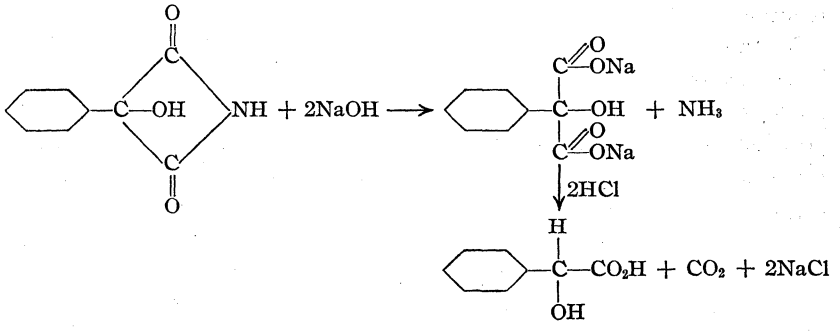
p-*s*-Butyl	89–90	6.01	5.86	66.85	6.43	66.74	6.52	38	105–106

Synthesis Using Ammonia Instead of Urea.—In this synthesis the procedure was the same as outlined above except that dry ammonia gas was bubbled slowly into the arylhydroxymalonic ester–sodium ethylate mixture instead of adding the urea. This procedure was carried out in three different cases using phenylhydroxymalonic ester, *p*-tolylhydroxymalonic ester and *p*-ethylphenylhydroxymalonic ester as starting materials. The corresponding azetidine derivatives were formed in yields of about 3%. The melting points, mixed melting points and N, C and H analyses checked with the compounds produced from urea and the corresponding malonic esters.

Proof of Structure.—A sample of 1–2 g. of each of the substituted azetidines was saponified with excess 20% aqueous sodium hydroxide by boiling the mixture for four hours. Ammonia gas was evolved, which would be anticipated from such treatment of imides. The saponified product was strongly acidified with hydrochloric acid and boiled for four hours during which time carbon dioxide was evolved. The acidified solution was extracted with ether, the ether evaporated and the residue crystallized from benzene. The resulting products were shown by their melting points and mixed melting points to be the corresponding mandelic acids. The reactions may be explained by the typical equations shown.



A summary of the data obtained from the compounds prepared is assembled in Table I.

The authors are indebted to Dr. Robert S. Shelton of the William S. Merrell Company for the pharmacological data, and to Dean William M. Blanchard of DePauw University who was instrumental in obtaining financial aid from The National Research Council, and from Mr. J. K. Lilly of Indianapolis, Indiana.

Summary

1. Six 2,4-diketo-3-hydroxy-3-arylazetidines have been prepared by the condensation of arylhydroxymalonic esters and urea.

2. These compounds failed to show any hypnotic activity when administered to rabbits. They did prove to be moderately toxic.

The Addition of Methoxyamine to α,β-Unsaturated Ketones and the Rearrangement of β-Methoxyaminoketones[1]

BY A. H. BLATT

We have found from some experiments designed to determine the usefulness of methoxyamine[2] as a reagent for carbonyl compounds that, while methoxyamine hydrochloride reacts readily with both aldehydes and ketones to form oxime methyl ethers, the free base reacts in this fashion only with aldehydes and the more reactive ketones. This observation, which is in qualitative agreement with studies on the rate of oxime formation in relation to the *p*H of the reaction medium,[3] suggested that methoxyamine might, like numerous other basic nitrogen compounds,[4] add to the conjugated system present in α,β-unsaturated ketones. Such addition, we have found, does take place and in the following paragraphs we report on one portion of a study of this addition reaction and the resulting addition products.

Methoxyamine adds readily and reversibly to benzalacetophenone and to a number of its analogs which contain a substituent in the *p* or *p'* position to furnish saturated β-methoxyamino ketones such as (I).

$$C_6H_5CH{=}CHCOC_6H_5 + CH_3ONH_2 \rightleftharpoons \underset{\displaystyle NHOCH_3}{\overset{\displaystyle C_6H_5CHCH_2COC_6H_5}{|}}$$

I

Methoxyamino-*bis*-propiophenones, such as VII, occasionally are formed also and from one unsaturated ketone, *p*-methylbenzalacetophenone, a *bis* compound of this type is the only product. The addition reaction is in itself unusual because it takes place in the absence of any added catalyst and because, when a strong base is added as a catalyst, the reaction does not stop with the formation of a β-methoxyamino ketone. Up to the present time the addition of methoxyamine to benzalacetophenone and eight substituted benzalacetophenones has been examined (see Table I). With every ketone, addition takes place. There are considerable variations in the yields of addition products obtained but differences in the solubilities of the products as well as in the position of equilibrium must be considered in order to account for the actual yields obtained, and there is no indication as yet of any regular influence on the addition reaction exerted by the substituent present in the unsaturated ketone.

In view of the large amount of information already available on the addition reactions of α,β-unsaturated ketones, there can be little doubt but that the addition of methoxyamine to these unsaturated ketones is 1,4 and that the addition products are constituted like that from benzalacetophenone whose structure is shown in formula (I). However, the rearrangement which takes place on treatment of these addition products with strong bases, and which will be described shortly, makes it imperative to secure unequivocal evidence for the structures assigned to the addition products. This evidence was obtained for the addition product of methoxyamine to benzalacetophenone, β-phenyl-β-methoxyaminopropiophenone (I), by oxidizing the material to a product whose structure was established by two independent syntheses.

When β-phenyl-β-methoxyaminopropiophenone, as its hydrochloride (II), is oxidized by hypochlorous acid,[5] it furnishes the monoxime methyl ether of dibenzoylmethane (III).

$$\left[\underset{\displaystyle NH_2OCH_3}{\overset{\displaystyle C_6H_5CHCH_2COC_6H_5}{|}}\right]Cl + HOCl \longrightarrow$$

II

$$C_6H_5C(=NOCH_3)CH_2COC_6H_5{}^{6} + 2HCl + H_2O$$

III

The structure of the oxime ether (III) is estab-

(1) Presented in part at the Milwaukee meeting of the American Chemical Society, September, 1938.

(2) The name methoxyamine is both more concise and more clearly descriptive than the usual name, α-methylhydroxylamine. Dr. E. J. Crane, Editor of *Chemical Abstracts*, to whom we are indebted for assistance in naming the methoxyamine addition products described in this paper, has also informed us that methoxyamine is the correct name. Compare Patterson, THIS JOURNAL, **55**, 3918 (1933).

(6) The configuration assigned to this oxime ether is purely arbitrary.

lished by its preparation, accompanied by the dioxime dimethyl ether (IV), from methoxyamine hydrochloride and dibenzoylmethane (a synthesis which takes advantage of the fact mentioned previously that methoxyamine hydrochloride, in contrast with the free base, reacts with ketonic carbonyl groups).

$$C_6H_5COCH_2COC_6H_5 \xrightarrow{CH_3ONH_3Cl} C_6H_5CCH_2COC_6H_5 + C_6H_5C(NOCH_3)CH_2C(NOCH_3)C_6H_5$$
(III: $C_6H_5CCH_2COC_6H_5$, $NOCH_3$; IV: $C_6H_5C(NOCH_3)CH_2C(NOCH_3)C_6H_5$)

This set of reactions, it should particularly be noted, establishes the location of the nitrogen atom in the addition product as attached to the carbon atom in the β-position to the carbonyl group.

A second synthesis of the monoxime methyl ether of dibenzoylmethane, which establishes at the same time that methoxyamine adds also to acetylenic ketones, is furnished by the reaction between methoxyamine and benzoylphenylacetylene. The 1,4-addition of methoxyamine to this ketone would furnish a product (V) which, as the eneamine tautomer of an oxime methyl ether, should rearrange to the same substance, (III), that was obtained by the oxidation of β-phenyl-β-methoxyaminopropiophenone (I). This expectation is realized for the addition of methoxyamine to benzoylphenylacetylene furnishes directly the monoxime methyl ether of dibenzoylmethane (III).

$$C_6H_5C{\equiv}CCOC_6H_5 + CH_3ONH_2 \longrightarrow \left[C_6H_5C(NHOCH_3){=}CHCOC_6H_5\right] \longrightarrow C_6H_5CCH_2COC_6H_5$$
(V: $C_6H_5C(NHOCH_3){=}CHCOC_6H_5$; III: $C_6H_5CCH_2COC_6H_5$, $NOCH_3$)

Finally, the fact may be mentioned, as corroborative negative evidence for 1,4-addition, that β-phenylbenzalacetophenone which does not undergo the customary 1,4-addition reactions[7] does not add methoxyamine.

It was stated earlier that the addition of methoxyamine to α,β-unsaturated ketones is reversible. This is shown by the behavior of the addition products on heating, either alone or in the presence of a methoxyamine acceptor. Usually the addition products can be distilled in a high vacuum but when they are heated at only moderately reduced pressures they dissociate to regenerate methoxyamine and an α,β-unsaturated ketone. The equilibrium in the addition reactions usually is quite favorable to the formation of the addition products and this is true whether the addition is carried out at room temperature or near the boiling point of the solvent, alcohol. Consequently the addition products can be heated in alcoholic solution to the boiling point of the solution without appreciable change. If, however, a methoxyamine acceptor, for example, benzaldehyde which as an aldehyde will react with the free base, is present, then the addition reaction is reversed and the unsaturated ketone is regenerated. In effect, this process utilizes the addition products as oximating agents.

$$C_6H_5CH(NHOCH_3)CH_2COC_6H_4Br\text{-}p + C_6H_5CHO \longrightarrow$$
(VI: $C_6H_5CH(NHOCH_3)CH_2COC_6H_4Br\text{-}p$)

$$C_6H_5CH{=}CHCOC_6H_4Br\text{-}p + C_6H_5CH{=}NOCH_3 + H_2O$$

The β-methoxyaminopropiophenones produced by the addition of methoxyamine to α,β-unsaturated ketones are O,N-disubstituted hydroxylamines and as such are weak bases. They will add to a second molecule of unsaturated ketone, they can be readily acetylated, and they form easily hydrolyzed salts with the halogen acids. Addition to a second molecule of unsaturated ketone furnishes methoxyimino-*bis*-propiophenones such as (VII). These *bis* compounds or trimolecular products are relatively unreactive, high melting and sparingly soluble substances.

$$C_6H_5CH(NHOCH_3)CH_2COC_6H_5 + C_6H_5CH{=}CHCOC_6H_5 \longrightarrow$$
(VII: $C_6H_5CH(NOCH_3)CH_2COC_6H_5$)

The acetyl derivatives of the β-methoxyaminopropiophenones (see Table II, p. 3498), which are formed in quantitative yield simply by dissolving the parent substances in acetic anhydride, are more sparingly soluble and crystallize better than do the addition products. The acetyl derivatives, like the parent compounds, regenerate α,β-unsaturated ketones on heating; unlike the parent compounds they also regenerate α,β-unsaturated compounds on treatment with sodium methylate. The salts formed by the addition compounds with the halogen acids can be hydrolyzed by solution in alcohol and dilution with water. If, however, these salts in alcoholic solution or the addition products in alcoholic acid are heated, the addition

(7) Kohler, *Am. Chem. J.*, **38**, 515 (1907).

reaction is reversed. And, since methoxyamine hydrochloride reacts with ketonic carbonyl groups the oxime methyl ether of the unsaturated ketone, as well as the unsaturated ketone, is formed. The process is illustrated by the equation

$$C_6H_5CHCH_2COC_6H_4Br\text{-}p + HCl \longrightarrow$$
$$\quad\quad |$$
$$\quad NHOCH_3$$
$$C_6H_5CH{=}CHCOC_6H_4Br\text{-}p + CH_3ONH_3Cl \longrightarrow$$
$$C_6H_5CH{=}CHCC_6H_4Br\text{-}p^6 + HCl + H_2O$$
$$\quad\quad\quad

TABLE I

Notes to Table I. All the products described are colorless solids; the β-methoxyaminopropiophenones are readily soluble in all the common solvents save petroleum ether. The letters in the column "Temperature" indicate that addition was made near the boiling point of the solution (H) or at room temperature (C). The yields reported refer to crude, washed addition products. No yields are reported for the *bis* compounds as they were obtained only in small amounts from reaction mixtures which had been allowed to stand for long periods of time. The addition product from anisalacetophenone could not be obtained solid; the oil left after evaporating the solvent and excess methoxyamine furnished a crystalline acetyl derivative, see Table II. The addition product from benzal-*p*-methylacetophenone was difficult to obtain as a solid and to handle once solid; the oil left after evaporating the solvent and excess methoxyamine was used to prepare the acetyl derivative, Table II, and the unsaturated amine, Table III.

product by a molecular weight determination (calcd. for $C_{31}H_{29}NO_3$: mol. wt., 463. Found: mol. wt. (camphor), 458) and by a synthesis from β-phenyl-β-methoxyaminopropiophenone (I) and benzalacetophenone. For this purpose 1.0 g. of the unsaturated ketone and 1.2 g. of the methoxyamino ketone were dissolved in 15 cc. of alcohol and left for sixty-seven days at room temperature. During this time, 0.6 g. of the sparingly soluble *bis* compound precipitated. On high vacuum distillation this material furnished benzalacetophenone.

The effect of acids on the β-methoxyaminopropiophenones and the reversal of the addition reaction which leads to their formation were examined using β-phenyl-β-methoxyamino-*p*-bromopropiophenone (VI), since the products obtained from the compound were easily handled. When a solution of 1.0 g. of the propiophenone (VI) in 16 cc. of alcohol, 1 cc. of concd. hydrochloric acid and 3 cc. of water was boiled for three hours then chilled, it deposited 0.35 g. of benzal-*p*-bromoacetophenone (mixed m. p.). The filtrate, after removal of the unsaturated ketone, left on slow evaporation benzal-*p*-bromoacetophenoneoxime methyl ether (VIII). This material was identified by comparison with a sample prepared by boiling for three hours an alcoholic solution containing benzal-*p*-bromoacetophenone and an equivalent amount of methoxyamine hydrochloride. The oxime ether (VIII), obtained by evaporating an ether extract of the reaction mixture, crystallizes from alcohol in long silky needles which melt at 77–78°.

Anal. Calcd. for $C_{16}H_{14}BrNO_2$: OCH_3, 9.8. Found: OCH_3, 9.6.

When 1.65 g. of β-phenyl-β-methoxyamino-*p*-bromopropiophenone in 5 cc. of methyl alcohol was boiled for forty-eight hours with two equivalents of benzaldehyde, the solution on cooling set to a paste. Filtration furnished 0.5 g. of benzal-*p*-bromoacetophenone, identified by comparison with an authentic sample.

Oxidation of β-Phenyl-β-methoxyaminopropiophenone (I).—One-half gram of the hydrochloride (II) was stirred into 50 cc. of cold water, and 20 cc. of cold sodium hypochlorite solution ("Oxol") was added. Dilute hydrochloric acid in excess was next added and the reaction mixture was stirred for an hour. The precipitated solid, which was slightly sticky and weighed 0.5 g., was crystallized from alcohol. It then melted at 114–115° and was shown to be the monoxime methyl ether of dibenzoylmethane (III) by a mixed melting point with a synthetic sample of that material.

Synthesis of the Monoxime Methyl Ether of Dibenzoylmethane (III).—A. When a solution of 4.5 g. of dibenzoylmethane and 1.7 g. of methoxyamine hydrochloride in 20 cc. of alcohol was boiled for two hours, then cooled, it deposited 3.4 g. of colorless solid which melted over the range 70–100°. Crystallization from alcohol furnished the pure monoxime ether (III) in fine silky needles which melted at 114–115°.

Anal. Calcd. for $C_{16}H_{15}NO_2$: OCH_3, 11.79. Found: OCH_3, 11.85.

The impurity accompanying the monoxime ether (III) and responsible for the low melting point of the crude product is the dioxime dimethyl ether of dibenzoylmethane (IV). The dioxime dimethyl ether can be prepared directly from dibenzoylmethane and two equivalents of methoxyamine hydrochloride or from the monoxime

α-Aminobenzalacetophenone can also be prepared, less satisfactorily, in a single reaction using benzalacetophenone, methoxyamine and alcoholic potassium hydroxide. α-Aminobenzal-p-methylacetophenone was prepared from the crude oily product obtained from benzal-p-methylacetophenone and methoxyamine. The yield of this amino ketone is, therefore, based on the unsaturated ketone used and is the over-all yield of two reactions. The amino ketone from β-phenyl-β-methoxyamino-p-methoxypropiophenone was an intractable oil.

methyl ether with the same reagent. The pure dioxime ether, crystallized from alcohol, melts at 57.5–58.5°.

Anal. Calcd. for $C_{17}H_{18}N_2O_2$: OCH_3, 21.98. Found: OCH_3, 21.4.

B. One gram of benzoylphenylacetylene[9] was dissolved in 5 cc. of warm methanol and 0.3 g. of methoxyamine was added. After eighteen hours at room temperature the solution set solid when rubbed with a stirring rod. On chilling and filtering, 1.0 g. of crude oxime ether, identified by comparison with a sample prepared from dibenzoylmethane, was obtained.

Acetylation of the β-methoxyaminopropiophenones takes place on dissolving them in excess acetic anhydride. In some cases, solution occurs at room temperature while in other cases gentle warming on the steam-bath for a minute or two is required. The acetyl derivatives crystallize when the reaction mixtures, after cooling to room temperature, are stirred with water to destroy the excess anhydride. The yields are quantitative and the products are all colorless solids. Detailed information about the acetylation products is summarized in Table II.

When the acetyl derivative of β-phenyl-β-methoxyamino-p-bromopropiophenone was distilled at 15 mm., it furnished benzal-p-bromoacetophenone. The same product, in quantitative yield, was obtained when this acetyl derivative suspended in methyl alcohol was treated in the cold with one equivalent of sodium methylate.

Rearrangement of the β-Methoxyaminopropiophenones to α-Aminobenzalacetophenones.—Although the conversion of the β-methoxyaminopropiophenones to unsaturated α-amino ketones can be effected using a rather wide range of concentrations, temperatures and reaction times, we have found it most convenient to dissolve one equivalent of the methoxyamino ketone in two equivalents of 2 *N* sodium methylate solution at about 60°, adding absolute methyl alcohol when necessary to bring about complete solution. The reaction mixture is kept warm until it develops a yellow to orange color, usually about ten minutes is required, then left to stand overnight. Next day on chilling, the α-amino ketone crystallizes. The transformation is probably finished in less time but this procedure ensures completeness of reaction. Estimates of the amounts of α-amino ketones which remain dissolved in the reaction mixture, based on rough determinations of the solubility of the α-amino ketones, indicate that the rearrangement is essentially quantitative. We shall describe in detail the conversion of two β-methoxyamino ketones to α-amino ketones for illustrative purposes. Other data on the rearrangements and products are given in Table III.

When 2.55 g. (0.01 mole) of β-phenyl-β-methoxyamino-

(9) We are indebted to Dr. R. C. Fuson for a sample of this ketone.

propiophenone (I) was dissolved by warming to 60° for ten minutes in 10 cc. of sodium methylate solution containing 0.46 g. (0.02 mole) of sodium and the orange-yellow solution was left for eighteen hours, it deposited on chilling 2.19 of α-aminobenzalacetophenone (IX); yield, 94%. The product, after crystallization from methyl alcohol, melted at 100–101°. This amino ketone, which had previously been prepared by a different method,[8] was identified by analysis, by the formation of a hydrochloride melting with decomposition at 180° (instantaneous melting point, 185°), and by hydrolysis on warming with dilute hydrochloric acid to phenylbenzylglyoxal which was isolated and characterized as the antimony derivative, m. p. and mixed m. p. 174–175°.

When 6.7 g. (0.02 mole) of β-phenyl-β-methoxyamino-*p*-bromopropiophenone (VI) was dissolved in 20 cc. of warm sodium methylate, containing 0.92 g. of sodium (0.04 mole), plus 20 cc. of absolute methyl alcohol and warmed for fifteen minutes the orange reaction mixture set solid on cooling. Chilling and filtering furnished 5.0 g. of α-aminobenzal-*p*-bromoacetophenone, a yield of 83%.

Summary

Methoxyamine adds to benzalacetophenone and its *p* or *p'* substituted analogs to furnish β-methoxyaminopropiophenones and β,β'-methoxyimino-*bis*-propiophenones. The same reagent adds also to benzoylphenylacetylene. The addition reaction has been shown to be reversible and the structures of the addition products have been established. The chemical behavior of the addition products has been described and it has been shown that the β-methoxyaminopropiophenones on treatment with strong bases lose a molecule of alcohol and rearrange to form α-amino unsaturated ketones.

FLUSHING, N. Y. RECEIVED SEPTEMBER 27, 1939

[A COMMUNICATION FROM THE LABORATORY OF ORGANIC CHEMISTRY OF THE UNIVERSITY OF WISCONSIN]

Preparation of Certain Amines

BY EDWARD J. SCHWOEGLER AND HOMER ADKINS

Alcohols react with primary and secondary amines under the influence of such hydrogenating and dehydrogenating catalysts as nickel,[1,2] palladium[3] and copper chromite[4,5] with the formation of secondary and tertiary amines.

$$ROH + R'NH_2 \longrightarrow RNHR' + H_2O \quad (1)$$
$$ROH + R'_2NH \longrightarrow RNR'_2 + H_2O \quad (2)$$

Since tertiary alcohols do not show this type of reaction it is plausible to asume that the primary function of the catalyst is to dehydrogenate the alcohol to an aldehyde or ketone. The latter would then react with an amine to give a product which is readily hydrogenated to an amine.

$$R_2CHOH \longrightarrow R_2CO + H_2 \quad (3)$$
$$R_2CO + R'NH_2 \longrightarrow R_2C(OH)(NHR') \quad (4)$$
$$R_2C(OH)(NHR) + H_2 \longrightarrow R_2CHNHR + H_2O \quad (5)$$

An alternative series of reactions depending upon the dehydrogenation of the original amine instead of the alcohol is not plausible for the product of reactions similar to (3), (4) and (5) would be an ether:

$$RCH_2NH_2 \longrightarrow RCH{=}NH + H_2 \quad (6)$$
$$RCH{=}NH + R'OH \longrightarrow RCH(NH_2)(OR') \quad (7)$$
$$RCH(NH_2)(OR') + H_2 \longrightarrow RCH_2OR' + NH_3 \quad (8)$$

However, a dehydrogenation as shown in (6) probably occurs, for secondary amines having the same alkyl groups as the primary amine are readily formed over palladium,[3] nickel[2] and copper chromite.[4] In fact this reaction constitutes an important side reaction when it is desired to combine an alcohol and an amine according to the type reactions (1) and (2). The series of probable reactions is

$$RCH_2NH_2 \longrightarrow RCH{=}NH + H_2 \quad (9)$$
$$RCH{=}NH + RCH_2NH_2 \longrightarrow RCH(NH_2)(NHCH_2R) \quad (10)$$
$$RCH(NH_2)(NHCH_2R) + H_2 \longrightarrow (RCH_2)_2NH + NH_3 \quad (11)$$

Reactions of the type shown in (1) and (2) go smoothly and almost quantitatively in certain cases, but this is by no means always true. It seemed desirable therefore to ascertain the optimum conditions for the reaction of representative alcohols and aliphatic amines. The data given in Table I indicate the yields which have been obtained under the specified conditions. A consid-

erable number of variations in the experimental conditions have been made and the ones specified for the various reactants gave the highest yields among those tried. It is probable that variations in the temperature and duration of reaction, ratio of catalyst to reactants, etc., would give even higher yields of the desired products.

The data in the table show very clearly that the optimum conditions vary with the alcohol and with the amine. The optimum yield varies over

[a] Equimolecular quantities (usually 0.2 mole) of amine and alcohol and 4 g. of copper chromite were used except in (c) where 3 to 4 g. of Raney nickel and (f) and (j) where 8 g. of copper chromite was the catalyst. Eighty ml. of dioxane was used as a solvent for 0.2 mole of amine except in (c) where an excess of alcohol, and (a) and (g) where diethyl ether was the reaction medium. All reactions were carried out under 125 atm. of hydrogen at the temperatures and for the duration of time indicated below: (a) and (e) twelve hours at 180°, (b) and (c) three and one-half hours at 200°, (d) and (f) three and one-half hours at 250°, (g), (h) and (j) twelve hours at 200°, (i) twelve hours at 250°.

wide limits even if comparisons are made with the same amine and different alcohols or the same alcohol with different amines. Among the four amines, the best yields were with piperidine while the poorest were with *n*-amylamine. This may be correlated with the fact that higher temperatures could be used with piperidine than with *n*-amylamine. The higher temperature which may be used with piperidine as contrasted with the primary amines is probably due to the fact that the latter may form secondary amines through reactions (9), (10) and (11). For example, yields as high as 52% of diphenethylamine were obtained at 250° over copper chromite. At 200° no appreciable amount of diphenethylamine was formed.

Mignonac was the first to prepare amines by the hydrogenation of aqueous ammoniacal or amine solutions of aldehydes and ketones.[6] Later it was shown that better yields of the amines were obtained if the ammonia or amine addition product of the aldehyde were isolated and the hydrogenation carried out in an organic solvent.[7] However, there has been described no practical method for preparing primary amines directly from aldehydes or ketones and ammonia.[8] The most satisfactory method for converting an aldehyde or ketone to a primary amine has been through the preparation of the oxime.[7,9]

Representative ketones and aldehydes have now been converted in good yields to the corresponding primary amines by dissolving the carbonyl compound in a mixture of methanol and liquid ammonia and hydrogenating over Raney nickel. The reaction mixture in most cases consisted of 0.5 mole of carbonyl compound, 0.7 mole of ammonia, 50 ml. of methanol and 3 to 4 g. of Raney nickel under 150 atm. of hydrogen. Preparations were also made on a slightly smaller scale and on quantities six times as large as those specified above. Except for benzaldehyde (125°) and furfural (125 to 140°) the temperature for reaction was 150°. The period of reaction was usually about one hour, though furfural was complete after ten minutes, while benzophenone was heated for three and one-half hours before the absorption of hydrogen ceased.

Among the compounds which have given good results are heptaldehyde, benzaldehyde, acetophenone, pinacolone and several dialkyl ketones. The yields of various amines were as follows: 2-methyl-4-aminopentane, 65%; α-phenethylamine, 64%; benzhydrylamine, 19%; 2,2-dimethyl-3-aminobutane, 51%; 5-aminononane, 72%; 2,4-dimethyl-3-aminopentane, 48%; benzylamine, 48%; *n*-heptylamine, 59%; and furfurylamine, 60%. Acetonylacetone under the same conditions gave 2,5-dimethylpyrrolidine, 28%, and 2,5-dimethylpyrrole, 59%, while acetylacetone underwent aminolysis to give acetamide in quantitative yield.

Secondary amines are formed in very consider-

able yields through the hydrogenation of cyanides. Seldom is the ratio of primary to secondary amine greater than 3 to 1 and in some instances it is not more than 2 to 1. The formation of the secondary amine probably results from the following series of reactions as originally suggested by von Braun[2]

$$RCN + H_2 \longrightarrow RCH{=}NH \quad (12)$$

$$RCH{=}NH + H_2 \longrightarrow RCH_2NH_2 \quad (13)$$

$$RCH{=}NH + RCH_2NH_2 \longrightarrow RCH\begin{matrix}NH_2\\NHCH_2R\end{matrix} \quad (14)$$

$$RCH\begin{matrix}NH_2\\NHCH_2R\end{matrix} + H_2 \longrightarrow (RCH_2)_2NH + NH_3 \quad (15)$$

It seemed possible therefore to minimize the formation of secondary amines by carrying out the hydrogenation in the presence of ammonia. The imine formed according to reaction (12) would then have less opportunity to undergo reaction (13) because ammonia would also add to the imine

$$RCH{=}NH + NH_3 \longrightarrow RCH\begin{matrix}NH_2\\NH_2\end{matrix} \quad (16)$$

The hydrogenolysis (17) of the product of reaction (16) would give a primary amine and not a secondary amine as would be produced by reaction (15) from the addition product of reaction (14).[10]

$$RCH\begin{matrix}NH_2\\NH_2\end{matrix} + H_2 \longrightarrow RCH_2NH_2 + NH_3 \quad (17)$$

The results of hydrogenating *n*-butyl cyanide and *n*-hexyl cyanide in the presence of ammonia at 125° over Raney nickel supported this hypothesis. The yields of secondary amine were less than 5% and the yields of the primary amines, $C_5H_{11}NH_2$ and $C_7H_{15}NH_2$, were from 90 to 95%. In these experiments from 0.4 to 0.7 mole of the cyanide was hydrogenated mixed with from 0.9 to 1.6 mole of ammonia.

The reactions were carried out in steel reaction vessels using standard equipment, procedures and catalysts.[11] The products were usually separated by fractionation through a modified Widmer column having a spiral 18 cm. in length with one turn of the helix per cm.[9] The technique for

(10) There is no evidence as to whether the reactions shown in (5), (11), (15) and (17) proceed through hydrogenolysis as indicated or through a loss of ammonia and the hydrogenation of the resulting imine.

(11) Adkins, "Reactions of Hydrogen, etc.," University of Wisconsin Press, Madison, Wisconsin, 1937.

using liquid ammonia has been described in connection with the preparation of diacetoneamine.[12]

Alcohols, amines, ketones, aldehydes and cyanides were freed of any halogen-containing impurity by means of Raney nickel before they were submitted to reaction. In other respects these compounds were prepared and purified by the usual procedures.

Amines distilling over with solvents were recovered as the hydrochlorides and the amines regenerated with alkali and purified by fractional distillation. Amines were characterized by analysis and by the formation of solid derivatives. Neutral equivalents were determined upon all the amines reported.

Analytical data and physical properties of several amines and their derivatives not previously reported are given in Table II. References for certain other amines and their derivatives are given herewith: N-ethylpiperidine,[13] N-*n*-propylpiperidine,[13] N-*i*-propylpiperidine,[13] N-*n*-butylpiperidine,[14] N-*n*-hexylpiperidine,[15] N-cyclohexylpiperidine,[2] N-*n*-dodecylpiperidine,[16] N-cyclohexylphenethylamine,[17] N-*n*-dodecylphenethylamine,[18] α-phenethylamine,[19] benzhydrylamine,[20] 5-aminononane,[21] benzylamine,[22] *n*-heptylamine,[23] furfurylamine,[8] 2,5-di-Me-pyrrole, N-*n*-butyl-*n*-amylamine,[24] 2,2-di-Me-3-aminopentane,[25] 2,4-di-Me-3-aminopentane.[26]

Summary

Favorable conditions for the reaction of eight representative alcohols with four different amines to give secondary and tertiary amines have been ascertained.

It has been found that representative aldehydes, dialkyl ketones and alkyl aryl ketones may be directly converted in good yields to primary amines by hydrogenating them over Raney nickel in an ammonia–methanol mixture.

The formation of secondary amines in the hydrogenation of cyanides over Raney nickel may be almost entirely prevented by carrying out the hydrogenation in the presence of sufficient ammonia.

The Conjugation of Amino Acids with Isocyanates of the Anthracene and 1,2-Benzanthracene Series[1]

BY LOUIS F. FIESER AND HUGH J. CREECH[2]

This communication describes results obtained in an extension of the program of research initiated by Franks and one of us[3,4,5] on the problem of conjugating carcinogenic hydrocarbons with proteins and investigating their possible immunizing action against hydrocarbon carcinogenesis. In the previous work the meso isocyanate derivatives of anthracene and 1,2,5,6-dibenzanthracene were prepared, characterized by reaction with simple amines and alcohols, and linked to various proteins by interaction in aqueous dioxane solution. The conjugated proteins were found to possess definite antigenic properties, varying with the nature of the prosthetic group, and experiments with preparations of 1,2,5,6-dibenzanthryl-9-carbamido-casein afforded some indications of an immunization against the action of dibenzanthracene. The material was also found to be mildly carcinogenic, and this property was discovered also in the conjugate from dibenzanthryl isocyanate and glycine.

As one step in the extension of this work we have prepared and characterized the isocyanates resulting from the interaction of phosgene with

(1) The investigations in this series were undertaken in coöperation with Dr. W. R. Franks of the Banting Institute and have been supported by a grant from the International Cancer Research Foundation.

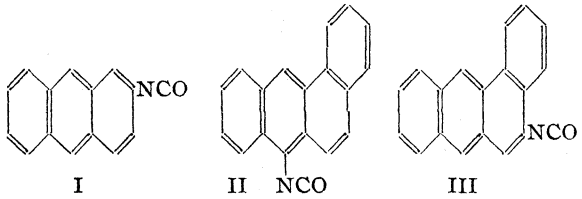
β-anthramine, 10-amino-1,2-benzanthracene[6] and 3-amino-1,2-benzanthracene.[7] These starting materials were selected largely because of their availability. While it is desirable eventually to produce protein derivatives having affixed residues to which can be ascribed both carcinogenic and non-carcinogenic characteristics, the information at hand provides little basis for foretelling the biological properties of simple functional derivatives of even the much studied 1,2-benzanthracene. Since the potently carcinogenic 10-methyl-1,2-benzanthracene contrasts sharply with the inactive 3-isomer while the 10- and 3-methoxy compounds are both weakly carcinogenic[8] the relationship between corresponding isomeric carbamido derivatives is entirely problematical and seemed worthy of investigation.

In order to provide samples for biological assay, and as a prelude to preparation of the protein derivatives, the isocyanates I–III were converted into



I II III

the methyl and ethyl carbamates (ArNHCOOR), the substituted ureas ($ArNHCONH_2$), disubstituted ureas (ArNHCONHAr), and carbamido ethanol derivatives ($ArNHCONHCH_2CH_2OH$). The 10-substituted 1,2-benzanthracene derivatives contrasted sharply with the corresponding compounds in the other two series in tending to separate in a gelatinous condition. Crystalline samples were obtained only after tedious manipulation, whereas the derivatives from I and III and also from 1,2,5,6-dibenzanthryl-9-isocyanate crystallized readily. It may be noted that Badger and Cook[9] encountered similar difficulties with other 10-substituted 1,2-benzanthracenes.

The preparation of carbamido acids by linking the isocyanates to amino acids is of interest as a possible route to water-soluble carcinogens[3,10] and because of Boyland and Levi's[11] observation that certain polynuclear aromatic hydrocarbons fed to animals are excreted in part in conjugation with amino acids. Furthermore, the experiments of White and White[12] suggest a possible interaction of amino acids with carcinogenic hydrocarbons in the organism, and the striking discovery of Kögl and Erxleben[13] of the presence of amino acids of "unnatural" configuration in the hydrolyzates from tumor tissue gives impetus to the extensive study of the rôle of amino acids in respect to malignant growth. The reaction of the isocyanates I–III with glycine and with ε-aminocaproic acid was studied in aqueous dioxane solution in order to gain further experience with a procedure which could be employed for conjugating the compounds with proteins.[3,5] The condensations proceeded satisfactorily under very mild conditions, and pure reaction products were obtained in a crystalline condition in the experiments with β-anthryl- and 1,2-benzanthryl-3-isocyanate and also from the reaction of 1,2,5,6-dibenzanthryl-9-isocyanate with each of the above amino acids; the dibenzanthryl carbamido acetic acid previously assayed[3] had not been isolated in a pure state. A tendency to form gels was again encountered in the 10-substituted 1,2-benzanthracene series and the carbamido acetic and caproic acids were not obtained crystalline. Suitable processes of precipitation gave amorphous preparations of satisfactory analysis, and the ethyl ester of the former compound was isolated in a crystalline form. The glycine conjugates are sensitive substances and decompose below the melting point or when heated in organic solvents at temperatures above about 50–60°. The caproic acid derivatives are more easily purified and melt sharply without decomposition.

The present experiments provide some assurance that the method of conjugation in aqueous dioxane solution is suitable for application to proteins, and results to be reported later have borne out this expectation. In a trial of pyridine as the solvent it was found that 1,2-benzanthryl-10-isocyanate in the absence of any other reagent is polymerized rapidly by pyridine at room temperature to an amorphous, high-melting product (dimer?[14]).

Experimental Part[15]

β-Anthryl Isocyanate.—β-Aminoanthracene was prepared in 40% yield from commercial β-aminoanthra-

quinone by the method of von Braun and Bayer.[16] After several crystallizations from acetone, methanol, and benzene–ligroin, the amine was obtained as bright greenish-yellow plates, m. p. 243.5–244.5° (in vacuum: 245–245.5°).[17]

Gradual addition of excess phosgene (20 g.) in toluene to a solution of the purified amine (3 g.) in benzene produced a flocculent white precipitate of the amine hydrochloride which disappeared after refluxing for about one-half hour. The solution was evaporated at diminished pressure (100 mm.) in an atmosphere of nitrogen until it became opalescent, and it was then filtered and transferred to a vacuum desiccator. The isocyanate crystallized on further removal of the solvent and recrystallization from benzene and from carbon tetrachloride gave 2.4 g. (70%) of small, faintly yellow needles, m. p. 207.5–208°.

Anal. Calcd. for $C_{15}H_9ON$: N, 6.39; C, 82.17; H, 4.14. Found: N, 6.66 (Kjeldahl), 6.64 (Dumas); C, 81.98; H, 4.10.

In the preparation of the derivatives listed below the crude reaction products were obtained in very nearly quantitative yield.

Methyl β-anthrylcarbamate was prepared by refluxing a solution of the isocyanate (100 mg.) in methanol (10 cc.) for one-half hour. Crystallized from methanol–ligroin the substance formed lustrous, weakly yellow plates, m. p. 231–231.5°.

Anal. Calcd. for $C_{16}H_{13}O_2N$: N, 5.57. Found: N, 5.59.

The **ethyl carbamate,** obtained by refluxing the isocyanate (200 mg.) in chloroform (20 cc.) with absolute ethanol (10 cc.) for fifteen minutes, formed glistening light yellow plates from ethanol–ligroin, m. p. 216–216.5°.

Anal. Calcd. for $C_{17}H_{15}O_2N$: N, 5.28. Found: N, 5.31.

β-Anthrylcarbamidoethanol.—On adding a solution of 250 mg. of the isocyanate in 20 cc. of chloroform to 0.25 cc. of β-aminoethanol in 10 cc. of chloroform an amorphous greenish precipitate formed at once; after short warming to 40° it was cooled and the product collected and washed with 35 cc. of warm chloroform. Crystallization from 75 cc. of ethanol containing 3 cc. of dioxane gave slender, bright yellow needles. In an evacuated capillary the substance darkened at 310° and melted at about 350°.

Anal. Calcd. for $C_{17}H_{15}O_2N_2$: N, 9.99; C, 72.84; H, 5.75. Found: N, 9.82; C, 73.10; H, 5.76.

β-Anthryl Urea.—To 150 mg. of the isocyanate in 15 cc. of dioxane there was added 5 cc. of dioxane containing several drops of concentrated ammonium hydroxide. The greenish-yellow material which precipitated was crystallized from dioxane, forming small yellow plates (unmelted at 360°).

Anal. Calcd. for $C_{15}H_{12}ON_2$: N, 11.80. Found: N, 11.74.

N,N'-Di-β-anthryl Urea.—A mixture of benzene solutions of the isocyanate and β-anthramine was refluxed for twenty minutes and cooled. The yellowish-brown precipitate was washed, dried and purified by solution in dioxane and precipitation with benzene or by evaporation. Crystals were not obtained; the amorphous material was unmelted at 340° (Calcd.: N, 6.79; found: 6.02, 6.06).

β-Anthrylcarbamidoacetic Acid.—A solution of 75 mg. of glycine in 3 cc. of water was brought to *p*H 8.5 (colorimetric) by suitable addition of sodium hydroxide and added with stirring to 200 mg. of β-anthryl isocyanate in 25 cc. of dioxane. A greenish precipitate appeared at once, and after ten minutes a large volume of water was added, the mixture was warmed to 40°, alkali was added to bring the *p*H to 8.5, and the solution was filtered. Dilute hydrochloric acid was added to the opalescent filtrate to bring the *p*H to 3.0, and the greenish-white, flocculent precipitate, separated by centrifugation, was dissolved either in 500 cc. of water adjusted to *p*H 8.5 or in 1% sodium carbonate solution. Filtration through a No. 50 Whatman paper removed a trace of insoluble material. The conjugate was reprecipitated and washed with copious amounts of slightly acidified water. The process of solution and precipitation was repeated twice and the product dried in a vacuum desiccator. Further purification of the amorphous material was accomplished using water–dioxane–ethanol (5:1:2) and cooling very slowly. Eventually the substance was obtained as slender yellow needles. In an evacuated capillary the substance darkened at 250° and melted at about 310° with decomposition.

Anal. Calcd. for $C_{17}H_{14}O_3N_2$: N, 9.51; C, 69.38; H, 4.80. Found: N, 9.70; C, 68.99; H, 4.74.

ε-(β-Anthrylcarbamido)-caproic acid was prepared by conjugation of the isocyanate with ε-aminocaproic acid[18] by the above procedure and the material purified by repeated precipitation was crystallized from water–dioxane–alcohol (2:1:3) and obtained as short, dull yellow needles which darkened slightly at 260° and melted at 285–286° (vacuum).

Anal. Calcd. for $C_{21}H_{22}O_3N_2$: N, 7.98. Found: N, 8.07.

Nitration of 1,2-Benzanthracene.—A nearly colorless commercial sample of the hydrocarbon, m. p. 161–162.5° (Fraenkel and Landau), and a yellowish sample, m. p. 159–161.5° (Dominion Tar and Chemical Co.), were found unsatisfactory for the reaction, apparently because of the presence of significant quantities of chrysene. A supply of pure 1,2-benzanthracene was consequently synthesized according to Bachmann,[19,20] the hydrolysis of the intermediate naphthyl tolyl ketimine being conducted by the procedure of Fieser and Seligman.[21] Purification of the crude yellow pyrolysis product (m. p. 158.5–160°) by filtration of a benzene solution through an alumina tower removed some of the color and raised the m. p. (160–161°), but subsequent treatment with maleic anhydride[19] gave blue-fluorescent colorless plates, m. p. 160.5–161° in 30% over-all yield.

On nitrating 50 g. of the pure hydrocarbon in six lots

by the procedure of the literature[6,22] with some trial variations the yields were from 25 to 45% and the combined yield of pure 10-nitro-1,2-benzanthracene, m. p. 164–164.5°, was 20.2 g. (33%). No pure products were isolated from the mother liquors.

10-Amino-1,2-benzanthracene.—Since hydrogenation[6] of the nitro compound did not appear practical for preparative purposes, other methods were tried. Using phenylhydrazine for the reduction, the yield was only 20%, but satisfactory results were obtained with stannous chloride. In a typical run a solution of 6 g. of the pure nitro compound in 250 cc. of hot glacial acetic acid was treated with 50 g. of stannous chloride in 60 cc. of hot concentrated hydrochloric acid. After refluxing for one-half hour with mechanical stirring, 50 cc. of glacial acetic acid was added to bring about complete solution. On cooling the yellow tin double salt crystallized and was washed with acetic acid, dilute hydrochloric acid, alcohol and ether. The dried solid (7.8 g.) was decomposed by stirring with 175 cc. of 1 *N* ammonium hydroxide at 5° for one-half hour and at room temperature for one and one-half hours. The yellow solid was dried and crystallized twice from ether–petroleum ether, giving 4.1 g. (77%) of yellow needles of the amine, m. p. 175.5–176° (176–176.5° in an evacuated tube).

1,2-Benzanthryl-10-isocyanate.—On proceeding as above, 7.5 g. of the amine gave 6.5 g. (78%) of the isocyanate as slightly yellow diamond-shaped plates, m. p. 144–144.5°, after crystallization from benzene–toluene and benzene–ligroin.

Anal. Calcd. for $C_{19}H_{11}ON$: N, 5.20; C, 84.74; H, 4.12. Found: N, 5.25; C, 84.68; H, 4.10.

The purification of the carbamates described below presented considerable difficulty because of their marked tendency to separate in a gelatinous condition. A similar property was noted by Morgan and Pettet[23] in methyl and ethyl *p*-xenylcarbamates. The substances are very soluble in methanol, chloroform, ether, benzene and carbon tetrachloride and on evaporation nearly to dryness separate as amorphous powders; the addition of petroleum ether, in which the solublity is slight, invariably led to separation as a gel.

Methyl 1,2-Benzanthryl-10-carbamate.—The isocyanate was refluxed with methanol for fifteen minutes, the solution was evaporated to dryness, and the yellowish-white residue washed with methanol (m. p. 224–225°). On evaporation of a solution of the substance in ether the solid separating on the walls melted at 223–224.5° and that deposited on the bottom melted at 226–227°. Another preparation, after repeated precipitation as a gel from dioxane, methanol, or benzene by suitable addition of petroleum ether or ligroin, dried to a white powder, m. p. 226–227°. This eventually was crystallized from methanol as tiny white needles, m. p. 227–227.5°.

Anal. Calcd. for $C_{20}H_{15}O_2N$: N, 4.65. Found: N, 4.78.

The **ethyl carbamate** after similar tedious manipulation finally crystallized from absolute ethanol as rosets of small, colorless needles, m. p. 204–204.5°.

Anal. Calcd. for $C_{21}H_{17}O_2N$: N, 4.44. Found: N, 4.63.

1,2-Benzanthryl-10-carbamidoethanol also initially formed a gel but eventually was obtained from absolute ethanol–dioxane as slender white needles, m. p. 247–248° (in vacuum), with slight darkening at 240°.

Anal. Calcd. for $C_{21}H_{18}O_2N_2$: N, 8.47. Found: N, 8.37.

1,2-Benzanthryl-10-urea.—Slow cooling of a solution of the dried gelatinous reaction product in dioxane–ethyl acetate gave fine, colorless needles, m. p. (in vacuum) 334–336°, dec.

Anal. Calcd. for $C_{19}H_{14}ON_2$: N, 9.78. Found: N, 9.42.

N,N′-Di-(1,2-benzanthryl-10)-urea.—The dried powder from the flocculent brown precipitate resulting from the interaction of the 10-isocyanate and the 10-amine was repeatedly deposited from dioxane in an amorphous condition but failed to crystallize (unmelted at 330°).

Anal. Calcd. for $C_{37}H_{24}ON_2$: N, 5.47. Found: N, 5.38.

Polymerization of 1,2-Benzanthryl-10-isocyanate.—Since difficulties were encountered in attempts to prepare derivatives of aromatic isocyanates in pyridine solution, trial was made of the action of this solvent on pure 1,2-benzanthryl-10-isocyanate. The substance (100 mg.) dissolved at once at room temperature in purified anhydrous pyridine (5 cc.) to give a yellow solution, and in a few minutes the polymer began to separate. Collected and washed with ether, this was obtained as a slightly yellow powder, m. p. 305–307° (vacuum), very sparingly soluble in dioxane or benzene and only moderately soluble in pyridine. The absence of unpolymerized material was shown by the observation that boiling alcohol dissolved only a trace of material and left a residue of the same melting point.

Anal. Calcd. for $(C_{19}H_{11}ON)_x$: N, 5.20. Found: N, 5.57.

1,2-Benzanthryl-10-carbamidoacetic Acid.—The conjugate prepared from 0.5 g. of the isocyanate and 0.2 g. of glycine by the above procedure separated on acidification of the aqueous solution as a gel, which on drying afforded 0.6 g. of a light brown powder (calcd.: N, 8.13; found: 8.78). After two more precipitations, the dried material (N, 7.49) was washed with cold ether to an almost colorless powder (N, 8.16). The substance decomposed when heated in organic solvents. The addition of petroleum ether to solutions of the conjugate in cold acetone–dioxane or aqueous dioxane gave light brown amorphous precipitates which darkened at 230–240° and melted with decomposition in the region 270–275° (found for different samples: N, 7.68, 7.77). The substance was not obtained crystalline.

The **ethyl ester** was prepared by adding 0.13 g. of glycine ethyl ester in 5 cc. of benzene to 325 mg. of the isocyanate in 15 cc. of benzene at 35°. A gelatinous precipitate separated at once and after shaking for fifteen minutes this was collected, dried and washed with benzene. The yellowish solid (0.4 g.) was dissolved in pyridine at 50°; on cooling a granular product separated and was washed with ether (0.24 g., colorless; attempted concentration

(22) Barnett and Mathews, *Chem. News*, **130**, 339 (1925).

of the filtrate led to decomposition). On slow cooling of a solution of this substance in ethanol–dioxane colorless microcrystals were obtained, m. p. 245–245.5°. Hydrolysis to the free acid was tried without success (decomposition).

Anal. Calcd. for $C_{23}H_{20}O_3N_2$: N, 7.52; C, 74.17; H, 5.41. Found: N, 7.67; C, 74.44; H, 5.34.

ε-(1,2-Benzanthryl-10-carbamido)-caproic acid was obtained initially as a flocculent precipitate. It formed a gel on the first two treatments with dioxane–ethanol–water and then was obtained as an amorphous precipitate giving when dried an almost colorless powder, m. p. 265–267°, with slight darkening at 200°.

Anal. Calcd. for $C_{25}H_{24}O_3N_2$: N, 7.00. Found: N, 7.06.

1,2,5,6-Dibenzanthryl-9-urea was prepared as above and obtained from dioxane in a colorless microcrystalline condition, m. p. 360–363°, dec. (vacuum).

Anal. Calcd. for $C_{23}H_{16}ON_2$: N, 8.33. Found: N, 8.19.

1,2,5,6-Dibenzanthryl-9-carbamidoacetic Acid.—This previously reported[3] substance has now been crystallized from dioxane–ethanol–water and obtained as slightly yellow needles darkening at 270° and melting at about 300° with decomposition.

Anal. Calcd. for $C_{25}H_{18}O_3N_2$: N, 7.10. Found: N, 6.64.

ε-(1,2,5,6-Dibenzanthryl-9-carbamido)-caproic acid crystallized from dioxane–ethanol–water as colorless plates which turned yellow at about 250°; m. p. about 305°.

Anal. Calcd. for $C_{29}H_{26}O_3N_2$: N, 6.21. Found: N, 6.07.

Attempted Formation of Ureas.—On refluxing a benzene solution of the 9-isocyanate and the 9-amine of 1,2,5,6-dibenzanthracene for two hours there was no evidence of reaction and both starting materials were isolated from the solution. The isocyanate reacted readily with aniline, however, giving an amorphous powder which was not obtained in a satisfactory condition. It was further found that the reaction proceeds readily with the corresponding *meso*-anthracene derivatives, giving **N,N'-di-(anthryl-9)-urea** (m. p. above 360°. Calcd.: N, 6.79. Found: N, 6.51). It therefore appears that the failure of the reaction between the two *meso*-dibenzanthracene derivatives is attributable to steric hindrance.[6,24]

1,2-Benzanthryl-3-isocyanate.—A supply of the 3-amine kindly synthesized by F. C. Novello by the previously described method[7] was recrystallized from ethanol and from benzene–ligroin, giving yellow needles, m. p. 211–212° (213.5–214° in an evacuated capillary). The isocyanate was prepared as usual (73% yield, pure) and obtained from benzene–ligroin as light yellow needles, m. p. 163–163.5°.

Anal. Calcd. for $C_{19}H_{11}ON$: N, 5.20; C, 84.74; H, 4.12. Found: N, 4.99; C, 84.83; H, 4.06.

Treated with pyridine at 25° the substance gave an amorphous, high melting polymer.

Methyl 1,2-benzanthryl-3-carbamate crystallized readily from methanol as slender white needles, m. p. 203.5–204°.

Anal. Calcd. for $C_{20}H_{15}O_2N$: N, 4.65; C, 79.71; H, 5.02. Found: N, 4.84; C, 79.57; H, 4.92.

The **ethyl carbamate** formed long, colorless needles from ethanol, m. p. 211.5–212° (Calcd.: N, 4.44. Found: N, 4.62).

1,2-Benzanthryl-3-carbamidoethanol at first separated from dioxane–ethanol in a flocculent condition but eventually formed colorless needles, m. p. 343–345° (vacuum).

Anal. Calcd. for $C_{21}H_{18}O_2N_2$: N, 8.47. Found: N, 8.50.

1,2-Benzanthryl-3-urea formed fine white needles, m. p. above 350°, from dioxane.

Anal. Calcd. for $C_{19}H_{14}ON_2$: N, 9.78. Found: N, 9.89.

The **N,N'-disubstituted urea** was obtained only as a light brown powder, m. p. above 350° (Calcd.: N, 5.47. Found: N, 5.31.).

1,2-Benzanthryl-3-carbamidoacetic acid separated from dioxane–ethanol–water as fragile, slightly yellow needles, m. p. about 310°, dec. (vacuum).

Anal. Calcd. for $C_{21}H_{16}O_3N_2$: N, 8.13. Found: N, 7.91.

ε-(1,2-Benzanthryl-3-carbamido)-caproic acid crystallized readily from dioxane–ethanol–water as glistening white needles, m. p. 295–297° (some darkening at 230°).

Anal. Calcd. for $C_{25}H_{24}O_3N_2$: N, 7.00; C, 74.97; H, 6.04. Found: N, 7.01; C, 74.84; H, 5.54.

Summary

β-Anthryl-, 1,2-benzanthryl-3- and 1,2-benzanthryl-10-isocyanate have been prepared and characterized by conversion to various carbamates and substituted ureas. The isocyanates were coupled with glycine and with ε-aminocaproic acid to give alkali-soluble substances some of which are being tested for carcinogenic activity. The method of conjugation in aqueous dioxane was found suitable for application to proteins.

The Synthesis of 5,6-Dimethylglucose

BY M. R. SALMON AND GARFIELD POWELL

In the synthesis of the various partially methylated sugars investigators have attempted to use a number of blocking agents in what may be termed an indirect synthesis from the acetone sugars or related cyclic acetals, that is to say, reagents which will block certain hydroxyl groups while the acetone, etc., residues are removed and replaced by methyl or other substituents. The esters of the carboxylic acids are not satisfactory blocking agents for this type of synthesis because of their tendency to migrate and to be removed under the basic conditions of methylation, and the toluenesulfonates sometimes have the undesirable property of causing Walden inversions upon removal. While the acetates, benzoates and tosylates occasionally have been used for syntheses of this type, it seems desirable to have alternative procedures available for more general use.

Most promising of the blocking agents which have been proposed appear to be the nitro groups used by a number of English investigators,[1] and the benzyl groups of Freudenberg[2] and Zemplén[3] and their co-workers, both of which lack the ability to migrate and may be removed readily by reduction. Since it is desirable to have several blocking agents with different properties available for use as occasion demands, we are presenting in this paper a study of the use of the benzoxymethyl group in the synthesis of the previously unknown 5,6-dimethylglucose. This group appears to be somewhat more stable to alkali than the nitro group and to be introduced into the sugar molecule under somewhat less drastic conditions than the benzyl group, but like these groups is readily removable by reduction. This reduction could be performed either with sodium and alcohol or catalytically. By analogy with the results of other investigations on the reductive scission of compounds containing the O-benzyl group we would expect the primary reduction products of the benzoxymethyl group to be toluene and formaldehyde, but our results indicate the production of methyl alcohol rather than formaldehyde by reduction with sodium and alcohol.

Chloromethyl benzyl ether reacts with diacetoneglucose either with the method used by Freudenberg or that used by Zemplén for the introduction of benzyl groups, but in boiling ether instead of at the higher temperatures necessary with benzyl chloride. The resulting 3-benzoxymethyldiacetoneglucose (I) was hydrolyzed under the usual conditions to 3-benzoxymethylmonoacetoneglucose (II) which was methylated to 5,6-dimethyl - 3 - benzoxymethyl - monoacetoneglucose (III). Reduction of this compound with sodium and alcohol gave 5,6-dimethyl-monoacetoneglucose (IV) and acid hydrolysis gave 5,6-dimethylglucose (V). To verify the structures we have assigned to these compounds we have degraded 5,6-dimethylglucose to dimethylglyceric acid by a method similar to that used by Jackson and Hudson[4] in the degradation of several glycosides. The dimethylglyceric acid was identified by a comparison of its derivatives with those of a sample of dimethylglyceric acid prepared by the methylation of glyceric acid.

It is interesting to compare 5,6-dimethylglucose with the 5-methylglucose described by von Vargha,[5] since neither of these compounds can form the normal pyranose ring. Both sugars have a very low rotation, they rapidly reduce cold Fehling solution and cold neutral permanganate and color the Schiff aldehyde reagent; properties which have been taken by von Vargha to indicate the presence of a considerable amount of the open chain aldehyde form.

We found that phenyl isocyanate formed readily crystallizable, easily purified derivatives with two intermediates (II and IV) which failed to form crystalline acetates or tosylates. We were able to crystallize 5,6-dimethyl-monoacetoneglucose only by seeding with crystals obtained by the hydrolysis of the corresponding urethan. The preparation of polyurethans of some free sugars and glycosides with phenyl isocyanate has been described,[6] but the products were amorphous and difficult to purify.

Experimental

Chloromethyl benzyl ether was prepared by the method of Hill and Keach.[7] This method is known to give variable results[7,8] and we obtained a large percentage of failures. By the addition of an equal volume of petroleum ether to the chloromethyl benzyl ether after separation of the water layer, the danger of decomposition on distillation was diminished and a good yield was obtained in the great majority of attempts at preparation.

3-Benzoxymethyl-diacetoneglucose. Method A.—Fifteen grams of diacetoneglucose was dissolved in 40 cc. of dry ether and allowed to react with the theoretical amount of sodium. The reaction took about two days at room temperature. When the reaction was complete traces of unreacted sodium were removed with a spatula and the theoretical amount of chloromethyl benzyl ether was added slowly. Considerable heat was evolved. When the reaction slowed down the ether was refluxed for a few hours and allowed to stand overnight. The ether solution was washed with aqueous sodium carbonate and then with water, dried over potassium carbonate and after removing the solvent the residue was distilled in vacuum. After a fore-run of diacetoneglucose the main fraction distilled at 163–177° at 0.2 mm. with a bath temperature of 214–245°; yield 12 g. or 55%.

Anal. Calcd. for $C_{20}H_{28}O_7$: C, 63.2; H, 7.4. Found: C, 63.3; H, 7.3.

In other preparations of this material the product was subjected to a careful fractionation in an unsuccessful attempt to obtain a crystalline product. The course of one of these fractionations was followed by analysis and it was found that the lower boiling fractions were several per cent. too high and the higher boiling fractions about 1% too low in carbon content. Diacetoneglucose is not the principal impurity. We believe the analysis quoted is in good agreement with theory only because of the accidental compensation of incidental impurities of higher and lower carbon contents.

All distillations recorded in this paper were carried out in flasks with wide, low side arms. Bumping was prevented by packing the boiling chamber with glass wool.

3-Benzoxymethyl-diacetoneglucose prepared in this way is a yellowish, slightly viscous oil. On reduction by the method described later in the preparation of 5,6-dimethyl-monoacetoneglucose we obtained diacetoneglucose in 78% yield based on the crude product. Reduction in hydrogen with palladium black in acid solution also gave diacetoneglucose. Colorless 3-benzoxymethyl-diacetoneglucose can be obtained by refluxing with aqueous alcoholic potassium hydroxide and redistilling.

Method B.—Ten grams of 3-acetyl-diacetoneglucose[9] was dissolved in 100 cc. of ether and 21 g. of chloromethyl benzyl ether was added. Eighty-five grams of powdered potassium hydroxide was added over the course of an hour while the mixture was stirred vigorously with a mechanical stirrer. The ether was refluxed for an hour and a half after the addition of the potassium hydroxide. Water sufficient to dissolve the inorganic materials was added and the two layers separated. The water layer was washed with a little ether, the combined ether extracts washed with a little water and dried over potassium carbonate. The residue after evaporation of the ether was distilled and the fraction boiling at 150–160° at 0.14 mm. was collected. This was redistilled and 4.5 g. was collected at 157–160° at 0.15 mm., bath temperature 210–230°. Hydrolysis with aqueous alcoholic hydrochloric acid gave 70% of the theoretical amount of formaldehyde, isolated as the dimethyldihydroresorcinol condensation product.[10]

3-Benzoxymethyl-monoacetoneglucose.—Ninety-six grams of 3-benzoxymethyl-diacetoneglucose (Method A, b. p. 150–170° at 0.1 mm.) was dissolved in 300 cc. of glacial acetic acid and 30 cc. of water was added. After standing for fourteen hours at room temperature the solvent was distilled off in vacuum and the residue dissolved in an additional 300 cc. of glacial acetic acid to which was added 50 cc. of water. This was allowed to stand for nine hours at room temperature, the solvents distilled off in vacuum, the residue mixed with water and sodium carbonate added in the amount necessary to neutralize the remaining acetic acid. The two layers were separated and the water layer extracted with 90 cc. of chloroform. A small amount of the chloroform solution was dried with sodium carbonate, the chloroform distilled off and the oily residue dried at 56° in vacuum for two hours.

Anal. Calcd. for $C_{17}H_{24}O_7$: C, 60.0; H, 7.1. Found: C, 58.2; H, 6.9.

3-Benzoxymethyl-monoacetoneglucose (1.23 g.) was reduced with sodium and absolute alcohol under the conditions described later in the preparation of 5,6-dimethyl-

monoacetoneglucose. Monoacetoneglucose was isolated from the product in a yield of 68% calculated on the crude product. 3-Benzoxymethyl-monoacetoneglucose (0.9 g.) was dissolved in 2 cc. of dry benzene and 0.75 g. of phenyl isocyanate was added. The solution was warmed in a bath at 85° for three hours. A few drops of absolute alcohol were added and the solution again warmed for a few minutes. The benzene was evaporated and the residue crystallized from aqueous alcohol. The crystals so obtained were dissolved in chloroform and filtered from a small amount of diphenylurea which was obtained as a by-product. After recrystallization from aqueous alcohol or benzene the product melted at 148–148.5° (corr.); yield about 0.7 g. crude or 0.4 g. of pure product. The same 5,6-dicarbanilyl-3-benzoxymethyl-monoacetoneglucose was obtained from 3-benzoxymethyl-diacetoneglucose prepared by either method A or B. For analysis the preparation was dried at 100° in a vacuum for two hours.

Anal. Calcd. for $C_{31}H_{34}N_2O_9$: C, 64.3; H, 5.9; N, 4.84. Found: C, 64.3; H, 5.8; N, 4.95.

5,6 - Dimethyl - 3 - benzoxymethyl - monoacetoneglucose.—Eighty-six grams of 3-benzoxymethyl-monoacetoneglucose was methylated twice with 300 cc. of dimethyl sulfate and 288 g. of sodium hydroxide each time, using the general conditions described by West and Holden.[11] The product from these methylations was methylated twice with silver oxide and 170 g. of methyl iodide each time. We are unable to account for the extreme difficulty of methylating this compound. The product was distilled twice in vacuum, the second time it was collected at 155–163° at 0.12 mm. with a bath temperature of 185–200°; yield 49 g.

Anal. Calcd. for $C_{17}H_{22}O_5(OCH_3)_2$: C, 62.0; H, 7.7; OCH_3, 16.85. Found: C, 62.6; H, 7.6; OCH_3, 13.85.

5,6-Dimethyl-monoacetoneglucose.—To 42 g. of 5,6-dimethyl-3-benzoxymethyl-monoacetoneglucose was added 57 g. of sodium. The flask was heated on the steam-bath under a reflux condenser and absolute alcohol was added over a period of six hours until all the sodium had been decomposed. Several hundred cc. of water was added and the solution almost neutralized with acetic acid. Most of the alcohol was distilled off on a steam-bath and the aqueous solution was extracted six times with 100 cc. of chloroform each time. The chloroform was distilled off and the residue was dissolved in 300 cc. of 90% acetic acid and allowed to hydrolyze for eighteen hours at room temperature to remove traces of diacetoneglucose which might still be present. The solvents were removed in vacuum, the residue taken up in water, neutralized with sodium carbonate and extracted with chloroform. The product distilled at 105–110° at 0.15 mm. with a bath temperature of 145–160°; yield 20 g. or 71%. When seeded with crystalline material obtained as described below it crystallized in rods completely and immediately with a rise in temperature. After recrystallization from low boiling ligroin it melted at 56–56.5° (corr.); $[\alpha]^{30}D$ −12.8 (water, c = 4.18).

Anal. Calcd. for $C_9H_{14}O_4(OCH_3)_2$: C, 53.2; H, 8.1; OCH_3, 25.0. Found: C, 53.2; H, 8.2; OCH_3, 23.2.

Crystallization of 5,6-Dimethyl-monoacetoneglucose.—One gram of non-crystalline 5,6-dimethyl-monoacetoneglucose was dissolved in 2 cc. of dry benzene and 0.5 g. of phenyl isocyanate added. The mixture was held in a water-bath at 85° for three hours. A few drops of absolute alcohol were added and the solution warmed for a few minutes. The benzene was evaporated and the product crystallized from aqueous alcohol; yield 0.7 g. of crude material. It was purified with very little loss by digesting with a few cc. of 20–40° petroleum ether. After two treatments it melted at 88–89° (corr.) and this value was unchanged by further treatment. The compound crystallized in flat plates or prisms from petroleum ether, in buttons from a mixture of benzene and petroleum ether, and from aqueous alcohol in long needles which melted several degrees lower; $[\alpha]^{30}D$ −12.3 (95% alcohol, c = 3.25).

Anal. Calcd. for $C_{16}H_{19}NO_5(OCH_3)_2$: C, 58.9; H, 6.9; N, 3.8; OCH_3, 16.9. Found: C, 59.5; H, 7.2; N, 3.9; OCH_3, 16.2.

In one preparation in which we used a drop of pyridine as a catalyst, we obtained another derivative which melted at 241–242° after recrystallization from acetone–alcohol, and gave an analysis corresponding approximately to the N,N′-diphenylallophanate of 5,6-dimethyl-monoacetoneglucose.

Anal. Calcd. for $C_{25}H_{30}N_2O_8$: C, 61.7; H, 6.2; N, 5.75. Found: C, 61.1; H, 6.2; N, 6.24.

One hundred and thirty mg. of sodium was dissolved in 5 cc. of absolute methyl alcohol and to this was added 750 mg. of 3-carbanilyl-5,6-dimethyl-monoacetoneglucose described above. The mixture was refluxed for one hour, water added to the appearance of a slight turbidity, the mixture seeded with phenyl methyl urethan and placed in the ice box. The next day phenyl methyl urethan had crystallized out in 50% of the theoretical quantity. The alcohol was evaporated off and the residue taken up with water and placed in the ice box to remove a further small crop of phenyl methyl urethan. This was filtered off and the filtrate extracted ten times with a third of its volume of petroleum ether to remove the last traces of phenyl methyl urethan. The water layer was treated with norite, filtered, and the sugar extracted with chloroform. The chloroform was distilled off in vacuum and the last traces of water were removed by distilling with a mixture of absolute alcohol and benzene. The residue crystallized on cooling and scratching with a glass rod. These crystals were used to seed the main crop of 5,6-dimethyl-monoacetoneglucose.

5,6-Dimethylglucose.—Two grams of 5,6-dimethyl-monoacetoneglucose was dissolved in 10 cc. of *N* hydrochloric acid and held in a bath at 80° for thirty minutes. The solution was cooled and the acid neutralized with silver carbonate. The filtrate was treated with hydrogen sulfide to remove the last traces of silver, shaken with carbon, filtered and evaporated to dryness in vacuum. The sugar is a colorless or light greenish-yellow oil which so far has failed to crystallize. When treated with Fehling solution at room temperature the solution becomes cloudy almost immediately and yellow copper oxide settles in about half an hour. Neutral potassium permanganate is decolorized instantly at room temperature. The sugar reddens fuchsin–sulfurous acid but the color does not develop as rapidly nor is it as deep as is typical of true aldehydes.

(11) West and Holden, THIS JOURNAL, **56**, 930 (1934).

After drying for one week in a vacuum desiccator over phosphorus pentoxide it showed $[\alpha]^{32}D$ +4.0 ± 0.3° (water, c = 2.4). No mutarotation was observed.

5,6-Dimethylglucose retains water so tenaciously that we were unable to get a satisfactory analysis. After two weeks in a vacuum desiccator over phosphorus pentoxide, the carbon and hydrogen analysis corresponded to a little more than half a mole of water per mole of sugar. The osazone was oily. The *p*-bromophenyl osazone was treated with carbon and recrystallized in poor yield from 95% alcohol. It formed very fine yellow needles melting at 155.5–156° dec. (corr.). It was dried for one hour in vacuum at 100° for analysis.

Anal. Calcd. for $C_{18}H_{18}Br_2N_4O_2(OCH_3)_2$: C, 44.1; H, 4.5; N, 10.3. Found: C, 44.3; H, 4.8; N, 10.4.

Glyceric acid was prepared by the method of Debus.[12] We failed to resolve it with brucine by the method reported in the literature to have given resolution.[13] The *d,l* mixture was methylated with silver oxide and methyl iodide and the product distilled in a vacuum.

Anal. Calcd. for $C_3H_3O(OCH_3)_3$: OCH_3, 62.8. Found: OCH_3, 55.2.

The ester was hydrolyzed with barium hydroxide, the excess barium removed with carbon dioxide, the solution of the barium salt of dimethylglyceric acid acidified with an excess of concentrated hydrochloric acid and extracted with chloroform for four hours in a continuous extraction apparatus. The chloroform extract was covered with a layer of water, the water layer made slightly basic to litmus with sodium hydroxide and then just acid to litmus with hydrochloric acid. The solution was evaporated to dryness in a vacuum but the sodium salt of dimethylglyceric acid failed to crystallize.

Sodium dimethylglycerate was converted to the *p*-bromophenacyl ester by warming with slightly less than the theoretical quantity of *p*-bromophenacyl bromide in alcohol for three hours. The ester was recrystallized to constant melting point by crystallizing alternately from 80% alcohol and from petroleum ether containing about 20% of benzene. It melted at 66.5–67.5° (corr.). The *p*-phenylphenacyl ester, prepared in the same way, was treated with carbon and recrystallized from alcohol by the very slow addition of water at 0°, m. p. 62.5–63° (corr.). Both esters were dried for analysis at 35° in vacuum for two hours.

Anal. Calcd. for $C_{13}H_{15}BrO_5$: C, 47.1; H, 4.6. Found: C, 47.4; H, 4.6. Calcd. for $C_{17}H_{14}O_3(OCH_3)_2$: C, 69.5; H, 6.1; OCH_3, 18.9. Found: C, 69.3; H, 5.9; OCH_3, 18.9.

Degradation of 5,6-dimethylglucose was carried out in a manner similar to that used by Jackson and Hudson[4] with several glycosides. When the degradation is carried out with large amounts of materials or in concentrated solutions, there is a tendency for the reaction mixture to become warm with the separation of iodine. This happened to some extent in one run using 1.5 g. of the sugar and 7 g. of periodic acid, but it apparently did not affect the course of the reaction. After standing overnight at room temperature, the oxidation mixture was filtered from the iodine which had separated and extracted with chloroform for twelve hours in a continuous extractor. The chloroform extract was covered with a layer of water, the chloroform evaporated on the steam-bath and the water solution filtered from more iodine which had separated. Excess bromine was added and the solution allowed to stand overnight at room temperature. The water was distilled down to a volume of 10–15 cc. in vacuum, 5 g. of hydrated barium hydroxide was added, the solution protected from the air with a tube of soda lime and heated on the steam-bath for a total period of ten hours to racemize the *d*-dimethylglyceric acid to the *d,l* mixture. The solution was diluted to a volume of several hundred cc. and the excess barium was removed with carbon dioxide. The filtrate from the barium carbonate was evaporated in a vacuum, acidified with concentrated hydrochloric acid, and extracted with chloroform in a continuous extractor. The chloroform extract was covered with a layer of water, the water solution made faintly alkaline to litmus with sodium hydroxide and then just acid with hydrochloric acid. The solvents were removed in vacuum and the product converted to the *p*-bromophenacyl ester and the *p*-phenylphenacyl ester. The *p*-bromophenacyl ester melted at 65.5–66.5° (corr.) after recrystallization and the mixed melting point with the *p*-bromophenacyl ester of dimethylglyceric acid was 66–67° (corr.). The *p*-phenylphenacyl ester melted at 62.5–63° (corr.) after recrystallization and the mixed melting point with the *p*-phenylphenacyl ester of dimethylglyceric acid was also 62.5–63° (corr.).

Anal. Calcd. for $C_{13}H_{15}BrO_5$: C, 47.1; H, 4.6. Found: C, 47.2; H, 4.6. Calcd. for $C_{17}H_{14}O_3(OCH_3)_2$: C, 69.5; H, 6.1; OCH_3, 18.9. Found: C, 69.8; H, 6.3; OCH_3, 18.2.

We wish to thank Mr. Saul Gottlieb for the microanalyses reported in this paper.

Summary

5,6-Dimethylglucose has been synthesized from diacetoneglucose using the benzoxymethyl group as a substituent for blocking the third hydroxyl group.

Urethans prepared with phenyl isocyanate were found to have many desirable properties as crystalline derivatives of some of our intermediates.

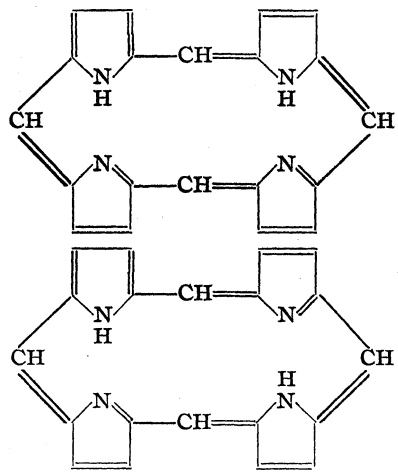
Infrared Studies of the Porphyrin Molecule

BY C. S. VESTLING AND J. R. DOWNING

The work of Hans Fischer and associates[1] has furnished strong evidence that Kuster's formulation of the porphyrin nucleus is the correct one. There are some details, however, which are lacking.

Corwin and Quattlebaum[2] exclude "resonance isomers" and discuss the possibility of *cis* or *trans* N-isomers in the porphyrin series



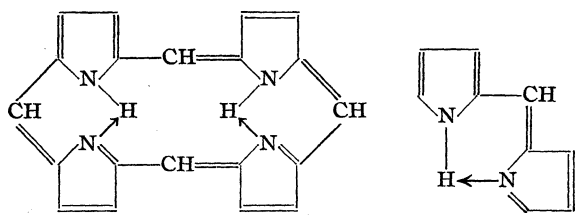
Fischer[3] has suggested the possibility of N-isomerism in dipyrrylmethenes. Conant and Bailey,[4] however, were unable to demonstrate N-isomerism in isomeric porphyrins by preparation of metallic complexes. The electrometric titrations of Conant, Chow and Dietz[5] in glacial acetic acid have been accepted as evidence for the presence of *two* basic groups in the prophyrins.

Preliminary examination of molecular models of the porphyrin nucleus indicates atomic distances which are distinctly favorable for the presence of N–H–N bonding. Hence it was decided to examine this problem using the method of infrared spectroscopy, originally proposed by Wulf.[6]

Infrared absorption spectra studies in this Laboratory[7] have proved to be of great value in structural work on organic acids, amides, and other compounds.[8,9] It is possible with this technique to identify various characteristic bonding frequencies. Their presence or absence can be demonstrated rather conclusively. Further, the method is especially applicable to small quantities of materials.

The problem was, therefore, that of noting the presence or absence of characteristic absorption peaks in a study of synthetic etioporphyrin I, iron etioporphyrin I chloride (etiohemin chloride), two dipyrrylmethenes, and the copper complex of one of them.

The data shown in the curves to follow suggest that hydrogen bonding *may* result in the structures below, which account for the observed lack of isomerism



Experimental

The prism spectrograph used in this work has been described.[10] The source of radiation was a 220-volt Nernst glower. The instrument was calibrated to 0.01 μ with reference to the 2.673 μ band of water vapor. Solutions in carbon tetrachloride were measured with carbon tetrachloride as a blank, and the molar absorption coefficient, K, was plotted against wave numbers (cm.$^{-1}$). K was calculated from the expression

$$K = \frac{1}{cd} \log \frac{I_0}{I}$$

where I is the intensity through the solution; I_0 is the intensity through an equal thickness of pure solvent; c is the molar concentration; and d the cell length. In cases where the concentration was indefinite because of low solubility, the absorption (log I_0/I) was plotted instead of the molar absorption coefficient.

The materials used in this investigation were carefully purified. Where possible, analyses of important compounds are reported.

The authors are indebted to Dr. R. E. Ellingson for a

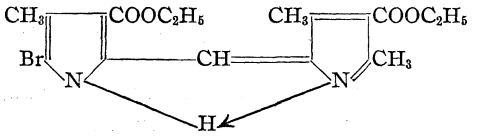
supply of 3,5,3′,5′-tetramethyl-4,4′-dicarbethoxydipyrrylmethene (Piloty's). Beautiful red needles of this compound were recrystallized from benzene–hexane; they decomposed at 190°. Hydrogenation with Adams platinum catalyst yielded white crystals of the dipyrrylmethane which melted at 228–229° (uncorr.) with some decomposition.

Anal. Calcd. for $C_{19}H_{24}O_4N_2$: N, 8.14. Found: N, 8.16.

3,4′,5 - Trimethyl - 3′,4 - dicarbethoxy - 5′ - bromodipyrrylmethane was synthesized as described below.



It must be pointed out that the exact structure of this compound is not conclusively proved, although the mode of synthesis and analysis suggest the structure given. 2,4-Dimethyl-3-carbethoxypyrrole was freshly recrystallized from cold methanol, dissolved in cold, dry ether (ice–salt temperature), and treated slowly with two moles of bromine (Baker C. P.) in cold ether. At first a flocculent light-colored precipitate formed; when one mole of bromine had been added, the system suddenly turned red. A vigorous evolution of hydrogen bromide took place throughout. The reaction product was a light red amorphous methene hydrobromide. The free base was obtained by grinding with cold concentrated ammonium hydroxide in a mortar and extracting with boiling hexane to yield after slow crystallization long (2 mm.), red needles.

Anal. Calcd. for $C_{18}H_{21}O_4N_2Br$: N, 6.85. Found: N, 6.89.

The copper complex of this material was prepared by prolonged shaking of a chloroform solution of the dipyrrylmethene hydrobromide with concentrated aqueous $CuSO_4 \cdot NH_4OH$. Macroscopic green crystals of the copper complex were obtained in good yield and used without analysis.

