ABSTRACT

The catalytic, enantioselective [3 + 2] cycloaddition reaction of 1-alkyl-substituted allenylsilanes with α -imino ester has been achieved by means of $[\text{Cu}(\text{MeCN})_4]\text{BF}_4/(\text{R})\text{-DM-SEGPHOS}$ catalyst to afford silyl-substituted dehydroproline derivatives in high yields and enantioselectivities.

The chiral Lewis acid-catalyzed cycloaddition reaction is a useful method for enantioselective formation of carbocyclic and heterocyclic compounds¹ which are important building blocks for natural product synthesis and thus attracts attention of synthetic organic chemists. α -Substituted allenylsilanes² are reported to work as counterparts of a cycloaddition reaction.³ Their application to enantioselective reaction is limited. For example, 1-methylallenylsilane undergoes [3 + 2] cycloaddition reaction with electron deficient olefins, aldehydes, and *N,O*-hemiacetal to give five-membered carbocycles and

heterocycles, respectively.⁴ Chiral Lewis acid-catalyzed [3 + 2] cycloaddition reaction with aldehydes leading to dihydrofuran derivatives has been reported.⁵ Catalytic enantioselective [3 + 2] cycloaddition reaction of allenylsilane with imine has not been reported as far as we know. Recently, we have reported Cu(I)-catalyzed enantioselective [2 + 2] cycloaddition reaction of 1-methoxyallenylsilane with α -imino ester.⁶ We wish to report herein enantioselective [3 + 2] cycloaddition reaction of α -alkylallenylsilane with α -imino ester by means of chiral Cu(I) catalyst.

At the outset, 1-methylallenylsilane **1a**⁷ and α -imino ester **2** were treated with $[\text{Cu}(\text{MeCN})_4]\text{BF}_4$ (10 mol %) in THF.⁶ Although no reaction proceeded at room temperature, [3 + 2] cycloaddition reaction took place under reflux conditions

Scheme 1. Catalytic [3 + 2] Cycloaddition Reaction with α -Imino Ester

to give silyl-substituted dehydropyrroline derivative **3a** in 19% yield. Use of benzene as a solvent improved the chemical yield to 91% (Scheme 1).

We attempted the cycloaddition reaction of **1a** with other imine derivatives such as $\text{PhCH}=\text{NPh}$, $\text{PhCH}=\text{NTs}$, and $\text{EtOCOCH}=\text{NC}_6\text{H}_4(p\text{-OMe})$ using $[\text{Cu}(\text{MeCN})_4]\text{BF}_4$ as the catalyst; no cycloadducts were obtained. It was found that use of highly reactive aldimine **2** is essential for the present cycloaddition reaction to proceed.

The asymmetric synthesis of silyl-substituted dehydropyrroline derivative **3a**⁸ was investigated and the results are shown in Table 1. Treatment of **1a** (1.0 equiv) and **2** (1.2

^a $[\text{Cu}(\text{MeCN})_4]\text{PF}_6$ was employed.

AD-H). $(R)\text{-SEGPHOS}$ ¹⁰ (entry 3) was more effective than $(R)\text{-Tol-BINAP}$ (entry 2). When $(R)\text{-DM-SEGPHOS}$ was used as a chiral ligand, the highest enantioselectivity (85% ee) was observed (entry 4). Use of 2.0 equiv of **2** significantly improved the chemical yield to 74% (entry 5). Other solvents gave inferior results (entries 6–8).

Other allenylsilanes were examined, and the results are shown in Table 2. Allenyl(*tert*-butyl)diphenylsilanes bearing bulky silyl group afforded cycloadducts in good enantioselective manner (entries 2–4). *tert*-Butyldimethylsilyl-, triphenylsilyl-, and triisopropylsilyl-substituted allenylsilanes also gave [3 + 2] cycloadducts (entries 5–7). It is noted that parent allenylsilane gave no cycloadduct (entry 8). The presence of α -alkyl group is essential for the present cycloaddition reaction to proceed.

Treatment of 2-alkyl-substituted pyrroline esters **3** with aqueous HI solution at room temperature for 2–3 h furnished desilylated γ -amino ketones **4** in high yields and without decreasing enantioselectivities (Table 3).

Table 3. Ring-Opening Reaction

entry	R	time (h)	yield of 4 (%)	ee of 4 (%)
1	Me (85% ee)	3	98	85
2	<i>n</i> -Pr (77% ee)	2	97	77
3	cyclohexyl (71% ee)	3	89	71

The 2-pyrroline esters described in this study afforded useful synthons. The vinylsilane functionality in pyrroline **3**

Scheme 2. Synthesis of Pyrrolidinone

is nucleophilic, and can be epoxidized with *m*-CPBA to produce epoxypyrrolidine **5**. Subsequent treatment with aqueous HI solution at room temperature furnished desilylated 3-pyrrolidinone **6** in a high yield (Scheme 2). The relative stereochemistry of **6** has not been determined.¹¹

Next, the absolute stereochemistry of γ -amino ketone **4a** (*R* = Me) was determined to be *S* by comparison of the optical rotation of **8**, which was prepared from **3a** via **4a**, with that of the authentic sample prepared from D-norleucine (Scheme 3). The absolute stereochemistry of pyrroline ester **3a** was thus found to be *S*. We surmised that the absolute

^a Methyleneedioxy moieties of (*R*)-DM-SEGPHOS are omitted for clarity.

stereochemistries of other γ -amino ketones and pyrrolines to be *S* by analogy.

The stereochemical outcome can be rationalized by the plausible transition state model as shown in Scheme 4.¹² Because the *Re*-face is blocked by the pseudoequatorial dimethylphenyl moiety, allenylsilane attacks the *Si*-face preferentially to give *S*-isomer selectively.

In summary, we have developed the first enantioselective [3 + 2] cycloaddition reaction of 1-alkyl-substituted allenylsilanes with α -imino ester by chiral Cu(I) catalyst. Use of (*R*)-DM-SEGPHOS as a chiral ligand resulted in high enantioselective cycloaddition reaction.
