5,7-Di(4-tert-butylphenyl)-6H-1,4-diazepine-2,3-dicarbonitrile, prepared by condensation of di(4-tert-butylbenzoyl) methane with diaminomaleodinitrile, affords upon template cyclotetramerization in the presence of magnesium(II) butoxide in n-butanol the Mg^{II} complex of octa-4-tert-butylphenyl substituted tetra(1,4-diazepino)porphyrazine. The strong solvent effect on its UV-Vis and ¹H NMR spectral properties is rationalized in terms of dimerization occurring very likely due to intermolecular hydrogen bonding between diazepine nitrogen atoms and water molecules. The monomer is present exclusively only in diluted solutions of aprotic solvents such as dimethyl sulfoxide and dimethylformamide. Addition of water or methanol leads to dimerization. The dimer exists also in pyridine and tetrahydrofuran solutions, as well in benzene and dichloromethane containing residual water or alcohol. The UV-Vis spectrum of the monomer is typical for Mg^{II} porphyrazines and contains a single Q band at ca. 680 nm. In its ¹H NMR spectrum the resonance of the CH₂ protons is not observed at ambient temperatures but appear as a broad signal at 4.4-4.5 ppm above 100 °C, which is characteristic for rapid inversion of the 1,4-diazepine ring in the 6H form. The Q band of the dimer is split into two components (major at 640-645 nm and minor at 680-685 nm). The dimer gives two doublets of the diastereotopic CH₂ protons (5.9-7.1 ppm for the equatorial and 4.8-6.1 ppm for the axial CH₂ protons, depending on the solvent) with characteristic geminal splitting of ca. 11-12 Hz. Formation of the dimer hinders the inversion of diazepine rings and two sharp doublets are observed even above 100 °C.

Keywords: Diazepine annulated porphyrazines, Mg^{II} complex, dimerization, UV-Vis and ¹H NMR spectroscopy.

Previously we have reported on the synthesis and properties of porphyrazines with fused 5,7-phenyl substituted 1,4-diazepinerings-symmetrical tetradiazepinoporphyrazines [Ph₈Dz₄PAH₂] and its metal complexes [Ph₈Dz₄PAM] (M = 2Li, 2Na, Mg, Zn, Cu, Co, Mn)^[1] and low-symmetry monodiazepinotribenzoporphyrazines [Ph₂DzBz₃PAM] (M = 2H, Mg).^[2] The annulated 1,4-diazepine rings can exist in principle either in the diimine (6*H*) or in the enamine (1*H*) form (Scheme 1) and some indications have been obtained that spectral properties of diazepinoporphyrazines might be strongly influenced by 6*H*/1*H* tautomerism.

Scheme 1. 6*H*/1*H* tautomerism of 1,4-diazepines.

The ¹H NMR spectra obtained for [Ph₈Dz₄PAM] and $[Ph_2DzBz_2PAM]$ (M = 2H, Mg, Zn) let us to conclude that the annulated 1,4-diazepine rings in these species are present in the 6H form. In the case of monoannulated species, typically for other 1,4-diazepines,[3] two doublets of the diastereotopic axial and equatorial CH, protons with characteristic geminal splitting of 11-12 Hz were observed at low temperatures, while at elevated temperatures they merge to a singlet due to rapid inversion of the diazepine ring. In contrast to that, in the case of tetraannulated derivatives [Ph_oDz₄PAM] (M = 2H, Mg, Zn) two sharp CH, doublets were observed even at 100°C indicating the rigidity of the diazepine rings in these species to the inversion process. For these species the axial CH, doublet is shifted unusually strong to the low field, and in their UV-Vis spectra the double Q band is observed, which is non-typical for the symmetrical porphyrazine complexes. The reasons of these phenomena remained so far unclear. In order to obtain derivatives with enhanced solubility in organic solvents enabling more detailed ¹H NMR study, in the present work we have prepared 4-tert-butylphenyl substituted derivative, which was isolated as the Mg^{II} aqua complex $[(^{t}BuPh)_{s}Dz_{4}PAMg(H_{2}O)]$ (8) (Scheme 2).

[⊗]Parts 1 and 2 – see Ref. [1a,b].

