ABSTRACT

6,7-Dehydrostipiamide has been synthesized in 23% yield in 15 steps in the longest linear sequence through the application of the Zr-catalyzed asymmetric carboalumination and the Pd-catalyzed organozinc cross-coupling in addition to the Brown crotylboration, the Corey-Peterson olefination, and the Corey-Fuchs reaction for carbon-carbon bond formation.

We report herein an efficient and selective synthesis of 6,7-dehydrostipiamide¹ (**1**), a nonnatural multidrug resistance reversal agent of high potency and low toxicity, in 23% yield over 15 steps in the longest linear sequence. Of the eight crucial carbon-carbon bond-forming steps in the synthesis, three employed Pd-catalyzed organozinc cross-coupling reactions,² while two single bonds to the asymmetric carbon

centers, i.e., C12 and C16, were constructed by using recently developed Zr-catalyzed asymmetric carboalumination³ and Brown crotylboration,⁴ respectively. Both of the trisubstituted alkenes at C10 and C14 were constructed through the use of the Corey version of the Peterson olefination (Corey-Peterson olefination hereafter),⁵ while introduction of C8 was

[†] We wish to dedicate this paper to the memory of Professor S. Masamune.

Scheme 1^a

^a Reagents and conditions: (a) (i) Me_3Al (2 equiv), 5% (+)-(NMI) $_2\text{ZrCl}_2$, IBAO (1 equiv); (ii) O_2 ; 85%. (b) $(\text{COCl})_2$, DMSO. (c) (i) $\text{Et}_3\text{SiClLiMeCH=NCy}$, THF, -20°C ; (ii) $\text{CF}_3\text{CO}_2\text{H}$, 0°C ; 81%. (d) (+)- $\text{lpc}_2\text{BCH}_2\text{CH=CHCH}_3$ -(E), THF-ether, -78°C , 15 h, 80%.

achieved by the Corey–Fuchs reaction.⁶ 6,7-Dehydrostipiamide,¹ as well as structurally related natural products, including stipiamide (phenalamide A₁) (2),^{1,7} phenalamide A₂ (3),⁸ and myxalamide A (4),⁹ have been synthesized since 1997. With the exception of asymmetric crotylboration, however, none of the carbon–carbon bond-forming reactions mentioned above have been employed in previously reported syntheses.

The preparation of a key intermediate **5** corresponding to the C11–C18 moiety was achieved only in four steps from 4-phenyl-1-butene in 55% overall yield, as summarized in Scheme 1. The Zr-catalyzed asymmetric carboalumination³ of 4-phenyl-1-butene with Me_3Al (2 molar equiv), 5 mol % (+)-(NMI) $_2\text{ZrCl}_2$,¹⁰ where NMI is 1-neomenthylindenyl derived from (+)-menthol, and isobutylaluminumoxane^{3e} (IBAO), prepared by the reaction of 1 molar equiv each of $t\text{Bu}_3\text{Al}$ and H_2O , in CH_2Cl_2 at 0°C produced, after oxidation with O_2 , (2*S*)-2-methyl-4-phenyl-1-butanol¹ (**6**) in 85% yield and 78% ee. Although the Mosher ester analysis¹¹ of **6** indicated an approximately 80% ee for **6**, signal overlappings in ^1H NMR spectra did not permit an accurate measurement of enantioselectivity for this case. So, **6** was oxidized by Swern oxidation¹² (96% yield) and then converted to the corresponding carboxylic acid with KMnO_4 – KH_2PO_4 in aqueous $t\text{BuOH}$ ¹³ (70% yield). The resultant carboxylic acid was treated with both *R* and *S* isomers of α -(1-aminoethyl)-

