## STUDIES ON THE EFFECT OF VARIOUS ANIONS AND PYRIDINE ON THE STEREOCHEMISTRY OF LANTHANIDE(III) COORDINATION COMPOUNDS OF 4[N-(2'-HYDROXY-1'-NAPHTHALIDENE)AMINO] ANTIPYRINE THIOSEMICARBAZONE

Ram K. Agarwal and Vinesh Kumar

Department of Chemistry, Lajpat Rai Postgraduate College, Sahibabad,  
Ghaziabad, India

*In the present studies, the effect of pyridine on stereochemistry of the coordination compounds of lanthanide(III) derived from 4[N-(2'-hydroxy-1'-naphthalidene)amino] antipyrine thiosemicarbazone (HNAAPTS) has been studied. The general composition of the present complexes is  $LnX_3 \cdot n(HNAAPTS) \cdot Py$  ( $Ln = La, Pr, Nd, Sm, Gd, Tb, Dy, or Ho$ ;  $X = NO_3$ ,  $n = 1$ ,  $x = Cl, NCS$  or  $ClO_4$ ,  $n = 2$ ,  $Py = pyridine$ ). All the complexes were characterized by elemental analyses, molecular weight, molar conductance, magnetic susceptibilities, infrared and electronic spectral studies. The infrared studies reveal that the HNAAPTS behaves as a neutral tridentate (N, N, S), while pyridine is coordinated to metal ions via its nitrogen atom. Nitrates are bicovalently bonded, while thiocyanate is coordinated through a strong N-atom. Perchlorate ions are not coordinating in coordination sphere. From electronic spectral data, nephelauxetic effect ( $\beta$ ), covalence factor ( $b^{1/2}$ ), Sinha parameter ( $\delta\%$ ), and the covalence angular overlap parameter ( $\eta$ ) have been calculated. Thermal stabilities of these complexes were studied by thermogravimetric analysis. In conclusion, the coordination number of lanthanides(III) in the present compounds is either seven or ten depending on the coordinating anions.*

## INTRODUCTION

The introduction of the nitrogen and sulfur atoms into the structure of organic compounds often has important consequences in their behavior towards metal ions. From the comparatively large atomic radius of sulfur atom and its lower electronegativity than nitrogen, one expects that sulfur-containing ligands will form less stable complexes than those containing nitrogen, but it has been observed that the affinity of sulfur for metal ions is often

**Figure 1** 4[N-(2'-Hydroxy-1'-naphthalidene)amino]antipyrine thiosemicarbazone (HNAPTS) (m.f.  $C_{23}H_{22}N_6OS$ ).

very close to the ligands containing nitrogen as donor atoms. Thiosemicarbazones are not well established as an important class of sulfur donor ligands.<sup>1-3</sup> The interest in developing the coordination chemistry of thiosemicarbazones is due to their biological and medicinal properties. They present a variety of biological activities ranging from antitumor to fungicide, bactericide, anti-inflammatory, and antiviral activities. From our laboratory, we have published oxovanadium(IV), copper(II),  $UO_2(VI)$ , Co(II), Ni, and Pt-metals complexes of thiosemicarbazones.<sup>4-7</sup> Although a number of trivalent lanthanide(III) complexes of semicarbazones have been reported,<sup>8</sup> less is known about the trivalent lanthanide(III) complexes of thiosemicarbazones.<sup>9,10</sup> In continuation of our work on 4-amino antipyrine-derived thiosemicarbazones complexes of metal ions, this article reports the effect of pyridine on stereochemistry of the coordination compounds of lanthanide(III) derived from 4[N-(2'-hydroxy-1'-naphthalidene)amino]antipyrine thiosemicarbazone (HNAPTS) (Figure 1).

