Introduction

Perfluorinated alkanes are more rigid and, due to their extremely low surface energy, less miscible than the corresponding perhydrogenated alkanes (fluorophobic effect). 1-3 Therefore, a suitable composition of a diblock or triblock low molar mass hydrocarbon containing perfluorinated and perhydrogenated segments produces a microsegregation which is responsible for the formation of highly ordered lamellar thermotropic (S_B)⁴⁻⁸ and lyotropic mesophases. By analogy with low molar mass compounds, alternating microblock copolymers containing perfluorinated and perhydrogenated segments also exhibit a highly ordered S_{B} phase.^{10,11} In addition, the induction^{12,13} and stabilization¹⁴⁻¹⁸ of other LC phases as well as the selfassembly^{19,20} of various architectures which yield LC phases via the semifluorination of various building blocks were subsequently reported from several laboratories. Conceptually, semifluorinated hydrocarbons are the simplest class of materials yielding LC phases, and they still present many unexplored capabilities. The first goal of this note is to report a novel synthetic method for the preparation of alternating multicomponent semifluorinated polyethylene with controlled chain ends. The second goal is to use this method for the rational design of the first semifluorinated polyethylenes which exhibit a nonlamellar thermotropic hexagonal columnar (Φ_h) LC phase.

Experimental Section

Materials. $Pd^0[PPh_3]_4$ was prepared according to a literature procedure. ²¹ 1,5-Hexadiene (98%), 1,7-octadiene (98%), and 1,9-decadiene (98%, all from Aldrich) were distilled from NaBH₄ prior to use. 1,4-Diiodoperfluorobutane (97%) and 1,6-diiodoperfluorohexane (97%, both from PCR) were washed with 5% $Na_2S_2O_3$, dried over MgSO₄, and filtered prior to use. 1,10-Diiodoperfluorodecane (PCR) and Bu_3SnH (97%, Aldrich) were used as received. Toluene was washed with H_2SO_4 until the washes were colorless and then washed with H_2O , dried over MgSO₄, filtered, and distilled from sodium benzophenone ketyl under N_2 . 2,2'-Azobis[isobutyronitrile] (AIBN) was recrystalized from MeOH at 4 °C. Silica gel, 1,1,2-trichlorotrifluoroethane (both from Fisher), and other conventional reagents were used as received.

Methods. ¹H, ¹⁹F (200, 188 MHz respectively) NMR spectra were recorded on a Varian Gemini 200 at 20 °C (except as indicated), with tetramethylsilane (TMS) internal standard for ¹H and fluorotrichloromethane (CFCl₃) internal standard for ¹⁹F. Relative molecular weights of polymers were measured by gel permeation chromatography (GPC) with a Perkin-Elmer Series 10 LC pump, equipped with an LC-100 column oven (40 °C), a UV detector, and Nelson PC Integrator software. A set of two Polymer Laboratories PL gel columns of 5×10^2 and 104 Å and THF eluent at 1 mL min-1 was used. Polystyrene standards were used for calibration. Differential scanning calorimetry (DSC) measurements were recorded on a Perkin-Elmer DSC-7. Indium and zinc were used as calibration standards. Heating and cooling rates were 10 °C min⁻¹. First-order transitions are reported as the maximum of endothermic and minimum of exothermic peaks. Glass transitions were calculated as the middle of the change in heat capacity. An Olympus BX-40 optical polarized microscope (100× magnification) equipped with a Mettler FP 82 hot stage and a Mettler FP 80 central processor was used to verify thermal transitions and characterize anisotropic textures. X-ray scattering patterns were recorded by using either a helium-filled flat-plate wide-angle (WAXS) camera or a pinholecollimated small-angle (SAXS) camera, and also by using an image plate area detector (MAR Research) with a graphitemonochromatized pinhole-collimated beam and a helium tent. The samples, in glass capillaries, were held in a temperaturecontrolled cell (± 0.1 °C). Ni-filtered Cu K α radiation was used.

