(Received July 26, 1990)

The paper reports synthesis of LC derivatives of different chemical classes containing terminal groups $-\text{OCHF}_2$, $-\text{OCF}_3$, $-\text{SCHF}_2$, $-\text{OC}_n\text{F}_{2n+1}$ and $-\text{C}_n\text{F}_{2n+1}$ and indicates their phase transition points and physico-chemical properties.

Keywords: synthesis, physical-chemical properties, fluorinated terminal groups

INTRODUCTION

The overwhelming majority of modern LCDs are based on the twist-effect¹ and require adequate LC materials of positive dielectric anisotropy ($\Delta\epsilon = \epsilon_{\parallel} - \epsilon_{\perp} > 0$). The most common way to obtain LC compounds with light positive $\Delta\epsilon$ is to introduce polar groups such as $-\text{CN}$, $-\text{NCS}$ and F into the terminal position of the LC molecule.

This paper presents synthetic scheme and physico-chemical properties of LC derivatives of different chemical classes containing terminal groups $-\text{OCHF}_2$, $-\text{OCF}_3$, $-\text{SCHF}_2$ and $-\text{OC}_n\text{F}_{2n+1}$ and $-\text{C}_n\text{F}_{2n+1}$.

RESULTS AND DISCUSSION

Experimental

The pyridine derivatives were obtained using the following general synthetic scheme²: diene condensation of the corresponding enamine with 1-acryloyl-4-substituted benzene, followed by reaction of the resulting 3-alkyl-6-(4-P-phenyl)-3,4-dihydro-

2-*N*-pyridine-2H-pyrans with hydroxylamine hydrochloride. Similarly, derivatives of 5,6,7,8-tetrahydroquinoline were prepared. The dioxane derivatives were synthesized by common procedure from corresponding *p*-substituted aldehydes.^{3,4} The pyrimidine derivatives were obtained from corresponding *p*-substituted benzamidine hydrochloride using the general synthetic scheme. The compound's structures were confirmed by NMR analysis. The element analysis proved satisfactory for all derivatives.

Mesomorphic and Physico-Chemical Properties

Procedures for measuring phase transition points, as well as dielectric, optical and viscous properties of liquid crystal compounds, are described in detail in Reference 5. Phase transition temperatures for the synthesized compounds are given in Table I along with clearing points, dielectric anisotropy $\Delta\epsilon$, optical anisotropy Δn and kinematic viscosity ν (at 20°C) obtained by extrapolation from the corresponding values for mixtures with ZLI-1132, as well as the same parameters for some known compounds taken from literature.

As follows from Table I, clearing points for pyridine derivatives of general formula (I) grow depending on the type of the terminal substituent as follows:

Replacement of the $-\text{CN}$ group by $-\text{OCF}_3$, $-\text{OCHF}_2$ or $-\text{SCHF}_2$ results in lower melting points, while introduction of $-\text{C}_n\text{F}_{2n+1}$ and $\text{OC}_n\text{F}_{2n+1}$ leads to a significant growth of clearing points and disappearance of polymorphism.

Table II gives measured values ϵ_{\parallel} , ϵ_{\perp} and $\Delta\epsilon$ for the series $-\text{OCHF}_2$ and $-\text{SCHF}_2$ derivatives belonging to different chemical classes.

In Table III values of dielectric constant $\epsilon_{\text{isotr.}}$ are given measured in the isotropic phase at $T = T_{\text{cl.}}$ for the fifth homolog series of polar derivatives having different chemical structures.

$$\epsilon_{\text{isotr.}} \approx \epsilon_{\text{av.}} = \frac{2\epsilon_{\perp} + \epsilon_{\parallel}}{3}$$

Study of dielectric properties in the isotropic phase allows the increase of number of compared substances by adding nonmesomorphic compounds as well as those having only a smectic phase.

As follows from Tables I–III, for the compounds whose dielectric properties were measured, a correlation with their calculated counterparts is observed permitting us to include in the comparative analysis of dielectric characteristics those liquid crystals for which calculation is the only possible way to evaluate their properties. According to Maier and Meier,⁶ dielectric anisotropy of LCs with polar molecules depends on polarizability of the molecule, magnitude of dipole moment, degree of ordering *S* and angle between dipole moment and axis of maximal polarizability of the molecule. Tables I–III show that for definite chemical structure

20. C_5H_{11} 	5.2

of LC, its dielectric anisotropy as a rule decreases in the same sequence as values of dipole moments for terminal groups —CN, —NCS, —OCHF₂, —OCF₃ and F diminish: 4.05 D, 3.59 D, 2.46 D, 2.36 D and 1.47 D, respectively.^{7,8}

The data given in Table I show that replacement of —CN group by terminal substituents —OCF₃, —OCHF₂, —SCHF₂ or —C_nF_{2n+1} results in lower values of optical anisotropy and kinematic viscosity.

CONCLUSION

The discussed LC compounds with fluorinated terminal substituents represent a new, promising class of liquid crystals whose characteristics allow to consider them as most suitable components to be used for development of liquid crystal materials.