## RESULTS AND DISCUSSION

The interaction of non-aqueous solutions of lanthanide(III) salts with HNAPTS in the presence of pyridine produces complexes of the general composition  $LnX_3 \cdot n(HNAPTS) \cdot Py$  ( $Ln = La, Pr, Nd, Sm, Gd, Tb, Dy, \text{ or } Ho$ ;  $X = NO_3$ ,  $n = 1$ ,  $X = Cl, NCS$  or  $ClO_4$ ,  $n = 2$ ,  $Py = \text{pyridine}$ ). The analytical data of these complexes are presented in Tables I–IV. All the complexes are quite stable and could be stored for months without any appreciable change. The complexes do not have sharp melting points, but decomposed upon heating beyond  $260^\circ C$ . The complexes are generally soluble in common organic solvents. The molar conductance values of these compounds in nitrobenzene are presented in Tables I–IV. The molar conductance values of chloro, thiocyanato, and nitrate complexes are too low to account for any dissociation; thus these complexes are considered to be non-electrolytes. The perchlorato complexes behave as 1:3 electrolytes in nitrobenzene.<sup>15</sup> Data on the molecular weight of the complexes in nitrobenzene are given in Tables I–IV along with values on the basis of established formulae of the complexes. The ratio of molecular weight observed for  $LnCl_3 \cdot 2(HNAPTS) \cdot Py$ ,  $Ln(NCS)_3 \cdot 2(HNAPTS) \cdot Py$ , and

$\text{Gd}(\text{NO}_3)_3 \cdot (\text{HNAAPTS}) \cdot \text{Py}$ ( $\text{C}_{28}\text{H}_{27}\text{N}_{10}\text{O}_{10}\text{SGd}$ )	18.30 (18.42)	16.24 (16.43)	3.70 (3.75)	847.0 (852.0)	1.9	07.82
$\text{Tb}(\text{NO}_3)_3 \cdot (\text{HNAAPTS}) \cdot \text{Py}$ ( $\text{C}_{28}\text{H}_{27}\text{N}_{10}\text{O}_{10}\text{STb}$ )	18.49 (18.61)	16.20 (16.39)	3.69 (3.74)	850.0 (854.0)	2.1	09.23
$\text{Dy}(\text{NO}_3)_3 \cdot (\text{HNAAPTS}) \cdot \text{Py}$ ( $\text{C}_{28}\text{H}_{27}\text{N}_{10}\text{O}_{10}\text{SDy}$ )	18.86 (18.95)	16.18 (16.32)	3.68 (3.73)	853.0 (857.5)	1.8	10.56
$\text{Ho}(\text{NO}_3)_3 \cdot (\text{HNAAPTS}) \cdot \text{Py}$ ( $\text{C}_{28}\text{H}_{27}\text{N}_{10}\text{O}_{10}\text{SHo}$ )	18.99 (19.18)	16.11 (16.27)	3.67 (3.72)	855.0 (860.0)	2.2	10.53

$\text{Ln}(\text{NO}_3)_3 \cdot (\text{HNAAPTS}) \cdot \text{Py}$  to that calculated is  $\sim 0.98$ , which shows that these complexes are monomeric in nature. In the case of  $\text{Ln}(\text{ClO}_4)_3 \cdot 2(\text{HNAAPTS}) \cdot \text{Py}$ , the ratio is found to be  $\sim 0.25$ . These data further support that four species are found in the perchlorate complexes.

The magnetic moment values of these complexes determined at room temperature (Tables I–IV) indicate that  $\text{La}(\text{III})$  complexes are diamagnetic in nature, where  $\text{Pr}(\text{III})$ ,  $\text{Nd}(\text{III})$ ,  $\text{Sm}(\text{III})$ ,  $\text{Gd}(\text{III})$ ,  $\text{Tb}(\text{III})$ ,  $\text{Dy}(\text{III})$ , and  $\text{Ho}(\text{III})$  complexes are paramagnetic in nature. The values found are close to the theoretical values<sup>8–10</sup> and show little deviation from the Van Vleck values, indicating very little participation of the  $4f$ -electrons in the bonding.

