The reactions of $[Fe_2\{\mu\text{-CN}(Me)R\}(\mu\text{-CO})(CO)_2(Cp)_2]SO_3CF_3$ ($Cp = \eta\text{-}C_5H_5$, R = Me **2a** or CH_2Ph **2b**) with a variety of carbon nucleophiles result in C-C bond formation at different sites of the molecules depending on the nature of the carbanions: (i) R'Li (R' = Me, Bu^n or Ph) and R'MgCl (R' = Me, CH_2Ph or Pr^i) added at the Cp ligand giving η^4 -cyclopentadiene complexes $[Fe_2\{\mu\text{-CN}(Me)R\}(\mu\text{-CO})(CO)_2(\eta^4\text{-}C_5H_5R')(Cp)]$ **3**; (ii) $Li_2Cu(CN)R'_2(R' = Me \text{ or } Bu^n)$ and $LiC\equiv CR'$ (R' = Ph or p-tolyl) afforded the stable acyl complexes $[Fe_2\{\mu\text{-CN}(Me)R\}-(\mu\text{-CO})(CO)\{C(O)R'\}(Cp)_2]$ **4** and $[Fe_2\{\mu\text{-CN}(Me)R\}(\mu\text{-CO})(CO)\{C(O)C\equiv CR'\}(Cp)_2]$ **5**, respectively. With $R \neq Me$ the NMR spectra of type 3–5 derivatives show the presence of two isomers arising from the double-bond character of the μ -C=N group ascertained from the crystal structure of $[Fe_2(\mu\text{-CN}(Me_2)(\mu\text{-CO})(CO)\{C(O)Bu^n\}(Cp)_2]$ **4b**. The structural study reveals the presence of interligand interactions involving the acyl oxygen and the μ - $C=NMe_2$ moiety which is also in accord with an extended-Hückel calculation of the charge distribution.

A number of new C-C bond forming reactions which take advantage of the strong electrophilic character of the bridging carbyne ligand in $[Fe_2(\mu-CR)(\mu-CO)(CO)_2(Cp)_2]^+$ $(Cp = \eta^5 C_5H_5$; R = H or alkyl) have been reported. They are based upon nucleophilic addition that invariably involves the μ -CR unit. By contrast, our studies have shown that carbon nucleophiles react with the thiocarbyne complex [Fe₂(μ-CSMe)(μ-CO)(CO)₂-(Cp)₂]⁺ 1 generating C-C bonds at a number of different sites. These include the C₅H₅ ring² (Grignard reagents), terminal CO³ (thienyllithium and phenylacetylide reagents), and the μcarbyne carbon (reactions with organocopper nucleophiles).3 Moreover nucleophilic attack at CO has been shown 3,4 to promote the formation of another C–C bond via C(O)R⁻–μ-CSMe coupling, affording alkylidene complexes of the type [Fe₂- $\{\mu\text{-C(SMe)C(O)R}\}(\mu\text{-CO)(CO)(Cp)}_2$] (R = H, OEt, CCPh or C₄H₂S).

In view of the fact that C-C bond forming reactions in binuclear transition-metal complexes are of considerable interest as models of related processes occurring on metal surfaces,⁵ we have recently extended our studies⁶ on the reaction of the bridging aminocarbyne complexes [Fe₂{μ-CN(Me)R}(μ-CO)- $(CO)_2(Cp)_2[SO_3CF_3](R = Me 2a, ^7 CH_2Ph 2b^8)$ with 2-thienyllithium. Compounds 1 and 2 are directly related, both presenting relevant π interaction between the bridging carbyne carbon and the adjacent π -donor heteroatom. Synthetic procedures to generate type 2 complexes and some of their spectroscopic features have been reinvestigated. Some reactions of 2 with nucleophiles, mostly directed to replace the CO ligand 9 or give addition at the bridging carbyne carbon, 10 have also been described. Herein we report on the reactions of 2a and 2b with several carbon nucleophiles including organo-magnesium, -copper and -lithium reagents. All give selective addition at the CO or Cp ligands. Together with the spectroscopic characterization, an X-ray crystallographic study of [Fe₂(μ-CNMe₂)(μ- $CO)(CO)\{C(O)Bu^n\}(Cp)_2$ 4b has unambiguously established the molecular structure of the acyl derivative.

Results and Discussion

Addition at the Cp ring

The reactions of complexes 2a and 2b with organolithium

Scheme 1 (i) R'Li or R'MgCl

reagents (LiR') in thf solution at -40 °C result in the formation of the η^4 -cyclopentadiene complexes [Fe₂{ μ -CN(Me)R}(μ -CO)(CO)₂(η^4 -C₅H₅R')(Cp)] (3a–3f) (Scheme 1). These complexes have been isolated after column chromatography in about 70–80% yield, and characterized by elemental analyses and spectroscopic methods.

The IR spectra of type 3 complexes exhibit a $\nu(CO)$ band pattern (e.g. for 3a in CH₂Cl₂: 1959, 1921 and 1771 cm⁻¹) which is consistent with the presence of two terminal and one bridging CO ligand. The stretching vibration of the μ -C-N(Me)R falls in the expected range (1570–1630 cm⁻¹). The absence of the characteristic IR absorption of the cyclopentadiene H-exo atom around 2750 cm⁻¹ suggests that R' addition has occurred at the exo-side of the C₅H₅ ring, as found in related Cp addition reactions.^{3,11} The ¹H NMR spectra of 3 generally show five peaks for the diastereotopic C₅H₅R ring protons (e.g. for 3a: δ 4.61, 4.22, 3.51, 3.43, 3.18). The corresponding C_5H_5R ring carbons show five distinct signals in the ¹³C NMR spectra (e.g. for 3a: δ 88.2, 84.6, 84.4, 70.3, 70.1). Owing to the differences between the Cp and η⁴-C₅H₅R' ligands, the Fe atoms are non-equivalent and the two N-bonded methyl groups in 3a-3c originate separate equally intense singlets. One singlet signal due to the Cp protons is also observed in both the ¹H and ¹³C NMR spectra of compounds 3a-3c [e.g. for 3a: δ 4.66 (¹H) and 85.3 (¹³C)]. These observations indicate that, in spite of the chiral nature of both Fe atoms, the complexes 3a-3c exist as single species in solution, presumably the cis isomer.8,10 By contrast the NMR

