(Received 21 August 2006 • accepted 1 November 2006)

**Abstract**—A bubbling fluidized bed reactor was used to study CO<sub>2</sub> capture from flue gas by using a potassium-based solid sorbent, sorbKX35 which was manufactured by the Korea Electric Power Research Institute. A dry sorbent, sorbKX35, consists of K<sub>2</sub>CO<sub>3</sub> for absorption and supporters for mechanical strength. To increase initial CO<sub>2</sub> removal, some amount of H<sub>2</sub>O was absorbed in the sorbent before injecting simulated flue gas. It was possible to achieve 100% CO<sub>2</sub> removal for more than 10 minutes at 60 °C and a residence time of 2 s with H<sub>2</sub>O pretreatment. When H<sub>2</sub>O pretreatment time was long enough to convert K<sub>2</sub>CO<sub>3</sub> of sorbKX35 into K<sub>2</sub>CO<sub>3</sub>·1.5H<sub>2</sub>O, CO<sub>2</sub> removal was excellent. The results obtained in this study can be used as basic data for designing and operating a large scale CO<sub>2</sub> capture process with two fluidized bed reactors.

Key words: Solid Sorbent, Fluidized Bed Reactor, CO<sub>2</sub>, H<sub>2</sub>O Pretreatment

### INTRODUCTION

The concentration of CO<sub>2</sub>, a green house gas, in the earth's atmosphere is increased by combusting fossil fuels to generate electricity. Since Russia ratified the Kyoto Protocol in 2004, research in CO<sub>2</sub> recovery and sequestration has attracted public attention across a variety of industrial fields. Several methods have been suggested for CO<sub>2</sub> recovery, including wet absorption, adsorption, membrane separation, and cryogenic separation. However, these methods need to overcome the limits of cost and energy required to treat the massive flue gas streams from fossil fuel-fired power plants. Recently, CO<sub>2</sub> capture using dry sorbents has been studied as an innovative concept for CO<sub>2</sub> recovery [1-5]. CO<sub>2</sub> is efficiently removed from a flue gas stream by reaction with solid sorbents while regeneration produces an off-gas containing only CO<sub>2</sub> and H<sub>2</sub>O. The condensation of an off-gas generates highly pure CO<sub>2</sub>, which is suitable for chemical feed stock or sequestration. Because solid sorbents are made of cheap alkali metals and carbonated sorbents can be regenerated with heat only from the flue gas stream, the solid sorbent process for CO<sub>2</sub> capture is thought to be cost-effective and energy-efficient. In the solid sorbent process, heat control is important to avoid hot spots generated during the highly exothermic carbonation reaction, and high superficial velocity is necessary to reduce reactor size. To meet these requirements a fluidized bed reactor could be the best candidate for the CO<sub>2</sub> capture process using dry sorbents. The fluidized bed reactor can give high heat and mass transfer rates between gas and particles, remove heat produced during exothermic reaction, maintain isothermal conditions through the

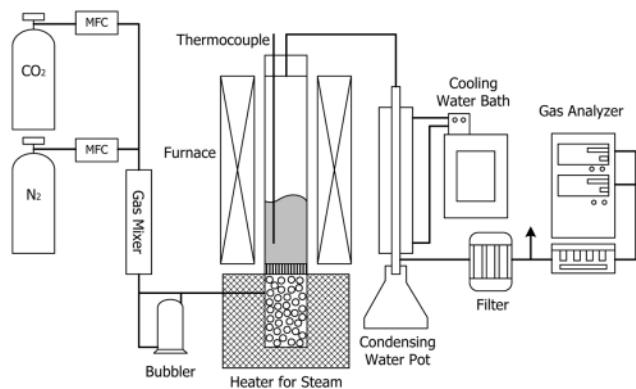

reactor due to rapid mixing and, accordingly, is suitable for large-scale operations [6].

The present work attempts to study the CO<sub>2</sub> capture characteristics and performance of a potassium-based solid sorbent in a bubbling fluidized bed reactor before designing and operating a large scale CO<sub>2</sub> capture process with two fluidized bed reactors. The effect of H<sub>2</sub>O pretreatment on CO<sub>2</sub> removal was closely examined to understand CO<sub>2</sub> capture characteristics of solid sorbent.

