ABSTRACT: 5-(1-Pyrenyl)-10,15,20-tris(4-methylpyridinium)porphine (H₂PTMPP) having a porphyrin ring and a pyrenyl substituent was synthesized. The compound H₂PTMPP bound to poly(dA)•poly(dT) double helix and poly(dA)•2poly(dT) triple helix in different styles. The results of H₂PTMPP binding to oligonucleotides, dA₁₄•dT₁₄ and dA₁₄•2dT₁₄, was also shown.

In this work, we have synthesized 5-(1-pyrenyl)-10,15,20-tris(4-methylpyridinium)porphine (H₂PTMPP) having a porphyrin ring and a pyrenyl substituent as shown in Fig. 1, and investigated spectrophotometrically interaction of the drug with DNAs such as poly(dA)•poly(dT) and dA₁₄•dT₁₄ double helices and poly(dA)•2poly(dT) and dA₁₄•2dT₁₄ triple helices. The absorption spectra of both drugs, 1.7x10⁻⁵ mol dm⁻³ H₂PTMPP and tetrakis(1-methyl-4-pyridinio)porphine (H₂TMpyP), were shown in Fig. 2. Both spectra showed one absorption peak at the Soret band (around 425 nm) due to the porphyrin ring of H₂PTMPP and H₂TMpyP. The spectrum of H₂PTMPP also showed a small absorption peak around 348 nm, while the peak was not found in the spectrum of H₂TMpyP. It suggests that the peak is due to the pyrene site of H₂PTMPP. Induced CD spectra in the Soret band (400-500 nm) of H₂TMpyP with poly(dA)•poly(dT) and poly(dA)•2poly(dT) were shown in Fig. 3. The concentration of these DNA helices were 1.7x10⁻⁵ mol dm⁻³. These two spectra are similar as an intense positive peak around 430 nm and a small negative peak around 415 nm. Induced CD spectra of H₂PTMPP with poly(dA)•poly(dT) and poly(dA)•2poly(dT)

[†]This paper is dedicated to Dr. Yoshihisa Mizuno on the occasion of his 75th birthday.

FIG. 1. Chemical structures of 5-(1-pyrenyl)-10,15,20-tris(4-methylpyridinium)-porphine (H₂PTMPP) (left) and tetrakis(1-methyl-4-pyridinio)porphine (H₂TMpyP) (right).

FIG. 2. Absorbance spectra of 1.7×10^{-5} mol dm⁻³ H₂TMpyP (left) and H₂PTMPP (right).

FIG. 3. CD spectra of H₂TMpyP (left) and H₂PTMPP (right) with poly(dA)•poly(dT) (—) and with poly(dA)•2poly(dT) (—) in 0.1 mol dm⁻³ NaCl buffer. The concentration of these helices and drugs were 1.7×10^{-5} mol dm⁻³.

under the same condition were also shown in the same figure. The spectrum of H₂PTMPP with poly(dA)•poly(dT) showed an intense positive peak around 450 nm and a negative peak around 430 nm, which is similar to that of H₂TMpyP with the double-helix DNA. On the other hand, the spectrum of H₂PTMPP with poly(dA)•2poly(dT) showed a negative peak around 460 nm and a positive peak around 430 nm, which is very different from that of H₂TMpyP with the triple-helix DNA. Since these induced CD spectra of H₂PTMPP with the double-helix and triple-helix DNAs showed opposite shapes, it is suggested that different binding-styles of H₂PTMPP with these DNAs may be due to the presence or absence of the intercalation of the pyrene site.

In order to get information about the effect of H₂PTMPP on the stability of double-helix and triple-helix DNAs, the melting curves of dA₁₄•dT₁₄ and dA₁₄•2dT₁₄ with/without the drug in 1.0 mol dm⁻³ NaCl buffer were measured. The obtained melting temperatures were listed in Table 1. The melting curve of 3.8×10⁻⁵ mol dm⁻³ dA₁₄•dT₁₄ (1.9×10⁻⁵ mol dm⁻³ per helix) showed one denaturing point at 50.1 °C, while that of 5.7×10⁻⁵ mol dm⁻³ dA₁₄•2dT₁₄ (1.9×10⁻⁵ mol dm⁻³ per helix) showed two melting points at 23.9 and 51.3 °C. The low and high melting temperatures should correspond to dissociations of Hoogsteen and Watson-Crick base pairs, respectively. The melting temperatures of the Watson-Crick base pairs were similar between the double helix (50.1 °C) and the triple helix (51.3 °C), but those of dA₁₄•dT₁₄ and dA₁₄•2dT₁₄ were about 34 °C lower than the obtained melting temperatures (84.0 and 85.6 °C) of the polynucleotides.