### Infrared Spectra

The important infrared bands of free ligands (HNAAPTS and pyridine) and their lanthanides(III) are presented in Table V. The strong bands in the free ligand (HNAAPTS) observed at  $3420$  and  $3310 \text{ cm}^{-1}$  due to  $\nu(\text{NH})$  remained unaffected after complexation. The ligand bend at  $1600 \text{ cm}^{-1}$  ( $\text{C}=\text{N}$  of imine nitrogen) that shifted to lower wave numbers on complexation suggests involvement of an unsaturated nitrogen atom of two azomethine groups in bonding with the metal ion.<sup>16</sup> Other bands observed in the free ligand are at  $1320$ ,  $1195 \text{ cm}^{-1}$  due to  $\nu(\text{C}=\text{S}) + \nu(\text{C}=\text{N}) + \nu(\text{C}-\text{N})$ ,  $1120$ ,  $1095 \text{ cm}^{-1}$  due to  $\delta(\text{NCS}) + \text{CS}$  bending, and  $840$ ,  $820 \text{ cm}^{-1}$  due to  $\nu(\text{C}=\text{S})$  stretching.<sup>17</sup> Coordination of sulfur with  $\text{Ln}^{3+}$  ion would result in displacement of electrons towards the latter, thus resulting in the weakening of ( $\text{C}=\text{S}$ ) bond. Hence on complexation, ( $\text{C}=\text{S}$ ) stretching vibrations should decrease and those of ( $\text{C}=\text{N}$ ) should increase.<sup>18</sup> In the present complexes, the bands at  $1320$  and  $1195 \text{ cm}^{-1}$  increased by  $50$ – $60 \text{ cm}^{-1}$ . Similarly, bending modes on ( $\text{N}-\text{C}-\text{S}$ ) and ( $\text{C}=\text{S}$ ) also increased, but to a lesser extent. On the other hand, on complexation the infrared bands at  $840$  and  $820 \text{ cm}^{-1}$  shifted to lower wave numbers

with reduced intensity. All these peculiar changes on complexation confidently preclude any unambiguous ascertainment of metal-sulfur bonding. The possibility of thione-thiol tautomerism ( $\text{H}-\text{N}-\text{C}-\text{S}$ ) ( $\text{C}-\text{N}-\text{S}-\text{H}$ ) in HNAAPTS has been ruled out, for there were no bands around  $2700\text{--}2500\text{ cm}^{-1}$ , which are characteristic of thiol groups displayed in the infrared absorption.<sup>19</sup> All the infrared spectral evidence suggested that the ligands, HNAAPTS acts as a neutral tridentate (N, N, S) in the lanthanide(III) complexes.

In the spectrum of pyridine, four strong absorptions occur in the range  $1600\text{--}1400\text{ cm}^{-1}$  due to  $\text{C}=\text{C}$ ,  $\text{C}=\text{N}$  stretching and ring vibrations.<sup>20,21</sup> Out of these, the absorptions associated with the cyclic ring are apparently unaffected on complexation, while those arising from the heterocyclic ring are shifted to higher frequencies due to tightening of the ring on coordination. This is suggestive of the view that the pyridine is bonded with the  $\text{Ln}^{3+}$  ion through the hetero-N atom.<sup>22</sup> In the far infrared region, the bands due to  $\nu(\text{Ln}-\text{N})/\nu(\text{Ln}-\text{S})$  are also observed.<sup>9,10</sup>

