## **ABSTRACT**

Oxazolidinone-functionalized enecarbamates show contrasting behavior upon oxidation by singlet oxygen and by ozone. The observed stereoselectivity difference indicates that the oxidation with ozone is subject to classic steric effects, whereas the very high selectivity in the photooxidation with singlet oxygen is derived from vibrational deactivation.

Understanding the mechanisms of organic reactions has led to vast advances in the area of asymmetric processes.<sup>1</sup> Unfortunately, asymmetric photoreactions<sup>2</sup> have not enjoyed the same level of attention as asymmetric thermal reactions. Recently, we reported a very high stereoselectivity in the photooxidation<sup>3,4</sup> of oxazolidinone-derived enecarbamates (Scheme 1) with singlet oxygen<sup>5</sup> (<sup>1</sup>O<sub>2</sub>), both in solution<sup>3</sup> and

in organized media. To elucidate the factors responsible for the high stereocontrol in this photooxidation, we have investigated the reactivity of ozone<sup>6</sup> ( $O_3$ ) with oxazolidinone-functionalized enecarbamates. The selectivity during photooxidation by  ${}^1O_2$  was shown to depend on the alkene geometry;<sup>3,4</sup> the (E)-isomer gives higher selectivity than the corresponding (Z)-isomer in isotropic media.<sup>3</sup> By investigating the reactivity of  $O_3$  with oxazolidinone-derived enecarbamates, we expected to gain insight into the high stereoselectivity observed with  ${}^1O_2$ , in view of the facts that (i)  $O_3$  and  ${}^1O_2$  are electrophilically similar in nature,  ${}^{5-7}$  (ii) the products upon oxidation with  ${}^1O_2$  and  $O_3$  are the same (Scheme 1), and (iii) the importance of *radiationless deactivation* (*physical quenching*) may be assessed during the oxidation process because  $O_3$  is a reactive ground-state species compared to  ${}^1O_2$ , an excited-state molecule.

$$ln(k_R/k_S) = ln[(100 + \% \text{ ee})/(100 - \% \text{ ee})]$$
 (1)

$$\ln(k_{\rm R}/k_{\rm S}) = \Delta \Delta S^{\dagger}_{\rm R-S}/R - \Delta \Delta H^{\dagger}_{\rm R-S}/RT \tag{2}$$

$$s = \frac{k_R}{k_S} = \frac{\ln[1 - C(1 + ee_{MDB})]}{\ln[1 - C(1 - ee_{MDB})]}$$
(3)

where C in eq 3 is the conversion and  $ee_{MDB}$  is the ee value of the MDB product.

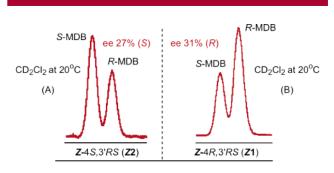

The epimeric pairs of oxazolidinone-derived (E)- and (Z)enecarbamates were oxidized with O3 in three different solvents (CD<sub>2</sub>Cl<sub>2</sub>, CDCl<sub>3</sub>, and CD<sub>3</sub>OD) at various temperatures (Table 1). The conversion was kept low to avoid side reactions,<sup>6</sup> and the enantiomeric excess (ee) was obtained by GC analysis of the methyldesoxybenzoin (MDB) product on a chiral stationary phase (Scheme 1). Inspection of Table 1 reveals the following features: (i) The same enantiomer of the MDB is enhanced upon varying the solvent, but a noticeable change in the ee values is observed at the same temperature for both (E)- and (Z)-enecarbamates; for example, at -70 °C, the ee values for O<sub>3</sub> oxidation of E1 in CD<sub>3</sub>OD is 4%; in CD<sub>2</sub>Cl<sub>2</sub>, 18%; and in CDCl<sub>3</sub>, 29%. (ii) The sense of the enhanced MDB enantiomer depends on the configuration at the C-4 position of the oxazolidinone ring as well as the alkene geometry; for example, E1 gave the (S)-MDB in excess, whereas the corresponding (Z)-isomer

**Figure 2.** Representative GC traces of product MDB for the oxidation of *E***1** by  $^{1}O_{2}$  (A) and  $O_{3}$  (B) in CD<sub>2</sub>Cl<sub>2</sub>.