Etioporphyrin I (1,3,5,7-tetramethyl-2,4,6,8-tetraethylporphin) was synthesized by Walter Schlesinger according to the methods of Fischer, *et al.*[1] The absorption maxima of the purified crystalline material in chloroform are: I, 484–508 mμ; II, 524–536 mμ; III, 560–570 mμ; IV, 610–618 mμ; order of intensity: I, II, III, IV.

Anal. (recrystallized material). Calcd. for $C_{32}H_{38}N_4$: C, 60.33; H, 7.94; N, 11.71. Found: C, 80.99, 79.83; H, 8.17, 7.93; N, 11.83.

The preparation of iron etioporphyrin I chloride will be described elsewhere. Beautiful macroscopic octagonal platelets of metallic luster were obtained porphyrin-free in better than 90% yields. Their purity was indicated by a series of reductive titrations.[11]

In the curves shown, the peaks at 3.30–3.50 μ are due to aliphatic C–H vibrations, since they are identical in frequency with absorption peaks observed in numerous other compounds containing such groups.

The significant peaks from the standpoint of this research are those at 3.03 μ in Fig. 1 (I), 3.11 μ in Fig. 1 (II) and 3.01 μ in Fig. 2 (I). The complete disappearance of these peaks (Figs. 1 (III) and 2 (II)) when metallic derivatives are formed by replacement of the hydrogens of the N–H groups shows that they are absorption maxima caused by N–H vibrations. In the case of etiohemin I (Fig. 2 (II)) the complete disappearance of the N–H peak indicates conclusively that both hydrogens attached to nitrogens in the porphyrin nucleus are replaced by the iron upon substitution.

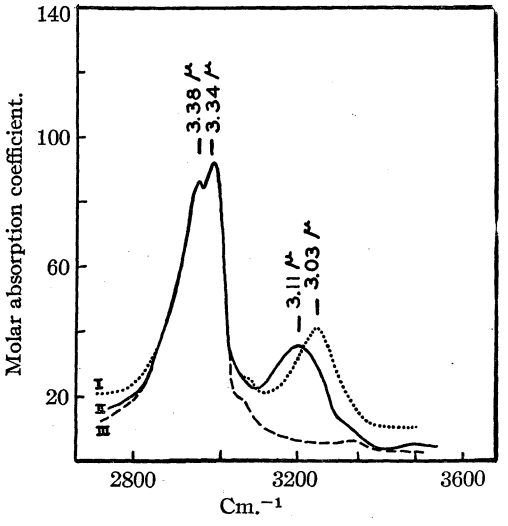


Fig. 1.—I, 3,4′,5-Trimethyl-3′,4-dicarbethoxy-5′-bromodipyrrylmethene (0.002 *M* in 10.180 cm. cell). II, 3,5,3′,5′-Tetramethyl-4,4′-dicarbethoxydipyrryl methene (0.008 *M* in 2.532 cm. cell). III, Copper complex of 3,4′,5-trimethyl-3′,4-dicarbethoxy-5′-bromodipyrrylmethene (0.002 *M* in 10.180 cm. cell.)

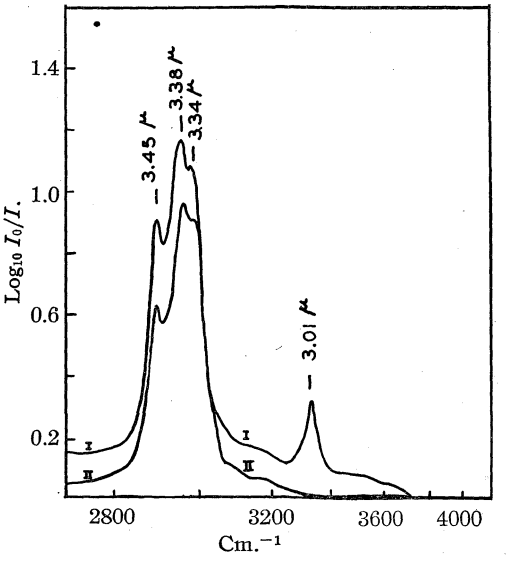

Fig. 2.—I, Etioporphyrin I (<0.001 *M* in 10.180 cm. cell). II, Etiohemin I (<0.0005 *M* in 10.180 cm. cell).

(11) C. S. Vestling, unpublished data.

The question of whether or not these peaks may be assigned to N–H–N bonding between the secondary pyrrole nitrogens and the tertiary nitrogens in these compounds arises from a consideration of the structures involved. It must be stated at once that infrared spectroscopy can only give evidence for *intra*molecular bonding when a set of absorption frequencies can be compared with those exhibited by like acceptors and donors in different molecules. On the other hand, *inter*molecular bonding between molecules of like or unlike species may be demonstrated conclusively by observing the effect of concentration changes in solution upon "bonded" or "unbonded" peaks. This criterion of course becomes inapplicable in testing for intramolecular bonding.

Since the absorption peaks in question differ markedly from the pyrrole N–H peak at 2.85 μ,[12] one is inclined to suggest that N–H–N bonding exists in these molecules. However, this is unproved as yet, since the character of the substituted pyrrole rings may have been changed in the formation of these compounds. This seems possible in light of the recent work on unbonded N–H frequencies.[13] Hence we can only state at present that the absorption peaks occur at frequencies which might be expected[12] if N–H–N bonding were existent in the porphin and dipyrrylmethene nuclei.

(12) A. M. Buswell, J. R. Downing and W. H. Rodebush, THIS JOURNAL, **61**, 3252 (1939).

The authors wish to express their gratitude to Professors A. M. Buswell and W. H. Rodebush for use of the infrared apparatus and for timely suggestions.

Summary

1. The infrared absorption of two dipyrrylmethenes, the copper complex of one of them, etioporphyrin I, and etiohemin I chloride has been measured. Replacement of acidic hydrogens with metal atoms eliminated nitrogen–hydrogen absorption in the dipyrrylmethenes and in etioporphyrin I.

2. The possibility of N–H–N bonding in these compounds is discussed.

The Hydrolysis of Bromine. The Hydration of the Halogens. The Mechanism of Certain Halogen Reactions

BY HERMAN A. LIEBHAFSKY

Corrections.—Jones and Baeckstrom[1] and Liebhafsky[2] have independently established 5.8 (10^{-9}) as the value of K_1, the equilibrium constant of the bromine hydrolysis, at 25°. The temperature coefficients of this reaction (*cf.* Ref. 2, Table II, last column) are probably more accurately known than is K_1 at any temperature except 25°. For these reasons, it is especially desirable to correct a computational error that Professors R. H. Gillette and H. A. Young of the Division of Chemistry, University of California at Davis, have kindly called to my attention. Through some mischance, 11.9(10^{-9}) at 35°, the result for Series 5, instead of 11.3(10^{-9}), the result for Series 7 (*cf.* Ref. 2, Table II), was used in deriving an incorrect equation for K_1 as a function of temperature. A table and a conclusion in Ref. 2 consequently should be changed to read as follows.

(1) Jones and Baeckstrom, THIS JOURNAL, **56**, 1517 (1934).
(2) Liebhafsky, *ibid.*, **56**, 1500 (1934).

TABLE IV (Ref. 2)

SUMMARY OF BEST VALUES FOR $K_1 \times 10^{-9}$ AT DIFFERENT TEMPERATURES

	0°	10°	25°	30°	35°
Liebhafsky	0.69	1.76	5.8	8.2	11.3
Computed	.88	1.95	(5.8)[a]	8.14	(11.3)[a]
Selected[b]	.70	1.78	5.8	8.3	11.3

[a] Value assumed in deriving the equation $\log K_1 = 0.6876 - 2660.3/T$ from which computed values were obtained. [b] Only these finally selected values for K_1 are expressed in activities. (Similar changes are to be made in Ref. 3, p. 95, Table I.)

Summary (Ref. 2)

4. The temperature variation of the K_1 for bromine is anomalous in the neighborhood of 10°; but the departure of $d(\log K_1)/d(1/T)$ from constancy is less pronounced than that observed by Jakowkin in the case of chlorine.

Also, the line "a. Measurements at 0° by Jones and Hartmann" has been omitted above the first row of data in Table III.

Hydration of the Halogens.—The temperature coefficients of halogen equilibria involving aqueous solutions are generally anomalous.[3] When the corresponding equilibrium constants are calculated in the usual manner—that is, by using (X_2), the concentration of free halogen in the aqueous solution—the log K_{X_2} *vs.* $1/T$ plot approaches a limiting straight line at higher temperatures but bends more and more sharply to the $1/T$ axis as 0° is approached. Figure 1 illustrates this behavior. While D', the distribution ratio of iodine between air and carbon tetrachloride, shows the orthodox temperature dependence, D, the distribution ratio between air and water, behaves anomalously.[4] This anomaly has found a reasonably satisfactory quantitative explanation in the assumption that the degree of hydration of the halogen is changing in the temperature region where the anomaly occurs; as 0° is approached, the equilibrium

$$\mathrm{U} + (h - u)\,\mathrm{H_2O} \rightleftarrows \mathrm{H} \qquad (1)$$
$$(\mathrm{H}) + (\mathrm{U}) = (X_2)$$

shifts so as to increase (H), the concentration of the more hydrated form. (The formula of U is $I_2 \cdot uH_2O$; that of H, $I_2 \cdot hH_2O$.) The correction of the above error tends to strengthen this explanation and has a bearing on the important problem of correlating kinetic and equilibrium data (cf. Ref. 3, p. 111). The data in Table 2d, Ref. 3, for the bromine hydrolysis should be:

d. For bromine from reaction 12 (*cf.* Table I)

T, °C.	35.0	25.0	10.0	0.0
$10^9 \times K_{Br_2}$ (measd.)	11.3	5.8	1.76	.69
d	(d = 0 assumed)		0.045	.106
(H)/(U)			.109	.276

$d = \log K_{Br_2}$ (calcd.) $- \log K_{Br_2}$ (measd.)
$\log K_{Br_2}$ (calcd.) $= 0.6876 - 2660.3/T$
$\Delta H_{H_2} = -14300$ cal.

The difference between d for 0° from kinetic (0.21) and equilibrium data (new value, 0.11) is now cut virtually in half (*cf.* Ref. 3, p. 95, last paragraph).

(3) Liebhafsky, *Chem. Rev.*, **17**, 89 (1935).

(4) The data for aqueous solutions have been reproduced from Ref. 3, where the original sources are cited. D' has been obtained for each temperature by dividing the vapor pressure of iodine in mm. of mercury [Baxter and Grose, THIS JOURNAL, **37**, 1061 (1915)] by the solubility in mole fractions of iodine for that solvent [Hildebrand and Jenks, *ibid.*, **42**, 2180 (1920)].

The calculated values[3] of the heats of hydration (Equilibrium 1) now are:

Type of measurement	Chlorine	Bromine	Iodine
Equilibrium (distribution between air and H_2O)	− 9,700 cal.	−13,100 cal.	−11,800 cal.
Equilibrium (hydrolysis of the halogen)	− 9,900 cal.	−14,300 cal.	
Equilibrium (distribution between CCl_4 and H_2O)	−10,700 cal.		
Kinetic (see text below)		−25,000 cal.	−22,800 cal.

The new value for bromine is in good agreement with the other value derived from equilibrium data.

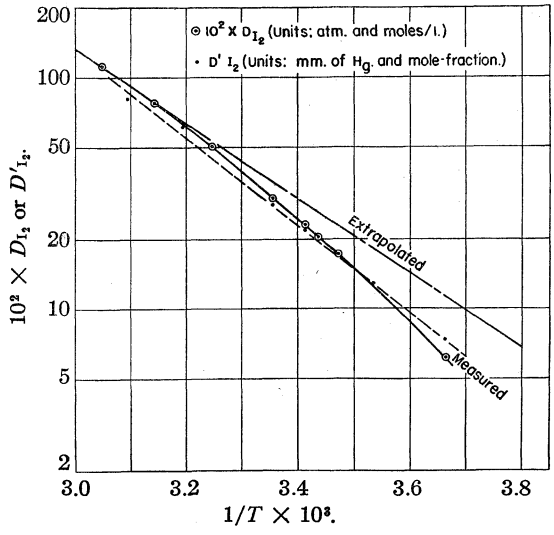

Fig. 1.—Distribution ratios for iodine between air and water (D, anomalous temperature coefficient), and between air and carbon tetrachloride (D', normal temperature coefficient). The plot is semi-logarithmic.

The specific rates at which hydrogen peroxide is oxidized by each of the three halogens, X_2, are the kinetic data from which heats of hydration were deduced. For bromine and iodine, these large (and, perhaps, unreasonably large) heats are obtained because the downward curvatures in the $1/T$ plots are more pronounced for the kinetic than for the equilibrium measurements. These unexplained minor inconsistencies should not be permitted to obscure the more important fact that for bromine and iodine both types of measurements reveal the existence of similar temperature coefficient anomalies. This fact indicates that the assumed mechanisms, which are of the type

Rapid equilibria

$$\mathrm{U} + \mathrm{H_2O} \rightleftarrows \mathrm{HXO} + \mathrm{H^+} + \mathrm{X^-} + u\mathrm{H_2O} \qquad (2a)$$
$$\mathrm{H} \rightleftarrows \mathrm{HXO} + \mathrm{H^+} + \mathrm{X^-} + (h - 1)\mathrm{H_2O} \qquad (2b)$$

Rate-determining

$$\text{step } \mathrm{H_2O_2} + \mathrm{HXO} \longrightarrow \mathrm{H_2O} + \mathrm{O_2} + \mathrm{H^+} + \mathrm{X^-} \qquad (3)$$

are in the main correct, for mechanisms of this

type will reflect a change in the ratio (H)/(U) because such a change necessarily causes a change in the ratio (HXO)/(X_2).

The reaction between chlorine and hydrogen peroxide,[5] however, does not appear to proceed mainly by such a mechanism; for the kinetic data give a linear log k *vs.* $1/T$ plot from 0 to 25°. (The temperature coefficient of the chlorine hydrolysis equilibrium is nearly twice as great at 0° as at the higher temperature.[6]) This conclusion is strengthened greatly by the experimental fact that hypochlorous acid when mixed directly with hydrogen peroxide reacted at approximately one-millionth the rate to be expected from kinetic measurements on the chlorine–hydrogen peroxide reaction.[7] The difficulty has been thoroughly discussed by Makower, who presented this conclusion as a third alternative explanation; the evidence from other reactions[3] seems convincing enough to warrant rejection of the other two. To summarize: The rate of the chlorine–hydrogen peroxide reaction, unlike the rates of the corresponding bromine and iodine reactions, is unaffected by the shift from U to H which occurs when the temperature of an aqueous X_2 solution is lowered. The mechanism of this reaction must therefore differ from the mechanisms of the other two.

The Reaction between Arsenious Acid and Iodine.—Roebuck's classical investigation[8a,b] of the reaction

$$H_3AsO_3 + I_3^- + H_2O = H_3AsO_4 + 2H^+ + 3I^- \quad (4)$$

was the first complete experimental demonstration of the relation obtaining between chemical kinetics and chemical equilibrium. The mechanism for the forward reaction

$$\text{Rapid equilibrium:} \quad I_3^- \rightleftarrows I_2 + I^- \quad (5)$$

$$\text{Rapid equilibrium:} \quad I_2 + H_2O \rightleftarrows HIO + H^+ + I^- \quad (6)$$

$$\text{Rate-determining step:} \quad HIO + H_3AsO_3 \longrightarrow H_3AsO_4 + H^+ + I^- \quad (7)$$

does not appear to have been questioned seriously although the work of Makower and Liebhafsky[9] left little doubt that further verification was desirable. Since hypoiodous acid is so unstable that it can scarcely be treated directly with arsenious acid in the absence of iodine, this verification was sought in a study of the temperature coefficient of the forward reaction.

The following measurements were made in 1932 in the Chemical Laboratory of the University of California at Berkeley. Since the rate law of the forward reaction has been established, it sufficed to perform the experiments under conditions such that no concentration except that of total iodine changed greatly during the course of an experiment. Sodium iodide, sodium meta-arsenite and perchloric acid solutions were mixed, diluted and placed in a thermostat; the reaction was begun by adding sodium triiodide solution that was also at thermostat temperature. The rate was measured by rapidly titrating samples of the reaction mixture withdrawn from time to time, with 0.02 N sodium thiosulfate. The detailed data for Experiment 5 are given in Fig. 2, where the thiosulfate titer is plotted on semi-logarithmic paper against the time. The initial

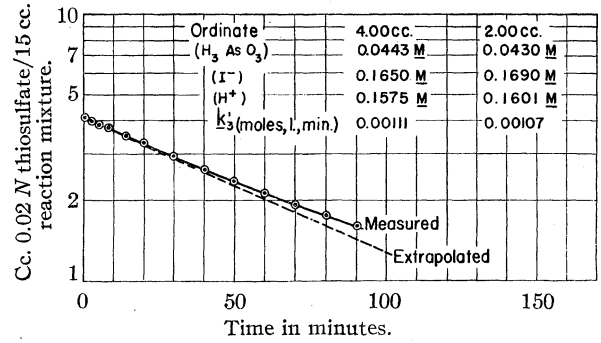

Fig. 2.—Detailed results for expt. 5 on the rate of reaction 4. The plot is semi-logarithmic.

concentrations for all experiments were nearly identical, except that the concentration of arsenious acid was cut in half for the experiments at the two highest temperatures. Under the concentration conditions chosen, the reaction is approximately first order; the deviations from straight lines in the log $\Sigma(I_2)$ *vs.* t plots were satisfactorily removed by correcting for the changes in (H^+), (I^-) and (H_3AsO_3) that occurred as the reaction proceeded. (The change in (H^+) caused by mixing meta-arsenite and perchloric acid was of course allowed for.) In other words, the rate law

$$-d(I_3^-)/dt = k_3' \frac{(I_3^-)}{(H^+)(I^-)^2}(H_3AsO_3) \quad (8)$$

was obeyed satisfactorily. The temperatures and results are summarized in Table I.

(9) Makower and Liebhafsky, *Trans. Faraday Soc.*, **29**, 597 (1933).

Comparison of the last two columns in Table I shows that here, as in the chlorine–hydrogen peroxide reaction, the logarithm of the specific rate is a linear function of $1/T$ to within the experimental error. Roebuck's[8c] value for k_3' at 0° in sulfuric acid solution is 9.4(10^{-4}) (units: moles, liters, minutes); this result, when corrected for the decreased acid concentration due to the presence of HSO_4^-, is in good agreement with the Table I value.[10] Roebuck gives several values for the temperature coefficient of k_3' between 0 and 10°; his highest value, 3.5,[8a] corresponds to a heat of activation $Q = +19{,}200$ cal.; his lowest, 3.17,[8b] to +17,710 cal., which is in fair agreement with +16,970 cal., the value from Table I.

TABLE I

TEMPERATURE COEFFICIENT DATA FOR THE ARSENIOUS ACID–IODINE REACTION

Experiment	T, °K.	$10^4 \times k_3'$ (meas.)	$10^4 \times k_3'$ (calcd.)[a]
3	273.1	6.7	6.6
4	273.1	6.5	6.6
5	277.7	10.9	11.2
6	283.5	21.6	21.1
7	288.1	36	34
8	293.1	58	57

[a] Calculated values from the equation $\log k_3' = 10.411 - (3710.0/T)$.

The magnitude of Q and its constancy (or near constancy) both suggest the necessity of revising the mechanism of the arsenious acid–iodine reaction. The heat of dissociation of triiodide ion (+4320 cal.)[8c] and the heat of hydrolysis of iodine (+22,700 cal.)[8c] must both be included in Q if the accepted mechanism is correct; on this basis the heat of activation for the rate-determining step between hypoiodous and arsenious acids would have a *negative* heat of activation of 10,000 cal. When Roebuck's work was reexamined some years ago,[8c] it was not known that a constant Q was in conflict with most of the data for aqueous halogen solutions[3]; as it now appears, the previous conclusion[11] that the rate-determining step has a negative temperature coefficient must be rejected, and the mechanism for the arsenious acid–iodine reaction revised.

The revised mechanism must meet the requirement that the rate at all temperatures be independent of the ratio (H)/(U). Perhaps the simplest mechanism that can be devised to meet this requirement is

Rapid equilibria

$$U + H_3AsO_3 \rightleftarrows A + H^+ + I^- \quad (9)$$

$$H + H_3AsO_3 \rightleftarrows B + H^+ + I^- \quad (10)$$

Rate-determining steps of identical specific rate

$$A \xrightarrow{k_1} H_3AsO_4 + H^+ + I^- \quad (11a)$$

$$B \xrightarrow{k_1} H_3AsO_4 + H^+ + I^- \quad (11b)$$

The device of having A and B decompose at the same (or nearly the same) specific rate is saved from being an obvious artifice by the fact that these two intermediate products differ only in the degree of hydration. An analogous mechanism would eliminate the conflict between equilibrium and kinetic data for the chlorine–hydrogen peroxide reaction.

A detailed discussion of the arguments for and against this mechanism is scarcely warranted. Accurate measurements of the equilibrium constant for the iodine hydrolysis over the temperature range in question would be more valuable than such a discussion; but these data, especially for the lower temperatures, will be difficult to obtain. The existence of accurate hydrolysis equilibrium measurements for the analogous chlorine–hydrogen peroxide reaction to some extent compensates this difficulty.

It may be pointed out, finally, that the equilibrium constant of a halogen reaction could, if heat capacity terms are ignored, be a linear function of $1/T$. This linearity will result if the forward (reverse) reaction has a mechanism like that outlined for the arsenious acid, while the reverse (forward) reaction proceeds by a mechanism whose temperature coefficient is normal. The triiodide equilibrium (Reaction 5) appears to be one case of this kind, and Equilibrium 4 another. Further experimental work to test these ideas is highly desirable.

Light Absorption by Iodine Solutions.—The General Electric recording spectrophotometer[12] was used to establish whether a characteristic change in the absorption of visible light accompanied the change in the hydration of iodine between 0 and 75°. For purposes of comparison, carbon tetrachloride solutions were also investigated at different temperatures. The ease with which iodine volatilizes from aqueous solutions is well known; this difficulty was minimized by filling the cell (5.15 cm. long) with the warm or

(10) (a) The dissociation constant at 25° of HSO_4^- in concentration units for the above reaction mixtures is near 0.03: Noyes and Sherrill, THIS JOURNAL, **48**, 186 (1926). (b) The corresponding heat of dissociation is small; Hamer, *ibid.*, **56**, 860 (1934).

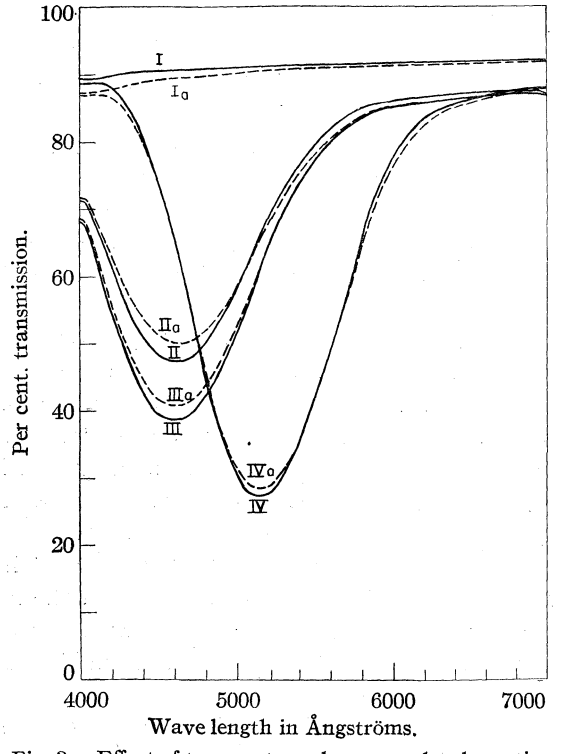

Fig. 3.—Effect of temperature change on the absorption of visible light by iodine solutions:

Curve	Solvent	Moles I_2/l.	T, °C.
I	CCl_4	None	25
Ia	CCl_4	None	50
II	H_2O	6×10^{-5}	24
IIa	H_2O	6×10^{-5}	76
III	H_2O	9×10^{-5}	0.3
IIIa	H_2O	9×10^{-5}	24
IV	CCl_4	9.5×10^{-5}	25
IVa	CCl_4	9.5×10^{-5}	51

cold solution, tracing its transmission curve (less than three minutes is required), and permitting the covered cell to stand until its contents reached room temperature, when the transmission was again measured. Some of the curves obtained are shown in Fig. 3; that the effect of changing temperature on the water-filled cell is very small is obvious from the uppermost curves in Fig. 4.

Figure 1 shows clearly that aqueous iodine solutions show anomalous temperature coefficients while carbon tetrachloride solutions do not; Fig. 3 shows that changing temperature affects light absorption by both solutions almost identically when the change in the absorption by carbon tetrachloride itself is allowed for. It follows, therefore, that the change in hydration presumably responsible for the curvature in Fig. 1 cannot be detected on the spectrophotometer, and that U is itself hydrated. The noticeable displacement toward longer wave lengths of Curve IIa, Fig. 3, indicates that the complete dehydration of iodine is beginning at 76°.

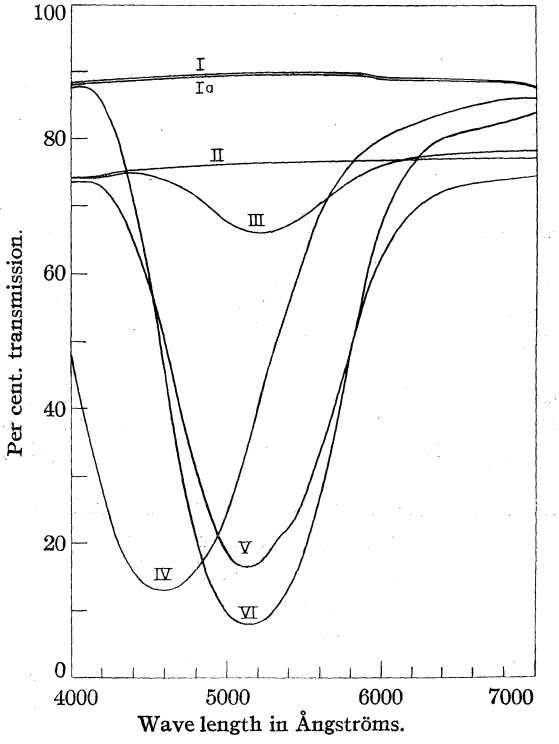

Fig. 4.—Absorption of visible light by gaseous and dissolved iodine:

Curve	Solvent	Moles I_2/l.	T, °C.
I	H_2O	None	25
Ia	H_2O	None	50
II	Air	None	25
III	Air	1.6×10^{-5}	25
IV	H_2O	2.36×10^{-4}	25
V	Air	Unknown	25
VI	CCl_4	2.39×10^{-4}	25

The small decrease in absorption with increasing temperature shown in Fig. 3 doubtless results from the concomitant increase in the number of iodine molecules in the first vibrational level, an explanation that Gibson, Rice and Bayliss[13] have shown to be quantitatively satisfactory in the case of gaseous chlorine. The fact that this decrease occurs to about the same extent for aqueous as for carbon tetrachloride solutions indicates that light absorption leads to comparable processes in both kinds of solutions, even though water probably forms definite solvates with iodine and carbon tetrachloride does not.

The failure of the spectrophotometer to detect the shift from U to H (which, according to results

(13) (a) Gibson and Bayliss, *Phys. Rev.*, **44**, 188 (1933); (b) Gibson, Rice and Bayliss, *ibid.*, p. 193.

given above, involves some 10,000 cal. at least) suggested that transmission curves be obtained for iodine vapor.[14] The vapor was generated by heating the quartz cell, into which a crystal of iodine had been placed, so that the ends remained hotter than the other portions. The room temperature curve was obtained after the cell had cooled; the corresponding concentration of iodine was calculated from its vapor pressure.[4] The data derived from the various curves in Fig. 4 are ($\log I_0/I = \epsilon \times 1 \times$ moles/liter):

Source	Solvent	$\lambda_{max.}$, Å.	$\epsilon_{max.}$	Width, W, at $\epsilon = 1/2\ \epsilon_{max.}$, Å.	Product $W \times \epsilon_{max.}$, Å.
Curve V	Air	5120	..	860	..
Curve III	Air	5200	810	850	$69(10^4)$
Curve VI	CCl_4	5140	870	860	$75(10^4)$
Curve IV	H_2O	4600	690	1010	$70(10^4)$
Ref 14	Inert gases	5200	830	880	$73(10^4)$

Although the work was done with reasonable care, extreme accuracy is not claimed for the $\epsilon_{max.}$ values; relative ϵ values and the positions of the absorption maxima are more reliable. A detailed comparison with the large amount of earlier work is not feasible—among other things, because the effects of differences in cell thickness and in concentration would have to be known. The parameters in the last two columns are given in an effort to describe the curves without listing the individual ϵ values. The product in the last column should be approximately proportional to the area under the curve, and its departure from constancy may be a partial measure of solvent influence.

The data from Curve III are obviously in good agreement with those derived from the "limiting" curve of Rabinowitsch and Wood.[14] In Curve V, the limiting conditions are probably not quite reached because of the higher pressure of iodine vapor; the slight "hump" near 5400 Å. results, as they have pointed out, from the superposition on the main band series of the series due to the first vibrational state. They state: "It is noteworthy that these humps appear in *solutions* of Br_2 and I_2 as well, showing that the vibrational quanta of these molecules are not strongly affected by dissolution in carbon tetrachloride and similar solvents." The spectrophotometric curves, published and unpublished, obtained in this Laboratory for iodine–carbon tetrachloride solutions do not support this conclusion since they do not show the "hump" in question. A small spectroscope that resolved the bands of iodine vapor showed no structure whatever in the absorption by a carbon tetrachloride solution. This empirical evidence of how completely the interaction of solvent with solute molecules modifies quantum restrictions could not, of course, have been obtained with the spectrophotometer, which has a slit width of 100 Å.

Figure 1 shows that approximately 9000 cal./mole is evolved when an infinitesimal amount of iodine vapor is dissolved in a saturated carbon tetrachloride solution. The spectrophotometric curves for vapor and solution are virtually identical, except that the solution shows a somewhat higher transition probability (higher value of $\epsilon_{max.}$ and of the product $W \times \epsilon_{max.}$).[15] The failure of the spectrophotometer to reflect the interaction of carbon tetrachloride with iodine makes its failure to detect the shift from U to H seem less serious.

The following differences in visible light absorption exist between solutions of iodine in carbon tetrachloride (in which there are no definite solvates) and solutions in water (in which definite hydrates are present): the absorption maximum in water 5–600 Å. further toward the violet; $\epsilon_{max.}$ is smaller; the absorption curve is broader (the product $W \times \epsilon_{max.}$, however, is approximately the same for both solutions). It is probable that these differences result from the formation of definite iodine–solvent compounds, but how and why is uncertain. Further work is necessary.

Summary

Certain corrections of earlier work on the bromine hydrolysis have strengthened the case for the hypothesis that the anomalous temperature coefficients associated with aqueous halogen solutions result from shifts in the hydration equilibria.

Temperature coefficient data for the arsenious acid–iodine reaction have been given.

Evidence against the conventional mechanisms

(14) Rabinowitsch and Wood, *Trans. Faraday Soc.*, **32**, 540 (1936). Professor H. Sponer kindly called this valuable paper to the author's attention after his own experimental work was completed.

(15) Rabinowitsch and Wood[14] hold a weakening of the selection rules by the electric fields of the solvent molecules responsible for the increase in transition probability. If this explanation and the work of Groh and Papp [*Z. physik. Chem.*, **A149**, 153 (1930)] are correct, the order of increasing influence by these electric fields for several solvents is carbon tetrachloride, hexane, carbon bisulfide, with only small differences among the three. Moreover, if water has a similar effect, this effect must be masked by others as the table above shows. The data for chlorine, which should show the effect most strongly, are worth consulting in this connection (*cf.* Fergusson, Slotin and Style, *Trans. Faraday Soc.*, **32**, 956 (1936), Fig. 2).

for this and the chlorine–hydrogen peroxide reaction seems strong enough to warrant their revision. One such revision has been carried out.

Anomalies in the temperature coefficients of processes in aqueous iodine solutions find no counterpart in the absorption of visible light by these solutions. Gaseous iodine in air and iodine dissolved in carbon tetrachloride are virtually indistinguishable with a spectrophotometer. Aqueous iodine solutions differ from them in three spectrophotometrically measurable ways.

Thermal and Photochemical Exchange Reactions of Bromine

BY J. NORTON WILSON AND ROSCOE G. DICKINSON

Several reactions involving exchange of bromine atoms between elementary bromine and bromine compounds in carbon tetrachloride solutions have been investigated in this Laboratory with the use of radioactive bromine. The results obtained from the study of the thermal reactions between bromine and arsenious bromide, stannic bromide, ethylene bromide, and trichlorobromomethane and the photochemical reaction between bromine and trichlorobromomethane are here described.

Experimental Method.—The thermal exchanges were investigated in general as follows. A solution of radioactive bromine in carbon tetrachloride was divided into two portions: the bromine was extracted from one of these portions and converted to silver bromide for electroscopic measurements; the other portion of the solution was mixed with a solution of the bromine compound to be investigated, and the mixture, hereafter referred to as the reaction mixture, was kept at a definite temperature for a convenient time; a precipitate of silver bromide was then prepared from either the bromine or the bromine compound in the mixture. The extent of exchange was then calculated from the known composition of the reaction mixture and the relative electroscopic activities of the two silver bromide precipitates, and is reported here as percentage of complete exchange. The electroscopic measurements were made by a method described elsewhere.[1]

The method used to prepare the dilute highly radioactive solutions of bromine used in the photochemical experiments may be of interest: a small amount of highly radioactive sodium bromide was prepared by the method of Erbacher and Philipp[2] from a large amount of ethylene bromide which had been exposed to slow neutrons from a radon–beryllium source. The sodium bromide, dissolved in a small amount of water, was shaken with a dilute solution of bromine in carbon tetrachloride. As was expected from the known rapidity of the exchange between bromine and bromide ion in aqueous solution,[3] exchange was rapid; the resulting solution of radioactive bromine was dried with phosphorus pentoxide, distilled and diluted to the desired concentration with carbon tetrachloride.

Experiments with Stannic and Arsenious Bromides.—The reaction mixtures were subjected immediately after mixing to vacuum distillation at 25° to remove bromine. The residue of metallic bromide was then hydrolyzed and the resulting bromide ion was precipitated as silver bromide for radioactivity measurements. Exchange was apparently complete with solutions containing 4 mole per cent. of bromine and 2 mole per cent. of either metallic bromide. Since the extent of exchange was calculated on the basis of the initial composition of the solution, exchange was probably completed before an appreciable fraction of the bromine had distilled away, *i. e.*, within about ten minutes. The time elapsing between the initial mixing of the solutions and the conclusion of the distillation was about thirty minutes.

Experiments with Ethylene Bromide.—The reaction mixtures were sealed in glass ampoules and kept in the dark at the desired temperature for a convenient time; the bromine was then extracted with sodium nitrite solution and converted to silver bromide. No exchange beyond the limits of experimental error was detected in a solution of the composition 24 mole per cent. Br_2, 28 mole per cent. $C_2H_4Br_2$, which was kept at 100° for sixty-five minutes. Experiments using lower concentrations and temperatures similarly indicated no exchange. In no experiment was the apparent extent of exchange greater than 3%; this value is less than the estimated experimental error.

Experiments with Trichlorobromomethane.—The thermal reactions were carried out similarly to those involving ethylene bromide. At concentrations of approximately 0.3 moles of bromine and 1 mole of CCl_3Br per liter, the apparent extents of exchange observed in solutions kept for four minutes at 25°, forty minutes at 95° and fifty minutes at 115° were, respectively, −5, 7 and 9%. These measurements are obviously uncertain by at least 5% of

(1) Wilson and Dickinson, THIS JOURNAL, **59**, 1358 (1937).

(2) Erbacher and Philipp, *Z. physik. Chem.*, **A176**, 169 (1936).

(3) Roginskii and Gophstein, *Physik. Z. Sowjetunion*, **7**, 672 (1935).

complete exchange and possibly more; it is doubtful whether any appreciable exchange occurred.

The photochemical experiments were carried out as follows. A solution of radioactive bromine and trichlorobromomethane in carbon tetrachloride was frozen with liquid air; the space above the solution was evacuated in order that oxygen might be largely removed. The solution was melted and separated *in vacuo* into two approximately equal portions which were then sealed off. One portion was thermostated and illuminated for a measured time with filtered radiation from a 500-watt tungsten lamp; the filter transmitted chiefly in the range 5000 to 6100 Å. The other portion was kept in the dark at the same temperature for the same time. After the illumination was completed, both solutions were cooled in the dark; the bromine was extracted from the same volume of each and converted to silver bromide for electroscopic measurements. A small volume of each solution was also analyzed for bromine.

A thermal exchange experiment was performed using the same technique: the solution was separated *in vacuo* into two portions; bromine from one portion was converted immediately to silver bromide; the other portion was kept in the dark at a high temperature for some time before the bromine extraction.

The results obtained with solutions containing about 0.003 mole of bromine and 0.08 mole of trichlorobromomethane per liter were as follows: thermal, solution heated at 76° for seventy-five minutes, −3% exchange; photochemical, solution illuminated at 76° for seventy minutes, 98% exchange. Two experiments in which solutions containing 0.003 mole of bromine and 0.02 mole of trichlorobromomethane per liter were illuminated at 76° for twenty minutes resulted in 86 and 97% exchange. Other experiments at higher temperatures or with longer illumination times also gave 85 to 100% exchange.

Summary

Investigation of the exchange of bromine between radioactive bromine and various bromine compounds has led to the following results: a rapid exchange occurs with arsenious bromide and with stannic bromide at room temperature in carbon tetrachloride solution (!); in the same solvent no exchange beyond the limits of experimental uncertainty was observed to occur with either ethylene bromide or trichlorobromomethane in the dark at 100°; a rapid exchange with trichlorobromomethane is induced by green light at 76°.

A convenient method has been described for the preparation of dilute and highly radioactive solutions of bromine in carbon tetrachloride.

The Molecular Structures of Glyoxal and Dimethylglyoxal by the Electron Diffraction Method

BY JAMES E. LUVALLE[1] AND VERNER SCHOMAKER

Introduction.—Extension to open chain hetero-atomic aliphatic compounds of the structural investigations[2] of the constitutional effect of different bonds upon adjacent bonds should provide useful information concerning the electronic structures and the extent of resonance in these molecules. The recent electron diffraction studies of formaldehyde[3] and acetaldehyde[4] have given a reliable value for the carbon–oxygen double bond distance. We have now extended the investigation of compounds containing the carbonyl group to glyoxal and dimethylglyoxal, both of which contain a pair of conjugated carbon–oxygen double bonds and present the possibility of free rotation around the carbon–carbon bond connecting the adjacent carbonyl groups. Furthermore, both substances are colored, glyoxal being the simplest colored compound whose molecules have a conjugated system. Of the compounds glyoxal, dimethylglyoxal, oxalyl chloride, oxamide, and oxalic acid, it is found that glyoxal and dimethylglyoxal are colored whereas the remaining compounds are colorless. All five of these compounds may be represented by the formula RCORCO and the difference in color between the first two compounds and the remaining three compounds suggests that there may be a structural difference between the two groups of compounds. Oxalyl chloride is now under investigation in these Laboratories by the electron diffraction method, and the X-ray study of crystals of oxamide is also under way.

(3) D. P. Stevenson, J. E. LuValle and V. Schomaker, *ibid.*, **61**, 2508 (1939).

(4) D. P. Stevenson, H. D. Burnham and V. Schomaker, *ibid.*, **61**, 2922 (1939).

Experimental.—Glyoxal was prepared by the oxidation of ethylene with selenium dioxide after the method of Riley and Friend.[5] The ethylene was oxidized in a 3 × 30 cm. Pyrex tube containing equal amounts by weight of phosphorus pentoxide and finely-ground selenium dioxide placed in alternating layers. At the ends of the tube there were longer (7 cm.) columns of phosphorus pentoxide and plugs of "Pyrex wool" (No. 9930). Gentle heating was necessary for starting the reaction. The glyoxal was collected in a trap at −60°. The ethylene was obtained from the Ohio Chemical Company and the selenium dioxide from the Eimer and Amend Company, New York.

Eastman "white label" dimethylglyoxal (b. p. 87–88.5°) was used without further purification.

The electron diffraction photographs were prepared with the apparatus described by Brockway.[6] The values of $s_0 = (4\pi/\lambda)\sin\theta/2$ given in the tables are averages of the values found by visual measurement of the ring diameters for ten or more films. The wave length of the electrons determined from transmission pictures of gold foil (a = 4.070 Å.) was 0.0611 Å. and the camera distance was 10.84 cm. The radial distribution functions[7] were calculated using the s_0 values of both the maxima and minima, and the coefficients, C_K, were determined from these s_0 values and the visually estimated intensities, I_K, according to the method recommended by Schomaker.[8]

Glyoxal.—The photographs of glyoxal are very good, extending to s_0 = 27 and showing thirteen maxima and shelves. The radial distribution curve (Fig. 1) calculated with the C_K and s_0 values of Table I shows four principal peaks at 1.18, 1.48, 2.34 and 3.45 Å., the last two peaks being more reliable than the first two. The peak at 1.18 Å. corresponds to the carbon–oxygen double bond distance, that at 1.48 Å. to the carbon–carbon distance, and that at 2.34 Å. to the long carbon–oxygen distance. These distances indicate a value of about 121° for the C—C=O angle. Resonance probably causes the molecule to be coplanar. Of the two coplanar configurations, the *trans* form is suggested by the strong radial distribution peak at 3.45 Å., this value being very close to that calculated for a *trans* model having the above parameters (3.41 Å.). The remaining small radial distribution peaks are probably without significance.

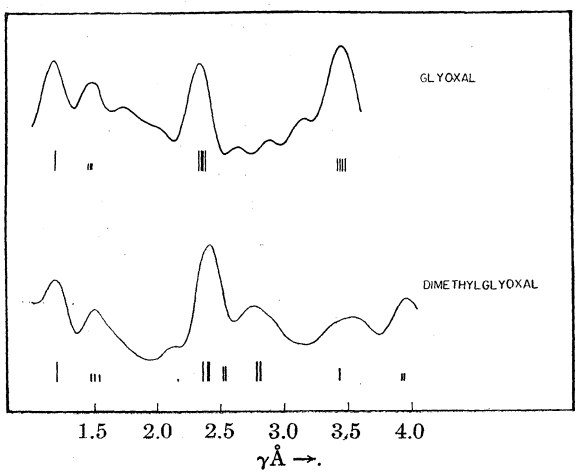

Fig. 1.—Radial distribution curves for glyoxal and dimethylglyoxal. The vertical lines beneath the curves show the various interatomic distances of the models used in the final determination of distances by the correlation method.

Twenty-four intensity curves were calculated with the ratio C—C/C=O varying from 1.38/1.20 to 1.52/1.20 and the angle C—C=O varying from 116° to 128°. The eight intensity curves of Fig. 2 were calculated for coplanar *trans* models with the distance C—H = 1.09 Å. and the angle H—C—C = 114°. A temperature factor was introduced into all the hydrogen terms in the intensity function.[6] If the C—H parameter here assumed were in error by 0.03 Å. the change would not be detected since the contribution of the hydrogen terms is small. The H—C—C angle parameter is likewise unimportant. The longer carbon–oxygen distance and the oxygen–oxygen distance in these models are compatible with the strong radial distribution peaks at 2.34 Å. and 3.45 Å. The faint seventh and tenth shelves which were measured and used in the radial distribution function cannot be distinguished definitely on any of the theoretical curves; however, this is shown by the work of Schomaker and Stevenson[9] on the interpretation of electron diffraction photographs not to be especially surprising.

Curves D and F of Fig. 2 reproduce the photographs satisfactorily, and curves C and E are nearly as good; in the final evaluation of parameters all four models have been used with models

	(C=O) = 1.20 ± 0.01 Å.											
	(C—C) = 1.47 ± 0.02 Å.											

[a] The models are described in the legend to Fig. 2. [b] Less reliable values, not included in taking the averages, are shown in parentheses. [c] The theoretical curve indicates no precisely measurable feature at this point. [d] The values of s_0 used in the radial distribution function were somewhat different than the ones given here; the weights show these terms were relatively unimportant.

D and F assigned weights three times as great as models C and E. Curves A, B, G and H are not at all satisfactory and the corresponding models were discarded.

It is concluded that the glyoxal molecule has the configuration and distances described by the following parameters: C—H = 1.09 Å. (assumed), C=O = 1.20 ± 0.01 Å., C—C = 1.47 ± 0.02 Å., angle C—C=O = 123° ± 2°. The molecule is probably coplanar and *trans;* the evidence for this view provided by the radial distribution function is supported by a strong dependence of the intensity curves upon the relative orientation of the carbonyl groups of the glyoxal molecule. Theoretical considerations[10] indicate that resonating systems tend to be coplanar. The electron diffraction data are not incompatible with a mixture containing a small fraction of molecules with the *cis* configuration. The data indicate that the amplitude of libration around the carbon–carbon bond is small.

Dimethylglyoxal.—The photographs of dimethylglyoxal are excellent, extending out to s_0 = 27 and showing eleven maxima and shelves. The s_0, I_K, and C_K values are given in Table II. The radial distribution curve (Fig. 1), calculated with the s_0 and C_K values of this table, has peaks at 1.19, (1.50), (2.12), 2.41, 2.75, (3.56), and 3.95 Å. (The less reliable peaks are enclosed in parentheses.) We can assume coplanarity of the molecule as it possesses a resonating system. The peak at 1.19 Å. corresponds to the carbon–oxygen

[a] The models are described in the legend to Fig. 3. [b] The theoretical curves do not show a precisely measurable feature at this point.

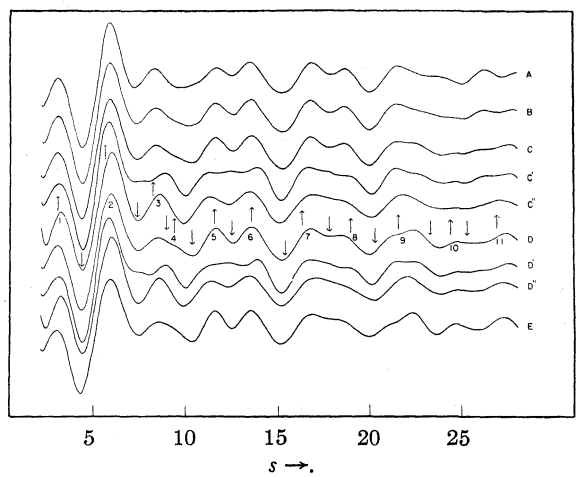

Fig. 3.—Theoretical intensity curves for dimethylglyoxal. All the curves have the following parameters in common: C—H = 1.09 Å. (assumed), C=O = 1.20 Å., C_2—C_3 = 1.47 Å., C_1—C_2 = 1.54 Å., and angle CO—C=O (α) = 123° ± 2°. Denoting angle CH_3—C=O by β we have: Curve A, $\beta = 125°$; Curve B, $\beta = 124°$; Curves C, C′, and C″, $\beta = 123°$; Curves D, D′, and D″, $\beta = 122°$; Curve E, $\beta = 121°$.

double bond distance, that at 1.50 Å. to the 2–3 carbon–carbon distance and the two 1–2 carbon–carbon distances, and that at 2.41 Å. to the 1–3 carbon–carbon distance and the two carbon–oxygen distances. The peak at 2.75 Å. may be attributed to the long carbon–oxygen distance of the molecule with the *trans* configuration or possibly to the long carbon–carbon distance for the *cis* configuration, and the broad peak at 3.56 Å. may represent the oxygen–oxygen distance for the *trans* configuration or the long carbon–oxygen distance for the *cis* configuration. However, the peak at 3.95 Å. can be attributed only to the long carbon–carbon (1–4) distance of the *trans* form, which indicates strongly that the molecule has the *trans* configuration.

Assuming that the distances and the C—C=O angle found for glyoxal hold for dimethylglyoxal, five models were set up and fifteen intensity curves calculated, five for the *cis* form, five for the *trans* form, and five in which the terms dependent upon the relative orientation of the acetyl groups were omitted from the intensity function. The angle β was varied from 119 to 125°.

Of the curves shown in Fig. 3, A, B, C, D and E are for the *trans* models, C′ and D′ are for the *cis* models, and C″ and D″ are the incomplete intensity curves corresponding to C and D, respectively. Curves C and D both give satisfactory agreement with the photographs except for the ninth and tenth maxima. On curve C, the ninth maximum is observed to have shifted to a smaller s value than that measured and the tenth maximum is too weak, whereas on curve D, the ninth maximum is observed to have shifted to a larger s value than that measured and the tenth maximum is too strong. The best model accordingly lies between model C and D. Examination of Fig. 3 shows that the remaining *trans* models, A, B, and E, are unsatisfactory and the *cis* models C′ and D′ are out of the question. Curves C″ and D″ show that the libration around the 2–3 carbon–carbon bond is not of great amplitude.

It is concluded that the dimethylglyoxal molecule is essentially coplanar and *trans* with the following parameter values: C—H = 1.09 Å., C_2—C_3 = 1.47 ± 0.02 Å., C_1—C_2 = 1.54 ± 0.02 Å., C=O = 1.20 ± 0.02 Å., angle CO—C=O (α) = 123° ± 2°, and angle CH_3—C=O (β) = 122.5° ± 1°. The electron diffraction data are not incompatible with a mixture containing a small fraction of *cis* molecules. The data indicate that the amplitude of libration around the (C_2–C_3) carbon–carbon bond is small. It must be emphasized that the determination of the configuration and distances in dimethylglyoxal is not as precise as that for glyoxal. The radial distribution curve strongly indicates this model but a model in which the 2–3 carbon–carbon bond is somewhat lengthened and the 1–2 and 3–4 carbon–carbon bonds are slightly shortened cannot be eliminated by the qualitative comparison, but such a model does not agree with the radial distribution function as well as our final model.

Discussion.—The observed shortening in both molecules of 0.07 Å. for the carbon–carbon bond connecting the adjacent carbonyl groups corresponds to 15 or 20% double bond character,[2b] and is nearly the same as that (1.46 Å.) reported for butadiene.[2d] The electron diffraction data for both glyoxal and dimethylglyoxal indicate restricted rotation around the carbonyl–carbonyl bond.

Calculation of the potential restricting rotation around the 2–3 carbon–carbon bond in dimethylglyoxal by the method of Beach and Stevenson[11] using Zahn's values[12] of the dipole moment and Smyth's values[13] of the group moments indicates that the potential barrier restricting rotation is steeper than a parabolic barrier and greater than 12 kcal. in height. Zahn[12] finds an amplitude of approximately 30° for the libration in dimethylglyoxal. Dipole moment data are not available for glyoxal, so that the corresponding calculation could not be made; however, the potential barrier should be of the same order of magnitude for both substances.

Calculation of the coulombic interactions for the *cis* and *trans* models of glyoxal and dimethylglyoxal using Smyth's values[13] of the bond moments shows that the *trans* glyoxal molecule is about 6.9 kcal./mole more stable than the *cis* configuration and that the *trans* dimethylglyoxal molecule is about 1.7 kcal./mole more stable than the *cis* configuration. Calculations of the ratio of the partition functions of *cis* to *trans* glyoxal and dimethylglyoxal are simplified by the assumption that the vibrational partition functions are the same for both the *cis* and *trans* configurations, the translational partition functions are the same; therefore, the calculation becomes the cal-

(11) J. Y. Beach and D. P. Stevenson, *J. Chem. Phys.*, **6**, 635 (1938).

(13) C. P. Smyth, *J. Phys. Chem.*, **41**, 209 (1937).

culation of the square root of the ratio of the product of the three principal moments of inertia for the two configurations. The ratios $[(I_1I_2I_3)_{cis}/(I_1I_2I_3)_{trans}]^{1/2}$ for the glyoxal and dimethylglyoxal molecules are 1.15 and 1.00, respectively. For the equilibrium *cis* $\rightleftarrows$ *trans* these values combined with the ΔE values given above correspond to equilibrium constants of 87,000 and 20 for glyoxal and dimethylglyoxal, respectively; that is, the fraction of *cis* glyoxal is negligible and that of *cis* dimethylglyoxal may be about 5%. These results agree with our electron diffraction investigations.

We express our thanks to Dr. Linus Pauling for his helpful criticism and discussion and to Dr. D. P. Stevenson for assistance with the calculations and helpful discussion.

Summary

The configurations of glyoxal and dimethylglyoxal as determined by the electron diffraction method are given by the following parameters:

Glyoxal: C—H = 1.09 Å. (assumed), C=O = 1.20 ± 0.01 Å., C—C = 1.47 ± 0.02 Å., angle C—C=O = 123° ± 2°

Dimethylglyoxal: C—H = 1.09 Å. (assumed), C=O = 1.20 ± 0.02 Å., C_2—C_3 = 1.47 ± 0.02 Å., C_1—C_2 = 1.54 ± 0.02 Å., angle CO—C=O = 123° ± 2°, angle CH_3—C=O = 122.5° ± 1°

The electron diffraction data and the dipole moment data as well as chemical information indicate uniformly that both molecules are coplanar with the *trans* configuration and that rotation around the carbon–carbon bond connecting the adjacent carbonyl groups is restricted.

Quantum Efficiency of Photosynthesis in Chlorella. II

BY H. G. PETERING,[1] B. M. DUGGAR AND FARRINGTON DANIELS

Photosynthesis in algae has been the object of an extended investigation in these laboratories. The quantum efficiency was found to be of the order of 0.05 molecule per quantum,[2] much lower than the older value of 0.25 reported by Warburg and Negelein.[3] In order to study further the reasons for this large discrepancy, a new method was developed[4] for the rapid determination of dissolved oxygen making use of the dropping mercury electrode. The respiration correction seemed to be the most important source of error, and the manometric method used by Warburg and Negelein involves a considerable time lag in determining the rate of respiration and of photosynthesis. If respiration is faster under the conditions imposed by photosynthesis, then a prompt determination of respiration after the light is turned off is necessary if arbitrary assumptions are to be minimized. Results obtained with the dropping mercury electrode are given here. They agree essentially with those reported earlier[2] and are in definite disagreement with those of Warburg and Negelein.[3] Recently Rieke[5] has reported a value of 0.24 obtained with the manometric method in agreement with Warburg and Negelein.

Experimental Procedure

The material was *Chlorella pyrenoidosa*, of the same strain as used before.[2] It was grown in pure culture on agar slants and periodically transferred to fresh slants or to liquid media. The liquid culture was essentially the salt nutrient recommended by Warburg and Negelein.[3] The composition was:

Agar medium, g.		Liquid nutrient, *M*	
$NaNO_3$	0.25	$MgSO_4$	0.020
$CaCl_2$	.25	KNO_3	.005
KH_2PO_4	.25	KH_2PO_4	.018
$MgSO_4$	.25	$FeSO_4$	.00001
Cane sugar	2.00		
Water	1 liter		

Distilled water from a block tin condenser was used in most of the experiments but no differences were noted when in some of the experiments tap water from Lake Mendota was used. The algae were grown in 300-cc. flasks on a water-cooled rack illuminated from the bottom, while air, to which had been added 5% carbon dioxide, was bubbled through. Warburg's recommendations were followed in a general way, exposing algal cultures to bright light (four 200-watt filament lamps at 30 cm.) for a week and then to weaker light (six 25-watt lamps at 45 cm.).

The cultures were not used after they were more than fourteen days old. A normal growth curve was obtained for the algae under these conditions, showing rapid growth from the fourth to the eighth day.

In preparing a sample for measurements the supernatant liquid was decanted and the remaining algal solution was diluted immediately with fresh nutrient solution, which had been passed through filter paper to provide sufficient organic material for proper action of the dropping mercury electrode. The *p*H of the solution was adjusted to 5.5, the value attained by the growing algae in about a week. In some earlier experiments the algae were concentrated by centrifuging and then diluting but in later experiments this was avoided since it may affect the respiration. The algae were diluted until 50–75% of the light was transmitted by a solution 1.6 cm. thick. This usually required the addition of ten volumes or more of the fresh nutrient solution.

A 500-watt projection lamp was used with a lens and filter system giving parallel light chiefly between 6100 and 7200 Å. with a sharp maximum at about 6400 Å. A Corning No. 243 signal red filter was used together with 9 cm. of an 0.05 *N* copper sulfate solution. In some of the experiments with higher light intensity the copper sulfate was 0.025 *N* and tests showed that 10 to 15% of the total radiation might have been in the longer red and short infrared, but very little of this could have been absorbed by passage through the 1.6 cm. cell.

The incident and transmitted light were measured with a large-area thermopile having thirty junctions. Calibration was effected with a U. S. Bureau of Standards radiation lamp and corrections were made for reflections at the windows. Each cm. deflection of the thermopile-galvanometer was equivalent to 72.5 ergs per second per sq. cm. The room was thermostated between 24 and 26°. All of the light falling on the reaction cell was homogeneous with respect to both color and intensity. The entire cell was illuminated and half or more of the light was transmitted. Since most of the transmitted light was scattered, the thermopile was placed as close behind the reaction cell as possible. Tests showed that the thermopile could be moved from side to side over a wide range and forward and backward for several millimeters without changing the galvanometer deflections. The total light transmitted was calculated by multiplying the light falling on the thermopile by the ratio of the area of the reaction cell to that of the thermopile.

The reaction cell, 4.5 × 3.1 cm. in cross section and 1.6 cm. in thickness,[6] was placed in front of the thermopile. The narrow neck at the top of the cell permitted the insertion of the thin capillary tip of the dropping mercury electrode and the U-tube at the bottom kept at constant level the anode pool of mercury, 1 sq. cm. in area. The algal suspension was added until it over-flowed the cell and then the cathode tip was inserted at the center without forming air bubbles. The mercury dropped at the rate of about 1 drop per second[7] and the galvanometer readings were taken at 1.00 volt and at 0.10 volt. The difference in galvanometer readings at the two voltages was a straight line function of the oxygen concentration[8] as determined by the Winkler chemical analysis for dissolved oxygen. At 25° the calibration gave 9×10^{-9} mole of oxygen per cc. for each cm. deflection. The algae were not stirred because the whole cell was illuminated and the algae did not settle appreciably during the time of the determination. Experiments in which the cell was shaken between measurements showed that the stirring was not necessary.

(6) Fig. 2B of reference 4.

(7) It is necessary to keep the dropping rate constant and the temperature of the room should not vary by more than 1 or 2°, particularly if a galvanometer shunt is used. It is essential that the drops of mercury coalesce immediately with the anode pool of mercury. If organic matter prevents this coalescence it is necessary to use an external anode connected through a salt bridge in agar.

Results

A series of twenty-nine determinations was first obtained with the Winkler titration method and the quantum yields were between 0.02 and 0.07 in agreement with the earlier work.[2] However, it was found that the rate of oxygen consumption after illumination changed with time and the method was abandoned in favor of the rapid electrical method described here which permits a prompt determination of the rates of

respiration and photosynthesis. An example of these measurements has been given.[9] The mercury was shown not to affect the living algae under the conditions of the experiment.

The results are shown in Figs. 1, 2, and 3 and in Table I. The temperature was always 24–26°.

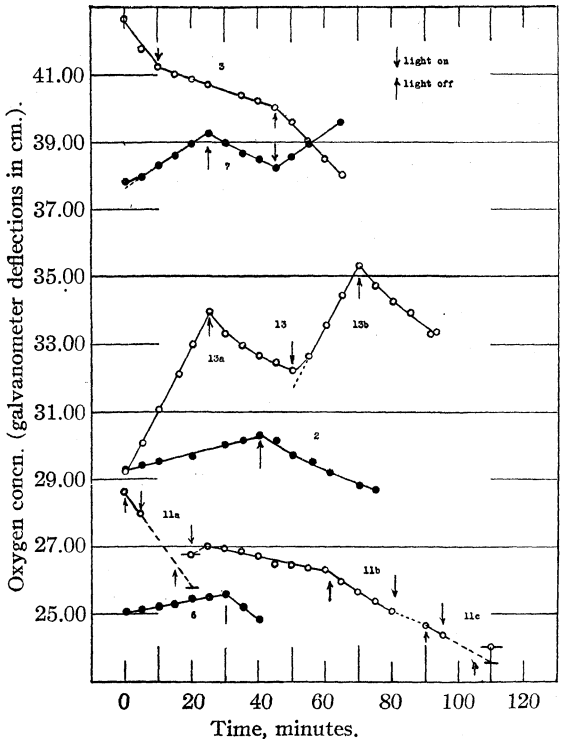

Fig. 1.—Oxygen concentration during photosynthesis and respiration.

Experiments with lower light intensities ranging from 1100 to 2200 ergs per second per sq. cm. are given first. The quantum yields range from 0.059 to 0.10. In expts. 13 to 18 the intensity was higher, 4500 to 6000, except that in expts. 16B and 17B the light intensity was reduced to about half the value in 16A and 17A by the introduction of a wire screen.

In expts. 3, 5 and 14, about 1% of glucose was added. In expt. 12, 1.0% of sodium glycolate was added. Experiments 16, 17 and 18 were practically the same except that in expt. 17 the solution was 0.05 *M* in sodium glycolate and in 18 it was 0.025 *M* in sodium glycolate and 0.025 *M* in glucose.

The method of calculation is illustrated with the data of experiment 13A.

Rate of oxygen change in light

$$\frac{(33.95 - 32.95)\text{ cm.}}{(25.0 - 20.0)\text{ min.}} = 0.20\text{ cm./min.}$$

Rate of oxygen change in dark

$$\frac{(33.30 - 33.95)\text{ cm.}}{(25.0 - 30.0)\text{ min.}} = -0.13\text{ cm./min.}$$

Rate of photosynthesis (corrected for respiration) = 0.20 − (−0.13) = 0.33 cm./min. In some experiments the calculations were made from tangents to the curves rather than from individual data.

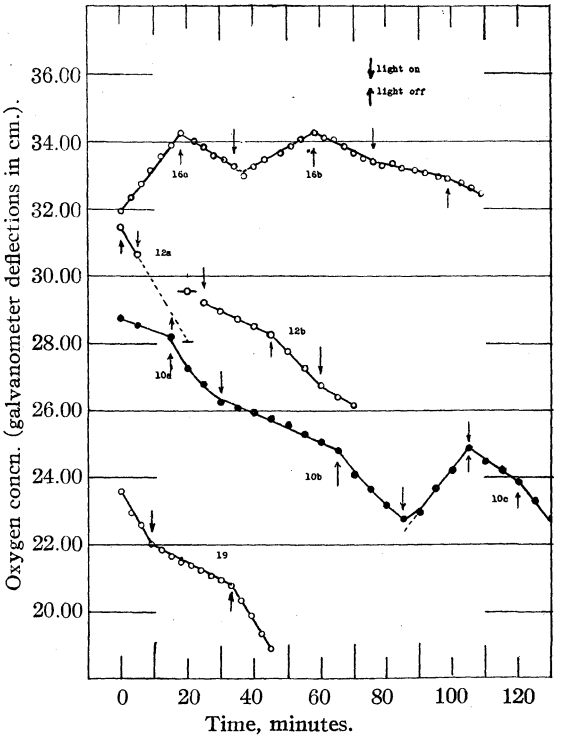

Fig. 2.—Oxygen concentration during photosynthesis and respiration.

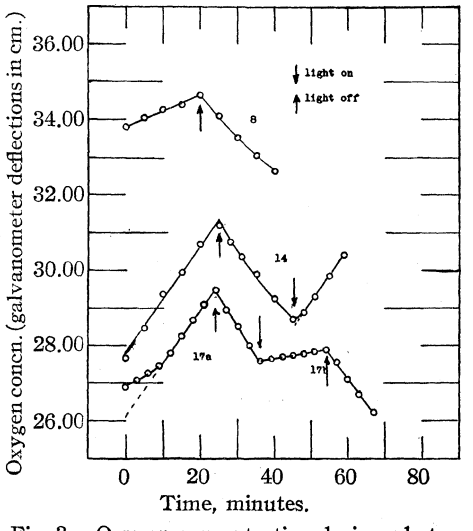

Fig. 3.—Oxygen concentration during photosynthesis and respiration.

(9) Reference 4, Fig. 5.

One unit cell volume is taken as 1 sq. cm. surface multiplied by the thickness of the cell, or 1.60 cc. One cm. deflection (difference between galvanometer reading with 1.00 volt and 0.100 volt) is equivalent to 9×10^{-9} mole of oxygen per cc. or 8.68×10^{15} molecules of oxygen per unit cell volume. The deflection of the thermopile back of the reaction cell was 45.0 cm. and 80.3 cm. when the cell was removed. With corrections for reflections, the incident light was 6080 ergs per second and the transmitted light 3620, giving an absorption per unit cell volume of 2460 ergs per second. At 6500 Å. one quantum contains 3.03×10^{-12} erg. Then the quantum yield is

$$\Phi = \frac{0.33 \times 8.68 \times 10^{15}}{2460 \times 60/3.03 \times 10^{-12}} = 0.059 \text{ molecule per quantum}$$

An hour later with the same light intensity, at 13B the slope was 0.18 cm. per minute in the light and −0.12 cm. in the dark, leading to a photosynthesis value of 0.30 cm. per minute and a quantum yield of 0.054.

The steady rate of respiration attained between the thirty-fifth and fiftieth minutes might be considered the significant rate, leading to a still lower quantum yield. In this period the slope is −0.05 cm. per minute. Combining this with the rate of oxygen uptake for the first exposure to a light a quantum yield of 0.045 is obtained; and combining it with the slope during the second exposure a value of 0.041. However, since there is disagreement regarding the value of quantum yields in photosynthesis, only the highest values are recorded in Table I. When the respiration rate decreased with time, the rate immediately after illumination was used in the calculations. The biologically significant and continuing quantum yields may be lower.

Discussion

A wide variety of conditions are covered by the data of Table I and Figs. 1, 2, 3, and yet the quantum yields are always low, *i. e.*, less than 0.10,[10] except in the case of 12A which was calculated in a different way. No correlation could be found between the quantum yield and the age or concentration of the algae or other factors. Many factors seem to influence the rate of respiration, such as the concentration of algae, the addition of glucose or glycolate and exposure to light, but the effect is compensated for in photosynthesis. When the slope for the oxygen change in the light is added to the slope for the oxygen change in the dark and combined with the amount of light absorbed, the quantum yields are almost always between 0.04 and 0.09. When the concentration of cells is low and the intensity of light is high, oxygen is evolved rapidly giving a positive slope but when the concentration is high and the light low, the respiration may be so great that illumination simply lessens the rate at which the oxygen is consumed and the slope of the oxygen-concentration–time curve remains negative but less steep.

Although the rate of respiration in the dark may change, it is seen that the amount of oxygen evolved in the light is a linear function of the time at constant light intensity. Apparently in the light a steady state of intermediate products may be reached which assures a uniform rate of respiration, at least over moderate time intervals.

In expts. 16B and 17B the light intensity was reduced by half, giving a slower rate of assimilation. However, the respiration was slower also with the result that the quantum yields are the same as in experiments 16A and 17A, respectively. Under these conditions the light must be the limiting factor because the rate of photosynthesis is directly proportional to the intensity.

It is well known that the addition of glucose accelerates respiration and in expts. 3, 5, 14, 17 and 18 this tendency is shown by the steeper curves. At low light intensities the quantum yields are not affected by this increased respiration but in expts. 14, 17 and 18 at higher light intensities there is evidence of an increase.

The discrepancy between the results obtained in this Laboratory and those obtained by Warburg and Negelein[2] and by Rieke[4] may be explained in part by the different methods of measurements. These investigators measured the oxygen change with a manometer and it is difficult under these conditions to obtain separately the actual rates of oxygen change in the light and in the dark on account of the time lag involved during the attainment of equilibrium between the gas phase and solution. Accordingly, a method of extrapolation was used[11] based on a few measurements and on the assumption that the rate of

(10) In new experiments, by Mr. W. E. Moore, to be reported later, algae from a different source have been used, the water has been specially purified and various inorganic and organic substances have been added. The same low quantum yields have been obtained consistently.

(11) This method is illustrated by Rieke in Fig. 1 of ref. 3.

respiration does not change. Periods of illumination and dark were chosen which were found experimentally to be favorable for the development of high apparent quantum yields.

Determinations 11A, 11C and 12A have been calculated by this extrapolation method as shown by the dotted lines in Fig. 1. After a period of illumination the algal suspension was kept in the dark for a period of five minutes. Oxygen concentrations were determined at the beginning of this dark period and at the end of the fifth minute. The light was turned on from the fifth to the fifteenth minute, and after five minutes in the dark the final reading was taken at the twentieth minute. The difference between this oxygen concentration and the value extrapolated from the fifth to the twentieth minute (assuming constant respiration), was used in calculating the amount of oxygen evolved during the ten-minute exposure to light. In 11A and 12A high values were obtained by this method of calculation. In 11C where the extrapolation sequence was started only after the algae had come to equilibrium with the light, as defined by a uniform rate of oxygen change (straight line), the calculations by the extrapolation method and the differential rate method are the same, and both are low.

The authors are glad to acknowledge the support of the Wisconsin Alumni Research Foundation in this investigation.

Summary

Quantum yields in photosynthesis by algae have been measured under a variety of conditions, making use of the dropping mercury electrode for the rapid measurement of dissolved oxygen. The results show that at 25°, 0.04 to 0.1 molecule of oxygen is evolved in photosynthesis by chlorella per quantum of red light absorbed. This efficiency is much lower than the efficiency 0.25 which has been hitherto accepted.

A Photocalorimeter. The Quantum Efficiency of Photosynthesis in Algae

BY JOHN L. MAGEE, THOMAS W. DEWITT, ELIZABETH COOLIDGE SMITH AND FARRINGTON DANIELS

The calorimeter described in this paper is designed to measure heat changes accompanying photochemical reactions. It was developed originally for determining thermally the quantum efficiency of photosynthesis by *Chlorella*. The hitherto accepted value of 0.25 molecule of carbon dioxide converted per quantum absorbed was obtained by Warburg and Negelein[1] with a differential manometer. Work originally undertaken in this Laboratory to extend the investigation of Warburg led to a much lower quantum yield, of the order of 0.05 molecule per quantum.[2] It was thus desirable to measure the quantum yield by other methods. Warburg's high efficiency demands that a large fraction of the absorbed radiation be converted into chemical energy while the lower efficiencies of Manning, Stauffer, Duggar and Daniels require that most of the radiation be dissipated as heat. A calorimetric method was suggested as an independent check on the work. The calorimeter consists of a small thin-walled quartz cell mounted in a cylindrical aluminum container. A multijunction thermocouple measures the temperature difference between the cell and container. A double thermostat keeps the latter at constant temperature. A thermopile placed behind the cell measures the amount of radiation transmitted. The calorimeter is calibrated at different light intensities by filling it with a solution of india ink or other chemically-inert, opaque liquid, and plotting galvanometer deflections against time until a steady state is reached. The heat evolved or absorbed in a chemical reaction can then be obtained by comparing the galvanometer–time curve with the curve for a chemically inert material under similar conditions.[2a]

Experimental Procedure

Apparatus.—The construction of the photocalorimeter is shown in Fig. 1. The cylindrical quartz cell with pol-

(2a) Dr. William A. Arnold of the Hopkins Marine Station of Stanford University at Pacific Grove, Calif., has developed independently a microcalorimeter which in August, 1938, was giving quantum yields with algae slightly greater than those obtained in this investigation.

ished ends, 2.3 cm. long and 1.3 cm. in diameter with two glass-stoppered openings in the top, has a capacity of 2.9 cc. It is supported by four fiber points in a hollow, cylindrical aluminum case 6.3 cm. long and 7.5 cm. in diameter having a central hole 4.5 cm. in diameter. The top of the case is removable for filling and emptying the reaction cell. Except for the front and rear faces, the quartz cell is silvered on the outside and covered with glyptal lacquer. The fifty copper–constantan thermocouple junctions, coated with glyptal lacquer, are fastened to the cell with de Khotinsky cement and the cold ends are attached in the same manner to the lacquered aluminum casing. The copper wire is no. 40 and the constantan wire no. 36, giving a total resistance of 34 ohms. The thermopile placed immediately behind the photocalorimeter has a surface larger than that of the calorimeter. It absorbs and measures all the transmitted light. It has twenty-eight junctions attached to the single, large, circular receiver and is enclosed in an aluminum block with a quartz window. The galvanometer (10 mm. per microvolt) is connected by a double pole switch to either the calorimeter or the thermopile.

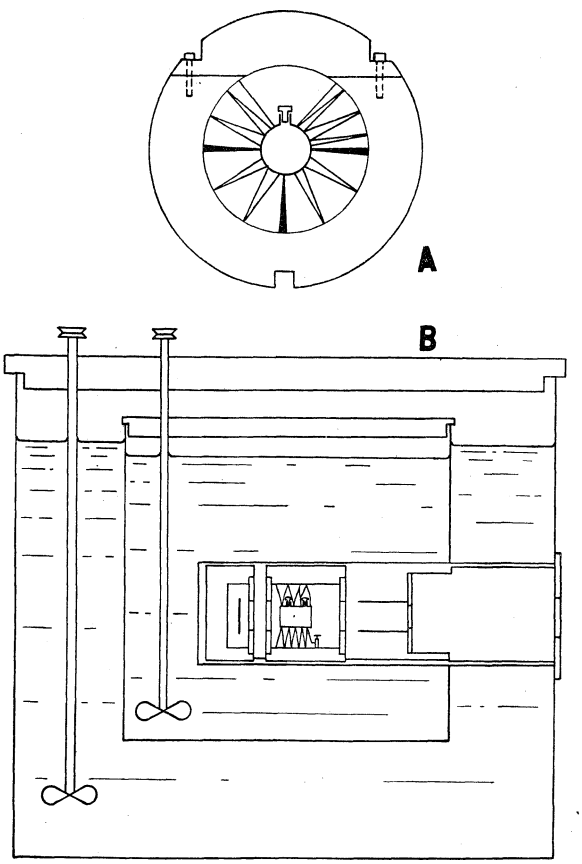

Fig. 1.—Photocalorimeter: A, end view; B, side view in thermostat.

A deflection of 1 cm. in the scale corresponds to a difference of 0.0003° in the calorimeter and it is essential therefore to have the cold junctions maintained at a very constant temperature. The problem was solved only after using a double thermostat, an outer one of water with a mercury regulator and stirrer, constant to 0.003°, and an inner one of oil supplied with a slow stirrer but no heater. The bottoms of the thermopile and calorimeter are slotted and run into the center of the inner thermostat along a track in a horizontal submarine tube as shown in Fig. 1B. In this way the cell is readily removed, filled and replaced in an exact position. After the thermopile and calorimeter are in position, a cylinder with quartz windows is telescoped inside of the thermostated tube and pushed flush with the outside of the thermostat. In this way circulation of cooler air is prevented. Thermal equilibrium is reached in about two hours after inserting the calorimeter and closing the tube.

For the measurements on *Chlorella*, a 500-watt projection lamp was used with a lens and three filters—a 10 cm. filter solution of 0.5% $CuSO_4$, 5 cm. of water, and a Corning signal red #243 filter. The parallel beam of light is diaphragmed down until it barely fills the whole calorimeter cell. The calorimeter is filled and emptied with micropipets having capillary outlets. The top of the aluminum block is removed and a piece of filter paper is placed over the top of the quartz calorimeter cell. The stoppers of the cell are allowed to protrude through holes in the filter paper and when they are replaced, the rims are dried and covered with a trace of glycerol. A slight variation in the calibration value from day to day was traced to different humidity of the laboratory air. Occasionally the galvanometer deflection in the dark was abnormal due to evaporation of traces of moisture, but this difficulty was corrected by sweeping through a current of dry air.

Calibration.—The thermopile registered 1 cm. deflection for each 102 ergs per second, as measured with a Bureau of Standards radiation lamp, after correction for the reflection at the quartz window. The calorimeter was calibrated with a beam of light and the thermopile as shown in Table I where R is the thermopile reading with the calorimeter removed and r is the thermopile reading when the light is partially absorbed by the calorimeter cell. The energies absorbed as shown in the third column contain small corrections for reflections at the rear window back into the calorimeter. A slight cloudiness on the calorimeter windows necessitated another correction when

TABLE I

CALIBRATION OF PHOTOCALORIMETER

				Average	84.4

measuring the heat of chemical reactions. The calorimeter–galvanometer deflections are given in the fourth column for the different energy imputs. These steady-state values are reached a few minutes after the light is introduced and remain constant indefinitely, as long as the intensity of light being absorbed remains constant. Under these conditions, the rate of absorption of radiant heat is exactly offset by the rate at which heat is lost to the colder aluminum block. Different absorbing materials were used, india ink and colloidal silver, and since both gave the same calibration value, it is safe to assume that they are chemically inert.

The calorimeter–galvanometer deflections are straight line functions of the amount of energy being absorbed, at least in the range 600 to 5300 ergs per second. The averaged result shows that each cm. deflection, in the steady state, corresponds to an absorption of 84.4 ergs per second.

The calibration described here was made before and during the first eleven experiments reported in Table II. Calibration measurements were repeated from time to time and it was found that the sensitivity of the calorimeter decreased slowly with use. The de Khotinsky cement was apparently unable to keep constant the thermal contact between the thermocouples and cell. The last determinations were made nine months later and in these, 1 cm. deflection corresponds to the absorption of 96 ergs per second.

The calorimeter was tested with the inversion of cane sugar and a value in good agreement with accepted values was obtained.[3] This reaction is, of course, thermal and serves as an entirely independent check on the calibration.

Measurements on Photosynthesis.—The algae used were *Chlorella vulgaris* or *Chlorella pyrenoidosa* grown under standard conditions in Warburg nutrient solution. The Department of Botany coöperated in this work. The details of the growing conditions are given elsewhere.[2,4] The light treatment was about the same for all: namely, one week at a high light intensity and one week at a lower light intensity.

