ABSTRACT

RhCl(PPh₃)₃ catalyzes a reaction of thiols with polychloroalkanes in the presence of triethylamine. This reaction serves as a convenient new method to produce formaldehyde dithioacetals, ethylenedithioethers, thioformates, and dithiocarbonic esters under mild conditions.

Many methods for the synthesis of formaldehyde dithioacetals (RSCH₂SR) are known, including the reaction of thiols with diiodomethane, dibromomethane, or dichloromethane under strongly basic conditions¹ and the reaction of thiols with formaldehyde derivatives under acidic conditions.² Demonstrably, the simplest method yet reported is the reaction of thiols with dichloromethane in the presence of *strong organic base* (1,8-diazabicyclo[5,4,0]undec-7-ene, DBU), as reported by Ono et al.³ The present study explored a rhodium-catalyzed reaction of thiols with polychloroalkanes in the presence of *weak organic base* (Et₃N); the reaction allows both simple operation and mild reaction conditions.

In general, thiols are believed to be poisons of transition metal catalysts. However, several recent reports concerning transition-metal-catalyzed reactions of thiols have explained the utility of transition metal catalysts in synthesis of sulfur compounds.^{4–6} Although platinum-catalyzed formaldehyde dithioacetal formation using thiols and CH₂I₂ has been reported,⁷ a catalytic method using thiols and CH₂Cl₂ has

not. Recently, we reported a cationic rhodium(I)/PPh₃-complex-catalyzed dehydrogenation of alkanethiols to disulfides under inert atmosphere.⁸ We found that the formaldehyde dithioacetal was obtained along with the disulfide through reaction of octanethiol with CH₂Cl₂ when dehydro-

examined, PPh₃ was the most effective (entries 1–8). The use of [Ir(cod)₂]BF₄ or [Rh(cod)Cl]₂ and the elimination of treatment of the catalyst with hydrogen engendered very low catalytic activity (entries 9–11). The highest catalytic activity was obtained using RhCl(PPh₃)₃ as a catalyst (entry 12). Finally, employing excess amounts of Et₃N furnished the desired methylenedithioether in 81% isolated yield (entry 13).⁹ No reaction was observed in the absence of rhodium catalyst (entry 14).

Table 2 shows the rhodium-catalyzed reactions of various thiols with polychloroalkanes, as investigated in polychloroalkane solvents.¹⁰ The reactions of both alkyl and aryl

^a Reactions were conducted using RhCl(PPh₃)₃ (0.025 mmol), Et₃N (0.5 mL), thiol (0.50 mmol), and polychloroalkane (2.0 mL) at room temperature for 24 h. ^b Isolated yields based on thiols. ^c At 80 °C. ^d RhCl(PPh₃)₃ (0.10 mmol) and polychloroalkane (10 mL) were used.

thiols with CH₂Cl₂ in the presence of 5% RhCl(PPh₃)₃ proceeded at room temperature to furnish the corresponding formaldehyde dithioacetals in good yield (entries 1–6). A hydroxy-substituted alkanethiol and a cysteine derivative can

(9) Not only tertiary amines but also secondary and primary amines (*n*-Bu₂NH and *n*-BuNH₂) can be used for this reaction, although the reaction rate is low.

(10) In all entries, <5% conversions were observed in the absence of rhodium catalyst.

be used (entries 4 and 5).¹¹ The reaction of a vicinal dichloride ($\text{CH}_2\text{ClCH}_2\text{Cl}$) proceeded at 80 °C to furnish the corresponding ethylenedithioethers in good yield (entries 7 and 8). Importantly, although high catalyst loading and diluted condition were required, the reaction of CHCl_3 and CCl_4 also proceeded at room temperature to give a thioformate and a dithiocarbonic ester, respectively, presumably through hydrolysis of corresponding polythiomethanes by silica gel chromatography (entries 9 and 10). The reaction of CHCl_3 and CCl_4 serves as a convenient new method for preparation of a thioformate and a dithiocarbonic ester starting from a thiol.

Next, we investigated the rhodium-catalyzed reaction of thiols with alkyl halides. The reaction proceeded cleanly in Et_3N without using excess alkylating reagents when a reactive primary alkyl chloride (benzyl chloride, eq 2) or a primary alkyl bromide (dodecyl bromide, eq 3) was used as an alkylating reagent. No reaction was observed in the absence of rhodium catalyst.

The reaction of dodecanethiol with CDCl_3 was investigated to gain mechanistic insight into this reaction (eq 4). Deuterium of CDCl_3 was quantitatively incorporated into the formyl group. Furthermore, the reaction of benzyl mercaptan with (*R*)-(1-chloroethyl)benzene (78% ee) furnished the corresponding sulfide with complete inversion of configuration (78% ee, eq 5).

Scheme 1 depicts a plausible mechanism of this reaction. We believe that the rhodium(I) catalyst oxidatively inserts

into the thiol $\text{S}-\text{H}$ bond, affording a rhodium(III) complex **A**. Elimination of HX with Et_3N furnishes rhodium(I) thiolate **B**, which reacted with alkyl halides in an $\text{S}_\text{N}2$ fashion, thereby furnishing sulfides and regenerating the rhodium(I) catalyst.

Scheme 1

In conclusion, we have established that $\text{RhCl}(\text{PPh}_3)_3$ catalyzes a reaction of thiols with polychloroalkanes in the presence of triethylamine. This reaction serves as a convenient new method to produce formaldehyde dithioacetals, ethylenedithioethers, thioformates, and dithiocarbonic esters under mild conditions.