 α and β forms

spectra of **3d–3f**, which contain the μ -CN(Me)CH₂Ph ligand, clearly show two unequal sets of resonances, indicating the presence of two isomeric forms. For example the ¹H NMR spectrum of **3d** exhibits two Cp signals, δ 4.73 and 4.64, and two NMe singlets, δ 3.74 and 3.64, of intensity ratio about 5:1. These isomers arise from the different orientations of R and R' with respect to the non-equivalent Fe atoms, caused by restricted rotation around the μ -C=N bond. Analogous isomeric forms have been previously observed in related complexes of the type [Fe₂(Cp)₂LL'(μ -CO){ μ -CN(Me)R}] (L = CO, L' = CNR ⁷ or CN ⁹) and indicated as α and β isomers.

Organomagnesium reagents (R'MgCl, R' = Me or CH₂Ph), like LiR', react with 2 to form the η^4 -cyclopentadiene complexes [Fe₂{ μ -CN(Me)R}(μ -CO)(CO)₂(η^4 -C₅H₅R')(Cp)] (3a, 3g–3i) (Scheme 1). The reactions, that have been carried out in tetrahydrofuran (thf) solution at 0 °C, afforded 3a, 3g–3i, as crystalline solids, in about 50% yield. Although yields are lower than those of the corresponding reactions with LiR, even in this case, type 3 compounds are the only observed reaction products. The spectroscopic properties of complexes 3g and 3h (see Experimental section) are in agreement with those discussed above for 3a–3c. Compound 3i, that differs from 3g in having the unsymmetrically N-substituted μ -CN(Me)CH₂Ph ligand in place of μ -CN(Me)₂, shows the presence, in the NMR spectra, of the α and β isomeric forms (see Experimental section).

Finally it is worth mentioning that a common feature for all complexes 3a–3i is the ^{13}C resonance due to the carbyne carbon of the μ -CN(Me)R ligand, that falls in the typical low-field shifted range around δ 330.

Addition at the CO ligand

Treatment of complexes 2a and 2b, in thf at $-40\,^{\circ}\text{C},$ with $\text{Li}_2\text{Cu}(\text{CN})R'_2,$ affords the acyl complexes $[Fe_2\{\mu\text{-CN}(Me)R\}-(\mu\text{-CO})(\text{CO})\{C(O)R'\}(Cp)_2]$ $(R=R'=Me~\textbf{4a};~R=Me,~R'=Bu^n~\textbf{4b};~R=CH_2\text{Ph},~R'=Bu^n~\textbf{4c})$ which have been isolated in about 70% yield after column chromatography (Scheme 2).

The IR spectra of $4\mathbf{a}-4\mathbf{c}$, in CH_2Cl_2 solution, exhibit one terminal and one bridging carbonyl absorption (*e.g.* for $4\mathbf{a}$ at 1963 and 1773s cm⁻¹, respectively) and a $\nu(COR)$ band at about 1600 cm⁻¹. Two distinct NMR signals, of the same intensity, are expected for the non-equivalent Cp groups of $4\mathbf{a}$ and $4\mathbf{b}$, unless

they are fortuitously coincident. Indeed two signals are shown in the 13 C NMR spectra (e.g. for 4a: δ 89.1, 86.8), but only one, somewhat broad, Cp resonance appears in the corresponding 1 H NMR spectra. Each of the non-equivalent N-bonded methyl groups gives rise to a singlet resonance (e.g. for 4a: δ 4.04 and 4.00). Key spectral features, in the 13 C NMR spectra, are the resonances of the aminocarbyne carbon, at about δ 330 and those attributable to the acyl carbon, around δ 268. The molecular structure of 4b has been determined by an X-ray diffraction study (see later). While 4a and 4b consist of one single isomer in solution, the 1 H NMR spectrum of 4c, containing the bridging amino carbyne ligand μ -CN(Me)CH₂Ph reveals, as expected, two sets of unequal resonances due to the presence of the α and β isomers in about 1:1 ratio.

The reactions between thf solutions of 2a, at -20 °C, and LiC = CR' (R = Ph or p-tolyl) have been investigated. The complexes $[Fe_2\{\mu\text{-CN}(Me)R\}(\mu\text{-CO})(CO)\{C(O)C\equiv CR'\}(Cp)_2]$ $(R' = Ph \ 5a \ or \ p\text{-tolyl} \ 5b)$ have been obtained in about 50% yield as crystalline solids after separation by column chromatography. By contrast with the above described reactions of alkyl- and aryl-lithium, lithium acetylides attack the CO instead of the Cp ligand, behaving like 2-thienyllithium (Lith), which we have found to form the corresponding acyl complex [Fe₂{μ-CN(Me)R}(μ -CO){C(O)th}($CO)_2(Cp)_2$].⁶ The lower basicity (or the softer nucleophilic character) of LiC≡CR' and Lith, compared to the alkyl- or aryl-lithium reagents, should explain why they resemble the organocopper nucleophiles, displaying the same preference for the addition at the CO. The characterization of 5a and 5b has been straightforward since their spectroscopic properties are similar to those of the related complexes 4a and 4b (see Experimental section). The presence of the terminally co-ordinated C(O)C≡CR' group is indicated by the occurrence of infrared absorptions at 2161 [v(C≡C)] and 1573 cm⁻¹ [v(CO)] and by the observation, in the ¹³C NMR, of resonances due to C≡C (δ 91.7, 88.2 for 5a) and C(O) (δ 251.8 for **5a**) in addition to those attributable to the aromatic carbons (usual range δ 140–120).