## Anions

The infrared spectral data of nitrate absorptions in lanthanide(III) nitrate complexes are summarized in Table S1 (available online in the Supplemental Materials). The lanthanide(III) nitrate complexes show two strong absorptions in the  $\sim 1525\text{--}1490\text{ cm}^{-1}$  and  $1290\text{--}1280\text{ cm}^{-1}$  regions is attributed to  $\nu_4$  and  $\nu_1$  modes of vibration of the covalently bonded nitrate group, suggesting that the nitrate groups lie inside the coordination sphere.<sup>23</sup> Other absorptions associated with the covalent nitrate groups are also observed in the spectra of the complexes. If the  $(\nu_4-\nu_1)$  difference is taken as an approximate measure of the covalency of the nitrate groups, a value of  $\sim 200\text{ cm}^{-1}$  for the complexes studied suggest strong covalency for the metal nitrate bonding. According to Lever et al.,<sup>24</sup> bidentate coordination of nitrate groups involves a greater distortion from  $\text{D}_{3h}$  symmetry than unidentate coordination, therefore bidentate complexes should show a large separation of  $(\nu_1+\nu_4)$ . Site symmetry lowering the coupling of the nitrate group via the metal ion to which they are coordinated to the occurrence of non-equivalent nitrate groups in the unit cells are some of the factors that may affect the occurrence of  $(\nu_1+\nu_4)$  combination bands. In the present studies, a separation of  $\sim 30\text{--}50\text{ cm}^{-1}$  in the combination bands in the  $1800\text{--}1700\text{ cm}^{-1}$  region suggests the bidentate nitrate coordination. The bidentate character of the nitrate groups has been established by X-ray<sup>25</sup> and neutron diffraction studies.<sup>26</sup> Thus it is inferred that in the present studies the nitrate groups may be bidentate in nature. Complexes of the thiocyanate ion are known for most of the complexes formation of metal ions. According to the concepts of Pearson,<sup>27</sup> the N- end of this ion is a hard base, and the S- end a soft base. Consequently, N-bonding is expected with the hard (class-A) metal ions, while S-bonding should take place with those of soft category (class-B). The  $\text{NCS}^-$  ion has been studied widely by infrared spectroscopy, which provides a means of establishing the bonding mode. Bailey et al.<sup>28</sup> suggested that the region near or above  $2100\text{ cm}^{-1}$  is for S-bonding, below this value is for N-bonding. The CS stretching frequency ( $\nu_2$ ) was assigned in the following regions:  $860\text{--}760\text{ cm}^{-1}$  for  $\text{M}-\text{NCS}$  and  $720\text{--}690\text{ cm}^{-1}$  for  $\text{M}-\text{SCN}$ . The NCS frequency ( $\nu_3$ ) is also different for the two isomers:  $490\text{--}450\text{ cm}^{-1}$  for the  $\text{M}-\text{NCS}$  and  $440\text{--}400\text{ cm}^{-1}$  for  $\text{M}-\text{SCN}$  group. Bridging thiocyanate groups usually give higher CN stretching frequencies than terminal NCS groups. Table S2 (Supplemental Materials) shows the infrared absorption  $\nu(\text{C}-\text{N})$  ( $\nu_1$ ),  $\nu(\text{C}-\text{S})$  ( $\nu_3$ ), and  $\delta(\text{N}-\text{C}-\text{S})$  ( $\nu_2$ ). These frequencies are associated with the terminal N-bonded isothiocyanate ions.<sup>29</sup> In all the perchlorato complexes, only two strong  $\nu_3$  and  $\nu_4$  bands are observed in the  $1090\text{--}1080\text{ cm}^{-1}$  and  $625\text{--}620\text{ cm}^{-1}$

regions, respectively (Table S3; Supplemental Materials), for the perchlorate ion, indicating that the tetrahedral symmetry has not been disturbed on complexation, and the perchlorate ions are not bonded to  $\text{Ln}^{3+}$  ion.<sup>30,31</sup> This conclusion is also supported by conductance and molecular weight data.

### Electronic Spectra

Typical spectral data for the solutions of the present mixed ligand complexes of  $\text{Ln}^{3+}$  ion with HNAAPTS and pyridine are presented in Tables S4–S7 (Supplemental Materials), and for comparison, data for an aqueous salt solution are also given. Lanthanide(III) has no significant absorption in the visible region. The absorption bands of Pr(III), Nd(III), Sm(III), Gd(III), and Dy(III) in the visible and near infrared regions appear due to transitions for the ground levels of  $^3\text{H}_4$ ,  $^4\text{I}_{9/2}$ ,  $^6\text{H}_{5/2}$ ,  $^5\text{S}_{7/2}$ , and  $^6\text{H}_{15/2}$  to the excited J-levels of the 4f-configuration, respectively. Some red shift or nephelauxetic effect is observed in the  $\text{CH}_3\text{CN}$  solutions of these complexes. This red shift is usually accepted as evidence of a higher degree of covalency than the presence of aquo compounds.<sup>32</sup> In all the complexes, marked enhancement in the intensity of the bands has been observed. This red shift of the hypersensitive bands has been utilized to calculate the nephelauxetic effect ( $\beta$ ) in these chelates. From the  $\beta$ -values, the covalence factor ( $b^{1/2}$ ), Sinha parameter ( $\delta\%$ ), (metal–ligand covalency percentage), and the covalency angular overlap parameter ( $\eta$ ) have been calculated. The positive values of  $(1-\beta)$  and  $\delta\%$  in these compounds suggest that the bonding between the metal and the ligand is covalent compared to the bonding between the metal and an aquo ion. The values of parameter of bonding ( $b^{1/2}$ ) and angular overlap parameter ( $\eta$ ) were found to be positive, indicating covalent bonding.