### EXPERIMENTAL

#### 1. Material and Apparatus

Fig. 1 shows a schematic diagram of the experimental apparatus, including a bubbling fluidized bed reactor. The apparatus consists of a gas injection part, reactor, gas post-treatment part, and gas analyzer. A reactor with an inner diameter of 0.05 m and a height of 0.8 m was made of quartz and placed inside of a furnace. Reactor temperature was controlled by a furnace and a temperature

controller and measured by thermocouples fitted in the reactor. To prevent an abrupt rise in temperature and to keep the temperature constant, cold air was blown to the reactor during the carbonation reaction. Each gas flow was quantitatively controlled with a mass flow controller (Brooks, Japan) and then provided to the reactor. Reactor product gases first flowed through a condenser to remove  $\text{H}_2\text{O}$ , then passed through a filter to remove dust, and finally, to a gas analyzer (ABB, USA) that can exclusively analyze  $\text{CO}_2$  every 10 seconds.

The solid sorbent, sorbKX35, used in this study was provided by the Korea Electric Power Research Institute (KEPRI). It consists of 35%  $\text{K}_2\text{CO}_3$  for absorption and 65% supporters for mechanical strength. SorbKX35 has a 1.06 g/cm<sup>3</sup> of bulk density, 92.0  $\mu\text{m}$  of mean particle diameter, and 34.9 m<sup>2</sup>/g of BET surface area. Highly pure  $\text{N}_2$  and  $\text{CO}_2$  were supplied by the Special Gas Company (Korea).

## 2. Procedure

Taking the real operation conditions in a large scale fluidized bed reactor into account, 125 g of the sorbent was put into the reactor to maintain a residence time of gas mixture of 2 s and a superficial velocity of 0.03 m/s. To simulate real flue gas composition, a gas mixture of  $\text{CO}_2$  10%,  $\text{N}_2$  77.8% and  $\text{H}_2\text{O}$  12.2% was provided. The  $\text{H}_2\text{O}$  needed for carbonation was fed by passing the  $\text{CO}_2$  and  $\text{N}_2$  through a temperature-controlled gas bubbler, and the feed line was heated to avoid  $\text{H}_2\text{O}$  condensation. The bubbler product was assumed to be saturated with  $\text{H}_2\text{O}$ , which was confirmed by measuring the relative humidity.  $\text{H}_2\text{O}$  pretreatment--meaning that only  $\text{N}_2$  was passed through a gas bubbler and as a result, the sorbent contains certain amount of  $\text{H}_2\text{O}$  before carbonation--was performed with a total flow rate of 2.9 L/min including  $\text{H}_2\text{O}$  to enhance the initial reaction rate. Regeneration was carried out at over 200 °C in  $\text{N}_2$ . At each carbonation, new sorbent calcined at 400 °C was used.

## RESULTS AND DISCUSSION

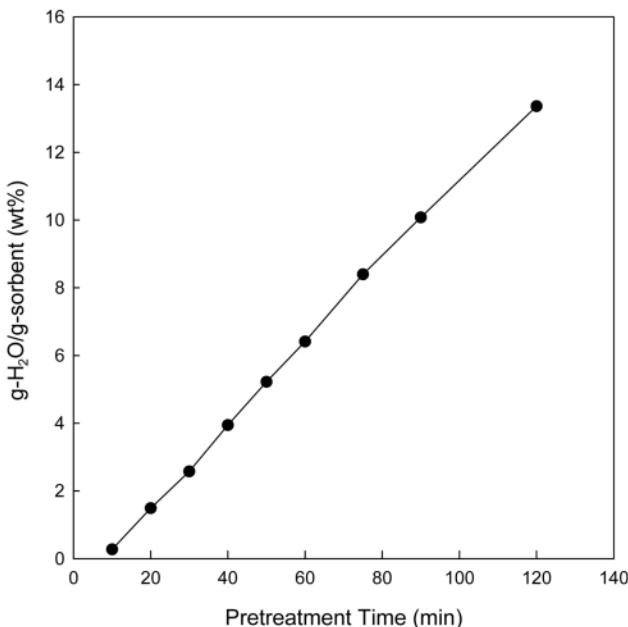

Fig. 2.  $\text{H}_2\text{O}$  content of sorbKX35 according to  $\text{H}_2\text{O}$  pretreatment time (bubbler at 50 °C)

The reaction involved in the  $\text{CO}_2$  capture using dry sorbents is

$$\text{K}_2\text{CO}_3 \cdot 1.5\text{H}_2\text{O} + \text{CO}_2 \leftrightarrow 2\text{KHCO}_3 + 0.5 \text{H}_2\text{O} \quad (1)$$

The reaction is reversible and highly exothermic, so heat control will be an important factor in a commercial system. Therefore, a fluidized bed reactor which has the advantage of heat dissipation can be a good solution for this process.