Preliminary measurements indicated that the algae use only a small fraction of the absorbed energy in photosynthesis, about 20%. These measurements were made on suspensions of algal cells (approximately 15,000,000 cells per cc.) in the Warburg nutrient solution and were complicated by the settling of the algae. The time required for the calorimeter system to reach equilibrium was so long that settling began to take place and it was impossible to obtain very accurate values of the thermal efficiency. The qualitative results, however, indicated that the low quantum yields were real.

It was found that the addition of less than 0.1% agar rendered the settling of the algae much slower. A gel was not formed. Agar was used in all of the reported work. Quantum yield measurements made with the dropping mercury electrode on these algae indicated that they behaved normally.[4]

Measurement of the steady-state deflections for the illuminated algae had to be delayed two hours for the calorimeter system to come to complete equilibrium. Enough carbon dioxide was present so that there was no danger of its exhaustion; accordingly the samples were usually illuminated while the equilibrium was being reached. In some experiments, the algae were left in the dark for the first hour and then illuminated the second hour. Photosynthesis steady-state values will be designated P.

In order to obtain the thermal efficiency of photosynthesizing algae, the rate of heat evolution due to respiration also must be known. The difference between the steady-state deflection during photosynthesis and the deflection caused by the respiration gives the net amount of absorbed radiation being dissipated as heat by the algae per unit time. The total absorption of energy is measured by means of the thermopile. The fraction of absorbed energy dissipated as heat is the ratio of these two quantities. A difficulty in determining the respiration value arises from the slowness of the calorimeter in reaching a steady-state value when illumination is started or discontinued. The algae, being in a closed cell, use up their oxygen and the respiration falls to a lower value before the proper deflection is reached. This difficulty was met by determining the rate of cooling immediately after the light is turned off.

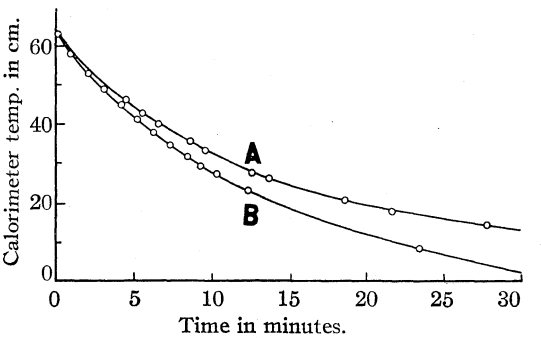

Fig. 2.—Cooling curves: A, with inert material; B, with respiring algae.

A cooling curve with inert material in the calorimeter is given at B in Fig. 2 and the cooling curve of algae after being illuminated is given at A. The slower rate of cooling of A is due to the heat added from respiration of the algae. Whereas curve B approaches zero deflection asymptotically, curve A approaches asymptotically a fixed deflection (temperature). This fixed deflection a is a measure of the respiration and is calculated from deflections shortly after turning off the light, since, at that time, the heat effect is not complicated by the settling of the algae nor the decreas-

[a] A determination on this sample with the dropping mercury electrode gave a quantum yield of 0.073.

ing rate of respiration caused by the gradual exhaustion of oxygen.

The calorimeter deflections, x, which are proportional to temperature differences, obey approximately the cooling law

$$\frac{-dx}{dt} = k(x - a)$$

or

$$\ln \frac{x - a}{x_0 - a} = -kt$$

where x_0 is the value of x when the time t is zero.

Then in the form

$$a = \frac{x - x_0 e^{-kt}}{1 - e^{-kt}}$$

it is easy to evaluate a from a few readings near the beginning of a cooling curve with algae. Constant k is evaluated from the slope of the straight line produced by plotting log x against t when the calorimeter is filled with an inert material, as in curve B.

In order to calculate the quantum yield from the thermal efficiency, an assumption regarding the chemical reaction must be made. It is generally believed that the photosynthesis reaction is

$$CO_2 + H_2O + Nh\nu \longrightarrow 1/6\ (C_6H_{12}O_2) + O_2 \qquad \Delta H = 112{,}000 \text{ cal.}$$

The energy of an einstein of the light used (approximately 6500 Å.) was roughly 43,000 cal. per mole. Thus, for the above reaction with 100% energy efficiency a maximum quantum yield of 43,000/112,000 = 0.38 is obtained. The observed energy efficiency multiplied by 0.38 gives the values listed as quantum yields.

The data are given in Table II for the seventeen experiments carried out in this way. The incident energy given in the first column is only slightly less than the incident energy per square cm. since the cell window is about 1 sq. cm.

An examination of the data of Table II shows that the conditions were varied over a considerable range, the incident light intensity ranging from 950 to 6700 ergs per second and the energy absorption by algae from 200 to 5100 ergs per second. The absorption of energy in the photocalorimeter is determined by the concentration of algae as well as by the intensity of incident light. The difference between the second and third columns is due partly to reflection and partly to a correction for energy absorbed in the imperfect face of the photocalorimeter. In some of the experiments the concentration of algae was so low that respiration was hardly detectable and the results cannot be considered accurate. In these experiments, there may have been a slight evaporation of moisture from the cell which balanced the heat

of respiration. Only the difference $P - a$ is important in determining the efficiency, however, and such errors cancel in the result.

In some cases the quantum efficiencies were determined also by the dropping mercury electrode,[4] using the same cultures of algae. The average quantum yield of the last six determinations is 0.077 by the calorimeter, and 0.063 by the dropping mercury electrode. In the third from the last, the two different measurements were made on samples of the same solution of algae at the same time. The agreement is within the experimental error.

Discussion

The average of the quantum yields obtained in Table II, namely, 0.08 molecule of carbon dioxide consumed per quantum absorbed, is in good agreement with other investigations in this Laboratory[2,4] and gives a much lower value than the generally accepted value of 0.25.[1]

The respiration corrections work in the direction to increase the efficiency and most of the uncertainty in the calculations of the quantum yield is connected with the measurements of this quantity. When the oxygen is partially depleted by respiration, the respiration is slower and subject to larger variations. Under these conditions, the rate of respiration may be affected by factors which do not matter when the oxygen supply is larger. After sufficient photosynthesis, there is, of course, an ample supply of oxygen, corresponding to saturation of oxygen.

The quantum yields apparently do not depend greatly upon the factors which change respiration rates.[5] The rate of respiration is not proportional to oxygen concentration or rate of photosynthesis, although at very low concentrations it tends to increase with both. The concentration of oxidizable intermediates is, of course, increased with increasing rate of photosynthesis, and so the general tendency is for respiration to increase with light intensity.

This work corroborates the low quantum yields in photosynthesis obtained in the Wisconsin laboratory and indicates that the algae are much less efficient than expected on the basis of Warburg's results. These efficiencies based on thermal measurements appear to run slightly higher than those based on measurements of oxygen. If such a difference should be definitely established, it might indicate the existence of intermediate steps involving less heat absorption than that which is involved in combining carbon dioxide and water to give oxygen and carbohydrate.

The authors wish to express their appreciation to Professor B. M. Duggar of the Department of Botany for advice; and to Dr. W. M. Manning, Dr. H. G. Petering, and Mr. W. E. Moore for advice and experimental assistance. The dropping mercury electrode measurements were made by Mr. Moore. They wish also to thank the Wisconsin Alumni Research Foundation for aid in carrying out this investigation.

Summary

1. A small calorimeter is described capable of measuring a rate of heat change as small as a millionth of a calorie per second. It is designed to admit light and thus give a measurement of heat changes accompanying photochemical reactions.

2. The thermal efficiency of photosynthesis by green algae has been measured. About four-fifths of the red light absorbed in living algae is converted into heat, leading to a quantum yield of about 0.08 molecule per quantum absorbed.

The Critical Increment of Ionic Reactions. IV. The Influence of Dielectric Constant and Ionic Strength[1]

BY LOUIS RAMPINO[2] AND W. J. SVIRBELY

In this investigation the conversion of ammonium cyanate to urea has been carried out over a temperature range of 30 to 60° in isodielectric mixtures of water with isopropanol over a dielectric range of 63.5 to 20. The critical increments obtained from the corresponding rate constants are compared with those obtained from theoretical equations previously derived and used.[3] Comparison is also made with other existing kinetics theories.

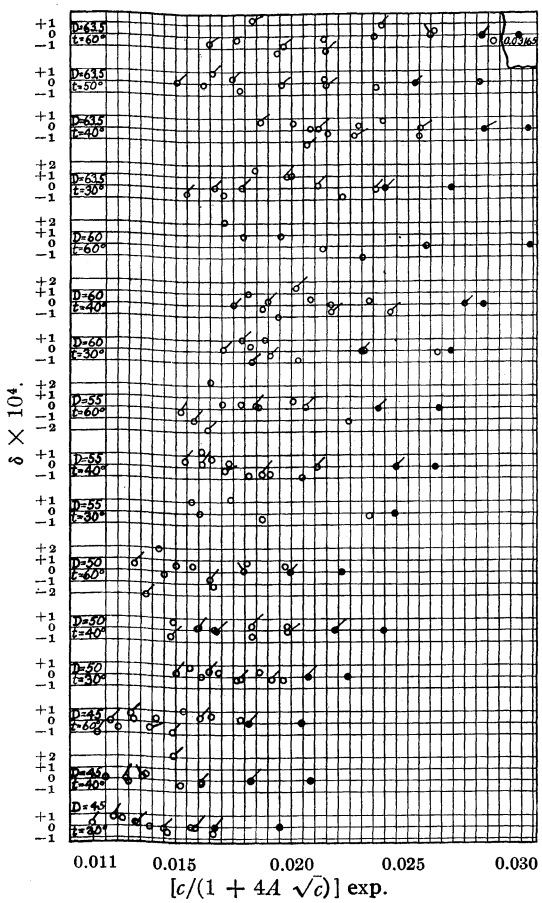

Fig. 1.—Isopropyl alcohol–water mixtures.

of sodium, the boiling point being 82° (uncorr.). All other materials were prepared or purified as described in previous papers,[3] which also describe the procedure used in this investigation. Temperatures were checked against a thermometer calibrated by the Bureau of Standards. Thermostat temperatures were maintained constant within ±0.01°. Dielectric constants for the isopropanol–water mixtures were taken from the work of Åkerlöf.[5]

Average values of the limiting velocity constant at $\mu = 0$ listed in Table I were obtained by means of the usual equation[3,6]

$$k_0 t = \left(\frac{1 + 4A\sqrt{C}}{C}\right) - \left(\frac{1 + 4A\sqrt{C^0}}{C^0}\right) \quad (1)$$

Derivations (δ) of the experimental value of $C/(1 + 4A\sqrt{C})$ from the value calculated from the average k_0 are plotted[3,6] against the experimental values of this function in Figs. 1 and 2. In Table II we give velocity constants (k_1) at $\sqrt{\mu} = 0.194$ obtained from k_0 by the relation[3,6]

$$k_1 = \frac{k_0}{1 + 2A\sqrt{\mu}} \quad (2)$$

If log k_0 is plotted against $1/T$ for the various isodielectric mixtures, then one may express the linear plots as well as those of log k_1 against $1/T$ by means of the general equation

$$\log k = \log K - (E/4.58T) \quad (3)$$

Values of log K_0 and E_0 and of log K_1 and E_1 obtained by means of equation (3) are listed in Tables I and II, respectively. Values of k_0 and k_1 calculated by equation (3) using the tabulated values of log K and E are also shown in the tables.

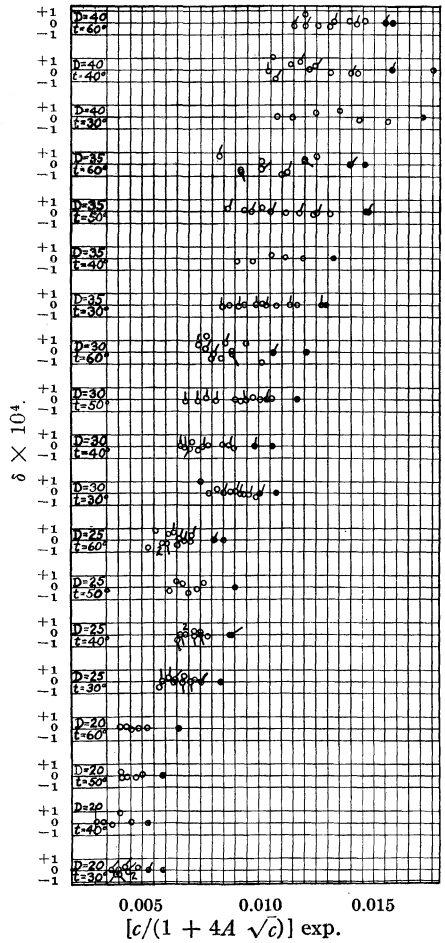

Fig. 2.—Isopropyl alcohol–water mixtures.

From the equation[3]

$$(E^0)\text{fixed comp.} = (E^{0*}_D) + 2.3RT^2\left(\frac{\partial \log k_0}{\partial D}\right)\frac{dD}{dT} \quad (4)$$

one obtains in this case using water as the solvent of fixed composition

$$(E^0)_{H_2O} - (E^{0*}_D) = 620T/D \quad (5)$$

At 50°, using equation (5), one calculates the difference between the two critical increments to be

(5) Åkerlöf, THIS JOURNAL, **54**, 4125 (1932).
(6) Warner and Warrick, *ibid.*, **57**, 1491 (1935).

2860 cal. Using the experimental values of the E_0's given in Table I and taking E_0 in water[3] to be 23,580 cal., one observes that the difference between the two critical increments varies between 2830 to 2700 cal. in the isodielectric mixtures from 63.5 to 30. The difference becomes larger at the dielectric values of 25 and 20. Thus E^{0*}_D apparently is independent of the dielectric constant over the major portion of the dielectric range covered.

One may calculate the critical increment at a fixed ionic strength by means of the equation[3]

$$E = E^0 + \frac{(12.5 \times 10^6 \sqrt{\mu} RT)}{(TD)^{3/2} + 8.36 \times 10^6 \sqrt{\mu}} \left(1 + \frac{\mathrm{d} \ln D}{\mathrm{d} \ln T}\right) \quad (6)$$

The values for E at $\sqrt{\mu} = 0.194$ have been obtained using equation (6) and are listed in Table II. These results are in good agreement with the E's obtained by equation (3).

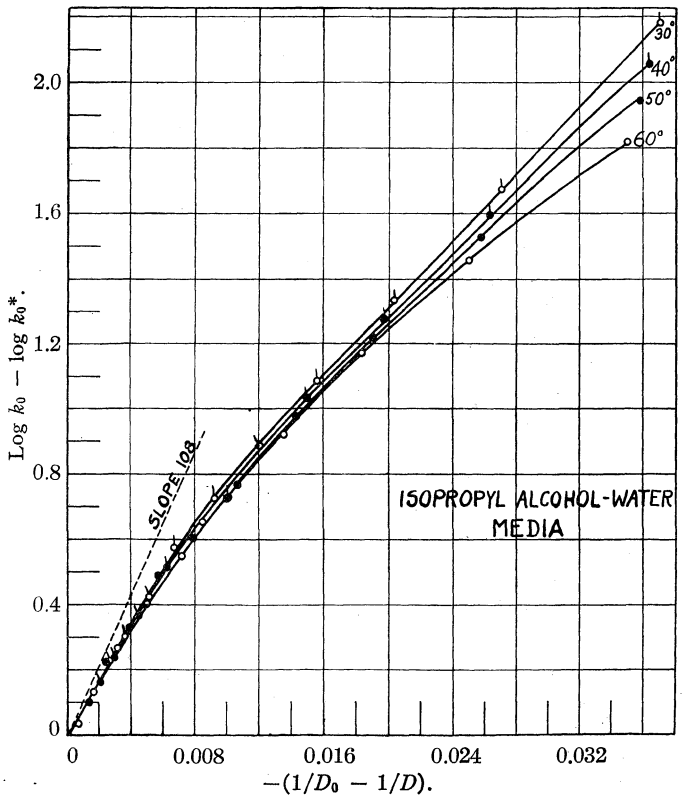

Fig. 3.

Deviations from the linearity predicted by Scatchard's[7] equation

$$\log k_0 - \log k_0^* = \frac{e^2 Z_A Z_B}{2.3KTr}\left(\frac{1}{D^0} - \frac{1}{D}\right) \quad (7)$$

are obtained when (log k_0 − log k_0*) are plotted against $(1/D^0 - 1/D)$. These plots are shown in Fig. 3 at the various temperatures. The limiting slopes of the curves are in fair agreement with the predicted values assuming $r = 2 \times 10^{-8}$ cm.

As pointed out before, an empirical relation can be obtained between the dielectric effect and the temperature effect on the value of the limiting velocity constant, namely

$$\left(\frac{\Delta k_0}{\Delta D}\right)_T = -C\left(\frac{\Delta k_0}{\Delta T}\right)_D \quad (8)$$

Using the values in Table I, one observes that C has an average value[8] of 0.52 from $D = 60$ to $D = 40$. On going to lower dielectrics C increases reaching an average value of 2.80 at $D = 20$.

Referring to the values of log K_0 and log K in Tables I and II, it is observed that for any isodielectric mixture the two values are fairly constant. However, as one goes to lower dielectrics (D = 63.5 to $D = 30$) a continual increase is obtained. This behavior of log K_0 is similar to that observed in the isodielectric glycol–water mixtures[3] and also in isodielectric dioxane–water mixtures (forthcoming paper). La Mer's[9] treatment for reactions predicts constancy[10] for the log K's (B in his notation).

Taking into account the various factors which should influence the critical increment, La Mer[9] developed an equation which in isodielectric media and at zero ionic strength becomes

$$(\Delta E^{0*}_D)_{\sqrt{\mu}=0} = \Delta E_0 + \frac{Z_A Z_B N e^2}{D}\left(\frac{1}{r_A + r_B}\right) \quad (9)$$

where (ΔE^{0*}_D) is the critical increment in isodielectric media, ΔE_0^* refers to the energy contribution for the reactants as uncharged molecules and the other terms have the usual meanings. Using the experimental values of ΔE^{0*}_D at $D = 63.5$ one calculates ΔE_0^* to be 23,360 cal. Values of ΔE^{0*}_D calculated from this value of ΔE_0^* by means of equation (9) assuming $(r_A + r_B) = 2 \times 10^{-8}$ cm. are given in Table I. The agreement at the higher dielectric constants is as good as should be expected considering the limitations imposed

(7) Scatchard, *Chem. Rev.*, **10**, 229 (1932).

(8) We wish to point out an error in the paper using glycol–water mixtures, Ref. 3, where C should be 0.55.

(9) Amis and La Mer, THIS JOURNAL, **61**, 905 (1939).

(10) It should be pointed out that this constancy is obeyed for this reaction in isodielectric methanol media.

on equation (9), especially due to the assumption of a constant value for $r_A + r_B$.[11]

In testing the collision theory in terms of the thermodynamic theory as developed by La Mer[9] the following equation is obtained when the P factor is assumed = 1

$$\frac{RT}{Nh} e^{\Delta S^*/R} = \frac{N}{1000} \sigma_{12}^2 \left[8\pi RT \left(\frac{1}{M_1} + \frac{1}{M_2}\right)\right]^{1/2} \quad (10)$$

where N = Avogadro's number, h = Planck's constant, M_1 and M_2 are the molecular weights of the reactants and σ_{12} is the distance of the approach between centers of reactants for an effective collision. Substituting in the various values at $t = 60°$ using $M_1 = 18$, $M_2 = 42$, and clearing one obtains

$$\log \sigma_{12} = {}^1/_2(\Delta S^*/2.3R) - 6.7125 \quad (11)$$

which in turn[9] leads to

$$\log \sigma_{12} = {}^1/_2 (\log K_0 - \log (RT/hN)) - 6.7125 \quad (12)$$

Since $\log RT/hN = 14.1520$ (min.$^{-1}$) at 60° then equation (12) becomes

$$\log \sigma_{12} = \frac{\log K_0}{2} - 13.791 \quad (13)$$

Using the values of $\log K_0$ given in Table I, σ_{12} can be determined in the various isodielectric media by means of equation (13). This method gives $\sigma_{12} = 4.83$ Å. at $D = 63.5$, and then σ_{12} increases to a maximum value of 19.4 Å. at $D = 30$. Thus at the higher dielectrics the collision theory is in satisfactory agreement with the thermodynamic treatment although at the lower dielectrics the agreement is less satisfactory.

Finally as to the behavior of this reaction in $D = 25$ and $D = 20$ media as evidenced by the very marked drop in ΔE and in $\log K_0$, we can offer no definite answer. Undoubtedly association plays some part as the dielectric constant is decreased and probably the mechanism of the reaction itself changes. Due to this uncertainty concerning the mechanism and the inadequacy of equations (1) and (2) in the solvents of lower dielectric constant, we are presenting the actual time–concentration data in Table III on typical experiments at 40° in solvents of dielectric constants 30, 25 and 20, along with the second order constants calculated for a mean ionic strength at various concentration ranges by the graphical method.[6]

TABLE III

(11) In glycol–water media the agreement between ΔE^*_D calculated and ΔE^*_D by experiment is comparable to that found in this investigation. It is rather surprising that considerably better agreement is found in methanol–water media.

Finally as to the behavior of this reaction in $D = 25$ and $D = 20$ media as evidenced by the very marked drop in ΔE and in $\log K_0$, we can offer no definite answer. Undoubtedly association plays some part as the dielectric constant is decreased and probably the mechanism of the reaction itself changes. Due to this uncertainty concerning the mechanism and the inadequacy of equations (1) and (2) in the solvents of lower dielectric constant, we are presenting the actual time–concentration data in Table III on typical experiments at 40° in solvents of dielectric constants 30, 25 and 20, along with the second order constants calculated for a mean ionic strength at various concentration ranges by the graphical method.[6]

Summary

1. The rate of conversion of ammonium cyanate to urea has been studied over the temperature range 30 to 60° in isodielectric mixtures of isopropanol with water over the dielectric range of 63.5 to 20.

2. The influence of ionic strength upon the observed critical increments at zero ionic strength is in good agreement with equations previously derived. It is observed that the critical increment is apparently independent of the dielectric constant in isodielectric mixtures over the major portion of the range investigated.

3. From $D = 63.5$ to $D = 40$, the following empirical relation holds

$$\left(\frac{\Delta k_0}{\Delta D}\right)_T = -0.52 \left(\frac{\Delta k_0}{\Delta T}\right)_D$$

4. At the higher dielectric constants, the influence of the dielectric constant of the solvent upon the rate constants is in as good agreement with the Scatchard–Christiansen theory as can reasonably be expected.

5. The value of the collision factor Z in the Arrhenius theory varies with dielectric constant.

6. Comparisons are made between the observed critical increments and those calculated by the thermodynamic treatment of La Mer.

7. The collision theory is shown to be in satisfactory agreement with the thermodynamic treatment at the higher dielectrics used.

BUFFALO, N. Y.
COLLEGE PARK, MARYLAND RECEIVED AUGUST 4, 1939

[JOINT CONTRIBUTION FROM THE CHEMISTRY LABORATORIES OF THE UNIVERSITY OF MARYLAND AND OF CANISIUS COLLEGE]

The Critical Increment of Ionic Reactions. V. The Influence of Dielectric Constant and Ionic Strength[1]

BY W. J. SVIRBELY AND JAMES LANDER

The investigation of the conversion of ammonium cyanate to urea in isodielectric mixtures of various solvent–water media has been continued in this research using isodielectric mixtures of dioxane–water. The reaction has been studied over a temperature range of 30 to 60° in isodielectric media having a dielectric constant range of 63.5 to 5. The critical increments obtained from the experimental data are compared with those calculated from theoretical equations previously given.[2] Comparison is also made with other existing solution kinetics theories.

Experimental and Discussion

The dioxane was refluxed over calcium oxide and over sodium for about twenty-four hours. It was then distilled twice, the middle portions of each run being collected. The final fraction had a freezing point of 11.72°. The preparation of other materials, purification, experimental procedure, etc., have already been described.[2] Dielectric constants for the dioxane–water media were taken from the work of Åkerlöf and Short.[3] In the preceding paper[2] of this series, these equations were given

$$k_0 t = \left(\frac{1 + 4A\sqrt{C}}{C}\right) - \left(\frac{1 + 4A\sqrt{C^0}}{C^0}\right) \quad (1)$$

$$k_1 = \frac{k_0}{1 + 2A\sqrt{\mu}} \quad (2)$$

$$\log k = \log K - \frac{E}{4.58T} \quad (3)$$

$$(E^0)_{\text{fixed comp.}} = (E^{0*}_D) + \frac{2.3RT^2}{} \left(\frac{\partial \log k_0}{\partial D}\right) \frac{dD}{dT} \quad (4)$$

$$E = E^0 + \frac{12.5 \times 10^6 \sqrt{\mu}\, RT}{(TD)^{3/2} + 8.36 \times 10^6 \sqrt{\mu}} \left(1 + \frac{\text{d ln } D}{\text{d ln } T}\right) \quad (5)$$

From equation (4) one obtains in dioxane–water media with water as the solvent of fixed composition the relation

$$(E^0)_{H_2O} - (E^{0*}_D) = 587T/D \quad (6)$$

Equation (6) leads to a difference of 2720 cal. between the two critical increments at 50°. The experimental differences using 23,580 cal.[2] for $(E^0)_{H_2O}$ and using the values of the E^{0*}_D's given in Table I vary from 3570 cal. at $D = 63.5$ to 4810 cal. at $D = 20$ and then they decrease again.

Reference to Table I shows that E^{0*}_D is apparently constant over part of the higher dielectic range, then it decreases until a minimum value around $D = 20$ is reached and after that a rapid increase occurs. We shall show later that even if we use a more extended equation for calculating the k_0's and consequently should get more reliable E_0's at the lower dielectrics, nevertheless the minimum still exists.

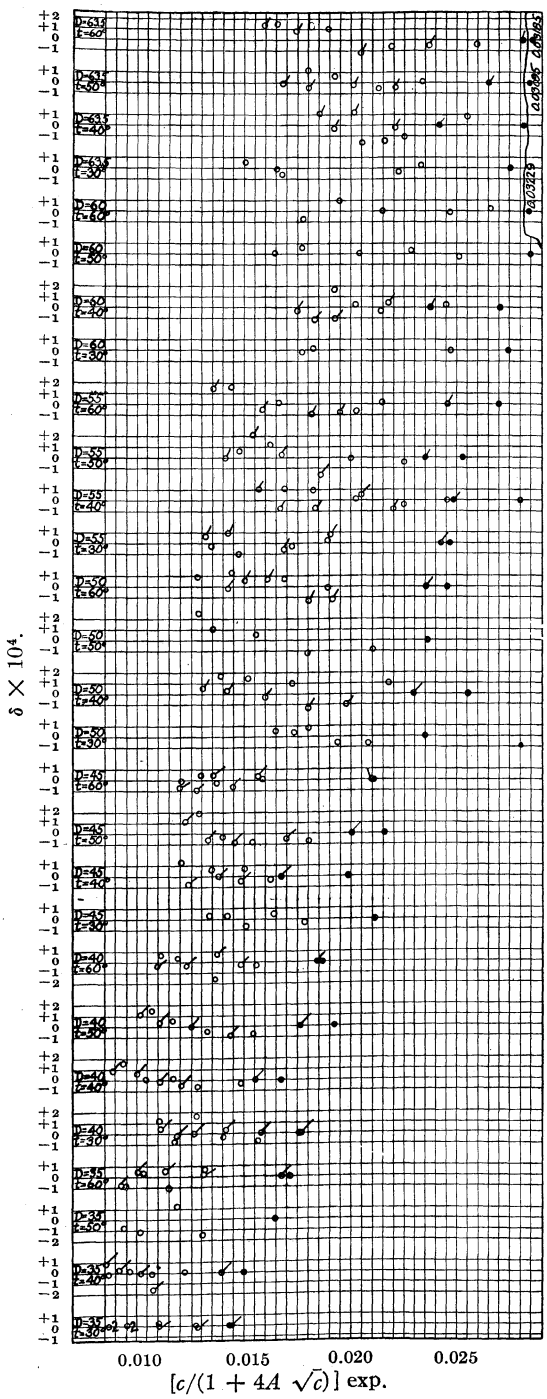

Fig. 1.—Dioxane–water mixtures.

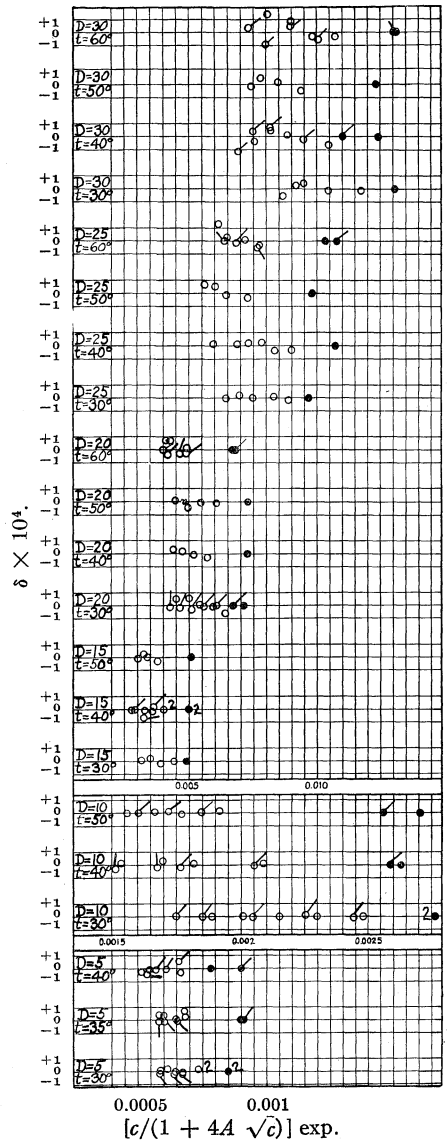

Fig. 2.—Dioxane–water mixtures.

Using equation 5, the values of E at $\sqrt{\mu} = 0.194$ have been calculated and collected in Table II. These results are in good agreement with the experimental E's.

Similarly to the results in the other solvent–water mixtures, we find in this case deviations from the linearity predicted by Scatchard's equation[4]

$$\log k_0 - \log k_0^* = \frac{e^2 Z_A Z_B}{2.3KTr}\left(\frac{1}{D^0} - \frac{1}{D}\right) \qquad (7)$$

when $(\log k_0 - \log k_0^*)$ is plotted against $(1/D^0 - 1/D)$. These plots are shown in Fig. 3 at the

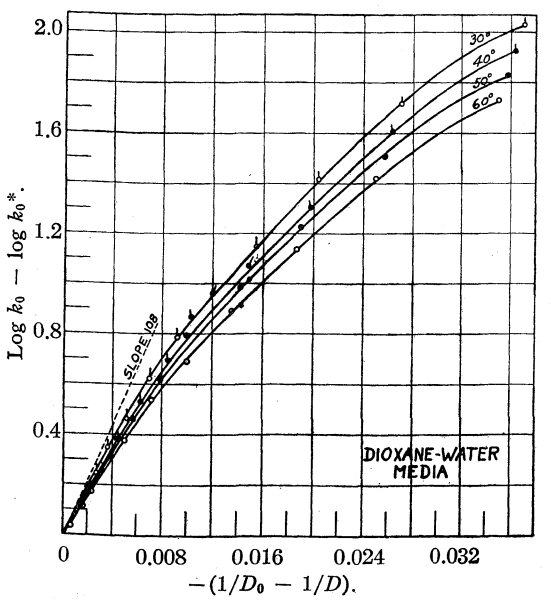

Fig. 3.

various temperatures. The limiting slopes of the curves are in good agreement with the predicted values assuming $r = 2 \times 10^{-8}$ cm. In Fig. 3 we have not shown all of the data obtained. The complete curves tend to flatten out although the slopes are still finite.

The effect of dielectric change and of temperature change on the limiting velocity constant can be expressed by the empirical relation[2]

$$\left(\frac{\Delta k_0}{\Delta D}\right)_T = -C\left(\frac{\Delta k_0}{\Delta T}\right)_D \qquad (8)$$

Using the values of k_0 listed in Table I, it can be shown that C has an average value of 0.61 from $D = 60$ to $D = 35$. On going to lower dielectrics the value of C increases, reaching a value of 14 at $D = 5$.

La Mer's[5] thermodynamic treatment of reactions predicts constancy for the log K's shown in Tables I and II. It is observed that the agreement between the log K's in the two tables in the same isodielectric mixture down to $D = 25$ is good. There is however a tendency toward increased values of the log K's as the dielectric constant is decreased. The increase is not as large however as in the isopropanol–water mixtures.[2]

In calculating critical increments La Mer[5] developed an equation which in isodielectric media and at zero ionic strength becomes

$$(\Delta E^{0*}_D)_{\sqrt{\mu}=0} = \Delta E_0{}^* + \frac{Z_A Z_B N e^2}{D}\left(\frac{1}{r_A + r_B}\right) \qquad (9)$$

$\Delta E_0{}^*$, the energy contribution for the reactants as uncharged molecules can be calculated from the value of (ΔE^{0*}_D) at $D = 63.5$ and is 22,620 cal. Using this value of $\Delta E_0{}^*$, values of ΔE^{0*}_D have been determined by means of equation (9) assuming $(r_A + r_B) = 2 \times 10^{-8}$ cm. and are given in Table I. Here again, as in the previous investigation, the agreement between ΔE^*_D calculated and ΔE^*_D by experiment is as good at the higher dielectric constants as could reasonably be expected.

Using La Mer's method[5] for testing the collision theory in terms of the thermodynamic theory, one can calculate σ_{12}, the distance of nearest approach between the centers of the reactants for an effective collision, by means of the equation[2]

$$\log \sigma_{12} = \log K_0/2 - 13.791 \qquad (10)$$

Using the values of log K_0 in Table I, one obtains $\sigma_{12} = 2.75$ Å. at $D = 63.5$. The values then increase to $\sigma_{12} = 5.42$ Å. at $D = 25$. It is interest-

(5) Amis and La Mer, THIS JOURNAL, **61**, 905 (1939).

ing to observe that using equation (10) at the higher dielectrics where it should hold best one obtains a variety of σ_{12} values for the reactants in the various solvent–water mixtures in which this reaction has been studied. For example, at D = 63.5, σ_{12} equals 1.24 Å., 3.54 Å., 4.83 Å., 2.75 Å. in methanol, glycol, isopropanol and dioxane mixtures, respectively. It is possible that specific solvent influences may be responsible for these variations.

One may compare the percentages by weight of the non-aqueous solvents in the solvent–water mixtures just mentioned at each temperature and at each dielectric value with the values of the limiting velocity constant obtained in order to observe whether the variation in the k_0's seems to depend on the amount of non-aqueous solvent added. No correlation is observed. Plots of log k_0 *versus* $1/D$ are shown in Fig. 4. It is seen that the dioxane, isopropanol, and glycol curves are fairly close to each other at each temperature although the order of the curves is not the same at all of the temperatures. However, placing each solvent in the order of increasing percentage of non-aqueous solvent, we have dioxane, isopropanol, methanol and glycol, respectively.

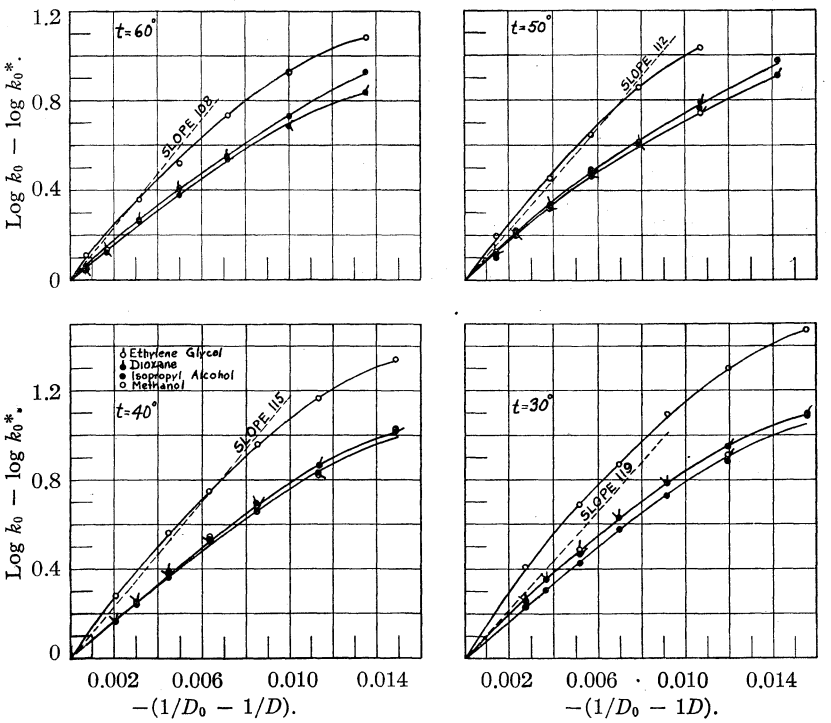

Fig. 4.

It was considered worth while to develop a more accurate method of calculating the limiting velocity constant and observe whether or not the new results would influence the conclusions previously drawn. Starting with the equation[4]

$$\ln k = \ln k_0 + \frac{2.3e^2Z_AZ_B\kappa}{DKT\ (1 + \kappa b)} \qquad (11)$$

substituting in the various terms and using the well-known relation

$$k = k_0 \frac{\gamma_A\gamma_B}{\gamma_x} \qquad (12)$$

one obtains

$$\frac{\gamma_A\gamma_B}{\gamma_x} = e - a\sqrt{\mu}/(b + d\sqrt{\mu}) \qquad (13)$$

where

$$a = 8.35 \times 10^6$$
$$b = (DT)^{3/2}$$
$$d = 100\ DT$$

Following Scatchard's[6] method equation (13) becomes

$$\frac{\gamma_A\gamma_B}{\gamma_x} = \frac{b + d\sqrt{\mu}}{b + d\sqrt{\mu} + a\sqrt{\mu}} \qquad (14)$$

Applying Scatchard's[6] treatment of the rate of reaction in a changing environment, the Brönsted rate equation on using equation 14 becomes

$$\frac{dx}{dt} = \frac{k_0C_0(1 - x)^2\ (b + d\sqrt{C_0}\sqrt{1 - x})}{b + (a + d)\sqrt{C_0}\sqrt{1 - x}} \qquad (15)$$

where $x = (C_0 - C)/C_0$. Clearing and integrating by parts equation (15) becomes

$$\left(\frac{2A\sqrt{C_0}}{b} + 1\right)\left(\frac{1}{C} - \frac{1}{C_0}\right) + \frac{2ad}{b^2}\ln\frac{\sqrt{C}\ (b + d\sqrt{C_0})}{\sqrt{C_0}\ (b + d\sqrt{C})} = k_0t \qquad (16)$$

Using equation (16) values of k_0 were calculated for some of the isodielectric media and are given in Table III. Comparison of the values of k_0 in Tables I and III shows that with equation (16) one obtains higher values of k_0 than with equation (1). However, the values of ΔE are not affected down to D = 25. The increase in log K_0

is still obtained. The minimum in ΔE is emphasized more than before due to the large increase in ΔE at $D = 5$. This increase may only be an apparent one due to the method of calculation and it may be necessary for an entirely new treatment in low dielectrics to allow for association effects.

In solvents of $D \geqq 25$, calculations by equation (1) and by (16) lead to essentially the same values for E and log K_0 and we therefore could see no advantage in recalculating all of our results by the use of equation (16). Equation (16) apparently represents only a slight improvement over equation (1) and neither equation is adequate for calculating true k_0 values in the solvents of lower dielectric constant. We, therefore, are giving the actual time–concentration data for typical experiments at 40° in solvents of dielectric constants 25, 20, 15, 10 and 5 in Table IV. The ordinary bimolecular constants over finite ranges of concentration are also given in the table.

Summary

1. The rate of conversion of ammonium cyanate to urea has been studied over the temperature range 30 to 60° in isodielectric mixtures of dioxane with water over a dielectric range 63.5 to 5.

2. The influence of ionic strength upon the observed critical increments at zero ionic strength is in good agreement with the theory. It is observed that the critical increment first decreases somewhat with the dielectric constant and then increases, with a minimum appearing at about $D = 20$.

3. From $D = 63.5$ to $D = 35$, the following empirical relation holds

$$\left(\frac{\Delta k_0}{\Delta D}\right)_T = -0.61 \left(\frac{\Delta k_0}{\Delta T}\right)_D$$

4. The influence of the dielectric constant upon the rate constants is in reasonably good agreement with the Scatchard–Christiansen theory at the higher dielectric constants.

5. The value of the collision factor Z varies somewhat with the dielectric constant, especially at the lower dielectric constants.

6. The collision theory is shown to be in satisfactory agreement with the thermodynamic treatment in the higher isodielectric mixtures.

7. The new method of calculating the limiting velocity constants leads to higher values but does not influence the conclusions previously drawn.

Thermal Data on Organic Compounds. XIX. Modern Combustion Data for Some Non-volatile Compounds Containing Carbon, Hydrogen and Oxygen

BY J. WILFRED RICHARDSON AND GEORGE S. PARKS

The heat of combustion of an organic compound constitutes a very important quantity in the calculation of the free energy of formation of the compound by means of the third law of thermodynamics and the fundamental equation $\Delta F = \Delta H - T\Delta S$. Unfortunately, until very recently it has often been the most serious source of error in the resulting free energy value because most of the available combustion data were determined prior to 1900 when calorimetric methods and the purification of substances had not reached so high a standard as at present. For this reason there is now a very urgent need for new combustion data on organic compounds, and accordingly an extensive program of such thermochemical studies has been undertaken at Stanford University.

In this paper we shall summarize the data obtained in an investigation of the heats of combustion of β-methylnaphthalene, phthalic anhydride, phthalic acid, anthracene, phenanthrene, stilbene, pyrene, *n*-hexadecane, cetyl alcohol, 1,3,5-triphenylbenzene, and a sample of polyisobutylene.

Method and Apparatus

The bomb calorimeter was chosen as the type to be used in this investigation because it is best suited for work with solids or liquids of low volatility. After considerable preliminary experimentation our calorimetric apparatus was finally patterned very closely after that described by Huffman and Ellis[1] and our entire procedure became essentially the same as theirs. For this reason we shall forego here any detailed description of our calorimetry and merely present the important characteristics of the apparatus and one or two minor differences from the methods of Huffman.

Our "Parr bomb" had a capacity of 390 ml. Platinum wire was employed as the ignition medium to avoid the somewhat uncertain correction due to oxidation of the iron wire, which is so often used; and the electrical energy introduced in the ignition process was determined accurately by measurements of time, current, and voltage. A small piece of cotton string (instead of the filter paper in Huffman's procedure) was ignited by the platinum wire and this in turn ignited the sample of material under study, which had been placed in a platinum crucible. The heat of combustion of the string was found to be 4169 (±2) cal. per gram, weighed in air. Before each combustion 1 ml. of water was placed in the bomb, which was then filled with pure commercial oxygen to a pressure of 30 atm. at 22°.

In many of the experiments the air initially in the bomb was washed out by filling the bomb at least twice with oxygen to a pressure of 5 atm. and then allowing it to escape until the pressure was reduced to 1 atm. However, there was always present a small quantity of nitrogen within the bomb and the consequent nitric acid produced in the combustion process was titrated with $N/14.55$ sodium carbonate solution. The magnitude of the thermal correction for this nitric acid, calculated on the basis of an evolution of 14,550 cal. per mole of aqueous nitric acid formed, was about 10 calories if the air was not previously washed out and about 1 calorie if it was washed out.

Water for the calorimeter, ordinarily 2780 g., was weighed to 0.05 g. on a high capacity balance. The mass of the material to be burned was determined to 0.00001 g. on a Kuhlmann microchemical balance.

The temperature rise in the calorimeter was measured by a platinum resistance thermometer calibrated by the Bureau of Standards, a Mueller thermometer bridge, a high sensitivity galvanometer, and a lamp-and-scale reading device, all supplied by the Leeds and Northrup Co. The sensitivity of the system was such that a change of 0.00001 ohm (0.0001°) in the resistance of the thermometer caused the reflection from the galvanometer mirror to shift 2 mm. on the scale. The galvanometer was used as a null point instrument in conjunction with a chronograph precise to 0.1 second.

The corrected temperature rise was calculated by the method described by Dickinson.[2] From this temperature rise and the sum of the energies supplied the energy equivalent of the system at 25° was calculated in the calibration experiments; and conversely with the aid of this last quantity the various combustion results were subsequently derived.

Units.—The unit of energy throughout this paper is the defined conventional calorie which has been derived from the international joule by multiplying by the factor 1.0004/4.185. The unit of mass is the gram true mass which is derived from the weight in air against brass weights by use of a suitable correction factor for buoyancy. In cases where the density of the material in question was not available in the literature, we have made rough estimates from the mass and volume of the pelleted substances. The molecular weights used are based on the 1939 table of atomic weights.[3]

Calibration of the Calorimeter.—Benzoic acid (sample 39e) supplied by the United States Bureau of Standards was burned in the bomb, under approximately the standard calorimetric conditions of Washburn,[4] to determine the energy equivalent of the calorimeter at 25°. For this sample Jessup and Green[5] have obtained a combustion

[a] This calibration was made with 2.0 g. less water in the calorimeter and hence 2.0 cal. have been added to the experimental result to bring it up to the "standard" conditions for our calorimeter.

Three different cylinders of oxygen were used during the course of the present investigation and two other cylinders have been used in subsequent work in this Laboratory. With each cylinder of oxygen a series of calibrations of the calorimeter was carried out with the standard benzoic acid. Usually the individual runs in a series were made at different stages of pressure during the use of the cylinder and in this connection no significant changes appeared during the decrease of the oxygen pressure. Table I contains the details for seven calibrations with Cylinder 2, which was used in about 60% of the combustions in the present study. The other four series of calibrations were similarly concordant among themselves and yielded means in excellent agreement with that tabulated here.

Purification of the Compounds

Highest purity Eastman Kodak Co. chemicals were the starting materials in the preparation of all the samples except those of pyrene and polyisobutylene. They were further purified in our Laboratory by recrystallization from suitable solvents and subsequent drying in an electric oven. After such preparation all crystalline materials were kept in desiccators over "dehydrite" and, for at least three days prior to combustion determinations, in vacuum desiccators with frequent evacuation. Ash determinations were made on all substances but, except in the cases of phenanthrene and sample 3 of pyrene, the results were negligible. In these two cases suitable corrections were made in the combustion values.

β-Methylnaphthalene.—Two samples were prepared independently by three successive crystallizations from absolute ethyl alcohol.

Phthalic Anhydride.—Four samples were prepared as follows. (1) The material was crystallized once from a mixture of equal parts of pure benzene and petroleum ether and then sublimed before use. (2) One crystallization was made in this case from a 50–50 mixture of benzene and isoöctane and this was followed by sublimation. (3) The third sample was subjected to one crystallization from "hexone"; the crystals were washed with benzene and then crystallized once from benzene. The product was then sublimed three times before using. (4) This sample was crystallized from "hexone," washed with benzene, then twice crystallized from benzene, and finally sublimed twice.

***o*-Phthalic Acid.**—Two separate samples were prepared by three crystallizations from specially distilled water.

Anthracene.—The original Eastman Kodak Co. product was a muddy yellow. After three crystallizations from benzene the material was of a light yellow color.

Phenanthrene.—This sample was the product of three crystallizations from benzene; it had 0.007% ash content.

Stilbene.—This sample was prepared by crystallizing three times from benzene.

Pyrene.—From the material purified by Jacobs and Parks[6] three samples, all light green in color, were prepared for these combustion measurements. (1) This was the product of one crystallization from benzene followed by one from "hexone." (2) For this sample the procedure was reversed, benzene being used for the solvent after "hexone." (3) Another quantity of pyrene was subjected to three crystallizations from benzene. Ash determinations on this sample showed 0.016% non-combustible.

***n*-Hexadecane.**—The Eastman Kodak Co. product (m. p. 16°) was used in its original form for sample 1. Sample 2 was prepared from some of this material by four crystallizations from a 50–50 mixture of *n*-propyl alcohol and methyl alcohol, followed by six crystallizations from ethylene dichloride. A careful qualitative test for chlorine in the final product (m. p. 17.0°) was negative.

Cetyl Alcohol.—Two samples were prepared. (1) The material (m. p. 48°) was recrystallized twice from methyl alcohol. In spite of being dried for several days in a vacuum desiccator, this sample had a pronounced odor and yielded combustion values averaging 0.071% lower than sample 2. As this indicated incomplete removal of the methyl alcohol, the data obtained for it have not been used in computing the final results in Table III. (2) This sample was prepared by two crystallizations from benzene as a solvent with subsequent drying.

1,3,5-Triphenylbenzene.—Four samples were prepared as follows. (1) This was the product of a crystallization from glacial acetic acid, followed by washing with ethyl alcohol and two crystallizations from ethyl alcohol. (2 and 3) These samples were crystallized three times from absolute ethyl alcohol. They were prepared separately at different stages of this study. (4) This material was twice crystallized from benzene.

Polyisobutylene.—This material was furnished in a very pure form by the Shell Development Company and was not subjected to any additional treatment before use. Its properties have been previously described by Ferry and Parks.[7] Its apparent molecular weight was about 4900, although of course it was a mixture of many polymers.

The Heats of Combustion and Derived Data

The experimental data for the combustions on the two samples of β-methylnaphthalene are presented in Table II. The energy evolved in the isothermal bomb process per g. at 25.0° is represented by $-\Delta U_B/m$ and the deviations of the

(6) Jacobs and Parks, THIS JOURNAL, **56**, 1513 (1934).

(7) Ferry and Parks, *J. Chem. Physics*, **4**, 70 (1936).

individual runs from the mean by Δ. The detailed experimental data for the remaining ten substances are essentially similar in character; they have been omitted here for reasons of spatial economy. Except in the case of cetyl alcohol previously cited, the different samples of any substance yielded extremely concordant combustion values.

2	.59076	5770.3	10.7	14.4	9725.1	−2.9
				Mean	9728.0	±1.8

Table III contains a summary of the experimental data for the heats of combustion of the eleven substances together with some important thermal data calculated therefrom. The number of combustions made in each particular case is given in the fifth column; the resulting mean values for $-\Delta U_B/m$ and the mean deviations (Δ) appear in the succeeding column. The values of the bomb process were then calculated per mole and corrected to the standard constant-volume process where the reactants and products are each at 1 atmosphere by means of the equations of Washburn.[4] The energy evolved in this hypothetical standard process is designated by the symbol $-\Delta U_R$. From this quantity $-\Delta H_R$, the heat evolved in the isobaric process at 1 atm., was obtained by addition of the proper work term. Finally, $-\Delta H^\circ_f$, the heat of formation of the compounds from the elements, was then calculated from $-\Delta H_R$ by use of 68,318 cal.[8] and 94,030 cal.[9] for the heats of formation of water and carbon dioxide, respectively.

The two liquids, *n*-hexadecane and polyisobutylene, were never evacuated in the vacuum desiccators and undoubtedly contained dissolved air. According to the solubility data in the "International Critical Tables"[10] and the more recent study of Frolich,[11] this dissolved air at saturation would amount to about 0.02% by weight; and therefore the values for $-\Delta U_R$ in Table III for these two substances have been arbitrarily increased by this percentage in the course of the calculation from the values of $-\Delta U_B/m$.

The uncertainties attached to the values of $-\Delta U_R$ have been calculated by use of the "precision error" described by Rossini.[12] This includes not only the "reaction error" for the combustion of the particular compound but also our "calibration error" of 0.012%, an "assigned error" (by Jessup and Green) of 0.023% on the standardizing substance, and an arbitrary allowance for a 10% uncertainty in the Washburn correction. In the cases of *n*-hexadecane and polyisobutylene an additional 20% uncertainty in the correction for air saturation was assumed.

For the remaining eight substances there are available in the literature a fair number of early values, mostly obtained around 1890, and a few really modern results. The early values[13] include determinations on all eight substances by Stohmann and his collaborators and a few results by Luginin and by Berthelot. Today it is practically impossible to translate these early data over to our modern standards. As published, they tend to run higher than our present results by amounts ranging up to 1.4%.

Coming to the modern data, where it is possible to put the heats of combustion on a better comparative basis with our new values, we find that Beckers'[14] results for cetyl alcohol and anthracene differ from ours by only −0.05 and +0.02%, respectively, the values of Verkade and Coops[15] for phthalic acid and phthalic anhydride exceed ours by 0.02 and 0.51%, and that of Swietoslawski[15] for phthalic anhydride is 0.04% above our result. In the case of stilbene Roth's value[13] exceeds the present result by 0.17%, that of Berner[16] by 0.07%. For phenanthrene other recent values[17] differ from that given here by −0.06 and +0.45%, and correspondingly for anthracene by +0.03 and +0.17%. For triphenylbenzene Professor Huffman at the California Institute of Technology has kindly made a pair of determinations on our original material with his own calorimetric apparatus. His mean result is 0.02% above that reported in this paper.

Acknowledgment.—Before concluding, we wish to thank Professor H. M. Huffman for his valuable advice and aid so generously given on many occasions during this investigation. We also desire to acknowledge our indebtedness to Mr. George E. Moore for purifying the samples of *n*-hexadecane and cetyl alcohol and making several of the combustions on these materials.

Summary

1. A bomb calorimeter has been calibrated and then used for precise measurements of the heats of combustion of the following eleven substances at 25° and constant volume: β-methylnaphthalene, phthalic anhydride, phthalic acid, anthracene, phenanthrene, stilbene, pyrene, *n*-hexadecane, cetyl alcohol, triphenylbenzene and polyisobutylene.

2. From these experimental results the corresponding heats of combustion and heats of formation at constant pressure have been calculated.

Raman Spectra of Acetylenes. II. Displacements and Depolarization Factors for Phenylacetylene and Derivatives of the Type $C_6H_5C{\equiv}CR$[1]

BY M. J. MURRAY AND FORREST F. CLEVELAND

As was indicated in the first paper of this series[2] (subsequently referred to as I) the line near 2200 cm.$^{-1}$ in disubstituted acetylenes is not single, but is split into two or more parts. To explain this doubling, Gredy[3] postulates the co-existence of two molecular forms each of which gives its own characteristic frequency. Kohlrausch, Pongratz and Seka[4] give some support to this hypothesis by the statement that more than one frequency, if only one molecular form is present, is difficult to understand. Badger[5] attributes the splitting to a Fermi resonance interaction between the fundamental in this region and an overtone of a frequency near 750 or 1100 cm.$^{-1}$, the latter of which should not appear in the Raman spectra. Glockler and Davis[6] accounted for the two lines in dimethylacetylene by supposing that one is due to a symmetrical, the other to an asymmetrical, vibration. If this is true for disubstituted acetylenes in general, the two frequencies in this region should have strikingly

(1) Much of the experimental work discussed in this paper was carried out at Lynchburg College.

different depolarization factors. The present investigation was designed to test this point with a number of available derivatives of phenylacetylene.

Experimental Procedure

The method used in determining the depolarization factors has been described elsewhere.[7] Since the spectra of phenylacetylene derivatives are more intense than those of the compounds therein measured, it was possible to decrease the slit width (thus giving better resolution) and to reduce to ninety minutes the time for each exposure.

The Raman frequencies of several of these compounds were reported in I.[2] Since in the present investigation a superior filter[8] and a spectrograph[7] having better optical parts and greater dispersion were used, it has been possible to obtain some of the frequencies with a greater degree of certainty than before. This remark applies especially to the frequencies near 3000 cm.$^{-1}$. Much of the improvement in this region, however, is due also to the use of a different photographic emulsion (Agfa Super Plenachrome Press) which was more sensitive to the green wave lengths. Since the acetylenic compounds used undergo photochemical decomposition rapidly when exposed to light of short wave length and since the filter used was exceedingly efficient in isolating Hg 4358 Å., it was necessary and desirable to use only this frequency for excitation. For example, with this filter the strongest line in the spectra (the 2200 cm.$^{-1}$ line) did not appear on the spectrograms as excited by Hg 4047 Å. Furthermore, all the mercury lines near 5000 Å. were completely eliminated by the filter except Hg 4916 Å. and Hg 4960 Å. which were severely weakened, the latter being observable with great difficulty on long exposures.

In certain cases, noted in the data, the material available was insufficient to fill the Raman tube, and it was necessary to add carbon tetrachloride. Experience proved that this had no observable effect upon the spectra. In a few instances where a carbon tetrachloride line chanced to coincide with one of the lines of the acetylenic compound, it was impossible to read the depolarization factor.

Results

In the tabulation of results the displacement in cm.$^{-1}$ is written first, followed by the estimated intensity in parentheses, which in turn is followed by the depolarization factor, except in cases where low intensity or other cause prevented its measurement. Lines which are unusually broad are designated by the letter b following the intensity notation. Data in regard to which there is some uncertainty are enclosed in brackets. Frequencies which were observed both as Stokes and anti-Stokes lines are designated by the sign ±. In the case of those compounds studied in I,[2] the present tabulation includes those frequencies for which depolarization factors have now been obtained, frequencies which have been redetermined with greater precision, and some frequencies not previously observed. Each new or revised value is indicated by an asterisk. The present estimated intensities are regarded as somewhat more reliable than those reported in I.[2] Because of improvements in technique given above which greatly facilitate measurement in the 3000 cm.$^{-1}$ region, the present values of frequencies above 2800 cm.$^{-1}$ should replace in entirety those given in I.[2]

1. Phenylacetylene ($C_6H_5C{\equiv}CH$).—Synthesized from bromostyrene,[9] b. p. 142°; previous data, Bourguel,[10] and Bourguel and Daure.[11]

$\Delta\nu$ = ±164(6).9; ±353(4).9; ±465(3)<.7; 517(2); ±530(3).9; 621(4b).9; 760(5).5; 1001(7).2; 1027(2)<.6; 1155(2); 1176(4).5; 1196(6).4; 1230(1); 1281(1); 1337(1); [1380(1)]; 1447(1); 1489(2b); 1601(9).8; 2113(10).6; 3066(8).5; 3142(1); 3288(3).

2. 1-Phenylpropyne-1 ($C_6H_5C{\equiv}CCH_3$).—Synthesized by action of dimethyl sulfate on sodium phenylacetylide in ether solution, b. p. 72–73° (15 mm.); previous data, Gredy,[12] Bourguel,[10] and Bourguel and Daure.[11]

$\Delta\nu$ = 149(2); 298(3).8; 388(4).7; 401(2); 510(1); 528(3).9; 626(3); 701(3); 758(2); 953(1); 971(6).3; 1001(7).3; 1030(2); 1053(½); 1160(4) and 1181(4)<.5; 1245(1); 1262(8).3; 1286(2); 1328(1); 1382(4b).9; 1436(3) and 1450(3).7; 1489(4) and 1500(4).7; 1601(9).7; 2214(9).6; 2231(4); 2246(10) and 2262(6).6; 2913(4) and 2930(3).4; 2955(1); 3066(4b).6; 3111(1); 3143(1).

2231 was measured on three different spectrograms, but only when the camera lens was diaphragmed to 1.0 cm. did 2246 and 2262 appear resolved.

3. 1-Chloro-2-phenylethyne ($C_6H_5C{\equiv}CCl$).—Synthesized by action of *p*-toluenesulfonyl chloride on sodium phenylacetylide, b. p. 73° (16 mm.); previous data, Bourguel and Daure.[11] Carbon tetrachloride added.

$\Delta\nu$ = 284(4); 334(3); 364(5).9; 500(2); 521(4); 619(3); 654(1); 754(2); 882(4); 1000(8).3; 1161(3); 1175(3); 1208(1); 1224(2); 1248(6).4; 1487(2); 1599(8).7; 2203(2); 2222(10).6; 3065(3) and 3079(2)<.8.

4. 3-Chloro-1-phenylpropyne-1 ($C_6H_5C{\equiv}CCH_2Cl$).—Carbon tetrachloride added; for previous data, see I.[2]

$\Delta\nu$ = 690(6b).5; 718(4).9; 980(7).4; 1006(2)<.9; 1159(3) and 1174(3).8; 1251(8).5; 1491(4)<.9; 1600(9).8; 2214(10) and 2231(10).7; 2263(4).7; 2956(3).6; 3064(5).6.

5. 3-Phenyl-2-propynol-1 ($C_6H_5C{\equiv}CCH_2OH$).—For previous data, see I.[2]

$\Delta\nu$ = ±188(4b).9; ±270(3) and 282(3).9; 366(3) and 382(5).6; 530(5).7; 573(4).9; 625(5).7; 713*(4).7; 756*(5).8; 956(6).3; ±1000(8).2; 1023*(4) and 1038*(2).3; 1158*(4).9; 1179(5).6; 1258(7).4; 1447*(4b).7; 1490*(5).6; 1603(9).7; 2202(6).6; 2242(10).7; 2278*(2); 2300*(2); 2433*(1); 2510*(1); 2555*(2); 2868*(4)<.6; 2914*(5) and 2935*(4).5; 3061(7).5.

(12) B. Gredy, *Compt. rend.*, **196**, 1119 (1933).

6. 3-Bromo-1-phenylpropyne-1 ($C_6H_5C{\equiv}CCH_2Br$).—Carbon tetrachloride added; for previous data, see I.[2]

$\Delta\nu$ = 609(6b).6; 987(6).4; 1206(5).6; 1269(3).8; 1599(8).7; 2226(10).6; 2265(4).6; 2950*(3)<.6; 3064(5).4.

7. 1-Phenylbutyne-1 ($C_6H_5C{\equiv}CCH_2CH_3$).—Synthesized by action of sodium phenylacetylide on ethyl *p*-toluenesulfonate, b. p. 83° (9 mm.); for previous data, see Gredy.[12]

$\Delta\nu$ = 180(2b).8; 383(3).7; 528(2) and 539(3).7; 624(2).9; 694(1).9; 757(2).9; 893(3)<.6; 999(8).3; 1016(2); 1069(1); 1161(3).7; 1184(4).6; 1240(2) and 1258(6).5; 1330(1).9; 1384(1).8; 1438(1b).8; 1493(2).7; 1599(8).8; 2206(4).7; 2238(10).7; 2839(1)<.7; 2914(3).6; 2931(3)[.3]; 2978(1b).9; 3061(5).6.

A few of Gredy's assignments appear open to some question: 470 e (e = Hg 4358 Å.) is probably 2238 k (k = Hg 4047 Å.).[13] 942 e, reported as a strong line by Gredy, appeared with small intensity and is likely 999 f (f = Hg 4347 Å.). 3025 k is probably 1258 e and 2944 k is probably 1177 e.

8. 4-Chloro-1-phenylbutyne-1 ($C_6H_5C{\equiv}CCH_2CH_2Cl$).—Carbon tetrachloride added; for previous data, see I.[2]

$\Delta\nu$ = 520(4) and 535(4).9; 624(3).9; 646(3) and 665(4).7; 700(3).9; 902*(2).6; 968*(2); 1000(6).3; 1023*(3)<.7; 1153*(3) and 1181(3).7; 1244(5).9; 1263(6).5; 1424(3).8; 1447(4).7; 1491(4).8; 1603(9).7; 2221(10) and 2246(10).6; 2918*(3b).5; 2959*(2); 2979*(2); 3063(6).5.

The frequency 987, previously reported, was not found in the present study.

9. 4-Phenyl-3-butynol-1 ($C_6H_5C{\equiv}CCH_2CH_2OH$).—Carbon tetrachloride added; for previous data, see I.[2]

$\Delta\nu$ = 386(2).9; 528(3b).9; 936(2)<.7; 980(2)<.9; 1000(7).3; 1162(3).9; 1181(3).6; 1241(5) and 1259(5).5; 1432(3) and 1440(3).7; 1602(9).8; 2214(4) and 2233(10).5; 2943*(3) and 2987*(3).5; 3063*(6).6.

10. 5-Chloro-1-phenylpentyne-1 ($C_6H_5C{\equiv}CCH_2CH_2CH_2Cl$).—Carbon tetrachloride added; for previous data, see I.[2]

$\Delta\nu$ = 373(3) and 408(1).7; 521(3).7; 625(3).7; 654(4).7; 693(3).7; 1000(7).2; 1154(3).9; 1177(3).6; 1258(7).5; 1435(4).7; 1489(3).7; 1600(8).7; 2220(10) and 2236(10).6; 2837*(1).8; 2913*(4).4; 2956(3).7; 3063(6).5.

11. 1,3-Diphenylpropyne ($C_6H_5C{\equiv}CCH_2C_6H_5$).—Synthesized by action of benzyl *p*-toluenesulfonate (2 moles) upon phenylacetylenemagnesium bromide (1 mole)[14]; b. p. 135–145° (2–3 mm.) (probably somewhat high due to superheating). Not distilled in column. Previous data, none.

$\Delta\nu$ = ±209(5).8; 279(1b); 327(1b); ±379(5); 488(1); 513(1); 528(4)<.9; 602(4) and 622(5).9; 712(1b); 757(3)<.6; 797(4).9; 813(3); 840(1); 850(1); 910(1b); 947(1); 981(8).2; 1005(8).1; 1032(4).6; 1156(4).9; 1181(6).6; 1249(8b).5; 1287(1b); 1328(1); 1422(3) and 1445(2)<.9; 1493(5).7; 1601(9).7; 2212(8).5; 2238(10).5; 2277(1b); 2317(1); 2435(1); 2558(1); 2817(1); 2883(5) and 2898(3).5; 3065(8b).5; [3202(1)].

12. 1-Phenyl-1-butynol-3 ($C_6H_5C{\equiv}CCHOHCH_3$).—Synthesized by action of acetaldehyde upon phenylacetylenemagnesium bromide, b. p. 123° (9 mm.); for previous data, see Gredy.[15]

$\Delta\nu$ = 174(4b) and 189(4).8; 260(1); 298(1); 349(1); 360(3).9; 433(1); 524(1); 546(4).8; 582(2).9; 621(2).9; 707(1b).9; 756(2).9; 850(1); 935(5).4; 1001(8).3; 1024(1); 1077(1); 1112(2b)<.6; 1158(4).6; 1175(4).6; 1237(1); 1255(7).4; 1276(1); 1323(1); 1385(1); 1445(2).7; 1491(3).7; 1599(9).7; 2198(4).7; 2233(10).6; 2870(2b).5; 2936(3b).4; 2985(2b).7; 3062(5).6.

Gredy's 463 e is probably 2233 k. 489 e was not observed in the present study. 1485 e may be a misprint for 1445 e.

A graphical presentation of those lines for which definite depolarization factors were obtained is given in Fig. 1. The broad lines in the figure correspond to cases in which two lines were not clearly separated on the polarization film. The depolarization factor, multiplied by 10 in order to simplify the diagram, is written near the line to which it corresponds. The height of the line is proportional to its intensity.

Discussion of Results

The data clearly indicate that in the seven cases where it was possible to distinguish two lines on the polarization film in the 2200 cm.$^{-1}$ region, they were both depolarized to the same degree, within experimental error. Since symmetrical vibrations are in general strongly polarized, asymmetrical vibrations strongly depolarized, it is thus impossible to account for the lines observed in the present study by supposing that they correspond one to a symmetrical, the other to an asymmetrical, vibration, as Glockler and Davis[6] state to be the case for dimethylacetylene.

The two molecular forms proposed by Gredy[3] to account for the splitting are $RC{\equiv}CR'$ and $\begin{matrix}R\\R'\end{matrix}\!\!>\!C^+{\equiv}C^-$. The presence of any appreciable portion of the latter compound seems to be ruled out, on a purely physical basis, however, by the extremely small dipole moments obtained for many symmetrical disubstituted acetylenes, such as diphenyl-, di-*n*-butyl-, and di-*n*-amylacetylene. Wenzke and Allard[16] conclude that the simplest structure consistent with zero moment is $RC{\equiv}CR'$ and state that "the presence of an appreciable portion of the acetylidene compound is obviated." Furthermore, the acetylidene form is very difficult to justify on the basis of the facts of organic chemistry.

In regard to Badger's suggestion that the split-

(13) 468 e in $C_6H_5C{\equiv}CCH_2CH_2CH_3$, measured by Gredy, is also probably 2238 k.

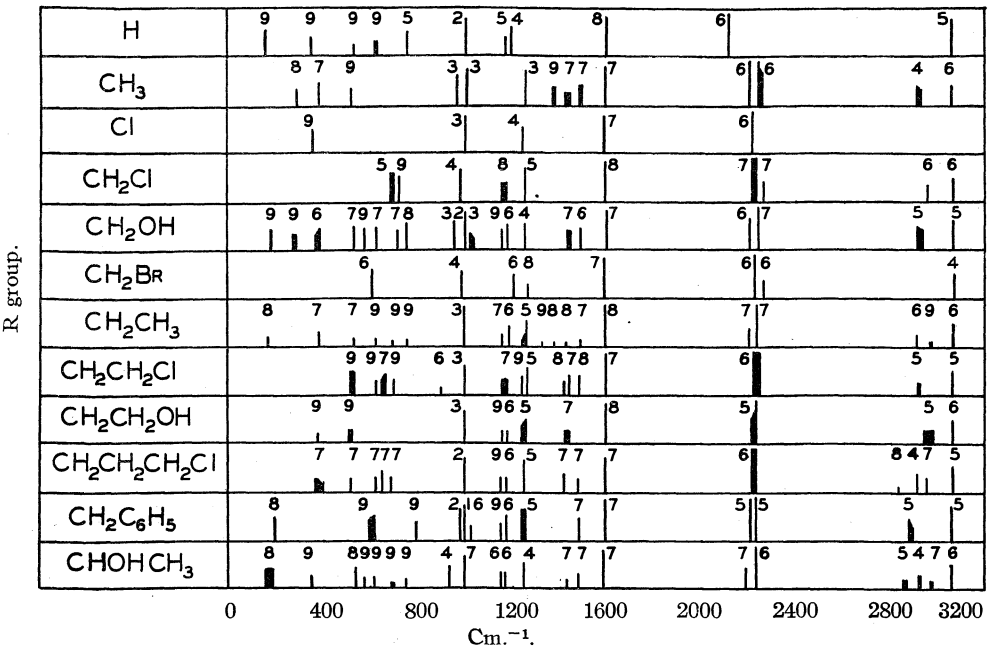

Fig. 1.—Raman spectra of compounds of the type $C_6H_5C{\equiv}CR$.

ting is due to a Fermi resonance interaction, it may be noted that there occurs in the present results no frequency whose first overtone would lie in the 2200 cm.$^{-1}$ region. This is in agreement with Badger's prediction that the frequency near 1100 cm.$^{-1}$ would not be active in the Raman effect. There is, however, a frequency at 756 cm.$^{-1}$ whose second overtone falls at approximately the same frequency as the mean of the two lines near 2200 cm.$^{-1}$. The extent of the agreement for the various compounds is indicated in Table I. It will be noticed that the frequency of the overtone is somewhat greater than the mean of the two frequencies in each case and although the 756 cm.$^{-1}$ frequency appears with remarkable constancy in the spectra of derivatives of phenylacetylene, it has not been observed with similar constancy in the spectra of other disubstituted acetylenes as would need be the case if it is to provide a universal cause for the splitting in acetylenic compounds. The investigation of Badger's hypothesis is being continued by studies in both Raman and infrared absorption spectra.[17]

TABLE I

FREQUENCY RELATIONS IN ACETYLENES OF TYPE $C_6H_5C{\equiv}CR$

R	"Triple bond" frequencies		Mean	Second overtone

Acknowledgment.—It is a pleasure to acknowledge grants in aid of this research program by the American Association for the Advancement of Science, Sigma Xi, and the Virginia Academy of Science.

Summary

1. Raman frequencies and depolarization factors are reported for twelve acetylenic compounds of the type $C_6H_5C{\equiv}CR$, where R is H, Cl, CH_3, C_2H_5, CH_2OH, CH_2Cl, CH_2Br, CH_2CH_2OH, CH_2CH_2Cl, $CHOHCH_3$, $CH_2C_6H_5$, and $CH_2CH_2CH_2Cl$.

2. The two lines near 2200 cm.$^{-1}$ were found to have the same depolarization factors, thus indicating that one frequency cannot correspond to a symmetrical, the other to an asymmetrical, vibration as Glockler and Davis have stated to be the case for dimethylacetylene.

CHICAGO, ILLINOIS RECEIVED SEPTEMBER 25, 1939

(17) In a recent paper on the Raman and infrared absorption spectra of dimethylacetylene, Crawford [*J. Chem. Phys.*, **7**, 555–562 (1939)] reports a weak frequency at 1126 cm.$^{-1}$ in the infrared spectrum which he regards as the fundamental whose first overtone interacts with the fundamental near 2270 cm.$^{-1}$ to produce the doublet 2233, 2310 observed in the Raman spectrum. In this case, the frequency of the overtone is less than the mean of the doublet, rather than greater as in the compounds discussed above.

Hydrogen Bonds Involving the C–H Link. VIII.[1] The Solubilities of Completely Halogenated Methanes in Organic Solvents

BY M. J. COPLEY, G. F. ZELLHOEFER AND C. S. MARVEL

A study[2] of the solubility of halogenated methanes in various organic solvents has shown that compounds of the type CHX_3 and CH_2X_2 (where X is either a chlorine or a fluorine atom) are more soluble in donor solvents which do not contain active hydrogen atoms than would be predicted from Raoult's law. To account for this increase in solubility over the calculated value, it has been postulated that C–H ⟵ O and C–H ⟵ N bonds are formed by the hydrogen of the halogenated methane and the oxygen and nitrogen atoms of the solvent molecules. If this explanation is the correct one, it is obvious that completely halogenated methanes (CX_4) would not show this enhanced solubility in donor solvents. The present paper contains solubility data on CCl_3F and CCl_2F_2 in a wide range of solvents. The solubilities are almost always lower than would be calculated, thus showing that compound formation between solvent and solute does not occur.

Solubility Data

The procedure followed in making the solubility measurements was described in a preceding publication.[2a] The solvents were carefully purified by distillation and their boiling or melting points were checked. The solubilities were measured at 32.2° over a limited pressure range. With few exceptions the vapor pressures of the solvents were negligible when compared with the solute pressures at which measurements were made. Where the vapor pressure of a solvent was appreciable, a correction was applied in obtaining the solubility. The experimental values of the solubility were reproducible to within 1%. The variation of solubility with change in pressure obeyed Henry's law to within the limits of experimental error in practically all cases.

The observed gram per gram and mole fraction solubilities of CCl_2F_2 and CCl_3F at pressures equal to their vapor pressure at 4.5° are given in Table I. Corresponding data for CH_2Cl_2 and $CHCl_2F$, taken from previous papers[2b,c] by the authors, are given wherever available. The statement in the table that the solubility is *very low* in acetamide and in phenol is based on the observation that when these solvents, which are solids at 32.2°, were melted, insufficient solute dissolved in the working pressure range to lower the melting point noticeably. The "ideal" or theoretical mole fractions stated at the top of Table I were calculated using Raoult's law and are the ratios of the vapor pressures[2b] at 4.5° to those[2b] at 32.2°.

Discussion

In practically every solvent examined the solubility of the CX_4 type is less than that calculated from Raoult's law. The very marked difference in the solubility of the CX_4 types in ethers from that of the CHX_3 and CH_2X_2 types in the same solvents emphasizes the role of hydrogen bonding in the solubility process. In solvents which are not characterized by the presence of donor atoms, the solubilities of the hydrogen containing halogenated methanes do not differ widely from the completely halogenated derivatives. In alcohols which are associated through O–H ⟵ O bonds the CX_4 type has a very low solubility as compared with $CHCl_2F$ and CH_2Cl_2. This suggests that although OH ⟵ O bonds are stronger than CH ⟵ O bonds, at equilibrium an appreciable number of CH ⟵ O bonds are present in a solution of a hydrogen containing halogenated methane in alcohol.

Both types of halogenated methanes have ex-

tremely low solubility in glycols. This indicates that association in the glycols is more complex than in simple alcohols. The association in glycols may be such as that shown in I in which dimer units are fused together by cross linkages into complex molecules very similar to the type previously suggested for simple amides.[2c]

Th esolubilities of the completely halogenated methanes in ethyl laurate and ethyl caprylate are higher than had been expected. In fact trichloromonofluoromethane has a solubility in excess of that calculated from Raoult's law in both of the esters. It is possible that this exception is due to the fact that the solubility calculated from the ratio of vapor pressures is lower than the value which would be obtained if fugacities were used.

The data on acetylacetone and acetonylacetone show that chelation in the former increases the solubility of the CX_4 type, whereas it decreases solubility of hydrogen containing halogenated methanes. Chelation undoubtedly renders acetylacetone less polar than the unchelated diketone

and the CX_4 type is consistently more soluble in the less polar solvents.

The extremely low solubilities of CCl_2F_2 and CCl_3F in aniline as compared to their solubilities in dimethylaniline and aliphatic amines support the suggestion made in an earlier paper that there is considerable association in primary aromatic amines.[2b]

The solubilities of $CHCl_2F$ in nitro compounds and nitriles show that these groups act as donor centers although when they are attached to a phenyl group[2b] they are much less effective donors than when attached to an alkyl group. A rather surprising case of solubility above the calculated amount was found in the case of $CHCl_2F$ in mesitylene.

Summary

The solubilities of CCl_2F_2 and of CCl_3F have been measured over a range of pressures in a wide variety of organic solvents. In practically every case the solubility was lower than that calculated from Raoult's law. These observations support the earlier postulation that intermolecular association through hydrogen bonding is an important factor in producing solubility of hydrogen containing halogenated methanes.

The Action of Elementary Fluorine on Organic Compounds. VI. The Vapor Phase Reaction between Ethane and Fluorine in Progressively Varying Proportions

BY JOHN D. CALFEE,[1] NOBUKAZU FUKUHARA AND LUCIUS A. BIGELOW

In a preceding communication (IV),[2] we have described preliminary experiments dealing with the vapor phase fluorination of ethane over a copper gauze catalyst, and the subsequent isolation of hexafluoroethane and other products. The present report describes a further study of this important reaction in which ethane and fluorine reacted in progressively varying proportions, and the more important products subsequently were separated and rectified. In each case, a perfectly quiet continuous change took place, which could be duplicated readily in every essential respect.