Scheme 2. Synthesis of [('BuPh)₈Dz₄PAMg(H₂O)] (8).

Experimental

General

UV-Vis spectra were registered on a Hitachi-U2000 spectrophotometer. ¹H NMR spectra were registered on a Bruker Avance 500 MHz instrument in deuterated solvents purchased from Deutero GmbH and were referenced to the residual peak of the corresponding non-deuterated solvent. All chemicals were obtained from Aldrich and used as received. Solvents were distilled prior use.

Synthetic Procedures

tert-Butylacetophenone 2. To a stirred suspension of AlCl₃ (32 g, 0.24 mol) in dry tert-butylbenzene 1 (68.5 g, 0.51 mol) acetic anhydride (25 g, 0.24 mol) was added during 30 min and then heated at 100 °C for further 30 min. Cooled reaction mixture was poured on ice, acidified with conc. aqueous HCl to dissolve aluminium hydroxide; organic products were extracted with diethyl ether and, after vacuum distillation, 2 was obtained as an oil (yield 60 g, 66.5%). MS m/z = 177 ([M+H]⁺). ¹H NMR (CDCl₃) δ ppm: 7.88 (2H, d, Ar*H*), 7.44 (2H, d, Ar*H*), 2.51 (3H, s, C*H*₃) 1.31 (9H, s, 'Bu).

Ethyl tert-butylbenzoate 4. Mixture of 4-tert-butylbenzoic acid 3 (100 g, 0.56 mol), ethanol (46 g, 1 mol), conc. H_2SO_4 (5 ml) in CHCl₃ was refluxed till complete separation of water. After cooling the reaction mixture was washed with water and NaHCO₃ solution, the organic layer was dried with Na₂SO₄ and the ethyl ester distilled under vacuum (yield 105 g, 90.7%). ¹H NMR (CDCl₃) δ ppm: 7.79 (2H, d, ArH), 7.43 (2H, d, ArH), 4.35 (2H, q, CH₂) 1.36 (3H, t, CH₃) 1.31 (9H, s, 'Bu).

Di(4-tert-butylbenzoyl)methane 5. Solution of 2 (17.6 g, 0.1 mol) and 4 (41.3 g, 0.2 mol) in THF (20 ml) was added drop-wise to a stirred suspension of NaH (6 g, 0.15 mol) in anhydrous THF (130 ml) to regulate the gas evolution (ca. 1 h). and then for its completion The reaction mixture was refluxed for further 15 min, cooled, and mixed with acetic acid (10 ml) and ice water (100 ml). Organic layer was separated, combined with ether extracts from the aqueous phase (2×100 ml), and dried over CaCl₂. The red oily residue after vacuum distillation of the solvent was crystallized by mixing with light petroleum and recrystallized from methanol (30 ml) to give 5 as yellow solid (yield - 20.2 g, 60%). ¹ H NMR (CDCl₃) δ ppm: 16.99 (1H, s, OH), 7.94 (2H, d, ArH), 7.54 (2H, d, ArH), 6.86 (1H, s, CH) 1.39 (18H, s, 'Bu).

5,7-Di(4-tert-butylphenyl)-6H-1,4-diazepine-2,3-dicarbonitrile~7. To solution of $\bf 5$ (5 g, 15 mmol) and diaminomaleodinitrile $\bf 6$ (1.6 g, 15 mmol) in anhydrous ethanol (60 ml) P_2O_5 (1.5 g) was added and the mixture was stirred for 1 h. After addition of further P_2O_5 (1.5 g) the mixture was refluxed for 6 h,

then its volume was reduced to 30% by evaporation of the solvent and the precipitate was filtered and washed with ethanol to give 7 as orange crystals (yield 5.77 g, 95%). ¹H NMR (CDCl₃) δ ppm: 7.92 (2H, d, J = 7.6 Hz, ArH), 7.46 (2H, d, J = 7.6 Hz, ArH) 5.73 (1H, d, J = 11 Hz, CH₂), 1.96 (1H, d, J = 11 Hz, CH₂), 1.31 (18H, s, 'Bu).