The reactions of $[Fe_2\{\mu\text{-CN}(Me)R\}(\mu\text{-CO})(CO)_2(Cp)_2]SO_3\text{-}CF_3$ **2a** and **2b** with carbon nucleophiles result in the formation of C–C bonds *via* addition at the C_5H_5 ring (Grignard reagents) or at the carbonyl ligand (organocopper and acetylide reagents). Neither displacement of the CO nor addition at the μ -carbyne carbon has been observed, although the latter are known reactions in diiron aminocarbyne chemistry. Several factors may exert a regio- and stereo-chemical control on the reactions of nucleophiles with metal carbonyl complexes bearing other π -acid ligands, 12 but in our case the site of the nucleophilic attack seems to be determined by the nature of the reagent. Indeed the addition of an alkyl group can be selectively directed to the Cp or carbonyl ligands of **2** simply by using the appropriate Grignard or organocopper reagent, respectively.

The reactivity of 2a and 2b with carbon nucleophiles can be compared with that of the recently reported 3 thiocarbyne 1. The μ -CSMe ligand appears more reactive than μ -CN(Me)R toward the organocopper nucleophiles. In fact $\text{Li}_2\text{Cu}(\text{CN})\text{R}'_2$ reagents are known to attack the bridging thioalkylidyne ligand of 1, affording μ -vinylidene and μ -alkylidene products, 3 whilst, in the case of 2 the addition occurs selectively at the CO ligand leaving the μ -CN(Me)R ligand intact. Such a difference should be the consequence of the stronger π interaction between the carbyne carbon and the adjacent N atom in μ -CN(Me)R compared to μ -CSMe. The strength of this interaction is well documented by a number of structural data (short C=N bond distances in the range 1.28-1.30 Å) 13 and by the absence of free rotation about C=N bond that is responsible for the observed α and β isomeric forms in complexes 3g-3i and 4.

The cationic carbyne complexes **2**, as well as **1**, react with Grignard reagents to give Cp ring addition products, but a significant difference can be envisaged in the relative stability of the complexes $[Fe_2(\mu-CX)(\mu-CO)(CO)_2(\eta^4-C_5H_5R')(Cp)]$ [X =

Scheme 3 (i) R'MgX; (ii) LiCCPh

N(Me)R or SMe] (Scheme 3). Whereas type 3 complexes [X=N(Me)R] are fairly stable, the corresponding thiocarbynes $[Fe_2(\mu\text{-CSMe})(\mu\text{-CO})(CO)_2(\eta^4\text{-}C_5H_5R')(Cp)]$ have been shown 2,3 to undergo hydrogen migration from the $\eta^4\text{-}C_5H_5R'$ ring to the bridging carbyne carbon and generate the alkylidene complexes $[Fe_2\{\mu\text{-C(H)SMe}\}(\mu\text{-CO})(CO)_2(\eta^5\text{-}C_5H_4R')(Cp)]$. The same stability trend has been found in the compounds obtained by nucleophilic attack at the terminal CO of 1 and 2. The μ -aminocarbyne complexes $[Fe_2\{\mu\text{-CN(Me)R}\}(\mu\text{-CO})(CO)\{C\text{-}(O)R'\}(Cp)_2]$ 4 and 5 can be isolated in good yields whilst the corresponding thiocarbynes $[Fe_2\{\mu\text{-CSMe}\}(\mu\text{-CO})(CO)\{C\text{-}(O)R'\}(Cp)_2]$ are supposed reaction intermediates, which finally afford the μ -alkylidene derivatives $[Fe-Fe_3\mu\text{-C(COR')SMe}](\mu\text{-CO})(CO)(Cp)_2]$ via C(O)R'-alkylidyne coupling (Scheme 3). 3,4

The different behavior can be ascribed to several factors. Among them, the double-bond character of the μ -C=N(Me)R interaction mentioned above should result in a less favorable aminocarbyne to aminocarbene ligand conversion with respect to the corresponding thiocarbyne to thiocarbene transformation. Furthermore the co-ordination of the sulfur to the Fe atom plays an important role in promoting the acyl-CSMe migratory coupling that accounts for the transformation of $[Fe_2(\mu\text{-CSMe})(\mu\text{-CO})(CO)\{C(O)CCPh\}(Cp)_2]$ into $[FeFe{\mu-C[C(O)CCPh]SMe}(\mu-CO)(CO)(Cp)_2](Scheme 3)$. The absence of a corresponding μ-CN(Me)R-acyl ligand coupling in complexes 4 and 5 may also be due to the lower tendency of the nitrogen, compared to sulfur, to co-ordinate to the Fe atom. In fact bridging thiocarbene ligands frequently adopt an η^2 co-ordination mode with S-metal interaction, 14 whereas this double bridging co-ordination is very rare among bridging aminocarbene complexes.15

Molecular structure of $[Fe_2(\mu\text{-CNMe}_2)(\mu\text{-CO})(CO)\{C(O)Bu^n\}$ - $(Cp)_2]$ 4b

The molecular structure of **4b** is reported in Fig. 1 and bond lengths and angles in Table 1. Its stereogeometry is consistent with that of the cation of **2a**. The inner diamond Fe₂C₂ is bent around the Fe–Fe bond [2.504(1) Å long] with a dihedral angle of 23.4(1)°. An effect of the attack of the Buⁿ group at one of the terminal CO ligands is the loss of the C_s symmetry of the parent cation and the formation of crystals containing a racemic mixture of asymmetric molecules. The bond parameters in this molecule are strictly equivalent to those found in [Fe₂{ μ -CN(Me)CH₂Ph}(μ -CO)(CO){C(O)C₄H₃S}(Cp)₂],⁶ obtained by reaction of a type **2** cation with thienyllithium. Therefore the rationalization of the electronic structure given for the latter species applies to the present one, *i.e.* the acyl ligand acts as a two-electron anionic ligand and the bridging

CNMe₂ group as a two-electron donor iminium cation. The slight asymmetry of the μ -CNMe₂ ligand [C(4)–Fe(1) 1.843(3), C(4)–Fe(2) 1.877(3) Å] and the strong asymmetry of the μ -CO ligand [C(3)–Fe(1) 1.843(3), C(3)–Fe(2) 2.002(3) Å] are explained by an increased back donation from the more electron rich Fe(1) atom.

