ABSTRACT

A mild, stereoselective method for the Ni-catalyzed synthesis of α -C-alkylglycosides is reported. This approach entails the reductive coupling of glycosyl bromides with activated alkenes at room temperature, with low alkene loading as an important feature. Diastereoselective coupling with 2-substituted acrylate derivatives was made possible through the use of 2.4-dimethyl-3-pentanol as a proton source.

The utility of *C*-glycosides as stabilized biological isosteres in pharmaceutical or biological research, as well as their appearance in natural products and their potential as useful building blocks for complex molecule synthesis, have been recognized for decades.^{1,2} This has led to a variety of synthetic approaches to C-glycosides,³ one of the more recognizable being the reductive trapping of glycosyl radicals with activated alkenes. First demonstrated by Giese and Baldwin for Bu₃SnH-mediated radical chain processes, 4 it has since been reported in reactions that employ transitionmetal complexes⁵ as stoichiometric promoters⁶ or catalysts.⁷ A ubiquitous feature in each variant is the stereoselective formation of an axial C-C linkage between the glycoside

and the coupling partner. Unfortunately, they also suffer from needing a significant excess (6-20 equiv) of the alkene partner and the requirement for stoichiometric amounts of a toxic heavy metal and/or moderate yields.

In light of these limitations, we postulated that a Ni catalyst, if appropriately tuned and partnered with a convenient and environmentally benign stoichiometric reductant and proton source, could improve the synthesis of Cglycosides. Intriguing was the possibility that a glycosyl

radical⁸ might be accessible and interceptible from the reaction of a low-valent Ni source and a glycosyl bromide, as postulated in the mechanism of our recently disclosed Nicatalyzed arylation of glycosyl bromides.^{9,10} The intermediacy of secondary alkyl radicals in Ni-catalyzed crosscoupling has been previously proposed.^{11–14}

Our investigation began with the reaction of aceto-1-bromoglucose **1** and methyl acrylate using catalytic Ni(COD)₂, pybox ligand **6a**, Zn as the terminal reductant, NH₄Br as a proton source, and DMA as solvent (Table 1, entry 1). ¹⁵ Encouraging was the 35% yield of the desired α -C-glucoside product **2**; however, this was accompanied

Table 2. Substrate Scope for Coupling of Monosubstituted Alkenes with Glucosyl Bromide 1"

by significant amounts of undesired byproducts from β -elimination 3, ¹⁶ hydrolysis 4, and overaddition 5. Optimization studies varying ligand and solvent led to a 70% yield of 2 with (R)-Ph-pybox 6b (entry 2), with only trace quantities of 3, 4, or 5 being observed. Though 6c gave a similar yield, a slight increase (5%) in glucal 3 was observed (entry 3). Interestingly, the (S)-enantiomer of 6b reduced the yield to 52% (entry 4), pointing to a stereochemical mismatch between ligand and sugar. Further changes with respect to ligand or solvent did not improve the yields (entries 5–10). Under no conditions was β -product detected for any reaction. Control experiments highlighted the critical role of ligand (entry 11) and Ni(0) (entry 12) for promoting the desired reactivity in favor of background elimination, which presumably occurs via a glycosyl-Zn species. ¹⁷

3 R	OAc OAc 24	61%			

^a Standard reaction conditions used. ¹⁵ ^b R = CH₂CH₂CO₂Me.

With optimized reaction conditions in hand, the scope of the alkene partner was examined (Table 2). Reaction with acrylate derivatives such as *tert*-butyl acrylate and acrylonitrile smoothly produced the desired products **9** and **10**, respectively, in good yields (entry 1 and 2), while (*E*)-methyl penta-2,4-dienoate gave the nonconjugated α-glucosyl ester **11** in 65% yield (entry 3). As anticipated, however, styrenederived alkenes proved more challenging (entry 4). Reaction with styrene and 4-methoxystyrene generated only trace amounts of **12** and **13**, respectively, with pyranose **4** being the major product. ¹⁸ Given the nucleophilic character of the glycosyl radical, ¹⁹ we predicted that electron-poor styrenes would be more reactive (entry 4, products **14–21**), and this was indeed the case, especially for 4-carbomethoxy- and 4-cyanostyrene.

In addition to 1, the Ni-catalyzed reductive coupling with methyl acrylate was successfully extended to other acetate-protected glycosyl bromides (Table 3, entries 1–3). The α -C-mannoside and α -C-galactoside products 22 and 23 were obtained in 76% and 60% yield, respectively, while the 5-dealkylated C-arabinoside was provided in 61% yield with diminished stereoselectivity. Benzoate-protected sugars were similarly well-behaved (entry 4), while Bn-protected glucosyl bromide was particularly prone to hydrolysis. 21

^a Standard reaction conditions used. ^{15 b} The dr refers to the stereocenter α to the methyl ester; ²² in all cases, the stereocenter at the anomeric carbon was formed with exclusive α selectivity. ^c Not determined.