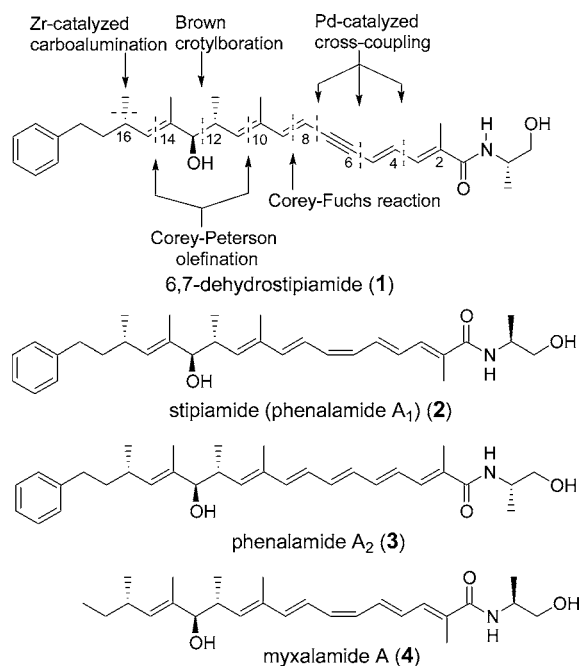

Figure 1.

naphthalene, $\text{NCPO}(\text{OEt})_2$, and NEt_3 in DMF;¹⁴ the carboxamide thus obtained in 92% yield was analyzed by GLC and NMR spectroscopy, both of which indicated an enantiomeric excess of 78%. The results presented above have also confirmed that little or no racemization occurs in the Swern oxidation step.

After Swern oxidation of **6**, the crudely obtained aldehyde was subjected to the Corey–Peterson olefination with a reagent generated in situ by treating *N*-cyclohexyl(2-triethylsilylpropylidene)imine with $t\text{BuLi}$ at -78°C .⁵ After treatment with CF_3COOH , the desired aldehyde **7** of $>99\%$ *E* was obtained in 81% yield. We initially converted **6** into **7** in four steps. Following the Swern oxidation of **6** as stated above, the Corey–Fuchs reaction,⁶ followed by conversion of the 1,1-dibromo-1-alkene thus formed into the corresponding methylalkyne (92% yield based on **6**), and subsequent hydrozirconation and carbonylation with $t\text{BuNC}$ ¹⁵ (87% yield) provided **7** in 80% combined yield from **6**. Clearly, the route shown in Scheme 1 is more efficient than either that described above or that involving the Horner–Emmons olefination reported previously.¹

Brown's asymmetric crotylboration⁴ of **7** using (+)-(*E*)-(CH₃CH=CHCH₂)BIPC₂ produced the desired **5** in 80% yield. The ^1H NMR spectra of the crude product obtained without isomeric separation revealed only two sets of doublets at 3.70 (d, $J = 8.7$ Hz) and 3.86 (d, $J = 7.2$ Hz) for the methine proton at C4 in ratio of $\geq 30:1$. Evidently, the configuration at C7 exerts little or no effect on the ^1H NMR signals for protons bonded to C3 and C4. The 3*R*,4*R*

Scheme 2^a

^a Reagents and conditions: (a) TBSCl, DMAP, imidazole. (b) AD-mix- α . (c) NaIO₄; 90% (over three steps); (d) (i) Et₃SiClLiMe-CH=NCy, THF, -20 °C; (ii) CF₃CO₂H, 0 °C; 80%. (e) CBr₄, PPh₃, Zn. (f) ⁿBuLi; (ii) NH₄Cl; 90%.

configuration may be tentatively, but safely, assigned to the major isomer on the basis of the use of (+)-(*E*)-(CH₃CH=CHCH₂)BIpc⁴ and the diastereomeric ratio of $\geq 30:1$ mandates that the configuration at both C3 and C4 is $\geq 97\%$ *R*.

Although the *S* and *R* configurations at C7 were indistinguishable by ¹H NMR spectroscopy (vide supra), ¹³C NMR spectra of crudely isolated **5** showed two sets of signals separated by at least 0.1 ppm for eight carbon atoms, including C7 (δ 31.79 (*S*) and 31.96 (*R*), *S*:*R* = 9:1). Column chromatography (silica gel, 1/25 ethyl acetate/hexanes) provided **5** ($\geq 80:1$ dr) in 80% yield from **7**. Thus, the stereoisomeric purity at C7 was improved to $\geq 99\%$ *S* by simple chromatography, and the overall enantiomeric purity of **5** may safely be estimated to be >99.9% ee.