 Mg^{II} complex, [('BuPh) $_8Dz_4PAMg(H_2O)$], 8. Magnesium metal (15 mg) was completely dissolved in dry butanol (30 ml) in the presence of a catalytic amount of I_2 (2-3 hours). The suspension of magnesium butoxide was cooled, the dinitrile 7 (500 mg, 1.22 mmol) was added and the mixture was refluxed for 5-6 h. The dark green solid obtained after evaporation of the solvent was recrystallized from acetone to give the crude Mg^{II} complex 8 (430 mg, yield 85%). The product was further purified by column chromatography (SiO $_2$, CH $_2$ Cl $_2$) which gave two fractions containing the Mg^{II} complex as differently hydrated forms 8a and 8b.

Mg^{II} complex **8a**. Calc. for C₁₀₈H₁₁₂N₁₆Mg×4H₂O×CH₂Cl₂ (%): C, 72.11; H, 6.77; N, 12.34. Found (%): C, 72.37; H, 6.42; N, 11.82. UV-Vis (CH₂Cl₂) $\lambda_{\rm max}$ nm (lgε): 345 (5.00), 375 (5.01), 589 (4.12), 640 (5.02), 679 (4.81). ¹H NMR (THF- $d_{\rm g}$) δ ppm: 8.22 (16H, d, 3J =7.9 Hz, ArH), 7.41 (16H, d, 3J =7.9 Hz, ArH), 6.04 (4H, d, 2J =12.8 Hz, eq-C H_2) 5.26 (4H, d, 2J =12.8 Hz, ax-C H_2) 1.49 (72H, s, 'Bu). Mg^{II} complex **8b**. Calc. for C₁₀₈H₁₁₂N₁₆Mg×2H₂O (%): C, 76.55; H, 6.90; N, 13.23. Found (%): C, 76.57; H, 6.84; N, 12.49.

Results and Discussion

Synthesis

The dinitrile precursor 7 has been obtained according to Scheme 2 starting from *tert*-butylbenzene 1 and *tert*-butyl benzoic acid 3, which were first converted to *tert*-butylacetophenone 2 and ethyl *tert*-butylbenzoate 4. Their condensation in the presence of NaH affords di(4-*tert*-butylbenzoyl)methane 5, existing in the enol form. Its reaction with diaminomaleodinitrile 6 in anhydrous ethanol provides the dinitrile 7.

Cyclotetramerization of **7** in the presence of magnesium butylate in refluxing *n*-butanol leads to the Mg^{II} complex **8**. It was isolated in two forms **8a** and **8b** obtained in the course of chromatography (SiO₂, CH₂Cl₂) as the 1st major and 2nd minor fractions, respectively. Solid samples obtained from both fractions are differently hydrated species [('BuPh)₈Dz₄PAMg(H₂O)]×3H₂O×CH₂Cl₂ (**8a**) and [('BuPh)₈Dz₄PAMg(H₂O)]×H₂O (**8b**). As is usual for the Mg^{II} complexes of porphyrazines,^[1a] one water molecule is assumed to be axially coordinated.

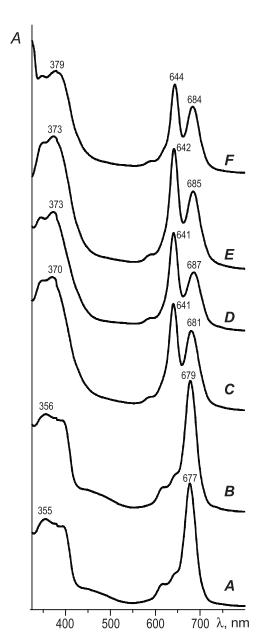

Figure 1. UV-Vis spectra of **8a** in DMF (A), DMSO (B), CH₂Cl₂ (C), THF (D), benzene (E) and pyridine (F). Concentration \sim 5

Spectral Properties of 8a

UV-Vis spectra of **8a** exhibit a strong solvent dependence (Figure 1) indicating that this complex can exist in two spectroscopically different forms (I and II).