The Apparatus.—The fluorination chamber consisted of a section of brass pipe filled with small squares of 20-mesh copper gauze, essentially the same as that described before.[2] However, two tubes filled with sodium fluoride were used instead of one to absorb hydrogen fluoride, and special precautions were taken to make certain that no air whatever was drawn into the apparatus when the condensing trap was cooled with liquid air. Also, the quantities of the reacting gases were measured carefully; the ethane by means of a calibrated flowmeter, and the fluorine through the known electrical efficiency of the generator, recently measured by Lewis[3] and shown to be nearly constant at about 80% during most of the life of the charge. Furthermore, the products were not passed through potassium hydroxide solution, but were distilled directly, since in general the ethane was in excess; thus no free fluorine was present.

The complete Booth–Podbielniak low-temperature rectification unit which was used to separate the products was constructed according to the principles described by Booth and Bozarth.[4] A diagram of the apparatus as adapted to our work, to be described in this and subsequent papers, is illustrated in Fig. 1. The unit consisted of three main parts, first, the boiler OO, the Podbielniak low-temperature column M, and the control manometer S with its contacts 1 and 2, together with the liquid air supply O and other accessories. Beyond the control valve K were the collecting system UU, VV, T, with manometers, and the melting point apparatus W. Finally came the gas density balance FF, with its thermostat, and an absolute manometer AA to measure accurately the pressures in the balance, as well as in any part of the receiving system. The temperature at the head of the column was measured by means of a thermocouple F, in connection with a recording potentiometer; and the boiler as well as the melting point apparatus was provided with a magnetic stirrer. The operating technique for this type of unit, together with the theoretical considerations involved, have been described before.[4]

Results and Discussion.—Four separate fluorinations of ethane were made in the manner already described, and the products condensed and rectified. There were isolated carbon tetrafluoride (b. p. −128°), two azeotropic mixtures, A and B, with constant boiling points, constant molecular weights, but wide melting ranges, ethane (b. p. −88°), hexafluoroethane (b. p. −78°), and some higher boiling material.

When azeotrope B (b. p. −96°, mol. wt. 64) was passed repeatedly through a 10% sodium hydroxide solution,

(1) This paper, and also III and IV of this series, have been constructed wholly or in part, from Mr. Calfee's Doctorate Thesis, presented to the Graduate School of Duke University in May, 1938.

(2) Calfee and Bigelow, THIS JOURNAL, **59**, 2072 (1937).

(4) Booth and Bozarth, *Ind. Eng. Chem.*, **29**, 476 (1937).

dried and redistilled, it boiled at −92°, with a mol. wt. of 62. The difference was due undoubtedly to the removal of a small amount of impurity, presumably carbon dioxide, which could have come from the generator. No evidence was found to indicate the presence of silicon tetrafluoride in this product, but when the sample boiling at −92° was mixed with considerable carbon dioxide and distilled again, it boiled from −98° to −96°. The azeotrope was shown by direct synthesis to consist of ethane and hexafluoroethane, in the approximate molecular ratio of 2:1, since a known mixture of these compounds had a constant boiling point of −92°, and a constant mol. wt. of 64.

Azeotrope A was less simple, however. Its boiling point was −104° at atmospheric pressure (mol. wt. 54), −91 to −90° at 1140 mm. (mol. wt. 52) and −108° at 390 mm. (mol. wt. 52). It did not contain ethylene (b. p. −103°), since it was inert to bromine; and it was not a mixture of ethane and fluoroform, which yielded an azeotrope boiling at −96° (mol. wt. 46).

When it was passed through a 10% solution of sodium hydroxide ten times, dried and redistilled, silica was deposited immediately in the alkaline solution, and the remaining material separated sharply into two fractions, one boiling at −92° (mol. wt. 62), and the other at about −87° (mol. wt. 31). These properties correspond to those of azeotrope B and ethane, respectively. From this it was clear that azeotrope A consisted of ethane, hexafluoroethane and silicon tetrafluoride, in the approximate molecular ratio of 6:1:1, corresponding to an average mol. wt. of 53.

Table I gives the collected results of the fluorinations in the form of a comparison of the volume ratios of the reacting gases with the quantities of the various fractions separated, these last being expressed in liquid volume % of the total condensate obtained in the same run.

TABLE I

THE COLLECTED RESULTS OF THE LOW TEMPERATURE FRACTIONATION OF THE FLUORINATED ETHANE

Liquid volume per cent. of:	Gas volume ratios of fluorine to ethane 1:1	2.3:1	4:1	6:1
Carbon tetrafluoride	5	12	21	12
Azeotrope A	11	17	21	18
Azeotrope B	31	52	14	0
Ethane	42	0	0	0
Hexafluoroethane	0	6	32	41
Residue b. p. > −78°	12	17	14	29

The total volumes of liquid condensate obtained in these runs were 88, 40, 28 and 17 ml., respectively, on a twenty-hour operating basis, and previous to rectification. The figures in the table are to be considered as semi-quantitative, since the measurement of liquid volumes at low temperatures had to be made on a comparison basis, the error being estimated as not greater than ± 3 units in the extreme case. When the fluorine to ethane ratio of 6:1 was used, free fluorine appeared in the condensate, giving it an orange color. It was necessary to remove this halogen before rectification, by repeated melting, freezing and exhausting the product, which may have affected somewhat the values observed in this case.

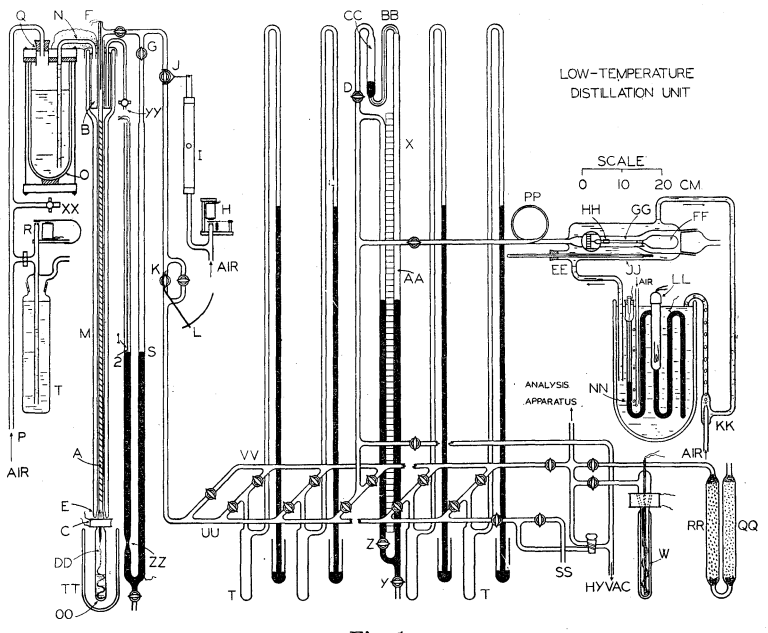

Fig. 1.

The trend of the results was quite clear, however. As the proportion of fluorine in the reaction mixture increased, the quantities of carbon tetrafluoride and hexafluoroethane increased, while the amount of ethane recovered decreased, as would be expected. Also azeotrope B was formed in maximum quantity under conditions when both of its components would be expected to be present in considerable proportions at the same time. The results also compare favorably with the preliminary observations reported earlier,[2] if the marked improvements in technique developed since then are considered. On the whole, it appears that direct fluorination is more similar to chlorination than has been supposed hitherto. A study of the influence upon this reaction of diluting the fluorine with nitrogen is now in progress.

The writers are glad to express here their thanks to Dr. H. S. Booth of Western Reserve University for timely suggestions during the early stages of this work.

Summary

Ethane has been fluorinated in the vapor phase, using progressively changing proportions of the reacting gases.

The more important products have been identified, and the approximate proportions in which they were formed have been determined.

Studies on Proteins in Liquid Ammonia. V. Reaction of Sodium in Liquid Ammonia with Peptones and Related Substances[1]

BY CLEMMY O. MILLER AND RICHARD G. ROBERTS

From previous work[2,3] reported in this series, it is known that certain amino acids, peptides, proteins and related substances are acidic in liquid ammonia. A preliminary report[4] on peptones studied under similar conditions has been made. In this paper we have compared the reactions of Armour's Meat Peptone, Merck's Meat Peptone and Witte's Peptone when metallic sodium is added to them in liquid ammonia by determining the hydrogen evolved from them, and correlating it with their nitrogen content. This method is also used to follow the course of an acid digestion of silk fibroin through several of its peptones, since it reveals the presence of certain compounds and reactive groups that do not affect a Sörensen formol titration or a Van Slyke amino nitrogen determination greatly. It has been noted by others[5] that certain procedures carried out in non-aqueous solvents can reveal groups that do not ordinarily dissociate in aqueous solutions.

Experimental

Method.—The manner of drying the liquid ammonia over sodium and of drying the peptones and related substances has been described previously, as has also been the apparatus for collecting and analyzing the hydrogen.[2,3] The silk peptones were prepared by treating silk fibroin with 70% sulfuric acid at room temperature for one, two, three, four and ten days according to the method described by Morrow[6] for the preparation of four day silk peptones. The synthetic silk peptone was simply a mixture of glycine, alanine and tyrosine made up in the proportions found in silk fibroin.

Discussion

Our work on amino acids showed that a linear curve rising at a forty-five degree angle was obtained when the varying amounts of sodium added were plotted against the hydrogen evolved for one nitrogen equivalent of the substances used. With dipeptides such as glycylglycine or glycyl-*dl*-alanine the curve is linear, but the slope is less than for the amino acids. The curve with proteins can be divided into three segments, one and three roughly paralleling the base line, while segment two roughly parallels the rising curve of the amino acids. Protein curves in general resemble a one-day digestion silk peptone (Fig. 1, curve III). Diketopiperazine gives a curve similar to the proteins except that segment two rises only about 50% as high on the average as the latter. In general the curves of peptones resemble the curve of diketopiperazine. As shown in Fig. 1 Armour's peptone (curve I) gives a smooth curve, while Witte's peptone (curve II) gives sharp segments as if a definite amount of sodium or hydrogen had to be absorbed before a definite quantity of acidic hydrogen could be liberated. For one to one ratios of sodium to nitrogen, Merck peptone is relatively more acidic than either Armour or Witte peptone. Curve III of the one-day digestion silk peptone resembles the curve of silk fibroin; it is still acting like a protein. By the second day, however, the acidity has dropped to that which is characteristic of peptones and the three-day digestion gives a typical peptone curve (IV). By the fourth day the digest has become increasingly acidic again, about equal to that of the one-day digest. The ten-day digest is more acidic than the four-day digest, and gives a curve characteristic of amino acids (V). The ten-day digest seems to be the limit of acidity for a silk fibroin hydrolyzed by sulfuric acid, since a mixture (glycine 53.3%, alanine 31.1% and tyrosine 15.6%), the proportions found in silk fibroin, and

the ten-day digest have the same acidity in liquid ammonia.

The acidic properties of silk fibroin, some of its peptones, and mixtures of its constituent amino acids with themselves and with diketopiperazine can be compared by taking the moles of hydrogen evolved from one nitrogen equivalent of these substances when they are treated with an excess of sodium in liquid ammonia. (For the meaning of above terms, see legend of Fig. 1.) Silk fibroin would start at a high level (0.339) remain at 0.294 for the one-day digest, pass through a minimum for the two-day (0.134) and three-day (0.144) digests and approach a maximum in the four-day (0.320) and in the ten-day (0.359) digests and synthetic mixture (0.358) which is of the same order of acidity as the original silk fibroin (0.339). That other mixtures of amino acids do not evolve the same quantity of hydrogen as the theoretical maximum (0.580) is shown by the equimolar mixture of glycine and tyrosine (0.385). The very marked effect of diketopiperazine in reducing the amount of hydrogen evolved is shown by the equimolar mixture of glycylglycine and diketopiperazine (0.021). That these last two substances tend to form a new compound is made evident by a change in the crystalline form, the solubility and the melting point of the new product. Tyrosine and glycine react in this way also since they do not liberate hydrogen additively when mixed, and likewise form a new compound as described above and before the sodium is added. Another interpretation of these results is that the rings present are more easily reduced by hydrogen in the presence of another acidic substance. However, Roberts and Horvitz have shown recently[7,8] by bio-assay of blood pressure in dogs that adrenalin forms a fairly stable conjugate with glycine in liquid ammonia that will not form at all in water.

If one follows the digestion of a protein by the methods of Sörensen or of Van Slyke, the carboxyl and amino groups would be found to increase even if some diketopiperazine were liberated or were formed during the process. However, in liquid ammonia the acidity as determined by the method described here would not increase, but would actually decrease during digestion if diketopiperazine were liberated or formed during the process of acid digestion or the following ammonolysis, since it would combine in liquid ammonia with the amino acids or peptides present. One interpretation of our data would indicate that diketopiperazines are liberated or formed during an acid digestion up to the three-day period, after which they are broken down to form peptides and amino acids.

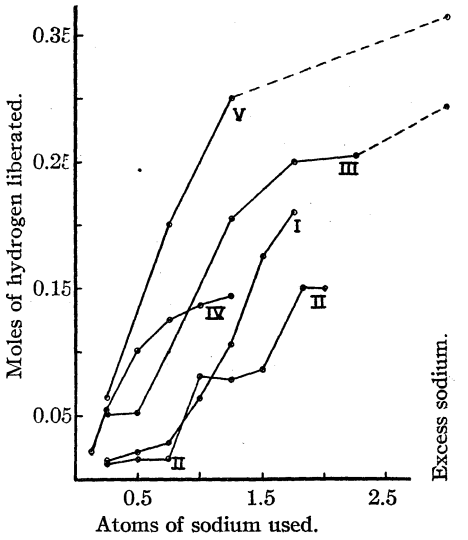

Fig. 1.—Curve I, Armour meat peptone; Curve II, Witte peptone; Curve III, 1-day digestion silk peptone; Curve IV, 3-day digestion silk peptone; Curve V, 10-day digestion silk peptone. In practice 1-g. samples were used, the sodium was added in small pieces and the hydrogen evolved varied from a few cc. to 0.1 l. or more. For convenience in plotting, the sodium is shown in gram atoms (23 g.) and the hydrogen in gram moles (2 g.) for 1 equivalent of nitrogen (14 g.) of the peptones. For a peptone containing 16% nitrogen by the method of Kjeldahl this would represent a sample of 62.5 g. The excess sodium represents an amount necessary to keep the liquid ammonia solution blue after the evolution of hydrogen has ceased. The excess may vary.

The relatively high acidity of native proteins in liquid ammonia is rather puzzling. However, this might be due to the acidity of the peptide hydrogen in long chains, if they are bent or folded in such a way as to bring phenyl or carbonyl groups into the immediate neighborhood of the nitrogen to which the replaceable hydrogen is attached. We did not find the peptide hydrogen of glycylglycine or glycyl-*dl*-alanine to be acidic. It might also come from other groups such as the hydrogen of the tertiary carbon in leucine or the hydrogen of the phenolic group in tyrosine. We have found both leucine and tyrosine to be more acidic in liquid ammonia than glycine or alanine. In his work with hydrocarbons, Wooster[9] found that

(8) R. G. Roberts and H. J. Horvitz, *Trans. Illinois State Acad. Sci.*, **31**, 141 (1938).

(9) C. B. Wooster, *Chem. Rev.*, **11**, 1 (1932).

hydrogen attached to a tertiary carbon atom is not replaceable by sodium in liquid ammonia unless at least two phenyl groups are attached to the same carbon. Hydrogen might also be evolved from side chains attached to the longer peptide chains or from diketopiperazines. We regard the variation in acidity as due to the nature of the starting material, and to the conditions of the digestion. We think of both proteins and peptones as being built up of peptides and diketopiperazines with the peptones containing a relatively large amount of diketopiperazines.

Summary

1. A study of the reaction of sodium in liquid ammonia with certain peptones has been made.

2. Peptones are acidic in liquid ammonia, and liberate hydrogen when sodium is added to them.

3. Peptones are more acidic in liquid ammonia than diketopiperazine, but less acidic than proteins or amino acids.

4. Silk peptones prepared by digesting silk fibroin for ten days pass through a minimum acidity on the second and third days.

5. Peptones are more closely related to diketopiperazine than are proteins in their acid reactions in liquid ammonia.

6. Peptones react in liquid ammonia as if they contained relatively more diketopiperazines than do proteins.

Reactions of Anils. II. Addition of Methyl Ketones to Benzalaniline in the Presence of Boron Fluoride

BY H. R. SNYDER, H. A. KORNBERG AND J. R. ROMIG

In connection with a study of the reactions of anils,[1] it became desirable to effect the addition of methyl ketones to these substances. The reaction has been known for several years,[2] but in many cases it is a very slow process. Boron fluoride would be expected[3] to combine with an anil to produce the linkage $>C=N\rightarrow BF_3$, in which the double bond must be highly polarized because of the charge on the nitrogen atom. As a consequence of the increased polarization the complex should undergo addition reactions more readily than the anil. These predictions now have been realized. The coördination compound (I) is obtained readily and its rapid reaction with methyl ketones affords a convenient method of preparing amino ketones corresponding to (II).

Procedure. Preparation of Benzalaniline–Boron Fluoride.—To a solution of 2.86 g. of benzalaniline in 155 cc. of dry ether was added 2 cc. of boron fluoride etherate. The precipitate which appeared was separated; analysis showed it to be high in boron. The mother liquor, after standing for several hours in a closed flask, deposited yellow needles, m. p. 135–145° (dec.). The product was analyzed for boron by the hydrogen peroxide oxidation method of Snyder, Kuck and Johnson.[4]

Anal. Calcd. for $C_{13}H_{11}NBF_3$: B, 4.35. Found: B, 4.44.

Addition of Methyl Ketones to Benzalaniline–Boron Fluoride.—One and one-half grams of the coördination compound was dissolved in 25 cc. of acetone. The solution warmed slightly. After a few minutes water was added and the mixture was cooled. The colorless needles of 1-anilino-1-phenylbutan-3-one were collected and recrystallized three times from dilute alcohol; yield, 0.5 g., m. p. 87–88°.

Anal. Calcd. for $C_{16}H_{17}ON$: N, 5.86; mol. wt., 239. Found: N, 5.86, 5.90; mol. wt., 251.

Substitution of ethyl methyl ketone for acetone gave 1-anilino-1-phenylpentan-3-one.[2] When the experiments were repeated with benzalaniline instead of the boron fluoride complex the anil was recovered.

For the preparation of amino ketones by this method the isolation of the coördination compound (I) is unnecessary. The reaction is effected more conveniently by adding boron fluoride etherate to a solution of the anil in an excess of the

9	Acetophenone	3, aq. MeOH	166–167[d]	62	Ref. 2			
10	Malonic ester[e]	3, aq. MeOH	98–99	6	Ref. 5			

[a] The procedure employed was as follows. A solution of 3.6 g. of benzalaniline in four times the equivalent amount of the ketone was stirred in an ice-bath while 2.8 g. of boron fluoride etherate was added. After standing in the ice-bath for five minutes the solution was poured into 100 cc. of ice and water. The oil which separated soon solidified and was recrystallized as indicated in the second column. [b] These compounds were dissolved in 5% hydrochloric acid, filtered and reprecipitated by sodium bicarbonate prior to crystallization. [c] The solid obtained when cyclohexanone was used could not be purified. [d] Mayer[2] gives 173° as the melting point of this compound. [e] Equivalent amounts of malonic ester and benzalaniline were used.

ketone. A summary of the results obtained by this method is given in the table. It should be mentioned that boron fluoride is not a true catalyst. For example, in variations of Expt. 9 of the table in which the molecular ratios of boron fluoride to benzalaniline were 0.1, 0.32, 0.50 and 0.75, the yields of crude amino ketone were 0, 20, 38 and 68%, respectively.

Of the methyl ketones tested, all but acetomesitylene, mesityl oxide and benzyl methyl ketone gave the expected products. Whereas cyclopentanone reacted readily, cyclohexanone[6] gave only a trace of solid product and α-tetralone gave none at all. Butyraldehyde, the only aldehyde tested, did not give a solid product. Of several compounds containing active methylene groups, only malonic ester gave an addition product. Methone and methyl cyanoacetate gave the benzal derivatives and dibenzoylmethane gave the enolic derivative, dibenzoylmethane boron difluoride.[7] From acetoacetic ester there was obtained only an intractable oil. The symmetrical ketones, diethyl ketone, di-*n*-butyl ketone and di-*n*-nonyl ketone, did not react under the conditions employed with methyl ketones. Benzyl cyanide, phenylacetylene, ethyl acetate and nitromethane likewise failed to give solid products.

(5) Goldstein, *Ber.*, **28**, 145 (1895).

(6) Pirrone describes the preparation of the amino ketone directly from cyclohexanone, benzaldehyde and aniline; *Gazz. chim. ital.*, **66**, 429 (1936).

(7) Morgan and Smith, *J. Chem. Soc.*, **125**, 1963 (1924).

Since the benzal derivatives of methone and methyl cyanoacetate were isolated, it seemed possible that the formation of amino ketones by this method might involve hydrolysis of the anil, reaction of the liberated aldehyde with the ketone, and addition of aniline to the unsaturated ketone so formed.[8] To test this possibility an experiment parallel to no. 1 was run, employing benzalacetone and aniline. Since none of the amino ketone was obtained, the alternate mechanism of direct addition of the ketone to the boron fluoride complex must be accepted.

In order to determine whether the addition of methyl ketones to benzalaniline–boron fluoride is reversible, a small amount of 1-anilino-1-phenylbutan-3-one (II, R = CH_3) was dissolved in an excess of pinacolone and treated with boron fluoride. In a similar experiment 1-anilino-1-phenyl-4,4-dimethylpentan-3-one (II, R = $(CH_3)_3C$) was treated with acetone and boron fluoride. The solutions were allowed to stand for one hour at room temperature. The starting material was recovered almost quantitatively from each, showing that the reaction is not reversible.

Summary

Benzalaniline and boron fluoride react in ether solution to give a coördination compound containing one molecule of each component.

The benzalaniline–boron fluoride complex un-

(8) Tambor and Weld, *Ber.*, **31**, 352 (1898).

dergoes rapid addition of methyl ketones and cyclopentanone. The reaction affords a convenient method of preparation of certain β-amino ketones.

The addition of methyl ketones to benzalaniline in the presence of boron fluoride is not a reversible process.

Reactions of Anils. III.[1] A New Type of Diels–Alder Reaction

BY H. R. SNYDER, R. B. HASBROUCK AND J. F. RICHARDSON

The reaction of maleic anhydride on compounds containing the structural unit >C=C—C=N— has now been examined in the course of a general study of the behavior in the Diels–Alder reaction of open-chain unsaturated systems containing nitrogen.[2] Since 2-ethyl-2-hexenalaniline (I) is easily available, it was selected for the study.

2-Ethyl-2-hexenalaniline reacts readily with maleic anhydride in boiling benzene. The product is a monobasic acid of the composition corresponding to one molecule of each reagent. This acid could not be reduced by sodium amalgam; hydrogen and platinum converted it into a dihydro derivative which could not be further hydrogenated. Both the original acid and the dihydro acids are extremely stable to hydrolysis, either with acids or bases. Fusion of the original acid with alkali brought about its decomposition into aniline and an acid of the composition $C_{11}H_{14}O_2$. Oxidation of the latter gave trimesic acid.

Since the condensation product is a monobasic acid, 1,4-addition of maleic anhydride to give the heterocyclic substance (II) is immediately excluded. An acid of the correct composition might be formed by addition to maleic anhydride, as has been observed in the case of certain pyrroles.[3] The primary addition product (III), by tautomerization and intramolecular amide formation, could then be transformed into the monobasic acid (IV). However, a substance having the formula (IV) should be reduced by sodium amalgam and should take up four hydrogen atoms on catalytic reduction. Furthermore, this formula does not account for the formation of an acid $C_{11}H_{14}O_2$ which can be oxidized to trimesic acid.

The formation of the condensation product and all its properties can be accounted for readily on the basis of an aldimine–eneamine tautomerism, involving a 1,5-shift of hydrogen, in the original anil (I ⇄ V). This transformation is not surprising, since the system —CH_2—C=C—C=N— is a vinylog of —CH_2—C=N— in which tautomerism is well known. Addition of maleic anhydride to the diene system of the tautomer gives the substance (VI) which, since it is at once an anhydride and a secondary amine, rearranges to form the bicyclic amido acid (VII).

A compound of the formula (VII) would be expected to resist the action of sodium amalgam and to give only a dihydro derivative on hydrogenation. Vigorous hydrolysis with alkali opens the amide ring to give the β-anilino acid salt (VIII). Loss of a molecule of aniline results in the formation of the dihydrobenzene derivative (IX). The latter is unstable; by expelling a molecule of potassium formate it is converted into the salt of 3,5-diethylbenzoic acid, $C_{11}H_{14}O_2$, (X). Oxidation of the latter gives trimesic acid (XI).

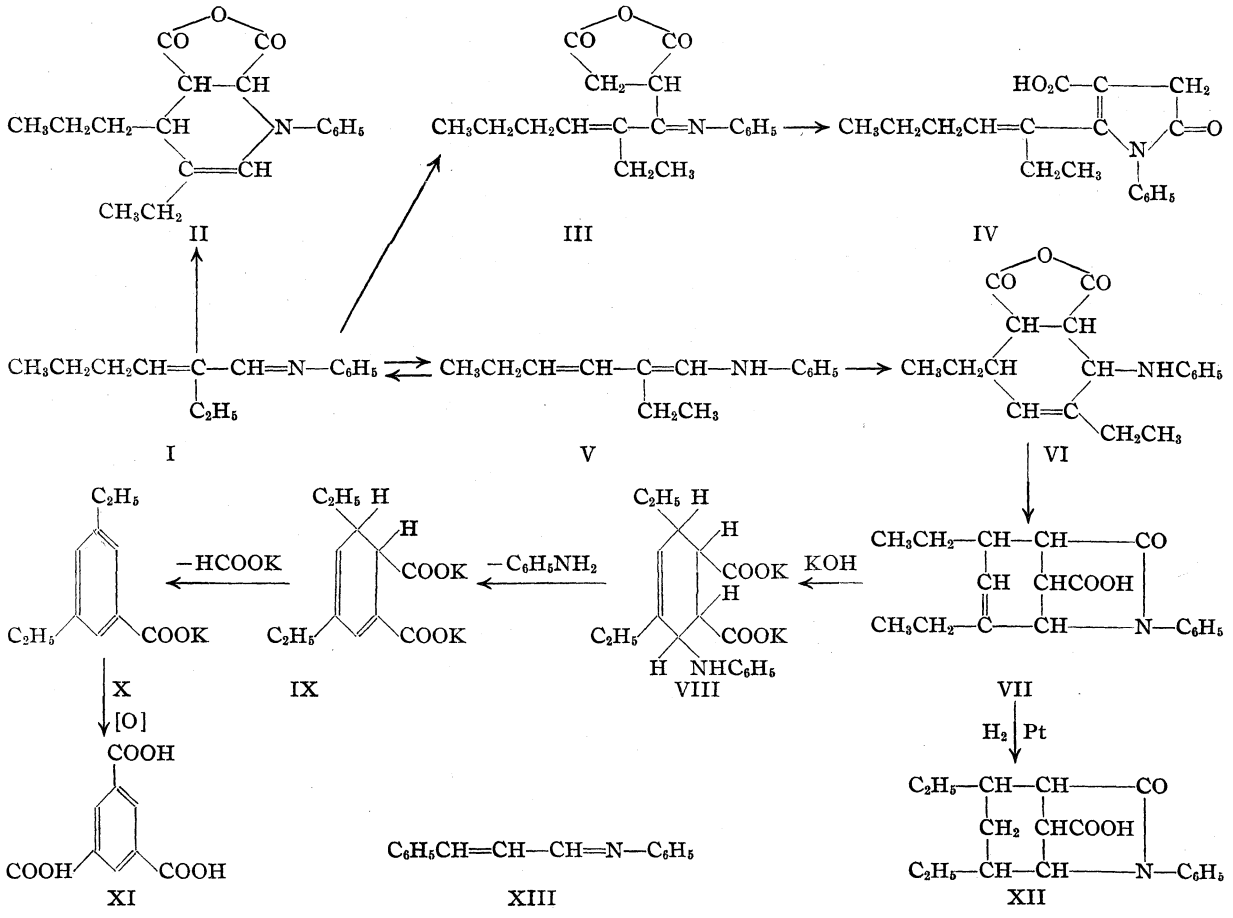
When this work was nearly complete, Bergmann[4] reported that cinnamalaniline (XIII) and maleic anhydride give only maleanilic acid and cinnamaldehyde. We have carefully reëxamined this case; the results have been in harmony with those of Bergmann, except that under highly anhydrous conditions the yield of maleanilic acid was negligible, as might have been expected from the observation[2] that, in reactions of this kind, the first step is addition of water to the carbon–nitrogen double bond. The failure of cinnamalaniline to undergo condensation supports the formulation given for the reaction of 2-ethyl-2-hexenalaniline; because the ε-carbon atom is part of the benzene ring, cinnamalaniline is unable to undergo the initial tautomerization.

(1) For the preceding paper in this series see Snyder, Kornberg and Romig, THIS JOURNAL, **61**, 3556 (1939).

(2) Snyder, Levin and Wiley, *ibid.*, **60**, 2025 (1938).

(3) Diels and Alder, *Ann.*, **486**, 211 (1931).

(4) Bergmann, THIS JOURNAL, **60**, 2811 (1938).



Experimental

Cinnamalaniline and maleic anhydride reacting in ether gave maleanilic acid, m. p. 193–195°, in yields varying from less than 2% (when dry ether was used) to 96% (when the theoretical amount of water was added). Similar results were obtained with benzene and dioxane solutions.

Preparation of 2-Ethyl-2-hexenalaniline.—To 40.2 g. of 2-ethyl-2-hexenal (Carbide and Carbon Chemicals Corporation) was added 30 g. of aniline. The solution was heated on the steam-bath for one minute and, after cooling, was allowed to stand at room temperature for fifteen minutes. The product was separated from the water layer by extraction with 100 cc. of benzene. After removal of the benzene, 48 g. (75%) of 2-ethyl-2-hexenalaniline (I) was distilled at 127–128° (2 mm.) (or 139.5–140.5° (6 mm.)); d^{20}_{20} 0.9379; $n^{20}D$ 1.5596; M_D calcd., 68.77, M_D found, 69.29.

Anal. Calcd. for $C_{14}H_{19}N$: C, 83.52; H, 9.52; N, 6.96. Found: C, 83.58; H, 9.42; N, 7.11.

Maleic anhydride and 2-ethyl-2-hexenalaniline in equilmolecular amounts, were dissolved in anhydrous benzene (1300 cc. per mole of anhydride). After standing for two hours in a closed flask the solution was filtered from a small amount of maleanilic acid. The clear solution was refluxed for three hours, atmospheric moisture being excluded by a calcium chloride tube. After standing for several days, or immediately after seeding, the solution deposited white crystals. After recrystallization from alcohol the product, 5,7-diethyl-2-phenyl-2-azabicyclo-(2,3,1)-oct-6-ene-3-one-8-carboxylic acid (VII), melting at 145–146°, was obtained in 75–80% yield.

Anal. Calcd. for $C_{18}H_{21}O_3N$: C, 72.24; H, 7.08; N, 4.68; neut. equiv., 299.2. Found: C, 72.46; H, 7.09; N, 4.78; neut. equiv., 302.

Catalytic Reduction of the Condensation Product.—A solution of 55 g. (0.184 mole) of the acid in 200 cc. of absolute alcohol was reduced at three atmospheres pressure over Adams platinum oxide catalyst. The pressure drop corresponded to 0.188 mole of hydrogen. The solution was filtered, treated with fresh catalyst and returned to the apparatus; no further reduction occurred. The dihydro acid (XII) was crystallized from dilute alcohol; yield 50 g. (90%). The air-dried material was a monohydrate; it decomposed at 120–130° and melted again at 177°; the neutral equivalent was found to be 322.5, as compared to a theoretical value of 319.2 for the monohydrate. Samples dried *in vacuo* melted at 177° and were anhydrous.

Anal. Calcd. for $C_{18}H_{23}O_3N$: C, 71.7; H, 7.70; N, 4.65; neut. equiv., 301.2. Found: C, 71.8; H, 7.73; N, 4.60; neut. equiv., 300.

The dihydro acid was converted to the chloride by treatment with thionyl chloride. Dry ammonia was

bubbled through a benzene solution of the crude chloride to give an 80% yield of the amide, recrystallized from alcohol, m. p. 187–188°.

Anal. Calcd. for $C_{18}H_{24}O_2N_2$: N, 9.33. Found: N, 9.33.

Hydrolysis of the Condensation Product (VII).—A number of attempts to hydrolyze the acid and its dihydro derivative by boiling with acids and bases were unsuccessful; the starting materials were recovered even after boiling for ten days with 10% sodium hydroxide.

To a solution of 20 g. of potassium hydroxide in 20 cc. of water in a nickel crucible was added 20 g. of (VII). The crucible was heated over a free flame while the mixture was carefully stirred. As water was driven off the mixture solidified; it then melted again and evolved aniline (identified as the benzoyl derivative from a run carried out in glass apparatus). When the evolution of aniline had stopped the hot mixture again solidified. It was dissolved in water and boiled with charcoal. The filtrate, on acidification, gave a yellow solid. This was dried and extracted with three 25-cc. portions of hot chloroform. The residue from evaporation of the chloroform was decolorized in methyl alcohol; after three recrystallizations from dilute methyl alcohol the product, 3,5-diethylbenzoic acid (X), melting at 133°, weighed 2.5 g.

Anal. Calcd. for $C_{11}H_{14}O_2$: C, 74.20; H, 7.87; neut. equiv., 178. Found: C, 74.05; H, 8.04; neut. equiv., 174.

Trimesic Acid (XI).—To a solution of 1 g. of 3,5-diethylbenzoic acid and 1 g. of potassium carbonate in about 50 cc. of water was added 7.0 g. of potassium permanganate. The mixture was heated until a vigorous reaction occurred; when the reaction subsided the mixture was heated for about ten minutes longer. The clear solution obtained after treatment with sulfur dioxide was acidified with hydrochloric acid and cooled in ice–salt. The white solid was collected, dissolved in aqueous potassium carbonate, precipitated with hydrochloric acid and dried. It did not melt at 300°. One-half gram of the acid was converted to the methyl ester by treatment with phosphorus pentachloride and methyl alcohol. After three crystallizations from methyl alcohol the ester melted at 146–147°. A sample prepared from authentic trimesic acid melted at 146–147°; mixtures of the two samples melted at 146–147°.

Anal. Calcd. for $C_{12}H_{12}O_6$: C, 57.1; H, 4.76. Found: C, 57.0; H, 4.87.

Summary

2-Ethyl-2-hexenalaniline and maleic anhydride give 75–80% yields of 5,7-diethyl-2-phenyl-2-azabicyclo-(2,3,1)-oct-6-ene-3-one-8-carboxylic acid. The structure of this product has been proved by reduction to the dihydro derivative, and by degradation to 3,5-diethylbenzoic acid which was oxidized to trimesic acid.

The reaction has been shown to occur through tautomerization of the anil and addition of maleic anhydride to the diene system of the resulting eneamine.

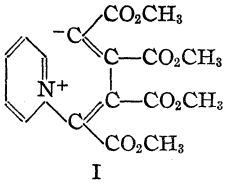
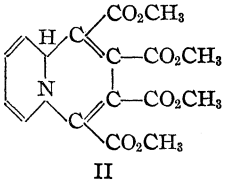
Reactions of Anils. IV.[1] The Reactions of Benzalaniline and Cinnamalaniline with Methyl Acetylenedicarboxylate

BY H. R. SNYDER, HARRY COHEN AND WM. J. TAPP

The behavior of simple anils toward methyl acetylenedicarboxylate is of interest in connection with the novel structure (I) assigned by Diels and Alder[2] to the labile isomer obtained from pyridine and this reagent. Since only the carbon–nitrogen double bond appears to be involved in the formation of this substance and its stable isomer (II), other compounds containing this linkage might be expected to give similar products.



I



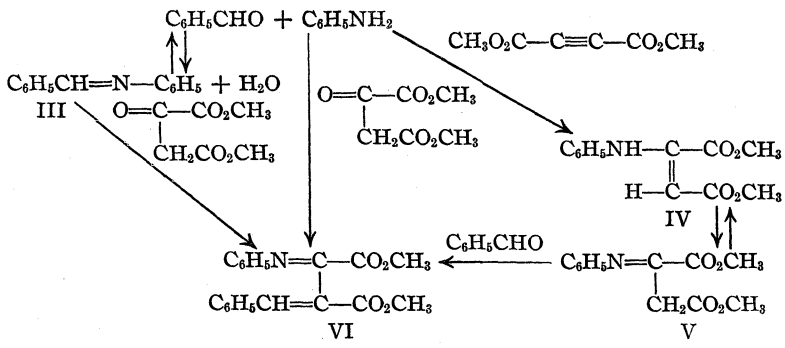
II

It has been found that benzalaniline and the acetylenic ester, reacting in commercial ether, give low yields of a substance (VI) having the composition corresponding to the addition of one molecule of the anil to one of the ester. However, the fact that the yields were greatly improved by the presence of a small amount of water suggested that the reaction involved hydrolysis of the anil. Addition of the liberated aniline to the acetylenic bond of the ester would give (IV), which by tautomerization (IV $\rightleftarrows$ V) and condensation with benzaldehyde would give (VI).

That the compound obtained has the structure (VI) was shown by its formation from methyl oxalacetate, benzaldehyde and aniline. It also could be obtained from methyl oxalacetate and benzalaniline in the presence of a trace of water, and from benzaldehyde, aniline and methyl acetyl-

(1) For the third communication in this series see THIS JOURNAL, 61, 3558 (1939).

(2) Diels and Alder, *Ann.*, 510, 87 (1934).



enedicarboxylate. The substance has the interesting property of dissolving in warm dilute alkali, and may be recovered unchanged from such a solution by acidification. This weakly acidic property must derive from the highly unsaturated character of the molecule.

Cinnamalaniline, $C_6H_5CH{=}CHCH{=}NC_6H_5$, which approximates more nearly the structural features of pyridine, reacts with the acetylenic ester to give two isomeric products of the composition corresponding to the addition of two molecules of the ester to one of the anil. This is the composition to be expected by analogy to the products from pyridine. When carried out in the absence of a solvent the reaction is highly exothermic, resembling in this respect also the reaction of pyridine and the ester. These compounds have not yet been obtained in quantities great enough to permit structural studies; since the work must be interrupted for a year it is being reported in its present status.

Experimental

Benzalaniline and Methyl Acetylenedicarboxylate.—A mixture of 8 g. of methyl acetylenedicarboxylate, 14 g. of benzalaniline, 2 g. of water and 50 cc. of absolute ether was allowed to stand for two days at room temperature. Filtration gave 3.8 g. of white crystals; after recrystallization from toluene the product, methyl α-benzal-α′-phenyliminosuccinate, melted at 192–193°. Similar results were obtained from aniline, benzaldehyde and methyl acetylenedicarboxylate in anhydrous ether.

Anal. Calcd. for $C_{19}H_{17}O_4N$: C, 70.6; H, 5.27; N, 4.34; methoxyl, 19.4; mol. wt., 323. Found: C, 70.44; H, 5.38; N, 4.34; methoxyl, 19.2; mol. wt., 353.

Benzalaniline and Methyl Oxalacetate.—A solution of 0.1 g. of methyl oxalacetate and 0.1 g. of benzalaniline in 1.0 cc. of wet ether deposited crystals after a few hours at room temperature. After two days these were removed by filtration and recrystallized from toluene; m. p. 192–193°; this melting point was not affected by admixture of the product described above.

Benzaldehyde, Aniline and Methyl Oxalacetate.—A solution of 0.1 g. of aniline, 0.1 g. of benzaldehyde and 0.2 g. of methyl oxalacetate in 3.0 cc. of absolute ether deposited crystals after a few hours. After recrystallization from toluene the product melted at 192–193°. The melting point was not affected by admixture of the above samples.

Cinnamalaniline and Methyl Acetylenedicarboxylate.—A solution of 2.8 g. of the ester and 4.0 g. of the anil in 70 cc. of petroleum ether was heated under reflux for two days. After decantation of the solvent, the residue was washed with petroleum ether and crystallized several times from methanol. The yellow crystals weighed 1.1 g. (23%) and melted at 166–167°.

Anal. Calcd. for $C_{27}H_{25}O_8N$: C, 66.0; H, 5.13; N, 2.86; methoxyl, 27.7; mol. wt., 491. Found: C, 66.10; H, 5.29; N, 3.13; methoxyl, 27.4; mol. wt., 441.

The higher-melting isomer was obtained by the following procedure. A flask containing 1.4 g. of the ester was cooled in an ice-bath and 2.0 g. of the anil was added with stirring. The mixture was kept in the ice-bath for four hours and was then allowed to stand at room temperature for two weeks. After washing with petroleum ether, the residue was dissolved in 15 cc. of toluene. The yellow crystals which separated from this solution after about two hours were collected and recrystallized from methanol; m. p. 309–310°, yield 0.05 to 0.10 g.

Anal. Calcd. for $C_{27}H_{25}O_8N$: C, 66.0; H, 5.13; N, 2.86; mol. wt., 491. Found: C, 66.2; H, 5.17; N, 2.90; mol. wt., 436.

Addition of petroleum ether to the toluene mother liquor caused precipitation of the low-melting isomer, which after crystallization from methanol melted at 166–167°; yield 0.5 g. (20%).

Summary

Benzalaniline reacts with methyl acetylenedicarboxylate in the presence of water to give methyl α-benzal-α′-phenyliminosuccinate. The same product may be obtained from benzaldehyde, aniline and methyl oxalacetate or from benzalaniline and methyl oxalacetate.

Cinnamalaniline and methyl acetylenedicarboxylate react to give two isomeric products of composition corresponding to one molecule of anil to two of the ester. The structures of these products have not been determined.

Preparation of Aminobenzoic Acid Esters of Substituted Monoalkylamino Alcohols[1]

BY SAMUEL D. GOLDBERG, WILLIAM F. RINGK AND PAUL E. SPOERRI

In previous papers, the preparation[2] and the pharmacological properties[3] of two new series of anesthetic compounds were described.

The result of the pharmacological work on these compounds suggested the investigation of the properties of a series of esters in which the side chain was limited to two carbon atoms, one carbon atom carrying two alkyl substituents, thus forming a branched side chain.

The preparation of a series of β-alkylamino-α,α-dimethylethanols, $HOC(CH_3)_2CH_2NHR$, where R represents an alkyl group, was therefore undertaken.

The preparation of these amino alcohols required the use of β-chloro-α,α-dimethylethanol which was synthesized according to the methods of Krassuski[4] and Michael and Leighton,[5] using the addition of hypochlorous acid to isobutylene.

The β-chloro-α,α-dimethylethanol together with an excess of a primary amine in a suitable solvent was refluxed for several hours and then carefully fractionated. The average yield of β-alkylamino-α,α-dimethylethanol was 52%.

The *p*-nitrobenzoic acid esters of the amino alcohols were obtained through the condensation of the amino alcohols with *p*-nitrobenzoyl chloride in an aqueous alkaline medium. The temperature of this reaction must be maintained between 30 to 40° for optimum yields. The nitro esters are all yellow solids.

These nitro esters were reduced with tin and hydrochloric acid to the anesthetic amino bases.

The hydrochlorides of the higher members of the series of the amino bases were in all cases very viscous yellow oils; the sulfates, on the other hand, were all white crystalline solids.

Two members of another series of amino alcohols were prepared utilizing the reaction between a Grignard reagent and a chloro ester[6] or a chloro ketone.[7,8] With ethylmagnesium iodide there is obtained β-chloro-α,α-diethylethanol which on reacting with *n*-butyl- and *i*-butylamines yields the corresponding amino alcohols.

When methylmagnesium iodide is used, these two methods of preparation serve as alternative methods for making β-chloro-α,α-dimethylethanol.

Experimental

β-Ethylamino-α,α-dimethylethanol, $HOC(CH_3)_2CH_2NHC_2H_5$.—In a 250-cc. pressure bottle was placed 31.4 g. (0.23 mole) of a 33% aqueous solution of monoethylamine and 100 cc. of water. To this was added 20 g. (0.18 mole) of β-chloro-α,α-dimethylethanol, the bottle immediately stoppered and shaken occasionally during the next twenty-four hours. The reaction mixture was treated with solid sodium hydroxide and cooled, the upper layer extracted with ether, the ether layer separated and dried over anhydrous sodium sulfate. The ether was evaporated and the residue distilled. Two fractionations of the distillate gave 12 g. (56%) of a water-white liquid with a slight ammoniacal odor, boiling at 152–153°.

Preparation of the Other Members of this Series.—The preparations of the β-methyl- and β-ethylamino-α,α-dimethylethanols were carried out as described above. The higher members of this series of amino alcohols, namely, the β-*n*-propyl-, β-*i*-propyl-, β-*n*-butyl-, β-*i*-butyl-, β-*n*-amyl- and β-*i*-amylamino-α,α-dimethylethanols were prepared in a slightly different manner. 95% ethyl alcohol was used as a solvent for the reactants and the mixtures refluxed from three to twenty-four hours. The reaction mixture was acidified with concentrated hydrochloric acid and vacuum distilled almost to dryness. To the cold residue in the flask was added cold 30% sodium hydroxide solution and the same procedure used for the purification.

In Table I are summarized the physical constants of this series of amino alcohols, the molecular refraction (using Eisenlohr's[9] atomic refraction values) and the analyses of the picrates. The picrates were crystallized from either benzene or xylene.

The nitro esters are prepared by condensing the amino alcohols with *p*-nitrobenzoyl chloride as follows:

β-*i*-Butylamino-α-dimethylethyl *p*-Nitrobenzoate, (iso)-$C_4H_9NHCH_2C(CH_3)_2COOC_6H_4NO_2$.—To 10 g. (0.069 mole) of β-isobutylamino-α,α-dimethylethanol and 5 g. of sodium hydroxide in 250 cc. of water was added with stirring 13 g. (0.07 mole) of powdered *p*-nitrobenzoyl chloride in one amount. The temperature of the reaction was controlled so that it did not go above 40°. An oil was soon formed which finally solidified after one-half

hour of stirring. The solid nitro ester was filtered off and washed with water until free of alkali. The nitro ester was recrystallized from benzene, m. p. 130–131°. The solid nitro ester was then reduced with tin and hydrochloric acid in the usual manner.

All of the esters were made similarly. In Table II are given the constants of the nitro and amino esters, as well as the analyses of the amino ester sulfates.

Pharmacology.—A preliminary pharmacological investigation of the sulfates of the β-*n*-propyl-, β-*n*-butyl, β-*i*-butyl-, and β-*n*-amyl-amino-α-dimethylethyl *p*-aminobenzoates was carried out. As a result of this investigation it was found that this series of anesthetics apparently was too toxic for injection purposes. However, the β-*n*-amyl derivative showed surface anesthetic activity to a high degree and was therefore tested further.[10]

Table III summarizes the toxicity tests of the sulfate of β-*n*-amylamino-α-dimethylethyl *p*-amino benzoate (abbreviated to *n*-amyl sulfate), Cocaine and Butyn.

In an anesthetized dog, *n*-amyl sulfate causes a slight reduction in blood pressure and a slight increase in pulse rate upon intravenous injection of a 1% solution. The intravenous toxicity for dogs is 20 mg./kg.

TABLE III

SUBCUTANEOUS TOXICITY

Compd.	Concn., %	Animal	No. of animals	M. L. D. mg./kg.	% died at M. L. D. indicated
n-Amyl sulfate	1	White mice	64	45	10
Cocaine	1	White mice	41	75–100	0–18
Cocaine	4	White mice	19	100–150	0–25
Butyn	1	White mice	26	25–50	0–12.5
Butyn	5	White mice	26	Approx. 50	14
n-Amyl sulfate	1	Guinea pigs	43	35–40	0–27
Intravenous Toxicity					
n-Amyl sulfate	1	White mice	9	10–15	0–100

Corneal anesthesia in the rabbit's eye, using a 1% *n*-amyl sulfate solution, a 4% cocaine solution and a 2% butyn solution produces anesthesia averaging eighty-seven, sixty-six and seventy-nine minutes, respectively, when from one to five drops of the solution are instilled into the rabbit's eyes. Immediate anesthesia was produced in all cases and no demonstrable irritations found in any treated eye. *n*-Amyl sulfate caused practically no mydriasis and no corneal erosion. Application of one drop of a 1% solution of *n*-amyl sulfate to the cornea of the rabbit's eye produces anesthesia last-

(10) We are indebted to Dr. Donald C. A. Butts of Philadelphia for the pharmacological investigation of this compound.

ing forty-three minutes while a 0.05% (1:2000) solution anesthetizes for six minutes. *n*-Amyl sulfate does not alter the intraocular tension of the rabbit's eye when used in 1% concentrations.

Summary

A series of new β-alkylamino-α,α-dimethylethanols has been prepared.

From these alcohols, as well as two β-alkylamino-α,α-diethylethanols, by combination with *p*-nitrobenzoyl chloride and reduction, there has been prepared a series of new esters.

A pharmacological study of one ester shows it to have interesting surface anesthetic properties.

Nickel as a Catalyst for the Hydrogenation of Aromatic Halogen Compounds

BY CHARLES F. WINANS*

The catalytic hydrogenation of *o*-nitrochlorobenzene over nickel was first attempted by Sabatier and Mailhe[1] who, however, obtained aniline hydrochloride as a result of a combined hydrogenation and dehalogenation. Furthermore, Sabatier and Espel[2] found that small amounts of halogen compounds did not interfere with the vapor phase reduction of benzene provided that some nickel remained in catalytically active form after a portion had been converted to nickel halide in removing the impurity. The simultaneous hydrogenation and dehalogenation of organic compounds has been effected by several workers[3] using platinum and palladium catalysts, and certain others have effected hydrogenation without the removal of halogen. Ellis[4] describes the preparation of a reduced nickel catalyst suitable for the production of chlorinated aromatic amines from the corresponding nitro compounds. Strangely, very little has appeared in the recent literature concerning the use of nickel for the hydrogenation of halogen compounds. The present paper attempts to demonstrate that the hydrogenation of these compounds is a general reaction which is applicable in an efficient and economical process.

The success of this conversion depends upon the choice of a stable halide, the use of a temperature below that at which dehalogenation occurs, and the use of a catalyst with sufficient mass of metal. These conditions have been met in the hydrogenation of aromatic halogen compounds at temperatures below 150° with Raney[5] nickel.

The substituents reducible below 150° which may be attached to the halogenated aromatic nucleus include the olefinic, acetylenic, nitro, nitroso, cyano, oximino, azido, azo, and carbonyl groups. Anils and hydro-amides may also be treated. It has not been possible to hydrogenate chlorobenzene to chlorocyclohexane, for at the temperature required to saturate the benzenoid ring halogen was removed giving rise to benzene in small amounts. Benzyl chloride gave some diphenylethane under similar conditions. In the aliphatic series 1-chloropropene, ω-chlorostyrene, *sym*-dichloroethylene, and tetrachloroethylene resisted saturation of the olefin bond.

The accompanying table gives the names of hydrogen acceptors and reaction products with physical properties and yields for fourteen different halogen compounds illustrating the behavior of several types. Most of the products were distilled from the reaction mixture. Others were obtained in crystalline form as solid product or hydrochloride derivative. All products were identified by the formation of known characteristic derivatives or by analysis.

The relative strength of attachment of chlorine, bromine, and iodine to the aromatic nucleus was demonstrated in the reduction of the halogenated nitrobenzenes. *p*-Chloronitrobenzene gave rise to *p*-chloroaniline even at 150° in nearly quantitative yield. *p*-Bromonitrobenzene was not quite so stable, but still the predominant product was *p*-bromaniline. *o*-Iodonitrobenzene was largely dehalogenated during reduction to aniline, only a small amount of *o*-iodoaniline being isolated from

the reaction mixture. Dinitrochlorobenzene lost chlorine to give *m*-phenylenediamine on reduction, even when the reaction temperature was maintained below 40°. On the other hand, the presence of two chlorine atoms in dichloronitrobenzene did not interfere at all in the conversion to dichloroaniline and similarly benzal-2,5-dichloroanil was reduced to benzyl-2,5-dichloroaniline.

When operating with a readily reducible compound such as *p*-chloronitrobenzene a single portion of catalyst has been used in six successive reductions with only slight diminution in activity as judged by reaction time and temperature. In addition, several catalysts which were no longer sufficiently active for more difficult hydrogenations served very well in these simpler conversions.

Experimental

Apparatus and Catalysts.—The shaking autoclave in which these reactions were carried out had a capacity of 900 ml. and was similar in design to those described by Adkins.[6] The reactants were placed directly in the steel autoclave, no liners of copper or glass being employed. The nickel catalyst was prepared from Raney alloy according to the method of Covert and Adkins.[7]

Manipulation.—All hydrogenations were run in ethanol solution, although other solvents which are compatible with reducible compound, product, and water may also be used. When the hydrogenations were attempted in aqueous suspension, the reaction stopped far short of completion. In general, 5% of catalyst based on the weight of the reducible compound was used, although amounts as low as 2% may be used with accompanying slower reaction rate. Temperature was maintained below 150°, and preferably below 125°. Hydrogen pressures as low as 20 atm. were satisfactory in these hydrogenations, but the reaction rate was quite slow. With pressures of 100 atm. or more the reaction was very vigorous and much heat was evolved.

The following description of an experiment in the hydrogenation of *p*-chloronitrobenzene is quite typical. A mixture of 300 g. of *p*-chloronitrobenzene (tech.), 400 ml. of alcohol, and 15 g. of Raney nickel was charged into the autoclave under 100 atm. hydrogen pressure. The autoclave was shaken and slowly heated above room temperature. At 50° absorption of hydrogen as judged by drop in gage pressure was quite rapid and external heating was discontinued. When the pressure had fallen to 20 atm. more hydrogen was admitted from the storage cylinder. After twenty-three minutes the theoretical amount of hydrogen had been absorbed at a maximum temperature of 100°. The cooled reaction mixture, after removal from the autoclave, was filtered from the catalyst and distilled to give 236 g. (97%) *p*-chloroaniline, b. p. 100–110° (8 mm.). The recovered catalyst could be used repeatedly in subsequent hydrogenations.

Summary

The hydrogenation of certain readily reducible groups attached to a halogenated aromatic nucleus has been accomplished with nickel catalyst. These halogenated compounds behave just as do their unhalogenated analogs in regard to time, temperature, and completeness of hydrogenation.

Hydrogenation of Aldehydes in the Presence of Ammonia

BY CHARLES F. WINANS*

The catalytic hydrogenation of hydro-amides derived from aldehydes such as benzaldehyde, furfuraldehyde, and trimethylacetaldehyde is known to give rise to equimolecular amounts of the corresponding primary and secondary amines.[1] The chemical reactions in the formation of hydrobenzamide are considered to be

$$RCHO + NH_3 \rightleftarrows RCH{=}NH + H_2O \quad (1)$$

$$3RCH{=}NH \rightleftarrows (RCH{=}N)_2CHR + NH_3 \quad (2)$$

These reactions are reversible as shown by Lach[2] who obtained Schiff bases and ammonia by treating hydrobenzamide with amines. The result of adding excess ammonia to hydrobenzamide should be to displace the equilibrium to the left, giving larger amounts of benzalimine which is readily reducible with nickel catalysts to benzylamine. Such is the case, and at the same time there is always produced a small amount of dibenzylamine which arises from the hydrogenation of that hydrobenzamide which has not been decomposed by ammonia.

The addition of one mole of benzaldehyde to one mole of hydrobenzamide with subsequent hydrogenation gives rise to predominant amounts of dibenzylamine. In this case the mechanism is considered to be different, in that the reaction involves, first, the hydrogenation of hydrobenzamide

$$(RCH{=}N)_2CHR + 3H_2 \longrightarrow (RCH_2)_2NH + RCH_2NH_2 \quad (3)$$

second, the reaction of benzaldehyde with benzyl amine

$$RCH_2NH_2 + RCHO \longrightarrow RCH_2N{=}CHR + H_2O \quad (4)$$

and, finally, the hydrogenation of the Schiff base to dibenzylamine

$$RCH_2N{=}CHR + H_2 \longrightarrow (RCH_2)_2NH \quad (5)$$

The use of preformed hydrobenzamide is not necessary, since the hydrogenation of mixtures of benzaldehyde and ammonia gives the same results. Thus, a mixture of 2 moles of aldehyde and 1 mole of ammonia produces the secondary amine predominantly on hydrogenation. A ratio of 3 moles of aldehyde to 2 moles of ammonia gives equimolecular amounts of primary and secondary amines, as if hydrobenzamide itself had been used. Finally, a mixture of one mole of aldehyde and one or more moles of ammonia produces mainly primary amine.

In this way a very effective method for controlling the type of hydrogenation product is made available. It is possible to obtain good yields only with those aldehydes which have no hydrogen on the alpha carbon atom. The use of aliphatic aldehydes should presumably lead to similar results, but the formation of tarry by-products through the aldol reaction or other condensation largely masks the production of amines.

Table I presents the results of several hydrogenations of benzaldehyde, *o*-methylbenzaldehyde, *o*-chlorobenzaldehyde, and furfuraldehyde with varying amounts of ammonia, showing the changes in proportions of products with changes in the aldehyde–ammonia ratio. Where low amounts of ammonia were used, the primary amine fraction contained some of the corresponding alcohol produced by direct hydrogenation of the aldehyde. Titration with standard acid gave the true amine content which is reported. In the other cases the products were substantially pure.

Table II gives summarizing data on the hydrogenation of preformed hydroamides in the presence of aldehydes or of ammonia. These results agree quite well with those of Table I for corresponding ratios of aldehyde and ammonia, and demonstrate that the proportions of products depend on the ratio of reactants and not on the method of addition.

Experimental

All hydrogenations were carried out in a steel shaking autoclave of the type described by Adkins.[3] Hydrogen pressure as low as 20 atmospheres has been quite satisfactory although higher pressures up to 100 atmospheres generally were used. Raney nickel in the amount of 3% on the aldehyde was very active, and a single portion of catalyst could be used a dozen times or more in successive hydrogenations. Temperatures in the range of 40–75° have been effective in these conversions.

Ammonia was most conveniently added as a standard alcoholic solution in those cases where accurately measured amounts were needed. For additions of ammonia in ex-

cess, the gas was led from a storage cylinder through high pressure connections directly into the autoclave.

A typical hydrogenation is described in detail. Three gram moles of benzaldehyde was added to a solution of 51 g. (3 moles) of ammonia in 300 ml. of cooled alcohol in the hydrogenation autoclave with 10 g. of Raney catalyst. Under an initial pressure of 90 atmospheres hydrogen absorption started at 40° and in half an hour was complete at a final temperature of 70°. Distillation of the filtered reaction product gave 287 g. (89.4%) of benzylamine, b. p. 70–80° (8 mm.), and 21.7 g. (7.1%) of dibenzylamine, b. p. 140–150° (7 mm.).

Ethyl alcohol was used as reaction medium throughout because it is miscible with both starting materials and products. A solvent of this type is necessary to maintain homogeneity where water is one of the products.

Acknowledgment.—The writer is grateful to Messrs. L. B. Sebrell and R. P. Dinsmore of the Goodyear Tire and Rubber Company for their interest in this work and for permission to publish the results.

Summary

The hydrogenation of aldehydes, such as benzaldehyde, containing no reactive hydrogen on the alpha carbon atom, in alcoholic ammonia solution may be accomplished at temperatures below 75°. By suitable control of the ratio of aldehyde to ammonia, the product may be predominantly primary amine or secondary amine.

Condensations Brought about by Bases. VII. The Acylation of Ethyl Isobutyryl-isobutyrate and the Cyclization of a 3,5-Diketo-ester by Means of Sodium Triphenylmethyl[1]

BY BOYD E. HUDSON, JR., AND CHARLES R. HAUSER

Ethyl isobutyryl-isobutyrate is readily synthesized in good yield either from the enolate of ethyl isobutyrate (prepared from the ester and sodium triphenylmethyl) and isobutyryl chloride,[2] or from ethyl α-bromoisobutyrate and magnesium[3]; the former method gives a purer product.[4]

Ethyl isobutyryl-isobutyrate (I) on treatment with sodium triphenylmethyl is converted into its sodium enolate, which is readily acylated. The enolate of (I) with acetyl chloride gives presumably compound (II), and with isobutyryl chloride gives compound (III).

In connection with the preparation of com-

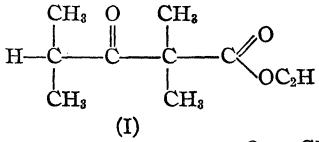
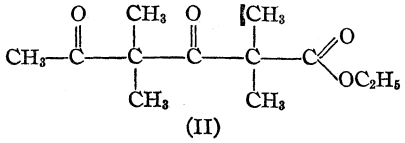
(4) Ethyl isobutyryl-isobutyrate also has been prepared by the self-condensation of ethyl isobutyrate in the presence of sodium triphenylmethyl, see Ref. 2a, p. 1823.

pound (III), it has been shown that this diketo ester is obtained when the reaction mixture, resulting from the self-condensation of ethyl isobutyrate[4] in the presence of sodium triphenylmethyl, is treated with isobutyryl chloride. The yield (42%) of compound (III) isolated in this case was only slightly less than that (46%) obtained when ethyl isobutyryl-isobutyrate was converted into its enolate, and the latter treated with isobutyryl chloride as discussed above. Since the free β-keto-ester does not condense with the acid chloride, this result shows that the ethyl isobutyryl-isobutyrate produced by the self-condensation of ethyl isobutyrate by means of sodium triphenylmethyl (even in the presence of excess ethyl isobutyrate) is in the form of its sodium enolate as postulated previously.[4]

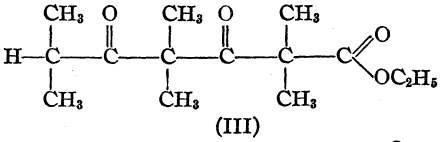
Compound (III) on treatment with sodium triphenylmethyl undergoes cyclization to give compound (IV). Compound (III) on treatment with sodium ethoxide undergoes cleavage, forming ethyl isobutyrate. Attempts to cyclize compound (II) with sodium ethoxide and with sodium triphenylmethyl apparently were unsuccessful; in both cases an alkali-soluble oil that could not be crystallized was obtained. Reisch[5] reported that the tetramethylphloroglucinol, which should result from cyclization of compound (II), is a solid melting at 187–188°.



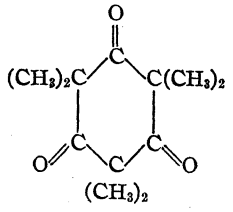
(I)



(II)



(III)



(IV)

The cyclization of compound (III) to give hexamethylphloroglucinol (IV) by means of sodium triphenylmethyl is of interest in connection with the acetoacetic ester condensation. In most ester-condensations of this type the β-keto-ester formed is converted into its enolate. However, similar to the case recently reported in which ethyl isobutyrate was condensed with ethyl benzoate,[6] the cyclization of compound (III) is an instance in which the Claisen[7] or acetoacetic ester type of condensation occurs even though the product formed cannot be converted into an enolate. It should be pointed out that neither of these condensations takes place in the presence of sodium ethoxide as condensing agent, and that they have been effected only by means of a stronger base, sodium triphenylmethyl.

Experimental[8]

Preparation of Ethyl Isobutyryl-isobutyrate. (a) From the Enolate of Ethyl Isobutyrate and Isobutyryl Chloride.[2]—To an ether solution of sodium triphenylmethyl[9] prepared from 63 g. of triphenylchloromethane (m. p. 112–113°), 1500 cc. of dry ether (dried with sodium), and 2000 g. of 1% sodium amalgam was added 21 g. (0.18 mole) of purified ethyl isobutyrate (b. p. 111–112°). After the solution had stood for ten minutes at room temperature with occasional shaking, 19.5 g. (0.18 mole) of isobutyryl chloride (Eastman Kodak Co.) was added rapidly with shaking. After standing in a closed flask for several hours, the reaction mixture was worked up by extracting with water, washing with 10% sodium carbonate solution, and drying first with anhydrous sodium sulfate and then with "Drierite." The solution was filtered and the ether distilled off until the volume of the residue was approximately 75 cc. The residue was chilled overnight in the refrigerator. The triphenylmethane which crystallized out was filtered off and washed with a small quantity of ether, the washings being added to the filtrate. After all the ether was removed by distillation at atmospheric pressure, the filtrate was vacuum-distilled, collecting up to 160° at 15 mm. The distillate was refractionated and the fraction boiling at 93.5–94.5° at 15 mm. collected; yield, 19 g., 55% of the theoretical amount.

(b) From Ethyl α-Bromoisobutyrate and Magnesium.[3]—A solution of 100 g. (0.52 mole) of ethyl α-bromoisobutyrate (Eastman) in an equal volume of dry ether was added to 16.6 g. (0.68 mole) of fresh magnesium turnings contained in a round-bottomed flask equipped with a reflux condenser. The reaction was started by adding a small crystal of iodine and warming the flask gently. After the reaction started, vigorous refluxing took place spontaneously. The reflux rate was moderated by the occasional application of an ice-bath. When spontaneous refluxing ceased, heat was applied and the mixture re-

fluxed for three hours longer. At the end of that time the reaction mixture was worked up by the cautious addition of ice, followed by dilute sulfuric acid. The ether layer was separated, washed with 10% sodium carbonate solution, and dried with anhydrous sodium sulfate. The ether was distilled off and the residue was vacuum-distilled on a metal-bath from a round-bottomed flask equipped with a six-inch (15 cm.) Widmer column. The fraction boiling at 90–94° at 15 mm. was collected; yield, 34 g., 72% of the theoretical amount.

Reaction of the Enolate of Ethyl Isobutyryl-isobutyrate with Isobutyryl Chloride.—To an ether solution of sodium triphenylmethyl[9] (containing 0.085 mole of base), prepared from 28 g. of triphenylchloromethane, 1000 g. of 1% sodium amalgam, and 750 cc. of dry ether, was added with shaking 16 g. (0.086 mole) of ethyl isobutyryl-isobutyrate. The flask was stoppered and the mixture allowed to stand at room temperature for four hours with frequent shaking. At the end of this time, the mixture was poured rapidly into a solution of 15 g. (0.14 mole) of isobutyryl chloride (Eastman) in 500 cc. of dry ether, the latter being agitated vigorously with a mechanical stirrer. The vessel was closed and the reaction mixture allowed to stand for four hours longer. Then the mixture was extracted twice with water, washed several times with 10% sodium carbonate solution, and dried with anhydrous sodium sulfate followed by "Drierite." The solution was filtered and most of the ether distilled off. The residue (approximately 40 cc.) was chilled overnight in the refrigerator. The triphenylmethane which had crystallized out was filtered off and washed with a small quantity of ether, the washings being added to the filtrate. After all of the ether was removed by distillation at atmospheric pressure, the filtrate was vacuum-distilled, collecting up to 160° at 15 mm. The distillate was refractionated and the fraction of ethyl 2,2,4,4,6-pentamethyl-3,5-diketoheptanoate (III) boiling at 136–138° at 15 mm. was collected; yield, 10 g., 46% of the theoretical amount based on the quantity of either ethyl isobutyryl-isobutyrate or of sodium triphenylmethyl used. A portion of the diketo-ester boiling at 137–138° was analyzed.

Anal.[10] Calcd. for $C_{14}H_{24}O_4$: C, 65.6; H, 9.45. Found: C, 65.2, 65.0; H, 9.57, 9.77.

Cyclization of Ethyl 2,2,4,4,6-Pentamethyl-3,5-diketoheptanoate to Hexamethylphloroglucinol.—Seven and one-half grams (0.029 mole) of the pentamethyl-diketoheptanoate was added to 250 cc. of an ether solution of sodium triphenylmethyl (containing about 0.03 mole of base) prepared as described in the preceding experiment. The red color of the base disappeared immediately with the formation of a precipitate. The reaction flask was stoppered and allowed to stand for three days with occasional shaking. At the end of this time, the mixture was acidified with excess glacial acetic acid, extracted with water, washed with 10% sodium carbonate solution, and dried with anhydrous sodium sulfate. The ether was distilled off and the residue vacuum-distilled. A fraction which solidified in the condenser came over at about 130–140° at 15 mm. The crystalline material was washed from the condenser with ether. The ether was evaporated and the residue recrystallized by dissolving in a minimum of ligroin (90–120°) at about 40° and chilling in a mixture of ice and acetone. A yield of 1.85 g. (30% of the theoretical amount) of hexamethylphloroglucinol melting at 79–80° was obtained. This melting point is in agreement with that reported in the literature for hexamethylphloroglucinol,[11] and was not lowered by the addition of an authentic specimen of that compound prepared[11] by the methylation of phloroglucinol.

Evidence that the Ethyl Isobutyryl-isobutyrate Obtained from Ethyl Isobutyrate and Sodium Triphenylmethyl is in the Form of its Enolate.—To an ether solution of sodium triphenylmethyl[9] (containing approximately 0.18 mole of base) prepared from 63 g. of triphenylchloromethane (m. p. 112–113°), 1500 cc. of dry ether (dried with sodium), and 2000 g. of 1% sodium amalgam was added 45 g. (0.39 mole) of purified ethyl isobutyrate (b. p. 111–112°). The flask was stoppered and allowed to stand for twenty-four hours with occasional shaking. At the end of that time the mixture was poured into a solution of 24 g. (0.22 mole) of isobutyryl chloride (Eastman) in 500 cc. of dry ether with vigorous mechanical stirring. The reaction mixture was allowed to stand in a closed vessel for an hour. It was then extracted with water, washed with several portions of 10% sodium carbonate solution, and dried with anhydrous sodium sulfate followed by "Drierite." The solution was filtered and the ether distilled off until the volume of the residue was approximately 75 cc. The liquid remaining was chilled overnight in the refrigerator. The crystallized triphenylmethane was filtered off and washed with a small quantity of ether, the washings being added to the filtrate. After the ether was removed by distillation (up to 50°), the remaining liquid was distilled, collecting up to 150° at atmospheric pressure. The residue was then vacuum-distilled, collecting up to 180° at 15 mm. Refractionation of the two distillates yielded the following fractions: (a) 106–121° at atm. press., 22 g. (ethyl isobutyrate); (b) 120° at atm. press. to 131° at 15 mm., 3 g.; (c) 136–138° at 15 mm., 6.3 g. (ethyl 2,2,4,4,6-pentamethyl-3,5-diketoheptanoate); (d) 131–139° at 15 mm., 2.2 g. (impure heptanoate).

Fraction (a) consisted practically entirely of ethyl isobutyrate; on redistillation most of the fraction boiled within the range commonly reported for this ester. Fraction (b) may have contained a little ethyl isobutyryl-isobutyrate but because of the wide boiling range and small quantity obtained no attempt was made to isolate this compound. It should be pointed out that ethyl isobutyryl-isobutyrate would be expected if the isobutyryl chloride used contained any isobutyric acid, since the latter would immediately convert the enolate into the free β-keto-ester.

Fraction (c) was regarded as pure ethyl 2,2,4,4,6-pentamethyl-3,5-diketoheptanoate, while fraction (d) probably consisted largely of this compound. The yield of heptanoate in fractions (c) and (d) was 42% of the theoretical amount, based on the quantity of sodium triphenylmethyl used. In the calculation of this yield it was taken into account that one-half the sodium triphenylmethyl was consumed in condensing ethyl isobutyrate with itself, and

(10) Micro-analysis by R. L. Peck.

(11) Spitzer, *Monatsh.*, **11**, 104 (1890).

that only the remaining half of the base served to enolize the condensation product, ethyl isobutyryl-isobutyrate. The heptanoate was cyclized to hexamethylphloroglucinol as described above; the latter was identified by the mixed melting point method.

Cleavage of Ethyl 2,2,4,4,6-Pentamethyl-3,5-diketoheptanoate by Sodium Ethoxide.—Sodium ethoxide was prepared by dissolving 1.80 g. (0.078 mole) of sodium in 150 cc. of absolute alcohol[12] contained in a flask equipped with a ground-glass joint. The excess alcohol was distilled off on an oil-bath and the residue heated for thirty minutes at 200° under a pressure of 10 mm. Dry nitrogen was admitted into the flask which was then allowed to cool to room temperature. To the sodium ethoxide was added a solution of 5.75 g. (0.022 mole) of ethyl 2,2,4,4,6-pentamethyl-3,5-diketoheptanoate in 500 cc. of dry ether. Several pieces of glass tubing about 2 cm. long were dropped into the flask and a well lubricated glass stopper was inserted and clamped in place. The flask was shaken vigorously until most of the cake of sodium ethoxide had been changed to a fine suspension. The mixture was allowed to stand for seven days with occasional shaking. At the end of that time the reaction mixture was acidified with 7 cc. of glacial acetic acid, extracted with water, washed with 10% sodium carbonate solution, and dried with anhydrous magnesium sulfate. Ether was distilled off through a six-inch (15-cm.) Widmer column. Practically all of the residue distilled over at 100–112°; yield, 5.5 g. This material was presumably ethyl isobutyrate; on redistillation most of it boiled at 109–112°, which is the boiling point commonly reported for this ester. The yield of 5.5 g. of ethyl isobutyrate obtained corresponds to 74% of the theoretical amount.

Reaction of Enolate of Ethyl Isobutyryl-isobutyrate with Acetyl Chloride.—To an ether solution of sodium triphenylmethyl,[9] prepared from 28 g. of triphenylchloromethane, 1000 g. of 1% sodium amalgam, and 750 cc. of dry ether, was added 15.6 g. (0.084 mole) of ethyl isobutyryl-isobutyrate. After standing for thirty minutes, the mixture was poured, with vigorous stirring, into a solution of 10 g. (0.126 mole) of acetyl chloride (Baker and Adamson, reagent grade) in 500 cc. of dry ether. After standing for thirty minutes longer, the mixture was extracted with water, washed several times with 10% sodium carbonate solution, and dried with anhydrous sodium sulfate followed by "Drierite." The solution was filtered, the ether distilled off, and the residue vacuum-distilled, collecting up to 160° at 15 mm. The distillate was vacuum-fractionated on a metal-bath, using a flask equipped with a five-inch (13-cm.) Vigreux column, and without the use of an ebullition tube. The fraction boiling at 122–124° at 15 mm., presumably ethyl 2,2,4,4-tetramethyl-3,5-diketohexanoate (II), was collected; yield, 10 g., 52% of the theoretical amount.

Anal.[10] Calcd. for $C_{12}H_{20}O_4$: C, 63.1; H, 8.83. Found: C, 62.9, 63.6; H, 8.92, 8.78.

Attempts to cyclize the compound synthesized above were unsuccessful. Five grams (0.022 mole) of the compound was added to an ether solution of sodium triphenylmethyl containing approximately 0.044 mole of base. The red color of the base disappeared immediately with the formation of a precipitate. The reaction mixture was allowed to stand overnight; it was then acidified with excess dilute hydrochloric acid and extracted with water. The resulting ether solution was extracted three times with 20% sodium hydroxide solution. The combined alkaline extracts were acidified with dilute hydrochloric acid and extracted with ether. Evaporation of the ether left an oily residue (2–3 g.) which could not be made to crystallize. A similar alkali-soluble oil was obtained when the reaction mixture was acidified ten minutes after the addition of the sodium triphenylmethyl. An alkali-soluble oil also was obtained when an ether solution of the compound was allowed to stand for four days with sodium ethoxide. The oil isolated in these experiments has not yet been identified. The reaction will be studied further.

Summary

1. The sodium enolate of ethyl isobutyryl-isobutyrate has been acylated with acetyl chloride and with isobutyryl chloride. The 3,5-diketo-ester, obtained with the latter acid chloride, on treatment with sodium triphenylmethyl undergoes cyclization to form hexamethylphloroglucinol. This cyclization does not take place in the presence of sodium ethoxide.

2. The significance of the cyclization reaction in relation to the acetoacetic ester type of condensation is discussed.

3. Evidence is presented that the ethyl isobutyryl-isobutyrate obtained from the self-condensation of ethyl isobutyrate by means of sodium triphenylmethyl is in the form of its sodium enolate.

4. Two syntheses of ethyl isobutyryl-isobutyrate are described.

The Catalytic Cracking of Aliphatic Hydrocarbons*

BY GUSTAV EGLOFF, J. C. MORRELL, CHARLES L. THOMAS AND HERMAN S. BLOCH

The thermal decomposition of long-chain aliphatic hydrocarbons is characterized by non-selective chain scission which is undesirable from a utilitarian viewpoint; but little systematic work has been done to develop catalysts which would induce a selective chain splitting. A review of the field[1] led to the conclusion that difficultly reducible refractory oxides were the best potential catalysts for carbon–carbon bond scission. In the present work the effect of an activated silica–alumina mass on the reactions of *n*-butenes, *n*-pentenes, *n*-octenes, cetene, *n*-octane and cetane was studied under conditions which allowed comparisons between (1) the catalyzed and the uncatalyzed reactions; (2) the cracking of paraffins and olefins of the same chain length and (3) homologs in both the paraffin and the olefin series.

Reactions of *n*-Butenes.—A mixture of *n*-butenes has been reported to isomerize to isobutene in the presence of a catalyst consisting of phosphoric acid on various supports.[2,3] Frost and co-workers[2] found that the reversible isomerization of butenes-1 and -2 to isobutene followed the equilibrium equation

$$\log K_p = \frac{304}{T} 0.528 \pm 0.020$$

At 300° the equilibrium mixture contained equal amounts of straight chain and branched chain butenes.

In our experiments the *n*-butenes were passed over the catalyst at temperatures varying from 385 to 600°; the results are summarized in Table I.

It is apparent that under the conditions employed considerable polymerization to higher-boiling materials and decomposition to lighter gases accompanies the isomerization to isobutene. The yield of liquid products reached a maximum of about 25% at 450° (at flow rates of 200–230 volumes of gas per volume of catalyst per hour) and then declined; the yield of light gases increased steadily with rise of temperature, but sharply decreased with rise of flow rate.

At space velocity 200–230, the isomerization was not sensitive to temperature change between 450 and 600°; the C_4 fraction of the product contained 24.1 ± 1.5% of isobutene. The total isobutene yield was raised, however, by increasing the space velocity at 600°, since the side reactions were cut down while the isobutene content of the C_4 product was unchanged. The fact that a 5.7-fold increase of space velocity produced no change in the isobutene content points to the attainment of a pseudo-equilibrium; that true equilibrium was not reached is indicated by the isobutene/*n*-butene ratio, which never exceeded 0.40, although according to the equation of Frost and co-workers[2] the equilibrium ratio ranges from 1.0 at 300° to 0.66 at 600°.