**$\text{LnCl}_3 \cdot 2(\text{HNAAPTS}) \cdot \text{Py}$  ( $\text{Ln} = \text{La, Pr, Sm, or Dy}$ ).** Thermoanalytical results of these compounds are presented in Table S8. The pyrolysis curves of these complexes indicate that in the 120–150°C temperature region, a loss of mass (6.76–6.92%) is due to complete evaporation of pyridine. There is no loss in mass up to 240°C, but in the 240–290°C temperature region, the loss of mass (42.63–43.40%) corresponds to loss of one molecule of HNAAPTS. A further loss of 78.26–79.86% in the temperature region shows the complete loss of HNAAPTS. The lanthanide oxide ( $\text{La}_2\text{O}_3$ ,  $\text{Pr}_6\text{O}_{11}$ ,  $\text{Sm}_2\text{O}_3$ ,  $\text{Dy}_2\text{O}_3$ ) was finally formed at  $\sim 820^\circ\text{C}$ . Above this temperature, there is no measurable change in mass observed.<sup>33</sup>

**$\text{Ln}(\text{NO}_3)_3 \cdot (\text{HNAAPTS}) \cdot \text{Py}$  ( $\text{Ln} = \text{Pr, Sm, or Tb}$ ).** Thermoanalytical results of these compounds are presented in Table S9 (Supplemental Materials). The pyrolysis curves of  $\text{Ln}(\text{NO}_3)_3 \cdot (\text{HNAAPTS}) \cdot \text{Py}$  ( $\text{Ln} = \text{Pr, Sm, or Tb}$ ) show that the compounds are anhydrous in nature. The thermal curves indicate that in the first stage, in the temperature region 120–155°C, there is a loss in mass (9.48–9.69%) due to loss of pyridine. In a second stage in the temperature region 240–360°C, the loss of (59.90–61.32%) is due to complete evaporation of HNAAPTS. Finally at  $\sim 825^\circ\text{C}$ , the constant mass is close to that expected for lanthanide oxide ( $\text{Pr}_6\text{O}_{11}$ ,  $\text{Sm}_2\text{O}_3$ ,  $\text{Tb}_4\text{O}_7$ ).<sup>33</sup>

**$\text{Ln}(\text{NCS})_3 \cdot 2(\text{HNAAPTS}) \cdot \text{Py}$  ( $\text{Ln} = \text{Nd, Dy, or Ho}$ ).** The analysis of pyrolysis data on these complexes are tabulated in Table S10 (Supplemental Materials). The thermograms of these complexes indicate virtually no change in mass up to 120°C. In the temperature zone of 120–145°C, a loss of 6.40–6.52% is observed due to complete loss of pyridine. In the 230–285°C temperature range, the loss in mass (40.28–41.22%) is due to removal of one molecule of HNAAPTS. A further loss in mass (74.84–76.10%) in the

310–340°C temperature region is due to complete evaporation of HNAAPTS. The residues obtained after heating up to  $\sim 825^\circ\text{C}$  to constant mass are close to those expected for the lanthanide oxides ( $\text{Nd}_2\text{O}_3$ ,  $\text{Dy}_2\text{O}_3$  or  $\text{Ho}_2\text{O}_3$ ).<sup>33</sup>

### Stereochemistry

**[Ln(HNAAPTS)(NO<sub>3</sub>)<sub>3</sub>·Py] (Ln = La, Pr, Nd, Sm, Gd, Tb, Dy or Ho).** The conductance measurement of these compounds in nitrobenzene indicates the non-ionic nature of these species. Hence all three nitrate groups are present inside the coordination sphere. Infrared data reveals the bidentate nature of NO<sub>3</sub><sup>-</sup>. HNAAPTS is a neutral tridentate (N, N, S) ligand, and pyridine is coordinated to the N-atom. Thus lanthanide ions are surrounded by six oxygen atoms, three nitrogen atoms, and 1 sulfur atom, thus producing a coordination number of 10 for the lanthanide ion<sup>34</sup> (Figure 2a).