The spectra in DMSO and DMF (type I, see Figure 1 spectra A,B) contain a single intense absorption band in the visible region ($\lambda_{max} = 679$ nm in DMSO and 677 nm in DMF) arising due to the lowest π - π * transition of the symmetrical porphyrazine π -chromophore (Q band). The broad Soret band in the UV-region has the main maximum at ca. 355 nm and a shoulder at ca. 400 nm; in addition a broad less intense absorption is observed in the 420-520 nm region. Such spectral pattern is typical for Mg^{II} porphyrazines. Thus, the single Q band for the Mg^{II} complex of octaphenyl substituted porphyrazine [Ph₈PAMg] is observed at 637 nm (in CHCl₃)^[1] and for Mg^{II} octaphenyltetrapyrazinoporphyrazine [Ph₈Pyz₄PAMg] at 655 nm (in pyridine), [2] while the maxima

of the broad Soret bands are located at ca. 370 nm for both species. This indicates that annulated diazepine rings in $\bf 8a$ are stronger involved in the conjugation with the porphyrazine π -chromophore than pyrazine rings in [Ph₈Pyz₄PAMg]. In the case of carbocyclic analog of $\bf 8a-Mg^{II}$ porphyrazine with fused cycloheptatriene fragments [Ph₈(HTr)₄PAMg] - the similar spectrum was observed, but the Q band was located at longer wavelength (713 nm in CHCl₃)^[3] than in $\bf 8a$ having two electronegative nitrogen atoms in each of the seven-member ring.

Unlike the type I spectra observed in DMSO and DMF, the spectra of $\bf 8a$ in $\rm CH_2Cl_2$, THF, benzene, and pyridine (type II, see Figure 1 spectra C-F) contain two bands in the visible region - the more intense band at ca. 640-645 nm (Q band) and the less intense band at 680-690 nm (Q_n band). Similar type II spectra in the same solvents were previously reported for non-*tert*-butylated derivative $[Ph_gDz_4PAMg(H_2O)]$. The more intense visible band was assigned to the porphyrazine π - π *-transition (Q band), while the appearance of the longwave component was connected with the presence of the diazepine ring in the 6H form and out-of-plane direction of the lone pairs of nitrogen atoms enabling the change transfer n- π * transition from the diazepine ring to the porphyrazine macrocycle. [1a]

However, it should be noted that spectra with similar double Q band are typical for bis-porphyrazine complexes having a strong exciton coupling between two adjacent macrocyclic units, e.g. for the sandwich and binuclear complexes of porphyrazines and phthalocyanines. [4,5] Therefore alternatively the type II spectra with a double Q band can be assigned to dimeric form of $\mathbf{8a}$ existing in such solvents as CH₂Cl₂, THF, benzene and pyridine.

It is known that aqua-complexes of Mg^{II} porphyrazines and Mg^{II} phthalocyanines can form dimeric species due to intermolecular H-bonding between and nitrogen atoms of one macrocycle (in the *meso*-positions and in the fused heterocycles) and water molecule coordinated to the Mg atom in the neighbouring macrocyclic unit. This kind of dimerization was observed both in the solid state^[6] and in CHCl₃ solution.^[7] However dissolution in pyridine or addition of methanol, which form H-bonds with the coordinated water molecule or substitute it, leads to monomers with a single sharp *Q* band. This is in contrast to the present species for which the type II spectra with a double *Q* band exist both

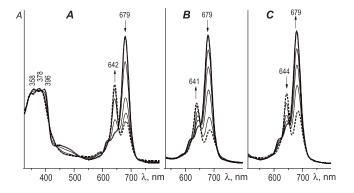

Figure 2. UV-Vis spectra of **8a** in DMSO (bold solid lines) and mixtures of DMSO with MeOH (A), H₂O (B) and pyridine (C). Dashed lines correspond to 50% MeOH (A), 20% H₂O (B), 100% pyridine (C). Thin lines show the intermediate spectra.

in weakly solvating solvents (benzene, $\mathrm{CH_2Cl_2}$, $\mathrm{CHCl_3}$) and in strongly coordinating pyridine. Moreover upon addition of pyridine, methanol or even water to the solution of **8a** in DMSO, the type I spectra with a single Q band is transformed to the type II spectra containing a double Q band (Figure 2). The final spectrum obtained in each case depends on the composition of the binary mixture. Complete conversion to the type II spectrum requires addition of 20% water or 50% MeOH, and occur in 100% pyridine.