Reactions of *n*-Pentenes.—The catalytic isomerization study was extended to the next higher homologs, *n*-pentenes. Although the thermal isomerization of both pentene-1 and -2 into isopentenes has been reported,[4] the work was not corroborated in a later publication by the same author,[5] and no reliable evidence of such isomerization, either thermal or catalytic, has been published[6]; the inter-isomerization of pentene-1 and -2, however, has been definitely established.[4,5]

n-Pentenes prepared by the catalytic dehydration of *n*-amyl alcohol were passed over the present catalyst at 400° with the results shown in Table II.

Distillation of the C_5 fraction after it had been hydrogenated over a nickel catalyst at 100° showed that it contained 82% of isopentane and 18% of *n*-pentane. The conversion of *n*-pentenes to methylbutenes, therefore, was 53%[7]; at the same time about 8% of gas and 17% of material boiling above pentenes were formed. Since the molar ratio of C_4 to C_6 hydrocarbons recovered was about 1.2, it seems likely that the major portion of these hydrocarbons was formed by the decomposition of pentene dimer.

[a] These gasifications correspond to an initial period of high catalytic activity.

Reactions of *n*-Octenes.—*n*-Octenes (prepared by the catalytic dehydration of octanol-2) not only isomerized when passed over the catalyst but also decomposed. The 20% cracking at 375° is in striking contrast to the 0.4% reaction of *n*-octenes obtained thermally at 364–369° by Hugel and Szayna[8] and the 7% obtained by them at 438–444°. The results of the catalytic cracking at 375, 385 and 400° are summarized in Table III.

The composition of the gases produced catalytically is in sharp contrast to that obtained by Hugel and Szayna in thermal cracking. At 438–444°, the gas formed in the latter process contained over 90% of paraffins and hydrogen; the gas obtained by catalytic cracking contained approximately 90% of propene and butenes, and only traces of materials lighter than the three-carbon hydrocarbons. The composition of the catalytically produced gas is unusual also for the fact that approximately equal quantities of normal and isobutene were present; this was especially true of the runs at 385 and 400°. This isobutene could be formed in at least three ways: (1) direct cracking of the *n*-octenes to give two straight-chain butenes followed by the isomerization of the *n*-butenes; (2) direct cracking of the *n*-octenes into two straight-chain C_4 radicals which are isomerized before rearranging to the

(8) Hugel and Szayna, *Ann. combustibles liquides*, **1**, 781 (1926).

olefin, and (3) the isomerization of the *n*-octenes to *iso*-octenes followed by cracking of the iso-octenes to yield isobutene.

Since this catalyst was also studied with *n*-butenes under similar conditions without producing equal amounts of iso- and *n*-butenes, hypothesis (1) seems unlikely. We have no direct evidence for or against hypothesis (2). Since iso-octenes were isolated there is little doubt that hypothesis (3) is entirely possible. Thus, although we are not able to exclude hypothesis (2), we are inclined to favor hypothesis (3).

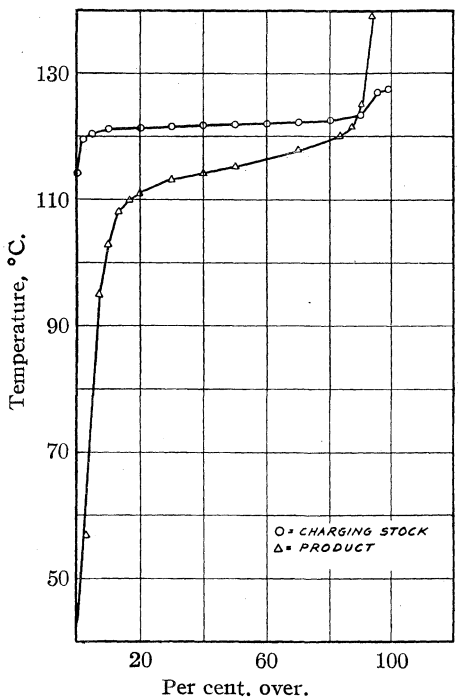

Fig. 1.—Catalytic decomposition of octenes -1 and -2 at 385°.

A study of the distillation curve of the liquid product obtained at 385° (Fig. 1) confirms the isomerization of the octenes; approximately 80% of the octene fraction consisted of iso-octenes boiling lower than the original but boiling above any C_7 olefins. In the 375° run, approximately 75% of the octene fraction consisted of these isoöctenes, as shown in Table III. The catalyst employed in this work was a more effective isomerizing agent than zinc chloride or phosphoric acid on pumice, which, according to Petrov and Cheltsova,[9] converted a mixture of octenes-1 and -2 to a maximum of 45–47% of isoöctenes, under comparable temperature conditions, but with much longer periods of contact.

To determine the constituents of the isoöctene fraction obtained at 375°, all of the product boiling below 121.5° was hydrogenated in the presence of a nickel catalyst at 100° and 100 kg./sq. cm. pressure, and the saturated product distilled on a 50 bubble-plate column of the Bruun type.[10] The distillation curve is shown in Fig. 2. From this curve and refractive indices of several of the fractions, the following hydrocarbons are suggested as likely constituents.[11]

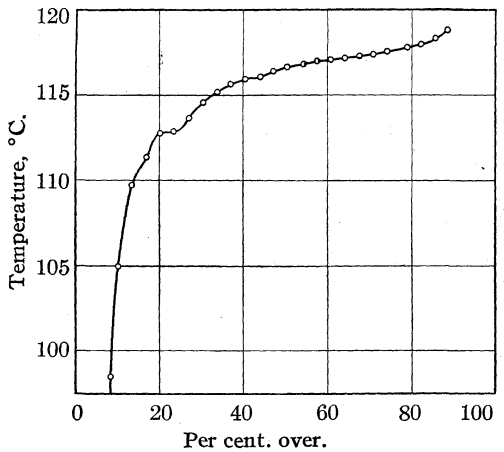

Fig. 2.—Hydrogenated isoöctenes formed from octenes-1 and -2 at 375°.

2,3,4-Trimethylpentane (b. p. 113.8°) corresponding to the first plateau (113.8–113.9°), is the only octane boiling between 111.5 and 114.6° except 2-methyl-3-ethylpentane (b. p. 114°) which is another possibility but is considered less likely.

2-Methylheptane (b. p. 117.2°) corresponds to the second plateau (117.0–117.1 corr.).

4-Methylheptane (b. p. 118.0°) and/or 3,4-dimethylhexane (b. p. 117.9°). The fraction boiling at 117.0–118.0° (corr.) had a refractive index (n^{20}D 1.3987) which indicated that it was probably a mixture of 2-methylheptane (n^{20}D 1.3936) and one or both of the above (n^{20}D 1.4035 and 1.4044, respectively). It seems less likely to contain 3-ethylhexane (b. p. 118.6°, n^{20}D 1.4014) and unlikely to be 3-methyl-3-ethylpentane (b. p. 118.4°, n^{20}D 1.4081).

3-Methylheptane (b. p. 119.0°, n^{20}D 1.3982). The fraction boiling at 118.0–118.8° (corr.) had a

(11) Grosse and Egloff, "Physical Constants of Paraffin Hydrocarbons," published by Universal Oil Products Co., Chicago, Ill., 1938.

refractive index $n^{20}D$ 1.3982, lower than that of the preceding fraction, and the fraction boiling at 118.8–119.8° (corr.) had an index $n^{20}D$ 1.3987. Since 3-methylheptane is the only octane boiling in this range with a refractive index below 1.4, considerable amounts of this hydrocarbon must have been present.

The over-all picture indicates that the catalyst effects extensive isomerization of *n*-octenes to methylheptenes, dimethylhexenes, and trimethylpentenes, probably by the migration both of alkyl groups and of the double bond. The isoöctenes then crack under the influence of the catalyst, principally to *n*- and isobutenes and to propene and pentenes.

The octene product was hydrogenated and fractionated into an isoöctane cut boiling at 106–119° (corr.). The A. S. T. M. octane number of this cut was 48.5; that of *n*-octane (obtained by hydrogenating the *n*-octenes used in these experiments) in the same engine was −20. This is additional proof that the carbon skeleton of the octene has been changed since, in general, the higher octane number of a given molecular weight paraffin is usually associated with the most highly branched isomer.

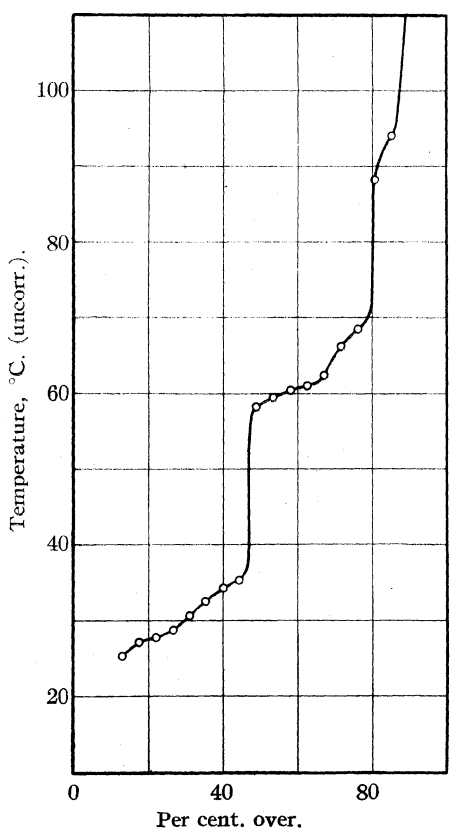

Fig. 3.—Distillation of hydrogenated gasoline from catalytic cracking of cetane.

Cetene Cracking.—From a study of the thermal reactions of cetene at 350 to 725°, Gault and his co-workers[12] concluded that at the lower temperatures olefinic products predominated, while at higher temperatures alicyclic and aromatic hydrocarbons were formed in increasing amounts. The maximum production of olefinic gases (66–68% of the gaseous product) occurred at 575 to 700°, while initial cracking of the cetene began at 450 to 550°, depending on the contact time. Hugel and Goldthorpe[13] found that metallic catalysts lowered the temperature at which reaction began.

With the catalyst used in the present work cetene showed incipient reaction at 300° with a liquid space velocity of four. The gasification under these conditions was only 0.07%, but 8% of the product (neglecting a small amount of residue) boiled over a 6° range immediately below the original boiling range (at reduced pressure). At 350° about 5.5% of the charge was cracked to gasoline and gas; but of the hexadecenes recovered, almost 50% boiled within a 9° range just below that of the original cetene. This fraction was believed to consist of lower-boiling isohexadecenes, since there were no gaseous products such as would have accompanied the formation of 14- and 15-carbon molecules. In run B-331 this lower-boiling hexadecene fraction was catalytically cracked at 350° under the same conditions as were employed for the original cetene; three times as much cracking was effected. These results tend to confirm the tentative conclusions reached in the *n*-octene experiments, namely, that the cracking of normally liquid straight-chain olefins over the present catalyst is largely preceded by isomerization.

The data obtained in the cracking of cetene at 300° to 450° are summarized in Table IV.

It will be noted that the proportion of low-boiling hexadecenes in the C_{16} fraction increases with rising temperature, until practically no cetene is left in the hexadecene fraction of the 450° run.

In order to approximate the course of the reactions, the products were expressed as moles formed per 100 moles of cetene converted to

[a] From low-boiling hexadecenes. [b] Of which only 10.2 were recovered, 5.8 assumed lost. [c] Of which only 6.8 were recovered, 12 assumed lost.

In both runs at 350° and in the test at 400°, approximately 200 moles of products were recovered from the cracking of 100 moles of hexadecenes. Practically all of the reaction taking place, therefore, must have been primary. At 450°, on the other hand, of the 200 moles formed by the primary reactions, 50 were cracked in secondary reactions, making it difficult to determine which products are primary and which secondary. For the other three runs, however, a reasonably complete picture of the primary reactions can be given, as shown in Table VI.

The parenthetical figures given for the 400° experiment represent alternate reactions which would also agree with the experimental results, but which would correspond to the different secondary reactions also shown in parentheses. Still others could be devised, but there is no basis for preferring any one set of secondary reactions. Since the amount of secondary reaction is small, however, the over-all picture of the primary reaction is not greatly altered.

The values given in Table VI are in excellent agreement with the molar values given in Table V. The close agreement between the results found for the cetene and the low boiling hexadecenes shows that the products derived from cetene are the same as those from the i-hexadecenes, and confirms the conclusion that the cracking of the former is preceded by isomerization.

TABLE VI

REACTIONS OCCURRING IN CRACKING OF CETENE

Primary cracking reaction	Moles reacting per 100 moles of cetene cracked 350°	350°[a]	400°	Secondary cracking reaction	Moles of primary product reacting per 100 moles of cetene cracked at 400°

[a] Charging stock: isomerized hexadecenes.

The distillation curves (obtained with a 17-plate vapor-jacketed column[14]) for the hydrogenated gasolines produced at 400 and 450° (Figs. 4 and 5) show plateaus at the same temperatures; but the lower plateaus are broader and the higher plateaus narrower in the 450° curve, corresponding to more secondary cracking of the higher-boiling primary products. This increase in the amount of low-boiling products is probably also responsible for the higher octane numbers found for both the unsaturated and the hydrogenated gasolines produced at 450°, as compared with the 400° product (see Table IV).

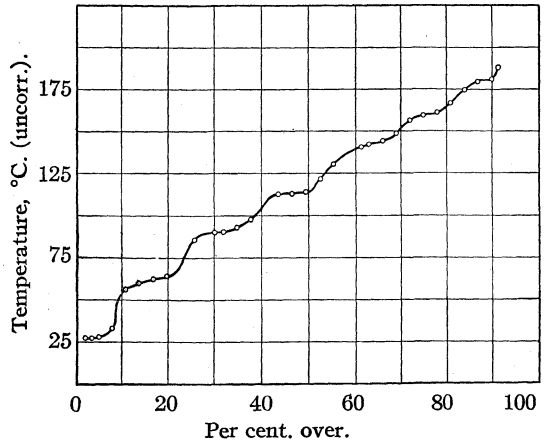

Fig. 4.—Distillation of hydrogenated gasoline from catalytic cracking of cetene at 400°.

The plateaus in the distillation curves indicate the presence of isopentane (28°), 2-methylpentane (60°) and possibly 3-methylpentane (63°) and 2,3-dimethylbutane (58°), the methylhexanes (90–92°) and possibly 2,3-dimethylpentane (90°), the methylheptanes (117–119°) and possibly 2,3-dimethylhexane (116°), the methyloctanes (about 142°), the methylnonanes (about 160–165°) or dimethyloctanes (about 156–160°), and the methyldecanes or dimethylnonanes (about 175–183°). The refractive indices and boiling points obtained at 450° are given in Table VII.

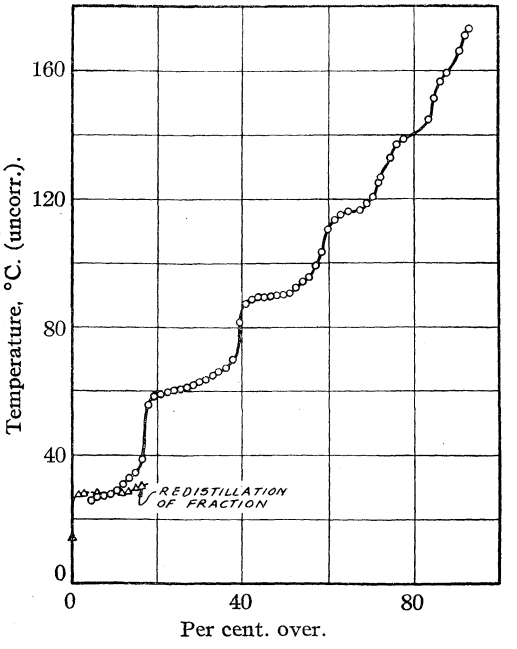

Fig. 5.—Distillation of hydrogenated gasoline from catalytic cracking of cetene at 450°.

It is significant that no appreciable amounts of normal paraffins were present in any fraction of the gasoline, showing that both fragments resulting from the cetene cracking are isomerized. Since thermal scission of an olefin molecule may be expected[4] to occur chiefly at the bond β to the double bond (an observation borne out in this

catalytic work by the absence of appreciable quantities of gaseous products containing fewer than three carbon atoms) and since it is further apparent from Table VI that scission takes place to an almost equal extent at each C—C bond of the molecule (except at the three bonds nearest each end of the chain) we may conclude that cetene is catalytically cracked chiefly according to the following successive steps: (1) isomerization of cetene to lower-boiling branched-chain hexadecenes, either with or without migration of the double bond; (2) scission of the chain to an almost equal extent at each bond except those near the extremities of the molecule; (3) isomerization of any normally liquid olefinic products to isoölefins; and (4) with longer contact times or at higher temperatures, secondary decomposition of the longer-chained primary products as in steps 2 and 3, so that the products having fewer than eight carbon atoms increase in amount, while those having more than eight carbon atoms decrease in amount.

It should further be pointed out that small amounts of paraffinic products are formed, and that corresponding to these there should also be either diolefins (not necessarily conjugated), acetylenes, cyclo-olefins, or aromatics in the product. Alternatively a small amount of carbon deposit on the catalyst accounts for the liberation of sufficient hydrogen to hydrogenate a portion of the olefinic product.

Cracking of *n*-Octane.—The previous work on the catalytic and pyrolytic decomposition of *n*-octane has already been adequately summarized.[15,16] In none of the catalytic work were refractory oxide catalysts employed; of the pyrolytic work, that of Marschner[16] is the most complete and was carried out under temperature conditions similar to the present work, so that his results are comparable.

The catalytic decomposition of *n*-octane was carried out at 525, 540, 555 and 570°, at a liquid space velocity of four volumes of liquid octane per volume of catalyst per hour. The results are summarized in Table VIII.

[a] Total paraffins; index 2.30. [b] Includes *n*-butenes. [c] Total paraffins; index 2.51. [d] Does not include gas dissolved in the liquid product which may amount to 1–2% of the octane charged.

Because of the small amount of reaction and of materials used, a complete analysis of the products was made only in the case of the 570° run. The results are shown in Table IX, together with comparable thermal results calculated from the data of Marschner.

TABLE IX

CATALYTIC AND PYROLYTIC CRACKING OF *n*-OCTANE

		Catalytic	Marschner, pyrolytic
Furnace temp., °C.		570	570
Contact time, seconds		1.0	12.7
Decompn., %		11.0	19.4
Moles of products per mole of octane cracked		2.4	3.2
Complete product analysis, moles per 100 moles of octane cracked	H_2	13	0.3
	CH_4	9	77
	C_2H_4	19	86
	C_2H_6	11	55
	C_3H_6	52	46
	C_3H_8	18	6.5
	C_4H_8	22	18

	C_5	73	15
	$C_6 + C_7$	16	21
Unaccounted, wt. % of charge		2.2	0.8

Although the degree of cracking in the two runs differs considerably, a comparison is justifiable because of Marschner's conclusion that for pyro-

(16) Marschner, *Ind. Eng. Chem.*, **30**, 554 (1938).

lytic decomposition "the product analyses were the same when decomposition was increased from 18 to 33%, . . . and differed but little from those obtained at 538°" where 11% cracking was obtained. Furthermore, the incomplete analyses of Dintzes and Zherko[17] for 13% conversion at 570° check closely those of Marschner for 19% decomposition at the same temperature, indicating that essentially the same reactions occur over a rather wide range of temperature and conversion.

It is clear from Table IX that the pyrolytic cracking results in a greater yield of methane, ethane and ethylene than the catalytic reaction, and a far smaller yield of C_5–C_7 hydrocarbons and of hydrogen. Furthermore, from the work of Marschner and of Dintzes and Zherko, it is estimated that to attain a pyrolytic cracking of 11% at 570°, a contact time of seven or eight seconds would be necessary. The catalyst therefore shortens the time of the reaction seven- to eightfold. It is also significant that the *n*-octenes decomposed so much more easily over the catalyst that at 375° there was twice as much cracking as with *n*-octane at 570° with comparable feed rates.

Cetane Cracking.—The cracking of cetane has been studied both thermally[12,18] and catalytically[19] by Gault and his associates, who concluded that in the absence of catalysts the carbon chain was broken indiscriminately at any point, but that with rising temperature the point of scission approached the chain end. The use of quartz or pumice tube-packing lowered the cracking temperature somewhat. This temperature lowering is probably due to more efficient heat transfer to the reacting system rather than to any catalytic properties of the quartz or pumice. The catalysts studied by Gault were of the metallic (*e. g.*, nickel) type so that the reactions produced involved the carbon–hydrogen bonds rather than the carbon–carbon bonds. Such catalytic results are not comparable with the present work.

In the present study cetane was cracked catalytically at 500° and liquid space velocity four. Because of the small amount of reaction and the limited amount of cetane available, the cetane recovered from the first pass (boiling in the original boiling range) was recycled and that recovered from the second pass was further recycled. The low-boiling liquid products of the three passes were combined and hydrogenated; the gases were separately analyzed, but showed substantially the same composition. The composite results are shown in Tables X and XI.

[a] Assumed molecular weight, 130. [b] Assumed molecular weight, 196.

From the fact that approximately 350 moles of reaction products was formed from 100 moles of cracked cetane, it is apparent that these are not the primary products, and no definite reaction mechanism can be postulated. It is interesting, however, that every mole reacting yielded approximately one mole each of C_3, C_4 and gasoline boiling-range hydrocarbons, indicating a selectivity of the catalyst for the formation of three-carbon and four-carbon fragments. In this respect the results differ from those of Gault[12,18] on thermal cracking, since his products led him to conclude that the initial step in the decomposition

(17) Dintzes and Zherko, *J. Gen. Chem.* (*U. S. S. R.*), **6**, 68 (1936).

(18) Gault and Barmann, *Ann. combustibles liquides*, **1**, 77 (1926); Gault and Hessel, *Compt. rend.*, **179**, 171 (1924); *Ann. chim.*, (10) **2**, 319 (1924).

(19) Gault and Sigwalt, *Ann. combustibles liquides*, **2**, 309, 543 (1927).

was the breaking-off of terminal groups forming methane and ethylene. Although exact comparisons with Gault's work are not possible due to the incompleteness of his data, it appears that in the experiments carried out in empty and packed tubes higher temperatures or longer contact times were required to attain the degree of cracking found in our experiments.

The preponderance of small molecules in the present study and the analytical data indicate either that the primary reaction products are more unstable than cetane itself, and that they are 75 to 100% decomposed to secondary products as compared with the 20% decomposition of cetane, or that the cetane molecule is ruptured at several points simultaneously.

The greater stability of *n*-octane as compared with cetane is indicated by the 11% decomposition of the former with the same catalyst and space velocity at a temperature 70° higher (570°) than that required to produce 20% decomposition of cetane.

The hydrogenated gasoline from the cetane decomposition had an A. S. T. M. octane number of 70. Distillation of this hydrogenated product on a 17-theoretical plate column of the vapor jacket[14] type, gave the curve shown in Fig. 3 and indicated the presence of isopentane (b. p. 28°), *n*-pentane (b. p. 36°), 2-methylpentane (b. p. 60°), *n*-hexane (b. p. 60°), and 2-methylhexane (b. p. 90°); 3-methylhexane (b. p. 92°) and 2,3-dimethylpentane (b. p. 90°) also may be present. No *n*-heptane appeared to be present; higher boiling constituents could not be determined because of the small amount of gasoline available. Isopentane, isohexane and isoheptane were all present in greater amounts than the corresponding normal compounds.

Experimental Part

Materials.—*n*-Butenes were prepared by the dehydration of butanol-2 over activated alumina. Low-temperature fractionation showed the following percentage composition: C_3 hydrocarbons 0.2, butene-1 fraction 15.2, butene-2 fraction 83.8, C_5 and higher 0.8. A small amount of isobutene and butanes may also have been present; the C_4 fraction showed 1.8% absorption in 64% sulfuric acid and 95% absorption in 87% sulfuric acid.

Pentene-1 was prepared from a selected cut (134.0–135.8°) of Eastman Technical pentanol-1 by dehydration over activated alumina at 400°. The pentene fraction was separated from the unreacted amyl alcohol and redistilled over sodium hydroxide in a 50-bubble cap column of the Bruun type.[10] The fraction used in this work boiled at 28–31°, and had a refractive index $n^{20}D$ 1.3720, as compared with the literature value of $n^{20}D$ 1.3711.[20] After hydrogenation the refractive index was $n^{20}D$ 1.3574 as compared with the literature value for *n*-pentane of $n^{20}D$ 1.3576. Distillation with a column of 17 theoretical plates efficiency, however, showed the presence of a maximum of 12.5% of isopentane and a minimum of 87.5% of *n*-pentane.

***n*-Octenes and *n*-Octane.**—The *n*-octenes used in the experiments at 385 and 400° were prepared by the dehydration of capryl alcohol over activated alumina at 400° and purified by distillation through a Hempel column. The distillation curve with a small laboratory column of 5 to 10 theoretical plates[21] is shown in Fig. 1. Approximately 10% boiled below 121°, and 7.5% above 125°; the refractive index was $n^{20}D$ 1.4131. The *n*-octenes used in the experiment at 375° were the fraction of the above octenes boiling at 121.2–124.9°, and had an index of refraction $n^{20}D$ 1.4133.

The *n*-octane was prepared by hydrogenation of the Hempel cut of *n*-octenes, and had a refractive index $n^{20}D$ 1.3978, as compared with the value[11] of 1.3980. The melting point was −58°.

Cetane.—Dupont Diesel Standard cetane was used without further purification.

Cetene.—Dupont cetene (technical) was redistilled *in vacuo* in a Claisen flask fitted with a 6-inch (15-cm.) Vigreux side-arm, and the fraction boiling at 148–151° at 7 mm. (d_4^{20} 0.778) was employed in this work; 13.5% of lower-boiling and 12% of higher-boiling material were discarded. All of the vacuum distillations analyzing the products were made in the same Claisen flask as that described above.

Experimental Procedure.—The charging stock was pumped by a copper-bellows pump[22] to an electrically heated preheater of stainless steel tubing maintained at such a temperature that the emergent vapor was at the reaction temperature, and thence into a 100-cc. stainless steel reaction chamber filled with 6–10 mesh granules of catalyst in a bed 15 cm. long. Although the catalyst chamber was supported in an electrically heated aluminum-bronze block which was maintained at a temperature constant to within ±1°, the actual temperature of the catalyst bed (which was read with a movable iron–constantan thermocouple) varied considerably because of the character of the reaction. For example, in the run with cetene at 450°, the reaction was endothermic and a temperature drop of 40° existed between the top of the bed and a point near the bottom. In the pentene run, however, there was a temperature rise in the first portion of the catalyst bed followed by a temperature drop so that although the furnace was maintained at 400°, the actual catalyst temperature varied between 448 and 370°. In the butene runs a temperature rise was observed also. A number of hypotheses have been considered to explain these unexpectedly large temperature changes, but as yet none of them is satisfactory.

The reaction products were led through a water condenser and a vertical ice reflux condenser fitted above a

(20) Leendertse, Tulleners and Waterman, *Rec. trav. chim.*, **53**, 715 (1934).

receiving flask for the liquid product. The gases were analyzed by a combined low-temperature fractionation and absorption analysis. In the analysis of the butenes 63% sulfuric acid was used to absorb isobutene and 87% acid the *n*-butenes. The condensable portion of the gases was collected in a dry-ice–trichloroethylene trap, and the C_5 and higher-boiling hydrocarbons recovered by a low-temperature distillation with the column previously described.[21] The dissolved gas was removed from the liquid product by the same column and separately analyzed, although in some cases a weighted composite sample of all the gaseous products was analyzed. Maleic anhydride absorption was used in butadiene determination.[23]

Summary

A number of hydrocarbons cracked at atmospheric pressure in the presence of an activated silica–alumina catalyst showed the following behavior:

1. A mixture of *n*-butenes underwent extensive catalytic isomerization to isobutene in the temperature range 385 to 600°, accompanied by polymerization and cracking. Between 450 and 600° the isobutene content of the C_4-product was 24.1 ± 1.5%.

2. *n*-Pentenes showed reactions similar to those of the butenes, yielding 50% of isopentenes at 400°.

3. A mixture of *n*-octenes underwent both catalytic isomerization to isoöctenes and catalytic cracking to gaseous products consisting principally of equal amounts of normal and isobutene. The results are consistent with the theory that isomerization precedes cracking. In the temperature range 375 to 400° the conversion was over 80%.

4. The primary catalytic reaction of cetene in the range 300 to 450° was isomerization to isohexadecenes; the secondary reaction was cracking to lower-boiling olefins, accompanied by isomerization of normal olefinic products to isoolefins. The isohexadecenes catalytically cracked approximately three times as rapidly as cetene itself.

5. *n*-Octane catalytically cracked seven to eight times as rapidly as in thermal decomposition, and the catalytic products contained more C_5–C_7 hydrocarbons and less methane, ethane, and ethylene than the pyrolytic products. The temperature required for the catalytic cracking of octane was 200° higher than that required for *n*-octenes.

6. Cetane was catalytically cracked largely to C_3, C_4 and C_5 hydrocarbons. The gasoline boiling-range products contained both branched-chain and straight-chain hydrocarbons, in contrast to the products of cetene cracking, which were essentially all branched-chain.

Although the behavior in thermal cracking of cetane and cetene is quite similar, cetane is far more stable toward catalytic cracking than cetene. In both cases, the products of catalytic cracking are quite different from those of pyrolytic cracking.

The Adsorption of Hydrogen by Copper Dispersed in Calcium Oxide

BY JOHN R. LEWIS, LAWRENCE J. E. HOFER AND HOWARD WHITEHEAD

Recently a paper[1] by Lewis and Taylor appeared in which the data for the adsorption of hydrogen by copper dispersed in magnesia were given. Papers by Joris, Verhulst and Taylor[2] and by Taylor and Joris[3] showed (1) that copper, when prepared by the method[1] of Lewis and Taylor, is highly dispersed in magnesia, and (2) that this dispersed copper is an excellent catalyst for hydrogenation reactions.

Because of the chemical similarity of magnesia and calcium oxide, one would expect that calcium oxide, like magnesia, would be an excellent dispersing medium for copper and therefore adsorption measurements and catalytic studies on copper dispersed in calcium oxide would prove to be of special interest.

This paper presents the data for the adsorption of hydrogen (1) on pure calcium oxide, and (2) on copper dispersed in calcium oxide.

Experimental

Apparatus.—The apparatus used for this work is a modified form of that used in Princeton for similar investigations.

Gases.—Hydrogen was prepared by the electrolysis of a 15% sodium hydroxide solution using nickel electrodes.

The gas was purified and dried by first passing it through anhydrous calcium chloride and then through an electrically heated tube (350°) containing platinized pumice, and finally through a phosphorus pentoxide drying tube.

Nitrogen, used to determine the dead space of the adsorption tube, was prepared by the reaction of ammonium chloride on sodium nitrite. The gas was purified and dried by first passing it over anhydrous calcium chloride, then over finely divided copper maintained at 500°, and finally through a phosphorus pentoxide drying tube.

Preparation of Adsorbents.—Adsorbent No. 1: Copper dispersed in calcium oxide.—A solution of copper ion and calcium ion in the ratio of approximately one Cu^{++} to four Ca^{++} was precipitated by the dropwise addition of the hydroxide while the solution was stirred vigorously. The precipitate was washed by decantation and then treated as follows: first it was heated at 120° for forty-eight hours, then at 350° for forty-eight hours. Finally the dried precipitate was placed in a suitable tube and sealed to the adsorption apparatus. The temperature was raised to 434° and a stream of hydrogen, 25 to 30 bubbles per minute, was passed through the tube for forty hours. At this point the copper oxide was completely reduced to metallic copper. Chemical analysis showed this adsorbent to contain 22.5% copper.

Adsorbent No. 1a: Pure calcium oxide.—This adsorbent was prepared in a manner similar to that used for adsorbent No. 1 except no copper was present. The temperatures and the times of drying were the same as for Adsorbent No. 1.

Adsorbent No. 2: Copper dispersed in calcium oxide.—A solution containing copper ion and calcium ion in the ratio of approximately one Cu^{++} to four Ca^{++} was precipitated as before. It was dried at 60° for twenty-four hours, then at 90° for three hours, then at 120° for ten hours and finally at 360° for seventy-two hours. The dried precipitate was then placed in a reaction tube and sealed to the adsorption apparatus. The tube and contents were heated to 210° with the "Hyvac" oil pump in operation. This was continued for twenty-four hours, after which a stream of hydrogen was passed through the tube containing the mixed oxides, temperature remaining at 210°, for one hundred and sixty-eight hours. At this point reduction of the copper oxide was complete. Chemical analysis showed this adsorbent to contain 19.3% copper.

Adsorbent No. 2a: Pure calcium oxide.—This adsorbent was prepared in exactly the same way as Adsorbent No. 2 except that copper was not present. The temperatures and times of drying were the same.

Experimental Results

The quantities of hydrogen, in cubic centimeters, which were adsorbed at 650 mm. and at various temperatures have been calculated to standard temperature and pressure (S. T. P.) and placed in Table I, and also shown graphically in Fig. 1. Due to the very slow rate at which equilibrium is reached, the quantities reported are not necessarily the true equilibrium values. Some measurements extended over a period of seventy-two hours before readings became sensibly constant. Duplicate runs checked within 10%.

TABLE I

THE VOLUME[a] OF HYDROGEN ADSORBED ON PURE CALCIUM OXIDE AND ON COPPER DISPERSED IN CALCIUM OXIDE

CC. PER GRAM (S. T. P.)

Temp., °A.	Adsorbent 1	Adsorbent 1a	Adsorbent 2	Adsorbent 2a
273	0.101	0.006	0.076	0.016
298	.107	.002	...	...
348	.206	.008	.321	.014
369	.172	.006	.191	.014
399	.132	.007	.162	.014
451	.106	.008	...	...
483	.079	.027	.032	.004
570	.184	.155	.072	.024
707	.097	.160	.064	.095

[a] The measurements were made on 25.94 g. of Adsorbent 1, 20.52 g. of Adsorbent 1a, 19.47 g. of Adsorbent 2, and 19.85 g. of Adsorbent 2a. From these were calculated the data which are given in this table.

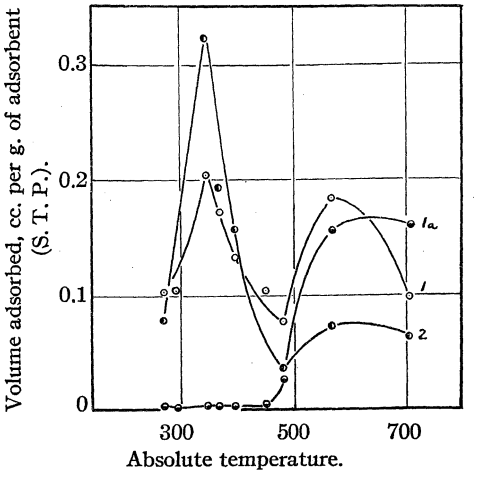

Fig. 1.—The adsorption of hydrogen on calcium oxide and on copper dispersed in calcium oxide at 650 mm. and at various temperatures: Curve 1a, cc. of gas on 1 g. of adsorbent 1a (pure calcium oxide); Curve 1, cc. of gas on 1 g. of adsorbent 1 (copper dispersed in calcium oxide); Curve 2, cc. of gas on 1 g. of adsorbent 2 (copper dispersed in calcium oxide).

The data in Table II and curves 1 and 2 in Fig. 2 were obtained by applying a correction to the values given in Table I. These corrected values were obtained by means of the equation

$$A_t = A_{Cu}F_{Cu} + A_{CaO}F_{CaO} \qquad (1)$$

where A_t is the total adsorption in cc. of hydrogen per g. of adsorbent. A_{Cu} is the adsorption due to copper; F_{Cu} is the fraction, by weight, of copper in the adsorbent; A_{CaO} is the adsorption of hydrogen in cc. per g. of pure calcium oxide; F_{CaO} is the

fraction by weight of calcium oxide in the adsorbent. The assumptions necessary to use Equation I are: (a) the adsorptive capacity of calcium oxide is the same in the pure state and when it is mixed with dispersed copper. (b) For each adsorbent, all the dispersed copper particles are in the same physical state, and their adsorptive capacity is not impaired until the sintering temperature is reached.

2	0.32	..	1.56	0.91	0.76	..	0.15	0.27	(−0.06)

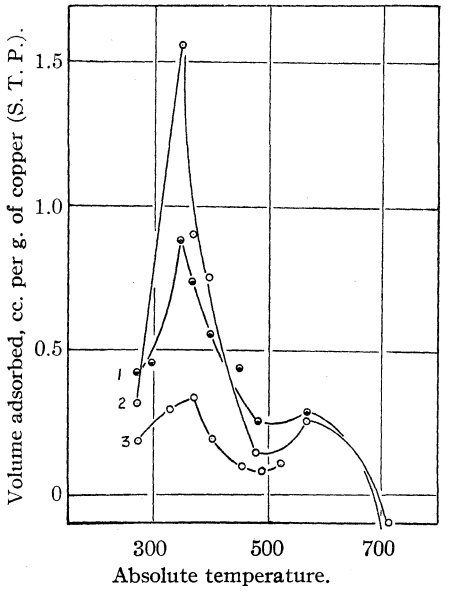

Fig. 2.—The adsorption of hydrogen on pure copper and on copper dispersed in calcium oxide at 650 mm. pressure and at various temperatures and corrected for the hydrogen adsorbed on the calcium oxide by the use of Equation (1). Curve 1 shows the cc. of gas per gram of copper dispersed in adsorbent 1; Curve 2 shows cc. of gas per g. of copper dispersed in adsorbent 2; Curve 3 is for pure copper and was taken from the paper by Lewis and Taylor for purposes of comparison.

Discussion of Results

An examination of the data in Table I and the curves in Fig. 1 show: (1) calcium oxide, curve 1a, is a poor adsorbent over the temperature range 300 to 475° A., but at 475° A. the adsorption increases rapidly with temperature rise until 570° A. is reached. From there on up to 707° A. the slope of the curve decreases. In general we can say that calcium oxide resembles magnesia in its ability to adsorb hydrogen.

Curve 1, Fig. 1, shows the adsorption on adsorbent 1, while curve 2 shows the adsorption on adsorbent 2. The difference in the amounts adsorbed by the two adsorbents, at the various temperatures, is attributed to the different methods used in their preparation. It is interesting to observe, however, that maximum and minimum adsorptions for each adsorbent come at practically the same temperatures. This indicates that the same type of activated adsorption is taking place on each adsorbent. It is also interesting to observe that adsorbent 2 is more effective at 348° A., whereas adsorbent 1 is more effective at 570° A. The higher adsorptive capacity of adsorbent 2 at 348° A. is attributed to the higher activity of the copper.[4,5] It is more active because (1) it was prepared by the reduction of the oxide at 210°, whereas the copper in adsorbent 1 was obtained by reducing the oxide at 434°, and (2) adsorbent 2 was always degassed at 210°, rather than at 434° the temperature used in degassing adsorbent 1. The higher adsorptive capacity of adsorbent 1 at 570° A. is due to the fact that it was completely dehydrated, whereas adsorbent 2 was not.

Using the equation as given above, the data in Table II and the curves in Fig. 2 were obtained. Curve 3, Fig. 2, was taken from the data obtained by Lewis and Taylor[6] for purposes of comparison. It will be observed that, when the adsorption on calcium oxide is corrected for, by use of the equation, the dispersed copper is a much more effective adsorbing agent than is the pure copper. The apparent negative adsorption for adsorbents 1 and 2 at 707° A. may be due to the fact that the calcium oxide is not adsorbing as much hydrogen at that temperature when it is mixed with the copper, as when it is pure. Also, at 707° A. copper may have lost part of its capacity for adsorbing hydrogen, due perhaps to the adsorption curve passing through a temperature minimum. The third possibility is that part of the calcium oxide is covered with copper, which makes that part of the oxide unavailable to the hydrogen.

Summary

1. The adsorption of hydrogen on pure calcium oxide and on copper dispersed in calcium

(4) Gauger and Taylor, THIS JOURNAL, **45**, 920 (1923).
(5) Pease, *ibid.*, **45**, 2296 (1923).
(6) Lewis and Taylor, *ibid.*, **60**, 877 (1938).

oxide has been measured at 650 mm. and at various temperatures.

2. Copper, when dispersed in calcium oxide, is a better adsorbent for hydrogen than is the pure copper.

3. In general the activated adsorption of hydrogen on calcium oxide and on copper dispersed in calcium oxide resembles the adsorption of hydrogen on magnesia and on copper dispersed in magnesia.

4. An equation has been suggested, the use of which permits the more uniform treatment of the data for copper dispersed in oxides.

SALT LAKE CITY, UTAH RECEIVED AUGUST 21, 1939

NOTES

Note on the Dipole Moment of 1-Chloroanthraquinone

BY ERNST BERGMANN AND ANNA WEIZMANN

In connection with a stereochemical investigation in the series of anthracene dichlorides, we reported, a short time ago,[1] some figures on the dipole moment of chloroanthraquinone, which we calculated to 1.9 *D*. Fischer and Rogowski[2] arrived recently at lower figures of 1.53 (in benzene) and 1.55 (in dioxane), respectively. Although without influence on the general results put forward in our paper, we have reinvestigated 1-chloroanthraquinone both in benzene and again in dioxane solution and have found 1.8 and 1.9 *D*, respectively. Following the procedure of the German authors, we have taken the average of the (atomic and) orientation polarization in order to calculate the electric moment, instead of extrapolating to infinite dilution, which would have given even a slightly higher figure.

The *significance* of figures in the tables is as in previous communications.

The Optical Activity of α-Bromopropionitrile

BY KENNETH L. BERRY AND JULIAN M. STURTEVANT

In connection with recent physical theories of optical rotatory power,[1,2] it would be of interest to know the optical properties of one or more compounds of simple, fixed structure, *i. e.*, compounds containing one asymmetric carbon atom substituted by four groups having optical axes of symmetry parallel with the valence bonds to the asymmetric carbon atom.

(1) Kirkwood, *J. Chem. Phys.*, **5**, 479 (1937).

(2) Condon, Altar and Eyring, *ibid.*, **5**, 753 (1937).

The simplest molecule heretofore available for purposes of comparison of theory with experiment is secondary butyl alcohol.[1,3,4] In view of the uncertainties introduced by the non-linearity of the ethyl and hydroxyl groups, this substance has proved not too satisfactory. Therefore, α-bromopropionitrile has been prepared in an optically active form, since it appears reasonable to assume that each of the groups attached to the asymmetric carbon atom has cylindrical symmetry. Strong evidence in favor of this assumption in the case of the nitrile group is given by Brockway,[5] who demonstrated the linearity of C—C≡N in methyl cyanide by the electron diffraction method, and by Weissberger and Sängewald,[6] who found a zero dipole moment for *p*-dicyanobenzene. The result of Bretscher[7] attributing a relatively large moment to 4,4′-dicyanodiphenyl has been considered anomalous by Le Fèvre and Vine,[8] and as not proving any lack of axial symmetry in this molecule.

Kirkwood's theory leads to the following simple expression for the rotatory parameter of an active molecule in terms of the geometrical configuration and the polarizability tensors of its constituent groups

$$g = g^{(0)} + g^{(1)} + \sum_{k=1}^{N+1} g_k$$

In molecules with only one asymmetric center the g_k vanish. Each term in $g^{(0)}$ vanishes if the optical axes of symmetry of the groups are parallel to the respective bonds linking them to the asymmetric carbon atom. The rotatory power must then be sought in higher terms which are considered by Kirkwood to be relatively unimportant. Thus α-bromopropionitrile might be expected to have a small specific rotation.

l-α-Bromopropionitrile was prepared from *l*-α-bromopropionic acid by asymmetric conversion. The rotation of the acid indicated it to be 67.1% levo and 32.9% dextro. It was converted to the amide and the latter dehydrated with phosphorus pentoxide to obtain the nitrile. After one distillation the nitrile had a specific rotation $[\alpha]^{25}D$ −5.29°, and after a second distillation $[\alpha]^{25}D$ −5.25°. The final product analyzed 10.44, 10.50, and 10.49% nitrogen (calcd. for $CH_3CHBrCN$, 10.46%). On the assumption that no racemization occurred during the synthesis, the calculated specific rotation for the optically pure compound is $[\alpha]^{25}D$ −15.33°. The true value would, of course, be higher if some racemization had occurred.

On first sight, this result indicates that greater importance should be attached to the higher approximations of the polarizability theory. Kirkwood[9] points out, however, that it is not unquestionable evidence since lateral optical anisotropy of sufficient magnitude to account for the observed rotation could be induced in the CN group, probably by the C-Br dipole.

Since this molecule is of considerable interest from a theoretical point of view, efforts will be made to prepare it in a state of higher optical purity. The refractive and rotatory dispersion behavior of the substance in the visible region will be determined.

A more unambiguous test of the importance of the higher terms in Kirkwood's theory would presumably be furnished by a molecule having only monatomic groups attached to the asymmetric carbon atom. Because of this fact and its general theoretical interest, fluorochlorobromomethane, CHFClBr, has been prepared. Attempts are at present being made to resolve it by various methods.

Desoxycholamine

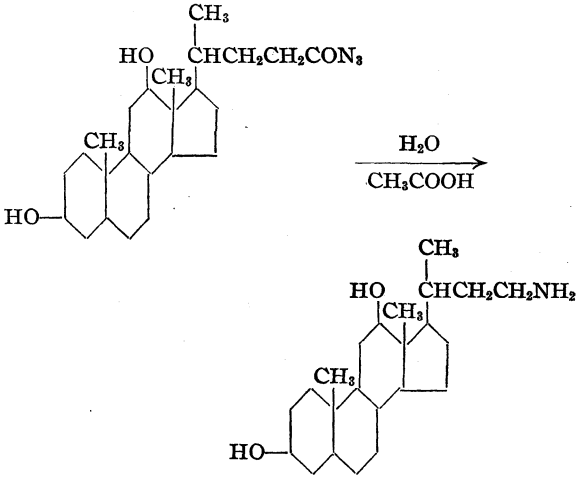
BY WILLIAM T. CALDWELL

In an article describing the preparation of cholamine by Lindemann's modification of the Curtius reaction,[1] attention was called to the fact that Borsche and Schwarz had distilled with caustic potash the urethan derived from cholylazide without, however, obtaining any of the desired amine by this application of the usual Curtius degradation. It was very interesting, therefore, to receive from Dr. Mihail Vanghelovici, in a private communication which he kindly sent, a description of a desoxycholamine whose preparation he reported to the Rumanian Academy of Sciences. He observed that, since his desoxycholamine had been prepared by the Curtius method, working at a pressure of 2 mm., it appeared to be

(1) Caldwell, THIS JOURNAL, **60**, 991 (1938).

much stabler than cholamine. The crude base, m. p. about 90°, yielded a microcrystalline solid, m. p. 118°, after repeated purification; it was strongly alkaline to red litmus moistened with methyl or ethyl alcohol and formed a hydrochloride, m. p. 247°, whose aqueous solution was extremely bitter.

Since I had prepared a desoxycholamine which differed from that described by Dr. Vanghelovici in the melting points, both of the free base and its hydrochloride, as well as in the comparative ease with which it could be obtained in nicely crystalline form from methanol, I am submitting a description of its preparation and some of its characteristics. Although there are differences in melting points, the two amines are alike in being strongly alkaline to red litmus moistened with methyl or ethyl alcohol and in the striking bitterness of their hydrochlorides. It appears not illogical to assume that they are stereoisomers; possibly epimerization occurred during the alkaline hydrolysis used in the Curtius degradation, since this type of change is effected by other alkaline reagents such as sodium alcoholate or metallic sodium in xylene.



Experimental Part

Twenty-two grams of desoxycholylhydrazide, m. p. 203°, was dissolved in 67 cc. of normal hydrochloric acid and 400 cc. of water. After adding 400 g. of ice, sodium nitrite (4.2 g.) in 50 cc. of water was added slowly with good stirring. The mixture was then stirred for an additional fifteen minutes and the azide filtered off with suction. The pressed, wet cake containing approximately 150 g. of water was transferred immediately to 210 g. of glacial acetic acid; it did not all dissolve but, upon gently warming on the steam-bath, the undissolved portion melted; evolution of gas began at about 45°, becoming more vigorous in the neighborhood of 60°; at the same time the amount of oil decreased but even after heating for four hours a small amount (about 1 g.) was visible. After cooling, the solution was filtered through a sintered glass funnel and cold aqueous potassium hydroxide added until the mixture became alkaline to phenolphthalein. The precipitate was then dissolved in alcoholic potassium hydroxide; after warming, this solution was diluted with a large amount of water and the precipitate washed by decantation with water until the aqueous washings gave no alkaline reaction with red litmus. The residual gum still contained a relatively large amount of non-basic material which was not investigated further; after its removal, the amine was purified by several recrystallizations from absolute methanol, from which it separated easily as fine, white crystals upon chilling and scratching the moderately concentrated solution.

Although these crystals were well formed and homogeneous, they did not melt sharply, their behavior depending upon the rate of heating; after beginning to soften at about 70°, they resolidified upon raising the temperature very slowly; finally, however, the substance melted sharply at 157–158°; yield, 3 g. The amine is so insoluble in water that it gives no basic reaction to red litmus moistened with water, at least within a reasonable length of time; on the other hand, it imparts a bright blue color at once to red litmus moistened with methyl or ethyl alcohol.

Analysis of the crystals, dried at room temperature over soda-lime and calcium chloride, indicated that they contained one molecule of methanol of crystallization.

Anal. Calcd. for $C_{23}H_{41}O_2N \cdot CH_3OH$: C, 72.86; H, 11.46. Found: C, 72.63; H, 11.60.

The free base, m. p. 158–159°, after warming for three hours in a drying pistol over metallic sodium at 5 mm. and 100°, was analyzed.

Anal. Calcd. for $C_{23}H_{41}O_2N$: C, 75.97; H, 11.36; N, 3.85. Found: C, 75.31, 75.84; H, 11.39, 11.44; N, 3.87, 3.77. Vanghelovici found: C, 75.37; H, 12.00; N, 3.82.

The hydrochloride, made by passing gaseous hydrogen chloride into a methyl alcoholic solution of the base, melted at 306° after sintering slightly at 300°. Unlike the base it is easily soluble in water.

Anal. Calcd. for $C_{23}H_{41}O_2N \cdot HCl$: Cl, 8.88. Found: Cl, 8.48. Vanghelovici calcd.: N, 3.50. Found: N, 3.80.

The Preparation of Primary Amines

BY ALEXANDER GALAT AND GERTRUDE ELION

The transformation of alkyl halides into primary amines by the formation of a double compound with hexamethylenetetramine, followed by alcoholysis in the presence of hydrogen chloride, affords a very convenient means for the preparation of primary amines.[1,2,3] As this method has

(1) Delépine, *Compt. rend.*, **120**, 501 (1895); **124**, 292 (1897); *Bull. soc. chim.*, [3] **17**, 290 (1897); [4] **31**, 108 (1922).
(2) Mannich and Hahn, *Ber.*, **44**, 1542 (1911).
(3) Foldi, *ibid.*, **53**, 1836 (1920).

been practiced in the past, the alkyl halide is added to a solution of hexamethylenetetramine in chloroform, and the addition compound, after it has precipitated, is filtered off. The alkyl iodides react with reasonable rapidity, but the chlorides and bromides react much more slowly, and if they are to be used as starting materials, they should be converted into the iodide by addition of sodium iodide in acetone solution.

This procedure has now been simplified by operating in a single solvent, alcohol, without isolation of the addition compound. The new procedure is as follows.

To a solution of 1 mole of hexamethylenetetramine in eight to ten times its weight of hot 95% alcohol slightly more than 1 mole of sodium iodide is added. One mole of the alkyl chloride or bromide is then added and the solution is allowed to stand until the precipitation is complete. The period of precipitation will vary from a few minutes to several weeks depending upon the substance. The longer the carbon chain the longer is the time required for the precipitation. The mixture containing the precipitate is saturated with hydrogen chloride gas, whereupon the precipitate dissolves and ammonium chloride precipitates. When the latter has been filtered off and the alcohol removed by distillation, the resultant impure hydrochloride is converted into the pure amine by distillation with an excess of sodium hydroxide.

The times of precipitation and the yields of several of the amines obtained were as follows: methylamine, one week, 72%; ethylamine, eight days, 82.5%; benzylamine, two hours, 82.5%; *p*-nitrobenzylamine, one day, 61%; phenylethylamine, three weeks, 54%. The products obtained were of high purity, having melting points closely in accord with the values given in the literature.

Synthesis of Organobismuth Compounds

BY HENRY GILMAN AND ALEXIS C. SVIGOON

Numerous methods are available for the preparation of organobismuth compounds. However, none among them starts with the diazonium complexes of bismuth salts, although such complexes have been described. Challenger and Wilkinson[1] have reported the preparation of benzenediazonium chloride–bismuth chloride and *p*-toluenediazonium chloride–bismuth chloride complexes; and Supniewski and Adams[2] the benzenediazonium chloride–bismuth chloride complex. No organobismuth compound is formed by interaction of *metallic* bismuth with benzenediazonium chloride.[3]

We are now reporting the conversion of these and other related complexes to the corresponding organobismuth compounds.

In a typical preparation (tri-*p*-tolylbismuth), an ice-cold solution of 0.1 mole of bismuth chloride in 16 cc. of concd. hydrochloric acid was added with stirring to an iced solution of 0.1 mole of *p*-toluenediazonium chloride prepared in the customary manner by diazotization of 10.7 g. of *p*-toluidine. The mixture became quite pasty and of a solid-like consistency as the complex formed. On the addition of 300 cc. of an ice-cold mixture of methyl and ethyl alcohols, a flaky white complex was precipitated. This diazonium complex was filtered, washed with cold methyl alcohol, and dried. The yield was 32.5 g.

Anal. Calcd. for $C_{21}H_{21}N_6BiCl_6$: Bi, 26.9. Found: Bi, 27.2 and 27.0.

A suspension of the *p*-toluenediazonium–bismuth chloride complex (32.5 g.) in 100 cc. of cold acetone was treated with 52.8 g. of copper powder. An evolution of gas took place in several minutes, and the solution became dark brown in color. After one-half hour an equal volume of 25% ammonium hydroxide was added, and then the mixture was diluted to 450 cc. with water. After standing for one hour the solid which had precipitated was filtered, dried, and extracted with dry chloroform. The solid remaining after removal of the chloroform was crystallized from methyl alcohol. The yield of pure tri-*p*-tolylbismuth was 3.07 g. and identification was completed by a mixed melting point determination (m. p., 116–117°) with an authentic specimen which melted at 116–117°.

The diazonium complexes were precipitated by methyl alcohol, ethyl alcohol, and more effectively by mixtures of methyl and ethyl alcohols. Higher alcohols may be better precipitants, and these are being examined together with media other than acetone for decomposing the complexes. A later report will give details on organobismuth compounds not now available, particularly those with solubilizing groups and groups of interest in connection with the cleavage and relative reactivities of unsymmetrical organobismuth compounds.

Preparation of Tricaprylin

BY E. B. HERSHBERG

Pure tricaprylin was required in quantity for use as a solvent medium in animal experiments now being conducted by Dr. Shields Warren with the carcinogenic compounds produced in this Laboratory.[1] The technical 90% caprylic acid produced by Armour and Company (Neo-Fat No. 7) proved to be a suitable source of the acid component. Purification is best effected by conversion with thionyl chloride to the acid chloride, for on careful fractionation octanoyl chloride can be obtained in a state of high purity. A large supply of the technical acid chloride was kindly supplied for the present work by the Armour and Company through the courtesy of H. M. Corley.

A detailed procedure for condensing octanoyl chloride with glycerol in the presence of quinoline was kindly made available to us by Dr. H. H. Young, Swift and Company, who obtained tricaprylin, m. p. 8.6–8.8°, by this method in 82% yield based on glycerol. A disadvantage of this process, noted by Dr. Young and in this Laboratory, is that the crude glyceride is contaminated with a yellow impurity which is retained on distillation and which is rather troublesome to eliminate by adsorption from solution when working with large quantities.

On trying the Schotten–Baumann method under conditions recommended by Menalda[2] it was found that the crude reaction product is completely colorless and that very pure tricaprylin can be obtained in this way in nearly 90% yield.

The technical (90%) octanoyl chloride was first distilled from a Claisen flask at a pressure of 10–30 mm. to make a rough separation and then carefully fractionated in a 1-meter column packed with glass helices. The material used boiled at 89.3–89.6° at 20 mm. (about 80% of the total). A 5-l., three-necked flask was charged with 73.5 g. of anhydrous[3] (vacuum distilled) glycerol, which was washed in with 25–50 cc. of water, and fitted with a Chromel wire stirrer[4] working through a wide glass tube mounted in the center opening to prevent loss by splashing. One of the side openings was fitted with a cork carrying a toluene thermometer and a small glass funnel; the other was equipped with a similar funnel. Simultaneous addition was then made of 410 g. of octanoyl chloride through one funnel and of a solution of 181 g. of 85% potassium hydroxide pellets in 375 cc. of water through the other. The liquids were run from constant-rate funnels[5] under a common air pressure of about 5 lb., which facilitated regulation. Since troublesome emulsions sometimes result from the presence of excess alkali, it is well to keep the acid chloride addition 25–50 cc. ahead of the alkali. The reagents were added in the course of about one hour, controlling the temperature to −5 to 0° by ice–salt cooling. Toward the end a stable emulsion formed; 75–100 cc. of ether was added to thin the mixture and provide better temperature distribution. Vigorous stirring was continued for three hours after the addition at a temperature of −10 to −5°; water and ether (1–1.5 l.) were then added and the layers separated. The ether layer was washed once with water and once with saturated sodium chloride solution and then filtered through a paper covered with a little anhydrous sodium sulfate.

After evaporation of the ether the colorless residue was distilled in a modified Claisen flask[6] connected with a ground-glass joint to a receiver (water cooling not required). After separation of a small fore-run (14 g., b. p. 150–233°) of mono- and diglycerides, the main fraction was distilled rapidly with a free flame and a good vacuum to avoid cracking. There was obtained 333 g. of colorless tricaprylin; as registered in the rapid distillation the b. p. was 233–235° at 1 mm. The yield is 89% based on the glycerol and 84% calculated from the acid chloride used. Careful distillation of a small sample gave the b. p. 233–233.5° corr. at 1.0 mm. (oil manometer[7]), freezing point 9.8–10.1° (compare 8–8.3°,[8] 9.45°[9]). Further purification by partial freezing and centrifugation was repeated twice without altering the freezing point.

When stirring was continued for only two hours

(1) We are indebted to Drs. M. J. Shear and M. B. Shimkin of the U. S. Public Health Service for making a trial of certain possible substitutes for lard as a medium for the injection of carcinogens, including the triglycerides suggested [Fieser, *Am. J. Cancer*, **34**, 37 (1938)] and certain other more readily available esters. In the first experiments with commercial esters, purified where required by Dr. Hershberg, tricaprylin appeared particularly satisfactory and large-scale tests with this glyceride were then initiated by Dr. Shimkin using a quantity of tricaprylin kindly prepared for us by Dr. H. H. Young of the Swift and Co. Research Laboratories.—L. F. FIESER.

A Photosensitized Production of Reducing Sugars from Starch

BY LAWRENCE J. HEIDT

Substances which reduce the Shaffer–Hartmann–Somogyi reagent are produced when light is absorbed by aqueous solutions containing uranyl sulfate and *starch*. The apparatus used to illuminate the solutions is described in *Science*, **90,** 473 (1939). The experimental procedure was the same as that given in THIS JOURNAL, **61,** 3223 (1939), for *sucrose*–uranyl solutions.

The ml. of hypo entered in Table I are calculated from the differences between S.–H.–S. estimations made simultaneously on the illuminated portions of a solution and on a portion kept in the dark, at the same temperature. When 5 ml. of water was added to 5 ml. of the S.–H.–S. reagent, the titration required 46.2 ml. of hypo, but 5 ml. of the unphotolyzed portions in Expts. 1, 2, 3, 4, 5 and 6 required 43.0, 45.5, 45.7, 42.8, 44.8 and 44.8 ml. of hypo, respectively. The potato starch, kindly supplied by Professor C. B. Purves, therefore contained very little reducing sugar, and both the illuminated and unphotolyzed solutions of starch in Expt. 4 appeared water-white.

Solutions were irradiated in quartz tubes at 21° with 8.5×10^{18} photons of λ 254 mμ per minute incident on each 11 ml. sample. The starch solutions were 0.008 *M* in uranyl sulfate in Expts. 1, 2 and 3; 0.0004 *M* in quinine sulfate in Expt. 5; 0.0003 *M* in the sodium salt of fluorescein (Eastman Kodak Technical Grade) in Expt. 6 and contained only starch and water in Expt. 4. Each ml. of hypo entered in Table I was equivalent to 5.7×10^{-5} g. of glucose in the uranyl sulfate solutions and to 5.5×10^{-5} g. of glucose in the others.

The experiments with quinine and fluorescein were undertaken to discover for this reaction other photosensitizers—preferably dyes and natural products that absorb sunlight. The amount of reducing substances produced when quinine or fluorescein was present, however, was less or little more than when they were absent and very much less than when uranyl sulfate was used. The intense blue fluorescence initially present in Expt. 5b disappeared toward the end of this photolysis and a light straw solution was formed, but in Expt. 6b the yellow fluorescence was only diminished. This also occurred in parallel experiments with solutions of quinine and fluorescein without starch and the *p*H likewise decreased but in the quinine solution the amount of reducing substances produced was less than 10% of that formed in Expt. 5b and none was formed from the fluorescein or from the uranyl sulfate alone in water.

Quantum yields, ϕ, represent the number of oxygen bridges (linking the glucose units) broken per photon of λ 254 mμ absorbed by the system if the measured product is glucose and one bridge is broken per molecule of glucose produced. This may be too simple an hypothesis except, perhaps, for the initial reaction.

In Expts. 4 and 6, ϕ is not given because the extinction coefficients of these solutions were not known at this wave length. Nevertheless, Expt. 4 shows that the measured reaction in Expts. 1, 2 and 3 is mainly a photosensitized reaction. Also in Expts. 1, 2 and 3, ϕ is smaller and falls more rapidly than for the photosensitized decomposition of sucrose at the same concentration of oxygen bridges, if there is one bridge per sucrose molecule and one per glucose unit in starch. This decrease in ϕ probably is due to the colloidal nature of starch solutions and the chain character of the starch molecule, both of which

protect some of the chemical bonds in starch that would otherwise enter the measured reaction.

CAMBRIDGE, MASS. RECEIVED OCTOBER 23, 1939

A New Method for the Cleavage of Unsaturated Fatty Acids[1]

BY CHI-YI HSING AND KOU-JEN CHANG

The methods for the cleavage of unsaturated fatty acids reported in the literature are either by energetic oxidations or by ozonization. On account of the side reactions, the degradation products are usually complex mixtures and the yields are very low.

Lead tetraacetate has been introduced by Criegee[2] as a reagent for the cleavage of glycols with excellent results. This oxidizing agent should be equally effective in oxidizing polyhydroxy fatty acids which in turn can be prepared easily from the corresponding unsaturated fatty acids by means of oxidation with alkaline potassium permanganate. It was found that 9,10-dihydroxyoctadecanoic acid (from oleic acid) was oxidized completely in twenty-four hours by lead tetraacetate in glacial acetic acid. As reaction products, pelargonic aldehyde and azelaic semialdehyde were isolated in the form of semicarbazones, each in a yield of about 85%. By using benzene as a solvent, 9,10,12-trihydroxyoctadecanoic acid (from ricinoleic acid, m. p. 111–112°) oxidized in four hours and about 90% of azelaic semi-aldehyde semicarbazone and a product melting at 112–113°, the character of which has not yet been determined, were obtained. A mixed melting point with starting material indicated it was different. The supposition is it may be β-hydroxypelargonic aldehyde semicarbazone or a related compound.

A more extensive study of this method for cleavage of unsaturated fatty acids of known and unknown structure will be reported later.

Experimental

In 10 cc. of glacial acetic acid which had been distilled over phosphorus pentoxide, was suspended 0.6740 g. of 9,10-dihydroxyoctadecanoic acid and to the mixture 0.95 g. of lead tetraacetate was added. This was shaken for twenty-four hours at room temperature. The solution was filtered and heated in a water-bath at 45° for five minutes. It was then treated with 15 cc. of water and a concentrated aqueous solution of 0.5 g. of semicarbazide hydrochloride and 0.6 g. of sodium acetate was added. To the reaction mixture was now introduced a few drops of methanol and it was then vigorously shaken. After standing in an ice box for twenty hours, the semicarbazones separated as a white precipitate. The precipitate was filtered and shaken with cold dilute aqueous sodium hydroxide to dissolve the azelaic semialdehyde semicarbazone. Undissolved, impure pelargonic aldehyde semicarbazone was filtered and washed with water. The alkaline filtrate was acidified with 2% hydrochloric acid. The precipitated azelaic semialdehyde semicarbazone was filtered, washed and dried, yield 0.434 g. (90%). After purification by crystallization from ethanol it melted at 163–164° (Harries and Thieme[3] reported 163°).

The alkali insoluble part consisted of lead chloride and pelargonic aldehyde semicarbazone. It was dissolved in methanol and the lead chloride was filtered. On evaporating the solution to a small volume, the semicarbazone separated as fine crystals melting at 99–100.5° (Bagard and Harries and Turk[4] reported 100°). The yield was 0.348 g. (82%).

Dependence of Conductance on Field Strength

BY DARWIN J. MEAD AND RAYMOND M. FUOSS

We recently reported the field dependence of the conductance of tetrabutylammonium picrate in diphenyl ether at 50° [THIS JOURNAL, **61**, 2047 (1939)]. We are indebted to Dr. L. Tonks of this Laboratory for calling to our attention a correction which we neglected. The limit approached by the Wien coefficient at zero concentration now agrees with Onsager's theoretical value, when the correction factor of $8/3\ \pi$ is applied.

Our measurements were made in a bridge circuit, in which balance is indicated by zero current in a detector circuit fed through a low-pass filter. Our solutions were non-linear impedances, and the detector showed balance for only the fundamental frequency. According to theory, the specific conductance κ is given by

$$\kappa(t) = \kappa_0 + A V_m \mid \sin \omega t \mid \qquad (1)$$

where κ_0 is the low voltage conductance, A is Onsager's coefficient and V_m is the peak voltage of the sinusoidal input at frequency f, with $\omega = 2\pi f$. The unit current then is

$$i(t) = \kappa_0 V_m \sin \omega t + A V_m^2 \sin \omega t \mid \sin \omega t \mid \qquad (2)$$

In order to find the fundamental in the non-linear term of (2), we simply expand it in a Fourier series

$$f(x) = \sin x \mid \sin x \mid = \Sigma a_n \sin nx$$

and take the first term, for which $a_1 = 8/3\ \pi$. Then from the point of view of the bridge detector

$$i(t) = V_m \sin \omega t\ (\kappa_0 + 8A\,V_m/3\pi) \qquad (3)$$

whence

$$\kappa = \kappa_0 + 8A\,V_m/3\pi \qquad (4)$$

Our experimental result was

$$\kappa = \kappa_0 + B\overline{V} \qquad (5)$$

where B is the experimental slope and $\overline{V} = 2\ V_m/\pi$ is the linear average voltage. Comparison of (4) and (5) gives

$$A = 3B/4 \qquad (6)$$

which brings our experimental result into exact agreement with the theoretical value.

The Viscosity of Liquid Ammonia

BY C. J. PLANK AND HERSCHEL HUNT

The viscosity of liquid ammonia is reported by Stakelbeck[1] to be 0.00218 g./cm. sec. at 20°, 0.00229 at 10°, 0.00238 at 0° and 0.00252 at −20°. He used the Lawaczec falling ball method. At −33.5° two values are reported, 0.002543[2] poise and 0.00260[3] poise.

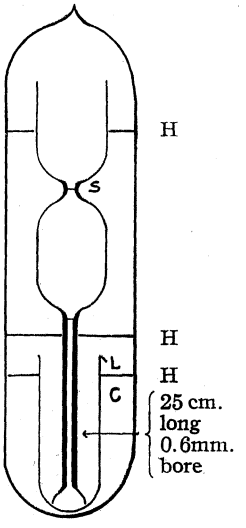

Fig. 1.—Viscometer.

The viscosity of ammonia at room temperature is important. Since Stakelbeck's results have a small temperature coefficient, we redetermined the viscosity at 5, 15 and 25°. Our apparatus is shown in Fig. 1. The apparatus was carefully dried by heating it under reduced pressure. It was calibrated with pure dry carbon disulfide and carbon tetrachloride. The following viscosities[4] and densities of these compounds were used.

Temp.	Carbon disulfide Density	Carbon disulfide Viscosity	Carbon tetrachloride Density	Carbon tetrachloride Viscosity
5°	1.2856	0.004125	1.6230	0.01233
15°	1.2750	.003805	1.6037	.010476
25°	1.2554	.003565	1.5843	.009027

The constants, C and C', of the equation

$$\eta = C\rho t - C'\rho/t$$

were determined at each temperature. The ammonia was dried over sodium and distilled under reduced pressure into the apparatus. After the outside jacket was sealed the apparatus could be rotated in order to fill the viscometer with the liquid. The supports, H's, held the viscometer perfectly vertical and rigid within the jacket when the outside jacket was placed in a vertical position.

The determinations were made in an air thermostat whose temperature was regulated to 0.05°. The time was measured with an accurately calibrated stop watch. Since the time of flow was in the neighborhood of four to eight minutes for the calibration and almost four minutes for the ammonia, the error in the measurement of time was not over 0.02%.

The apparatus was designed as shown because a closed system was necessary, and by having container C full of liquid when the meniscus passes S, a constant head was ensured. A fine lip, L, on C ensured a delivery of the liquids at the same level, so that a change in surface tension of the liquids did not interfere. The small head also increased the time of flow. It is difficult to fill the apparatus with cold ammonia by distillation and get the desired hydrostatic head when the liquid becomes warm. Two viscometers were used and the results are in excellent agreement. The viscosities and densities at the three temperatures are:

Temp., °C.	Density g./cc.	Viscometer number 1	Viscometer number 2	Viscosity of NH_3 (av., g./cm. sec.)
5°	0.63197	0.001628	0.001607	0.001618
15°	.61821	.001468	.001446	.001457
25°	.60427	.001350	.001350	.001350

The densities were determined by the pycnometer method. These data, if we can judge by the long extrapolation, are in good agreement with the low temperature values in the literature. Stakelbeck's results would indicate that the temperature coefficient of viscosity for ammonia is much smaller than the coefficient for any other known liquid. His results agree with ours if we multiply

The Preparation of Grignard Reagents from Magnesium Amalgams

BY EUGENE G. ROCHOW

Magnesium amalgams have been used for the preparation of magnesium alkyls and aryls,[1] and for the coupling of ketones with chloro-esters and chloro-ethers.[2,3,4] In view of the high reactivity of dilute amalgams of magnesium toward oxygen and water, it seemed interesting to investigate the formation of methylmagnesium halides from such amalgams, and then to follow with experiments on other less reactive halides.

The phase diagram for the system Mg–Hg shows two compounds, $MgHg_2$ and MgHg. Below 168° the equilibrium condition at the low magnesium end is a mixture of $MgHg_2$ crystals and liquid, and hence the reported solubility of magnesium in mercury (3% at 250°, 1% at 100° and probably 0.1% at room temp.) must refer to the solubility of $MgHg_2$. Since $MgHg_2$ contains 5.71% magnesium by weight, amalgams of this or greater concentration of magnesium will be solids, and amalgams in the range 5 to 0.1% magnesium will normally be mixtures of $MgHg_2$ with increasing proportions of liquid.

Amalgams containing from 0.1 to 1.0% of magnesium were prepared in an all-glass apparatus under an atmosphere of purified nitrogen.[5] The dissolution of magnesium in mercury is strongly exothermic, so no external heating was required. After cooling in the stream of nitrogen, 50 cc. of a 0.1 *N* solution of methylmagnesium chloride was added through the condenser and methyl bromide was admitted. The purpose of the methylmagnesium chloride was to eliminate difficulties in starting, which would have confused the results obtained.

After refluxing the amalgam with the solution of methyl bromide for several hours, samples of the ether layer were withdrawn for determination of total CH_3MgX by evolution of methane with water. The increase of CH_3MgX over that added at the start was calculated as % yield based on the magnesium. Typical results were:

% Mg in amalgam	Yield of RMgX, %
0.1	0
0.5	4.1
1.0	25.3

Unreacted magnesium was evident in the mercury layer in each case as soon as the amalgam was exposed to the air. Attempts were made to displace a possible equilibrium between $MgHg_2$ and RMgX, but the results indicated that there was no such equilibrium. Dilute magnesium amalgams did not seem to react at all with methyl chloride, and the iodide is reported to form the R_2Mg compound under such conditions.[1]

The odor of mercury dimethyl was detected in some of the experiments. Metallic mercury does not react with RMgX to form R_2Hg,[6] but mercury halides would do so readily, and such halides might have been formed in small quantity.

The experiments indicate that the yield of RMgX from magnesium amalgams increases with the concentration of magnesium in the amalgam, and with the increasing possibility of free magnesium in the amalgam mixture. It may be concluded that $MgHg_2$ does not participate in the Grignard reaction as readily as magnesium, and that mercury therefore has an inhibiting effect on the reaction.

(1) Fleck, *Ann.*, **276**, 129 (1893).

(2) Sommelet, *Ann. chim. phys.*, (8) **9**, 484 (1906). Superficial amalgamation by addition of a trace of $HgCl_2$ was used here to start the reaction.

(3) Darzens, *Compt. rend.*, **151**, 883 (1910).

(4) Grignard, *Bull. soc. chim.*, **128**, 1285 (1926).

(5) The dilute amalgams are very sensitive to traces of oxygen and moisture, and it was found that the ordinary purification methods had to be supplemented by passing the gas through a 1% Mg amalgam before use.

Addition of Compounds of Dicyclohexylamine

BY CHARLES F. WINANS

In the hydrogenation of cyclohexanone in the presence of ammonia to form cyclohexylamine, a crystalline compound, m. p. 46°, formed in the cooled residue after distilling cyclohexylamine. This solid was found only when there was an insufficient amount of ammonia for complete reaction of the carbonyl group. Distillation of this product separated it into equivalent amounts of cyclohexanol and dicyclohexylamine, which recombined with evolution of heat to give the original crystalline material.

The preparation of a number of analogous addition compounds was attempted with several amines and hydroxy compounds. Usually a solid formed on mixing equimolecular amounts of the materials at room temperature, but sometimes chilling was required. Recrystallization was effected by cooling a solution of the addition compound in ether or petroleum ether.

A typical example of the preparation of these compounds is as follows. A solution of 10 g. of dicyclohexylamine in 10 ml. of petroleum ether was mixed with 5 g. of cyclohexanol in 10 ml. of petroleum ether. The clear solution was strongly chilled to deposit crystals which were filtered out, washed with petroleum ether and dried in air; m. p. 47–48°. *Anal.* Calcd. for $(C_6H_{11})_2NH \cdot C_6H_{11}OH$: N, 4.99. Found: N, 4.87.

The table gives data on a number of these materials. Several recrystallized products melted below room temperature, but the existence of a compound is shown by the analysis of the melt.

The only known reference[1] on this subject is an article by Fougue, who described the formation of a hydrate (m. p. 23°) and an alcoholate (m. p. 28°) of dicyclohexylamine, but who did not discover the apparent generality of this behavior. It is, furthermore, quite surprising that these materials were not found earlier in view of the large amount of work done on reactions of cyclohexanol with ammonia and of cyclohexanone and hydrogen with ammonia, where conditions for isolation of an addition compound must have been at least as favorable as in this case.

STEROLS. LXXXI. CONVERSION OF SARSASAPOGENIN TO PREGNANEDIOL-3(α),20(α)

Sir:

In studying the reaction of sarsasapogenin with acetic anhydride at 200° we have obtained a product in good yield (after alkaline hydrolysis) of the composition $C_{27}H_{44}O_3$, m. p. 171–173°, which we are tentatively designating as pseudosarsasapogenin. *Anal.* Calcd. for $C_{27}H_{44}O_3$: C, 77.8; H, 10.6. Found: C, 77.8; H, 10.6. Pseudosarsasapogenin upon mild oxidation with chromic anhydride in acetic acid gives a good yield of an unsaturated diketone, m. p. 201–203°. *Anal.* Calcd. for $C_{21}H_{30}O_2$: C, 80.2; H, 9.6. Found: C, 80.1; H, 9.6. This diketone upon reduction with sodium and ethanol gave a product, m. p. 236–239°, which gave no depression with an authentic sample of pregnanediol-3(α),20(α), m. p. 237–239°. *Anal.* Calcd. for $C_{21}H_{36}O_2$: C, 78.8; H, 11.3. Found: C, 78.7; H, 11.3. Acetylation of this reduction product with hot acetic anhydride gave an acetate of m. p. 177–179° which gave no depression with an authentic sample of the diacetate of pregnanediol-3(α),20(α) m. p. 177–179°. *Anal.* Calcd. for $C_{25}H_{40}O_4$: C, 74.2; H, 10.0. Found: C, 74.2; H, 10.0.

The ready availability of sarsasapogenin makes it now one of the most suitable sources of hormones such as progesterone, testosterone and desoxycorticosterone. The details of the work concerning the preparation and reactions of pseudosarsasapogenin, and its conversion to the above hormones will be published in a forthcoming issue of THIS JOURNAL.

We wish to thank Parke, Davis and Company for their generous help and assistance in the various phases of this work.

2-(*p*-AMINOBENZENESULFONAMIDO)-THIAZOLE: A NEW CHEMOTHERAPEUTIC AGENT

Sir:

Fosbinder and Walter [THIS JOURNAL, **61**, 2032 (1939)] reported the preparation of 2-(*p*-aminobenzenesulfonamido)-thiazole and stated that it had good activity in experimental streptococcic and pneumococcic infections in mice. Our own studies had already reached the point where promising pharmacologic and chemotherapeutic results (van Dyke, Rake, Greep, McKee, in press) warranted therapeutic trial of this drug and we assembled the following descriptive data for that purpose.