To increase reactivity of the sorbent during carbonation,  $\text{H}_2\text{O}$  pretreatment was carried out. As can be seen in Fig. 2,  $\text{H}_2\text{O}$  content of the sorbent, expressed as g- $\text{H}_2\text{O}$ /g-sorbent (wt%), was linearly increased with increasing pretreatment time. Theoretical  $\text{H}_2\text{O}$  content to convert all of  $\text{K}_2\text{CO}_3$  of sorbKX35 to  $\text{K}_2\text{CO}_3 \cdot 1.5\text{H}_2\text{O}$  is 6.8%. When 125 g of sorbKX35, which gave residence time of 2 s in the reactor, was used,  $\text{H}_2\text{O}$  pretreatment time of about 60 min was needed to achieve  $\text{H}_2\text{O}$  content of 6.8%. However, because feed gas contains  $\text{H}_2\text{O}$  of 12.2% at the bubbler temperature of 50 °C,  $\text{H}_2\text{O}$  pretreatment of 60 min can give excessive  $\text{H}_2\text{O}$  during carbonation reaction, which can cause agglomeration of the sorbent due to high deliquescence of  $\text{K}_2\text{CO}_3$ .

Fig. 3 shows  $\text{CO}_2$  concentration (dry basis) changes during carbonation and regeneration reactions using sorbKX35 in a bubbling fluidized bed reactor. Carbonation was carried out at 60 °C in 10%  $\text{CO}_2$ , 77.8%  $\text{N}_2$  and 12.2%  $\text{H}_2\text{O}$ , while regeneration occurred at 200 °C in  $\text{N}_2$ . The left part of the figure represents the carbonation reaction and the right part the regeneration reaction. An initial  $\text{CO}_2$  concentration of 0%, corresponding to 100%  $\text{CO}_2$  removal, was continued for about 10 min before increasing abruptly to about 5% and then increased slowly during the rest of carbonation reaction. 100%  $\text{CO}_2$  removal for initial 10 min suggests that sorbKX35 can perform well in a large scale  $\text{CO}_2$  capture process with two fluidized bed reactors.

Fig. 4 represents the effect of  $\text{H}_2\text{O}$  pretreatment time on  $\text{CO}_2$  removal. Without  $\text{H}_2\text{O}$  pretreatment,  $\text{CO}_2$  removal decreased abruptly