Synthesis of 3-X/Y/Z(A/B/C)-x/y/z(a/b/c). Method A: 3-6/8/10(33/33/33)-4/6/10(29/29/29). A 25 mL Schlenk tube containing a Teflon-coated magnetic stirring bar was charged with 0.439 g (0.966 mmol) of 1,4-diiodoperfluorobutane, 0.547 g (0.988 mmol) of 1,6-diiodoperfluorohexane, 0.722 g (0.958 mmol) of 1,10-diiodoperfluorodecane, 0.093 g (1.1 mmol) of 1,5hexadiene, 0.124 g (1.1 mmol) of 1,7-octadiene, and 0.152 g (1.1 mmol) of 1,9-decadiene. The mixture was subjected to five freeze-pump-thaw cycles. Pd[PPh₃]₄ was added in two 0.07 g (0.07 mmol) portions, and the mixture was stirred at room temperature until the increase in viscosity caused the stirring to stop (<30 min). The polymer was dissolved in 2 mL of THF and precipitated into 70 mL of MeOH. The crude polymer was then dissolved in 10:1 hexanes/THF and chromatographed on silica gel using a gradient eluent (hexanes to hexanes/THF 100:1) to yield 1.2 g (57%) of a slightly yellow gummy solid. GPC: $M_{\rm n}=7300,~M_{\rm w}/M_{\rm n}=1.8.~^{\rm l}$ H NMR (CDCl₃, TMS, ppm): δ 1.26–2.20 (m, CH₂), 2.59–3.10 (m, CF₂CH₂CHI), 4.34 (m, CF_2CH_2CHI), 4.90-5.18 (m, CH_2 =CH), 5.65-5.91 (m, CH₂=CH). ¹⁹F NMR (CDCl₃, CFCl₃, ppm): δ -113.70 (q, CF_2CH_2CHI , $J_{F-H} = 266.4 \text{ Hz}$, -122.27 (s, $CF_2CF_2CF_2CH_2$), -124.12 (s, $CF_2CF_2CH_2$).

Method B: 3-10/0/0(100/0/0)-4/6/0(50/50/0). This polymerization was carried out according to a literature procedure. 10 A 25 mL Schlenk tube containing a Teflon-coated magnetic stirring bar was charged with 0.626 g (1.12 mmol) of 1,6-diiodoperfluorohexane, 0.508 g (1.12 mmol) of 1,4-diiodoperfluorobutane, and 0.310 g (2.24 mmol) of 1,9-decadiene. The mixture was subjected to five freeze-pump-thaw cycles and placed in an 80 °C oil bath, and 0.295 g (1.80 mmol) of AIBN was added in 0.024 g portions over 3 h. The oil bath temperature was gradually increased to 135 °C during this period. A cold finger was inserted into the Schlenk tube, and the residual AIBN as well as its decomposition products was sublimed under vacuum. The resulting polymer was then dried overnight at 90 °C under vacuum, yielding 1.4 g (93%) of an orange viscous liquid. GPC: $M_n = 10~300$, $M_w/M_n = 2.3$. 1 H NMR (CDCl₃, TMS, ppm): δ 1.26-2.20 (m, CH₂), 2.59-3.10 (m, CF₂CH₂CHI), 4.34 (m, CF₂CH₂CHI), 4.90-5.18 (m,

reaction²² and the Pd(0) single electron transfer (SET) reaction. The SET reaction²³ was successfully used in our laboratory for the synthesis of a large variety of functional semifluorinated building blocks which required very mild reaction conditions. $^{13,18-20}$ Both reactions are performed in bulk. The second step in both reaction procedures consists of the quantitative reduction of iodide groups with $Bu_3SnH.^{10,24}$

Scheme 2 outlines the mechanism of the AIBNinitiated polymerization reaction (method B). This reaction is initiated at 80 °C and requires a high polymerization temperature to produce high conversions. Since the source of radicals (AIBN) is consumed, this polymerization requires a high concentration of initiator. Due to the inability to control the concentration of radicals under these conditions, besides initiation, propagation, iodine transfer, and termination, the undesired chain transfer *via* H-abstraction takes place. The SET Pd(0)-catalyzed reaction (method A) is carried out at room temperature, under very mild reaction conditions, and with an extremely small concentration of radicals which are in dynamic equilibrium with their covalent iodide species. The concentration of radicals in the SET polymerization is controlled by the concentration of the Pd(0) catalyst. By analogy with "living" radical polymerizations initiated via related metalcatalyzed processes,25 chain transfer via H-abstraction is not observed in this polymerization (Scheme 3). In addition, the SET-catalyzed polymerization can be performed either in bulk or in solution. Therefore, a stoichiometric imbalance between the two monomers yields polymers with controlled chain ends. A combination of ¹H and ¹⁹F spectroscopies was used for the characterization of the polymers obtained by both synthetic methods. Figure 1 presents ¹⁹F NMR spectra of selected polymers obtained by SET (method A, spectrum a) and AIBN (method B, spectra b and c)