The 2-(*p*-aminobenzenesulfonamido)-thiazole prepared by us had the m. p. 197–197.5° (uncor.), 202.0–202.5° (cor.).

Its solubility in alcohol at 26° was 525 mg. per 100 cc. In water at 26° the solubility was about 60 mg. per 100 cc., giving *p*H 6.03, which is almost twice the solubility of sulfapyridine.

Our 2-(*p*-acetaminobenzenesulfonamido)-thiazole had m. p. 256–257° as reported by Fosbinder and Walter. **2-(*p*-Aminobenzenesulfonamido)-thiazole sodium salt** was prepared by a method essentially that described by Marshall [*Science*, **88**, 597 (1938)] for the sodium salt of sulfapyridine, m. p. 256.0–256.5° (uncor.) or 264.5–265.0° (cor.). *Anal.* Calcd. for $C_9H_8N_3O_2S_2Na$: Na, 8.30. Found: Na, 8.33. It was readily soluble in cold water. A 2% solution had a *p*H of 9.57.

2-(*p*-Aminobenzenesulfonamido)-thiazole hydrochloride was prepared by adding alcoholic hydrogen chloride to an alcoholic solution of the free base and adding ether; m. p. 193–197° (uncor.); solubility in water less than 2% with *p*H 1.28; loses hydrogen chloride on standing.

The potentiometric titration curves for the acidification of 2% solution of the sodium salts of 2(*p*-aminobenzenesulfonamido)-thiazole (Sulfathiazole), and sulfapyridine are submitted in Fig. 1. It will be seen that "Sulfathiazole" is more strongly acidic than sulfapyridine.

In addition to the 2-(*p*-aminobenzenesulfonamido)-4-methylthiazole of m. p. 237–238°, we prepared the next higher homolog, 2-(*p*-aminobenzenesulfonamido)-4-ethylthiazole, and found its melting point surprisingly lower, 149.5–150.5°.

Marshall's colorimetric method [*Science*, **88**, 85 (1938)] for the estimation of sulfapyridine has been found applicable to "Sulfathiazole." By this method, however, one cannot distinguish between sulfapyridine and "Sulfathiazole."

A good test has been found which distinguishes clearly between the two drugs. Thus, when a solution of the sodium salt of "Sulfathiazole" is treated with cupric sulfate solution, a characteristic purple precipitate is formed. With sulfapyridine an apple green precipitate is formed which gradually changes to greenish brown. This test has been used successfully on a few mg. of material. The precipitates have been characterized as follows: sulfapyridine, brown; calcd. for $(C_{11}H_{10}N_3O_2S)_2Cu$: Cu, 11.36. Found: Cu, 11.12. "Sulfathiazole," purple; calcd. for $(C_9H_8N_3O_2S_2)_2Cu$: Cu, 11.12. Found: Cu, 11.09.

Since these precipitates can be ashed and esti-

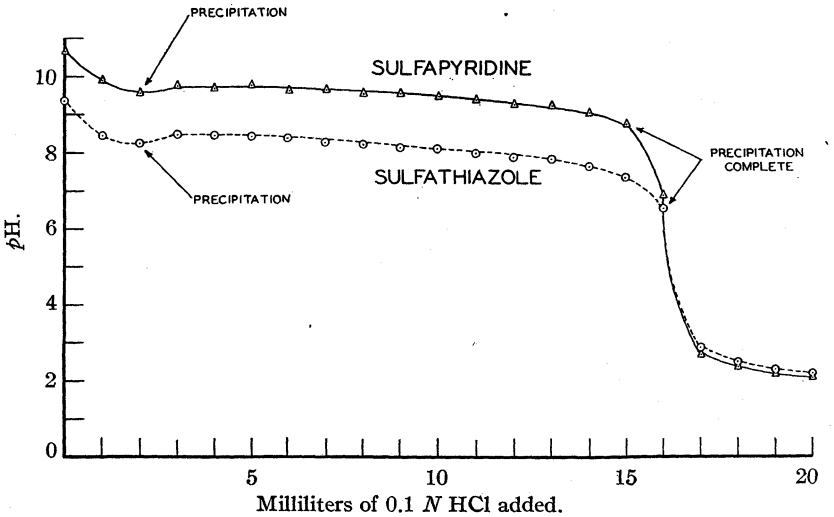

Fig. 1.—Potentiometric titrations of solutions of the sodium salts of sulfapyridine and sulfathiazole: 2% solution of sulfapyridine sodium salt, △; 2% solution of sulfathiazole sodium salt, ⊙.

mated as cupric oxide, we are at present developing quantitative methods for these two drugs as well as sulfanilamide.

BIOTIN AS A GROWTH FACTOR FOR THE BUTYL ALCOHOL PRODUCING ANAEROBES

Sir:

Recently the "growth factor" requirements of the butyl alcohol-producing clostridia has excited considerable interest.[1,2,3] It has been found that several species of these organisms require a widely distributed organic acid, which cannot be replaced by any known available growth factors.

Using the test conditions of McDaniel, *et al.*,[3] and a culture of *Clostridium butylicum* (Amer. Type Culture Coll. No. 6015), we have shown that biotin[4] is the only accessory substance required by this organism for luxuriant growth even on a synthetic medium.

The results of three tests are given in Table I, the first two on the basal medium of McDaniel, *et al.*,[3] the third using a basal medium exactly the same except that an additional 0.1% asparagin was substituted for the casein hydrolysate. Cultures 2 and 3 were subcultured from the unsupplemented tube of culture 1. Turbidities at the end of the three-day incubation period were measured quantitatively with the thermoelectric turbidimeter described by Williams, *et al.*[5] The galvanometer scale was set to read zero with the uninoculated medium in the cell; a reading of 100 corresponds to complete opacity.

TABLE I

Micrograms supplement per cc. of medium	Turbidities (galvanometer readings) — Subcultures — Culture 1 (1–3 diln.) hydrolyzed casein medium	Culture 2 (1–2 diln.) hydrolyzed casein medium	Culture 3 (undiluted) asparagin medium
Biotin Supplement			
0.000000	15.0	17.0	2.2
.0000133	25.0	19.0	10.2
.0000266	32.0	24.0	29.0
.000053	46.0	34.0	54.0
.00010	60.0	49.0	75.0
.00020	68.0	66.0	88.0
.00066	81.0	67.0	94.0
Liver Concentrate Supplement			
.0133	33.0	28.0	39.0
.0333	52.0	39.0	60.0
.0666	65.0	58.0	79.0
.1332	66.0	66.0	94.0
.2664	67.0	74.0	94.0
.6660	70.0	68.0	96.0

The "liver concentrate" was prepared in accordance with work of McDaniel, *et al.*, and was kindly furnished by Dr. Woolley. Biotin proved to be approximately 500 times as active as this concentrate and it is evidently the only substance required in addition to the ordinary nutrients. Hydrolyzed casein evidently contains small amounts of some substance which is in this case physiologically equivalent to biotin. Whether the response which we have obtained is specific for biotin cannot at present be stated. In any event, these results supply further evidence for the great physiological activity of biotin.

We wish to express our thanks to Professor Kögl, who kindly furnished us with the sample of biotin which made this work possible.

ON THE ABSORPTION SPECTRUM OF HYPERICIN

Sir:

The pigments of *Hypericum perforatum* causing photosensitization in animals are spectroscopically closely related to irradiated oxypenicilliopsin from *Penicilliopsis clavariaeformis* [A. E. Oxford, *Chem. and Ind.*, **57**, 975 (1938); C. Dhéré and V. Castelli, *C. R. Soc. Biol.*, **131**, 669 (1939); C. Dhéré, *ibid.*, **131**, 672 (1939)].

Extracted hypericin was found chromatographically to consist of five components, and we have designated the two most abundant as X and Y. Samples were interchanged with Professor Raistrick, and component Y and irradiated oxypenicilliopsin appear very similar but not identical in chemical behavior. We wish at this juncture to supplement spectroscopic observations by Dhéré and Castelli on these pigments. We have checked their absorption maxima in absolute alcohol within 10 Å. and are in fair agreement as to the intensities.

In Table I we show the effect of solvent composition on the absorption maxima. Values are

[a] Band slightly asymmetric. [b] Ia > Ib in intensity. [c] Ib > Ia in intensity. [d] Band not discernible.

averages of several readings made visually, and are accurate within ± 10 Å. Of particular interest is the co-existence of two distinct spectral types in homogeneous solutions comprised of mixtures of acetone and ether. The case of europium salts [*J. Chem. Physics*, **7**, 824 (1939)] is the only comparable instance of which we are aware.

We have segregated the spectra into three types: A_1, A_2, and B. Hypericin was considered to have four absorption bands in the visible, and this is still true in aqueous acetone, aqueous alcohol and pyridine (type A_1). Unpublished curves for the pigment in 90% aqueous acetone show a slight but definite asymmetry for band Ia and, to an even smaller extent, for band IIa in the regions where Ib and IIb occur as maxima in the anhydrous solvent (type A_2). These curves were obtained spectrophotoelectrically with a high degree of precision and there is no doubt as to the absence of Ib and IIb in the aqueous solvent at room temperature.

The ether spectrum (type B) is essentially different as shown by the fact that Ic (5690 Å.) is absent from anhydrous acetone and alcohol. The pigment is soluble with difficulty in ether. When an ether solution is shaken with water most of the pigment separates at the interface. It has been suggested that a hydrate is formed, as one could not account otherwise for such a decrease in solubility.

Relative intensities, photometrically determined in acetone, are: Ia > Ib, IIa > IIb > IV > IIIa; in ether: Ib > Ic, IIb > IV > IIc > IIIb. In acetone the fluorescence is a vivid red, whereas in ether it is distinctly orange.

The data suggest the existence of a different molecular species in ether, possibly an addition compound because the pigment is hydroxylated. This is capable of co-existence with a second type (A_2) in anhydrous alcohol– or acetone–ether mixtures. In the presence of water or pyridine it disappears, leaving a spectrum of type A_1.

A Text-Book of Quantitative Chemical Analysis. By ALEX. CHARLES CUMMING, O.B.E., D.Sc., F.I.C., and SYDNEY ALEXANDER KAY, D.Sc., formerly Lecturer in Chemistry in the University of Edinburgh. Seventh edition revised by FRANCIS CLINT GUTHRIE, M.A., F.I.C., and JOHN TRENGOVE NANCE, M.A., Lecturer in Chemistry in the University of Liverpool. D. Van Nostrand Company, Inc., 250 Fourth Avenue, New York, N. Y., 1939. xv + 496 pp. 85 figs. 15 × 23 cm. Price, $5.00.

The scope of this book is indicated by the titles of the eight parts into which it is divided, namely: I, General Principles; II, Volumetric Analysis; III, Gravimetric Analysis; IV, Colorimetric Methods; V, Systematic Quantitative Analysis; VI, The Analysis of Simple Ores and Alloys; VII, Gas Analysis; and VIII, Water Analysis. More than the usual number of specific determinations are to be found in each part.

Fundamental principles and theoretical interpretations are only briefly treated. There are simple but adequate directions of procedure. Reasons for a particular step are seldom given. Students might reasonably ask why, on page 216, 2% ammonium nitrate is recommended as a solution for washing precipitated $Fe(OH)_3$, while on page 267, hot water, and on page 397, 2% ammonium acetate are recommended for the same purpose.

The definition of *p*H on page 60 makes use of hydrogen-ion concentration in terms of *grams* per liter rather than in terms of gram-ions per liter.

Useful tables and reference works are included in the Appendix.

CHESTER M. ALTER

Schopenhauer und die Chemie. By A. MITTASCH. Carl Winter's Universitätsbuchhandlung, Lutherstrasse 59, Heidelberg, Germany, 1939. v + 92 pages. 17 × 24.5 cm. Price, RM. 2.50.

Dr. Mittasch, known particularly for his work on catalysis, on its theory and on its practical application in chemical engineering, on its history, and on its background and implications, is to be reckoned among the more philosophical of contemporary writers on the history of chemistry. The present little book supports the conviction, already finding expression in an ever-increasing number of studies and publications, that the history of thought and the history of science is one and the same. Speculation and positive knowledge in the long run are parallel, as the fibers which make up a thread are parallel, more than parallel for they are bound together, intertwined, overlapped.

The book consists of four principal parts, which deal respectively with Schopenhauer's knowledge of the chemistry of his time, with his view of the significance and importance of chemistry, with his philosophy of chemistry, and with the significance for the future of Schopenhauer's philosophy of chemistry. So far as the reviewer can see, Schopenhauer made no greater use of the chemistry of his time than did other contemporaneous alert and intelligent thinkers. Certainly no more than Emerson. No more than Shakespeare in his time. Probably less wisely than Francis Bacon made use of the scientific knowledge of his day. The charge may even be made that Schopenhauer, as several of the philosophants of the present are doing, used the concepts and jargon of science to arrive at conclusions which could have been reached more clearly by less devious methods. His final judgment concerning the order of things is not greatly different from the judgment which Omar Khayyam reached, more than seven centuries earlier, on the basis of scientific evidence only slightly more meager, and refused to accept as final. The book is a reprint from the 26th Yearbook of the Schopenhauer-Gesellschaft, 1939, and will be of interest especially to students of Schopenhauer—for whom, if they happen to be humanists of the old style, Mittasch has done a real, eye-opening service.

TENNEY L. DAVIS

Thermodynamics and Chemistry. By F. H. MACDOUGALL, M.A., Ph.D., Professor of Physical Chemistry, University of Minnesota. Third Edition. John Wiley and Sons, Inc., 440 Fourth Avenue, New York, N. Y., 1939. ix + 491 pp. 52 figs. 15.5 × 23.5 cm. Price, $5.00.

The reviewer liked this book in the previous editions [review of second edition, THIS JOURNAL, 49, 1610 (1927)]. More material is now included, notably on the calculation of thermodynamic functions with the aid of quantum statistical mechanics. The author writes extremely well and clearly. The printing is excellent.

The book seems to be comparatively free from errors. There is considerable revision of the thermodynamic presentation in the direction of the methods of Gibbs and of Lewis and Randall and there are naturally some errors not present in the earlier editions. Some of these follow. Page 44, first line, "if p is constant" invites erroneous interpretation and has no correct one. Page 108, a criterion for stable equilibrium is expressed by a *differential equality* which does not exclude neutral or unstable equilibrium. This is mitigated by the text immediately following. Page 145, the sentence before Eq. (41) and also the one following it imply the popular and unsatisfactory definition of function: y is a function of x if y varies with x. Page 148, the validity of Eq. (60) is not as stated and the conclusion just below Eq. (62) does not really follow. This conclusion implies that we cannot salt-out a dyestuff. Page 211, the expression "in view of equation X-50, it is clear . . ." is optimistic, since in that equation the potentials and mole numbers are for the independent components but in the vanishing term of XII-7 they are for the greater number of "substances." It would seem clearer to begin at once with Eq. (8) as an obvious consequence of the consideration of the free energy as a function (at

constant T and p) of the masses of the "substances" even when they are not independently variable. Page 253, in order to arrive at Eq. (8) one must postulate further that the ratio of the fugacity to the pressure approaches the limit unity as the pressure approaches zero. The substitution of one "zero" for another under the logarithm sign is not legitimate in the circumstances. This too-simple explanation has been given by others, and can here be remedied by a small change in Eq. (6).

The more modern thermodynamic treatment seems to make here a somewhat greater demand on the previous mathematical experience of the instructor than did that of the earlier editions. He should add to the material of the new and useful chapter on Mathematical Apparatus (1) a definition of function, (2) the statement that the mathematicians have proved that Eq. (III-1) applies also when the variables are not independent and (3) a brief discussion of the theory of dimensions, such as that given in the earlier editions, but extended to recognize the mole as a unit of quantity of substance. The addition (2) is the more important as several commentators on chemical thermodynamics have stated or implied the contrary fact about the equation.

L. J. GILLESPIE

Der disperse Bau der festen Systeme. Allgemeine Theorie der Verunreinigung fester Systeme. (The Disperse Structure of Solid Systems. General Theory of Contamination of Solid Systems.) By Professor D. BALAREW, Sofia. Verlag von Theodor Steinkopff, Dresden-Blasewitz, Germany, 1939. 240 pp. 45 figs. Price, RM. 10; bound, RM. 11.50.

This publication covers Volume 50 of the *Kolloid Beihefte* and is published as a separate monograph. During the last few years, Balarew has published his views on the disperse structure of solids in several issues of the *Kolloid Beihefte*. According to Balarew, all solids have a colloidal-disperse structure, regardless of whether they consist of colloidal particles or of more perfect macrocrystals. The latter always are growth agglomerates and have a porous structure. Balarew rejects the view of the physicists (Kossel, Stransky, Volmer) on the growth of crystals and claims that all crystals grow "jumpwise" by addition—not of individual ions—but of elementary building stones. He tries to substantiate his views by referring to many experimental data. His monograph is not easily read, as Balarew repeats himself on almost every page. All authors to whom reference is made (with the exception of Wo. Ostwald) are badly criticized. Such criticism might have a stimulating effect toward further research, were it not for the fact that many references are incomplete and incorrect. To mention one example: the existence of postprecipitation is still denied although it has been established conclusively in a great number of cases.

It is of interest to get acquainted with Balarew's views even if one does not agree with him in many respects. It would have been preferable, however, if the author had published his ideas in a much more concise and exact form. Considering how little is offered, the price of the monograph is very high.

I. M. KOLTHOFF

Anleitung zur organischen qualitativen Analyse. (Introduction to Organic Qualitative Analysis.) By DR. HERMANN STAUDINGER, Professor of Chemistry and Director of the Chemical Laboratory, University of Freiburg i. Br. Third edition, revised with the assistance of Dr. Werner Kern, Frankfurt a. M. Verlag von Julius Springer, Linkstrasse 22–24, Berlin W 9, Germany, 1939. xvi + 157 pp. 14 × 21 cm. Price, RM. 6.90.

Ten years have elapsed since the appearance of the second edition of this little volume. The new edition contains twelve more pages of text than its predecessor and appears to differ from it only in minor clarifications of text, and the inclusion of references to the more outstanding relevant papers of the decade.

As before, the material is divided into a general introductory section (42 pages) and the "special part" (99) which constitutes the real meat of the book. The scheme of identification is based primarily on volatility and solubility. It makes no serious attempt to deal with the characterization of specific compounds but is rather extensively concerned with the behavior of the various classes and groups of organic compounds. For this reason the book is intensely suggestive and continues to be a valuable tool to both teacher and student.

No organic chemist will wish to deprive himself of the services of this stimulating volume. Those who have worn out their old editions will welcome this new one; those who have not yet made its acquaintance cannot afford to delay this privilege any longer.

ERNEST H. HUNTRESS

Justus von Liebig. Die Lebensgeschichte eines Chemikers. (The Life Study of a Chemist.) By RICHARD BLUNCK. Wilhelm Limpert Verlag, Berlin SW 68, Germany, 1938. 320 pp. 14 × 21.5 cm.

This interesting biography of Liebig is addressed to the general reader rather than to the specialist or the chemist. It deals most fully with the years of Liebig's youth and early triumphs, since this period throws most light on his genius and personality.

The biographer is frankly sympathetic and appreciative rather than analytical and critical. He can, however, hardly be blamed for his tolerance; Liebig's brilliance, high ideals, passionate devotion to his subject and commanding personality adequately counterbalance his frequent unreasonableness and indeed perversity. His ardent advocacy of a united Germany at the time when his country was weak and divided also must endear him to the German of today.

One incident in Liebig's career deserves greater emphasis than the biographer gives it. Liebig was once arrested and incarcerated for his participation in a minor political uprising against the government among the students at the University of Bonn. He was pardoned by Duke Ludwig the First, and shortly thereafter, on the recommendation of Liebig's teacher, Professor Kastner, Duke Ludwig granted him funds from his private purse sufficient for a two years' study of chemistry at Paris, the then scientific capital of Europe. It is not every ruler who is wise and fortunate enough to pick a Liebig for his benefactions!

ARTHUR B. LAMB

Iodine and the Incidence of Goiter. By J. F. McCLENDON, Professor of Physiological Chemistry, University of Minnesota. The University of Minnesota Press, Minneapolis, Minn., 1939. vi + 126 pp. Illustrated. 22 × 28.5 cm. $5.00.

In his preface to this book the author points out that the book has been written at the suggestion of and for the benefit of research workers, especially those interested in goiter prophylaxis.

The book does not deal with the anatomy of the thyroid gland, the classification of goiter, or anything directly concerned with medical treatment.

It represents, however, a very complete review of the literature on the incidence of endemic goiter and its correlation to the distribution of iodine. This is the general viewpoint of the book, but it also contains extensive tables of the iodine content of soil, water and atmosphere, and of the various plants and animals, including all foodstuffs. A great material has conscientiously been collected by the author from chemical and medical journals all over the world. The material is condensed in brief chapters in a very successful way, and all figures handy-arranged in tables.

For those studying the problems of the etiology of endemic goiter the book will be very useful. But it is also valuable for all interested in nutrition, as almost all papers concerning the iodine content of foods will be found quoted in the book.

The author hopes that the reader will be convinced of the fact that "iodine is not only a drug, but also an essential food constituent and that lack of it may lead to a deficiency disease just as may the lack of a vitamin. In other words, iodine should have a place not only in an individual but also in preventive medicine, which aims to prevent disease in large populations."

GULBRAND LUNDE

Theoretical and Applied Electrochemistry. By MAURICE DE KAY THOMPSON, Professor of Electrochemistry, Massachusetts Institute of Technology. Third edition. The Macmillan Company, 60 Fifth Avenue, New York, N. Y., 1939. xxi + 535 pp. 234 figs. 15 × 22 cm. Price, $5.00.

"Theoretical and Applied Electrochemistry" consists of three parts; the first is "Theoretical Electrochemistry," with six chapters; the second, "Applied Electrochemistry of Aqueous Solution," with ten chapters; the third "Electric Furnaces and their Products," with five chapters.

The first three chapters deal with Faraday's law, electrolytic dissociation theory and electrical conductance. The fourth chapter entitled "Electrokinetic Phenomena" presents briefly electrophoresis, electroösmosis, the theory for the double layer on a colloidal wall, the ζ-potential of the colloidal particle. The fifth chapter is on electromotive force, and is the longest in the book, 55 pages; it includes seven pages of tables of reference electrodes, standard single potential electrodes, and oxidation–reduction potentials. Chapter six is on electrolysis and polarization, and within it hydrogen overvoltage receives nine pages.

Part II begins with a chapter (VII) on electrochemical analysis; next, chapter VIII, a very important one, on electroplating and galvanoplasty, takes up electroplating equipment, cleaning, pickling, nickel plating, cobalt, cobalt–nickel, zinc, chromium plating and many others. Chapter IX deals with the electrolytic extraction and refining of metals. In electrolytic extraction . . . "the ore is leached with a solvent that dissolves the metal, and the metal is deposited from the purified solution by electrolyzing with an unattackable anode." The solvents for copper ores are dilute sulfuric acid and ferric sulfate, or hot cupric chloride solution.

The definition quoted serves to distinguish electrolytic extraction from electrolytic refining, for in the latter the anodes consist of the impure metal, and the . . . "impure anodes are electrolyzed . . . and deposited on the cathode." The electrolytic extraction of copper, zinc, cadmium, nickel, manganese, silver, and other metals from ores is presented. The electrolytic refining of essentially the same metals is given with the conspicuous exception of Ni. On looking back over the extraction processes, one finds a method for nickel (p. 237, upper half), but to conform with the author's own definition, it should have been classed as a refining process, not as an extraction one. Electrolytic copper refining is fully treated, with many interesting details (pp. 240 to 257).

Chapter X describes electrolytic oxidation and reduction; the products by oxidation include chromic acid, permanganate, ferricyanide, and persulfate. Oddly enough, almost nothing is said regarding the production of hydrogen peroxide by electrolytic methods.

Electrolysis of alkali halides, which forms chapter XI, includes hypochlorite cells, chlorate cells, cells for "the production of chlorine and hydrate" under which latter heading the diaphragm cells are first and well treated, with numerous illustrations (pp. 298–312), and second, the mercury cells (pp. 313–316).

Chapter XII gives the electrolytic production of hydrogen, oxygen and heavy water, and the electrolytic purification of water.

Chapter XIII deals with primary cells, and chapter XIV with the lead storage cell (17 pages), the Edison storage cell (8 pages) and three others. Chapter XV has applications of electrokinetic phenomena (5 pages) and chapter XVI corrosion (2 pages).

Part III, as said before, deals with electric furnaces and their products. Chapter XX in this part deals with "The Fixation of Atmospheric Nitrogen," by the action of electricity on air only, and by nitrifying calcium carbide.

There are problems in nearly all the chapters, and a set of solutions and answers, which will be valuable to readers away from the classroom.

The description of subject matter just given contains at the same time various comments and these will be supplemented by the following remarks:

The preface states that the theoretical part was added to the original applied electrochemistry portion of the first edition at the request of many users of the book; without doubt, such users find it useful to have theoretical considerations at hand. Such a benefit depends in greater part upon a close correlation between the two, really three, parts and it is the reviewer's impression that such correlation might be improved. To give a definite example, let

a casual reader decide that upon coming to the alkali halide cells in Part II, he needs to know the theoretical decomposition voltage for sodium chloride in water solution at a definite temperature. The text for the cells presents no discussion; the index under decomposition voltage refers him to p. 179 where he finds an experimental decomposition voltage defined, but not directions for computation. To find a method for computing the desired voltage will require much searching of the text.

Several passages did not seem quite clear; thus, p. 180, lines 4–12, p. 184, lines 20–25, p. 78, lines 9–12; and the index, it may be remarked, has a startlingly large number of proper names.

The reviewer is anxious to call attention to other features in the book which will be welcomed; several have been indicated previously in the description of the subject matter. The treatment is all-inclusive, or essentially so. Next, the theoretical treatment has been brought into harmony with the latest developments (among others, for example, p. 89). Many items in the "applied" divisions will be novel to a large number of readers. Especially attractive to the reviewer are the sections in Part II dealing with the purification of water by electrolysis (p. 325), the hypochlorite cells (p. 294) and chlorate cells (p. 296), and the formation of sorbitol and mannitol by electrolytic reduction (p. 286).

EMIL RAYMOND RIEGEL

Standard Methods of Chemical Analysis. By WILFRED W. SCOTT, Sc.D., Late Professor of Chemistry, University of Southern California. Fifth Edition, edited by N. HOWELL FURMAN, Ph.D., Professor of Chemistry, Princeton University, in collaboration with eminent specialists. Vol. I, the Elements; Vol. II, Special Subjects. D. Van Nostrand Company, Inc., 250 Fourth Avenue, New York, N. Y., 1939. xxxi + xxi + 2551 + 97 (index) pp. Illustrated. 16 × 24 cm. Price, $17.00.

The last edition of this well-known book was published in 1925. According to the preface of the present edition "an extensive revision ... was in progress during the years 1930–2 and approximately half of the first volume was in galley proof when the work was interrupted by the death of Professor W. W. Scott. A further revision and extension of the book was undertaken in 1936 by the present editor in coöperation with the majority of the former collaborators, or their associates, and a number of new contributors."

As in the previous edition Volume I is devoted to the elements, qualitative tests, and various useful tables, and Volume II is given over to special subjects. Only a page by page comparison of the new edition with the previous one could make clear the extent of the changes and improvements effected by the revision. About one-third of the chapters have been entirely rewritten, and advantage has been taken of a complete resetting of type to revise thoroughly most of the other chapters. Besides these changes eight new chapters have been introduced: Rhenium; Ferrous Alloys based on the methods of the American Society for Testing Materials; Electrometric *p*H Measurement; Colorimetric *p*H Measurement; Conductometric Titrations; Chemical Microscopy; Quantitative Microanalysis; Analysis of Rubber Compounding Ingredients; Quantitative Spectrographic Analysis.

The reviewer's only regret is that the editors did not take the opportunity of a new edition to bring the whole book up to a more nearly uniform level of modernization. For instance, there is an excellent 87-page chapter on Quantitative Microchemical Analysis replete with references through 1937, but there is also a 21-page chapter on Methods for the Determination of Solubility which is reprinted from the 1919 edition of Seidell's "Solubilities." This, of course, is an extreme example and the criticism holds for only one or two of the less important topics.

The value of this book is greatly enhanced by the new edition. The collection of concise and clear procedures for so many diverse analyses will make it practically indispensable in the analytical laboratory; the wide range of topics and the wealth of information will make it a useful acquisition for every chemical library.

ARTHUR F. SCOTT

Essentials of Physiological Chemistry. By ARTHUR K. ANDERSON. Second edition. John Wiley and Sons, Inc., 440 Fourth Avenue, New York, N. Y., 1939. 323 pp. Price, $2.75.

In the second edition, this book has been brought up to date, and contains revised sections on lipids, oxidation and reduction enzymes, respiration, carbohydrate metabolism, vitamins and hormones, etc. There is also added a new chapter on the "Composition of Tissues" which is very helpful in correlating the chemistry of the animal body with its physiology.

Since the book is designed for students of human nutrition it contains many points of interest for the general reader, aside from its value to the student in biochemistry. The writer finds that the material is well organized and generally accurate. He would question, however, the statement that "Colostrum is rich in antibodies and is, therefore, an important factor in rendering infants immune to contagious diseases" (p. 129). How are these proteins taken into the body? He also regrets a diagrammatic formula for oxyhemoglobin which he does not feel represents the present state of knowledge of the substance (p. 222).

WILLIAM F. ROSS

Protein Metabolism in the Plant. By ALBERT CHARLES CHIBNALL, Professor of Biochemistry, Imperial College of Science and Technology, University of London. Yale University Press, New Haven, Conn., 1939. xv + 306 pp. Illustrated. 16 × 24 cm. Price, $4.00.

The appearance of a specialized monograph in plant biochemistry is a rare event. The field of animal biochemistry has attracted so many workers that monographs on various aspects of the field are taken as a matter of course. Even textbooks rarely deal adequately with plant chemistry, and are usually restricted almost entirely to the biochemistry of mammals and of man. Yet, as is well known, most of the important syntheses on which human life depends, such as the production of proteins, carbohydrates, alkaloids and vitamins are carried out by plants. It is to

be hoped that the next decade or so will witness a deeper appreciation of the importance of this fact and a considerable increase in the amount of work carried out on problems of plant physiology and biochemistry.

In this volume of Silliman Lectures, delivered last year at Yale University, Professor Chibnall has covered all aspects of nitrogen metabolism in plants, with the exception of those parts of the field dealing with alkaloids, purines and other non-protein constituents. The limitation on the amount of work done has a certain advantage here, in that it has been possible to include a variety of investigations ranging from the pure chemistry of proteins to the physiology of buds, without sacrificing any of the detail which is essential to critical evaluation of the material.

The book consists really of three parts. In the first five chapters are traced the gradual development of the concept of asparagine and glutamine as intermediates in the breakdown and resynthesis of proteins in seedlings, from the discovery of asparagine in 1806, through the extensive experiments of E. Schulze, lasting over 33 years, to the modern position. It might be suggested that the historical treatment in the opening 3 chapters is unnecessarily extensive. Professor Chibnall's attempt to reduce some of Schulze's experiments to "balance sheets" is certainly not very happy, perhaps because in the "balance sheets" no clear separation is made between the substances lost and those gained. His extensive recalculation of the original data (which must have involved a great deal of labor) has, however, greatly contributed to the clarity of the presentation. Two chapters then discuss the preparation and properties of leaf proteins, a field to which Professor Chibnall and his associates have made major contributions. In the last four chapters nitrogen transformations in isolated leaves are considered. This field, of course, remains in an unsatisfactory state because of the quite unexplained proteolysis which occurs when leaves are detached. Three appendices, one by J. W. H. Lugg, deal with analytical procedures.

The spirit of these lectures is that of the experimentalist thoroughly familiar with the pitfalls of the field, and a number of unpublished experiments from the author's laboratory are included throughout the book. This close contact with the laboratory gives life to all the discussion. In his critical synthesis of miscellaneous facts, garnered from a scattered literature, into a presentation of the subject as a closely interwoven whole, Professor Chibnall has done a great service not only to those in the field but to physiologists and biological chemists in general.

KENNETH V. THIMANN

Spectrochimica Acta. Ein Forschungsarchiv. (Spectrochemistry.) Band I, Heft 1. Verlag von Julius Springer, Linkstrasse 22–24, Berlin W 9, Germany, 1939. 92 pp. 56 figs. 17.5 × 26 cm. Price, RM. 8.60.

A rather inauspicious moment has been chosen for the entrance of this new journal into a field which badly needs a unifying influence. The present literature of spectrochemical analysis is so widely scattered in journals of chemistry, physics, biology, medicine, geology, and metallurgy that it is almost impossible to keep abreast of developments with ordinary library facilities. A journal devoted solely to spectrochemical analysis should be of great assistance in this respect, and it is to be hoped that it can survive the war.

In the first paper, Kaiser reports some experimental results on the effects of various factors on the relative intensities of lines emitted from a spark. From these results he is able to draw conclusions and set up certain rules which should be of great assistance in developing a technique for spark analysis.

Rollwagen has carried out a similar task for the d. c. arc, and emphasizes particularly the essential differences between the cathode layer and the positive column of the arc.

Scheibe and Martin describe a very interesting new technique for local microanalysis, in which a spark strikes to a moving sample, and the spectrum falls on a plate which moves synchronously with the sample. In this way they are able to trace differences of composition of individual grains within a metal, and detect concentrations of impurities at grain boundaries.

Gatterer and Junkes describe the quantitative determination of traces of europium in samarium, and McClelland and Whalley describe a technique which they have found useful in the analysis of various non-ferrous alloys.

The journal also includes a series of abstracts of recent books and papers dealing with spectrochemical analysis.

Additions and Corrections

NOTICE TO READERS.—For the convenience of those who wish to cut out the corrections and attach them to the margins of the articles corrected, they have been printed upon one side of the page only.

1933, VOL. 55

Victor K. La Mer and W. George Parks. The Partial and Integral Heats of Dilution of Cadmium Sulfate Solutions from Electromotive Force Measurements.

Page 4349. In Table V, the 20° values in the last four columns should read: 0.0207 instead of 0.0144; 0.323 instead of 0.358; 5,236 instead of 5,789; and 3,579 instead of 3,858.—VICTOR K. LA MER.

1937, VOL. 59

C. S. Fuller and C. L. Erickson. An X-Ray Study of Some Linear Polyesters.

Page 347. In Fig. 1(e) and (f) "the fiber axis directions on the X-ray fiber patterns of trimethylene sebacate and diethylene sebacate polyesters were inadvertently rotated through 90 degrees."

Page 348. As a result of the error on Page 347, these corrections are needed in Table II: "The correct lengths corresponding to the chemical repeating units are 15.4 ± 0.1 Å. and 17.8 ± 0.1 Å. for trimethylene and diethylene sebacate, respectively. The fiber periods or lengths of the X-ray repeating units along the fiber axis are probably multiples of these values. The designation of the various reflections in Table II is also erroneous. The general conclusions reached previously in regard to the chain configurations in the solid state of the two esters in question are not altered essentially by these corrections. As in the case of the results previously reported, the above values of the lengths of the chemical repeating units necessitate a considerable shortening of the planar zigzag chain configuration. Present evidence, however, favors a uniform "tub" form of chain instead of one in which the shortening occurs entirely in the glycol portion of the ester as was previously suggested."—C. S. FULLER.

K. A. Krieger and Martin Kilpatrick. The Conductance of Mixtures of Strong Electrolytes.

Page 1879. Column 1, line 18 for "in 1 kg. of water" read "in 1 kg. of solution." The effect of this error is to make the cell constant and the quantities dependent upon it slightly too large. The following changes should therefore be made to convert our conductances to the Jones and Bradshaw standard:

Page 1880. The values in Table I in the columns headed Λ_K(obsd.) and Λ_K(calcd.) and the left member of equation (2) should be reduced by 0.068%.

Page 1881. Column I, following line 18. The column marked Λ(obsd.) should be reduced by 0.068%.

Page 1882. Table III. The values in the column headed 1000 $C_{sp.}$(obsd.) should be reduced by 0.068%. In Table II, Λ_1° becomes 38.59 and ω_{12} and ω_{21} change correspondingly. This change in cell constant enters into the mixture effect in a rather complicated way, the values in Table III, under the heading $\Delta C_{sp.}$ (%) obsd., becoming, reading downward: +0.01, −0.04, −0.09, −0.01, −0.13, −0.04, −0.11, −0.04, −0.08, −0.04, −0.04, −0.07, −0.10, −0.06, −0.09, −0.09, −0.09, −0.10, and −0.12.

It will be observed that the corrected values are in better agreement with the theoretical values than those previously reported. With the exception of three points, the agreement is probably within the experimental error, although the observed values seem to fall consistently below the calculated ones (numerically) at the higher concentrations.—K. A. KRIEGER.

Page 2640. In column 2, line 2 from end, for "Ethyl 2-(2′-Methoxybenzoyl)-benzoate" read "Ethyl 2-(2′-Methoxybenzyl)-benzoate."

In column 2, line 1 from end, for "2-(2′-methoxybenzoyl)-benzoic acid" read "2-(2′-methoxybenzyl)-benzoic acid."

Page 2641. In column 1, line 16, for "ethyl 2-(2′-methoxybenzoyl)-benzoate" read "2-(2′-methoxybenzyl)-benzoate."—F. F. BLICKE.

Philip G. Stevens, W. Edward Higbee and Robert T. Armstrong. The Influence of Branched Chains on Optical Activity. The Configuration of Propyl-*t*-butylcarbinol, with a Note on the Relation between Rotatory Power and Chemical Character.

Page 2659. In Table III, 5th line, 3rd column, read −0.72 instead of +0.72.—PHILIP G. STEVENS.

E. Bergmann. The Dimerization of 3-Phenylindene.

Page 2816. The formula shown here should have a double bond between the second and third carbon in the left-hand indene ring.

Roger Adams, T. A. Geissman and R. C. Morris. Structure of Gossypol. XVII. Nitration Products of Gossypol Hexamethyl Ether, Gossypolone Tetramethyl Ether and Gossypolonic Acid Tetramethyl Ether.

Page 2971. In column 2, under heading "Oxidation of Compound IV to, etc." line 8, for "Compound V" read "Compound IV" and line 11, for "Compound V" read "Compound VI."—ROGER ADAMS.

Walter A. Hynes, Leo K. Yanowski and Morris Schiller. A Modified Method for the Preparation of Monochloropentamminocobaltic Chloride (Purpureocobaltic Chloride).

Page 3053. "The method described here duplicates almost exactly one proposed by Willard and Hall in their paper, 'The Separation of Cobalt by means of Phenylthiohydantoic Acid,' THIS JOURNAL, **44**, 2219 (1922). Since the method of Dr. Willard was mentioned as a mere incidental to the balance of the work reported and was not indicated in the published title of his article, we had not included his article in our list of literature references."—W. A. HYNES.

George Scatchard, W. J. Hamer and S. E. Wood. Isotonic Solutions. I. The Chemical Potential of Water in Aqueous Solutions of Sodium Chloride, Potassium Chloride, Sulfuric Acid, Sucrose, Urea and Glycerol at 25°.

Page 3066. The points at concentrations above 1 *M* representing the measurements of Frazer and Norris in Fig. 1 and those of Lovelace, Frazer and Sease in Fig. 2, should be lowered about 0.004.

Page 3068. In column 1, line 5 from bottom, for "0.65 cal./mole" read "43 cal./mole."—GEORGE SCATCHARD.

1939, VOL. 61

Dorothy Nightingale and Lee Irvin Smith. The Action of Aluminum Chloride on Aromatic Hydrocarbons. I. The 1,3-Dimethyl-4-butylbenzenes.

Page 102. In column 1, the diagram should read:

1,3-dimethyl-4-*n*-butylbenzene ⟶ 1,3-dimethyl-5-*s*-butylbenzene

1,3-dimethyl-4-*s*-butylbenzene ⟶ 1,3-dimethyl-5-*t*-butylbenzene

1,3-dimethyl-4-*t*-butylbenzene ⟶ 1,3-dimethyl-5-*t*-butylbenzene

—DOROTHY NIGHTINGALE and LEE IRVIN SMITH.

G. P. Baxter (Chairman), M. Guichard, O. Hönigschmid and R. Whytlaw-Gray. Ninth Report of the Committee on Atomic Weights of the International Union of Chemistry.

Page 225. In the ninth report of the Committee on Atomic Weights of the International Union of Chemistry through an unfortunate error the uncertainty in the composition of purpureo ruthenium chloride estimated by Gleu and Rehm (*Z. anorg. allgem. Chem.*, **235**, 352 (1937)) is given as 0.1–0.2 per cent. instead of 0.01–0.02 per cent., and the uncertainty in the atomic weight of ruthenium as 0.3 unit instead of 0.03 unit. In spite of this optimistic estimate by Gleu and Rehm, the Committee feel that further experimental evidence is necessary before making any change in the atomic weight of ruthenium in the Table.—G. P. BAXTER.

Joseph R. Spies and Thomas H. Harris, Jr. Some Salts of 2-Oxy-6,8-diaminopurine.

Page 352. In column 1, line 1 (after table), for "ninety-three milligrams" read "nine hundred and thirty milligrams."—JOSEPH R. SPIES.

Harold Hibbert. Studies on Lignin and Related Compounds. XXXVII. The Structure of Lignin and the Nature of Plant Synthesis.

Page 729. In column 2, line 9, for "IV" read "VI."—HAROLD HIBBERT.

Edward S. Amis and Victor K. La Mer. The Entropies and Energies of Activation of Ionic Reactions. The Kinetics of the Alkaline Fading of Brom Phenol Blue in Isodielectric Media.

Page 910. "In Table IV, columns $k_{k=0}$ and Log $k_{k=0}$ for 31.5% EtOH should read 0.971 and −0.013, respectively; for 42.8% MeOH, the corresponding values are 0.935 and −0.029."—VICTOR K. LA MER.

Roger Adams and Madison Hunt. Structure of Gossypol. XIX. Synthesis of 1,2-Dihydroxy-3-isopropyl-6-benzoic Acid.

Page 1132. Column 1, line 2, for "apogossypolic acid (II)" read "apogossypolic acid (V)."—ROGER ADAMS.

Roger Adams and B. R. Baker. Structure of Gossypol. XXI. Synthesis of 1,2-Dimethoxy-3-isopropyl-4-benzoic Acid and of Apogossypolic Acid.

Page 1139. In column 2, line 10 from bottom, read "b. p. 157–158°" for "b. p. 157–168°."

Page 1140. In column 1, line 13 from top, read "added 5 g. of magnesium" for "added 1 g. of magnesium."

Page 1141. In column 1, last line, read "α-bromoacetate" for "α-bromopropionate."—ROGER ADAMS.

F. F. Blicke and H. C. Parke. Alkylaminoalkyl Esters of Aminonaphthoic Acids as Local Anesthetics.

Page 1202. In Table II, the melting point of compound 6 should read "203–204°" instead of "114–115°."—F. F. BLICKE.

Manfred Kiese and A. Baird Hastings. The Dissociation Constant of Hypobromous Acid.

Page 1291. Line 4. "The statement regarding the absence of data on the dissociation constant of hypobromous acid is in error. Shilov and Gladtchikova, THIS JOURNAL, **60**, 490 (1938), R. M. Chapin, *ibid.*, **56**, 2211 (1934), and A. Skrabal and R. Skrabal, *Monatsh.*, **71** 273 (1938), have found values for the constant."—MANFRED KIESE and A. BAIRD HASTINGS.

Herbert I. Bernstein and Frank C. Whitmore. The Common Basis of Intramolecular Rearrangements. V. Inversion of Configuration in Semipinacolic Deamination. The Configurational Relationship between (+)-Alanine and (+)-Methylphenylacetic Acid.

Page 1324. Column 1. "The first carbon in the second formula is left electronically deficient by the removal of the amino group with complete octet. This should be indicated by six dots and an asterisk."—F. C. WHITMORE.

Herbert S. Harned and Calvin Calmon. The Properties of Electrolytes in Mixtures of Water and Organic Solvents. I. Hydrochloric Acid in Ethanol- and Isopropanol-Water Mixtures of High Dielectric Constant.

Page 1492. The sign on the right of equation (4) should be changed to +, that on the right of equation (5) to −. This error affects the results in columns headed E_c^0 and E_N^0 in the last two columns of Table III (page 1493).—HERBERT S. HARNED.

Frank T. Gucker, Jr., and Charles E. Moser. The Coefficient of Expansibility of Aqueous Solutions of Urea at 27.5° Calculated from the Densities at 25 and 30°.

Page 1558. Column 2. In equation 6 the last term should read:

$$\frac{1}{d_1}\left[\frac{\partial A_2}{\partial T} - 2A_3\alpha_1 + \frac{A_2}{d_1}\left(\frac{\partial A_1}{\partial T}\right)\right]c^3 + \ldots \qquad (6)$$

—FRANK T. GUCKER, JR.

M. S. Kharasch, Cheves Walling and Frank R. Mayo. The Addition of Hydrogen Halides to *cis*- and *trans*-2-Pentene.

Page 1562. In Table II the various temperatures marked 75, 78 and 80 indicate the temperature of an acetone–solid carbon dioxide bath and should be prefixed by a minus sign.—CHEVES WALLING.

Louis F. Fieser and William S. Johnson. Syntheses in the 1,2-Benzanthracene and Chrysene Series.

Page 1652. Column 1, line 5, for "5-Methyl-8-keto-3,4,5,6,7,8-hexahydrophenanthrene (IX)" read "5-Methyl-8-keto-3,4,5,6,7,8-hexahydro-1,2-benzanthracene (IX)."—L. F. FIESER.

Cheves Walling, M. S. Kharasch and F. R. Mayo. The Peroxide Effect in the Addition of Reagents to Unsaturated Compounds. XX. The Addition of Hydrogen Bromide to 2-Butyne and 2-Bromo-2-butene.

Page 1711. In footnote (4) for "see ref. 7" read "see ref. 9."—CHEVES WALLING.

Philip G. Stevens. The Rearrangement of α-Hydroxy Carbonyl Compounds.

Page 1714. Column 1, line 13, for "Fischer's discovery" read "the discovery by Fischer, Taube and Baer." Column 1, footnote (3), for "Fischer, *ibid.*" read "Fischer, Taube and Baer, *ibid.*"—PHILIP G. STEVENS.

James J. Lingane. Thermodynamic Significance of Polarographic Half-Wave Potentials of Simple Metal Ions at the Dropping Mercury Electrode.

Page 2102. "Due to an error in respect to concentration units the calculated average value of k, 0.005 mole fraction per microamp., given in the concluding paragraph is incorrect. The correct average value of k is 5×10^{-6} mole fraction per microamp., or 0.3 millimole per liter of amalgam per microamp. As a consequence the statements in the concluding paragraph are incorrect. The rate of diffusion of the deposited metal atoms in the mercury drops is about equal to that of the reducible metal ions in the solution, and not much slower, as was previously concluded."—JAMES J. LINGANE.

M. L. Wolfrom, D. R. Myers and E. N. Lassettre. The Molecular Size of Starch by the Mercaptalation Method.

Page 2175. Column 2, line 1, in the formula for "%S +" read "%S ×."—M. L. WOLFROM.

Subject Index to Volume LXI, 1939

ABIETIC acid, compn. of so-called pyro-, 247; dihydrodibromo-, 1228; dihydro-, in pine oleoresin and rosin, 1230; conversion of *l*-, into a *d*-, 2247; hydroxyl and amino dehydro-, 2528; lactonization of dihydro-*l*- ... 3197
Abundance, variation in relative, of C isotopes ... 697
Acetal, *aldehydo-d*-mannose pentaacetate Et hemi-, 574; glyoxal tetramethyl, (corr.), 755; hydrolysis of dimethyl, of glucose and galactose, 1408; of chloro-, and bromoacetaldehydes ... 1705
Acetaldehyde, in the peel of citrus fruits, 635; mol. structure of, 2922; photolysis of azomethane–, mixts ... 3024
Acetamide, condensation of pyruvic acid and ... 483
p-Acetaminobenzenesulfonyl chloride, purification of 2977
4-Acetaminodiphenyls, bromination of some substituted ... 767
Acetic acid, activity coeff. of, in KAc, 65; transference of acetates in anhyd., 147; system: $ZnAc_2$–HCl–, 2164; ionization const. of, 2377; derivs. of estrone and α-estradiol, 2974; identification of propionic acid in presence of ... 2974
2-Acetobenzofuran, reduction of, and its derivs. ... 2705
Acetomesitylene, condensation of bromomagnesium deriv. of ... 2362
Acetometallates ... 3340
Acetone, catalytic interaction of, and isopropyl alc. with D on Pt, 1336; comparison of, Et Me ketone and diethyl ketone, 2492; *d*- and *l*-ribosidodihydroxy-, tetraacetates ... 3012
Acetone derivatives, of *d*-galactose dimethylacetal and dibenzylthiol ... 2444
Acetonedicarboxylate, action of *p*-tolyl isothiocyanate on Et ... 2966
Acetone-glyceraldehyde, studies on ... 761
l(−)Acetone glycerol, prepn. of ... 761
Acetones, *sym.*-dialkoxy- ... 433
Acetophenone, reacn. of chlorosulfonic acid with, 389; substitution effects in catalyzed, iodination, 2779; acid catalyzed enolization of, derivs., 2785; kinetics of iodination of, in H_2SO_4 and $HClO_4$, 2791; hydrogenation of, to cyclohexylmethylcarbinol ... 3292
Acetophenone, 2,5-dihydroxy- ... 2651
Acetoxy group, replacement of diazo group by ... 143
Acetoxyl, addn. of, to ethylene ... 1457
Acetylacetonate, vapor pressure of Th ... 876
Acetylation, of carbohydrates by ketene, 426; of amides of aldonic acids, 1110; of lactic esters by ketene, 2727; direct, of aromatic hydrocarbons with ketene ... 3438
Acetyl bromide, photolysis of ... 800
Acetylene, catalytic interaction of, and H on Pt ... 3396
Acetylenedicarboxylic acid, reacn. of benzalaniline and cinnamalaniline with Me ester of ... 3560
Acetylene glycols, 1,2-diaryl- ... 975, 2010
Acetylene polysulfones ... 2710
Acetylenes, benzoylmesityl-, 410; prepn. of α-alkyl-β-alkenyl-, 572; chlorination of vinyl-, in MeOH, 1458; hydrogenations of, 1868; diphenylketene–phenyl-, reacn., 2619; hydrogenation of substituted, with Raney Ni, 2897; Raman spectra of ... 3546
Acetylenic compounds, electron diffraction of, 927; H bonding by negatively substituted groups ... 1599
Acetyl-5-fluorosalicylic acid, prepn. of ... 2317
Acetyl iodide, thermal decompn. of ... 3284
Acetylureas, halogen- ... 1377
Acids. (See also *Amino acids; Fatty acids; Hydrogen ion; Sulfonic acids.*) –base indicators in MeOH, 16; esterification kinetics of *n*-aliphatic, 254; substituents and dissocn. consts. of org., 555; hydrolysis of nitriles with, 560; higher *n*-aliphatic, and Me and Et esters, 577; reacn. of $Ba(OH)_2$ and monobasic sugar, 779; catalytic hydrogenation of org., in alkaline soln., 843; setting time of silica gels from various, 1020; kinetics of saponification of Et esters of *n*-aliphatic, 1172; kinetics of catalyzed esterification of Me and Ph substituted aliphatic, in MeOH, 1176; pressure–area relations of fatty, and alc. monolayers, 1180; viscosity of long chain fatty, 1188; esterification of highly hindered, 1290; use of 4,4′-diaminodiphenylmethane to identify monobasic satd. aliphatic, 1604; primary and secondary, and bases, 1886; substituents and dissocn. of aromatic, 1977; calcn. of base rate consts. from, rate consts., 2018; polyhydric alc.–polybasic, reacn., 2258, 2268; rate of dissoln. of Fe in, 2290; pressure oxidation of carbonaceous materials to, 2398; relation between resonance stabilized chelate rings and, 2475; catalyzed ester hydrolysis, 2584; catalyzed enolization of acetophenone derivs., 2785; glycerides of unsatd. fatty, 3051; identification of org., using *p*-chlorobenzyl pseudothiuronium chloride, 3251; α,β-diglycerides of fatty, 3328; general, effect on invertase activity 3330
Acrylic acid, polymers of Me α-haloacrylates ... 3156
Acrylyl chloride, structure of poly- ... 3244
Activation energy, of enzyme reacns., 403; of ionic reacns., 905; (corr.) ... 3603
Activity coefficients, of AcOH in KAc, 65; of $LaCl_3$, 200; mechanism of solvolytic reacns. of org. halides and use of, in eq. for a reacn. velocity, 1630; of Ba and Sr carbonates, 2154; of strong electrolytes ... 3030
Acylation, inter- and intramol., with HF, 1272; of aromatic compds ... 1795
Acyl compounds, from 2-hydroxy-9,10-dihydrophenanthrene, 1; N^4-, of sulfanilamide ... 1198
Acyl halides, reacn. of some furans with ... 2667
Acyloins, from *t*-butylglyoxal ... 1937
N^1-Acylsulfanilamides ... 2950
Addition reactions. See *Reactions.*
Adsorption, of H on supported Ni, 270; of gases by graphite, 528; d. of vapors adsorbed on charcoal, 873; of EtI on a plane surface of Fe, 1117; combination of electrophoretic and chromatographic, methods, 1292; of pigments, 1317; chromatographic, and dipoles, 1611; Die chromatographische (Zechmeister, Cholnoky, book review), 1934; of *cis*- and *trans*-azobenzene, 2228; of methylene blue by curd fibers of Na palmitate, 2540; studies on enamel, dentine and bone, 2588; of H by Cu in CaO. 3580
Aerobacillus macerans, new amylase from ... 2900
Alanine, β-(4-methylthiazolyl-5)-, 891; configurational relationship between (+)-MePhAcOH and (+)-, 1324; (corr.) 3603; formation of β-, by pantothenic acid cleavage, 1421; *dl*-β-cyclohexyl- 2471
Albumin, *p*H of irradiated egg, solns., 1953; serum (crystalline horse) ... 2884, 2888
Alcohols. (See also *Butyl alcohol; Ethyl alcohol; Methanol.*) condensation of *t*-aliphatic, with aromatic compds., 69; action of caustic alkali and of alkaline salts on, 99; aq. soly. of some unsatd., 807; parachors of *t*-, 900; pressure–area relations of fatty acid and, monolayers, 1180; substituted anilino, 1321; action of periodic acid on α-amino, 1615; catalytic dehydration of C_6-C_8 aliphatic, 1751; tritylation expts. in sugar, series, 1827; polyhydric, –polybasic acid reacn., 2258, 2268; aromatization of fatty, 2525; $PbAc_4$ oxidation of 1,2,3-poly-, 2607; condensation of phenols and hydroquinones with allylic, 2615; absorption studies of ethoxy, 2679; monoalkyl phthalates from *n*-aliphatic, 2909; α,ω-amino, 3439, 3440; aminobenzoic acid esters of monoalkylamino ... 3562

Alcoholysis, rates of, of aralkyl *p*-nitrobenzoates.... 2383
Aldehydes, photolysis of aliphatic, 273; constituents from ethanolysis of spruce and maple woods, 523; anhydride condensation with, in Perkin synthesis, 786; prepn. and properties of, containing D in the functional group, 1374; synthesis of, by Stephen's method, 2248; hydrogenation of, with NH_3..... 3566
Aldehydo sugars, new approach to synthesis of..... 1156
Aldohexomethylo-pyranosides, periodic acid cleavage of Me..... 1660
Aldonic acids, acetylated amides of..... 1110
Aldonic γ-lactones, rotations of the..... 1525
Aldoxime, salicyl-, and hydroxybenz-, as flotation reagents, 1247; *n*-hept-, and *n*-oct-, as flotation reagents..... 1250
Alepric acid, homolog of chaulmoogric acid..... 2349
Aleprestic acid, homolog of chaulmoogric acid..... 2349
Aleprolic acid, homolog of chaulmoogric acid..... 2349
Aleprylic acid, homolog of chaulmoogric acid..... 2349
Alfalfa, α-spinasterol from, 2467; sterols of, seed oil 2910
Algae, quantum efficiency of photosynthesis in..... 3529
Aliphatic acids. See *Acids; Fatty acids.*
Aliphatic compounds. See *Organic compounds.*
Alkali, action of caustic, on alcs..... 99
Alkali halides, activity coeffs. of..... 3030
Alkali metals, interconversion of Bi and, 1170; addn. of, to stilbenes..... 2106
Alkaline salts, action of, on alcs..... 99
Alkaloids, *Erythrina*, 1232, 3053; octalupine, a new, 1523; cinchona, in pneumonia, 1783; The Plant (Henry, book review), 1935; veratrine, 2252; monocrotaline, 2815, (corr. 3605), 2819, 2822; thermal reduction of dichromic acid by..... 3455
Alkanes, naphthylamino-..... 1780
Alkanolamines.....1321, 2658
Alkenes, isomerization of, on alumina and thoria.... 1762
Alkenylation, of phenol with 4-chloro- and 4-bromo-2-hexene..... 3079
Alkoxy diphenyls, odor of..... 3083
Alkylacetanilidobarbituric acids, *p*-ethoxy derivs. of 2962
α-Alkyl-β-alkenylacetylenes, prepn. of..... 572
Alkylaminoalkyl aminonaphthoates, as local anesthetics.....1200, (corr.) 3603
Alkylation, of phenols, 348; nuclear, in presence of HF, 1010; allylic, of benzene with HF, 1521; of benzene by esters, 1821; of α-sulfonylamides, 3139; reductive, of aromatic primary amines.... 3145
Alkylcyclopentanes, isomerization of..... 1076
Alkylfluorophenols, synthesis of some..... 161
Alkyl halides, Na saccharin in identifying, 15; mol. freedom and melting in, 1695; carbonium ions and hydrolysis of, 1948; mol. structure of some, 2643; triiodophenyl ethers to identify..... 2666
5-*n*-Alkylresorcinols, synthesis of..... 232
Alkyl sulfonates, Na salts of higher..... 539
α-Alkylsulfonylamides..... 3386
Alkynes. See "acetylenic" under *Hydrocarbons.*
Allenes, rearrangements of tetraaryldi-..... 895
Alloxantines, structure of..... 2089
Allyl compounds, condensation of phenols and hydroquinones with..... 2615
Allylic rearrangements.....12, 3070
D-Altronic acid, oxidative degradation of sedoheptulose to..... 343
D-Altrosan, crystalline..... 214
Alumina, isomerization of alkenes on, 1762; Ni–, catalyst..... 2524
Aluminum, a volatile compd. of B, H and..... 536
Aluminum bromide, parachor of, in benzene..... 3237
Aluminum chloride, in condensation of *t*-dimethyl amyl carbinols with phenol, 69; action of, on 1,3-dimethyl-4-butylbenzenes, 101, (corr.) 3603; rearrangement of 1,3-dimethyl-4-*t*-butylbenzene with, 1411; condensation of O compds. with benzene, 1413; rearrangement of toluene derivs., 2128; rearrangement of xylenes, 2131; reacn. of *p*-fluorophenol with benzene and..... 2556
Aluminum halides, paraffin–hexahydroaromatic hydrocarbon reacns. with..... 640
Aluminum isopropoxide, reduction of α-bromocyclohexanone with..... 1610
Aluminum oxyiodide, hydrosols, action of, on H_2O_2. 401
Aluminum sulfate, system: Li_2SO_4–H_2O–..... 2689
Amalgams, Cd–Bi, of const. Cd^{++} activity..... 652
Amides, condensation of α-keto acids and, 483; acetylated, of aldonic acids, 1110; hydrogenation of hydroxy-, 1675; alkylation of α-sulfonyl-, 3139; addn. of N-halo-, to olefins..... 3425
Amines, as antispasmodics, 91, 93, 771, 774; *s*-, by the Leuckart synthesis, 520; alkanol, 1321, 2658; addn. of aryl, to alkynes, 1462; *t*-alkyl primary, 1790; sulfanilamido derivs. of heterocyclic, 2032; *o*-nitrobenzenesulfenyl chloride in identification of, 2340; acid catalysis in, 2387; isomeric thujyl-, 2477; a test for aryl-, 2554; H exchange reacns. of aromatic *t*-, 2597; hydrolysis of, 2704; orientation and substituted, of dibenzofuran, 2836; aromatic, and 3-nitro-6-bromonitrostyrene, 2969; dipole moments and structures of, 3067; *s*-α-furfuryl, 3133; reductive alkylation of aromatic primary, 3145; reduction of nitroparaffins to, 3194; addn. of methoxy-, to α,β-unsatd. ketones, 3494; prepn. of certain, 3499; prepn. of primary..... 3585
Amino acids, Chemistry of, and Proteins (Schmidt, book review), 219; heavy O exchange reacns. of proteins and, 880; conjugation of, with isocyanates of anthracene and 1,2-benzanthracene series..... 3502
1-Aminoacridine, identity of 1-nitroacridone-4-carboxylic acid with..... 2247
Amino alcohols, piperazine derivs. from, 532; action of periodic acid on α-, 1615; α,β-, 3439, 3440; aminobenzoic acid esters of monoalkyl-..... 3562
2-(*p*-Aminobenzenesulfonamido)-thiazole, as therapeutic agent..... 3593
Aminobenzoic acids, dipole moment of, in dioxane, 3238; esters of substituted monoalkylamino alcs. 3562
Aminocodides..... 2186
Amino dehydroabietic acids..... 2528
Aminodiol, phthalic anhydride–, reacn..... 3381
2-Aminofluorenone, ring cleavage of..... 816
Aminohydroxy derivatives, of dibenzofuran..... 954
4-Amino-4′-hydroxydiphenylsulfone, chemotherapy of..... 2763
Amino ketones. See *Ketones.*
Aminomethanethiol, derivs..... 3134
Aminomonopersulfuric acid, formed from H_2SO_4 and H azide..... 1083
Aminomorphides..... 2186
Aminonaphthoic acids, alkylaminoalkyl, esters as local anesthetics.....1200, (corr.) 3603
α-Aminopelargonic acid, synthesis of..... 2485
m-Aminophenol, arsenicals derived from..... 355
py-Aminoquinolines, prepn. of, and derivs., 3320; coupling reacns. of..... 3322
Ammino compounds, of triphenyllead chloride..... 1687
Ammines, interconversion of acido and aquo rhodium pent-..... 699
Ammonia, reacns. of $ZrBr_4$ in liquid, 121; reacn. of esters with Na in liquid, 215; free energy of, 437; action of liquid, solns. of Na, K and K amide upon Bi oxyiodide, 1692; reduction of metal oxides in liquid, 2502; action of liquid, on SO_3 addn. compds., 3392; proteins in liquid, 3554; hydrogenation of aldehydes with, 3566; viscosity of liquid.. 3590
Ammonium acetate, Hittorf transference no. of, in AcOH..... 147
Ammonium cyanate, urea–, conversion..... 3534
Ammonium hexafluogermanate, structure of..... 2849
Ammonium hydroxides, pyrolysis of *bis*-quaternary, related to 1,2- and 2,3-butenes..... 1943
Ammonium salts, cleavage of quaternary, by Na_2S.. 2895
Ammonium selenate, system: $CaSeO_4$–H_2O–..... 1251
Ammonium sulfamates, and substituted..... 914
Ammonolysis, of benzoylisocyandichloride..... 632
Amperometric titrations..... 3402

Amyl apocupreine ether..... 1783
Amylase, influence of heavy water on barley, 125; conversion of starch to crystalline dextrins by a new..... 2900
t-Amylcyclopentane, synthesis of..... 2728
α-Amylo-dextrin, mol. wt. of, from potato starch... 1504
β-Amylose, mol. wt. of, from corn starch by means of the ultracentrifuge..... 1495
Anagyrine, from a lupine plant..... 3327
Analysis, identification of alkyl halides, 15; detn. of thiamin by thiochrome assay, 179; Qual. Inorg. (Berry, book review), 218; Qual., of Inorg. Materials (Meldrum, Flosdorf, book review), 218; Course in Qual., Based on Macro and Semi-Micro Methods (Belcher, Williams, book review), 218; und Konstitutionsermittlung org. Berbindungen (Meyer, book review), 221; thiosulfate titration of Cl, 265; acid–base indicators in MeOH, 330; of glyoxal tetramethyl acetal, 428; Die anal. Verwendung von *o*-Oxychinolin und seiner Deriv. (Berg, book review), 758; solvent effect in active H and carbonyl, 865; standardization of strong oxidizing agents with KI by the acetone method, 1690; Volumetric, Including the, of Gases and Simple Gravimetric Detns. (Berry, book review), 1933; Les origines françaises de la (Jouniaux, book review), 1934; Systematic Qual. Org. (Middleton, book review), 1934; colorimetric detn. of Pd, 2058; use of concn. cell in quant., 2237; Karl Fischer reagent, 2407; Inorg. Quant. (Fales, Kenny, book review), 2565; Calcns. of Quant. Chem. (Hamilton, Simpson, book review), 2567; Micromethods of Quant. Org. Elementary (Niederl, Niederl, book review), 2985; wet combustion method for detn. of C, O equiv., 3001; Text-Book of Quant. Chem. (Guthrie, Nance, book review), 3596; Anleitung zur org. qual. (Staudinger, Kern, book review), 3597; Standard Methods of Chem. (Scott, Furman, book review)..... 3599
Androstane, 2,3-dihydroxy-, derivs..... 1332
Anesthetics, urethans as local, 888; local, derived from α-picoline, 961; alkylaminoalkyl esters of aminonaphthoic acids as local, 1200, (corr.) 3603; local, from β-(2-piperidyl)-ethanol..... 1713
α-Angelica lactone, polymer from..... 1682
Anhydride, condensation with the aldehyde in the Perkin synthesis..... 786
Anhydrosarsasapogenoic acid, ultraviolet absorption spectra of..... 532
Aniline, reacn. of BCl_3 with, 1378; energy–vol. coeffs. of, 2515; thermodynamics of nitrobenzene–mixts., 2877; potentials of indo-..... 376
Aniline hydriodide, conductance of..... 1592
Aniline hydrochloride, conductance of..... 1592
Anilino alcohols, prepn. of substituted..... 1321
Anils, reacns. of.....3556, 3558, 3560
Anthocyanins, precursors of, of autumn foliage, 1160; precursors of, 1605; variable colors of flower petals. 1606
Anthracene, reacn. of Br with, in dioxane..... 3360
Anthracenes, conjugation of amino acids with isocyanates of..... 3502
Anthraquinones, iodinated, 2662; dipole moment of 1-chloro-..... 3583
Anthrones, hydroxy- and methoxyphenyl- (corr.)... 3601
Antihemorrhagic compounds, synthesis of..... .....1611, 1612, 1923, 1924, 1925, 1926, 1928, 1932, 2206, 2557, 2558, 2559, 2561, 2563
Antispasmodics.....91, 93, 771, 774
Antimony, thermodynamics of Pb–, system, 2594; thermodynamics of Zn–, system..... 3170
Antimony trisulfide, crystal structure of..... 1920
Apocamphane-1-acetic acid, synthesis of 2-keto-.... 3445
1-Apocamphanes, replacement reacns. in 1-substituted..... 3184
Apocupreine, amyl and hydroxyalkyl, ethers..... 1783
Apogossypolic acid, synthesis of.....1138, (corr.) 3603
d-Arabinose oxime, mutarotation of..... 2111
Area, pressure–, relations of fatty acid and alc. monolayers, 1180; pressure–, relations of expanded monolayers of myristic and pentadecylic acids... 2040
Aromatic compounds. See *Organic compounds*.
Aromatization, of heptane, heptene and hexene isomers on Cr_2O_3, 1766; of *n*-octane and *n*-decane, 2524; of fatty alcs..... 2525
Aroyl-*o*-benzoic acids, thio compds. from..... 2765
Arsenic, Bettendorff's, test, catalyzed by Hg..... 968
Arsenic compounds, recovery of Ge from arsenious sulfide sublimates, 236; derived from *m*-aminophenol, 355; of phenylmethylcarbinol, 357; arsenated phenoxybutanols..... 1236
Arsines, yields of..... 530
Arsonic acid, *p*-sulfonamidophenyl-..... 2105
Arsonium compounds..... 88
Arloxy ketones, use of, in synthesis of quinolines by Pfitzinger reacn..... 1355
Asymmetric reduction, of β-Me cinnamic acid..3295, 3297
Atomic physics, Allgemeine Grundlagen, Theorie des Atombaus (Bechert, Gerthsen, book review)..... 978
Atomic weights, 9th report of committee on..... .....223, (corr.) 3603
Atoms, reactivity of, and groups in org. compds.... 1418
Azetidine derivatives..... 3491
Azobenzene, adsorption of *cis*- and *trans*-, 2228; heat of combustion of *cis*- and *trans*-..... 2925
Azo compounds, N-benzyl..... 2029
Azomethane, photolysis of, and of acetaldehyde–, mixts..... 3024
p-Azophenol, *cis-trans* isomerism of α- and β-..... 2775

BACTERIA, fumaric acid production by *Rhizopus* molds, 127; lipids of *Monilia albicans*, 281; vitamin B_6, a growth promoting factor for yeast.....1931, 1932
Bacteriophage, Chemistry of Pepsin, Trypsin and (Northrop, book review)..... 2571
Barbituric acids, isopropenyl-, 96; substituted vinyl, 353, 776; Ph alkyl N substitution and reactivity in, 1015; 5-sulfonyl-, 2033; alkylacetanilido-.... 2962
Barium carbonate, activity coeff. of..... 2154
Barium compounds, soly. of, in dioxane–H_2O solvents..... 3274
Barium hydroxide, reacn. of, and monobasic sugar acids..... 779
Barium iodate, soly. of, monohydrate..... 3268
Barium molybdate, m. p. of..... 969
Barley, effect of heavy water on, amylases, 125; a glucosan from, roots..... 1223
Base, acid–, indicators in MeOH, 16; kinetics of reacns. of EtI with, in EtOH–H_2O mixts., 488; condensations by, 786, 793, 3567; primary and secondary acids and, 1886; trinitrotriphenylmethide ion as a secondary and primary, 1894; calcn. of, rate consts. from acid rate consts., 2018; Schiff, hydrochlorides..... 2554
Benzalaniline, addn. of Me ketones to, 3556; reacn. with Me acetylenedicarboxylate..... 3560
Benzaldehyde, in cherry juice..... 667
Benzanthracene, *meso* substituted 1,2-derivs., 136; 8-Me-1,2-, 168; 6-chloro-10-Me-1,2-, 244; 9-Me-1,2,5,6-di-, 862; syntheses in 1,2-, series, 1647, (corr.) 3605; synthesis of 1',9-methylene-1,2-, and related compds., 1740; 9,10-dialkyl-1,2-, 2358; 9,10 - dimethyl - 2',3',6',7'-tetramethoxy-1,2,5,6-di-, 3058; conjugation of amino acids with isocyanates of 1,2-..... 3502
Benzene, vapor pressure lowering of phenol in, 54; condensation of propene and isobutene with, with $FeCl_3$, 663; $AlCl_3$ condensation of O compds. with, 1413; allylic alkylation of, with HF, 1521; structure of, 1769; alkylation of, by esters, 1821; directive influence of elec. moment on substitution in, ring, 2555; reacn. of *p*-fluorophenol with, and $AlCl_3$, 2556; parachor of $AlBr_3$ in..... 3237
Benzene, polymethyl-, 284; Friedel–Crafts reacn. of *n*-octadecyl-, 478; Jacobsen reacn. on ethyltrimethyl-, 989; prepn. of *sym*-trialkyl-, 1163; amino

alkyl substituted, 1981; condensation of dichloronitro-, 2658; reacn. of, with methylcyclobutene and methylenecyclobutane with H_2SO_4..... 3374
Benzenediazonium chloride, coupling reacns. of aminoquinolines with..... 3322
Benzene-1,2,3,4-tetracarboxylic acid..... 288
Benzil, enediol from hexaethyl-..... 2010
Benzimidazole, prepn. of L-tartaric acid from the racemic form through resolution by a substituted, base..... 1266
Benzoic acid, O exchange of, and water..... 2580
Benzoic acid, esters of 3,5-dihydroxy-, 531; 1,2-dihydroxy-3-isopropyl-6-, 1132, (corr.) 3603; 1,2-dihydroxy-3-isopropyl-5-, 1134; 1,2-dimethoxy-3-isopropyl-4-, 1138, (corr.) 3603; esterification velocities of, and cyclohexanol, 2167; iodinated benzoyl-, 2662; thio compds. from aroyl-*o*-, 2765; propylallyloxy-, 3043; ethylallyloxy-, 3047; ethers of *p*-hydroxy-, 3050; dipole moment of amino-, in dioxane..... 3238
Benzoins, synthesis of mixed..... 412
Benzonitrile, 3,4,5-trimethoxy-..... 2175
Benzophenone, 3,3′-dimethyl-4,4′-dihydroxy-..... 2664
Benzopyrylium salts, halogen substituted..... 1475
5,6-Benzoquinolines, synthesis of..... 2890
Benzothiazoles, related to quinoline antimalarials... 2013
Benzoylbenzoic acids, iodinated..... 2662
Benzoyl chloride, reactivities of Cl in, derivs..... 1418
Benzoylformic acid, from styrene..... 2979
Benzoyl halides, reacn. rates of, with di-*p*-tolylmercury..... 743
Benzoylisocyandichloride, ammonolysis of..... 632
Benzoylmesitylacetylene..... 410
3,4-Benzpyrene, orientation of, in substitution reacns..... 1565
N-Benzyl azo compounds..... 2029
Benzyldimethylphenylammonium chloride, cleavage of, by S-contg. salts..... 668
Benzylglucopyranoside tetraacetates, $TiCl_4$–, reacn. 2978
4-Benzyl-1,2-naphthoquinone, synthesis from β-naphthohydroquinone of a tautomer of..... 596
Benzyluracils, catalytic hydrogenation of 5-, and 6-. 74
Beryllium, normal and basic org. salts of..... 1817
Beryllium chloride, reacns. of..... 1817
Beryllium orthosilicate, sp. heat at low temp. of.... 1217
Beryllium oxide, sp. heat at low temp. of..... 1217
Betaine, pyrrolidinium analogs of..... 1195
Bettendorff's arsenic test, catalyzed by Hg..... 968
Bicarbonate ion, O exchange between CO_2, $CO_3^=$, H_2O and..... 534
Biochemistry, Fortschritte der (Haurowitz, book review), 221; for Medical, Dental and College Students (Harrow, book review), 759; Outlines of (Gortner, book review), 982; Org. and (Plimmer, book review), 982; Annual Review of (Luck, Smith, book review)..... 2570
Biotin, as growth factor for BuOH producing anaerobes..... 3594
Biphenyls, positive Br of dibromo-, 166; 2,2′-dianisoyl-, 526; bromination of some 4-acetamino-, 767; 4,4′-dihydroxy-, 1921; stereochemistry of, 2179, 2182, 2825, 2828; odor of alkoxy, 3083; oxidation of polybromo-..... 3487
Birch lignin, extraction of, with formic acid..... 1477
Bismuth, Cd–, amalgams of const. Cd^{++} activity, 652; interconversion of, and alkali metals..... 1170
Bismuth compounds, synthesis of organo-..... 3586
Bismuth oxyiodide, action of alkali metals on, in liquid NH_3..... 1692
Bisulfite, reacn. of styrene with..... 3092
Boiling point, elevation, 497, 500; elevation of NaCl, 1123; of aliphatic compds., 3235; calcn. of, nos. of aliphatic compd..... 3236
Bonds, correlation between electronegativity series of org. radicals and, moments, 1483; H bonding by negatively substituted CH groups, 1599; H, by S–H, 3161; of H in N compds., 3252; H, involving C–H link..... 3550
Bone, adsorption studies on..... 2588
Boric acid, soly. curves of, and Na borates, 917; color reacn. of flavone derivs..... 2303
Borine trimethylammine, Me derivs. of..... 1078
Boron, a volatile compd. of Al, H and..... 536
Boron chloride, reacn. of, with aniline..... 1378
Boron compounds, soly. curves of H_3BO_3 and Na borates, 917; N-organo..... 1378
Boron fluoride, methylation of aromatic compds. by Me_2O–, 1463; *cis-trans* isomerization with, 1595; addn. of Me ketones to benzlaniline with..... 3556
Boron hydrides.....673, 1078
Boron trifluoride, propylene polymers from isopropyl alc. and..... 973
Brassicasterol, hydrogenation of..... 142
Bromides, rearrangements of pentenyl, hexenyl and heptenyl..... 3070
Bromination, of trimethylethylene, 215, 217; mono-, and di-, of some 4-acetaminodiphenyls, 767; of 4-PhPh benzoate, 1447; of 4-PhPh acetate..... 3037
Bromine, positive, of dibromobiphenyls, 166; equil. reacn. between, and BrCl, 1432; O and reacn. of cyclopropane with, 2139; reacn. of, with anthracene in dioxane, 3360; hydrolysis of, 3513; thermal and photochem. exchange reacns. of..... 3519
Bromine chloride, thermodynamic consts. of..... 1432
Bromine compounds, dissocn. const. of HBrO..... 1291
Bromoacetaldehyde, synthesis of acetals of..... 1705
Bromoacetic acid, Reformatsky reacn. in prepn. of large quantities of bromoacetic ester..... 970
Bromobenzene, PhMgBr–hexa-, reacn., 1788; energy–vol. coeffs. of..... 2515
3-Bromo-2-butanols, reacn. of the, with HBr, 1576; reacn. of *erythro-* and *threo-*, with HBr..... 2845
2-Bromo-2-butene, addn. of HBr to....1711, (corr.) 3605
α-Bromocyclohexanone, reduction of, with Al isopropoxide..... 1610
Bromodiphenyls, oxidation of heteronuclear-substituted poly-..... 3487
Bromofluorides, phosphoryl..... 3120
4-Bromo-2-hexene, alkenylation of phenol with..... 3079
Bromomagnesium enolates, condensation of, of mesityl ketones..... 2362
2-Bromomethylfuran..... 2249
m-Bromophenol, prepn. of..... 969
m-Bromophenyl acetate, prepn. of..... 143
α-Bromopropionitrile, optical activity of..... 3583
Bromotrichloromethane..... 435
Brom phenol blue, kinetics of alkaline fading of.... .....905, (corr.) 3603
Butadiene-1,3, structure of..... 1769
n-Butane, vapor pressure and crit. consts. of, 24; compressibility of and eq. of state for gaseous, 26; decompn. of, 208; inhibition of decompn. of..... 1024
Butane, diiodo-, from tetrahydrofuran, 525; 1,3,3-trialkoxy-, 887; conversion of 2,3-diacetoxy-, to 2,3-dibromo-, 1581; 2,2-dimethyl-, 3099; mol. structures of 2,3-dibromo-..... 3173
Butanedione, 4,4-dimethoxy-1,4-diphenyl-1,3-, enol. 1465
Butane-*bis*-(trimethylammonium) hydroxides, pyrolysis of..... 1943
Butanol. See *Butyl alcohol.*
Butanols, arsenated phenoxy-, 1236; 3-bromo-2-, 1576; reacn. of *erythro-* and *threo*-3-bromo-2-, with HBr..... 2845
i-Butene, condensation of propene and, with benzene with $FeCl_3$..... 663
Butenes, formation of, from 2,3-dibromobutanes by action of I^-, 1645; cracking of..... 3571
5-[α-(*s*-Butoxy)]-ethyl-5-alkyl hydantoins..... 3376
Butyl alcohol, viscosity of *n*-, 82; biotin as growth factor for, producing anaerobes..... 3594
Butylammonium picrate, conductance of tetra-, in diphenyl ether..... 2047
Butylammonium salts, catalytic effect of, on aminolysis of Et phenylacetate in anhyd. *n*-butylamine. 2387
Butylbenzenes, $AlCl_3$ on 1,3-dimethyl-4-, 101, (correction), 3603; rearrangement of 1,3-dimethyl-4-*t*-. 1411

i-Butyl bromide, dielec. behavior of..... 2063
t-Butyl chloride, solvolysis of..... 1635
s-Butyl α-chloroethyl ether, keto ethers derived from..... 1226
n-Butyl chlorosulfite, use of, in Friedel–Crafts reacn. 2452
n-Butyl chlorosulfonate, use of, in Friedel–Crafts reacn..... 2452
t-Butylcyclopentane, synthesis of..... 2728
t-Butylethylene, vapor phase catalytic conversion of. 230
t-Butylglyoxal, acyloins from..... 1937
t-Butyl halides, mol. rotation and polymorphism in. 2798
t-Butyl ketones, synthesis of..... 683
Butylmagnesium bromide, action of *i*-, on 3,4,5-trimethoxybenzonitrile, 2175; system: $MgBr_2$–Et_2O–*n*-..... 3436
t-Butylmalonic acid, prepn. of, and derivs., 637; prepn. of, from neopentyl chloride..... 965
t-Butylmethylcarbinol, vapor phase catalytic conversion of..... 230
2-*n*-Butyl-α-naphthol, synthesis of..... 2487
2-Butyne, addn. of HBr to, 1711, (correction)..... 3605
Butyric acid, rate of dehydration of β-hydroxy-, 2271; identification of propionic acid in presence of..... 2974
Butyronitrile, α-hydroxylaminoiso-..... 754
i-Butyrylisobutyric acid, acylation of, Et ester of, with Na triphenylmethyl..... 3567