We next turned our attention to 1,1-disubstituted and trisubstituted alkenes, with diastereocontrol as an important goal. To this end, the coupling of glucosyl bromides $\bf 1$ and $\bf 27$ with methyl methacrylate was utilized as a probe system (Table 4). Using the previously optimized conditions, *C*-glycoside $\bf 28$ was obtained in high yield and with excellent selectivity for the α anomer, but with poor diastereoselectivity (1.4:1) at the stereocenter α to the methyl carboxylate (entry 1). Use of Bz-protected $\bf 27$ did not significantly improve the dr (entry 2), nor did variation of the chiral ligand (entries $\bf 3-5$). Chiral, enantiopure methacryloyl esters such as bornyl or menthyl methacrylate (not shown) also failed to affect the diastereoselection.

Since protonation of a transition-metal enolate intermediate was presumed to be stereodetermining, we then examined the proton source itself. While the use of sterically hindered ammonium salts such as (—)-sparteine•H₂SO₄ resulted in diastereoselectivities only slightly greater than 2:1 (entry 6), alcohols elucidated clear improvement (entries 7–15).²² Increases in steric bulk and branching improved the dr to 5:1 with ⁱPr₂CHOH (entry 10),²³ but chiral alcohols (entries 12–14) were inferior. Finally, reaction of Ac-protected 1 using the ⁱPr₂CHOH proton source (entry 15) resulted in lower diastereoselectivity than that observed for the Bz-protected 27 (entry 10).

Org. Lett., Vol. 11, No. 4, 2009

⁽¹⁷⁾ The Zn-mediated reductive elimination of aceto-1-glycosyl bromides is well known from the Fischer–Zach glycal synthesis: Fischer, E.; Zach, K. Sitzungsber. Kl. Preuss. Akad. Wiss. 1913, 27, 311.

⁽¹⁸⁾ Attempts to suppress hydrolysis product 4 through the use of desiccants (molecular sieves, etc.) were unsuccessful.

⁽¹⁹⁾ For example, see: (a) Liu, Y.; Gallagher, T. *Org. Lett.* **2004**, 6, 2445. (b) SanMartin, R.; Tavassoli, B.; Walsh, K. E.; Walter, D. S.; Gallagher, T. *Org. Lett.* **2000**, 2, 4051.

⁽²⁰⁾ For examples of the known difficulty in obtaining high selectivity in reactions of arabinosyl-type radicals, see refs 1 and 6d.

⁽²¹⁾ Attempts to improve yields by using the Bn-protected glucosyl or mannosyl chlorides failed (no reaction).

⁽²²⁾ Bz-protected products simplified the assessment of dr by ¹H NMR; for this reason, glucosyl bromide **27** was used thereafter.

⁽²³⁾ The configuration of the stereocenter α to the methyl ester in the major isomer of **29** was determined by single-crystal X-ray analysis (see the Supporting Information).

Table 5. Coupling of Substituted Alkenes with Glucosyl Bromides **1** and **27**^a

entry	alkene	product	yield (dr) ^b
1	30	BzO O O O O O O O O O O O O O O O O O O	50% (7:1)°
2	0 Ne 32	BzO BzO O O O O O O O O O O O O O O O O	74% (5:1) ^c

5	Me CO_2Me CO_2Me 38	BzO 39 BzO CO ₂ Me	56% (1.2:1) ^c
	30	ĆO₂Me	

^a Standard reaction conditions used.¹⁵ In all cases, the anomeric stereocenter was formed with exclusive α selectivity. ^c The α-stereocenter is drawn by analogy to the crystallographically characterized **29**, which was additionally corroborated by conversion of **33** to **29**.²⁵

The optimal conditions for diastereoselective coupling were then applied to various geminally disubstituted alkenes (Table 5). Reaction of **27** with α -methylene- γ -butyrolactone and 3-methacryloyloxazolidin-2-one²⁴ proceeded smoothly and with good dr (entries 1 and 2). More sterically demanding alkenes like methyl 2-phenylacrylate and (1S,4R)-3-methylenebicyclo[2.2.1]heptan-2-one (entries 3–4) proceeded successfully, with applicability to enones being demonstrated by the latter. Although 3-substituted or trisubstituted methyl acrylates generally demonstrated poor reactivity, dimethyl 2-ethylidenemalonate gave **39** in 56% yield

Scheme 1. Ni-Catalyzed Coupling of 27 with 40^a

^a Standard reaction conditions used, ¹⁵ with glucosyl bromide **27**, ligand **6b**, and NH₄Br.

(1.2:1 dr) (entry 5), indicating a greater electron-withdrawing requirement for these more hindered partners.

In addition to the exquisite α -selectivity for the glucosyl and mannosyl substrates and the need for activated (electrophilic) alkene acceptors, the coupling of vinyl cyclopropyl malonate 40 (Scheme 1) with 27 generated the ring-opened 41 rather than cyclopropane product 42. While the intermediacy of radicals explains each of our observations, a mechanism relying on olefin insertion into a Ni-glycosyl intermediate followed by transmetalation to zinc cannot be rigorously ruled out. 26

In summary, we have demonstrated a mild, Sn-free Nicatalyzed reductive coupling of glycosyl bromides with electron deficient alkenes featuring low alkene stoichiometry requirements. The diastereoselectivity of reactions with 2-substituted acrylate derivatives was significantly improved through the use of ⁱPr₂CHOH as a proton source. Efforts to expand this method are ongoing.