¹H NMR spectra of 8a (Figure 3, Table 1) also evidence that depending on the solvent this species can exist in different forms I and II and provide further arguments for their assignment as monomer and dimer, respectively. Spectra in non-coordinating and weakly solvating solvents such as $C_{\epsilon}D_{\epsilon}$ or $CD_{\epsilon}Cl_{\epsilon}$ (Figure 3 B) contain very broad absorption in the aromatic region and evidence about strong association of 8a in solutions with concentration 1-2 mM. Addition of methanol- d_4 (ca. 5%) to a solution of **8a** in C₆D₆ or CD₂Cl₂ leads to a very well resolved spectrum (Figure 3 C). Along with two doublets in the aromatic region (8.0-8.3 and 7.3-7.4 ppm, $^{3}J = 7.9$ Hz) belonging to the *ortho*- and *meta*-phenyl protons and a singlet of the tert-butyl protons at 1.2-1.5 ppm, two doublets are observed at 6.0-6.5 and 4.8-5.4 ppm. They can be unequivocally assigned on the basis of their integral intensity and characteristic geminal splitting ${}^{2}J = 12.2 \text{ Hz}$ to the resonances of the diastereotopic CH, protons in the equatorial and axial positions (eq-CH₂ and ax-CH₂). Similar well-resolved spectra are observed in pure Py- d_s and in THF d_{\circ} (Figure 3 D and E). Such spectral pattern is similar with that observed for the dinitrile precursor 7 (Figure 3 A) and indicates that in these solvents 8a exists as a single form II which have all fused 1,4-diazepine rings in the diimine form (6H tautomer) with equivalent tert-butylphenyl groups.

The solubility of 8a in DMSO and DMF is lower than in CH_2Cl_2 , THF or pyridine. The ¹H NMR spectrum of a saturated solution (~0.1 mM) in DMSO- d_6 indicates the presence of two species (Figure 4 A). The first one contains

singlet of the tert-butyl group at 1.44 ppm and two broad signals of diastereotopic CH, protons at 5.93 and 5.01 ppm. For the other species the signals of *ortho*- and *meta*-protons are observed in a lower field (8.50 and 7.66 ppm); the tertbutyl singlet is at 1.36 ppm and the signal of the CH₂ protons is absent. In the spectrum of diluted solution (0.027 mM, Figure 4 B) the intensity of signals at 8.02, 7.43 and 1.44 ppm characteristic for the type II form is decreased and two resonances of the CH₂ protons practically disappear. It was possible to record the UV-Vis spectrum of this 0.027 mM solution in a thin cuvette (Figure 5 insert C, solid line). It corresponds to a type I form (Q band at 679 nm) with some admixture of the type II form (a small maximum at 640 nm) which disappears completely only in a more diluted solution (0.004 mM, Figure 5 insert C, dotted line). These data show that type I form of **8a** is predominant in the diluted DMSO solutions while in saturated ones it coexists with the type II form.

The positions of the *ortho*- and *meta*-proton resonances for the type I form (8.50 and 7.66 ppm) are similar with the corresponding *ortho*- and *meta*-phenyl resonances in the spectrum of the monodiazepine derivative [Ph₂DzBz₃PAMg] (8.5 and 7.6 ppm in DMSO- $d_6^{(2)}$). The absence of the CH₂ signals corresponding to this set of *tert*-butylphenyl resonances is explained by rapid inversion of the diazepine rings leading to strong broadening of resonances in the spectra measured near the coalescence temperature T_c . Very often 1,4-diazepine derivatives have the T_c value close to ambient temperatures, and resonances of the diastereotopic CH₂ protons can be observed only at low temperatures as two doublets or as a singlet at elevated temperatures.^[3] Indeed, in the case of monodiazepinoporphyrazine [Ph₂DzBz₃PA-Mg(H₂O)] the CH₂ resonances also could not be seen at room

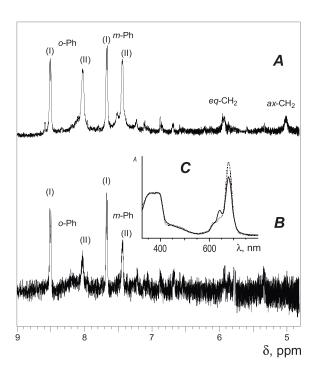

Figure 4. ¹H NMR spectra of **8a** in DMSO- d_6 at 298 K. A - saturated solution (ca. 0.1 mM); B - diluted solution (0.027 mM). The UV-Vis spectrum of this solution is shown in the insert C (solid line) in comparison with the spectrum of 0.004 mM solution (dotted line).