CADMIUM, Bi–, amalgams of const. Cd^{++} activity. 652
Cadmium bromide, thermodynamics of, in aq. solns. 308
Cadmium halides, heats of formation and entropies of..... 1040
Cadmium ion, entropy of..... 522
Cadmium nitrate, heats of soln. and diln. of water–, system..... 260
Cadmium sulfate, heat of diln. of (correction)..... 3601
Caffeic acid, α-(*p*-xylylene)-2,5-di-(6′-amino-dimethyl)-..... 3058
Calcium hydride, rate of formation and dissocn. of. 318
Calcium oxalate, soly. of, in aq. urea solns..... 334
Calcium oxide, adsorption of H by Cu in..... 3580
Calcium selenate, system: $(NH_4)_2SeO_4$–H_2O–..... 1251
Calorimeter, heats of diln. of sucrose with a new micro-, 459; low temp. precision adiabatic, adapted to condensed gases from 10°K. to room temp., 1533; a photo-..... 3529
Calorimetry, in detn. of heat of combustion..... 2639
Camphanes, inversion in apo-..... 3184
Camphene..... 971
ω-Camphor series..... 3445
Caoutchicol, isolation of..... 585
Caprylin, tri-..... 3587
Carbamic acid, alkyl γ-diethylaminopropylcarbamates as local anesthetics..... 888
bis-(Carbethoxymethanesulfonyl)-methanes, dialkyl. 2001
Carbinols, dissocn. of triphenyl-, in MeOH, 16; condensation of *t*-dimethylamyl-, with phenols, 69; conversion of *t*-Bu-Me-, 230; arsenic derivs. of phenylmethyl-, 357; halogenation of optically active *t*-, 1295; triaryl-.....2902, 2905
Carbitol, mixing of, with H_2O..... 373
Carbohydrases, glucose dimethylacetal-, reacn..... 1833
Carbohydrates, acetylation of, by ketene, 426; reacns. of, and polysaccharides, 1905, 1910, 1912, 1916; prepn. of fully methylated..... 2442
Carbon, chromioxalate–oxalate ion interchange using radio-, 570; radioactive, in photosynthesis studies, 661; variation in relative abundance of, isotopes, 697; cleavage of Me aldohexomethylo-pyranosides, 1660; oxidation of, materials to org. acids by O, 2398; F–, reacn., 2962; detn. of, O equiv. and empirical formula by HIO_3 oxidation, 3001; combustion data on non-volatile org. compds., 3543; H bonds involving H-, link..... 3550
Carbonate ion, O exchange between CO_2, HCO_3^-, H_2O and..... 534
Carbonates, reacn. of, with dichloro-dipropylenediamine cobaltic chloride..... 3199
Carbonato pentammine cobaltic bromide, aquation of..... 3229
Carbon compounds, Chemistry of. Vol. II. Alicyclic Compds. and Natural Products (Taylor, Millidge, book review)..... 1298
Carbon dioxide, soly. of, in H_2O, 315; O exchange between HCO_3^-, CO_3^{--} and H_2O, 534; Hg-sensitized decompn. of, in light, 716; reduction of, by graphite and coke..... 2053
Carbon disulfide, non-interchange of elementary radiosulfur with..... 2970
Carbonium ions, and hydrolysis of alkyl halides.... 1946
Carbon suboxide, reacn. of, with MeMgI..... 457
Carbon tetrabromide, sp. heat and heats of fusion and transition of..... 1555
Carbon tetrachloride, vapor–liquid equil. in AcOEt–, 2691; equil. of cyclohexane–, mixts..... 3206
Carbonyl, solvent effect in Grignard analysis for... 865
Carbonyl compounds, reacn. of diborane with, 673; rearrangement of α-hydroxy, 1714, (correction) 3605; infrared absorption of some..... 2812
Carbonyl groups, reduction of conjugated systems with terminal..... 1854
Carbonyl sulfide, photolysis and extinction coeffs. of. 151
2,2′,6-Carboxybiphenyl, racemization rate of..2825, 2828
Carboxylic acids, ring cleavage of fluorenone-4-, 1358; esterification and O exchange of, 2584; infrared absorption of some..... 2812
Carcinogenic hydrocarbons..... 157
Carotenoids, presence of, in olfactory area of the steer..... 1929
Catalase, in cottonseeds..... 2417
Catechol, inactivation of tyrosinase in oxidation of. 2601
Catalysis, hydrogenation of 5 and 6-benzyluracils, 74; vapor phase conversion of *t*-Bu-methylcarbinol and -ethylene, 230; oxidation in cycloparaffin series, 633; hydrogenation of org. acids in alkaline soln., 843; interaction of acetone and isopropyl alc. with D on Pt, 1336; identity of polysulfones prepared by peroxide, and under influence of ultraviolet light, 1603; dehydration of C_6-C_8 aliphatic alcs., 1751; hydroxylation of unsatd. substances with functional groups, 1844; homogeneous catalytic hydrogenation, 2230; acid, in amines, 2387; substitution effects in oxonium ion catalyzed iodination of acetophenone derivs., 2779; mechanism of acid catalyzed enolization of acetophenone derivs., 2785; I, in dichloroethylene isomerization, 3259; interaction, of acetylene and H on Pt, 3396; peroxide-catalyzed reacn. of sulfuryl chloride with ethylenic compds., 3432; cracking of aliphatic hydrocarbons..... 3571
Catalysts, $AlCl_3$ in condensation of *t*-dimethyl amyl carbinols with phenol, 69; promoter effect of $PtCl_4$ on Raney Ni, 384; hydrogenation of ethane on Co, 503; paraffin–hexahydroaromatic hydrocarbon reacns. with Al halides, 640; condensation of olefins with benzene in presence of $FeCl_3$, 663; HF as, 949, 1010; Hg as, for Bettendorff's As test, 968; Ni in hydrogenation of cyclohexene, 1056; acylations with HF, 1272; rearrangement of 1,3-dimethyl-4-*t*-butylbenzene with $AlCl_3$, 1411; $AlCl_3$ condensation of O compds. with benzene, 1413; HF as a condensing agent, 1521; isomerization of alkenes on alumina and thoria, 1762; aromatization of heptene, heptane and hexene isomers on Cr_2O_3, 1766; propene–isoolefins reacn. with H_2SO_4, 1825; $AlCl_3$ rearrangement of toluene derivs., 2128; $AlCl_3$ rearrangement of xylenes, 2131; peroxide catalyzed chlorination of hydrocarbons, 2142; oxidation of carbonaceous materials to org. acids by O, 2398; Ni–Al, in aromatization of *n*-octane and *n*-decane, 2524; Raney Ni in hydrogenation of acetylenes, 2897; sulfonation reacns. with sulfuryl chloride, 3089; Raney Ni in *d*-glucose reduction of β-methylcinnamic acid, 3297; H_2SO_4 in benzene–methylcyclobutene reacn., 3374; addn. of Me ketones to benzalaniline with

BF_3, 3556; Ni as, for hydrogenation of halogen compds., 3564; hydrogenation of aldehydes with NH_3 ... 3566
Cellobiose, cleavage of, and celtrobiose by emulsin.. 1834
Cellosolve, mixing of, with H_2O ... 373
Cells, satd. standard, with small temp. coeffs., 652; photovoltaic, 1805; satd. standard, with small temp. coeffs., 2687; without transference for *p*H detn. ... 2983
Cellulose, studies, 154; mol. size of methylated, 1072; arrangement of substituents in, derivs., 2222; degradation of oriented, structures by polarized ultraviolet light ... 2995
Cellulose acetate, unesterified primary and secondary hydroxyls in acetone soluble ... 3458, 3463
Celtrobiose, cleavage of cellobiose and, by emulsin.. 1834
Cerin, and friedelin ... 3074
Cesium, normal electrode potential of ... 709
Cetenes, cracking of ... 3571
Cevine, oxidation of ... 2252
Chalcones, polyhydroxy- ... 861
Charcoal, d. of vapors adsorbed on ... 873
Chaulmoogra oils, analysis of ... 3442
Chaulmoogric acid, new homologs of, 2349; analysis of *Hydnocarpus wightiana* oil ... 2351
Chelate compounds, as flotation reagents ... 1247
Chelate rings, relation between resonance stabilized, and acidity ... 2475
Chemical constitution, of D-α,α-mannooctose, 1268; inversion of, in semipinacolic deamination, 1324; relation between, temp. and, of pure liquids, 1625; viscosity and ... 1734
Chemiluminescence ... 2392
Chemistry, A Course of Study in Chem. Principles (Noyes, Sherrill, book review), 220; Thorpe's Dictionary of Applied. Vol. II (Thorpe, Whiteley, book review), 222; Second Year College (Chapin, Steiner, book review), 537; General (Schoch, Felsing, book review), 979; Application of, to Agriculture (Hedges, Brayton, book review), 1297; Dictionary of Sci. Terms as Used in the Various Sciences (Beadnell, book review) ... 1933
Chemotherapy. See *Therapeutics*.
Cherry juice, volatile flavor and fixed acids of Montmorency ... 667
Chlorella, quantum efficiency of photosynthesis in.. 3525
Chlorides, soly. of $HgCl_2$ in aq., solns., 920; action of Na on high mol. wt. fatty acid, 1019; action of Li on an optically active aliphatic, 1203; parachors of a series of *t*- ... 3107
Chlorination, of isothioureas, 176; of vinylacetylene in MeOH, 1458; of 1-hexyne in reactive solvents, 1460; with sulfuryl chloride, 2142, 3432; of Bu trichloroacetates ... 3361
Chlorine, thiosulfate titration of, 265; thermal H–, reacn., 391, 396; reactivities of, in BzCl derivs., 1418; equil. reacn. between, and BrCl, 1432; thermodynamics of, 1970; action of, on thiocyanates ... 2548
Chloroacetaldehyde, synthesis of acetals of ... 1705
Chloroacetic acid, quantum yield of mono-, hydrolysis ... 2299
1-Chloroanthraquinone, dipole moment ... 3583
Chlorobenzene, energy–vol. coeffs. of ... 2515
p-Chlorobenzyl pseudothiuronium chloride, as reagent ... 3251
Chlorocarbonic acid, homogeneous decompn. of Et ester of ... 3176
Chloroethane, internal rotation in 1,1,2-tri- ... 3127
2-Chlorofluorenone, ring cleavage of ... 816
Chlorogalum pomeridianum, isolation of gitogenin from ... 1707
Chlorogenin, position of nuclear hydroxyl groups in, 946; reacns. of ... 3479
4-Chloro-2-hexene, alkenylation of phenol with ... 3079
α,ω - Chlorohydrins, N - Ph - N' - (ω - hydroxyalkyl)-piperazines from ... 3439
Chloromethane, action of triphenyl-, on α-Me-D-mannopyranoside, 1528; di-*o*-tolyl- ... 3238
6-Chloro-10-methyl-1,2-benzanthracene, synthesis of, and related compds ... 244
Chlorosulfonic acid, reacn. of, with acetophenone... 389
etio-Cholanic acids, from the pregnanediols ... 1329
Cholanthrene, fluorescence and crystal forms of Me-, Et-, and iso-propyl- ... 157
Choleic acid, isolation of vitamin K as a ... 745
Cholestadienes, prepn. of 3,5- and 4,6- ... 171
Cholestanonone, reduction of, and derivs., 1992; structure of *i*- ... 3483
Cholesterilene, study of ... 171
Cholesterilene ... 971
Cholesterol, prepn. of progesterone from ... 893
Cholesterol derivatives ... 3022
Choline, piperidinium analogs of, 638; pyrrolidinium analogs of ... 1195
Chromans, oxidation products of 6-hydroxy- ... 2424
Chromate, amperometric titration of Pb with ... 3402
Chromatograph, Adsorptionsmethoden (Zechmeister, Cholnoky, book review) ... 1934
Chromic acid, thermal reduction of di-, by alkaloids. 3455
Chromic oxide, aromatization of heptane, heptene and hexene isomers on ... 1766
Chromioxalate ion, interchange between, and oxalate ion using radio C ... 570
Chromium, racemic org. mols. in optically active complex ions of ... 2402
Chrysanthin, identity of pyrethrosin with ... 1607
Chrysene, 2,8-diphenyl- ... 895
Chrysene series, syntheses in, 1647, (corr.) 3605; synthetic expts. in ... 2134
Cinchona alkaloids, in pneumonia ... 1783
Cinchonine, thermal reduction of dichromic acid by.. 3455
Cinnamalaniline, reacn. of, with Me acetylenedicarboxylate ... 3560
Cinnamic acid, β-Me- ... 3295, 3297
Cinnamyl chloride, action of Mg on ... 12
Citrates ... 681
Citrus fruits, acetaldehyde in, peel ... 635
Claisen rearrangement ... 3085
Claviceps paspali, active principle in ... 966
Cleavage. See *Decomposition; Degradation; Hydrolysis; Saponification*, etc.
Coal, reduction of CO_2 by graphite and coke ... 2053
Cobalt, hydrogenation of ethane on, catalysts, 503; racemic org. mols. in optically active complex ions of ... 2402
Cobalt ammine, salts of 12-molybdophosphoric acid. 2022
Cobalt compounds, stereochemistry of complex, 3199; aquation of carbonato pentammine cobaltic bromide, 3229; prepn. of monochloropentamminocobaltic chloride (corr.) ... 3603
Codides, amino- ... 2186
Coefficient of expansion, of aq. urea solns., 1558, ... (corr.) 3605
Collagen, isoelec. pt. of ... 2302
Colloid chemistry, Grundlagen der Textilveredlung (Valkó, book review), 1299; of leaf and flower pigments, 1605; Colloidal Phenomena. An Introduction to the Science of Colloids (Hauser, book review) ... 1935
Colloids, Al oxyiodide hydrosols, 401; influence of ionic strength and *p*H on electrophoretic mobility, 2092; compn. of colloidal Pt micelle, 2234; Pd sols prepared by elec. sparking, 2295; paraffin-chain sulfonic acids as, electrolytes ... 3210
Colorimetry, detn. of Pd with *p*-nitrosodiphenylamine ... 2058
Columbium, reacn. with I ... 838
Columbium compounds, structure of K heptafluocolumbate ... 1252
Compressibility, of *n*-butane, 26; and soly. of metals in acids ... 746
Condensation, of *t*-dimethyl amyl carbinols with phenol, 69; of ketones with phenols, 345; of paraformaldehyde with aromatic ketones ... 414

Condensations, by bases, 786, 793, 3567; $AlCl_3$, of alcs., ethers and esters with aromatic hydrocarbons, 1413; steric hindrance in ketone–phenol, 1785; of phenols and hydroquinones with allylic alcs., allylic halides and conjugated dienes, 2615; products of monoethanolamine and dichloronitrobenzenes ... 2658
Condensing agent, HF as, 1521, 1795, 1821; $FeCl_3$ as. 2553
Conductivity, of salts in tricresyl phosphate, 294; elec., of Na decyl, dodecyl and hexadecyl sulfonate solns., 549; dielec. const. of conducting solns., 565; elec., of pure and mixed salt solns., 1219; of strong electrolytes, 1393; of amine hydrochlorides, 1592; dependence of, on field strength, 2047; of tributylammonium picrate in ethylene chloride, 3257; dependence of, on field strength, 3589; of mixts. of strong electrolytes ... (corr.) 3601
Configuration. See *Chemical constitution.*
Conjugated systems, reduction of, with terminal carbonyl groups ... 1854
Conjugation, of amino acids with isocyanates of anthracenes ... 3502
Copper, flotation of, ores, 1247, 1250; electrode spectral sensitivity, 1805; adsorption of H by, in CaO ... 3580
Copper compounds, olefin–cuprous halide reacn., 1960; relation of cuprous creatinine to tests for sugar in urine ... 2389
Copper sulfate, neutral salt effect on, hydrolysis, 118; reacn. of Zn with ... 1798
Coprostanediol-3,4, oxidation of ... 3317
Corn starch, mol. wt. of β-amylose from ... 1495
Cottonseeds, compn. of, 2037; catalase in ... 2417
Coumaran derivatives ... 2322, 2328, 2705
Coumaranes, phenolic, 348; synthesis of cyclo-alkyl 1785
Coupling, of organomagnesium halides with halides of group 8 metals ... 957
Creatinine, relation of cuprous, to tests for sugar in urine ... 2389
p-Cresol, deamination of glycine in presence of, 752; oxidation of, by tyrosinase, 1507; seleno *o*- and *m*- 2972
Cresyl phosphate, conductance of salts in tri-, 294; vapor pressure of tri-*m*- ... 2737
Critical constants, of *n*-butane, 24; of ethane ... 924
Critical increment, of ionic reacns. ... 3534, 3538
Crotalaria retusa, monocrotaline from ... 2815, (corr. 3605), 2819, 2822
Crotalaria spectabilis, monocrotaline from ... 2815 (corr. 3605), 2819, 2822
Crotonaldehyde, photolysis of, 273; photochem. oxidation of ... 582
Croton bean, isoguanine from ... 350
Crotonic acid, β-hydroxybutyric acid–, reacn., 2271; addn. of HBr to ... 2693
Crotyl alcohol, interconversion of, and methylvinylcarbinol in aq. H_2SO_4 ... 2564
Crystal Chemistry, An Introduction to (Evans, book review) ... 2570
Crystals, mol. and cybotactic wt. of ... 1812
Crystal structure, $Nd(BrO_3)_3 \cdot 9H_2O$ ... 1544
ψ-Cumohydroquinone, autoxidation of ... 360
Cyameluric acid, ionization const. of ... 3420
Cyandichloride, ammonolysis of benzoyliso- ... 632
Cyanide, equil. between ferrohemoglobin, -ion and, ferrohemoglobin ... 1263
Cyanogen, structure of, 927; thermodynamics of .. 2940
Cyanogen bromide, structure of ... 299
Cyanogen chloride, structure of ... 299
Cybotactic weight, measurements of resinous and crystalline materials ... 1812
Cyclane peroxides ... 2430
Cyclic compounds. (See also *Ring.*) cyclic ketones prepared by ring enlargment, 1057; isomerization of cyclohexane and methylcyclopentane, 1717; bicyclic structures prohibiting Walden inversion. 3184
Cyclization. See *Ring closure.*
Cyclo-alkyl coumaranes, synthesis of ... 1785
Cyclo-alkylene phenols, synthesis of ... 1785
Cyclobutane, reacn. of benzene with methylene- ... 3374
Cyclobutene, reacn. of benzene with Me- ... 3374
Cyclohexane, isomerization of, 1717; thermodynamics of methylcyclopentane–, isomerization, 2561; equil. of CCl_4–, mixts. ... 3206
Cyclohexanol, dehydration of *trans*-2-Me-, 1847; esterification velocities of benzoic acids and ... 2167
Cyclohexanone, prepn. and pyrolysis of ... 3359
Cyclohexene, hydrogenation of, with Ni, 1056; addn. of H halide to, 1454; coördination complexes of Hg^{++} with ... 3102
9,10-Cyclohexenophenanthrene, synthesis of ... 3131
dl-β-Cyclohexylalanine, synthesis of ... 2471
Cyclohexylmethylcarbinol, hydrogenation of acetophenone to ... 3292
Cycloöctatetrene, structure of ... 1943
Cycloöctene, dehydrogenation of ... 1260
Cycloparaffin, catalytic oxidations in, series ... 633
Cyclopentadiene, structure of ... 1769
Cyclopentadienes, some 1,4-diaryl-1,3- ... 1326
Cyclopentane, synthesis of *t*-Bu- and *t*-amyl- ... 2728
9,10-Cyclopentenophenanthrene, synthesis of ... 3131
Cyclopropane, O effect in reacn. of, with Br and HBr 2139
p-Cymene, nitration of ... 2469

DEAMINATION, of glycine in presence of tyrosinase and *p*-cresol, 752; inversion of configuration in semipinacolic ... 1324, (corr.) 3603
Debye, salting-out theory ... 228
Decamethylene polyesters, X-ray investigation of ... 2575
n-Decane, aromatization of ... 2524
1-Decene-1,10-dicarboxylic acid ... 3434
Deguelin, crystalline solvates of inactive ... 486
Dehydration, of hydroxy compds. by pyrolysis of K sulfate esters, 971; catalytic, of C_6-C_8 aliphatic alcs., 1751; of *trans*-2-methylcyclohexanol ... 1847
Dehydroabietic acid, hydroxyl and amino derivs. of 2528
Dehydroabietinol, hydroxyl and amino derivs. of ... 2528
Dehydroandrosterone, a pregnane compd. from ... 79
7-Dehydrocholestene isomer ... 171
Dehydrogenation, of cycloöctene, 1260; low temp., of hydroaromatic rings, 1407; of *trans*-dodecahydrophenanthrene ... 2003
Density, of vapors adsorbed on charcoal, 873; of aq. NaOH solns ... 1027
Dentine, adsorption studies on ... 2588
Desapogossypolone tetramethyl ether, attempts to prepare ... 2083
Desmotropism, of xanthine derivs ... 2483
Desoxycholamine ... 3584
Desoxycholic acid, relation between Me ester of *etio*- and Me dihydroxy-*etio*-cholanate derived from digoxigenin ... 1614
Desoxysarsasapogenin ... 1284
Deuterium. (See also "isotopes of" under *Hydrogen;* and "heavy" under *Water.*) catalyzed interaction of, with acetone and isopropanol, 1336; protium–, ratio, 1342; aldehydes with, in the functional group, 1374; H–, ratio and at. wt. of H, 2025; Pd–, equil., 2496; H and, exchange between nitramide and water ... 2552
Deuterium oxide, d. of pure, 878; thermodynamics of KCl in H_2O–D_2O mixt. ... 1487
Dextrins, conversion of starch to crystalline, by a new amylase ... 2900
Diacetone dulcitols, structures of α-, and β-, 611; structures of ... 2432
2,3-Diacetoxybutane, conversion of, to 2,3-dibromobutane ... 1581
1,2-Diacylethylene glycols ... 3246
N^1,N^4-Diacylsulfanilamides ... 2950
Diacylureas, derived from branched chain aliphatic acids ... 408
Dialkoxyacetones, sym ... 433
9,10-Dialkyl-1,2-benzanthracenes, synthesis of ... 2358
Dialkyl *bis*-(carbethoxymethanesulfonyl)-methanes 2001
trans-3,4-Dialkyloctalones, study of ... 2003

5-(Dialkylvinyl)-5-alkyl barbituric acids..... 776
Dialuric acids, substituted..... 2736
4,4′Diaminodiphenylmethane, to identify monobasic satd. aliphatic acids..... 1604
4,4′-Diaminodiphenylsulfone, chemotherapy of..... 2763
1,2-Diarylacetylene glycols.....975, 2010
1,4-Diaryl-1,3-cyclopentadienes, some..... 1326
Diazo coupling, of 2-, 3-, and 4-hydroxy dibenzofuran compds..... 3146
Diazo group, replacement of, by acetoxy group..... 143
Diazonium salts, reduction of, to hydrocarbons with alkaline formaldehyde..... 2418
Dibenzofuran, heteronuclear substitution in, 643; metalation of some, derivs., 951; aminohydroxy derivs. of, 954; 1-monosubstituted, 1365; metalation of some bromo derivs., 1371; amines of, 2836; (1,4- and 1,4,6-derivs. of).....3146, 3149
Dibenzoylethylene, condensation of hexadiene-2,4 with..... 2083
Dibenzoylmethane, infrared absorption spectra of... 2812
Dibenzyl, 3,4-dihydro-5-Me-3′-methoxy-..... 1001
Dibenzyl sebacate, 2246; vapor pressure of..... 2737
Dibenzylthiol, 4,5-monoacetone deriv. of *d*-galactose. 2444
Diborane, reacn. of, with carbonyl compds..... 637
Dibromobiphenyls, positive Br of..... 166
2,3-Dibromobutane, conversion of 2,3-diacetoxybutane to, 1581; formation of butenes from, by I^-, 1645; electro diffraction investigation of mol. structures of *meso* and racemic..... 3173
Dibutyl phthalate, vapor pressure of..... 2737
Dicetyl, d. and transition pts. of..... 1114
Dichloro-dipropylenediamine cobaltic chloride, reacn. of carbonates with..... 3199
Dichloroethylene, equil. and kinetics of, isomerization..... 3259
Dichlorofluorenones, ring cleavage of 1,8-, 1,6- and 3,6-, with KOH in diphenyl ether..... 1066
Dichlorogermane, dipole moment and structure of... 3063
Dichloronitrobenzenes, condensation of..... 2658
Dichromate, amperometric titration of Pb with..... 3402
Dichromic acid, oxidation of echinocystic acid, 2421; thermal reduction of, by quinine, hydroquinine and cinchonine in H_2SO_4..... 3455
Dicyclohexylamine, addn. of compds. of..... 3591
Dielectric behavior, of protein zein solns., 718; of *i*-Bu and *i*-amyl bromides..... 2063
Dielectric constant, of conducting solns., 565; entropy of ionization in solns. of low, 973; mol. freedom and melting in alkyl halides, 1695; of polyvinyl chloride–tricresyl phosphate plastics, 2334; and ionic strength in ionic reacns.....3534, 3538
Diels–Alder reaction, new type of..... 3558
Dienes, reacn. between diphenylketene and certain, 7; condensation of phenols and hydroquinones with allylic..... 2615
Diene synthesis, β-nitrostyrene in..... 521
Dienols, obtained from unsatd. 1,4-diketones..... 1854
Dienynes, cyclication of..... 2003
γ-Diethylaminopropylcarbamates, alkyl, as local anesthetics..... 888
bis-(β-Diethylaminoethyl) sulfide, formation of..... 2971
Diethyl ether, vapor pressure of $ZnBr_2$–, solns..... 1949
Diethyl ketone, decompn. of, at short wave lengths.. 2492
Diffusion, velocity and mol. wt., 1745, 1747; by electrolysis with microelectrodes..... 3344
Digitogenin, reacns. of, and gitogenin..... 2724
Digitonin, precipitability of steroid sapogenins by... 2717
α,β-Diglycerides, prepn. of, of fatty acids..... 3328
Diglycolic anhydride, pyrolysis of..... 3490
Digoxigenin, Me dihydroxy-*etio*-cholanate from..... 1614
Dihydroabietic acid, in pine oleoresin and rosin..... 1230
Dihydro-*l*-abietic acid, lactonization of..... 3197
Dihydrodibromoabietic acid..... 1228
3,4-Dihydro-5-methyl-3′-methoxydibenzyl, synthesis of..... 1001
Dihydropimaric acid, hydration of..... 967
Dihydro-*l*-pimaric acid, lactonization of..... 3197
Dihydrosarsasapogenin, oxidation products of..... 3477
Dihydroxamic acids, substituents and decompn. rates of K salts of..... 618
2,5-Dihydroxyacetophenone, coloring matters derived from..... 2651
2,3-Dihydroxyandrostane derivatives..... 1332
3,5-Dihydroxybenzoic acid, esters of..... 531
Dihydroxy-*etio*-cholanic acid, Me ester of, from digoxigenin..... 1614
4,4′-Dihydroxydiphenyl, sulfonic acid esters of..... 1921
1,2-Dihydroxy-3-isopropyl-6-benzoic acid, synthesis of.....1132, (corr.) 3603
1,2-Dihydroxy-3-isopropyl-5-benzoic acid, synthesis of..... 1134
1,4-Diiodobutane, from tetrahydrofuran..... 525
2,4-Diketo-3-hydroxy-3-arylazetidines..... 3491
Diketones. *See Ketones.*
1,4-Dimesityl-2-phenyl 1,4-diketones..... 3010
4,4-Dimethoxy-1,4-diphenyl-1,3-butanedione enol... 1465
1,2-Dimethoxy-3-isopropyl-4-benzoic acid, synthesis of.....1138, (corr.) 3603
2,4-Dimethoxyquinazoline-5-carboxylic acid, Me esters of..... 2170
Dimethyl acetal, behavior of, of glucose and galactose under hydrolytic and glycoside-forming conditions, 1408; prepn. of, from *d*-fructosediethylmercaptal, 1671; 4,5-monoacetone deriv. of *d*-galactose..... 2444
Dimethylamine, thermodynamic consts of..... 1539
4′-Dimethylaminobiphenyldiphenylcarbinol, and its relation to dye color theory..... 2902
t-Dimethyl amyl carbinols, condensation of, with phenol..... 69
1,3-Dimethylbenzoylene-urea-5-carboxylic acid, Me esters of..... 2170
2,2-Dimethylbutane, isolation of, from natural gas.. 3099
1,3-Dimethyl-4-butylbenzenes, action of $AlCl_3$ on .....101, (corr.) 3603
1,3-Dimethyl-4-*t*-butylbenzene, rearrangement of, with $AlCl_3$..... 1411
Dimethyldiborane..... 1078
3,3′-Dimethyl-4,4′-dihydroxybenzophenone..... 2664
1,4-Dimethyl-6,7-dihydroxyphenanthrene, synthesis of, from *p*-xylylacetic acid and 6-nitroveratraldehyde..... 2461
2,4-Dimethyl-8-ethylquinoline, isolation of..... 1017
5,6-Dimethylglucose, synthesis of..... 3507
Dimethylglyoxal, structure of..... 3520
Dimethylmagnesium, relative reactivities of Me-MgCl and..... 1152
2,3-Dimethyl-1,4-naphthoquinone, PhMgBr–, reacn. 3310
1,4-Dimethylphenanthrenes, some, related to morphol..... 3055
3,6-Di-(2,4-dimethylphenyl)-hydroquinones, and derivs..... 2182
2,4-Dimethyl-8-*n*-propylquinoline, isolation of..... 2609
2,5-Dimethyltetrahydrofuran, reacn. with acyl halides..... 2667
9,10 - Dimethyl - 2′,3′,6′,7′ - tetramethoxy - 1,2,5,6-dibenzanthracene, synthesis of..... 3058
5,5-Dimethylthiazolinephenols..... 1145
Diones, pyridazine derivs. of steroid..... 2976
Dioxadiene..... 3020
Dioxane, thermodynamics of HCl in water–, 44, 48, 49; ionization const. of water in H_2O–, 2374, 2377; ethanol–, system, 2460; transference nos. of HCl in H_2O–, mixts., 3113; dipole moment of aminobenzoic acids in, 3238; soly. of salts in H_2O–, solvents, 3274; Br–anthracene reacn. in..... 3360
Dioxanes, monoalkyl-..... 3016
Diphenic acids, ring cleavage of 2-substituted fluorenones in diphenyl ether, 816; fluorenones and, ...1066, 1358
2,8-Diphenylchrysene, synthesis of..... 895
sym.-Diphenylethane, synthesis of, derivs..... 1001
Diphenyl ether, ring cleavage of 2-substituted fluorenones with KOH in..... 816
Diphenyliodonium nitrate, nitration of..... 3061

Diphenylketene, reacn. between, and dienes, 7; reacn. between, and phenylacetylene..... 2619
Diphenyllead dihalides..... 1609
1,4-Diphenyl-2-mesityl 1,4-diketones..... 3007
Diphenylmethane, 4,4'-diamino-..... 1604
Diphenylmethane, as a thermometric standard at 25°. 1796
Diphenylnaphthalenes..... 608
Diphenylselenides..... 2306
Diphenylselenium dihydroxides..... 2306
Diphenyl sulfide, reacn. of S with halogenated..... 387
Diphtheria toxin, mol. wt. of the, protein..... 533
Dipicrylaminates, properties of..... 2285
Dipole moment. See *Electric moment.*
Dipoles. *See Molecules.*
Di-*n*-propyltetrahydrothiophene-1,1-dioxides, 3,4- and 2,5-..... 2714
Dissociation, of triphenylcarbinols in MeOH, 16; of hexa-*m*-biphenylethane, 77; of hydantoin, 423; consts. of org. acids, 555; const. of HBrO, 1291; (corr.) 3603; equil. of HgO in dil. HNO_3, 1730; substituents and, const. of aromatic acids, 1977; effect of substitution on, of hexaarylethanes, 2769, 2771; of HIO_3..... 3268
Distillation, fractionation of H isotopes in EtOH.... 2453
Dithiocyanates, identification of olefins as..... 750
Di-*o*-tolylchloromethane, prepn. of..... 3238
Di-*p*-tolylmercury, reacn. rates of benzoyl halides with, 743; treatment of neopentyl halides with... 1591
Divinyl sulfide, reacn. with Ag_2O..... 915
trans-Dodecahydrophenanthrene, dehydrogenation of..... 2003
Dotriacontane, d. and transition pts. of..... 1114
Double bonds. (See also *Conjugation; Diene number; Iodine number*, etc.); phenol and hydroquinone condensation with..... 2615
Dulcitols, structures of α- and β-diacetone, 611; structures of diacetone..... 2432
Dyes, relation of 4'-dimethylaminobiphenyldiphenylcarbinol to, color, 2902; occurrence of color with trixenylcarbonium salts..... 2905

ECHINOCYSTIC acid, oxidation of, and derivs., 983; dichromic acid oxidation of..... 2421
Elaidinization, of linoleic acid..... 1062
Electrical properties, of multimol. films, 1425; of solids.....2529, 2334
Electric moment, directive influence of, on substitution in benzene ring, 2555; of ozone, silicobromoform and dichlorogermane, 3063; of certain nitro compds. and amines, 3067; of aminobenzoic acids in dioxane, 3238; of 1-chloroanthraquinone..... 3583
Electrochemistry, of Gases and other Dielectrics (Glockler, Lind, book review), 1936; Principles of (MacInnes, book review), 2253; Theoretical and Applied (Thompson, book review)..... 3598
Electrode. (See also *Potential.*) normal, potential of Cs, 709; Potential Behaviour of Corroding Metals in Aq. Solns. (Gatty, Spooner, book review), 757; dropping Hg, 825; polarographic current–voltage curves with dropping amalgam, 976; migration current in the dropping Hg, 1045; Cu, Ag and Au, spectral sensitivity, 1805; potentials of simple metals at the dropping Hg, 2099, (corr.) 3605; AgI and Hg_2I_2, 2592; diffusion by electrolysis with micro-..... 3344
Electrolysis, prepn. of glucuronic acid, 870; of PrMgBr in Et ether, 898; diffusion by, with microelectrodes..... 3344
Electrolytes, thermodynamics of bi-univalent, 308, 1040; conductivities of strong, 1393; thermodynamics of strong, in H_2O–D_2O mixts., 1487; properties of, in mixts. of H_2O and org. solvents, 1491; (corr.) 3605; and viscosity of pectin solns., 2313; properties of, in H_2O–org. solvent mixts., 2374, 2377, 3113; sulfates in, of Weston cell, 2687; activity coeffs. of strong, 3030; paraffin-chain sulfonic acids as colloidal, 3210; properties of elec. solns., 3257; $BaIO_3$ soly. in uni-univalent, solns., 3268; conductance of mixts. of strong (corr.)..... 3601
Electromagnetics, A Discussion of Fundamentals (O'Rahilly, book review)..... 218
Electromotive force. See *Potential, electric.*
Electron, diffraction investigation of cyanogen chloride and bromide, 299; diffraction investigation of mol. structures of ethylene chlorobromide and ethylene bromide, 303; diffraction of acetylenic compds., 927; diffraction of glycine, 1087; mol. structure of tetranitromethane by, diffraction, 1127; diffraction investigation of $P_4O_6S_4$, 1130; diffraction investigation of structure of benzene, pyridine, pyrazine, butadiene-1,3, cyclopentadiene, furan, pyrrole and thiophene, 1769; "effective, d." and chem. behavior, 2161; diffraction study of formaldehyde, 2508; diffraction of some alkyl halides, 2643; Ions, and Ionizing Radiations (Crowther, book review), 2984; diffraction of 2,3-dibromobutanes, 3173; sharing ability of org. radicals, 3289; diffraction of glyoxal and dimethylglyoxal..... 3520
Electronegativity, bond moments and, of org. radicals..... 1483
Electro-optical effect, in certain viruses..... 2412
Electrophoretic analysis, modification of Schlieren method for use in..... 529
Electrostatic effect, of substituents on dissocn. consts. of aromatic acids..... 1977
Elements, Oxidation States of, and their Potentials in Aq. Solns. (Latimer, book review)..... 2565
Eleostearic acid, behavior of Wijs soln. with α-, 2277; molar refractivity and parachor of α- and β-, 2283; pseudo-..... 3292
Emulsin, cleavage of cellobiose and celtrobiose by.. 1834
Enamel, adsorption studies on..... 2588
Ene-diol, 1,2-diarylacetylene glycols, a new type of. 975
Energy, relations in transformations from 3 to 2-dimensional systems, 1702; vol.–, coeffs. of aniline, nitro-, bromo- and chlorobenzene..... 2515
Enolates, bromomagnesium, of mesityl ketones.... 2362
Enolization. See *Isomerization.*
Entropy, of aq. Zn and Cd ions, 522; of Te, 564; of ionic reacns., 905, 3603; of Cd halides, 1040; of dimethylamine, 1539; spreading of myristic and pentadecylic acids, 1702; of Cl, 1970; of HCN, 2626; of cyanogen, 2940; of propylene..... 2980
Entropy of ionization, in solns. of low dielec. const.. 973
Enzyme, activation energy of, reacns., 403; und ihre Wirkungen (Oppenheimer, book review), 538; prepn. of *d*-galacturonic acid, 2701; pectic, 2544; Respiratory (Elvehjem, Wilson, book review), 2568; Crystalline (Northrop, book review), 2571; mol. wt. and assocn. of, urease..... 3180
Equation of state, for gaseous *n*-butane..... 26
Equilenin, total synthesis of, 974; oxidation and reduction products of..... 3314
Equilibrium. (See also *Phase rule;* and *Pressure.*) magnetic study of, between ferrohemoglobin, cyanide ion and cyanide ferrohemoglobin, 1263; vapor–liquid, in CCl_4–AcOEt, 2691; analysis of random, mixtures, 2755; vapor–liquid..... 3206
Erythramine, a new alkaloid, 1232; constitution of. 3053
Erythrina alkaloids.....1232, 3053
dl-Erythronic lactone, reduction of, to *dl*-erythrose. 1720
dl-Erythrose, reduction of *dl*-erythronic lactone to.. 1720
Esterification, kinetics of MeOH and *n*-aliphatic acids, 254; of highly hindered acids, 1290; velocities of benzoic acids and cyclohexanol, 2167; of carboxylic acids, 2584; kinetics of poly-..... 3334
Esters, reacn. of, with Na in NH_3, 215; of higher *n*-aliphatic acids, 577; alkylation of benzene by, 1821; X-ray study of decamethylene poly-, 2575; X-ray study of linear poly- (correction)..... 3601
α-Estradiol, AcOH derivs. of..... 2974
α-Estrodiol, highly branched aliphatic esters of.... 1922
Estrone, highly branched aliphatic esters of, 1922; AcOH derivs. of..... 2974

Ethane, hydrogenation of, on Co catalysts, 503; crit. consts. of, 924; compressibility of gaseous, in high d. region, 926; F–, reacn. 3552
Ethanes, dissociation of hexaaryl-, 77, 2008, 2769; kinetics of reacns. of iodo-, with bases in EtOH–H_2O, 488; synthesis of sym. diphenyl-, derivs., 1001; adsorption of iodo-, on a plane surface of Fe, 1117; mol. structure of chloro-, 2643; disproportionation of hexa-*p*-alkylphenyl-, and effect of *o*-, *m*-, and *p*-alkyl groups on dissocn. of hexaaryl-, 2771; trichloro-, 3127; synthesis of α-2-methoxyphenyl-β,β,β-triphenyl- 3192
Ethanol, local anesthetics from β-(2-piperidyl)- 1713
Ethanolamine, condensation products of mono- 2658
Ethanolysis, of spruce wood, 509; of maple wood, 516; of spruce and maple wood, 523; of spruce and maple woods, 868; of maple wood, 2198, (correction) 3605
Ethers. (See also *Ethyl ether*.) keto, derived from *s*-Bu α-chloroethyl, 1226; substituted, derived from ethylene chlorohydrin, 1574; amyl and hydroxyalkyl apocupreine, 1783; vapor pressure of $ZnBr_2$–diethyl, solns., 1949; conductance of tetrabutylammonium picrate in diphenyl, 2047; of gossypol, 2077, 2083; triiodophenyl, to identify alkyl halides, 2666; iodo derivs. of Ph, 2702; rearrangement of Ph allyl, 3039, 3042, 3043, 3047; of *p*-hydroxybenzoic acid, 3050; rearrangement of allyl *p*-tolyl 3085
Ethoxy alcohols, absorption studies of 2679
p-Ethoxyalkylacetanilidobarbituric acids 2962
Ethoxymethyldiallylcarbinamine, and some analogs. 1790
Ethyl acetate, vapor–liquid equil. in CCl_4– 2691
Ethylal, hydrolysis of 2510
Ethyl alcohol, decompn. of trinitrobenzoates in, 186; EtI–base kinetics in H_2O–, mixts., 488; salting-out in phenylthiourea–, system, 228; properties of HCl in H_2O–, mixts., 1491; system: toluene–water–, 1694; fractionation of H isotopes in, distillation, 2453; dioxane–, system 2460
Ethylallyloxybenzoic acid, isomeric Et esters of *p*-α- and -γ- 3047
Ethylamine, partial vapor pressures of aq., solns. 2808
Ethyl disulfide, oxidation of, by BrO^- 1955
Ethylene, polymerization of, 798; addn. of halogen and acetoxyl to 1457
Ethylene, bromination of trimethyl-, 215, 217; conversion of *t*-Bu-, 230; Na, carbide, 750; isomerization of dichloro- 3259
Ethylene bromide, internal rotation in 303
Ethylene chloride, conductance of tributylammonium picrate in 3257
Ethylene chlorobromide, internal rotation in 303
Ethylene chlorohydrin, reacn. kinetics of, and hydroxyl ion, 1205; substituted ethers derived from. 1574
Ethylenediamines, monoacyl- 822, 3195
Ethylene glycol, partial pressure of HCl in 2504
Ethylene glycols, 1,2-diacyl- 3246
Ethylene halides, sp. heat of 3349
Ethylenic compounds, peroxide-catalyzed reacn. of sulfuryl chloride with 3432
Ethyleneimine derivatives, attempts to prepare optically active, with an asymmetric N atom 2464
Ethylene oxide, non-reacn. of, and MeOH 527
Ethyl ether, system: *n*-BuMgBr–$MgBr_2$– 3436
Ethylmesitylene, prepn. of 284
Ethyl methyl ketone, a comparison of acetone, diethyl ketone and 2492
Ethylpseudocumenes, prepn. of 3- and 5- 284
β-Ethylsorboside, and its tetraacetate 2669
Ethyl sulfide, *bis*-(β-diethylamino-) 2971
α-Ethylthioglucofuranoside, hydrolysis of 1450
α-Ethylthioglucopyranoside, formation of, from glucose ethylmercaptal 1930
Ethyltrimethylbenzenes, Jacobsen reacn. on 989
Europium, salts of 2455
Exchange. See under *Reactions*.
Extinction coefficients, of gaseous carbonyl sulfide 151
Extraction, counter-current acid, of kero bases, 2609; multiple acid, in isolation of quinolines 2612, 2613

FATTY acid. (See also *Acids*.) absence of, in cereal starches, 212; synthetic glycerides of unsatd., 3051; α,β-diglycerides of, 3328; cleavage of unsatd. 3589
Fermentation, of maltose 291
Fermentation chemistry, Praktikum (Bernhauer, book review) 2985
Ferricyanide, neutral salts on the iodide–, reacn. 116
Ferrimyoglobin, magnetic properties of 2150
Ferrohemoglobin, equil. between, cyanide ion, and cyanide 1263
Films, pressure–area relations of fatty acid and alc. monolayers, 1180; viscosity of long chain fatty acids, 1188; elec. properties of multimol., 1425; expanded monolayers of myristic and pentadecylic acids, 2040; elec. characteristics of mol. 3162
Fischer, Karl, reagent in analysis 2407
Flavone derivatives, boric acid color reacn. of 2303
Flavylium salts 1475
Flotation, chelate compds. as, reagents, 1247; normal oximes as reagents, 1250; Principles of (Wark, book review) 1296
Fluidity, relation between, temp. and chem. constitution of pure liquids 1625
Fluorene, structure of 2115
Fluorenones, ring cleavage of 2-substituted, 816; and diphenic acids 1066, 1358
Fluorescein, structure of, derivs. 2919
Fluorescence, and Phosphorescence (Hirschlaff, book review), 979; quenching of, in aq. soln. 2634
Fluorides, aliphatic di-, 938; potentiometric detn. of, 2237; structures of complex, 2849; phosphoryl bromo- 3120
Fluorination, of PCl_3, 2927; of PBr_3, 2934; of phosphoryl trichloride 2937
Fluorine, F–F distance in KHF_2, 2590; C–, reacn., 2962; action of, on org. compds. 3552
Fluorine compounds, alkylfluorophenols, 161; structure of K heptafluocolumbate and -tantalate, 1252; acetyl-5-fluorosalicylic acid, 2317; fluorinated derivs. of propane, 2489; soly. of SiF_4, 2555; fluorinated aromatic mercurials 3005
Fluorocarbons 2962
p-Fluorophenol, reacn. of, with benzene and $AlCl_3$ 2556
Foods, Structure and Compn. of, Vol. IV (Winton, Winton, book review), 1297; Handbuch der. Vol. V (Juckenack, Bames, Bleyer, Grossfeld, book review) 2569
Formaldehyde, alkaline, reduction of diazonium salts, 2418; structure of, from electron diffraction. 2508
Formaldehyde sulfoxylate derivatives, of sulfanilamide 617
Formic acid, hydrolysis equil. of, esters, 1443; extraction of birch lignin with, 1477; benzoyl-, from styrene, 2979; kinetics of thermal decompn. of Et ester of 3203
Free energy, of NH_3 437
Free radicals, of type of Wurster's salts 1981
Friedel–Crafts reactions, cleavage rearrangements in, of furans, 473; *n*-octadecylbenzene, 478; hydrocarbon syntheses by, 1163; use of *n*-Bu chlorosulfonate and chlorosulfite in, 2452; ketene in 3438
Friedelin, cerin and 3074
Friedonic acid, study of 3074
Fructose, 1-β-glucosido- 2675
d-Fructosediethylmercaptal, prepn. of dimethyl acetal and methylfuranosides from 1671
L-Fucose, α- and β-Me pyranosides of, and their triacetates 1658
Fumaric acid, production of, by *Rhizopus* molds 127
Fungi, pathogenic, studies 281
Furan, structure of 1769
Furan, 1,4-diiodobutane from tetrahydro-, 525; dibenzo-, 643, 951, 954, 1365, 1371, 2836, 3146, 3149; amino ketones from tetrahydrobenzo(b)naphtho-

(2,3-*d*)-, 1148; 2-bromomethyl-, 2249; reduction of 2-acetobenzo-, 2705; tetrahydro, and 2,5-dimethyltetrahydro-, reacn. with acyl halides..... 2667
Furan compounds, *p*-methoxyphenyl-2-furyllead compds..... 739
Furanosides, glyco- and thioglyco-.....1450, 1671
Furan series, orientation in..... 473
s-α-Furfuryl amines..... 3133
α-Furfuryl bromide..... 2249

GADOLINIUM oxide, magnetic susceptibility of... 1384
L-Galactomethylose. See L-*Fucose*.
L-Galactonic acid, oxidative degradation of perseulose to..... 340
Galactose, new synthesis of *l*-, 611; hydrolysis of dimethyl acetals of, 1408; acetone derivs. of *d*-, dimethylacetal and dibenzylthiol..... 2444
d-Galacturonic acid, enzymic prepn. of, 2701; prepn. of..... 2973
D-Gala-L-gala-octose, aldehydo derivs. of..... 1270
L-Galaheptulose, proof of structure and configuration of..... 336
D-α,α-Galaoctose, aldehydo derivs. of..... 1270
Gallium, extraction of, from germanite, 236; sesquioxide and hydroxides of, 1210; $HClO_4$–, reacn... 3122
Gallium perchlorate hydrates, prepn. of..... 3122
Gases, adsorption of, by graphite, 528; Electrochemistry of, and Other Dielectrics (Glockler, Lind, book review)..... 1936
Gas reactions, Exptl. Methods in (Farkas, Melville, book review),..... 2568
Geigerin, non-identity of pyrethrosin with..... 1607
Gel, formation by org. salts in MeOH solns., 670; setting time of silica, from various acids..... 1020
Gelatin, effect of *p*H on particle size in, solns., 1747; effect of non-electrolytes on time of setting of, gels..... 1749
Germanite, extraction of Ge and Ga from..... 236
Germanium, recovery of, from arsenious sulfide sublimates..... 236
Germanium compounds, K and NH_4 hexafluogermanates, 2849; structure of dichlorogermane, 3063; magnetic measurements on hexaphenyldigermane..... 3168
Gitogenin, isolation of, from *Chlorogalum pomeridianum*, 1707; reacns. of digitogenin and..... 2724
d-Glucoheptulose, reduction products of..... 3370
Glucosan, water-sol., from barley roots..... 1223
Glucose, hydrolysis of dimethyl acetals of..... 1408
d-Glucose, condensation with phenol, 1005; asymmetric reduction of β-methylcinnamic acid by.... 3297
Glucose, 5,6-dimethyl-..... 3507
Glucose dimethylacetal, carbohydrases–, reacn..... 1833
Glucose ethylmercaptal, α-ethylthioglucopyranoside from..... 1930
Glucoside, prepn. of rhamnose from naringin, 175; 2,4,6-trimethyl-β-Ph- and -benzyl-D-..... 1831
1-β-Glucosidofructose, synthesis of..... 2675
Glucuronic acid, electrolytic prepn. of..... 870
Glyceraldehyde, acetone-, and *l*-..... 761
Glycerides, synthetic, of unsatd. fatty acids, 3051; α,β-di-, of fatty acids..... 3328
Glycerol, *l*(−)acetone, 761; phthalic anhydride–, reacn..... 2258
Glyceryl phthalate, from phthalic acid..... 2268
Glycine, deamination of, with tyrosinase and *p*-cresol, 752; crystal structure of..... 1087
Glycofuranosides.....1450, 1671
Glycolic acid, spruce lignin–thio-, reacn..... 277
Glycolic anhydride, pyrolysis of di-..... 3490
Glycols, 1,2-diarylacetylene, 975, 2010; synthesis of higher polyoxyethylene, 1905; synthesis of 90- and 186-membered oxyethylene, 1910; relation between chain length and viscosity of polyoxyethylene, 1912; precipitability of pure hemicolloidal polyoxyethylene, 1916; $PbAc_4$ oxidation of 1,2-, 2607; infrared absorption studies of, 2679; 1,2-diacylethylene..... 3246
Glycosides, oxidation of, by Pb tetraacetate, 1667; photochem. production of reducing sugars from, by ultraviolet light, 2981; oxidation of, by $PbAc_4$. 3379
Glyoxals, aryl-, and steric hindrance, 480; acyloins from *t*-Bu-, 1937; structure of, and dimethyl-.. 3520
Glyoxal tetramethyl acetal, prepn. and estimation of, 428; (correction)..... 755
Gold, magnetic field and resistance of, 238; electrode spectral sensitivity..... 1805
Gonadotropic hormone, homogeneity of, prepns. isolated from pregnancy urine..... 2251
Gossypol, structure of, 1132 (correction, 3603), ...1134, 1138 (correction 3603), 2077, 2083
Gossypol ethers, and reduction products, 2077; structure of (correction)..... 3601
erythro-Granulose, mol. wt. of..... 1504
Graphite, adsorption of gases by..... 528
Grignard analysis, solvent effect in, for active H and carbonyl..... 865
Grignard reagents, reacns. of aryl, with Si halides, 363; coupling org. radicals by, 2551; reacn. of, with homophthalic anhydride, 2760; prepn. of, from Mg amalgams..... 3591

HALIDES. (See also *Alkyl halides*.) coupling reacn. of organomagnesium, with group 8 metal, 957; heats of formation and entropies of Zn and Cd, 1040; halogen–, exchange reacn. in aq. soln., 1215; addn. of H, to 2-pentene, 1559, (correction) 3605; mechanism of solvolytic reacns. of org., 1630; mol. freedom and melting in alkyl, 1695; carbonium ion and hydrolysis of alkyl, 1946; condensation of phenols and hydroquinones with allylic, 2615; *t*-Bu, 2798; activity coeffs. of alkali, 3030; structure of polyvinyl..... 3241
N-Haloamides, addn. of, to olefins..... 3425
Haloform reaction, rate of, and effect of halogens in. 241
Halogen-acetylureas..... 1377
Halogenation, of optically active *t*-carbinols..... 1295
Halogen compounds, hydrogenation of aromatic.... 3564
Halogen derivatives, reacn. of S with, of diphenyl sulfide..... 387
Halogens, effect of, in the haloform reacn., 241; reacns. of 3-hexene with, and, acids, 940; halide–, exchange reacns. in aq. soln., 1215; addn. of, and acetoxyl to ethylene, 1457; hydration of..... 3513
Heat capacity, of aq. sucrose solns., 459; of Te, 564; of dimethylamine, 1539; of Cl, 1970; of propylene, 2366; of TiO_2, 2405; of HCN, 2626; of cyanogen, 2940; of propylene..... 2980
Heat of combustion, of some mono- and disaccharides, 1726; of *cis* and *trans*-azobenzene..... 2925
Heat of dilution, of aq. systems of Zn and Cd nitrates, 260; of sucrose, 459; of $CdSO_4$ (correction). 3601
Heat of formation, of Zn and Cd halides, 1040; of hydrazine, 2639; of some non-volatile org. compds. 3543
Heat of fusion, of dimethylamine, 1539; of CBr_4, 1555; of Cl, 1970; of propylene, 2366; of cyanogen. 2940
Heat of solution, of aq. systems of Zn and Cd nitrates..... 260
Heat of transition, of CBr_4..... 1555
Heat of vaporization, of dimethylamine, 1539; of Cl, 1970; of propylene, 2366; of HCN, 2626; of cyanogen..... 2940
Helenium, constituents of, species..... 1836
Helium, viscosity of liquid, II, 654; leakage of, through Pyrex glass at room temp., 1597; Ne–, content of sea water..... 2806
Hemoglobin, equil. between ferro-, cyanide ion and cyanide ferro-..... 1263
Heptanes, Raman spectra of, 689; aromatization of, isomers on Cr_2O_3..... 1766
Heptene, aromatization of, isomers on Cr_2O_3..... 1766
Herty, Charles Holmes, obituary of..... 1619
Hexa-*p*-alkylphenylethanes, disproportionation of... 2771
Hexaarylethanes, effect of substitution on dissocn. of.....77, 2008, 2769

Hexa-*m*-biphenylethane, dissocn. of..... 77
Hexabromobenzene, PhMgBr–, reacn..... 1788
Hexadiene-2,4, condensation of, with dibenzoylethylene..... 2083
Hexaethylbenzil, an enediol from..... 2010
Hexane, 2,2-dimethylbutane from natural gas..... 3099
Hexanes, Raman spectra of..... 689
Hexaphenyldigermane, magnetic measurements on. 3168
Hexatriene, synthesis of, and polymers..... 2318
Hexene, aromatization of, isomers on Cr_2O_3..... 1766
Hexene, reacns. of 3-, 940, 1002; addn. of H halide to 3-, 1454; hydrogenation of cyclo-, 1056; alkenylation of phenol with 4-chloro-2- and 4-bromo-2-..... 3079
Hexylamine, addn. compds. of dicyclo-..... 3591
1-Hexyne, chlorination of..... 1460
History of chemistry, Schopenhauer und die Chemie (Mittasch, book review), 3596; Justus von Liebig (Blunck, book review)..... 3597
Hittorf transference numbers, of acetates in AcOH, 147; of thiosulfate with triiodide..... 1554
Homophthalic anhydride, Grignard reagent–, reacn. 2760
Hormones, Vitamine und, und ihre tech. Darstellung. Dritter Teil. Darstellung von Hormonpräparaten (ausser Sexualhormonpräparaten) (Vincke, book review), 756; La Chimie des Vitamines et des (Sivadjian, book review), 756; gonadotropic, from pregnancy urine, 2251; Methodik der Hormonforschung (Bomskov, book review), 2983; wound, of plants..... 3434
Hydantoin, dissocn. of..... 423
Hydantoin derivatives, synthesis of..... 2029
Hydantoins, 5-[α-(*s*-butoxy)]-Et-5-alkyl..... 3376
Hydration, of dihydropimaric acid, 967; of unsatd. compds..... 2271
Hydrazine, heat of formation of, and, hydrate..... 2639
Hydrazoic acid, infrared absorption of..... 2809
Hydrides, of B.....673, 1078
Hydrindene, structure of, derivs..... 2916
Hydrindenes, maleic anhydride–vinyl, reacn..... 1405
α-Hydrindone..... 2553
Hydrobromic acid, addition of, to cyclohexene and 3-hexene, 1454; reacn. of the 3-bromo-2-butanols with, 1576; addn. of, to 2-butyne and 2-bromo-2-butene, 1711, (correction) 3605; O and reacn. of cyclopropane with, 2139; addn. of, to trimethylethylene, styrene, crotonic acid and Et crotonate, 2693; reacn. of 3-bromo-2-butanols with..... 2845
Hydrocarbons, action of $AlCl_3$ on aromatic, 101, (correction) 3603; carcinogenic, 157; attempts to prepare methylene radical from, 213; hexahydroaromatic, –paraffins reacns., 640; condensation of α-methoxystyrene with, 666; refraction data on liquid C_8-, 751; kinetics of, decompn., 977; Polycyclic Aromatic (Weizmann, Bergmann, book review), 979; condensations of 3-hexene with aromatic, 1002; syntheses by Friedel–Crafts reacn., 1163; thermal decompn. of petroleum, into free radicals, 1400; $AlCl_3$ condensation of alcs., ethers and esters with aromatic, 1413; addn. of aryl amines to alkynes, 1462; internal rotation and resonance in, 1876; peroxide-catalyzed chlorination of, 2142; reduction of diazonium salts to, with alkaline formaldehyde, 2418; acetylation of aromatic, with ketene, 3438; catalytic cracking of aliphatic..... 3571
Hydrochloric acid, thermodynamics of, 44, 48, 49; cleavage rates of *p*-methoxyphenyl-2-furyllead compds., 739; addn. of, to cyclohexene and 3-hexene, 1454; properties of, in EtOH– and *i*-PrOH–H_2O mixts., 1491, (correction) 3605; system: $ZnAc_2$–AcOH–, 2164; partial pressure of, in ethylene glycol, 2504; transference nos. of, in dioxane–H_2O mixts., 3113; effect of, concn. on Ag reduction of molybdate..... 3125
Hydrofluoric acid, as a condensing agent, 949; nuclear alkylation in presence of..... 1010
Hydrogen, sorption of, on supported Ni, 270; the thermal Cl–, reacn., 391, 396; a volatile compd. of Al, B and, 536; solvent effect in active, Grignard analysis, 865; reacns. of, with pyrrole derivs., 1104; D–H ratio, 1342; NO_2 sensitized O–, reacn., 1350; thermodynamics of KCl in H_2O–D_2O mixts., 1487; chem. sepn. of, isotopes, 1594; bonding by negatively substituted CH groups (VI) acetylenic compds., 1599; H–D ratio and at. wt. of, 2025; fractionation of, isotopes in EtOH distillation, 2453; and D exchange between nitramide and water, 2552; exchange reacns. of aromatic *t*-amines, 2597; degassing of, charged Pd, 2683; bonding by S–H, 3161; bonding of, in N compds., 3252; photochem. decompn. of solid, compds., 3393; catalytic interaction of acetylene and, on Pt, 3396; combustion data on non-volatile org. compds., 3543; bonds involving C–, link, 3550; adsorption of, by Cu in CaO..... 3580
Hydrogenation, catalytic, of 5- and 6-benzyluracils, 74; of brassicasterol, 142; of ethane on Co catalysts, 503; catalytic, of org. acids in alkaline soln., 843; simultaneous de-, –, of cyclohexene in presence of Ni, 1056; of hydroxyamides, 1675; of some acetylenes, 1868; homogeneous catalytic, 2230; of substituted acetylenes with Raney Ni, 2897; of acetophenone to cyclohexylmethylcarbinol, 3292; of 1,3-diketones to ketols, 3303; of aromatic halogen compds., 3564; of aldehydes with NH_3..... 3566
Hydrogen azide, aminomonopersulfuric acid formed from H_2SO_4 and..... 1083
Hydrogen bromide. See *Hydrobromic acid.*
Hydrogen chloride. See *Hydrochloric acid.*
Hydrogen cyanide, thermodynamics of..... 2626
Hydrogen fluoride, mol. structure of, 19; inter- and intramol. acylations with, 1272; as a condensing agent.....1521, 1795, 1821
Hydrogen halides, addn. of, to *cis*- and *trans*-2-pentene, 1559, (correction)..... 3605
Hydrogen ion concentration, effect of *p*H on particle size in gelatin solns., 1747; changes in *p*H of irradiated egg albumin solns., 1953; ionic strength and *p*H on electrophoretic mobility, 2092; cells without transference for *p*H detn..... 2983
Hydrogen peroxide, action of Al oxyiodide hydrosols on..... 401
Hydrogen perselenide, existence of..... 440
Hydrolysis. (See also *Hydration; Saponification.*) neutral salt effect on $CuSO_4$, 118; of nitriles with acids, 560; of dimethyl acetals of glucose and galactose, 1408; equil. of formic acid esters, 1443; of α-ethylthioglucofuranoside, 1450; carbonium ions and, of alkyl halides, 1946; of ethylal, 2510; enzymic, of pectins, 2544; acid catalyzed ester, 2584; of amines, 2704; of stannous ion in stannous perchlorate solns., 3342; degradation of cyamelluric and hydromelonic acids, 3420; of bromine and halogens..... 3513
Hydromelonic acid, ionization const. of..... 3420
Hydroquinine, thermal reduction of dichromic acid by..... 3455
Hydroquinone, derivs. of hydroxy-, ethers, 144; autoxidation of ψ-cumo-, 360; inhibition of sulfite in, autoxidation, 442; reduction of Ag^+ by, 648; 3,6-di-(2,4-dimethylphenyl)-, 2182; condensation of, with allylic alcs., halides and dienes..... 2615
Hydroxyalkyl apocupreine ether..... 1783
Hydroxyamides, hydrogenation of..... 1675
p-Hydroxybenzoic acid, ethers of..... 3050
o-Hydroxybenzophenone oximes, stereoisomeric.... 214
β-Hydroxybutyric acid, crotonic acid–, reacn..... 2271
6-Hydroxychromans, oxidation products of..... 2424
4-Hydroxycoumaran-3-one, synthesis of..... 2328
Hydroxydibenzofurans, diazo coupling of 2-, 3- and 4-..... 3146
2-Hydroxy-9,10-dihydrophenanthrene, acyl compds. from..... 1

2-Hydroxyfluorenone, ring cleavage of..... 816
Hydroxyhydroquinone, derivs. of, ethers..... 144
Hydroxylamine, reduction of Ag ions by, 2379; sulfamic acid from SO_2–, reacn..... 3389
α-Hydroxylaminoisobutyronitrile, in synthesizing porphyrexide and porphyrindine..... 754
Hydroxylation, of unsatd. substances..... 1844
Hydroxyl groups, position of nuclear, in chlorogenin. 946
Hydroxylic compounds, infrared bands and assocn. of some..... 1396
Hydroxyl ion, reacn. kinetics of ethylene chlorohydrin and..... 1205
Hydroxyls, unesterified primary, and secondary, in acetone sol. cellulose acetate.....3458, 3463
α-Hydroxypropiovanillone, synthesis and properties of..... 2204
o-Hydroxyquinoline, Die anal. Verwendung von, und seiner Deriv. (Berg, book review)..... 758
Hydurilic acids, substituted..... 2736
Hypericin, absorption spectrum of..... 3594
Hypobromous acid, dissocn. const. of, 1291; (correction)..... 3603
Hyponitrous acid, thermodynamics of..... 1550

ILKOVIC equation, of polarographic diffusion currents..... 825
Indicators, acid–base, in MeOH..... 330
Indoanilines, oxidation–reduction potentials of..... 376
Inorganic chemistry, Gmelins Handbuch der Rhodium (Pietsch, book review), 537; Gmelins Handbuch der Osmium (Pietsch, book review), 980; Lehrbuch der (Riesenfeld, book review)..... 2566
Inorganic compounds, stereochemistry of complex inorg., 2402; stereochemistry of complex..... 3199
Insulin, structure of..... 2982
Inversion. See *Isomerization; Sucrose; Walden inversion.*
Invertase, acid effect on, activity..... 3330
Iodic acid, detn. of C, O equiv. and empirical formula by, oxidation, 3001; dissocn. const. of..... 3268
Iodide, neutral salts on the ferricyanide–, reacn.... 116
Iodide electrodes, Ag and mercurous..... 2592
Iodide ion, formation of butenes from 2,3-dibromobutanes by..... 1645
Iodination, substitution effects in catalyzed acetophenone, 2779; kinetics of, of acetophenone in H_2SO_4 and $HClO_4$..... 2791
Iodine, reacn. of Ta, Cb and V with, 838; Pb–, voltaic cell, 2522; contact potential of, film on W, 3027; and Incidence of Goiter (McClendon, book review)..... 3598
Iodine compounds, adsorption of EtI on a plane surface of Fe, 1117; reacn. of thiosulfate with triiodide, 1554; triiodophenyl ethers to identify alkyl halides, 2666; iodo derivs. of Ph ether, 2702; catalysis in dichloroethylene isomerization, 3259; kinetic studies on..... 3284
1-Iodoanthraquinone, prepn. and m. p. of..... 1600
Iodonium nitrate, nitration of diphenyl-..... 3061
Iodonium salts, metallic decompn. of some..... 2944
m-Iodophenyl acetate, prepn. of..... 143
Iodotrichloromethane..... 435
Ionization. (See also *Conductivity.*) concn., consts. of indicators and acids in MeOH, 330; substituents and, const. of org. acids, 555; const. of aci-nitroethane, 753; ionic strength and *p*H on electrophoretic mobility, 2092; influence of ionic strength on quenching of fluorescence in aq. solns., 2634; second, const. of oxalic acid, 3111; consts. of cyameluric and hydromelonic acids..... 3420
Ions, entropies of ionic reacns., 905, (correction) 3603; ionic character in diatomic mols., 1051; Electrons and Ionizing Radiations (Crowther, book review), 2984; activity coeffs. of strong electrolytes, 3030; crit. increment of ionic reacns.....3534, 3538
Iron, adsorption of EtI on a plane surface of, 1117; rate of dissoln. of, in acids..... 2290
Iron chloride, condensation of olefins with benzene in presence of $FeCl_3$, 663; $FeCl_3$ as a condensing agent..... 2553
Iron compounds, equil. between ferrohemoglobin, cyanide ion and cyanide ferrohemoglobin..... 1263
Isoamyl bromide, dielec. behavior of..... 2063
Isocrotyl chloride, mol. structure of..... 2643
Isocyanates, conjugation of amino acids with, of anthracenes..... 3502
Isoguanine, from the croton bean..... 350
Isomerism, identification of *cis-trans* isomers by rate studies, 1640; *cis-trans*, of α- and β-*p*-azophenol. 2775
Isomerization. (See also *Rearrangements.*) kinetics of, of aci to nitro forms of nitroethane, 692; of alkylcyclopentanes, 1076; *cis-trans*, with BF_3, 1595; of cyclohexane and methylcyclopentane, 1717; of alkenes on alumina and thoria, 1762; acid catalyzed, of acetophenone derivs., 2785; equil. and kinetics of dichloroethylene..... 3259
Isopropanol, properties of HCl in H_2O–, mixts..... 1491
Isopropenyl barbituric acids..... 96
Isopropyl alcohol, propylene polymers from, and BF_3, 973; catalytic interaction of acetone and, with D on Pt..... 1336
20-Isopropylcholanthrene..... 157
Isopropylmagnesium bromide, electrolysis of, in Et ether..... 898
Isoquinoline acids, synthesis of..... 183
Isothioureas, chlorination of..... 176
Isotonic solutions (corrected)..... 3603

JACOBSEN reaction, on ethyltrimethylbenzenes... 989

KETENE, reacn. between diphenyl-, and dienes... 7
Ketene, acetylation of carbohydrates by, 426; acetylation of lactic esters by, 2727; and its dimer, 3355; in Friedel–Crafts reacn..... 3438
Keto acid, structure of C_{22}, 1285; condensation of α-, and amides..... 483
2-Keto-apocamphane-1-acetic acid, synthesis of.... 3445
Keto-enol, tautomerism of pyruvate ion..... 590
Keto ethers, derived from *s*-Bu α-chloroethyl ether. 1226
Ketols, hydrogenation of 1,3-diketones to..... 3303
Ketones, condensations of, with phenols, 345; condensation of diethyl, with resorcinol, 348; condensation of paraformaldehyde with mesityl, 414; synthesis of aliphatic *t*-Bu, 683; prepn. of cyclic, by ring enlargement, 1057; amino, from tetrahydrobenzo(b)naphtho(2,3-d)furan, 1148; reduction of α-di-, 1281; use of aryloxy, in synthesis of quinolines by Pfitzinger reacn., 1355; steric hindrance in phenol–, condensations, 1785; dienols obtained from unsatd. 1,4-di-, 1854; Wolff–Kishner reduction of steroid, 1992; bromomagnesium enolates of mesityl, 2362; decompn. of diethyl, at short wave lengths, 2492; sugar series, 2669, 2675; alkoxy, used in Pfitzinger synthesis of quinolines, 2730; 1,4-diphenyl-2-mesityl 1,4-di-, 3007; 1,4-dimesityl-2-Ph 1,4-di-, 3010; polymer of Me vinyl, 3234; hydrogenation of 1,3-di-, to ketols, 3303; relative oxidation potentials of, 3364; rearrangement of β-methoxyamino-, 3494; addn. of Me, to benzalaniline..... 3556
Ketonic steroids, from cows' pregnancy urine and bulls' urine..... 944
β-Ketonitriles, methylation of..... 1940
Ketosulfone, new synthesis of a cyclic..... 389
Keturonic acids, isolation of, as crystalline alkaloidal salts..... 1822
Kinetics, der Phasenbildung (Volmer, book review). 2566

LACTARIUS *piperatus*, tyrosinase from..... 2946
Lactic acid, acetylation of, esters by ketene..... 2727
γ-Lactones, rotations of the aldonic..... 1525
Lactonization, of dihydro-*l*-abietic and dihydro-*l*-pimaric acids..... 3197
Lanthanum chloride, activity coeffs. of..... 200
Lanthanum compounds, residual paramagnetism in. 85
Latent heat, of myristic and pentadecylic acids.... 1702

Lauric acid, system: Na palmitate–NaCl–H_2O–, 30; thermodynamic behavior of liquid crystalline, solns. 37
Lead, I–, voltaic cell, 2522; thermodynamics of Sb–, system, 2594; –U ratio in uraninite, 2742; amperometric titration of, with dichromate 3402
Lead compounds, reactivities of organolead radicals and derivs., 731; HCl cleavage rates of *p*-methoxyphenyl-2-furyllead compds., 739; tetraphenyl- and diphenyllead dihalides, 1609; prepn. and reacns. of some triphenyllead derivs., 1685; ammino compds. of triphenyllead chloride, 1687; Et, 2748, 2755, 2758; interchange of triethyllead chloride and radioactive tetraethyllead 3300
Lead orthophosphate, crystalline 2249
Lead oxides, hydrous, normal and active Pb monoxides, 58; soly. of, in alkaline solns. 367
Lead sulfate, aging of, 191; rate of soln. of, as a test for aging 195
Lead tetraacetate, prepn. of, 972; oxidation of certain glycosides by, 1667, 3379; oxidation of 1,2-glycols or 1,2,3-polyalcs. 2607
Leuckart synthesis, *s*-amines by 520
Liebig, Justus von (Blunck, book review) 3597
Light. (See also *Photochemistry; Spectra* etc.) irradiation of egg albumin solns., 1953; degradation of oriented cellulose structures by polarized ultraviolet 2995
Lignin, studies on, and related compds., 509, 516, 725, (correction 3603), 865, 868, 1477, 2190, 2194, 2196, 2198, (correction 3605), 2204, 2698; thioglycolic acid–spruce, reacn., 277; reconversion of an "extracted," into its primary bldg. units, 530; isolation and methylation of native, 2120; syringyl radical in plant products 2556
Linoleic acid, linoleyl alc. prepared by Na reduction of, 482; elaidinization of, 1062; sepn. of oleic acid from 1142
Linolein, mono- and tri- 3051
Linoleyl alcohol, prepared by Na reduction of linoleic acid 482
Lipids, of *Monilia albicans* 281
Liquids, theory of, structure, 1436; relation between fluidity, temp. and chem. constitution of pure, 1625; vapor–, equil. in CCl_4–AcOEt, 2691; vapor–, equil. 3206
Lithium, action of, on an optically active aliphatic chloride 1203
Lithium compounds, metalation in organo-, prepn., 106; oxidation of PhLi, 1603; some Na–SiO_2–, systems 2863
Lithium metasilicate, phase equil. relations in system Na_2SiO_3– 2157
Lithium sulfate, system: $Al_2(SO_4)_3$–H_2O– 2689
Lossen rearrangement, in decompn. of K dihydroxamates 618
Luminescence, sono-, and sonic chemi- 2392
Lupine studies 1523, 3327

