## CHROMIUM CLUSTER COMPLEXES FROM CAGE-OPENING OF POLYCHALCOGEN-PNICOGEN MOLECULES

LAI YOONG GOH\*, CHEN WEI and RICHARD C.S. WONG

Department of Chemistry, University of Malaya, 59100 Kuala Lumpur, Malaysia

**Abstract** The reactions of  $[\text{CpCr}(\text{CO})_3]_2$  with  $\text{P}_4\text{E}_3$  ( $\text{E} = \text{S}, \text{Se}$ ) are described, with the structural features and thermal stability of the novel tetrachromium complexes  $\text{Cp}_4\text{Cr}_4(\text{CO})_9(\text{P}_4\text{E}_3)$  ( $\text{E} = \text{S}, \text{Se}$ ) and  $\text{Cp}_4\text{Cr}_4(\text{CO})_8(\text{P}_2\text{Se}_2)$  being highlighted.

### INTRODUCTION

Our studies on the reactivity of  $[\text{CpCr}(\text{CO})_3]_2$  towards Groups 15 and 16 main group elements<sup>1–5</sup>, have been extended to the  $\text{P}_4\text{E}_3$  ( $\text{E} = \text{S}, \text{Se}$ ) cage molecules.

In its reactions with transition metals, the  $\text{P}_4\text{E}_3$  molecules have been observed to undergo both nondisruptive and disruptive processes, depending on the oxidation state and ligand environment of the metal atom. Thus, the  $\text{P}_4\text{E}_3$  molecule either coordinates intact via its apical P atom, or fragments extensively, resulting in complexes containing  $\text{P}_3$ ,  $\text{P}_2\text{S}_3$  and  $\text{P}_4\text{S}$  ligands<sup>6</sup>. We describe below cases where  $\text{P}_4\text{E}_3$  undergoes multiple bond cleavage without fragmentation to produce novel tetrachromium complexes.

### THE REACTIONS

#### *With $\text{P}_4\text{S}_3$*

An ambient temperature reaction of  $[\text{CpCr}(\text{CO})_3]_2$  (**1**) with one mole equivalent of  $\text{P}_4\text{S}_3$  for 13 days produces the tetrachromium complex  $\text{Cp}_4\text{Cr}_4(\text{CO})_9(\text{P}_4\text{S}_3)$  (**2A**) in *ca.* 66% yield. In view of the facile dissociation of **1** in solution into the 17-electron monomeric species  $[\text{CpCr}(\text{CO})_3]$ , it is conceivable that the reaction proceeds via a radical attack on the  $\text{P}_4\text{S}_3$  cage, as illustrated in Scheme 1. Other products include  $[\text{CpCr}(\text{CO})_2]_2\text{S}$  (**3**) (13%),  $\text{CpCr}(\text{CO})_2\text{P}_3$  (**4**) (2%) and  $\text{CpCr}(\text{CO})_3\text{H}$  (**5**) (19%). In a similar reaction at 60 °C for 3 h, the yield of **2A** was substantially reduced to 22%, with an increased yield of **3** (36%) and the formation of the cubane complex  $\text{Cp}_4\text{Cr}_4\text{S}_4$  (**6**) (7%), accompanied by lower yields of **4** (*ca.* 1%) and **5** (3%). This variation in product composition agrees with independent observations on the thermolytic degradation of **2A** at 80 °C for 3.5 h to **3** (23%), **4** (10%), **6** (57%) and  $[\text{CpCr}(\text{CO})_2]_2\text{P}_2$  (**7**) (10%) (see Scheme 2).

Scheme 1

The isolation of the hydride **5** was indeed unexpected. It was characterised spectrally, chromatographically via TLC *vis-a-vis* an authentic sample and by single crystal X-ray diffraction analysis. One may speculate that the  $[\text{CpCr}(\text{CO})_3]$  radical trapped inside the  $\text{P}_4\text{S}_3$  cage is able to abstract a H atom from the solvent. In this context, we have observed that **5** was not formed in the presence of isoprene.