Another feature to be commented upon is that the acyl ligands C(O)Buⁿ and C(O)th in the respective molecules have the same orientation around the Fe-C axis with the acyl oxygen pointing towards the iminium ligand. This may indicate that the preferred direction of CO attack by the carbanions is from the less hindered side opposite to the iminium grouping and/or the presence of stabilizing interligand interactions involving the acyl oxygen [O(2)]. An analysis of the non-bonded contacts shows the following distances of atoms in the iminium ligand from O(2): N 3.01, C(4) 2.79, C(5) 4.07, C(6) 3.04, H(2) 3.02, H(3) 2.65 Å, some of these values being shorter than the sum of the van der Waals radii. 16 In addition a comparison of the C(4)-Fe-C angles formed by the C(1) (carbonyl) and C(2) (acyl) atoms [89.4, 87.4(2)°, respectively] indicates that the interactions between O(2) and the iminium atoms are at least not repulsive, otherwise the C(4)-Fe(1)-C(2) angle would have been found to be the wider one.

An extended-Hückel calculation of the charge distribution in the molecule (Table 2) shows, as expected, negative charges localized on the three oxygen atoms with the most negative value on O(2). On the contrary the positive charges are distributed on the iron atoms, and on the carbons connected to both

Table 2 Charges (eV) at relevant atoms in molecule 4b obtained by extended-Hückel calculations

| Fe(1) | +0.224 | C(4) | +0.036 |

oxygen and nitrogen atoms. It is noteworthy that the C(6) and C(4) atoms (+0.085, +0.036 eV, respectively) are at a distance less than the van der Waals radii sum from the acyl oxygen [O(2), -0.373 eV]. This situation indicates a favourable interligand electrostatic interaction.

The Fe(1)–C(2) (acyl) bond length [1.972(3) Å] can be compared to the few analogous values reported so far: 1.964(4) Å in $[Fe_2\{\mu\text{-CN}(Me)\text{CH}_2\text{Ph}\}(\mu\text{-CO})(\text{CO})\{\text{C}(\text{O})\text{th}\}(\text{Cp})_2]^6$ 1.992(8) Å in $[Fe(\text{CO})\{\text{C}(\text{O})\text{Bu}^n\}(\text{Cp})(\text{Ph}_3)]$, ¹⁷ 1.976(6) Å in $[Fe(\text{CO})(\text{CH}_3\text{CO})(\text{Cp})\{\text{Ph}_2\text{PNHCH}(Me)(\text{Ph})\}]$. ¹⁸

Experimental

All the reactions were routinely carried out under nitrogen by standard Schlenk techniques. Solvents were distilled immediately before use under nitrogen from appropriate drying agents. Glassware was oven-dried before use. Infrared spectra were recorded on a Perkin-Elmer 983-G spectrophotometer, ¹H and ¹³C NMR spectra on a Varian Gemini 200. The shiftless relaxation reagent [Cr(acac)₃] (acac = acetylacetonate) was added to solutions studied by ¹³C NMR spectroscopy. Elemental analyses were performed by Pascher Microanalytical Laboratory (Remagen, Germany). All the reagents were commercial products (Aldrich) of the highest purity available and used as received; [Fe₂(CO)₄(Cp)₂] was from Strem. Compounds [Fe₂- $(\mu\text{-CNMe}_2)(\mu\text{-CO})(\text{CO})_2(\text{Cp})_2|\text{SO}_3\text{CF}_3$ 2a⁷ and [Fe₂{ μ -CN-(Me)CH₂Ph}(μ -CO)(CO)₂(Cp)₂]SO₃CF₃ **2b**⁸ were synthesized according to published methods. The species Li₂Cu(CN)R'₂ were prepared from CuCN and the appropriate organolithium reagent according to the literature.19

Syntheses

[Fe₂(μ -CNMe₂)(μ -CO)(CO)₂(C₅H₅Me)(Cp)] 3a. Method a. Methyllithium (0.34 cm³ of a solution 1.5 m in Et_2O) was added to a stirred solution of 2a (0.25 g, 0.47 mmol) in thf (15 cm³) at −40 °C. The solution was then warmed to room temperature, stirred for an additional 30 min and filtered on a Celite pad. Removal of the solvent and chromatography on an alumina column, with CH₂Cl₂-hexane mixture (1:2 v/v) as eluent, gave a green band, which afforded dark green crystals of 3a (0.16 g, 87%) (Found: C, 51.1; H, 5.0. C₁₇H₁₉Fe₂NO₃ requires C, 51.4; H, 4.8%); $v_{\text{max}}/\text{cm}^{-1}$ (CH₂Cl₂) 1959vs, 1921m and 1771s (CO) and 1561mw (C=N); δ_H(CDCl₃) 4.66 (5 H, s, Cp), 4.61, 4.22, 3.51, 3.43, 3.18 (5 H, m, C_5H_5Me), 3.91 (3 H, s, NMe), 3.79 (3 H, s, NMe) and 0.47 [d, J(HH) 6.2 Hz, C_5H_5Me]; $\delta_C(CD_2Cl_2)$ 330.0 (μ-CNMe₂), 266.9 (μ-CO), 222.9, 214.3 (CO), 85.3 (Cp), 88.2, 84.6, 84.4, 70.3, 70.1 (C_5H_5Me), 52.4, 52.1 (NMe) and 29.6 (C_5H_5Me).

