Silica triflate, as a new and stable silica-based reagent, is prepared by a reaction of silica gel with trifluoromethane sulfonyl chloride at room temperature. This reagent can be used for the efficient and selective formylation of alcohols in the presence of phenols in a relatively short reaction time and high yields under heterogeneous reaction conditions.

**Keywords** Formylation; heterogeneous reaction conditions; silica triflate; silica gel; trifluoromethane sulfonyl chloride

Because of the importance of formate esters as useful synthetic reagents and intermediates,<sup>1</sup> formylation of the hydroxyl group is considered one of the most widely used transformations in organic chemistry.<sup>2,3</sup> Despite these uses and considerable potential, the formyl protecting group has been rather overlooked. This is partly due to the fact that efficient formylation procedures under mild conditions are not available. The direct esterification of alcohols with carboxylic acids

Received October 12, 2006; accepted October 25, 2006.

Partial support of this work by the Guilan and Teacher Training Universities Research Councils is acknowledged. F. Shirini is thankful to Guilan Science and Technology Park (GSTP) for its continuous support. F. Shirini is also indebted to Dr. M. Mottaghitalab for his sincere assistance.

is a reversible process that needs to eliminate water from the reaction mixture to drive the process to completion; thus the method is generally avoided. The acid halide or anhydride procedure is unsuitable for formylation because formyl halides and anhydride are unstable. Several formylation procedures have been reported over the years. These are based on formylation with formic acid in the presence of a dehydrating agent (Ac<sub>2</sub>O, <sup>4</sup> DCC, <sup>5</sup> and 1,1'-oxalyldiimidazole<sup>6</sup>), transesterification with methyl/ethyl formate (catalyzed by silica-gel supported metal sulphate)<sup>7</sup> Ce(OTf)<sub>4</sub>,<sup>8</sup> Cu(NO<sub>3</sub>)<sub>2</sub>.3H<sub>2</sub>O,<sup>9</sup> PPh<sub>3</sub>/CBr<sub>4</sub>,<sup>10</sup> methods, however, use uncommon and in some cases moisture sensitive or thermally unstable reagents that need to be prepared before use, in some cases, by multistep procedures employing expensive catalysts. Many of these methods also suffer from some of the following limitations: elevated temperatures, long reaction times, inert atmosphere, separation of the spent or deformylated reagent, acidic reaction conditions or work-up, side reactions, and moderate yields.

In recent years our research group, as many others, focused on the development of the application of silica gel and its new derivatives in organic chemistry. Along these studies we have reported that these reagents are able to be used efficiently in many organic reactions.<sup>20</sup> In continuation of these studies we have found that trifluoromethane sulfonyl chloride reacts with silica gel, in an easy, clean, and immediate reaction, to give silica triflate (I) and HCl gas as the only products (Scheme 1).

$$SiO_2 OH + CISO_3CF_3 OSO_3CF_3 + HCI$$
(I)

#### **SCHEME 1**

We anticipated that silica triflate, as a new triflate derivative, would be able to accelerate the formylation of alcohols as the other reported triflates<sup>14,15</sup> (Scheme 2).

A variety of alcohols including primary, secondary, tertiary, and benzylic ones were converted to their formate esters in a single step by mixing the alcohol, formic acid, and silica triflate in refluxing hexane in good to high yields (Table I). The formylation of allylic alcohols was not clean and gave a complex mixture of products along with the unreacted

#### **SCHEME 2**

alcohol, so this method is not suitable for the formylation of these kinds of alcohols (Table I). Phenols remained unreacted under these conditions, indicating that the reaction could be selective for the formylation of alcohols in the presence of phenols. The selectivity was demonstrated by competitive reactions, in which equimolar mixtures of an alcohol and a phenol were subjected to formylation, whereby the alcohols were completely formylated and the phenols were mostly recovered unchanged (Table II).

We have found that silica triflate is a reusable catalyst, and even after five runs for the formylation of alcohols, the catalytic activity of the reagent was almost the same as the freshly used catalyst. The stability of the composition of the reagent was demonstrated by its IR spectra, which were the same before and after the reactions.

It should be noted that the formylation reaction did not proceed using silica gel and trifluoromethane sulfonyl chloride alone or by the separate addition of these reagents to the reaction mixture (Table 1). These results indicate that SiOTf is the reagent responsible for the catalytic activity observed.

In order to show the efficiency of the present method, Table III compares some of the results with some of those reported in the literature. <sup>11,19</sup>

In conclusion this article reports the synthesis of a new triflate derivative based on silica gel and its applications in the efficient formy-lation of alcohols. Mild reaction conditions, simplicity of the procedure, short reaction times, good to high yields of the products, heterogeneous reaction conditions, and general applicability for primary through tertiary alcohols make this method a useful addition to the existing methodologies. Work on the effect of silica triflate on other types of organic reactions is currently ongoing in our laboratory.

## **EXPERIMENTAL**

#### General

Chemicals were purchased from Fluka, Merck (Darmstadt, Germany), and Aldrich Chemical Companies. Products were characterized by their

<sup>&</sup>lt;sup>b</sup>Isolated yield.

stirring at r.t. Gas was evolved from the reaction vessel immediately. After the addition was complete, the mixture was shaken for 30 min. The reaction mixture was washed with 50 mL of dry  $\rm CH_2Cl_2$  and dried under vacuum. Silica triflate was obtained as a white solid (20.4–20.6 g), which was stored in a capped bottle. In order to determine the amount of active triflate content of the reagent, the produced HCl from the previously discussed reaction was titrated with 0.1 M aq NaOH. The results from several runs showed the formation of 0.018–0.020 mol of HCl; therefore, the amount of active triflate was determined to be 1 mmol per 1.04–1.08 g silica triflate; IR (KBr): 1255, 1230 ( $\upsilon_{S=O}$ ), 1130, 1010 ( $\upsilon_{C=F}$ ), 955, 820, 650, 530, 500 cm<sup>-1</sup>.

### **General Procedure**

A mixture of alcohol (1 mmol), formic acid (0.055 g, 1.2 mmol), and silica triflate (0.06–0.12 g) in hexane (4 mL) was heated at reflux. The progress of the reaction was monitored by GC or TLC. After completion of the reaction, the mixture was filtered, and the solid residue was washed with n-hexane (3 mL). The solvent was removed under reduced pressure. Water (20 mL) was added to the residue, and the product was extracted with  $CH_2Cl_2$  (2  $\times$  10 mL). The combined organic layer was washed with saturated  $NaHCO_3$  solution (2  $\times$  10 mL) and dried over anhydrous  $MgSO_4$ . Evaporation of the solvent under reduced pressure gave almost pure products (Table I). Further purification was carried out by column chromatography on silica gel to afford pure formate.