**[Ln(HNAAPTS)<sub>2</sub>Cl<sub>3</sub>·Py] (Ln = La, Pr, Nd, Sm, Gd, Tb, Dy, or Ho).** The non-electrolytic behavior of the chloro complexes suggest that all the chloro ions are present in coordination sphere. HNAAPTS is a neutral tridentate ligand (N, N, S) and pyridine is coordinated to the central metal ion through heterocyclic-N atom. Thus lanthanide ions are surrounded by three chloro, five nitrogen, and two sulfur atoms, thus producing a coordination number 10 for the lanthanide ion<sup>34</sup> (Figure 2b).

**[Ln(HNAAPTS)<sub>2</sub>(NCS)<sub>3</sub>·Py] (Ln = La, Pr, Nd, Sm, Gd, Tb, Dy, or Ho).** The non-electrolytic behavior and infrared studies of these chelates suggests that all the NCS ions are coordinated to the Ln<sup>3+</sup> ion via the N-atom. HNAAPTS is a neutral tridentate ligand (N, N, S-donor), and pyridine is a neutral N-donor ligand, thus a coordination number 10 for the lanthanide ion has been suggested in all these compounds<sup>34</sup> (Figure 2c).

**[Ln(HNAAPTS)<sub>2</sub>Py](ClO<sub>4</sub>)<sub>3</sub> (Ln = La, Pr, Nd, Sm, Gd, Tb, Dy, or Ho).** The molar conductance of these compounds in nitrobenzene indicates that they behave as 1:3 electrolyses. Hence none of the 3-ClO<sub>4</sub><sup>-</sup> is bonded to the central Ln<sup>3+</sup> ion, and they are present outside the coordination sphere. Infrared spectra and thermal studies further indicate the absence of either aquo ligand or ethanol and, hence, a coordination number of 7 has been assigned in these compounds<sup>34</sup> (Figure 2d).

## EXPERIMENTAL

The lanthanide chloride nitrate and oxides were obtained from Rare Earth Products Ltd. (India) and were used without further purification. The lanthanide perchlorates were prepared by heating the corresponding oxides with perchloric acid and evaporating off the excess acid. The lanthanide isothiocyanates were prepared by adding a warm ethanolic solution of KCNS. The precipitate of KNO<sub>3</sub> rapidly coagulated. The volume of the solution was reduced on a water bath, cooled, and filtered, and the filtrate was used for complexation. The ligand HNAAPTS was synthesized from 4-aminoantipyrine by the method reported in the literature.<sup>11</sup> The secondary ligand pyridine was obtained from Aldrich Chemical and used as received.

### Synthesis of the Complexes

All the complexes were prepared in non-aqueous media and isolated as solids by different methods described below:

(b)

(c)

(d)

**Figure 2** Proposed structure of lanthanide(III) complexes of HNAAPTS and pyridine. (a)  $[\text{Ln}(\text{HNAAPTS})(\text{NO}_3)_3 \cdot \text{Py}]$ , (b)  $[\text{Ln}(\text{HNAAPTS})_2\text{Cl}_3 \cdot \text{Py}]$ , (c)  $[\text{Ln}(\text{HNAAPTS})_2(\text{NCS})_3 \cdot \text{Py}]$ , (d)  $[\text{Ln}(\text{HNAAPTS})_2 \cdot \text{Py}](\text{ClO}_4)_3$ .

(i).  **$\text{Ln}(\text{NO}_3)_3 \cdot (\text{HNAAPTS}) \cdot \text{Py}$  ( $\text{Ln} = \text{La, Pr, Nd, Sm, Gd, Tb, Dy, or Ho}$ ).** All these nitrate complexes were prepared by mixing the methanolic solutions of the respective lanthanide(III) nitrate (1 mmol, 0.325–0.351 g in methanol, 10 mL), HNAAPTS (1 mmol, 0.407 g in methanol, 10 mL), and pyridine (1 mmol, 0.079 g in methanol, 10 mL) in the molar ratio 1:1:1 and refluxing the resulting mixture for ca. 3 h. The resulting solution was concentrated by evaporation on a water bath the left overnight. The yellow product was separated by filtration, washed with hot methanol, and dried in vacuo over  $\text{P}_4\text{O}_{10}$ .