temperature (the coalescence temperature $T_c \sim 265$ K), but can be observed as two doublets below 210 K (6.45 and 2.55 ppm in THF- d_8) and or as a singlet at 4.42 ppm at elevated temperature (363 K in DMSO- d_c).^[2]

For our Mg^{II} complex 8a we have also recorded the ¹H NMR spectra in DMSO- d_6 , in DMF- d_7 and in Py- d_5 at various temperatures. The high temperature spectra recorded in DMSO- d_6 were only of very poor quality in the 3-5 ppm region, probably due to large water content. However, in the spectrum recorded at 393 K there was an indication for the appearance of a new broad signal at ca. 4.4 ppm. The signal of the CH₂ protons under conditions of the rapid inversion of diazepine rings can be better seen in DMF-d₂ at 393 K (Figure 5). This spectrum contains two set of signals - 8.62 and 8.27 ppm for ortho-, 7.67 and 7.50 ppm for meta-phenyl protons, 1.35 and 1.44 ppm for tert-butyl protons indicating that two forms of **8a** (I and II) coexist in a saturated DMF-d_a solution. In addition to the equatorial and axial CH₂ signals of the type II set (6.12 and 5.26 ppm), the broadened signal corresponding to the type I set appears at 4.50 ppm above 370 K. Unfortunately, at low temperatures the solubility in DMF is decreased and strong association occurs. This does not allow us to observe the splitting of this signal in the conditions of a slow ring inversion process.

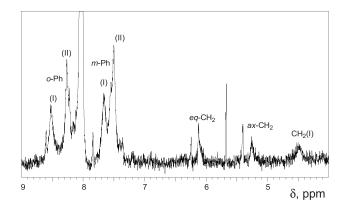

Figure 5. ¹H NMR spectra of **8a** in DMF- d_7 at 393 K (saturated solution).

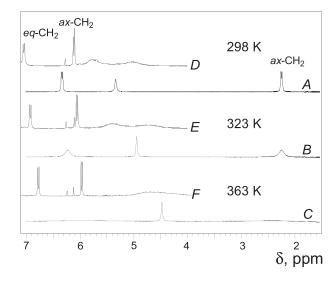

Figure 6. Temperature dependence of the α -CH₂ resonances in the ¹H NMR spectra of **7** (20 mM) (*A-C*) and **8a** (5 mM) (*D-F*) in pyridine- d_s .

We have also studied the influence of temperature on the ¹H NMR spectra of the dinitrile precursor **7** and the Mg^{II} complex **8a** in Py-*d*₅ solutions (Figure 6).

In the case of the dinitrile 7 two doublets of diastereotopic CH₂ protons (2.25 and 6.33 ppm) with characteristic geminal splitting ${}^{2}J = 11$ Hz are observed already at room temperature and disappear upon heating (Figure 6 A-C). Their position is typical for other 1,4-diazepine derivatives having the 6H form, but the coalescence temperature (T_a \sim 363 K in Py- d_s) is higher, which might be connected with electron-withdrawing influence of the CN-groups increasing the rigidity of the diazepine ring to the inversion process. For 5,7-diphenyl-2,3-benzo-1,4-diazepine^[3] in Py- d_s the $T_a \sim 273$ K and two CH₂ doublets observed only upon cooling (2.18 and 5.66 ppm at 223 K) merge to a singlet at elevated temperature (3.80 ppm at 353 K). It is remarkable that for the Mg^{II} complex 8a the doublets of the CH₂ protons are retained sharp in a Py- d_s solution even at elevated temperatures (Figure 6 D-F). Moreover, for 8a the resonances of the equatorial and especially of the axial CH, protons (7.03 and 6.10 ppm in Py- d_s , respectively) are shifted to the low field as compared to the dinitrile 7 (by 0.7 and 3.9 ppm) or other compounds containing 1,4-diazepine ring in the 6H form (e.g. 5,7-diphenyl-2,3-benzo-1,4diazepine or MgII complex of monodiazepinoporphyrazine [Ph,DzBz,PAMg(H,O)]). At the same time the resonances of aromatic protons in the *ortho-* and *meta-*positions of the phenyl rings for the form II of 8a are shifted to the stronger field as compared to the form I and monodiazepine species [Ph,DzBz,PAMg(H,O)].

