Dehydrocoupling of 2,3,4,5-tetraphenylsilole dihydride 1 with various inorganic hydrides (such as Red-Al, N-Selectride, and super-hydride) produces polysiloles 2 in high yields. The polysiloles emit green light at 520 nm and are electroluminescent at 520 nm.

Keywords: dehydrocoupling; silole dihydride; polysilole; photoluminescence; electroluminescence; green light

INTRODUCTION

Silole is a silicon-containing five-membered cyclic diene, and it attracted considerable attention because of its electronic properties [1] and potential application materials in devices such as light-emitting electron-transporting diodes (LED's) [2]. The high electron-accepting ability of the silole conjugation attributed to the $\sigma - \pi$ arising interaction between the σ -orbital of the σ -bonded silicon atom and the π -orbital of the butadiene moiety of the ring [3-5]. polysiloles are regarded as Silicon-catenated a new class of polysilanes with $\sigma - \pi$ conjugation between the σ -orbital delocalized over the polysilane main chain and the localized on the *cis*-butadiene moiety in every silole ring [6]. West et al. recently prepared polysiloles in about 30% yield from the dehalocoupling of 1,1-dichlorotetraphenylsilole lithium, sodium, and potassium [7]. In this paper we report the effective synthesis and optoelectronic properties of polysilole.

RESULTS AND DISCUSSION

2 have easily synthesized been from the dehydrocoupling of 1 using various hydrides in high yields.

In a typical procedure, to a Schlenk flask containing 1 (0.50 g. 0.29 mmol) in THF (2.00 mL) was injected Red-Al (or Vitride; Na[H₂Al(OCH₂CH₂OMe)₂]) at 25 °C. The reaction immediately turned burgundy with vigorous gas evolution and finally yielded clear orange solution. After 24 hour, the mixture was passed rapidly through a silica gel column (10 x 2 cm) using 100 mL THF as an eluent. Removal of the volatile materials under reduced pressure gave 0.42 g (84% yield) of 2 as light yellow powder. NMR (CDCl₃, 300 MHz, δ ppm): 4.46 (s, SiH), 6.80 - 7.40 (m br, Ph); ¹³C NMR (CDCl₃, 300 MHz, δ ppm): 125.8 - 131.7, 137.0 - 140.0 (m br, Ph); IR (KBr pellet, cm⁻¹): 2130 (ν _{Si-H}); GPC $M_w = 4100$, $M_n = 3900$, $M_w/M_n = 1.1$; UV (THF, λ_{max} nm): 300. Similarly, the dehydrocoupling reactions of 1 with N-selectride and super-hydride were also carried out. The results are summarized in Table 1.

TABLE 1. GPC characterizations for the dehydrocoupling reactions of 1 with hydrides^a

Hydrides ^b	% Mol. wt. ^c			
	Yield	M_w	M_n	M_w/M_n
Red-Al	84	4100	3900	1.1
N-Selectride	82	4800	4000	1.2
Super-Hydride	87	5800	4790	1.2

^a Stirred at 25 °C for 24 h. ^b [Silole]/[Hydride] = 2.0. ^c Determined by GPC in THF (vs polystyrene).

The weight average molecular weights of the obtained polysiloles ranged from 4000 to 5000. These polysiloles have characteristic absorption around 300 nm, assigned to the σ - σ

transition of the Si-Si backbone chain in the UV absorption spectra, and are photoluminescent, emitting green light at 520 nm where the excitation was at 330 nm. Especially, these polymers are strongly electroluminescent around 520 nm. The LEDs (active area: 2.4×3 mm²) were prepared by the spin-coating of 2 on a clean ITO glass plate (resistance: 300 hm/cm^2) and the subsequent vacuum-deposition of an Mg:Ag layer as a cathode at a pressure of 1×10^6 torr. The LEDs were operated at 100μ A pulse current. The EL spectrum and the absorption/photoluminescence spectra of polysilole are shown in Figure 1 and Figure 2, respectively.

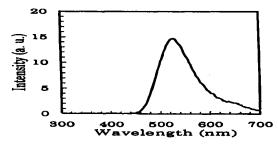

FIGURE 1. Electroluminescence spectrum of 2 at 25 $^{\circ}$ C.

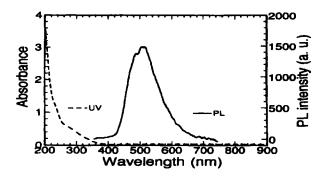

FIGURE 2. Absorption and photoluminescence spectra of 2 at 25 $^{\circ}$ C.