The stability of these helices, dA₁₄•dT₁₄ and dA₁₄•2dT₁₄ were greatly influenced by H₂PTMPP. The Watson-Crick base pairs were stabilized by 6.8 °C for dA₁₄•dT₁₄ and 5.4 °C for dA₁₄•2dT₁₄ at the same concentration of described above, indicating the same increments of the melting temperatures. Surprisingly, the melting curve of dA₁₄•2dT₁₄ showed only one melting point as well as the double helix. It suggests that the Hoogsteen base pairs of dA₁₄•2dT₁₄ may be dissociated by H₂PTMPP. It was reported that ethidium affected a certain 22-mer nucleotide to destabilize Hoogsteen base pairs but stabilize Watson-Crick base pairs.¹⁾ In this study, the addition of H₂PTMPP to dA₁₄•dT₁₄ and dA₁₄•2dT₁₄ also showed that Hoogsteen base pairs of dA₁₄•2dT₁₄ were destabilized while Watson-Crick base pairs were stabilized by the drug. It is supposed that the weak Hoogsteen base pairs of dA₁₄•2dT₁₄ were dissociated by H₂PTMPP and the drug tends to bind to the double helix of dA₁₄•dT₁₄. Thus, it was suggested that the drug H₂PTMPP synthesized in this work has a possibility of distinguishing the double helix and the triple helix of the DNAs.

Table 1. Melting temperatures ($^{\circ}\text{C}$) of $\text{dA}_{14}\cdot\text{dT}_{14}$ and $\text{dA}_{14}\cdot 2\text{dT}_{14}$ in 1.0 mol dm^{-3} NaCl-phosphate buffer in the presence and absence of H_2PTMPP

	$\text{dA}_{14}\cdot\text{dT}_{14}$	$\text{dA}_{14}\cdot 2\text{dT}_{14}$	
	Watson-Crick base pair	Watson-Crick base pair	Hoogsteen base pair
without H_2PTMPP	50.1	51.3	23.9
with H_2PTMPP	56.9	56.7	< 0

EXPERIMENTAL

Materials. 5-(1-pyrenyl)-10,15,20-tris(4-pyridyl)porphine (H_2PTPP) iodide was prepared by condensation of mixtures of pyridine-4-carboxaldehyde and 1-pyrenecarboxaldehyde with pyrrole. Crude H_2PTPP was purified by column chromatography eluted with dichloromethane/methanol 97:3. H_2PTPP (Mw: 741.86) was methylated by methyl iodide. Crude 5-(1-pyrenyl)-10,15,20-tris(4-methylpyridinium)porphine (H_2PTMPP) iodide thus obtained was dried under vacuum. Pure H_2PTMPP (Mw: 1187.68) was obtained by precipitation from methanol (14.7 % yield based on 1-pyrenecarboxaldehyde used here). The structure was established by UV-Vis, NMR, and mass spectrometry.²⁾ Tetrakis(1-methyl-4-pyridinio)porphine (H_2TMpyP) were purchased from Dojin Chemical Co. and used without further purification.

Polynucleotides, poly(dA) and poly(dT), were obtained from Pharmacia. Shorter deoxyribonucleotides, dA_{14} and dT_{14} , were synthesized with a phosphoramidite method on an Applied Biosystems model 391 DNA/RNA synthesizer. The cleavage and deblocking of the synthesized oligomers were done by a treatment with a concentrated ammonia at $50\text{ }^{\circ}\text{C}$ overnight. After the detritylation, the oligonucleotides were purified by a high-performance liquid chromatography (HPLC).

All solutions were prepared in a buffer consisting of $10\text{ mmol dm}^{-3}\text{ Na}_2\text{HPO}_4$ and $1.0\text{ mmol dm}^{-3}\text{ Na}_2\text{EDTA}$. Each buffer solution was adjusted to the desired Na^+ concentration by adding NaCl and followed by adjustment of the pH to 7.0. Concentrations of the nucleic acids, H_2PTMPP , and H_2TMpyP were determined spectrophotometrically using the following extinction coefficients; $\epsilon_{259} = 6000\text{ mol dm}^{-3}\text{ cm}^{-1}$ for poly(dA)•poly(dT),³⁾ $\epsilon_{260} = 8100\text{ mol dm}^{-3}\text{ cm}^{-1}$ for poly(dT),³⁾ $\epsilon_{260} = 114000\text{ mol dm}^{-3}\text{ cm}^{-1}$ for dA_{14} ,⁴⁾ $\epsilon_{260} = 171000\text{ mol dm}^{-3}\text{ cm}^{-1}$ for dT_{14} ,⁴⁾ $\epsilon_{422} = 120000\text{ mol dm}^{-3}\text{ cm}^{-1}$ for H_2PTMPP ,²⁾ and $\epsilon_{424} = 226000\text{ mol dm}^{-3}\text{ cm}^{-1}$ for

H₂TMpyP.⁵⁾ For a preparation of DNA double and triple helices, pyrimidine strands and purine strands were mixed to 1:1 or 2:1 molar ratio in an appropriate buffer.

Absorbance measurements. Absorbance measurements were done with Hitachi U-3200 and U-3210 spectrophotometers. Absorbance vs. temperature UV melting curves were measured at 260 nm on these spectrophotometers equipped with Hitachi SPR-10 thermoprogramers. The melting temperatures (T_m) were measured for the DNA double and triple helices without or with an equimolar concentration of the drugs. The heating rate was 0.2 or 0.5 °C/min. The cuvette-holding chamber was flushed with a constant stream of dry N₂ gas to avoid water condensation on the cuvette exterior at the low temperature range.

Circular dichroism measurements. Circular dichroism (CD) measurements were carried out on a Jasco J-600 spectropolarimeter equipped with a temperature control unit. Wavelengths were scanned from 500 to 200 nm and CD spectra were recorded at 5°C. The cuvette-holding chamber was flushed with a constant stream of dry N₂ gas.