[Fe₂(μ-CNMe₂)(μ-CO)(CO)₂(C₅H₅Buⁿ)(Cp)] 3b. Compound 3b was prepared as described for the synthesis of 3a by treating 2a (0.265 g, 0.50 mmol) with LiBuⁿ (0.31 cm³ of a 1.6 M solution in hexane). Yield 0.17 g, 78% (Found: C, 54.6; H, 5.7. C₂₀H₂₅Fe₂NO₃ requires C, 54.7; H, 5.7%); v_{max}/cm^{-1} (CH₂Cl₂) 1958vs, 1920m and 1770s (CO) and 1561mw (C=N); δ_{H} (CDCl₃) 4.66 (5 H, s, Cp), 4.60, 4.24, 3.52, 3.35, 3.20 (5 H, m, C₅H₅Me), 3.90 (3 H, s, NMe), 3.77 (3 H, s, NMe), 1.13–0.68 (9 H, m,

 C_5H_5Bu''); $\delta_C(CD_2Cl_2)$ 330.0 (μ - $CNMe_2$), 267.2 (μ -CO), 222.9, 214.2 (CO), 85.4 (Cp), 88.9, 85.1, 68.8, 68.7, 58.1 (C_5H_5Me), 52.2, 52.1 (NMe), 44.1, 29.1, 23.2 and 14.2 (C_5H_5Bu'').

[Fe₂(μ-CNMe₂)(μ-CO)(CO)₂(C₅H₅Ph)(Cp)] 3c. Compound 3c was prepared as described for the synthesis of 3a by treating 2a (0.238 g, 0.45 mmol) with LiPh (0.25 cm³ of a 1.8 м solution in hexane). Yield 0.17 g, 83% (Found: C, 57.5; H, 4.7. C₂₂H₂₁Fe₂NO₃ requires C, 57.6; H, 4.6%); ν_{max}/cm⁻¹ (CH₂Cl₂) 1962vs, 1925m and 1774s (CO) and 1561mw (C=N); $\delta_{\rm H}$ (CDCl₃) 7.2–6.9 (5 H, m, C₅H₅Ph), 4.70 (5 H, s, Cp), 4.69, 4.60, 4.34, 3.61, 3.39 (5 H, m, C₅H₅Ph), 3.90 (3 H, s, NMe), 3.80 (3 H, s, NMe); $\delta_{\rm C}$ (CD₂Cl₂) 330.1 (μ-CNMe₂), 267.1 (μ-CO), 222.5, 214.4 (CO), 149.2, 128.8, 126.6, 126.3 (C₅H₅Ph), 85.9 (Cp), 89.3, 85.2, 67.7, 67.5, 61.5 (C_5 H₅Ph), 52.7 and 52.6 (NMe).

 $[Fe_2\{\mu-CN(Me)CH_2Ph\}(\mu-CO)(CO)_2(C_5H_5Me)(Cp)]$ 3d. The procedure was the same as that used for the preparation of compound 3a except that 2b (0.32 g, 0.55 mmol) was used instead of 2a yielding 3d (0.21 g, 82%) (Found: C, 58.4; H, 4.9. $C_{23}H_{23}Fe_2NO_3$ requires C, 58.4; H, 4.9%); v_{max}/cm^{-1} (CH₂Cl₂) 1960vs, 1925m and 1788s (CO) and 1518mw (C=N); $\delta_{H}(CDCl_{3})$ (α isomer) 7.52–7.24 (5 H, m, Ph), 5.49 [1 H, d, J(AB) 14, CH_2Ph], 5.22 [1 H, d, J(AB) 14, CH_2Ph], 4.73 (5 H, s, Cp), 4.67, 4.30, 3.53, 3.43, 3.00 (5 H, m, C₅H₅Me), 3.74 (3 H, s, NMe) and0.42 [3 H, d, J(HH) 6 Hz, C₅H₅Me]; (β isomer) 7.52–7.24 (5 H, m, Ph), 5.67 [1 H, d, J(AB) 15, CH₂Ph], 5.43 [1 H, d, J(AB) 15, CH₂Ph], 4.64 (5 H, s, Cp), 4.67, 4.38, 3.53, 3.43, 3.25 (5 H, m, C_5H_5Me), 3.64 (3 H, s, NMe) and 0.50 [3 H, d, J(HH) 6 Hz, C_5H_5Me]; $\alpha:\beta$ isomers ratio $\approx 2.2:1$; $\delta_C(CD_2Cl_2)$ (α isomer) 333.1 (μ-CNMe₂), 266.9 (μ-CO), 223.3, 214.6 (CO), 136.9, 129.8, 128.7, 127.7 (Ph), 85.9 (Cp), 88.9, 85.2, 71.0, 70.5 (C₅H₅Me), 52.7 (NCH₂Ph), 49.8 (NMe) and 29.4 (C_5H_5Me); (β isomer) 333.8 (μ-CNMe₂), 266.3 (μ-CO), 223.3, 214.9 (CO), 136.5, 129.8, 128.7, 127.7 (Ph), 85.8 (Cp), 88.9, 85.2, 71.1, 70.3 (C₅H₅Me), $52.9 \text{ (NCH}_2\text{Ph)}$, 49.9 (NMe) and $29.6 \text{ (C}_5\text{H}_5\text{Me)}$.

[Fe₂{μ-CN(Me)CH₂Ph}(μ-CO)(CO)₂(C₅H₅Buⁿ)(Cp)] 3e. The procedure was the same as that used for the preparation of compound 3b except that 2b (0.28 g, 0.48 mmol) was used instead of 2a yielding 3e (0.17 g, 68%) (Found: C, 60.5; H, 5.8. $C_{26}H_{29}Fe_2NO_3$ requires C, 60.6; H, 5.7%); v_{max}/cm^{-1} (CH₂Cl₂) 1957vs, 1926m and 1786s (CO) and 1519mw (C=N); δ_H (CDCl₃) (α isomer) 7.50–7.18 (5 H, m, Ph), 5.43 [1 H, d, J(AB) 15, C H_2 Ph], 5.24 [1 H, d, J(AB) 15 Hz, C H_2 Ph], 4.73 (5 H, s, Cp), 4.67, 4.30, 3.54, 3.31, 3.02 (5 H, m, C₅ H_5 Buⁿ), 3.71 (3 H, s, NMe), 1.2–0.5 (9 H, m, Buⁿ); (β isomer) 7.50–7.18 (5 H, m, Ph), 5.68 [1 H, d, J(AB) 15, C H_2 Ph], 5.44 [1 H, d, J(AB) 15 Hz, C H_2 Ph], 4.65 (5 H, s, Cp), 4.67, 4.38, 3.54, 3.31, 3.02 (5 H, m, C₅ H_5 Buⁿ), 3.62 (3 H, s, NMe) and 1.2–0.5 (9 H, m, Buⁿ); α:β isomers ratio ≈ 2.5:1.