It is evident from Table 1 that there is no solvent or temperature dependence of the ee values for (E)-enecarbamates upon oxidation with O<sub>3</sub>, which is in sharp contrast to the photooxidation<sup>3</sup> with <sup>1</sup>O<sub>2</sub> (Table 2; Figure 2). Clearly, the extent of stereoselectivity in the oxidation of E1 with  $O_3$ (Table 1) differs from that of  ${}^{1}O_{2}$  (Table 2). Further, the (Z)enecarbamates do not show any solvent or temperature dependence upon oxidation with O3, a result similar to the <sup>1</sup>O<sub>2</sub> oxidation.<sup>3</sup> To understand the difference in the behavior of the oxazolidinone-functionalized enecarbamates toward the oxidation of  $O_3$  and  ${}^1O_2$ , we computed the differential activation enthalpy  $(\Delta \Delta H^{\ddagger})$  and entropy  $(\Delta \Delta S^{\ddagger})$  values, which are directly related to the ee values through egs 1 and 2.8 These data are listed in Tables 1 and 2, which reveal that there is no significant difference in the activation parameters for the oxidation of the (E)- and (Z)-enecarbamates with O<sub>3</sub>. The sharp contrast in the differential activation parameters for the oxidation of E1 by  $O_3$  and  ${}^1O_2$  is revealing (Tables 1 and 2); for example, in the oxidation of E1 in CD<sub>2</sub>-Cl<sub>2</sub>, the  $\Delta\Delta S^{\ddagger}$  and  $\Delta\Delta H^{\ddagger}$  values for O<sub>3</sub> are 1.49 cal mol<sup>-1</sup>  $K^{-1}$  and 0.16 kcal mol<sup>-1</sup>, respectively, compared to -15 cal  $\text{mol}^{-1} \text{ K}^{-1}$  and  $-4.0 \text{ kcal mol}^{-1}$  for  ${}^{1}\text{O}_{2}$ . Thus, the ee value of the MDB product is a critical balance of the enthalpy (molecular) and entropy (environmental) terms, which are inter-

 $<sup>^</sup>a$  A ca. 50/50 mixture of diastereomers (total concentration 3.0  $\times$   $10^{-3}$  M) in an NMR tube under  $O_2$  pressure was used, with methylene blue (3.7  $\times$   $10^{-4}$  M) as a sensitizer.  $^b$  Determined by GC analysis.  $^c$  Determined by  $^1\text{H}$  NMR spectroscopy.  $^d$  From eq 3.  $^e$  From eqs 1 and 2.  $\Delta\Delta H^{\ddagger}$  given in (kcal mol $^{-1}$ );  $\Delta\Delta S^{\ddagger}$  given in (cal mol $^{-1}$  K $^{-1}$ ).

related by eqs 1 and 2.8 Consequently, the large contribution from the differential activation parameters for the  $^{1}O_{2}$  oxidation (Table 2) suggests that the transition state is conformationally flexible and its solvation—desolvation behavior is crucial. Expectedly, the temperature and solvent variations influence the stereodifferentiating step.8 Enthalpic control applies when the stereoselectivity is enhanced upon decreasing the temperature, a phenomenon common to many thermal asymmetric reactions. In contrast, the low contribution from the differential activation parameters for the  $O_{3}$  oxidation indicates that the transition state is more rigid and is not influenced by the variation of the external factors (solvent/temperature) of the system. Expectedly, there is no noticeable change in the extent of the ee values, and the sense of the enhanced enantiomer remains the same upon oxidation by  $O_{3}$ .

As mentioned above, the ee value depends on the extent of conversion. The ratio of the rates of formation (relative rates) of the enantiomeric products may be computed from the observed ee value at a given conversion by means of eq 3, where  $k_R/k_S$  is **s**, the stereoselectivity factor. <sup>10</sup> Inspection of Table 1 shows that the **s** factor at best is about 2 for oxidation of enecarbamates by O<sub>3</sub>. The low **s** factor will lead to a wide variation in the ee values at different converisons, <sup>10</sup> as observed for the O<sub>3</sub> oxidation, for which the ee values are moderate at low and small at high conversions. For example, 36% ee was observed at 9% conversion and only 4% ee at 36% conversion for the oxidation of Z2 by O<sub>3</sub> in CD<sub>2</sub>Cl<sub>2</sub> at -70 °C. The consequence of the difference in the **s** factors in the oxidation by O<sub>3</sub> and <sup>1</sup>O<sub>2</sub> is best illustrated in Figure 3. <sup>10</sup> Under identical conditions, the ee value is 97%

**Figure 3.** GC traces of product MDB for the oxidation of E1 by  $O_3$  and  $^1O_2$  at -70 °C in  $CD_3OD$  and the plot of % ee versus % conversion (simulated from eq 3; ref 10d) to illustrate the consequence of the difference in the s factors.

for the  ${}^{1}O_{2}$  oxidation (**s** factor of 72) compared to only 4% for the  $O_{3}$  oxidation (**s** factor of about 1.1).

