SYNTHESIS AND REACTIVITY OF SILYLATED PHOSPHORUS COMPOUNDS

ROBERT H. NEILSON

Department of Chemistry, Texas Christian University,
Fort Worth, Texas 76129, U.S.A.

Abstract The preparative and derivative chemistry of several silylated (methylene)phosphines including $(\text{Me}_3\text{Si})_2\text{NP}=\text{CHSiMe}_3$, $\text{MesP}=\text{C}(\text{SiMe}_3)_2$, and a stable 1-phosphadiene system is reported.

INTRODUCTION

The chemistry of compounds containing the Si-N-P and/or Si-C-P linkages is usually markedly different from that of the nonsilylated analogues. On the one hand, the steric bulk and π -acceptor properties of silyl groups can be used to kinetically stabilize a variety of "low-coordinate" phosphorus systems. Alternatively, the Si-N or Si-C bonds may often serve as reactive sites so that processes such as intramolecular silyl group rearrangements and condensation reactions via silane elimination are commonly found. We report here several illustrative examples from areas of current interest in our laboratory involving silyl-substituted (methylene)phosphines.

REACTIONS OF A SILYLATED AMINO(METHYLENE)PHOSPHINE

The synthesis of a stable, trisilylated amino(methylene)phosphine **1** has been recently accomplished either by dehydrohalogenation¹ or thermolysis² of appropriate chlorophosphine precursors. As an extension of these studies, we are interested in the reactivity of **1** and related compounds including novel phosphadienes.

The modes of reactivity of compound **1** are quite varied but can be divided roughly into two general categories. Among the first type, are relatively straightforward reactions in which the $\text{Si}_2\text{N-P-C}$ linkage remains intact (Scheme I)³. These include: metal complexation via the phosphorus lone pair (**2**), oxidation to a 3-coordinate phosphorane (**3**), addition of polar reagents to the $\text{P}=\text{C}$ bond (**4-6**), and 2+2 cycloaddition with a silene (**7**).

SCHEME I (R = SiMe₃)SCHEME II (R = SiMe₃)

Reactions of the second type (Scheme II)³ are more complex processes in which cleavage of the Si-N and/or P-N bonds are involved. These results, while surprising at first, seem to have a common underlying feature. In each case, the initial product, a 3-coordinate phosphine formed by addition to the P=C bond, is apparently more reactive toward the given reagent than is the (methylene)phosphine itself.

SYNTHESIS OF A 1-PHOSPHADIENE

We have also prepared a variety of other amino(methylene)-phosphines, including the stable 1-phosphadiene 12³, by the dehydrohalogenation route. Proton, ¹³C, and ³¹P NMR data are all consistent with the depicted geometry about the double bonds. Studies of the reactivity of 12 are in progress.

P-MESITYL SUBSTITUTED (METHYLENE)PHOSPHINES

The mesityl group is also known to be effective⁴, though less so than (Me₃Si)₂N⁵, in stabilizing various low-coordinate phosphorus systems. We have recently prepared [bis(trimethylsilyl)methylene] (mesityl)phosphine 13 and have studied its reactions with several reagents (Scheme III)³ for comparison with the (Me₃Si)₂N-substituted analogues. Noteworthy aspects of this work include: (a) the new, stable 3-coordinate phosphoranes 15 and 16, (b) the PCS 3-membered ring system 17, and (c) the anion 18 whose derivatives 19 and 20 illustrate its ambident nature. X-ray crystallographic studies of compounds 16 and 17 are currently being conducted in order to confirm the structural assignments.

SCHEME III (R = SiMe₃)
