## SUBSTITUENT EFFECTS ON GEOMETRIES OF IMINOPHOSPHANES AND DISPHOSPHENES. THE EFFECT OF $\sigma$ -PUSH-PULL SUBSTITUTION

### W.W. Schoeller, T. Busch and W. Haug

Fakultät für Chemie der Universität Bielefeld, FRG

<u>Abstract</u>. The combination of electron withdrawing/donating substituents ( $\sigma$ -push pull substituents) causes unusual bonding features in iminophosphanes and diphosphenes, as explored by quantum chemical ab initio calculations at SCF and MCSCF level. For the diphosphenes the predictions are confirmed by a selected variety of double bond systems, synthesized and structurally characterized for this purpose.

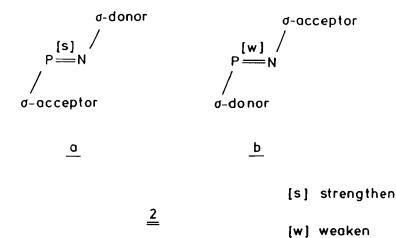

The flowering of the chemistry of low coordinated P(III) double bonded system ist best witnessed in the richness of experimental structures hitherto reported on iminophosphanes  $^{1,2}$ .

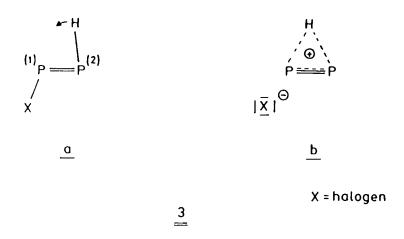

1

It prompted us to develop a general theory of substituents on the structures of iminophosphanes  $^3$ ,  $\underline{la}$ , and the electronically related substituted diphosphenes  $^4$ ,  $\underline{lb}$ . In fact it will be shown that substituents can cause considerable deformation of geometry, different in  $\underline{la}$  compared with  $\underline{lb}$ .  $\sigma$ -push-pull substitution,  $\underline{2}$ , results novel structural features in these systems.

In case of the iminophosphanes, la, trans to cis isomerization occurs with a (relatively) low energy barrier for nitrogen inversion<sup>5</sup>. Quantum chemical calculations<sup>3</sup> indicate a strong dependence of the N-inversion barrier on the substituents  $R_1$  and  $R_2$ ; e.g., for trans to cis isomerization  $R_1/R_2$ =H/H 13.5 [kcal per mole], F/H 7.3; Cl/H 9.0; NH<sub>2</sub> (planar)/H 8.9, H/CH<sub>3</sub> 12.9; H/SiH<sub>3</sub> 2.0 [determined by location of ground state and transition state geometries]. Hence electronegative substituents at P and/or electropositive substituents at N extremely lower the N-inversion barrier. Concomitantly the lowering of the N-inversion barrier (e.g.,  $R_1$ =F,  $R_2$ =SiH<sub>3</sub>) pronounces ground state geometries with short PN double bonds and makes the nitrogen environment more linear. In more detail on the basis of the quantum chemical analysis  $^3$  one can differentiate between two classes of  $\sigma$ -push-pull substitution. In 2a the central PN bond will be strengthened (s) or as in 2b weakened (w) due to substituent effects<sup>3</sup>. Theory is in full accord with experiment which results iminophosphanes with a short (PN-150.0 (pm),  $R_1$ -OMes\*,  $R_2$ -Mes\*6) or a long (PN-159.8,  $R_1$ -TMP [tetramethylpiperidyl],  $R_2$ -N(SiMe<sub>3</sub>)<sub>2</sub><sup>7</sup>) central  $\pi$ -bond. For substituents capable of additional  $\pi$ -mesomeric interactions,  $R_1$ - $R_2$ - $NH_2$ , the  $\sigma$ -effects superimpose the  $\pi$ -effects. They can be additive or counteractive. Again it is in full accord with experiment<sup>1,2</sup>.

In case of diphosphenes,  $\underline{1b}$ , the combination of  $\sigma$ -electron withdrawing/donating substituents causes a different effect, the attempted briding in push-pull substituted diphosphenes,  $\underline{3}$ .

Quantum chemical calculations on a variety of model systems  $3 \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  evidence a decrease of the valence angle  $X \times (X-F, C1, NH_2, CH_3, H)$  and  $X \times (X-F, C1, NH_2, L)$  and  $X \times (X-F, C1, NH_2, L)$  and  $X \times (X-F, C1, NH_2, L)$  and  $X \times (X-F, L)$  a

Further quantum chemical investigations lead to the following general conclusions: (1) For 10 electron species HXY (X,Y=C,Si,N,P etc.) a linear geometry is preferred in case one of the constituents X(Y) is of the first long period (C,N) and the other from the higher long periods (Si,P) with the heavy atoms always terminal rather than central. For HXY with X and Y constituted both from higher rows, a bridged nonclassical

structure is observed, as predicted previously for Si<sub>2</sub>H<sub>2</sub><sup>8</sup>.