Scheme 2

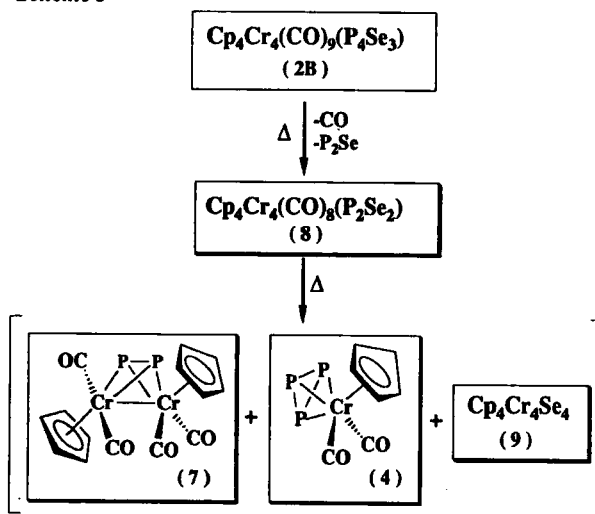

### With $\text{P}_4\text{Se}_3$

The reaction of **1** with one molar equivalent of  $\text{P}_4\text{Se}_3$  at ambient temperature for 6 days produced a mixture of  $\text{Cp}_4\text{Cr}_4(\text{CO})_9(\text{P}_4\text{Se}_3)$  (**2B**) (48%),  $\text{Cp}_4\text{Cr}_4(\text{CO})_8(\text{P}_2\text{Se}_2)$  (**8**) (13%), **4** (8%) and **7** (16%) and a small amount of the hydride **5**. A similar reaction for 12 days yielded **2B** (31%), **8** (34%), **4** (14%) and  $\text{Cp}_4\text{Cr}_4\text{Se}_4$  (**9**) (*ca.* 1 %). These

observations are in agreement with the thermal degradation of **2B** which gave after 4 h at 60 °C, the complexes **8** (51%), **4** (5%), **7** (10%) and **9** (13%) (see Scheme 3).

**Scheme 3**

## THE STRUCTURES OF 2

The complexes **2A** and **2B** possess strikingly similar molecular structures shown in Figure 1 for **2A**. It is seen that  $\text{P}_4\text{S}_3$  has undergone cleavage of P2-S1, P4-S2 and P3-P4 bonds, with concomitant bond formation between P2 and P4, giving a five-membered  $\text{P}_4\text{S}$  ring with two external S atoms, viz. S1 at P1 and S2 at P2. Together with  $\text{Cr}_4$ , this five-membered ring forms a bicyclo [2.1.1] system, possessing common vertices at P3 and P4. The  $\text{P}_4\text{S}$  ring bridges four  $[\text{CpCr}(\text{CO})_n]$  ( $n = 2$  or 3) fragments through its four P atoms. Each of the Cr atoms is five-coordinate, possessing a four-legged piano stool geometry. Thus Cr3, coordinated to one atom of the  $\text{P}_4\text{S}_3$  ligand, is linked to three CO groups, while the other three Cr atoms, each coordinated to two atoms of the  $\text{P}_4\text{S}_3$  ligand, is linked to two CO groups.

Figure 1  
Molecular structure of **2A**

The molecular structure of **8** will be presented if solved in time for the symposium.

### *Concluding Remarks*

Such an example of multiple bond cleavage without fragmentation of the  $P_4E_3$  cage by a transition metal complex as found in **2**, has not hitherto been observed. Slight cage rearrangement has occurred in the insertion of a  $Cr(CO)_5$  fragment into the isostructural Zintl ion  $As_7^{3-7}$ , and of three  $Ni(CO)$  fragments into  $Sb_7^{3-8}$ . The extensive cage-opening cum structural rearrangement of the  $P_4E_3$  cage described here may be attributed to the unusual reactivity of the radical-like 17-electron  $[CpCr(CO)_3]$  fragment, as was observed in the formation of the polyphosphidochromium cluster  $[CpCr(CO)_2]_5P_{10}$  from elemental  $P_4$ .<sup>5</sup>