All these peculiarities that are observed in the ¹H NMR spectra of the form II being in agreement with double Q band in its UV-Vis spectra are indicative about a dimeric nature of this form. One can suppose that the dimer can be formed due to hydrogen bonding between diazepine nitrogens of two neighbouring macrocycles occuring with participation of water and/or other solvent molecules. As can be seen from Table 1 the solvent has a considerable influence on the chemical shifts of the protons in the form II, especially on the position of CH, doublets. Molecular model of the simplest of various possible structures (Figure 7) illustrates that due to steric hindrance between two adjacent parallel macrocyclic units only a single boat shape conformation is possible for all diazepine rings and they should be resistant to the inversion process. Influence of the π -ring currents in the adjacent macrocycle and phenyl rings causes the observed shifts of the proton resonances in the dimeric form II as compared to the

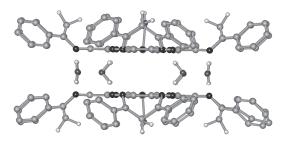

Figure 7. Possible structure of the dimeric form of 8a, obtained by molecular modeling.

monomer I and monodiazepinoporphyrazine [Ph₂DzBz₃PA-Mg(H₂O)]. Very strong down-field shift observed for the resonance of the axial proton of the CH₂ group might indicate that this proton due to its considerable acidic properties is also involved in hydrogen bonding.

The dimer is stable in solvents, which can not compete with the diazepine nitrogens in H-bonding with water molecule (CH₂Cl₂, benzene, THF, pyridine and other similar solvents). However upon dissolution in aprotic solvents such as DMF and DMSO the dimers are destroyed since these solvents, strongly solvating water, "extract" water molecules from the dimeric units. The dimerization occurs again when excess of water is added.

Spectral Properties of Form 8b

The form **8b** obtained as the 2nd minor fraction during chromatography of the crude MgII complex 8, has lesser content of hydrated water. The preliminary spectral study indicates that less hydrated form 8b is most likely a monomer, which is dimerized in the appropriate conditions. Indeed, both UV-Vis and ¹H NMR spectra of **8b** recorded promptly after dissolution in solvents, in which form 8a exists exclusively as a dimer, correspond to the mixture of two species. Thus, the spectrum in CH₂Cl₂ contains in the visible region two bands of almost equal intensity at 643 and 683 nm. In the ¹H NMR spectra in Py-d₅ two set of signals are observed. The minor set (aromatic doublets at 8.65 and 7.16 ppm, CH, doublets at 7.04 and 6.11 and tertbutyl singlet at 1.21 ppm) is similar to the signals observed for 8a (form II). The other set contains aromatic multiplets at 8.4-8.5 ppm and 7.4-7.5 ppm and tert-butyl singlets at 1.14-1.17 ppm.

Conclusions

Mg^{II} complex of tetradiazepinoporphyrazine bearing two tert-butylphenyl groups in each annulated diazepine ring has being prepared. Its UV-Vis and ¹H NMR spectra exhibit a strong solvent dependence, which is interpreted as being due to the presence of dimeric and/or monomeric forms. Evidence has being obtained that hydrated complex exists in the dimeric form which is stable in nonsolvating solvents (CH2Cl2, benzene), in THF and pyridine. The monomeric form exist only in diluted aprotic solvents like DMF and DMSO, while concentrated solutions contain mixture of the monomeric and dimeric forms. Addition of water or methanol to diluted DMSO solution also leads to dimerization. It is supposed that dimerization occurs due to hydrogen bonding between the diazepine nitrogen atoms in the neighbouring macrocyclic units through intermediate water and solvent molecules. Study of the free base macrocycle and complexes with transition metals as well as the preparation of single crystals suitable for X-Ray diffraction study are in progress.