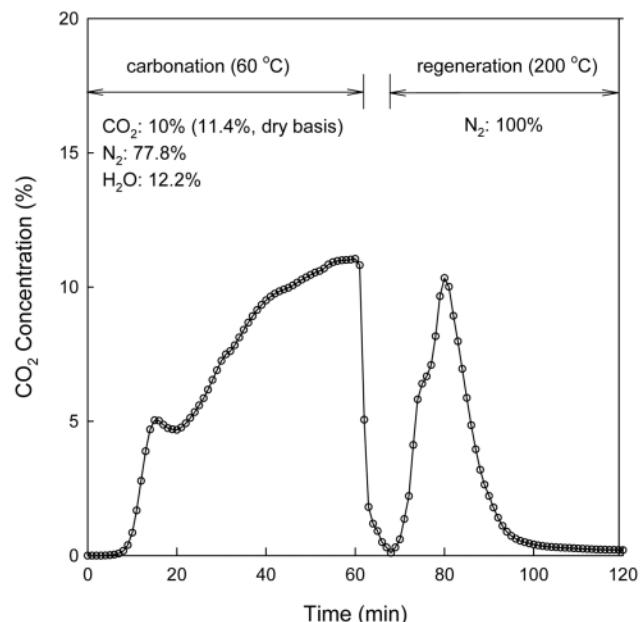

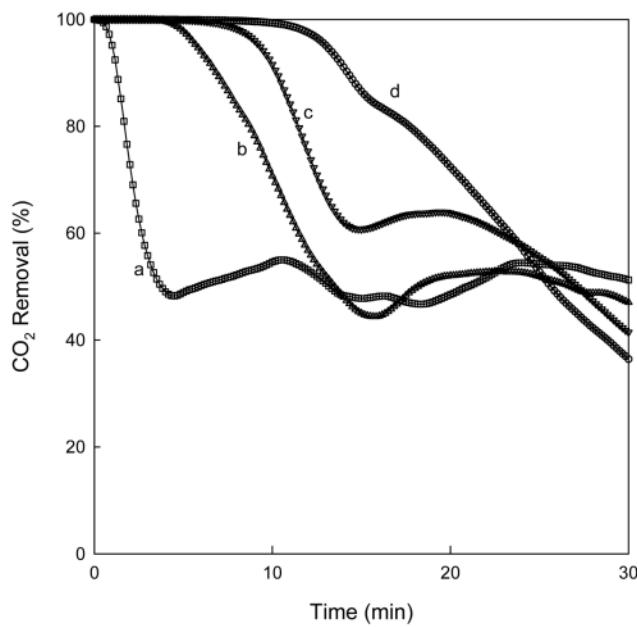

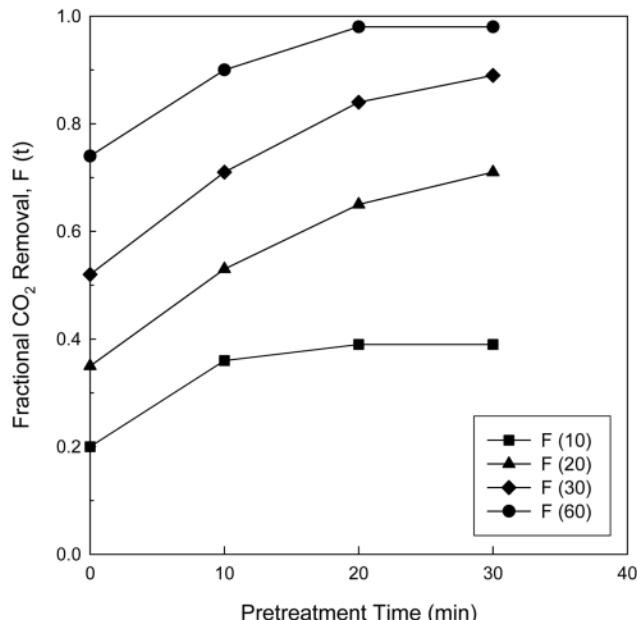

Fig. 3.  $\text{CO}_2$  concentration during carbonation-regeneration cycle ( $\text{H}_2\text{O}$  pretreatment for 20 min before carbonation, bubbler at 50 °C).

**Fig. 4. Effect of  $\text{H}_2\text{O}$  pretreatment time on  $\text{CO}_2$  removal (bubbler at  $50^\circ\text{C}$ , reactor at  $60^\circ\text{C}$ ). a: 0 min; b: 10 min; c: 20 min; d: 30 min.**

from the beginning, whereas with  $\text{H}_2\text{O}$  pretreatment, 100%  $\text{CO}_2$  removal was maintained for about 10 min before monotonic decrease. When feed gas was injected into the reactor without  $\text{H}_2\text{O}$  pretreatment, a residence time of 2 s in the reactor seemed to be insufficient for  $\text{CO}_2$  and  $\text{H}_2\text{O}$  in the feed gas to react with the  $\text{K}_2\text{CO}_3$  of sorbKX35 to form  $\text{K}_2\text{CO}_3 \cdot 1.5\text{H}_2\text{O}$  and further to form  $\text{KHCO}_3$  through carbonation. However, when  $\text{K}_2\text{CO}_3$  of sorbKX35 was converted into  $\text{K}_2\text{CO}_3 \cdot 1.5\text{H}_2\text{O}$  in advance with  $\text{H}_2\text{O}$  pretreatment, the sorbent showed its full performance at such a short residence time.

**Fig. 5. Fractional  $\text{CO}_2$  removal,  $F(t)$ , according to  $\text{H}_2\text{O}$  pretreatment time (bubbler at  $50^\circ\text{C}$ , reactor at  $60^\circ\text{C}$ ).**

SorbKX35 was manufactured by controlling surface area and pore volume to enhance the capability of water sorption and the reactivity.

