**ABSTRACT** Absorption spectra and TEM and STM images are observed on C<sub>60</sub> thin films prepared by MBE technique. Superconductivity behaviors of alkali metal-doped single crystals and thin films are also reported.

### INTRODUCTION

Since the first preparation of C<sub>60</sub> molecules,<sup>1</sup> a lot of novel characters of the molecule have been revealed and versatilities for investigation not only on the molecule (Fullerene) but also on the solid state (Fullerite) have been much more increased after the invention of the preparation method for large amount of C<sub>60</sub> material.<sup>2</sup> Moreover, the discovery of superconductivity of potassium-doped C<sub>60</sub> has greatly accelerated the study on the solid state C<sub>60</sub>. In the first report by Hebard et al., thin film of K-doped C<sub>60</sub> as well as powders were proved to show superconducting transition around 18K.<sup>3</sup> Elaborated studies on metal-doped C<sub>60</sub> polycrystalline powders have shown the superconducting transitions for K<sub>3</sub>C<sub>60</sub>, Rb<sub>3</sub>C<sub>60</sub>, Cs<sub>2</sub>RbC<sub>60</sub> and Rb<sub>3-x</sub>Tl<sub>x</sub>C<sub>60</sub> at 19.3, 30, 33 and 42.5K, respectively.<sup>4,5,6</sup>

In this report we show structural features and some optical properties of fullerite films prepared by MBE technique.<sup>7</sup> We also present electrical transport behaviors of alkali metal-doped fullerides single crystals as well as films.

### RESULTS AND DISCUSSION

TEM images of a fullerite film showed epitaxial growth of C<sub>60</sub> crystal on an LiF single crystal of which structure is fcc. The optical absorption spectrum of the fullerite film manifested the appearance of forbidden bands in the molecular state around 450 and 650 nm besides the similar absorption bands in the 200–400 nm region of molecular

absorption.<sup>7</sup> These bands may be assigned to the transition associated with the HOMO-LUMO gap transition. STM image of a monomolecular film of C<sub>60</sub> on an HOPG showed one-dimensional chain structure of molecules. Details of the observation will appear elsewhere.

Furthermore, a deposited film C<sub>60</sub>(~60 nm in thickness) on quartz substrate showed distinct nonlinear optical effect, SHG and THG. There should be some asymmetry in the vertical direction in the film to afford the SHG. A rather high  $\chi^{(3)}$  was also estimated to be  $2 \times 10^{-10}$  esu for the THG.<sup>8</sup>

Alkali metal doping to single crystals or thin films was carried out under various conditions. A single crystal obtained from CS<sub>2</sub> solution was doped with potassium at 200-220°C for 28 hrs and annealed at 230°C for 12 hrs. The resistivity of the crystal before doping was higher than  $10^8 \Omega\text{cm}$  at room temperature, and it was reduced to ~10 m $\Omega\text{cm}$  after doping and annealing. The temperature dependence of the resistivity of this crystal was "metallic" from room temperature to 20 K, and superconductivity transition took place at 19-20 K very sharply.<sup>9</sup> This is the first observation of the metallic behavior on the resistivity measurement so far.

Superconductivity of the K-doped films was also observed at 2-15 K with a little diffuse transition, although there were more difficulties in doping conditions compared with single crystal case. Doping experiments with other alkali metals or other metals are on the way.