Conversion of **5** into another key intermediate **8** was achieved in seven steps in 56% combined yield. Protection of **5** with ^tBuMe₂SiCl (TBSCl) proceeded in 96% yield, and the resultant product was converted to aldehyde **9** by two successive oxidations; first with AD-mix- α ¹⁶ (Aldrich), and then with NaIO₄, as reported previously,¹ in 94% combined yield. Conversion of **9** into **10** was achieved by using the Corey–Peterson olefination in 80% yield (>99% *E*). The Corey–Fuchs reaction⁶ of **10** with CBr₄, PPh₃, and Zn (98% yield), treatment of the product with ⁿBuLi followed by acidification to give **11** (92% yield), and its hydrozirconation–iodinolysis (86% yield) provided **8** as a $\geq 99\%$ isomerically pure compound (Scheme 2).

In the previously reported synthesis of stipiamide and 6,7-dehydrostipiamide,¹ **10** was directly converted to **8** by the reaction of **10** with CHI₃ and CrCl₂¹⁷ in 70% yield. It reduces the number of steps by two but also reduces the yield by 7%. In our hands, an *E*/*Z* ratio of approximately 5 was observed, and a concern about the scalability of the process was also expressed.¹ We also investigated the applicability

of a tandem alkynylation–methylation reaction of 1,1-dibromo-1-alkenes, recently reported by us.¹⁸ To this end, aldehyde **9** was subjected to the Corey–Fuchs reaction⁶ (98% yield). The product was first alkynylated with BrZnC \equiv CSiMe₃ in the presence of 5% Cl₂Pd(DPEphos), where DPEphos is bis(*o*-diphenylphosphinophenyl) ether, and 10% DIBAL-H in 75% yield; subsequent methylation with Me₂Zn in the presence of Pd(^tBu₃P)₂ in quantitative yield, followed by desilylation with K₂CO₃ and MeOH (98% yield), gave **11** (>98% stereoisomerically pure) in 72% combined yield over three steps from **9**. The combined yield indicated above is the same as that shown in Scheme 2. We judge that the two procedures are of comparable merits.

For a convergent final assembly of the carbon framework of 6,7-dehydrostipiamide, ethyl (2*E*,4*E*)-2-methyl-2,4-heptadien-6-ynoate (**12**) was prepared, as recently reported by us.¹⁹ Thus, (*E*)-1-bromo-4-trimethylsilyl-1-buten-3-yne,²⁰ obtained in 81% yield by treating commercially available (Aldrich) (*E*)-ICH=CHBr with Me₃SiC \equiv CZnBr in the presence of 2% Pd(PPh₃)₄, was successively treated with ^tBuLi (2.0 equiv) in ether, ZnBr₂, THF, and (*E*)-BrCH=C(Me)COOEt in the presence of 2% Cl₂Pd(PPh₃)₂ and 4% DIBAL-H in THF (95% yield). After desilylation with K₂CO₃ and EtOH, **12** was obtained in 76% combined yield over three steps from (*E*)-ICH=CHBr, Me₃SiC \equiv CZnBr, and (*E*)-BrCH=C(Me)CO₂Et. The ¹³C NMR spectrum of **12** indicated it to be >98% *E,E*. For the critical cross-coupling between **8** and **12**, **12** was first converted to its Zn derivative (**13**) via lithiation with LDA (1 equiv) in THF, followed by treatment with dry ZnBr₂ in THF. Its cross-coupling with **8**, in the presence of 5% Cl₂Pd(PPh₃)₂ and 10% DIBAL-H,² proceeded cleanly to give **14** (>99% isomerically pure) in 94% yield. Thus, the synthesis of **14** was achieved in 29% yield over 12 steps in the longest linear sequence (Schemes 1–3).

As recently reported by us,¹⁹ **12** can be converted to (*E,E,E*)-BrCH=CHC \equiv CCH=CHCH=C(Me)COOEt (**15**) in 82% yield by the Pd-catalyzed reaction of the zinc derivative of **12** with (*E*)-ICH=CHBr. We therefore sought a more convergent and potentially superior route to **14** through the use of **15**. To this end, **9** was converted to >99% pure **16** via the Corey–Fuchs reaction in 96% yield over two steps (Scheme 4). To our disappointment, however, hydrozirconation of **16** with HZrCp₂Cl (2 equiv),²¹ followed by successive addition of ZnCl₂ (2 equiv), **15** (1.2 equiv), and a catalyst consisting of 5 mol % Cl₂Pd(PPh₃)₂, 10 mol % tris(*o*-furyl)-phosphine (TFP), and 10 mol % DIBAL-H in THF at 23 °C for 20 h, led to the formation of the desired compound **14** only in 57% yield. Upon iodinolysis of the hydrozirconation mixture derived from **16**, the corresponding 2-iodo derivative **17** and its 3-iodo isomer were isolated in 74 and 18% yields, respectively, after chromatographic separation. The formation of the unwanted regioisomer must be partially responsible for the low yield of **14**. To probe this issue further, the