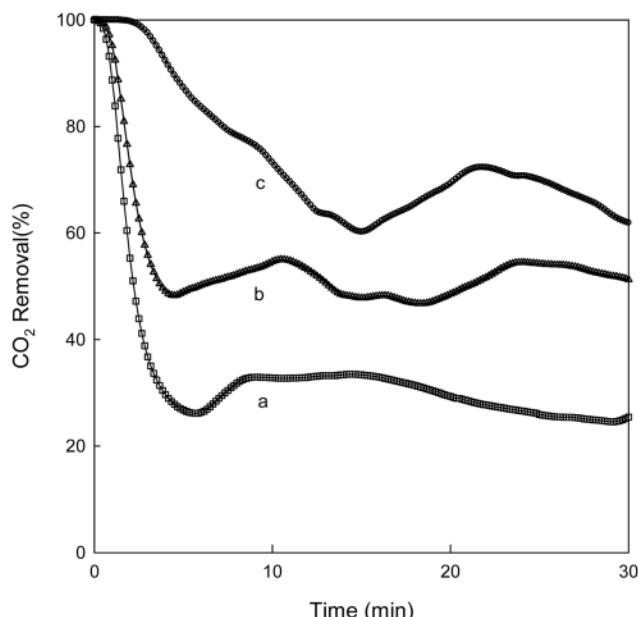

To understand more detailed  $\text{CO}_2$  removal performance with  $\text{H}_2\text{O}$  pretreatment, the results were presented as fractional  $\text{CO}_2$  removal,  $F(t)$ , which is defined as follows:

$$F(t) = \frac{\text{captured } \text{CO}_2 \text{ amount for reaction time } t \text{ [min]}}{\text{theoretical } \text{CO}_2 \text{ capture capacity}} \quad (2)$$

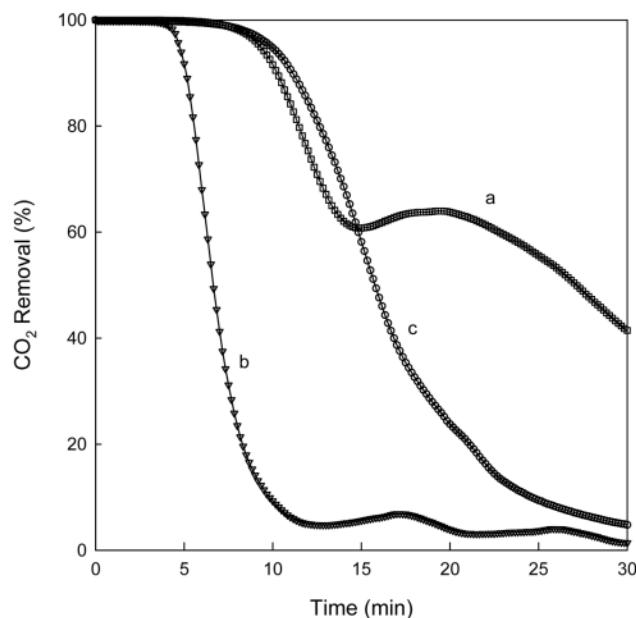

From Fig. 5, as  $\text{H}_2\text{O}$  pretreatment time increases, fractional  $\text{CO}_2$  removal generally increases. However, 20 min  $\text{H}_2\text{O}$  pretreatment appears to be sufficient for reactivity and  $\text{CO}_2$  removal in the initial stage.  $\text{H}_2\text{O}$  pretreatment for a much longer period of time can hinder fluidization of sorbKX35 in a fluidized bed reactor due to agglomeration, so that appropriate  $\text{H}_2\text{O}$  pretreatment time should be selected by considering both the reactivity of sorbent and efficiency of the operation. In a commercial system, the most important factor to increase the initial reaction rate will be the development of the method for supplying  $\text{H}_2\text{O}$  to the reactor sufficiently and effectively.

In Fig. 6, the effect of bubbler temperature on  $\text{CO}_2$  removal was investigated. Without  $\text{H}_2\text{O}$  pretreatment, the amount of  $\text{H}_2\text{O}$  being provided to the reactor was varied by controlling the bubbler temperature. Bubbler temperatures of 40, 50, and  $60^\circ\text{C}$  correspond to 7.3, 12.2, and 19.7%  $\text{H}_2\text{O}$  in the feed gas, respectively. As bubbler temperature increased,  $\text{CO}_2$  removal was generally increased. From Fig. 6, supplying more  $\text{H}_2\text{O}$  during carbonation seems to be favorable for  $\text{CO}_2$  removal. However, from Fig. 4-6, it should be noted that in the reactor of such a short residence time of 2 s,  $\text{H}_2\text{O}$  pretreatment before carbonation is more effective and important than  $\text{H}_2\text{O}$  supply during carbonation to achieve higher  $\text{CO}_2$  removal and to operate the system stably.