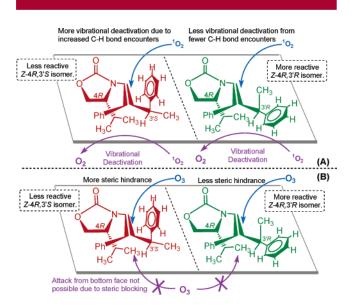

It is evident from Table 1 that both (E)- and (Z)-enecarbamates give only moderate ee values in the  $O_3$  oxidation. In general, the (Z)-isomers display comparable or higher

<sup>(8) (</sup>a) Inoue, Y. *Chem. Rev.* **1992**, *92*, 741–70. (b) Buschmann, H.; Scharf, H.-D.; Hoffmann, N.; Esser, P. *Angew. Chem., Int. Ed. Engl.* **1991**, *30*, 477–515. (c) Otera, J.; Sakamoto, K.; Tsukamoto, T.; Orita, A. *Tetrahedron Lett.* **1998**, *39*, 3201.

stereoselectivity than the corresponding E isomers, which is in contrast to the observed trend of  ${}^{1}O_{2}$ , for which the E isomer exhibits a very high stereoselectivity (ee >97%) compared to the (Z)-isomer. ${}^{3}$  We speculate that the steric hindrance experienced by  $O_{3}$  is reflected in the observed selectivity. As shown in Figure 4B, ${}^{11}$  the approach of  $O_{3}$ 

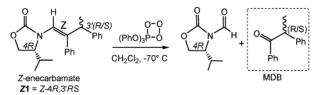

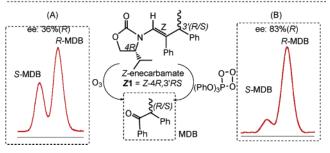

**Figure 4.** Control of the oxidant approach through deactivation and steric effects for  ${}^{1}O_{2}$  (A) and  $O_{3}$  (B).

onto the double bond from the bottom is hindered by the isopropyl group, such that  $O_3$  is forced to come in from the top. Moreover, enrichment of the MDB enantiomer depends on the configuration at the C-3′ position (Figure 4). For example, in the case of Z1, the (4R,3'R)-(Z)-isomer is more reactive than the (4R,3'S)-(Z)-diastereomer, which affords (R)-MDB in excess (Figure 4).

If steric effects play a dominant role in the O<sub>3</sub> oxidation, then the observed ee values should be higher when a bulky oxidant is employed. This exception was tested with triphenyl phosphite ozonide (Scheme 2), which is reported to undergo direct addition to alkenes through a perepoxide-like transition state at -70 °C. <sup>13</sup> As shown in Scheme 2, an ee value of 83% ((*R*)-MDB) was observed with *Z*1 upon triphenyl phosphite ozonide [P(OPh)<sub>3</sub>O<sub>3</sub>] oxidation, <sup>13</sup> compared to an ee value of only 36% ((*R*)-MDB) with O<sub>3</sub>. Besides steric

effects, dipole-induced interactions of the oxidizing species with the enecarbamates may significantly differ to result in a different stereoselectivity.

The high stereoselectivity observed for  ${}^{1}O_{2}$  (~97% ee at −70 °C; CD<sub>3</sub>OD; Table 2), relates presumably to its electronically excited nature, since it may be vibrationally deactivated on encountering C-H bonds. 3,5,12 Thus, the productive chemical pathway is in competition with the unproductive physical quenching process through deactivation by C-H bonds. The oxidation efficiency of <sup>1</sup>O<sub>2</sub> is, therefore, determined by which of the two processes dominates. In previous quenching studies on oxazolidinonederived enecarbamates, we demonstrated that the major pathway is unproductive physical quenching rather than the useful chemical mode.<sup>12</sup> The isopropyl group at the C-4 position of the oxazolidinone chiral auxiliary is apparently responsible for the vibrational deactivation of <sup>1</sup>O<sub>2</sub>, since it abundantly furnishes C-H bonds. Evidently, a process that leads to a high stereoselectivity in the product formation must be void of such vibrational deactivation. We are currently examining the deuteration of the substrates at the C-4 and C-3' stereogenic centers to better understand the high stereoselectivity displayed by <sup>1</sup>O<sub>2</sub>.