MAGNESIUM, action of, on cinnamyl chloride 12
Magnesium bromide, system: *n*-BuMgBr–Et_2O– 3436
Magnesium compounds, reacn. of C suboxide with MeMgI, 457; electrolysis of PrMgBr in Et ether, 898; coupling of organomagnesium halides with group 8 metal halides, 957; styrene oxide–MeMgI reacn., 996; relative reactivities of MeMgCl and $diMe_2Mg$, 1152; hexabromobenzene–PhMgBr reacn., 1788; action of *i*-BuMgBr on 3,4,5-trimethoxybenzonitrile, 2175; condensation of bromomagnesium derivs. of acetomesitylene, 2362; 2,3-dimethyl-1,4-naphthoquinone–PhMgBr reacn., 3310; Grignard reagents prepared from Mg amalgams 3591
Magnetic flux, distribution around a cylinder 1384
Magnetic measurements, on hexaphenyldigermane 3168
Magnetism, residual para-, in La compds., 85; effect of a magnetic field on elec. resistance of Au and Ag, 238; of myoglobin and ferrimyoglobin 2150
Malaria, benzothiazoles, as antimalarials 2013
Maleic anhydride, reacn. between, and vinyl hydrindenes, 1405; thiophene deriv.-, reacn., 2733, (correction) 3605
Malonic acid, *t*-Bu, and derivs., 637; prepn. of *t*-Bu, from neopentyl chloride 965
Maltose, fermentation of 291
Manganese, sp. heat of 203
Manganous selenide, sp. heat of 203
Manganous telluride, sp. heat of 203
Mannofuranoside, crystalline β-methyl 534
D-Mannoheptulose, synthesis of, and derivs. 1654
D-Manno-L-manno-octose, configuration of 1268
D-α,α-Mannooctose, configuration of 1268
Mannopyranoside, periodic acid oxidation of β-Me-D-, 959; action of triphenylchloromethane on α-Me-D- 1528
Mannosedimethylacetal, crystalline 534
aldehydo-d-Mannose pentaacetate ethyl hemiacetal. 574
Maple wood, ethanolysis of, 516, 523, 868, 2198, (correction) 3605
Melanins, studies on 2178
Melezitose, structure of 2675
Mercaptalation, mol. size of starch by, method, 2172, (correction) 3605
Mercaptals, acetone derivs. of, of monosaccharides. 2444
Mercaptans, H bonding in aryl 3161
Mercuric chloride, soly. of, in aq. chloride solns., 920; soly. of, in chloride solns. 2744
Mercuric halides, soly. of, in K halide solns. 2744
Mercuric ion, coördination complexes of, with cyclohexene 3102
Mercuric oxide, equil. of, in dil. HNO_3 1730
Mercurous iodide, electrode 2592
Mercury, sensitized decompn. of CO_2 in light, 716; dropping, electrode, 825, 1045; as catalyst for Bettendorff's As test, 968; potentials of simple metals at the dropping, electrode, 2099, (correction) 3605
Mercury compounds, reacn. of rates of benzoyl halides with di-*p*-tolylmercury, 743; treatment of neopentyl halides with di-*p*-tolylmercury, 1591; fluorinated mercurials 3005
Mesityl diketones 3007, 3010
Mesitylene, prepn. of Et- 284
Mesitylglyoxal, benzoins from 412
Mesityl ketones, condensation of paraformaldehyde with, 414; bromomagnesium enolates of 2362
Metalation, in organolithium compd. prepn., 106; of some org. compds. 109
Metal oxides, reduction of, in liquid NH_3 2502
Metals, relation between compressibility and soly. of, in acids, 746; Electrode Potential Behavior of Corroding, in Aq. Solns. (Gatty, Spooner, book review), 757; potentials of simple, ions at the dropping Hg electrode, 2099; analysis of alkyl mixts. 2755
Metal salts, addn. products of, with S and O compds. 28
Methanes, bromotrichloro-, and iodotrichloro-, 435; infrared absorption of the phenyl-, 1053; dialkyl *bis*-(carbethoxymethanesulfonyl)-, 2001; mol. structure of bromo, 2643; soly. of completely halogenated 3550
Methanethiol, amino-, derivs. 3134
Methanol, dissocn. of triphenylcarbinols in, 16; vol. changes in the toluene–, system, 67; salting-out in urea–, system, 228; esterification kinetics of, 254; acid–base indicators in, 330; non-reacn. of ethylene oxide and, 527; gel formation by org. salts in, soln., 670; kinetics of esterification of substituted aliphatic acids in 1176
Methionine, stability of keto acid from 2252
Methoxyamine, addn. of, to α,β-unsatd. ketones 3494
2,2′,6-Methoxybiphenyl, racemization rate of 2828
p-Methoxyphenyl-2-furyllead, HCl cleavage of, compds. 739
α-(*o*-Methoxyphenyl)-propionic acid, synthesis of 3039

α-2-Methoxyphenyl-β,β,β-triphenylethane, synthesis of ... 3192
α-Methoxystyrene, condensation of, with hydrocarbons ... 666
Methyl alcohol. See *Methanol.*
Methyl aldohexomethyl-*o*-pyranosides, periodic acid cleavage of ... 1660
Methylamine, *P–V–T* relations for gaseous mono- .. 2457
Methylated carbohydrates, prepn. of ... 2442
Methylation, nuclear, of phenols, 765; of aromatic compds. by Me_2O–BF_3, 1463; of β-ketonitriles, 1940; of native lignin, 2120; orientation of nuclear, in phenols and naphthols ... 2354
8-Methyl-1,2-benzanthracene ... 168
2,2′,6-Methylbiphenyl, racemization rate of .. 2825, 2828
Methyl chloroform, mol. structure of ... 2643
β-Methylcinnamic acid, prepn. and reduction of, 3295; *d*-glucose reduction of ... 3297
Methyl cyanide, structure of ... 927
Methylcyclobutene, reacn. of benzene with ... 3374
trans-2-Methylcyclohexanol, dehydration of ... 1847
Methyl cyclopentane, isomerization of, 1717; thermodynamics of cyclohexane–, isomerization ... 2561
9-Methyl-1,2,5,6-dibenzanthracene ... 862
Methylene, oxidation of, groups by ozone ... 429
Methyleneaminoacetonitrile, prepn. of ... 212
1′,9-Methylene-1,2-benzanthracene, and related compds ... 1740
Methylene blue, sorption of, by curd fibers of Na palmitate ... 2540
Methylenecyclobutane, reacn. of benzene with ... 3374
3-(2′-Methylenecyclohexylidene-1′)-propene-1, synthesis of ... 2534
Methylene radical, attempts to prepare ... 213
Methyl-*d*-erythroside, structure of a ... 2111
Methyl ether, methylation of aromatic compds. by BF_3– ... 1463
Methylfuranosides, prepn. of, from *d*-fructosediethylmercaptal ... 1671
Methyl α-haloacrylates, polymers of ... 3156
2-Methyl-3-β-hydroxy-ethyl-N-[(2-Me-6-amino-pyrimidyl-(5))-methyl]-pyridinium bromide hydrobromide, synthesis of ... 2562
Methylmagnesium chloride, relative reactivities of, and di-Me_2Mg ... 1152
Methylmagnesium iodide, reacn. of C suboxide with, 457; styrene oxide–, reacn ... 996
β-Methylmannofuranoside, crystalline ... 534
Methyl-D-mannopyranoside, periodic acid oxidation of β-, 959; action of triphenylchloromethane on α- ... 1528
9-Methylphenanthrene, synthesis of ... 2184
Methylphenylacetic acid, configurational relationship between (+)-alanine and (+)-, 1324, (correction) . 3603
2-Methyl-3-phytyl-1,4-naphthoquinone, synthesis of, 2559; identity of, with vitamin K_1 ... 2561
4-Methyl-5-*n*-propyl-2,6-dimethoxypyrimidine, mol. rearrangement of ... 3377
Methyl pyranosides, α- and β-, of L-fucose ... 1658
5-Methylthiazolinephenols ... 1145
β-(4-Methylthiazolyl-5)-alanine ... 891
Methylvinylcarbinol, interconversion of crotyl alc. and ... 2564
Methyl vinyl ketone, reacns. of polymer of ... 3234
Methyne, oxidation of, groups by ozone ... 429
Micelle formation, in Na sulfonates ... 539, 544, 549
Microchemistry, Micromethods of Quant. Org. Elementary Analysis (Niederl, Niederl, book review) . 2985
Microscopy, Handbook of Chem. (Chamot, Mason, book review) ... 221
Minerals, radioactive detn. of protactinium in siliceous terrestrial and meteoritic material ... 3451
Molecular weight, of β-amylose, 1495; of α-amylodextrin, 1504; diffusion velocity and, 1745, 1747; measurements of resinous and crystalline materials, 1812; effects of, on reacn. rates ... 3334
Molecules, structure of HF, 19; mol. structure of cyanogen chloride and bromide, 299; internal rotation in ethylene chlorobromide and ethylene bromide, 303; electron diffraction of some acetylenes, 927; ionic character in diatomic, 1051; size of methylated cellulose, 1072; crystal structure of glycine, 1087; structure of tetranitromethane, 1127; structure of $P_4O_6S_4$, 1130; mol. interaction in monolayers, 1188; intramol. rearrangements, 1324, (correction) 3603; elec. properties of multimol. films, 1425; intramol. reacn. between neighboring substituents of vinyl polymers, 1518; common basis of intramol. rearrangements, 1586; structure of 1,2,4,5-tetrabromocyclohexane, 1601; relations between rotatory power and structure in the sugar group, 1658; mol. freedom and melting in alkyl halides, 1695; shape of protein, 1841; internal rotation and resonance in hydrocarbons, 1876; vitrification and crystallization of org., 2063; mol. size of starch, 2172, (correction) 3605; racemic org., in complexes of Co and Cr, 2402; structure of formaldehyde, 2508; structures of some alkyl halides, 2643; random inter-, exchange of org. radicals, 2748; mol. rotation and polymorphism in *t*-Bu halides, 2798; structure of acetaldehyde, 2922; dipole moments and structures of ozone, silicobromoform and dichlorogermane, 3063; dipole moments and structures of some nitro compds. and amines, 3067; internal rotation in 1,1,2-trichloroethane, 3127; elec. characteristics of mol. films, 3162; structure of 2,3-dibromobutanes, 3173; structure of aliphatic compds. and their b. ps., 3235, 3236; structure of sulfuryl fluoride and thiophosphoryl fluoride, 3264; rearrangements in sterols, 3483; structure of glyoxal and dimethylglyoxal, 3520; chromatographic adsorption and dipoles ... 1611
Molybdate, HCl and Ag reduction of ... 3125
Molybdenum compounds, m. p. of Ba molybdate, 969; K molybdocyanide dihydrate ... 2853
12-Molybdophosphoric acid, cobalt ammine salts of . 2022
Molybdotellurates, prepn. of 3 alkali ... 1810
Monilia albicans, lipids of ... 281
Monoacylethylenediamines, prepn. and cyclization of ... 822, 3195
Monoalkyldioxanes ... 3016
Monochloroacetic acid, quantum yield of, hydrolysis ... 2299
Monocrotalic acid ... 2822
Monocrotaline, structure of, 2815 (correction 3605), ... 2819, 2822
Monocrotic acid, from hydrolysis of monocrotaline .. 2819
Monoethanolamine, condensation products of ... 2658
Monolayers, pressure–area relations of fatty acid and alc., 1180; mol. interaction in, 1188; pressure–area and pressure–temp. relations of expanded, of myristic and pentadecylic acids ... 2040
Monolinolein ... 3051
Monomethylamine, *P–V–T* relations for ... 2457
Morphides, amino- ... 2186
Morphol, some 1,4-dimethylphenanthrenes related to ... 3055
Morpholine, morpholino alcs ... 3440
Morpholine condensations ... 2552
Munroe, C. E., biography of ... 1301
Murexides, structure of ... 2089
Mushroom, tyrosinase from wild ... 2946
Mutarotation, of tetramethyl-α-*d*-glucopyranose and -mannopyranose, 2103; of *d*-arabinose oxime 2111
Myoglobin, magnetic properties of, and ferri- ... 2150
Myosin, denaturation of ... 1613
Myristic acid, latent heat and spreading entropy of, 1702; pressure–area and pressure–temp. relations of expanded monolayers of ... 2040

NAPHTHALENE, polynitro aromatic compds. as addn. compds. with ... 748
Naphthalenes, diphenyl-, 608; structure of, derivs .. 2916
β-Naphthohydroquinone, synthesis from, of a tautomer of 4-benzyl-1,2-naphthoquinone ... 596

Naphthoic acid, alkylaminoalkyl amino, esters, 1200, (correction) ... 3603
Naphthols, orientation of nuclear methylation in phenols and, 2354; 2-*n*-Bu-*α*- ... 2487
Naphthoquinone, 4-alkyl derivs. of 1,2-, 417; 4-benzyl-1,2-, 596; antihemorrhagic activity of, 1611, 1923, 1924, 1925, 1926, 1928, 1932, 2006, 2557, 2558, 2559, 2561, 2563, 3216; PhMgBr–2,3-dimethyl-1,4-, reacn. ... 3310
α-Naphthylamine hydriodide, conductance of, in aniline soln. ... 1592
Naphthylaminoalkanes ... 1780
Naringin, rhamnose from ... 175
Natural products, Chemistry of C Compds. Vol. II. Alicyclic Compds. and (Taylor, Millidge, book review), 1298; Fortschritte der (Zechmeister, book review) ... 2569
Neodymium bromate enneahydrate, crystal structure of ... 1544
Neon, He–, content of sea water ... 2806
Neopentyl bromide, prepn. of ... 1585
Neopentyl chloride, prepn. of *t*-butylmalonic acid from, 965; reacn. of, with Na ... 1616
Neopentyl halides, treatment of, with di-*p*-tolylmercury ... 1591
Neopentyl iodide, prepn. of, 1585; reacns. of ... 1586
Neotigogenin, a new steroid sapogenin ... 2420
Nickel, sorption of H on supported, 270; promoter effect of $PtCl_4$ on Raney, 384; as catalyst in hydrogenation of cyclohexene, 1056; alumina-, catalyst, 2524; hydrogenation of substituted acetylenes with Raney, 2897; Raney, in reduction of *β*-methylcinnamic acid, 3297; as catalyst for hydrogenation of aromatic halogen compds. ... 3564
Nickel oxalate, hydrated double salt of, and K oxalate ... 965
Nirvanol, colored derivs. of ... 2029
Nitramide, H and D exchange between, and water. 2552
Nitrates, oscillation frequencies of ... 1382
Nitration, of *p*-cymene, 2469; of diphenyliodonium nitrate ... 3061
Nitric acid, equil. of HgO in dil., solns. ... 1730
Nitriles, hydrolysis of, with acids, 560; methylation of *β*-keto- ... 1940
Nitrites, oscillation frequencies of ... 2987
1-Nitroacridone-4-carboxylic acid, identity with 1-aminoacridine ... 2247
Nitrobenzene, energy-vol. coeffs. of, 2515; thermodynamics of aniline–, mixts. ... 2877
Nitrobenzenes, condensation of dichloro- ... 2658
o-Nitrobenzenesulfenyl chloride, to identify amines.. 2340
Nitrobenzoates, decompn. of tri-, in EtOH, 186; alcoholysis rates of aralkyl *p*- ... 2383
2,2′,6-Nitrobiphenyl, racemization rate of ... 2825
3-Nitro-6-bromonitrostyrene, aromatic amines and.. 2969
6-Nitrocarvacrylamine, synthesis of ... 2469
Nitro compounds, dipole moments and structures of certain ... 3067
Nitroethane, isomerization of, 692; ionization const. of aci- ... 753
Nitrogen, products formed by chlorination of isothioureas, 176; Ph alkyl, substitution in barbituric acids, 1015; stereochemistry of tervalent, 1927; compds. in petroleum distillates ... 2609, 2612, 2613
Nitrogen compounds, polynitro aromatic compds. as addn. compds. with naphthalene, 748; in petroleum distillates, 1017; bonding of H in ... 3252
Nitrogen oxides, inhibition by NO of decompn. of *n*-butane, 1024; NO_2 sensitized H–O reacn., 1350; equil. reacn. between NO and BrCl ... 1432
Nitroparaffins, reduction of, to amines ... 3194
Nitrophenols, soly. of Na and K salts of ... 3302
p-Nitrosodiphenylamine, colorimetric detn. of Pd with ... 2058
β-Nitrostyrene, in the diene synthesis ... 521
Nitrosyl bromide, equil. reacn. between, and BrCl.. 1432
Nitrosyl chloride, equil. reacn. between, and BrCl.. 1432
6-Nitroveratraldehyde, 1,4-dimethyl-6,7-dihydroxyphenanthrene from *p*-xylylacetic acid and ... 2461
Non-electrolytes, effect of, on time of setting of gelatin gels ... 1749

9,10-OCTADECANE-DIOL, synthesis of ... 630
cis-9-Octadecene, synthesis of ... 630
n-Octadecylbenzene, Friedel–Crafts reacn. of, and diacylations ... 478
9-Octadecyne, synthesis of ... 630
Octalones, *trans*-3,4-dialkyl- ... 2003
Octalupine, a new alkaloid ... 1523
n-Octane, aromatization of ... 2524
Octenes, dehydrogenation of cyclo-, 1260; cracking of ... 3511
Octanol, aq. soly. of ... 525
Octatetrene, structure of cyclo- ... 1943
Oil, compn. of watermelon seed, 889; alfalfa seed, 2910; chaulmoogra ... 2351, 3442
Olefins, reacns. of thiol compds. with aliphatic, 71; identification of, as dithiocyanates, 750; propene–iso-, reacn. with H_2SO_4, 1825; reacn. of, with solid cuprous halides, 1960; addn. of N-haloamides to.. 3425
Oleic acid, prepn. of, 1142; in *Sapindus drummondii* seeds, 2697; viscosity of aq. Na oleate ... 2990
Onium compounds ... 638, 1195
Optical rotation, of the aldonic *γ*-lactones, 1525; loss of optical activity in reacn. of *erythro*- and *threo*-3-bromo-2-butanols with HBr, 2845; relations between, and structure of sugar groups, 2972; of Zn lactate, 3234; of *α*-bromopropionitrile, 3583; configuration of propyl-*t*-butylcarbinol (correction) ... 3601
Organic chemistry, Analyse und Konstitutionsermittlung org. Verbindungen (Meyer, book review), 221; Lehrbuch der (Langenbeck, book review), 537; (Karrer, book review), 756; Experimentierkunst (Weygand, book review), 757; Problems in (Huntress, book review), 979; and Bio-chemistry (Plimmer, book review), 982; Practical (Mann, Saunders, book review), 1297; Systematic Qual. Org. Analysis (Middleton, book review), 1934; Lehrbuch der (Karrer, book review), 2565; Chemistry of Org. Compds. (Conant, Tishler, book review), 2567; Textbook of (Wertheim, book review), 2568; Fortschritte der, Naturstoffe (Zechmeister, book review), 2569; Qual. (Campbell, book review), 3240; Org. Syntheses (Johnson, book review), 3239; Anleitung zur org. qual. Analyse (Staudinger, Kern, book review), 3597; Essentials of Physiol. Chemistry (Anderson, book review) ... 3599
Organic compounds, sulfides, 83; metalation in, 106, 109; dissocn. consts. of org. acids, 555; methylation of aromatic by Me_2O–BF_3, 1463; mechanism of solvolytic reacns. of org. halides, 1630; acylation of aromatics, 1795; ring structure in aliphatic, 1963; mol. structure of, and their b. ps., 3235; calcn. of b. p. nos. of, 3236; thermal data on, 3543; action of F on ... 3552
Organic liquids, viscosity of SO_2–, solns. ... 112
Organic parachors, of *t*-alcs. ... 900
Organic salts, gel formation by, in MeOH soln. ... 670
Organic synthesis, Unit Processes in (Groggins, book review) ... 217
Organometallic compounds, relative reactivities of, ... 731, 739, 741, 743, 957, 1170, 1513
Orthoquinone, monoxime inner complexes ... 2624
Osage orange pigments ... 2832
Oscillation frequency, of nitrates, 1382; of nitrites.. 2987
Osmium, Gmelins Handbuch der anorg. Chemie (Pietsch, book review) ... 980
Osmosis, Lectures on (Schreinemakers, book review) ... 981
Oxalate ion, interchange between chromioxalate ion and, using radio-C ... 570
Oxalic acid, second ionization const. of ... 3111

Oxidation, of perseulose to L-galactonic acid, 340; of sedoheptulose to D-altronic acid, 343; aut-, of ψ-cumohydroquinone, 360; –reduction potentials of substituted quinoneanils and indoanilines, 376; of methyne and methylene groups by ozone, 429; processes, 442; photochem., of crotonaldehyde, 582; catalytic, in cycloparaffin series, 633; deamination of glycine with tyrosinase and *p*-cresol, 752; periodic acid, of β-Me-D-mannopyranoside, 959; of *p*-cresol, by tyrosinase, 1507; periodic acid, of α,α-trehalose, 1530; of phenyllithium, 1603; periodic acid, of Me aldohexomethylopyranosides, 1660; of certain glycosides by Pb tetraacetate, 1667; standardization of strong oxidizing agents with KI by the acetone method, 1690; of Et_2S_2 by BrO^-, 1955; of carbonaceous materials to org. acids by O, 2398; inactivation of tyrosinase in, of catechol, 2601; of 1,2-glycols or 1,2,3-polyalcs. by $PbAc_4$, 2607; potentials of ketones, 3364; of glycosides..... 3379
Oximes, *o*-hydroxybenzophenone, 214; normal, as flotation reagents, 1250; reduction of nitroparaffins to..... 3194
Oxonium ion, substitution effects in, catalyzed acetophenone iodination..... 2779
2-Oxy-6-aminopurine, structure of..... 350
2-Oxy-6,8-diaminopurine, salts of, 351, (correction) 3603
Oxyethylene glycols, 90- and 186-membered, 1910; poly.....1905, 1912, 1916
Oxygen, addn. products of metallic salts with, compds., 28; exchange between CO_2, HCO_3^-, $CO_3^=$ and H_2O, 534; heavy, exchange reacns. of proteins and amino acids, 880; NO_2 sensitized H–, reacn., 1350; effect in reacn. of cyclopropane with Br and HBr, 2139; pressure oxidation of carbonaceous materials to org. acids by, 2398; exchange of BzOH and water, 2580; exchange of carboxylic acids, 2584; He–Ne content of sea water, and relation to, content, 2806; detn. of C, equiv. and empirical formula by oxidation, 3001; combustion data on non-volatile org. compds..... 3543
Oxygen compounds, $AlCl_3$ condensation of, with benzene..... 1413
Ozone, oxidation of methyne and methylene groups by, 429; action of, on isolated lignins, 2698; dipole moment and structure of..... 3063

PALLADIUM, colorimetric detn. of, with *p*-nitrosodiphenylamine, 2058; purified, sols prepared by elec. sparking, 2295; D–, equil., 2496; degassing of H-charged..... 2683
Palmitic acid, system: Na laurate–NaCl–H_2O–, 30; thermodynamic behavior of liquid crystalline, solns., 37; transformation of Na palmitate from crystal to liquid, 808; sorption of methylene blue by curd fibers of Na palmitate..... 2540
Pantothenic acid, anal. and detn. of constituent groups of, 454; and the filtrate factor, 975; nature and partial synthesis of chick antidermatitis factor, 977, 1421; as a factor in rat nutrition, 1615; as growth factor for the Dochez NY5 strain of hemolytic streptococcus..... 1616
Parachors, org., of *t*-alcs., 900; study of org., 3107; of $AlBr_3$ in benzene..... 3237
Paraffin-chain sulfonic acids, as colloidal electrolytes. 3210
Paraffins, reacns. with hexahydroaromatic hydrocarbons with Al halides, 640; reduction of nitro-, to amines..... 3194
Paraformaldehyde, condensation of, with mesityl ketones..... 414
Pectic enzymes..... 2544
Pectin solutions, electrolytes and viscosity of....681, 2313
Pelargonic acid, α-amino-..... 2485
Pentadecylic acid, latent heat and spreading entropy of, 1702; pressure–area and pressure–temp. relations of expanded monolayers of..... 2040
Pentanes, isomerization of alkylcyclo-..... 1076
Pentenes, addn. of H halides to *cis*- and *trans*-2-, 1559, (correction) 3605; cracking of..... 3571
1-Pentynepolysulfone, $C_{10}H_{16}SO_2$ from..... 2710
Pepsin, Chemistry of, Trypsin and Bacteriophage (Northrop, book review)..... 2571
Peptones, reacn. of Na in NH_3 with..... 3554
Perchloric acid, iodination of acetophenone in, 2791; Ga–, reacn..... 3122
Periodate, crystalline substance from starches oxidized by..... 1290
Periodic acid, oxidation of β-Me-D-mannopyranoside, 959; oxidation of α,α-trehalose, 1530; action of, on α-amino alcs., 1615; cleavage of Me aldohexomethylo-pyranosides..... 1660
Perkin synthesis, anhydride condensation in, 786; mechanism of..... 793
Peroxide, catalyzed chlorination of hydrocarbons, 2142; cyclane, 2430; catalyzed reacn. of sulfuryl chloride with ethylenic compds..... 3432
Peroxide effect, in addn. of reagents to unsatd. compds., 1711, (correction) 3605; in addn. of reagents to unsatd. substances.....2693, 3092
Perseulose, proof of structure and configuration of, 336; oxidative degradation of, to L-galactonic acid..... 340
Petroleum, N compds. in, distillates, 1017; acidic constituents of a Calif. straight-run gasoline distillate, 2448, (correction) 3605; N compds. in, distillates.....2609, 2612, 2613
Pfitzinger reaction, 1350; synthesis of quinolines... 2730
Pharmacy, Galénique (Goris, Liot, book review).... 2984
Phase formation, Kinetic der (Volmer, book review). 2566
Phase rule. (See also *Equilibrium; Pressure*) Study of Na palmitate–Na laurate–NaCl–H_2O, 30; and Phase Reacns. (Bowden, book review), 758; and its Applications (Findlay, Campbell, book review). 1299
Phenacite, sp. heat at low temp. of..... 1217
Phenanthrene, dehydrogenation of *trans*-dodecahydro-, 2003; 1,4-dimethyl-6,7-dihydroxy-, 2461; some 1,4-dimethyl-, related to morphol..... 3055
Phenanthrene derivatives, synthesis of..... .....1524, 2184, 2958, 3131
Phenanthrene series, studies in..... 1
Phenol, vapor pressure lowering of, in benzene, 54; alkenylation of, with 4-chloro- and 4-bromo-2-hexene..... 3079
Phenoldiphenein, constitution of so-called..... 526
Phenols, condensation of *t*-dimethylamylcarbinols with, 69; alkylfluoro-, 161; condensations of ketones with, 345; synthesis of phenolic coumaranes, 348; nuclear methylation of, 765; condensations of 3-hexene with, 1002; *d*-glucose-, condensation, 1005; thiazoline-, 1145; steric hindrance in ketone–, condensations, 1785; orientation of nuclear methylation in, and naphthols, 2354; condensation of, with allylic alcs., halides and dienes, 2615; viscosity of..... 2990
Phenoxybutanols, arsenated..... 1236
Phenylacetic acid, catalytic effect of various butylammonium salts on aminolysis of Et ester of, in anhyd. *n*-butylamine..... 2387
Phenylacetylene, diphenylketene–, reacn., 2619; Raman spectra of..... 3546
Phenyl allyl ethers, rearrangement of..... .....3039, 3042, 3043, 3047
Phenylanthrones, hydroxy- and methoxy- (correction)..... 3601
Phenylethanes, substitution and dissocn. of, 2008; α-2-methoxyphenyl-β,β,β-tri-..... 3192
Phenyl ether, iodo derivs. of..... 2702
N-Phenyl-N′-(ω-hydroxyalkyl)-piperazines, from α,ω-chlorohydrins..... 3439
3-Phenylindene, dimerization of (correction)..... 3601
Phenyllithium, oxidation of..... 1603
Phenylmagnesium bromide, hexabromobenzene–, reacn., 1788; 2,3-dimethyl-1,4-naphthoquinone–, reacn..... 3310

Phenylmethanes, infrared absorption of..... 1053
Phenylmethylcarbinol, arsenic derivs. of..... 357
4-Phenylphenyl acetate, bromination of..... 3037
4-Phenylphenyl benzoate, bromination of..... 1447
Phenylpropiol-4-chlorothioanilide..... 104
Phenylpropiol-4-iodoanilide, reacns. of, and similar amides..... 105
Phenylresorcinols, synthesis of 4- and 5-..... 166
Phenyl sulfides, identification of..... 684
Phenylsulfones, chemotherapy of aminodi-..... 2763
Phenylthiourea, salting-out in EtOH–, system..... 228
Phosphate ion, adsorption of, by enamel, dentine and bone..... 2588
Phosphorescence, of tetraphenylmethane and related substances, 523; Fluorescence and (Hirschlaff, book review)..... 979
Phosphorus, in tobacco mosaic virus..... 535
Phosphorus compounds, conductance of salts in tricresyl phosphate, 294; structure of thiophosphoryl fluoride..... 3264
Phosphorus sulfoxide, electron diffraction investigation of..... 1130
Phosphorus tribromide, fluorination of..... 2934
Phosphorus trichloride, fluorination of.....2927, 2937
Phosphoryl bromofluorides..... 3120
Phosphotungstic acid, in refining vitamin K extracts. 532
Photocalorimeter..... 3529
Photochemical studies..... 2492
Photochemistry, photochem. oxidation of crotonaldehyde, 582; Hg-sensitized decompn. of CO_2 in light, 716; quantum yield of monochloroacetic acid hydrolysis, 2299; and Mechanism of Chem. Reacns. (Rollefson, Burton, book review), 2567; quenching of fluorescence, 2634; production of reducing sugars from glycosides by ultraviolet light, 2981; degradation of cellulose structures by polarized ultraviolet light, 2995; decompn. of solid H compds. at low temps., 3393; exchange reacns. of Br, 3519; production of reducing sugars from starch..... 3588
Photography, its Principles and Practice (Neblette, book review)..... 537
Photolysis, of gaseous carbonyl sulfide, 151; of crotonaldehyde, 273; of acetyl bromide, 800; of azomethane, 3024; of sucrose..... 3223
Photosynthesis, radioactive C in, study, 661; quantum efficiency of, in chlorella, 3525; quantum efficiency of, in algae..... 3529
Photovoltaic cells..... 1805
Physical chemistry, Kurzes Lehrbuch der (Jellinek, book review), 980; Expts. (Livingston, book review), 980; Kurzes Lehrbuch der (Ulich, Cruse, book review), 1298; Précis de (Berthoud, book review), 1299; Introduction to Principles of (Maass, Steacie)..... 2254
Physics, für Studierende an Technischen Hochschulen und Universitäten (Wessel, book review)..... 1933
Phthalic acid, glyceryl phthalate from, 2268; monoalkyl phthalates from *n*-aliphatic alcs..... 2909
Phthalic anhydride, glycerol-, reacn., 2258; Grignard reagent–homo-, reacn., 2760; aminodiol–, reacn..... 3381
Phthalidyl compounds..... 2765
Phthalyl urea, derivs..... 2218
Phthiocol, anti-hemorrhagic activity of pure synthetic..... 1611
Physiological chemistry, Essentials of (Anderson, book review)..... 3599
α-Picoline, local anesthetics derived from..... 961
Picric acid, conductance of tetrabutylammonium picrate in diphenyl ether, 2047; conductance of tributylammonium picrate in ethylene chloride... 3257
Picrylaminates, di-..... 2285
Pigments, colloid chemistry of leaf and flower, 1605; pomiferin, from osage oranges..... 2832
Pimaric acid, hydration of dihydro-, 967; lactonization of dihydro-*l*-..... 3197
Pinacolic deamination, inversion of configuration in semi-, 1324; (correction)..... 3603
Piperazine derivatives, 2704, 3439; from amino alcs. 532
Piperidine derivatives..... 961
Piperidinium, analogs of choline and homologs..... 638
β-(2-Piperidyl)-ethanol, local anesthetics from..... 1713
Piperonyl group, absence of, in lignin structure..... 2196
Plants, The, Alkaloids (Henry, book review), 1935; wound hormones of, 3434; Protein Metabolism in (Chibnall, book review)..... 3599
Plant synthesis, nature of, 725; (correction)..... 3603
Plastics, polyvinyl chloride.....2329, 2334, 2737
Platinic chloride, promoter effect of, on Raney Ni.. 384
Platinum, catalytic interaction of acetone and isopropanol with D on, 1336; compn. of colloidal, micelle, 2234; catalytic interaction of acetylene and H on..... 3396
Pneumonia, cinchona alkaloids in..... 1783
Polarograph, study of keto-enol tautomerism of pyruvate ion, 590; Ilkovic eq. of, diffusion currents, 825; current–voltage curves with dropping amalgam electrodes, 976; measurements with dropping Hg electrode, 2099, (correction)..... 3605
Polarometric titrations..... 3402
Polyacrylyl chloride, structure of..... 3244
Polyenes, syntheses of..... 2318
Polyhydroxychalcones, prepn. of..... 861
Polymerization. (See also *Rearrangement.*) of ethylene..... 798
Polymers, from α-angelica lactone, 1682; structure of vinyl.....3156, 3241, 3244
Polymethylbenzenes..... 284
Polymorphism, in *t*-Bu halides..... 2798
Polyoxyethylene glycols, synthesis of the higher, 1905; relation between chain length and viscosity of, 1912; precipitability of pure hemicolloidal.... 1916
Polysaccharides, reacns. of carbohydrates and, 1905, 1910, 1912, 1916; Chemie der Zucker und (Micheel, book review)..... 3239
Polystyrene, phys. consts. of..... 3449
Polysulfones, structural identity of, prepared by peroxide catalysis and under the influence of ultraviolet light, 1603; vinyl chloride, 2709; acetylene, 2710..... 2714
Polyvinyl chloride, thermal history and properties of, plastics, 2329; elec. properties of tricresyl phosphate..... 2334
Polyvinyl chloride plastics, vapor pressure of tri-*m*-cresyl phosphate over..... 2737
Polyvinyl halides, structure of..... 3241
Pomiferin, from osage oranges..... 2832
Porphine, structure of, ring system..... 2912
Porphyrexide, synthesis of..... 754
Porphyrin, infrared studies of, mol..... 3511
Porphyrin studies..... 2912
Porphyrindine, synthesis of..... 754
Potassium, isotopes of, in phosphate rocks and soils, 1597; action of, on Bi oxyiodide in liquid NH_3.... 1692
Potassium acetate, activity coeff. of AcOH in..... 65
Potassium amide, action of, on Bi oxyiodide in liquid NH_3..... 1692
Potassium bifluoride, F–F distance in..... 2590
Potassium chloride, thermodynamics of, in H_2O–D_2O mixts..... 1487
Potassium compounds, substituents and decompn. rates of K salts of dihydroxamic acids, 618; structures of K-heptafluocolumbate and -tantalate, 1252; K bromate–chlorate system, 1974; soly. of K salts of nitrophenols..... 3302
Potassium halides, soly. of mercuric halides in..... 2744
Potassium hexafluogermanate, structure of..... 2849
Potassium hydroxide, ring cleavage of 2-substituted fluorenones with, in diphenyl ether, 816; ring cleavage of dichlorofluorenones with, in diphenyl ether..... 1066
Potassium iodide, standardization of strong oxidizing agents with, by the acetone method..... 1690
Potassium molybdocyanide dihydrate, structure of.. 2853

Potassium nitrite, absorption spectrum of..... 2987
Potassium oxalate, hydrated double salt of Ni oxalate and..... 965
Potato starch, mol. wt. of α-amylo-dextrin from.... 1504
Potential, thermodynamics of HCl in dioxane–water mixts. from e. m. f. measurements, 44, 48, 49; of $LaCl_3$, 200; oxidation–reduction, of substituted quinoneanils and indoanilines, 376; thermodynamics of NaCl solns. from e. m. f. measurements, 495; normal electrode, of Cs, 709; of simple metals at the dropping Hg electrode, 2099; (correction) 3605; in Pb–I voltaic cell, 2522; Oxidation States of Elements and, in Aq. Solns. (Latimer, book review), 2565; sulfates in electrolytes of Weston cells, 2687; contact, of an I film on W, 3027; elec. characteristics of mol. films, 3162; oxidation, of ketones, 3364; chem. of H_2O (correction)..... 3603
Potentiometer, detn. of fluoride..... 2237
Precipitates, aging of.....191, 195, 1036, 3409, 3414
Pregnane, a, compd. from dehydroandrosterone.... 79
Pregnanediol-3(α),20(α), conversion of sarsasapogenin to..... 3592
Pregnanediols, *etio*-cholanic acids from, 1329; steroid content of mares pregnancy urine..... 2537
Pregnanediones, reduction products of, 588; progesterone from *allo*-..... 1333
Pregnanetriol-β, structure of..... 855
Pregnanetriol-3,4,20(α), oxidation of..... 3317
Pregnanone-20..... 852
allo-Pregnanone-20..... 852
Δ^4-Pregnenone-3..... 586
Prehnitic acid..... 288
Pressure, area–, relations of fatty acid and alc. monolayers, 1180; area–, and temp.–, relations of expanded monolayers of myristic and pentadecylic acids, 2040; *V–T*–, relations for gaseous monomethylamine, 2457; *V–T*–, relations in solns., 2525; *V–T*–, relations in solns..... 2877
Progesterone, reduction products of, 588; prepn. of, from cholesterol, 893; from *allo*-pregnanedione.. 1333
Propane, fluorinated derivs. of..... 2489
Propene, condensation of, and isobutene with benzene with $FeCl_3$, 663; reacn. of, with isoölefins with H_2SO_4..... 1825
Propionic acid, identification of, in presence of acetic and butyric acids, 2974; α-(*o*-methoxyphenyl)-.. 3039
Propylallyloxybenzoic acid, isomeric Et esters of *p*-α- and -γ-..... 3043
i-Propyl bromide, mol. structure of..... 2643
Propyl-*t*-butylcarbinol, configuration of (correction). 3601
i-Propyl chloride, mol. structure of..... 2643
Propylene, polymers from isopropyl alc. and BF_3, 973; inhibition by, of decompn. of *n*-butane, 1024; thermodynamics of, 2366; entropy and heat capacity of..... 2980
Propylenediamine cobaltic chloride, dichloro-di-.... 3199
n-Propylmagnesium bromide, electrolysis of, in Et ether..... 898
Protactinium, radioactive detn. of, in siliceous terrestrial and meteoritic material..... 3451
Proteins, Chemistry of the Amino Acids and (Schmidt, book review), 219; Chemistry of the (Lloyd, Shore, book review), 219; mol. wt. of the diphtheria toxin, 533; dielec. behavior of, zein solns., 718; structure of, 755, 1860; heavy O exchange reacns. of, and amino acids, 880; shape of, mols., 1841; in liquid NH_3, 3554; Metabolism in the Plant (Chibnall, book review)..... 3599
Protium. See *Hydrogen*.
Pschorr reaction, in synthesis of 1,4-dimethyl-6,7-dihydroxyphenanthrene, 2461; applied to α-(*p*-xylylene)-2,5-di-(6′-aminodimethylcaffeic acid).. 3058
Pseudocumenes, 3- and 5-ethyl-..... 284
Purine, 2-oxy-6-amino-, 350; 2-oxy-6,8-diamino-, salts, 351; (correction)..... 3603
Pyranoid ring, possibility of different conformations of..... 2972
Pyranose, mutarotation of tetramethyl-α-*d*-gluco-, and -manno-..... 2103
Pyranosides, α- and β-Me, of L-fucose, and triacetates, 1658; periodic acid cleavage of Me aldohexomethylo-, 1660; action of $TiCl_4$ on benzylgluco-, tetraacetates..... 2978
Pyrazine, structure of..... 1769
Pyrethrosin, identity of, with chrysanthin..... 1607
Pyridazine derivatives, of steroid diones..... 2976
Pyridine, structure of..... 1769
Pyridinium bromide, 2-Me-3-β-hydroxy-Et-N-[(2-Me-6-aminopyrimidyl-(5))-Me]-, hydrobromide..... 2562
Pyrimidine researches.....74, 3377
Pyroabietic acid, compn. of so-called..... 247
Pyrolysis, of petroleum hydrocarbons..... 1400
Pyrrole, reacns. of H with, derivs., 1104; structure of..... 1769
Pyrrolidinium analogs, of choline and betaine..... 1195
Pyruvate ion, keto-enol tautomerism of, studies polarographically..... 590
Pyruvic acid, condensation of, and acetamide..... 483

QUANTUM efficiency, of photosynthesis in chlorella, 3525; of photosynthesis in algae..... 3529
Quantum mechanics, Introductory (Rojansky, book review)..... 759
Quaternary ammonium salts, cleavage of..... 668
Quinazolines..... 2170
Quinine, thermal reduction of dichromic acid by.... 3455
Quinolines, 2,4-dimethyl-8-ethyl-, 1017; use of aryloxy ketones in synthesis of, by Pfitzinger reacn., 1355; benzothiazoles related to, antimalarials, 2013; 2,4-dimethyl-8-*n*-propyl-, 2609; 2,3,4-trimethyl-8-ethyl-, 2612; 2,3,4-trimethyl-8-*n*-propyl-, 2613; Pfitzinger synthesis of, 2730; 1,2,3,4-tetrahydro-, series, 2830; synthesis of substituted, and 5,6-benzo-, 2890; α-substituted tetrahydro-, 3289; *py*-amino-, 3320; orientation in, ring..... 3322
Quinoneanils, oxidation–reduction potentials of.... 376
Quinones, antihemorrhagic activity of naphtho-, 1611, 1923, 1924, 1925, 1926, 1928, 1932, 2206, 2557, 2558, 2559, 2561, 2563, 3216; reacn. of thiol compds. with, 450; ortho-, monoxime inner complexes..... 2624

RACEMIZATION, prepn. of L-tartaric acid from racemic tartaric acid, 1266; rates of nitro-, carboxy- and methyl-biphenyls.....2825, 2828
Radicals, thermal decompn. of petroleum hydrocarbons into free, 1400; bond moments and electronegativity of org., 1483; coupling org., by Grignard reagent, 2551; random intermol. exchange of org., 2748; electron sharing ability of org..... 3289
Radioactivity, chromioxalate–oxalate ion interchange using radio-C, 570; C in study of photosynthesis, 661; vapor pressure of Th acetylacetonate by, measurements, 876; exchange reacns. with radiosulfur, 1032; halogen–halide exchange, 1215; non-interchange of elementary radiosulfur with CS_2, 2970; detn. of Pa in siliceous terrestrial and meteoritic material, 3451; exchange reacns. of Br..... 3519
Raman effect. See *Spectra*.
Rays, Roentgen, investigation of decamethylene polyesters, 2575; study of some linear polyesters (correction)..... 3601
Reactions. (See also *Diels–Alder reaction; Friedel–Crafts reaction; Pschorr reaction.*) heavy O exchange, of proteins and amino acids, 880; entropies and energies of activation of ionic, 905; exchange, with radiosulfur, 1032; halogen–halide exchange, in aq. soln., 1215; Pfitzinger, 1355; equil., between NO, Br, Cl, NOBr and NOCl, and BrCl, 1432; H exchange, of aromatic *t*-amines, 2597; redistribution, 2748, 2755, 2758, 3300; sulfonation, with sulfuryl chloride, 3089; phthalic

anhydride–aminodiol, 3381; exchange, of Br, 3519; crit. increment of ionic..... 3534
Reaction velocity. (See also *Kinetics.*) kinetics of decompn. of trinitrobenzoates in EtOH, 186; decompn. of *n*-butane, 208; rate of the haloform reacn., 241; kinetics of the catalyzed esterification of MeOH and *n*-aliphatic acids, 254; rate of formation and dissocn. of CaH_2, 318; autoxidation of ψ-cumohydroquinone, 360; kinetics of the thermal H–Cl reacn., 391, 396; activation energy of enzyme reacns. and, 403; sulfite inhibition on hydroquinone oxidation, 442; EtI–base kinetics in EtOH–H_2O, 488; O exchange between CO_2, HCO_3^-, $CO_3^=$, carbonate and H_2O, 534; decompn. rates of K salts of dihydroxamic acids, 618; kinetics of isomerization of aci to nitro forms of nitroethane, 692; theory of absolute, and polymerization of ethylene, 798; of alkaline fading of brom phenol blue, 905, (correction), 3603; kinetics of hydrocarbon decompn., 977; decompn. of *n*-butane, 1024; kinetics of sapon. of Et esters of *n*-aliphatic acids, 1172; kinetics of esterification of substituted aliphatic acids in MeOH, 1176; kinetic salt effect of ethylene chlorohydrin and hydroxyl ion, 1205; NO_2 sensitized H–O reacn., 1350; hydrolysis equil. of formic acid esters, 1443; mechanism of solvolytic reacns. of org. halides, 1630; solvolysis of *t*-BuCl, 1635; identification of *cis-trans* isomers by rate studies, 1640; equil. of HgO in dil. HNO_3 solns., 1730; oxidation of Et_2S_2 by BrO^-, 1955; calcn. of base rate consts. from acid rate consts., 2018; esterification velocities of benzoic acids and cyclohexanol, 2167; rate of hydration of crotonic acid, and dehydration of β-hydroxybutyric acid, 2271; rate of dissoln. of Fe in acids, 2290; alcoholysis rates of aralkyl *p*-nitrobenzoates, 2383; hydrolysis of ethylal, 2510; Photochemistry and Mechanism of Chem. Reacns. (Rollefson, Burton, book review), 2567; O exchange of BzOH and water, 2580; O exchange of carboxylic acids, 2584; quenching of fluorescence in aq. solns., 2634; substitution effects in catalyzed acetophenone iodination, 2779; mechanism of acid catalyzed enolization of acetophenone derivs., 2785; kinetics of iodination of acetophenone in H_2SO_4 and $HClO_4$, 2791; racemization rates of biphenyls, 2825, 2828; homogeneous decompn. of Et chlorocarbonate, 3176; kinetics of thermal decompn. of Et formate, 3203; aquation of carbonato pentammine cobaltic bromide, 3229; thermal isomerization of dichloroethylene, 3259; kinetic studies on I derivs., 3284; kinetics of polyesterification, 3334; thermal reduction of dichromic acid by alkaloids, 3455; hydrolysis of Br and halogens.... 3513
Reactivity, relative, of organometallic compds., 731, 739, 741, 743, 957, 1170, 1513; of Cl in BzCl derivs..... 1418
Reagents, peroxide effect in addn. of, to unsatd. compds., 1711, (correction, 3605).....2693, 3092
Rearrangements. (See also *Isomerization; Mutarotation.*) allylic, 12, 741, 3070; cleavage, in Friedel–Crafts reacns. of furans, 473; Lossen, 618; of tetraaryldiallenes, 895; intramol. 1324, (correction), 3603; of 1,3-dimethyl-4-*t*-butylbenzene, 1411; common basis of intramol., 1586; of Ph allyl ethers, 3039, 3042, 3043, 3047; of phenyl ether from alkenylation of phenol with 4-chloro- and 4-bromo-2-hexene, 3079; Claisen, 3085; of α-hydroxy carbonyl compds., 1714; mol., in sterols..... 3483
Reduction, oxidation–, potentials of substituted quinoneanils and indoanilines, 376; linoleyl alc. prepared by Na, of linoleic acid, 482; of Ag^+ by hydroquinone, 648; of α-diketones, 1281; mechanism of, of conjugated systems with terminal carbonyl groups, 1854; Wolff–Kishner, of steroid ketones, 1992; of CO_2 by graphite and coke, 2053; of Ag ions by hydroxylamine, 2379; of metal oxides in liquid NH_3, 2502; of 2-acetobenzofuran, 2705; alkylation of aromatic primary amines.... 3145
Redistribution reaction.....2748, 2755, 2758, 3300
Reformatsky reaction, prepn. of bromoacetic ester in large quantities..... 970
Refraction, data on liquid C_3-hydrocarbons, 751; electro-optical effect in viruses..... 2412
Resins, mol. and cybotactic wt. of..... 1812
Resistance, magnetic field and elec., of Au and Ag.. 238
Resonance, internal rotation and, in hydrocarbons.. 1876
Resorcinols, synthesis of 4- and 5-phenyl-, 166; 5-*n*-alkyl-, 232; alkoxyalkyl derivs. of, 249; condensation of diethyl ketone with..... 348
Rhamnose, prepn. of, from naringin..... 175
Rhizopus, fumaric acid production by, molds..... 127
Rhodium. Gmelins Handbuch der anorg. Chemie (Pietsch, book review)..... 537
Rhodium pentammines, interconversion of acido and aquo..... 699
Ribosidodihydroxyacetone tetraacetates, *d*- and *l*-, with an orthoester structure..... 3012
Ricinoleic acid..... 3464
Ricinus communis..... 3464
Ring, cleavage of 2-substituted fluorenones, 816; prepn. of cyclic ketones by, enlargement, 1057; cleavage of dichlorofluorenones with KOH in diphenyl ether, 1066; cleavage of fluorenone-4-carboxylic acids, 1358; low temp. dehydrogenation of hydroaromatic, 1407; evidence for, structure in aliphatic org. compds., 1963; relation between resonance stabilized chelate, and acidity, 2475; porphine, system, 2912; orientation in quinoline..... 3322
Ring closure, of monoacylethylenediamines, 822; of dienynes..... 2003
Rosin, dihydroabietic acid in..... 1230
Rotation. See *Molecules; Optical rotation.*
Rye, sterols of, germ oil..... 1901

SACCHARIDES, heats of combustion of some mono- and di-, 1726; reacns. of carbohydrates and poly-, 1905, 1910, 1912, 1916; acetone derivs. of mercaptals of mono-..... 2444
Saccharin, Na, in identifying alkyl halides..... 15
Saccharolactone Methyl ester..... 664
Sakurai, J., biography of..... 2255
Salicylic acid, acetyl-5-fluoro-..... 2317
Salting-out, Debye, theory in phenylthiourea–EtOH and urea–MeOH systems..... 228
Salts, addn. products of metallic, with S and O compds., 28; neutral, effect on the ferricyanide–iodide reacn., 116; neutral, effect on $CuSO_4$ hydrolysis, 118; conductance of some, in tricresyl phosphate, 294; elec. conductances of pure and mixed, solns..... 1219
Sapindus drummondii, compn. of, seeds..... 2697
Sapogenins.....983, 1707, 2420, 2421, 2717, 2976
Saponification, kinetics of, of Et esters of *n*-aliphatic acids..... 1172
Saponins.....983, 1707, 2420, 2421, 2717, 2976
Sarsasapogenin, 1849; structure of side chain of, 846; oxidation products of, 1285, 2072, 2722, 3477; position of hydroxyl group in, 1291; conversion of, to pregnanediol-3(α),20(α)..... 3592
epi-Sarsasapogenin..... 943
Sarsasapogenin derivatives.....943, 1284, 1921
Sarsasapogenoic acid, and related compds.....1849, 2072
Sarsasapogenoic acid, ultraviolet absorption spectrum of anhydro-..... 532
Schiff base, hydrochlorides..... 2554
Schlieren method, modification of, for use in electrophoretic analysis..... 529
Sebacic acid, dibenzyl ester of..... 2246
Sedimentation of α-amylo-dextrin..... 1504
Sedoheptulose, oxidative degradation of, to D-altronic acid..... 343
Selenium compounds, sp. heat of MnSe, 203; hydro-

gen perselenide, 440; system: $CaSeO_4$–$(NH_4)_2SeO_4$–H_2O, 1251; organo-, 2306; seleno *o*- and *m*-cresols ... 2972
Selenium iodide, existence of a ... 3401
Serum albumin, (crystalline horse) ... 2884, 2888
Silica, gels from various acids, 1020; some Na–Li–, systems ... 2863
Silicates, Feuerfeste Baustoffe silikatischer und silikathaltiger Massen (Koeppel, book review) ... 1617
Silicobromoform, dipole moment and structure of ... 3063
Silicon compounds, reacns. of aryl Grignard reagents with Si halides, 363; sp. heats of Na silicates ... 471
Silicon tetrafluoride, soly. of, in org. solvents ... 2555
Silver, magnetic field and resistance of, 238; electrode spectral sensitivity, 1805; HCl and, reduction of molybdate ... 3125
Silver bromide, co-pptn. of AgCl with, 1036; detn. of sp. surface of, by radioactive and dye method, 3409; aging of ... 3414
Silver chloride, co-pptn. of, with AgBr ... 1036
Silver compounds, soly. of, in dioxane–H_2O solvents ... 3274
Silver iodide, electrode ... 2592
Silver ions, reduction of, by hydroquinone, 648; reduction of, by hydroxylamine ... 2379
Silver oxide, divinyl sulfide reacn. with ... 915
Sitosterol, in rye germ oil, 1901; isolation of α_3-, 1903; structure of α_1- ... 2308
Soap, phase rule study of mixed, system, 30; transformation of Na palmitate from crystal to liquid, 808; sorption of methylene blue by Na palmitate ... 2540
Sodium, reacn. of esters with, in liquid NH_3, 215; action of, on high mol. wt. fatty acid chlorides, 1019; action of, on Bi oxyiodide in liquid NH_3, 1692; reacn. of, in NH_3 with peptones ... 3554
Sodium acetate, Hittorf transference no. of, in AcOH ... 147
Sodium borates, soly. curves of H_3BO_3 and ... 917
Sodium chloride, thermodynamics of, solns., 495; b. p. elevation of, 500, 1123; reacn. of SO_2 with ... 834
Sodium compounds, system: Na palmitate–Na laurate–H_2O–NaCl, 30; solubilities, micelle formation and hydrates of Na salts of higher alkyl sulfonates, 539; Na bromate–chlorate system, 1974; some lithium–silica–, systems, 2863; soly. of Na salts, of nitrophenols ... 3302
Sodium dodecyl sulfonate, densities and viscosities of, solns., in relation to micelle formation ... 544
Sodium ethylene carbide ... 750
Sodium hydroxide, d. of aq., solns ... 1027
Sodium metasilicate, phase equil. relations in system Li_2SiO_3– ... 2157
Sodium nitrite, absorption spectrum of ... 2987
Sodium saccharin, in identifying alkyl halides ... 15
Sodium silicates, sp. heats of ... 471
Sodium sulfide, cleavage of quaternary ammonium salts ... 2895
Sodium sulfonate, elec. conductance of Na decyl, dodecyl and hexadecyl sulfonate solns ... 549
Sodium triphenylmethyl, condensations by ... 3567
Solids, elec. properties of, 2329, 2334; Der disperse Bau der festen Systeme (Balarew, book review) ... 3597
Sols. See *Colloids*.
Solubility, compressibility and, of metals in acids, 746; aq., of some unsatd. alcs., 807; curves of H_3BO_3 and Na borates, 917; of salts in dioxane–H_2O solvents, 3274; of halogenated methanes ... 3550
Solutions, apparatus for study of aq., b. ps., 497; dielec. const. of conducting, 565; *P–V–T* relations in ... 2515, 2877
Solvates, phys. studies of non-aq ... 1949
Solvent, effect of, in Grignard analysis for active H and carbonyl, 865; effects in addn. reacns., 1454; electrolytes in H_2O–org., mixts ... 3113
Solvolysis, reacns. of org. halides, 1630; of *t*-BuCl ... 1635
Sonoluminescence ... 2392
l-Sorbose, isorotation in, series ... 2669
Sørensen, S. P. L., obituary of ... 2573
Specific heat, at low temp. of Mn, MnSe and MnTe, 203; of *o*-, *m*-, and disilicates of Na, 471; at low temps. of BeO and Be_2SiO_4, 1217; of CBr_4, 1555; of ethylene halides ... 3349
Specific surface, of Zn oxides ... 1317
Spectra. (See also *Extinction coefficient; Fluorescence; Light.*) ultraviolet absorption, of anhydrosarsasapogenoic acid, 532; Raman, of hexanes and heptanes, 689; infrared absorption, of the phenylmethanes, 1053; infrared bands and assocn. of some hydroxylic compds., 1396; Cu, Ag and Au electrode spectral sensitivity, 1805; absorption, of amino alkyl substituted benzenes, 1981; infrared absorption studies of some glycols and ethoxy alcs., 2679; infrared absorption studies, 2809, 3252; infrared absorption, of some carbonyl compds., 2812; of osajins, 2832; oscillation frequencies of nitrites, 2987; infrared studies of porphyrin mol., 3511; Raman, of acetylenes, 3546; absorption, of hypericin ... 3594
Spectrochemistry, Ein Forschungsarchiv (book review) ... 3600
Spectroscopy, Proc. of the 6th Summer Conference on, and its Applications (Harrison, book review) ... 1933
α-Spinasterol, isolation of, from alfalfa ... 2467
Spruce wood, ethanolysis of ... 509, 523, 868
Stannous ion, hydrolysis of ... 3342
Stannous perchlorate solns., hydrolysis of stannous ion in ... 3342
Starch, absence of, fatty acid in cereal, 212; crystalline substance from, oxidized by periodate, 1290; mol. size of, by mercaptalation method, 2172, (correction) 3605; conversion of, to crystalline dextrins by a new amylose, 2900; reducing sugars from ... 3588
Stereochemistry. (See also *Isomerism.*) of tervalent N, 1927; of biphenyls, 2179, 2182, 2825, 2828; of complex inorg. compds ... 2402, 3199
Stereoisomerism, of unsatd. compds ... 1640, 1645
Steric hindrance, arylglyoxals and, 480; in ketone–phenol condensations ... 1785
Sterility, prepn. of anti-, factors ... 765
Sterols, 585, 586, 588, 846, 852, 855, 943, 944, 946, 1284, 1285, 1287, 1291, 1329, 1332, 1333, 1516, 1921, 1922, 2072, 2537, 2719, 2722, 2724, 2974, 3022, 3314, 3317, 3476, 3477, 3479; a pregnane compd. from dehydroandrosterone, 79; brassicasterol, 142; study of cholestadienes and cholesterilene, 171; prepn. of progesterone from cholesterol, 893; total synthesis of equilenin, 974; 3,4-dihydro-5-Me-3′-methoxydibenzyl, 1001; Me 12-*epi-etio*-desoxycholate, 1614; of rye germ oil, 1901; isolation of α_3-sitosterol, 1903; reduction of steroid ketones, 1992; α_1-sito-, 2308; α-spinasterol, 2467; precipitability of steroid sapogenins by digitonin, 2717; of alfalfa seed oil, 2910; stigmasterol 22,23-dibromide, 2956; pyridazine derivs. of steroid diones, 2976; mol. rearrangements in, 3483; desoxycholamine ... 358
Stibines, yields of ... 530
Stigmasterol 22,23-dibromide ... 2956
Stilbenes, addn. of alkali metals to ... 2106
Stokes–Einstein diffusion equation, limits of validity of ... 1745
Strontium carbonate, activity coeff. of ... 2154
Strontium chromate, soly. of ... 746
Styrene, addn. of HBr to, 2693; benzoylformic acid from, 2979; aromatic amines and 3-nitro-6-bromo-nitro-, 2969; reacn. of, with bisulfite, 3092; phys. consts. of, and poly- ... 3449
Styrene oxide, MeMgI–, reacn ... 996
Substitution, effect of, on dissocn. of hexaarylethanes, 77, 2769; Ph alkyl N, in barbituric acids, 1015; effects in catalyzed acetophenone iodination ... 2779
Sucrose, heat of diln. of, 459; photolysis of ... 3223
Sugars. (See also *Carbohydrates; Polysaccharides.*) D-altrosan, 214; structure of perseulose, 336; oxidative degradation of perseulose to L-galactonic acid, 340; oxidative degradation of sedoheptulose to D-altronic acid, 343; *aldehydo-d*-mannose penta-

acetate Et hemiacetal, 574; synthesis of *l*-galactose, 611; saccharolactone Me ester, 664; reacn. of $Ba(OH)_2$ and monobasic acids, 779; periodic acid oxidation of β-Me-D-mannopyranoside, 959; phenol–, condensations, 1005; synthesis of 2,4,6-trimethylglucose, 1112; new approach to synthesis of aldehydo, 1156; water-sol. glucosan from barley roots, 1223; configuration of D-α,α-mannooctose, 1268; aldehydo derivs. of D-α,α-galaoctose, 1270; mol. wt. of α-amylo-dextrin, 1504; synthesis of D-mannoheptulose, 1654; relations between rotatory power and structure in the, group, 1658; periodic acid cleavage of Me aldohexomethylopyranosides, 1660; oxidation of glycosides by Pb tetraacetate, 1667; glyco- and thioglyco-furanosides, 1671; heats of combustion of some saccharides, 1726; keturonic acids from carbohydrates, 1822; tritylation expts. in, 1827; 2,4,6-trimethyl-β-phenyl- and -benzyl-D-glucosides, 1831; glucose dimethylacetal–carbohydrases reacn., 1833; cleavage of cellobiose and celtrobiose by emulsin, 1834; α-ethylthioglucopyranoside, 1930; mutarotation of tetramethyl-α-*d*-glucopyranose and -mannopyranose, 2103; tetrose, 2111; structures of diacetone dulcitols, 2432; methylated carbohydrates, 2442; acetone derivs. of mercaptals of monosaccharides, 2444; ketone, series, 2669, 2675; conversion of starch to crystalline dextrins by a new amylase, 2900; relations between rotatory power and structure in, group, 2972; photochem. production of reducing, from glycosides by ultraviolet light, 2981; ribose derivs., 3012; Chemie der, und polysaccharide (Micheel, book review), 3239; reduction products of *d*-glucoheptulose, 3370; 5,6-dimethylglucose, 3507; photosensitized production of reducing, from starch 3588
Sulfamates, ammonium 914
Sulfamic acid, opt. properties of, 2551; from hydroxylamine–SO_2 reacn. 3389
Sulfanilamide, derivs. in chemotherapy, 613; formaldehyde sulfoxylate derivs. of, 617; N^4-acyl derivs. of 1198
Sulfanilamide derivatives 2342, 2346, 2950
Sulfanilamido derivatives, of heterocyclic amines ... 2032
Sulfides, sp. gravities and refractive indices of aliphatic, 83; identification of alkyl Ph 684
Sulfite, cooking process, 277; inhibitory action of, in hydroquinone autoxidation 442
2-Sulfofluorenone, ring cleavage of 816
p-Sulfonamidophenylarsonic acid 2105
Sulfonates, studies of 539, 544, 549
Sulfonation, reacns. with sulfuryl chloride 3089
Sulfonefluorescein, structure of, derivs. 2919
Sulfones, synthesis of a cyclic keto-, 389; identification of alkyl Ph, 684; poly- 1603
Sulfonic acids, esters of 4,4′-dihydroxydiphenyl, 1921; paraffin-chain, as colloidal electrolytes 3210
Sulfonium salts, aryl 80
Sulfonylamides, alkylation of α-, 3139; α-alkyl- 3386
5-Sulfonylbarbituric acids 2033
Sulfophenylarsonic acids, and certain derivs. 2105
Sulfoxides, identification of alkyl Ph 684
Sulfur, addn. products of metal salts and, compds., 28; reacn. of, with halogenated diphenyl sulfides, 387; in tobacco mosaic virus, 535; cleavage of benzyldimethylphenylammonium chloride by, contg. salts, 668; exchange reacns. with radio-, 1032; non-interchange of radio, with CS_2, 2970; H bonding by H– 3161
Sulfur dioxide, viscosity of org. liquid–, solns., 112; viscosity of, solns., 3353; sulfamic acid from hydroxylamine–, reacn. 3389
Sulfuric acid, reacns. of 3-hexene with, 940; aminomonopersulfuric acid formed from, and H azide, 1083; propene–isoölefins reacn. with, 1825; vapor pressure of aq., solns., 2370; iodination of acetophenone in, 2791; in benzene–methylcyclobutene reacn. 3374
Sulfur trioxide, reacn. of, with NaCl, 834; action of NH_3 on, addn. compds. 3392
Sulfuryl chloride, chlorinations with, 2142, 3432; sulfonation reacns. with, 3089; org. syntheses with 3250
Sulfuryl fluoride, mol. structure of 3264
Surface. (See also *Films*.) sp., of Zn oxides 1317
Syringyl radical, in plant products 2190, 2556
Systems, binary liquid 2691

TANNINS, constitution of natural 2651
Tantalum, reacn. with I 838
Tantalum compounds, structure of K heptafluotantalate 1252
L-Tartaric acid, prepn. of, from racemic 1266
Tautomerism, keto-enol, of pyruvate ion 590
Tectorigenin, structure of 2322
Tellurium, heat capacity and entropy of 564
Tellurium compounds, sp. heat of MnTe, 203; 3 alkali molybdotellurates 1810
Temperature, satd. standard cells with small, coeff., 652; low, dehydrogenation of hydroaromatic rings, 1407; low, precision adiabatic calorimeter, 1533; relation between, fluidity and chem. constitution of pure liquids, 1625; diphenylmethane as a thermometric standard, 1796; pressure–, relations of expanded monolayers of myristic and pentadecylic acids, 2040; *P–V–*, relations for gaseous monomethylamine, 2457; *P–V–*, relations in solns., 2515, 2877; low, photochem. decompn. of solid H compds. 3393
Tenulin 1836
Tetraaryldiallenes, rearrangements of 895
1,2,4,5-Tetrabromocyclohexane, mol. structure of ... 1601
Tetrabutylammonium picrate, conductance of, in diphenyl ether 2047
Tetraethyllead, interchange of triethyllead chloride and radioactive 3300
Tetrahydrobenzo(b)naphtho(2,3-d)furan amino ketones from 1148
Tetrahydrofuran, 1,4-diiodobutane from, 525; reacn. with acyl halides 2667
Tetrahydroquinolines, α-substituted, 3289; synthesis in 1,2,3,4-, series 2830
Tetralin, structure of, derivs. 2916
Tetramethyl-α-*d*-glucopyranose, mutarotation of ... 2103
Tetramethyl-α-*d*-mannopyranose, mutarotation of .. 2103
Tetranitromethane, mol. structure of 1127
Tetraphenyllead dihalides 1609
Tetraphenylmethane, phosphorescence of 523
Ternary systems. See *Systems*.
Terpenoid amines 2477
Tetrose sugars, chemistry of 2111
Textile finishing, Kolloidchem. Grundlagen der (Valkó, book review) 1299
Thallium, relative reactivities of triphenyl- 1513
Therapeutics, org. compds. in, 613, 617; of 4,4′-diaminodiphenylsulfone, 4 - amino - 4′ - hydroxydiphenylsulfone and related compds., 2763; 2-(*p*-aminobenzenesulfonamido)-thiazole as, agent 3593
Thermal chemistry, of org. compds. 3543
Thermodynamics. (See also *Entropy; Heat of Reaction*, etc.) behavior of Na palmitate and Na laurate solns., 37; of HCl in dioxane–water mixts., 44, 48, 49; of $CdBr_2$ in aq. solns., 308; of NaCl solns., 495; of bi-univalent electrolytes, 1040; consts. of BrCl, 1432; of KCl in H_2O–D_2O mixts., 1487; of dimethylamine, 1539; of $H_2N_2O_2$, 1550; of propylene, 2366; of TiO_2, 2405; of Pb–Sb system, 2594; of HCN, 2626; of aniline–nitrobenzene mixts., 2877; of Zn–Sb system, 3170; and Chemistry (MacDougall, book review) 3596
Thermometry, diphenylmethane, as a thermometric standard 1796
Thiamin. See "B_1" under *Vitamins*.
Thiazoles, researches on, 2013; 2-(*p*-aminobenzenesulfonamido)-, as chemotherapeutic agent 3593
Thiazolinephenols 1145

Thiazolines, 2-thio-4-aryl- 1830
Thioamides 104, 105
Thioanilide, phenylpropiol-4-chloro-, 104; phenylpropiol-4-iodo- 105
2-Thio-4-arylthiazolines, syntheses of 1830
Thiochrome, detn. of thiamin by, assay 179
Thio compounds, derived from aroyl-*o*-benzoic acids. 2765
Thiocyanates, identification of olefins as di-, 750; action of Cl on, 2548; *p*-tolyl iso-, action on Et acetonedicarboxylate 2966
Thioglycofuranosides 1450, 1671
Thioglycolic acid, reacn. between, and spruce lignin. 277
Thiol compounds, reacn. of, with aliphatic olefins, 71; reacn. of, with quinones, 450; aminomethanethiol derivs., 3134; aryl mercaptans 3161
Thiophene, structure of 1769
Thiophene derivative, maleic anhydride–, reacn., 2733; (correction) 3605
Thiophenedioxides, di-*n*-propyltetrahydro- 2714
Thiophosphoryl fluoride, mol. structure of 3264
Thiosulfate, titration of Cl, 265; heat of reacn. of, with triiodide 1554
Thiourea, chlorination of iso- 176
Thiuronium chloride, *p*-chlorobenzyl pseudo-, as reagent 3251
Thoria, isomerization of alkenes on 1762
Thorium acetylacetonate, vapor pressure of, by radioactivity measurements 876
Thujylamines, isomeric 2477
Thyroxine, analog of 2472
Tigogenin, position of hydroxyl group in, 1291; reacns. of 1516
Titanium dioxide, thermodynamics of 2405
Titanium tetrachloride, action of, on benzylglucopyranoside tetraacetates 2978
Titrations, amperometric 3402
Tobacco, S and P in, mosaic virus 535
α-Tocopherol, oxidation products of 2424
Toluene, volume changes in the MeOH–, system, 67; system: EtOH–H_2O–, 1694; rearrangement of, derivs. by $AlCl_3$ action 2128
Tolylchloromethane, prepn. of di-*o*- 3238
p-Tolyl ether, rearrangement of allyl 3085
p-Tolyl isothiocyanate, action of, on Et acetonedicarboxylate 2966
Tolylmethyl, disproportionation of tri-*p*- 2769
Transference numbers, Hittorf, of Na and NH_4Ac in anhyd. AcOH, 147; of HCl in H_2O and dioxane–H_2O mixts 3113
Traumatin, synthesis of a 3434
α,α-Trehalose, periodic acid oxidation of 1530
1,3,3-Trialkoxybutanes 887
Trialkylbenzenes, prepn. of *sym.*- 1163
Triarylcarbinols 2902, 2905
Tributylammonium picrate, conductance of, in ethylene chloride 3257
Tricaprylin, prepn. of 3587
Trichloroacetic acid, chlorination of Bu ester of 3361
1,1,2-Trichloroethane, internal rotation in 3127
Tricresyl phosphate, conductance of salts in, 294; elec. properties of the system polyvinyl chloride–. 2334
Tri-*m*-cresyl phosphate, vapor pressures and accommodation coeffs. of, over polyvinyl chloride plastics 2737
Triethyllead chloride, interchange of, and radioactive tetraethyllead 3300
Triiodide, heat of reacn. of thiosulfate with 1554
Triiodophenyl ethers, to identify alkyl halides 2666
Trilinolein 3051
3,4,5-Trimethoxybenzonitrile, action of *i*-BuMgBr on. 2175
2,4,6-Trimethyl-β-benzyl-D-glucosides 1831
Trimethylethylene, bromination of, 215, 217; addn. of HBr to 2693
2,3,4-Trimethyl-8-ethylquinoline 2612
2,4,6-Trimethylglucose, synthesis of 1112
2,2,3-Trimethylpentanol-3, aq. soly. of 525
2,4,6-Trimethyl-β-phenyl-D-glucosides 1831
2,3,4-Trimethyl-8-*n*-propylquinoline 2613
Trinitrobenzoates, decompn. of, in EtOH 186
Trinitrotriphenylmethide ion, as a secondary and primary base 1894
Triphenylcarbinols, dissocn. of, in MeOH 16
Triphenylchloromethane, action of, on α-Me-D-mannopyranoside 1528
Triphenylene, Me homologs of 2958
Triphenyllead, prepn. and reacns. of some, derivs. 1685
Triphenyllead chloride, ammino compds. of 1687
Triphenylmethide ion, trinitro- 1894
Triphenylthallium, relative reactivities of 1513
Tri-*p*-tolylmethyl, disproportionation of 2769
Tritylation, in sugar alc. series 1827
Trixenylcarbonium salts, occurrence of color with 2905
Trypsin, Chemistry of Pepsin, Bacteriophage and (Northrop, book review) 2571
Tung oil, Wijs soln.–, reacn. 2277
Tungsten, contact potential of I film on 3027
Turanose, structure of 2675
Tyrosinase, deamination of glycine in presence of, 752; oxidation of *p*-cresol by, 1507; inactivation of, in catechol oxidation, 2601; from the wild mushroom 2946

ULTRACENTRIFUGE, mol. wt. of β-amylose from corn starch by means of 1495
Unsaturated compounds. (See also *Hydrocarbons; Olefins.*) stereoisomerism of, 1640, 1645; hydroxylation of, 1844; peroxide effect in addn. of reagents to, 1711, (correction) 3605, 2693, 3092; hydration of 2271
Uracils, catalytic hydrogenation of 5-benzyl and 6-benzyl- 74
Urane derivatives, of sterols 2719
Uraninite, Pied des Monts 2742
Uranyl sulfate, photolysis of sucrose in, solns. 3223
Urea, salting-out in MeOH–, system, 228; Ca oxylate soly. in aq., solns., 334; coeff. of expansibility of aq., solns., 1558, (correction) 3605; ammonium cyanate–, conversion 3534
Ureas, diacyl-, 408; halogen-acetyl, 1377; phthalyl, derivs. 2218
Urease, mol. wt. and assocn. of 3180
Urethans, as local anesthetics 888

VANADIUM, reacn. with I 838
Vanillone, α-hydroxypropio- 2204
Vapor, d. of, adsorbed on charcoal, 873; –liquid equil. in system CCl_4–AcOEt, 2691; liquid–, equil. 3206
Vapor pressure, of *n*-butane, 24; lowering of phenol in benzene, 54; of Th acetylacetonate, by radioactivity measurements, 876; of dimethylamine, 1539; of $ZnBr_2$–diethyl ether solns., 1949; of Cl, 1970; of propylene, 2366; of aq. H_2SO_4 solns., 2370; of HCN, 2626; of tri-*m*-cresyl phosphate over polyvinyl chloride plastics, 2737; partial, of aq. ethylamine solns., 2808; of cyanogen 2940
Veratrine alkaloids 2252
Vinylacetylene, chlorination of, in MeOH 1458
Vinyl barbituric acids, substituted 96, 353, 776
Vinyl chloride polysulfone 2709
Vinyl hydrindenes, maleic anhydride–, reacn. 1405
Vinyl ketone, polymer of Me 3234
Vinyl polymers, intramol. reacn. between neighboring substituents of, 1518; structure of 1682, 3156, 3234, 3241, 3244
Viruses, electro-optical effect in 2412
Viscosity, of *n*-butanol, 82; of SO_2 solns. in org. liquids, 112; of Na dodecyl sulfonate solns., 544; of liquid He II, 654; of pectin solns., 681; of long chain fatty acids, 1188; and constitution, 1734; of pectin solns., 2313; of aq. Na oleate and phenols, 2990; effects of, on reacn. rates 3334
Vitamins, detn. of, B_1 by thiochrome assay, 179; und Hormone und ihre tech. Darstellung. Dritter Teil (Vincke, book review), 756; La Chimie des, et des Hormones (Sivadjian, book review), 756; thiamin analogs, 891; structure of B_6, 1237, 1242; syn-

thesis of B_6, 1245, 3307; B_1 (Thiamine) and its Use in Medicine (Williams, Spies, book review), 1617; presence of, A in olfactory area of the steer, 1929; B_6, a growth promoting factor for yeast, 1931; B_6 as a yeast nutrilite, 1932; chemistry of, E, 2424, 2615, 3079; synthesis of antirachitic, 2534; phosphotungstic acid in refining extracts containing, K, 532; isolation of, K as a choleic acid, 745; isolation of K_1 and K_2, 1295; color reacns. in, K concentrates, 1610; anti-hemorrhagic activity of pure synthetic phthiocol, 1611; derivs. of, K_1 and K_2, 1612; color reacn. for, K, 1613; constitution of, K_1, 1928; antihemorrhagic activity of naphthoquinones, 1923; simple compds. with, K activity, 1924; quinones having, K activity, 1925; antihemorrhagic compds., 1926; K activity of some quinones, 1932; synthesis of quinones related to, K_1 and K_2, 2206; α-spinasterol from alfalfa, 2467; synthetic and natural antihemorrhagic compds., 2557; constitution and synthesis of K_1, 2558; synthetic approach to K_1, 2559; synthesis of 2-Me-3-phytyl-1,4-naphthoquinone, 2559, (correction) 3605; identity of synthetic 2-Me-3-phytyl-1,4-naphthoquinone and K_1, 2561; K potencies of synthetic compds., 2563; antihemorrhagic activity of simple compds., 2563; naphthoquinones of, K type of structure, 3216; synthesis of, K_1 3467
Volume, *P–T–*, relations for gaseous monomethylamine, 2457; *P–T–*, relations in solns. 2515, 2877

WALDEN inversion, in solvolysis of *t*-BuCl, 1635; bicyclic structures prohibiting 3184
Water, system: Na palmitate–Na laurate–NaCl–, 30; thermodynamics of HCl in dioxane–, 44, 48, 49; influence of heavy, on barley amylases, 125; densities of D_2O–H_2O mixts., 198; aq. systems of Zn and Cd nitrates, 260; mixing of cellosolve and carbitol with, 373; detn. of, in org. liquid mixts., 524; detn. of water in org. liquid mixts., 524; isomerization of nitroethane in H_2O and D_2O, 692; system: $CaSeO_4$–$(NH_4)_2SeO_4$–, 1251; temp. of max. d. of D_2O and of its mixts. with H_2O, 1293; d. of natural, from various sources, 1342; properties of HCl in EtOH–, and *i*-PrOH–, mixts., 1491; (correction) 3605; system: Et alc.–toluene–, 1694; K and Na bromate–chlorate systems, 1974; properties of electrolytes in org. solvent–, mixts. 2374, 2377, 3113; H and D exchange between nitramide and, 2552; O exchange of BzOH and, 2580; system: Li_2SO_4–$Al_2(SO_4)_3$–, 2689; He–Ne content of sea, and relation to O content, 2806; soly. of salts in dioxane–, solvents, 3274; chem. potential of, in NaCl and KCl solns. (correction) .. 3603
Watermelon seed oil, compn. of 889
Weston cell, sulfates in electrolytes of 2687
Wijs solution, tung oil–, reacn. 2277
Wolff–Kishner reduction, of steroid ketones 1992
Wurster's salts, free radicals of type of 1981

XANTHINE derivatives, desmotropism of 2483
Xenylcarbonium salts, occurrence of color with tri-, salts 2905
Xylenes, rearrangement of, by $AlCl_3$ 2131
p-Xylylacetic acid, 1,4-dimethyl-6,7-dihydroxyphenanthrene from, and 6-nitroveratraldehyde 2461
α-(*p*-Xylylene)-2,5-di-(6′-aminodimethylcaffeic acid) application of Pschorr reaction to 3058

YEAST, fermentation of maltose, 291; als Heil-, Nähr- und Futtermittel (Schülein, book review), 757; vitamin B_6, a growth promoting factor for ... 1931, 1932

ZEIN, dielec. behavior of protein, solns. 718
Zinc, reacn. of, with $CuSO_4$, 1798; thermodynamics of Sb–, system 3170
Zinc acetate, system: HCl–AcOH– 2164
Zinc bromide, vapor pressure of diethyl ether–, solns. 1949
Zinc compounds, acetozincate 3340
Zinc ion, entropy and heat capacity of 522
Zinc halides, heats of formation and entropies of 1040
Zinc lactate, rotatory power of 3234
Zinc nitrate, heats of soln. and diln. of water–, system 260
Zinc oxides, sp. surface of 1317
Zirconium tetrabromide, reacns. of, in liquid NH_3 .. 121