(ii).  **$\text{LnCl}_3 \cdot 2(\text{HNAAPTS}) \cdot \text{Py} / \text{Ln}(\text{NCS})_3 \cdot 2(\text{HNAAPTS}) \cdot \text{Py}$  ( $\text{Ln} = \text{La, Pr, Nd, Sm, Gd, Tb, Dy, or Ho}$ ).** The corresponding lanthanide(III) chloride (1 mmol, 0.245–0.271 g in methanol, 10 mL)/lanthanide(III) thiocyanate (1 mmol, 0.313–0.339 g in methanol, 10 mL) and ligands [HNAAPTS (2 mmol, 0.814 g in 20 mL of methanol) and pyridine (1 mmol, 0.079 g in methanol, 10 mL)] were taken in 1:2:1 molar ratio (all in hot methanol), and the reduction mixture was refluxed for  $\sim 2\text{--}3$  h on a water bath. The reaction mixture was then concentrated on a water bath until a precipitate was obtained (digested for  $\sim 0.5$  h), then it was filtered, washed thoroughly with methanol and finally with anhydrous diethyl ether, and dried over  $\text{P}_4\text{O}_{10}$  in a vacuum desiccator.

(iii).  **$\text{Ln}(\text{ClO}_4)_3 \cdot 2(\text{HNAAPTS}) \cdot \text{Py}$  ( $\text{Ln} = \text{La, Pr, Nd, Sm, Gd, Tb, Dy, or Ho}$ ).** Lanthanide(III) perchlorate (1 mmol, 0.438–0.464 g in methanol, 10 mL), HNAAPTS (2 mmol, 0.814 g in methanol, 20 mL), and pyridine (1 mmol, 0.079 g in methanol, 10 mL) were placed in a 100 mL capacity round bottom flask. The reaction mixture was refluxed for  $\sim 3$  h, and the resulting solution was concentrated to a viscous mass. It was washed several times with small portions of hot benzene, and finally the solid mass was washed with anhydrous diethyl ether, collected, and dried over  $\text{P}_4\text{O}_{10}$ .

### Physical Measurements and Analytical Estimations

The metal content was estimated as its oxide by direct combustion in a platinum crucible. The estimation was further confirmed by dissolving the product of direct combustion in dil. HCl. The acid extract was transferred into a flask, and the pH was adjusted to 5.8–6.4 by the addition of an acetic acid–sodium acetate buffer and was then titrated against 0.1 M–EDTA using xylenol-orange as an indicator. The results from both the methods were compared and found to be within the experimental errors. The nitrogen contents of the compounds were estimated by the Kjeldahl method in the laboratory. The percentage of sulfur was estimated in the laboratory by standard method. The perchlorate was estimated by the method as suggested by Kurz et al.,<sup>12</sup> and the chloro and thiocyanato were determined by Volhard's method. The molecular weight of the complexes was determined cryoscopically in freezing nitrobenzene using a Beckmann thermometer of accuracy  $\pm 0.01^\circ\text{C}$  in the laboratory. The conductivity measurements were carried out using a Toshniwal conductivity bridge (type CL 01/01) and a dip type cell operated at 220 volts AC mains. All the measurements were done at room temperature in nitrobenzene. The magnetic measurements were carried out at room temperature with a Gouy's balance and  $[\text{HgCo}(\text{SCN})_4]$  was used as a calibrant. The infrared spectra of the complexes were recorded on a Perkin-Elmer infrared spectrophotometer model in KBr in the range of  $4000\text{--}200\text{ cm}^{-1}$ . A higher Uvispeck spectrophotometer with 1 cm quartz cell was employed for recording the visible spectra of the complexes. The red shift of the hypersensitive bands has been utilized to calculate the nephelauxetic effect ( $\beta$ ) in these chelate compounds. From the  $\beta$ -values, the covalence factors ( $b^{\frac{1}{2}}$ ), Sinha parameters ( $\delta\%$ ) (metal–ligand covalency percentage) and the covalency

angular overlap parameter ( $\eta$ ) have been calculated by the following equations:<sup>13,14</sup>

$$b^{1/2} = 1/2[(1 - \beta)^{1/2}]$$

$$\delta(\%) = [(1 - \beta')/\beta] \times 100$$

$$\eta = (1 - \beta^{1/2})/\beta$$

Thermogravimetric analysis of lanthanide(III) chelate compounds was carried out in static air with open sample holder and a small platinum boat, and the heating rate was 6°/min.