As previously mentioned, to convert all of  $\text{K}_2\text{CO}_3$  of sorbKX35 into  $\text{K}_2\text{CO}_3 \cdot 1.5\text{H}_2\text{O}$  through  $\text{H}_2\text{O}$  pretreatment, sorbent should contain  $\text{H}_2\text{O}$  content of 6.8 wt%, which can be obtained by 60 min  $\text{H}_2\text{O}$

**Fig. 6. Effect of bubbler temperature on  $\text{CO}_2$  removal (reactor at  $60^\circ\text{C}$ ). a:  $40^\circ\text{C}$ ; b:  $50^\circ\text{C}$ ; c:  $60^\circ\text{C}$ .**

**Fig. 7. Effect of H<sub>2</sub>O pretreatment on CO<sub>2</sub> removal (bubbler at 50 °C, reactor at 60 °C). a: 20 min pretreatment & reaction with H<sub>2</sub>O; b: 20 min pretreatment & rxn without H<sub>2</sub>O; c: 60 min pretreatment & reaction without H<sub>2</sub>O.**

pretreatment. As can be seen in Fig. 7, the case of 60 min pretreatment and no H<sub>2</sub>O supply during carbonation showed almost the same CO<sub>2</sub> removal for initial 15 min as that of 20 min pretreatment and H<sub>2</sub>O supply during carbonation, while the case of 20 min pretreatment and no H<sub>2</sub>O supply during carbonation showed lower CO<sub>2</sub> removal. If perfect H<sub>2</sub>O pretreatment, meaning perfect conversion of K<sub>2</sub>CO<sub>3</sub> to K<sub>2</sub>CO<sub>3</sub>·1.5H<sub>2</sub>O, was guaranteed, H<sub>2</sub>O supply during carbonation could be minimized.

Although in the present study regeneration occurred in N<sub>2</sub> to quantitatively analyze CO<sub>2</sub> from a reactor, in a commercial process regeneration should be carried out in steam for the produced pure CO<sub>2</sub> stream to be applied in subsequent use or sequestration. The commercial process for CO<sub>2</sub> capture using dry sorbent consists of two fluidized bed reactors. Carbonation occurs at a transport fluidized bed reactor, while regeneration at a bubbling fluidized bed reactor. A carbonated sorbent from a transport reactor is collected in the cyclone and recycled to a bubbling reactor where CO<sub>2</sub> and H<sub>2</sub>O are produced through regeneration. Before the regenerated sorbent is transferred back to the carbonator, the sorbent momentarily stays at a loop seal placed between the carbonator and the regenerator to pretreat sorbent with H<sub>2</sub>O and to cool sorbent to the carbonation temperature for the increased reaction rate in the carbonator. There are several key factors for commercial success of this process. First, attrition-resistant and mechanically strong sorbent should be provided and it should show little or no reduction in initial reaction rate and capture capacity through repeated cycles. Second, carbonation

should be carried out at as low temperature as possible without condensing H<sub>2</sub>O in the flue gas. In addition, heat from exothermic reactions should be well dissipated to keep the carbonation temperature constant. Finally, H<sub>2</sub>O should be effectively injected into the carbonator to increase the initial reaction rate. The results obtained in this study can be used as basic data in designing and operating a CO<sub>2</sub> capture process of a large scale with two fluidized bed reactors.

## CONCLUSIONS

CO<sub>2</sub> capture from flue gas by using a potassium-based solid sorbent was investigated in a bubbling fluidized bed reactor. The sorbent was pretreated with H<sub>2</sub>O before carbonation to increase reactivity and CO<sub>2</sub> removal in the initial stage. Without H<sub>2</sub>O pretreatment, CO<sub>2</sub> removal decreased abruptly from the beginning, whereas with H<sub>2</sub>O pretreatment, 100% CO<sub>2</sub> removal was maintained for about 10 min before monotonic decrease. In the reactor of a short residence time of 2 s, H<sub>2</sub>O pretreatment before carbonation was more effective and important than H<sub>2</sub>O supply during carbonation to achieve higher CO<sub>2</sub> removal and to operate the system stably. The results obtained in this study can be used as basic data for designing and operating a large scale CO<sub>2</sub> capture process with two fluidized bed reactors.
