**Abstract** The synthesis and antiviral potential of some thiophosphonocarboxylates, bithiophosphonates and related nucleoside conjugates is summarized.

### INTRODUCTION

Thiophosphonoformic acid (TPFA), a thio analogue of the anti-viral agent phosphonoformic acid (PFA), is readily synthesized by Lawesson's reagent (LR) thionation of trimethyl PFA to trimethyl TPFA ((CH<sub>3</sub>O)<sub>2</sub>P(O)CO<sub>2</sub>CH<sub>3</sub> → (CH<sub>3</sub>O)<sub>2</sub>P(S)CO<sub>2</sub>CH<sub>3</sub>), followed by alkaline hydrolysis.<sup>1</sup> Compared to PFA, TPFA has a similar IC<sub>50</sub> for inhibition of human immunodeficiency virus (HIV-1) reverse transcriptase (RT), and also for inhibition of HIV-1 p24 expression in human cells *in vitro*, but is 2–3x less inhibitory to human α DNA polymerase.<sup>1, 2</sup> TPFA is slowly converted to PFA in the p24 antigen capture assay, raising the possibility that it could function to some degree as a prodrug of the latter compound.<sup>2</sup> The replacement of S for O in PFA might also affect bioavailability, toxicity or other pharmacological properties of the drug. In this brief overview, we present our recent work on: 1) Lawesson synthesis of phosphonoacetate and bisphosphonate analogues of TPFA, and their evaluation as HIV-1 inhibitors; 2) *in vivo* chemistry and pharmacokinetics of TPFA bearing on its potential as an anti-viral drug; 3) synthesis and HIV-1 inhibition characteristics of novel TPFA conjugates with AZT and several other dideoxynucleosides. New compounds were characterized by <sup>1</sup>H, <sup>13</sup>C and <sup>31</sup>P NMR and by elemental analysis.

### RESULTS AND DISCUSSION

LR thionation of phosphonocarboxylates (RO)<sub>2</sub>P(O)CXYCO<sub>2</sub>R, **1** (**1a**: R = Me, XY = HH; **1b**: R = Et, XY = HH; **1c**: R = Me, XY = HCl; **1d**: R = Me, XY = ClCl) regioselectively gave the thiophosphoryl derivatives (RO)<sub>2</sub>P(S)CXYCO<sub>2</sub>R, **2** (**2a–2d**) (32–67%), whereas bisphosphonate esters (RO)<sub>2</sub>P(O)CH<sub>2</sub>P(O)(OR)<sub>2</sub>, **3** (**3a**: R = Me; **3b**, R = Et; **3c**, R = *i*Pr) and the phosphinylmethylphosphonate ester (EtO)PhP(O)CH<sub>2</sub>P(O)(OEt)<sub>2</sub>, **4** were dithionated by LR, giving (RO)<sub>2</sub>P(S)CH<sub>2</sub>P(S)(OR)<sub>2</sub>, **5a–5c** (13–50%) and (EtO)PhP(S)CH<sub>2</sub>P(S)(OEt)<sub>2</sub>, **6** (10%), respectively. Yields were higher for substrates having a

more electron-withdrawing P(O) substituent ( $\text{Me}_3\text{TPFA} > \mathbf{1d} > \mathbf{1c} > \mathbf{1a}$ ) but decreased with bulkier phosphonate ester alkyl groups in the series  $\mathbf{3a-c}$ .

Pathways for complete and partial hydrolysis of  $\mathbf{2}$  and  $\mathbf{5}$  were explored<sup>3</sup>. Trisodium thiophosphonoacetate ( $\text{Na}_3\text{TPAA}$ ,  $\mathbf{7}$ ) was obtained from the trimethyl ester  $\mathbf{1a}$  by either BTMS/ $\text{OH}^-$  or direct alkaline hydrolysis, but these methods were unsuccessful with the  $\alpha$ -chloro TPAA esters  $\mathbf{1c}$  and  $\mathbf{1d}$ . Tetramethyl methylenebis[thiophosphonate]  $\mathbf{3a}$  was converted to its  $\text{Na}_2^+$  *sym* -O,O-dimethyl ( $\mathbf{8}$ ),  $\text{Na}_2^+$  S,S-dimethyl ( $\mathbf{9}$ ) and  $\text{Na}_4^+$  ( $\mathbf{10}$ ) salts by reaction with BTMS/NaOH, NaI and ITMS<sup>3</sup>/NaOH, respectively. Thiono  $\rightarrow$  thiolo rearrangement (as in  $\mathbf{9}$ ) was also observed when trimethyl phosphonocarboxylates (*e.g.*  $\mathbf{2a}$ ) were monodemethylated with NaI. Unlike trisodium TPFA ( $\mathbf{11}$ ) or trisodium PFA ( $\mathbf{12}$ ), none of the thiophosphonates, or partial esters thereof, thus prepared showed significant activity in the p24 inhibition assay, suggesting that further efforts be concentrated on  $\mathbf{11}$ .

HPLC-EC analysis of plasma or urine from felines dosed with  $\mathbf{11}$  reveals that TPFA is partly metabolized *in vivo* to PFA. Thus, in 6 h 42.3% of TPFA administered i.v. (800  $\mu\text{g/kg}$ ) was excreted (urine) as 23.5% TPFA, 13.8% PFA and 5.0% of a metabolite identified by GC-MS and <sup>31</sup>P NMR as thiophosphorous acid (TPA).<sup>4</sup> Mean oral bioavailability of TPFA in enteric-coated capsules was  $> 2\times$  greater for TPFA (22%; 28% including PFA from TPFA) vs. PFA (8%). In a similar study<sup>5</sup> using a canine model, partial conversion *in vivo* of TPFA (400  $\mu\text{g/kg}$  dosage; 95% of dose) to PFA (8.3%) and TPA (8.6%) was also observed (balance recovered as TPFA), and oral bioavailability of TPFA was  $> 3\times$  vs. PFA (44.5% vs. slightly more than 12%) with cimetidine pretreatment. In the same model, PFA (400  $\mu\text{g/kg}$ ) caused a dramatic decrease ( $>70\%$ ) in creatinine clearance, whereas TPFA had essentially no effect on this sensitive measure of renal function.

Our results prompted us to investigate synthesis of novel O,O-dimethyl ( $\mathbf{13-16}$ ) and O-methyl ( $\mathbf{17-20}$ ) thiono TPFA conjugates of dideoxynucleoside HIV inhibitors: AZT, ddA, ddI and ddC. The dimethyl esters were prepared in 35–45% yield by condensing the nucleoside partner with the phosphoryl chloride  $\text{CH}_3\text{O}_2\text{P(S)Cl(OCH}_3\text{)}$   $\mathbf{21}$ , obtained by treatment of  $\text{Me}_3\text{PFA}$  with  $\text{PCl}_5$  in  $\text{CCl}_4$  followed by LR thionation. Preliminary HIV-1 p24 inhibition data for some of these compounds gave apparent  $\text{IC}_{50}$  values of 0.09–23  $\mu\text{M}$  ( $\mathbf{13-15}$ ), compared to 1–10  $\mu\text{M}$  for  $\mathbf{17-19}$ . Reference  $\text{IC}_{50}$  values for conjugate moieties were 0.05–0.06 (AZT), 0.3–0.8 (ddA), 0.5–1 (ddI) and 10–15 (TPFA)  $\mu\text{M}$ . Investigation of conjugate reactivities under assay conditions is in progress.