[Fe₂{μ-CN(Me)CH₂Ph}(μ-CO)(CO)₂(C₅H₅Ph)(Cp)] 3f. The procedure was the same as that used for the preparation of compound 3c except that 2b (0.26 g, 0.45 mmol) was used instead of 2a yielding 3f (0.15 g, 61%) (Found: C, 62.5; H, 4.7. C₂₈H₂₅Fe₂NO₃ requires C, 62.8; H, 4.7%); v_{max}/cm^{-1} (CH₂Cl₂) 1965vs, 1928m and 1776s (CO) and 1520mw (C=N); $δ_H$ (CDCl₃) (α isomer) 7.50–6.90 (10 H, m, Ph), 5.53 [1 H, d, *J*(AB) 15, CH₂Ph], 5.27 [1 H, d, *J*(AB) 15 Hz, CH₂Ph], 4.74 (5 H, s, Cp), 4.60, 4.37, 3.45, 3.21 (5 H, m, C₅H₅Me) and 3.74; (β isomer) 7.50–6.90 (10 H, m, Ph), 5.67 [1 H, d, *J*(AB) 15, CH₂Ph], 5.43 [1 H, d, *J*(AB) 15 Hz, CH₂Ph], 4.66 (5 H, s, Cp), 4.60, 4.42, 3.45, 3.21 (5 H, m, C₅H₅Me) and 3.68 (3 H, s, NMe); α:β isomers ratio ≈ 2.6:1.

[Fe₂(μ -CNMe₂)(μ -CO)(CO)₂(C₅H₅Me)(Cp)] 3a. Method b. Complex 2a (0.18 g, 0.34 mmol) was treated with a slight excess of MeMgCl (0.36 mmol) in thf (20 cm³) at 0 °C. The mixture was then stirred at room temperature for about 30 min and

filtered on an alumina pad. Removal of the solvent under reduced pressure and chromatography on an alumina column with a CH_2Cl_2 -hexane mixture (1:3 v/v) as eluent afforded a brownish green fraction of **3a** (67 mg, 50%).

[Fe₂(μ-CNMe₂)(μ-CO)(CO)₂{C₅H₅(CH₂Ph)}(Cp)] 3g. Freshly prepared PhCH₂MgCl (0.30 mmol) in thf solution (10 cm³) was added to a solution of **2a** (0.14 g, 0.27 mmol) in thf (15 cm³) at 0 °C. Work-up of the reaction mixture as described for the synthesis of **3a** (method b) yielded **3g** (55 mg, 43%) (Found: C, 58.3; H, 4.9. C₂₃H₂₃Fe₂NO₃ requires C, 58.4; H, 4.9%); ν_{max}/cm^{-1} (CH₂Cl₂) 1961vs, 1923m and 1774s (CO), 1561mw and 1537mw (C=N); $\delta_{H}(CDCl_3)$ 7.30–6.90 (5 H, m, Ph), 4.59 (5 H, s, Cp), 4.20, 3.51, 3.42, 3.08 (5 H, m, C₅H₅CH₂Ph), 3.81 (3 H, s, NMe), 3.65 (3 H, s, NMe) and 1.98 (2 H, m, CH₂Ph); $\delta_{C}(CD_2Cl_2)$ 329.8 (μ-CNMe₂), 267.1 (μ-CO), 222.7, 214.3 (CO), 140.5, 129.4, 128.6, 125.9 (C₅H₅CH₂Ph), 85.7 (Cp), 88.8, 85.1, 67.9, 67.8, 59.3 (C₅H₅CH₂Ph), 52.4, 53.2 (NMe) and 51.0 (C₅H₅CH₂Ph).

[Fe₂(μ-CNMe₂)(μ-CO)(CO)₂(C₅H₅Prⁱ)(Cp)] 3h. Compound 3h was prepared as described for 3g by treating 2a (0.24 g, 0.45 mmol) with freshly prepared PrⁱMgCl (0.48 mmol). Yield 96 mg, 47% (Found: C, 54.0; H, 5.5. $C_{19}H_{23}Fe_2NO_3$ requires C, 53.7; H, 5.4%); v_{max}/cm^{-1} (CH₂Cl₂) 1958vs, 1920m and 1770s (CO), 1555mw and 1537mw (C=N); δ_{H} (CDCl₃) 4.67 (5 H, s, Cp), 4.60, 4.28, 3.49, 3.30, 3.04 (5 H, m, $C_{5}H_{5}Pr^{i}$), 3.89 (3 H, s, NMe), 3.76 (3 H, s, NMe) and 0.68 (6 H, m, Prⁱ); δ_{C} (CD₂Cl₂) 330.3 (μ-CNMe₂), 267.8 (μ-CO), 223.0, 214.6 (CO), 85.8 (Cp), 89.2, 85.5, 67.5, 67.3, 65.7 ($C_{5}H_{5}Pr^{i}$), 52.5, 52.4 (NMe), 41.3 and 19.8 ($C_{5}H_{5}Pr^{i}$).