Scheme 3. Mechanism of Pd(0)-Initiated Single Electron Transfer (SET) Polymerization of α,ω-Diiodoperfluoroalkanes with α,ω-Dienes

methods (assignments are given in the figure), which support the mechanisms outlined in Schemes 2 and 3 and the structure from the top of each spectrum. The olefinic chain ends of these telechelic polymers can be functionalized further via conventional organic reactions. Table 1 lists the characterization data of 3-X/Y/Z(A/B/C)-x/y/z(a/b/c).

Chart 1 depicts the formation of the lamellar S_B phase in binary alternating copolymers and of the Φ_h mesophase in multiblock alternating copolymers generated from dissimilar repeat units. Increasing the number of the repeat units of the binary alternating copolymer to more than two via changing the length of at least one of the two monomers breaks the ability to register fluorinated and hydrogenated blocks into individual layers to form the lamellar S_B phase and consequently yields a Φ_h phase. This synthetic technique was developed and used extensively in our laboratory to generate a Φ_h mesophase in main-chain LC copolymers. This

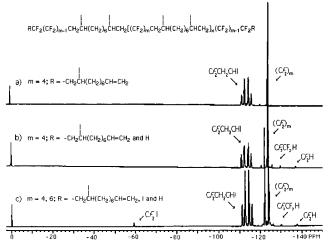

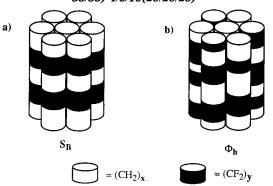

Figure 1. (a) Representative ¹⁹F NMR spectrum of 3-10/0/ 0(100/0/0)-4/0/0(87/0/0) obtained by Pd[PPh₃]₄-initiated polymerization (method A) of 1,9-decadiene with 1,4-diiodoperfluorobutane using an excess of 1,9-decadiene; (b) Representative ¹⁹F NMR spectrum of **3**-10/0/0(100/0/0)-4/0/0(87/ 0/0) synthesized by AIBN-initiated polymerization (method B) of 1,9-decadiene with 1,4-diiodoperfluorobutane using an excess of 1,9-decadiene. (c) Representative ¹⁹F NMR spectrum of 3-10/0/0(100/0/0)-4/6/0(50/50/0) obtained by AIBNinitiated polymerization (method B) using a 1:1 molar ratio of 1,9-decadiene and 1,4-diiodoperfluorobutane, and 1,6-diiodoperfluorohexane.

Chart 1. Schematic Representation of (a) the S_B Phase of $4-6/0/0(100/0/0)-\hat{6}/0/0(100/0/0)$ Copolymer and (b) the Hexagonal Columnar (Φ_h) Phase of 4-6/8/10(33/ 33/33)-4/6/10(29/29/29)

series of experiments has demonstrated the application of this strategy to semifluorinated paraffins. Increasing the number of repeat units from two to three, five, and, respectively, six dissimilar perfluorinated and perhydrogenated segment lengths transforms the S_B phase of the parent binary alternating copolymer to a Φ_h LC phase. The Φ_h phase of these polymers was characterized by a combination of techniques consisting of DSC, X-ray diffraction, and thermal optical polarized microscopy (fan shape texture with homeotropic domains). Table 2 summarizes the characterization data for selected examples of semifluorinated polyethylenes. More detailed investigations of the physical properties of these polymers are in progress and will be presented elsewhere.

Acknowledgment. Financial support by the National Science Foundation (DMR-92-06781 and DMR-91-2227) USA, the Engineering and Physical Science Research Council, UK, and NATO (traveling grant) is gratefully acknowledged.
