## POSSIBLE EVIDENCE FOR A NEW MECHANISM FOR REACTION OF TRIMETHYLPHOSPHINE WITH DIOXYGEN

H. D. BURKETT, W. E. HILL\* and S. D. WORLEY\*

*Department of Chemistry, Auburn University, Alabama 36849, U.S.A.*

*(Received December 17, 1983; in final form February 28, 1984)*

Evidence is presented suggesting that the mechanism for reaction of trimethylphosphine with dioxygen proceeds through  $\text{Me}_3\text{PO}_2$  as an intermediate. A mechanistic scheme is proposed to explain the products observed and the spectroscopic data obtained.

### INTRODUCTION

The reactions of trialkylphosphines with dioxygen have been shown to produce  $\text{R}_3\text{PO}$ ,  $\text{R}_2\text{P}(\text{O})\text{OR}$ ,  $\text{RP}(\text{O})(\text{OR})_2$ , and  $\text{P}(\text{O})(\text{OR})_3$  in solution.<sup>1</sup> Neat samples of  $\text{P}(n\text{-C}_4\text{H}_9)_3$  reacted with dioxygen to give only  $\text{R}_3\text{PO}$ ,  $\text{R}_2\text{P}(\text{O})\text{OR}$ , and  $\text{R}_2\text{POR}$ . A free radical mechanism involving  $\text{R}^\cdot$ ,  $\text{RO}^\cdot$ , and  $\text{RO}_2^\cdot$  was proposed, and the suggestion was made that dioxygen reacts with a hydrocarbon radical rather than at phosphorus—the key intermediates being the formation of the trivalent species  $\text{R}_2\text{POR}$ ,  $\text{RP}(\text{OR})_2$ , and  $\text{P}(\text{OR})_3$ . The nature of the initiation process was not identified. Kinetic studies of the reactions initiated by azobisisobutyronitrile (AIBN) are consistent with a free radical mechanism, and the suggestion was made that impurities could provide the initiation step for the reactions in the absence of AIBN.<sup>2</sup>

In contrast to the reactions of tertiary phosphines, dialkylphosphines react with dioxygen in solution or neat to give only dialkylphosphine oxides.<sup>3</sup> These reactions also showed the characteristics of free radical reactions (e.g. inhibition by hydroquinone), but it was believed that the reactions were initiated by the formation of  $\text{R}_2\dot{\text{P}}(\text{H})\text{O}-\text{O}^\cdot$ .

We now report the results of a study of the gas phase reaction of  $\text{PMe}_3$  with dioxygen and suggest a possible mechanism which is consistent with that proposed for dialkylphosphines.

### RESULTS AND DISCUSSION

Trimethylphosphine (10 torr) and dioxygen-16 (30 torr) were mixed in a gas infrared cell and the reaction monitored by infrared spectroscopy over a period of two days. In addition to the usual infrared bands for trimethylphosphine an infrared band at

\*Author to whom all correspondence should be addressed.

1060  $\text{cm}^{-1}$  characteristic of the  $\nu(\text{P})\text{OC}$  vibration in  $\text{Me}_2\text{P}^{16}\text{OMe}$  was observed.<sup>4</sup> If mixtures of  $^{18}\text{O}_2$  (15 torr) and  $^{16}\text{O}_2$  (15 torr) were used, an additional band at 1034  $\text{cm}^{-1}$  assigned to  $\text{Me}_2\text{P}^{18}\text{OMe}$  was also observed. No other changes in the infrared spectrum were apparent.

Mass spectral analyses of the mixture of  $\text{PMe}_3$  with  $^{16}\text{O}_2$  at low pressure (40 torr) gave a peak at  $m/e$  124 albeit in low relative abundance assignable to a  $\text{Me}_3\text{P}^{16}\text{O}_3^+$  species. This could not be due to  $\text{P}(\text{OMe})_3$  or  $\text{MeP}(\text{O})(\text{OMe})_2$  since neither species was observed by  $^{31}\text{P}$  nmr of either the gas or solid products under these conditions. If one of these species were responsible for the  $m/e$  124 ion in low abundance because of low volatility, it would almost certainly have been detected in the  $^{31}\text{P}$  nmr of the dissolved products of the gas-phase reaction. Other fragments assigned to species containing three oxygens were observed at  $m/e$  109 (assigned to  $\text{Me}_2\text{PO}_3^+$ ),  $m/e$  94 (assigned to  $\text{MePO}_3^+$ ), and  $m/e$  79 (assigned to  $\text{PO}_3^+$ ). Fragments containing two oxygen atoms were observed at  $m/e$  108 ( $\text{Me}_3\text{PO}_2^+$ ),  $m/e$  93 ( $\text{Me}_2\text{PO}_2^+$ ), and  $m/e$  63 ( $\text{PO}_2^+$ ).

Mixtures of  $\text{PMe}_3$  with  $^{18}\text{O}_2$  (ca. 40 torr) gave a species at  $m/e$  130 assigned to  $\text{Me}_3\text{P}^{18}\text{O}_2^+$ . Fragments containing two oxygen-18 atoms were observed at  $m/e$  112 ( $\text{Me}_3\text{P}^{18}\text{O}_2^+$ ) and  $m/e$  97 ( $\text{Me}_2\text{P}^{18}\text{O}_2^+$ ).