[Fe₂{μ-CN(Me)CH₂Ph}(μ-CO)(CO)₂{C_sH_s(CH₂Ph)}(Cp)] 3i. The complex 3i was prepared as described for the synthesis of 3g by treating 2b (0.35 g, 0.60 mmol) with an equimolar amount of freshly prepared PhCH₂MgCl. Yield 0.15 g, 45% (Found: C, 63.4; H, 5.0. C₂₉H₂₇Fe₂NO₃ requires C, 63.4; H, 4.9%); v_{max}/cm^{-1} (CH₂Cl₂) 1959vs, 1927m and 1786s (CO) and 1518mw (C=N); $δ_{H}$ (CDCl₃) (α isomer) 7.50–6.90 (10 H, m, Ph), 5.35 [1 H, d, *J*(AB) 15, NCH₂Ph], 5.21 [1 H, d, *J*(AB) 15 Hz, NCH₂Ph], 4.71 (5 H, s, Cp), 4.68, 4.32, 3.73, 3.52, 3.08 (5 H, m, C₅H₅CH₂Ph), 3.71 (3 H, s, NMe) and 1.96 (2 H, m, CH₂Ph); (β isomer) 7.50–6.90 (10 H, m, Ph), 5.65 [1 H, d, *J*(AB) 15, NCH₂Ph], 5.39 [1 H, d, *J*(AB) 15 Hz, NCH₂Ph], 4.63 (5 H, s, Cp), 4.68, 4.38, 3.73, 3.52, 3.22 (5 H, m, C₅H₅CH₂Ph), 3.57 (3 H, s, NMe) and 1.96 (2 H, m, CH₂Ph); α:β isomers ratio ≈ 2.2:1.

 $[Fe_2(\mu\text{-CNMe}_2)(\mu\text{-CO})(CO)\{C(O)Me\}(Cp)_2]$ 4a. Compound **2a** (0.21 g, 0.40 mmol) in thf (15 cm³) at -40 °C was treated with a solution of Li₂Cu(CN)Me₂ prepared from dry CuCN (45 mg, 0.5 mmol) and LiMe (1.1 mmol) in thf (10 cm³) at -80 °C. The mixture was then warmed to room temperature and stirred for an additional 30 min. Filtration on a Celite pad and removal of the solvent gave a brown residue that was chromatographed on an alumina column with a CH₂Cl₂-hexane mixture (1:1 v/v) as eluent. A green band was collected and afforded dark green crystals of 4a (0.11 g, 71%) (Found: C, 51.2; H, 4.8. $C_{17}H_{19}Fe_2NO_3$ requires C, 51.4; H, 4.8%); v_{max}/cm^{-1} (CH₂Cl₂) 1963vs, 1773s and 1601m (CO) and 1549mw (C=N); δ_{H} (CDCl₃) 4.71 (10 H, s, Cp), 4.04 (3 H, s, Me), 4.00 (3 H, s, Me) and 2.08 (3 H, s, COMe); $\delta_{C}(CD_{2}Cl_{2})$ 331.0 (μ -CNMe₂), 269.3, 268.0 (μ -CO and COMe), 215.1 (CO), 89.1, 86.8 (Cp), 52.6, 51.4 (NMe₂) and 46.4 (COMe).

[Fe₂(μ-CNMe₂)(μ-CO)(CO){C(O)Buⁿ}(Cp)₂] **4b.** The complex **4b** was prepared as described for the synthesis of **4a** by reacting **2a** (0.30 g, 0.56 mmol) with a slight excess of Li₂Cu(CN)Bu₂. Yield 0.18 g, 75% (Found: C, 54.8; H, 5.7. $C_{20}H_{25}Fe_2NO_3$ requires C, 54.7; H, 5.7%); v_{max}/cm^{-1} (CH₂Cl₂) 1958vs, 1771s and 1599m (CO) and 1544mw (C=N); δ_H (CDCl₃)

4.62 (10 H, s, Cp), 4.06 (3 H, s, NMe), 3.99 (3 H, s, NMe), 2.78–2.48 [2 H, m, $CH_2(CH_2)_2CH_3$], 0.96 [4 H, m, $CH_2(CH_2)_2CH_3$] and 0.68 [3 H, m, $CH_2(CH_2)_2CH_3$]; $\delta_C(CD_2Cl_2)$ 330.9 (μ -CNMe₂), 269.3, 269.2 (μ -CO and COBuⁿ), 215.0 (CO), 88.9, 86.7 (Cp), 59.7, 28.1, 22.8, 14.4 (Buⁿ), 52.5 and 51.2 (NMe).

 $[Fe_{2}\{\mu\text{-CN}(Me)CH_{2}Ph\}(\mu\text{-CO})(CO)\{C(O)Bu^{n}\}(Cp)_{2}]$ Compound 4c was prepared following the same procedure described for the synthesis of 4b except that 2b (0.28 g, 0.48 mmol) was used instead of 2a. Yield 0.19 g, 77% (Found: C, 60.6; H, 5.6. $C_{26}H_{29}Fe_2NO_3$ requires C, 60.6; H, 5.7%); $v_{max}/v_{$ cm⁻¹ (CH₂Cl₂) 1959vs, 1777s and 1610m (CO) and 1524mw (C=N); δ_{H} (CDCl₃) (α isomer) 7.50–7.36 (5 H, m, Ph), 5.82 [1 H, d, J(AB) 15, CH₂Ph], 5.51 [1 H, d, J(AB) 15 Hz, CH₂Ph], 4.77 (5 H, s, Cp), 4.67 (5 H, s, Cp), 3.99 (2 H, s, NMe), 2.91–2.50 [2 H, m, CH₂(CH₂)₂CH₃], 1.08 [4 H, m, CH₂(CH₂)₂CH₃] and 0.76 [3 H, m, $CH_2(CH_2)_2CH_3$]; (β isomer) 7.50–7.36 (5 H, m, Ph), 6.19 [1 H, d, J(AB) 16, CH₂Ph], 5.41 [1 H, d, J(AB) 16 Hz, CH₂Ph], 4.77 (5 H, s, Cp), 4.62 (5 H, s, Cp), 3.92 (3 H, s, NMe), 2.91-2.50 [2 H, m, $CH_2(CH_2)_2CH_3$], 1.08 [4 H, m, CH_2 - $(CH_2)_2CH_3$] and 0.76 [3 H, m, $CH_2(CH_2)_2CH_3$]; $\alpha:\beta$ isomers ratio = 0.9:1; $\delta_C(CD_3CN)$ ($\alpha + \beta$ isomers) 334.6, 333.9 (μ -CNMe₂), 269.4, 269.1, 268.6, 268.0 (μ-CO and COBuⁿ), 215.3, 214.9 (CO), 137.8–127.6 (Ph), 89.2, 87.0, 86.9 (Cp), 70.5, 68.9 (NCH₂Ph), 60.1, 59.9, 28.3, 28.2, 22.9, 14.4 (Buⁿ), 50.3 and 48.5 (NMe).