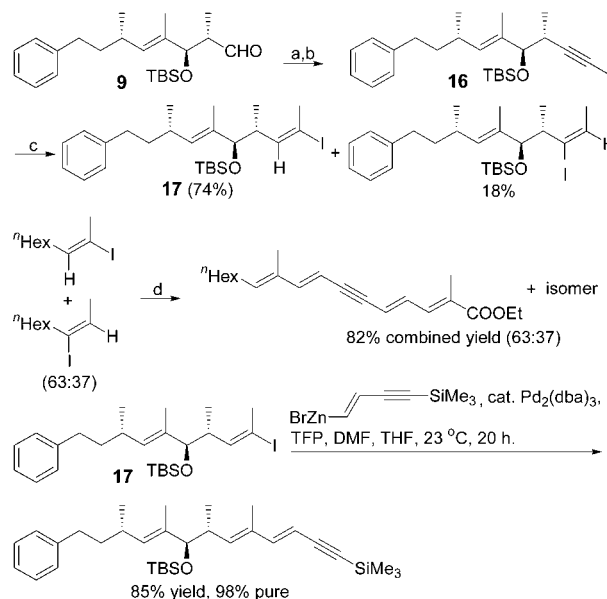

Scheme 3^a

^a Reagents and conditions: (a) TBAF, THF , 23°C , 24 h; (b) LiOH , $\text{THF-MeOH-H}_2\text{O}$; (c) $(S)\text{-MeCH(NH}_2\text{)CH}_2\text{OH}$, PyBroP , $^i\text{Pr}_2\text{NEt}$, CH_2Cl_2 ; 78% yield over three steps.

regioisomerically pure 2-iodo isomer **17** was zincated via lithiation and cross-coupled with **15** under various sets of catalytic conditions, but the yields of **14** were mysteriously and uniformly low ($\leq 30\%$); the major side reaction is deiodination of **17** ($\sim 60\%$). Attempts to generate the zinc derivatives of **15** were also disappointing. And yet, both **15** and **17** were shown to be highly satisfactory cross-coupling partners in favorable cases, as shown in Scheme 4.

As summarized in Scheme 3, no difficulty was encountered in converting **14** into the final product **1** in 78% combined yield over three steps. After desilylation with TBAF (85%), ester hydrolysis with LiOH in $\text{THF-MeOH-H}_2\text{O}$ (96%), followed by amidation with 2 equiv of $(S)\text{-MeCH(NH}_2\text{)CH}_2\text{OH}$ (97% ee, Aldrich) using $^i\text{Pr}_2\text{NEt}$ (3 equiv) and bromotripyrrolidinophosphonium hexafluorophosphate (PyBroP , Fluka),^{1,22} provided >99% isomerically pure **1** in 95% yield. This linear three-step final assembly

Scheme 4^a

^a Reagents and conditions: (a) CBr_4 , PPh_3 , Zn ; (b) (i) $^n\text{BuLi}$ (3.3 equiv); (ii) MeI (5 equiv); 96% over two steps. (c) (i) HZrCp_2Cl (2 equiv); (ii) I_2 (1.6 equiv). (d) (i) $^n\text{BuLi}$ then ZnBr_2 ; (ii) $(E,E)\text{-BrCH=CHC=CCH=CHCH=C(Me)COOEt}$ (**15**), cat. $\text{Pd}_2(\text{dba})_3$, TFP [tris(2-furyl)phosphine], DMF , THF , 23°C , 20 h.

of **1** adds a couple of steps in the longest linear sequence relative to a more convergent synthesis involving the use of preamidated intermediates.¹ However, the significantly higher amidation yield of 91% combined yield indicated above, as compared with those reported (54–59%), and an opportunity for readily introducing different amines well justify this strategy. The synthesis of 6,7-dehydrostipiamide (**1**) in 23% overall yield over the 15-step longest linear sequence should prove to be practically attractive as a synthetic route not only to **1** but also to related compounds, including **2–4**.