The  $^{31}\text{P}\{^1\text{H}\}$  nmr of the gas mixture was obtained by condensing the gas into an nmr tube along with  $\text{CDCl}_3$ , and the tube was then sealed. The only species observed at  $-60^\circ\text{C}$  was  $\text{PMe}_3$  and small amounts of  $\text{Me}_2\text{POMe}$  ( $\delta_{\text{P}} = -61.4$  and  $+124$  ppm, respectively).<sup>4,5</sup>

If a gas mixture of  $\text{PMe}_3$  and  $\text{O}_2$  is made at a pressure of ca. 1 atm, reaction is observed in a matter of seconds as evidenced by the formation of a white non-volatile solid. The  $^{31}\text{P}\{^1\text{H}\}$  nmr spectrum of this solid showed it to be a mixture of  $\text{Me}_2\text{P}(\text{O})\text{OMe}$  (20%) and  $\text{Me}_3\text{PO}$  (80%).<sup>6</sup> Infrared analysis of the solid confirmed these results.<sup>7</sup> The infrared spectrum of the volatiles again showed the presence of  $\text{Me}_2\text{POMe}$ , and the  $^{31}\text{P}$  nmr at  $-60^\circ\text{C}$  confirmed the presence of  $\text{Me}_2\text{POMe}$  as well as a trace amount of  $\text{MeP}(\text{O})(\text{OMe})_2$ .

In view of our results several points can be made. The reaction products observed by us for the gas phase reaction of  $\text{PMe}_3$  with dioxygen are of the same class as those observed by Buckler for the neat reaction of  $\text{P}(\text{Bu})_3$  with  $\text{O}_2$ .<sup>1</sup> However, the observation of a  $\text{Me}_3\text{PO}_3^+$  species in the mass spectrum of the gas mixture suggests that a possible initiation process for the reaction different from that proposed by Buckler<sup>1</sup> may be involved. A mechanism consistent with the observations of Buckler and also our results is shown in Scheme 1. For the initiation step (1) we suggest the formation of  $\text{Me}_3\text{PO}_2^{\cdot}$ , since other workers have shown that both tertiary<sup>1,2</sup> and dialkyl phosphines<sup>3</sup> all react via a radical pathway. The formation of  $\text{Me}_2\text{P}(\text{O})\text{OMe}$  could occur by methyl migration on  $\text{Me}_3\text{PO}_2^{\cdot}$  or  $\text{Me}_3\text{P} \begin{smallmatrix} \text{O} & \text{O} \\ \diagdown & / \\ & \text{O} & \text{O} \end{smallmatrix} \text{PMe}_3$  in a manner similar to the proposal of Itzstein and Jenkins for phenyl migration,<sup>8</sup> or it could occur through a termination step such as 7. Although ozonides similar to  $\text{Me}_3\text{PO}_3$  have been shown to be very unstable and decompose to give trialkylphosphine oxides and singlet dioxygen,<sup>9</sup> we feel that a rearrangement such as that shown in step 6 would be competitive with decomposition in the gas phase for the specific case of methyl migration. The resulting diradical could then react with  $\text{PMe}_3$  in a termination step to produce the two observed solid products  $\text{Me}_3\text{PO}$  and  $\text{Me}_2\text{P}(\text{O})\text{OMe}$  (step 7) or in

SCHEME 1

a propagation step to produce the primary gas product  $\text{Me}_2\text{POMe}$  and  $\text{Me}_3\dot{\text{P}}\text{O}_2$ . Of course,  $\text{Me}_3\text{PO}$  could also be produced from a termination reaction of the  $\text{Me}_3\dot{\text{P}}\text{O}_2$  with  $\text{PMe}_3$  as shown in step 1. This proposed mechanism does not utilize the methyl or methoxy radicals which would be primary species involved in propagation in a Buckler-type mechanism. However, we would emphasize that our proposed mechanism refers only to the gas-phase reaction of dioxygen and trimethylphosphine.

## EXPERIMENTAL

**Materials.** Trimethylphosphine (Strem Chemical Company) was transferred to a previously dried glass vessel equipped with a Teflon stopcock in a nitrogen filled dry box. The phosphine was then degassed on a vacuum line using 3–4 freeze/thaw cycles. High purity oxygen was obtained from Matheson.  $^{18}\text{O}_2$  (99.8%) was purchased from Alfa Inorganics, Inc.

**Spectra.** Infrared spectra were recorded on a Perkin-Elmer 580 or 983 Spectrophotometer equipped with a Perkin-Elmer Data Station using a vacuum-tight 10 cm cell having KRS-5 windows.  $^1\text{H}$  nmr spectra were obtained on a Varian EM 390 spectrophotometer at 90 MHz, and  $^{31}\text{P}$  nmr spectra were recorded on a Varian CFT 20 spectrophotometer at 32.1 MHz (in  $\text{C}_6\text{D}_6$  or  $\text{CDCl}_3$ ). Gas-phase products were condensed in a cooled nmr tube (at 77 K) which was then sealed on a vacuum line; solids were dissolved in solvent and loaded into nmr tubes in a dry box. Chemical shifts were measured relative to internal TMS and external 85%  $\text{H}_3\text{PO}_4$ . Mass spectral data were obtained on a DuPont 491-B mass spectrometer equipped with a Finnigan INCOS data station; gas aliquots were taken directly from the infrared cell.

**Preparation of Gas Mixtures.** Reactions were carried out at room temperature in preheated (at  $10^{-6}$  torr) glass vessels. Trimethyl phosphine was expanded into the vessel (glass blub or IR cell), and dioxygen was added at various pressures greater than that of the phosphine.