[Fe₂(μ -CNMe₂)(μ -CO)(CO){C(O)C \equiv CPh}(Cp)₂] 5a. To a stirred solution of 2a (0.22 g, 0.41 mmol) in thf (15 cm³) at -20 °C was added a slight excess of LiC≡CPh (0.45 mmol) freshly prepared from PhC=CH and BuLi. The mixture was stirred for 60 min, warmed to room temperature and then filtered on a Celite pad. Removal of the solvent and chromatography of the residue on an alumina column with a CH₂Cl₂hexane mixture (1:1 v/v) as eluent gave a greenish brown fraction which was collected. Crystallization from CH2Cl2 layered with pentane at -20 °C yielded **5a** (0.11 g, 56%) (Found: C, 59.8; H, 4.7. C₂₄H₂₁Fe₂NO₃ requires C, 59.7; H, 4.4%); v_{max}/ cm⁻¹ (CH₂Cl₂) 1969vs, 1790s and 1573m (CO), 1550mw (C=N) and 2161w (C \equiv C); δ_H (CDCl₃) 7.55–7.29 (5 H, m, Ph), 4.86 (5 H, s, Cp), 4.76 (5 H, s, Cp), 4.10 (3 H, s, NMe) and 4.06 (3 H, s, NMe); $\delta_{C}(CDCl_{3})$ 331.3 (μ -CNMe₂), 266.2 (μ -CO), 251.8 $(COC \equiv)$, 214.8 (CO), 132.5, 129.4, 129.0, 123.5 (Ph), 90.8, 87.0 (Cp), 91.7, 88.2 (C \equiv C), 52.8 and 51.5 (NMe₂).

[Fe₂(μ-CNMe₂)(μ-CO)(CO){C(O)C≡CC₆H₄Me-4}(Cp)₂] 5b. Compound 5b was obtained as described for the synthesis of 5a starting from 2a (0.26 g, 0.48 mmol) and LiC≡CC₆H₄Me-4, freshly generated from 4-ethynyltoluene and BuLi. Yield 0.11 g, 48% (Found: C, 57.0; H, 4.9. C₂₂H₂₃Fe₂NO₃ requires C, 57.3; H, 5.0%); $v_{\text{max}}/\text{cm}^{-1}$ (CH₂Cl₂) 1968vs, 1790s and 1606m (CO), 1571m (C=N) and 2163w (C≡C); $δ_{\text{H}}$ (CDCl₃) 7.42–7.15 (4 H, m, Ph), 4.86 (5 H, s, Cp), 4.77 (5 H, s, Cp), 4.11 (3 H, s, NMe), 4.06 (3 H, s, NMe) and 2.36 (3 H, s, C₆H₄Me); $δ_{\text{C}}$ (CDCl₃) 330.7 (μ-CNMe₂), 267.0 (μ-CO), 251.6 (COC≡), 214.8 (CO), 139.9, 132.5, 129.8, 120.3 (C₆H₄Me), 90.7, 87.0 (Cp), 91.5, 86.9 (C≡C), 52.8, 51.4 (NMe₂) and 21.9 (C₆H₄Me).

Crystallography

Crystal data and details of the data collection for $[Fe_2-(\mu-CNMe_2)(\mu-CO)(CO)\{C(O)Bu^n\}(Cp)_2]$ **4b** are given in Table 3. The diffraction experiments were carried out at room temperature on a fully automated Enraf-Nonius CAD-4 diffractometer using graphite-monochromated Mo-K α radiation. The unit-cell parameters were determined by a least-squares fitting procedure using 25 reflections. Data were corrected for Lorentz and polarization effects. No decay correction was necessary. An empirical absorption correction was applied by using the azimuthal scan method. The positions of the metal atoms

 $^{a}R1 = \Sigma ||F_{0}| - |F_{c}||/\Sigma |F_{0}|$. $^{b}wR2 = [\Sigma w(F_{0}^{2} - F_{c}^{2})^{2}/\Sigma w(F_{0}^{2})^{2}]^{\frac{1}{2}}$ where w = $1/[\sigma^2(F_o^2) + (aP)^2 + bP]$ where $P = (F_o^2 + 2F_c^2)/3$.

were found by direct methods using the SHELXS 86 program²¹ and all the non-hydrogen atoms located from Fourier-difference syntheses. The hydrogen atoms of the methyl group were located from successive Fourier-difference maps and a constraint of equal C-H bonds was applied. The cyclopentadienyl hydrogen atoms were added in calculated positions. The final refinement on F^2 proceeded by full-matrix least-squares calculations (SHELXL 93)²² using anisotropic thermal parameters for all the non-hydrogen atoms. The methyl and methylene H atoms were assigned an isotropic thermal parameter 1.2 times $U_{\rm eq}$ of the carbon atoms to which they were attached. In the final Fourier-difference synthesis the electron density was found in the range -0.54 to 0.88 e $Å^{-3}$.

CCDC reference number 186/758.

Extended-Hückel molecular orbital calculations 23 were carried out on the experimental structure using the modified Wolfberg-Helmholz formula.²⁴ Standard atomic parameters were used for C, O, N and H, while that for Fe was taken from the literature.²⁵ A self-consistent charge calculation was performed assuming a quadratic dependence of H_{ii} on charge.
